Volume 3
Coordination Chemistry
of s, p, and f metals

Introduction to Volume 3

Volume 3 describes the Coordination Chemistry of the *s*-, *p*-, and *f*-block metals.

Chapter 1 is concerned with the 1*s* and 2*s* metals and describes trends in the development of their chemistry since the mid-1980s, such as the increased use of sterically bulky ligands, recognition of importance of non-ionic interactions, reappraisal of the “spectator” role of *s*-block ions, and the application of computational methods. Biological roles of these elements are discussed in Volume 8.

Chapter 2 is concerned with the chemistry of scandium, yttrium, and the lanthanides and is discussed according to the nature of the ligand in which the donor is from Groups 14–17. Divalent and tetravalent lanthanide chemistry is also described.

Chapter 3 describes the chemistry of the actinides, including the historical development. The chemistry described is subdivided according to whether the actinide is early (thorium to plutonium) or late (transplutonium elements). Within this subdivision, the chemistry is further classified according to the oxidation state of the metal (ranging from +3 to +7), and the type of donor (ranging from elements of Groups 15–17). The chapter also contains information pertaining to element separation and aspects of nuclear technology (which is not discussed in Volume 9 and therefore represents a departure from the format of *Comprehensive Coordination Chemistry*).

Chapter 4 describes the chemistry of aluminum and gallium. In addition to aluminum(III) and gallium(III) coordination complexes, this chapter also focuses on complexes with aluminum–aluminum and gallium–gallium bonds, and also describes cyclogallenes and metalloaromaticity.

Chapter 5 describes the chemistry of indium and thallium, including subvalent compounds of indium(II), thallium(II), and thallium(I). Applications of indium and thallium complexes are also described.

Chapter 6 describes the chemistry of arsenic, antimony, and bismuth, including a discussion of the role that these elements play in the environment and biology and medicine. Applications of these complexes are also discussed.

Chapter 7 describes the chemistry of germanium, tin, and lead according to M^{IV} and M^{II} oxidation states. Within this classification, the chemistry is further subdivided according to ligand type, which ranges from elements of Groups 13–17.

COMPREHENSIVE COORDINATION CHEMISTRY II

From Biology to Nanotechnology

Second Edition

Edited by

J.A. McCleverty, University of Bristol, UK

T.J. Meyer, Los Alamos National Laboratory, Los Alamos, USA

Description

This is the sequel of what has become a classic in the field, Comprehensive Coordination Chemistry. The first edition, CCC-I, appeared in 1987 under the editorship of Sir Geoffrey Wilkinson (Editor-in-Chief), Robert D. Gillard and Jon A. McCleverty (Executive Editors). It was intended to give a contemporary overview of the field, providing both a convenient first source of information and a vehicle to stimulate further advances in the field. The second edition, CCC-II, builds on the first and will survey developments since 1980 authoritatively and critically with a greater emphasis on current trends in biology, materials science and other areas of contemporary scientific interest. Since the 1980s, an astonishing growth and specialisation of knowledge within coordination chemistry, including the rapid development of interdisciplinary fields has made it impossible to provide a totally comprehensive review. CCC-II provides its readers with reliable and informative background information in particular areas based on key primary and secondary references. It gives a clear overview of the state-of-the-art research findings in those areas that the International Advisory Board, the Volume Editors, and the Editors-in-Chief believed to be especially important to the field. CCC-II will provide researchers at all levels of sophistication, from academia, industry and national labs, with an unparalleled depth of coverage.

Bibliographic Information

10-Volume Set - Comprehensive Coordination Chemistry II

Hardbound, ISBN: 0-08-043748-6, 9500 pages

Imprint: ELSEVIER

Price:

USD 5,975

EUR 6,274 Books and electronic products are priced in US dollars (USD) and euro (EUR). USD prices apply world-wide except in Europe and Japan. EUR prices apply in Europe and Japan. 3.1.1 INTRODUCTION AND REVIEW OF COORDINATION PROPERTIES

Even though they occupy adjacent columns of the periodic table and possess marked electronic similarities, the 12 members of the *s*-block elements nevertheless form coordination compounds of surprising diversity. The alkali (Group 1, Li to Fr) and alkaline-earth (Group 2, Be to Ra) metals share n^{sx} valence electron configurations in their elemental state ($x = 1$, alkali metals; $x = 2$, alkaline-earth metals), and have low ionization potentials. Consequently, they all display—with some important exceptions—only +1 (for Group 1) and +2 (for Group 2) oxidation states. The highly electropositive nature of the metals also means that their bonds to other elements are strongly polar, and compounds of the *s*-block elements are often taken as exemplars of ionic bonding.

The uniform chemistry that these electronic similarities might imply is strongly modulated by large variations in radii and coordination numbers. The change from four-coordinate Li^+ (0.59 Å) to 12-coordinate Cs^+ (1.88 Å)¹ represents more than a three-fold difference in size; the change from four-coordinate Be^{2+} (0.27 Å) to 12-coordinate Ba^{2+} (1.61 Å) is nearly six-fold. With noble gas electron configurations for the ions, bonding in *s*-block compounds is largely nondirectional,

and strongly influenced by ligand packing around the metals. Although to a first approximation the geometries of many mononuclear *s*-block coordination complexes are roughly spherical, the presence of multidentate and sterically bulky ligands can produce highly irregular structures.

One of the consequences of the large increase in the number of structurally characterized compounds reported since the publication of *Comprehensive Coordination Chemistry* (CCC, 1987) is that some of the long-standing expectations for Group 1 and 2 chemistry need to be qualified. A conventional generalization holds that the coordination number (c.n.) of a complex should rise steadily with the size of the metal ion, and there is in fact abundant data to support this assumption for small monodentate ligands. For example, analysis of water-coordinated ions indicates that the most common c.n. for Be^{2+} ,² Mg^{2+} ,³ and Ca^{2+} are four, six, and six to eight, respectively.⁴ When more complex aggregates or those containing sterically bulky or macrocyclic ligands are considered, however, the relationship between ion size and c.n. is weakened; e.g., lithium is found with a c.n. of eight in the now-common $[(12\text{-crown-4})_2\text{Li}]^+$ ion (first structurally authenticated in 1984),⁵ whereas barium is only three-coordinate in $\{[\text{Ba}[\text{N}(\text{SiMe}_3)_2]_2]_2\}$.⁶ Similarly, the standard classification of *s*-block ions as hard (type a) Lewis acids leads to the prediction that ligands with hard donor atoms (e.g., O, N, halogens) will routinely be preferred over softer (type b) donors. This is often true, but studies of the “cation- π ” interaction (see Section 3.1.2.2) have demonstrated that the binding of *s*-block ions to “soft” donors can be quite robust; the gas-phase interaction energy of the K^+ ion with benzene, for example, is greater than that to water.⁷ Furthermore, the toxicity of certain barium compounds may be related to the ability of the Ba^{2+} to coordinate to “soft” disulfide linkages, even in the presence of harder oxygen-based residues.⁸

The alkali- and alkaline-earth metals are widespread on earth (four of the eight most common elements in the earth’s crust are *s*-block elements) and their compounds are ubiquitous in daily life. Considering that an estimated one-third of all proteins require a metal ion for their structure or function,⁴ and that the most common metals in biological systems are from these two families (Na^+ , K^+ , Mg^{2+} , Ca^{2+}), the importance of the Group 1 and 2 elements to biology cannot be overestimated.

In the last 20 years, interest in current and potential applications of these elements in oxide- or sulfide-containing materials such as the superconducting cuprates,⁹ ferroelectric ceramics,^{10,11} and phosphor systems has also sharply increased. There has been a correspondingly intensive search for molecular precursors to these species that could be used in chemical vapor deposition (CVD), sol-gel, or spray pyrolysis methods of fabrication.^{12–14} All of these factors mean that the coordination compounds of the *s*-block metals are becoming increasingly important to many branches of chemistry and biology, and the reported chemistry for these elements is vast. Although the number of compounds known for each metal varies substantially, only francium (Fr), all of whose isotopes are radioactive and short-lived (the longest is ^{223}Fr with $t_{1/2} = 22$ min, thereby making it the most unstable of the first 103 elements), has no reported coordination complexes.

The number of reports of new compounds has increased to the point that it is no longer possible to provide exhaustive coverage of them within the confines of a reasonably sized work. As one example, there were as of the end of the year 2000 over 1,100 crystallographically characterized coordination compounds containing an *s*-block element and one or more coordinated water molecules; fewer than 150 of these structures were reported before 1985.

3.1.2 TRENDS SINCE THE MID-1980s

During the last third of the twentieth century, the coordination chemistry of the *s*-block elements gained new-found recognition as being essential to the development of materials science and biology, and eminently worthy of study on its own merits. Prior to the 1967 discovery by Petersen of the ability of crown ethers to form robust complexes with even the largest alkali- and alkaline-earth metals,¹⁵ the prospects for an extensive coordination chemistry of the *s*-block elements appeared dim. The “macrocyclic revolution” generated new interest in Group 1 and 2 complexes, however, and the early developments with ligands such as the crown ethers, cryptands, and calixarenes were documented in CCC (1987). More recent advances in the chemistry of macrocyclic *s*-block complexes have been described in *Comprehensive Supramolecular Chemistry*.

The development of *s*-block metal chemistry in the last 15 years has been accelerated by several other trends, including the expanded use of sterically bulky ligands, the growing recognition that

a strictly electrostatic view of the interaction of the Group 1 and Group 2 metals with their ligands is too limiting, and that “cation- π ” interactions have an important role to play in their chemistry. Associated with the last item is the acknowledgment that *s*-block ions are not necessarily passive counterions in complexes of the main group and transition metals, but may critically alter the structure of these species. Finally, the increasing power of computers and the emergence of density functional theory methods of computation have made calculations on *s*-block species more common, more accurate, and more important than ever before as a probe of bonding and structure and as a guide to reactivity. Each of these trends is examined in turn below.

3.1.2.1 Increased Use of Sterically Bulky Ligands

Although Li^+ , Be^{2+} and Mg^{2+} are about the size of first row transition metals (e.g., Fe^{2+}) or the lighter *p*-block ions (Ge^{2+} , P^{2+}), Na^+ and Ca^{2+} , with radii of approximately 1.0 Å, are roughly the size of the largest trivalent lanthanides. The radii of Cs^+ and Ba^{2+} are comparable to those of polyatomic cations such as NH_4^+ and PH_4^+ .¹⁶ Not only does the large radii of the *s*-block metals accommodate high coordination numbers, but in the presence of sterically compact ligands (e.g., $-\text{NH}_2$, $-\text{OMe}$, halides), extensive oligomerization or polymerization will also occur, leading to the formation of nonmolecular compounds of limited solubility or volatility.

The demand for sources of the *s*-block metal ions that would be useful for materials synthesis¹² or in biological applications has led to a large increase in the use of ligands that are sterically bulky and/or contain internally chelating groups. The resulting compounds are often monomers or low oligomers (dimers, trimers), and their well-defined stoichiometries and reproducible behavior have aided attempts to develop a consistent picture of *s*-block metal reactivity, down to the level of individual metal–ligand bonds. The many clathrate and calixarene complexes described in *CCC* (1987) and *Comprehensive Supramolecular Chemistry* are well-known examples of the influence of steric effects on Group 1 and 2 metal compounds. Numerous cases are known in nonmacrocyclic systems as well; e.g., the oligomeric $[\text{KOCH}_3]_x$ is soluble only in water and alcohols, but $[\text{K}(\mu_3\text{-OBu}^t)]_4$ is a cubane-like tetramer^{17,18} that is soluble in ether and aromatic hydrocarbons. Similarly, the amides $\text{M}(\text{NR}_2)_2$ ($\text{M} = \text{Mg}, \text{Ca}, \text{Sr}, \text{Ba}$) are nonmolecular solids with ionic lattices when $\text{R} = \text{H}$, but are discrete dimers $[\text{M}(\text{NR}_2)_2]_2$ when $\text{R} = \text{SiMe}_3$, and are soluble in hydrocarbons.¹⁹

Metal centers that are coordinated with sterically bulky groups usually have lower formal coordination numbers than their counterparts with smaller ligands, sometimes as small as three for Cs^+ and Ba^{2+} . In such cases, secondary intramolecular contacts between the ligand and metal can occur. These can be subtle, as in the agostic interactions between the SiMe_3 groups on amido ligands and metal centers (e.g., in $[(\text{Me}_3\text{Si})_2\text{N}]_3\text{LiMg}$)²⁰ or more obvious, as in the cation- π interactions discussed in the next section. In any case, further progress with the *s*-block metals can be expected to make even greater use of sterically demanding substituents, including those with internally chelating groups.

3.1.2.2 Recognition of the Importance of Non-ionic Interactions

The conventional approach to understanding bonding in *s*-block coordination complexes views the metal–ligand interactions as essentially electrostatic; i.e., that the metals can be considered as nonpolarizable mono- or dipositive ions, with the ligands arranged around them to maximize cation/anion contacts and minimize intramolecular steric interactions. Even this “simple” analysis can lead to structures that are quite complex, but it has been clear since the 1960s that a more sophisticated analysis of bonding must be used in some cases. The gaseous Group 2 dihalides (MF_2 ($\text{M} = \text{Ca}, \text{Sr}, \text{Ba}$); MCl_2 ($\text{M} = \text{Sr}, \text{Ba}$); BaI_2),^{21–23} for example, are nonlinear, contrary to the predictions of electrostatic bonding. An argument based on the “reverse polarization” of the metal core electrons by the ligands has been used to explain their geometry, an analysis that makes correct predictions about the ordering of the bending for the dihalides (i.e., $\text{Ca} < \text{Sr} < \text{Ba}$; $\text{F} < \text{Cl} < \text{Br} < \text{I}$).^{22,23} Other *ab initio* calculations on Group 1 complexes M^+L_2 ($\text{M} = \text{K}, \text{Rb}, \text{Cs}$; $\text{L} = \text{NH}_3, \text{H}_2\text{O}, \text{HF}$) that have employed quasirelativistic pseudopotentials and flexible, polarized basis sets indicate that bent $\text{L}—\text{M}—\text{L}$ arrangements are favored energetically over linear structures for $\text{M} = \text{Rb}, \text{Cs}$.²⁴ The source of the bending has been ascribed to polarization of the cation by the ligand field,²⁴ although whether the noble-gas cores of the metal cations are polarizable

enough to account for the observed bending has been questioned.²⁵ The “reverse polarization” analysis can be recast in molecular orbital terms; i.e., bending leads to a reduction in the antibonding character in the HOMO. This interpretation has been examined in detail with calculations on RaF_2 .²⁶

An alternative explanation for the bending in ML_2 species has focused on the possibility that metal d orbitals might be involved. Support for this is provided by calculations that indicate a wide range of small molecules, including MH_2 , MLi_2 , $\text{M}(\text{BeH})_2$, $\text{M}(\text{BH}_2)_2$, $\text{M}(\text{CH}_3)_2$, $\text{M}(\text{NH}_2)_2$, $\text{M}(\text{OH})_2$, and MX_2 ($\text{M} = \text{Ca}, \text{Sr}, \text{Ba}$) should be bent, at least partially as an effect of metal d -orbital occupancy.^{24,27–31} The energies involved in bending are sometimes substantial (e.g., the linearization energy of $\text{Ba}(\text{NH}_2)_2$ is placed at ca. 28 kJ mol^{-1}).²⁹ Complexes of Ba^{2+} with three NH_3 , H_2O , or HF ligands have been computed to prefer pyramidal over trigonal-planar arrangements, although the pyramidalization energy is less than 1 kcal mol^{-1} . Spectroscopic confirmation of the bending angles in most of these small molecules is not yet available, however.

However fascinating these effects from incipient covalency might be, they are of low energy, and may be masked by steric effects or crystal packing forces in solid-state structures. A different sort of noncovalent influence that has gained recognition in the past two decades is the so-called “cation- π interaction,” which describes the involvement of cations with a ligand’s π -electrons (usually, but not necessarily, those in an aromatic ring).⁷ Table 1 lists some observed and calculated binding energies for monocations and various π -donors. Note particularly that the interaction energy of benzene with the “hard” K^+ ion ($19.2 \text{ kcal mol}^{-1}$), for example, is even slightly greater than to water in the gas phase. The interaction energy falls in the order $\text{Li}^+ > \text{Na}^+ > \text{K}^+ > \text{Rb}^+$, which is expected for an ionic interaction, but the binding order is more a marker of the strength of the interaction, rather than evidence of an ionic origin for the effect. Several factors are thought to contribute to the cation- π phenomenon, including induced dipoles in aromatic rings, donor-acceptor and charge transfer effects, and the fact that sp^2 -hybridized carbon is more electronegative than is hydrogen.

The cation- π interaction is believed to be operative in many biological systems, such as K^+ -selective channel pores,³² and Na^+ -dependent allosteric regulation in serine proteases.³³ There are also coordination complexes of the s -block elements that display pronounced M^{n+} -arene interactions to coordinated ligands. Many examples could be cited; representative ones are provided by the reaction of $\text{Ga}(\text{mesityl})_3$ or $\text{In}(\text{mesityl})_3$ (mesityl = 2,4,6- $\text{Me}_3\text{C}_6\text{H}_2$) with CsF in acetonitrile, which yields $[\{\text{Cs}(\text{MeCN})_2\}\{\text{mes}_3\text{GaF}\}]_2 \cdot 2\text{MeCN}$ and $[\{\text{Cs}(\text{MeCN})_2\}\{\text{mes}_3\text{InF}\}]_2 \cdot 2\text{MeCN}$, respectively. A similar reaction with $\text{Ga}(\text{CH}_2\text{Ph})_3$ gives $[\text{Cs}\{(\text{PhCH}_2)_3\text{GaF}\}]_2 \cdot 2\text{MeCN}$. The structures are constructed around $(\text{CsF})_2$ rings and display Cs —phenyl interactions (see Figure 1).³⁴ In the structure of $\text{Na}[\text{Nd}(\text{OC}_5\text{H}_3\text{Ph}_{2-2,6})_4]$, formed from NdCl_3 and $\text{Na}(\text{OC}_5\text{H}_3\text{Ph}_{2-2,6})$ in 1,3,5-tri-*t*-butylbenzene at 300°C , the sodium is coordinated to three bridging oxygen atoms and exhibits cation- π interactions with three phenyl groups.³⁵

3.1.2.3 Reappraisal of the “Spectator” Role of *s*-Block Ions

Considering the prevalence of cation- π interactions, it is not surprising that in some cases *s*-block ions may play an important role in modifying the structure and bonding of metal complexes. This represents a more direct kind of interaction than is usually credited to the ions when they are viewed as “spectator” species, i.e., simply as countercharges to complex anions. In many cases, verification of the “nonspectator” role of *s*-block species requires structural authentication through X-ray crystallography, so it is natural that a growing awareness of the importance of such interactions has coincided with the increase in crystallographically characterized compounds during the last two decades.

The consequences of the interaction vary significantly, and only a few examples are detailed here; others can be found throughout this chapter. At one level, cation- π interactions can be responsible for the existence of coordination polymers by serving as interanionic bridges, e.g., reaction of $\text{La}_2[\text{OC}_6\text{H}_3(\text{Pr}^i)_2\text{-2,6}]_6$ with two equivalents of $\text{Cs}[\text{OC}_6\text{H}_3(\text{Pr}^i)_2\text{-2,6}]$ in THF yields the base-free caesium salt $\text{Cs}^+[\text{La}(\text{OC}_6\text{H}_3(\text{Pr}^i)_2\text{-2,6})_4]^-$.³⁶ The latter is an oligomer, in which the caesium ions, supported only by π -interactions (Cs^+ -ring plane = 3.6 Å), bind the lanthanum aryloxide anions together (see Figure 2). Similar interactions are observed in $(\text{Cs}_2)^{2+}[\text{La}(\text{OC}_6\text{H}_3(\text{Pr}^i)_2\text{-2,6})_5]^{2-}$.³⁷

In other cases, intramolecular interactions with *s*-block metal ions may materially change the nature of the associated complexes. Although it involves organometallic complexes, examination

Figure 2 The structure of base-free oligomer $\text{Cs}^+[\text{La}(\text{OC}_6\text{H}_3(\text{Pr}^i)_2\text{-2,6})_4]^-$, supported only by cation- π interactions.

of several such cases is instructive. The sodium metal reduction of $[(2,4,6-(\text{Pr}^i)_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3]\text{GaCl}_2$ in Et_2O gives red-black crystals of a compound with the molecular formula $\text{Na}_2[\text{Ga}(2,4,6-(\text{Pr}^i)_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3]_2$.³⁸ X-ray crystallographic analysis indicates that the compound has a dimeric structure with a 2.319(3) Å Ga–Ga separation. Based on several criteria, including the presence of two-coordinate gallium and the relatively short bond, an argument has been made that the compound contains a $\text{Ga}\equiv\text{Ga}$ triple bond, i.e., that the compound could be viewed as containing the $[\text{RGa}\equiv\text{GaR}]^{2-}$ ion. Discussion over the appropriateness of this description has been extensive; arguments in favor of a high Ga–Ga bond order (≥ 2.5)^{39,40} and those preferring a lower value (≤ 2)^{41–44} have used a variety of computational tests to substantiate their viewpoints. Early in the debate it was observed, however, that the sodium “counterions” are in a strategic position in the molecule; i.e., where they can engage in a π -interaction between phenyl rings (Na–ring plane 2.75–2.81 Å) (see Figure 3).⁴⁵ It has since been recognized that the Na^+ -arene interaction is responsible for at least some of the short Ga–Ga distance; calculations cannot reproduce the metal separation if the anion is modeled simply as isolated $[\text{HGaGaH}]^{2-}$ or $[\text{MeGaGaMe}]^{2-}$ units.^{39,46}

It is clear that the presence of Na^+ is critical to the existence of the molecule; if potassium is substituted for sodium in the reduction of $[(2,4,6-(\text{Pr}^i)_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3]\text{GaCl}_2$, the very different $\text{K}_2[\text{Ga}_4(\text{C}_6\text{H}_3-2,6-(2,4,6-(\text{Pr}^i)_3\text{C}_6\text{H}_2)_2)_2]$ moiety is isolated (see Figure 4).⁴⁷ The almost square Ga_4 ring is capped on both sides by K^+ ions that are at somewhat different distances from the plane (3.53, 3.82 Å). The potassium ions are clearly involved with phenyl groups on the ligands at distances of 3.1 Å. It is apparent that the identity of the alkali metal cation is critical to the formation of the compounds, and that it is incorrect to view the *s*-block ions as freely interchangeable.

There are other examples of Group 1 ions involved in other main-group systems, many of which are organometallic species and outside the scope of this chapter. There are also compounds in which an *s*-block ion serves as both a linker in a coordination polymer and as an integral part of a metal aggregate, such as the $[\text{K}(18\text{-crown-6})]_3\text{KSn}_9$ cluster (see Figure 5).⁴⁸

3.1.2.4 Application of Computational Methods to Complexes

The enormous increase in readily available computing power since the 1980s has greatly affected the study of *s*-block metal complexes. A long-standing assumption that the Group 1 and 2 metal ions (especially the former) could be successfully modeled as point charges in molecular orbital

Figure 3 Na–phenyl contacts in $\text{Na}_2[\text{Ga}(2,4,6-(\text{Pr}^i)_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3]_2$.

Figure 4 The structure of $\text{K}_2[\text{Ga}_4(\text{C}_6\text{H}_3\text{-}2,6\text{-(}2,4,6\text{-(Pr}^i\text{)}_3\text{C}_6\text{H}_2)_2]$, illustrating the K^+ –phenyl interactions.

calculations has been shown to be increasingly inadequate. Schleyer first demonstrated with calculations on organolithium complexes that attempts to understand the bonding and reactivity of *s*-block complexes severely test the performance of *ab initio* computational methods.^{49,50} Owing to their lack of valence electrons, alkali and alkaline-earth complexes are formally electron deficient and conformationally “floppy,” and only small energies (often $1\text{--}2\text{ kcal mol}^{-1}$) are required to alter their geometries by large amounts (e.g., bond angles by 20° or more). In such cases, the inclusion of electron correlation effects becomes critical to an accurate description of the structure of the molecules. Traditional Hartree–Fock approaches, especially when combined with small or minimal basis sets, are generally inadequate for these complexes. Some of the

Figure 5 The structure of the tin aggregate, $[\text{K}(18\text{-crown-}6)]_3\text{KSn}_9$.

quantitative or semiquantitative agreement claimed in the past between observed and calculated energies and structures must now be ascribed to fortuitous cancellation of errors.

Density functional theory (DFT) methods, which implicitly incorporate electron correlation in a computationally efficient form, have found wide use in main-group chemistry.^{51–53} In general, they have been more successful than Hartree–Fock techniques in dealing with organoalkali and organoalkaline-earth molecules, and there is growing evidence of their successful use with coordination complexes. Nevertheless, a wide range of computational techniques continues to be used in *s*-block element chemistry, from molecular modeling and semiempirical methods, to high-level coupled cluster and DFT approaches. Representative samples of the application of computational investigations to *s*-block coordination compounds are found in the sections below.

3.1.3 MACROCYCLIC COMPOUNDS

As noted in Section 3.1.2, the introduction of the crown ethers in the late 1960s gave legitimacy to the concept of stable coordination complexes of the alkali metals. Their presence, and that of many other macrocyclic counterparts (e.g., porphyrins) and three-dimensional chelators (e.g., cryptands, calixarenes) is now pervasive in both alkali and alkaline-earth coordination chemistry, and the literature on these complexes is vast. Early work in this area was summarized in CCC (1987), and examined in a more focused manner in *Comprehensive Supramolecular Chemistry*. It is not the intent of this section to repeat such material, but rather to highlight new developments since the mid-1990s. In some cases, specialist reviews are available on these subjects; they will be noted where relevant.

3.1.3.1 Porphyrins and Phthalocyanines

The *s*-block metal most commonly complexed to a porphyrin is magnesium, and many such compounds have been prepared in the course of studies on models for bacteriochlorophyll.⁵⁴ These include the metallotetraphenylporphyrin cation radical (MgTPP^{+*}), obtained as its perchlorate salt,⁵⁵ and the neutral MgTPP , isolated as an adduct with (1-methylimidazole),⁵⁶ 4-picoline,⁵⁶ piperidine,⁵⁶ water,^{57,58} and methanol.⁵⁸ Related magnesium porphyrin derivatives have been prepared in the study of photosynthetic reaction centers; e.g., the tetrakis(4-methoxyphenyl) H_2O adduct,⁵⁹ and octaethylporphyrinato dimers, whose strength of coupling (reflected also in UV/vis spectra) is strongly dependent on the polarity of the solvent.⁶⁰ The tetraphenylporphyrin framework does not undergo significant structural change on oxidation, thus making neutral molecules realistic models for radical cationic species.

MgTPP has also been examined as a substrate for constructing “porphyrin sponges,” i.e., lattice clathrates that can reversibly absorb and release guest molecules.^{61–65} Such guests as methyl benzoate,⁶² propanol and (*R*)-phenethylamine have been structurally authenticated; other examples are known.⁶⁴

Porphyrin complexes of *s*-block metals other than magnesium have received less attention. Reaction of free-base porphyrins (H_2Por = octaethylporphyrin (H_2OEP), *meso*-tetra-phenylporphyrin, *meso*-tetra-*p*-tolylporphyrin, *meso*-tetrakis(4-*t*-butylphenyl)porphyrin, and *meso*-tetrakis(3,4,5-trimethoxyphenyl)porphyrin (H_2TMPP)) with two equivalents of $\text{MN}(\text{SiMe}_3)_2$ ($\text{M} = \text{Li}, \text{Na}, \text{K}$) in THF or dimethoxyethane (DME) yields $\text{M}_2(\text{THF})_4\text{Por}$ and $\text{M}_2(\text{DME})_2\text{Por}$, respectively. The lithium derivatives crystallize from THF, DME, and diacetone alcohol as 1:1 $[\text{LiQ}_n][\text{Li}(\text{Por})]$ salts ($\text{Q} = \text{THF}$, $n = 4$; $\text{Q} = \text{DME}$, diacetone alcohol (DAA), $n = 2$).⁶⁶ The lithium TMPP derivative crystallizes from acetone, and consists of $[\text{Li}(\text{TMPP})]^-$ and a $[\text{Li}(\text{DAA})_2]^+$ counterion; the octaethylporphyrin derivative is isolated as the $[\text{Li}(\text{THF})_4]^+ [\text{LiOEP}]^-$ salt.⁶⁷ ^7Li NMR spectroscopy and conductivity measurements indicate that these ionic structures are retained in polar solvents; in relatively nonpolar solvents, symmetrical ion-paired structures are observed.

The solid state structure of the centrosymmetric dilithium tetraphenylporphyrin bis(diethyletherate) differs from the salt-like compounds, in that the $[\text{Li}(\text{Et}_2\text{O})]^+$ moiety is coordinated to both faces of the porphyrin in a square pyramidal fashion ($\text{Li}-\text{N} = 2.23\text{--}2.32 \text{ \AA}$).⁶⁸ A related motif is found in the case of sodium octaethylporphyrinate; X-ray crystallography reveals two $\text{Na}(\text{THF})_2$ moieties symmetrically bound to all four nitrogen atoms, one on each face of the porphyrin ring ($\text{Na}-\text{N}(\text{av}) = 2.48 \text{ \AA}$). The structure of the potassium derivative $\text{K}_2(\text{py})_4(\text{OEP})$ is similar ($\text{K}-\text{N}(\text{av}) = 2.84 \text{ \AA}$).⁶⁶

Although attempts to prepare the neutral lithium octaethylporphyrin radical ($[\text{Li}(\text{OEP})\cdot]$) have been unsuccessful, neutral π -radicals of three Li porphyrins, tetraphenylporphyrin $[\text{Li}(\text{TPP})\cdot]$, tetra(pentafluorophenyl)porphyrin $[\text{Li}(\text{PFP})\cdot]$, and tetra(3,5-bis-*tert*-butylphenyl)porphyrin $[\text{Li}(\text{TBP})\cdot]$ are available from the dilithium porphyrins by oxidation with ferrocenium hexafluorophosphate in THF or dichloromethane.⁶⁹ The resulting lithium porphyrin radicals have been isolated by crystallization; $[\text{Li}(\text{TPP})\cdot]$ is insoluble in acetone and in nonpolar solvents, whereas $[\text{Li}(\text{PFP})\cdot]$ and $[\text{Li}(\text{TBP})\cdot]$ are soluble in acetone, with the latter slightly soluble even in toluene and benzene. The UV/vis spectra of the radicals have been studied in acetonitrile solutions, which display negligible Λ_{M} values; this indicates that the compounds exist as tight ion pairs. The absence of hyperfine splitting for $[\text{Li}(\text{TPP})\cdot]$ and $[\text{Li}(\text{PFP})\cdot]$ at room temperature in solution and in the solid state suggests that they exist in the $^2A_{1u}$ ground state, which has low spin density on the *meso*-carbons and the nitrogen atoms.

Crystallization of $[\text{Li}(\text{TPP})\cdot]$ from dichloromethane and diethyl ether yields purple crystals; the solid state structure indicates that the lithium atom is bound in the plane of the porphyrin. The porphyrin macrocycle is slightly ruffled, with opposite pyrrolic carbons up to 0.3 Å above or below the mean porphyrin plane.⁶⁹

Several examples of porphyrin complexes of calcium are now known. Activated calcium in THF reacts with H_2OEP at room temperature, producing the bimetallic complex $\text{Et}_8\text{N}_4\text{Ca}_2(\text{THF})_4$ in 73% yield. Subsequent reaction of the calcium complex with $\text{Et}_8\text{N}_4\text{Li}_4(\text{THF})_4$ in THF generates the calcium–lithium complex $\text{Et}_8\text{N}_4\text{CaLi}_2(\text{THF})_3$. Both have been structurally characterized.⁷⁰ 5,10,15,20-Tetrakis(4-*t*-butylphenyl)porphyrin (H_2L) reacts with activated calcium to give CaL , which in turn reacts with pyridine with or without added NaI or $\text{CaI}_2(\text{THF})_4$ to give $\text{CaL}(\text{Py})_3$, $[\text{CaNaL}(\text{Py})_6]\text{I}$ and $\text{Ca}_3\text{L}_2(\text{MeCN})_4\text{I}_2$, respectively. In $\text{CaL}(\text{Py})_3$, the calcium is seven-coordinate, and is displaced from the N_4 plane of the porphyrin. $\text{Ca}_3\text{L}_2(\text{MeCN})_4\text{I}_2$ is a double-decker sandwich compound with the outer two calcium atoms coordinated by four porphyrin N atoms, two acetonitriles and an iodide (see Figure 6). The results indicate that in polar aprotic solvents, calcium porphyrin derivatives can be stable.⁷¹

Phthalocyanine ligands, structurally related to porphyrins, confer distinctive optoelectronic properties on their complexes. Lithium phthalocyanine (LiPc) forms stacks in the solid state with a $\text{Li}—\text{Li}'$ distance of 3.245 Å,⁷² this is longer than in the metal (3.04 Å), but less than the sum of the van der Waals thicknesses of the rings (see Figure 7). The extra electron left from removing two hydrogen atoms and replacing them with Li^+ is delocalized in the central ring of the

Figure 6 The double decker sandwich porphyrin complex $\text{Ca}_3\text{L}_2(\text{MeCN})_4\text{I}_2$.

Figure 7 Stacking observed in lithium phthalocyanine (LiPc).

macrocyclic.⁷³ Despite the stacking of the molecules, and the anticipated overlap of the π orbitals of the Pc ligand,⁷⁴ LiPc is in fact a semiconductor⁷⁵ with an optical gap of 0.5 eV, and not a one-dimensional conductor. Magnetic susceptibility, heat capacity, and optical conductivity measurements indicate that LiPc should be considered a Mott–Hubbard insulator.⁷⁶ The localized electrons behave as an $S=1/2$ antiferromagnetic spin chain. The related iodinated compound LiPcI is EPR silent, reflecting the loss of unpaired electrons. It is an intrinsic semiconductor, with diamagnetic susceptibility.⁷⁶

Magnesium phthalocyanine (MgPc) is a blue semiconductor with a thin film optical band gap of 2.6 eV;⁷⁷ its X-phase exhibits an intense near-IR-absorption.⁷⁸ It has attracted attention as a material for laser printer photoreceptors,⁷⁹ optical disks based on GaAsAl laser diodes,⁸⁰ and photovoltaic devices.⁸¹ Crystalline $\text{MgPc}/(\text{H}_2\text{O})_2 \cdot (N\text{-methyl-2-pyrrolidone})_2$ exhibits a near-IR absorption whose spectral shape is similar to that of the X-phase.^{78,82} The near-IR absorption has been interpreted from the standpoint of exciton coupling effects. Structures have been calculated for both MgPc and its radical anion doublet (MgPc^-), using *ab initio* (6–31G(d,p)) and semiempirical (INDO/1) SCF approaches. The anion displays first-order Jahn–Teller distortion, and the effect that varying the degree of distortion has on the computed anion spectrum has been examined.⁸³

3.1.3.2 Group 16 Ligands

3.1.3.2.1 Crown ethers

Crown ether complexes of the *s*-block metals number in the many hundreds,⁸⁴ and reviews focused on them, including their use in separation chemistry^{85–87} and selective ion extractions,^{88,89} are extensive.^{90–96} Growing interest has been expressed in the use of macrocyclic ethers in the design of electroactive polymers.⁹⁷

The 12-crown-4 ring is often complexed with lithium,⁹⁸ and the sandwich $[(12\text{-crown-4})_2\text{Li}]^+$ ion is common, although examples with Na^+ ,^{99–106} K^+ ,¹⁰⁶ Rb^+ ,¹⁰⁶ and Mg^{2+} ¹⁰⁷ ions are known. The centrosymmetric dimer $[\text{Li}(12\text{-crown-4})]_2^{2+}$, in which each lithium ion forms an intermolecular Li—O bond with a neighboring crown ether molecule (Li—O = 2.01 Å) in a rectangular four-membered Li_2O_2 ring has been described.¹⁰⁸

Cation-coordinating macrocycles have been used to form amorphous electrolytes; if the cavity of the macrocycle is larger than that of the cation, the resulting complex is a glass that has a subambient glass transition temperature and high ionic conductivity.^{109,110} Coordination of the lithium ion in $\text{Li}[\text{CF}_3\text{SO}_2\text{N}(\text{CH}_2)_3\text{OCH}_3]$ by 12-crown-4, for example, lengthens the Li—N distance to 2.01 Å, which indicates a weakening of the interaction between the lithium cation and the $[\text{CF}_3\text{SO}_2\text{N}(\text{CH}_2)_3\text{OCH}_3]^-$ anion.¹¹¹ Such an environment may facilitate ionic conductivity.

Molecular conductors have been constructed by using supramolecular cations as counterions to complex anions. For example, the charge-transfer salt $\text{Li}_{0.6}(15\text{-crown-5})[\text{Ni}(\text{dmit})_2]_2 \cdot \text{H}_2\text{O}$ (dmit = 2-thioxo-1,3-dithiol-4,5-dithiolate) exhibits both electron and ion conductivity: the stacks of the Ni complex provide a pathway for electron conduction, and stacks of the crown ethers provide channels for Li-ion motion.¹¹² The μ -crown cation $\{[\text{Li}(12\text{-crown-4})](\mu\text{-}12\text{-crown-}4)[\text{Li}(12\text{-crown-4})]\}^{2+}$ has been generated as the counterion to $[\text{Ni}(\text{dmit})_2]^{2-}$.¹⁰⁶ The salt displays a room temperature conductivity of 30 S cm^{-1} and exhibits a semiconductor-semiconductor phase transition on the application of pressure or on lowering the temperature.

The 15-crown-5 ring binds a larger range of *s*-block ions than does 12-crown-4, and simple $[\text{M}(15\text{-crown-5})]^+$ or $[\text{L}_n\text{M}(15\text{-crown-5})]^+$ ($\text{L} = \text{H}_2\text{O}$, halide, ether, acetonitrile, etc.) complexes are common. Sandwich species of the form $[(15\text{-crown-5})_2\text{M}]^+$ ($\text{M} = \text{K}^+$,^{113,114} Cs^+ ,¹¹⁵ Ba^{2+} ,¹¹⁶) are known, including the chloride-bridged species $\{[\text{Li}(15\text{-crown-5})](\mu\text{-Cl})[\text{Li}(15\text{-crown-5})]\}^+$.¹¹⁷

The reaction of lithium chloride with 15-crown-5 in THF produces an extended chain structure consisting of alkali metals and bridging halogens. The repeating units, $\text{Li}(\mu\text{-Cl})\text{Li}(15\text{-crown-5})$, are connected by additional bridging Cl atoms. One lithium has close contacts with one Cl (2.34 Å) and all five oxygen atoms of 15-crown-5, and the other Li is close to three Cl (2.35–2.38 Å) and one oxygen of 15-crown-5 (see Figure 8). With the use of hydrated lithium chloride, the lithium is coordinated to all five oxygen atoms of the crown as well as to an additional oxygen atom from H_2O in a distorted pentagonal pyramidal geometry. The Cl^- counteranion is isolated from the Li^+ cation, and is hydrogen-bonded to the coordinated water molecule.¹¹⁸

The reaction of NaBr or KBr with 15-crown-5 and TlBr_3 in ethanol produces the unusual self-assembled cations $\{[\text{M}(15\text{-crown-5})]_4\text{Br}\}^{3+}$, whose formation has been templated by the bromide anion. The crystal structure of $\{[\text{Na}(15\text{-crown-5})]_4\text{Br}\}[\text{TlBr}_4]$ reveals that the bromide is surrounded by four Na(15-crown-5) units with crystallographically imposed D_{2d} -symmetry (Na—Br = 2.89 Å; cf. 2.98 in NaBr) (see Figure 9). A folded network of TlBr_4^- anions surrounds the cations.¹¹⁹

The 18-crown-6 ether is widely represented among the *s*-block elements, and is found in a large range of compounds, either as the simple $[(18\text{-crown-6})\text{M}]^+$ ion, coordinated with various anions ((18-crown-6)ML; $\text{L} = \text{H}_2\text{O}$, ethers, alcohols, HMPA, NH_3 , etc.) or as the sandwich species $[(18\text{-crown-6})_2\text{M}]^+$. It is often thought to fit best with K^+ or Sr^{2+} , but Rb^+ can sit in the center

Figure 8 The structure of the LiCl/15-crown-5 polymer.

Figure 9 The solid state structure of the $[\{\text{Na}(\text{15-crown-5})\}_4\text{Br}]^+$ cation.

of the crown, occupying a crystallographic inversion site (Rb—O bond length of 2.82–2.87 Å).¹²⁰ “Club sandwiches” of the form $[(\text{18-crown-6})\text{Cs}(\text{18-crown-6})\text{Cs}(\text{18-crown-6})]^{2+}$ have been described; the central 18-crown-6 ring displays longer coordination interactions (Cs—O = 3.51 Å (av)) than the end crowns (Cs—O = 3.27 Å (av)) (see Figure 10).^{121,122}

The study of luminescence has often involved alkali metal crown complexes. Luminescent copper(I) halide complexes have been isolated from the reaction of elemental copper with NH_4X (X = I, Br or SCN), RbI and 18-crown-6 in MeCN. Halo- or pseudohalo-cuprate(I) anions crystallize with the geometrically rigid crown ether cation $[\text{Rb}(\text{18-crown-6})]^+$. The complexes $[\{\text{Rb}(\text{18-crown-6})\}_2\text{MeCN}][\text{Cu}_4\text{I}_6]$, $[\text{Rb}(\text{18-crown-6})][\text{Rb}(\text{18-crown-6})(\text{MeCN})_3]_2[\{\text{Rb}(\text{18-crown-6})\}_6\text{Cu}_4\text{I}_7][\text{Cu}_7\text{I}_{10}]_2$, $\{\text{Rb}(\text{18-crown-6})\}[\text{Cu}_3\text{I}_3\text{Br}]_\infty$ and $\{\text{Rb}(\text{18-crown-6})\}[\text{Cu}_2(\text{SCN})_3]_\infty$ have been characterized. The first three complexes display temperature-sensitive emission spectra in the solid state.¹²³ The structure of the second is unusually complex: one $[\text{Rb}(\text{18-crown-6})]^+$ cation and two $[\text{Rb}(\text{18-crown-6})(\text{MeCN})_3]^+$ cations, the bulky supramolecular cation $[\{\text{Rb}(\text{18-crown-6})\}_6\text{Cu}_4\text{I}_7]^{3+}$ (see Figure 11) and the crown-like $[\text{Cu}_7\text{I}_{10}]^{3-}$ cluster are present.¹²³

Luminescence and electronic energy transport characteristics of supramolecular $[\text{M}(\text{18-crown-6})_4\text{MnBr}_4][\text{TlBr}_4]_2$ (M = Rb, K) complexes (see Figure 12) were studied in the expectation that $[\text{MnBr}_4]^{2-}$ ions would be effective luminescent probes for solid state (18-crown-6) rotation-conformational

Figure 10 The structure of the “club sandwich” cation $[(\text{18-crown-6})\text{Cs}(\text{18-crown-6})\text{Cs}(\text{18-crown-6})]^{2+}$.

Figure 11 The structure of the supramolecular cation $[\{\text{Rb}(18\text{-crown-6})\}_3\text{Cu}_4\text{I}_7]^{3+}$.

motion. Luminescence and excitation spectra are normal when $M = \text{Rb}$ (a strong emission at 77 K with λ_{max} of 535 nm is observed, with weak room temperature luminescence), but when $M = \text{K}$, an unusual orange emission with $\lambda_{\text{max}} \approx 570$ nm is observed; it has been attributed to crystal defects.¹²⁴

When reduced, fullerene can be supported by $[\text{K}(18\text{-crown-6})]^+$. Paramagnetic red-black $[\text{K}(18\text{-crown-6})]_3[\text{C}_{60}]$ is prepared by dissolving potassium in molten 18-crown-6, followed by addition of C_{60} , or by reducing C_{60} with potassium in DMF followed by reaction with 18-crown-6. In the solid state, the potassium ions bind to the six oxygen atoms of the crown ethers; two potassium ions are η^6 -bonded to opposite 6-membered rings on C_{60}^{3-} , whereas the third is bound to a crown ether as well as to two toluene molecules (see Figure 13).¹²⁵

Figure 12 The structure of the $[\text{Rb}(18\text{-crown-6})_4\text{MnBr}_4]^{2+}$ cation.

Figure 13 The structure of $[K(18\text{-crown-6})]_3[C_{60}]$.

In the solid state, the macrocyclic complex $Rb_3(18\text{-crown-6})_3Cu_2[N(CN)_2]_5$ includes polymeric dicyanoamidocuprate(I) anions, and the Cu atoms are coordinated at the nitrile nitrogens (Cu—N = 1.89–2.07 Å). There are two types of Cu atoms with different environments, planar-trigonal and tetrahedral. The $[Rb(18\text{-crown-6})]^+$ units form puckered planes about 11 Å apart (see Figure 14).¹²⁶

Large crown ethers have been investigated for their sometimes unexpected ion selectivities. The structural origins of the selectivity of Rb^+ ion over other alkali metal ions by tribenzo-21-crown-7 has been elucidated from single-crystal X-ray structures of $Cs[\text{tribenzo-21-crown-7}]\text{NO}_3$, $\{[Rb(4,4\text{-bis-}t\text{-butylbenzo,benzo-21-crown-7})(\text{dioxane})]_2(\mu\text{-dioxane})\}\text{Cl}$, and $Na[4,4\text{-bis-}t\text{-butylbenzo,benzo-21-crown-7}]\text{ReO}_4$. Different crown conformations are observed for each structure. Molecular mechanics calculations on the conformers suggest that the selectivity found for the crown for Rb^+ and Cs^+ over the smaller Na^+ can be largely attributed to the energetically unfavorable conformation that must be adopted to achieve heptadentate coordination with optimum Na—O distances. The selectivity for Rb^+ over Cs^+ may be a consequence of stronger Rb—O bonds, which outweigh the small (0.7–0.9 kcal mol^{−1}) steric preference for Cs^+ over Rb^+ .¹²⁷

Alkali metal picrates have been used to measure formation constants for crown ethers in solution, but the selectivity of benzo crown ethers for metal picrates, relative to the analogous chlorides, nitrates, perchlorates, and thiocyanates, may vary significantly. Apparently, π – π interactions between the picrate ions and the aromatic ring(s) on the crown are responsible for the difference. The importance of the “picrate effect” rises as the number of benzo groups in the crown ether is increased, and it varies with their location in the macrocycle. The dependence of the picrate ¹H NMR chemical shift on the metal cation and/or macrocycle identity has been used to study picrate-crown ether π -stacking in large crown ether (18, 21, and 24-membered) complexes.¹²⁸

3.1.3.2.2 Cryptands and related species

The *s*-block metals are commonly complexed with the macrocyclic cryptands, sephulchrates, and related species¹²⁹ to form large, non-interacting cations that are used to stabilize a variety of anions, such as metal clusters (e.g., Ge_5^{2-} ,¹³⁰ Ge_9^{3-} ,¹³¹ Ge_{18}^{6-} ,¹³² Sn_5^{2-} ,¹³³ Sn_9^{3-} ,^{134,135}

Figure 14 Section of the lattice of $\text{Rb}_3(18\text{-crown-6})_3\text{Cu}_2[\text{N}(\text{CN})_5]_5$.

$\text{Sn}_2\text{Se}_6^{4-}$,¹³⁶ $\text{K}_2\text{Sn}_2\text{Te}_6^{2-}$,¹³⁶ Pb_9^{3-} ,^{134,137} Pb_9^{4-} ,¹³⁷ $\text{Pb}_2\text{S}_3^{2-}$,¹³⁸ $\text{Pb}_2\text{Se}_3^{2-}$,¹³⁸ $\text{PbTe}_3\text{Te}_3^{3-}$,¹³⁸
 $\text{Pb}_2\text{Te}_3^{2-}$,¹³⁹ $\text{As}_2\text{S}_4^{2-}$,¹⁴⁰ $\text{As}_4\text{Se}_6^{2-}$,¹⁴⁰ $\text{As}_{10}\text{S}_3^{2-}$,¹⁴⁰ $\text{Sb}_2\text{Se}_4^{2-}$,¹⁴⁰ $\text{Bi}_3\text{Ga}^{2-}$,¹⁴¹ $\text{Bi}_3\text{In}^{2-}$,¹⁴¹
 $\text{Bi}_5\text{In}_4^{3-}$,¹⁴¹ $\text{Se}_{10}\text{Sn}_4^{4-}$,¹⁴² $\text{Se}_2\text{Te}_2^{2-}$,¹⁴³ $\text{Te}_2\text{Te}_2^{2-}$,¹⁴³ and MoAs_8^{2-} .¹⁴⁴

The relative inertness of cryptands has made them especially useful for the isolation of otherwise highly reactive or unstable anions. For example, the reaction between RbO_3 and 18-crown-6 in liquid ammonia permits the isolation of the crystalline ozonide complex $[\text{Rb}(18\text{-crown-6})]\text{O}_3\cdot\text{NH}_3$.¹⁴⁵ The use of cryptands is required to isolate complexes derived from the less stable LiO_3 and NaO_3 in liquid ammonia; crystalline ozonide complexes $\{\text{Li}[2.1.1]\}\text{O}_3$ ($[2.2.1]=4,7,13,18\text{-tetraoxa-1,10-diazabicyclo}[8.5.5]\text{icicosane}$) and $\{\text{Na}[2.2.2]\}\text{O}_3$ ($[2.2.2]=4,7,13,16,21,24\text{-hexaoxa-1,10-diazabicyclo}[8.8.8]\text{hexacosane}$) can be obtained that contain the bent O_3^- anion.¹⁴⁶ The diamagnetic Bi_2^{2-} anion has been isolated as its $[\text{K}([2.2.2]\text{crypt})]_2$ salt.¹⁴⁷ Each “naked” anion ($\text{Bi}-\text{Bi}=2.8377(7)\text{Å}$) is surrounded by eight $[\text{K-crypt}]^+$ cations, and it is notable that the dianion has been stabilized without the bulky substituents usually required for isolation of multiply bonded main-group species (see Figure 15).¹⁴⁸

The fulleride dianion has been isolated in the solid state as $[\text{K}([2.2.2]\text{crypt})]_2[\text{C}_{60}]$; its structure consists of alternating layers of ordered C_{60}^{2-} anions and $[\text{K}([2.2.2]\text{crypt})]^+$ cations.¹⁴⁹ The complete separation of the anions ($>13.77\text{Å}$) by the cations allows EPR and magnetic susceptibility measurements on the isolated fulleride.

3.1.3.2.3 Calixarenes

Calixarenes, the cyclic oligomers formed from condensation reactions between *para*-substituted phenols and formaldehyde, are inexpensive compounds that are stable to both basic and acidic media.^{150,151}

Figure 15 The $[K([2.2.2]crypt)]$ salt of the Bi_2^{2-} anion.

Their ability to complex both neutral and ionic species has driven their employment as complexing agents, extractants,^{152–156} in chemical sensing (detection) devices,^{157–159} and as catalysts.^{160,161}

Calixarenes excel in the complexation of large ions, and this has been exploited in the development of ligands for radium.¹⁶² ^{223}Ra ($t_{1/2} = 11.4$ d) is an α -particle emitter that has been evaluated for use in cell-directed therapy of cancer. Such use requires that it be attached to a monoclonal antibody or related targeting protein with high specificity, and that the complex exhibit kinetic stability at physiological pH in the presence of much greater concentrations of other potentially binding ions such as Mg^{2+} and Ca^{2+} . The lipophilic acrylic polyether carboxylic acid, bis-1,8-(2'-carboxy-3-naphthoxy)-3,6-dioxaoctane, exhibits selectivity for Ra^{2+} over Ba^{2+} , but does not have adequate binding stability to serve in radiotherapy.¹⁶³

Bifunctional radium-selective ligands together with effective linkers to the protein antibody have been developed from the 1,3-alkoxycalix[4]arene-crown-6 cavity, which has a high selectivity for Cs^+ over K^+ .¹⁶⁴ Modified with proton-ionizable crowns with carboxylate sidearms to enhance the binding of alkaline-earth ions, the two ionizable calixarene-crowns, *p*-*t*-butylcalix[4]arene-crown-6-dicarboxylic acid (see Figure 16(a)) and *p*-*t*-butylcalix[4]arene-crown-6-dihydroxamic acid (see Figure 16(b)), are able to extract greater than 99.9% of radium in the presence of Mg^{2+} , Ca^{2+} , Sr^{2+} , and Ba^{2+} . The lariat arms prevent radium from escaping from the cavity, and the complexes display kinetic stability in the presence of serum-abundant metal ions including Na^+ , K^+ , Mg^{2+} , Ca^{2+} , and Zn^{2+} at relatively high concentrations (10^{-2} M) and pH 7.4.

The ability of calixarenes to bind large metal ions with high kinetic stability is important in the search for complexants for radionuclides such as ^{137}Cs ($t_{1/2} = 30.2$ yr) and ^{85}Sr ($t_{1/2} = 65$ d) from the reprocessing of exhausted nuclear fuel.¹⁶⁵ There has been considerable interest in caesium-complexed calix[4]-bis-crowns as selective Cs -carriers.¹⁶⁶ Transport isotherms of trace level ^{137}Cs through supported liquid membranes containing calix[4]-bis-crowns have been determined as a function of the ionic concentration of the aqueous feeder solutions, and 1,3-calix[4]-bis-*o*-benzo-crown-6 appears to be much more efficient in decontamination than mixtures of crown ethers and acidic exchangers, especially in highly acidic media.¹⁶⁷

Figure 16 Two ionizable calixarene-crowns used to complex Ra^{2+} .

The complexing properties of 1,3-calix[4]-bis-crown-6 towards Cs^+ ions have been studied by ^{133}Cs and ^1H -NMR spectroscopy. Crystal structures of caesium complexes indicate that the cations are bound in the polyether loops (e.g., the dinitrato complex, see Figure 17), and suggest that the ligand is preorganized for Cs^+ ion complexation. This may explain the high selectivity displayed toward the cation.¹⁶⁸ Caesium ions are also observed to bind to the polyether loops in the substituted calixarenes prepared from the base-catalyzed reactions of calix[4]crown-6 with $\text{TsO}(\text{CH}_2\text{CH}_2\text{O})_2\text{X}(\text{OCH}_2\text{CH}_2)_2\text{OTs}$ [$\text{X} = o\text{-C}_6\text{H}_4$, 2,3-naphthalenediyl].¹⁶⁹ Similar caesium binding is observed in the binuclear complex formed from 1,3-calix[4]-bis-crown-6 and caesium iodide. The two Cs^+ ions are located at the center of a coordination site defined by the six oxygen atoms of the crown-ether chains, and are bonded to six oxygen atoms and iodide counterions; they also interact with the two closest benzene rings.¹⁷⁰

Cone diallyloxybis-crown-4 calix[6]arene and its 1,2,3-alternate stereoisomer have been isolated in 11% and 15% yields, respectively, by bridging a 1,4-diallyloxy calix[6]arene with triethylene glycol di-*p*-tosylate, 4-MeOC₆H₄SO₂OCH₂(CH₂OCH₂)₂CH₂OSO₂C₆H₄-4-Me. Both conformers form 1:1 complexes with all alkali metal ions, but are structurally preorganized such that each exhibits a strong preference for the caesium ion. The structure of the complex between the cone

Figure 17 Dinitrato derivative of Cs^+ and 1,3-calix[4]-bis-crown-6.

calixarene and caesium tetraphenylborate reveals cooperative complexation of caesium by both crown-4-ethers (see Figure 18). The association constants of caesium and rubidium ions with the cone stereoisomer are 20–50 times greater than that for the 1,2,3-alternate stereoisomer; cooperative binding of cations by the two crown ether moieties is not possible for the latter. The Cs^+/Na^+ selectivity factor for the cone isomer is found to be 1,500, while that of the 1,2,3-alternate stereoisomer is 140.¹⁷¹

1,3-Dialkoxycalix[4]arene-crown-6 ligands are obtained in the fixed 1,3-alternate conformation in 63–85% yield by the reaction of the corresponding 1,3-dialkoxycalix[4]arenes with pentaethylene glycol ditosylate in acetonitrile in the presence of Cs_2CO_3 . The corresponding cone conformer of the diisopropyl derivative has been synthesized via selective demethylation of the 1,3-dimethoxycalix-crown and subsequent dialkylation. Extraction with alkali metal picrates reveals a strong preference of the ligands for Cs^+ ; greater than 99.8% of Cs^+ can be removed at $\text{pH}=0$ from solutions that are 4 M in Na^+ . Thermodynamic measurements obtained for the complexation of the diisopropyl derivative indicate a high stability constant in methanol ($\log \beta = 6.4 \pm 0.4$). The entropy of complexation ($T\Delta S = -15 \text{ kJ mol}^{-1}$) is less negative than for other crown ethers, and probably derives from the preorganization of the ligand. Both X-ray crystallographic and solution NMR studies confirm that the cation is positioned between the two aromatic rings.¹⁷²

In an interesting variation on the use of calixarenes to complex caesium ions, when $[\text{HNC}_5\text{H}_5]_2[\text{UO}_2\text{Cl}_4]$ is treated with *t*-Bu-calix[6]arene (H_6L) in pyridine, no reaction is observed, even after refluxing for 12 hours. When one equivalent of caesium triflate is added to the mixture, however, the pale yellow color of the solution immediately turns deep red, and a heterotrimetallic complex of the *t*-Bu-calix[6]arene can be isolated. The crystal structure of the compound reveals that two uranyl cations and a caesium atom are coordinated to the macrocycle (see Figure 19).¹⁷³ The two uranyl cations are bound in an external fashion to the macrocycle through the deprotonated oxygens of the phenolate groups. The caesium cation is bound to the two protonated oxygens of the calixarene that do not form bonds with uranium, and is also bound in an approximately η^6 -fashion to the faces of the two phenolic rings (mean Cs-centroid distance = 3.35 Å). NMR experiments (^1H and ^{133}Cs) indicate that the caesium cation interacts with H_6L in pyridine and changes its conformation, which is critical for subsequent binding of the uranyl cation.

Calix[6]- and calix[8]-arene amides have been found to be efficient ionophores for the selective extraction of strontium from highly acidic radioactive solutions.¹⁷⁴ Often low concentrations of strontium ion (ca. 10^{-3} M) must be removed in the presence of much higher alkali metal ions (e.g., $[\text{Na}^+] = 4 \text{ M}$), and therefore ligands with high $\text{Sr}^{2+}/\text{Na}^+$ selectivity are desirable.¹⁷⁵ Strontium complexes of calixarene amides, in particular, have been studied as part of the search for high alkaline-earth selectivity. A *p*-*t*-butylcalix[6]arene hexaamide forms a 1:1 complex with strontium picrate, whereas related *p*-*t*-butylcalix[8]arene and *p*-methoxycalix[8]arene octaamides encapsulate two strontium cations each. The binding geometries of the metal cations depend on the ligand size and whether a chloride or picrate counteranion is present.¹⁷⁶ The higher $\text{Sr}^{2+}/\text{Na}^+$ selectivity shown by calix[8]arene derivatives compared to those of calix[6]- and calix[4]-arene

Figure 18 Cooperative complexation of caesium by both crown-4-ethers in a cone calixarene.

Figure 19 Cooperative binding of two uranyl cations and a caesium atom within a Bu^t-calix[6]arene.

amides appears to be mainly a consequence of the low binding ability of the larger calixarene ligands towards the sodium cation, which in turn stems from its small size relative to the calixarene cavity.

Various homo- and heterometallic aggregates can be constructed within calixarene frameworks. Tetralithiation of *p*-*t*-butylcalix[4]arene (H₄L) in the presence of wet HMPA affords the monomeric complex (Li₄LLiOH₄·HMPA), in which LiOH is incorporated into an Li₅O₅ core based on a square pyramid of Li atoms. When the same reaction is conducted with dry HMPA, a dimeric LiOH-free species containing an Li₈O₈ core formed by the edge-sharing of two square pyramids of Li atoms is generated (see Figure 20).¹⁷⁷ The deprotonation of substituted (Prⁱ and Bu^t) calix[8]arenes (H₈L) with BuⁿLi in DMF followed by reaction with anhydrous SrBr₂ yields the discrete, structurally authenticated molecular complexes Li₄Sr₂(H₂L)(O₂CC₄H₉)₂(DMF)₈ (the Prⁱ derivative is depicted in Figure 21). The heterometallic Li₄Sr₂ cores fit within the flexible cavities of the calix[8]arene.¹⁷⁸

Cation- π interactions, which are frequently encountered in calixarenes complexes, are observed in three related potassium complexes of calix[6]arenes, [K₂(MeOH)₅]{*p*-H-calix[6]arene-2H}, [K₂(MeOH)₄]{*p*-*t*-butylcalix[6]arene-2H} and [K₂(H₂O)₅]{*p*-H-calix[6]arene-2H}. The crystal

Figure 20 Octalithium aggregate formed from lithiation of *p*-tert-butylcalix[4]arene in dry HMPA.

Figure 21 Structure of the strontium derivative $\text{Li}_4\text{Sr}_2(\text{H}_2\text{L})(\text{O}_2\text{CC}_4\text{H}_9)_2(\text{DMF})_8$ formed from $\text{Pr}^i\text{calix}[8]$ arene (H_8L).

structure of each complex indicates that the doubly deprotonated macrocyclic ligand incorporates two K^+ ions and adopts the double partial cone conformation. The structures of the first two are similar in that one K^+ ion is positioned near the center of the cavity of the macrocycle and binds to four phenolic oxygens and two methanol ligands, while the other K^+ ion binds to either phenolic oxygen and four methanols, or to three methanols. In the structure of the aqua complex, each of the two K^+ ions are mirror-related and linked to each other through three bridging waters. Close contact between K^+ ion and aryl rings is observed in all three structures.¹⁷⁹

3.1.3.2.4 Alkalides and electrides

Alkalides and electrides are salts in which alkali metals (Na, K, Rb, Cs; Li derivatives are unknown) and electrons, respectively, are the anionic species. The formal $\text{M}(-1)$ oxidation state of the alkalide ions gives them closed subshell ns^2 electron configurations, and the extra electron gives them large effective sizes, $\sim 2.7 \text{ \AA}$ for Na^- to $\sim 3.5 \text{ \AA}$ for Cs^- .¹⁸⁰ The crystal structures of known electrides are similar to the corresponding alkalides except that the anionic sites are empty.¹⁸¹ The field of alkalides and electrides expanded tremendously in the 1980s and 1990s through the work of Dye and co-workers, and the first structurally characterized alkalide ($\text{Cs}^+(\text{18-crown-6})\text{Na}^-$)¹⁸² and electride ($\text{Cs}^+(\text{18-crown-6})2\text{e}^-$)¹⁸³ came from his group. The area has been reviewed in *Comprehensive Supramolecular Chemistry*¹⁸⁴ and other summaries are available.^{185,186}

Recent work has helped to refine the understanding of the physical and magnetic properties of these systems. The synthesis, structure, polymorphism, and electronic and magnetic properties of the electride $\text{Rb}(\text{cryptand}[2.2.2])\text{e}^-$ have been described. Depending on the manner of preparation and the temperature, the antiferromagnetic electride can display a range of electrical conductivity, from poor ($< 10^{-4} \text{ S cm}^{-1}$)—consistent with localized electrons—to near-metallic electrical conductivity.¹⁸⁷ Studies of the phase transitions in $\text{Cs}^+(\text{18-crown-6})_2\text{e}^-$ with NMR, EPR, and variable-temperature powder X-ray diffraction indicates that it undergoes a slow irreversible

transition above 230 K from a crystalline low temperature phase to a disordered Curie–Weiss paramagnetic high temperature phase.¹⁸⁸

Ligands other than crowns and cryptands, which are the most common complexants of the cations in alkalides and electrides, have begun to receive more investigation. The properties of the lithium–sodium–methylamine system ($\text{LiNa}(\text{CH}_3\text{NH}_2)_n$) have been examined as a function of n . The phase diagram (established with DTA) shows the presence of a compound with $n \approx 6$, which melts congruently at 168.5 ± 0.5 K. A combination of EPR and alkali-metal NMR spectroscopies and static magnetic susceptibilities data indicate that the sodide $\text{LiNa}(\text{CH}_3\text{NH}_2)_4$ could be considered a type of near-metal in the liquid state, with a conductivity similar to that of $\text{Li}(\text{CH}_3\text{NH}_2)_4$ (conductivity of around 400 S cm^{-1}).¹⁸⁹

By using compounds that have only C–N linkages and no amine hydrogens, alkalides with improved thermal stability can be generated. Thus when 4,7,13,16,21,24-hexamethyl-1,4-7,10,13,16,21,24-octaazabicyclo[8.8.8]hexacosane (i.e., the fully methylated aza analog of cryptand[2.2.2]) is allowed to react with NaK or K in MeNH_2 , the corresponding sodide or potasside salt is formed. Characterized with thin film reflectance spectral data, SQUID (Superconducting QUantum Interference Device) measurements, and crystallography, these represent the first alkalides that are stable at, and even slightly above, room temperature (~ 50 – 60°C).¹⁹⁰ An interesting extension of this concept led to the examination of 3⁶ adamantane as a ligand. The reaction of protonated 3⁶ adamantane glycolate with Na in liquid NH_3 converts the glycolate into the disodium salt $\text{NaOCH}_2\text{COONa}$, releasing H_2 and 3⁶ AdzH^+ cations. These subsequently recombine with Na^- anions to form the complex 3⁶ AdzH^+Na^- (Equation(1)):

The sodide, stable to -25°C , has been dubbed an “inverse sodium hydride” (see Figure 22).¹⁹¹ The strategy of using kinetically trapped cations in polyaza cages may lead to new classes of stabilized alkalides and electrides.

Parallels have been proposed between the dissolution of the alkali metals in nonaqueous solvents and the interactions of alkali metals with zeolites.^{192,193} The sorption of sodium or potassium vapor into dehydrated zeolites produces intensely colored compounds, ranging from burgundy red to deep blue, depending upon the metal concentration. A combination of EPR,

Figure 22 The structure of the “inverse sodium hydride” 3⁶ AdzH^+Na^- . The sodide anion is drawn approximately to scale.

magnetic susceptibility, and powder neutron diffraction measurements has been applied to the characterization of the sodium- and potassium-based “cluster crystals” in zeolites Y and A, respectively.¹⁹⁴ It has been suggested that molecular wires might be constructed in the one-dimensional channels of alkali metal-loaded zeolite L.^{195,196}

3.1.4 NONMACROCYCLIC COMPLEXES

3.1.4.1 Hydroborates

In this section, only monoboron ligands (e.g., BH_3 , BH_4^-) are considered, and not those containing higher boranes or B—B bonded units. Until the mid-1980s, the tetrahydroborate anion BH_4^- (“borohydride”) was considered to be an essentially noncoordinating anion in alkali metal chemistry. This was a reasonable conclusion, as its MBH_4 salts crystallize with ionic lattices (e.g., NaBH_4 has the NaCl structure)¹⁹⁷ and are high-melting solids. The beryllium compound $\text{Be}(\text{BH}_4)_2$ was known to be polymeric in the solid state,¹⁹⁸ although it is monomeric in the gas phase with six-coordinate Be (i.e., each BH_4 group is η^3 -).^{199–201} Disagreements over its conformation led to many, sometimes conflicting, computational studies.^{202–212} The chemistry of the alkaline-earth borohydrides has been reviewed.²¹³

In conjunction with auxiliary ligands, a wide variety of coordination geometries have now been structurally authenticated for the *s*-block borohydride ions, including η^1 -, η^2 -, and η^3 - modes (see Table 2). In some cases, the compounds are prepared by recrystallizing the $\text{M}(\text{BH}_4)_n$ salts or their THF adducts in the presence of the supporting ligand (e.g., pyridine, trimethyltriazacyclononane²¹⁴ bipy (2,2'-bipyridyl), pyrazolylborates,²¹⁵ diglyme, and 18-crown-6²¹⁶). In the case of pyridine and substituted pyridine solvates, IR and ^{11}B -NMR data do not provide definitive information about the coordination modes of the BH_4^- ligands.²¹⁴

The coordination chemistry of other $\text{BH}_n^{(3-n)}$ ligands has been developed with the *s*-block elements. The reaction of Na metal with $\text{Me}_2\text{NH}\cdot\text{BH}_3$ in THF yields $\text{Na}[(\text{H}_3\text{B})_2\text{NMe}_2]$, which can be isolated as a THF solvate $\{\text{Na}[(\text{H}_3\text{B})_2\text{NMe}_2]\}_5\cdot\text{THF}$, and which reduces aldehydes, ketones, acyl chlorides, and esters to the corresponding alcohols.²¹⁷ Addition of 15-crown-5 or benzo-15-crown-5 to a THF solution of $\text{Na}[(\text{H}_3\text{B})_2\text{NMe}_2]$ yields $\text{Na}[(\text{H}_3\text{B})_2\text{NMe}_2]\cdot 15\text{-crown-5}$ and $\text{Na}[(\text{H}_3\text{B})_2\text{NMe}_2]\cdot\text{benzo-15-crown-5}$, respectively. $\{\text{Na}[(\text{H}_3\text{B})_2\text{NMe}_2]\}_5\cdot\text{THF}$ crystallizes in an extended three-dimensional lattice, in which the Na atoms are coordinated by six to nine hydridic hydrogens. $\text{Na}[(\text{H}_3\text{B})_2\text{NMe}_2]\cdot\text{benzo-15-crown-5}$ is a molecular compound in the solid state, with a $[(\mu\text{-H-BH}_2)_2\text{-N}(\text{CH}_3)_2]^-$ ligand; only one hydrogen atom of each BH_3 group coordinates to the Na center.

The reaction between NaSH and $\text{THF}\cdot\text{BH}_3$ under dehydrogenation conditions or between anhydrous Na_2S and $\text{THF}\cdot\text{BH}_3$ produces $\text{Na}[\text{H}_3\text{B}-\mu_2\text{-S}(\text{B}_2\text{H}_5)]$, whose structure has been examined with SCF calculations.²¹⁸ Addition of NaBH_4 to $\text{Na}[\text{H}_3\text{B}-\mu_2\text{-S}(\text{B}_2\text{H}_5)]$ in diglyme or triglyme generates the $[\text{S}(\text{BH}_3)_4]^{2-}$ ion, which has been crystallized as $[\text{Na}(\text{triglyme})]_2[\text{S}(\text{BH}_3)_4]$. The latter contains a μ_4 -sulfur atom, i.e., $[(\text{triglyme})\text{Na}(\mu\text{-H})\text{BH}_2(\mu\text{-H})_2\text{BH}]_2(\mu_4\text{-S})$ ($\text{Na}-\text{S} = 2.75, 2.92 \text{ \AA}$) (see Figure 23).

The “superhydride” anion (BET_3H^-) has been isolated and crystallographically characterized as its sodium derivative. Two moles of sodium superhydride (NaHBET_3) and one mole of mesitylene form a crystalline compound that has been characterized with differential scanning calorimetry and single-crystal X-ray diffraction. The molecule consists of a central dimeric $\text{Na}_2(\mu\text{-HBET}_3)_2$ core; each sodium is also coordinated to another bridging HBET_3 anion that is in turn bound to another sodium atom. The two terminal sodium ions display η^6 -cation- π interactions to two mesitylene rings (see Figure 24).²¹⁹

Deprotonation of $\text{Me}_2\text{NH}\cdot\text{BH}_3$ with Bu^nLi generates lithium(dimethylamino)trihydroborate, $\text{Li}(\text{Me}_2\text{NBH}_3)$, which is found to be unstable in most ethers, reversibly decomposing into lithium hydride and $\text{Li}(\text{Me}_2\text{N-BH}_2\text{-NMe}_2\text{-BH}_3)$. Five solvates of (TMEDA, dioxane, 1,3-dioxolane, 1,3,5-trioxane, 12-crown-4) were characterized by X-ray diffraction. Only the TMEDA adduct displays Li-H-B interactions; i.e., two (TMEDA)Li units are connected to one another by $\text{Li}(\mu\text{-H})\text{BH}_2\text{-NMe}_2$ bridges.²²⁰

The reaction of 2,6-Mes₂C₆H₃Li and BBr_3 produces the 2,6-Mes₂C₆H₃BBr₂ derivative in good yield. Reduction of the latter with KC_8 affords potassium 9-borafluorenyl salts. The product isolated from reduction with four equivalents of KC_8 in diethyl ether, crystallizes from THF/hexane as a centrosymmetric dimer in which two THF molecules solvate each potassium ion and also interact with the 9-H and 9-Me groups of the 9-borafluorenyl rings. The product from the reduction of the arylboron dibromide with excess KC_8 in benzene also forms a centrosymmetric dimer; each potassium ion is η^6 -coordinated by benzene in addition to the solvation by 9-H and 9-Me groups from the 9-borafluorenyl rings.²²¹

Figure 23 The structure of $[(\text{triglyme})\text{Na}(\mu\text{-H})\text{BH}_2(\mu\text{-H})_2\text{BH}]_2(\mu_4\text{-S})$.

Figure 24 The structure of the sodium derivative of the “superhydride” anion, $\text{Na}[\text{HB}(\text{Et})_3]$.

The reaction of 3,5-bis(trifluoromethyl)pyrazole and KBH_4 in toluene at 115–120 °C produces white $\text{K}[\text{H}_2\text{B}(3,5\text{-(CF}_3)_2\text{pz})_2]$, characterized with ^1H , ^{13}C , and ^{19}F spectroscopy. It has a polymeric structure resulting from close contacts between the potassium ion and the nitrogens, some of the fluorines of the CF_3 groups on the 3- and 5-positions, and a hydrogen of the BH_2 moieties. Each potassium center is coordinated to three nitrogens (2.82–3.04 Å), five fluorines (2.81–3.33 Å) and to a hydrogen ($\text{K}-\text{H}=2.77$ Å) (see Figure 25). The potassium salt has been used in the synthesis of $\text{Cu}(\text{II})$ and $\text{Zn}(\text{II})$ derivatives.²²²

3.1.4.2 Group 14 Ligands

In this section are covered complexes that contain *s*-block–(Si, Ge, Sn, Pb) bonds as their primary point of interest. Cluster compounds that contain Group 14–Group 14 bonds, or in which an

Figure 25 The structure of $\text{K}[\text{H}_2\text{B}(3,5\text{-(CF}_3)_2\text{pz})_2]$.

alkali or alkaline-earth metal is involved peripherally (e.g., the Na(THF)₂ units in the tin cube [(Si(Bu^t)₃)₆Sn₈](Na(THF)₂)₂)²²³ are not considered here.

A variety of monomeric species with terminal *s*-block–Group 14 bonds are known and have been structurally characterized (see Table 3). (THF)₃Li–E(SiMe₃)₃ complexes are commonly prepared from the reaction of E(SiMe₃)₄ with MeLi, which eliminates SiMe₄ (E = Si,²²⁴ Ge,²²⁵ Sn²²⁶). A one-pot synthesis is available for the preparation of (THF)₃Li–Sn(SiMe₃)₃ by the reaction of chlorotrimethylsilane and lithium wire; the resulting Li(THF)_n•SiMe₃ is treated with

Table 3 Structurally authenticated *s*-block complexes with group 14 ligands.

a 1:4 molar equivalent of tin(IV) chloride.²²⁷ Multinuclear NMR spectroscopy has been used to verify the correspondence between solution and solid state structures; direct observation of $^1J(^7\text{Li}-^{117,119}\text{Sn})=412\text{ Hz}$ in a solution of pentamethyldiethylenetriamine (PMDTA) Li-SnPh_3 , for example, confirmed that the Sn-Li bond observed in the solid state (2.87 \AA (av)) persists in solution.²²⁸

Treating the persilyl-substituted 1,1-bis(triisopropylsilyl)-2,3-bis(trimethylsilyl)silirene with Li in THF results in cleavage of two Si-C bonds in the three-membered ring, yielding $\text{Li}_2\text{Si}[\text{Si}(\text{Pr}^i)_3]_2$ and $\text{Me}_3\text{SiC}\equiv\text{CSiMe}_3$ (see Scheme 1). A THF adduct was structurally characterized by X-ray crystallography and NMR spectroscopy ($^1J(^{29}\text{Si}-^6\text{Li})=15.0\text{ Hz}$). Reaction of the dilithiosilane with $\text{Br}_2\text{Si}[\text{Si}(\text{Pr}^i)_3]_2$ in THF gave the disilene $(\text{Pr}^i_3\text{Si})_2\text{Si}=\text{Si}(\text{Si}(\text{Pr}^i)_3)_2$ in almost quantitative yield.²²⁹

Scheme 1

Derivatives of the bulky “supersilyl” ligand ($-\text{SiBu}^t_3$) can be isolated from the reaction of lithium, sodium, or potassium with Bu^t_3SiX halides in alkanes or THF, and optionally in the presence of donors including ethers, amines, and aromatic hydrocarbons. Ethers can be exchanged for stronger donors like PMDTA, 18-crown-6, and cryptand-222.²³⁰ Alkali metal supersilyl complexes are extremely water- and air-sensitive; and because the $-\text{SiBu}^t_3$ ligand is strongly basic, complexes such as $(18\text{-crown-6})\text{NaSiBu}^t_3$ and $(\text{cryptand-222})(\text{Na,K})\text{SiBu}^t_3$ are unstable owing to their tendency to deprotonate the crown and cryptand, respectively. Even weak bases such as THF or benzene can be deprotonated, with concomitant formation of HSiBu^t_3 . The complexes couple in the presence of AgNO_3 to generate the disilane $\text{Bu}^t_3\text{Si-SiBu}^t_3$, and react with Me_3SiX to form $\text{Me}_3\text{Si-SiBu}^t_3$. At 100°C , Bu^t_3SiX oxidizes M-SiBu^t_3 (Equation(2)):

The supersilyl radical will abstract a hydrogen atom from alkanes to form HSiBu^t_3 and $\text{R}\cdot$; the latter can then generate secondary products.²³⁰

The reaction between $\text{Zn}[\text{Si}(\text{SiMe}_3)_3]_2$ and potassium, rubidium, and caesium in heptane affords the donor-free derivatives.²³¹ The use of boiling *n*-heptane with sodium can be used to produce $\text{NaSi}(\text{SiMe}_3)_3$. NMR and Raman spectra, structural analysis, and calculations on model systems indicate that the bonding is largely ionic in the compounds. The unsolvated species $[\text{MSi}(\text{SiMe}_3)_3]_2$ are cyclic dimers with almost planar M_2Si_2 rings; various benzene and toluene solvates are known also.

Large aggregates containing M-Si bonds have been formed by a variety of methods. Treatment of SiH_4 with dispersed Na in diglyme at 100°C yields $[\text{Na}_8(\text{OCH}_2\text{CH}_2\text{OCH}_2\text{CH}_2\text{OMe})_6(\text{SiH}_3)_2]$.²³² The eight sodium atoms form a cube, the faces of which are capped by the alkoxo oxygen atoms of the three ligands, which in turn are each bound to four sodium atoms ($\text{Na-O}=2.30\text{--}2.42\text{ \AA}$). The sodium and oxygen atoms generate an approximate rhombododecahedron. Six of the eight sodium atoms are five-fold coordinated to oxygen atoms, and the coordination of the other two Na atoms is completed by SiH_3^- ions, which have inverted C_{3v} symmetry (i.e., Na-Si-H angle $58\text{--}62^\circ$) (see Figure 26). Despite the strange appearance of the latter, *ab initio* calculations (MP4/6-31G(d)) on the simplified model compound $(\text{NaOH})_3\text{NaSiH}_3$ indicate that the form with inverted hydrogens is 6 kJ mol^{-1} lower in energy than the uninverted form; electrostatic (rather than agostic) interactions ($\text{H}^{\delta-}-\text{Na}^{\delta+}$) between the SiH_3 group and the three adjacent sodium atoms stabilize the inverted form.

Figure 26 The structure of $[\text{Na}_8(\text{OCH}_2\text{CH}_2\text{OCH}_2\text{CH}_2\text{OMe})_6(\text{SiH}_3)_2]$, with its inverted SiH_3 moieties.

Agostic $\text{Si}-\text{H}-\text{Li}$ contacts (i.e. less than 3.0 \AA) are not present in the solvent-free X-ray crystal structure of $[\text{Li}\{\text{Me}_2\text{Si}(\text{H})\text{NBU}^t\}_3]$; shorter $\text{Bu}^t\text{CH}_3-\text{Li}$ distances (2.8 \AA) are observed instead. In toluene solution at -80°C , solution, the $^1\text{H}-^6\text{Li}$ HOESY (Heteronuclear Overhauser Enhancement Spectroscopy) spectrum of $\text{Li}[\text{Me}_2\text{Si}(\text{H})\text{NBU}^t]$ confirms that the trimeric species lacks $\text{Si}-\text{H}-\text{Li}$ interactions, but two other species with strong $\text{Si}-\text{H}-\text{Li}$ interactions are present also. Computations on the model system $\text{Li}-\text{HN}-\text{SiH}_3$ suggest that $\text{Si}-\text{H}-\text{Li}$ interactions are energetically favored and result in increased $\text{Si}-\text{H}$ distances and decreased $\text{Si}-\text{H}$ frequencies.²³³ In contrast, the related magnesium-based compound $\text{Mg}_2[\text{Me}_2\text{Si}(\text{H})\text{NBU}^t]_4$ does display evidence of agostic $\text{Si}-\text{H}-\text{Mg}$ contacts in the solid state. The two short agostic $\text{Si}-\text{H}-\text{Mg}$ interactions ($\text{Mg}-\text{H} = 2.2, 2.5 \text{ \AA}$) are represented by two low $\nu(\text{Si}-\text{H})$ frequencies in the IR spectrum ($2,040, 1,880 \text{ cm}^{-1}$).²³³

The bonding between Li and Sn and Pb has been investigated computationally with SCF/HF (Self-Consistent Field/Hartree-Fock) methods in the model compounds LiSnPh_3 and LiPbPh_3 .²³⁴ The $6p_z$ orbital of the lead in LiPbPh_3 is oriented toward the lithium atom, and hence the $\text{Pb}-\text{Li}$ bond involves the $\text{Pb}(6p_z + 6s)-\text{Li}(2s)$ orbitals, and not the $\text{Pb}(6s)-\text{Li}(2s)$ orbitals only. The other lobe of the $6p_z$ orbital is directed between the phenyl rings on the lead, and is able to interact with them. The compression of the phenyl ligands toward the z -axis is evident in the $\text{C}(\text{phenyl})-\text{Pb}-\text{C}(\text{phenyl})$ angle of 102° calculated for the model compound, which compares favorably with the corresponding angle of 94.3° observed crystallographically in the complex $(\text{PMDTA})\text{Li}-\text{PbPh}_3$.

3.1.4.3 Group 15 Ligands

3.1.4.3.1 Nitrogen donor ligands

(i) Amides, especially bis(trimethylsilyl)amides

Whereas the parent amides of the s -block metals ($\text{M}(\text{NH}_2)_{1,2}$) possess either ionic lattices or framework structures,¹⁹⁷ replacement of the hydrogen atoms with groups of increasing size leads to molecular complexes. Group 1 and 2 amido complexes are remarkably versatile reagents, and are used both in organic synthesis²³⁵ and to prepare a wide variety of derivatives of other main-group and transition metal complexes. Issues in the coordination chemistry of amidolithium reagents that are concerned chiefly with applications in synthetic organic chemistry are summarized elsewhere.²³⁶⁻²⁴²

A widely used class of s -block amido complexes is that containing the bis(trimethylsilyl) group, $-\text{N}(\text{SiMe})_2$. Examples of these compounds were synthesized by Wannagat in the 1960s,²⁴³ but all

the *s*-block metals (excepting Fr and Ra) are now represented. The chemistry of the heavy alkaline-earth derivatives has been extensively developed by Westerhausen;²⁴⁴ this chemistry has been reviewed.¹⁹

Synthesis of the *s*-block metal bis(trimethylsilyl)amides is varied, and representative routes are summarized in Table 4. The lithium compound can be prepared by reaction of LiBuⁿ with hexamethyldisilazane ($pK_a = 25.8$) (Table 4, Equation (1)),²⁴⁵ and the sodium derivative is available by transmetalation of the metal with Hg[N(SiMe₃)₂]₂ at room temperature (Table 4, Equation (2)).²⁴⁶ The monomeric Be[N(SiMe₃)₂]₂ can be prepared from the reaction of (Et₂O)-BeCl₂ with Na[N(SiMe₃)₂] (Table 4, Equation (4)),²⁴⁷ whereas reaction of MgBuⁿ₂ with HN(SiMe₃)₂ produces Mg[N(SiMe₃)₂]₂ in quantitative yield (Table 4, Equation (5)).²⁴⁸ The heavy alkaline-earth derivatives are available from reaction of Ca, Sr, and Ba with M[N(SiMe₃)₂]₂ (M = Sn, Hg) (Table 4, Equations (2) and (3))²⁴⁹ or with HN(SiMe₃)₂ in THF (Table 4, Equation (6)) or THF/NH₃ (Table 4, Equations (7a)–(7c)). The approach relies on the solubility of ammonia in ethereal solvents (especially tetrahydrofuran) (Table 4, Equation (7a)), the dissolution of the metal in the saturated ammonia/THF solution (Table 4, Equation (7b)), and the reactivity of the dissolved metal with the parent amine (Table 4, Equation (7c)). The ammonia is a catalyst in the process.²⁵⁰ Halide metathesis with MN(SiMe₃)₂ (M = Na, K) has been used for the calcium, strontium, and barium derivatives (Table 4, Equation (8)),²⁴⁹ Other reactions involving metal alkoxides²⁵¹ and paratoluenesulfonates²⁵² have been reported.

Synthesis of the compounds is sensitive to the reaction conditions and identity of the metals. For example, the dimeric [MN(SiMe₃)₂]₂ (M = Rb, Cs) species form from the reaction of the metal in refluxing neat hexamethyldisilazane (Table 4, Equation (9)).²⁵³ If caesium is first dissolved in liquid ammonia, however, addition of HN(SiMe₃)₂ results in the formation of a mono(trimethylsilyl)amido complex, [CsHN(SiMe₃)₂]₄.²⁵⁴ The latter is a tetrameric species in which one N—Si bond of the original amine has been broken, and the remaining N—Si bond is short enough (1.59(1) Å) to suggest the presence of some degree of multiple bonding (see Figure 27). The formula of heterometallic amido complexes can also be difficult to predict; e.g., addition of LiN(SiMe₃)₂ to Ca[N(SiMe₃)₂]₂ in THF produces the heterometallic species [Ca{N(SiMe₃)₂}₂{μ-N(SiMe₃)₂}₂Li(THF)]; if the barium amido complex is used instead, [Ba{N(SiMe₃)₂}₂(THF)₃][Li₂{μ-N(SiMe₃)₂}₂(THF)₂] can be isolated.²⁵⁵

A large number of structurally characterized bis(trimethylsilyl)amido complexes now exist; Table 5 gives a representative selection of monometallic homoleptic compounds, both base-free and with coordinated ethers. Other examples are known with coordinated fluorobenzenes,²⁵⁶ isonitriles,²⁵⁷ methylated pyridines,²⁵⁸ various amines (TMEDA, PMDTA, TMPDA (Tetra-methylpropylenediamine), BzNMe₂ (benzylidimethylamine)),²⁵⁹ Ph₃PO,²⁶⁰ (BuⁿO)(Prⁱ)CO,²⁶¹ and 1,3-(Prⁱ)₂-3,4,5,6-tetrahydropyrimid-2-ylidene.²⁶² Their structures illustrate the complex interactions between metal size, ligand bulk, and molecular structure that exist with these metals. For example, among the alkali metal base-free species, the unsolvated Li derivative crystallizes as a cyclic trimer,²⁶³ whereas the Na salt is found both as a trimer²⁶⁴ and as infinite chains of [Na-N(SiMe₃)₂]_n units.²⁶⁵ The potassium,²⁶⁶ rubidium, and caesium²⁵³ derivatives exist as discrete dimers in the solid state, constructed around planar [M—N]₂ frameworks.

In the Group 2 derivatives, less diversity is found: the beryllium complex is monomeric,^{267,268} probably for steric reasons, but the Mg–Ba compounds are dimers.⁶ Although the M—Si

$\text{M}^{\text{I}} + x\text{sHNR}_2 \rightarrow \text{M}^{\text{I}}\text{N}(\text{SiMe}_3)_2 + 1/2 \text{ H}_2$	(9)

M^I = alkali metal; M^{II} = alkaline-earth metal; X = halide; S = coordinated solvent.

Figure 27 The structure of the tetrameric mono(trimethylsilyl)amido complex, $[\text{CsHN}(\text{SiMe}_3)_2]_4$.

distances change as expected with the increasing size of the cation, the difference between terminal and bridging N—Si distances decreases with the larger metals.

Solution and gas-phase structures do not always match those in the solid state: unsolvated bis(trimethylsilyl)amido]lithium and -sodium are dimeric in hydrocarbon solutions, for example, and $\text{LiN}(\text{SiMe}_3)_2$ remains a dimer in the gas phase,²⁶⁹ although the sodium²⁷⁰ and magnesium²⁷¹ derivatives are primarily or exclusively monomeric. $\text{Mg}[\text{N}(\text{SiMe}_3)_2]_2$ will dissociate into monomers in aromatic solvents,²⁴⁹ whereas the $\text{M}[\text{N}(\text{SiMe}_3)_2]_2$ ($\text{M} = \text{Ca}, \text{Sr}, \text{Ba}$) derivatives are dimeric in solution, as evidenced by cryoscopic molecular weights.²⁴⁹

The correlation between the Si—N distance and the Si—N—Si' angle in metal silylamides has been the subject of considerable discussion.^{265,272–274} Partial multiple bonding between Si and N, in which the lone pair electrons on nitrogen are delocalized onto silicon, has been invoked as an explanation for the Si—N distance/Si—N—Si' angle relationships, but steric interactions may also play a critical role in determining the geometries. In fact, the Si—Si' separation is relatively constant at $\sim 3.0 \text{ \AA}$ for a variety of transition metal, main group, and *f*-element bis(trimethylsilyl) amide complexes,²⁶⁶ and is probably of steric origin; i.e., bis(trimethylsilyl)amide complexes containing short Si—N bonds must necessarily possess relatively large Si—N—Si' angles to avoid violating a minimum SiMe_3 — SiMe_3 separation.

The trimethylsilyl groups are associated with hydrocarbon solubility of the base-free and ether adducts. This is a particularly remarkable property, in that the metal atoms in many of the structures are exposed to external molecules, and are not appreciably shielded by the trimethylsilyl group of the amido ligands (see Figure 28). Strong ion pairing interaction between the M^{n+} and the $\text{N}(\text{SiMe}_3)_2^-$ ions probably contributes to their solubility.²⁶⁶

Extensive NMR data (^1H , ^{13}C , ^{15}N , ^{29}Si) exist for these species;¹⁹ the $\delta(\text{N})$ and $\delta(\text{SiMe}_3)$ shifts are sensitive to the identity of the metal center. In the case of the alkaline-earth compounds, differences in the chemical shifts and coupling constants for the bridging and terminal $-\text{SiN}(\text{Me}_3)_2$ groups disappear for the barium derivatives, an indication that they are in fast exchange.

Owing to the widespread use of Lewis bases to activate alkyllithium and amidolithium reagents in organic synthesis, the relationship between solvation and aggregation in the reactivity of lithium complexes is of considerable importance. The conventional interpretation of the activation phenomenon holds that bases disrupt the oligomers in which alkyllithium and amidolithium complexes are typically found (i.e., tetramers for CH_3Li , hexamers for Bu^nLi , etc.), and it is the monomers that are the reactive species. Experimental evidence to the contrary, however, has been provided by Collum and co-workers,^{275–306} who have examined the molecularity of solvated amidolithiums with ^6Li , ^{15}N , and ^{13}C -NMR spectroscopy, and have argued that strongly coordinated ligands do not necessarily promote higher reactivity, nor do similar reaction rates automatically imply similar mechanisms.^{307,308}

The structural chemistry and solution behavior of lithium diisopropylamide ($\text{LiN}(\text{CHMe}_2)_2$, LDA) typifies the complexities of these systems. Although the base-free compound crystallizes as infinite helical chains with two-coordinate lithium and four-coordinate nitrogen,³⁰⁹ it is isolated from *N,N,N',N'*-tetramethylethylenediamine (TMEDA)/hexane mixtures as an infinite array of

dimers linked by bridging (nonchelating) TMEDA ligands (see Figure 29).²⁹⁵ Lithium-6 and ¹⁵N-NMR spectroscopic studies indicate that LDA in neat TMEDA exists as a cyclic dimer bearing a single η^1 -coordinated TMEDA ligand on each lithium. However, the equilibrium between solvent-free LDA and the TMEDA-solvated dimer shows a strong temperature dependence; TMEDA coordinates readily only at low temperature, and high TMEDA concentrations are required to saturate the lithium coordination spheres at ambient temperature.²⁹⁵

NMR spectroscopic studies of ⁶Li-¹⁵N labeled lithium hexamethyldisilazide in solvents including THF, 2-methyltetrahydrofuran (2-MeTHF), 2,2-dimethyltetrahydrofuran (2,2-Me₂THF), diethyl ether (Et₂O), *t*-butyl methyl ether (Bu^tOMe), *n*-butyl methyl ether (BuⁿOMe), tetrahydropyran (THP), methyl *i*-propyl ether (PrⁱOMe), and trimethylene oxide (oxetane) have been used to characterize the nature of the solvated species. Mono-, di-, and mixed-solvated dimers can be identified in the limit of slow solvent exchange, but ligand exchange is too fast to observe

Figure 28 Space-filling drawing of $[\text{KN}(\text{SiMe}_3)_2]_2$, indicating the exposure of the potassium atom.

bound and free diisopropyl ether (Pr_2O), *t*-amyl methyl ether ($\text{Me}_2(\text{Et})\text{COMe}$), and 2,2,5,5-tetramethyltetrahydrofuran (2,2,5,5- Me_4THF). Relative free energies and enthalpies of $\text{LiN}(\text{SiMe}_3)_2$ dimer solvation display an approximately inverse correlation of binding energy and ligand steric demand, but there is no simple correlation between reduced aggregation state and increasing strength of the lithium–solvent interaction. Contributions from solvation enthalpy and entropy, with the added complication of variable solvation numbers (higher with more sterically compact solvents) affect the measured free energies of aggregation.²⁸⁵

The structures of lithiated phenylacetonitrile and 1-naphthylacetonitrile have been studied in THF and HMPA–THF solution. In pure THF, ^7Li -NMR line width studies suggest that these species exist as contact ion pairs. In the presence of 0.25–2 equivalents of HMPA, HMPA-solvated monomeric and dimeric contact ion pairs can be identified with ^{31}P and ^7Li -NMR spectroscopy, but with four to six equivalents of added HMPA, NMR spectra provide direct evidence for the formation of HMPA-solvated separated ion pairs.³¹⁰

Figure 29 Portion of the solid state structure of TMEDA-adducted $\text{LiN}(\text{CHMe}_2)_2$.

The complexity of the solvation of lithium bases has also been demonstrated by studies of LiNPr_2 mediated ester enolization of $\text{Bu}^t\text{-cyclohexanecarboxylate}$ in four different solvents (THF, Bu^tOMe , HMPA/THF and DMPU/THF (DMPU = 1,3-dimethyl-3,4,5,6-tetrahydro-2(1H)-pyrimidone)).³¹¹ Even when experiments are designed to exclude mixed aggregate effects, four different mechanisms with nearly identical rates are observed, involving:

- (i) disolvated monomers in THF,
- (ii) monosolvated dimers in Bu^tOMe ,
- (iii) both monosolvated monomer and tetrasolvated dimers in HMPA/THF, and
- (iv) mono- and disolvated monomers in DMPU/THF.

Both monomeric and aggregated species (e.g., “open” dimers in Bu^tOMe and triple ions in HMPA/THF) are reactive. In related work in which aggregate formation was maximized, it was shown that the rates of enolization in the presence of the mixed aggregates are much lower and solvent dependent.³¹² The autoinhibition correlates with the relative stabilities of the mixed aggregates; the stabilities do not, however, correlate in a straightforward manner with the ligating properties of the solvent.

A particularly interesting development in heterometallic amido complexes are the so-called “inverse crown ether” complexes. These 8-membered $(\text{M}-\text{N}-\text{Mg}-\text{N})_2$ rings ($\text{M} = \text{Li}, \text{Na}, \text{K}$)^{20,313,314} act as polymetallic hosts to anionic species. Most common are oxo or peroxy species, in which the O^{2-} or O_2^{2-} ions are derived from molecular oxygen, although hydride encapsulation has also been described.³¹⁵ Larger 12-membered $(\text{NaNMgNNaN})_2^{2+}$ or 24-membered $(\text{KNMgN})_6^{2+}$ variants, which function as single or multiple traps for arene-based anions, are also known.³¹⁶

In a typical preparation of an “inverse crown”, the reaction of *n*-butyllithium with dibutylmagnesium and oxygenated 2,2,6,6-tetramethylpiperidine (LH) affords the complex $[\text{L}_4\text{Li}_2\text{Mg}_2\text{O}]$. The same reaction with *n*-butylsodium in place of *n*-butyllithium and $\text{HN}(\text{SiMe}_3)_2$ in place of tetramethylpiperidine yields $[(\text{Me}_3\text{Si})_2\text{N}]_4\text{Na}_2\text{Mg}_2(\text{O}_2)_x(\text{O})_{1-x}$.³¹³ The structure of the related $[(\text{Me}_3\text{Si})_2\text{N}]_4\text{Li}_2\text{Mg}_2(\text{O}_2)_x(\text{O})_{1-x}$ contains a side-on bonded peroxide molecule occupying a square-planar site. The four disordered metal atoms achieve a three-coordinate geometry by bridging to amido N atoms, producing an eight-membered ring (see Figure 30; an oxide atom replaces the peroxide molecule in approximately 30% of the molecules within the bulk lattice; it is positioned at the center of the $\text{O}(1)-\text{O}(1')$ bond).²⁰

Compounds that are both heterometallic and contain mixed-amido ligand sets are rare. A novel example is found from the reaction of the magnesium amide $\text{Mg}(\text{TMP})_2$ ($\text{TMP} = 2,2,6,6\text{-tetramethylpiperidine}$ (TMP)) with the lithium amide $\text{LiN}(\text{SiMe}_3)_2$ in hydrocarbon solution. A sterically promoted hydrogen transfer/amine elimination process occurs, yielding the mixed lithium–magnesium, mixed amide $(R,R/S,S)\text{-}\{\text{LiMg}(\text{TMP})[\text{CH}_2\text{Si}(\text{Me})_2\text{N}(\text{SiMe}_3)]\}_2$.³¹⁷ Its molecular structure is dimeric, composed of dinuclear (LiNMgN) monomeric fragments with pendant Me_2SiCH_2 arms that bind intramolecularly through the methylene CH_2 unit to the Mg center

Figure 30 The structure of the “inverse crown ether” complex $[(\text{Me}_3\text{Si})_2\text{N}]_4\text{Li}_2\text{Mg}_2(\text{O}_2)_x(\text{O})_{1-x}$.

Figure 31 The structure of the lithium–magnesium, mixed amide (*R,R/S,S*)-{LiMg(TMP)[CH₂Si(Me)₂N-(SiMe₃)]₂.

(see Figure 31). Dimerization occurs through intermolecular bonds from the methylene CH₂ unit to the Mg center of the other monomeric fragment. The formally two-coordinate lithium atoms are engaged in agostic interactions with one TMP and the methyl of a bis(trimethylsilylamido) group. Interestingly, the nitrogen atoms N(1) and N(4) of two N(SiMe₃)₂ groups are chiral; each binds to one Li and one Mg center, and to one SiMe₃ and one SiMe₂CH₂ group. Only the enantiomeric *R,R* and *S,S* pair has been observed.

(ii) Imidoalkalis

The imidoalkalis, RR'C=NM, constitute a large family of compounds that encompass M—N, M—O and M—C rings and aggregates of various sizes. They were the first group of compounds in which the concepts of “ring-stacking” and “ring-laddering” were systematically developed.^{318–323} They are useful precursors to imido complexes of *p*-block and transition metal elements, for example (Equation (3)):

With the bulky base HMPA, a dimeric imidolithium can be isolated (i.e., (Bu^tC=NLi·HMPA)₂ (Li—N = 1.92, 1.95 Å)³²⁴). With less sterically demanding bases, more complex aggregates can form. For example, (Ph₂C=NLi·Py)₄ has a cubane structure that can be viewed as two stacked (LiN)₂ four-membered ring systems (see Figure 32).³²⁴ The cube is considerably distorted, with three distinct ranges of Li—N distances (2.03, 2.08, and 3.16 Å (av)). Somewhat greater uniformity is observed in the cubic imidolithium complex {Li[N=C(Bu^t)CHCHC(SiMe₃)(CH₂)₂CH₂]}₄, formed from the reaction of 2-trimethylsilylcyclohexenyllithium with (Bu^t)CN (Li—N = 1.99–2.04 Å).³²⁵

Larger clusters are also known; among the first to be structurally authenticated was {Li[N=C(Bu^t)₂]}₆ (Figure 33);³²⁶ the structure of {Li[N=C(NMe₂)₂]}₆ is similar. Both are based on folded chair-shaped Li₆ rings held together by triply bridging N=CR₂ groups; the μ₃-imino ligands function as three-electron donors, forming one two-center Li—N bond and one three-center Li₂N bond to isosceles triangles of bridged metal atoms. The mean Li—Li distance in the metal rings is 2.35 Å in {Li[N=C(Bu^t)₂]}₆, and the mean dihedral angle between Li₆ chair seats and backs is 85°. The N atoms of the bridging N=CR₂ groups are roughly equidistant from the three bridged Li atoms (Li—N = 2.06 Å (av)).³²⁶ The stacked ring motif is found in the related hexameric compounds [LiN=C(C₆H₅)C(CH₃)₃]₆ (generated from (Bu^t)C≡N and PhLi or C₆H₅C≡N and Bu^tLi) and [LiN=C(C₆H₅)NMe₂]₆ (generated from C₆H₅C≡N and LiNMe₂ or Me₂NC≡N and LiC₆H₅).^{318,327}

A rare example of a heterometallic imido complex is the triple-stacked Li₄Na₂[N=C(Ph)(Bu^t)]₆, prepared from the reaction of PhLi and PhNa with (Bu^t)NC (see Figure 34). The molecule has six metal sites in a triple-layered stack of four-membered M—N rings, with the outer rings containing lithium and the central ring containing sodium; the latter is four-coordinate.³²⁸

Figure 32 The structure of $(\text{Ph}_2\text{C}=\text{NLi}\cdot\text{py})_4$, constructed from stacked $(\text{LiN})_2$ rings.

(iii) *Thiocyanates*

Thiocyanate (SCN^-), and to a lesser extent, selenocyanate (SeCN^-) ions are among the classic ambidentate ligands. The conventional expectation is that they should display *N*-coordination to the “class a” *s*-block metals, and the majority of crystallographically characterized examples support this. Thiocyanate ions are often found in complexes with macrocyclic ligands, such as crown ethers,^{329–358} azacrowns,^{359–374} cryptands,³⁷⁵ glymes,^{376–379} hemispherands,³⁸⁰ paracyclophanes,³⁸¹ and other polydentate oxygen ligands.^{382–386} Nonmacrocyclic thiocyanate compounds are found with water,^{335,387} pyridines,^{388–391} THF,³⁹² acetates,³⁹³ HMPA,^{394–397} TMPDA,³⁹⁸ phenolate³⁹⁹ and other more complex ligands.^{400,401} Homoleptic examples also exist (e.g., $[\text{Ca}(\text{NCS})_6]^{4-}$,³³⁴ $[\text{Rb}(\text{NCS})_4]^{3-}$, $[\text{Cs}(\text{NCS})_4]^{3-}$ ⁴⁰²). In the case of the complex of (*E*)-9,10-diphenyl-2,5,8,11,14,17-hexaoxaoctadec-9-ene with NaSCN , a unique $\text{Na}_3(\mu_3\text{-NCS})$ arrangement is found (see Figure 35).⁴⁰³

Notwithstanding these examples, the preference for *N*-coordination is not absolute. *S*-bound NCS^- ligands are found bound to potassium in crown ether complexes.^{369,404} For example, the 3',5'-difluoro-4'-hydroxybenzyl-armed monoaza-15-crown-5 ether forms *F*-bridged polymer-like

Figure 33 The structure of $\{\text{Li}[\text{N}=\text{C}(\text{Bu}^1)_2]\}_6$, based on folded chair-shaped Li_6 rings.

Figure 34 The structure of the bimetallic triple-stacked complex $\text{Li}_4\text{Na}_2[\text{N}=\text{C}(\text{Ph})(\text{Bu}^t)]_6$.

complexes with MSCN ($\text{M} = \text{K}, \text{Rb}$) in the solid state and in solution. The thiocyanate ligands are *S*-bound and terminal in the potassium complex, *S*-bound and bridging in the rubidium derivative (see Figure 36).⁴⁰⁵

Bridging SCN ligands will naturally have both *N*- and *S*-bound ends. Such ligands are found in the 1:1 TMEDA complex of lithium thiocyanate, $(\text{LiSCN} \cdot \text{TMEDA})_n$ prepared from solid NH_4SCN and Bu^nLi in TMEDA/hexane. In hydrocarbon solvents, it assumes a dimeric, purely *N*- Li bridged structure, but in the solid state it exists as a polymeric solid with lithium ions linked by SCN ligands ($\text{Li}-\text{N} = 1.96 \text{ \AA}$; $\text{Li}-\text{S} = 2.57 \text{ \AA}$).⁴⁰⁶ Similar bridged structures are adopted by SCN ions spanning potassium complexed azacrown ligands,⁴⁰⁷ and barium-complexed bipyridine.⁴⁰⁸

A more complex arrangement is generated from the reaction of solid NH_4SCN with solid NaH and HMPA (1:1:2 molar ratios) in toluene, which produces both the discrete dimer $[\text{NaNCS}-(\mu\text{-HMPA})(\text{HMPA})]_2$ with bridging and terminal HMPA ligands and *N*-bound NCS^- ligands, and the polymeric $(\text{NaNCS} \cdot \text{HMPA})_n$, which has both *N*- and *S*-bound NCS^- ligands ($\text{Na}-\text{N} = 2.33 \text{ \AA}$; $\text{Na}-\text{S} = 2.89 \text{ \AA}$).³⁹⁵ The detection of radicals with EPR spectroscopy suggests that the reaction proceeds via an electron-transfer mechanism.

Heterobimetallic species containing $\mu\text{-SCN}$ ligands are found in the polymeric chain structures $[\text{K}(18\text{-crown-6})(\eta^5\text{-C}_5\text{Me}_5)_2\text{Yb}(\text{NCS})_2]_\infty$,⁴⁰⁹ $[\text{K}(18\text{-crown-6})(\mu\text{-SCN})]_2\text{UO}_2(\text{NCS})_2(\text{H}_2\text{O})$,⁴¹⁰ and

Figure 35 The structure of complex formed between (*E*)-9,10-diphenyl-2,5,8,11,14,17-hexaoxaoctadec-9-ene and NaSCN .

Figure 36 Portion of the polymeric lattice of an *S*-bound thiocyanate rubidium crown ether complex.

$[\text{K}(\text{18-crown-6})]_2\text{K}[\text{Bi}(\text{SCN})_6]$, which exists in two isomeric forms.⁴¹¹ In the yellow form, octahedral $[\text{Bi}(\text{SCN})_6]^{3-}$ anions are surrounded by four $[\text{K}(\text{18-crown-6})]_2$ units in a layered arrangement; all the thiocyanates are *N*-bound to potassium. In the yellow form, the thiocyanatobismuth anions have four *S*-bonded and two *trans N*-bonded thiocyanate ligands, and are arranged in parallel columns separated by K^+ cations; each potassium has two *trans S*-bound and four *N*-bound thiocyanate ligands. Two $[\text{K}(\text{18-crown-6})]^+$ units are located between the columns.⁴¹¹

Structurally characterized selenocyanate complexes of the *s*-block metals are much rarer, but as befits the softer nature of selenium relative to sulfur, all known examples are *N*-bound.^{411–414}

(iv) *N*-donor stabilized metal-centered radicals

The 1,4-di-*t*-butyl-1,4-diazabutadiene ligand ($(\text{Bu}^t)_2\text{DAB}$) is able to stabilize a ligand-centered radical with lithium,⁴¹⁵ or triplet biradicals with magnesium, calcium, and strontium.⁴¹⁶ The dark green lithium species can be generated from $(t\text{-Bu})_2\text{DAB}$ and sonicated lithium in hexane; activated magnesium will react with $(\text{Bu}^t)_2\text{DAB}$ in THF to form the deep red $\text{Mg}[(\text{Bu}^t)_2\text{DAB}]_2$. EPR measurements ($g_{\text{av}} = 2.0034$ for Li ⁴¹⁵; 2.0036 for Mg ⁴¹⁷), DFT calculations,⁴¹⁸ and X-ray single-crystal structural studies have been used to characterize the products. The lithium compound, for which calculations suggest the metal–ligand interaction is primarily ionic, displays a tetrahedral coordination geometry (see Figure 37). One $(\text{Bu}^t)_2\text{DAB}$ ligand (involving N1 and N4) has a geometry consistent with a radical anion ($\text{Li}—\text{N}(\text{mean}) = 1.995 \text{ \AA}$; $\text{N}—\text{Li}—\text{N} = 88.3(3)^\circ$); the other is bound as a simple neutral ligand ($\text{Li}—\text{N}(\text{mean}) = 3.141 \text{ \AA}$; $\text{N}—\text{Li}—\text{N} = 79.5(2)^\circ$). In the magnesium compound, the metal center is also tetrahedrally coordinated, but the molecule

Figure 37 The structure of the lithium complex of 1,4-di-*t*-butyl-1,4-diazabutadiene.

possesses nearly $2mm$ symmetry, and both ligands display features consistent with radical anions ($\text{Mg}-\text{N} = 2.070(7), 2.067(7) \text{ \AA}$; $\text{Mg}-\text{N} = 83.1(3), 82.4(3)^\circ$). It should be noted that it is possible to prepare beryllium, calcium and barium complexes of the diazabutadiene ligand that contain doubly-reduced ligands; the complexes $[\text{Be}(1,4\text{-bis}(4\text{-methylphenyl})\text{-}2,3\text{-diphenyl-}1,3\text{-diazabutadiene})(\text{THF})_2]$ (black-green),⁴¹⁹ $[\text{Ca}(\text{NRCPh}=\text{CPh}=\text{NR-}N,N')(\text{DME})_2]$ ($\text{R} = \text{C}_6\text{H}_4\text{-}4\text{-Me}$) (orange) and $[\text{Ba}_2(\text{DME})_3(\text{NPhCPh}=\text{CPhNPh})_2\text{DME}]$ (red) have been structurally characterized.⁴²⁰

(v) Other nitrogen donor ligands

The pyrazolate anion, $[\text{C}_3\text{H}_3\text{N}_2]^-$, is isoelectronic with the cyclopentadienyl anion, and has been incorporated into s -block metal complexes. Reaction of the disubstituted pyrazoles $3,5\text{-R}_2\text{pzH}$ ($\text{R} = \text{Bu}^t$ or Ph) with KH in THF yields $[(3,5\text{-R}_2\text{pz})\text{K}(\text{THF})_n]_6$ [$\text{R} = \text{Bu}^t$, $n = 0$; $\text{R} = \text{Ph}$, $n = 1$]. The crystal structure of the hexameric drum-shaped diphenylpyrazolato derivative (see Figure 38) indicates that each potassium is bonded in an η^2 -manner to one pyrazolato ligand, in an η^1 -fashion to two adjacent ligands, and to a single THF ligand. The complex serves as a pyrazolato transfer reagent to titanium and tantalum.⁴²¹

The hexadentate ligand $\text{bis}\{3\text{-}[6\text{-(}2,2'\text{-bipyridyl)}]\text{pyrazol-}1\text{-yl}\}\text{hydroborate}$ contains two terdentate chelating arms joined by a $[\text{BH}_2]^-$ spacer. Its potassium derivative crystallizes in the form of a double helix, in which each metal ion is six-coordinated by a terdentate arm from each of the two (pyrazol-1-yl)hydroborate ligands; the two ligands are bridging, and folded at the $-\text{BH}_2-$ linkage (see Figure 39).⁴²²

The reaction of magnesium bromide with potassium 3,5-di-*tert*-butylpyrazolate, $\text{K}[\text{Bu}^t_2\text{pz}]$, in toluene affords $\text{Mg}_2(\text{Bu}^t_2\text{pz})_4$; in THF the product is $\text{Mg}_2(\text{Bu}^t_2\text{pz})_4(\text{THF})_2$.⁴²³ Both of these are dinuclear complexes with two bridging pyrazolato and two chelating η^2 -pyrazolato ligands. TMEDA binds to the unsolvated compound or displaces THF from the solvate to give $\text{Mg}(\text{Bu}^t_2\text{pz})_2$ (TMEDA), which is a mononuclear species with two η^2 -pyrazolates and chelating TMEDA.

Reaction of CaBr_2 with two equivalents of $\text{K}[\text{Bu}^t_2\text{pz}]$ in THF yields $\text{Ca}(\text{Bu}^t_2\text{pz})_2(\text{THF})_2$, which on treatment with pyridine, TMEDA, PMDETA, triglyme, and tetraglyme generates the adducts $\text{Ca}(\text{Bu}^t_2\text{pz})_2(\text{Py})_3$, $\text{Ca}(\text{Bu}^t_2\text{pz})_2(\text{TMEDA})$, $\text{Ca}(\text{Bu}^t_2\text{pz})_2(\text{PMDETA})$, $\text{Ca}(\text{Bu}^t_2\text{pz})_2(\text{triglyme})$, and $\text{Ca}(\text{Bu}^t_2\text{pz})_2(\text{tetraglyme})$, respectively. A related series of THF, PMDETA, triglyme, and tetraglyme adducts of the 3,5-dimethylpyrazolate anion can also be prepared. The Bu^t pyrazolato complexes are mononuclear, with η^2 -bound ligands. The compounds have been investigated for

Figure 38 The structure of the hexameric complex $[(3,5\text{-Ph}_2\text{pz})\text{K}(\text{THF})_n]_6$.

Figure 39 The structure of the potassium derivative of bis{3-[6-(2,2'-bipyridyl)]pyrazol-1-yl}hydroborate.

their potential use in CVD, but only $\text{Ca}(\text{Bu}^t\text{pz})_2(\text{triglyme})$ displays appreciable volatility, subliming at 160°C (0.1 mmHg), and even then, decomposition by triglyme ligand loss is competitive with sublimation. In other complexes, unfavorable steric interactions between the pyrazolato ligands and the neutral donors leads to the loss of the latter on heating before sublimation occurs.⁴²⁴

In the synthesis of barium 3,5-dimethylpyrazolate from barium metal and the pyrazole, silicone joint grease and *cyclo*-(Me_2SiO)₄ are cleaved, forming the complex $[(\text{THF})_6\text{Ba}_6(3,5\text{-dimethylpyrazolato})_8\{(\text{OSiMe}_2)_2\text{O}\}_2]^{2-}$. Two $[\text{O}(\text{SiMe}_2)_2]^{2-}$ bidentate chelating siloxane anions are coordinated above and below a nearly hexagonal Ba_6^{2+} layer that has been compared to the (110) layer in cubic body-centered metallic barium (see Figure 40). Eight σ/π coordinated pyrazolate anions flank the barium layer, and six coordinated THF molecules are located at the periphery of the Ba_6 plane.⁴²⁵

In its *s*-block complexes, the amidinate ligand, $[\text{RC}(\text{NR}')(\text{NR}'')]^-$,⁴²⁶ displays bonding arrangements that are strongly metal- and substituent-dependent. It is commonly found as a delocalized, bidentate moiety, forming four-membered $\text{M}-\text{N}-\text{C}-\text{N}$ rings. Among the structurally authenticated monometallic species are $[\text{PhC}(\text{NSiMe}_3)(\text{N-myrtanyl})]\text{Li}\cdot\text{TMEDA}$ (which is chiral by virtue of the myrtanyl group),⁴²⁷ $[\text{PhC}(\text{NSiMe}_3)_2]_2\text{Be}$,⁴²⁸ $[\text{PhC}(\text{NSiMe}_3)_2]_2\text{Mg}(\text{THF})_2$,⁴²⁹ $[\text{PhC}(\text{NSiMe}_3)_2]_2\text{Mg}(\text{NCPH})_2$,⁴³⁰ $[2\text{-Py}(\text{CH}_2)_2\text{NC}(p\text{-MePh})\text{NPh}]_2\text{Mg}$ (with a intramolecularly coordinated pendant pyridine),⁴³¹ $[\text{PhC}(\text{NSiMe}_3)_2]_2\text{Ca}(\text{THF})_2$,⁴³² and $[\text{PhC}(\text{NSiMe}_3)_2]_2\text{Ba}(\text{THF})(\text{DME})$.⁴³³

Extreme steric bulk on the amidinate ligand can force it to become monodentate, as in the lithium complex derived from *N,N'*-diisopropyl(2,6-dimesityl)benzamidinate. The TMEDA adduct (see Figure 41) displays a short $\text{N}-\text{Li}$ bond (1.94 Å), and the $\text{N}-\text{C}-\text{N}$ bond lengths suggests that the amidinate is not fully delocalized ($\text{C1}-\text{N1} = 1.32$ Å and $\text{C1}-\text{N2} = 1.34$ Å).⁴³⁴

Bimetallic complexes are represented by $\{[\text{N}(\text{SiMe}_3)\text{C}(\text{Ph})\text{NC}(\text{Ph})=\text{C}(\text{SiMe}_3)_2\text{Li}](\text{CNPh})\}_2$ ⁴³⁵ $\{[\mu_2\text{-}N,N'\text{-di}(p\text{-tolyl})\text{formamidinato-}N,N,N']\text{Li}(\text{Et}_2\text{O})\}_2$,⁴³⁶ $\{[\text{N}(\text{SiMe}_3)\text{C}(\text{Ph})\text{N}(\text{CH}_2)_3\text{NMe}_2]\text{Li}\}_2$ (with a γ -pendant amine functionality),⁴³⁷ $[\text{MeC}_6\text{H}_4\text{C}(\text{NSiMe}_3)_2\text{Li}(\text{THF})]_2$ and $[\text{PhC}(\text{NSiMe}_3)_2\text{Na}(\text{Et}_2\text{O})]_2\cdot\text{Et}_2\text{O}$, whose $\text{M}-\text{M}'$ distances (2.42 and 2.74 Å, respectively) are 80% and 73% of those in the metals,⁴³⁸ and $[4\text{-MeC}_6\text{H}_4\text{C}(\text{NSiMe}_3)_2\text{Li}(\text{NCC}_6\text{H}_4\text{Me-4})]_2$. The latter has two four-coordinated Li cations bound in an *N,N'*-bidentate π -fashion to one amidinato anion, thereby forming a double diazaallyl Li bridge, and in a monodentate σ -fashion to a nitrogen lone pair of a

Figure 40 The structure of $[(\text{THF})_6\text{Ba}_6(3,5\text{-dimethylpyrazolato})_8\{(\text{OSiMe}_2)_2\text{O}\}_2]$.

Figure 41 The structure of the TMEDA adduct of the lithium derivative of *N,N*-diisopropyl(2,6-dimesityl)-benzamidine.

second amidinate (see Figure 42). In solution, the different Li-amidinate bonding arrangements ($\sigma \rightleftharpoons \pi$) rapidly interconvert.⁴³⁹

More elaborate polymetallic species are also known. The reaction of benzonitrile with $\text{LiN}(\text{SiMe}_3)_2$ in hexane affords the trimeric complex $[\text{Li}_3\{\text{PhC}(\text{NSiMe}_3)_2\}_3(\text{NCPh})]$.⁴⁴⁰ Two of the lithium cations are coordinated by three nitrogen atoms of two phenylamidinate anions, and the other cation is ligated by four nitrogen atoms of two chelating phenylamidinate anions and an adducted benzonitrile molecule (see Figure 43). The tetra- and hexametallic boraamidinate complexes $\{[\text{Bu}^n\text{B}(\text{NBu}^t)_2]\text{Li}_2\}_2$ and $\{[\text{MeB}(\text{NBu}^t)_2]\text{Li}_2\}_3$ have been synthesized from the reaction of $\text{B}[\text{N}(\text{H})(\text{Bu}^t)]_3$ with three equivalents of BuLi or LiMe , respectively. The tetrametallic derivative possesses a 10-atom $\text{Li}_4\text{B}_2\text{N}_4$ framework isostructural with the $\text{Li}_4\text{Si}_2\text{N}_4$ core in $\{\text{Li}_2[\text{Me}_2\text{Si}(\text{NBu}^t)_2]\}_2$.⁴⁴¹ The larger aggregate is constructed around a distorted $\text{Li}_6[\text{N}(\text{Bu}^t)]_6$ hexagonal prism,

Figure 42 The structure of $[4\text{-MeC}_6\text{H}_4\text{C}(\text{NSiMe}_3)_2]\text{Li}(\text{NCC}_6\text{H}_4\text{Me-4})_2$.

Figure 43 The structure of the trimeric complex $[\text{Li}_3\{\text{PhC}(\text{NSiMe}_3)_2\}_3(\text{NCPh})]$.

in which alternate Li_2N_2 rings are N,N' -capped by a BMe unit, generating a tricapped hexagonal prismatic cluster (see [Figure 44](#)).⁴⁴²

The reaction of lithium cyclopentylamide in the presence of traces of H_2O generates the large aggregate $[\{(c\text{-C}_5\text{H}_9)\text{N}(\text{H})\}_{12}(\text{O})\text{Li}_{14}]$.⁴⁴³ In contrast to the ladders and rings that dominate the analysis of many amido and imido complexes, the molecule contains a salt-like, distorted, face-centered cube of lithium cations surrounding its central oxo anion ($\text{Li}-\text{O} = 1.89 \text{ \AA}$).

The elegantly simple cations $[\text{Ba}(\text{NH}_3)_n]^{2+}$ are generated in the course of reducing the fullerenes C_{60} and C_{70} with barium in liquid ammonia. The X-ray crystal structure of $[\text{Ba}(\text{NH}_3)_7]\text{C}_{60}^{2-}\cdot\text{NH}_3$ reveals a monocapped trigonal antiprism around the metal, with an ordered C_{60} dianion.⁴⁴⁴ An even more highly coordinated barium cation, $[\text{Ba}(\text{NH}_3)_9]^{2+}$ ($\text{Ba}-\text{N} = 2.89\text{--}2.97 \text{ \AA}$), was identified from the reduction of C_{70} . The coordination geometry around barium is a distorted tricapped trigonal prism; the fullerene units are linked in slightly zigzagging linear chains by single C—C bonds (1.53 \AA) (see [Figure 45](#)).⁴⁴⁵

3.1.4.3.2 Phosphorus donor ligands

The interaction of *s*-block metals and phosphorus-based ligands takes many forms, from neutral phosphines and anionic diphosphides $[\text{PR}]^{2-}$, to mixed (P,N) and (P,S) donors. The area has been one of intensive investigation, and there is practical interest in the use of such compounds in organophosphorus synthesis. The area has witnessed considerable growth: prior to 1985, fewer than five compounds containing an *s*-block element bonded to phosphorus had been structurally authenticated; by the end of 2000, the total was over 200. Extensive reviews of the area have appeared.^{19,322,446–448}

(i) Neutral phosphines

As expected from the mismatch between the type a *s*-block metals and the type b character of neutral phosphines, adducts of the *s*-block metals with coordinated PR_3 groups are rare; examples are found among organometallic species,⁴⁴⁹ but not usually with coordination complexes. Pendant phosphines that form part of a chelating ligand can be isolated, however, such as in the tetrameric sodium enolate $\{\text{Na}[(\text{Pr}^i)_2\text{PC}(\text{H})=\text{C}(\text{O})\text{Ph}]\}_4$, with a Na–P interaction at 2.85 Å.⁴⁵⁰ and the chelating diphenylphosphino arms found in $\{\text{Li}[\mu\text{-OC}(\text{CMe}_3)_2\text{CH}_2\text{PR}_2]\}_2$ (R = Me, Ph) (Li–P distance = 2.50, 2.65 Å).⁴⁵¹

(ii) Monosubstituted phosphido complexes

Group 1 and Group 2 compounds containing the dinegative PR^{2-} unit are not common, but complex structures can be formed from them. Magnesium forms several types with $\text{Mg}_{2m}\text{P}_{2m}$ cores. The magnesiation of tri(*t*-butyl)silylphosphine with $\text{Mg}(\text{Bu}^n)_2$ in THF yields tetrameric $[(\text{THF})\text{MgPSi}(\text{Bu}^t)_3]_4$.⁴⁵² The central Mg_4P_4 cube is only slightly distorted, with Mg–P ranging from 2.55 to 2.59 Å. When the reaction is conducted in toluene, the larger aggregate $\text{Mg}_6[\text{P}(\text{H})\text{Si}(\text{Bu}^t)_3]_4\text{P}[\text{Si}(\text{Bu}^t)_3]_2$ is generated. A Mg_4P_2 octahedron is at the center, with the phosphorus atoms in a *trans* position. The Mg–Mg edges are bridged by the $\text{P}(\text{H})\text{Si}(\text{Bu}^t)_3$ substituents. A refluxing toluene solution of $\text{Mg}_6[\text{P}(\text{H})\text{Si}(\text{Bu}^t)_3]_4\text{P}[\text{Si}(\text{Bu}^t)_3]_2$ will eliminate $\text{H}_2\text{PSi}(\text{Bu}^t)_3$ and precipitate the hexameric $[\text{MgPSi}(\text{Bu}^t)_3]_6$.

Its structure is based on a Mg_6P_6 hexagonal drum, with $\text{Mg}-\text{P}$ distances varying between 2.47 and 2.51 Å in the six-membered Mg_3P_3 ring, and 2.50–2.60 Å between the two rings (see Figure 46).⁴⁵³ Large $\text{M}_n(\text{PR})_m$ aggregates have been synthesized with lithium reagents; e.g., dilithiation of $\text{H}_2\text{PSi}(\text{Pr}^i)_3$ produces the hexadecametallic cluster $\text{Li}_{16}(\text{PSi}(\text{Pr}^i)_3)_{10}$.⁴⁵⁴ It is a doubly capped Archimedean antiprism with ten phosphorus centers and a lithium atom located on each deltahedral face.

The parent phosphide anion (PH_2^-) has been structurally authenticated only in lithium complexes (i.e., $\text{Li}(\text{PH}_2)(\text{DME})_2$ ($\text{Li}-\text{P}=2.60$ Å),⁴⁵⁵ $[\text{Li}(\text{PH}_2)(\text{DME})]_n$ ($\text{Li}-\text{P}=2.60$ Å)^{456,457}) but examples of $\text{M}(\text{P}(\text{H})\text{R})_n$ compounds are more common. Among these are aryl-substituted species $\text{MP}(\text{H})\text{Ar}$, where Ar = phenyl,⁴⁵⁸ mesityl,^{459–461} 2,4,6-tri-*t*-butylphenylphosphide,^{462,463} 2,6-dimesitylphenylphosphide,^{464,465} and 2,6-dimesitylphenylphosphide.⁴⁶² The latter ligand forms a bimetallic sandwich complex with 18-crown-6 that displays cation- π interactions ($\text{Cs}-\text{P}=3.42$ Å; $\text{Cs}-\text{C}$ distance = $3.48-3.77$ Å) (see Figure 47).⁴⁶² Other primary phosphido complexes include those with $-\text{P}(\text{H})\text{CH}_3$,⁴⁶⁶ $-\text{P}(\text{H})(\text{Bu}^t)$,⁴⁶⁷ $-\text{P}(\text{H})(\text{c-C}_6\text{H}_{11})$,^{468,469} and $-\text{P}(\text{H})\text{Si}(\text{Pr}^i)_3$.^{244,453,470–473}

The triisopropylsilylphosphido ligand has been used to generate a variety of polymetallic species. For example, metalation of $\text{H}_2\text{PSi}(\text{Pr}^i)_3$ with $\text{Ca}(\text{THF})_2[\text{N}(\text{SiMe}_3)_2]_2$ in tetrahydropyran (THP) in a molar ratio of 3:2 yields $(\text{Me}_3\text{Si})_2\text{N}[\mu-\text{P}(\text{H})\text{Si}(\text{Pr}^i)_3]_3\text{Ca}(\text{THP})_3$; the complex contains a trigonal-bipyramidal Ca_2P_3 core, with the metal atoms on the apices;⁴⁷³ a presumably similar complex (based on NMR evidence) can be made with THF as the supporting ether.⁴⁷⁴ A heteroleptic complex, $(\text{THF})_2\text{Ba}[\text{N}(\text{SiMe}_3)_2][\text{P}(\text{H})\text{Si}(\text{Bu}^t)_3]$, can be derived from the equimolar reaction of (tri-*tert*-butylsilyl)phosphine with $(\text{THF})_2\text{Ba}[\text{N}(\text{SiMe}_3)_2]_2$ in toluene. Addition of a second equivalent of $\text{H}_2\text{PSi}(\text{Bu}^t)_3$ to the latter affords $(\text{THF})\text{Ba}_3(\text{PSi}(\text{Bu}^t)_3)_2[\text{P}(\text{H})\text{Si}(\text{Bu}^t)_3]_2$ (see Figure 48); it can be viewed as a Ba_4P_4 heterocubane, with two opposite faces capped by $(\text{THF})\text{Ba}[\text{P}(\text{H})\text{Si}(\text{Bu}^t)_3]_2$ units.⁴⁷³ An Sr_4P_4 cube serves as the core of $[\text{Sr}(\text{THF})_2(\mu-\text{PHSi}(\text{Pr}^i)_3)_2\{\text{Sr}_2(\mu_4-\text{PSi}(\text{Pr}^i)_3)_2\}_2\text{Sr}(\mu-\text{PHSi}(\text{Pr}^i)_3)_2(\text{THF})_2]$, which is formed by elimination of $\text{PH}_2\text{Si}(\text{Pr}^i)_3$ from $\text{Sr}(\text{THF})_4(\text{PH}(\text{Pr}^i)_3)_2$ in toluene.²⁴⁴

Complexes are also known that contain both PR^{2-} and PHR^- functionalities.⁴⁷⁵ The silaphosphane $\text{R}_2\text{Si}(\text{PH}_2)[\text{P}(\text{H})\text{SiPh}_3]$ ($\text{R}_2\text{Si} = (2,4,6-(\text{Pr}^i)_3\text{C}_6\text{H}_2)(\text{Bu}^t)\text{Si}$) reacts with Bu^nLi with loss of butane to form the tetrametallic dimer $\{\text{Li}_2(\text{PSiPh}_3)[\text{P}(\text{H})(\mu-\text{SiR}_2)]\}_2$. On further treatment with LiCl the latter generates an Li_{10}P_8 aggregate, a “dimer of dimers,” in which two of the tetrametallic dimers are joined at a central $(\text{LiCl})_2$ ring (see Figure 49).⁴⁷⁶ Treatment of ethyl tris(triisopropylsilylphosphino)silane, $\text{EtSi}\{\text{P}[\text{Si}(\text{Pr}^i)_3]\text{H}\}_3$, with either Bu^nLi or Bu^nNa leads to distinctly different products. The lithium derivative, $\{\text{EtSi}[\text{P}(\text{Si}(\text{Pr}^i)_3)\text{Li}]\}_2$, has a distorted

Figure 46 The structure of the hexameric complex $[\text{MgPSi}(\text{Bu}^t)_3]_6$.

Figure 47 The structure of the 18-crown-6 complex of caesium 2,6-dimesitylphenylphosphide.

rhombic dodecahedral $\text{Si}_2\text{P}_6\text{Li}_6$ framework, whereas the product from the sodium reaction has an open polyhedral structure, with two bridging sodium atoms, each coordinated η^2 to a molecule of the toluene solvent (see Figure 50). It is thought that the mismatch between $\text{Si}-\text{P}$ (2.2 Å) and $\text{Na}-\text{P}$ (2.8 Å) distances prohibits the formation of a closed structure.⁴⁷⁶

(iii) *Disubstituted phosphido complexes*

Disubstituted phosphido ligands $[\text{PRR}']^-$ have been incorporated into numerous *s*-block complexes. Many examples are known, and are covered in detail in the previously cited reviews; only

Figure 48 The structure of $(\text{THF})\text{Ba}_3(\text{PSi}(\text{Bu}^t)_3)_2[\text{P}(\text{H})\text{Si}(\text{Bu}^t)_3]_2$.

representative systems need be presented here. A particularly well-studied class of these complexes are those with trialkylsilyl groups as substituents, especially the bis(trimethyl)silyl moiety.¹⁹ Synthetic methods for these compounds vary, from direct metalation (e.g., the reaction of $\text{HPN}(\text{SiMe}_3)_2$ with KH or $\text{KO}(\text{Bu}^t)$ produces $\text{KP}(\text{SiMe}_3)_2$; $(\text{Bu}^n)_2\text{Mg}$ and $\text{HPN}(\text{SiMe}_3)_2$ generate $\text{Mg}[\text{P}(\text{SiMe}_3)_2]$ to metathesis (e.g., $\text{M}[\text{N}(\text{SiMe}_3)_2]_2$ ($\text{M} = \text{Mg}, \text{Ca}, \text{Sr}, \text{Ba}$) react with $\text{HP}(\text{SiR}_3)$ to produce the corresponding phosphides). Representative complexes are listed in Table 6. In donor solvents (ether, THF), the complexes are monomeric; in hydrocarbons, monomer/dimer equilibria can be observed in NMR spectra.

Other series of phosphido complexes are well-established, including those containing the ligands $\text{P}(\text{Bu}^t)_2$ ^{477,478} and PPh_2^- . The compact size of the latter permits extensive bridging to occur, generating polymeric structures. $\{\text{Li}(\text{Et}_2\text{O})\text{PPh}_2\}_\infty$, $\{\text{Li}(\text{THF})_2\text{PPh}_2\}_\infty$, and the related $\{\text{Li}(\text{THF})\text{P}(\text{cyclohexyl})_2\}_\infty$, for example, all have infinite $-\text{Li}-\text{P}-\text{Li}-\text{P}-$ chains in the solid state, with distorted tetrahedral coordination around phosphorus.⁴⁷⁹ A similar arrangement is found in $[\text{Li}(\text{DME})\text{PPh}_2]_\infty$.⁴⁷⁷ Sodium diphenylphosphide, NaPPh_2 , prepared from sodium and PClPh_2 in refluxing dioxane, crystallizes from dioxane as $[\text{Na}_4(\mu\text{-dioxane})_8/2(\mu\text{-dioxane})(\text{PPh}_2)_4]_\infty$, which includes a dioxane molecule suspended within eight-membered Na_4P_4 rings ($\text{Na}-\text{P} = 2.88\text{--}3.00\text{ \AA}$); the rings, in turn, are linked by additional dioxane molecules to form a network structure (Figure 51).⁴⁸⁰ The solid-state structure of $[\text{K}(\text{dioxane})_2\text{PPh}_2]_\infty$ displays π -interactions between the potassium ions and aryl rings of a neighboring PPh_2 anion, thereby generating a three-dimensional framework.⁴⁸¹

The effect of steric bulk in limiting oligomerization is evident in the structures of $[(\text{TMEDA})\text{-LiPPh}_2]_2$, which is a dimer, and $(\text{PMDTA})\text{LiPPh}_2$, which is a monomer ($\text{Li}-\text{P} = 2.57\text{ \AA}$). Lithium-7 and ^{31}P -NMR spectroscopic studies indicate that both solid-state structures are retained in arene solvents, although the TMEDA adduct dissociates to some extent.⁴⁸² Alternatively, extra bulk on the phenyl rings will limit oligomerization; thus unlike the oligomeric $\{\text{Li}(\text{Et}_2\text{O})_2\text{PPh}_2\}_\infty$, $[\text{Li}(\text{OEt}_2)\text{P}(\text{mesityl})_2]_2$ is a discrete dimer.⁴⁵⁹

The ladder structures found in *s*-block amides are common structural motifs in phosphides as well. Solvent free $[\text{LiP}(\text{SiMe}_3)_2]_6$ displays such an arrangement in the solid state, with four five-coordinate and two four-coordinate P atoms and four three-coordinate and two two-coordinate Li atoms; the $\text{Li}-\text{P}$ distances range from 2.38 \AA to 2.63 \AA (see Figure 52).⁴⁸³ $\text{Li}_4(\mu_2\text{-PR}_2)_2(\mu_3\text{-PR}_2)_2(\text{THF})_2$, formed from the reaction of $\text{P}(\text{SiMe}_3)_3$ with Bu^nLi in THF, has a fused tricyclic $(\text{LiP})_4$ ladder skeleton. The Li atoms are three-coordinate, with each of the two terminal lithiums bound to two P atoms and one THF, while the two internal lithiums have three phosphorus atoms as neighbors (see Figure 53).⁴⁸⁴ In solution, there is no NMR evidence for ^{31}P

Table 6 Selected bond lengths (\AA) and angles ($^\circ$) of the complexes $(\text{L})\text{M}[\text{P}(\text{SiR}_3)_2]_n$ as well as chemical $^{31}\text{P}\{^1\text{H}\}$ shifts of the bis(phosphanides).

Figure 51 Portion of the lattice of $[\text{Na}_4(\mu\text{-dioxane})_{8/2}(\mu\text{-dioxane})(\text{PPh}_2)_4]_\infty$.

coupling. Other ladder structure are known, including $[(\text{THF})\text{LiCl} \cdot (\text{THF})_2\text{LiP}(\text{Bu}^t)_2]_2$ ⁴⁸⁵ and $[\text{R-PLi}_2(\text{F-R})]_2$ (R = diisopropyl-(2,4,6-triisopropylphenyl)silane.⁴⁸⁶

Compounds containing a variety of substituted heteroallyl-like ligands, with PCP (bis(phosphino)methanides),^{487–491} PNP (bis(phosphino)amides),⁴⁹² NCP,⁴⁹³ PSiP (diphosphasilalyl),^{494,495} and PPP (triphosphides)^{496,497} frameworks are known. Some of these complexes can adopt a variety of coordination modes; in $\text{Rb}(18\text{-crown-6})(\text{N}(\text{PPh}_2)_2)$, the phosphinoamide is P,P-ligated,⁴⁹² whereas in $(\text{THF})_3\text{LiN}(\text{PPh}_2)_2$, the ligand is bound $\eta^2\text{-P,N}$. Phosphorous-31 and ^6Li -NMR spectroscopy indicate that the structure of the latter in THF solution is similar to that in the solid state; dynamic ^{31}P -NMR spectroscopic measurements indicate that an $8.1 \text{ kcal mol}^{-1}$ rotation barrier exists around the P—N bonds.⁴⁹⁸ The utility of some of these complexes as ligand transfer reagents has been investigated. Thus from the reactions of ZrCl_4 with $\{(\text{TMEDA})\text{-Li}[\text{CH}(\text{PMe}_2)(\text{SiMe}_3)]_2\}$, a mixture of the compounds $\text{Cl}_{(4-n)}\text{Zr}[\text{CH}(\text{PMe}_2)(\text{SiMe}_3)]_n$ ($n = 1\text{--}4$) has been characterized with NMR spectroscopy. With $(\text{TMEDA})\{\text{Li}[\text{C}(\text{PMe}_2)(\text{SiMe}_3)_2]\}_2$, only the disubstituted product $\text{Cl}_2\text{Zr}[\text{C}(\text{PMe}_2)(\text{SiMe}_3)_2]_2$ is obtained.^{499,500}

Figure 53 The structure of $\text{Li}_4(\mu_2\text{-PR}_2)_2(\mu_3\text{-PR}_2)_2(\text{THF})_2$.

3.1.4.3.3 Arsenic donor ligands

Early reports describing the preparation of *s*-block arsenides such as $\text{Ca}(\text{AsH}_2)_2$ and $\text{Ca}(\text{AsHMe})_2$ provided few details on their properties.⁵⁰¹ That situation has changed with the use of silyl-substituted arsenic ligands, and compounds containing them display considerable structural diversity. This area has been reviewed.⁵⁰²

Sometimes arsines themselves are the starting materials for *s*-block derivatives. The preparation of $[\text{Li}(\text{AsH}_2)(\text{DME})_2]$ from AsH_3 has been reported,⁴⁵⁵ and in the solid state it possesses a trigonal bipyramidal metal center with the AsH_2 residue in an equatorial site ($\text{Li}-\text{As} = 2.699 \text{ \AA}$). The reaction of Bu^nLi with PhAsH_2 in toluene-THF produces the primary arsenide $[\text{PhAsHLi} \cdot 2\text{THF}]_\infty$. It crystallizes in the form of helical polymers; the right-hand enantiomorph was identified in the lattice (see Figure 54).⁵⁰³ The reaction of $(n,s\text{-butyl})_2\text{Mg}$ with bis(trimethylsilyl)arsine in THF yields $[(\text{Me}_3\text{Si})_2\text{As}]_2\text{Mg}(\text{THF})_2$. The magnesium atom is in a distorted tetrahedral environment ($\text{Mg}-\text{As} = 2.59, 2.60 \text{ \AA}$; $\text{Mg}-\text{O} = 2.05, 2.06 \text{ \AA}$), whereas the environment around arsenic is pyramidal.⁵⁰⁴

Many arsenic derivatives have been synthesized from bis(trimethylsilyl)amido complexes. The 2:1 reaction of $\text{AsH}_2\text{SiPr}_3^i$ with $\text{Ba}[\text{N}(\text{SiMe}_3)_2]_2 \cdot 2(\text{THF})$ in THF affords the bis(arsenide) complex $[\text{Ba}(\text{THF})_3\{\mu\text{-As}(\text{H})\text{SiPr}_3^i\}_3\text{BaAs}(\text{H})\text{SiPr}_3^i(\text{THF})_2]_n$.⁴⁷³ $\text{M}(\text{NR}_2)_2$ ($\text{M} = \text{Ca}, \text{Sr}$; $\text{R} = \text{Me}_3\text{Si}$) react with HAsR_2 in THF to give $(\text{R}_2\text{As})_2\text{M}(\text{THF})_4$.⁵⁰⁵ Both $(\text{R}_2\text{As})_2\text{Ca}(\text{THF})_4$ and $(\text{R}_2\text{As})_2\text{Sr}(\text{THF})_4$ exist as colorless *trans*-isomers with a nearly linear $\text{As}-\text{M}-\text{As}$ moiety; however, the light-sensitive Sr analog contains two different configurations for the As atoms. One As atom is surrounded in a nearly trigonal planar manner with an $\text{Sr}-\text{As}$ bond length of 3.10 \AA , whereas the other arsenic atom has an angle sum of 338° and an $\text{Sr}-\text{As}$ distance of 3.15 \AA .

Metallation of $\text{As}[\text{SiMe}_2(\text{Bu}^t)]_2\text{H}$ with $\text{Ba}[\text{N}(\text{SiMe}_3)_2]_2 \cdot 4(\text{THF})$ generates $\text{Ba}[\text{As}(\text{SiMe}_2\text{-}(\text{Bu}^t))]_2 \cdot 4(\text{THF})$ (see Figure 55), which in the solid state exists as a distorted pentagonal bipyramid with apical arsenic atoms and a vacant equatorial site shielded by the trialkylsilyl groups. The $\text{As}-\text{Ba}-\text{As}'$ angle is 140.8° . When the compound is recrystallized from toluene, THF ligands are lost to give the dimeric $\{\text{Ba}[\text{As}(\text{SiMe}_2(\text{Bu}^t))]_2(\text{THF})\}_2$ (see Figure 56), which contains four-coordinate Ba centers.⁵⁰⁶ The magnesiumation of $\text{AsH}_2(\text{SiPr}_3^i)$ in THF yields $[\text{Mg}(\text{THF})\text{AsSiPr}_3^i]_4$ (see Figure 57), constructed around a Mg_4As_4 cube.⁵⁰⁷

Reaction of $\text{AsH}_2(\text{SiPr}_3^i)$ with $\text{M}[\text{N}(\text{SiMe}_3)_2]_2 \cdot 2(\text{THF})$ ($\text{M} = \text{Ca}$ or Sr) produces $\text{M}[\text{As}(\text{H})\text{SiPr}_3^i]_2(\text{THF})_4$, which is in equilibrium with the dimers $\text{M}[\text{As}(\text{H})\text{SiPr}_3^i][\mu\text{-As}(\text{H})\text{SiPr}_3^i]_3\text{M}(\text{THF})_3$ by elimination of THF. Reaction of the equilibrium mixtures with diphenylbutadiyne gives the metal bis(THF)bis(2,5-diphenylarsolide) species. A mechanism based on intermolecular H/SiPr_3^i exchange has been proposed that explains the formation of both the $[\text{As}(\text{SiPr}_3^i)_2]^-$ and 2,5-diphenyl-3,4-bis(phenylethynyl)arsolide anions; the latter was isolated as a solvent-separated ion pair with the binuclear $[(\text{THF})_3\text{Ca}\{\mu\text{-As}(\text{H})\text{SiPr}_3^i\}_3\text{Ca}(\text{THF})_3]^+$ cation (see Figure 58).⁵⁰⁸

Figure 54 Portion of the helical structure of $[\text{PhAsHLi} \cdot 2\text{THF}]_{\infty}$.

The solid state structure of the lithium arsenide $\{\text{Li}_2[\mu_2\text{-As}(\text{SiMe}_3)_2][\mu_3\text{-As}(\text{SiMe}_3)_2](\text{THF})\}_2$ reveals a $[\text{LiAs}]_4$ ladder-like framework with four antiparallel adjacent As–Li rungs (see Figure 59). The two Li atoms of the central ring each bridge three As centers, while the two Li atoms on the outer rings each span two As atoms and are coordinated to one THF molecule. The Li arsenide $[\text{((Me}_3\text{Si)}_2\text{As)Li(THF)}_2]_2$ crystallizes as a centrosymmetric dimer constructed around a four-membered As–Li–As–Li ring; each Li atom is coordinated to two molecules of THF.⁵⁰⁹

Reaction of two equivalents of $\text{LiAsH}_2(\text{DME})$ with $(2,4,6\text{-triisopropylphenyl})_2\text{SiF}_2$ at 20°C in THF gives $(2,4,6\text{-triisopropylphenyl})_2\text{SiFAsHLi}$ in quantitative yield.⁵¹⁰ The product reacts with $[\text{Pr}^i_3\text{Si}]\text{SO}_2\text{CF}_3$ to give $(2,4,6\text{-triisopropylphenyl})_2\text{SiFAsHSiPr}^i_3$, which upon lithiation with Bu^nLi

Figure 55 The structure of $\text{Ba}[\text{As}(\text{SiMe}_2(\text{Bu}^t))_2]_2 \cdot 4(\text{THF})$.

Figure 57 The structure of $[\text{Mg}(\text{THF})\text{AsSiPr}^i_3]_4$.

Figure 58 Schematic structure of the binuclear cation $[(\text{THF})_3\text{Ca}\{\mu\text{-As}(\text{H})\text{SiPr}^i_3\}_3\text{Ca}(\text{THF})_3]^+$.

Figure 59 The structure of $\{\text{Li}_2[\mu_2\text{-As}(\text{SiMe}_3)_2][\mu_3\text{-As}(\text{SiMe}_3)_2](\text{THF})\}_2$.

in THF-hexane produces $(2,4,6\text{-triisopropylphenyl})_2\text{SiFAs}\{\text{Li}(\text{THF})_2\}\{\text{SiPr}^i_3\}$ (see [Figure 60](#)). The latter undergoes thermal elimination of LiF and THF in toluene at 80°C to produce the arsanylidene silane $(2,4,6\text{-triisopropylphenyl})_2\text{Si}=\text{AsSiPr}^i_3$.

A variety of large clusters have been formed by lithiation of arsine derivatives. Treatment of AsRH_2 ($\text{R} = \text{SiMe}_2\text{C}(\text{Pr}^i)\text{Me}_2$) with Li_2O -containing Bu^nLi generates the orange-yellow $(\text{RAs})_{12}\text{Li}_{26}\text{O}$ aggregate, which is based on a slightly distorted As_{12} icosahedron with all faces capped by lithium. Four Li^+ cations are located in the center of the roughly spherical framework; the ions encapsulate a Li_2O molecule, thereby generating an octahedral $[\text{Li}_6\text{O}]^{4+}$ core (see [Figure 61](#)).⁵¹¹ Partial lithiation of AsRH_2 in the presence of LiOH leads to the isolation of the intermediate species $[\text{Li}_{20}\text{O}(\text{RAsH})_6(\text{RAs})_6]$, which contains wheel-like $[\text{Li}_{18}\text{As}_{12}]$ ladder structures with $[\text{Li}_2\text{O}]$ units acting as the “stabilizing axis” of the wheel; it is isotopic with a phosphorus analogue.⁴⁵⁴ Dilithiation of $\text{AsH}_2\text{SiPr}^i_3$ produces the decameric cluster $\text{Li}_{16}(\text{AsSiPr}^i_3)_{10}$. It forms a doubly capped Archimedean antiprism with ten arsenic centers and a lithium atom located on each deltahedral face.⁴⁵⁴

3.1.4.4 Group 16 Ligands

3.1.4.4.1 Oxygen donor ligands

The generally high oxophilicity of the alkali and alkaline-earth elements gives oxygen donor ligands a prominent place in *s*-block coordination chemistry. Oxygen donor ligands, of which

Figure 60 The structure of $(2,4,6\text{-triisopropylphenyl})_2\text{SiFAs}\{\text{Li}(\text{THF})_2\}\{\text{SiPr}^i_3\}$.

Figure 61 The structure of the $(\text{RAs})_{12}\text{Li}_{26}\text{O}$ aggregate ($\text{R} = \text{SiMe}_2\text{CPr}^i\text{Me}_2$). The alkyl groups have been removed for clarity.

carboxylates, diketonates, enolates, and alkoxides and aryloxides are considered here, are found in a vast array of *s*-block complexes. The interest in their properties encompasses inorganic synthesis (many *s*-block complexes are used as transfer reagents for *p*-, *d*-, and *f*-block complexes), materials chemistry (e.g., precursors to metal oxides), and the biological realm (water and oxygen-containing organic functional groups play a critical role in defining the structure and reactions of many proteins and enzymes).

(i) Carboxylates

Compared to other *s*-block metal complexes with anionic oxygen donors, the metal carboxylates are particularly robust; although often hygroscopic, they will not decompose upon absorption of water, and are as a class quite thermally stable. Their handling is thus simpler than alkoxides and aryloxides. The bonding arrangements of calcium carboxylates were reviewed in the early 1980s,⁵¹² and the chemistry of Group 2 carboxylates and thiocarboxylates, and their potential applications as reagents in CVD have been extensively reviewed.¹³

Carboxylates can form structurally complex units, often assisted by the presence of bridging water molecules, which can generate three-dimensional networks. For example, in the crystal structure of $[\text{Mg}\{\text{C}_2\text{H}_4(\text{CO}_2\text{Et})_2\}_3]^{2+}[\text{MgCl}_4]$, the cations are linked by other diethyl succinate ligands to form a linear polymer. In the cation, each magnesium atom is octahedrally coordinated by six carbonyl oxygen atoms of ethyl succinate molecules.⁵¹³ A more complex infinite two-dimensional structure exists in barium diethyl 1,3-dithiepane-2-ylidenemalonate via intermetallic coordination of the dicarboxylic groups. The metal center adopts a nine-coordinate geometry with three different carboxylate bonding arrangements (chelated monodentate, bidentate η^2 , monodentate) and two water molecules. Each ligand is associated with five barium atoms, in the form of a layer structure (see Figure 62).⁵¹⁴

Even ostensibly monomeric complexes can display close contacts in the solid state that will affect their reactivity. Bis(*trans*-but-2-enoato)calcium forms discrete molecules with intermolecular Ca–O contacts (2.36 Å) that are only slightly longer than the intramolecular bonds

Figure 62 Portion of the lattice of barium diethyl 1,3-dithiepane-2-ylidenemalonate, illustrating the various carboxylate binding modes present.

(Ca—O = 2.30 Å). The closeness of the molecules help explains why under irradiation with γ -rays from ^{60}Co , a solid-state cyclodimerization reaction is induced, producing *cis,trans*-nepetic acid, one of four possible diastereomers.⁵¹⁵ Related radiation-induced chemistry is displayed by aquated (3-butenato)calcium, $\text{Ca}(\text{CH}_2=\text{CHCH}_2\text{CO}_2)_2(\text{H}_2\text{O})$, synthesized from 3-butenic acid and calcium carbonate. The carboxylate is a two-dimensional coordination polymer with nearly parallel vinyl groups and short $-\text{C}=\text{C}-\text{C}=\text{C}-$ contacts of 3.73 Å and 3.90 Å (see Figure 63).⁵¹⁶

Alkali metal ions are commonly used to complex carboxylic acids of biological importance for structural analysis. Examples of such derivatives include 2-epimutalomycin-potassium dihydrate and 28-epimutalomycin-potassium (metabolites from mutalomycin fermentation),⁵¹⁷ the rubidium salt of CP-80,219 (an antibiotic related to dianemycin),⁵¹⁸ kijimicinate-rubidium hexane solvate (a polyether antibiotic),⁵¹⁹ griseocheline-calcium (an antifungal antibiotic),⁵²⁰ the sodium salt of the antibiotic A204A,⁵²¹ and the potassium salt of the polyether antibiotic monensin A dihydrate.⁵²² Comparison of the conformation of the latter with the sodium derivative reveals structural

Figure 63 Portion of the lattice of $\text{Ca}(\text{CH}_2=\text{CHCH}_2\text{CO}_2)_2(\text{H}_2\text{O})$, illustrating the close packing of the vinyl groups.

features that help explain the selectivity of monensin for Na^+ over K^+ . In the K^+ derivative, the conformation of the dioxaspiro-fused ring is altered and, according to the results of molecular mechanics calculations, raised in energy compared to the highly conserved Na^+ -complexed form.⁵²¹

Liquid carboxylate salts of the Group 2 elements are readily prepared via the reaction of polyether carboxylic acids such as 2-[2-(2-methoxy)ethoxy]ethoxyacetic acid (MEEA) and (2-[2-(2-methoxyethoxy)ethoxy]acetic acid (MEEAA) with metal hydroxides, carbonates, and alkoxides.^{523–525} These salts can be used directly in organometallic deposition processes to prepare ceramic films. They have also been used as solvents for transition metal or lanthanide nitrates and acetates in liquid precursors for polyceramics. Such monocarboxylates are generally highly soluble in a range of solvents including H_2O , methanol, acetone, THF, CHCl_3 , and CH_2Cl_2 .

Unlike the carboxylates prepared from MEAA and MEEAA, the calcium, strontium, and barium derivatives of the dicarboxylic 3,6,9-trioxaundecanedioic acid (TODD) are solids at room temperature, and display little solubility in solvents less polar than H_2O and MeOH .⁵²⁵ In the solid state, the calcium compound $\text{Ca}(\text{TODD})(\text{H}_2\text{O})_2$ forms a discrete dinuclear unit in which bridging carboxylates span the two calcium centers and all the oxygen atoms except one belonging to a carboxylate group are coordinated to the metal centers (see Figure 64). The ligand is twisted into a fan-like shape in order to allow the oxygen atoms to approach the metal center closely enough to bond ($\text{Ca}-\text{O}(\text{ether}) = 2.46\text{--}2.63\text{ \AA}$).

Potassium, rubidium and caesium thiocarboxylates (MS_2CR ; $\text{M} = \text{K}, \text{Rb}, \text{Cs}$; $\text{R} = \text{Me}, \text{Et}, \text{Pr}^i$, cyclohexyl, Ph, 2- and 4- MeC_6H_4 , 4- MeO and 4- ClC_6H_4 , 2,4,6- $\text{Me}_3\text{C}_6\text{H}_2$) have been synthesized by reaction of thiocarboxylic acid or its *O*-trimethylsilyl esters with KF , RbF , and CsF .^{526,527} The structures of several of the derivatives have been determined, including potassium benzene-, 2-methoxybenzene-, and 4-methoxybenzenecarbothioates, rubidium and caesium 2-methoxybenzenecarbothioate, potassium 2-methoxybenzenecarboselenoate, and rubidium 2-methoxybenzenecarbotelluroate. The metal derivatives have a dimeric structure in which the O and/or S atom is associated with the metal of the opposite molecule. In the 2-methoxybenzenecarbothioates, dimeric metal thiolate units held together by both the chelating thiocarboxylate groups and the *o*-methoxy functionalities form the motif for polymeric structures (see Figure 65).⁵²⁷ The $\text{C}(sp^2)\text{--S}$ distances of the thiocarboxylate groups range from 1.70–1.72 Å; this value is close enough to that of a C–S single bond to indicate that the negative charges may be partially localized on the sulfur atoms.

(ii) Diketonates

Metal diketonates, the salts of β -diketones and β -ketoimines, are of interest for their usefulness as reagents (principally the alkali metal derivatives) and as potential precursors (the alkaline-earth derivatives) for CVD.⁵²⁸ The latter are discussed in additional detail in Section 3.1.4.4.1(vi), and Group 2 β -diketonates used for this purpose have been extensively reviewed.¹³ Considerable interest has been expressed in fluorinated derivatives, which can display substantially increased volatility relative to the hydrocarbon compounds. Commonly used β -diketones and β -ketoimines

Figure 64 The structure of the calcium derivative of 3,6,9-trioxaundecanedioic acid.

Figure 65 The dimeric motif in the solid state structure of rubidium 2-methoxybenzenecarbothioate.

and their abbreviations are listed in Table 7. Note that the 2,2,6,6,-tetramethylheptane-3,5-dionate anion is variously abbreviated in the literature as THD, TMHD, and DPM.

The deprotonation of β -diketones and β -ketoimines can be accomplished by a variety of methods including reaction with aqueous solutions of metal chlorides,⁵²⁹ hydroxides, carbonates,⁵³⁰ or ethoxides.^{531,532} For example, reaction of $\text{Mg}(\text{OEt})_2$ and $[\text{Ca}(\text{OEt})(\text{EtOH})_4]_n$ with HTMHD (1:2) yields the homoleptic β -diketonate compounds $\text{M}(\text{TMHD})_2$; the calcium complex

is a rare example of a homoleptic β -diketonate complex, and has a triangular core with 6-coordinate calcium atoms (see Figure 66).^{533,534} Metathetical reaction of the sodium salts of THD with hydrated barium chloride has been used to prepare hydrated diketonates.⁵³⁵

Metalla- β -diketonates of the *s*-block compounds are sensitive compounds, and despite the interest in their application to CVD processes, differences in handling procedures have led to conflicting reports of reactivity and volatility. The use of auxiliary Lewis bases, including NH_3 , THF, pyridine, and HTMHD has been claimed to increase the volatility of β -diketonates, ostensibly by causing deoligomerization of aggregates.^{536–538} However, in the course of studies of the often ill-characterized “ $\text{Ba}(\text{THD})_2$ ” with the potential base NEt_3 , the peroxo complex $[\text{Ba}_6(\text{THD})_{10}(\text{H}_2\text{O})_4(\text{OH})_2(\text{O}_2)][\text{HNEt}_3]_2$ was isolated and structurally authenticated (see Figure 67).⁵³⁹ In this complex, which is based on an octahedron of Ba atoms and contains a μ_4 -peroxo group ($\text{O}=\text{O}=1.48\text{ \AA}$), the oxygen source is evidently ambient air and/or water.

At times, only small changes in steric bulk are enough to affect the aggregation of complexes. For example, crystallographic examination of $\text{M}(\text{THD})_2(\text{THF})_4$ ($\text{M}=\text{Sr}$ or Ba) has shown them to have mononuclear structures; interestingly, the analogous diethyl ether and tetrahydropyran complexes ($[\text{M}(\text{THD})_2(\text{THP})_2]_2$ and $[\text{M}(\text{THD})_2(\text{Et}_2\text{O})]_2$, respectively) are dinuclear.⁵⁴⁰ Adduct formation with polyethers or polyamines^{541–543} has been used in attempts to inhibit aggregation and consequently raise volatility, and the improvement in properties can be substantial. Complexation of tetraglyme to $\text{Ba}(\text{TDFND})_2$ for example, lowers the melting point by 96°C and the sublimation temperature by 60°C , so that the adduct sublimates at 90°C and 10^{-2} torr.^{544,545} In the structure of the adduct, the tetraglyme is found wrapped around the metal, enforcing its mononuclearity and lowering intermolecular forces (see Figure 68).⁵⁴⁶

(iii) Enolates

Metal enolates of the *s*-block metals encompass a variety of forms, depending on the nature of the R group and the presence of auxiliary bases coordinated to the metal. Some are of a simple nature, e.g., $[\text{ArC}(\text{CH}_2\text{O})\text{O}][\text{K}(\text{18-crown-6})]$ ($\text{Ar}=\text{Ph}$, 2-MeOC₆H₄, 1,3,5-Me₃C₆H₂), $[\text{PhC}(\text{=CHMe})\text{O}-\text{K}(\text{18-crown-6})]$, and $[\text{PhC}(\text{CH}_2\text{O})][\text{K}(\text{crypt-2,2,2})]$,⁵⁴⁷ and not discussed further, and some derivatives are mentioned in this Chapter in the context of other chemistry; e.g., the ketoiminato “lariat crowns” investigated for use in CVD chemistry.⁵⁴⁸ (See also Section 3.1.4.4.1(vi)) A tetrameric sodium complex with a chelating phosphine ligand⁴⁵⁰ has also been discussed elsewhere (see Section 3.1.4.3.2). In this section, focus is placed on aggregates of enolates, from dimers to larger clusters.

Dimeric enolates have been isolated in the course of studies on the effects of H-bonding on deuteration; the trimethylethylenediamine adducts of $[(Z)\text{-MeCH}=\text{C}(\text{OLi})\text{NMe}_2]_2$ and $[\text{CH}_2=\text{C}(\text{OLi})\text{CMe}_3]_2$ have μ_2 -enolate moieties.⁵⁴⁹ The *N,N'*-dimethyl-*N,N'*-(1,3-propanediyl)urea

Figure 66 The structure of the trimeric $\text{Ca}(\text{TMHD})_2$.

Figure 67 The structure of the peroxo complex $[\text{Ba}_6(\text{THD})_{10}(\text{H}_2\text{O})_4(\text{OH})_2(\text{O}_2)][\text{HNEt}_3]_2$.

solvate of lithium 1,3-(Bu^t)₂-1,3-butadienolate also displays a central four-membered ($\text{Li}-\text{O}$)₂ ring, and curiously, the $\text{Li}-\text{C}=\text{O}$ angle is bent (153° , 156°), and not linear as theoretical considerations would predict.⁵⁵⁰ The magnesium complex $((Z)\text{-BrMgOC}(\text{CMe}_3)=\text{CH-Me})_2\cdot(\text{Et}_2\text{O})_2$ is likewise dimeric, and its bridging enolate O atoms form slightly puckered ($\text{Mg}-\text{O}$)₂ rings.⁵⁵¹

The Hauser base reagents Pr_2NMgCl and Pr_2NMgBr react with a variety of enolizable ketones to yield magnesium enolates. They cannot be isolated in the presence of THF, but when diethyl ether is used as a solvent and in the presence of HMPA, the halomagnesium enolate compounds $\{(\text{Bu}^t)\text{C}(\text{=CH}_2)\text{OMgBr}\cdot\text{HMPA}\}_2$ and $\text{Me}_2\text{CHC}(\text{=CMe}_2)\text{OMgBr}\cdot\text{HMPA}$ can be identified. The former is a dimer, with enolate bridges, whereas the latter is a simple monomer. A computational study (HF/6-31G(d)) indicated that the enolate anion $[\text{H}(\text{CH}_2=\text{CO})^-]$ will bridge in preference to the halides F^- , Cl^- , and Br^- , and that the amido anions Me_2N^- , $(\text{H}_3\text{Si})_2\text{N}^-$, and $(\text{Me}_3\text{Si})_2\text{N}^-$ are favored over the chloride anion in three-coordinate dimer systems. The presence of solvents may switch the bridging preferences, however.⁵⁵²

Figure 68 The structure of the tetraglyme adduct of $\text{Ba}(\text{TDFND})_2$.

Mixed enolate/amides have been found with the same core structure as pure enolates; e.g., MeC(O)CMe_3 reacts with $\text{LiN}(\text{SiMe}_3)_2$ and DME to afford $\text{Li}_2(\text{CH}_2\text{C(O)CMe}_3)[\text{N}(\text{SiMe}_3)_2]\cdot 2\text{DME}$, and $\text{Me}_2\text{CO}_2\text{CMe}_3$ reacts with $\text{NaN}(\text{SiMe}_3)_2$ and TMEDA to yield $\text{Na}_2(\text{MeCH}_2\text{CO}_2\text{CMe}_3)[\text{N}(\text{SiMe}_3)_2]\cdot 2\text{TMEDA}$. The two compounds, prepared as models in stereoselectively enhanced enolate reactions, have slightly puckered rings and predictably longer Li—N than Li—O bonds (2.07 Å and 1.87 Å, respectively, in the lithium complex).⁵⁵³

Aggregates consisting of lithium halides (LiBr, LiI) with lithium amides or enolates (i.e., $\text{LiOC}(\text{Pr}^t)=\text{CMe}_2$) have been identified as either heterodimers or -trimers (for amido species) or heterodimers only (for the enolate complexes).⁵⁵⁴ An *ab initio* and semiempirical PM3 theoretical study of model systems shows that solvated heterodimers between LiBr and either LiNH_2 or $\text{LiOC}(\text{H})=\text{CH}_2$ are favored over the respective homodimeric species, and that a stable eight-membered ring transition state exists for the enolization step between $\text{LiCl}\cdot\text{LiNH}_2$ and acetaldehyde. The dissociation of donor solvents is computed to require more energy for heterodimers than for homodimers.

A triple anion complex containing enolate, amide, and halide functionalities can be isolated from the mixture of *n*-butyl bromide, hexamethyldisilazane, TMEDA, Bu^nLi and pinacolone (Bu^tCOME). The resulting solution of LiBr, $\text{LiN}(\text{SiMe}_3)_2$, $\text{LiOC}(\text{Bu}^t)=\text{CH}_2$, and TMEDA produces crystals of $\text{Li}_4(\mu_4\text{-Br})(\mu\text{-OC}(\text{Bu}^t)=\text{CH}_2)_2(\mu\text{-N}(\text{SiMe}_3)_2)(\text{TMEDA})_2$, which, instead of forming a ladder-type structure, consists of a planar butterfly of four lithium atoms bonded to a $\mu_4\text{-Br}$; the stability of this arrangement has been studied with semi-empirical (PM3) and *ab initio* HF/LANL2DZ computations.⁵⁵⁵

The most common aggregate above the dimers are the cubes, which are known for lithium, sodium and magnesium. Condensation of lithium pinacolate and pivalaldehyde produces an aldolate that in the presence of pyridine leads to the isolation of tetrameric 4:3 and 4:4 enolate-pyridine complexes; these are constructed around Li_4O_4 cubes (see Figure 69).⁵⁵⁶

The reaction of tetramethyl-1,3-cyclobutanedione with R_3SiLi ($\text{R} = \text{Me}_3\text{Si}$ or Et) and Et_3GeLi results in the opening of the cyclobutanedione ring to give the corresponding β -ketoacylsilane lithium enolates, which after aqueous workup afford the β -ketoacylsilanes $\text{Me}_2\text{CHCOCMe}_2\text{COR}$. The lithium enolate itself ($\text{R} = \text{SiMe}_3$) is constructed around a Li_4O_4 cube, with chelating enolate anions (see Figure 70). *Ab initio* calculations (HF/6-31G(d)) were used to demonstrate that Li^+ complexation in the enolate weakens the hyperconjugative interactions between the O lone pair (n_o) and the $\sigma\text{-C-Si}$ orbital, and is responsible for the two new transitions observed in the UV/vis spectra; one is red-shifted, and the other blue-shifted relative to the absorptions of the corresponding β -ketoacylsilanes.⁵⁵⁷

Cocrystallization of either LiOCMe_3 or KOCMe_3 with preformed potassium or lithium enolate derived from MeCOCMe_3 in the presence of THF yields a novel aggregate composed of four

Figure 69 The structure of tetrakis((μ_3 -*tert*-butylethenolato-*O,O,O*)-pyridine-lithium).

Figure 70 The structure of the lithium enolate tetrakis(μ_3 -1-tris(trimethylsilyl)silyl-2,2,4-trimethylpentane-1,3-dionato- O,O')-tetra-lithium.

enolate residues, four *t*-butoxides, four Li^+ , five K^+ , a KOH residue and five THF molecules (see Figure 71). The polymetallic compound is based on a square-based pyramid of potassium ions, with each edge bridged by an O atom. Triply bridging lithium ions span the oxygens on the sides of the pyramid.⁵⁵⁸

Figure 71 The structure of tetrakis($(\mu_4$ -*tert*-butoxo- O,O,O,O)-(μ_3 -1-methylenepentoxo- O,O,O))-(μ_4 -hydroxo)-pentakis(tetrahydrofuran)-tetra-lithium-penta-potassium.

The heterometallic aggregate $[\text{Li}_2\text{Na}_4\{\text{OC}(=\text{CH}_2)(\text{Bu}^t)\}_6((\text{Pr}^i)_2\text{NH})_2]$ has been prepared from sodium diisopropylamide, sodium diisopropylamide, and pinacolone, and has been structurally authenticated by X-ray crystallography. It possesses a distorted triple-layered stack consisting of a $(\text{Na}-\text{O})_2$ ring sandwiched between two $\text{Li}-\text{O}-\text{Na}-\text{O}$ rings. Interestingly, two edges of the face-sharing cubes are absent; the $\text{Na}-\text{O}$ separations are 2.88 Å, whereas other $\text{Na}-\text{O}$ contacts in the molecule range from 2.29–2.42 Å (see Figure 72). The difference in size between Li and Na, combined with contacts between the $\text{H}_2\text{C}=\text{C}$ moieties of the enolates and metals, are probably responsible for the open stack structure. The fact that coordinated diisopropylamine is found at each end of the cluster demonstrates that the free base itself (as distinct from the metallated amide) may influence the regioselectivities of incoming reactants.⁵⁵⁹

A complete thermochemical analysis has been described for the aldol reaction of lithiopinacolone with pivalaldehyde in hexane at 25 °C and in cyclohexane at 25 °C and 6 °C.⁵⁶⁰ Reactions were performed in the presence and absence of THF, TMEDA, and DME. The heats of reaction of pivalaldehyde with the hexameric lithiopinacolone, the tetrameric and dimeric enolate-ligand complexes as well as heats of interaction of the hexameric enolate with the ligands were determined, and it was found that the tetrameric lithium aldolate product does not complex with any of the three ligands in hydrocarbon solution. Caution was raised about proposed mechanisms based on data not gathered under modern synthetic reaction conditions. The unsolvated hexameric enolate, $(\text{Me}_3\text{CCOCH}_2\text{Li})_6$, has a classic drum shape and nearly S_6 symmetry (see Figure 73).^{561,562}

The reaction products between $\text{Mg}[\text{N}(\text{SiMe}_3)_2]_2$ and 2,4,6-trimethylacetophenone in hexane solution have been determined with ^1H -NMR spectroscopic analysis of the solids precipitated from solution.⁵⁶³ Only enolate and unenolized ketone are present in the solids, and the absence of any amide suggests formation of a magnesium bis(enolate). Formation of the latter (in preference to an amido(aldolate)) probably reflects a combination of steric crowding and electronic characteristics of the ketone that retard the addition reaction. The structure of the isolated bis(enolate), $\text{Mg}_4\{\text{OC}(2,4,6\text{-trimethylphenyl})=\text{CH}_2\}_8\{\text{O}=\text{C}(2,4,6\text{-trimethylphenyl})\text{Me}\}_2(\text{C}_6\text{H}_5\text{Me})_2$, reveals four metals in a linear arrangement with six bridging and two terminal enolates and two terminal ketones; three orthogonal $(\text{Mg}-\text{O})_2$ rings are thereby formed (see Figure 74).

(iv) Alkoxides and aryloxides

Alkali and alkaline-earth derivatives of phenol and the lower alcohols (methoxides, ethoxides) have been known for more than a century. Traditional applications for them include use as lubricants (e.g., lithium greases), polymerization catalysts, and surfactant stabilizers. Based on their solubility and volatility (both generally low), alkaline-earth alkoxides were presumed to be

Figure 72 The structure of $[\text{Li}_2\text{Na}_4\{\text{OC}(=\text{CH}_2)(\text{Bu}^t)\}_6((\text{Pr}^i)_2\text{NH})_2]$.

Figure 74 The structure of $\text{Mg}_4\{\text{OC}(2,4,6\text{-trimethylphenyl})=\text{CH}_2\}_8\{\text{O}=\text{C}(2,4,6\text{-trimethylphenyl})\text{Me}\}_2 (\text{C}_6\text{H}_5\text{Me})_2$.

oligomeric or polymeric substances, although until the last quarter of the twentieth century comparatively little was known of their structural chemistry.⁵⁶⁴

The interest expressed in ion transport across biological membranes in the 1970s^{565,566} and early 1980s, and the discovery of superconducting oxides in the mid-1980s⁵⁶⁷ initiated intensive study of *s*-block alkoxides, especially in their role as precursors to metal oxides and halides.¹² The area has expanded considerably since the 1980s, and extensive reviews of various subjects in alkoxide chemistry, especially the alkaline-earth derivatives, are now available.^{13,564,568–570}

Standard approaches to metal alkoxide synthesis (see Table 8) involve the direct reaction of the bulk metal in the neat alcohol, sometimes under reflux conditions (Table 8, Equation (1)). In practice, this generally works well for Group 1 species, but side reactions stemming from the heterogeneous nature of the system often complicate the reactions with the Group 2 metals; oxo-alkoxide complexes are often formed from the latter.^{571–574} Degradation of the alkoxide ligand may be involved, but in the reaction of *t*-butanol with barium metal, for example, a diolato ligand is found coordinated to the metal (Equation(4)):

Table 8 Synthetic methods for the preparation of *s*-block alkoxide and aryloxide complexes.

$\text{Ba} + 4 \text{ Zr}(\text{OPr}^{\text{I}})_4\cdot\text{Pr}^{\text{I}}\text{OH} \rightarrow \text{Ba}\{\text{Zr}_2(\text{OPr}^{\text{I}})_9\}_2 + 2\text{HOPr}^{\text{I}} + \text{H}_2$	(9b)

M^{I} = alkali metal; M^{II} = alkaline-earth metal; X = halide; S = coordinated solvent.

Since the diolate is not formed in toluene, the THF solvent is its most likely source.⁵⁷³ Metal-coordinated alcohol molecules frequently accompany the isolated alkoxides, and the rate and possible the yield of reactions are dependent on the cleanliness of the surface of the metal (the use of activated metals can be helpful),^{575,576} the acidity of the alcohol, and the solubility of the resulting complex. A variation on this method allows the metal to react with the alcohol in polar coordinating solvents, such as ethers (Table 8, Equation (2)); oligomerization of the resultant complex, depending on how tightly the solvent is held, can complicate the isolation of binary alkoxides. Solvent-free metal vapor synthesis has been used to form calcium and barium aryloxides.²⁵¹

Syntheses that exploit the solubility of the alkaline-earth metals in liquid ammonia have proven practical for alkoxide work, as they generate high yields, reaction rates, and purity (Table 8, Equation (3)). In a refinement of this approach, Caulton and co-workers have used dissolved ammonia in an ethereal solvent, usually THF, to effect the production of a number of alkoxides of barium,^{573,577} and this method has also been examined with calcium and strontium (Table 8, Equations (4a) to (4c)).⁵⁷⁸ Displacement reactions using alkali metal alkoxides and alkaline-earth dihalides (Table 8, Equation (5)),^{579–581} and between alkaline-earth hydrides or amides and alcohols (Table 8, Equations (6) and (7)),²⁵¹ have been examined, but alkali-metal halide impurities, incomplete reactions, and unexpected equilibria and byproducts can affect the usefulness of these approaches.

Heterometallic alkoxides of calcium, strontium, and barium with transition or posttransition metals have been formed by reactions with the preformed alkoxides (e.g., Table 8, Equations (8a) and (8b)).^{582,583} A variation on this approach generates the Group 2 alkoxides *in situ* by reaction of the metal with an alcohol and/or another alkoxide (e.g., Table 8, Equations (9a) and (9b)).^{564,584}

Alkoxide and aryloxide complexes are moisture-sensitive, and are usually colorless or white solids with melting points substantially above room temperature. An interesting exception to this generalization is provided by the brown barium alkoxides $\text{Ba}[\text{O}(\text{CH}_2\text{CH}_2\text{O})_n\text{CH}_3]_2$ ($n = 2, 3$), formed from the reaction of elemental barium with a stoichiometric quantity of the polyether alcohol in THF.⁵⁸⁵ They are soluble in diethylether, THF and aromatic hydrocarbons, and are liquid at room temperature.

The number of structurally characterized homo- and heterometallic alkoxides and aryloxides of the *s*-block elements is now in the hundreds, and the previously cited reviews should be consulted for extensive listings.^{13,564,568–570} A large amount of structural diversity exists in the compounds, and monomers up to nonametallic clusters and polymeric species are represented. In this regard, the large molecular aggregate $\text{Ca}_9(\text{OCH}_2\text{CH}_2\text{OMe})_{18}(\text{HOCH}_2\text{CH}_2\text{OMe})_2$ is particularly interesting. Isolated from the reaction of calcium metal with methoxyethanol,⁵⁸⁶ it represents a transition between the polymeric Group 2 alkoxides of the lower alcohols (e.g., $\text{Ca}(\text{OMe})_{2[\text{x}]}$, $\text{Ba}(\text{OEt})_{2[\text{x}]}$) and the mono- or dinuclear complexes formed with bulkier alcohols. The central $\text{Ca}_9(\mu_3\text{-O})_8(\mu_2\text{-O})_8\text{O}_{20}$ section displays three six-coordinate metals and six seven-coordinate metals that can be viewed as filling octahedral holes in two close-packed oxygen layers (average $\text{Ca}-(\mu_3\text{-O}) = 2.39 \text{ \AA}$; $\text{Ca}-(\mu_2\text{-O}) = 2.29 \text{ \AA}$; $\text{Ca}-(\text{O}_{\text{ether}}) = 2.60 \text{ \AA}$) (see Figure 75). As such, the $\text{Ca}-\text{O}$ substructure mimics part of the CdI_2 lattice. The particular size of the aggregate has been suggested as representing thermodynamic compromise between maximizing the coordination number of the calcium atoms and the number of independent particles.

Figure 75 The structure of the calcium–oxygen core of $\text{Ca}_9(\text{OCH}_2\text{CH}_2\text{OMe})_{18}(\text{HOCH}_2\text{CH}_2\text{OMe})_2$.

The variety of M–O bonding modes available (e.g., μ_1 , μ_2 , μ_3) and the potential contribution from M–O π -bonding in *s*-block alkoxides and aryloxides have made quantitative and even qualitative predictions of structures problematic. The difficulties encountered when analyzing the bonding with terminal oxygen-based ligands are compounded with bridging ligands, and there are few generalizations available for accurately predicting their structural details.⁵⁸⁷ Nevertheless, some trends have become clearer as the number of crystallographically characterized alkoxides and mono(alkoxides) of low nuclearity has increased. The ability of the larger metals to accommodate more ligands in their coordination spheres and hence to form more extensive aggregates is counterbalanced by their lower Lewis acidity. It is not axiomatic, for example, that barium compounds will have higher coordination numbers than their calcium analogs.⁵⁸¹ This inherent electronic effect can be reinforced by the presence of sterically demanding ligands.

An illustration of these principles is provided by the Group 2 aryloxide complexes. The calcium and barium derivatives of 2,6-di-*t*-butyl-4-methylphenol (BHT) were the first monomeric alkoxides of the heavier alkaline-earth metals to be structurally characterized;^{251,581} the strontium derivative has also been crystallographically examined.⁵⁷⁶ The dominating effect of the extremely bulky BHT ligands is evident from the fact that the three aryloxides are isostructural monomers, even though there is a substantial change in metal radii from 1.00 Å (Ca^{2+}) to 1.35 Å (Ba^{2+}). The complexes display distorted trigonal bipyramidal geometries, with two of the THF ligands lying on the axes in a nearly linear arrangement ($\text{O}—\text{M}—\text{O}' = 177–179^\circ$). The remaining THF and the two aryloxide ligands lie in the equatorial plane (see Figure 76). Although metal radii have usually been thought to play a key role in determining metal–ligand geometries, it appears that the ligand charge (and the operation of either “primary” and “dative” metal–ligand bonding)⁵⁸⁸ may be just as critical. The aryloxide complexes display a nonadditive relationship between metal radii and metal–alkoxide distances; the increase in M–OR distance from calcium to barium (2.20 Å to 2.40 Å; $\Delta = 0.20$ Å) is considerably smaller than the increase in metal radii (0.93 Å to 1.30 Å; $\Delta = 0.37$ Å). The M–THF distances, however, do vary approximately as the metal radii (2.40 Å to 2.73 Å; $\Delta = 0.33$ Å). The packing of ligands around the metal may also serve to control coordination geometries.⁵⁸⁰

$\text{Ba}(\text{BHT})_2(\text{THF})_3$ reacts readily with BaI_2 in THF to produce the dimeric mono(alkoxide) complex $[\text{IBa}(\text{BHT})(\text{THF})_3]_2$ (see Figure 77).⁵⁸⁰ The coordination geometry around the barium atoms is distorted octahedral, with the two bridging iodides, the BHT, and a THF ligand in one plane, and two additional THF molecules lying above and below the plane ($\text{Ba}—\text{I} (\text{I}') = 3.44$ (3.59) Å and $\text{Ba}—\text{OAr} = 2.41$ Å). The compound could be viewed as having been formed by the fusion of two coordinately unsaturated “ $\text{IBa}(\text{BHT})(\text{THF})_3$ ” fragments, but the fact that a stable tetrasolvate (i.e., $\text{IBa}(\text{BHT})(\text{THF})_4$) has not been isolated is telling, in that the monomeric mono(aryloxide) $\text{ICaBHT}(\text{THF})_4$ can be synthesized, despite being constructed around a smaller metal center.⁵⁸⁰

The flexibility of the *s*-block coordination sphere is particularly evident with heterometallic clusters. This is strikingly evident in the mixed Li–heavier alkali metal *t*-butoxides $[(\text{Bu}^t\text{O})_8\text{Li}_4\text{M}_4]$ ($\text{M} = \text{Na}, \text{K}, \text{Rb}, \text{Cs}$), which form a structurally authenticated homologous series.^{589,590} They are

Figure 76 The structure of $\text{Ca}(\text{BHT})_2(\text{THF})_3$.

Figure 77 The structure of the iodide-bridged mono(alkoxide) dimer, $[\text{IBa}(\text{BHT})(\text{THF})_3]_2$.

constructed around $(\text{M}^+)_4$ planes, capped with chelating $(\text{O}_4\text{Li}_2)^{2-}$ dianions, and contain a “breastplate structure” that involves $\mu_3\text{-Li}$, $\mu_4\text{-M}$, $\mu_3\text{-O}$, and $\mu_4\text{-O}$ atoms (see Figure 78). *Ab initio* calculations indicate that the assembly of the triple ion sandwich is exothermic. The flexibility of this “breastplate” framework has been suggested to be an important, but underappreciated, structural motif in heterometallic cluster chemistry. In other heterometallic alkoxides, where closed structure forms are not present, it can be difficult to describe the coordination geometry in terms of regular polyhedra.⁵⁶⁸ For example, all the metal atoms in the alkane-soluble $[\text{BaZr}_2(\text{OPr}^i)_{10}]_2$ are six-coordinate; the Zr atoms can be viewed as occupying the centers of two face-sharing octahedra, with the Ba atoms connected by one $[\mu_2\text{-OPr}^i]^-$ and two $[\mu_3\text{-OPr}^i]^-$ ligands from each Zr (see Figure 79). The barium atoms have geometries only loosely related to octahedra, as the Ba—O distances range from 2.55 Å to 2.90 Å, with “trans” O—Ba—O’ angles varying from 114.6° to 167.6°.

(v) Other oxygen donor ligands

Calixarene-based M_5 [calix[4]arene sulfonates]· $x\text{H}_2\text{O}$ ($\text{M} = \text{Na}$ ($x = 12$); K ($x = 8$); Rb ($x = 5$); Cs ($x = 4$)) have been used to construct supramolecular assemblies. They have been structurally characterized, and exist as bilayers of anionic truncated pyramids in the “cone” configuration;

Figure 78 The structure of $(\text{Bu}^t\text{O})_8\text{Li}_4\text{Cs}_4$.

Figure 79 The structure of $[\text{BaZr}_2(\text{OPr}^i)_{10}]_2$.

their structures have been compared to those for clay minerals.⁵⁹¹ On the addition of pyridine *N*-oxide and lanthanide ions, the calixarenes assemble in a parallel alignment with spherical and helical tubular structures. Alkali ions (e.g., Na^+) assist in stabilizing the tubular assemblies (formed with various M^{3+} lanthanide ions) by coordinating to the sulfonate groups of calixarenes in adjacent turns of the helix.⁵⁹² Many examples of the self-assembly in aqueous solutions of bowl-shaped sodium *p*-sulfonatocalix[4,5]arenes are now known, and extensive reviews are available.^{593,594} The complexes have found uses in selective isolation of Keggin ions,⁵⁹⁵ chiral recognition,⁵⁹⁶ and fullerene selectivity.⁵⁹⁷

A water-soluble sulfonated crown ether (see Figure 80) has been prepared and used as an ion size selection reagent. In the synergistic extraction of alkaline earth ions with 4-benzoyl-3-methyl-1-phenyl-5-pyrazolone and trioctylphosphine oxide in cyclohexane, addition of the sulfonated crown ether shifted the extraction for the larger ions to a higher pH level, thereby improving the separation.⁵⁹⁸

The first structurally authenticated molecular peroxide of an *s*-block element was reported in the form of the dodecameric lithium *t*-butyl peroxide, $\{\text{Li}[\eta^2\text{-O}_2(\text{Bu}^t)]\}_{12}$.⁵⁹⁹ Isolated from the reaction of Bu^tLi and molecular oxygen, the lithium ion bridges the two peroxide oxygens, lengthening the O—O bond to 1.48 Å (see Figure 81). Quantum chemical calculations on the reaction between MeLi with LiOOH to give MeOLi and LiOH were used as a model for the formation of the compound, which can be viewed as an intermediate in alkoxide generation. The oxygen-scavenging properties of alkali metal-containing organometallic compounds, which can result in encapsulated oxide or peroxide ions, have been reviewed.⁶⁰⁰

Figure 80 The structure of a sulfonated crown ether usable as an ion size selective masking reagent.

Figure 81 The structure of the lithium tert-butyl peroxide, $\{\text{Li}[\eta^2\text{-O}_2(\text{Bu}^t)]\}_{12}$.

(vi) Chemical vapor deposition

The technique of CVD; sometimes abbreviated as MOCVD (metalorganic chemical vapor deposition) has been under intensive development for the *s*-block elements, and particularly the alkaline-earth metals, since the late 1980s.^{13,601–604} The production of complex oxides of calcium, strontium, and barium, such as the perovskite-based titanates $(\text{Sr},\text{Ba})\text{TiO}_3$ and superconducting cuprates (e.g., $\text{YBa}_2\text{Cu}_3\text{O}_{7-x}$),^{9,605} has been a focus of much of this research. In addition, cerium-doped alkaline-earth sulfides (e.g., $(\text{Ca},\text{Sr},\text{Ba})\text{S}$, CaGa_2S_4)⁶⁰⁶ are of interest as phosphors for electroluminescent devices, as are sodium and potassium dopants for color modification.⁶⁰⁷ Volatile sources of magnesium are required for CVD-doping of the Group 13 nitrides that serve as the basis for blue and green light-emitting and laser diodes.^{608–611}

Owing to the low volatility or unfavorable deposition properties of alkaline-earth compounds such as the simple metal alkoxides and acac (acetylacetonate) derivatives, they are usually unsuitable as precursors to electronic materials. The approaches used to obtain reagents more useful as precursors for CVD work have generally focused on the reduction of intermolecular forces by the use of sterically bulky ligands (e.g., $[\text{THD}]^-$, $[\text{OCH}(\text{CMe}_3)_2]^-$),^{531,533,612–614} fluorinated derivatives (e.g., $[\text{OC}_4\text{F}_9]^-$),^{615,616} ligands with internally chelating groups (e.g., $\text{O}(\text{CH}_2\text{CH}_2\text{OCH}_3)^-$ or “lar-i-ats” (e.g., $(\text{RCOCHC}(\text{NR}')\text{Me})_2$ ($\text{R} = t\text{-Bu}$; $\text{R}' = (\text{CH}_2\text{CH}_2\text{O})_2\text{Me}$)),^{548,617} polyethers (e.g., $\text{Ba}(\text{HFA})_2 \cdot \text{CH}_3\text{O}(\text{CH}_2\text{CH}_2\text{O})_{6-n}\text{-C}_4\text{H}_9$ (see Figure 82)),⁶¹⁸ and the addition of Lewis bases (e.g., OR_2 , NH_3) to alkoxides to form adducts.⁶¹⁹ Coordination compounds such as amides,²⁵⁸ amidinates,⁶²⁰ and pyrazolates⁴²³ have been proposed as alternatives to the use of the organometallic reagents (Cp_2Mg , $(\text{MeCp})_2\text{Mg}$) that dominate magnesium CVD. Some of the currently used compounds in *s*-block CVD are described in more detail in appropriate sections elsewhere in this Chapter. Extensive review articles on alkaline-earth CVD are also available.^{12,14,621}

The demands for high purity reagents and consistent gas-phase behavior are especially critical in *s*-block chemistry, and consistent pictures of CVD reactivity are not always easy to obtain. Problems with residues in deposited materials are common. For example, fluorinated compounds are favored for their increased volatility, but their use can lead to the deposition of metal fluorides that contaminate the deposited oxides.⁶²² Films of the high-*T_c* superconductor $(\text{TlO})_m\text{Ba}_2\text{Ca}_{n-1}\text{Cu}_n\text{O}_{2n+2}$ ($m = 1, 2$; $n = 1, 2, 3$) generated under MOCVD conditions from $\text{Ba}(\text{HFA})_2$ (tetraglyme), $\text{Ca}(\text{dipivaloylmethanate})_2$, and $\text{Cu}(\text{acac})_2$, for example, are contaminated with both BaF_2 and CaF_2 ; extra processing is required to remove the fluorides.⁹ Handling problems also occur with fluorinated compounds; for example, partial hydration of $\text{Ca}(\text{HFA})_2$ samples with attendant lowering of their vapor pressure is difficult to avoid.⁶²³

Owing to the sensitivity of alkaline-earth alkoxides and their derivatives to air and moisture, their application to systems of practical interest is not always straightforward. Early reports on the thermal behavior of the widely-used barium oxide precursor “ $\text{Ba}(\text{THD})_2$,” for example, indicated that ~25–40% of the material remains unsublimed under oxide forming conditions.^{624,625} Such reports are now thought to reflect the use of partially hydrolyzed and/or

Figure 82 The structure of $\text{Ba}(\text{HFA})_2 \cdot \text{CH}_3\text{O}(\text{CH}_2\text{CH}_2\text{O})_6\text{-}n\text{-C}_4\text{H}_9$.

adducted material, which would reduce volatilities, as later thermal gravimetric analysis indicated that only a 5–6% residue remains after heating to 410 °C.⁵³¹

The solid state structure of “ $\text{Ba}(\text{THD})_2$ ” has also been the subject of controversy. An X-ray crystal structure of the commercially available “anhydrous $\text{Ba}(\text{THD})_2$ ” was found to be a partially hydrolyzed pentabarium aggregate, described as $\text{Ba}_5(\text{THD})_9(\text{OH})(\text{H}_2\text{O})_3$.⁶²⁶ Re-analysis of the structural parameters has suggested that it be formulated as the even more degraded species $\text{Ba}_5(\text{THD})_5(\text{HTHD})_4(\text{O})(\text{OH})_3$.⁶²⁷ Rigorously anhydrous $\text{Ba}(\text{THD})_2$ has been the subject of several structural investigations,^{531,628,629} the most accurate of which appears to be the low temperature study of Drake and co-workers.⁵³¹ The complex crystallizes as a centrosymmetric tetramer, with the seven-coordinate barium atoms extensively bridged by THD ligands. Two of the barium atoms ($\text{Ba}(1)$ and $\text{Ba}(1')$) are coordinated by one terminal THD ligand; four other coordination modes of the remaining β -diketonates are also observed in the structure (see Figure 83). Some $\text{Ba}-\text{O}$ bonding interactions are long (up to 3.14 Å) and weak, which may account for the ease with which the tetramer is disrupted by Lewis bases to yield dimeric species such as $[\text{Ba}_2(\text{THD})_4\text{L}_2]_2$ ($\text{L} = \text{NH}_3, \text{Et}_2\text{O}$).^{619,630}

Considerable care is obviously needed in handling Group 2 alkoxides and related compounds reliably in CVD applications. In some cases, the use of mixtures of precursors with different ligands (e.g., β -diketonates, β -ketoesterates, alkoxides) can lead to ligand exchange reactions that improve stability toward moisture.⁶²¹ The development of aerosol-assisted CVD (AACVD) has meant that the volatility of precursors is no longer as critical, and wider varieties of precursors can be used.^{631–633}

Figure 83 The structure of $\text{Ba}_4(\text{THD})_8$; the *t*-butyl groups have been removed from the THD ligands for clarity.

3.1.4.4.2 Sulfur donor ligands

Driven in part by interest in potential materials applications,^{634–637} the number of *s*-block complexes containing ligands with sulfur donors has increased tremendously since the 1980s. The structures of hundreds of such compounds are now known, even though the first crystal structure of a lithium thiolate did not appear until 1985.⁶³⁸

The *s*-block thiolates $M(SR)_n$ are generally synthesized by one of three routes: hydrogen elimination from a metal hydride (used for Na and K, Equation (5a));⁶³⁹ alkane elimination from an alkyl lithium (Equation (5b));⁶⁴⁰ and metallation (used for Na–Cs, Equation (5c)).⁶⁴¹

Such compounds take a variety of forms including monomers, dimers, trimers, cubes, fused cubes, and large rings and polymers; predictably, the degree of aggregation is dictated to a large extent by the steric bulk of the thiolate and associated ligands. The area of *s*-block thiolates has received repeated comprehensive review,^{642–646} and simple thiolates and most carboxythiolates,^{527,647} including intramolecularly stabilized species, are not covered further here.

The reaction of [tris(3-*p*-tolylpyrazolyl)hydroborate]MgMe with H_2S produces the monomeric hydrosulfido complex [tris(3-*p*-tolylpyrazolyl)hydroborate]MgSH, which has been structurally authenticated; the Mg—S bond length is 2.35 Å.⁶⁴⁸ Other monodentate sulfur ligands include 2-(1-methylethyl)-1,3-dimethyl-1,3,2-diazaphosphorinane 2-sulfide, whose lithium complex has been modeled with molecular orbital calculations,⁶⁴⁹ 1,3-dimethyl-2-benzylidene-2-thioxo-1,3,2-diazaphosphorinane-S,S),⁶⁵⁰ and *N*-diisopropoxythiophosphorylthiobenzamine.^{651,652}

Polysulfide linkages have been incorporated into several *s*-block complexes, with the S_6^{2-} anion being especially common. Sulfur powder reacts with Bu^nLi , lithium metal or solid lithium hydride in toluene/TMEDA, or with $LiBH_4$ with THF to afford $Li_2S_6 \cdot (TMEDA)_2$.⁶⁵³ The same compound can also be prepared directly from the reaction of Li_2S_2 with TMEDA in toluene.⁶⁵⁴ The compound contains a central Li_2S_2 ring (Li—S = 2.49 Å) (see Figure 84), and in donor solvents, the S_6^{2-} residue cleaves to give the blue S_3^{2-} radical anion. A tetraethylethylenediamine (TEEDA) analogue to the TMEDA complex can be prepared by a Li_2S_2 /TEEDA/toluene combination, but if the triply coordinating PMDETA is substituted instead, a bridging tetrasulfido unit is formed that has a zigzag chain structure.⁶⁵⁵ The sodium PMDETA counterpart, formed from sodium hydride and sulfur in toluene/PMDETA, again contains an S_6^{2-} residue that is bound in a manner similar to that found in the Li/TMEDA and Li/TEEDA aggregates (Na—S = 2.82, 2.91 Å).⁶⁵⁶

The hexasulfido moiety can be found in a chain form even with a large metal if crown ethers are present as supporting ligands. Thus reaction of 18-crown-6 and K_2S_5 in acetonitrile leads to $K(18\text{-crown-6})_2S_6 \cdot 2MeCN$, from which the acetonitrile is easily lost. The S_6^{2-} anion is suspended as a *transoid* chain between two crown ether-coordinated potassium atoms (K—S = 3.08 Å).⁶⁵⁷ If an even larger metal is used, however, the hexasulfido anion reverts to its ring binding mode, e.g., a

Figure 84 The structure of $Li_2S_6 \cdot (TMEDA)_2$.

multidecker stack involving crown ethers and polysulfide anions can be isolated from the reaction of dibenzo-18-crown-6, Cs_2CO_3 , and sulfur in H_2S -saturated acetonitrile.⁶⁵⁸ Molecules of $\text{Cs}_4(\text{dibenzo-18-crown-6})_3(\text{S}_6)_2 \cdot 2\text{MeCN}$ are built of stacks of three crown ether molecules and two hexasulfide chains with the cations located between them ($\text{Cs}-\text{S}=3.46\text{--}3.55\text{ \AA}$) (see Figure 85). The conformation of the hexasulfide chains is all-*cis*.⁶⁵⁸

Dithiocarboxylic acids and their trimethylsilyl esters readily react with potassium, rubidium, and caesium fluorides to give MS_2CR complexes ($\text{M}=\text{K}, \text{Rb}, \text{Cs}$; $\text{R}=\text{Me}, \text{Et}, \text{Pr}^i, \text{cyclohexyl}, \text{Ph}, 2\text{- and } 4\text{-MeC}_6\text{H}_4, 4\text{-MeO and } 4\text{-ClC}_6\text{H}_4, 2,4,6\text{-Me}_3\text{C}_6\text{H}_2$) in moderate to good yields. The ammonium derivatives $\text{Me}_4\text{NS}_2\text{CR}$ can be prepared by the reaction of NaS_2CR with Me_4NCl . The structures of KS_2CEt , $\text{RbS}_2\text{SC}_6\text{H}_4\text{Me-4}$, and $\text{CsS}_2\text{CC}_6\text{H}_4\text{Me-4}$ have been characterized crystallographically. They have a dimeric structure, $(\text{RCSSM})_2$, in which the two dithiocarboxylate groups are chelated to the metal cations that are located on the upper and lower sides of the plane involving the two opposing dithiocarboxylate groups (e.g., Figure 86; $\text{Rb}-\text{S}=3.47\text{ \AA}$ (av)). The K^+ ions display cation- π interactions with the tolyl fragment of a neighboring molecule, whereas the Rb^+ and Cs^+ cations interact with two neighboring tolyl fragments. The sodium salt was found to be a monomer, with η^1 -bound ligands. ($\text{Na}-\text{S}=1.81\text{ \AA}$; $\text{S}-\text{Na}-\text{S}=116.9^\circ$).⁵²⁶

A variety of heterocycles will react to form complexes with M-S interactions, including 2-sulfanylbenthiazole,⁶⁵⁹ 1-methyl-1H-tetrazole-5-thiol,⁶⁶⁰ benzoxazole-2(1H)-thione,⁶⁶¹ 5-(1-naphthylamino)-1,2,3,4-thiadiazole,⁶⁶² 2-mercaptobenzoxazole,⁶⁶³ and 5-mercapto-1-naphthyltetrazole.⁶⁶² Some of these ligands undergo alkali-promoted rearrangement on complexation, such as the transformation of 5-amino-substituted thiadiazoles into 5-thio-substituted tetrazoles. For example, when solid $\text{Ba}(\text{OH})_2$ suspended in toluene containing HMPA reacts with 5-(1-naphthylamino)-1,2,3,4-thiadiazole, the monomeric $\text{Ba}[5\text{-mercapto-1-naphthyltetrazole-N,S}]_2 \cdot 3\text{HMPA}$ complex is formed.⁶⁶²

Complexes derived from 2-mercaptopyrimidine, 2-mercaptothiazoline, and 2-mercaptobenzimidazole have been described.⁶⁶⁴ The latter is a dimer in which each lithium is chelated by an N—C—S unit of the organic dianion; the two end lithium atoms of the dimer are each coordinated to two terminal HMPA molecules, whereas the two central lithium atoms are linked by two μ -HMPA molecules (see Figure 87). The reasons for the difference between this structure and those displayed by the other complexes (which in the case of the 2-mercaptothiazoline complex contains direct S—Li bonding) have been examined with *ab initio* calculations. The option of generating a strong C=N bond in the 2-mercaptothiazoline complex rather than a weaker C=S bond apparently drives the lithium-sulfur interaction.

Thiocarbamates and dithiocarbonates, which have attracted interest as possible sources of metal sulfides, are known with a variety of *s*-block metals, including lithium,⁶⁶⁵ calcium,^{392,666} strontium,⁶⁶⁶ and barium.⁶⁶⁶ Dithiocarbonates have been formed by CS_2 insertion into metal alkoxide bonds.⁶⁶⁶ Magnesium-isothiocyanate and -carbodiimide insertion products, e.g., $\text{Mg}(\text{SCPhN}(\text{Bu}^t))_2(\text{THF})_2$, $\text{Mg}(\text{SCPhNPh})_2(\text{THF})_2$, $\text{Mg}(\text{Pr}^i\text{NCRN}(\text{Pr}^i))_2(\text{THF})_2$ ($\text{R}=\text{Ph}, \text{Et}$ or Pr^i) and $\text{Mg}(\text{Bu}^i\text{NCEtN}(\text{Bu}^t))_2(\text{THF})_2$ have been synthesized by the reaction between MgR_2 ($\text{R}=\text{Ph}, \text{Et}$ or Pr^i) and various isothiocyanates and carbodiimides in THF solution. The reaction of $\text{Mg}(\text{SCPhN}(\text{Bu}^t))_2(\text{THF})_2$ with an excess of PhNCO cyclotrimerizes the latter to afford $(\text{PhNCO})_3 \cdot \text{THF}$.⁶⁶⁷

Figure 85 The structure of $\text{Cs}_4(\text{dibenzo-18-crown-6})_3(\text{S}_6)_2 \cdot 2\text{MeCN}$.

Figure 86 The structure of $(\text{RbS}_2\text{C}_6\text{H}_4\text{Me-4})_2$.

Figure 87 The structure of bis((μ_2 -2-mercaptobenzimidazolinato-*N,N,S,S*)-(μ_2 -hexamethylphosphoramido-*O,O*)-bis(hexamethylphosphoramide)-dilithium).

Larger rings with S—M contacts have been prepared by a variety of routes. The reaction of the sodium salt of $\text{Ph}_2\text{P}(\text{S})\text{NHP}(\text{S})\text{Ph}_2$ with either triglyme or tetraglyme affords the corresponding adducts $\text{Na}\{\text{Ph}_2\text{P}(\text{S})\text{NP}(\text{S})\text{Ph}_2\}$ (glyme), which are monomeric species with all four oxygen atoms of the glyme moieties coordinated to the Na^+ cations. The sulfur atoms of the $[\text{Ph}_2\text{P}(\text{S})\text{NP}(\text{S})\text{Ph}_2]^-$ anion are bound in a symmetrical fashion to the sodium cations, forming six-membered S—P—N—P—S—Na rings ($\text{Na—S}=2.84\text{--}3.08\text{ \AA}$).⁶⁶⁸ The reaction of 1,3-dimethyl-2-iminoimidazoline with KMe gives the corresponding potassium imidate, from which (1,3-dimethylimidazolin-2-imino) CS_2K is obtained in almost quantitative yield. Its crystal structure (see Figure 88) contains a framework in which rings of K_2 units bridged by the four sulfur atoms of two thiolate ligands are connected by N and S bridges.⁶⁶⁹ The addition of MeLi or BuLi to alkyl isothiocyanates produces Li thioamidates $\{\text{Li}[\text{RCS}(\text{NR}')]\}_n$. When $\text{R}=\text{Bu}$ and $\text{R}'=\text{Bu}^t$, the unsolvated hexamer $\{\text{Li}[\text{BuCS}(\text{NBu}^t)]\}_2$ is obtained. In contrast, the solvated derivatives $\{\text{Li}\cdot\text{THF}[\text{MeCS}(\text{NBu}^t)]\}_\infty$ and $\{\text{Li}\cdot 2\text{THF}[\text{MeCS}(\text{NMe})]\}_\infty$ form single-strand polymers.⁶⁷⁰

More complex S, N, O interactions are found in the polymeric $(\text{Cs}(5,5\text{-dimethyl-4-oxoimidazolidine-2-thione})\text{OH})_\infty$, which was isolated in an attempt to prepare the Cs salt of the mono-anion of 5,5-dimethyl-4-oxoimidazolidine-2-thione. The polymeric complex consists of layers of $(\text{Cs}(5,5\text{-dimethyl-4-oxoimidazolidine-2-thione})\text{OH})_\infty$ along the crystallographic [010] plane. Each Cs atom displays eight-fold coordination with four different thione molecules and three hydroxy molecules and 3 OH^- groups as surrounding ligands (see Figure 89).⁶⁷¹

Dropwise addition of Bu^nLi to a slight excess of the isothiocyanate Bu^tNCS in hexane yields hexagonal prisms of $\text{Li}[\text{CS}(\text{NBu}^t)(\text{Bu}^n)]$. X-ray crystallography reveals that the molecule is constructed around hexagonal Li_6S_6 aggregates, in which the $\text{Bu}^n\text{CN}(\text{Bu}^t)$ bridges form a paddle-wheel arrangement with D_{3d} symmetry (see Figure 90).⁶⁷²

Ab initio calculations on mono- and di-lithiated derivatives of thiourea have been used to predict that Li atom(s) will bridge N and S centers, leading to lengthening of the C—bond and shortening of one or both of the C—bonds in thiourea. Structurally authenticated di-lithiated diphenylthiourea, $[\text{PhNLiC}(=\text{NPh})\text{SLi}\cdot 2\text{HMPA}]_2$, contains monomeric units with S—Li and $\text{N}(\mu_2\text{—Li})\text{N}$ bonds, these monomers then being linked by $\text{N}:\rightarrow\text{Li}$ coordination (see Figure 91).⁶⁷³

Figure 88 Portion of the structure of dipotassium (μ_4 -bis(1,3-dimethylimidazoline-2-dithiocarbimato)). Acetonitrile of crystallization is in the center of the rings.

An investigation of the lithiation and CS_2 -insertion reactions of $(\text{Ph})(\text{pyridyl})\text{CH}_2$ precursors (reactions used in the synthesis of ketene dithioacetals) lead to the monolithiated complexes $(\text{Ph})(\text{pyridyl})\text{CHCS}_2\text{Li}\cdot\text{TMEDA}$ ($\text{R}_1 = \text{Ph}$, $\text{R}_2 = \text{pyridyl}$) and $(\text{H})(2\text{-methylpyrazine})\text{CHCS}_2\text{Li}\cdot\text{TMEDA}$ ($\text{R}_1 = \text{H}$, $\text{R}_2 = 2\text{-methylpyrazine}$). Interestingly, attempted second lithiation of the former complex fails to give the anticipated $(\text{Ph})(\text{pyridyl})\text{C}=\text{CS}_2\text{Li}_2$, but synthetic and ^1H -NMR spectroscopic evidence indicates that the 2-methylpyrazine complex can be lithiated further.⁶⁷⁴

Bis(pentamethylcyclopentadienyl)phosphine $(\text{C}_5\text{Me}_5)_2\text{PH}$ reacts with S under basic conditions to give the corresponding dithiophosphinate salt $\text{Li}[(\text{C}_5\text{Me}_5)_2\text{PS}_2]$ (see Figure 92), which is formed via the intermediate $(\text{C}_5\text{Me}_5)_2\text{P}(\text{S})\text{H}$. The corresponding transition metal dithiophosphinate is formed on treatment with Co(II) chloride.⁶⁷⁵

Reaction of 2-mercapto-1-methylimidazole and 2-mercapto-1-mesitylimidazole with LiBH_4 in toluene produces the corresponding lithiated derivatives. The bidentate coordination of the sulfur atoms to lithium is augmented by donation from one of the B—H groups of the imidazole ligands. In the mesityl derivative, $\text{Li—B} = 2.80, 3.09 \text{ \AA}$ (values for two independent molecules);

Figure 91 The structure of urea, $[\text{PhNLiC}(=\text{NPh})\text{SLi} \cdot 2\text{HMPA}]_2$.

Figure 92 The structure of $\{(\text{DME})\text{Li}\}[(\text{C}_5\text{Me}_5)_2\text{PS}_2]_2$.

Li–H distance = 1.86, 2.34 Å (see [Figure 93](#)). Similar coordination is observed in thallium and zinc derivatives.⁶⁷⁶

3.1.4.4.3 Selenium and tellurium donor ligands

Only after the publication of CCC (1987) were well-characterized coordination compounds of the *s*-block elements containing bonds to Se or Te described. As a rule selenium or tellurium donor

Figure 93 The structure of lithium bis((μ_2 -bis(2-mercapto-1-mesitylimidazolyl)dihydrogenborate-H).

ligands possess large, sterically demanding substituents that confer kinetic stability on the complexes.

Direct insertion of elemental Se into the Li—C bond of $(\text{THF})_3\text{LiC}(\text{SiMe}_3)_3$ in DME produces $(\text{DME})\text{LiSeC}(\text{SiMe}_3)_3$.⁶⁷⁷ The related centrosymmetric dimer $[(\text{DME})\text{LiSeSi}(\text{SiMe}_3)_3]_2$ has also been structurally characterized (Li—Se = 2.57, 2.62 Å).⁶⁷⁸ Interestingly, Te is displaced from $(\text{THF})_2\text{LiTeSi}(\text{SiMe}_3)_3$ by Se in THF at -55°C in a novel chalcogen metathesis reaction (Equation(6)):

Use of the analogous germanium $(\text{THF})_2\text{LiTeGe}(\text{SiMe}_3)_3$ reagent gives only intractable materials when treated with Se.⁶⁷⁷

The 1:1 reaction of $[\text{PhC}\equiv\text{CLi}]_n$ with Se metal in THF/TMEDA gives the monomeric insertion product $\text{PhC}\equiv\text{CSeLi}\cdot\text{TMEDA}\cdot\text{THF}$.⁶⁷⁹ Selenium also inserts into the Li—N bond of lithium 2,2,6,6-tetramethylpiperidide to form lithium 2,2,6,6-tetramethylpiperidinoselenolate. In the complex, one Li atom is coordinated tetrahedrally by two molecules of THF and two Se atoms, whereas the other Li atom exhibits an approximately rectangular-planar coordination by two (N, Se)-chelating groups. The Li atoms are bridged by two Se atoms, thus forming a planar Li_2Se_2 core (see Figure 94).⁶⁸⁰ *Ab initio* Hartree–Fock calculations indicate that a hypothetical nonchelated

Figure 94 The structure of lithium 2,2,6,6-tetramethylpiperidinoselenolate.

dimer would be of distinctly higher energy than the observed form—apparently charge transfer from Se to N supports the (N, Se)-chelation.

The $-\text{Se}(\text{aryl})$ moiety is commonly incorporated into complexes; for example, 2,2'-bipyridine (bipy) forms coordination complexes with lithium benzeneselenolate and lithium pyridine-2-selenolate. The compounds can be recrystallized from THF, in which they are highly soluble. Dimeric $\{\text{Li}(\text{bipy})(\text{SePh})\}_2$ contains two lithium ions bridged by a pair of symmetrical benzeneselenolate ligands, with bidentate bipy ligands bound to each lithium ion ($\text{Li}-\text{Se} = 2.55, 2.59 \text{ \AA}$). In $\{\text{Li}(\text{bipy})(\text{NC}_5\text{H}_4\text{Se})\}_2$, each lithium ion is coordinated to a bidentate bipy ligand, one bridging selenium atom, and the nitrogen atom from the second bridging pyridine-2-selenolate ligand, thus forming an eight-membered $[\text{Li}-\text{Se}-\text{C}-\text{N}]_2$ ring with a chair conformation ($\text{Li}-\text{Se} = 2.62 \text{ \AA}$).⁶⁸¹

Monomeric $(\text{THF})_3\text{LiSe}(2,4,6\text{-tri-}t\text{-butylphenyl})$ can be produced from the reaction of $\text{HSe}(2,4,6\text{-tri-}t\text{-butylphenyl})$ and Bu^nLi ⁶⁸² or by the reduction of bis(2,4,6-tri-*t*-butylphenyl) diselenide (R_2Se_2) by LiBEt_3H ⁶⁸³ in the complex, the lithium center is bound to the three THF molecules and the selenium in a pseudotetrahedral manner ($\text{Li}-\text{Se} = 2.57 \text{ \AA}$). The lithium selenolate reacts with Bu^tPCl , CH_2Cl_2 , Me_3SiCl , Me_3SnCl , and Ph_3PAuCl to give Bu^t_2PSeR , RSeCH_2Cl (or $(\text{RSe})_2\text{CH}_2$), Me_3SiSeR , Me_3SnSeR and Ph_3PAuSeR , respectively.⁶⁸³

Lithiation of $\text{HSe}(2,4,6\text{-(Me}_3\text{C)}_3\text{C}_6\text{H}_2)$ with BuLi in the presence of one equivalent of THF produces $[\text{Li}(\text{THF})\text{Se}(2,4,6\text{-(Me}_3\text{C)}_3\text{C}_6\text{H}_2)]_3$. The molecule has a Li_3Se_3 core, with pyramidal coordination at Se and almost planar Li coordination (sum of angles around Li = $355\text{--}360^\circ$).⁶⁸⁴

Direct reaction of potassium or rubidium metal with the sterically encumbering selenol $\text{HSeC}_6\text{H}_6\text{-2,6-Trip}_2$ ($\text{Trip} = 2,4,6\text{-Pr}^t_3\text{C}_6\text{H}_2^-$) stabilizes the dimeric selenates $\text{MSeC}_6\text{H}_3\text{-2,6-Trip}_2$ ($\text{M} = \text{K, Rb}$). The compounds, characterized with ^1H -, ^{13}C -, and ^{77}Se -NMR and IR spectroscopy, crystallize as toluene solvates with M_2Se_2 cores. Each potassium or rubidium interacts in a π -fashion with two *ortho*-aryl groups and also σ -bonds to the chalcogens. The π -interaction is retained even in the presence of donor solvents (Et_2O).⁶⁸⁵

Reaction of the sterically encumbered silylselenanol $\text{HSeSi}(\text{SiMe}_3)_3$ with either Bu_2Mg or the bis(trimethylsilyl)amides of Ca, Sr, and Ba in the presence of Lewis bases yields crystalline alkaline-earth selenolates. The Mg selenolate has been crystallized as a tris((dimethylphosphino)methyl)-*t*-butylsilane complex, whereas the Ca, Sr, and Ba complexes have been isolated as TMEDA adducts. The magnesium complex is constructed around a six-membered $\text{P}-\text{Mg}-\text{P}-\text{C}-\text{S}-\text{C}$ ring that is puckered in a chair conformation. The strontium complex has $\text{Sr}-\text{Se} = 2.94 \text{ \AA}$ with a linear $\text{Se}-\text{Sr}-\text{Se}'$ core.⁶⁸⁶

The reaction of MgBr_2 with two equivalents of the sterically demanding $[\text{Li}\{\text{Se}(2,4,6\text{-Bu}^t_3\text{C}_6\text{H}_2)\}_2(\text{THF})_2]$ in THF generates the mononuclear $\text{Mg}\{\text{Se}(2,4,6\text{-Bu}^t_3\text{C}_6\text{H}_2)\}_2(\text{THF})_2$ ($\text{Mg}-\text{Se} = 2.53 \text{ \AA}$; $\text{Se}-\text{Mg}-\text{Se}' = 122.2^\circ$) in good yield.⁶⁸⁷ The treatment of $\text{SrI}_2(\text{THF})_5$ with two equivalents of $[\text{K}\{\text{Se}(2,4,6\text{-Bu}^t_3\text{C}_6\text{H}_2)\}_2(\text{THF})_4 \cdot 2\text{THF}]$ in THF produces $\text{Sr}\{\text{Se}(2,4,6\text{-Bu}^t_3\text{C}_6\text{H}_2)\}_2(\text{THF})_4 \cdot 2\text{THF}$ in good yield. The latter displays a distorted octahedral environment at the metal center ($\text{Sr}-\text{Se} = 3.07 \text{ \AA}$; $\text{Se}-\text{Sr}-\text{Se}' = 171.9^\circ$).⁶⁸⁸

The Mg phenylselenolate complex $[\text{tris}(3\text{-}p\text{-tolylpyrazolyl})\text{borate}]\text{MgSePh}$ was synthesized by the reactions of $[\text{tris}(3\text{-}p\text{-tolylpyrazolyl})\text{borate}]\text{MgMe}$ with PhSeH and Ph_2Se_2 . The solid state structure indicates that the magnesium is coordinated to three nitrogen atoms of the pyrazolate ligand and to the SePh ligand ($\text{Mg}-\text{Se} = 2.50 \text{ \AA}$).⁶⁸⁹ The structurally characterized monomeric hydroselenido complex $[\text{tris}(3\text{-}p\text{-tolylpyrazolyl})\text{borate}]\text{MgSeH}$ was synthesized by the reaction of $[\text{tris}(3\text{-}p\text{-tolylpyrazolyl})\text{borate}]\text{MgMe}$ with H_2Se ($\text{Mg}-\text{SeH} = 2.465(2) \text{ \AA}$). The complex reacts with $[\text{tris}(3\text{-}p\text{-tolylpyrazolyl})\text{borate}]\text{MgMe}$ to give the dinuclear bridging selenido complex $\{[\text{tris}(3\text{-}p\text{-tolylpyrazolyl})\text{borate}]\text{Mg}\}_2\text{Se}$; the $\text{Mg}-\text{Se}-\text{Mg}'$ moiety is linear.⁶⁴⁸

The structurally authenticated compounds $\text{Ba}\{\text{Se}(2,4,6\text{-tri-}t\text{-butylphenyl})\}_2(\text{THF})_4$ (monomer, $\text{Ba}-\text{Se} = 3.28 \text{ \AA}$), $[\text{Ba}(\text{18-crown-6})(\text{HMPA})_2][\text{Se}(2,4,6\text{-tri-}t\text{-butylphenyl})_2]$ (solvent separated ion triple), $[\text{Ba}\{\text{Se}(2,4,6\text{-triisopropylphenyl})\}_2(\text{Py})_3(\text{THF})_2]$ (dimer, $\mu\text{-Ba}-\text{Se} = 3.30, 3.42 \text{ \AA}$) and $[\text{Ba}\{\text{Se}(2,4,6\text{-triisopropylphenyl})\}_2(\text{18-crown-6})]$ (monomer, $\text{Ba}-\text{Se} = 3.23, 3.24 \text{ \AA}$) have been prepared by reductive insertion of Ba (dissolved in NH_3) into the $\text{Se}-\text{Se}$ bond of corresponding diorganodiselenides.⁶⁹⁰ Various heteroatomic aggregates containing selenium and displaying interactions with alkali metals have been described and structurally characterized, including $(\text{TMEDA})_2\text{Li}_2\text{Se}_4$ (distorted trigonal prismatic Li_2Se_4 core),⁶⁹¹ $\text{Li}_2\text{Se}_5(\text{PMDETA})_2$ (Li ions bound to terminal Se atoms of a zigzag chain),⁶⁵⁵ $(\text{Et}_4\text{N})_3\text{Na}[\text{Ru}(\text{CO})_2(\text{Se}_4)_2]_2$ (two $[\text{Ru}(\text{CO})(\text{Se}_4)_2]_2^{2-}$ ions are bound to an octahedrally coordinated Na^+ atom, with $\text{Na}-\text{Se} = 3.00 \text{ \AA}$ (av)),⁶⁹² and $[(\text{NMe}_4)_3\text{KSn}_2\text{Se}_6]_\infty$ (K ions link $\text{Sn}_2\text{Se}_6^{4-}$ units, $\text{K}-\text{Se} = 3.34 \text{ \AA}$ (av)).¹³⁶

The reaction between $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$ and $(\text{SeCH}_2\text{CH}_2\text{Se})^{2-}$ in EtOH generates the $[\text{Ni}(\text{SeCH}_2\text{CH}_2\text{Se})_2]^{2-}$ ion, which has been isolated as its potassium and tetramethylammonium

salts. The potassium ions in $K_2[Ni(SeCH_2CH_2Se)_2] \cdot 2EtOH$ display close contacts between the Se atoms of the ligands ($K-Se$ distance = 3.39–3.60 Å) in the anions, and the ethanolic oxygen atoms ($K-O$ distance = ca. 2.8 Å).⁶⁹³ The 1:1 reaction of $Ph_2P(Se)N(SiMe_3)_2$ with potassium *t*-butoxide in THF at room temperature produces $(K[Ph_2P(Se)NSiMe_3] \cdot THF)_2$. The dimeric complex contains two four-membered $N-P-Se-K$ rings fused to a central K_2Se_2 ring ($K-Se$ = 3.37–3.42 Å).⁶⁹⁴ The bimetallic complex $[(Py)_2Yb(SeC_6H_5)_2(\mu-SeC_6H_5)_2Li(Py)_2]$ contains a $Li-Se-Yb^{III}-Se$ ring ($Li-Se$ = 2.57, 2.69 Å); the phenylselenolato ligands are the only anionic ligands on the ytterbium center.⁶⁹⁵

Sodium polyselenide reacts with Ph_2PCl in THF/EtOH to give a mixture of products, including the oligomeric $Na_2[Ph_2PSe_2]_2 \cdot THF \cdot 5H_2O$, which consists of a central polymeric core built up of $Na(H_2O)_6$ and $Na(H_2O)_3(THF)(Se)$ units ($Na-Se$ = 2.98 Å) with additional hydrogen bonds to $[Ph_2PSe_2]^-$.⁶⁹⁶ Selenium and $[(Bu^tNH)P(\mu-N-Bu^t)_2(NH-Bu^t)]$ react to form *cis*- $[(Bu^tNH)(Se)P(\mu-N-Bu^t)_2(Se)(NH-Bu^t)]$, which will react with $KN(SiMe_3)_2$ to produce $\{[(THF)K[Bu^tN(Se)P(\mu-N-Bu^t)_2P(Se)NBu^t]K(THF)_2]_2\}_\infty$. It forms an infinite network of twenty-membered $K_6Se_6P_4N_4$ rings involving two types of $K-Se$ interactions ($K-Se$ = 3.26–3.42 Å) (see Figure 95).⁶⁹⁷

The bulky (tris(trimethylsilyl)silyl)tellurido ligand, $-TeSi(SiMe_3)_3$, has been incorporated into a variety of *s*-block coordination compounds. Metalation of $HTe\{Si(SiMe_3)_3\}$ with $BuLi$ yields pale yellow $LiTe\{Si(SiMe_3)_3\}$; crystals obtained from cyclopentane solution indicate that the compound is a hexamer.⁶⁹⁸ It forms a centrosymmetric but distorted hexagonal prism that is built up alternately of Li and $Te\{Si(SiMe_3)_3\}$; the $(LiTe)_6$ rings are slightly puckered and adopt a chair conformation (see Figure 96).⁶⁹⁸

Tellurium inserts the $Li-Si$ bond of $(THF)_3LiSi(SiMe_3)_3$ in THF to produce colorless $(THF)_2LiTeSi(SiMe_3)_3$, which crystallizes as a dimer with a planar $Li-Te-Li'-Te'$ ring and two tris(trimethylsilyl)silyl substituents in a *trans* position. The same compound can be prepared from $(THF)Li[N(SiMe_3)_2]$ and $HTeSi(SiMe_3)_3$; it has been crystallographically characterized as the dimeric mono-THF solvate, $[(THF)LiTeSi(SiMe_3)_3]_2$.⁶⁷⁷ 1,2-Dimethoxyethane displaces the THF from $(THF)_2LiTeSi(SiMe_3)_3$ to form the dimeric $(DME)LiTeSi(SiMe_3)_3$, which can also be formed directly from the reaction of $LiSi(SiMe_3)_3 \cdot 1.5(DME)$ and Te in DME.⁶⁹⁹ Reduction of the ditelluride $(SiMe_3)_2TeTeSi(SiMe_3)_3$ with Na/Hg in THF yields colorless crystals of the sodium derivative $(THF)_{0.5}NaTeSi(SiMe_3)_3$. Tellurolysis of $MN(SiMe_3)_2$ ($M = Li, Na$) or $KOCMe_3$ with the tellurol $HTeSi(SiMe_3)_3$ in hexane gives the toluene-soluble, base free tellurolate derivatives $MTeSi(SiMe_3)_3$ ($M = Li, Na, K$). A TMEDA derivative of the potassium complex $(TMEDA)KTeSi(SiMe_3)_3$ can also be isolated.⁷⁰⁰

Reduction of $(2,4,6-Me_3C_6H_2)_2Te_2$ and $(2,4,6-Pr^i_3C_6H_2)_2Te_2$ with two equivalents of $LiEt_3BH$ in THF produces the lithium tellurolates $(2,4,6-Me_3C_6H_2)_2TeLi(THF)_{1.5}$ and $(2,4,6-Pr^i_3C_6H_2)_2TeLi(THF)_{2.5}$, respectively. Direct Te insertion into the $C-Li$ bond of $(2,4,6-Bu^t_3C_6H_2)Li(THF)_3$ in THF produces the structurally authenticated $(2,4,6-Bu^t_3C_6H_2)TeLi(THF)_3$, while a similar reaction between elemental tellurium and $(o-C_6H_4CH_2NMe_2)Li$ yields the chelating tellurolate $(o-C_6H_4CH_2NMe_2)TeLi(DME)$. The action of Na/Hg amalgam on THF solutions of

Figure 95 The structural motif of $\{[(THF)K[Bu^tN(Se)P(\mu-N-Bu^t)_2P(Se)NBu^t]K(THF)_2]_2\}_\infty$.

Figure 96 The structure of $\{\text{LiTe}[\text{Si}(\text{SiMe}_3)_3]\}_6$.

$(2,4,6\text{-Me}_3\text{C}_6\text{H}_2)_2\text{Te}_2$ or $(2,4,6\text{-Pr}^i_3\text{C}_6\text{H}_2)_2\text{Te}_2$ followed by work-up with TMEDA or DME leads to the sodium tellurolates. Treatment of $(2,4,6\text{-Pr}^i_3\text{C}_6\text{H}_2)_2\text{Te}_2$ with two equivalents of $\text{K}[\text{Bu}^s_3\text{BH}]$ in THF gives the polymeric tellurolate, $(2,4,6\text{-Pr}^i_3\text{C}_6\text{H}_2)_2\text{TeK}(\text{THF})_{1.33}$. The infinite ladder-like structure is disrupted by reaction with 18-crown-6, which generates a monomeric derivative.⁷⁰¹

Reaction of $\text{HTeSi}(\text{SiMe}_3)_3$ with Bu_2Mg in hexane gives the base-free, homoleptic tellurolate $\text{Mg}[\text{TeSi}(\text{SiMe}_3)_3]_2$ as colorless plates; recrystallization in THF gives the bis(THF) adduct.^{686,702} The analogous pyridine adduct was prepared by the same reactions in pyridine; both the pyridine and tellurolate ligands are displaced by 12-crown-4 to form $[\text{Mg}(12\text{-C-}4)_2][\text{TeSi}(\text{SiMe}_3)_3]_2$. Reactions between two equivalents of $\text{HTeSi}(\text{SiMe}_3)_3$ and $\text{M}[\text{N}(\text{SiMe}_3)_2](\text{THF})_2$ ($\text{M} = \text{Ca}, \text{Sr}, \text{Ba}$) in hexane or toluene (for Ca) gives high yields of the corresponding tellurolate complexes, which can be isolated as THF adducts; pyridine adducts can also be formed.^{686,702,703} The calcium compound displays a high field shift of the $^{125}\text{Te}\{^1\text{H}\}$ -NMR resonance ($-2,204$ ppm vs. Me_2Te), and its crystal structure contains calcium in a distorted octahedral environment ($\text{Ca}-\text{Te} = 3.19$ Å; $\text{Ca}-\text{O} = 2.36$ and 2.41 Å); the two tellurido ligands are in a *trans* position. The $(\text{Py})_5\text{Ba}[\text{TeSi}(\text{SiMe}_3)_3]_2$ complex displays a distorted pentagonal bipyramidal environment, with $\text{Ba}-\text{Te} = 3.38$ Å, $\text{Te}-\text{Ba}-\text{Te} = 171.9^\circ$.⁶⁸⁶

3.1.4.5 Group 17 Ligands

Halides of the *s*-block metals such as NaCl and CaCl_2 are among the most widely known of all compounds, and their uses are legion.⁷⁰⁴ The molecular structure and spectra of the Group 1 and 2 halides have been reviewed.^{705–707} The use of the halides as reagents means that numerous *s*-block compounds with terminal halide ligands are known⁷⁰⁸ and in many cases have been structurally characterized (e.g., adducts with nitrogen and mixed nitrogen-oxygen bases such as MeCN , Py , *en* (ethylene-1,2-diamine), *dien* (diethylenetriamine), TMEN (tetramethylenediamine), DMF , *phen*, *bipy*, *terpy*, substituted pyridines, water, and ROH ($\text{R} = \text{Me}, \text{Pr}, \text{Bu}$).^{709–718} Often their structures and bond distances are adequately rationalized with fundamental electrostatic arguments. The focus of this section is on features of molecular halide complexes that are distinctive or have provided new insights into bonding and reactivity.

The molecular structures of the gas-phase alkaline-earth dihalides have been a source of continuing interest. Gas-phase electron diffraction (GED) and mass spectrometric (MS) measurements confirm that the vapor phase structure of BeCl_2 at 274°C is mostly that of a linear monomer, with a thermal average $\text{Be}-\text{Cl}$ distance of $1.798(4)$ Å. A small amount (2.5%) of a halide-bridged dimer form is also present, however, with $\text{Be}-\text{Cl}_{\text{term}} = 1.83(1)$ Å, $\text{Be}-\text{Cl}_{\text{bridg}} = 1.97(2)$, and $\text{Cl}_{\text{term}}-\text{Be}-\text{Cl}_{\text{bridg}} = 134(4)^\circ$.⁷¹⁹ Dimers (ca. 1%) have also been detected in MgX_2 vapor.⁷²⁰

The structures of the gaseous dihalides of calcium, strontium, and barium have been reviewed.^{705,707} As noted in Section 3.1.2.2, CaF_2 , SrF_2 , SrCl_2 , and BaF_2 , BaCl_2 , and BaBr_2 have permanent molecular dipole moments in the gas phase. The structure of RaF_2 , although not experimentally known, is also calculated to be bent ($\text{F—Ra—F} = 118^\circ$; $\text{Ra—F} = 2.30 \text{ \AA}$).²⁶ Such bending defies interpretation using simple VSEPR (Valence Shell Electron Pair Repulsion) theory,^{24,721} and there is not yet agreement on the most satisfactory rationale for it. Some degree of covalency, whether in the guise of polarization arguments, or more explicitly in molecular orbital terms, is evidently required as part of the explanation.

A series of $\text{M}_x\text{X}_y(\text{THF})_n$ adducts for $\text{M} = \text{Li}, \text{Be}, \text{Mg}, \text{Ca}, \text{Sr},$ and Ba have been structurally authenticated (see Table 9). Although the distances mostly follow the trends expected from additivity of metal and ligand radii, maximum coordination numbers are not always sterically dictated;⁵⁸⁰ Ca^{2+} and Sm^{3+} are almost exactly the same size (1.0 \AA),¹ for example, yet calcium coordinates to only four THF ligands in addition to the two iodides, whereas the $[\text{SmI}_2(\text{THF})_5]^+$ cation crystallizes from THF with two iodides and five THFs in the plane of the Sm atom.⁷²² Another THF ligand could bind to the calcium without undue steric crowding.

In conjunction with other molecular halide complexes with various O-donor ligands such water and acetone, correspondences between the metal coordination number and solid-state structures have been identified.⁷²³ For the barium iodides, a progression is observed from the parent nonmolecular BaI_2 (PbCl_2 lattice type)⁷²⁴ to framework (e.g., $[\text{BaI}_2(\mu\text{-H}_2\text{O})_2]_n$), layer ($[\text{BaI}_2(\mu\text{-H}_2\text{O})(\text{OCMe}_2)]_n$), chain ($[\text{Ba}(\mu\text{-I})_2(\text{THF})_3]_n$) and finally monomeric structures ($\text{BaI}_2(\text{THF})_5$). Coming almost full circle, the latter can be partially hydrolyzed to form $\text{Ba}(\text{OH})(\text{H}_2\text{O})_4$, in which a three-dimensional network between molecules is constructed via H bonds. The iodohydroxide is a possible intermediate in the generation of sol-gels, leading ultimately to $[\text{Ba}(\text{OH})_2\text{-(H}_2\text{O)}_x]$.⁷²⁵

The propensity for halides to bridge can lead to the formation of larger aggregates, particularly with the highly polarizing Li^+ cation. The three lithium heterocubanes that have been described, i.e., $[\text{LiCl}(\text{HMPTA})]_4$,⁷²⁶ $[\text{LiBr}(\text{Et}_2\text{O})]_4$,⁷²⁷ and $[\text{LiI}(\text{NET}_3)]_4$,⁷²⁸ are formed by special and/or adventitious routes. The iodo complex, for example, is isolated from the reaction of $\text{LiN}(\text{SiMe}_3)_2$ with the metastable GaI or AlI in the presence of NET_3 ; it cannot be obtained directly from a mixture of LiI and NET_3 . The energetics of the formation of $[\text{LiI}(\text{NET}_3)]_4$ and its stability with respect to solid LiI have been examined with DFT calculations. These suggest that the activation energy of the solvation of solid LiI to give monomeric $[\text{LiI}(\text{NET}_3)]$ as an intermediate is too high, and consequently the presence of energetic donors such as the metastable monovalent Ga or Al is required.

“Opening” the cube leads to ladder-like structures such as $\text{Li}_4\text{Cl}_4(\text{azetidine})_2[\text{N-(3-aminopropyl)-azetidine}]_2$,⁷²⁹ $\text{Li}_4\text{I}_4(2,4,6\text{-trimethylpyridine})_6$,⁷³⁰ and $\text{Li}_4\text{Br}_4(2,6\text{-dimethylpyridine})_6$.⁷³¹ The latter, prepared by recrystallizing LiBr in pyridine, has a structure typical for the class; i.e., a stepped tetramer (see Figure 97). A more complex species, $\{\text{LiLiLiLiLiLi}(\text{THF})\}_2$, is formed as a side product of the reaction of $[\text{LiL}(\text{THF})_n]$ ($\text{L} = N,N\text{-dimethyl-}N'\text{-trimethylsilylethane-1,2-diamide}$)

with $\text{LuCl}_3(\text{THF})_2$ in THF. $\{\text{LiLiLiLiLiLi}(\text{THF})\}_2$ has a LiCl bonded between LiLi and $\text{LiLi}(\text{THF})$ units, thereby generating a “three-rung ladder”, which is further connected by $\text{Li}—\text{Cl}$ bonds to a second $\text{LiLiLiLiLiLi}(\text{THF})$ moiety (see Figure 98).⁷³² Finally, from the reaction of GeBr_4 with two equivalents of $\text{Li}_2[1\text{-naphthylamide}]$ in $\text{THF}-\text{Et}_2\text{O}$, the infinite corrugated ladder $(\text{LiBr}\cdot\text{THF})_\infty$ can be isolated.⁷³³ It can be regarded as the product of the association of cubes of $(\text{LiBr}\cdot\text{THF})_4$ (see Figure 99). The more straightforward reaction of LiX ($\text{X} = \text{Cl}, \text{Br}, \text{I}$) with TMEDA gives adducts with the empirical formulas $(\text{LiCl})_3(\text{TMEDA})_2$, $[\text{Li}(\text{TMEDA})\text{Br}]_2$, and $[\text{Li}(\text{TMEDA})\text{I}]_2$;⁷³⁴ the bromide and iodide are conventional $\mu-\mu'$ -dihalo bridged dimers with four-coordinate N_2LiX_2 environments around lithium, but the chloride forms polymeric sheets based on a double cubane Li_6Cl_6 unit that is solvated by chelating and bridging TMEDAs (see Figure 100).

The strongly polarizing power of the Li^+ cation can cause otherwise noncoordinating anions to be incorporated into complexes. For example, the reaction of NH_4PF_6 with Bu^nLi in toluene containing PMDETA yields $[(\text{PMDETA})\text{LiPF}_6]_2$, in which PF_6^- anions bridge $(\text{PMDETA})\text{Li}^+$ units via $\text{Li}-\text{F}$ interactions (1.91 Å and 3.14 Å) (see Figure 101). *Ab initio* MO calculations indicate that the charge on the N of PMDETA is more negative (-0.59 e^-) than on the F of PF_6^- (-0.49 e^-), but that a second PMDETA ligand could not fit around the small Li^+ cation, thus leaving it open to bind to the hexafluorophosphate anion.⁷³⁵

An unusual class of compounds at the border between solid state and organometallic chemistry have been prepared that contain the $(\text{C}_3\text{R}_3)\text{TiF}_2$ fragment as a stabilizing agent. The reaction in

Figure 99 Portion of the infinite ladder of $(\text{LiBr}\cdot\text{THF})_\infty$.

THF of $(\text{C}_5\text{Me}_5)\text{TiF}_3$ and either metallic sodium or calcium in the presence of mercury forms the sparingly hydrocarbon-soluble clusters $(\text{C}_5\text{Me}_5)_{12}\text{Ti}_{14}\text{Na}_{18}\text{F}_{48}(\text{THF})_6$ and $[(\text{C}_5\text{Me}_5)\text{TiF}_2]_6\text{CaF}_2(\text{THF})_2$, respectively.⁷³⁶ The former contains a complex central $[(\text{TiF}_3)_2(\text{NaF})_{18}]$ core, in which the sodium atoms are either five- or six-coordinate to THF and/or F atoms. The average Na—F distance in the complex (2.32 Å) is remarkably close to that in solid NaF (2.31 Å), although there is no real structural resemblance between the two systems. The structural correspondence to fluorite is not strong in the calcium complex either, but like CaF_2 , the central metal is eight-coordinate, and the average Ca—F distance is close to that in fluorite (see [Figure 102](#)).

Compounds similar to these (i.e., $\{(\text{C}_5\text{Me}_5)\text{TiF}_3\}_4\text{CaF}_2$ and $\{(\text{C}_5\text{Me}_4\text{Et})\text{TiF}_3\}_4\text{CaF}_2$) have been formed from the reaction between $(\text{C}_5\text{Me}_5)\text{TiF}_3$ or $(\text{C}_5\text{Me}_4\text{Et})\text{TiF}_3$ in the presence of CaF_2

Figure 100 Portion of the polymeric sheets formed from association of $(\text{LiCl})_3(\text{TMEDA})_2$.

Figure 101 The structure of $[(\text{PMDETA})\text{LiPF}_6]_2$.

Figure 102 The structure of $[(\text{C}_5\text{Me}_5)\text{TiF}_3]_4\text{CaF}_2(\text{THF})_2$.

(prepared *in situ* from Me_3SnF and CaCl_2).⁷³⁷ Recrystallization of the latter two compounds in the presence of HMPA results in the formation of $\{(\text{C}_5\text{Me}_5)\text{TiF}_3\}_4(\text{CaF}_2)(\text{HMPA})$ and $\{(\text{C}_5\text{Me}_4\text{Et})\text{TiF}_3\}_4(\text{CaF}_2)(\text{HMPA})$, respectively. When the latter is dissolved in CDCl_3 , the HMPA dissociates completely, a process studied with ^1H -, ^{19}F -, and variable-temperature NMR. A molecule of solvent probably occupies the site on the organometallic complex vacated by the HMPA, and a temperature-dependent equilibrium exists between the solvent-solvated species and $\{(\text{C}_5\text{Me}_4\text{Et})\text{TiF}_3\}_4\text{CaF}_2$. With increasing temperature, the equilibrium is entropy-shifted to the non-solvated form.⁷³⁸ A related system containing lithium has been formed from the reaction of two equivalents of $(\text{C}_5\text{Me}_5)\text{TiF}_3$ with LiF (generated from Me_3SnF and LiCl) in THF. In the solid state, the lithium atom is coordinated by four F atoms ($\text{Li}-\text{F} = 1.90 \text{ \AA}$ (av)); in solution, it is in equilibrium with $\text{Li}[(\text{C}_5\text{Me}_5)_2\text{Ti}_2\text{F}_7]$ and $(\text{C}_5\text{Me}_5)_2\text{Ti}_2\text{F}_6$.⁷³⁹

3.2

Scandium, Yttrium, and the Lanthanides

S. COTTON

Uppingham School, UK

3.2.1	SCANDIUM	94
3.2.1.1	Introduction	94
3.2.1.2	Group 14 Ligands	94
3.2.1.3	Group 15 Ligands	95
3.2.1.3.1	<i>Ammonia and amines</i>	95
3.2.1.3.2	<i>Thiocyanates</i>	95
3.2.1.3.3	<i>Amides</i>	96
3.2.1.3.4	<i>Compounds of porphyrins and other macrocyclic ligands</i>	96
3.2.1.3.5	<i>Compounds with P- and N, P-donor ligands</i>	97
3.2.1.4	Group 16 Ligands	98
3.2.1.4.1	<i>Salts and the aqua ion</i>	98
3.2.1.4.2	<i>Complexes of other group 16-donor ligands</i>	102
3.2.1.4.3	<i>Alkoxides</i>	103
3.2.1.4.4	<i>Diketonates and other chelating ligands</i>	103
3.2.1.4.5	<i>Crown ether complexes and related systems</i>	104
3.2.1.5	Mixed Group 15 and 16 Donors	106
3.2.1.6	Complexes of Group 17 Ligands	106
3.2.1.6.1	<i>Binary halides and simple complexes</i>	106
3.2.1.6.2	<i>Other halide complexes</i>	107
3.2.2	YTTRIUM AND THE LANTHANIDES	108
3.2.2.1	Introduction	108
3.2.2.2	Group 14 Ligands	109
3.2.2.2.1	<i>Alkyls</i>	109

3.2.1 SCANDIUM

3.2.1.1 Introduction

Scandium is still a neglected element. It is the most expensive metal in its period (caused by the fact that its even distribution in the earth means that there are no rich ores) and its chemistry is virtually exclusively that of the +3 oxidation state, so that it is not classed as a transition metal and is often “silent” to spectroscopy and not amenable to study by many of the usual spectroscopic tools of the coordination chemist. Chemists have often either tended to assume that complexes of Sc^{3+} are just like those of the tripositive ions of the 3*d* transition metals or that they resemble lanthanide complexes. Neither of these assumptions is correct—how incorrect we are now realizing. Scandium chemistry is starting to exhibit characteristics all of its own, and possibly the burgeoning use of scandium compounds in organic synthesis may drive a real expansion of scandium chemistry.

Several “early” structures of scandium compounds that were reported, such as $[\text{ScCl}_3(\text{THF})_3]^1$ and $[\text{Sc}(\text{acac})_3]^2$ (acac = acetylacetonate) featured a coordination number of six; this, taken together with the coordination number of six exhibited by its oxide and halides, was probably responsible for the view, often unstated, that scandium compounds were generally six-coordinate. It is now becoming clear that, since Sc^{3+} is a larger ion than any of the succeeding 3*d* transition metal ions (the ionic radius of six-coordinate Sc^{3+} is 0.745 Å³, contrast Ti^{3+} 0.670 Å), it infrequently exhibits a coordination number greater than six in its complexes. On the other hand, it is smaller than lutetium, the last lanthanide (ionic radii of six-coordinate Sc^{3+} , La^{3+} , and Lu^{3+} are 0.745 Å, 1.032 Å, and 0.861 Å respectively), and thus tends to exhibit lower coordination numbers than the lanthanides; although there are sometimes similarities with lutetium,⁴ this point should not be over emphasized. (This point is demonstrated in Table 1, which shows comparative coordination numbers of Sc, La, and Lu in a number of typical binary compounds and complexes.) Whilst it could fairly be stated⁵ in 1987 that “in those crystal structures that are known, Sc^{3+} is predominantly six-coordinated,” the position has now changed; all the coordination numbers between three and nine are confirmed by X-ray diffraction work.

The last major review of the coordination chemistry of scandium appeared in 1987; whilst other reviews have appeared concerned with scandium chemistry,^{6,7} with its structural chemistry,⁸ and with the role of scandium inorganic synthesis,^{9,10} this section is concerned with covering the area from the previous review, though for the sake of readability, there will be occasional reference to earlier work.

3.2.1.2 Group 14 Ligands

Some simple alkyl and aryl compounds of metals in normal oxidation states can be considered as honorary coordination compounds.

Triphenylscandium was the first well-characterized organoscandium compound with a σ -bonded ligand, but its structure has been unknown, although believed to be polymeric. The THF adduct, $[\text{ScPh}_3(\text{THF})_2]$, stable at -35°C , is monomeric, however, and has a trigonal

Table 1 Coordination numbers (C.N.) of a number of related Sc, La, and Lu complexes.

Compound	Sc compound/complex formula	C.N.	La compound/complex formula	C.N.	Lu compound/complex formula	C.N.
Oxide	Sc ₂ O ₃	6	La ₂ O ₃	7	Lu ₂ O ₃	6

Ph ₃ PO complex of nitrate	Sc(η ² -NO ₃) ₃ (Ph ₃ PO) ₂	8	La(η ¹ -NO ₃)(η ² -NO ₃)(Ph ₃ PO) ₂	9	[Lu(η ² -NO ₃) ₂ (Ph ₃ PO) ₄]NO ₃	8

bipyramidal structure with axial THF molecules.¹¹ Its instability suggests that, on warming, loss of THF molecules occurs, with concomitant formation of polyhapto-linkages and oligomerization. A stable octahedral permethylate species exists in the form of the [ScMe₆]^{3−} ion, isolated as its tris(TMEDA) salt from the reaction of ScCl₃ with MeLi in the presence of excess TMEDA.¹² There is good evidence for [Sc(CH₂SiMe₃)₃(THF)₂],¹³ although it has not been isolated or reported, there seems no reason why the alkyl [Sc{CH(SiMe₃)₂}]₃ should not exist,^{14,15} by analogy with [M{CH(SiMe₃)₂}]₃ (M = Y, La, Pr, Nd, Sm, Lu) and with the corresponding silylamides.

Certain porphyrin derivatives with metal–carbon σ bonds are discussed in Section 3.2.1.3.4.

It should be noted that there are organometallic compounds involving polyhapto ligands that contain linkages such as Sc–Te that are not found in coordination compounds. In addition, a number of recent reviews on the organometallic chemistry of the lanthanides include reference to scandium compounds.^{16–20}

3.2.1.3 Group 15 Ligands

3.2.1.3.1 Ammonia and amines

Anhydrous ScX₃ (X = Cl, Br, I) reacts with gaseous ammonia forming ammine complexes²¹ such as ScX₃·5NH₃ (X = Cl, Br) and ScX₃·4NH₃. (X = Cl, Br, I). Nothing is known about the structures of any of these compounds but recently the first ammine complex to be characterized,²² (NH₄)₂[Sc(NH₃)I₅] has been obtained as pink crystals from the reaction of NH₄I and metallic scandium in a sealed tube at 500 °C. Scandium has octahedral coordination with Sc–N = 3.29(2) Å and Sc–I = 2.856(5)–2.899(5) Å. There are no further reports concerning simple complexes of bipy and phen (bipy = 2,2′-bipyridyl; phen = 1,10-phenanthroline) with scandium, but a little work has been carried with terdentate ligands. The complex [Sc(terpy)(NO₃)₃], (terpy = 2,2′,6′,2′′-terpyridyl) formed when scandium nitrate reacts with terpy in MeCN, has effective “8.5”-coordination with one very asymmetrically bidentate nitrate; in contrast to the later lanthanides (see Section 3.2.2.3.4) where reaction of the hydrated lanthanide nitrates in MeCN gives nine-coordinate [Ln(terpy)(NO₃)₃].^{23,24} Another terdentate ligand, 4-amino-bis(2,6-(2-pyridyl))-1,3,5-triazine (abptz), forms a complex [Sc(abptz)(NO₃)₃] which contains eight-coordinate scandium with one nitrate monodentate.²⁵

3.2.1.3.2 Thiocyanates

Compared with the lanthanides (Section 3.2.2.3.7) little study has been made of these. However, like the corresponding lanthanide complexes with this counter-ion, [Bu₄N]₃[Sc(NCS)₆] has octahedrally coordinated scandium.²⁶

3.2.1.3.3 Amides

Like the succeeding 3d transition metals scandium forms a three-coordinate silylamide $\text{Sc}[\text{N}(\text{SiMe}_3)_2]_3$ but unlike them its solid state structure is pyramidal, not planar, in which respect it resembles the lanthanides and uranium. Like the silylamides of 3d metals, however, it does not form adducts with Lewis bases, presumably on steric grounds. However, the less congested amide $[\text{Sc}\{\text{N}(\text{SiHMe}_2)_2\}_3]$ forms a THF adduct $[\text{Sc}\{\text{N}(\text{SiHMe}_2)_2\}_3(\text{THF})]$, which has distorted tetrahedral coordination of scandium, with short $\text{Sc}\cdots\text{Si}$ contacts in the solid state; this is in contrast to the five-coordinate $[\text{Ln}\{\text{N}(\text{SiHMe}_2)_2\}_3(\text{THF})_2]$.²⁷ Another amide, a triamidoamine complex with four-coordinate of scandium (see Scheme 1) distils on heating the corresponding “ate” complex.²⁸

Scheme 1

Scandium (and similar yttrium) benzamidinate complexes $[\{\text{RC}_6\text{H}_4\text{C}(\text{NSiMe}_3)_2\}_2\text{ScCl}(\text{THF})]$ ($\text{R} = \text{H}, \text{MeO}$) have been reported²⁹ and are believed to have octahedral structures (1).

The dichloro-lithium adduct (2) has also been characterized crystallographically,³⁰ but the lithium-free halides are better synthons for a range of hydrocarbyls and hydride, $[\{\text{PhC}(\text{NSiMe}_3)_2\}_2\text{ScR}]$ ($\text{R} = \text{CH}_2\text{SiMe}_3, 2,4,6\text{-Me}_3\text{C}_6\text{H}_2, \text{CH}_2\text{SiMe}_2\text{Ph}, \text{H}$). Unlike the corresponding Cp^*_2ScR systems, these show no signs of σ -bond metathesis on heating in hydrocarbon solvents. On the other hand, $[\{\text{PhC}(\text{NSiMe}_3)_2\}_2\text{Sc}(\text{CH}_2\text{SiMe}_3)]$ undergoes hydrogenolysis on reaction with H_2 (1 atm) in benzene or alkanes:

The IR spectrum of the hydride (3) shows a band due to $\nu(\text{Sc}-\text{H})$ for bridging hydrogens at $1,283\text{ cm}^{-1}$ (shifted to 907 cm^{-1} on deuteration) whilst the structure of the hydride features $\text{Sc}-\text{H}$ bonds of 1.87 \AA to 2.00 \AA . This inserts $\text{PhC}\equiv\text{CPh}$ forming the alkenyl $[\{\text{PhC}(\text{NSiMe}_3)_2\}_2\text{ScC}(\text{Ph})=\text{CH}(\text{Ph})]$.

3.2.1.3.4 Compounds of porphyrins and other macrocyclic ligands

A range of porphyrins and phthalocyanines exist; syntheses often involve the high-temperature routes typical of the transition metals; thus when ScCl_3 is refluxed with H_2TTP (H_2TTP = meso-tetratolylporphyrin) in 1-chloronaphthalene, $\text{Sc}(\text{TTP})\text{Cl}$ is formed.³¹ This has the expected square pyramidal structure with Sc 0.68 \AA above the N_4 basal plane ($\text{Sc}-\text{Cl} = 2.32\text{ \AA}$; $\text{Sc}-\text{N} = 2.17\text{--}2.18\text{ \AA}$).

Inadvertent hydrolysis of $\text{Sc}(\text{TTP})(\text{C}_5\text{Me}_5)$ leads to the oxo-bridged dimer $[\text{Sc}(\text{TTP})]_2(\mu\text{-O})$; this has a bent (110°) $\text{Sc}-\text{O}-\text{Sc}$ bridge. Recently a high-yield low-temperature route^{32,33} to $\text{Sc}(\text{OEP})\text{Cl}$ ($\text{H}_2\text{OEP} = 2,3,7,8,12,13,17,18$ -octaethylporphyrin) has been utilized in toluene solution at 100°C :

Though moisture-sensitive in solution, $\text{Sc}(\text{OEP})\text{Cl}$ forms air-stable red crystals. The chloride can be replaced by alkoxy, alkylamide, alkyl, and cyclopentadienyl groups. The structures have been reported of two σ -alkyls $\text{Sc}(\text{OEP})\text{R}$ ($\text{R} = \text{Me}$, $\text{CH}(\text{SiMe}_3)_2$), both of which have the anticipated square pyramidal structure with Sc out of the basal plane (by 0.66 \AA in the methyl structure) and $\text{Sc}-\text{N} \approx 2.16 \text{ \AA}$. The bond lengths for $[\text{Sc}(\text{OEP})\{\text{Me}\}]-\text{Sc}-\text{C}$ $3.246(3) \text{ \AA}$ ($\text{Sc}-\text{N} = 2.151, 2.152, 2.157, 2.158 \text{ \AA}$; average of 2.1545 \AA) and for $[\text{Sc}(\text{OEP})\{\text{CH}(\text{SiMe}_3)_2\}]-\text{Sc}-\text{C}$ $3.243(8) \text{ \AA}$ ($\text{Sc}-\text{N} = 2.142, 2.151, 2.162, 2.196 \text{ \AA}$; average of 2.163 \AA) show very similar $\text{Sc}-\text{C}$ bond lengths in an uncrowded environment. Hydrolysis of all $\text{Sc}(\text{OEP})\text{X}$ derivatives produces a dimeric hydroxy derivative $[(\text{OEP})\text{Sc}(\mu\text{-OH})_2\text{Sc}(\text{OEP})]$.

In the presence of scandium perchlorate, 2,6-diacetylpyridine condenses with *m*-phenylenediamine to form a macrocyclic complex $\text{ScL}(\text{ClO}_4)_3 \cdot 4\text{H}_2\text{O}$ (**L** is shown as **(4)**). The structure has not been determined, but the perchlorates are not coordinated.³⁴ The reaction probably proceeds via the (isolable) complex $\text{Sc}(\text{diacetylpyridine})_2(\text{ClO}_4)_3 \cdot 7\text{H}_2\text{O}$.

The template reaction of 2,6-diacetylpyridine with 3,3'-diaminodipropylamine in the presence of ScCl_3 or $\text{Sc}(\text{ClO}_4)_3$ gives complexes of a 14-membered N_4 macrocycle (**(5)**).³⁵

3.2.1.3.5 Compounds with P- and N, P-donor ligands

These are as yet rare, given the limited ability of a hard acid like Sc^{3+} to bind to a soft base like a tertiary phosphine. Recent developments include the synthesis of $\text{ScCl}_2(\text{THF})[\text{N}(\text{SiMe}_2\text{CH}_2\text{P}^t)_2]$

(4)

(5)

from $\text{ScCl}_3(\text{THF})_3$ and $\text{LiN}(\text{SiMe}_2\text{CH}_2\text{PPr}^i_2)_2$. This has to be carried out in toluene since the reaction in THF is a failure, recalling the lack of reactivity of lithium alkyls and aryls with $\text{Cp}^*\text{ScCl}(\text{THF})$. The THF complex, which has a *mer*-octahedral structure ((6); XRD data) loses its THF on pumping.³⁴

(6)

The chlorines can be replaced by alkyl groups using RLi (but not RMgX or R_2Zn) to afford alkyls $\text{ScR}_2[\text{N}(\text{SiMe}_2\text{CH}_2\text{PPr}^i_2)_2]$ ((7): $\text{R} = \text{Me}, \text{Et}, \text{CH}_2\text{SiMe}_3$) which are very hydrocarbon-soluble and have to be recrystallized from $(\text{Me}_3\text{Si})_2\text{O}$. They have trigonal bipyramidal five-coordinate structures (XRD data; $\text{R} = \text{Et}, \text{CH}_2\text{SiMe}_3$); despite the fact that they are formally 12-electron compounds, there is no evidence for agostic interactions between scandium and β -hydrogens.

Another compound featuring $\text{Sc}-\text{P}$ bonding is the phosphomethanide $\text{Sc}[\text{C}(\text{PMe}_2)_2\text{X}]_3$ ((8); $\text{X} = \text{SiMe}_3, \text{PMe}_2$)

where the ligands bind in a fashion intermediate between σ -chelating and π -type (η^3)-coordination.³⁵

3.2.1.4 Group 16 Ligands

3.2.1.4.1 Salts and the aqua ion

(i) Anhydrous and hydrated salts

A recent synthesis³⁸ of anhydrous $\text{Sc}(\text{ClO}_4)_3$ from hydrated scandium chloride proceeds via an orange adduct $[\text{Sc}(\text{ClO}_4)_3 \cdot 0.25\text{Cl}_2\text{O}_6]$ that loses the Cl_2O_6 in vacuo at 95°C (see Scheme (2)).

Infrared and Raman spectra are similar to those of anhydrous gallium perchlorate and are interpreted in terms of the presence of bridging bidentate perchlorates.

Scheme 2

Grey anhydrous scandium triflate, $[\text{Sc}(\text{O}_3\text{SCF}_3)_3]$ (triflate = trifluoromethane sulfonate), has been obtained³⁹ by dehydration of the hydrate at 190–200 °C; the hydrated salt was itself obtained from the reaction of hydrated scandium chloride and dilute triflic acid. $[\text{Sc}(\text{O}_3\text{SCF}_3)_3]$, in which triflate is believed to act as a bidentate ligand (similar to perchlorate in $\text{Sc}(\text{ClO}_4)_3$), is not isomorphous with the lanthanide analogues.

The anhydrous scandium carboxylates $\text{Sc}(\text{OCOR})_3$ ($\text{R} = \text{H}, \text{CH}_3$) have long been known to have polymeric structures with six-coordinate scandium.⁴⁰ Scandium formate has a 2-D polymeric structure whilst in the acetate, chains of Sc^{3+} ions are bridged by acetate groups with essentially octahedral coordination of scandium. Similar bridging and six-coordination is found in the chloroacetate. Scandium propynoate (R is $\text{C}\equiv\text{CH}$) crystallizes anhydrous from aqueous solution⁴¹ and has an infinite three-dimensional structure, again with six-coordinate scandium ($\text{Sc}-\text{O} = 2.081\text{--}2.091(2) \text{ \AA}$). On γ -irradiation, it changes color from colorless to orange, a change accompanied by a gradual disappearance of the $\nu(\text{C}\equiv\text{C})$ stretching mode in the IR spectrum, indicating conversion to a poly(propynoate).

Hydrated scandium perchlorate has long been known but it is only recently that $\text{Sc}(\text{ClO}_4)_3 \cdot 6\text{H}_2\text{O}$ has been shown⁴² to be isomorphous with the lanthanide analogues thus containing $[\text{Sc}(\text{OH}_2)_6]^{3+}$ ions, although neither details of the structure nor bond lengths have not been reported. On dehydration $\text{Sc}(\text{ClO}_4)_3 \cdot 6\text{H}_2\text{O}$ forms $\text{Sc}(\text{OH})(\text{ClO}_4)_2 \cdot \text{H}_2\text{O}$, which has a sheet structure with octahedral coordination of scandium. A number of other hydrated scandium salts of uncertain structure have been known for many years^{43–45} such as the very hygroscopic $\text{Sc}(\text{NO}_3)_3 \cdot n\text{H}_2\text{O}$ ($n = 2, 3, 4$) and $\text{Sc}(\text{BrO}_3)_3 \cdot 3\text{H}_2\text{O}$; the formulae of these complexes indicate that anion coordination is likely. However, $[\text{Sc}(\text{NO}_3)_3(\text{H}_2\text{O})_2]$ and $[\text{Sc}(\text{NO}_3)_3(\text{H}_2\text{O})_3]$ molecules, eight and nine-coordinate respectively, have been encapsulated inside crown ethers^{46–49} indicating a likely structure for the coordination sphere in the hydrated nitrate.

It was only in 1995 that the first structure of a hydrated salt of scandium containing only water molecules in its coordination sphere was reported.⁵⁰ Refluxing scandium oxide with triflic acid leads to the isolation of hydrated scandium triflate $\text{Sc}(\text{O}_3\text{SCF}_3)_3 \cdot 9\text{H}_2\text{O}$. It is isomorphous with the hydrated lanthanide triflates, containing tricapped trigonally prismatic coordinate scandium in the $[\text{Sc}(\text{H}_2\text{O})_9]^{3+}$ ions, with $\text{Sc}-\text{O}$ (vertices) = 2.171(9) Å and $\text{Sc}-\text{O}$ (face capped) 2.47(2) Å.

The fact that this structure is observed for all $\text{M}(\text{O}_3\text{SCF}_3)_3 \cdot 9\text{H}_2\text{O}$ ($\text{M} = \text{Sc}, \text{Y}, \text{La-Lu}$), irrespective of ionic radius, reflects the role of hydrogen bonding between the coordinated water molecules and the triflate groups in stabilizing the structure and has no implications for the coordination number of scandium in aqueous solution. The high coordination number of nine is the maximum yet observed for scandium.

Reaction of refluxing aqueous $\text{HC}(\text{SO}_2\text{CF}_3)_3$ with scandium oxide yields the triflide salt $[\text{Sc}(\text{OH}_2)_7](\text{C}(\text{SO}_2\text{CF}_3)_3)_3$. The crystal structure, though complicated by disorder, was solved to an R value of 0.095 and revealed⁵¹ two scandium-containing sites, with coordination geometries described as either distorted capped trigonal prismatic (80%) or distorted pentagonal bipyramid (20%). For the main site Sc—O distances fall in the range 2.113(13)–3.222(10) Å, averaging 2.17 Å. In contrast, the ytterbium analogue contains eight-coordinate $[\text{Yb}(\text{OH}_2)_8]^{3+}$ ions.

Recrystallization of the scandium halides (except the fluoride) from slightly acidified aqueous solution (to prevent the hydrolysis that could otherwise result in the hydroxy-bridged dimers discussed below) gives the hydrated salts $\text{ScX}_3 \cdot 7\text{H}_2\text{O}$ (X = Cl, Br) and $\text{ScI}_3 \cdot 8\text{H}_2\text{O}$. X-ray diffraction studies show them all to contain $[\text{Sc}(\text{OH}_2)_7]^{3+}$ ions; in the chloride and iodide, the coordination geometry is essentially pentagonal bipyramidal, whilst in the iodide there is a substantial distortion. Axial Sc—O bonds tend to be shorter than those in the pentagonal plane; thus, in the chloride, the axial Sc—O distance is 2.098 Å; the equatorial distances average 2.183 Å.⁵² In view of the tendency of many of the lanthanide halides to contain coordinated halide ions, the chlorides in particular, the absence of halide from the coordination sphere of scandium in these compounds is remarkable.

Overall then, the existence of the three scandium-containing ions $[\text{Sc}(\text{OH}_2)_x]^{3+}$ (x = 6, 7, 9) in five different solid salts indicates that in itself X-ray diffraction data on solids cannot be relied upon to indicate the coordination number in aqueous solution. Ultimately, it is the solubility of a particular salt that determines which compound crystallizes out from aqueous solution.

Three other salts where water shares the coordination sphere of scandium with anions have been studied. Yellow needles obtained⁵³ from the reaction of freshly precipitated $\text{Sc}(\text{OH})_3$ with picric acid proved to be a 1:1 adduct with picric acid, *trans*- $[\text{Sc}(\text{OH}_2)_4(\text{pic})_2](\text{pic})(\text{Hpic}) \cdot 8.2\text{H}_2\text{O}$ (Hpic = $\text{HOC}_6\text{H}_2(\text{NO}_2)_3$ -2,4,6); scandium is present as part of a six-coordinate cation, with $\text{Sc} \cdots \text{OH}_2 = 2.100(9)$, $2.102(9)$, $2.113(9)$ and $2.121(8)$ Å, and Sc—O 2.019(8), 2.046(8) Å.

In contrast, hydrated scandium tosylate, $\text{Sc}(\text{SO}_3\text{C}_6\text{H}_4\text{CH}_3)_3 \cdot 6\text{H}_2\text{O}$ contains⁵⁴ *cis*-coordinated tosylate ligands in a six-coordinate cation having the structure *cis*- $[\text{Sc}(\text{OH}_2)_4(\text{SO}_3\text{C}_6\text{H}_4\text{CH}_3)_2]^+$ with $\text{Sc} \cdots \text{OH}_2$ 2.097(4), 2.118(4), 2.119(4) and 2.132(4) Å; Sc—O 2.021(4), 2.067(4) Å. In contrast, the later lanthanides form square antiprismatic $[\text{Ln}(\text{OH}_2)_6(\text{SO}_3\text{C}_6\text{H}_4\text{CH}_3)_2]^+$ (Ln = Sm, Gd, Ho, Er, Yb, Y) cations). In the final example, $\text{ScCl}_3(\text{H}_2\text{O})_3$ molecules have been encapsulated in a cryptand ligand, rather as hydrated scandium nitrate is trapped by crown ethers. In $[\text{H}_2\text{L}] \text{mer-ScCl}_3(\text{H}_2\text{O})_3 \cdot 3\text{H}_2\text{O}$ (L = cryptand-2,2,2)⁵⁵ the $\text{Sc} \cdots \text{OH}_2$ distances are 2.078(10), 2.132(9), and 2.155(9) Å. All these six-coordinate compounds have average $\text{Sc} \cdots \text{OH}_2$ distances of around 2.11 Å; these are in line with a predicted value for $\text{Sc} \cdots \text{OH}_2$ in six coordination of 2.10–2.11 Å, extrapolating from the $\text{Ti} \cdots \text{OH}_2$ distances of 2.018–2.046 Å found⁵⁶ in the tosylate salt of the $[\text{Ti}(\text{OH}_2)_6]^{3+}$ ion, making allowance for the radius of the scandium ion being 0.075 Å greater.³

In addition to these compounds, a number of dimeric salts containing the di- μ -hydroxy bridged species $[(\text{H}_2\text{O})_5\text{Sc}(\mu\text{-OH})_2\text{Sc}(\text{H}_2\text{O})_5]^{4+}$ ions (9) have been characterized.

Attempted synthesis⁵⁷ of scandium benzene sulfonate from ScCl_3 and sodium benzene sulfonate led to the isolation of the dimer $[(\text{H}_2\text{O})_5\text{Sc}(\mu\text{-OH})_2\text{Sc}(\text{H}_2\text{O})_5](\text{C}_6\text{H}_5\text{SO}_3)_4 \cdot 4\text{H}_2\text{O}$. This contains seven-coordinate scandium with an approximately pentagonal bipyramidal coordination geometry. The axial $\text{Sc} \cdots \text{OH}_2$ bonds average 2.146 Å and the equatorial $\text{Sc} \cdots \text{OH}_2$ bonds average 3.227 Å, whilst the $\text{Sc} \cdots \text{OH}$ bridge distances of 2.072 Å are shorter than the terminal Sc—O distances of 2.111–2.125 Å in the $[\text{Sc}(\text{OH})_6]^{3-}$ ion (see Section 2.1.4.3) and certainly do not give any evidence for congestion in the coordination sphere of scandium. Crystallization of hydrated scandium chloride from *n*- and *iso*-propanol (where presumably some hydrolysis occurred) gives the related substance $[(\text{H}_2\text{O})_5\text{Sc}(\mu\text{-OH})_2\text{Sc}(\text{H}_2\text{O})_5]\text{Cl}_4 \cdot 2\text{H}_2\text{O}$ whilst the analogous $[(\text{H}_2\text{O})_5\text{Sc}(\mu\text{-OH})_2\text{Sc}(\text{H}_2\text{O})_5]\text{Br}_4 \cdot 2\text{H}_2\text{O}$ has been made from scandium bromide.⁵⁸ In these two compounds, the coordination geometry has been described as close to a monocapped trigonal prism, but most significantly the average

$\text{Sc}\cdots\text{OH}_2$ (see Table 2) and the $\text{Sc}-\text{OH}$ bond lengths are similar in all three of these dimers. An independent structure of $[(\text{H}_2\text{O})_5\text{Sc}(\mu\text{-OH})_2\text{Sc}(\text{H}_2\text{O})_5]\text{Cl}_4$ has been reported.⁵⁹

These $[(\text{H}_2\text{O})_5\text{Sc}(\mu\text{-OH})_2\text{Sc}(\text{H}_2\text{O})_5]^{4+}$ ions are significant in that they are believed to be formed in the first stage of the hydrolysis of the scandium aqua ion, and the coordination geometry involving scandium bound to seven water molecules and hydroxide ions can clearly derive from a $[\text{Sc}(\text{OH}_2)_7]^{3+}$ ion, in the way that $[(\text{H}_2\text{O})_4\text{Fe}(\mu\text{-OH})_2\text{Fe}(\text{H}_2\text{O})_4]^{4+}$ is believed to relate to the $[\text{Fe}(\text{OH}_2)_6]^{3+}$ ion.

The complex $[(\text{picolinate})_2(\text{H}_2\text{O})\text{Sc}(\mu\text{-OH})_2\text{Sc}(\text{OH}_2)(\text{picolinate})_2]$ shares with the preceding compounds double hydroxy bridges and seven-coordinate scandium.⁶⁰ Here the $\text{Sc}\cdots\text{OH}_2$ distance is 2.172(2) Å whilst the $\text{Sc}-\text{O}$ bridge distances are 2.063(2) Å and 2.080(1) Å, similar to those in the three hydroxy-bridged aqua species. The average $\text{Sc}-\text{OH}_2$ bond lengths in these four compounds that contain seven-coordinate scandium lie in the range 2.175–2.194 Å, significantly longer than in the six-coordinate complexes.

(ii) The scandium aqua ion

For many years, there was no concrete evidence for the coordination number of scandium in aqueous solution; it has been generally assumed, without any solid evidence, that the scandium aqua ion was $[\text{Sc}(\text{OH}_2)_6]^{3+}$. Possibly this was done by analogy with the ions of the succeeding transition metals, all of which form $[\text{M}(\text{OH}_2)_6]^{3+}$ ($\text{M} = \text{Ti}-\text{Co}$), yet one cogent argument against this is the fact that Sc^{3+} has an ionic radius substantially greater than that of the succeeding 3d metals (0.745 Å in six-coordination), intermediate between that of Ti^{3+} (0.670 Å) and the lanthanides ($\text{La}^{3+} = 1.032$ Å; $\text{Lu}^{3+} = 0.861$ Å). In solution, the lanthanides form $[\text{Ln}(\text{OH}_2)_9]^{3+}$ aqua ions for the early lanthanides and $[\text{Ln}(\text{OH}_2)_8]^{3+}$ aqua ions for the later ones. Purely on steric grounds, a coordination number intermediate between 6 and 8 might be predicted for scandium.

Japanese workers used vibrational spectroscopy in an important study.⁶¹ They compared the Raman spectra of acidic ($\text{pH} < 2$) solutions and glasses of $\text{Sc}^{3+}(\text{aq})$ and $\text{Al}^{3+}(\text{aq})$, the latter being a known example of six coordination, finding significant differences in both the number and polarization of bands. Glasses of $[\text{Al}(\text{OH}_2)_6]^{3+}$ show three bands (one polarized) in the region expected for metal–ligand stretching vibrations; three are predicted (ν_1 (a_{1g}), ν_2 (e_g) and ν_5 (t_{2g})) for an octahedral ion. Glasses of $\text{Sc}^{3+}(\text{aq})$ show four bands (two polarized) in the corresponding region, at 450 (p), 410, 375 and 310 (p) cm^{-1} . In contrast to the three Raman-active metal–ligand stretching vibrations of the octahedral $[\text{Sc}(\text{OH}_2)_6]^{3+}$ ion, a pentagonal bipyramidal $[\text{Sc}(\text{OH}_2)_7]^{3+}$ ion with D_{5h} local symmetry would give rise to five bands, two with a_1' symmetry that would be expected to be polarized. At the pH of the measurements, significant amounts of a dimeric ion $[(\text{H}_2\text{O})_5\text{Sc}(\mu\text{-OH})_2\text{Sc}(\text{H}_2\text{O})_5]^{4+}$ are unlikely, and in fact any species of lower symmetry would give rise to more bands. An important point is that spectra of $\text{Sc}(\text{ClO}_4)_3$ yield similar results to those obtained from the chloride, indicating that anion coordination is not significant under these conditions.

In a subsequent study from the same workers, X-ray diffraction data obtained from scandium perchlorate solutions⁶² indicated a $\text{Sc}-\text{O}$ distance of 2.180(7) Å with a coordination number of 7.4(4). The sharpness of the peak at 2.180 Å suggested that all $\text{Sc}-\text{O}$ bond lengths in the solution were comparable, rather than falling into two groups, as found in the crystal structure of the $[\text{Sc}(\text{OH}_2)_9]^{3+}$ ion. X-ray absorption fine structure (XAFS) data from scandium triflate solutions also indicate a $\text{Sc}-\text{O}$ distance of 2.18(2) Å, but no coordination number could be unambiguously obtained from the XAFS measurements, though the data were not consonant with a tricapped trigonal prismatic nine-coordinate structure. This $\text{Sc}-\text{O}$ distance of 2.18 Å, nearly 0.1 Å longer than that found for six-coordination, fits well with the Sc –water distances found in the seven-coordinate $[\text{Sc}(\text{OH}_2)_7]^{3+}$ species.

Considering all the data, it seems most likely that the predominant species present in rather acidic aqueous solution is a pentagonal bipyramidal $[\text{Sc}(\text{OH}_2)_7]^{3+}$ ion, with an average $\text{Sc}-\text{O}$ distance around 2.18 Å.

(iii) Hydroxide complexes

$\text{M}_3[\text{Sc}(\text{OH})_6]$ ($\text{M} = \text{K}, \text{Rb}$) complexes have been isolated from the reaction of scandium nitrate with amide and nitrate ions in supercritical ammonia.⁶³ X-ray diffraction studies confirm the presence of octahedral $[\text{Sc}(\text{OH})_6]^{3-}$ ions. The $\text{Sc}-\text{O}$ bond distance is 2.111(9) Å in $\text{Rb}_3[\text{Sc}(\text{OH})_6]$ and 2.120(4)–2.125(4) Å in $\text{K}_3[\text{Sc}(\text{OH})_6]$.

3.2.1.4.2 Complexes of other group 16-donor ligands

Scandium forms complexes with a wide range of polar O-donor ligands, such as pyridine N-oxide, dimethyl sulfoxide, triphenylphosphine- and arsine oxides, and hexamethylphosphoramide being examples. In general, the complexes reported have tended to fall into two main series with ScL_3X_3 typical where X is a coordinating anion like chloride and ScL_6X_3 (the norm when noncoordinating anions like perchlorate are present). Where nitrate features as a ligand, higher coordination numbers are possible, because of the small “bite” angle of bidentate nitrate group. X-ray data are still rather limited.

The structures^{1,54} of *mer*- $\text{Sc}(\text{THF})_3\text{Cl}_3$ and *mer*- $\text{Sc}(\text{H}_2\text{O})_3\text{Cl}_3$ have recently been complemented by $\text{Sc}(\text{THF})_2(\text{H}_2\text{O})\text{Cl}_3$, synthesized⁶⁴ by reaction of the stoichiometric amount of water with $\text{Sc}(\text{THF})_3\text{Cl}_3$. Compound (10) shows that the *mer*- geometry is retained; the Sc—Cl distance *trans*- to water is shorter (Sc—Cl of 2.399 Å) than the mutually *trans*-Sc—Cl distances (2.477(3) Å and 2.478(3) Å).

It did not prove possible to isolate the “missing” member of the series, $[\text{Sc}(\text{THF})(\text{H}_2\text{O})_2\text{Cl}_3]$ by the same route.

Scandium triflate reacts with Ph_3PO in ethanol forming $\text{Sc}(\text{OTf})_3(\text{Ph}_3\text{PO})_4$, (OTf = triflate) which has the structure *trans*- $[\text{Sc}(\text{OTf})_2(\text{Ph}_3\text{PO})_4]\text{OTf}$, featuring octahedrally coordinated scandium, with monodentate triflates. In $[\text{Sc}(\text{OTf})_2(\text{Ph}_3\text{PO})_4]\text{OTf}$, Sc—O (PPh_3) distances lie in the range 2.051(2)–2.090(2) Å, with Sc—O(Tf) 2.111(2) Å and 2.138(2) Å. It has some catalytic activity for reactions like the nitration of anisole, but less than that of the hydrated scandium triflate.⁶⁵

Numerous scandium nitrate complexes with phosphine oxides, $[\text{Sc}(\text{NO}_3)_3(\text{Ph}_3\text{PO})_2]$, $[\text{Sc}(\text{NO}_3)_2(\text{Ph}_2\text{MePO})_4](\text{NO}_3)$, $[\text{Sc}(\text{NO}_3)_3(\text{Ph}_2\text{MePO})_2]$, $[\text{Sc}(\text{NO}_3)_3(\text{Me}_3\text{PO})_2(\text{EtOH})]$, and $[\text{Sc}(\text{Me}_3\text{PO})_6](\text{NO}_3)_3$ have been synthesized.⁶⁶ $[\text{Sc}(\text{NO}_3)_3(\text{Ph}_3\text{PO})_2]$ has an eight-coordinate structure with symmetrically bidentate nitrates; Sc—O(PPh_3) being 2.047–2.068(7) Å and Sc—O (nitrate) lying in the range 3.205(8)–2.311(7) Å. This complex is obtained from all stoichiometries of reaction mixture, but with Ph_2MePO , two different complexes can be made. With a 1:1 or 2:1 molar ratio, $[\text{Sc}(\text{NO}_3)_3(\text{Ph}_2\text{MePO})_3]$ is obtained, which appears to have all nitrates coordinated, although it is not clear if they are all bidentate. With a 4:1 (or higher) ligand:scandium ratio, the product is $\text{Sc}(\text{NO}_3)_3(\text{Ph}_2\text{MePO})_4$. In solution, it gives a broad resonance in the ^{31}P -NMR spectrum at room temperature, which separates on cooling into separate signals characteristic of $\text{Sc}(\text{NO}_3)_3(\text{Ph}_2\text{MePO})_4$ and $\text{Sc}(\text{NO}_3)_3(\text{Ph}_2\text{MePO})_3$. In the solid state, it has the structure $[\text{Sc}(\text{NO}_3)_2(\text{Ph}_2\text{MePO})_4](\text{NO}_3)$, again with symmetrically bidentate nitrates; Sc—O(P) being 2.088–2.099(6) Å and Sc—O (nitrate) lying in the range 2.311(6)–2.425(6) Å, the nitrate groups being *trans*- to each other. Reaction of scandium nitrate with a large excess of Me_3PO results in $[\text{Sc}(\text{Me}_3\text{PO})_6](\text{NO}_3)_3$, the IR spectra of which indicate only ionic nitrate groups; there is NMR evidence of it dissociating to a species such as $[\text{Sc}(\text{Me}_3\text{PO})_5(\text{NO}_3)](\text{NO}_3)_2$ in solution in the absence of excess ligand. $[\text{Sc}(\text{NO}_3)_3(\text{Me}_3\text{PO})_2(\text{EtOH})]$ is obtained from scandium nitrate and Me_3PO reacting in a 1:12 ratio in ethanol.

In contrast to the reaction with Ph_3PO , where only $[\text{Sc}(\text{NO}_3)_3(\text{Ph}_3\text{PO})_2]$ can be isolated, Ph_3AsO forms 2:1 and 3:1 complexes.⁶⁷ Reaction between scandium nitrate and Ph_3AsO in acetone gives $[\text{Sc}(\text{NO}_3)_3(\text{Ph}_3\text{AsO})_2]$, whilst reaction in ethanol affords $\text{Sc}(\text{NO}_3)_3(\text{Ph}_3\text{AsO})_3$, shown by X-ray diffraction to be seven-coordinate $[\text{Sc}(\text{NO}_3)_2(\text{Ph}_3\text{AsO})_3]\text{NO}_3$. The polyhedron can be regarded as derived from a trigonal bipyramid, if the coordinated bidentate nitrates (which lie in the equatorial plane) are thought of as occupying a single site. Sc—O nitrate distances fall in the range 3.250–3.267 Å. The equatorial Sc—O distance is 1.999 Å and the axial ones 1.996–2.030 Å. Addition of further Ph_3AsO does not displace any more nitrate groups. On reaction between scandium nitrate and Me_3AsO in cold ethanol, $[\text{Sc}(\text{Me}_3\text{AsO})_6](\text{NO}_3)_3$ is obtained; the cation has octahedrally coordinated scandium with Sc—O in the range 2.064–2.100 Å. There is evidence for nitrates entering the coordination sphere in solution in the absence of excess Me_3AsO .⁵⁵ Scandium NMR spectroscopy has been successfully applied to these nitrate complexes.

Several halide complexes have been isolated in the solid state,⁶⁸ namely $[\text{ScCl}(\text{Me}_3\text{PO})_5]\text{Cl}_2$, $[\text{Sc}(\text{Me}_3\text{PO})_6]\text{X}_3$ ($\text{X} = \text{Br}, \text{I}$), $[\text{ScX}_2(\text{Ph}_3\text{PO})_4]\text{X}$, $[\text{ScX}_2(\text{Ph}_3\text{AsO})_4]\text{X}$ ($\text{X} = \text{Cl}, \text{Br}, \text{I}$), $[\text{Sc}(\text{Me}_3\text{AsO})_6]\text{X}_3$ ($\text{X} = \text{Cl}, \text{Br}, \text{I}$), $[\text{ScCl}_3(\text{Ph}_2\text{MePO})_3]$, and $[\text{ScBr}_2(\text{Ph}_3\text{MePO})_4]\text{Br}$, whilst others have been identified in solution by multinuclear NMR. The structure of *trans*- $[\text{ScBr}_2(\text{Ph}_3\text{PO})_4]\text{Br}$ shows a linear $\text{Br}-\text{Sc}-\text{Br}$ arrangement with typical $\text{Sc}-\text{O}$ distances of approximately 2.07 Å, and $\text{Sc}-\text{Br}$ of 2.652(1) Å and 2.661(1) Å. *trans*- $[\text{ScCl}_2(\text{Ph}_3\text{AsO})_4]\text{Cl}$ similarly has an octahedral geometry at scandium, with $\text{Sc}-\text{O}$ in the range 2.059–2.089(7) Å and $\text{Sc}-\text{Cl}$ distances, at 2.545 Å and 2.562(4) Å, rather long in comparison with $\text{Sc}-\text{Cl}$ distances in other chloro complexes like $[\text{ScCl}_3(\text{THF})_3]$. $[\text{Sc}(\text{Me}_3\text{AsO})_6]\text{Br}_3$ has $\text{Sc}-\text{O}$ distances in the range 2.08(2)–2.11(2) Å, closely comparable with those in the nitrate salt. The picture that emerges from these studies is one in which chloride has a considerably greater affinity for Sc^{3+} than do the heavier halogens.

Reaction of anhydrous scandium triflate with HMPA gives $\text{Sc}(\text{HMPA})_4(\text{CF}_3\text{SO}_3)_3$, which contains *trans*- $[\text{Sc}(\text{HMPA})_4(\text{CF}_3\text{SO}_3)_2]^+$ ions, similar compounds being formed by most lanthanides (Ce–Lu).⁶⁹ Though $\text{Sc}-\text{O}$ bond lengths have not been published, it was reported that the $\text{P}-\text{O}$ bond length is relatively long compared to those in most of the lanthanide compounds, a possible reflection of the strength of the $\text{Sc}-\text{O}$ bond.

Unlike the lanthanides, which form tetrahydro-2-pyrimidone (pu) complexes $[\text{Lnpu}_8](\text{CF}_3\text{SO}_3)_3$ with square antiprismatic eight-coordination, scandium yields $[\text{Scpu}_6](\text{CF}_3\text{SO}_3)_3$, which unexpectedly has trigonal antiprismatic coordination of scandium, possibly partly induced by side-on interactions between pairs of pu ligands.⁷⁰ Complexes with various N-oxides $\text{ScL}_6(\text{CF}_3\text{SO}_3)_3$ ($\text{L} = \text{pyridine N-oxide}, 2\text{-picoline N-oxide}, 3\text{-picoline N-oxide}, 4\text{-picoline N-oxide}$) and $\text{ScL}_5(\text{H}_2\text{O})(\text{CF}_3\text{SO}_3)_3$ have been synthesized, all of these presumably contain octahedrally coordinated scandium.⁷¹

Six- and seven-coordination is found in the scandium picrate complex of *trans*-1,4-dithiane-1,4-dioxide (TDHD), $[\text{Sc}_6(\text{pic})_6(\text{TDHD})_3(\text{OH})_{10}(\text{H}_2\text{O})_2](\text{pic})_2(\text{H}_2\text{O})_{10}$ which has hexameric clusters of scandium ions, joined by TDHD bridges.⁷² Four of the scandiums are six-coordinate and two are seven-coordinate. Complexes with naphthyridine N-oxide (napyo) have been synthesized.⁷³ Those reported are $\text{Sc}(\text{napyo})_2(\text{NO}_3)_3$, $\text{Sc}(\text{napyo})_4(\text{ClO}_4)_3$, $\text{Sc}(\text{napyo})_4(\text{NCS})_3$, and $\text{Sc}(\text{napyo})_3\text{Cl}_3$; these are respectively 1:1, 1:3, 1:3, and non-electrolytes in solution. The chloride is thus presumably six-coordinate, but no diffraction data are reported. 1,10-Phenanthroline N-oxide complexes $\text{Sc}(\text{phenNO})_4(\text{NCS})_3$ and $\text{Sc}(\text{phenNO})_3\text{Cl}_3$, with presumably similar structures, have also been made.⁷⁴ Octahedral coordination is found in $[\text{ScCl}_3(\text{DME})(\text{MeCN})]$ and $[\text{ScCl}_3(\text{diglyme})]$.⁷⁵

The coordination of the nitrate groups in the complexes of phosphine and arsine oxides already discussed is generally symmetrically bidentate. However, in $\text{Rb}_2[\text{Sc}(\text{NO}_3)_5]$ there are three bidentate and two monodentate nitrates,⁷⁶ resulting in eight-coordination for scandium, in contrast to $(\text{NO}^+)_2[\text{Sc}(\text{NO}_3)_5]^{2-}$, where one monodentate and four bidentate nitrates give nine-coordinate scandium.⁷⁷

3.2.1.4.3 Alkoxides

Scandium alkoxides represent a class of compound as yet with poorly characterized structures. Attempted synthesis of the isopropoxide $\text{Sc}(\text{OPr}^i)_3$ results in the production⁷⁸ of a pentanuclear compound $[\text{Sc}_5\text{O}(\text{OPr}^i)_{13}]$, similar to those formed by yttrium, ytterbium, and indium. It has the structure $[\text{Sc}_5(\mu_5\text{O})(\mu_3\text{-OPr}^i)_4(\mu_2\text{-OPr}^i)_4(\text{OPr}^i)_5]$. Anodic oxidation of scandium in aliphatic alcohols has been used as a pathway to scandium alkoxides $[\text{Sc}(\text{OR})_3]$ ($\text{R} = \text{Me}, \text{Et}$) and $[\text{Sc}_5\text{O}(\text{OPr}^i)_{13}]$.⁷⁹ The elusive structure of the methoxide $[\text{Sc}(\text{OMe})_3]$ is not yet known but it does appear not to contain an oxo ligand, and to be a polymer. Alcoholysis of $[\text{Sc}_5\text{O}(\text{OPr}^i)_{13}]$ leads to $[\text{Sc}(\text{OR})_3]$ ($\text{R} = \text{Me}, \text{Et}, \text{Bu}^n$), $[\text{Sc}_5\text{O}(\text{OBu}^s)_{13}]$, and $[\text{Sc}_5\text{O}(\text{OPr}^i)_8(\text{OBu}^i)_5]$. Some scandium alkoxo-aluminates $[\text{Sc}(\text{Al}(\text{OR})_4)_3]$ ($\text{R} = \text{Et}, \text{Bu}^n$) have also been reported.

3.2.1.4.4 Diketonates and other chelating ligands

Since the determination² of the structure of tris(acetylacetonato)scandium ($\text{Sc}-\text{O}$ of 2.061–2.082 Å, average $\text{Sc}-\text{O}$ 2.070(9) Å), several other diketonates have been examined, though no detailed structures have been reported. The compound *mer*- $[\text{Sc}(\text{CF}_3\text{COCHCOCH}_3)_3]$ is isostructural with the aluminium, gallium, rhodium, and iridium analogues,⁸⁰ as well as those of the 3d metals V–Co whilst the dipivaloylmethanide $[\text{Sc}(\text{Me}_3\text{COCHCOMe}_3)_3]$ is isostructural with the iron and indium analogues.⁸¹ Scandium α -diketonates such as $[\text{Sc}(\text{tropolonate})_3]$ form adducts in

solution with trioctylphosphine oxide (TOPO); β -diketonates like $[\text{Sc}(\text{acac})_3]$ do not.⁸² In the gas phase, $[\text{Sc}(\text{acac})_3]$ has C_3 symmetry, in contrast to the D_3 symmetry in the crystal.⁸³

Scandium β -diketonates $[\text{Sc}(\text{tmod})_3]$ and $[\text{Sc}(\text{mhd})_3]$ (tmod = 2,2,7-trimethyloctane-3,5-dionate; mhd = 6-methylheptane-2,4-dionate) have been studied as liquid-injection MOCVD precursors for Sc_2O_3 with a view to their use in the synthesis of the pyroelectric material $\text{Pb}(\text{Sc}_{0.5}\text{Ta}_{0.5})\text{O}_3$ (PST).⁸⁴ Acetylpyrazolones also act as chelating ligands. In a comparative study of the coordinating ability of the ligand HPMTFP (1-phenyl-3-methyl-4-trifluoroacetyl-pyrazolone-5),⁸⁵ it was found that scandium formed a seven-coordinate adduct $[\text{Sc}(\text{PMTFP})_3(\text{OPPh}_3)]$ whilst neodymium forms the eight-coordinate $[\text{Nd}(\text{PMTFP})_3(\text{OPPh}_3)_2]$. (The Sc—OP distance quoted in the paper (1.198 Å) appears to be in error; other Sc—O distances are in the range 2.12–3.27 Å.)

3.2.1.4.5 Crown ether complexes and related systems

Although some crown ether complexes of scandium were made at the time that the lanthanide complexes were first made, it is only recently that they have been investigated systematically and definitive structural information has become available, mainly due to Willey and co-workers.^{55,86,89–92}

Resemblance to the lanthanides extends to the existence of two series; “inner sphere” complexes exist in which scandium is bound directly to the oxygens in the crown ether ring, whilst in a second class, a crown ether is present in the second coordination sphere of the scandium, hydrogen-bonded to a scandium aqua-species. Scandium nitrate imitates the later lanthanide nitrates in only forming “outer sphere” complexes with the larger rings such as 18-crown-6, although it seems possibly that scandium nitrate might complex directly with a small crown like 12-crown-4, but this does not seem to have been explored.

Although the structure of hydrated scandium nitrate itself has not been reported, both 8- and 9-coordinate $[\text{Sc}(\text{NO}_3)_3(\text{H}_2\text{O})_2]$ and $[\text{Sc}(\text{NO}_3)_3(\text{H}_2\text{O})_3]$ molecules have been encapsulated by crown ethers, and several structures have been reported for such “outer sphere” complexes.^{43–49} In the $[[\text{Sc}(\text{NO}_3)_3(\text{H}_2\text{O})_3] \cdot 18\text{-crown-6}]$ complex, Sc—O(water) distances are 2.120(6), 3.221(6), and 2.303(15) Å, whilst the Sc—O(nitrate) distances of 3.227(6), 3.240(17), 3.243(5), 2.342(7), 2.348(16), and 2.366(7) Å show similar trends. In contrast, the Sc \cdots OH₂ distances in $[\text{Sc}(\text{NO}_3)_3(\text{H}_2\text{O})_2] \cdot 15\text{-crown-5}$ are 2.120 and 2.143 Å, whilst the Sc—O (ether) distances span a range of 2.195–3.245 Å. Similarly, in $[\text{Sc}(\text{NO}_3)_3(\text{H}_2\text{O})_2] \cdot \text{benzo-15-crown-5}$, the Sc \cdots OH₂ distances are 2.123(3) and 2.143(3) Å, and the Sc—O (ether) distances range from 2.158(3) to 3.248(3) Å. It can be seen that the Sc—O bond lengths in the nine-coordinate $[\text{Sc}(\text{NO}_3)_3(\text{H}_2\text{O})_3]$ complex span a wider range than in the $[\text{Sc}(\text{NO}_3)_3(\text{H}_2\text{O})_2]$ complexes, suggesting that there is some steric congestion here, and comparison of the Sc \cdots O (H₂O) distances indicates that the third water molecule in $[[\text{Sc}(\text{NO}_3)_3(\text{H}_2\text{O})_3] \cdot 18\text{-crown-6}]$ is loosely held.

In contrast, a cryptand ligand has been used⁵⁵ to encapsulate and isolate a mixed aqua/chloro species in $[\text{H}_2\text{L}] \text{ mer-ScCl}_3(\text{H}_2\text{O})_3 \cdot 3 \text{ H}_2\text{O}$ (L = cryptand-2,2,2). The scandium-containing species has Sc—O 2.078(10), 2.132(9) and 2.155(9) Å with Sc—Cl 2.413(6), 2.419(4), and 2.419(5) Å, and is closely comparable to the familiar *mer-ScCl*₃(THF)₃.

Direct scandium–crown ether complexation could give rise to two types of complex, firstly “extra-cavity” complexes, in which the coordinated scandium lies outside the ligand cavity, in a kind of half-sandwich structure, and secondly “intra-cavity” complexes, where scandium fits into the cavity within the crown ether ring. To date, the latter are more common, and generally feature a ScCl_2 moiety threaded through the ligand cavity. A ⁴⁵Sc-NMR study of crown ethers led to the characterization of $[\text{ScCl}_2(\text{crown})]^+$ (crown = 15-crown-5, dibenzo-24-crown-8, dibenzo-30-crown-10, 1-aza-15-crown-5, and 1-aza-18-crown-6) whilst $[\text{ScCl}_2(12\text{-crown-4})]^+$ and $[\text{Sc}(12\text{-crown-4})_2]^+$ have both been established.⁸⁶ Reaction of $\text{ScCl}_3(\text{MeCN})_3$ with 15-crown-5 affords a 1:1 complex.⁸⁷ No structural information is available, but it might have a half-sandwich molecular structure $[\text{ScCl}_3(15\text{-crown-5})]$ or alternatively be $[\text{ScCl}_2(15\text{-crown-5})]^+\text{Cl}^-$. However, in the presence of CuCl_2 , the “threaded” complex $\{[\text{ScCl}_2(15\text{-crown-5})]^+\}_2[\text{CuCl}_4^{2-}]$ is obtained. The cation (11) has pentagonal bipyramidal seven-coordination of scandium; five oxygens form an approximately planar equatorial belt with a near linear (176.4–179.8°) Cl—Sc—Cl unit threaded through the crown ether ring roughly at right angles to the O₅ plane, with Sc—O distances falling into a narrow range of 2.09–2.15 Å. Here CuCl_2 has acted as a halide ion abstractor, making it possible for insertion of the ScCl_2 moiety into the crown ether cavity.

Quite independently, a systematic study has explored the reaction of SbCl_5 as a chloride ion extractor with acetonitrile solutions of $\text{ScCl}_3(\text{THF})_3$. This generates a solvated $[\text{ScCl}_2]^+$ unit,

which reacts with the crown ether, replacing the weakly coordinated nitrile (and THF) ligands (see Scheme (3)).

Scheme 3

Reaction of $\text{ScCl}_3(\text{THF})_3$ with SbCl_5 in the absence of crown ether affords $[\text{ScCl}_2(\text{THF})_4]^+[\text{SbCl}_5(\text{thf})]^-$; in contrast, Y and La form $[\text{MCl}_2(\text{THF})_5]^+[\text{SbCl}_5(\text{THF})]^-$ ($\text{M} = \text{Y}, \text{La}$).⁸⁸

The first crown ether complex made by this route to be reported⁸⁹ was $[\text{ScCl}_2(18\text{-crown-6})]^+[\text{SbCl}_6]^-$. The crystal structure of this compound shows that one oxygen atom in the crown ether remains uncoordinated to the metal, confirming the preference of scandium for pentagonal bipyramidal coordination; Sc—O distances fall in the range 2.190–3.229 Å. Subsequently, the related $[\text{ScCl}_2(\text{crown})]^+[\text{SbCl}_6]^-$ (crown = 15-crown-5,⁹⁰ benzo-15-crown-5,⁹⁰ and dibenzo-18-crown-6⁹¹) complexes have been isolated; all are believed to have a pentagonal bipyramidal coordination geometry, which has been confirmed crystallographically for the benzo-15-crown-5 complex.

In contrast, the 1.8 Å diameter of the cavity in the tetradentate 12-crown-4 ring is too small for a $[\text{ScCl}_2]^+$ ion to fit, so an “extra-cavity” (half-sandwich) structure (12) has been suggested for $[\text{ScCl}_2(12\text{-crown-4})(\text{MeCN})]^+[\text{SbCl}_6]^-$, though no diffraction data are available. Unlike the “intra-cavity” crown ether complexes already mentioned, a MeCN is believed to coordinate, again reflecting scandium’s preference for seven-coordination.⁹⁰

Larger oxacrown rings have more donor atoms and are also more flexible. Reaction of $\text{ScCl}_3(\text{THF})_3$ and 1 mole of SbCl_5 with 1 mole of a larger crown ether affords the complexes $[\text{ScCl}_2(\text{dibenzo-24-crown-8})(\text{H}_2\text{O})]^+ \text{SbCl}_6^- \cdot 2\text{MeCN}$ and $[\text{ScCl}_2(\text{dibenzo-30-crown-10})(\text{H}_2\text{O})_2]^+ \text{SbCl}_6^- \cdot \text{MeCN} \cdot \text{H}_2\text{O}$. Both cations again feature seven-coordinate scandium in a pentagonal bipyramidal environment.⁹¹ The water molecules (probably arising from either charcoal or solvent used in recrystallization) play an important role in the structure, apart from coordinating to the metal, they also hydrogen-bond to oxygens in the crown ether that are not coordinated to scandium. Whereas a smaller crown ether like 18-crown-6, not to mention 15-crown-5 or benzo-15-crown-5, can occupy five equatorial sites round scandium with little ring distortion and concomitant strain, this

is not possible for the larger ethers with eight or ten oxygens in the ring. It should also be noted that whilst the dibenzo-30-crown-10 ligand has a large enough cavity to accommodate two scandium ions, it does not do so. The scandium–water distances in these compounds are intermediate in length between those found in the six and seven-coordinate aqua complexes, probably because the macrocyclic ligands have the flexibility to ensure a small “bite” for each donor atom.

Use of excess SbCl_5 permits the extraction of further chlorides from the crown ether complexes.⁹¹ Thus reaction of $[\text{ScCl}_3(\text{THF})_3]$ in MeCN with 3 moles of SbCl_5 and dibenzo-18-crown-6 leads to the complex $[\text{ScCl}(\text{dibenzo-18-crown-6})(\text{MeCN})]^{2+}(\text{SbCl}_6^-)_2$; this reacts with a large excess of SbCl_5 forming a species identified by NMR as $[\text{Sc}(\text{dibenzo-18-crown-6})(\text{MeCN})_2]^{3+}$.

Another route to complete halide extraction involves the use of SbCl_5 and SbCl_3 together (see Scheme (4)). The cation contains a Sc^{3+} ion sandwiched between two 12-crown-4 molecules in approximately square antiprismatic eight-coordination with Sc–O distances in the range 2.160(8)–3.274(9) Å, averaging 3.212 Å.⁹²

Scheme 4

The structure of a di- μ -oxo bridged calix[3]arene complex has been reported⁹³ whilst other complexes have been isolated with *p-t*-butylcalix[*n*]arenes ($n = 4, 6, 8$). *p-t*-Butylcalix[4]arene forms a 2:1 complex whilst *p-t*-butylcalix[6]arene and *p-t*-butylcalix[8]arene form 1:1 complexes, but these compounds at present lack structural characterization.⁹⁴

3.2.1.5 Mixed Group 15 and 16 Donors

In contrast with the lanthanides and the 3*d* metals, until recently no structure had been reported of a complex of scandium with either EDTA or DTPA (DTPA = diethylenetriaminepentaacetic acid). $\text{NH}_4[\text{Sc}(\text{EDTA})(\text{H}_2\text{O})_2] \cdot 3\text{H}_2\text{O}$ has eight-coordinate scandium.⁹⁵ In this compound, EDTA is, as might be expected, hexadentate, whilst there are two coordinated water molecules, in contrast to the norm of one for 3*d* metals such as Fe^{3+} (but fewer than for the early lanthanides, again in line with expectations based on ionic radii). Bond lengths are 2.1434, 2.1440, 2.1464, 2.1665, 3.2514, and 3.2848 Å (Sc–O) and 2.4568 and 2.4582 Å (Sc–N). The scandium–oxygen bond lengths involving the coordinated water molecules (3.25–3.28 Å) are similar to those in aqua species mentioned in Section 3.2.1.4.1. Eight-coordinate scandium is also found in the structure of $\text{MnSc}(\text{DTPA}) \cdot 4\text{H}_2\text{O}$, which has octadentate DTPA occupying the coordination sphere of scandium with no coordinated water molecules,⁹⁶ in contradistinction to the nine-coordinate magnetic resonance imaging (MRI) contrast agent $[\text{Gd}(\text{DTPA})(\text{H}_2\text{O})]^{2-}$; scandium is bound to five oxygens (Sc–O 2.116(3)–2.197(3) Å) and three nitrogens (Sc–N 2.377(3)–2.489(3) Å), the distances being similar to those in the EDTA complex.

These two compounds nicely illustrate the tendency of Sc^{3+} to adopt coordination numbers intermediate between those of the M^{3+} ions in the first transition series and those found for the Ln^{3+} ions.

3.2.1.6 Complexes of Group 17 Ligands

3.2.1.6.1 Binary halides and simple complexes

Although the binary halides in the solid state all have giant structures⁶ (all but the fluoride (WO_3 structure) having the FeCl_3 (BiI_3) structure), they exhibit molecular structures in the gas phase and many complexes are known.

A neutron-diffraction refinement of the ScCl_3 structure (using ScCl_3 prepared by reductive chlorination of Sc_2O_3 at 900°C) gives an average Sc—Cl distance of 2.52 Å (Sc—Sc 3.68 Å).⁹⁷

In the gas phase, most recent electron-diffraction data at 1,750 K indicate isolated ScF_3 molecules to be planar or nearly so⁹⁸ with Sc—F = 1.847 Å; studies on ScI_3 indicate⁹⁹ the presence of both monomers and dimers in the vapor at 1,050 K; the monomers have Sc—I 2.62 Å with a I—Sc—I angle of $117(3)^\circ$. Most recently, density functional theory calculations¹⁰⁰ on ScCl_3 and Sc_2Cl_6 dimers favor a planar D_{3h} monomeric structure for the former (Sc—Cl 3.285 Å) and a D_{2h} dichloro-bridged structure for the dimer with Sc—Cl (terminal) of 3.260 Å and Sc—Cl of 2.475 Å. Electron-diffraction studies on ScCl_3 vapor indicate a slight distortion to a C_{3v} pyramidal structure having Sc—Cl of 3.291 Å and Cl—Sc—Cl angle of 119.8° ; in comparison with six-coordinate ScCl_3 in the solid state, the shorter Sc—Cl bond lengths in the three- and four-coordinate vapor phase species are to be expected.

KScF_4 has a layered structure¹⁰¹ in which scandium acquires six-coordination by edge-sharing alternate *cis*- and *trans*- corners with Sc—F terminal bond lengths in the range 1.941–1.983 Å and bridging distances of 2.009–2.038 Å. Na_3ScF_6 has the cryolite structure¹⁰² with an average Sc—F distance of 2.007 Å. High-pressure studies of Na_3ScF_6 (cryolite structure) indicate little change in the octahedral coordination of scandium up to 27.9 kbar.¹⁰³ Sr_2ScF_7 has seven-coordinate scandium, however.¹⁰⁴ Rb_2KScF_6 , synthesized by heating stoichiometric amounts of RbF , KF , and ScF_3 at 700°C , exists in three different crystalline forms.¹⁰⁵ The lowest temperature (monoclinic) form has a structure related to cryolite; on warming to 223 K, it transforms to a tetragonal structure and on further warming to 252 K changes to a cubic elpasolite structure. K_2NaScF_6 also has the cubic elpasolite structure.¹⁰⁶ Ba_2ScCl_7 , synthesized from a 1:1 molar mixture of BaCl_2 and ScCl_3 at 580°C , has the structure $\text{Ba}_2[\text{ScCl}_6]\text{Cl}$ in which the Sc—Cl bond lengths in the octahedral anion fall in the range 2.42–2.52 Å (average 2.48 Å).¹⁰⁷ Na_3ScCl_6 , made by heating NaCl and ScCl_3 together in a stoichiometric ratio, has the cryolite structure and is isotopic with Na_3LnCl_6 ($\text{Ln} = \text{Dy-Lu, Y}$)¹⁰⁸ whilst $\text{Cs}_2\text{LiScCl}_6$ has the elpasolite structure with Sc—Cl of 2.476–2.481 Å.¹⁰⁶ Heating a 1:1 mixture of NaCl and ScCl_3 together at 630°C affords NaScCl_4 , isostructural with NaLuCl_4 ; Na^+ and Sc^{3+} ions occupy 1/4 of the octahedral sites between the layers of chloride ions, the structure being made up of *cis*-edge-sharing ScCl_6 octahedra.¹⁰⁹ Reaction of lanthanide oxides with NH_4Cl is a classic route to anhydrous lanthanide chlorides; DTA study of the reaction of Sc_2O_3 with NH_4Cl indicates that $(\text{NH}_4)_3\text{ScCl}_6$, $(\text{NH}_4)_2\text{ScCl}_5(\text{H}_2\text{O})$, and $(\text{NH}_4)_3\text{Sc}_2\text{Cl}_9$ are formed as intermediates.¹¹⁰

Na_3ScBr_6 has the Na_3CrCl_6 structure.¹¹¹ Study of the CsI-ScI_6 phase diagram identified the compounds Cs_3ScI_6 and $\text{Cs}_3\text{Sc}_2\text{I}_9$, whilst ScI_4^- ions are believed to exist in the molten phase.¹¹² Raman spectra of the vapor over CsI-ScI_3 melts exhibited bands at 127 and 153 cm^{-1} , assigned to stretching vibrations in CsScI_4 and ScI_3 molecules respectively, whilst Sc—I stretching frequencies of 119 cm^{-1} and 129 cm^{-1} have been assigned to ScI_6^{3-} and ScI_4^- ions respectively.

3.2.1.6.2 Other halide complexes

The reduced chlorides, ScCl , Sc_5Cl_8 , $\text{Sc}_7\text{Cl}_{10}$, $\text{Sc}_7\text{Cl}_{12}$, synthesized by chemical transport reactions from Sc/ScCl_3 mixtures, have been well established for years and have been reviewed.¹¹³ They mostly contain chains of edge-sharing octahedra, with $\text{Sc}_6\text{Cl}_{12}^{3-}$ octahedra in $\text{Sc}_7\text{Cl}_{12}$. Sc_2Br_3 is also known. Some attention has now been given to iodides. The metallic diiodide is the only intermediate in the Sc/ScI_3 system,¹¹⁴ it is readily prepared by the reaction of Sc with ScI_3 in the range $550\text{--}870^\circ\text{C}$. The actual composition of the compound is $\text{Sc}_{0.93}\text{I}_2$; it has a cation-deficient CdI_2 structure, with Sc—I of 2.934 Å. In the field of iodide complexes, reaction of Sc , ScI_3 , and LiI or NaI at $750\text{--}850^\circ\text{C}$ has been found to give the intensely air-sensitive LiScI_3 and $\text{Na}_{0.5}\text{ScI}_3$.¹¹⁵ Both contain chains of confacial octahedra. LiScI_3 has essentially undistorted ScI_6 trigonal antiprisms (with Sc—I 2.91 Å) centered upon scandium atoms (Sc—Sc 3.384 Å) as in the previously established RbScX_3 ($\text{X} = \text{Cl, Br}$) and CsScX_3 ($\text{X} = \text{Cl, Br, I}$). $\text{Na}_{0.5}\text{ScI}_3$, however, has some pairing of the scandiums; alternate Sc—Sc distances are 3.278 and 3.572 Å; the larger average Sc—Sc separation reflects reduction in bonding electron population compared with LiScI_3 . LiScI_3 is weakly paramagnetic and $\text{Na}_{0.5}\text{ScI}_3$ has a small temperature-independent paramagnetism.¹¹⁶

Metallothermic reduction of ScCl_3 by caesium in the presence of carbon gives $\text{Cs}_4[\text{Sc}_6\text{C}]\text{Cl}_{13}$;¹¹⁷ it contains an isolated Sc_6C cluster surrounded by 18 bridging chlorides. Heating ScI_3 and MI_2 ($\text{M} = \text{Co, Ni}$) with scandium at $750\text{--}950^\circ\text{C}$ gives clusters $\text{Sc}_7\text{MI}_{12}$ having a $\text{Sc}(\text{Sc}_6\text{MI}_{12})$ structure. Other clusters $\text{Sc}(\text{Sc}_6\text{XCl}_{12})$ ($\text{X} = \text{B, N}$) and $\text{Sc}(\text{Sc}_6\text{YI}_{12})$ ($\text{Y} = \text{B, C}$) have also been reported.¹¹⁸

Table 2 A summary of key properties of the lanthanides, transition metals, and Group I metals.

	<i>4f</i>	<i>3d</i>	<i>Group I</i>
Electron configurations of ions	Variable	Variable	Noble gas
Stable oxidation states	Usually +3	Variable	1
Coordination numbers in complexes	Commonly 8–10	Usually 6	Often 4–6
Coordination polyhedra in complexes	Minimise repulsion	Directional	Minimise repulsion
Trends in coordination numbers	Often constant in block	Often constant in block	Increase down group
Donor atoms in complexes	“Hard” preferred	“Hard” and “soft”	“Hard” preferred
Hydration energy	High	Usually moderate	Low
Ligand exchange reactions	Usually fast	Fast and slow	Fast
Magnetic properties of ions	Independent of environment	Depends on environment and ligand field	None
Electronic spectra of ions	Sharp lines	Broad lines	None
Crystal field effects in complexes	Weak	Strong	None
Organometallics in Low oxidation states	Few	Common	None
Multiply bonded atoms in complexes	None	Common	None

3.2.2 YTTRIUM AND THE LANTHANIDES

3.2.2.1 Introduction

The lanthanides exhibit a number of features in their chemistry that differentiate them from the *d*-block metals:

- (i) A wide range of coordination numbers (generally 6–12, but numbers of 2–4 are known).
- (ii) Coordination geometries are determined by ligand steric factors rather than crystal field effects.
- (iii) They generally form labile “ionic” complexes that undergo facile exchange of ligand (though when multidentate complexing agents like DTPA are used, high stability constants obtain).
- (iv) The *4f* orbitals in the Ln^{3+} ion do not participate directly in bonding. Their spectroscopic and magnetic properties are thus largely uninfluenced by the ligand.
- (v) Small crystal-field splittings and very sharp electronic spectra in comparison with the *d*-block metals.
- (vi) They prefer anionic ligands with donor atoms of rather high electronegativity (e.g., O, F).
- (vii) They readily form hydrated complexes (on account of the high hydration energy of the small Ln^{3+} ion) and this can cause uncertainty in assigning coordination numbers.
- (viii) Insoluble hydroxides precipitate at neutral pH unless complexing agents are present.
- (ix) The chemistry is largely that of one (3+) oxidation state.
- (x) They do not form $\text{Ln}=\text{O}$ or $\text{Ln}\equiv\text{N}$ multiple bonds of the type known for many transition metals and certain actinides.

A summary of key properties of the lanthanides, transition metals, and Group 1 and 2 metals appears in Table 2.

Since the appearance of the previous review in this series,⁵ there have appeared three textbooks with a substantial content of lanthanide chemistry^{119–121} as well as a review (to late 1992) summarizing the coordination chemistry of scandium, yttrium, and the lanthanides⁶ as well as a text covering many important areas of lanthanide chemistry.¹²² Other books have appeared with valuable preparative details of both starting materials and key compounds¹²³ and reviews of important areas extending into

coordination chemistry,^{124,125} applications of lanthanides in synthetic organic chemistry,^{126,127} the biochemistry of the elements¹²⁸ and various historical perspectives.¹²⁹

The burgeoning growth in lanthanide chemistry within the last 20 years has many reasons, but three areas responsible for this may be mentioned. Interest in mixed-oxide “warm superconductors” from the late 1980s has stimulated research in volatile materials such as alkoxides and diketonates; medicinal applications including magnetic resonance imaging agents has driven work with complexes of poly(aminocarboxylate) complexes; the increasing use of reagents such as SmI₂ as a one-electron reductant; and lanthanide triflates as Lewis acids in synthetic organic chemistry.

3.2.2.2 Group 14 Ligands

3.2.2.2.1 Alkyls

Reaction of lanthanide trichlorides with LiCH(SiMe₃)₂ tends to result in the formation of chlorine-containing complexes (see Scheme (5)). A different synthetic route, eliminating the presence of halide, has been adopted to synthesize [Ln{CH(SiMe₃)₂}]₃, involving replacement of aryloxide groups in [Ln(OC₆H₃Bu^t_{2-2,6})₃], thus obviating the possibility of chloride retention

In the initial report of these compounds, [La{CH(SiMe₃)₂}]₃ and [Sm{CH(SiMe₃)₂}]₃ were both synthesized by this route.¹³⁰ They have pyramidal structures, similar to those found in the silylamides [Ln{N(SiMe₃)₂}]₃, with La—C of 2.515(9) Å and Sm—C of 2.33(2) Å; such pyramidal structures may be adopted in the solid state to minimize nonbonding interactions involving the ligands. Bond lengths can be compared with those in the analogous¹³¹ U{CH(SiMe₃)₂}]₃ where U—C = 2.48(2) Å; the U—C distance is 0.03 shorter than La—C, on ionic radius grounds a discrepancy of 0.01 Å is expected.

The structure of the pyramidal three-coordinate [Y{CH(SiMe₃)₂}]₃ has also been reported,¹³² whilst other members of the series to have been synthesized are [Ln{CH(SiMe₃)₂}]₃ (Ln = Pr, Nd, Sm, Er and Lu)^{133–135} Single-crystal-absorption and linear dichroism spectra have been reported and analyzed for Ln = Pr, Nd, Sm, and Er.^{134,135}

Chemically [Ln{CH(SiMe₃)₂}]₃ compounds behave as Lewis acids. They are of course attacked by moisture, but also react with nucleophiles such as amines and phenols to form the corresponding lanthanide silylamides and aryloxides¹³⁰

They are also attacked by methyllithium forming bridged species¹³⁶

Scheme 5

The samarium compound has a roughly linear bridge and a long Li—CH₃ bond (2.42 Å) but a short Sm—CH₃ bond (2.33(3) Å), thus the bridge can be termed asymmetric. The Sm—C(CH(SiMe₃)₂)₃ bonds (2.49(3), 2.52(3), and 2.53(3) Å) are similar in length to those in [La{CH(SiMe₃)₂}₃]. Even more striking examples of electrophilic behavior have been reported for [Lu{CH(SiMe₃)₂}₃]. It, but not [La{CH(SiMe₃)₂}₃], reacts with KCl in ether, forming [(Et₂O)K(μ-Cl)Lu{CH(SiMe₃)₂}₃]. It has been remarked¹³⁷ that it is noteworthy that solvation of the potassium and coordination of the chloride to potassium and lutetium compensate for the loss of lattice energy (The KBr analogue can be prepared similarly). Ether is removed on gentle heating in vacuo, the product being [K(μ-Cl)Lu{CH(SiMe₃)₂}₃], which dissolves in toluene forming [(η⁶-C₇H₈)₂K(μ-Cl)Lu{CH(SiMe₃)₂}₃]. This compound contains a rather bent K—Cl—Lu bridge (145.9°) whilst the Lu—Cl distance is 2.515 Å. The Lu—C distances are 2.324(10), 2.349(10), and 2.357(8) Å; allowing for the difference in radii, these resemble those in [La{CH(SiMe₃)₂}₃]. Reaction of YCl₃ with LiCH(SiMe₃)₂ in diethyl ether leads to [(Et₂O)₃Li(μ-Cl)Y{CH(SiMe₃)₂}₃],¹³⁸ where Y—C is 2.423(12) Å, similar to those in the bridged lanthanum and lutetium compounds.

The CH₂SiMe₃ ligand is less sterically demanding so that [Ln(CH₂SiMe₃)₃] are coordinatively unsaturated. Thus reaction of ytterbium chips with Me₃SiCH₂I in THF gives [Yb(CH₂SiMe₃)₃(THF)₂]. This has the expected trigonal bipyramidal structure with axial THF molecules (Yb—O averages 2.330 Å). The average Yb—C distance is 2.374 Å.¹³⁹ Similarly, Yb reacts with Me₃CCH₂I in THF to form trigonal bipyramidal [Yb(CH₂CMe₃)₃(THF)₂].¹⁴⁰ Unlike the case with -CH₂SiMe₃, four of the bulkier -CH(SiMe₃)₂ ligands cannot be so readily accommodated round a lanthanide ion; just as the isolobal -N(SiMe₃)₂ ligand cannot replace the fourth chlorine in ThCl₄, leading to the isolation of [ThCl{N(SiMe₃)₂}₃], the chloride in [YbCl{CH(SiMe₃)₂}₃][−] cannot be replaced. The [YbCl{CH(SiMe₃)₂}₃][−] ion has a distorted tetrahedral structure with Yb—C distances of 2.372(16), 2.373(24) and 2.391(20) Å and Yb—Cl of 2.486 Å; the environment is similar to that of lanthanum in [(pmdeta)Li(μ-Cl)La{CH(SiMe₃)₂}₃]. The La—C distances (2.55(2), 2.58(2), and 2.60(2) Å; mean value 2.57(3) Å) and C—La—C angles (average 108.8°) in the latter are, however, very similar to those in the three-coordinate pyramidal [La{CH(SiMe₃)₂}₃] (La—C 2.515 Å; 109.9°) suggesting that the chloride bridge causes minimal distortion. Li[Er{CH(SiMe₃)₂}₄] can, however, be obtained by heating a solution of [Li(THF)₄][ErCl{CH(SiMe₃)₂}₃] in hexane, possibly by a disproportionation reaction.¹⁴¹ A complex, [(Me₃SiCH₂)_x(Me₃CO)_{1-x}Y(μ-OCMe₃)₄][Li(THF)₄](μ₄-Cl)][Y(CH₂SiMe₃)₄], containing the tetrahedral [Y(CH₂SiMe₃)₄][−] ion has been isolated from the reaction of YCl₃ with LiOCMe₃ and LiCH₂SiMe₃.¹⁴² Y—C distances are in the range 2.403(8) Å to 2.420(9) Å, averaging 2.41(2) Å (which, allowing for the ionic radius differences, are very similar to the Yb—C distances in [Yb{CH(SiMe₃)₂}₃Cl][−]).

Simple methyls Ln(CH₃)₃ would be coordinatively unsaturated. However, fully characterized anionic species have been obtained as [Ln(CH₃)₆]^{3−} anions by the reaction of excess (6.5 mols) MeLi with LnCl₃ in ether in the presence of 3 moles of a chelating ligand, either tetramethylethylenediamine or tris(1,2-dimethoxyethane) (L-L), the compounds having the formulae [Li(L-L)]₃[M(CH₃)₆]^{143,144}

The structures of three of the compounds have been determined; they show essentially octahedral coordination of the lanthanide with bond angles around 90°. Average lanthanum—carbon distances are 2.563(18) Å (Ho); 2.57(2) Å (Er), and 2.53(2) Å (Lu). More complicated lanthanide methyl species have been synthesized by another route, involving reaction of main-group methyls, Lewis acids, with lanthanide alkoxides¹⁴⁵ and amides,¹⁴⁶ a process of the type implicated in the lanthanide-catalyzed polymerization of conjugated dienes

The amide products do not have the anticipated symmetrical structure, instead one MMe₃ group does not form a μ-methyl bridge. Reaction with excess MMe₃ gives heterometallic peralkyls

[Ln{(μ-Me)₂Me₂}₃]; a partially-exchanged product has been fully characterized.¹⁴⁶ The heterometallic peralkyls (M = Al) form inclusion compounds where Al₂Me₆ molecules are trapped in channels between the [Ln{(μ-Me)₂AlMe₂}₃] molecules.¹⁴⁷

Triaryls of the heavier lanthanides have been synthesized by a reaction that does not involve salt elimination. Extended reaction at room temperature between powdered Ln (Ln = Ho, Er, Tm, Lu) and Ph₂Hg in the presence of catalytic amounts of LnI₃ affords the σ-aryls *fac*-LnPh₃(THF)₃. With Eu and Yb the divalent compounds LnPh₂(THF)₂ are obtained.^{148,149} The structures of the erbium and thulium compounds show them to have molecular structures with octahedral coordination of the lanthanides with bond lengths of Er—C = 2.412, 2.440, and 2.442 Å and Tm—C = 2.416, 2.421, and 2.425 Å. There is some indication of steric crowding indicated by C—Ln—C angles of 99.2–103.5° (Er) and 99.8–104.2° (Tm), whilst the Ln—C bond lengths also seem slightly long in comparison with PhGdCl₂·4THF, as discussed below.

Yellow YbPh₃(THF)₃ is a minor product of the reaction between (C₁₀H₈)Yb(THF)₂ and Ph₂Hg along with the mixed valence Yb₂Ph₅(THF)₄ system. Yb₂Ph₅(THF)₄, which has the structure Ph₂(THF)Yb(μ-Ph)₃Yb(THF)₃, has been viewed as an association of Yb^{II}Ph₂(THF) and Yb^{III}Ph₃(THF)₃ though there is some η² character in some of the bridging interactions. The terminal Yb^{III}—C distances average 2.42 Å, in line with the values for [LnPh₃(THF)₃] (Ln = Er, Tm); though the bridging Yb—C distances are, as expected rather longer (averaging 2.60 Å), the Yb^{III}—C distances are in two cases slightly shorter than the Yb^{II}—C distances.

Lanthanide triphenyls are now firmly established for the heavier lanthanides (Ho–Lu), but it remains to be seen if [LnPh₃(THF)₄] is feasible for the lighter metals (and whether [ScPh₃(THF)₃] can be isolated).

Monophenyls have been isolated by using a deficit of reagent. Thus reaction between LnCl₃ and PhLi (0.5 mol) in THF gives PhLnCl₂·*n*THF (Sm, Gd *n* = 4; Pr *n* = 3); the seven-coordinate gadolinium compound has a Gd—C distance of 2.416(24) Å. This is relatively short compared to the triphenyls, evidence for possible crowding in them.¹⁵⁰

Six-coordination is also found in [(dmp)YbCl₂(N-Meim)₂py].toluene¹⁵¹ (dmp = 2,6-dimesitylphenyl; N-Meim = N-methylimidazole) whilst distorted trigonal bipyramidal five-coordination exists in [Ln(Dnp)Cl₂(THF)₂] (Dnp = 2,6-di(1-naphthyl)phenyl; Ln = Y, Yb, Tm).¹⁵² Donor-functionalized terphenyl derivatives have also been made.¹⁵³ [(Danip)Yb(μ₂-Cl)₂(μ₃-Cl)Li(thf)]₂ and [(Danip)Ln(μ₂-Cl)₂(μ₂-Cl)Li(thf)]₂ (Ln = Y, Sm) have structures based on LiCl-bridged (DanipLnCl₂) units stabilized through additional coordination of two methoxy groups to lanthanum. (Danip = 2,6-di(o-anisol)phenyl.)

The first structural characterization of cationic lanthanide alkyl complexes has been achieved.¹⁵⁴ [Ln(CH₂SiMe₃)₃(THF)₂] (Ln = Y, Lu) react with B(C₆X₅)₃ (X = H, F) in the presence of crown ethers forming [Ln(CH₂SiMe₃)₂(CE)(THF)_{*n*}]⁺[B(C₆X₅)₃(CH₂SiMe₃)][−] (CE = [12]-crown-4, *n* = 1; CE = [15]-crown-5, [18]-crown-6, *n* = 0). In all these complexes, the crown ethers utilise all their donor atoms.

In THF but in the absence of crown ether, [Lu(CH₂SiMe₃)₃(THF)₂] reacts with B(C₆F₅)₃ forming [Lu(CH₂SiMe₃)₂(THF)₃]⁺[B(C₆F₅)₃(CH₂SiMe₃)][−]. In [Ln(CH₂SiMe₃)₂([12]-crown-4)-(THF)]⁺[B(C₆X₅)₃(CH₂SiMe₃)][−], Lu—C distances are 2.340 and 2.354 Å, whilst Lu—O distances are in the range 2.406–2.503 Å. The Lu—O (THF) distance is 2.307 Å. In [Ln(CH₂SiMe₃)₂([15]-crown-5)]⁺[B(C₆X₅)₃(CH₂SiMe₃)][−], Lu—C distances are 2.345 Å and 2.364 Å, whilst Lu—O distances are in the range 2.359–2.421 Å, whilst in [Ln(CH₂SiMe₃)₂([18]-crown-6)]⁺[B(C₆X₅)₃(CH₂SiMe₃)][−], Lu—C distances are 2.366 Å and 2.371 Å, whilst Lu—O distances are in the range 2.399–2.524 Å.

A number of lanthanide carbene derivatives, [ErL₃Cl₃], [Y(L){N(SiMe₃)₂}₃(THF)], and *trans*-[Y(L)₂{N(SiMe₃)₂}₃] (L = 1,3-dimethylimidazolin-2-ylidene) have been synthesized.¹⁵⁵

3.2.2.3 Group 15 Ligands

3.2.2.3.1 Ammonia and other monodentate neutral ligands

Because of the basicity of the ligand, and consequent inability to form isolable complexes in supercritical solution, ammonia complexes have scarcely been studied. However, the first homoleptic lanthanide ammine complexes, [Yb(NH₃)₈][Cu(S₄)₂].NH₃, [Yb(NH₃)₈]-[Ag(S₄)₂].2NH₃, and [La(NH₃)₉][Cu(S₄)₂] have been synthesized by reactions in aqueous ammonia.¹⁵⁶

Direct reaction of the lanthanide halides with pyridine gives pyridine complexes of the lanthanides,¹⁵⁷ with the synthesis of $[\text{YCl}_3\text{Py}_4]$ and $[\text{LnCl}_3\text{Py}_4] \cdot 0.5\text{Py}$ ($\text{Ln} = \text{La}, \text{Er}$). These all have pentagonal bipyramidal structures, with two chlorines occupying the axial positions. In the yttrium compound, the axial $\text{Y}-\text{Cl}$ distances are virtually identical at 2.5994(7) Å and 2.6006(7) Å, with the equatorial distance being 2.6388(7) Å; the $\text{Y}-\text{N}$ distances are in the range 2.487–2.578(2) Å. In the lanthanum and erbium compounds, the pattern in $\text{M}-\text{Cl}$ distances is similar, with axial distances of 2.652 Å and 2.661(1) Å and an equatorial distance of 2.679 Å in the lanthanum compound; and with axial distances of 2.5578(8) Å and 2.5840 Å and an equatorial distance of 2.6211(8) Å in the erbium compound. It will be interesting to see whether this stoichiometry is maintained to the end of the series, as this would be a rare example of the same structure persisting with decreasing ionic radius (compare $[\text{LnL}_2(\text{NO}_3)_3]$ ($\text{L} = \text{phen}, \text{bipy}$)). $[\text{Ml}_3\text{py}_4]$ ($\text{M} = \text{Ce}, \text{Nd}$) have been used as starting materials in the syntheses of terpy complexes.¹⁵⁸

Piperazine has been reported to form 8:1 complexes with lanthanide perchlorates but as yet there is no structural information.¹⁵⁹ A number of complexes of N-methylimidazole (N-Meim) have been made, $[\text{SmI}_3(\text{THF})_3]$ reacts with N-Meim forming¹⁶⁰ square-antiprismatic $[\text{Sm}(\text{Meim})_8]\text{I}_3$, whilst $[\text{YX}_2(\text{N-Meim})_5]^+\text{X}^-$, ($\text{X} = \text{Cl}, \text{Br}$); $[\text{YCl}_2(\text{N-Meim})_5]^+[\text{YCl}_4(\text{N-Meim})_2]^-$; and $[\text{Ce}(\text{NO}_3)_3(\text{N-Meim})_4]$ have also been characterized.¹⁶¹

3.2.2.3.2 Nitrile complexes

Among nitriles, CH_3CN in particular has been widely employed as a solvent in nonaqueous lanthanide chemistry, but little is known about its complexes until recently.

A NMR study of lanthanum nitrate solutions in MeCN led to the identification of a number of complexes including $[\text{La}(\text{NO}_3)_3(\text{MeCN})_4]$ and $[\text{La}(\text{NO}_3)_3(\text{MeCN})_3(\text{H}_2\text{O})]$, but they were not isolated.^{162,163} A few complexes such as $[\text{Eu}(\text{MeCN})_x(\text{BF}_4)_3]$ ($x \sim 3$) have previously been prepared, in this case by oxidation of metallic Eu by NOBF_4 , but have lacked structural characterization.¹⁶⁴

However, in the 1990s syntheses were reported^{165–167} for MeCN complexes $[\text{Ln}(\text{MeCN})_n]\text{X}_3$. Routes have included the reaction of LnCl_3 with AlCl_3 in MeCN, reaction of the labile complexes $\text{La}(\text{OSO})_x(\text{AsF}_6)_3$ with MeCN, and ultrasonication of mixtures of the lanthanide metal with AlCl_3 and MeCN in C_2Cl_6 ; among others, a series $[\text{Ln}(\text{MeCN})_9](\text{AlCl}_4)_3 \cdot \text{MeCN}$ ($\text{Ln} = \text{La}, \text{Pr}, \text{Nd}, \text{Sm}-\text{Tb}, \text{Ho}, \text{Yb}$) has been made. The structures of $[\text{La}(\text{MeCN})_9](\text{AsF}_6)_3 \cdot \text{MeCN}$; $[\text{Sm}(\text{MeCN})_9](\text{AsF}_6)_3 \cdot 3\text{MeCN}$; $[\text{Ln}(\text{MeCN})_9](\text{AlCl}_4)_3 \cdot \text{MeCN}$ ($\text{Ln} = \text{Pr}, \text{Sm}$) and $[\text{Yb}(\text{MeCN})_8](\text{AlCl}_4)_3$ have all been reported. The $[\text{Ln}(\text{MeCN})_9]^{3+}$ ion has the familiar trigonal prismatic coordination of the lanthanide; $\text{La}-\text{N}$ bond lengths in $[\text{La}(\text{MeCN})_9](\text{AsF}_6)_3 \cdot \text{MeCN}$ fall in the range 2.575(9)–2.650(5) Å whilst in $[\text{Sm}(\text{MeCN})_9](\text{AsF}_6)_3 \cdot 3\text{MeCN}$ the $\text{Sm}-\text{N}$ bonds span 2.510(5)–2.546(5) Å. $[\text{Yb}(\text{MeCN})_8](\text{AlCl}_4)_3$ has dodecahedral eight-coordination of ytterbium with $\text{Yb}-\text{N}$ bonds between 2.367(5) Å and 2.422(4) Å.

A number of adducts of the silylamides $[\text{Ln}(\text{N}(\text{SiMe}_3)_2)_3]$ form nitrile adducts; they are discussed in Section 3.2.2.3.5.

3.2.2.3.3 2,2'-Bipyridyl, 1,10-phenanthroline and other bidentate neutral ligands

Many complexes of 2,2'-Bipyridyl (bipy) and 1,10-phenanthroline (phen) have been examined in detail in a series of papers by White and his co-workers.

Both 1:1 and 2:1 complexes of lanthanide chlorides with bipy have lately received detailed and extensive crystallographic study.^{168,169} Compounds synthesized by reaction in ethanol and characterized include $[(\text{bipy})\text{Ln}(\text{OH}_2)_6]\text{Cl}_3$ ($\text{Ln} = \text{Ho}-\text{Lu}, \text{Y}$), $[(\text{bipy})\text{Ln}(\text{OH}_2)_6]\text{Cl}_3 \cdot \text{bipy} \cdot 2\text{H}_2\text{O}$ ($\text{Ln} = \text{Er}-\text{Lu}, \text{Y}$), $[(\text{bipy})\text{Ln}(\text{OH}_2)_4\text{Cl}_2]\text{Cl} \cdot \text{H}_2\text{O}$, $[(\text{bipy})(\text{EtOH})_2\text{Cl}_2\text{La}(\mu\text{-Cl})_2\text{LaCl}_2(\text{EtOH})_2(\text{bipy})]$, $[(\text{bipy})_2\text{La}(\text{OH}_2)_4\text{Cl}_2]\text{Cl}_2 \cdot 2\text{H}_2\text{O}$, $[(\text{bipy})_2\text{Pr}(\text{OH}_2)\text{Cl}_3] \cdot 0.5 \text{EtOH}$, $[(\text{bipy})_2\text{Ln}(\text{OH}_2)_2\text{Cl}_2]\text{Cl}$ ($\text{Ln} = \text{Pr}, \text{Er}$), $[(\text{bipy})_2\text{Ln}(\text{OH}_2)\text{Cl}_3] \cdot \text{EtOH}$ ($\text{Ln} = \text{Nd}, \text{Eu}$), $[(\text{bipy})_2\text{Cl}_2\text{La}(\mu\text{-Cl})_2\text{LaCl}_2(\text{bipy})_2] \cdot \text{EtOH}$, and $[(\text{bipy})_2\text{YbCl}_3]$. For the 1:1 complexes of early lanthanides like La and Pr, the tendency seems to be for the formation of neutral complexes containing all available chloride ions and frequently binuclear in composition, usually containing at least two solvent molecules per lanthanide. By later in the series, mononuclear species tend to become more normal, and chloride ions are often excluded from the coordination sphere by solvent molecules. In the case of the 2:1 complexes, nine-coordination is possible at the start of the series in $[(\text{bipy})_2\text{Ln}(\text{OH}_2)_4\text{Cl}]\text{Cl}_2 \cdot 2\text{H}_2\text{O}$, whilst by

the end of the series ytterbium is seven-coordinate in $[(\text{bipy})_2\text{YbCl}_3]$. M—N bond lengths contract from 2.724–2.787 Å in the lanthanum compound to 2.439–2.479 Å in the ytterbium compound. The situation has been described as “a multidimensional jigsaw puzzle which still requires a great deal of work for its complete description.”

Bipyridyl complexes with lanthanide bromides do not seem to have received attention, but the first lanthanide iodide complexes were reported in 1999. In a comparative study with UI_3 , complexation of bipy with ($\text{Ln} = \text{Ce}, \text{Nd}$) was investigated.¹⁷⁰ UI_3 and CeI_3 both form 1:1 and 1:2 complexes in solution, with a 1:3 complex at high bipy concentrations, whereas NdI_3 only forms a 1:2 complex. The structure of $[\text{CeI}_3(\text{bipy})_2(\text{py})] \cdot 5\text{py} \cdot \text{bipy}$ was reported; it has eight-coordinate Ce, with Ce—N (bipy) = 2.67(3) Å, Ce—I (average 3.23(3) Å) and Ce—N 2.678(9) Å. Reaction of $[\text{NdI}_3(\text{py})_4]$ and bipy in attempts to make the Nd analogue resulted in dimeric $[(\text{bipy})_3\text{Nd}(\mu\text{-OH})_2\text{Nd}(\text{bipy})_3]\text{I}_4 \cdot 3\text{Py}$, presumably due to inadvertent hydrolysis.¹⁷¹

The reaction between bipy and $\text{La}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$ has been studied in MeCN solution by multi-nuclear NMR; species identified in solution include $\text{La}(\text{MeCN})_4(\text{NO}_3)_3$, $\text{La}(\text{MeCN})_2(\text{bipy})(\text{NO}_3)_3$ and of course the final product $\text{La}(\text{bipy})_2(\text{NO}_3)_3$.¹⁶³

Complexes $\text{Ln}(\text{bipy})_2(\text{NO}_3)_3$ have been studied in more detail than the other bipy complexes; all appear to have 10-coordinate structures with all nitrates present as bidentate ligands. The coordination geometry has been variously described as a bicapped dodecahedron and as a sphenocorona. Unlike the La complex, the Lu complex does not possess disorder about the twofold axis. Lu—N distances are 2.46–2.67(1) Å and Lu—O distances in the range 2.426(9)–2.556(9) Å.¹⁷² $[\text{Y}(\text{bipy})_2(\text{NO}_3)_3]$ is, like $[\text{Y}(\text{phen})_2(\text{NO}_3)_3]$, isostructural with its lanthanide analogues.¹⁷³ Similarly, the structure of $[\text{Nd}(\text{bipy})_2(\text{NO}_3)_3]$ has been shown to be isostructural with $[\text{Ln}(\text{bipy})_2(\text{NO}_3)_3]$ ($\text{Ln} = \text{Y}, \text{La}, \text{Lu}$).¹⁷⁴ A number of compounds $\text{Ln}(\text{bipy})_3(\text{NO}_3)_3$ ($\text{Ln} = \text{Ce}, \text{Pr}, \text{Nd}, \text{Yb}$) have been reported;¹⁷⁵ the neodymium complex was shown to be $[\text{Nd}(\text{bipy})_2(\text{NO}_3)_3] \cdot \text{bipy}$, with the third bipy molecule not associating with the neodymium-containing complex.¹⁷⁴

In the presence of 15-crown-5, reaction of lanthanum nitrate with bipy in MeOH–MeCN led to $[\text{La}(\text{bipy})(\text{NO}_3)_3(\text{H}_2\text{O})_2(\text{MeOH})] \cdot 15\text{-crown-5}$, which has 11-coordinate lanthanum.¹⁷⁶ The increase in coordination number in comparison with $[\text{La}(\text{bipy})_2(\text{NO}_3)_3]$ results in an slight (and possibly not statistically significant) increase in La—N distance from 2.66 Å to 2.70 Å, and in La—O from 2.56–2.63 Å to 2.69 Å. The presence of the coordinated MeOH molecule supplies a fifth hydrogen atom so that hydrogen bonds can be formed to all the crown ether oxygens. In another synthesis in the presence of a crown ether, a 10-coordinate complex, $[\text{La}(\text{bipy})(\text{NO}_3)_3(\text{H}_2\text{O})_2] \cdot \text{benzo-15-crown-5}$, is obtained.¹⁷⁷

Among carboxylate complexes, $[\text{Eu}(o\text{-ABA})_3(\text{bipy})] \cdot \text{bipy}$ ($o\text{-ABA} = o\text{-aminobenzoate}$) is dimeric with four bridging carboxylates, one chelating carboxylate, and a bipyridyl ligand affording eight-coordinate europium.¹⁷⁸ $[\{\text{Pr}(\text{O}_2\text{CCMe}_3)_3(\text{bipy})\}_3]$ has two bidentate bridging and two tridentate cyclic bridging carboxylates; praseodymium is nine-coordinate.¹⁷⁹ The dimethoxybenzoate complex $[\text{La}(2,3\text{-DMOBA})_3(2,2'\text{-bpy})]$ is a dimer with the lanthanum atoms bridged by four carboxylates. The central La atom is nine-coordinate, having distorted monocapped square-antiprism geometry.¹⁸⁰ $[\text{La}_2(\text{O}_2\text{CC}\equiv\text{CH})_6(\text{bipy})_2(\text{H}_2\text{O})_2] \cdot 4\text{H}_2\text{O} \cdot 2 \text{ bipy}$ does not undergoes solid-state polymerization when exposed to ^{60}Co γ -rays.¹⁸¹

A considerable number of bipy (and phen) adducts of lanthanide dithiocarbamates $[\text{Ln}(\text{S}_2\text{CNR}_2)_3(\text{L})]$ have been synthesized, usually by one-pot syntheses; the interest here is in their potential as precursors to lanthanide sulfides. $[\text{Ln}(\text{S}_2\text{CNMe}_2)_3(\text{bipy})]$ ($\text{Ln} = \text{La}, \text{Pr}, \text{Nd}, \text{Sm-Yb}, \text{Y}$) and $[\text{Ln}(\text{S}_2\text{CNEt}_2)_3(\text{bipy})]$ ($\text{Ln} = \text{La}, \text{Pr}, \text{Nd}, \text{Sm-Lu}, \text{Y}$) have been synthesized.¹⁸² The structure of $[\text{Er}(\text{S}_2\text{CNEt}_2)_3(\text{bipy})]$ has been determined¹⁸³ as has that of $[\text{Eu}(\text{bipy})(\text{S}_2\text{CNEt}_2)_3]$.¹⁸⁴ The synthesis of $[\text{Sm}(\text{S}_2\text{CNEt}_2)_3(\text{L})]$ ($\text{L} = \text{phen}, \text{bipy}$) and the structure of $[\text{Sm}(\text{S}_2\text{CNEt}_2)_3(\text{bipy})]$ have been reported.¹⁸⁵ The related $[\text{Eu}(\text{L})(\text{S}_2\text{P}^i\text{Bu}_2)_3]$ ($\text{L} = \text{phen}, \text{bipy}$) have monomeric structures with distorted dodecahedral coordination of europium.¹⁸⁶

Among phenanthroline complexes, one feature present in many solid-state structures is π — π stacking between the planar phenanthroline rings. The first complex with a noncoordinating anion to be characterized fully was $[\text{Ce}(\text{phen})_4(\text{MeCN})_2](\text{ClO}_4)_3 \cdot 3\text{MeCN}$, which has 10-coordinate cerium in a bicapped square antiprismatic geometry.¹⁸⁷

As with bipy, a considerable number of chloride complexes have been examined in detail.¹⁶⁹ Compounds characterized by crystallography include $[(\text{phen})_2\text{La}(\text{OH}_2)_5]\text{Cl}_3 \cdot \text{phen} \cdot 4\text{H}_2\text{O}$, $[(\text{phen})_2\text{La}(\text{OH}_2)_5]\text{Cl}_3 \cdot \text{MeOH} \cdot \text{H}_2\text{O}$, $[(\text{bipy})_2\text{Ln}(\text{OH}_2)_4\text{Cl}]\text{Cl}_2 \cdot 2\text{H}_2\text{O}$, $[(\text{phen})_2\text{Lu}(\text{OH}_2)_4]\text{Cl}_3 \cdot 2\text{H}_2\text{O}$, $[(\text{phen})_2\text{Ln}(\text{OH}_2)_3\text{Cl}]\text{Cl}_2 \cdot \text{H}_2\text{O}$ ($\text{Ln} = \text{Dy}, \text{Er}, \text{Y}$), and $[(\text{phen})_2\text{Ln}(\text{OH}_2)_3\text{Cl}_3] \cdot \text{MeOH}$ ($\text{Ln} = \text{La}, \text{Pr}, \text{Nd}, \text{Eu}$). Nine-coordination is possible for compounds like $[(\text{phen})_2\text{Ln}(\text{OH}_2)_5]\text{Cl}_3 \cdot \text{phen} \cdot 4\text{H}_2\text{O}$ whilst by the end of the lanthanide series eight-coordination is more normal in $[(\text{phen})_2\text{-}$

$\text{Lu}(\text{OH}_2)_4\text{Cl}_3 \cdot 2\text{H}_2\text{O}$ and $[(\text{phen})_2\text{Er}(\text{OH}_2)_3\text{Cl}]\text{Cl}_2 \cdot \text{H}_2\text{O}$. An apparent 3:1 complex, $\text{La}(\text{phen})_3\text{Cl}_3 \cdot 9\text{H}_2\text{O}$ has been shown to be $[\text{La}(\text{phen})_2(\text{OH}_2)_5]\text{Cl}_3 \cdot 4\text{H}_2\text{O} \cdot \text{phen}$.¹⁸⁸

The first structure of a $[\text{Ln}(\text{phen})_2(\text{NO}_3)_3]$ complex was reported in 1992 for the lanthanum compound.¹⁶² It closely resembled the established bipy analogue in that the three nitrate groups were bidentate and the lanthanum was 10-coordinate. The structural information was complemented by a multinuclear solution (^1H -, ^{13}C -, ^{17}O -, and ^{139}La) NMR study. The structure of the other "extreme" member of the series, the lutetium complex, was reported in 1996.¹⁷² Unlike the La complex, but like $[\text{Lu}(\text{bipy})_2(\text{NO}_3)_3]$, the study was not complicated by disorder. The complexes appear to form an isomorphous and isostructural series. On moving from the lanthanum to the lutetium compound, the $\text{Ln}-\text{N}$ distances decrease from 2.646(3)–2.701(3) Å (La) to 2.462(8)–2.479(8) Å (Lu), and the range of $\text{Ln}-\text{O}$ distances decreases from 2.580(3)–2.611(3) Å for the lanthanum compound to 2.364(8)–2.525(6) Å for the lutetium complex. Several structures have subsequently been reported of other $[\text{Ln}(\text{phen})_2(\text{NO}_3)_3]$ systems.^{173,189–191} $[\text{Ln}(\text{phen})_2(\text{NO}_3)_3]$ ($\text{Ln} = \text{Pr}$,¹⁸⁹ Nd ,^{189,192} Sm ,¹⁸⁹ Eu ,^{189,190} Dy ,¹⁸⁹ Y ^{173,191}) are isostructural; the individual complex molecules associate by $\pi-\pi$ stacking into one dimensional chains which themselves arrange into pseudo-one-dimensional close packed patterns.¹⁸⁹ Luminescence spectra of Eu^{3+} -containing $[\text{Ln}(\text{phen})_2(\text{NO}_3)_3]$ ($\text{Ln} = \text{Y}$, La , Nd , Lu) have been investigated.¹⁹⁰ $[\text{Y}(\text{phen})_2(\text{NO}_3)_3]$ is, like $[\text{Y}(\text{bipy})_2(\text{NO}_3)_3]$ isostructural with its lanthanide analogues,⁷² as well as with its lanthanide analogues, with $\text{Y}-\text{O}$ distance in the range 2.477–2.516 Å and $\text{Y}-\text{N}$ bonds of 2.492 Å and 2.549 Å. $\pi-\pi$ stacking between the rings of neighboring phen ligands with an interplanar separation of 3.51 Å leads them to associate into one-dimensional chains.¹⁹¹ A complex analyzing as $\text{La}(\text{phen})_4(\text{NO}_3)_3 \cdot 3\text{H}_2\text{O}$ is $[\text{La}(\text{phen})_2(\text{H}_2\text{O})_2(\text{NO}_3)_2] \cdot \text{NO}_3 \cdot 2\text{phen} \cdot \text{H}_2\text{O}$ with intermolecular $\pi-\pi$ stacking.¹⁹²

In another phenanthroline complex, the structure of $[\text{phenH}][\text{La}(\text{NO}_3)_4(\text{H}_2\text{O})(\text{phen})] \cdot \text{H}_2\text{O}$ features what are becoming the familiar $\pi-\pi$ interactions, this time between the $[\text{phenH}]^+$ ions.¹⁹³ Other phen complexes reported are new dinuclear species $[(\text{phen})_2(\text{H}_2\text{O})_2\text{Ln}(\mu\text{-OH})_2\text{Ln}(\text{H}_2\text{O})_2(\text{phen})_2](\text{NO}_3)_4 \cdot 2\text{phen}$ ($\text{Ln} = \text{Er}$, Lu).¹⁹⁴

Reaction of lutetium acetate and phen in ethanol afforded $\text{Lu}(\text{O}_2\text{CCH}_3)_3 \cdot (\text{phen}) \cdot \text{H}_2\text{O}$ which is dinuclear $[(\text{phen})(\text{CH}_3\text{COO})\text{Lu}(\mu\text{-O}_2\text{CCH}_3)_4\text{Lu}(\text{CH}_3\text{COO})(\text{phen})]$. The terminal acetate groups are symmetrically bidentate; two of the bridging acetates are symmetrical, the other pair bridging in such a way that one of the two oxygens is bound to both lutetiums and the other is bound only to one. $\text{Lu}-\text{N}$ is 2.486(4)–2.551(5) Å and terminal $\text{Lu}-\text{O}$ bonds 2.323–2.503(5)(5) Å.¹⁹⁵ Similarly, $\text{Ln}(\text{OAc})_3 \cdot \text{phen}$ ($\text{Ln} = \text{La}$, Ce) is¹⁹⁶ dimeric $[(\text{AcO})(\text{phen})\text{Ln}(\mu\text{-OAc})_4\text{Ln}(\text{phen})(\text{OAc})]$ with two types of bridging acetate. The cerium compound gives a triplet EPR spectrum at 4.2 K, showing a bridging interaction between the two ceriums ($D = 0.21 \text{ cm}^{-1}$); magnetic measurements to low temperatures on both compounds confirm weak interactions.

A phenanthroline complex of europium caproate, $[\text{Eu}(\text{O}_2\text{CC}_5\text{H}_{11})_3(\text{phen})]$, has a dimeric structure in which each europium is bound to a chelating phenanthroline and one bidentate carboxylate as well as additionally to two bidentate bridging carboxylates and two tridentate bridging carboxylates, giving nine-coordinate europium. Some subtle splitting of bands in the fluorescence spectrum has been ascribed to vibronic interactions.¹⁹⁷ As already discussed in the section on bipy, a number of complexes of the type $[\text{Ln}(\text{phen})(\text{S}_2\text{CNR}_2)_3]$ have been synthesized and studied, with structures determined for the eight-coordinate $[\text{Ln}(\text{phen})(\text{S}_2\text{CNEt}_2)_3]$ ($\text{Ln} = \text{Eu}$,¹⁹⁸ Yb ¹⁸⁴). Improved syntheses are reported for $[\text{Ln}(\text{S}_2\text{CNR}_2)_3(\text{phen})]$ ($\text{Ln} = \text{Eu}$, Er ; $\text{NR}_2 = \text{NEt}_2$, NMeCy ; $\text{N}(\text{CH}_2)_3$).¹⁹⁹ The synthesis of $[\text{Sm}(\text{S}_2\text{CNEt}_2)_3(\text{phen})]$ has been reported.¹⁸⁵

Solvothermal synthesis of $[\text{La}(\text{en})_4\text{Cl}]\text{In}_2\text{Te}_4$ has been reported; the cation has monocapped square antiprismatic coordination.²⁰⁰ Reaction of Y_2S_3 with NH_4I in en at 568 K yields crystals of eight-coordinate $[\text{Y}(\text{en})_4](\text{SH})_{2.72}\text{I}_{0.28}$; a similar reaction in anhydrous ammonia yields an uncharacterized complex, probably an ammine.²⁰¹

Stability constants of 1:1 and 2:1 complexes with diethylenetriamine (dien) have been determined by potentiometry.²⁰²

3.2.2.3.4 Complexes of terpyridyl and other tridentate ligands

There has been a great awakening of interest in complexes of 2,2':6',2''-terpyridyl (terpy), parallel developments in its coordination chemistry with the *d*-block metals. Tridentate N-donor ligands are efficient in separating actinides from lanthanides selectively by solvent extraction. 2,4,6-tris-2-pyridyl-1,3,5-triazine (tptz) and terpyridyl (terpy) and their derivatives have been

popular ligands for study. Phenyl-substituted terpyridyls have been studied as extractants with lower solubility in aqueous phases.

Reaction of aqueous lanthanide chlorides with alcoholic solutions of terpy affords complexes $\text{Ln}(\text{terpy})\text{Cl}_3 \cdot x\text{H}_2\text{O}$ ($\text{Ln} = \text{La-Nd}$, $x = 8$; $\text{Ln} = \text{Sm}$, $x = 7.6$; $\text{Ln} = \text{Eu}$, $x = 7.45$; $\text{Ln} = \text{Gd}$, $x = 7.1$; $\text{Ln} = \text{Tb-Er}$, Yb-Lu , $x = 7$; $\text{Ln} = \text{Tm}$, Y , $x = 6$). They contain $[\text{Ln}(\text{terpy})\text{Cl}(\text{H}_2\text{O})_n]^{2+}$ ions ($\text{Ln} = \text{La-Nd}$, $n = 5$; $\text{Ln} = \text{Sm-Lu}$, $n = 4$).

On proceeding from La to Nd in the series of $[\text{Ln}(\text{terpy})\text{Cl}(\text{H}_2\text{O})_5]^{2+}$ ions, there are the expected contractions in Ln-Cl , from 2.903(2) Å to 2.855(1) Å; in average Ln-N distance, from 2.688 Å to 2.616 Å; and in average Ln-O distance, from 2.561 Å to 2.505 Å. Similarly, in the $[\text{Ln}(\text{terpy})\text{Cl}(\text{H}_2\text{O})_4]^{2+}$ ions, on passing from Sm to Lu, there are decreases in Ln-Cl , from 2.794(2) Å to 2.665(2) Å; in the average Ln-N distance, from 2.513 Å to 2.457 Å; and in average Ln-O distance, from 2.475 Å to 2.317 Å. In addition, a compound $\text{Sm}(\text{terpy})\text{Cl}_3 \cdot \text{H}_2\text{O}$ was found to be dimeric $[(\text{terpy})(\text{H}_2\text{O})\text{Cl}_2\text{Sm}(\mu\text{-Cl})_2\text{Sm}(\text{H}_2\text{O})\text{Cl}_2(\text{terpy})]$, containing eight-coordinate samarium.²⁰³

Bromide complexes of terpy have been studied²⁰⁴ with two families, nine-coordinate $[\text{Ln}(\text{terpy})(\text{H}_2\text{O})_6]\text{Br}_3 \cdot \text{H}_2\text{O}$ ($\text{Ln} = \text{La-Er}$) and eight-coordinate $[\text{Ln}(\text{terpy})(\text{H}_2\text{O})_5]\text{Br}_3 \cdot 3\text{H}_2\text{O}$ ($\text{Ln} = \text{Tm-Lu}$). These to some extent resemble the chlorides, though there is no halide in the coordination sphere in any of these compounds. For the $[\text{Ln}(\text{terpy})(\text{H}_2\text{O})_6]^{3+}$ ions, the Ln-N distances contract from 2.656–2.684 Å (La) to 2.39–2.44 Å (Lu), with similar contractions being evident in the Ln-O distances. Towards the end of the lanthanide series, there is a tendency for a hydroxy-bridged dimeric species to be formed in preference, but usually acidification converts it into the mononuclear complex. The dimers contain bridging hydroxy groups, not halides as found in $[(\text{terpy})(\text{H}_2\text{O})\text{Cl}_2\text{Sm}(\mu\text{-Cl})_2\text{Sm}(\text{H}_2\text{O})\text{Cl}_2(\text{terpy})]$, reflecting the decreasing coordinating power of bromide. Indeed, overall the absence of any bromide coordination should be noted, but these complexes were obtained by crystallization from solutions of hydrated LnBr_3 and terpy in ethanol, and in view of the recent isolation of 2:1 terpy complexes of lanthanide iodides with all iodides coordinated, syntheses using other stoichiometries, anhydrous bromides, and less coordinating solvents would be expected to afford complexes such as $[\text{Ln}(\text{terpy})_2\text{Br}_2]\text{Br}$.²⁰⁴

Terpy reacts with solutions of LnI_3 in anhydrous pyridine forming²⁰⁵ eight-coordinate $[\text{Ln}(\text{terpy})_2\text{I}_2]\text{I}$ ($\text{Ln} = \text{Ce, Nd}$) and a nine-coordinate uranium analogue $[\text{U}(\text{terpy})_2\text{I}_2(\text{py})]\text{I}$ has been made. $[\text{Ce}(\text{terpy})_2\text{I}_2]\text{I}$ crystallizes from slightly damp solvents forming nine-coordinate $[\text{Ce}(\text{terpy})_2\text{I}_2(\text{H}_2\text{O})]\text{I}$. Ln-N bond lengths average at 2.63(2) Å for the Ce complex and 2.60(2) Å for the Nd complex; Ln-I distances average 3.182(3) Å and 3.153(4) Å respectively. Proton-NMR competition experiments indicate that terpy has a stronger affinity for U^{III} than for Ce^{III} or Nd^{III} . A comparison of structural data for $[\text{Ce}(\text{terpy})_2\text{I}_2(\text{H}_2\text{O})]\text{I}$ and $[\text{U}(\text{terpy})_2\text{I}_2(\text{py})]\text{I}$ indicates that the average U-N distance is shorter by about 0.05 Å, though on size grounds they would be expected to be very similar. It has been suggested that this shortening reflects a π back-bonding interaction between the 5f orbitals of uranium and the terpyridyl ligand which is absent in the lanthanide complex.²⁰⁵

The classic nine-coordinate $[\text{Ln}(\text{terpy})_3](\text{ClO}_4)_3$ complexes have been reinvestigated.²⁰⁶ Reaction of terpy with lanthanide perchlorates in MeCN affords $[\text{La}(\text{terpy})_3](\text{ClO}_4)_3 \cdot 2\text{MeCN} \cdot 0.67\text{H}_2\text{O}$, $[\text{Ln}(\text{terpy})_3](\text{ClO}_4)_3 \cdot \text{MeCN} \cdot \text{H}_2\text{O}$ ($\text{Ln} = \text{Ce, Pr, Sm, Eu}$), and $[\text{Ln}(\text{terpy})_3](\text{ClO}_4)_3$ (Eu, Lu, Y); all of these have nine-coordinate $[\text{Ln}(\text{terpy})_3]^{3+}$ cations. The Ln-N bond lengths show the expected contraction; Ce-N distances fall into the range 2.622–2.679 Å whilst Lu-N distances are 2.437–2.553 Å.²⁰⁶ Complexes of 4-alkylated terpyridyls, $[\text{Ln}(4\text{-Rterpy})_3](\text{ClO}_4)_3$ ($\text{Ln} = \text{La, Eu, Tb}$; $\text{R} = \text{Et, Bu}^t$) have been synthesized; introducing these alkyl groups considerably increases the luminescence efficiency, possibly due to the bulk of the alkyl group preventing approach of deactivating molecules, as well as their electronic effects.²⁰⁷

Complexes of bridged terpy ligands have been examined;²⁰⁸ thus europium has tricapped trigonal prismatic nine-coordination in $[\text{EuL}_3](\text{ClO}_4)_3$ ($\text{L} = 3,3':5,3'$ -dimethylenetripyridyl); the ligand contains ethylene bridges between the pyridine rings in the ligand molecules, giving a more stable triple helical $[\text{EuL}_3]^{3+}$ complex species, again with D_3 symmetry as found round europium in $[\text{Eu}(\text{terpy})_3](\text{ClO}_4)_3$.

Previous reports of nitrate complexes were limited to synthetic studies²⁰⁹ reporting 1:1 complexes with various degrees of hydration. A large number of complexes have been reported in the literature in recent years; interest has been reawakened by the possibility of using related ligands in the separation of lanthanide fission products from actinides in the reprocessing of nuclear fuel rods. It is now clear that the situation is complex and that various stoichiometries are obtainable, depending not least upon the solvent used. For the majority of complexes, a 1:1 terpy:lanthanide ratio obtains. The first of the recent studies was carried out by Bensimon and Frechette.²¹⁰ Addition of terpy to a solution of $\text{La}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$ in MeCN was followed by ^1H -, ^{17}O - and ^{139}La -NMR investigations. A number of species were identified to be present in solution, namely

[La(terpy)(NO₃)₃(MeCN)], [La(terpy)(NO₃)₃(H₂O)], [Ln(terpy)(NO₃)₄(MeCN)][−], [Ln(terpy)(NO₃)₄(H₂O)][−], and [Ln(terpy)₂(NO₃)₂]⁺. The complex Ln(terpy)_{1.5}(NO₃)₃ was isolated from a MeCN solution with a 8:1 terpy:La ratio and was shown by X-ray diffraction to possess the structure [Ln(terpy)₂(NO₃)₂]⁺[Ln(terpy)(NO₃)₄][−]. In the 10-coordinate cation, La—O are 2.627(11)–2.646(11) Å whilst La—N distances lie in the range 2.649(12)–2.685(10) Å with one outlier at 2.736(13) Å. In the 11-coordinate anion, La—N are 2.705(13), 2.709(13), and 2.769(12) Å; La—O fall into a bracket between 2.608(13)–2.684 (13) Å. Subsequently it has been found²¹¹ that reactions of hydrated lanthanide nitrates with up to four moles of terpy in CH₃CN afford complexes with a similar 1.5:1 stoichiometry, [Ln(terpy)₂(NO₃)₂]⁺[Ln(terpy)(NO₃)₄][−] (Ln = Nd, Sm, Tb, Dy, Ho). In these, however, the lanthanide is 10-coordinate in both the cation and the anion, one nitrate group in the anion being monodentate, in contrast to the anion in the 1.5:1 complex of the larger lanthanum ion, where all nitrates are bidentate; this is evidently a consequence of congestion arising around the smaller lanthanide ions. In the [Nd(terpy)₂(NO₃)₂]⁺ cation, Nd—N distances are 2.592(7)–2.651(6) Å and Nd—O 2.526(5)–2.598(6) Å, whilst in [Nd(terpy)(NO₃)₄][−], Nd—N distances are 2.591(7)–2.600(6) Å, the monodentate Nd—O bond is 2.434 (7) Å, and the Nd—O distances in the bidentate groups are rather widely spread at 2.548(6)–2.644(7) Å. In the [Ho(terpy)₂(NO₃)₂]⁺ cation, Ho—N distances are 2.538(7)–2.605(7) Å and Ho—O 2.405(6)–2.598(6) Å, whilst in [Ho(terpy)(NO₃)₄][−], Ho—N distances are 2.531(7)–2.544(7) Å, the monodentate Ho—O bond is 2.323(6) Å and the Ho—O distances in the bidentate groups are even more widely spread at 2.435(7)–2.580(7) Å. The increasing asymmetry in the bond to the nitrate groups suggests that congestion is again increasing. A [Sm(terpy)(NO₃)₄][−] anion has also been isolated from acidified solution as the (terpyH₂)²⁺ salt.²¹² This is an 11-coordinate anion with four bidentate nitrates (in contrast to the three bidentate and one monodentate group in the the [Sm(terpy)₂(NO₃)₂]⁺ salt) with eight Sm—O distances ranging from 2.494(5) Å to 2.742(5) Å (averaging 2.56 Å), contrasting with the six bidentate Sm—O distances of 2.497(13)–2.613(13) Å and one monodentate distance of 2.370(14) Å in the [Sm(terpy)₂(NO₃)₂]⁺ salt. The Sm—N distances average 2.637 Å in the 11-coordinate anion ((terpyH₂)²⁺ salt) and 2.569 Å in the 10-coordinate anion ([Sm(terpy)₂(NO₃)₂]⁺ salt). Clearly factors such as the energetics of ionic packing can have a pronounced effect on coordination geometry, in the absence of the strong crystal-field effects that would apply in a transition-metal analogue. The [Ce(terpy)(NO₃)₄][−] ion is found in (Hpy)[Ce(NO₃)₄(terpy)]py, formed by addition of pyridine to a day-old mixture of cerium nitrate and terpy in MeCN.²¹³ The coordination polyhedron of the Ce atom is irregular; the cerium is 11-coordinate, with four bidentate nitrates, the Ce—N distances being 2.682(2), 2.685(2), and 2.705(2) Å. Seven of the Ce—O distances span 2.537(2)–2.712(2) Å, the eighth being 2.942(3) Å.²¹³

A study by Semenova and White covered the whole lanthanide series. In this they examined the reaction of the hydrated nitrates with one mole of terpy in MeCN, followed by recrystallization of the initial complex from water. They found²¹⁴ that the earlier members of the lanthanide series form 10-coordinate [Ln(terpy)(NO₃)₂(H₂O)₃]NO₃ (Ln = La–Gd) and the later lanthanides form nine-coordinate [Ln(terpy)(NO₃)₂(H₂O)₂]NO₃·2H₂O (Ln = Tb, Lu, Y). These compounds result from solvolysis by water of an initial [Ln(terpy)(NO₃)₃(H₂O)_x] species (see below), displacing one nitrate group. Detailed structures have been reported for the La, Gd, Tb, Lu, and Y complexes. They show a girdle of ligands comprising a virtually planar terdentate terpy ligand and two or three water molecules coordinated round the “waist” of the metal, with bidentate nitrates completing the coordination sphere above and below the metal. In the [Ln(terpy)(NO₃)₂(H₂O)₃]³⁺ ions, the range of Ln—N distances contracts from 2.632(4)–2.688(3) Å (Ln = La) to 2.52(1)–2.56(1) Å (Ln = Gd), with a similar pattern in the Ln—O distances. The range of Ln—N distances in the [Tb(terpy)(NO₃)₂(H₂O)₂]³⁺ ion is 2.50(1)–2.52(1) Å, contracting to 2.469(6)–2.474(6) Å in [Lu(terpy)(NO₃)₂(H₂O)₂]³⁺ ion.²¹⁴ The structure of [Gd(terpy)(NO₃)₂(H₂O)₃]NO₃ has been reported independently.²¹⁵

When the hydrated nitrates react directly with terpy in MeCN, without added water, the initial products are [Ln(terpy)(NO₃)₃(H₂O)_x]. Compounds Ln(terpy)(NO₃)₃·H₂O (Ln = La, Pr, Er, Yb) and Ln(terpy)(NO₃)₃ (Ln = Gd, Yb) have been reported, but these have lacked structural information.^{216,217} In a more detailed study,²¹¹ reaction of the hydrated lanthanide nitrates with terpy in CH₃CN was found to afford [Nd(terpy)(NO₃)₃(H₂O)], [Ln(terpy)(NO₃)₃(H₂O)]·terpy (Ln = Ho, Er, Tm, Yb), and [Yb(terpy)(NO₃)₃], all of which feature solely bidentate nitrates. In [Tm(terpy)(NO₃)₃(H₂O)], one nitrate is monodentate. In 10-coordinate [Nd(terpy)(NO₃)₃(H₂O)], there is quite a bit of asymmetry in the Nd—N distances (2.586(10)–2.703(13) Å); the Nd—O (water) distance is 2.488(8) Å and the Nd—O nitrate distances span the range 2.530(9)–2.632(9) Å, averaging 2.567 Å. In [Ln(terpy)(NO₃)₃(H₂O)]·terpy (Ln = Ho, Er, Tm, Yb), the binding of the

terpy ligand to the lanthanide is more symmetrical. $[\text{Tm}(\text{terpy})(\text{NO}_3)_3(\text{H}_2\text{O})]$ has a Tm—O bond length for the monodentate group, of 3.251 Å, 0.12 Å, shorter than any of the Tm—O distances in the bidentate groups, whilst there is considerable asymmetry in a bidentate group in $[\text{Ln}(\text{terpy})(\text{NO}_3)_3(\text{H}_2\text{O})]\cdot\text{terpy}$, where the Ho—O distances are 2.431(8) Å and 2.725(11) Å, such that the nitrate has been considered intermediate between mono- and bidentate. The smallest of the lanthanide ions covered in this study, ytterbium, forms a complex with no water in its coordination sphere, but three bidentate nitrates. In $[\text{Yb}(\text{terpy})(\text{NO}_3)_3]$, Yb—O distances range from 2.364(8) Å to 2.406(10) Å, apart from one at 2.456(9) Å, whilst Yb—N distances are 2.417(7)–2.419(8) Å.²¹¹ Reaction of yttrium nitrate with terpy in MeCN yields two yttrium complexes.²¹⁸ Reaction with two moles of MeCN followed by crystallization gave crystals of nine-coordinate $[\text{Y}(\text{terpy})(\text{NO}_3)_3(\text{H}_2\text{O})]\cdot\text{terpy}\cdot 3\text{MeCN}$ containing two bidentate and one monodentate nitrate groups. Y—N distances average 2.497 Å, Y—OH₂ is 2.311 Å, and Y—O (nitrate) distances are 2.311 Å for the monodentate group and range from 2.390 Å to 2.504 Å (average 2.445 Å) for the bidentate groupings. Layering of more dilute solutions with ether formed $[\text{Y}(\text{terpy})(\text{NO}_3)_3(\text{H}_2\text{O})]$, with 10-coordinate molecules with three bidentate nitrates. Here Y—N distances average 2.519 Å and the Y—O distances within the bidentate nitrates average 2.508 Å within a range between 2.414 Å and 2.523 Å, with an outlier at 2.736 Å, over 0.2 Å greater than the others, indicating considerable congestion in the coordination sphere.²¹⁸

In contrast to the early lanthanides, where the same complex is obtained from synthesis in either acetonitrile or ethanol, solvent affects the structure for the 1:1 complexes of later lanthanides. The first indication of this was the discovery that the reaction of hydrated erbium nitrate with terpy in ethanol affords $[\text{Er}(\text{terpy})(\text{NO}_3)_3\cdot(\text{C}_2\text{H}_5\text{OH})]$ which contains both bidentate and monodentate nitrates as well as a coordinated ethanol.²¹⁹ Erbium is nine-coordinate in this complex. Er—N bond lengths (2.456(8)–2.485(8) Å) are very similar to those in the eight-coordinate $[\text{Er}(\text{terpy})\text{Cl}(\text{H}_2\text{O})_4]\text{Cl}_2\cdot 3\text{H}_2\text{O}$; two nitrates are bidentate, with Er—O distances averaging 2.416 Å, some 0.14 Å longer than that of the Er—O bond involving the monodentate nitrate Er—O (3.278(7) Å). A second oxygen in this monodentate nitrate is hydrogen bonded to the coordinated ethanol molecule (Er—O = 2.333(8) Å). Another feature of this structure is short C—H···O interactions involving nitrate oxygens and hydrogens of the terpyridyl ligand in other molecules.

Reaction of later lanthanide nitrates with terpy in MeCN solution affords nine-coordinate $[\text{Ln}(\text{terpy})(\text{NO}_3)_3]$ (Ln = Yb, Lu). Solvolysis of a nitrate group in $[\text{Yb}(\text{terpy})(\text{NO}_3)_3]$ is stereoselective, the nitrate *trans*- to the terpy ligand being replaced by ethanol and by water, with the formation of $[\text{Yb}(\text{terpy})(\text{NO}_3)_3(\text{EtOH})]$ (which has one monodentate nitrate) and $[\text{Yb}(\text{terpy})(\text{NO}_3)_2(\text{H}_2\text{O})_2]\text{NO}_3\cdot 2\text{H}_2\text{O}$ respectively. A similar effect is noted in the lutetium analogue with the isolation of an unusual complex $[\text{Lu}(\text{terpy})(\text{NO}_3)_2(\text{H}_2\text{O})(\text{EtOH})](\text{NO}_3)$, where both water and ethanol are bound to lutetium in preference to nitrate coordination, as well as the ethanol solvate $[\text{Lu}(\text{terpy})(\text{NO}_3)_3(\text{EtOH})]$. In $[\text{Lu}(\text{terpy})(\text{NO}_3)_3]$, Lu—N distances are 2.379–2.407 Å and Lu—O bonds fall into the range 2.350–2.440 Å, so that even with the smallest lanthanide, all the nitrates are essentially bidentate. Replacement of a bidentate nitrate *trans*- to the terpy by a coordinated ethanol and a monodentate nitrate causes a certain reorganization in the coordination sphere, with Lu—N bonds increasing by about 0.06 Å; the Lu—O (water) distance is 3.279(3) Å and the Lu—O(ONO₂) distance is 3.279(3) Å, showing that the Lu—O bond is about 0.1 Å shorter than for an oxygen atom in a bidentate nitrate group.²⁴

The 11-coordinate $[\text{La}(\text{NO}_3)_3(\text{terpy})(\text{MeOH})_2]$ has been isolated from the reaction of lanthanum nitrate with terpy in methanol, the lanthanum being 11-coordinate, with three bidentate nitrates, the La—N distances being 2.688 (3), 2.700 (3), and 2.715(3) Å. Five of the La—O (nitrate) distances span 2.596(3)–2.727(3) Å, the sixth being 2.926(3) Å; La—O (methanol) bonds are 2.560(2) Å and 2.580 (2) Å.²¹⁴ In the isomorphous $[\text{Ce}(\text{NO}_3)_3(\text{terpy})(\text{MeOH})_2]$, whose polyhedron is described as an icosahedron with two vertices replaced by one, the Ce—N distances are 2.682(2), 2.685(2), and 2.705(2) Å. Five of the Ce—O (nitrate) distances span 2.578(2)–2.712(2) Å, the sixth being 2.942(3) Å; Ce—O (methanol) bonds are 2.537(2) Å and 2.559(2) Å.²¹³ Thus a wide range of 1:1 complexes are known, though the picture is not yet complete, and some findings have yet to be reported. The role of solvent is critical in these syntheses.

Mononuclear $[\text{Yb}(\text{O}_2\text{CCCl}_3)_3\cdot(\text{terpy})\cdot\text{MeOH}]$ contains coordinated methanol and two unidentate carboxylates and one bidentate carboxylate affording eight coordinate ytterbium and $[\text{Ln}(\text{O}_2\text{CCCl}_3)_3\cdot(\text{terpy})\cdot(\text{H}_2\text{O})]$ (Ln = La–Nd) are dimeric with nine-coordinate lanthanides. A compound $[\text{Lu}(\text{O}_2\text{CCCl}_3)_3\cdot(\text{terpy})\cdot(\text{H}_2\text{O})]$ contains both the foregoing geometries.¹⁹⁵

Several reports have appeared of the syntheses and structures of mixed-ligand quaternary complexes involving terpy, $[\text{Yb}(\text{acac})(\text{terpy})(\text{NO}_3)_2]$,²²⁰ $[\text{Nd}(\text{hfac})(\text{terpy})(\text{NO}_3)_2(\text{H}_2\text{O})]$,²²¹

[Ln(hfac)₂(terpy)(NO₃)] (Ln = Gd, Dy, Er, Tb, Yb),²²¹ [Nd(terpy)(dbm)(NO₃)₂],²²¹ and [Ln(terpy)-(dbm)₂(NO₃)] (Ln = Pr, Ho)²²² all of which were crystallographically characterized. (Hhfac = hexafluoroacetylacetone; Hdbm = dibenzoylmethane.) A full report has appeared on a series of these compounds; [Ln(terpy)(NO₃)₂(acac)(H₂O)_n] (Ln = La, Pr, *n* = 1; Ln = Nd–Lu, *n* = 0).²²³ They exhibit three different solid-state structures. [La(terpy)(NO₃)₂(acac)(H₂O)] is 10-coordinate, with two bidentate nitrates and a chelating diketonate and a coordinated water; [Pr(terpy)(NO₃)₂(acac)(H₂O)] is nine-coordinate, with one monodentate and one bidentate nitrate and a chelating diketonate and a coordinated water; and the remainder are [Ln(terpy)(NO₃)₂(acac)]. (Nd–Lu) with two bidentate nitrates and a chelating diketonate.

Complexes of 2,4,6-tris-2-pyridyl-1,3,5-triazine (tptz) have been reinvestigated. Tptz acts as a terdentate ligand in the structures of [Eu(tptz)Cl₃(MeOH)₂]·2MeOH (eight-coordinate) and [Pr(tptz)(OAc)₃]₂·2MeOH (10-coordinate). The latter²²⁴ features the presence of double ($\eta^2, \mu-1,1$) acetate bridges increasingly familiar from other lanthanide carboxylate complexes. Pr–N distances fall into a range 2.674(6)–2.717(6) Å, rather larger than those in the nine-coordinate [Pr(terpy)Cl(H₂O)₅]²⁺ ion. In the [Eu(tptz)Cl₃(MeOH)₂] molecule, Eu–N distances are 2.555(4) Å to the central nitrogen and 2.616(4)–2.645(4) Å for the nitrogens in the pyridine rings.²²⁴ Although it has proved difficult to obtain good quality crystals from MeCN solution, the structure of [Sm(tptz)(NO₃)₃(H₂O)]·2H₂O has been determined and shows it to contain 10-coordinate Sm with all nitrates bidentate.²¹⁶ Sm–N distances are 2.571(4) Å to the central nitrogen and 2.631(4)–2.644(5) Å for the nitrogens in the pyridine rings, showing a similar pattern to the europium complex. The bond to the water molecule, at 2.420(4) Å, is as usual in the terpy analogues, considerably shorter than the Sm–O (nitrate) bonds, which lie in a range 2.492(4)–2.615(4) Å.

A very detailed study has been made²²⁶ of lanthanide nitrate complexes of 4-amino-bis(2,6-(2-pyridyl))-1,3,5-triazine (abptz). Many of these compounds resemble corresponding terpy complexes and gradually a picture is being built up of how the structure and stoichiometry depend on factors such as the radius of the metal ion, composition of the reaction mixture, and the solvent employed. Complexes [La(abptz)(NO₃)₃(H₂O)₂] (11-coordinate), [Ln(abptz)-(NO₃)₃(H₂O)] (Ln = La, Pr–Sm; 10-coordinate), [Ln(abptz)(NO₃)₃(H₂O)] (Ln = Yb, Y; nine-coordinate, with one monodentate nitrate), [Ln(abptz)(NO₃)₂(H₂O)₃]NO₃ (Ln = Nd, Sm; 10-coordinate) and [Ln(abptz)(NO₃)₂(H₂O)₂]NO₃ (Ln = Eu–Lu; nine-coordinate) have all been crystallographically characterized.²²⁶ These compounds exhibit the trends in bond distances already commented on in discussing terpyridyl complexes, but some general points are relevant here. The fact that 10- and 11-coordinate [La(abptz)(NO₃)₃(H₂O)_n] (*n* = 1, 2) can be obtained, unlike subsequent lanthanides which, at most, adopt just 10-coordination (although no data were reported for cerium) shows that the position of lanthanum as the largest lanthanide ion sometimes causes it to behave atypically. A comparison between the two lanthanum complexes shows the decrease in coordination number from 11 to 10 is accompanied by a decrease in La–O (water) distance from 2.589(4) Å and 2.610(4) Å to 2.483(5) Å; similarly, the La–N distances decrease from 2.739(4), 2.755(5), and 2.805(6) Å in the 11-coordinate compound to 2.576(5), 2.625(5), and 2.641(5) Å in 10-coordinate [La(abptz)(NO₃)₃(H₂O)]. The range of La–O (nitrate) distances decreases from 2.628(4)–2.702(5) Å, with an outlier at 2.805(6) Å in [La(abptz)(NO₃)₃(H₂O)₂], to 2.525(5)–2.620(5) Å in [La(abptz)(NO₃)₃(H₂O)], indication of the congestion in the coordination sphere in the 11-coordinate complex. Across the family of 10-coordinate [La(abptz)(NO₃)₃(H₂O)] (La = La, Pr, Nd, Sm) species, there is a general tendency towards contraction of bond lengths with increasing atomic number, but with irregularities, partly because the Nd complex is not isomorphous with the others. Compounds [Ln(abptz)(NO₃)₂(H₂O)₃]NO₃ (Ln = Nd, Sm; 10-coordinate) and [Ln(abptz)(NO₃)₂(H₂O)₂]NO₃ (Ln = Eu–Lu) are clearly analogous to the terpy complexes studied by White and co-workers.²¹⁴ They can be regarded as having a girdle round the “waist” of the metal comprised of the abptz ligand and two or three water molecules, with two bidentate nitrates coordinated to the metal in axial positions. A comparison of the structures of the two 10-coordinate species [Nd(abptz)(NO₃)₃(H₂O)] and [Nd(abptz)(NO₃)₂(H₂O)₃]NO₃ is informative. Average Nd–N distances are 2.605 Å and 2.603 Å respectively; average Nd–O(H₂O) distances are 2.470 Å and 2.485 Å respectively, closely comparable, but the Nd–O (nitrate) distances for [Nd(abptz)(NO₃)₃(H₂O)] fall within a range of 2.546(4)–2.597(4) Å, averaging 2.568 Å, whilst for [Nd(abptz)(NO₃)₂(H₂O)₃]NO₃ the respective values are 2.588(6), 2.602(5), 2.608(5), and 2.728(7) Å, averaging 2.632 Å. There is thus congestion brought about by replacing a compact nitrate group by two water molecules, leading to an increased tendency for one nitrate group to become monodentate. This view is supported by the value of 2.849(14) Å for the “long” Sm–O distance in [Sm(abptz)(NO₃)₂(H₂O)₃]NO₃. At this point, further contraction in the lanthanide

radius evidently results in ejection of a water from the coordination sphere (rather than the presence of three waters and a monodentate nitrate) with the formation of $[\text{Ln}(\text{abptz})(\text{NO}_3)_2(\text{H}_2\text{O})_2]\text{NO}_3$ ($\text{Ln} = \text{Eu} - \text{Lu}$). These exhibit the usual trend of decreasing bond lengths with increasing atomic number until in the case of the lutetium complex there is some evidence for steric strain again. The compounds $[\text{Ln}(\text{abptz})(\text{NO}_3)_3(\text{H}_2\text{O})]$ ($\text{Ln} = \text{Yb}, \text{Y}$) are nine-coordinate, with one monodentate nitrate, rather than the alternative $[\text{Ln}(\text{abptz})(\text{NO}_3)_3]$, with three monodentate nitrates, adopted for $[\text{Ln}(\text{terpy})(\text{NO}_3)_3]$ for Yb, Lu and some other later lanthanides, suggesting that subtle factors are at work in the adoption of this structure. Extensive hydrogen-bonding networks are present in the structures of all these compounds. Complexes of 2,6-bis(5,6-dialkyl-1,2,4-triazin-3-yl)pyridines have attracted attention as extremely effective selective complexing agents for the actinides, and a few studies of model lanthanide complexes have been reported.^{227–229} The $[\text{Ln}(\text{Pr}^n\text{btp})_3]^{3+}$ ($\text{Ln} = \text{Sm}, \text{Tm}, \text{Yb}$) cations are nine-coordinate in a number of salts, displacing weakly coordinating anions such as iodide,²²⁷ whilst the similar $[\text{Ce}(\text{Rbtp})_3]\text{I}_3$ ($\text{R} = \text{Me}, \text{Pr}^n$) have been reported,²²⁸ comparative studies showing that Ce has a lesser affinity for Pr^nbtp than uranium(III). These $[\text{LnL}_3]^{3+}$ species have not been isolated for the early lanthanides, however; they instead form some novel dinuclear complexes $[\text{Ln}_2\text{L}_2(\text{NO}_3)_6]$ ($\text{R} = \text{Me}; \text{Ln} = \text{La}, \text{Pr}, \text{Nd}, \text{Sm}$).²²⁹ In these compounds, the lanthanides are bound to three bidentate nitrates and one terdentate ligand, with one oxygen atom additionally coordinating to the other lanthanide, affording 10-coordination overall. Species $[\text{NdL}(\text{NO}_3)_3(\text{EtOH})]$ ($\text{R} = \text{Et}$) and $[[\text{NdL}_2(\text{NO}_3)_2]^+][\text{Nd}(\text{NO}_3)_5]$ ($\text{R} = \text{Bu}^i$) have also been characterized. This plethora of stoichiometric variation is striking, and it would be interesting to know whether it occurs in solution too. Complexes (2:1) are formed by 2,6-bis(benzimidazol-2'-yl)pyridine, $[\text{Ln}(\text{bzimpy})_2(\text{NO}_3)_2]\text{NO}_3$, which exhibit strong luminescence ($\text{Ln} = \text{Eu}, \text{Tb}$).^{230,231} In $[\text{Eu}(\text{mbzimpy})_3](\text{ClO}_4)_3$ europium has tricapped trigonal prismatic nine-coordination ($\text{mbzimpy} = 2,6\text{-bis}(1\text{-methylbenzimidazol-2-yl})\text{pyridine}$); fluorescence spectra indicate that this geometry is maintained in solution. The cation has approximately C_3 symmetry in the solid state and fluorescence spectra support this. $[\text{Eu}(\text{mbzimpy})_3](\text{ClO}_4)_3$ has $\text{Eu}-\text{N}$ distances in the range 2.576(5)–2.613(7) Å.²³² Similar complexes $[\text{Ln}(\text{mbzimpy})_3](\text{ClO}_4)_3$ can be made for other lanthanides ($\text{Ln} = \text{La}, \text{Gd}$, and Tb), but for lutetium only $[\text{Lu}(\text{mbzimpy})_3(\text{H}_2\text{O})(\text{MeOH})](\text{ClO}_4)_3$ can be isolated; the eight-coordinate cation has $\text{Lu}-\text{N}$ distances of 2.37(1)–2.46(1) Å, $\text{Lu}-\text{O}(\text{H}_2\text{O}) = 3.29(1)$ Å and $\text{Lu}-\text{O}(\text{MeOH}) = 2.35(1)$ Å. Spectrophotometric titrations indicate that 1:1, 1:2, and 1:3 complexes are formed in solution throughout the lanthanide series but the $[\text{Ln}(\text{mbzimpy})_3]^{3+}$ ion is less stable for heavier (and smaller) lanthanides Ho, Yb, and Lu. A similar effect occurs with the related terdentate ligands 2,6-bis(1-X-benzimidazol-2-yl)pyridine ($\text{X} = \text{Pr}, 3,5\text{-dimethoxybenzyl}$).²³³ The 1:1 and 1:2 complexes formed by this ligand show the normal thermodynamic behavior associated with electrostatic effects, but the tris complexes $[\text{Ln}(\text{mbzimpy})_3]^{3+}$ display unusual selectivity for the mid-lanthanide ions.²³⁴ The triple-helical structure found in the crystal structure of the Eu complex appears to be retained in solution for the others, with control of the coordination cavity caused by intrastrand $\pi-\pi$ stackings maximized at Gd. Only the 1:2 complex could be isolated for Yb, a hydroxy-bridged dimer $[(\text{mbzimpy})_2\text{Yb}(\text{H}_2\text{O})(\mu\text{-OH})_2\text{Yb}(\text{mbzimpy})_2](\text{ClO}_4)_4$, with eight-coordinate Yb. This has $\text{Yb}-\text{N}$ distances of 2.420(5) Å to 2.567(5) Å and $\text{Yb}-\text{O}$ distances 3.231(4)–3.235(5) Å. A spectroscopic study of $[\text{Ln}(\text{mbzimpy})(\text{NO}_3)_3(\text{MeOH})]$ ($\text{Ln} = \text{Eu}, \text{Tb}$) indicates that the ligand has similar photophysical properties to terpy.²³⁵ 2,6-Bis(1'-ethyl-5'-methylbenzimidazol-2'-yl)pyridine (L) reacts with lanthanide perchlorates in a similar way, forming mononuclear triple-helical complexes $[\text{LnL}_3](\text{ClO}_4)_3$ ($\text{Ln} = \text{Eu}, \text{Gd}, \text{Tb}$). $[\text{EuL}_3](\text{ClO}_4)_3 \cdot 4\text{MeCN}$ has slightly distorted tricapped trigonal prismatic coordination of Eu, with $\text{Eu}-\text{N}$ distances of 2.53(2)–2.66(2) Å. The presence of the ethyl groups causes a slide of the strands which distorts the trigonal symmetry, as shown in the luminescence spectra.²³⁶ When two terdentate bzimpy ligands are linked by a “spacer” to discourage formation of a mononuclear complex, self-assembly leads to a triple helical binuclear complex, $[\text{Ln}_2\text{L}_3](\text{ClO}_4)_6$ ($\text{Ln} = \text{La}, \text{Eu}, \text{Gd}, \text{Tb}, \text{Lu}; \text{L} = \text{bis}[1\text{-methyl-2-(6'-[1''-(3,5-dimethoxybenzyl)-benzimidazol-2''-yl]pyrid-2'-yl)]\text{benzimidazol-5-yl]methane}$). The structure of $[\text{Eu}_2\text{L}_3](\text{ClO}_4)_6 \cdot 9\text{MeCN}$ shows europium has tricapped trigonal prismatic nine-coordination with $\text{Eu}-\text{N}$ distances of 2.54(3)–2.64(3) Å, averaging 2.59(6) Å, the europium site having pseudo- D_3 symmetry. Luminescence studies support this view but confirm that secondary interactions with lattice waters in $[\text{Eu}_2\text{L}_3](\text{ClO}_4)_6 \cdot n\text{H}_2\text{O}$ ($n = 2$ or 9) destroy this high symmetry.^{237,238}

Another approach to forming these helical species is to use ligands in essence derived from the bis(benzimidazol-2'-yl)pyridine family, with the benzimidazole rings replaced with carboxamide moieties, so that they remain tridentate ligands, but with a NO_2 donor group. The purpose of this was to obtain more strongly luminescent species. Thus N,N,N',N'-tetraethylpyridine-2,6-dicarboxamide (L) forms $[\text{LnL}_3]^{3+}$ complex ions across the lanthanide series.²³⁹ Structures for $[\text{LaL}_3](\text{ClO}_4)_3$ and $[\text{EuL}_3](\text{CF}_3\text{SO}_3)_3$ show that each ligand strand is meridionally tri-coordinated,

producing tricapped trigonal prismatic coordination of the lanthanides with near D_3 symmetry. Ranges of Ln—O distances are 2.470(5)–2.527(6) Å for the La complex and 2.392(5)–2.426(5) Å for the europium complex; corresponding ranges for the Ln—N bonds are 2.679(7)–2.731(7) Å and 2.547(6)–2.569(9) Å for the La and Eu complexes respectively. The lanthanum complex is more distorted and fluorescence studies on Eu^{3+} doped into the La, Gd, and Lu complexes suggest that the ligand cavity is a better match for the heavier lanthanide ions.²³⁹ An alternative approach, using a simpler ligand, diethyl pyridine-2,6-dicarboxylate, showed that it formed complexes with 1:1, 1:2, and 1:3 stoichiometries in solution. These have low stabilities and the 1:3 complexes cannot be isolated in the solid state. The 2:1 complex $[\text{EuL}_2(\text{CF}_3\text{SO}_3)_2(\text{OH}_2)](\text{CF}_3\text{SO}_3)$ contains nine-coordinate europium; the amide ligands are indeed tridentate, with Eu—N distances of 2.542(8)–2.573(7) Å; Eu—O (ester) of 2.458(7)–2.561(6) Å, Eu—O (water) 2.392(8) Å and Eu—O (triflate) 2.361(6)–2.412(8) Å. The Eu—O distances for the ester oxygens are especially long, reflecting the weakness of the coordination.²⁴⁰ Using segmental ligands from the bis(1-alkyl-2-[6'-(N,N-diethylcarbamoyl)pyridin-2'-yl]benzimidazol-5-yl)methane (L) family, which contain two linked N_2O donors, triple-stranded helicate complexes $[\text{Ln}_2\text{L}_3](\text{ClO}_4)_3$ are obtained; their structure is confirmed by X-ray diffraction on the Tb member and the triple helical structure is maintained in solution to judge from NMR and ES-MS measurements.²⁴¹ Quantum yield determinations on the Eu complex indicate luminescence 50 times stronger than in corresponding compounds containing benzimidazole groups rather than carboxamide groups. Use of lanthanide triflates as starting materials tends to result in double-stranded complexes containing coordinated triflate. Use of the segmental ligand bis(1-ethyl-2-[6'-(carboxy)pyridin-2'-yl]benzimidazol-5-yl)methane, a molecule of which contains two distinct N_2O donor groups, leads to the formation of complexes $[\text{Ln}_2\text{L}_3](\text{ClO}_4)_3$, again across the whole lanthanide series. The three helical ligands wrap round the metal ions, again achieving pseudo- D_3 symmetries; NMR spectra indicate that time-averaged D_3 symmetries are maintained in solution.²⁴²

A detailed study has been reported of lanthanide nitrate complexes of the terdentate triazole ligand 2,6-bis(5-methyl-1,2,4-triazol-3-yl)-pyridine (DMTZP) which behaves as a planar terdentate ligand resembling terpy, tptz, and their fellows. Complexes isolated and examined crystallographically include $[\text{La}(\text{DMTZP})(\text{NO}_3)(\text{H}_2\text{O})_5](\text{NO}_3)_2$, $[\text{Ln}(\text{DMTZP})(\text{NO}_3)_3(\text{H}_2\text{O})]$ (Ln = Nd, Sm, Tb); $[\text{Ho}(\text{DMTZP})(\text{NO}_3)_3(\text{H}_2\text{O})]$ (with one monodentate nitrate), and $[\text{Ln}(\text{DMTZP})(\text{NO}_3)_3]$ (Ln = Er, Yb) have all been characterized crystallographically.²⁴³ The tendency towards decreasing coordination number with smaller lanthanide ion noted elsewhere is marked here, but one particularly unusual feature is the presence of only one coordinated nitrate group in the 10-coordinate complex $[\text{La}(\text{DMTZP})(\text{NO}_3)(\text{H}_2\text{O})_5](\text{NO}_3)_2$. Normally only one nitrate is replaced, usually lying *trans*- to the terdentate ligand, and it would be interesting to know whether this is caused by the particular ligand type or whether there is some other cause. The La—N bond lengths are 2.713(18), 2.724(17), and 2.774(12) Å (average 2.737 Å) in comparison with values of 2.576(5), 2.625(5), and 2.641(5) Å, average 2.614 Å in 10-coordinate $[\text{La}(\text{abptz})(\text{NO}_3)_3(\text{H}_2\text{O})]$, suggesting there is congestion here. A comparison between the 10-coordinate species $[\text{Nd}(\text{DMTZP})(\text{NO}_3)_3(\text{H}_2\text{O})]$ and $[\text{Nd}(\text{abptz})(\text{NO}_3)_3(\text{H}_2\text{O})]$ indicates longer Nd—N bonds in the former (2.652 Å vs. 2.605 Å) but longer Nd—O (nitrate) distances in the latter (2.549 Å for the DMTZP complex vs. 2.5671 Å for the abptz complex) which may reflect the strength of metal–ligand bonding.²⁴³

Several complexes of the tripodal tetradentate ligands tpza and tpa (tpa = tris[(2-pyridyl)methyl]amine; tpza = tris[(2-pyrazinyl)methyl]amine) have been made.²⁴⁴ $[\text{Ln}(\text{tpa})\text{Cl}_3]$ (Ln = Eu, Tb, Lu) have seven-coordination, with average Ln—N distances decreasing from 2.585 Å (Eu) to 2.520 Å (Lu) and M—Cl distances changing from 2.664 Å (Eu) to 2.602 Å (Lu). The larger neodymium ion can accommodate a coordinated solvent molecule in the eight-coordinate Nd analogue, $[\text{Nd}(\text{tpa})\text{Cl}_3(\text{MeOH})]$, where the increase in coordination number causes an increase in average Nd—Cl distance to 2.760 Å but more significantly results in one of the Nd—N bonds in the “equivalent” pyridyl arms, at 2.7021(14) Å, being appreciably longer than the other two (2.601(2) Å and 2.620(2) Å). Reaction of the lanthanide perchlorates with tpza in MeCN affords $[\text{Ln}(\text{tpza})(\text{H}_2\text{O})_3(\text{MeCN})_3](\text{ClO}_4)_3$ (Ln = La, Nd, Eu). The structure of the Nd compound shows that it has 10-coordinate neodymium, with Nd—N (tpza) in the range 2.719(7) Å to 2.770(8) Å, Nd—N (MeCN) of 2.620(9)–2.698(8) Å and Nd—O 2.424(6) Å to 2.543(6) Å. $[\text{M}_3(\text{THF})_4]$ (M = La, U) reacts with²⁴⁵ tpza forming $[\text{M}(\text{tpza})\text{I}_3(\text{NCMe})]$ and $[\text{M}(\text{tpza})\text{I}_3(\text{THF})]$. The tripodal tpza is tetradentate, so that these complexes are all eight-coordinate. In the MeCN adducts, the M—N (pyrazine) distances are very similar, whilst the U—N (MeCN) distance is 0.05 Å shorter than the distance in the corresponding La complex, whereas in $[\text{M}(\text{tpza})\text{I}_3(\text{THF})]$, the M—N distance is 0.05 Å shorter than in the La complex. These findings are interpreted in terms of some covalent contribution to the U—N bonding.

Reaction of ethanolic lanthanide nitrates with the hexadentate ligand tpen (tpen = tetrakis-(2-pyridylmethyl)-1,2-ethylenediamine) gives the complexes $\text{Ln}(\text{tpen})(\text{NO}_3)_3 \cdot 3\text{H}_2\text{O}$ ($\text{Ln} = \text{La}, \text{Tb}$).²⁴⁹ These are $[\text{Ln}(\text{tpen})(\text{NO}_3)_2]\text{NO}_3$ with the lanthanide coordinated to six nitrogens from tpen and two bidentate nitrates. The mean La—N bond length is 2.720(21) Å and the mean La—O bond is 2.583(13) Å; corresponding values for the terbium complex are Tb—N = 2.624(29) Å and Tb—O = 2.492(33) Å. Investigations on complexation of tpen and Ln^{3+} confirms that these complexes are also stable in aqueous solution.²⁵⁰ The tetradentate 2,2':6',2'':6'',2''':6'''-quaterpyridine (qtpy) and hexadentate 2,2':6',2'':6'',2''':6''',2''':6''',2''':6'''-sexipyridine (spy) ligands form 1:1 complexes with yttrium and europium nitrates respectively. Reaction of yttrium chloride with hot methanolic qtpy gives $[\text{Y}(\text{qtpy})\text{Cl}_3(\text{H}_2\text{O})_6]$ of unknown structure, and $\text{Y}(\text{qtpy})(\text{NO}_3)_3(\text{H}_2\text{O})_2$, which contains nine-coordinate $[\text{Y}(\text{qtpy})(\text{NO}_3)_2(\text{H}_2\text{O})]^{+}$ cations. The quaterpyridine ligand is essentially planar (recalling the behavior of terpy) and the water molecule is also coordinated in the same plane; the two symmetrically bidentate nitrate groups coordinate above and below the plane of the qtpy. The Y—O (water) distance is 2.321(8) Å and Y—N distances fall in the narrow range 2.464(8)–2.469(9) Å whilst Y—O 2.403(7)–2.434(8) Å.²⁵¹ Reaction of spy with hot methanolic europium nitrate leads to $[\text{Eu}(\text{spy})(\text{NO}_3)_2]\text{NO}_3$ (the ionic nitrate can be exchanged for PF_6). This contains 10-coordinate $[\text{Eu}(\text{spy})(\text{NO}_3)_2]^{+}$ cations where the hexadentate spy twists itself helically round the metal. The two coordinated nitrates are bidentate (Eu—O 2.504(16)–2.558(16) Å, whilst the Eu—N distances fall in the range 2.536(14)–2.589(10) Å.²⁵² There is obviously considerable scope here for further investigation.

Developments here have included a considerable broadening in the range of alkylamide ligands investigated. Several more $[\text{Ln}(\text{N}(\text{SiMe}_3)_2)_3]$ ($\text{Ln} = \text{Y}, \text{Ce}, \text{Dy}, \text{Er}, \text{and Yb}$) have had their structures determined, in addition to earlier structures of the Nd and Eu complexes.^{253–256} Reactions of LnI_3 with $\text{LiN}(\text{SiMe}_3)_2$ have been investigated.²⁵⁷ With LaI_3 and SmI_3 , a mixture of $[\text{LnI}(\text{N}((\text{SiMe}_3)_2)_2)]$ and $[\text{Ln}(\text{N}((\text{SiMe}_3)_2)_3)]$ obtains; in contrast, only $[\text{YbI}(\text{N}((\text{SiMe}_3)_2)_2)]$ can be isolated for ytterbium. In the case of Ln , the dimeric $[(\text{THF})(\text{Me}_3\text{Si})_2\text{N})_2\text{Ln}(\mu\text{-I})_2\text{La}(\text{N}((\text{SiMe}_3)_2)_2(\text{THF}))]$ has been crystallized. Anhydrous lanthanide triflates are good alternatives to LnCl_3 for making $[\text{Ln}(\text{N}(\text{SiMe}_3)_2)_3]$ ($\text{Ln} = \text{La}, \text{Nd}, \text{Sm}, \text{Er}$) which in turn react forming acyclic Schiff base complexes.²⁵⁸ $[\text{Ln}(\text{N}(\text{SiMe}_3)_2)_3]$ ($\text{Ln} = \text{Y}, \text{La-Nd}, \text{Sm}, \text{Eu}, \text{Tb-Ho}, \text{Tm-Yb}$) react with CyNC ($\text{Cy} = \text{cyclohexyl}$) forming five-coordinate adducts $[\text{Ln}(\text{N}(\text{SiMe}_3)_2)_3(\text{CyNC})_2]$. The crystal structure of the Nd complex confirms the trigonal bipyramidal geometry.²⁵⁹ The Nd-N distances are 2.331–2.341 Å and Nd-C 2.737(6) Å. The Nd-N distance can be compared with that of 3.29(2) Å in the parent $[\text{Nd}(\text{N}(\text{SiMe}_3)_2)_3]$, indicating a degree of congestion, especially in the long Nd-C distances. $[\text{Y}(\text{N}(\text{SiMe}_3)_2)_3]$ forms a tbp (trigonal bipyramidal) adduct $[\text{Y}(\text{N}(\text{SiMe}_3)_2)_3(\text{PhCN})_2]$ with axial nitriles;²⁵³ in a preparation under similar conditions, the corresponding bis(trimethylsilyl)methyl is isolated as the four-coordinate adduct $[\text{Y}(\text{CH}(\text{SiMe}_3)_2)_3(\mu\text{-Cl})\text{Li}(\text{Et}_2\text{O})_3]$. The structure of three-coordinate $[\text{Yb}(\text{N}(\text{SiMe}_3)_2)_3]$ (Yb-N 2.183 (5) Å) has been reported, analogous to other lanthanide homologues.²⁶⁰ It was one of several products from the reaction of YbCl_3 and $\text{NaN}(\text{SiMe}_3)_2$ in a 1:2 molar ratio, along with $[\text{Yb}(\text{N}(\text{SiMe}_3)_2)_2(\mu\text{-Cl})(\text{THF})_2]$ and

[Yb₃Cl₄O((N(SiMe₃)₂)₃(THF))₃]. The latter is a trinuclear cluster with a triangle of ytterbiums, where Yb is octahedrally coordinated by an amide nitrogen, a THF, two μ_2 -chlorine atoms and a μ_3 -chlorine and μ_3 -oxygen. Extended heating of [Yb(N(SiMe₃)₂)₂(μ -Cl)(THF)]₂ in heptane at 90 °C results in the removal of THF, affording the base-free [Yb(N(SiMe₃)₂)₂(μ -Cl)]₂, which contains four-coordinate ytterbium. Removal of the THF molecules from the solvate means that the base-free compound exhibits structural unsaturation with a shortening of Yb—N and Yb—Cl from 2.185 Å and 2.683 Å respectively in [Yb(N(SiMe₃)₂)₂(μ -Cl)(THF)]₂ to 2.144 Å and 2.623 Å respectively in [Yb(N(SiMe₃)₂)₂(μ -Cl)]₂. The peroxo complex [Yb₂(N(SiMe₃)₂)₄(μ -O₂)(THF)]₂ has also been examined.²⁶⁰ Several others have investigated the reaction of LnCl₃ with a deficit of Li N(SiMe₃)₂ that affords [Ln(N(SiMe₃)₂)₂(μ -Cl)(THF)]₂ (Ln = Eu,²⁶¹ Gd,²⁶¹ Yb,²⁶¹ Ce,²⁶² Nd,²⁶² and Sm²⁶³).

[(Me₃Si)₂N]₂(THF)Sm(μ -X)₂Sm(THF)((N(SiMe₃)₂)₂) (X = Cl, Br) have symmetrical halogen bridges.²⁶⁴ LnCl₃ reacts with two moles of Na[N(SiMe₃)₂] forming dimeric [(Me₃Si)₂N]₂(THF)Ln(μ -Cl)₂Ln(THF)((N(SiMe₃)₂)₂) (Ln = Ce, Nd); they can also be prepared by redistribution reactions between LnCl₃ and [Ln(N(SiMe₃)₂)₃]. The structure of the Nd compound was determined.²⁶⁴ The three-coordinate amides [Ln(N(SiMe₃)₂)₃] do not react with tris(*t*-butyl)methanol (tritox-H) but the less hindered [Ln(N(SiHMe₂)₂)₃] undergo clean solvolysis affording [Ln(tritox)₃-(THF)] (Ln = Y, Nd, Dy, Er). Structures have been reported for four-coordinate [Ln(tritox)₃(THF)] (Ln = Y, Nd) and five-coordinate [Ln(N(SiHMe₂)₂)₃(THF)₂] (Ln = Nd, Y).²⁶⁵

[Ln{N(SiHMe₂)₂}₃(THF)₂] (Ln = Y, La-Lu) are isostructural, with trigonal bipyramidal coordination; structures have now been determined for the La and Lu compounds, in addition to the Nd and Y analogues previously reported.²⁶⁶ The structure of [Sm(N(SiHMe₂)₂)₃(THF)₂] is *tbp* with axial THF ligands.²⁶⁷ [Y(N(SiHMe₂)₂)₃(THF)₂] readily reacts with [*p*-*t*-butylcalix[4]arene]H₄ at room temperature exchanging all the amide ligands forming a dimeric calix[4]arene complex.²⁶⁸ [Ln(N(SiHMe₂)₂)₃(THF)₂] (Ln = Y, La) react with substituted bisoxazolinates forming mono and bis(bisoxazolate) complexes.²⁶⁹ [Nd{N(SiMe₃)₂}₃] and [Nd{N(SiHMe₂)₂}₃(THF)₂] have been anchored to the internal walls of microporous MCM-41 (mesoporous silicate) as potential catalyst precursors.²⁷⁰ The amides [Ln(N(SiHMe₂)₂)₃(THF)₂] (Ln = Y, La) has been grafted onto MCM-41 then used as precursors for immobilized [Ln(fod)_n] (fod = 1,1,1,2,2,3,3-heptafluoro-7,7-dimethyl-4,6-octanedionate) species, which are promising catalysts for the Danishefsky heterogeneous Diels–Alder reaction. Untethered [Ln(N(SiHMe₂)₂)₃(THF)₂] can be used to make [Ln(fod)₃] in good yield.²⁷¹ Amides [Ln{N(SiMe₃)(2,6-Pr^{*i*}₂C₆H₃)}₂(THF)₂] have been reported to have distorted tetrahedral structures.²⁷² [Yb{N(SiMe₃)(2,6-Pr^{*i*}₂C₆H₃)}₂(THF)₂] partially desolvates in vacuo forming [Yb{N(SiMe₃)(2,6-Pr^{*i*}₂C₆H₃)}₂(THF)]. Use of a highly fluorinated amide has permitted the synthesis of [Sm(N(SiMe₃)(C₆F₅)₃)₃] (**13**) in which there are many Sm···F and agostic interactions.

The neodymium compound [η^6 -C₆H₅Me]Nd(N(C₆F₅)₃)₃] has a η^6 -bonded toluene molecule with a distorted piano-stool geometry.²⁷³ [Sm(N(C₆F₅)(SiMe₃)₃)(THF)] (**14**) has the distorted tetrahedral

(13)

[illegible]

A systematic study has been made of lanthanide arylamides.²⁹³ Reaction of NdCl_3 with KNHAr ($\text{Ar} = \text{Ph}$) leads to $[\text{Nd}(\text{NHPh})_3 \cdot 3\text{KCl}]$, reminiscent of the adducts of the dimethylamides. Using

the bulkier 2,6-Me₂C₆H₃ group, anionic species [K(THF)₆]₂[{Ln(μ-NH(2,6-Me₂C₆H₃))(NH-(2,6-Me₂C₆H₃)₃)₂}] (Ln = Nd, Sm) and [K(DME)(THF)₃]₂[{Y₂(μ-NH(2,6-Me₂C₆H₃))₂(μ-Cl)(NH(2,6-Me₂C₆H₃)₄)(THF)₂}] are formed. The even more demanding 2,6-Prⁱ₂C₆H₃ group leads to octahedral [Nd(NH-2,6-Prⁱ₂C₆H₃)₃(THF)₃] and trigonal bipyramidal [Ln(NH-2,6-Prⁱ₂C₆H₃)₃(THF)₂] (Ln = Y, Yb). Unsolvated dimeric compounds [{Ln(μ-NH(2,6-2,6-Prⁱ₂C₆H₃))(NH(2,6-Prⁱ₂C₆H₃)₂)₂] (Ln = Y, Yb) are produced by amine exchange with [Ln{N(SiMe₃)₂}₃].²⁹⁴ Phenylamides have been used to make polynuclear lanthanide amides including [Ln₂Br₄(μ-NHPh)₂(THF)₅] (Ln = Sm, Gd); [Ln₄(μ₄-O)(NHPh)₃(OSiMe₂NPh)₆-Na₅(THF)₇].THF (Ln = Gd, Yb) have also been reported.

Reaction of [SmCl₃(THF)₃] with LiNR₂ (R = Cy, Prⁱ) give products dependent upon R, [(Cy₂N)₂Sm(μ-Cl)(THF)]₂ and [(Prⁱ₂N)₂SmCl₃Li(TMEDA)₂]. The former can be converted into monomeric [Sm(NCy₂)₃(THF)].²⁹⁵ A new family of compounds of anionic lanthanide silylamides has been reported ((15); Ln = Sm, Eu, Gd–Tm, Lu; (L)₃ = (THF)₃, (Et₂O)₃, and (THF)₂(Et₂O)) which features four-coordinate lanthanides.²⁹⁶ They do not afford neutral tris(complexes) on heating.

(15)

A chelating bis(silylamide) ligand forms yttrium complexes, including a five-coordinate methyl (16).²⁹⁷

(16)

K[Er(η²-Bu^tpz)₄] and [K(18-crown-6)(DME)(C₆H₅Me)] [Er(η²-Bu^tpz)₄] are the first homoleptic lanthanide pyrazolides; in the unsolvated compound, the potassium ions are η³-bonded to two pyrazolides.²⁹⁸ Reaction of Bu^tpzH with lanthanide metals and mercury at 220 °C affords [Ln(η²-Bu^tpz)₃] (Ln = Nd, Sm) and [Yb₂(η²-Bu^tpz)₅], the latter having the structure [(η²-Bu^tpz)Yb^{II}(μ-η²: η²-Bu^tpz)₂Yb^{III}(η²-Bu^tpz)₂].²⁹⁹ Other 3,5-di-*t*-butylpyrazolides to be reported include [Y(η²-Bu^tpz)₃L₂] (L = Py, THF), [Er(η²-Bu^tpz)₃L₂] (L = Py, 4-*t*-BuPy, 4-*n*-BuimH), [Er(η²-Bu^tpz)₃(Bu^tpzH)] and [Lu(η²-Bu^tpz)₃(4-*t*-Bupy)₂]. Several of these have been shown to have monomeric structures though the unsolvated [Y(η²-Bu^tpz)₃] is evidently oligomeric.³⁰⁰ Study has been made³⁰¹ of compounds using a β-diketiminato ligand, (L-L)[−] (L-L = (R)NC(Ph)C(H)C(Ph)N(R) (where R = Me₃Si); reaction of LnCl₃ or LnI₃ with Na(L-L) gives [Ln(L-L)₂Cl] (Ln = Ce, Pr, Nd, Sm, Eu, Yb) and [Tm(L-L)₂]. [Ce(L-L)₂Cl] reacts with LiCHR₂ forming [Ce(L-L)₂(CHR₂)]; this compound and [Nd(L-L)₂Cl] both have monomeric structures. The N-substituted guanidates [M{CyNC{N(SiMe₃)₂}NCy}₂(μ-Cl)₂LiS₂] (M = Sm, Yb; S = Et₂O, 1/2 TMEDA) have been synthesized and offer a route to solvent-free alkyls and amides, of which [Sm{CyNC{N(SiMe₃)₂}NCy}₂(CH(SiMe₃)₂)] and [Yb{CyNC{N(SiMe₃)₂}NCy}₂(N(SiMe₃)₂)] have been characterized.³⁰²

Benzamidinates have been studied, often using this ligand in association with cyclopentadienyl type ligands. Yttrium (and scandium) complexes have been investigated³⁰³ and monomeric [(PhC(N(SiMe₃)₂)₂)Ln] complexes have been obtained.³⁰⁴ [(PhC(N(SiMe₃)₂)₂)YCl(THF)] can be turned into [(PhC(N(SiMe₃)₂)₂)YR(THF)] (R = BH₄, N(SiMe₃)₂, CH₂Ph, CH(SiMe₃)₂, etc.) and, by hydrogenolysis of [(PhC(N(SiMe₃)₂)₂)Y(CH(SiMe₃)₂)(THF)], into dimeric hydrides [{(PhC(N(SiMe₃)₂)₂)Y(μ-H)}₂].³⁰⁵

3.2.2.3.6 Polypyrazolylborates

The following abbreviations are used here: Tp = tris(pyrazolyl)borate; Tp^{Bupy} = tris(3-((4-*t*-butyl)pyrid-2-yl)-pyrazol-1-yl)borate; $\text{Tp}^{\text{cpd-}}$ = Hydrotris[3-(carboxypyrrolidido)pyrazol-1-yl]borate; Tp^{Me_2} = tris(3,5-dimethylpyrazolyl)borate; $\text{Tp}^{\text{Me}_2,4\text{Et}}$ = tris(3,5-dimethyl-4-ethylpyrazolyl) borate; Tp^{Ms} = tris(3-mesitylpyrazolyl)borate; $\text{Tp}^{\text{Ms}*}$ = bis(3-mesitylpyrazolyl)(5-mesitylpyrazolyl) borate; Tp^{Ph_2} = tris(3,5-diphenylpyrazolyl)borate; $\text{Tp}^{2\text{-pyr}}$ = tris(3-(2-pyridyl)pyrazolyl)borate; Tp^{Th_2} = tris(3,5-dithienylpyrazolyl)borate; $\text{Bp}^{(\text{COC})\text{Py}}$ = bis[3-(2-pyrid-2-yl)5-(methoxymethyl) pyrazol-1-yl]hydroborate.

F-element poly(pyrazolyl)borates have been reviewed.^{306,307} $[\text{LnTp}_3]$ have been synthesized (Ln = Sc, Y, La–Nd, Sm–Lu); the structure of the Pr and Nd compounds show the lanthanides to be nine-coordinate, though an eight-coordinate structure is adopted by later metals (e.g., Yb).³⁰⁸ Working with a 2:1 ratio of reactants, complexes $[\text{Ln}(\text{Tp})_2\text{Cl}(\text{THF})]$ are formed. The structure of the corresponding hydrate is known $[\text{Y}(\text{Tp})_2\text{Cl}(\text{H}_2\text{O})]$.³⁰⁹ Using totally moisture-free conditions, seven-coordinate $[\text{Ln}(\text{Tp})_2\text{Cl}]$ is formed, but this readily adds water forming $[\text{Ln}(\text{Tp})_2\text{Cl}(\text{H}_2\text{O})]$.³¹⁰ Reaction of $\text{LnCl}_3 \cdot 6\text{H}_2\text{O}$ with KTp affords $[\text{Ln}(\text{Tp})_2(\text{L})\text{Cl}]$ (Ln = Lu, Nd, L = HPz; Ln = Lu, L = H_2O); with *N*-methylpyrazole, $[\text{LnCl}\{\text{Tp}\}_2(\text{N-Mepz})]$ are obtained, these reacting with Na(quin) (quin = 8-quinolate) to form $[\text{Ln}\{\text{Tp}\}_2(\text{quin})]$. $[\text{Nd}(\text{Tp})_2(\text{L})\text{Cl}]$ (L = HPz, H_2O) have square antiprismatic coordination of neodymium.³¹¹ Reaction of $[\text{Y}(\text{NCS})_3(\text{phen})_3]$ with KTp leads to the isolation of $[\{\text{Y}(\text{Tp})(\text{NCS})(\text{phen})(\mu\text{-OH})\}_2]$.³¹² $[\text{Ln}(\text{Tp})_2(\text{L})]$ (L = salicylaldehyde or 5-methoxysalicylaldehyde; Ln = Y, Pr to Lu) have been synthesized. Several picolinate N-oxide complexes $[\text{Ln}(\text{Tp})_2(\text{ONC}_5\text{H}_4\text{CO}_2\text{-}2)]$ have been synthesized; the structure of the eight-coordinate terbium compound shows the picolinate N-oxide to chelate.³¹³ $[\text{Eu}(\text{Tp})_2(5\text{-methoxysalicylaldehyde})]$ has the dodecahedral eight-coordination characteristic of europium.³¹⁴ Structures are reported of $[\text{Eu}(\text{Tp})_2(\mu\text{-O}_2\text{CPh})_2]$, $[\text{Eu}(\text{Tp})(\mu\text{-O}_2\text{CPh})_2]_2$, $[\text{Eu}(\text{Tp})_2(\text{OC}(\text{Me})\text{CHC}(\text{Me})\text{O})]$, and $[\text{Eu}(\text{Tp})_2(\text{OC}(\text{Ph})\text{CHC}(\text{Ph})\text{O})]$, as well as $[(\text{Gd}(\text{Tp})_2)_2(\mu\text{-}1,4\text{-}(\text{O}_2\text{C})_2\text{C}_6\text{H}_4)]$.³¹⁵ A few simple mono Tp complexes are known,³¹⁶ such as $[\text{Y}(\text{Tp})\text{X}_2(\text{THF})_2]$ (X = Cl, Br) and $[\text{Nd}(\text{Tp})\text{I}_2(\text{THF})_2]$ (X-ray). A very wide range of compounds, many of Sm, Eu, and Yb, in both the +2 and +3 states, have been synthesized with Tp^{Me_2} . Use of the lanthanide triflate in synthesis leads to $\text{Ln}(\text{Tp}^{\text{Me}_2})_2(\text{OTf})$. Triflate coordinates for the lighter lanthanides, as in $[\text{Nd}(\text{Tp}^{\text{Me}_2})_2(\text{O}_3\text{SCF}_3)]$ whereas the smaller lanthanides form ionic $[\text{Ln}(\text{Tp}^{\text{Me}_2})_2]\text{O}_3\text{SCF}_3$, as in the ytterbium compound.^{317,318} The triflates form mono(MeCN) adducts, the MeCN being bound in $[\text{La}(\text{Tp}^{\text{Me}_2})_2(\text{MeCN})]\text{O}_3\text{SCF}_3$ but not in $[\text{Nd}(\text{Tp}^{\text{Me}_2})_2(\text{O}_3\text{SCF}_3)]\cdot\text{MeCN}$. This can be regarded as a type of ionization isomerism.³¹⁹ Dodecahedral eight-coordination is found in these and in $[\text{La}(\text{Tp}^{\text{Me}_2})_2(\text{NO}_3)]$. Reaction of KTp^{Me_2} with LnCl_3 in THF gives $[\text{Ln}(\text{Tp}^{\text{Me}_2})_2\text{X}]$, from which the chloride can be replaced by other ligands such as diketonates. A range of $\text{Sm}(\text{Tp}^{\text{Me}_2})_2\text{X}$ compounds,³²⁰ where X = F, Cl, have monomeric seven-coordinate molecular structures, but for X = I and BPh_4 , the compounds are $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2]^+\text{X}^-$. A comparison of the ytterbium(II) and (III) compounds $[\text{Yb}(\text{Tp}^{\text{Me}_2})_2]$ and $[\text{Yb}(\text{Tp}^{\text{Me}_2})_2]\text{O}_3\text{SCF}_3$ show six-coordination for ytterbium in both cases, with Yb–N bond lengths ca. 0.16 Å longer in the Yb^{II} compound.³¹⁸ The samarium(II) poly(pyrazolyl)borate $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2]$ undergoes a one-electron oxidation with $[\text{Hg}(\text{C}\equiv\text{CPh})_2]$ forming monomeric seven-coordinate $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2(\text{C}\equiv\text{CPh})]$.³²¹ This undergoes a remarkable rearrangement at 105 °C in benzene solution with the exchange between a pyrazole ring and a alkynyl group, forming $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2((\text{HB}(\text{Me}_2\text{pz})_2(\text{C}\equiv\text{CPh}))(\text{Me}_2\text{pz}))]$. Reaction of $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2\text{Cl}]$ with NaOR (R = Ph, $\text{C}_6\text{H}_4\text{-}4\text{-Bu}^t$) affords $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2(\text{OR})]$.³²² Analogues with the heavier chalcogenides, $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2(\text{SR})]$ (R = Ph, CH_2Ph), $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2(\text{SR})]$ (R = Ph, $\text{C}_6\text{H}_4\text{-}4\text{-Bu}^t$), and $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2(\text{TePh})]$ (as well as analogues with the $\text{Tp}^{\text{Me}_2\text{Et}}$ ligand) have been made by reductive cleavage of dichalcogenides with $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2]$. ($\text{Tp}^{\text{Me}_2\text{Et}}$ = tris(3,5-dimethyl-4-ethylpyrazolyl)borate). The structures of $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2(\text{SR})]$ (R = Ph, $\text{C}_6\text{H}_4\text{-}4\text{-Bu}^t$) display a distortion due to twisting of a ligand about a B–N bond and π -stacking of a pyrazolyl ring with a phenyl group. Samarium superoxide complexes with the hydrotris(3,5-dimethylpyrazolyl)borate ligand, as well as a compound with a μ_3 -oxo group have been investigated.^{323,324} Mono Tp complexes have been made,^{325,326} from the reaction of one mole of KTp^{Me_2} with LnCl_3 in THF (Ln = Y, Nd). $[\text{Nd}(\text{Tp}^{\text{Me}_2})\text{I}_2(\text{THF})]$ only has one THF bound, in contrast to the Tp analogue, showing the greater steric demands of the Tp^{Me_2} ligand. The halogens can be replaced to afford alkyls and aryls $[\text{Nd}(\text{Tp}^{\text{Me}_2})\text{R}_2(\text{THF})]$ (R is, for example, CH_2SiMe_3 , Ph) which on hydrogenolysis give catalytically active hydrides.³²⁶ Using a 2:1 reaction stoichiometry, $(\text{Tp}^{2\text{-pyr}})$ forms 2:1 complexes such as $[\text{Sm}(\text{Tp}^{2\text{-pyr}})_2]^+$ with icosahedral 12-coordination of samarium.^{327,328} $[\text{Eu}(\text{trop})(\text{NO}_3)(\text{Tp}^{2\text{-pyr}})]$ contains a hexadentate pyrazolylborate and bidentate tropolone and nitrate ligands giving eight-coordination. In $[\text{Tb}(\text{dbm})_2(\text{Tp}^{2\text{-pyr}})]$, one arm of the pyrazolylborate is pendant, so it is

tetradentate, giving eight-coordinate terbium.^{329,330} Reaction of $\text{KTp}^{2\text{-pyr}}$ with hydrated LnCl_3 in methanolic NH_4PF_6 remarkably leads to fluoride abstraction and the isolation of $[\text{Ln}(\text{Tp}^{2\text{-pyr}})\text{F}(\text{MeOH})_2]\text{PF}_6$ ($\text{Ln} = \text{Sm}, \text{Eu}, \text{Gd}, \text{Tb}, \text{Ho}, \text{Yb}$), the bulk of the podand inhibiting the formation of a fluoride bridged oligomer. In the absence of NH_4PF_6 , nitrate complexes such as $[\text{Ln}(\text{Tp}^{2\text{-pyr}})(\text{NO}_3)_2]$ can be isolated.³³¹ Hydrotris[3-(carboxypyrrolidido)pyrazol-1-yl]borate ($\text{Tp}^{\text{cpd-}}$) is a potentially hexadentate N_3O_3 donor, and forms complexes $[\text{Ln}(\text{Tp}^{\text{cpd-}})_2]\text{PF}_6$ ($\text{Ln} = \text{La}, \text{Nd}, \text{Sm}$) in which one ligand is acting as a N_3O_3 donor and the other as a N_2O_2 donor.³³² Tris[3-((4-*t*-butyl)pyrid-2-yl)-pyrazol-1-yl]-hydroborate (1-) (Tp^{Bupy}) is potentially hexadentate and bis[3-(2-pyrid-2-yl)-5-(methoxymethyl)pyrazol-1-yl]hydroborate (1-) ($\text{Bp}^{(\text{COC})\text{Py}}$) is potentially tetradentate. Owing to nitrates being bidentate, $[\text{La}(\text{Tp}^{\text{Bupy}})(\text{NO}_3)_2]$ has 10-coordinate lanthanum, as has $[\text{La}(\text{Bp}^{(\text{COC})\text{Py}})_2(\text{NO}_3)]$, but in $[\text{La}(\text{Bp}^{(\text{COC})\text{Py}})_2(\text{CF}_3\text{SO}_3)]$ the presence of a monodentate triflate causes lanthanum to be nine-coordinate.³³³ A number of studies have been made of ligands that are not tris(pyrazolyl)borates. $[\text{Yb}(\text{B}(\text{pz})_4)_3]\cdot\text{EtOH}$ has eight-coordinated ytterbium, one pyrazolylborate being bidentate.³³⁴

A number of $[\text{Ln}\{\text{H}_2\text{B}(\text{Me}_2\text{-pz})_2\}_3]$ ($\text{Ln} = \text{Y}, \text{Ce}, \text{Sm}, \text{Yb}$) have been investigated whilst a study of luminescence spectra of $[\text{Tb}\{\text{H}_2\text{B}(\text{Me}_2\text{-pz})_2\}_3]$ in the solid state or in nonpolar solvents is consistent with the maintenance of a trigonal prismatic arrangement of nitrogens about Tb with three further weak $\text{B-H}\cdots\text{Tb}$ interactions; on dissolution in polar solvents the spectrum changes.³³⁵

Using $\text{Bp}^{2\text{-pyr}}$, the bis(pyrazolyl)borate analogue of $\text{Tp}^{2\text{-pyr}}$, complexes $[\text{Ln}(\text{Bp}^{2\text{-pyr}})_2(\text{NO}_3)]$ ($\text{Ln} = \text{Eu}, \text{Gd}, \text{Tb}$) and $[\text{Eu}(\text{Bp}^{2\text{-pyr}})_2(\text{DMF})]\text{ClO}_4$ have been isolated.^{336,337}

Eight-coordinate $[\text{Sm}\{\text{B}(\text{pz})_4\}_2(\text{sal})]$ shows stereochemical nonrigid behavior in solution.³³⁸

3.2.2.3.7 Thiocyanate

The thiocyanate group has been studied in detail as a ligand for lanthanide(III) ions in recent years. Recent extensive studies by Japanese workers in particular have shown that the stoichiometry and structure of the anionic complex obtained depends greatly upon factors such as the counter ion used, upon the solvent employed, etc. The complexes are generally made by reaction of the lanthanide thiocyanate with the alkylammonium thiocyanate in a suitable solvent (e.g., an alcohol) or mixture of solvents. $[\text{NEt}_4]_3[\text{Ln}(\text{NCS})_6]\cdot\text{solvent}$ ($\text{M} = \text{Er}, \text{Yb}$; solvent = C_6H_6 , $\text{C}_6\text{H}_5\text{F}$, $\text{C}_6\text{H}_5\text{Cl}$, $\text{C}_6\text{H}_5\text{CH}_3$) have octahedrally coordinated lanthanides;³³⁹ similarly $[\text{NBu}^n_4]_3[\text{Ln}(\text{NCS})_6]$ ($\text{M} = \text{Y}, \text{Pr}-\text{Yb}$) are known to be six-coordinate, exemplified in the structure of the neodymium compound.³⁴⁰ Reaction of lanthanide thiocyanates with tetramethylammonium thiocyanate in methanol-water, followed by slow crystallization, gives $[\text{NEt}_4]_4[\text{Ln}(\text{NCS})_7(\text{H}_2\text{O})]$ ($\text{Ln} = \text{La}-\text{Nd}, \text{Dy}, \text{Er}$) which have a cubic eight-coordinate geometry round the lanthanides.³⁴¹ A synthesis in which crystallization is achieved by evaporation in a desiccator over benzene affords $[\text{NEt}_4][\text{Ln}(\text{NCS})_4(\text{H}_2\text{O})_4]$ ($\text{Ln} = \text{Nd}, \text{Eu}$) with square-antiprismatic coordination.³⁴² In contrast, if the water is removed by forming an azeotrope with benzene-ethanol and vacuum evaporation, followed by crystallization of a methanolic solution in benzene vapor, crystals of $[\text{NEt}_4]_4[\text{Ln}(\text{NCS})_7]\cdot\text{benzene}$ ($\text{Ln} = \text{La}, \text{Pr}$) are obtained, which have a capped trigonal prismatic geometry.³⁴³ Reaction of the lanthanide thiocyanates with tetramethylammonium thiocyanate in methanol-water, followed by slow crystallization usually affords $[\text{NMe}_4]_3[\text{Ln}(\text{NCS})_6(\text{MeOH})(\text{H}_2\text{O})]$ ($\text{Ln} = \text{La}-\text{Nd}, \text{Sm}-\text{Dy}, \text{Er}$), which have lanthanides in a square antiprismatic environment. However, by working in a water-free environment, $[\text{NMe}_4]_4[\text{Ln}(\text{NCS})_7]$ ($\text{Ln} = \text{Dy}, \text{Er}, \text{Yb}$) were obtained, in which the coordination geometry most closely approximates to a pentagonal bipyramid.³⁴⁴ Crystallization of a methanolic solution of the reactants in benzene vapor, gives crystals of $[\text{NMe}_4]_5[\text{Ln}(\text{NCS})_8]\cdot 2\text{C}_6\text{H}_6$.³⁴⁵

3.2.2.4 Group 15 Ligands Involving Phosphorus

A small but increasing selection of these compounds has been reported.

$[\text{Nd}(\text{P}(\text{SiMe}_3)_2)_3(\text{THF})_2]$ has a trigonal bipyramidal structure,³⁴⁶ whilst unsolvated $[\text{Y}(\text{P}(\text{SiMe}_3)_2)_3]$ is a dimer, $[\text{Yb}(\text{P}(\text{SiMe}_3)_2)_2(\mu\text{-P}(\text{SiMe}_3)_2)]_2$, with tetrahedral coordination of yttrium. The average Y—P terminal bond length is 2.677 Å and the bridging Y—P distances average 2.848 Å.^{347,348} $\text{Sm}(\text{O}_3\text{SCF}_3)_3$ reacts with LiPbU^t_2 forming $[(\text{THF})_2\text{Li}(\mu\text{-PbU}^t_2)_2]_2\text{Sm}$ with tetrahedral coordination of samarium by four phosphorus atoms.³⁴⁹ Other compounds

such as $[\text{La}(\text{N}(\text{SiMe}_3)_2)_2(\text{Ph}_3\text{PO})_2(\text{PPh}_2)]^{350}$ have involved the presence of other donor groups, sometimes as chelating ligands where the other donor atom in the chelate is a “harder” base and assists coordination, as in compounds such as $[\text{Nd}(\text{OCBu}^t_2\text{CH}_2\text{PMe}_2)_3]^{351}$ or the organometallic $[\text{Y}(\text{C}_3\text{H}_5)\{\text{N}(\text{SiMe}_2\text{CH}_2\text{PMe}_2)_2(\mu\text{-Cl})_2\}]^{352}$.

3.2.2.5 Group 16 Ligands Involving Oxygen

3.2.2.5.1 The aqua ion and hydrated salts

The nature of the lanthanide aqua ion has been the source of much study but now appears to be fairly well understood. Much of the evidence (though not the most recent) is covered in an authoritative review.³⁵³

To summarize, the coordination number of $[\text{Ln}(\text{H}_2\text{O})_n]^{3+}(\text{aq})$ is believed to be nine for the early lanthanides (La–Eu) and eight for the later metals (Dy–Lu), with the intermediate metals exhibiting a mixture of species. The nine-coordinate species are assigned tricapped trigonal prismatic structures and the eight-coordinate species square antiprismatic coordination. A considerable amount of spectroscopic data has led to this conclusion, using a range of techniques. An early deduction for coordination numbers in solution was that the visible spectrum of $\text{Nd}^{3+}(\text{aq})$ and $[\text{Nd}(\text{H}_2\text{O})_9]^{3+}$ ions in solid neodymium bromate are very similar to each other and quite different to those of Nd^{3+} ions in eight-coordinate environments. Among the recent data, ^{17}O -NMR data for water exchange by the hydrated ion were interpreted in terms of a constant coordination number across the series, as rate constants varied smoothly with atomic number.³⁵⁴ In contrast, virtually all other measurements point to a decrease. Neutron-scattering measurements on the solutions of the aqua ions indicate a decrease in coordination number.³⁵⁵ A neutron-diffraction study of $\text{Nd}(\text{ClO}_4)_3$ and $\text{Sm}(\text{ClO}_4)_3$ in solution indicates coordination numbers of 9.0 and 8.5 respectively, indicating that there are both eight and nine-coordinate species present for samarium.³⁵⁶ Values of ~ 7.9 have been obtained for Dy^{3+} and Lu^{3+} ; a molecular dynamics simulation study of lanthanide ions in aqueous solution found that it was necessary to include allowance for polarization of the water molecule by lanthanide ions to get good agreement with this.³⁵⁷ EXAFS spectra of aqueous solutions of lanthanum perchlorate are in close agreement with solid $[\text{Ln}(\text{H}_2\text{O})_9](\text{CF}_3\text{SO}_3)_3$, suggesting a coordination number of nine for $\text{La}^{3+}(\text{aq})$.³⁵⁸ In a study of chloride complexation by the lanthanides, hydration numbers of the aqua ions were deduced by EXAFS, values being 9.2 (La), 9.3 (Ce), 9.5 (Nd), 9.3 (Eu), 8.7 (Yb), and 9.7 (Y).³⁵⁹ In contrast to the actinides, ability to coordinate chloride decreases across the series, with Yb^{3+} showing no tendency to do so in 14 M LiCl. Information from hydration studies of lanthanide and actinide(III) ions by laser-induced fluorescence spectroscopy has been combined with other techniques to indicate a change in hydration number from nine to eight in the Eu–Tb and Bk–Es regions of the series.^{360,361} A luminescence study of lanthanide complexes reveals a linear correlation between the decay constant and the number of coordinated water molecules,³⁶² used to calculate first coordination sphere hydration numbers of 9.0, 9.1, 8.3, and 8.4 for Sm^{3+} , Eu^{3+} , Tb^{3+} , and Dy^{3+} , respectively. X-ray scattering of yttrium chloride solutions at pH 1.2 indicate about eight water molecules in the first coordination sphere. It has been known for some time that the amount of $[\text{Ln}(\text{H}_2\text{O})_9]^{3+}$ (Ln is, for example, Gd, Eu) increases as the water content of solutions decreases. This has been rationalized by considering outer-sphere complex formation as well.³⁶³ A molecular dynamics simulation³⁶⁴ for water exchange between $[\text{Ln}(\text{H}_2\text{O})_n]^{3+}$ and bulk water reveals very fast exchange between the bulk water and the hydrated samarium ion to maintain the equilibrium between $[\text{Sm}(\text{H}_2\text{O})_9]^{3+}$ and $[\text{Sm}(\text{H}_2\text{O})_8]^{3+}$. Monte Carlo simulations of $\text{Ln}^{3+}(\text{aq})$ ions have been reported,³⁶⁵ agreeing with a change in coordination number from nine to eight in mid-series and with a dissociative mechanism for the ennea-aqua ions. An investigation of the transport properties of the trivalent lanthanide (and actinide ions) using radiochemical methods indicated a change in hydration number in each series.³⁶⁶

Hydrated salts are readily prepared by reaction of the lanthanide oxide or carbonate with the acid. Salts of non-coordinating anions most often crystallize as salts $[\text{Ln}(\text{OH}_2)_9]\text{X}_3$ (X is, for example, bromate, triflate, ethylsulfate, tosylate). A study of a series of triflates, $[\text{Ln}(\text{OH}_2)_9](\text{CF}_3\text{SO}_3)_3$, (Ln = La–Nd, Sm–Dy, Yb, Lu), have been examined in detail.³⁶⁷ Their structures resemble the corresponding bromates and ethylsulfates in being hexagonal, all containing the tricapped trigonal prismatic $[\text{Ln}(\text{OH}_2)_9]^{3+}$ ion, even for the later lanthanides. The crystals of the triflate contain columns of $[\text{Ln}(\text{OH}_2)_9]^{3+}$ cations and CF_3SO_3^- ions, with the columns

linked by a three-dimensional network of hydrogen bonds. This is presumably a factor that stabilizes this structure and favours its isolation, even for the later lanthanides (Gd–Lu), where the eight-coordinate $[\text{Ln}(\text{OH}_2)_8]^{3+}$ ion predominates in solution (as will be seen, this ion does crystallize with certain other counter ions), and similar arguments are likely to apply to the ethylsulfates and bromates. The lanthanide–water distances for the positions capping the prism faces and at the vertices are different. Moreover, on crossing the series from La to Lu, the Ln–O distance decreases from 2.611 Å to 2.519 Å for the three face-capping oxygens but change more steeply from 2.513 Å to 3.287 Å for the six apical oxygens.³⁶⁷ The series of ethylsulfates, $[\text{Ln}(\text{OH}_2)_9](\text{C}_2\text{H}_5\text{SO}_4)_3$, have been studied at 298 K and 171 K more recently, with comparable results.³⁶⁸ However, changing the counter-ion can affect the aqua species isolated. In contrast, the perchlorate salts are $[\text{Ln}(\text{OH}_2)_6](\text{ClO}_4)_3$ and $[\text{terpyH}_2]_2[\text{Tb}(\text{OH}_2)_8]_7\text{Cl}_7 \cdot 8/3\text{H}_2\text{O}$ contains³⁶⁹ a “pure” aqua ion formed even in the presence of a large excess of chloride ions. Other eight-coordinate lanthanides are found in $[\text{Eu}(\text{OH}_2)_8]_2(\text{V}_{10}\text{O}_{28}) \cdot 8\text{H}_2\text{O}$ ^{370,371} and eight-coordinate ytterbium in ytterbium trifluoride, $[\text{Yb}(\text{OH}_2)_8][\text{C}(\text{O}_2\text{SCF}_3)_2]_3$ (the scandium analogue being seven-coordinate).⁵¹ Another encapsulated inside a crown ether is $[\text{Lu}(\text{OH}_2)_8]^{3+}$ in $[\text{Lu}(\text{OH}_2)_8]\text{Cl}_3 \cdot 1.5(12\text{-crown-4}) \cdot 2\text{H}_2\text{O}$, though this is the normal CN for the lutetium aqua ion.³⁷² Early lanthanides (La–Nd) form $[\text{Ln}(\text{OH}_2)_9](p\text{-MeC}_6\text{H}_4\text{SO}_3)_3$ with the usual trigonal prismatic coordination but for the later lanthanide ions the tosylates Ln ($p\text{-MeC}_6\text{H}_4\text{SO}_3$)₃·9H₂O contain $[\text{Ln}(\text{OH}_2)_6(p\text{-MeC}_6\text{H}_4\text{SO}_3)_2]^+$ ions (Ln = Sm, Gd, Dy, Ho, Er, Yb, Y) in distorted dodecahedral eight-coordination.^{373,374}

It has been known for over 20 years that the hydrated lanthanide perchlorates $\text{Ln}(\text{ClO}_4)_3 \cdot 6\text{H}_2\text{O}$ contain octahedral $[\text{Ln}(\text{H}_2\text{O})_6]^{3+}$ ions in the solid state. Their isolation, however, must reflect a balance of factors such as solubility and hydrogen-bonding in the solid state, as the close similarity between the EXAFS spectra of aqueous solutions of lanthanum perchlorate and the spectrum of solid $[\text{Ln}(\text{H}_2\text{O})_9](\text{CF}_3\text{SO}_3)_3$, indicates a coordination number of nine for $\text{La}^{3+}(\text{aq})$ in the perchlorate solutions.³⁵⁸ Similarly, the fact that erbium is eight-coordinate in $[\text{Er}(\text{OH}_2)_8](\text{ClO}_4)_3 \cdot (\text{dioxan}) \cdot 2\text{H}_2\text{O}$ shows the fine balance here.³⁷⁵ Lower hydrates than the hexahydrates exist. Partial dehydration of $\text{Ln}(\text{ClO}_4)_3 \cdot 6\text{H}_2\text{O}$ (Ln = Er, Lu) gives $\text{Lu}(\text{ClO}_4)_3 \cdot 3\text{H}_2\text{O}$ and $\text{Er}(\text{ClO}_4)_3 \cdot \text{H}_2\text{O}$, both of which have eightfold coordination of the lanthanide.³⁷⁶ Similarly, $\text{Yb}(\text{ClO}_4)_3 \cdot \text{H}_2\text{O}$ has been shown to have bi- and tridentate perchlorate groups giving eight-coordinate ytterbium.³⁷⁷ The anhydrous perchlorates exist in high and low-temperature forms, both with nine-coordinate lanthanides, with terdentate perchlorates.^{378,379} Anhydrous $\text{Ln}(\text{ClO}_4)_3$ (Ln = La–Er, Y) have a UCl_3 -type structure, confirmed by powder,³⁸⁰ and single-crystal studies.³⁸¹ The anhydrous triflates $[\text{Ln}(\text{O}_3\text{SCF}_3)_3]$ (Ln = Dy, Ho) decompose to LnF_3 on heating; their IR spectra suggest that triflate acts as a bidentate bridging ligand.³⁸² Stepwise thermal decomposition of several lanthanide triflates has been examined, with LnF_3 as the eventual product.³⁸³ The structures of several methanesulfonates have been reported,³⁸⁴ in all cases methanesulfonate acts as a bidentate ligand. $[\text{Ln}(\text{O}_3\text{SMe})_3 \cdot 2\text{H}_2\text{O}]$ (Ln = Ce, Sm, Tb) are isostructural, with eight-coordinate lanthanides, whilst ytterbium is seven-coordinate in $[\text{Yb}(\text{O}_3\text{SMe})_3]$.

Among the hydrated nitrates, there is a clear decrease in coordination number as the ionic radius of the lanthanide increases.³⁸⁵ All nitrate groups are coordinated as bidentate ligands in these compounds, but the number of waters of crystallization is no guide to how many are actually bound to the metal. Thus compounds $\text{Ln}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$ are known for La–Dy and Y. Of these, the lanthanum and cerium compounds are $[\text{Ln}(\text{NO}_3)_3 \cdot (\text{H}_2\text{O})_5] \cdot \text{H}_2\text{O}$ (Ln = La, Ce) with 11-coordinate lanthanides whilst the others are $[\text{Ln}(\text{NO}_3)_3 \cdot (\text{H}_2\text{O})_4] \cdot 2\text{H}_2\text{O}$ (Ln = Pr–Dy, Y) with 10-coordination for the metal. Under different conditions, a series of pentahydrates $\text{Ln}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$ is obtained (Ln = Eu, Dy–Yb), which also contain $[\text{Ln}(\text{NO}_3)_3 \cdot (\text{H}_2\text{O})_4]$ molecules. Lutetium forms $\text{Ln}(\text{NO}_3)_3 \cdot 4\text{H}_2\text{O}$ and $\text{Ln}(\text{NO}_3)_3 \cdot 3\text{H}_2\text{O}$, isolated under very similar conditions, both of which contain nine-coordinate $[\text{Lu}(\text{NO}_3)_3 \cdot (\text{H}_2\text{O})_3]$ molecules.³⁸⁵

The chlorides of La and Ce, $\text{LnCl}_3 \cdot 7\text{H}_2\text{O}$ are dimeric $[(\text{H}_2\text{O})_7\text{Ln}(\mu\text{-Cl})_2\text{Ln}(\text{OH}_2)_7]\text{Cl}_4$ with what has been described as singly capped square antiprismatic coordination of the metals whilst $\text{LnCl}_3 \cdot 6\text{H}_2\text{O}$ (Ln = Nd–Lu) have antiprismatic $[\text{LnCl}_2(\text{H}_2\text{O})_6]^+$ ions with the coordinated chlorides on opposite sides of the polyhedron. There are extensive hydrogen bonding networks involving both coordinated and non-coordinated chlorides and water molecules.³⁸⁶ Thermal dehydration of $\text{CeCl}_3 \cdot 7\text{H}_2\text{O}$ established³⁸⁷ the existence of $\text{CeCl}_3 \cdot x\text{H}_2\text{O}$ ($x = 6, 3, 2, 1$); the hexahydrate has monomeric $[\text{CeCl}_2(\text{H}_2\text{O})_6]^+$ ions whilst the trihydrate has a structure based on a chain of $[\text{CeCl}_4/2\text{Cl}(\text{H}_2\text{O})_3]$ units. Three different stoichiometries exist for the hydrated bromides, which tend to be deliquescent. Lanthanum and cerium form $\text{LnBr}_3 \cdot 7\text{H}_2\text{O}$, which are isomorphous with the corresponding chlorides in being dimeric $[(\text{H}_2\text{O})_7\text{Ln}(\mu\text{-Br})_2\text{Ln}(\text{OH}_2)_7]\text{Br}_4$. Hexahydrates $\text{LnBr}_3 \cdot 6\text{H}_2\text{O}$ (Ln = Pr–Dy) again resemble heavier rare earth chlorides in being

[LnBr₂(H₂O)₆]Br (though this resemblance does not extend to the end of the lanthanide series for the bromides). A comparison between corresponding chlorides and bromides indicates that the Ln—O distances, though shorter, show more sensitivity to the lanthanide contraction than the Ln—halogen distances. The heaviest lanthanides form LnBr₃·8H₂O (Ln = Ho–Lu) which are [Ln(H₂O)₈]Br₃, with no bromide coordinated, and which resemble a structure found in the hydrated iodides of the heavier lanthanides.³⁸⁸ Study of the hydrated iodides has been difficult because of their deliquescence and their tendency to oxidation in air. Recent diffraction studies,³⁸⁹ however, indicated that the iodides of the earlier metals are LnX₃·9H₂O (Ln = La–Ho), containing the familiar tricapped trigonal prismatic [Ln(OH₂)₉]³⁺ ions. Compared with the triflates and other complexes containing the tricapped trigonal prismatic nine-coordinate species, the spread of Ln—O distances is much smaller, falling in the range 2.552–2.576 Å for Ln = La and similarly between 2.403 Å and 2.405 Å for the holmium compound. The average Ln—O distance decreases from 2.55 Å (Ln = La) to 2.40 Å in the holmium compound. Coordinated water molecules all interact with iodides ions, not water molecules. For the heavier lanthanides, LnX₃·10H₂O (Ln = Er–Lu) contain square antiprismatic [Ln(OH₂)₈]³⁺ ions; similarly here the coordinated water molecules tend to have iodides for nearest neighbors, rather than hydrogen bonding to the lattice waters. No iodide ions are coordinated in either phase, unlike the lanthanide chlorides and bromides. The structures of the anhydrous acetates have been discussed in a series of papers. Reaction of the oxide or carbonate with acetic acid affords hydrated salts [Ln(CH₃COO)₃·nH₂O] (a number of hydrates can be isolated, but usually Ln = La–Ce, *n* = 1.5; Ln = Pr–Sm, *n* = 3; Ln = Gd–Lu, Y, *n* = 4) which can decompose to basic salts on attempted dehydration. Anhydrous lanthanum acetate has been synthesized from reaction of La₂O₃ and CH₃COONH₄ in a melt (under different conditions (NH₄)₃[La(CH₃COO)₆] is obtained).³⁹⁰ It contains 10-coordinate lanthanum, involving both chelating and bridging acetates, the latter having one oxygen bound to two different lanthanum ions and the second oxygen just bound to one. La—O distances lie in the range 2.474(3) Å to 2.794(3) Å, with an average of 2.615 Å. Ce(CH₃COO)₃ is isostructural. Both nine and 10-coordinate praseodymium are found in Pr(CH₃COO)₃, synthesized by dehydration of Pr(CH₃COO)₃·1.5H₂O at 180 °C.³⁹¹ For the two types of nine-coordinate Pr sites, the average Pr—O distances are 2.535 Å and 2.556 Å, whilst for the 10-coordinate site the average Pr—O distance is 2.611 Å. Like La(CH₃COO)₃ this has a three-dimensional network structure, whereas the later metals adopt chain structures in Ln(CH₃COO)₃. For later lanthanides, anhydrous acetates have been synthesized by crystallization from diluted acetic acid solutions of their oxides and caesium acetate at 120 °C. Holmium acetate adopts a structure shared with other Ln(CH₃COO)₃ (Ln = Sm–Er, Y). Here holmium occupies two slightly different eight-coordinate sites, with average Ho—O distances of 2.370 Å and 2.381 Å. Ln(CH₃COO)₃ (Ln = Tm–Lu) have the structure exemplified by Lu(CH₃COO)₃, in which Lu is seven-coordinate (average Lu—O 3.275 Å). On heating, both these structures change to the six-coordinate Sc(CH₃COO)₃ structure, this drop in coordination number being accompanied by an acetate group switching to a symmetrical bridging mode.³⁹² A number of different hydrated acetates have been characterized. The hydrated acetates, unlike the acetates of transition metals like Cr^{III}, Fe^{III}, and Ru^{III}, do not adopt oxo-centred structures with M₃O cores, presumably owing to the inability of the lanthanides to form π-bonds. A study³⁹³ of the “maximally hydrated” acetates (obtained by crystallization of neutral aqueous solutions at room temperature) has identified three main series, though it certainly seems that for any given lanthanide there may be two or more phases with nearly equal stabilities under ambient conditions. The sesquihydrates [Ln(CH₃COO)₃·1½ H₂O] (Ln = La–Pr) have structures with acetate bridged chains crosslinked by further acetate bridges; the lanthanides being nine and 10-coordinated by bridging and chelating acetates. The monohydrates [Ln(CH₃COO)₃·H₂O] (Ln = Ce–Nd) have one-dimensional polymeric structures with acetate bridges, the lanthanides being nine-coordinate in this case, whilst the tetrahydrates [Ln(CH₃COO)₃·4H₂O] (Ln = Sm–Lu) are acetate-bridged dimers, the lanthanides again being nine-coordinate. Some of the acetate bridges in these compounds are asymmetric, again featuring one oxygen being bound to two lanthanide ions and the other oxygen bound to one. In addition to these compounds, crystallization of europium acetate from acidic solution leads to the isolation of dimeric species [Eu₂(CH₃COO)₆(H₂O)₄]·2CH₃COOH and [Eu₂(CH₃COO)₆(H₂O)₂(CH₃COOH)₂], the latter being related to the former by replacement of two coordinated water molecules by two monodentate acetic acids.

[Sm(CH₃COO)₃·3H₂O]·CH₃COOH has nine-coordinate samarium.³⁹⁴ Hydrated praseodymium propionate, Pr(C₃H₇COO)₃·3H₂O, contains two distinctly different praseodymium sites. Each praseodymium is coordinated by four bidentate bridging carboxylates; additionally one is bound to three water molecules, the other is additionally bound to two bidentate propionates.³⁹⁵ Sm(OAc)₃·AcOH has nine-coordinate samarium.³⁹⁶ The structural and thermal behavior of a series of hydrated

neodymium alkanoates have been studied.³⁹⁷ The butanoate $\text{Nd}(\text{C}_3\text{H}_7\text{COO})_3(\text{H}_2\text{O})$ has a zigzag chain structure containing nine-coordinate neodymium in capped square antiprismatic coordination, there being two different neodymium sites. One neodymium is bound to four bridging tridentate carboxylates and one bridging bidentate group, as well as to two waters; the other neodymium is coordinated to four bridging tridentate carboxylates, one bridging bidentate carboxylate, and one chelating carboxylate. The higher homologues have a similar structure. They display a thermotropic mesophase, which has been identified as a smectic A phase.

Some series of hydrated trifluoro- and trichloroacetates have been studied too.³⁹⁸ $[\text{Ln}(\text{CF}_3\text{COO})_3 \cdot 3\text{H}_2\text{O}]$ ($\text{Ln} = \text{La}, \text{Ce}$) are two-dimensional polymers containing eight-coordinate lanthanides, whilst $[\text{Ln}(\text{CF}_3\text{COO})_3 \cdot 3\text{H}_2\text{O}]$ ($\text{Ln} = \text{Pr} - \text{Lu}$) have seven-coordinate lanthanides in dimeric units with four bridging carboxylates. $[\text{La}(\text{CCl}_3\text{COO})_3 \cdot 5\text{H}_2\text{O}]$ and $[\text{Ce}(\text{CCl}_3\text{COO})_3 \cdot 3\text{H}_2\text{O}]$ are linear one-dimensional polymers with nine- and eight-coordinate lanthanides respectively. $[\text{Ln}(\text{CCl}_3\text{COO})_3 \cdot 2\text{H}_2\text{O}]$ ($\text{Ln} = \text{Pr} - \text{Lu}$) are also linear polymers with a bridging water molecule rather than just carboxylate bridges. In these compounds the carboxylate groups act as bridging bidentate ligands or as terminal monodentate groups. Ethanol adducts of the trichloroacetates have also been characterized. $[\text{Ln}(\text{CCl}_3\text{COO})_3 \cdot 3\text{EtOH}]$ ($\text{Ln} = \text{La}, \text{Yb}$) are dimers with eight-coordinate lanthanides; four carboxylates bridge whilst the other four coordination positions of the lanthanide are occupied by three ethanol molecules and one carboxylate.³⁹⁸ A number of lanthanide salts of unsaturated acids, including acrylic, methacrylic, maleic, and fumaric acids, have been synthesized. Anhydrous europium methacrylate, $[\text{Eu}(\text{H}_2\text{C}=\text{C}(\text{Me})\text{CO}_2)_3]$, has a chain structure in which Eu is eight-coordinate, one carboxylate acting as a bidentate bridging ligand and the other two also bridging, but with one oxygen bound to two europium, the chelate-bridging mode familiar through a number of lanthanide carboxylate structures. Both this compound and the acrylates $[\text{Ln}(\text{H}_2\text{C}=\text{CHCO}_2)_3]$ ($\text{Ln} = \text{Eu}, \text{Tb}$) undergo radical-induced polymerization.³⁹⁹ $[\text{La}_2(\text{O}_2\text{CC}\equiv\text{CH})_6(\text{H}_2\text{O})_4] \cdot 2\text{H}_2\text{O}$ undergoes solid-state polymerization when exposed to ^{60}Co γ -rays.⁴⁰⁰ Fast-ion bombardment of lanthanide acetate and malonate salts⁴⁰¹ leads to clustering as a result of ion-molecule reactions to give in the general case the ion $[(\text{LnO})_x(\text{RCO}_2)_y\text{O}_z]^+$ with x reaching four, y reaching three, and z reaching four. Binary clusters $[(\text{LnO})_x\text{O}_y]^+$ are also found, with x reaching high values. Some combinations of x , y , and z are associated with markedly high levels of stability, e.g., in $[(\text{PrO})_2(\text{CH}_3\text{CO}_2)_2\text{O}]^+$, $[(\text{PrO})_4(\text{CH}_3\text{CO}_2)_2\text{O}]^+$, $[(\text{TbO})_4(\text{CH}_3\text{CO}_2)]^+$, $[\text{Ho}(\text{CH}_3\text{CO}_2)]^+$, and $[(\text{LaO})(\text{malonate})\text{O}_4]^+$. Other carboxylates studied include $[\text{Ce}(\text{O}_2\text{CR})_3(\text{H}_2\text{O})_2]$ ($\text{RCO}_2 = \text{laurate, stearate, octate}$); they can be used to make photosensitive polythene films.⁴⁰² $[\text{Gd}(\text{CF}_3\text{CO}_2)_3 \cdot 3\text{H}_2\text{O}]$ is a dimer with bridging trifluoroacetates.⁴⁰³ Praseodymium is also nine-coordinate in $[\text{Pr}(\text{O}_2\text{CR})_3(\text{H}_2\text{O})]_\infty$ ($\text{R} = 2,6\text{-difluorobenzoate}$),⁴⁰⁴ whilst $\text{Pr}(\text{O}_2\text{CH}_2\text{CH}_2\text{CH}_3)_3 \cdot 3\text{H}_2\text{O}$ has an infinite chain structure in which pairs of praseodymiums are bridged by four tridentate bridging propionates,⁴⁰⁵ and $[\text{Dy}(\text{C}_5\text{H}_4\text{N}-2\text{-CO}_2)_3(\text{H}_2\text{O})_2]$ has eight-coordinate dysprosium.⁴⁰⁶ Among a variety of other salts to be studied are the dialkylcarbamates $[\text{Ln}_4(\text{O}_2\text{CNPr}^1_2)_{12}]$ ($\text{Ln} = \text{Nd}, \text{Gd}, \text{Ho}, \text{Yb}$) with a steady contraction in $\text{Ln}-\text{O}$ distances, averaging 14%, across the lanthanide series.⁴⁰⁷ A variety of sulfate structures exists, where both water and sulfates are bound to the metal, usually with nine-coordinate.⁴⁰⁸ Erbium is six-coordinate in $\text{Er}_2(\text{SO}_4)_3$, seven-coordinate in $\text{Er}(\text{SO}_4)(\text{HSO}_4)$ and eight-coordinate in $\text{Er}(\text{HSO}_4)_3$. EXAFS studies of aqua complexes and polyaminepolycarboxylate complexes have also been used to obtain coordination numbers.⁴⁰⁹ Thiocyanates contain $\text{Ln}(\text{NCS})_3(\text{H}_2\text{O})_6$ ($\text{Ln} = \text{La} - \text{Dy}$) and $\text{Ln}(\text{NCS})_3(\text{H}_2\text{O})_5$ ($\text{Ln} = \text{Sm} - \text{Eu}$) molecules. Lanthanum thiocyanate reacts with hexamethylene tetramine forming $[\text{La}(\text{NCS})_3 \cdot 2[\text{N}_4(\text{CH}_2)_6] \cdot 9\text{H}_2\text{O}]$, which contains $[\text{La}(\text{NCS})_2 \cdot (\text{H}_2\text{O})_7]^+$ ions.⁴¹⁰ Structural and magnetic properties are reported for $[\text{Me}_2\text{NH}_2][\text{MCl}_4(\text{H}_2\text{O})_2]$ ($\text{M} = \text{Nd}, \text{Pr}$), which contain edge-connected $[\text{MCl}_4\text{Cl}_2(\text{H}_2\text{O})_2]$ trigondodecahedra.^{411,412}

$\text{Pr}(\text{ClO}_3)_3 \cdot 2\text{H}_2\text{O}$ has praseodymium coordinated by seven different chlorates and two water molecules.⁴¹³ Lanthanum is nine-coordinate in $\text{Rb}[\text{La}(\text{OAc})_4]$ in which each La is coordinated by six different acetate groups in a chain structure.⁴¹⁴ Thulium nitrilotriacetate, $[\text{Tm}(\text{NTA}) \cdot (\text{H}_2\text{O})_2] \cdot 2\text{H}_2\text{O}$, has a ladder-like structure.⁴¹⁵

Mixing aqueous solutions of PrCl_3 and $\text{Pr}(\text{NO}_3)_3$ gives green crystals of $\text{PrCl}_2(\text{NO}_3) \cdot 5\text{H}_2\text{O}$, which contains $[\text{PrCl}_2(\text{OH}_2)_6]^+$ and $[\text{PrCl}_2(\text{NO}_3)_2(\text{OH}_2)_4]^-$.⁴¹⁶

$\text{Ce}(\text{NO}_3)_5(\text{H}_3\text{O})_2(\text{H}_2\text{O})$ has⁴¹⁷ 12-coordinate cerium (six bidentate nitrates), whilst in polymeric $[\text{La}(\text{O}_2\text{P}(\text{OMe})_2)_3]$, lanthanum is octahedrally coordinated⁴¹⁸ by six oxygens from six bridging ligands. The role of the counter ion in structure is indicated⁴¹⁹ by $\text{Rb}_2[\text{Y}(\text{NO}_3)_5]$ (eight-coordinate), as the (NO) salt is 10-coordinate.

Carbonate complexes have been increasingly studied because of their importance in mobilizing the actinides in the environment; lanthanide complexes are nonradioactive models for the later

actinides. The first mononuclear lanthanide carbonate complex⁴²⁰ has been structurally characterized in the form of $[\text{N}(\text{CH}_2)_3]_5[\text{Nd}(\text{CO}_3)_4]$. In contrast, the anions in $[\text{Co}(\text{NH}_3)_6][\text{Sm}(\text{CO}_3)_3 \cdot (\text{H}_2\text{O})] \cdot 4\text{H}_2\text{O}$ are linked in a zigzag chain structure with $\mu\text{-}\eta^2\text{-}\eta^1$ carbonate bridges affording nine-coordinate samarium.⁴²¹ Similar bridges are found in the one-dimensional chains⁴²² in $[\text{Co}(\text{NH}_3)_6]_6[\text{K}_2(\text{H}_2\text{O})_{10}][\text{Nd}_2(\text{CO}_3)_8] \cdot 20\text{H}_2\text{O}$, formed on mixing solutions of $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3$, $\text{Nd}(\text{NO}_3)_3$, and K_2CO_3 .

3.2.2.5.2 Phosphine and arsine oxides, and other neutral monodentate donors

Much more is now known about the structures of these compounds. Lanthanide triflates reacts with Ph_3PO in ethanol forming $\text{Ln}(\text{OTf})_3(\text{Ph}_3\text{PO})_4$ ($\text{Ln} = \text{La}, \text{Nd}, \text{Er}, \text{Lu}$). All have the structure $[\text{Ln}(\text{OTf})_2(\text{Ph}_3\text{PO})_4]\text{OTf}$; the erbium and lutetium compounds have octahedral coordination, like the Sc analogue, but the complexes of the larger La and Nd have seven-coordination with one triflate being bidentate (from IR evidence, the transition between six and seven-coordination seems to occur at Sm. The Nd—O (PPh_3) distances in $[\text{Nd}(\text{OTf})_2(\text{Ph}_3\text{PO})_4]\text{OTf}$ are in the range 2.304(2)–2.339(2) Å, with Nd—O(Tf) 2.408(2) Å (monodentate) and 2.6553–2.624(2) Å (bidentate); in $[\text{Lu}(\text{OTf})_2(\text{Ph}_3\text{PO})_4]\text{OTf}$, Lu—O (PPh_3) distances lie in the range 2.156(5)–2.199(5) Å, with Lu—O(Tf) 3.202(6) Å and 3.232(5). In a study of complexes of yttrium halides with phosphine oxides,⁴²³ it was found that $\text{YF}_3 \cdot 1/2 \text{H}_2\text{O}$ shows no signs of reaction with these ligands, but a wide range of complexes have been isolated with the other halides. The complexes actually isolated are $[\text{YX}_2(\text{Ph}_3\text{PO})_4]\text{Z}$ ($\text{X} = \text{Cl}, \text{Br}, \text{I}; \text{Z} = \text{X}$ or PF_6); $[\text{YX}_3(\text{Ph}_2\text{MePO})_3]$; $[\text{YCl}_2(\text{Ph}_2\text{MePO})_4]\text{PF}_6$; $[\text{YCl}(\text{Ph}_3\text{PO})_5](\text{SbCl}_6)_2$; $[\text{Y}(\text{Me}_3\text{PO})_6]\text{X}_3$ ($\text{X} = \text{Cl}, \text{Br}, \text{I}$); $[\text{YX}_2(\text{Ph}_3\text{AsO})_4]\text{X}$ ($\text{X} = \text{Cl}, \text{Br}, \text{I}_3$); $[\text{Y}(\text{Me}_3\text{AsO})_6]\text{Cl}_3$; and $[\text{YCl}_2(\text{L-L})_4]\text{Cl}$ ($\text{L-L} = o\text{-C}_6\text{H}_4(\text{P}(=\text{O})\text{Ph}_2)_2$ or $\text{Ph}_2\text{P}(\text{O})\text{CH}_2\text{P}(\text{O})\text{Ph}_2$) have all been synthesized and characterized by multinuclear NMR. Most of these compounds were obtained by reaction of the hydrated halide with the tertiary phosphine or arsine oxide in ethanol, acetone, or CH_2Cl_2 , using a range of stoichiometries. Reaction of YCl_3 with Ph_2MePO in ethanol or acetone gives $[\text{YCl}_3(\text{Ph}_2\text{MePO})_3]$ irrespective of ratio, but in the presence of NH_4PF_6 , $[\text{YCl}_2(\text{Ph}_2\text{MePO})_4]\text{PF}_6$ was isolated. In the presence of the chloride ion abstractor SbCl_5 , $[\text{YCl}_2(\text{Ph}_3\text{PO})_4]\text{Cl}$ forms $[\text{YCl}(\text{Ph}_3\text{PO})_5](\text{SbCl}_6)_2$. Structures have been reported for $[\text{YCl}_2(\text{Ph}_3\text{PO})_4]\text{Cl} \cdot 2\frac{1}{2}\text{EtOH} \cdot \text{H}_2\text{O}$, $[\text{YBr}_2(\text{Ph}_3\text{PO})_4]\text{PF}_6 \cdot \text{Et}_2\text{O}$, and $[\text{Y}(\text{Me}_3\text{PO})_6]\text{Br}_3$. $[\text{YCl}_2(\text{Ph}_3\text{PO})_4]\text{Cl} \cdot 2\frac{1}{2}\text{EtOH} \cdot \text{H}_2\text{O}$ contains a *trans*-octahedral cation with $\text{Y—Cl} = 2.613(2)$ Å and $2.625(1)$ Å and Y—O distances in the range 3.223(3)–3.233(3) Å. A similar geometry is found in the *trans*- $[\text{YBr}_2(\text{Ph}_3\text{PO})_4]$ cation, with $\text{Y—Br} = 2.775(1)$ Å and $2.794(1)$ Å and Y—O distances in the range 3.220(4)–3.233(5) Å. In $[\text{Y}(\text{Me}_3\text{PO})_6]\text{Br}_3$, coordination approximates to the octahedron, with Y—O distances between 3.214(5) Å and 3.233(5) Å and O—Y—O angles in the range 89.6–91.4°. Octahedral coordination of yttrium seems to be the rule for all these compounds. $\text{CeCl}_3 \cdot 6\text{H}_2\text{O}$ reacts with Me_3PO in MeOH forming $[\text{Ce}(\text{Me}_3\text{PO})_4\text{Cl}_3] \cdot 4\text{H}_2\text{O}$; on slow crystallization of a MeNO_2 solution in air, crystals of $[\text{Ce}(\text{Me}_3\text{PO})_4(\text{H}_2\text{O})_4]\text{Cl}_3 \cdot 3\text{H}_2\text{O}$ result. The coordination sphere can be described as a triangulated dodecahedron; this can be described as two interpenetrating tetrahedra with a flattened tetrahedron formed by the four phosphine oxides and an elongated tetrahedron formed by the four coordinated waters.⁴²⁴ $[\text{Ln}(\text{Ph}_3\text{PO})_5\text{Cl}](\text{FeCl}_4)_2$ ($\text{Ln} = \text{La-Nd}, \text{Sm-Er}, \text{Y}$) have been made; it is possibly surprising to have five of these round a lanthanide.⁴²⁵ A number of yttrium nitrate complexes, $[\text{Y}(\text{NO}_3)_3(\text{L})_3]$ ($\text{L} = \text{Ph}_3\text{PO}, \text{Ph}_2\text{MePO}, \text{Me}_3\text{PO}$), $[\text{Y}(\text{NO}_3)_3(\text{L})_2(\text{EtOH})]$ ($\text{L} = \text{Ph}_3\text{PO}, \text{Ph}_2\text{MePO}$), $[\text{Y}(\text{NO}_3)_3(\text{Me}_3\text{PO})_2(\text{H}_2\text{O})]$, and $[\text{Y}(\text{NO}_3)_2(\text{Ph}_3\text{PO})_4](\text{NO}_3)$ have been synthesized from the reactions of yttrium nitrate and the ligand, and their ⁹⁹Y NMR spectra reported.⁴²⁶ Whilst only one complex is generally isolated from a particular solution, ³¹P-NMR studies show that a mixture of species is frequently present, and complexes with different stoichiometries can be isolated by altering reaction conditions. Thus reaction of $\text{Y}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$ with one or two moles of Ph_3PO in boiling ethanol gives $[\text{Y}(\text{NO}_3)_3 \cdot (\text{Ph}_3\text{PO})_2(\text{EtOH})]$ whilst four moles of triphenylphosphine oxide gives $\text{Y}(\text{NO}_3)_3(\text{Ph}_3\text{PO})_3$, and reaction with six moles of Ph_3PO in cold ethanol affords $\text{Y}(\text{NO}_3)_3(\text{Ph}_3\text{PO})_4$, the latter being $[\text{Y}(\text{NO}_3)_2(\text{Ph}_3\text{PO})_4]\text{NO}_3$. Structures have been determined for $[\text{Y}(\text{NO}_3)_3(\text{L})_3]$ ($\text{L} = \text{Ph}_3\text{PO}, \text{Ph}_2\text{MePO}, \text{Me}_3\text{PO}$) and $[\text{Y}(\text{NO}_3)_3(\text{Ph}_3\text{PO})_2(\text{EtOH})]$. All of these have nine-coordinate yttrium with bidentate nitrates, but if the nitrate groups are conceived of as occupying one coordination position, the geometry can be described as *mer*-octahedral for the Ph_3PO and Ph_2MePO complexes, and *fac*- for the Me_3PO complex. In $[\text{Y}(\text{NO}_3)_3(\text{Ph}_3\text{PO})_3]$, $\text{Y—O}(\text{P})$ distances are 3.269, 3.283, and 3.284(5) Å and $\text{Y—O}(\text{N})$ distances lie in the range 2.403(5)–2.506(5) Å whilst in $[\text{Y}(\text{NO}_3)_3(\text{Me}_3\text{PO})_3]$ they are similar, $\text{Y—O}(\text{P})$ distances being

3.262(7), 3.279(7), and 3.281(7) Å and Y-OM(N) being 2.441(7)–2.520(7) Å.⁴²⁶ A detailed study has been made of the reactions of lanthanide nitrates with a large excess of Ph₃PO in acetone.⁴²⁷ Early lanthanides (La–Nd) form [Ln(NO₃)₃(Ph₃PO)₄], which in the solid state have the structure [Ln(η²-NO₃)₂(η¹-NO₃)(Ph₃PO)₄]; in solution (Me₂CO or CH₂Cl₂) they dissociate into [Ln(NO₃)₃(Ph₃PO)₃] and Ph₃PO and reaction in ethanol gives only [Ln(NO₃)₃(Ph₃PO)₃]. The crystal structure of [Ln(NO₃)₃(Ph₃PO)₄] shows that lanthanum is nine-coordinate with two bidentate nitrates (La–O = 2.656(8) Å and 2.695(8) Å) and one monodentate nitrate (La–O = 2.585(17) Å); all four phosphine oxides are coordinated with La–O 2.449(8) Å and 2.488(7) Å. The Ce, Pr, and Nd complexes appear to have the same structure. The corresponding reaction in ethanol affords [Ln(NO₃)₃(Ph₃PO)₃], of which series the structure of the lanthanum complex has been determined. [La(NO₃)₃(Ph₃PO)₃]·CHCl₃·EtOH has three bidentate nitrate groups, adopting the *mer*-pseudooctahedral structure (considering nitrate to occupy one coordination position). La–O(P) distances lie in the range 2.373 Å to 2.427 Å and La–O(N) distances are 3.283–2.681 Å. The slightly shorter La–O(P) distances in the tetrakis complex suggest greater steric demand by the triphenylphosphine oxide ligand. For the nitrates of Sm–Gd, reaction with Ph₃PO in either ethanol or acetone results in only [Ln(NO₃)₃(Ph₃PO)₃]2Me₂CO; 4:1 complexes do not seem isolable, possibly because of solubility factors. The corresponding reaction with later lanthanides (Tb–Lu) in cold ethanol gives [Ln(NO₃)₂(Ph₃PO)₄]NO₃, whilst [Ln(NO₃)₃(Ph₃PO)₃]·2Me₂CO are readily obtained from propanone. In the case of lutetium, the structure of [Lu(NO₃)₂(Ph₃PO)₄]NO₃ has been determined. The symmetrical bidentate nitrates are mutually *trans*- with Lu–O 2.429(10) Å and 2.406(9) Å; Lu–O(P) distances are 2.181(9) Å and 3.220(9) Å. In other studies, structures have been determined for a number of [Ln(NO₃)₃(Ph₃PO)₂(EtOH)].⁴²⁸ The cerium complex has Ce–O(P) distances of 2.369(2) Å and 2.385(2) Å; Ce–O (nitrate) are 2.549(3), 2.563(3), 2.572(3), 2.575(3), 2.580(3), and 2.596(3) Å; Ce–O (EtOH) is 2.515 Å. Other structures have been reported for the neodymium,⁴²⁹ samarium,⁴³⁰ and europium⁴³¹ analogues. As noted earlier a number of nine-coordinate lanthanides are also found in [Ln(NO₃)₃(Ph₃PO)₃]. An alternative synthesis of [Ce(NO₃)₃(Ph₃PO)₃] is from the reaction of (NH₄)₂[Ce(NO₃)₆] and Ph₃PO in propanone which tends to lead to reduction.⁴³² The Ce–O (NO₃) distances range from 2.58(1) Å to 2.63(1) Å whilst Ce–O (OPPh₃) distances are shorter at 2.39(1)–2.42(1) Å. Similarly [Sm(NO₃)₃(Ph₃PO)₃]·2acetone and [Sm(NO₃)₃(Ph₃QO)₂(EtOH)]·acetone (Q = P, As) were all shown to have nine-coordinate samarium.⁴³³

A similar study of reactions of the lanthanide nitrates with the slightly less bulky diphenylmethylphosphine oxide has been made.⁴³⁴ Reaction in a 1:2.5 molar ratio in acetone gives [Ln(η²-NO₃)₃(Ph₂MePO)₃] for all lanthanides, which are monomers. If the bidentate nitrates are thought of as occupying one coordination position, the structure of nine-coordinate [La(NO₃)₃(Ph₂MePO)₃] corresponds to a *fac*-octahedron, in contrast to the pseudomeridional structure of the Ph₃PO analogue (again tending to suggest the lessened steric effects associated with Ph₂MePO). La–O(P) distances are 2.407, 2.418, and 2.436 Å, whilst La–O(N) bond lengths are in the range 2.584 Å to 2.641 Å; if it is assumed that the other lanthanides form complexes with similar structures, this is a rare case of the same structure type being adopted across the whole lanthanide series, despite the reduction in size of the Ln³⁺ ion. On adding small amounts of Ph₂MePO to solutions of [Ln(NO₃)₃(Ph₂MePO)₃] (Ln = La, Ce), an additional NMR resonance is detected but there is no increase in conductance, indicating a 4:1 species is obtained (at very high Ph₂MePO concentrations, the conductivity increases and another new resonance appears, possibly due to the nonisolable [Ln(NO₃)₂(Ph₂MePO)₅]⁺). A 4:1 complex has been isolated from solution for lanthanum only and the structure of [La(η²-NO₃)₃(Ph₂MePO)₄] determined. It is ten-coordinate, with all nitrates bidentate, in contrast to [Ln(NO₃)₃(Ph₃PO)₄]. The La–O bond lengths are, as expected, longer than those in nine-coordinate [La(NO₃)₃(Ph₂MePO)₃], with La–O(P) = 2.462 Å and 2.513 Å and La–O(N) lengths in the range 2.649–2.708 Å. [Ln(NO₃)₃(Ph₂MePO)₃] (Ln = Pr–Tb) are unaffected in solution by excess ligand but others (Ln = Dy–Lu) tend to dissociate into [Ln(NO₃)₂(Ph₂MePO)₄]⁺; compounds [Ln(η²-NO₃)₂(Ph₂MePO)₄]PF₆ have been isolated for these metals. The structure of the ytterbium compound shows that the eight-coordinate cation contains a rough YbO₄ square involving the four phosphine oxide ligands (Yb–O(P) = 2.186–3.222 Å) with bidentate nitrates attached to ytterbium above and below the plane of the square (Yb–O(N) = 2.410–2.452 Å).

When Ph₃AsO was reacted with lanthanum nitrate, reaction in acetone solution led to [La(NO₃)₂(Ph₃AsO)₄]NO₃ and [La(NO₃)₃(Ph₃AsO)₃], depending upon the stoichiometry of the mixture. From ethanolic solution, [La(NO₃)₃(Ph₃AsO)₂(EtOH)] was obtained. [La(NO₃)₂(Ph₃AsO)₄]NO₃ has eight-coordinate lanthanum, with bidentate nitrates *trans*- to each other on opposite sides of the YbO₄ unit formed by the lanthanum and four-coordinated arsine oxides, similar to the yttrium analogue. La–O(As) distances are 2.340–2.361 Å whilst La–O(N) distances are 2.635–2.656 Å.

$[\text{La}(\text{NO}_3)_3(\text{Ph}_3\text{AsO})_2(\text{EtOH})]$ has the pseudomeridional coordination described for several $[\text{Ln}(\text{NO}_3)_3(\text{Ph}_3\text{PO})_2(\text{EtOH})]$ species and also known for the Sm analogue. $\text{La}-\text{O}(\text{N})$ distances fall in the range 2.581–2.664 Å and $\text{La}-\text{O}(\text{As})$ are 2.324–2.347 Å and $\text{La}-\text{O}(\text{EtOH})$ is 2.552 Å. Reaction of lanthanum nitrate with Me_3AsO in acetone yields $[\text{La}(\text{Me}_3\text{AsO})_6](\text{NO}_3)_3$, believed to be octahedral like the Sc and Y analogues, and decomposing to $\text{La}(\text{Me}_3\text{AsO})_4(\text{NO}_3)_3$, which has two bidentate nitrates and one monodentate one, like the Ph_3PO analogue. Reaction in ethanol affords $[\text{La}(\text{NO}_3)_3(\text{Me}_3\text{AsO})_2(\text{H}_2\text{O})]$.⁴³⁵ $[\text{Eu}(\text{NO}_3)_3(\text{Ph}_3\text{AsO})_3] \cdot 4\text{H}_2\text{O}$ again has the pseudomeridional structure.⁴³⁶ The structure of the mixed-metal compound $[\text{La}(\text{NO}_3)_2(\text{Ph}_3\text{PO})_4][\text{Ni}(\text{C}_4\text{N}_2\text{S}_2)_2] \cdot 2\text{MeOH}$ has been reported.⁴³⁷

$\text{Nd}_2(\text{S}_2\text{O}_6)_3 \cdot 14\text{H}_2\text{O}$ has each neodymium bound to six water molecules and to three oxygens from different dithionates; in $\text{Nd}_2(\text{S}_2\text{O}_6)_3(\text{Ph}_3\text{PO})_4 \cdot 8\text{H}_2\text{O}$, each neodymium is eight-coordinate, bound to two phosphine oxides, four water molecules, and two dithionates (one monodentate, one a bridging ligand).⁴³⁸ Mass spectra are reported⁴³⁹ of the dithionates $[\text{Ln}_2(\text{S}_2\text{O}_3)_3]$ and their Ph_3PO complexes, together with the structure of $[\text{Pr}_2(\text{S}_2\text{O}_3)_3(\text{Ph}_3\text{PO})_6(\text{H}_2\text{O})_6]$.

An unusual route has been described to synthesize hexamethylphosphoramide complexes of lanthanum. A mixture of lanthanum metal, NH_4NCS , and HMPA in toluene reacts when subjected to ultrasonication followed by heating, forming monomeric $\text{La}(\text{NCS})_3(\text{HMPA})_4$. Using the appropriate ammonium salt, $\text{Y}(\text{NCS})_3(\text{HMPA})_3$, $\text{LaBr}_3(\text{HMPA})_4$, and $\text{La}(\text{NO}_3)_3(\text{HMPA})_3$ were similarly obtained; $\text{La}(\text{NO}_3)_3(\text{HMPA})_3$ has a nine-coordinate structure with bidentate nitrates.⁴⁴⁰ The complexes *mer*- $[\text{LnCl}_3(\text{HMPA})_3]$ have been established for many years, a recent example being *mer*- $[\text{YbCl}_3(\text{HMPA})_3]$.⁴⁴¹ Now the synthesis of isomorphous *fac*- $[\text{LnCl}_3(\text{HMPA})_3]$ ($\text{Ln} = \text{La}, \text{Pr}, \text{Nd}, \text{Sm}, \text{Eu}, \text{Gd}$; full structure for Sm) has been reported⁴⁴² to set alongside the *mer*-isomers; the isomerization was followed in solution by NMR, and is believed to occur by an associative mechanism. $[\text{Ln}(\text{HMPA})_6](\text{BrO}_4)_3$ are isomorphous with $[\text{Ln}(\text{HMPA})_6]\text{X}_3$ ($\text{Ln} = \text{La}-\text{Lu}$; $\text{X} = \text{ClO}_4, \text{ReO}_4$).^{443,444} Applications of a solution of SmI_2 in HMPA as a one-electron reductant in organic syntheses have doubtless prompted studies of samarium complexes of HMPA. $[\text{SmI}_3(\text{HMPA})_4]$, prepared from Sm and CH_2I_2 in HMPA/THF, scavenges traces of water forming $[\text{Sm}(\text{HMPA})_2(\text{H}_2\text{O})_5]\text{I}_3 \cdot 2\text{HMPA}$ and $[\text{Sm}(\text{H}_2\text{O})_4(\text{HMPA})_3]\text{I}_3$, both with pentagonal bipyramidally coordinated samarium.⁴⁴⁵ A similar compound, $[\text{Sm}(\text{H}_2\text{O})_3(\text{HMPA})_4]\text{I}_3$ has been isolated as a by-product from a reaction mixture.⁴⁴⁶

Other samarium complexes of hexamethylphosphoramide to have their structures reported are $[\text{Sm}(\text{H}_2\text{O})_5(\text{HMPA})_2]\text{I}_3(\text{HMPA})_2$, $[\text{Sm}(\text{H}_2\text{O})_3(\text{HMPA})_4]\text{I}_3$, $[\text{SmCl}(\text{H}_2\text{O})_4(\text{HMPA})_2]\text{Cl}_2 \cdot \text{THF}$, $[\text{SmCl}(\text{HMPA})_5](\text{BPh}_4)_2$, $[\text{Sm}(\text{O}_3\text{SCF}_3)_2(\text{HMPA})_4](\text{O}_3\text{SCF}_3)$, $[\text{Sm}(\text{O}_3\text{SCF}_3)_3(\text{H}_2\text{O})(\text{HMPA})_3]$, and $[\text{Sm}(\text{hmpa})_3(\eta^2\text{-NO}_3)_3]$.⁴⁴⁷

Syntheses and structures are also reported for the Sm^{III} complexes $[\text{SmBr}_3(\text{HMPA})_2(\text{THF})]$ and $[\text{SmBr}_2(\text{HMPA})_4]\text{Br} \cdot \text{THF}$.⁴⁴⁸ In contrast (but in keeping with the lower stability of Tm^{II}) $[\text{TmI}_2(\text{DME})_3]$ reacts with HMPA forming $[\text{TmI}_3(\text{HMPA})_4]$; this recrystallizes from pyridine as (depending on conditions) $[\text{TmI}_2(\text{HMPA})_4] \cdot 5\text{Py}$ or $[\text{TmI}(\text{Py})(\text{HMPA})_4]\text{I}_2$.⁴⁴⁹

Isolated studies have been made before of the lanthanide nitrate complexes of dimethylsulfoxide, but now a single study has been made of the whole series.⁴⁵⁰ The earlier metals ($\text{La}-\text{Sm}$) form 4:1 complexes whilst smaller metal ions ($\text{Eu}-\text{Lu}, \text{Y}$) form 3:1 complexes. There is no evidence to support earlier suggestions that both 3:1 and 4:1 species can exist for the same lanthanide (e.g., Gd). $\text{Ln}(\text{DMSO})_4(\text{NO}_3)_3$ ($\text{Ln} = \text{La}-\text{Sm}$) are 10-coordinate in the solid state. $\text{Ln}-\text{O}$ bond lengths are 2.451–2.488 Å ($\text{La}-\text{O}(\text{DMSO})$) and 2.647–2.738 Å ($\text{La}-\text{O}(\text{NO}_3)$) whereas $\text{Sm}-\text{O}$ distances are 2.360–2.409 Å ($\text{La}-\text{O}(\text{DMSO})$) and $\text{Sm}-\text{O}$ 2.540–2.749 Å ($\text{La}-\text{O}(\text{NO}_3)$). With the heavier metals nine-coordinate $\text{Ln}(\text{DMSO})_3(\text{NO}_3)_3$ ($\text{Ln} = \text{Eu}-\text{Lu}, \text{Y}$) species are formed. In $\text{Eu}(\text{DMSO})_3(\text{NO}_3)_3$ $\text{Eu}-\text{O}$ bond lengths are 2.314–2.352 Å ($\text{Eu}-\text{O}(\text{DMSO})$) and $\text{Eu}-\text{O}$ 2.478–2.541 Å ($\text{Eu}-\text{O}(\text{NO}_3)$) whereas $\text{Lu}-\text{O}$ distances are 3.215–3.235 Å ($\text{Lu}-\text{O}(\text{DMSO})$) and ($\text{La}-\text{O}$ 2.359–2.475 Å ($\text{Lu}-\text{O}(\text{NO}_3)$). All nitrates are bidentate. The structure of $[\text{Y}(\text{DMSO})_3(\text{NO}_3)_3]$ shows it to be nine-coordinate, like the Eu, Er , and Lu analogues; the degree of asymmetry in the $\text{Y}-\text{O}$ (nitrate) bond varies; in one group, $\text{Y}-\text{O}$ distances are 2.439(6) Å and 2.458(6) Å, whilst in the other two nitrates, distances are 2.445(6) Å and 2.502(7) Å and 2.415(7) Å and 2.469(7) Å. $\text{Y}-\text{O}$ (DMSO) distances are 3.259(6), 3.276(6), and 2.301(5) Å.⁴⁵¹ Eight DMSO molecules can fit round lanthanum as in $\text{Ln}(\text{DMSO})_8[\text{Cr}(\text{NCS})_6]$, with $\text{La}-\text{O}$ distances in the range 2.46–2.51 Å.⁴⁵² The EXAFS spectra of $[\text{Ln}(\text{DMSO})_8](\text{CF}_3\text{SO}_3)_3$ in both the solid state and in DMSO solution are very similar, indicating the same coordination geometry in both; $\text{La}-\text{O}$ distances deduced are 2.486 Å and 2.504 Å respectively.³⁵⁸

Tetrahydrofuran complexes of the lanthanide chlorides have attracted considerable attention. The anhydrous trichlorides are themselves very useful starting materials in the synthesis of compounds such as alkoxides and aryloxides, alkylamides, and organometallic compounds in

general; however, they are difficult to prepare from the hydrated chlorides and are also difficult to prepare by dehydration of the hydrated chlorides.^{453–455} Some routes such as dehydration of the hydrated halides with SOCl_2 or triethylorthophosphate have given hydrated complexes $[\text{LnCl}_3(\text{H}_2\text{O})(\text{THF})]_n$. The THF complexes therefore have considerable utility as synthons. A range of stoichiometries is known. Reaction of the lanthanide metals with HgCl_2 in THF has been employed but presents problems in separating excess metal.^{456,457} One synthesis reported is from reaction of the metals and Me_3SiCl in MeOH .⁴⁵⁸ Perhaps the best route is sonication of lanthanide powders and C_2Cl_6 in THF.⁴⁵⁹ The formulae and structures of these complexes present considerable diversity. Five different stoichiometries of $\text{LnCl}_3(\text{THF})_x$ (x is, for example, 2, 2.5, 3, 3.5, 4) and six different structure types have been identified in these complexes. The compound obtained not only depends upon the lanthanide and the reaction stoichiometry but upon reaction conditions. The pattern across the series reflects an overall decrease in coordination number from eight (La) to six (Lu). Lanthanum is unique in forming $[\text{LaCl}_3(\text{THF})_2]$ which has a single-stranded polymer— $\text{La}(\mu\text{-Cl})_3(\text{THF})_2\text{La}(\mu\text{-Cl})_3(\text{THF})_2\text{La}$ —with *cis*-THF molecules and square antiprismatic eight-coordination of lanthanum.⁴⁵⁹ Bridging La—Cl distances are necessarily long, at 2.870(3)–2.968(3) Å, and La—O distances 2.549(7)–2.595(7) Å. $[\text{LnCl}_3(\text{THF})_2](\text{Ce–Nd})$ are different, although again polymeric, in this case seven-coordinate $\cdots\text{LaCl}(\text{thf})_2(\mu\text{-Cl})_2\text{LnCl}(\text{thf})_2(\mu\text{-Cl})_2\cdots$. The compound $[\text{PrCl}_3(\text{THF})_2]$ has Pr—Cl (terminal) 2.633(1) Å and 2.808(1)–2.850(2) Å for the bridging chlorines; Pr—O are 2.472(3)–2.498(4) Å. A third type, found for Nd–Gd, are monomeric seven-coordinate $[\text{LnCl}_3(\text{THF})_4]$, whilst Gd–Tm form a nominal $[\text{LnCl}_3(\text{THF})_{3.5}]$, which in fact has an ionic structure $[\text{LnCl}_2(\text{THF})_5]^+[\text{LnCl}_4(\text{THF})_2]^-$, containing a seven-coordinate cation and octahedrally coordinated six-coordinate anion, both with *trans*- geometries. In the cation of $[\text{ErCl}_2(\text{THF})_5]^+[\text{ErCl}_4(\text{THF})_2]^-$, Er—Cl is 2.554(3) Å whilst Er—O distances range from 2.353(6) Å to 2.402(9) Å; in the anion, Er—Cl distances are 2.585(3) Å to 2.594(3) Å and Er—O 3.294(7) Å. Ytterbium forms a dimeric $[\text{Cl}_2(\text{THF})_2\text{Yb}(\mu\text{-Cl})_2\text{Yb}(\text{THF})_2\text{Cl}_2]$, whilst both ytterbium and lutetium form a monomeric octahedral $[\text{LnCl}_3(\text{THF})_3]$ ($\text{Ln} = \text{Yb}, \text{Lu}$) long familiar with scandium. In $[\text{YbCl}_3(\text{THF})_3]$, Yb—Cl distances are 2.513(4)–2.533(3) Å and Yb—O are 3.254–2.337(8) Å. Structures have been reported for many individual compounds and far-IR spectra of the complexes have been correlated with structural type.⁴⁵⁹

An independent report of the structure of $\text{ErCl}_3(\text{THF})_{3.5}$ has appeared,⁴⁶⁰ showing it to be the expected $[\text{ErCl}_2(\text{THF})_5]^+[\text{ErCl}_4(\text{thf})_2]^-$; the structure of $[\text{EuCl}_3(\text{THF})_4]$ has also been determined again.⁴⁶¹ $[\text{YCl}_3(\text{THF})_{3.5}]$ is confirmed to be $[\text{trans-YCl}_2(\text{THF})_5][\text{trans-YCl}_4(\text{THF})_2]$ whilst $[\text{YCl}_3(\text{THF})_2]$ has a chain structure with double chlorine bridges, having pentagonal bipyramidal coordination.⁴⁶² In another important paper reporting the structures of a number of complexes of THF and related ligands; $[\text{PrCl}(\mu\text{-Cl})_2(\text{THF})_2]_n$, $[\text{Nd}(\mu\text{-Cl})_3(\text{THF})(\text{H}_2\text{O})]_n$ and $[\text{GdCl}_3(\text{THF})_4]$ were all obtained from the dehydration of the hydrated chloride with thionyl chloride; their structures were reported and patterns in the structures in the series $[\text{LnCl}_3(\text{THF})_n]$ ($n = 2, 3, 3.5$, and 4) discussed.⁴⁶³ The chain structure of $[\text{NdCl}_3(\text{THF})_2]$ has been examined⁴⁶⁴ and $[\text{DyCl}_3(\text{THF})_{3.5}]$ has been shown⁴⁶⁵ to be $[\text{DyCl}_2(\text{THF})_5]^+[\text{DyCl}_4(\text{THF})_2]^- \cdot \text{LaCl}_3(\text{THF})(\text{H}_2\text{O})$ is a polymer with eight-coordinate lanthanum, $[\text{La}(\mu\text{-Cl})_3(\text{THF})(\text{H}_2\text{O})]_n$, isostructural with the Ce and Nd analogues.⁴⁶⁶ Sometimes the structures of other ether complexes have been determined. Thus the structures of both $[\text{DyCl}_3(\text{DME})_2]$ and $[\text{DyCl}_2(\text{THF})_5]^+[\text{DyCl}_4(\text{THF})_2]^-$ have been reported.⁴⁶⁷ Although most work has been concentrated on the chlorides, reports of other THF complexes have appeared. Reaction of lanthanum metal with CH_2X_2 ($\text{X} = \text{Br}, \text{I}$) under ultrasound conditions in THF affords $\text{LaX}_3(\text{THF})_4$; recrystallization of $[\text{LaBr}_3(\text{THF})_4]$ from 1,2-dimethoxyethane (DME) or bis(2-methoxyethyl)ether (diglyme) affords dimeric $[\text{LaBr}_2(\mu\text{-Br})(\text{DME})_2]_2$ and $[\text{LaBr}_2(\text{diglyme})_2]^+[\text{LaBr}_4(\text{diglyme})]^-$. Lanthanides react with hexachloroethane in DME forming $[\text{LnCl}_3(\text{DME})_2]$ ($\text{Ln} = \text{La}, \text{Nd}, \text{Er}, \text{Yb}$); similar reaction in MeCN affords $[\text{YbCl}_2(\text{MeCN})_5]_2^+[\text{YbCl}_3(\text{MeCN})(\mu\text{-Cl})_2\text{YbCl}_3(\text{MeCN})]$. Yb reacts with 1,2-dibromoethane in THF or DME forming $[\text{YbBr}_3(\text{THF})_3]$ or $[\text{YbBr}_3(\text{DME})_2]$.⁴⁶⁸ La and $\text{ICH}_2\text{CH}_2\text{I}$ in THF react on

Table 3 Lanthanide chloride complexes with THF.

Description of types: 1. $\text{La}(\text{THF})_2(\mu\text{-Cl})_3\text{Ln}(\text{THF})_2(\mu\text{-Cl})_3\text{La}$ 2. $\text{LaCl}(\text{THF})_2(\mu\text{-Cl})_2\text{LnCl}(\text{THF})_2(\mu\text{-Cl})_2\text{La}$ 3. $[\text{LnCl}_3(\text{THF})_4]$ 4. $[\text{LnCl}_2(\text{THF})_5]^+[\text{LnCl}_4(\text{THF})_2]^-$ 5. $[\text{Cl}_2(\text{THF})_2\text{Ln}(\mu\text{-Cl})_2\text{Ln}(\text{THF})_2\text{Cl}_2]$ 6. $[\text{LnCl}_3(\text{THF})_3]$.

exposure in sunlight forming $[\text{LaI}_2(\text{THF})_5]\text{I}_3$.⁴⁶⁹ Structures of $[\text{SmCl}_3(\text{THF})_4]$, $[\text{ErCl}_2(\text{THF})_5]^+$ $[\text{ErCl}_4(\text{THF})_2]^-$, $[\text{ErCl}_3(\text{DME})_2]$, and $[\text{Na}(18\text{-crown-}6)(\text{THF})_2]^+[\text{YbBr}_4(\text{thf})_2]^-$ were also reported in this work. $[\text{NdBr}_3(\text{THF})_4]$ has a pentagonal bipyramidal structure and has been studied in the context of butadiene polymerization.⁴⁷⁰ La reacts with $\text{C}_2\text{H}_4\text{I}_2$ in THF forming $[\text{LaI}_3(\text{THF})_4]$.⁴⁷¹ The structures of $[\text{LnI}_2(\text{THF})_5]^+[\text{LnI}_4(\text{thf})_2]^-$ has been reported, where $\text{Ln} = \text{Sm}$ ⁴⁷², Yb ⁴⁷³; the former was produced by O_2 oxidation of solutions of SmI_2 in THF. New types of THF complex, $[\text{Pr}(\text{THF})_4(\text{NO}_3)_3]$ and $[\text{Ln}(\text{THF})_3(\text{NO}_3)_3]$ ($\text{Ln} = \text{Ho}$, Yb) as well as the dimethoxyethane complexes $[\text{Ln}(\text{DME})_2(\text{NO}_3)_3]$ ($\text{Ln} = \text{Pr}$, Ho) have been reported.⁴⁷⁴ The structure of $[\text{Ce}(\text{DME})_2(\text{NO}_3)_3]$ has also been reported.⁴⁷⁵

Thiocyanate complexes have been synthesized by metathesis, from LnCl_3 and KNCS in THF, followed by filtering off the KCl . They appear to have the same formula, $\text{Ln}(\text{NCS})_3(\text{THF})_4$, across the series, but with a significant difference. Thus the ytterbium compound is a monomer, having a pentagonal bipyramidal structure with two axial thiocyanates. There is quite a lot of variation on $\text{Yb}-\text{O}$ distances; if the $\text{Yb}-\text{O}$ bond is inserted between two THF ligands, then the $\text{Yb}-\text{O}$ distance is 2.36–2.40 Å; if THF inserted between a NCS and a THF, then $\text{Yb}-\text{O}$ is in the range 3.22–3.25 Å, indicating the importance of steric effects. $\text{Yb}-\text{N}$ distances are 3.22–2.31 Å.⁴⁷⁶ For earlier lanthanides, the same stoichiometry $\text{Ln}(\text{NCS})_3(\text{THF})_4$ obtains, but there is association by $\text{Ln}\cdots\text{SNC}-\text{Ln}$ bridges so lanthanides are in eight-coordinate square antiprismatic coordination. $\text{Ln}-\text{S}$ interactions are in the region of 3.10 Å (Nd) to 3.26 Å (Er), increasing in length as Ln gets smaller suggesting that the interaction weakens as steric crowding increases. These compounds are obtained for all Ln from Pr to Er .⁴⁷⁷ Reactions of LnCl_3 with SnCl_4 in THF gives $[\text{trans-LnCl}_2(\text{THF})_4]^+[\text{SnCl}_5\text{THF}]^-$ ($\text{Ln} = \text{Ce}$, Gd , Yb), containing a cation having the familiar pentagonal bipyramidal coordination.⁴⁷⁸

Among complexes of urea derivatives, $[\text{Ln}(\text{pu})_8](\text{OTf})_3$ ($\text{Ln} = \text{La}-\text{Lu}$ except Pm , Y) have been synthesized and the structures of the $\text{Nd}-\text{Ho}$, Yb , and Y compounds determined.⁴⁷⁹ $[\text{Sm}(\text{pu})_8](\text{O}_3\text{SCF}_3)_3$ ($\text{pu} = \text{tetrahydr-2-pyrimidinone}$) has samarium in square antiprismatic eight-coordination.⁴⁸⁰ A number of lactam complexes have been studied. Two families of lactam complexes $[\text{Ln}(\varepsilon\text{-caprolactam})_8](\text{CF}_3\text{SO}_3)_3$ ($\text{Ln} = \text{La}-\text{Eu}$) and $[\text{Ln}(\varepsilon\text{-caprolactam})_7](\text{CF}_3\text{SO}_3)_3$ ($\text{Ln} = \text{Gd}$, Tb , Dy , Yb , Lu);⁴⁸¹ $[\text{Ln}(\delta\text{-valerolactam})_8](\text{ReO}_4)_3$ ($\text{Ln} = \text{Pr}$, Nd , Sm , and Eu) and $[\text{Ln}(\delta\text{-valerolactam})_7](\text{ReO}_4)_3$ ($\text{Ln} = \text{Tb}$)⁴⁸² whose stoichiometries appear to reflect the lanthanide contraction have been synthesized. The cation in $[\text{Pr}(\varepsilon\text{-caprolactam})_8](\text{CF}_3\text{SO}_3)_3$ has slightly distorted dodecahedral geometry whilst in $[\text{Eu}(\varepsilon\text{-caprolactam})_8](\text{ReO}_4)_3$ it is square antiprismatic. $[\text{Sm}(\text{NO}_3)_3(\text{N-butylcaprolactam})_3]$ contains samarium in a distorted tricapped trigonal prismatic environment.⁴⁸³ Among the δ -valerolactam complexes $[\text{Ln}(\delta\text{-valerolactam})_8](\text{ClO}_4)_3$ ($\text{Ln} = \text{Pr}-\text{Ho}$) and $[\text{Ln}(\delta\text{-valerolactam})_7](\text{ClO}_4)_3$ ($\text{Ln} = \text{Er}-\text{Lu}$, Y), the neodymium complex has been found to have square antiprismatic eight-coordination.⁴⁸⁴ Crystallization of LnCl_3 from neat ε -caprolactone and ε -caprolactone/THF mixtures^{485,486} affords a variety of complexes, including $[\text{MCl}(\mu\text{-Cl})_2(\text{THF})_2]_\infty$ ($\text{M} = \text{Ce}$, Nd), $[\text{TbCl}_2(\text{THF})_5]^+[\text{TbCl}_4(\text{thf})_2]^-$, $\text{YCl}_3(\varepsilon\text{-caprolactone})_3$, and $[\text{M}(\varepsilon\text{-caprolactone})_8]^{3+}[\text{Cl}_3\text{M}(\mu\text{-Cl})_3\text{MCl}_3]^{3-}$ ($\text{M} = \text{Nd}$, Sm). Lanthanides react with iodine in propan-2-ol affording pentagonal bipyramidal $[\text{LnI}_3(\text{HOPr}^i)_4]$ ($\text{Ln} = \text{La}$, Ce , Nd).⁴⁸⁷

3.2.2.5.3 Diketonates

Although there has been no similar development in diketonate chemistry remotely resembling the outburst of shift reagent work in the 1970s, research has continued to progress, with potential applications such as precursors for high-temperature superconductors and chemical vapor deposition agents. Synthetic approaches have become more sophisticated, with direct syntheses from convenient starting materials like the oxides, or the avoidance of water (which can be hard to remove from adducts) are two ideas. Volatile adducts with molecules like glyme have been promising new developments. It has long been recognized that conventional synthetic methods for the acetylacetonates yield hydrates, $[\text{Ln}(\text{acac})_3(\text{H}_2\text{O})_n]$, from which the water cannot be removed without some decomposition. Reaction of $[\text{Y}\{\text{N}(\text{SiMe}_3)_2\}_3]$ with Hacac gives hydrocarbon-soluble $[\text{Y}(\text{acac})_3]_n$; from NMR measurements, $n \sim 4$. Attempted slow crystallization and inadvertent hydrolysis led to $[\text{Y}_4(\text{OH})_2(\text{acac})_{10}]$, a molecule with a diamond shaped Y_4 core, having $\mu_4\text{-OH}$ groups above and below the plane, and each acac terminal, affording eight-coordinate Y . Controlled vacuum thermolysis (85°C) of $[\text{Y}(\text{acac})_3(\text{H}_2\text{O})_3]$ gives a product that can be crystallized from benzene to form $[\text{Y}_4(\text{OH})_2(\text{acac})_{10}] \cdot \text{C}_6\text{H}_6$. It was suggested that hydrogen-bonding between water molecules and acac oxygens in $[\text{Y}(\text{acac})_3(\text{H}_2\text{O})_3]$ leads to the loss of acacH on

thermolysis.⁴⁸⁸ $[Y(acac)_3]$ reacts with carboxylate alumoxanes in a *chimie douce* route to YAG that affords the advantage of greater processability of the pre-ceramic.⁴⁸⁹ A solid state synthesis has been reported⁴⁹⁰ for $[Pr(acac)_3]$ from anhydrous $PrCl_3$ and Macac ($M = Li, Na$). $[Ce(acac)_3 \cdot (H_2O)_2] \cdot H_2O$ is isomorphous with the Eu and Y analogues, with square antiprismatic coordination of cerium.⁴⁹¹ The coordination geometry in $[Ln(acac)_3(phen)]$ ($Ln = Ce, Pr$) is described as slightly distorted square antiprismatic.⁴⁹² Compounds $[Ln(acac)_3(Ph_3PO)_3]$ have been reported for most of the lanthanides, but there is no structural information as of 2003. If all three phosphine oxides were coordinated, these would be stereochemically congested molecules.⁴⁹³

$Y(acac)_3$ can be brominated with N-bromosuccinimide at carbon-3 forming $Y(3-Bracac)_3$, isolated as a monohydrate. NMR spectroscopy shows that in solution two rings chelate via O and Br, the other by two oxygens; the molecule is fluxional.⁴⁹⁴

The luminescence of $[Tb(acac)_3(phen)]$ doped into alumina decreases with increasing oxygen concentration and has potential as an oxygen sensor.⁴⁹⁵ $[Yb(acac)_2(OAc)(OH_2)]_2$ has dodecahedral eight-coordination of ytterbium.⁴⁹⁶ Mass spectra of $Ln(acac)_3$ give evidence that compounds of Eu, Sm, and Yb undergo oxidation state change from Ln^{III} to Ln^{II} . Ce and Gd do not.⁴⁹⁷ $[Y(PhCOCHCOPh)_3]$ and its MeCN adduct have been synthesized and evaluated as a precursor for thin oxide films by chemical beam epitaxy.⁴⁹⁸ Reaction of $[Gd(tmhd)_3]_2$ with various polyethers affords a range of monomeric and dimeric glyme complexes such as $[Gd(tmhd)_3(diglyme)]$ and $[Gd(tmhd)_3(triglyme)]$ which exhibit good volatility and thermal stability.⁴⁹⁹ (Htmhd = 2,2,6,6-tetramethyl-3,5-heptanedione.) In $[Er(tmhd)_3]_2$ tetraglyme the bridging tetraglyme binds to each erbium through two oxygens, completing distorted square antiprismatic environments for erbium.⁵⁰⁰ Diketonates $[Y(tmhd)_3 \cdot H_2O]_2$, $[Y(tmhd)_3]$, and $[Y(tmod)_3]_2$ (tmod = 2,2,7-trimethylcatane-3,5-dionate) are also possible CVD compounds.⁵⁰¹ Checked syntheses of $[Y(tmhd)_3(H_2O)]$ and $[Y(tmhd)_3]$ have been published.⁵⁰² Structures of the triboluminescent complexes $[Ln(tmhd)_3(4-Me_2Npy)]$ have been determined.⁵⁰³

$[Ln(tmhd)_3(Me_2phen)]$ ($Ln = La, Eu, Tb, Ho$) has two square antiprismatic isomers in the unit cell. Emissions from both isomers can be discerned in the fluorescence spectrum of the Eu compound and shows unusually high splitting of the $^5D_0 \rightarrow ^7F_0$ transition.⁵⁰⁴ $Eu(tmhd)_3(terpy)$ is nine-coordinate, again with two slightly different molecules present in the crystal, its luminescence spectrum shows a broad but unresolved $^5D_0 \rightarrow ^7F_0$ transition, even at 77 K. Average Eu—O and Eu—N distances are 2.380 Å and 2.645 Å respectively, whereas for the second isomer they are 2.385 Å and 2.663 Å.⁵⁰⁵

The versatility of diketonates like $Ln(tmhd)_3$ ($Ln = Eu, Y$) is well illustrated by their ability to form carbene adducts.⁵⁰⁶ An eight-coordinate diketonate $[Eu(dbm)_3(bath)]$ (bath = bathophenanthroline) (dbm = dibenzoylmethanide) has found application as a high-efficiency emitter in an electroluminescent device.⁵⁰⁷ EXAFS measurements on $[Ln(hfac)_3(OH_2)_2]$ ($hfac = \text{hexafluoroacetylacetonate}$; $Ln = Pr, Eu$) indicate a coordination number of about 11, suggesting that some $Ln \cdots F$ interactions are present.⁵⁰⁸ A one-pot synthesis of $[Eu(hfac)_3, L]$ ($L = \text{terpy, diglyme}$) from Eu_2O_3 and $Hhfac$ in the presence of L has been described⁵⁰⁹ as has a one-step route⁵¹⁰ to $Ln(\text{diketonate})_3$ (diketonate is, for example, acac, tfa, dpm, etc.) via lanthanide methyls prepared *in situ* from $LaCl_3$ and $MeLi$. La_2O_3 and $Hhfac$ react together with tetraglyme in hexane forming $[La(hfac)_3(\text{tetraglyme})]$, an air stable and volatile (95 °C, 10^{-4} mm Hg) potential MOCVD precursor.⁵¹¹ Similar compounds $[La(hfac)_3(\text{monoglyme}) \cdot H_2O]$, $[La(hfac)_3(\text{diglyme})]$, and $[La(hfac)_3(\text{triglyme})]$ have also been prepared.⁵¹² ($Hhfac = 1,1,1,5,5,5\text{-hexafluoropentane-2,4-dione}$; monoglyme = $Me(OCH_2CH_2)OMe$; diglyme = $Me(OCH_2CH_2)_2OMe$; triglyme = $Me(OCH_2CH_2)_3OMe$; tetraglyme = $Me(OCH_2CH_2)_4OMe$; terpy = 2,2':6',2''-terpyridyl). Glyme complexes $[La(hfac)_3, \text{diglyme}]$ and $[La(hfac)_3, \text{triglyme}]$ are highly volatile potential MOCVD precursors⁵¹³ as are $[Gd(hfac)_3, \text{monoglyme}]$ and $[Gd(hfac)_3, \text{diglyme}]$.⁵¹⁴ Eu_2O_3 reacts directly with $Hhfac$ ($Hhfa = \text{hexafluoroacetylacetone}$) in the presence of tridentate ligands L ($L = \text{terpy, diglyme, and bis(2-methoxyethyl)ether}$) to afford $[Eu(hfa)_3, L]$. The volatile and thermally stable $[Eu(hfa)_3(\text{diglyme})]$ has a capped square antiprismatic geometry.⁵¹⁵ $[Y(hfac)_3]$ reacts with monoglyme and diglyme forming monomeric adducts $[Y(hfac)_3(\text{glyme})]$ which are eight and nine-coordinate respectively.⁵¹⁶ In contrast, triglyme and tetraglyme form the ionic substances $[Y(hfac)_2(\text{glyme})]^+[Y(hfac)_4]^-$. Sublimation of $[Y(hfac)_2(\text{triglyme})]^+[Y(hfac)_4]^-$ in the presence of "adventitious" water yields the outer-sphere glyme complex $[Y(hfac)_3(OH_2)_2](\text{triglyme})$ which has an infinite chain structure. Eight-coordinate $[Ln(hfac)_3(\text{diglyme})]$ ($Ln = La, Nd, Sm, Eu, Gd$; $hfac = \text{hexafluoroacetylacetonate}$; diglyme = $CH_3OCH_2CH_2OCH_2CH_2OCH_3$) have been synthesized by the reaction of Ln_2O_3 with $Hhfac$ and diglyme in toluene.^{517,518} Under these conditions CeO_2 does not form an isolable complex but $[Ln(hfac)_3(\text{diglyme})]$ ($Ln = Ce, Tb$) can be made by a substitution of another diketonate complex, reacting $[Ln(acac)_3]$ with a slight excess of $Hhfac$ and diglyme. The Nd, Eu, Sm, and Gd compounds undergo reaction with metallic potassium

to form $[\text{LnF}(\text{hfac})_3\text{K}(\text{diglyme})]_2$, in which the lanthanide is still in the 3+ state, fluorine having been abstracted from an hfac ligand. In these compounds, the lanthanide is still eight-coordinate, bound to two bridging fluorides, three oxygens from bridging hfac ligands, and also to a terdentate triglyme.⁵¹⁹ $[\{\text{Ce}(\text{fod})_3(\text{tetraglyme})\}_2]$ (tetraglyme = tetraethylene glycol dimethyl ether) has been synthesized; because of its volatility and stability, it shows promise as a source of thick ceria films through MOCVD.⁵²⁰

A 1:1 complex of $[\text{Eu}(\text{fod})_3]$ and Michler's ketone emits red luminescence under daylight illumination.⁵²¹ Chemical shifts in the NMR spectra of adducts of $[\text{Ln}(\text{fod})_3(\text{bipy})]$ and $[\text{Ln}(\text{fod})_3(\text{phen})]$ are dipolar in origin.⁵²² $[\text{Eu}(\text{ttfa})_3(\text{phen})]$ (ttfa = thenoyltrifluoroacetate) has been doped into organically modified silicate matrices; on reaction with hexamethyldisilazane, a composite phosphor with high emission intensity was formed.⁵²³ The first perfluoroacetylacetonate complexes have been reported.⁵²⁴

$[\text{Eu}(\text{OAc})_3]$ reacts with acacF-7H to form nine-coordinate $[\text{Ln}(\text{acacF-7})_3(\text{CH}_3\text{COOH})_3]$ in which the acetic acid molecules are coordinated by the C=O group; one carbonyl group of the diketone is hydrogen bonded to an acetic acid molecule (and the corresponding Eu—O bond is slightly lengthened). The acetic acids are readily displaced by phosphine oxides with the formation of complexes such as eight-coordinate $[\text{Ln}(\text{acacF-7})_3(\text{OPPh}_3)_2]$. A number of dimeric tetraglyme complexes $[\text{Ce}_2(\text{diketonate})_6(\text{tetraglyme})]$ (tetraglyme = $\text{CH}_3\text{O}(\text{CH}_2\text{CH}_2\text{O})_4\text{CH}_3$; diketone = etbd; 1,1,1,5,5,5-hexafluoropentane-2,5-dione, 1,1,1,2,2,3,3-heptafluoro-7,7-dimethyloctane-4,6-dione) have been made.⁵²⁵ Syntheses of methylpivaloylacetates of Y, Ba and Cu have been reported⁵²⁶ including the structure of $[\text{Y}(\text{mpa})_3(\text{bipy})]$ (mpaH = methylpivaloylacetate) whilst tris(tropolonato) samarium has been synthesized electrochemically.⁵²⁷ Fluorinated diketone complexes $[\text{Ln}(\text{RCOCHCOR}')_3]$ (R, R' are, for example, CF_3 , C_3F_7 , Bu^t , etc.) have been shown to be efficient and rapid transport agents for potassium benzyloxocarbonylamino acids.⁵²⁸

Lanthanide β -diketonates of fluorinated ligands form 1:1 complexes with amino acids, enabling their extraction, transport, and chiral recognition.⁵²⁹ $[\text{Eu}(\text{bta})_3(\text{H}_2\text{O})_2]$ and $[\text{Eu}(\text{bta})_3(\text{Ph}_3\text{PO})_2]$ (bta = benzoyl-1,1,1-trifluoroacetylacetonate) both have dodecahedral eight-coordination of europium.⁵³⁰ $[\text{Tris}(4,4,4\text{-trifluoro-1-phenyl-1,3-butanedionate})(1,10\text{-phenanthroline-N-oxide})\text{europium}]$ exhibits very high luminescence quantum yields at room temperature and shows promise as a light-conversion molecular device.⁵³¹ Europium and terbium β -diketonates have been used in organic electroluminescent devices.⁵³² Luminescence spectra of a number of nitrogen base adducts of $[\text{Ln}(\text{diketonate})_3]$ (diketonate = acac, fod, PhCOCHCOPh) have been used to obtain information about the symmetry around the lanthanide ion.⁵³³ The adducts $[\text{Eu}(\text{btfa})_3 \cdot (\text{bipy})]$ and $[\text{Eu}(\text{bzac})_3 \cdot (\text{bipy})]$ (btfa = 4,4,4-trifluoro-1-phenyl-2,4-butanedione; bzac = 1-phenyl-2,4-butanedione) have been reported, as well as the structure of $[\text{Eu}(\text{btfa})_3 \cdot (\text{bipy})]$; the fluorinated compound shows a higher quantum yield in fluorescence.⁵³⁴ The volatility and the effect of the conjugated system of the ligand upon the luminescence of adducts of europium β -diketonates has been examined, with a view to the synthesis of electroluminescent devices.⁵³⁵

Coordination polyhedra for the diketonates and their adducts remain a fertile area of research. In addition to compounds already discussed, many other structures have been published. Structures have been reported for the neutral diketonates $[\text{Eu}(\text{dbm})_3(\text{bipy})]$,⁵³⁶ $[\text{Eu}(\text{C}_6\text{H}_5\text{COCHCOCF}_3)_3(\text{Ph}_3\text{PO})_2]$ ⁵³⁷ and $[\text{Ho}(\text{Me}_3\text{CCOCHCOCMe}_3)_3(\text{pivalic acid})]$ ⁵³⁸ $[\text{Gd}(\text{hfpd})_3(\text{Me}_2\text{CO})(\text{H}_2\text{O})]$ has square antiprismatic coordination (hfpd = 1,1,1,5,5,5-hexafluoropentane-2,4-dione) whilst $[\text{Gd}_3(\mu_3\text{-OH})(\mu_2\text{-H}_2\text{O})_2(\text{H}_2\text{O})_4(\text{hfpd})_8]$ has a structure with a M_4O_6 core.⁵³⁹ $[\text{M}(\text{dpm})_3(\text{H}_2\text{O})]$ (M = Y, Gd) reacts with hmteta (hmteta = hexamethyltriethylenetetramine, $\text{Me}_2\text{N}(\text{CH}_2\text{CH}_2\text{NMe})_2\text{CH}_2\text{CH}_2\text{NMe}_2$) forming dimeric $[(\text{dpm})_3\text{M}(\mu\text{-hmteta})\text{M}(\text{dpm})_3]$ in which only three of the four nitrogen atoms in the amine are bound to yttrium.⁵⁴⁰ $[\text{Eu}(\text{TAN})_3(\text{bipy})]$ (TAN = 4,4,4-trifluoro-1-(2-naphthyl)-1,3-butanedionate) crystallizes in two forms with slightly different coordination polyhedra, one bicapped trigonal prismatic, the other square antiprismatic.⁵⁴¹ A new β -diketonate ligand, 1,3-di-(2-furyl)-1,3-propanedione(dfp), has been used to make the complex $[\text{Eu}(\text{dfp})_3(\text{phen})]$, a red emitter fabricated into a double layer electroluminescent device.⁵⁴² Other $[\text{Eu}(\text{R}_1\text{COCHCOR}_2)_3(\text{phen})]$ (R_1 , R_2 are, for example, Me, Ph) have been doped into blue-emitting conjugated polymers, producing pure red-emitting LEDs.⁵⁴³ Enhanced luminescence has been noted for some Nd and Eu β -diketonates in polymer matrices.⁵⁴⁴ Achiral $[\text{Ln}(\text{diketonate})_3]$ systems form 1:1 complexes with amino alcohols that give CD spectra dependent upon the absolute configuration of the substrate.⁵⁴⁵ Heterobimetallic compounds have been studied lately on account of their structures and magnetic properties. They are also potential MOCVD single-source precursors. The series $[\text{Ni}(\text{salen})\text{La}(\text{hfa})_3]$ (Ln = Y, La–Yb) which have similar structures to several of the known $[\text{Cu}(\text{salen})\text{La}(\text{hfa})_3]$ compounds sublime without decomposition in vacuo.⁵⁴⁶

Co-crystallization of a mixture of $[\text{Y}(\text{hfa})_3]$ and $[\text{Cu}(\text{acac})_2]$ affords $[\text{Y}(\text{hfa})_3(\text{H}_2\text{O})_2\text{Cu}(\text{acac})_2]$ (hfa = hexafluoroacetylacetonate) in which the individual metal diketonate complexes are linked by hydrogen bonds.⁵⁴⁷ Heating in vacuum induces ligand exchange and the liberation of gaseous $[\text{Cu}(\text{hfa})_2]$. Structures of heterodinuclear complexes show lanthanide-copper distances of approximately 3.2 Å and some tetrahedral distortion around copper. There is a small ferromagnetic interaction between the lanthanide and copper ions ($J = 0.8 \text{ cm}^{-1}$).⁵⁴⁸

Reactions between copper or lanthanide tmhd complexes and copper or barium aminoalkoxides have been investigated⁵⁴⁹ and the structures of $[\text{PrCu}(\eta^2\text{-tmhd})_3(\mu\text{-}\eta^2\text{-O}(\text{CH}_2)_2\text{NMe}_2)_2]$ and of $[\text{Y}_2(\eta^2\text{-tmhd})_4(\mu\text{-}\eta^2\text{-OCH}(\text{CH}_2\text{NMe}_2)_2)_2]$ determined.

$[\text{CuLGd}(\text{hfac})_2]_2(\text{H}_3\text{L} = 1\text{-(2-hydroxybenzamido)-2-(2-hydroxy-3-methoxybenzylideneamino)ethane})$ is a cyclic Gd_2Cu_2 complex with a $S = 8$ ground state due to ferromagnetic coupling between Gd and Cu.⁵⁵⁰

The first lanthanide β -ketoiminate complexes have been made^{551,552} including $[\text{Yb}(\text{Bu}^t\text{-CO.CH.C}(\text{Bu}^t)\text{NPr}^n)_3]$. Fluorine-free ketoiminates $[\text{Ln}(\text{miki})_3]$ ($\text{Ln} = \text{Ce}, \text{Nd}, \text{Er}$) (17) are highly volatile and low-melting fluorine free precursors for MOCVD of lanthanide oxide thin films.

(17)

Anionic complexes have also attracted attention. $\text{Na}[\text{Er}(\text{pta})_4]$ (pta = pivaloyltrifluoroacetylacetonate) contains tetragonally antiprismatic coordination of erbium.⁵⁵³ $[\text{NH}_4][\text{Ce}(\text{etbd})_4]$ (etbd = 1-ethoxy-4,4,4-trifluorobutane-1,3-dionate), has distorted square antiprismatic coordination of Ce.⁵⁵⁴ $(\text{Et}_4\text{N})[\text{Eu}(\text{dbm})_4]$ is triboluminescent (emits light when fractured)—an effect generally associated with non-centric space groups. It had been claimed that this compound was an exception,⁵⁵⁵ but this has shown not to be the case.⁵⁵⁶ Interest has been shown⁵⁵⁷ in second-order nonlinear optical Langmuir–Blodgett films based on $[\text{Eu}(\text{dbm})_4]^-$. Salts of the $[\text{Ln}(\text{ttfa})_4]^-$ ion have attracted attention. The synthesis and structure of (E)-N-ethyl-4-(2-(4'-dimethylaminophenyl)ethenyl) pyridinium $[\text{La}(\text{ttfa})_4]^{558}$ are reported. $\text{M}[\text{Eu}(\text{ttfa})_4]$ (ttfa = thenoyltrifluoroacetate) are soluble in common organic solvents and thus suitable for doping into polymer films to make light-emitting diodes.⁵⁵⁹ The structure and fluorescence spectrum of the ethylpyridinium salt of $[\text{Eu}(\text{ttfa})_4]^-$ has been determined.⁵⁶⁰ Study of luminescence from (N,N-distearylmethylammonium)[$\text{Eu}(\text{ttfa})_4]$ shows enhancement of the intensity of luminescence from the 5D_1 excited state relative to the 5D_0 state in monolayers compared with either solutions or the crystalline state.⁵⁶¹ Second-harmonic generation from monolayers of hemicyanine salts of $[\text{Eu}(\text{ttfa})_4]^-$ has been reported.⁵⁶² Another anionic complex has been used to prepare a photoactive bilayer lipid membrane.⁵⁶³

3.2.2.5.4 Alkoxides and aryloxides

Many alkoxides in particular have been known since the 1960s, but interest in them has been stimulated recently by their potential use as precursors for deposition of metal oxides using the sol-gel or MOCVD process. A review covering the literature to 1990 has appeared.⁵⁶⁴ Traditionally, alkoxides are made by salt-elimination reactions of lanthanide chlorides with alkali metal alkoxides (or aryloxides) which sometimes causes chloride retention

but increasingly other sources of the lanthanide, like amide complexes, are being used⁵⁶⁵ in order to avoid possible chloride retention (and –ate ion formation)

A route useful in a few cases is the reaction between lanthanide metal chips and the alcohol (usually isopropanol) in the presence of HgCl_2 catalyst

Simple methoxides like $\text{La}(\text{OMe})_3$ are ill-defined structurally but are oligomeric. Reaction of erbium chips with isopropanol as described affords principally the oxo-centred cluster $\text{Er}_5\text{O}(\text{OPr}^i)_{13}$ (with a square-pyramidal core) but there is evidence that gentle work-up gives an alkoxide “ $\text{Ln}(\text{OPr}^i)_3$ ” without an oxogroup.⁵⁶⁶

Reaction of $\text{Nd}\{\text{N}(\text{SiMe}_3)_2\}_3$ with diisopropylmethanol in hexane in the presence of THF gives the binuclear $[\text{Nd}(\text{OCHPr}^i)_2(\text{THF})]_2$

This has the structure $[(\text{Pr}^i\text{CHO})_2(\text{THF})\text{Nd}(\mu\text{-OCHPr}^i)_2\text{Nd}(\text{THF})(\text{OCHPr}^i)_2]$.

The THF ligands are readily exchanged for pyridine to form $[\text{Nd}_2(\text{OCHPr}^i)_6(\text{Py})_2]$, whilst reaction with 1,2-dimethoxyethane (DME) gives $[\text{Nd}_2(\text{OCHPr}^i)_6(\mu\text{-DME})]$, in which the binuclear alkoxy-bridged dimer units survive, linked to each other by bridging dimethoxyethane molecules.⁵⁶⁷ Neodymium has trigonal bipyramidal coordination in all these compounds. Reaction of $\text{Ln}\{\text{N}(\text{SiMe}_3)_2\}_3$ with neopentanol gives neopentoxides $[\text{Ln}(\text{OCH}_2\text{Bu}^t)_3]_4$ ($\text{Ln} = \text{La}, \text{Nd}$) that are tetramers based on a square of lanthanides with each lanthanide bound to one terminal and four bridging alkoxides. Nonbonding $\text{La}\text{—}\text{La}$ distances are 3.85 Å in the lanthanum compound; terminal $\text{La}\text{—}\text{O}$ distances are ~ 2.16 Å and bridging $\text{La}\text{—}\text{O}$ distances $\sim 2.37\text{—}2.44$ Å. IR spectra in both the solid state and solution show absorption bands at $\sim 2,680\text{ cm}^{-1}$, ascribed to $\text{Ln}\cdots\text{H}\text{—}\text{C}$ agostic interactions.⁵⁶⁸ Using more bulky alkoxide groups, trinuclear complexes which are not oxo-centered have been obtained, using the route of alcoholysis of the amide, in the form of $\text{Ln}_3(\text{OR})_9(\text{ROH})_2$ ($\text{Ln} = \text{Y}, \text{R} = \text{Bu}^t, \text{Am}^t$; $\text{Ln} = \text{La}, \text{R} = \text{Bu}^t$). Increasing ligand bulk further enables the isolation of dimers $[\text{Ln}(\text{OR})_3]_2$ ($\text{Ln} = \text{Y}, \text{R} = \text{CMe}_2\text{Pr}^i, \text{CMeEtPr}^i, \text{CEt}_3$; $\text{Ln} = \text{La}; \text{R} = \text{CMe}_2\text{Pr}^i, \text{CMeEtPr}^i$). $\text{La}_3(\text{OBu}^t)_9(\text{Bu}^t\text{OH})_2$ has the structure $[\text{La}_3(\mu_3\text{-OBu}^t)_2(\mu\text{-OBu}^t)_3(\text{OBu}^t)_4(\text{Bu}^t\text{OH})_2]$ in which the La_3 triangle is capped by two $\mu_3\text{-OBu}^t$ groups; lanthanum is octahedrally coordinated.⁵⁶⁹ Reaction of NdCl_3 with NaOBu^t in THF affords a THF-solvated *t*-butoxide of neodymium, shown to be $[\text{Nd}_3(\mu_3\text{-OR})_2(\mu\text{-OR})_3(\text{OR})_4(\text{THF})_2]$ ($\text{R} = \text{Bu}^t$). Combined with one mole of MgR'_2 ($\text{R}' = n\text{-hexyl}$), it is a catalyst for the pseudo-living polymerization of ethene.⁵⁷⁰ Refluxing $[\text{Ln}_3(\text{OBu}^t)_9(\text{Bu}^t\text{OH})_2]$ ($\text{Ln} = \text{La}, \text{Nd}, \text{Yb}$) in toluene gives⁵⁷¹ the oxo-centered $[\text{Ln}_3\text{O}(\text{OBu}^t)_3]$. Higher nuclearity clusters $[\text{Ln}_4\text{O}_3(\text{OBu}^t)_6]$ ($\text{Ln} = \text{Pr}, \text{Y}$) have been obtained from similar reactions. Alkylation of “ $\text{Ln}(\text{O-Bu}^t)_3$ ” with AlMe_3 give related mixed alkyl/alkoxy bridged $[\text{Ln}(\mu\text{-OBu}^t)_3(\mu\text{-Me})_3(\text{AlMe}_2)_3]$ ($\text{Ln} = \text{Pr}, \text{Nd}, \text{Y}$).⁵⁷² The alternative route to butoxides, using salt-elimination from LnCl_3 and the alkali-metal alkoxide has in some cases given chlorine-containing products, such as $\text{Y}_3(\text{OBu}^t)_8\text{Cl}(\text{THF})_2$ and $\text{Y}_3(\text{OBu}^t)_7\text{Cl}_2(\text{THF})_2$, although $\text{Ln}_3(\text{OBu}^t)_9(\text{THF})_2$ ($\text{Ln} = \text{La}, \text{Y}$) have also been made.^{573–575} Using an even bulkier ligand affords⁵⁷⁶ the compound $\text{Ce}(\text{OCBu}^t)_3$ which is believed to be a monomer. It undergoes high-yield thermolysis in vacuo at 150°C affording an alkoxy-bridged dimer $[(\text{Bu}^t_2\text{CHO})_2\text{Ce}(\mu\text{-OCHBu}^t)_2\text{Ce}(\text{OCHBu}^t)_2]$ with four-coordinate cerium

Reaction of $[\text{Gd}\{\text{N}(\text{SiMe}_3)_2\}_3]$ with $(\text{Me}_3\text{Si})_3\text{SiOH}$ in THF gives hexane-soluble $[\text{Gd}\{\text{OSi}(\text{SiMe}_3)_3\}_3(\text{THF})_2]$, a compound that can also be made from GdCl_3 and $(\text{Me}_3\text{Si})_3\text{SiONa}$. This has a trigonal bipyramidal structure with axial THF molecules, $\text{Gd}\text{—}\text{O}(\text{OR}) = 2.142$ Å and $\text{Gd}\text{—}\text{O}(\text{THF}) = 2.314$ and 2.448 Å.⁵⁷⁷ $[\text{Gd}\{\text{OSi}(\text{SiMe}_3)_3\}_3(\text{MeCN})_2]$ can be made similarly in acetonitrile. $[\text{Gd}\{\text{OSi}(\text{SiMe}_3)_3\}_3(\text{THF})_2]$ reacts with DABCO (1,4-diazabicyclo[3.2.2]octane) forming $[\text{Gd}\{\text{OSi}(\text{SiMe}_3)_3\}_3(\text{DABCO})]$ which again has a trigonal bipyramidal structure with DABCO acting as a monodentate ligand instead of the hoped-for coordination polymer; here $\text{Gd}\text{—}\text{O}(\text{OR}) = 2.161$ Å and $\text{Gd}\text{—}\text{O}(\text{THF}) = 2.520$ Å. Reaction of $[\text{Gd}\{\text{OSi}(\text{SiMe}_3)_3\}_3(\text{THF})_2]$ with 4,4'-bipyridyl gives $[\text{Gd}\{\text{OSi}(\text{SiMe}_3)_3\}_3(4,4\text{-bipy})_2]$, possibly a monomer, from which one mole of bipy can be leached in MeCN forming what is believed to be a polymer, $[\text{Gd}\{\text{OSi}(\text{SiMe}_3)_3\}_3(4,4\text{-bipy})_2]_n$. Reaction of $[\text{La}\{\text{N}(\text{SiMe}_3)_2\}_3]$ with $(\text{Me}_3\text{Si})_3\text{SiOH}$ in THF gives hexane-soluble $\text{La}\{\text{OSi}(\text{SiMe}_3)_3\}_3(\text{THF})_4$,

believed to be $[\text{La}\{\text{OSi}(\text{SiMe}_3)_3\}_3(\text{THF})_3]\cdot\text{THF}$. The homoleptic silyloxides $[\text{La}\{\text{OSi}(\text{SiMe}_3)_3\}_3]$ cannot be made by direct exchange between $[\text{Ln}\{\text{N}(\text{SiMe}_3)_2\}_3]$ with $(\text{Me}_3\text{Si})_3\text{SiOH}$ in a nonpolar solvent, however. $\text{La}\{\text{OSi}(\text{SiMe}_3)_3\}_3(\text{THF})_n$ lose their THF on sublimation in vacuum. $\text{La}\{\text{OSi}(\text{SiMe}_3)_3\}_3(\text{THF})_n$ absorb CO_2 from the atmosphere forming carbonates. A number of $\text{Ln}\{\text{OQPh}_3\}_3$ ($\text{Ln} = \text{Y, La, Ce}$; $\text{Q} = \text{C, Si}$) have been synthesized. Some of these are definitely dimers, such as $[\text{La}(\text{OCPh}_3)_2(\mu\text{-OCPh}_3)]_2$ and $[\text{Ce}(\text{OSiPh}_3)_2(\mu\text{-OSiPh}_3)]_2$ respectively.⁵⁷⁸ As expected, the bridging $\text{M}-\text{O}$ distances are longer than the terminal ones; in $[\text{La}(\text{OCPh}_3)_2(\mu\text{-OCPh}_3)]_2$, the $\text{La}-\text{O}$ (terminal) are 2.175–2.184 Å whilst $\text{La}-\text{O}$ (bridging) = 2.389–2.483 Å. All these compounds may conveniently be synthesized by the alcoholysis of $[\text{Ln}\{\text{N}(\text{SiMe}_3)_2\}_3]$ ($\text{Ln} = \text{La, Ce}$). ²⁹ Si -NMR studies suggest that $[\text{Y}(\text{OSiPh}_3)_2(\mu\text{-OSiPh}_3)]_2$ retains its dimeric structure in solution.⁵⁷⁹ In this solid state the $\text{Y}-\text{O}$ (terminal) distances are 2.058–2.062 Å whilst $\text{Y}-\text{O}$ (bridging) = 3.211–3.288 Å. The shorter terminal bond lengths are again expected, and may be compared with values of 2.118–2.138 Å in five and six-coordinate Lewis base adducts. The alkoxide bridges can be cleaved by Lewis bases^{580–582} (Py , THF , $\text{Bu}_3\text{P}=\text{O}$) forming adducts such as *fac*- $\text{Ln}(\text{OSiPh}_3)_3(\text{THF})_3$ ($\text{Ln} = \text{Y, La, Ce}$) and $\text{Ln}(\text{OSiPh}_3)_3(\text{OPBu}_3)_2$ (trigonal bipyramidal, with axial phosphine oxides), as well as the ionic $[\text{K}(\text{DME})_4][\text{Y}(\text{OSiPh}_3)_4(\text{DME})]$. In $\text{Y}(\text{OSiPh}_3)_3(\text{THF})_3$ $\text{Y}-\text{OR}$ bond lengths fall in the range 2.118–2.138 Å whilst $\text{Y}-\text{O}(\text{THF})$ distances are 2.374–2.462 Å, whilst in $\text{Y}(\text{OSiPh}_3)_3(\text{OPBu}_3)_2$ $\text{Y}-\text{OR}$ bond lengths are in the range 2.118–2.129 Å whilst $\text{Y}-\text{O}(\text{THF})$ distances are 3.261–3.266 Å. A comparison of the structures of $\text{Ln}(\text{OSiPh}_3)_3(\text{THF})_3$ ($\text{Ln} = \text{La, Y}$) indicates that although these compounds are isostructural, there was a greater contraction in the $\text{Ln}-\text{O}(\text{THF})$ bond length than in the $\text{Ln}-\text{OR}$ distance on passing from La to Y , interpreted in terms of a greater “malleability” in the weaker bonds to the ether. In a further study of lanthanide silyloxides, the structures of $[\text{Gd}(\text{OSi}(\text{SiMe}_3)_3)_3(\text{L})_2]$ ($\text{L} = \text{THF}$; $2\text{L} = \text{H}_2\text{N}(\text{C}_2\text{H}_4)\text{NH}_2$) show them to have *thp* coordination of gadolinium. $[\text{Gd}(\text{OSi}(\text{SiMe}_3)_3)_3(\text{THF})_2]$ and $[\text{La}(\text{OSi}(\text{SiMe}_3)_3)_3(\text{THF})_4]$ both absorb CO_2 to give carbonates; they also lose THF in vacuo on sublimation at 205 °C to afford homoleptic silyloxides.⁵⁸³ A chloro-bridged dimer, $[\text{Nd}(\text{OSiBu}^t)_3)_2(\text{THF})(\mu\text{-Cl})_2]$ has been characterized.⁵⁸⁴ Silanol ligands with alkylamide groups enable the isolation⁵⁸⁵ of volatile monomers like five-coordinate $[\text{Y}\{\text{OSi}(\text{Bu}^t)[(\text{CH}_2)_3\text{NMe}_2]_2\}_3]$ where one amide is uncoordinated. An yttrium compound with a remarkable cyclic decameric structure, $[\text{Y}(\text{OCH}_2\text{CH}_2\text{OCH}_3)_3]_{10}$ has been made both by reaction of yttrium chips with 2-methoxyethanol and by alcoholysis of $\text{Y}_5\text{O}(\text{OPr}^i)_{13}$. Yttrium attains pentagonal bipyramidal seven-coordination by forming one terminal $\text{Y}-\text{O}$ link and by linking to six bridging oxygens.⁵⁸⁶ As they are easily made, “ $[\text{Ln}(\text{OPr}^i)_3]$ ”, which may be clusters (see below), have attracted attention as catalysts and as starting materials. Thus $[\text{Y}(\text{OPr}^i)_3]$ catalyzes the ring-opening of epoxides with Me_3SiN_3 .⁵⁸⁷ $[\text{La}(\text{OPr}^i)_3]$ is a very efficient catalyst for the transesterification of esters with alcohols.⁵⁸⁸ $[\text{La}(\text{OPr}^i)_3]$ reacts with anthracenebis(resorcinol) forming an insoluble 1:2 polycondensate which catalyzes enolization and aldol reactions of ketones such as cyclohexanone in pure water at normal pH.⁵⁸⁹

A number of oxo-centered clusters have attracted attention. Compounds previously formulated as $\text{Ln}(\text{OPr}^i)_3$ have been recognized^{566,590–594} as $\text{Ln}_5\text{O}(\text{OPr}^i)_{13}$ ($\text{Ln} = \text{Y, Yb, Er, Nd, Gd, Eu, Pr}$) and more of these undoubtedly can be made. Crystallography has established the structures of most of these compounds, and shown them to be clusters $[\text{Ln}_5(\mu_5\text{-O})(\mu_3\text{-OPr}^i)_4(\mu_2\text{-OPr}^i)_4(\text{OPr}^i)_5]$ containing a square-pyramidal arrangement of the lanthanides around a μ_5 -oxo group. The μ_2 groups link basal metal atoms and the μ_3 groups link two basal metal atoms with an apical atom. Thus in $[\text{Y}_5(\mu_5\text{-O})(\mu_3\text{-OPr}^i)_4(\mu_2\text{-OPr}^i)_4(\text{OPr}^i)_5]$, the $\text{Y}-\text{O}$ bond distances follow the expected pattern $\text{Y}-\mu_3\text{-OR} > \text{Y}-\mu_2\text{-OR} > \text{Y}-\text{OR}$ (they average 3.27, 3.25, and 2.01 Å respectively). The $\text{Y}-\mu_3\text{-OR}$ distances involving the apical Y are, at 2.18–2.32 Å, significantly shorter than those involving the basal yttriums at 2.37–2.45 Å; the $\text{Y}-\mu_5\text{-O}$ distances are at 2.35 Å, rather longer than those involving $\mu_3\text{-OR}$. The metal–metal distances are relatively long (3.26–3.38 Å in the ytterbium compound; 3.30–3.47 Å in the yttrium compound) showing the absence of metal–metal bonding. The ⁸⁹ Y -NMR spectrum of $\text{Y}_5\text{O}(\text{OPr}^i)_{13}$ shows two signals with an intensity ratio of 4:1 confirming the retention of the square pyramidal structure in solution.⁵⁹⁰ Syntheses have been reported for the oxo-centered alkoxides $[\text{Ln}_5\text{O}(\text{OPr}^i)_{13}]$ ($\text{Ln} = \text{Nd, Gd}$); they have similar structures, based on a square pyramidal M_5O core, to the known Er compound, a structure largely retained in solution. They react with $[\text{Al}_4(\text{OPr}^i)_{12}]$ forming $[\text{LnAl}_3(\text{OPr}^i)_{12}]$.⁵⁹³ Reaction of EuCl_3 with KOPr^i followed by stoichiometric hydrolysis yields $\text{Eu}_5\text{O}(\text{OPr}^i)_{13}$, whereas reaction of Eu metal with HOPr^i in toluene gives the mixed-valence $\text{Eu}_4(\text{OPr}^i)_{10}(\text{HOPr}^i)_3$.⁵⁹⁴ Praseodymium alkoxides have been investigated,⁵⁹⁵ a number of oxo-centered species being isolated. Reaction of Pr metal with ROH affords $[\text{Pr}_5\text{O}(\text{OR})_{13}]$ ($\text{R} = \text{Pr}^i, \text{Am}^i$), $[\text{Pr}_6\text{O}_2(\text{ONp})_8]$ ($\text{Np} = \text{neopentyl}$), and $[\text{Pr}(\text{OC}_2\text{H}_4\text{NMe}_2)_3]$. Alcoholysis of $[\text{Pr}\{\text{N}(\text{SiMe}_3)_2\}_3]$ gives $[\text{Pr}_4\text{O}(\text{ONp})_{10}]$, $[\text{Pr}_4\text{O}_2(\text{ONp})_8]$, $[\text{Pr}_3(\text{OR})_9(\text{ROH})_2]$ ($\text{R} = \text{Bu}^t, \text{Am}^i$), and $[\text{Pr}_4\text{O}_2(\text{OC}_2\text{H}_4\text{OMe})_8]$. Reaction of Nd chips with isopropanol in the presence of $\text{Hg}(\text{OAc})_2$ as the customary

catalyst affords two neodymium alkoxides. $[\text{Nd}(\text{OPr}^i)_3(\text{Pr}^i\text{OH})]$ is tetrameric, with a structure similar to $[\text{Ti}(\text{OMe})_3]_4$, involving six-coordinate neodymium. The second product is an oxo-centered compound, $\text{Nd}_5\text{O}(\text{OPr}^i)_{13}(\text{Pr}^i\text{OH})_2$, which in contrast to the square pyramidal $\text{Ln}_5\text{O}(\text{OPr}^i)_{13}$ has a M_5O trigonal bipyramidal core. $\text{Nd}-\text{O}$ distances vary from 2.121 Å for a terminal linkage to 2.719 Å for a $\text{Nd}-\mu_5-\text{O}$ bond.⁵⁹⁶ Several mixed-metal alkoxides have been synthesized, including $[\text{Y}_4\text{PrO}(\text{OPr}^i)_{13}]$ which has the familiar structure $[\text{Y}_4\text{Pr}(\mu_5-\text{O})(\mu_3-\text{OR})_4(\mu-\text{OR})(\text{OR})_5]$. The structure of $[\text{Pr}_4(\mu_4-\text{O})(\mu_3, \eta^2-\text{OR})_4(\mu, \eta^1-\text{OR})(\text{OR})(\text{OPMe}_3)_2]$ was also determined. $[\text{Y}_5\text{O}(\text{OPr}^i)_{13}]$ reacts with HACAC forming $[\text{Y}_2(\mu-\text{OAc})_2(\text{ACAC})_4(\text{H}_2\text{O})_2]$.⁵⁹⁷ $[\text{Ln}\{\text{N}(\text{SiMe}_3)_2\}_3]$ ($\text{Ln} = \text{Y}, \text{Lu}$) undergo alcoholysis with donor-functionalized alcohols $\text{HOCR}_2\text{CH}_2\text{do}$ ($\text{do} = \text{OMe}, \text{R} = \text{Me}, \text{Et}; \text{do} = \text{NMe}_2, \text{R} = \text{Me}$) forming volatile, alkane soluble $[\text{Ln}(\text{OCR}_2\text{CH}_2\text{do})_3]$. $[\text{Lu}(\text{OCMe}_2\text{CH}_2\text{OMe})_3]$ is dimeric; inadvertent hydrolysis yields the novel $[\text{Lu}_4(\text{O})(\text{OH})(\text{OCMe}_2\text{CH}_2\text{OMe})_9]$ whose Lu_4O_{15} core has a butterfly rather than a tetrahedral geometry.⁵⁹⁸ A cluster involving six metal atoms is $\text{Gd}_6\text{O}(\text{OCH}_2\text{CH}_2\text{OCH}_3)_{16}$, obtained from the Hg^{II} catalyzed reaction of gadolinium with 2-methoxyethanol or by alcohol exchange with $\text{Gd}_5\text{O}(\text{OPr}^i)_{13}$. It has the structure $[\text{Gd}_6(\mu_4-\text{O})(\mu_3, \eta^2-\text{OR})_4(\mu, \eta^2-\text{OR})_6(\mu, \eta^1-\text{OR})_2(\text{OR})_4]$ ($\text{R} = \text{OCH}_2\text{CH}_2\text{OCH}_3$), with four gadoliniums surrounding the oxo ligand and two only bound to alkoxides. $\text{Gd}-\text{O}$ bond lengths fall into the range 2.152–2.674 Å, showing the pattern $\text{Gd}-\text{OR} < \text{Gd}-\mu_4-\text{O} < \text{Gd}-\mu-\text{OR} < \text{Gd}-\mu_3-\text{OR} < \text{Gd}-\text{OR}$ (ether). The gadolinium atoms are seven and eight-coordinate.⁵⁹⁹ A number of volatile fluoroalkoxides, some also involving sodium, have been described; including $[\text{Y}\{\text{OCH}(\text{CF}_3)_2\}_3\cdot\text{L}_3]$ ($\text{L} = \text{THF}, \text{Pr}^i\text{OH}$), $[\text{YNa}_3\{\text{OCH}(\text{CF}_3)_2\}_6(\text{THF})_3]$, $[\text{YNa}_2\{\text{OCMe}(\text{CF}_3)_2\}_5(\text{THF})_3]$ and $[\text{YNa}_2\{\text{OC}(\text{CF}_3)\text{Me}_2\}_5\cdot\text{THF}]$. The sodium is retained on sublimation, but the Lewis base is lost.^{600,601} A number of volatile hexafluoro-*t*-butoxides have also been synthesized.^{602,603} The Raman spectrum of $[\text{Eu}(\text{OCH}(\text{CF}_3)_2)_3]$ indicates strong $\text{Eu}\cdots\text{F}$ interactions; acid hydrolysis gives EuF_3 .⁶⁰⁴ A number of mixed metal alkoxo/diketonates (of obvious utility as possible materials for the synthesis of thin superconductor films) have been synthesized and the structure of $[\text{BaY}_2(\mu-\text{OCH}(\text{CF}_3)_2)_4(\text{tmhd})_4]$ determined.⁶⁰⁵

There have been major developments in aryloxide chemistry. There is now known a wide range of aryloxides $\text{Ln}(\text{OAr})_3$, some solvated, but some can be isolated as three-coordinate monomers, especially with 2,6-di-*t*-butylaryloxides. Tested syntheses have appeared⁶⁰⁶ for $[\text{Ln}(\text{OC}_6\text{H}_3\text{Bu}^t_{2-2,6-\text{Me}-4})_3]$ ($\text{Ln} = \text{Y}, \text{La}, \text{Pr}, \text{Nd}, \text{Dy}-\text{Er}, \text{Yb}$) and $[\text{Ln}(\text{OC}_6\text{H}_3\text{Bu}^t_{2-2,6})_3]$ ($\text{Ln} = \text{Y}, \text{La}, \text{Sm}$). In these three-coordinate species, the possibility arises of the LnO_3 grouping being planar or pyramidal, as in the silylamides $[\text{Ln}\{\text{N}(\text{SiMe}_3)_2\}_3]$. Both possibilities seem to be realized. $[\text{Y}(\text{OC}_6\text{H}_3\text{Bu}^t_{2-2,6})_3]$ is trigonal planar⁶⁰⁷ but $[\text{Ce}(\text{OC}_6\text{H}_2\text{Bu}^t_{2-2,6-\text{Me}-4})_3]$ is trigonal pyramidal.⁶⁰⁸ Possibly the balance of small and variable Van der Waals forces is the determining factor. $[\text{Sm}(\text{OR})_3]$ ($\text{R} = 2,6\text{-Bu}^t_{2-4}\text{-MeC}_6\text{H}_2$)⁶⁰⁹ is a catalyst for the Michael reaction of ketones with α,β -unsaturated ketones that also shows catalytic activity for tandem Aldol–Tischenko reaction of ketones and aldehydes to form 1,3-diol monoesters. Solvates and adducts are sometimes obtained, even with these bulky aryloxides, thus NdCl_3 reacts with three moles of RONa ($\text{R} = 2,6\text{-Bu}^t_{2-4}\text{-MeC}_6\text{H}_2$) forming four-coordinate $[\text{Nd}(\text{OR})_3(\text{THF})]$; ⁶¹⁰ using four moles of RONa , $[\text{Na}(\text{THF})_6][\text{Nd}(\text{OR})_4]$ was obtained, again with tetrahedrally coordinated neodymium. The structure of four-coordinate $[\text{Sm}(\text{OR})_3(\text{OPPh}_3)]$ ($\text{R} = 2,6\text{-Bu}^t_{2-4}\text{-MeC}_6\text{H}_2$) has been determined.⁶¹¹ Using the relatively unhindered 2,6-dimethylphenoxide ligand, reaction of YCl_3 with $\text{NaOC}_6\text{H}_3\text{Me}_2\text{-2,6}$ in THF has been found to afford six-coordinate $[\text{Y}(\text{OC}_6\text{H}_3\text{Me}_2\text{-2,6})_3(\text{THF})_3]$, isolated as the *fac*-isomer. If this is crystallized from toluene, a dimer $[\text{Y}(\text{OAr})_3(\text{THF})_2]$ is formed, having the structure $[(\text{ArO})_2(\text{THF})\text{Y}(\mu-\text{OAr})_2\text{Y}(\text{THF})(\text{OAr})_2]$. This equilibrium is completely reversible. In the dimer, yttrium is in square-pyramidal five-coordination. Bridging $\text{Y}-\text{O}$ distances are as usual longer, at 3.275–3.277 Å, than the terminal $\text{Y}-\text{O}$ distances of 2.046–2.075 Å.⁶¹² Terbium metal reacts with phenols in refluxing isopropanol (probably via intermediate isopropoxides) forming *fac*- $[\text{Tb}(\text{OC}_6\text{H}_3\text{Me}_2\text{-2,6})_3(\text{THF})_3]$ and $[\text{Tb}(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_3(\text{THF})_2]$, the latter having a trigonal bipyramidal structure with axial thf molecules.⁶¹³ Although terbium is a relatively unreactive lanthanide metal, the reaction proceeds well with mercury salts as catalysts. A polyether complex $[\text{La}(\text{OC}_6\text{H}_3\text{Me}_2\text{-2,6})_3\{\text{MeO}(\text{CH}_2\text{OCH}_2\text{O})_4\text{Me}\}]$ is monomeric with eight-coordinate lanthanum.⁶¹⁴ The slightly bulkier 2,6-diisopropylphenolate ligand leads to unsolvated $\text{Ln}(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_3$ species which are in fact η^6 -arene bridged dimers $\text{Ln}_2(\text{OC}_6\text{H}_3\text{-Pr}^i_{2-2,6})_6$. These dissolve in THF to form conventionally bound trigonal bipyramidal THF adducts $[\text{Ln}(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_3(\text{THF})_2]$ (axial THF ligands)⁶¹⁵ ($\text{Ln} = \text{Pr}, \text{Nd}, \text{Sm}, \text{Gd}, \text{Er}, \text{Yb}, \text{Lu}$). These compounds form Lewis base adducts, including those with ammonia. The structures of $[\text{La}_2(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_6(\text{NH}_3)_2]$, $[\text{La}(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_3(\text{NH}_3)_4]$ and $[\text{La}(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_3(\text{THF})_2]$ have been determined.⁶¹⁶ $[\text{La}_2(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_6]$ is bridged by two η^6 -aryl groups. Like the other THF adducts, $[\text{Sm}(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_3(\text{THF})_2]$ is *tbpy* with axial THF molecules;⁶¹⁷ it is the synthon for $[\text{Sm}(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_3(\text{Py})_2]$, $[\text{Sm}(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_3(\text{Py})_3]$, $\text{K}[\text{Sm}(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_4]$ and $\text{K}[\text{Sm}(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_4(\text{Py})]$.

Reaction of $[\text{Ln}_2(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_6]$ with $\text{LiOC}_6\text{H}_3\text{Pr}^i_{2-2,6}$ or $\text{NaOC}_6\text{H}_3\text{Pr}^i_{2-2,6}$ yields $[(\text{THF})\text{La}(\text{OC}_6\text{H}_3\text{-Pr}^i_{2-2,6})_2(\mu-\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_2\text{Li}(\text{THF})]$ and $[(\text{THF})\text{La}(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_2(\mu-\text{OC}_6\text{H}_3\text{-Pr}^i_{2-2,6})_2\text{Na}(\text{THF})]$

respectively⁶¹⁸; the corresponding reaction with $\text{CsOC}_6\text{H}_3\text{Pr}^{\text{i}}_{2-2,6}$ affords $[\text{CsLa}(\text{OC}_6\text{H}_3\text{Pr}^{\text{i}}_{2-2,6})_4]$. The latter contains alternating Cs^+ and $[\text{La}(\text{OC}_6\text{H}_3\text{Pr}^{\text{i}}_{2-2,6})_4]^-$ ions in a one-dimensional chain structure held together by Cs-arene π -interactions. Similar interactions are found in $[\text{Cs}_2\text{La}(\text{OC}_6\text{H}_3\text{Pr}^{\text{i}}_{2-2,6})_5]$.⁶¹⁹ Similarly the aryloxide $\text{K}[\text{Ln}(\text{OC}_6\text{H}_3\text{Pr}^{\text{i}}_{2-2,6})_4]$ has aryloxide anion chains bridged by K-arene interactions;⁶²⁰ this compound is obtained even when just three moles of KOAr are reacted with LnCl_3 , another example of “alkali-metal retention.” The phenolates $[\text{Ln}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_3]$ ($\text{Ln} = \text{La, Ce, Pr, Nd, Gd, Ho, Er, Lu, Y}$) have been synthesized from the reaction of $\text{HOC}_6\text{H}_3\text{Ph}_{2-2,6}$ and the lanthanide in the presence of mercury at 200°C . All have monomeric structures with the lanthanide slightly out of the O_3 plane, but with some additional ring-metal interactions.⁶²¹ $[\text{Ln}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_3(\text{THF})_2] \cdot 2 \text{ THF}$ ($\text{dpp} = 2,6$ -diphenylphenolate; $\text{Ln} = \text{La, Nd}$) have “conventional” five-coordinate trigonal bipyramidal coordination of the metal with one axial and one equatorial THF;^{622,623} in contrast, $[\text{Nd}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_3(\text{THF})]$ has pseudo-tbp coordination with three equatorial phenoxides, an apical THF and an apical position occupied by a phenyl group, and, as already remarked, unsolvated $[\text{Nd}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_3]$ also features Nd-ring interactions.

Crystallization of $[\text{Yb}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_3(\text{THF})_2]$ from DME affords $[\text{Yb}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_3(\text{DME})] \cdot 0.5\text{DME}$; both this and the Nd analogue have a *sp* structure with an axial aryloxide ligand and two *cis*-aryloxides in the basal plane.⁶²⁴ A number of anionic diphenylphenolates have been made.⁶²⁵ LnCl_3 ($\text{Ln} = \text{Nd, Er}$) react with $\text{Na}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6}) \cdot 0.5\text{THF}$ in 1,3,5-tri-*t*-butylbenzene at 300°C forming $[\text{Na}\{\text{Ln}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_4\}]$; on crystallization of $[\text{Na}\{\text{Ln}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_4\}]$ from DME or diglyme the species $[\text{Na}(\text{diglyme})_2][\text{Ln}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_4]$ and $[\text{Na}(\text{dme})_3][\text{Ln}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_4]$ which contain discrete anions are obtained. $[\text{ClLn}(\text{OR})_3\text{Na}]$ ($\text{Ln} = \text{Lu, Y}$) and $[\text{ClY}(\text{OR}')_3\text{Y}(\text{OR}')_3\text{Na}]$ ($\text{OR} = 4\text{-O-2,6-(CH}_2\text{NMe}_2)_2\text{C}_6\text{H}_2$; $\text{OR}' = 2\text{-OC}_6\text{H}_4(\text{CH}_2\text{NMe}_2)$). Reaction of $[\text{Y}\{\text{N}(\text{SiMe}_3)_2\}_3]$ and $[\text{Ba}\{\text{N}(\text{SiMe}_3)_2\}_2]$ with Bu^tOH yields $[\text{YBa}_2(\text{OBu}^t)_7(\text{Bu}^t\text{OH})]$, which has a triangular structure with two μ_3 and three μ_2 ligands.⁶²⁶ “Unsolvated” $[\text{NaLa}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_4]$ contains $[\text{La}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_4]^-$ with sodium bound to three oxygens and interacting with three different phenyl groups.⁶¹⁹ Another route to Yb^{III} aryloxides involves oxidation of the Yb^{II} aryloxides $[\text{Yb}(\text{OAr})_2(\text{THF})_2]$ ($\text{Ar} = \text{OC}_6\text{H}_2\text{Bu}^t_{2-2,6}\text{-R-4}$; $\text{R} = \text{H, Me, Bu}^t$) with HgX_2 or CH_2X_2 ($\text{X} = \text{Cl, Br, I}$) affording $[\text{Yb}(\text{OAr})_2\text{X}(\text{THF})_2]$; $[\text{Yb}(\text{OAr})_2\text{I}(\text{THF})_2]$ ($\text{R} = \text{Me}$) has a square pyramidal structure with apical iodine and *trans*- aryloxides and THF molecules. Inadvertent hydrolysis of $[\text{Yb}(\text{OAr})_2\text{Cl}(\text{THF})_2]$ ($\text{R} = \text{H}$) affords the hydroxy-bridged dimer $[(\text{ArO})_2(\text{THF})\text{Yb}(\mu\text{-OH})_2\text{Yb}(\text{OAr})_2(\text{THF})]$, also with five-coordinate ytterbium.⁶²⁷ Other aryloxides have been synthesized using O-amino phenolate ligands to facilitate binding of anions and cations in the complexes.⁶²⁸ Normally alkoxides, aryloxides, and amides are hydrolyzed by even traces of water, but the structure of a water adduct of an aryloxide, $[\text{Pr}(\text{OC}_6\text{H}_2(\text{CH}_2\text{NMe}_2)_{3-2,4,6})_3(\text{H}_2\text{O})_2]$ has been reported; its structure shows two of the aryloxides to be bidentate, so that the praseodymium is seven-coordinate.⁶²⁹

3.2.2.6 Mixed Group 15 and 16 Donors

3.2.2.6.1 MRI agents

Magnetic resonance imaging (MRI) is probably the most important new application of lanthanide compounds to emerge in the last 20 years. Many hospitals now have MRI scanners and use contrast agents in examinations. The introduction of lanthanide-based contrast agents has revolutionized diagnostics, assisting doctors in distinguishing between normal and diseased tissue and thus improving prognosis. A book on MRI agents, mainly concerned with gadolinium complexes, has now appeared.⁶³⁰ Various reviews, all relevant, have appeared since the previous volume,^{631–639} some more detailed than others.^{631–634} The literature relevant to gadolinium complexes with possible MRI applications is immense and expanding, so for comprehensive coverage the interested reader is referred to the above reviews. MRI relies on detecting the NMR signals of water molecules in the body as a function of space. Since 60% of the body is water, it is the obvious substance to examine. Spatial information is obtained by making the ^1H resonance frequency position-dependent. Thus, within a particular piece of tissue, otherwise-identical water protons resonate at slightly different frequencies dependent upon their position in the field, so that the resulting NMR signal is spatially encoded and a two-dimensional image is obtained. The signal intensity depends upon the relaxation times of the protons. In general, the shorter the relaxation times, the more intense the signal. The imaging agent enhances the contrast to distinguish between healthy and diseased tissue. MRI uses a paramagnetic contrast agent, which shortens the relaxation time (t_1) for the protons in water molecules in that tissue.

What makes a good MRI agent? The choice is dictated by a combination of several factors:

- (i) high magnetic moment,
- (ii) long electron spin relaxation time,
- (iii) osmolality similar to serum,
- (iv) low toxicity,
- (v) solubility,
- (vi) targeting tissue, and
- (vii) coordinated water molecules.

The Gd^{3+} ion is especially suitable for its magnetic properties on account of its large number of unpaired electrons ($S = 7/2$) and because its magnetic properties are isotropic. Its relatively long electron-spin relaxation time, at $\sim 10^{-9}$ s, is more suitable than other highly paramagnetic ions such as Dy^{3+} , Eu^{3+} , and Yb^{3+} ($\sim 10^{-13}$ s). Taken together, these factors are very favorable for nuclear spin relaxation. However, since the free Gd^{3+} ion is toxic (the LD_{50} is $\sim 0.1 \text{ mmol kg}^{-1}$, which is less than the imaging dose, which is normally of the order of 5 g for a human), complexed Gd^{3+} is used, using a ligand that forms a very stable complex *in vivo*. Relaxation times are shorter the nearer the water molecules are to the Gd^{3+} ion, so that the complex ideally must have water molecules in the coordination sphere, the more the better, so that more solvent water molecules can readily be exchanged with coordinated water molecules; however, the use of multidentate ligands to ensure a high stability constant for the gadolinium complex (to minimize the amount of toxic, free Gd^{3+} ions present) tends to reduce the number of bound waters, and in practice most contrast agents have one coordinated water.

Complexes of polyaminocarboxylic acids such as $[\text{Gd}(\text{DTPA})(\text{H}_2\text{O})]^{2-}$ (gadopentetate dimeglumine; Magnevist) or $[\text{Gd}(\text{DOTA})(\text{H}_2\text{O})]^-$ (gadoterate meglumine; Dotarem) have been widely used; these meet most of the above criteria. Both neutral and charged complexes are used, the former having less osmotic effect and the latter being more hydrophilic, so that amide derivatives like $[\text{Gd}(\text{DTPA-BMA})(\text{H}_2\text{O})]$ (gadodiamide; Omniscan) have advantages. (DTPA = diethylenetriaminepentaacetate; DOTA = DOTA = 1,4,7,10-tetraaza-cyclododecane- N , N' , N'' , N''' -tetraacetate; DTPA-BMA = dimethylamide of diethylenetriaminepentaacetic acid).

3.2.2.6.2 EDTA complexes

These have not been much studied of late, since although EDTA forms relatively stable complexes with Gd^{3+} ($\log K = 17.35$) and the complex $[\text{Gd}(\text{EDTA})(\text{H}_2\text{O})_n]^{2-}$ ($n = 2-3$) will, owing to the lower denticity of EDTA compared to DTPA, have the advantage of more coordinated water molecules, nevertheless its tolerability in animal studies was poor and it was therefore superseded by DTPA, which forms a more stable gadolinium complex ($\log K$ for $[\text{Gd}(\text{DTPA})(\text{H}_2\text{O})]^{2-} = 22.46$).⁶⁴⁰ The thermodynamics of complex formation by aminopolycarboxylic acids with lanthanides have been discussed.⁶⁴¹ The pattern of solid-state structures of lanthanide EDTA complexes previously determined is that there is a change in the number of coordinated waters from three to two near the end of the series, following the lanthanide contraction. $\text{Na}[\text{Ln}(\text{EDTA})(\text{H}_2\text{O})_3] \cdot 5\text{H}_2\text{O}$ ($\text{Ln} = \text{La}, \text{Nd}, \text{Eu}$) are isostructural, with nine-coordinate lanthanides.⁶⁴² $[\text{K}[\text{Yb}(\text{EDTA})(\text{OH}_2)_2] \cdot 5\text{H}_2\text{O}]$ contains eight-coordinate ytterbium.⁶⁴³ Structures of several $\text{M}[\text{Ln}(\text{EDTA})(\text{H}_2\text{O})_n]$ ($\text{M} = \text{alkali metal}$; $\text{Ln} = \text{lanthanide}$) show that the coordination number depends upon the ionic radii of both the lanthanide and the alkali metal.⁶⁴⁴ The complex (guanidinium)₂ $[[\text{Eu}(\text{EDTA})\text{F}(\text{H}_2\text{O})]_2] \cdot 2\text{H}_2\text{O}$ contains nine-coordinate europiums linked to two fluorine bridges.⁶⁴⁵ UV/vis studies⁶⁴⁶ on the ${}^7\text{F}_0 \rightarrow {}^5\text{D}_0$ transition in Eu^{3+} complexes of polyaminocarboxylates such as EDTA and PDTA indicate an equilibrium in solution between eight- and nine-coordinate complex species, as known for the aqua ion. ${}^{17}\text{O}$ -NMR studies were also reported on a number of eight-coordinate species $[\text{Ln}(\text{PDTA})(\text{H}_2\text{O})_2]^-$ ($\text{Ln} = \text{Tb}, \text{Dy}, \text{Er}, \text{Tm}, \text{Yb}$) and $[\text{Er}(\text{EDTA})(\text{H}_2\text{O})_2]^-$.

3.2.2.6.3 Complexes of DTPA and its derivatives

Many solid-state structures have been determined for complexes of DTPA and its derivatives with Gd^{3+} and other Ln^{3+} ions. In $\text{Na}_2[\text{Gd}(\text{dtpa})(\text{H}_2\text{O})]$, dtpa is octadentate and one water molecule is coordinated (18).⁶⁴⁷

(18)

The Gd—O(H₂O) distance is 2.490 Å, Gd—O (carboxylate) distances fall in the range 2.363–2.437 Å and Gd—N 2.582 Å (central N) and 2.626–2.710 Å. Similar ions are present in the Ba[Gd(dtpa)(H₂O)]⁶⁴⁸ and (CN₃H₆)₂[Gd(dtpa)(H₂O)]⁶⁴⁹ and in Ba[Nd(dtpa)(H₂O)]⁶⁵⁰. On the other hand, a number of salts are known, like (NH₄)₂[Gd(dtpa)](H₂O), which have no water coordinated in the solid state. Instead, a hydrogen bonding network involving the ammonium ions causes Gd(dtpa) units to associate⁶⁵¹ into dimers, in contrast to the monomeric nature of Na₂[Gd(dtpa)(H₂O)].

Similarly Cs₄[Dy(dtpa)]₂ has an unprecedented dimeric structure in which Dy is nine-coordinate (as in other dtpa complexes) but with the ninth coordination position occupied by a bridging carboxylate, rather than a water molecule.⁶⁵² The structure and optical spectra of [(NH₂)₃]₂[Nd(dtpa)(H₂O)]·7H₂O have been reported.⁶⁵³ The structure of K₂[Yb(dtpa)(H₂O)] has been determined at low temperatures; in addition to the bound water, there are six waters in the outer coordination sphere and another molecule hydrogen bonded to carboxylate oxygens and significantly near the metal ion, prompting a reassessment of the relaxivity data for the Gd analogue, taking account of second-sphere water molecules.⁶⁵⁴ The structure found in salts like Na₂[Gd(dtpa)(H₂O)] is thought to represent the species found in solution data from a number of measurements on solutions containing [Ln(dtpa)(H₂O)]_n²⁻ species, such as luminescence spectra of the Eu and Tb analogues indicate that one water molecule is coordinated.^{655–658} A wide variety of complexes of amide derivatives of DTPA have been synthesized, in order to create neutral species; likewise a number of other octadentate pentacarboxylic acids and their derivatives have also been investigated. The structure of [Lu(bba-DTPA)(H₂O)] (bba-dtpa = bis(benzylamide) of dtpa) has been determined;⁶⁵⁹ [Gd(bba-DTPA)(H₂O)] has a relaxivity comparable to other dtpa amide complexes. Complexes of the bis(phenylamide) of DTPA with Gd, Y, and Lu have been reported;⁶⁶⁰ the gadolinium complex having a comparable proton relaxation enhancement to [Gd-DTPA]²⁻. NMR indicates that the yttrium complex of the bis(butylamide) of DTPA exists as one eight-coordinate isomer in solution.⁶⁶¹ A ¹⁷O-NMR study of amide derivatives of [Gd(DTPA)(H₂O)]²⁻ has been carried out;⁶⁶² results indicating dissociatively activated water exchange. The potential MRI contrast agent, [Gd(DTPA-BMEA)(H₂O)] has very similar properties to the existing [Gd(DTPA-BMA)(H₂O)].⁶⁶³ (DTPA-BMEA is compound (19)).

(19)

Stability constants have been determined for MS-325, a rationally designed contrast agent based on Gd(DTPA) with a sidechain containing a phosphate group and a lipophilic diphenylcyclohexyl moiety which gives a strong noncovalent interaction with human serum albumin. This gives MS-325 three advantages over $[\text{Gd}(\text{DTPA})]^{2-}$, namely targeting the agent to blood; slowing down the tumbling time and hence improving the relaxation enhancement by up to an order of magnitude; and increasing the half-life of the drug *in vivo*.⁶⁶⁴ MS-325 (**20**) has a high affinity for serum proteins and a greater proton relaxivity than Gd-DTPA itself.⁶⁶⁵

Five bis(amide) derivatives of DTPA form neutral Gd complexes⁶⁶⁶ with similar relaxivity to $[\text{Gd}(\text{dtpa})(\text{H}_2\text{O})]^{2-}$. The structure of a gadolinium complex of a bis(amide) of DTPA (**21**), a potential contrast agent, has been determined.⁶⁶⁷

The Gd^{3+} complex of a diamide (**22**) has an octadentate ligand in a nine-coordinate tricapped trigonal prismatic molecule with one coordinated water molecule.⁶⁶⁸

Its relaxivity is comparable to that of $[\text{Gd}(\text{DTPA})(\text{H}_2\text{O})]^{2-}$. A study⁶⁶⁹ of the complexes of DTPA, related ligands and diamides with Gd^{3+} and Ca^{2+} has shown that the amide groups in the diamides do not contribute to calcium complexation but do enhance Gd^{3+} complexation. $[\text{La}(\text{DTPA-dien})(\text{H}_2\text{O})_2](\text{CF}_3\text{SO}_3)_2 \cdot 18\text{H}_2\text{O}$ is a carboxylate-bridged dimer in the solid state whilst $[\text{Eu}(\text{DTPA-dien})_4](\text{CF}_3\text{SO}_3)_4 \cdot 6\text{CF}_3\text{SO}_3\text{Na} \cdot 20\text{H}_2\text{O}$ is a carboxylate-bridged tetramer; in solution, the europium tetramer breaks up and binds a water molecule.⁶⁷⁰ The structures of other amide complexes have been determined.^{671–677}

Relaxivity and other studies on other Gd DTPA bis(amide) complexes have been reported.^{678–683} Dissociation kinetics of Ce and Gd complexes of bis(amide) ligands derived from DTPA have been studied.⁶⁸⁴ Complexes of a new octadentate ligand H₅BOPTA (**23**) similar to DTPA have been made.

Na₂[Gd(BOPTA)(H₂O)] has nine-coordinate gadolinium, with one coordinated water molecule.⁶⁸⁵ Spin-lattice relaxation data for the Gd³⁺ complex of 3,6,10-tri(carboxymethyl)-3,6,10-triazadodecanoic acid (**24**) indicates that there is probably one water molecule coordinated.⁶⁸⁶

Very high relaxivities have been found for three Gd(DTPA-bisamide)alkyl copolymers.⁶⁸⁷ A gadolinium complex of a substituted DTPA (**25**) was undergoing phase III clinical trials at the end of the twentieth century as a liver-specific contrast agent for MRI.⁶⁸⁸

Complexes of monoamide derivatives of dtpa with Ln³⁺ ions have been studied. Their stability constants are, as expected, less than those of dtpa itself.⁶⁸⁹ Using [Gd(DTPA)]²⁻ it has now been shown that these complexes get absorbed by the DNA of the cell they have been used to locate. If the gadolinium is subjected to thermal neutron treatment, short-range high-energy electrons are emitted that can kill the tumour cell whilst nearby healthy tissue is unaffected.⁶⁹⁰

3.2.2.6.4 Complexes of DOTA and other complexing agents

The potentially octadentate ligand DOTA (1,4,7,10-tetra(carboxymethyl)-1,4,7,10-tetraazacyclododecane, has been widely studied. It forms very stable lanthanide complexes with one water molecule coordinated, $[\text{Ln}(\text{DOTA})(\text{H}_2\text{O})]^-$ (**26**). $\log K$ for $[\text{Gd}(\text{DOTA})(\text{H}_2\text{O})]^-$ is ~ 24.7 , compared with the value of 22.46 for $[\text{Gd}(\text{DTPA})(\text{H}_2\text{O})]^{2-}$.

Crystal structures have been reported for a number of these complexes. The structure of $\text{Na}[\text{Gd}(\text{DOTA})(\text{H}_2\text{O})] \cdot 4\text{H}_2\text{O}$ shows that gadolinium is nine-coordinate^{691,692} in the solid state, with $\text{Gd}-\text{O}(\text{water})$ at 2.458 Å, and $\text{Gd}-\text{O}$ distances in the range 2.362–2.370 Å and $\text{Gd}-\text{N}$ distances between 2.648 Å and 2.679 Å. The Y,^{692,693} Eu,⁶⁹⁴ Lu,⁶⁹⁵ and Ho⁶⁹⁶ complexes have the same structure, whereas in the solid state, $\text{Na}[\text{La}(\text{DOTA})\text{La}(\text{HDOTA})] \cdot 10\text{H}_2\text{O}$ has a novel structure in which two $[\text{La}(\text{DOTA})]^-$ units are joined by a carboxylate bridge.⁶⁹⁷ Kinetics of formation and dissociation of $[\text{Eu}(\text{DOTA})]^-$ and $[\text{Yb}(\text{DOTA})]^-$ have been investigated.⁶⁹⁸ NMR study of $[\text{Yb}(\text{DOTA})]^-$ shows two conformations related by slow inter- and intramolecular exchange.⁶⁹⁹ Conformation and coordination equilibria in DOTA complexes have been studied by ^1H -NMR.⁷⁰⁰ An EXAFS study of $[\text{Gd}(\text{DOTA})(\text{H}_2\text{O})]^-$ and $[\text{Gd}(\text{DTPA})(\text{H}_2\text{O})]^{2-}$ in the solid state and solution permits comparison with existing solid-state diffraction data.⁷⁰¹ The stability constants of $[\text{Ce}(\text{DOTA})]^-$ and $[\text{Yb}(\text{DOTA})]^-$ are reported as $10^{24.6}$ and $10^{26.4}$ respectively.⁷⁰² Measurements of excited state lifetimes of europium(III) complexes with DOTA-derived ligands show that N—H and C—H vibrations allow a vibronic deactivation pathway of the $\text{Eu } ^5\text{D}_0$ excited state; estimates of apparent hydration states can be made.⁷⁰³ The solid-state structure of $[\text{Gd}(\text{DTMA})(\text{H}_2\text{O})]^{3+}$ (DTMA = DOTA tetrakis(methylamide) (**27**)) is a capped square antiprism.⁷⁰⁴ In solution the complex has only limited stability ($\log K = 12.8$). NMR studies of the La, Gd, Ho, and Yb complexes of the DOTA analogue (**28**) have been reported.⁷⁰⁵

Stability constants have been measured for the Gd and Y complexes of DOTA, DO3A (1,4,7,10-tetraazacyclododecane-1,4,7-triacetic acid) and HP-DO3A (10-(2-hydroxypropyl)-1,4,7,10-tetraazacyclododecane-1,4,7-triacetic acid); the Gd and Y complexes of HP-DO3A are isostructural.⁷⁰⁶ (again capped square-antiprismatic nine-coordination). If one carboxylic acid sidechain in H_4DOTA is replaced by hydrogen, the resulting acid, $\text{H}_3\text{DO3A}$, forms neutral lanthanide complexes. In solution they are believed to have two water molecules coordinated so that the species present is $[\text{Gd}(\text{DO3A})(\text{H}_2\text{O})_2]$. Other derivatives have been made in which the fourth carboxylic acid group is replaced by hydroxyalkyl groups that are marketed and approved for use ($-\text{CH}_2\text{CH}(\text{CH}_3)\text{OH} = \text{Prohance}$; $-\text{CH}(\text{CH}_2\text{OH})\text{CH}(\text{OH})\text{CH}_2\text{OH} = \text{Gadovist}$). These compounds have a sidechain hydroxyalkyl group coordinated, in addition to four nitrogens, three carboxylate oxygens, and a water molecule (**29**).^{706,707}

A temperature-dependent UV–visible study⁷⁰⁸ on $[\text{Eu}(\text{DO3A})(\text{H}_2\text{O})_n]$ shows the existence of a hydration equilibrium with $n = 1, 2$, strongly weighted towards $[\text{Eu}(\text{DO3A})(\text{H}_2\text{O})_2]$. Extrapolation to the Gd analogue indicated a water exchange rate in $[\text{Gd}(\text{DO3A})(\text{H}_2\text{O})_n]$ to be twice as fast as in

$[\text{Gd}(\text{DOTA})(\text{H}_2\text{O})]^-$ but still much slower than in $[\text{Gd}(\text{H}_2\text{O})_8]^{3+}$ (DO3A = 1,4,7-tris (carboxymethyl)1,4,7,10-tetraazacyclododecane). The complex $\text{Pr}[\text{moe-do3a}]$ (30) has been reported to be an *in vivo* NMR thermometer.⁷⁰⁹

The thermodynamics of Gd^{3+} complexation by DOTA and DO3A, leading to determination of the thermodynamic parameters, has been studied.⁷¹⁰ The first gadolinium complex to bind two water molecules that appears to have a high relaxivity, and minimizes anion and protein binding, $[\text{Gd}(\text{DO3A})]^{2-}$, has been described.⁷¹¹ The gadolinium complex of $\text{BO}(\text{DO3A})_2^{6-}$ (31), $[\text{BO}\{\text{Gd}(\text{DO3A})(\text{H}_2\text{O})\}_2]$, has been designed as a MRI agent with slow rotation and rapid water exchange⁷¹² to enhance ^1H relaxivity.

A DOTA-based contrast agent (**32**) has a high relaxivity owing to its capability to self-organize in micelles.⁷¹³ A gadolinium complex with a DOTA-derived ligand that acts as a “smart” MRI agent that reports on specific enzymatic activity has been reported.⁷¹⁴ A ligand based on a tetraaza macrocycle with four attached phosphinate groups forms stable eight-coordinate lanthanide complexes; although water does not enter the coordination sphere, the Gd complex is a promising outer-sphere MRI agent.⁷¹⁵ Diamides and other ligands affording neutral gadolinium complexes with concomitant advantages as MRI agents continue to be studied. Neutral Eu, Gd, and Yb complexes of a tetraaza macrocycle (**33**) with three phosphinate and one carboxamide side arms have been synthesized.⁷¹⁶

Lanthanide complexes $[\text{Ln}(\text{DO2A})(\text{H}_2\text{O})_n]^+$ of the potentially hexadentate DO2A have been studied by measuring the lanthanide-induced shifts in the ^{17}O -NMR spectra.⁷¹⁷ Analysis of the contact contribution indicates a decrease in the hydration number from $n=3$ ($\text{Ln}=\text{Ce-Eu}$) to $n=2$ ($\text{Ln}=\text{Tb-Lu}$). Study of the $^7D_0 \rightarrow ^5F_0$ transition in the UV-visible spectra of the Eu complex indicates an equilibrium in solution between eight and nine-coordinate species. (DO2A = 1,7-bis(carboxymethyl)1,4,7,10-tetraazacyclododecane).

Gadolinium complexes of *N*-tris(2-aminoethyl)amine-*N,N',N'',N''',N''''*-hexaacetic acid (H_6ttaha) (**34**) and *N*-(pyrid-2-yl-methyl)ethylenediamine-*N,N',N''*-triacetic acid (H_3PEDTA) are potential NMR imaging agents.⁷¹⁸

Two lanthanide complexes of triethylenetetramine-*N,N,N',N',N'',N''',N''''*-hexaacetic acid (H_6ttaha), $[\text{C}(\text{NH}_2)_3]_2[\text{La}(\text{ttaha})] \cdot 3\text{H}_2\text{O}$ and $[\text{C}(\text{NH}_2)_3]_2[\text{Nd}(\text{ttaha})] \cdot 5\text{H}_2\text{O}$, have been characterized.⁷¹⁹ The former compound has 10-coordinate lanthanum, with four nitrogens and all six carboxylate groups bound to the metal, though the one protonated carboxylate has a $\text{La}-\text{O}$ distance about 0.3 Å longer than the other $\text{La}-\text{O}$ distances; the neodymium compound has nine-coordinate neodymium, with the $-\text{COOH}$ group uncoordinated. The nine-coordinate anion in $[\text{C}(\text{NH}_2)_3]_2[\text{Gd}(\text{Httaha})] \cdot 5\text{H}_2\text{O}$ has no coordinated waters and thus is a poor MRI agent⁷²⁰ but can be used as a reference standard since its relaxivity is caused by “outer-sphere” (i.e., non-coordinated) water interactions.

The ttaha ligand is heptadentate (H_6ttaha = tris(2-aminoethyl)amine hexaacetic acid) but nine-coordination is attained in $[\text{C}(\text{NH}_2)_3]_3[\text{Gd}(\text{ttaha})] \cdot 3\text{H}_2\text{O}$ in the solid state by coordination of two

carboxylate oxygens from neighboring complexes. However in solution, when binding to Gd^{3+} , the ttaha has one leg free, acting as a heptadentate ligand; two water molecules also coordinate, giving it a high relaxivity compared to many MRI agents,⁷²¹ so that it acts as a MRI agent. $\text{K}[\text{La}(\text{Httha})(\text{H}_2\text{O})].8\text{H}_2\text{O}$ (**35**) (H_6ttha = triethylenetetraamine hexaacetic acid) has lanthanum in a bicapped square antiprismatic geometry⁷²² whilst $\text{K}_3[\text{Yb}(\text{ttaha})].5\text{H}_2\text{O}$ (**36**) has four nitrogens and five carboxylate oxygens bound to ytterbium.⁷²³

Solution dynamics of complexes of EGTA^{4-} (3,12-bis(carboxymethyl)-6,9-dioxa-3,12-diazatetradecanedioate) have been studied; a change in coordination number from 10 to eight is believed to occur across the lanthanide series.⁷²⁴ Binuclear La and Y complexes of 9,14-dioxo-1,4,7,10,13-pentaaza-1,4,7-cyclopentadecanetriacetic acid have nine-coordinate lanthanides.⁷²⁵ Lanthanide polyamine carboxylates and complexes of macrocycles with pendant amide groups show promise as catalysts for RNA cleavage,^{726,727} such complexes have considerable stability in aqueous solution.⁷²⁸ Complexes of amides of calixarenes have been investigated, including study of relaxivity.^{729,730} A 10-coordinate Gd complex with a relaxivity 3.5 times greater than $[\text{Gd}(\text{dtpa})]^{2-}$ has been reported.⁷³¹ $[\text{Gd}(\text{DOTP})]^{5-}$ (DOTP = 1,4,7,10-tetraazacyclododecane- $\text{N},\text{N}',\text{N}'',\text{N}'''$ -tetrakis(methylenephosphonate)) has been used as a relaxation agent in the study of human adult haemoglobin.⁷³²

Stability constants for $[\text{Ln}(\text{dotp})]^{5-}$ complexes have been determined; $\log K$ ranges from 27.6 (La) to 29.6 (Lu) (dotp = 1,4,7,10-tetraazacyclododecane-1,4,7,10-tetrakis(methylenephosphonic acid)).⁷³³ In view of its use as a cation-shift reagent, it is notable that ^{23}Na -NMR studies⁷³⁴ show NH_4^+ and K^+ compete effectively with Na^+ for the binding sites on $[\text{Tm}(\text{dotp})]^{5-}$. Ca^{2+} and Mg^{2+} also complex with $[\text{Tm}(\text{dotp})]^{5-}$.

Molecular mechanics calculations have been reported⁷³⁵ for a number of gadolinium complexes, including those with EDTA, dtpa, dtpa-bma and do3a. Other molecular mechanics calculations using a simple force field, computable on a PC, have been reported for $[\text{Gd}(\text{edta})(\text{OH}_2)_3]^-$ and a variety of Schiff base complexes.⁷³⁶ NMR and EPR studies are also reported on a number of compounds of this type.⁷³⁷ In the solid state, $[\text{La}(\text{pedta})(\text{H}_2\text{O})].2\text{H}_2\text{O}$ (pedta = N -(pyrid-2-ylmethyl)ethylenediamine- $\text{N},\text{N}',\text{N}''$ -triacetate) adopts a polymeric structure, giving 10-coordinate La; in solution, luminescence results for the Eu complex indicate three coordinated water molecules.⁷³⁸

Complexes $[\text{Ln}(\text{hedtra})(\text{H}_2\text{O})_n]$ (Ln = most lanthanides; H_3hedtra = N-(2-hydroxyethyl)ethylene-diamine triacetic acid) have been synthesized. They fall into three series; $[\text{M}(\text{hedtra})-(\text{H}_2\text{O})_2] \cdot 3\text{H}_2\text{O}$ (M = Ho, Tm) have eight-coordinate square antiprismatic coordination in which the acid is coordinating through the hydroxo oxygen in addition to the two nitrogens and three carboxylate oxygen atoms.⁷³⁹ A DOTA-based peptide complexed with ^{90}Y has been studied with a view to receptor-mediated radiotherapy. The structure of the yttrium complex of the model peptide DOTA-D-PheNH₂ shows it to have eight-coordinate yttrium.⁷⁴⁰ Gadolinium-loaded nanoparticles have been examined as potential contrast agents.⁷⁴¹ Bis(amide) derivatives of ethylenedioxydiethylenedinitrilotetraacetic acid (H_4egta) form cationic gadolinium complexes.⁷⁴² The increase in positive charge results in a slower water exchange rate; the complexes have rather lower stability constants than $[\text{Gd}(\text{egta})]^-$ and are thus not suitable for use as MRI agents *in vivo*. In a study of the luminescence properties of $[\text{EuTETA}]^-$ and $[\text{EuDOTA}]^-$, (TETA = 1,4,8,11-tetraazacyclotetradecane-1,4,8,11-tetraacetate), the structure of the $[\text{EuTETA}]^-$ ion has been determined.⁷⁴³ Lanthanide complexes of a new potentially heptadentate macrocycle, 1,4,7,10-tetraazacyclodecane-1,4,7,10-tetramethyltrimethylenetrakis(phenylphosphinic acid) (H_3L), have been studied. Dimeric complexes $[\text{LnL}]_2$ have phosphinic acid bridges and eight-coordinate lanthanides; additionally a water molecule is present at a distance strongly dependent upon the Ln^{III} ion. The dimer is strong enough to resist coordination by donors like Ph_3PO .⁷⁴⁴ CoCO_3 , $\text{Gd}(\text{OH})_3$, and H_4DCTA react to form a novel cluster $[\text{Gd}_2\text{Co}_2(\mu_4\text{-O})(\mu\text{-H}_2\text{O})(\text{DCTA})_2 \cdot (\text{H}_2\text{O})_6] \cdot 10\text{H}_2\text{O}$, which features four metal ions round a central oxide and with bridging waters and carboxylate groups.⁷⁴⁵ A study of the kinetics of formation of DCTA complexes of Ln^{3+} ions indicates that they are first order in the reactants⁷⁴⁶ (H_4DCTA = trans-1,2-diaminocyclohexane-N,N,N',N'-tetraacetic acid).

A nonadentate ligand based on 1,4,7-triazacyclononane has three amine nitrogen, three imine nitrogen, and three carboxylate oxygen donor atoms; it forms isostructural La, Sm, and Y complexes.⁷⁴⁷ Tetrahydrofuran-2,3,4,5-tetracarboxylic acid (THFTCA) forms unexpectedly weak complexes with the uranyl ion and unexpectedly large sensitivity to the ionic radius of Ln^{3+} in complex formation. A study of the thermodynamics of complex formation by THFTCA with Ln^{3+} ions (Ln = La, Nd, Eu, Dy, Tm) and UO_2^{2+} indicates that these anomalies arise from the complexation entropy rather than the enthalpy.⁷⁴⁸ Derivatives of 3,6,10-tri(carboxymethyl)-3,6,10-triazadodecanoic acid form Gd^{3+} complexes that are more stable than the Gd-DTPA complex and optimal water exchange rates, thus having potential as MRI contrast agents.⁷⁴⁹ Reversible intramolecular binding of a sulfonamide sidechain in some gadolinium macrocyclic complexes has been used to effect pH-dependent relaxivity.⁷⁵⁰ Other studies with complexes of ligands derived from tetraazamacrocycles include phosphonate ligands,⁷⁵¹ chiral amides,⁷⁵² di-⁷⁵³ and triacids.^{754,755} The role of water exchange in attaining maximum relaxivity in MRI agents has been examined.⁷⁵⁶

3.2.2.6.5 Complexes of mixed Group 15 and 16 donors as spectroscopic probes

In addition to their applications as MRI contrast agents, there is considerable interest in applications of lanthanide complexes of these complexing agents as spectroscopic probes.

The area has been well reviewed and selected examples are discussed here.^{757,758} Ln^{III} (Ln = Eu, Tb, Y) complexes of a macrocycle with a pendant dansyl group ((**37**): $\text{R} = \text{CH}_3$, CF_3 , OCH_3) have been synthesized; reversible intramolecular binding of the dansyl group is achieved by varying the pH (Scheme 6). This does not affect luminescence of the Tb and Eu complexes, as the chromophore triplet state is not populated, but protonation of the NMe_2 group does sensitize luminescence of the Eu complex.⁷⁵⁹ The effect on the Eu^{3+} or Tb^{3+} luminescence, and its pH dependence, of changing ligand substituents and hence the energy of the ligand singlet or triplet states has been examined. The resulting complexes have been incorporated into thin film sol-gel matrices and evaluated as pH sensors.⁷⁶⁰ Time-resolved near-IR luminescence of the Yb^{3+} and Nd^{3+} complexes of the Lehn cryptand ligand have been investigated. Luminescent lifetimes of the Yb complex have been used to determine the number of inner-sphere water molecules, but the Nd complex exhibits unexpectedly long luminescent lifetimes.⁷⁶¹ A terbium complex (**38**) is the first example of a molecular logic gate corresponding to a two-input INHIBIT function; the output, (a terbium emission line) is only observed when the “inputs,” the presence of proteins and the absence of oxygen, are both satisfied.⁷⁶²

Scheme 6

(37)

(38)

When Nd or Yb complexes of a similar macrocycle are covalently linked to a palladium porphyrin complex, this sensitizes near-IR emission from the lanthanide, enhanced in the absence of oxygen and in the presence of a nucleic acid.⁷⁶³ Another application of luminescence accompanies the terbium complex shown in (39) whose luminescence is enhanced by binding to zinc, and can therefore signal for that metal.⁷⁶⁴

Terbium and europium complexes (40) with pH sensitive luminescence have been described.⁷⁶⁵ At high pH, the amine group in the sidechain is deprotonated and able to coordinate to the metal.

A study has been made of the emission of some related Tb and Eu macrocyclic complexes, immobilized in a sol-gel glass, which is made pH-dependent either by perturbing the energy of the aryl singlet or triplet state, or by modulating the degree of quenching of the lanthanide excited state.⁷⁶⁶ The effect of bicarbonate chelation on the polarized luminescence from chiral europium (41) and terbium complexes has been followed.^{767,768} The change in geometry (and chirality) at the metal on bicarbonate binding has a pronounced effect upon the emission polarization.

The luminescence of terbium (42) and europium macrocyclic complexes have been studied and found to depend upon pH. The phenanthridine sidechain acts as a photosensitizer and (42) exhibits luminescence quenched by molecular oxygen; corresponding Eu compounds exhibit halide-quenched emission.^{769,770}

3.2.2.7 Complexes of Macrocycles Involving Group 15 and 16 Donors

3.2.2.7.1 Porphyrins and phthalocyanines

Compounds fall into a number of series, simple mono- derivatives, simple sandwich compounds (both homogeneous and heterogeneous) and triple-decker sandwiches. In the case of the sandwich compounds, both anionic species and neutral species are known, the latter containing the tervalent lanthanide bound to one one-electron oxidized tetrapyrrole ligand. Reactions of Ln(acac)₃ with H₂TPP and other porphyrins in boiling solvents like trichlorobenzene have been reported to give products like [Ln(acac)(porph)] although for the earlier lanthanides Ln(H)(porph)₂ seems more usual. On extended reflux, the double-decker sandwiches [Ln₂(porph)₃] tend to result. The initial synthesis gives a high yield but this is reduced considerably on chromatographic purification.⁷⁷¹ Thus refluxing [Eu(acac)₃] with H₂OEP in 1,2,4-trichlorobenzene for four hours leads to a mixture of [Eu(OEP)₂] and [Eu₂(OEP)₃] (along with a small amount of [Eu(OEP)(OAc)]), the former being a good deal more soluble in organic solvents, so that the mixture is separable by crystallization.⁷⁷² [Eu(OEP)₂], isomorphous with [Ce(OEP)₂] and similar compounds, has square antiprismatic coordination of Eu with staggered porphyrin rings, Eu—N distances being in the range 2.473(4)–2.556(4) Å. [Eu(OEP)₂] undergoes

R e.g. CF_3 , CH_3 , OCH_3

Ar e.g. $p\text{-CF}_3$, $p\text{-CH}_3$, $p\text{-CH}_3\text{OPh}$

(40)

(41)

reduction to $[\text{Eu}(\text{OEP})_2]^-$ using sodium naphthalenide. Similarly cerium triple-deckers $\text{Ce}_2(\text{OEP})_3$ and double-deckers $\text{Ce}(\text{OEP})_2$ have been reported.⁷⁷³ The triple-decker is paramagnetic and relatively insoluble, whilst the double-decker is more soluble and diamagnetic. It can be oxidized to $[\text{Ce}(\text{OEP})_2]^+$. Syntheses generally give a mixture of products, so that careful separations are often the order of the day. Thus refluxing freshly-prepared $[\text{Sm}(\text{acac})(\text{TPP})]$ with Li_2OEP for three hours leads to a mixture of various complexes including $[\text{SmH}(\text{OEP})(\text{TPP})]$, $[\text{SmH}(\text{TPP})_2]$, and $[\text{Sm}_2(\text{OEP})_3]$, separable by chromatography.⁷⁷⁴ $[\text{SmH}(\text{OEP})(\text{TPP})]$ has a sandwich structure with square antiprismatic coordination of Sm, with mean Sm—N (tpp) distances of 2.538(4) Å and Sm—N (oep) of 2.563(4) Å. Other, less forcing, methods have been described involving reaction of homolytic alkyls and alkoxides with H_2OEP .^{775,776} $[\text{LuR}_3]$ ($\text{R} = \text{CH}(\text{SiMe}_3)_2$) react with H_2OEP in toluene forming $[\text{Ln}(\text{OEP})\text{R}]$. $[\text{Lu}(\text{OEP})(\text{CH}(\text{SiMe}_3)_2)]$ has a square pyramidal structure with a highly dished porphyrin skeleton; Lu—C is 2.374(8) Å and Lu—N bonds are in the range 3.236(7)–3.296(7) Å; the lutetium atom is 0.918 Å above the plane of the porphyrin ring. Steric effects are clearly important as this route does not work with the lanthanum or yttrium analogues, or with more demanding porphyrins such as tetratolylporphyrin or tetramesitylporphyrin. $[\text{Lu}(\text{OEP})(\text{CH}(\text{SiMe}_3)_2)]$ reacts with protic species, forming the aryloxide $[\text{Lu}(\text{OEP})(\text{OAr})]$ ($\text{Ar} = \text{O}-2,6\text{-C}_6\text{H}_3\text{Bu}^t_2$). A more direct route is the reaction between $[\text{M}(\text{OAr})_3]$ ($\text{M} = \text{Lu}, \text{Y}$) and

H₂OEP, which yields [M(OEP)(OAr)]; these then can be reacted with LiCH(SiMe₃)₂ in a more convenient route to the alkyls [M(OEP)(CH(SiMe₃)₂)] (M = Lu, Y). These undergo hydrolysis forming the dimers [(OEP)M(μ-OH)₂M(OEP)]. [Lu(OEP)(OAr)] reacts with MeLi forming [(OEP)Y(μ-Me)₂Li(OEt₂)] which in turn reacts with AlMe₃ affording [(OEP)Y(μ-Me)₂AlMe₂]; this activates oxygen forming [(OEP)Y(μ-OMe)₂AlMe₂].^{775,776} An up-to-date high-yield route⁷⁷⁷ for later members of the [Ln(TPP)Cl] series is provided by reaction of [LnCl₃(THF)₃] (Ln = Ho, Er, Tm, Yb) with Li₂TPP(DME)₂ in refluxing toluene. Use of the hydrocarbon solvent forces precipitation of LiCl, reducing possibilities of -ate complexes; after removal of LiCl, [Ln(TPP)Cl(DME)] crystallizes from the cold reaction mixture. Structures have been reported for the seven-coordinate Ho and Yb compounds; the DME and Cl are coordinated to the metal on the same side of the porphyrin ring, which takes on a saddle-shaped distortion. In [Ln(TPP)Cl(DME)], Yb—N = 2.324(2) Å, Yb—Cl = 2.605 Å, and the Yb—O distances are 2.395 Å and 2.438 Å, with Yb 1.105(1) Å above the N₄ plane of the ring; corresponding values for the Ho compound are Ho—N = 2.357(2) Å, Ho—Cl = 2.603 Å, and the Yb—O distances are 2.459 Å and 2.473 Å, with Ho 1.154(3) Å above the N₄ plane. *In situ* prepared⁷⁷⁸ [Ln{(N(SiMe₃)₂)₃·x(Li(THF)₃)}] reacts with H₂(porph) (porph is, for example, TTP, TMPP) forming [Ln(TMPP)(OH₂)₃]Cl (Ln = Yb, Er, Y) and [Yb(TTP)(OH₂)₂(THF)]Cl. Using an excess of [Ln(NR₂)₃·x(Li(THF)₃)] the product depends upon the nature of both R and the porphyrin, giving either mono or dinuclear complexes.⁷⁷⁹ Compounds studied structurally include [YCl(TTP)-(CH₃OCH₂CH₂)₂O]; [YCl(TPP)₂(H₂O)][YCl(TPP)(H₂O)(THF)]·2THF·H₂O; [{Yb(TMPP)(μ-OH)}₂]; [{Yb(TMTP)}₂(μ-OH)(μ-OCH₂CH₂OCH₃)]; and [YbCl(TPP)(H₂O)(THF)] (TTP = tetratolylporphyrin; TMPP = tetrakis(p-methoxyphenyl)porphyrin). [Yb(N(SiMe₃)₂)₃·xLiCl(THF)₃] reacts with H₂TTP in refluxing bis(2-methoxyethyl)ether forming the oxalate bridged dimer [(TPP)Yb(MeO(CH₂)₂OMe)₂(μ-η²:η²-O₂CCO₂)].⁷⁸⁰

Syntheses of [Ln(TPP)Cl] (Ln = Eu, Gd, Tm) and [Tm(TPP)(OAc)] have been given.⁷⁸¹ Gadolinium is eight-coordinate in [Gd(TPP)(acac)(H₂O)₂]·6H₂O·3TCB.⁷⁸² A achiral gadolinium porphyrin complex extracts chiral amino acids from aqueous solution forming complexes that exhibit chirality-specific CD activities.⁷⁸³ The structure of [Tb(β-Cl₈tpp)(O₂CMe)(Me₂SO)₂] shows a pronounced saddle distortion of the porphyrin ring.⁷⁸⁴ The structures of two dilutetium cofacial porphyrin dimers, in which each lutetium is bound to two(μ-OH) groups as well as to four porphyrin nitrogens, have been determined.⁷⁸⁵ Studies of [Ln(OEP)₂] (La, Nd, Eu) indicate that the electron hole is delocalized over both the porphyrin rings in the electronic and vibrational timescales;⁷⁸⁶ similarly studies by a number of techniques on [Ln₂(OEP)₃] systems indicate strong intra-ligand interactions with electron hole again being delocalized over all three rings.⁷⁸⁷ Proton NMR spectra of [Ln₂(OEP)₃] give evidence for inter-ring steric crowding and concomitant limited rotation of the OEP ligands.⁷⁸⁸ NMR spectra of the asymmetric double-decker sandwich compounds [LnH(oep)(tpp)] (Ln = Dy, Lu) have been analyzed.⁷⁸⁹ Synthesis of lipophilic lanthanide(III) bis(tetrapyrrolylporphyrinates) and their conversion into water-soluble N-methylated systems are reported.⁷⁹⁰ Lanthanide porphyrine complexes, [Ln(OPTAP)₂] (Ln = Ce, Eu, Lu) and a triple-decker [Eu₃(OPTAP)₃] have π-radical electronic structures whilst the sandwich structure of the cerium compound has been confirmed by X-ray

diffraction.⁷⁹¹ An investigation into complexes of general type Ln_xPc_y shows that Ln_2Pc_3 mainly obtained for La and Nd, becoming less plentiful for Eu and Gd; later on in the series $[\text{LnHpc}_2]$ is become the norm for Dy, Yb, and Lu.⁷⁹² Sandwich structures are reported for $(\text{Bu}_4\text{N})[\text{Ln}^{\text{III}}(\text{pc})_2]$ compounds ($\text{Ln} = \text{Nd}, \text{Gd}, \text{Ho}, \text{Lu}$). The skew angle between the two pc rings increases as the ionic radius decreases, apparently depending upon the $\pi-\pi$ interaction between the two rings. Syntheses of the green $[\text{Ln}^{\text{III}}(\text{pc})_2]$ ($\text{Ln} = \text{La-Lu}$ except Ce, Pr; pc = phthalocyaninate) by electrochemical oxidation of $(\text{Bu}_4\text{N})[\text{Ln}^{\text{III}}(\text{pc})_2]$ are reported;⁷⁹³ one phthalocyanine ligand is present as a pc^- π -radical, the other as pc^{2-} . The structure of $\alpha\text{-I}[\text{Er}(\text{pc})_2]$ shows two equivalent, slightly saucer-shaped, pc rings and distorted square antiprismatic coordination of erbium,⁷⁹⁴ whilst in $[\text{La}(\text{pc})_2]\cdot\text{CH}_2\text{Cl}_2$ one pc is planar, the other convex, again with square antiprismatic coordination.⁷⁹⁵ Spectroscopic and structural information on $[\text{Na}(18\text{-crown-6})][\text{Lu}(\text{pc})_2]$, $[\text{NBu}_4][\text{Lu}(\text{pc})_2]$, and $[\text{LuHPC}_2]$ has been published.⁷⁹⁶ $[\text{Lu}(\text{pc})_2]$, presumably $[\text{Lu}(\text{pc})(\text{pc}^-)]$ has a sandwich structure with staggered rings.^{797,798} A study of the magnetic properties of the tert-butylphthalocyanine complexes $[\text{Lu}(\text{Bu}(\text{pc})_2)]$ concludes that the green forms are $\text{H}[\text{Lu}(\text{Bu}(\text{pc})_2)]$.⁷⁹⁹ The lanthanide ion has square antiprismatic coordination in the isostructural series $(\text{PNP})[\text{Lu}(\text{pc})_2]$ ($\text{Lu} = \text{La-Tm}$).⁸⁰⁰ Detailed characterization has been reported of the compounds $[\text{Lu}(2,3\text{-nc})_2]$ and $[\text{Lu}(2,3\text{-nc})(\text{pc})]$ (2,3-nc = 2,3-naphthalocyaninate) in which the unpaired electron is delocalized over the two macrocycles.⁸⁰¹ Bis(phthalocyaninato) lutetium complexes with long-chain alkyl groups substituents on the pyrrole rings display three kinds of discotic mesophase and also three primary colors of electrochromism.⁸⁰² A new sandwich bis(phthalocyanine) complex of lutetium with eight hexylthio groups has been characterized.⁸⁰³ The synthesis has been reported of the triple-decker sandwich, $[\text{Lu}_2(1,2\text{-naphthacyaninato})_3]$.⁸⁰⁴ Reaction of Gd with 1,2-dicyanobenzene under a nitrogen atmosphere leads to a bicyclic gadolinium phthalocyanine with a trigonal prismatic GdN_6 coordination geometry.⁸⁰⁵ Reaction of a metal salt with 1,2-cyanobenzene affords $\text{K}[\text{M}(\text{pc}^{2-})_2]$ ($\text{M} = \text{La}, \text{Ce}, \text{Pr}, \text{Sm}$), convertible into other salts $\text{Bu}_4\text{N}[\text{M}(\text{pc}^{2-})_2]$ ($\text{M} = \text{La}, \text{Ce}, \text{Pr}, \text{Sm}$) and $\text{Pe}_4\text{N}[\text{La}(\text{pc}^{2-})_2]$. The metallic bronze $[\text{M}(\text{pc}^{2-})_2]\text{I}_2$ ($\text{M} = \text{Sc}, \text{Y}$) have been made similarly in the presence of NH_4I ; these react with Bu_4NOH forming $\text{Bu}_4\text{N}[\text{M}(\text{pc}^{2-})_2]\cdot x\text{MeOH}$ ($\text{M} = \text{Sc}, \text{Y}$; $0 < x < 1$). Crystal structures show M—N distances that increase monotonically with ionic radius of the metal ion.⁸⁰⁶ $[\text{Ln}^{\text{III}}(\text{pc})(\text{tpp})]$ ($\text{Ln} = \text{La}, \text{Pr}, \text{Nd}, \text{Eu}, \text{Gd}, \text{Er}, \text{Lu}, \text{Y}$) have been synthesized;⁸⁰⁷ their spectroscopic properties are consistent with a one-electron oxidized π -radical phthalocyanine group, $\text{Pc}^{\bullet-}$. The structures of $[\text{La}(\text{pc})(\text{tpp})]$ and $[\text{Gd}(\text{pc})(\text{tpp})]^+\text{SbCl}_6^-$ were determined. The two rings in these compounds adopt a staggered arrangement. In $[\text{La}(\text{pc})(\text{tpp})]$, the average La—N distances are 2.520(3) Å for the porphyrin ring and 2.590(3) Å for the phthalocyanine ring, the corresponding values for $[\text{Gd}(\text{pc})(\text{tpp})]^+\text{SbCl}_6^-$ being 2.452(7) Å and 2.450(7) Å respectively. A one-pot synthesis has been reported⁸⁰⁸ for $[\text{Ln}(\text{Nc})(\text{TBPP})]$ ($\text{Ln} = \text{La}, \text{Pr}, \text{Nd}, \text{Sm-Tm}$) from the reaction of $\text{Ln}(\text{acac})_3\cdot n\text{H}_2\text{O}$ with the free naphthalocyanines and porphyrins in the presence of 1,8-diazabicyclo[5.4.0]undec-7-ene in *n*-octanol. Dilanthanide triple-decker porphyrin and phthalocyanine complexes have excited interest for some time, not least because of their potential in molecular information storage applications. Originally, methods for making homoleptic triple-decker porphyrin complexes relied on refluxing a lanthanide acetylacetonate with a porphyrin in 1,2,4-trichlorobenzene, forming a lanthanide acetylacetonate porphyrin complex, which was subsequently reacted with a lithiated phthalocyanine.⁸⁰⁹ Previous synthetic routes have tended to yield mixtures of $[(\text{Pc})\text{Ln}(\text{Por})\text{Ln}(\text{Pc})]$, $[(\text{Pc})\text{Ln}(\text{Pc})\text{Ln}(\text{Por})]$, and $[(\text{Por})\text{Ln}(\text{pc})\text{Ln}(\text{Por})]$. Sandwich compounds result from the action of Li_2Pc on $[\text{Ln}(\text{acac})(\text{TPP})]$, of the types $[(\text{TPP})\text{Ln}(\text{pc})\text{Ln}(\text{TPP})]$ and $[(\text{pc})\text{Ln}(\text{pc})\text{Ln}(\text{TPP})]$ along with $[(\text{pc})\text{Ln}(\text{TPP})]$.⁸¹⁰ New routes have been described to unsymmetrical $[\text{Ln}(\text{pc})(\text{pc}')]$ and $[\text{Ln}(\text{pc})(\text{por})]$ systems.^{811,812} Heteroleptic triple deckers $[\text{Eu}_2(\text{pc})_2(\text{por})]$ and $[\text{Eu}_2(\text{pc})(\text{por})_2]$ have also been synthesized.⁸¹³ $[\text{CeI}(\text{N}(\text{SiMe}_3)_2)_2]$ with a porphyrin to form a half-sandwich $[(\text{Por})\text{EuX}]$ or $[(\text{Por})\text{CeX}']$ ($\text{X} = \text{Cl}, \text{N}(\text{SiMe}_3)_2$; $\text{X}' = \text{I}, \text{N}(\text{SiMe}_3)_2$); this on reaction with Li_2Pc gives a double-decker $[(\text{Por})\text{Ln}(\text{Pc})]$. $[(\text{Por}')\text{EuX}]$ react with $[\text{Eu}(\text{pc})_2]$ to form a triple-decker; similarly, $[(\text{Por}')\text{CeX}']$ reacts with europium double deckers to give triple deckers $[(\text{Por}')\text{Ce}(\text{tBPc})\text{Eu}(\text{Por}^2)]$ and $[(\text{Por}')\text{Ce}(\text{tBPc})\text{Eu}(\text{tBPc})]$.⁸¹⁴ In the triple-decker $[(\text{T4-OMePP})\text{Nd}(\text{Pc})\text{Nd}(\text{Pc})]$, the three rings are exactly parallel and perpendicular to the Nd—Nd axis. The Nd—Nd separation is 3.688(9) Å, the Nd—N (porphyrin) distance is 2.47(2) Å, the Nd—N(Pc) distance being 2.43(2), 2.57(2), and 2.74(2) Å, the latter being that involving the neodymium also bound to the porphyrin. The longest Nd—N distances are those involving the shared phthalocyanine ring. The neodymium sandwiched between the two phthalocyanines has square antiprismatic coordination, whilst the environment of the other neodymium is described as a distorted cube;⁸¹⁵ (T4-OMePP = tetrakis(4-methoxyphenyl)porphyrin). Reaction of $[\text{Ce}(\text{acac})_3(\text{H}_2\text{O})_2]$ with H_2TPP , followed by further reaction with Li_2Pc (and correspondingly with other porphyrins and phthalocyanines) led to a mixture of $[\text{Ce}^{\text{IV}}(\text{TPP})(\text{Pc})]$, $[(\text{TPP})\text{Ce}^{\text{III}}(\text{Pc})\text{Ce}^{\text{III}}(\text{TPP})]$, and $[(\text{Pc})\text{Ce}^{\text{III}}(\text{TPP})\text{Ce}^{\text{III}}(\text{Pc})]$. The structures of the compounds show

distorted cubic coordination of cerium.⁸¹⁶ In [(TPP)Ce^{III}(Pc(OMe)₈)Ce^{III}(TPP)], Ce—N (porphyrin) = 2.469(3) Å, and Ce—N (pc) 2.721(3) Å, with Ce—Ce 3.844(3) Å; in [(Pc)Ce^{III}(TP(MeO)P)-Ce^{III}(Pc)] Ce—N (porphyrin) = 2.727(2) Å, and Ce—N (pc) 2.473(2) Å, with Ce—Ce 3.664(2) Å. As seems to be general, the bigger bond lengths involve the “shared” ring. Pc(OMe)₈ = 2,3,9,10,12,13,17,18-octamethoxy(phthalocyaninate); TP(MeO)P = mesotetra (anisyl)porphyrinate. [Sm^{III}H(oep)(tpp)] has a sandwich structure, again with square antiprismatic coordination,⁸¹⁷ there is evidence to suggest that it is best represented by [Sm^{III}(oepH)(tpp)]. The first yttrium porphyrinogen complex has been prepared.⁸¹⁸ Remarkably, porphyrinogen complexes of neodymium and praseodymium fix N₂ and reduce it to the N₂²⁻ anion in dimeric μ -N₂ complexes.⁸¹⁹ Ln(acac)₃ react with (tpyp)H₂ forming [Ln(tpyp)(acac)] (tpypH₂ = meso-tetrakis(4-pyridyl)porphyrin; Ln = Sm, Eu, Gd, Tb);⁸²⁰ on methylation, they are converted into the cationic monoporphyrinates [Ln(tmepyp)(acac)].

3.2.2.7.2 Texaphyrins

A new type of complex is provided by the texaphyrins, compounds of “extended” porphyrins where the ring contains five donor nitrogens. These have attracted considerable interest because of their possible medicinal applications.^{821–825} Two texaphyrin complexes are undergoing clinical trials; a gadolinium compound ((43); Gd-tex; XCYTRIN) is an effective radiation sensitizer for tumor cells. It assists the production of reactive oxygen-containing species, whilst the presence of the Gd³⁺ ion means that the cancerous lesions to which it localizes can be studied by MRI; it was undergoing Phase III clinical testing in 2002. The lutetium analogue ((44); Lu-Tex)^{826,827} selectively absorbs light in the far-infrared (λ_{\max} of 732 nm), localizes preferentially to cancerous tissue (like the Gd analogue), is water soluble (again like the Gd analogue), and generates singlet oxygen in high quantum yield. One form (LUTRINTM) is being developed for photodynamic therapy for breast cancer, where it is in Phase II trials, and another, (ANTRINTM) is being developed for photoangioplasty, where it has potential for treating arteriosclerosis, for example as an imaging agent for the study of retinal vascular disease,⁸²⁸ since it photosensitizes human or bovine red blood cells on irradiation at 730 nm.⁸²⁹

One report indicates Gd-texaphyrin to be a tumor sensitive sensitizer detectable at MRI,⁸³⁰ but another study casts doubt on its potential as a radiosensitizing agent.⁸³¹ The effect of axial ligation by nitrate and phosphate on the NMR spectra of paramagnetic lanthanide texaphyrins has been studied;⁸³² the structure of [Dy(tx)(Ph₃PO₄)₂] shows approximately pentagonal bipyramidal coordination (tx = texaphyrin). A ¹³C-NMR study of [Ln(tx)(NO₃)₂] has been reported⁸³³ and spectroscopic studies have been reported on texaphyrin complexes for a wide range of lanthanides, examining the influence of the metal ion and its spin state.⁸³⁴ Phosphoramidite derivatives of dysprosium texaphyrin have been used to prepare ribozyme analogues.⁸³⁵

3.2.2.7.3 Crown ethers and other macrocycles

The ability of lanthanides to form stable crown ether complexes was first developed in the 1970s. Two types of complexes are known, those where the crown ether is directly bonded to the lanthanide and those where the crown ether hydrogen-bonds to a coordinated water molecule. The choice is determined by the match between the size of the central cavity in the crown ether ring and the size of the lanthanide ion. A striking comment on the developments in crown ether chemistry is the synthesis of the first structurally characterization of cationic lanthanide alkyl complexes.¹⁵⁵ [Ln(CH₂SiMe₃)₃(THF)₂] (Ln = Y, Lu) react with B(C₆X₅)₃ (X = H, F) in the presence of crown ethers forming [Ln(CH₂SiMe₃)₂(CE)(THF)_{*n*}]⁺[B(C₆X₅)₃(CH₂SiMe₃)₃][−] (CE = [12]-crown-4, *n* = 1; CE = [15]-crown-5, [18]-crown-6, *n* = 0). In all these complexes, the crown ethers utilize all their donor atoms. In THF, but in the absence of crown ether, [Lu(CH₂SiMe₃)₃(THF)₂] reacts with B(C₆F₅)₃ forming [Lu(CH₂SiMe₃)₂(THF)₃]⁺[B(C₆X₅)₃(CH₂SiMe₃)₃][−].

The first crown ether complexes to be made were usually with lanthanide nitrates; when crown ethers complex with lanthanide nitrates, the two ligands generally combine to saturate the coordination sphere, but since chloride is a monodentate ligand, coordinative saturation is not always achieved that way and indeed chlorides are frequently displaced from the coordination sphere by water. This account therefore begins with lanthanide chloride complexes. 12-crown 4 tends to give complexes of the type [Ln(H₂O)₅(12-C-4)]Cl₃·2H₂O and [LnCl₂(H₂O)₂(12-C-4)]Cl·2H₂O but coordinating ability is affected by the presence of water and other solvents.⁸³⁶ The crown ether does not coordinate to the

(43)

(44)

lanthanide at all in $[\text{Lu}(\text{H}_2\text{O})_8] \cdot 1\frac{1}{2} (12\text{-C-4}) \cdot 2\text{H}_2\text{O}$, instead forming hydrogen bonds to coordinated water molecules.⁸³⁷ With the larger lanthanum ion, $[\text{LaCl}_3(12\text{-crown-4})(\text{MeOH})]$ is eight-coordinate, owing to a molecule of solvent coordinating.⁸³⁸ By modifying conditions, different complexes can be obtained. Thus in MeCN or MeOH, normal syntheses from NdCl_3 and 15-crown-5 get complexes where $[\text{Nd}(\text{H}_2\text{O})_9]^{3+}$ and $[\text{NdCl}_2(\text{H}_2\text{O})_6]^+$ ions are hydrogen-bonded to the crown ether, without direct lanthanide-crown ether bonding. However by electrocrystallization, you get eight-coordinate $[\text{Nd}(15\text{-crown-5})\text{Cl}_3]$.⁸³⁹ Similarly, in the eight-coordinate $[\text{Pr}(15\text{-crown-5})\text{Cl}_3]$, Pr—Cl distances are 2.707, 2.724, and 2.736 Å, averaging 2.722 Å.⁸⁴⁰ Further structures determined include $[\text{Er}(\text{H}_2\text{O})_8]\text{Cl}_3 \cdot 15\text{-crown-5}$.⁸⁴¹ The structures of $[\text{LaCl}_3(15\text{-crown-5})]$ and $[\text{LaCl}_2(\text{phen})(\text{OH})_2(\mu\text{-Cl})_2(15\text{-crown-5} \cdot \text{MeCN})]$ show lanthanum-crown ether coordination in the former but not the latter.⁸⁴² Ytterbium is not bound to the crown ether in $[\text{Yb}(\text{OH})_2]_2\text{Cl}_3 \cdot 15\text{-crown-5}$.⁸⁴³ 18-Crown-6 forms two series of complexes with lanthanide chlorides $[\text{LnCl}(\text{H}_2\text{O})_2(18\text{-crown-6})]\text{Cl}_2 \cdot 2\text{H}_2\text{O}$ ($\text{Ln} = \text{Pr-Tb}$) and $[\text{LnCl}_2(\text{H}_2\text{O})(18\text{-crown-6})]\text{Cl} \cdot 2\text{H}_2\text{O}$ ($\text{Ln} = \text{La, Ce}$) although, depending upon

conditions, $[\text{LnCl}_3(18\text{-crown-6})]$ can also be made. Its inability to form complexes with the chlorides of the smaller lanthanides is ascribed to a lack of flexibility found in polyethylene glycols, which can form such complexes.⁸⁴⁴ New oxonium complexes $(\text{H}_3\text{O}_4)[\text{LaCl}_2(\text{H}_2\text{O})-(18\text{-crown-6})]\text{Cl}_2$ and $(\text{H}_3\text{O})[\text{EuCl}(\text{H}_2\text{O})_2(18\text{-crown-6})]\text{Cl}_2$ have been reported.⁸⁴⁵ Unusually, chloride is found in the first coordination sphere of lanthanum as well as nitrate in the serendipitously discovered mixed anion complexes $[\text{LaCl}_2(\text{NO}_3)(12\text{-crown-4})]_2$ and $[\text{LaCl}_2(\text{NO}_3)(18\text{-crown-6})]$; the structure of $[\text{La}(\text{OH})_4(\text{NO}_3)(12\text{-crown-4})]\text{Cl}_2\cdot\text{MeCN}$ has also been reported.⁸⁴⁶ Structures have been determined for the in-cavity complex $[\text{SmI}_3(\text{dibenzo-18-crown-6})]$ ⁸⁴⁷ (tricapped trigonal prismatic) and the out-of-cavity complex $[\text{LaBr}_3(12\text{-crown-4})(\text{acetone})]$ ⁸⁴⁸ (distorted square antiprismatic). The complex $[\text{La}_2\text{I}_2(\mu\text{-OH})_2(\text{dibenzo-18-crown-6})_2](\text{I}_3)\text{I}$ was isolated from the reaction of LaI_3 with the crown ether in MeCN; evidently a hydrolysis product, it contains nine-coordinate lanthanum⁸⁴⁹ with the lanthanide sitting in the cavity. The out-of cavity hydroxide-bridged cationic complex $[\text{Y}(\text{OH})(\text{benzo-15-crown-5})(\text{MeCN})]_2\text{I}_2$ results from the reaction of YI_3 and the crown ether in MeCN.⁸⁵⁰ In the presence of SbCl_5 , halide abstraction reactions of LnCl_3 ($\text{Ln} = \text{La}, \text{Y}$) form $[\text{Ln}(\text{MeCN})_3(18\text{-crown-6})](\text{SbCl}_6)_3$ and $[\text{Ln}(\text{MeCN})_5(12\text{-crown-4})](\text{SbCl}_6)_3$.⁸⁵¹ The crown ether dibenzo-18-crown-6 forms $[\text{Pr}(\text{dibenzo-18-crown-6})\text{Cl}_2(\text{H}_2\text{O})]\text{SbCl}_6$ containing nine-coordinate praseodymium.⁸⁵² $[\text{GdCl}_2(\text{dibenzo-18-crown-6})(\text{MeCN})]\text{SbCl}_6$ similarly has nine-coordinate gadolinium, with a roughly planar hexadentate crown ether giving a 2:6:1 coordination geometry;⁸⁵³ in contrast, $[\text{Dy}_2(\text{dibenzo-18-crown-6})_2\text{Cl}_4]_2[\text{Dy}_2(\text{MeCN})_2\text{Cl}_8]$ contains dimeric cations (and anions) linked by double chloride bridges.⁸⁵⁴ Many nitrate complexes continue to be characterized. $[\text{La}(\text{NO}_3)_3(12\text{-crown-4})(\text{H}_2\text{O})]$ and $[\text{Yb}(\text{NO}_3)_3(12\text{-crown-4})]$ have 11 and 10-coordinate lanthanides respectively.⁸⁵⁵ Yttrium is not bound to the crown ether in $[\text{Y}(\text{NO}_3)_3(\text{OH})_2(\text{Me}_2\text{-16-crown-5})(\text{H}_2\text{O})]$.⁸⁵⁶ The crown ether is nonbonded in $[\text{Ln}(\text{NO}_3)_3(\text{OH})_2]_3(\text{NO}_3)_2(15\text{-crown-5})$ ($\text{Ln} = \text{Y}, \text{Gd}, \text{Lu}$).⁸⁵⁷ Structural characterization has been achieved for $[\text{Pr}(\text{NO}_3)_3(18\text{-crown-6})]$ and $[\text{Ln}(\text{NO}_3)_3(\text{H}_2\text{O})_3]\cdot 18\text{-crown-6}$.⁸⁵⁸ ($\text{Ln} = \text{Y}, \text{Eu}, \text{Tb-Lu}$). The complex $[\text{La}(\text{NO}_3)_3(\text{H}_2\text{O})_2(\text{MeOH})(\text{bipy})]\cdot 15\text{-crown-5}$ features an unbound crown ether and simultaneous coordination of both water and methanol.⁸⁵⁹ Crown ethers are well known to encapsulate many lanthanide salts. When heavier lanthanide nitrates are recrystallized in the presence of 18-crown-6, $[\text{Ln}(\text{NO}_3)_3(\text{H}_2\text{O})_3]$ molecules are encapsulated into the crown ether ($\text{Ln} = \text{Sm}, \text{Eu}, \text{Yb}$).³⁸⁸ The tosylates $[\text{Ln}(\text{tos})_3(\text{H}_2\text{O})_6]$ cannot be incorporated.⁸⁶⁰ 4-*t*-Butylbenzo-15-crown-5 (*L*) forms $[\text{La}(\text{NO}_3)_3\cdot\text{L}\cdot 0.5\text{MeCN}]$ in which $[\text{La}(\text{NO}_3)_3\cdot\text{L}]$ molecules have 11-coordinate lanthanum,⁸⁶¹ broadly similar in geometry to the benzo-15-crown-5 and cyclohexyl-15-crown-5 analogues. Europium is 10-coordinate⁸⁶² in $[\text{Eu}(\text{NO}_3)_2(16\text{-crown-5})(\text{MeCN})]^+$ (in contrast to 11-coordinate La in $[\text{La}(\text{NO}_3)_3(16\text{-crown-5})]$; however, the smaller lutetium does not coordinate to 16-crown-5, for $[\text{Lu}(\text{NO}_3)_3(\text{H}_2\text{O})_3]$ molecules hydrogen-bond to the crown ether. Benzo-15-crown-5 has been used to extract europium in the presence of picrate with a diaphragm electrolyser.⁸⁶³

Comparative studies between crown ethers and the noncyclic glymes (linear polyethers) suggest that glyme complexes are favored — the chelate effect is thus more important than the macrocyclic effect. The more flexible glymes may accommodate water molecules and other small ligands (e.g., anions) more easily. Solubility effects may play a part too!⁸⁶⁴

The factors affecting the complexes formed by LnX_3 , $\text{Ln}(\text{NCS})_3$, and $\text{Ln}(\text{NO}_3)_3$ with polyethylene glycols have been examined.⁸⁶⁵ The chain length is the main factor controlling the coordination sphere and thus the number of additional inner sphere ligands present. Hydrogen bonding involving the terminal OH groups and water molecules generates supermolecular structures. Solubility of hydrated lanthanide chlorides in diethylene glycol and triethylene glycol (teg) has been studied;⁸⁶⁶ the structure of nine-coordinate $[\text{Nd}(\text{teg})_3]\text{Cl}_3$ has been determined. Three yttrium polyalcohol complexes have been synthesized. $[\text{Y}\{(\text{HOCH}_2)_3\text{CMe}\}_2\text{Cl}_2]\text{Cl}\cdot\text{MeOH}$ and $[\text{Y}\{(\text{HOCH}_2)_3\text{CN}(\text{CH}_2\text{CH}_2\text{OH})_2\}_2\text{Cl}_2\cdot\text{MeOH}]\text{Cl}$ both have eight-coordinate yttrium; in $[\text{Y}\{(\text{HOCH}_2)_3\text{CMe}\}_2(\text{NO}_3)(\text{H}_2\text{O})](\text{NO}_3)_2$ yttrium is nine-coordinate, with one bidentate nitrate.⁸⁶⁷ Structures have been reported for $[\text{Pr}(\text{NO}_3)_3(\text{stilbeno-15-crown-5})]$ and $[\text{Nd}(\text{NO}_3)_3(\text{EO}_5)]$ ($\text{EO}_5 = \text{tetraethyleneglycol}$);⁸⁶⁸ the lanthanide is 11-coordinate in both. Unlike $[\text{Pr}(\text{NO}_3)_3(\text{stilbeno-15-crown-5})]$, the Nd analogue is unstable and reacts with formic acid forming $[\text{Nd}(\text{NO}_3)_3(\text{EO}_5)]$. Lanthanides are nine-coordinate in $[\text{Ln}(\text{EO}_2)_3](\text{ClO}_4)_3\cdot 3\text{H}_2\text{O}$ ($\text{Ln} = \text{Nd}, \text{Ho}$; $\text{EO}_2 = \text{diethylene glycol}$). Europium triflate complexes of homochiral polyether and polyethylene glycol ligands have been characterized.⁸⁶⁹

Complexes of lanthanide triflates with polyethene glycol ($\text{HO}(\text{CH}_2\text{CH}_2\text{O})_n\text{H}$; $n = 2, 3, 4$) and polyethene glycol dimethyl ether ($\text{MeO}(\text{CH}_2\text{CH}_2\text{O})_n\text{Me}$; $n = 2, 3, 4$) are effective Lewis acid catalysts for the Diels–Alder reaction and for the allylation of aldehydes with allyltributyltin.⁸⁷⁰ Structures have been reported for $[\text{La}(\text{OTf})_3(\text{THF})(\text{HO}(\text{CH}_2\text{CH}_2\text{O})_4\text{H})]$, $[\text{Dy}(\text{OTf})_2(\text{MeO}(\text{CH}_2\text{CH}_2\text{O})_4\text{Me})(\text{H}_2\text{O})_2](\text{OTf})$, and $[\text{Eu}(\text{OTf})_3(\text{MeO}(\text{CHPhCHPhCH}_2(\text{OCH}_2\text{CH}_2)_2\text{OCHPhCH}_2\text{OCH}_2\text{CH}_2\text{O})_4\text{Me})(\text{H}_2\text{O})_2](\text{OTf})$, and

PhOMe)].^{871,872} 2,2'-Bipyridyl complexes of Eu^{3+} and Tb^{3+} bound to (poly)ethylene glycol are strongly luminescent.⁸⁷³ In $[\text{La}(\text{NO}_3)_3(\text{triethyleneglycol})(\text{H}_2\text{O})]$, lanthanum is 11-coordinate.⁸⁷⁴ $[\text{CeCl}(\text{tetraglyme})(\text{H}_2\text{O})_3]\text{Cl}_2 \cdot \text{H}_2\text{O}$ has nine-coordinate cations.⁸⁷⁵ $[\text{PrCl}_3(\text{tetraethyleneglycol})]_2$ has nine-coordinate praseodymium.⁸⁷⁶ Pentaethylene glycol (EO_5) forms two series of nine-coordinate complexes with lanthanide chlorides, $[\text{LnCl}_2(\text{H}_2\text{O})(\text{EO}_5)]\text{Cl} \cdot 2\text{H}_2\text{O}$ ($\text{Ln} = \text{La}-\text{Pr}$) and $[\text{Ln}(\text{H}_2\text{O})_3(\text{EO}_5)]\text{Cl}_3 \cdot \text{H}_2\text{O}$ ($\text{Ln} = \text{Sm}-\text{Lu}, \text{Y}$).⁸⁷⁷ The ability of polyethylene glycols to wrap themselves round a lanthanide ion irrespective of size, makes them more flexible coordinating agents than crown ethers. The serendipitous synthesis of the 10-coordinate $[\text{NdCl}(\text{NO}_3)_2(\text{tetraglyme})]$ has been reported.⁸⁷⁸ Cerium is nine-coordinate in $[\text{Ce}(\text{NCS})_3(\text{tetraethyleneglycol})(\text{H}_2\text{O})]$.⁸⁷⁹

The study of lanthanide thiocyanate complexes of crown ethers and other macrocycles commenced during the mid-1990s. Nine-coordinate europium is found in $[\text{M}(\text{NCS})_3\text{L}]$ ($\text{M} = \text{La}, \text{Eu}$; $\text{L} = (2,3,7,18\text{-tetramethyl-}3,6,14,17,23,24\text{-hexaazatricyclo-[}17.3.1.1^{8,12}\text{]-tetracos-1(23),2,6,8(24),9,11,13,17,19,21\text{-decaene-N}^3, \text{N}^6, \text{N}^{14}, \text{N}^{17}, \text{N}^{23}, \text{N}^{24})$).^{880,881} and in $[\text{M}(\text{NCS})_3(\text{tdco})]$ ⁸⁸² ($\text{M} = \text{Eu}, \text{Yb}$; $\text{tdco} = 1,7,10,16\text{-tetraoxo-}4,13\text{-diazacyclooctadecane}$). Several thiocyanate complexes of the tetradentate 13-crown-4 have been isolated in $[\text{Ln}(\text{NCS})_3(13\text{-crown-}4)(\text{H}_2\text{O})_2]$ ($\text{Ln} = \text{La}, \text{Pr}-\text{Tb}, \text{Er}-\text{Yb}$)⁸⁸³ whilst lanthanum is 10-coordinate in $[\text{La}(\text{NCS})_3(18\text{-crown-}6)(\text{DMF})]$.⁸⁸⁴ In the compounds $[\text{Ln}(\text{dibenzylidiaz-}18\text{-crown-}6)(\text{NCS})_3]$ ($\text{Ln} = \text{Ce}, \text{Nd}, \text{Eu}$),^{885,886} the lanthanide is bound to two nitrogens and four oxygens in the crown ether as well as three N-bonded thiocyanates. Thus in the cerium complex, $\text{Ce}-\text{N}(\text{NCS})$ distances are 2.496(3), 2.523(3), and 2.544(3) Å; $\text{Ce}-\text{O}$ 2.565(2), 2.574(2), 2.603(2), and 2.635(2) Å; $\text{Ce}-\text{N}(\text{ring})$ distances are 2.782(3) Å and 2.810(3) Å. The $\text{CeN}_3(\text{NCS})$ moiety exists as a trigonal planar arrangement at the center of the macrocycle cavity with the trigonal plane perpendicular to the plane of the macrocycle. A number of complexes involve the lanthanide bonding to nitrogens in rings, either in aza crowns or in more classic macrocycles like cyclen. 1,4,7,10,13-Pentazacyclopentadecane (L) forms nitrate complexes $[\text{Ln}(\text{L})(\text{NO}_3)_3]$ ($\text{Ln} = \text{Y}, \text{La}-\text{Yb}$ except $\text{Ce}, \text{Pm}, \text{Ho}$); the structure of $[\text{La}(\text{L})(\text{NO}_3)_3]$ shows it to have 11-coordinate lanthanum.⁸⁸⁷ As another example of structurally characterized complex of a N-donor macrocycle, $[\text{Nd}(\text{[18]aneN}_6)(\text{NO}_3)_3]$ has two monodentate and one bidentate nitrate giving 10-coordination.⁸⁸⁸ Schiff base complexes can be synthesized by reaction of a lanthanide salt with a diamine and a suitable carbonyl derivative such as 2,6-diacetylpyridine.⁸⁸⁹ A number of complexes of Schiff base and aminephenol ligands have been reported,⁸⁹⁰⁻⁸⁹² including a dinuclear complex where two Schiff base ligands bridge two lanthanums in a sandwich.⁸⁹² Polymeric complexes of the 1,5,9,13-tetraazacyclohexadecane ligand are reported.⁸⁹³ Several studies of hexaaza macrocycle complexes have appeared,⁸⁹⁴⁻⁸⁹⁶ typically reporting structures of 10- and 12-coordinate lanthanum complexes, whilst a nine-coordinate N_6 macrocycle Gd complex $[\text{GdL}(\text{H}_2\text{O})_2]^{3+}$ studied as possible MRI agent,⁸⁹⁷ and another series of complexes is believed to have a N_3O_3 macrocycle coordinating to the lanthanides.⁸⁹⁸ A σ -bonded organometallic of a deprotonated macrocycle (HMAC = aza-18-crown-6) $[\text{Y}\{\text{CH}(\text{SiMe}_3)_2\}(\text{MAC})]$ has been synthesized.⁸⁹⁹ $[\text{Er}(\text{CF}_3\text{SO}_3)_3(\text{cyclen})(\text{MeCN})]$ has an eight-coordinate structure with monodentate triflates.⁹⁰⁰ A number of complexes of a cyclen-based ligand system bearing four amide arms attached to the ring have been examined.⁹⁰¹ Three Eu^{III} complexes ($\text{R} = \text{Ph}, 4\text{-NO}_2\text{Ph}, \text{CH}_2(4\text{-NO}_2\text{Ph})$) have been synthesized and their structures determined; the twist angle between the O_4 and N_4 planes is mainly determined by the flexibility of the pendant arms. In a study of the luminescence properties of Ln^{III} complexes ($\text{Ln} = \text{Sm}, \text{Eu}, \text{Tb}$), it was found that the efficiency of $\text{L} \rightarrow \text{Ln}$ intramolecular energy transfer is affected by both the gap between the ligand triplet state and the excited state and the donor-acceptor distance and the orientation of the chromophore. There is interest in lanthanide complexes capable of cleaving DNA continues. Dimeric Y and Nd macrocycle complexes are active catalysts for the degradation of double-stranded DNA, whereas the corresponding monomeric complexes are inactive. The mechanism probably involves random attack at single strands in which closed circular plasmid DNA is converted to a nicked intermediate, followed by attacks on this.⁹⁰² The hydrolysis of phosphate esters by yttrium complexes with bis-trispropane and related ligands has also been studied.⁹⁰³

Cryptands have attracted steady interest, partly because of their applications. Ln^{3+} ions are not complexed by them under conditions where Ln^{2+} ions, such as Eu^{2+} and Sm^{2+} are, and thermodynamic functions have been evaluated.⁹⁰⁴ The application of europium cryptate complexes to bioassays has become significant,^{905,906} this principle has been extended to diagnosis of mutations.⁹⁰⁷ Such compounds have used cryptate ligands containing three bipy units,^{908,909} in which the Ln^{3+} ion is contained within a ligand cavity; though bis(isoquinoline dioxide) within the cryptate has been used to ligate.⁹¹⁰⁻⁹¹² The Nd and Yb complexes of the cryptate ligands containing three bipy units have also been shown to luminesce in the near-IR.⁹¹³ Another application has been the use of lanthanide cryptates of the early lanthanides ($\text{La}, \text{Ce}, \text{Eu}$) as

catalysts in the hydrolysis of phosphate monoesters,⁹¹⁴ diesters,⁹¹⁵ and trimesters.⁹¹⁶ The structure of $[\text{La}(3.2.1)\text{Cl}_2]\text{Cl}$. MeOH shows lanthanum to be nine-coordinate, though luminescence measurements on the europium complex of (3.2.1) show three water molecules to be coordinated in solution. The dissociation kinetics of the Eu complex of 4,7,13,16,21-pentaoxa-1,10-diazabicyclo[8.8.5]tricosane has been studied by monitoring its absorption spectrum.⁹¹⁷ The electrochemistry of Sm, Eu, and Yb complexes of the cryptates (3.2.2), (3.2.1), and (2.1.1) has been studied; stability constants have been determined from the redox potentials.⁹¹⁸ The Ln^{II} cryptate complexes were found to be more stable in DMF than the Ln^{III} analogues. A one-pot synthesis of yttrium and lanthanum cryptates has been described.⁹¹⁹ Cryptands have been described that have phenolic and amine donor sets and can accommodate one or two lanthanide ions.⁹²⁰ A europium(III) complex of a N_6 -donor cryptate that includes two bipy units has nine-coordination completed by three chlorides.⁹²¹ Its luminescence is modulated by pH, owing to protonation of the amine groups in the backbone. A combinatorial approach⁹²² has been applied to the formation of a yttrium-containing molecular capsule $[\{18\text{-crown-6}\}(\{\text{Y}(\text{H}_2\text{O})_7\}^{3+})_{1.33}(\text{p-sulfatocalix}[4]\text{arene}^{4-})_2]$. The first d - f heteronuclear cryptate, involving nine-coordinate dysprosium and six-coordinate copper, has been reported.⁹²³ The europium complex of a novel podand ligand has N_3O_6 coordination of europium.⁹²⁴ Other structures of two 10-coordinate lanthanum complexes were reported.⁹²⁵ Eight- and nine-coordinate gadolinium cryptates have been described.⁹²⁶

3.2.2.7.4 Calixarenes

The large Bu^t -calix[8]arene (LH_6) can accommodate a metal at both end, forming complexes $[\text{Ln}_2(\text{H}_6\text{L})(\text{DMSO})_5]$ ($\text{Ln} = \text{La}, \text{Eu}, \text{Tm}, \text{Lu}$; $\text{L} = p$ - t -Butylcalix[8]arene).^{927,928} A calix[4]arene, p - t -butylcalix[4]arene (H_4L), forms a dimeric europium complex $[\text{Eu}_2(\text{HL})_2(\text{DMF})_4] \cdot 7\text{DMF}$, in which the Eu^{3+} ion is seven-coordinate, bound to two DMF molecule, two bridging oxygens and three terminal oxygens from the macrocycle. The $\text{Eu}-\text{O}$ (calixarene) bonds are very short, around 2.15 Å.⁹²⁹ When an “expanded” calixarene containing another donor atom in the ring ($\text{H}_4\text{L}'$) was employed, a similar binuclear complex $[\text{Eu}_2(\text{HL}')_2(\text{DMSO})_2]$ was obtained, with seven-coordination of europium again, being just bound to one coordinated DMSO molecule.⁹³⁰ p - t -Butylcalix[8]arene (H_8L) forms a 1:1 complex with Eu^{III} . The calixarene is bidentate in $[\text{Eu}(\text{H}_6\text{L})(\text{NO}_3)(\text{DMF})_4] \cdot 3\text{DMF}$.⁹³¹ p -Butylcalix[5]arene (H_5L) forms dimeric lanthanide complexes $[\text{Ln}_2(\text{H}_2\text{L})_2(\text{DMSO})_2]$ ($\text{Ln} = \text{Eu}, \text{Gd}, \text{Tb}$).⁹³² The larger p -butylcalix[8]arene and p -nitrocalix[8]arene (H_8L) rings each incorporate two lanthanides, forming $[\text{Ln}_2(\text{H}_2\text{L})(\text{DMF})_5]$ ($\text{Ln} = \text{Eu}, \text{Lu}$). The structures of europium complexes of both p -butylcalix[5]arene and p -nitrocalix[8]arene both contain eight-coordinate europium.⁹³³ p -Chloro- N -benzylhexahomotriazacalix[3]arene forms a 1:1 complex with neodymium nitrate in which neodymium is bound to three bidentate nitrates and to three phenolic oxygens in the calixarene.⁹³⁴ Much of the work with calixarenes has been prompted by their potential in separating lanthanides for uranium and other metals. A calixarene ligand with two amide substituents has been synthesized as an extractant for lanthanides; dimeric Sm and Eu and monomeric Lu complexes have been prepared;^{935,936} similarly an erbium complex of a calixarene ligand with four amide substituents, $[\text{Er}(\text{L}^1\text{-2H})(\text{picrate})]$ ($\text{L}^1 = 5,11,17,23$ -Tetra- t -butyl-25,27-bis(diethylcarbamoylmethoxy)calix[4]arene) has been reported.⁹³⁷ Syntheses and structures are reported for $[\text{Tm}(\text{L-2H})(\text{A})]$, $[\text{Ce}(\text{L-2H})(\text{A})(\text{HOMe})_2] \cdot \text{HA}$, $[\text{PrLA}_3]$, and $\text{L} \cdot 2\text{HA}$. ($\text{L} = 5,11,17,23$ -tetra- t -butyl-25,27-bis(diethylcarbamoylmethoxy)-26,28-dihydroxycalix[4]arene, $\text{HA} = \text{picric acid}$).⁹³⁸ Hexahomotrioxacalix[3]arene macrocycles selectively bond Sc^{3+} , Y^{3+} , and lanthanides, forming μ -aryloxobridged dimers.⁹³⁹ Calix[4]arenes substituted by acetamidophosphine oxide groups at the rim show selectivity, not just to trivalent ions but also to light lanthanides and actinides.⁹⁴⁰ Calix[4]arene podands and barrelands incorporating bipy groups form lanthanide complexes; their Eu^{3+} and Tb^{3+} complexes have high metal luminescence quantum yields.⁹⁴¹ A calixarene with four phosphine oxides attached has been fixed to silica particles and the resulting system has been found to give very efficient extraction of Eu^{3+} and Ce^{3+} from simulated waste.⁹⁴² A calix[4]arene complex of Gd^{3+} binds noncovalently to human serum albumin and is a potential contrast agent.⁹⁴³

3.2.2.8 Group 16 Ligands Involving Sulfur, Selenium, and Tellurium

Complexes of lanthanides of neutral S-donors were unprecedented until 2002. Reaction of $\text{LaI}_3(\text{THF})_3$ with 9S3 (9S3 = 1,4,7-trithiacyclononane) affords eight-coordinate $[\text{LaI}_3(9\text{S3})_3]$

(MeCN)₂]; the Ce analogue has been studied in solution by NMR. La—S distances are 3.064, 3.089, and 4.126 Å; La—I are 3.114, 3.177, and 3.186 Å and La—N 2.641 and 2.672 Å.⁹⁴⁴ A number of studies have concerned bidentate thiolates, especially dithiocarbamates. Their adducts, especially with phen or bipy, seem more stable than the parent complexes, possibly because of coordinative saturation (and are discussed in Section 3.2.2.3.3). Another way in which this can be achieved is by forming an ionic complex. These points are illustrated by the first lanthanide chalcogenocarboxylate complexes [Sm(RCOS)₃(THF)₂] and [Na(THF)₄][Sm(RCSS)₄] (R = 4-MeC₆H₄)⁹⁴⁵ and by monoalkyldithiocarbamates (RNH₃)[Ln(S₂CNHR)₄] (Ln = La–Nd, Sm–Gd; R = Me, Et), which have been synthesized for the lighter lanthanides.⁹⁴⁶ The structure and luminescence of Na[Eu(S₂CNMe₂)₄] have reported, europium having dodecahedral eight-coordination. The two slightly different types of europium coordination sites in the lattice are reflected in the multiplicity of signals in the luminescence spectrum.⁹⁴⁷ Europium is also eight-coordinate in (Ph₄P)[Eu(S₂P(OEt)₂)₄]⁹⁴⁸ and in [Me₂NH₂][Nd(S₂CNMe₂)₄],⁹⁴⁹ a member of a series [Me₂NH₂][Ln(S₂CNMe₂)₄] (Ln = La, Pr–Nd, Sm–Ho). [Me₂NH₂][Ln(S₂CNMe₂)₄], [MeNH₃][La(S₂CNMe₂)₄], [EtNH₃][La(S₂CNHMe)₄], and [Ln(S₂CNMe₂)₃(DMSO)₂] exhibit wide antibacterial activity.⁹⁵⁰

The first monomeric lanthanide thiolates, [Ln(SBu¹)₃] (Ln = La, Ce, Pr, Nd, Eu, Yb, Y) have been made⁹⁵¹ from [Ln{(N(SiMe₃)₂)₃}] and HSBu¹. They are intensively reactive, doubtless owing to coordinative unsaturation, and the adducts [(BuS¹)₂(bipy)Ln(μ-SBu¹)₂Ln(bipy)(SBu¹)₂] (Ln = Y, Yb) have been isolated. Transmetalation of Sm with Hg(SC₆F₅)₂ affords Sm(SC₆F₅)₃; this has the solid-state structure [(THF)₂Sm(μ₂-SC₆F₅)(SC₆F₅)₂]₂. It undergoes thermal decomposition to SmF₃.⁹⁵² Use of SC₆F₅ as a ligand gives stabler and more hydrocarbon-soluble products, which have been isolated as Lewis base adducts. The large Ce³⁺ ion forms the seven-coordinate dimer [Ce(SC₆F₅)₃(THF)₃]₂ with thiolate bridges, whilst Ho and Er give monomeric [Ln(SC₆F₅)₃(THF)₃] (Ln = Ho, Er). Other adducts [Ln(SC₆F₅)₃(py)₄] (Ln = Sm, Yb) and [Er(SC₆F₅)₃(DME)₂] have also been isolated. Many of these compounds feature Ln⋯F interactions.⁹⁵³ Lanthanide metals react with organic disulfides forming thiolates like [Yb(SAr)₃(Py)₃] (Ar = 2,4,6-triisopropylphenyl).⁹⁵⁴ A series of thiophenolates and their selenium analogues have been synthesized and examined. [Ln(SPh)₃(Py)₃]₂ (Ln = Ho, Tm) have two thiolate bridges with seven-coordinate lanthanides; [Sm(SPh)₃(Py)₂]₄ has a linear arrangement of four seven-coordinate samariums with three, two, and three μ₂-bridging thiolates and [Sm(SPh)₃(THF)₄]_n is a polymer. [Ln(SePh)₃(THF)₃] (Ln = Tm, Ho, Er) have monomeric *fac*-octahedral structures; [Sm(SePh)₃(Py)₃]₂ has two selenothiolate bridges with seven-coordinate samarium; and [Ln₃(SePh)₉(THF)₄]_n (Ln = Pr, Nd, Sm) are polymeric with three doubly bridging selenothiolates.⁹⁵⁵ The thiolate [{(Et₃CS)₂Y(μ-SCEt₃)Py₂}₂] is dimeric with a planar Y₂S₂ core.⁹⁵⁶ THF solutions of thiolates Ln(SPh)₃ react with S forming octanuclear clusters [Ln₈S₆(SPh)₁₂(THF)₈] (Ln = Ce, Pr, Nd, Sm, Gd, Tb, Dy, Ho, Er), their structure is based on a cube of lanthanides, edge bridged by mercaptides and face-bridged by sulfur;⁹⁵⁷ analogous pyridine clusters [Ln₈S₆(SPh)₁₂(Py)₈] (Ln = Nd, Sm, Er) have also been isolated.⁹⁵⁸ Clusters are also found in [Yb₄Se₄(SePh)₄(Py)₈] and in [Yb₆S₆(SPh)₆(Py)₁₀].⁹⁵⁹ Ph₂Se₂ reacts with lanthanide amalgams⁹⁶⁰ and pyridine forming Ln(SePh)₃Py₃ (Ln = Ho, Tm, Yb); these are dimeric with seven-coordinate lanthanides. In contrast, [Yb(SPh)₃Py₃] has a monomeric meridional structure. Thermolysis of the selenolates gives Ln₂Se₃ (Ln = Tm, Yb) and a mixture of MSe and MSe₂ (M = Ho). In addition to the mononuclear [Yb(SePh)₃(THF)₃], the tetranuclear [Yb₄(SePh)₈O₂(THF)₆] and ionic [Yb₃(SePh)₆(DME)₄][Yb(SePh)₄(DME)] are reported.⁹⁶¹ Reaction of Sm with PhSeSePh in THF gives⁹⁶² a cluster [Sm₈Se₆(SePh)₁₂(THF)₈] whilst Sm(SePh)₃ reacts with S in DME affording [Sm₇S₇(SePh)₆(DME)₇]⁺[Hg₃(SePh)₇][−] [Ln₈E₆(EPh)₁₂L₈] clusters (E = S, Se; Ln = lanthanide; L = Lewis base) can be prepared by reduction of Se—C bonds by low-valent Ln or by reaction of Ln(SePh)₃. Structures reported include [Sm₈E₆(SPh)₁₂(THF)₈] (E = S, Se) and [Sm₈Se₆(SePh)₁₂(Py)₈]. They contain cubes of lanthanide ions with E^{2−} ions capping the faces and EPh bridging the edges of the cube. Reaction of Nd(SePh)₃ with Se to form [Nd₈Se₆(SePh)₁₂(Py)₈] shows that this series is not restricted to redox-active lanthanides.⁹⁶³ La(SeSi(SiMe₃)₃)₃ is thought to be a three-coordinate monomer in toluene⁹⁶⁴ but the Y analogue is postulated to be dimeric {Y(SeSi(SiMe₃)₃)₂(μ-SeSi(SiMe₃)₃)₂} (a surprise, in view of the smaller size of yttrium). Lewis base adducts such as Ln(SeSi(SiMe₃)₃)₃(THF)₂ (Ln = La, Sm, Yb) have been made. Tellurolate analogues Ln(TeSi(SiMe₃)₃)₃ (Ln = La, Ce, Y) have been prepared and the structure of the dmpe adduct [La(TeSi(SiMe₃)₃)₃(dmpe)₂] determined, the latter having a distorted pentagonal bipyramidal structure with two axial tellurolates. A number of pyridinethiolate (Spy; 2-S-NC₅H₄) complexes have been characterized. Ce(SPy)₃ reacts with Et₄P[SPy] forming [Et₄P][Ce(SPy)₄], in which cerium is eight-coordinate; [Et₄P][Ln(SPy)₄] (Ln = Ho, Tm) were also reported. [Yb(SPy)₃] crystallizes from pyridine as eight-coordinate [Yb(SPy)₃(py)₂].⁹⁶⁵ The europium(III) pyridinethiolate [PET₄][Eu(SPy)₄] have been synthesized⁹⁶⁶ as well as some Eu^{II} compounds. Pyridine 2-thiolates [Ln(SC₅H₄N)₂(HMPA)₃]⁺ (Ln = Pr, Nd, Sm, Eu, Er, Yb), formed by a cleavage

reaction of 2,2'-dipyridyl disulfide in HMPA with iodine and Ln, have pentagonal bipyramidal coordination of the lanthanides.⁹⁶⁷ A number of heterometallic Lanthanide-Group 12 chalcogenolates have been reported⁹⁶⁸ including $[\text{Py}_3\text{Eu}(\mu_2\text{-SePh})_2(\mu_3\text{-SePh})\text{Hg}(\text{SePh})_2]$, $[(\text{THF})_4\text{Eu}(\mu_2\text{-SePh})_3\text{Zn}(\text{SePh})]$, $[\text{Sm}(\text{THF})_7][\text{Zn}_4(\mu_2\text{-SePh})_6(\text{SePh})_4]$, and $[\text{Yb}(\text{THF})_6][\text{Hg}_5(\mu_2\text{-SePh})_8(\text{SePh})_4]\cdot 2\text{THF}$. Reaction of later lanthanides with mixtures of I_2 and PhSeSePh in THF, followed by reaction with Se in pyridine affords $[(\text{THF})_6\text{Ln}_4\text{I}_2(\text{SeSe})_4(\mu_4\text{-Se})]\cdot\text{THF}$ (Ln = Tm, Ho, Er, Yb). These are clusters containing a square array of Ln^{III} ions connected through a single $(\mu_4\text{-Se})$ ligand. There are two I^- ligands coordinating nonadjacent Ln^{III} ions on the side of the cluster opposite the $(\mu_4\text{-Se})$, and the edges of the square are bridged by $\mu_2\text{-SeSe}$ groups. With a 1/1/1/1 Yb/I/ Ph_2S_2 /Se stoichiometry, the product is $[\text{Yb}_6\text{Se}_6\text{I}_6(\text{THF})_{10}]$ which contains a Yb_4Se_4 cubane fragment, with an additional Yb_2Se_2 layer capping one face of the cube. Upon thermolysis, the selenium rich compounds give iodine-free Ln_2Se_3 .⁹⁶⁹

3.2.2.8.1 Group 17 ligands

The structure of LiKYF_5 has been determined.⁹⁷⁰ NH_4LnF_4 (Ln = La–Dy) have been synthesized; the structure of NH_4DyF_4 was reported.⁹⁷¹ Pentagonal bipyramidal coordination of Y is found in two tetrafluorometallates.^{972,973} NaMCl_4 (M = Eu–Yb, Y) have the $\alpha\text{-NiWO}_4$ structure at room temperature with six-coordinate lanthanides;⁹⁷⁴ at high temperatures, they change to the seven-coordinate NaGdCl_4 structure. Na_2MCl_5 (M = Sm, Eu, Gd) adopt the Na_2PrCl_5 structure, again with seven-coordination.⁹⁷⁵ Gadolinium is eight-coordinate in BaGdCl_5 .⁹⁷⁶ Na_2EuCl_5 reacts with Eu to form⁹⁷⁷ the mixed valence compound NaEu_2Cl_6 . $\text{Cs}_2\text{K}[\text{LnCl}_6]$ (Ln = Eu, Tb) have the cubic elpasolite structure.⁹⁷⁸

$\text{Rb}_3\text{MCl}_6\cdot 2\text{H}_2\text{O}$ (M = La–Nd) contain eight-coordinate lanthanides⁹⁷⁹ in anionic trimers $[\text{Ln}_3\text{Cl}_{12}(\text{H}_2\text{O})_6]^{3-}$. $\text{Cs}_3\text{LnCl}_6\cdot 3\text{H}_2\text{O}$ (Ln = La–Nd) contain slightly distorted capped trigonal prismatic coordination of Ln in edge-linked $[\text{LaCl}_2\text{Cl}_{4/2}(\text{H}_2\text{O})_3]^-_\infty$ units; on dehydration, Cs_3LnCl_6 are formed, with two structural types.⁹⁸⁰ On thermal decomposition,⁹⁸¹ $(\text{NH}_4)_3\text{YCl}_6$ first forms $(\text{NH}_4)_2\text{Y}_2\text{Cl}_7$ then YCl_3 . MCl_3 (M = all Ln except Pm; Y) react with PyHCl in THF forming $(\text{PyH})_3\text{MCl}_6\cdot\text{THF}$, whose THF is lost in vacuo.⁹⁸² Reaction of RbCl and LnCl_3 at 850°C leads to hexachlorometallates, and the structure of $\text{Rb}_3[\text{YCl}_6]$ has been determined.⁹⁸³ $\text{Li}_3[\text{YCl}_6]$ is an ionic conductor.⁹⁸⁴ $(\text{NHMe}_3)_4[\text{YbCl}_7]$ has six-coordinate Yb.⁹⁸⁵ $\text{Ba}_2[\text{EuCl}_7]$ is isostructural with $\text{Ba}_2[\text{LnCl}_7]$ (Ln = Gd–Lu, Y), but not with $\text{Ba}_2[\text{ScCl}_6]\text{Cl}$, containing capped trigonal prismatic $[\text{EuCl}_7]^{2-}$ ions.⁹⁸⁶ $[\text{Cs}_4\text{YbCl}_7]$ contains discrete $[\text{YbCl}_6]^{3-}$ octahedra.⁹⁸⁷ Complex holmium chlorides synthesized⁹⁸⁸ include Cs_4HoCl_7 and Cs_3HoCl_6 . Enthalpies of formation have been determined for LaX_3 as $-258.5 \pm 0.8 \text{ kcal mol}^{-1}$ (X = Cl); $-218.7 \pm 1.7 \text{ kcal mol}^{-1}$ (X = Br); and $-166.9 \pm 2.0 \text{ kcal mol}^{-1}$ (X = I);⁹⁸⁹ values have also been calculated for $(\text{NH}_4)_2\text{LaX}_5$,⁹⁸⁹ $(\text{NH}_4)_2\text{Y}_2\text{Cl}_7$, and $(\text{NH}_4)_3\text{YX}_6$.⁹⁹⁰ Structural and magnetic properties are reported for $[\text{Me}_2\text{NH}_2][\text{MCl}_4(\text{H}_2\text{O})_2]$ (M = Nd, Pr), which contain edge-connected $[\text{MCl}_{4/2}\text{Cl}_2(\text{H}_2\text{O})_2]$ trigon-dodecahedra.^{991,992} $\text{Cs}_3\text{Lu}_2\text{Cl}_9$ is isostructural with $\text{Cs}_3\text{Tb}_2\text{Cl}_9$.⁹⁹³

$\text{Cs}_3[\text{Yb}_2\text{Cl}_9]$ and $\text{Cs}_3[\text{Yb}_2\text{Br}_9]$ have been synthesized and studied by high resolution inelastic neutron scattering.⁹⁹⁴ Polymeric species such as $[\text{Ln}_2\text{Cl}_{11}]^{5-}$ are indicated in conductivity studies on LnCl_3 and M_3LnCl_6 (M = K, Rb, Cs; Ln = La, Ce, Pr, Nd).⁹⁹⁵

$(\text{NH}_4)_2\text{PrBr}_5$ is isostructural with K_2PrBr_5 , where edge sharing between the PrBr_5 units gives capped trigonal prismatic seven-coordinate praseodymium.⁹⁹⁶ Li_3LnBr_6 (Ln = Sm–Lu, Y) have been synthesized and the structure of Li_3ErBr_6 determined (Er–Br 2.767 \AA).⁹⁹⁷

$\text{Rb}_2\text{Li}[\text{DyBr}_6]$ has a tetragonally distorted elpasolite structure.⁹⁹⁸ MCl_3 (M = Tb, Dy) react with PPh_4Cl in MeCN forming $\text{Ph}_4\text{P}[\text{MCl}_4(\text{MeCN})]$ which contain dimeric $[(\text{MeCN})\text{Cl}_3\text{M}(\mu\text{-Cl})_2\text{MCl}_3(\text{MeCN})]^{2-}$ anions.⁹⁹⁹

3.2.2.9 Complexes of the Ln^{2+} ion

3.2.2.9.1 Group 14 ligands

A number of simple alkyls and aryls have been made. The use of a bulky silicon-substituted *t*-butyl ligand permitted the isolation^{1000,1001} of simple monomeric (bent) alkyls $[\text{Ln}\{\text{C}(\text{SiMe}_3)_3\}_2]$ (Ln = Eu, Yb) which are sublimeable in vacuo. Other compounds include $[\text{Yb}\{\text{C}(\text{SiMe}_3)_2(\text{SiMe}_2\text{X})\}]$ (X = $\text{CH}=\text{CH}_2$; $\text{CH}_2\text{CH}_2\text{OEt}$) and Grignard analogues $[\text{Yb}\{\text{C}(\text{SiMe}_3)_2(\text{SiMe}_2\text{X})\}]\text{I.OEt}_2]$

(X = Me, CH=CH₂, Ph, OMe), synthesized from RI and Yb. The alkyl ytterbium iodides have iodo-bridged dimeric structures, containing four-coordinate ytterbium when X = Me, but five-coordinate for X = OMe, due to chelation. When R = CH=CH₂, Ph, OMe (but not Me), the equilibrium can be displaced to the right on heating

Reaction of powdered Ln (Ln = Eu, Yb) and Ph₂Hg in the presence of catalytic amounts of LnI₃ affords the compounds LnPh₂(THF)₂.^{148,149} [YbPh₂(THF)₂] has been used as a synthon in the preparation of [Yb(GePh₃)₂(THF)₄].¹⁰⁰² Structural characterization of lanthanide(II) aryls has been achieved by two groups. One approach has been to use a very bulky aryl ligand; compounds [Ln(Dpp)I(THF)₃] and [Ln(Dpp)₂(THF)₂] (Ln = Eu, Yb) have been made, with structures determined for [Yb(Dpp)I(THF)₃] and [Eu(Dpp)₂(THF)₂] (Dpp = 2,6-Ph₂C₆H₃).¹⁰⁰³ Similarly in [Yb(Dpp)₂(THF)₂] the geometry is a strongly distorted tetrahedron, with Yb—C bonds averaging 2.520 Å and Yb—O bonds averaging 2.412 Å.¹⁰⁰⁴ There are additionally two weak η¹-π-arene interactions (Yb—C 3.138 Å) involving α-carbons of the terphenyl groups. The pentafluorophenyl [Eu(C₆F₅)₂(THF)₅] has the pentagonal bipyramidal coordination geometry familiar for simple coordination compounds.¹⁰⁰⁵ Homoleptic Yb^{II} aluminates YbAl₂R₈ (R = Me, Et, Buⁱ) have been made by a silylamide elimination reaction between [Yb(N(SiMe₃)₂)₂(THF)₂] and excess AlR₃. The methyl compound is an involatile and insoluble oligomer, but hexane-soluble YbAl₂Et₈ has a three-dimensional network based on [Yb(AlEt₄)₃]⁺ and [Yb(AlEt₄)₃][−] fragments linked by bridging α-carbons and secondary Yb⋯H—C agostic interactions.¹⁰⁰⁶

3.2.2.9.2 Group 15 ligands involving nitrogen

[SmI₂(THF)₂] reacts with *N*-methylimidazole (*N*-Meim) forming [SmI₂(*N*-Meim)₄]. On recrystallization from hot THF, this loses a molecule of *N*-Meim and dimerizes, forming [{SmI(μ-*I*)(*N*-Meim)₃}]₂. This contains six-coordinate Sm, with Sm—I = 3.237(1) Å (terminal) and 3.280(1)–3.307(1) Å (bridging); Sm—N distances are 2.621(7)–2.641(6) Å. On slow crystallization, this tends to oxidize to Sm^{III} complexes. Eu behaves similarly in forming [EuI₂(*N*-Meim)₄] and [{EuI(μ-*I*)(*N*-Meim)₃}]₂.¹⁰⁰⁷ LnI₂ (Ln = Sm, Yb) reacts with substituted pyridines in THF forming [LnI₂(pyridine)₄]; the structures of [LnI₂(3,5-lutidine)₄] (Ln = Sm, Yb) and [YbI₂(4-*t*-Butpy)₄] were determined, all have *trans*- structures.¹⁰⁰⁸ Deacon *et al.* have reported¹⁰⁰⁹ a rich and extensive chemistry of the ytterbium(II) complex [Yb(NCS)₂(THF)₂], which undergoes a range of oxidative addition reactions affording complexes such as Yb(NCS)₃(THF)₄, Yb(NCS)₃(Odpp)(THF)₃ (HOdpp = 2,6-diphenylphenol), and Yb(NCS)₂(Cp)(THF)₃. The THF ligands in Yb(NCS)₂(THF)₂ can be replaced by DME forming eight-coordinate Yb(NCS)₂(DME)₃. Yb(NCS)₂(THF)₂ reacts with CCl₃CCl₃ forming Yb(NCS)₂Cl(THF)₄, which turns out to have the solid-state structure [YbCl₂(THF)₅]⁺[Yb(NCS)₄(THF)₃][−] in contrast to the monomer Yb(NCS)₃(THF)₄. Oxidation of Yb(NCS)₂(THF)₂ with TiO₂CPh initially affords a solvated of Yb(NCS)₂(O₂CPh) which then gives a mixture of Yb(NCS)₃(THF)₄ and dimeric [[Yb(NCS)(O₂CPh)₂(THF)₂]]₂, the latter having a [Yb(μ-O₂CPh)₄Yb] core with both bi- and tridentate bridging benzoates. Ph₂CO reacts with Yb(NCS)₂(THF)₂ producing another dimer, [[Yb(NCS)₂(THF)₃]]₂(μ-OC(Ph)₂C(Ph)₂O)], where two benzophenones have coupled together. In the area of amides, [SmI₂(THF)₂] reacts with KNPh₂ to form [Sm(NPh₂)₂(THF)₄] where the coordination geometry approximates to trigonal prismatic.²⁹⁵ New syntheses are reported for [Ln{N(SiMe₃)₂}(THF)₂] (Ln = Sm, Yb).¹⁰¹⁰ New amides [Ln{N(SiMe₃)(2,6-Prⁱ₂C₆H₃)₂}(THF)₂] have been reported to have distorted tetrahedral structures.¹⁰¹¹ [Yb{N(SiMe₃)(2,6-Prⁱ₂C₆H₃)₂}(THF)₂] partially desolvates in vacuo forming [Yb{N(SiMe₃)(2,6-Prⁱ₂C₆H₃)₂}(THF)]; [Yb{N(SiMe₃)₂}(THF)₂] desolvates completely to [Yb{N(SiMe₃)₂}] on heating in vacuo. The structures have been determined of [Sm(N(SiMe₃)₂)(THF)₂] and of the dimer [Sm₂{N(SiMe₂)₂}(DME)₂(THF)₂(μ-*I*)₂], in the latter, Sm—O (THF) is 2.592 Å; Sm—O (DME) 2.685 Å; and Sm—I 3.847 Å. The former contains significant short-Sm⋯C distances, evidence for agostic interactions.¹⁰¹² The Sm^{II} amide [Sm(N(SiHMe₂)₂)(THF)_x] (x < 1) crystallizes from hexane as a remarkable trimeric [Sm{μ-N(SiHMe₂)₂}]₃[Sm{N(SiHMe₂)₂}(THF)₂], in which coordinative saturation involves multiple metal⋯SiH β-agostic interactions.¹⁰¹³ [KSm{N(SiMe₃)₂}]₃, which is oligomeric, has been reported.¹⁰¹⁴ A large number of europium(II), samarium(II), and ytterbium(II) η²-pyrazolides have been synthesized; [Ln{(Me₂pz)₃}(THF)] (Ln = La, Er) are considered to be¹⁰¹⁵ a centrosymmetric dimer with four

chelating and two bridging pyrazolides and two bridging THF ligands. Compounds $[\text{Ln}\{(\text{Ph}_2\text{pz})_3\}(\text{THF})_x]$ ($\text{Ln} = \text{Sc}, \text{Y}, \text{Gd}, \text{Er}, n = 2$; $\text{Ln} = \text{Lu}, n = 3$) are also reported; $[\text{Ln}\{(\text{Ph}_2\text{pz})_3\}(\text{THF})_2]$ are believed to be eight-coordinate. $[\text{Er}\{(\text{Ph}_2\text{pz})_3\}(\text{DME})_2]$ has nine-coordinate erbium, with three chelating pyrazolates,¹⁰¹⁶ one chelating and one η^1 -dme; $[\text{Nd}\{(\text{Bu}^t\text{pz})_3\}(\text{DME})]$ has a structure based on chains of $\text{Nd}\{(\text{Bu}^t\text{pz})_3\}$ units bridged by DME.¹⁰¹⁶ $[\text{Yb}(\text{Ph}_2\text{pz})_2(\text{DME})_2]$ has two chelating dimethoxyethane ligands and two η^2 3,5-diphenylpyrazolates.¹⁰¹⁷ $[\text{Ln}(\eta^2\text{-Ph}_2\text{Pz})_2(\text{OPPh}_3)_2]$ ($\text{Ln} = \text{Er}, \text{Nd}$) are eight-coordinate; $[\text{Ln}(\eta^2\text{-Ph}_2\text{Pz})_2(\text{THF})_3]$ ($\text{Ln} = \text{La}, \text{Nd}$) are nine-coordinate.¹⁰¹⁸ Syntheses are reported of $[\text{Ln}(\text{Bu}^t\text{pz})_3(\text{THF})_2]$ and $[\text{Ln}(\text{Bu}^t\text{pz})_3(\text{Ph}_3\text{PO})_2]$ ($\text{Bu}^t\text{pz} = 3,5$ di-*t*-butylpyrazolato). The compound $[\text{Er}(\text{Bu}^t\text{pz})_3(\text{THF})_2]$ has eight-coordinate erbium with chelating pyrazole ligands.¹⁰¹⁹ Structures have been reported for $[\text{Ln}(\eta^2\text{-Ph}_2\text{pz})_2(\text{DME})_2]$ ($\text{Ln} = \text{Sm}, \text{Eu}$), $[\text{Eu}(\eta^2\text{-Bu}^t\text{pz})_2(\text{dme})_2]$, and for some analogous 7-azaindolides. ($\text{Me}_2\text{pz} = 3,5$ -dimethylpyrazolide; $\text{Ph}_2\text{pz} = 3,5$ -diphenylpyrazolide; $\text{Bu}^t\text{pz} = 3,5$ -di-*t*-butylpyrazolide).²⁹⁷ Reaction of Bu^tpzH with lanthanide metals and mercury at 220°C affords $[\text{Eu}(\eta^2\text{-Bu}^t\text{pz})_2]$; and $[\text{Yb}_2(\eta^2\text{-Bu}^t\text{pz})_5]$, the latter having the structure $[(\eta^2\text{-Bu}^t\text{pz})\text{Yb}^{\text{II}}(\mu\text{-}\eta^2\text{:}\eta^2\text{-Bu}^t\text{pz})_2\text{Yb}^{\text{III}}(\eta^2\text{-Bu}^t\text{pz})_2]$.¹⁰²⁰ Several carbazoyl complexes have been synthesized; in all cases so far, it behaves as a monohapto-amide. $[\text{Eu}(\text{carbazoyl})_2(\text{THF})_4]$ is *cis*-,¹⁰²¹ as $[\text{Yb}(\text{carbazoyl})_2(\text{THF})_4]$ is presumed to be. On dissolution in DME/THF, $[\text{Yb}(\text{carbazole})_2(\text{THF})_4]$ forms all *cis*- $[\text{Yb}(\text{carbazoyl})_2(\text{DME})(\text{THF})_2]$. This has $\text{Yb}-\text{N} = 2.43(3)\text{--}2.45(2)\text{ \AA}$; $\text{Yb}-\text{O}(\text{THF}) = 2.41(2)\text{--}2.48(2)\text{ \AA}$ and $\text{Yb}-\text{O}(\text{DME}) = 2.44(2)\text{--}2.46(1)\text{ \AA}$.¹⁰²² $[\text{SmI}_2(\text{THF})_2]$ reacts with potassium carbazoyl forming *cis*- $[\text{Sm}(\text{carbazoyl})_2(\text{THF})_4]$; this has $\text{Sm}-\text{N}$ of $2.565(13)\text{ \AA}$ and $\text{Sm}-\text{O}$ of $2.582(7)\text{ \AA}$. *cis*- $[\text{Sm}(\text{carbazoyl})_2(\text{THF})_4]$ reacts with *N*-methylimidazole to form *trans*- $[\text{Sm}(\text{carbazoyl})_2(\text{N-Meim})_4]$, which has $\text{Sm}-\text{N}(\text{carbazoyl}) = 2.591(3)\text{ \AA}$ and $\text{Sm}-\text{N}(\text{N-Meim}) = 2.685(14)\text{ \AA}$.¹⁰²³ Some Ln^{II} β -diketiminates have also been made, $[\text{Ln}(\text{L-L})_2(\text{THF})_2]$ ($\text{Ln} = \text{Sm}, \text{Yb}$), $[\text{Ln}(\text{L-L})_2]$ and $[\text{Ln}(\text{L-L}')_2]$ ($\text{L-L}' = (\text{R})\text{NC}(\text{Ph})\text{C}(\text{H})\text{C}(\text{Bu}^t\text{NR})$). LnCl_3 reacts with $[\{\text{Me}_2\text{SiN}(\text{R})\text{Li}_2\}]$ ($\text{R} = \text{Ph}, \text{Bu}^t$) forming¹⁰²⁴ chloride bridged dimers $[\{(\text{R})\text{NSiMe}_2\text{SiMe}_2\text{N}(\text{R})\}\text{Ln}(\mu\text{-Cl})(\text{THF})_2]$ ($\text{Ln} = \text{Nd}, \text{Gd}, \text{Yb}$) which can be converted into trifluoroacetates $[\{(\text{Bu}^t\text{N})\text{SiMe}_2\text{SiMe}_2\text{N}(\text{Bu}^t)\}\text{Ln}(\mu\text{-OCOCF}_3)(\text{THF})_2]$. The benzaminate $[\{\text{PhC}(\text{N}(\text{SiMe}_3)_2)_2\}\text{Yb}(\text{THF})_2]$ has been made.¹⁰²⁵

Polypyrazolylborates have been very extensively investigated. SmCl_2 reacts with one mole of KTp in THF forming $[\text{SmCl}(\text{Tp})_2(\text{Hpz})]$ which has square antiprismatic coordination of samarium.¹⁰²⁶ $[\text{Sm}(\text{Tp})\text{Cl}(\text{L})]$ ($\text{L} = \text{Hpz}, \text{N-Mepz}$) react with sodium β -diketonates forming $[\text{Sm}(\text{Tp})(\text{ACAC})]$, $[\text{Sm}(\text{Tp})(\text{tfac})]$ and $[\text{Sm}(\text{Tp})(\text{hfac})]$. $[\text{SmCl}(\text{Tp})(\text{Hpz})]$ reacts with $\text{K}[\text{BH}_2\text{pz}_2]$ forming the bicapped trigonal prismatic $[\text{SmCl}(\text{Tp})(\text{BH}_2\text{pz}_2)]$ whilst $[\text{SmCl}(\text{Tp})(\text{Hpz})]$ is square-antiprismatic.¹⁰²⁷ $[\text{Ln}(\text{Tp})_2(\text{THF})_2]$ and $[\text{Ln}(\text{Tp}^{\text{Me}_2})_2]$ ($\text{Ln} = \text{Eu}, \text{Sm}$ and Yb) have been synthesized;¹⁰²⁷ the latter are very insoluble and are usually purified by sublimation in the cases of the Eu and Yb compounds.^{318,1029} Using Tp^{Me_2} , a very wide range of compounds has been synthesized. $[\text{Ln}(\text{Tp}^{\text{Me}_2})_2]$ ($\text{Ln} = \text{Sm}, \text{Yb}, \text{Eu}$) tend to be insoluble, but introduction of an additional 4-ethyl group increases solubility in $[\text{Ln}(\text{Tp}^{\text{Me}_2, 4\text{Et}})_2]$ ($\text{Ln} = \text{Sm}, \text{Yb}, \text{Eu}$), whilst $[\text{Ln}(\text{Tp}^{\text{Ph}_2})_2]$ ($\text{Ln} = \text{Sm}, \text{Yb}$) and $[\text{Ln}(\text{Tp}^{\text{Th}_2})_2]$ ($\text{Ln} = \text{Sm}, \text{Yb}, \text{Eu}$) have also been made. These compounds tend to have six-coordinate trigonal antiprismatic coordination of the lanthanide.³²⁰ The THF molecules in $[\text{Ln}(\text{Tp})_2(\text{THF})_2]$ can be replaced by other donors, as seen in the structures¹⁰³⁰ of $[\text{Eu}(\text{Tp})_2(\text{L})_2]$ ($\text{L} = \text{Ph}_2\text{SO}, (\text{Me}_2\text{N})_2\text{C}=\text{O}$). $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2]$ undergoes a range of one electron transfer reactions, whilst complexes of the sterically demanding $\text{Tp}^{\text{But, Me}}$ ligand $[\text{Sm}(\text{Tp}^{\text{But, Me}})\text{R}]$ are resistant to redistribution reactions.¹⁰³¹ $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2]$ has six-coordinate samarium. In its wide range of oxidations,^{318,1032} it forms $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2\text{X}]$ ($\text{X} = \text{Cl}, \text{Br}, \text{F}$) by halogen abstraction from organic compounds, and $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2\text{I}]$ by iodine oxidation. Reaction with TlBPh_4 gives $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2]\text{BPh}_4$. $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2]$ cleaves dichalcogenides REER forming $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2(\text{ER})]$ (R is, for example, $\text{Ph}, \text{E} = \text{S}, \text{Se}$).¹⁰³³ $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2]$ reacts with azobenzene forming $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2(\text{N}_2\text{Ph}_2)]$ where the Tp^{Me_2} ligands remain tridentate.¹⁰³⁴ $[\text{Sm}\{\text{Tp}^{\text{Me}_2}\}_2]$ reacts with dioxygen forming the first lanthanide superoxo complex $[\text{Sm}\{\text{Tp}^{\text{Me}_2}\}_2(\eta^2\text{-O}_2)]$,¹⁰³⁵ isotopic substitution confirmed this assignment. X-ray diffraction shows that O_2 is bound side-on. The samarium(II) poly(pyrazolyl)borate $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2]$ undergoes a one-electron oxidation with $[\text{Hg}(\text{C}\equiv\text{CPh})_2]$ forming monomeric seven-coordinate $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2(\text{C}\equiv\text{CPh})]$.³²¹ This undergoes a remarkable rearrangement at 105°C in benzene solution with the exchange between a pyrazole ring and an alkynyl group, forming $[\text{Sm}(\text{Tp}^{\text{Me}_2})_2((\text{HB}(\text{Me}_2\text{pz})_2(\text{C}\equiv\text{CPh}))(\text{Me}_2\text{pz}))]$. The insolubility of $[\text{Ln}(\text{Tp}^{\text{Me}_2})_2]$ makes it difficult to obtain mono(Tp^{Me_2}) complexes, as the equilibrium gets driven to the right, even with a 1:1 stoichiometry in reaction mixture

This can be obviated by using a bulky hydrotris(3-*t*-butyl-5-methylpyrazolyl) borate ligand ($\text{Tp}^{\text{Bu},\text{Me}}$), which affords monomeric ytterbium(II) compounds with just one pyrazolylborate bound to ytterbium such as $[\text{Yb}(\text{Tp}^{\text{Bu},\text{Me}})\text{I}(\text{L})_n]$ ($\text{L} = \text{THF}$, Bu^tNC , $n = 1$; $\text{L} = 3,5$ -lutidine, $n = 2$), $[\text{Yb}(\text{Tp}^{\text{Bu},\text{Me}})(\text{N}(\text{SiMe}_3)_2)]$, and $[\text{Yb}(\text{Tp}^{\text{Bu},\text{Me}})(\text{CH}(\text{SiMe}_3)_2)]$.^{318,1036}

It is still possible to obtain bis complexes with $\text{Tp}^{\text{tBu},\text{Me}}$, but $[\text{Ln}(\text{Tp}^{\text{tBu},\text{Me}})_2]$ ($\text{Ln} = \text{Sm}$, Yb) shows¹⁰³⁷ two different mode of ligand bonding; one is a conventional η^3 -ligand, the other is bound via two nitrogen atoms and an agostic $\text{B}-\text{H}\cdots\text{Sm}$ interaction. The NMR spectrum of $[\text{Yb}(\text{Tp}^{\text{tBu},\text{Me}})_2]$ shows¹⁸² $\text{Yb}-\text{HB}$ coupling, confirming that the agostic interaction persists in solution. Use of a bulky ligand stabilizes the dimeric hydride $[(\text{Tp}^{\text{Bu},\text{Me}})\text{Yb}(\mu\text{-H})_2\text{Yb}(\text{Tp}^{\text{Bu},\text{Me}})]$ which does have a rich chemistry,^{1038,1039} forming an ene-diolate by CO insertion and reacting with alkynes. In $[\text{Eu}(\text{B}(\text{pz})_4)_2(\text{THF})_2]$, (pz = pyrazolyl) europium has the expected eight-coordination.³³⁴ Analogous $[\text{Ln}(\text{B}(\text{pz})_4)_2(\text{THF})_2]$ ($\text{Ln} = \text{Sm}$, Yb) react with alkyl halides forming $[\text{Ln}(\text{B}(\text{pz})_4)_3]$ by oxidative disproportionation. A europium(II) poly(pyrazolyl)borate complex (45) exhibits an orange electroluminescence.¹⁰⁴⁰

(45)

$[\text{SmI}_2(\text{THF})_2]$ reacts¹⁰⁴¹ with a dipyrrolide dianion under N_2 forming a remarkable tetranuclear dinitrogen complex $[(\mu\text{-Ph}_2\text{C}(\eta^1:\eta^5\text{-C}_4\text{H}_3\text{N})_2)\text{Sm}]_4(\mu\text{-}\eta^1:\eta^1:\eta^2:\eta^2\text{-N}_2)]$.

3.2.2.9.3 Group 15 ligands involving phosphorus

A number of organophosphides of divalent lanthanides have been reported, with structures of $[\text{Yb}(\text{PPh}_2)_2(\text{THF})_4]$,¹⁰⁴² $[\text{Sm}(\text{PPh}_2)_2(\text{N-Methylimidazole})_4]$,¹⁰⁴³ and $[\text{Yb}\{\text{P}(\text{mesityl})_2\}_2(\text{THF})_4]$,¹⁰⁴³ all having *trans*-octahedral structures. Both $[\text{YbI}_2(\text{THF})_2]$ and $[\text{Yb}\{\text{N}(\text{SiMe}_3)_2\}_2(\text{THF})_2]$ react with KPPH_2 forming $[\text{Yb}(\text{PPh}_2)_2(\text{THF})_4]$; the THF can be displaced by *N*-methylimidazole forming *trans*- $[\text{Yb}(\text{PPh}_2)_2(\text{N-mim})_4]$.¹⁰⁴⁴ The structures of the compounds $[\text{Sm}(\text{P}(\text{mesityl})_2)_2(\text{THF})_4]$ and $[\text{Sm}(\text{As}(\text{mesityl})_2)_2(\text{THF})_4]$ have been reported.¹⁰⁴⁵ $[\text{Ln}(\text{P}(\text{H})(\text{mes}^*))_2(\text{THF})_4]$ ($\text{Ln} = \text{Eu}$, Yb ; $\text{mes}^* = 2,4,6\text{-Bu}^t\text{C}_6\text{H}_2$) are the first lanthanide complexes with primary phosphide ligands;¹⁰⁴⁶ they feature distorted octahedral coordination of the lanthanide. The three isostructural phosphides $[(\text{THF})_2\text{Li}(\mu\text{-P}^t\text{Bu})_2\text{M}(\mu\text{-P}^t\text{Bu})_2\text{Li}(\text{THF})_2]$ ($\text{M} = \text{Sm}$, Eu , Yb) have tetrahedrally coordinated lanthanides.¹⁰⁴⁷ The structure of *trans*- $[\text{Eu}(\text{PPh}_2)_2(\text{N-mim})_4]$ has been determined.¹⁰⁴⁸ A monomeric four-coordinate phosphide complex, $[\text{Sm}(\text{P}(\text{CH}(\text{SiMe}_3)_2)(\text{C}_6\text{H}_4\text{-2-NMe}_2)_2)]$ has been reported.¹⁰⁴⁹ $[\text{SmI}_2(\text{THF})_2]$ reacts with $\text{KP}(\text{SiMe}_3)_2$ forming $\text{Sm}_2\{\text{P}(\text{SiMe}_3)_2\}_4(\text{THF})_3$, which has the unsymmetrical structure $[(\text{Me}_3\text{Si})_2\text{P}]\text{Sm}(\mu\text{-P}(\text{SiMe}_3)_2)_3\text{Sm}(\text{THF})_3]$.¹⁰⁵⁰ Sm^{II} and Yb^{II} complexes of chelating secondary phosphide ligands have also been reported.¹⁰⁵¹

3.2.2.9.4 Group 16 ligands involving oxygen

The rate of water exchange at the europium(II) aqua ion, believed to be $[\text{Eu}(\text{OH}_2)_8]^{2+}$, is the fastest ever measured for a non Jahn–Teller ion.¹⁰⁵² $\text{YbI}_2\cdot\text{H}_2\text{O}$ has six-coordinate Yb (5 I, 1 O).¹⁰⁵³ $\text{KEu}(\text{CH}_3\text{COO})_3$ is the first ternary Eu^{II} carboxylate, with eight and nine-coordinate Eu .¹⁰⁵⁴

[Ln(O₃SCF₃)₃] have been widely used for years; now [Ln(O₃SCF₃)₂] (Ln = Sm, Yb) have been prepared¹⁰⁵⁵ by reduction of the Ln^{III} analogues and used as pinacol coupling catalysts. A large number of complexes of O-donors, particularly of SmI₂ have been examined, because of the importance of SmI₂ as a one-electron reductant in organic synthesis, much of which has been carried out using hexamethylphosphoramide (HMPA) as a solvent.^{1056–1060} The addition of HMPA to THF solutions of SmI₂ brings considerable rate enhancement; HMPA is a suspected carcinogen so certain alternative ligands have been investigated. The structures of a number of complexes, both of HMPA and other O-donors, have been investigated, shedding light on SmI₂-promoted reactions. In general these compounds of amide ligands have a coordination number of six, suggesting steric effects at work, in addition to pointing to strong electron-donating power of the ligands, as the CN of Sm^{II} complexes is usually in the range seven to nine. [LnI₂(THF)₂] (Ln = Sm, Yb¹⁰⁶¹ and Eu^{1062,1063}) are useful starting materials, conveniently made by reaction of Ln with ICH₂CH₂I. Under other circumstances, different complexes result. The initial product of crystallization of SmI₂ from THF is pentagonal bipyramidal [SmI₂(THF)₅];¹⁰⁶⁴ other seven-coordinate complexes obtained using mixtures of THF and dimethoxyethane are [SmI₂(THF)₃(DME)] and [SmI₂(THF)(DME)₂]. In [SmI₂(DME)₂(THF)] Sm—O (DME) is 2.618 Å; Sm—O (THF) is 2.530 Å; and Sm—I is 3.246 Å, whilst in [SmI₂(DME)(THF)₃] Sm—O (DME) is 2.641 Å; Sm—O (THF) is 2.571 Å; and Sm—I is 3.323 Å. YbI₂ reacts with 4.5 moles HMPA in THF forming [Yb(HMPA)₄(THF)₂]I₂; a similar reaction with SmI₂ affords [Sm(HMPA)₄]I₂. Excess HMPA gives [Sm(HMPA)₆]I₂. These compounds all have six-coordinate Ln^{II}. In SmI₂(HMPA)₄, average bond lengths of Sm—O are 2.500 Å and Sm—I are 3.390 Å, whereas in [Sm(HMPA)₆]I₂ the Sm—O distances average 2.53 Å.¹⁰⁶⁵ For comparison, in [SmI₂(Ph₃PO)₄], Sm—O is 3.27(1) Å.¹⁰⁶⁶ SmI₂(THF)₂ reacts with two moles of tetramethylurea (tmu) forming¹⁰⁶⁷ [SmI₂(tmu)₂(THF)₂] (tmu = -tetramethylurea) has an all *trans*-geometry, with Sm—O (tmu) of 2.446 Å, Sm—O (THF) of 2.528 Å, with Sm—I of 3.061 Å and 3.317 Å. Using excess tmu did not result in the isolation of a complex where the other THF ligands had been replaced. Another complex to be isolated is *trans*-[SmI₂(dmi)₄] (dmi = 1,3-dimethyl-2-imidazolidione, N,N-dimethylacetamide); here all the THF groups have been substituted. The average Sm—O distance here is 2.48 Å whilst the Sm—I distances are even longer, at 3.345 Å and 3.579 Å. *trans*-[SmI₂(dma)₄] (dma = dimethylacetamide) has similar Sm—O distances, averaging 2.45 Å and Sm—I 3.309 Å. Use of four moles (i.e., a deficit on the stoichiometric amount) of dimethylpropylene urea (dmpu) causes displacement of the iodides from SmI₂(THF)₂ forming [Sm(dmpu)₆]I₂ where the cation has a distorted trigonal antiprismatic geometry; Sm—O distances are 2.475–2.488 Å; however if just two moles of dmpu are used in the reaction, [SmI₂(dmpu)₃(THF)] results, in which the iodides are *trans*- and the dmpu ligands have a *mer*-arrangement.

The developing coordination chemistry of Sm^{II} has thrown up some interesting cases of isomerism. Reaction of SmI₂(THF)₂ with diglyme results in the isolation of *trans*-[SmI₂{O(CH₂-CH₂OMe)₂}₂], whilst the *cis*-isomer was obtained as a by-product in the reaction of SmI₂ with *t*-BuOK in diglyme. These were the first examples to be isolated of geometric isomers in an eight-coordinate complex.^{1068,1069} The Sm—O distances in *cis*-[SmI₂{diglyme}₂], fall into the range 2.653–2.699 Å, averaging 2.68 Å, which is slightly shorter than the value for the *trans*-isomer. The Sm—I distances in the *cis*-isomer, however, at 3.332–3.333 Å, are significantly longer than those in *trans*-[SmI₂{diglyme}₂] (3.265 Å). In another interesting study,¹⁰⁷⁰ reaction of SmI₂ with 1,2-diiodoethane at 50 °C yields [SmI₂(DME)₃]. Crystallization at –20 °C affords racemic [SmI₂(DME)₃], whilst crystallization from solution at ambient temperature yields a mixture of crystals of the two different enantiomers. Sm—I distances are 2.3550(8) Å and 2.3832(8) Å and Sm—O distances range from 2.656(7) Å to 2.681(6) Å. It was suggested that interactions between methyl groups prevent ready interconversion. The samarium(II) complex [(DME)₂BrSm(μ-Br)₂SmBr(DME)₂] has been synthesized.¹⁰⁷¹ A number of solvated Yb^{II} and Sm^{II} complexes, mainly with diethylene glycol dimethylether(dime), have been characterized,¹⁰⁷² notably [Yb(dime)₃]²⁺, [Yb(dime)₂(MeCN)₂]²⁺, [Yb(dime)(MeCN)₅]²⁺, and [Yb(py)₅(MeCN)₂]²⁺; these have tricapped trigonal prismatic, square antiprismatic, and pentagonal bipyramidal coordination respectively.

Reaction of Nd and Dy with I₂ at 1,500 °C followed by dissolution of the product affords [LnI₂(DME)₃] and [LnI₂(THF)₃] (Ln = Nd, Dy).¹⁰⁷³ [NdI₂(THF)₃] has the familiar pentagonal bipyramidal structure with axial iodines.¹⁰⁷⁴ [TmI₂(DME)₂(THF)] has a similar coordination geometry. [TmI₂(DME)₂] is the first molecular Tm^{II} compound;¹⁰⁷⁵ one DME is monodentate, the iodides occupy axial positions in a pentagonal bipyramidal geometry. Another Tm^{II} complex, this time with a calixarene, has been made.¹⁰⁷⁶ The first lanthanide(II) diketonate, [Eu(tmhd)₂(DME)₂], has been made, by reaction of [EuI₂(THF)₂] with Kthd in THF, evaporation

and crystallization from DME. The Sm analogue, $[\text{Sm}(\text{tmhd})_2(\text{DME})_2]$ has also been synthesized by a similar route; it decomposes to $[\text{Sm}(\text{tmhd})_3(\text{DME})]$ on keeping a solution at -34°C for two weeks (tmhd = $\text{Me}_3\text{CCOCHCOCMe}_3$; dme = dimethoxyethane).¹⁰⁷⁷ The Eu^{II} crown ether complex $[\text{Eu}(\text{benzo-15-crown-5})_2](\text{ClO}_4)_2$ has been synthesized by electrochemical reduction of a solution of $\text{Eu}(\text{ClO}_4)_3$ and benzo-15-crown-5 in $\text{MeOH}/\text{H}_2\text{O}$. It contains 10-coordinate europium, with $\text{Eu}-\text{O}$ distances in the range 2.662(3)–2.728(4) Å. This compound exhibits strong luminescence, taking on a violet hue in daylight.¹⁰⁷⁸ The Eu^{II} EDTA complex $\text{Na}_3[\text{Eu}(\text{EDTA})]\text{Cl}\cdot 7\text{H}_2\text{O}$ is in fact polymeric in the solid state with europium bound to two nitrogens and to six carboxylate oxygens.¹⁰⁷⁹ $[(\text{NH}_2)_3]_3[\text{Eu}^{\text{II}}(\text{dtpa})(\text{H}_2\text{O})]\cdot 8\text{H}_2\text{O}$ is isostructural with the Sr analogue.¹⁰⁸⁰ In solution, $[\text{Eu}^{\text{II}}(\text{dtpa})(\text{H}_2\text{O})]^{3-}$ is less stable to oxidation than $\text{Eu}^{2+}(\text{aq})$.¹⁰⁸¹

The redox stability of complexes of two other ligands, ODDA^{2-} and ODDM^{4-} have been studied; both $[\text{Eu}^{\text{II}}(\text{ODDA})(\text{H}_2\text{O})]$ and $[\text{Eu}^{\text{II}}(\text{ODDM})]^{2-}$ are more stable¹⁰⁸² and the ODDM complex has a significantly greater stability constant than $[\text{Eu}^{\text{II}}(\text{dtpa})(\text{H}_2\text{O})]^{3-}$ (log K values of 13.07 vs. 10.08 respectively) (ODDM^{4-} = 1,4,10,13-tetraoxa-7,16-diaza-cyclooctadecane-7,16-dimalonate; ODDA^{2-} = 1,4,10,13-tetraoxa-7,16-diazacyclooctadecane-7,16-diacetate). A number of Ln^{II} aryloxides have been reported including $[\text{Eu}(\text{OC}_6\text{H}_2\text{Bu}^t_{2-2,6-\text{Me-4}})_2(\text{THF})_3]$.¹⁰⁸³ $[\text{Yb}(\text{OC}_6\text{H}_2\text{Bu}^t_{2-2,6-\text{Me-4}})_2(\text{Et}_2\text{O})_2]$ and dimeric $[\text{Yb}(\text{OC}_6\text{H}_2\text{Bu}^t_{2-2,6-\text{Me-4}})_2]^{1084}$ $[\text{Sm}\{\text{N}(\text{SiMe}_3)_2\}_2(\text{THF})_3]$ reacts with $\text{HOC}_6\text{H}_3\text{Bu}^t_{2-2,6-\text{Me-4}}$ forming¹⁰⁸⁵ five-coordinate $[\text{Sm}(\text{OC}_6\text{H}_3\text{Bu}^t_{2-2,6-\text{Me-4}})_2(\text{THF})_3]$; $\{\text{KSm}\{\text{N}(\text{SiMe}_3)_2\}_3\}$ reacts with $\text{HOC}_6\text{H}_3\text{Bu}^t_{2-2,6-\text{Me-4}}$ forming $[\text{KSm}(\text{OC}_6\text{H}_3\text{Bu}^t_{2-2,6-\text{Me-4}})_3(\text{THF})]_\infty$ which has tetrahedral coordination of Sm^{II} and in which potassium ions act as bridges with K-arene interactions. $[\text{Sm}\{\text{N}(\text{SiMe}_3)_2\}_2(\text{THF})_2]$ reacts with $\text{HOC}_6\text{H}_3\text{Bu}^t_{2-2,6-\text{Me-4}}$ forming the five-coordinate aryloxide $[\text{Sm}\{\text{OC}_6\text{H}_3\text{Bu}^t_{2-2,6-\text{Me-4}}\}_2(\text{THF})_3]$ which is a convenient synthon for a number of Sm^{II} and Sm^{III} compounds.¹⁰⁸⁶

Eu reacts with 2-methoxyethanol¹⁰⁸⁷ forming the hydrocarbon-soluble oligomer $[\text{Eu}(\text{OCH}_2\text{CH}_2\text{OMe})_2]_n$ ($n > 10$ in toluene). This reacts with 2,6-dimethylphenol or 2,6-diisopropylphenol forming the tetrametallic $[[\text{Eu}(\mu^3-\eta^2-\text{OCH}_2\text{CH}_2\text{OMe})(\eta^2-\text{OCH}_2\text{CH}_2\text{OMe})(\text{OC}_6\text{H}_3\text{R}_{2-2,6})][\text{H}^+]_4]$ ($\text{R} = \text{Me}, \text{Pr}^i$). These have a tetrahedron of seven-coordinate europium atoms, each bound to one terminal bidentate alkoxide, one bridging bidentate alkoxide, a terminal aryloxide, and two bridging oxygens from other aryloxides. $[\text{Eu}(\text{OCH}_2\text{CH}_2\text{OMe})_2]_n$ reacts with Me_3Al forming the hexametallic $[\text{Me}_3\text{Al}(\mu-\eta^2-\text{OCH}_2\text{CH}_2\text{OMe})\text{Eu}(\mu-\eta^2-\text{OCH}_2\text{CH}_2\text{Me})_2(\text{AlMe}_2)_2]$. 2,6-Disubstituted phenols react with Eu in liquid NH_3 forming $[\text{Eu}(\text{OC}_6\text{H}_3\text{Bu}^t_{2-2,6})_2(\text{NCMe})_4]$ and $[\text{Eu}_4(\mu-\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_4(\text{OC}_6\text{H}_3\text{Pr}^i_{2-2,6})_2(\mu_3-\text{OH})_2(\text{NCMe})_6]$.¹⁰⁸⁸ An interesting variety of phenoxides with a range of europium polyhedra have been reported. Eu reacts with Pr^iOH forming¹⁰⁸⁹ arene-soluble $[\text{Eu}(\text{OPr}^i)_2(\text{THF})_x]_n$ which is a synthon for a trimetallic dimethylphenoxide $[\text{Eu}(\text{OC}_6\text{H}_3\text{-2,6-Me}_2)_2]_3$ that reacts with isopropanol vapor forming a cluster $\text{H}_{10}[\text{Eu}_8\text{O}_8(\text{OC}_6\text{H}_3\text{-2,6-Me}_2)_2(\text{OPr}^i)_2(\text{THF})_6]$, containing a cubic arrangement of europiums. Other clusters have been formed by direct reaction between Eu and phenols, such as $\text{H}_x[\text{Eu}_8\text{O}_6(\text{OC}_6\text{H}_3\text{-2,6-Me}_2)_{12}(\text{OPr}^i)_8]$ and $\text{H}_5[\text{Eu}_5\text{O}_5(\text{OC}_6\text{H}_3\text{-2,6-Pr}^i)_6(\text{MeCN})_8]$. $\text{H}_{18}[[\text{Eu}_9\text{O}_8(\text{OC}_6\text{H}_3\text{-2,6-Me}_2)_{10}(\text{THF})_{10}]]$ $[\text{Eu}_9\text{O}_9(\text{OC}_6\text{H}_3\text{-2,6-Me}_2)_{10}(\text{THF})_6]$ was also synthesized. 2,6-diphenylphenol (dppOH) reacts with Eu or Yb on heating in the presence of mercury¹⁰⁹⁰ forming $[\text{Ln}(\text{Odpp})_2]$. These have the structures $[\text{Eu}_2(\text{Odpp})(\mu-\text{Odpp})_3]$ and $[\text{Yb}_2(\text{Odpp})(\mu-\text{Odpp})_3]$ whilst small amounts of the mixed-valence $[\text{Yb}_2(\mu-\text{Odpp})_3]^+[\text{Yb}(\text{Odpp})_4]^-$ were also obtained. All three compounds have additional Ln-aryl interactions. Europium in liquid ammonia reacts with 2,6-dimethylphenol forming the asymmetric $[(\text{DME})(\text{RO})\text{Eu}^{\text{II}}(\mu-\text{RO})_3\text{Eu}^{\text{II}}(\text{DME})_2]$ ($\text{R} = 2,6\text{-Me}_2\text{C}_6\text{H}_3$).¹⁰⁹¹ Reduction of $[\text{Yb}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_3(\text{THF})_2]$ leads to the isolation of $[\text{Yb}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_2(\text{THF})_3]$ and $[\text{Yb}(\text{OC}_6\text{H}_3\text{Ph}_{2-2,6})_2(\text{DME})_2]$; the former has a tbp structure with axial aryloxides.⁶²⁴

Another divalent compound is¹⁰⁹² $\text{tbp}[\text{Sm}(\text{OAr})_2(\text{THF})_3]\cdot \text{THF}$ ($\text{Ar} = 2,6\text{-Bu}^t_{2-4}\text{-Me-C}_6\text{H}_2$). $[\text{Sm}(\text{OAr})_2(\text{THF})_4]$ ($\text{Ar} = 2,6\text{-Bu}^t_{2-4}\text{C}_6\text{H}_3$) catalyzes¹⁰⁹³ the polymerization of phenyl isocyanate. Three-coordinate Yb^{II} exists in $[\{\text{YbX}(\mu\text{-X})_2\}(\text{X} = \text{OAr}, \text{OC}(\text{Bu}^t)_3)]$ and $[\{\text{Yb}(\text{NR}_2)(\mu\text{-X})\}_2]$ ($\text{X} = \text{OAr}, \text{OC}(\text{Bu}^t)_3$) where $\text{Ar} = 2,6\text{-Bu}^t_{2-4}\text{-Me-C}_6\text{H}_2$; $\text{R} = \text{SiMe}_3$.¹⁰⁹⁴ The first Ln^{II} siloxide to be characterized¹⁰⁹⁵ structurally is $[\{\text{Yb}(\text{OSiMe}_2\text{Bu}^t)(\eta^2\text{-DME})(\mu\text{-OSiMe}_2\text{Bu}^t)\}_2]$.

3.2.2.9.5 Group 16 ligands involving sulfur, selenium, and tellurium

Ytterbium reacts with organic disulfides forming $[\text{Yb}(\text{SAr})_2(\text{Py})_2]$ ($\text{Ar} = 2,4,6\text{-triisopropylphenyl}$).⁹⁵⁴ Transmetalation of Sm and Eu with $\text{Hg}(\text{SC}_6\text{F}_5)_2$ affords $\text{Sm}(\text{SC}_6\text{F}_5)_3$ and $\text{Eu}(\text{SC}_6\text{F}_5)_2$ respectively; these have the solid-state structures $[(\text{THF})_2\text{Sm}(\mu_2\text{-SC}_6\text{F}_5)(\text{SC}_6\text{F}_5)_2]_2$ and $[(\text{THF})_2\text{Eu}(\mu_2\text{-SC}_6\text{F}_5)_2]_n$, the latter being a one-dimensional polymer.⁹⁵² These undergo

thermal decomposition to LnF_3 . Some remarkable Ln^{II} thiolates have been reported, in the form of $[\text{Ln}(\text{SAr})_2]$ ($\text{Ar} = 2,6\text{-Trip}_2\text{C}_6\text{H}_3$; $\text{trip} = 2,4,6\text{-Pr}_3\text{C}_6\text{H}_2$). Though formally two-coordinate (and though in the case of the europium compound, uncoordinated THF is present in the lattice), there are $\eta^6\text{-}\pi$ -interactions present. Structures are also reported of six-coordinate $[\text{Yb}(\text{SAr})_2(\text{DME})_2]$ and the Yb^{III} compound $[\text{YbI}(\text{SAr})_2(\text{THF})_3]$.¹⁰⁹⁶ A sterically crowded Yb^{II} thiolate $[\text{Yb}(\text{SAr}^*)(\text{THF})_4]$ ($\text{Ar}^* = 2,6\text{-Trip}_2\text{C}_6\text{H}_3$, where Trip is $2,4,6\text{-}^i\text{Pr}_3\text{C}_6\text{H}_2$) has the *trans*- structure now becoming familiar for these Ln^{II} systems.¹⁰⁹⁷ The overcrowding caused by the sterically encumbered Ar^* ligands is reflected in the large Yb-S-C angle of 151.16° . A number of pyridinethiolate (Spy ; $2\text{-S-NC}_5\text{H}_4$) complexes have been characterized.⁹⁶⁵ $[\text{Yb}(\text{SPy})_2]$ crystallizes from pyridine as seven-coordinate $[\text{Yb}(\text{SPy})_2(\text{Py})_3]$. Europium pyridinethiolates $[\text{Eu}(\text{SPy})_2(\text{Py})_4]$ and $[\text{Eu}(\text{SPy})_2(\text{bipy})(\text{THF})_2]$ have been synthesized.⁹⁶⁶ Heterometallic chalcogenides $[(\text{THF})_2\text{Eu}(\mu_2\text{-SePh})_6\text{Pb}_2]$, $[\text{Yb}(\text{THF})_6][\text{Sn}(\text{SePh})_3]_2$, and $[\text{Py}_2\text{Eu}(2\text{-S-NC}_5\text{H}_4)_2\text{Sn}(2\text{-S-NC}_5\text{H}_4)_2]_n$ have been characterized.¹⁰⁹⁸ $\text{Ln}(\text{SePh})_2$ reacts with selenium in DME forming heterovalent clusters $[\text{Ln}_4\text{Se}(\text{SePh})_8(\text{DME})_4]$ ($\text{Ln} = \text{Sm}, \text{Yb}, \text{Nd}^{\text{III}}/\text{Yb}^{\text{II}}, \text{Sm}^{\text{III}}/\text{Yb}^{\text{II}}$) which contain a square of lanthanide ions with a capping selenide.¹⁰⁹⁹ Lanthanide(II) selenolate and tellurolate complexes,^{1100–1102} usually obtained as etherates, are possible precursors to lanthanide monochalcogenides. $\text{M}(\text{TePh})_2$ ($\text{M} = \text{Yb}, \text{Eu}$) crystallize as one-dimensional polymers like $[(\text{THF})_2\text{Eu}(\text{TePh})_2]_\infty$ and $[(\text{THF})_2\text{Yb}(\text{TePh})_{2.1/2}(\text{THF})]_\infty$. $[\text{Ln}(\text{ESi}(\text{SiMe}_3)_3)_2(\text{tmeda})_2]$ ($\text{Ln} = \text{Eu}, \text{Yb}$; $\text{E} = \text{Se}, \text{Te}$) have been reported and the structures of $[\text{Yb}(\text{SeSiMe}_3)_3]_2(\text{tmeda})_2$ and $[\{\text{Eu}(\text{SeSiMe}_3)_3\}_2(\text{dmpe})_2]_2$ determined; the ytterbium tmeda complexes eliminate $\text{E}(\text{Si}(\text{SiMe}_3)_3)_2$ at 200°C affording YbSe and YbTe .

3.2.2.9.6 Group 17 ligands

Rb_4TmI_6 , synthesized by heating a mixture of RbI , Tm , and HgI_2 , has the K_4CdI_6 structure with trigonal antiprismatic coordination of Tm .¹¹⁰³ RbYbI_3 has a structure based on edge-sharing $[\text{YbI}_6]$ octahedra.¹¹⁰⁴ M_2EuI_6 ($\text{M} = \text{Cs}, \text{Rb}$) have isolated $[\text{EuI}_6]^{2-}$ ions,¹¹⁰⁵ similarly Rb_2YbI_6 has octahedral $[\text{YbI}_6]^{2-}$ ions.¹¹⁰⁶ Reduction of MX_3 ($\text{M} = \text{Sm}, \text{Dy}, \text{Tm}, \text{Yb}$; $\text{X} = \text{Br}, \text{I}$) with alkali metals, In , and Tl (A) leads generally to the ternary compounds AMX_3 and AM_2X_5 ; some similar compounds with divalent metals ($\text{Ca}, \text{Sr}, \text{Ba}$) have also been made.¹¹⁰⁷ LiDy_2Br_5 , prepared by reduction of DyBr_3 with Li metal at 700°C , is isostructural with LiDy_2Cl_5 , LiYb_2Cl_5 , and LiLn_2Br_5 ($\text{Ln} = \text{Sm}, \text{Tm}$).^{1108,1109}

3.2.2.10 Complexes of the Ln^{4+} ion

There have been fewer developments here than in the (+2) state.

3.2.2.10.1 Group 15 ligands

A highlight here is the synthesis of the first Ln^{IV} silylamide. Although it cannot be oxidized with Cl_2 , $[\text{Ce}(\text{N}(\text{SiMe}_3)_2)_3]$ reacts with TeCl_4 forming $[\text{CeCl}(\text{N}(\text{SiMe}_3)_2)_3]$; this has a trigonal prismatic structure, with Ce 0.36 \AA out of the N_3 basal plane (and, interestingly a 0.05 \AA lengthening of the N-Si bond).¹¹¹⁰ A preliminary mention of the reaction of PPh_3Br_2 with $[\text{Ce}(\text{N}(\text{SiMe}_3)_2)_3]$ forming $[\text{CeBr}(\text{N}(\text{SiMe}_3)_2)_3]$ may also be noted. A previous Ce^{IV} amide was synthesized by iodine oxidation of a cerium(III) compound of a triamidoamine, affording a notable compound with a rare $\text{Ce}^{\text{IV}}\text{-I}$ linkage (Scheme 9); analogous oxidation with X_2 ($\text{X} = \text{Cl}, \text{Br}$) yields mixed-valence dimers.¹¹¹¹

The reaction of $2,4,6\text{-tri-}t\text{-butylpyridyl-1,3,5-triazine}$ (L) with $(\text{NH}_4)_2[\text{Ce}(\text{NO}_3)_6]$ leads to a number of species,¹¹¹² including 11-coordinate $[\text{Ce}(\text{L})(\text{NO}_3)_4]$, $[\text{Ce}(\text{NO}_3)_5(\text{OH}_2)]^-$, and $[\text{Ce}(\text{NO}_3)_6(\text{OEt})]^{2-}$ (all crystallographically characterized). Syntheses are reported for some Ce^{IV} bis (porphyrinates).^{1113,1114} NMR shows that the two porphyrin rings do not rotate with respect to each other even at 140°C . COSY NMR-spectral data have been reported for Ce^{IV} porphyrins.¹¹¹⁵ Ring oxidized Ce^{IV} phthalocyanines have been prepared¹¹¹⁶ by oxidation of $[\text{Ce}^{\text{IV}}(\text{pc})_2]$ or $[\text{Ce}^{\text{III}}(\text{pc})_2]^-$, and the structure of $[\text{Ce}^{\text{IV}}(\text{pc})_2](\text{BF}_4)_{0.33}$ determined. The synthesis and structure of $[\text{Ce}^{\text{IV}}(\text{pc})_2]$ is reported.¹¹¹⁷

3.2.2.10.2 Group 16 ligands

Hydrated cerium(IV) triflate dehydrates on stirring with triflic anhydride.¹¹¹⁸ It is potentially a valuable source of other Ce^{IV} compounds. The crystal structure of (NH₄)₄Ce(SO₄)₄·2H₂O has been reported,¹¹¹⁹ together with a DTA study involving (NH₄)₂Ce(SO₄)₃, (NH₄)₂Ce(NO₃)₆, and Cs₂Ce(NO₃)₆. MgCe(NO₃)₆·8H₂O is isomorphous with the Th analogue, containing 12-coordinate [Ce(NO₃)₆]²⁻ ions;¹¹²⁰ K₂Ce(NO₃)₆ exists in two polymorphs,¹¹²¹ again with icosahedral [Ce(NO₃)₆]²⁻. The iodates Ce^{IV}HIO₆·4H₂O and MCe^{IV}IO₆·*n*H₂O (M = alkali metal) have been reported.¹¹²² A number of diketonates are now better characterized, prompted by the possibility of using them as CVD materials and petrol additives, as well as a source of cerium oxide as an oxygen store for catalytic converters. Thus the coordination geometries in the air stable potential CVD precursors [Ce(tmhd)₄] and [Ce(pmhd)₄] (tmhd = 2,2,6,6-tetramethyl-3,5-heptanedionate; pmhd = 1-phenyl-5-methylhexane-1,3-dionate) are now known to be distorted dodecahedral and square antiprismatic respectively; the former sublimes unchanged whilst the latter is involatile.¹¹²³ [Ce{Me₃CCOCHCOCMe₂(OMe)}₄] is square antiprismatic.¹¹²⁴ Alkoxides are among the more important (and best characterized) Ce^{IV} compounds. General methods are available to make many Ce(OR)₄ (R, e.g., Me, Et, OPrⁱ, *n*-C₈H₁₇).¹¹²⁵

As usual, many of these alkoxides are oligomers, though coordinative saturation can be achieved by adduct formation. Ce(OSiPh₃)₄, prepared by alcoholysis of Ce(OPrⁱ)₄ in dimethoxyethane, is isolated as [Ce(OSiPh₃)₄(DME)_{*x*}] (0.5 < *x* < 1). Crystals of [Ce(OSiPh₃)₄(DME)] display octahedral coordination of cerium with Ce—O (Si) of 2.10–2.14 Å and two rather long Ce—O (ether) bonds at 2.58–2.59 Å. Although the solid is air- and moisture-stable, it undergoes immediate reaction with HACAC forming Ce(ACAC)₄.¹¹²⁶ Thermal desolvation of [Ce(OPrⁱ)₄(HOPrⁱ)₂] affords [Ce₄O(OPrⁱ)₁₄], which has the structure [Ce₄(μ₄-O)(μ₃-OPrⁱ)₂(μ-OPrⁱ)₈(OPrⁱ)₁₄].¹¹²⁷ Alcohol exchange between [Ce₂(OPrⁱ)₈(PrⁱOH)₂] and hexafluoroisopropanol (Hhfp) affords [Ce(hfip)₄(thf)₂(PrⁱOH)_{*x*}], convertible into the stable adducts [Ce(hfip)₄L₂] (L₂ = 2 bipy; tmen; diglyme) {diglyme = 2,5,8-trioxanonane; tmen = *N,N,N',N'*-tetramethylethane-1,2-diamine}. Reaction with pmdien (pmdien = *N,N,N',N',N'*-pentamethyldiethylenetriamine) results in [Ce(hfip)₃(OPrⁱ)(pmdien)] and [Hpmdien]₂[Ce(hfip)₆], the latter having octahedrally coordinated Ce.¹¹²⁸ [Ce₂(OPrⁱ)₈(PrⁱOH)₂] reacts with Hthd (Hthd = 2,2,6,6-tetramethylheptane-3,5-dione) and barium isoperoxide forming [Ba₄Ce₂(μ₆-O)(thd)₄(μ₃-OPrⁱ)₈(OPrⁱ)₂].¹¹²⁹ Reaction of (NH₄)₂Ce(NO₃)₆ with two to eight equivalents of NaOCMe₃ has given a range of *t*-butoxide species, represented by general formulae Ce(OCMe₃)_{*a*}(NO₃)_{*b*}(solvent)_{*c*}Na_{*d*} (*a* = 1–6; *b* = 0–3; *c* = 2, 4; *d* = 0, 2) in addition to NaCe₂(OCMe₃)₉ and Ce₃O(OCMe₃)₁₀. (NH₄)₂Ce(NO₃)₆ reacts with three moles of NaOCMe₃ forming Ce(OCMe₃)(NO₃)₃, isolable as Ce(OCMe₃)(NO₃)₃(HOCMe₃)₂. This reacts with one mole of NaOCMe₃ forming Ce(OCMe₃)₂(NO₃)₂(HOCMe₃)₂ or Ce(OCMe₃)₂(NO₃)₂(THF)₂. Ce(OCMe₃)₂(NO₃)₂(HOCMe₃)₂ has eight-coordinate cerium, or, if each bidentate nitrate is considered to occupy one coordination position, the coordination geometry at Ce approximates to distorted octahedral, with Ce—O (Bu^t) distances of 2.023 Å and 2.025 Å; the Ce—O (NO₃) distances average 2.56 Å and the Ce—O (alcohol) distances 2.521–2.529 Å. Further reaction of “Ce(OCMe₃)₂(NO₃)₂” with NaOCMe₃ yields Ce(OCMe₃)₃(NO₃) and Ce(OCMe₃)₄(THF)₂. Ce(OCMe₃)₄(THF)₂ reacts with excess NaOCMe₃ to afford Na₂Ce(OCMe₃)₆(DME)₂ which has octahedral [Ce(OCMe₃)₆]²⁻ ions surrounded by Na(DME)⁺ ions, sodium being coordinated facially to three oxygens of the CeO₆ unit. The Ce—O distances vary, as two butoxides are terminal (Ce—O of 2.141 Å), two are doubly bridging (Ce—O of 3.230 Å) and two are triply bridging (Ce—O of 2.374 Å). Ce(OCMe₃)₄(THF)₂ reacts with 0.5 mole of NaOCMe₃ to form NaCe₂(OCMe₃)₉. Both NaCe₂(OCMe₃)₉ and Ce(OCMe₃)₄(THF)₂ slowly convert in solution into Ce₃O(OCMe₃)₁₀.¹¹³⁰ The alkoxide group plays an important role in stabilizing the Ce^{IV} state, witness the existence of [CeCp₂(OBu^t)₂] and [CeCp₃(OBu^t)] when other Ce^{IV} organometallics cannot be isolated says something about the role of OR is supporting the (IV) state of cerium.¹¹³¹ An improved synthesis of [Ce(NO₃)₄(Ph₃PO)₂], from (NH₄)₂[Ce(NO₃)₆] and Ph₃PO in MeCN is reported; it was also stated, however, that the literature reaction of (NH₄)₂[Ce(NO₃)₆] and Ph₃PO in propanone tends to lead to reduction and the formation of [Ce(NO₃)₃(Ph₃PO)₃].⁴³² Newer Ce^{IV} THF complexes, [CeClZ(THF)₅] [Ce(THF)Cl₅] (Z = Cl, NO₃) have been synthesized.¹¹³²

3.2.2.10.3 Group 17 ligands

Fluorination of cerium oxide with NH_4HF_2 affords $(\text{NH}_4)_4[\text{CeF}_8]$.¹¹³³ $\beta\text{-BaTbF}_6$ has a structure¹¹³⁴ based on infinite chains of edge-sharing $[\text{TbF}_8]^{4-}$ units. $\alpha\text{-BaTbF}_6$ contains $[\text{Tb}_4\text{F}_{26}]^{10-}$ ions based on association of four square antiprisms by sharing corners and edges.¹¹³⁵

3.3.1 INTRODUCTION

3.3.1.1 Historical Development of Actinide Coordination Chemistry

Investigation of the coordination chemistry of the actinide elements began with the isolation of uranium from a pitchblende sample in 1789;¹ thorium was similarly isolated from thorite mineral samples in 1829.² The chemistry of these elements remained somewhat obscure until the discovery in 1895 by Becquerel that uranium undergoes radioactive decay. Interest in the chemistry (and more specifically the nuclear chemistry) of the earliest actinide elements blossomed (including protactinium),³ as scientists sought to understand and systematize the chemical and radioactive properties of naturally occurring radioactive elements. The discovery of artificial radioactivity in 1934 proved to be the next watershed development in the history of the actinide elements, as the promise was offered of truly synthesizing new elements not previously found in nature. The development of man-made elements began in 1940 with the production of neptunium.⁴

Coordination chemistry (in the form of descriptive chemistry) played a key role in this discovery phase. The chemical properties of the elements (redox characteristics and stoichiometry of simple compounds such as oxides and halides) were often used to argue for their placement in the periodic table. It was for this reason that a series of compounds was first proposed in which the 5*f*-orbitals were being successively populated. The first actinides were considered to be members of a new *d*-transition series, until it became clear that their chemical properties did not mimic those of their supposed congeners. Although thorium is chemically similar to group 4 elements, and uranium can bear some similarity to group 6 metals, neptunium did not share many similarities with group 7 elements, and plutonium bore no resemblance to osmium or other group 8 elements. Seaborg first developed the hypothesis that the actinide elements actually constituted a second “*f*-transition series,” analogous to the lanthanide elements. With this recognition, the search began to populate all positions in the series. Table 1 provides a listing of the manmade actinide elements, along with their dates of first synthesis.

The discovery of nuclear fission in 1938 proved the next driver in the development of coordination chemistry. Uranium-235 and plutonium-239 both undergo fission with slow neutrons, and can support neutron chain reactions, making them suitable for weaponization in the context of the Manhattan project. This rapidly drove the development of large-scale separation chemistry, as methods were developed to separate and purify these elements. While the first recovery processes employed precipitation methods (e.g., the bismuth phosphate cycle for plutonium isolation),

Table 1 Man-made actinide elements.

subsequent methods employed extraction of actinide ions from aqueous into nonaqueous solution by the use of organic extractants such as ethers, amines, or organophosphates. With increasing sophistication required in separation processes (e.g., separation of actinides from lanthanides), new classes of extractants have appeared including bifunctional and chelating ligands. Some emphasis will be given in this chapter to the use of these types of extractants in the separation of the elements, given the historical importance of this application.

Investigations of the nonaqueous coordination chemistry of the actinides began with the Manhattan project. Isotopic separation of uranium and plutonium generally involved distillation or centrifugation of volatile metal complexes. While the higher oxidation state fluoride complexes had favorable volatility, their corrosive properties led to a search for alternative classes of compounds. These investigations supported the development of several new classes of compounds, including volatile alkoxide and borohydride complexes. The expansion of these interests to include the organometallic chemistry of the elements began in 1956 (shortly after the discovery of ferrocene in 1951) with the preparation of the first cyclopentadienyl complexes of actinides.⁵ Organometallic chemistry of the actinide elements lies outside the scope of this chapter, and no discussion will be provided of complexes containing carbon-based σ -bonding (i.e., alkyl, aryl) or π -bonding ligands. For further information on organometallic chemistry, the reader is referred to other recent reviews.⁶

Most recently, interest has grown in the chemistry of the early actinides in biologically and environmentally relevant conditions, as interest has turned to the remediation of contaminated sites, and the evaluation of long-term fate and transport in the environment. The first impact of this has been to stimulate research in the aqueous coordination chemistry of actinides under conditions dissimilar to process media (near-neutral pH, lower concentration, lower ionic strength). Research has also focused on the complexation of actinides by ligands that are derived from (or which mimic) metal complexation under biological conditions, such as catecholate groups or amino acids. These classes of ligands will be included in the context of the broader suite of multidentate ligands.

A comprehensive treatment of the early literature covering several ligand classes is available in the Gmelin series; emphasis in this chapter will be placed on referencing more recent developments. Where primary literature has not been cited, information has been drawn from Gmelin as a primary reference.⁷

The depictions of molecular structures presented were generated using the program Crystal-Maker 2,⁸ using atomic coordinates obtained from the Cambridge Structural Database.⁹ Several of the tables have been reproduced from the Actinide chapter by K. W. Bagnall in the previous edition of *Comprehensive Coordination Chemistry* (CCC, 1987); this served as the starting point for many ligand classes.

3.3.1.1.1 Characteristics of the actinides

It should be noted that one of the most significant characteristics of the actinides is their radioactivity; all isotopes are radioactive, although some have half-lives of greater than 1×10^5 years. Precautions must be taken in their handling, ranging from the use of special enclosures (HEPA-filtered exhaust hoods, negative-pressure gloveboxes) to the use of shielded facilities.

Similarities exist between the chemical characteristics of the actinides and those of the lanthanides. The metal ions are generally considered to be relatively “hard” Lewis acids, susceptible to complexation by hard (i.e., first row donor atom) ligands and to hydrolysis. Both actinide and lanthanide ions are affected by the “lanthanide contraction,” resulting in a contraction of ionic radius and an increasing reluctance to exhibit higher oxidation states later in the series. Most species are paramagnetic, although the electron spin–nuclear spin relaxation times often permit observation of NMR spectra, and disfavor observation of ESR spectra except at low temperatures. The elements display more than one accessible oxidation state, and one-electron redox chemistry is common.

The actinide elements display much more diversity in their chemistry than their lanthanide counterparts, however. The greater radial extent and energetic availability of the 5*f*- and 6*d*-orbitals result in increased interaction with ligand-based orbitals. While the electronic structure of lanthanide complexes is dominated by spin-orbit coupling and electron–electron repulsion, that of actinide complexes is often significantly impacted by ligand-field effects, leading to complex optical spectra. Due to the energetic accessibility of metal valence electrons early in the series, the early actinides display a much wider range of attainable oxidation states (see Table 2), and the bonding in chemical compounds is often described to be somewhat more covalent than that in

Table 2 Known oxidation states of the actinide elements.

<i>Th</i>	<i>Pa</i>	<i>U</i>	<i>Np</i>	<i>Pu</i>	<i>Am</i>	<i>Cm</i>	<i>Bk</i>	<i>Cf</i>	<i>Es</i>	<i>Fm</i>	<i>Md</i>	<i>No</i>	<i>Lw</i>

		6	6	6	6								
			7	7	7								

lanthanide complexes.¹⁰ Therefore, it may be said that the coordination chemistry of the actinides is richer and more varied than that for the lanthanide elements.

Some distinction may be made between the chemistry of the early actinide elements (Th–Pu) and that of the later actinide elements (Am–Lw). The early actinide metals are much more readily available, either from natural ores or as products of nuclear materials and fuel production. The later actinides are rarer, and are only available in extremely limited quantities from specialized sources. The early actinides have the greatest range of accessible oxidation states. Isotopes of the early actinides generally have longer half-lives, reducing the risk of self-radiolysis inherent to compounds of radioactive elements (and yielding more stable products). Finally, broader interest exists in the technological applications of the early actinides, due to their role both in energy production and nuclear weapons production. The more widespread use of these elements has also contributed to a more acute need to investigate their behavior in the environment. For all these reasons, the coordination chemistry of the early actinide elements is much more developed, and will be discussed separately.

3.3.1.1.2 Coordination numbers and geometries

Actinide ions display relatively large ionic radii, and therefore support higher coordination numbers; coordination numbers of 8–10 are common, and 12- and 14-coordinate metal centers have been observed (see Table 3). Because ionic radii decrease across the series, however, accessible coordination numbers often decrease across the series for a given oxidation state with the same ligand. Although metal–ligand orbital overlap in complexes of the actinides may exceed that in lanthanide compounds, the actinides still exhibit chemical behavior largely consistent with ionic bonding. As a consequence, the geometry of coordination complexes is not strongly driven by orbital considerations, but rather by steric considerations (ligand–ligand repulsions). Ligands are generally labile, and kinetic barriers for reactions are most often moderate.

3.3.2 EARLY ACTINIDE METALS—THORIUM TO PLUTONIUM

The chemistry of the early actinide metals has been most extensively studied for many reasons. Chief among these is the availability of materials for study. Thorium and uranium obtained from ores as described above have been available for chemical investigations for well over 100 years. In fact, all early actinide elements may be found in nature, although only thorium, protactinium, and uranium are present in sufficient quantities to justify extraction. The remaining early actinide elements, neptunium and plutonium, are produced in large quantities in nuclear reactors.

A second reason for the wealth of chemical investigations of the early actinide elements is the relative diversity of their chemistry. While the chemistry of the later actinides is most often restricted to that of the tri- and tetravalent oxidation states, compounds of the early actinides can be isolated in all oxidation states from +3 to +7. The accessibility of a range of oxidation states is the impetus for significant chemical interest in the early actinides, but also vastly complicates investigation of these elements under some circumstances, such as aqueous redox behavior. In the case of plutonium, ions in four different oxidation states (+3, +4, +5, and +6) can exist simultaneously in comparable concentrations in the same solution.

The most practical reason for interest in the chemistry of the early actinides is their technological importance. In particular, the importance of uranium and plutonium in applications ranging from nuclear power to radiothermal generators for deep space missions. The production and use of nuclear materials in nuclear weapons from the 1940s has also driven the development of a great deal of the chemistry of these metals, from their separation and isolation to investigations of their behavior under biologically relevant conditions.

3.3.2.1 Trivalent Oxidation State

3.3.2.1.1 General characteristics

With the exception of thorium and protactinium, all of the early actinides possess a stable +3 ion in aqueous solution, although higher oxidation states are more stable under aerobic conditions. Trivalent compounds of the early actinides are structurally similar to those of their trivalent lanthanide counterparts, but their reaction chemistry can differ significantly, due to the enhanced ability of the actinides to act as reductants. Examples of trivalent coordination compounds of thorium and protactinium are rare. The early actinides possess large ionic radii (effective ionic radii = 1.00–1.06 Å in six-coordinate metal complexes),¹¹ and can therefore support large coordination numbers in chemical compounds; 12-coordinate metal centers are common, and coordination numbers as high as 14 have been observed.

3.3.2.1.2 Simple donor ligands

(i) Ligands containing anionic group 15 donor atoms

Amide ligands. The trivalent chemistry of the actinides with N-donor ligands is limited to sterically bulky ligands that provide kinetic stabilization against ligand exchange and polymerization. The bis(trimethylsilyl)amide ligand ($\text{N}(\text{SiMe}_3)_2^-$) supports a wide array of oxidation states of uranium.

Trivalent homoleptic complexes $\text{An}[\text{N}(\text{SiMe}_3)_2]_3$ have been generated for uranium, neptunium, and plutonium^{12–14} by metathesis reactions (see Equations (1) and (2)). The molecular structure of $\text{U}[\text{N}(\text{SiMe}_3)_2]_3$ has been determined:¹⁵

(An = U, Np, Pu)

The geometry about the uranium center is trigonal pyramidal, with a U—N distance of 3.320(4) Å, and a N—U—N angle of 116.24(7)°. The magnetic susceptibility shows that the complex has an effective moment comparable to those determined for trivalent metallocenes and halides ($\mu_{\text{eff}} = 3.354(4)$, $\theta = -13$ K at 5 kG), consistent with a $5f^3$ electronic configuration. A low energy $5f$ ionization band observed in the photoelectron spectroscopy is consistent with the electronic configuration.¹⁶ The steric congestion about the metal center prohibits isolation of stable adducts.

A tris(amido)amine framework, consisting of the ligand $\{\text{N}[\text{CH}_2\text{CH}_2\text{N}(\text{Si}(\text{Bu}^t)\text{Me}_2)]_3\}^{3-}$, has been used to produce U^{III} derivatives. Initial attempts to reduce the complex $\{\text{N}[\text{CH}_2\text{CH}_2\text{N}(\text{Si}(\text{Bu}^t)\text{Me}_2)]_3\}\text{UCl}$ resulted in the formation of a mixed-valence complex $\{\text{N}[\text{CH}_2\text{CH}_2\text{N}(\text{Si}(\text{Bu}^t)\text{Me}_2)]_3\}\text{U}_2(\mu\text{-Cl})$.¹⁷ The bimetallic complex is thought to possess electronically distinct U^{III} and U^{IV} centers. The purple U^{III} species, $\text{N}[\text{CH}_2\text{CH}_2\text{N}(\text{Si}(\text{Bu}^t)\text{Me}_2)]_3\text{U}$, was originally isolated by fractional sublimation of the bimetallic $\text{U}^{\text{III}}/\text{U}^{\text{IV}}$ complex.¹⁸ This complex can be prepared directly by reduction of $\text{N}[\text{CH}_2\text{CH}_2\text{N}(\text{Si}(\text{Bu}^t)\text{Me}_2)]_3\text{UI}$ by potassium in pentane. A variety of adducts of this complex have been reported.¹⁹ Reaction of the U^{III} complex with dinitrogen produces one of the most unusual adducts isolated in this system (see Equation (3)):

Despite the apparent reversibility of the N_2 addition in solution (based on ^1H -NMR experimental data), a molecular structure of the complex was obtained¹⁸ (see Figure 1).

Figure 1 Crystal structure of $\{N[CH_2CH_2N(Si(Bu^t)Me_2)U]_2(\mu^2-\eta^2: \eta^2-N_2)\}$ (Roussel and Scott *J. Am. Chem. Soc.* **1998**, *120*, 1070).

The N–N distance in the dinitrogen unit is essentially unperturbed. Metrical data, along with magnetic data, suggest that the complex is best formulated as a U^{III} species. The electronic structure of this complex has been investigated; the only significant U–N₂–U interaction was found to consist of $U \rightarrow N_2 \pi$ backbonding.²⁰

An additional bulky amide ligand type, which supports novel coordination complexes of lower valent uranium has been developed. Complexes of the formula $U(NR\text{Ar})_3(\text{THF})$ ($R = Bu^t$, adamantyl; $\text{Ar} = 3,5\text{-Me}_2\text{C}_6\text{H}_3$) cannot be generated directly from trivalent halide precursors; instead, they are produced in the reduction of the uranium(IV) iodide complex by sodium amalgam.²¹

Aside from the neutral tris(amido)actinide complexes that have been prepared with sterically encumbering ligands as described, an alternate approach to the stabilization of trivalent actinide amides is the generation of anionic “ate”-type complexes. As an example, reaction of $UI_3(\text{THF})_4$ with excess KHNAr ($\text{Ar} = 2,6\text{-Pr}^i_2\text{C}_6\text{H}_3$) produces the anionic complex $[K(\text{THF})_2]_2[U(\text{NHA}r)_5]$ which has been crystallographically characterized.²²

Polypyrazolylborate ligands. Monoanionic poly(pyrazolyl)borate ligands ($B(\text{pz})_4^-$, $\text{HB}(\text{pz})_3^-$, $\text{H}_2\text{B}(\text{pz})_2^-$, and substituted derivatives, $\text{pz} = \text{pyrazol-1-yl}$) commonly bind to *f*-elements in either a trihapto or dihapto geometry through nitrogen atoms in the pyrazolyl substituents. Most chemistry with trivalent actinides involves the substituted ligand $\text{HB}(3,5\text{-Me}_2\text{pz})_3^-$. The complex $U[\text{HB}(3,5\text{-Me}_2\text{pz})_3]_2\text{Cl}$ has been generated both by metathesis reaction of UCl_3 with $\text{K}[\text{HB}(3,5\text{-Me}_2\text{pz})_3]$ ²³ and by reduction of the U^{IV} precursor $U[\text{HB}(3,5\text{-Me}_2\text{pz})_3]_2\text{Cl}_3$ with sodium naphthalenide.²⁴ The complex is somewhat unstable, and upon recrystallization can be oxidized to generate the tetravalent oxo complex $\{UCl[\text{HB}(3,5\text{-Me}_2\text{pz})_3](\mu\text{-O})\}_4$.²⁵ The use of uranium triiodide has become increasingly common in the synthesis of trivalent complexes. Reaction of $UI_3(\text{THF})_4$ with $M[\text{HB}(3,5\text{-Me}_2\text{pz})_3]$ ($M = \text{Na}, \text{K}$) in a 1:1 or 1:2 ratio results in the formation of the compounds $U[\text{HB}(3,5\text{-Me}_2\text{pz})_3]_2(\text{THF})_2$ and $U[\text{HB}(3,5\text{-Me}_2\text{pz})_3]_2\text{I}$ respectively.^{26,27} In the monoligand compound the pyrazolylborate ligand is tridentate, while the bis(ligand) compound demonstrates two different coordination modes for the two $[\text{HB}(3,5\text{-Me}_2\text{pz})_3]$ groups. One of the ligands is η^3 -coordinated to the metal center, while in the second ligand, two of the pyrazolyl rings appear to coordinate in a “side-on” type of arrangement with the N—N bond of the ring within bonding distance to the uranium atom. Upon abstraction of the iodide ligand with TIBPh_4 , however, this ligand reverts to a conventional tridentate geometry; the uranium center is seven-coordinate in $\{U[\text{HB}(3,5\text{-Me}_2\text{pz})_3]_2(\text{THF})\}^+$; the tetrahydrofuran ligand occupies the seventh site. A limited number of U^{III} complexes have been reported with other pyrazolylborate ligands. Uranium trichloride or triiodide react with bis(pyrazolyl)borate ligands to generate the species and

$\text{U}[\text{H}_2\text{B}(3,5\text{-Me}_2\text{pz})_2]_3$ and $\text{U}[\text{H}_2\text{B}(\text{pz})_2]_3(\text{THF})$.^{28,29} The coordinated tetrahydrofuran may be removed from the latter to yield the base-free complex $\text{U}[\text{H}_2\text{B}(\text{pz})_2]_3$. The solid state structure of $\text{U}[\text{H}_2\text{B}(3,5\text{-Me}_2\text{pz})_2]_3$ reveals that the metal lies in a trigonal prismatic arrangement of six pyrazole nitrogen atoms, with the three rectangular faces of the trigonal prism capped by three B—H bonds. When a related ligand devoid of B—H bonds is employed, such as $(\text{Ph}_2\text{B}(\text{pz})_2)$, the resulting tris(ligand) complex $\text{U}[\text{Ph}_2\text{B}(\text{pz})_2]_3$ contains a six-coordinate uranium center.³⁰ The lower coordination number may be reflected in the shorter U—N bond distances in the crystal structures. However, the bond distance is only very slightly shorter and may not be statistically significant (2.53(3) Å, vs. 2.59(3) Å or 2.58(3) Å in the 10- and nine-coordinate complexes, respectively). A mixed halide/bis(pyrazolyl)borate complex has been produced by the reaction of $\text{UI}_3(\text{THF})_4$ with $\text{K}[\text{H}_2\text{B}(3\text{-Bu}^t, 5\text{-Mepz})_2]$. The complex $\text{UI}_2[\text{H}_2\text{B}(3\text{-Bu}^t, 5\text{-Mepz})_2](\text{THF})_2$ reacts with triphenylphosphine oxide to yield the base adduct $\text{UI}_2[\text{H}_2\text{B}(3\text{-Bu}^t, 5\text{-Mepz})_2](\text{OPPh}_3)_2$.³⁰ Only one complex of a trivalent transuranic metal has been reported; reaction of PuCl_3 with $\text{M}[\text{HB}(3,5\text{-Me}_2\text{pz})_3]$ in refluxing THF generates the dimeric complex $[\text{PuCl}(\mu\text{-Cl})\{\text{HB}(3,5\text{-Me}_2\text{pz})_3\}-(3,5\text{-Me}_2\text{pzH})]_2$.³¹ A particularly interesting encapsulating ligand is found in the tris(3-(2-pyridyl)-pyrazol-1-yl)-borate ligand ($^{\text{py}}\text{Tp}$). Reaction of the potassium salt of this ligand with $\text{UI}_3(\text{THF})_4$ forms the complex $[\text{pyTp}_2\text{U}]\text{I}$, or in the presence of NaBPh_4 , $[\text{pyTp}_2\text{U}][\text{BPh}_4]$.³² The structure of this complex is found in Figure 2. The complex consists of a rare example of 12-coordinate uranium, where the metal lies in an icosahedral coordination environment. The pyrazolylborate groups are approximately staggered with respect to one another, and six pyridyl nitrogens form the equatorial belt.

(ii) Ligands containing neutral group 15 donor atoms

The chemistry of simple actinide complexes employing neutral group 15-atom donor complexes is extensive.

Ammonia. Ammonia adducts of trivalent uranium are rare. The trihalide complexes of uranium and plutonium are reported to form adducts when exposed to liquid or gaseous ammonia. Higher-coordinate complexes (e.g., $\text{UCl}_3 \cdot 7\text{NH}_3$) are suggested to be stable at lower temperatures; above room temperature the complex loses ammonia to form $\text{UCl}_3 \cdot 3\text{NH}_3$. Further ligand loss occurs above 45 °C to yield $\text{UCl}_3 \cdot \text{NH}_3$. Uranium tribromide has been reported to yield

Figure 2 Crystal structure of $[\text{pyTp}_2\text{U}][\text{BPh}_4]$ (Amoroso, Jeffery *et al.*, *Chem. Commun.* **1995**, 1881).

adducts with either four or six molecules of ammonia, depending on the conditions of preparation. The products $\text{PuCl}_3 \cdot 8\text{NH}_3$ and $\text{PuI}_3 \cdot 9\text{NH}_3$ have been reported;³³ they appear to be similarly susceptible to loss of ammonia. There are no reported adducts of trivalent actinides with neutral amines.

Heterocyclic ligands. The advent of the use of trivalent actinide iodides has enabled the characterization of pyridine adducts of uranium, neptunium, and plutonium.^{13,34} The complexes AnI_3py_4 ($\text{An} = \text{U}, \text{Np}, \text{Pu}$; $\text{py} = \text{pyridine}$) are generated from actinide metals and halide sources in coordinating solvents. They are readily soluble in organic solvents, and serve as convenient precursors to a variety of trivalent actinide species.^{14,35} Several related adducts have been generated using neutral tris(*N*-heterocycle)amine ligands. Reaction of tris((2-pyridyl)methyl)amine (tpa) with $[\text{UI}_3(\text{THF})_4]$ in pyridine results in the isolation of $\text{U}(\text{tpa})\text{I}_3(\text{pyridine})$.³⁶ The analogous complex $[\text{U}(\text{Mentb})_2]\text{I}_3$ complex was prepared by treating $[\text{UI}_3(\text{THF})_4]$ with two equivalents of tris(*N*-methylbenzimidazol-2-ylmethyl)amine (Mentb). Crystallographic studies of the latter reveal that the uranium center is eight-coordinate; the two tetradentate tris(imidazolylmethyl)amine groups fold around the metal center in a pseudo- D_3 symmetric manner. Solution NMR studies in pyridine show a large difference in the behavior of Mentb and tpa towards uranium binding; the bis(ligand) complex of Mentb is found to be more stable in solution than that of tpa. A related complex employing the tris[(2,2'-bipyridin-6-yl)methyl]amine (tbpa) ligand, $[\text{UI}_2(\text{tbpa})][\text{I} \cdot \text{py}]$, has also been reported.³⁷ The complexation of uranium triiodide by 2,2'-bipyridine (bipy) has been investigated in anhydrous pyridine solution.³⁸ At room temperature, both a 1:1 and 1:2 complex ($\text{U}:\text{bipy}$) are observed to form in solution; the 1:2 complex appears to be enthalpically favored. Addition of excess ligand permits observation of a 1:3 complex at low temperature. The " $\text{U}(\text{bipy})_2\text{I}_3$ " complex formed in solution behaves as a 1:1 electrolyte, suggesting a formulation $[\text{U}(\text{bipy})_2\text{I}_2][\text{I}]$. The complex $\text{UI}_3(\text{bipy})_2(\text{py}) \cdot \text{py}$ was isolated from solution and structurally characterized.

Nitriles. The simple acetonitrile adducts $\text{UCl}_3 \cdot \text{MeCN}$ and $\text{NpCl}_3 \cdot 4\text{MeCN}$ have been reported; the Np-237 Mössbauer spectrum of the latter has been reported.³⁹ As in the case of *N*-heterocyclic ligands, the isolation of nitrile adducts of trivalent uranium have been spurred by the availability of soluble iodide starting materials. The complex $\text{UI}_3(\text{MeCN})_4$ has been prepared and characterized crystallographically as well as by magnetic susceptibility and solid-state absorption spectroscopy,⁴⁰ and the complexes $\text{UCl}_3(\text{MeCN})(\text{H}_2\text{O})_5$ and $\text{NH}_4[\text{UBr}_2(\text{MeCN})_2(\text{H}_2\text{O})_3][\text{Br}]_2$ have been isolated.^{41,42}

Phosphines. A limited number of trivalent uranium borohydride phosphine complexes have been reported. The complexes $\text{U}(\text{BH}_4)_3(\text{dmpe})_2$ ($\text{dmpe} = \text{bis}(1,2\text{-dimethylphosphino})\text{ethane}$)⁴³ and $\text{U}(\text{BH}_4)_3(o\text{-PPh}_2(\text{C}_6\text{H}_4\text{N}))_2$ ⁴⁴ are prepared from the reaction of $\text{U}(\text{BH}_4)_3(\text{THF})_x$ and the corresponding ligand, while $\text{U}(\text{MeBH}_3)_3(\text{dmpe})_2$ ⁴⁵ is generated when the tetravalent precursor $\text{U}(\text{BH}_4)_4(\text{dmpe})$ is heated in the presence of excess dmpe.

(iii) Ligands containing anionic group 16 donor atoms

Oxides. The binary oxide, Pu_2O_3 , has been observed as an intermediate between Pu and PuO_2 and it has hexagonal and cubic forms. The hexagonal phase is of the La_2O_3 "type A," rare earth sesquioxide structure and contains seven-coordinate Pu^{III} . The analogous Np phase probably exists as a bulk compound, but has not been as well studied. It has been observed in an XPS study on the oxidation of Np metal.⁴⁶ Ternary oxides are generally prepared from high temperature reactions of binary oxides. One class has the general formula PuMO_3 , where $\text{M} = \text{Al}, \text{V}, \text{Cr}, \text{Mn}$, and the perovskite structure, in which MO_6 octahedra are linked in a network and 12-coordinate Pu^{III} ions are located in the interstices between octahedra. Quaternary oxides of Pu^{III} are also known, such as $\text{Ba}_2\text{PuNbO}_6$ and $\text{Ba}_2\text{PuTaO}_6$.

Hydroxides. The hydrolysis and carbonate complexation of the actinides has been recently reviewed.⁴⁷ Plutonium(III) hydrolysis is not well known because Pu^{III} is readily oxidized to Pu^{IV} in aqueous solutions, particularly at near-neutral and basic pH. The first hydrolysis product, $\text{Pu}(\text{OH})^{2+}$, has been identified in acid solution up to pH ~ 3 (where it is about 70% formed) before oxidation to Pu^{IV} prevents further study.⁴⁸ The first hydrolysis product of Np^{III} has been similarly studied.⁴⁶ The hydroxide solids, $\text{Pu}(\text{OH})_3 \cdot x\text{H}_2\text{O}$ and $\text{Np}(\text{OH})_3 \cdot x\text{H}_2\text{O}$, are prepared by precipitation and presumed to be isostructural with $\text{Am}(\text{OH})_3$.

Carbonates. Trivalent actinide carbonates generally oxidize rapidly to An^{IV} species. Only the u^{III} and Np^{III} complexes of this type, generally prepared via reduction, have been studied in

any detail. In aqueous Pu^{III} solutions, there is evidence for the stepwise formation of the carbonate complexes, $\text{Pu}(\text{CO}_3)^+$ and $\text{Pu}(\text{CO}_3)_2$. Additional carbonate and hydroxocarbonate complexes may form, but are immediately oxidized to Pu^{IV} species. Neptunium(III) carbonate, hypothesized to be $\text{Np}(\text{CO}_3)_3^{3-}$, has been prepared by electrochemical reduction of Np^{IV} carbonate.⁴⁹

Nitrates and Phosphates. Trivalent nitrate species have been prepared in nitric acid solution, but they are unstable with respect to oxidation. A plutonium nitrate has been prepared, and by analogy with the lanthanides presumed to be $\text{Pu}(\text{NO}_3)_3$, although it was not characterized.⁵⁰ Neptunium and plutonium phosphates solution species are proposed to have the formula $\text{An}(\text{H}_2\text{PO}_4)_n^{3-n}$ ($n=1-4$), but not spectroscopically or structurally characterized.⁵¹ For Pu^{III} , the blue, hexagonal $\text{PuPO}_4 \cdot 0.5\text{H}_2\text{O}$ has been prepared by precipitation from acid solution and heated to yield the anhydrate. Additional binary, ternary, and quaternary phosphates have been prepared by Bamberger and others and have generally been characterized by chemical analysis, Raman, and X-ray powder diffraction.⁵²

Sulfates. Sulfate complexes in solution, of the form $\text{An}(\text{SO}_4)_n^{3-2n}$ ($n=1,2$), have been reported for Pu^{III} .⁵³ These anions can be precipitated as hydrates; and partially dehydrated solids can be obtained by addition of less polar solvents. There is some evidence for a Pu^{III} sulfate, $\text{Pu}_2(\text{SO}_4)_3 \cdot x\text{H}_2\text{O}$, but it is not as well characterized as the complex salts. Hydrated sulfato complexes of the type $\text{MAn}(\text{SO}_4)_2 \cdot x\text{H}_2\text{O}$, where An is U, Pu, and M is a monovalent cation, are known. The Pu^{III} sulfate, $\text{KPu}(\text{SO}_4)_2 \cdot \text{H}_2\text{O}$ and the dehydrate are isostructural with the Nd^{III} analogues. Similarly, the $\text{NH}_4\text{Pu}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ is isomorphous with the corresponding Ce^{III} compound. The structures of U^{III} sulfates have been reconsidered with some new X-ray diffraction data. A crystal structure of $(\text{NH}_4)_2\text{U}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ show that U is nine-coordinate with six oxygen atoms from four sulfate groups and the remaining three inner-sphere waters. A noncoordinated water is also present. The nonhydrate $(\text{NH}_4)_2\text{U}_2(\text{SO}_4)_4 \cdot 9\text{H}_2\text{O}$ likely contains nine and 12-coordinate U, in contrast with Am sulfate, $\text{Am}_2(\text{SO}_4)_3 \cdot 8\text{H}_2\text{O}$, which is comprised of eight coordinate Am^{III} .⁵⁴ Salts of other complex anions, such as $\text{K}_5\text{An}(\text{SO}_4)_4 \cdot 4\text{H}_2\text{O}$ are also known for Np^{III} and Pu^{III} .

Alkoxide Compounds. Despite the variety of higher valent actinide alkoxide complexes since the 1950s, successful preparations of trivalent actinide compounds employing alkoxide ligands have only appeared in the literature since the 1980s. Much of the attention regarding synthesis of trivalent actinide alkoxides has focused on the preparation of homoleptic uranium(III) aryloxide complexes. Among the earliest reports is that involving reaction of three equivalents of sodium phenoxide with $\text{UCl}_3(\text{THF})_x$ in THF, from which a light red-brown solution was obtained;⁵⁵ the reaction did not result in the isolation of $\text{U}(\text{OPh})_3$. It was later reported that alcoholysis of $\text{U}[\text{N}(\text{SiMe}_3)_2]_3$ with three equivalents of $\text{HO-2,6-R}_2\text{C}_6\text{H}_3$ ($\text{R}=\text{Bu}^t, \text{Pr}^i$) in hexane produced dark green ($\text{R}=\text{Bu}^t$) or dark purple ($\text{R}=\text{Pr}^i$) solutions from which homoleptic $[\text{U}(\text{O-2,6-R}_2\text{C}_6\text{H}_3)_3]_x$ ($\text{R}=\text{Bu}^t, x=1$; $\text{R}=\text{Pr}^i, x=2$) compounds were isolated⁵⁶ (see Equation (4)). The molecular structure of $[\text{U}(\text{O-2,6-Pr}^i_2\text{C}_6\text{H}_3)_3]_2$ demonstrates an unprecedented structure composed of a centrosymmetric bis η^6 -arene-bridged dimer (see Figure 3). Based upon analysis of the infrared spectrum, it was suggested that $\text{U}(\text{O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_3$ is monomeric. Similarly, hexane solutions of $\text{An}[\text{N}(\text{SiMe}_3)_2]_3$ ($\text{An}=\text{Np}, \text{Pu}$) react with three equivalents of $\text{HO-2,6-Bu}^t_2\text{C}_6\text{H}_3$ to form $\text{An}(\text{O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_3$.¹⁴

A number of adducts of uranium trisaryloxides are readily prepared. The THF adduct, $\text{U}(\text{O-2,4,6-Me}_3\text{C}_6\text{H}_2)_3(\text{THF})_2$, is isolated from the reaction of $\text{NaO-2,4,6-Me}_3\text{C}_6\text{H}_3$ with $\text{UCl}_3(\text{THF})_x$ in tetrahydrofuran.⁵⁷ Sattelberger and co-workers reported that the compound $\text{U}(\text{O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_3$ readily coordinates a number of Lewis bases (THF, EtCN, Ph_3PO) to form isolable, and presumably tetrahedral 1:1 adducts, $\text{LU}(\text{O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_3$.⁵⁶ Analysis of the $^1\text{H-NMR}$ spectra and infrared data suggest that both a 1:1 and 1:2 adduct are obtained upon coordination of CNBu^t to $\text{U}(\text{O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_3$.⁵⁸ Alternatively, a THF adduct can simply be prepared by allowing three equivalents of $\text{KO-2,6-R}_2\text{C}_6\text{H}_3$ ($\text{R}=\text{Pr}^i, \text{Bu}^t, x=1$; $\text{R}=\text{Me}, x=2$) to react with $\text{U}(\text{I}_3)(\text{THF})_4$ in tetrahydrofuran to produce a dark red solution from which $\text{U}(\text{O-2,6-R}_2\text{C}_6\text{H}_3)_3(\text{THF})_x$ is isolated⁵⁹ (see Equation (5)):

Figure 3 Crystal structure of $[\text{U}(\text{O}-2,6\text{-Pr}^i_2\text{C}_6\text{H}_3)_2]_2$ (Van Der Sluys, Burns *et al.* *Inorg. Chem.* **1998**, *110*, 5924).

An assessment of the relative binding constants of Lewis bases with different donor sites (triphenylphosphine oxide, *N,N*-di-*iso*-propylbenzamide, 4,4'-dimethoxybenzophenone) to the Pu^{III} trisaryloxide, $\text{Pu}(\text{O}-2,6\text{-Bu}^t_2\text{C}_6\text{H}_3)_3$, has been reported using variable temperature ^1H -NMR spectroscopy.⁶⁰

Only one study has suggested the formation of an actinide(III) alkoxide ($-\text{OR}$) compound in which R is an alkyl. A recent investigation of the reactivity of Pu^{III} *iso*-propoxide, prepared *in situ* from the reaction of $\text{Pu}[\text{N}(\text{SiMe}_3)_2]_3$ and three equivalents HOPr^i , indicates that the trivalent alkoxide complex is an effective catalyst in the Meerwein–Ponndorf–Verley reduction of ketones by isopropanol.⁶¹

Triflate complexes. Another recent addition to this class of compounds is the isolation of a trivalent trifluoromethanesulfonate ($\text{OTf}^- = \text{triflate}$) derivative of uranium, $\text{U}(\text{OTf})_3$, from the reaction of UH_3 and triflic acid.⁶² A Lewis base adduct of the complex was prepared to facilitate characterization; the complex $[\text{U}(\text{OTf})_2(\text{OPPh}_3)_4][\text{OTf}]$ has been crystallographically characterized, and possesses both a monodentate and a bidentate triflate ligand in the coordination sphere of the metal.

Sulfur donor ligands. A ligand related to the pyrazolylborate family has been employed to stabilize a U^{III} cation. The reaction of bis(2-mercapto-1-methylimidazolyl)borate, $[\text{H}(\text{R})\text{-B}(\text{timMe})_2]^-$ ($\text{R} = \text{H}, \text{Ph}$) with $\text{UI}_3(\text{THF})_4$ and $\text{Ti}(\text{BPh}_4)$ generates the ionic species $\{\text{U}[\text{H}(\text{R})\text{B}(\text{timMe})_2](\text{THF})_3\}^+\{\text{BPh}_4\}^-$.⁶³ The uranium atom in these species lies within a distorted tricapped trigonal prism of ligands consisting of four sulfur atoms and two hydrogen atoms from the borate ligands and three THF oxygen atoms (Figure 4).

(iv) Ligands containing neutral group 16 donor atoms

The class of oxo-donor atom ligands is the most prevalent in actinide coordination chemistry, owing to their predominant use in separation chemistry of the *f*-elements.

Aqua species. A number of investigations of trivalent actinide ions in aqueous media have been directed at identifying the coordination environment of the metal center. Examination by luminescence, X-ray absorption (i.e., extended X-ray absorption fine structure (EXAFS)), and NMR spectrometry suggest that the early actinides are likely ligated by nine water molecules.^{64–68} Confirmation of this assignment may be found in the crystal structure of $[\text{Pu}(\text{H}_2\text{O})_9][\text{CF}_3\text{SO}_3]_3$, prepared by the dissolution of plutonium metal in triflic acid.⁶⁹ The plutonium ion in this complex is coordinated by nine water molecules arranged in an ideal tricapped trigonal prismatic geometry with $\text{Pu}-\text{O}$ distances of 2.574(3) Å and 2.476(2) Å (Figure 5).

Figure 4 Crystal structure of $\{U[H(R)B(timMe)_2]_2(THF)_2\}\{BPh_4\}$ (Maria, Domingos *et al. Inorg. Chem.* **2001**, *40*, 6863).

Figure 5 Crystal structure of $[Pu(H_2O)_9][CF_3SO_3]_3$, showing Pu^{III} aqua with ideal tricapped trigonal prismatic geometry (Matonic, Scott *et al. Inorg. Chem.* **2000**, *40*, 2638).

There are many examples of hydrates of solid actinide halide complexes (see Table 4). In some instances, the complexes are reported to be easily dehydrated, and it is therefore suggested that the metal ion is not coordinated by water. This is most often the case where $X = F$, and strong $M-F-M$ bridge bonding in the solid precludes the formation of molecular hydrates. In other cases, complexes (e.g., $AnCl_3 \cdot 6H_2O$, $An = Pu, Am$; $AnBr_3 \cdot 6H_2O$, $An = U, Np, Pu$) and have been found to be isostructural with known lanthanide halide hydrates of the formula $[LnX_2(H_2O)_6]X$. The molecular structure of the anionic complex $[NH_4][UCl_4(H_2O)_4]$ has been reported.⁷⁰

Ethers, cyclic ethers. The complex $UCl_3(THF)_n$ was reported by Moody *et al.*⁷¹ and subsequently used by a number of researchers as a precursor for entry into U^{III} chemistry. The molecular nature of the complex was not well characterized, however. Subsequently, the complex $UI_3(THF)_4$ was prepared via halide oxidation of uranium metal and structurally characterized.¹³ The metal center is found to lie within a pentagonal bipyramidal coordination environment, with

two axial and one equatorial iodide ligands. Neptunium and plutonium analogues of this complex have been reported,^{14,34,35} these species now serve as the most common reagents for entry into trivalent actinide molecular chemistry.

Carbamides. A series of U^{III} homoleptic complexes of the ligands antipyrine (2,3-dimethyl-1-phenylpyrazol-5-one, ap) and pyrimidone (4-dimethylaminoantipyrine, dma) have been prepared from complex halide precursors in the presence of the appropriate ligand. Reaction of RbUCl₄·5H₂O with ap results in the formation of the ionic species [U(ap)₆]Cl₃, whereas reaction of NH₄UCl₄·5H₂O and NaBPh₄ with these ligands yields the corresponding tetraphenylborate species, [U(ap)₆](BPh₄)₃ and [U(dma)₆](BPh₄)₃.^{72,73}

Phosphine oxides. The complex [U(OTf)₂(OPPh₃)₄][OTf] (OTf = triflate) has been prepared by the reaction of U(OTf)₃ with phosphine oxide. One of the inner sphere triflate ligands is monodentate, and the other is bidentate, supporting an overall pentagonal bipyramidal coordination environment about the uranium center.⁶²

(v) Ligands containing group 17 donor atoms

The preparation and properties of halides of the actinides have been described fully.⁷ As most of these complexes are solid state, rather than molecular in nature, only overview information on classes of compounds will be provided. Adducts of the halide complexes will be discussed in the context of compounds of the respective Lewis bases (*vide infra*).

Binary halides. Trihalide complexes of all elements Ac–Pu have been reported except for thorium and protactinium; trihalide complexes are among the few reported complexes of actinium. The trifluorides, MF₃ (M = Ac, U, Np, Pu), exist in a LaF₃-type structure. Most can be prepared by precipitation from solution or hydrofluorination of oxides, although the uranium fluoride is formed in reduction reactions, and is highly sensitive to hydrolysis. The trichlorides, MCl₃ (M = Ac, U, Np, Pu) and tribromides, MBr₃ (M = Ac, U, α-Np), adopt the UCl₃-type structure in which the nine-coordinate metal atom lies at the center of a tricapped trigonal prism. β-NpBr₃ and PuBr₃ have the eight-coordinate PuBr₃-type structure in which the coordination geometry is a bicapped trigonal prism and this is found also for the triiodides, MI₃ (M = U, Np, Pu). The complexes PaI₃ and ThI₃ have been reported, although their identification is more tentative.

Complex halides. Ternary fluoride complexes of trivalent uranium, neptunium, and plutonium are well known, and are formed by the reaction of binary halides and additional metal halides (alkali halides) in melts, solvents such as thionyl chloride, or by precipitation from aqueous solution. Fewer chloroactinates and bromoactinates are known. Complexes of the formula MAnX₄, M₂AnX₅, M₃AnX₆, M'AnX₅, and M'₂AnX₇ (M = alkali metal; M' = alkaline earth) are the most common, although more complex formulations (e.g., MAn₂Cl₇) have also been reported.

Common structural types have been reported among these groups of compounds. The complex NaPuF₄ is isostructural with NaNdF₄⁷⁴ and therefore consists of a tricapped trigonal prismatic

arrangement of fluorine atoms about the metal center. Published reports on the complex CsUCl_4 differ in their assignment of the symmetry of the structure.^{75,76} The compounds M_2AnX_5 contain metal centers in either a monocapped trigonal prismatic or distorted pentagonal bipyramidal coordination environment.^{77,78} Diffraction data for SrUCl_5 is available, although the structure has not been unambiguously assigned.⁷⁶ Complexes of the formula $\text{M}'_2\text{AnX}_7$ are isostructural with related lanthanide complexes, and are therefore assumed to contain metal centers that lie within a monocapped trigonal prismatic arrangement of halide ions.^{76,79} Complexes of the formula M_3AnCl_6 are known for uranium, neptunium, and plutonium; these compounds contain isolated AnCl_6^- ions.⁷⁶

3.3.2.1.3 Chelating ligands

(i) Multidentate donor ligands

Hydroxamate. Hydroxamate complexes of trivalent actinides can be prepared directly in aqueous solution and other polar solvents and extracted into organic solvents, but due to the high thermodynamic stability of the corresponding tetravalent actinide complexes they are rapidly oxidized. They can also be prepared in solution via electrochemical reduction of the tetravalent complexes. These complexes have been studied for their role in separating high and low valent actinides in nuclear fuel processing schemes.⁸⁰

Catecholate. Am^{III} and Pu^{III} complexes of sulfonated and carboxylated catecholamide ligands (CAMS and CAMC), including potentially octadentate chelators have been studied for their potential utility in removing actinides from humans via chelation. The complex coordination is pH dependent, with a triscatecholate Pu^{III} complex forming above pH 12. The stoichiometry of the Am^{III} complex was not determined; however, its optical absorbance characteristics were determined.⁸¹

8-Hydroxyquinoline and derivatives. Trivalent plutonium complexes with 8-hydroxyquinoline (Oxine, Ox) of the formula $\text{An}(\text{Ox})_3$ are prepared by precipitation from aqueous solution in the presence of sulyte or dithionite as a reducing agent (to retain An^{III}). Attempts to prepare analogous U^{III} and Np^{III} complexes result in immediate oxidation.

Oxalate. The trivalent oxalates have been widely used in actinide separation and purification. For this application the very low solubility and physical properties of $\text{Pu}_2(\text{C}_2\text{O}_4)_3 \cdot x\text{H}_2\text{O}$ are key. These solids are often precursors that are dehydrated and fired to produce oxides, such as PuO_2 and AmO_2 .

Oxalate complexes in solution are mainly of the form, $\text{Pu}(\text{C}_2\text{O}_4)_n^{3-2n}$, $n = 2-4$. The intermediate $\text{Pu}(\text{C}_2\text{O}_4)_3^{3-}$ is relatively unimportant, as is the species $\text{Pu}(\text{HC}_2\text{O}_4)_4^-$, which predominates in the narrow pH range 1.7 to 2.2.⁸²

Polyoxometallates. Polyoxometallates of the group 6 transition metals (iso- and heteropolyoxoanions) form a special class of metallate ligands for the actinide elements. These species can incorporate other atoms as either primary or secondary (peripheral) heteroatoms. Primary heteroatoms are necessary to complete the polyoxoanion structure; secondary heteroatoms can be removed without disruption of the stable polyanion unit. The early actinides serve in both roles in known compounds.

The relative large ionic radii of actinide cations require polyoxometallate ligands that can generate high coordination numbers at the metal center. Complexes of three main classes of polyoxoanions have been described: decatungstometallates $[\text{An}^{\text{IV}}\text{W}_{10}\text{O}_{36}]^{8-}$, $\text{An} = \text{Th}, \text{U}$; dodecamolybdometallates $[\text{An}^{\text{IV}}\text{Mo}_{12}\text{O}_{42}]^{8-}$, $\text{An} = \text{Th}, \text{U}$, or Np ; and derivatives of the Keggin and Dawson structures, $[\text{An}[\text{XW}_{11}\text{O}_{39}]_2]^{n-}$ and $[\text{An}[\text{X}_2\text{W}_{17}\text{O}_{61}]_2]^{n-}$ ($\text{X} = \text{P}, \text{Si}, \text{B}, \text{As}$; $\text{An} = \text{Th}, \text{U}, \text{Np}, \text{Pu}$). Of these, only one has been reported to stabilize a trivalent actinide. Reaction of Pu^{III} with the anions $\text{PW}_{11}\text{O}_{39}^{7-}$, $\text{P}_2\text{W}_{17}\text{O}_{61}^{10-}$, $\text{SiW}_{11}\text{O}_{39}^{8-}$, $\text{BW}_{11}\text{O}_{39}^{9-}$, and $\text{AsW}_{11}\text{O}_{39}^{7-}$, result in the isolation of 1:2 ($\text{An}:\text{ligand}$) complexes as potassium or cesium salts.⁸³

(ii) Macrocyclic ligands

Crown ethers. Metal and crown ether complexes have to fulfill two requirements to form stable complexes. First, the coordination sphere of the metal must be stabilized by the crown ether and any complexing anions. A trivalent uranium coordination sphere is typically satisfied

with a coordination number between seven or eight for crown ether inclusion complexes. Second, the oxidation state of the metal must be counterbalanced to neutralize the charge. This is easily accomplished with numerous ligands, ranging from coordinating species such as nitrate to those that are relatively noncoordinating like perchlorate. Through the use of EXAFS analysis using the uranium L_{III} absorption edge, as well as X-ray single crystal diffraction, a proposed solution of U^{III} forming an inclusion complex with dicyclohexyl-18-crown-6 (dch-18-crown-6) has been determined. The uranium is bound in a *trans* manner to two BH_4^- anions, yielding the monovalent cation, $U(BH_4)_2^+$. When the $U(BH_4)_2^+$ complexes with dch-18-crown-6, the proposed structure is similar to that of $(UO_2)(dch-18-crown-6)$, to be discussed later in this chapter. The resulting geometry around the U^{III} is hexagonal bipyramidal with equatorial crown ether complexation. The anion for the complex is a trivalent uranium ion oxidized to the U^{IV} species and complexed with five chlorides and one BH_4^- , giving the divalent anion $[U^{IV}Cl_5BH_4]^{2-}$. The coordination environment of the anion is pseudo-octahedral.⁸⁴

3.3.2.1.4 Borohydride and aluminohydride ligands

Borohydride compounds of trivalent actinides are limited to those of uranium. The initial reports of $U(BH_4)_3$ indicated it was prepared from thermal or photochemical decomposition of $U(BH_4)_4$ ^{85–89} as in Equation (6):

Other methods for its preparation invariably result in the isolation of Lewis base adducts. The complexes $U(BH_4)_3(THF)_x$ ⁷¹ and $U(BH_4)_3(18-crown-6)_2$ ⁹⁰ were prepared by the metathesis reaction of $LiBH_4$ with $UCl_3(THF)_x$ or $UCl_3(18-crown-6)$ in THF. Although the stoichiometry of the THF adduct was not characterized in the initial report, the compound was later prepared from the reaction of UH_3 and BH_3 in THF, and characterized to be $U(BH_4)_3(THF)_3$.⁹¹ The molecular structure of the compound reveals that it adopts an octahedral geometry about the metal center with the borohydride and THF ligands mutually facial; all borohydride ligands are tridentate.

The THF adduct of $U(BH_4)_3$ serves as a useful reagent in the synthesis of other base adducts. Reaction of $U(BH_4)_3(THF)_x$ with dmpe (1,2-dimethylphosphinoethane) results in the formation of $U(BH_4)_3(dmpe)_2$.⁴³ The uranium center in this complex has a pentagonal bipyramidal geometry (considering each BH_4 unit as one ligand). Two of the borohydride ligands are tridentate, while the third is bidentate, presumably owing to steric encumbrance at the metal center. Reduction in the coordination number reduces this strain; the five-coordinate complex $U(BH_4)_3(Ph_2Ppy)_2$, similarly prepared from the reaction of $U(BH_4)_3(THF)_x$ and 2-(diphenylphosphino)pyridine, possess three tridentate borohydride ligands.⁴⁴

Trivalent borohydride Lewis base adduct complexes can also be prepared by reduction of their tetravalent analogues. Reduction of $U(BH_4)_4$ in the presence of phosphines is reported to yield the adducts $U(BH_4)_3L_2$ ($L = PEt_3, PEt_2Ph$).⁹² Thermolysis of $U(MeBH_3)_4(dmpe)$ in the presence of excess dmpe results in reduction of the metal center to generate the complex $U(MeBH_3)_3(dmpe)_2$.⁴⁵ In select cases, reduction leads to the formation of polymetallic complexes. Reduction of $U(BH_4)_4$ in the presence of crown ether ligands such as 18-crown-6 or dicyclohexyl-(18-crown-6) generates products of the overall stoichiometry $U_3(BH_4)_9(crown)_2$.⁹³ Subsequent investigation of the complex $U_3(BH_4)_9(18-crown-6)_2$ by EXAFS suggest a structural model in which $U(BH_4)_2^+$ cations are coordinated within the cavity of the crown ligands, while the other uranium resides within a $[U(BH_4)_5]^{2-}$ coordination environment.⁹⁴

Trivalent cationic and anionic borohydride complexes have also been generated. Protonation of $U(BH_4)_3(THF)_3$ with $[NEt_3H][BPh_4]$ yields the cationic species $[U(BH_4)_2(THF)_5][BPh_4]$.⁹⁵ The uranium atom adopts a pentagonal bipyramidal geometry, with tridentate borohydride ligands in the apical positions. The anionic compound $[Na(18-crown-6)][U(BH_4)_4]$ has been isolated from the reaction of $U(BH_4)_3(THF)_3$ with $NaBH_4$ in the presence of 18-crown-6.⁹⁶

Attempts have been made to isolate aluminohydride analogs in trivalent chemistry. Reaction of UCl_3 with three equivalents of $LiAlH_4$ yields a gray powder, proposed to be $U(AlH_4)_3$.⁹⁷ The complex is reported to decompose at temperatures above $-20^\circ C$.

3.3.2.2 Tetravalent Oxidation State

3.3.2.2.1 General characteristics

All early actinides from thorium to plutonium possess a stable +4 ion in aqueous solution; this is the most stable oxidation state for thorium and generally for plutonium. The high charge on tetravalent actinide ions renders them susceptible to solvation, hydrolysis, and polymerization reactions. The ions are readily hydrolyzed, and therefore act as Brønsted acids in aqueous media, and as potent Lewis acids in much of their coordination chemistry (both aqueous and nonaqueous). Ionic radii are in general smaller than that for comparable trivalent metal cations (effective ionic radii = 0.96–1.06 Å in eight-coordinate metal complexes),¹¹ but are still sufficiently large to routinely support high coordination numbers.

3.3.2.2.2 Simple donor ligands

(i) Ligands containing group 14 donor atoms

The small steric size and propensity of cyanide groups to bridge metal centers have limited their use as ligands in molecular coordination chemistry of the actinides, where they are prone to form amorphous polymeric products. Limited metathesis studies have been conducted. Reaction of tetravalent halides with alkali metal cyanides in liquid ammonia is reported to give rise to a product of the formula $UX_3(CN) \cdot 4NH_3$,⁹⁸ whereas use of the larger thorium ion yields unidentified products.

The neutral isocyanide ligands (CNR, R = alkyl, aryl) have been used extensively in organometallic actinide chemistry, where they are commonly observed to undergo insertion reactions into metal-carbon sigma bonds.^{99,100} These ligands are relatively weak bases in coordination chemistry, however, and few complexes have been isolated. Lewis base adducts of a tetravalent halides, $AnX_4(CNc-C_6H_{11})_4$ (An = Th, X = I; An = U, X = Cl, Br, I), were generated by direct reaction of the constituents in organic solvent.¹⁰¹ As is characteristic for isocyanide ligands acting principally as σ -donor ligands, the isocyanide $\nu C-N$ band in the IR spectra of these complexes moves approximately 50 cm^{-1} to higher frequency than that in free isocyanide ligand.

(ii) Ligands containing anionic group 15 donor atoms

Amide complexes. The first report of a tetravalent actinide amide complex was the isolation of $U(NEt_2)_4$.¹⁰² In general, compounds of the formula $An(NR_2)_4$ (An = Th, U) are generated by reaction of metal tetrahalides and alkali metal amide salts in nonaqueous solvents. $U(NEt_2)_4$ has been found to exist as a dimer both in the solid state and in benzene solution,¹⁰³ with uranium centers bridged by two diethylamido groups. With even smaller alkyl substituents, larger aggregates are obtained; the molecular structure of $U(NMe_2)_4$ reveals it to be a trimer in the solid state.¹⁰⁴ Each metal lies within a roughly octahedral arrangement of amide ligands, with the central metal sharing an octahedral face with each of its neighboring uranium centers. The polymeric structures can be broken up by the addition of Lewis bases; addition of two equivalents of hexamethylphosphoramide (HMPA) to $U(NMe_2)_4$ leads to the isolation of the monomeric base adduct $U(NMe_2)_4(HMPA)_2$,¹⁰⁵ which exists as a mixture of *cis*- and *trans*-isomers in solution. Monomeric homoleptic anionic complexes can also be isolated; reaction of UCl_4 with excess lithium amide salts $LiNMe_2$ and $LiNEt_2$ in THF results in the isolation of the complexes $[Li(THF)]_2[U(NMe_2)_6]$ and $[Li(THF)][U(NEt_2)_5]$, respectively.¹⁰⁶

Larger amide ligands give rise to monomeric products. $U(NPh_2)_4$ may be prepared either by reaction of UCl_4 with $LiNPh_2$, or by aminolysis reaction of $HNPh_2$ with $U(NEt_2)_4$, or the uranium metallacycle $U[N(SiMe_3)(SiMe_2CH_2)][N(SiMe_3)_2]_2$.^{107,108} The uranium atom lies within a severely distorted tetrahedron of nitrogen atoms. If the filtrate from the metathesis reaction is allowed to react slowly with air, a product of partial hydrolysis is isolated ($[Li(OEt_2)\{UO(NPh_2)_3\}_2]$), which contains terminal amide ligands and two μ^3 -Li, U, U'-oxo ligands. Higher coordination numbers can be observed; reaction of $ThBr_4(THF)_x$ with four equivalents of $KNPh_2$ in THF results in the isolation

of $\text{Th}(\text{NPh}_2)_4(\text{THF})$, while use of the smaller amide NMePh^- yields the bis-tetrahydrofuran adduct $\text{Th}(\text{NMePh})_4(\text{THF})_2$.¹⁰⁹ A related five-coordinate amide complex $\text{K}[\text{Th}(\text{NMePh})_5]$ can be prepared by reaction of thorium tetrabromide with five equivalents of $\text{K}(\text{NMePh})$.

The smaller alkylamide complexes are susceptible to redistribution reactions. Reaction of UCl_4 and $\text{U}(\text{NEt}_2)_4$ in a 1:1 or 3:1 ratio generates the complexes $\text{U}(\text{NEt}_2)_2\text{Cl}_2$ and $\text{U}(\text{NEt}_2)\text{Cl}_3(\text{THF})$ in high yield.¹¹⁰ In contrast, the complex $\text{U}(\text{NEt}_2)_3\text{Cl}$ is not stable in solution, but exists in equilibrium with $\text{U}(\text{NEt}_2)_2\text{Cl}_2$ and $\text{U}(\text{NEt}_2)_4$.

The bis(trimethylsilyl)amido ligand has been used extensively in supporting the tetravalent chemistry of thorium and uranium. Tetravalent complexes of the formula $\text{ClAn}[\text{N}(\text{SiMe}_3)_2]_3$ ($\text{An} = \text{Th}, \text{U}$) have been prepared¹¹¹ from the 3:1 reaction of $\text{NaN}(\text{SiMe}_3)_2$ with AnCl_4 (Equation (7)), and the complex $\text{Cl}_2\text{U}[\text{N}(\text{SiMe}_3)_2]_2(\text{DME})$ can be generated from a 2:1 reaction of ligand:halide salt.¹¹² Substituted complexes of the formula $\text{RAn}[\text{N}(\text{SiMe}_3)_2]_3$ ($\text{An} = \text{Th}, \text{U}$; $\text{R} = \text{Me}, \text{Et}, \text{Pr}^i, \text{Bu}, \text{BH}_4$) are formed by the reaction of $\text{ClAn}[\text{N}(\text{SiMe}_3)_2]_3$ with the appropriate lithium or magnesium reagents.^{111,113} Unlike comparable cyclopentadienyl analogues, the methyl compound does not undergo ready insertion of CO, although a number of other insertion and protonation reactions have been reported, including insertion of ketones, aldehydes, isocyanides, and aliphatic nitriles.^{113,114} The methyl ligand is further susceptible to removal by protic reagents such as secondary amines:

The hydride compounds $\text{HAn}[\text{N}(\text{SiMe}_3)_2]_3$ ($\text{An} = \text{Th}, \text{U}$) are the sole products of attempts to introduce an additional equivalent of the bis(trimethylsilyl)amide ligand.¹¹⁵ Reaction of the uranium hydride complex with the Lewis acid $\text{B}(\text{C}_6\text{F}_5)_3$ results in loss of H_2 and formation of the zwitterionic product $\text{U}^+[\text{N}(\text{SiMe}_3)_2]_2[\text{N}(\text{SiMe}_3)(\text{SiMe}_2\text{CH}_2\text{B}^-(\text{C}_6\text{F}_5)_3)]$.¹¹⁶

Pyrolysis of the hydrides result in the loss of dihydrogen and the formation of an unusual metallocycle¹¹⁷ (see Equation (8)):

The metallocycles of uranium and thorium have been shown to undergo a large number of insertion and protonation reactions,^{118–124} as shown in Figure 6. In some cases these reactions (such as reduction of carbonyl-containing organic compounds) have been found to be stereoselective.

Reactions of the metallocycle complexes with protic reagents are frequently used to generate derivatives. For example, reaction of $\text{An}[\text{N}(\text{SiMe}_3)(\text{SiMe}_2\text{CH}_2)]_2[\text{N}(\text{SiMe}_3)_2]_2$ ($\text{An} = \text{Th}, \text{U}$) with excess aryl alcohols generates the complexes $\text{An}(\text{O}-2,6-\text{R}_2\text{C}_6\text{H}_3)_3[\text{N}(\text{SiMe}_3)_2]$,^{125,126} and reaction with a stoichiometric amount of aryl alcohol or aryl thiol yields the mixed ligand complexes $\text{An}(\text{E}-2,6-\text{R}_2\text{C}_6\text{H}_3)[\text{N}(\text{SiMe}_3)_2]_3$ ($\text{E} = \text{O}, \text{S}$).^{126,127} Reaction of the thorium metallocyclic complex $\text{Th}[\text{N}(\text{SiMe}_3)(\text{SiMe}_2\text{CH}_2)]_2[\text{N}(\text{SiMe}_3)_2]_2$ with smaller protic amines similarly results in incomplete transamination; reaction with four equivalents of HNMePh yields only the mixed amide complex $\text{Th}(\text{NMePh})_2[\text{N}(\text{SiMe}_3)_2]_2$.¹⁰⁹

The bis(trimethylsilyl)amide ligand is capable of supporting the formation of organoimido complexes at actinide centers. The tetravalent uranium dimer $\{\text{U}[\text{N}(\text{SiMe}_3)_2]_2(\mu\text{-N-}p\text{-C}_6\text{H}_4\text{Me})\}_2$ was prepared by reaction of $\text{ClU}[\text{N}(\text{SiMe}_3)_2]_3$ with $\text{LiHN}(p\text{-C}_6\text{H}_4\text{Me})$,¹²⁸ presumably by α -elimination of $\text{HN}(\text{SiMe}_3)_2$ from an intermediate amide complex. As observed for the related cyclopentadienyl compound, the arylimido ligand bridges the two metal centers in an asymmetric fashion, with $\text{U}-\text{N}$ bond distances of 3.378(3) Å and 2.172(2) Å.

Tris(amido)amine ligands, $\text{N}[\text{CH}_2\text{CH}_2\text{NR}]_3^{3-}$ ($\text{R} = \text{trialkylsilyl}$), support unusual reactivity in the early actinides. Complexes of both thorium and uranium have been generated by metathesis reactions involving both the ligands $\text{N}[\text{CH}_2\text{CH}_2\text{N}(\text{SiMe}_3)]_3^{3-}$ and $\text{N}[\text{CH}_2\text{CH}_2\text{N}(\text{Si}(\text{Bu}^t)\text{Me}_2)]_3^{3-}$.

Figure 6 Reactions of uranium metallacycle $\text{Ux}[\text{N}(\text{SiMe}_3)(\text{SiMe}_2\text{CH}_2)]_2[\text{N}(\text{SiMe}_3)_2]_2$.

The complexes $[\{\text{N}[\text{CH}_2\text{CH}_2\text{NSiMe}_3]_3\}\text{AnCl}]_2$ ($\text{An} = \text{Th, U}$) were first reported;¹²⁹ the molecular structure of the uranium complex demonstrated it was dimeric in the solid state. The chloride ligand may be substituted, and derivatives incorporating cyclopentadienyl, borohydride, alkoxide, amide, and diazabutadiene derivatives have been characterized.^{130–132} Attempts to alkylate the complex $\text{N}[\text{CH}_2\text{CH}_2\text{N}(\text{Si}(\text{Bu}^t)\text{Me}_2)]_3\text{UI}$ with alkyl lithium or alkylpotassium reagents resulted in

the isolation of a metallacyclic product resulting from intramolecular activation of a methyl group, as shown in Equation (9):¹³⁴

The U—C bond length in the metallacyclic unit is unusually long (2.752(11) Å), and is susceptible to protonation by alcohols, amines, and terminal alkynes; reaction with pyridine leads to the generation of a η^2 -pyridyl complex.

The bulky amide ligand, NRAr- (R = Bu^t, adamantyl; Ar = 3,5-Me₂C₆H₃) has been used to synthesize monomeric complexes of U^{IV}. Complexes of the formula UI(NRAr)₃ may be prepared by the reaction of UI₃(THF)₄ with LiNRAr;²¹ oxidation of the uranium center is presumed to be accompanied by sacrificial generation of U⁰. A limited number of tetravalent derivatives of this ligand set have been reported, including the silyl complex [N(*t*-Bu)Ar]₃USi(SiMe₃)₃¹³⁵ and the bridging cyanoimide complex [N(Bu^t)Ar]₃U(μ-CN)U[N(Bu^t)Ar]₃ (Ar = 3,5-Me₂C₆H₃).¹³⁶ Reaction of the trivalent complex with Mo[NPh(R')]₃ (R' = Bu^t, adamantyl) under dinitrogen results in the formation of (NRAr)₃U(μ-N₂)Mo[NPh(R')]₃, which contains a linear Mo—N—N—U unit.²¹ Both metals are seemingly best regarded as tetravalent. Reduction of UI(NRAr)₃ by KC₈ in toluene has been found to give rise to an interesting series of bridging arene complexes.^{137,138} Reduction of IU[N(R)Ar]₃ (R = Bu^t, Ar = 3,5-Me₂C₆H₃) by KC₈ generates the complex (μ-C₇H₈){U[N(R)Ar]₃}₂. A related compound (μ-C₇H₈){U[N(R)Ar]₃}₂ (R = adamantyl), could also be generated in low yield by reaction of UI₃(THF)₄ with LiN(R)Ar(OEt₂) in toluene. These species serve as convenient precursors into U^{IV} derivatives. Reaction of (μ-C₇H₈){U[N(R)Ar]₃}₂ (R = Bu^t, Ar = 3,5-Me₂C₆H₃) with Ph₂S₂ generates a dimeric thiolate-bridged species, [U(μ-SPh)(SPh)[N(R)Ar]₂]₂, and reaction of the μ-arene complex with azobenzene yields the bridging imido complex [U(μ-NPh)[N(R)Ar]₂]₂.¹³⁷

Polymetallic species are formed in the aminolysis reactions of U(NEt₂)₄ with chelating diamines.^{107,139} Reaction of U(NEt₂)₄ with *N,N'*-dimethylethylenediamine generates principally a trimeric product, U₃(MeNCH₂CH₂NMe)₆; a tetramer U₄(MeNCH₂CH₂NMe)₈ is obtained as a byproduct. Bimetallic complexes are similarly formed when bi- or polydentate ligands are used. The introduction by metathesis of the potentially tridentate ligand [(Prⁱ)₂PCH₂CH₂]₂N[−] into the coordination sphere of thorium and uranium sheds light on the relative ionic radius of the two metals. Reaction of ThCl₄ with two equivalents of the amide salt results in the formation of {[(Prⁱ)₂PCH₂CH₂]₂N[−]ThCl(μ-Cl)}₂, in which each metal center is seven-coordinate. Each amide ligand is bidentate through the amide and one phosphine donor site; one pendant phosphine arm remains uncoordinated. In contrast, structural characterization of the analogous uranium complex reveals that eight-coordinate metal centers are in the dimeric complex; one amide ligand is tridentate, while the second is bidentate, with an uncomplexed phosphine arm.¹⁴⁰

A series of cationic uranium amide complexes have recently been generated by protonation of neutral amide precursors with an acidic trialkylammonium salt of the weakly coordinating anion tetraphenylborate. The neutral species U(NEt₂)₂Cl₂ and U(NEt₂)Cl₃(THF) may be treated with NHET₃BPh₄ to generate the cationic species [U(NEt₂)Cl₂(THF)₂][BPh₄]⁺ and [UCl₃(THF)₂][BPh₄]⁺, respectively. Reaction of NHET₃BPh₄ with U(NEt₂)₄ generates the monocation [U(NEt₂)₃]⁺; this can be further protonated in refluxing THF to generate the dication [U(NEt₂)₂(THF)₃]²⁺. Similarly, reaction of [U(NEt₂)Cl₂(THF)₂][BPh₄]⁺ with additional ammonium salt at room temperature results in the formation of [UCl₂(THF)₄]²⁺. The molecular structure of [U(NEt₂)₃(THF)₃][BPh₄]⁺ (Figure 7) and the pyridine adduct [U(NEt₂)₂(py)₅][BPh₄]⁺¹¹⁰ have been reported. The former contains a pseudooctahedral uranium atom, with a facial arrangement of amide ligands. The latter possesses *trans* amide ligands, with five pyridine ligands arrayed in the equatorial plane. Attempts to reduce U^{IV} cationic species such as [U(NEt₂)₃]⁺ with sodium amalgam resulted only in the isolation of U(NEt₂)₄, suggesting disproportionation of the uranium-(III) intermediate.¹⁴¹ The cationic species [U(NEt₂)₃][BPh₄]⁺ has been demonstrated to catalyze the dehydrocoupling of primary alkylamines and phenylsilane to generate the aminosilanes PhSiH_{3-x}-(NHR)_x (x = 1–3).¹⁴² In addition, the same species will catalyze the selective dimerization of terminal alkynes.¹⁴³

Figure 7 Crystal structure of $[\text{U}(\text{NEt}_2)_3(\text{THF})_3][\text{BPh}_4]$ (Berthet, Boisson *et al.* *J. Chem. Soc., Dalton Trans.* **1995**, 3019).

Amidinate complexes. Amidinate ligands have been employed as ancillary ligands in the generation of compounds of tetravalent uranium and thorium. Reaction of $\text{Li}[\text{N}(\text{SiMe}_3)_2]$ and $\text{Na}[\text{N}(\text{SiMe}_3)_2]$ with *para*-substituted benzonitriles yields the benzamidinate ligands $\text{M}[4\text{-RC}_6\text{H}_4\text{C}(\text{NSiMe}_3)_2]$ ($\text{M} = \text{Li}, \text{Na}$; $\text{R} = \text{H}, \text{Me}, \text{OMe}, \text{CF}_3$). Alternatively, more substituted $\text{Li}[2,4,6\text{-R}_3\text{C}_6\text{H}_2\text{C}(\text{NSiMe}_3)_2]$ ($\text{R} = \text{CF}_3, \text{Me}$) is generated by the addition of aryllithium reagents to $\text{Me}_3\text{SiNCNSiMe}_3$. Amidinate ligands (L) have been used to generate complexes of the formula L_2AnCl_2 ($\text{An} = \text{Th}, \text{U}$) and L_3AnCl (for less sterically demanding substituents) by metathesis reactions.¹⁴⁴ Substitution of the halide precursors has been reported to generate methyl and borohydride derivatives.¹⁴⁵ The molecular structure of the complex $[\text{C}_6\text{H}_5\text{C}(\text{NSiMe}_3)_2]_3\text{UMe}$ has been determined. The benzamidinate ligands coordinate to the metal center in a η^3 -manner; the relatively long $\text{U}-\text{C}$ σ bond of $2.498(5)\text{\AA}$ is taken as an indication of steric crowding in the complex. Related amidinate and 1-aza- allyl ligands also have been shown to generate bis-(ligand)thorium dichloride complexes,¹⁴⁶ as well as an interesting mixed valence $\text{U}^{\text{III}}/\text{U}^{\text{IV}}$ complex.¹⁴⁷

Phosphide complexes. Rare examples of actinide phosphide complexes devoid of organometallic co-ligands (such as alkyl, cyclopentadienyl, or cyclooctatetraenyl) exist for tetravalent uranium and thorium. The reaction of ThCl_4 and four equivalents of the monoanionic and potentially tridentate ligand $(\text{PMe}_2\text{CH}_2\text{CH}_2)_2\text{P}^-$ (as the lithium salt) results in the formation of $\text{Th}[\text{P}(\text{CH}_2\text{CH}_2\text{PMe}_2)_2]_4$, a homoleptic phosphido complex.¹⁴⁸ The molecular structure of the complex indicates that each phosphine ligand has one coordinated and one uncomplexed phosphine arm, yielding an eight-coordinate metal center. The compound is fluxional in solution at temperatures above -80°C . The uranium analogue, $\text{U}[\text{P}(\text{CH}_2\text{CH}_2\text{PMe}_2)_2]_4$, has also been prepared,¹⁴⁹ and has been shown to have a similar structure. Although the compounds are isostructural, they do not exhibit identical chemical behavior. Although the thorium complex will insert CO , the uranium compound will not.¹⁴⁹ The product of the thorium reaction is an unusual product of “double insertion” where the CO is incorporated into a diphospha-alkoxide.¹⁵⁰ The two phosphide phosphorus atoms become bonded to the inserted carbon atom, and the newly-generated P_2CO unit is η^3 -bonded to the thorium center (see Figure 8).

Polypyrazolylborate ligands. The first report of an actinide complex employing a poly-(pyrazolyl)borate ligand was the preparation of complexes of the formula $\text{U}[\text{BH}_2(\text{pz})_2]_4$, $\text{U}[\text{HB}(\text{pz})_3]_4$, and $\text{U}[\text{HB}(\text{pz})_3]_2\text{Cl}_2$ by reaction of UCl_4 with the potassium salt of the appropriate ligand.¹⁵¹ On the basis of ^{13}C -NMR spectroscopy, the $\text{HB}(\text{pz})_3$ ligands were assigned as bidentate in the complex $\text{U}[\text{HB}(\text{pz})_3]_2\text{Cl}_2$, while the complex $\text{U}[\text{HB}(\text{pz})_3]_4$ was speculated to have two bidentate and two tridentate ligands.¹⁵²

The first report of metathesis reactions with thorium involved the preparation of the complexes $\text{Th}[\text{HB}(\text{pz})_3]_{4-n}\text{X}_n$ ($n = 2, \text{X} = \text{Cl}, \text{Br}$; $n = 1, \text{X} = \text{Cl}$), $\text{Th}[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]\text{Cl}_2$, $\text{Th}[\text{B}(\text{pz})_4]_2\text{Br}_2$, and adducts of the complexes $\text{Th}[\text{HB}(\text{pz})_3]\text{Cl}_3$ and $\text{Th}[\text{HB}(\text{pz})_3]_4$,¹⁵³ although subsequent reports have appeared of other derivatives, including $\text{Th}[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]\text{Cl}_3$.¹⁵⁴ The larger ionic radius of thorium enables higher coordination numbers; unlike the uranium complexes, the thorium

Figure 8 Phospha-alkoxide complex generated by insertion of carbon monoxide into a homoleptic thorium dialkylphosphide complex (Edwards, Hursthouse *et al.* *J. Chem. Soc., Chem. Commun.* **1994**, 1249).

derivatives $\text{Th}[\text{HB}(\text{pz})_3]_2\text{X}_2$ ($\text{X} = \text{Cl}, \text{Br}$) were proposed to have tridentate pyrazolylborate ligands on the basis of spectroscopy.

Several routes have been identified to produce $\text{U}[\text{HB}(\text{pz})_3]_2$, including reaction of $\text{U}[\text{I}_4]$ with two equivalents of $\text{K}[\text{HB}(\text{pz})_3]$ in CH_2Cl_2 ¹⁵⁵ and oxidation of $\text{U}[\text{HB}(\text{pz})_3]_2\text{I}(\text{THF})_2$ with iodine.¹⁵⁶ The reaction of $\text{U}[\text{I}_4]$ with two equivalents of $\text{K}[\text{HB}(\text{pz})_3]$ in THF does not yield the same compound. The iodobutoxide complex $\text{U}[\text{HB}(\text{pz})_3]_2\text{I}(\text{O}(\text{CH}_2)_4\text{I})$ was isolated, presumably generated by ring-opening of solvent.¹⁵⁵ The smaller size of the U^{IV} ion, combined with the larger steric size of the $[\text{HB}(3,5\text{-Me}_2\text{pz})_3]$ ligand inhibits formation of bis(ligand) complexes of the substituted poly(pyrazolyl)borate; reaction of UCl_4 with two equivalents of $\text{K}[\text{HB}(3,5\text{-Me}_2\text{pz})_3]$ leads to ligand degradation and the formation of $\text{UCl}_2[\text{HB}(3,5\text{-Me}_2\text{pz})_3](3,5\text{-Me}_2\text{pz})$.¹⁵⁷

The complex $\text{UCl}_3[\text{HB}(3,5\text{-Me}_2\text{pz})_3](\text{THF})$ contains a relatively weakly coordinated solvent molecule; the base free complex can be isolated, and has been crystallographically characterized.¹⁵⁸ The THF is also readily replaced by a number of other coordinating bases, permitting comparisons of relative ligand affinity. The relative affinities of a series of bases for $\text{UCl}_3[\text{HB}(3,5\text{-Me}_2\text{pz})_3]$ was found to be: $\text{OPPh}_3 > \text{C}_6\text{H}_{11}\text{NC} > \text{PhCN} > \text{MeCN} > \text{OP}(\text{OEt})_3 > \text{OP}(\text{O-Bu}^n)_3 > \text{C}_5\text{H}_5\text{N} > \text{THF}$.

Attempts to introduce a larger poly(pyrazolyl)borate ligand have demonstrated the steric limits of this system. Reaction of UCl_4 with one equivalent of the thallium salt of $[\text{HB}(3\text{-Mspz})_3]^-$ ($\text{Ms} = \text{mesityl}$) generates only the product containing an isomerized ligand, $\text{UCl}_3[[\text{HB}(3\text{-Mspz})_2(5\text{-Mspz})]$.¹⁵⁹

A variety of metathesis reactions have been carried out with the bis(ligand) actinide species $\text{An}[\text{HB}(\text{pz})_3]_2\text{Cl}_2$ to generate complexes containing oxygen, nitrogen, or sulfur donors.^{160–163} Steric factors can be significant in these reactions. For example, reaction of bulky alkylamides with $\text{U}[\text{HB}(\text{pz})_3]_2\text{Cl}_2$ generates only the monoamide complexes $\text{U}[\text{HB}(\text{pz})_3]_2\text{Cl}(\text{NR}_2)$.

In an attempt to reduce the steric constraints of the ancillary ligands, derivatives of the mono-(pyrazolylborate) complexes $\text{An}[\text{HB}(3,5\text{-Me}_2\text{pz})_3]\text{Cl}_3(\text{THF})$ have also been prepared.^{160,164–167} As before, the degree of substitution is often dependent on the size of the ligand introduced; tris(amide) derivatives such as $\text{An}[\text{HB}(3,5\text{-Me}_2\text{pz})_3](\text{NR}_2)_3$ can be produced for $\text{R} = \text{Et}, \text{Ph}$, whereas for the larger ligand $\text{N}(\text{SiMe}_3)_2^-$, only a monoamide complex can be isolated. The monoalkoxide and monoaryloxide complexes of thorium have been reported to be unstable; uranium mono- and bis(phenoxide) complexes are only stable in the presence of a coordinating molecule of THF.¹⁶⁰

The neptunium derivatives $\text{Np}[\text{HB}(\text{pz})_3]_2\text{Cl}_2$ and $\text{Np}[\text{HB}(3,5\text{-Me}_2\text{pz})_3]\text{Cl}_3(\text{THF})$ have been produced from NpCl_4 .¹⁶⁸

Reaction of uranium tetrachloride with two equivalents of the bulky ligand $\text{B}(\text{pz})_4^-$ as the potassium salt yields the complex $[\text{B}(\text{pz})_4]_2\text{UCl}_2$.¹⁶⁹ Although a limited number of derivatives of

Figure 9 Crystal structure of $[\text{B}(\text{pz})_4]_2\text{UCl}_2$ (Campello, Domingos *et al.* *J. Organomet. Chem.* **1999**, 579, 5–17).

this compound could be produced, in general the ligand set provided less thermal stability than comparable complexes of the “ $\text{U}[\text{HB}(\text{pz})_3]_2$ ” fragment. The complex $[\text{B}(\text{pz})_4]_2\text{UCl}_2$ displays eight-coordinate geometry in the solid state, in an distorted square antiprismatic arrangement of ligands (Figure 9). The complex is fluxional in solution; ^1H -NMR spectra demonstrate that all coordinated pyrazolylborate rings are equivalent. For the derivatives $[\text{B}(\text{pz})_4]_2\text{UCl}(\text{O}-\text{Bu}^t)$, $[\text{B}(\text{pz})_4]_2\text{UCl}(\text{O}-2,4,6\text{-Me}_3\text{C}_6\text{H}_2)$, $[\text{B}(\text{pz})_4]_2\text{U}(\text{S}-\text{Pr}^i)_2$, and $[\text{B}(\text{pz})_4]_2\text{U}(\text{O}-\text{Bu}^t)_2$, it is possible to slow down the interconversion of the typical eight-coordinate polyhedra (square antiprism—dodecahedron—bicapped trigonal prism). At higher temperatures, it was possible for some of these compounds to reach a regime where all pyrazolyl groups were equivalent on the NMR timescale, indicating dissociative exchange of free and coordinated rings.

The potassium salt of the “podand” ligand tris[3-(2-pyridyl)-pyrazol-1-yl]borate ($^{\text{py}}\text{Tp}$) reacts with thorium tetra(nitrate) to generate the complex $(^{\text{py}}\text{Tp})\text{Th}(\text{NO}_3)_3$.¹⁷⁰ The crystal structure of the complex reveals that the metal center is 12-coordinate, binding to the six nitrogen atoms of the podand ligand, and to two of the oxygen atoms of each nitrate. The molecule has three-fold symmetry, and the nitrates are located between the bidentate arms of the podand.

Thiocyanate and selenocyanate. A variety of tetravalent complexes of actinides are known incorporating the thiocyanate ligand, NCS^- (Table 5). The most prevalent member of this class is the anion $\text{An}(\text{NCS})_8^{4-}$. The tetraethylammonium complexes are known for $\text{An} = \text{Th}, \text{Pa}, \text{U}, \text{Np}$, and Pu . All possess a similar crystal structure, in which the metal ion lies within a cubic arrangement of thiocyanate ligands. The structure is dependent on counterion, however; the structure of the anion in $\text{Cs}_4\text{U}(\text{NCS})_8 \cdot \text{H}_2\text{O}$ reveals that the coordination environment about the uranium atom is square antiprismatic. When dehydrated, the complexes $\text{M}_4\text{An}(\text{NCS})_8$ ($\text{M} = \text{Cs}, \text{Rb}$; $\text{An} = \text{Th}, \text{U}$) possess a dodecahedral metal environment in the solid state, but square antiprismatic geometry in acetone solution.¹⁷¹ The analogous selenocyanate complexes $(\text{NEt}_4)_4\text{An}(\text{NCSe})_8$ ($\text{An} = \text{U}, \text{Pa}$) have also been reported; they are isostructural with their isocyanate counterparts.

Neutral complexes of the thiocyanate ligands can be isolated as Lewis base adducts. Thorium and uranium form tetra(hydrate) complexes $\text{An}(\text{NCS})_4(\text{H}_2\text{O})_4$. The compound $\text{U}(\text{NCS})_4(\text{piperazine})$ has been reported.¹⁷² The neutral adducts $\text{Th}(\text{NCS})_4(\text{L})_4$ and $\text{U}(\text{NCS})_4(\text{L})_3$ ($\text{L} = \text{N}, \text{N}$ -diisopropylpropionamide) have been structurally characterized.¹⁷³ The smaller size of the uranium ion is reflected in the isolation of a seven-coordinate compound, while an eight-coordinate thorium compound is formed. If more sterically demanding carbamide ligands are employed ($\text{L} = \text{N}, \text{N}$ -diisopropylbutyramide, $\text{L}' = \text{N}, \text{N}$ -dicyclohexylacetamide), seven-coordinate thorium complexes, $\text{Th}(\text{NCS})_4(\text{L})_3$ and $\text{Th}(\text{NCS})_2\text{Cl}_2(\text{L}')_3$, can be isolated.¹⁷⁴

Sulfenamide. A homoleptic sulfenamido complex of uranium has been isolated from the reaction of $\text{Li}(\text{Bu}^t\text{NSPh})$ with UCl_4 in the presence of PMe_3 in toluene.¹⁷⁵ The complex $\text{U}(\text{PhS}=\text{N}-\text{Bu}^t)_4$ possesses two η^2 -coordinated sulfenamide ligands, and is nearly isostructural with the analogous zirconium complex.

(iii) Ligands containing neutral group 15 donor atoms

Ammonia. Ammonia adducts have been characterized for tetravalent halides of thorium, uranium, and plutonium. Adducts of all of the uranium halides have been reported,⁷ as have adducts for thorium tetrachloride, -bromide, -iodide, and plutonium tetrachloride. Most lose ammonia at elevated temperatures. There is some ambiguity concerning the identity of these compounds as conflicting reports of the chemical composition exist. For example, $\text{Cs}_2[\text{PuCl}_6]$ is reported to react with ammonia to yield the simple adduct, $\text{PuCl}_4 \cdot x\text{NH}_3$, and yet it has been suggested that the related thorium chloride and bromide “ate” complexes $[\text{ThX}_6]^{2-}$ undergo ammonolysis in liquid ammonia to generate amide complexes of the composition $(\text{NH}_4)_2\text{ThBr}_2(\text{NH}_2)_2$.¹⁷⁶ Similar controversy exists in reports of possible ammonolysis of other tetravalent thorium complexes, such as the nitrate and the sulfate.

Amines, hydrazines, and hydroxylamines. Amine complexes are known for tetravalent complexes of the earliest actinides (Th, U), particularly for the halides, nitrates, and oxalates. The complexes are generated either in neat amine, or by addition of amine to the parent compound in a nonaqueous solvent. Some of the known simple amine compounds are presented in Table 6. The molecular structure of $\text{ThCl}_4(\text{NMe}_3)_3$ has been determined.¹⁷⁷ The coordination environment about the metal is a chloride capped octahedron. A very limited number of adducts exist in which a tetravalent actinide is coordinated by a hydrazine or hydroxylamine ligand; the parent compound is generally a halide or sulfate complex. Cationic metal hydrates coordinated with primary, secondary, or tertiary amines have also been isolated with acetylacetonate, nitrate, or oxalate as counterions.

Given the apparent lability of amines coordinated to tetravalent actinide centers, amine complexes have often been stabilized by the introduction of a chelating diaminoalkane or diaminoarene. The most common derivatives are those of the parent actinide halides,¹⁷⁸ as shown in Table 7. Both the complexes UCl₄(tmeda)₂ (tmeda = *N,N,N',N'*-tetramethylethylenediamine)¹⁷⁹ and ThCl₄-(tmeda)₂¹⁸⁰ have been characterized crystallographically. Both complexes are eight-coordinate with bidentate tmeda ligands. The geometry about the metal center approximates a *D*_{2d} dodecahedron. The tmeda ligands are readily replaced by chelating diphosphine ligands (*vide infra*), indicating that the tetravalent actinides have a stronger affinity for softer phosphine donors.

These complexes can act as reagents in subsequent reactions,¹⁷⁸ although displacement of the tmeda ligand is observed. The tetravalent derivative U(MeBH₃)₄(tmeda) has been reported, although it was produced by displacement of THF from the complex U(MeBH₃)₄(THF)_x.¹⁸¹

Heterocyclic ligands. *N*-heterocyclic adducts of simple tetravalent actinide salts exist for halides, nitrates, carboxylates, alkoxides, and perchlorate complexes of thorium, as well as halides and alkoxides of uranium. Most common among these are complexes with pyridine and its derivatives. Coordination number for the metal center range from six to eight (Table 8). The

steric bulk of the ligand dictates the precise coordination number. Thorium will coordinate eight ligands in the complexes $[\text{Th}(\text{L})_8](\text{ClO}_4)_4$ (L = pyridine, 2-Me-pyridine), whereas the bulkier L = 2,4-Me₂-pyridine and 2,6-Me₂-pyridine supports only six coordinate thorium in $[\text{Th}(\text{L})_6](\text{ClO}_4)_4$.¹⁸² Compounds of uranium and thorium halides and perchlorates have also been isolated with coordinating piperidine, quinoline, and isoquinoline ligands and their derivatives. As in the case of pyridine derivatives, the metal centers are most often eight-coordinate. Displacement of halides is possible to maintain this coordination environment. For example, the quinoline complex $\text{ThI}_4 \cdot \text{C}_9\text{H}_7\text{N}$ behaves as the 1:2 electrolyte $[\text{ThI}_2\text{L}_6]\text{I}_2$ in solution, suggesting that the metal center remains eight-coordinate.¹⁸³

Bidentate heterocyclic ligands (e.g., 2,2'-bipyridine, bipy, or 1,10-phenanthroline, phen) are also commonly used as coordinating bases in tetravalent chemistry, although there are few structurally characterized examples. These ligands are also presumed to support metal coordination numbers up to eight. Some of these complexes are neutral, such as $\text{ThX}_4(\text{bipy})_2$ (X = Cl, Br, NCS),¹⁸⁴ whereas some behave as salts in solution, indicating displacement of the counterion from the primary coordination sphere of the metal ion.¹⁸² 2,2'-Bipyridine and 1,10-phenanthroline can also act as Brønsted bases in reactions with protic solvents. Reaction of UCl_4 and bipy or phen in alcohols such as ethanol results in the formation of products of partial alcoholysis such as $\text{UCl}_3(\text{OEt})\text{bipy}_2$, accompanied by the formation of $(\text{bipyH})_2\text{UCl}_6$.¹⁸⁵

Other N-containing heterocycles that have been employed as coordinating bases include phenazine, phthalazine, pyrazine, triazine, imidazole, and piperazine, as well as pyridine-containing complexes such as terpyridine, dipyridylethanes, dipyridylketone, and dipyridylamine. In some cases it has been speculated that the products of ligands containing more than one nitrogen in the ring are polymeric, with ligands coordinated through both nitrogen atoms. In a more recent study of coordination piperazine compounds of uranium tetrahalides, perchlorates, and thiocyanates, however,¹⁷² optical spectroscopy is consistent with six- and eight-coordinate coordination environments about the uranium centers in many of the derivatives reported, suggesting simpler coordination modes.

Nitriles. Nitrile complexes of uranium and thorium halides have been well studied, particularly complexes of acetonitrile (MeCN). Halide complexes $\text{AnX}_4(\text{MeCN})_n$ were initially prepared either by reaction of the anhydrous halide with acetonitrile, or by electrochemical dissolution of a thorium anode in the presence of dissolved chlorine. Initial estimates of stoichiometry suggested $n = 2$ or 4, depending on the steric bulk of the base. It has been suggested from UV-visible spectroscopy that most complexes possess eight-coordinate metal centers, although with larger nitriles (e.g., Bu^tCN), complexes of the formula $\text{UX}_4(\text{Bu}^t\text{CN})_3$ could be isolated. The molecular structure of $\text{UCl}_4(\text{MeCN})_4$ has been determined,¹⁸⁶ confirming the coordination number of the metal center.

More recently, more well defined adducts of the tetrahalides with acetonitrile have been isolated by oxidation of the appropriate metal (uranium, thorium) by halide sources in the presence of the nitrile.¹⁸⁷ It has been reported that addition of more strongly coordinating bases to $\text{UI}_4(\text{MeCN})_4$ in acetonitrile can generate Lewis base adducts (e.g., $\text{UI}_4(\text{tmu})_2$, tmu = tetramethylurea). The complex appears to undergo some halide or nitrile dissociation in polar media, however; addition of OPPh_3 to a solution in THF yields only the THF ring-opened product $\text{UI}_2(\text{OCH}_2\text{CH}_2\text{CH}_2\text{CH}_2)_2(\text{OPPh}_3)_2$.¹⁸⁸

Aliphatic phosphines. As discussed in Section 3.3.2.2(ii), tetravalent actinide complexes possess a surprisingly high affinity for soft phosphine donor groups. In addition to the pendant phosphinoamine and phosphine complexes discussed previously, a number of other tetravalent complexes of uranium and thorium containing neutral phosphine ligands have been reported. The first report of a phosphine adduct of a tetrahalide was the bridging diphosphine complex $[\text{UCl}_4]_2(\text{dppe})$.¹⁸⁹ All other reports of diphosphine complexes have involved chelation of a single metal center, and the species $\text{ThX}_4(\text{dmpe})_2$ (X = Cl, I) and $\text{UX}_4(\text{dmpe})_2$ (X = Cl, Br) have been characterized.¹⁹⁰ The diphosphine remains coordinated during metathesis reactions, and the derivatives $\text{AnX}_4(\text{dmpe})_2$ (An = U, Th; X = Me, OPh) can be prepared by reaction with the appropriate lithium reagents.¹⁹⁰ The slightly larger benzyl group forces displacement of one of the chelating diphosphine ligands, resulting in the formation of $\text{An}(\text{CH}_2\text{Ph})_4(\text{dmpe})$ (An = U, Th).¹⁹¹

A single uranium halide adduct of a monodentate phosphine has been reported; reaction of UCl_4 with excess PMe_3 permits isolation of the trimethylphosphine adduct, $\text{UCl}_4(\text{PMe}_3)_3$.¹⁹⁰

Arsines. The ligand *o*-phenylenebis(dimethylarsine) (diars) has been used to complex actinide halides. The complexes $\text{PaCl}_4(\text{diars})$ and $\text{UCl}_4(\text{diars})$ have been reported. Both are produced by the reduction of pentavalent precursors in solution upon addition of the arsine.¹⁹²

(iv) *Ligands containing anionic group 16 donor atoms*

Oxides. Due to their importance as nuclear fuel material, actinide oxides have been intensively investigated. They are very complicated compounds, due to the formation of nonstoichiometric or polymorphic materials. The dioxides, AnO_2 , have the fluorite structure, wherein the actinide has eight nearest neighbor oxygen atoms in a cubic geometry. They can be readily prepared by heating of the actinide hydroxide, oxalate, carbonate, peroxide, nitrate, and other oxyacid salts. For the elements beyond thorium, sub- and superstoichiometric oxides remain an area of research. This is mostly due to two main issues. The dominant disposal or repository form of nuclear waste is spent fuel rods, which are based on UO_2 . It is very insoluble in its crystalline form; however, as the material ages it becomes brittle, and under common conditions undergoes phase transformations to hydroxides and oxidized forms that would significantly increase uranium solubility and potential for release into the environment. Secondly, there is concern that stored Pu will be slightly hydrated and highly self-irradiated Pu^0 and PuO_2 and may transform to PuO_{2+x} , which is significantly less stable.¹⁹³ Earlier reports suggested that PuO_{2+x} , like UO_{2+x} , contains interstitial oxygen in clusters of defect sites. There is more recent spectroscopic data, however, that suggest the presence of actinyl species.^{194–196}

Ternary actinide(IV) oxides are numerous and varied. Some classic types are M_2AnO_3 ($\text{M} = \text{Na}, \text{K}, \text{Rb}, \text{Cs}$; $\text{An} = \text{Th-Pu}$), BaAnO_3 (for Th–Pu), and Li_8PuO_6 , which can be prepared by fusing the respective actinide and alkali or alkaline earth oxides to form double oxides. In addition, ternary thorium oxides have been reported with lanthanides ($(\text{ThCe})\text{O}_2$, $(\text{ThCe})\text{O}_{2-x}$ with $x < 0.25$), niobium ($\text{Th}_{0.25}\text{NbO}_3$), tantalum (ThTa_2O_7 , $\text{Th}_2\text{Ta}_2\text{O}_9$), molybdenum ($\text{Th}(\text{MoO}_4)_2$, ThMo_2O_8), germanium (ThGeO_4), titanium and vanadium. Analogous U and Pu phases are known for most of these compounds. Superconducting properties have been observed in the δ -compound $\text{Nd}_{2-x}\text{Th}_x\text{CuO}_4$ at $x = 0.16$.

Hydroxides. Pure and mixed metal actinide hydroxides have been studied for their potential utility in nuclear fuel processing. At the other end of the nuclear cycle, the hydroxides are important in spent fuel aging and dissolution, and environmental contamination. Tetravalent actinides hydrolyze readily, with Th^{IV} more resistant and Pu^{IV} more likely to undergo hydrolysis than U^{IV} and Np^{IV} . All of these ions hydrolyze in a stepwise manner to yield monomeric products of formula $\text{An}(\text{OH})_n^{4-n}$ with $n = 1, 2, 3$ and 4, in addition to a number of polymeric species. The most prevalent and well characterized are the mono- and tetra-hydroxides, $\text{An}(\text{OH})^{3+}$ and $\text{An}(\text{OH})_4$.^{197–199} Characterization of isolated bis and tri-hydroxides is frustrated by the propensity of hydroxide to bridge actinide centers to yield polymers. For example, for thorium, other hydroxides include the dimers, $\text{Th}_2(\text{OH})_2^{6+}$ and $\text{Th}_2(\text{OH})_4^{4+}$, the tetramers, $\text{Th}_4(\text{OH})_8^{8+}$ and $\text{Th}_4(\text{OH})_{12}^{4+}$, and two hexamers, $\text{Th}_6(\text{OH})_{14}^{10+}$ or $\text{Th}_6(\text{OH})_{15}^{9+}$.^{200–203} These polynuclear complexes are common in chloride and nitrate solutions. It is noteworthy that these polynuclear hydrolysis products have only been well defined for thorium (i.e., not for other tetravalent actinide ions). For U^{IV} there is limited evidence for polymeric species such as $\text{U}_6(\text{OH})_{15}^{9+}$.¹⁹⁷ Characterization of additional distinct Pu^{IV} hydroxide species has been thwarted by the formation of the colloidal oxy/hydroxide. This form is very common in aqueous Pu chemistry and can form under widely varying conditions, including in concentrated electrolytes. It has a distinctive optical absorbance spectrum, can range in size from ten to hundreds of angstroms, and is generally described as hydroxylated nanoparticles of PuO_2 .

The An^{IV} hydroxide solids are amorphous and their exact composition and structure are not known.²⁰⁴ Ternary hydroxides have been characterized, mostly for Th. The structure of $\text{Th}(\text{OH})_2\text{-CrO}_4\cdot\text{H}_2\text{O}$ is built up of infinite chains, $[\text{Th}(\text{OH})_2]_n^{2n+}$ containing two almost parallel rows of OH groups so that each thorium atom is in contact with four OH groups; the CrO_4^{2-} groups are so packed that each thorium atom is in contact with four oxygen atoms of four different CrO_4^{2-} groups, making up a square antiprismatic arrangement of oxygen atoms about each thorium atom. The structure of $\text{Th}(\text{OH})_2\text{SO}_4\cdot\text{H}_2\text{O}$ is similar.

Peroxides and other dichalcogenides. Peroxide ligands oxidize uranium and protactinium, so peroxo complexes of tetravalent early actinides are restricted to $\text{An} = \text{Th}, \text{Np},$ and Pu . The compounds $\text{AnO}_4\cdot x\text{H}_2\text{O}$ precipitated from dilute acid solutions of neptunium(IV) and plutonium(IV) by hydrogen peroxide appear to be actinide(IV) compounds, although the stoichiometry has not been well determined. Pu^{IV} peroxide evidences two crystalline forms, hexagonal and cubic face-centered.⁸² The former contains 3–3.4 and the latter, 3 peroxo oxygens atoms per Pu. Soluble intermediates of the type $[\text{Pu}(\mu\text{-O}_2)_2\text{Pu}]^{4+}$ reportedly form at low hydrogen peroxide concentrations. The hydrated thorium peroxide sulfate, $\text{Th}(\text{O}_2)_4(\text{SO}_4)\cdot 3\text{H}_2\text{O}$, is very stable. Several mixed-ligand thorium peroxo complexes have been isolated, including the sulfate $\text{Th}(\text{O}_2)(\text{SO}_4)\cdot\text{H}_2\text{O}$, carboxylates $\text{Th}(\text{O}_2)(\text{RCO}_2)$, phenoxo compounds, and mixed composition

(and potentially polymetallic) halides and nitrates, Th(O₂)_{1.6}(A[−])_{0.5}(O^{2−})_{0.15}·2.5H₂O with A = Cl or NO₃.

The reaction of uranium metal with polyselenides in molten potassium polyselenide generates an interesting molecular diselenide complex K₄[U(η²-Se₂)₄],²⁰⁵ containing a discrete U(η²-Se₂)₄[−] anion.

Carbonates. Actinide carbonates have been very thoroughly studied by a variety of solution and solid state techniques. These complexes are of interest because of their fundamental chemistry and environmental behavior, including aspects of actinide mineralogy. In addition, separation schemes based on carbonate have been proposed. Coordination numbers are generally quite high, eight to ten; carbonate is bound to the metal center in a bidentate fashion and is often hydrogen-bonded to outer sphere waters or counter ions (see Table 9).

Aqueous carbonate complexes of An^{IV} ions, An(CO₃)_n^{4−2n}, n = 1–5, form stepwise with increasing solution pH and carbonate concentration.^{46,197,202,206} As with other oxoanionic ligand systems, the stability of the carbonate complexes decreases across the series, such that the pentacarbonato complex is well studied for Th^{IV} and U^{IV}. The tetracarbonato complex is more important for Np^{IV} and Pu^{IV} in solution, although salts of the pentacarbonato anion are known across the series. Most studies of Th, U, Np, and Pu do indicate that mixed hydroxycarbonate complexes, An(OH)_x(CO₃)_y^{(2y+4−x)−}, e.g., Th(OH)₃(CO₃)[−] for Th, are important in describing the aqueous solution behavior. For the lower order carbonates the actinide is presumably nine or ten-coordinate with waters and bidentate carbonate in the inner coordination sphere. For the penta- and hexacarbonato complexes there is no evidence that any water molecules remain bound to the actinide center.

Actinide(IV) carbonato solids of general formula M_xAn(CO₃)_y·nH₂O have been prepared for a variety of metal cations (M = Na⁺, K⁺, NH₄⁺, C(NH₂)₃²⁺, y = 4, 5, 6, 8). The only well-characterized actinide(IV) hexacarbonato compound is the mineral tuliokite Na₆BaTh(CO₃)₆·6H₂O.²⁰⁷ The three dimensional structure consists of alternating chains of barium and thorium icosahedra which share common polyhedral faces. The sodium atoms are found interspersed between the barium and thorium columns. The thorium chains contain discrete Th(CO₃)₆^{8−} icosahedra, which have three mutually perpendicular planes formed by the *trans* carbonate ligands, giving virtual *T_h* symmetry.

The pentacarbonato salts of thorium(IV) and uranium(IV) are among the most well-studied actinide solids. They can be prepared directly by precipitation from carbonate solutions, or indirectly by the decomposition of oxalates or reduction of actinyl(V, VI) species. The salts of formula M₆An(CO₃)₅·nH₂O (An = Th, U; M₆ = Na₆, K₆, Tl₆, [Co(NH₃)₆]₂, [C(NH₂)₃]₃(NH₄)₃,

$[\text{C}(\text{NH}_2)_3]_6$; $n=4-12$) have all been reported.^{208–210} These hydrated salts contain bidentate carbonate ligands and no water molecules bound directly to the central actinide. Structures from single crystal X-ray diffraction studies are known for salts of $\text{Th}(\text{CO}_3)_5^{6-}$. For example, triclinic $\text{Na}_6\text{Th}(\text{CO}_3)_5 \cdot 12\text{H}_2\text{O}$ contains Th^{IV} coordinated to 10 oxygen atoms of five bidentate carbonate ligands in an irregular geometry.^{211–213} Use of the hydrogen-bond donating guanidinium cation provides a more regular geometric structure in $[\text{C}(\text{NH}_2)_3]_6[\text{Th}(\text{CO}_3)_5]$, where the coordination geometry about the metal is hexagonal bipyramidal, comprised of three bidentate carbonate ligands in an approximately hexagonal plane and two *trans* bidentate carbonate ligands occupying pseudo-axial positions.²¹⁴ Uranium(IV) carbonates are readily oxidized in air to uranium(VI) complexes, and are therefore not as well characterized. The potassium salt, $\text{K}_6\text{U}(\text{CO}_3)_5 \cdot 6\text{H}_2\text{O}$, can be prepared by dissolution of freshly prepared U^{IV} hydroxide in K_2CO_3 solution in the presence of CO_2 , and the guanidinium salt can be prepared by addition of guanidinium carbonate to a warm $\text{U}(\text{SO}_4)_2$ solution, followed by cooling.²¹⁵

Salts of An^{IV} carbonates of lower carbonate to actinide ratio have also been reported but are far less common and detailed structural information is generally not available. Simple, binary thorium(IV) carbonates of formula $\text{Th}(\text{CO}_3)_2$ and $\text{Th}(\text{CO}_3)_2 \cdot n\text{H}_2\text{O}$ ($n=0.5$ and 3.00) are reported to form during the pyrolysis of $\text{Th}(\text{C}_2\text{O}_4)_2$, or by heating thorium hydroxide under CO_2 .²¹⁶ Solids of formula $\text{ThO}(\text{CO}_3)$ and $\text{Th}(\text{OH})_2(\text{CO}_3) \cdot 2\text{H}_2\text{O}$ have also been reported, but not characterized.²¹⁶ An example of a mixed ligand carbonate is the carbonatothorofluorothorate(IV), $(\text{CN}_3\text{H}_6)_5[\text{Th}(\text{CO}_3)_3\text{F}_3]$, which is nine-coordinate. Th^{IV} is bonded to three bidentate carbonate groups and three terminal fluorine atoms to give a monocapped square antiprismatic geometry in this complex.

Tetracarboxato U^{IV} salts, such as $[\text{C}(\text{NH}_2)_3]_4[\text{U}(\text{CO}_3)_4]$ and $[\text{C}(\text{NH}_2)_3]_3(\text{NH}_4)[\text{U}(\text{CO}_3)_4]$ have been reported,²¹⁵ and a tricarboxate is reportedly formed by addition of ethylenediammonium sulfate to uranium(IV) solutions of $(\text{NH}_4)_2\text{CO}_3$ or KHCO_3 followed by precipitation of $[\text{C}_2\text{H}_4(\text{NH}_3)_2][\text{U}(\text{CO}_3)_3(\text{H}_2\text{O})] \cdot 2\text{H}_2\text{O}$.²¹⁵ Hydrolysis of this complex occurs with dissolution to give $[\text{C}_2\text{H}_4(\text{NH}_3)_2]_2[\text{U}_2(\text{OH})_2(\text{CO}_3)_5(\text{H}_2\text{O})_4] \cdot 2\text{H}_2\text{O}$ or $[\text{C}_2\text{H}_4(\text{NH}_3)_2][\text{U}(\text{OH})_2(\text{CO}_3)_2(\text{H}_2\text{O})_2] \cdot \text{H}_2\text{O}$.

Plutonium(IV) carbonate complexes can be similarly prepared, as demonstrated by the single-crystal X-ray diffraction structure reported for the precipitated sodium salt, $[\text{Na}_6\text{Pu}(\text{CO}_3)_5]_2 \cdot \text{Na}_2\text{CO}_3 \cdot 33\text{H}_2\text{O}$.²¹⁷ Plutonium is coordinated by 10 carbonate oxygens in the anion shown in Figure 10. This type of complex can also be prepared by dissolving plutonium(IV) oxalate in the alkali metal carbonate solution and precipitating the solid by addition of alcohols. Depending on reaction conditions, green amorphous powders of compositions $\text{K}_4\text{Pu}(\text{CO}_3)_4 \cdot n\text{H}_2\text{O}$, $\text{K}_6\text{Pu}(\text{CO}_3)_5 \cdot n\text{H}_2\text{O}$, $\text{K}_8\text{Pu}(\text{CO}_3)_6 \cdot n\text{H}_2\text{O}$, and $\text{K}_{12}\text{Pu}(\text{CO}_3)_8 \cdot n\text{H}_2\text{O}$ have all been reported.²¹⁸ Sodium salts of formula $\text{Na}_4\text{Pu}(\text{CO}_3)_4 \cdot 3\text{H}_2\text{O}$, $\text{Na}_6\text{Pu}(\text{CO}_3)_5 \cdot 2\text{H}_2\text{O}$, and $\text{Na}_6\text{Pu}(\text{CO}_3)_5 \cdot 4\text{H}_2\text{O}$ have been claimed as light green crystalline compounds that appear to dehydrate in air.²¹⁸ Similarly, the $(\text{NH}_4)_4\text{Pu}(\text{CO}_3)_4 \cdot 4\text{H}_2\text{O}$ and $[\text{Co}(\text{NH}_3)_6]_2\text{Pu}(\text{CO}_3)_5 \cdot 5\text{H}_2\text{O}$ salts

Figure 10 The pentacarboxato Pu^{IV} anion from the crystal structure of the hydrated sodium salt (Clark, Conradson *et al. Inorganic Chemistry* **1998**, 37, 2893–2899).

have been reported.²¹⁹ Although few of these compounds have been well characterized, their formulas are consistent with the known Th^{IV} phases, and they are presumably isostructural with them.

Carboxylates. Aminocarboxylate and other polycarboxylate actinide complexes are typically formed in aqueous solution by addition of actinide(IV) salts to a solution of the polycarboxylic acid ligand. Most have been characterized by NMR and optical visible and infrared spectroscopy, and a very few have been fully structurally characterized using single-crystal X-ray diffraction. They can also form by reduction of the metal ion present in higher oxidation states, as demonstrated for Pu(VI) and Pu(V) . Tetravalent actinide ions form 1:1 complexes An(IV)-L ($\text{L} = \text{NTA}$, HEDTA , EDTA , DTPA , citrate) in acidic solutions, but even hexadentate EDTA leaves coordination sites for hydrolysis, polymerization, or other additional complexation, often at higher pH. For example, mixed aminocarboxylate/hydroxide, An(IV)-L(OH)_x , and aminocarboxylate/carbonate complexes, have been prepared for Th(IV) and Pu(IV) . Several additional types of mixed ligand Th(IV) complexes have been characterized, including ThLL' , where $\text{L} = \text{NTA}$, HEDTA , EDTA , CDTA or DTPA ; $\text{L}' = \text{halide}$, resorcinol (*res*), 2-methylresorcinol (2-Me-*res*), 5-methylresorcinol (5-Me-*res*) or 4-chlororesorcinol (4-Cl-*res*), salicylic acid (*SA*) or 5-sulfosalicylic acid (*SSA*), ethylenediamine, 1,2-propylenediamine, 1,3-propylenediamine, diethylenetriamine or triethylenetetramine, and purines, and pyrimidines (adenosine, guanosine, cytidine, uridine, adenine, etc.). Complexes with 2:1 aminocarboxylate to actinide ion ratio are isolated from solutions containing excess ligand and are more stable with respect to hydrolysis. The crystal structure of U(IV) and Th(IV) complexes $(\text{CN}_3\text{H}_6)_3[\text{AnEDTAF}_3]$ reveal that the central actinide atom is surrounded by 3F atoms, 4O atoms, and 2N atoms, with EDTA in a *gauche* conformation. Malonic acid complexes with thorium(IV) to create a distorted square antiprism coordination environment. The malonic acid complexes through both acid groups in a 1,5 arrangement to create a six-membered ring. The ring is planar where it complexes with the thorium, but the alpha carbon deviates from the plane. This is illustrated in Figure 11. Addition of a water molecule raises the coordination number from eight to nine forming a monocapped square antiprism where the capped face is more planar than the uncapped faced.

Since malonic acid is a diacid, the formation of polymeric chains is possible. Uranium(IV) has been shown to form polymeric chains creating a three-dimensional lattice. For every uranium atom, three water molecules are complexed along with two tridentate malonic acids (η^2 is present and a μ^2 is also present). The polymeric chain is depicted in Figure 12.²²⁰

Nitrates. Aqueous nitrate complexes (see Table 10) of An^{IV} ions are very well studied mostly because of their importance in nuclear material processing, particularly in liquid/liquid extractions and ion exchange chromatography. The solution species, $\text{An}(\text{NO}_3)_n^{4-n}$, $n = 1-6$, have been extensively studied for Th^{IV} and Pu^{IV} . Numerous cationic resins have been developed that have strong affinity for the hexanitrate species, $\text{Pu}(\text{NO}_3)_6^{2-}$. Although later work suggests that this complex is not present at significant concentration in the absence of resins, even in concentrated nitrate solution. There is good evidence, including recent NMR and EXAFS data, that indicates the mono-, bis-, tetra-, and the hexa- complexes are significant, but the tris- and penta-nitrato complexes are not.²²¹ X-ray absorbance data for the system suggest aquo ligation decreases in the inner sphere even before sequential planar, bidentate nitrates bind the metal center. The coordination numbers in these complexes is approximately 11–12 for the first coordination sphere, with average bond

Table 10 Actinide(IV) nitrate complexes.

$\text{M}^{\text{I}}_2[\text{An}(\text{NO}_3)_6]$	Generally known for $\text{An} = \text{Th}, \text{U}, \text{Pu}$; $\text{M}^{\text{I}} = \text{NH}_4$, K, Rb, Cs, Tl, Et_4N , Bu^n , $\text{Me}_2(\text{PhCH}_2)_2\text{N}$, $\text{Me}_3(\text{PhCH}_2)\text{N}$, $\text{C}_5\text{H}_5\text{NH}$,...; $\text{An} = \text{U}, \text{Pu}$; $\text{M}^{\text{I}} = \text{C}_9\text{H}_7\text{NH}$ (quinolinium) $\text{An} = \text{Th}$; $\text{M}^{\text{I}} = \text{NO}, \text{NO}_2$
$\text{M}^{\text{II}}[\text{An}(\text{NO}_3)_6] \cdot 8\text{H}_2\text{O}$	Generally known for $\text{An} = \text{Th}, \text{U}, \text{Pu}$; $\text{M}^{\text{II}} = \text{Mg}$, Zn, Co, Ni; $\text{An} = \text{Th}$; $\text{M}^{\text{II}} = \text{Mn}$,
$(\text{bipyH}_2)[\text{U}(\text{NO}_3)_6]$	$\text{M}^{\text{I}} = \text{Na}$, $x = 8.5$; K, $x = 6$
$\text{M}^{\text{I}}\text{Th}(\text{NO}_3)_5 \cdot x\text{H}_2\text{O}$	$\text{An} = \text{Th}$, $x = 4$; U, $x = 3$
$\text{K}_3\text{H}_3\text{An}(\text{NO}_3)_{10} \cdot x\text{H}_2\text{O}$	

distances of 2.49 Å (nitrate) and 2.38 Å (water).²²² Stability and the relative importance of the mono- and bisnitrate complexes have recently been re-evaluated.²²³

Numerous additional solution studies on mixed ligand, nitrate complexes have been performed in the development and performance testing of extractants. Most notably these include tributylphosphate (TBP) and other phosphine oxides. As other examples, a variety of mixed amide, nitrate complexes have been proposed based upon NMR, IR and extraction behavior.^{224–226} The composition and proposed structures of these types of species are described in the sections corresponding to the functionality of the extractant.

Actinide(IV) nitrates solids are readily formed in nitric acid by dissolution of hydroxides or carbonates followed by precipitation (Table 10). Depending upon the pH of solution, crystalline orthorhombic $\text{An}(\text{NO}_3)_4 \cdot 5\text{H}_2\text{O}$ ($\text{An} = \text{Th}, \text{Np}, \text{Pu}$), or for Th^{IV} , $\text{Th}(\text{NO}_3)_4 \cdot 4\text{H}_2\text{O}$ can be obtained.²²⁷ For Pu, the tetranitrate pentahydrate can also be prepared by heating a Pu^{VI} nitrate salt.²²⁸ The coordination geometry about the 11-coordinate thorium atom in $[\text{Th}(\text{NO}_3)_4 \cdot 5\text{H}_2\text{O} \cdot ([\text{Th}(\text{NO}_3)_4 \cdot (\text{H}_2\text{O})_3]) \cdot 2\text{H}_2\text{O}]$ is a monocapped trigonal prism in which four of the prism apices are occupied by bidentate nitrate groups. In the dimeric basic nitrate, $[\text{Th}_2(\text{OH})_2(\text{NO}_3)_6(\text{H}_2\text{O})_6] \cdot 2\text{H}_2\text{O}$, the thorium atoms are bridged by two OH groups, and each thorium atom is also coordinated to three bidentate nitrate groups and three water molecules. The geometry can be considered as a rather distorted dodecahedron in which the nitrate groups occupy three apices.

Anhydrous $\text{Th}(\text{NO}_3)_4$ is obtained by heating more complex nitrates under vacuum. Hexanitratato complexes are obtained from moderately concentrated (8 M to 14 M) nitric acid, in the presence of sulfamic acid to inhibit oxidation by nitrite in the case of uranium(IV). The nitrate groups in these compounds are bidentate and the structure of the anion is distorted icosahedral,

such as in $[M(H_2O)_6][Th(NO_3)_6] \cdot 2H_2O$, where $M = Mg, Zn, Co, Ni$. The anions in similar Pu^{IV} salts, such as $M_2Pu(NO_3)_6 \cdot 2H_2O$, where $M = Rb, Cs, NH_4$, and pyridinium, are presumably isostructural.²²⁹ Uranium(IV) does not form solid binary nitrates, but is apparent in ternary phases of the general formula $M_2[U(NO_3)_6]$, where $M = NH_4, Rb, Cs$, and $M[U(NO_3)_6] \cdot 8H_2O$, where $M = Mg, Zn$.

Phosphates. Because of their very low solubility, as exemplified by stable minerals and ore bodies, actinide phosphates have been proposed as potential radioactive waste forms.²³⁰ Together with this property, the multiple protonation states and possible coordination modes make the solution An^{IV} phosphate species particularly challenging to characterize. Generally, complexes of the formula $An(H_3PO_4)_x(H_2PO_4)_y^{(4-y)+}$ ($x = 0, 1$; $y = 0, 1, 2$) have been proposed to form under acidic conditions, $An(HPO_4)_3(H_2PO_4)_x^{(2+x)-}$ ($x = 1, 2$), at neutral pH, and $An(HPO_4)_x^{4-2x}$ ($x = 1-3$) under basic conditions.

In the solid state, the major classes actinide(IV) phosphate are orthophosphates, hydrogenphosphates, pyrophosphates, metaphosphates, and polyphosphates.^{231,232} In addition there are numerous ternary compounds, mixed valent uranium phosphates, halophosphates, organophosphates, and most recently, open framework and templated phases.²³³

Binary and ternary thorium compounds have been synthesized with varying ratios of metal, thorium and phosphate. Recently, Bernard *et al.* reported two distinct thorium types in $Th_4(PO_4)_4(P_2O_7)$, one eight-coordinate with oxygen from five phosphate and one diphosphate group around the thorium atom.²³⁴ Ternary compounds of the general formula $M^I Th_2(PO_4)_3$ and $M^{II} Th(PO_4)_2$ with $M^I =$ alkali cation, Tl, Ag, Cu ,^{235,236} and $M^{II} = Ca, Sr, Cd, Pb$,^{237,238} have been studied. In the structure of $NaTh_2(PO_4)_3$, thorium is eight-coordinate, and the local coordination environment can be described as $[Th(\eta^2-PO_4)_2(\eta^1-PO_4)_4]$ in a pseudosquare bipyramidal configuration with bidentate phosphates in the axial positions and monodentate phosphates in the equatorial positions. The Th^{IV} ion in $KTh_2(PO_4)_3$ is nine-coordinate with a local coordination environment described as $[Th(\eta^2-PO_4)_2(\eta^1-PO_4)_5]$ containing both bridging and bidentate phosphate groups. In $Na_2Th(PO_4)_3$ two different thorium atoms are identified with eight and ten neighboring oxygen atoms.²³⁹

Few uranium(IV) phosphates have been fully characterized. They generally include the uranium atom in seven-coordinate, distorted pentagonal bipyramidal; eight coordinate, square antiprismatic; or nine-coordinate irregular geometries. Hydrogen phosphates, $U(HPO_4)_2 \cdot xH_2O$ can be prepared by precipitation from phosphoric acid solutions. Among them the bis- and tetrahydrates are the best characterized but single-crystal data are still lacking.²⁴⁰ The simplest binary phase is the triclinic metaphosphate, $U(PO_3)_4$, with eight-coordinate square antiprisms of UO_8 connected by $(P_4O_{12})^{4-}$ rings.^{241,242} The ortho phosphate UP_2O_7 can be prepared by thermal decomposition of the uranyl hydrogen phosphates. The mixed valent orthophosphate, $U(UO_2)(PO_4)_2$, can be prepared either via a solid state reaction, combining UO_2 and ammonium phosphates or by reducing uranyl chloride with hydrazine, followed by addition of concentrate phosphoric acid.²⁴³ In the structure seven-coordinate U^{IV} alternate with uranyl within $PaCl_5$ type chains, which are connected by phosphate groups to form a three-dimensional network. The coordination environment about the metal center is similar to that found in $U_2O(PO_4)_2$, which is thought to be the correct formula for compounds previously believed to be $(UO)_2P_2O_7$.²⁴⁴ $U_2O_3P_2O_7$ and $U_3O_5P_2O_7$ have been synthesized containing uranium in the oxidation state +IV and +VI in a ratio 1:1 and 2:1, respectively.²⁴⁵

The pyrophosphate of uranium(IV) has been obtained and the structure determined to belong to the ZrP_2O_7 -type structure.²⁴⁶ Octahedral sites in the zirconium phosphates can accommodate U^{IV} , as exemplified by the Na dizirconium tris(phosphate) structural family ([NZP]). An end member in this study was monoclinic $KU_2Zr(PO_4)_3$, which contains nine-coordinate U^{IV} .²⁴⁷ Compounds of the general formula $MU_2(PO_4)_3$ have been reported for $M = Li, Na$, and K , where U^{IV} is nine coordinate; similar compounds could not be obtained with the larger Rb and Cs ions.²⁴⁸ Recent examples of three-dimensional structures exist for the halophosphate phases, $UXPO_4 \cdot 2H_2O$, $x = Cl, Br$.²⁴⁹ In these compounds, all four phosphate oxygens are bound to uranium atoms, and the U^{IV} is in a distorted pentagonal bipyramidal geometry.

Fewer, but still numerous, Pu phosphates have been characterized.⁸² Plutonium metaphosphate, orthorhombic $Pu(PO_3)_4$, can be crystallized from solutions of PuO_2 in metahosphoric acid.²⁵⁰ The hydrogen phosphate, $Pu(HPO_4)_2 \cdot xH_2O$ is prepared by precipitation from phosphoric acid solutions and can be used as precursor for other phosphates. Red $Pu_2H-(PO_4)_3 \cdot xH_2O$ is made by heating the hydrodiphosphate; decomposition above $100^\circ C$ reportedly yields $Pu_3(PO_4)_4 \cdot xH_2O$. Anhydrous Pu pyrophosphate PuP_2O_7 , has been prepared by the thermal decomposition of plutonium

$Rb_4U_2(SO_4)_3(C_2O_4)_3 \cdot xH_2O$	$x = 0, 4 \text{ or } 6$

oxalatophosphates.^{52,251} Pyro- and metaphosphates of Np^{IV} and two double orthophosphates $NaNp_2(PO_4)_3$ and $Na_2Np(PO_4)_2$ have been prepared and determined to be isostructural with the analogous Th^{IV} and U^{IV} compounds.²⁵²

Alkyl phosphates, $U\{O_2P(OR)_2\}_4$ ($R = Me, Et \text{ or } Bu$) and $U\{O_2PH(OR)\}_4$ ($R = Me, Et, PR' \text{ or } Bu''$), have been reported, as has the phenyl derivative, $U(O_3PPh)_2$. Plutonium monobutyl phosphate was reportedly prepared by addition of monobutyl phosphate to Pu^{IV} in nitric acid solution.

Sulfates and sulfites. Sulfate has high affinity for tetravalent actinides and forms complexes of the type $An(SO_4)_n^{4-2n}$ ($n = 1, 2$) in solution, with the tetrasulfato being the most important (predominant at sulfate concentrations greater than 0.2 M), and the trissulfato not detected under most conditions. These anions can be precipitated as hydrates and subsequently dehydrated at 400 °C. Representative An^{IV} sulfate complexes are shown in Table 11. For example, hydrated thorium sulfate, $Th(SO_4)_2 \cdot nH_2O$ ($n = 9, 8, 6, 4$), is easily crystallized from thorium and sulfuric acid. Analogous U^{IV} and Pu^{IV} compounds are well known; the red tetrahydrate Pu^{IV} phase is noteworthy because of its very high purity.⁸² The octahydrate loses four waters at relatively low temperature, and can be fully dehydrated. The common bicapped square antiprismatic geometry is adopted by the An^{IV} centers in the tetra- and octahydrates.²⁵³ For uranium, the basic salt, $UOSO_4 \cdot 2H_2O$, is formed in sulfate solution at neutral pH. Ternary salts have been characterized, such as the green Pu^{IV} compounds, $M_4An(SO_4)_4 \cdot xH_2O$ where M is K or NH_4 . The penta-sulfato complex has not been identified in solution, but the potassium and other monovalent salts, $M_6An(SO_4)_5 \cdot xH_2O$ have been characterized.

Fluorosulfates, $U(SO_3F)_4$, $U(SO_3F)_2$, and $MU(SO_3F)_6$, ($M = Mg, Zn$) have been obtained by treating $U(MeCO_2)_4$, with HSO_3F .²⁵⁴ The compound $U(SO_3F)_4$ appears to involve two mono- and two bi-dentate SO_3F groups. The structure of the anion in $K_4Th(SO_4)_4 \cdot 2H_2O$ consists of chains of thorium atoms linked by pairs of bridging sulfate groups, and the coordination geometry about the thorium atom is a tricapped trigonal prism.

A simple sulfite is known for Th^{IV} , $Th(SO_3)_2 \cdot 4H_2O$. Salts of hydrated complexes are known for thorium(IV) and uranium(IV) (see Table 12), both of which form a series of hydrated salts of what

Table 12 Actinide(IV) sulfites and sulfito complexes.

$Th(SO_3)_2 \cdot 4H_2O$ $M^I_2Th(SO_3)_3 \cdot xH_2O$	$M^I = Na, x = 5; K, x = 7.5; NH_4, x = 4; CN_3H_6$ (guanidinium), $x = 12$
$M^I_4Th(SO_3)_4 \cdot xH_2O$ $Na_{2n}U(SO_3)_{n+2} \cdot xH_2O$ $Na_{2n}M^{IV}(SO_3)_n(C_2O_4)_2 \cdot xH_2O$	$M^I = Na, x = 3 \text{ or } 6; NH_4, x = 5$ $n = 3, 4, 5 \text{ and } 6; x, \text{ unspecified}$ $M^{IV} = Th; n = 3, 4, 5 \text{ or } 7, x = 5 \text{ to } 6; M^{IV} = Th;$ $n = 3, 4, 5 \text{ or } 7, x = 5 \text{ to } 6; n = 9, x = 6$ $n = 3, x = 5; n = 4, x = 4;$ $n = 5, x = 7.5; n = 6, x = 7 \text{ to } 8$
$Ba_6Th(SO_3)_6(C_2O_4)_2 \cdot 7H_2O$	

appear to be sulfiteoxalato complex anions, but definitive characterization is needed. They are obtained by dissolving thorium oxalate in concentrated aqueous sodium sulfite.

Perchlorates and iodates. Thorium perchlorate forms upon dissolution of thorium hydroxide in perchloric acid and crystallizes as $\text{Th}(\text{ClO}_4)_4 \cdot 4\text{H}_2\text{O}$. The precipitation of tetravalent actinides as iodates has long been used to separate these elements from lanthanides at low pH. One of the earliest forms that ^{239}Pu was isolated in was that of $\text{Pu}(\text{IO}_3)_4$.²⁵⁵ The structure and most properties of $\text{Pu}(\text{IO}_3)_4$ are currently unknown, but a remarkable feature is that it is insoluble in 6M HNO_3 .

Alkoxides. In 1954, Bradley and co-workers reported the synthesis of the thorium tetra-kisalkoxide compound $\text{Th}(\text{O}^i\text{Pr})_4$ (see Equation (10)); other rational reaction routes yield impure products.²⁵⁶ Additional $\text{Th}(\text{OR})_4$ compounds ($\text{R} = \text{Me}, \text{Et}, \text{Bu}, \text{Bu}^t, \text{pentyl}, \text{CH}_2\text{CMe}_3, \text{OCHMeEt}, \text{OCHEt}_2, \text{CMe}_2\text{Et}, \text{CMeEt}_2, \text{CMe}_2\text{Pr}, \text{CMe}_2\text{Pr}^i, \text{CEt}_3, \text{CMeEtPr}, \text{CMeEtPr}^i$) are prepared from alcoholysis of $\text{Th}(\text{OPr}^i)_4$ ^{256,257} (see Equation (11)). Subsequent studies confirmed that alcoholysis of $[(\text{Me}_3\text{Si})_2\text{N}]_2\text{Th}(\text{CH}_2\text{SiMe}_2\text{NSiMe}_3)$ with HOPr^i generates a homoleptic compound of empirical formula $\text{Th}(\text{OPr}^i)_4$.²⁵⁸ Addition of either excess pyridine to the fresh reaction mixture of $[(\text{Me}_3\text{Si})_2\text{N}]_2\text{Th}(\text{CH}_2\text{SiMe}_2\text{NSiMe}_3)$ and HOPr^i or a stoichiometric amount of pyridine to the metathesis reaction of $\text{UBr}_4(\text{THF})_4$ and four equivalents of KOPr^i permits isolation of the tetramer $\text{Th}_4(\text{OPr}^i)_{16}(\text{py})_2$. A similar reaction between the metallacycle and pentan-3-ol in the presence of pyridine yields the dimer $\text{Th}_2(\text{OCHEt}_2)_8(\text{py})_2$. In solution studies, treatment of the metallacycle $[(\text{Me}_3\text{Si})_2\text{N}]_2\text{Th}(\text{CH}_2\text{SiMe}_2\text{NSiMe}_3)$ with four equivalents of the bulkier alcohol $\text{HOCH}(\text{Pr}^i)_2$ yields the dimer $[\text{Th}(\text{OCHPr}^i_2)_4]_2$, which exists in equilibrium with monomer $\text{Th}(\text{OCHPr}^i_2)_4$.²⁵⁹ Addition of Lewis bases dimethoxyethane or quinuclidine to this dimer allows for the isolation of $[\text{Th}(\text{OCHPr}^i_2)_4(\text{DME})]$ or $[\text{Th}(\text{OCHPr}^i_2)_4(\text{C}_7\text{H}_{13}\text{N})]$, respectively. Similar reaction products employing tertiary alkoxide ligands were investigated. The metathesis reaction of $\text{ThI}_4(\text{THF})_4$ with four equivalents of KOBU^t in the presence of pyridine generates $\text{Th}(\text{OBU}^t)_4(\text{py})_2$, and alcoholysis of $[(\text{Me}_3\text{Si})_2\text{N}]_2\text{Th}(\text{CH}_2\text{SiMe}_2\text{NSiMe}_3)$ with HOBU^t provides the dimer $\text{Th}_2(\text{OBU}^t)_8(\text{HOBU}^t)$.²⁶⁰ The coordinated alcohol of the latter compound is deprotonated by $\text{Na}[\text{N}(\text{SiMe}_3)_2]$ to yield $\text{NaTh}_2(\text{OBU}^t)_9$, while addition of a stoichiometric amount of water to $\text{Th}_2(\text{OBU}^t)_8(\text{HOBU}^t)$ under reflux conditions in toluene yields the cluster $\text{Th}_3\text{O}(\text{OBU}^t)_{10}$ where one alkoxy group and the oxo are both triply bridging the three thorium centers. Lewis base adducts of homoleptic alkoxides may be isolated, such as the complex $\text{Th}(\text{OBU}^t)_4(\text{py})_2$. (see Figure 13):

Figure 13 Crystal structure of $\text{Th}(\text{OBU}^t)_4(\text{py})_2$ (Clark and Watkin *Inorg. Chem.* **1993**, 32, 1766–1772).

Gilman and co-workers reported the synthesis of uranium tetrakisalkoxide complexes U(OR)_4 ($\text{R}' = \text{Et}$, $\text{R} = \text{Me}$, Et ; $\text{R}' = \text{H}_2$, $\text{R} = \text{Bu}^t$) from alcoholysis and metathesis reactions¹⁰² (see Equations (12) and (13)):

Additional uranium tetrakisalkoxides (U(OPr)_4 , $\text{U(OPr}^i)_4$) were prepared via metathesis routes carried out in dimethylcellosolve. In one report, it was suggested that Gilman's initial report of $\text{U(OBu}^t)_4$ actually represented an oxidized uranium *t*-butoxide species.²⁶¹ Cotton and co-workers later published the structure of $\text{UO}_3(\text{OBu}^t)_{10}$, a product isolated from Gilman's reported procedure for the synthesis of $\text{U(OBu}^t)_4$.²⁶² If, however, this reaction mixture is maintained at $\leq -10^\circ\text{C}$, then the complex $\text{KU}_2(\text{OBu}^t)_9$ is isolated; this is readily oxidized to $\text{U}_2(\text{OBu}^t)_9$ in solution.^{263,264} A high-yield synthesis of the neutral species $\text{U}_2(\text{OBu}^t)_8(\text{HOBu}^t)$ was reported from reaction of *t*-butanol with either $[(\text{Me}_3\text{Si})_2\text{N}]_2\text{U}[\text{N}(\text{SiMe}_3)\text{SiMe}_2\text{CH}_2]$ or $\text{U(NEt}_2)_4$.²⁶³ Treatment of $\text{U}_2(\text{OBu}^t)_8(\text{HOBu}^t)$ with KOBu^t or KH further yields $\text{KU}_2(\text{OBu}^t)_9$. Both $\text{U}_2(\text{OBu}^t)_8(\text{HOBu}^t)$ and $\text{KU}_2(\text{OBu}^t)_9$ react with O_2 to form $\text{U}_2(\text{OBu}^t)_9$, or with H_2O to form $\text{U}_3\text{O}(\text{OBu}^t)_{10}$. A spectroscopic study has been carried out on the $[\text{U}_2(\text{OBu}^t)_9]^-$ dimeric anion in the presence of different cations (H^+ , K^+ , and TBA^+); it reveals the sensitivity of the $5f-5f$ spectra to the coordination sphere of the anion.²⁶⁵

Alternative routes to homoleptic U^{IV} alkoxide complexes have been described, including electrochemical generation of $\text{U(OCH}_2\text{CH}_3)_4$ from uranium metal in ethanol,²⁶⁶ alcoholysis (ROH ; $\text{R} = \text{Et}$, Pr^i , Bu^t) of $\text{U}(\eta\text{-C}_3\text{H}_5)_4$ at -30°C ,²⁶⁷ and generation of $\text{U[OCH(Bu}^t)_2]_4$ via metathesis reactions. The latter yields the addition compound $\text{LiU(Me)[OCH(Bu}^t)_2]_4$ in the presence of LiMe .²⁶⁸ Analogous fluoroalkoxide compounds $\text{U(OC(CF}_3)_3)_4(\text{THF})_2$ and $\text{U(OCH(CF}_3)_2)_4(\text{THF})_2$ have been prepared from the reactions of UCl_4 and respective sodium alkoxide in tetrahydrofuran.¹²

The preparation of homoleptic neptunium tetrakisalkoxides, Np(OR)_4 ($\text{R} = \text{Me}$, Et) has been reported²⁶⁹ (Equation (14)). $\text{Pu(OPr}^i)_4\text{-HOPr}^i$ was purified from a reaction mixture of $(\text{C}_5\text{H}_6\text{N})_2\text{PuCl}_6$, HOPr^i , and NH_3 ; the authors further suggested that alcoholysis of $\text{Pu(OPr}^i)_4$ with HOBu^t produced $\text{Pu(OBu}^t)_4$.²⁷⁰

The molecular and electronic structures of a variety of uranium(IV) aryloxide compounds have been described. Sattelberger and co-workers reported the first structural characterization of a homoleptic tetrakisaryloxide compound, $\text{U(O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_4$, prepared from alcoholysis of the metallacycle $[(\text{Me}_3\text{Si})_2\text{N}]_2\text{U}(\text{CH}_2\text{SiMe}_2\text{N}(\text{SiMe}_3)_2)$ with $\text{HO-2,6-Bu}^t_2\text{C}_6\text{H}_3$ in refluxing toluene.^{125,126} Subsequent studies show that $\text{U(O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_4$ can also be generated from the metathesis reaction between $\text{UI}_4(\text{CH}_3\text{CN})_4$ or UCl_4 and $\text{KO-2,6-Bu}^t_2\text{C}_6\text{H}_3$ in tetrahydrofuran at room temperature or from oxidation of $\text{U(O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_3$ by molecular oxygen.^{271,272} An investigation of the electronic structure of this highly symmetric, $5f^2$ compound using low temperature absorption spectroscopy was reported.²⁷³ The syntheses of $\text{Th(O-2,6-R}_2\text{C}_6\text{H}_3)_4$ ($\text{R} = \text{Me}$, Pr^i) and $\text{U(O-2,6-Pr}^i_2\text{C}_6\text{H}_3)_4$ using an aminolysis reaction in toluene were also described, but a metathesis route using the $\text{ThI}_4(\text{THF})_4$ precursor is necessary to generate the analogous thorium *t*-butoxide substituted derivative, $\text{Th(O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_4$.^{59,126}

Lewis base adducts of thorium(IV) and uranium(IV) aryloxides are readily prepared. Initial reports of phenoxide compounds of uranium(IV) describe NH_3 derivatives from the reaction of UCl_4 or UOCl_2 with appropriate phenols in the presence of ammonia²⁷⁴ (see Equations (15) to (17)):

Alkoxide/phosphine uranium(IV) complexes $\text{Th(OPh)}_4(\text{dmpe})_2$ and $\text{U(OPh)}_4(\text{dmpe})_2$ are isolated as toluene solvates from the alcohol exchange of HOPh with $\text{M(Me)}_4(\text{dmpe})_2$ ($\text{M} = \text{Th}, \text{U}$).¹⁹⁰ Analogous Lewis base adducts of thorium tetrakis(aryloxide) complexes ($\text{Th(O-2,6-R}_2\text{C}_6\text{H}_3)_4(\text{THF})_2$, ($\text{R} = \text{Me}, \text{Pr}^i$) $\text{Th(O-2,6-Me}_2\text{C}_6\text{H}_3)_4(\text{py})_2$, and $\text{Th(O-4-Bu}^i\text{C}_6\text{H}_4)_4(\text{py})_3$) have been reported.^{59,126} Coordination of the less sterically demanding but more electron poor aryloxide ligand, $\text{O-2,6-Cl}_2\text{C}_6\text{H}_3$, produces $\text{U(O-2,6-Cl}_2\text{C}_6\text{H}_3)_4(\text{THF})_2$.²⁷⁵

A convenient preparation of the mono- and bisalkoxide uranium derivatives $\text{U(BH}_4)_3(\text{OCHR}_2)(\text{THF})_2$ and $\text{U(BH}_4)_2(\text{OCHR}_2)_2(\text{THF})_2$ ($\text{R} = \text{CHMe}_2, \text{CHPh}_2, \text{C}_6\text{H}_{11}$) involves the reduction of an appropriate ketone with $\text{U(BH}_4)_4$ in tetrahydrofuran.²⁷⁶ The monoalkoxides are alternatively prepared from the reaction of the ketones with four equivalents of UCl_4 in the presence of LiBH_4 , treatment of $\text{U(BH}_4)_4$ with the $\text{B(OCHR}_2)_n\text{H}_{3-n}$ ($\text{R} = \text{OPr}^i, \text{OCy}$) formed from the reaction of excess ketone employed in the reaction with liberated BH_3 , the redistribution reaction of $\text{U(BH}_4)_2(\text{OR})_2(\text{THF})_2$ with $\text{U(BH}_4)_4$ ($\text{R} = \text{Pr}^i, \text{Cy}$), or the addition of the respective alcohols, HOPr^i , HOCHPh_2 , or HOCy , to $\text{U(BH}_4)_4$. Similar products were obtained from reactions between $\text{U(BH}_4)_4$ and ketones 2-methylcyclohexanone, 4-*t*-butylcyclohexanone and norcamphor.

A comparison between the electronic influence of the tri-*t*-butylmethoxide ligand (tritox = $\text{OC(Bu}^t)_3$) and sterically analogous cyclopentadienyl ligand on a uranium(IV) metal center has been conducted.^{277,278} The tetravalent uranium complexes (tritox) $\text{UCl}_3(\text{THF})_x$ and (tritox) $_2\text{-UCl}_2(\text{THF})_2$ have been isolated; these species serve as precursors in the isolation of a series of mixed ligand compounds: ((tritox) $_2(\text{C}_5\text{H}_5)\text{UCl}$; (tritox) $_2\text{UR}_2$, $\text{R} = \text{BH}_4, \text{CH(COMe)}_3$, $\eta\text{-C}_3\text{H}_5$, CH_2Ph ; (tritox) $\text{U(BH}_4)_3(\text{THF})$, (tritox) $_2\text{U(BH}_4)_2$, (tritox) $_3\text{U(BH}_4)$).

Actinide(IV) alkoxide complexes have been reported which are coordinated by a variety of other bulky ligand sets. Uranium(IV) amido compounds are reagents for the preparation of homoleptic uranium(IV) alkoxides as well as mixed alkoxide/amido species. A variety of mixed aryloxide-diethylamide derivatives have been prepared including $(\text{U(NEt}_2)(\text{O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_3$ and $\text{U(NEt}_2)(\text{O-2,6-R}_2\text{C}_6\text{H}_3)_3$, $\text{R} = \text{Pr}^i, \text{Bu}^t$).^{279,280} The previously described metallacycle $[(\text{Me}_3\text{Si})_2\text{N}]_2\text{MCH}_2\text{Si(Me)}_2\text{NSiMe}_3$ ($\text{M} = \text{Th}, \text{U}$) is a useful starting material for the preparation of both homoleptic and mixed alkoxide/amide actinides compounds, including the compounds $\text{Th(O-2,6-Me}_2\text{C}_6\text{H}_3)[\text{N(SiMe}_3)_2]_3$, $\text{Th(O-2,6-Bu}^t_2\text{C}_6\text{H}_3)[\text{N(SiMe}_3)_2]_3$, $\text{Th(O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_2\text{-[N(SiMe}_3)_2]_2$, $\text{Th(O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_3[\text{N(SiMe}_3)_2]$, $\text{U(O-2,6-Pr}^i_2\text{C}_6\text{H}_3)[\text{N(SiMe}_3)_2]_3$, $\text{U(O-2,6-Bu}^t_2\text{C}_6\text{H}_3)[\text{N(SiMe}_3)_2]_3$, as well as the products $\text{Th}_4(\text{OPr}^i)_{16}(\text{py})_2$, $\text{Th}_2(\text{OCHEt}_2)_8$, $[\text{Th(OCHPr}^i)_4]_2$, $\text{M}_2(\text{OBu}^t)_8(\text{HOBu}^t)$ ($\text{M} = \text{Th}, \text{U}$) and U(OR)_4 ($\text{M} = \text{Th}, \text{R} = 2,6\text{-Bu}^t_2\text{C}_6\text{H}_3$; $\text{M} = \text{U}, \text{R} = 2,6\text{-Bu}^t_2\text{C}_6\text{H}_3$ or $2,6\text{-Pr}^i_2\text{C}_6\text{H}_3$) (*vide supra*).¹¹⁹ Substituted triamidoamine uranium(IV) compounds $\text{U(N(CH}_2\text{CH}_2\text{NSiMe}_3)_3)(\text{OR})$ ($\text{R} = ^t\text{Bu}, ^t\text{C}_4\text{F}_9, \text{Ph}, 2,6\text{-}^t\text{Bu}_2\text{-4-MeC}_6\text{H}_2$) and three *ate* derivatives $[\text{U(N(CH}_2\text{CH}_2\text{NSiMe}_3)_3)(\text{OR})(\text{OR}')\text{Li(THF)}_n]$ ($\text{R}, \text{R}' = \text{Bu}^t, \text{Ph}$) are prepared via reactions of the (triamidoamine)uranium chloride compound with an appropriate alkali metal alkoxide.¹³²

Appropriate chalcogenide sources allow for the one-electron oxidation of $\text{U(O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_3$ to chalcogenide-bridged uranium(IV) dimers $(\mu\text{-X})[\text{U(O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_3]_2$ ($\text{X} = \text{O}$, oxidant = N_2O , NO , Me_3NO , pyNO ; $\text{X} = \text{S}$, oxidant = COS , Ph_3PS).²⁷²

Mixed halide/alkoxide ligand compounds have also been reported. Derivatization of $\text{Th(OCH(Pr}^i)_2)_4(\text{py})_2$ with Me_3SiI yields $\text{ThI(OCH(Pr}^i)_2)_3(\text{py})_2$.²⁸¹ The compound $\text{UI}_2(\text{OPr}^i)_2(\text{HOPr}^i)$ is prepared by treatment of U metal with iodine in the presence of HOPr^i ; the product of solvent loss, $\text{U}_2\text{I}_4(\text{OPr}^i)_4(\text{HOPr}^i)$, is isolated under reduced pressure.²⁸² The instability of $\text{UI}_4(\text{MeCN})$ to tetrahydrofuran solvent allows for ring-opening of THF and recrystallization of $\text{UI}_2(\text{OCH}_2\text{CH}_2\text{CH}_2\text{CH}_2)_2(\text{Ph}_3\text{PO})_2$ following addition of triphenylphosphine oxide.¹⁸⁸ Other routes to mixed aryloxide-halide species include oxidation of $\text{U(O-2,6-Bu}^t_2\text{C}_6\text{H}_3)_3$ by a variety

of halogenating agents. Compounds of the formula $XU(O-2,6-Bu^t_2C_6H_3)_3$ ($X = F, Cl, Br, I$; oxidant = $AgBF_4, AgPF_6, C_6H_5CH_2Cl, PCl_5, AgBr, CBr_4, PBr_5, I_2, HCl_3, C_2I_4$) and $X_2U(O-2,6-Bu^t_2C_6H_3)_2$ ($X = I$; oxidant = Cl_4) have been prepared.^{271,272} Lappert and co-workers reported the synthesis of mixed ligand compounds $UCl_2(O-2,6-Bu^t_2C_6H_3)_2$, and $[Li(THF)_3UCl_2(O-2,6-Bu^t_2C_6H_3)_2(\mu-Cl)]$.²⁷⁹ In one report, $Th(OR)_4$ ($R = Pr^i, Bu^t$) was allowed to react with various quantities of acetyl chloride, resulting in the formation of mixed halide/alkoxide compounds and in the case of the Bu^t compounds, alkoxide/halide/acetate derivatives.²⁸³ The compound $UCl_2(Et_2)_2-xHOEt_2$ was isolated from a reaction of uranium metal with ethanol in CCl_4 .²⁶⁶ In an attempt to oxidize $Np(OEt)_4$ in the presence of bromine, $NpBr(OEt)_3$ and $NpBr_2(OEt)_2$ were generated.²⁶⁹

Thiolates. The first reported reaction route to homoleptic thiolate compounds (reaction of uranium tetrakisdiethylamide with four equivalents of either ethanethiol or butanethiol) appeared in 1956¹⁰² (Equation (18)); this reaction was subsequently reinvestigated.²⁸⁴ The homoleptic thiolate complexes are reported to be insoluble, but the addition of Lewis bases permits isolation of monomeric products; the complex $U(SPr^i)_4(hmpa)_2$ ($hmpa$ = hexamethylphosphoramide) has been crystallographically characterized.²⁸⁴ Protonation of $U(SPr^i)_4(hmpa)_2$ with $[NEt_3H][BPh_4]_2$ in the presence of $hmpa$ generates $[U(SPr^i)_2(hmpa)_2][BPh_4]$, and iodinolysis of $U(SPr^i)_4$ in pyridine yields the iodo derivatives $[U(SPr^i)_{4-n}I_n(py)_n]$ ($n = 1-3$). The complex $[U(SPr^i)_2I_2(py)_3]$ has been characterized by single-crystal X-ray diffraction.²⁸⁴ A uranium-sulfur cluster, $U_3S(SBu^t)_{10}$, is isolated from the reaction of uranium tetrakisdiethylamide and *t*-butylthiol, a reaction expected to afford $U(SBu^t)_4$.^{284,285} The Lewis base adduct, $U(SBu^t)_4(py)_3$, is obtained from this same reaction in the presence of pyridine, and the pyridine adduct is then cleanly converted to $U_3S(SBu^t)_{10}$ in refluxing benzene. Other synthetic routes employing reaction of either UCl_4 or $U(BH_4)_4$ with $NaSR$ lead to the formation of the red ionic complexes $[Na(THF)_3]_2[U(SR)_6]$ ($R = Bu, Pr^i, Bu^t, Ph$). It has been suggested that protonation of $[Na(THF)_3]_2[U(SBu)_6]$ with NEt_3HBPPh_4 forms the green compound $U(SBu)_4$ first reported by Gilman.^{102,286} Treatment of $U(BH_4)_4$ with $HSBu$ also allows for the preparation of $U(SBu)_4$.²⁸⁴

The synthesis and characterization of uranium(IV) phenylthiolates has also been investigated. In contrast with the reactions of $U(NEt)_4$ with alkylthiols to form either uranium(VI) tetrakis-thiolates $U(SR)_4$ ($R = Et, Bu, Pr^i$)^{102,286} or the cluster $[U_3S(S^tBu)_{10}]$,²⁸⁵ the reaction of phenylthiol with uranium(IV) tetrakisdiethylamide affords the red ionic product $[NEt_2H_2][U(SPh)_6]$.²⁸⁷ The reaction mixture of UCl_4 with $NaSPh$, $CuSPh$, and PPh_3 yields red $[(Ph_3P)Cu(\mu-SPh)_3U(\mu-SPh)_3Cu(PPh_3)]$, which has a core uranium environment analogous to that found in $[Na(THF)_3]_2[U(SR)_6]$.^{284,287,288} Homoleptic uranium(IV) tetrakisphenylthiolates are synthesized from reaction of either $U(BH_4)_4$ or $U(SBu)_4$ with phenylthiol, thiol exchange of $U(SBu)_4$ with $HSPh$, or oxidation of uranium metal with $RSSR$ ($R = Et, Pr^i, Ph$).²⁸⁴

Thorium and uranium thiolates coordinated by additional bulky ligands can be prepared. Reaction of the uranium metallacycle $[{(Me_3Si)_2N}_2]_2U(CH_2SiMe_2NSiMe_3)$ with one equivalent of 2,6-dimethylthiophenol allows for the isolation of monothiolate $U(S-2,6-Me_2C_6H_3)[N-(SiMe_3)_2]_3$.¹²⁷

The reactivity of select uranium(IV) thiolate compounds has been investigated. The product $(SPr^i)_2C=S$ was identified from reaction of carbon disulfide with $U(SPr^i)_4$.²⁸⁴

Triflates. Actinide triflate complexes have been investigated both as promising reagents for further synthesis, and as potent Lewis acids. The initial reports of triflate complexes of tetravalent actinides were thorium species $Th[N(SiMe_3)_2](OTf)_3$ and $Th[N(SiMe_3)_2]_3(OTf)$, generated by protonation of the correspondent thorium metallacycle by triflic acid.²⁸⁹ Subsequently, routes have been devised for the generation of the homoleptic compound $U(OTf)_4$ by treatment of the trivalent triflate with triflic acid, or by reaction of UCl_4 with $TfOH$.⁶² The tetravalent triflate reacts with triphenylphosphine oxide to generate the complex $U(OTf)_4(OPPh_3)_2$.

(v) *Ligands containing neutral group 16 donor atoms*

Aqua species. The coordination number of tetravalent actinide ions Th^{4+} and U^{4+} has been examined in aqueous solution.²⁹⁰ These studies suggest the metal ions have 10 ± 1 water molecules in their primary coordination sphere, at distances of 2.45 Å (Th) or 2.42 Å (U).

Early literature contains a large number of hydrates of tetravalent actinides, but as in the case of the trivalent species, it is difficult to ascertain whether these constitute complexes with water in the inner coordination sphere of the metal ion. It has been suggested that ease of removal of one water of hydration indicates it resides principally in the lattice. As an illustration of this, the reported actinide sulfate hydrates, $\text{An}(\text{SO}_4)_4 \cdot 8\text{H}_2\text{O}$, ($\text{An} = \text{Th}, \text{U}, \text{Pu}$) readily lose four molecules of water at temperatures $< 100^\circ\text{C}$. The fact that four molecules of water remain in the inner coordination sphere has been confirmed by single crystal X-ray diffraction.²⁵³ Coordination numbers as high as 10 (bicapped square antiprismatic arrangement of atoms about the metal center) have been reported for complexes with multidentate anions such as the hydroxyacetate $\text{U}(\text{OHCH}_2\text{CO}_2)_4(\text{H}_2\text{O})_2$ ²⁹¹ and the pyridine-2,6-dicarboxylate $\text{Th}\{\text{C}_5\text{H}_3\text{N}-2,6-(\text{CO}_2)_2\}_2(\text{H}_2\text{O})_4$.²⁹² Aqua complexes can also display relatively high coordination numbers, particularly when the metal coordination sphere does not contain other strongly coordinating ligands. Examples of this may be found in the compounds $\{\text{Th}(\mu\text{-OH})(\text{H}_2\text{O})_5(\text{pic})\}_2[\text{pic}]_4$ ($\text{pic} = \text{picrate}$)²⁹³ $[\text{ThCl}_2(\text{H}_2\text{O})_7]\text{Cl}_2 \cdot 18\text{-crown-6}$,²⁹⁴ and $[\text{UBr}(\text{H}_2\text{O})_8]\text{Br}_3 \cdot \text{H}_2\text{O}$ ²⁹⁵ in which the inner coordination sphere of the metal is heavily hydrated.

Ethers, cyclic ethers. As previously discussed, the actinide centers are often regarded to universally prefer hard Lewis base ligands, and yet in some instances (e.g., replacement of ethers by phosphines), it has been found that ethers do not serve as strong ligands. In nearly all isolated structures of tetravalent actinides with ethers, the coordinating base is either a cyclic ether (the constrained angle about oxygen increases the σ -orbital character in lone pairs and thereby the donor strength) or a bidentate di-ether such as 1,2-dimethoxyethane (dme), although the diethyl and dimethyl ether complexes of tetrahalides have been reported.

Several structures of actinide etherate complexes have appeared in recent years. Thorium complexes such as $\text{ThBr}_4(\text{THF})_4$,²⁹⁶ $\text{ThCl}_4(\text{H}_2\text{O})(\text{THF})_3$,²⁹⁷ and in $\text{ThBr}_4(\text{dme})_2$ ²⁹⁸ display distorted dodecahedral geometry. The smaller size of tetravalent uranium reduces the metal coordination number in $\text{UCl}_4(\text{THF})_3$.²⁹⁹ One bimetallic halide etherate has been reported; the complex $[\text{UCl}_3(\mu\text{-Cl})(\text{THF})_2]_2$ has been structurally characterized.³⁰⁰ The molecular structure of $[\text{NBu}_4][\text{UCl}_5(\text{THF})]$ has also been reported,³⁰¹ the metal center in this complex is pseudooctahedral.

Alcohols. Alcohols are among the most common “solvate” ligands in actinide chemistry (Table 13); historically the hydrated chloride complexes were reacted with alcohol in benzene, and the water of hydration removed by azeotropic distillation of the benzene. More recent examples result from the crystallization of anhydrous halides from alcoholic solvent. Similarly, solvates of alkoxide complexes result from metathesis or solvolysis reactions in alcohol. The molecular structures of the halides $\text{AnCl}_4(\text{Pr}^i\text{OH})_4$ ($\text{An} = \text{Th}, \text{U}$) have been reported,³⁰² the coordination geometry about the metal is a distorted dodecahedron.

As in the presence of aqua complexes, the presence of crown ethers facilitates the crystallization of actinide halide solvate complexes; in this manner $\text{ThCl}_4(\text{EtOH})_3(\text{H}_2\text{O}) \cdot 18\text{-crown-6}$ and $\text{ThCl}_4(\text{MeOH})_2(\text{H}_2\text{O})_2 \cdot 15\text{-crown-5}$ have been isolated.^{303,304}

Ketones, aldehydes, esters. Complexes of ketones, aldehydes, and esters have been made with uranium and thorium halide complexes by isolating the product from a ligand-containing solution. Ethyl- and *n*-propyl acetates also react with uranium tetrachloride to yield mixed halide-acetate salts with ester as an additional coordinating base.

Carbamides. Carbamides (along with the closely related ureas, *vide infra*) constitute one of the most numerous ligand sets available for actinide coordination (RCONR'_2). Despite

the presence of another heteroatom, coordination to the metal center generally occurs through the oxygen atom. Initial investigations of coordination chemistry emphasized the effect of contraction in metal ion radius in tetravalent halides across the actinide series (An = Th, U, Np, Pu) on the coordination number of the metal ion.³⁰⁵ Complexes of the stoichiometry AnCl₄·xL can be prepared from the reactions of AnCl₆²⁻ and the appropriate ligand; for the larger amides CH₃CON(Prⁱ)₂ and CH₃CH₂CON(Prⁱ)₂ the neptunium and plutonium chlorides form adducts where *x* = 2, whereas for the smaller amide HCON(Me)₂, *x* = 2.5. Similar correlations between steric size of a coordinating amide ligand and actinide coordination number have been noted for uranium and thorium nitrates,^{306,307} carboxylates,³⁰⁸ and thiocyanates.³⁰⁹ The complexes are stable in protic (and potentially coordinating) solvents such as alcohols and carboxylic acids, but are decomposed in water. Several monoamide derivatives of plutonium(IV) nitrate have been isolated; these are reported to form the adducts Pu(NO₃)₄(L)₃ (L = amide).³¹⁰

A number of complexes of monodentate amides have been structurally characterized with varying numbers of ligands, including those in Table 14. A limited number of complexes have also been reported for related lactam and antipyrine ligands.

Ureas. Urea adducts (and those of the closely related *N*-alkylated derivatives) may be prepared from nonaqueous solvents; alternatively, preparation in aqueous alcoholic solution leads to the formation of hydrates. In contrast to the carbamides discussed above, there is relatively little variability in the coordination number of reported urea adducts of tetravalent actinides. Most complexes are either six- or seven-coordinate; higher coordination numbers are observed for the larger thorium ion (Table 15).

The six-coordinate complexes are octahedral with the neutral ligands occupying *trans* positions. The eight-coordinate complex Th(NCS)₄[OC(NMe₂)₂]₄ is best described as a slightly distorted dodecahedron.

N-oxides, phosphine oxides, arsine oxides, and related ligands. The vast majority of compounds associated with this class of ligands contain phosphine oxide or similar ligands; compounds reported in the literature with coordinated phosphine oxide ligands are too numerous to list (to illustrate, Table 16 presents just simple “binary compounds” of the formula $\text{AnX}_4 \cdot n\text{L}$). Organophosphate esters are the principal extractant in a number of actinide liquid–liquid separation and purification schemes, and so the structural chemistry of the $\text{P}=\text{O}$ bond has drawn a great deal of attention. The prototypical species for this class of compounds is $\text{AnX}_4(\text{Ph}_3\text{PO})_2$ ($\text{An} = \text{Th}, \text{Pa}, \text{U}, \text{Np}, \text{Pu}$; $\text{X} = \text{Cl}, \text{Br}$). Both *cis*- and *trans*-octahedral coordination geometries have been identified; for the most part, complexes are isostructural for a given halide. A number of more recent structurally characterized examples are presented in Table 17.

By comparison, many fewer complexes of *N*-oxides and arsine oxides have been discussed. Given the relatively oxidizing nature of *N*-oxide compounds, it is difficult to stabilize tetravalent actinide complexes with these ligands except in the case of thorium, where no higher oxidation state is available. In this case, base adducts are known for a number of different simple inorganic salts of thorium (Table 18). Most complexes are those of pyridine *N*-oxide and related heterocyclic *N*-oxides. For more strongly complexing anions (e.g., NCS^- , lighter halides), the complexes do not behave as electrolytes in solution and form adducts with two or three neutral base ligands, indicating that no anion dissociation takes place. For less strongly coordinating ligands (nitrate, iodide, perchlorate, etc.), larger numbers of *N*-oxide ligands

Figure 14 General diagram of phosphine oxide.

coordinate (up to eight or nine), indicating that no inner-sphere anion coordination to the metal takes place.

The few known arsine oxide complexes are very similar in behavior to the corresponding phosphine oxide analogues. The only structurally characterized examples of this class are $UCl_4(Et_3AsO)_2$ ³¹¹ and $UBr_4(Ph_3AsO)_2$,³¹² both are *trans* octahedral.

Phosphine oxides have the general structure shown in Figure 14. The commercially available compound Cyanex 923 (TRPO), available through Cytec Inc., Canada, is a mixture of four trialkyl phosphine oxides, with substituents as indicated in Table 19. TRPO is very favorable as an extractant due to its hydrophobicity, solubility in organics, and stability with respect to hydrolysis.³¹³ TRPO has been investigated as an extractant for Th^{IV} from nitric acid solutions into xylene. Extractant dependency analysis shows that the uptake of Th^{IV} into the organic phase increases (slope of two) with increasing extractant concentration. Hence, the expected stoichiometry for the extraction is given by Equation (19):

As a comparison, the extraction of Th^{IV} from xylene by trioctylphosphine oxide (TOPO), Cyanex 921 (similarly available through Cytec Inc.) (Table 19), has also been studied and extractant dependency indicates a 1:2 metal:extractant complex ratio like that seen for TRPO.

IR data for the $Th^{IV}/TRPO$ complex shows that the phosphoryl stretching frequency moves down in energy from $1,146\text{ cm}^{-1}$ to a lower value of $1,095\text{ cm}^{-1}$, indicating a direct interaction between the phosphoryl oxygen and the Th^{IV} metal in the extracted complex.³¹⁴

Plutonium(IV) has also been extracted by a series of phosphine oxides including TRPO, bis(2,4,4-trimethylpentyl)octylphosphine oxide, commercially known as Cyanex 925 and TOPO.

Cyanex 925 with Pu^{IV} shows the best extractive ability in nitrate media due to better complexing ability of the nitrate anion to the metal. At high acid concentrations, nitric acid competes with $Pu(NO_3)_4$ for the binding site of Cyanex 925, causing the uptake of Pu^{IV} to fall off. At high HCl and $HClO_4$ concentrations, Pu^{IV} uptake increases dramatically due to the easier formation of neutral Pu^{IV} complexes and hydration considerations.

Extractant dependencies from both HCl and HNO_3 into various organic solvents show a slope of two for the uptake of Pu^{IV} by Cyanex 925. The resultant complexation stoichiometry in nitrate media is as shown in Equation (20):³¹⁵

Table 19 R-group substituents for various type of phosphine oxide extractants.

Extractant	Alkyl chain (R) length
Cyanex 923 (TRPO) (4 components)	$R_1 = R_2 = R_3 = C_8H_{17}$; $R_1 = C_8H_{17}$, $R_2 = R_3 = C_6H_{13}$; $R_1 = C_6H_{13}$, $R_2 = R_3 = C_8H_{17}$; $R_1 = R_2 = R_3 = C_6H_{13}$
Cyanex 921 (TOPO)	$R_1 = R_2 = R_3 = C_8H_{17}$
Cyanex 925	$R_1 = C_8H_{17}$, $R_2 = R_3 = 2,4,4\text{-trimethyl pentyl}$

Figure 15 Crystal structure of $\text{UBr}_4(\text{C}_{18}\text{H}_{15}\text{PO})_2$ Bombieri, Benetollo *et al.* *J. Chem. Soc., Dalton-Trans.* **1983**, 343).

A representative crystal structure of U^{IV} with two triphenylphosphine oxide molecules and four bromide ions is shown in Figure 15. Coordination of the triphenylphosphine oxide ligands occurs via the oxygen of the $\text{P}=\text{O}$ group in *trans* positions. The bromide atoms coordinate equatorially, making the uranium six-coordinate with an octahedral geometry.³¹⁶

Sulfoxides. Sulfoxides, particularly dimethylsulfoxide (DMSO), can act as oxygen-donor ligands to the electropositive actinides Th, U, Np, and Pu (Table 20). These complexes are most often prepared by reaction of the actinide salt (halides, nitrates, perchlorates) with the ligand in nonaqueous media, although some complexes can be prepared by anion exchange starting with the parent halide sulfoxide adduct. Adducts of the formula AnI_3L_4 ($\text{An} = \text{U}$, Np, Pu; $\text{L} = \text{DMSO}$) are prepared by oxidation of the corresponding metal by iodine in DMSO.¹⁴

Dimethylsulfoxide acts as a strong donor, leading to the formation of ionic compounds in the presence of excess base. The molecular structure of $\text{UCl}_4 \cdot 3\text{DMSO}$ reveals it to be $[\text{UCl}_2(\text{DMSO})_6][\text{UCl}_6]$;³¹⁷ the uranium atom in the cation lies at the center of a distorted dodecahedron. Other reported complexes have a large number of associated sulfoxide molecules. These species are likely also to be ionic, as indicated by their IR spectra. With bulky sulfoxides as ancillary ligands, complexes with lower coordination numbers can be isolated; the complex $\text{UCl}_4(\text{Bu}^i_2\text{SO})_2$ possesses *trans*-octahedral geometry.³¹²

Thioethers. As in the case of ethers, complexes contain either cyclic thioethers (e.g., tetrahydrothiophene, THT) or bidentate dithioethers such as $\text{MeSCH}_2\text{CH}_2\text{SMe}$. There is one report of a dimethyldithioethane complex of a halide, $\text{UCl}_4(\text{MeSCH}_2\text{CH}_2\text{SMe})_2$. The only structurally characterized complexes are those of borohydride derivatives $\text{U}(\text{MeBH}_3)_4(\text{MeSCH}_2\text{CH}_2\text{SMe})$ ¹⁸¹ and $[\text{U}(\text{MeBH}_3)_4(\mu\text{-THT})_2]$.³¹⁸

Thioureas. A few thorium complexes of the formula $\text{ThCl}_4(\text{L})_x$ have been reported ($\text{L} = \text{SC}(\text{NH}_2)_2$, $x = 2, 8$; $\text{L} = \text{SC}(\text{NH}_2)(\text{NH}p\text{-ClC}_6\text{H}_4)$, $x = 4$; and $\text{L} = \text{S}(\text{cyclo-CNHCH}_2\text{CH}_2\text{NH})$, $x = 8$).

Phosphine sulfides, selenides. Phosphine sulfides and selenides do not often act as Lewis bases towards tetravalent actinides, owing to their propensity for chalcogen transfer. Only the thorium complex $\text{ThCl}_4(\text{SePPh}_3)_2$ has been reported.³¹⁹

(vi) Ligands containing group 17 donor atoms

Binary halides. Hydrous fluoride complexes are generally obtained by precipitation of the metal ion from aqueous solution, while anhydrous fluorides are produced from halogenation of oxides, or by thermal decomposition of salts (e.g., NH_4UF_5). The anhydrous tetrafluoride complexes of thorium, protactinium, uranium, neptunium, and plutonium are known; all are halogen-bridged polymers in the solid state. The complexes are isostructural; the metal center lies within a distorted square antiprismatic arrangement of fluoride ions. Hydrous fluorides can display alternate geometries; in the compound $\text{Np}_3\text{F}_{12} \cdot \text{H}_2\text{O}$, there are three distinct neptunium sites, none of which is coordinated by the water of hydration.³²⁰

Tetrachloride and tetrabromide complexes are known for thorium, protactinium, uranium, neptunium, and plutonium. These are similarly produced by halide-based oxidation of metals or hydrides, or by halogenation of oxides. A common structural type is reported for most compounds. The reported structure of thorium tetrachloride reveals that the coordination geometry about the metal is dodecahedral.³²¹ The compounds are generally volatile and can be sublimed. The gas-phase electron diffraction structure of UCl_4 ³²² suggests that the molecule is tetrahedral, with a U–Cl distance of 2.51 Å.

The iodide complexes are somewhat less stable, and well-characterized examples exist only for thorium, protactinium, and uranium. The thorium and uranium derivatives can be conveniently prepared by the reaction of iodine and metal, while protactinium tetraiodide is generated by reduction of PaI_5 . The molecular structure of ThI_4 has been examined;³²³ the metal lies within a distorted square antiprism of iodide ions.

Complex halides. A large number of complex halides of tetravalent actinides have been prepared, particularly for the fluoride complexes.³²⁴ The most common formulations are shown in Table 21.

Prototype structures within these classes of compounds have been determined. The structure of $LiUF_5$ ³²⁵ is also representative of the compounds of thorium, protactinium, neptunium, and

Table 21 Classes of complex halides of tetravalent actinides.

plutonium. The uranium atom in this structure is surrounded by nine fluorides in a tricapped trigonal prismatic array, with adjacent prisms sharing edges and corners. This local coordination environment persists in other complex fluorides such as KAn_2F_9 ($\text{An} = \text{Th–Pu}$)³²⁶ and $\text{MAn}_3\text{F}_{13}$ ($\text{M} = \text{NH}_4, \text{Rb}; \text{An} = \text{Th, U, Np}$).³²⁷ Compounds of the type M_2AnF_6 ($\text{M} = \text{Rb}; \text{An} = \text{U, Np, Pu}$) contain chains of AnF_8 dodecahedra, whereas in the complexes of the lighter alkali metals ($\text{M} = \text{Na, K}; \text{An} = \text{U}$), the UF_9 polyhedra are tricapped trigonal prisms.^{326,328} The compound $\text{CoAnF}_6 \cdot 3\text{H}_2\text{O}$ ($\text{An} = \text{U, Np}$) consists of chains of units $[\text{AnF}_8(\text{H}_2\text{O})]$ (capped square antiprisms sharing two fluorides).³²⁹ Compounds of the formula $(\text{NH}_4)_4\text{AnF}_8$ generally contain distinct dodecahedral $[\text{AnF}_8]^{4-}$ ions ($\text{An} = \text{Th, U, Pa, Np, Pu}$);³³⁰ the exception is the thorium compound, in which ThF_9 tricapped trigonal prisms share edges to form chains.³³¹

More recently, a number of novel uranium fluoride complexes have been produced in hydrothermal syntheses in the presence of organic structure-directing agents^{332–336} (see Table 22). Reactions of UO_2 with aqueous orthophosphoric acid, aqueous hydrofluoric acid, and organic templating agents such as alkanediamines generate a variety of solid-state structures incorporating negatively charged sheets of uranium fluoride polyhedra separated by alkylammonium counterions and occluded water molecules. In most of the layered structures, the layers are constructed from equivalent UF_9 tricapped trigonal prisms that share three edges and two corners, whereas the complex $[\text{HN}(\text{CH}_2\text{CH}_2\text{NH}_3)_3]\text{U}_5\text{F}_{24}$ contains both UF_8 bicapped trigonal prisms and UF_9 tricapped trigonal prisms. The ammonium ions can subsequently be exchanged for a wide range of group 1, group 2, and transition metals. A subsequent study investigated the role of water stoichiometry in determining the structure of the product in the $\text{UO}_2/2\text{-methyl-piperazine}/\text{HF(aq.)}/\text{H}_2\text{O}$ system.

Table 22 Uranium(IV) fluoride complexes produced by hydrothermal syntheses.

C. Burns *Inorg. Chem.* **2001**, 40, 1347–51.

The reaction conditions appear to control the dimensionality of the complexes; an increase in solution acidity results in an increase in bridging between uranium centers. The complex $(\text{C}_5\text{N}_2\text{H}_{14})_2(\text{H}_3\text{O})\text{U}_2\text{F}_{13}$ is a molecular, or “zero-dimensional,” phase consisting of dimeric $[\text{U}_2\text{F}_{13}]^{5-}$ units separated by 2-methyl-piperazine and hydronium cations. Each dimer consists of face-sharing trigonal prisms, wherein uranium cations are bonded to eight fluorine atoms in a distorted bicapped trigonal prismatic coordination. $(\text{C}_5\text{N}_2\text{H}_{14})_2\text{U}_2\text{F}_{12} \cdot \text{H}_2\text{O}$ has a one-dimensional structure and contains uranium fluoride chains formed from edge-sharing polyhedra with eight-coordinate uranium. $(\text{C}_5\text{N}_2\text{H}_{14})(\text{H}_3\text{O})\text{U}_2\text{F}_{11}$ consists of anionic sheets of nine-coordinate uranium cations that are separated by protonated 2-methyl-piperazine and occluded hydronium cations. The related aqua complex $(\text{C}_5\text{H}_{14}\text{N}_2)\text{U}_2\text{F}_{10}(\text{H}_2\text{O})$ ³³⁷ has also been prepared under hydrothermal conditions, and possesses a uranium fluoride chain structure. The complexes $(\text{NH}_4)_7\text{U}_6\text{F}_{31}$ and $(\text{NH}_4)\text{U}_3\text{F}_{13}$ are prepared in the presence of DABCO as the templating base;³³⁶ the ammonium counterion is presumed to arise from decomposition of the organic base. $(\text{NH}_4)_7\text{U}_6\text{F}_{31}$ consists of chains of nine-coordinate uranium fluoride polyhedra, while $(\text{NH}_4)\text{U}_3\text{F}_{13}$ consists of a three-dimensional network.

The heavier halides display a significantly reduced propensity to form bridging structures, and the dominant class of complexes is that containing the $[\text{AnX}_6]^{2-}$ unit, although evidence exists for short chain-like ions such as $[\text{Th}_2\text{Cl}_{10}]^{2-}$, $[\text{Th}_3\text{Cl}_{14}]^{2-}$, and $[\text{Th}_3\text{Cl}_{10}]^{2+}$ in thorium-rich molten salts such as ThCl_4 , A_2ThCl_6 , and A_3ThCl_7 ($\text{A} = \text{Li}, \text{Na}, \text{K}, \text{Cs}$).³³⁸ Crystallographically characterized examples of complexes $\text{A}_2[\text{AnX}_6]$ ($\text{An} = \text{U}, \text{Np}$; $\text{X} = \text{Cl}, \text{Br}, \text{I}$) reveal octahedral coordination about the metal center.^{339–342}

Crystallization of complex halides from solution containing crown ethers results not in the complexation of the actinide by the ether oxygen atoms, but rather in the isolation of $[\text{AnX}_6]^{2-}$ salts in which the crown appears to act as a crystallization aid.^{304,343–345}

Oxohalides. A number of oxohalides of the formula AnOX_2 have been reported; the structure of PaOCl_2 consists of an infinite polymer in which the Pa atoms are seven-, eight-, and nine-coordinate.³⁴⁶

3.3.2.2.3 Chelating ligands

(i) Multidentate donor ligands

Hydroxamates, cupferron, and related ligands. As anionic oxygen donor ligands, hydroxamates have a strong affinity for the oxophilic tetravalent actinides, with solution complex formation constants generally greatest for Pu^{IV} and decreasing as follows: $\text{Pu}^{\text{IV}} > \text{Np}^{\text{IV}} > \text{U}^{\text{IV}} > \text{U}^{\text{VI}}$. A significant effort has been made to prepare ligands with high specific affinity and selectivity for actinides that could be used for mammalian chelation therapy or as a specific extractant. A biomimetic approach to such ligand design, based on naturally occurring hydroxamate and catecholate siderophores and hydroxypyridinoate moieties, has been the most vital. The actinide

complexes reported include synthetic and biogenic bi-, hexa- and octadentate hydroxamates. Proposed therapeutic removal of actinides has evolved from substituting a nontoxic metal for the metal bound in blood and tissue, to chelating the Pu with general or specific chelating agents.^{347–352}

Simple bidentate hydroxamates commonly bind actinides via replacement of the hydroxamate proton by the metal to form a five-membered chelate ring. The known $M^{IV}L_4$ complexes are usually prepared by treating an aqueous solution of the metal with an excess of the hydroxamic acid.^{353,354} The complexes $Th[(CH_3)_2CHN(O)O(O)R]_4$ ($R = C(CH_3)_3$ (**1**), or $CH_2C(CH_3)_3$ (**2**)) have been prepared directly in aqueous solution. The U^{IV} analog of (**1**) was prepared similarly, but it is unstable and undergoes an internal oxygen transfer reaction to form a bis(hydroxamato)uranyl complex. These complexes have been characterized using single-crystal X-ray diffraction and optical absorbance spectroscopy. Complex (**1**) has approximately S_4 symmetry and the eight-coordinate polyhedron is nearly cubic, whereas the structure of (**2**) shows an eight-coordinate metal, with D_{2d} trigonal-faced dodecahedral geometry (Figure 16).³⁵⁵ Somewhat surprisingly, one hydroxamic acid, $(PhCO)NHOH$, has been reported to behave as a neutral ligand in a postulated 10-coordinate complex, $Th(NO_3)_4((PhCO)NHOH)_2$; however, the stoichiometry of the complex has not been confirmed nor has the complex been fully characterized. Several complexes of *N*-phenyl-benzoylhydroxamic acid (HL^1) and cupferron (*N*-nitrosophenylhydroxylamine, HL^2) have been reported.³⁵⁶ The complexes $Th(L^1)_4 \cdot 4H_2O$ and $Th(L^1)_3 \cdot 2H_2O$ have been prepared by reacting an aqueous solution of thorium nitrate with an excess of the ligand. $Th(L^2)_4 \cdot H_2O$ was obtained similarly from combination of thorium nitrate and cupferron in $H_2O/MeOH$. Several other ternary complexes, including $Th(L^2)_4Ph_3PO$, $Th(L^2)_4py$, and $Th(L^2)_4dmf$, were prepared by treating solutions of $Th(L^2)_4 \cdot H_2O$ in $CHCl_3$ with an excess of the ancillary ligand. Some U^{IV} complexes of cupferronate and neocupferronate were prepared and characterized by optical absorbance, vibrational, and electron spin resonance spectroscopy.^{357,358} However, their solution and solid-state structures have not been determined.

The complexation of actinides with multidentate hydroxamate ligands comprise naturally-occurring siderophores and synthetic ligands designed based on these Fe^{III} chelators. For example, a series of ligands based on desferrioxamines have been synthesized and their metal complexes characterized. The structure of a Pu^{IV} -desferrioxamine E complex was determined from X-ray diffraction analysis³⁵⁹ (Figure 17). Other types of ferrioxamine complexes of Th^{IV} and Pu^{IV} have been characterized in solution by NMR, potentiometry, and optical absorbance spectroscopy, including desferrioxamine B (DFO), octadentate derivatives [*N*-(2,3-dihydroxy-4-carboxybenzoyl)desferrioxamine B (DFOCAMC), *N*-(1,2-dihydro-1-hydroxy-2-oxypyridin-6-yl)carbonyl)desferrioxamine B (DFO-1,2-HOPO), and *N*-(2,3-dihydroxy-4-(methylyamido)benzoyl)-desferrioxamine B (DFOMTA)].³⁶⁰

The complexation of thorium(IV) and plutonium(IV) with a tetrahydroxamate ligand based on the cyclohexane-1,2-diyl dinitrilotetraacetate complexon, with hydroxamate instead of carboxylate groups has been reported. The speciation appears to be pH dependent. Up to pH 9 the complexes

Figure 16 Crystal structures of $Th[(CH_3)_2CHN(O)O(O)R]_4$ ($R = C(CH_3)_3$ (**1**) or $CH_2C(CH_3)_3$ (**2**)). (Smith and Raymond *J. Am. Chem. Soc.* **1981**, *103*, 3341–3349).

Figure 17 Plutonium(IV) coordination sphere in the crystal structure of Pu^{IV} complexed by the siderophore desferrioxamine E (Neu, Matonic *et al.* *Angew. Chem., Int. Ed. Engl.* **2000**, 39, 1442–1444).

are monomeric; then dimeric complexes, M₂L₂, have been suggested based on the magnetic properties of these complexes and modeling calculations.³⁶¹

Catecholate. Actinide(IV) complexes formed by catechol and the related compounds resorcinol, phloroglucinol, orcinol, and pyrogallol include the mono, bis, tris, and tetra complexes as well as polymeric compounds (Table 23). Thorium dichloride catecholate, and the corresponding resorcinolate, phloroglucinolate, and orcinolate have been obtained by evaporating an ether solution of the components to dryness and heating the residue until the evolution of hydrogen chloride ceased. When thorium tetrachloride is added to an excess of the molten catechol using this preparation, the product is H₂[Th(C₆H₄O₂)₃].³⁶² More common complexes are tetrakis(catecholato)uranate(IV) and -thorate(IV) complexes Na₄[M(C₆H₄O₂)₄]·21H₂O, M = Th, U, which are obtained from basic aqueous solutions of the metal chlorides. The complexes show *D*_{2d} molecular symmetry (structure determined by single-crystal X-ray diffraction, see Figure 18).³⁶³ The geometry of the anion is a trigonal faced dodecahedron and the oxygen atoms of the water molecules form a hydrogen-bonded network through the crystal. The other compounds, thorium(IV) bis derivatives of 2,2'-dihydroxybiphenyl or dinaphthyl and 1,8-dihydroxynaphthalene, ThL₂, are precipitated from methanolic solutions of the tetrachloride and the diol in the presence of base. These complexes have not been structurally characterized.³⁶²

Tiron complexes of Th^{IV} and other actinides have been prepared, generally in aqueous solution.³⁶⁴ The EXAFS data have been modeled to include binding of the sulfonate group to Th^{IV} at low pH. This preferred complexation of a sulfonate over a catecholate, even at low pH, is unexpected. Bidentate catechol ligation of thorium Th(tiron)_x, (*x* ≥ 2), has been proposed at very high excess Tiron.

Table 23 Actinide(IV) catecholates and related compounds.

Figure 18 Crystal structures of $\text{Na}_4[\text{M}(\text{C}_6\text{H}_4\text{O}_2)_4] \cdot 21\text{H}_2\text{O}$, $\text{M} = \text{Th}, \text{U}$ (Sofen, Abu-Dari *et al.* *J. Am. Chem. Soc.* **1978**, 100, 7882–7887).

The similarities between Pu^{IV} and Fe^{III} (charge to ionic radius ratios, formation of highly insoluble hydroxides) have stimulated the design of specific Pu^{IV} sequestering agents modeled after iron(III) chelators.^{81,347,350,365} This approach led to the design of potentially octadentate catecholamide ligands including both catechol only and mixed functional catechol and hydroxypyridinone ligands. These ligands have been studied for intended application in mammalian actinide decorporation.^{366–368} Plutonium and americium complexes have been reported for a series of sulfonated and carboxylated catechols. The stoichiometry of the complexes formed depends on pH. Above pH 12, the Pu^{IV} complex is tetrakis(catecholate) and at neutral pH it is tris(catecholate).^{81,365} Tetravalent actinide complexes can also be prepared indirectly. For example, the reduction of Np^{V} by catecholate and hydroxypyridinoate ligands yields a Np^{IV} species as determined using X-ray absorbance spectroscopy.³⁵⁰

Pyoverdin. Pyoverdin complexes of tetravalent actinides have been investigated due to the potential of this class of ligand to solubilize and sequester these metals (as they do for Fe^{III}). At near-neutral pH pyoverdine forms a 1:1 Pu:pyoverdine complex with Pu^{IV} . The stoichiometry changes to 1:2 when excess ligand is present. Thorium(IV), U^{IV} , and U^{VI} complexes have also been reported. Their optical absorbance spectroscopic properties, but no structural studies, are reported. The selectivity of pyoverdin for common actinides in the order $\text{Th}^{\text{IV}} > \text{U}^{\text{IV}} > \text{U}^{\text{VI}}$ has been proposed.^{369,370}

Pyridonate. Tetravalent Th^{IV} and U^{IV} complexes of 1 oxy-2-pyridonate, $\text{Th}(\text{C}_5\text{H}_4\text{NO}_2)_4\text{H}_2\text{O}$, and $\text{U}(\text{C}_5\text{H}_4\text{NO}_2)_4\text{CHCl}_3$, have been prepared by slowly adding a basic aqueous solution of excess ligand to solutions of the metal tetrachlorides. The crystal structure of the thorium complex, $\text{Th}(\text{C}_5\text{H}_4\text{NO}_2)_4\text{H}_2\text{O}$, shows a nine-coordinate, neutral complex of low symmetry. Four bidentate ligands and one water molecule are bonded to thorium to form a D_{3h} tricapped trigonal prismatic coordination geometry.³⁷¹ The related compound $\text{Th}(\text{C}_5\text{H}_4\text{NO}_2)_4\text{-MeOH}$ was prepared by refluxing a methanolic solution of thorium nitrate with excess *O*-hydroxypyridine-*N*-oxide. The complex has the same general coordination geometry as the aqueous complex, with methoxide in the inner coordination sphere.³⁷² Multifunctional ligands containing one to four hydroxypyridinone binding units have been researched for their potential use in actinide separations and chelation therapy. For example, the octadentate, mixed hydroxypyridinone (HOPO) ligand, 3,4,3-LI-(1,2-Me-3,2-HOPO), when administered orally, removes actinides from animals more efficiently than any injected ligand studied previous.^{349,367,373}

1-hydroxy-6-*N*-octylcarboxamide-2(1H)-pyridinone (octyl-1,2-HOPO) has been shown to be a highly selective extractant for tetravalent plutonium from acidic solutions. The structure of octyl-1,2-HOPO is illustrated in Figure 19. The general equilibrium for the extraction from nitric acid solutions is given in Equation (21):

Figure 19 Octyl-1,2-HOPO.

In Equation (21) the ligand acts in a deprotonated bidentate manner, where m can range from 0 to 4. While the hydroxypyridinonate ligands are themselves a class of compounds, their ability to extract Pu^{IV} is directly related to their protonation constants. Octyl-1,2-HOPO has the lowest protonation constants among all hydroxypyridinonates thus making it the best agent for extraction from acid solutions, particularly at low acid concentrations.

Extractant dependency at low concentrations indicates independent behavior, even though high distributions are obtained. At high concentrations, slope analysis gives a value of four as discussed in the equilibrium above. This could possibly be explained by the presence of $\text{Pu}(\text{HOPO})(\text{NO}_3)_3$ at low concentration and at $\text{Pu}(\text{HOPO})_4$ at higher concentrations.²²⁶

From an X-ray single crystal diffraction study of Th^{IV} with a 1-hydroxy-2(1H)-pyridinone, a coordination number of nine can be seen. This coordination number is due to four of the bidentate ligands chelating to thorium with the additional complexation of one methanol molecule, as illustrated in Figure 20.³⁷⁴

8-Hydroxyquinoline and derivatives. The complex of Th^{IV} with 8-hydroxyquinoline(Ox), $\text{Th}(\text{Ox})_4 \cdot \text{HOx}$ was prepared by precipitation from aqueous solution.³⁷⁵ The IR spectra of the Th complexes have absorbance frequencies corresponding to a $\text{N-H} \cdots \text{O}$ bond, similar to those observed in the spectrum of $\text{UO}_2(\text{Ox})_2\text{HOx}$. This vibrational band is not observed in $\text{Th}(\text{Ox})_4$, suggesting that HOx is bound to the metal through the phenolic O in this case.³⁷⁶ Several other complexes of Th^{IV} with 8-hydroxyquinoline derivatives have also been prepared similarly, including those with 7-nitroso-8-hydroxyquinoline-5-sulfonic acid³⁷⁷ and 5-chloro-7-nitro-8-hydroxyquinoline.³⁷⁸ When $\text{Th}(\text{Ox})_4 \cdot \text{HOx}$ is dissolved in DMSO, the $\text{Th}(\text{Ox})_4 \cdot 2(\text{DMSO})$ complex forms, in which only one DMSO is coordinated to the metal center. The complexes were characterized in solution by vibrational spectroscopy. The molecular structure of the complex determined from X-ray diffraction is shown in Figure 21. The oxine groups are arranged in a distorted square antiprismatic configuration about the metal ion, with the coordinated DMSO in a capping position.³⁷⁹ Similarly, in the complex $\text{Th}(\text{Ox})_4\text{DMF}$, the four 8-quinolinolato ligands are bidentate, and a DMF ligand, bonded through the oxygen, completes the coordination sphere. In this case the coordination polyhedron of the thorium atom is best described as a slightly distorted tricapped trigonal prism.³⁸⁰ Analogous heavier actinide complexes of Np and Pu with 8-hydroxyquinoline

and some of its 2-, 5-, 7-Me- and halogen-substituted derivatives have been reported and assigned the stoichiometries $Np(Ox)_4$ and $Pu(Ox)_4$.³⁸¹

Carbamate. Thorium(IV) and uranium(IV) carbamate complexes $M(R_2NCX_2)$ are usually obtained by the insertion of CX_2 ($X = O, S, Se$) or COS into the metal–nitrogen bonds of thorium(IV) and uranium(IV) dialkylamides $M(NR_2)_4$.³⁸² The complexes are precipitated from *n*-hexane solutions of the M^{IV} -tetrakis dialkylamide by addition of excess CX_2 . A much simpler route is by reaction of UCl_4 with R_2NH and carbon dioxide in benzene ($R = Et$) or toluene ($R = Me$). The carbamates precipitate on addition of *n*-heptane after concentrating the solution.³⁸³ Complexes in Table 24 have been reported, based mostly on elemental analysis, IR and NMR spectroscopy. The complex $U(Et_2NCO_2)_4$, prepared by reaction of UCl_4 with Et_2NH and CO_2 , is a monomer in benzene and the 1H -NMR spectra of this compound indicate that the alkyl groups are equivalent. A by-product of the preparation of $U(Et_2NCO_2)_4$ from the tetrachloride and the amine is a product of composition $U_4O_2(Et_2NCO_2)_{12}$. This is a tetramer in which there are two inequivalent uranium(IV) sites. One U^{IV} is coordinated in a distorted tricapped trigonal prism, and the geometry of the other does not fit any type of regular polyhedron.³⁸³ These compounds are very sensitive to oxygen and water. Related Th^{IV} and U^{IV} thiocarbamates $M(R_2NCXY)$ (X and Y are O or S) are obtained similarly from the dialkylamides $M(NR_2)_4$. For example, $M(OSCNEt_2)_4$ and $M(S_2CNEt_2)_4$ have been characterized in direct analogy with the carbamates.³⁸² Related pyrazolylborate complexes of the form, $U(O_2CR)_2L_2$ ($R = NEt_2, Me; L = \text{tris(pyrazolyl)borate}$) have also been prepared and characterized by elemental analysis and NMR, IR, and reflectance spectroscopies.³⁸⁴ $Cp_2U(XYCNEt_2)_2$ ($X, Y = O \text{ or } S$ and $X = O, Y = S$) were prepared by treating $Cp_2U(NEt_2)_2$ with CS_2 , COS, and CO_2 . The compounds, $Cp_2U(S_2CNEt_2)_2$ and $Cp_2U(OSCNEt_2)_2$ are monomeric in benzene; for $Cp_2U(O_2CNEt_2)_2$ polymeric behavior is indicated. Spectroscopic data are consistent with a bidentate coordination of the carbamate ligands in all cases. The coordination geometry around the U center is pseudooctahedral with cyclopentadienyl groups occupying mutually *cis* positions.^{385–387}

Oxalate. A large number of oxalato and mixed oxalato complexes (Tables 25 and 26) have been reported. The hydrated oxalates, $M(C_2O_4)_2 \cdot xH_2O$ ($x = 0, 1, 2$ or 6) are precipitated from aqueous media. The Th^{IV} and U^{IV} compounds are isomorphous. The neptunium(IV) compound consists of $[Np(C_2O_4)_2]_n$ layers, in which all oxalato ions are tridentate chelate-bridged, and the coordination polyhedron of the neptunium atom is a distorted cube comprised of eight oxygen atoms from four

oxalate ligands. The hydrated basic oxalate, $UO(C_2O_4) \cdot 6H_2O$, precipitates on photoreduction of $UO_2(HCO_2)_2$ in the presence of oxalic acid. Other hydrates are known; some authors describe them as hydroxo compounds [e.g., $U(OH)_2(C_2O_4) \cdot 5H_2O$], but this requires confirmation.

A few salts of the trisoxalato actinide(IV) anions are known, such as the acid benzylquinolinium compounds (Table 25), but the more usual complexes are the tetraoxalato and pentaoxalato species. The coordination geometry of the 10-coordinate thorium atom in the anion of $K_4[Th(C_2O_4)_4] \cdot 4H_2O$ ³⁸⁸ is a slightly irregular bicapped square antiprism with an oxalate bridged structure that is cross-linked into a three-dimensional framework by hydrogen bonding (Figure 22). The geometry in both crystal modifications of $K_4[U(C_2O_4)_4] \cdot 4H_2O$ ³⁸⁹ is the same as in the thorium compound. In one phase the three bidentate C_2O_4 groups and a tetradentate bridging C_2O_4 group link the metal atoms in a one dimensional polymeric array; the other phase is isostructural with the thorium compound. The uranium atom in $Ba_2U(C_2O_4)_4 \cdot 8H_2O$ is nine-coordinate, bound by four oxalates and one water molecule. The coordination geometry about the U atom is between tricapped trigonal prism and mono capped square antiprism.³⁹⁰ Ba atoms interact with the oxalate O atoms, making the oxalates appear as quadridentate ligands that bridges U and Ba atoms. Additional An^{IV} oxalato complexes with molar ratios 1:5 or 1:6 metal ion to oxalate have been reported, but little is known about their coordination geometry and they could be mixtures of other known oxalato compounds.

Analysis of crystals of M₂Np₂(C₂O₄)₅·nH₂O (M = H, Na, K, and NH₄) by electronic absorption spectroscopy in the long wave region of the spectrum showed that the coordination polyhedron of neptunium(IV) in these compounds differs from that in previously studied crystal compounds of Np^{IV}. The crystal structure of H₂Np₂(C₂O₄)₅·9H₂O (Figure 23) shows that Np⁴⁺ cations and C₂O₄²⁻ anions form an openwork skeleton with channels extending along z-axis of the crystal. Oxonium cations and H₂O molecules are located in the channels. Two independent neptunium(IV) atoms are surrounded by oxygen atoms of five oxalate ions and four water molecules (CN 12); the coordination polyhedron is a distorted hexagonal analogue of cubooctahedron.³⁹¹

Mixed oxalates and oxalato complexes (Table 24) also require further investigation. The sulfito and sulfato oxalates have been mentioned earlier and an equally large number of carbonato-oxalato species have been recorded,^{388,392} some of which may well be mixtures. In addition to the compounds listed in Table 24, products of the rather unlikely compositions K₇[U(OH)(C₂O₄)₂(CO₃)₃]·6H₂O and K₁₆[U₂(OH)₂(C₂O₄)₃(CO₃)₈]·10H₂O have been reported.

Polymeric K₂MnU(C₂O₄)₄·9H₂O³⁹³ has been prepared by the reaction of the tetraoxalato uranate compound, K₄U(C₂O₄)₄, with Mn^{II} in aqueous solution. The U ion is linked to four Mn^{II} ions via each of its oxalate ligands. The U^{IV} ion is nine-coordinate, bonded to four oxalate ligands and one water molecule.

β-Diketonates. β-Diketones chelate with metal ions, including actinides, to form neutral species via the deprotonated enolate anions as illustrated in Figure 24.³⁹⁴ A very wide array of homoleptic complexes of the general formula An(R¹COCR²COR³)₄ have been reported for

Figure 22 Oxalate bridged three-dimensional structure of $K_4[Th(C_2O_4)_4] \cdot 4H_2O$; oxalates bridge in each plane, either directly or via hydrogen-bonding (Akhtar and Smith *Acta Crystallographica, Section B* **1975**, 31, 1361).

Figure 23 Oxalato bridge Np^{IV} centers in the crystal structure of $H_2Np_2(C_2O_4)_5 \cdot H_2O$ (Bykhovskii, Kuz'mina *et al. Radiokhimiya* **1988**, 30, 37–41).

An=Th, U, Np, and Pu. In complexing with metal ions, the β -diketones form planar six-member chelate rings with elimination of the enol proton. The simpler β -diketones, such as acetylacetone (HAA), are fairly water soluble, but form complexes that may be soluble in organic solvents. This is especially true for the An^{IV} ions which form strong complexes with HAA and can be effectively sequestered to the organic phase, making HAA a potentially useful extractant (See [Table 27](#)). The four stability constants in [Table 27](#) for tetravalent actinides imply that four HAA ligands coordinate with each metal ion in the formation of the extracted neutral ML_4 complexes.³⁹⁵

Like with trivalent actinides (*vide infra*), 2-thenoyltrifluoroacetone (HTTA) is also effective at complexing with tetravalent actinides. Extractant dependency studies have shown than Th^{IV} displays a 1:4 extraction stoichiometry (Th:extractant) with HTTA.³⁹⁶

Figure 24 Bond tautomerism in β -diketone and β -diketonate.

Table 27 Stability constants for acetylacetonate complexes and distribution constants (from benzene or chloroform) in perchlorate media.^a

^a Adapted from Ahrland, S. In *The Chemistry of the Actinide Elements*; J. Katz, G. Seaborg, L. Morss, Eds.; Chapman and Hall: New York, 1986; Vol. 2, p 1480.

In perchlorate media, HTTA extracts Th^{IV} according to the extraction equilibrium equation (Equation (22)). This arguably makes HTTA a potentially useful extractant for Th^{IV} by itself:³⁹⁷

In many cases, synergists are added to HTTA extraction systems to enhance the separation of actinide ions. One example is the addition of the crown ethers (CE) dibenzo-18-crown-6, dicyclohexyl-18-crown-6, dibenzyl 24-crown-8, and benzyl-15-crown-5. These crown ethers have been shown to synergistically enhance extraction into benzene and the increase follows $Eu^{3+} > UO_2^{2+} > Th^{4+}$. The extraction equilibrium for crown ether/HTTA systems for the separation of Th^{IV} is shown in Equation (23). The binding of the crown ether in the extracted complex seems to be a function of crown ether basicity and steric effects:³⁹⁶

Bis(1-phenyl-3-methyl-4-acylpyrazol-5-one) derivatives of the type H_2BP_n , where $n = 3, 4, 5, 6, 7, 8, 10$, and 22 , will extract the tetravalent actinides U^{4+} , Np^{4+} , and Pu^{4+} . As with the trivalent actinides, the H_2BP_n proved a better extractant than 1-phenyl-3-methyl-4-benzoylpyrazolone-5 (HPBMP), and the highest extractability occurred with the H_2BP_7 and H_2BP_8 ligands. Dependency studies indicate that 1:2 ($An:L$) complexes are formed for U^{IV} , Np^{IV} , and Pu^{IV} upon extraction from nitrate media into chloroform. Perchlorate solutions caused precipitates to form for various n values (4–6), probably due to ion pair formation in greater than 5 M $HClO_4$ solutions.³⁹⁸

An oxa-derivative of HPBMP, 3-phenyl-4-acetyl-5-isoxazolone (HPAI), has been studied as an attractive extractant for Th^{IV} . The structure is illustrated in Figure 25. HPAI, like other

Figure 25 3-Phenyl-4-acetyl-5-isoxazolone (HPAI).

β -diketones, acts as a bidentate ligand in its enolic form. Extractant dependency indicates that four HPAI molecules are involved in the extraction of Th^{IV} from nitrate media into 4-methyl-2-pentanone. HPAI shows higher extractability than both HPMBP and HTTA due to the lower $\text{p}K_{\text{a}}$ value of the ligand. IR spectrophotometric measurements indicate deprotonation of the enolic hydroxy group, allowing the charged oxygen to chelate with the metal. This is confirmed by $\text{C}=\text{O}$ stretch shifts and the presence of typical $400\text{--}500\text{ cm}^{-1}$ metal/ligand bands, suggesting that the carbonyl oxygen is involved in the chelation. The lack of bands between $3,100\text{ cm}^{-1}$ and $3,600\text{ cm}^{-1}$ confirm that no nitrogen interactions are occurring with the metal. Additionally, there is no coordination of water to the metal complex.³⁹⁹

CMPO. CMPO, or octyl(phenyl)-*N,N*-diisobutylcarbamoylmethylphosphine oxide (see Figure 26), was developed by Horwitz and co-workers as an efficient actinide extractant for use in the TRUEX process in the remediation of acidic nuclear waste solutions. Derivatives of carbamoylphosphine oxides (CMPO) have been studied in nuclear fuel processing schemes involved in transmutation concepts.⁴⁰⁰

In general, bifunctional carbamoylmethylphosphonates (CMP) and carbamoylmethylphosphine oxides (CMPO) readily form complexes with actinide ions in aqueous and nonaqueous solutions. Complexes isolated in the solid state contain ligands chelated to the central metal ion, and the bidentate chelate interaction has been confirmed by single crystal X-ray structure determinations with uranyl and Th^{IV} .^{401–403} However, spectroscopic studies of several complexes suggest that the ligands may only bind in a monodentate mode in solution, and this characteristic probably plays a role in determining the solvent extraction performance.⁴⁰⁴ Although data for actinide complexes are sparse, trifunctional CMP and CMPO-like ligands containing two $\text{P}=\text{O}$ donor groups and an amide or ester group also have been studied as actinide chelators.^{405,40} In these cases, the ligands generally form bidentate chelates where a six-membered ring results and the third donor group acts as a bridging connector to another metal/ligand unit.

While the TRUEX process has been optimized for the removal of trivalent actinides, particularly Am^{III} , from nuclear waste solutions, CMPO has the ability to complex with and extract tetravalent actinides as well. Th^{IV} , Np^{IV} , and Pu^{IV} are all effectively extracted from hydrochloric acid solutions into tetrachloroethylene, even at moderate HCl concentrations, with extractability following the trend $\text{Pu}^{\text{IV}} > \text{Np}^{\text{IV}} > \text{Th}^{\text{IV}}$ under all experimental conditions. Additionally, Pu^{IV} shows the highest extraction efficiency of all actinides by CMPO into TBP-dodecane

Figure 26 CMPO.

at HNO_3 concentrations up to 6 M. Extractant dependency studies show that CPMO complexes with Th^{IV} in a 3:1 ligand:metal stoichiometry to form the extracted species (see Equation (24)):

Interestingly, extractant dependency shows two different extracted species with Pu^{IV} depending on the acid from which it is extracted. Slope analysis for Pu^{IV} from HNO_3 solutions indicate the formation of a 2:1 CMPO: Pu^{IV} complex, while in HCl a 3:1 complex is observed (see Equations (25) and (26)):

It is proposed that coordination of CMPO with Pu^{IV} is similar to that in Am^{III} , meaning that monodentate coordination through the phosphoryl oxygen is observed for the nitrate complexes, and bidentate coordination through both the phosphoryl and carbonyl oxygen atoms occurs for the chloride complexes, yielding a coordination number of 10 for Pu^{IV} , which is interesting since it must change its extractant dependency to maintain the same coordination number in both types of complexes.⁴⁰⁷

Polydentate *P,P*- and *N,P*-dioxides. The coordination chemistry of polydentate phosphine oxides with actinide ions is of interest since several of these ligands show unique solvent extraction properties.^{408,409}

Polyfunctional phosphinopyridine *N,P*-dioxides, (phosphinomethyl)pyridine *N,P*-dioxides and bis(phosphinomethyl)pyridine *N,P,P*-trioxides have been prepared, and selected coordination chemistry with actinide ions has been explored. The phosphinopyridine *N,P*-dioxides form bidentate chelates with uranyl and Th^{IV} , and in the solid state these complexes display six-membered chelate rings that appear to be relatively sterically congested.^{410,411} The solvent extraction properties of these ligands are not unique since they resemble the performance of trialkylphosphine oxides.⁴¹²

The coordination chemistry of the (phosphinomethyl)pyridine *N,P*-dioxides and bis(phosphinomethyl)pyridine *N,P,P*-trioxides shows that seven-membered chelate ring structures are quite stable when formed with trivalent and tetravalent actinide ions. For example, crystal structure determinations for 2:1 complexes between the trifunctional ligand, 2,6- $[\text{Ph}_2\text{P}(\text{O})\text{CH}_2]_2\text{C}_5\text{H}_3\text{NO}$ and $\text{Pu}(\text{NO}_3)_4$ and $\text{Th}(\text{NO}_3)_4$ show that two ligands bond in a tridentate fashion to the actinide ions. Two bidentate nitrate ions also appear in the inner coordination sphere, but two are displaced to the outer sphere.^{413,414} The structures also show that the metal ions are “encased” in a lipophilic envelope generated by the ligands, and as a result, the complexes are soluble in organic solvents. The bifunctional ligand 2- $[\text{Ph}_2\text{P}(\text{O})\text{CH}_2]\text{C}_5\text{H}_4\text{NO}$ and $\text{Pu}(\text{NO}_3)_4$ produce a 2:1 complex $[\text{Pu}(\text{L})_2(\text{NO}_3)_3][\text{Pu}(\text{NO}_3)_6]_{0.5}$ when combined in a 1:1 ratio. The two bifunctional ligands chelate to the Pu^{IV} ion along with three bidentate nitrate ions resulting in a coordination number of 10. Interestingly, an expected 4:1 ligand/metal chelate structure, related to that found with lanthanide ions, was not isolated. Solvent extraction studies with chloroform and dodecane soluble derivatives of these two ligands show performance closely parallel with CMPO ligands in the same solvents.^{415–417}

Diphosphonic acids. Phosphorus-based extractants with the structure shown in Figure 27 are known as phosphonic acids. They are highly acidic and tend to form protonated complexes. Diphosphonic acids have been studied for the extraction of tetravalent actinides such as Th^{IV} . *P,P'*-di(2-ethylhexyl)methanediphosphonic acid ($\text{H}_2\text{DEH}[\text{MDP}]$) (see Figure 28) shows limited

Figure 27 General diagram of a phosphonic acid.

Figure 28 P,P' -di(2-ethylhexyl)alkanediphosphonic acids ($n=1$: $H_2DEH[MDP]$; $n=2$: $H_2DEH[EDP]$; $n=4$: $H_2DEH[BuDP]$).

acid dependency for Th^{IV} that allows $H_2DEH[MDP]$ to behave like a neutral extractant, even at high acid concentrations, due to the competition between nitric acid and the metal for the phosphoryl donor site.

Interestingly, extractant dependency studies with Th^{IV} show a very small slope over the entire extractant concentration range, indicating that its extraction is independent of both variables—nitric acid concentration and extractant concentration. This is indicative of a low solubility of the metal/extractant complex in both phases, perhaps due to a phenomenon observed in uranium/dialkylpyrophosphoric acid extractions, where the actinide is part of a highly polymerized complex present in the organic layer. This colloidal species is probably formed via oxo-bridges and can be precipitated at high Th^{IV} concentrations.⁴¹⁸

P,P' -di(2-ethylhexyl)ethanediphosphonic acid ($H_2DEH[EDP]$) extraction with Th^{IV} into *o*-xylene shows no acid or extractant dependency. At low Th^{IV} concentrations, extraction occurs via bonding with the phosphoryl oxygens, giving the protonated complexes. At high Th^{IV} concentrations, complexation leads to the release of H^+ ions. Furthermore, the lack of acid and extractant dependency leads to the conclusion that the extracted complexes are polymeric in nature under all conditions.⁴¹⁹

Interestingly P,P' -di(2-ethylhexyl)butanediphosphonic acid ($H_2DEH[BuDP]$) shows a strong extractant dependency with Th^{IV} , especially at higher nitric acid concentrations. At lower acidities, a zero dependency is observed, indicating the formation of a polymeric species. At higher acidities, this behavior is not observed.⁴²⁰ Unlike Am^{III} , where complexation stoichiometry depends on extractant concentration, extractant dependency studies show a slope of two for Th^{IV} with all three extractants; $H_2DEH[MDP]$, $H_2DEH[EDP]$, and $H_2DEH[BuDP]$. Considering the observed acid dependency having a slope of three, it is likely that Th^{IV} is extracted by a mechanism involving $Th(NO_3)_3(L)(HL)$ species, where $Th(NO_3)_4$ only becomes important at high acid concentrations, where L is one of the three diphosphonic acids.⁴²¹

Diamides. Malonamides are a relatively new class of extractants that have chelating abilities with tetravalent actinides as well as with the lanthanides. Malonamides are nonphosphorus containing extractants and are completely incinerable since they contain only carbon, hydrogen, oxygen, and nitrogen, thus following the “CHON” principle. Malonamides are amide-substituted malonic acids and have the general structure seen in Figure 29.

The R groups in Figure 29 can be hydrogenic, aliphatic, or aromatic, and the extracting properties of malonamides can be fine-tuned by varying the identity of these substituents. The R_1 chain is usually a methyl or ethyl chain to decrease the steric hindrance that can occur when complexing. R_2 can be an aliphatic or aromatic carbon chain. R_3 is usually a long carbon chain to aid in the solubility of the malonamide in an organic solvent.

Figure 29 General diagram of a malonamide.

Several studies have looked at the extraction of Th^{IV} and Pu^{IV} ions by malonamides of varying structural character. Nigond *et al.* investigated the extraction of Pu^{IV} from nitric acid media with the malonamide *N,N'*-dimethyl-*N,N'*-dibutyltetradecylmalonamide (DMDBTDMA).⁴²² UV-vis experiments indicate the presence of two extracted species that are formed according to the following equilibria shown in Equation (27) ($n=1$ or 2):

The complexes that are formed are nonionic, and coordination to the Pu^{IV} metal occurs in a bidentate mode through the carbonyl oxygens of the malonamide ligand. IR spectroscopy indicates C_{2v} geometry of the extracted complex due to nitrate stretching bands at $1530\text{--}1540 \text{ cm}^{-1}$ and 1280 cm^{-1} . The extracted species from complexation with DMDBTDMA are different than those that would be obtained with monamides, where the anionic complex $\text{Pu}(\text{NO}_3)_6\text{H}_2(\text{amide})_x$ would be observed in the organic phase. Monamides are weaker complexants for Pu^{IV} than are malonamides, due to nitrate/metal competition at high acid concentrations.⁴²²

Nair *et al.* studied the extraction of Pu^{IV} by *N,N'*-methyl-*N,N'*-butylmalonamide (MBMA),⁴²³ *N,N,N',N'*-tetra-butyl-malonamide (TBMA), and its more sterically-hindered analogue, *N,N,N',N'*-tetra-isobutyl-malonamide (TiBMA).⁴²³ Extractant dependency studies yield a slope of two for the malonamide ligands complexing with Pu^{IV} in extraction to the organic phase.⁴²⁴

Studies with Pu^{IV} polymer have shown that efficient extraction is possible by pentaalkylpropane diamides over a large range of nitric acid concentrations (1–5 M). The extractive ability of the diamide is found to depend on the age of the plutonium polymer. When the polymer is over six months old, better extraction is observed, although the mechanism is not clearly understood.⁴²⁵

The oxygen-based diglycolamide (see Figure 30), *N,N'*-dimethyl-*N,N'*-dihexyl-3-oxapentanediamide (DMDHOPDA) is also an effective extractant for Th^{IV} with HTTA as a synergist, and experimental data indicates that two extracted species may be present. As a result, limits were set on the experimental conditions for the extraction of only one of the two species ($-2.7 < \log[\text{DMDHOPDA}] < -2$), resulting in an extraction stoichiometry consistent with the extraction of $\text{Th}(\text{TTA})(\text{DMDHOPDA})(\text{ClO}_4)_3$ into the organic phase. Without the synergist, the coordination environment around thorium is filled by the addition of another diglycolamide and the perchloric anion for charge balance to generate $\text{Th}(\text{DMDHOPA})_2(\text{ClO}_4)_4$.^{397,426}

The sulfur-based thiodiglycolamides, as seen in Figure 31, *N,N'*-dimethyl-*N,N'*-dihexyl-3-thiopentanediamide (DMDHTPDA) and *N,N'*-dihexyl-3-thiopentanediamide (DHTPDA), both extract thorium(IV) with HTTA as a synergist in the same manner. The extraction stoichiometry

Figure 30 General diagram of a diglycolamide.

Figure 31 General diagram of a thiodiglycolamide.

for both DMDHTPDA and DHTPHA (L) is given by Equation (28). Extraction by the ligand alone is negligible, indicating a synergistic mechanism with HTTA:

Polyoxometallates. As previously discussed, several classes of polyoxometallates can serve as ligands in the complexation of tetravalent actinide ions. The first of these is the decatungstometallates, $[\text{An}^{\text{IV}}\text{W}_{10}\text{O}_{36}]^{8-}$, $\text{An} = \text{Th}, \text{U}$.^{427,428} The molecular structure of the uranium complex has been determined.^{427,429} The actinide ion in this complex is eight-coordinate, ligated by two tetradentate W_5O_{18} groups (lacunary derivatives of the W_9O_{19} structure). The overall symmetry of the anion is close to D_{4d} , with U—O bond lengths of 2.29–3.32 Å. Although six distinct oxygen chemical environments exist in the structure, only three signals are observed in the ^{17}O -NMR spectra.⁴³⁰ The complexes are not stable outside the pH range 5.5–8.5.

Among the first polyoxometallate complexes to be prepared were those of the dodecamolybdometallate family, $[\text{AnMo}_{12}\text{O}_{42}]^{8-}$ ($\text{An} = \text{tetravalent Th, U, Np}$). The thorium complex was first prepared,^{431,432} followed later by uranium and neptunium analogues.^{433,434} The structure of the complexes contains an icosahedrally coordinated actinide surrounded by six face-sharing Mo_2O_9 units linked by corner sharing.⁴³⁵ A variety of other characterization data on these complexes have been reported.^{436–439} The uranium compound appears to undergo reversible oxidation to form a U^{V} complex.⁴³⁸ The complexes $[\text{AnMo}_{12}\text{O}_{42}]^{8-}$ ($\text{An} = \text{Th, U}$) can themselves further act as ligands toward other metal cations. Weak complexes of $\text{AnMo}_{12}\text{O}_{42}$ with varying stoichiometries form in aqueous solution with $\text{M} = \text{divalent (Mn, Fe, Co, Ni, Zn, Cd, Cu), trivalent (Y, Er, Yb), and tetravalent (Th) cations}$.^{440,441} In the crystallographically characterized examples $(\text{NH}_4)_2\text{[UMo}_{12}\text{O}_{42}(\text{Er}-(\text{H}_2\text{O})_5)_2] \cdot n\text{H}_2\text{O}$ and $(\text{NH}_4)_3\text{[UThMo}_{12}\text{O}_{42}]$,^{442,443} $[\text{UMo}_{12}\text{O}_{42}]^{8-}$ serves as a tridentate ligand towards the other metal centers.

The complexes $\text{Th}[\text{XMo}_{12}\text{O}_{40}]^{n-}$ ($\text{X} = \text{P, Si}$) have been proposed principally from analytical data.

A more extensive set of actinide complexes is formed with tungstates of the Keggin and Dawson structure, $\text{An}[\text{XW}_{11}\text{O}_{39}]_2^{n-}$ and $\text{An}[\text{X}_2\text{W}_{17}\text{O}_{61}]_2^{n-}$ ($\text{X} = \text{P, Si, B, As; An} = \text{Th, U, Np, Pu}$).^{438,444–449} These ligands form very stable complexes of tetravalent lanthanides and actinides. A review of complexes of *f*-elements with this class of polyoxometalates provides references to a range of characterization data.⁴⁵⁰ The lacunary heteropolyanions act as tetradentate ligands toward the actinide center, generating an eight-coordinate metal center in an approximate square antiprismatic geometry.⁴⁵¹ Although the stability of molybdenum analogs is markedly decreased, a few mixed-metal analogs have been isolated, including $\text{K}_{10}[\text{An}(\text{PMo}_2\text{W}_9\text{O}_{39})_2] \cdot 22\text{H}_2\text{O}$ and $\text{K}_{16}[\text{An}(\text{P}_2\text{MoW}_{16}\text{O}_{61})_2] \cdot 28\text{H}_2\text{O}$ ($\text{An} = \text{Th, U}$).^{452,453}

Other. Complexes of tetravalent uranium have been synthesized using the anion $\{(\text{C}_5\text{H}_5)\text{Co}[\text{PO}(\text{OEt})_2]_3\}^-$, or a Kläui ligand, as the ancillary group. The complexes $\text{LuCl}_3(\text{THF})$ ⁴⁵⁴ and L_2UCl_2 ,⁴⁵⁵ $\text{L} = \{(\text{C}_5\text{H}_5)\text{Co}[\text{PO}(\text{OEt})_2]_3\}^-$, have been prepared by metathesis reactions employing uranium tetrachloride. The molecular structure of the complexes indicate that the cobalt tris(phosphate) complex is tridentate, coordinating the uranium center through the three $\text{P}=\text{O}$ groups (see Figure 32).

(ii) Schiff base-derived ligands

Schiff bases are macrocyclic or macro-acyclic ligands that typically contain both nitrogen and oxygen donors and are often polydentate in coordinating ability. However, the identity of the donor can be varied between sulfur, phosphorus, nitrogen, and oxygen to change the donor properties, and hence the coordination abilities, of the ligand. Schiff bases are sometimes synthesized as compartmental ligands where binding at one site influences a change in conformation in another site on the molecule for cooperative complexation with two or more metal ions metals. Schiff bases have been traditionally prepared by the condensation reaction between a formyl- or carbonyl-containing derivative with primary amine groups in the presence of certain metal ions, such as alkaline earth cations, that act as templating agents. However, tailoring of the Schiff base often requires modifications to this very simplistic synthetic procedure.⁴⁵⁶

Thorium(IV) has been reacted with a pentadentate compartmental ligand for the first crystal structure reported on a complex with Th^{IV} as a binucleating metal ion. The crystal structure of the complex has been solved to reveal two $\text{Mg}[\text{Th}_2\text{L}_3]_2 \cdot 6\text{H}_2\text{O}$ units in the unit cell. Each Th_2L_3^- anion, where all the oxygen atoms are deprotonated, comprises a dinuclear unit, where the two

Figure 32 Crystal structure of $\text{LUCl}_3(\text{THF})$ ($\text{L} = \{(\text{C}_5\text{H}_5)\text{Co}[\text{PO}(\text{OEt})_2]_3\}$) (Wedler, Gilje *et al. J. Organomet. Chem.* **1991**, 411, 271).

thorium atoms are coordinated in a bridging fashion with the three central oxygen atoms from three separate ligands (i.e., each central oxygen donates to both thorium atoms). Each ligand then donates an oxygen and nitrogen to one thorium atom and the other oxygen and nitrogen to the second thorium atom. The thorium atoms each have a coordination number of nine and adopt a slightly distorted tricapped trigonal prismatic conformation.⁴⁵⁷

Examples of bidentate Schiff bases as extractants for Th^{IV} have also been illustrated. The ligands *N*-salicylidene-*p*-toluidine (HSalTol) and *N*-salicylidene-*p*-phenetidine (HSalPhen) can nearly quantitatively extract Th^{IV} from chloride media into benzene at a pH of 7. The deprotonated form of both ligands (designated HSB) is proposed to take place in complexing with Th^{IV} according to the following extraction equilibrium obtained from slope analysis (see Equation (29)):

The maximum in the extraction at pH 7 indicates that solubilization of the extracted complex due to hydrolysis or ligand dissolution at high basicity.⁴⁵⁸

(iii) Macrocyclic ligands

N-Heterocyclic ligands. Porphyrins (see Figure 33) have been shown to complex well with late transition metals and have recently been shown to complex with actinides of varying oxidation state. Porphyrins are good as complexing agents, but have poor selectivity. The coordination of the actinide with a porphyrin is controlled by the oxidation state of the actinide, the cavity size of the porphyrin, and the molar ratio between the metal and the porphyrin. There are cases of the metal being completely contained within the cavity, adjacent to the cavity, or being sandwiched between multiple porphyrins.⁴⁵⁹

5,10,15,20-Tetraphenylporphyrin (H_2TPP) complexes with thorium to yield the product $\text{Th}(\text{TPP})_2$. As indicated by X-ray single crystal diffraction data, a 2:1 sandwich style coordination is present, which creates a coordination number of eight around the thorium. The phenyl groups which are attached to the porphyrin cause some distortion in the square antiprismatic geometry, causing the ligands to be offset by about a 30° angle, as seen in Figure 34.

2,3,7,8,12,13,17,18-Octaethylporphyrin (H_2OEP) and thorium complex to give a crystal structure similar to that seen with H_2TPP and thorium. In $\text{Th}(\text{OEP})_2$, the coordination environment around the thorium is an ideal square antiprism. The replacement of phenyl groups with ethyl chains removes any steric hindrance that was present in $\text{Th}(\text{TPP})_2$. This is illustrated in Figure 35.⁴⁶⁰

Figure 33 A simple porphyrin.

Figure 34 Crystal structure of $[\text{Th}(\text{C}_{44}\text{H}_{28}\text{N}_4)_2] \cdot \text{C}_7\text{H}_8$ (top and side views) (Girolami, Gorlin *et al. Journal of Coordination Chemistry* **1994**, 32, 173–212).

Figure 35 Crystal structure of $\text{Th}(\text{C}_{36}\text{H}_{44}\text{N}_4)_2$ (top and side views) (Girolami, Gorlin *et al. Journal of Coordination Chemistry* **1994**, 32, 173–212).

A study of H_2OEP ligand complexes with U^{IV} and Th^{IV} in the presence of a coordinating solvent such as THF, benzonitrile, and pyridine give complexes of the type $[\text{M}^{\text{IV}}(\text{OEP})\text{Cl}_2\text{L}_n]$, where L is the solvent-type ligand. From NMR and IR data, the proposed structure (Figure 36) is similar to the $\text{Th}(\text{OEP})_2$ structure, except two solvent molecules are bound to the metal along with two chlorides anions taking the place of one of the porphinato ligands. This would give the metal a coordination number of eight.⁴⁶¹

When H_2TPP is treated with a five-fold excess of anhydrous UCl_4 and 2,6-lutidine in benzonitrile, the resulting structure is reported to be $\text{U}(\text{TPP})\text{Cl}_2$. Upon crystallization from THF, a solvent adduct is formed of the type $\text{U}(\text{TPP})\text{Cl}_2(\text{THF})$. In Figure 36, a 4:3 piano stool coordination geometry of the solvent adduct structure is observed with the uranium being complexed above the cavity of the porphyrin, due to the TPP cavity being too small to form a uranium inclusion complex. Bonding is also improved via the “saucer-shape” of the porphyrin ring. The chlorides maintain charge balance, while the THF increases the coordination up from six to seven. The coordination around the uranium is not a traditional coordination arrangement.⁴⁶²

While not common, porphyrins can complex in a manner so as to create a trimeric metalloporphyrin as in the case with $[(\text{TPP})\text{Th}(\text{OH})_2]_3 \cdot \text{H}_2\text{O}$. The thorium atoms lie within a square antiprismatic coordination environment with the hydroxides bridging between thorium atoms. The bridging oxygens of the hydroxide group are in an ideal trigonal prism with respect to one another. This environment around the thorium atoms can be seen in Figure 37, where all water molecules and hydrogen and carbon atoms in the porphyrin rings have been removed for clarity.⁴⁶³

Examples of $(\eta^5\text{-C}_4\text{N})$ coordination in pyrrole-derived macrocycles may be found in the reaction products of uranium halides with the tetraanion of the macrocycle $\{[(-\text{CH}_2)_5]_4\text{-calix[4]tetrapyrrole}\}$.⁴⁶⁴ As described in Equation (30), the reaction of $\text{U}(\text{THF})_4$ with the potassium salt of the tetrapyrroliate in THF generates a dinuclear U^{IV} complex, $\{[(-\text{CH}_2)_5]_4\text{-calix[4]tetrapyrrole}\}\text{-UK}(\text{THF})_3]_2(\mu\text{-O}) \cdot 2\text{THF}$; the oxo group is proposed to come from deoxygenation of a THF molecule:

Figure 36 Crystal structure of $\text{U}(\text{C}_{44}\text{H}_{28}\text{N}_4)\text{Cl}_2(\text{C}_4\text{H}_8\text{O})$ (top and side views) (Girolami, Milam *et al. Inorganic Chemistry* **1987**, 26, 343–344).

Figure 37 Crystal structure of $[(\text{C}_{44}\text{H}_{28}\text{N}_4)_3\text{Th}(\text{OH})_2]_3 \cdot 2\text{H}_2\text{O} \cdot 3\text{C}_7\text{H}_6$ (Kadish, Liu *et al. J. Am. Chem. Soc.* **1988**, 110, 6455–6462).

Reaction of $\text{UI}_3(\text{THF})_4$ with the corresponding lithium tetrapyrrolide salt in a 1:2 ratio generates instead $[\{(-\text{CH}_2)_5\}_4\text{-calix[4]tetrapyrrole}\}\text{ULi}(\text{THF})_2]_2 \cdot \text{hexane}$, in which the β -carbon of one of the pyrrole rings has undergone a metallation reaction. Reaction of the potassium salt with $\text{UI}_3(\text{DME})_4$ avoids the complication of THF activation, and the simple trivalent uranate complex, $[\{(-\text{CH}_2)_5\}_4\text{-calix[4]tetrapyrrole}\}\text{U}(\text{DME})][\text{K}(\text{DME})]$, is generated. The geometry about the metal center in these compounds is qualitatively similar to a metallocene complex. The ligand adopts a σ/π bonding mode, in which two of the four pyrrole rings in the macrocycle are η^5 -bonded to the uranium, and the other two rings are σ -coordinated only through the pyrrole nitrogen. The U—N (σ) bond lengths for the tetravalent derivatives range from 3.39 Å to 2.47 Å; these distances are slightly longer in the trivalent derivative (~ 2.53 Å). The π -coordination of the pyrrole ring yields somewhat longer U—N bond distances (~ 2.65 Å in tetravalent compounds, 2.74 Å in the trivalent compound), and U—C_{pyrrole} bond distances that range from 2.68 Å to 2.88 Å.

Reaction of $\text{UI}_3(\text{THF})_4$ with $[\text{Li}(\text{THF})_4]\{[(-\text{CH}_2)_5]_4\text{-calix[4]tetrapyrrole}\}$ in a 1:2 ratio generates the dinuclear complex $[\text{Li}(\text{THF})_4]_2[\text{U}_2\text{I}_4\{[(-\text{CH}_2)_5]_4\text{-calix[4]tetrapyrrole}\}]$.⁴⁶⁵ Partial reduction of UCl_4 , followed by reaction with one half of an equivalent of the lithium salt is reported to generate the mixed-valence compound $[\text{Li}(\text{THF})_2](\mu\text{-Cl})_2\{\text{U}_2[(-\text{CH}_2)_5]_4\text{-calix[4]tetrapyrrole}\}\text{Cl}_2 \cdot \text{THF}$. Both of these complexes display alternate $\sigma/\eta^5, \pi$ -coordination to opposite pairs of pyrrole ligands in a single tetrapyrrole group. The bridging nature of the macrocyclic ligand brings the uranium centers into relatively close proximity (3.4560(8) Å and 3.365(6) Å, respectively); magnetic susceptibility measurements on the $\text{U}^{\text{III}}/\text{U}^{\text{III}}$ dimer suggests weak antiferromagnetic coupling occurs between metal centers.

Crown ethers. X-ray single crystal diffraction was used to determine the crystal structure of $\text{U}^{\text{IV}}\text{Cl}_3(\text{dicyclohexyl-18-crown-6})$ as seen in Figure 38. The coordination geometry around the uranium is distorted tricapped trigonal prism where the two planar triangles are offset from one another. This geometry is formed through the nonplanar oxygens of the crown ether and three chlorides bound to the uranium. Distortion of the crown ether is required in order to achieve complexation with the uranium.

Figure 38 Crystal structure of $[\text{UCl}_3(\text{C}_{20}\text{H}_{40}\text{O}_6)]_2 \cdot \text{UCl}_6(\text{C}_3\text{H}_8)_2$ depicting the coordination of the U^{IV} in one of the crown complexes (de Villardi, Charpin *et al.* *J. Chem. Soc., Chem. Commun.* **1978**, 90–92).

3.3.2.2.4 Borohydride ligands

Borohydride complexes of the tetravalent actinides are more common and members of the series $\text{An}(\text{BH}_4)_4$ exist for $\text{An} = \text{Th}, \text{Pa}, \text{U}, \text{Np}, \text{and Pu}$. The initial method employed for the preparation of $\text{An}(\text{BH}_4)_4$ involved reaction of AnCl_4 or AnF_4 with $\text{Al}(\text{BH}_4)_3$ or $\text{Li}(\text{BH}_4)$,^{85,466,467} (see Equation (31)):

Other synthetic routes have been reported,^{468,469} including metathesis reactions in ethereal solvents.⁴⁷⁰ Given the difference in ionic radii of the metal ions, it is not surprising that not all $\text{An}(\text{BH}_4)_4$ compounds are isomorphous. Two different polymeric morphologies of $\text{U}(\text{BH}_4)_4$ have been identified.^{471–474} In the most common form,^{471,472} the uranium atom is coordinated by six borohydride ligands in a pseudooctahedral fashion. Two *cis*-borohydride groups are tridentate, while the other four are bidentate, and bridge two uranium atoms. The overall polymeric chain is helical. Another form has been identified in which the two tridentate borohydride groups reside in *trans*-positions of the octahedron, while equatorial bidentate BH_4 groups bridge metal centers to create a polymeric sheet structure.^{466,475} $\text{Th}(\text{BH}_4)_4$ and $\text{Pa}(\text{BH}_4)_4$ are reported to be isostructural with the major form of $\text{U}(\text{BH}_4)_4$.^{466,475} In contrast, the neptunium and plutonium compounds are monomeric, with a pseudotetrahedral arrangement of tridentate borohydride groups surrounding the metal center.⁴⁷⁵

Substituted analogues $\text{An}(\text{MeBH}_3)_4$ ($\text{An} = \text{Th}, \text{Pa}, \text{U}, \text{Np}$) have been prepared either by reaction of $\text{An}(\text{BH}_4)_4$ with BMe_3 (see Equation (32)),⁴⁷⁶ or by metathesis routes employing LiBH_3Me (see Equation (33)):^{477–479}

As in the case of trivalent borohydride complexes, a number of base adducts have been prepared and characterized. In the case of adducts of $\text{U}(\text{BH}_4)_4$, the size of the base can control the dimensionality of the resulting product. The 1:1 adducts with small dialkylethers (e.g., $[\text{U}(\text{BH}_4)_4(\text{OMe}_2)]_n$, $[\text{U}(\text{BH}_4)_4(\text{OEt}_2)]_n$)⁴⁸⁰ form chains in the solid state, in which bidentate borohydride groups bridge pseudooctahedral uranium centers; the remaining borohydride groups are tridentate, and the remaining coordination site is occupied by the ether ligand. Use of the slightly larger Pr^n_2O ligand results in the formation of an unusual dimer formulated as $(\text{Pr}^n_2\text{O})_2(\eta^3\text{-BH}_4)_3\text{U}(\mu\text{-}\eta^2, \eta^2\text{-BH}_4)\text{U}(\eta^3\text{-BH}_4)_4$ ⁴⁸¹ (see Figure 39). Use of the methylborohydride group inhibits the formation of polymeric products, due to its inability to act as a bridging bidentate ligand. Therefore, the diethylether and THF adducts of $\text{Th}(\text{MeBH}_3)_4$ are found to be dimeric, with two

Figure 39 Crystal structure of $(n\text{-Pr}_2\text{O})_2(\eta^3\text{-BH}_4)_3\text{U}(\mu\text{-}\eta^2, \eta^2\text{-BH}_4)\text{U}(\eta^3\text{-BH}_4)_4$ (Zalkin, Rietz *et al.* *Inorg. Chem.* **1978**, 17, 661).

bridging methylborohydride ligands.⁴⁸² The complex $(\text{MeBH}_3)_3\text{Th}(\mu\text{-MeBH}_3)_2\text{Th}(\text{MeBH}_3)_3(\text{OEt}_2)$ only exhibits ether coordination to one end of the dimer, presumably due to steric factors.

Tetrahydrofuran forms 2:1 adducts with $\text{U}(\text{BH}_4)_4$ and $\text{U}(\text{MeBH}_3)_4$. In the solid state the complexes exist as a pseudooctahedral monomer with *trans*-THF ligands and tridentate borohydride groups.^{318,483,484} The tetrahydrothiophene analog of $\text{U}(\text{MeBH}_3)_4$ is not isostructural. The complex $[\text{U}(\text{MeBH}_3)_4(\text{THT})]_2$ is a dimer with metal centers bridged by the sulfur atoms of the tetrahydrothiophene groups.³¹⁸ The complex $\text{U}(\text{BH}_4)_4(\text{OPPh}_3)_2$ has also been reported.^{485,486}

Coordination of $\text{U}(\text{MeBH}_3)_4$ by the bidentate ligands $\text{Me}_2\text{PCH}_2\text{CH}_2\text{PMe}_2$, $\text{MeOCH}_2\text{CH}_2\text{OMe}$, $\text{Me}_2\text{NCH}_2\text{CH}_2\text{NMe}_2$, and $\text{MeSCH}_2\text{CH}_2\text{SMe}$ produces monomeric, octahedral adducts.^{45,181}

Few cationic or anionic derivatives are known. Addition of LiBH_4 to $\text{Th}(\text{BH}_4)_4$ is reported to generate the “ate” complexes $\text{Li}[\text{Th}(\text{BH}_4)_5]$ and $\text{Li}_2[\text{Th}(\text{BH}_4)_6]$.⁴⁷⁰

3.3.2.3 Pentavalent Oxidation State

3.3.2.3.1 General characteristics

Protactinium, uranium, neptunium, and plutonium all can be generated in the pentavalent oxidation state in aqueous media, although hydrolysis results in the formation of the dioxo species AnO_2^+ for all but protactinium. The NpO_2^+ ion is most stable in aqueous solutions; in contrast, UO_2^+ and PuO_2^+ disproportionate readily. The actinyl ions display a linear O—An—O unit, and coordination chemistry is restricted to that of the equatorial plane, or “belly band” about the metal center. The lower charge-to-surface area ratio of these ions makes them much weaker acids, thereby reducing hydrolysis. Complexes of pentavalent early actinides not containing the AnO_2^+ unit can be isolated from nonaqueous media, either by oxidation of lower valent precursors or from reactions employing precursors such as the pentavalent halides.

3.3.2.3.2 Simple donor ligands

(i) Ligands containing anionic group 15 donor atoms

Amide complexes. Pentavalent amide and related N-donor complexes of the actinides are relatively rare in comparison to analogous alkoxide complexes (*vide infra*). In most cases, these species are prepared by oxidation of tetravalent precursors. The complexes $[\text{Li}(\text{THF})]_2\text{[U}(\text{NMe}_2)_6]$ and $[\text{Li}(\text{THF})][\text{U}(\text{NEt}_2)_5]$, prepared by the reaction of UCl_4 with excess lithium amide salts LiNMe_2 and LiNEt_2 in THF,¹⁰⁶ can be oxidized by either TIBPh_4 or AgI to generate the uranium(V) species $[\text{U}(\text{NMe}_2)_6]^-$ and $\text{U}(\text{NEt}_2)_5$, with concomitant formation of Ti^0 or Ag^0 .^{104,106} Determination of the molecular weight of $\text{U}(\text{NEt}_2)_5$ indicates that it is a monomer in benzene solution.

In several instances, the generation of a uranium(V) complex is the result of fortuitous oxidation during reaction. A hexakis(amido)uranate complex, $[\text{Li}(\text{THF})_x][\text{U}(\text{dbabh})_6]^-$ ($\text{Hdbabh} = 2,3,5,6\text{-dibenzo-7-azabicyclo[2.2.1]hepta-2,5-diene}$) is generated in an unusual redox reaction employing $\text{UI}_3(\text{THF})_4$ as a starting material (see Equation (34)):⁴⁸⁷

The complex $\text{UCl}_2\{\text{N}[\text{CH}_2\text{CH}_2\text{P}(\text{Pr}^i)_2]_2\}_3$ has also been reported.⁴⁸⁸ This complex was produced adventitiously in the reaction of UCl_4 with $\text{LiN}[\text{CH}_2\text{CH}_2\text{P}(\text{Pr}^i)_2]_2$, presumably by oxidation of U^{IV} by traces of oxygen.

Amidinate complexes. In other cases, isolation of U^{V} comes about as the result of aerobic oxidation. The interesting pentavalent benzamidinate derivative $[\text{4-MeC}_6\text{H}_4\text{C}(\text{NSiMe}_3)_2]_2\text{UCl}_3$ was produced by adventitious aerobic oxidation during reaction of UCl_4 with the corresponding silylated benzimidine (Equation 35).⁴⁸⁹

(ii) Ligands containing neutral group 15 donor atoms

Ammonia and amines. Complexes of pentavalent actinides with ammonia or amine adducts are rare. The only reported members of this series are adducts of the electron-poor alkoxide complex, $\text{U}(\text{OCH}_2\text{CF}_3)_5$. The ammonia adduct, $\text{U}(\text{OCH}_2\text{CF}_3)_5 \cdot (6-12)\text{NH}_3$, was proposed as the product of the reaction between UCl_5 and $\text{CF}_3\text{CH}_2\text{OH}$ in the presence of excess ammonia. The amine adducts $\text{U}(\text{OCH}_2\text{CF}_3)_5 \cdot x\text{R}_2\text{NH}$ ($x=3$, $\text{R}=\text{Me}$; $x=2$, $\text{R}=\text{Pr}^n$) and $\text{U}(\text{OCH}_2\text{CF}_3)_5 \cdot 2\text{NMe}_3$ are prepared by reaction of the alkoxide complex with excess amine in ether, followed by removal of the solvent under reduced pressure, and vacuum distillation of the products. All are reported to be green liquids.

Heterocyclic ligands. Complexes of UCl_5 with a variety of *N*-heterocyclic ligands, including pyridine, 2-mercaptopyridine, quinoline, isoquinoline, 2,2'-bipyridine, pyrazole, and substituted pyrazoles, pyrazine, phthalazine, and phenazine have been reported. These complexes are generally prepared by reaction of the ligand with UCl_5 or its trichloroacetyl chloride compound, $\text{UCl}_5 \cdot \text{C}_3\text{Cl}_4\text{O}$. The majority of the complexes in this series are not well characterized. In addition, ambiguity exists in several cases regarding the ligand to metal ratio, which also brings into question the coordination number of the uranium species. In at least one case ($\text{UCl}_5 \cdot \text{bipy}$), the complex is a 1:1 electrolyte in solution, and is therefore probably best formulated as $[\text{UCl}_4(\text{bipy})]\text{Cl}$.⁴⁹⁰ Adducts have been reported to form between *N*-heterocycles 1,10-phenanthroline, and phenazine and the ion UOCl_5^{2-} ; ^{491,492} it is likely that these are ionic species in solution as well.

A more thorough study has been conducted of the chemistry of UF_5 with the heterocyclic bases 2-fluoropyridine (F-py) and 2,2-bipyridine (bipy).⁴⁹³ While the reaction of F-py with $\beta\text{-UF}_5$ appears to lead to reduction of the metal center, reaction with bipy in acetonitrile generated the compounds $\text{UF}_5(\text{bipy})$ and $[(\text{bipy})_2\text{H}][\text{UF}_6]$ (obtained in the presence of excess bipy). The complex $\text{UF}_5(\text{bipy})$ has been characterized by single crystal X-ray diffraction. Two different morphologies may be isolated from solution, depending on the temperature of the reaction. In both forms, the coordination geometry about the uranium center is a distorted fluoride monocapped trigonal prism (see Figure 40).

Nitriles. Reaction of UF_5 in acetonitrile with either Me_3SiCl or UCl_5 gives rise to the mixed halide nitrile adduct, $\text{UCl}_2\text{F}_3(\text{MeCN})$.⁴⁹⁴ Acetonitrile adducts of the pentabromide complexes $\text{AnBr}_5(\text{MeCN})_x$ ($\text{An}=\text{Pa}$, $x=3$; $\text{An}=\text{U}$, $x=2-3$) have also been reported, as has the complex $\text{Pa}_2\text{O}(\text{NO}_3)_8 \cdot 2\text{MeCN}$.⁴⁹⁵

Phosphines, arsines. It has been reported that the adducts $\text{UCl}_5(\text{PPh}_3)$ and $\text{UCl}_5(\text{dppe})$ can be prepared by reaction of UCl_5 with the corresponding phosphine,^{490,496} although subsequent

Figure 40 Crystal structure of $\text{UF}_5(\text{bipy})$ (Arnaudet, Bougon *et al.* *Inorg. Chem.* **1994**, 33, 4510).

papers have called these formulations into question.⁴⁹⁷ One example of a crystallographically characterized pentavalent phosphine complex has appeared; the complex $\text{UCl}_2[\{(\text{Pr}^{\text{I}})_2\text{PCH}_2\text{CH}_2\}_2\text{N}\}_3$ has been reported.⁴⁸⁸

The diars complex $\text{PaCl}_5(\text{diars})_x$ ($x = 1-2$) has been reported (diars = *o*-phenylenebis(dimethylarsine)).¹⁹²

Thiocyanate and selenocyanate. Thiocyanate complexes of dioxoneptunium(V) have been prepared. The species $\text{Cs}_4[\text{NpO}_2(\text{NCS})_5]$ and $\text{NpO}_2(\text{NCS})(\text{urea})_4$ have been reported; the latter complex has been structurally characterized.⁴⁹⁸

(iii) Ligands containing anionic group 16 donor atoms

Oxides. The most common pentavalent actinide oxides are the monoclinic Pa_2O_5 and Np_2O_5 .⁴⁹⁹ There are also mixed valent oxides, such as U_3O_8 and some evidence that the superstoichiometric oxide PuO_{2+x} contains Pu^{V} .⁵⁰⁰ Ternary oxides, M_3AnO_4 and M_7AnO_6 exist for $\text{An} = \text{Pa}, \text{U}, \text{Np}$, and Pu , where M is generally an alkali metal and $\text{Ba}_2\text{U}_2\text{O}_7$ has been reported.

Hydroxides. The hydrolysis of Np^{V} has been studied more than that of any other pentavalent actinide because it is the most stable oxidation state for Np and it is an actinide ion of significant concern for environmental migration. Pentavalent uranium disproportionates in aqueous solution at pH values where hydrolysis would occur. Hydrolysis products for Pa^{V} , Pu^{V} , and Am^{V} are very similar to, but much less stable than those of Np, so only Np hydroxides will be described in detail. Neptunyl hydrolyzes at about pH 9, to form the stepwise products, $\text{NpO}_2(\text{OH})$ and $\text{NpO}_2(\text{OH})_2^{2+}$, which have been identified by optical absorbance and Raman spectroscopy.⁵⁰¹⁻⁵⁰³ In addition to the hydroxide these complexes likely have two or three inner-sphere waters in the equatorial plane and pentagonal bipyramidal coordination geometry.

The monohydroxide hydrate solid is amorphous and has not been fully structurally characterized. Attempts to increase the crystallinity have produced Np_2O_5 . Mixed hydroxo carbonato complexes, such as $\text{NpO}_2(\text{OH})(\text{CO}_3)_2^{4-}$ or $\text{NpO}_2(\text{OH})_2(\text{CO}_3)^{4-}$ have been proposed to explain the solubility behavior of Np^{V} solids in basic carbonate solution but they have not been characterized.

Single crystal structure X-ray diffraction analyses and structural classification of synthetic and natural mineral phases have revealed interesting actinide coordination chemistry.^{504,505} This approach has led to the identification of U^{V} in $\text{CaU}(\text{UO}_2)_2(\text{CO}_3)\text{O}_4(\text{OH})(\text{H}_2\text{O})_7$, the mineral wyartite.⁵⁰⁶ The structure contains three unique U positions. Two of these are uranyl ions with the typical pentagonal-bipyramidal coordination. The third is also seven-coordinate, but does not contain 'yL' oxygens; and polyhedral geometry and electroneutrality requirements indicate that this site contains U^{V} .

Carbonates and Carboxylates. Pentavalent actinide carbonato complexes are generally prepared by addition of alkali metal carbonate solutions to acidic solutions of the An^{V} ion. For example, the mono-, bis- or triscarbonato Np complexes, $\text{NpO}_2(\text{CO}_3)^-$, $\text{NpO}_2(\text{CO}_3)_2^{3-}$, and $\text{NpO}_2(\text{CO}_3)_3^{5-}$, can be isolated by varying the carbonate concentration.⁵⁰⁷ The triscarbonato complexes of Np^{V} and Pu^{V} can also be prepared electrochemically, and the U^{V} complexes has only been prepared electrochemically from $\text{UO}_2(\text{CO}_3)_3^{4-}$.⁵⁰⁸ These complexes all have the general actinyl carbonate structure with the axial AnO_2 and the oxygen atoms of the aquo and bidentate carbonate ligands arrayed about the equatorial plane to form a pentagonal or hexagonal bipyramidal coordination polyhedron. The triscarbonato complex is isostructural with the hexavalent analog, with a longer actinyl distance of 1.85 Å (vs. ~ 1.75 Å for Np^{VI}) and very similar carbonate bond distances.⁵⁰⁹ Interestingly, the Raman frequencies of the actinyl decrease linearly with increasing atomic number of the actinide.⁵¹⁰ Mixed hydroxo carbonates, $\text{NpO}_2(\text{CO}_3)_2(\text{OH})^{2-}$ and $\text{NpO}_2(\text{CO}_3)_2(\text{OH})_2^{3-}$, have been studied in solution.⁵⁰²

Solids corresponding to nearly all of the solution species (the U^{V} is one exception) have been prepared as microcrystalline powders via precipitation.⁵¹¹⁻⁵¹⁵ The structures of compounds $\text{MNpO}_2(\text{CO}_3)$ and $\text{M}_3\text{AnO}_2(\text{CO}_3)_2$, where M is an alkali metal or ammonium, have been described in detail.^{47,515,516} These compounds show interesting structural changes due to the alkali metal cation present (size), the size similarity of hydrated ions such as K and NpO_2^+ , and the extent of hydration.

For example, for $\text{MNpO}_2(\text{CO}_3)$ where $\text{M} = \text{Cs}^+, \text{Rb}^+, \text{NH}_4^+, \text{K}^+, \text{Na}^+$, and Li^+ , a hexagonal-to-orthorhombic phase change is observed within the $\text{NpO}_2(\text{CO}_3)$ layer at the potassium-sodium boundary. The solids both contain actinyl carbonate layers and the hexagonal and orthorhombic sheets are related by displacement of the chains of actinyl units through half a translation along

the crystallographic a -axis. The orthorhombic structure appears to allow for the closer contacts necessary for the smaller sodium and lithium cations. The potassium monocarbonate appears to swell along the c -axis with (reversible) hydration, suggesting the pentavalent actinides have a more complex structure than the actinyl(VI) carbonate layers and may be represented by the general formula of $\text{KAnO}_2(\text{CO}_3) \cdot n\text{H}_2\text{O}$ with intercalated water molecules (see Figure 41).

The bicarbonato solid $\text{M}_3\text{NpO}_2(\text{CO}_3)_2$ maintains the same orthorhombic layered structure as seen in $\text{MAnO}_2(\text{CO}_3)$, except that one half of the AnO_2^+ ions in the anionic carbonate layer have been replaced by alkali metal cations. One can envision that M^+ and AnO_2^+ cations form alternating chains within the familiar hexagonal sheet and give rise to the approximate composition $[\text{M}_{0.5}(\text{AnO}_2)_{0.5}(\text{CO}_3)]$ within the layer. The cation and anion layers are now oriented such that an alkali metal cation, M^+ , lies directly above and below the linear AnO_2^+ ion of adjacent sheets. The anionic carbonate layer and the cationic potassium layers line up such that they are parallel to the crystallographic c -axis, and this allows for an $\text{M}-\text{O}=\text{An}$ interaction between layers. In this way, a second infinite chain of $\text{O}=\text{An}=\text{O}-\text{M}-\text{O}=\text{An}=\text{O}$ units is formed, resulting in a maximally ordered structure.

The observations by Volkov *et al.*⁵¹⁷ that alkali cations can occupy the same sites as the AnO_2^+ ion explains the structure of $\text{M}_3\text{AnO}_2(\text{CO}_3)_2$, and may explain the presence of nonstoichiometric solids such $\text{M}_4\text{AnO}_2(\text{CO}_3)_{2.5} \cdot n\text{H}_2\text{O}$ (see Figure 42). This solid could easily arise from further replacement of AnO_2^+ ions in the layers by alkali metal cations, M^+ . In this way it was proposed that solids of intermediate compositions $\text{M}_{(3+2x)}\text{AnO}_2(\text{CO}_3)_{(2+x)} \cdot n\text{H}_2\text{O}$, where $0 = x = 0.5$, with cations and waters exchanging into the solid, could exist while still preserving the basic structural features.⁵¹⁷

Neptunium(V) complexes with polycarboxylic acid ligand are the most described among other actinides in the pentavalent oxidation state. In solution of EDTA at pH 5–6 $\text{NpO}_2\text{Y}^{3-}$ is formed, its thermodynamic stability and the complex extractability have been reported. With citric acid at pH 4–5 the compounds $\text{NpO}_2\text{Cit}^{2-}$ and NpO_2Hcit are formed. The formation $[\text{Co}(\text{NH}_3)_6][\text{NpO}_2\text{L}] \cdot 3\text{H}_2\text{O}$, and $(\text{NpO}_2)_2\text{H}_2\text{L} \cdot 5\text{H}_2\text{O}$ through the reaction of NpO_2^+ with $\text{EDTA}(\text{H}_4\text{L})$ in aqueous solution has been reported.

Nitrates. No inner-sphere An^{V} nitrate solution complexes have been characterized. The solid nitrates of Np^{V} and Pa^{V} , $\text{NpO}_2(\text{NO}_3) \cdot x\text{H}_2\text{O}$ ($x=1, 5$), $\text{RbNpO}_2(\text{NO}_3)_2 \cdot \text{H}_2\text{O}$, and $\text{PaO}(\text{NO}_3)_3 \cdot x\text{H}_2\text{O}$ ($x=1-4$) can be precipitated from aqueous solution at high nitrate concentrations.⁵¹⁸ The hexanitratoprotactinates, $\text{MPa}(\text{NO}_3)_6$, where M is a alkali metal or quaternary amine, have been prepared by treating the chloro complex salts MPaCl_6 with liquid N_2O_5 . The acid, $\text{MPa}(\text{NO}_3)_6$ is also known. In these compounds the protactinium(V) is presumably 12-coordinate by comparison with the tetravalent Np and Th nitrates. Neptunyl(V) nitrates have been starting materials for the preparation of “cation–cation” complexes, where actinyl ion interactions such as $\text{Np}^{\text{V}}-\text{Np}^{\text{V}}$ and $\text{Np}^{\text{V}}-\text{U}^{\text{VI}}$ are thought to be significant. An interesting solid in this class is the orthorhombic $\text{Cs}_4(\text{NpO}_2)_3\text{Cl}_6(\text{NO}_3)_2 \cdot \text{H}_2\text{O}$, in which pentagonal bipyramidal Np polyhedra are linked to form layers of composition $[(\text{NpO}_2)_2\text{Cl}_4(\text{NpO}_2)(\text{Cl})(\text{H}_2\text{O})]_n^{4n-}$.⁵¹⁹ Both

Figure 41 Molecular structures of $\text{MNpO}_2(\text{CO}_3)$ (two morphologies).

Figure 42 Molecular structure of $M_3AnO_2(CO_3)_2$.

this compound and its mixed-valent Np^V/Np^{VI} decomposition product, which also contains neptunyl oligomers, have structures and bond distances that suggest actinyl–actinyl interactions.⁵²⁰ While these structural features in the solid state can be alternatively attributed to packing forces, the numerous reports of increased extraction of one actinyl with the addition of another actinyl suggest the interaction may be significant.⁵²¹ For example, the extraction of Np^V with CMPO from nitric acid increases with the addition of U^{VI} .⁵²² A pentavalent actinide nitrite complex, NpO_2NO_2 , was reported in a study of Np complexation by a variety of inorganic ligands but it has not been characterized.⁵²³

Phosphates and arsenates. Neptunyl and plutonyl phosphate complexes have been prepared from An^{IV} phosphoric acid solutions. There is good evidence for $NpO_2HPO_4^-$ and $PuO_2HPO_4^-$, but their structures were not reported.^{524,525} Additional complexes undoubtedly are formed, but their stoichiometries are not certain.⁴⁶ Protactinium phosphate solids, such as $PaO_2(H_2PO_4)_3 \cdot 2H_2O$, have been reported, but without structural information. Similarly Pa^V and Np^V arsenato complexes, such as $H_3PaO_2(PhAsO_3)_2$ $NpO_2H_2PO_4$ have been reported, but no structural information is available for them.

Sulfates and selenates. Two types of neptunyl sulfates have been well characterized. The simple binary salt, $(NpO_2)_2SO_4 \cdot xH_2O$, where $x=2, 4.5$, and 6, can be precipitated from neptunyl sulfuric acid solutions. And bis(sulfato) complexes, $[Co(NH_3)_6]NpO_2(SO_4)_2 \cdot 3H_2O$ and $[Co(NH_3)_6]NpO_2(SO_4)_2 \cdot M_2SO_4 \cdot xH_2O$, where $M=Na, K$ can be isolated by adding Np^V to the preparation of $Co(NH_3)_6(SO_4)_2$.⁵²⁶ Interestingly, Am^V analogues of these sulfates have been reported, but those for Pu^V have not. Protactinium oxosulfate, $H_3PaO(SO_4)_3$ can be precipitated from H_2SO_4/HF . Similarly, $H_3PaO(SeO_4)_3$ can be precipitated from H_2SeO_4/HF solutions of Pa^V .

Perchlorates and iodates. Hydrated neptunium(V) iodate and a salt of a complex anion, $[Co(NH_3)_6](NpO_2)_2(IO_3)_5 \cdot 4H_2O$, have been reported based on elemental analyses and powder diffraction data. The structure of $NpO_2(IO_3)$ was determined by single crystal X-ray diffraction.⁵²⁷ Its structure consists of neptunyl(V) cations linked to one another by both $NpO_2^+ - NpO_2^+$ bonds and bridging iodate anions creating a pentagonal bipyramidal NpO_7 unit. Oxygen atoms from the iodate anions occupy three of the equatorial sites in the NpO_7 units. Both oxo atoms of the neptunyl(V) units are involved in coordinating adjacent Np^V centers, leading to the creation of a two-dimensional neptunium oxide sheet. A perrhenate complex of Pa^V , $PaO(ReO_4)_3 \cdot xH_2O$, has also been reported.

Alkoxide complexes. In contrast to the propensity of many uranium(V) species to disproportionate to uranium(IV) and uranium(VI), homoleptic uranium(V) alkoxide compounds are quite stable toward disproportionation. Gilman and co-workers reported the synthesis of dark brown uranium(V) pentakis(ethoxide) from a metathesis reaction between UCl_4 and four equivalents of sodium ethoxide.⁵²⁸ In this early report, it was noted that better yields were obtained “when no great care was taken to exclude air from the reaction,” and in the presence of oxygen, the product yield was 80%. The mechanism shown in Equations (36) and (37) was suggested for this reaction.

Molecular weight determinations were consistent with a dimeric structure, $[\text{U}(\text{OCH}_2\text{CH}_3)_5]_2$, and the compound can be distilled at 123 °C (0.001 Torr). Species that are thermally stable, distillable or sublimable are desirable for use in the separation of metal isotopes. The number of ensuing reports describing various synthetic routes to $[\text{U}(\text{OCH}_2\text{CH}_3)_5]_2$ are evidence of that motive.^{528–536} Some of these methods are described by Equations (38) to (43):

Uranium(V) homoleptic pentakisalkoxides, mixed alkoxides, oxo/alkoxides ($\text{UO}(\text{OR})_3$), or solvate derivatives (OR , $\text{R} = \text{Me}$, Pr , Pr^i , Bu , Bu^i , Bu^s , Bu^t , CH_2CF_3 , $\text{CH}_2\text{CH}=\text{CH}_2$, $(\text{CH}_2)_4\text{CH}_3$, $\text{CH}_2\text{CH}_2\text{Pr}^i$, CH_2CHMeEt , CH_2Bu^t , CHEt_2 , CHMePr , CHMePr^i , CMe_2Et , CMe_2Pr , CMe_2Pr^i , CMeEt_2 , CMeEtPr^i , CET_3) were prepared using these reaction routes or simple alcohol exchange in refluxing benzene.^{262,529,537,538} Displaced ethanol is removed azeotropically with benzene.

Molecular weight determinations of uranium(V) pentakisalkoxide complexes^{537–540} suggest that most are dimeric, except for polymeric $[\text{U}(\text{OMe})_5]_x$ and a few species incorporating sterically bulky alkoxide ligands. Spectroscopic data (absorption, ^1H NMR) supports the prediction that $[\text{U}^{\text{V}}(\text{OCH}_2\text{CH}_3)_5]_x$ exists as a dimer at room temperature, and ^1H -NMR analysis suggests that $[\text{U}^{\text{V}}(\text{OPr}^i)_5]_x$ exists as a monomer–dimer equilibrium at room temperature.^{541–544} The structure of $[\text{U}(\text{OPr}^i)_5]_2$ dimer was later confirmed and further elucidated by single crystal X-ray diffraction analysis. The compound has an edge-sharing bioctahedral structure.²⁶²

Attempts to prepare other homoleptic $\text{An}(\text{OCH}_2\text{CH}_3)_5$ compounds ($\text{An} = \text{Pa}$, Np) have been reported. Protactinium(V) pentakisethoxide was prepared from the metathesis reaction between PaCl_5 and $\text{NaOCH}_2\text{CH}_3$ in ethanol, and the compound was formulated as $[\text{Pa}(\text{OCH}_2\text{CH}_3)_5]_x$ ($x > 5$) based upon analysis of the infrared spectrum and molecular weight determination in benzene.⁵⁴⁵ Another study showed that oxidation of $\text{Np}(\text{OCH}_2\text{CH}_3)_4$ with bromine and $\text{NaOCH}_2\text{CH}_3$ in CCl_4 produced $\text{NpBr}(\text{OCH}_2\text{CH}_3)_4$.²⁶⁹ Further addition of $\text{NaOCH}_2\text{CH}_3$ to a solution of $\text{NpBr}(\text{OCH}_2\text{CH}_3)_4$ in tetrahydrofuran only resulted in reduction to an unidentified Np^{IV} species, based on absorption spectra of the solution.

Complex salts have also been prepared. The $\text{M}[\text{U}(\text{OCH}_2\text{CH}_3)_6]_x$ salts ($\text{M} = \text{Na}$, $x = 1$; Ca , $x = 2$; Al , $x = 3$) were prepared by allowing $\text{U}(\text{OCH}_2\text{CH}_3)_5$ to react with respective metal alkoxides in a 1:1 ratio.^{530,543} $\text{NaU}(\text{OCH}_2\text{CH}_3)_6$ decomposed with heat, but $\text{Ca}[\text{U}(\text{OCH}_2\text{CH}_3)_6]_2$ was purified by sublimation and $\text{Al}[\text{U}(\text{OCH}_2\text{CH}_3)_5]_3$ can be distilled.

Lewis base adducts of $\text{U}(\text{OCH}_2\text{CH}_3)_5$ have been prepared with acetonitrile, THF, pyridine, and SO_2 ,⁵⁴³ and adducts of $\text{U}(\text{OCH}_2\text{CF}_3)_5$ were prepared with a number of aliphatic amines (NMe_3 , NPrH_2 , NPr^iH_2 , NPr_2H , NMe_2H , ethylenimine).^{529,530} Later reports of the synthesis of polyfluoroalkoxides ethanol adducts $\text{U}[\text{OC}(\text{CF}_3)_3]_4(\text{OCH}_2\text{CH}_3)(\text{HOCH}_2\text{CH}_3)$, and $\text{U}[\text{OCH}(\text{CF}_3)_2]_4(\text{OCH}_2\text{CH}_3)(\text{HOCH}_2\text{CH}_3)$ from the reaction between the respective fluorinated alcohol with $\text{U}(\text{OCH}_2\text{CH}_3)_5$ ^{543,546} determined these complexes to be monomeric.

A variety of mixed ligand/alkoxide uranium(V) products are also isolable. Substitution compounds ($\text{U}(\text{OR})_4\text{L}$, $\text{U}(\text{OR})_3\text{L}_2$, $\text{U}(\text{OR})_2\text{L}_3$) were prepared from the reactions of $\text{U}(\text{OCH}_2\text{CH}_3)_5$ with HCl , β -ketoesters (2,2,2-trifluoroaceto acetate, methyl acetate, ethyl acetate), acetyl chlorides

(MeCO₂R, R = Et, Prⁱ, Pentyl^l) or β -diketones (acetylacetone, benzoylacetone).^{530,547,548} Other mixed halogen/alkoxide uranate products have been reported.⁵⁴⁹ Anhydrous ethanol was allowed to react with hexahalogenouranates, MU^VX₆ (M = N(CH₂CH₃)₄, As(C₆H₅)₄; X = Cl, Br) at room temperature to yield MU(OCH₂CH₃)₂X₄. The reaction of HF with U(OCH₂CH₃)₅ is suggested to form U(OCH₂CH₃)₂F₃.⁵⁴³

The mixed valence dinuclear species U₂(OBU^t)₉ was obtained from unstable K[U₂(OBU^t)₉]. The dimer crystallizes as a face-sharing bioctahedron.²⁶² Theoretical studies have been carried out to understand the lack of metal–metal bonding in these dinuclear uranium alkoxide structures.⁵⁵⁰

Syntheses of a variety of uranium(V) species employing phenoxide ligands have been described. In the preparation of uranium(V) aryloxy compounds via alcohol exchange, both products of partial alcohol replacement (U(OC₆H₅)₄(OCH₂CH₃) and U(OC₆H₅)₃(OCH₂CH₃)₂)⁵⁵¹ and complete exchange (U(OPh)₅)⁵⁴³ have been reported from reactions with U(OCH₂CH₃)₅, depending on stoichiometry and reaction conditions. The synthesis and characterization of analogous uranium(V) perfluorophenoxide, U(OC₆F₅)₅(HOCH₂CH₃), have also been presented.⁵⁴³ The metathesis reaction between CsUCl₆ and NaOC₆H₅, followed by extraction with *N,N*-dimethylformamide led to an “ate” product of composition close to U(OC₆H₅)₄Cl·2 DMF.⁵⁵¹ A unique U^V/U^{VI} mixed valence uranium phenoxide aggregate, {[U^V(OC₆H₅)₃(THF)]₂[U^{VI}O₂(THF)]₂}-(μ -OC₆H₅)₄(μ -O)₂, was synthesized by the reaction of NaOC₆H₅ with UCl₃·xTHF in tetrahydrofuran.⁵⁵ The structure of the complex consists of two seven-coordinate uranium(V) metal centers and two five-coordinate uranyl groups (U^{VI}O₂²⁺) bridged by phenoxide and oxo ligands.

Thiolate complexes. Uranium(V) thiolate compounds have also been prepared. It was reported that addition of H₅C₆SSC₆H₅ to UCl₅·Cl₂C=CClCOCl allowed for the formation of a uranium(V) arylsulfide compound, [UCl₄(SPh)]₂, as characterized by elemental analysis.^{490,552} In another report, *p*-thiocresol was allowed to react with [U^V(OCH₂CH₃)₅]_x in benzene under reflux to obtain U(SC₆H₄CH₃)₄(OCH₂H₃) in 74% yield.⁵⁵¹ Reactions of [U^V(OCH₂CH₃)₅]_x were carried out with a series of thiosalicylic, thiolactic, and thiobenzoic acids, as well as alkyl thioglycolates in variable stoichiometric ratios to form substitution compounds that were characterized by elemental analysis.⁵⁵³

(iv) Ligands containing neutral group 16 donor atoms

The pentavalent oxidation state is accessible for the early actinides uranium, protactinium, neptunium, and plutonium. Pentavalent species with neutral Group 16 bases can include either adducts of AnX₅ or complexes incorporating oxo-containing cations, AnO³⁺ or AnO₂⁺.

Aqua species. Ready hydrolysis ensures that all aqua species of pentavalent actinide species include oxo or hydroxide ligands. Representative aqua species are presented in Table 28. Early reports of hydrates were unable to differentiate between coordinated water and water included in the lattice of a complex. There are several structurally characterized examples in this class. Examples include the complex [(NpO₂)₂(SO₄)(H₂O)], in which the water is bound to one of the two neptunium centers to complete a coordination number of eight,⁵⁵⁴ and NpO₂·ClO₄·4H₂O,⁵⁵⁵ which is shown to be an ionic complex with four water molecules in equatorial positions of the pentagonal bipyramidal geometry. Other structurally characterized neptunyl hydrates include (NpO₂)₂(NO₃)₂·5H₂O,⁵⁵⁶ NpO₂Cl·H₂O,⁵⁵⁴ and the tri- and tetrahydrates of neptunyl malonate, (NpO₂)₂C₃H₂O₄·xH₂O (*x* = 3, 4).⁵⁵⁶

Ethers. The only reported ether compounds of pentavalent actinides are the species UCl₅·ether, where ether = THF or R₂O (R = Me, Et, Prⁱ, Buⁿ, and *i*-C₅H₁₁). Dioxane is suggested to form either both 1:1 and 1:3 (U:L) adducts.⁵⁵⁷

Ketones, aldehydes, esters. Adducts of UCl₅ with a number of ketone derivatives of polycyclic aromatics have been reported. The complexes UCl₅·L (L = anthr-10-one, 9-methyleneanthr-10-one, 1,9-benzoanthr-10-one, and 9-benzylideneanthr-10-one) are likely six coordinate. The ligands anthr-10-one and 1,9-benzoanthr-10-one also appear to form 1:2 (An:L) complexes. The trichloroacetyl chloride complex UCl₅·Cl₂C=CClCOCl has been identified as the initial product of the reaction of UO₃ with hexachloropropene; this species subsequently thermally decomposes to yield UCl₅. Under the common reaction conditions the UCl₅ thus generated spontaneously converts to UCl₄.

The ester complexes U(OR)₄·MeCO₂R (R = Et, X = Cl or Br; R = Prⁱ, X = Cl) were generated by the reaction of U(OR)₅ with acyl halides MeCOX.

Carbamides. The only reported carbamide complex is U(OC₆H₅)₄Cl·2DMF.⁵⁵¹

Urea. The complex NpO₂(NCS)(urea)₄ has been structurally characterized;⁴⁹⁸ the four urea molecules lie in the equatorial plane of the pentagonal bipyramidal geometry.

Phosphine oxide. Many reported actinide-phosphine oxide adducts are those of the actinide halide complexes (see Table 29). Most are obtained by direct reaction of the two constituents in nonaqueous media. UCl₅(OPPh₃) has been structurally characterized;⁵⁵⁸ the coordination environment is best described as approximately octahedral.

Sulfoxide. The complex Pa(tropolonate)₄Cl·DMSO has been reported.⁵⁵⁹

Phosphine sulfide, phosphine selenide. Considering the aforementioned instability of P=S and P=Se bonds, it is not surprising that the only reported complexes in this class involve Pa^V, the most stable actinide of that oxidation state. The complexes PaX₅L (X = Cl, Br; L = Ph₃PS, (Ph₂PS)₂CH₂, Ph₃PSe, and (Ph₂PSe)₂CH₂ have been identified.⁵⁶⁰

(v) Ligands containing Group 17 ligands

Binary halides. A number of homoleptic halides of pentavalent protactinium, uranium, and neptunium have been reported. In particular, the fluoride complexes AnF₅ are prepared by high

Table 29 Complexes of actinide(V) compounds with *P*-oxides.

temperature oxidation of the tetravalent fluorides with fluorine or other potent fluorinating agents (e.g., KrF_2), or by reduction of the hexafluorides with iodine or PF_3 . The synthesis of NpF_5 by oxidation of $[\text{NpF}_6]^-$ with BrF_3 in anhydrous HF has also been reported.⁵⁶¹ Two crystallographic forms (α -, β -) exist for UF_5 ; the neptunium compound is reported to be isostructural with α - UF_5 ,⁵⁶² whereas PaF_5 has the same structure as β - UF_5 .⁵⁶³ In the alpha form, the uranium lies within an octahedral coordination environment. In the beta form, the uranium center is eight-coordinate, with a geometry intermediate between dodecahedral and square antiprismatic.⁵⁶⁴

Heavier pentahalides have also been reported for protactinium and uranium. Protactinium is reported to form PaCl_5 , PaBr_5 , and PaI_5 ; the chloride and bromide derivatives have been structurally characterized.^{565,566} UCl_5 exists in two morphologies (α -, β -); UBr_5 appears to be isostructural with β - UCl_5 .

Several mixed halides $\text{AnX}_n\text{X}'_{5-n}$ have also been reported.

Complex halides. The major classes of complex halides are $\text{M}[\text{AnX}_6]$, $\text{M}_2[\text{AnX}_7]$, and $\text{M}_3[\text{AnX}_8]$ (M = alkali metal). The complexes are generally prepared either by reaction of the appropriate pentahalide complex with the alkali metal halide salt, or by *in situ* reaction, where the pentahalide is produced directly in the presence of MX . The uranium complexes $\text{M}[\text{UX}_6]$ ($\text{X} = \text{F}, \text{Cl}$); the metal ion is octahedrally coordinated,^{567–570} as are the actinide centers in $[\text{NO}][\text{AnF}_6]$ ($\text{An} = \text{Np}, \text{Pu}$).⁵⁷¹ For the larger protactinium ion, higher coordination numbers can be accommodated, and the complex RbPaF_6 , the metal center is eight-coordinate.⁵⁷² Similarly, the compounds MPaF_7 display a nine-coordinate metal center,⁵⁷³ whereas the smaller metal ions in Rb_2AnF_7 ($\text{An} = \text{Np}, \text{Pu}$) can only accommodate seven fluoride ions in their coordination sphere. The octafluoro complexes $\text{Na}_3[\text{AnX}_8]$ ($\text{An} = \text{Pa}, \text{U}, \text{Np}$) have been reported; each the metal center lies in a cubic environment.⁵⁷⁴

Oxohalides. Binary oxohalides of the formulae AnOX_3 , AnO_2X , An_2OX_8 , $\text{An}_2\text{O}_3\text{X}_4$, and $\text{An}_3\text{O}_7\text{X}$ have been reported, most commonly for protactinium, but also in some cases for uranium and neptunium. The complexes are polymeric in the solid state; the structure of PaOBr_3 demonstrates that the metal center is in a pentagonal bipyramidal geometry of three oxygen and four bromine atoms.⁵⁷⁵ The structure of $\text{NpO}_2\text{Cl} \cdot \text{H}_2\text{O}$ has been determined.⁵⁷⁶

A limited number of complex oxohalide complexes have been characterized. Complexes of the classes $(\text{NR}_4)_2[\text{AnOX}_5]$, MAnO_2X_2 , and $\text{M}_3[\text{UO}_2\text{Cl}_4]$ (M = alkali metal) have been reported. Several members of the latter class have been structurally characterized and display a pseudo-octahedral geometry about the metal center.⁵⁷⁷

3.3.2.3.3 Chelating ligand

(i) Multidentate donor ligands

Hydroxamate. Similar to trivalent hydroxamates, pentavalent actinide hydroxamate complexes are generally unstable relative to tetravalent and/or hexavalent complexes. Pu^{VI} or Pu^{V} hydroxamate complexes can be prepared; however, at near-neutral and basic pH they rapidly reduce to Pu^{IV} complexes.⁸⁰

8-Hydroxyquinoline and derivatives. A Np^{V} complex of 8-hydroxyquinoline $\text{NpO}_2(\text{Ox})(\text{H}_2\text{O})_2$ has been prepared by precipitation from aqueous solution.⁵⁷⁸ The $\text{NpO}_2(\text{Ox}) \cdot \text{DMSO}$ is prepared by replacing the two water molecules by DMSO. The bis(quinoline) complex, $\text{NpO}_2(\text{Ox})_2^-$ is formed by increasing the pH of a $\text{NpO}_2(\text{Ox})(\text{H}_2\text{O})_2$ solution. This anion precipitates as $[(\text{C}_6\text{H}_5)_4\text{As}][\text{NpO}_2(\text{Ox})_2 \cdot \text{H}_2\text{O}]$ with addition of tetraphenylarsonium chloride.

Oxalate. Pentavalent actinide oxalates are limited to a few Np^{V} hydrated oxalates and oxalato complex salts (see Table 26). The structure of a simple neptunyl oxalate complex $(\text{NpO}_2)_2 \cdot (\text{C}_2\text{O}_4) \cdot 6\text{H}_2\text{O}$ has been determined by X-ray diffraction. The complex was precipitated from aqueous solutions by the reaction of NpO_2NO_3 and $(\text{NH}_4)_2\text{C}_2\text{O}_4$. The structure of the complex consists of electroneutral layers of $(\text{NpO}_2)_2 (\text{C}_2\text{O}_4) \cdot 4\text{H}_2\text{O}$ between which coordinated aqua ligands and waters of crystallization are located. Neptunyl(V) acts as a monodentate ligand for the adjacent Np and oxalate coordinates each Np in a bidentate mode.⁵⁷⁹

Diamides. Sasaki and Choppin used the diglycolamide, *N,N'*-dimethyl-*N,N'*-dihexyl-3-oxapentanediamide (DMDHOPDA), to successfully extract Np^{V} from an aqueous NaClO_4 solution into nitrobenzene or toluene (less effective). This is significant since Np^{V} possesses weak complexation ability with organic extractants. NpO_2^+ was characterized in solution by absorption spectroscopy. Extraction dependency studies show nonintegral slopes, indicative of $\text{NpO}_2(\text{DMDHOPDA})^+$ and $\text{NpO}_2(\text{DMDHOPDA})^{2+}$ species being present in the

extracted phase; pH studies also show an acid dependence on its extraction (90% complete at a pH of 3).⁵⁸⁰

Polyoxometallates. The relatively high negative charge of the Dawson and Keggin anions $[\text{XW}_{11}\text{O}_{39}]^{n-}$ and $[\text{X}_2\text{W}_{17}\text{O}_{61}]^{n-}$ render them capable of supporting actinides in higher oxidation states. Chemical or electrochemical oxidation of the U^{IV} species $\text{U}[\text{PW}_{11}\text{O}_{39}]_2^{10-}$, $\text{U}[\text{P}_2\text{W}_{17}\text{O}_{61}]_2^{16-}$, and $\text{U}[\text{SiW}_{11}\text{O}_{39}]_2^{12-}$ results in the formation of stable pentavalent complexes without the formation of actinyl-type species.^{438,581} Other examples of the complexation of pentavalent actinides with polyoxometallates indicate somewhat weaker bonding. Absorption spectroscopy suggests the complexation of Np^{V} by $[\text{P}_2\text{W}_{17}\text{O}_{61}]^{10-}$ in solution, but this complexation is suppressed by the addition of excess Na^+ or K^+ , suggesting that the pentavalent actinide may be only weakly coordinated to the outer sphere of the oxoanion as the actinyl species NpO_2^+ .^{582,583}

(ii) Macrocyclic ligands

N-Heterocyclic ligands. The porphyrin [22]hexaphyrin(1.0.1.0.0.0) has been complexed with NpO_2^+ to form an inclusion complex. This complex was studied by single crystal X-ray diffraction and the crystal structure is shown in Figure 43. In this complex the neptunium and the nitrogen atoms of the porphyrin are almost perfectly co-planar. The coordination around the neptunium is nearly an ideal hexagonal bipyramidal with the two oxo-ligands being *trans* to the equatorial plane.⁵⁸⁴

The plutonium(V) analog of the neptunium(V) [22]hexaphyrin(1.0.1.0.0.0) was confirmed by UV-vis spectroscopy. In this complex, plutonium(VI) is exposed to the ligand and is reduced to plutonium(V). It is postulated that the coordination is the same as the neptunium(V) complex.⁵⁸⁵

Crown ethers. In neptunium(V) and neptunium(VI) crown ether complexes, the two axial oxygen ligands help in forming more stable complexes. The reaction of neptunium(VI) with 18-crown-6 in the presence of 1 M HX ($\text{X}=\text{ClO}_4$ or CF_3SO) results in the reduction of neptunium(VI) to neptunium(V), thus allowing better metal complexation. The geometry around Np^{V} in the complex is hexagonal bipyramidal. Disorder in the crystal leads to two possible spatial locations for the crown ether: 30° offset from one another and each refined with 50/50 occupancy. This does not affect the coordination environment of the metal.⁵⁸⁶

3.3.2.4 Hexavalent Oxidation State

3.3.2.4.1 General characteristics

Stable hexavalent ions of the type AnO_2^{2+} ($\text{An}=\text{U}, \text{Np}, \text{Pu}$) can be generated in aqueous media. The uranyl ion (UO_2^{2+}) is the most stable form of uranium in aqueous media under aerobic conditions. In general, aqueous Np^{VI} and Pu^{VI} compounds can be prepared from Np^{V} and Pu^{IV}

Figure 43 Crystal structure of $[\text{NpO}_2(\text{C}_{44}\text{H}_{51}\text{N}_6)](\text{HN}(\text{C}_2\text{H}_5)_3)$ (Sessler, Seidel, *et al. Angew. Chem., Int. Ed. Engl.* **2001**, *40*, 591).

or Pu^{V} electrochemically by adding chemical oxidants such as ozone. Resulting Pu^{VI} complexes are generally more stable than Np^{VI} complexes, but both classes are far less stable than their U^{VI} analogues. For example, hydrated Np^{VI} and Pu^{VI} carbonates will decompose to Np^{V} carbonates and Pu^{IV} oxyhydroxides, respectively, in days to weeks, depending on the initial preparation. The hexavalent actinyl ions also display a linear $\text{O}-\text{An}-\text{O}$ unit, with other ligands coordinating roughly in the plane bisecting and perpendicular to this unit. Consistent with the lower thermodynamic stability of NpO_2^{2+} and PuO_2^{2+} , these ions possess weaker $\text{An}-\text{O}$ bonds. Non-actinyl coordination complexes of hexavalent actinides are rare, and are limited to a few ligand types (generally those containing halide or alkoxide ligands, although one example of a stable homoleptic amide complex of U^{VI} has been reported).

3.3.2.4.2 Simple donor ligands

(i) Ligands containing group 14 donor atoms

The most recent class of Group 14 donor ligands to be employed in actinide chemistry is that of *N*-heterocyclic carbenes. These ligands act as σ -donor bases toward a number of metals in coordination chemistry. Reaction of $\text{UO}_2\text{Cl}_2(\text{THF})_3$ with 1,3-dimesitylimidazole-2-ylidene and its 4,5-dichlorosubstituted derivative generate 1:2 (uranium:carbene) adducts, $\text{UO}_2\text{Cl}_2(\text{L})_2$.⁵⁸⁷ Crystallographic characterization reveals an octahedral metal center, with *trans*-oxo, chloro, and carbene ligands. The uranium–carbon bond distances in these species are long at 2.626(7) Å and 2.609(4) Å, consistent with the formulation of the C–U bond as a dative interaction.

A rare example of U–C interaction in hexavalent actinide chemistry is found in the isolation of a bis(iminophosphorano)methanide complex of the uranyl ion.⁵⁸⁸ Reaction of $\text{UO}_2\text{Cl}_2(\text{THF})_3$ with $\text{Na}[\text{CH}(\text{Ph}_2\text{P}=\text{NSiMe}_3)_2]$ generates the dimer $\{\text{UO}_2(\mu\text{-Cl})[\text{CH}(\text{Ph}_2\text{P}=\text{NSiMe}_3)_2]\}_2$. The U–C distance is 2.691(8) Å; the length indicates a very weak interaction, although it falls within the sum of the van der Waals radii of the two atoms.

An adduct of uranyl chloride with cyclohexylisocyanide has been reported.¹⁰¹

(ii) Ligands containing anionic group 15 donor atoms

Amide complexes.

Hexavalent complexes containing N-donor ligands comprise two major classes: homoleptic amide complexes, and species derived from the uranyl ion (UO_2^{2+}). Only two homoleptic amide complexes have been reported. The complex $\text{U}(\text{NMe}_2)_6$ is reportedly produced in the oxidation of $[\text{U}(\text{NMe}_2)_6]^-$ by silver iodide;^{104,106} the complex is unstable in solution, and could be characterized only by its NMR spectrum. It decomposes to form $\text{U}(\text{NMe}_2)_5$ and unidentified side products. A more stable hexavalent amide complex is produced by the oxidation of $[\text{Li}(\text{THF})_x][\text{U}(\text{dbabh})_6]^-$ ($\text{Hdbabh} = 2,3:5,6$ -dibenzo-7-azabicyclo[2.2.1]hepta-2,5-diene) by any of several oxidants (air, Cp_2Fe^+ , Ag^+ , I_2).⁴⁸⁷ The complex $\text{U}(\text{dbabh})_6$ has been characterized crystallographically (see Figure 44). The coordination environment of the metal center is nearly octahedral, with U–N distances ranging from 2.178(6) Å to 2.208(5) Å. Density functional theory (DFT) calculations suggest that the HOMO is triply degenerate with U–N π -bonding character. Although the orbitals are largely nitrogen-based, they contain contributions from U 6*d* and 5*f*-orbitals.

A series of uranyl complexes containing the bis(trimethyl)silylamide ligand have been reported.^{12,589,590} The complex $\text{UO}_2[\text{N}(\text{SiMe}_3)_2]_2(\text{THF})_2$ is produced in the reaction of UO_2Cl_2 with two equivalents of $\text{K}[\text{N}(\text{SiMe}_3)_2]$. The anionic species $[\text{Na}(\text{THF})_2]_2\{\text{UO}_2[\text{N}(\text{SiMe}_3)_2]_4\}$ is produced in the reaction of UO_2Cl_2 and excess $\text{Na}[\text{N}(\text{SiMe}_3)_2]$. The intervening members of the series, $[\text{M}(\text{THF})_2]\{\text{UO}_2[\text{N}(\text{SiMe}_3)_2]_3\}$ ($\text{M} = \text{Na}, \text{K}$) have been more recently reported, and serve as rare examples of uranyl complexes with only three ligands in the equatorial plane. While the sodium derivative can only be produced by Lewis-acid abstraction or protonation of $\text{N}(\text{SiMe}_3)_2^-$ from the “ate” complex $[\text{Na}(\text{THF})_2]_2\{\text{UO}_2[\text{N}(\text{SiMe}_3)_2]_4\}$, the potassium derivative may be directly synthesized by reaction of $[\text{UO}_2\text{Cl}_2(\text{THF})_2]_2$ with $\text{K}[\text{N}(\text{SiMe}_3)_2]$. A base adduct, $\text{UO}_2[\text{N}(\text{SiMe}_3)_2]_2(\text{OPPh}_3)_2$, has also been reported.⁵⁹¹ Attempts to introduce more electron-rich ligands into the coordination sphere of the uranyl ion are found to result in reduction of the metal center. Reaction of $[\text{K}(18\text{-crown-6})]_2[\text{UO}_2\text{Cl}_4]$ with the tris(amido)amine ligand $\text{Li}_3[\text{N}(\text{CH}_2\text{CH}_2\text{NSi}(\text{Bu}^t)\text{Me}_2)_3]$ produces the mixed valence oxo- and imido-containing species $[\text{K}(18\text{-crown-6})(\text{Et}_2\text{O})][\text{UO}(2\text{-CH}_2\text{CH}_2\text{N}(\text{CH}_2\text{CH}_2\text{NSi}(\text{Bu}^t)\text{Me}_2)_2)]_2$

Figure 44 Crystal structure of $\text{U}(\text{dbabh})_6$ (Meyer, Mindiola *et al.* *Angew. Chem., Int. Ed. Engl.* **2000**, *39*, 3063–3066).

as the major isolated uranium product in moderate yield.⁵⁹² The multidentate triamidoamine ligand coordinates to uranium through the capping amine and two of the three pendant amido ligands, while the third pendant amido donor has been activated to generate a bridging imido ligand by loss of the silyl substituent. One of the uranyl oxo groups is retained as a terminal ligand to complete the coordination sphere for each uranium center. The oxo and imido nitrogen may be regarded as the axial ligands of a capped trigonal bipyramidal geometry about the metal center, while the two amido ligands and the other imido donor occupy equatorial coordination sites. The central amine of the tripodal set serves as the capping ligand.

Amidinate ligands. The benzamidinate ligand has also been found to coordinate the uranyl ion. The uranyl complex, $[\text{C}_6\text{H}_5\text{C}(\text{NSiMe}_3)_2]\text{UO}_2$, was prepared by a metathesis reaction with UO_2Cl_2 .⁵⁹³

Pyrazolylborate. Only one reported complex of a tris(pyrazolyl)borate complex has been reported. The chelating ligand tris[3-(2-pyridyl)-pyrazol-1-yl]borate ($^{\text{py}}\text{Tp}$) reacts in a 1:1 ratio with uranyl nitrate to yield the complex $\text{UO}_2(^{\text{py}}\text{Tp})(\text{OEt})$ after recrystallization from $\text{EtOH}/\text{CH}_2\text{Cl}_2$.¹⁷⁰ The ethoxide ligand is presumably derived from the alcohol of recrystallization. The three bidentate arms of the pyrazolylborate ligand are incapable of spanning the equatorial plane of the uranyl unit; instead two arms provide four ligands of the pentagonal bipyramidal plane. The third arm of the ligand is pendant, with the pyridyl and pyrazolyl rings adopting a *trans*-coplanar arrangement (see Figure 45).

Phosphoraniminato complexes. A very different class of species with U—N bonds is derived from the uranyl ion by replacement of one or both of the oxo groups by a phosphoran iminato group ($\text{PR}_3\text{-N}^{2-}$). The first example of such a complex, $[\text{PPh}_4][\text{UOCl}_4\{\text{NP}(m\text{-Tol})_3\}]$ (Tol = tolyl) was generated in modest yield by elimination of Me_3SiCl from the mono-oxo complex $[\text{UOCl}_5]^-$ (Equation (44)).⁵⁹⁴

Figure 45 Crystal structure of $\text{UO}_2(\text{pyTp})(\text{OEt})$ (pyTp=tris[3-(2-pyridyl)-pyrazol-1-yl]borate) (Amoroso, Jeffery *et al.* *Polyhedron* **1995**, 15, 2023–2027).

The procedure was subsequently extended to include other members of the class $[\text{UOCl}_4\{\text{NPR}_3\}]^-$.⁵⁹⁵ The resulting complexes are stable in the absence of moisture; in the presence of water they undergo rapid hydrolysis to generate uranyl salts. The molecular structure of the compound $[\text{PPh}_4][\text{UOCl}_4\{\text{NP}(m\text{-Tol})_3\}]$ reveals that the O—U—N unit retains the linearity inherent to the actinyl species ($179.0(6)^\circ$), and that the U—O bond is within the range expected for uranyl complexes (1.759(13) Å). The U—N bond is short (1.901(14) Å), suggesting a significant degree of metal–ligand multiple bonding. Bis(iminato) complexes $\text{UCl}_4\{\text{NPR}_3\}_2$ can be isolated from the same reaction mixture by controlling the conditions under which the products are isolated. They appear to be formed concurrently with $\text{UO}_2\text{Cl}_4^{2-}$, although isolated complexes of $[\text{UOCl}_4\{\text{NPR}_3\}]^-$ appear to be stable to redistribution. In the vibrational spectra of these species the antisymmetric U—N—P stretching frequencies in the oxo-iminato complexes appear to lie at higher frequencies than those in the bis(iminato) species. This has been cited as supporting evidence for the existence of an inverse *trans* influence in actinide complexes.⁵⁹⁶ More recently, a sulfiliminato analogue, $[\text{PPh}_4][\text{UOCl}_4\{\text{NSPh}_2\}]$, has been produced by the reaction of $[\text{PPh}_4][\text{UOCl}_5]$ with $\text{Me}_3\text{Si}\{\text{NSPh}_2\}$.⁵⁹⁷

Additional support for the existence of non-oxo uranyl analogues may be found in the reactions of uranium atoms with small molecules (N_2 , NO, CO, etc.) in argon matrices. Although not stable outside of the stabilizing matrix, vibrational spectroscopy is consistent with the formation of other linear triatomic species such as NUN, NUO, and CUO.^{598–601}

Cyanate and thiocyanate. Cyanate salts of the uranyl ion are thought to be formed in reactions of uranyl and $\text{Et}_4\text{N}(\text{NCO})$. The complex $(\text{Et}_4\text{N})_2[\text{UO}_2(\text{NCO})_4(\text{H}_2\text{O})]$ has been reported,⁶⁰² and the partially hydrolyzed salt $\text{K}_3[(\text{U}_2\text{O}_5)(\text{NCO})_5]\cdot\text{H}_2\text{O}$ has also been reported. Although no complexes have been isolated, anions of the formula $[\text{UO}_2(\text{NCO})_4]^{2-}$ and $[\text{UO}_2(\text{NCO})\text{Cl}_3]^{2-}$ are thought to be formed in solutions containing $\text{UO}_2\text{Cl}_4^{2-}$ and $\text{R}_4\text{N}[\text{Ag}(\text{NCO})_2]$, on the basis of IR data.⁶⁰³

Neutral complexes of the formula $\text{UO}_2(\text{NCS})_2(\text{H}_2\text{O})_x$ have been reported, as have monoanionic species containing the $[\text{UO}_2(\text{NCS})_3\text{L}_x]^-$ anion and the complex anion $[\text{UO}_2(\text{NCS})_5]^{3-}$. The complex $\text{Cs}_3[\text{UO}_2(\text{NCS})_5]$ has been crystallographically characterized;⁶⁰⁴ as expected, the metal lies within a pentagonal bipyramidal coordination sphere.

It has been found that addition of crown ethers facilitates the crystallization of anionic derivatives. In this manner, the anion $[\text{UO}_2(\text{NCS})_4(\text{H}_2\text{O})]^-$ has been isolated both as the ammonium and potassium salts.⁶⁰⁵

Azide. There are few reports of actinide azide complexes. One compound isolated by the reaction of uranyl with tetraalkylammonium azide salts has an extended structure in the solid state.⁶⁰⁶ The structure of catena-(tetraethylammonium bis(μ_2 -azido-*N,N*)azidodioxouranium incorporates a chain of uranyl ions bridged in the equatorial plane by two azide group; each uranyl is further ligated by a terminal azide to complete a pentagonal bipyramidal coordination environment about uranium. If a tetramethylammonium counterion is used, the large aggregate $[\text{NMe}_4]_8[(\text{UO}_2)_6(\mu_3\text{-O})_2(\mu_2\text{-N}_3)_8(\text{N}_3)_8]$ is isolated (see Figure 46).

(iii) *Ligands containing neutral group 15 donor atoms*

All neutral base adducts of hexavalent actinides are those of the dioxo, or actinyl ions (AnO_2^{2+}). Although at least one report has appeared which indicates the stability of base adducts of UF_6 ,⁶⁰⁷ However, subsequent researchers have demonstrated that reduction occurs in these systems.⁴⁹³

Ammonia and amines. A number of ammonia and amine adducts of uranyl complexes have been reported (see Tables 30 and 31), isolated from reaction of the uranyl salt with amine either in aqueous or nonaqueous media. The molecular structure of the acetylacetonate derivative $\text{UO}_2(\text{CF}_3\text{COCHCOCF}_3)(\text{NH}_3)$ is prototypical of the class. The uranyl *trans*-dioxo geometry is preserved, and the ammonia nitrogen is one of the five coordinating atoms in the “belly band” of the ion.⁶⁰⁸ Occasionally ammonia can react with the coordinating ligand; reaction with electron-rich acetylacetonate ligands leads to condensation to form β -ketoimine complexes. Several proposed hydrazine adducts of the uranyl ion have also been reported,⁶⁰⁹ although little characterization data is available. Several simple salts of uranyl with chelating diamine ligands have also been reported (see Table 32).

Heterocyclic ligands. Complexes of actinyl complexes with coordinating *N*-heterocycles in the equatorial plane are proposed to have metal coordination numbers ranging from six to eight, depending on the anion and the size of the base (*cf.* uranyl complexes presented in Table 33). Several compounds containing pyridine or bidentate heterocyclic ligands have been crystallographically characterized, and are found to contain seven- or eight-coordinate actinide(VI) ions. The structure of $\text{UO}_2(\text{NO}_3)_2(\text{py})_2$ has been determined.⁶¹⁰ The complex consists of an eight-coordinate (considering nitrate as bidentate) uranium, with mutually *trans*-pyridine and nitrate ligands. A *cis* geometry of two nitrate ligands is enforced by the use of the chelating ligand 1,10-phenanthroline (phen) in the complex $\text{UO}_2(\text{NO}_3)_2(\text{phen})$;⁶¹¹ this ligand also coordinates to the uranyl species $[\text{UO}_2(\text{O}_2\text{CCH}_3)(\text{phen})(\mu\text{-OH})]_2$.⁶¹¹ Monopyridine adducts $\text{AnO}_2(\text{acac})_2(\text{py})$

(An = U, Np; acac = acetylacetonate) provide examples of seven-coordinate uranium.⁶¹² In the presence of weakly coordinating anions, it is possible to displace the anion from the coordination sphere of the metal (as is proposed for the complex $[\text{UO}_2(\text{py})_5][\text{ClO}_4]_2$), but formation of ionic salts is not always the outcome. The base-free complex $\text{UO}_2(\text{OTf})_2$ (OTf = triflate) is generated from the reaction of UO_3 with triflic acid or its anhydride. Given the weakly coordinating nature of the triflate ion, it might be anticipated that it could readily be replaced by N-heterocyclic ligands. Recrystallization of $\text{UO}_2(\text{OTf})_2$ from pyridine, however, merely results in the base adduct

Table 33 Some complexes of N-heterocyclic ligands with dioxouranium(VI) compounds.

$\text{UO}_2(\text{OTf})_2(\text{py})_3$.⁶¹³ It is only in the structure of the hydrolysis product, $[\{\text{UO}_2(\text{py})_4\}_2(\mu\text{-O})][\text{OTf}]_2$, that displacement of the triflate anions is observed.

N-heterocyclic adducts have also been reported for piperidine, quinoline, isoquinoline, imidizoles, dipyridylamines, 2,2-bipyridine, and 1,10-phenanthroline.

Nitriles. Acetonitrile adducts have been reported for several uranyl salts, including the chloride and nitrate. Although lower metal coordination numbers (e.g., five) have been suggested in the formulation of some of these compounds, it is likely that the species contain six- or seven-coordinate metal ions. As illustration of this, the molecular structure of $\text{UO}_2\text{Cl}_2(\text{MeCN})_2(\text{H}_2\text{O})$ ⁶¹⁴ possesses a seven-coordinate uranium center, with mutually *trans*-acetonitrile and chloride ligands.

The adduct $\{(\text{C}_{10}\text{H}_{21})_4\text{N}\}\text{NpO}_2\text{Cl}_3 \cdot \text{MeCN}$ has also been reported.⁶¹⁵

(iv) Ligands containing anionic group 16 donor atoms

Oxides. The binary actinide oxides include AnO_3 , An_3O_8 , $\text{An}_4\text{O}_{9-y}$, and $\text{AnO}_{2\pm x}$ with all of the phases well characterized in the solid state for U. An additional oxide, An_3O_7 has been reported,⁶¹⁶ the distinct stoichiometric tetragonal phase is not prevalent and many reported occurrences may in fact correspond to mixtures of the other more stable oxides.⁶¹⁷ In addition to being characterized by X-ray diffraction studies, X-ray photoelectron spectroscopy, and optical and X-ray absorbance techniques have also been used to distinguish the phases.^{196,618,619}

Although there have been numerous reports of analogous phases that may contain Np^{VI} and Pu^{VI} , and there is evidence for some of them in the oxidation of mixed U, Np, Pu oxide fuels, most have not been structurally characterized or otherwise confirmed. For example, neptunium trioxide has been reported, and is thought to be the solid formed from neptunyl hydroxide precipitates (formulated as either $\text{NpO}_3 \cdot 2\text{H}_2\text{O}$ or $\text{NpO}_2(\text{OH})_2 \cdot \text{H}_2\text{O}$).^{620,621} Plutonium trioxide has only been observed in the gas phase when PuO_2 or (U, Pu) O_2 are oxidized.⁶²² Reported preparations of Np_3O_8 , yielded instead Np_2O_5 , or mixtures of Np_2O_5 and NpO_2 .^{499,623} The superstoichiometric $\text{PuO}_{2\pm x}$ was reported to

contain Pu^{VI} ,¹⁹³ however, more recent X-ray absorbance studies suggests that both the hydrated solid and solution suspension contain Pu^{V} .⁵⁰⁰

Uranium trioxide has been very well studied in part because of its applications in the nuclear fuel cycle. It occurs naturally in pitchblende and is generally prepared by thermal decomposition of oxide hydrates and uranyl salts or oxidation of lower oxides or halides.⁶²⁴ The trioxide has been isolated in six well-defined stoichiometric modifications as well as a substoichiometric $\text{UO}_{2.9}$. The alpha phase comprises a three-dimensional network of chains of bicapped hexagonal prisms of UO_8 polyhedra and it contains structural features observed in numerous mineral phases. The U—O bond length along the chains are 2.083 Å and the bonds in the pentagonal chains are 2.07 to 2.7 Å. This coordination geometry is also observed in molecular hydroxides. The uranyl type bond length is 2.08 Å and the bonds in the hexagonal plane range from 2.03 Å to 2.80 Å in length. The trioxide decomposes into lower oxides prior to melting or subliming.

Uranium trioxide is a key precursor to UF_4 and UF_6 , which are used in the isotopic enrichment of nuclear fuels.^{625–627} It is also used in the production of UO_2 fuel,⁶²⁸ and microspheres of UO_3 can themselves be used as nuclear fuel. Fabrication of UO_3 microspheres has been accomplished using sol-gel or internal gelation processes.^{629–632} Finally, UO_3 is also a support for catalytic oxidative destructive of organics.^{633,634}

Triuranium octaoxide, U_3O_8 , is also found in pitchblende. The common centered orthorhombic structure contains staggered chains of UO_7 , similar to molecular uranyl species. XPS studies of U_3O_8 have indicated the presence of two oxidation states, U^{IV} and U^{VI} , in a 1:2 ratio, respectively.⁶³⁵ The relatively flexible structure and mixed valency allows for super- and substoichiometric phase formation, depending on the temperature and O_2 partial pressure during preparation. The preparation of U_3O_8 has been accomplished by thermal decomposition of uraninites, oxide hydrates and uranyl salts. In addition to the varying U/O ratios, U_3O_8 has been found to exist in at least five crystalline forms.

Industrially, U_3O_8 has been shown to be active in the decomposition of organics, including benzene and butanes,^{636,637} and as supports for methane steam reforming catalysts.⁶³⁸ In the nuclear fuel industry, U_3O_8 is an oxidation product of UO_2 (SIMFUEL), and thus a major component of spent fuel rods.^{639,640} The density of U_3O_8 is significantly less than that of UO_2 and as a result, the production of U_3O_8 in nuclear fuel can lead to the destruction of the UO_2 pellet by pulverization. Triuranium octaoxide is used in the initial production of UO_2 pellets for fuel,^{641,642} in the manufacturing of MOX (mixed oxide) pellets,⁶⁴³ as well as a dispersive nuclear fuel itself.⁶⁴⁴

Two oxygen-rich UO_{2+x} phases, U_3O_7 , and U_4O_9 contain U^{VI} units with unusual coordination geometries. The beta form of triuranium heptaoxide, formed by the low temperature oxidation of UO_2 , has an anion excess defect structure. The tetragonal, alpha- U_3O_7 is naturally occurring, although rare.⁶⁴⁵ The cubic phase U_4O_9 has different coordination geometries of uranium; uranium polyhedra from eight- to eleven-coordinate are found in interesting combinations within the unit cell, including UO_{11} polyhedra and UO_8 square antiprisms (see Figure 47).⁶⁴⁶

The uranyl oxide hydrates are important corrosion products of uraninite and UO_2 in spent nuclear fuel under oxidizing conditions. However, the systematics of the structures had not been well described until the studies reported by Miller *et al.*⁵⁰⁵ With the exception of the synthetic $\text{UO}_2(\text{OH})_2$ polymorphs, all hydrate crystal structures are based on sheets of edge-sharing uranyl pentagonal or square bipyramids. Only four structural unit chains are required to construct the uranyl oxide hydrate sheets (as well as the structurally similar U_3O_8 sheets). One chain is made up

Figure 47 An unusual 11-coordinate U^{IV} within the extended structure of U_4O_9 with a pseudotricapped cubic geometry, where the longer, “capping” oxygens are shown in white (Bevan, Grey *et al. J. Solid State Chem.* **1986**, 61(1), 1–7).

of hexagonally coordinated uranyl ions sharing opposing edges. A second chain, composed of pentagonal bipyramids sharing edges and alternating with trigonal vacancies, is present in all other UOH sheets. Another zigzag chain consists of edge-sharing pentagonal bipyramids forming a zigzag chain. And the remaining structural unit is a discontinuous “chain” of rhombic bipyramids. This chain occurs in sheets which contain only four-coordinate uranyl ion and those containing both four- and five-coordinate uranyl ions. Burns, Miller, and Ewing have similarly analyzed a large number of U^{VI} minerals and describe their systematic structural and thermodynamic properties using a number of uranyl polyhedra.⁵⁰⁵

There are a tremendous number of ternary oxides, generally alkali and alkaline earth salts of the form M_2AnO_4 and MAnO_4 with many known for U, Np, and Pu. In addition, there are large families of uranates, with the sodium and ammonium salts being the most common. In nuclear fuels production the “yellow cake” contains ammonium diuranate which is actually a mixture of compounds ranging from $(\text{NH}_4)_2\text{UO}_4$ to $(\text{NH}_4)_2\text{U}_8\text{O}_{25}$, and having the approximate composition $(\text{NH}_4)_2\text{U}_2\text{O}_7$.⁶⁴⁷ Also characterized are Li_4AnO_4 for Np, Pu, M_2UO_4 , M_2UO_5 , $\text{M}_2\text{U}_2\text{O}_7$, $\text{Li}_2\text{U}_3\text{O}_{10}$, $\text{Li}_2\text{U}_4\text{O}_{12}$, $\text{Cs}_2\text{Np}_3\text{O}_{10}$, Li_6AnO_6 , for Np, Pu, and $\text{M}_2\text{Np}_2\text{O}_7$, many characterized by Cordfunke and co-workers.^{648–654} The phase Li_6AnO_6 and its transition to $\text{Li}_2\text{U}_3\text{O}_{10}$ has been re-evaluated.⁶⁵⁵ The structure of the anion in $\text{Li}_2\text{U}_3\text{O}_{10}$ ($\text{Li}_2(\text{UO}_2)_3\text{O}_4$) consists of octahedral $(\text{UO}_2)\text{O}_4$ and pentagonal bipyramidal $(\text{UO}_2)\text{O}_5$ groups linked by oxygen bridges.⁶⁵⁶ Burns and co-workers have characterized numerous hydrated ternary oxy/hydroxides, particularly those containing Na, NH_4 , Ca, and Pb, related to minerals.^{657–660}

Hydroxides. The hydrolysis of hexavalent actinides has been studied extensively and recently reviewed.^{46,197,661,662} For uranyl, the primary solution and solid state species have been well characterized and include polymers and low dimensional solids. An impressive number of potentiometric titration studies established several solution species that have been confirmed by fluorescence, X-ray absorbance, and X-ray diffraction studies. The products often have interesting structural features, including linked uranyl oxo/hydroxo/aqua polyhedra. Within these structures U centers are generally seven-coordinate, with pentagonal bipyramidal geometry, but also may be six- or eight-coordinate with rhombic and hexagonal bipyramidal geometries.

At approximately micromolar and lower solution concentrations, the initial hydrolysis product is $\text{UO}_2(\text{OH})^+$, which likely has four waters in addition to the hydroxide in the equatorial plane and a pentagonal bipyramidal geometry.^{663,664} The hydrolysis proceeds stepwise to form the bishydroxo, $\text{UO}_2(\text{OH})_2$, which has very low solubility. At higher uranium concentrations the first hydrolysis product is the dimer, $(\text{UO}_2)_2(\text{OH})_2^{2+}$, with two bridging hydroxides and pseudopentagonal bipyramidal coordination of the dioxo, hydroxo, and aquo oxygens.^{197,665} Further hydrolysis products include the trimeric uranyl hydroxide complexes $(\text{UO}_2)_3(\text{OH})_5^+$ and $(\text{UO}_2)_3(\text{OH})_4^{2+}$.¹⁹⁷ A triply bridging oxygen has been identified in an adamantane-like trimer of this type, the species $[(\text{UO}_2)_3(\mu_3\text{-O})(\mu_2\text{-OH})_3]^+$, formed in the sol-gel process.⁶⁶⁶ There is good evidence for additional trimeric species with the formulas $(\text{UO}_2)_3(\text{OH})_7^-$, $(\text{UO}_2)_3(\text{OH})_8^{2-}$, and $(\text{UO}_2)_3(\text{OH})_{10}^{4-}$.⁶⁶⁷

Solids precipitated from these systems have been formulated based on stoichiometry as $\text{UO}_2(\text{OH})_2$ or various hydrated $\text{UO}_3 \cdot x\text{H}_2\text{O}$ phases, but their structural formulas can be very complicated. Several researchers have recently analyzed these hydroxides and related weathered minerals, such as schoepite ($[(\text{UO}_2)_8\text{O}_2(\text{OH})_{12}](\text{H}_2\text{O})_{12}$), metaschoepite, and becquerelite ($\text{Ca}[(\text{UO}_2)_6\text{O}_4(\text{OH})_6] \cdot 8\text{H}_2\text{O}$), and have described useful structural classifications.^{505,668–673} The schoepite structure, for example, consists of $(\text{UO}_2)_8\text{O}_2(\text{OH})_{12}$ sheets of edge- and corner-sharing uranyl pentagonal bipyramids that are hydrogen-bonded to each other through interstitial waters.⁶⁷⁴ There are also a large number and variety of mixed ligand hydroxide species, particularly for carbonate and other oxoanion complexes.

There are a number of structurally interesting mixed-ligand uranyl hydroxides. For example, the basic compound of composition $\text{Zn}(\text{UO}_2)_2\text{SO}_4(\text{OH})_4 \cdot 1.5\text{H}_2\text{O}$, has a structure based on chains of $\text{UO}_2(\text{OH})_3\text{O}_2$ pentagonal bipyramids containing tridentate bridging OH^- groups. Species of this type have also been studied in solution, but the complexity of the system has precluded structural characterization.⁶⁷³ There are many hydrated binary and ternary uranium oxides, such as the uraninites, that contain uranyl hydroxide complexes within their structure.

There is much less known about the hydrolysis of the transuranic ions. Data indicate they hydrolyze at higher pH, approximately 5–6 for Pu^{VI} , and form the stepwise hydroxide products $\text{AnO}_2(\text{OH})^+$ and $\text{AnO}_2(\text{OH})_2$. Tetrahydroxide species have been suggested, but not yet well characterized. Polymerization is less pronounced than for uranyl, with dimers, $(\text{AnO}_2)_2(\text{OH})_2^{2+}$, indicated in Pu^{VI} and Np^{VI} solutions of approximately 0.1 mM and higher concentrations. Only one trimeric species, $(\text{NpO}_2)_3(\text{OH})_5^+$, is suggested for Np^{VI} , and none have been identified for Pu^{VI} .

Peroxides. Peroxide has been used on a large scale in the production of “yellow cake” in uranium processing. There is a simple U^{VI} peroxide, $\text{UO}_4 \cdot 2\text{H}_2\text{O}$, which is probably of the form $[(\text{UO}_2)(\text{O}_2)(\text{H}_2\text{O})]$. Hydrated salts of peroxo complex anions, such as $\text{Na}_4\text{AnO}_2(\text{O}_2)_3 \cdot 9\text{H}_2\text{O}$, have been prepared. The anion has approximate D_{3h} symmetry, common to many actinyl oxoanion complexes, with three coplanar peroxide groups surrounding the linear uranyl group.⁶⁷⁵ Ternary uranyl peroxide complexes containing triphenyl phosphine oxides and related ligands $[\text{U}(\text{O})(\text{O}_2)\text{L}_2] \cdot \text{H}_2\text{O}$, $\text{L} = \text{Ph}_3\text{PO}$, Ph_3AsO , pyNO have been prepared.⁶⁷⁶ Uranyl complexes with bridging peroxide, such as $\text{M}_6[(\text{UO}_2)_2(\mu\text{-O}_2)(\text{C}_2\text{O}_4)]$, $\text{M} = \text{Na}$, K , NH_4 , have been prepared by combining the peroxide, $\text{UO}_4 \cdot 2\text{H}_2\text{O}$, with oxalates, carbonates, and other salts.

Carbonates. Hexavalent actinide carbonates have been very thoroughly studied by a variety of solution and solid state techniques. These complexes are of interest not only because of their fundamental chemistry and environmental behavior, but also because of extensive industrial applications, such as in uranium mining and nuclear fuel production and reprocessing. Uranyl carbonates are very soluble, very stable, and can be readily precipitated to produce powders suitable for industrial scale transformations.

A general feature seen in all actinyl carbonate structures is that the linear triatomic AnO_2 unit forms the axis of a hexagonal bipyramidal coordination polyhedron and the oxygen atoms of the carbonate ligand are arrayed about the equator. In solution, carbonate complexation is stepwise with increasing pH and carbonate concentration to yield the mono-, bis-, and triscarbonate species, $\text{AnO}_2(\text{CO}_3)$, $\text{AnO}_2(\text{CO}_3)_2^{2-}$, $\text{AnO}_2(\text{CO}_3)_3^{4-}$ (for $\text{An} = \text{U}$, Np , and Pu). For uranyl there is also a great deal of evidence for additional polymeric species and $(\text{UO}_2)_2(\text{CO}_3)(\text{OH})_3^-$, $(\text{UO}_2)_3\text{O}(\text{OH})_2(\text{HCO}_3)^+$, and $(\text{UO}_2)_{11}(\text{CO}_3)_6(\text{OH})_{12}^{2-}$ under conditions of high metal ion concentration or high ionic strength.¹⁹⁷ In the solid state, $\text{AnO}_2(\text{CO}_3)$, $\text{M}_6(\text{AnO}_2)_3(\text{CO}_3)_6$, and $\text{M}_4\text{AnO}_2(\text{CO}_3)_3$ are well characterized for uranium. The analogous neptunium and plutonium solids are not as well described, and only the triscarbonate complex is known for americium. (A very high carbonate concentration has been used to stabilize this high oxidation state for Am). Bicarbonate complexes are, at most, minor species. Those that had been reported previously are now generally believed to be ternary carbonate, hydroxo species, or the known pure carbonates.

The triscarbonate species have hexagonal bipyramidal geometry and can be readily precipitated to form salts with monovalent cations. Single crystal X-ray diffraction studies have been reported for a large number of this type of uranyl carbonate and a few of the neptunyl analogues. The anion in the $\text{M}_4\text{AnO}_2(\text{CO}_3)_3$ and $\text{M}'_2\text{AnO}_2(\text{CO}_3)_3$ salts, where M is an alkali metal or other monovalent cation and M' is a alkali earth or other divalent cation, essentially has the same coordination geometry, with approximately D_{3h} symmetry, where three bidentate carbonate ligands lie in the plane perpendicular to the actinyl axis (see Figure 48). Structural parameters vary little among the many compounds, with $\text{An}=\text{O}$ bond distances of 1.7–1.9 Å, and $\text{An}-\text{O}$ carbonate bond lengths of 2.4–2.6 Å. Not only are the triscarbonate uranyl complexes among the most studied synthetic compounds, they are also the basis for numerous naturally occurring minerals, such as andersonite ($\text{Na}_2\text{CaUO}_2(\text{CO}_3)_4 \cdot n\text{H}_2\text{O}$), bayleyite ($\text{Mg}_2\text{UO}_2(\text{CO}_3)_4 \cdot n\text{H}_2\text{O}$), and liebigite ($\text{Ca}_2\text{UO}_2(\text{CO}_3)_3 \cdot 10\text{H}_2\text{O}$), to name a few.^{505,677} Uranyl carbonate units can be linked together via counter ions or hydrogen bonds or to form polyhedra clusters and sheets as exemplified in new calcium uranyl carbonates.⁶⁷⁸

Figure 48 The triscarbonate uranyl anion in the crystal structure of the hydrated guanadinium salt, showing the hexagonal bipyramidal coordination of U^{VI} that is common to most uranyl oxo anion complexes (Anderson, Bombieri *et al.* *J. Chem. Soc., Dalton Trans.* **1972**, 2059).

Analogous Np^{VI} and Pu^{VI} carbonates can be assumed to be isostructural with the well-characterized uranyl compounds, albeit with slightly shorter bond distances to reflect the actinide contraction. For the triscarbonato complexes of Np^{VI} this has been confirmed by the structures of $\text{K}_4\text{NpO}_2(\text{CO}_3)_3$ by single-crystal structure determination of $[(\text{CH}_3)_4\text{N}]\text{NpO}_2(\text{CO}_3)_3$.^{679,680}

For uranyl, the biscarbonato species, which is likely seven-coordinate, is in equilibrium with the hexakiscarbonato trimer, $(\text{UO}_2)_3(\text{CO}_3)_6^{6-}$, and is therefore prevalent only at relatively low uranium concentrations.⁶⁸¹ The trimer, $(\text{UO}_2)_3(\text{CO}_3)_6^{6-}$, was inferred from NMR data and other solution methods until being structurally characterized using EXAFS and single crystal X-ray diffraction (Figure 49).⁶⁸² The anion in $[\text{C}(\text{NH}_2)_3]_6[(\text{UO}_2)_3(\text{CO}_3)_6] \cdot 6.5\text{H}_2\text{O}$ possesses nearly ideal D_{3h} symmetry in which the three uranyl axis are perpendicular to the plane defined by the six carbonates and the three uranium atoms.⁶⁸² A number of solids previously believed to contain the monomeric biscarbonato uranium(VI) complex may in fact also be salts of this anion. Similar to the hexavalent hydroxides, polymer formation, or at least stability of polymers, appears to decrease dramatically across the series. Mixed actinyl trimers, such as $[(\text{UO}_2)_2(\text{NpO}_2)(\text{CO}_3)_6]$, have been identified from NMR and optical absorbance studies for both Np and Pu;^{683,684} however, $(\text{NpO}_2)_3(\text{CO}_3)_6^{6-}$ and $(\text{PuO}_2)_3(\text{CO}_3)_6^{6-}$, have not been isolated in the solid state.

The solid state structure of rutherfordine, UO_2CO_3 , has been determined from crystals of both the natural mineral and synthetic samples (see Figure 50). It has a layered structure in which the local coordination environment of the uranyl ion is hexagonal bipyramidal, with the uranyl units perpendicular to the orthorhombic plane. Each uranium atom forms six equatorial bonds with the oxygen atoms from two bidentate and two monodentate carbonates. The neptunyl and plutonyl analogs are isostructural with UO_2CO_3 based on Rietveldt analysis of powder X-ray diffraction data.

Figure 49 The pseudo D_{3h} symmetric trimeric uranyl carbonate anion in the crystal structure of $[\text{C}(\text{NH}_2)_3]_6[(\text{UO}_2)_3(\text{CO}_3)_6] \cdot 6.5\text{H}_2\text{O}$ (Allen, Bucher *et al. Inorg. Chem.* **1995**, 34, 4797–4807).

Figure 50 Uranyl carbonate layers in the crystal structure of the mineral rutherfordine, UO_2CO_3 (Finch, Cooper *et al. Canadian Mineralogist* **1999**, 37, 929–938).

In addition to the pure carbonates and hydroxy carbonates, there are mixed-ligand uranyl carbonates, such as in $K_4[UO_2(O_2)(CO_3)_2]$ and $K_3[UO_2F_3(CO_3)]$.

Nitrates. The actinyl nitrates are weak complexes formed in the presence of excess nitrate. For uranyl, the mono-, bis-, and trisnitrato actinyl species, $AnO_2(NO_3)^+$, $AnO_2(NO_3)_2$, $AnO_2(NO_3)_3^-$ have been inferred from spectrophotometric solution studies. For neptunyl only the mono- and bis-, and for plutonyl only the mono-, species are significant. The coordination geometries of these complexes are presumably the same as the related carbonates, although some of the species may be protonated in the nitrate system. Indeed, a protonated tris species $HUO_2(NO_3)_3$ is reported; but as a minor species and not in most studies. Mixed tributylphosphate (TBP), nitrate complexes have been widely studied, including an EXAFS study of the structural changes as the actinyl species are reduced to An^{IV} .⁶⁸⁵

The hydrated solids, $AnO_2(NO_3)_2 \cdot xH_2O$, are easily obtained and are very common An^{VI} starting materials. The orthorhombic uranyl nitrate hexahydrate is prepared from dilute nitric acid solutions, and the trihydrate from concentrated acid. Analogous neptunyl and plutonyl trihydrate and hexahydrate solids have also been studied. Uranyl nitrates are used on an industrial scale in the nuclear fuel cycle; for example, for extraction by TBP and other separations processes. Trisnitrato actinyl salts $MAnO_2(NO_3)_3 \cdot xH_2O$ where M is a monovalent cation are well known.^{468,686} The anions in this class of compounds are isostructural. The complex Np^{VI} anion in $RbNpO_2(NO_3)_3$, for example, consists of a hexagonal bipyramidal arrangement of oxygen atoms about the Np atom with six oxygen atoms from the bidentate nitrate groups in the equatorial plane. Nitrites of the formula AnO_2NO_2 have been prepared and characterized, but quantitative structural data are lacking.

Phosphates. Most actinyl phosphates have been prepared in aqueous solution at low pH and very high phosphate concentrations. These conditions lead to a number of species in equilibria, with most containing one or two partially protonated phosphates. The products are relatively insoluble making structural and spectroscopic characterization of the species even more challenging. The major species identified are $UO_2(PO_4)^-$, $UO_2(HPO_4)$, $UO_2(H_2PO_4)^+$, $UO_2(H_2PO_4)_2$, $UO_2(H_3PO_4)^{2+}$, and $UO_2(H_3PO_4)(H_2PO_4)^+$. A detailed discussion of the complex formation in the uranium– $H_kP_mO_n$ system and its chemical thermodynamics has been reported.¹⁹⁷ Since Np^{VI} and Pu^{VI} are far less stable at low pH and generally have less affinity for oxoanionic ligands than U^{VI} , the species that have been characterized contain less protonated forms of the ligand and the bis ligand complexes are less stable. For Np^{VI} , $NpO_2H_2PO_4^-$, $NpO_2(HPO_4)$, and $NpO_2(HPO_4)_2^{2-}$ have been reported. Only the first two are known for Pu^{VI} .^{687,688}

Uranium(VI) phosphates have been widely investigated and can be divided in several structure types: orthophosphates $M(UO_2)_n(PO_4)_m \cdot xH_2O$, hydrogenphosphates $M(UO_2)_n(H_kPO_4)_m \cdot xH_2O$, pyrophosphates $U_mO_nP_2O_7$, metaphosphates $(UO_2)_n(PO_3)_m \cdot xH_2O$, and polyphosphates $(UO_2)_n(P_aO_b)_m \cdot xH_2O$.⁶⁸⁹ They have commonly been prepared from dissolution of uranium metal in phosphoric or mixed acid solutions, by addition of phosphate to aqueous solutions of the nitrates, or by decomposition.^{689,690}

More recently hydrothermal conditions and amine or ammonium structure-directing agents have been used to prepare $[NH_4Et_3][(UO_2)_2(PO_4)HPO_4]$ and $[NPr_4][(UO_2)_3(PO_4)HPO_4)_2]$ (Figure 51).²³³ The structures of these compounds contain infinite chains of edge-sharing UO_7 pentagonal bipyramids cross linked by bridging PO_4 tetrahedra to form two-dimensional anionic sheets. This same method yielded the first uranyl phosphate with a three-dimensional open framework structure, $[Et_2NH_2]_2(UO_2)_5(PO_4)_4$ (Figure 52).⁶⁹¹

Several salts of formula, $M(UO_2)_n(PO_4)_m \cdot xH_2O$, where $M = H^+$, M^+ or M^{2+} , have also been characterized. Some of the latter compounds are identical with natural minerals. In fact the Ca salt, the very common mineral autunite $Ca[(UO_2)(PO_4)_2] \cdot 11H_2O$, has recently been redetermined.⁶⁹² This same group has prepared the Cs, Rb, and K salts by hydrothermal methods. The structures consist of sheets of phosphate tetrahedra and uranyl pentagonal bipyramids, $[(UO_2)(PO_4)]^-$. These sheets are connected by a uranyl pentagonal bipyramid in the interlayer that shares corners with two phosphate tetrahedra on each of two adjacent sheets and whose fifth equatorial ligand is water.⁶⁹³ The hydrogen uranyl phosphates readily exchange the hydrogen with alkali or alkaline earth metals.

The tetrahydrate, $H(UO_2)(PO_4) \cdot 4H_2O$, is reported to form three different polymorphic modifications at room temperature.⁶⁹⁴ The geometry about the uranyl ion in $K_4(UO_2)(PO_4)_2$ is tetragonal bipyramidal with four oxygen atoms in the equatorial plane from four tetrahedral phosphate groups, making up a $[UO_2](PO_4)_2]_n^{4n-}$ layer.⁶⁹⁵ The neutral compound, $(UO_2)_3(PO_4)_2 \cdot xH_2O$, has been synthesized as mono-, tetra-, and hexahydrate. Orthorhombic $(UO_2)_3(PO_4)_2 \cdot 4.8H_2O$ was prepared by addition of 0.5 M uranyl nitrate to 0.36 M H_3PO_4 at 60 °C and pH 1.⁶⁹⁶

Figure 51 Phosphate coordination geometries and cocrystallized template from the structure-directed preparation of a layered uranyl phosphate (Francis, Drewitt *et al. Chem. Commun.* **1998**, 279–280).

A few uranyl metaphosphates have been reported. $\text{UO}_2(\text{PO}_3)_2$ is formed in 85% H_3PO_4 at 300–350 °C or by thermal decomposition of $\text{UO}_2(\text{H}_2\text{PO}_4)_2$ at 800–850 °C. In addition, there are uranyl phosphites, $\text{UO}_2\text{HPO}_3 \cdot x\text{H}_2\text{O}$, $x=0,3$, and hypophosphites $\text{UO}_2(\text{H}_2\text{PO}_2)_2 \cdot x\text{H}_2\text{O}$. A new phosphite with a three-dimensional structure was recently prepared using hydrothermal methods.⁶⁹⁷

The trihydrate of uranyl dihydrogenphosphates, $\text{UO}_2(\text{H}_2\text{PO}_4)_2 \cdot 3\text{H}_2\text{O}$, has been obtained from a suspension of $\text{HUO}_2\text{PO}_4 \cdot 4\text{H}_2\text{O}$ in 85% phosphoric acid after stirring for several days. The monohydrate is also known. It has been reported that $\text{UO}_2\text{HPO}_4 \cdot 3\text{H}_2\text{O}$ behaves as a solid ionic conductor because of H^+ mobility across the hydrogen bonds network in the compound.⁶⁹⁸ Pyrophosphates, $(\text{UO}_2)_2\text{P}_2\text{O}_7$ and $\text{UO}_2\text{H}_2\text{P}_2\text{O}_7$ have been studied.⁶⁹⁹

Uranium(VI) polyphosphates, $(\text{UO}_2)_2(\text{P}_3\text{O}_{10})_2 \cdot x\text{H}_2\text{O}$, were obtained by precipitation of a uranyl solution with $\text{Na}_5\text{P}_3\text{O}_{10}$. $\text{M}_2\text{UO}_2\text{P}_2\text{O}_7$, with M = alkali metal, have been synthesized by heating

Figure 52 Coordination environment (a) about uranyl and within and (b) between uranyl phosphate layers in the first organically templated open-framework uranium phosphate, $[\text{Et}_2\text{NH}_2]_2[(\text{UO}_2)_5(\text{PO}_4)_4]$ (Danis, Runde *et al. Chem. Commun.* **2001**, 2378–2379).

uranyl nitrate in the presence of alkali metal pyrophosphates and ammonium dihydrogenphosphate. The new mixed valence $\text{U}(\text{UO}_2)(\text{PO}_4)_2$ has been synthesized and characterized spectroscopically showing the absence of pyrophosphate and the existence of the dioxocation unit, UO_2^{2+} , as one of the two independent U atoms. Bidentate phosphates are connecting the chains generating a three-dimensional network.⁷⁰⁰

Several Np^{VI} and Pu^{VI} phosphates have been prepared well-characterized. They have not been characterized by single-crystal X-ray diffraction; thus their coordination chemistry has not been fully described.

Arsenates. Similar to the phosphates, the actinyl arsenate AsO_3 , AsO_4 , and As_2O_7 units bind to the actinide center to produce open framework and extended structures. The arsenates have not been studied in solution, as expected given their low solubilities. Examples of recently characterized arsenates include $(\text{UO}_2)_3(\text{AsO}_4)_2$, $(\text{UO}_2)_2\text{As}_2\text{O}_7$, and $\text{UO}_2(\text{AsO}_3)_2$.^{689,699,701}

Molybdates. Common types of molybdates are $\text{M}_2(\text{UO}_2)(\text{MoO}_4)_2 \cdot x\text{H}_2\text{O}$ and $\text{M}_6(\text{UO}_2)(\text{MoO}_4)_4 \cdot x\text{H}_2\text{O}$, where M is a monovalent cation (Na, K, Rb, Cs, NH_4).^{702,703} Structures of these compounds include linked MoO_4 tetrahedra and uranyl square bipyramids and/or uranyl pentagonal bipyramids. Some related and characterized molybdates include alkyl amine salts, $(\text{C}_6\text{H}_{14}\text{N}_2)_3(\text{UO}_2)_5(\text{MoO}_4)_8 \cdot 4\text{H}_2\text{O}$ and $(\text{C}_2\text{H}_{10}\text{N}_2)[(\text{UO}_2)(\text{MoO}_4)_2]$, which contain sheets of molybdate linked uranyl bipyramids, and the amine cations in the interlayers.⁷⁰⁴ A silver salt $(\text{Ag}_6(\text{UO}_2)_3(\text{MoO}_4)_5)$ has been reported; it is one of the dozens of known inorganic uranyl compounds containing sheets of polyhedra that contain trimers of uranyl pentagonal bipyramids that are connected only by the sharing of vertices with other polyhedra.⁷⁰⁵ Transuranic analogues formulated as $\text{NpO}_2\text{MoO}_4 \cdot x\text{H}_2\text{O}$ and $\text{PuO}_2\text{MoO}_4 \cdot x\text{H}_2\text{O}$ and $\text{Pu}(\text{M} = \text{Np}, \text{Pu})$ have also been prepared.^{706,707}

The common six- and seven-coordinate uranyl-based polyhedra are also observed in the extended structures of uranyl molybdates containing Mo_2O_7 units. For example, the mineral iriginite, $[(\text{UO}_2)\text{Mo}_2\text{O}_7(\text{H}_2\text{O})_2](\text{H}_2\text{O})$, and the hydrothermally prepared $[(\text{UO}_2)\text{Mo}_2\text{O}_7(\text{H}_2\text{O})_2]$, which is formed under more basic conditions, contain electroneutral sheets of $[(\text{UO}_2)\text{Mo}_2\text{O}_7(\text{H}_2\text{O})_2]$.⁷⁰⁵

Sulfates and sulfites. Mono- and bis-sulfate complexes of actinyl ions, AnO_2SO_4 and $\text{AnO}_2(\text{SO}_4)_2^{2-}$, are generally prepared from acidic solutions. The geometry about the actinide metal center is pentagonal biipyramidal from actinyl, sulfato, and aquo oxygen atoms. A tris(sulfato) complex has been reported, but it is very weak if it does exist. Ternary hydroxo, sulfato complexes have been reported for uranyl, but they have not been structurally characterized.

These solution species can be precipitated to prepare uranyl sulfate hydrates. The anhydrate and additional hydrates are formed after subsequent dehydration or other treatments to complete the series, $\text{UO}_2\text{SO}_4 \cdot x\text{H}_2\text{O}$, where $x = 0, 0.5, 1, 2, 2.5, 3, 3.5$ and $\text{UO}_2(\text{SO}_4)_2 \cdot x\text{H}_2\text{O}$, where $x = 0, 4, 8$. The same types of compounds have been prepared for Np^{VI} and Pu^{VI} , but they are not as numerous or as well characterized. Like the carbonates, the sulfates have been used in leaching uranium from ore. After acidic dissolution, addition of ammonia gives a precipitate thought to be $(\text{NH}_4)_2(\text{UO}_2)_2\text{SO}_4(\text{OH})_4 \cdot n\text{H}_2\text{O}$. While the solution ternary hydroxo, sulfato complexes are not yet well known, the related solid, $\text{M}_2(\text{UO}_2)_6(\text{SO}_4)_3(\text{OH})_{10} \cdot 8\text{H}_2\text{O}$ ($\text{M} = \text{divalent cation}$), the mineral zippeite, has been known since the early nineteenth century.⁷⁰⁸ New uranyl sulfates with extended structures containing both inner- and outer-sphere sulfates continue to be discovered.^{709,710} Novel hydrothermal synthetic methods, such as the organic templating that has produced interesting uranyl fluorides and phosphates has also been applied to prepare uranyl sulfates, such as $[\text{N}_4\text{H}_{12}](\text{UO}_2)_6(\text{H}_2\text{O})(\text{SO}_4)_7$.⁷¹¹ The fluorosulfate, $\text{UO}_2(\text{SO}_3\text{F})_2$, is obtained by treating $\text{UO}_2(\text{MeCO}_2)_2$ with HSO_3F .²⁵⁴ A large number of ternary U^{VI} sulfates of the general formula $\text{M}(\text{UO}_2)_m(\text{SO}_4)_n \cdot x\text{H}_2\text{O}$, where $\text{M} = \text{alkali metals, ammonia or transition metals (Mn, Cd, Hg)}$, have been reported. A layered structure is observed for $(\text{NH}_4)_2\text{UO}_2(\text{SO}_4)_2 \cdot 2\text{H}_2\text{O}$ with local pentagonal biipyramidal coordination around the uranium atom, and bridging sulfate groups joining the uranyl polyhedra.⁷¹² In $\text{K}_4\text{UO}_2(\text{SO}_4)_3$ each uranium in the pentagonal bipyramid is coordinated to five oxygen atoms from four sulfate groups in the equatorial plane.⁷¹³ Analogous sulfates have been isolated for Np^{VI} and characterized by IR and X-ray diffraction.⁷¹⁴

Similar to the sulfates, mono- and bis(sulfites) have been prepared in solution and precipitated as the solids, UO_2SO_3 and $\text{UO}_2\text{SO}_3 \cdot 4.5\text{H}_2\text{O}$. The analogous Np and Pu compounds have not been structurally characterized.

Selenates, selenites, and tellurates. Uranyl selenates and selenites have been prepared and can be expected to have the same coordination features as the sulfates and sulfites. In addition to the selenate, UO_2SeO_4 , the ternary selenite $(\text{UO}_2)_2(\text{OH})_2(\text{SeO}_3)$, has been reported to form in

uranyl, selenous acid solutions.^{715,716} A uranyl tellurate, UO_2TeO_4 , has been reported, but no tellurites.¹⁹⁷

Perchlorates, iodates. Actinyl(VI) iodates are generally prepared via hydrothermal syntheses, rather than solid state reactions owing to the thermal disproportionation of iodate at high-temperature. In the absence of additional cations, $\text{UO}_2(\text{IO}_3)_2$, $\text{AnO}_2(\text{IO}_3)_2(\text{H}_2\text{O})$ ($\text{An} = \text{U}$, Np), and $\text{AnO}_2(\text{IO}_3)_2 \cdot \text{H}_2\text{O}$ ($\text{An} = \text{Np}$, Pu) form under both mild and supercritical hydrothermal conditions.^{717,718} $\text{UO}_2(\text{IO}_3)_2$ is one-dimensional, and contains chains of edge-sharing UO_8 hexagonal pyramids. $\text{AnO}_2(\text{IO}_3)_2(\text{H}_2\text{O})$ ($\text{An} = \text{U}$, Np) and $\text{AnO}_2(\text{IO}_3)_2 \cdot \text{H}_2\text{O}$ ($\text{An} = \text{Np}$, Pu) are both layered and contain AnO_7 pentagonal bipyramids linked by iodate anions. The structure of $\text{AnO}_2(\text{IO}_3)_2 \cdot \text{H}_2\text{O}$ ($\text{An} = \text{Np}$, Pu) is also polar owing to the alignment of the stereochemically active lone-pair of electrons on the iodate anions. The incorporation of alkali metal, alkaline-earth metal, and main group cations into these hydrothermal syntheses allows for the isolation of structurally complex compounds exemplified by $\text{M}_2[(\text{UO}_2)_3(\text{IO}_3)_4\text{O}_2]$ ($\text{M} = \text{K}$, Rb , Tl) and $\text{M}[(\text{UO}_2)_2(\text{IO}_3)_2\text{O}_2]$ ($\text{M} = \text{Sr}$, Ba , Pb).⁷¹⁷ The former compounds contain one-dimensional chains of edge-sharing UO_6 tetragonal bipyramids and UO_7 pentagonal bipyramids. The latter compounds contain one-dimensional ribbons of distorted UO_7 pentagonal bipyramids that share edges. In both cases, the edges of the one-dimensional chains are terminated by iodate anions. Finally, UO_2^{2+} can be used to stabilize the new iodate anion, tetraoxoiodate(V), IO_4^{3-} , in $\text{Ag}_4(\text{UO}_2)_4(\text{IO}_3)_2(\text{IO}_4)_2\text{O}_2$.⁷¹⁷ The uranium oxide substructure of $\text{Ag}_4(\text{UO}_2)_4(\text{IO}_3)_2(\text{IO}_4)_2\text{O}_2$ contains ribbons of edge-sharing UO_8 hexagonal bipyramids and UO_7 pentagonal bipyramids.

Crystals of uranyl perchlorate, $\text{UO}_2(\text{ClO}_4)_2 \cdot x\text{H}_2\text{O}$, have been obtained with six and seven hydration water molecules. The uranyl is coordinated with five water molecules in the equatorial plane with a distance of $\text{U}-\text{O}(\text{aqua})$ of 2.45 Å. The unit cells contain two $[\text{ClO}_4]^-$ and one or two molecules of hydration water held together by hydrogen bonding.⁷¹⁹ Because perchlorates and perchloric acid solutions (similar to nitrates) are very common starting materials in actinyl chemistry there are numerous types of perchlorate containing structures. Examples are provided by the diperchlorates of uranyl complexes of neutral donor ligands, as in the phosphoramidate complex.⁷²⁰

Carboxylates. Uranyl complexes formed with numerous aminocarboxylate ligands, such as IMDA, NTA, HEDTA, EDTA, CDTA, or DTPA, have been prepared in water and other very polar solvents and characterized predominantly by optical and NMR spectroscopy. Mixed ligand complexes, MLL' have also been reported, with the secondary ligands including resorcinols, salicylic acids, amines, and nucleosides, (e.g. adenosine, guanosine, adenine, etc.) EDTA and mixed EDTA, hydroxide complexes of $\text{Pu}(\text{VI})$ have been reported; but these complexes slowly reduce to corresponding $\text{Pu}(\text{IV})$ compounds. In complexes of malonic acid derivatives with the uranyl ion, bidentate bonding is unaffected by the substitution of the alpha carbon. X-ray single crystal diffraction of the complex $(\text{C}_4\text{H}_{12}\text{N}_2)[\text{UO}_2(\text{C}_4\text{H}_4\text{O}_4)_2(\text{H}_2\text{O})] \cdot 2\text{H}_2\text{O}$ shows that alkyl substitution on the alpha carbon of malonic acid has no effect on the coordination environment around the uranium. In all cases, pentagonal bipyramidal coordination is observed around the uranium with the ligand forming a six-membered ring. To achieve the desired coordination around the uranium, one water molecule is complexed in the inner sphere. The six-membered rings are not planar in nature; in fact, the alpha carbons stray away from planarity in a *trans* orientation to one another.⁷²¹

In some cases, malonic acid has been shown to bridge between two uranyl ions. In the structure of $(\text{C}_{10}\text{H}_{26}\text{N}_2)[(\text{UO}_2)_3(\text{C}_7\text{H}_{10}\text{O}_4)_3] \cdot 2\text{H}_2\text{O}$, the two bridging malonic acids clearly create pentagonal bipyramidal geometry around the uranium. The malonic acid bonds in two possible ways: either as a bidentate ligand or as a tridentate ligand where one acid molecule has 1,3-bridging between two uranyl moieties and another is monodentate to the uranyl group.⁷²¹

Malonic acid has the ability to form several different polymeric complexes with uranyl, many of which have been studied by X-ray single crystal diffraction. A zig-zag polymer is shown in Figure 53 having two different coordination environments around the uranium atoms. In this polymeric chain, two closely-neighboring uraniums are bridged by two tetradentate malonic acid ligands. One of the carboxylic acids has μ^2 bonding forming an oxo-bridge between the two uraniums. The other carboxylic acid forms a monodentate bond to one of the uraniums. Also bound to each uranium is a tridentate malonic acid molecule with one side having an η^2 bond through one of the carboxylic acids and the other having monodentate coordination to the third uranium of the asymmetric group. The two uraniums which are doubly bridged have a hexagonal bipyramidal coordination environment while the third uranium has a pentagonal bipyramidal environment.⁷²¹

Another version of the previous polymeric chain has been studied with X-ray crystallography, where the only difference lies in the uranyl with the pentagonal bipyramidal coordination.

Figure 53 Crystal structure of $(\text{C}_{10}\text{H}_{26}\text{N}_2)[(\text{UO}_2)_3(\text{C}_7\text{H}_{10}\text{O}_4)_5] \cdot 2\text{H}_2\text{O}$ depicting the polymeric coordination of the U^{VI} (Zhang, Collison *et al.* *Polyhedron* **2002**, 21, 81–96).

In another case, the bidentate malonic acid is replaced with two *trans*-water molecules, leaving the coordination environment the same, but causing the *trans*-oxo ligands to rotate 90° .⁷²²

Alkoxides. Exposure of the pentavalent alkoxide complex $\text{U}(\text{OCH}_2\text{CH}_3)_5$ to oxygen was first reported to produce a small amount of a volatile and thermally unstable red liquid byproduct.⁷²³ Elemental analysis of the compound was consistent with the stoichiometry $\text{U}(\text{OCH}_2\text{CH}_3)_6$, and molecular weight determinations suggested a monomeric structure in benzene. Improved yields of $\text{U}(\text{OCH}_2\text{CH}_3)_6$ have been achieved using other reaction routes (see Equations (45) to (47)):

Reduction of $\text{U}(\text{OCH}_2\text{CH}_3)_6$ to the more stable $\text{U}^{\text{V}}(\text{OCH}_2\text{CH}_3)_5$ occurs in the presence of $\text{U}^{\text{IV}}(\text{OCH}_2\text{CH}_3)_4$, ethanethiol, diethylamine, or ethyl cyanoacetate in ether solution.

Other homoleptic uranium(VI) hexakisalkoxides are prepared from alcohol exchange reactions of $\text{U}(\text{OCH}_2\text{CH}_3)_6$ with other alcohols (OR: R = Me, Pr, Pr^i , Bu).⁷²³

Bradley reported that homoleptic uranium hexakis(alkoxide) complexes coordinated by secondary and tertiary alkoxides ($\text{U}(\text{OR})_6$; R = Pr^i , Bu^s, Bu^t) were produced from thermal disproportionation of $\text{UO}(\text{OR})_4$ (*vide supra*).⁷²⁴ $\text{U}(\text{OMe})_6$ was initially prepared from oxidation of $\text{U}^{\text{V}}(\text{OMe})_5$ in the presence of benzoyl peroxide.⁷²³ Interest in a more convenient synthetic route to $\text{U}(\text{OMe})_6$ was stimulated by its potential use in uranium isotope separation, which can be achieved with a CO_2 laser.^{725–727} Facile syntheses of $\text{U}(\text{OMe})_6$ were reported by different groups (see Equations (48) to (51)).^{725,726,728}

Chemical, vibrational spectroscopic, and infrared multiphoton photochemical properties of $\text{U}(\text{OMe})_6$ were reported⁷²⁵ and the electronic structure and bonding of this compound was

investigated by using a combination of He I/He II photoelectron spectroscopy and discrete variational DV-X α molecular orbital calculations.⁷²⁹

The reaction of $\text{U}(\text{OCH}(\text{CH}_3)_2)_6$ with lithium, magnesium, or aluminum alkyls does not generate uranate(VI) compounds containing uranium–carbon bonds, but rather addition complexes.⁵⁴⁴ The structures of these products, $(\text{MeLi})_3\text{-U}(\text{OPr}^i)_6$, $(\text{R}_2\text{Mg})_3\text{-U}(\text{OPr}^i)_6$ ($\text{R} = \text{Me}$, CH_2Bu^i , CH_2SiMe_3), and $(\text{Me}_3\text{Al})_6\text{-U}(\text{OPr}^i)_6$, were suggested based upon ^1H -NMR spectroscopic analysis. There was no evidence that an anionic complex could be prepared from treatment of $\text{U}(\text{OCH}_2\text{CH}_3)_6$ with $\text{NaOCH}_2\text{CH}_3$.⁷²³

Mixed uranium(VI) halide/alkoxide products have been described. The compound $\text{U}(\text{OCH}_2\text{CH}_3)_5\text{Cl}$ is prepared by reaction of one equivalent of HCl with $\text{U}(\text{OCH}_2\text{CH}_3)_6$. A thermally unstable mixed halide/alkoxide compound, $\text{U}(\text{OMe})\text{F}_5$, is prepared from the reaction of UF_6 with MeOH in CFCl_3 at -90°C .⁷³⁰ The methoxyfluorouranium(VI) compounds, $\text{U}(\text{OCH}_3)_n\text{F}_{6-n}$, $n = 1-5$, are obtained from the reaction of UF_6 with $\text{Me}_3\text{Si}(\text{OMe})$ or $\text{U}(\text{OMe})_6$.⁷²⁵ Characterization by ^1H - and ^{19}F -NMR spectroscopy suggests that these monomers have six-coordinate uranium centers, and undergo rapid intermolecular ligand exchange.

The first uranyl alkoxide complex, uranyl di-*iso*-amyloxide, was reported in 1952.⁷³¹ Conflicting reports ensued regarding the composition of uranyl bisalkoxide compounds. Gilman and co-workers reported that the yellow brown, ether and alcohol soluble uranyl ethoxide, $\text{UO}_2(\text{OCH}_2\text{CH}_3)_2\cdot 3\text{HOCH}_2\text{CH}_3$, was prepared from a metathesis reaction between anhydrous uranyl chloride and sodium ethoxide, and the bright red ethanol soluble uranyl *t*-butoxide analogue, $\text{UO}_2(\text{OBu}^i)_2\cdot 4\text{HOBu}^i$, was formed upon oxidation of $\text{U}^{\text{IV}}(\text{OBu}^i)_4$.⁷³² Bradley and co-workers, however, were unable to reproduce the preparation of $\text{UO}_2(\text{OCH}_2\text{CH}_3)_2\cdot 3\text{HOCH}_2\text{CH}_3$ using Gilman's synthetic procedure. A compound of stoichiometry $\text{UO}_2(\text{OCH}_2\text{CH}_3)_2\cdot 2\text{HOCH}_2\text{CH}_3$ was instead prepared from the metathesis reaction between UO_2Cl_2 and $\text{LiOCH}_2\text{CH}_3$ or ethanol exchange with uranyl methoxide.⁷²⁴

In a later report, $\text{UO}_2(\text{OMe})_2\cdot \text{MeOH}$ was prepared from solvolysis of uranyl nitrate in alcohol solutions in the presence of tridecylamine as the deprotonating base, although no yield was reported.⁷³³ Alcohol exchange was identified between $\text{UO}_2(\text{OMe})_2$ and primary alcohols (OR : $\text{R} = \text{Et}$, Pr , Bu^i , amyl), generating a new route for the production of uranyl bisalkoxides.⁷²⁴ However, when $\text{UO}_2(\text{OMe})_2$ was allowed to react with secondary or tertiary alcohols (OR : $\text{R} = \text{Pr}^i$, Bu^s , Bu^t), the exchange was accompanied by redistribution resulting in loss of a uranyl oxo ligand to form $\text{UO}(\text{OR})_4\cdot \text{HOR}$ (along with an insoluble residue), which further disproportionated to $\text{U}(\text{OR})_6$ upon heating. The compound assignments were based solely upon elemental analysis.

Subsequent studies in nonalcoholic solvent confirm that redistributive exchange of uranyl oxo and ancillary alkoxide ligands can occur. Reaction of two equivalents of potassium *t*-butoxide with uranyl chloride results in the formation of the trimetallic species $[\text{UO}_2(\text{OBu}^t)_2][\text{UO}(\text{OBu}^t)_4]_2$.⁷³⁴ Apparently, redistributive exchange is precluded by steric saturation of the uranyl alkoxide through coordination of a strong Lewis base. The complex $\text{UO}_2(\text{OBu}^t)_2(\text{Ph}_3\text{PO})_2$ is prepared from the reaction of KOBu^t and $\text{UO}_2\text{Cl}_2(\text{Ph}_3\text{PO})_2$ in tetrahydrofuran.⁵⁹¹

Electron-poor donor alkoxide ligands, such as aryloxides or fluoroalkoxides, also inhibit ligand redistribution. The metathesis reaction of $\text{UO}_2(\text{NO}_3)_2\cdot 2\text{THF}$ with sodium nonafluoro-*t*-butoxide yielded the yellow diamagnetic complex $\text{UO}_2[\text{OC}(\text{CF}_3)_3]_2\cdot 2\text{THF}$.¹² In order to assess the relative influence of steric versus electronic effects on formation of oxo-alkoxide bridged species, a series of binary uranyl alkoxide complexes were studied.⁷³⁵ The reaction of uranyl chloride with primary alkoxide potassium neopentoxide gives as the sole isolable species a uranium complex generated by replacement of each oxo ligand by two alkoxide groups, $\text{U}(\text{OCH}_2\text{CH}_3)_6$. A reaction pathway for the redistributive exchange of alkoxide and oxo ligands was proposed. Sterically bulky alkoxide ligands inhibit redistributive exchange. Metathesis reactions of KOR ($\text{R} = \text{CHPh}_2$, $\text{CH}(\text{Bu}^i)\text{Ph}$) with uranyl chloride allowed for the isolation of simple monomeric uranyl species, $\text{UO}_2(\text{OCHPh}_2)_2(\text{THF})_2$ and $\text{UO}_2[\text{OCH}(\text{Bu}^i)\text{Ph}]_2(\text{THF})_2$. Larger aggregates can be isolated utilizing bulky alkoxide ligands. The tetrameric aggregate, $[\text{UO}_2(\text{OCH}(\text{Pr}^i)_2)_2]_4$, was isolated from the reaction of $\text{KOCH}(\text{Pr}^i)_2$ with uranyl chloride. Mixed ligand uranyl alkoxide compounds have been reported. A chloride alkoxide compound, $\text{U}_2\text{O}_5\text{Cl}(\text{OPr}^i)\cdot 0.5\text{CH}_3\text{COOPr}^i$, was reported in which Bradley's proposed uranyl isopropoxide species, $\text{U}_2\text{O}_5(\text{OPr}^i)_2\cdot 2\text{HOPr}^i$ (*vide supra*) was reacted with one equivalent of acetyl chloride in refluxing benzene.^{724,736} A series of air and moisture stable monothiocarbamate uranyl alkoxide products, $[\text{R}_2\text{NH}_2][\text{UO}_2(\text{R}_2\text{NCOS})_2(\text{OR}')]$ ($\text{R} = \text{Me}$, Et , Pr ; $\text{R}' = \text{Me}$, Et), were prepared from the reaction of uranyl chloride trihydrate with a solution in which carbonyl sulfide was bubbled through dipropylamine in ethanol.⁷³⁷⁻⁷³⁹ Uranyl phenoxide compounds have also been prepared. In an initial study of binary uranyl aryloxides, compounds $\text{UO}_2(\text{OR})_2$ ($\text{R} = \text{Ph}$, 2- $\text{NO}_2\text{C}_6\text{H}_4$, 2- ClC_6H_4) were prepared from refluxing uranyl

chloride or uranyl acetate with an excess of the appropriate phenol in xylene.⁷⁴⁰ The authors suggested that these species were polymeric, but could form monomeric Lewis base adducts in the presence of the appropriate ligands (pyridine, piperidine, phenanthroline). They also reported that the salts, $M_2UO_2(OC_6H_5)_4$ ($M = Na, K$) were isolated from a refluxing solution of $UO_2(OC_6H_5)_2$ and two equivalents of MOR in xylene. Subsequently, a series of uranyl aryloxide complexes ($UO_2(O-2,6-Bu^t_2C_6H_3)_2(THF)_2$, $UO_2(O-2,6-Ph_2C_6H_3)_2(THF)_2$, $[UO_2(O-2,6-Cl_2C_6H_3)_2(THF)_2]_2$, and $[UO_2(O-2,6-Me_2C_6H_3)Cl(THF)_2]_2$) were prepared via metathesis reactions between uranyl chloride and the appropriate *o*-substituted phenoxides.⁷⁴¹ The formation of monomeric or dimeric compounds appears to be dictated purely by the steric requirements of the ligands. Alcoholysis of uranyl amide complexes with substituted phenols leads to the formation of neutral ($UO_2(O-2,6-Pr^i_2C_6H_3)_2(py)_3$) and anionic $[Na(THF)_3]_2[UO_2(O-2,6-Me_2C_6H_3)_4]$ uranyl phenoxide species.⁵⁸⁹ A series of pyridine uranyl phenoxide adducts, $UO_2(OR)_2 \cdot n C_5H_5N$, were prepared (OR: $R = Ph$, $n = 1$; $R = p-ClC_6H_4$, $n = 1$; $R = p-MeC_6H_4$, $n = 1$; $R = o-MeC_6H_4$, $n = 3$).²⁷⁴ A series of pyridinium “ate” species $[pyH]_2[UO_2(OR)_4]$ were also reported.

Thiolates, selenates. Few thiolate complexes of uranyl exist. Those complexes that have been prepared are stabilized by the use of ligands with pendant heteroatom bases that can coordinate to the metal center.^{742,743} Reaction of $UO_2(NO_3)_2$ with pyridine-2-thiol and 3-trimethylsilyl-pyridine-2-thiol results in the formation of the complexes $[HSC_5H_4][UO_2(NO_3)_2(SC_5H_4N)]$ and $[(C_5H_3NS-3-SiMe_3)_2H][UO_2(NO_3)_2(C_5H_3NS-3-SiMe_3)]$, wherein each uranyl contains a 2-mercaptopyridine ligand in the equatorial ligand plane.⁷⁴⁴ The latter contains a protonated disulfide counterion derived from coupling of two pyridylthiol anions. When reaction of uranyl nitrate with 2-mercaptopyrimidine or 2-mercapto-4-methylpyrimidine is carried out in the presence of atmospheric oxygen and triethylamine, the binuclear complexes $[HNEt_3]_2[(UO_2)_2(O_2)(SC_4N_2H_3)_4]$ and $[HNEt_3][H(UO_2)_2(O_2)(SC_4N_2H_2Me)_4] \cdot Me_2CO \cdot 0.5Et_3N$ are isolated; these species are unique examples of peroxo-bridged diuranyl compounds.⁷⁴⁵ The analogous reaction with 2-mercaptopyridine yields the tetranuclear bridging oxo complex $[HNEt_3]_2[(UO_2)_4(O)_2(SC_5NH_4)_6] \cdot Me_2CO$.⁷⁴⁵

Triflates. The synthesis of $UO_2(O_3SCF_3)_2(H_2O)_n$ was first reported in 1994,⁷⁴⁶ and involved the treatment of UO_3 with triflic acid in water. The molecular structure of the complex $UO_2(O_3SCF_3)_2(H_2O)_3 \cdot 2(15\text{-crown-5})$ was subsequently reported,⁷⁴⁷ as was the solution spectrum of $UO_2(O_3SCF_3)_2(MeCN)_3$. The metal coordination environment in both complexes are best regarded as pentagonal bipyramidal uranyl units. Anhydrous and solvent free uranyl triflate has since been prepared by several routes,⁶¹³ but most conveniently by reaction of UO_3 with neat triflic acid or triflic anhydride at elevated temperatures. As discussed above, recrystallization of $UO_2(OTf)_2$ from pyridine generates the base adduct $UO_2(OTf)_2(py)_3$.

(v) Ligands containing neutral group 16 donor atoms

The dominant species in the +6 oxidation state is the actinyl ion, AnO_2^{2+} ; where the most stable member of the series is the uranyl ion, UO_2^{2+} . The majority of well-characterized coordination compounds are of this species, with the exception of some halide and hydroxide complexes.

Aqua species. Among isolated solids, hydrates of actinyl species are common (see Table 34), although it is not always clear that water is coordinated directly to the metal center. The equatorial plane of the actinyl ion can accommodate between one and five coordinated water molecules, depending both on the extent of inner-sphere anion coordination and the size of the metal ion. A total coordination number of seven for the metal ion is very common; pentagonal bipyramidal geometries are found in such complexes as $(enH_2)[UO_2F_4(H_2O)]$ ⁷⁴⁸ and $UO_2(acac)_2 \cdot (H_2O)$.⁷⁴⁹ EXAFS investigations indicate that the aquated uranyl ion in solution also has the expected pentagonal bipyramidal structure $[UO_2(H_2O)_5]^{2+}$.⁷⁴⁶ An experimental study of the exchange between $[UO_2(H_2O)_5]^{2+}$ and bulk water (observing ^{17}O -NMR signals) suggests that the mechanism for exchange is dissociative.⁷⁵⁰ Crown ethers have been found to effect the inclusion of uranyl hydrates. Crystallization of a variety of uranyl salts from acids (or from biphasic liquid clathrate systems¹³³) in the presence of crowns results in the formation of these inclusion compounds. Some of the structurally characterized examples in this class are listed in Table 35. Little structural variability is observed in these complexes; all display metal coordination numbers of seven or eight.

Ethers. Complexes with dialkylether ligands (as well as tetrahydrofuran) have been reported for uranyl chlorides, nitrates, thiocyanides, perchlorates, and *beta*-diketonate ligands. The formulation of the complexes would suggest uranium coordination numbers ranging from six

to eight. The rigid directionality and hence accessibility of the electron pairs (donor strength) of tetrahydrofuran make it particularly well suited to facilitate isolation of uranyl complexes. The molecular structures of several THF adducts have been determined (see Table 36). The complex $\text{UO}_2\text{Cl}_2(\text{THF})_3$ is isolated from the dehydration of $\text{UO}_2\text{Cl}_2(\text{H}_2\text{O})_x$ by Me_3SiCl in THF; it readily loses THF under reduced pressure to generate the known compound $[\text{UO}_2\text{Cl}(\mu\text{-Cl})(\text{THF})_2]_2$. This species is particularly useful as an anhydrous reagent for subsequent nonaqueous synthetic chemistry.

Alcohols. Alcohol adducts of uranyl species of the formula $\text{UO}_2\text{X}_2 \cdot y\text{ROH}$ ($\text{X} = \text{Cl}, \text{NO}_3, \text{MeCO}_2$, alkoxides, *beta*-diketonates, tropolonate, etc.; $y = 1\text{--}3$) have been reported. In some instances, adducts are formed in alcohol solvent, while in others they are prepared by removal of water by azeotropic distillation. An interesting example of an alcohol adduct is the compound formed between uranyl chloride and the polyethyleneglycol (PEG), hexaethyleneglycol, $\text{UO}_2\text{Cl}_2 \cdot (\text{H}_2\text{O})(\text{PEG})$.⁷⁵¹ The molecular structure of this and a handful of other structurally characterized complexes in this class^{752,753} demonstrate that the coordination geometry about the uranium atom is pentagonal bipyramidal.

Ketones, aldehydes, esters. The majority of representatives in this class of compounds contain cyclic or acyclic ketones as ligands (see Table 37). Complexes are known for uranyl halides, nitrates, cyanates, *beta*-diketonates, etc. The formulation of the compounds would suggest typical six- to eight-coordinate uranium. Confirmation of this is found in the structure of the acetic acid solvate $\text{UO}_2\text{Cl}_2[\text{OC}(\text{CH}=\text{CHPh})_2]_2 \cdot 2\text{MeCO}_2\text{H}$. The uranium center is six-coordinate, with all of the identical ligands mutually *trans*. Fewer compounds are known of aldehydes and organic esters, most of the formula $\text{UO}_2\text{X}_2(\text{L})_2$ ($\text{X} = \text{chloride, nitrate, L} = \text{aldehyde, ester}$), although mixed ligand (carbonyl-containing base, water) species have also been reported.

Carbamide and related ligands. Given the somewhat “harder” acid nature of actinyl ions relative to lower oxidation states, carbonyl-containing compounds constitute strong donor groups, and carbamides are perhaps the most widely studied type of ligand in this class (see Table 38); monamides are widely explored in extraction chemistry. This class of compounds also includes closely related ligands such as lactams, lactones, and antipyrines. In particular, the use of antipyrine (atp) for precipitating uranyl from solution in the presence of thiocyanate (presumably as $\text{UO}_2(\text{SCN})_2(\text{atp})_3$) was used as an assay for uranium in minerals. Adducts are most often prepared by direct reaction of actinyl salt and ligand in nonaqueous media. The stoichiometry of the adducts is controlled by the size of the coordinating ligand; stoichiometries between 1:1 and 1:5 (metal:ligand) are observed. The molecular structures of a number of amide complexes have been determined; most are monomeric, and possess uranium coordination numbers of seven or eight (see Table 39).

Oxoanions promote the formation of dimeric or polymeric products. The local coordination environment in these species is that of pentagonal bipyramidal uranyl groups with two neutral ligands and three oxo groups from two different bridging sulfate, chromate, or acetate groups.⁷⁵⁴

Extraction of U^{VI} from nitrate and thiocyanate solutions into various organic solvents has been performed using three different monamides: *N,N*-methylbutyldecanamide (MBDA), *N,N*-dibutyldecanamide (DBDA), and *N,N*-dihexyldecanamide (DHDA). Distributions from nitrate vary as a function of organic diluent and are greatest for aromatic diluents. A similar trend is not observed for thiocyanate. The extraction equilibria from NO_3^- and SCN^- media from slope analysis are as follows (see Equations (52) and (53); L = ligand):

Table 39 Structurally characterized U^{VI} carbamides.

Extraction of uranyl with all three amides was always much higher from the SCN[−] solution than from the NO₃[−] solution, possibly indicating a more stable U^{VI}/SCN[−] complex. IR spectra and ¹H-NMR data confirm the bonding of the amide carbonyl directly to the metal ion in all three ligands. Lack of OH stretching modes in the IR spectra eliminates the presence of water in the extracted complexes. IR data also confirms direct bonding on NO₃[−] and SCN[−] to the metal. These analyses confirm the slope analysis observations.⁷⁵⁵

The monamides *N,N*-di(ethyl-2-hexyl)butanamide (DOBA) and *N,N*-di(ethyl-2-hexyl)-*i*-butanamide (DOiBA) extract U^{VI}, as well as the lower oxidation state An^{IV}. DOiBA tends to have lower extractive ability due to the bulky isobutyl groups attached to the nitrogen. Uranium(VI) extracts better than Pu^{IV} for both monamides and always forms 2:1 U^{VI}/monamide complexes. Hence, the observed extracted complexes at low acidity are UO₂(NO₃)₂(DOBA)₂ and UO₂(NO₃)₂(DOiBA)₂. IR analysis indicates direct carbonyl bonding to the metal and C_{2v} geometry in the final extracted complexes. Metal nitrate anions coordinated with protonated ligands are the likely species extracted in high acid conditions.⁷⁵⁶

Ureas. The coordination environment of complexes with urea (and related) ligands is very similar to that of carbamide ligands (see Table 40). Nearly all representatives of this class consist structurally of pentagonal bipyramidal uranyl units. Adducts with three or four neutral ligands are monomeric; those with two urea ligands are dimeric (edge sharing units bridged by anionic ligands). Polymeric sulfate complexes have been characterized, UO₂(SO₄)·2urea and UO₂(SO₄)·3urea,^{757,758} with pentagonal bipyramidal uranyl units linked by either tri- or bidentate sulfate groups, respectively.

One structure of a homoleptic uranyl urea compound has been reported, [UO₂(*N,N,N'*-tetramethylurea)₄][B₁₂H₁₂],⁷⁵⁹ in which four urea groups lie in the equatorial plane of an octahedral uranium.

Nitroalkanes. A limited number of solvates of uranyl salts have been reported to crystallize from nitromethane or nitrobenzene solutions, including the following formulations UO₂(NO₃)₂·2RNO₂ and UO₂(ClO₄)₂·2MeNO₂.

Amine *N*-oxides, phosphine oxides, arsine oxides, and related ligands. The prototypical system for extraction of the uranyl ion from aqueous solution into organic solvent is tributylphosphate in hydrocarbons such as kerosene. This has stimulated interest in understanding the coordination chemistry of actinyl ions with P=O (and related) functional groups in order to optimize extraction efficiency or discrimination among actinides to be separated. Of all classes of neutral group 16-atom donor ligands, phosphine oxide adducts are the most common examples of complexes of transuranic elements (Np, Pu).

Base adducts are most often prepared by direct reaction of actinyl salt and ligand in nonaqueous media. The donor strength of this class of ligands is evidenced by the fact that phosphine

oxide adducts will form in solution with a stoichiometric amount of ligand even in such potentially coordinating solvents as acetonitrile, ethanol, or 1,2-dimethoxyethane.⁷⁶⁰ The reported stoichiometry of complexes prepared ranges from 1:1 to 5:1 (L:An) (see Table 41), with higher ligand to metal ratios resulting in the case of weakly coordinating anions (such as perchlorate) where ionic complexes [AnO₂L_x][ClO₄]₂ might reasonably be expected to form. The complexes are usually identified by the intense IR-active νP=O stretching frequency. The frequency of free trialkylphosphine oxides generally falls between 1150–1200 cm⁻¹; reduction in this frequency by ~100 cm⁻¹ is common upon coordination.

The coordination environment about the metal atoms is very frequently octahedral; higher coordination numbers such as eight arise from coordination of bidentate counterions (acetate, nitrate). The most common geometry for octahedral complexes is *trans*, although a *cis* isomer of UO₂Cl₂(OPPh₃)₂ has been isolated,⁷⁶¹ and a *cis* geometry is observed for the derivative UO₂-(OBu^t)₂(OPPh₃)₂.⁵⁹¹

Commercially available Cyanex 923, or TRPO (see Table 19), has been used for the successful extraction of U^{VI} ions from nitric acid solutions into xylene. Extractant dependency gives a slope of two for hexavalent uranium, similar to the behavior observed for trioctylphosphine oxide (T-OPO). The extraction stoichiometry for TRPO with UO₂²⁺ is given by Equation (54):

The shift in the phosphoryl stretching frequency for complexes of TRPO with U^{VI} to lower values (1146 cm⁻¹ to 1071 cm⁻¹) indicate strong donation of the phosphoryl oxygen lone pair to the metal center, and comparison with Th^{IV} indicate a stronger U^{VI} complex.³¹⁴

Tributylphosphate (TBP) is used as an extractant in the PUREX process for the selective extraction of both Pu^{IV} and U^{VI} ions (see Figure 54). As discussed in Section 3.3.2.2.3.1.9, TBP is used as a synergist with CMPO in the TRUEX process for the treatment of nuclear wastes.

The equilibrium for the extraction of UO₂²⁺ by TBP into various organic solvent from nitric acid media has been thoroughly characterized; the extracted species is proposed to be UO₂(NO₃)₂·2TBP.⁷⁶²

Den Auwer *et al.*⁷⁶³ have studied the complexation of the uranyl ion by a series of trialkyl and triaryl phosphates: tri-*i*-butylphosphate(TiBP), tri-*n*-butylphosphate(TBP), trimethylphosphate(TMP), and triphenylphosphate(TPhP) by EXAFS. EXAFS was used to help better understand the coordination environment of the extracted complexes, as well as the extractive ability of the organophosphorus compounds.

In the experiment uranyl nitrate was dissolved into excess TBP, TiBP, TMP, and TPhP and the spectra were taken both in the solid state at 77 K and also at room temperature as a liquid using the uranium L_{III} edge. From the experiments it was determined that all four ligands coordinated

**Figure 54** Tributylphosphate (TBP).

similarly to the uranium center. Table 42 shows that the distance between the U–O(P) does not differ much with a change in the alkyl group. The change that is observed may possibly be attributed to the cone angle of the ligand, with the less sterically hindered group being the methyl groups and the most sterically hindered being the phenyl groups. With nitrate and trialkylphosphate ligands being bidentate and monodentate, respectively, the resulting coordination around the uranium is hexagonal bipyramidal with the complex formula of $[\text{UO}_2(\text{NO}_3)_2\text{X}_2]$ where X is TBP, TiBP, TMP or TPhP.⁷⁶³

The EXAFS data are in agreement with structures solved by X-ray single crystal diffraction. It has been shown that uranyl and neptunyl complexes with TPhP are isostructural. The hexagonal bipyramidal coordination geometry around the metal center can be seen in Figure 55. The observed complexes are $\text{UO}_2(\text{NO}_3)_2(\text{TPhP}_2)$ and $\text{NpO}_2(\text{NO}_3)_2(\text{TPhP}_2)$.

Table 42 Best fit parameters for uranium to nearest neighbor (r , Å) from adjusted, filtered EXAFS spectra. (Den Auwer, Charbonnel, *et al.*, *Polyhedron*, **1998**, 17, 4507.)

**Figure 55** Crystal structure of $\text{NpO}_2(\text{NO}_3)_2(\text{C}_{18}\text{H}_{15}\text{PO})_2$ (Alcock, Roberts *et al.* *J. Chem. Soc., Dalton Trans.* **1982**, 25).

If the anion bound to the neptunyl is changed from the bidentate singly-charged nitrate ion to the monodentate singly-charged chloride anion, the coordination geometry around the neptunium changes to square bipyramidal. This type of coordination sphere for an actinyl complex is not as favored; most actinyl complexes have coordination numbers of seven or eight. The difference in the coordination sphere around the neptunium can be seen in Figure 56.⁷⁶⁴

Monophosphoric acid-based extractants have the general structure shown in Figure 57. The compound di-(2-ethylhexyl)-phosphoric acid (DEHPA) has been used to extract U^{VI} from various acid solutions, including hydrochloric, nitric, and sulfuric acids, into kerosene. At low acidities, the extraction mechanism for all three types of acid favors the formation of a U^{VI} /DEHPA polymer complex, dictated by the equilibrium shown in Equation (55) ($\text{L} = (\text{C}_8\text{H}_{17}\text{O})_2\text{PO}_2^-$). For both HNO_3 and HCl at higher acidities, the U^{VI} cation is extracted by a mechanism similar to that with nonionic reagents to form neutral complexes of the type $\text{UO}_2\text{X}_2(\text{HL})_2$:

The partitioning of U^{VI} from HCl increases with increasing metal concentration up to around 0.05 M, indicating that two DEHPA molecules complex with the uranyl ion, similar to sulfuric and nitric acid solutions. This suggests the formation of other extracted species at high U^{IV} loadings.

Addition of a synergist to the DEHPA/ HCl extraction system such as tributylphosphate (TBP) has a two-sided effect in improving extraction at high acidity and hindering extraction at low acidity. At low acidity, as in the analogous sulfuric acid system, the presence of TBP disrupts the creation of polymeric complexes between U^{VI} and DEHPA.^{765–767}

Figure 56 Crystal structure of $\text{NpO}_2\text{Cl}_2(\text{C}_{18}\text{H}_{15}\text{PO})_2$ (Alcock, Roberts *et al.* *J. Chem. Soc., Dalton Trans.* **1982**, 25).

Figure 57 General diagram of a phosphoric acid.

Synergism in the sulfuric acid/ U^{VI} system by the addition of both DEHPA and TBP results in a 1:2:2 ($\text{U}:\text{DEHPA}:\text{TBP}$) extraction stoichiometry with deprotonation of the phosphoric acid. Synergism is observed at high acidities, leading to better distribution coefficients, but at lower acidities, an antagonistic effect is observed due to the reason discussed above. Absorption spectroscopy data suggests the above equilibrium, where P—O stretching frequencies for DEHPA are shifted to lower values and those for TBP are unchanged, confirming that the extracted complex involves hydrogen bonding to the phosphoryl group of DEHPA.⁷⁶⁸

A similar study has looked at the extraction of both U^{VI} and Pu^{VI} by di-(2-ethylhexyl)phosphoric acid from perchloric acid into dodecane, toluene, and chloroform. Extractant dependency studies show two molecules of DEHPA complex with one U^{VI} or Pu^{VI} ion in the extracted species, accompanied by the liberation of two protons. This agrees with the ion exchange mechanism reported by Sato for U^{VI} from HCl media at low acid concentrations.

Addition of tri-*n*-octylphosphine oxide (TOPO), a proposed synergist, to the system works to improve the uptake of both actinide ions. Two plausible complexation stoichiometries have been reported for the synergistic effect of TOPO, suggesting the formation of two different extracted species (see Equations (56) and (57)):⁷⁶⁹

Sulfur-containing derivatives of phosphoric acids, such as di-2-ethylhexyl-dithiophosphoric acid (HEHdtp), have been used to extract U^{VI} , presumably for the softer nature of the sulfur atom. Various noncoordinating solvents, including cyclohexane, chloroform, and carbon tetrachloride, have been used for extractions from perchlorate solutions. Analysis of distribution data indicates that the extraction of U^{VI} into these oxygen-free solvents occurs by way of an ion-exchange mechanism, similar to previous studies involving benzene. Slope analysis studies in all three solvents give

a value of two, suggesting that $\text{UO}_2(\text{Ehdtp})_2$ is formed. Studies conducted as a function of pH show that no type of polymeric species is formed in the extracted or aqueous phases. Additionally, analysis of the results in the chlorinated solvents tend to suggest that the polarity of the solvent is not a major factor in the extraction of U^{VI} .

It is observed that shorter alkyl chain dithiophosphoric acid extractants show poorer extracting ability than the HEhdtp, which can be explained as a solubility phenomenon, causing the branched alkyl chain, 2-ethylhexyl, to favor the organic phase.⁸³⁶

A relatively large number of *N*-oxide complexes with the uranyl ion have been reported employing both the trimethylamine *N*-oxide and pyridine *N*-oxide ligands (see Table 43). The latter has been particularly used in the isolation of beta-diketonate complexes of the general type, $\text{UO}_2\text{L}_2(\text{pyNO})$. Common formulations for monomers include $\text{UO}_2\text{L}_2(\text{N-oxide})_x$ ($x = 2$ or 3) for monodentate L, $\text{UO}_2\text{L}_2(\text{N-oxide})$ for bidentate L, and $[\text{UO}_2(\text{N-oxide})_x][\text{L}]_2$ ($x = 4$ or 5) for weakly coordinating anions. Structurally characterized examples of this class of adducts include $\text{UO}_2(\text{Et}_2\text{NCS}_2)_2(\text{ONMe}_3)$,⁷⁷⁰ and the compounds derived from *N*-oxides of polycyclic heteroaromatic ligands: $\text{UO}_2(\text{NO}_3)_2(2,2'\text{-bipyridine-}N,N'\text{-dioxide-O,O})$ and $[\text{UO}_2(\text{NO}_3)(2,2'\text{-bipyridine-}N,N'\text{-dioxide-O,O})_2](\text{NO}_3)$.⁷⁷¹

There are fewer reported examples of arsine oxide adducts of actinyl species. Most appear to have structures similar to those of their phosphorus analogs. As an example, the complexes $\text{UO}_2(\text{O}_2\text{CMe})_2(\text{OAsPh}_3)_2$ and $[\text{UO}_2(\text{O}_2\text{CMe})_2(\text{OAsPh}_3)]_2$ are isomorphous with the phosphine oxide complexes. The molecular structure of $\text{UO}_2(\text{NO}_3)_2(\text{OAsPh}_3)_2$ has been determined;⁷⁷² the complex possesses *trans*-nitrate and arsine oxide ligands in the equatorial plane. Analysis of the metrical data indicates some shortening of the U—O (As) bond lengths with respect to the U—O (P) bond lengths in $\text{UO}_2(\text{NO}_3)_2(\text{OPPh}_3)_2$.

Sulfoxides. Table 44 presents some of the reported derivatives of actinyl ions coordinated by sulfoxide and related ligands. These ligands coordinate through the oxide oxygen atom in the equatorial plane of the actinyl ion. Coordination numbers about the metal can range from six to eight, as is typical for actinyl species. One of the most common geometries of complexes is

trans-UO₂L₂(OSR₂)₂, as exemplified by the molecular structures of UO₂(NO₃)₂(OSMe₂)₂⁷⁷³ and UO₂(NO₃)₂(*p*-tolyl-*n*-butylsulfoxide)₂.⁷⁷⁴ Weakly coordinating anions promote the formation of homoleptic ionic sulfoxide complexes such as [UO₂(OSMe₂)₅](ClO₄)₂⁷⁷⁵ and [UO₂(OSMe₂)₅](BF₄)₂.⁷⁷⁶ Finally, sulfoxides have frequently been used in coordinating uranyl *beta*-diketonate complexes, generating 1:1 adducts such as UO₂(PhCOCHCOPh)₂[OS(Me)CH₂Ph]⁷⁷⁷ and UO₂(PhCOCHCOPh)₂(OSPh₂).⁷⁷⁸

Thioureas. A modest number of thiourea complexes of the uranyl ion have been reported (see Table 45), although none have been structurally characterized to date.

(vi) Ligands containing group 17 ligands

Binary halides. The stability of hexavalent halide complexes of the actinides is restricted to the lighter halides. The hexafluoride complexes of uranium, neptunium, and plutonium are well known, and have been studied extensively in the development of volatility processes for isotope separation. Uranium hexafluoride is a colorless, readily sublimable solid with a high vapor pressure (120 torr) at room temperature. It can be produced by a large number of routes, generally involving fluorination of lower-valent compounds, or oxidation of the tetravalent precursor [UF₆]²⁻. A review of the preparation and properties of UF₆ has been published.⁷⁷⁹ NpF₆ is an orange solid with similarly low melting point and high volatility. Although somewhat less stable than the uranium and neptunium analogues, reddish-brown PuF₆ can be prepared, and has been studied thoroughly. All hexafluoride complexes are octahedral in both the solid state and gas phase.

One binary chloride complex has been isolated. UCl₆ may be prepared by chlorination of lower-valent chlorides, chlorination of UF₆ with BCl₃, or by the disproportionation of UCl₅ at 102–150 °C under high vacuum. The complex is volatile, although it decomposes at relatively low temperatures (178 °C).

Complex halides. A large number of complex fluorides of the formula M(UF₇) (M = alkali metal) and M₂(UF₈) have been produced by reaction of MF with UF₆ or by thermal decomposition of M(UF₇), respectively.^{780,781} High temperature fluorination of M₃UF₇ is reported to yield M₃UF₉ (M = K, Rb).⁷⁸²

Oxohalides. Oxohalide complexes of hexavalent actinides have been prepared for U, Np, and Pu. Complexes of the formula AnOF₄ have been reported, for An = U, Np, and Pu; these are prepared by controlled hydrolysis of the hexafluoride complexes. The complexes contain actinides in a pentagonal bipyramidal coordination environment. The most common form^{783–785} has the oxo ligand and one fluoride ligand in the axial positions (an alternate phase of UOF₄ has also been identified).⁷⁸⁶ Dioxo complexes are somewhat more common, owing to the thermodynamic stability of the actinyl (AnO₂²⁺) unit. The complexes AnO₂X₂ (An = U, X = F, Cl, Br; An = Np, X = F; An = Pu, X = F, Cl) have been reported. The compound PuO₂Cl₂·6H₂O is reported to be unstable, and decomposes slowly to a Pu^{IV} species. One common means of preparation of the actinyl halides is dissolution of AnO₃ in the corresponding acid HX.

Complex oxohalides are derived from the binary species, including the classes M₂AnO₂X₄·2H₂O (An = U, Np, Pu; M = alkali metal or ammonium; X = F, Cl, Br), MAnO₂F₃·xH₂O (An = U, M = ammonium; An = Pu, M = alkali metal, ammonium), M₃[AnO₂F₅] (An = U, Np, Pu; M = alkali metal), M₂AnO₂Cl₄ (An = U, Pu; M = alkali metal or ammonium), MUO₂Cl₄ or MUO₂F₄·4H₂O (M = group 2 or group 12 dication), M(AnO₂)₂F₅·xH₂O or M(UO₂)₂Cl₅ (An = U, Pu; M = alkali metal or ammonium), M₃(UO₃)₃F₇·xH₂O or M₃(UO₃)₃Cl₇,

$M_2U_2O_5Cl_4 \cdot xH_2O$ (M = alkali metal), and KUO_3Cl . The hydrated compounds are obtained by crystallization from HCl ; the anhydrous compounds are generated from molten salts. The *trans*-dioxo geometry of the actinyl ions is preserved in these species and the metal ions are generally six- or seven-coordinate. The molecular structure of organic salts of $[UO_2Br_4]^{2-}$ have been examined;^{342,787} these confirm the pseudooctahedral coordination environment of the metal center. As in the case of hexahalogenates of uranium, crown ether ligands have been found to promote the crystallization of $[UO_2Cl_4]^{2-}$ in different salts.^{344,345,788–790}

As in the case of U^{IV} , hydrothermal syntheses using structure-directing organic agents have been reported to yield unusual new classes of complex uranyl fluorides.^{334–336,791} Reaction of uranyl acetate, uranyl nitrate, or UO_3 in aqueous HF solutions with organic bases (piperazine, pyridine, pyrazole, DABCO) generates a range of structures in which “ UO_2F_5 ” pentagonal bipyramidal units share vertices and/or edges to form structures of variable dimensionality, from molecular complexes such as $(C_4N_2H_{12})UO_2F_4 \cdot 3H_2O$, to chains (e.g., $(C_5H_6N)UO_2F_3$, $(C_3H_5N)UO_2F_3$) to sheets (e.g., $(C_4N_2H_{12})_2(U_2O_4F_5)_4 \cdot 11H_2O$, $(C_6H_{14}N_2)(UO_2)_2F_6$, $(C_5H_6N)U_2O_4F_5$, $(C_3H_5N)U_2O_4F_5 \cdot 1.75H_2O$), and three-dimensional structures (e.g., $(C_4N_2H_{12})U_2O_4F_6$). A mixed-valence U^{IV}/U^{VI} complex,³³⁶ $(C_6H_{14}N_2)_2(UO_2)_2F_5UF_7 \cdot H_2O$, containing a chain-like structure has also been reported.

3.3.2.4.3 Chelating ligands

(i) Multidentate donor ligands

Hydroxamates, cupferron and related ligands. Most of the hexavalent actinide complexes reported involve the complexation of uranium(VI) by cupferron and its derivatives to form 1:2 and 1:3 $U:L$ complexes. Several complexes of the form $(NH_4)_2[UO_2L_2L']$, $(NH_4)_2[UO_2L_2X_2]$ ($L' = CO_3^{2-}$, $C_2O_4^{2-}$, $X = F$, Cl ; HL = cupferron) and $NH_4UO_2(C_6H_5N_2O_2)_3$ have been prepared by reacting excess ligand with the metal ion.^{792,793} Uranyl complexes of *N*-phenyl-benzoylhydroxamic acid (HL^1), cupferron *N*-nitrosophenylhydroxylamine, $(HL^2) UO_2(L^1)_2A$ ($A = MeOH$, Ph_3PO , DMF , py) and $UO_2(L^1)_2DMF \cdot H_2O$, have been reported. The complexes were characterized by elemental analysis and optical absorbance spectroscopy, and some were also characterized by X-ray diffraction. The structure of $UO_2(L^1)_2MeOH$ shows a seven-coordinate pentagonal bipyramidal geometry around the uranium center (see Figure 58). The inner coordination sphere of U is composed of two bidentate hydroxamato ligands, one methanol in the equatorial plane, and the axial uranyl oxygens. The methanol molecule is easily replaced by other neutral, more basic monodentate ligands, such as Ph_3PO , $DMSO$, DMF , or pyridine.³⁵⁶ A similar structure of $UO_2(L)_2EtOH$ ($L = p$ -isopropylbenzophenylhydroxamic acid) has been reported.⁷⁹⁴ Neocupferron forms 3:1 complexes with dioxouranium(VI) of the type $M[UO_2-(C_{10}H_7O_2N_2)_3] \cdot xH_2O$ and $M'[UO_2(C_{10}H_7O_2N_2)_3]_2 \cdot xH_2O$, where M and M' are univalent and divalent cations.⁷⁹⁵ Additional complexes with similar stoichiometries and structures have been reported and

Figure 58 Structure of $UO_2(L^1)_2MeOH$ (Casellato, Vigato *et al. Inorg. Chim. Acta* **1984**, *81*, 47–54).

characterized in solution by conductance, DTA, NMR, and IR and UV spectra.^{795–797} In the presence of acetohydroxamic acid and desferrioxamines, Pu^{VI} and Np^{VI} reduce to the Pu^{IV} and Np^{IV} complexes, respectively, at pH-dependent rates.⁸⁰

Catecholate. Pyrocatecholates of composition UO₂(1,2-C₆H₄O₂)·xH₂O (x = 1 or 3) and (pyH)-H[UO₂(1,2-C₆H₄O₂)(OH)]·H₂O, as well as the resorcinol compound, UO₂·(1,3-C₆H₄O₂), have been reported. The uranyl complexes formed in aqueous solution with 4,5-dihydroxy-3,5-benzenedisulfonate (Tiron) have been postulated to be trimeric, with the stoichiometry 3:3 UO₂²⁺:tiron based on EXAFS studies.³⁶⁴ Mixed catecholate–hydroxypyridinonate ligands are described in the pyridonate section.

Pyridonate. Uranyl complexes with tetradentate ligands composed of two hydroxypyridonate groups linked by an amine [UO₂(L¹)₂·DMF], [UO₂L³·DMSO], [UO₂L⁴·DMSO]DM·DMSO]DMSO·H₂O·0.5C₆H₁₂ and [UO₂L⁵·DMSO]·DMSO have been prepared and structurally characterized (see Figure 59).⁷⁹⁸ These uranyl complexes have been prepared by refluxing a methanolic solution containing equivalent amounts of UO₂(ClO₄)₂ and the hydroxypyridinone ligand. The linking amines are propaneamine, 1,3-diaminopropane, 1,4-diaminobutane, 1,5-diaminopentane respectively. In these complexes uranyl is bound by four oxygens from the hydroxypyridinone ligands and one solvent oxygen to generate a pentagonal bipyramidal coordination polyhedron as shown in Figure 60.

The extractant 1-hydroxy-6-*N*-octylcarboxamide-2(1H)-pyridinone (octyl-1,2-HOPO) has an appreciable affinity for Pu^{VI}, though much less than for Pu^{IV} under identical conditions. The equilibrium for the extraction from nitric acid media is given by Equation (58). Deprotonated HOPO generally coordinates the metal in a bidentate fashion, but in this case, m can range from 0 to 2. Extraction is greatest at low acid concentrations of around 0.001 M. Extractant dependency gives a slope of 1.3, which equates to a value of 2 for m in the above extraction stoichiometry.²²⁶

A series of multidentate ligands containing catecholate or hydroxypyridinonate metal binding groups for removal of actinides *in vivo* have been developed. Tetradentate ligands with two bidentate groups per chelator molecule attached to linear 4- or 5-carbon backbones were the most promising of a series of ligands studied, with respect to metal removal from mammals.³⁵⁰

8-Hydroxyquinoline and derivatives. Uranyl complexes of 8-hydroxyquinoline (Ox = oxine) and its derivatives have been prepared in aqueous solution.^{375,377,799–803} The solid state IR spectra of [UO₂(Ox)_n(HOx)] shows that Ox is bound to the metal through the phenolic O, the proton

Figure 59 Crystal structure of [UO₂(L¹)₂·DMF], [UO₂L³·DMSO] (Xu and Raymond *Inorganic Chemistry* 1999, 38, 308–315).

Figure 60 Crystal structure of $[\text{UO}_2(\text{L}^1)_2 \cdot \text{DMF}]$, $[\text{UO}_2\text{L}^3 \cdot \text{DMSO}]$.

forming an intramolecular H-bond between the N atom of the adducted molecule and the O atom of a neighboring chelate ring.³⁷⁶ This bonding was confirmed by the structure of the complex $\text{UO}_2(\text{Ox})_2\text{HOx} \cdot \text{L}$ obtained by X-ray diffraction studies (Figure 61).⁸⁰⁴ The crystal structure shows that the three hydroxyquinoline ligands are in the plane perpendicular to the uranyl unit. Two of the hydroxyquinoline ligands are bidentate and the third is monodentate; its nitrogen is linked to one of the phenolic oxygens. Similarly, the uranyl complex formed with 5,7-dihalo-8-hydroxyquinoline precipitated from an aqueous acetone solution has been formulated as $\text{UO}_2(5,7\text{X},\text{Ox})_2\text{OC}(\text{CH}_3)_2$ based upon IR analysis. The presence of the acetone molecule instead of a third Ox is attributed to steric hindrance. Salts of triquinoline complexes, $\text{M}[\text{UO}_2(\text{Ox})_3]$ ($\text{M} = \text{Na}^+$, NR_4^+ , Ph_4As^+) can be prepared by increasing the pH of the solution containing $\text{UO}_2(\text{Ox})_2\text{HOx}$. Analysis of the anions by ^1H NMR shows that the three ligands are equivalently bound to the metal, presumably to yield hexagonal bipyramidal geometry.⁸⁰⁵ Chelates of Np^{VI}

Figure 61 The structure of $\text{UO}_2(\text{Ox})_2\text{HOx} \cdot \text{CHCl}_3$ (Hall, Rae *et al. Acta. Cris.* **1987**, 22, 258).

and Pu^{VI} could not be prepared, as the hexavalent ions are reduced to a lower oxidation state at pH values where metal-ligand complexes would form.⁵⁷⁸ This is expected given the redox sensitivity of the ligand and the high thermodynamic stability of the resultant An^{IV} complexes.

Carbamate. Carbamate-containing derivatives of uranyl nitrate, uranyl oxalate, uranyl acetate, and other uranyl complexes of simple oxoanions ($[\text{UO}_2(\text{NO}_3)_2\text{L}_2]$, $[\text{UO}_2(\text{tropolonate})_2\text{L}]$, $[\text{UO}_2(\text{acetate})(\text{OH})\text{L}]$, $[\text{UO}_2(\text{oxalate})\text{L}]$, and $[\text{UO}_2(\text{phthalate})\text{L}]_n$) have been prepared by addition of ethyl carbamate to uranyl salts. Bis(ethylcarbamate) dinitratodioxouranium(VI) $[\text{UO}_2(\text{NO}_3)_2\text{L}_2]$, for example, shows an irregular hexagonal bipyramidal geometry in which the linear uranyl group is perpendicular to the equatorial plane formed by four oxygen atoms of two nitrate groups and the two amidic oxygen atoms from the ethyl carbamate ligand (Figure 62).⁸⁰⁶

A related uranyl complex with the disulfide ligand, has been prepared and characterized by X-ray diffraction. The structure of $[(n\text{-C}_3\text{H}_7)_2\text{NH}_2]_2[\text{UO}_2((n\text{-C}_3\text{H}_7)_2\text{NCOS})_2(\text{S}_2)]$ consists of $[(n\text{-C}_3\text{H}_7)_2\text{NH}_2]^+$ cations and $[\text{UO}_2((n\text{-C}_3\text{H}_7)_2\text{NCOS})_2(\text{S}_2)]^{2-}$ anions with the uranium atom at the center of an irregular hexagonal bipyramid. The equatorial coordination plane contains the disulfide (S_2^{2-}) group bonded in a “side-on” fashion and two oxygen and two sulfur donor atoms from the mono-thiocarbamate ligands. The nitrogen atom in the dipropylammonium cation is hydrogen bonded to the uranyl oxygen atoms (see Figure 63).⁸⁰⁷

A dinuclear mixed ligand uranyl complex with dioxime, carbonate, and oxalate ligands $(\text{C}_2\text{N}_2\text{H}_{10})_2[(\text{UO}_2)_2(\text{CO}_3)(\text{C}_2\text{O}_4)(\text{C}_3\text{H}_4\text{N}_2\text{O}_2)]\cdot\text{H}_2\text{O}$ has been reported and characterized by X-ray diffraction.⁸⁰⁸ The uranyl ions in the dimer are six-coordinate, characterized by the presence of one three membered, one four membered, and one five membered chelate ring in the equatorial plane.

Several uranyl dithiocarbamates $\text{UO}_2(\text{R}_2\text{NCS}_2)_2\cdot\text{L}$ have been prepared via precipitation from solutions containing potassium R-dithiocarbamate and uranyl acetate.⁸⁰⁹ Uranyl diethylthiocarbamate complexes with triphenylphosphine, triphenylarsine oxide, or trimethylamine *N*-oxide (L) $\text{UO}_2(\text{Et}_2\text{NCS}_2)_2\cdot\text{L}$, L = $(\text{C}_6\text{H}_5)_3\text{AsO}$, $(\text{C}_6\text{H}_5)_3\text{PO}$, and $(\text{CH}_3)_3\text{NO}$ have been prepared by the reaction of L with $\text{K}[\text{UO}_2(\text{Et}_2\text{NCS}_2)_3]\cdot\text{H}_2\text{O}$.^{810,811} Structural characterization reveals the uranium metal center is commonly seven-coordinate, at the center of a distorted pentagonal bipyramid, with the linear uranyl unit perpendicular to a plane containing four sulfur atoms of two carbamate groups and one oxygen atom from an ancillary ligand (see Figure 64).

Similarly, many tris(R-carbamate)dioxouranium(VI) complexes (exemplified by $\text{K}[\text{UO}_2(\text{Et}_2\text{NCS}_2)_3]\cdot\text{H}_2\text{O}$) have been reported. The complexes are prepared by reacting uranyl acetate with the R-carbamate salt obtained by addition of R-amine to an aqueous solution containing equimolar amounts of carbon disulfide and potassium hydroxide.^{810,812,813}

Oxalate. A large number of actinide(VI) oxalate and mixed ligand oxalate complexes have been reported (see Table 46). Different coordination modes of uranyl by the oxalate group have

Figure 62 Structure of $\text{UO}_2(\text{NO}_3)_2\text{L}_2$ L = ethylcarbamate (Graziani, Bombieri *et al. J. Chem. Soc., Dalton Trans.* 1973, 451–454).

Figure 63 Molecular structure of $[(n\text{-C}_3\text{H}_7)_2\text{NH}_2]_2[\text{UO}_2((n\text{-C}_3\text{H}_7)_2\text{NCOS})_2(\text{S}_2)]$ (Perry, Zalkin *et al. Inorg. Chem.* **1982**, *21*, 237–240).

been reported. The typical coordination modes of the oxalato anions are bidentate, as in $\text{UO}_2\text{C}_2\text{O}_4 \cdot 3\text{H}_2\text{O}$, and tetradentate bridging as in $[(\text{NpO}_2)_2\text{C}_2\text{O}_4 \cdot 4\text{H}_2\text{O}]_n$ (see Figure 65). Bidentate chelating and bidentate bridging coordination modes are also observed as in $\text{M}^{\text{I}}_6[(\text{UO}_2)_2(\text{C}_2\text{O}_4)_5]$. The trioxalatouranyl complexes $\text{M}^{\text{I}}_4[\text{UO}_2(\text{C}_2\text{O}_4)_3]$ are characterized by the standard bidentate chelating (with the formation of a five membered ring) and bidentate chelating having a four-membered chelating ring. As expected, the coordination sphere about the metal center is very similar to that observed in carbonato complexes. The complex $\text{UO}_2\text{C}_2\text{O}_4 \cdot 3\text{H}_2\text{O}$ has a pentagonal bipyramidal coordination geometry comprised of four oxygen atoms from two independent C_2O_4 groups and one from the water molecule in the equatorial plane. Each C_2O_4 group is tetradentate, bridging two UO_2^{2+} ions.

Many complexes of the type $\text{M}^{\text{I}}[\text{UO}_2(\text{C}_2\text{O}_4)_2]$ and hydrates $\text{M}_n[\text{MO}_2(\text{C}_2\text{O}_4)_2\text{L}] \cdot x\text{H}_2\text{O}$ are also known (see Table 46). In the complex $\text{K}_2[\text{UO}_2(\text{C}_2\text{O}_4)_2\{\text{CO}(\text{NH}_2)_2\}] \cdot \text{H}_2\text{O}$, the basic structural unit is $[\text{UO}_2(\text{C}_2\text{O}_4)_2\{\text{CO}(\text{NH}_2)_2\}]^{2-}$, in which U has pentagonal bipyramidal UO_7 coordination.⁸¹⁴ The

Figure 64 Structure of $\text{UO}_2(\text{Et}_2\text{NCS}_2)_2 \cdot \text{L}$, $\text{L} = (\text{C}_6\text{H}_5)_3\text{AsO}$, $(\text{C}_6\text{H}_5)_3\text{PO}$, and $(\text{CH}_3)_3\text{NO}$ (Graziani, Zarli *et al. Inorg. Chem.* **1970**, *9*, 2116–1124; Forsellini, Bombieri *et al. Inorg. Nucl. Chem. Lett.* **1972**, *8*, 461–463).

Figure 65 $(\text{NpO}_2)_2(\text{C}_2\text{O}_4) \cdot 4\text{H}_2\text{O}$ (Grigor'ev, Charushnikova *et al.* *Zh. Neorg. Khim.* **1996**, 41, 539).

U-containing complexes are connected in a three-dimensional framework by potassium ions and a system of hydrogen bonds with the hydrogen atoms of urea molecules. The complex $\text{Rb}_2[\text{UO}_2(\text{SO}_4)\text{C}_2\text{O}_4] \cdot \text{H}_2\text{O}$, prepared by reacting $\text{UO}_2\text{C}_2\text{O}_4 \cdot 3\text{H}_2\text{O}$ with Rb_2SO_4 , has similar structural features about the uranium center with pentagonal bipyramidal (UO_7) coordination geometry.^{815, 816} For the complex $\text{Cs}_4[\text{UO}_2(\text{C}_2\text{O}_4)_2(\text{SO}_4)]$ (see Figure 66) prepared in an analogous fashion from the oxalate trihydrate and Cs_2SO_4 , the uranium also has pentagonal bipyramidal coordination geometry, with the axial uranyl oxygen atoms perpendicular to the equatorial plane composed of four oxygen atoms from two bidentate oxalates and one sulfate oxygen.⁸¹⁷ The coordination polyhedron of uranium in the complex $[(\text{UO}_2)_2(\text{C}_2\text{O}_4)(\text{SeO}_4)_4]$ is approximately pentagonal bipyramidal UO_7 , with the axial uranyl unit and five equatorial oxygen atoms from one bidentate oxalate group and three selenate ions (see Figure 67).⁸¹⁹

The coordination polyhedron of uranium in the polymeric anion $[\text{UO}_2(\text{C}_2\text{O}_4)_2]^{2n-}$ in $((\text{NH}_4)_2[\text{UO}_2(\text{C}_2\text{O}_4)_2])_n$ is also pentagonal bipyramidal, with axial uranyl oxygen atoms. In the infinite chains $[(\text{UO}_2)(\text{C}_2\text{O}_4)_2]^{2n-}$ one oxalate ligand is coordinated to uranyl via all four oxygen atoms, bridging two uranium centers; the other is bidentate to one uranium atom and unidentate to another.⁸¹⁸

Figure 66 The structure of the complex $\text{Cs}_4\text{UO}_2(\text{C}_2\text{O}_4)_2(\text{SO}_4)$ (Mikhailov, Gorbunova *et al.* *Zhurnal Neorganicheskoi Khimii* **2000**, 45, 1825–1829).

Figure 67 Structure of $[(\text{UO}_2)_2(\text{C}_2\text{O}_4)(\text{SeO}_4)_4]$ (Alcock *J. Chem. Soc., Dalton. Trans.* **1973**, 1614; Mikhailov, Gorbunova *et al. Zhurnal Neorganicheskoi Khimii* **2000**, 45, 1999–2002).

The oxalate groups in the anion of $(\text{NH}_4)_4[\text{UO}_2(\text{C}_2\text{O}_4)_3]$ are all bidentate, giving rise to distorted hexagonal bipyramidal coordination geometry,⁸¹⁸ whereas in the polymeric anion of $(\text{NH}_4)_4[(\text{UO}_2)_2(\text{C}_2\text{O}_4)_3]$ the coordination geometry is pentagonal bipyramidal, with one quadridentate C_2O_4 group coordinated to two uranium atoms and the other bidentate to one and unidentate to a second uranium atom, forming infinite double chains $[(\text{C}_2\text{O}_4)\text{UO}_2(\text{C}_2\text{O}_4)\text{UO}_2(\text{C}_2\text{O}_4)]_n^{2n-1}$.⁸¹⁸ In $\text{K}_6[(\text{UO}_2)_2(\text{C}_2\text{O}_4)_5] \cdot \text{H}_2\text{O}$, the coordination geometry is again pentagonal bipyramidal, with two oxygen atoms each from two bidentate C_2O_4 groups and one from the bridging C_2O_4 group in the equatorial plane.⁸²⁰

A single crystal X-ray diffraction study of a mixed-ligand uranyl complex with a bidentate carbonate group has been reported. The complex $(\text{C}_2\text{N}_2\text{H}_{10})_2[(\text{UO}_2)_2(\text{CO}_3)(\text{C}_2\text{O}_4)_2(\text{C}_3\text{H}_4\text{N}_2\text{O}_2)] \cdot \text{H}_2\text{O}$ has been prepared by reacting $[\text{UO}_2(\text{C}_2\text{O}_4)(\text{H}_2\text{O})]^-$ ion with α -dioxime in the presence of carbonate. The uranyl moieties in the dimer have a coordination number of eight and are characterized by the presence of one three-membered, one four-membered, and one five-membered chelate ring in the equatorial plane (see Figure 68).^{808,821,822}

Figure 68 Structure of $(\text{C}_2\text{N}_2\text{H}_{10})_2[(\text{UO}_2)_2(\text{CO}_3)(\text{C}_2\text{O}_4)_2(\text{C}_3\text{H}_4\text{N}_2\text{O}_2)] \cdot \text{H}_2\text{O}$ (Beirakhov, Orlova *et al. Zh. Neorg. Khim.* **1998**, 44, 1414–1419).

A number of basic oxalates, such as $(\text{UO}_2)_2\text{C}_2\text{O}_4(\text{OH})_2 \cdot 2\text{H}_2\text{O}$, and salts of basic oxalato complex ions of the types $\text{M}_3^{\text{I}}\text{UO}_2(\text{C}_2\text{O}_4)_2(\text{OH})$ and $\text{M}_5^{\text{I}}(\text{UO}_2)_2(\text{C}_2\text{O}_4)_4(\text{OH})$ have also been reported, as well as salts of a wide range of peroxo-, halogeno-, sulfato-, selenito-, selenato-, thiocyanato-, and carbonato-oxalato complex anions. Only the preparation and stoichiometries of these complexes have been reported.

β -Diketones. In a few cases, the β -diketone has been reported to act as a neutral ligand to the uranyl ion, but by far the most common type of compound is UO_2L_2 , where L is the deprotonated β -diketonate ligand. Many members of this class of compounds have been characterized with a range of substituents. In addition, a number of mixed ligand complexes have been reported, such as the mixed halide species $[\text{UO}_2(\text{CH}_3\text{-COCHCOCH}_3)\text{F}(\text{H}_2\text{O})_2] \cdot 3\text{H}_2\text{O}$ and $\text{K}_2[\text{UO}_2(\text{CH}_3\text{COCHCOCH}_3)\text{F}_3]$.⁸²³

The extraction of U^{VI} by a synergistic mixture of 2-thenoyltrifluoroacetone (HTTA) and tributylphosphate (TBP) from nitric acid media into benzene has been studied. Previous literature reports have described the synergistically extracted species as $\text{UO}_2(\text{NO}_3)(\text{TTA}) \cdot \text{TBP}$. However, Patil *et al.*⁸²⁴ have used extraction studies to show that the nitrate anion is not present in the extracted complex. Rather, the only species involved in the synergistic extraction is $\text{UO}_2(\text{TTA})_2 \cdot \text{TBP}$.⁸²⁴

HTTA has been shown to extract tri- and tetravalent actinides with crown ethers as synergists according to a "size-fitting" effect. The first crystal structures of UO_2^{2+} with HTTA and two different crown ethers have been reported: $[\text{UO}_2(\text{TTA})_2\text{H}_2\text{O}]_2(\text{benzo-15-crown-5})$ and $[\text{UO}_2(\text{TTA})_2(\mu\text{-H}_2\text{O})]_2(\text{H}_2\text{O})_2(\text{dibenzo-18-crown-6})$.

Both compounds were formed by the reaction of $[\text{UO}_2(\text{TTA})_2 \cdot 2\text{H}_2\text{O}]$ with either benzo-15-crown-5 or dibenzo-18-crown-6 in chloroform. In the stable benzo-15-crown-5 structure, two $[\text{UO}_2(\text{TTA})_2 \cdot \text{H}_2\text{O}]$ units are coordinated to the crown ether via bridging due to the hydrogen bonding interaction of the hydrogen on a water molecule and various crown ether oxygens. Interestingly, no direct crown ether/uranyl coordination exists in the molecule; rather the hexavalent uranium atom is surrounded by seven oxygen atoms (four from two TTA ligands, one from water, and the two axial uranyl oxygens) to give pentagonal bipyramidal geometry.

In the dibenzo-18-crown-6 complex, a $[\text{UO}_2(\text{TTA})_2 \cdot \text{H}_2\text{O}]$ group has the uranyl bound to two TTA units and a water molecule, once again giving pentagonal bipyramidal geometry around the uranium. Two of these seven-coordinate units form hydrogen bonded dimers via one hydrogen from the water molecule and the uranyl oxygen to give the $[\text{UO}_2(\text{TTA})_2(\mu\text{-H}_2\text{O})]_2$ complex. The other hydrogen from the water molecule is hydrogen bonded to a second water molecule (second coordination sphere), which is in turn weakly coordinated to two crown ether oxygen atoms (third coordination sphere).⁸²⁵

Bis(1-phenyl-3-methyl-4-acylpyrazol-5-one) derivatives of the type H_2BP_n , where n equals 3, 4, 5, 6, 7, 8, 10, and 22, will also extract the hexavalent actinide UO_2^{2+} from both perchlorate and nitrate media into chloroform. As with all other actinide ions, H_2BP_n extracted better than HPBP and the highest extractability occurred with the H_2BP_7 and H_2BP_8 ligands. The extracted species for the uranyl ion was found to vary according to polymethylene chain length:

The longer chain length extractants form 1:1 complexes, allowing the two bifunctional groups of BP_n to coordinate in a bidentate manner. The shorter chain lengths do not allow a bidentate coordination, thus forcing two ligands to coordinate in a monodentate fashion with the metal.³⁹⁸

3-phenyl-4-acetyl-5-isoxazolone (HPAI) extractant dependency indicates that two HPAI molecules are involved in the extraction of U^{VI} from nitrate media into 4-methyl-2-pentanone in an ionic mechanism. IR spectrophotometric measurements indicate chelate interaction similar to those in Th^{IV} . Deprotonation of the enolic hydroxyl group allows the charged oxygen atoms to chelate with the metal. This is confirmed by shift of the $\text{C}=\text{O}$ stretching frequency in the IR spectrum and the presence of typical $400\text{--}500\text{ cm}^{-1}$ metal/ligand bands, suggesting that the

carbonyl oxygen is involved in the chelation. The lack of features between $3,100\text{ cm}^{-1}$ and $3,600\text{ cm}^{-1}$ confirm that no nitrogen interactions are occurring with the metal. Additionally, there is no coordination of water to the metal complex.³⁹⁹

Amino acids. The interaction of uranyl with a number of amino acids have been investigated, motivated by the interest in *in vivo* actinide chemistry and potential actinide–nucleic acid interactions. Most of the investigations focused on the determination of the stability constants of the resulting complexes. The nature of amino acid structures suggests potentially strong bond formation between uranyl and carboxylate oxygens. A stronger binding of Th^{4+} over UO_2^{2+} is expected. Most of the reports have investigated the aqueous formation of the Th^{4+} and UO_2^{2+} complexes by addition of the amino acid to a solution of the metal ion prepared from its most soluble salts (e.g., $\text{UO}_2(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$). Potentiometric, spectrophotometric titrations, calorimetry and polarography techniques have been applied.

Uranyl forms 1:1 complexes with amino acids in acidic aqueous solution. Complexes of up to a 1:3 U:amino acid ratio may form, when the amino acid is not sterically limited and can form favorable chelate rings. The complexes generally have a hexagonal bipyramidal structure, in which dioxo uranyl is perpendicular to the equatorial plane that contains bidentate coordinated carboxylates (Figure 69).⁸²⁶ Complexes of UO_2^{2+} , and Th^{4+} with the α -amino acids (H_2L) serine, cysteine, methionine, threonine, substituted glycines,^{827,828} succinate, aspartate, glutamate,⁸²⁹ glycylglycine, L(+)-asparagines, D,L- β -phenylalanine, D,L- α -alanine, and α -amino isobutyric acid,⁸³⁰ alanine, phenylalanine, valine, leucine, and isoleucine⁸²⁷ have been reported. Most of those complexes contain the amino acids in the zwitterionic form binding the metal through the ionized carboxyl group. Amino acids like L-serine and L-threonine which have carboxyl, hydroxy, and amino groups have a potential to bind uranyl in a tridentate fashion; however, mostly bidentate carboxylate binding has been observed. The exception is the uranyl complex with 4-amino-3-hydroxybutyric acid in which the hydroxy group is on the fourth carbon, making it possible to form two chelate rings, one involving both the carboxylate and the hydroxy groups.⁸³¹

Mixed ligand uranyl amino acid complexes, containing malonic, diglycolic, glutaric, maleic, glycolic thioglycolic acids, and the simple amino acids β -alanine and glycine have been reported. These complexes are prepared by addition of the ligand to solutions containing 1:1 β -alanine- UO_2 complex.⁸³² The synthesis of mixed ligand fluoro complexes of the type $\text{A}_3[\text{UO}_2(\text{R})_2\text{F}_5] \cdot n\text{H}_2\text{O}$ [$n = 2$ or 3 , $\text{A} = \text{K}$ or NH_4^+ , $\text{R} = \text{glycine, alanine, cysteine}$] have been reported. The complexes were characterized by a combination of chemical analysis, solution conductance measurements, and spectroscopic studies. The complexation of uranyl by glycine and alanine occurs in the zwitterionic form of the amino acid; whereas, cysteine is reported to be present as a uninegative ligand. In all of these mixed-ligand complexes the amino acids bind uranyl in unidentate fashion through one carboxylate oxygen atom.⁸²³

CMPO. As with tetravalent actinides, CMPO has the ability to strongly extract hexavalent actinides along with trivalent americium. Extractant dependency studies from hydrochloric and

Figure 69 Molecular structure of $[\text{UO}_2(\gamma\text{-aminobutanoic acid})_3](\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}[\text{UO}_2(\text{L}')_3](\text{NO}_3)_2 \cdot \text{H}_2\text{O}$ (Bismondo, Casellato *et al. Inorganica Chimica Acta* **1985**, 110, 205–210).

nitric acid solutions show a 2:1 coordination stoichiometry for the CMPO–uranyl extracted species:

It is assumed CMPO coordination with uranyl is the same as that for the trivalent and tetravalent actinides. Monodentate coordination occurs via the phosphoryl oxygen for the nitrate complexes and bidentate coordination occurs through both the phosphoryl and carbonyl oxygen atoms for the chloride complex, leading to a coordination number of eight for both kinds of complexes.⁴⁰⁷

A crystal structure of a UO_2^{2+} complex with octyl(phenyl)-*N,N*-diisobutylcarbamoylmethylphosphine oxide and nitrate has been reported (see Figure 70).¹⁰¹⁵ The stoichiometry of the complex is $\text{UO}_2(\text{NO}_3)_2 \cdot \text{CMPO}$ and shows bidentate coordination through both the phosphoryl and carbonyl oxygen atoms on CMPO. While it is difficult to compare species in solution with those observed in the solid state, the structure is interesting since it shows a 1:1 complex of CMPO and uranyl, as well as bidentate CMPO coordination in a nitrate complex. This is in contrast to the solution-phase complex proposed by Horwitz and co-workers in 1987.⁴⁰⁷

Diamides. Studies on the complexation of the uranyl (UO_2^{2+}) ion with amide-based extractants are very common in the literature. Malonamides, in general, are very effective extractants for U^{VI} . The extraction of U^{VI} by the malonamide, *N,N'*-dimethyl-*N,N'*-dibutyltetradecylmalonamide (DMDBDTMA), has been characterized to gain useful insights into metal/diamide complexation. UV–vis analysis indicates only one extracted, nonacidic species in the complexation of uranyl with DMDBDTMA as shown in Equation (62). UV–vis and IR spectra indicate that the source of nitrate in the complex is from nitrate salt rather than the nitric acid. As in the Pu^{IV} system, the position of the nitrate bands in IR spectroscopy indicates a C_{2v} geometry. The malonamide extracted species are nonionic in contrast to monoamide counterparts where ion-pairs are common at high acidities:⁴²²

The extraction of U^{VI} in HNO_3 into toluene by *N,N,N',N'*-tetrabutylmalonamide (TBMA) indicates a 3:1 ligand/metal coordination in the extracted species. IR stretching frequencies at $1,606 \text{ cm}^{-1}$ and $1,574 \text{ cm}^{-1}$ indicate the bidentate nature of the malonamide ligand, and the absence frequencies at 746 cm^{-1} , $1,031 \text{ cm}^{-1}$, and $1,267 \text{ cm}^{-1}$ indicate that the nitrate anion is not directly coordinated to the uranyl ion.⁸³³

A crystal structure of a $\text{UO}_2^{2+}/\text{NO}_3/\text{malonamide}$ complex has been reported by Lumetta *et al.*⁸³⁴ Uranyl nitrate has been crystallized with *N,N,N',N'*-tetramethylmalonamide (TMMA)

Figure 70 Crystal structure of $\text{UO}_2(\text{NO}_3)_2(\text{C}_{24}\text{H}_{42}\text{PO}_2\text{N})$ (Cherfa, Pécaut *et al.* *Z. Kristallogr.-New Crys. Struct.* **1999**, 214, 523–525).

Figure 71 Crystal structure of $\text{UO}_2(\text{NO}_3)_2(\text{C}_7\text{H}_{14}\text{N}_2\text{O}_2)$ (Lumetta, McNamara *et al. Inorganica Chimica Acta* **2000**, 309, 103–108).

acting as a bidentate ligand through both carbonyl oxygens, giving the formula $\text{UO}_2(\text{NO}_3)_2(\text{TMMA})$ (see Figure 71). The nitrate groups are bidentate, and the nitrate malonamide ligands all coordinate equatorially to the linear uranyl fragment, giving the hexagonal bipyramidal geometry.⁸³⁴

The oxygen-containing diglycolamides, DMDHOPDA and DHOPDA, as well as the sulfur containing ones, DMDHTPDA and DHTPDA, are all very effective U^{VI} extractants when synergistically combined with thenoyltrifluoroacetone (HTTA). The stoichiometry for the extraction by all four diglycolamides (L) can be described by Equation (63). All four ligands probably serve as bidentate β -diketonate groups in the extracted species:^{397,426}

Adipicamides, like malonamides, are diamides with a butylene group bridging the carbonyl groups of the amides (see Figure 72). *N,N,N',N'*-tetrabutyladipicamide (TBAA) was shown to extract U^{VI} and Th^{IV} from nitric acid, where U^{VI} extraction decreases at high acid concentrations due to proton/metal competition for the TBAA coordination site. The extracted complex as determined by the slope in an extraction dependence is suggested to be $\text{UO}_2(\text{NO}_3)_2 \cdot \text{TBAA}$.⁸³⁵

Diphosphonic acids. *P,P'*-di(2-ethylhexyl) methanediphosphonic acid ($\text{H}_2\text{DEH}[\text{MDP}]$) is effective at extracting hexavalent actinides such as U^{VI} from *o*-xylene. Similar to Th^{IV} , extraction of U^{VI} shows minimal acid dependency due to the competition between the metal and nitric acid for the binding site. Extractant dependency studies for U^{VI} show interesting behavior at low acid concentrations where no extractant dependency is observed, possibly due to the coexistence of species having differing stoichiometries, protonation, and aqueous stabilities which have not been characterized.⁴¹⁸

The extraction of $\text{U}(\text{VI})$ into oxylene by *P,P'*-di(2-ethylhexyl) ethanediphosphonic acid ($\text{H}_2\text{DEH}[\text{EDP}]$) is slightly more efficient than the methylene counterpart while showing no acid dependency. Extractant dependency analysis indicates a complexation equilibrium that is more complicated than $\text{Am}(\text{III})$, although it is believed that both occur via a similar mechanism under some experimental conditions: the hydrated $\text{U}(\text{VI})$ metal is transferred into the cavity of an aggregated micelle with release of H^+ ions.⁴¹⁹

Figure 72 General diagram of an adipicamide.

With *P,P'*-di(2-ethylhexyl) butanediphosphonic acid ($\text{H}_2\text{DEH}[\text{BuDP}]$), U(VI) data analysis points to the formation of two separate extracted complexes with different stoichiometries whose mechanisms are not consistent with extraction via a micelle mechanism.⁴²⁰

Similar extractions using $\text{H}_2\text{DEH}[\text{MDP}]$, $\text{H}_2\text{DEH}[\text{EDP}]$, and $\text{H}_2\text{DEH}[\text{BuDP}]$ in 1-decanol show differences in the distribution ratios due to the depolymerizing nature of the solvent, causing the extractants to exist as monomers in solution. Extractant dependency studies yield a slope of nearly two for the U^{VI} ion, suggesting that $\text{UO}_2\text{L}\cdot\text{H}_2\text{L}$ or $\text{UO}_2(\text{HL})_2$ species are present, where L refers to the doubly deprotonated acid. However, the lower value of 1.5 for the $\text{H}_2\text{DEH}[\text{MDP}]$ slope indicates that $\text{UO}_2\text{NO}_3(\text{HL})\cdot\text{H}_2\text{L}$ may also be present in the organic phase.⁴²⁰

Polyoxometalates. Complexation of higher valent actinides by polyoxometalate complexes is weaker than that for tri- and tetravalent cations, due to the low charge and steric constraints imposed by the *trans*-dioxo geometry of the prevalent actinyl geometry (e.g., AnO_2^{2+}). In one study, the stability constants of 1:1 complexes of the uranyl ion with several heteropolymolybdates ($\text{CrMo}_6\text{O}_{24}\text{H}_6^{3-}$, $\text{IMo}_6\text{O}_{24}^{5-}$, $\text{TeMo}_6\text{O}_{24}^{6-}$, and $\text{MnMo}_9\text{O}_{32}^{6-}$) and isopolymetalates ($\text{V}_{10}\text{O}_{28}^{6-}$ and $\text{Mo}_7\text{O}_{24}^{6-}$) were determined; these fell in the range 2–4.⁸³⁷ Conflicting evidence exists for the complexation of uranyl by the Keggin and Dawson ions; some reports suggest stability constants on the order of $\log \beta = 1$,⁸³⁸ while other studies reported no evidence of complexation at lower acid strengths.⁸³⁹ NpO_2^{2+} appears to form weak complexes with $\text{P}_2\text{W}_{17}\text{O}_{61}^{10-}$, except in higher ionic strength solutions.⁵⁸²

Other. The complex $[\text{Pt}_2(\text{PPh}_3)_4(\mu^3\text{-S})_2\text{UO}_2(\eta^2\text{-NO}_3)_2]$ was prepared by direct reaction of the constituent metal species;⁸⁴⁰ the molecular structure has been determined.

(ii) Schiff base ligands

The most commonly used actinide in Schiff base coordination studies is the uranyl ion. Many comprehensive reviews pulling together numerous examples of U^{VI} (primarily) coordination with these ligands have been published and the reader is referred to these for a more thorough discussion.^{456,841–843} A few current representative examples will be presented here.

Recently, the novel design of compartmental Schiff bases has led to the incorporation of crown ether moieties into the macrocyclic structure. One such ligand containing an N_3O_2 Schiff base and a O_2O_n ($n = 3$ [$\text{H}_2\text{L}_\text{A}$] or 4 [$\text{H}_2\text{L}_\text{B}$]) crown-ether functionality (see Figure 73) have been used to

Figure 73 Diagram of compartmental Schiff base ligand ($n = 1$ or 2).

complex U^{VI} . The bi-compartmental nature of this ligand allows for metal ion recognition and complexation at two independent sites within the molecule.

Previous studies have shown that the compartments are very selective for certain metal ions, with alkaline earth metals and 4f-metals preferring the “hard” crown ether-like chamber and transition metals preferring the “soft” Schiff base chamber. Due to the soft nature of the uranyl ion and its transition metal-like character, it is always observed to prefer coordination to the Schiff base site on the ligand. As a result, uranyl is seven-coordinate in a pentagonal bipyramidal geometry with the three nitrogen and two deprotonated oxygen Schiff base donors. This leaves the potential for the formation of heterodinuclear complexes with metal ions occupying the crown ether-like chamber.

While many Schiff bases are known to contain mixed nitrogen and oxygen donors, pure nitrogen donor ligands are also known such as the pyrrole-derived ligands, three of which are illustrated in Figure 74. Each of the three ligands coordinates with the uranyl ion as a hexadentate ligand as indicated by X-ray crystallography (see Figure 75). The complexes of the first two ligands (non-phenyl) are both nonplanar, the second even more so than the first. The third complex with the phenyl-containing ligand is completely planar, probably due to the steric constraints imposed by the phenyl rings. While changes in the ring size and shape cause distinct changes in the overall geometry of the complex itself, it has little influence on the inner-sphere coordination adopted by the uranyl ion. In all three cases, the uranium atom adopts nearly ideal hexagonal bipyramidal geometry via coordination with all six equatorial nitrogen atoms. In complexes with the first two ligands, the $U-N_{\text{pyrrole}}$ bond distances are very similar, as are the $U-N_{\text{imine}}$ bond distances. The major difference occurs for the third complex where the $U-N_{\text{pyrrole}}$ and $U-N_{\text{imine}}$ bond lengths are shorter and longer, respectively.⁸⁴⁴

(iii) Macrocyclic ligands

N-Heterocyclic ligands. The oxidized form of [24]hexaphyrin(1.0.1.0.0.0) was created when exposed to uranium(VI), and formed a [22]hexaphyrin(1.0.1.0.0.0)/ UO_2^{+2} inclusion complex. The crystal structure, as solved by X-ray single crystal diffraction, is shown in Figure 76. The nitrogen atoms from the porphyrin have some deviation from the least squares plane. This gives a slightly disordered hexagonal bipyramidal with the oxo ligands *trans* to one another.⁵⁸⁴

Calixarenes. Calixarenes are macrocyclic donor ligands that have the ability to bind with a wide range of metal ions, including actinides, due to the synthesis and availability of a series of various ring sizes. The most basic structure of a calixarene is a cyclic arrangement of phenol units linked by methylene groups, where the phenols can act as anionic ligands for the actinide center. A generalized example of a calix[4]arene ligand is shown in Figure 77.

Figure 74 Diagrams of pyrrole-derived Schiff bases.

Figure 75 Crystal structure of $\text{UO}_2(\text{C}_{24}\text{H}_{32}\text{N}_6)$ (Sessler, Mody *et al.* *Inorganica Chimica Acta* **1996**, 246, 23–30).

Figure 76 Crystal structure of $\text{UO}_2(\text{C}_{44}\text{H}_{51}\text{N}_6)$ (Sessler, Seidel *et al.* *Angew. Chem., Int. Ed., Engl.* **2001**, 40, 591–594).

Figure 77 General diagram of a calixarene.

Oxa-calixarenes have $-\text{CH}_2\text{O}-\text{H}_2\text{C}-$ units replacing the methylene bridges connecting phenol groups. Aza- and thia- crown derivatives, with nitrogen and sulfur replacing the oxygens, are also common. A recent review by Thuéry *et al.*⁸⁴⁵ gives an in-depth analysis of the coordination chemistry of phenolic calixarenes. As of 2003, the only actinides whose coordination with calixarenes has been observed or investigated are U^{V} and U^{VI} , with only a single known example of Th^{IV} . All complexation of calixarenes with actinides is known to occur only via the phenolic

oxygen atoms, with the common mode for UO_2^{2+} being through four deprotonated phenolic-OH groups, yielding an anionic complex. However, U^{VI} is known to accept as few as three donors and as many as five, but never six, in its complexation with calixarenes. In bonding to any metal, including actinides, calixarene coordination is controlled by the number and geometry of the donor oxygen atoms in the macrocyclic ring.

Basic calixarenes of the type calix[n]arene have been complexed with U^{VI} with n ranging from 3 to 9, including 12, and can be either inclusion complexes or exclusion complexes (see Table 47). Inclusion complex have three or more phenolic-oxygen bonds with the uranium, essentially enclosing the metal entirely, and the exclusion complexes have three or less, leading to a less than perfect encircling of the metal.⁸⁴⁵

While calixarenes have great potential as being extractants for actinides, particularly in the hexavalent state, most of their coordination chemistry is known by isolation and structural characterization of discrete complexes. The compound *p-t*-butylhexahomotriooxacalix[3]arene forms a complex with the uranyl ion to generate an unusually low coordination number. Two similar complexes were obtained: $[(\text{UO}_2^{2+})(\text{L}^{3-})(\text{HNet}_3^+)] \cdot 3\text{H}_2\text{O}$ and $[(\text{UO}_2^{2+})(\text{L}_3^-)(\text{HDABCO}^+)] \cdot 3\text{CH}_3\text{OH}$, where HL_3 is the calixarene and DABCO is diazabicyclo[2.2.2]octane. A crystal structure of $[(\text{UO}_2^{2+})(\text{L}^{3-})(\text{HNet}_3^+)] \cdot 3\text{H}_2\text{O}$ is shown in Figure 78. The linear uranyl fragment is coordinated to all three deprotonated phenolic-oxygen atoms in its equatorial plane and is at the center of the calixarene. The ether oxygens do not participate in bonding, which is the case for nearly all calixarene/actinide complexes. The uranyl is not completely co-planar with its three bound oxygens and adopts a pseudotrigonal coordination geometry. The entire calixarene ligand adopts a “cone-like” conformation around the metal.⁸⁴⁶

The first reported crystal structure of a calixarene/actinide complex was that of the bis(homo-oxa)-*p-t*-butylcalix[4]arene ligand coordinated with the uranyl ion.⁸⁴⁷ The uranyl ion forms a 1:1 inclusion complex with the calixarene, unsymmetrically binding the ligand via the four phenolic-oxygen atoms, giving a chemical formula of $[(\text{UO}_2^{2+})(\text{L}^{4-})(\text{HNet}_3^+)_2] \cdot 2\text{H}_2\text{O}$, where H_4L is the calixarene ligand. The interaction of the metal with the etherial oxygen is weak, if at all present, due to the lone pair of electrons pointing away from the uranium. As with other calixarenes, the geometry of the ligand itself is cone-shaped around the metal.⁸⁴⁸

p-t-Butylcalix[5]arene bonds with uranyl to give the inclusion complex $[(\text{UO}_2^{2+})(\text{HL}^{4-})(\text{HNet}_3^+)_2] \cdot 2\text{MeOH}$, where H_5L is the neutral form of the ligand. The linear uranyl fragment sits in the cavity of the calixarene ring and bonds equatorially with the five phenolic oxygens, four of which are in their anionic forms from deprotonation. U—O bond lengths for three of the five bonds fall between 2.25 Å and 3.30 Å, with the fourth and fifth being significantly longer at 2.571(7) Å and 2.836(8) Å. The bonding environment around the uranium from the phenolic oxygens is a pentagonal one, with an overall configuration of pentagonal bipyramidal. From a side profile, the calixarene takes its usual cone configuration around the metal center (see Figure 79).⁸⁴⁹

p-t-Butylcalix[6]arene complexes with uranyl are unique in that they have not been observed to form inclusion complexes with the metal. Only exclusion complexes are observed with 2:1, 2:2, and 3:3 metal:ligand stoichiometries. Similarly, calix[7]arenes only have the ability to complex with uranyl via one or both of its trimeric or tetrameric subunits.⁸⁵⁰

Table 47 Coordination geometry of various uranyl calixarene complexes.^a

Ligand	Coordination of complex
Hexahomotriooxacalix[3]arene	Pseudo-trigonal
Calix[4]arene	No “internal” complex formed
Dihomooxacalix[4]arene	Square planar
Tetrahomodioxacalix[4]arene	Square planar
Octahomotetraoxacalix[4]arene	Pentagonal
Calix[5]arene	Pentagonal
Calix[6]arene	No “internal” complex formed
Tetrahomodioxacalix[6]arene	Square planar
Calix[7]arene	Square planar; direct UO_2^{2+} — UO_2^{2+} bonding
Calix[8]arene	Pentagonal
Octahomotetraoxacalix[8]arene	Pentagonal
Calix[9]arene	Pentagonal
Calix[12]arene	Pentagonal; two dimers

^a Table taken from Thuéry, P.; Nierlich, M.; Vicens, J.; Masci, B. *J. Chem. Soc., Dalton Trans.*, **2001**, 867–874.

Figure 78 Crystal structure of $[(\text{UO}_2)(\text{C}_{36}\text{H}_{45}\text{O}_6)(\text{HN}(\text{C}_2\text{H}_5)_3)] \cdot 3\text{H}_2\text{O}$ (Thuéry, Nierlich *et al. J. Chem. Soc., Dalton Trans.* **1999**, 3151–3152).

Figure 79 Crystal structure of $[(\text{UO}_2)(\text{C}_{55}\text{H}_{66}\text{O}_5)](\text{HN}(\text{C}_2\text{H}_5)_3)_2 \cdot (\text{CH}_3\text{OH})_2$ (Thuéry, P. and Nierlich, M. *J. Incl. Phenom. Mol. Recogn. Chem.* **1997**, 27, 13).

A bimetallic inclusion complex is formed when $\text{UO}_2(\text{NO}_3)_2$ reacts with *p-t*-butylcalix[8]arene. The resulting complex stoichiometry is $[(\text{UO}_2^{2+})_2(\text{H}_4\text{L}^{4-})(\text{OH}^-)]^- \cdot 2\text{HNEt}_3^+ \cdot \text{OH}^- \cdot 2\text{NEt}_3 \cdot 3\text{H}_2\text{O} \cdot 4\text{-CH}_3\text{CN}$ where the fully protonated ligand is given by H_8L . Two linear UO_2^{2+} fragments lie within the calixarene ring and each are equatorially bonded to four phenolic oxygens, only two of which remain protonated. A bridging OH^- group gives each uranyl ion a distorted pentagonal arrangement with the bonded oxygens, typical for uranyl coordination. The uranium adopts a pentagonal bipyramidal arrangement, slightly distorted due to the equatorial environment being slightly nonplanar as seen in Figure 80. U—O bond lengths are observed to vary with the protonation, or lack thereof, of the oxygen.⁸⁵¹

The largest calixarene that has been used in complexation with UO_2^{2+} is *t*-butylcalix[12]arene. Two bimetallic uranyl units (four uranyl groups) are enclosed within the ring, giving it a stoichiometry of $[\text{HNEt}_3]_2\{[(\text{UO}_2^{2+})_2(\text{NO}_3)_2(\text{py})]_2(\text{H}_4\text{L})\}$, where H_4L^{8-} is the deprotonated form of the ligand. The bimetallic uranyl units are assembled with bridging nitrate anions. Each bimetallic array has both uranium atoms bound to five phenolic oxygens, four of which are in a deprotonated form. The remaining two phenols in the calixarene are unbound. In each bimetallic unit, one uranium is bound to three phenolic oxygens and the other uranium bound to two, with the third coordination site being occupied by a pyridine molecule. The resulting geometry around the uranyl is a pentagonal arrangement as illustrated in Figure 81.⁸⁵²

Crown ethers. U^{VI} -crown ether chemistry has been extensively studied due to the wide variety of complexes that can be formed. Uranyl can form both inclusion and exclusion complexes with both hetero- and homocrown ethers. Exclusion complexes can form bonds to other metals in the crown ether cavity directly or via hydrogen bonds to crown ether oxygens. The nature of complexation is dependent on the chemical environment.

Both EXAFS spectroscopy and X-ray single crystal diffraction have been used to study uranyl complexes with 18-crown-6 and dicyclohexyl-18-crown-6 (dch-18-crown-6) in the presence of the

Figure 80 Crystal structure of $(\text{HN}(\text{C}_2\text{H}_5)_3)_2[(\text{UO}_2)_2(\text{C}_{88}\text{H}_{108}\text{O}_8)(\text{OH})] \cdot (\text{N}(\text{C}_2\text{H}_5)_3)_2 \cdot (\text{H}_2\text{O})_3 \cdot (\text{CH}_3\text{CN})_4$ and of the calixarene ligand with the metal complex removed for clarity (Thuéry, Keller *et al. Acta Crystallogr., Section C* **1995**, C51, 1570–1574).

Figure 81 Crystal structure of $[\text{HN}(\text{C}_2\text{H}_5)_3]_2\{[(\text{UO}_2)_2(\text{NO}_3)(\text{C}_5\text{H}_5\text{N})](\text{C}_{132}\text{H}_{152}\text{O}_{12})\}$ and of the ligand with the uranium complexes removed (Leverd, Dumazet-Bonnamour *et al. Chem. Commun.* **2000**, 493–494).

trifluoromethanesulfonate (OTf^-) anion. The EXAFS data was collected using the uranium L_{III} absorption edge in both solution and solid state for $\text{UO}_2(18\text{-crown-6})(\text{OTf})_2$ and $\text{UO}_2(\text{dch-18-crown-6})(\text{OTf})_2$. A comparison of EXAFS and X-ray diffraction models is provided in Table 48. It can be concluded from the data that the coordination in the solid state is probably very similar to coordination in solution. Both techniques are consistent with proposed hexagonal bipyramidal coordination geometry around the uranium. No significant deviations are observed in the planarity of the equatorial coordination region, indicating a nearly ideal geometry (Figure 82). Deviations from ideality are indicated by the sum of the O—U—O bond angles (ideal 360°); in $\text{UO}_2(18\text{-crown-6})$ the sum is 363.3° while in the $\text{UO}_2(\text{dch-18-crown-6})$ the sum is 366.8° .⁸⁵³

Table 48 A comparison of EXAFS and X-ray diffraction data showing distance(*R*) to nearest neighbors (Peshayes, Keller *et al. Polyhedron*, **1994**, 13, 1725).

Complex		R_{EXAFS} (Å)		$R_{\text{X-ray}}$
		Solution	Solid	Solid
$\text{UO}_2(18\text{-crown-6})(\text{OTf})_2$	U—O_{ax}	1.77	1.77	1.64(5)
	U—O_{eq}	2.58	2.57	2.50(5)
	U—C_{eq}	3.49	3.45	3.49(8)
$\text{UO}_2(\text{dch-18-crown-6})(\text{Tf})_2$	U—O_{ax}	1.77	1.76	1.78(5)
	U—O_{eq}	2.59	2.63	2.58(8)
	U—C_{eq}	3.49	3.53	3.47(9)

Figure 82 Crystal structure of $[\text{UO}_2(\text{C}_{12}\text{H}_{24}\text{O}_6)] \cdot (\text{CF}_3\text{SO}_3)_2$ (Deshayes, Keller *et al. Polyhedron* **1994**, 13, 1725).

Azacrowns have been studied as possible extractants for the uranyl cation. Complexation of actinyls by azacrowns (possessing slightly softer nitrogen donor atoms) is less favored than the harder oxygen donors of traditional crown ethers. Crowns can be completely substituted, as in 18-azacrown-6, or only partly substituted as in diaza-18-crown-6. While substitution of a softer donor atom does effect the strength of the ligand, the presence of a weakly-complexing anion such as OTf^- offers limited competition for complexation to the uranyl. The coordination environment is not affected by the presence of nitrogen donors; the uranyl still adopts a hexagonal bipyramidal coordination geometry. The nitrogen donors also tend to effect the planarity of the equatorial region of a complex. In the $\text{UO}_2(\text{diaza-18-crown-6})$, the sum of the equatorial donor angles is 361.2° ; this represents the closest geometry to ideality of any of the substituted or unsubstituted 18-crown-6 ligands. The complex $\text{UO}_2(18\text{-azacrown-6})$ has the greatest deviation with a donor angle sum of 378.8° .^{854,855}

Uranium(VI)/crown ether complexes can form polymeric chains in the presence of anions such as sulfate. Each uranyl is bound to two water molecules and one oxygen from three different sulfate anions. Each sulfate anion therefore serves as a μ^3 -bridging ligand to three uraniums. The crown ethers are not complexed to the polymer chain but instead surround it in a sheet-like fashion. An example of this polymeric network with 12-crown-4 can be seen in Figure 83. The inorganic polymer chains are separated from each other by the formation of an organic crown ether layer, resulting in organic/inorganic layering. Hydrogen bonding occurs between each crown ether and an adjacent water molecule to form the organic layer; this water in turn hydrogen bonds to the inorganic chain.

The complex $[\text{UO}_2(\text{SO}_4)(\text{H}_2\text{O})_2] \cdot 0.5(18\text{-crown-6})$ exhibits another means of forming polymers wherein the uranyl-sulfate bridging forms a zig-zag-like polymeric pattern. For each uranyl unit, one of the three equatorial water ligands is hydrogen bonded to two bridging sulfate ions via oxygen atoms on the sulfate. The remaining two water molecules are hydrogen bonded to uncomplexed 18-crown-6 molecules. These crown ethers exist on both sides of the polymer in an alternating fashion.

The complex $[(\text{H}_3\text{O})(18\text{-crown-6})]_2[(\text{UO}_2(\text{NO}_3)_2)_2\text{C}_2\text{O}_4]$ consists of stacked $[(\text{UO}_2(\text{NO}_3)_2)_2\text{C}_2\text{O}_4]^{2-}$ anions surrounded by stacked $[(\text{H}_3\text{O})(18\text{-crown-6})]^+$ cations. In the anions,

Figure 83 Crystal structure of $\{[\text{UO}_2(\text{SO}_4)(\text{H}_2\text{O})_2] \cdot 0.5(\text{C}_8\text{H}_{16}\text{O}_4)(\text{H}_2\text{O})\}_n$ depicting the coordination of the U^{VI} in a sulfate polymeric chain (Rogers, Bond *et al. Inorg. Chem.* **1991**, 30, 2671).

two bidentate nitrate ions coordinate to a single uranyl and two of these uranyl/nitrate units are bridged by an oxalate moiety where two oxygens are bound to each uranyl. This arrangement creates a hexagonal bipyramidal geometry around each uranium. In the cation, the hydronium ion sits in the cavity of the crown ether.⁸⁵⁶

Polymeric and bridged complexes are not the only form of exclusionary crown complexes with uranyl. In complexes of the uranate ions $\text{UO}_2\text{X}_4^{2-}$ (where $\text{X} = \text{Cl}$ or Br), sandwiching of the metal unit between crown ether-complexed counterions can occur. In cationic 12-crown-4 complexes with lithium, 15-crown-5 complexes with sodium, and 18-crown-6 complexes with potassium, the negatively charged uranyl complex will bridge between two crown ether/group 1 metal cations. The uranium center in these complexes lies in a pseudooctahedral coordination environment. Structures differ in the nature of the alkali metal-uranium bridging groups. In some cases, the two metal centers are bridged by two halide ligands as seen in Figure 84. In this structure, the two equatorial bromides bond to the potassium in an 18-crown-6/potassium complex. The uranyl oxo groups remain uncoordinated to the alkali metal. In the $[\text{K}(18\text{-crown-6})]_2[\text{UO}_2\text{Br}_4]$ complex the $\text{O}=\text{U}\cdots\text{K}$ angle is 63° , and 56° in the chloro complex, indicating that actinyl moiety is tilted toward the potassium atoms, possibly to bring the uranyl oxo group into proximity with the acidic alkali metal.

In the complex $[\text{Na}(15\text{-crown-5})]_2[\text{UO}_2\text{Cl}_4]$, some of the “sandwiches” display a comparable geometry, in which the $\text{O}=\text{U}\cdots\text{Na}$ angle is observed to be 87° . A second type of bonding was also observed in this species, however, in which a single chloride coordinates to each sodium atom in the crown ether/sodium complex. The $\text{O}=\text{U}\cdots\text{Na}$ angle is much more acute (31°), with the axial oxygens tilted toward the sodium for a weak interaction. The size of the halide ligand impacts the coordination mode; in the analogous bromide complex the sodium and uranium centers are bridged by one bromide anion and a uranyl oxo group, leaving the other two bromide atoms unbound and a $\text{Br}-\text{U}\cdots\text{Na}$ angle of 90° (see Figure 85). The size of the cation also influences the coordination geometry; in the complex $[\text{Li}(12\text{-crown-2})]_2[\text{UO}_2\text{Cl}_4]$, bridging occurs only via the uranyl oxo groups.⁶⁹¹

Figure 84 Crystal structure of $[\text{K}(\text{C}_{12}\text{H}_{24}\text{O}_6)]_2[\text{UO}_2\text{Br}_4]$ (Danis, Lin *et al. Inorganic Chemistry* **2001**, 40, 3389–3394).

3.3.2.5 Heptavalent Oxidation State

3.3.2.5.1 General characteristics

Heptavalent neptunium and plutonium can be prepared in highly alkaline aqueous media via electrochemical or chemical oxidation of An^{IV} , An^{V} , or An^{VI} species, with Np^{VII} being more easily obtained and isolated than Pu^{VII} .^{857–863} The complexes formed have been characterized in solution primarily by optical absorbance and vibrational spectroscopy, and more recently by NMR and EXAFS, and in the solid state by EXAFS and X-ray diffraction. Most research in this area was conducted at the Russian Academy of Sciences.

3.3.2.5.2 Simple donor ligands

(i) Ligands containing group 16 donor atoms

Hydroxide and aqua complexes. The coordination environment of Np^{VII} in solution remains topical because the species stabilized under highly alkaline conditions could be technologically useful in nuclear waste processing. In addition it provides an opportunity to examine structure/bonding relationships in f^0 systems with unusual coordination geometries. Solution studies report various coordination geometries, including a dioxo moiety coordinated equatorially by hydroxo or aquo ligands,^{858,864} and a square planar tetraoxo complex with two additional axial hydroxo ligands.⁸⁶⁵ The tetraoxo Np^{VII} coordination is common in the solid state. Analogies with other high-valent actinide ions, including An^{VI} species suggest that the hydroxy neptunyl ion $(\text{NpO}_2)(\text{OH})_x(\text{H}_2\text{O})_y$ is the prevalent species in solution. In contrast, the oxo anions of hexa- and heptavalent transition metals exhibit tetrahedral MO_4 coordination. Recent EXAFS and computational studies provide evidence that Np^{VII} has a tetraoxo first coordination sphere, slightly distorted from square-planar geometry, with a $\text{Np}—\text{O}$ bond distance of 1.87 Å, with two hydroxy ligands at a distance of 3.3 Å (see Figure 86). This unusual coordination environment appears to result from a competition for ligand electron density among d - and f -orbitals of various symmetries of the Np atom, with a slight distortion from square-planar-based geometry favored by increased f -orbital participation in bonding with oxygen p -orbitals.^{866,867} Interestingly, the $\text{Np}^{\text{VI}}/\text{Np}^{\text{VII}}$ redox couple is reversible, indicating rapid electron exchange between the two forms. Considering the stoichiometry and conformations of the complexes, slow electron exchange and irreversible electrode potentials may be expected. However, the $\text{NpO}_4(\text{OH})_2^{3-}$ species may be considered a deprotonated form of $\text{NpO}_2(\text{OH})_4^-$; and proton-transfer reactions are often rapid. This reasoning may explain the relative instability of Pu^{VII} species in solution and suggests that dioxo Np^{VII} species may be observed under less basic conditions.⁸⁶⁷

A large number of hydrated solid compounds, such as $\text{M}(\text{NpO}_4) \cdot x\text{H}_2\text{O}$, $\text{M}_3[(\text{NpO}_4)(\text{OH})_2]_2 \cdot x\text{H}_2\text{O}$ or $\text{M}(\text{NpO}_4)(\text{OH})_2 \cdot 5\text{H}_2\text{O}$, have been prepared by oxidation of Np^{VI} followed by precipitation of complex Np^{VII} anions from aqueous alkaline solutions using alkali ($\text{M} = \text{Cs}, \text{K}, \text{Na}, \text{Li}$), alkaline earth ($\text{M} = \text{Ca}, \text{Sr}, \text{Ba}$), or hydrogen-bond donating cations, such as cobalt hexamine and cobalt ethylene diamine. Many of these complexes were initially reported to contain the MO_5^{3-} anion, as in the formulation $\text{K}_3\text{NpO}_5 \cdot x\text{H}_2\text{O}$; however, structural characterization has revealed the coordination geometry of the Np^{VII} to be tetragonal bipyramidal, with two hydroxide ligands in the axial positions, and the formula to be $\text{K}_3(\text{NpO}_4)(\text{OH})_2 \cdot 2.2\text{H}_2\text{O}$.⁸⁶⁸ Single crystal X-ray structures have been determined for compounds such as $\text{Na}_3\text{NpO}_4(\text{OH})_2 \cdot n\text{H}_2\text{O}$ ⁸⁶⁹ and $\text{Co}(\text{NH}_3)_6\text{NpO}_4(\text{OH})_2 \cdot 2\text{H}_2\text{O}$ ^{864,870} which also contain $\text{NpO}_4(\text{OH})_2^{3-}$ in this highly unusual coordination geometry. Crystalline samples of analogous Pu^{VII} compounds

Figure 86 Coordination environment of Np^{VII} in aqueous solution.

Figure 87 Neptunium coordination environment in $\text{Li}[\text{Co}(\text{NH}_3)_6][(\text{Np}_2\text{O}_8)(\text{OH})_2]$.

have been prepared.⁸⁷¹ Similar, nonhydrated Np^{VII} and Pu^{VII} salts can be prepared by heating alkali metal peroxides with Np and Pu dioxides above 250 °C.

The ternary oxides Li_5NpO_6 and Li_5PuO_6 have been obtained by heating the actinide dioxide with lithium oxide in oxygen at ~400 °C.⁸⁷² The AnO_6^{5-} anion appears to be octahedral. The IR spectrum of $\text{Li}_3(\text{NpO}_2)(\text{OH})_6$ has been reported for a sample that was obtained by dissolving $\text{NpO}_2(\text{OH})_3 \cdot 3\text{H}_2\text{O}$ in aqueous lithium hydroxide followed by solvent evaporation. The compound $\text{Li}[\text{Co}(\text{NH}_3)_6][(\text{Np}_2\text{O}_8)(\text{OH})_2] \cdot 2\text{H}_2\text{O}$, was isolated from a lithium hydroxide solution of neptunium-(VII) by adding $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3$. In the structure there are two independent neptunium centers, each coordinated by an octahedron of oxygen atoms; the octahedra share corners to form a chain (see Figure 87).⁸⁷³ A carbonate complex has also been proposed, but not yet characterized.

3.3.2.5.3 Chelating ligands

There is some evidence that $\text{NpO}_4(\text{OH})_2^{3-}$ can be extracted into organic solvents by phenol and pyrazolone ligands that replace hydroxide in the inner coordination sphere. For example, extraction by bis(2-hydroxy-5-octylbenzyl)amine or 2-hydroxy-5-tert-butylphenyl disulfide was confirmed by ^{13}C NMR. Optical absorption data indicated that Np^{VII} reduction to Np^{VI} does occur, but that Np^{VI} is extracted more slowly and with smaller distribution coefficients than is Np^{VII} .^{874,875}

3.3.3 THE LATER ACTINIDE METALS—TRANSPLUTONIUM ELEMENTS

Americium and curium are by far the most studied transplutonium elements, being available in milligram to gram quantities. The inorganic and organic complexes of Am and Cm, in addition to other chemistry of these elements, are described in detail in the element-specific chapters on Am and Cm chemistry by Runde and Schulz¹⁰⁴³ and Lumetta, Thompson, Penneman, and Eller,¹⁰⁴⁴ respectively, in “The Chemistry of the Actinide and Transactinide Elements,” to be published in 2003. A recommended review of the chemical thermodynamic data of Am compounds has been published by the Nuclear Energy Agency and the Organisation for Economic Co-operation and Development.⁸⁷⁶ This reference reports critically evaluated stability constants for most characterized Am solids and solution species (and, by analogy, most expected Cm compounds). Myasoedov and Kremliaikova⁸⁷⁷ have reviewed Russian literature up to the mid-1980s on americium and curium chemistry, including separations.⁸⁷⁷ A subsequent review has described research in this area up to 1994.⁸⁷⁸

The coordination chemistry of the heavier transplutonium elements relevant to separations is often the first type of chemistry examined for these metals. Indeed, a great deal of actinide coordination chemistry was founded in the separations developed in the 1950s and 1960s. For elements prepared an “atom-at-a-time” this information is first used to determine preferred oxidation state(s) and group classification of new heavy and super heavy elements. There are recent reviews that describe this chemistry for transactinides.^{879–882} This approach remains very useful, as demonstrated by recent reports of the chemistry of element 108.⁸⁸³ Being highly radioactive, the elements beyond plutonium have autoradiolytic properties that strongly affects their oxidation state and coordination chemistry, particularly in solution. These reactions and their corresponding rates are well described for the early actinides by Newton.^{884–886}

Most transplutonium chemistry was performed either in initial chemical characterization by groups in the USA and Russia in the 1950s and 1960s or in the continuing effort to develop

lanthanide/actinide and actinide/actinide separations in these countries, as well as in France, India, and Japan. The majority of the coordination chemistry is related to the development and testing of new and improved liquid/liquid extraction processes. Worldwide, aside from purely academic investigations, scientists and engineers are motivated to find new ways to remove minor amounts of neptunium, plutonium, and americium from various stored wastes or reactor fuel so that final disposal is easier and less expensive and so energy production is efficient and economically affordable. In addition, aqueous complexes, such as hydroxides, carbonates, phosphates, and sulfates, are being studied in the context of potential release from nuclear waste and nuclear fuel repositories.

Extraction processes (TRUEX, PUREX, Talspeak, DIAMEX, PARC, etc.) generally involve complexation of transplutonium elements by alkyl phosphines, phosphine oxides, phosphoric acids, carbamoyl phosphonates, diamides, and thiophosphinates in aqueous/organic extractions, within derivatized solid supports, or on coated particles. There are excellent reviews of the processes and significant complexes by Mathur *et al.*⁴⁰⁹ and selected chapters in “The Chemistry of the Actinide and Transactinide Elements” to be published in 2003.^{1043,1044} Work on the separation for nuclear waste management in the United States, France, and Russia have been reviewed.^{887–889}

In the last two decades the coordination chemistry of these elements has benefited greatly from advances in time-resolved laser fluorescence (TRLIFS) and synchrotron-based X-ray absorbance spectroscopies (XANES and XAFS). The advantageous luminescence properties of Am^{III} and Cm^{III} allow the study of dilute solutions ($\sim 10^{-5}$ M for Am and $\sim 10^{-9}$ M for Cm) and complex matrices and require relatively small masses of material.^{890–894} Similarly, EXAFS has been used to study the coordination of americium in organic chelator complexes,⁸⁹⁵ and inorganic complexes with P₅W₃₀O₁₁₀^{15–896} and chloride.⁸⁹⁷

By analogy with lighter actinides and from experimental data, the coordination geometries of transplutonium ions in a range of oxidation states can be generalized. Americium(VI) and (V) generally have coordination numbers ranging from six to nine and most often adopt coordination environments of pentagonal bipyramidal and hexagonal bipyramidal for actinyl species, and cubic, octahedral, square antiprismatic, tricapped trigonal prismatic, or irregular geometries for nonactinyl species. The trivalent and tetravalent transplutonium compounds can have coordination numbers as high as twelve, and the most common regular geometries being octahedral, tricapped trigonal prismatic, and dodecahedral.

3.3.3.1 Divalent Oxidation State (Am, Cm, Cf, Es, Fm, Md, No)

3.3.3.1.1 General characteristics

Of the divalent transplutonium actinides, only Am compounds have been prepared in any significant quantity.

3.3.3.1.2 Simple donor ligands

(i) Ligands containing group 16 donor atoms

Oxides and aqueous. Although AmO has been reported, characterization data are inconsistent. It likely that the monoxide can only be synthesized under high pressure from Am metal and Am₂O₃, in a manner analogous to some lanthanide oxides. Cm^{II} is unknown other than as a transient aqueous species and a species coprecipitated from melts, and possibly in CmO.

(ii) Ligands containing group 17 donor atoms

While solid structures are generally rare for divalent americium compounds, the black halides AmCl₂, AmBr₂,⁸⁹⁸ and AmI₂⁸⁹⁹ have been prepared by reacting metallic americium with the corresponding mercuric halides at 300–400 °C. Interestingly, all three compounds crystallize in different lattices: orthorhombic AmCl₂, tetragonal AmBr₂, and monoclinic AmI₂. Ternary Am^{II} halides may be prepared from americium trihalides with americium metal and lithium metal as reductants.⁹⁰⁰ The californium(II) and einsteinium(II) dihalides have been prepared by hydrogen reduction of the

trihalides at high temperatures. Californium bromide has also been obtained by heating Cf_2O_3 in HBr , and there is also tracer level evidence for the formation of FmCl_2 .

3.3.3.2 Trivalent Oxidation State (Am–Lr)

3.3.3.2.1 General characteristics

The coordination chemistry of trivalent transplutonium elements is very similar to the trivalent lanthanides of similar ionic radii. Coordination numbers of six, and eight to ten, and coordination polyhedra of octahedron, square antiprism, tricapped trigonal prism and mono-capped square anti-prism are common. In agreement with other actinide(III) ions the stability of transplutonium complexes with monovalent inorganic ligands follows the order: $\text{F}^- > \text{H}_2\text{PO}_4^- > \text{SCN}^- > \text{NO}_3^- > \text{Cl}^- > \text{ClO}_4^-$. In some cases, the stability of the trivalent actinide complex is slightly greater than that of the corresponding lanthanide complex, due to a combination of bonding and solvation differences.^{51,901,902} As discussed widely, this difference in stability can be used to effectively separate Am^{III} from lanthanide elements.

3.3.3.2.2 Simple donor ligands

(i) Ligands containing group 15 donor atoms

The Am^{III} thiocyanates have been studied intensively because of the separation of lanthanide and actinide elements in thiocyanate media. Three complexes of general formula $\text{Am}(\text{SCN})_n^{3-n}$ ($n = 1-3$) have been identified from spectroscopic and solvent extraction data.

(ii) Ligands containing group 16 donor atoms

Oxides. Binary oxides of the formula An_2O_3 have been prepared and well characterized for Am, Cm, Bk, and Cf, while the heavier transplutonium oxides have generally only been prepared on the scale of micrograms or less. Three crystal modifications (similar to lanthanides) have been reported for both Am_2O_3 and Cm_2O_3 , two of which have been found for Bk_2O_3 (A and C types) and for Am_2O_3 (A and B types). These oxides are generally prepared by heating oxyanion complex precipitates, such as $\text{An}_2(\text{C}_2\text{O}_4)_3$, or AnO_2 compounds at temperatures greater than 600°C . For both Am and Cm, An_2O_3 transforms to the hexagonal phase at room temperature within about three years due to self-irradiation.⁹⁰³ Additional phases are predicted based on phase diagrams of related lanthanide systems. The ternary oxide LiAmO_2 is obtained by heating AmO_2 with Li_2O in hydrogen at 600°C . Other ternary oxides include $\text{M}(\text{AnO}_2)_2$ ($\text{M} = \text{Sr}$ or Ba) and MAlO_3 , reported for both Am and Cm, and the Cm oxides, $\text{Cm}_2\text{O}_2\text{Sb}$ and $\text{Cm}_2\text{O}_2\text{Bi}$,⁹⁰⁴ BaCmO_3 ,⁹⁰⁵ and Cm_2CuO_4 .⁹⁰⁶ The latter is of interest by its analogy to M_2CuO_4 ($\text{M} = \text{La}$, Pr – Eu), which are parent compounds for high-temperature superconductors. Although Cm_2CuO_4 is isostructural with the M_2CuO_4 ($\text{M} = \text{Pr}$ – Gd) series, its Th-doped analogue is not superconducting, unlike analogous Pr – Eu doped materials.

Hydroxide, aqua, and hydrates. From the similar absorption spectra of Am^{3+} in aqueous solution, AmCl_3 , and in LaCl_3 , and the linear relationship between the decay rate of the americium fluorescence and the number of inner-sphere water molecules, it has been concluded that Am^{III} is coordinated by nine inner-sphere water molecules.^{907–909} Similarly, the hydration number for the Cm^{III} ion has been estimated to be nine on the basis of fluorescence lifetimes.^{910,911} EXAFS studies of aqueous Am^{3+} and Cm^{3+} , however, have suggested coordination numbers closer to 10.⁶⁴ EXAFS investigation of Cf^{3+} in aqueous solution indicates a coordination number of $8.5 (\pm 1.5)$, with a Cf – O distances of $2.41 \pm 0.02 \text{ \AA}$.⁹¹² This coordination number was confirmed for Am in the solid state by isolation of single crystals of the triflate salt of nonaqua complex, which contains a tricapped, trigonal prismatic cation that is isostructural with the analogous Pu^{III} compound.⁶⁹

The trivalent transplutonium ions have stepwise hydrolysis products of the type $\text{An}(\text{OH})_n^{3-n}$, where $n = 1, 2, 3$, with $n = 4$ species postulated for Am^{III} . The Cm species have been studied using

time-resolved laser fluorescence spectroscopy,⁹¹³ the Am species using optical spectroscopy, and the heavier actinide hydroxides less directly using precipitation methods. In the solid state, the trishydroxides, $\text{An}(\text{OH})_3$ (An = Am, Cm, Bk, and Cf) can be prepared by aging aqueous hydroxide precipitates.⁹¹⁴ The Am hydroxide can also be prepared by hydration of Am_2O_3 with steam at 225 °C.⁹¹⁵

Hydrates of the oxoanion and halide complexes are numerous and are mostly isostructural with the hydrated lanthanide chlorides. In the hydrated salicylate, $\text{AmL}_3 \cdot \text{H}_2\text{O}$, one water molecule is in the inner coordination sphere of the Am^{III} cation. The hydrated xenate(VIII), $\text{Am}_4(\text{XeO}_6)_3 \cdot 40\text{H}_2\text{O}$, has also been reported.

Oxoanions. Trivalent transplutonium nitrates can be isolated by evaporation of nitric acid solutions of the ions. For example, curium trinitrate, $^{244}\text{Cm}(\text{NO}_3)_3$, has been characterized. The phosphates are much more numerous and complicated, due to the multiple protonation states of the ligand. The solution complexes, AnHPO_4^+ and $\text{An}(\text{H}_2\text{PO}_4)_n^{3-n}$ ($n = 1-4$) have been used to interpret cation exchange, solvent extraction and spectroscopic data.⁹¹⁶ However, some of those data could be reinterpreted as solvation changes with concomitant changes in ionic strength, and not discrete inner-sphere phosphate complexes. The phosphate solids that have been isolated by precipitation include hydrates, such as $\text{AnPO}_4 \cdot 0.5\text{H}_2\text{O}$ (An = Am, Cm)⁹¹⁷⁻⁹¹⁹ and dehydrated AnPO_4 . For Am^{III} , the anhydrous compound has also been obtained by reacting AmO_2 with stoichiometric amounts of $(\text{NH}_4)_2\text{HPO}_4$ at 600–1000 °C. Hobart *et al.* reported the Raman spectra of the phosphate salts, as well as those of the salts of a number of other oxyanion complexes.⁹²⁰

Sulfate complexes in solution, of the form $\text{An}(\text{SO}_4)_2^{3-2n}$ ($n = 1, 2$) have been reported. These anions can be precipitated as hydrates $\text{An}_2(\text{SO}_4)_3 \cdot 8\text{H}_2\text{O}$ ⁹²¹ and partially dehydrated solids can be obtained by addition of less polar solvents.⁹³³ Anhydrous sulfates, such as $\text{An}_2(\text{SO}_4)_3$ (An = Am, Cm, or Cf) are also prepared by heating the hydrate to a temperature of 500–600 °C in air.⁹²² A number of double sulfates of Am^{III} with formulas $\text{MAm}(\text{SO}_4)_2 \cdot x\text{H}_2\text{O}$ ($\text{M} = \text{K}, \text{Na}, \text{Rb}, \text{Cs}, \text{Tl}$; $x = 0, 1, 2, 4$), $\text{K}_3\text{Am}(\text{SO}_4)_3 \cdot x\text{H}_2\text{O}$, and $\text{M}_8\text{Am}_2(\text{SO}_4)_7$ ($\text{M} = \text{K}, \text{Cs}, \text{Tl}$) have been prepared by adding metal sulfate to Am^{3+} in sulfuric acid solutions. The oxosulfates, $\text{An}_2\text{O}_2\text{SO}_4$ (An = Cm or Cf), have been reported; the curium compound is obtained by heating Cm^{III} -loaded resin (sulfonate form) in a stream of oxygen at 900 °C; it has a body-centered orthorhombic structure.⁹²³

Tabuteau and Pages^{924,925} investigated the Am–molybdate and Am–tungstate systems. By reacting stoichiometric amounts of AmO_2 and MoO_3 or WO_3 at 1,080 °C, the monoclinic $\text{Am}_2(\text{MoO}_4)_3$ and $\text{Am}_2(\text{WO}_4)_3$ are prepared; with potassium present and at lower temperature, ternary phases, $\text{KAm}(\text{MoO}_4)_2$ and $\text{K}_5\text{Am}(\text{MoO}_4)_4$, are isolated. Higher order tungstate and heteropolyanionic complexes have been studied, including for their use as solution precursors to solid state materials. Shirokova *et al.*⁹²⁶ reported the complexation of Am^{III} with *N,N*-dimethylacetamide and the Keggin-type heteropolyanion $\text{PW}_{12}\text{O}_{40}^{3-}$. Complexes of Am^{III} and Cm^{III} with $\text{W}_{10}\text{O}_{36}^{12-}$, $\text{PW}_{11}\text{O}_{39}^{7-}$ and $\text{SiW}_{11}\text{O}_{39}^{8-}$ have also been prepared.⁹²⁷⁻⁹³⁰ In contrast, Williams *et al.* reported that Am^{III} can be integrated into the Preyssler anion, $\text{AmP}_5\text{W}_{30}\text{O}_{110}^{12-}$.⁸⁹⁶

Carbonates and carboxylates. The trivalent transplutonium formate, carbonate, and oxalate complexes have been relatively well studied. The oxalato complexes, particularly $\text{Am}_2(\text{C}_2\text{O}_4)_3 \cdot 10\text{H}_2\text{O}$, have been used extensively for separations and other processing. The carbonates have been studied primarily in the context of waste management and environmental risk. Americium formate can be prepared by evaporating a solution of $\text{Am}(\text{OH})_3$ in concentrated formic acid. The binary Am^{III} carbonate, $\text{Am}_2(\text{CO}_3)_3 \cdot 4\text{H}_2\text{O}$ precipitates from a CO_2 -saturated solution of NaHCO_3 .^{931,932} The analogous Cm^{III} solid forms after addition of K_2CO_3 to Cm^{III} solution.⁹³³ The ternary compounds $\text{NaAm}(\text{CO}_3)_2 \cdot 4\text{H}_2\text{O}$ and $\text{Na}_3\text{Am}(\text{CO}_3)_3 \cdot 4\text{H}_2\text{O}$ can also be precipitated from bicarbonate solutions.⁸⁵⁹ In analogy to neodymium and europium analogs, orthorhombic AmOHCO_3 was characterized by X-ray powder diffraction data.^{931,934} A hexagonal form has been reported, but not confirmed.⁹³⁵ The anhydrous carbonates, $\text{An}_2(\text{CO}_3)_3$ ($\text{M} = \text{Am}$ or Cm) are formed by the radiolytic decomposition of the oxalate or by heating the anhydrous oxalates.

The hydrated oxalate, $\text{Am}_2(\text{C}_2\text{O}_4)_3 \cdot x\text{H}_2\text{O}$ ($x = 7, 9, 10$ or 11), is precipitated from aqueous solutions containing americium(III) by oxalic acid and the anhydrous oxalate is obtained by heating the decahydrate above 340 °C.⁹³⁶ The corresponding Bk and Cf solids are precipitated from acid solutions by oxalic acid. Both the Am and Cm oxalates are used for calcination to the oxides. For example, oxalate precipitation has been used to process large amounts of ^{244}Cm , with subsequent metathesis with 0.5 M hydroxide to form $\text{Cm}(\text{OH})_3$.^{937,938} The ternary oxalate complexes of general formula $\text{MAm}(\text{C}_2\text{O}_4)_2 \cdot x\text{H}_2\text{O}$ have been prepared from Am^{III} oxalate and MC_2O_4 ($\text{M} = \text{NH}_4, \text{Na}, \text{K}, \text{Cs}$) in neutral solution.⁹³⁹ It has been demonstrated that a substantial

Figure 88 General diagrams of phosphinic acid, monothiophosphinic acid and dithiophosphinic acid, respectively.

separation of americium from lanthanum can be obtained by fractional precipitation of americium and lanthanum oxalates; about 50% of the lanthanum can be rejected at each stage with only about 4% of the americium.

Phosphoric, phosphinic, and phosphonic acid. Phosphinic acid-based extractants contain the $\text{P}(\text{O})\text{OH}$ acid functionality as well as two R groups attached to the phosphorus, where R can be hydrogenic, aliphatic, or aromatic. Sulfur containing derivatives are known as monothiophosphinic acids, where the phosphonyl oxygen is replaced with a sulfur, and dithiophosphinic acids, where both oxygens are replaced with sulfur (Figure 88).

In the extraction of trivalent lanthanides and actinides with phosphinic acids, the hard donor nature of oxygen makes it difficult to effectively distinguish between the hard cations Ln^{III} and An^{III} , thus making separation of one from the other difficult. The replacement of oxygen with softer donor atoms such as sulfur make Ln^{III} and An^{III} more distinguishable, hence the development of mono- and dithiophosphinic acids as more effective extractants in the separation of these species. In most studies, the dithiophosphinic acids have been proven to be the most effective agents for selectively separating these ions. To this end, Am^{III} and Cm^{III} complexes with bis(2,4,4-trimethylpentyl)phosphinic acid (HC272), bis(2,4,4-trimethylpentyl)monothiophosphinic acid (HC302), and bis(2,4,4-trimethylpentyl)dithiophosphinic acid (HC301) (extracted into *n*-dodecane), all available through Cytec, Inc., Canada, have been studied by visible absorption spectroscopy and X-ray absorption fine structure spectroscopy (XAFS) to determine the origin of this selectivity.

XAFS spectroscopy attempts to model experimental data to propose a coordination environment of a metal complex. XAFS modeling proposed that for HC272 there is only oxygen donation to the Am^{III} and Cm^{III} inner coordination sphere, while for HC301, only sulfur donation is observed. Am^{III} and Cm^{III} HC302 complexes have both oxygen and sulfur bound to the metal. These coordination models make sense in light of the chemical structure of the extractants.

When an excess of HC272 is present in the organic phase, it is proposed to coordinate to trivalent actinides in a fashion similar to most oxygen-containing diphosphinic acids, yielding a coordination stoichiometry of $\text{M}[\text{H}(\text{C272})_2]_3$. The bonding consists of three $\text{H}(\text{C272})_2^-$ hydrogen-bonded dimers coordinated in a bidentate mode to the metal as seen in Figure 89, allowing for excellent extraction into a non polar organic phase. XAFS modeling also indicates that the hexacoordinate complexes of HC272 arrange in a distorted octahedral (O_h) geometry, comparable to most An^{III} ions in highly ionic coordination complexes.⁹⁴⁰

Coordination studies of monothiophosphinic acids with actinides are scarce in the literature. Slope analysis from extractant dependency studies using trivalent curium indicate a 3:1 stoichiometry for the coordination of HC302 with the metal.⁹⁴¹ XAFS studies indicate that all $\text{M}-\text{HC302}$ bonds are shorter than those typically observed with R_2POS^- complexes and are more like bond lengths seen in hexacoordinate R_2PO_2^- and R_2PS_2^- complexes. These studies also show that the extracted complex consists of a trivalent actinide cation coordinated with two monodentate C302^- molecules through oxygen, one bidentate C302^- molecule through both oxygen and sulfur, and one water molecule, all of which are bound in the inner sphere as seen in Figure 90. Although the coordination number of between four and five shown above is unusually low for actinide cations, it is consistent with all experimental and modeling data.

XAFS data for complexes of Cm^{III} with the HC301 extractant indicate only sulfur donation to the metal in the inner sphere of coordination. HC301 forms 3:1 complexes with the trivalent actinides and are coordinated in a bidentate mode as seen in Figure 91. Data indicates a hexacoordinate structure that resembles D_3 symmetry in lanthanide dithiophosphinic acid complexes.

Figure 89 Predicted complexation of HC272 with Cm^{III} from XAFS (Jensen and Bond, *J. Am. Chem. Soc.* **2002**, 124, 9870–9877).

Figure 90 Proposed diagram of HC302 complexation of Cm^{III} from XAFS.

Figure 91 Predicted complexation of HC301 with Cm^{III} from XAFS (Jensen and Bond, *J. Am. Chem. Soc.* **2002**, 124, 9870–9877).

The fact that dithiophosphinic acids show the greatest selectivity for An^{III} over Ln^{III} as compared to phosphinic and monothiophosphinic acids is due to an increased covalency in the $\text{An}-\text{S}$ bonds but not necessarily a shorter $\text{An}-\text{S}$ bond. In addition, trivalent actinides show a thermodynamic preference to form bonds with soft donor atoms. The structural differences observed in the complexes of An^{III} with the three ligands studied are due to differences in the hard and soft nature of the oxygen and sulfur atoms, respectively, and their hydrogen-bonding ability.⁹⁴⁰

A study by Zhu *et al.* using purified HC301 (>99% bis(2,4,4-trimethylpentyl)dithiophosphinic acid) in kerosene seems to indicate a different reaction stoichiometry with trivalent americium.⁹⁴³ Previous studies indicated that the extractant is mainly found in a dimeric form at higher extractant concentration ranges.⁹⁴² Slope analyses in the more recent study, however, show a pH dependence using nitric acid of about three and a log extractant dependence of about two,⁹⁴³ suggesting an alternate extraction stoichiometry for Am^{III} with HC301 in kerosene as shown in Equation (64):

Despite this stoichiometry ambiguity, both studies suggest a high selectivity for trivalent actinides over lanthanides by dithiophosphinic acids.⁹⁴³

A group of aromatic dithiophosphinic acids, R₂PS(SH), where R = C₆H₅, ClC₆H₄, FC₆H₄, and CH₃C₆H₄, have been made and used with various synergists to extract trivalent actinides from nitric acid media into toluene. Extraction of Am^{III} requires the presence of a synergist such as tributyl phosphate (TBP), and extraction ratios increase in the order (C₆H₅)₂PS(SH) < (FC₆H₄)₂PS(SH) < (ClC₆H₄)₂PS(SH).

Slope analyses to determine the extraction stoichiometries of Am^{III} for both the C₆H₅ and ClC₆H₄ extractants were performed to determine pH, TBP, and extractant dependencies. For Am^{III}, many nonintegral slopes were obtained, indicating that mixed complexes with varying stoichiometries are being extracted. It is believed that the extractants may act similarly to Cyanex 301 and form complexes of the type AmA₃(HA)_xTBP_y, but the values for *x* and *y* are still undetermined and further work needs to be done. Trioctylphosphine oxide was found to be the best synergist for Am^{III} extraction.⁹⁴⁴

Phosphine oxides. Few molecular complexes of trivalent transplutonium elements have been reported. Several studies examine the extraction chemistry of Am³⁺, Cm³⁺, and Bk³⁺ with a combination of β-diketones and tri-*n*-alkyl phosphine oxides and trialkylphosphates. From these, compounds reported to be of the formula AnL₃(R₃PO)_x (An = Am, Cm; R = *n*-octyl, BuⁿO) were isolated, where L = CF₃COCHCOR (R = Me, CF₃, Buⁿ).^{945–947} The stoichiometry of the complexes (An:P=O) was not always reported. The complex Am(CF₃COCHCOCF₃)₃[OP(OBuⁿ)₃]₂ is reported to be volatile at 175 °C.⁹⁴⁷

(iii) Ligands containing group 17 donor atoms

The trivalent transplutonium halides have been extensively studied. Several reviews deal specifically with actinide halides.^{948–951} In aqueous solution the mono- and bis-complexes have been characterized, with the formation of the latter decreasing down the halide series. For example, AmF²⁺ and AmF₂⁺ have been studied, but only a very weak monochloride complex AmCl²⁺ has been reported. These species are reported to have coordination numbers as high as 11, although recent EXAFS studies show that the hydration number decreases with increasing halide concentration (and ionic strength) at concentrations below which the halo complexes form. These data suggest the coordination numbers of the mixed aquo halo complexes are probably seven to ten.

In the solid state, the complete series AnX₃ (X = F, Cl, Br, I) are known for Am and Cm and most are known for Bk–Es. A variety of preparative methods have been reported and reviewed, from single step element combinations at high temperature, to treatment of oxides with anhydrous HX, to complex salt precipitation followed by multistep decompositions. The trifluorides are prevalent and can be prepared by dehydrating precipitates from HF or other concentrated fluoride solutions, or by treating oxides or hydroxides with HF_(g). Most adopt the 11-coordinate LaF₃ structure. One form of BkF₃ and the known form of CfF₃ and EsF₃ have the eight-coordinate, high temperature LaF₃-type structure. With a larger anion, the chlorides have the nine-coordinate hexagonal UCl₃-type structure across the series to Cf, for which one form has this nine-coordinate structure and a second modification has the eight-coordinate PuBr₃ structure. The chlorides can be prepared by treating the oxides or oxychlorides with anhydrous HCl at elevated temperature. The tribromides (Am, Cm, Bk) and α-AmI₃ are isostructural with the PuBr₃. However, β-AmI₃ and the other triiodides (Cm, Bk, Cf) have the orthorhombic six-coordinate BiI₃ structure (Am is the only dimorphic actinide triiodide).⁹⁵²

The oxyhalides AmOCl, AmOI, and CmOCl are isostructural PbClF type (hexagonal), and contain nine coordinate An^{III} surrounded by four oxygens and five halides. Americium(III) oxyboride has also been prepared, but the structure is unconfirmed.

Hydrates of the oxoanion and halide complexes are numerous for Am^{III} and Cm^{III} and a few have also been reported for Bk^{III} and Cf^{III} . The hexahydrate trichlorides and tribromides, $\text{AnCl}_3 \cdot 6\text{H}_2\text{O}$ ($\text{An} = \text{Am}$ or Bk) and $\text{AnBr}_3 \cdot 6\text{H}_2\text{O}$ ($\text{An} = \text{Am}$ or Cf), are isostructural with the hydrated lanthanide chlorides and involve mixed ligand complexes, such as $[\text{AnCl}_2(\text{H}_2\text{O})_6]^+$.

Many other trihalide adducts have been prepared. For example, americium chloride has been treated with a number of salts to yield $\text{AmCl}_3 \cdot \text{MCl}$ where MCl is LiCl, CsCl, $(\text{C}_4\text{H}_9)_4\text{NCl}$, or $(\text{C}_2\text{H}_5)_4\text{NCl}$.

Ternary complexes, such as MAmX_4 , M_2AmX_5 , KAm_2F_7 , and M_2AmX_6 and M_3AmX_3 , where M = an alkali earth metal, have been prepared and characterized for Am and some are also known for heavier transplutonium ions. The fluoro complexes MAmX_4 (M = phosphonium) are isostructural with the analogous Pu^{III} compounds. Octahedral anions, such as AmCl_6^{3-} and AmBr_6^{3-} are present in M_2AmX_5 and in triphenylphosphonium salts in anhydrous ethanol.⁹⁵³

3.3.3.2.3 Chelating ligands

CMPO. Carbamoylmethylphosphine oxide (CMPO) acts as a neutral extractant in complexing with Am^{III} in both nitric acid (low to high concentrations) and hydrochloric acid (moderate to high concentrations). Extractant dependency studies have shown the stoichiometric relationship between the CMPO ligand and the actinide to be 3:1 in forming the extracted species in both nitric and hydrochloric acid systems as indicated in Equation (65):

In the TRUEX process, CMPO is typically used with tributylphosphate (TBP) as a phase modifier and some organic solvent such as dodecane, carbon tetrachloride, tetrachloroethylene, or paraffinic hydrocarbons. Distribution studies indicate that the Am^{III} /nitrate/CMPO complex is considerably more extractable than the analogous chloride complex at low/moderate acid concentrations due to the soft nature and larger hydration energy of the chloride ion. While CMPO extracts tetra- and hexavalent actinides in addition to trivalent actinides, selective partitioning of Am^{III} over the higher oxidation states can be achieved by suitable selection of acid concentrations.⁹⁵⁴ Complexation of CMPO with Am^{III} occurs in one of two ways. In nitrate complexes, monodentate coordination between the electronegative phosphoryl oxygen and the metal center occurs. In chloro complexes, bidentate coordination occurs with the metal center via the phosphoryl oxygen, as well as the carbonyl oxygen. This leads to a coordination number of nine for both types of complexes.⁹⁵⁵

Comparative studies have shown that changing the substituents attached to the phosphoryl group alters the basicity of the donor group and strengthens or weakens the extractive ability of the molecule. Substitution with two alkoxy groups, as in dihexyl-*N,N*-diethylcarbamoylmethylphosphine oxide, decreases the basicity of the donor group and lowers the Am^{III} extraction. Substitution with two phenyl groups also shows an inductive effect, but less so than an alkoxy substitution.⁹⁵⁶

The effectiveness of CMPO tends to drop off at high acid concentration due to the competition between actinide cations and protons at the basic bonding site on CMPO. CMPO extraction is also very dependent upon the diluent, making generalized statements about CMPO extraction very difficult.⁹⁵⁷

β -Diketonate. The hydrated americium β -diketonate compounds, $\text{AmL}_3 \cdot x\text{H}_2\text{O}$, $\text{HL} = (\text{HL} = \text{MeCOCH}_2\text{COMe}, \text{CF}_3\text{COCH}_2\text{COPh}, \text{CF}_3\text{COCH}_2\text{CO}(2\text{-C}_4\text{H}_9\text{S}), \text{and } \text{Bu}^t\text{COCHCO-Bu}^t)$, are precipitated from aqueous or ethanolic Am^{III} solutions. The latter is isomorphous with the analogous Ln^{III} chelates of similar ionic radii, in which the central metal atoms are seven coordinate. The Bk^{III} compounds, $\text{Bk}(\text{CF}_3\text{COCHCOR})_3$ ($\text{R} = \text{CF}_3, \text{Bu}^t$ and $2\text{-C}_4\text{H}_9\text{S}$), have been

obtained by a solvent extraction method. The salt $\text{CsAn}(\text{HFAA})_4 \cdot x\text{H}_2\text{O}$, where HFAA = hexafluoroacetylacetonate, has been studied in detail for $\text{An} = \text{Am}$, Cm , Bk , Cf , and Es .⁹⁵⁸ This compound forms readily when HFAA is added to ethanol solutions of the trivalent actinides in the presence of cesium ion. The coordination environment about the metal center in the anion of these salts is dodecahedral. Base adducts of fluorinated diketones have been isolated, including those of tributyl phosphate or trioctylphosphine oxide.⁹⁴⁶

2-Thenoyltrifluoroacetone (HTTA) (Figure 92) has been used as an extraction agent with some soft donor ligands for Am^{III} in the presence of Eu^{III} . The soft donor ligands used include triphenylamine (Ph_3N), triphenylarsine (Ph_3As), and triphenylphosphine (Ph_3P). The addition of Ph_3As and Ph_3P showed a synergistic enhancement of the extraction into benzene, with the latter showing a greater effect. In both cases, the ligand and synergist combinations showed no preference for Am^{III} over Eu^{III} , and the soft donor ligands gave weaker distribution ratios than previous studies with hard donor ligands. Extractant dependency indicates that three HTTA molecules are involved in the complexation.⁹⁵⁹

The extraction of trivalent actinides with β -diketones in the presence of crown ethers has also been investigated. Trifluoroacetylacetonate (HTFA), HTTA, benzoyltrifluoroacetone (HBFA), and 2-naphthoyltrifluoroacetone (HNFA) have all been used with 18-crown-6 to remove Am^{III} and Cm^{III} from perchlorate media into 1,2-dichloroethane. It has been shown that the mechanism of extraction for all of the β -diketones (HA) is the formation of a cationic complex via a synergistic ion-pair extraction (SIPE) as shown in Equation (66):

The preference of the SIPE for the trivalent actinides is due to the stabilization of the crown ether/ M^{III} bonds due to a “size-fitting effect” where the diameter of the metal ion matches that of the crown ether cavity, leading to significantly greater extraction efficiency due to this synergistic effect.⁹⁶⁰

Another widely studied β -diketone for the extraction of trivalent actinides has been 1-phenyl-3-methyl-4-benzoylpyrazolone-5 (HPMBP), illustrated in Figure 93. The extraction of Am^{III} , Cm^{III} , Bk^{III} , and Cf^{III} by HPMBP may be expressed in two ways. First, the extraction of Cm^{III} has been observed to follow the extraction equilibrium shown in Equation (67):

Figure 92 Thenoyltrifluoroacetone (HTTA).

Figure 93 1-phenyl-3-methyl-4-benzoylpyrazolone-5 (HPMBP).

In contrast, Am^{III} , Bk^{III} , and Cf^{III} extraction equilibria are characterized by the formation of self-adduct species as shown in Equation (68):

In the above equilibrium, extractant dependency studies have indicated that $n = 1$ for Am^{III} and Bk^{III} and $n = 2$ for Cf^{III} . These stoichiometries have been observed for extractions into chloroform, and the self-adduct formation with trivalent actinides has been possibly connected with “tetrads” where Cm is one of the minima. Extractions into xylene, however, leads to the formation of self-adducts with all four actinides due to better distribution coefficients in xylene over chloroform. The formation of self-adducts is due to ligand concentration, ionization constant of the ligand, basicity of the bound ligand, solvent identity, and oxidation state of the metal ion.

The addition of a neutral donor synergist such as tri-*n*-octylphosphine(TOPO) oxide to the above HPBMP extractions leads to the equilibrium shown in Equation (69). The equation holds true for all four trivalent actinides and m can take the value of one or two:⁹⁶¹

Derivatives of HPBMP of the type bis(1-phenyl-3-methyl-4-acylpyrazol-5-one), hereafter referred to as H_2BP_n , where $n = 3, 4, 5, 6, 7, 8, 10$, and 22 have been studied as quadridentate extractants for trivalent actinides (from both perchlorate and nitrate media into chloroform (Figure 94). These derivatives were found to extract better than HPBMP due to their multidentate nature and high hydrophobic character. For Am^{III} , Cm^{III} , and Cf^{III} , the highest degree of extraction was obtained with the H_2BP_7 and H_2BP_8 ligands. Extraction dependency for n equals 5–8, 10, and 22 indicates that the extraction equilibrium involves one singly and one doubly deprotonated ligand in the extracted species.

For H_2BP_3 and H_2BP_4 , similar dependency studies indicate that another equilibrium mechanism may come into play where one H_2BP_n ligand is coordinated with the species being $\text{M}(\text{BP}_n)(\text{OH})$ or $\text{M}(\text{HBP}_n)(\text{OH})_2$.³⁹⁸

Diamides. Malonamides have excellent chelating abilities with trivalent actinides such as Am^{III} , as well as with the lanthanides. The extracting ability of malonamides tends to increase with the decreasing basicity of the molecule; this phenomenon is due to lower proton/metal competition with the less basic malonamide. Spjuth *et al.*⁹⁵⁷ studied the uptake of Am^{III} from HNO_3 solutions by malonamides that had been tailored to vary the basicity of the ligand (see Table 49).

The coordination of the malonamides with Am^{III} is believed to be bidentate in nature via the carbonyl oxygens. The oxygen in alkoxy R_3 substituents is not believed to take part in binding to the Am^{III} metal. As nitric acid concentration increases, the average number of HNO_3 molecules associated with each malonamide in the organic phase increases, with a maximum of four occurring for BUDOPx (*N,N'*-dimethyl-*N,N'*-dibutylundecylpropoxy malonamide), but differing depending on R-groups.⁹⁵⁷

In malonamides, one nitrogen substituent is usually a methyl group to minimize the steric interactions that may hinder complexation. In order to make the malonamide soluble in organics, the other nitrogen substituent is typically a long alkyl chain.⁹⁶² However, the presence of a phenyl

Figure 94 Bis(1-phenyl-3-methyl-4-acylpyrazol-5-one) (H_2BP_n) ($n = 3-8, 10$ or 22).

Table 49 Basicity of substituted malonamides (reproduced from Spjuth, L., *et al. Solvent Extr. Ion Exch.* **2000**, 18, 1.).

R_1	R_2	R_3	Abbreviation	Basicity
methyl	butyl	$C_{14}H_{29}$	BTD	Most basic
methyl	butyl	$C_{18}H_{37}$	BOD ^a	
methyl	cyclohexyl	$C_{14}H_{29}$	CHTD	
methyl	butyl	$C_3H_6OC_{11}H_{23}$	BUDOPx	
methyl	butyl	$C_2H_4OC_{12}H_{25}$	BDDEx	Least basic
methyl	octyl	$C_2H_4OC_6H_{13}$	OHEx	
methyl	phenyl	$C_{14}H_{29}$	PHTD	
methyl	4-chlorophenyl	$C_{14}H_{29}$	CLPHTD	

^a Basicity data not available; assumed to be similar to BTD and CHTD

group allows for increased electron withdrawing ability and lower basicity, thus making phenyl-substituted malonamides better complexing reagents for Am^{III} than the alkyl-substituted analogs.⁹⁵⁷ Addition of a long alkyl or alkoxy chain (14 carbons or more) at the malonamide methylene carbon leads to even better solubility in the organic phase, leading to enhanced extractive power.⁹⁶² Studies where the methylene substituent is a hydrogen atom, such as in N,N' -dimethyl- N,N' -dibutylmalonamide and N,N' -dimethyl- N,N' -dioctylmalonamide, show poorer extractive ability than those with long alkyl/alkoxy chains, probably due to the a lower solubility of the metal complex in the organic phase.^{429,963}

Mechanisms for the extraction of Am^{III} or Cm^{III} can be either coordination or ion-pair, depending on acid concentrations as suggested by a study using the CHTD (N,N' -dimethyl- N,N' -dicyclohexyltetradecyl) malonamide and PHTD (N,N' -dimethyl- N,N' -diphenyltetradecyl malonamide malonamides). At low nitric acid concentrations, a coordination mechanism is suspected due to lower competition between protons and the actinide for the carbonyl oxygens (L = malonamide ligand, M = Am , Cm). Extractant dependency studies indicate that $n = 2-4$ malonamide molecules in the extracted species. At moderate and high nitric acid concentrations, two ion-pair mechanisms dominate, respectively as shown in Equations (70) and (71). Under these conditions, the malonamide is likely protonated at one or both carbonyl oxygens:⁹⁶⁴

Sasaki and Choppin have looked at diglycolamides and thiodiglycolamides with thenoyltrifluoroacetate (HTTA) in perchlorate solutions as more effective extractants for trivalent actinides. The diamides examined were N,N' -dimethyl- N,N' -dihexyl-3-oxapentanediamide (DMDHOPDA), N,N' -dihexyl-3-oxapentanediamide (DHOPDA), N,N' -dimethyl- N,N' -dihexyl-3-thiopentanediamide (DMDHTPDA), and N,N' -dihexyl-3-thiopentanediamide (DHTPDA). When trivalent americium was present only with the diamide, poor extraction was seen, probably due to hydrogen bonding and the soft donor nature of the sulfur atoms. Addition of HTTA, however, showed a synergistic effect and drastically increased the complexation and extraction ability of the diamide. Extraction stoichiometry from dependency studies for Am^{III} is given by Equation (72), where L is a diamide:^{397,426,965}

Coordination of the diamide with the metal ion can occur in both a bidentate mode through both carbonyl oxygens or one carbonyl oxygen and the bridging oxygen/sulfur, or in a tridentate mode via both carbonyl oxygens and the bridging atom.⁹⁶⁶

Diphosphonic acids. The diphosphonic acids such as the compound P,P' -di(2-ethylhexyl) methane-diphosphonic acid ($H_2DEH[MDP]$) have been investigated as extractants for Am^{III} from nitric acid into *o*-xylene. The acid dependence for Am^{III} extraction by $H_2DEH[MDP]$ shows unusual behavior compared to other actinide cations. Am^{III} shows a peak maximum in the nitric acid range 0.1 to 1 M (0.1F $H_2DEH[MDP]$). At lower acidities, a positively charged complex is formed, resulting in a 1:1 Am^{III} /extractant complex which favors the aqueous phase, giving low distribution ratios. In the

aqueous phase, the positive charge on the complex is balanced by negatively charged nitrate species. At higher acidities, 1:2 complexes are predicted, allowing neutralization of the trivalent charge by the extractant, eliminating the need for nitrate anions. Extractant dependency studies confirm these varying complexation stoichiometries.⁴¹⁸ The observed 2:1 stoichiometry at high acidities is due to the existence of the extractant in a dimeric form induced by the solvent.⁴²¹

The related compounds, *P,P'*-di(2-ethylhexyl)ethanediphosphonic acid ($\text{H}_2\text{DEH}[\text{EDP}]$) and *P,P'*-di(2-ethylhexyl)butanediphosphonic acid ($\text{H}_2\text{DEH}[\text{BuDP}]$) have also been studied for the extraction of Am^{III} . Studies have shown that the increasing length of the alkyl bridge in the diphosphonic acids has the effect of decreasing the stability of the metal/extractant complexes formed due to their bidentate nature in forming chelating rings.⁹⁶⁷ Hence, the extraction efficiency for Am^{III} by this series of acidic extractants follows the order $\text{H}_2\text{DEH}[\text{MDP}] > \text{H}_2\text{DEH}[\text{EDP}] > \text{H}_2\text{DEH}[\text{BuDP}]$. An interesting phenomenon observed for $\text{H}_2\text{DEH}[\text{EDP}]$ is the high degree of aggregation that the compound undergoes in the *o*-xylene diluent. It is believed that it forms inverted micelles with an aggregation number of six, leading to an extraction mechanism where the Am^{III} is hydrated and transferred into the hydrophilic interior of the aggregated micelle, followed by release of H^+ ions. The interaction of Am^{III} here is weaker than that in $\text{H}_2\text{DEH}[\text{MDP}]$, probably due to the hydration of the metal and its tendency to behave as a monodentate ligand.⁴¹⁹

The longer length of the alkyl bridge in $\text{H}_2\text{DEH}[\text{BuDP}]$ causes it to behave even more as a monodentate extractant and lowering its extractant efficiency. It has a lower aggregation state than its $\text{H}_2\text{DEH}[\text{EDP}]$, causing Am^{III} complexes to form containing two trimers of the extractant (consistent with the observed extractant dependency of two).⁴²⁰

Similar studies in the depolymerizing diluent 1-decanol, where the diluent competes for hydrogen bonding with the phosphoryl functional sites, causes the extractants to exist as monomers in solution. Additionally, 1-decanol has the effect of suppressing metal extraction, and extractant dependency studies indicate slopes of one (1:1 metal/extractant complexes) to three (1:3 metal/extractant complexes) for Am^{III} at the lowest and highest extractant concentrations, respectively. The suppression of metal ion extraction by 1-decanol is presumably due to the hydrogen bonding described above, thereby increasing competition for the chelating site.⁴²¹

The acidic extractant *P,P'*-di(ethylhexyl)benzene-1,2-diphosphonic acid ($\text{H}_2\text{DEH}[1,2\text{-BzDP}]$), shown in Figure 95, has been investigated as an extractant for Am^{III} into *o*-xylene due to the rigidity of functional groups on the benzene ring and the low likelihood for aggregation. $\text{H}_2\text{DEH}[1,2\text{-BzDP}]$ is unstable at room temperature, but was found to be sufficiently stable in *o*-xylene with refrigeration. The extractability of Am^{III} with this ligand (compared with analogues with alkane backbones) follows the order $\text{H}_2\text{DEH}[1,2\text{-BzDP}] > \text{H}_2\text{DEH}[\text{MDP}] > \text{H}_2\text{DEH}[\text{EDP}] > \text{H}_2\text{DEH}[\text{BuDP}]$ over a wide range of nitric acid concentrations. Extractant dependency studies indicate a complexation stoichiometry of 1:3 for metal to extractant.

The entrapment of Am^{III} by three extractant molecules leads to the conclusion that the $\text{H}_2\text{DEH}[1,2\text{-BzDP}]$ exists as a monomer in *o*-xylene, unlike $\text{H}_2\text{DEH}[\text{MDP}]$ where dimers yield a complex stoichiometry of two.⁹⁶⁷

Other. Hydroxyquinoline complexes have also been prepared from aqueous solution and have the form AmL_3 , where HL is 8-hydroxyquinoline, 5-chloro- or 5,7-dichloro-8-hydroxyquinoline. There is

Figure 95 $\text{H}_2\text{DEH}[1,2\text{-BzDP}]$.

solvent extraction evidence for the Cf^{III} 5,7-dichloro-8-hydroxyquinoline complex. The citrate complexes have been prepared in solution and their simple salts $\text{Am}(\text{C}_6\text{H}_5\text{O}_7) \cdot x\text{H}_2\text{O}$ have been characterized. The citrate complex can be crystallized by the use of an hydrogen bond donor such as cobalt hexamine to form the solid $[\text{Co}(\text{NH}_3)_6][\text{Am}(\text{C}_6\text{H}_5\text{O}_7)_2] \cdot x\text{H}_2\text{O}$.⁹⁶⁸ An interesting structure determined using single crystal X-ray diffraction is that of the salicylate complex $\text{Am}(\text{C}_7\text{H}_5\text{O}_3)_3 \cdot \text{H}_2\text{O}$. In this molecule each Am^{III} is linked to six different salicylate groups and is surrounded by nine oxygen atoms, eight from the salicylate groups and one from the water molecule; two salicylate groups are bidentate, one via its carboxylate group and the other via its carboxylate and phenolic groups, and the other four are monodentate via the carboxylate group (Figure 96). Danford *et al.*⁹⁶⁹ precipitated the dipivaloylmethane complex $\text{Am}(\text{C}_{11}\text{H}_{19}\text{O}_2)_3$ by adding aqueous Am^{III} sulfate to a solution of dipivaloylmethane and NaOH in 70% aqueous ethanol.

3.3.3.2.4 Macrocyclic ligands

The bis(phthalocyanine) (Pc) complex, $\text{Am}(\text{Pc})_2^-$, has been obtained by heating AmI_3 with *o*-phthalodinitrile in 1-chloronaphthalene, or from americium(III) acetate and *o*-phthalodinitrile; it is probably a sandwich compound similar to those obtained with the tripositive lanthanides.⁹⁷⁰

3.3.3.3 Tetraivalent Oxidation State (Am, Cm, Bk, Cf)

3.3.3.3.1 General characteristics

Americium(IV) is stable in concentrated H_3PO_4 , $\text{K}_4\text{P}_2\text{O}_7$, phosphotungstate, and fluoride (NH_4F , KF) solutions, and is otherwise reduced to Am^{III} . It can be prepared by dissolving $\text{Am}(\text{OH})_4$ in concentrated NH_4F solutions and it is not reduced by water.⁹⁷¹ In contrast to americium, the oxidation of Cm^{III} to Cm^{IV} is achieved only with the strongest oxidizing agents, and only two reports claim evidence for an oxidation state greater than +4.^{972,973}

Other than the CmF_4/MF system, the only claims for chemically generated Cm^{IV} in solution are the reports that red solutions result when aqueous Cm^{III} solutions are mixed with potassium peroxydisulfate and heteropolyanions such as $[\text{P}_2\text{W}_{17}\text{O}_{61}]^{10-}$.^{446,447} The polytungstate Cm^{IV} complexes, $\text{CmW}_{10}\text{O}_{36}^{8-}$, $\text{Cm}(\text{SiW}_{11}\text{O}_{39})^{12-}$, and $\text{Cm}(\text{PW}_{11}\text{O}_{39})_2^{10-}$, display chemiluminescence upon reduction to Cm^{III} .^{927,974} Chemiluminescence has also been observed during dissolution of the Cm^{IV} double oxide Li_xCmO_y in mineral acids.⁹⁷⁵

3.3.3.3.2 Simple donor ligands

(i) Ligands containing group 16 donor atoms

Oxides. All the reported dioxides, AnO_2 ($\text{An} = \text{Am}, \text{Cm}, \text{Bk}$ and Cf) possess the fluorite structure. Interestingly, the lattice parameters determined for AmO_2 have not been consistent.⁹⁷⁶⁻⁹⁷⁸ Morss and co-workers⁹⁷⁹ reported a neutron diffraction and magnetic susceptibility study of Cm dioxide prepared by calcination of Cm^{III} oxalate. Based on the lattice parameter, the stoichiometry of this material was reported to be $\text{CmO}_{1.99 \pm 0.01}$, indicating that the material essentially contained only Cm^{IV} . Nevertheless, the effective paramagnetic moment was found to be $(3.36 \pm 0.06) \mu_B$, a value which had previously been attributed to the presence of Cm^{III} . These data possibly suggest $\text{AnO}_{2 \pm x}$ phases should be considered for Am and Cm, as they have been for Pu. The oxides can be prepared by heating a variety of oxoanion complexes (e.g., nitrates, oxalates, etc.) in air or oxygen above 600 °C. Other binary oxides are not known.

Ternary oxides of the types M_2AmO_3 ($\text{M} = \text{Li}, \text{Na}$), MAmO_3 , and Li_2AnO_6 ($\text{An} = \text{Am}, \text{Cm}$) have been recorded. They are obtained by heating the dioxides with the alkali or alkaline earth metal oxide at high temperatures under vacuum or in nitrogen. The ternary oxides BaCmO_3 ⁹⁰⁵ and Cm_2CuO_4 ⁹⁰⁶ have recently been reported.

Hydroxides. Attempts to characterize $\text{Am}(\text{OH})_4$ have not yet been successful. A precipitate reported to be $\text{Am}(\text{OH})_4$ has been obtained by heating $\text{Am}(\text{OH})_3$ at 90 °C in 0.2 M NaOH with

with the stability constant expected based on those of the analogous pentacarbonato species of lighter actinides. No solid Am^{IV} carbonates are known, but the limiting complex is likely isostructural with the analogous Pu^{IV} carbonate shown above.

Other. The only tetravalent transplutonium silicate known, $^{241}\text{AmSiO}_4$, is obtained by reacting $\text{Am}(\text{OH})_4$ with excess SiO_2 in NaHCO_3 solution at 230°C . This solid is patented to be used in manufactured alpha sources.

Polyoxometallates have been used recently to stabilize Am^{IV} . Chartier *et al.* reported spectroscopic evidence for the formation of $\text{AmP}_2\text{W}_{17}\text{O}_{61}^{6-}$ and $\text{Am}(\text{P}_2\text{W}_{17}\text{O}_{61})_2^{16-}$ via their absorbance bands at 789 nm and 560 nm, respectively.⁹²⁸ However, formation of a red Cm^{IV} complex in phosphotungstate solution was achieved by the use of peroxydisulfate as the oxidant.⁴⁴⁷ Kosyakov *et al.* demonstrated that, in such solutions, the Cm^{IV} is reduced much more rapidly than can be accounted for by radiolytic effects, while Am^{IV} in such solutions is much more stable, being reduced at a rate attributable to radiolytic effects alone.⁴⁴⁶

(ii) Ligands containing group 17 donor atoms

The tetrafluorides AnF_4 ($\text{An} = \text{Am}, \text{Cm}, \text{Bk}$ and Cf) are obtained by fluorination of lower-valent oxides or halides under elevated temperature and pressure.^{562,984,985} All have the eight-coordinate UF_4 structure. The optical absorbance spectrum of Am^{IV} in concentrated fluoride solution resembles very closely that of solid AmF_4 , suggesting the solution species has a similar coordination environment. CmF_4 is prepared by fluorine oxidation of the trifluoride; the curium ion in the solid is eight-coordinate, and lies within a square coordination environment.^{562,948,984} Magnetic susceptibility measurements suggest a fluoride-deficient structure, CmF_{4-x} .^{986,987} The orthorhombic fluoro complex Rb_2AmF_6 is formed in concentrated aqueous fluoride solutions with RbAmO_2F_2 or $\text{Am}(\text{OH})_4$ and is isostructural with Rb_2UF_6 , containing chains of fluoride dodecahedra.^{948,988} The related LiAnF_5 is isostructural with LiUF_5 . The Bk^{IV} complex, Cs_2BkCl_6 , has been prepared and characterized, but surprisingly, it is not isostructural with the analogous Pu^{IV} and Ce^{IV} compounds. Compounds of composition $\text{M}_7\text{An}_6\text{F}_{31}$ ($\text{M} = \text{Na}, \text{K}$ and $\text{An} = \text{Am}, \text{Cm}, \text{Bk}$) are also known.^{989,990} The compounds were prepared by direct fluorination of evaporated salt mixtures of MX and CmX_3 at about 300°C . The basic coordination polyhedron is a square antiprism.⁹⁴⁸ In tetragonal LiCmF_5 , the curium coordination is tricapped trigonal prismatic.⁹⁴⁸ Hexafluorides and oxyfluorides CmF_6 and CmOF_3 (as well as NpOF_3 , NpF_7 , PuO_3F , AmF_5 , AmF_6 , and EsF_4) have been reported using thermochromatographic techniques,⁹⁷³ but there has been no independent confirmation of these species.

3.3.3.3.3 Chelating ligands

β -Diketonates. The berkelium(IV) complexes BkL_4 ($\text{HL} = \text{CF}_3\text{COCH}_2\text{COBu}^t$ and $\text{CF}_3\text{COCH}_2\text{CO}(2\text{-C}_4\text{H}_9\text{S})$) are formed by solvent extraction of aqueous Bk^{IV} solutions with the β -diketone.

Other. The first Am^{IV} compound with an organic ligand was prepared by reacting AmI_3 at 200°C with phthalodinitrile in 1-chloronaphthene to yield the dark violet phthalocyanine compound $\text{Am}(\text{C}_{32}\text{H}_{16}\text{N}_8)_2$.⁹⁹¹ There is evidence that americium also forms the monophthalocyaninato complex.

3.3.3.4 Pentavalent Oxidation State (Am)

3.3.3.4.1 General characteristics

There is tracer scale evidence for the formation of the Cf^{V} during ozonization of ^{249}Bk and subsequent decay to ^{249}Cf . However, the only stable isolated pentavalent transplutonium compounds are Am^{V} species. Americium(V) can be prepared in solution by oxidizing Am^{III} in near-neutral and alkaline aqueous solution using oxidants such as ozone, hypochlorite and peroxydisulfate or alternatively by electrochemically or chemically reducing Am^{VI} .^{992,993} It can also be isolated from mixtures of Am^{III} , Am^{V} , and Am^{VI} by extracting AmO_2^+ using thenoyltrifluoroacetone in isobutanol.⁹⁹⁴ Americium(V) can be isolated in the solid state as sodium Am^{V} carbonate by heating a 2 M Na_2CO_3 Am^{VI} solution up to 60°C or in solution by dissolution of An^{VI} hydroxides in mineral acids.^{995,996} More

exotic methods include the dissolution of solid Li_3AmO_4 in dilute perchloric acid or the electrolytic oxidation of Am^{III} in iodate solutions.⁹⁹⁷

3.3.3.4.2 Simple donor ligands

(i) Ligands containing group 16 donor atoms

Oxide. Simple binary oxides are unknown. However, ternary oxides, such as Na_3AmO_4 , Li_3AmO_4 , and Li_7AmO_6 , are obtained by heating AmO_2 with the alkali metal oxide. These compounds have been characterized by X-ray diffraction.

Aquo and hydroxides. By analogy with lighter actinides and from recent experimental data, Am^{V} is thought to be coordinated by four or five water molecules in the equatorial plane, in addition to the two axial actinyl oxygens. EXAFS spectral data are consistent with this coordination geometry as demonstrated by Williams *et al.*⁸⁹⁶ In addition, Shilov and Yusov analyzed reported variations in the $\text{Am}^{\text{V}}/\text{VI}$ potentials and the stability constants of the actinyl(V) oxalate complexes and proposed the same coordination number and geometry.⁹⁹⁸ Solubility studies indicate the hydrolysis products of AmO_2^+ are $\text{AmO}_2(\text{OH})$ and $\text{AmO}_2(\text{OH})_2^-$, with structures and constants similar to those known for Np^{V} .⁹⁹⁹ Tananaev suggests the formation of $\text{AmO}_2(\text{OH})_3^{2-}$ and $\text{AmO}_2(\text{OH})_4^{3-}$ in highly alkaline media based on absorbance spectroscopy measurements of Am^{V} in LiOH solutions.¹⁰⁰⁰ Species isolated under these conditions include the ternary Am^{V} hydroxides, $\text{MAmO}_2(\text{OH})_2 \cdot n\text{H}_2\text{O}$ at 0.1–0.5 M $[\text{OH}^-]$ and $\text{M}_2\text{AmO}_2(\text{OH})_3 \cdot n\text{H}_2\text{O}$ (M = Na, K, Rb, Cs) at 0.5–2.0 M $[\text{OH}^-]$, which have been characterized by a variety of solution techniques, including vibrational spectroscopy.^{993,1001}

Carbonates and carboxylates. A number of carbonates of general formula, MAmO_2CO_3 (M = K, Na, Rb, Cs or NH_4) have been synthesized by precipitation of Am^{V} in dilute bicarbonate solutions of the corresponding cation.^{511,513,932,1002,1003} The use of a large excess of alkali carbonate yields the $\text{K}_3\text{AmO}_2(\text{CO}_3)_2$ and $\text{K}_5\text{AmO}_2(\text{CO}_3)_3$ solids, which are almost certainly isostructural with the potassium neptunyl(V) carbonates described in the pentavalent carbonate section.^{512,1004} The solids can alternatively be prepared by electrochemical reduction of americium(VI) in carbonate solutions. The $\text{Am}=\text{O}$ and $\text{Am}-\text{O}_{\text{eq}}$ bond distances are calculated from X-ray powder diffraction data to be 1.935 Å and 2.568 Å respectively. Both distances are significantly longer than those in the Np^{V} compounds, i.e., 1.75 Å for $\text{Np}=\text{O}$ and 2.46 Å for $\text{Np}-\text{O}_{\text{eq}}$ in aqueous $\text{NpO}_2(\text{CO}_3)_n^{1-2n}$ complexes.⁵⁰⁹ The acetato complex salt, $\text{Cs}_2\text{AmO}_2(\text{CH}_3\text{CO}_2)_3$, has been prepared by precipitation from solution and is isostructural with the analogous neptunium(V) and plutonium(V) compounds. Hydrated oxalato complex salts $\text{MAmO}_2\text{C}_2\text{O}_4 \cdot x\text{H}_2\text{O}$ (M = K, Cs) were prepared by precipitation. The vibrational spectra of acetate and carbonates complexes have been reported.⁵¹⁰

Oxoanion complexes. Fedoseev and Budentseva⁹²⁹ claimed the preparation of the Am sulfates, $(\text{AmO}_2)_2(\text{SO}_4) \cdot x\text{H}_2\text{O}$, from evaporation of a Am^{V} -containing sulfuric acid solution, and two double salts, $\text{CsAmO}_2\text{SO}_4 \cdot x\text{H}_2\text{O}$ from evaporation of a solution containing $(\text{AmO}_2)_2(\text{SO}_4)$ and Cs_2SO_4 in a 3:1 ratio. They also report that $\text{Co}(\text{NH}_3)_6\text{AmO}_2(\text{SO}_4)_2 \cdot 2\text{H}_2\text{O}$ can be prepared by simply including Am^{V} in the chemicals used to prepare $\text{Co}(\text{NH}_3)_6(\text{SO}_4)_2$.⁹²⁹ Am^{V} sulfate also crystallizes from an ozonated solution of $\text{Am}(\text{OH})_3$ after addition of sulfuric acid and subsequent evaporation. A simple chromate salt, $(\text{AmO}_2)_x(\text{CrO}_4)_y \cdot \text{H}_2\text{O}$, has been reportedly prepared by slow evaporation of a Am^{V} /chromic acid solution.¹⁰⁰⁵ Optical spectroscopic data confirm the presence of Am^{V} in the solid, but the composition is unknown.

(ii) Ligands containing group 17 donor atoms

The ternary Am^{V} fluorides, KAmO_2F_2 and RbAmO_2F_2 , precipitate from concentrated aqueous fluoride solutions of Am^{V} and consist of AmO_2F_2^- layers held together by K^+ or Rb^+ ions from the rhombohedral KAmO_2F_2 , where americium is eight-coordinate with two axial oxygen atoms and six fluorides in the equatorial plane.⁵¹³ In contact with acidic RbF solution, RbAmO_2F_2 reduces overnight to Rb_2AmF_6 .⁹⁸⁸ The chloride $\text{Cs}_3\text{AmO}_2\text{Cl}_4$ precipitates with ethanol from 6 M HCl containing Am^{V} hydroxide and CsCl ¹⁰⁰⁶ and is isostructural with the analogous Np^{V} compound.

3.3.3.5 Hexavalent Oxidation State(Am)

3.3.3.5.1 General characteristics

Some theoretical work suggests that Cm^{VI} may be even more stable than Am^{VI} , and the lack of success in preparing Cm^{VI} may result from the low stability of Cm^{V} and the high $\text{Cm}^{\text{IV}}/\text{Cm}^{\text{III}}$ potential.^{1007,1008} One report claims the synthesis of Cm^{VI} by beta decay of $^{242}\text{AmO}_2^+$.⁹⁷²

Many of the classic partitioning processes rely on the formation of Am^{VI} to facilitate separation from trivalent lanthanides or heavier trivalent actinides. Americium(VI) can be prepared in basic aqueous solutions from Am^{III} using powerful oxidants, such as peroxydisulfate, and from Am^{V} using weaker oxidants, such as Ce^{IV} .¹⁰⁰⁹ It can be precipitated from solution as a carbonate by electrolytic or ozone oxidation of concentrated carbonate solutions of Am^{III} or Am^{V} , or solubilized by dissolution of sodium americyl(VI) acetate. These oxidations and the resulting coordination compounds have been used for relatively large scale processing. For examples, Stephanou *et al.*¹⁰¹⁰ found that Cm^{III} could be separated from Am by oxidizing the latter to Am^{VI} with potassium persulfate, precipitating CmF_3 , and retaining soluble Am^{VI} . Proctor *et al.*^{1011,1012} used precipitation of cerium peroxide to separate gram quantities of americium from cerium, and precipitation of lanthanide trifluorides to accomplish lanthanide/actinide separation. Solution species and aqueous precipitates of Am^{VI} and Am^{V} generally have pentagonal or hexagonal bipyrimidal coordination geometries with mono- or bidentate ligands in the plane perpendicular to the americyl moiety.

3.3.3.5.1.1 Ligands containing group 16 donor atoms

Oxides. AmO_3 is unknown. Ternary oxides of the type M_2AmO_4 ($\text{M}=\text{K}$, Rb or Cs), M_6AmO_6 ($\text{M}=\text{Li}$ or Na), and Ba_3AmO_6 , prepared by heating AmO_2 with the metal hydroxide or oxide in oxygen, have been reported.^{997,1013,1014,1016}

Aqua, hydroxides. In aqueous solution, Am^{VI} likely has five water molecules coordinated in the equatorial plane based on EXAFS studies of lighter hexavalent actinides. Spectroscopic data indicate the formation of Am^{VI} hydrolysis species of general formula $\text{AmO}_2(\text{OH})_n^{2-n}$, where $n=1, 2$, (and minor species, $n=3$ and 4), which can be generated from ozone oxidation of basic Am^{III} or Am^{V} solutions or $\text{Am}(\text{OH})_3$ solid.¹⁰¹⁷ In alkali hydroxide solutions, the Am^{VI} gradually reduces to form a light-tan solid which, when dissolved in mineral acid, yields Am^{V} . It is claimed that Am^{VI} disproportionates into Am^{VII} and Am^{V} in greater than 10 M NaOH solutions.¹⁰¹⁸ The stoichiometric solid, $\text{AmO}_2(\text{OH})_2$, has been suggested to precipitate in slightly basic concentrated NaCl solutions under inert atmosphere, but its amorphous nature of the solid phase precluded diffraction characterization.^{981,982,1019}

Oxoanion complexes. The nitrate complexes $\text{MAmO}_2(\text{NO}_3)_3$ ($\text{M}=\text{Rb}$ or Cs) are precipitated from nitric acid solutions of americium(VI) and have been characterized by powder X-ray diffraction and IR spectroscopy. Hydrated phosphato and arsenato complex salts of the form $\text{MAmO}_2\text{PO}_4 \cdot x\text{H}_2\text{O}$ ($\text{M}=\text{K}$, Rb , Cs or NH_4) are precipitated from americium(VI) solutions at pH 3.5–4 and are similar to analogous U^{VI} and Np^{VI} compounds. Lawaltd *et al.*¹⁰²⁰ also report the precipitation of Am^{VI} arsenates via complexation of Am^{VI} with *N,N*-dimethylacetamide and the Keggin-type heteropolyanion $\text{PW}_{12}\text{O}_{40}^{3-}$ to prepare Am^{VI} phosphates that are converted to arsenates.¹⁰²⁰ The obtained compounds were isostructural with the analogous Am^{VI} phosphates. The hydrated sulfato complex salt, $\text{Co}(\text{NH}_3)_6(\text{HSO}_4)_2(\text{AmO}_2(\text{SO}_4)_3) \cdot n\text{H}_2\text{O}$ is prepared by addition of cobalt hexamine to an aqueous Am^{VI} sulfate solution. It is isostructural with the analogous U^{VI} and Np^{VI} compounds.¹⁰²¹ A reported chromate complex, prepared from Am^{V} , chromic acid solution and reported to be $\text{AmO}_2\text{CrO}_4 \cdot \text{H}_2\text{O}$ is likely an Am^{V} (and not Am^{VI}) complex, based on optical absorbance spectroscopy.¹⁰⁰⁵ Fedoseev *et al* report the synthesis of $\text{AmO}_2\text{Mo}_2\text{O}_7 \cdot 3\text{H}_2\text{O}$ at 100 °C; however, no phase characterization is provided.¹⁰²²

Carbonates and carboxylates. By analogy with U^{VI} carbonates, one may expect mono-, bis-, and triscarbonato complexes in solution and in the solid state, containing bidentate carbonates in the equatorial plane perpendicular to the americyl oxygens. The Raman shifts have been used to distinguish these species, particularly the mono- and biscarbonate.^{510,1023} However, only the limiting triscarbonate complex, $\text{AmO}_2(\text{CO}_3)_3^{4-}$, has been very well studied in solution^{876,983} and isolated in the solid state as $\text{M}_4\text{AmO}_2(\text{CO}_3)_3$ ($\text{M}=\text{Cs}$ or NH_4).¹⁰²⁴ Crystalline cubic sodium americyl acetate, $\text{NaAmO}_2(\text{OOCCH}_3)_3$, can be prepared by addition of sodium acetate to an

acidic Am^{VI} solution.^{1025,1026} The vibrational spectrum has been measured and the structure was inferred by comparison with the structures of lighter actinyl carbonates.^{1027–1029} Oxalate salts of Am^{VI} have also been prepared similarly by precipitation from aqueous solution and structurally characterized by powder X-ray diffraction. These complexes are isolated in the solid state as $\text{MAmO}_2\text{C}_2\text{O}_4 \cdot x\text{H}_2\text{O}$, ($\text{M} = \text{K}$ or Cs).¹⁰³⁰

Other. The pyridine- and *N*-oxypyridine-2-carboxylates, AmO_2L_2 , have been obtained from aqueous solutions of americium(VI) and the acid HL; the *N*-oxide 2-carboxylate is formed as the dihydrate.¹⁰³¹ di-(2-ethylhexylphosphoric acid (HDEHP) solutions have been used to selectively extract Am^{VI} from Cm^{III} in such systems rapid reduction of Am^{VI} to lower oxidation states is a problem.¹⁰³²

Ligands containing group 17 donor atoms. The binary Am^{VI} fluoride, AmO_2F_2 , has been prepared by reacting solid sodium Am^{VI} acetate with anhydrous HF containing a small amount of F_2 at -196°C .¹⁰³³ The compound is isostructural with other actinyl(VI) fluorides. The complex chloride, $\text{Cs}_2\text{AmO}_2\text{Cl}_4$, is obtained by the unusual oxidation of $\text{Cs}_3\text{AmO}_2\text{Cl}_4$ in concentrated HCl.¹⁰³⁴ Its cubic form appears to transform to a monoclinic form when washed with small volumes of concentrated HCl.¹⁰⁰⁶ It is suggested that the cubic form is likely to be a mixed oxidation state compound of formula $\text{Cs}_7(\text{AmO}_2)(\text{AmO}_2)_2\text{Cl}_{12}$.¹⁰³⁵ Conflicting claims have been put forth concerning the existence of AmF_6 . More recently, Gibson and Haire¹⁰³⁶ have reported that they were not able to confirm the existence of AmF_6 , despite exhaustive efforts. Interestingly, Am^{VI} hexachloride appears to be sufficiently stable to permit X-ray crystallographic studies.

3.3.3.6 Heptavalent Oxidation State

Green solutions believed to be Am^{VII} are prepared by oxidation of Am^{VI} in concentrated aqueous basic solution by either ozone or the O^\cdot radical.^{1037,1038} In contrast to Np^{VII} , and similar to Pu^{VII} , Am^{VII} is unstable and reduces to the hexavalent state within minutes. A review on the chemistry of heptavalent transplutonium elements can be found in the *Handbook of the Physics and Chemistry of the Actinides*.¹⁰³⁹

3.3.4 OTHER SOURCES

Several reviews were invaluable in surveying advances in actinide coordination chemistry, including the following: *Gmelin Handbook of Inorganic Chemistry* published in 1988 and the supplements on thorium and uranium;^{7,216} the chapters on thorium and uranium in the *Kirk-Othmer Encyclopedia of Chemical Technology*, 4th edition, 1997 by D. L. Clark, D. W. Keogh, M. P. Neu, and W. Runde;^{1040,1041} *The Chemistry of the Actinide Elements*, 2nd edition, edited by Katz, J. J., Seaborg, G. T., Morss, L. R., 1986;¹⁰⁴⁵ preprints of the element-specific chapters on Am and Cm chemistry by Runde and Schulz and Lumetta, Thompson, Penneman, and Eller, respectively,^{1043,1044} in *The Chemistry of the Actinide and Transactinide Elements*, to be published in 2003; *Handbook on the Physics and Chemistry of the Actinides* edited by A. J. Freeman and C. Keller, 1985;¹⁰⁴⁶ The Nuclear Energy Agency and the Organisation for Economic Co-operation and Development critical reviews of the chemical thermodynamic data of U, Am, and Np and Pu (U volume edited by I. Grenthe, J. Fuger, R. J. M. Konigs, R. J. Lemire, A. B. Muller, C. Nguyen-Trung, H. Wanner;¹⁹⁷ Am volume edited by Silva, R. J. Bidoglio, G., Rand, M. H., Robouch, P. B., Wanner, H., Puigdomenech, I.,⁸⁷⁶ Np and Pu volume edited by Lemire, R. J., Fuger, J., Nitsche, H., Potter, P., Rand, M. H., Rydberg, J., Spahiu, K., Sullivan, J. C., Ullman, W. J., Vitorge, P., Wanner, H.;⁴⁶ *Actinide partitioning—a review in Solvent Extraction and Ion Exchange*, 2001 by Mathur, J. N., Murali, M. S., Nash, K. L.;⁴⁰⁹ *The Crystal Chemistry of Uranium in Reviews in Mineralogy*, 1999 by Peter Burns.¹⁰⁴³

ACKNOWLEDGEMENTS

We thank Dr. Marianne Wilkerson for significant contributions to the sections on alkoxide and thiolate chemistry. We thank Dr. Jeff Golden for technical input and assistance with all aspects of manuscript preparation. Dr. Brian Scott assisted with structural database searching and provided crystallographic data from structures determined at Los Alamos National Laboratory, and Halo

Golden assisted with the preparation of tables. Finally, we are grateful to Drs. Wolfgang Runde and P. Gary Eller for providing their reviews and references on Am and Cm chemistry.

3.4.1 ALUMINUM

3.4.1.1 Introduction

The coordination chemistry of aluminum is as rich as it is varied. The striking range and diversity of coordination modes of aluminum atoms spans both traditional inorganic chemistry and contemporary organometallic chemistry. Indeed, the coordination chemistry of aluminum goes beyond that which may be expected for an ns^2p^1 valence configuration. The fact that aluminum is the most abundant terrestrial metal only adds to the allure of this main group metal. The history

of aluminum is equally fascinating. As an element that once held the crown jewels of France and was valued as a precious metal, to a critical component in various industrial and catalytic processes, aluminum has, in many regards, done it all. The coordination modes of aluminum virtually spans the gamut of structural motifs from low coordinate three-coordinate (trigonal planar and T-shaped) and normal four-coordinate (tetrahedral) to high coordinate five-coordinate (trigonal bipyramidal and square pyramidal) and six-coordinate (octahedral). Even seven-coordinate (pentagonal bipyramidal) has been reported. This contribution will emphasize this wide diversity as a function of the type of compound. While the coordination chemistry of aluminum was discussed in *Comprehensive Coordination Chemistry* (CCC, 1987) this review does not seek to repeat that accomplishment. Rather, this review will endeavor to concentrate more on the discoveries in the intervening years with more of an emphasis on the organometallic chemistry of aluminum and gallium. To this end, some historical background is in order.

3.4.1.2 Group 14 Ligands

Of the group 14-based ligands, the most important by far are the carbon-based congeners. The organometallic chemistry of aluminum is quite overwhelming. The Lewis acidity of aluminum alkyls and aryls is the dominant feature in chemistry. The organometallic Al—C bond has proven particularly important in a variety of industrial and catalytic processes. Reports of organoaluminum compounds date back to the eighteenth century. The direct synthesis of aluminum alkyls was a significant accomplishment in the development of this field (Equation (1)).

The literature reveals a number of perhaps more convenient routes to aluminum alkyls. These include a simple oxidation–reduction reaction of aluminum metal with dialkylmercury compounds (Equation (2)).

Other preparative routes to aluminum alkyls include reaction of aluminum halides with organometallic reagents such as lithium alkyls (Equation (3)).

or Grignard reagents (Equation (4)).

These routes are often more desirable than those involving organomercury reagents due to toxicity concerns.

The simple aluminum alkyls ($\text{R} = \text{Me}, \text{Et}, \text{Pr}^i$, etc.) are colorless, mobile, pyrophoric liquids. The pyrophoric nature of these substances may be traced to the considerable Al—O bond strength compared to the Al—C bond strength. Even though in Equations (1)–(4) the aluminum alkyls are depicted as R_3Al monomers with the aluminum atoms ostensibly in three-coordinate trigonal planar environments, in fact these substances are dimeric, R_6Al_2 , with the aluminum atoms in four-coordinate tetrahedral environments. The bridging carbon atoms in these organoaluminum dimers are engaged in electron deficient, three center-two electron (3c-2e), bonding schemes. Although some debate initially ensued concerning the nature of the bonding in Me_6Al_2 ,^{1,2} single crystal X-ray diffraction data³ provided unambiguous data confirming the dimeric electron-deficient

Figure 1 Solid-state structure of Me_6Al_2 .

nature of these compounds. The Al–C–Al bond angle in Al_2Me_6 (Figure 1) is $\sim 75^\circ$. The Al–C_{br} bond distance of 2.12 Å is considerably longer than the Al–C_{ter} bond distance of 1.95 Å. These factors result in a general weakness of the Al–C–Al bridges. Indeed, upon reaction the dimer readily cleaves in a symmetrical fashion across the electron deficient bridge providing R_3Al units.

A classic synthetic route to alkylaluminum halides is reaction of aluminum metal with alkyl halides. This procedure affords alkylaluminum sesquihalides, equimolar mixtures of dialkylaluminum halides and alkylaluminum dihalides (Equation (5)).

Of course, these compounds are also dimeric, containing electron-deficient bonds with the aluminum atoms in four-coordinate tetrahedral environments. It is significant that the Al–X–Al angle in alkylaluminum halides is considerably widened from that observed in Me_6Al_2 (75°) to $\sim 90^\circ$.

Alkylaluminum halides are important as they are often utilized to prepare other organoaluminum products. In particular, an industrial preparation of trimethylaluminum involves the sodium metal reduction of dimethylaluminum chloride, $[\text{Me}_2\text{AlCl}]_2$ (Equation (6)).

Although triphenylaluminum (2) exists as a dimer (Figure 2)^{4,5} (with the aluminum atoms in four-coordinate tetrahedral environments) in the solid state with bridging η^1 -phenyl groups—and is thus more accurately referred to as di- μ -phenyl-bis(diphenylaluminum)—sterically demanding carbon-based ligands can substantially affect the coordination environment of aluminum. It should be noted that the dimethylphenylaluminum derivatives of triphenylaluminum, di- μ -phenyl-bis(dimethylaluminum), $[\text{Me}_2\text{PhAl}]_2$, and tetra-*o*-tolyl-bis(μ -*o*-tolyl)dialuminum—the ortho-ligated toluene derivative—exists as a tetrahedral dimer about bridging η^1 -phenyl groups.⁶

The role of sterically demanding ligand systems and their effect on the coordination of aluminum is conveniently illustrated when comparing the phenyl ligand with the mesityl ligand. Trimesitylaluminum, Mes_3Al ⁷ (Mes = 1,3,5-trimethylphenyl), is prepared by reaction of dimesityl-mercury with aluminum metal (Equation (7)).

Figure 2 Solid-state structure of Ph_6Al_2 .

The steric demands of the mesityl ligands in Mes_3Al are critical in the aluminum atom assuming a virtually perfect three-coordinate trigonal planar coordination. The Al–C bond distance was shown to be 1.995(8) Å while the C–Al–C bond angle was 120° . The mesityl ligands are arranged in a propeller fashion about the metal center at dihedral angles of 55° (Figure 3).

The tetrahydrofuran adduct of trimesitylaluminum, $\text{Mes}_3\text{Al} \cdot \text{THF}$ was subsequently reported.⁸ While the coordination of the aluminum atom in $\text{Mes}_3\text{Al} \cdot \text{THF}$ is distorted four-coordinate tetrahedral, the most meaningful comparison concerns the orientation of the three mesityl rings. In $\text{Mes}_3\text{Al} \cdot \text{THF}$ the mesityl ligands are no longer equivalent with dihedral angles of 56° relative to the AlC_3 basal plane. Rather, the mesityl rings now reside at angles of $96.6(2)^\circ$, $45.4(2)^\circ$, and $20.4(3)^\circ$. The tetrahedral environment of the aluminum atom is distorted as evidenced by the fact that two of the C–Al–C bond angles are approximately 120° while one is much smaller (and closer to that which is expected for a tetrahedral atoms) at 108.6° .

A particularly intriguing organoaluminum compound involving carbon-based ligands involves a recently reported carbene complex. Reaction of trimethylaluminum with 1,3-diisopropyl-4,5-dimethyl-imidazol-2-ylidene was carried out to afford the first organo-group 13 metal-carbenes, $\text{Me}_3\text{M}:\text{carbene}$ ($\text{M} = \text{Al}, \text{Ga}$).⁹ The ability of Lewis acids such as trimethylaluminum to form stable adduct complexes with suitable Lewis bases such as amines, phosphines, and oxygen containing compounds is obvious and well documented. Nonetheless, the concept of a “carbon-based” Lewis acid center interacting with a Lewis acid such as Me_3Al had received little attention. This compound is noteworthy in that while the four-coordinate tetrahedral coordination of the aluminum atom is not in itself unusual, the fact that the compound is monomeric is significant. Prior to the discovery of this compound, if an aluminum atom was involved in four-coordinate tetrahedral bonding to four carbon atoms, the resulting compound was almost always dimeric.

Figure 3 Solid-state structure of $(\text{Mes})^3\text{Al1}$.

The independent $\text{Al}-\text{C}_{(\text{methyl})}$ bond distances in $\text{Me}_3\text{Al}:\text{carbene}$ of $1.940(5)\text{ \AA}$ and $2.062(7)\text{ \AA}$, compares to $2.124(6)\text{ \AA}$ for the $\text{Al}-\text{C}_{(\text{carbene})}$ bond distance. These distances are further placed in perspective when comparing them with the values reported for $\text{Al}-\text{C}$ bond distances in Me_6Al_2 and Ph_6Al_2 .

Certainly no discussion of the coordination chemistry of aluminum with carbon-based ligands would be complete without a discussion of the cyclopentadienyl ligand. This ligand, arguably the most important throughout the whole of organometallic chemistry, has an ever increasing chemistry with aluminum. Cyclopentadienyl(dimethyl)aluminum, a volatile solid isolated from reaction of trimethylaluminum with cyclopentadiene, displays different structures depending upon the physical state. For example, in the gas-phase it is monomeric with the cyclopentadiene (Cp) ligand interacting in a η^2 fashion with the aluminum atom basically being three-coordinate trigonal bipyramidal. However, in the solid state¹⁰ the compound assumes a polymeric nature with each Me_2Al unit being bridged by an η^1 -Cp ring. The closely related dicyclopentadienyl-(methyl)aluminum displays a dramatically different structural motif.¹¹ In the solid state this compound has unambiguously been shown to be a monomer with the Cp ligand interacting in a η^2 fashion—effectively resulting in the aluminum atom being five-coordinate square pyramidal. In this compound the molecule is monomeric with the aromatic rings residing in a somewhat asymmetric η^2 orientation.

The methyl(pentamethylcyclopentadienyl)aluminum chloride dimer, $[(\text{C}_5\text{Me}_5)\text{MeAlCl}]_2$, is prepared from reaction of dimethylaluminum chloride with (pentamethylcyclopentadienyl)lithium in toluene.¹² The solid-state structure of this compound reveals that the C_5Me_5^- ligand interacts with the aluminum centers in an η^3 fashion across μ -chloro bridges.

A particularly interesting recently reported cyclopentadienylaluminum compound is the $[(\text{C}_5\text{Me}_5)_2\text{Al}]^+$ cation, isolated from reaction of $(\text{C}_5\text{Me}_5)_2\text{AlMe}$ with $\text{B}(\text{C}_6\text{F}_5)_3$ in methylene chloride (Equation (8)).

The authors note that this compound may be stored for months at -17°C without appreciable decomposition. The $[(\text{C}_5\text{Me}_5)_2\text{Al}]^+$ cation (Figure 4) sports a perfectly linear (ring-centroid)-

Figure 4 Solid-state structure of $[\text{C}_5\text{Me}_5)_2\text{Al}]^+$.

Al-(ring centroid) angle of 180° . The C_5Me_5^- ligands are staggered relative to each other at a value of 36° .

Similar compounds containing the bis(pentamethylcyclopentadienyl)aluminum cation have been reported by other workers.¹³

3.4.1.3 Group 15 Ligands

3.4.1.3.1 Nitrogen ligands

Reactions between nitrogen species and aluminum compounds may be traced back to the 1800s. The most fundamental reaction in this regard is that of Me_3Al with ammonia (Equation (9)):

This reaction was initially studied by Wiberg¹⁴ as a means to approach aluminum nitride. The thermodynamic driving force in this reaction is methane elimination (even though with each successive methane molecule that is eliminated, the subsequent elimination becomes more difficult). The reaction of trimethylaluminum with dimethylamine is another classic reaction which, after initially forming the Lewis acid–base adduct, $\text{Me}_3\text{Al}:\text{N}(\text{H})\text{Me}_2$, forms the $[\text{Me}_2\text{Al}-\text{NMe}_2]_2$ dimer upon heating.¹⁵ The formation of dimers and trimers with extensive Al–N association was quickly recognized¹⁶ as a hallmark of the reactions of Me_3Al with simple amines.

The reaction of Me_3Al with methylamine proved to be very interesting.¹⁷ Two products were suggested by NMR. After considerable effort the solid-state crystal structures of the reaction products confirmed *cis*- and *trans*-stereoisomers of $[\text{Me}_2\text{Al}-\text{N}(\text{H})\text{Me}]_3$.¹⁸ Both isomers contained nonplanar Al_3N_3 rings: a chair conformation was observed for the *cis*- $[\text{Me}_2\text{Al}-\text{N}(\text{H})\text{Me}]_3$ isomer, while a boat conformation was shown for the *trans*-isomer.

These reactions were subsequently found to be much more complicated than initially reported. Indeed, large clusters containing from eight to twelve aluminum atoms were ultimately isolated and characterized by single crystal X-ray diffraction.^{19,20} The coordination of the aluminum

atoms in all of these compounds, interesting as they are, was generally unremarkable as four-coordinate tetrahedral.

Sterically demanding amines have afforded a rich chemistry with organoaluminum compounds. The steric demands of a given amine are most prominently manifest in the coordination about the aluminum center. The 1980s proved to a rich decade for this type of work. Three prominent sterically demanding amines are aniline (**1**), 2,4,6-trimethylaniline (**2**), and 2,6-diisopropylaniline (**3**) (although the phenyl ligand is not generally considered to be sterically demanding, it is included in this group for comparative purposes).

One of the most interesting reactions involves trimethylaluminum with 2,6-diisopropylaniline.²¹ The initial product is an aluminum–nitrogen dimer, however, upon further heating additional alkane elimination occurs resulting in the Al–N trimer (Equation (10)):

X-ray structural data confirmed the trimeric nature of $[\text{MeAl-NC}_6\text{H}_3(i\text{-Pr})_2]_3$ (Figure 5). A number of points are noteworthy regarding this compound. The neutral compound resided about a three-fold axis with a planar Al–N six-membered ring with the phenyl rings of the amine nearly orthogonal with the central plane. The bond angles at the aluminum and nitrogen atoms are $115.3(5)^\circ$ and $124.7(5)^\circ$, respectively. While the overall structure of this compound bears a striking resemblance to borazine, an argument for true delocalization and aromaticity in this compound is problematic. In particular among other factors, the inter-ring Al–N bond distances are inequivalent.

Another interesting product is obtained from the condensation reaction of trimethylaluminum with mesitylamine. Similar to the previous compound, reaction of trimethylaluminum with mesitylamine initially yields a characteristic Al_2N_2 dimer. Further heating gives the aluminum–nitrogen tetramer $[\text{MeAlNC}_6\text{H}_2\text{Me}_3]_4$.²² This unique “Al–N cube” may be viewed as the “fusing” of two Al_2N_2 dimers. The coordination sphere of each aluminum atom is completed by one methyl group and three nitrogen atoms. Similarly, the coordination sphere of each nitrogen atom is tetrahedral being completed by one mesityl group and three aluminum atoms of the cube. Thus, each atom residing in the cube is tetrahedral. The mean Al–N distance in this tetramer ($1.948(7)\text{ \AA}$) and the Al–C bond distance ($1.949(3)\text{ \AA}$) are unremarkable. Although Al–N tetramers are reasonably rare, the literature does reveal others involving various amines and LiAlH_4 .²³

It is informative to consider the dynamics that ultimately lead to an Al–N trimer rather than an Al–N tetramer. In both cases above the aluminum source was the same, trimethylaluminum. Thus, it is reasonable to examine the amine. The more sterically demanding amine, $\text{H}_2\text{NC}_6\text{H}_3\text{Pr}_2$, with the isopropyl groups give the trimer while the amine with less steric constraints around the

Figure 5 Solid-state structure of $[\text{MeAl-NC}_6\text{H}_3(\text{Pr}^i)_2]_3$.

nitrogen center, mesitylamine, gives the tetramer. We will later see that the steric demands of ligands on the aluminum (and gallium) centers will have an even more profound influence on the nature of the resulting compound.

Reaction of trimethylaluminum with the smallest aryl-based amine, aniline, is also intriguing. Although the initial product was not completely characterized, it was suggested to have the approximate formulation of $[\text{Me}_2\text{AlN}(\text{H})\text{Ph}]_n$. Subsequent heating of this product gave, in low yield, $[\text{MeAlN}(\text{Ph})]_6$.²⁴ Inclusion of solvent molecules into the crystal lattice made the structural solution problematic, but the structure of the molecule was unambiguously determined. The molecule resides about a S_6 axis. Along the sides of the hexamer are planar Al_2N_2 four-membered rings. Once can conceptualize that this hexamer is the combining of two Al_3N_3 units. The Al–N bond distances in this compound fall into two distinct categories: those in the Al_3N_3 rings (1.912(6) Å) and those within the Al_2N_2 four-membered rings (1.951(6) Å).

Due to the flexibility of the pendant amine groups, open-chain amines have demonstrated a varied chemistry in the coordination chemistry of organoaluminum species. For example, reaction of trimethylaluminum with diethylenetriamine results in a complex wherein the two open-chain amines are “bridged” by a series of four organoaluminum moieties.²⁵ It is noteworthy that the two middle aluminum atoms were found to be five-coordinate square pyramidal. This was the first example of a compound containing two five-coordinate aluminum atoms in square pyramidal environments. The only example of a six-coordinate aluminum alkyl was isolated from reaction of trimethylaluminum with $\text{N}(\text{CH}_2\text{CH}_2\text{OH})_3$.²⁶ The molecule contained an Al_4O_6 core with two six-coordinate (distorted) octahedral aluminum atoms. The Al–C bond distance to the octahedral aluminum atoms 1.99(1) Å. Nitrogen-based crown ethers, azacrowns, are useful complexing agents for transition metals. The two most important azacrowns are cyclam [14]ane N_4 (**4**) and cyclen [12]ane N_4 (**5**). The driving force in the reaction of Me_3Al with such macrocyclic amines is a combination of the propensity to form Lewis acid–base adducts coupled with the thermodynamic advantage of Al–C/N–H bond cleavage and alkane elimination. Reaction of Me_3Al with [14]ane N_4 involves exhaustive alkane elimination and results in $[\text{Me}_3\text{Al}]_2[14]\text{ane-N}_4[\text{AlMe}]_2$.²⁷ Particularly noteworthy is the fact that the molecule resides about an Al_2N_4 four-membered ring while Me_3Al units occupy the other nitrogen sites (see Figure 6). The shorter Al–N bond distances are associated with the Al_2N_2 ring while the longer bond distances are associated with the terminal trimethylaluminum adducts.

After the reporting of this compound a number of studies followed concerning [14]aneN₄ and various organoaluminum species were carried out. A particularly interesting product was isolated from reaction of trimethylaluminum with [14]aneN₄ in the presence of ZrCl₄, [Al·[14]aneN₄AlMe₂][Me₂AlCl]₂.²⁸ The most striking feature of the cation is the octahedral coordination of the central aluminum atom. Indeed, the [14]aneN₄ azacrown ether has been drawn back or pinned back by the dimethylaluminum unit, to further expose the nitrogen atoms. The coordination sphere of the central aluminum atom is completed by the four nitrogen atoms of the azacrown and by two μ -chlorine atoms.

3.4.1.3.2 Phosphorus and arsenic ligands

The sterically demanding phosphine tris(trimethylsilyl)phosphine, P(SiMe₃)₃, proved to be very important in the development of the chemistry of the Al–P bond. A number of aluminum–phosphorus adducts were reported in the last decade. In particular, Cl₃Al·P(SiMe₃)₃ toluene and Br₃Al·P(SiMe₃)₃ toluene, with Al–P bond distances of 2.392(4) Å and 2.391(6) Å, respectively, were reported.²⁹ These virtually identical Al–P bond distances are extremely short. The aluminum atoms in both complexes may be described as four-coordinate tetrahedral.

In many respects the organometallic chemistry of alkylaluminum halides with lithiated phosphines is very similar to that of the amines. The reaction chemistry with organoaluminum

Figure 6 Solid-state structure of [Me₃Al]₂[14]aneN₄[AlMe₂].

moieties is driven by initial adduct formation followed by Al–X and Li–P bond cleavage (and salt elimination). The compounds themselves are frequently Al_2P_2 four-membered ring centered dimers. Reaction of alkylaluminum halides with $\text{P}(\text{SiMe}_3)_3$ proved to be interesting. For example, reaction of EtAlCl_2 with $\text{P}(\text{SiMe}_3)_3$ yields the adduct $\text{EtCl}_2\text{Al}\cdot\text{P}(\text{SiMe}_3)_3$ (Al–P: 2.435(3) Å). In the same study, the dimeric compound $[\text{Et}_2\text{AlP}(\text{SiMe}_3)_2]_2$ (**6**) was prepared from reaction of EtAlCl_2 with $\text{LiP}(\text{SiMe}_3)_2$ at -78°C .³⁰ This molecule contains a planar Al_2P_2 four-membered ring with the Al–P bond distance being 2.460(1) Å. Isolated from a similar synthetic scheme, this same laboratory reported the first example of an aluminum–phosphorus–arsenic mixed-pnictogen ring compound in $[\text{Et}_2\text{Al}\{\text{Me}_3\text{Si}\}_2\text{PAs}\{\text{SiMe}_3\}_2\text{AlEt}_2]$.³¹

The pentamethylcyclopentadienyl ligand, C_5Me_5 , has played a significant role in the development of the chemistry concerning the Al–As bond. Reaction of $[(\text{C}_5\text{Me}_5)\text{Al}]_4$ (*vide infra*) with $[\text{Bu}^t\text{As}]_4$ in toluene gives yellow crystals of $\text{As}_2[\text{Al}(\text{C}_5\text{Me}_5)]_3$.³² While the gross structural features of this compound will be discussed in more detail later in this chapter, at this point the As_2Al_3 core will be examined (Figure 7). The two arsenic atoms are centered above and below the Al_3 ring at a distance of 2.48 Å. This Al–As bond distance is shorter than that reported in $[\text{Et}_2\text{Al}\{\text{Me}_3\text{Si}\}_2\text{PAs}\{\text{SiMe}_3\}_2\text{AlEt}_2]$ of 2.299(1) Å and 2.494(1) Å.

Another noteworthy aluminum–arsenic compound is the trimeric $[\text{Me}_2\text{AlAsPh}_2]_3$, isolated from reaction of trimethylaluminum with diphenylarsine, Ph_2AsH .³³ This compound was one of the first Al–As six-membered ring compounds to be structurally characterized by single crystal X-ray diffraction. As shown in Figure 8, the Al–As ring is in a chair conformation with approximate tetrahedral environment about both Al and As atoms. The Al–As bond distances in this compound range from 2.512(3) Å to 2.542(3) Å.

Figure 7 Solid-state structure of As_2Al_3 core of $\text{As}_2[\text{AlCp}^*]_3$.

Figure 8 Solid-state structure of $[\text{Me}_2\text{Al-AsPh}_2]_3$.

3.4.1.4 Group 16 Ligands

3.4.1.4.1 Oxygen ligands

By far the most important group 16 compounds with aluminum are those of oxygen. This is due not only to the fact that the Al–O bond is the thermodynamic driving force behind much of the chemistry of aluminum, but also due to the fact that Al–O compounds have found great utility in various industrial and catalytic processes. Indeed, one of the most important recent developments in this area may be found in a class of compounds known as aluminoxanes. Aluminoxanes, methylaluminoxane (MAO) in particular, are very active cocatalysts in Ziegler–Natta systems. Two of the most common Al–O compounds are aluminum hydroxide, $\text{Al}(\text{OH})_3$, and aluminum oxide, Al_2O_3 .

The substantial bond strength of the Al–O bond is a major driving force in the chemistry of aluminum. This is evidenced by the ability of aluminum metal to form the ubiquitous Al_2O_3 oxide. Indeed, the pyrophoric nature of aluminum alkyls is traced to the great affinity between aluminum and oxygen. Certainly the simplest oxygen-based ligand is dioxygen itself. It is significant, therefore, that the literature reveals few discrete organoaluminum–dioxygen species. One notable example may be found in the reaction of potassium superoxide with trimethylaluminum in the presence of dibenzo-18-crown-6 (Equation (11)). The major point of interest

in the ionic $[\text{K} \cdot \text{dibenzo-18-crown-6}][\text{Me}_3\text{Al}\{\text{O}_2\}\text{AlMe}_3]^{34}$ compound is the dioxygen-based $[\text{Me}_3\text{Al}\{\text{O}_2\}\text{AlMe}_3]^-$ anion (Figure 9). An X-ray crystal structure of this compound confirms a most unusual bonding mode for oxygen—the two Me_3Al units are bridged by one of the oxygen atoms in an η^1 fashion. The rather long O–O bond distance of 1.47(2) Å was supported by the IR spectrum in which the stretch was observed at 851 cm^{-1} . The Al–O bond distances were 1.852(9) and 1.868(9) Å, while the Al–O–Al bond angle was $128.3(7)^\circ$. The value of $128.3(7)^\circ$ for the Al–O–Al is comparable to the Al–N–Al bond angle observed for $\text{K}[\text{Al}_2\text{Me}_6\text{N}_3]$.³⁵ Of course, the coordination of the aluminum atoms in this interesting anion is four-coordinate tetrahedral.

Figure 9 Solid-state structure $\text{Me}_3\text{Al}\{\text{O}_2\}\text{AlMe}_3]^-$ anion.

In fact, the major point of interest in this anion is not the coordination of the aluminum atoms but rather the unusual coordination of the oxygen atoms.

3.4.1.4.2 Crown ethers

An extensive chemistry has developed in the past two decades concerning the interaction of organoaluminum species with macrocyclic polyethers—crown ethers. Again, this chemistry is driven by the considerable Al–O bond strength. Characteristic of these compounds is a distortion of the crown ether by the organoaluminum species, essentially pulling the crown ether “inside-out”. While 1,4-para-dioxane certainly does not technically qualify as a crown ether, it does share some similarities. To this end, this discussion begins with the simple Lewis acid–Lewis base complex bis(trimethylaluminum)-*p*-dioxane, $\text{Me}_3\text{Al}(\text{dioxane})\text{AlMe}_3$ (7).³⁶ As illustrated in the compound below, the dioxane resides in a chair configuration as the two Me_3Al units bond to the two oxygen atoms. The Al–O bond distance in (7) is 2.02(2) Å.

Crown ethers (8)–(11), facilitated by the seminal discoveries of Pedersen,^{37,38} have found great utility as phase transfer catalysts and as alkali metal complexing agents. This fact notwithstanding, the past two decades has witnessed the development of a rich crown ether chemistry involving organometallic compounds of aluminum. Distinct from the coordination mode observed for alkali metal ions (wherein the metal ion resides inside the macrocyclic cavity), aluminum alkyls typically form neutral Lewis acid–Lewis base complexes and reside along the macrocyclic perimeter (leaving the cavity empty). Alkylaluminum halides, given the appropriate crown ether, can reside within the crown ether cavity resulting in high coordination number (five or six) organoaluminum-crown ether cations.

The bis(trimethylaluminum)·12-crown-4 complex, $[\text{AlMe}_3]_2\cdot 12\text{-crown-4}$, is a logical starting point. Prepared by reaction of trimethylaluminum with 12-crown-4,³⁹ the complex forms colorless crystals. The four oxygen atoms in 12-crown-4 were observed to be coplanar. The Al–O bond distance of 1.977(3) Å is remarkable as it compares to 2.02(2) Å reported for the dioxane-trimethylaluminum compound. Indeed, the overall conformation of this compound is quite similar to that observed in this compound as well.

The product from the reaction of ethylaluminum dichloride with 12-crown-4 gives an unusual complex cation with an AlCl_2 fragment being complexed by the crown ether, $[\text{Cl}_2\text{Al}\cdot 12\text{-crown-4}][\text{Cl}_3\text{AlEt}]$.⁴⁰ While the Al–O bond distances are unremarkable, the aluminum resides in an octahedral environment with the crown ether being pulled back, allowing more of an “on edge” coordination mode for the crown ether (Figure 10). The orientation of the crown ether is noteworthy in this complex as it has been distorted and completely “drawn back” thereby more fully exposing the oxygen atoms. The aluminum atom, with its coordination sphere completed by the two chlorine atoms in equatorial positions, thus resides in an octahedral environment. The fact that the aluminum atom is octahedral in the smallest crown ether, 12-crown-4, is all the more impressive when one considers that octahedral coordination is also observed for the much larger 18-crown-6.

Octahedral coordination has also been observed for the larger 18-crown-6 with organoaluminum moieties. In the ionic complex $[\text{Cl}_2\text{Al}\cdot 18\text{-crown-6}][\text{Cl}_3\text{AlEt}]$ ⁴⁰ the aluminum atom is also found in an octahedral environment in the cation with four of the oxygen atoms of the crown ether bonding to the aluminum atom. With both 12-crown-4 and 18-crown-6 the generation of the Cl_2Al^+ cation from the respective alkylaluminum dihalide was cited as being critical in the preparation of these compounds.

A number of points are noteworthy with respect to the metrical values in the $[\text{Cl}_2\text{Al}\cdot 12\text{-crown-4}]^+$ and $[\text{Cl}_2\text{Al}\cdot 18\text{-crown-6}]^+$ cations. Regarding $[\text{Cl}_2\text{Al}\cdot 12\text{-crown-4}]^+$, the Al–Cl bond distances (2.200(8) Å and 2.202(5) Å) were considered rather long, while the Al–O bond distances (mean of 1.96(2) Å) fall within the expected range of aluminum–oxygen donor–acceptor bond distances. The larger 18-crown-6 displayed a wide range of Al–O bond distances (1.946(5) Å to 2.065(4) Å) while the Al–Cl bond distances (2.148(3) Å and 2.210(2) Å) were comparable to those observed with 12-crown-4. A particularly interesting complex, $[\text{Cl}_2\text{Al}\cdot \text{benzo-15-crown-5}][\text{Cl}_3\text{AlEt}]$,⁴¹ results from reaction of benzo-15-crown-5 with ethylaluminum dichloride in toluene (Figure 11). As the coordination of aluminum in the anion is unremarkable four-coordinate tetrahedral, most of the

Figure 10 Solid-state structure of $[\text{Cl}_2\text{Al}\cdot 12\text{-crown-4}]^+$ cation.

Figure 11 Solid-state structure of $[\text{Cl}_2\text{Al}\cdot\text{benzo-15-crown-5}]^+$ cation.

interest is directed toward the cation. In the $[\text{Cl}_2\text{Al}\cdot\text{benzo-15-crown-5}]$ cation the aluminum atom resides in an extremely rare seven-coordinate pentagonal bipyramidal geometry. The Al–O bond distances for the oxygen atoms adjacent to the aromatic group (2.28(1) Å and 2.30(1) Å) are considerably longer than those to the other three oxygen atoms (2.03(1) Å, 2.06(1) Å, and 2.08(1) Å). Consequently, the aluminum atom is located “off-center” in the crown ether cavity even as the metal atom is coplanar with the five oxygen atoms. Thus, the coordination sphere of aluminum consists of five equatorial oxygen atoms and two axial chlorine atoms (Al–Cl: 2.202(5) Å and 2.197(7) Å). It is intriguing that the aluminum atoms in complexes with 12-crown-4 and 18-crown-6 assumed octahedral structures, yet the rare pentagonal bipyramidal is found with benzo-15-crown-5.

With the larger crown ethers neutral trimethylaluminum compounds have been obtained. For example, the first reported organoaluminum-crown ether complexes were $[\text{AlMe}_3]_2\cdot\text{dibenzo-18-crown-6}$ and $[\text{AlMe}_3]_4\cdot\text{15-crown-5}$ (Figures 12 and 13).⁴² These compounds were prepared by

Figure 12 Solid-state structure of $[\text{AlMe}_3]_2\cdot\text{dibenzo-18-crown-6}$.

Figure 13 Solid-state structure of $[\text{AlMe}_3]_4 \cdot 15\text{-crown-5}$.

reaction of excess trimethylaluminum with the respective crown ether. While it seems logical that the last remaining oxygen atom in $[\text{AlMe}_3]_4 \cdot 15\text{-crown-5}$ could not be complexed by an Me_3Al unit (as it is forced toward the interior of the macrocyclic cavity), it is unexpected that with the larger dibenzo-18-crown-6 none of the remaining four oxygen atoms could be attacked by an Me_3Al unit. However, the authors suggested that the benzo rings imparted sufficient steric hindrance to discourage Me_3Al coordination to neighboring (four) oxygen atoms. In both compounds, the Me_3Al units served to “pull” the oxygen atoms along the macrocyclic perimeter affording a rather elongated and “flattened” orientation for the crown ether. Moreover, principally due to the absence of benzo groups, 15-crown-5 was deemed to be more flexible than dibenzo-18-crown-6. The six oxygen atoms of dibenzo-18-crown-6 assumed a chair configuration thereby allowing substantial Al–O interaction (by the two trimethylaluminum units), as evidenced by the Al–O bond distance of 1.967(3) Å in $[\text{AlMe}_3]_2 \cdot \text{dibenzo-18-crown-6}$. It is ironic that 15-crown-5 being more flexible, yet the mean Al–O bond distance in $[\text{AlMe}_3]_4 \cdot 15\text{-crown-5}$ is considerably longer at 2.005(6) Å. The coordination of the aluminum atoms in these complexes were unremarkable four-coordinate tetrahedral.

Lastly, the mixed tetraoxo-diaza derivative of 18-crown-6, diaza-18-crown-6, has also been utilized to stabilize aluminum atoms in high coordination environments. In particular, the $[(\text{EtAl})_2 \cdot \text{diaza-18-crown-6}]^{2+}$ cation displays the aluminum center in a rare square pyramidal environment.⁴³

3.4.1.4.3 Sulfur, selenium, and tellurium ligands

The chemistry of sulfur-based ligands with aluminum is striking in its range and diversity. While the organoaluminum chemistry of sulfur bears some resemblance to that of oxygen, there are notable differences. Perhaps most notable is the fact that sulfur is larger, softer, and more polarizable than oxygen. This has a direct bearing on the manner in which the sulfur center interacts with aluminum. The corresponding chemistry with selenium and tellurium ligands has not been developed to a comparable extent.

The aluminum–sulfur bond has not been explored to an extent comparable to that of the corresponding aluminum–oxygen bond. However, there does exist an interesting coordination chemistry of organoaluminum species involving sulfur-containing ligands. An unusual Al–S linear oligomer was reported for $[\text{Me}_2\text{AlSMe}]_n$,⁴⁴ with an Al–S bond distance of 2.348 Å. There is data that suggest that this substance exists in the gas phase as a cyclic Al_2S_2 dimer with the methyl

groups oriented in a trans conformation.⁴⁵ Another Al-S compound, $\text{K}[\text{Al}_2\text{Me}_6\text{SCN}]$, was synthesized containing the thiocyanide ligand and was characterized with an Al-S bond distance of 2.489(2) Å.⁴⁶ The coordination of aluminum in both of these compounds may be described as four-coordinate tetrahedral.

3.4.1.4.4 Sulfur-based crown ethers

The two most important thiacycrown ethers are [14]aneS₄ (**12**) and [12]aneS₄ (**13**) (the thia equivalents of the aza-based crown ethers [14]aneN₄ and [12]aneN₄, respectively). Unlike oxygen-based crown ethers, sulfur-based crown ethers, thiacycrown ethers, have a demonstrated ability to complex transition metals as opposed to alkali and alkaline earth metals. Nonetheless, interesting thiacycrown ether complexes have been isolated with organoaluminum moieties.

Reaction of trimethylaluminum with [14]aneS₄ gives $[\text{Me}_3\text{Al}]_4[14]\text{aneS}_4$ (Figure 14).⁴⁷ The conformation of the thiacycrown ether was surprising as it assumed an “*exo-dentate*” geometry. Specifically, instead of the sulfur atoms residing along the macrocyclic cavity (as is the case for neutral oxygen-based crown ethers), the sulfur atoms have been pulled on the outside. Also noteworthy is the Al-S bond distance of 2.512(2) Å and 2.531(2) Å. These bond distances are considerably longer than those cited for $[\text{Me}_2\text{AlSMe}]_n$ (2.348 Å) and $\text{K}[\text{Al}_2\text{Me}_6\text{SCN}]$ (2.489(2) Å).

Perhaps the most interesting organoaluminum-thiacycrown ether complex is the $[\text{Me}_3\text{Al}]\cdot[12]\text{aneS}_4$ complex (Figure 15).⁴⁸ Although the reaction was performed with a four-fold excess of trimethylaluminum with [12]aneS₄ only the 1:1 crystalline compound was isolated. Upon examination of the coordination of the $[\text{Me}_3\text{Al}]\cdot[12]\text{aneS}_4$ monomer, the coordination of the

Figure 14 Solid-state structure of $[\text{Me}_3\text{Al}]_4[14]\text{aneS}_4$.

Figure 15 Solid-state structure of $[\text{Me}_3\text{Al}][12]\text{aneS}_4$.

aluminum atom appears decidedly nontetrahedral. Indeed, the aluminum atom appears to be coplanar with the three carbon atoms of the methyl groups. Thus, the “immediate” coordination of the aluminum atom goes beyond “distorted tetrahedral” and may be described as “trigonal pyramidal” with an extremely long Al–S bond distance of 2.718(3) Å. Indeed, the special coordination of the local environment about the aluminum atom suggested a more expansive view was in order. Upon examination of the unit cell it became clear that the coordination of the aluminum atom is not four-coordinate, but rather it is best described as five-coordinate as each aluminum atom has a secondary interaction with the sulfur atom of a neighboring [12]aneS₄ complex. The secondary Al–S contact is 3.052(3) Å. It is this secondary Al–S interaction, coupled with the primary Al–S interaction (bond), which causes the planarity of the Me₃Al unit. Thus, the coordination of the aluminum atom(s) in the “extended” [Me₃Al]·[12]aneS₄ complex is best described as five-coordinate trigonal bipyramidal. Essentially, a planar Me₃Al unit bridges two [12]aneS₄ moieties.

The literature reveals only a few examples of compounds that contain a direct Al–Se bond and fewer still of compounds that contain an Al–Te bond.

3.4.1.5 Group 17 Ligands

3.4.1.5.1 Hydride ligands

The fact that hydrogen can exist as either a cation (i.e., HCl) or an anion (i.e., NaH) belies its station as the simplest element. The chemistry of the H[−] hydride resembles that of the halides. Relative to a singular compound, the chemistry of aluminum hydride is embodied in the ubiquitous lithium aluminum hydride, LiAlH₄. This notwithstanding, relatively few compounds exist wherein a single hydrogen atom serves as a bridge between two organoaluminum moieties. One such compound results from the reaction of sodium hydride with trimethylaluminum, in the presence of 15-crown-5. This reaction yields the unusual [Me₃Al{H}AlMe₃][−] anion.⁴⁹ Unlike the “bent” superoxide-based [Me₃Al{O₂}AlMe₃][−] anion (previously discussed), the X-ray structure of the [Me₃Al{H}AlMe₃][−] anion (Figure 16) unexpectedly reveals a perfectly linear, 180°, Al–H–Al linkage with an Al–H bond distance of 1.65 Å. The aluminum–hydride bond was comparable to that observed in the dimethylaluminum hydride dimer, [Me₂AlH]₂. The fact that the coordination of the aluminum atom in both [Me₃Al{O₂}AlMe₃][−] and [Me₃Al{H}AlMe₃][−] is tetrahedral does not diminish the remarkable nature of these organoaluminum anions.

3.4.1.5.2 Halide ligands

The coordination of aluminum with halogen-based ligands is generally straight forward. The halogen serves as a simple monodentate ligand with a 1− charge. The corresponding coordination of the aluminum atom is simple four-coordinate tetrahedral. In particular, in the simple alkylaluminum

Figure 16 Solid-state structure of $[\text{Me}_3\text{Al}\{\text{H}\}\text{AlMe}_3]^-$ anion.

dihalides or dialkylaluminum halides the compounds exist as electron deficient dimers with μ -bridging halides (in much the same way as simple dimeric aluminum alkyls).

3.4.1.6 Compounds Containing Al–Al Bonds

3.4.1.6.1 Neutral compounds containing the Al–Al bond

The history of compounds containing Al–Al bonds is as colorful as it is interesting. Reports of organometallic alanes, compounds containing the iconic Al–Al bond, may be found as early as 1966.^{50–54} However, these early reports are now viewed with considerable skepticism as neither spectroscopic nor compelling structural data were presented. As a point of origin, the Al–Al bond distance in aluminum metal has been reported as 2.348 Å. The first organometallic compound unambiguously shown to contain an Al–Al bond, tetrakis[bis(trimethylsilyl)methyl]dialane, $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{AlAl}[\text{CH}(\text{SiMe}_3)_2]_2$, was reported in 1988.⁵⁵ This yellow crystalline compound was isolated from the potassium reduction of chloro-bis[bis(trimethylsilyl)methyl]aluminum (Equation (12)) (Figure 17):

The Al–Al bond distance of 2.660(1) Å observed in $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{AlAl}[\text{CH}(\text{SiMe}_3)_2]_2$ is a benchmark in organometallic chemistry as it stands as the first structural confirmation of a compound containing an Al–Al bond. The coordination of the aluminum atoms is also interesting as the core of the molecule is a planar $\text{C}_2\text{Al}-\text{AlC}_2$ core. It is interesting that the trigonal planar AlC_2 fragments are coplanar.

The “valence isomer of a dialane,” $(\eta^5\text{-C}_5\text{Me}_5)\text{Al}-\text{Al}(\text{C}_6\text{F}_5)_3$, was prepared by treatment of $[\text{Al}(\eta^5\text{-C}_5\text{Me}_5)]_4$ with $\text{Al}(\text{C}_6\text{F}_5)_3$.⁵⁶ This compound is notable as it has an Al–Al bond wherein the two aluminum atoms reside in distinctly different coordination environments. Specifically, one aluminum atom $[(\text{C}_6\text{F}_5)_3\text{Al}]$ is four-coordinate tetrahedral while the other one $[(\eta^5\text{-C}_5\text{Me}_5)\text{Al}]$ is basically two-coordinate interacting in a η^5 fashion with the pentamethylcyclopentadienyl ligand. The Al–Al–ring centroid bond angle deviates from linearity at 170.1(3)°. The Al–Al bond distance was shown to be 2.591(3) Å.

Reactivity of $[(\text{C}_5\text{Me}_5)\text{Al}]_4$ has proven particularly interesting. Reaction of $[(\text{C}_5\text{Me}_5)\text{Al}]_4$ with $[\text{Bu}^t\text{As}]_4$ gives a compound with a polyhedral As_2Al_3 framework, $\text{As}_2[(\text{C}_5\text{Me}_5)\text{Al}]_3$,³² (along with 2-methylpropane and isobutene). This novel $\text{As}_2[(\text{C}_5\text{Me}_5)\text{Al}]_3$ compound was isolated as yellow

Figure 17 Solid-state structure of $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{Al}-\text{Al}[\text{CH}(\text{SiMe}_3)_2]_2$.

Figure 18 Solid-state structure of $\text{As}_2[\text{Cp}^*\text{Al}]_3$.

crystals (Figure 18). While the short Al–As bond has been previously discussed herein, the Al_3 three-membered ring is noteworthy. The Al–Al bond distance in $\text{As}_2[\text{Cp}^*\text{Al}]_3$ is 2.83 Å. This bond distance is slightly longer than those reported for $\text{R}_2\text{Al}-\text{AlR}_2$ ($\text{R} = \text{CH}(\text{SiMe}_3)_2$, 2.66 Å) and $[(\text{C}_5\text{Me}_5)\text{Al}]_4$ (2.77 Å). The authors suggest that there are only twelve electrons available for the nine bonds in the As_2Al_3 framework. Consequently, this results in an electron deficient situation. The bonding in the As_2Al_3 polyhedral, therefore, is suggested to be similar to that in the *closo*-boranes.

The gas-phase generation of aluminum(I) chloride, AlCl , in the presence of bis(pentamethylcyclopentadienyl)magnesium yields the tetramer $[(\text{C}_5\text{Me}_5)\text{Al}]_4$ (Equation (13)).⁵⁷

This most novel compound contains an Al_4 tetrahedra core (each aluminum atom bonds to three other aluminum atoms) with pentamethylcyclopentadienyl ligands beyond the metallic center (Figure 19). The coordination of the aluminum atoms is technically tetrahedral as each aluminum atom bonds in a π -fashion to the pentamethylcyclopentadienyl ligand. The mean Al–Al bond distance in $[(\text{C}_5\text{Me}_5)\text{Al}]_4$ of 2.773(4) Å is expectedly longer than that observed for $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{AlAl}[\text{CH}(\text{SiMe}_3)_2]_2$ (2.660(1) Å). The ^{27}Al -NMR spectrum (70.4 MHz, external standard $[\text{Al}(\text{H}_2\text{O})_6]^{3+}$) of $[(\text{C}_5\text{Me}_5)\text{Al}]_4$ in benzene displayed a sharp signal at $\delta = -80.8$ ($\omega_{1/2} = 170$ Hz). This compound was also noteworthy in that it was the first molecular aluminum(I) compound stable under normal conditions (structurally characterized by single crystal X-ray diffraction). The relative weakness of the Al–Al bonds in $[(\text{C}_5\text{Me}_5)\text{Al}]_4$ was supported by quantum chemical calculations⁵⁸ and by the fact that monomeric $(\text{C}_5\text{Me}_5)\text{Al}$ units⁵⁹ could be obtained (both in solution and in the gas phase) by simply heating the $[(\text{C}_5\text{Me}_5)\text{Al}]_4$.

It should be noted that a second compound containing an Al_4 -tetrahedra core was subsequently reported by the same research group.⁶⁰ In this study, reaction of $(\text{AlI} \cdot \text{NEt}_3)_4$ with donor-free Bu^t_3SiNa in toluene gives the tetramer $[(\text{Bu}^t_3\text{Si})\text{Al}]_4$. The Al–Al bond distance in $[(\text{Bu}^t_3\text{Si})\text{Al}]_4$ (2.604 Å) is shorter than the corresponding metal–metal distances reported for $[(\text{C}_5\text{Me}_5)\text{Al}]_4$ (0.17 Å shorter) and $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{AlAl}[\text{CH}(\text{SiMe}_3)_2]_2$ (0.06 Å). Unlike the case for $[(\text{C}_5\text{Me}_5)\text{Al}]_4$ which yielded a very pronounced ^{27}Al -NMR signal, the $[(\text{Bu}^t_3\text{Si})\text{Al}]_4$ tetramer did not readily yield an ^{27}Al -NMR spectrum due, in part, to a “different HOMO-LUMO gap” (as compared to $[(\text{C}_5\text{Me}_5)\text{Al}]_4$).

Even as we are often intrigued by compounds possessing short bonds, it is also important to examine the other extreme: those compounds with exceedingly long, in this case Al–Al, bonds. Reaction of AlX_3 (X = Cl or Br) with $\text{Na}[\text{SiBu}^t_3]$ yields $[\text{Bu}^t_3\text{Si}]_2\text{AlAl}[\text{SiBu}^t_3]_2$.⁶¹ At a distance of 2.751(2) Å the central $\text{Si}_2\text{Al}–\text{AlSi}_2$ core of $[\text{Bu}^t_3\text{Si}]_2\text{AlAl}[\text{SiBu}^t_3]_2$, with as D_{2d} symmetry, has the longest Al–Al bond distance on record. In notable contrast, the next section will discuss compounds containing a measure of π -bonding.

Figure 19 Solid-state structure of $[(\text{C}_5\text{Me}_5)\text{Al}]_4$.

In terms of cluster compounds containing more than four aluminum atoms, recent advances have proven quite encouraging. A novel aluminum cluster, $\text{K}_2[\text{Bu}^i\text{Al}]_{12}$, was obtained from the potassium metal reduction of diisobutylaluminum bromide.⁶² This most unusual cluster has twelve aluminum atoms in a virtually perfect icosahedral geometry (Figure 20). This product was obtained in low yield as deeply red-colored crystals from a brown reaction mixture. The mean Al–Al bond distance of 2.660 Å in $\text{K}_2[\text{Bu}^i\text{Al}]_{12}$ is virtually identical to the Al–Al bond distance reported for the first organometallic alane, $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{AlAl}[\text{CH}(\text{SiMe}_3)_2]_2$, 2.660(1) Å. This is somewhat surprising in that in the cluster there is more steric repulsion in such a cluster. Logic would suggest just the opposite: the small dialane dimer would have the shorter metal–metal interaction instead of the larger metallic cluster.

Figure 20 Solid-state structure of $\text{K}_2[\text{Bu}^i\text{Al}]_{12}$ core showing the Al_{12} cluster.

Other interesting aluminum cluster compounds have prominently utilized the Al(I) species. In particular, reaction of $\text{LiN}(\text{SiMe}_3)_2$ with a solution of Al(I) provided $\text{Al}_{77}\text{R}_{20}^{2-}$.⁶³ This compound remains the largest metalloid cluster yet structurally characterized. The authors viewed this cluster “as an intermediate on the way to aluminum metal.” Schnöckel *et al.* subsequently reported that the $\text{Al}_{77}\text{R}_{20}^{2-}$ cluster is actually made up of smaller substituents including Al_7R_6^- ⁶⁴ and $\text{Al}_{12}\text{R}_8^-$.⁶⁵ Another interesting aluminum cluster, containing an Al_{14} core, results from a variation of the procedure established to prepare the $\text{Al}_{77}\text{R}_{20}^{2-}$ cluster.⁶⁶ The fact that these clusters contain more metal–metal bonds than metal–ligand bonds contributes to the authors employing the term “metalloid clusters” to distinguish them from traditional metallic clusters.

3.4.1.6.2 Radical anions: A degree of multiple bonding in the Al–Al bond

Soon after the experimental realization of compounds containing Al–Al bonds the concept of multiple bonding between two aluminum atoms began to gain attention. Beginning with the iconic compound of Uhl,⁵⁵ Pörschke *et al.*⁶⁷ allowed this compound to interact with lithium metal at -30°C , resulting in a black–violet solution. Crystallization of the product was achieved by the addition of TMEDA to complex the lithium ion leaving the $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{Al–Al}[\text{CH}(\text{SiMe}_3)_2]_2^-$ radical anion at 0°C . Most importantly, an X-ray crystal structure of the radical anion revealed 2.53 Å for the Al–Al bond (Figure 21). This represents a significant shortening of the Al–Al bond from the neutral alane (2.660(1) Å) distance. This is consistent with a measure of multiple bonding between the two metal atoms. The environment about the two aluminum atoms in the radical anion remain unchanged from that of the neutral species: three-coordinate trigonal planar.

3.4.2 GALLIUM

3.4.2.1 Introduction

In striking contrast to the ubiquitous nature of aluminum, gallium may legitimately be considered to be a rare element. Indeed, some of the so-called “rare earth metals” are more terrestrially abundant

Figure 21 Solid-state structure of $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{Al}-\text{Al}[\text{CH}(\text{SiMe}_3)_2]_2^-$.

than gallium. However, the history of gallium is just as interesting and engaging as that of aluminum. Paul-E'mile Lecoq de Boisbaudran is credited with discovering the element that would become known as gallium in 1875. He isolated little more than a single gram of this element from several hundred kilograms of the appropriate zinc blende ore. A particularly amusing historical anecdote concerns Dmitri Mendeleev and Lecoq de Boisbaudran. In his genius, Mendeleev had “predicted” the discovery of eka-aluminum, gallium, five years before Lecoq de Boisbaudran’s actual discovery. Upon Lecoq de Boisbaudran’s initial reporting of some of the physical properties of this new element Mendeleev wrote to him suggesting that he double check his value for the density of this new element as it was at odds with the value Mendeleev had predicted five years earlier. Upon closer examination of the density of gallium, Lecoq de Boisbaudran found that the experimental value for the density was indeed the value that Mendeleev had predicted.

There are significant differences between aluminum and gallium that directly affects the coordination chemistry exhibited by the two elements. One of the most intriguing points concern the atomic radius of gallium compared with that of aluminum. In striking contrast to the periodic trend of atomic radii increasing as one descends a given group, the atomic radius of gallium is observed to be slightly smaller (1.26 Å) than aluminum (1.48 Å). While size of the central atom is a prominent factor in coordination chemistry, it is difficult to quantitatively ascertain this effect relative to aluminum and gallium. Perhaps a more significant difference, as demonstrated by trimethylaluminum, is that aluminum often forms electron deficient bonding to obtain an octet of electrons. In notable contrast, gallium is perfectly at ease with only six electrons.

3.4.2.2 Group 14 Ligands

Similar to aluminum, the most important group 14 ligands for gallium are carbon based. The first organometallic compound of gallium, triethylgallium monoetherrate, $\text{Et}_3\text{Ga}\cdot\text{OEt}_2$, was reported in 1932 from reaction of ethylmagnesium bromide with gallium bromide in diethyl ether (Equation (14)):

Figure 22 Solid-state structure of Ph_3Ga .

These workers also stated that the ether-free triethylgallium derivative, Et_3Ga , could be prepared by a redox reaction between gallium metal and diethylmercury. Trimethylgallium, like triethylgallium, is a monomer with the gallium atom residing in a trigonal planar environment. Indeed, the gallium atom in the simplest organometallic compound, trimethylgallium, Me_3Ga ,⁶⁸ has been shown by gas phase electron diffraction to reside in a virtually idealized trigonal planar geometry.

A wealth of interesting chemistry concerns sterically demanding carbon-based ligands bonding to gallium. In this regard, the discussion must begin with the interactions of the phenyl, C_6H_5 -, ligand with gallium even though this ligand is not normally considered to be sterically demanding. Triphenylgallium, Ph_3Ga ,⁶⁹ is a convenient point of entry for this discussion. As supported by the solid-state crystal structure, the gallium atom in triphenylgallium is, on first glance, shown to reside in an unremarkable three-coordinate trigonal planar environment with Ga–C bond distances of 1.946(7) Å (Figure 22). A clue that the reality of the situation may be a bit more complicated is first hinted in the orientation of the phenyl rings. The three phenyl rings are observed to reside at dihedral angles of 0°, 13°, and 32° relative to the GaC_3 plane. Upon closer examination of the unit cell of this compound one observes that this arrangement of the phenyl rings allows for a significant secondary interaction of the gallium center with the *meta*-carbon atoms of other Ph_3Ga units. Thus—although not recognized or reported in the original article—the coordination of the gallium atom in Ph_3Ga may be best described as five-coordinate trigonal bipyramidal.

The synthesis and molecular structure of trimesitylgallium in 1986 marked the beginning of an exciting period in the organometallic chemistry of gallium. Trimesitylgallium was prepared by reaction of the Grignard reagent mesitylmagnesium bromide with gallium chloride (Equation (15)):⁷⁰

The solid-state structure of this compound (Figure 23) reveals that the aromatic rings of Mes_3Ga are configured in a propeller arrangement at angles of 55.9° (relative to the GaC_3 basal plane). Indeed, the orientation of the mesityl groups provide substantial protection of the metal center rendering a virtually idealized trigonal planar geometry (C–Ga–C angle: 120°) about the deeply protected gallium center.

Figure 23 Solid-state structure of Mes_3Ga .

One of the most sterically demanding ligand systems used with gallium is the class of aryl-based *ortho*-substituted phenyl derivatives known as *m*-terphenyls.⁷¹ Reaction of 2,6-dimesitylphenyllithium with gallium chloride forms bis(2,6-dimesitylphenyl)gallium chloride, $(\text{Mes}_2\text{C}_6\text{H}_3)_2\text{GaCl}$ (Figure 24).⁷² Although the Ga–C bond length (1.956 Å and 2.000 Å) and Ga–Cl bond length (2.177(5) Å) were expectedly somewhat longer than normal, this compound was significant as this was the first example of a main group metal accommodating two such large sterically demanding ligands. Perhaps most significant, however, is the coordination about the gallium center. The steric bulk of the two ligands is such that the C–Ga–C bond angle has been significantly widened from 120° expected for trigonal planar (observed for Mes_3Ga) $153.5(5)^\circ$. Quite distinct from the trigonal planar coordination observed for gallium in Mes_3Ga , the gallium coordination in $(\text{Mes}_2\text{C}_6\text{H}_3)_2\text{GaCl}$ is T-shaped. Indeed, the $153.5(5)^\circ$ C–Ga–C bond angle in $(\text{Mes}_2\text{C}_6\text{H}_3)_2\text{GaCl}$ is significantly greater than the corresponding C–Ga–C bond angle of $135.6(2)^\circ$ for bis(2,4,6-*tert*-butylphenyl)gallium chloride, $(\text{Bu}^t_3\text{C}_6\text{H}_2)_2\text{GaCl}$,⁷³ or the $134.3(3)^\circ$ C–Ga–C bond angle for bis(diphenylphenyl)gallium iodide, $(\text{C}_6\text{H}_5)_2\text{C}_6\text{H}_3\text{GaI}$.⁷⁴ The significance of the T-shaped coordination for gallium lies in the fact that this generally obscure geometry is normally reserved for interhalogen compounds like ClF_3 and BrF_3 . In such compounds the T-shaped geometry is predicated by the presence of two lone pairs of electrons in the equatorial plane on the central halogen atom. It is noteworthy, therefore, that the T-shaped geometry in $(\text{Mes}_2\text{C}_6\text{H}_3)_2\text{GaCl}$ results entirely from the interaction between the two sterically demanding ligands. It should be noted that the corresponding isostructural bis(2,6-dimesitylphenyl)gallium bromide, $(\text{Mes}_2\text{C}_6\text{H}_3)_2\text{GaBr}$,⁷² has been prepared and shown to be isostructural (C–Ga–C: 153.2°) with $(\text{Mes}_2\text{C}_6\text{H}_3)_2\text{GaCl}$.

While the organogallium chemistry of the cyclopentadienyl-based ligands (i.e., the pentamethyl derivative) will be discussed in detail later, it should be noted that a novel “ferrocenylgallane,” $[(\eta^5\text{-C}_5\text{H}_5)\text{Fe}(\eta^5\text{-C}_5\text{H}_4)][\text{Me}_2\text{Ga}]_2[(\eta^5\text{-C}_5\text{H}_5)\text{Fe}(\eta^5\text{-C}_5\text{H}_4)]$, has been synthesized from reaction of

Figure 24 Solid-state structure of $(\text{Mes}_2\text{C}_6\text{H}_3)_2\text{GaCl}$.

Figure 25 Solid-state structure of $[(\eta^5\text{-C}_5\text{H}_5)\text{Fe}(\eta^5\text{-C}_5\text{H}_4)][\text{Me}_2\text{Ga}]_2[(\eta^5\text{-C}_5\text{H}_5)\text{Fe}(\eta^5\text{-C}_5\text{H}_4)]$.

(chloromercurio)ferrocene, $[(\eta^5\text{-C}_5\text{H}_5)\text{Fe}(\eta^5\text{-C}_5\text{H}_4)\text{HgCl}]$, with trimethylgallium in toluene.⁷⁵ This ferrocenylgallane essentially consists of two ferrocene units bridged by two dimethylgallium units (Figure 25). The molecule resides about a center of symmetry located at the center of a planar, if asymmetric, Ga–C–Ga–C four-membered ring. While the ferrocenyl moieties are largely undistorted, the Ga–C bond distance of 2.587(5) Å was considered to be quite long. The coordination of the gallium atoms is distorted tetrahedral. However, upon closer examination, one can see that the coordination of the gallium centers may also be considered trigonal pyramidal wherein the trigonal plane consists of a Me_2Ga unit and one carbon atom of the ferrocenyl unit to give $\text{Me}_2\text{GaC}_{\text{Cp}}$. The fourth coordination site is completed by the axial approach of the carbon (Cp) approach of the other ferrocenyl unit.

3.4.2.3 Group 15 Ligands

3.4.2.3.1 Nitrogen ligands

The organogallium chemistry of nitrogen ligands is generally quite similar to that of aluminum with nitrogen ligands. Specifically, Lewis acid–Lewis base adducts are initially formed with primary amines. Further reaction leading to dimers or higher oligomers is driven by alkane elimination. In general, gallium is capable of all of the coordination modes displayed by aluminum earlier in this chapter. Thus, the coordination modes of gallium with various amines can range from three-coordinate trigonal planar to six-coordinate octahedral.

Although the coordination of gallium with nitrogen-based crown ethers, azacrown ethers, is not as well developed as that of aluminum, reports have demonstrated that gallium behaves in a fashion similar to that of its lighter congener with [14]aneN₄.⁷⁶

3.4.2.3.2 Phosphorus, arsenic, and antimony ligands

An informative reaction in this regard involves that of trimethylgallium with the sterically demanding phosphine, tris(trimethylsilyl)phosphine (Me₃Si)₃P (Equation (16)):

This reaction, aided by evolution of tetramethylsilane, affords the organogallium dimer [Me₂Ga–P(SiMe₃)₂]₂.⁷⁷ The X-ray structure of this compound, while revealing the gallium atoms in four-coordinate tetrahedral environments, also highlights the planar Ga₂P₂(Ga–P: 2.456(1) Å; P–Ga–P: 88.0°; Ga–P–Ga: 90.0(1)) four-membered core of the molecule. Such “III–V” compounds were of interest as they often served as single-source molecular precursors to various materials. Indeed, the corresponding indium analog was shown to give indium phosphide upon pyrolysis.⁷⁸ Like nitrogen, the most common Ga–P structural motif is the Ga₂P₂ four-membered ring dimer. Nonetheless, Ga₃P₃ six-membered rings have also been reported. For example, reaction of trimethylgallium with diphenylphosphine results in [Me₂GaPPh₃]₃.⁷⁹ The Ga₃P₃ ring is in a chair conformation with Ga–P bond distances of 2.433(1) Å. The coordination of the gallium (and phosphorus) atoms is four-coordinate tetrahedral.

A striking gallium–phosphorus compound containing a P–P bond was isolated from reaction of the Lewis acid–Lewis base adduct Me₃GaPMe₃ with P(SiMe₃)₃, [P(SiMe₃)(Me₂Ga)₂]PP[(GaMe₂)₂P(SiMe₃)₂].⁸⁰ The adduct, possessing C_{3v} symmetry was allowed to react with an excess of tris(trimethylsilyl)phosphine to give [P(SiMe₃)(Me₂Ga)₂]PP[(GaMe₂)₂P(SiMe₃)₂]. While the coordination of the four gallium atoms in this complex is generally unremarkable as four-coordinate tetrahedral, the most noteworthy feature is the P–P bond of 2.25(3) Å. This complex represents a rare example of a phosphinogallane containing a P–P bond.

The organometallic coordination of gallium with arsenic ligands is quite similar to that of phosphorus. In particular, the predominant structural motif in gallium–arsenic compounds would be Ga–As dimers with a Ga₂As₂ four-membered ring core. The coordination of the arsenic and gallium atoms in such compounds would be tetrahedral. Typical examples of such compounds include [Me₂GaAs(Bu^t)₂]₂,⁸¹ and [Ph₂GaAs(CH₂SiMe₃)₂]₂.⁸² Occasionally, a Ga–As trimer with a Ga₃As₃ six-membered ring has been isolated. For example, although [Me₂GaAs(Prⁱ)₂]₃ is a trimer (with the Ga atoms in four-coordinate tetrahedral environments) it is surprising that the ring was reported to have a distorted boat confirmation.⁸³

The literature reveals a paucity of compounds containing the Ga–Sb bond. However, antimony seems to behave in a fashion similar to that of its lighter congeners. For example it can readily form Lewis acid–base adducts, (Bu^t)₃GaSb(Et₃).⁸⁴ Trimers such as [Me₂GaSb(SiMe₃)₂]₃ have also been reported.⁸⁵ The coordination of gallium in both of these compounds is unremarkable four-coordinate tetrahedral.

3.4.3.4 Group 16 Ligands

3.4.3.4.1 Crown ethers

The coordination chemistry of gallium with crown ethers is not developed to the same extent as that of aluminum. Indeed, the literature reveals only bis(trimethylgallium)(dibenzo-18-crown-6, $[\text{GaMe}_3]_2 \cdot \text{dibenzo-18-crown-6}$,⁸⁶ the gallium analog of the previously reported aluminum complex, $[\text{AlMe}_3]_2 \cdot \text{dibenzo-18-crown-6}$. The coordination of the gallium atoms in $[\text{GaMe}_3]_2 \cdot \text{dibenzo-18-crown-6}$ is of course tetrahedral. Indeed, diaza-18-crown-6 has been shown to stabilize a gallium center in a five-coordinate trigonal bipyramidal environment.⁸⁷

3.4.2.5 Group 17 Ligands

Of the gallium compounds concerning group 17 ligands, the gallium halides may be considered the “work horses” of gallium chemistry as they are often the starting reagents. The gallium halides are differentiated from their aluminum analogs in their respective structures: the aluminum halides are dimeric with electron deficient Al–X–Al bridges (with the aluminum atoms being four-coordinate tetrahedral), while the gallium halides are monomeric, with the gallium atoms being three-coordinate trigonal planar. The first structurally characterized monomeric organogallium dihalides involved compounds of the type sMesGaX_2 ($\text{X} = \text{Cl}, \text{Br}$; $\text{sMes} = \text{supermesityl}, \text{Bu}^t_3\text{C}_6\text{H}_2$).⁸⁸ The coordination of the gallium atoms in sMesGaX_2 is three-coordinate trigonal planar. The monomeric nature of these compounds is particularly significant when one considers (Figure 26) that organogallium dihalides with considerably more sterically demanding ligands have been shown to be dimeric. In particular, even when the sterically demanding 2,6-dimesitylphenyl ligand is employed, the organogallium dichloride dimer (with $\mu\text{-Cl}$ bridges), $[(\text{Mes}_2\text{C}_6\text{H}_3)\text{GaCl}_2]_2$,⁸⁹ is isolated in the solid state. Thus, the monomeric nature of sMesGaX_2 is all the more remarkable considering the fact that dimers are found for much more sterically demanding ligands.

Figure 26 Solid-state structure of sMesGaCl_2 .

3.4.2.5.1 Two-coordinate gallium centers

As should be evident at this point, depending upon the steric demands of the ligand, gallium is equally disposed to be three-coordinate trigonal planar or four-coordinate tetrahedral. With macrocyclic ligands such as crown ethers gallium can achieve five-coordinate square pyramidal or trigonal bipyramidal geometries. Only in the last few years have reports appeared describing gallium with novel two-coordinate motifs.

Reaction of solvent-free $\text{Li}\{(\text{NDippCMe})_2\text{CH}\}$ ($\text{Dipp} = \text{C}_6\text{H}_3\text{Pr}^i_{2-2,6}$), “GaI,” and potassium metal in toluene gave yellow crystals of $\text{Ga}\{(\text{NDippCMe})_2\text{CH}\}$.⁹⁰ This striking compound

features a two-coordinate gallium center in an extremely rare “V-shaped” (N–Ga–N: 87.53(5)°) structure (Figure 27). Moreover, the metal center was described as a six-electron gallium(I) center: electronically analogous to a singlet carbene carbon system. The authors suggested that the steric demands of this ligand are approximately similar to some of the sterically demanding *m*-terphenyl ligands. Equally amazing about this compound is the presence of a “lone pair” of electrons on the gallium center. This would suggest possibly significant Lewis base chemistry.

Another example of a two-coordinate gallium center is found in $[(\text{Pr}^i_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3]\text{GaFe}(\text{CO})_4$ (Figure 28), isolated from reaction of $[(\text{Pr}^i_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3]\text{GaCl}_2$ with $\text{Na}_2[\text{Fe}(\text{CO})_4]$.⁹¹ Although this compound was described by the authors as a *ferrogallyne*, a compound containing an iron–gallium triple bond (*vide infra*), the issue at hand is that the gallium atom in $[(\text{Pr}^i_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3]\text{GaFe}(\text{CO})_4$ is unambiguously two-coordinate with a C–Ga–Fe bond angle of 179.2(1)°. The Ga–Fe bond reported for $[(\text{Pr}^i_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3]\text{GaFe}(\text{CO})_4$ of 2.2248(7) Å is among the shortest on record.

3.4.2.6 Compounds Containing Ga–Ga Bonds

3.4.2.6.1 Neutral compounds containing the Ga–Ga bond

The first inorganic compound shown to contain a Ga–Ga bond is traced to the structure of bis[dibromo(1,4-dioxane)gallium], $\text{Br}_2\text{GaGaBr}_2(\text{dioxane})_2$ (**14**). X-ray structural data on $\text{Br}_2\text{GaGaBr}_2(\text{dioxane})_2$ ⁹² confirmed the existence of a Ga–Ga bond in this solvent-stabilized species with the gallium atoms officially being in the (II) oxidation state (and not a “mixed” $\text{Ga}^{\text{(I)}}[\text{Ga}^{\text{(III)}}]$ system). The Ga–Ga bond in $\text{Br}_2\text{GaGaBr}_2(\text{dioxane})_2$ was determined to be 2.395(6) Å. Similarly, the chloro derivative bis[dichloro(1,4-dioxane)gallium], $\text{Cl}_2\text{GaGaCl}_2(\text{dioxane})_2$ (Ga–Ga: 2.406(1) Å; Ga–Cl: 2.406(1) Å; Ga–O: 2.021(5) Å), was reported to be isostructural with the bromine congener.⁹³ The coordination of $\text{X}_2\text{GaGaX}_2(\text{dioxane})_2$ (X = Br, Cl) is four-coordinate tetrahedral in both cases.

Almost two decades after the reporting of the structure of $\text{X}_2\text{GaGaX}_2(\text{dioxane})_2$ another modification of a dioxane-stabilized gallium(II) halide was reported. Room temperature (instead of 0 °C as in the original preparation) crystallization of Ga_2Cl_4 from a dioxane solution affords $\text{Cl}_2\text{GaGaCl}_2(\text{dioxane})_4$ (Figure 29).⁹⁴ A number of issues are noteworthy concerning this compound. First of all, this compound is significant as it is a rare example of a dimeric compound containing a Ga–Ga bond wherein both gallium atoms are five-coordinate. For example, unlike the previous modification, in this case the coordination of both gallium atoms is five-coordinate. The coordination sphere of the gallium atoms in $\text{Cl}_2\text{GaGaCl}_2(\text{dioxane})_4$ is completed by two chlorine atoms, two dioxane units, and a gallium atom. The coordination is virtually idealized trigonal bipyramidal (O–Ga–O: 179.10(10)°). While the Ga–O bond distance of 2.4087(19) Å in $\text{Cl}_2\text{GaGaCl}_2(\text{dioxane})_4$ is considerably longer than that reported for $\text{Cl}_2\text{GaGaCl}_2(\text{dioxane})_2$ (2.021(5) Å), the Ga–Cl bond distance of 2.1721(7) Å in $\text{Cl}_2\text{GaGaCl}_2(\text{dioxane})_4$ is substantially shorter than the $\text{Cl}_2\text{GaGaCl}_2(\text{dioxane})_2$ value (2.406(1) Å). Perhaps the most significant difference between the bis(dioxane) and quadro(dioxane) gallium(II) chloride modifications is found in the

Ga–Ga bond distances: $\text{Cl}_2\text{GaGaCl}_2(\text{dioxane})_2$, Ga–Ga: 2.406(1) Å; $\text{Cl}_2\text{GaGaCl}_2(\text{dioxane})_4$, Ga–Ga: 2.3825(9) Å. It is most surprising that the Ga–Ga bond distance is shorter for the compound wherein the coordination number is higher. Logic would predict just the opposite!

The first organometallic compound containing a Ga–Ga bond, tetrakis[bis(trimethylsilyl)methyl]digallane, $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{GaGa}[\text{CH}(\text{SiMe}_3)_2]_2$ (Figure 30), was reported in 1989.⁹⁵ This compound was prepared from reaction of the dioxane stabilized gallium(II) bromide, $\text{Br}_2\text{GaGaBr}_2(\text{dioxane})_2$, with four equivalents of bis(trimethylsilyl)methyl lithium, $\text{LiCH}(\text{SiMe}_3)_2$. The Ga–Ga bond distance in $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{GaGa}[\text{CH}(\text{SiMe}_3)_2]_2$, isolated as yellow crystals from *n*-pentane, was determined to be 2.541(1) Å. This compound, like its aluminum analog, was shown to have a planar $\text{C}_2\text{M–MC}_2$ unit. However, the metal–metal bond distance in $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{GaGa}[\text{CH}(\text{SiMe}_3)_2]_2$ is 1.2 Å shorter than that observed for the aluminum analog. In addition, this compound exhibits a UV–vis absorption at 370 nm which was assigned to the Ga–Ga bond. It should be noted that even though the gallium(II) bromide bis(dioxane) starting compound contained a Ga–Ga bond (2.395(6) Å), it was conserved (and lengthened) in the organometallic compound.

Figure 30 Solid-state structure of $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{Ga–Ga}[\text{CH}(\text{SiMe}_3)_2]_2$.

The chemistry of molecules containing “gallium chains”, strings of more than two gallium atoms, has not been extensively developed. To date, only a few such compounds have been reported. Reaction of the obscure “GaI” with phosphines resulted in a most unexpected product. This gallium subhalide was prepared by the ultrasonic irradiation of gallium metal and I_2 . In the presence of triethylphosphine, “GaI” in toluene at -78°C results in $[\text{Et}_3\text{P–GaI}_2]_2\text{Ga(I)PET}_3$.²⁹ The most striking point concerning this compound is the fact that it contains the first reported example of a “gallium chain” of three gallium atoms, $-\text{Ga–Ga–Ga}-$. It is noteworthy that the Ga–Ga bonds in this compound were shown to be reasonably short and asymmetric at distances of 2.451(1) Å and 2.460(1) Å. Moreover, this compound has mixed valences. Specifically, the center, bridging gallium atom was considered Ga(I) while the two terminal metal atoms were considered Ga(II). The Ga–Ga–Ga bond angle was shown to be $121.9(1)^\circ$.

A few years later another compound containing a “gallium chain” was reported. Interestingly, this case also involved phosphines. In this instance, reaction of $[(\text{Pr}^i_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3]_2\text{GaCl}_2$ with $\text{P}(\text{SiMe}_3)_3$ was shown to give the unusual organometallic compound $[(\text{Pr}^i_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3]\text{Ga}\{\text{H}_2\text{P–Ga(H)PH}_2\}\text{Ga}[\text{C}_6\text{H}_3(\text{C}_6\text{H}_2\text{Pr}^i_3)]$ (**15**).⁹⁶ Owing to the unusual nature of this compound characterization assumed added significance. To this end, this compound was characterized by multinuclear NMR, complete elemental analyses (C, H, Ga, and P), IR spectroscopy, and single crystal X-ray diffraction. The compound represented the first report of an organometallic compound containing a gallium chain, $-\text{Ga–Ga–Ga}-$. Surprisingly, yet consistent with the first gallium chain compound, $[\text{Et}_3\text{PGAuI}_2]_2\text{Ga(I)PET}_3$, the metallic chain is quite asymmetric with Ga–P

distances of 2.5145(13) Å and 2.7778(14) Å. The Ga–Ga–Ga bond angle in $[(\text{Pr}^i_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3]\text{-Ga}\{\text{H}_2\text{PGa}(\text{H})\text{PH}_2\}\text{Ga}[\text{C}_6\text{H}_3(\text{C}_6\text{H}_2\text{Pr}^i_3)]$ is particularly acute at $69.68(4)^\circ$. This value is more than 50° less than the corresponding bond angle in $[\text{Et}_3\text{PGaI}_2]_2\text{Ga}(\text{I})\text{PEt}_3$. Indeed, this compound may be considered to have a Ga_3P_2 core (Figure 31).

The cluster chemistry of gallium is a fertile, if still emerging, area of study. In most of the gallium clusters isolated sterically demanding ligands have been utilized. In a rather circuitous reaction involving the ultrasonication of gallium metal with iodine, both insoluble gallium subhalides and toluene-soluble “ Ga_2I_3 ” were isolated. Addition of tris(trimethylsilyl)silyllithium·(THF)₃ to this complicated reaction yields an interesting ionic complex in which the anion contains a Ga_4Si trigonal bipyramidal core.⁹⁷ It was ambiguous whether there was Ga–Ga bonding in the equatorial plane.

Reaction of $\text{Ga}_2\text{Br}_4(\text{dioxane})_2$ with a fourfold excess of $\text{LiC}(\text{SiMe}_3)_3$ results in another interesting gallium cluster: $[(\text{Me}_3\text{Si})_3\text{C}]\text{Ga}]_4$, a compound with a gallium tetrahedral core (16).⁹⁸ Each of the gallium atoms reside at the corners of an almost idealized pyramid. The mean Ga–Ga bond distance in the pyramid is 2.688 Å. This compound was reported to be thermally stable, decomposing only above 255°C . Moreover, it was reported to be air-stable for months without significant decomposition. This compound is overall quite similar to the previously discussed Al_4 tetrahedral pyramid.

Figure 31 Solid-state structure of $[(\text{Pr}^i_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3]\text{Ga}\{\text{H}_2\text{PGa}(\text{H})\text{PH}_2\}\text{Ga}[\text{C}_6\text{H}_3(\text{C}_6\text{H}_2\text{Pr}^i_3)]$.

In 2001 a striking compound was prepared wherein two tetrahedra of gallium atoms are bridged by a single Ga–Ga bond. At the heart of this synthesis is the fabrication of gallium(I) bromide, GaBr. Reaction of trimethylsilyllithium (dissolved in toluene at -78°C) with a GaBr solution was carried out. After workup a black residue was reported to remain. One of the products isolated from this residue was the neutral octagallane $[\{(\text{Me}_3\text{Si})_3\text{C}\}_6\text{Ga}_8]$.⁹⁹ The X-ray crystal structure of $[\{(\text{Me}_3\text{Si})_3\text{C}\}_6\text{Ga}_8]$ showing the Ga_8 core is shown in Figure 32. All angles within the triangular faces of the tetrahedra are virtually idealized 60° . It is surprising that the Ga–Ga bond distances in $[\{(\text{Me}_3\text{Si})_3\text{C}\}_6\text{Ga}_8]$ vary within a narrow range (2.605 Å to 2.648 Å). Perhaps even more surprising is the fact that the Ga–Ga bond distances in $[\{(\text{Me}_3\text{Si})_3\text{C}\}_6\text{Ga}_8]$ are significantly shorter than the corresponding distances reported for $[\{(\text{Me}_3\text{Si})_3\text{C}\}_4\text{Ga}]_4$ (Ga–Ga_{mean}: 2.688 Å). Indeed, the Ga–Ga bond connecting the two tetrahedra is 2.6143(11) Å. This was the first example of “two tetrahedral R_3M_4 units linked by a single metal–metal bond” for clusters containing one element.

A hexameric aggregate of (pentamethylcyclopentadienyl)gallium(I) was recently reported.¹⁰⁰ These workers grew a single crystal of this compound by “cooling a molten sample of the pure, freshly condensed material.” The structure of the compound reveals a Ga_6 core inside a pentamethylcyclopentadienyl perimeter. The authors note that the Ga_6 unit “is not strictly octahedral but compressed along a C_3 axis to give two distinct Ga_3 units”. While the C_5Me_5^- ligands interact with the gallium atoms in an η_5 fashion, the authors argue that the “orientation of the C_5Me_5^- ligands with respect to the M_6 core is consistent with a second order Jahn–Teller effect. It is important to note that other gallium clusters have been reported. For example, clusters containing nine, $\text{Ga}_9(\text{CMe}_3)_9$,¹⁰¹ and twelve, $[\text{Ga}_{12}(\text{Flu})_{10}]^{2-}$ (Flu = fluorenyl),¹⁰² gallium atoms have recently been prepared and characterized.

Figure 32 Solid-state structure of $[\{(\text{Me}_3\text{Si})_3\text{C}\}_6\text{Ga}_8]$.

3.4.2.6.2 Radical anions and multiple bond character

The concept of a Ga–Ga bond with multiple bond character has only recently been brought to the fore. Perhaps the most compelling studies are those that provide a direct “gallane” to “gallene” comparison. The first gallane, $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{GaGa}[\text{CH}(\text{SiMe}_3)_2]_2$ (Ga–Ga: 2.541(1) Å), was reduced with ethyllithium to give the radical anion $[(\text{Me}_3\text{Si})_2\text{HC}]_2\text{GaGa}[\text{CH}(\text{SiMe}_3)_2]_2^-$ (Equation (17)).¹⁰³

The Ga–Ga bond in the radical anion was determined to be 3.401(1) Å, a decrease of 0.14 Å from the neutral gallane. While the data strongly supports a measure of *p*-bonding among the gallium atoms, the coordination about the metal centers is unchanged from the neutral gallane (three-coordinate trigonal planar). Others have obtained similar results in different gallane to gallene comparisons.¹⁰⁴

3.4.2.6.3 Cyclogallenes and metalloaromaticity

One of the more exciting developments in the coordination chemistry of gallium in the past few years has been the realization of metalloaromaticity. Metalloaromaticity, by definition, is traditional aromaticity exhibited by a metallic ring system rather than a carbon ring system. The first metalloaromatic compound was prepared by the sodium metal reduction of $(\text{Mes}_2\text{C}_6\text{H}_3)\text{GaCl}_2$ to give $\text{Na}_2[(\text{Mes}_2\text{C}_6\text{H}_3)\text{Ga}]_3$ (Figure 33).¹⁰⁵ As shown, the gallium atoms are three-coordinate in virtually idealized trigonal planar environments. The Ga–Ga–Ga bond angles within the ring are 60.01(1)°, while the Ga–Ga bond distance is 2.441(1) Å. The potassium-based cyclogallene, $\text{K}_2[(\text{Mes}_2\text{C}_6\text{H}_3)\text{Ga}]_3$, has also been reported.¹⁰⁶ In these compounds, the sodium atoms are not engaging in any meaningful metal–metal bonding with the gallium atoms (sodium–gallium approach: 3.1 Å). The sodium atoms appear to be assisted by subtle interactions with the π -cloud of the *m*-terphenyl ligands. Various computational quantum chemistry calculations, in addition to agreement with Schleyer’s NICS (Nucleus Independent Chemical Shift),¹⁰⁷ have confirmed the metalloaromatic natures of these compounds.^{108,109}

Figure 33 Solid-state structure of $\text{Na}_2[(\text{Mes}_2\text{C}_6\text{H}_3)\text{Ga}]_3$.

3.4.2.6.4 Ga–Ga triple bonds

Sodium metal reduction of $[(\text{Pr}^i_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3]\text{GaCl}_2$ does not result in a compound containing three-coordinate gallium atoms (like the cyclogallenes), rather, a most unexpected compound containing two-coordinate gallium atoms is isolated, $\text{Na}_2[\{(\text{Pr}^i_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3\}\text{Ga}\equiv\text{Ga}\{\text{C}_6\text{H}_3(\text{C}_6\text{H}_2\text{Pr}^i_3)_2\}]$ (see Figure 34).¹¹⁰ The two-coordinate nature of each gallium atom simply consists of one sterically demanding ligand and the other gallium atom. Again, the sodium atoms do not appear to be engaging the gallium atoms. The Ga–Ga bond distance of 2.319(3) Å is noteworthy as being very short. Even though the bond angles about the two gallium atoms are decidedly nonlinear at angles of 128.5(4)° and 133.5(4)°, the authors referred to this compound as a *gallyne*—the first example of a gallium–gallium triple bond. While this description of the bonding was initially challenged,¹¹¹ the compelling nature of the compound is well documented.^{112,113} Subsequent computational quantum chemistry calculations, including bond order analysis, provided a firm basis for the triple bond description.^{114,115} Review articles have been published on the concept of triple bonding between two gallium atoms.^{116–118}

Figure 34 Solid-state structure of $\text{Na}_2[\{(\text{Pr}^i_3\text{C}_6\text{H}_2)_2\text{C}_6\text{H}_3\}\text{Ga}\equiv\text{Ga}\{\text{C}_6\text{H}_3(\text{C}_6\text{H}_2\text{Pr}^i_3)_2\}]$.

ACKNOWLEDGEMENTS

The author is indebted to a number of gifted co-workers and students for their contributions over the years. Some of their names may be found in the list of references. Special thanks are extended to Jason K. Vohs for his expertise in generating many of the graphics for this chapter.

3.5.1 INDIUM

3.5.1.1 Introduction

The metallic element indium is the second heaviest member of the group 13 family. Indium has the electronic configuration of $[\text{Kr}]4d^{10}5s^25p^1$, and forms compounds in the oxidation states I, II, and III. Coordination compounds with indium in the trivalent state are the most common. In this

chapter, primarily the developments in indium coordination chemistry since the early 1980s will be surveyed. *Comprehensive Coordination Chemistry-I* (CCC, 1987) is an excellent reference source for pre-1980 work.¹ In general, organometallic compounds are outside the scope of this chapter. Still, there is a huge body of literature that covers various aspects of indium coordination chemistry. Fortunately, there are several treatises pertinent to the coordination, organometallic, and general chemistry of indium.¹⁻²¹ For categories where there is a large amount of more recent work, and for early background material, the reader will be directed to some of these sources for more detailed coverage of the topic.

3.5.1.2 Indium (III)

3.5.1.2.1 Group 14 ligands

(i) Carbon ligands

The vast majority of molecules that belong to this category are organoindium compounds. Review articles on the chemistry of such compounds are available.¹¹⁻¹⁴ Although the carbon monoxide complexes of indium are unknown, the isoelectronic cyanide ligand forms thermally stable adducts with indium(III). During the attempted synthesis of indium oxycyanide by the action of cyanogen on indium oxyiodide, the monoclinic form of $\text{In}(\text{CN})_3$ was obtained in low yield as a by-product.²² Recently, a new form of indium(III) cyanide has been prepared in excellent yield by a low-temperature solution method, using InCl_3 and Me_3SiCN as starting materials.²³ X-ray crystallographic data show that $\text{In}(\text{CN})_3$ has a cubic structure with an octahedrally coordinated indium atom surrounded by an average of three carbon and three nitrogen atoms. This material readily, and reversibly, incorporates Kr gas into the empty cavities to form $\text{In}(\text{CN})_3 \cdot \text{Kr}$.²³

(ii) Silicon, germanium, tin, and lead ligands

A few silyl complexes of indium(III) are known. The homoleptic trimethylsilyl derivative $\text{In}(\text{SiMe}_3)_3$ was reported in 1969.¹ It is a highly thermally, light- and oxygen-sensitive compound. Compounds with higher thermal stability have been obtained using sterically more demanding silyl ligands. For example, $\{(\text{Me}_3\text{Si})_3\text{Si}\}_2\text{In}(\mu\text{-Cl})_2\text{Li}(\text{THF})_2$ (**1**) has been prepared by treating InCl_3 with $\{(\text{Me}_3\text{Si})_3\text{Si}\}\text{Li}(\text{THF})_3$.²⁴ It features a tetrahedral indium center with an unusually large Si—In—Si bond angle ($139.9(2)^\circ$). The synthesis of $(t\text{-Bu}_2\text{PhSi})_3\text{In}$ (**2**),²⁵ $\{(\text{Me}_5\text{C}_5)_2\text{Me-Si}\}_2\text{InMe}$,²⁶ and the silyl indium halides $(t\text{-Bu}_3\text{Si})_n\text{InX}_{3-n}$ ($\text{X} = \text{halide}$, $n = 1, 2$)²⁷⁻²⁹ and $t\text{-Bu}_2\text{Ph-SiInCl}_2$ ²⁵ have also been reported. The synthesis of $(t\text{-Bu}_2\text{PhSi})_3\text{In}$ and $(t\text{-Bu}_3\text{Si})_3\text{In}$ involves a metathesis process between indium(III) halides and the sodium salt of the corresponding silyl ligand. The $\{(\text{Me}_5\text{C}_5)_2\text{Si}(\text{Me})\}_2\text{InMe}$ ²⁶ has been obtained in high yield by treating the silylene $(\text{Me}_5\text{C}_5)_2\text{Si}$ with InMe_3 . Some of the indium halide derivatives form adducts with oxygen- and nitrogen-containing donors.^{25,27,28} For example, the dichlorides react with THF to form $t\text{-Bu}_2\text{Ph-SiInCl}_2(\text{THF})$ and $t\text{-Bu}_3\text{SiInCl}_2(\text{THF})$. The monochloride compound $(t\text{-Bu}_3\text{Si})_2\text{InCl}$ reacts with AlCl_3 to give an ionic indium species $[(t\text{-Bu}_3\text{Si})_2\text{In}][\text{AlCl}_4]$.

Compounds with In—Ge (e.g., $(\text{Et}_3\text{Ge})_3\text{In}$)¹ and In—Sn bonds are rare. A series of stannyl compounds of the type $\text{Ph}_3\text{SnInX}_2(\text{TMEDA})$ with apparently five-coordinate indium centers have been obtained from the reaction between InX in toluene/TMEDA ($\text{X} = \text{Cl}, \text{Br}, \text{I}$) and Ph_3SnX .³⁰ The treatment of $\text{Ph}_3\text{SnInCl}_2(\text{TMEDA})$ with Et_4NCl leads to $[\text{Et}_4\text{N}][\text{Ph}_3\text{SnInCl}_3]$. The compound $\text{L}_2\text{InSnPh}_3$ ($\text{L} = 2\text{-}[(\text{dimethylamino})\text{methyl}]\text{phenyl}$) can be synthesized using the chloro derivative L_2InCl and the sodium salt of SnPh_3^- .³¹ There are no reports of coordination compounds with In—Pb bonds.

3.5.1.2.2 Group 15 ligands

(i) Nitrogen ligands

(a) *Neutral monodentate nitrogen ligands.* Neutral nitrogen donors form a variety of adducts with indium in the trivalent state. Indium salts, in particular those with weakly coordinating anions such as BF_4^- , NO_3^- , or ClO_4^- , form cationic species like $[\text{In}(\text{en})_3]^{3+}$, $[\text{In}(\text{py})_6]^{3+}$, $[\text{In}(\text{bipy})_3]^{3+}$, and $[\text{In}(\text{phen})_3]^{3+}$.^{1,3,4} The formation of adducts containing acetonitrile donors, e.g., $[\text{In}(\text{NCMe})_6](\text{BF}_4)_3$, is also established.³² The cation $[\text{In}(\text{NH}_3)_6]^{3+}$ is present in liquid ammonia.¹ However, X-ray crystal structural data are not available. An ammonia adduct $\text{InF}_2(\text{NH}_2)(\text{NH}_3)$ has been prepared by reacting ammonium fluoride and indium nitride in supercritical ammonia.³³ The solid-state structure consists of octahedral indium moieties linked by fluoride and amide ligands. In addition, each indium atom is coordinated to one terminal F and one terminal NH_3 molecule.

(b) *Azide, NCO, and NCS ligands.* Indium nitride is an important semiconductor material.³⁴ Relatively milder routes (ideally below 600°C) are preferred for the generation of indium nitride, due to its low thermal stability. Thus there is a constant need for new precursor material that generates InN under low-temperature conditions. One impetus for studying indium complexes of nitrogen-ligand compounds such as azido and amido derivatives is their potential utility in InN -related applications.

The isolation of several indium(III) adducts containing azide groups has been reported. These include Cl_2InN_3 , Br_2InN_3 , $\text{Cl}_2\text{InN}_3(\text{py})_2$, $\text{Cl}_2\text{InN}_3(\text{THF})_2$, $[(\text{py})_2\text{Na}][(\text{py})_2\text{In}(\text{N}_3)_4]$, $(\text{py})_3\text{In}(\text{N}_3)_3$, $(2,2',2''\text{-terpyridine})\text{In}(\text{N}_3)_3$, and $(2,2',2''\text{-terpyridine})\text{In}(\text{N}_3)_2(\text{O}_2\text{C}(\text{CH}_2)_2\text{CH}_2\text{OH})$.^{35–39} Syntheses of $[(\text{py})_2\text{Na}][(\text{py})_2\text{In}(\text{N}_3)_4]$, $(\text{py})_3\text{In}(\text{N}_3)_3$, $(2,2',2''\text{-terpyridine})\text{In}(\text{N}_3)_3$, and $(2,2',2''\text{-terpyridine})\text{In}(\text{N}_3)_2(\text{O}_2\text{C}(\text{CH}_2)_2\text{CH}_2\text{OH})$ involve the use of InCl_3 and sodium azide in the initial step.^{36,38,39} Haloidindium azides Cl_2InN_3 , Br_2InN_3 , $\text{Cl}_2\text{InN}_3(\text{py})_2$, and $\text{Cl}_2\text{InN}_3(\text{THF})_2$ have been synthesized, starting with the appropriate indium(III) halide and Me_3SiN_3 .³⁵ They are reported to have relatively high thermal stability. $\text{In}(\text{N}_3)_3$, in contrast, is an explosive solid; Lewis-base adducts like $(\text{py})_3\text{In}(\text{N}_3)_3$ and $(2,2',2''\text{-terpyridine})\text{In}(\text{N}_3)_3$ are relatively less dangerous.

The pyridine adduct $(\text{py})_3\text{In}(\text{N}_3)_3$ (3) is monomeric in the solid state. The indium atom adopts *mer*-octahedral geometry. In pyridine, the IR absorption bands corresponding to azide stretch appear at $2,084$, $2,068$, and $2,055\text{ cm}^{-1}$. $\text{Cl}_2\text{InN}_3(\text{THF})_2$ (4) forms dimers in the solid state, with a planar In_2N_2 core. Azido groups occupy the bridging sites. The X-ray crystal structures of $[(\text{py})_2\text{Na}][(\text{py})_2\text{In}(\text{N}_3)_4]$ and $(2,2',2''\text{-terpyridine})\text{In}(\text{N}_3)_2(\text{O}_2\text{C}(\text{CH}_2)_2\text{CH}_2\text{OH})$ have also been reported.

(3)

(4)

A few cyanate complexes of indium are reported. These include $\text{In}(\text{NCO})_3(\text{py})_3$, $\text{In}(\text{NCO})_3(\text{DMSO})_3$, and anionic species like $[\text{In}(\text{NCO})_3]^-$.^{40,41} Indium(III) adducts containing different ligand combinations of cyanate, fluoride, and water have been investigated using NMR spectroscopy.⁴² The thiocyanate (or more correctly, isothiocyanate, considering the common mode of bonding with indium(III)) derivatives are relatively more common.¹¹⁵ ^{115}In NMR spectroscopy was used to study the reactions of indium(III) halides with halide and pseudohalide ions, and to observe NCS^- and NO_2^- complexes of indium(III).⁴³ The detection of *N*-bonded $[\text{In}(\text{NCS})_6]^{3-}$ and $[\text{In}(\text{NO}_2)_6]^{3-}$, and the unique four- to six-coordination equilibrium, were observed between these and the tetracoordinated anions. The X-ray crystal structure of $[\text{Bu}_4\text{N}]_3[\text{In}(\text{NCS})_6]$ reveals that the six isothiocyanate ligands coordinate to indium octahedrally through the nitrogen atoms.⁴⁴ A calorimetric study of the coordination behavior of isothiocyanate ions in DMF has indicated the formation of $[\text{InNCS}(\text{DMF})_5]^{2+}$, $[\text{In}(\text{NCS})_2(\text{DMF})_4]^+$, $[\text{In}(\text{NCS})_3(\text{DMF})_3]$, $[\text{In}(\text{NCS})_4]^-$, and $[\text{In}(\text{NCS})_5]^{2-}$.⁴⁵ Indium(III) isothiocyanate has been synthesized from InCl_3 and KSCN , and used in the preparation of ionic salts containing $[\text{In}(\text{NCS})_4(\text{bipy})]^-$ and $[\text{In}(\text{NCS})_4(\text{py})_2]^-$ anions, as well as compounds with indium-transition-metal bonds such as $[\text{In}(\text{NCS})\{\text{W}(\text{CO})_3(\text{Cp})\}_2]$.^{46,47} The solid-state structural data of some of these ionic isothiocyanate compounds are available.⁴⁷

(c) *Amido and imido ligands.* A convenient route to indium(III) amide has been reported. The reaction of indium(III) iodide with three equivalents of KNH_2 in anhydrous liquid ammonia affords $\text{In}(\text{NH}_2)_3$, which is insoluble in NH_3 but dissolves in NH_3 solutions containing KNH_2 to produce $\text{K}_x\text{In}(\text{NH}_2)_{3+x}$.⁴⁸ Related sodium indium amide may be obtained using a similar route. The compound $\text{Li}_3\text{In}(\text{NH}_2)_6$ can be synthesized from a mixture of InI_3 , LiI , and KNH_2 . Upon thermolysis, $\text{In}(\text{NH}_2)_3$, $\text{K}_x\text{In}(\text{NH}_2)_{3+x}$, and $\text{Na}_x\text{In}(\text{NH}_2)_{3+x}$ give InN , whereas $\text{Li}_3\text{In}(\text{NH}_2)_6$ affords Li_3InN_2 .

H_2InNH_2 has been generated in argon matrices and characterized using IR spectroscopy.^{49,50} Univalent and divalent indium amide derivatives are also observed under these conditions.

Many indium(III) adducts derived from primary or secondary amido ligands have been reported.⁵¹ Syntheses of essentially all nonorganoindium amido complexes involve a salt-elimination process. The compound $(\text{THF})_3\text{Li}(\mu\text{-Cl})\text{Cl}_2\text{InN}(\text{SiMe}_3)(\text{Dipp})$ (**5**) ($\text{Dipp} = 2,6\text{-}(i\text{-Pr})\text{C}_6\text{H}_3$) represents a rare dihaloindium amide. It is obtained by the reaction of InCl_3 with $\text{LiN}(\text{SiMe}_3)(\text{Dipp})$ in tetrahydrofuran.⁵² Although this reaction leads to the formation of an In-N bond, the LiCl elimination is incomplete. The phosphoranylidiniminodinium(III) adduct $[\text{Cl}_2(\text{DMF})\text{-In}(\text{NPPH}_3)_2]$ also has different ligands, in addition to nitrogen-based donors bonded to the indium atom. It is a dimeric molecule with pentacoordinate indium sites and NPPH_3 bridges.⁵³ The bromo derivative $\text{BrIn}(\text{tmp})_2$ ($\text{tmp} = 2,2,6,6\text{-tetramethylpiperidinato}$) is reported to be monomeric in solution and in the gas phase.⁵⁴

The compounds $\text{In}[\text{N}(\text{SiMe}_3)_2]_3$,⁵⁵ $\text{In}(\text{tmp})_3$,⁵⁴ $\text{In}[\text{N}(\text{H})(2,4,6\text{-}(t\text{-Bu})_3\text{C}_6\text{H}_2)]_3$,⁵⁶ $\text{In}(\text{NEt}_2)_3$,⁵⁷ $\text{In}(\text{NCy}_2)_3$,⁵⁸ $\text{In}[\text{N}(\text{SiMe}_3)\text{Ph}]_3$, $\text{In}[\text{N}(\text{SiMe}_3)t\text{-Bu}]_3$, and $\text{In}[\text{N}(\text{SiHMe}_2)t\text{-Bu}]_3$ have been obtained as solvent- or halide-free indium(III) adducts via a metathesis route.⁵⁹ The use of smaller amido groups may lead to solvent-coordinated products or "ate" complexes. For example, the diethyl ether-coordinated compound $(\text{Et}_2\text{O})\text{In}[\text{N}(\text{SiMe}_3)\text{Ph}]_3$ (**6**) was obtained initially during the synthesis of $\text{In}[\text{N}(\text{SiMe}_3)\text{Ph}]_3$ using InCl_3 and $\text{LiN}(\text{SiMe}_3)\text{Ph}$ in Et_2O . However, the coordinated ether

can be removed easily by dissolving the adduct in CH_2Cl_2 , followed by the removal of solvent under reduced pressure. The attempted synthesis of $\text{In}[\text{N}(\text{SiMe}_3)\text{Me}]_3$ in Et_2O formed $\text{Li}\{\text{In}[\text{N}(\text{SiMe}_3)\text{Me}]_4\}$.⁵⁹ However, the tris-amido adduct $(\text{py})\text{In}[\text{N}(\text{SiMe}_3)\text{Me}]_3$ may be obtained by performing the reaction in pyridine. The neutral indium(III) complex $(\text{py})\text{In}(\text{NPh}_2)_3$ (7) can be synthesized using InCl_3 and LiNPPH_2 in pyridine.⁵⁹ $[\text{Li}(\text{THF})_4][\text{ClIn}(\text{NPh}_2)_3]$ (8) is obtained if the reaction is carried out in THF. The pyridine coordinated $(\text{py})_2\text{In}[\text{N}(\text{H})(2,6-(i\text{-Pr})_2\text{C}_6\text{H}_3)]_3$ (9) and the *p*-(dimethylamino)pyridine adducts $(p\text{-Me}_2\text{Npy})\text{In}[\text{N}(\text{SiHMe}_2)t\text{-Bu}]_3$ and $(p\text{-Me}_2\text{Npy})\text{In}[\text{N}(\text{SiMe}_3)\text{Me}]_3$ have also been reported.^{56,59} The reaction of InCl_3 with 3 or 4 equivalents of LiNCy_2 (Cy =cyclohexyl) affords only the neutral, trigonal-planar $\text{In}(\text{III})$ derivative $\text{In}(\text{NCy}_2)_3$.⁵⁸ The use of 4 equivalents of $\text{LiN}(\text{CH}_2\text{Ph})_2$, however, leads to the ionic product $[\text{Li}(\text{THF})_4][\text{In}\{\text{N}(\text{CH}_2\text{Ph})_2\}_4]$.

The solid-state structures of $\text{In}[\text{N}(\text{SiMe}_3)_2]_3$,⁶⁰ $\text{In}(\text{tmp})_3$, and $\text{In}[\text{N}(\text{H})2,4,6-(t\text{-Bu})_3\text{C}_6\text{H}_2]_3$ show that they are monomeric molecules with planar, three-coordinate indium centers. $\text{In}[\text{N}(\text{SiMe}_3)_2]_3$ reacts with CsF in toluene to produce $[\text{Cs}(\text{toluene})_3][\text{FIn}[\text{N}(\text{SiMe}_3)_2]_3]$.⁶¹ The solid-state structure shows an essentially linear Cs-F-In moiety (174°). The four-coordinate indium(III) complexes $(\text{Et}_2\text{O})\text{In}[\text{N}(\text{SiMe}_3)\text{Ph}]_3$ (**6**), $(\text{py})\text{In}(\text{NPh}_2)_3$ (**7**), and $(p\text{-Me}_2\text{Npy})\text{In}[\text{N}(\text{SiHMe}_2)t\text{-Bu}]_3$ have severely distorted tetrahedral metal sites (closer to the planar $\text{In}(\text{amido-N})_3\text{kernel}$).⁵⁹ The compound $[\text{Li}(\text{THF})_4][\text{ClIn}(\text{NPh}_2)_3]$ (**8**) features a four-coordinate indium atom with the expected tetrahedral geometry. The X-ray crystal structure of $(\text{py})_2\text{In}[\text{N}(\text{H})(2,6-(i\text{-Pr})_2\text{C}_6\text{H}_3)]_3$ (**9**) shows a five-coordinate, trigonal-bipyramidal indium center in which the axial sites are occupied by the two pyridine molecules.⁵⁶ Crystalline $(p\text{-Me}_2\text{Npy})\text{Li}\{\text{In}[\text{N}(\text{SiMe}_3)\text{Me}]_4\}$ has been obtained by treating $\text{Li}\{\text{In}[\text{N}(\text{SiMe}_3)\text{Me}]_4\}$ with p -(dimethylamino)pyridine, and characterized using X-ray crystallography.⁵⁹

One of the main interests in indium amides has been their potential utility as single-source precursors for indium nitride materials. They also serve as starting materials in the synthesis of various other indium compounds. For instance, amides such as $\text{In}(\text{NEt}_2)_3$ and $\text{In}[\text{N}(\text{SiMe}_3)t\text{-Bu}]_3$ react with alcohols or thiols to produce indium(III) alkoxides or thiolates, respectively.

The reaction of InX_3 ($\text{X} = \text{Cl}, \text{Br}, \text{I}$) with two equivalents of $\text{LiN}(\text{H})(t\text{-Bu})$ led to imido derivatives $[\text{In}_4\text{X}_4(t\text{-BuN})_4]$ (**10**) with In_4N_4 heterocubane structures. The reaction involving InBr_3 also produced a minor by-product $[\text{In}_3\text{Br}_4(t\text{-BuN})(t\text{-BuNH})_3]$ (**11**).⁶²

(d) *Multidentate ligands.* The dimeric $[\text{ClIn}(\text{N}(\text{Me})\text{SiMe}_2)_2\text{NMe}]_2$ and monomeric $\text{LiIn}[(\text{NSiMe}_3)_2\text{SiMe}_2]_2$ complexes feature bidentate amido donors.^{63,64} The synthesis involves the treatment of $\text{Li}_2(\text{N}(\text{Me})\text{SiMe}_2)_2\text{NMe}$ and $\text{Li}_2(\text{NSiMe}_3)_2\text{SiMe}_2$ with InCl_3 at 1:1 or 2:1 molar ratio, respectively. The reaction of $\text{Li}_2(\text{N}(\text{Me})\text{SiMe}_2)_2\text{NMe}$ with InCl_3 at 4:1 molar ratio affords an indium(III) compound $[\text{Li}\{\text{In}(\text{HN}(\text{Me})\text{SiMe}_2\text{NMe})_2(\text{MeNSiMe}_2\text{NMe})\}]_2$, with a $\text{Li}_2\text{In}_2\text{Si}_2\text{N}_4$ adamantane-like core.⁶³

Indium complexes of bidentate nitrogen-ligand systems such as triazenide, amidinate, aminotroponimate, and β -ketiminate have been reported. These ligands feature unsaturated ligand backbones. The reaction of InCl_3 with either one or two equivalents of 1,3-diphenyltriazene in the presence of triethylamine gives an ionic product $[\text{HNEt}_3][\text{InCl}_2(\text{PhNNNPh})_2]$, rather than the expected neutral species $\text{InCl}_2(\text{PhNNNPh})$ or $\text{InCl}(\text{PhNNNPh})_2$.^{65,66} Interestingly, $[\text{HNEt}_3][\text{InCl}_2(\text{PhNNNPh})_2]$ reacts with a variety of Lewis bases to produce neutral indium(III) complexes $[\text{InCl}_2(\text{PhNNNPh})\text{L}_2]$ ($\text{L} = \text{pyridine}, 3,5\text{-dimethylpyridine}, \text{PET}_3; \text{L}_2 = 2,2'\text{-bipyridine}, 1,10\text{-phenanthroline}, \text{Me}_2\text{PCH}_2\text{CH}_2\text{PMe}_2$, or $\text{Et}_2\text{PCH}_2\text{CH}_2\text{PEt}_2$). The $[\text{InCl}_2(\text{PhNNNPh})_2]^-$ anion has a six-coordinate indium center with a highly distorted octahedral geometry. The $\text{tris}(1,3\text{-diphenyltriazenido})\text{indium(III)}\text{In}(\text{PhNNNPh})_3$ complex was prepared via an alkyl-group-elimination route (usually the preferred method for the synthesis of organoindium derivatives) using InMe_3 and $\text{H}(\text{PhNNNPh})$.⁶⁵

The amidinate complex $\{\text{In}[\text{CyNC}(\text{H})\text{NCy}]_2\text{Cl}\}_2$ (**12**) may be obtained by treating InCl_3 with two equivalents of $\text{Li}[\text{CyNC}(\text{H})\text{NCy}]$, or by reacting Me_2InCl with two equivalents of $\text{H}[\text{CyNC}(\text{H})\text{NCy}]$.⁶⁷ It has a dimeric, lantern-type structure with an unusual square-pyramidal geometry at the indium atoms.⁶⁷ In this molecule, four formamidinate ligands bridge the two indium atoms, while the chlorides occupy the apical sites. Bulkier substituents on the ligand backbone afford indium(III) adducts in which the amidinate serves as a chelating donor. Syntheses of $\text{In}[\text{CyNC}(\text{Me})\text{NCy}]_2\text{Cl}$, $\text{In}[\text{CyNC}(t\text{-Bu})\text{NCy}]_2\text{Cl}$ (**13**), and $\text{In}[\text{Me}_3\text{SiNC}(t\text{-Bu})\text{NSiMe}_3]_2\text{Cl}$, as

well as the tris(amidinate) derivative $\text{In}[\text{CyNC}(\text{Me})\text{NCy}]_3$, were reported.⁶⁸ The crystal-structure determination of $\text{In}[\text{CyNC}(t\text{-Bu})\text{NCy}]_2\text{Cl}$ (**13**) reveals that the indium atom adopts a distorted trigonal-bipyramidal geometry, with the chloride occupying one of the equatorial positions. The dichloroindium compound $[\text{Me}_3\text{SiNC}(\text{Ph})\text{NSiMe}_3]\text{InCl}_2$ was obtained via a trimethylsilyl chloride elimination route.^{69,70}

Unlike the triazenide or amidinate ligands that form four-membered metallacycles, the aminotroponimines coordinate to metal ions forming five-membered metallacycles.⁷¹ The dichloro $\text{In}(\text{III})$ adduct $[(i\text{-Pr})_2\text{ATI}]\text{InCl}_2$ (**14**) ($[(\text{Me})_2\text{ATI}] = N$ -*i*-propyl-2-(*i*-propylamino)troponimine) has been synthesized using InCl_3 and $[(i\text{-Pr})_2\text{ATI}]\text{Li}$.⁷² It has a tetrahedral indium center. The bis(aminotroponimine) adduct $[(\text{Me})_2\text{ATI}]_2\text{InCl}$ (**15**) was obtained via an oxidative ligand-transfer process involving $[(\text{Me})_2\text{ATI}]_2\text{Sn}$ and InCl .^{71,73} Its solid-state structure shows a slightly distorted trigonal-bipyramidal geometry at indium, with the chloride ion occupying one of the equatorial sites. This molecule shows fluxional behavior in solution at room temperature. Indium (III) complexes containing bridged aminotroponiminate ligands have also been synthesized. The indium atom in $[(i\text{-Pr})_2\text{TP}]\text{InCl}$ ($[(i\text{-Pr})_2\text{TP}] = 1,3$ -di[2-(isopropylamino)troponimine]propane) is five-coordinate and the geometry may be described as a distorted tetragonal pyramid.⁷⁴ The chloride ion occupies the apical position. The chloride may be replaced by a *t*-BuO⁻ group using *t*-BuOK to obtain $[(i\text{-Pr})_2\text{TP}]\text{In}(\text{OBu}^t)$.

The β -ketiminate ligands typically form six-membered metallacycles. Synthesis of $[\text{HC}\{(\text{Me})\text{C}(2,6\text{-}(i\text{-Pr})_2\text{C}_6\text{H}_3)\text{H}\}_2]\text{InX}_2$ ($\text{X} = \text{Cl}$ (**16**) or I) via a salt-elimination process has been reported.⁷⁵ It features the expected tetrahedral metal sites. An alkyl-elimination method involving Me_3In and 2-(benzylamino)pyridine starting material has been used in the synthesis of the six-coordinate, tris-ligand complex $\text{In}[\text{N}(\text{CH}_2\text{Ph})\text{C}_5\text{H}_4\text{N}]_3$.⁷⁶ The 3-(2-pyridyl)pyrazolate ligand has been used in the isolation of a dichloroindium(III) derivative.⁷⁷ $\text{In}\{[(3\text{-Py})\text{Pz}]\text{InCl}_2(\text{DME})\}_2$, the 3-(2-pyridyl)pyrazolate ligand serves as a bridging as well as a chelating ligand for $\text{InCl}_2(\text{DME})$ fragments. Each indium atom has an $\text{N}_3\text{Cl}_2\text{O}$ coordination sphere.

The dibenzo-tetraaza macrocycle 5,7,12,14-tetramethyldibenzo[*b,i*][1,6,9,10]-tetraazacyclotetradecene (H_2TMTAA) is considered to be the intermediate between saturated cyclam-type ligands and aromatic porphyrin systems.⁷⁸ Treatment of Li_2TMTAA with indium(III) chloride yields $ClIn(TMTAA)$ (17).^{78,79} The $In-Cl$ fragment occupies a site above the N_4 plane of the saddle-shaped macrocycle, with indium adopting a square-pyramidal geometry.⁷⁸ The chloride can be substituted by $-N(SiMe_3)_2$ and $-OSiMe_3$ groups to obtain $(TMTAA)InN(SiMe_3)_2$ and $(TMTAA)InOSiMe_3$, respectively.

Poly(pyrazolyl)borate ligands play an important role in indium coordination chemistry.⁸⁰ Indium(III) adducts of bis-, tris-, and tetrakis(pyrazolyl)borates have been synthesized and the structures and chemistry have been investigated. The reaction of $[H_2B(Pz)_2]K$ (Pz = pyrazolyl) with $In(NO_3)_3$ or $InCl_3$ at 3:1 molar ratio affords $[H_2B(Pz)_2]_3In$.^{81,82} The solid-state data show that the octahedrally coordinated indium center is surrounded by three puckered bis(pyrazolyl)borate ligands.⁸¹ It is also possible to synthesize $[H_2B(Pz)_2]_2InCl$ and $[H_2B(Pz)_2]InCl_2$ using $InCl_3$ and $[H_2B(Pz)_2]K$ in appropriate proportions.⁸² The reaction of $[H_2B(Pz)_2]_2InCl$ with CH_3CO_2Na , or $[H_2B(Pz)_2]_3In$ with CH_3CO_2H , leads to the acetate derivative $[H_2B(Pz)_2]_2In(O_2CCH_3)$.⁸²

In the absence of adverse steric constraints, the tris(pyrazolyl)borates have a tendency to produce six-coordinate $In(III)$ complexes. $[HB(3,5-(Me)_2Pz)_3]InCl_2(THF)$,⁸³ $[HB(3,5-(Me)_2Pz)_3]InCl_2(NCCH_3)$,⁸⁴ $[HB(3,5-(Me)_2Pz)_3]InCl_2(3,5-(Me)_2PzH)$,⁸³ and $[HB(3,5-(Me)_2Pz)_3]InI_2(3,5-(Me)_2PzH)$ ⁸⁵ have been isolated from reaction mixtures involving $[HB(3,5-(Me)_2Pz)_3]K$ and $InCl_3$ or InI_3 . Cationic, six-coordinate species containing $\{[HB(3,5-(Me)_2Pz)_3]_2In\}^+$ and $\{[HB(Pz)_3]_2In\}^+$ moieties, and the related tris(pyrazolyl)gallate adduct $\{[MeGa(Pz)_3]_2In\}[InI_4]$, are known.^{83,86} They have been obtained as by-products resulting from the disproportionation of $In(I)$ reagents. Alternative routes to $\{[HB(Pz)_3]_2In\}^+$ involve halide abstraction from $[HB(Pz)_3]_2InCl$ using $AgBF_4$, or methyl-group abstraction from $[HB(Pz)_3]_2InMe$ using $[HNEt_3][BPh_4]$, or treating $InCl_3$ with one equivalent of $[HB(Pz)_3]K$.⁸³ In a toluene/dichloromethane solution, $[HB(Pz)_3]_2InCl$ exists as a mixture of ionic $\{[HB(Pz)_3]_2In\}Cl$ and covalent $[HB(Pz)_3]_2InCl$ forms. The compound $\{[HB(Pz)_3]_2In\}\{[HB(Pz)_3]InCl_3\}$ (18) is an interesting example where there is a six-coordinate anion and a cation in the same molecule. It was obtained using $InCl_3$ and $[HB(Pz)_3]K$ at 2:3 molar ratio in a THF/ H_2O solvent system.⁸³ X-ray data show that both indium centers have octahedral geometry.

Tetrakis(pyrazolyl)borate complexes of $In(III)$ ⁸³ $[B(Pz)_4]_3In$, $[B(Pz)_4]_2InCl$, and mixed-ligand complexes such as $[HB(3,5-(Me)_2Pz)_3]InCl[H_2B(Pz)_2]$, $[HB(3,5-(Me)_2Pz)_3]InCl[H_2B(3,5-(Me)_2Pz)_2]$, $[HB(3,5-(Me)_2Pz)_3]InCl[HB(Pz)_3]$, and $[HB(3,5-(Me)_2Pz)_3]InCl[B(Pz)_4]$, have been synthesized.⁸⁷ All these adducts are believed to feature six-coordinate indium sites. The crystal structure of $[HB(3,5-(Me)_2Pz)_3]InCl[H_2B(Pz)_2]$ shows that the indium center has a distorted octahedral geometry.

Ligand-substitution chemistry at the indium center has been investigated. Most of these reactions concern the halide substitution of $[HB(3,5-(Me)_2Pz)_3]InCl_2(THF)$ by C-, N-, O-, and S-based ligands.⁸⁰ For example, $[HB(3,5-(Me)_2Pz)_3]InCl_2(THF)$ reacts with K_2S_5 to form the $In(III)$ polysulfide complex $[HB(3,5-(Me)_2Pz)_3]In(S_4)(3,5-(Me)_2PzH)$.⁸⁸ The related $[HB(3,5-(t-Bu)_2Pz)_3]In(S_4)$ is also known, although it was synthesized by treating an $In(I)$ adduct with

sulfur.⁸⁹ Metal adducts of formally monovalent indium are obtained by reacting $[\text{HB}(3,5\text{-(Me)}_2\text{Pz})_3]\text{InCl}_2(\text{THF})$ with $[\text{Fe}(\text{CO})_4]^{2-}$ and $[\text{W}(\text{CO})_5]^{2-}$.⁹⁰ Several products resulting from the hydrolysis of tris(pyrazolyl)boratoindium(III) complexes have also been isolated.⁸⁵

The mixed-ligand complex $\{[\text{CpCo}\{\text{P}(\text{O})(\text{OMe})_2\}_3]\text{In}[\text{HB}(\text{Pz})_3]\}\text{X}$ ($\text{X} = \text{InCl}_4$ (**19**) or PF_6) contains two different tripodal ligands (N_3 and O_3 type).^{91,92} It was synthesized starting from a 1:1:2 mixture of $[\text{CpCo}\{\text{P}(\text{O})(\text{OMe})_2\}_3]\text{Ag}$, $[\text{HB}(\text{Pz})_3]\text{Ti}$, and InCl_3 . Interestingly, no homoleptic products (e.g., $\{[\text{HB}(\text{Pz})_3]\text{In}\}^+$) result from this mixture. However, heating a mixture of $\{[\text{CpCo}\{\text{P}(\text{O})(\text{OMe})_2\}_3]_2\text{In}\}\text{PF}_6$ and $\{[\text{HB}(\text{Pz})_3]\text{In}\}\text{PF}_6$ for two days in water/MeOH produces $\{[\text{CpCo}\{\text{P}(\text{O})(\text{OMe})_2\}_3]\text{In}[\text{HB}(\text{Pz})_3]\}\text{PF}_6$. The indium atom features octahedral geometry with a *fac*- N_3O_3 coordination sphere. The related $\{[\text{CpCo}\{\text{P}(\text{O})(\text{OMe})_2\}_3]\text{In}[\text{HB}(3,5\text{-(Me)}_2\text{Pz})_3]\}\text{AgCl}_2$ has been prepared from $[\text{HB}(3,5\text{-(Me)}_2\text{Pz})_3]\text{InCl}_2(\text{NCCH}_3)$ and $[\text{CpCo}\{\text{P}(\text{O})(\text{OMe})_2\}_3]\text{Ag}$. The synthesis of $\{[\text{HB}(\text{Pz})_3]_2\text{In}\}\text{PF}_6$ using $[\text{HB}(\text{Pz})_3]\text{Ti}$ as a ligand-transfer agent is also described.⁹¹

Indium(III) porphyrin complexes have been investigated by many groups.^{93–113} They are of interest for applications related to photodynamic therapy, radiolabeled indium chemistry, light-emitting devices, photovoltaic cells, metal-catalyzed oxidation, and sensors. The indium(III) chloro derivatives of *meso*-tetraphenylporphine (TPPH₂), *meso*-tetrakis(*p*-methoxyphenyl)porphine (TMPPH₂), and *meso*-tetrakis(*p*-tolyl)porphine were reported in the early 1970s.¹¹⁴ Synthesis typically involves the treatment of an indium(III) halide with the free ligand in an acetic acid/sodium acetate mixture. The indium(III) porphyrin complexes with axial acetate groups, such as $\text{In}(\text{TPP})(\text{OAc})$, $\text{In}(\text{TPYP})(\text{OAc})$ (TPYP = *meso*-tetra(4-pyridyl)porphyrinato), and $\text{In}(\text{TMPP})(\text{OAc})$, can be obtained directly and in high yield by using In_2O_3 instead of InCl_3 in the above mixture.¹⁰¹ Various other porphyrin-ligand systems, in particular OEP²⁻ (2,3,7,8,12,13,17,18-octaethylporphyrinato), have also been used to complex $\text{In}(\text{III})$ ions. Indium(III) porphyrin complexes with axial halide, N-donor, and O-donor groups (as well as alkyl, aryl, or transition-metal substituents) have been investigated.^{96,101,105,107,108,113,115–119}

A series of indium(III) porphyrin complexes (porphyrin = TPP, OEP, *Tp*-CF₃PP) containing axial tetrazolato and triazolato ligands have been prepared by the cycloaddition reactions of

azidoindium(III) porphyrin complexes with nitriles and alkynes. Based on the mode of tetrazole or triazole linkage, two different isomers are possible (kinetic and the thermodynamic product). Structural and spectroscopic data reveal that the coordination mode of the tetrazolato or triazolato group depends on the alkyl or aryl substituent on the azolate moiety.^{105,120} The crystal structure of (OEP)InL (L = 5-methyltetrazolate (**20**), 4-phenyltetrazolate (**21**)) reveals that the phenyl substituent occupies the tetrazolate ring 4-position, whereas the methyl group prefers the 5-position. The most important factor that determines the bonding mode of the crystallized product seems to be steric.¹²⁰ Redox properties and the reactivity towards donors such as pyridine or *N*-methyl imidazole have also been described.^{108,118}

The indium center adopts a square-pyramidal geometry when coordinated to the porphyrin ligand and a monodentate donor (e.g., (TPP)InCl (**22**) or 10-(4'-*N*-pyridyl)-5,15,20-triphenylporphyrinatoindium(III) chloride).^{115,116} The indium atom occupies a site above the plane formed by the four porphyrin nitrogen atoms. Solid-state structures of six-coordinate indium derivatives containing chelating bidentate ligands are known. In(TPYP)(OAc) (**23**) has an asymmetric bidentate acetato group, whereas in In(TMPP)(OAc) the two In–O(acetato) distances are equal.¹⁰¹ Synthesis of [indium(III)(octaethyloxophlorin)]₂ featuring an oxophlorin ligand has been reported.¹²¹ The X-ray structure shows a centrosymmetric dimer with the two metallaoxophlorin units linked by In–O bonding.

Phthalocyanine derivatives of indium(III) have attracted even more interest.^{94,122–144} Some indium phthalocyanine adducts show interesting nonlinear optical properties.^{123,124,134} For example, *tert*-butyl-substituted chloro(phthalocyaninato)indium(III) (*t*-Bu)₄PcInCl (**24**) is one of the best substances for optical-limiting applications.¹³⁴ Optical limiters limit the intensity of transmitted light once the input intensity exceeds a threshold value. This ability is useful for the protection of sensitive objects, such as human eyes or light sensors from high-intensity light beams.

Synthesis of indium phthalocyanine complexes usually involves the assembly of a ring system in the presence of an indium source. For example, (*t*-Bu)₄PcInCl(chloro(tetra-*tert*-butyl)phthalocyaninato)indium(III)) or (*n*-C₅H₁₁)₈PcInCl(chloro(octa-*n*-pentyl)phthalocyaninato)indium(III))

(22)

(23)

(24)

may be synthesized directly from a mixture of 4-*tert*-butylphthalonitrile or 4,5-bis(*n*-pentyl)phthalonitrile and InCl_3 in dry quinoline containing a catalytic amount of DBU.¹³⁰ Indium(III) adducts of various ring-substituted naphthalocyanines (e.g., (25)) can also be obtained by using a similar route, starting with naphthalenedicarbonitrile or more reactive diiminoisoindolines and InCl_3 .^{122,145} The use of indium metal and indium alloys has also been described.^{128,139–141} The compound PcInI -(iodo(phthalocyaninato)indium(III)) was synthesized from the reaction of indium powder with 1,2-dicyanobenzene under a stream of iodine.¹²⁸

Indium(III) phthalocyanine complexes show a rich structural diversity. Compounds like PcInI are monomeric, with a five-coordinate, square-pyramidal geometry at indium. The indium atom is located out of the N_4 plane, and the phthalocyaninato ring forms a dome shape.¹²⁸ In general,

this type of ring distortion is observed when the metal atom is too large (about 0.7 Å or larger) to fit into the phthalocyaninato core.¹²⁶ Tetra *n*-butylammonium salts of *cis*-[PcInX₂][−] (X = F (26), Cl, CN, HCO₂) compounds have been synthesized starting from PcInCl or *cis*-[PcIn(OH)₂][−].¹³¹ The X-ray crystal structure of [n-Bu₄][PcInF₂] (26) shows that the indium center is six-coordinate and the fluorides occupy *cis*-sites. Compounds containing the anion [PcInX₂][−] (X = NCO, NO₂) are also known.^{136,138} The carbonato derivative [n-Bu₄][PcInCO₃] features a *cis*-chelating ligand.¹³²

There are sandwich-type complexes of In(III) featuring phthalocyanine ligands. The neutral [Pc₂In] (27) is an interesting paramagnetic compound in which the In(III) is coordinated to a Pc^{2−} and to the radical anion Pc^{•−}.¹³⁹ It was obtained by a direct reaction of InMg alloy and 1,2-dicyanobenzene.¹³⁹ The magnetic susceptibility measurement exhibits Curie-Weiss behavior. Structural data show that both halves of the sandwich are equivalent. The indium site is eight-coordinate and shows distorted square antiprismatic geometry. Compounds with anionic [Pc₂In][−] moieties have also been prepared.¹²⁶

The iodine-doped, paramagnetic compound [Pc₂In](I₃)_{2/3} can be synthesized directly from In–Tl alloy and 1,2-dicyanobenzene under a stream of iodine.¹⁴⁶ The solid-state structure features one-dimensional stacks of [Pc₂In] columns and I₃ chains. A triple-decker indium(III) phthalocyanine complex [Pc₃In₂], which is diamagnetic, has been obtained by reacting In–Sn alloy with 1,2-dicyanobenzene at 210 °C.¹⁴¹ Indium atoms are six-coordinate, and are located between the phthalocyanine rings. An indium(III) derivative of a bicyclic phthalocyanine system has also been synthesized and structurally characterized.¹⁴⁰

(ii) Phosphorus, arsenic, antimony, and bismuth ligands

Synthesis of ionic indium(III) compounds such as $[\text{In}(\text{PPh}_3)_4](\text{ClO}_4)_3$, $[\text{In}(\text{AsPh}_3)_4]\text{ClO}_4$, or $[\text{In}(\text{diphos})_2]\text{ClO}_4$ have been reported.^{1,3,4}

The preparation of nanometer-size isolated particles of group III–V materials such as InP is very challenging. It has been shown that indium(III) phosphides serve as useful single-source precursors to such material. The decomposition of $(t\text{-Bu}_2\text{P})_3\text{In}$ (which has been obtained by reacting InCl_3 with three equivalents of $t\text{-Bu}_2\text{PLi}$)¹⁴⁷ in refluxing 4-ethylpyridine leads to nanometer-size InP.¹⁴⁸ This material shows clear quantum confinement effects. Nanocrystalline InP has been obtained from a mixture of InCl_3 and $(\text{Me}_3\text{Si})_3\text{P}$ via dechlorosilylation followed by thermolysis.¹⁴⁹ An intermediate product of this process, believed to be an oligomeric $[\text{Cl}_2\text{InP}(\text{SiMe}_3)_2]_n$, has been isolated as a yellow powder.¹⁵⁰ A low-temperature route to indium phosphide involving InCl_3 , yellow phosphorus, and KBH_4 in ethylenediamine is also reported.¹⁵¹ InAs and InSb may also be obtained via a similar technique.^{152,153} The reaction of InCl_3 with $t\text{-Bu}_2\text{PSiMe}_3$ leads to $[(t\text{-Bu}_2\text{P})_2\text{InCl}]_2$ (**28**), which contains an In_2P_2 ring.¹⁵⁴ Each tetrahedrally coordinated indium atom is linked by two bridging $t\text{-Bu}_2\text{P}$ groups, a terminal $t\text{-Bu}_2\text{P}$ group, and a terminal Cl atom.¹⁵⁴ Reaction of InCl with the potassium salt of phospholyl anion $[\text{K}(18\text{-crown-6})][\text{PC}_4\text{Me}_4]$ has resulted in the indium(III) adduct $[(\eta^1\text{-PC}_4\text{Me}_4)_2\text{In}(\mu\text{-Cl})_2\text{K}(18\text{-crown-6})]$ (**29**).¹⁵⁵ This is believed to be a product of a disproportionation reaction.¹⁵⁵ A compound with an In_4P_4 core has been observed in $[\{\text{Cp}(\text{CO})_3\text{Mo}\}_4\text{In}_4(\text{PSiMe}_3)_4]$.¹⁵⁶ The InCl_3 reacts with 4 equivalents of LiPPh_2 in tetrahydrofuran to give $[\text{Li}(\text{THF})_4][\text{In}(\text{PPh}_2)_4]$.¹⁵⁷ It is not possible to synthesize the analogous “ate” complex with bulkier $t\text{-Bu}_2\text{P}^-$ ligands.

The synthesis of $(t\text{-Bu}_2\text{As})_3\text{In}$ via a salt-elimination process has also been reported.¹⁴⁷ The stibido indium(III) complex $[(t\text{-Bu}_2\text{Sb})_2\text{InCl}]_2$ (**30**) was obtained by the interaction of InCl_3 with $[t\text{-Bu}_2\text{SbSiMe}_3]_2$.¹⁵⁸ The X-ray crystal structure reveals that it is a dimer with stibido groups, rather than chlorides, acting as bridges.

Reaction of indium(III) chloride with three equivalents of $\text{LiN}(\text{PPh}_2)_2$ in tetrahydrofuran affords the phosphazene complex $\text{In}[(\text{PPh}_2)_2\text{N}]_3$ (**31**) as a yellow solid.¹⁵⁹ The solid-state structure shows that the six-coordinate indium atom is surrounded by three chelate rings in a propeller-like conformation.

3.5.1.2.3 Group 16 ligands

(i) Oxygen ligands

(a) *Neutral oxygen ligands.* Ionic compounds of indium(III) with neutral oxygen are easily obtained by using indium salts of weakly coordinating anions. The existence of compounds with In^{3+} coordinated to water, dimethyl formamide, dimethyl sulfoxide, acetone, hexamethylphosphoramide, and $\text{OP}(\text{OMe})_3$ has been established by various methods.^{1,160–162} X-ray crystallographic data demonstrate the presence of octahedrally coordinated indium in $[\text{In}(\text{H}_2\text{O})_6]^{3+}$ and $[\text{In}(\text{DMSO})_6]^{3+}$ ions.^{163–165} All the DMSO ligands are O-bonded. The structure of the hydrated indium(III) ions in aqueous perchlorate and nitrate solutions has been investigated by large-angle

X-ray scattering and extended X-ray absorption fine-structure techniques.¹⁶⁶ Data indicate that the indium ion is coordinated by six water molecules, and the In—O bond distance in the first hydration sphere is 2.131(7) Å. Changes in concentration or the anion had no influence on this distance. This In—O distance is very similar to the In—O distances observed for $[\text{In}(\text{H}_2\text{O})_6]^{3+}$ ion in the solid state.^{164,167}

(b) *Hydroxide and oxide ligands.* Hydrolysis of aqueous indium(III) ions occurs easily, leading to indium hydroxo species, and finally to insoluble $\text{In}(\text{OH})_3$.^{1,168,169} This is one of the challenges associated with designing indium complexes for radiopharmaceutical applications.¹⁷⁰ Indium(III) hydroxide can also be prepared at 0°C by sonicating an aqueous InCl_3 solution.¹⁷¹ It was obtained as needle-shaped, nanosized material. There are few well-authenticated indium adducts containing hydroxo ligands.^{172–174} Indium(III) bromide reacts with 1,4-triazacyclononane (L) to give LInBr_3 .¹⁷² The hydrolysis of this adduct in alkaline aqueous solution leads to the first well-authenticated In(III) μ -hydroxo complex. The dithionate salt $[\text{L}_4\text{In}_4(\mu\text{-OH})_6](\text{S}_2\text{O}_6)_3$ contains $[\text{L}_4\text{In}_4(\mu\text{-OH})_6]^{6+}$ cations, with an adamantane-like $\text{In}_4(\text{OH})_6$ skeleton. The hydrolysis of LInBr_3 in sodium acetate affords a neutral, oxo-bridged dimer $\text{L}_2\text{In}_2(\mu\text{-O})(\text{MeCO}_2)_4$. The compound $[\text{In}_2\text{LCl}_4(\mu\text{-OH})_2]$ (L = bis[3-(2-pyridyl)pyrazol-1-yl]methane) is also a rare In(III) complex with bridging hydroxide ligands.¹⁷³ It has two pseudo-octahedral indium centers with *cis,cis,cis*- $\text{N}_2\text{O}_2\text{Cl}_2$ coordination environments.

The 1,3,5-triamino-1,3,5-trideoxy-*cis*-inositol (H_3taci) ligand (capable of N- or O bonding) shows an interesting group trend in which the ligand adopts O_6 , O_3N_3 , and N_6 modes of coordination for trivalent Al, Ga, and Tl ions, respectively.¹⁷⁵ The product obtained from the In(III) system is somewhat different.¹⁷⁶ $\text{In}(\text{NO}_3)_3$ reacted with H_3taci in MeOH to give $[\text{In}_6\text{O}(\text{taci})_4](\text{NO}_3)_4 \cdot 8\text{H}_2\text{O}$, which was characterized by NMR and mass spectroscopy and by X-ray crystallography. The crystal structure shows that the central O^{2-} ion is surrounded by six indium atoms in an octahedral arrangement. This In_6O moiety is bonded to four hexadentate taci ligands, resulting in a larger octahedral In_6O_{13} core.¹⁷⁶

(c) *Alkoxide ligands.* There is a significant interest in indium alkoxides because of their potential use as CVD precursors for indium oxide films.^{177,178} Doped or undoped indium oxide thin films are used as heat insulators, transparent and conductive ceramics, solar-cell windows, and display panels. A series of tris(alkoxide) compounds $\text{In}(\text{OR})_3$ (R = Me, Et, *i*-Pr, *n*-Bu, *s*-Bu, *t*-Bu, pentyl) was reported in the mid-1970s.¹⁷⁹ The isopropyl derivative was obtained from a reaction of InCl_3 with *i*-PrONa, and was used in the preparation of other alkoxides. Subsequent work suggested that this (*i*-PrO)₃In may not be a simple homoleptic alkoxide. For example, an oxo-centered cluster $\text{In}_5(\mu_5\text{-O})(\mu_3\text{-O-}i\text{-Pr})_4(\mu_2\text{-O-}i\text{-Pr})_4(\text{O-}i\text{-Pr})_5$ can be obtained using the same starting materials under similar conditions.^{180,181}

More recently it has been shown that indium amides serve as convenient starting materials for obtaining alkoxide derivatives.¹⁷⁸ For example, $\text{In}[\text{N}(\text{SiMe}_3)t\text{-Bu}]_3$ reacts with *t*-BuOH, EtMe_2COH , Et_2MeCOH , and *i*-PrMe₂COH to yield dimeric $[\text{In}(\mu\text{-OR})(\text{OR})_2]_2$ (R = *t*-Bu (32), EtMe_2C , Et_2MeC , and *i*-PrMe₂C) alkoxides. Indium alkoxides with less bulky substituents have also been prepared, e.g., (*i*-PrO)₃In and $(\text{Et}_2\text{HCO})_3\text{In}$ (33). The $(\text{Et}_2\text{HCO})_3\text{In}$ is a tetramer in the solid state, whereas the insoluble isopropoxide analogue is believed to be a polymeric compound. The indium(III) amides $\text{In}(\text{tmp})_3$ and $\text{In}(\text{NEt}_2)_3$ may also be used as starting materials for preparing alkoxides. Among this group of alkoxides, $[\text{In}(\mu\text{-OCMe}_2\text{Et})(\text{OCMe}_2\text{Et})_2]_2$ is reported to be the best precursor candidate for the deposition of indium oxide films.

(32)

Acidic alkoxides ($\text{pK}_a(\text{O-H})$ of less than 10–11) also react with $\text{In}[\text{N}(\text{SiMe}_3)t\text{-Bu}]_3$ to afford alkoxides.¹⁷⁸ However, *t*-BuNH₂ resulting from the amido ligand decomposition often incorporates into the product. For example, an $\text{In}[\text{N}(\text{SiMe}_3)t\text{-Bu}]_3$ and 2,6-(*i*-Pr)₂C₆H₃OH mixture produces $[2,6-(i\text{-Pr})_2\text{C}_6\text{H}_3\text{O}]_3\text{In}(t\text{-BuNH}_2)_2$.

The reactivity of some of the indium(III) alkoxides has been investigated. Monomeric molecules can be obtained by treating indium alkoxide aggregates with good Lewis bases, such as *p*-(dimethylamino)pyridine. Accordingly, compounds with *p*-(dimethylamino)pyridine donors, $\text{In}(\text{OCMe}_2)_3(p\text{-Me}_2\text{Npy})$ and $\text{In}(\text{OCMe}_3)_3(p\text{-Me}_2\text{Npy})_2$, were synthesized and structurally characterized. They show four- and five-coordinate indium centers, respectively. The *p*-Me₂Npy ligands occupy axial positions of the five-coordinate, trigonal-bipyramidal system. The β -diketonate derivative $[\text{CH}\{(t\text{-Bu})\text{CO}\}_2]_2\text{In}(\mu\text{-OCMe}_3)_2\text{In}(\text{OCMe}_3)_2$ has also been obtained by the reaction of $\text{In}(\text{OCMe}_3)_3$ with $[(t\text{-Bu})\text{CO}]_2\text{CH}_2$.

The synthesis and chemistry of indium fluoroalkoxides have also been reported.¹⁸² For less acidic alkoxides, $\text{In}[\text{N}(\text{SiMe}_3)t\text{-Bu}]_3$ again serves as a good starting point. $[\text{In}\{\mu\text{-OCMe}_2(\text{CF}_3)\}_2\{\text{OCMe}_2(\text{CF}_3)\}_2]_2$ was obtained by treating the $\text{In}(\text{III})$ amide $\text{In}[\text{N}(\text{SiMe}_3)t\text{-Bu}]_3$ with $\text{HOCMe}_2(\text{CF}_3)$. More acidic alcohols produce *t*-BuNH₂-incorporated products, such as $\text{In}\{\text{OCMe}(\text{CF}_3)_2\}_3(t\text{-BuNH}_2)$, $\text{In}\{\text{OCH}(\text{CF}_3)_2\}_3(t\text{-BuNH}_2)_3$, and $[(t\text{-BuNH}_2)[\text{In}\{\text{OCH}(\text{CF}_3)_2\}_4(t\text{-BuNH}_2)]]$. Reactions involving $\text{In}(\text{tmp})_3$ and $\text{In}(\text{NEt}_2)_3$ amides are less complicated, because they do not contain hydrolysable N-Si bonds. Synthesis and structures of trigonal bipyramidal $[\text{H}_2\text{NEt}_2][\text{In}\{\text{OCH}(\text{CF}_3)_2\}_4(\text{HNEt}_2)]$ and *mer*-octahedral $\text{In}[\text{OCMe}(\text{CF}_3)_2]_3(\text{py})_3$ (**34**) have been reported as well. Chiral indium alkoxides were obtained by reacting $\text{Li}_2(S)\text{-BINOLate}$ ($(S)\text{-BINOL} = (S)\text{-}(-)\text{-}2,2'\text{-dihydroxy-1,1'-binaphthyl}$) with InCl_3 in tetrahydrofuran.¹⁸³ Mixed-metal products were obtained, with three (*S*)-BINOLate ligands forming a distorted octahedral coordination sphere at indium.

(d) *Multidentate oxygen ligands.* Acetylacetonate complexes of indium(III) are also of interest as potential CVD precursors for the deposition of indium oxide materials. A number of homoleptic β -diketonates have been synthesized, including $[\text{CH}\{(\text{Me})\text{CO}\}_2]_3\text{In}$, $[\text{CH}\{(t\text{-Bu})\text{CO}\}_2]_3\text{In}$ and $[\text{CH}\{(\text{CF}_3)\text{CO}\}_2]_3\text{In}$.¹⁸⁴⁻¹⁹¹ $[\text{CH}\{(\text{CF}_3)\text{CO}\}_2]_3\text{In}$ can be synthesized from the free ligand and $\text{In}(\text{NO}_3)_3$, or $[\text{CH}\{(\text{CF}_3)\text{CO}\}_2]\text{Na}$ and InCl_3 .^{191,192} Indium metal also reacts with bis(diketonato)-copper(II) derivatives $(\text{R}^1\text{COCHCOR}^2)_2\text{Cu}$ ($\text{R}^1, \text{R}^2 = \text{Me, Me; or Ph, Ph; or Me, Ph; or Me, } t\text{-Bu}$) to afford tris(diketonato)indium(III) adducts.¹⁸⁹ The use of the parent diketone and $\text{In}(\text{OH})_3$ to prepare indium(III) diketonates has been described as well.

X-ray structural data are available for some of these adducts.^{184,193} The structure of $[\text{CH}\{(\text{CF}_3)\text{CO}\}_2]_3\text{In}$ has been determined by gas-phase electron diffraction.¹⁹² The coordination geometry at indium is described as distorted octahedral. The compounds $[\text{CH}\{(\text{Me})\text{CO}\}_2]_3\text{In}$ and $[\text{CH}\{(t\text{-Bu})\text{CO}\}_2]_3\text{In}$ have been used as precursors for indium oxide materials.¹⁹⁴⁻¹⁹⁷

A liquid-liquid extraction study using several β -diketonates and Al^{3+} and In^{3+} ions reveals that the metal-ion extraction ability of β -diketonate ligands depends on the distance between the two oxygen atoms and the interligand distance.¹⁹⁰ The ligands $\text{MeCOCH}_2\text{COME}$ and $\text{PhCOCH}_2\text{-COME}$ extract both smaller Al^{3+} and larger In^{3+} ions well. The $\text{PhCOC}(\text{Ph})\text{HCOME}$ does not extract In^{3+} , because the phenyl group at the α -position prevents $\text{PhCOC}(\text{Ph})\text{HCOME}$ from widening its bite size to accommodate the larger indium ion. Ligands with bulky terminal substituents, e.g., $\text{PhCOCH}_2\text{COPh}$, allow only the larger In^{3+} ion to be readily extracted.

Mono-, bis-, and tris-monothio- β -diketonate complexes of In(III) have been prepared.^{186,198–201} The crystal structure of $\text{In}(\text{PhCSC}(\text{H})\text{COPh})_3$ (**35**) shows that the indium has a distorted octahedral coordination with a *fac* arrangement of the S and O ligand atoms.

Tris(tropolonato)indium(III) may be prepared in water from tropolone and indium(III) nitrate.²⁰² The indium center shows octahedral coordination. This tropolonato adduct is lipid-soluble and may be of radiopharmaceutical interest. The stability of adducts formed between trioctylphosphine oxide and tris(tropolonato)indium(III) has been investigated experimentally and computationally.²⁰³ Unlike the gallium analogue, the indium complex can accommodate trioctylphosphine oxide while increasing its coordination number to seven. The thallium analogue can also take in one trioctylphosphine oxide. Indium derivatives of other chelating oxygen donors such as quinones,^{204–207} γ -pyrone,²⁰⁸ and pyridinone^{209–217} have also been reported.

Indium halides react with *t*-butyl substituted orthoquinones to give either catecholate or semiquinonate complexes. For example, InI_3 reacts with two equivalents of $(\text{TBSQ})\text{Na}$ ($\text{TBSQ} = 3,5\text{-di-}t\text{-butyl-1,2-benzoquinonate}$) to afford a paramagnetic product $(\text{TBSQ})_2\text{InI}$.²⁰⁶ The EPR data of $(\text{TBSQ})_2\text{InI}$ show characteristic signals attributable to semiquinonate (an anion radical) ligands bonded to an indium(III) center (with $A_{\text{In}} = 7.2 \text{ G}$). Hyperfine constants for coupling to ^{115}In ($I = 9/2$) are about 5–7 G for similar In(III) adducts (for comparison, the monovalent derivatives show higher coupling constant values in the 9–10 G range).²¹⁸ Although the $(\text{TBSQ})_2\text{InI}$ species is present in solution, attempts to obtain a crystalline product by coordinating 4-methylpyridine molecules to indium led to the formation of the catecholate (TBC) derivative $[(\text{TBC})\text{InI}(4\text{-Mepy})_2]_2$ (**36**). Crystalline indium(III) complexes containing semiquinonate ligands are known. For example, solid $(\text{TBSQ})\text{InI}_2(4\text{-Mepy})_2$ can be obtained starting either with indium(II) iodide or InI_3 . The compound $(\text{TBSQ})\text{InBr}_2(4\text{-Mepy})_2$ (**37**) has been obtained starting

with InBr_3 . The crystal structures of $(\text{TBSQ})\text{InX}_2(4\text{-Mepy})_2$ ($\text{X} = \text{Br}, \text{I}$) show that indium has a pseudooctahedral $\text{O}_2\text{N}_2\text{X}_2$ coordination sphere.^{205,219}

The chemistry of quinolinolato derivatives of In(III) has been investigated.^{220–223} The crystal structure of tris(8-quinolinolato)indium(III) reveals that the indium has a pseudo *mer*-octahedral N_3O_3 coordination sphere. The ^{111}In analogue of this compound is useful for radiolabeling applications of white blood cells or platelets.^{170,224,225}

Indium carboxylates and related compounds such as acetate, formate, and oxalate derivatives have been synthesized and investigated by various methods.^{1,3,4,226} The structures of the In(III) oxalate complexes $[\text{In}_2(\text{C}_2\text{O}_4)_3(\text{H}_2\text{O})_4] \cdot 2\text{H}_2\text{O}$, $\text{NH}_4[\text{In}(\text{C}_2\text{O}_4)_2] \cdot 2\text{H}_2\text{O}$, and $\text{Na}[\text{In}(\text{C}_2\text{O}_4)_2] \cdot 2\text{H}_2\text{O}$ have been studied using X-ray crystallography.²²⁷ Thermal decomposition of $\text{NH}_4[\text{In}(\text{C}_2\text{O}_4)_2] \cdot 2\text{H}_2\text{O}$ leads to indium oxide.²²⁸ The thermal behavior of mixed indium–thallium salts has also been examined.^{229,230} Thermal decomposition of indium(III) formate provides another route to indium oxide materials.²³¹ It is possible to synthesize indium oxalato complexes with fluoride ligands. The preparation of $\text{In}(\text{C}_2\text{O}_4)\text{F}$ and $[\text{In}(\text{C}_2\text{O}_4)\text{F}_2]^-$ has been reported.²³²

(e) *Polyoxyanion ligands.* Indium(III) compounds of polyoxyanions such as nitrate, sulfate, phosphate, and chlorate are well known.^{1,4} Some of the work on indium phosphates in the late 1990s centered on developing different three-dimensional structures using organic templates.^{233–242} Indium phosphonate derivatives have also been investigated as building blocks for preparing materials with well-defined internal spaces.^{243–246}

Several periodato complexes of indium(III) have been obtained by using $\text{In}(\text{NO}_3)_3$ and H_5IO_6 . At $\text{pH} < 1$, a crystalline product $\text{H}_{11}\text{I}_2\text{InO}_{14}$ forms.²⁴⁷ At higher pH, insoluble, amorphous material of composition $\text{In}_5(\text{IO}_6)_3 \cdot n\text{H}_2\text{O}$ and $\text{H}_3\text{In}_4(\text{IO}_6)_3 \cdot n\text{H}_2\text{O}$ was produced.

(ii) Sulfur, selenium, tellurium ligands

(a) *Neutral sulfur ligands.* Neutral, sulfur-based donors, such as thioether and thiourea, form adducts with indium ions. The tridentate 1,4,7-trithiacyclononane reacts with InCl_3 to form a 1:1 adduct.¹⁷² Structural data are not available. Cationic, neutral, and anionic indium(III) complexes of thiourea have been described.^{4,248,249}

(b) *Thiolate ligands.* Alkyl and aryl thiolate derivatives of indium(III) can be synthesized by several methods. For example, $\text{In}(\text{SEt})_3$, $\text{In}(\text{S-}i\text{-Bu})_3$, and $\text{In}(\text{SCMe}_2\text{Et})_3$ have been synthesized by an electrochemical method using an indium anode and the appropriate thiol in an acetonitrile medium.²⁵⁰ This method also allows the synthesis of aryl thiolate complexes like $\text{In}(\text{SPh})_3$, $\text{In}(\text{SC}_6\text{F}_5)_3$, $\text{In}(\text{S-}p\text{-tolyl})_3$, and $\text{In}(\text{SC}_{10}\text{H}_7)_3$, as well as low-valent indium thiolates. A metathesis route (involving InCl_3 and NaSPh)²⁵¹ and an oxidative addition pathway (using indium metal and PhSSPh)²⁵² to $\text{In}(\text{SPh})_3$ are also available. $\text{In}[\text{S}(2,4,6\text{-}(t\text{-Bu})_3\text{C}_6\text{H}_2)]_3$ (**38**) has been synthesized by an amine-elimination process²⁵³ using $\text{In}[\text{N}(\text{SiMe}_3)_2]_3$ and three equivalents of 2,4,6- $(t\text{-Bu})_3\text{C}_6\text{H}_2\text{SH}$ in toluene. It is a rare monomeric indium thiolate, and has a trigonal-planar indium center. The steric bulk of the ligand obviously prevents aggregation. $\text{In}[\text{N}(\text{SiMe}_3)(t\text{-Bu})]_3$ serves as a good starting point for $\text{In}(\text{S-}t\text{-Bu})_3$ and $\text{In}(\text{S-}i\text{-Pr})_3$.²⁵⁴ The compound $\text{In}(\text{S-}t\text{-Bu})_3$ is believed to be a dimer, whereas $\text{In}(\text{S-}i\text{-Pr})_3$ is a polymeric solid.

$\text{In}[\text{S}(2,4,6\text{-}(i\text{-Pr})_3\text{C}_6\text{H}_2)]_3$ is a yellow oil at room temperature.²⁵⁵ Solid samples containing $\text{In}[\text{S}(2,4,6\text{-}(i\text{-Pr})_3\text{C}_6\text{H}_2)]_3$ may be obtained by coordinating THF or acetonitrile to the indium atom. $\text{In}[\text{S}(2,4,6\text{-}(i\text{-Pr})_3\text{C}_6\text{H}_2)]_3(\text{THF})$ and $\text{In}[\text{S}(2,4,6\text{-}(i\text{-Pr})_3\text{C}_6\text{H}_2)]_3(\text{CH}_3\text{CN})_2$ have been structurally characterized. The thiolate ligands of the indium(III) complexes $[2\text{-(MeO)-5-(Me)C}_6\text{H}_3\text{-S}]_3\text{In}$ and $[o\text{-(Me}_2\text{NCH}_2\text{)C}_6\text{H}_4\text{S}]_3\text{In}$ have additional O- and N-donor sites.²⁵⁵ An electrochemical route has been utilized to synthesize $\text{In}[2\text{-(Ph}_2\text{P)C}_6\text{H}_4\text{S}]_3$, $\text{In}[2\text{-(Ph}_2\text{P)-6-(Me}_3\text{Si)C}_6\text{H}_3\text{S}][2\text{-(Ph}_2\text{PO)-6-(Me}_3\text{Si)C}_6\text{H}_3\text{S}]$, $\text{In}[2\text{-(Ph}_2\text{PO)-6-(Me}_3\text{Si)C}_6\text{H}_3\text{S}]_3$, and $[\text{NMe}_4][\text{In}\{\text{PhP}(\text{C}_6\text{H}_4\text{S-2})_2\}_2]^-$.²⁵⁶ The additional P- and/or O donors present on these thiolate ligands coordinate intramolecularly to indium forming octahedral structures with InS_3P_3 , $\text{InS}_3\text{P}_2\text{O}$, and InS_4P_2 cores, respectively. The compound $\text{In}[2\text{-(Ph}_2\text{P)C}_6\text{H}_4\text{S}]_3$ (**39**) shows the *mer*-conformation. Phosphorus atoms of $[\text{In}\{\text{PhP}(\text{C}_6\text{H}_4\text{S-2})_2\}_2]^-$ anion occupy *cis*-sites of an octahedron.

The Lewis-acidic property at the indium center also allows the synthesis of $\text{In}(\text{S-}t\text{-Bu})_3(\text{py})$, $\text{In}(\text{S-}t\text{-Bu})_3(p\text{-Me}_2\text{Npy})_2$,²⁵⁴ $\text{In}(\text{SPh})_3(\text{py})_2$,²⁵⁷ and $\text{In}[\text{S}(2,4,6\text{-(CF}_3)_3\text{C}_6\text{H}_2)]_3(\text{Et}_2\text{O})$.²⁵⁸ X-ray crystallographic data are available. The compounds $\text{In}(\text{S-}t\text{-Bu})_3(p\text{-Me}_2\text{Npy})_2$ and $\text{In}(\text{SPh})_3(\text{py})_2$ have

trigonal-bipyramidal structures, with the apical sites occupied by pyridines. The $\text{In}(\text{S}-t\text{-Bu})_3(\text{py})$ and $\text{In}[\text{S}(2,4,6\text{-(CF}_3)_3\text{C}_6\text{H}_2)]_3(\text{Et}_2\text{O})$ have four-coordinate, tetrahedral indium atoms.

Synthesis of indium(III) thiolates containing halide donors have also been reported. The oxidative addition reactions of InX ($\text{X} = \text{Cl}, \text{Br}, \text{I}$) with PhSSPh yields $(\text{PhS})_2\text{InX}$.^{4,259} Related selenolates can also be synthesized, using PhSeSePh instead of PhSSPh .²⁵⁹

Ionic indium(III) thiolate compounds $[\text{Ph}_4\text{P}][\text{In}(\text{S}-t\text{-Bu})_4]$ and $[\text{Ph}_4\text{P}][\text{In}(\text{SCH}_2\text{CH}_2\text{S})_2]$ were obtained using InCl_3 and the appropriate thiolate $t\text{-BuSK}$ or $\text{NaSCH}_2\text{CH}_2\text{SNa}$ in the presence of a PPh_4^+ salt. The synthesis of $[\text{XIn}(\text{SPh})_3]^-$ ($\text{X} = \text{Cl}, \text{Br}, \text{I}$) salts was achieved by treating $\text{In}(\text{SPh})_3$ with tetraalkyl ammonium salts.²⁵¹ Anionic moieties have four-coordinate, tetrahedral indium atoms. The first indium–copper cluster $[\text{Ph}_4\text{P}][\text{Cu}_6\text{In}_3(\text{SEt})_{16}]$ has been prepared, using $[\text{Cu}(\text{CH}_3\text{CN})_4]\text{PF}_6^-$ and $[\text{Ph}_4\text{P}][\text{In}(\text{SEt})_4]$. Its crystal structure shows an adamantanoid $\text{Cu}_6\text{In}_3\text{S}_{13}$ framework (40).²⁶⁰

One of the primary interests in indium thiolates concerns their potential utility as precursors for chemical vapor deposition of indium sulfide and related materials. Thermal decomposition of $\text{In}[\text{S}(2,4,6\text{-(}i\text{-Pr)}_3\text{C}_6\text{H}_2)]_3$, $[2\text{-(MeO)-5-(Me)C}_6\text{H}_3\text{S}]_3\text{In}$, and $[o\text{-(Me}_2\text{NCH}_2)\text{C}_6\text{H}_4\text{S}]_3\text{In}$ leads to In_2S_3 .²⁵⁵ Indium thiocarboxylates are also useful in this regard.²⁶¹ A sonochemical method for In_2S_3 involves the sonication of InCl_3 and thioacetamide in an aqueous solution at room temperature. At 0°C , In_2O_3 was the major product.²⁶² Compounds like $[\text{Ph}_4\text{P}][\text{Cu}_6\text{In}_3(\text{SEt})_{16}]$ are of interest as potential sources of InCuS_2 materials. $(\text{Ph}_3\text{P})_2\text{AgIn}\{\text{SC}(\text{O})\text{R}\}_4$ ($\text{R} = \text{Me}$ or Ph), which is derived from thiocarboxylate ligands, serves as an excellent precursor for AgInS_2 and AgIn_5S_8 materials. The indium(III) in $(\text{Ph}_3\text{P})_2\text{AgIn}\{\text{SC}(\text{O})\text{Ph}\}_4$ adopts a distorted octahedral coordination geometry.²⁶³

(c) *Chelating anionic sulfur ligands.* The chemistry of indium(III) complexes containing bidentate sulfur donors such as dithiocarbamates $[\text{S}_2\text{CNR}_2]^-$, dithiophosphates $[\text{S}_2\text{P}(\text{OR})_2]^-$, dithiophosphinates $[\text{S}_2\text{PR}_2]^-$, and dithioarsinates $[\text{S}_2\text{AsR}_2]^-$ has been investigated.^{264–283} The synthesis of $\text{In}[\text{S}_2\text{CNEt}_2]_3$ using a weakly acidic solution of an indium salt and sodium diethyldithiocarbamate

was reported many years ago, in the early 1940s.²⁸⁴ Since then, many different tris(dialkyldithiocarbamates) complexes of indium, including $\text{In}[\text{S}_2\text{CNR}_2]_3$ ($\text{R} = \text{Me}, \text{Et}, n\text{-Pr}, i\text{-Pr}, n\text{-Bu}, i\text{-Bu}$), have been synthesized and characterized structurally, spectroscopically, and by thermodynamic methods.^{267,269,273–275,277,279,280,284} Their use in the preparation of indium sulfide material, however, is more recent.^{265,275,285} For example, the tris(dialkyldithiocarbamates) $\text{In}[\text{S}_2\text{CN}(\text{Me})n\text{-Bu}]_3$ and $\text{In}[\text{S}_2\text{CN}(\text{Me})n\text{-hexyl}]_3$ serve as excellent precursors for depositing In_2S_3 films under CVD conditions.²⁸⁵ Indium(III) derivatives containing internally functionalized dithiocarbamate ligands, $[\text{S}_2\text{CN}(\text{CH}_2\text{CH}_2)_2\text{O}]^-$, (**41**), and $[\text{S}_2\text{CN}(\text{CH}_2\text{CH}_2)_2\text{NMe}]^-$, are also known.^{264,265}

A common route to synthesis involves the use of InCl_3 and the sodium salt of dialkyldithiocarbamate.^{264,284} This method also allows the isolation of mixed-ligand adducts, e.g., $\text{Cl}_2\text{In}[\text{S}_2\text{CN}(\text{CH}_2\text{CH}_2)_2\text{O}]$, $\text{ClIn}[\text{S}_2\text{CN}(\text{CH}_2\text{CH}_2)_2\text{O}]_2$, $\text{O}(\text{CH}_2\text{CH}_2\text{S})_2\text{In}[\text{S}_2\text{CN}(\text{CH}_2\text{CH}_2)_2\text{O}]$, and $\text{O}(\text{CH}_2\text{CH}_2\text{S})_2\text{In}[\text{S}_2\text{CN}(\text{CH}_2\text{CH}_2)_2\text{NMe}]$.²⁶⁴ A related, but much simpler method uses an acidic solution of $\text{In}(\text{III})$ (generated from indium metal and HCl) and dialkylammonium dialkyldithiocarbamate ($[\text{R}_2\text{NH}_2][\text{S}_2\text{CNR}_2]$, synthesized from R_2NH and excess CS_2 in acetone).²⁶⁹ Upon treatment of this mixture with NaOH , $\text{In}[\text{S}_2\text{CNR}_2]_3$ ($\text{R} = \text{Me}, \text{Et}, n\text{-Pr}, i\text{-Bu}$) precipitates as a white solid. $\text{In}[\text{S}_2\text{CNMe}_2]_3$ has been obtained from a reaction of $\text{Me}_2\text{NC}(\text{S})\text{SS}(\text{S})\text{CNMe}_2$ with indium metal in refluxing xylene. The diethyl analogue could not be obtained by this method.²⁶⁹ The same reagents react in 4-methylpyridine at room temperature to afford $\text{In}[\text{S}_2\text{CNMe}_2]_3$.^{267,274} Electrochemical methods that use a sacrificial indium anode and $\text{Me}_2\text{NC}(\text{S})\text{SS}(\text{S})\text{CNMe}_2$ are also reported.^{269,276,277} Reaction of InX ($\text{X} = \text{Cl}, \text{Br}, \text{I}$) with $\text{Et}_2\text{NC}(\text{S})\text{SS}(\text{S})\text{CNEt}_2$ gives $\text{In}[\text{S}_2\text{CNEt}_2]_3$.²⁶⁹ This reaction is believed to go through an $\text{XIn}[\text{S}_2\text{CNEt}_2]_2$ intermediate.

Tris(dialkyldithiocarbamato)indium(III) compounds $\text{In}[\text{S}_2\text{CNR}_2]_3$ exist as discrete molecules with distorted octahedral indium sites.^{264,280} The related $\text{In}[\text{S}_2\text{COEt}]_3$ has a similar structure.²⁸⁶ The five-coordinate $\text{ClIn}[\text{S}_2\text{CN}(i\text{-Pr})_2]_3$ displays square-pyramidal geometry.²⁷³ Compounds such as $\text{In}[\text{S}_2\text{CO}-i\text{-Pr}]_3$ serve as precursors for indium sulfide films.²⁸⁷

Dialkylmonothiocarbamate derivatives of indium(III) can be prepared using either the sodium or lithium salt of the carbamate ligand and InCl_3 . Compounds $\text{In}[\text{SOCNR}_2]_3$ ($\text{R} = \text{Et}, i\text{-Pr}$) (**42**) have been prepared, structurally characterized, and used successfully as single-source precursors for the deposition of $\beta\text{-In}_2\text{S}_3$ films by low-pressure MOCVD at temperatures of 300–500 °C.^{288–290} These monomeric compounds feature a distorted trigonal-prismatic geometry, with *mer*- O_3S_3 conformation at indium.

Indium(III) dithiophosphate $[\text{S}_2\text{P}(\text{OR})_2]^-$,^{270,272,278} dithiophosphinate $[\text{S}_2\text{PR}_2]^-$,^{266,268,281–283,291} and dithioarsinate $[\text{S}_2\text{AsR}_2]^-$ complexes²⁷¹ contain somewhat similar sulfur-based chelating ligands. The compound $\text{In}[\text{S}_2\text{P}(i\text{-Bu})_2]_3$ can be prepared by treating InCl_3 with $\text{Na}[\text{S}_2\text{P}(i\text{-Bu})_2]$.²⁶⁶ The ammonium salt of the ligand has been used in the synthesis of $\text{In}[\text{S}_2\text{P}(\text{OR})_2]_3$ ($\text{R} = \text{Et}, n\text{-Pr}, i\text{-Pr}$, etc.).^{272,278} The structurally characterized complexes are all monomeric, and contain six-coordinate indium atoms with distorted octahedral geometry.^{266,270–272,281,283,291} More descriptive, and perhaps more proper, ways of describing the deviations from ideal octahedral geometry (often observed with these four-membered chelates) were discussed.²⁷¹ An X-ray

crystallographic study reveals that $\text{In}[\text{S}_2\text{P}(i\text{-Bu})_2]$ and $\text{Ga}[\text{S}_2\text{P}(i\text{-Bu})_2]_3$ are not isostructural, which is rare for closely related systems of indium and gallium with S/S or O/O chelates.²⁶⁶

The imidobis(diphenylphosphinechalcogenide) ligands $[\text{Ph}_2\text{P}(\text{X})\text{NP}(\text{X})\text{Ph}_2]^-$ ($\text{X} = \text{O}, \text{S}, \text{Se}$) also form complexes with indium(III). They feature six-membered, phosphazene metallacycles. The dithioindium adduct $[\text{Ph}_2\text{P}(\text{S})\text{NP}(\text{S})\text{Ph}_2]_3\text{In}$,²⁹² and the related $[\text{Ph}_2\text{P}(\text{O})\text{NP}(\text{O})\text{Ph}_2]_3\text{In}$,^{292,293} $[\text{Ph}_2\text{P}(\text{Se})\text{NP}(\text{Se})\text{Ph}_2]_3\text{In}$,²⁹⁴ and $[\text{Ph}_2\text{P}(\text{S})\text{NP}(\text{O})\text{Ph}_2]_3\text{In}$ ²⁹⁵ have been reported, including their X-ray crystal structural data. Indium adducts have distorted octahedral geometry. The structure of the mixed-donor tris(chelate) complex $[\text{Ph}_2\text{P}(\text{S})\text{NP}(\text{O})\text{Ph}_2]_3\text{In}$ corresponds to the *fac*-isomer. It was prepared by reacting $[\text{Ph}_2\text{P}(\text{S})\text{NP}(\text{O})\text{Ph}_2]\text{K}$ with InCl_3 in a 3:1 molar ratio. Interestingly, the attempted synthesis of $[\text{Ph}_2\text{P}(\text{S})\text{NP}(\text{Se})\text{Ph}_2]_3\text{In}$ by following a similar route leads only to the bis ligand adduct $[\text{Ph}_2\text{P}(\text{S})\text{NP}(\text{Se})\text{Ph}_2]_2\text{InCl}$. It is monomeric, and has a five-coordinate, distorted trigonal-bipyramidal indium center. The Cl and the Se atoms occupy the equatorial sites. Five-coordinate indium(III) adducts containing symmetric imidophosphinate ligands have also been reported. These include $[i\text{-Pr}_2\text{P}(\text{S})\text{NP}(\text{S})i\text{-Pr}_2]_2\text{InCl}$, $[i\text{-Pr}_2\text{P}(\text{Se})\text{NP}(\text{Se})i\text{-Pr}_2]_2\text{InCl}$, and $[\text{Ph}_2\text{P}(\text{Se})\text{NP}(\text{Se})\text{Ph}_2]_2\text{InCl}$.²⁹⁶ They were obtained by the 2:1 stoichiometric reaction of the potassium or the sodium salt of the ligand with InCl_3 . They all have distorted trigonal-bipyramidal geometry with equatorially bound chlorides.

Indium(III) complexes of dianionic sulfur ligands are mostly those derived from toluene-3,4-dithiolate (TDT^{2-}), 1,2-dicyanoethylene-1,2-dithiolate (MNT^{2-}), 1,2-ethanedithiol (EDT^{2-}), or 1,1-dicyanoethylene-2,2-dithiolate ($i\text{-MNT}^{2-}$). Various adducts (e.g., four-coordinate $[\text{In}(\text{MNT})_2]^-$, five-coordinate $[\text{XIn}(i\text{-MNT})_2]^{2-}$ ($\text{X} = \text{Cl}, \text{Br}, \text{or I}$), or six-coordinate $[\text{In}(i\text{-MNT})_3]^{3-}$) have been reported.^{1,4}

A number of indium thiolato complexes containing additional nitrogen-donor sites have been described in the literature. These include pyridine-2-thionate derivatives $\text{In}(\text{pyS})_3$ (**43**),^{282,297} $\text{In}(\text{3-CF}_3\text{pyS})_3$,²⁹⁸ $\text{In}(\text{3-Me}_3\text{SipyS})_3$,²⁹⁷ and pyrimidine-2-thionates $\text{In}(\text{RpymS})_3$ ($\text{R} = \text{H}; 4,6\text{-Me}_2; 5\text{-Et-4,6-Me}_2; 4,6\text{-(Me, CF}_3\text{)}$).²⁹⁹ The compounds $\text{In}(\text{pyS})_3$ and $\text{In}(\text{3-Me}_3\text{SipyS})_3$ were prepared using $\text{In}(\text{NO}_3)_3$, pyridine-2-thiole derivative and Et_3N in ethanol. Under anaerobic conditions in ethanol and with the use of InCl_3 and $\text{H}(\text{pyS})$, an alkoxy-bridged dimer $[\text{In}(\text{pyS})_2(\text{OEt})]_2$ could be isolated.²⁹⁷ Electrochemical oxidation of a sacrificial indium anode in a nonaqueous solution containing the precursor ligand is the method used in the synthesis of $\text{In}(\text{RpymS})_3$. It is considered to be the preferred synthetic route to most of these compounds.²⁹⁸ It is believed that the electrochemical reactions proceed via indium(I) derivatives.²⁹⁸ Hydrogen gas forms at the cathode.

Solution NMR spectroscopic data of these tris(ligand) adducts point to the existence of *fac*- S_3N_3 isomers in solution. The same structure is retained in the solid state for $\text{In}(\text{pyS})_3$, $\text{In}(\text{3-CF}_3\text{pyS})_3$, $\text{In}(\text{3-Me}_3\text{SipyS})_3$, and $\text{In}(\text{pymS})_3$.²⁹⁸ However, the compound $\text{In}(5\text{-Et-4,6-Me}_2\text{pymS})_3$ adopts a *mer* conformation in the solid state.²⁹⁹ The indium(III) complexes of

1-hydroxypyridine-2-thione (HPT) have also been synthesized by an electrochemical method.³⁰⁰ The $\text{In}(\text{PT})_3$ prefers the *fac* arrangement of ligands in chloroform, but crystallizes in the *mer* conformation.

(d) *Selenium and tellurium ligands.* Group III/V material involving heavier chalcogens is also of interest.^{301–303} Thus, as in the case of lighter thiulates, indium(III) selenolates and tellurolates have been investigated as possible single-source precursors for group III/V materials. However, compared to indium(III) thiulates, relatively little is known about the structures and properties of the heavier analogues. Neutral homoleptic complexes $[\text{In}(\text{SePh})_3]_n$,^{257,304} $[\text{In}[\text{Se}(2,4,6\text{-}(t\text{-Bu})_3\text{C}_6\text{H}_2)]_3]$ (44), $[\text{In}[\text{SeC}(\text{SiMe}_3)_3]_3]$,³⁰⁵ $[\text{In}[\text{SeSi}(\text{SiMe}_3)_3]_3]$,³⁰⁵ and $[\text{In}[\text{TeSi}(\text{SiMe}_3)_3]_3]$ have been synthesized.³⁰⁵

The diselenide PhSeSePh reacts with indium metal in refluxing toluene to give $\text{In}(\text{SePh})_3$. The iodo derivative $\text{InI}(\text{SePh})_2$ can be obtained by adding iodine to the mixture.²⁵² InCl_3 reacts with three equivalents of $(\text{DME})\text{LiSeC}(\text{SiMe}_3)_3$ to afford $[\text{In}[\text{SeC}(\text{SiMe}_3)_3]_3]$, whereas with $(\text{THF})_2\text{LiSeSi}(\text{SiMe}_3)_3$ a THF adduct $(\text{THF})[\text{In}[\text{SeSi}(\text{SiMe}_3)_3]_3]$ was obtained.³⁰⁵ The THF-free compound $[\text{In}[\text{SeSi}(\text{SiMe}_3)_3]_3]$ and the related tellurium derivative $[\text{In}[\text{TeSi}(\text{SiMe}_3)_3]_3]$ can be synthesized by treating Cp_3In with $\text{HSeSi}(\text{SiMe}_3)_3$ and $\text{HTeSi}(\text{SiMe}_3)_3$, respectively. The synthesis of $[\text{In}[\text{Se}(2,4,6\text{-}(t\text{-Bu})_3\text{C}_6\text{H}_2)]_3]$ involves an alkane-elimination process between $\text{HSe}(2,4,6\text{-}(t\text{-Bu})_3\text{C}_6\text{H}_2)$ and Et_3In .²⁵³ The indium hydride complex $\text{InH}_3(\text{PCy}_3)$ and PhMMPH ($\text{M} = \text{S}, \text{Se}, \text{Te}$) in DME were utilized in the synthesis of $[\text{In}(\text{MPh})_3(\text{PCy}_3)]$.³⁰⁶

The Lewis acidity of the indium center is apparent in the formation of adduct compounds like $\text{In}(\text{SePh})_3(\text{PPh}_3)_2$, $\text{In}(\text{SePh})_3(\text{PCy}_3)$, $\text{In}(\text{TePh})_3(\text{PCy}_3)$, $\text{In}(\text{SePh})_3(\text{py})_2$, $\text{In}(\text{SePh})_3(2,2'\text{-bipy})$, $\text{In}(\text{SePh})_3(\text{phen})$, $[\text{In}[\text{SeSi}(\text{SiMe}_3)_3]_3(\text{THF})]$, $[\text{In}[\text{SeSi}(\text{SiMe}_3)_3]_3(\text{py})]$, $[\text{In}[\text{SeSi}(\text{SiMe}_3)_3]_3(\text{TMEDA})]$, $[\text{In}[\text{SeSi}(\text{SiMe}_3)_3]_3(\text{DMPE})]$, and $\{[\text{In}[\text{SeSi}(\text{SiMe}_3)_3]_3]_2(\mu\text{-DMPE})\}$ ($\text{DMPE} = 1,2\text{-bis}(\text{dimethylphosphino})\text{ethane}$).^{252,305} Although $[\text{In}[\text{TeSi}(\text{SiMe}_3)_3]_3]$ also forms adducts with Lewis bases, attempts to isolate adduct complexes have resulted in significant decomposition to the indium-free products $\text{Te}[\text{Si}(\text{SiMe}_3)_3]_2$ and $[\text{TeSi}(\text{SiMe}_3)_3]_2$. Note, however, that the $[\text{In}(\text{TePh})_3(\text{PCy}_3)]$ has been isolated as a thermally stable solid and characterized using X-ray crystallography.³⁰⁶

The indium selenolate $[\text{PPh}_4][\text{In}(\text{SePh})_4]$ can be prepared by treating InCl_3 with NaSePh , followed by the addition of $[\text{PPh}_4]\text{Cl}$.³⁰⁷ Interestingly, if the product resulting from InCl_3 and

NaSePh is added to a flask containing NaBH_4 and elemental sulfur (not Se), a hydroselenido derivative $[\text{In}(\text{SeH})(\text{SePh})_3]^-$ can be isolated. Compounds like $[\text{PPh}_4][\text{In}(\text{SeH})(\text{SePh})_3]$ with hydroselenido ligands are rare.

The treatment of neutral $\text{In}(\text{SePh})_3$ with $[\text{PPh}_4]\text{Br}$ also results in a selenolate adduct compound $[\text{PPh}_4][\text{BrIn}(\text{SePh})_3]$.²⁵⁷ A copper–indium complex with bridging selenolates $(\text{Ph}_3\text{P})_2\text{Cu}[\text{In}(\mu\text{-SeEt})_2(\text{SeEt})_2]$ was also reported.³⁰⁸ The action of selenium on $[\text{HB}(3,5\text{-}(t\text{-Bu})_2\text{Pz})_3]\text{In}$ or $[(t\text{-Bu}_3\text{Si})_2\text{In}]_2$ affords $[\text{HB}(3,5\text{-}(t\text{-Bu})_2\text{Pz})_3]\text{InSe}$ or $(t\text{-Bu}_3\text{SiIn})_4\text{Se}_4$ (**45**), respectively.²⁹ The tellurium does not react with $[\text{HB}(3,5\text{-}(t\text{-Bu})_2\text{Pz})_3]\text{In}$.³⁰⁹

The indium selenolate complex $[2,4,6\text{-}(t\text{-Bu})_3\text{C}_6\text{H}_2\text{Se}]_3\text{In}$ (**44**) shows trigonal planar coordination of the indium atom.²⁵³ The compound $\text{In}[\text{SeSi}(\text{SiMe}_3)_3]_3$ is also monomeric.³⁰⁵ The indium atom appears to have close contacts with hydrogen atoms of methyl groups. Although the indium is four-coordinate in $\{\text{In}[\text{SeSi}(\text{SiMe}_3)_3]_3\}_2(\mu\text{-DMPE})$ (**46**), it adopts a flattened tetrahedral geometry.³⁰⁵ The anions $[\text{In}(\text{SePh})_4]^-$ and $[\text{In}(\text{SeH})(\text{SePh})_3]^-$ (**47**) and the phosphine adducts $\text{In}(\text{MPh})_3(\text{PCy}_3)$ ($\text{M} = \text{S}, \text{Se}, \text{Te}$) feature the expected tetrahedral coordination.^{306,307} The IR stretching frequency corresponding to the Se–H stretch appears at $2,241\text{ cm}^{-1}$. The neutral $\text{In}(\text{SePh})_3$ (**48**) and (**49**), which lacks bulky substituents, is polymeric. However, it shows two crystalline modifications, a monoclinic form (**48**) that has six-coordinate, octahedral indium centers,²⁵⁷ and a triclinic version (**49**) featuring five-coordinate, trigonal-bipyramidal indium sites.³⁰⁴

The $\text{In}(\text{III})$ adducts $[\text{Ph}_2\text{P}(\text{Se})\text{NP}(\text{Se})\text{Ph}_2]_3\text{In}$ and $[i\text{-Pr}_2\text{P}(\text{Se})\text{NP}(\text{Se})i\text{-Pr}_2]_2\text{InCl}$, containing chelating ligands, were described earlier. Dialkylselenocarbamate derivatives of indium, like $\text{In}[\text{Se}_2\text{CN}(\text{Me})n\text{-hexyl}]_3$, are useful CVD precursor compounds for the deposition of In_2Se_3 films.³¹⁰ $\text{In}[\text{Se}_2\text{CN}(\text{Me})n\text{-hexyl}]_3$ has been synthesized using InCl_3 , CSe_2 , and N -methylhexylamine. Ternary material CuInSe_2 has been prepared from a stoichiometric mixture of $\text{In}[\text{Se}_2\text{CN}(\text{Me})n\text{-hexyl}]_3$ and $\text{Cu}[\text{Se}_2\text{CN}(\text{Me})n\text{-hexyl}]_2$.^{311,312} Pyrolysis of $\text{In}(\text{SePh})_3$ affords hexagonal films of In_2Se_3 . $\text{In}(\text{SePh})_3$ has also been used in the preparation of III/V material using a spray MOCVD technique.³¹³

The pyridineselenolate ($[\text{SePy}]^-$) and the 3-(trimethylsilyl) pyridineselenolate ($[\text{3-Me}_3\text{SipySe}]^-$) ligands form air-stable, homoleptic In(III) compounds $\text{In}(\text{SePy})_3$ and $\text{In}(\text{3-Me}_3\text{SipySe})_3$.^{314,315} The $\text{In}(\text{SePy})_3$ has been synthesized by an electrochemical or a thermal method using indium metal and 2,2'-dipyridyldiselenide. Arrangements of the donor atoms of $\text{In}(\text{SePy})_3$ (50) and $\text{In}(\text{3-Me}_3\text{SipySe})_3$ around indium correspond to the *fac*-isomer. The same structures are maintained in solution, as indicated by the presence of single peak at δ 399 in the ^{77}Se NMR spectrum.²⁹⁸ Compound $\text{In}(\text{SePy})_3$ decomposes at 220 °C to afford In_2Se_3 .³¹⁴

3.5.1.2.4 Group 17 ligands

Indium(III) fluoride, chloride, bromide, and iodide are commercially available compounds. They are ionic compounds with six-coordinate metal sites.² The dimeric In_2I_6 (β -form) is also known.^{316,317} Thermal decomposition of $(\text{NH}_4)_3\text{InF}_6$ is one of the routes to InF_3 .⁷ InF_3 -based glass materials are important in optics-related applications. Unlike the Tl(III) derivative, which hydrolyses in water, InF_3 is insoluble in water. Hydrates of InF_3 are obtained by the evaporation of HF solutions of InF_3 . The other trihalides of indium (InX_3 ; X = Cl, Br, I) are hygroscopic compounds and can be synthesized directly from the elements. InI_3 may be obtained easily by reacting indium with I_2 in diethyl ether.³¹⁸ These halides are widely used as starting materials for the synthesis of various other indium compounds.

Indium(III) halides form adducts with a variety of neutral and anionic donors of group 15, 16, or 17 elements. This area has been explored actively for many years. The interest in these adducts ranges from learning the effects of d^{10} configuration on the structure and stability of complexes, through their possible use as precursors for MOCVD processes (e.g., InN, InP material), to potential catalytic applications. Types of coordination compound formed by indium(III) halides (InX_3) include InX_3L , InX_3L_2 , InX_3L_3 , $[\text{InX}_2\text{L}_2]^+$, $[\text{InX}_2\text{L}_4]^+$, $[\text{InX}_4\text{L}_2]^-$, $[\text{InX}_5\text{L}_2]^{2-}$, $[\text{InX}_4]^-$, $[\text{InX}_5]^{2-}$, and $[\text{InX}_6]^{3-}$ (L = neutral donor). Note that not all these types are reported for all the halides. Based on the reported data, chloride derivatives appear to be the most diverse.

Donor–acceptor complexes involving indium(III) have been investigated using computational methods.^{319,320} A recent theoretical study of $\text{MX}_3\text{--D}$ (M = Al, Ga, In; X = F, Cl, Br, I; D = YH_3 , YX_3 , X^- ; Y = N, P, As), using self-consistent field and non-Hartree–Fock/density functional (B3LYP) methods with effective core potentials, reveals that the donor–acceptor strength decreases in the order $\text{F} > \text{Cl} > \text{Br} > \text{I}$ and $\text{Al} > \text{Ga} < \text{In}$ for all the donors D .³²⁰ The study also finds that for all indium(III) (and Al and Ga) halides, the donor strength follows the order $\text{X}^- > \text{NH}_3 > \text{H}_2\text{O} > \text{PH}_3 > \text{AsH}_3 > \text{PX}_3$.

(i) Halides and carbon ligands

One of a rare group of donor–acceptor adducts concerns the nucleophilic carbene complexes of indium(III) halides.³²¹ Carbene complexes of boron,³²² aluminum,³²³ gallium,³²⁴ and thallium³²⁵ have also been reported. The 1:1 adducts $\text{Cl}_3\text{In}[\text{C}\{\text{N}(i\text{-Pr})\text{CMe}\}_2]$, $\text{Br}_3\text{In}[\text{C}\{\text{N}(i\text{-Pr})\text{CMe}\}_2]$ (**51**), and 1:2 adducts $\text{Cl}_3\text{In}[\text{C}\{\text{N}(i\text{-Pr})\text{CMe}\}_2]_2$, $\text{Br}_3\text{In}[\text{C}\{\text{N}(i\text{-Pr})\text{CMe}\}_2]_2$ (**52**) can be synthesized by treating the appropriate InX_3 (X = Cl, Br) with either one or two equivalents of “stable” carbene $\text{C}\{\text{N}(i\text{-Pr})\text{CMe}\}_2$.³²¹ The reaction at 1:5 metal halide-to-carbene ratio produced only 1:2 adducts, suggesting that the 1:3 complexes are sterically not viable. The conductivity and the ^{115}In NMR spectra suggest that the solid-state structures are retained in methylene chloride solutions, and are not in equilibrium with ionic structures of the type $[\text{InX}_2\text{L}_2][\text{InX}_4]$. For example, no signals corresponding to $[\text{InCl}_4]^-$ and $[\text{InBr}_4]^-$ ions were observed in ^{115}In NMR spectra at δ 430 and 176, respectively.

The X-ray data reveal that $\text{Br}_3\text{In}[\text{C}\{\text{N}(i\text{-Pr})\text{CMe}\}_2]$ (**51**) is monomeric and tetrahedral. Both the 1:2 adducts $\text{Cl}_3\text{In}[\text{C}\{\text{N}(i\text{-Pr})\text{CMe}\}_2]_2$ and $\text{Br}_3\text{In}[\text{C}\{\text{N}(i\text{-Pr})\text{CMe}\}_2]_2$ (**52**) show essentially trigonal-bipyramidal indium sites but unusual halide ion coordination, with halide ions occupying one equatorial and two axial sites. Most 1:2 adducts between indium(III) halides and neutral donors show three equatorial halides. Ionic compounds featuring $\{\text{Cl}_4\text{In}[\text{C}\{\text{N}(i\text{-Pr})\text{CMe}\}_2]\}^-$ and $\{\text{Br}_4\text{In}[\text{C}\{\text{N}(i\text{-Pr})\text{CMe}\}_2]\}^-$ (**53**) anions have been obtained by treating a 1:1 mixture of InX_3 (X = Cl, Br) and $[\text{C}\{\text{N}(i\text{-Pr})\text{CMe}\}_2]$ with half an equivalent of water.³²¹ The resulting ionic compounds $\{\text{H}[\text{C}\{\text{N}(i\text{-Pr})\text{CMe}\}_2]\}^+\{\text{X}_4\text{In}[\text{C}\{\text{N}(i\text{-Pr})\text{CMe}\}_2]\}^-$ are fluxional in solution at room temperature. Only one set of heterocyclic resonances has been observed in ^1H and ^{13}C NMR spectra for the coordinated carbene and the imidazolium cation. The anions show trigonal-bipyramidal geometry at indium, with the carbene occupying an equatorial site.

(52)

(53)

Indium halide compounds with ylide donors have been reported.^{326,327} The reaction of InBr with CH_2Br_2 leads to $\text{Br}_2\text{InCH}_2\text{Br}$, which upon treatment with PPh_3 produces $\text{Br}_3\text{InCH}_2\text{PPh}_3$. Several other adducts of the type $\text{Br}_3\text{InCH}_2\text{L}$ ($\text{L} = \text{NEt}_3$, AsPh_3 , SbPh_3 , $\text{SC}(\text{NMe}_2)_2$) are also known.^{326,327} Some of these compounds have been analyzed by X-ray crystallography, semi-empirical quantum-mechanical methods, mass spectroscopy, and by thermogravimetric methods.

(ii) Halides and group 15 and group 16 ligands

Data on group 15, 16, and 17 donor adducts of indium(III) halides are more numerous. Compounds of the type InX_3L include $\text{InCl}_3(\text{OCMe}_2)$, $\text{InCl}_3(\text{OCPh}_2)$, $\text{InCl}_3(\text{OPCl}_3)$,⁷ $\text{InI}_3(\text{py})$,⁷ $\text{InI}_3(\text{L})$ ($\text{L} = \text{PPh}_3$, $\text{P}(i\text{-Pr})_3$, $\text{P}(\text{SiMe}_3)_3$, PPhPh_2 , $\text{PH}(t\text{-Bu})_2$, AsPh_3).^{328–332} Structurally characterized compounds of this type reveal the expected tetrahedral geometry at the indium. The $\text{InI}_3[\text{P}(i\text{-Pr})_3]$ can be synthesized by stirring a mixture of indium powder and $\text{I}_2\text{P}(i\text{-Pr})_3$ (2:3 molar ratio) in Et_2O for 7 days.³³⁰ Interestingly, the reaction involving $\text{I}_2\text{P}(n\text{-Pr})_3$ which contains the *n*-propyl substituents leads to a divalent indium iodide product. Reaction of $(\text{Et}_2\text{O})\text{InI}_3$ with PPh_3 or AsPh_3 affords $\text{InI}_3(\text{L})$ ($\text{L} = \text{PPh}_3$ or AsPh_3) along with five-coordinate adducts $\text{InI}_3(\text{L})_2$.³²⁹

The five-coordinate compounds are well represented. Some example of InX_3L_2 type include $\text{InCl}_3(\text{THF})_2$,³³³ $\text{InCl}_3(\text{NMe}_3)_2$,³³⁴ $\text{InCl}_3\{\text{OC}(\text{NMe}_2)_2\}_2$,³³⁵ $\text{InCl}_3\{\text{SC}(\text{NMe}_2)_2\}_2$,³³⁵ $\text{InCl}_3\{\text{SC}[\text{N}(\text{Me})\text{CH}]_2\}_2$,³³⁶ $\text{InCl}_3(\text{PMe}_3)_2$,³³⁷ $\text{InBr}_3(\text{THF})_2$,³³⁸ $\text{InBr}_3\{\text{SC}[\text{N}(\text{Me})\text{CH}]_2\}_2$,³³⁶ $\text{InBr}_3(\text{PPhMe}_2)_2$,³³⁹ $\text{InI}_3(\text{PPhMe}_2)_2$,³³⁹ $\text{InI}_3(\text{PPh}_3)_2$,³³² and $\text{InI}_3(\text{AsPh}_3)_2$.³²⁹ Solid-state structures (e.g., $\text{InCl}_3(\text{NMe}_3)_2$, $\text{InCl}_3(\text{PMe}_3)_2$, and $\text{InCl}_3\{\text{OC}(\text{NMe}_2)_2\}_2$ (54))^{334,335,337} consist of trigonal-bipyramidal indium sites with halides occupying the sites at the equatorial belt. There are exceptions, as in $\text{InCl}_3\{\text{SC}(\text{NMe}_2)_2\}_2$ (55),³³⁵ $\text{InCl}_3\{\text{SC}[\text{N}(\text{Me})\text{CH}]_2\}_2$,³³⁶ $\text{InBr}_3\{\text{SC}[\text{N}(\text{Me})\text{CH}]_2\}_2$,³³⁶ and in the bis(carbene) adduct.³²¹ These adducts show structures with one halide occupying an equatorial site and the remaining two at axial positions. The compounds $\text{InCl}_3\{\text{SC}[\text{N}(\text{Me})\text{CH}]_2\}_2$ and $\text{InBr}_3\{\text{SC}[\text{N}(\text{Me})\text{CH}]_2\}_2$ have been synthesized by treating $\text{InCl}_3 \cdot 4\text{H}_2\text{O}$ and InBr_3 with a slight excess of 1,3-dimethyl-2(3H)-imidazolethione in hot $\text{CH}_3\text{CN}/\text{EtOH}$.³³⁶

Compounds $\text{InF}_3(\text{bipy})(\text{H}_2\text{O})$,³⁴⁰ $\text{InCl}_3(\text{H}_2\text{O})_3$,³⁴¹ $\text{InCl}_3(\text{THF})_3$,³⁴² $\text{InCl}_3(\text{PhMe}_2\text{PO})_3$, $\text{InCl}_3(\text{Me}_2\text{SO})_3$,³⁴³ $\text{InCl}_3(\text{Me}_3\text{PO})_3$,³⁴³ $\text{InBr}_3(\text{Me}_2\text{SO})_3$,³⁴³ $\text{InCl}_3(\text{Me}_3\text{PO})_3$,³⁴³ and $\text{InI}_3(4\text{-Mepy})_3$ ³⁴⁴ represent InX_3L_3 -type molecules. Structural data show octahedral indium sites. However, both *mer*- and *fac*-configurations have been observed. The compounds $\text{InCl}_3(\text{PhMe}_2\text{PO})_3$, $\text{InCl}_3(\text{Me}_2\text{SO})_3$ (56), and $\text{InBr}_3(\text{Me}_2\text{SO})_3$ show the *fac*-configuration,³⁴³ whereas $\text{InF}_3(\text{bipy})(\text{H}_2\text{O})$,³⁴⁰ $\text{InCl}_3(\text{Me}_3\text{PO})_3$ (57), and $\text{InI}_3(4\text{-Mepy})_3$ are *mer*-octahedral.^{343,344}

A group of aqua complexes of In(III) have been obtained as a part of supramolecular assemblies.³⁴⁵ A macrocyclic cavitand cucurbituril has been used to facilitate the crystallization process. Compounds featuring $[\text{InCl}_2(\text{H}_2\text{O})_4]^+$, $[\text{InCl}_4(\text{H}_2\text{O})_2]^-$, and $[\text{In}(\text{H}_2\text{O})_6]^{3+}$ ions have been isolated and characterized by X-ray crystallography. The cation $[\text{InCl}_2(\text{H}_2\text{O})_4]^+$ has the *trans* arrangement of chlorides. The anion $[\text{InCl}_4(\text{H}_2\text{O})_2]^-$ shows both *cis* and *trans* isomers; *cis*- $[\text{InCl}_4(\text{H}_2\text{O})_2]^-$ has also been obtained using the $[\text{S}_4\text{N}_3]^+$ cation.³⁴⁶ Molecules with $[\text{InCl}_5(\text{H}_2\text{O})_2]^{2-}$ and $[\text{InBr}_5(\text{H}_2\text{O})_2]^{2-}$ ions are also known.^{347,348}

A study of indium(III)–iodine bond lengths as a function of coordination number of the indium shows a systematic change. The symmetry or the charge of the adduct has only a minor effect. For well-authenticated four-, five-, and six-coordinate systems, the average In—I distances are about 2.68, 2.73, and 2.83 Å, respectively.³⁴⁴

Overall, many factors—such as the halide ion, steric and electronic properties of the neutral donor, solvent, crystal packing forces, etc.—seem to control the nature of the product. Even minor variations lead to major structural changes.³⁴³ For example, $\text{InCl}_3(\text{Me}_2\text{SO})_3$ (56) shows *fac*-octahedral configuration, whereas $\text{InCl}_3(\text{Me}_3\text{PO})_3$ (57) adopts the *mer* conformation. The $\text{InCl}_3(\text{Me}_3\text{PS})_2$ is a five-coordinate complex. The compound $\text{InCl}_3(\text{Ph}_2\text{MePO})_3$ is covalent, while

the bromide analogue $[\text{InBr}_2(\text{Ph}_2\text{MePO})_4][\text{InBr}_4]$ is ionic. The chloride of the bulkier Ph_3PO is also ionic, $[\text{InCl}_2(\text{Ph}_3\text{PO})_4][\text{InCl}_4]$.

(iii) *Halides and multidentate ligands*

Cyclic tetraamine ligands such as cyclams (**58**) and cyclens (**59**) form adducts with indium halides.^{349,350} Synthesis of $[\text{InX}_2(\text{cyclam})][\text{InX}_4]_3$ ($\text{X} = \text{Cl}, \text{Br}, \text{I}$) and the 1:1 InBr_3 adducts of cross-bridged cyclam (1,4,8,11-tetraazabicyclo[6.6.2]hexadecane) and cross-bridged cyclen (1,4,7,10-tetraazabicyclo[5.5.2]tetradecane) have been reported. It is reported that, compared to cyclam and cyclen ligands, the cross-bridged ligands afford more kinetically inert metal complexes. Such adducts are of interest as potential indium-111-based pharmaceutical agents. The crystal structure of $\text{InBr}_3(1,4,7,10\text{-tetraazabicyclo[5.5.2]tetradecane})^+$ (**60**) cations and bromide ions. The indium site is hexacoordinate and has a distorted octahedral geometry, with two bromides occupying *cis* sites.³⁵⁰ Indium complexes of smaller ring systems are also known. Indium(III) chloride and bromide react with 1,4,7-triazacyclononane ($[9]\text{aneN}_3$) and 1,4,7-trimethyl-1,4,7-triazacyclononane ($\text{Me}_3[9]\text{aneN}_3$) to produce 1:1 complexes.^{172,338} The X-ray crystal structure of $\text{InBr}_3(\text{Me}_3[9]\text{aneN}_3)$ (**61**) reveals *fac*-coordination of the macrocycle. A similar structure is observed for the InBr_3 adduct of 1,3,5-trimethyl-1,3,5-triazacyclohexane.³³⁸

cyclam

(58)

cyclen

(59)

(60)

(61)

Reaction of 1,2-bis-(diphenylphosphanyl)benzene (DP) with an equimolar quantity of InCl_3 affords $[(\text{DP})_2\text{InCl}_2][\text{InCl}_4]$.³⁵¹ The ionic structure was confirmed by X-ray crystallography. The indium atom in the cation adopts an octahedral geometry, and the chlorides occupy *trans* positions. The InBr_3 and InI_3 reactions lead to neutral, five-coordinate $(\text{DP})\text{InX}_3$ compounds. The reaction of DP ligand with InBr_3 and InI_3 at 1:2 molar ratio, however, produces ionic $[(\text{DP})\text{InX}_2][\text{InX}_4]$ ($\text{X} = \text{Br}$ or I).³⁵¹ The chelating, potentially tridentate phosphine ligand, bis[2-(diphenylphosphanyl)phenyl]phenylphosphane (TP), also reacts with InCl_3 and InI_3 forming ionic species $[(\text{TP})\text{InX}_2][\text{InX}_4]$ ($\text{X} = \text{Cl}$ or I).^{351,352} However, the indium centers are four-coordinate,

and the phosphine ligand (although it has three P-donor sites) acts only as a bidentate donor. The indium atoms in these cations adopt essentially tetrahedral geometry.

The pyridine-2,6-bis(acetyloxime) acts as a tridentate chelator for In(III).^{353,354} The reaction of 2,6-(HONCMe)₂C₅H₃N with InCl₃ in MeOH yields seven-coordinate, distorted pentagonal-bipyramidal InCl₃[2,6-(HONCMe)₂C₅H₃N](MeOH). The related, but bulkier, Schiff-base ligand 2,6-(PhNCMe)₂C₅H₃N forms a six-coordinate adduct InCl₃[2,6-(PhNCMe)₂C₅H₃N] (**62**). The MeOH can be replaced with Cl[−] or water to obtain {InCl₄[2,6-(HONCMe)₂C₅H₃N]}[−] or InCl₃[2,6-(HONCMe)₂C₅H₃N](OH₂), respectively. These seven-coordinate adducts feature indium atoms with pentagonal-bipyramidal geometry. The chloride groups may be replaced by monoanionic dialkylthiocarbamates and pyridine-2-thiolate (PyS) ligands, or by dianionic oxalato (oxa) groups.³⁵⁴ Compound In(oxa)Cl[2,6-(HONCMe)₂C₅H₃N](OH₂) (**63**) is seven-coordinate, and has a pentagonal-bipyramidal indium center as well. The oxalato and amine oxime ligands form the pentagon.

(62)

(63)

A few crown ether complexes of indium(III) have been reported. These include [InI₂(dibenzo-24-crown-8)(H₂O)](InI₄),³⁵⁵ [InX₂(dibenzo-18-crown-6)][InX₄] (X = Cl, Br, I),³⁴⁹ [InI₂(18-crown-6)][InI₄],³⁵⁶ and [In(12-crown-4)₂][SbCl₆].³⁵⁷ Crown ether-containing solids of aqua InCl₃ adducts were noted.^{358,359} Synthesis of [InI₂(dibenzo-24-crown-8)(H₂O)][InI₄] involves the treatment of two equivalents of InI₃ with dibenzo-24-crown-8 in acetonitrile. The solid-state structural data show the InI₂ moiety located off-center within the crown ether cavity, with indium ions forming four bonds to ether oxygens and one to a water molecule. The compound [InI₂(18-crown-6)][InI₄] (**64**) has been prepared by the reaction of InI₃·OEt₂ with 18-crown-6. Again, the typical InI₂⁺ threading through the ring is observed. The [In(12-crown-4)₂]⁺ cation, which contains a smaller crown ether, features an eight-coordinate indium sandwiched between the two crown ethers.

(iv) Anionic complexes with halide ligands

Anionic indium(III) species containing only halides (e.g., [InX₄][−], [InX₅]^{2−}, [InX₆]^{3−}) have been well known for many years.^{1,3,4} The tetrahalo ion [InX₄][−] (X = Cl, Br, I) is a common counter-ion for cationic indium(III) compounds. It adopts tetrahedral geometry. The structure of the anion in [Et₄N]₂[InCl₅] (**65**) is particularly interesting, because it does not show the expected trigonal-bipyramidal geometry for a five-coordinate species.^{360,361} It has a distorted square-pyramidal

(64)

geometry, which is rare for a main-group compound.³⁶² The thallium salt $[\text{Et}_4\text{N}]_2[\text{TlCl}_5]$ is reported to be isomorphous with the indium analogue. The pentacoordinate anion in $[\text{PPh}_4]_2[\text{InCl}_5] \cdot \text{CH}_3\text{CN}$ (**66**), however, adopts trigonal-bipyramidal geometry.³⁶³ It should be noted that the energies are not much different for the trigonal-bipyramidal and square-pyramidal geometries.⁷ The pentacoordinate $[\text{InBr}_5]^{2-}$ and hexacoordinate $[\text{InBr}_6]^{3-}$ ions are known.³⁶⁴ $[\text{InBr}_6]^{3-}$ displays the expected octahedral arrangement of bromides around indium(III). The pentabromoindate anion in $[4\text{-ClC}_5\text{H}_4\text{NH}]_2[\text{InBr}_5]$ adopts a rare, square-pyramidal geometry.³⁶⁴

(65)

(66)

3.5.1.3.5 Hydride ligands

Indane or its aggregates are believed to be too unstable to exist as thermally stable species at room temperature.^{365–367} Theoretical calculations predict that In_2H_6 is thermodynamically unstable in both the gas phase and as a solid.³⁶⁷ However, since 1998 there have been some

notable developments involving InH_3 complexes.³⁶⁸ It is possible to synthesize tertiary amine complexes of InH_3 such as Me_3NInH_3 , (quinuclidine) InH_3 , and $[\text{N}(\text{CH}_2)_3\text{N}]\text{InH}_3$. These adducts decompose at room temperature, resulting in indium metal, H_2 , and free amine. The compound Me_3NInH_3 , however, can be decomposed in the presence of ammonia to obtain InN .³⁶⁸ The (quinuclidine) InH_3 and LiBr afford an interesting indium aggregate $[(\text{quinuclidine})_2\text{H}][\text{In}\{\text{InBr}_2(\text{quinuclidine})\}_4]$, featuring a tetrahedron of indium atoms around an indium center.³⁶⁸

Phosphine adducts of InH_3 (prepared using LiInH_4 and Me_3NHCl , and then treating the resulting Me_3NInH_3 adduct with a phosphine) show better thermal stability in the solid state. Among the known InH_3 adducts of phosphines, the 1:1 and 1:2 Cy_3P adducts ((67), (68)) are the most stable.^{306,369} Imidazol-2-ylidene (nucleophilic carbene) complexes of indane, $[(\text{MeCN}(i\text{-Pr}))_2\text{C}]\text{InH}_3$ (69), and $[(\text{HCN}(\text{Mes}))_2\text{C}]\text{InH}_3$ (70) have been synthesized.^{370,371} Solid samples of $[(\text{HCN}(\text{Mes}))_2\text{C}]\text{InH}_3$ are stable up to 115°C .

Some of these InH_3 adducts are useful starting materials for the preparation of other In-H compounds. The carbene adduct $[(\text{HCN}(\text{Mes}))_2\text{C}]\text{InH}_3$ reacts with quinuclidine $\cdot\text{HCl}$ to produce $[(\text{HCN}(\text{Mes}))_2\text{C}]\text{InH}_2\text{Cl}$. *In situ*-generated Me_3NInH_3 reacts with LiPCy_2 to give the trimeric phosphido-indium hydride complex $(\text{H}_2\text{InPCy}_2)_3$.³⁶⁸ Review articles on the chemistry of group 13 hydrides, and more recent work involving donor stabilized InH_3 , are available.^{365,366,368}

There are several reports of organoindium compounds containing In-H bonds. These include $[\text{Li}(\text{THF})_2][\{\text{Me}_3\text{Si}\}_3\text{C}\}_2\text{In}_2\text{H}_5]$,³⁷² $\text{K}[\text{H}\{\text{In}(\text{CH}_2\text{CMe}_3)_3\}_2]$,³⁷³ $\text{K}_3[\text{K}(\text{Me}_2\text{SiO})_7][\text{HIn}(\text{CH}_2\text{CMe}_3)_3]_4$,³⁷⁴ $\text{HIn}\{2\text{-Me}_2\text{NCH}_2(\text{C}_6\text{H}_4)\}_2$,³⁷⁵ $\text{Me}_2\text{InB}_3\text{H}_8$,³⁷⁶ and $[\text{Li}(\text{TMEDA})_2][\text{H}(\text{InMe}_3)_2]$.³⁷⁷ The anionic indium species MInH_4 ($\text{M} = \text{Li-Cs}$)³⁷⁸ and $\text{Li}[\text{InH}_{4-n}\text{Ph}_n]$ (where $n = 1, 2$)³⁷⁹ are also known.

In addition to the coordination compounds, InH_3 and a variety of molecules containing In-H bonds have been generated in solid argon matrices.^{49,50,380-382} These include HInCl_2 , H_2InCl ,

H_2InNH_2 , and H_2InPH_2 . The IR data of these species are reported. There is also a growing interest in the use of indium hydrides in organic synthesis.^{365,383,384} For example, indium hydride species generated from a mixture of InCl_3 and NaBH_4 are shown to be promising alternatives to Bu_3SnH systems.

3.5.1.2.6 Mixed-donor-atom ligands

Mixed-donor-atom ligands play an important role in indium(III) coordination chemistry. One important application concerns their use in the synthesis of indium-111- (γ -emitter, half-life = 67.9 h) based radiopharmaceutical agents.¹⁷⁰ Choosing the ideal metal–ligand combination for this purpose is challenging. The metal adduct formation step should be fast, and resulting indium must be kinetically and thermodynamically stable. Hydrolysis reactions leading to indium hydroxo derivatives or $\text{In}(\text{OH})_3$ are a concern. Furthermore, the complex should be stable enough to prevent exchange of indium from the radiopharmaceutical to transferrin (a plasma protein with a high affinity for indium(III), $\log K_1 = 18.74$).³⁸⁵ A large variety of multidentate ligands containing various combinations of N, O, and/or S donors have been used in the preparation of indium adducts for possible pharmaceutical use.^{170,386–398} Multidentate ligands with neutral nitrogen and anionic sulfur donors,³⁹⁹ and 6-coordinate metal sites appear to be the best.⁴⁰⁰ The most popular ligand for indium-111, however, is diethylenetriaminepentaacetic acid (DTPA) (**71**).¹⁷⁰

The diaqua(2,6-diacetylpyridinedisemicarbazone)indium(III) cation (**72**) represents the first example featuring a pentagonal bipyramidal indium site.⁴⁰¹ It was isolated as $[\text{In}(\text{H}_2\text{DAPSC})(\text{H}_2\text{O})_2](\text{NO}_3)_2(\text{OH})$ by reacting hydrated indium nitrate and 2,6-diacetylpyridine bis(semicarbazone) (H_2DAPSC) in a water–ethanol solution.

The chloroindium(III) complex of 1,4,7-triazacyclononanetriacetic acid also features pentagonal-bipyramidal geometry.⁴⁰² The chloride and one of the tertiary nitrogens occupy the axial sites. The compound $\{\text{O}[\text{In}(\text{HDAPTSC})(\text{OH})]_2\}$ (**73**) (where H_2DAPTSC = 2,6-diacetylpyridine bis(thiosemicarbazone)) has two distorted pentagonal-bipyramidal units bridged by an oxo group.¹⁷⁴ The indium atoms also have terminal hydroxo ligands. Semicarbazone and thiosemicarbazone complexes of indium have been reviewed.⁴⁰³

(73)

Transition-metal complexes of indium and indium adducts are available.⁴⁰⁴ Structures, bonding, reactivity, and their materials-related applications are of current interest in the early 2000s.

3.5.1.3 Indium (II)

3.5.1.3.1 Group 14 ligands

Several well-defined In(II) compounds are known, and a few of these contain bulky silyl substituents such as supersilyl ($t\text{-Bu}_3\text{Si-}$) and hypersilyl ($[\text{Me}_3\text{Si}]_3\text{Si-}$) groups. The ruby-red colored $\{[(\text{Me}_3\text{Si})_3\text{Si}]_2\text{In}\}_2$ (**74**) has been isolated in low yield from a reaction between InCl_3 and $(\text{Me}_3\text{Si})_3\text{SiLi}$ in 1:3 molar ratio.⁴⁰⁵ The major products of this reaction are $[(\text{Me}_3\text{Si})_3\text{Si}]_2$, indium metal, and LiCl . The In—In bond distance is 2.868(1) Å. The reaction between $t\text{-Bu}_3\text{SiNa}$ and $(\text{Me}_5\text{C}_5)\text{In}$ or InCl_3 or InBr leads to deep violet $[(t\text{-Bu}_3\text{Si})_2\text{In}]_2$ (**75**).^{406–408} The red-violet $[(t\text{-Bu}_2\text{PhSi})_2\text{In}]_2$ (**76**) can also be synthesized using similar routes.²⁹ The solid-state structures of $[(t\text{-Bu}_3\text{Si})_2\text{In}]_2$ and $[(t\text{-Bu}_2\text{PhSi})_2\text{In}]_2$ show trigonal-planar indium sites, orthogonal InInSi_2 planes, and a relatively long In—In distance of 2.922(1) and 2.938(1) Å, respectively.^{29,407} The divalent $[(t\text{-Bu}_3\text{Si})_2\text{In}]_2$ may be used in the synthesis of both subvalent and trivalent indium compounds. For example, thermolysis of $[(t\text{-Bu}_3\text{Si})_2\text{In}]_2$ in boiling heptanes affords $(t\text{-Bu}_3\text{Si})_8\text{In}_{12}$.⁴⁰⁸ The indium(III) complexes $(t\text{-Bu}_3\text{Si})\text{InF}_2$ and $(t\text{-Bu}_3\text{Si})\text{InBr}_2$ were obtained by treating $[(t\text{-Bu}_3\text{Si})_2\text{In}]_2$ with AgF_2 or HBr , respectively.²⁸ The action of selenium on $[(t\text{-Bu}_3\text{Si})_2\text{In}]_2$ yields a heterocubane $(t\text{-Bu}_3\text{Si-In})_4\text{Se}_4$.²⁹

A few well-characterized organoindium(II) compounds are also known. These include $\{[(\text{Me}_3\text{Si})_2\text{CH}]_2\text{In}\}_2$ (In—In = 2.828(1) Å), $\{[2,4,6\text{-(CF}_3)_3\text{C}_6\text{H}_2]_2\text{In}\}_2$ (In—In = 2.744(2) Å), $\{[2,4,6\text{-(}i\text{-Pr)}_3\text{C}_6\text{H}_2]_2\text{In}\}_2$ (In—In = 2.775(2) Å), $\{[2,6\text{-(Me}_2\text{NCH}_2)_2\text{C}_6\text{H}_3](\text{Cl})\text{In}\}_2$ (In—In = 2.7162(8) Å), $\{[(\text{Me}_3\text{Si})_2\text{C(Ph)C(Me}_3\text{Si)N}]\text{InBr}\}_2$ (In—In = 2.728(4) Å).^{409–412} Perfluoroiodo organics R_fI ($\text{R}_f = n\text{-C}_y\text{F}_{2y+1}$ ($y = 1, 2, 3, 4, 6$), $i\text{-C}_3\text{F}_7$, C_6F_5) and $\text{C}_6\text{F}_5\text{Br}$ react with indium metal in polyethers or THF to generate oxidative addition products of the general formula R_fInX ($\text{X} = \text{Cl, Br}$) involving In(II).⁴¹³

In addition to In—C linkages, compounds $\{[2,6\text{-(Me}_2\text{NCH}_2)_2\text{C}_6\text{H}_3](\text{Cl})\text{In}\}_2$ and $\{[(\text{Me}_3\text{Si})_2\text{C(Ph)C(Me}_3\text{Si)N}]\text{InBr}\}_2$ have In—halide and In—N bonds. The coordination numbers at the indium are 4 and 5, respectively. The preparation of $\{[2,6\text{-(Me}_2\text{NCH}_2)_2\text{C}_6\text{H}_3](\text{Cl})\text{In}\}_2$ involves the use of an In(III) precursor, whereas $\{[(\text{Me}_3\text{Si})_2\text{C(Ph)C(Me}_3\text{Si)N}]\text{InBr}\}_2$ was a result of a disproportionation reaction involving In(I). Triindylindane $\{[2,4,6\text{-(}i\text{-Pr)}_3\text{C}_6\text{H}_2]_2\text{In}\}_3\text{In}$ has been prepared.⁴¹⁴ A collection of M—M bond distances (M = group 13 element) of metallanes is available.^{410,412}

(74)

(75)

(76)

3.5.1.3.2 Group 15 ligands

The first well-characterized amide of In(II) was isolated using the cyclic silazane $[(t\text{-BuNSiMe})_2(t\text{-BuN})_2]\text{H}_2$ ligand system.⁴¹⁵ The reduction of $[(t\text{-BuNSiMe})_2(t\text{-BuN})_2]\text{InCl}$ using sodium naphthalene provides a convenient entry route to indium(II) species $\{[(t\text{-BuNSiMe})_2(t\text{-BuN})_2]\text{In}\}_2$ (77). The related bis(*tert*-butylamido)cyclodiphosphazane $[(t\text{-BuNP})_2(t\text{-BuN})_2]^{2-}$ ligand system is also useful in this regard. However, $\{[(t\text{-BuNP})_2(t\text{-BuN})_2]\text{In}\}_2$ (78) has been obtained, as a redox disproportionation product, starting with InCl and the dilithium salt of $[(t\text{-BuNP})_2(t\text{-BuN})_2]^{2-}$.⁴¹⁶ In contrast to indium, the related thallium(I) derivative does not undergo disproportionation. The two indium(II) amido complexes $\{[(t\text{-BuNSiMe})_2(t\text{-BuN})_2]\text{In}\}_2$ and $\{[(t\text{-BuNP})_2(t\text{-BuN})_2]\text{In}\}_2$ are isostructural, and contain indium cages linked by unsupported In—In bonds with bond distances of 2.768(1) and 2.7720(4) Å, respectively. The indium atoms are four-coordinate, with each atom bonded to three nitrogens and an indium atom.

A mixed-valent In(I)/In(II) amide $[\text{MeC}(\text{CH}_2\text{NSiMe}_3)_3\text{In}_2]_2$ (**79**) can be obtained via a transmetalation reaction between the lithium salt of the ligand and InCl.⁴¹⁷ The thallium analogue is also known. The key feature is the In_2^{4+} fragment with an In—In bond distance of 2.8067(9) Å. Interestingly, this bond distance is even longer than the Tl—Tl distance in $[\text{MeC}(\text{CH}_2\text{NSiMe}_3)_3\text{Tl}_2]_2$, (2.734(2) Å), but lies in the range found for covalent In—In bonds. The In—In bond is well shielded by the tripodal, *N*-SiMe₃-substituted ligand. This is reflected in the lack of reactivity towards isocyanides and heteroallenes, which were found to insert into In—In bonds of related compounds.

The redox disproportionation tendency of monovalent In(I) systems is further exemplified by the formation of $[\{\text{C}_{10}\text{H}_6(\text{Me}_3\text{SiN})_2\}\text{In}(\text{THF})]_2$ (**80**) during the attempted metal exchange of $[\text{C}_{10}\text{H}_6(\text{Me}_3\text{SiN})_2]\text{Li}_2(\text{THF})_4$ with InCl in tetrahydrofuran.⁴¹⁸ The In—In distance of 2.7237(6) Å in this molecule is one of the shortest established for a diindane. The related thallium analogue shows metal–ligand (rather than metal–metal) redox chemistry.

(80)

The compound $\{syn-In[PhP(CH_2SiMe_2NSiMe_2CH_2)_2PPh]\}_2$ (**81**) represents an example in which an In(II) species has been stabilized by a macrocyclic ligand.⁴¹⁹ Reduction of $[PhP(CH_2SiMe_2NSiMe_2CH_2)_2PPh]InCl$ with KC_8 in diethyl ether yields the dimeric In(II) complex as a colorless solid. The indium atoms exhibit distorted trigonal-bipyramidal geometries. The In—In bond length of 2.7618(12) Å is in the normal range.

(81)

An interesting route to indium(II) compounds was discovered during an investigation of the oxidizing power of R_3PI_2 ($R = Ph, i\text{-}Pr, n\text{-}Pr$) with indium metal powder.³³⁰ The action of $(n\text{-}Pr)_3PI_2$ on indium metal in diethyl ether leads to colorless, solid $[(n\text{-}Pr)_3PInI_2]_2$ (**82**). The use of $(i\text{-}Pr)_3PI_2$ or Ph_3PI_2 with indium metal leads only to indium(III) iodides. In $[(n\text{-}Pr)_3PInI_2]_2$, the indium atoms have tetrahedral geometry, and the In—In distance is 2.745(3) Å.

(82)

Close to nanometer size, molecular, group III/V compound $[In_3(In_2)_3(PhP)_4(Ph_2P_2)_3Cl_7-(PEt_3)_3]$, featuring an unusual 19-atom cage, has been obtained from the reaction of $InCl_3$ with Et_3P and $PhP(SiMe_3)_2$. The 19-atom polyhedron, which has a diameter of about 0.7 nm, is built up by three formally trivalent indium atoms, six formally divalent indium atoms, and ten phosphorus atoms.⁴²⁰

3.5.1.3.3 Group 16 ligands

During an investigation involving InCl and Ph_3PAuCl in tetrahydrofuran, an indium(II) species was isolated as a colorless solid.⁴²¹ It was identified by X-ray crystallography as the tetrakis-THF adduct of the InCl_2 dimer (**83**). The indium atoms adopt trigonal-bipyramidal geometry. The dioxane complex of the lighter member gallium, $[(\text{dioxane})\text{Cl}_2\text{Ga}]_2$, has tetrahedrally coordinated metal atoms. It is also possible to prepare $[(\text{THF})_2\text{Cl}_2\text{In}]_2$ (**83**) by the reaction of In metal and InCl_3 in xylene, followed by the addition of tetrahydrofuran. The Raman spectrum of $[(\text{THF})_2\text{Cl}_2\text{In}]_2$ shows an absorption at 180 cm^{-1} , suggesting that the $\text{In}-\text{In}$ bond is retained in solution. The gold-containing indium adduct $(\text{dppe})_2\text{Au}_3\text{In}_3(\text{THF})_6$, containing two divalent indium atoms, may be obtained in the presence of 1,2-bis(diphenylphosphino)ethane(dppe) ligand.⁴²¹

(**83**)

An electrochemical route to indium(II) thiolates has been described.²⁵⁰ The electrochemical oxidation of anodic indium in acetonitrile and certain thiols leads to $\text{In}_2(\text{SR})_4$ ($\text{R} = \text{C}_5\text{H}_{11}$, naphthalide) derivatives. Thiols with different substituents produce In(I) or In(III) products. The corresponding oxidation of thallium metal gives only Tl(I) thiolates.

3.5.1.3.4 Group 17 ligands

Some of the earliest work on In(II) compounds centered around the identity of InX_2 ($\text{X} = \text{halide}$).^{1,2,218} Structures of the type $\text{X}_2\text{In}-\text{InX}_2$ and $\text{In}[\text{InX}_4]$ fit the observed diamagnetic property of these halides. The structures of bromides and iodides have been confirmed to be of the latter type.^{422,423} They involve indium(I) cations together with $[\text{InX}_4]^-$ anions.

There are several mixed-valent bromides involving In(II) as well (e.g., $\text{In}_2\text{Br}_3 = \text{In}^{\text{I}}_2[\text{In}^{\text{II}}\text{Br}_6]$, $\text{In}_5\text{Br}_7 = \text{In}^{\text{I}}_3[\text{In}^{\text{II}}_2\text{Br}_6]\text{Br}$).^{2,424} The $[\text{In}^{\text{II}}_2\text{Br}_6]^{2-}$ unit features an $\text{In}-\text{In}$ bond. The exact nature, or even the existence, of binary compounds of InCl_2 stoichiometry is less clear, and the early literature provides conflicting results.^{218,425,426} However, there are various indium subchlorides known, including In_2Cl_3 , In_5Cl_9 , and In_7Cl_9 .^{2,427} They are formulated as mixed-valent compounds of In(I) and In(III) ions. Evidence has been found, during the electrochemical oxidation of indium metal in liquid ammonia solutions of NH_4X ($\text{X} = \text{Cl, Br, I}$), for the formation of In(II) species at the anode.⁴²⁸ In the NH_4I -containing mixture, Raman data confirm the presence of In_2I_4 . However, the isolation of neutral or anionic In(II) derivatives has not been successful, since the disproportionation reaction occurs on removal of solvent to give indium metal, In(I) , and In(III) derivatives.

Preparation of a series of $\text{In}_2\text{X}_4 \cdot 2\text{L}$ and $\text{In}_2\text{X}_4 \cdot 4\text{L}$ ($\text{X} = \text{Cl, Br, or I}$; $\text{L} = \text{O, N, P, or S donors}$) has been reported.^{2,3,218,429,430} These neutral In(II) halide complexes may be synthesized by treating the dihalide with various donors at low temperatures, or by starting with InX and InX_3 compounds. The presence of $\text{In}-\text{In}$ bonds in $\text{In}_2\text{X}_4 \cdot 2\text{L}$ and $\text{In}_2\text{X}_4 \cdot 4\text{L}$ adducts is supported by Raman spectroscopic data. The reaction between InX ($\text{X} = \text{Cl, Br, I}$) and InY_3 (Br, I) in toluene- CH_2Cl_2 -TMEDA solution at low temperature ($< -20^\circ\text{C}$) produces an In(II) species $\text{XYIn}-\text{InY}_2$.⁴³¹ The crystal structure of $\text{In}_2\text{Br}_3 \cdot \text{TMEDA}$ ($\text{TMEDA} = N,N,N',N'$ -tetramethylethanediamine) has

been obtained.⁴³² It exhibits five-coordinate indium atoms with distorted trigonal-bipyramidal geometry, joined by an In—In bond 2.775(2) Å in length. The corresponding reaction with InCl₃ does not produce analogous chloro derivatives. A structural study of In₂X₄·(1,2-dioxane)₂ (X = Cl and Br) using NQR spectroscopy has been reported.⁴²⁶ Synthesis of In₂X₄·(1,2-dioxane)₂ involves the use of In metal and InX₃ starting materials. The isolation of [(*n*-Pr)₃PInI₂]₂ and [(THF)₂Cl₂In]₂ during the attempted syntheses of various other products has been described in earlier sections.

Anionic derivatives In₂X₆^{2−} (X = Cl, Br, I) can also be prepared and isolated as stable solid materials.² For example, the reaction between In₂X₄ and Bu₄NX leads to anionic systems. Vibrational spectroscopic data support the existence of In—In bonded species.⁴ The reaction between InCl and PPh₄Cl in acetonitrile has resulted in [PPh₄]₂[In₂Cl₆], which contains centrosymmetric [In₂Cl₆]^{2−} (**84**) ions having an In—In bond of length 2.727(1) Å.³⁶³ The ternary In(II) bromide complex KInBr₃ (formulated as K₂[In₂Br₆]) has been prepared from InBr₃, KBr, and In.⁴³³ The X-ray powder diffraction data indicate that the [In₂Br₆]^{2−} ion has an eclipsed, ethane-like structure.

3.5.1.3.5 Hydride ligands

There are no reports of well-characterized InH₂ or its adducts. However, the indium(II) hydride species HInNH₂ and HInPH₂ have been generated by thermal and photoactivated reactions of indium metal atoms with NH₃ or PH₃ in solid argon matrices.^{381,382} They have been identified by their IR spectra.

3.5.1.4 Indium(I)

3.5.1.4.1 Group 14 ligands

A dark green compound (*t*-Bu₃Si)₆In₈ (**85**) with an In₈ cluster framework has been isolated from a reaction between *t*-Bu₃SiNa and (Me₅C₅)In.⁴⁰⁶ This species is thermally stable up to 100 °C in solutions with the exclusion of light. The indium atom arrangement may be described as a doubly capped octahedron. The indium(II) species [(*t*-Bu₃Si)₂In]₂ is one of the by-products of this reaction. An even larger cluster compound (*t*-Bu₃Si)₈In₁₂ (**86**) results from the thermolysis of [(*t*-Bu₃Si)₂In]₂ in boiling heptane for 22 hours.⁴⁰⁸ This black-violet, crystalline solid has a polyhedral framework of indium atoms, with the shape of a stretched ellipsoid rather than the icosahedron, and a longitudinal diameter of 750 pm. Thus these molecules reach nanoparticle sizes. The In—In bond distances range from 2.80 to 3.30 Å.

Synthesis of InC₆H₃-2,6-Trip₂ (where Trip = 2,4,6-(*i*-Pr)₃C₆H₂)⁴³⁴ and [(Me₃Si)₃CIn]₄^{435–437}, and the matrix isolation of MeIn⁴³⁸, are particularly noteworthy developments in organo-indium(I) chemistry. X-ray data of InC₆H₃-2,6-Trip₂ and [(Me₃Si)₃CIn]₄ show the presence of a one-coordinate indium center and a tetrahedral In₄ core, respectively. They show interesting metal-ion coordination and oxidation chemistry.^{409,434,436} Among indium(I) compounds, some of the earliest (e.g., In(C₅H₅)) was isolated in 1957) and the most widely known complexes are those containing cyclopentadienyl ligands.^{13,218}

(85)

(86)

3.5.1.4.2 Group 15 ligands

As indicated in an earlier section, the amido indium(I/II) species $[\text{MeC}(\text{CH}_2\text{NSiMe}_3)_3\text{In}_2]_2$ is known.⁴¹⁷ The solid-state structure shows a longer In—N distance, with the monovalent indium atoms (d_{average} : In(I)—N = 2.43 Å, In(II)—N = 2.17 Å).

Tris(pyrazolyl)borate ligands play an important role in indium(I) chemistry.⁴³⁹ This is perhaps not surprising, considering the close similarity between the ubiquitous cyclopentadienyl and tris(pyrazolyl)borate systems,⁴⁴⁰ and the well-established utility of cyclopentadienyl ligands in indium(I) chemistry. The first thermally stable tris(pyrazolyl)boratoindium(I) adduct $[\text{HB}(3\text{-(Ph)Pz})_3]\text{In}$ (**87**) was reported in 1994.⁴⁴¹ It is an air-stable, monomeric compound. Shortly thereafter, the In(I) compounds of alkylated tris(pyrazolyl)borates were reported. These included $[\text{HB}(3\text{-(}t\text{-Bu)Pz})_3]\text{In}$,⁴⁴² $[\text{HB}(3,5\text{-(}t\text{-Bu)}_2\text{Pz})_3]\text{In}$,⁴⁴³ and the fluoralkylated-ligand compound $[\text{HB}(3,5\text{-(CF}_3)_2\text{Pz})_3]\text{In}$ (**88**).^{444,445} The alkali-metal derivatives of the ligand and InI or InCl have been utilized in the preparation of $[\text{HB}(3\text{-(Ph)Pz})_3]\text{In}$ and $[\text{HB}(3,5\text{-(}t\text{-Bu)}_2\text{Pz})_3]\text{In}$. The thallium(I) and silver(I) complexes were used as ligand-transfer agents in the synthesis of $[\text{HB}(3\text{-(}t\text{-Bu)Pz})_3]\text{In}$ and $[\text{HB}(3,5\text{-(CF}_3)_2\text{Pz})_3]\text{In}$.

Unlike some of the cyclopentadienylinidum(I) compounds (e.g., $(\text{Me}_5\text{C}_5)\text{In}$ is hexameric in the solid state), none of these tris(pyrazolyl)borates show any intermolecular $\text{In}\cdots\text{In}$ interactions. It should be noted, however, that $[\text{HB}(3\text{-(Ph)Pz})_3]\text{In}$, $[\text{HB}(3\text{-(}t\text{-Bu)Pz})_3]\text{In}$, $[\text{HB}(3,5\text{-(}t\text{-Bu)}_2\text{Pz})_3]\text{In}$, and $[\text{HB}(3,5\text{-(CF}_3)_2\text{Pz})_3]\text{In}$ contain much more sterically demanding ligands. The disproportionation of In(I) to In metal and In(III) has been observed in the presence of $[\text{HB}(3,5\text{-(CH}_3)_2\text{Pz})_3]^-$.⁸⁶ The compounds $[\text{HB}(3\text{-(Ph)Pz})_3]\text{In}$, $[\text{HB}(3\text{-(}t\text{-Bu)Pz})_3]\text{In}$, and $[\text{HB}(3,5\text{-(CF}_3)_2\text{Pz})_3]\text{In}$ show C_{3v} molecular symmetry. $[\text{HB}(3,5\text{-(}t\text{-Bu)}_2\text{Pz})_3]\text{In}$ exhibits a structure in which the $[\text{HB}(3,5\text{-(}t\text{-Bu)}_2\text{Pz})_3]^-$ ligand adopts a highly twisted configuration, due to the intraligand repulsive interactions of the *tert*-butyl substituents.

Main-group and transition-metal adducts such as $[\text{HB}(5\text{-(}t\text{-Bu)Pz})(3\text{-(}t\text{-Bu)Pz})_2](5\text{-(}t\text{-Bu)PzH})\text{In-InI}_3$ (**89**),⁴⁴⁶ $[\text{HB}(3,5\text{-(CH}_3)_2\text{Pz})_3]\text{InFe}(\text{CO})_4$ (**90**), and $[\text{HB}(3,5\text{-(CH}_3)_2\text{Pz})_3]\text{InW}(\text{CO})_5$ are known.⁹⁰ The iron and tungsten adducts, however, have been obtained using In(III) precursors. The terminal selenido complex $[\text{HB}(3,5\text{-(}t\text{-Bu)}_2\text{Pz})_3]\text{InSe}$ may be obtained by the addition of selenium

(87)

(88)

to the In(I) adduct $[\text{HB}(3,5\text{-}(t\text{-Bu})_2\text{Pz})_3]\text{In}$.⁴⁴⁷ The indium(I) alkyl complex $\{(\text{Me}_3\text{Si})_3\text{C}\}\text{In}_4$, however, does not afford similar adducts with selenium. $[\text{HB}(3,5\text{-}(t\text{-Bu})_2\text{Pz})_3]\text{In}(\text{S}_4)$ and $[\text{HB}(3,5\text{-}(t\text{-Bu})_2\text{Pz})_3]\text{InI}_2$ have also been prepared from In(I) starting materials.⁸⁹ The zinc alkyl derivative $[\text{HB}(3\text{-}(t\text{-Bu})\text{Pz})_3]\text{ZnEt}$ may be obtained by treating $[\text{HB}(3\text{-}(t\text{-Bu})\text{Pz})_3]\text{In}$ with Et_2Zn .⁴⁴²

(89)

(90)

Co-condensation of indium vapor and $t\text{-BuC}\equiv\text{P}$ at 77 K affords two phosphacyclopentadienyl derivatives of In(I), $\text{In}[\eta^5\text{-P}_2\text{C}_3(t\text{-Bu})_3]$ (**91**) and $\text{In}[\eta^5\text{-P}_3\text{C}_2(t\text{-Bu})_2]$ (**92**).^{448,449} These compounds are volatile solids. X-ray data of $\text{In}[\eta^5\text{-P}_2\text{C}_3(t\text{-Bu})_3]$ show a monomeric structure, whereas $\text{In}[\eta^5\text{-P}_3\text{C}_2(t\text{-Bu})_2]$ adopts a structure in which half-sandwich units are linked into chains by weak interactions between the indium atoms and the neighboring triphospholyl rings. $\text{In}[\eta^5\text{-P}_3\text{C}_2(t\text{-Bu})_2]$ may also be synthesized using InI and $\text{K}[\text{P}_3\text{C}_2(t\text{-Bu})_2]$. Unlike the tris(pyrazolyl)boratoindium(I) derivatives, the indium(I) center in $\text{In}[\eta^5\text{-P}_3\text{C}_2(t\text{-Bu})_2]$ does not act as a Lewis-base site.

3.5.1.4.3 Group 16 ligands

An interesting indium(I) alkoxide $[(2,4,6\text{-}(\text{CF}_3)_3\text{C}_6\text{H}_2\text{O})\text{In}]_2$ (**93**), featuring two-coordinate, bent indium sites, has been reported.⁴⁵⁰ This compound is synthesized from CpIn and 2,4,6- $(\text{CF}_3)_3\text{C}_6\text{H}_2\text{OH}$ in hexane, and features a planar In_2O_2 core. The reaction of $\text{Sn}(\mu\text{-}t\text{-BuO})_3\text{I}$ or

$[\text{Sn}(t\text{-BuO})_3\text{Na}]_2$ with InBr yields an alkoxide $\text{Sn}(\mu\text{-}t\text{-BuO})_3\text{In}$ (**94**) featuring both $\text{Sn}(\text{II})$ and $\text{In}(\text{I})$ sites.⁴⁵¹ A study of Lewis-base properties at the two low-valent, main-group metal sites reveals that transition-metal carbonyl fragments coordinate to the indium(I) site first and then to the tin atom(II).

When indium metal is treated with 3,5-di-*tert*-butyl-1,2-benzoquinone (TBQ) in a 1:3 mole ratio, a paramagnetic, green solid $\text{In}(\text{TBSQ})(\text{TBQ})_2$ (where $\text{TBSQ} = 3,5\text{-di-}t\text{-Bu-1,2-benzo-semiquinonate}$) forms. The same product may be obtained from InI_3 and three equivalents of NaTBSQ .⁴⁵² The ESR results confirm that the indium atom in this product is in the +1 state (and also confirm the presence of the semiquinone moiety).²¹⁸ The paramagnetic indium(I) compound $\text{In}(\text{TBSQ})$ has also been reported. It can be stabilized by coordination to 1,10-phenanthroline.²¹⁸

The reaction of $\text{In}(\text{I})$ with an aqueous thiosulphate solution leads to $\text{In}_2\text{S}_2\text{O}_3 \cdot 2(\text{H}_2\text{O})$, $\text{In}_2\text{S}_2\text{O}_3 \cdot \text{In-OH} \cdot 2(\text{H}_2\text{O})$, and $\text{In}_2\text{S}_2\text{O}_3 \cdot 2\text{InNO}_3 \cdot 2(\text{H}_2\text{O})$. These compounds have been characterized by IR spectroscopy, X-ray diffraction, and by thermal analytical methods.⁴⁵³ A study of $\text{In}/\text{In}(\text{NO}_3)_3$ disproportionation to InNO_3 has been carried out, and shows that the nitrate ion exhibits a much stronger stabilizing influence on $\text{In}(\text{I})$ than Cl^- , SO_4^{2-} , Br^- , or ClO_4^- .⁴⁵⁴

The electrochemical oxidation of anodic indium in acetonitrile solutions of aromatic diols $R(OH)_2$ (diol = 1,2-dihydroxybenzene, 2,3-dihydroxynaphthalene, 2,2'-dihydroxybiphenyl, 1,2-dihydroxy-tetrabromobenzene) leads to indium(I) derivatives of $In[OR(OH)]$.⁴⁵⁵ The deprotonation of $-OH$ by Et_3N produces the anionic derivatives.

Related sulfur-donor compounds may also be prepared using electrochemical methods.⁴⁵⁶ The electrochemical oxidation of anodic indium in the presence of alkanediols $(R(SH)_2)$ produces $In[SR(SH)]$ (R = various hydrocarbon bridges such as 1,2- C_2H_4 , 1,3- C_3H_6 , 1,4- C_4H_8). Interestingly, under these conditions, thallium always produces $Tl_2(S_2R)$. The syntheses of alkene- and arenethiolato derivatives of indium $InSR$ (R = Et, Bu), $In_2(SR)_4$ (R = C_5H_{11} , 2- $C_{10}H_7$), and $In(SR)_3$ (R = Ph, C_6F_5) have also been reported.²⁵⁰ Again, thallium behaves somewhat differently under similar conditions. In general, electrochemical technique is simple, and leads to products in high yield. Furthermore, products are often low-valent derivatives. Some of the advantages and unique features of electrochemical synthesis have been described.⁴⁵⁷

Indium(I) complexes of Se and Te donors are known.³⁰⁵ The reaction between $InCl$ and $(Me_3Si)_3SiELi(THF)_2$ (E = Se or Te) and $InCl$ leads to the metathesis product $(Me_3Si)_3SiEIn$. Chalcogenolysis with $CpIn$ also affords the same $In(I)$ selenolate or tellurolate. These indium(I) compounds are light-sensitive compounds. No solid-state structural data are available.

3.5.1.4.4 Group 17 ligands

Binary fluoride, chloride, bromide, and iodide derivatives of indium(I) are known. Among these InI is the most stable, whereas InF is known as an unstable gaseous species.⁷ Many of these $In(I)$ halides serve as useful sources of $In(I)$ for chemical reactions.²¹⁸ Although they have a high tendency to disproportionate in solutions containing water or other bases, and are insoluble in common solvents, a few methods are now available to deliver $In(I)$ in soluble form. For example, InX (X = Cl, Br, I) forms relatively stable solutions in mixtures of aromatic solvents and nitrogen donors like TMEDA at low temperatures.²¹⁸ The structures of these adducts are not well established. The effects of temperature on the stability, and the concentration of TMEDA on the solubility, of indium(I) species have been described. Interestingly, in ammonia $InBr$ and InI disproportionate easily to produce indium(III) halide complexes. Solutions of indium(I) may also be prepared by the treatment of In/Hg with silver trifluoromethanesulfonate in dry acetonitrile.⁴⁵⁸ In the absence of O_2 , these solutions are stable for over five days. These mixtures serve as useful $In(I)$ sources for synthetic applications.⁴⁵⁹ The $InBF_4$ salt has been synthesized from the reaction of indium metal with anhydrous HF and BF_3 .⁴⁶⁰

Several mixed-valent halide compounds (e.g., $In_2Cl_3 = In^I_3[In^{III}Cl_6]$, $In_7Cl_9 = In^I_6[In^{III}Cl_9]$, $In_5Cl_9 = In^I_3[In^{III}_2Cl_9]$, $InBr_2 = In^I[In^{III}Br_4]$, $In_2Br_3 = In^I_2[In^{III}_2Br_6]$, $In_4Br_7 = In^I_5In^{III}_3Br_{14}$, $In_5Br_7 = In^I_3[In^{III}_2Br_6]Br$, $In_7Br_9 = In^I_6In^{III}Br_9$, and $InI_2 = In^I[In^{III}I_4]$) are known.^{2,427,461–463} Heating $InCl$ with $InCl_3$ or $SnCl_2$ produces In_7Cl_6 via a redox process. The In_7Br_9 has a structure similar to that of the chloride analogue.⁴⁶² The solid-state structure of the bromide In_4Br_7 reveals unusual coordination numbers for $In(I)$ of 10 and 12.⁴⁶¹ Evidence for the formation of $[InBr_2]^-$, along with $InBr$, has been reported when excess indium dissolves in HBr acid.⁴⁶⁴

The mixed-valent gold–indium cluster $[Au_3In_3Cl_6(dppe)_2]$ is composed of $In(I)$ and $In(II)$ atoms. Synthetic details were presented in an earlier section. Insertion and redox reactions of $In(I)$ halides have been described. For example, oxidative addition reactions of InX (X = Cl, Br, I) with $PhSSPh$ yields indium(III) thiolates of the type $(PhS)_2InX$.^{4,259} Unexpected $In(II)$ or $In(III)$ products are common in reactions involving indium(I) halides, which result from facile disproportionation processes. Several such cases were described with divalent indium compounds.

3.5.2 THALLIUM

3.5.2.1 Introduction

Thallium is the largest and the heaviest element of the group 13 family. The metal and its compounds are dangerously toxic, even at low levels. It is a cumulative poison, and the lethal dose is considered to be about 13 mg of thallium for each kg of human body weight (or less than 1 g of a thallium compound in a single ingestion). The ability of free $Tl(I)$ ions in aqueous

solutions to mimic potassium is one of the main causes of its high toxicity.⁴⁶⁵ However, thallium-201 compounds are still useful for the diagnosis of myocardial perfusion.⁴⁶⁶

Thallium has the electronic configuration of $[\text{Xe}]4f^{14}5d^{10}6s^26p^1$, and forms compounds in the oxidation states I, II, and III. Thallium(II) derivatives are relatively rare. In general the bonding between Tl(III) and a donor is more covalent in nature, whereas Tl(I) compounds show more ionic behavior. Interactions between the Tl(I) atoms of neighboring molecules are common. The theoretical explanation has been controversial.^{467–470} The coordination chemistry of Tl(III) is complicated by the highly oxidizing power of thallium(III) in both aqueous and nonaqueous solutions.

In this review, primarily the developments in thallium coordination chemistry since the early 1980s will be surveyed. CCC (1987) is an excellent reference source for work prior to that time.¹ In general, organometallic compounds are outside the scope of this article. There are several useful review and reference articles that describe thallium chemistry, including organothallium work.^{1,6–8,12,14,16–19,471–475} Thallium is an important element in the field of high-temperature superconducting materials.⁴⁷⁶

3.5.2.2 Thallium (III)

3.5.2.2.1 Group 14 ligands

(i) Carbon ligands

A detailed, multimethod study of hydrated Tl(III) cyanide species in aqueous solution reveals that Tl(III) forms very strong complexes with cyanide ions (even stronger than halide–Tl(III) interactions).^{477,478} Formation of a series of Tl(III) complexes $\text{Tl}(\text{CN})_n^{3-n}$ ($n = 1–4$) has been established, and the solution structures and stability constants were reported. The mono- and dicyano complexes $[\text{Tl}(\text{CN})(\text{OH}_2)_5]^{2+}$ and $[\text{Tl}(\text{CN})_2(\text{OH}_2)_4]^+$ show six-coordinate thallium centers, whereas $\text{Tl}(\text{CN})_3(\text{OH}_2)$ and $[\text{Tl}(\text{CN})_4]^-$ have four-coordinate Tl(III) ions.

The equilibria, dynamics, and structures of $[\text{Tl}(\text{edta})\text{X}]^{2-}$ ($\text{X} = \text{halide or pseudohalide}$) have been investigated.⁴⁷⁹ The one-bond ^{205}Tl – ^{13}C coupling constant for $[\text{Tl}(\text{edta})\text{CN}]^{2-}$ is found to be 10,479 Hz. This indicates a strong Tl–C bond. The solid state structure of $\text{Na}_2[\text{Tl}(\text{edta})\text{CN}]$ shows that the seven-coordinate thallium atom sits in the “edta-pocket” formed by the two nitrogen and four oxygen atoms with an axial bond to the cyanide ion (Tl–C = 2.14(3) Å).⁴⁷⁹ Thallium(III) porphyrin complexes containing cyanide ligands are known.^{480–482} The cyano group occupies an axial coordination site. The $^1J(^{205}\text{Tl}$ – $^{13}\text{C})$ coupling constants are large and typically $>5,000$ Hz.^{480,482} The X-ray crystal structure of *meso*-tetra(4-pyridyl)porphyrinatothallium(III)cyanide, $\text{Tl}(\text{TPYP})(\text{CN})$, shows that thallium–carbon (cyanide) distance is 2.12(2) Å. The characteristic IR band for ν_{CN} appears at $2,163\text{ cm}^{-1}$.⁴⁸²

It is possible to prepare oligonuclear Pt–Tl compounds by using thallium(III) cyano complexes and $[\text{Pt}(\text{CN})_4]^{2-}$.⁴⁸³ The relative oxidation states of the metal atoms were estimated from their ^{195}Pt and ^{205}Tl NMR data, confirming that the $[(\text{NC})_5\text{Pt}–\text{Tl}(\text{CN})_n]^{n-}$ ($n = 1–3$) adducts can be considered as metastable intermediates in a two-electron process leading to Tl(I) and Pt(IV) final products.⁴⁸³ These Pt–Tl bonded products show remarkably large one-bond ^{195}Pt – ^{205}Tl spin–spin coupling constants, ranging from 25 to 71 kHz.⁴⁸⁴ They have also been studied computationally.^{485,486} Systems with such short metal–metal distances between relatively heavy atoms (e.g., Au, Pt, Tl, Pb) display interesting electronic properties.^{487,488}

There are no Tl(III) carbonyl complexes isoelectronic with $[\text{Tl}(\text{CN})_2]^+$. Theoretical studies predict that it would be difficult to observe $[\text{Tl}(\text{CO})_2]^{3+}$ experimentally. Organothallium(III) compounds are well known, in particular those involving one or more noncarbon substituents of the type R_2TlX or RTlX_2 .^{473,474} Those compounds will not be considered here.

(ii) Silicon, germanium, tin, and lead ligands

Silyl thallium halides $(t\text{-Bu}_3\text{Si})_n\text{TlX}_{3-n}$ ($\text{X} = \text{halide}, n = 1, 2$) have been reported. These compounds display relatively low thermal stability.^{28,29,489} $(t\text{-Bu}_3\text{Si})_2\text{TlCl}$ has been obtained by the addition of Me_3SiCl to a mixture containing TlCl_3 and $t\text{-Bu}_3\text{SiNa}$ in a 1:3 molar ratio.⁴⁸⁹ The reaction

between TlCl_3 and $t\text{-Bu}_3\text{SiNa}$ at a 1:2 molar ratio has produced thallium clusters $[(t\text{-Bu})_3\text{Si}]_4\text{Tl}_3\text{Cl}$ and $[(t\text{-Bu})_3\text{Si}]_6\text{Tl}_6\text{Cl}_2$, containing covalently linked Tl atoms.⁴⁸⁹

Tris(trimethylsilyl)thallium is prepared by the reaction between $\text{Hg}(\text{SiMe}_3)_2$ and trimethyl thallium.² Apart from the pre-1984 work, there are no significant new developments in Tl—Sn, Tl—Ge, or Tl—Pb bonded compounds.^{1,3}

3.5.2.2.2 Group 15 ligands

(i) Nitrogen ligands

Simple complexes of thallium(III) with neutral nitrogen donors like ammonia or amines are not known in aqueous solution. The hydrolysis in aqueous solutions leading to hydroxo complexes $\text{Tl}(\text{OH})_n^{3-n}$ ($n = 1, 2$) is one of the complications.⁴⁹⁰ Mixed hydroxo complexes of Tl(III) containing ethylenediamine (en) are known.^{491,492} Additional ligands on thallium can prevent the hydrolysis tendency. Complexes of the formula $[\text{Tl}(\text{en})_3]\text{X}_3$, $[\text{TlX}_2(\text{en})_2][\text{TlX}_4]$, and $[\text{TlX}_2(\text{en})_2]\text{X}_3$ ($\text{X} = \text{Cl}$ or Br) have been synthesized and identified based on IR spectroscopic or conductivity and molecular weight data.^{493,494} More recently, the formation of $[\text{Tl}(\text{en})_n]^{3+}$ ($n = 1-3$) complexes in a pyridine solution has been established by NMR spectroscopy.⁴⁹⁵ The compound $[\text{Tl}(\text{en})_3][\text{ClO}_4]_3$ has been crystallized and characterized using X-ray crystallography. The thallium ion features a distorted octahedral geometry, with nitrogen atoms of the three chelating ethylenediamine ligands forming the coordination sphere. The Tl(III) coordination chemistry involving diethylenetriamine (dien) and N,N,N',N' -tetrakis(2-aminoethyl)ethane-1,2-diamine (penten)⁴⁹⁶ has also been investigated, including the solid-state structures of $[\text{Tl}(\text{dien})_2][\text{ClO}_4]_3$ and $[\text{Tl}(\text{NO}_3)(\text{penten})](\text{NO}_3)_2$. Thallium(III) nitrate and 1,4,7-triazacyclononane (L) at 1:4 ratio produce $[\text{L}_2\text{Tl}](\text{NO}_3)_3$.⁴⁹⁷ The N,N,N' -trimethyl-1,4,7-triazacyclononane (L') derivatives of Tl(I) may also be synthesized from TlNO_3 .

The ligand 1,3,5-triamino-1,3,5-trideoxy-*cis*-inositol (taci) is an interesting one, since it can provide four different coordination sites with variable softness and size. It features both nitrogen- and oxygen-donor sites. The metal coordination chemistry of taci with group 13 elements has been investigated.¹⁷⁵ Single-crystal X-ray analysis revealed a TiN_6 coordination sphere for Tl $(\text{taci})_2(\text{NO}_3)_3 \cdot 2\text{H}_2\text{O}$ (**95**). Interestingly, the aluminum(III) in $\text{Al}(\text{taci})_2\text{Br}_3 \cdot 7\text{H}_2\text{O}$ shows AlO_6 bonding, whereas gallium(III) in $\text{Ga}(\text{taci})_2(\text{NO}_3)_3 \cdot 3\text{H}_2\text{O}$ adopts a GaN_3O_3 coordination sphere. The indium(III) shows an unusual structure, with a $(\mu_6\text{-O})\text{In}_6$ unit.¹⁷⁶

(95)

Reacting TlCl_3 with the silylated amidine $\text{PhC}(\text{NSiMe}_3)\text{N}(\text{SiMe}_3)_2$ gives the ionic derivative $[\text{PhC}(\text{NHSiMe}_3)_2][\text{PhC}(\text{NSiMe}_3)_2\text{TlCl}_3]$ (**96**).⁴⁹⁸ The anion exhibits a five-coordinate thallium site in which the thallium atom is surrounded by three chlorine atoms and by two nitrogen atoms of the amidinato ligand. The axial sites of the trigonal bipyramid are occupied by one nitrogen and one chloride atom.

(96)

A dinuclear thallium(III) complex, tris[di(4,4'-phenyltriazenido)phenylmethane]dithallium(III), is formed by the reaction of TlNO_3 with di(4,4'-phenyltriazeno)phenylmethane in the presence of NaOH and air.⁴⁹⁹ Each complex contains three doubly deprotonated bis(triazenido) ions $(\text{PhN}_3\text{C}_6\text{H}_4\text{CH}_2\text{C}_6\text{H}_4\text{N}_3\text{Ph})^{2-}$ and two six-coordinate Tl^{3+} ions with trigonal-prismatic coordination of six N atoms.

Thallium(III) complexes of porphyrins are common.^{97–99,117,480–482,500–515} Most studies involve 2,3,7,8,12,13,17,18-octaethylporphyrin (H_2OEP) and 5,10,15,20-tetraphenylporphyrin (H_2TPP) ligand systems. Synthesis, structures, spectroscopic data, and electrochemistry have been investigated. The typical coordination number at thallium(III) is either 5 or 6, and the coordination geometry may be described as a square-based pyramid formed by the porphyrin, in which the apical site is occupied either by a monodentate ligand (e.g., Cl , CN) or by a bidentate group (e.g., acetate). The X-ray crystal structure of $\text{Tl}(\text{TPYP})(\text{CN})$ ⁴⁸² (*meso*-tetra(4-pyridyl)porphyrinatothallium(III) cyanide) or $\text{Tl}(\text{TPP})\text{CN}$ ⁵¹⁶ shows distorted square-pyramidal geometry at thallium. The thallium center in $\text{Tl}(\text{TPYP})(\text{OAc})$ is six-coordinate, but the acetate group coordinates in asymmetric fashion, with two different $\text{Tl}-\text{O}$ distances.⁵⁰⁷ In contrast, the X-ray structure of $\text{Tl}(\text{III})$ *meso*-tetraphenylporphyrin acetate shows that the acetate group is coordinated as a symmetrically bonded bidentate ligand.⁵¹⁷ The *N*-methyltetraphenylporphyrin thallium(III) complex $\text{Tl}(\text{N-Me-TPP})(\text{OAc})_2$ has two *cis*-chelating acetate groups and an eight-coordinate thallium atom with a square-based antiprism geometry.⁵⁰⁰ An unusual 4:3 tetragonal base-trigonal base, piano-stool, seven-coordinate geometry has been observed in $\text{Tl}(\text{N-Me-TPP})(\text{O}_2\text{CCF}_3)_2$.⁵¹⁸ The compound $\text{Tl}(\text{TPP})(\text{OSO}_2\text{CF}_3)(\text{THF})$ (**97**) features a six-coordinate thallium site, but a rare transoid geometry.⁵⁰³

(97)

Heterometallic homo- and heteroleptic porphyrinate dimers with metal–thallium bonds have been described. These include $(\text{OEP})\text{Rh}-\text{Tl}(\text{OEP})$, $(\text{TPP})\text{Rh}-\text{Tl}(\text{OEP})$, $(\text{OEP})\text{Rh}-\text{Tl}(\text{TPP})$, and $(\text{TPP})\text{Rh}-\text{Tl}(\text{TPP})$.⁵¹⁹ The UV–visible spectroscopy confirms the presence of a strong $\pi-\pi$ interaction between the macrocycles in each metal derivative.

Several phthalocyanato thallium(III) compounds have been synthesized and characterized.⁵²⁰ Oxidation of dithalliumphthalocyaninate with excess iodine affords a blue-green iodophthalocyaninatothallium(III) derivative.⁵²¹ The thallium center has a tetragonal-pyramidal arrangement, with the iodo group occupying the axial site. The thallium atom is displaced out of the N_4 plane towards iodide by about 0.959 Å. Treatment of this iodo derivative (Pc)TlI with $n\text{-Bu}_4\text{NX}$ ($X = \text{Cl}, \text{ONO}, \text{NCO}$) yields $[n\text{-Bu}_4\text{N}][\text{cis}-(\text{Pc})\text{TlX}_2]$ adducts.⁵²² Optical, vibrational data and the solid-state structures of $[n\text{-Bu}_4\text{N}][\text{cis}-(\text{Pc})\text{Tl}(\text{ONO})_2]$ and $[n\text{-Bu}_4\text{N}][\text{cis}-(\text{Pc})\text{TlCl}_2]$ have been reported. The Tl(III) adducts $[n\text{-Bu}_4\text{N}][\text{cis}-(\text{Pc})\text{Tl}(\text{ONO})_2]$ (**98**) and $[n\text{-Bu}_4\text{N}][\text{cis}-(\text{Pc})\text{TlCl}_2]$ feature eight- and six-coordinate thallium sites, respectively.

Complete lithiation of the tripodal amine $\text{HC}\{\text{SiMe}_2\text{NH}(p\text{-Tol})\}_3$ with $n\text{-BuLi}$, followed by the reaction with TlCl_3 , affords the Tl(III) amide $\text{HC}\{\text{SiMe}_2\text{NTl}(p\text{-Tol})\}_3$ (**99**). The same product may be obtained by treating the $\text{HC}\{\text{SiMe}_2\text{NLi}(p\text{-Tol})\}_3$ with three equivalents of TlCl . If the lithiation and transmetalation are performed in one step, an interesting mixed-valent amide $[\text{HC}\{\text{SiMe}_2\text{N}(p\text{-Tol})\}_3(n\text{-BuTl})\text{Tl}]$ (**100**) forms.⁵²³ The mixed-valent amide $\{\text{CH}_2[\text{CH}_2\text{NSiMe}_3]_2\}_2\text{Tl}^{\text{III}}\text{Tl}^{\text{I}}$, which features a bidentate ligand, has been prepared by treating two equivalents of the Tl(I) amide $\text{CH}_2[\text{CH}_2\text{N}(\text{Tl})\text{SiMe}_3]_2$ with one equivalent of TlCl_3 .⁵²⁴

Thallium(III) adducts with a mixed-donor surrounding can be found in seven-coordinate $[\text{Tl}(\text{edta})\text{OH}]^{2-}$, $[\text{Tl}(\text{edta})\text{CN}]^{2-}$,⁴⁷⁹ $[\text{Tl}(\text{bipy})_3(\text{DMSO})]^{3+}$,⁵²⁵ and eight-coordinate $[\text{Tl}(\text{bipy})_2(\text{NO}_3)_3]$, $[\text{Tl}(\text{tpen})(\text{NO}_3)](\text{ClO}_4)_2$ adducts (edta = ethylenediaminetetraacetate tpen = N,N,N',N' -tetrakis-(2-pyridylmethyl)ethylenediamine).⁵²⁵ The thallium(III) ion has also been encapsulated in an iminophenolate cryptand ligand.⁵²⁶ The NMR spectroscopic data suggest that the thallium(III) is held strongly within the host.

(ii) Phosphorus, arsenic, antimony, and bismuth ligands

There appear to be no notable nonorganothallium compounds that belong in this category. The highly oxidizing thallium(III) ion will most likely present problems during the synthesis of thallium(III) complexes of these soft donors. However, there are a few organothallium derivatives,^{527,528} and Tl(III) adducts of sulfur ligands are known.

3.5.2.2.3 Group 16 ligands

(i) Oxygen ligands

Solid-state data show that hexaaquathallium(III) ion has six water molecules coordinated to Tl(III) in a regular octahedral fashion.⁵²⁹ However, in solution the water molecules are quite labile.^{530,531} These solutions are acidic and the resulting hydroxides are fairly stable. Thallium(III) hydroxo species have also been investigated.⁴⁷¹ The solid-state structure of the first hydroxothallate, $\text{Ba}_2[\text{Tl}(\text{OH})_6]\text{OH}$, has been reported.⁵³² It was synthesized by reacting $\text{Tl}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ with NaOH in the presence of barium hydroxide. The structure and vibrational spectra of the DMSO-solvated Tl(III) ion were studied in a DMSO solution and in the solid state. The X-ray crystal structure of $[\text{Tl}(\text{DMSO})_6](\text{ClO}_4)_3$ has been reported.⁵³³

Although Tl(III) adducts of β -diketones are not available, the homoleptic tropolonato derivative has been synthesized. The tris(tropolonato)thallium(III) can bind to trioctylphosphine oxide forming seven-coordinate complexes.²⁰³ The indium(III) analogue behaves similarly.

Thallium(III) salts of polyoxyanions, including those of nitrate, halogenates, sulfate, phosphate, and acetate have been prepared, often starting from the thallium(III) oxide, and some solid-state structures have been investigated.^{471,534–537} Thallium(III) acetate is a useful reagent in organic synthesis. Mixed-ligand complexes of thallium(III) containing donors in addition to oxygen have also been investigated.^{538,539}

(ii) Sulfur, selenium, tellurium ligands

Thallium(III) complexes in which the coordination sphere is made up exclusively of heavier, group 16 donors are rare.^{540–545} The high oxidizing power of Tl(III) poses difficulties during the synthesis of such complexes. There are several early reports concerning the synthesis and structures of tris(*N,N*-dimethyldithiocarbamato)thallium(III) and tris(*N,N*-diethyldithiocarbamato) thallium(III) adducts, and compounds of the type $[\text{Tl}(\text{dithiolene})_2]^-$ (where dithiolene = 1,2- $\text{S}_2\text{C}_2\text{H}_2$, 4,5- $\text{S}_2\text{C}_6\text{H}_2(\text{CH}_3)_2$, 1,2- $\text{S}_2\text{C}_2(\text{CN})_2$).^{540,541,546} Thallium adducts of the type $[\text{Tl}(\text{dithiolene})_3]^{3-}$ are also known.^{547–549} Tris chelate adducts of Tl(III) containing 1,3-dithiole-2-thione-4,5-dithiolate (dmit) and 1,2-dithiole-3-thione-4,5-dithiolate (dmt) ligands can be synthesized using the alkali-metal salts of the ligand and $[\text{Ph}_4\text{As}][\text{TiCl}_4]$ as the thallium source. $[\text{Ph}_4\text{As}]_3[\text{Tl}(\text{dmit})_3]$ and $[\text{Ph}_4\text{As}]_3[\text{Tl}(\text{dmt})_3]$ have been isolated as red-brown and red crystalline solids, respectively.⁵⁴⁷

The Tl(III) adduct of dicyclohexyldithiophosphinic acid $[\text{Tl}\{\text{S}_2\text{PCy}_2\}_3]$ has been reported.⁵⁵⁰ The reaction between diphenylthallium(III) compounds TlPh_2X ($\text{X} = \text{Br}, \text{OH}$ or S_2PCy_2) and dicyclohexyldithiophosphinic acid, $\text{HS}(\text{S})\text{PCy}_2$, has resulted in the loss of one or more phenyl groups, leading to $\text{Tl}\{\text{S}_2\text{PCy}_2\}_3$ (**101**) as one of the products. The thallium atom is coordinated to three pairs of S atoms from two very anisobidentate ligands and one symmetrically bonded dithiophosphinate.

Anionic, tridentate tris(mercaptoimidazolyl)borates $[\text{Tm}^{\text{R}}]^-$ systems are useful for isolation of Tl(III) complexes.^{542,543} Six-coordinate, sandwich complexes $\{[\text{Tm}^{\text{Ph}}]_2\text{Tl}\}\text{ClO}_4$, $\{[\text{Tm}^{\text{Me}}]_2\text{Tl}\}\text{I}$ (**102**), and $\{[\text{Tm}^{\text{Me}}]_2\text{Tl}\}\text{TiI}_4$ have been synthesized and structurally characterized. The compound $\{[\text{Tm}^{\text{Me}}]_2\text{Tl}\}\text{I}$ has been isolated as a by-product during the synthesis of a tris(mercaptoimidazolyl)boratozinc complex using a thallium(I) starting material $[\text{Tm}^{\text{Me}}]\text{Tl}$.^{542,543} Attempted synthesis of

$\{[\text{Tm}^{\text{Me}}]_2\text{Tl}\}^+$ using $[\text{Tm}^{\text{Me}}]\text{Na}$ and $\text{Tl}(\text{NO}_3)_3$ has been a failure, due to oxidation reductions between the $\text{Tl}(\text{III})$ ion and the ligand borohydride function. However, $[\text{Tm}^{\text{Me}}]_2\text{Tl}\text{Tl}_4$ can be synthesized in good yield by treating the $[\text{Tm}^{\text{Me}}]\text{Tl}$ with excess iodine. It is believed that, unlike the free ligand, the $\text{Tl}(\text{I})$ complexed ligand is more resistant to oxidation by $\text{Tl}(\text{III})$. The compound $\{[\text{Tm}^{\text{Ph}}]_2\text{Tl}\}\text{ClO}_4$ has been synthesized directly from $\{[\text{Tm}^{\text{Ph}}]\text{Li}\}$ and $\text{Tl}(\text{ClO}_4)_3 \cdot x\text{H}_2\text{O}$. The solid-state structures of these tris(mercaptoimidazolyl)boratothallium(III) complexes show that the thallium ion is coordinated to six sulfur donors in a regular octahedral fashion. The $\text{Tl}-\text{S}$ distances are 2.69 Å.

Electrochemical oxidation of thallium in the presence of 1-hydroxypyridine-2-thione (HPT) affords the thallium(I) adduct along with $\text{Tl}(\text{PT})_3$ (**103**).³⁰⁰ The thallium atom is bonded to three oxygens and three sulfur atoms in an octahedral fashion, forming the *mer*-isomer. The ^{205}Tl NMR spectrum of $\text{Tl}(\text{PT})_3$ exhibits the resonance due to thallium(III) at δ 2,968. The related thallium(I) adduct $\text{Tl}(\text{PT})$ displays the signal due to thallium(I) at δ 2,697.

3.5.2.2.4 Group 17 ligands

Compared with the trihalides of lighter, group 13 elements, the corresponding thallium(III) derivatives are less stable. TlF_3 hydrolyses easily in water, producing $\text{Tl}(\text{OH})_3$.^{7,471} Thus, hydrates of TlF_3 are not available. True double salts of the type MTlF_4 ($\text{M} = \text{Li}$ or Na) and MTlF_6 ($\text{M} = \text{Na}$, K , Rb , and Cs) compounds containing the TlF_6^{3-} anion have been reported. TlI_3 is isomorphous with CsI_3 , and is best described as $\text{Tl}(\text{I})$ triiodide. The $\text{Tl}^{\text{I}} \text{I}_3$ formulation is also consistent with the standard reduction potentials.⁷ However, when treated with excess I^- TlI_4^- forms, in which the $\text{Tl}(\text{III})$ state becomes stable. There are many complexes containing the TlI_4^- ion.^{551–559} The chlorides and bromides of $\text{Tl}(\text{III})$ show the most diverse coordination chemistry. Thallium(III) halides form complexes with a variety of N, O, and halide donors.^{560–582} The $\text{Tl}(\text{III})$ adducts containing donors like P or S are rare, because of the oxidation reactions of the P- or S-donor center by the $\text{Tl}(\text{III})$ ions.

The nucleophilic carbene complexes of TlCl_3 and TlBr_3 have been reported.³²⁵ These adducts are unique in that the divalent carbon site not only survives the oxidizing power of $\text{Tl}(\text{III})$, but also acts as a donor to $\text{Tl}(\text{III})$. The adducts $\text{Cl}_3\text{Tl}[\text{C}\{\text{N}(\text{Mes})\text{CH}\}_2]$, $\text{Cl}_3\text{Tl}[\text{C}\{\text{N}(\text{Mes})\text{CBr}\}_2]$, and $\text{Br}_3\text{Tl}[\text{C}\{\text{N}(\text{Mes})\text{CH}\}_2]$ can be synthesized by treating TlX_3 with “stable” carbenes $\text{C}\{\text{N}(\text{Mes})\text{CH}\}_2$ or $\text{C}\{\text{N}(\text{Mes})\text{CBr}\}_2$. Although these complexes are moisture-sensitive, they possess high thermal stability. The bis(carbene) adduct $\text{Cl}_3\text{Tl}[\text{C}\{\text{N}(\text{Mes})\text{CH}\}_2]\text{C}\{\text{N}(\text{Me})\text{C}(\text{Me})\}_2$ has also been prepared. The molecular structure of $\text{Cl}_3\text{Tl}[\text{C}\{\text{N}(\text{Mes})\text{CH}\}_2]$ (**104**) has been reported. The thallium center adopts a distorted tetrahedral environment. The $\text{Tl}-\text{C}(\text{carbene})$ distance is 2.179(9) Å. Heating a mesitylene solution of $\text{Cl}_3\text{Tl}[\text{C}\{\text{N}(\text{Mes})\text{CH}\}_2]$ and $\text{Br}_3\text{Tl}[\text{C}\{\text{N}(\text{Mes})\text{CH}\}_2]$ to 163°C leads to decomposition, resulting in the thallium(I) halide and the oxidized carbene product $[\text{XC}\{\text{N}(\text{Mes})\text{CH}\}_2]\text{X}$.

$\text{TlCl}_3(\text{py})_3$ and $\text{TlBr}_3(\text{py})_3$ feature octahedral Tl(III) centers with *mer*-geometry.^{583,584} $\text{TlBr}_3(\text{OPPh}_3)_2$, $[\text{TlBr}_3(\mu\text{-C}_4\text{H}_8\text{O}_2)]$ and $\text{TlBr}_3(\text{py})_2$ have trigonal-bipyramidal thallium centers in the solid state.^{585–587} A series of Tl(III) compounds of the type $\text{TiClBrI}(\text{L})_2$ (L = various pyridine *N*-oxides, HMPA, OPPh_3) containing three different halides on a single thallium atom have been prepared and characterized.⁵⁷¹ These compounds have been prepared by the action of IBr on TlCl in acetonitrile with the ligand present. The solid-state structure of $\text{TlClBrI}(\text{OPPh}_3)_2$ (**105**) has been reported. The thallium atom displays distorted trigonal-bipyramidal geometry, with the halide ions occupying the sites of the equatorial plane. Complexes of mixed halides such as TlBrCl_2 , TlBrI_2 , TlCl_2I , and TlCl_2Br have also been synthesized.^{569,570}

Thallium(III) chloride reacts with 1,4,7-triazacyclononane and 1,4,7-trimethyl-1,4,7-triazacyclononane to produce 1:1 complexes.⁴⁹⁷ It is also possible to prepare the InBr_3 adduct of 1,4,7-triazacyclononane. As noted earlier, the hydrolysis of this compound leads to the first well-authenticated In(III) μ -hydroxo complex.

Chlorothallate(III) complexes of various solid state structures are known.^{588–599} Compounds with octahedral $[\text{TlCl}_6]^{3-}$ and tetrahedral $[\text{TlCl}_4]^-$ anions in the solid state have been well documented.⁵⁸⁸ Pentanediammonium and 4-chloropyridinium salts of chlorothallates(III) contain distorted square-pyramidal $[\text{TlCl}_5]^{2-}$ (**106**) anions.^{589,590} The presence of anions of the type $[\text{Tl}_2\text{Cl}_9]^{3-}$,^{600,601} and $[\text{Tl}_2\text{Cl}_{10}]^{4-}$ has also been established.^{590,593}

Bromothallate(III) complexes also show variable coordination numbers and structural diversity for the thallium(III) ion.^{588,591,602–605} X-ray data, supported by Raman analysis, showed that the $[\text{TlBr}_5]^{2-}$ ion of 1,1,4,4-tetramethylpiperazinium and *N,N'*-dimethyltriethylenediammonium salts adopts a trigonal-bipyramidal geometry.⁶⁰⁴ Compounds derived from 4,4'-dimethyl-2,2'-bipyridinium cation contain unusual bromothallate units, with four short Tl-Br bonds and one long Tl-Br interaction. The *N*-methyl-1,3-propanediammonium salt of $[\text{TlBr}_5]^{2-}$ is known. The X-ray

structure reveals a distorted square pyramid with one long, additional Tl—Br contact.⁶⁰⁶ Salts with octahedral $[\text{TlBr}_6]^{3-}$ and tetrahedral $[\text{TlBr}_4]^-$ anions are well known.⁵⁹¹ The anion $[\text{Tl}_2\text{Br}_9]^{3-}$ has also been reported.⁶⁰³

3.5.2.3.5 Hydride ligands

The chemistry of group 13 hydrides has been reviewed.⁵ Thallium hydrides are the least stable among group 13 hydrides. Stability and the properties of Tl(III) hydrides have been analyzed by computational methods. Results suggest that Tl_2H_6 is thermodynamically unstable in both the gas phase and as a solid. Despite some claims in early literature, it is unlikely that TlH_3 aggregates may exist in the uncoordinated state. LiTlH_4 can be synthesized, but it decomposes rapidly at 0°C . TlBH_4 is a thermally stable compound.²

3.5.2.3 Thallium (II)

Only a very few well-authenticated molecules of divalent thallium are known.^{2,3} The silyl derivatives of Tl(II) of the type $\text{R}_2\text{Tl—TlR}_2$ where $\text{R} = \text{Si}(\text{SiMe}_3)_3$ (**107**), $\text{Si}(t\text{-Bu})_3$ (**108**), and $\text{Si}(t\text{-Bu})_2\text{Ph}$ (**109**) have been synthesized and structurally characterized.^{28,29,407,607} Dark red $\{[(\text{Me}_3\text{Si})_3\text{Si}]_2\text{Tl}\}_2$ has been obtained from a reaction between $\text{TlN}(\text{SiMe}_3)_2$ and $(\text{Me}_3\text{Si})_3\text{SiRb}$ in a toluene/pentane mixture.⁶⁰⁷ Interestingly, the use of $(\text{Me}_3\text{Si})_3\text{SiM}$ ($\text{M} = \text{Li}, \text{Na}, \text{K}, \text{Rb}, \text{Cs}$) and TlX ($\text{X} = \text{Cl}, \text{I}$) does not lead to Tl—Si bonded compounds, but results only in the formation of elemental Tl, MX, and $[(\text{Me}_3\text{Si})_3\text{Si}]_2$. The thallium(II) derivative $\{[(\text{Me}_3\text{Si})_3\text{Si}]_2\text{Tl}\}_2$ slowly decomposes in solution. However, solid samples are stable even in air for a short period. The crystal structure shows an approximately C_2 -symmetric Tl_2Si_4 framework with a Tl—Tl bond length of $2.9142(5) \text{ \AA}$ and a TlTlSi_2 dihedral angle of 78.1° . The synthesis of $\{\text{Tl}[\text{Si}(t\text{-Bu})_3]_2\}_2$ involves the use of TlBr and an alkali-metal salt $\text{NaSi}(t\text{-Bu})_3$.⁴⁰⁷ Thallium(II) radicals $(t\text{-Bu})_3\text{SiTl}\cdot$ were suggested as being present in benzene solutions at room temperature to account for the unusually dark green color, the band-rich EPR signal, and some of the decomposition products. The compound $\{\text{Tl}[\text{Si}(t\text{-Bu})_2\text{Ph}]_2\}_2$ has been synthesized by treating TlBr with $\text{NaSi}(t\text{-Bu})_2\text{Ph}$ in tetrahydrofuran.²⁹ It is a dark-blue-colored compound. According to X-ray crystal structure analysis, the thallium atoms in $\{\text{Tl}[\text{Si}(t\text{-Bu})_3]_2\}_2$ and $\{\text{Tl}[\text{Si}(t\text{-Bu})_2\text{Ph}]_2\}_2$ are planar, and coordinated with two Si atoms and one Tl atom. The Tl—Tl bond distances are $2.996(2)$ and $2.881(2) \text{ \AA}$, respectively. The TlTlSi_2 dihedral angles are 89.6° and 82.2° , respectively. Larger substituents on the Tl lead to greater dihedral angles. For the $\{\text{M}[\text{Si}(t\text{-Bu})_3]_2\}_2$ series ($\text{M} = \text{Al}, \text{In}, \text{Tl}$), the λ_{max} value of the visible absorption shifts with increasing atomic number and with increasing angle between the Si_2EE planes to a longer wavelength.²⁹ Selenium reacts with $\{\text{Tl}[\text{Si}(t\text{-Bu})_3]_2\}_2$ to give heterocubane $(t\text{-Bu}_3\text{SiTl})_4\text{Se}_4$ (see (**45**) for a related structure).²⁹

(107)

Molecular properties of organothallium compounds such as Me_2Tl have been calculated. The Tl—Me dissociation energy shows that Me_2Tl is unstable with respect to the disproportionation into either Me_3Tl and MeTl or $2\text{Me}_3\text{Tl}$ and Tl .⁶⁰⁸ A paramagnetic Tl(II) complex $[\text{NBu}_4]_2[\text{Tl}\{\text{Pt}(\text{C}_6\text{F}_5)_4\}_2]$ containing a linear Pt—Tl—Pt core has been reported.⁶⁰⁹

(108)

(109)

(110)

The diamagnetic, mixed-valent Tl(I)/Tl(II) amide $[\text{MeC}(\text{CH}_2\text{NSiMe}_3)_3\text{Tl}_2]_2$ has been obtained from the reaction between TlCl and $\text{MeC}\{\text{CH}_2\text{N}(\text{Li})\text{SiMe}_3\}_3(\text{dioxane})_3$ in tetrahydrofuran.⁴¹⁷ The compound $[\text{MeC}(\text{CH}_2\text{NSiMe}_3)_3\text{Tl}_2]_2$ is a red solid. It is also possible to prepare the related indium analogue, which is yellow in color, using a similar procedure. The key feature of $[\text{MeC}(\text{CH}_2\text{NSiMe}_3)_3\text{Tl}_2]_2$ is the metal-metal-bonded Tl_2^{4+} fragment, which is shielded by the ligand framework. The Tl—Tl distance of 2.734(2) Å is relatively short compared to corresponding bond distances for silylated Tl(II) derivatives^{29,607} described above.

The halides of compositions TlCl_2 and TlBr_2 are in fact $\text{Tl}^{\text{I}}[\text{Tl}^{\text{III}}\text{X}_4]$ species. Monovalent Tl is the most stable oxidation state for thallium in halide systems.

3.5.2.4 Thallium (I)

The monovalent thallium ion, with its relatively large ionic radius (1.50 Å for a 6-coordinate ion), has only weak electrostatic interactions with its ligands. The valence-shell electronic configuration of $d^{10}s^2$ with a lone pair makes the covalent interactions weak as well. Overall, the thallium ion is weakly solvated in most solvents, and crystallizes even without any coordinated solvent molecules. Thallium(I) compounds are the most widely explored group among thallium derivatives. The Tl^+ state is also the most stable ion in aqueous solutions.

3.5.2.4.1 Group 14 ligands

The thallium(I) ion forms salts with the cyanide ion.¹ However, the solution chemistry of $TlCN$ is not well developed. In contrast, the cyanides of $Tl(III)$ have been investigated in some detail.

The organothallium(I) compound $[(Me_3Si)_3CTl]_4$ features a distorted tetrahedron of Tl atoms in the solid state.⁶¹⁰ It is much less thermally stable than the analogous indium complex. An interesting, monomeric arylthallium(I) compound $TlC_6H_3-2,6-Trip_2$ (where $Trip = 2,4,6-(i-Pr)_3C_6H_2$) with a singly coordinated thallium atom has been described.⁶¹¹ Cyclopentadienyl complexes of $Tl(I)$ are well known.⁶¹² Recently, the synthesis of an interesting $Tl(I)$ derivative ($\eta^5-C_{60}Ph_5$) Tl involving C_{60} was reported.⁶¹³ The crystal structure reveals that the $Tl(I)$ atom is bonded to C_{60} in η^5 -fashion, and it lies deeply buried in a cavity created by the five phenyl groups.

Trithallane $[(t-Bu)_3Si]_4Tl_3Cl$ (**111**) and hexathallane $[(t-Bu)_3Si]_6Tl_6Cl_2$ (**112**) have been obtained during an attempt to synthesize $[(t-Bu)_3Si]_2TlCl$ from $(t-Bu)_3SiNa$ and $TlCl_3$.⁴⁸⁹ These cluster compounds show high sensitivity to light, air, and moisture. A possible reaction pathway for the formation of $[(t-Bu)_3Si]_4Tl_3Cl$ and $[(t-Bu)_3Si]_6Tl_6Cl_2$ is also presented. The compound $[(t-Bu)_3Si]_4Tl_3Cl$, which is red in color, has a planar, four-membered Tl_3Cl core. The black hexathallane contains two four-membered Tl_3Cl rings which are linked by $Tl-Tl$ and $Tl-Cl$ interactions.

3.5.2.4.2 Group 15 ligands

(i) Nitrogen ligands

(a) *Neutral nitrogen ligands.* Little is known about thallium(I) adducts of neutral monodentate nitrogen donors like ammonia. Solution equilibria involving $Tl(I)$ and ammonia have been investigated.⁶¹⁴⁻⁶¹⁶ Data indicate the formation of mono- and diamminethallium(I) complexes. Studies involving pyridine and thallium(I) ions in aqueous solutions of NH_4ClO_4 suggest that, compared to NH_3 , pyridine forms more stable adducts with $Tl(I)$.⁶¹⁷ Thallium(I) methylamine interactions have been investigated using ^{205}Tl NMR spectroscopy.⁶¹⁸ The cyanomanganese carbonyls *trans*- $[Mn(CN)(CO)(dppm)_2]$, *cis*- and *trans*- $[Mn(CN)(CO)\{P(OR)_3\}(dppm)]$ ($R = Ph, Et$; $dppm = Ph_2PCH_2CH_2PPh_2$), upon treatment with $TlPF_6$, form $Tl-N$ -bonded complexes.⁶¹⁹ The formation of products with core geometries of the type $Tl(\mu-NC)Mn$, $\{Tl(\mu-NC)Mn\}_2$, and $Tl\{(\mu-NC)Mn\}_2$ is observed.

Compared to neutral monodentate nitrogen donors, multidentate systems fare better in forming isolable $Tl(I)$ adducts. Bidentate nitrogen donors like 2,2'-bipyridine (bipy) and 1,10-phenanthroline

(phen) form TlL_2^+ cations.¹ The thallium–iron carbonyl compounds $[\text{L}_2\text{Tl}\{\text{Fe}(\text{CO})_4\}_2]^-$ contain bidentate nitrogen donors L_2 such as bipy, en, phen, and tmda.⁶²⁰ The Tl(I) encapsulated compound $[\text{TlRh}_4(\mu\text{-}2,6\text{-pyridinedithiolate})_2(\text{cod})_2]^+$ shows an unusual see-saw coordination environment of the thallium atom, and pyridine–thallium coordination.⁶²¹

The coordination chemistry of tris(2-pyridylmethyl)amine (TPA) with thallium(I) has been investigated. The reaction of TlNO_3 with TPA in aqueous acetonitrile results in $[\text{Tl}(\text{TPA})]\text{NO}_3$.⁶²² Crystals of this compound were found to be $[\text{Tl}(\text{TPA})]_2[\text{H}_3\text{O}][\text{NO}_3]_3$. The solid consists of two different $[\text{Tl}(\text{TPA})]^+$ cations, one four-coordinate, while the second contains a seven-coordinate Tl site due to bonding to the three nitrate ions. Tris(pyrazolyl)methane⁶²³ ligands also form Tl(I) complexes readily. Treatment of $\text{HC}(3,5\text{-Me}_2\text{Pz})_3$ with TlPF_6 in tetrahydrofuran results in the immediate precipitation of $\{[\text{HC}(3,5\text{-Me}_2\text{Pz})_3]_2\text{Tl}\}[\text{PF}_6]$ (**113**).⁶²³ The mono ligand adduct $\{[\text{HC}(3,5\text{-Me}_2\text{Pz})_3]\text{Tl}\}[\text{PF}_6]$ can be synthesized in acetone by using a mixture of 1:1 ligand/Tl(I) molar. The $\{[\text{HC}(3,5\text{-Me}_2\text{Pz})_3]_2\text{Tl}\}[\text{PF}_6]$ complex has an octahedral structure with a stereochemically inactive lone pair. The coordination geometry at thallium in $\{[\text{HC}(3,5\text{-Me}_2\text{Pz})_3]\text{Tl}\}[\text{PF}_6]$ is trigonal pyramidal. Tris(pyrazolyl)methane ligands are closely related to the anionic tris(pyrazolyl)borates.

Thallium nitrate reacts with N,N',N'' -trimethyl-1,4,7-triazacyclononane (L) in the presence of NaPF_6 to yield the colorless solid $\text{TlL}[\text{PF}_6]$.⁴⁹⁷ Crystals of $\text{TlL}[\text{PF}_6]$ consists of discrete TlL^+ cations and PF_6^- anions. The thallium(I) lone pair is stereochemically active in the solid.⁴⁹⁷ Monomeric, four-coordinate Tl(I) complexes of mono-pendant-arm 1,4,7-triazacyclononane ligands have also been synthesized and characterized by X-ray crystallography.⁶²⁴ The aminocryptand $\text{N}\{\text{CH}_2\text{CH}_2\text{N}(\text{H})\text{CH}_2\text{C}_6\text{H}_4\text{CH}_2\text{N}(\text{H})\text{CH}_2\text{CH}_2\}\text{N}$ has a large enough cavity to hold two metal ions in close proximity. The dilithium adduct of $\text{N}\{\text{CH}_2\text{CH}_2\text{N}(\text{H})\text{CH}_2\text{C}_6\text{H}_4\text{CH}_2\text{N}(\text{H})\text{CH}_2\text{CH}_2\}\text{N}$ (**114**) can be synthesized by treating the cryptate with $\text{CF}_3\text{SO}_3\text{Tl}$.⁶²⁵ The thallium encapsulation, and the fact that it holds two Tl(I) ions closer to each other, have been established by NMR spectroscopy and

(113)

(114)

by solid-state structural studies. The $\text{Tl}\cdots\text{Tl}$ distance of $4.3755(4)$ Å is longer than that observed in most dimeric or quasi-dimeric structures. However, the NMR data show that the two $^{205,203}\text{Tl}$ nuclei are coupled to each other through space with $J_{(\text{Tl},\text{Tl})} \gg 17$ Hz. This is the largest recorded through-space coupling between Tl atoms, indicating strong $\text{Tl}\cdots\text{Tl}$ interaction in solution.

(b) *Amido ligands, monoanionic.* The bis(trimethylsilyl)amido derivative of thallium $(\text{Me}_3\text{Si})_2\text{NTl}$ (115) has been synthesized by treating $(\text{Me}_3\text{Si})_2\text{NTl}$ with TlCl in toluene.⁶²⁶ It is monomeric in benzene and in the gas phase.⁶²⁷ It has a cyclic dimeric structure in the solid state, with intermolecular $\text{Tl}\cdots\text{Tl}$ interactions. Related $(2,6-(i\text{-Pr})_2\text{C}_6\text{H}_3)(\text{Me}_3\text{Si})\text{NTl}$ can be synthesized using a similar procedure.⁶²⁸ It is a tetramer in the solid state. This amide shows weak $\text{Tl}\cdots\text{Tl}$ and Tl –arene interactions.

The bis(8-quinolynyl)amido (BQA) complex of Tl(I) has been synthesized by a transmetalation process involving the lithium derivative of the ligand and TlOTf .⁶²⁹ The $[\text{BQA}]\text{Tl}$ (116) exists as a monomeric species in solution. This compound serves as a good ligand-transfer agent for the preparation of group 10 metal adducts of the $[\text{BQA}]$ ligand.

(c) *Diamido ligands.* Difunctional thallium amides can also be synthesized. The reaction of $\text{CH}_2[\text{CH}_2\text{N}\{\text{Li}(\text{dioxane})\}\text{SiMe}_2\text{R}]_2$ ($\text{R} = \text{Me}$ or $t\text{-Bu}$) with TlCl leads to $\text{CH}_2[\text{CH}_2\text{N}(\text{Tl})\text{SiMe}_2\text{R}]_2$ (117).⁶³⁰ The thallium amide with the larger $t\text{-Bu}$ group shows no significant $\text{Tl}\cdots\text{Tl}$ contacts. Mixed-valence amides like $\{\text{CH}_2[\text{CH}_2\text{NSiMe}_3]_2\}_2\text{Tl}^{\text{III}}\text{Tl}^{\text{I}}$ (118) and the related indium analogue $\{\text{CH}_2[\text{CH}_2\text{NSiMe}_3]_2\}_2\text{In}^{\text{III}}\text{Tl}^{\text{I}}$ have been prepared.⁵²⁴ The trivalent metal ion occupies the center of the tetrahedral coordination sphere of the amide nitrogens. The lithium ions of the diamide $[(2\text{-C}_5\text{H}_4\text{N})\text{C}(\text{CH}_3)(\text{CH}_2\text{N}(\text{Li})\text{SiMe}_3)_2]_2$ may be substituted in a stepwise manner to obtain a mixed lithium/thallium amide $[(2\text{-C}_5\text{H}_4\text{N})\text{C}(\text{CH}_3)(\text{CH}_2\text{N}(\text{Li})\text{SiMe}_3)(\text{CH}_2\text{N}(\text{Tl})\text{SiMe}_3)]_2$ and the Tl(I) diamide $[(2\text{-C}_5\text{H}_4\text{N})\text{C}(\text{CH}_3)(\text{CH}_2\text{N}(\text{Tl})\text{SiMe}_3)_2]_2$.⁶³¹ Similar substitution of the lithium by a thallium ion has been achieved in $[\text{C}_{10}\text{H}_6\{\text{N}(\text{Li}(\text{THF})_2\text{SiMe}_3)_2\}]$ to obtain $[\text{C}_{10}\text{H}_6\{\text{N}(\text{Tl})\text{SiMe}_3\}]$ and $[\text{C}_{10}\text{H}_6\{\text{N}(\text{Tl})\text{SiMe}_3\}_2]$ (119).⁶³²

The thallium amido $[\text{C}_{10}\text{H}_6\{\text{N}(\text{Tl})\text{Si}(\text{R})\text{Me}_2\}_2]$ ($\text{R} = \text{Me}$, $t\text{-Bu}$) derivatives, upon heating in dioxane to 90°C , undergo metal–ligand redox chemistry leading to 4,9-diaminoperylenequinone-3,10-diimine derivatives.⁴¹⁸ The 4,9-diaminoperylenequinone-3,10-diimine is known; however, its synthesis is not an easy task. Related oxygen analogues are employed in photodynamic therapy and show cancerostatic and antiviral activity. The thallium route may provide an alternative, more convenient pathway for

such organic compounds. Interestingly, the diindium analog $[\text{C}_{10}\text{H}_6\{\text{N}(\text{In})\text{SiMe}_3\}_2]$ shows metal–metal redox chemistry leading to an In(II) complex $[\{\text{C}_{10}\text{H}_6(\text{Me}_3\text{SiN})_2\}\text{In}(\text{THF})]_2$.⁴¹⁸

(119)

The thallium(I) complex of the bis(*tert*-butylamido)cyclodiphosphazane $[(t\text{-BuNP})_2(t\text{-BuNTl})_2]^{2-}$ ligand system is known. $[(t\text{-BuNP})_2(t\text{-BuNTl})_2]$ (**120**) has a dinuclear heterocubane structure.⁴¹⁶ The related $[(t\text{-BuNSiMe})_2(t\text{-BuNTl})_2]$ has also been synthesized and structurally characterized.⁶³³

(d) *Triamido ligands*. A few triamido derivatives of thallium are known.^{523,634,635} They show different chemistry. They include $\text{MeSi}(\text{Me}_3\text{CNTl})_3$,⁶³⁶ $\text{MeC}[\text{CH}_2\text{N}(\text{Tl})\text{SiMe}_3]_3$ (**121**),⁶³⁴ $(\text{C}_6\text{H}_5)\text{C}[\text{CH}_2\text{N}(\text{Tl})\text{SiMe}_3]_3$,⁶³⁴ and $\text{MeSi}[\text{SiMe}_2\text{N}(\text{Tl})t\text{-Bu}]_3$ (**122**). The compound $\text{MeSi}(\text{Me}_3\text{CNTl})_3$ shows a dimeric structure in the solid state, with $\text{Tl}\cdots\text{Tl}$ interactions. In fact, most of the thallium amides show $\text{Tl}\cdots\text{Tl}$ interactions in the absence of stronger interactions with other functional groups in the molecule. The X-ray crystal structures of $(\text{C}_6\text{H}_5)\text{C}[\text{CH}_2\text{N}(\text{Tl})\text{SiMe}_3]_3$ and $\text{CH}_3\text{C}[\text{CH}_2\text{N}(\text{Tl})\text{SiMe}_3]_3$ demonstrate the relative importance of metal–arene vs. metal–metal interactions in thallium amide chemistry. In the tripodal Tl(I) amide with a phenyl group at the apical position of the ligand backbone, the competition between $\text{Tl}\cdots\text{Tl}$ interaction and $\text{Tl}\cdots\text{arene}$ interaction leads to an infinite chain structure in the solid state. The related $\text{CH}_3\text{C}[\text{CH}_2\text{N}(\text{Tl})\text{SiMe}_3]_3$ is dimeric in the solid state.

During the synthesis of $\text{HC}[\text{SiMe}_2\text{N}(\text{Tl})t\text{-Bu}]_3$, competing redox processes lead to the precipitation of thallium metal and the formation of $[\text{HC}\{\text{SiMe}_2\text{N}(\text{H})t\text{-Bu}\}\{\text{SiMe}_2\text{N}(\text{Tl})t\text{-Bu}\}_2]$ (**123**).⁶³⁷

(120)

(121)

(122)

(123)

Interestingly, this does not happen during the synthesis of $\text{MeSi}[\text{SiMe}_2\text{N}(\text{Tl})t\text{-Bu}]_3$. However, it is possible to obtain the partially demetalated thallium amide $[\text{MeSi}\{\text{SiMe}_2\text{N}(\text{H})t\text{-Bu}\}\{\text{SiMe}_2\text{N}(\text{Tl})t\text{-Bu}\}_2]$ via the controlled thermolysis of $\text{MeSi}[\text{SiMe}_2\text{N}(\text{Tl})t\text{-Bu}]_3$.⁶³⁵

The mixed-valent Tl(I)/Tl(II) species $[\text{MeC}(\text{CH}_2\text{NSiMe}_3)_3\text{Ti}_2]_2$, featuring rare Tl(II) sites, was described in a previous section.⁴¹⁷ The $[\text{HC}\{\text{SiMe}_2\text{N}(p\text{-Tol})\}_3]^{3-}$ ligand system affords a mixed-valent Tl(I)/Tl(III) system $[\text{HC}\{\text{SiMe}_2\text{N}(p\text{-Tol})\}_3(\text{TlBu})\text{Tl}]$. It also contains a donor-stabilized *n*-butylthallium(III) unit.⁵²³

(e) *Pyrazolates and related ligands.* Pyrazolate adducts of Tl(I) are of significant value for pyrazole-transfer reactions. Some of these reactions proceed with the reduction of Tl(I) to thallium metal. The reaction between pyrazoles 3,5-(Ph)₂PzH or 3-Me-5-PhPzH or 3-(2'-pyridyl)PzH with TlOEt proceeds with the elimination of ethanol to produce the corresponding Tl(I) pyrazolates.^{638–640} In addition, compounds such as Tl(bin) (binH = 4,5-dihydro-2*H*-benz[g]indazole) and 4-Me-3,5-(Ph)₂PzTl, Tl(azin) (azin = 7-azaindazole) have been reported.^{639,641} The synthesis of 3,5-(*t*-Bu)₂PzTl was not successful via the ethanol-elimination method.⁶⁴¹

These compounds show a diverse range of thallium(I)-pyrazolate bonding modes. These include, $\mu\text{-}\eta^1\text{:}\eta^1$, $\mu^3\text{-}\eta^1\text{:}\eta^1\text{:}\eta^1$, $\mu^3\text{-}\eta^1\text{:}\eta^2\text{:}\eta^1$, and η^5 bonding modes.⁶³⁹ In addition, Tl \cdots Tl interactions are common. The compound 3-(2'-pyridyl)PzTl (**124**) displays a zigzag arrangement of pyrazolato-bridged thallium atoms.⁶⁴⁰ Thallium(I) pyrazolates like 3,5-(Ph)₂PzTl served as important precursors for the synthesis of lanthanoid pyrazolate complexes via a redox transmetalation process.^{638,641}

Tetrazole derivatives of Tl(I) may be prepared starting with Tl₂SO₄ or TlOEt.⁶⁴² Thallium complexes of nucleobases are reported, and they are of obvious interest for their biological relevance.^{643,644} Early work involving imidazolate and benzotriazolate adducts is also known. Volatile thallium(I) pyrrole⁶⁴⁵ derivatives have been reported as well.

(f) *Other anionic nitrogen ligands with unsaturated backbones.* Reaction of 1,3,5-triazine with (Me₃Si)₂NTl in toluene affords a novel product, 1,3,5,7-tetraazaheptatrienylthallium(I), involving both formally an $\alpha\text{-}\omega$ Me₃Si shift and a ring opening.⁶⁴⁶ The molecular structure consists of four units, each comprising of two thallium atoms and two $[\{\text{Me}_3\text{SiNC}(\text{H})\text{N}\}_2\text{CH}]^-$ ligands (**125**).

A thallium(I) β -diketiminate, $[\text{HC}\{(\text{Me})\text{C}(\text{C}_6\text{H}_3\text{-2,6-Me}_2\text{N})_2\}\text{Tl}]$, and its use in the preparation of copper(I) complexes are reported.⁶⁴⁷ No structural data are available on this compound. Thallium(I) complexes of 1,3-diphenyltriazene⁶⁴⁸ and 1,5-di-*p*-tolylpentaazadienes have been synthesized and structurally characterized.

Thallium derivatives of the tetracyanoethylene system are of interest as reagents for the introduction of $[\text{TCNE}]^{\bullet -}$ and $[\text{TCNE}]^{2-}$ (useful in the preparation of molecular-based magnets) via a halide- abstraction

process. The synthesis and the reactivity of $\text{Tl}[\text{TCNE}]$ and $\text{Tl}_2[\text{TCNE}]$ have been investigated.⁶⁴⁹ The structure of $\text{Tl}[\text{TCNE}]$ consists of square-antiprismatic, eight-coordinate thallium sites.

(g) *Poly(pyrazolyl)borate ligands.* Thallium(I) complexes of bis-, tris-, and tetrakis(pyrazolyl)borates are clearly one of the largest, most well-characterized groups of thallium compounds containing $\text{Tl}-\text{N}$ bonds.^{439,440,650,651} The thallium(I) derivatives of poly(pyrazolyl)borates are used extensively as ligand-transfer reagents in the synthesis of various metal complexes.⁶⁵⁰ They are usually milder, less reducing, and more stable than the corresponding alkali-metal salts. The thallium salts also facilitate the purification and characterization of the new poly(pyrazolyl)borate ligand systems. This choice is particularly valuable and commonly utilized in the synthesis of poly(pyrazolyl)borate ligands with bulky substituents.

Several thallium(I) complexes of the bis(pyrazolyl)borate ligand have been described. These include $[\text{H}_2\text{B}(\text{Pz})_2]\text{Tl}$ (**126**) (bis(pyrazolyl)hydroboratothallium(I)),⁶⁵² $[\text{H}_2\text{B}(3-(9\text{-trityl})\text{Pz})_2]\text{Tl}$,⁶⁵³ $[\text{H}_2\text{B}(3-(2\text{-pyridyl})\text{Pz})_2]\text{Tl}$,⁶⁵⁴ $[\text{H}_2\text{B}(3-(2\text{-pyrazinyl})\text{Pz})_2]\text{Tl}$,⁶⁵⁵ $[\text{H}_2\text{B}\{3-[6-(2,2'\text{-bipyridyl})]\text{Pz}\}_2]\text{Tl}$,⁶⁵⁶ $[\text{H}_2\text{B}(3-(t\text{-Bu}), 5-(\text{Me})\text{Pz})_2]\text{Tl}$ (**127**), and $[\text{H}_2\text{B}(3-(t\text{-Bu}), 5-(i\text{-Pr})\text{Pz})_2]\text{Tl}$, $[\text{H}_2\text{B}(3,5-(t\text{-Bu})_2\text{Pz})_2]\text{Tl}$,⁶⁵⁷ as well as thallium(I) adducts of asymmetric systems $[\text{H}_2\text{B}(\text{Pz})(3,5-(t\text{-Bu})_2\text{Pz})]\text{Tl}$, $[\text{H}_2\text{B}(3,5-(\text{Me})_2\text{Pz})(3,5-(t\text{-Bu})_2\text{Pz})]\text{Tl}$, and $[\text{H}_2\text{B}(3-(9\text{-trityl})\text{Pz})(3,5-(t\text{-Bu})_2\text{Pz})]\text{Tl}$.⁶⁵⁸ Typical synthetic procedures involve the metathesis reaction of a thallium(I) salt (e.g., thallium(I) formate, thallium(I) acetate, thallium(I) nitrate) with the appropriate alkali-metal bis(pyrazolyl)borate derivative.

Solid-state structures often show a monomeric structure with two-coordinate thallium(I) sites, with additional weak, secondary $\text{Tl}\cdots\text{H}-\text{B}$ interactions. The compounds $[\text{H}_2\text{B}(3-(t\text{-Bu}), 5-(\text{Me})\text{Pz})_2]\text{Tl}$ (**127**), $[\text{H}_2\text{B}(3-(t\text{-Bu}), 5-(i\text{-Pr})\text{Pz})_2]\text{Tl}$, $[\text{H}_2\text{B}(3-(9\text{-trityl})\text{Pz})_2]\text{Tl}$, $[\text{H}_2\text{B}(\text{Pz})(3,5-(t\text{-Bu})_2\text{Pz})]\text{Tl}$, and $[\text{H}_2\text{B}(3,5-(t\text{-Bu})_2\text{Pz})_2]\text{Tl}$ adopt this type of structure. $[\text{H}_2\text{B}(\text{Pz})_2]\text{Tl}$ (**126**), in contrast, is dimeric in the solid state, with additional intermolecular $\text{Tl}\cdots\text{Tl}$ contacts of 3.70 Å length.⁶⁵² The close $\text{Tl}\cdots\text{Tl}$ contact observed in $[\text{H}_2\text{B}\{3-[6-(2,2'\text{-bipyridyl})]\text{Pz}\}_2]\text{Tl}$ has been attributed to π -stacking.⁶⁵⁶ The compounds $[\text{H}_2\text{B}(3-(2\text{-pyridyl})\text{Pz})_2]\text{Tl}$ (**128**) and $[\text{H}_2\text{B}(3-(2\text{-pyrazinyl})\text{Pz})_2]\text{Tl}$ contain additional nitrogen-donor sites on the ligand backbone.^{654,655} The thallium(I) atoms in these compounds

prefer those nitrogen donors over $\text{Tl} \cdots \text{H}-\text{B}$ contacts. The ligand-transfer ability of some of these adducts has also been investigated.⁶⁵⁹

The tris(pyrazolyl)boratothallium(I) compounds are the most widely studied among thallium poly(pyrazolyl)borates. An excellent recent review article has appeared that covers the synthesis, structures, properties, and applications of tris(pyrazolyl)boratothallium(I).⁶⁵⁰

The Tl(I) adduct of the parent tris(pyrazolyl)borate $[\text{HB}(\text{Pz})_3]\text{Tl}$ (**129**)⁶⁶⁰ is known, as well as many ligand varieties with different pyrazolyl groups and/or boron substituents. Substituents at the pyrazolyl ring 3-position are the closest to the thallium ion. They have the greatest influence both sterically and electronically on thallium (or any other metal ion coordinated to this ligand system). Compounds of the $[\text{HB}(3-(\text{R})\text{Pz})_3]\text{Tl}$ type that have been reported include: R = cyclopropyl,⁶⁶¹ *i*-Pr,⁶⁶¹ *t*-BuCH₂,⁶⁶² cyclohexyl,⁶⁶³ *t*-Bu,⁶⁶⁴ Ph,⁶⁶⁵ 2-pyridyl,⁶⁶⁶ 2(pinene[4,5]-pyridyl),⁶⁶⁷ 2-thienyl,⁶⁶⁸ 4-MeC₆H₄,^{668,669} 2-MeOC₆H₄,⁶⁷⁰ 4-MeOC₆H₄,^{668,669} 4-ClC₆H₄,⁶⁶⁸ 2,4,6-Me₃C₆H₂,⁶⁷¹ 9-anthryl,⁶⁷² 1-naphthyl,⁶⁷³ 2-naphthyl,⁶⁷³ and 9-tryptcyl.⁶⁵³

In addition, thallium adducts featuring 3,4- and 3,5-disubstituted pyrazole-containing ligand systems are known. They include $[\text{HB}(1,4\text{-dihydroindeno}[1,2\text{-c}]\text{Pz})_3]\text{Tl}$,⁶⁷⁴ $[\text{HB}(3-(i\text{-Pr}), 4(\text{Br})\text{Pz})_3]\text{Tl}$,⁶⁷⁵ $[\text{HB}(3,5-(\text{Me})_2\text{Pz})_3]\text{Tl}$,⁶⁷⁶ $[\text{HB}(3-(\text{CF}_3), 5-(\text{Me})\text{Pz})_3]\text{Tl}$,⁶⁷⁷ $[\text{HB}(3-(\text{CF}_3), 5-(2\text{-thienyl})\text{Pz})_3]\text{Tl}$,⁶⁷⁸ $[\text{HB}(3,5-(\text{CF}_3)_2\text{Pz})_3]\text{Tl}$ (**130**),⁶⁷⁹ $[\text{HB}(3,5-(i\text{-Pr})_2\text{Pz})_3]\text{Tl}$,⁶⁸⁰ $[\text{HB}(3-(\text{Ph}), 5-(\text{Me})\text{Pz})_3]\text{Tl}$,⁶⁷⁴ $[\text{HB}(3,5-(4-(t\text{-Bu})\text{C}_6\text{H}_4)_2\text{Pz})_3]\text{Tl}$,⁶⁸¹ $[\text{HB}(3-(t\text{-Bu}), 5-(\text{Me})\text{Pz})_3]\text{Tl}$,⁶⁶⁴ $[\text{HB}(3-(t\text{-Bu}), 5-(i\text{-Pr})\text{Pz})_3]\text{Tl}$ (**131**),⁶⁶⁸ and $[\text{HB}(3,5-(t\text{-Bu})_2\text{Pz})_3]\text{Tl}$.⁶⁸² Although the substituents at the 4- or 5-position of the pyrazolyl ring are further away from the metal center, they also exert enough influence, and thus serve as valuable tools to control the chemistry of tris(pyrazolyl)borate metal adducts. The compounds $[\text{HB}(\text{Pz})_2(3,5-(t\text{-Bu})_2\text{Pz})]\text{Tl}$ (**132**),⁶⁸³ and $[\text{HB}(5-(\text{Mes})\text{Pz})(3-(\text{Mes})\text{Pz})_2]\text{Tl}$ ⁶⁷¹ contain two different pyrazolyl ligands on the boron atom. Such ligand systems are rare. A few tetrakis(pyrazolyl)boratothallium(I) adducts are also known.⁶⁶⁸

(130)

(131)

(132)

As with bis(pyrazolyl)borates, the synthesis of Tl(I) complexes involves the metathesis reaction between an alkali-metal tris(pyrazolyl)borate and a thallium salt. The triptycyl-substituted complex $[\text{HB}(3-(9\text{-triptycyl})\text{Pz})_3]\text{Tl}$ has been synthesized from the reaction between $[\text{H}_2\text{B}(3-(9\text{-triptycyl})\text{Pz})_2]\text{Tl}$ and 3-(9-triptycyl)PzH at 170 °C.⁶⁵³ A promising, much milder route involving TlOEt is also available. The reaction of RBBR_2 (R = Me, cymtrenyl (Cym), methylcymtrenyl (Cym')),

ferrocenyl (Fc)), pyrazole derivative, and NEt_3 in toluene at room temperature, followed by the addition of TlOEt , affords the thallium(I) tris(pyrazolyl)borate complex.^{676,684,685} The compounds $[\text{MeB}(\text{Pz})_3]\text{Tl}$, $[\text{MeB}(3,5\text{-(Me)}_2\text{Pz})_3]\text{Tl}$, $[\text{MeB}(3\text{-(Me)Pz})_3]\text{Tl}$, $[\text{MeB}(3,5\text{-(Me)}_2\text{Pz})_3]\text{Tl}$, $[\text{CymB}(\text{Pz})_3]\text{Tl}$, $[\text{CymB}(4\text{-C}_6\text{H}_{11}\text{CH}_2\text{Pz})_3]\text{Tl}$, $[\text{Cym}'\text{B}(\text{Pz})_3]\text{Tl}$, and $[\text{FcB}(\text{Pz})_3]\text{Tl}$ have been prepared using this route.

The majority of the tris(pyrazolyl)boratothallium(I) adducts show monomeric structures with C_3 symmetric coordination of the tripodal ligand to the thallium(I) center. The Tl-N distances fall in the 3.50–2.73 Å range. The parent system $[\text{HB}(\text{Pz})_3]\text{Tl}$ ⁶⁶⁰ shows a structure in which $[\text{HB}(\text{Pz})_3]\text{Tl}$ units are arranged in a chain with long $\text{Tl}\cdots\text{Tl}$ separations. $[\text{HB}(3\text{-(4-MeC}_6\text{H}_4)\text{Pz})_3]\text{Tl}$ is dimeric with $\text{Tl}\cdots\text{Tl}$ distances of 3.86 Å.⁶⁸⁶ However, the B-Tl-Tl-B sequence is collinear. The Tl(I) complex $[\text{HB}(3\text{-(cyclopropyl)Pz})_3]\text{Tl}$ (**133**) is a tetramer with a perfect tetrahedral Tl_4 core. The $\text{Tl}\cdots\text{Tl}$ distance is 3.6468(4) Å.⁶⁶¹ This distance is shorter than twice the van der Waals radius (3.92 Å), and only slightly longer than the Tl-Tl separation in elemental thallium (3.41 Å). It is not possible to predict the type of aggregation based on the ring substituents. The closely related $[\text{HB}(3\text{-(}i\text{-Pr)Pz})_3]\text{Tl}$ is a monomer.⁶⁶¹ The complex $[\text{PhB}(3\text{-(}t\text{-Bu)Pz})_3]\text{Tl}$ (**134**) shows an unusual structure in which one of the pyrazolyl groups is rotated by around 90° , and the Tl interacts with the pyrazolyl-ring nitrogen atom attached directly to the boron, via a p -orbital component of the aromatic π -system of the pyrazolyl ring.⁶⁸⁷ In solution at room temperature, $[\text{PhB}(3\text{-(}t\text{-Bu)Pz})_3]\text{Tl}$ is stereochemically nonrigid on the NMR timescale. The repulsive methyl-methyl interaction forces $[\text{MeB}(3,5\text{-(Me)}_2\text{Pz})_3]\text{Tl}$ (**135**) to adopt the 2_1 -helicoidal chain structure.⁶⁷⁶ The $[\text{MeB}(3,5\text{-(Me)}_2\text{Pz})_3]^-$ ligand shows a unique bridging coordination, rather than the expected trihapto, C_3 -symmetrical thallium coordination.

The compounds $[\text{CymB}(\text{Pz})_3]\text{Tl}$ (**136**)⁶⁸⁵ and $[\text{FcB}(\text{Pz})_3]\text{Tl}$ ⁶⁸⁴ show polymeric structures, with bridging $\text{B}(\text{Pz})_3$ fragments in the solid state. This is a result of unfavorable steric interaction between the substituent on boron and the hydrogen atoms on the pyrazolyl ring 5-position. The structure of $[\text{Cym}'\text{B}(\text{Pz})_3]\text{Tl}$ is somewhat related, but it adopts a macrocyclic tetrameric structure rather than a linear polymeric structure. Ligands with secondary donors on the backbone may form additional bonds to the thallium atom. For example, in $[\text{HB}(3\text{-(2-pyridyl)Pz})_3]\text{Tl}$, weak $\text{Tl}\cdots\text{N}$ interactions between pyridyl nitrogens and the Tl atom have been observed.⁶⁶⁶ $[\text{HB}(3\text{-(2-MeOC}_6\text{H}_4)\text{Pz})_3]\text{Tl}$ features close intramolecular $\text{Tl}\cdots\text{O}$ interactions.⁶⁷⁰

NMR spectroscopy also plays a large role in the characterization of poly(pyrazolyl)borato thallium adducts.^{650,668,688} Coupling to spin-active ^{205}Tl and ^{203}Tl ($I=1/2$) provides additional information about the solution structure. However, it is important to consider that nuclear relaxation due to chemical shift anisotropy has a significant effect on the apparent coupling constants to thallium.⁶⁷⁷ It has been shown that higher applied magnetic field strengths and lower temperatures notably reduce the apparent $J_{\text{Tl-H}}$ and $J_{\text{Tl-C}}$ values. Some tris(pyrazolyl)borato thallium(I) adducts show photoluminescence, which originates from the metal-centered sp triplet of the Tl^{+1} ion.⁶⁸⁹ This technique provides information about the $\text{Tl}\cdots\text{Tl}$ interactions in the solid state.

The ligand-transfer chemistry of tris(pyrazolyl)boratothallium(I) compounds has been investigated extensively.⁶⁵⁰ These adducts undergo metathesis reactions with a variety of metal halides or metal alkyl compounds, leading to the elimination of thallium halide (precipitates) or thallium alkyl products (which usually decompose to thallium metal) and the desired tris(pyrazolyl)borato metal adduct. The reaction of $[\text{HB}(3\text{-(}i\text{-Bu)Pz})_3]\text{Tl}$ with MeMgX offers the choice of an alkyl or a halide for the $\text{Tl}(\text{I})$.⁶⁹⁰ The thallium(I) prefers the iodide when treated with MeMgI , but forms the thallium alkyl derivative when $\text{X}=\text{Cl}$ or Br . Ligand-transfer reactions of $[\text{HB}(3\text{-(}i\text{-Bu)Pz})_3]\text{Tl}$ leading to a monovalent indium product have also been described.⁴⁴²

(h) *Other anionic poly(azolyl) ligands.* The closely related tris(pyrazolyl)methanesulfonate⁶⁹¹ and tris(indazolyl)borate (**137**) ligands also form $\text{Tl}(\text{I})$ complexes readily. The water-soluble, hydrolytically stable tris(pyrazolyl)methanesulfonate (Tpms) ligand adduct of $\text{Tl}(\text{I})$ has been prepared using $[\text{Tpms}]\text{Li}$ and excess thallium(I) carbonate in water.^{691,692} The Tpms ligand is a weakly coordinating ligand, and the donor properties are comparable to those of $[\text{HB}(3,5\text{-(CF}_3)_2\text{Pz})_3]^-$ or $[\text{HB}(3\text{-(CF}_3)_2,5\text{-(CH}_3)\text{Pz})_3]^-$.⁶⁹¹ The tris(indazolyl)borates follow chemistry very similar to those of tris(pyrazolyl)borate relatives. The thallium adducts $[\text{HB}(7\text{-(}i\text{-Bu)indazolyl})_3]\text{Tl}$,⁶⁹³ $[\text{HB}(7(R)\text{-(}i\text{-Pr)-4(R)-(Me)-4,5,6,7-tetrahydro-2-indazolyl})_3]\text{Tl}$,⁶⁹⁴ $[\text{HB}(7(S)\text{-(}i\text{-Bu)-4(R)-(Me)-4,5,6,7-tetrahydro-2-indazolyl})_3]\text{Tl}$,⁶⁹⁴ $[\text{HB}(2H\text{-benz[g]indazol-2-yl})_3]\text{Tl}$,⁶⁷⁴ $[\text{HB}(2H\text{-benz[g]-4,5-dihydroindazol-2-yl})_3]\text{Tl}$,⁶⁷⁴ and $[\text{HB}(3\text{-Me-2H-benz[g]-4,5-dihydroindazol-2-yl})_3]\text{Tl}$ ⁶⁷⁴ have been synthesized, and some chemistry has been investigated. Most of these studies involving indazole derivatives are focused on the development of chiral ligand systems.

A tris(imidazolyl)borate (**138**) complex of thallium(I) has been synthesized.⁶⁹⁵ The solid-state structure of hydrotris(imidazolyl)boratothallium(I) consists of one-dimensional, twisted, ladder-like strands, and three-coordinate thallium centers.⁶⁹⁵ Due to the position of the nitrogen donors, the tris(imidazolyl)borate ligand is not capable of forming metal chelates as are observed in tris(pyrazolyl)borates. Poly(benzotriazolyl)borate ligands have some features of both tris(pyrazolyl)borate and tris(imidazolyl)borate systems. Thallium(I) complexes of bis-, tris-, and tetrakis(benzotriazolyl)borates are reported. These adducts have been synthesized by treating the corresponding potassium derivative with an equimolar quantity of thallium(I) formate.⁶⁹⁶

(137)

(138)

The reaction of 3-(2-pyridyl)PzH with POBr₃ in toluene–NEt₃ yields a hydrolysis product bis[3-(2-pyridyl)pyrazolyl]phosphinate, rather than the expected phosphines oxide OP(3-(2-pyridyl)Pz)₃.⁶⁹⁷ The Tl(I) derivative of this ligand has been isolated and characterized.

(i) *Porphyrin and phthalocyanine ligands.* Thallium complexes of macrocyclic, nitrogen-based ligands such as porphyrin^{97,698–700} and phthalocyanine^{701–703} have been synthesized. The porphyrin adducts may be synthesized by treating the free ligand with TlOEt.⁷⁰⁰ Thallium(I) complexes of 2,3,7,8,12,13,17,18-octaethylporphyrin (H₂OEP) and 5,10,15,20-tetraphenylporphyrin (H₂TPP) have two thallium(I) ions per porphyrin ligand. The crystal structure of [Tl(THF)]₂(OEP)] shows that the thallium(I) atoms are four-coordinate, with bonds to three OEP nitrogens and one tetrahydrofuran molecule, and reside on opposite sides of the porphyrin.⁶⁹⁸ Electrochemical studies on TPP complex of thallium(I) in DMF have been described.⁶⁹⁹ The dithallium phthalocyanine Tl₂Pc (**139**) is a rare example of a group 13 dimetallophthalocyanine.⁷⁰¹ The most interesting feature of this material is its very high conductivity ($\sigma > 10^4 \Omega^{-1} \text{cm}^{-1}$), which is comparable even to metals. The two-dimensional skeleton formed by the intramolecular Tl–Tl contacts and intermolecular Tl–N_{aza} contacts is the key to this efficient charge transportation found in Tl₂Pc.⁷⁰²

(139)

(ii) *Phosphorus, arsenic, antimony, and bismuth ligands*

Coordination compounds containing thallium(I) and heavier group 15 elements are rare. Synthesis of a tris(phosphino)borate thallium adduct has been reported. The reaction between [PhB(CH₂PPh₂)₃Li](TMEDA) and TlPF₆ affords [PhB(CH₂PPh₂)₃Tl] (**140**) as a yellow powder. The ³¹P NMR spectrum shows two doublets with ¹J_{Tl–P} of 5,214 Hz and 5,168 Hz, as a result of

coupling to ^{205}Tl and ^{203}Tl isotopes. Typical $^1J_{\text{Tl-P}}$ coupling constants for Tl(III) phosphine adducts are in the region of 1,500 Hz.^{527,528} The $[\text{PhB}(\text{CH}_2\text{PPh}_2)_3]^-$ ligand binds to the thallium ion in a tridentate fashion. This thallium(I) adduct serves as a ligand-transfer agent to transition-metal ions. It is possible to synthesize the Co(II) adduct $[\text{PhB}(\text{CH}_2\text{PPh}_2)_3]\text{CoI}$ using $[\text{PhB}(\text{CH}_2\text{PPh}_2)_3]\text{Tl}$ and CoI_2 . The use of lithium $[\text{PhB}(\text{CH}_2\text{PPh}_2)_3]\text{Li}(\text{TMEDA})$ with CoI_2 does not lead cleanly to the expected cobalt complex.

A heat- and air-stable diphosphastibolol complex of Tl(I) has been synthesized using $[\text{Li}(\text{TMEDA})_2][1,4,2\text{-P}_2\text{SbC}_2(t\text{-Bu})_2]$ and TlCl .⁷⁰⁴ The solid-state structure of $\text{Tl}[\eta^5\text{-}1,4,2\text{-P}_2\text{SbC}_2(t\text{-Bu})_2]$ (**141**) reveals a double-stranded, zigzag polymeric chain structure with intermolecular thallium–phosphorus interactions. The triphospholyl complex $\text{Tl}[\eta^5\text{-}1,4,2\text{-P}_3\text{C}_2(t\text{-Bu})_2]$ consists of weakly interacting monomeric half-sandwich units in the solid state.⁷⁰⁵ The related Ga(I) and In(I) derivatives have also been synthesized.^{448,449,705} Both $\text{Tl}[\eta^5\text{-}1,4,2\text{-P}_3\text{C}_2(t\text{-Bu})_2]$ and $\text{Tl}[\eta^5\text{-}1,4,2\text{-P}_2\text{SbC}_2(t\text{-Bu})_2]$ exit as monomeric species in the gas phase. The thallium–phosphorus coupling in the NMR spectra was not observed, perhaps indicating an ionic nature of bonding. Compounds $\text{Tl}[\eta^5\text{-}1,4,2\text{-P}_3\text{C}_2(t\text{-Bu})_2]$ and $\text{Tl}[\eta^5\text{-}1,4,2\text{-P}_2\text{SbC}_2(t\text{-Bu})_2]$ are useful oxidizing, ligand-transfer agents for lanthanide metals.⁷⁰⁶

3.5.2.4.3 Group 16 ligands

(i) Oxygen ligands

(a) *Neutral oxygen ligands.* Thallium(I) forms only weak interactions with most solvent molecules. Therefore, well-defined molecules with solvated Tl(I) ions are not common. The structure of solvated thallium(I) ion in aqueous, DMSO, and *N,N'*-dimethylpropyleneurea solutions has been investigated by large-angle X-ray scattering and EXAFS methods.⁷⁰⁷ The Tl(I) coordinates to four water molecules with two short and two long distances. The solvation by DMSO and *N,N'*-dimethylpropyleneurea involves two short and four long solvent–Tl bonds. The different Tl–O bond lengths are believed to be due to the effects of stereochemically active lone pairs. More detailed information about the coordination geometry at Tl(I) in solution could not be obtained, because of weak Tl–solvent interactions. Thallium-ion binding by crown ethers and calixarenes has been investigated. One of the motivations for this work is to develop thallium(I) ion-selective analytical methods.^{708–715} Owing to the toxic effects of thallium, the ability to quickly detect Tl^+ in biological fluids is important. Dibenzo-16-crown-4 has shown high selectivity for thallium(I) over sodium, potassium, and rubidium ions. Thallium-205 and carbon-13 NMR spectroscopy have been used to determine the stabilities of 18-crown-6 ligands with different structures and similar cavity sizes.⁷¹⁶ Several structurally characterized Tl(I) adducts of crown ethers are known, including those involving 12-crown-4 and even 30-crown-10.^{357,551,713,717–722} In calixarenes, the π -coordination also contributes to the Tl(I) binding.

(b) *Hydroxide ligands.* Thallium complexes of anionic oxygen donors are relatively more common. Thallium(I) oxide is a hygroscopic solid and on contact with water forms TlOH . Solutions of TlOH are basic. The basic strength is about 10^5 , 10 times greater than for NH_3 and calcium(II) hydroxide, respectively.⁴⁷¹ There is also evidence for the formation of $[\text{Tl}(\text{OH})_2]^-$ species in solution.⁷²³

(c) *Alkoxide ligands.* Although thallium(I) alkoxides, TlOR , have been known since the 1800s, the detailed structural details became available only recently.^{724,725} Their synthesis usually involves

a reaction between Tl and ROH, or TlOH and ROH, or Tl_2O and ROH.¹ They are useful as thallium(I) transfer agents, alkoxide donors, and for the preparation of mixed alkoxides.^{451,725}

Based on Tl NMR spectroscopy and molecular-weight studies, cubane structures have been proposed for TlOR ($\text{R} = \text{Et}, i\text{-Pr}, t\text{-Bu}$).^{726,727} Early work has revealed only the partial structure of $[\text{Tl}(\text{OMe})_4]_4$ (**142**).⁷²⁸ The crystal structure of $[\text{Tl}(\text{OCH}_2\text{CMe}_3)_4]_4$ has been reported as a $[\text{Tl}-\text{O}]_4$ cubane core.⁷²⁴ Thallium(I) triphenylsilanolate also contains similar cubic units.⁷²⁹ Reaction of poly(dimethylsiloxane) (silicone grease) with TlOEt led to the ladder polymer $[\{\text{Tl}_2(\text{OSiMe}_2\text{O})_2\}_n]$ containing $[\text{Tl}-\text{O}]_4$ cuboids.⁷²⁹ The compounds $[\text{Tl}\{\mu\text{-O}(\text{C}_6\text{H}_4)(\text{C}_6\text{H}_4\text{OH})\}_2]$ and $[\text{Tl}\{\text{OC}_6\text{H}_2\text{-2,4,6-(CF}_3)_3\}_2]$ (**143**) are dimers,^{730,731} whereas $[\text{Tl}\{\text{OC}_6\text{H}_3\text{-2,6-(CH}_3)_2\}_2]_n$ (**144**) and $[\text{Tl}\{\text{OC}_6\text{H}_3\text{-2,6-(}i\text{-Pr)}_2\}_2]_n$ feature polymeric chain structures.⁷²⁴

(142)

(143)

(144)

Mixed-metal alkoxide complexes of thallium are also known. For example, $\text{Sn}(\mu\text{-}t\text{-BuO})_3\text{Tl}$ has both Sn(II) and Tl(I) ions.⁴⁵¹ The thallium site is unreactive as a donor for metal carbonyls. However, as indicated earlier, the indium(I) site of the indium analogue shows Lewis-base character. The Sn(IV)/Tl(I) mixed alkoxide $[\text{Sn}(\text{EtO})_6\text{Tl}_2]$ exists as a one-dimensional polymer.⁷³² This adduct reacts quantitatively with SnCl_2 to form the homoleptic, mixed-valent $[\text{Sn}_2(\text{OEt})_6]_n$. Thallium–titanium double alkoxides have been synthesized using thallium alkoxide as one of the starting materials.⁷²⁵

The study of reactions between TlOH and TlOEt with starch derived from different sources shows that potato starch binds thallium(I) chemically, whereas corn starch forms simple adducts with TlOH or TlOEt.⁷³³ The iodination of thallium salts of phenols has been investigated.⁷³⁴

(d) *β-diketonate ligands.* Thallium(I) *β*-diketonates have been known for many years. These include the Tl(I) adducts of more common acetylacetonates, $[\{\text{CH}\{\text{C}(\text{O})\text{CH}_3\}_2\}]^-$ and $[\{\text{CH}\{\text{C}(\text{O})\text{CF}_3\}_2\}]^-$.^{735,736} Recent studies reveal how simple thallium(I) *β*-diketonates can self-assemble to give discotic structures, via the formation of disk-like dimers, by means of Tl–Tl bonds reinforced with Tl–O bonds between the neighboring molecules.^{737,738} This work is aimed at understanding the relationships between crystalline phases and liquid crystals. Ferroelectric liquid crystals containing palladium have also been prepared, using the thallium *β*-diketonato derivatives.⁷³⁹

Thallium β -diketonato complexes $[\text{TI}\{\text{CH}\{\text{C}(\text{O})\text{R}\}_2\}]$ ($\text{R} = \text{Me}, \text{Ph}$) react with an excess of CS_2 to give 1,1-ethylenedithiolato complexes of thallium(I).⁷⁴⁰ A volatile chelate (2,2,6,6-tetramethyl-3,5-heptanedionato)thallium(I) has been described.⁷⁴¹ This thallium adduct in $\text{CF}_2\text{Cl}_2/\text{O}_2$ and $\text{CF}_3\text{Br}/\text{O}_2$ gas mixtures has been used under CVD conditions to prepare TIX ($\text{X} = \text{Cl}, \text{Br}$). Solvent extraction of thallium(I) ions in aqueous solutions into chloroform was explored using several β -diketones.⁷⁴²

(e) *Other anionic oxygen ligands.* Attempts to prepare Tl(III) complexes of orthoquinone derivatives have been unsuccessful, leading only to Tl(I) adducts containing the semiquinonate anion.^{452,731} These compounds are paramagnetic and colored. The paramagnetic property is due to the presence of the semiquinonate anion radical.

A large number of thallium(I) carboxylates have been synthesized and characterized by IR spectra.^{743–745} X-ray diffraction methods have indicated that Tl(I) formate exists in solution as a tetramer.^{746,747} Thallium saccharinate has been synthesized and characterized using crystallography.⁷⁴⁸ It has a polymeric structure with eight- and five-coordinate thallium sites. Thallium(I) salts of the antibiotic lasalocid-A have been prepared.⁷⁴⁹

Many Tl(I) derivatives of polyoxy anions are known, and they are of interest for applications ranging from materials to chemical synthesis.^{750–766}

Several molecular structures, including those of Tl(I) nitrate,^{755,756} iodate,⁷⁵⁷ borate,⁷⁵⁸ germanate,⁷⁵⁸ sulfate,^{759,760} phosphates,^{761–764} arsenate,⁷⁵³ chromate,⁷⁶⁵ and selenate,⁷⁶⁶ have been reported. Heterobimetallic compounds with Tl–O interactions have been reported.^{767,768} Their metal–thallium bonding and their photophysical properties are of particular interest.

(ii) Sulfur, selenium, tellurium ligands

(a) *Neutral sulfur ligands.* Thallium(I)-ion solvation by *N,N*-dimethylthioformamide has been investigated by large-angle X-ray scattering and EXAFS methods.⁷⁰⁷ Although the solutions were prepared from the thallium(III) salt $\text{Tl}(\text{OTf})_3$, the ²⁰⁵Tl NMR measurements and the absence of typical Tl(III)–S bond distances suggest that the metal ion in the solution is in the monovalent form, i.e., thallium(III) has been completely reduced to Tl(I) by the solvent. Data show that there are two groups of Tl–S distances, two long and four short Tl–S bonds. This indicates that the lone pair of electrons on thallium plays a significant stereochemical role in the solvated Tl(I) ion. The stability and ligand-exchange properties of thiourea complexes of Tl(I) in aqueous solutions have been investigated.^{769,770}

Just as do crown ethers, crown thioethers also form complexes with thallium(I) ion.^{544,771–773} These include $[\text{Tl}([9]\text{aneS}_3)][\text{PF}_6]$, $[\text{Tl}([18]\text{aneS}_6)][\text{PF}_6]$, and $[\text{Tl}([24]\text{aneS}_8)][\text{PF}_6]$ ($[24]\text{aneS}_8 = 1,4,7,10,13,16,19,22$ -octathiacyclotetrasane).^{771–773} These adducts can be synthesized by treating the crown thioether with TlPF_6 , or by starting with TlNO_3 followed by the addition of NH_4PF_6 . These studies provide useful information for the design of selective metal-complexing agents for the transport and uptake of toxic heavy metals like thallium.

Its crystal structure shows that $[\text{Tl}([24]\text{aneS}_8)][\text{PF}_6]$ adopts a polymeric structure. The thallium atoms are eight-coordinate, and bridge two thioether crowns to give a sinusoidal chain.⁷⁷² The Tl(I) complex of the smaller ring adduct $[\text{Tl}([18]\text{aneS}_6)][\text{PF}_6]$ shows that the thallium atom bonds strongly to the six sulfur donors of the macrocycle, with two additional weak interactions to the sulfurs of the neighboring ring.⁷⁷³ The related thallium complex of the mixed-donor crown- $[18]\text{aneN}_2\text{S}_4$ (1,4,10,13-tetrathia-7,16-diazacyclooctadecane) has also been prepared.⁷⁷³ The structure of $[\text{Tl}([18]\text{aneN}_2\text{S}_4)][\text{PF}_6]$ (**145**) shows the Tl ion occupying the cradle formed by the macrocycle, leaving the top face of the metal center exposed. The adduct $[\text{Tl}([9]\text{aneS}_3)][\text{PF}_6]$ (**146**)

(145)

(146)

featuring the smallest crown, [9]aneS₃, shows that the thallium atoms are coordinated facially to the [9]aneS₃, with one additional secondary Tl—S bond formed between the Tl and a sulfur atom of the neighboring ring.⁷⁷¹ Further secondary interaction between the fluorine atoms of the anion results in overall eight-coordinate thallium sites.

(b) *Thiolate ligands.* A number of thallium(I) thiolates have been synthesized and characterized.^{250,774–781} In addition to their fundamental interest, thallium thiolates are useful in analytical and materials chemistry fields, and for modeling the toxic effects of heavy metals.^{776,782–786} The thallium thiolates TlSPh, TlSCH₂Ph, TlS(*t*-Bu), and 2,4,6-(CF₃)₃C₆H₂STl can be synthesized by treating Tl₂CO₃ with the corresponding sodium thiolate.^{774,775,780} The reaction between (*t*-BuO)₃SiSH and TlNO₃, or 2,4,6-(CF₃)₃C₆H₂SH with EtOTl, affords (*t*-BuO)₃SiSTl,⁷⁸¹ or 2,4,6-(CF₃)₃C₆H₂STl,⁷⁸⁰ respectively. Electrochemical methods have also been utilized to produce thallium thiolates such as *o*-CH₃C₆H₄STl, *m*-CH₃C₆H₄STl, 2-C₁₀H₇STl, and alkanedithiolates of thallium(I).²⁵⁰ Alkanedithiols of the type Tl₂(S₂R) (R = alkane bridges –C_{*n*}H_{2*n*}–) have been synthesized via an electrochemical route as well.⁴⁵⁶

Thallium(I) thiolates display an interesting structural diversity. The thiophenol derivative is an ionic product, with [Tl₇(SPh)₆]⁺ cations and anions [Tl₅(SPh)₆][–].⁷⁷⁵ The compound [(*t*-BuO)₃SiSTl]₂ (147) is a dimer.⁷⁸¹ The *t*-butyl derivative [TlS(*t*-Bu)]₈ is a covalent octamer.⁷⁷⁵ The solid-state structure of TlS(*i*-Pr) contains [Tl₄{S(*i*-Pr)}₅][–] cages linked by additional thallium cations.⁷⁸⁷ The compounds TlSCH₂Ph and TlSC₆H₁₁ contain Tl₂S₂ ring-coupled, two-dimensional polymers.^{775,787} A similar, folded-ladder structure is adopted by the polymeric [2,4,6-(CF₃)₃C₆H₂STl]_{*n*} (148).⁷⁸⁰

Under anaerobic conditions, the reaction of TlCl, TlNO₃, or Tl₂CO₃ with solutions of NaOMe and 1,2-(HS)₂C₆H₄ yields, after metathesis with [Et₄N]Br, yellow crystals of [Et₄N]₂[{Tl(1,2-(μ-S)₂C₆H₄)₂}₂] (149).⁷⁸⁷ This compound contains rectangular-bipyramidal [Tl₄Tl] cages, with an S₄ rectangle sandwiched between two thallium atoms. Interestingly, only the Tl(III) product [Et₄N][Tl(1,2-S₂C₆H₄)₂] forms with the same 1:2 thallium salt to 1,2-(NaS)₂C₆H₄ stoichiometry, if the reaction is carried out under aerobic conditions. Thallium(I) derivatives of monocyclopentadienylbis(arene-1,2-dithiolato)-titanium(IV) have been synthesized and structurally characterized.⁷⁸⁸

(149)

The thallium thiolate arising from the mixed donor tetrahydrofurfurylthiole (HStfff) has been prepared using NaStfff and TlPF₆.⁷⁷⁸ It forms a polymeric thallium thiolate salt $[\{\text{Tl}_7(\text{Stfff})_6\}_n][\text{PF}_6]_n$, and features an unusual, octahedrally coordinated Tl(I) linking novel Tl₆S₆ prismane units.

Acetylacetonato complexes of Tl(I) have been converted into 1,1-ethylenedithiolato complexes by treatment with carbon disulfide.⁷⁴⁰ The compounds $[\text{Tl}_2\{\text{S}_2\text{C}=\text{C}\{\text{C}(\text{O})\text{R}\}_2\}]_n$ (R = Me, Ph) have been obtained in quantitative yield.

(c) *Other anionic sulfur ligands.* Bis- and tris(mercaptoimidazolyl)borates are closely related to bis(pyrazolyl)borate and tris(pyrazolyl)borate ligands, but they contain softer sulfur-donor sites. Recently, a series of bis- and tris(mercaptoimidazolyl)borate ligands $[\text{Bm}^{\text{R}}]^-$ and $[\text{Tm}^{\text{R}}]^-$, as well as tris(mercaptothiazolyl)borate $[\text{Tz}]^-$, tris(mercaptobenzothiazolyl)borate $[\text{Tbz}]^-$, and bis(mercaptoimidazolyl)(pyrazolyl)hydroborato $[\text{PzBm}^{\text{R}}]^-$, ligands and their thallium(I) derivatives have been synthesized and characterized.^{543,789–791} The bis(mercaptoimidazolyl)(pyrazolyl)hydroborato represents a hybrid $[\text{S}_2\text{N}]$ system.

The reaction between $[\text{Bm}^{\text{Me}}]\text{Li}$ and $\text{CH}_3\text{CO}_2\text{Tl}$ in MeOH provides the Tl(I) derivative $\{[\text{Bm}^{\text{Me}}]\text{Tl}\}_x$ with an oligonuclear solid-state structure.⁷⁸⁹ It has four-membered Tl₂S₂ cores, and bridging thiazolyl groups. Related $\{[\text{Tm}^{\text{Ph}}]\text{Tl}\}_2$ is a dimer in the solid state.⁵⁴³ The compound $\{[\text{Bm}^{\text{Me}}]\text{Tl}\}_x$ reacts with Me_2Zn or ZnI_2 to produce $[\text{Bm}^{\text{Me}}]\text{ZnMe}$ or $[\text{Bm}^{\text{Me}}]\text{ZnI}$. The Tl(I) adducts $[\text{Tz}]\text{Tl}$, $[\text{Tbz}]\text{Tl}$, and $[\text{PzBm}^{\text{Me}}]\text{Tl}$ have also been prepared, and $\{[\text{Tbz}]\text{Tl}\}_x$ has shown to be polymeric.^{543,790}

Closely related to these systems is the tripodal sulfur-based donor, the phenyltris((*tert*-butylthio)methyl)borate ligand $[\text{PhB}(\text{CH}_2\text{SBu}^t)_3]^-$.⁷⁹² The thallium(I) adduct $[\text{PhB}(\text{CH}_2\text{SBu}^t)_3]^-$ (150) can be prepared by treating the product from the excess $\text{LiCH}_2\text{SBu}^t$ and PhBCl_2 reaction with aqueous TlNO_3 . It forms a one-dimensional, extended structure with Tl–S and Tl–phenyl ring interactions. $[\text{PhB}(\text{CH}_2\text{SBu}^t)_3]^-$ serves as an excellent ligand-transfer agent.

(150)

There are several early reports that describe the synthesis and characterization of monomeric $[\text{Tl}(1,1\text{-S}_2\text{PET}_2)]$ and dimeric $[\text{Tl}(1,1\text{-S}_2\text{CNR}_2)]_2$ [R = Me, Et, *n*-Pr, *i*-Pr, *n*-Bu or *i*-Bu] thallium(I) adducts.^{303,793–799} The synthesis of the first thallium(I) polysulfides and chalcogenide cages has been described.^{800–802} The two-coordinate Tl(I) compound $[\text{Pt}_2\text{Tl}(\mu_3\text{-S})_2(\text{PPh}_3)_4]\text{X}$ (X = NO₃ or PF₆)

is described as having a “Mexican hat-like” structure.⁸⁰³ The heterobimetallic complex $\text{AuTl}[\text{CH}_2\text{P}(\text{S})\text{Ph}_2]_2$, with short Au–Tl interactions and Tl–S bonds, is known.⁸⁰⁴

(d) *Selenium and tellurium ligands*. Examples of thallium selenolates and tellurolates are less numerous. The electrochemical oxidation of thallium in nonaqueous solutions of PhSe–SePh leads to PhSeTl.⁸⁰⁵ It is also possible to obtain the same product from an oxidative addition process, using a mixture of Tl and PhSe–SePh in refluxing toluene.²⁵² The related thiolate PhSTl could not be obtained using this latter method. With indium, both the thiolate and the selenolate could be obtained using the appropriate disulfide or diselenide, but the product is the In(III) derivative rather than the In(I) product. The thallium(I) selenolate $\text{TlSeSi}(\text{SiMe}_3)_3$ and tellurolate $\text{TlTeSi}(\text{SiMe}_3)_3$ have been prepared by chalcogenolysis of CpTl.³⁰⁵ Attempts to prepare Tl(III) derivatives were unsuccessful, leading to the oxidation of the ligands to produce $[\text{MSi}(\text{SiMe}_3)_3]_2$ (M = Se or Te).

Selenium donor adducts of thallium(I), $\text{Tl}(\text{Et}_2\text{PSeS})$ and $\text{Tl}(\text{Et}_2\text{PSe}_2)$ are known.^{806,807} The 2,2-dicyanoethylene diselenolate-containing compound $[\text{AsPh}_4]_2[\text{Tl}_2\{\text{Se}_2\text{C}=\text{C}(\text{CN})_2\}_2]$ has been prepared.⁸⁰⁸ This complex is a dimer with Se_4Tl_2 octahedral units. The synthesis of (*N,N*-diethyl-*N'*-benzoylselenoureato)thallium(I) has been achieved by treating thallium(I) acetate with *N,N*-diethyl-*N'*-benzoylselenourea.⁸⁰⁹ It crystallizes as dimers forming Tl_2Se_4 rings.

3.5.2.4.4 Group 17 ligands

Fluoride, chloride, bromide, and iodide derivatives of thallium(I) are well known. Their solubilities and photosensitivity are similar to the corresponding silver(I) systems. TlF is water-soluble, whereas the chlorides, bromides, and iodides are water-insoluble solids. This property is exploited in ligand-transfer chemistry involving thallium precursors. Some solid-state structures of thallium(I) salts of weakly coordinated anions show $\text{Tl}\cdots\text{halide}$ interactions.^{810–815} Selective abstraction of a fluoride from a C–F bond, leading to thallium fluoride, has been described.⁸¹⁶ The compound $[\{\text{P}(\text{CH}_2\text{CH}_2\text{PPh}_2)_3\}\text{RuH}(\eta^1\text{-ClTi})]\text{PF}_6$ represents the first metal complex containing an $\eta^1\text{-Cl}$ -bonded TlCl ligand.⁸¹⁷ This compound act as a thallium(I)-ion carrier.

3.5.2.4.5 Hydride ligands

Polymeric $[\text{TiH}]_n$ have been reported as one of the decomposition products of TiH_3 . However, there is no convincing experimental evidence to support the existence of this species in the condensed phase.^{365,366} It is possible to observe TiH in the gas phase. Reports containing theoretical studies on the bonding and stability of TiH and the related high-valent analogues are available.^{467,469}

3.6.1 INTRODUCTION

This chapter deals with the coordination chemistry of the three heaviest elements of group 15, specifically arsenic, antimony, and bismuth. We have followed a working definition of coordination complexes as those containing group 15 compounds behaving as Lewis acids to either neutral or charged donor ligands and have not included simple halides, oxides, etc. which fall into the wider area of the inorganic chemistry of these elements. The distinction in some cases is not clear-cut and a pragmatic approach has been adopted, with borderline cases usually included.

In this section some general points about the area are made and previous major literature sources, including books and review articles dealing with all three elements are listed. Reviews dealing with only one element or particular ligand types are referred to in the appropriate sections below.

All three elements have long been known to chemists, despite their rarity in the Earth's crust (As ca. 1.8 ppm, Sb 0.02 ppm, and Bi 0.008 ppm), which places bismuth similar in abundance to Pt or Au.¹ The common oxidation states (III and V) are shared by all the group 15 elements, but apart from similar stoichiometries there is little resemblance between the properties of nitrogen compounds and those of the three heaviest elements.^{2,3} The resemblance of the latter to phosphorus is closer, although trends down the group are irregular, resulting in a rich and diverse chemistry. Examples of the irregularities are the reduced stability of the V oxidation state for As and Bi compared with P and Sb (attributed respectively to the effects of insertion of the 3d elements and of the lanthanides), and in the electronegativities, which on the Allred-Rochow scale fall $N > As > P > Sb > Bi$, although the Pauling scale is more regular $N > P \geq As > Sb > Bi$.¹

There are a number of compounds containing homoatomic bonds that fall outside the formal oxidation state III or V classification, e.g., Zintl anions and homoatomic cations of Sb or Bi, but these have little or no coordination chemistry.

A good general survey of the properties of As, Sb, and Bi is given by Carmalt and Norman.⁴ Both common oxidation states exhibit Lewis acidity (and the III state also shows Lewis basicity) in both cases resulting in complexes in which the group 15 atom's outer electron count exceeds an octet. Although the traditional bonding model in such complexes invoked *d*-orbitals, the bonds are now more usually described in terms of delocalized 3-center-4-electron bonds, based upon *s*- and *p*-orbitals. For the Lewis acid complexes of the III oxidation state, the concept of primary E—X bonding in the parent Lewis acid (EX_3 , E = As, Sb, or Bi; X = halide) and secondary bonds to the Lewis base, utilizing E—X σ^* as acceptor orbitals, is a useful approach.⁴ The primary/secondary bonding and the 3-center-4-electron bonds are not distinct models but may be shown to be variants of the same basic model.⁵ The best description of this approach is in the review by Carmalt and Norman.⁴

There is an extensive literature on the chemistry of As, Sb, and Bi: in addition to recent editions of standard textbooks,^{2,3} there is a book edited by Norman,⁶ which includes a chapter⁷ devoted to the coordination chemistry of these elements, as well as the article by McAuliffe in *Comprehensive Coordination Chemistry* (CCC, 1987).⁸ The vast organic chemistry of these elements falls outside the scope of the present chapter. Sources providing recent coverage of the organic chemistry include chapters by Wardell,^{9,10} in *Comprehensive Organometallic Chemistry I and II*, a volume in the Patai series (*The Chemistry of Organic Arsenic, Antimony and Bismuth Compounds*),¹¹ and chapters in Norman's book.⁶ These texts also list many reviews on specific classes of organo-derivatives.

Studies of the Lewis base complexes of ER_3 compounds remains an active area of modern coordination chemistry, and we have described recent developments in the synthesis of arsine, stibine, and bismuthine ligands elsewhere in the present work (see Chapter 1.16).

The classification adopted in this chapter is generally based upon the Periodic group of the donor atoms, describing sequentially complexes formed by the lightest through the heaviest donor ligands, with neutral donor ligands preceding charged anions, and with the E^{III} oxidation state complexes described before those of E^V . Mixed donor ligands create some problems, and the approach adopted has been pragmatic, including them with the nearest analogues. It is hoped that this will not prove problematic in practice. Finally, we have used the convention where the term “*pseudo*,” prefixing the polyhedral geometry, refers to the overall geometry at the group 15 ion including a lone pair, i.e., *pseudo*-octahedral refers to a molecule with five ligands around the central ion and one lone pair, those six units being disposed in an octahedral array.

3.6.2 ARSENIC

In addition to the reviews listed in Section 3.6.1, there is an article detailing the structures, properties and bonding of penta-coordinate arsenic compounds.¹²

3.6.2.1 Group 14 Compounds

The conventional As^{III} and As^V compounds have As—C single bonds and are based upon AsR_3 and AsR_5 and their substituted variants with halogens, oxide, etc. In addition, there have been significant recent developments in the chemistry of compounds containing homo-element bonds

(RAs)_n and multiple bonds to carbon such as $\text{RC}\equiv\text{As}$, $\text{R}^1_2\text{C}=\text{AsR}^2$, $\text{RAs}=\text{AsR}$, $\text{R}^1_3\text{As}=\text{CR}^2_2$, pyridine ($\text{C}_5\text{H}_5\text{As}$), and pyrrole ($\text{C}_4\text{H}_4\text{AsR}$) analogues and their transition metal complexes.^{13–15}

Examples of bonds between arsenic and the heavier elements of group 14 are mostly of the type $\text{AsR}^1_{3-n}(\text{YR}^2_3)_n$ ($\text{Y} = \text{Si, Ge, Sn, or Pb}$) which are analogues of triorganoarsines and usually included in treatments of organoarsenic derivatives.¹¹

3.6.2.2 Group 15 Compounds

The commonest examples of As–N bonds are found in aminoarsines, $\text{As}(\text{NR}_2)_3$, usually discussed together with organoarsines,¹¹ and arsenic complexes with nitrogen Lewis bases are few. The reaction of molten AsX_3 ($\text{X} = \text{Br or I}$) with NH_3 , or heating As_2O_3 with the appropriate NH_4X gave $[\text{AsX}_3(\text{NH}_3)]$;¹⁶ the AsCl_3 complex was not obtained although it has been described in older literature. The $[\text{AsX}_3(\text{NMe}_3)]$ ($\text{X} = \text{Cl or Br}$) formed by direct combination of AsX_3 and NMe_3 in the absence of solvent have a *pseudo*-trigonal bipyramidal geometry, with axial amine and with one equatorial position occupied by the lone pair.¹⁷ The macrocycle 1,4,7-trimethyl-1,4,7-triazacyclononane ($\text{Me}_3[9]\text{aneN}_3$) reacts with AsCl_3 in MeCN to give white $[\text{AsCl}_3(\text{Me}_3[9]\text{aneN}_3)]$ which probably has a half-sandwich structure.¹⁸ Controlled hydrolysis in MeCN solution produces $[\text{AsCl}_2(\text{Me}_3[9]\text{aneN}_3)]^+$ isolated and structurally characterized as a salt with the unusual $[\text{As}_2\text{OCl}_5]^-$ anion. The cation has a *pseudo*-octahedral geometry with the lone pair occupying one vertex *trans* to *N*. In contrast, the simple adducts formed from AsCl_3 and $\text{Me}_4[14]\text{aneN}_4$ have not been characterized, although their hydrolysis products, including $[\text{H}_2\text{Me}_4[14]\text{aneN}_4][\text{As}_4\text{O}_2\text{Cl}_{10}]$, have been characterized structurally.¹⁹

The pincer anion $[2,6-(\text{Me}_2\text{NCH}_2)_2\text{C}_6\text{H}_3]^-$ (**1**) reacts with AsCl_3 to give colorless $[\text{AsCl}_2(\mathbf{1})]$, which probably has a square-pyramidal geometry (cf., the Sb analogue) with a N_2CCl_2 donor set.²⁰ Reduction of this complex with LiAlH_4 produces $[\text{AsH}_2(\mathbf{1})]$ a colorless, distillable liquid. In contrast, the 1:1 complex of (**2**) with AsCl_3 has a structure based upon a trigonal bipyramid with a vacant equatorial site and axial NMe_2 and Cl groups.²¹ Using the ligands (**2**) and (**3**) (**L**) it is possible to isolate complexes $[\text{AsL}_3]$ which contain trigonal pyramidal AsC_3 skeletons, with As–C bond lengths typical of single bonds, and longer secondary As–N interactions completing a distorted octahedron (Figure 1).²²

The instability of AsCl_5 would seem to preclude an extensive coordination chemistry, but AsF_5 is a very strong Lewis acid. Many of its reported reactions involve abstraction of fluoride from main group fluorides or oxide-fluorides to form cationic derivatives as $[\text{AsF}_6]^-$ salts (q.v.). Simple *N*-base adducts are more rare. The simplest, $[\text{AsF}_5(\text{NH}_3)]$, is formed from the constituents in solution in liquid SO_2 , and is quantitatively converted into $[\text{NH}_4][\text{AsF}_6]$ by HF .²³ $[\text{AsF}_5(\text{NHET}_2)]$ has been detected in solution in MeCN by ^{19}F NMR spectroscopy.²⁴ Klapötke and co-workers^{23,25–27} have reported 1:1 adducts of AsF_5 with MeCN , pyridine, H_2NCN , C_2N_2 , HCN , FCN , ClCN , BrCN , ICN , $\text{CH}_2(\text{CN})_2$, and $\text{CCl}_2(\text{CN})_2$; only $\text{CH}_2(\text{CN})_2$ appears to form a $[\text{L}(\text{AsF}_5)_2]$ adduct. The complexes were characterized by analysis, vibrational, and NMR spectroscopy. In contrast, triazine ($\text{C}_3\text{N}_3\text{H}_3$) forms adducts $[(\text{C}_3\text{N}_3\text{H}_3)(\text{AsF}_5)_n]$ ($n = 1, 2, \text{ or } 3$)²⁸ and the structure of the complex with $n = 1$ shows the expected six-coordinate As bonded to one nitrogen of the triazine ring. Other structurally characterized examples of *N*-coordinated ligand adducts are $[\text{AsF}_5\text{L}]$ ($\text{L} = \text{MeSCN}$,²⁹ NMe_2SOF_2 ,³⁰ benzo-2,1,3-thiadiazole, and benzo-1,2,3-thiadiazole³¹).

Highly explosive azides of As^{III} and As^{V} of types $[\text{As}(\text{N}_3)_4]^-$, $[\text{As}(\text{N}_3)_6]^-$, and $[\text{As}(\text{N}_3)_4]^+$ are obtained by reaction of the appropriate arsenic halide with NaN_3 or TMSN_3 . Although $[\text{As}(\text{N}_3)_3]$ is known, attempts to isolate $[\text{As}(\text{N}_3)_5]$ have failed.^{32,33}

The reactions of AsX_3 with PR_3 or AsR_3 were first examined many years ago and, depending upon the Lewis acid–Lewis base combination and the reaction conditions, were reported to

Figure 1 The structure of $[\text{As}(\text{2-Me}_2\text{NCH}_2\text{C}_6\text{H}_4)_3]$ (reproduced by permission of the American Chemical Society from *Inorg. Chem.* **1996**, 35, 6179–6183).

produce adducts $[\text{AsX}_3\text{L}_n]$ ($\text{X} = \text{Cl}, \text{Br}, \text{or I}$, $\text{L} = \text{PR}_3$ or AsR_3 , $n = 1$, (rarely) 2) or salts $[\text{R}_3\text{EAsX}_2]\text{X}$ ($\text{E} = \text{P}$ or As , $\text{R} = \text{alkyl}$ or aryl). In contrast, SbR_3 usually caused reduction-forming SbR_3X_2 .³⁴ In some cases RAsX_2 behaved similarly, but generally no reaction occurred with R_2AsX , consistent with reduced Lewis acidity as X was replaced by R . Reinvestigation of the reactions of AsX_3 ($\text{X} = \text{Cl}, \text{Br}, \text{or I}$) with PMe_3 ($\text{X} \neq \text{Cl}$) or AsMe_3 in dry CH_2Cl_2 ,³⁵ and of AsCl_3 with AsEt_3 ,³⁴ found 1:1 adducts were formed irrespective of the ratio of the reactants. However, in the $\text{AsCl}_3\text{-PMe}_3$ system both 1:1 and 1:2 adducts could be isolated depending upon the conditions.³⁵ The X-ray structure of $[\{\text{AsCl}_3(\text{AsEt}_3)\}_2]$ shows a dimer with asymmetric chlorine bridges and axial *anti*- AsEt_3 groups,³⁶ and the other 1:1 adducts are likely to be similar. The structure of $[\text{AsCl}_3(\text{PMe}_3)]$ is based upon a similar dimer unit, but the lattice shows two crystallographically independent units, one with five-coordinate As , the second with $[5 + 1]$ -coordination due to long-range interdimer $\text{Cl} \cdots \text{As}$ interactions (Figure 2).³⁵ Diphosphines and diarsines including *o*- $\text{C}_6\text{H}_4(\text{PMe}_2)_2$, *o*- $\text{C}_6\text{H}_4(\text{PPh}_2)_2$, and *o*- $\text{C}_6\text{H}_4(\text{AsMe}_2)_2$, and the triarsine $\text{MeC}(\text{CH}_2\text{AsMe}_2)_3$ also form 1:1 adducts with AsX_3 .³⁵ The X-ray structures of $[\{\text{AsX}_3(o\text{-C}_6\text{H}_4(\text{AsMe}_2)_2)_2\}]$ ($\text{X} = \text{Br}$ or I) show dimeric units with asymmetric dihalo-bridges (Figure 3).³⁵

3.6.2.3 Group 16 Compounds

Arsenic(III) has a considerable affinity for charged O- or S-donor ligands, the latter including dithioacid chelates, but complexes with neutral O, S, or Se donor ligands are much rarer. Here complexes of neutral ligands are discussed first and then complexes with charged anions.

Tetrahydrofuran complexes $[\text{Ph}_4\text{P}][\text{AsX}_4(\text{THF})_2]$ ($\text{X} = \text{Cl}$ or Br) were the unexpected major products of photolysis of $\text{W}(\text{CO})_6 + [\text{Ph}_4\text{P}]_2[\text{As}_2\text{Cl}_8]$ and $\text{Cr}(\text{CO})_6 + [\text{Ph}_4\text{P}][\text{As}_2\text{SBr}_5]$ in THF.³⁷ Both are regular octahedral anions with *trans*-THF ligands and hence a stereochemically inactive lone pair—although the As—O and As—X bonds are long, probably attributable to the effect of the lone pair. Crown ether adducts are also characterized by unusually long As—O bonds. The known examples are $[\text{AsCl}_3(12\text{-crown-4})]$ ³⁸ and $[\text{AsX}_3(15\text{-crown-5})]$ ($\text{X} = \text{Cl}, \text{Br}, \text{or I}$),^{38,39} but 18-crown-6 failed to give a pure complex. The structures retain the pyramidal AsX_3 unit of the parent halide capped by the crown ether oxygens giving, respectively, seven- and eight-coordinate As , but with very long As—O bonds (Figure 4).

Arsenic(III) halides function as very weak Lewis acids towards thio- or seleno-ethers (no telluroether adducts are known). The products are hydrolytically unstable and extensively dissociated in solution. In all these complexes the $\text{As—S}(\text{Se})$ bonds are very long, indicative of weak,

Figure 2 The structure of $[\text{AsCl}_3(\text{PMe}_3)]$ and the packing showing the intermolecular interactions (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **2002**, 1188–1192).

Figure 3 The structure of $[\text{AsBr}_3\{o\text{-C}_6\text{H}_4(\text{AsMe}_2)_2\}]$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **2002**, 1188–1192).

Figure 4 The structure of $[\text{AsCl}_3(15\text{-crown-}5)]$ (reproduced by permission of the International Union of Crystallography from *Acta Crystallogr., Sect. B* **1993**, 49, 507–514).

Figure 5 The structure of $[\text{AsCl}_3\{[9]\text{aneS}_3\}]$ (reproduced by permission of the American Chemical Society from *Inorg. Chem.* **2002**, 41, 2070–2076).

secondary interactions. Thus, AsX_3 ($\text{X} = \text{Br}$ or I) react with $\text{MeSCH}_2\text{CH}_2\text{SMe}$ in dry CH_2Cl_2 to form 1:1 adducts which are dihalo-bridged dimers with distorted octahedral arsenic coordinated to a chelating dithioether and two terminal and two asymmetrically bridging halides.⁴⁰ In contrast, the $[\text{AsX}_3\{[9]\text{aneS}_3\}]$ ($\text{X} = \text{Cl}$, Br , or I) are monomeric; the structure of the distorted octahedral chloride is shown in Figure 5.⁴⁰ The 1:1 complex with the tetrathioether macrocycle

[14]aneS₄, [AsCl₃{[14]aneS₄}], is completely different, based upon six-coordinate As coordinated to two S atoms of different thioethers, two terminal and two bridging Cl (to different As), which produces an infinite sheet polymer.⁴⁰ Among the products of the reaction of AsI₃ with thioacetic acid were orange-red crystals shown by an X-ray structure determination to be the monomeric 1:1 AsI₃ adduct of 1,3,5,7-(tetramethyl)-2,4,6,8,9,10-(hexathia) adamantane, in which the pyramidal AsI₃ group is weakly bonded to three sulfurs in the adamantane (Figure 6).⁴¹

In contrast to SbX₃ or BiX₃ (q.v.), under similar reaction conditions, AsX₃ fail to give complexes with acyclic selenoethers such as MeSeCH₂CH₂SeMe or MeC(CH₂SeMe)₃. However, macrocyclic selenoethers are more effective ligands affording [AsX₃{[8]aneSe₂}], [(AsX₃)₂{[16]aneSe₄}] (X = Cl, Br, or I), [(AsCl₃)₄{[24]aneSe₆}], and [(AsBr₃)₂{[24]aneSe₆}].^{40,42} The [16]aneSe₄ complexes contain asymmetric dihalo-bridged As₂X₆ units linked into 3-D polymers by the tetraselenoether, with each Se bonded to a different As center. The unique structure of [(AsCl₃)₄{[24]aneSe₆}] (Figure 7) shows a weakly associated As₂Cl₆ unit *endo* to the ring where it is coordinated to four seleniums (two per As), whilst the other two seleniums coordinate *exo* to pyramidal AsCl₃ groups which have a *pseudo*-trigonal bipyramidal geometry due to the stereochemically active lone pair.⁴²

The only thioether complex with As^V is [AsF₅(Me₂S)], an involatile white solid made from Me₂S and AsF₅ at low temperature, although its properties were not described.⁴³

Arsenic compounds with charged O-donor ligands include such diverse species as arsenite and arsenate esters, spiroarsoranes,⁴⁴ and arsenic carboxylates. Recent examples include the tetrahalocatecholate derivatives (4),⁴⁵ the triethanolamine derived (5),⁴⁶ and 2-Cl-4,4,6,6-tetramethyl-1,3,2-dioxarsenane.⁴⁷ The reaction of As(NMe₂)₃ with *p*-Rcalix[4]arenes (R = Bu^t or H) gives mono- or di-arsenic derivatives (6) which have been structurally characterized.⁴⁸ In the presence of moisture the oxo-bridged (7) is formed. *N*-coordinated base adducts of cyclic arsenites are known with 8-hydroxyquinolate(1-) (8), formed from [ClAs(O-R-O)] (R = CH₂CMe₂CH₂, 2,2'-C₆H₄OC₆H₄, (Bu^t)₂C₆H₂CH₂C₆H₂(Bu^t)₂) and 8-hydroxyquinoline in the presence of base.⁴⁹⁻⁵¹ The reaction of [ClAs(OCH₂CMe₂CH₂O)] with Me₂C(CH₂OH)₂ and base gives the As^V compound (9), which also reacts with 8-hydroxyquinoline to give (10).⁴⁹ Organoarsenic(V) compounds of structure type (9), with R groups replacing the apical Cl,

Figure 6 The structure of [AsI₃(1,3,5,7-Me₄-2,4,6,8,9,10-(hexathia)adamantane)] (reproduced by permission of Elsevier Science from *Inorg. Chim. Acta* **1982**, 64, L83–L84).

Figure 7 The structure of $[(\text{AsCl}_3)_4\{[24]\text{aneSe}_6\}]$ (reproduced by permission of the American Chemical Society from *J. Am. Chem. Soc.* **2001**, 123, 11801–11802).

have been studied and the effects of substituents upon the distorted five-coordinate structures examined.⁵² The structure of the tris(catecholato)arsenate(V) anion (as the $[\text{H}_7\text{O}_3]^+$ salt) has been determined.⁵³

The reaction of acetic anhydride with As_2O_3 produces both $[\text{As}(\text{O}_2\text{CMe})_3]$ and $[\text{As}_2\text{O}(\text{O}_2\text{CMe})_4]$. The arsenic environment in each is based upon a pyramidal AsO_3 core with longer $\text{As}\cdots\text{O}$ contacts completing a distorted octahedron or distorted square pyramid, respectively.⁵⁴ Arsenic α -hydroxycarboxylates have more complicated structures. The arsenic(III)-tartaric acid complexes, related to the important tartrato-antimonates, have structures based upon the dimer unit (**11**) with a distorted *pseudo*-trigonal bipyramidal geometry at As with the lone pair equatorially disposed. In $[\text{Na}_8\text{As}_{10}(\text{C}_4\text{H}_2\text{O}_6)_8(\text{C}_4\text{H}_3\text{O}_6)_2(\text{H}_2\text{O})_{19}]$ the dimer units (**11**) are linked via Na^+ cations into a complex polymeric network.^{55,56} In related silver salts $[\text{Ag}_9\text{As}_{10}(\text{C}_4\text{H}_2\text{O}_6)_9(\text{C}_4\text{H}_3\text{O}_6)(\text{H}_4\text{As}_2\text{O}_5)(\text{H}_2\text{O})_{10}]$ and $[\text{Ag}_5\text{As}_4(\text{C}_4\text{H}_2\text{O}_6)_4(\text{H}_2\text{O})_5\text{Y}]$ ($\text{Y} = \text{NO}_3$ or ClO_4) the structures are based upon the dimer units but $\text{As}-\text{Ag}$ bonds are also present.^{55,56} 1,2-Dihydroxycyclohexane-1,2-dicarboxylic acid also forms an As^{III} complex based upon a similar dimer unit, and ^{13}C NMR spectroscopy shows the expected stereoisomers and some dissociation of the carboxylate from the arsenic in solution.⁵⁷

Methanesulfonate complexes of As^{III} include $[\text{As}(\text{MeSO}_3)_3]$, $[\text{As}(\text{MeSO}_3)_4]^-$, $[\text{AsO}(\text{MeSO}_3)_2]^-$, and $[\text{AsO}(\text{MeSO}_3)]$.⁵⁸ The $[\text{As}(\text{MeSO}_3)_3]$ forms adducts with pyridine or *N,N*-DMF. Mixed fluoride–fluorosulfonates of both As^{III} and As^{V} are known, including $[\text{AsF}_n(\text{SO}_3\text{F})_{5-n}]$ ($n = 2-4$).⁵⁹

Arsenic(III) has great affinity for anionic sulfur chelates including xanthate (ROCS_2^-), dithiocarbamate (R_2NCS_2^-), and dithiophosphate ($(\text{RO})_2\text{PS}_2^-$), and this area has been reviewed recently.⁶⁰ In contrast to antimony which forms compounds in oxidation state III and V, arsenic(V) is reduced by these ligands. The most popular synthetic route is reaction of AsCl_3 with the sodium, or sometimes the ammonium, salt of the dithioacid, although reactions of $\text{As}(\text{OR})_3$ or As_2O_3 with the dithiophosphorus acid have also been used.⁶⁰ Replacement of AsCl_3 by RAsCl_2 or R_2AsCl results in the corresponding organoarsenic derivatives. The complexes synthesized are listed in Table 1 and here we discuss various points of interest.

In the $[\text{As}(\text{S}_2\text{COR})_3]$ ($\text{R} = \text{Me}, \text{Et}, \text{Pr}^i, \text{CH}_2\text{CH}_2\text{CMe}_3$) complexes distorted six-coordinate As is present and within each xanthate ligand there is one short and one longer As—S bond.^{61,62,64,65} The distortion is greater in As compared to Sb or Bi analogues, consistent with greater stereochemical effect of the lone pair.

(11)

The arsenic dithiocarbamates also show distorted structures: in $[\text{As}(\text{S}_2\text{CN}(\text{Me})\text{CH}_2\text{CH}_2\text{OH})_3]$ the structure is based on a distorted octahedron,⁷¹ whereas in $[\text{As}(\text{S}_2\text{CN}(\text{CH}_2\text{CH}_2\text{OH})_2)_3]$ the geometry is a distorted trigonal prism (Figure 8) with three short As—S bonds (2.34(2) Å) and three much longer As—S interactions (2.84(2) Å).⁷⁴ The effect of the group 15 acceptor is also marked—the antimony analogue is best described as distorted pentagonal pyramidal (q.v.).⁷⁴ In

mixed ligand complexes different motifs are found: in [As(SCH₂CH₂S)(S₂CN-morphyl-4)] the dithiocarbamate coordination is essentially monodentate,⁷³ whereas in [AsPh(S₂CNEt₂)₂] or [AsMe(S₂CNEt₂)₂] there are three short bonds (one As—C and two As—S) with two much longer As···S interactions (Figure 9).⁷⁵

Dithiophosphate and dithiophosphinate complexes of arsenic are listed in Table 1. Spectroscopic data have been reported for many examples but structural data are more rare. In [AsPh{S₂P(OPrⁱ)₂}]₂] the structure is an approximate square pyramid with an apical Ph group and very asymmetric chelation by the dithiophosphates, in which the As—S bonds differ by 0.082 Å (Figure 10).⁸² The arsocane dithiophosphinates [{Y(CH₂CH₂S)₂}As(S₂PPh₂)] (Y = O or S) show very distorted five-coordination with primary bonds to the thiolate sulfurs and to one sulfur of the dithiophosphinate, with weaker interactions to the second sulfur in the dithiophosphinate and an endocyclic *trans*-annular interaction to the O or S of the ring (Figure 11).^{88,89} In addition to the mixed species noted above, simple dithiolate complexes are also known including [AsCl(tdt)] (tdt = toluenedithiolate(2–)). The structure of the latter reveals an essentially three-coordinate pyramidal As center coordinated to a chelating dithiolate and a single chlorine, and the stacking appears to involve weak As···Ph contacts.⁹⁰ In contrast to Sb or Bi, arsenic does not appear to form complexes with a higher ligand:metal ratio.

3.6.2.4 Group 17 Compounds

Haloarsenic anions are known in both III and V oxidation states, although the structural diversity is less than in the antimony and bismuth analogues. For the As^{III} species a variety of stoichiometries

Figure 8 The structure of $[\text{As}\{\text{S}_2\text{CN}(\text{CH}_2\text{CH}_2\text{OH})_2\}_3]$ (reproduced by permission of Elsevier Science from *Polyhedron* **1997**, 16, 1211–1221).

Figure 9 The structure of $[\text{AsMe}(\text{S}_2\text{CNET}_2)_2]$ (reproduced by permission of Elsevier Science from *J. Organomet. Chem.* **1997**, 538, 129–134).

have been identified; it is also clear that the structural units present cannot be deduced simply from the stoichiometries.⁹¹ In marked contrast to the As^{V} fluoroanions, those of As^{III} have been studied little. The structure of $[\text{AsF}_4]^-$ has been determined (as the hexamethylpiperidinium salt) and shows the expected bisphenoidal (SF_4 -like) geometry, with longer axial (1.862(2), 1.878(8) Å) than equatorial (1.724(2), 1.727(2) Å) bonds.⁹² The structure present in $\text{K}_2\text{As}_2\text{F}_7$ consists of $[\text{AsF}_4]^-$ anions weakly associated with AsF_3 molecules.⁹³

The syntheses of the heavier haloanions are from AsX_3 , X^- , and an appropriate cation, and the major feature of interest is the structural units present. The simplest stoichiometry is $[\text{AsX}_4]^-$ known for $\text{X} = \text{Cl}$, Br , or I , none of which contain monomeric anions. The chloro- and bromo-compounds are dimeric $[\text{As}_2\text{X}_8]^{2-}$ with edge-shared square pyramidal units with *anti*-apical halides and relatively symmetrical bridges. X-ray structures are available for $[\text{NPhMeH}_2]_2[\text{As}_2\text{Cl}_8]$,⁹⁴ $[\text{Ph}_4\text{P}]_2[\text{As}_2\text{Cl}_8]$,⁹⁵ $[\text{Ph}_4\text{P}]_2[\text{As}_2\text{Br}_8]$,⁹⁶ $[\text{Pr}_4\text{N}]_2[\text{As}_2\text{Br}_8]$,⁹⁶ and $[\text{NPhMeH}_2]_2[\text{As}_2\text{Br}_8]$.⁹⁷ The $[\text{Ph}_4\text{P}]_2[\text{As}_2\text{I}_8]$ also belongs to this type.⁹⁸ However, with pyridinium cations the complexes

Figure 10 The structure of $[\text{AsPh}\{\text{S}_2\text{P}(\text{OPr}^i)_2\}_2]$ (reproduced by permission of the American Chemical Society from *Inorg. Chem.* **1985**, 24, 3280–3284).

Figure 11 The structure of $[\{\text{O}(\text{CH}_2\text{CH}_2\text{S})_2\}\text{As}(\text{S}_2\text{PPh}_2)]$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **1996**, 4135–4141).

of stoichiometry $[\text{PyH}][\text{AsX}_4]$ ($\text{X} = \text{Br}$ or I) contain approximately octahedrally coordinated As, with an infinite polymer chain anion with *cis* dihalobridges (Figure 12).^{97,98}

Discrete confacial bioctahedral anions are present in $[\text{PyH}]_3[\text{As}_2\text{Cl}_9]$,⁹⁴ $[\text{PyH}]_3[\text{As}_2\text{Br}_9]$ ⁹⁷ (Figure 13), and $[\text{piperidineH}]_4[\text{As}_2\text{Br}_9]\text{Br}$.⁹⁶ The environment about As is close to octahedral (although the bridging As–X are longer than terminal As–X as expected) and the bridges symmetric. In the $[\text{Et}_3\text{NH}]_3[\text{As}_3\text{Br}_{12}]$ ^{99,100} and $[\text{Me}_3\text{NH}]_3[\text{As}_3\text{I}_{12}]$ ¹⁰⁰ there are discrete trimeric anions based upon face sharing octahedra with a common vertex (Figure 14). Two anions of formula $[\text{As}_8\text{X}_{28}]^{4-}$ are known, but with different structures. In the $[\text{S}_5\text{N}_5]_4[\text{As}_8\text{Cl}_{28}] \cdot 2\text{S}_4\text{N}_4$, made serendipitously from $(\text{NSCl})_3$ and As_2O_3 in CH_2Cl_2 , a complex structure occurs which can be viewed as a cubane $[\text{As}_4\text{Cl}_{16}]^{4-}$ core (presently unknown as a discrete species) to which is attached four AsCl_3 units.¹⁰¹ $[\text{Et}_3\text{NH}]_4[\text{As}_8\text{I}_{28}]$ has a different structure based upon AsI_6 edge-linked octahedra (Figure 15).⁹⁸

The arsenic(V) fluoroanion $[\text{AsF}_6]^-$ which is a regular octahedron in the K^+ salt, is well known,¹⁰² and often considered a “noncoordinating” anion. In fact, like other related species, it is better viewed as “weakly coordinating” and is known to bind to metals in the absence of other ligands.¹⁰³ In many cases where it is found as a product of fluoride abstraction from nonmetal

Figure 12 The structure of $[\text{AsBr}_4]_n^-$ (reproduced by permission of the publishers from *Z. Naturforsch.*, **B** **1984**, 39, 1257–1261).

Figure 13 The structure of $[\text{As}_2\text{Br}_9]^{3-}$ (reproduced by permission of the publishers from *Z. Naturforsch.*, **B** **1984**, 39, 1257–1261).

fluorides or oxofluorides by AsF_5 , the resulting $[\text{AsF}_6]^-$ “anion” is clearly associated with the cations through directional As–F–cation interactions. The anion $[\text{F}_5\text{AsFAsF}_5]^-$ is also well known.¹⁰⁴ Although the Sb and Bi analogues are known, the $[\text{AsF}_7]^{2-}$ anion has not been prepared.¹⁰⁵ The yellow $[\text{AsCl}_6]^-$ has been isolated as its PPh_4^+ salt by treatment of $[\text{As}_2\text{Cl}_8]^{2-}$ with Cl_2 or O_3 in CH_2Cl_2 at low temperatures.¹⁰⁶ A number of fluorochloroarsenates(V) $[\text{AsF}_{6-n}\text{Cl}_n]^-$ have been identified in MeCN solution by multinuclear NMR studies, as has $[\text{AsF}_5\text{Br}]^-$.¹⁰⁷

Oxo-haloarsenates which have been obtained and characterized structurally include $[\text{As}_2\text{OCl}_5]^-$,¹⁸ $[\text{As}_2\text{OCl}_6]^{2-}$,^{94,108} and $[\text{As}_4\text{O}_2\text{Cl}_{10}]^{2-}$.^{19,108,109} All contain both Cl and oxygen bridges, the last having the structure shown in Figure 16. Arsenic(V) anions include $[\text{F}_5\text{AsOAsF}_5]^{2-}$ and $[\text{F}_4\text{As}(\text{O})_2\text{AsF}_4]^{2-}$ and the sulfur-bridged $[\text{F}_5\text{AsSAsF}_5]^{2-}$.¹¹⁰

Figure 14 The structure of $[\text{As}_3\text{Br}_{12}]^{3-}$ (reproduced by permission of the publishers from *Z. Naturforsch., B* **1992**, 47, 1079–1084).

Figure 15 The structure of $[\text{As}_8\text{I}_{28}]^{4-}$ (reproduced by permission of the publishers from *Z. Naturforsch., B* **1988**, 43, 789–794).

3.6.2.5 Arsenic in the Environment, Biology, and Medicine

Arsenic is widely distributed in nature and man-made distribution occurs through mining, smelting, pesticides, and the use of fossil fuels. The vast majority of the forms identified in the environment are simple inorganic (oxide, oxo-anions) or organic (especially methylated forms)

Figure 16 The structure of $[\text{As}_4\text{O}_2\text{Cl}_{10}]^{2-}$ (reproduced by permission of the publishers from *Z. Naturforsch., B* 2001, 56, 301–305).

and coordination chemistry plays only a small role. Several recent review articles should be consulted for details.^{111–114} Medical uses of arsenic coordination complexes are similarly unimportant, in contrast to antimony and especially bismuth complexes (q.v.). Thiols such as 2,3-dithiopropanol (British anti-Lewisite) or 2,3-dithiosuccinic acid were developed many years ago for use in chelation therapy for heavy metal (including As) poisoning, and rely on the high affinity of As for sulfur ligands.¹¹¹

3.6.3 ANTIMONY

The first major difference between the coordination chemistry of antimony compared to those of arsenic or bismuth is the significantly greater stability of the Sb^{V} state, which forms coordination complexes with a wide range of ligands. In contrast, for the other two elements the complexes of E^{V} are mostly halooanions or compounds with charged oxygen donor ligands. In general, the treatment follows the pattern established above with periodic group of the donor atom, and with Sb^{III} complexes described before Sb^{V} .

3.6.3.1 Group 14 Compounds

In addition to reviews of organoantimony chemistry noted in Section 3.6.1, there are articles dealing with low-coordination number species such as $(\text{RSb})_n$, $\text{RSb}=\text{SbR}$, $\text{C}_5\text{H}_5\text{Sb}$, $\text{RP}=\text{SbR}$, and their transition metal derivatives.^{13,14,115–118}

The silylstibines, $\text{Sb}(\text{SiR}_3)_3$, provide the only series of examples of Si–Sb bonds and are normally treated with other organostibines.^{11,116} Such compounds have found use in the preparation of (III)–(V) materials via pyrolysis of their group 13 adducts.¹¹⁹ There are also examples of $\text{Sb}(\text{YR}_3)_3$ ($\text{Y} = \text{Ge}, \text{Sn}, \text{or Pb}$) types.¹¹⁶

3.6.3.2 Group 15 Compounds

3.6.3.2.1 N-donor ligands

The reaction of molten SbX_3 ($\text{X} = \text{Br}$ or I) with NH_3 produced $[\text{SbX}_3(\text{NH}_3)]$, whilst SbCl_3 and NH_3 in diethyl ether formed $[\text{SbCl}_3(\text{NH}_3)_2]$.¹⁶ Trimethylamine forms both 1:1 and 1:2 adducts with SbCl_3 or SbBr_3 , and 1:1 adducts have been described with NH_2Me , NHMe_2 , and

PhNH_2 .^{16,17} Vibrational spectroscopy suggests the 1:1 complexes are *pseudo*-trigonal bipyramidal with axial amine and with an equatorial vertex occupied by the lone pair, whilst the 1:2 compounds probably have a structure based upon an octahedron where one vertex is occupied by the lone pair, as established by the X-ray crystal structure of $[\text{SbCl}_3(\text{PhNH}_2)_2]$.¹²⁰ The structure of the yellow $[\text{SbCl}_3(2,2'\text{-bipyridyl})]$ is based upon a distorted five-coordinate geometry (N_2Cl_3 donor set) with $\text{Sb}-\text{Cl}=2.55 \text{ \AA}$ (av). This unit forms a long contact to a further Cl from a neighboring molecule (3.34 \AA) completing a very distorted octahedron.¹²¹ Distorted square pyramidal ($\text{N}_2\text{O}_2\text{X}$ donor set) molecules are present in $[\text{SbX}(1,10\text{-phen})(\text{cat})]$ ($\text{X}=\text{F}, \text{Cl}, \text{Br}, \text{or I}$; $1,10\text{-phen}=1,10\text{-phenanthroline}$, $\text{cat}=\text{phenylene-1,2-diolate}(2-)$),^{122,123} whereas in $[\text{Sb}(1,10\text{-phen})_2(\text{cat})]\text{BPh}_4$ there is very distorted N_4O_2 coordination.¹²⁴

The aza-macrocyclic $\text{Me}_3[9]\text{aneN}_3$ produces a 1:1 complex with SbCl_3 of unknown structure,¹⁸ but in the presence of SbCl_5 a similar reaction yields the complex $[\text{SbCl}_2(\text{Me}_3[9]\text{aneN}_3)]\text{SbCl}_6$, with a distorted square pyramidal cation.¹²⁵ Hydrolysis of $[\text{SbCl}_3(\text{Me}_3[9]\text{aneN}_3)]$, or reaction of SbCl_3 and 1,4,8,11-tetramethyltetraazacyclotetradecane in wet MeCN, gave oxochloroantimonate anions (q.v.) with the protonated macrocycle as cations.^{18,19} The phthalocyanine derivative $[\text{Sb}(\text{pc})_2]^-$ has been isolated by heating together SbI_3 , $1,2\text{-C}_6\text{H}_4(\text{CN})_2$, and KOMe. The structure as the Bu_4N^+ or PNP^+ salts show a distorted eight-coordinate antimony environment.¹²⁶

The reaction of SbCl_3 with three equivalents of 2-(dimethylaminomethyl)phenyl lithium ($\text{Li}^+(3)^-$) produces $[\text{Sb}\{\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)\}_3]$ which has a similar geometry to its arsenic analogue (Figure 1), but with rather stronger E–N coordination suggested by comparison of the bond lengths.²² Using appropriate ratios of $\text{SbCl}_3:(3)$ $[\text{SbCl}_2\{\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)\}]$ and $[\text{SbCl}\{\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)\}_2]$ can be isolated. These again have structures based upon strong Sb–C bonds with weaker interactions with the amine functions completing distorted *pseudo*-trigonal bipyramidal geometry with an equatorially disposed lone pair.²¹ Treatment of $[\text{SbCl}\{\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)\}_2]$ with TiPF_6 in THF affords the related cation $[\text{Sb}\{\text{C}_6\text{H}_4(\text{CH}_2\text{NMe}_2)\}_2]\text{PF}_6$ which is also *pseudo*-trigonal bipyramidal with axial N and equatorial C atoms.¹²⁷ 8-(Dimethylamino)-1-naphthyl (**2**) also forms $[\text{SbCl}_2(\text{2})]$ and $[\text{SbCl}(\text{2})_2]$ complexes,²¹ whereas with 2,6-bis[(dimethylamino)methyl]phenyl (**1**) the product is $[\text{SbCl}_2(\text{1})]$ which has a distorted square-pyramidal geometry with an apical C atom (Figure 17).²⁰ *Trans*-annular $\text{Sb}\cdots\text{N}$ coordination is present in the heterocyclic rings $\text{R}^1\text{Sb}[(\text{CH}_2)_3]_2\text{NR}^2$ ($\text{R}^1=\text{Cl}, \text{I}, \text{Ph}$; $\text{R}^2=\text{Me}, \text{Bz}, \text{Bu}^i$, etc.)^{128,129} which have structures based upon a *pseudo*-trigonal bipyramid with axial N and R and an equatorial lone pair.

Schiff base ligands form complexes with both Sb^{III} and Sb^{V} .^{130–134} Examples are known where the Schiff base coordinates as a neutral ligand bonded only via the azomethine nitrogen(s) to both *cis*- and *trans*- SbCl_4^+ units,¹³² or as anions bonded both through the azomethine-N and deprotonated *o*-hydroxyphenyl groups.¹³⁴

Antimony pentafluoride forms 1:1 adducts with HCN and C_2N_2 and the structure of the latter reveals a linear NCCN-SbF_5 linkage.²⁷ Related adducts of SbCl_5 including $[\text{SbCl}_5(\text{L})]$ ($\text{L}=\text{ICN}, \text{BrCN}, \text{ClCN}, 1/2\text{C}_2\text{N}_2, \text{NH}_2\text{CN}, \text{pyridine}$) have been prepared and the X-ray structures of

Figure 17 The structure of $[\text{SbCl}_2\{2,6\text{-(Me}_2\text{NCH}_2)_2\text{C}_6\text{H}_3\}]$ (reproduced by permission of Elsevier Science from *Inorg. Chim. Acta* **1992**, 198–200, 271–274).

[SbCl₅(ClCN)] and [(SbCl₅)₂(C₂N₂)] determined.¹³⁵ A substantial range of organonitrile adducts of SbCl₅ have been described, including [SbCl₅(RCN)] (R = Me, Ph, various isomers of MeC₆H₄–, Me₂C₆H₃–, ClC₆H₄–, NH₂C₆H₄–).^{136–139} The reaction of SbCl₃ with TMSNPR₃ (R = Ph or Me) formed the phosphine-iminato compounds [SbCl₂(NPR₃)], which react further with SbCl₅ in MeCN to form [SbCl(NPPh₃)(MeCN)₂][SbCl₆]₂ or [Sb₂Cl₅(NPMe₃)₂–(MeCN)][SbCl₆].¹⁴⁰ The former contains dimeric cations with Sb^{III}Cl(MeCN)₂ units bridged by two NPPh₃, whereas the latter is a mixed-valence cation with Sb^{III}Cl(MeCN) and Sb^VCl₄ units also bridged by two phosphine-iminato groups.

Unstable (often highly explosive) antimony azides have been synthesized recently.^{32,141} The parent Sb(N₃)₃ is made from AgN₃ and SbI₃ in MeCN, whilst reaction of [SbCl₄]⁺, [SbCl₄][–], and [SbCl₆][–] with TMSN₃ gave [Sb(N₃)₄]⁺, [Sb(N₃)₄][–], and [Sb(N₃)₆][–], respectively. Attempts to isolate [Sb(N₃)₅] were unsuccessful, although some Lewis base adducts [Sb(N₃)₅(L)] (L = py, NH₃, quinoline, etc.) are known.¹⁴²

3.6.3.2.2 P-, As-, and Sb-donor ligands

Early studies³² reported that PR₃ or AsR₃ formed 1:1 or rarely 2:1 adducts with SbX₃. A reinvestigation¹⁴³ of the reaction of PMe₃ and SbI₃ in THF identified the yellow product as [Sb₂I₆(PMe₃)₂]·THF which has a structure based upon two edge-linked square pyramidal SbI₄P units with apical phosphines arranged *anti* to the plane. Weaker Sb···I contacts link the molecules into a polymer. In contrast, the reaction of SbBr₃ and PET₃ in THF gave crystals of [PET₃H][Sb₂Br₇(PET₃)₂] which has the structure shown in Figure 18.¹⁴⁴ Bidentate diphosphines and diarsines (Me₂P(CH₂)₂PMe₂, *o*-C₆H₄(PMe₂)₂, *o*-C₆H₄(AsMe₂)₂, *o*-C₆H₄(PPh₂)₂, Ph₂As(CH₂)₂AsPh₂) form 1:1 complexes with SbX₃ (X = Cl, Br, or I), which are probably based upon edge-sharing dimers with *pseudo*-octahedral antimony centers.^{144,145} An alternative description is in terms of primary SbX₃ units with weaker secondary bonding to the group 15 donor and bridging halides. The structure has been established for [Sb₂Br₆{Me₂P(CH₂)₂PMe₂}₂] (Figure 19) and [Sb₂Br₆{*o*-C₆H₄(PPh₂)₂}₂]. A polymorph of the former has been identified,¹⁴⁴ which contains a central Sb₂Br₆{Me₂P(CH₂)₂PMe₂}₂ linked via single bromine bridges to two SbBr₃{Me₂P(CH₂)₂PMe₂} units. The 1:1 complexes of the triarsine MeC(CH₂AsMe₂)₃, [SbX₃{MeC(CH₂AsMe₂)₃}], may also be dimers.¹⁴⁵ Recrystallization of [Sb₂Cl₆{*o*-C₆H₄(AsMe₂)₂}₂] from hot ethanol gave the 1:1 which has a polymeric structure composed of [SbCl₂{*o*-C₆H₄(AsMe₂)₂}]⁺ and (SbCl₄)[–] units linked into sheets through Cl-bridges (Figure 20).¹⁴⁵ A discrete distorted octahedral anion is present in [Py₂H][SbI₄{Me₂P(CH₂)₂PMe₂}] formed by recrystallizing [SbI₃{Me₂P(CH₂)₂PMe₂}] from pyridine.¹⁴⁶

Adducts of Me₃Sb with SbI₃ and SbI₂Me have been characterized by X-ray crystallography. The former, isolated from THF solution as [Sb₂I₆(SbMe₃)₂(THF)₂], is a centrosymmetric dimer

Figure 18 The structure of the anion in [PET₃H][Sb₂Br₇(PET₃)₂] (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **1994**, 1753–1757).

Figure 19 The structure of $[\text{Sb}_2\text{Br}_6(\text{Me}_2\text{PCH}_2\text{CH}_2\text{PMe}_2)_2]$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **1994**, 1743–1751).

Figure 20 The structure of the asymmetric unit in $[\text{Sb}_2\text{Cl}_6\{o\text{-C}_6\text{H}_4(\text{AsMe}_2)_2\}]$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **2001**, 1007–1012).

based on a planar $\text{I}_2\text{Sb}(\mu^2\text{-I})_2\text{SbI}_2$ core with axial SbMe_3 and THF ligands arranged *anti* (Figure 21). The $\text{Sb}-\text{O}(\text{THF})$ bonds are weak, secondary interactions.¹⁴⁷ In contrast, in $[\text{SbI}_2\text{-Me}(\text{SbMe}_3)]$, which is formed by the spontaneous rearrangement of SbMe_2I in the presence or absence of solvent, the structure is based upon a *pseudo*-trigonal bipyramidal antimony with the lone pair, the Me group, and SbMe_3 occupying equatorial positions (Figure 22).^{148,149}

3.6.3.3 Group 16 Compounds

3.6.3.3.1 O-donor ligands

The crown ethers 12-crown-4, 15-crown-5, and 18-crown-6 form 1:1 adducts with SbCl_3 , all of which have structures based upon a pyramidal SbCl_3 unit with much weaker interactions to 4, 5, or 6 crown ether oxygens respectively, completing a half sandwich structure (Figure 23).^{38,150,151} The $[\text{SbCl}_3(15\text{-crown-5})]$ and $[\text{SbCl}_3(12\text{-crown-4})]$ have also been studied by EXAFS and these results are in good agreement with the single crystal X-ray data.¹⁵² The complex $[\text{SbCl}_2(18\text{-crown-6})][\text{SbCl}_6]$

Figure 21 The structure of $[\text{Sb}_2\text{I}_6(\text{SbMe}_3)_2(\text{THF})_2]$ (reproduced by permission of Wiley-VCH from *Z. Anorg. Allg. Chem.* **1998**, 624, 81–84).

Figure 22 The structure of $[\text{SbI}_2\text{Me}(\text{SbMe}_3)]$ (reproduced by permission of the Royal Society of Chemistry from *Chem. Commun.* **1994**, 875–876).

is formed by reaction of the crown ether with a mixture of SbCl_3 and SbCl_5 in MeCN .¹⁵³ The structure of the cation is shown in Figure 24 and is based upon primary coordination in a *pseudo*-trigonal bipyramid with axial oxygens, and notably these $\text{Sb}-\text{O}_{\text{transO}}$ are 0.2 Å shorter than the weak, secondary bonds to the other four oxygens. In marked contrast, $[\text{SbCl}(\text{15-crown-5})][\text{SbCl}_6]_2$ has a pentagonal pyramidal cation (Figure 25) with the lone pair occupying the vacant site *trans* to the chloride.¹⁵⁴ The complexes of dibenzo-24-crown-8 are neutral, of type $[(\text{SbX}_3)_2\{\text{dibenzo-24-crown-8}\}]$ ($\text{X} = \text{Cl}$ or Br).¹⁵⁵ The structure of the chloride derivative shows the two antimony atoms bonded to opposite sides of the crown via three chlorines and five oxygens. In the bromide species the coordination is also via three bromines, but only four oxygens.¹⁵⁵

The antimony(III) complexes of the maleonitriledithiolate derivatized crown ethers, $\text{mn-15S}_2\text{O}_3$ and $\text{mn-18S}_2\text{O}_4$ (**12**) have also been prepared.¹⁵⁶ In $[\text{SbCl}_3(\text{mn-15S}_2\text{O}_3)]$ the structure is of the half-sandwich type (Figure 26) with rather longer $\text{Sb}-\text{O}$ bonds than in the simple crown complexes

Figure 23 The structure of $[\text{SbCl}_3(18\text{-crown-6})]$ (reproduced by permission of Elsevier Science from *Inorg. Chim. Acta* **1990**, 167, 115–118).

Figure 24 The structure of $[\text{SbCl}_2(18\text{-crown-6})]^+$ (reproduced by permission of Wiley-VCH from *Z. Anorg. Allg. Chem.* **1992**, 618, 93–97).

Figure 25 The structure of $[\text{SbCl}(15\text{-crown-5})]^{2+}$ (reproduced by permission of Wiley-VCH from *Angew. Chem., Int. Ed. Engl.* **1992**, 31, 334–335).

and long Sb—S (ca. 3.4 Å). In $[\text{SbCl}_3(\text{mn-18S}_2\text{O}_4)]$ the sulfurs are uncoordinated and the Sb is bonded only to the four oxygens.¹⁵⁶ In contrast, the reaction of $\text{Na}[\text{SbCl}_6]$ with $\text{mn-18S}_2\text{O}_4$ produces $[\text{Na}(\text{mn-S}_2\text{O}_4)_2][\text{SbCl}_6]$ in which the Na ion is sandwiched between the two crowns and coordinated to the eight oxygens.¹⁵⁶

Figure 26 The structure of $[\text{SbCl}_3(\text{mn-15S}_2\text{O}_3)]$ (reproduced by permission of the publishers from *Z. Naturforsch., B* 1999, 54, 799–806).

pnictogen or chalcogen oxides, ethers or amides form O-bonded adducts with both SbCl_3 and SbCl_5 . Typical examples that have been characterized include $[\text{SbCl}_5\text{L}]$ ($\text{L} = \text{PyNO}$,¹⁵⁷ Me_3NO ,¹⁵⁷ $(\text{RO})_3\text{PO}$,^{138,139} Me_2O ,^{138,139} THF ,^{138,139} DMSO ,^{138,139,158}). The structure of $[\text{SbCl}_5(\text{DMSO})]$ shows the sulfoxide is O-bonded to Sb^{V} .¹⁵⁸ Spectroscopic studies show that the stabilities of these complexes follow Gutmann's donor numbers, and NMR studies are consistent with a dissociative ligand exchange mechanism.^{138,139} An organoantimony example is the cation in $[\text{Ph}_2\text{Sb}\{(\text{Me}_2\text{N})_3\text{PO}\}_2]\text{PF}_6$, made from PhSbCl_2 , $(\text{Me}_2\text{N})_3\text{PO}$, and TIPF_6 (the reaction is accompanied by a phenyl migration).¹²⁷ The structure of the cation is *pseudo*-trigonal bipyramidal with the lone pair and Ph groups equatorially disposed.

A variety of antimony(III) and antimony(V) alkoxides and mixed halo-alkoxides are known, the majority of which are oligomeric via asymmetric $\text{Sb}-\text{O}\cdots\text{Sb}$ bridges. The Sb^{III} examples include $[\text{Sb}(\text{OMe})_3]_n$ (six-coordinate Sb with a 3-D network—(13)),¹⁶⁰ $[\text{Sb}(\text{OPr}^i)_3]_2$ (four-coordinate Sb with a *pseudo*-trigonal bipyramidal geometry in a dimer—(14)),¹⁶¹ and $[\text{Sb}(2,6\text{-Me}_2\text{C}_6\text{H}_3\text{O})_3]$ (trigonal pyramidal monomer).¹⁶² The halo-alkoxides are also polymeric— $[\text{SbCl}(\text{OEt})_2]_n$, $[\text{SbCl}_2(\text{OEt})]_n$, and $[\text{SbCl}_2(\text{OEt})\cdot\text{NHMe}_2]_n$ contain six-coordinate antimony, whereas $[\text{SbCl}(\text{OPr}^i)_2]_2$ is five-coordinate.^{160,161,163,164} The Sb^{V} alkoxides which have been structurally characterized are based upon six-coordinate antimony. The simplest, $[\text{Sb}(\text{OMe})_5]_2$ is a dimer (Figure 27),¹⁶⁵ $[\text{Sb}(\text{OEt})_5(\text{NH}_3)]$ is monomeric (O_5N donor set),¹⁶² and $[\text{SbBr}_2\text{Me}(\text{OMe})_2]_2$ ¹⁶⁶ is dimeric with OMe bridges.

Antimony phenoxides are also readily prepared. Catechol (CatH_2 , $1,2\text{-C}_6\text{H}_4(\text{OH})_2$) and $\text{Sb}(\text{OPr}^i)_3$ form $[\text{Sb}(\text{cat})(\text{OPr}^i)_3]$ and $[\text{Sb}(\text{cat})(\text{catH})]$, the latter being converted on reaction with M^2OMe ($\text{M}^2 = \text{Li}$, Na , or K) into $\text{M}^2[\text{Sb}(\text{cat})_2]$.¹⁶⁷ The structure of $[\text{NH}_4][\text{Sb}(\text{cat})_2]$ reveals a *pseudo*-trigonal bipyramidal geometry with an equatorial lone pair.¹⁶⁷ The $[\text{PyH}][\text{Sb}(\text{o-C}_6\text{Cl}_4\text{O}_2)\text{Cl}_2]$ is also *pseudo*-trigonal bipyramidal with asymmetric chlorine bridges giving an

Figure 27 The structure of $[\text{Sb}(\text{OMe})_5]$ (reproduced by permission of Wiley-VCH from *Z. Anorg. Allg. Chem.* **1981**, 474, 157–170).

(13)

(14)

extended structure.¹⁶⁸ The antimony(V) species $[\text{SbCl}_4(\text{ACAC})]$ (ACAC = acetylacetonate) is a discrete six-coordinate complex.¹⁶⁹ Adducts of SbCl_5 with methoxyethanol, 1,2-ethanediol, and 1,2-dimethoxyethane are readily prepared, but the alcohol complexes are prone to elimination of HCl to give stibocycles.¹⁷⁰ Organoantimony halides also react with O-, or mixed O/N-donor ligands, for example, R_3SbBr_2 ($\text{R} = \text{Ph}$ or Me) react with LH (LH = acetylacetonate, 8-hydroxyquinoline, salicylaldehyde, 2-hydroxyacetophenone) and NaOMe in benzene/methanol to give $\text{R}_3\text{Sb}(\text{OMe})\text{L}$, which appear to be six-coordinate.¹⁷¹

Methanesulfonic anhydride ($\text{Me}_2\text{S}_2\text{O}_5$) dissolves Sb_2O_3 on prolonged heating to form $[\text{Sb}(\text{O}_3\text{SMe})_3]$, which reacts further with $\text{Cs}[\text{MeSO}_3]$ in MeSO_3H to give $\text{Cs}[\text{Sb}(\text{O}_3\text{SMe})_4]$.⁵⁸ In contrast to the well-characterized $[\text{As}(\text{OTeF}_5)_5]$ and $[\text{Bi}(\text{OTeF}_5)_5]$, $[\text{Sb}(\text{OTeF}_5)_5]$ is unstable and has not been isolated in a pure state.^{172,173} However, the anion $[\text{Sb}(\text{OTeF}_5)_6]^-$ has been made from $[\text{NR}_4][\text{SbCl}_6]$ and AgOTeF_5 in CH_2Cl_2 , or by formation of $[\text{Sb}^{\text{III}}(\text{OTeF}_5)_4]^-$ from $[\text{Sb}(\text{OTeF}_5)_3]$ and $[\text{NR}_4][\text{TeOF}_5]$ followed by oxidation with $[\text{Xe}(\text{OTeF}_5)_2]$.^{173,174} The $[\text{Sb}(\text{OTeF}_5)_6]^-$ is a useful addition to the list of “weakly coordinating” anions.¹⁰³ Antimony(III) fluoride-fluorosulfates, $[\text{SbF}_2(\text{SO}_3\text{F})]$, $[\text{SbF}(\text{SO}_3\text{F})_2]$, and $[\text{Sb}(\text{SO}_3\text{F})_3]$, have been synthesized and characterized structurally.¹⁷⁵ The first is obtained from Sb and HSO_3F , the others from Sb and $\text{S}_2\text{O}_6\text{F}_2$ under appropriate conditions, and the structures of all three reveal triply bridging O-bound fluorosulfate groups.¹⁷⁵ Oxidation of elemental Sb with a large excess of $\text{S}_2\text{O}_6\text{F}_2$ in the presence of CsSO_3F gives $\text{Cs}[\text{Sb}(\text{SO}_3\text{F})_6]$, which has a discrete octahedral anion.^{176,177} Oxidation of SbF_3 with $\text{S}_2\text{O}_6\text{F}_2$ yields Sb^{V} fluoride-fluorosulfates $[\text{SbF}_3(\text{SO}_3\text{F})_2]$, $[\text{SbF}_4(\text{SO}_3\text{F})]$, and $[\text{Sb}_2\text{F}_9(\text{SO}_3\text{F})]$.¹⁷⁸

Antimony(V) forms complexes with organophosphorus acids.^{179–186} These include $[\{\text{SbCl}_4(\text{O}_2\text{PR}_2)_2\}_2]$ ($\text{R} = \text{Me}, \text{Cl}, \text{OPh}, \text{OMe}$) made from SbCl_5 and the acid in methanol,^{179,180,182} which are oxo-bridged dimers (Figure 28). Other examples are $[\text{Cl}_3\text{Sb}(\text{O})\{\text{R}(\text{MeO})\text{PO}_2\}(\text{OMe})\text{SbCl}_3]$, ($\text{R} = 4\text{-ClC}_6\text{H}_4\text{CH}_2, \text{Me}, \text{Et}, \text{PhCH}_2\text{CH}_2\text{O}_2\text{NC}_6\text{H}_4\text{CH}_2$) $[\text{Cl}_3\text{Sb}(\text{O})\{(\text{PhO})_2\text{PO}_2\}_2\text{SbCl}_3]$, and

$[\text{Cl}_3\text{Sb}(\text{O})\{(\text{PhO})_2\text{PO}_2\}(\text{OMe})\text{SbCl}_3]$,^{183–186} which also contain bridging organophosphorus anions. Organoantimony(V) phosphinates include $[\{\text{Ph}_2\text{SbCl}(\text{O}_2\text{PR}_2)\}_2\text{O}]$ ($\text{R} = \text{c-hexyl, c-octyl}$), made from Ph_2SbCl_3 , $\text{Ag}(\text{MeCO}_2)$, and $\text{R}_2\text{PO}_2\text{H}$,^{187,188} which have the structure shown in Figure 29. A tetramer of the dicyclohexylphosphinate complex has also been characterized structurally.¹⁸⁸ Triorganoantimony species $[\text{R}^1_3\text{Sb}(\text{O}_2\text{PR}^2_2)_2]$ are made from R^1_3SbX_2 and the silver salt of phosphinic acid,^{189–191} and partial hydrolysis produces $[\text{R}^1_3\text{Sb}(\text{OH})(\text{O}_2\text{PR}^2_2)]$, which may also be obtained directly from $\text{R}^1_3\text{Sb}(\text{OH})_2$ and $\text{R}^2_2\text{PO}_2\text{H}$. There are also oxo-bridged complexes of type $[\{\text{R}^1_3\text{Sb}(\text{O}_2\text{PMe}_2)\}_2\text{O}]$ ($\text{R}^1 = \text{Ph, } o\text{-tolyl}$), $[\{\text{Ph}_3\text{Sb}(\text{O}_2\text{AsR}^2_2)\}_2\text{O}]$ ($\text{R}^2 = \text{Me or Ph}$) and $[(\text{R}_2\text{Sb})_2(\text{O})_2(\text{O}_2\text{AsMe}_2)_2]$ (Figure 30).¹⁹²

Figure 28 The structure of $[\{\text{SbCl}_4(\text{O}_2\text{PMe}_2)\}_2]$ (reproduced by permission of Wiley-VCH from *Z. Anorg. Allg. Chem.* **1981**, 472, 102–108).

Figure 30 The structure of $[(\text{Ph}_2\text{Sb})_2(\text{O})_2(\text{O}_2\text{AsMe}_2)_2]$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **1997**, 2785–2792).

There is a substantial literature dealing with antimony carboxylates and polyaminocarboxylates. 1,2-Dihydroxycyclohexane-1,2-dicarboxylic acid (both \pm and *meso* forms) form $\text{Na}_2[\text{Sb}_2(\text{C}_8\text{H}_8\text{O}_6)_2] \cdot x\text{H}_2\text{O}$ which are dinuclear in solution.⁵⁶ In the medically important antimony tartrates the usual building block is the dimeric anion **(15)** found in alkali and alkaline earth metal salts.^{193,194} The silver(I) complex $[\text{Ag}_4\text{Sb}_4(\text{C}_4\text{H}_2\text{O}_6)_4(\text{H}_2\text{O})_4]$ contains this repeating tetramer unit linked into a polymeric network.¹⁹⁵ Antimony(III) citrates also exhibit a range of building blocks. In $\text{Li}[\text{Sb}(\text{C}_6\text{H}_6\text{O}_7)_2(\text{H}_2\text{O})] \cdot 2\text{H}_2\text{O}$ and $\text{Na}[\text{Sb}(\text{C}_6\text{H}_6\text{O}_7)_2(\text{H}_2\text{O})_2] \cdot \text{H}_2\text{O}$ the antimony has a *pseudo*-trigonal bipyramidal geometry with the lone pair equatorial, and two citrate anions each coordinating via one deprotonated carboxylate and one deprotonated hydroxy group.^{196,197} The same basic antimony coordination is present in the isostructural $\text{M}_2[\text{Sb}_4(\text{C}_6\text{H}_4\text{O}_7)_2(\text{C}_6\text{H}_5\text{O}_7)_2(\text{C}_6\text{H}_6\text{O}_7)_4(\text{H}_2\text{O})_2]$ ($\text{M} = \text{K}$ or Rb)^{56,197} which are based upon tetrameric units with three differently charged citrate anions (Figure 31), in $\text{Ag}_2[\text{Sb}_2(\text{C}_6\text{H}_6\text{O}_7)_4]$ ¹⁹⁶ and $\text{Cu}[\text{Sb}(\text{C}_6\text{H}_6\text{O}_7)(\text{C}_6\text{H}_5\text{O}_7)(\text{H}_2\text{O})_2] \cdot 2\text{H}_2\text{O}$.¹⁹⁸

Antimony(III) polyaminocarboxylates have also been studied in considerable detail.^{199–205} In the EDTA^{4-} complexes the antimony is coordinated to two N- and four O-donors generating a *pseudo*-pentagonal bipyramid with the seventh vertex occupied by the lone pair. With hard, small cations (Li or Na) the lone pair usually occupies an equatorial position, whereas with large, soft cations (NR_4 , Cs, aminoguanidinium) the lone pair is axially disposed. However, there is also evidence that H-bonding and packing interactions may affect the geometries adopted. Some of these metal complexes are useful precursors to metal-antimony oxides via pyrolysis in air. The propylenediaminetetra-acetate⁴⁻ (PDTA^{4-}) complexes, $\text{M}[\text{Sb}(\text{PDTA})] \cdot \text{H}_2\text{O}$ ($\text{M} = \text{H}$, NH_4 , or

Figure 31 The structure of the citrate complex $\text{Rb}_2[\text{Sb}_4(\text{C}_6\text{H}_4\text{O}_7)_2(\text{C}_6\text{H}_5\text{O}_7)_2(\text{C}_6\text{H}_6\text{O}_7)_4(\text{H}_2\text{O})_2]$ (reproduced by permission of the Australian Chemical Society from *Aust. J. Chem.* **2000**, 53, 917–924).

Figure 32 The structure of the propylenediaminetetracetate complex $[\text{Sb}(\text{PDTA})]^-$ (reproduced by permission of Elsevier Science from *Inorg. Chim. Acta* **1995**, 232, 161–165).

Na), also contain *pseudo*-pentagonal bipyramidal anions with an axial lone pair (Figure 32).^{206,207} *Pseudo*-seven-coordinate antimony (six O/N-donors and a lone pair) is also present in complex anions derived from 1,2-cyclohexanediamine-*N,N,N',N'*-tetra-acetic acid,^{208,209} diethylenetriamine-penta-acetic acid,^{210–212} and triethylenetetraminehexa-acetic acid.²¹³ Several of these complexes show anti-tumor activity, which appears to vary with the fine detail of the geometry.

3.6.3.3.2 S-, Se-, and Te-donor ligands

Antimony(III) halides behave as weak Lewis acids towards neutral sulfur or selenium donor ligands. The products have a wide variety of structures but these are mostly built upon a pyramidal SbX_3 unit, which forms weak secondary bonds to the neutral donor and sometimes, weak asymmetric halide bridges. The antimony environments are often very asymmetric due to a combination of the constraints imposed by the ligands and varying degrees of stereochemical activity by the lone pair.²¹⁴ The reaction of SbX_3 ($\text{X} = \text{Cl}, \text{Br}, \text{or I}$) with $\text{MeE}(\text{CH}_2)_n\text{EMe}$ ($n = 2$ or 3), $\text{MeC}(\text{CH}_2\text{EMe})_3$ ($\text{E} = \text{S or Se}$), $[\text{8}]_{\text{aneSe}_2}$, $[\text{12}]_{\text{aneS}_4}$, and $[\text{16}]_{\text{aneS}_4}$ forms yellow, orange, or red complexes with a 1:1 stoichiometry.^{214–216} $[\text{SbCl}_3\{\text{MeS}(\text{CH}_2)_2\text{SMe}\}]$ contains distorted octahedral antimony coordination based upon three terminal Cl and three S atoms from different dithioethers; of the three-coordinated S atoms, two bridge to neighboring antimony centers using both lone pairs available on S, and one is terminal, generating a 2-D network. The structure of $[\text{SbBr}_3\{\text{MeS}(\text{CH}_2)_3\text{SMe}\}]$ (Figure 33) is similar.²¹⁵ In contrast, the structure of $[\text{SbCl}_3\{\text{MeSe}(\text{CH}_2)_3\text{SeMe}\}]$ is based upon weakly associated Sb_2Cl_6 dimers linked by bridging diselenoethers (Figure 34). The tripodal tridentate $\text{MeC}(\text{CH}_2\text{SMe})_3$ forms a 1:1 complex with SbCl_3 which is essentially five-coordinate with bridging bidentate trithioether ligands forming infinite chains.²¹⁶ In contrast, the $[\text{SbI}_3\{\text{MeC}(\text{CH}_2\text{SMe})_3\}]$ is based upon six-coordinate antimony with Sb_2I_6 dimers linked into chains by bridging thioethers.²¹⁶ The selenoether $[\text{SbBr}_3\{\text{MeC}(\text{CH}_2\text{SeMe})_3\}]$ is different again, with octahedral *fac* SbBr_3Se_3 units, with the selenoether ligands bidentate to one antimony and monodentate to a second.

In $[\text{SbCl}_3\{[\text{9}]_{\text{aneS}_3}\}]$ there is seven-coordinate antimony, based upon three terminal chlorines, three sulfur donors from one macrocycle, and a bridging S atom from a neighboring molecule, producing a chain structure (Figure 35).²¹⁷ In contrast, $[\text{SbI}_3\{[\text{9}]_{\text{aneS}_3}\}]$, which involves the more sterically demanding iodo ligands, is a discrete octahedron with no significant evidence for a stereochemically active lone pair.²¹⁸ The complexes of $[\text{14}]_{\text{aneS}_4}$ are of 2:1 Sb:ligand stoichiometry, and the structure of the bromide derivative shows (Figure 36) weakly associated Sb_2Br_6 units with distorted octahedral coordination completed by *cis* S_2 -coordination at each antimony from different tetrathioethers.²¹⁶ The macrocyclic tetraselenoether complex $[(\text{SbBr}_3)_2\{[\text{16}]_{\text{aneSe}_4}\}]$ has a sheet structure²¹⁵ based upon each selenium atom bonded to a different SbBr_3 unit which are five-coordinate (Br_3Se_2). Finally, in $[(\text{SbCl}_3)_2\{[\text{18}]_{\text{aneS}_6}\}]$ there are two SbCl_3 units each coordinated to three sulfur atoms and disposed on opposite sides of the mean plane of the macrocycle.²¹⁷ Complexes with a $[\text{SbX}_3(\text{L})]$ stoichiometry have been obtained for $\text{L} = \text{MeTe}(\text{CH}_2)_3\text{TeMe}$ or $\text{MeC}(\text{CH}_2\text{TeMe})_3$, but their structures are not yet known.²¹⁴

Figure 33 The polymeric structure of $[\text{SbBr}_3\{\text{MeS}(\text{CH}_2)_3\text{SMe}\}]$ (reproduced by permission of the Royal Society of Chemistry from *Chem. Commun.* **2001**, 95–96).

Figure 35 The structure of $[\text{SbCl}_3\{[9]\text{aneS}_3\}]$ (reproduced by permission of the Royal Society of Chemistry from *Chem. Commun.* **1991**, 271–272).

A variety of other neutral sulfur ligands form adducts with SbX_3 including thioureas, thiones, and thiophenes,^{215–222} most of which appear to contain five-coordinate, *pseudo*-octahedral antimony with a stereochemically active lone pair. Dithio-oxamides ($\text{RHNC}(\text{S})\text{C}(\text{S})\text{NHR}$); $\text{R} = \text{Me}$, Et , Pr^i , Bu^n , $c\text{-C}_6\text{H}_{11}$) form $[\text{SbX}_3(\text{ligand})_{1.5}]$ ($\text{X} = \text{Cl}$, Br) in which each ligand is bound to two antimony centers via bidentate (S_2) bridging and the lone pair on antimony is not stereochemically active,^{224,225} whereas dithiomalonamides ($\text{RHNC}(\text{S})\text{CH}_2\text{C}(\text{S})\text{NHR}$) chelate, producing *pseudo*-octahedral complexes in which the lone pair clearly occupies one vertex.²²⁶ In $[\text{Sb}_2\text{Br}_6(\text{SPPH}_3)_2]$ and $[\text{Sb}_2\text{I}_6(\text{SePPH}_3)_2]$, prepared from the constituents in CH_2Cl_2 ,²²⁷ there are centrosymmetric halide-bridged dimers, and it appears that intramolecular $\text{Sb}\cdots\text{Ph}$ contacts complete the six-coordination about antimony. In contrast, $[\{\text{SbBr}_3(\text{SPMe}_2\text{Ph})\}_4]$ is a tetramer with both Br and S bridges (Figure 37).²²⁷

Antimony has a great affinity for charged sulfur ligands which include thiolates, xanthates (ROCS_2^-), dithiocarbamates (R_2NCS_2^-), and dithiophosphates ($(\text{RO})_2\text{PS}_2^-$).⁵⁶ In contrast to arsenic, where this chemistry is limited to oxidation state III, antimony forms compounds in oxidation states III and V. The xanthate, dithiocarbamate, and dithiophosphate complexes are mostly made by reaction of antimony(III) halides or organohalides with Na , NH_4 , or Ag salts of the acids. Complexes

Figure 36 The asymmetric unit (a) and the 3-D network (b) of $[(\text{SbBr}_3)_2\{[14]\text{aneS}_4\}]$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **2001**, 1621–1627).

reported in the last 20 years are listed in Table 2. The coordination of the dithioacid is often asymmetric and the geometry at the antimony center is distorted both by the constraints of the ligand structure and the effect of the lone pair. For example, in $[\text{SbBr}(\text{S}_2\text{COEt})_2]$ ²³⁰ the structure is a zig-zag chain polymer with antimony in an S_4Br_2 environment. However, in $[\text{PhSb}(\text{S}_2\text{COEt})_2]$ there is one Sb—C and two Sb—S primary bonds, two weaker Sb—S secondary bonds from the asymmetrically chelated xanthate, and a weak intermolecular $\text{Sb}\cdots\text{S}$ contact.²³² In $[\text{Sb}(\text{oxine})_2(\text{S}_2\text{COEt})]$, which is a *pseudo*-pentagonal bipyramid ($\text{N}_2\text{O}_2\text{S}_2$ plus the lone pair), the xanthate is close to symmetrically chelated. This contrasts with the very asymmetric coordination in $[\text{Sb}(\text{S}_2\text{COEt})_3]$ where the Sb—S bonds within each chelate differ by ca. 0.5 Å.²²⁹

Structures have also been determined for a variety of dithiocarbamate complexes, the dithiocarbamate groups usually coordinating as bidentate chelates containing markedly different Sb—S bond

Figure 37 The tetrameric structure of [SbBr₃(SPMe₂Ph)] (reproduced by permission of the publishers from *Z. Naturforsch., B* **1990**, 45, 1355–1362).

lengths.^{74,76,240,243–245} The tris(*N,N'*-iminodiethanoldithiocarbamato)antimony is best described as a distorted pentagonal pyramid (Figure 38), which contrasts with the trigonal antiprismatic arsenic analogue.⁷⁴ The halo-dithiocarbamates [Sb(S₂CNEt₂)₂I],²⁴⁶ and [Sb(S₂CNC₅H₈)₂I]²⁴⁷ have infinite chain structures with chelating dithiocarbamates and iodide bridges (Figure 39).

Similarly, the tris(dithiophosphate) complexes are based upon distorted octahedra with the differences in Sb—S within each ligand being up to 0.5 Å, and with the lone pair capping the open face associated with the long Sb—S bonds.^{252,254} The [PhSb{S₂P(OPrⁱ)₂}₂] is square pyramidal and isostructural with its arsenic analogue.⁸² The diphenyldithiophosphinate complex, [Ph₂Sb(S₂PPh₂)], is a dimer with square-pyramidal antimony centers (Figure 40),²⁵⁵ but [Ph₂Sb(Y)] (Y = O₂PPh₂ or OSPPH₂) are *pseudo*-trigonal bipyramidal polymers (Figure 41).^{257,259}

In contrast to other group 15 elements, antimony also forms dithioacid complexes in oxidation state V, although even these are readily reduced. Triorgano-dithiophosphate, -dithiocarbamate, and -xanthate complexes, [SbR₃(dithioanion)₂], are prepared from SbR₃Cl₂ and the sodium salt of the dithioacid^{180,237,261,262} These have trigonal bipyramidal structures with equatorial R groups and monodentate, axially bound dithioanions (Figure 42). Notably, in the related [SbMe₃(OSPPH₂)₂] the anions are O-bonded to Sb^V.²⁶¹

Antimony(III) also has a high affinity for thiolate ligands. The [Sb(SR)₃] complexes are formed by simple SR[−] ligands including SPh[−], S(4-MeC₆H₄)[−], S(3,5-Me₂C₆H₃)[−], S(2,4,6-Me₃C₆H₂)[−], S(2,4,6-Prⁱ₃C₆H₂)[−], and there are more complex variants such as [Sb₂(SCH₂CH₂SCH₂CH₂S)₃].^{265–268} Their syntheses are usually straightforward, from Li(Na)SR and SbCl₃, although other routes such as reaction of RSH with Sb(OR)₃ or Sb(NR₂)₃ are also used. The structures are based upon trigonal-pyramidal coordination at antimony (Figure 43) and with the smaller R-groups, weaker secondary interactions either intermolecular to other thiolate sulfur atoms or to aryl rings. The bulkier thiolate complexes are effectively three coordinate monomers.

Toluene-2,3-dithiol (tdtH₂) reacts with SbCl₃ to form [SbCl(tdt)] which is probably trigonal pyramidal like the As analogue (q.v.).⁹⁰ A 1:2 SbCl₃:tdtH₂ reaction ratio formed yellow [Sb(tdt)(tdtH)] from which base removes the final proton, but the product is the purple Sb^V

Figure 38 The structure of $[\text{Sb}\{\text{S}_2\text{CN}(\text{CH}_2\text{CH}_2\text{OH})_2\}_3]$ (reproduced by permission of Elsevier Science from *Polyhedron* **1997**, 16, 1211–1221).

anion, $[\text{Sb}(\text{tdt})_3]^-$, presumably formed by air oxidation.⁹⁰ The $[\text{Sb}(\text{tdt})_3]^-$ has an octahedral geometry, although the Sb—S distances span 0.16 Å. Similar reactions using the Li salt of benzene-1,2-dithiol in the absence of air gave yellow $\text{Li}[\text{Sb}(o\text{-C}_6\text{H}_4\text{S}_2)_2]$ which was shown to be a *pseudo*-trigonal bipyramid (Figure 44) and which reacted with further dithiol in dry oxygen to form the purple $[\text{Sb}\{o\text{-C}_6\text{H}_4\text{S}_2\}_3]^-$.²⁶⁹ 2-Pyridinethiol forms $[\text{Sb}(\text{C}_5\text{H}_4\text{NS})_3]$, the structure of which shows a trigonal pyramidal SbS_3 unit (Sb—S = 2.472(2) Å), with weak association of the nitrogens (Sb \cdots N = 2.830(2) Å).²⁷⁰ 2-Aminothiophenol ($o\text{-C}_6\text{H}_4\text{SH}(\text{NH}_2)$) forms $[\text{Sb}\{o\text{-C}_6\text{H}_4\text{S}(\text{NH}_2)\}_3]$ which is probably similar.²⁷¹ The $[\text{Sb}\{\text{S}-(2,4,6\text{-Me}_3\text{C}_6\text{H}_2)\}_2]$ has been isolated from the reaction of $[\text{SbI}(\text{OEt})_2]$ with the thiol.²⁶⁵

There is a more limited number of selenolate and telluroate analogues including $[\text{Sb}\{\text{Se}(2,4,6\text{-R}_3\text{C}_6\text{H}_2)\}_3]$ (R = Me, Prⁱ, Buⁱ),²⁶⁷ $[\text{Sb}\{\text{SeSi}(\text{SiMe}_3)_3\}_3]$,²⁷² and $[\text{Sb}\{\text{TeSi}(\text{SiMe}_3)_3\}_3]$.²⁷²

4,5-Dithio-1,3-dithiole-2-thione (dmitH₂) (**16**) complexes of Sb^{III} have been prepared from $[\text{Zn}(\text{dmit})_2]^{2-}$, SbBr₃, and NaNCS in acetone, and have been isolated with a variety of cations.^{273,274} The structure is based upon a *pseudo*-trigonal bipyramidal anion with an equatorial lone pair. The cations present control intermolecular Sb \cdots S interactions: in the $[\text{Et}_4\text{N}]^+$ salt two additional Sb \cdots S interactions lead to a *pseudo*-pentagonal bipyramidal arrangement in a 2-D network, whereas with $[\text{1,4-dimethylpyridinium}]^+$ dimers are present. The reaction of $[\text{Zn}(\text{dmit})_2]^{2-}$, SbI₃, and I₂ in dry THF produced black $[\text{Sb}(\text{dmit})_3]^-$ which contains octahedral anions, linked into a 3-D structure by S \cdots S contacts.²⁷⁵ In $[\text{PhSb}(\text{dmit})]\cdot\text{THF}$, prepared from Na₂dmit and PhSbCl₂, there is a *pseudo*-pentagonal bipyramidal arrangement based upon a chelated dmit, O-coordinated THF, the lone pair, and secondary Sb \cdots S intermolecular contacts.²⁷⁶ In the antimony(V) compounds, $[\text{R}_2\text{Sb}(\text{dmit})_2]^-$ (R = Ph, *p*-tolyl) the R groups occupy *cis* positions on a slightly distorted octahedron.²⁷⁷

(16)

Figure 39 The polymeric chain in $[\text{Sb}(\text{S}_2\text{CNEt}_2)_2\text{I}]\cdot\text{CHCl}_3$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **1981**, 1360–1365).

The only example of a diselenolate complex is $[\text{Sb}(\text{mns})_2]^{3-}$ ($\text{mns} = [\text{Se}_2\text{C}_2(\text{CN})_2]^{2-}$) made by combination of K, Sb_2Se_3 , and Se in liquid ammonia in the presence of [2,2,2]crypt, followed by extraction with MeCN.²⁷⁸ The anion is tetrahedral with formally Sb^{I} , although presumably the ligand is “noninnocent.” Curiously, the corresponding reaction with arsenic gives an As^{V} selenide, $[\text{AsSe}_3(\text{CH}_2\text{CN})]^{2-}$.²⁷⁸

There has been much recent interest in the synthesis and structures of antimony polychalcogenides. There are two comprehensive reviews^{279,280} of these compounds which also place their structures in the context of those of related elements, and these should be consulted for details of work pre-1998. Examples reported since then include $[\text{Sb}_3\text{S}_5]^-$, $[\text{Sb}_4\text{S}_7]^-$, $[\text{Sb}_4\text{S}_8]^{4-}$, $[\text{Sb}_2\text{S}_5]^{4-}$, $[\text{Sb}_3\text{S}_{25}]^{3-}$, and $[\text{Sb}_2\text{S}_{15}]^{2-}$.^{281–284} The stoichiometries provide little guide to the molecular units present or the connectivities. For example, in the material of stoichiometry $[\text{PPh}_4]_3[\text{Sb}_3\text{S}_{25}]$, two quite different polythioantimonate ions are present, $[\text{Sb}_2\text{S}_{17}]^{2-}$ and $[\text{Sb}_2\text{S}_{16}]^{2-}$ (Figure 45).²⁸¹

3.6.3.4 Group 17 Ligands

The haloanions of Sb^{III} have a surprisingly wide range of stoichiometries and structures, and several different structural motifs have been identified for particular $\text{Sb}:\text{X}$ stoichiometries. In the

Figure 40 The structure of [Ph₂Sb(S₂SPPH₂)] (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **1986**, 1031–1034).

larger anions, there is often asymmetric halide bridging and the distinction between intra- and intermolecular Sb···X is not always clear. Most of the interest resides in the solid-state structures, and the aim here has been to summarize the major types known, giving representative references. Some of the anions with the heavier halides exhibit a variety of phases which show ferroelectric or ferroelastic behavior. The field has been reviewed twice.^{91,285}

Figure 42 The structure of $[\text{SbMe}_3(\text{S}_2\text{PPh}_2)_2]$ (reproduced by permission of Taylor & Francis Ltd. from *Main Group Met. Chem.* **1995**, 18, 387–390).

Figure 43 The structure of $[\text{Sb}(\text{SC}_6\text{H}_4\text{Me-4})_3]$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **1995**, 2129–2135).

Much of the systematics of the Sb^{III} fluoroanions were established pre-1980, including identification of $[\text{SbF}_4]^-$, $[\text{Sb}_2\text{F}_7]^-$, $[\text{Sb}_3\text{F}_{10}]^-$, and $[\text{Sb}_4\text{F}_{13}]^-$ and this work has been discussed by Sawyer and Gillespie.²⁸⁵ There are also mixed-valence $\text{Sb}^{\text{III}}\text{--Sb}^{\text{V}}$ fluoro-anions and cations, obtained from $\text{SbF}_3 + \text{SbF}_5$, by fluorination of Sb under controlled conditions, or during the syntheses of homoatomic cations of group 16 or 17 in superacid media containing SbF_5 .²⁸⁵ Further examples of the mixed-valence materials include Sb_7F_{29} ($=3\text{SbF}_3 \cdot 4\text{SbF}_5$, which is structurally described as $[\text{Sb}^{\text{III}}\text{F}][\text{Sb}^{\text{III}}\text{F}_2]_2[\text{Sb}^{\text{V}}\text{F}_6]_4$),²⁸⁶ $\text{Sb}_{11}\text{F}_{43}$ ($=6\text{SbF}_3 \cdot 5\text{SbF}_5$, $[\text{Sb}^{\text{III}}_6\text{F}_{13}][\text{Sb}^{\text{V}}\text{F}_6]_5$),²⁸⁷ and two forms of Sb_8F_{30} ($[\text{Sb}^{\text{III}}_5\text{F}_{12}][\text{Sb}^{\text{V}}\text{F}_6]_3$)²⁸⁸ and $[\text{Sb}^{\text{III}}_2\text{F}_3][\text{Sb}^{\text{III}}_3\text{F}_7][\text{Sb}^{\text{V}}\text{F}_6]_3$).²⁸⁹ (The formulations given are those of the authors, and those adopted for the cations involve a subjective judgment between intra- and intermolecular $\text{Sb}^{\text{III}}\text{--F}$ bond lengths.) Typical of the complex products obtained with group 16 homoatomic cations are $[[\text{S}_8][\text{Sb}_3\text{F}_{14}][\text{SbF}_6]]$ and $[[\text{S}_4][\text{Sb}_2\text{F}_4][\text{Sb}_2\text{F}_5][\text{SbF}_6]_5]$.²⁹⁰

The simplest fluoroantimonate, $[\text{SbF}_4]^-$ is found in $[\text{NMe}_4]^+$,²⁹¹ guanidinium⁺,²⁹² and $[\text{H}_3\text{NCH}_2\text{CH}_2\text{NH}_3]^{2+}$ salts;²⁹³ it has the expected *pseudo*-trigonal bipyramidal geometry, with an equatorial lone pair and longer axial ($\text{av} = 2.015 \text{ \AA}$) than equatorial ($\text{av} = 1.906 \text{ \AA}$) Sb--F

Figure 44 The structure of $[\text{Sb}(1,2\text{-S}_2\text{C}_6\text{H}_4)_2]^-$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **1994**, 1213–1218).

bonds.²⁹¹ Larger fluoroantimonate(III) anions include $[\text{H}_4([14]\text{aneN}_4)][\text{Sb}_4\text{F}_{16}]$, which contains tetrameric anions (Figure 46), $[\text{H}_2([14]\text{aneN}_4)][\text{Sb}_2\text{F}_{10}] \cdot 2\text{HF}$ (Figure 47), $[\text{H}_4([14]\text{aneN}_4)]_2\text{-}[\text{Sb}_4\text{F}_{15}][\text{HF}_2]\text{F}_4$,²⁹⁴ $[\text{NH}_4]_3[\text{Sb}_4\text{F}_{15}]$, and $\text{Cs}_3[\text{Sb}_4\text{F}_{15}]$ which have different structures,²⁹⁵ and $\text{NaCs}_3[\text{Sb}_4\text{F}_{16}] \cdot \text{H}_2\text{O}$.²⁹⁶

The simplest stoichiometry for a chloroantimonate(III) is $[\text{SbCl}_4]^-$, but this is usually found in dimer or polymer units. The $[\text{Sb}_2\text{Cl}_8]^{2-}$ anion, composed of edge-sharing square pyramidal units with the apical chlorides *anti*, is found in the $[\text{Bu}^t\text{H}_3\text{N}]^+$,²⁹⁷ $[\text{Pr}_4\text{N}]^+$,²⁹⁸ and $[1,1'\text{-Me}_2\text{-4,4'\text{-bipyridinium}}]^{2+}$ ²⁹⁹ salts, the last containing two crystallographically distinct anions which differ significantly in the asymmetry of the bridges. Curiously, in $[\text{Bu}^n_4\text{N}]_2[\text{Sb}_2\text{Cl}_8]$, which is also an edge-shared dimer, the apical chlorines are *syn* not *anti*.²⁹⁸

Polymeric zig-zag chains composed of distorted SbCl_6 units sharing adjacent edges are present in $[\text{Mg}(\text{MeCN})_6][\text{SbCl}_4]_2$,³⁰⁰ $[\text{Fe}([9]\text{aneS}_3)_2][\text{SbCl}_4]_2$,³⁰¹ $[\text{Fe}(\text{Cp})_2]_2[\text{SbCl}_4]_2[\text{SbCl}_3]$,³⁰² and $[N,N',N'',N'''\text{-Me}_4\text{-guinidinium}][\text{SbCl}_4]$.³⁰³ Examples of $[\text{Sb}_4\text{Cl}_{16}]^{4-}$ units include those with $[\text{Et}_4\text{N}]^+$ (Figure 48)²⁹⁸ and $[\text{EtMe}_2\text{PhN}]^+$,³⁰⁴ whilst the $[\text{H}_2\text{thiamine}]^{2+}$ salt contains a chain of four antimony atoms $[\text{Cl}_3\text{Sb}(\mu\text{-Cl})_2\text{SbCl}_2(\mu\text{-Cl})_2\text{SbCl}_2(\mu\text{-Cl})_2\text{SbCl}_3]^{4-}$, the outer two being five-coordinate.³⁰⁵

The mononuclear $[\text{SbCl}_5]^{2-}$ unit, with a square-pyramidal geometry, is present in $[\text{NEt}_4]^+$ ³⁰⁶ and $[\text{HMe}_2\text{NCH}_2\text{CH}_2\text{NH}_3]^{2+}$ ³⁰⁷ salts, whilst the edge-shared bi-octahedral $[\text{Sb}_2\text{Cl}_{10}]^{4-}$ was isolated with $[\text{H}_2\text{thiamine}]^{2+}$ cations.³⁰⁸ Polymeric chains based upon vertex-linked SbCl_6 octahedra are present in $[\text{NMe}_2\text{H}_2]_2[\text{SbCl}_5]$,³⁰⁹ $[\text{C}_5\text{H}_{12}\text{N}]_2[\text{SbCl}_5]$,³¹⁰ and $[4,4'\text{-bipyridinium}][\text{SbCl}_5]$.³¹¹ However, in $[2,2'\text{-bipyridinium}][\text{SbCl}_5]$ there is a tetrameric unit (Figure 49).³¹¹ The well-known hexachloroantimonate(III), $[\text{SbCl}_6]^{3-}$, is close to a regular octahedron with a stereochemically inactive lone pair.²⁹⁸

The $[\text{Sb}_2\text{Cl}_9]^{3-}$ ion is known both as a discrete confacial bioctahedron as in $[\text{H}_2([9]\text{aneN}_3)]_2[\text{Sb}_2\text{Cl}_9]\text{Cl} \cdot \text{MeCN}$,¹⁸ and as a polymer in $[\text{Y}]_3[\text{Sb}_3\text{Cl}_9]$ ($\text{Y} = \text{Hpy}$ or $\text{C}(\text{NH}_2)_3$).^{312,313} Two examples of the $[\text{Sb}_2\text{Cl}_{11}]^{5-}$ anion have been structurally characterized, both of which contain octahedral SbCl_6 units sharing a vertex.^{161,314} The largest discrete chloroantimonate(III) anion is in $[\text{Me}_4\text{N}]_4[\text{Sb}_8\text{Cl}_{28}]$, which consists of eight face-sharing octahedra.³¹⁵ Bromoantimonate(III) anions mostly resemble the chloro-analogues. Structurally characterized examples include the $[\text{PPh}_4]_2[\text{Sb}_2\text{Br}_8]$ (edge-shared dimer with *anti* disposed apical Br),^{227,316} $[4\text{-MeC}_5\text{H}_4\text{NH}]_2[\text{SbBr}_5]$ (dimer),³¹⁷ and $[\text{H}_3\text{N}(\text{CH}_2)_6\text{NH}_3][\text{SbBr}_5]$ (*cis* edge-linked polymer).³¹⁸

Figure 45 The structures of $[\text{Sb}_2\text{S}_{17}]^{2-}$, $[\text{Sb}_2\text{S}_{16}]^{2-}$, and $[\text{Sb}_2\text{S}_{15}]^{2-}$ (reproduced by permission of Wiley-VCH from *Z. Anorg. Allg. Chem.* **1998**, 624, 310–314).

For the $[\text{Sb}_2\text{Br}_9]^{3-}$ type, those with $[\text{NMe}_4]^+$,³¹² and $[\text{EtMe}_2\text{PhN}]^+$,³¹⁹ are confacial bioctahedra which contrast with the polymer structure present in $[\text{Hpy}]_3[\text{Sb}_2\text{Cl}_9]$ (above). Hall *et al.*³¹² also prepared $[\text{Hpy}]_3[\text{Sb}_2\text{Cl}_{9-x}\text{Br}_x]$ ($x = 1-8$), $\text{Cs}_3[\text{Sb}_2\text{Cl}_6\text{Br}_3]$, and $\text{Cs}_3[\text{Sb}_2\text{Cl}_3\text{Br}_6]$, and a single crystal X-ray structure determination on $[\text{NMe}_4]_3[\text{Sb}_2\text{Cl}_6\text{Br}_3]$ showed a confacial bioctahedron with bromine bridges. X-ray powder patterns suggested the other bromochloroantimonates(III) were discrete dimers. In $[\text{H}_3\text{NCH}_2\text{CH}_2\text{NH}_3]_5[\text{Sb}_2\text{Br}_{11}] \cdot 4\text{H}_2\text{O}$, discrete dimeric anions are linked into chains by hydrogen-bonded water molecules.³²⁰ Two larger anions are $[\text{LH}]_4[\text{Sb}_4\text{Br}_{16}]$

Figure 46 The structure of tetrameric $[\text{Sb}_4\text{F}_{16}]^{4-}$ (reproduced by permission of Wiley-VCH from *Z. Anorg. Allg. Chem.* **1996**, 622, 105–111).

Figure 47 The structure of dimeric $[\text{Sb}_2\text{F}_{10}]^{2-} \cdot 2\text{HF}$ (reproduced by permission of Wiley-VCH from *Z. Anorg. Allg. Chem.* **1996**, 622, 105–111).

($\text{L} = 2\text{-amino-1,3,4-thiadiazolium}$),³²¹ and $[\text{PPh}_4][\text{Sb}_8\text{Br}_{28}]$.³²² Both have antimony in distorted edge-shared octahedral environments. Other mixed halide species are $[\text{Hpy}][\text{SbBr}_2\text{Cl}_2]$, an infinite polymer,^{312,323} and $[\text{Hpy}]_8[\text{Sb}_4\text{Br}_{12}\text{Cl}_8]$.³²³

Iodoantimonates(III) have shown an extraordinary structural diversity, particularly in the larger anions. The dinuclear examples are $[\text{Me}_3\text{BzN}][\text{Sb}_2\text{I}_7]$ (polymeric),³²⁴ $[\text{PPh}_4]_2[\text{Sb}_2\text{I}_8]$ (dimer *anti*-axial iodides),³²⁵ $\text{Cs}_3[\text{Sb}_2\text{I}_9]$,³²⁶ and $[\text{EtMe}_2\text{PhN}]_3[\text{Sb}_2\text{I}_9]$ (both confacial bioctahedron),³²⁷ whilst $[\text{H}_3\text{N}(\text{CH}_2)_6\text{NH}_3][\text{SbI}_5]$ is a polymer with SbI_6 octahedra sharing *cis* vertices.³¹⁸ Three types with an $[\text{Sb}_3\text{I}_{10}]^-$ stoichiometry are known: in $[\text{PPh}_4][\text{Sb}_3\text{I}_{10}]$ (Figure 50)³²⁸ and $[\text{Cu}(\text{MeCN})_3][\text{Sb}_3\text{I}_{10}]$ (Figure 51)³²⁹ the distorted octahedral antimony centers are linked in different ways, whereas in $[\text{Me}_3\{2\text{-(4-NO}_2\text{C}_6\text{H}_4)\text{CH}_2\text{CCH}_2\}\text{N}][\text{Sb}_3\text{I}_{10}]$ there are close packed iodides with antimony disordered within the octahedral holes.³³⁰ An $[\text{Sb}_3\text{I}_{11}]^{2-}$ anion is present in the $[\text{Cu}(\text{MeCN})_4]^+$ salt.³³¹ In $[\text{K}(15\text{-crown-5})_2][\text{Sb}_3\text{I}_{12}]$ there are three face-sharing SbI_6 units (alternatively described as an SbI_6 octahedron with two opposite faces capped by SbI_3 groups).³³² If four faces of SbI_6 are capped by SbI_3 , the result is shown in Figure 52a and is found in

Figure 48 The structure of $[\text{Sb}_4\text{Cl}_{16}]^{4-}$ (reproduced by permission of the publishers from *Z. Naturforsch.*, **B** **1982**, 37, 1584–1589).

$[\text{H}\{\text{OP}(\text{NMe}_2)_3\}_2]_3[\text{Sb}_5\text{I}_{18}]$,³³³ whereas an isomeric form in $[\text{NMe}_4]_3[\text{Sb}_5\text{I}_{18}]$ is an SbI_6 unit with four edges sharing a common vertex and bridged by SbI_3 units (Figure 52b).³³¹

Three isomers of $[\text{Sb}_6\text{I}_{22}]^{4-}$ are known; in $[\text{Fe}(\text{Cp})_2]_4[\text{Sb}_6\text{I}_{22}]$, $[\text{EtMe}_2\text{PhN}]_4[\text{Sb}_6\text{I}_{22}]$,³⁰⁴ and [tetramethylpyrazinium] $_4[\text{Sb}_6\text{I}_{22}]$ ³³⁴ the unit is based upon Sb_4I_{16} with two opposite triangular faces capped by SbI_3 ,³³¹ whereas in $[\text{Fe}(1,10\text{-phen})_3]_2[\text{Sb}_6\text{I}_{22}] \cdot 2\text{MeCN}$,³³⁵ and $[\text{Et}_3\text{BzN}]_4[\text{Sb}_6\text{I}_{22}]$ ³³⁷ the two capping SbI_3 groups are differently placed. Three isomers of $[\text{Sb}_8\text{I}_{28}]^{4-}$ have also been identified.^{324,333,335,337} In the $[\text{PPh}_4]^+$ or $[\text{H}(\text{DMPU})_2]^+$ ($\text{DMPU} = N,N'$ -dimethylpropylene urea)³³³ a relatively regular unit is present (Figure 53), but the other two are based upon SbI_3 units edge- or face-bridging with smaller iodoantimonate anions.

A variety of organohaloantimonates(III) have been prepared and structurally characterized. Since the organo-groups normally occupy terminal positions, these anions are much less prone to polymerization than the homoleptic halo-analogues. The $[\text{Ph}_2\text{SbX}_2]^-$ ($\text{X} = \text{Cl}, \text{Br}, \text{or I}$)^{338–341} are *pseudo*-trigonal bipyramidal with axial X groups and an equatorial lone pair. $[\text{PhSbCl}_4]^{2-}$ is monomeric,³³⁸ but $[\text{PhSbX}_3]^-$ ($\text{X}_3 = \text{Cl}_3, \text{ClBr}_2, \text{I}_3$) are $(\mu\text{-X})_2$ dimers.^{338,340,341} The $[\text{Ph}_2\text{Sb}_2\text{X}_7]^{3-}$ ($\text{X} = \text{Cl}, \text{Br}, \text{or I}$) contain square pyramidal PhSbX_4 units sharing a common vertex.^{339,341}

Haloantimonate(V) chemistry is much simpler than that just discussed and is dominated by the $[\text{SbF}_6]^-$ and $[\text{SbCl}_6]^-$ anions. Both octahedral anions are popular choices as weakly coordinating anions in many areas of coordination chemistry,¹⁰³ but also commonly arise from abstraction of a halide ion from other reagents during the use of SbF_5 or SbCl_5 as powerful Lewis acids in organic, inorganic, and organometallic synthesis. Good examples are provided by the many main group and transition metal fluoro- or oxofluoro-cations, with $[\text{SbF}_6]^-$ produced in this way.³⁴² The singly F-bridged $[\text{Sb}_2\text{F}_{11}]^-$ and $[\text{Sb}_3\text{F}_{16}]^-$ ions are sometimes formed in these reactions. The pentagonal bipyramidal $[\text{SbF}_7]^{2-}$ ion has recently been prepared by heating two molar equivalents of MF and SbF_5 ($\text{M} = \text{K or Cs}$) or from NMe_4F and SbF_5 in MeCN.¹⁰⁵ Five of the eight possible isomers of mixed $[\text{SbF}_{6-n}\text{Cl}_n]^-$ ($n = 1\text{--}5$) have been identified in solution by ^{19}F and ^{121}Sb NMR spectroscopy, and some isolated (impure).³⁴³ A range of $[\text{SbBr}_{6-n}\text{Cl}_n]^-$ anions has

Figure 49 The tetrameric unit in $[\text{BipyH}_2][\text{SbCl}_5]$ (reproduced by permission of the publishers from *Z. Naturforsch., B* **1983**, 38, 1615–1619).

Figure 50 The polymer chain in one isomer of $[\text{Sb}_3\text{I}_{10}]^-$ (reproduced by permission of the publishers from *Z. Naturforsch., B* **1987**, 42, 1493–1499).

also been detected in MeCN solution by NMR methods.^{344,345} Organohaloantimonates(V) are similarly six-coordinate, including $[\text{SbPhX}_5]^-$ ($\text{X} = \text{Cl}$ or Br), $\text{trans-}[\text{SbPh}_2\text{Cl}_4]^-$, and $[\text{SbRCl}_{5-n}\text{Br}_n]^-$ ($\text{R} = \text{Ph}$ or Me).^{346–349}

The $[\text{Sb}_2\text{OCl}_6]^{2-}$ and some related $[\text{Sb}_2\text{OCl}_{6-n}\text{Br}_n]^{2-}$ anions were prepared by cautious hydrolysis of $[\text{Sb}_2\text{Cl}_9]^{3-}$ or $[\text{SbCl}_{9-n}\text{Br}_n]^{3-}$.³⁵⁰ The structure has been established in several salts,^{18,19,351} and is shown in (17). The anion in $[\text{NH}_4]_3[\text{Sb}_2\text{OCl}_7]$ has a third bridging Cl group forming a chain structure.³⁵² In the thiochloroanions $[\text{Sb}_2\text{SCl}_5]^-$ and $[\text{Sb}_2\text{SCl}_6]^{2-}$, obtained from Na_2S_4 and $[\text{Sb}_3\text{Cl}_{11}]^{2-}$ or $[\text{Sb}_2\text{Cl}_8]^{2-}$, respectively, the sulfur and one or two chlorines form the bridges.³⁵³

Figure 51 The structure of a second polymeric isomer of $[\text{Sb}_3\text{I}_{10}]^-$ (reproduced by permission of Wiley-VCH from *Angew. Chem., Int. Ed. Engl.* **1986**, 25, 825).

3.6.3.5 Antimony in the Environment, Biology, and Medicine

The environmental distribution of antimony is wide, and it has been estimated that the atmospheric distribution resulting from man's activities (fossil fuels, mining, etc.) is greater than from natural sources. Most of the forms are simple inorganics in the form of oxides and oxoanions. Although some methylantimony species are found, their mode of production is not clear and attempts to demonstrate biological methylation have been inconclusive.¹¹²

However, in contrast to arsenic, antimony compounds remain of medicinal importance, particularly in the treatment of various parasitic infections including leishmaniasis, schistosomiasis, and trypanosomiasis. Coordination compounds used include the sodium or potassium antimony tartrates and substituted catecholate complexes, which are O-donor complexes, whilst S-donors are utilized in 2,3-dithiosuccinate derivatives.^{111,113} While the mode of action is unclear in many cases, the attraction of these compounds, in addition to their clinical effectiveness, is their simplicity of manufacture and low cost.

3.6.4 BISMUTH

In addition to the general reviews cited in Section 3.6.1, there is a detailed review by Briand and Burford³⁵⁴ which describes bismuth complexes of groups 15 and 16 donor ligands. In contrast to antimony, there is very little coordination chemistry of bismuth in the V oxidation state, compounds being limited to fluoroanions and a few organobismuth species.

3.6.4.1 Group 14 Compounds

Despite the relative weakness and high reactivity of Bi—C bonds, there is an extensive chemistry of organobismuth compounds. In addition to the reviews noted in Section 3.6.1, other articles specifically focused on bismuth are available.^{116,355,356} The review by Silvestri *et al.*³⁵⁶ contains detailed descriptions of the structures of complexes of organobismuth compounds and contains much pertinent data on the stereochemistries adopted by bismuth. Organobismuth analogues of

Figure 52 The structures of two forms of $[\text{Sb}_5\text{I}_{18}]^{3-}$ (reproduced by permission of (a) Elsevier Science from *Polyhedron* **1993**, 12, 2081–2090, and (b) Wiley-VCH from *Angew. Chem. Int. Ed. Engl.* **1989**, 28, 344–345).

pyridine, and examples of $\text{RBi}=\text{BiR}$ and $(\text{RBi})_n$ are the least stable of group 15 compounds of these types.^{13,118} Like their antimony analogues, silylbismuthines have been prepared and explored as MOCVD precursors for (III)–(V) materials.¹¹⁹

3.6.4.2 Group 15 Compounds

3.6.4.2.1 N-donor ligands

There are many examples with nitrogen heterocycles, but aliphatic amine complexes are of low stability^{357,358} and few are known. There has been recent interest in bismuth amides as precursors for both bismuth-containing semiconductors and superconductors. The simplest examples, $[\text{Bi}(\text{NMe}_2)_3]$ and $[\text{Bi}(\text{NPh}_2)_3]$, made from LiNR_2 and BiCl_3 , are unstable to air and light. Both are trigonal pyramidal monomers.^{359,360} In other systems, more complex products result: from lithiated 2,6- $\text{Pr}_2\text{C}_6\text{H}_3\text{NH}_2$ and BiCl_3 the cyclic dimer (**18**) is formed,³⁶¹ whilst 2,6- $\text{Me}_2\text{C}_6\text{H}_3\text{NH}_2$

Figure 53 The structure of one form of $[\text{Sb}_8\text{I}_{28}]^{4-}$ (reproduced by permission of Elsevier Science from *Polyhedron* **1993**, 12, 2081–2090).

produced the tetramer (**19**).³⁶² Using the bulkier “supermesityl” group in $\text{NH}_2(2,4,6\text{-Bu}^t\text{C}_6\text{H}_2)$ produces monomeric tris(amide) complexes with both antimony and bismuth, although neither arsenic nor phosphorus form analogous compounds.³⁶³ The mononuclear compound with the chelating tripodal triamide, $[\{\text{HC}(\text{SiMe}_2\text{NBU}^t)_3\}\text{Bi}]$, is both air and light stable.³⁶⁴

(18)

(19)

The reaction of heated BiBr_3 or BiI_3 with gaseous NH_3 results in $[\text{BiX}_3(\text{NH}_3)]$ complexes, and BiBr_3 reacts with amines (NH_2Me , NHMe_2 , NMe_3 , or NH_2Ph) in benzene to give 1:1 complexes.¹⁶ None have been structurally characterized. Bismuth complexes with aminoalcohols, aminothiols, and aminocarboxylic acids are discussed in Section 3.6.4.3. The carbanionic ligand (**1**) forms $[\text{Bi}(\text{1})\text{Cl}_2]$ which almost certainly has the bismuth coordinated to a CN_2Cl_2 donor set.²⁰ From the reaction of BiCl_3 and three equivalents of (**3**), $(2\text{-Me}_2\text{NCH}_2\text{C}_6\text{H}_4)^-$, the product is colorless $[\text{Bi}(\text{3})_3]$, which has the same structure as the antimony analogue with a trigonal pyramidal BiC_3 core and three weaker Bi-N interactions completing a distorted octahedron.²² The same reagents in a 1:2 ratio produce $[\text{Bi}(\text{3})_2\text{Cl}]$ which is best described as a *pseudo*-trigonal bipyramid with apical N and Cl atoms, two equatorial C and with the lone pair occupying the third equatorial position; the second dimethylamino-group is only very weakly associated.²¹ Treatment of this complex with TIPF_6 removes the chlorine and forms $[\text{Bi}(\text{3})_2]\text{PF}_6$ which is also *pseudo*-trigonal bipyramidal with axial amines and an equatorial lone pair.¹²⁷ From 8-(dimethylamino)-1-naphthyllithium, $[\text{Li}(\text{2})]$, both $[\text{Bi}(\text{2})\text{Cl}_2]$ and $[\text{Bi}(\text{2})_2\text{Cl}]$ are formed depending upon the conditions,²¹ but attempts to make $[\text{Bi}(\text{3})\text{Cl}_2]$ directly failed. Comproportionation of $[\text{Bi}(\text{3})_3]$ and BiCl_3 in Et_2O did give $[\text{Bi}(\text{3})\text{Cl}_2]$, but this proved insoluble in common solvents. However, metathesis with NaI gave $[\text{Bi}(\text{3})\text{I}_2]$ which has an iodide-bridged dimer structure with square-pyramidal geometry at bismuth (Figure 54).²¹ There are closely related organobismuth species including $[\text{Bi}(4\text{-MeC}_6\text{H}_4)(2\text{-Me}_2\text{NCH}_2\text{C}_6\text{H}_4)\text{Cl}]$,³⁶⁵ and $[\text{Bi}(\text{Ph})\{2\text{-(R)-1-Me}_2\text{N(Me)CHC}_6\text{H}_4\}\text{Cl}]$.³⁶⁶

The triaza macrocycle $\text{Me}_3[9]\text{aneN}_3$ reacts with BiCl_3 in MeCN to form yellow $[\text{Bi}(\text{Me}_3[9]\text{aneN}_3)\text{Cl}_3]$ which has a discrete distorted octahedral structure.^{18,367} A derivatized variant, 1-carboxymethyl-4,7-bis(1-methylimidazol-2-ylmethyl)-1,4,7-triazacyclononane, (LH) forms $[\text{BiCl}]\text{BPh}_4$, which is dimeric with each bismuth eight-coordinate, and bonded to the three macrocycle and two imidazole nitrogens, a chlorine, and two carboxylate oxygens, the carboxylates forming the bridges.³⁶⁸ Bismuth compounds with tetra-azamacrocycles^{357,358,369,370} also have

Figure 54 The structure of $[\text{BiI}_2(2\text{-Me}_2\text{NCH}_2\text{C}_6\text{H}_4)]$ (reproduced by permission of the American Chemical Society from *Inorg. Chem.* **1997**, 36, 2770–2776).

high coordination numbers. In $[\text{Bi}([12]\text{aneN}_4)(\text{H}_2\text{O})(\text{ClO}_4)_3]$, made from Bi_2O_3 , HClO_4 , and $[12]\text{aneN}_4$, the bismuth is eight-coordinate with a square antiprismatic geometry composed of the four macrocyclic nitrogens on one face and four oxygens (water and three $\eta^1\text{-ClO}_4$ groups) on the other (Figure 55).³⁶⁹ The pendant arm analogue (20) forms $[\text{Bi}(\mathbf{20})](\text{ClO}_4)_3 \cdot \text{H}_2\text{O}$ in which the bismuth is coordinated to an N_4O_4 -donor set from (20), with a weakly coordinated perchlorate (3.34 \AA) interacting through the O_4 face.³⁷⁰ Bismuth(III) porphyrins have been little studied.^{371–373} The dark green $[\text{Bi}(\text{TTP})][\text{NO}_3]$ ($\text{TTPH}_2 = \text{meso-tetra-}p\text{-tolylporphyrin}$) is made from TTPH_2 and bismuth nitrate in pyridine.³⁷¹ The $[\text{Bi}(\text{OEP})][\text{CF}_3\text{SO}_3]$ ($\text{OEPH}_2 = \text{octaethylporphyrin}$) has a

dimeric structure with two $\text{Bi}(\text{OEP})^+$ units linked by bridging CF_3SO_3^- groups, producing seven-coordinate bismuth.³⁷² The complex of the pendant arm porphyrin (**21**) is also a dimer, with a distorted square antiprismatic bismuth coordination environment composed of the four nitrogens of the porphyrin, two oxygens from a nitrate group, a water molecule, and an ester oxygen.³⁷³

Bismuth phthalocyanines $[\text{Bi}(\text{pc})\text{X}]$ ($\text{X} = \text{Cl}, \text{Br}, \text{or } \text{NO}_3$, $\text{pcH}_2 = \text{phthalocyanine}$) are made by heating pcH_2 with the bismuth salt in Me_2CO or MeCN , or by heating BiX_3 with 1,2-dicyanobenzene.³⁷⁴ However, when 1,2-dicyanobenzene and bismuth are heated in iodine vapor, the product is $[\text{Bi}(\text{pc})_4][\text{Bi}_4\text{I}_{16}]$.³⁷⁵ Eight-coordinate bismuth is present in $[\text{Bi}(\text{pc})_2]^-$ ¹²⁶ which is anodically oxidized to green $[\text{Bi}(\text{pc})_2]$, and by bromine to purple $[\text{Bi}(\text{pc})_2]\text{Br}_x$ ($1.5 \leq x \leq 2.5$).³⁷⁶ The triple-decker phthalocyanine $[\text{Bi}_2(\text{pc})_3]$ consists of three pc rings with Bi atoms in a distorted square antiprismatic arrangement and interacting more strongly with the peripheral than the central pc ring.^{377,378} The orange bicyclophtalocyanine shown in Figure 56 is made from $\text{Bi}(\text{OAc})_3$ and 1,2-dicyanobenzene and contains bismuth in a very distorted trigonal prismatic arrangement.³⁷⁹

Crystallization of a 1:1 mixture of BiCl_3 and SbCl_5 from anhydrous MeCN produced $[\text{BiCl}_2(\text{MeCN})_4][\text{SbCl}_6]$.³⁸⁰ The reaction of BiCl_3 and pyridine afforded $[\text{pyH}]_2[\text{BiCl}_5(\text{py})]$ which has a nearly octahedral anion.³⁸¹ The same anion has been obtained serendipitously in two other compounds,^{382,383} and $[(4\text{-pic})\text{H}][\text{BiBrCl}_5(4\text{-pic})]$.³⁸¹ The *cis*- $[\text{BiI}_4(\text{py})_2]^-$,³⁸⁴ and *trans*- $[\text{BiBr}_4(\text{py})_2]^-$,³⁸⁵ are also known. From excess pyridine and BiI_3 the product is *mer*- $[\text{BiI}_3(\text{py})_3]$,³⁸⁵ whilst BiCl_3 affords the pentagonal bipyramidal $[\text{BiCl}_3(\text{py})_4]$ with axial Cls.³⁸⁵

Figure 56 The structure of $[\text{Bi}(1,24\text{-bicyclophtalocyaninato})]$ (reproduced by permission of Wiley-VCH from *Eur. J. Inorg. Chem.* **2001**, 1343–1352).

Phenylbismuth halides form adducts with py, 4-MeC₅H₄N, and 4-Bu^tC₅H₄N(L) of type [BiPhX₂(L)₂] (X = Cl, Br, or I) which are square pyramidal with apical Ph and *trans*-X groups, which associate weakly into dimers (Figure 57) or chains via Bi⋯X bridges.³⁸⁵ Hydrolysis of [BiPhCl₂(Bu^tC₅H₄N)₂] produced [Bu^tC₅H₄NH][BiCl₃Ph(Bu^tC₅H₄N)], which is also square pyramidal with an apical Ph group. In none of these compounds is there much evidence of stereochemical activity by the bismuth lone pair. Diphenylbismuth halide adducts are rarer, but in [BiPh₂(MeC₅H₄N)] the structure is a *pseudo*-trigonal bipyramid with equatorial Ph's and the lone pair, again with weak association into chains by long Bi⋯I contacts.³⁸⁵ Cationic [BiPh₂(py)₂]Y (Y = BF₄, PF₆) can be obtained from BiPh₂Br, py and, TiY.³⁸⁴

The reactions of 2,2'-bipyridyl or 1,10-phenanthroline with bismuth halides have been studied in detail.^{386–391} Under some conditions the products are halobismuthate anions with protonated heterocycle cations (q.v. Section 3.6.4.4), but from reactions in acetonitrile or DMSO a range of structural types with coordinated diimines have been obtained. The 1:1 complexes [BiX₃L] (X = Br or I, L = 2,2'-bipy; X = Br, L = 1,10-phen) are dihalo-bridged dimers based upon distorted octahedral bismuth (Figure 58a).³⁸⁹ The BiCl₃/2,2'-bipy system produces a [BiCl₃(2,2'-bipy)_{1.5}] which has an unusual structure containing (Figure 58b) a single chloride bridge between a seven-coordinate (N₄Cl₃) and a six-coordinate (N₂Cl₄) bismuth center.³⁸⁹ The 2:1 complexes [BiX₃(L)₂] (X = Br or I, L = 2,2'-bipy, 1,10-phen; X = Cl, L = 1,10-phen) are all seven-coordinate monomers with distorted pentagonal bipyramidal geometries (the distortion appears to arise from the geometric constraints of the diimines).³⁹⁰ The isolation of [BiCl₃(2,2'-bipy)₂] is problematic and a pure sample has not been obtained. Decomposition of the 2:1 bromo complex³⁸⁷ produced [2,2'-bipyH][BiBr₄(2,2'-bipy)]. The chloro analogue has also been obtained. These are the expected (*cis*) octahedral monomers. Using DMSO as solvent produced [BiX₃(1,10-phen)(DMSO)₂]·DMSO (X = Cl or Br), [BiI₃(2,2'-bipy)(DMSO)], and [BiI₃(1,10-phen)(DMSO)_{1.5}].³⁸⁸ The chloro- and bromo-compounds have seven-coordinate, pentagonal bipyramidal structures composed of one chelating diimine, three halides, and two O-bound DMSO ligands. The structure of [BiI₃(2,2'-bipy)(DMSO)] is a distorted octahedron with DMSO *trans* to (I), whilst [BiI₃(1,10-phen)(DMSO)_{1.5}] is ionic with the constitution [BiI₂(1,10-phen)(DMSO)₃][BiI₄(1,10-phen)].³⁸⁸ Far IR and Raman spectra were reported for this extensive series of complexes.^{387–390} Bismuth nitrate and 1,10-phenanthroline or 2,2'-bipyridyl produce [Bi(NO₃)₃(diimine)₂] which are

Figure 57 The structure of dimer of [BiPhCl₂(4-MeC₅H₄N)₂] (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **1999**, 2837–2843).

Figure 58 The structures of three 2,2-bipyridyl complexes: (a) the dimeric $[\text{BiI}_3(2,2'\text{-bipy})]$, (b) the dimeric $[\text{BiCl}_3(2,2'\text{-bipy})_{1.5}]$, and (c) mononuclear $[\text{Bi}(\text{NO}_3)_3(2,2'\text{-bipy})_2]$ (reproduced by permission of the Australian Chemical Society from *Aust. J. Chem.* **1998**, 51, 325–330, and *Aust. J. Chem.* **1998**, 51, 337–342).

10-coordinate with three bidentate nitrato-groups (Figure 58c).³⁹¹ From a lower Bi:1,10-phen ratio in DMSO, the product was $[\text{Bi}_2(1,10\text{-phen})_2(\text{OH})_2(\text{NO}_3)_4]$ containing eight-coordinate bismuth (N_2O_6), based upon one diimine and two bidentate nitrates per bismuth, linked by two hydroxide bridges.³⁹¹ Other 2,2'-bipyridyl complexes are $[\text{Bi}(2,2'\text{-bipy})_2(\text{NCS})_3]$, which is dimeric with eight-coordinate bismuth, linked by two bridging thiocyanates,³⁹² and $[\text{Bi}(2,2'\text{-bipy})(\text{S}_2\text{C-NEt}_2)_2\text{I}_2]$, a seven-coordinate dimer ($\text{N}_2\text{S}_2\text{I}_3$) with two bridging iodines.³⁹³ The $[\text{Bi}(\text{terpy})(\text{S}_2\text{C-NEt}_2)_2\text{I}_2]$ is a pentagonal bipyramidal monomer with axial iodines,³⁹³ but the structure of $[\text{Bi}(\text{terpy})(\text{NCS})_3]$ ³⁹⁴ is unknown.

There are 1:1 complexes $[\text{BiX}_3(\mathbf{22})]$ ($\text{X} = \text{Cl}, \text{Br}, \text{I}, \text{NCS}$) of the Schiff base (**22**) of unknown structure.^{386,394} More unusual examples of Bi–N coordination are found in the phosphine imine complexes $[\{\text{BiF}_2(\text{NPEt}_3)(\text{HNPEt}_3)\}_2]$ and $[\text{Bi}_2\text{I}(\text{NPPH}_3)_4]\text{I}_3$.³⁹⁵ The former, itself a very rare example of a coordination complex derived from BiF_3 , has a structure based upon a Bi_2N_2 four-membered ring using the NPEt_3^- groups, with terminal F's and HNPEt_3 ligands.

(22)

The azide chemistry of bismuth is limited to $[\text{Bi}(\text{N}_3)_3]$.³⁹⁶

3.6.4.2.2 P- and As-donor ligands

Only a limited number of bismuth phosphines have been reported. The reaction of BiBr_3 with neat PMe_3 produced yellow $[\text{Bi}_2\text{Br}_6(\text{PMe}_3)_4]$ which has a centrosymmetric structure (**23**), in which the bridges are very asymmetric.^{143,397} The reaction of BiBr_3 and PMe_2Ph in THF produced $[\text{Bi}_2\text{Br}_6(\text{PMe}_2\text{Ph})_2(\text{OPMe}_2\text{Ph})_2]$ (as a result of adventitious oxidation), which has the same basic structure.³⁹⁷ However, from BiBr_3 and PET_3 , the product had a 1:1 stoichiometry and contained a tetrameric unit (Figure 59).¹⁴² Two anionic species are known: the $[\text{PPh}_4][\text{BiI}_4(\text{PMe}_2\text{Ph})_2]$ is a distorted octahedron with *cis* phosphines,¹⁴⁴ whilst the anion in $[\text{PMe}_3\text{H}][\text{Bi}_2\text{Br}_7(\text{PMe}_3)_2]$ is a chain polymer based upon a planar $\text{Br}_2\text{Bi}(\mu^2\text{-Br})_2\text{BiBr}_2$ core with *anti*-axial PMe_3 groups, and with the axial bromines bridging the units.³⁹⁸ Diphosphines including $\text{Me}_2\text{PCH}_2\text{CH}_2\text{PMe}_2$,¹⁴⁴ *o*- $\text{C}_6\text{H}_4(\text{PMe}_2)_2$,¹⁴⁵ *o*- $\text{C}_6\text{H}_4(\text{PPh}_2)_2$,¹⁴⁵ and $\text{Ph}_2\text{PCH}_2\text{CH}_2\text{PPh}_2$,^{386,399,400} typically give 1:1 complexes all of which probably have the same structure or type as established for $[\text{Bi}_2\text{Br}_6(\text{Me}_2\text{PCH}_2\text{CH}_2\text{PMe}_2)_2]$,¹⁴⁴ and $[\text{Bi}_2\text{Cl}_6(\text{Ph}_2\text{PCH}_2\text{CH}_2\text{PPh}_2)_2]$,⁴⁰⁰ as halide-bridged dimers similar to those formed by antimony (Figure 19). However, in $[\text{Bi}_2\text{Cl}_6(\text{Ph}_2\text{PCH}_2\text{CH}_2\text{PPh}_2)_2]$ (Figure 60) there are diphosphine bridges,⁴⁰⁰ a motif common in transition metal complexes with this ligand attributed to the shorter interdonor linkage. A $[\text{Bi}_2\text{Cl}_6(\text{Ph}_2\text{PCH}_2\text{CH}_2\text{PPh}_2)_3]$ complex has two BiCl_3 (diphosphine) groups singly bridged by the third diphosphine giving six-coordinate bismuth.⁴⁰⁰ In several of these systems adventitious oxygen produces diphosphine dioxide complexes^{145,399} (see Section 3.6.4.3).

There seem to be no thoroughly characterized bismuth complexes with monodentate arsines, but diarsines include $[\text{BiX}_3(\text{diarsine})]$ ($\text{X} = \text{Cl}, \text{Br}, \text{or I}$; diarsine = $\text{Ph}_2\text{AsCH}_2\text{CH}_2\text{AsPh}_2$ ^{145,399} and *o*- $\text{C}_6\text{H}_4(\text{AsMe}_2)_2$ ¹⁴⁵). The structure of $[\text{Bi}_2\text{I}_6\{o\text{-C}_6\text{H}_4(\text{AsMe}_2)_2\}_2]$ shows the same halide-bridged dimer type¹⁴⁵ (Figure 19) as found for the diphosphines and this is probably present in all. The

(23)

Figure 60 The structure of $[\text{Bi}_2\text{Cl}_6(\text{Ph}_2\text{PCH}_2\text{PPh}_2)_2]$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **1996**, 1063–1067).

triarsine $\text{MeC}(\text{CH}_2\text{AsMe}_2)_3$ also forms 1:1 complexes with BiX_3 .¹⁴⁵ The diarsine complexes show a tendency to oxidize to the corresponding diarsine dioxides.³⁹⁹ NMR studies show that most of the phosphine and arsine complexes are labile in solution and extensively dissociated. There appear to be no examples of stibine complexes (contrast antimony Section 3.6.3.2.2), whilst the reaction of BiX_3 with BiR_3 typically yields the scrambled products $\text{BiX}_{3-x}\text{R}_x$.³⁵⁵

3.6.4.3 Group 16 Compounds

3.6.4.3.1 O-donor ligands

In aqueous solution and in the absence of coordinating ligands, arsenic and antimony are present either as oxides, oxoanions, or their protonated forms such as $\text{As}(\text{OH})_3$.^{2,3,6} However, for bismuth a wide range of basic salts are known and various polynuclear cations have been proposed or

identified. The aquo-ion $[\text{Bi}(\text{H}_2\text{O})_9]^{3+}$ has been isolated as the CF_3SO_3^- salt by reaction of Bi_2O_3 , $\text{CF}_3\text{SO}_3\text{H}$, and $(\text{CF}_3\text{SO}_2)_2\text{O}$.⁴⁰¹ The cation has a tricapped trigonal prismatic structure. The non-aquo ion appears to be specific to the triflate system, in HClO_4 or HNO_3 media the cation is the hexanuclear $[\text{Bi}_6\text{O}_4(\text{OH})_4]^{6+}$, which has a bismuth octahedron with face-bridging oxide and hydroxide groups.⁴⁰² X-ray structures of $[\text{Bi}(\text{H}_2\text{O})_9][\text{CF}_3\text{SO}_3]_3$ (O_9), $[\text{Bi}(\text{DMSO})_8][\text{ClO}_4]_3$ (O_8), and $[\text{Bi}(\text{N,N'}\text{-dimethylpropyleneurea})_6][\text{ClO}_4]_3$ (O_6) provide examples of bismuth in homoleptic O-donor environments with different coordination numbers (Figure 61).⁴⁰³ Bismuth L^{III} edge EXAFS and LAXS studies⁴⁰³ of strongly acidic aqueous solutions of Bi^{3+} were consistent with $[\text{Bi}(\text{H}_2\text{O})_8]^{3+}$; data were also reported for bismuth triflate solutions in various liquid organic

Figure 61 The structures of $[\text{Bi}(\text{H}_2\text{O})_9]^{3+}$ and $[\text{Bi}(\text{DMSO})_8]^{3+}$ (reproduced by permission of the American Chemical Society from *Inorg. Chem.* **2000**, 39, 4012–4021).

ligands. The structures of various basic bismuth oxo-salts have been described, e.g., $[\text{Bi}_2(\text{H}_2\text{O})_2(\text{SO}_4)_2(\text{OH})_2]$ and $[\text{Bi}_2\text{O}(\text{OH})_2]\text{SO}_4$. The former has a planar $[\text{Bi}_2(\text{OH})_2]^{2+}$ core with the bismuth coordination completed by a water molecule and one oxygen from each of three different sulfate groups.⁴⁰⁴ In the second species, which is a further stage of hydrolysis, there are $[\{\text{Bi}(\text{OH})^{2+}\}_n]$ chains bridged by oxides.⁴⁰⁵

Tetrahydrofuran adducts include *fac*- $[\text{BiX}_3(\text{THF})_3]$ ($\text{X} = \text{Cl}$ or Br),^{406,407} $[\text{BiCl}_3(\text{THF})_2]$ which is a polymer with pentagonal bipyramidal bismuth,⁴⁰⁶ and $[\text{Bi}_2\text{Cl}_8(\text{THF})_2]^{2-}$, an edge-shared bioctahedron with *anti*-axial THF groups.¹⁴⁷ The three $[\text{BiPhX}_2(\text{THF})]$ ($\text{X} = \text{Cl}$, Br , or I) are isostructural with essentially square-pyramidal bismuth centers linked by single halide bridges, the sixth position being occupied by a weak $\pi\text{-Ph}\cdots\text{Bi}$ contact.⁴⁰⁸ The polyethers $\text{ROCH}_2\text{CH}_2\text{OCH}_2\text{CH}_2\text{OR}$ ($\text{R} = \text{Me}$ or Et) behave as tridentates in $[\text{BiCl}_3(\text{ether})]$ which are dichloro-bridged dimers with pentagonal bipyramidal bismuth.⁴⁰⁷ Longer chains in the polyethyleneglycols $\text{HO}(\text{CH}_2\text{CH}_2\text{O})_n\text{CH}_2\text{CH}_2\text{OH}$ ($n = 3, 4, 5$, or 6) also produce $[\text{BiX}_3(\text{glycol})]$ ($\text{X} = \text{Cl}$ or Br), which are bicapped trigonal prisms (O_5X_3), although some ionic forms of type $[\text{BiX}_2(\text{glycol})]^+$ are also known.⁴⁰⁹ These polyethyleneglycols and bismuth nitrate form $[\{\text{Bi}(\text{NO}_3)_2(\text{glycol-H})\}_2]$, in which one end of the ligand has been deprotonated, and the resulting alkoxides bridge the bismuth centers. Most of the ether oxygens coordinate to the Bi centers along with two bidentate nitrates (Figure 62).⁴¹⁰ An ionic form, $[\text{Bi}(\text{NO}_3)_2(\text{glycol})][\text{Bi}(\text{NO}_3)_2(\text{glycol-2H})]\cdot 2\text{H}_2\text{O}$ (glycol = $n = 4$), contains a neutral glycol in the cation and a doubly deprotonated form in the anion.⁴¹⁰

Structures have been determined for a variety of BiX_3 -crown ether adducts; in general the structures are based upon a pyramidal BiX_3 group with the crown weakly capping the open face.^{38,409,411,412} The bond lengths suggest that bismuth interacts more strongly with the crowns than either As or Sb with bismuth halides the smaller crowns 12-crown-4, 15-crown-5, and benzo-15-crown-5 generate mononuclear seven- and eight-coordinate bismuth respectively.^{38,409,411,412} However, $[\text{Bi}(\text{NO}_3)_3(12\text{-crown-4})]$ is 10-coordinate with three bidentate nitrate groups.⁴¹⁰ In the presence of SbCl_5 , BiCl_3 , and 12-crown-4 react in MeCN solution to form $[\text{Bi}(12\text{-crown-4})_2(\text{MeCN})][\text{SbCl}_6]_3$, which contains nine-coordinate bismuth,⁴¹³ whereas 15-crown-5 gives the eight-coordinate monocation $[\text{BiCl}_2(15\text{-crown-5})(\text{MeCN})][\text{SbCl}_6]$.¹⁵⁴ The larger ring in 18-crown-6 offers a number of bonding motifs. In $[\text{Bi}(\text{NO}_3)_3(\text{H}_2\text{O})_3(18\text{-crown-6})]$ ⁴¹⁰ the bismuth is coordinated to three waters and three bidentate nitrates, with the crown H-bonded to the water but not interacting directly with the bismuth. In the $\text{BiCl}_3/18\text{-crown-6}$ system, four different structures have been identified: $[\text{BiCl}_3(18\text{-crown-6})]$ (nine-coordinate O_6Cl_3);⁴¹⁴ $[\text{BiCl}_3(18\text{-crown-6})(\text{H}_2\text{O})]$ (seven-coordinate $\text{O}_3\text{Cl}_3 + \text{O}(\text{water})$);⁴¹⁵ $[\text{BiCl}_3(18\text{-crown-6})(\text{MeOH})]$ (seven-coordinate $\text{O}_3\text{Cl}_3 + \text{O}(\text{methanol})$).⁴⁰⁹ In $[\text{BiCl}_2(18\text{-crown-6})_2][\text{Bi}_2\text{Cl}_8]$ and $[\text{BiBr}_2(18\text{-crown-6})][\text{BiBr}_4]$ the cation is a bicapped trigonal prism (O_6X_2) which can be regarded as the product of halide abstraction

Figure 62 The structure of $[\{\text{Bi}(\text{NO}_3)_2(\text{glycol-H})\}_2]$ (reproduced by permission of the American Chemical Society from *J. Am. Chem. Soc.* **1992**, 114, 2967–2977).

by the weak Lewis acid BiX_3 .^{409,412} Using the stronger Lewis acid SbCl_5 , results in the dication $[\text{BiCl}(\text{18-crown-6})(\text{MeCN})_2][\text{SbCl}_6]_2 (\text{O}_6\text{N}_2\text{Cl})$.¹⁵⁴ Finally, the large ring dibenzo-24-crown-8 coordinates two molecules of BiCl_3 on opposite faces of the crown (Figure 63), with each bismuth coordinated to five oxygens and three chlorines.¹⁵⁵ The maleonitrile-dithiacrown ether $\text{mn-15-S}_2\text{O}_3$ (12a) forms $[\text{BiCl}_3(\text{mn-15-S}_2\text{O}_3)]$ which has bismuth in a $\text{Cl}_3\text{S}_2\text{O}_3$ environment, whilst the related $\text{mn-18-S}_2\text{O}_4$ (12b) binds only via the four oxygens in $[\text{BiCl}_3(\text{mn-18-S}_2\text{O}_4)]$.¹⁵⁶

pnictogen- and chalcogen-oxides form a number of O-bonded bismuth complexes including $\text{trans-BiI}_2\{\text{OP}(\text{NMe}_2)_3\}_4^+$, $[\text{Bi}_2\text{I}_6\{\text{OP}(\text{NMe}_2)_3\}_2]$,⁴¹⁵ $[\text{BiX}_3(\text{DMSO})_3]$ ($\text{X} = \text{Cl}, \text{Br}$), $[\text{Bi}_2\text{I}_4(\mu\text{-I})_2(\text{DMSO})_4]$,⁴¹⁶ $[\text{BiX}_3(\text{diimine})(\text{DMSO})_2]$ (see Section 3.6.4.2.1 above),³⁸⁸ $[\text{Bi}(\text{DMSO})_8]^{3+}$ (see Section 3.6.4.3.1 above),⁴⁰³ $[\text{Bi}(\text{NO}_3)_3(\text{DMSO})_3]$ (nine-coordinate with three bidentate nitrates),³⁹¹ $[\text{Bi}_2\text{Ph}_2\text{Br}_4(\text{OPPh}_3)_2]$,⁴¹⁷ $[\text{Bi}(2,4,6\text{-Me}_3\text{C}_6\text{H}_2)_2\text{BrL}]$ ($\text{L} = \text{OSPh}_2, \text{OP}(\text{NMe}_2)_3$),⁴¹⁷ $[\text{BiR}_2(\text{L}^2)_2]\text{PF}_6$ ($\text{L}^2 = \text{OPPh}_3, \text{OP}(\text{NMe}_2)_3$; $\text{R} = \text{Ph}, 4\text{-MeC}_6\text{H}_4, 2,4,6\text{-Me}_3\text{C}_6\text{H}_2$),³⁸⁴ and $[\text{BiPh}\{\text{OP}(\text{NMe}_2)_3\}_4][\text{PF}_6]_2$.³⁸⁴ Complexes with transition metal fragments which overall are isoelectronic with $[\text{BiX}_2\text{L}_2]^+$ are also known and have Bi-metal bonds, e.g., $[\text{Bi}\{\text{OP}(\text{NMe}_2)_3\}_2\{\text{Fe}(\text{CO})_2(\text{Cp})_2\}_2]^+$.⁴¹⁸

As described in Section 3.6.4.2.2, the adventitious oxidation of diphosphines or diarsines in the presence of BiX_3 result in complexes of the corresponding dioxide ligands.^{145,400} Structurally characterized examples include $[\text{Bi}_2\text{Cl}_6\{\text{Ph}_2\text{P}(\text{O})\text{CH}_2\text{P}(\text{O})\text{Ph}_2\}_2]$, structure (24), which contrasts with that of the “parent” diphosphine complex (Figure 60),⁴⁰⁰ and $[\text{BiCl}_3(\text{THF})\{\text{o-C}_6\text{H}_4\text{P}(\text{O})\text{Ph}_2\}_2]$,¹⁴⁵ but the product isolated from the reaction involving $\text{Ph}_2\text{AsCH}_2\text{CH}_2\text{AsPh}_2$ is $[\text{BiCl}_3\{\text{Ph}_2\text{As}(\text{O})\text{CH}_2\text{CH}_2\text{As}(\text{O})\text{Ph}_2\}\{\text{Ph}_2\text{MeAsO}\}]$, in which the Ph_2MeAsO apparently comes from cleavage of the diarsine.⁴⁰⁰ The complexes can be made directly from the diphosphine dioxide and BiX_3 , e.g., $[\text{BiX}_3(\text{THF})_n\{\text{o-C}_6\text{H}_4\text{P}(\text{O})\text{Ph}_2\}_2]$, $\text{X} = \text{Cl}, n = 1$; $\text{X} = \text{Br}, n = 0$.¹⁴⁵ Pyridine *N*-oxides also form complexes, e.g., ligands (25) function as tridentates in $[\text{Bi}(\text{NO}_3)_3(\text{25})]$ containing nine-coordinate bismuth.⁴¹⁹ In its deprotonated form imidobis(diphenylphosphine oxide) (26) coordinates to bismuth in the distorted octahedral $[\text{Bi}\{(\text{Ph}_2(\text{O})\text{P})_2\text{N}\}_3]$.⁴²⁰

Figure 63 The structure of $[(\text{BiCl}_3)_2(\text{dibenzo-24-crown-8})]$ (reproduced by permission of Elsevier Science from *Inorg. Chem. Acta* **2000**, 300, 1004–1013).

Bismuth alkoxides are usually prepared from $\text{Na}(\text{Li})\text{OR}$ and BiX_3 in benzene or THF, or by alcoholysis of $[\text{Bi}(\text{NR}_2)_3]$. Most examples are di- or polymeric and poorly soluble in organic solvents, although often sublimable in vacuum. The recent interest is due to the possible use of such complexes in CVD processes for bismuth oxide materials. Reaction of $[\text{Bi}(\text{NMe}_2)_3]$ with ROH ($\text{R} = \text{Pr}^i$, $\text{CH}_2\text{CH}_2\text{OMe}$, $\text{CH}_2\text{CH}_2\text{NMe}_2$, $\text{CHMeCH}_2\text{NMe}_2$, CMe_2Et) gave high yields of soluble and volatile $[\text{Bi}(\text{OR})_3]$.^{421,422} The structure of $[\text{Bi}(\text{OCH}_2\text{CH}_2\text{OMe})_3]$ reveals a 1-D chain with square pyramidal bismuth composed of four bridging and one terminal alkoxides. In contrast, $[\text{Bi}(\text{OCMe}_2\text{CH}_2\text{OMe})_3]$ is a six-coordinate monomer.⁴²³ Other alkylalkoxides are $[\text{Bi}(\text{O}^t\text{Bu})_3]_n$,^{422,423} and $[\text{Bi}(\mu\text{-OCH}_2\text{CMe}_3)(\text{OCH}_2\text{CMe}_3)_2(\text{HOCH}_2\text{CMe}_3)_2]$.⁴²⁵ The phenoxide $[\text{Bi}\{\text{O}(2,4,6\text{-Me}_3\text{C}_6\text{H}_2)\}_3]$ is a trigonal pyramidal monomer, and $[\text{Bi}(\text{OBu}^t)_3]$ also appears to be mononuclear.⁴²⁶ The latter reacts with KOBu^t to give $\text{K}[\text{Bu}(\text{OBi}^t)_4]$ in which the bismuth has a *pseudo*-trigonal bipyramidal environment with $\text{RO}\cdots\text{K}$ interactions linking the units into a 1-D polymer.⁴²⁷ In contrast, NaOBu^t and $[\text{Bi}(\text{OBu}^t)_3]$ produce $\text{Na}_4[\text{Bi}_2\text{O}(\text{OBu}^t)_8]$.⁴²⁷

Fluorinated alkoxides have been examined in attempts to improve volatility.^{428–431} The reaction of BiCl_3 with $\text{NaOCH}(\text{CF}_3)_2$ in THF produces dimeric $[\text{Bi}\{\text{OCH}(\text{CF}_3)_2\}_2\{\mu\text{-OCH}(\text{CF}_3)_2\}(\text{THF})_2]$ which has a structure containing two square-pyramidal bismuth units bridged by alkoxides (27). Similar complexes are formed by OC_6F_5^- and NMR studies show monomer–dimer equilibria occur in solution.⁴³¹ Under carefully controlled conditions, NaOC_6F_5 and $[\text{Bi}(\text{OC}_6\text{F}_5)_3]$ react to form $\text{Na}[\text{Bi}(\text{OC}_6\text{F}_5)_4]$ (solvate) which is polymeric, based upon square-pyramidal bismuth. Under other conditions oxo-alkoxides form, such as $[\text{Na}_4\text{Bi}_2\text{O}(\text{OC}_6\text{F}_5)_8(\text{THF})_4]$.⁴²⁹ Oligomerization and oxide formation also occur when $[\text{Bi}(\text{OC}_6\text{F}_5)_3]$ is dissolved in various organic solvents, and the products have complex structures based upon $\mu^3\text{-O}$, $\mu^4\text{-O}$, $\mu^3\text{-OR}$, and $\mu^2\text{-OR}$ groups.⁴³⁰ Mixed bismuth-transition metal or bismuth-alkaline earth metal alkoxides have also been synthesized, including $[\{\text{BiCl}_3\text{OV}(\text{OC}_2\text{H}_4\text{OMe})_3\}_2]$,⁴³² $[\text{Bi}_4\text{Ba}_4\text{O}_2(\text{OEt})_{12}(\text{dpm})_4]$ (dpm = tetramethylheptane-3,5-dione),⁴³³ and $[\text{BiTi}_2\text{O}(\text{OPr}^i)_9]$.⁴³⁴

(27)

Bismuth catecholates $\text{M}[\text{Bi}(\text{cat})_2] \cdot n\text{H}_2\text{O}$ ($\text{M} = \text{Na}$, K , NH_4 , etc.) have been known for many years, and a recent structure determination on the ammonium salt, $\text{NH}_4[\text{Bi}(\text{O}_2\text{C}_6\text{H}_4)_2] \cdot \text{C}_6\text{H}_4(\text{OH})_2 \cdot 2\text{H}_2\text{O}$ revealed a discrete dimer based upon *pseudo*-trigonal bipyramidal bismuth.⁴³⁵ In contrast, the neutral $[\text{Bi}_2(\text{OCH}_2\text{CH}_2\text{O})_3]$ derived from ethyleneglycol is polymeric with the basic dimer core linked into a 3-D polymer by alkoxide bridges.⁴³⁵ Bismuth siloxides such as $[\text{Bi}(\text{O}^t\text{SiPh}_3)_3]_n$ and $[\text{Bi}(\text{OSiPh}_3)_3(\text{THF})_3]$ are known, the latter a discrete monomer.^{422,423}

β -Diketonates include $[\text{Bi}(\text{ACAC})_3]$,⁴³⁷ and $[\text{Bi}(\text{dpm})_3]$.⁴³⁸ Tropolone derivatives have attracted interest as anti-*Helicobacter pylori* agents. Various types are known, including $[\text{Bi}_2(\text{NO}_3)_2(\text{trop})_4]$ (tropH = tropolone) which is a dimer (Figure 64), $[\text{Bi}(\text{trop})_2(\text{H}_2\text{O})]\text{NO}_3$, $[\text{BiPh}(\text{trop})_2]$, and $[\text{Bi}(\text{trop})_4]^-$ all of which are essentially monomers.³⁸⁹

Methanesulfonates of bismuth include $[\text{Bi}(\text{O}_3\text{SMe})_3]$, prepared from Bi_2O_3 and methanesulfonic anhydride. This is converted to $[\text{Bi}(\text{O}_3\text{SMe})_4]^-$ by reaction with $\text{M}[\text{O}_3\text{SMe}]$ ($\text{M} = \text{Na}$, NH_4 , etc.).⁵⁸

Figure 64 The structure of $[\text{Bi}_2(\text{NO}_3)_2(\text{trop})_4]$ (reproduced by permission of Wiley-VCH from *Chem. Ber.* **1995**, 128, 335–342).

The bismuth(V) teflate, $[\text{Bi}(\text{OTeF}_5)_5]$, is made from BiF_5 and $\text{B}(\text{OTeF}_5)_3$ in a freon and is stable at room temperature. It reacts with $[\text{NMe}_4][\text{OTeF}_5]$ to form the octahedral $[\text{Bi}(\text{OTeF}_5)_6]^-$.¹⁷³

Bismuth carboxylates show a wide variety of structural motifs. In $\text{K}_2[\text{Bi}(\text{HCO}_2)_5]$ bidentate formate groups are present.⁴⁴⁰ Bismuth acetate $[\text{Bi}(\text{O}_2\text{CMe})_3]$ has a layered structure,⁴⁴¹ but in the presence of thiourea (tu), two complexes can be isolated. $[\text{Bi}(\text{O}_2\text{CMe})_3(\text{tu})_3]$ is a nine-coordinate monomer, but $[\text{Bi}_2(\text{O}_2\text{CMe})_6(\text{tu})_3(\text{H}_2\text{O})]$ is ionic with a $[\text{Bi}_2(\text{O}_2\text{CMe})_4(\text{tu})_6]^{2+}$ cation and a $[\text{Bi}_2(\text{O}_2\text{CMe})_8]^{2-}$ anion, the latter with acetate bridges (28).⁴⁴² Bismuth pivalate, $[\text{Bi}(\text{O}_2\text{CCMe}_3)_3]$, is a tetramer,⁴⁴³ whereas $[\text{Bi}(\text{O}_2\text{CCF}_3)_3] \cdot \text{CF}_3\text{CO}_2\text{H}$,⁴⁴⁴ and $[\text{Bi}(\text{O}_2\text{CPh})_3]$,⁴⁴⁵ are chain polymers in both cases with nine-coordinate bismuth centers. The subtle factors involved in bismuth carboxylate geometries are well illustrated by a series of complexes $[\text{diamineH}_2][\text{BiPh}(\text{O}_2\text{CCF}_3)_4]$, where the anion geometry depends upon the cation present.⁴⁴⁶ In $\text{K}[\text{Bi}(\text{C}_2\text{O}_4)_2] \cdot 5\text{H}_2\text{O}$, obtained by hydrolysis of squaric acid derivatives, a 3-D network polymer is present.⁴⁴⁷

(28)

Figure 65 The structure of the bismuth malate complex (reproduced by permission of Wiley-VCH from *Chem. Ber.* **1993**, 126, 51–56).

In contrast to antimony, few bismuth phosphonates have been described, and only two have been structurally characterized. The $[\text{Bi}(\text{O}_3\text{PCH}_2\text{CH}_2\text{CO}_2)\cdot\text{H}_2\text{O}]$ is polymeric with a layer structure.⁴⁴⁸ However, $\text{Bu}^t\text{PO}_3\text{H}$ reacts with BiPh_3 to form a $[\text{Bi}(\text{O}_3\text{PBu}^t)_3]$ phase as major product and as minor product, a 14-atom bismuth cluster $[\text{Bi}_{14}\text{O}_{10}(\text{O}_3\text{PBu}^t)_{10}(\text{HO}_3\text{PBu}^t)_2\cdot 3\text{C}_6\text{H}_6\cdot 4\text{H}_2\text{O}]$.⁴⁴⁹

Hydroxycarboxylic acid compounds of bismuth have been used in various medicines for many years, but the number and speciation of the complexes present is often far from clear. Recent work has produced structural characterizations of a range of examples, and solution studies are beginning to elucidate the complex equilibria present. In the tartrate complexes $[\text{Bi}(\text{H}_3\text{tart})(\text{H}_2\text{tart})\cdot 3\text{H}_2\text{O}]$ and $\text{NH}_4[\text{Bi}(\text{H}_2\text{tart})_2(\text{H}_2\text{O})]\cdot\text{H}_2\text{O}$ ($\text{H}_4\text{tart} = \text{HO}_2\text{CCH}(\text{OH})\text{CH}(\text{OH})\text{CO}_2\text{H}$), the bismuth is nine-coordinate, bonded to four bridging bidentate tartrate ligands (three bond via alkoxy/carboxy O-donors and one bonds via two carboxy oxygens) and a water molecule. The tartrates bridge neighboring bismuth centers to produce a polymeric network.^{450,451} Bismuth malate $[\text{Bi}(\text{mal})\cdot\text{H}_2\text{O}]$ ($\text{H}_3\text{mal} = \text{HO}_2\text{CCH}_2\text{CH}(\text{OH})\text{CO}_2\text{H}$) is also nine-coordinate with three different coordination modes exhibited by the chelating malate anions (Figure 65).⁴⁵¹ Rather similar structural features are present in bismuth lactate $[\text{Bi}(\text{MeCH}(\text{OH})\text{CO}_2)_3]$.⁴⁵²

Bismuth citrate systems, often in the form of “colloidal bismuth subcitrate” are widely used medicinally, although the chemical speciation has been unclear. As a result of recent work,^{453–458} some of the key structural features of crystalline bismuth citrates have been established, and the complex solution equilibria probed as a function of composition and pH. A common building block is the dimer unit shown in (29) (Figure 66) in which a citrate ligand functions as a tridentate chelate to one bismuth, and interacts more weakly through one carboxylate function to the second bismuth. In most of the structurally characterized bismuth citrates, this building block, in different degrees of protonation, is supplemented by H bonding to water molecules, and interaction with $\text{K}/\text{Na}/\text{NH}_4$ cations when present. A dodecanuclear cluster has been identified in $[\text{NH}_4]_{12}[\text{Bi}_{12}\text{O}_8(\text{cit})_8]\cdot 10\text{H}_2\text{O}$ ($\text{H}_4\text{cit} = \text{citric acid}$).⁴⁵⁷

3.6.4.3.2 N/O-donor ligands

Polydentate N,O-donor ligands form stable complexes with bismuth(III), usually with high coordination numbers. The aminocarboxylates have been examined in detail and a considerable amount of X-ray structural data are available (Table 3). The general synthetic route is reaction of Bi_2O_3 , $\text{Bi}(\text{OH})_3$, or basic bismuth carbonate with the ligand in water, followed by addition of the appropriate cations (where present) and adjustment of the pH. The bismuth coordination number varies between seven and 10 depending upon the complex, with water or other small ligands being incorporated to achieve this if necessary. For EDTA^{4-} derivatives the ligand is always hexadentate

with the structures varying from discrete anions with H_2O or thiourea co-ligands, through dimers with carboxylate bridges, to 1-D chains.

O^a = oxygen atom from citrate or water molecule

(29)

The description of the geometries at bismuth is not straightforward due to the distortions produced by the polydentate ligands (Figure 67). The highest coordination number observed is in the complex $[\text{Bi}(\text{H}_3\text{TTHA})]\cdot 3\text{H}_2\text{O}$ where the bismuth is 10-coordinate and approximates to a bi-capped square antiprism.⁴⁸⁵ The nine-coordinate $[\text{Bi}(\text{HDTPA})(\text{H}_2\text{O})]^-$ and $[\text{Bi}(\text{DTPA})]^{2-}$ complexes are mono-capped square antiprisms,^{462,483} but for the eight-coordinate complexes the structures are more variable— $[\text{Bi}(\text{HEDTA})]\cdot 2\text{H}_2\text{O}$ (bicapped trigonal prism), $[\text{Bi}(\text{EDTA})]^-$ (bicapped octahedron), and $[\text{Bi}(\text{HEDTA})]$ (square antiprism).^{459,468}

Nitrilotriacetic acid, $\text{N}(\text{CH}_2\text{CO}_2\text{H})_3$ (H_3NTA), iminodiacetic acid, $\text{HN}(\text{CH}_2\text{CO}_2\text{H})_2$ (H_2IDA), (2-hydroxyethyl)iminodiacetic acid, $\text{HOCH}_2\text{CH}_2\text{N}(\text{CH}_2\text{CO}_2\text{H})_2$ (H_3ONDA), and (*N*-hydroxy)-ethylethylenediaminetetra-acetic acid, $(\text{HO}_2\text{CCH}_2)_2\text{NCH}_2\text{CH}_2\text{N}(\text{CH}_2\text{CH}_2\text{OH})(\text{CH}_2\text{CO}_2\text{H})$ (H_4OEDTA), form similar complexes (Table 3).

Various other N,O-donor ligands complex with bismuth(III), including the heptadentate saltren H_3 , ($\text{LH}_3 = \text{N}(\text{CH}_2\text{CHN}=\text{CHC}_6\text{H}_4\text{OH})_3$), which forms $[\text{BiL}]$ containing seven-coordinate bismuth in an N_4O_3 environment.⁴⁹³ The triaminetriol (taci H_3 , (30)) forms $[\text{Bi}_3(\text{taci})_2](\text{NO}_3)_3$ and $[\text{Bi}_3(\text{taci})_2]\text{Cl}_3\cdot 6\text{H}_2\text{O}$ the latter having the structure shown in Figure 68 in which each bismuth is coordinated $\text{N}_2\text{O}_4\text{Cl}_2$.⁴⁹⁴ 2,6-Diacetylpyridinebis(2-thenoylhydrazone) (H_2DAPT , (31)) forms $[\text{Bi}(\text{HDAPT})\text{X}_2]\cdot \text{DMSO}\cdot \text{H}_2\text{O}$ ($\text{X} = \text{Cl}, \text{Br}, \text{I}, \text{NCS}$) and $[\text{Bi}(\text{DAPT})\text{Y}]\cdot \text{DMSO}$ ($\text{Y} = \text{Cl}, \text{OH}, \text{N}_3$)^{495,496} which are pentagonal bipyramidal and pentagonal pyramidal respectively with the ligand occupying the five equatorial positions. Other N,O-ligands are (32) which forms a $[\text{Bi}(\text{L-H})_3]$ complex,⁴⁹⁷ and (33) which coordinates is a singly deprotonated form in the dinuclear $[\text{Bi}_2((33)\text{-H})_2(\text{O}_2\text{CCF}_3)_4(\text{THF})_2]$.⁴⁹⁸

3.6.4.3.3 *S*-, *Se*-, and *Te*-donor ligands

The first, and still the only structurally characterized, monodentate thioether complex of bismuth is $[\text{SMe}_3]_2[\text{Bi}_2\text{I}_8(\text{SMe}_2)_2]$, obtained in very poor yield from BiI_3 dissolved in a large excess of SMe_2 . The structure of the anion is an edge-shared bioctahedron with *anti*-axial positioning of the SMe_2 ligands.⁴⁹⁹ From BiCl_3 and $\text{MeSCH}_2\text{CH}_2\text{CH}_2\text{SMe}$ in CH_2Cl_2 the product is $[\text{BiCl}_3(\text{MeSCH}_2\text{CH}_2\text{CH}_2\text{SMe})]^{214,500}$ which is a 3-D polymer based upon Bi_4Cl_4 “open-cradle” units linked by bridging dithioethers (Figure 69). From MeCN solutions of BiX_3 ($\text{X} = \text{Cl}$ or Br) and $\text{MeSCH}_2\text{CH}_2\text{CH}_2\text{SMe}$ the products were $[\text{BiX}_3(\text{MeSCH}_2\text{CH}_2\text{CH}_2\text{SMe})]$, which have polymer sheet structures based upon planar Bi_2X_6 units cross-linked by dithioether bridges (Figure 70).⁵⁰¹ The shorter chain dithioether $\text{MeSCH}_2\text{CH}_2\text{SMe}$ forms $[\text{BiX}_3(\text{MeSCH}_2\text{CH}_2\text{SMe})_2]$ ($\text{X} = \text{Cl}$, Br , or I) and the structure of the bromide derivative revealed a pentagonal bipyramidal monomer with axial bromines and two chelating dithioethers.⁵⁰¹ In contrast, the $[\text{Bi}_2\text{Br}_6(\text{PhSCH}_2\text{CH}_2\text{SPh})]$ has infinite chains of Bi_2Br_6 groups linked via bromine-bridges with almost orthogonal thioether ligands cross-linking the

Figure 69 The tetramer unit in $[\text{BiCl}_3\{\text{MeS}(\text{CH}_2)_3\text{SMe}\}]$ (reproduced by permission of the Royal Society of Chemistry from *Chem. Commun.* **1998**, 2159–2160).

Figure 70 The polymeric structure of $[\text{BiBr}_3\{\text{MeS}(\text{CH}_2)_3\text{SMe}\}]$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **2000**, 859–865).

chains. The structures of $[\text{BiX}_3\{\text{MeC}(\text{CH}_2\text{SMe})_3\}]$ are unknown,⁵⁰¹ but that of $[\text{BiCl}_3\{\text{Me-Si}(\text{CH}_2\text{SMe})_3\}]$ ⁵⁰² is polymeric with two different bismuth environments—one is BiS_3Cl_3 and the other BiS_2Cl_4 (**34**) and these units are linked by a single chloride bridge and by the trithioethers.

(34)

Bismuth trichloride complexes of the crown thioethers [9]aneS₃, [12]aneS₄, [15]aneS₅, and [18]aneS₆ have the common motif of a pyramidal BiCl₃ group capped by the weakly bound macrocycle using all the sulfur donors.^{217,503,504} The larger [24]aneS₈ maintains the same basic motif in [(BiCl₃)₂([24]aneS₈)] with pyramidal BiCl₃ units coordinated to five sulfur donors (two of which are common to both bismuth) on opposite sides of the ring (Figure 71).⁵⁰⁵

There are no monodentate selenoether complexes, but the majority of those of the bidentate and polydentates differ in detail both from the antimony analogues and from the bismuth thioethers described above.²¹⁴ The 1:1 complexes [BiX₃(MeSeCH₂CH₂SeMe)] are of unknown structure, but the [BiX₃(MeSeCH₂CH₂CH₂SeMe)] complexes have analogous structures to the dithioether ligands with planar Bi₂X₆ units bridged by diselenoethers to give octahedral coordination at bismuth.⁵⁰¹

The structures of the MeC(CH₂SeMe)₃ complexes differ with the halide present. In [BiCl₃-{MeC(CH₂SeMe)₃}] there are Bi₂Cl₆ units linked by tripodal selenoethers coordinated as bidentate chelates to one bismuth and monodentate to a second to produce seven-coordinate bismuth centers and a 2-D sheet polymer.⁵⁰¹ However, in [Bi₂I₆{MeC(CH₂SeMe)₃}₂] there are discrete dimers with six-coordinate bismuth, the unit composed of a twisted Bi₂I₆ rhomboidal core further bound to two bidentate triselenoethers.⁵⁰¹

The selenoether macrocycle complexes have completely different structures to those of the sulfur macrocycles. The [BiX₃L] (X = Cl or Br; L = [8]aneSe₂, [16]aneSe₄, and [24]aneSe₆) are deep orange-yellow solids.⁵⁰⁶ The structures of [BiCl₃{[8]aneSe₂}] and [BiBr₃{[16]aneSe₄}] are ladder polymers with planar Bi₂X₆ units bridged (unusually) by *trans* selenoether ligands giving distorted octahedral coordination at bismuth (Figure 72).⁵⁰⁶ Unfortunately, the structures of [BiX₃{[16]aneS₄}] which would provide a direct comparison are unknown.⁵⁰⁶

Bismuth telluroether complexes are very rare; the structure of the first such example [BiBr₃(PhMeTe)] shows a planar Br₂Bi(μ-Br)₂BiBr₂ group with the PhMeTe ligands completing an *anti*-square pyramidal arrangement. These dimer units are then linked into chains via further long-range bromide bridges resulting in a distorted six-coordinate bismuth geometry.⁵⁰⁷

Figure 71 The structure of [(BiCl₃)₂([24]aneS₈)] (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **1998**, 3961–3968).

Figure 72 The polymeric chain in $[\text{BiBr}_3(\text{[16]aneSe}_4)]$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **2000**, 2163–2166).

Bismuth complexes of a variety of thiones are known and some have been discussed already in mixed ligand complexes.^{442,463,476,477} For tu there are seven- and eight-coordinate bismuth nitrate complexes, $[\text{Bi}(\text{NO}_3)(\text{tu})_5][\text{NO}_3]_2$ and $[\text{Bi}(\text{NO}_3)_3(\text{tu})_2]$, respectively.⁵⁰⁸ Related ligands, which mostly form six-coordinate complexes with bismuth halides with the ligand S-bonded, include those of 1-allyl-3(2-pyridyl)thiourea,⁵⁰⁹ 1-phenyl-3(2-pyridyl)thiourea,⁵¹⁰ 3,4,5,6-tetrahydropyrimidine-2(1H)-thione,⁵¹¹ benzimidazole-2(3H)-thione,⁵¹¹ and imidazolidine-2-thione.⁵¹² The charged ligand (35) forms the S-bound zwitterion $[\text{BiCl}_5(\text{35})]^-$,⁵¹³ and the anionic (36) forms a $\mu\text{-Cl}_2$ dimer $[\text{Bi}_2\text{Cl}_4(\text{36})_2]$.⁵¹⁴ A related ligand (37) hydridotris(thioxotriazolyl)borate(1-) forms red crystals of $[\text{Bi}(\text{37})_2]\text{Cl}\cdot\text{H}_2\text{O}$ in which the bismuth is coordinated to six thione S atoms.⁵¹⁵ Bismuth thiocyanate complexes, $[\text{Bi}(\text{SCN})(\text{NCS})_2(\text{L})_3]$ and $[\text{Bi}(\text{NCS})\text{S}(\text{H}_2\text{O})(\text{L})]\cdot\text{H}_2\text{O}$ ($\text{L} = 1,3$ -dimethyl-2(3H)-imidazolethione) have been prepared and characterized by X-ray crystallography; both have six-coordinate bismuth centers.⁵¹⁶ There are also semicarbazones,⁵¹⁷ various heterocyclic thiones^{518,519} and dithio-oxamide,^{224,520} which bond to bismuth as neutral S-donors. A few examples of phosphine sulfide complexes are known, for example, $\text{Pr}^n_2\text{P}(\text{S})\text{P}(\text{S})\text{Pr}^n_2$ forms $[\text{BiCl}_3\{\text{Pr}^n_2\text{P}(\text{S})\text{P}(\text{S})\text{Pr}^n_2\}]$ which is a μ -dibromide bridged dimer with chelating diphosphine disulfides.⁵²¹ The iminodiphosphinesulfide $\text{HN}[\text{P}(\text{S})\text{Me}_2]_2$ forms a tris(chelate) in its monoanionic form in $[\text{Bi}\{\text{N}[\text{P}(\text{S})\text{Me}_2]_2\}_3]$,⁵²² and there is a related complex formed by the $[\text{Ph}_2\text{P}(\text{S})]\text{HN}[\text{P}(\text{Se})\text{PPh}_2]$ which contains a very rare example of a bismuth-phosphine selenide linkage.⁵²³

Dithioacid complexes of bismuth are numerous (Table 4) and repeat many of the structural motifs of their arsenic and antimony analogues, most notably the very asymmetric coordination (“anisobidentate”), although, as a consequence of the larger bismuth atom, higher coordination numbers are more evident. In the xanthates, seven-coordinate bismuth appears to be favored, although this is achieved in different ways: in $[\text{Bi}(\text{S}_2\text{COR})_3]$ ($\text{R} = \text{PhCH}_2$, $\text{c-C}_6\text{H}_{11}$, Bu^n) there are

centrosymmetric dimers,^{526,531} $[\text{Bi}(\text{S}_2\text{COPr}^i)_3]$ is a chain polymer,⁵²⁸ whilst $[\text{Bi}(\text{S}_2\text{COEt})_3]$ is more highly polymerized.⁵²⁶

The compound $[\text{Bi}\{\text{S}_2\text{CN}(\text{CH}_2\text{CH}_2\text{OH})_2\}_3]$ is a dimer with square antiprismatic bismuth (Figure 73)⁷⁴ whereas the As and Sb analogues are mononuclear (q.v.). The synthesis and structures of a range of halo(dithiocarbamato)bismuth derivatives have been reported.^{393,534–538} Generally these are polymeric. In $[\text{Bi}(\text{S}_2\text{CNEt}_2)_2\text{I}]$ there is a zig-zag chain linking six-coordinate bismuth centers with *cis*- I_2S_4 donor sets, through single iodine bridges, whereas the bromide, $[\text{Bi}(\text{S}_2\text{CNEt}_2)_2\text{Br}]$, is based upon a centrosymmetric tetramer.⁵³³ The $[\text{Bi}(\text{S}_2\text{CNEt}_2)_2\text{I}_2]$ is different

Figure 73 The structure of $[\text{Bi}\{\text{S}_2\text{CN}(\text{CH}_2\text{CH}_2\text{OH})_2\}_3]$ (reproduced by permission of Elsevier Science from *Polyhedron* **1997**, 16, 1211–1221).

Figure 74 The dimer structure in $[\text{Bi}(\text{S}_2\text{PMe}_2)_3]$ (reproduced by permission of Elsevier Science from *Polyhedron*, **1994**, 13, 547–552).

again, an infinite polymer this time with I_2S bridges between each pair of bismuth centers giving facially bridged units.⁵³⁵ The anion in $[\text{Et}_4\text{N}][\text{Bi}(\text{S}_2\text{NET}_2)\text{I}_3]$ is dimeric $[\text{I}_2(\text{S}_2\text{CNET}_2)\text{Bi}(\mu\text{-I})_2\text{Bi}(\text{S}_2\text{CNET}_2)\text{I}_2]^{2-}$,⁵³⁷ whereas in $[\text{Bi}_5(\text{S}_2\text{CNET}_2)_8\text{X}_7]$ ($\text{X} = \text{Cl}$, Br , or I) obtained by recrystallizing $[\text{Bi}(\text{S}_2\text{CNET}_2)\text{X}_2]$ from *N,N*-DMF, there is a central BiX_6 unit which links with four $\text{Bi}(\text{S}_2\text{CNET}_2)_2$ groups, although in detail there are three different bismuth coordination environments.⁴³⁹

Of the three structurally characterized dithiophosphates with simple R groups, $[\text{Bi}\{\text{S}_2\text{P}(\text{OEt})_2\}_3]$ is six-coordinate (distorted octahedral), but $[\text{Bi}\{\text{S}_2\text{P}(\text{OR})_2\}_3]$ ($\text{R} = \text{Ph}$ or Me) are dimeric with distorted pentagonal bipyramidal bismuth.^{540–543} Similarly, in the dithiophosphinate series $[\text{Bi}(\text{S}_2\text{PR}_2)_3]$ $\text{R} = \text{Et}$ is distorted octahedral, whereas $\text{R} = \text{Me}$ or Ph are dimeric (Figure 74).^{544–547} One curious observation is that in $[\text{Bi}(\text{S}_2\text{PEt}_2)_3]$ (Figure 75) the Bi–S bonds within the chelate rings are very similar (2.794(5), 2.782(5) Å) which contrasts with the anisobidentate coordination

Figure 75 The monomeric $[\text{Bi}(\text{S}_2\text{PETe}_2)_3]$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **1987**, 1257–1259).

(ca. 0.2 Å) found in many bismuth dithioacid complexes. The dimeric $[\text{Bi}(\text{S}_2\text{PR}_2)_3]$ have Bi—S_{terminal} bonds which range 3.641(3)–3.025(3) Å. The dithiophosphate, $[\text{Bi}\{\text{S}_2\text{P}[\text{OCHMeCHMeO}]\}_3]$, also has very similar Bi—S bond lengths,⁵⁴² whereas the few other structurally characterized examples are rather more asymmetrically coordinated. The disparate bond lengths in the dithioacid chelates of As, Sb, and Bi have been variously attributed to a combination of the radius of the central atom, small chelate bite, and the degree of stereochemical activity of the lone pair on the central atom, but the fine details of the structures are not understood.

The high affinity of bismuth for charged sulfur ligands results in the ready generation of bismuth thiolates from a range of bismuth salts and an appropriate thiol, although reaction of $\text{Na}(\text{Li})\text{SR}$ with BiCl_3 or of BiPh_3 with RSH have also been used.^{266,267,549–552} Examples are $[\text{Bi}(\text{SR})_3]$ ($\text{R} = \text{CH}_2\text{Ph}$,⁵⁵⁰ 2,4,6- $\text{Bu}^t\text{C}_6\text{H}_2$,^{267,549} 4-Me C_6H_4 ,²⁶⁶ 2,6-Me $_2\text{C}_6\text{H}_3$,²⁶⁶ 3,5-Me $_2\text{C}_6\text{H}_3$,²⁶⁶ 2,4,6-Me $_3\text{C}_6\text{H}_2$,²⁶⁷ 2,4,6- $\text{Pr}^i\text{C}_6\text{H}_2$,²⁶⁶ $\text{C}_6\text{H}_4\text{F}$,⁵⁵² and C_6F_5 ^{266,551}). The structure of $[\text{Bi}\{\text{S}(2,4,6\text{-Bu}^t\text{C}_6\text{H}_2)\}_3]$ shows a pyramidal monomer,⁵⁴⁹ but $[\text{Bi}(\text{SC}_6\text{F}_5)_3]$ is a weakly associated dimer (38).⁵⁵³ Unexpectedly, the reaction of NaSC_6F_5 and BiCl_3 in THF gave $[\text{Na}_2(\text{THF})_4][\text{Bi}(\text{SC}_6\text{F}_5)_5]$ with a square pyramidal anion.⁵⁵³ This Lewis acidity of $[\text{Bi}(\text{SC}_6\text{F}_5)_3]$ is demonstrated by the formation of a range of adducts with neutral and anionic ligands.⁵⁵¹ These include orange $[\text{Bi}(\text{SC}_6\text{F}_5)_3(\text{SPPH}_3)]$ which is dimeric through asymmetric thiolate bridges (as in the parent), resulting in square pyramidal bismuth. In contrast, $[\text{Bi}(\text{SC}_6\text{F}_5)_3(\text{L})_2]$ ($\text{L} = \text{OPPh}_3$, *N,N'*-dimethylpropyleneurea, $\text{OP}(\text{NMe}_2)_3$, OSPh_2) are square-pyramidal monomers with apical SC_6F_5 and *cis* basal SC_6F_5 . The compound $[\text{Bi}(\text{SC}_6\text{F}_5)_3\{\text{SC}(\text{NHMe})_2\}_3]$ is close to a regular octahedron. Toluene-3,4-dithiol (tdtH_2) and BiCl_3 react in 1:1 ratio in CHCl_3 to form $[\text{BiCl}(\text{tdt})]$ whilst excess dithiol and NEt_3 give $[\text{Bi}(\text{tdt})_2]^-$.⁹⁰ The structure of the dithiolato-anion $[\text{Bi}\{\text{S}_2\text{C}_2(\text{CN})_2\}_2]^-$ (as its AsPh_4^+ salt) shows polymeric chains with six-coordinate bismuth, with adjacent Bi atoms bridged by two dithiolate groups.⁵⁵⁴ The dithione-dithiol dmitH_2 (16) forms $[\text{A}][\text{Bi}(\text{dmit})_2]$ ($\text{A} = \text{AsPh}_4$, NBu_4 , NEt_4 , etc.) by metathesis between BiBr_3 and $[\text{A}][\text{Zn}(\text{dmit})_2]$. These have polymeric chain structures usually described as *pseudo*-pentagonal bipyramidal at bismuth (S_6 plus lone pair). The anion arrangements vary with the cation present.^{555–557} Alkanedithiols $\text{HS}(\text{CH}_2)_n\text{SH}$ ($n = 2–4$) react with slurries of BiCl_3 to form $[\text{BiCl}\{\text{S}(\text{CH}_2)_n\text{S}\}]$ which have chelate structures (39).⁵⁵⁸ If these complexes are reacted further with aqueous NaNO_3 and more dithiol, the final chloride is removed to give complexes of type (40).⁵⁵⁸ The X-ray structures also reveal intermolecular secondary $\text{Bi}\cdots\text{Cl}$ and $\text{Bi}\cdots\text{S}$ interactions which link the bismuth heterocycles into chains with seven-coordinate bismuth centers. If the dithiol contains a further donor group in the chain, $\text{HSCH}_2\text{CH}_2\text{QCH}_2\text{CH}_2\text{SH}$ ($\text{Q} = \text{O}$, S , or NR), *trans*-annular interactions produce bismocanes (41), which have structures based upon *pseudo*-trigonal bipyramidal geometry with axial Cl and Q.^{558–560} There are organobismuth analogues where Ph or Me groups replace the Cl.^{559,560} Dithiol-dithioether ligands have also been complexed with Bi^{III} .⁵⁶¹

Selenolates and tellurolates are rarer and mostly have bulky R groups, e.g., $[\text{Bi}(\text{SeR}^1)_3]$ ($\text{R}^1 = 2,4,6\text{-R}_3\text{C}_6\text{H}_2$, $\text{R}^2 = \text{Me}$, Pr^i or Bu^i),²⁶⁷ $[\text{Bi}\{\text{SeSi}(\text{SiMe}_3)_3\}_3]$,²⁷² and $[\text{Bi}\{\text{TeSi}(\text{SiMe}_3)_3\}_3]$ ²⁷² which are probably pyramidal monomers, although no examples have been structurally characterized. The structure of $[\text{Bi}(\text{SeR})_3]$ ($\text{SeR} = (42)$) has been determined and contains primary Bi—Se bonds (3.691–2.745 Å) and secondary $\text{Bi}\cdots\text{N}$ interactions (2.827–2.952 Å) with the lone pair appearing to point into the N_3 face of the very distorted octahedron (Figure 76).⁵⁶² The small SePh^- ligand, introduced via reaction of TMSSePh with BiBr_3 , produced clusters $[\text{Bi}_4(\mu\text{-SePh})_5(\text{SePh})_8]$ and $[\text{Bi}_6(\mu\text{-SePh})_6(\text{SePh})_{10}\text{Br}]$.⁵⁶³ The SeCN^- ligand forms $[\text{K}_3(\text{N,N'}\text{-dimethylpropyleneurea})_4][\text{Bi}(\text{SeCN})_6]$, which is Se-bonded (in $[\text{Bi}(\text{SCN})_6]^{3-}$ the thiocyanate is S-bonded).^{564,565}

3.6.4.3.4 S/O- and S/N-donor ligands

Thioethanol $\text{HOCH}_2\text{CH}_2\text{SH}$, reacts with most bismuth salts to give $[\text{Bi}(\text{HOCH}_2\text{CH}_2\text{S})_2\text{Y}]$ ($\text{Y} = \text{Cl}$, Br , NO_3 , ClO_4 , MeCO_2 , etc.).^{566,567} The structures contain a BiS_2O_2 core which then link in various ways depending upon the anion. The nitrate ion weakly chelates and there are long intermolecular $\text{Bi}\cdots\text{S}$ linkages, whilst in the chloride the units weakly associate via Cl and S bridges (Figure 77).⁵⁶⁶ Deprotonation of the alcohol function is rare but occurs in $[\text{Bi}(\text{SCH}_2\text{CH}_2\text{O})(\text{HOCH}_2\text{CH}_2\text{S})]$ which has a similar BiS_2O_2 core although with a much shorter Bi—O distance involving the alkoxide (2.195(9) Å) compared with the alcohol (2.577(9) Å). The structure is polymeric via alkoxide bridges.⁵⁶⁷ The alkoxide is protonated by acetic acid or by excess thioethanol, the latter reaction producing $[\text{Bi}(\text{HOCH}_2\text{CH}_2\text{S})_3]$.⁵⁶⁷ If the K^+ salt of (methyl-ester)methanethiolate reacts with BiCl_3 in ethanol the product is $[\text{Bi}(\text{SCH}_2\text{CO}_2\text{Me})_2\text{Cl}]$, which is polymeric with a seven-coordinate bismuth center ($\text{S}_4\text{O}_2\text{Cl}$) (Figure 78), whilst excess of the ligand formed $[\text{Bi}(\text{SCH}_2\text{CO}_2\text{Me})_3]$ which is a dimer with unsymmetrical thiolate bridges.⁵⁶⁸ Ketothiolate complexes $[\text{Bi}(\text{L-H})_3]$ $\text{LH} = \text{benzoylthiobenzoylmethanes}$, $\text{PhC}(\text{S})\text{CHC}(\text{O})\text{R}$ ($\text{R} = \text{C}_6\text{H}_4\text{H}$, $\text{C}_6\text{H}_4\text{OMe}$, $\text{C}_6\text{H}_4\text{Cl}$) are dimeric with *pseudo*-pentagonal bipyramidal bismuth with one thiolate donor and the lone pair occupying apical positions, and two asymmetric thiolate bridges.⁵⁶⁹

Aminoethanethiolates are, as might be expected, also good ligands for bismuth.^{570–572} The reaction of BiCl_3 or $\text{Bi}(\text{NO}_3)_3$ with $\text{H}_2\text{NCH}_2\text{CH}_2\text{SH}$, depending upon the reaction conditions yields $[\text{Bi}(\text{H}_2\text{NCH}_2\text{CH}_2\text{S})_3]$ or $[\text{BiY}(\text{H}_2\text{NCH}_2\text{CH}_2\text{S})_2]$ ($\text{Y} = \text{Cl}$ or NO_3), whilst from $\text{Me}_2\text{NCH}_2\text{CH}_2\text{SH}$ it is possible to make analogues of these and also $[\text{Bi}(\text{Me}_2\text{NCH}_2\text{CH}_2\text{S})\text{Cl}_2]$ and $[\text{Bi}(\text{SCH}_2\text{CH}_2\text{NMe}_2\text{H})\text{Cl}_3]$. In the latter, the ammonium function is (of necessity) uncoordinated and the structure is a zig-zag polymer with alternating $(\mu\text{-SR})_2$ and $(\mu\text{-Cl})_2$ bridges, with two terminal chlorines completing a six-coordinate bismuth environment.⁵⁷⁰ In the other complexes, the aminoethanethiolates function as *N,S* chelates with longer intermolecular $\text{Bi}\cdots\text{S}$ coordination. The $[\text{Bi}(\text{Me}_2\text{NCH}_2\text{CH}_2\text{S})\text{Cl}_2]$ was isolated as an adduct with HCl and the structure (43) reveals four bismuth atoms arranged around the central chloride ion.⁵⁷¹

Figure 76 The structure of the bismuth selenolate $[\text{Bi}(\mathbf{42})_3]$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Res.* **1999**, 416–417).

Figure 77 The polymeric unit in $[\text{BiCl}(\text{HOCH}_2\text{CH}_2\text{S})_2]$ (reproduced by permission of the American Chemical Society from *Inorg. Chem.* **1997**, 36, 2855–2860).

Other N,S-donor ligands which have been complexed with bismuth include 2-aminobenzenethiol (L) as $[\text{Bi}(\text{L-H})_3]$ and $[\text{BiCl}_3\text{L}_3]$,²⁷¹ 8-quinolinethiolate,⁵⁷³ and 2-methyl-1-quinolinethiolate,⁵⁷⁴ which form $[\text{BiL}_3]$ (N_3S_3) with strongly bound pyramidal BiS_3 and weak Bi—N bonds. The hindered pyridinethiolate $[\text{Bi}(2\text{-SC}_5\text{H}_3\text{N-3-SiMe}_3)_3]$ also shows strong Bi—S bonding, with a distorted pentagonal pyramidal S_3N_3 geometry with one apical S and a lone pair in the other apical site.⁵⁷⁵ Dithizone LH (**44**) also binds as an N,S chelate in $[\text{Bi}(\text{L})_3]$.⁵⁷⁶

Figure 78 The polymeric unit in $[\text{Bi}(\text{SCH}_2\text{CO}_2\text{Me})_2\text{Cl}]$ (reproduced by permission of the Royal Society of Chemistry from *Chem. Commun.* **2000**, 13–14).

2,6-Diacetylpyridinebis(thiosemicarbazone) (dapsH_2), in its dianionic form, gives a 1:1 complex with bismuth azide, $[\text{BiN}_3(\text{daps})]$, in which the ligand coordinates to the equatorial plane of a *pseudo*-pentagonal bipyramid (N_3S_2) with the azide apical.⁴⁹⁶

3.6.4.4 Group 17 Compounds

Haloanions of bismuth(V) are limited to the fluorides. Halobismuthates(III) and organohalobismuthates(III) exhibit a range of structures and among the heavier halogens there is considerable similarity to their antimony(III) analogues. The halobismuthate(III) (not fluorides) structures have been reviewed by Fisher and Norman.⁹¹

Fluorobismuthates(III) with stoichiometries $\text{M}[\text{BiF}_4]$, $\text{M}_2[\text{BiF}_5]$, $\text{M}_3[\text{BiF}_6]$, $\text{M}[\text{Bi}_3\text{F}_{10}]$, and $\text{M}_3[\text{Bi}_2\text{F}_9]$ ($\text{M} = \text{K}, \text{Rb}, \text{Cs}$, and sometimes Na, Li) have been prepared usually by melting together the components, although some have been isolated from aqueous HF solutions.^{577–584} Much of the structural data are based on powder X-ray diffraction, but structures are typically polymeric with the bismuth in a distorted nine-coordinate environment similar to that in BiF_3 or the Tysonite structure. There has been considerable interest in these compounds as fast fluoride ion conductors.⁵⁸⁵

The $\text{M}[\text{BiF}_6]$ ($\text{M} = \text{alkali metal}$) are made from MF and BiF_5 in anhydrous HF or by heating the constituents under fluorine pressure. There are also many examples with nonmetal cations $[\text{ClF}_2]^+$, $[\text{BrF}_2]^+$, etc. whilst $[\text{NR}_4][\text{BiF}_6]$ are made from NR_4F and BiF_5 in anhydrous HF.^{586,587}

The ^{209}Bi NMR spectrum of $[\text{BiF}_6]^-$ is a binomial septet confirming the regular O_h geometry.⁵⁸⁸ The hexafluorobismuthate(V) ion seems to be the only well-established six-coordinate form, and in contrast to antimony there seems to be no evidence for $[\text{Bi}_2\text{F}_{11}]^-$ anions.⁵⁸⁶ The $\text{M}_2[\text{BiF}_7]$ ($\text{M} = \text{Na}, \text{K}, \text{Rb}, \text{Cs}$) are made by combination of BiF_5 and excess MF under fluorine, whilst $[\text{NMe}_4][\text{BiF}_7]$ is made from NMe_4F and BiF_5 in MeCN .¹⁰⁵ The $[\text{BiF}_7]^{2-}$ ion decomposes in anhydrous HF to give $[\text{BiF}_6]^-$ and $[\text{HF}_2]^-$. The vibrational spectra are consistent with discrete pentagonal bipyramidal anions.¹⁰⁵ There is no evidence for $[\text{BiF}_8]^{3-}$.

The halobismuthates(III) are made by combination of BiX_3 and the appropriate cation in either organic solvents or aqueous acid. The major interest is in the structural units present in the anions and this section will illustrate the types known rather than list all the examples in the literature. There has also been some interest in the ferroelastic or ferroelectric properties of some of the halobismuthate phases.

The simplest chlorobismuthate(III) stoichiometry is $[\text{BiCl}_4]^-$ but this is never mononuclear. In $[\text{BiCl}_2(18\text{-crown-6})][\text{Bi}_2\text{Cl}_8]$ the anion is an edge-shared dimer with *anti*-apical Cl 's and square-pyramidal bismuth coordination.⁴¹² The reaction of MgCl_2 and BiCl_3 in MeCN produced $[\text{Mg}(\text{MeCN})_6][\text{Bi}_4\text{Cl}_{16}]$ which has a discrete centrosymmetric anion (Figure 79).³⁸⁰ Infinite polymers based upon BiCl_6 units sharing edges are present in $[\text{NEt}_2\text{H}_2][\text{BiCl}_4]$ ⁵⁸⁹ and $[\text{phenH}][\text{BiCl}_4]$.⁵⁹⁰ There appear to be no examples of a monomeric $[\text{BiCl}_5]^{2-}$ anion, the two motifs established are edge-linked bioctahedral $[\text{Cl}_4\text{Bi}(\mu\text{-Cl})_2\text{BiCl}_4]^{4-}$ found in K^+ ,⁵⁹¹ and $(1\text{H}^+, 5\text{H}^+ \text{-S-methylisothio-carbonohydrazidium})$,⁵⁹² salts and infinite polymers with BiCl_6 octahedra linked through two *cis* vertices into chains as in $[\text{phenH}_2][\text{BiCl}_5]$,⁵⁹⁰ and $[\text{H}_3\text{N}(\text{CH}_2)_6\text{NH}_3][\text{BiCl}_5]$.³¹⁸ A unique tetramer has recently been identified in $[\text{bipyH}_2]_4[\text{Bi}_4\text{Cl}_{20}]$, also based upon BiCl_6 units linked via *cis* vertices but generating a square array.⁵⁹⁰ The $[\text{BiCl}_6]^{3-}$ ion which is discrete and usually close to octahedral (consistent with minimal stereochemical activity of the lone pair⁹¹) is well established. Recent X-ray structures containing this anion include $[(\text{phenH})(\text{phenH}_2)(\text{H}_2\text{O})_2][\text{BiCl}_6]$,⁵⁹⁰ $[\text{NMe}_2\text{H}_2]_4[\text{BiCl}_6]\text{Cl}$,⁵⁹³ and $[2,6\text{-Me}_2\text{C}_5\text{H}_3\text{NH}]_3[\text{BiCl}_6]$.⁵⁹⁰ The $[\text{Bi}_2\text{Cl}_9]^{3-}$ anion is a confacial bioctahedron in the $[\text{bipyH}]^+$,⁵⁹⁰ $[\text{NMe}_4]^+$,⁵⁹⁴ and $[\text{NPhMeEt}_2]^+$ ⁵⁹⁵ salts, whereas 1-D double chains are present in the Cs^+ ⁵⁹⁶ and $[\text{NMeH}_3]^+$ salts.⁵⁹⁴

Figure 79 Representation of the tetranuclear anion $[\text{Bi}_4\text{Cl}_{16}]^{4-}$ (reproduced by permission of the Royal Society of Chemistry from *J. Chem. Soc., Dalton Trans.* **1991**, 961–965).

Two other chlorobismuthates, known in single examples are $[\text{NMeH}_3]_5[\text{Bi}_2\text{Cl}_{11}]$, which has BiCl_6 octahedra sharing a common vertex,⁵⁹⁷ and the largest reported example is $[\text{NEt}_4]_6[\text{Bi}_8\text{Cl}_{30}]$ shown in Figure 80.⁵⁹⁸

Bromobismuthates(III) repeat many of the motifs of the chlorides. Thus $[\text{BiBr}_4]^-$ and $[\text{BiBr}_5]^{2-}$ appear never to be mononuclear⁹¹ the former being either chain polymers or a tetramer $[\text{Bi}_4\text{Br}_{16}]^{4-}$ with a structure of the type shown in Figure 79.⁵⁹⁹ The bioctahedral $[\text{Bi}_2\text{Br}_{10}]^{4-}$ ion is present in salts with $[2,5\text{-diamino-1,3,4-thiadiazolium}]^+$,⁶⁰⁰ and $[\text{Sr}(\text{H}_2\text{O})_8]^{2+}$.⁶⁰¹ What can be seen either as a substituted variant of this or as a solvated $[\text{Bi}_2\text{Br}_8]^{2-}$ is found in $[\text{PPh}_4]_2[\text{Bi}_2\text{Br}_8(\text{Me}_2\text{CO})_2]$, which has the structure shown in (45).⁶⁰² Octahedral $[\text{BiBr}_6]^{3-}$ is present in the $[\text{NMe}_2\text{H}_2]^+$,⁶⁰³ $[\text{PhCH}_2\text{CH}_2\text{NH}_3]^+$,⁶⁰⁴ and $[2,6\text{-Me}_2\text{C}_5\text{H}_3\text{NH}]^+$ salts.⁵⁹⁰ The $[\text{Bi}_2\text{Br}_9]^{3-}$ exists as confacial bioctahedral and as chain polymeric forms.^{594,596,605} Larger bromobismuthates are $[\text{Bi}_2\text{Br}_{11}]^{5-}$ (isostructural with the chloride),⁶⁰⁶ $[\text{Bi}_6\text{Br}_{22}]^{4-}$ (Figure 81), and $[\text{Bi}_8\text{Br}_{28}]^{4-}$.⁶⁰⁵

(45)

Neither $[\text{BiI}_4]^-$ nor $[\text{BiI}_5]^{2-}$ are known in monomeric forms. In $[\text{bipyH}][\text{BiI}_4]$ ⁵⁹⁰ and $[2\text{-amino-1,3,4-thiadiazolium}][\text{BiI}_4]$ ⁶⁰⁷ there are chains of *cis* edged-shared BiI_6 octahedra, whilst $[(\text{PhCH}_2)_4\text{P}]_2[\text{Bi}_2\text{I}_8]$ is the first example of an iodobismuthate with square-pyramidal bismuth coordination.⁶⁰⁸ $[\text{BipyH}]_2[\text{BiI}_5]$ has a discrete $[\text{I}_4\text{Bi}(\mu\text{-I})_2\text{BiI}_4]^{4-}$ anion,⁵⁹⁰ and chains of $[\text{BiI}_6]$ octahedra are found in $[\text{H}_3\text{N-R-NH}_3][\text{BiI}_5]$ (R various long chain organic groups).^{318,609} Isolated $[\text{BiI}_6]^{3-}$ octahedra are found in $[\text{PhCH}_2\text{CH}_2\text{NH}_3]_2[\text{BiI}_6]\text{I}$,⁶⁰⁴ and $[\text{MeCOCH}_2\text{NC}_5\text{H}_5]_2[\text{C}_5\text{H}_4\text{NH}][\text{BiI}_6]$.⁶¹⁰ The $[\text{Bi}_2\text{I}_9]^{3-}$ ion is present as discrete confacial bioctahedra in the $[\text{NMe}_4]^+$ and $[\text{NEt}_2\text{H}_2]^+$ salts, although polymeric in the Cs^+ salt.^{611,612} Three face sharing BiI_6 octahedra generate the $[\text{Bi}_3\text{I}_{12}]^{3-}$ anion found in salts with $[\text{NBu}_4]^+$,⁶¹⁴ and $[N,N'\text{-dimethylpropyleneurea}]^{+337}$ cations, whilst extension to a chain of five face sharing octahedra is found in $[\text{Ph}_4\text{P}]_3[\text{Bi}_5\text{I}_{18}]$.³³⁶ If four BiI_6 octahedra share edges, one structure is $[\text{Bi}_4\text{I}_{16}]^{4-}$ which has the geometry shown for the chlorine analogue in Figure 79.^{375,614} In $[\text{Q}]_4[\text{Bi}_6\text{I}_{22}]$ (Q = $\text{PhCH}_2\text{Et}_3\text{N}$, Ph_4P , Et_4P , EtMe_2PhN) the anion has the structure type shown in Figure 81,^{336,399,595,615} removal of a BiI_3 unit generates $[\text{Bi}_5\text{I}_{19}]^{4-}$,⁶¹⁵ whilst addition of two more BiI_3 groups generates $[\text{Bi}_8\text{I}_{28}]^{4-}$, the largest discrete iodobismuthate presently known.⁶¹⁶ Infinite chains are present in

Figure 80 The structure of $[\text{Bi}_8\text{Cl}_{30}]^{6-}$ (reproduced by permission of Elsevier Science from *J. Phys. Chem. Solids* **1989**, 50, 1265–1269).

Figure 81 The structure of $[\text{Bi}_6\text{Br}_{22}]^{4-}$ (reproduced by permission of Wiley-VCH from *Z. Anorg. Allg. Chem.* **2001**, 627, 2261–2268).

$[\text{NBu}^n_4][\text{Bi}_2\text{I}_7]$ which consists of Bi_4I_{16} units sharing common bridging iodines, and $[\text{Ph}_4\text{P}]_2[\text{Bi}_3\text{I}_{11}]$ is similarly related to Bi_6I_{24} .⁶¹⁶ Finally in $[\text{Bi}_4\text{I}_{14}(\text{THF})_2]^{2-}$ there is the $[\text{Bi}_4\text{X}_{16}]^{4-}$ type (Figure 79) with two terminal halides replaced by tetrahydrofuran.⁶¹⁵

Organohalobismuthine anions are also known. $[\text{BiPh}_2\text{X}_2]^-$ ($\text{X} = \text{Br}$ or I) are *pseudo*-trigonal bipyramids with the lone pair occupying an equatorial position. $[\text{BiPhI}_2(\text{THF})]$ reacts with $[\text{NEt}_4]\text{I}$ to form $[\text{NEt}_4]_2[\text{Bi}_2\text{Ph}_2\text{I}_6]$ which is a discrete dimer with edge-linked square pyramids.^{408,617} Mixed halobismuthines, $[\text{BiPhX}_2\text{Y}]^-$ ($\text{X} = \text{Cl}$ or Br ; $\text{Y} = \text{Cl}$, Br , or I) are also known.⁶¹⁸

3.6.4.5 Bismuth in the Environment, Biology, and Medicine

Bismuth is a rare element, mostly recovered as a by-product of lead and copper ore processing. Industrially, its major uses are as the element in various alloys, in simple inorganic chemicals and in medicine. Only the last of these relates to the coordination chemistry. Unusually for elements in this area of the periodic table, bismuth compounds are of low toxicity, in general markedly less so than arsenic and antimony analogues.^{111–113} Indeed it seems that the majority of cases of bismuth poisoning have occurred during medical therapy rather than due to industrial exposure. Bismuth is used widely in treatment for intestinal disorders, anti-ulcer treatments, with much recent interest in the eradication of *Helicobacter pylori*.⁶¹⁹ There are three detailed reviews which describe bismuth compounds with biological or medicinal relevances,⁶²⁰ bismuth anti-ulcer complexes,⁶²¹ and the biological and medicinal chemistry of bismuth,⁶²² which should be consulted for details. A further article discusses the coordination chemistry of metals in medicine-target sites for bismuth.⁶²³ The medicinal preparations range from simple inorganic salts to bismuth complexes of carboxylic, hydroxo- and amino-carboxylates, of which the colloidal bismuth subcitrate is a widely used example. Many of the preparations are mixtures of complexes and the chemical speciation is ill-defined.

3.7.1 INTRODUCTION

As has been cogently observed¹ the elements of Group 14 exhibit perhaps the most diverse chemical behavior seen for the members of any single group. This has the benefit of making Group 14 a fascinating area of study as well as a richly rewarding one—there is no such thing as “handle-turning” in the study of these elements. The variation in stability of oxidation states, the

Table 1 Significant properties of germanium, tin, and lead.^a

Element	Electron configuration	Covalent radius (Å)	NMR nucleus (% abundance)
Germanium	[Ar]3d ¹⁰ 4s ² 4p ²	1.22	⁷³ Ge (7.8)
Tin	[Kr]4d ¹⁰ 5s ² 5p ²	1.41	¹¹⁹ Sn (8.7) ¹¹⁷ Sn (7.7)
Lead	[Xe]4f ¹⁴ 5d ¹⁰ 6s ² 6p ²	1.54	²⁰⁷ Pb (22.6)

^a Massey, A. G. *Main Group Chemistry*, 2nd. ed., Wiley: Chichester, 2000.

wide tolerance for coordination numbers, ligand types, and coordination geometries all work together to ensure that there is never a dull moment.

There are some overarching considerations that relate to these elements and offer some useful guidelines to their general behavior in terms of their coordination chemistry. The lightest of these elements, germanium, occurs predominantly in the M^{IV} oxidation state and where found as M^{II}, its reactions tend towards to its oxidation. The range of coordination numbers for germanium is narrower than those seen for tin or lead, four or five being the most commonly observed. Tin, equally content in either oxidation state, can form complexes of higher coordination number but may form perfectly stable low coordination number complexes, especially in the lower oxidation state. Lead, the heaviest of the triad, prefers the lower oxidation state and exhibits coordination numbers between two and 10, although some of these higher coordination numbers may be somewhat moot. There is no doubt, however, that lead spans the range of highest to lowest coordination number shown amongst these elements.

There is no marked preference for hard or soft donors, as all three elements are equally able to form complexes with both hard and soft donors in both oxidation states. Further, as post-transition elements, they adopt geometries in their complexes that do not follow regular patterns, such as transition metals do, but rather are governed by the number and nature of ligands present in their complexes.

These simple considerations in hand, the coordination chemistry of these elements becomes largely explicable. Fortunately, there are exceptions and surprises to keep the level of interest high and to drive the exploration of this area.

It is extremely fortunate that Group 14 also offers some potent spectroscopic tools for the investigation of its complexes. All three elements have at least one NMR active nucleus, and while ¹¹⁹Sn has been widely studied for many years,^{2,3} it is only recently that solution ²⁰⁷Pb and ⁷³Ge spectra have become widely available to the synthetic chemist (Table 1). Additionally, Mössbauer spectroscopy is very useful in the assignment of coordination number, oxidation state, and geometry in tin complexes, and the expansion of crystallography has been of great utility in all areas.

While this is not a review of organometallic chemistry a great number of organo- substituted compounds are included where the remainder of the ligand set is of interest. This seems justified in that, for these compounds, the organic ligands are usually playing a spectator role and serve only to support and stabilize the metal.

3.7.2 COMPLEXES WITH CARBON DONOR LIGANDS

Excluding organic ligands, there are few examples of complexes of M(14) with carbon donor ligands. Most cyanide and cyanate complexes have been known for some time, although there are always new examples to be found. The simplest examples of complexes with M(14)—C bonds are the carbides, and a number of new routes to such compounds have been reported.

Thermolysis of C(GeH₃)₄, prepared from the four-fold insertion of GeCl₂·diox into CBr₄⁴ followed by reduction with LiAlH₄, gives the binary carbide Ge₄C, which exhibits a diamond structure.⁵ Complex M(14) carbide-containing compounds M₂M(14)C (M = Ti, Hf, Zr, Nb; M(14) = Sn; M = Zr, Hf; M(14) = Pb) have been prepared from heating the respective elements together at 1,200–1,325 °C for 4–48 h. The lead compounds, reported for the first time, are unstable under ambient conditions, and exhibit hardness and conductivity comparable with other such carbides.^{6,7} Carbides M(3)M(14)C (M = Al, Sc, La–Nd, Sm, Gd–Lu; M(14) = Sn, Pb) have been prepared and all have been shown to exhibit Perovskite structures.⁸ The direct combination of barium, germanium, and carbon in elemental form at 1,260 °C gives Ba₃Ge₄C₂,

a moisture-sensitive carbide with semiconductor properties. The compound comprises $[\text{Ge}_4]^{4-}$ units with Ge—Ge bond lengths of 2.517 Å and $[\text{C}_2]^{2-}$ with C—C bond lengths of 1.20 Å. The carbide also reacts with NH_4Cl to give ethyne and a range of germanes.⁹

Bis(trimesitylgermylcarbodiimido)germylene is stable in the absence of oxygen or water but rapidly decomposes at 50 °C to give a mixture of bis(trimesitylgermyl)carbodiimide and poly(carbidodiimido)germylene, whereas hydrolysis leads to the monogermylated derivative of cyanamide as both trimesitylgermyl cyanamide and trimesitylgermyl carbodiimide.¹⁰ The related $(\text{mes})_3\text{-Ge}(\text{CN})$ has been characterized crystallographically and found to have a distorted tetrahedral geometry at the metal.¹¹

Germanium(II) cyanide is a highly moisture-sensitive compound that is stable in solution as $\text{Ge}(\text{CN})_2$ in the absence of air, moisture, or Lewis bases but forms an intractable liquid on isolation, possibly due to irreversible oligomerization. Prepared by the reaction of germanium(II) chloride and silver cyanide in refluxing THF, the complex was identified in solution by IR (νCN 2,090 cm^{-1}) and by trapping reactions.¹²

Tin and tin cluster cyano complexes SnCN^- , $\text{Sn}(\text{CN})_2^-$, Sn_2CN^- , Sn_3CN^- , and Sn_4CN^- have been studied by a combination of anion photoelectron spectroscopy and DFT calculations.¹³ Further cyanide complexes can be prepared from the reaction of SnCl_4 with $\text{TMS}(\text{CN})$, forming Cl_3SnCN , or from the oxidative addition of $\text{X}(\text{CN})$ ($\text{X} = \text{Br}, \text{I}$) to SnCl_2 , forming $\text{SnCl}_2\text{X}(\text{CN})$. Both the IR and Mössbauer spectroscopic data indicate a polymeric structure for these compounds in the solid state with bridging ambidentate cyano groups. In the preparation of $\text{SnCl}_2\text{Br}(\text{CN})$, a second species of composition $\text{SnCl}_2\text{Br}(\text{CN})(\text{THF})_{0.5}$ was isolated, which was identified spectroscopically as a mixture of $[\text{SnCl}_2\text{Br}(\text{CN})]_n$ and monomeric $\text{SnCl}_2\text{Br}(\text{CN})(\text{THF})_2$, which has a near octahedral geometry with *trans* disposition of the solvent ligands.¹⁴

A rare example of a M(14) carbonyl complex has been formed in the gas-phase ion-molecule reaction of GeH_4 with CO, where ions of the type $[\text{GeH}_n(\text{CO})]^+$ can be detected. Similarly, the carbonates $[\text{GeH}_n(\text{CO}_2)]^+$ can be prepared by the analogous reaction with CO_2 .¹⁵ These transient compounds are a tantalizing indication of what may be available to traditional synthetic chemists if the right approach can be found.

3.7.3 COMPLEXES WITH M(14)—M(14) BONDS

Catenation is a pronounced feature of Group 14 chemistry, especially for the lighter members and the ease with which stable M(14)—M(14) bonds may be formed has resulted in research involving the preparation and study of complexes that have such bonds. Examples of complexes that comprise bonding between atoms of the same element are numerous and range from dinuclear compounds to large polynuclear assemblies.

3.7.3.1 Complexes with M(14)—M(14) Homoelement Bonds

Larger molecules $(\text{R}_2\text{Ge})_n$ are on the whole less stable than the equivalent silicon or carbon analogues, and are prone to thermal and photochemical reactions, including elimination of R_2Ge monomers and the concomitant formation of ring-contracted products. The photolysis of $(\text{R}_2\text{Ge})_n$ ($\text{R} = \text{Me}$, $n = 6$ ¹⁶; $\text{R} = \text{Pr}^i$, $n = 4$ ¹⁷) gives the ring-contracted products, the R_2Ge monomer and $(\text{R}_2\text{Ge})_2$ dimers, detected spectroscopically. The monomeric diorganogermanes are not stable but can be trapped, such as in reaction with carbon tetrachloride, forming R_2GeCl_2 . Complexes $(\text{R}_2\text{M})_2$, ($\text{M} = \text{Ge}, \text{Sn}, \text{Pb}$) where R is a very large group, are comparatively stable and the area has been reviewed.^{18,19}

Bis(dimethylgermyl)methane reacts with $(\text{Bu}^i)_2\text{Hg}$ —mercury to give the heterocyclic product 1,3,5,7,2,6-tetragermadimercurocene, which extrudes mercury to form 1,1,2,2,4,4,5,5-octamethyl-1,2,4,5-perhydotetragermine, a six-membered ring with two germanium—germanium bonds.²⁰ The sulfur-containing cycloheptyne (**1**) reacts directly with $\text{GeCl}_2 \cdot \text{diox}$ to give (**2**), a digermacyclobutene with a Ge—Ge bond length of 2.380 Å (Scheme 1). There is no evidence either in the solid or in solution of any transannular Ge—S interaction.²¹ The same alkyne reacts with tin(II) chloride to give a mononuclear complex.²²

Trimetallacyclopropanes, germanium or tin triangles, have emerged as a fascinating subset of compounds with M(14)—M(14) bonds. The first fully characterized germanium example was $[(2,6\text{-Me}_2\text{C}_6\text{H}_3)_2\text{Ge}]_3$ prepared by the reaction of $(\text{acac})_2\text{GeCl}_2$ ($\text{acac} = \text{acetylacetonate}$) with

Scheme 1

(2,6-Me₂C₆H₃)MgBr. The complex has a regular triangular array of the metals with intermetallic bond lengths 2.543–2.547 Å and in common with the larger arrays, the complex forms (R₂Ge)₂ on photolysis.²³ An improved general synthesis using R₂GeCl₂, magnesium and magnesium bromide subsequently broadened the field.²⁴

Triangular [Cl(Bu^t₃Si)Ge]₃ has been prepared from the reaction of GeCl₂·diox with Na[SiBu^t₃] and its subsequent conversion to [(Bu^t₃Si)₂GeGe(SiBu^t₃)=Ge(SiBu^t₃)] has been examined by ²⁹Si NMR. This study implicates both Na[Ge(Cl)(SiBu^t₃)Ge(Cl)₂(SiBu^t₃)] and [(Bu^t₃Si)(Cl)Ge]₂ as intermediates in the reaction. These were trapped from the reaction mixture, in the former case by addition of further Bu^t₃SiCl and in the latter by addition of isoprene to give (3).²⁵ The presence of large organic groups seems to be essential to the formation of the ring structure, as the reaction of germanium(II) chloride with Li[2,4,6-Bu^t₃C₆H₂], Li[R] gives mononuclear RGeCl²⁶ or R₂Ge²⁷ complexes depending upon stoichiometry. Even though this is a fairly big group it seems that it is not large enough to promote the formation of the trimer.

The reaction of GeCl₂·diox with Li[EBu^t₃] (E = Si, Ge) gives (4) (Scheme 2), that comprises an unsaturated Ge—Ge double bond. The geometry of (4) is an isosceles triangle, comprising one Ge—Ge double bond (2.239 Å) and two Ge—Ge single bonds (2.519 Å). The exocyclic Ge—Si bonds show a marked difference depending upon whether the germanium to which they are attached to is doubly (2.448 Å) or singly bonded (2.629 Å) to germanium.²⁸ The product (4) is liable to oxidation by [Ph₃C][BPh₄] yielding the monocation (5). Structural analysis of (5) shows that the intermetallic bonds within the triangle are all equivalent, 2.33 Å, a value intermediate between double (ca. 2.24 Å) and single (ca. 2.52 Å), indicating that the compound is aromatized.²⁹

Scheme 2

The unsaturated triangulo germanium complexes are stable, but can undergo a number of reactions typical of double bonds. The complex (Bu^t₃Si)(mes)Ge{Ge(SiBu^t₃)₂} (mes = 2,4,6-trimethylphenyl) undergoes (2 + 2) cycloaddition reactions with phenylalkyne to give 1,4,5-trigerma-5-mes-2-phenylbicyclo[2.1.0]pent-2-ene and (2 + 4) cycloaddition with isoprene to give 1,4,5-trigerma-7-mes-bicyclo[4.1.0]hept-3-ene.³⁰

Triangulo (Bu^t₂Ge)₃ inserts PhNC to give trigerma-butanamine (6), and in a similar fashion, the chalcogens sulfur and selenium insert to give the chalcogermetanes (7) and (8), the selenium compound being planar (Scheme 3).³¹

Scheme 3

Reaction of (2,6-mes₂C₆H₃)GeCl with KC₈ gives the cyclotrigermanyl radical **(9)**, which again has all equivalent Ge—Ge bonds (2.35 Å). The blue crystalline product shows an EPR spectrum with low values of hyperfine coupling, indicating that the single electron is probably in a low-lying π antibonding orbital. Further reduction of **(9)** with an excess of KC₈ gives the ring-opened trigermanyl allyl anion **(10)**, isolated as its deep green potassium salt (Scheme 4). The angle Ge—Ge—Ge is 159°, and the bond lengths Ge—Ge are 2.42 Å, slightly shorter than single bond length. These data all point to aromatization in this rather unusual product.³²

Scheme 4

The same reducing agent has been used to convert (2,6-trip₂C₆H₃)SnCl (trip = 2,4,6-triisopropyl-phenyl) to the radical anionic dimer [(2,6-trip₂C₆H₃Sn)₂]^{•−} **(11)**. Crystallographic analysis reveals

a moderately long Sn—Sn bond of 2.812 Å and this, taken with the angle $C_{\text{ipso}}\text{—Sn—Sn}$ of 95.2° seem to preclude any Sn—Sn π bonding.³³ The deep red product $[(\text{Ph}_2\text{Sn})_2]^-$ can be prepared by the reaction of Ph_2SnCl_2 with lithium in liquid ammonia. In this case, the compound is centrosymmetric and has a Sn—Sn bond length of 2.91 Å, significantly longer than the more sterically congested (11). The complex (12), comprising an asymmetric anionic chelating ligand, has a similar Sn—Sn bond (2.869 Å).³⁴ The reaction of LiMe with $[\text{2,6-(trip}_2\text{C}_6\text{H}_3)(\text{Cl})\text{Sn}]$ gives a stable heavy analogue of methyl methylene, as $\text{Me}_2(\text{2,6-trip}_2\text{C}_6\text{H}_3)\text{SnSn}(\text{2,6-trip}_2\text{C}_6\text{H}_3)$, with a tin(IV)—tin(II) bond.³⁵ Another example of a complex with a tin(IV)—tin(II) bond is available from the reaction of tin(II) chloride with the Grignard reagent prepared from 2-(diphenylphosphino)bromobenzene, (13).³⁶ Reduction of $(\text{2,6-trip}_2\text{C}_6\text{H}_2)\text{PbBr}$ with lithium aluminum hydride according to an unknown mechanism gives the dimer $[(\text{2,6-trip}_2\text{C}_6\text{H}_2)\text{Pb}]_2$ which has a trans bent geometry and a Pb—Pb bond of 3.118 Å, which seems closer to a single than a multiple bond.³⁷

Tin complexes $(\text{R}_2\text{Sn})_3$ have been less studied than their germanium counterparts but are no less readily prepared. The reaction of $(\text{2,6-Et}_2\text{C}_6\text{H}_3)_2\text{SnCl}_2$ with lithium naphthalenide gives $(\text{R}_2\text{Sn})_3$ with intermetallic bond lengths of 2.854–2.870 Å.³⁸

The first example of a molecular compound with a tetrahedral $[\text{Ge}_4]$ unit has been prepared in the reaction of $\text{GeCl}_2 \cdot \text{diox}$ and $\text{Na}[\text{SiBu}^t_3]_4$, as $[\text{GeSiBu}^t_3]_4$. The bond lengths Ge—Ge are 2.44 Å, intermediate between double and single bond values.³⁹ Germanium(II) iodide reacts with $\text{Na}_2[\text{Cr}_2(\text{CO})_{10}]$ in the presence of 2,2'-bipyridyl(bipy) to form $[\text{Ge}\{\text{Cr}(\text{CO})_5\}]_6$ (14), an octahedral cluster of germanium substituted with organometallic ligands. The complex has as its core a Zintl ion unknown in the free state and has intermetallic bonds that are shorter than those seen in other Zintl ions such as $[\text{Ge}_9]$ (2.521–2.541 cf. 2.52–3.00 Å).⁴⁰ The corresponding tin complex is prepared from the reaction of $\text{K}_2[\text{Cr}(\text{CO})_5]$ and tin(II) chloride without the diimine ligand.⁴¹

An alternative geometry for a $[\text{Ge}]_6$ framework is trigonal prismatic, and an example of a complex with this structure is $(\text{TMS}_2\text{CHGe})_6$ prepared from the corresponding Grignard reagent and germanium(IV) chloride. The complex has two distinct Ge—Ge bonds, on the triangular face (2.579 Å) and on the quadratic face (2.526 Å).⁴²

The same framework is also seen in the tin compound $[\text{Bu}^t_3\text{SiSn}]_6$ (15), prepared from $(\text{TMS}_2\text{N})_2\text{Sn}$ and 12 equivalents of $\text{Na}[\text{SiBu}^t_3]$.⁴³ Larger again, the octagermacubane $[(\text{2,6-Et}_2\text{C}_6\text{H}_3)\text{Ge}]_8$ ⁴⁴ and octastannacubane⁴⁵ have been prepared by dehalocoupling reactions of RMX_3 with Mg/MgBr . A complex of lower nuclearity with a different structural motif is

2,2,4,4,5,5,-hexakis(2,6-Et₂C₆H₃)pentastanna[1,1,1]propellane, prepared by the thermolysis of [(2,6-Et₂C₆H₃)₂Sn]₃ in refluxing xylene.⁴⁶ From the same thermolysis it is also possible to isolate the first heavy M(14) prismane (2,6-Et₂C₆H₃)₁₀pentacyclo[6.2.0.02,7.03,6.04,10.05,9]decastanna-decane (16).⁴⁷

(15)

(16)

Other homoelement assemblies can be found in the extensive family of Zintl anions. Of interest in this area is the recently reported synthesis of [Ge₉]⁴⁻ from the direct combination of Cs and Ge at 900 °C. The structure of [Ge₉]⁴⁻ in Cs₄Ge₉ is a monocapped square antiprism. The same synthetic approach can be used to prepare the series of compounds M₁₂Ge₁₇ (M = Na, K, Rb, Cs) that comprises one [Ge₉]⁴⁻ and two [Ge₄]⁴⁻ clusters.^{48,49} A polymeric assembly can be isolated from the en and 18-C-6 extraction of KGe₄ as a linear polymer of vertex linked ligand free [Ge₉]²⁻ clusters.⁵⁰ The Zintl ions in the complexes M^IAuM(14)₄ (M^I = K, Rb, Cs, M(14) = Sn, Pb) have been studied crystallographically and shown to comprise chains of tetrahedra of M(14) bridged by gold ions,⁵¹ similar to the cadmium-bridged [Pb₄] tetrahedra in the structure of K₆Pb₈Cd.⁵² A discussion of the cluster compounds of the heavier M(14) elements has been published.^{53,54}

3.7.3.2 Complexes with M(14)—M(14) Heteroelement Bonds

The propensity for catenation may be exploited further to prepare M^I(14)—M^{II}(14) species that comprise direct bonds between different members of Group 14. This is a relatively young area of research but there are already many fascinating examples of such compounds in the literature.

Although there are many examples of compounds that have frameworks based upon Si_n rings, there are very few examples of such rings incorporating heteroatoms. Substituted gerमतetrasilacyclopentanes [(R¹₂Si)₄GeR²₂] (R¹ = Prⁱ, R² = CH₂SiMe₃ or Ph; R¹ = CH₂Bu^t, R² = Ph) are stable compounds but can be photolyzed to give either R²₂Ge and the ring contracted cyclosilanes or a range of silenes, disilenes, germens, and silagermenes, depending upon the organic substituents.⁵⁵

The complexes TMSGePh₃, Me₃GeSiPh₃, FpMe₂SiGeMe₃, FpMe₂GeSiMe₃, IFpMe₂SiGeMe₃, IFpMe₂GeSiMe₃, IFpMe₂SiGePh₃, IFpMe₂GeSiPh₃, and FcSiMe₂GeMe₂Fc (Fp = CpFe(CO)₂, IFp = (indenyl)Fe(CO)₂, Fc = ferrocene) were prepared and their decomposition under mass spectral conditions examined to probe the nature of the Si—Ge bond. For the bimetallic species, the main feature of the mass spectra is the presence of peaks due to products formed by R group scrambling. For the trimetallic species, the Fe—Si—Ge linkage cleaves predominantly at the Si—Ge bond, giving Fp silylene products, whereas the complexes with the Fe—Ge—Si linkage cleaves at the Fe—Ge bond, indicating that the Fe—Ge bond is less stabilized than the Fe—Si bond, which is in turn more stabilized than the Ge—Si bond.⁵⁶

The disilane MeBu^t₂Si—SiBr₃ reacts with (MeBu^t₂Si)₂GeCl₂ in the presence of sodium metal to give the triangular complex (17). The Si=Si double bond is short at 2.146 Å giving a pronounced isosceles geometry to the ring. Thermal or photochemical rearrangement gives the cyclic germa-silene (18) (Scheme 5).⁵⁷ Further germa-silenes R¹₂Si=GeR²₂ are available either from the reaction of Li₂[R¹₂Si] and R²₂GeCl₂ (R¹ = Prⁱ₃Si, Bu^t₂MeSi, R² = mes, 2,4,6-Prⁱ₃C₆H₂), trapped by addition of methanol to give the silane hydride and germanium methoxide,⁵⁸ or from the photolysis of (mes₂Ge)₂Si(mes)₂. The product from this latter reaction, mes₂Ge=Si(mes)₂,

rearranges to give the mixed valence complex $(\text{mes}_3\text{Si})\text{Ge}(\text{mes})$. The M^{II} amides (**19**) react to form the tetranuclear (**20**) (Scheme 6) presumably by a similar mechanism, whereas the tin amide gives (**21**) (Scheme 7).⁵⁹

Scheme 5

Scheme 6

Scheme 7

The reaction of $[\text{mes}_2\text{GeCl}]_2$ with $\text{mes}_2\text{SiCl}_2$ in the presence of a reducing agent gives the heteroelement triangle $(\text{mes}_2\text{Ge})_2\text{Si}(\text{mes})_2$. Upon photolysis, the complex eliminates mes_2Ge in preference to mes_2Si and gives the germyl silylene $\text{mes}_2\text{GeSi}(\text{mes})_2$.⁶⁰ The other member of the (M^1M^2) triangle series, $\text{R}_2\text{Ge}(\text{SiR}_2)_2$, can be prepared by the reaction of germanium(II) chloride with $\text{Li}[\text{Si}(\text{SiMe}_3)_3]$, forming $\text{TMSGe}[\text{Si}(\text{SiMe}_3)_2]_2$. The mechanism by which this reaction proceeds is not clear but the preparation has a moderately high yield. The bond lengths $\text{Ge}-\text{Si}$ are 2.35 and 2.391 Å, and $\text{Si}-\text{Si}$ is 2.366 Å. In the same paper, the structure of $(12\text{-C-4-Li})(\text{TMS}_3\text{Ge})$ is reported.⁶¹

The dihydride (**22**) can be lithiated and subsequently reacted with $(\text{trip})_2\text{SnF}_2$ to give the heterobimetallic (**23**) (Scheme 8). The germanium can be lithiated again with the loss of the remaining hydride to form the heterotrimetallic (**24**). This reacts with alkyl halides, such as MeI , to give the corresponding germanium alkyl, or alternatively (**24**) can eliminate LiF to give the first stannagermene (**25**). The tin—germanium double bond is extremely reactive and so the complex is trapped, either by addition of alcohols to give the germanium hydride and tin alkoxide or by thermal rearrangement to give the triangular $(\text{R}_2\text{Sn})_2\text{GeR}_2$.⁶²

Scheme 8

Surprisingly, the first organosilyl plumbane $\text{Pb}(\text{SiMe}_3)_4$ was only reported as recently as 1983, the tetrahedral compound obtained from the reaction of lead(II) chloride with $\text{Mg}(\text{SiMe}_3)_2$.⁶³

Amides $(\text{TMS}_2\text{N})_2\text{M}^{\text{II}}$ ($\text{M} = \text{Sn}, \text{Pb}$) react directly with $\text{K}[\text{Si}(\text{SiMe}_3)_3]$ to give $(\text{TMS}_3\text{Si})_2\text{M}^{\text{II}}$. The lead complex is monomeric with $\text{Pb}-\text{Si}$ bond lengths of 3.70 Å, whereas the tin complex dimerizes to form a distannane with a *trans* configuration and a $\text{Sn}-\text{Sn}$ bond length of 2.82 Å. This bond is long for a distannane and is close to the expected value for a single bond, which indicates the extent to which the steric and electronic effects exerted by the ligands influence the interaction of the metals.⁶⁴

The tin(II) complex $[1,8-\{\text{N}(\text{CH}_2\text{Bu}^t)\}_2\text{C}_{10}\text{H}_6]\text{Sn}$ reacts with $[2,6-(\text{NMe}_2)_2\text{C}_6\text{H}_3]_2\text{M}$ ($\text{M} = \text{Ge}, \text{Sn}$) to form the dinuclear complexes (26) (Scheme 9). The bonding in these has been interpreted in terms of a donor-acceptor interaction between the more electron-rich metals with the aryl ligands to the more electron-deficient nitrogen-bound tin.⁶⁵

Scheme 9

3.7.4 COMPLEXES WITH GROUP 15 LIGANDS

The M(14) nitrides, phosphides, and arsenides are materials with industrially useful properties, and while these are fascinating areas and although there is a wealth of literature relating to these compounds they do not fall within the scope of this article. Some materials or methods of preparation that relate to this group of compounds that are new are covered because they are of more general interest.

3.7.4.1 Complexes with Neutral Monodentate Nitrogen Ligands

New complexes of monodentate nitrogen ligands are rare, as such ligands have been studied for many years. However, some seemingly simple ligands can be used to prepare complexes that have features that transcend expectations.

Neutral monodentate *N*-donor ligands have been used to prepare monomeric six-coordinate tin(IV) complexes all-*trans* $\text{R}_2\text{SnX}_2(\text{L})_2$ ($\text{R} = \text{cyclohexyl (Cy)}, \text{Ph}$, $\text{X} = \text{Br}$, $\text{L} = \text{pyrazole, imidazole}$,⁶⁶ $\text{R} = \text{Ph}$, vinyl, $\text{X} = \text{Cl}$, $\text{L} = \text{pyrazole}$ ⁶⁷). However, the product of the reaction between Ph_2SnCl_2 and pyrazine has an overall stoichiometry of $\text{Ph}_2\text{SnCl}_2(\text{pyrazine})_{0.75}$, and consists in the solid state of alternating layers of polymeric $[\text{Ph}_2\text{SnCl}_2(\text{pyrazine})]_n$, which has a six-coordinate

tin center, and mononuclear $\text{Ph}_2\text{SnCl}_2(\text{pyrazine})$, which has a five-coordinate tin. If Me_2SnCl_2 is used, the product is exclusively $[(\text{Me}_2\text{SnCl}_2)_2(\text{pyrazine})]_n$, an indication of the subtle variety of behavior exhibited by tin in its coordination compounds. Solid-state ^{119}Sn NMR can differentiate between the two discrete tin centers in the phenyl compounds. Crystallographic analysis reveals long Sn—N bonds of 2.961 and 3.783 Å in the polymeric compound and 2.683 Å in the dimer.⁶⁸

Diphenyllead dichloride coordinates two equivalents of imidazole to give the six-coordinate complex with trans organic ligands and bond lengths Pb—N 2.45 Å.⁶⁹

3.7.4.2 Complexes with Anionic Monodentate Nitrogen Ligands

The structure of $\gamma\text{-Ge}_3\text{N}_4$, prepared from either $\alpha\text{-Ge}_3\text{N}_4$ or $\beta\text{-Ge}_3\text{N}_4$ at elevated temperatures and pressures (1,000 °C, 12 GPa) has a spinel structure and F_{d3m} symmetry. The structure comprises both octahedral and tetrahedral coordination of germanium by nitrogen (Ge—N 1.996 and 1.879 Å, respectively).⁷⁰ The binary tin nitride Sn_3N_4 has been prepared by the reaction of tin(IV) bromide with KNH_2 in liquid ammonia. The product itself is amorphous and decomposes directly to the elements at temperatures approaching 420 °C.⁷¹ Ternary nitrides $\text{Sr}_3\text{Ge}_2\text{N}_2$ and Sr_2GeN_2 have been prepared from Na, NaN_3 , Sr, and Ge at 750 °C. The former exhibits a structure with zig-zag chains of Ge^{2-} ions, and both have $[\text{GeN}_2]^{4-}$ ions, with angles N—Ge—N of 113.6° and bond lengths Ge—N ranging between 1.85–1.88 Å.⁷² The complex lead nitride $\text{La}_5\text{Pb}_3\text{N}$ is available from the reaction of La, La_4Pb_3 , and LaN at 1,050–1,250 °C. The structure is an isopointal interstitial derivative of the Cr_2B_3 structure type. The Pb—Pb separation of 3.550 Å seems to preclude any significant Pb—Pb interaction.⁷³

A number of azides of Group 14 metals have been prepared and reported following a growth in interest in such complexes, in part due to their potential application as precursors to metal nitrides. The germanium(IV) monoazide $(\text{mes})_3\text{Ge}(\text{N}_3)$ has been prepared and shown to have a distorted tetrahedral geometry at the germanium and an almost perfectly linear azide.¹¹ Treating $(\text{acac})_2\text{GeCl}_2$ with sodium azide in refluxing acetonitrile forms the *cis* diazide $(\text{acac})_2\text{Ge}(\text{N}_3)_2$ ⁷⁴ and the first neutral octahedral triazide of germanium, $[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]\text{Ge}(\text{N}_3)_3$, has also been reported.⁷⁵ The impressive homoleptic hexaazide anion $[\text{Ge}(\text{N}_3)_6]^{2-}$ has been prepared for the first time and a number of its reactions explored. In the solid state, the anion has idealized S_2 symmetry as its $[(\text{PPh}_3)_2\text{N}]^+_2$ salt, with no close interactions between the ions, whereas the $[\text{Na}_2(\text{THF})_3(\text{Et}_2\text{O})]^{2+}$ salt has C_1 symmetry, with short $\text{Na}\cdots\text{N}$ contacts of 2.410–2.636 Å. Addition of the nitrogen donor ligands bipy or phen (L) (phen = 1,10-phenanthroline) gives the first neutral octahedral tetraazide complexes $\text{LGe}(\text{N}_3)_4$. A ^{14}N NMR study gave values of δ for N_α of –288.9 and for N_γ –208.⁷⁶

Triphenyltin(IV) azide and a number of its 1:1 adducts (py, py-NO, HMPA, Ph_3PO) have been prepared and all of these complexes have been found to exhibit a five-coordinate geometry in the solid state. For $\text{Ph}_3\text{Sn}(\text{N}_3)$ this is achieved, in the absence of additional ligands, through 1,3 bridging azido groups that link two tin centers to form dimers through the formation of eight-membered $[\text{Sn}_2\text{N}_6]$ rings.⁷⁷ This difference in structure compared to $\text{mes}_3\text{Ge}(\text{N}_3)$ is more likely to be a result of the smaller radius of germanium rather than the larger co-ligands in that complex. In reaction with 1,4- $(\text{SCN})_2\text{-C}_6\text{H}_4$ triorganotin azides $\text{R}_3\text{Sn}_3(\text{N}_3)_3$ (R = Me, Et, Buⁿ, Ph) form the dinuclear complexes (27), which can be converted to the lead analogue by reaction with triphenyllead chloride (Scheme 10).⁷⁸

Scheme 10

Azides of the lower oxidation state are less stable but nonetheless several have been reported, including $[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]\text{Ge}(\text{N}_3)$ (pz = pyrazolyl),⁷⁵ $(\text{K}_\text{L})\text{Ge}(\text{N}_3)$ (K_L = Klau's ligand)⁷⁹ (aminotropinimate) $\text{M}(\text{N}_3)$ (M = Ge, Sn),⁸⁰ and $(\text{N,N'-mes}_2\text{-1,5-diazapentadienyl})\text{M}(\text{N}_3)$ (M = Ge, Sn).⁸¹ These complexes all exhibit geometries consistent with stereochemically active lone pairs and

linear or near-linear azides. There is considerable ionic character in $[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]\text{Ge}(\text{N}_3)$, dissociating in polar solvents to give well separated $[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]\text{Ge}^+$ and $(\text{N}_3)^-$ ions. The ^{14}N NMR spectrum of the latter complex has $\delta \text{N}_\alpha -291$, $\text{N}_\beta -136$, and $\text{N}_\gamma -215$ for the germanium complex and -292 , -136 , and -223 for the tin complex. The recent advances in covalent azide coordination chemistry of main group elements have been reviewed.⁸²

Tin isothiocyanato complexes $(\text{PhMe}_2\text{Si})\text{Sn}(\text{Me})_2(\text{NCS})$,⁸³ $\text{Ph}_3\text{Sn}(\text{pyridinium-2-carboxylato-})(\text{NCS})$,⁸⁴ and $\text{R}^1\text{R}^2\text{SnL}(\text{NCS})_2$ ($\text{R}^1, \text{R}^2 = \text{Ph}_2$, $(4\text{-tolyl})_2$, $(3\text{-ClC}_6\text{H}_4)_2$, $(4\text{-ClC}_6\text{H}_4)_2$, Me , Et , Et Pr^n ; $\text{L} = \text{neutral } \kappa^1\text{O-donor}$) have been reported.⁸⁵ The first of these is claimed to be the first example of a four-coordinate tin(IV) isothiocyanate. The second has an overall trigonal bipyramidal (tbp) geometry at the tin with all three phenyl groups equatorial and the isothiocyanate ligand axial, trans to the *O*-bound Zwitterionic pyridine carboxaldehyde. The series of complexes that are the third example have been examined by Mössbauer spectroscopy to explore the relationship between ligand type and the selectivity between *cis* and *trans* coordination of the organic ligands. This spectroscopic technique is useful in determining the coordination number, the geometry, and in favorable cases, the relative disposition of the ligands about the tin center.

The complex anions $[\text{SnX}_{6-n}\text{Y}_n]^{2-}$ ($\text{X} = \text{Cl}, \text{Br}$; $\text{Y} = \text{CN}^-$ or SCN^-) have been studied by ^{119}Sn NMR in solution and a correlation between the value of δ and the number and nature of the ligands on the anion established.⁸⁶

The reaction between the seemingly simple reagents tin(IV) chloride and $(\text{TMSN})_2\text{C}$ gives the remarkable tetranuclear (**28**).⁸⁷ The compound is stable and isolated in good yield, an example of a bridging mode for a monodentate *N*-donor ligand a role that nitrogen ligands play in many complexes of the heavier M(14) congeners. A mixed oxidation state dimer (**29**) is formed from the reaction of $[\text{SnI}(\text{NPPH}_3)]_2$ with sodium metal in a reaction that seems to proceed with loss of NaSn_x . The complex has a planar $[\text{SnN}]_2$ ring with bond lengths $\text{Sn-N}_{\text{terminal}} 1.990$ (ave.) $\text{Sn}^{\text{IV}}\text{-N}_{\text{bridging}} 1.957$, and $\text{Sn}^{\text{II}}\text{-N} 2.25 \text{ \AA}$.⁸⁸

The triorganogermanium amine $\text{mes}_3\text{GeNH}_2$ is prone to Ge-N cleavage reactions by protic reagents, indicative of the relative polarity of the Ge-N bond, whereas reaction with $\text{Bu}^t\text{C}(\text{O})\text{Cl}$ gives an intact acylamino germane.⁸⁹ Complexes with bridging and terminal Ge-NH_2 functionality can be prepared from the reaction of $\text{H}_3\text{Ge}[\text{N}(\text{SiMe}_3)(2\text{-6-Pr}^i\text{-C}_6\text{H}_3)]$ with ammonia, giving $[(\text{NH}_2)_2\text{Ge}\{\text{N}(\text{SiMe}_3)(2\text{-6-Pr}^i\text{-C}_6\text{H}_3)\}]_2\text{NH}$ (**30**) (Scheme 11).⁹⁰ Tetrakis(trimethylhydrazido)-germanium(IV) (**31**) is available from the reaction of $\text{Li}[\text{N}(\text{Me})\text{NMe}_2]$ with germanium(IV) chloride.

Scheme 11

Structural studies show that N_α is slightly pyramidal and that there is no N_β -Ge interaction,⁹¹ a surprising result in light of the β interactions seen for closely related systems.⁹²

(31)

The lead amide $Bu^t_3PbNH_2$ has been prepared by the reaction of Bu^t_3PbCl with $LiNH_2$ and the amine protons shown to be liable to further exchange reactions. With $Li[SiMe_3]$, the asymmetric secondary amine $(Bu^t_3Pb)(SiMe_3)NH$ can be prepared.⁹³ Normal coordinate analysis of the series of organolead amines Me_3PbNH_2 , $(Pr^i_3Pb)_2NH$, and $(Me_3Pb)_3N$, together with their isotopically labeled counterparts has been carried out. In each case, a force constant for $Pb-N$ of $1.95 \times 10^2 \text{ Nm}^{-1}$ is found, a value that indicates the strongly ionic character of the $Pb-N$ bond. This finding is in good agreement with the reaction behavior of organolead amides.⁹⁴

Germanimine (32) has been prepared in the reaction of the sterically stabilized germanium(II) dialkyl $Ge[CH(SiMe_3)_2]_2$ with $Me_2Si(N_3)_2$. It rapidly rearranges to the more stable silanimine (33) which itself dimerizes to (34), which comprises two terminal germanium azides (Scheme 12). Hydrolysis of (33) or (34) yields the silatetrazole (35), comprising a single exocyclic germanium azide.⁹⁵ Taking $R_2Si(N_3)_2$ ($R = \text{mes}, Bu^t$) and two equivalents of the same germanium alkyl gives digermanimines (36), and for the case where R is mes , the bond length $Ge-N_\alpha$ is 1.681 Å. In the case where R is Bu^t the corresponding rearrangement gives (37), a cyclic silanimingermane (Scheme 13).⁹⁶ Similarly, germanimine (38) can be prepared from mes_2GeBr_2 and $Li[1-(NH)-2,4,6-(F)_3C_6H_2]$. In this example, the germanimine is sufficiently stable to be isolated, and the $Ge=N$ double bond reactivity can be explored. The system is susceptible to a number of typical double bond reactions, such as the addition of chloroform to give the secondary amine $(\text{mes})_2(\text{CCl}_3)GeN(H)C_6H_2F_3$, or of nitron to give (39), a $[GeN_2OC]$ germacycle (Scheme 14).⁹⁷ The reaction of $\text{mes}N_3$ with $Sn[2,4,6-(CF_3)_3C_6H_2]_2$ gives a product with a ring structure, with no $Sn-N$ double bond (40).⁹⁸ The sterically encumbered germanium(II) amine $Ge[N(SiMe_3)_2]_2$ reacts with primary arylamine $(2,6-Pr^i_2C_6H_3)NH_2$ to give the planar germazane (41), where each germanium(II) ion has two $(RN-)$ bridging groups, leading to a two-dimensional assembly.⁹⁹ The bond lengths $Ge-N$ are 1.859 Å (ave.) and the angles $N-Ge-N$ and $Ge-N-Ge$ are 101.8 and 138.0°, respectively, showing a departure from the geometry of an ideal six-membered ring.

The simple homoleptic M^{II} amides $M^{II}(NMe_2)_2$ ($M = Sn, Pb$) preferentially dimerize with one terminal and two bridging amides on each metal. Both compounds are thermally unstable and decompose to a variety of intractable products.¹⁰⁰

The tin amide $Sn^{II}(NMe_2)_2$ reacts with primary amines RNH_2 to form cubane complexes $[SnNR]_4$. These cubanes are three-dimensional arrays formed in contrast to the planar germazane (41) as a result of the ability of the larger tin(II) ion to accommodate three nitrogens in its coordination sphere. A range of amines can be used to prepare these cubes, including some relatively nonacidic examples.¹⁰¹ The amines can also comprise some secondary functionality that can be further exploited, such as the complexes (42), where the amines carry groups that promote further association of the cubes in a controlled fashion in the solid state.¹⁰² Addition of sterically demanding amines RNH_2 to $Sn(NMe_2)_2$ ($R = \text{mes}, 2,6-Pr^i_2C_6H_3$) gives complexes such

Scheme 12

Scheme 13

Scheme 14

as (43), which may represent intermediates along the reaction pathway that leads to the formation of cubane complexes and as such may offer an insight into the reaction mechanism.¹⁰³

Such tin cubanes are prone to substitution reactions with organolithium reagents, so the reaction of $[(\text{Bu}^t\text{N})\text{Sn}]_4$ with six equivalents of $\text{Li}[\text{naphthyl}]$ forms the vertex-substituted (44). The same cubane reacts with $\text{Li}[(\text{Cy})\text{HP}]$ to give $[(\text{CyP})_3\text{Sn}_2]_2(\text{Li}(\text{THF})_4) \cdot \text{THF}_2$, the first structurally characterized polyphosphinidine tin(II) anion.¹⁰⁴

The reaction of benzonitrile, Bu^tLi and lead(II) chloride is the unexpected $(\text{THF})\text{Li}[(\text{Ph})(\text{Bu}^t)\text{C}=\text{N}]_3\text{Pb}$, a rare lead imino complex, in which the alkyl lithium reagent has added across the nitrile triple bond and generated a lithium imide that has reacted *in situ* with the lead(II) chloride. The anionic complex has a pyramidal geometry at the lead, and in the solid state, the lithium ion bridges the three nitrogens on the opposite face to the lead.¹⁰⁵

3.7.4.3 Complexes with Neutral Bidentate Nitrogen Ligands

Ligands based upon bipyridyl have extensive application in coordination chemistry and have long been a popular subject for study. These ligands can form stable complexes with metals from

Table 2 NMR data for diimine complexes of germanium(IV).

Complex	$\delta^{73}\text{Ge}$	$\Delta\nu_{1/2}(\text{Hz})$	$\delta^{14}\text{N}$
BipyGeCl ₄	−313.7	35	
BipyGeCl ₃ (NCS)	−319.5	22	−266.1
BipyGeCl ₂ (NCS) ₂	−327.1	35	−232.9
BipyGeCl(NCS) ₃	−340.2	32	−237.5
BipyGe(NCS) ₄	−351.8	48	−242.2
1,10-phenGeCl ₄	−319.4	150	
[Ge(NCS) ₆] ^{2−}	−442.5		

throughout the periodic table, and Group 14 is certainly no exception, with a range of complexes available with such diimine ligands.

The enthalpies of formation of the complexes M(14)Cl₄(bipy) (M(14) = Ge, Sn) were determined by calorimetric methods.¹⁰⁶ The germanium complex reacts with KSCN to form the series of complexes (bipy)GeCl_x(NCS)_{4−x}¹⁰⁷ and the values of δ (⁷³Ge) for these complexes are given in (Table 2). Despite the great utility of ¹¹⁹Sn NMR, there have been relatively few reports of research where ⁷³Ge NMR is used as an analytical technique, and the values given for these compounds are amongst the earliest such data reported. There is a linear change in δ with the change in electronic character of the donor set, a phenomenon well known in NMR but seen very rarely for this nucleus. In the same report, the value of δ for [Ge(NCS)₆]^{2−} is also given, −442.5, the first value for a ⁷³Ge NMR chemical shift ever reported for a six-coordinate complex.¹⁰⁸

The structure of SnCl₄(phen) closely approaches a regular octahedron¹⁰⁹ whereas the mixed organohalo complexes ROC(O)CH(Me)CH₂SnCl₃(L) (L = bipy, phen) exhibit a strongly distorted octahedral geometry at the tin despite having changed only one halide for a relatively sterically undemanding organic ligand.¹¹⁰

A range of complexes of general formula R₂SnCl₂(L) (L = bipy derivative) have been reported, research that is driven at least in part by the reported antitumor activity of complexes Me₂X₂Sn(L) (X = Cl, Br, I, L = bipy, phen).¹¹¹ For the majority of these a *trans* disposition of the two R groups is observed (L = bipy, R = Me, Buⁿ, Prⁱ, bn,¹¹² Prⁱ¹¹³, Buⁿ, CH₂CH₂CN,¹¹⁴ Ph;¹¹⁵ L = 4,4′-Me₂-bipy, R = C₅H₈¹¹⁶). An exception to this seems to be (4-tolyl)₂SnCl₂(bipy), where crystallographic investigation reveals a *cis* disposition of the two organic ligands and *trans* halides.¹¹⁷ For the complex (4-ClC₆H₄)₂SnCl₂(4,4′-Me₂-bipy), both isomers can be prepared by varying the reaction conditions. Addition of the ligand to an ethanolic solution of (4-ClC₆H₄)₂SnCl₂ results in the *cis* form, which can be recrystallized from hot methanol to give the *trans* form exclusively.¹¹⁸ The first example of *mer* coordination in a six-coordinate triorganotin compound is found in (3,4,7,8-Me₄-phen)Ph₃Sn(TfO).¹¹⁹

A less conventional, but nonetheless interesting, set of complexes of tin with bipy or phen can be prepared from the reaction of R₃SnCl with the diimines. The complexes [R₃SnCl(H₂O)(L)]₂ have two five-coordinate tin centers with equatorial disposition of the three phenyl groups and the chloro and the O-bound water in the *trans* positions. Each water is hydrogen bonded to the nitrogens of two diimine ligands, and these diimines are further hydrogen bonded to the protons on the aqua ligand of a second R₃SnCl(H₂O) to give a hydrogen-bond linked dimer (R = Ph,¹²⁰ 4-ClC₆H₄¹²¹).

The bimetallic species bis(dichloromethylstannyl)methane coordinates one equivalent of bipy to form the asymmetric (45) with both four- and six-coordinate tin centers (Scheme 15). Bis(chlorodimethylstannyl)methane has been used to explore the bridging capability of pyrazine ligands (Scheme 16).¹²²

Cationic complexes [R₃Sn(L)]ClO₄ (R = Ph, Buⁿ; L = py₂, γ -picoline₂, bipy, phen) are available from the reaction of R₃SnCl with (L)AgClO₄ or directly from R₃SnClO₄ with (L). The complexes are 1,1 electrolytes in solution, and spectroscopic evidence indicates a *tbp* geometry with axial disposition of the N-donors for the monodentate ligands.¹²³

Bisimidazoles also present a chelating diimine donor set and are similarly effective ligands. The six-coordinate complexes (46) (X = Cl or Br; R = Me,¹²⁴ Et, or Buⁿ¹²⁵ exhibit *trans* R groups in the same way as do complexes of bipy derivatives. For the complex where X is Br and R is Me, the average Sn—N bond length is 2.305 Å and the overall geometry is close to octahedral. In the same study, dimeric complexes (R₂SnX₂)₂(μ -N,N′-dimethyl-bisimidazole) comprising bridging bisimidazoles and five-coordinate tin centers are also reported, along

Scheme 15

Scheme 16

with the complex ions $(\text{NEt}_4)_2[(\text{R}_2\text{SnX}_3)_2(\mu\text{-}N,N'\text{-dimethyl-bisimidazole})]$. The latter species also have bridging imidazoles but comprise six-coordinate tin centers in the solid state. The NMR data indicate that these dinuclear complex ions dissociate into monomers in solution. The ability to bridge metal centers in this way is a property of bis-imidazoles that is distinct from bipy derivatives.

Arylazo-2-pyridines coordinate R_2SnCl_2 ($\text{R} = \text{Me}, \text{Ph}$) to give the octahedral complexes (47). Spectroscopic evidence indicates that again a *trans* disposition of R groups is preferred. The angles C-Sn-C were calculated based on Parish's relationship as $148\text{--}155^\circ$ ($\text{R} = \text{Me}$) and $148\text{--}150^\circ$ ($\text{R} = \text{Ph}$).¹²⁶ The similar (48) shows *trans* methyl groups according to a crystallographic study, where the 2-MeO moiety has no bonding interaction with the tin center.¹²⁷

Tin(II) chloride complexes bipy or phen to give mononuclear $(\text{L})\text{SnCl}_2$ complexes with distorted *tbp* geometries.¹²⁸ Lead(II) perchlorate coordinates four phen ligands in the nine-coordinate $[(\text{phen})_4\text{Pb}(\kappa^1\text{-ClO}_4)]\text{ClO}_4$. The geometry at the metal is best described as a monocapped square antiprism.¹²⁹ With lead(II) thiocyanate, phen gives a dimeric complex $[(\text{phen})_2\text{Pb}(\text{SCN})_2]_2$ where each lead coordinates two diimines, one monodentate, and two bridging thiocyanates, giving an overall seven-coordinate lead¹³⁰ and with the mixed thiocyanate nitrate system, a monomeric seven-coordinate complex $[(\text{phen})_2\text{Pb}(\text{SCN})(\text{NO}_3)]$ with a chelating nitrate.¹³¹

3.7.4.4 Complexes with Anionic Bidentate Nitrogen Ligands

The ligand (**49**) reacts with two equivalents of $\text{GeCl}_2 \cdot \text{diox}$ to give the linear (**50**), with two-coordinate germanium centers ($\text{Ge}-\text{N}$ 1.856 Å, $\text{N}-\text{Ge}-\text{N}$ 80.93°) (Scheme 17). Tin, in the corresponding reaction, forms the complex (**51**), which has a geometry more closely related to a cubane structure ($\text{Sn}-\text{N}$ 2.247 Å, $\text{N}-\text{Sn}-\text{N}$ 110.8°).¹³²

Scheme 17

The dianionic ligand 1,3- Bu^t_2 -2,2- Me_2 -4,4- Cl_2 -1,2,3,4- λ -4-diazasilide has been used to prepare stannetidine (**52**). Reaction with AgTfO yields the unexpected (**53**), where the product rearranges following halide-TfO metathesis to allow the formation of a thermodynamically favorable $\text{Si}-\text{O}$ bond. In the solid state (**53**) is a coordination polymer and comprises tbp tin centers. The $\text{Sn}-\text{O}$ bonds are short (2.005 Å) probably due to the geometric constraints of the $[\text{SiN}_2\text{Sn}]$ ring.¹³³ Compound (**52**) also reacts with HX ($\text{X} = \text{Cl}, \text{Br}$) to give the three-coordinate addition product (**54**), formulated as a Zwitterion with no oxidation of the metal.¹³⁴ $(\text{RC}(\text{Ncy})_2)_2\text{Sn}$ (**55**)¹³⁵ is converted to the thione (**56**) by sulfide transfer from styrene sulfide ($\text{Sn}-\text{S}$ 2.28 Å) (Scheme 18). The stannathione rapidly dimerizes with formation of a $(\text{SnS})_2$ ring ($\text{Sn}-\text{S}$ 2.42–2.47 Å).¹³⁶ Oxidative addition of diphenyl chalcogenide PhEPh ($\text{E} = \text{S}, \text{Se}$) to $[(\text{CyN})_2\text{CR}]_2\text{M}^{\text{II}}$ ($\text{M} = \text{Ge}, \text{Sn}; \text{R} = \text{Me}, \text{Bu}^t$) proceeds with cleavage of the $\text{E}-\text{E}$ bond and addition of both phenyl chalcogenide fragments to the metal, giving six-coordinate products $[(\text{CyN})_2\text{CR}]_2\text{M}^{\text{IV}}(\text{EPh})_2$. For the mixed amidinate amide complexes $[(\text{CyN})_2\text{CR}][\text{N}(\text{SiMe}_3)_2]\text{M}^{\text{II}}$ the reaction proceeds

in a similar fashion, giving $[(\text{CyN})_2\text{CR}][\text{N}(\text{SiMe}_3)_2]\text{M}^{\text{IV}}(\text{EPh})_2$. For the germanium complex, spectroscopic and crystallographic data show that the complex is four-coordinate, in which the amidinate ligand is coordinated through one nitrogen only, whereas the tin complex is five-coordinate with the chelating amidinate intact.¹³⁷

Scheme 18

Aminoiminophosphoranes $\text{Bu}^t_2\text{P}(\text{NH})(\text{NH}_2)$ and $(\text{H}_2\text{NPPH}_2)(\text{Ph}_2\text{PNH})\text{N}$ react with diamino-stannanes $\text{R}_2\text{Sn}(\text{NET}_2)_2$ ($\text{R} = \text{Me}, \text{Bu}^n$) to give tricyclic stannaphosphazenes (57) and (58) comprising fused $[\text{SnN}_2]$, $[\text{SnN}_2\text{P}]$, and $[\text{SnN}_3\text{P}_2]$ rings.¹³⁸

The dilithium salt of aminoborane (59) reacts with lead(II) chloride to give the dimeric (60) in which the lead is chelated by one ligand and has a bridging interaction with a nitrogen from a second ligand. The lead is three-coordinate and is stable in this configuration.¹³⁹ The geometry is similar to that found in $[\text{Pb}(\text{NR}_2)]_4$ complexes.¹⁴⁰

3.7.4.5 Complexes with Polypyrazolyl Ligands

Polypyrazolylmethyl ligands and their anionic analogues polypyrazolylborohydrides exhibit a range of coordination behavior with $\text{M}(14)$ ions. The complexes that they form with $\text{M}(14)$

ions are usually mononuclear, where they coordinate through either two or three nitrogens in a chelate or facial tridentate fashion.

Bis(pyrazolyl)methanes are neutral chelating ligands that form six membered rings upon coordination. The complexes $(\kappa^2\text{-H}_2\text{Cpz}_2)\text{R}_{4-x}\text{SnX}_x$ ($\text{R} = \text{Me, Ph; X} = \text{Cl, Br; } x = 4, 3, 2$) show fluxional behavior in solution at ambient temperatures by NMR spectroscopy. Additionally, in acetone solution there is evidence from conductivity measurements that the pyrazolyl ligand fully dissociates.¹⁴¹ Furthermore, in the range of complexes $(\kappa^2\text{-L})\text{R}_x\text{SnX}_{4-m}\cdot y\text{H}_2\text{O}$ ($\text{L} = \text{H}_2\text{C}$ (4-Me-pz)₂, H_2C (3,4,5-Me₃-pz)₂, $(\text{H}_2\text{Cpz})_2$, H_2C (3,5-Me₂-pz)₂; $\text{R} = \text{Me, Et, Bu}^n, \text{Ph; X} = \text{Cl, Br, I; } n = 0, 1, 2; y = 1, 1.5, 2$) conductivity measurements taken on chloroform or acetone solutions suggest that when x is two, there is extensive dissociation of the chelating ligand, while in the cases where x is one or four, the six-coordinate structure is retained in solution. Structural analysis of the octahedral complex $[\kappa^2\text{-H}_2\text{C}(4\text{-Me-pz})_2]\text{Me}_2\text{SnCl}_2$ shows again a trans disposition of the two methyl groups and Sn—N bond lengths of 2.436 Å (ave.).^{142,143} The molecular structure of $[\kappa^2\text{-H}_2\text{C}(3,5\text{-Me}_2\text{-pz})_2]\text{Ph}_2\text{SnCl}_2$ exhibits a distorted octahedral geometry with the phenyl groups disposed trans and the chelating ligand has typical Sn—N bond lengths (2.448 and 2.520 Å). The complex also shows moderate activity against L1210 mouse leukemia cells with LD₅₀ of 0.39 μM.¹⁴⁴

Complexes $(\text{L})\text{R}_2\text{SnCl}_2$ ($\text{L} = \text{H}_2\text{Cpz}_2, \text{HCpz}_3, \text{HC}(3,5\text{-Me}_2\text{-pz})_3, 1,2\text{-py-3,5-Me}_2\text{-pz}, \text{H}_2\text{C}(2\text{-py})_2$; $\text{R} = \text{Me, Et, Pr}^n$) are six-coordinate nonelectrolytes in acetonitrile solution with trans organic groups. In chloroform solution, all the bidentate ligands dissociate, whereas the tris(pyrazolyl)-methanes remain coordinated, but are chelated through two of the nitrogen donors.¹⁴⁵ Complexes $(\text{L})\text{R}_n\text{SnX}_{4-n}$ ($\text{L} = \text{H}_2\text{Cpz}_2, \text{H}_2\text{C}(3,5\text{-Me}_2\text{-pz})_2, \text{Me}_2\text{Cpz}_2, \text{R} = \text{Me, Ph; X} = \text{Cl, Br; } n = 0, 1, 2$) have been examined by ¹¹⁹Sn Mössbauer spectroscopy and the coordination number and geometry of the complexes assigned with success based on this technique. All of the complexes have six-coordinate geometry incorporating chelation of the pyrazolyl ligands with the exception of the complexes $(\text{Me}_2\text{Cpz}_2)\text{R}_2\text{SnX}_2$ where the decreased Lewis acidity of the metal and the increased size of the ligand combine to prevent the formation of this complex.¹⁴⁶

The tris(pyrazolyl)methanes $\text{HCpz}_3, \text{HC}(4\text{-Me-pz})_3, \text{HC}(3,5\text{-Me}_2\text{-pz})_3, \text{HC}(3,4,5\text{-Me}_3\text{-pz})_3$, and $\text{HC}(3\text{-Me-pz})_2(5\text{-Me-pz})$ react with RSnCl_3 ($\text{R} = \text{Me, Bu}^n, \text{Ph}$) to form complexes $[(\text{L})\text{SnRCl}_2]^+[\text{RSnCl}_4]^-$ and $\{[(\text{L})\text{SnRCl}_2]^+\}_2[\text{RSnCl}_5]^{2-}$ and with SnX_4 ($\text{X} = \text{Cl, Br, I}$) to form $[(\text{L})\text{SnX}_3]^+[\text{RSnCl}_4]^-$ and $\{[(\text{L})\text{SnCl}_3]^+\}_2[\text{RSnCl}_5]^{2-}$, respectively. The structures of $\{[\text{HC}(4\text{-Me-pz})_3\text{SnBuCl}_2]^+\}_2[\text{BuSnCl}_5]^{2-}$, $[\text{HC}(3,5\text{-Me}_2\text{-pz})_3\text{SnMeCl}_2]^+[\text{MeSnCl}_4]^-$, and $[\text{HC}(3,4,5\text{-Me}_3\text{-pz})_3\text{SnBr}_3]^+[\text{SnBr}_5]^-$ show distorted octahedral environments for the tin centers in the cations, with bond lengths Sn—N of 2.22–2.32 Å, and tbp or distorted octahedral environments for the five- and six-coordinate anions, respectively.¹⁴⁷ The sterically demanding ligand $\text{HC}(3,5\text{-Me}_2\text{-pz})_3$ forms complexes of general formula $[\kappa^3\text{-HC}(3,5\text{-Me}_2\text{-pz})_3\text{M}^{\text{II}}]\text{Y}_2$ ($\text{M} = \text{Sn, Y} = \text{CF}_3\text{SO}_3^-, \text{X; M} = \text{Pb, Y} = \text{BF}_4^-, \text{X}$). In both cases, the metal is three coordinate with distances Pb—N of 2.379–2.434 Å from a crystallographic study. Treatment of PbX with excess $\text{HC}(3,5\text{-Me}_2\text{-pz})_3$ in acetone solution gives $\{[\kappa^3\text{-HC}(3,5\text{-Me}_2\text{-pz})_3]_2\text{Pb}\}[\text{BF}_4^-]_2$, which exhibits a trigonally distorted octahedral geometry and Pb—N distances of 2.634 Å. This particular geometry indicates that the remaining lone pair is not stereochemically active in this complex, in contrast to the corresponding complex prepared using the unsubstituted ligand, which exhibits a distorted six-coordinate geometry with distance Pb—N of 2.609–3.789 Å. The closely related $[\text{HB}(3\text{-Bu}^t\text{-5-Me-pz})_3]\text{SnCl}$ shows a tbp structure with an axial Sn—Cl of 2.601 Å and an equatorial stereochemically active lone pair.¹⁴⁸

Reaction of PbX with $\text{K}[\text{HB}(\text{pz})_3]$ or $\text{K}[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]$ leads to the mixed ligand complexes $[\{\kappa^2\text{-HC}(3,5\text{-Me}_2\text{-pz})_3\}(\kappa^3\text{-L})\text{Pb}]\text{BF}_4^-$. Where $\text{L} = [\text{HB}(3,5\text{-Me}_2\text{-pz})_3]$ the complex has a five-coordinate geometry where the pyrazolylmethane is bidentate, and shows longer Pb—N bonds (3.745–2.827 Å) than the pyrazolylborohydride Pb—N (2.375–2.475 Å).¹⁴⁹

Reaction of $\text{Pb}(\text{ACAC})_2$ with two equivalents of $\text{HB}(\text{Arf})_4$ in CH_2Cl_2 followed by $\text{HC}(\text{pz})_3$ or $\text{HC}(3,5\text{-Me}_2\text{-pz})_3$ gives the complexes $[\text{L}_2\text{Pb}]^{2+}[\text{B}(\text{Arf})_4]^{2-}$ ($\text{Arf} = 3,5\text{-(CF}_3)_2\text{-C}_6\text{H}_3$). For the $\text{HC}(\text{pz})_3$ complex, the lead has a distorted octahedral geometry with a stereochemically active lone pair, while the complex with the more sterically encumbered $\text{HC}(3,5\text{-Me}_2\text{-pz})_3$ has a trigonally distorted octahedral structure with a stereochemically inactive lone pair.¹⁵⁰

The anionic polypyrazolylborohydride complexes might be expected to show some similarities to the neutral polypyrazolylmethanes. However, some differences are seen, e.g., the diethyl bis(pyrazolyl)borate $\text{K}[\text{Et}_2\text{B}(\text{pz})_2]$ reacts with Et_2GeCl_2 with cleavage of the B—N bonds to yield $\text{Et}_2\text{B}(\text{pz})\text{B}(\text{Et})_2$ and $\text{Et}_2\text{Ge}(\kappa^1\text{-pz})_2$.¹⁵¹

Di- and triorgano tin complexes of dihydro and diphenyl bis(pyrazolyl)borates are chelated through the two nitrogen donors to give five-coordinate complexes.¹⁵² Bis- and

tris(pyrazolyl)borohydride form the complexes $[\text{H}_m\text{B}(\text{pz})_l]\text{Me}_n\text{SnCl}_{3-n}$ ($l = 2, 3$; $m = 1, 2$; $n = 0-3$) that are five- ($m = 2$) or six- ($m = 1$) coordinate. The solid-state structure of $[\text{H}_2\text{B}(\text{pz})_2]\text{Me}_2\text{SnCl}$ shows tbp geometry at the tin with axial Cl and nitrogen ligands.¹⁵³ $[\text{HB}(3\text{-Me-pz})_3]\text{SnCl}_2\text{Ph}$ is stereochemically rigid at ambient temperatures.¹⁵⁴

The first tris(pyrazolyl)borohydride complex of germanium(II) was prepared directly from $\text{K}[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]$ and $\text{GeCl}_2\cdot\text{diox}$ and isolated as its iodide $[\kappa^3\text{-HB}(3,5\text{-Me}_2\text{-pz})_3\text{Ge}]\text{I}$ ¹⁵⁵ and cyanide salts.¹⁵⁶ The solid-state structure of the iodide reveals well separated germanium containing cations and iodide anions, and that the geometry at the germanium is distorted tetrahedral, with the lone pair occupying the fourth vertex.

The three-coordinate complex $[\kappa^2\text{-H}_2\text{B}(\text{pz})_2]\text{SnCl}$ has in the solid state a trigonal pyramidal geometry at the tin with the angles about the tin averaging 86° , indicating that the lone pair is again stereochemically active and occupies the fourth equatorial vertex. There are indications of a weak interaction between the tin and the chloro ligand of a neighboring molecule in the crystal. The structure of $[\kappa^2\text{-H}_2\text{B}(\text{pz})_2]_2\text{Sn}$ is approximately tbp, with the fifth vertex occupied by the lone pair. In solution, ^1H NMR experiments show that the molecule is stereochemically nonrigid, with axial and equatorial sites exchanging with a barrier of $10.2\text{ Kcal mol}^{-1}$ and boat-boat rearrangements taking place with similar energy barriers. Comparable fluxional processes to these are also seen for $\text{HB}(3,5\text{-Me}_2\text{-pz})_3\text{SnCl}$.¹⁵⁷ In the same study, $[\text{B}(\text{pz})_4]_2\text{Sn}$ was found to have two chelated ligands and a tbp structure in the solid state, with similar fluxional behavior. The low temperature limit NMR spectrum shows a 3:1 pattern indicative of a structure with three equilibrating pyrazolyl groups that interact with the tin and a fourth that does not.

A number of tin(II) complexes of general formula $[\text{HB}(\text{pz})_3](\text{L})\text{SnCl}$ and $(\text{L})_2\text{Sn}$ have been reported ($\text{L} = \text{H}_2\text{B}(\text{pz})_2$, $\text{H}_2\text{B}(3\text{-Me-pz})_2$, $\text{Ph}_2\text{B}(\text{pz})_2$, $\text{HB}(\text{pz})_3$, $\text{HB}(3,5\text{-Me}_2\text{-pz})_3$, $\text{B}(\text{pz})_4$, $\text{B}(3\text{-Me-pz})_4$), and their solution¹⁵⁸ and solid-state ^{119}Sn NMR spectra measured.¹⁵⁹ The values of δ are constant for $[\text{H}_2\text{B}(\text{pz})_2]_2\text{Sn}$, and $[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]_2\text{Sn}$ in both states indicating that there is a strong similarity between the structures of these complexes. The value of δ for $[\text{HB}(\text{pz})_3]_2\text{Sn}$ in the solid state is centered between these two complexes. Analysis of the spinning side band patterns for the MASNMR spectra of these complexes indicates a close similarity between $[\text{H}_2\text{B}(\text{pz})_2]_2\text{Sn}$ and $[\text{HB}(\text{pz})_3]_2\text{Sn}$, whereas $[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]_2\text{Sn}$ has a substantially different pattern. These results suggest that the two former complexes have the same geometry at the metal, the complex comprising a four-coordinate tin. The spectra for $[\text{H}_2\text{B}(\text{pz})_2]\text{SnCl}$ are distinctly different in the two states, presumably due to the presence of moderately strong bridging intermolecular $\text{Sn}\cdots\text{Cl}$ interactions in the solid state that are disrupted in solution, giving distinct coordination environments in the two different states. The bond lengths $\text{Sn}-\text{N}$ in $[\text{HB}\{3,5\text{-(CF}_3)_2\text{-pz}\}]\text{SnCl}$ are longer than the those in the protio complex, a reflection of the difference in the electronic character between the two ligands.¹⁶⁰

The crystal structure of $[\text{HB}(\text{pz})_3]_2\text{Sn}$ has been determined and the tin found to exhibit an octahedral coordination geometry, with one tri- and one bidentate $[\text{HB}(\text{pz})_3]$, with the sixth coordination site occupied by the lone pair. The bond lengths $\text{Sn}-\text{N}$ are in the range of $2.263\text{--}3.732\text{ \AA}$, and the nitrogens that lie *cis* to the lone pair deviate from the expected square plane, with three angles between $72.3\text{--}79.4^\circ$ and one at 124.4° . This solid-state distortion correlates well with the solution ^{119}Sn NMR data which has δ between the values seen for four- and five-coordinate tin(II).¹⁶¹

The reaction of lead(II) chloride with $\text{K}[\text{H}_2\text{B}(\text{pz})_2]$, $\text{K}[\text{HB}(\text{pz})_3]$, $\text{K}[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]$, and $\text{K}[\text{B}(\text{pz})_4]$ gives products $(\text{L})_2\text{Pb}$ in all cases. For $[\text{B}(\text{pz})_4]_2\text{Pb}$, the structure is a distorted tbp, with two chelating ligands and an equatorial vertex occupied by the inert pair. As is seen with the tin analogue, the room temperature NMR indicates that the molecule is stereochemically nonrigid with four equilibrating pyrazolyl groups, but at 184 K , a 3:1 pattern is seen. For $[\text{HB}(\text{pz})_3]_2\text{Pb}$ the structure in the solid state is a monocapped octahedron, with the inert pair occupying the capping position.

A comparison of the structures of the neutral bispolypyrazolyl methane and -polypyrazolylborohydride complexes of lead(II) have similar structures, indicating that to some extent the structurally similar ligands do form similar complexes.¹⁶²

The issue of the stereochemical activity of the inert pair is explored further in the complexes of tin(II) and lead(II) with $[\text{HB}(\text{pz})_3]$, $[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]$, and $[\text{B}(\text{pz})_4]$. For both metals, the complexes $[\text{B}(\text{pz})_4]_2\text{M}^{\text{II}}$ are four coordinate with two chelating ligands whereas the geometry of $[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]_2\text{Sn}$ is close to octahedral with one tri- and one bidentate ligand, with the inert pair occupying the sixth position.¹⁶³ In comparison, $[\text{HB}(3,5\text{-Me}_2\text{-pz})_3]_2\text{Pb}$ is six coordinate with a trigonally distorted octahedral geometry, indicating the absence of a stereochemically active lone pair.^{164,165} There is a complex interplay of factors which govern whether the inert

pair is stereochemically active or not for complexes of $M(14)^{II}$ ($M = \text{Sn, Pb}$) and it seems clear from the experimental observations that lead(II) is more likely to be influenced by the steric effects of the ligand set than is tin(II).

An example of an eight-coordinate lead(II) complex is given by $[\text{HB}(1,2,4\text{-triazolyl})_3]_2\text{-Pb}(\text{H}_2\text{O})_2$. From the same reaction mixture, a polymeric material $[\{\text{HB}(1,2,4\text{-triazolyl})_3\}(\kappa^1\text{-NO}_3\text{-O})(\text{H}_2\text{O})\text{Pb}]_\infty$ was identified crystallographically and the geometry at the lead suggested that the metal had a stereochemically active lone pair.¹⁶⁶

3.7.4.6 Complexes with Tridentate Nitrogen Ligands

Lead(II) thiocyanate forms a linear polymeric compound with 2,2':6',2''-terpyridine(terpy), $[(\text{terpy})\text{Pb}(\text{SCN})_2]_\infty$, comprising seven-coordinate lead centers coordinating three pyridyl nitrogens and two *N*-bound and two *S*-bound bridging thiocyanates.¹⁶⁷

The tridentate 2,6-diacetylpyridine dihydrazone reacts directly with a solution of lead(II) nitrate to give $(\text{L})\text{Pb}(\text{NO}_3)_2$ where all three nitrogens coordinate the lead ($\text{Pb}-\text{N}_{\text{py}}$ 2.49 $\text{Pb}-\text{N}$ 2.50, 2.59 Å) and each lead is further chelated by two nitrates in an asymmetric fashion ($\text{Pb}-\text{O}$ 2.52, 2.86; 2.58, 2.93 Å) and has two monodentate interactions with the third nitrate oxygen of a neighboring molecule ($\text{Pb}-\text{O}$ 3.08–3.19 Å). The overall coordination number of the lead in the solid is nine, of which five are short contacts, and four are comparatively long.¹⁶⁸ Triazacyclononane forms 1:1 complexes with lead(II) of good stability, with irregular six-coordinate geometry at the lead in the case of the nitrate and perchlorate salts.¹⁶⁹

3.7.4.7 Complexes with Tetradentate Nitrogen Ligands

Tetraaza macrocycles are tremendously powerful ligands and have wide application in coordination chemistry. The $M(14)$ complexes of these ligands have a number of interesting applications, although the importance of these have only recently come to light. For this reason, the $M(14)$ complexes of these ligands are not as widely studied as the corresponding complexes of metals from some other groups.

Porphyrins have a demonstrated propensity to accumulate in cancerous tissues, metal alkyls are powerful alkylating agents, and elemental germanium has been shown to have anticancer properties, so it is not to be wondered at that dimethyl-5,10,15,20-tetrakis(3',5'- $\text{Bu}^t_2\text{C}_6\text{H}_3$)porphyrinato-germanium(IV) (**61**) has been prepared. The germanium is six coordinate, with *trans* methyl groups ($\text{Ge}-\text{C}$ 1.99 Å, $\text{Ge}-\text{N}$ 2.02 Å) and the complex has been shown to be active against neoplastic tissues both *in vitro* and *in vivo*.^{170,171}

Germanium complexes $(\text{por})\text{GeX}_2$ (por = dianion of TPP, octaethylporphyrin (OEP); $\text{X} = \text{OH, ClO}_4$) have been shown to undergo single electron oxidation by electrochemical methods with a potential that varies according to the nature of the porphyrin. For the hydroxy complexes, the first electron is removed from the ligand, giving $(\text{por})\text{Ge}(\text{OH})(\text{Y})$, where Y is the anion of the

supporting electrolyte, whereas for the perchlorate complexes, the first electron is removed from the π system of the porphyrin.^{172,173}

Diorgano germanium porphyrins are photoactive, such that visible light irradiation of (TPP)GeR₂ (R = Me, Buⁿ) in degassed chloroform solution gives (TPP)GeRCl.¹⁷³ EPR investigation of the mechanism of the photolysis of (OEP)GeR₂ (R = Ph, 4-HOC₆H₄, 4-ClC₆H₄) shows the existence of a Zwitterionic intermediate [(OEP)⁻GeR]⁺R. The complex can be made photostable if R is a good quenching group, such as ferrocene, as in the photochemically robust complex (OEP)Ge(Fc)₂.¹⁷⁴

In the absence of light, diorgano germanium porphyrin complexes are stable but have long been known to react with oxygen. The products of this oxidation process have been formulated speculatively as germanium-bound peroxyalkyl complexes¹⁷⁵ an assignment confirmed by the report of the crystal structure of (TPP)Ge(O₂R)₂ (R = Et, Bu^t).¹⁷⁶

Polymeric [(tbp)GeO]_n prepared from the thermolysis of (tbp)Ge(OH)₂, in turn obtained from the hydrolysis of (tbp)GeCl₂, is converted to a range of conducting polymers by the introduction of sub-stoichiometric quantities of iodine as [(tbp)Ge(O)_x(I)_y].¹⁷⁷

Six-coordinate complexes (por)SnX₂ have been studied because of the ability of some of these to inhibit the enzyme, heme oxygenase, believed to be responsible for the disease hyperbilirubinemia in infants¹⁷⁸ and because of their potential application in photodynamic therapy.¹⁷⁹ Many complexes (por)SnX₂ are known where X is not an R group (X = F, NO₃,¹⁸⁰ OH, C₆H₅CO₂, 2-(OH)C₆HCO₂,¹⁸¹ or N₃¹⁸² but if X is a σ -bonded R group, the complexes are not generally stable. An example of a stable (por)Sn(R)(X) complex was found from the reaction of (por)Sn^{II} (por = OEP, TPP, TMP, TTP) (TTP = dianion of tetratolyporphyrin, TMP = dianion of tetramesitylporphyrin) with MeI forming (por)Sn(Me)(I).¹⁸³

Typically complexes (por)SnR₂ exhibit a trans disposition of the two R groups, but *cis*-(TPP)SnPh₂ is available from the reaction of Ph₂SnCl₂ with the dilithium salt of the porphyrin. The complex is configurationally stable in the absence of light, but rapidly rearranges to the *trans* geometry on exposure to visible light.¹⁸⁴

Bis-amido tin porphyrins *trans* (TTP)Sn(N(R)Ph)₂ (R = H, Ph) and *cis* (TTP)Sn(1,2-(NH)₂C₆H₄) have been prepared and shown to be more stable than the analogous Sn—C bonded alkyl or aryl complexes. The increased stability of these nitrogen bound ligands is probably a function of their increased basicity.¹⁸⁵

The ¹¹⁹Sn NMR spectra of a number of complexes (TPP)SnX₂ (X = CF₃SO₃, ClO₄, CF₃CO₂, NO₃, Cl₂CHCO₂, 2-(OH)C₆H₄CO₂, HCO₂, BnO, AcO, 4-NO₂C₆H₄O, 4-BrC₆H₄O, 4-MeC₆H₄O, OH, MeO, F, Cl, Br, I) have been examined, and a correlation between the change in δ with the change in axial ligand established. This is particularly interesting as it may ultimately help in establishing the nature of the axial ligands on tin porphyrin complexes *in vivo*.¹⁸⁶ Another spectroscopic property of tin porphyrins is exploited in the use of (por)Sn^{II}(H₂O)₂ as a shift reagent for carboxylates. Coordination of carboxylates to the tin leads to a large shift in δ and so is a sensitive and useful probe.¹⁸⁷

The electrochemical activity of (por)Sn^{II} for a variety of porphyrins has been investigated and it has been shown that the first one electron reductions are all centered upon the ring system. Two-electron oxidation in the presence of supporting electrolyte comprising perchlorate leads to (por)Sn(sol)ClO₄ (sol = FHF, CH₃CN).¹⁸⁸

Treating (TPP)SnE (E = S, Se) with (TTP)Sn in toluene results in the reversible transfer of the chalcogenide, forming (TPP)Sn^{II} and (TTP)SnE. The reactions proceed with second-order kinetics and seems to involve a bridging chalcogenido intermediate.¹⁸⁶ The same result has also been found for amidinate complexes.¹⁸⁹

The synthesis of lead(II) porphyrin complexes has been efficiently performed in a solid-state reaction. Grinding together equimolar amounts of (por)H₂ (porH₂ = meso-(4-HO-C₆H₄)₄-porphyrin, meso-(4-MeOC₆H₄)₄-porphyrin, or meso-(4-NO₂-C₆H₄)₄-porphyrin) with lead(II) acetate in a pestle and mortar with a trace of acetone leads to the (por)Pb^{II} complexes in excellent yield after chromatographic purification.¹⁹⁰

Main group metal complexes of phthalocyanines (pc) are of some interest as one-dimensional conducting materials where the structures exhibit stacking. It is of interest that a recent reinvestigation of (pc)Ge^{II}, which shows quite different spectral characteristics from those expected, reveals that the literature preparative route does not yield this compound, as the structure of the ligand does not remain intact throughout the synthesis of the complex. The synthesis, which uses germanium(IV) chloride as a template to form (pc)GeCl₂ followed by borohydride reduction, yields not the anticipated (pc)Ge^{II} but the ring contracted α,β,γ -(triazatetrabenzcorrole)Ge^{IV} (**62**) a new tetrapyrrole macrocycle.¹⁹¹

Cofacially joined polymeric metallophthalocyanines with bridging oxo ligands $[(pc)MO]_n$ ($M = Ge, Sn$) have been prepared by a new route and are themselves precursors to electronically conductive polymers. The vibrational spectra of the polymers were investigated using isotopic substitution (^{18}O), and identification of the stretching modes has afforded a method for estimating the molecular weights of the polymers. For typical samples, the value of n for germanium is 70 and for tin is 100.¹⁹²

Tetraaza macrocyclic ligands tetramethyl- and octamethyltetraazaanulene (TMTAA, OMTAA) (**63**) and (**64**) are analogous to porphyrins, in that they are dibasic, approximately planar N_4 donor ligands. Complexes $(L)M^{II}$ ($M = Ge, Sn$; $L = TMTAA$)¹⁹³ are four coordinate and in the case of (OMTAA)Sn, crystallography shows the metal to be 1.12 Å out of the N_4 plane. These complexes are liable to oxidative addition reactions, such as with elemental chalcogens sulfur, selenium (Ge, Sn), and tellurium (Ge) that form the corresponding five-coordinate monochalogenides.^{194,195} In reaction with N_2O the tin(II) complex forms the oxo-bridged product $[(OMTAA)Sn]_2O$ with no indication of a mononuclear product with a terminal oxo ligand.¹⁹⁶ Oxidative addition of I_2 to $(OMTAA)Sn^{II}$ leads to the diiodide, which has a *trans* disposition of iodides, as shown by crystallography. This geometry is consistent with other known complexes $(TMTAA)SnX_2$, ($X = Cl, ONO_2$).¹⁹⁷ The bond lengths Sn-I are long (2.885 and 2.909 Å) and so it is perhaps unsurprising that one iodide is labile and, in the presence of excess I_2 , in THF solution ionizes to form $[(OMTAA)SnI(THF)]I_3$. The tin(IV) is nearly coplanar with the four nitrogen donors, less than 0.2 Å out of plane.¹⁹⁸ The only confirmed examples of *cis* coordination in such complexes is in the products of the reactions of $(OMTAA)M(E)$ ($M = Ge, Sn$; $E = S, Se$) with C_2H_4S , (**65**).¹⁹⁹

(62)

R = H, TMTAAH₂ (**63**); R = Me, OMTAAH₂ (**64**)

(65)

3.7.4.8 Complexes with Polydentate Nitrogen Ligands

Macrocyclic ligands with all-nitrogen donor sets are much studied and both tin and, in particular, lead are popular subjects in coordination studies of these ligands. Examples of such ligands used to complex tin include (**66**) and (**67**), prepared by Schiff-base condensations.²⁰⁰ The complex (**68**) was isolated from an attempted template synthesis of a macrocycle²⁰¹ in which the condensation of the component parts of the ligand was incomplete.²⁰²

Lead(II) is a useful metal for such studies as it is relatively redox inert and has the ability to form complexes with a wide range of coordination numbers and with almost any donor atom type. Substituted triazacyclonanes (**69**)–(**71**) form 1:1 complexes with lead(II) and (**72**) forms a 1:2 complex in which two lead ions are coordinated, one in each of the distinct sites. In each case, the complexes were isolated as their (tetraphenyl)borate salts and in the cases where the complexes were characterized crystallographically, a close η^6 type interaction was seen with one of the phenyl groups of the counterion (Scheme 19).²⁰³

Scheme 19

Macrocyclic ligands will, under favorable conditions, form complexes of greater stability than an open-chain ligand with similar donor groups and geometry. A comparative study of the linear and cyclic polyamines (**73**)–(**80**) shows a maximum value for $\log K$ for the smallest cyclic polyamine under constant conditions.²⁰⁴ A similar result is seen for tetraazacycles, where again the highest value for $\log K$ is seen a complex formed by a small ring ligand (**81**).²⁰⁵ The related (**82**) coordinated lead through all six nitrogen donors in the solid, with an overall nine coordination completed by a chelating perchlorate and a molecule of water.²⁰⁶

Larger polyazacycles with N_5 – N_7 donor sets are found in the series of ligands (83) based upon phen. The ligand which forms the most stable complex is again the smallest example.²⁰⁷ Similar design strategy produced the ligands (84) and (85), which coordinate lead within the ligand cavity through the pyridine nitrogens. The construction of the ligand is such that the aliphatic amines are not able to coordinate a metal ion bound to the bipy group because of steric constraints and so the ligand may be protonated at these nitrogens without disrupting the complex. Where the bipy moiety is oriented outward, the lead is bound within the ligand again this time by the aliphatic amines alone.²⁰⁸ Very large polyazacycles, such as (86), can coordinate two lead ions.²⁰⁹

3.7.4.9 Complexes with Phosphorus or Arsenic Ligands

In contrast to nitrogen donor ligands, which have a rich and varied coordination chemistry with Group 14 metals, complexes of phosphorus and arsenic donors are encountered less commonly, especially for neutral donors. Descending Group 14 there is a pronounced decrease in Lewis acidity, most evident for tin(II) and lead(II), which may go some way to explaining this reduced affinity. There are, however, definite suggestions in the literature of further chemistry waiting to be uncovered in this area.

3.7.4.9.1 Complexes of M^{IV} with phosphines or arsines

The interaction of germanium(IV) chloride with a number of monodentate triorganophosphine ligands PR_3 ($R = \text{Me, Et, Pr}^n, \text{Bu}^n, \text{cy, 2,6-(MeO)}_2\text{C}_6\text{H}_3, \text{2,4,6-(MeO)}_3\text{C}_6\text{H}_2, \text{Bn, Me}_2\text{N, Et}_2\text{N, Pr}^i_2\text{N}$) leads exclusively to the ionic germanium(II) complexes $[PR_3Cl][GeCl_3]$. This is in distinct contrast to the expected 1:1 or 1:2 adducts of germanium(IV), some of which have been previously claimed in the literature from this preparative route. The structure of $[\text{Bu}^n_3\text{PCl}][\text{GeCl}_3]$ shows no close interaction of the ion pair, and a trigonal pyramidal geometry at the germanium.²¹⁰ With triphenylphosphine, no reaction is seen, an observation of interest since the mixture of germanium(IV) chloride and triphenylphosphine has been used as a reagent for the reduction of α -bromo carboxylic acids.²¹¹

The first fully characterized germanium(IV) arsine complex, $(\text{Me}_3\text{As})_2\text{GeCl}_4$, can be prepared from the direct reaction of the arsine with halide, and has *trans* structure with Ge-As of 2.472 Å.²¹⁰

Tin(IV) chloride or bromide reacts with Bu^n_3P to give 1:2 complexes with octahedral geometry. These are particularly interesting subjects for ^{119}Sn NMR studies, as the $^{119}\text{Sn}-^{31}\text{P}$ spin interactions give information relating to the solution structure of the complexes that is not otherwise available. For $(\text{Bu}^n_3\text{P})_2\text{SnX}_4$, δ ^{119}Sn is -575 and $J^{119}\text{Sn}-^{31}\text{P}$ is $2,395$ ($X = \text{Cl}$) or -953 and $1,960$ Hz ($X = \text{Br}$). Mixing equimolar amounts of these two in solution leads quickly to the mixed species $(\text{Bu}^n_3\text{P})_2\text{SnCl}_x\text{Br}_{4-x}$ which show values of δ and J intermediate between the two single halide species. There is a clear additive change in the values of δ which is in turn related to the electronegativity of the halide ligands, and rapidity of the halide exchange is a common feature of complexes of tin(IV) with more than two halides.²¹² These species can be characterized by NMR methods in solution to a degree that they cannot be in the solid state.

An attractive alternative preparation of halophosphine complexes of tin(IV) is the reaction of tin metal powder and triorganophosphorus(V) dihalides R_3PX_2 ($\text{R}_3 = \text{Ph}_3, \text{Ph}_2\text{Me, PhMe}_2; X = \text{Br, I}$). The products are both *cis* and *trans* $(\text{R}_3\text{P})_2\text{SnX}_4$ suggesting that the formation takes place stepwise, initially forming $(\text{R}_3\text{PX})(\text{SnX}_3)$ which would then react with a further phosphine to give either isomer with no preference.^{213,214}

Analysis of coupling constants $^{119}\text{Sn}-^{31}\text{P}$ for complexes $(\text{R}_3\text{P})_2\text{SnX}_4$ ($\text{R}_3 = \text{Ph}_2\text{Me, Bu}^n_3$) and $(\text{Ph}_2\text{P})_2(\text{CH}_2)_n\text{SnX}_{4-m}\text{Me}_m$ ($n = 1, 2, 3; X = \text{Cl, Br}; m = 0, 1$) indicate that Sn-P bonds are strengthened when the bond is *trans* to an electron donating ligand.²¹⁵

Triorganophosphines react readily with tin(IV) complexes providing the tin center is sufficiently Lewis acidic. For complexes $\text{R}_n\text{SnX}_{4-n}$, coordination of one phosphine usually proceeds readily for $n \leq 3$, but for the tetraorganotin complex, no coordination of phosphine is observed.

The complexes Ph_3SnCl , R_2SnCl_2 , and $(\text{R} = \text{Et, Pr, Bu}^n, \text{Ph})$ coordinate Bu^n_3P to form 1:1 adducts, a complexation readily monitored by ^{119}Sn and ^{31}P NMR. Coordination is accompanied by a significant shift in the ^{119}Sn δ to lower field, and the change in multiplicity arising from $^{119}\text{Sn}-^{31}\text{P}$ coupling is an aid to determining stoichiometry and geometry in the complex. For R_2SnCl_3 ($\text{R} = \text{Bu}^n, \text{Ph}$) complexation is accompanied by a scrambling of the ligands between tin centers to give a number of complexes.²¹⁶ A similar scrambling of ligands is seen for the complex ions $[(\text{Bu}^n_3\text{P})(\text{Me})\text{SnCl}_4]^-$, which exhibits a single doublet in its ^{119}Sn NMR spectrum at intermediate temperatures, indicating either preferential formation of a single isomer in solution or a fluxional process that is rapid on the NMR timescale. Mixing equimolar amounts of $[(\text{Bu}^n_3\text{P})(\text{Me})\text{SnCl}_4]^-$ and $[(\text{Bu}^n_3\text{P})(\text{Me})\text{SnBr}_4]^-$ gives a solution that shows a ^{119}Sn NMR that indicates that all isomers $[(\text{Bu}^n_3\text{P})(\text{Me})\text{SnCl}_n\text{Br}_{4-n}]^-$ are formed. Since this must involve interionic transfer of halide, the solution behavior of these ions is clearly somewhat involved.²¹⁷

The complexation of $\text{R}_n\text{SnX}_{4-n}$ ($\text{R} = \text{Me, Et, Bu}^n; X = \text{Cl, Br, I}$) by Bu^n_3P ($n = 1-3$) shows increasing enthalpy of formation in the sequence $\text{Cl} < \text{Br} < \text{I}$ for any given formulation, the reverse sequence of the acid strengthening effects arising from the increasing electronegativity

of the halide. The equilibrium constants for formation increase in the order $I < Br < Cl$, indicating that the entropy term may be dominant for this complexation.²¹⁸

Chelating bisphosphines bis(diphenylphosphino)methane (dppm) and 2-bis(diphenylphosphino)ethane (dppe) react with Ph_2SnX_2 ($X = Cl, Br$) to give five coordinate complexes with monodentate attachment of the phosphines. The more rigid (+)-(R,R)-1,2-bis(methylphenylphosphino)benzene chelates successfully to the same organotin halides, giving octahedral complexes. Phenyltrichloro tin(IV) reacts with each of the chelating phosphines to form six-coordinate complexes, again with scrambling of the ligands to form a number of products.²¹⁹

Siladiarsine ($2,4,6-Pr^i_3-C_6H_2$)($Bu^tSi(AsH_2)_2$) can be lithiated and treated with $(mes)(Bu^t)GeF_2$ to give (87), a diarsenagermane which can be further converted to (88). The structure of (88) shows a degree of asymmetry in the As—M bonds, with distances As—Si of 2.39 Å and As—Ge of 2.45 Å.²²⁰

The reaction of $Bu^t_2SnCl_2$ with $Na[AsH_2]$ in liquid ammonia yields $[Bu^tSnAsH]_2$ with a central $(SnAs)_2$ ring. In the same solvent $Bu^t_2Sn(NHBu^t)_2$ reacts with $Na[AsH_2]$ to give $[Bu^tSnAsH]_3$, with a $(SnAs)_3$ ring.²²¹

Further spectroscopic information can be gathered in the far IR, and the spectra of $LSnX_4$ ($L = (R_2P)_2(CH_2)_n$; $R = Me, Et, Ph$; $n = 2, X = Cl, Br, I$) have been measured between 400 cm^{-1} and 40 cm^{-1} . In this region, the M—P stretching modes can be found between 116–110, and the M—X stretching vibrations at 310–295 (chloro), 210–208 (bromo), and 185–156 cm^{-1} (iodo) have been assigned.²²²

3.7.4.9.2 Complexes of M^{II} with phosphines or arsines

Triphenyl phosphine coordinates germanium(II) chloride²²³ or iodide²²⁴ to form 1:1 complexes with tbp geometry at the metal and bond lengths $Ge-P$ 2.511 Å and 2.507 Å, respectively. These complexes are in some ways analogous to ylides ($R^1_3P=CR^2_2$) and have some properties in common with these lighter homologues.

The availability of solution ^{119}Sn and ^{207}Pb NMR for the study of complexes is a great boon to the coordination chemist. An elegant study of the interaction of a number of multidentate phosphine ligands with $M[SbF_6]_2$ ($M = Sn, Pb$) has been published and offers insight into the solution structure of complexes which is difficult to obtain in other ways. Solutions of $M[SbF_6]_2$ in nitromethane were treated with polydentate phosphines dppe, $PhP[(CH_2)_2PPh_2]_2$, $MeC(CH_2PPh_2)_3$, $P[(CH_2)_2PPh_2]_3$, and $[Ph_2P(CH_2)_2]_2P(CH_2)_2PPh_2$. The values of δ for ^{119}Sn cover the range -586 to -792 and for ^{207}Pb 60 to -269 . The greatest change in shift for both nuclei is seen on coordination of any phosphorus donors (cf. δ for “free” M^{II} ; $Sn = -1,540$, $Pb = -3,342$) where the subsequent changes in shift as the number of phosphorus ligands coordinated to the metal increases is small compared to the change associated with going from the effectively solvated $M[SbF_6]_2$ to the phosphine complex. The multiplicity of the peaks is of tremendous utility in assigning the number of phosphorus donors coordinated as the couplings between the phosphorus and the metal are well resolved.²²⁵

Alkynyl phosphine Bu^tCP coordinates $(TMS_2CH)_2Ge$ with a side-on $\kappa^2 [P,C]$ interaction to give a *pseudo*-tetrahedral product (89), the first example of a phosphagermirane. The geometry is somewhat distorted because of the difference in steric demand of the phosphine in comparison to the organic ligands.²²⁶ The corresponding tin compound reacts with the same alkynyl phosphine to form the phosphadistannacyclobutene (90).²²⁷

Reaction of the anion of dppm with MCl_2 ($M = Ge, Sn, Pb$) forms complexes $[CH(PPh_2)_2]_2M$ that exhibit three-coordinate geometry in the solid state, one ligand chelating through both

(89)

(90)

(91)

phosphorus and one coordinating in a monodentate fashion through the central carbon. In solution, the complexes are fluxional, where the ligands undergo a (κ^2 - κ^1 - κ^2) process. For the bulkier $[\text{C}(\text{SiMe}_3)(\text{PPh}_2)_2]\text{M}$, the bischolate structure is preferred.^{228–231}

The potentially tridentate monobasic ligand $[\text{C}(\text{PMe}_2)_3]^-$ forms the four coordinate (91) in reaction as its lithium salt with $\text{GeCl}_2 \cdot \text{diox}$. The geometry about the germanium(II) is tbp, with the lone pair occupying an axial position, and the complex has three short Ge—P bond lengths (2.359, 2.368, and 2.546 Å) and one longer interaction (2.926 Å). The corresponding tin complex has four similar bond lengths (2.602, 2.598, 3.790, and 2.839 Å), which suggests that the smaller germanium is less able to accommodate all four donor groups than the larger tin. In solution, the tin complex is stereochemically nonrigid and undergoes a *pseudo*-rotation that equilibrates the axial and equatorial sites according to NMR data. At elevated temperature all six phosphorus atoms equilibrate indicating that all phosphorus donors coordinate the tin during the fluxional process.^{232, 233}

The reaction of $\text{GeCl}_2 \cdot \text{diox}$ with $[\text{C}(\text{PMe}_2)_2\text{X}]^-$ ($\text{X} = \text{PMe}_2, \text{SiMe}_3$) in the presence of magnesium gives the bisphosphide-supported Ge—Ge bonded dimer (92) which, on further reaction with additional $\text{GeCl}_2 \cdot \text{diox}$ gives the remarkable pentagermane (93) (Scheme 20). With germanium(IV) chloride, the octahedral $[\text{C}(\text{PMe}_2)_2\text{X}]_2\text{GeCl}_2$ is formed, with a *trans* disposition of the halides.²³⁴

(92)

(93)

Scheme 20

3.7.4.9.3 Complexes of M^{IV} with phosphides or arsinides

The highly reactive phosphides $\text{Ge}(\text{PH}_2)_4$ and $\text{HGe}(\text{PH}_2)_3$ can be prepared in low yield from the reaction of germanium(IV) chloride with $\text{Li}[\text{Al}(\text{PH}_2)_4]$. The complexes were characterized by NMR spectroscopy as they are thermally unstable, decomposing to germanium(IV) phosphide and phosphine.²³⁵ Germanium(IV) phosphides R_2PGeCl_3 are available from the oxidative addition of R_2PCl to GeCl_2 . The reaction is reversible, the starting materials recoverable from the thermolysis of the product. The reaction proceeds through initial coordination of the GeCl_2 by the chlorodiorgano phosphine to form an intermediate complex $(\text{R}_2\text{ClP})\text{GeCl}_2$. The corresponding reaction of GeCl_2 with RPCl_2 ($\text{R} = \text{Pr}^i, \text{Bu}^t, \text{Ad}$) gives the bis(trichlorogermyl)phosphines $\text{RP}(\text{GeCl}_3)_2$ and a number of cyclic products (94)–(96).²³⁶

The 1,2,3,4-diphosphadigermatane (97) is prepared by the reaction of $(\text{mes})(\text{Bu}^t)\text{GeF}_2$ with $[(\text{dme})\text{Li}][\text{PH}_2]$. The structure of the ring is *trans* with respect to the germanium. The bonds Ge—P are almost identical at 2.346 and 2.348 Å, and the internal angles Ge—P—Ge and P—Ge—P are 84.8° and 95.3°, respectively, a close approximation to a regular square.²³⁷

The near-tetrahedral diphosphagermiranes (**98**) have been prepared from the reaction of R_2GeCl_2 ($R = Et, Ph$) and $K_2[(Bu^tP)_2]$. The dianionic bisphosphide also reacts with germanium(IV) chloride to give the unexpected 1,2,4,5,6,7-hexa- Bu^t -1,2,4,5,6,7-hexaphospha-3-germaspiro[2,4]heptane (**99**).²³⁸

Diphosphinylmethanide $[C(PMe_2)_2SiMe_3]^-$ reacts with Me_2MX_2 ($M = Ge, Sn$; $X = Cl, Br$) to form the six-coordinate complexes *cis*- $Me_2M[C(PMe_2)_2SiMe_3]_2$. Both complexes show inequivalent metal-phosphorus interactions, with two short and two long bonds. In the tin complex, which has a greater tendency to hypervalency, this difference is less than in the germanium complex, in which the structure has a greater degree of $[4+2]$ character.²³⁹

The first examples of germanium-phosphorus double bonds have been reported for $(mes)_2Ge=P(2,4,6-R_3C_6H_2)$ ($R = Pr^i, Bu^t$)²⁴⁰ prepared by the reaction of $(mes)_2GeF_2$ with $Li[PH(2,4,6-Bu^t_3C_6H_2)]$ yielding the intermediate $(mes)_2Ge(F)P(H)(2,4,6-Pr^i_3C_6H_2)$. Subsequent lithiation of this product and elimination of LiF gives the germaphosphirane in good yield. The double bond is liable to addition reactions of RH ($R = OH, MeO, Cl, Me_3P=CH$)²⁴¹ or the chalcogens sulfur or selenium, giving the germathia- or germaselenaphosphines (**100**). Heating with excess chalcogen gives $[(mes)_2GeS]_2$ and $ArP(S)_2$.²⁴² The corresponding stannaphosphirane can be prepared by a similar route.²⁴³

Bis(diorganochlorostanna)phosphine (**101**) can be converted to the Sn_2N_2SiP cyclohexane (**102**) by the sequence shown in (Scheme 21), forming a wholly inorganic six-membered ring.²⁴⁴

3.7.4.9.4 Complexes of M^{II} with phosphides or arsinides

Reaction of the primary silylalkyl phosphine $R^1_3SiPH_2$ with R^2_2Sn ($R^2 = N(SiMe_3)_2, 2,4,6-(CF_3)_3C_6H_2$) gives the hexanuclear complex (**103**) by a mechanism involving elimination of R^2H . The structure of (**103**) is a distorted hexagonal prism, with bond length $Sn-P$ of 2.626 Å (ave.) and angles $P-Sn-P$ ranging between 86.9° and 100.7° , values which are not greatly different

Scheme 21

for those seen for monomeric complexes $(\text{R}_2\text{P})_2\text{Sn}$. The same reaction carried out in the presence of tin(II) chloride leads to the isolation of the SnCl_2 bridged dimer (104).²⁴⁵ The tin–phosphorus bond lengths in the hexamer are longer than those found in $(\text{R}_2\text{P})_2\text{Sn}$ compounds, such as those found in the series of complexes $[(\text{Pr}^i_3\text{Si})(\text{R})\text{E}]_2\text{M}$ ($\text{R} = \text{trip}_2\text{SiF}$, $\text{E} = \text{P}$, $\text{M} = \text{Ge}$, Sn ; $\text{R} = \text{trip}_2\text{SiF}$, $\text{E} = \text{As}$, $\text{M} = \text{Sn}$; $\text{R} = (\text{trip})\text{Bu}^t\text{SiF}$, $\text{E} = \text{P}$, $\text{M} = \text{Pb}$).²⁴⁶ These complexes are monomeric, as is $[(\text{Ph}_3\text{Si})_2\text{P}]_2\text{Sn}$,²⁴⁷ where the complexes with a smaller ligand $(\text{TMS}_2\text{P})_2\text{M}$ ($\text{M} = \text{Sn}$, Pb) are dimeric with bridging phosphorus groups.²⁴⁸ Simple lead(II) phosphides $(\text{Bu}^t_2\text{P})_2\text{Pb}$ can be prepared directly from the lithium phosphide and lead(II) chloride²⁴⁹ where adjusting the stoichiometry gives $\text{Li}[(\text{Bu}^t_2\text{P})_3\text{Pb}]$ with a three-coordinate lead and a central $[\text{PbP}_2\text{Li}]$ ring.²⁵⁰

Pnictide complexes can also be formed by the elimination of TMSCl , as in the reaction of tin(II) chloride with $(\text{Bu}^t)_2\text{TMSE}$ ($\text{E} = \text{P}$, As), which forms $[\text{Bu}^t_2\text{ESnCl}]_2$ ($\text{E} = \text{P}$ ²⁵¹ or As ²⁵²). The structure of the arsenide has been determined and exhibits bond length $\text{Sn}—\text{As}$ 3.773 Å, a comparatively rare bond, and angles $\text{As}—\text{Sn}—\text{As}$ of 77.8°.²⁵³

The first example of a lithio arsinoorganogermane has been reported as the product of the reaction of Bu^tGeF_3 and six equivalents of $\text{Li}[(\text{Pr}^i_3\text{Si})\text{HAs}]$ (105).²⁵⁴ The structure is a distorted rhombododecahedron and has $\text{As}—\text{Ge}$ bonds of 2.442–2.447 Å.²⁵⁴

3.7.5 COMPLEXES WITH GROUP 16 LIGANDS

In much the same way that complexes of Group 14 metal ions with nitrogen ligands outnumber those with other Group 15 donor atoms, complexes of oxygen donors are the most numerous amongst Group 16 donor ligands. This is true for hard donors, such as hydroxy groups, as well as soft donors, such as crown ethers, for all three metals, though there are still enough complexes of the heavier chalcogens to make them a diverse and an interesting subject area.

3.7.5.1 Complexes with Neutral Oxygen Ligands

Sulfoxides are widely studied ambidentate ligands with donor properties that in some ways respond to the character of the metal to which they coordinate. In the majority of their complexes they coordinate through the oxygen, and the complex $(\text{DMSO})_2\text{GeCl}_4$ is no exception. An IR study shows bands due to the Ge—O stretches at 506 and 495 cm^{-1} .²⁵⁵ Structural studies of diphenylsulfoxide complexes $(\text{Ph}_2\text{SO})_2\text{SnI}_4$ and $(\text{Ph}_2\text{SO})_2\text{Sn}(\text{Me})\text{I}_3$ show *cis* coordination of the sulfoxide ligands.²⁵⁶ Dibenzylsulfoxide coordinates Me_2SnCl_2 to give a *tbp* complex with the sulfoxide oxygen and one chloride in the apical positions.²⁵⁷ The nitrate ligands in $\text{Me}_2\text{Sn}(\text{NO}_3)_2$ readily dissociate, despite being potentially chelating, so that complexes $[\text{Me}_2\text{Sn}(\text{L})_4](\text{NO}_3)_2$ are readily prepared ($\text{L} = \text{DMSO}$ ²⁵⁸ or H_2O ²⁵⁹).

Complexes of lead(II) with DMSO ligands $[(\text{DMSO})_n(\text{ClO}_4)_2\text{Pb}]$ can be isolated from solutions of lead(II) perchlorate in DMSO where $n=3$ or 5 . For $[(\text{DMSO})_3(\text{ClO}_4)_2\text{Pb}]_2$ two different isomers are formed with either perchlorate or DMSO oxygens acting as the bridging ligands (**106**). Interestingly, there is no indication of any sulfur bound sulfoxide on this apparently soft lead(II) center.²⁶⁰ Diphenyllead dichloride coordinates two equivalents of DMSO or HMPA through the oxygen termini to give six-coordinate complexes with *trans* organic ligands and bonds Pb—O of 2.482 and 2.536 Å , respectively.²⁶¹

Phosphine oxides are popular ligands for tin(IV), and many examples of monodentate R_3PO complexes are known.²⁶² Interaction of a range of organotin halides with $\text{dppe}(\text{O})_2$ or *cis* $[\text{Ph}_2\text{P}(\text{O})\text{CH}]_2$ leads to monomeric six-coordinate complexes with chelation of the bisphosphine dioxide. The complexation of the related monodentate phosphine oxides Ph_2MePO and Ph_3PO follows a different pattern, with *trans* coordination of the two monodentate ligands preferred. The triaryl phosphine oxide is the least effective base, and there is NMR evidence that in solution the $\text{dppe}(\text{O})_2$ is coordinated in a monodentate fashion. The structures show a typical *trans* arrangement of the two alkyl groups.^{263,264} Cationic tin centers can be stabilized by $\text{dppe}(\text{O})_2$ such as $[\text{SnMe}_2\{\text{dppe}(\text{O})_2\}_2]^{2+}[(\text{MeSO}_2)_2\text{N}]^-$ prepared from the reaction of $\text{Me}_2\text{Sn}\{(\text{MeSO}_2)_2\text{N}\}_2$ with $\text{dppe}(\text{O})_2$.²⁶⁵

The doubly oxidized form of dppm chelates $\text{Ph}_2\text{Sn}(\text{NO}_3)_2$ to give the seven-coordinate complex $(\text{dppmO}_2)\text{Ph}_2\text{Sn}(\kappa^2\text{-NO}_3)(\kappa^1\text{-NO}_3)$. Chelation of the bisphosphine dioxide gives rise to a six-membered ring with Sn—O bonds of 2.237 and 2.223 Å . The remainder of the ligand set is made up of a bidentate and a monodentate nitrate (Sn—O 2.472 and 2.350 ; 2.289 Å , respectively). The doubly oxidized arsenic analogue of dppe (dpaeO_2) coordinates in a rather different fashion, bridging two tin centers to give $[\text{Ph}_3\text{Sn}(\kappa^1\text{-NO}_3)]_2(\mu\text{-}\kappa^1, \kappa^1\text{-dpaeO}_2)$.²⁶⁶ The potentially chelating ligand $\text{Me}_2\text{NC}(\text{H})[\text{P}(\text{O})(\text{OEt})_2]_2$ reacts with Me_2SnCl_2 to form the robust dinuclear complex (**107**) comprising a 12-membered ring.²⁶⁷

The complexation of lead(II) perchlorate by the Schiff-base ligands 3-MeO-salenH₂, 3-MeO-saltrenH₃, and saltrenH₃ (salen = *N,N'*-bis(salicylaldehyde)ethylenediamine, saltren = *N,N',N'''*-tris(salicylaldehyde)tris(2-aminoethyl)amine) gives complexes in which they coordinate as innocent ligands through neutral phenolic oxygens. Structural analysis reveals *exo* coordination of the metal, with the ligand pocket occupied by the ionizable protons. In the case of 3-MeOsalenH₂, the lead is three-coordinate by the two oxygens of the Schiff-base and a molecule of methanol, and in the other cases is three coordinate through the ligand oxygens alone. Solution NMR studies show that the molecules are fluxional at ambient temperatures.²⁶⁸ Nitriloacetamide is a neutral [O₃] donor ligand that coordinates tin to form a 10-coordinate complex cation [(NTA)₂(κ²-NO₃)Pb]⁺ in which the remaining lone pair is not stereochemically active.²⁶⁹

Macrocyclic *O*-donor ligands 1,3-xylyl 18-C-5 reacts with tin complexes Me_{3-*n*}SnCl_{*n*+1} (*n* = 0, 1, 2) to form complexes that do not show inclusion of the tin inside the macrocycle, but rather coordination of the metal in an *exo* fashion. The structure of MeSnCl₃(H₂O)₂(1,3-xylyl-18-C-6) shows a six-coordinate tin center with *cis* coordination of two *O*-bound water molecules. These water molecules are in turn hydrogen-bonded to four adjacent oxygens of the crown ether, in a manner similar to the coordination of diimine ligands seen previously.²⁷⁰ The slightly larger 18-C-6 chelates tin(IV) chloride to give a six-coordinate tin complex (Sn—O 2.237 and 2.212 Å).²⁷¹ Lead(II) can be more successfully included in the cavity of a crown ether, as shown by the complexes [(15-C-5)(SCN)₂Pb], which has an eight coordinate lead bound by all five of the ether oxygens,²⁷² and both [(18-C-6)(SCN)₂Pb] and [(*cis*-anti-*cis*-cy₂-18-C-6) (SCN)Pb], which show a hexagonal bipyramidal geometry at the lead, with the median plane described by the macrocyclic ligand.²⁷³ With lead(II) acetate, a different configuration results, whereby in the crystal the lead is 10-coordinate with two bidentate acetate ligands bound *cis* on one side of the lead and the hexadentate crown ether bound on the other face of the lead.²⁷⁴

3.7.5.2 Complexes with Anionic Monodentate Oxygen Ligands

Sterically stabilized germanium(II) alkyls (2,4,6-Bu^{*t*}₃C₆H₂)₂Ge and (2,4,6-Pr^{*i*}₃C₆H₂)[2,4,6-(CH(SiMe₃)₂)₃C₆H₂)]Ge undergo oxygen transfer reactions with various *N*-oxides to form the corresponding germanones that in turn react with isocyanates RNCO to give complexes (108) (Scheme 22). If the germanones are allowed to stand in solution (ca. 10 h) then they undergo intramolecular activations forming the diastereomeric (109).^{275,276}

Scheme 22

(109)

Carbohydrates react with Bu^n_2SnO with elimination of water to give complexes that have geometries that depend upon the particular sugar. Of 19 different sugars investigated, Mössbauer spectroscopy identified products with octahedral, *thp*, and tetrahedral geometries at the tin with a preponderance of *thp*.²⁷⁷

Hydrolysis of monoorganogermanium chlorides RGeCl_3 ($\text{R} = \text{Pr}^i$, *cy*, *mes*) gives the germanium sesquioxanes $(\text{RGe})_6\text{O}_9$, (110). The core structure is a $(\text{GeO})_3$ ring, linked through three bridging oxo ligands to a second such ring. The structural diversity of silsesquioxanes has attracted a great deal of attention and it is to be hoped that the germanium analogues will be as studied.²⁷⁸ The new germanate $(\text{C}_2\text{H}_8\text{N}_2)(\text{C}_2\text{H}_{10}\text{N}_2)[\text{Ge}_9\text{O}_{18}(\text{OH})_4]$ is synthesized by hydrothermal methods from germanium and TMEDA. The structure comprises $\text{Ge}_9\text{O}_{22}(\text{OH})_4$ units with four-, five-, and six-coordinate germanium ions.²⁷⁹ Solid argon matrix isolated germanium(II) oxides $(\text{GeO})_n$ ($n = 1-4$) were studied by IR. The structure of $(\text{GeO})_2$ is planar cyclic, $(\text{GeO})_3$ has the highly symmetrical D_{3h} ring structure and contrary to previous ideas, $(\text{GeO})_4$ is found to be a cubane.²⁸⁰

Alkoxides of the acidic trioorganosilanol Ph_3SiOH reacts with $[\text{M}(\text{OBu}^t)_2]_n$ ($\text{M} = \text{Ge}, \text{Sn}, \text{Pb}$) to form discrete dimeric complexes $[(\text{Ph}_3\text{SiO})\text{MO}]_2$ with a central $(\text{MO})_2$ ring.²⁸¹ Hydrolysis of R_nSnX_3 gives cage complexes with structures related to the silsesquioxanes, such as $[(\text{Pr}^i\text{Sn})_{12}\text{O}_{14}(\text{OH})_6]^{2+}$. The complex comprises a football-shaped framework of (SnO) units, where the tin atoms exhibit square pyramidal geometries and comprise half-chair $(\text{SnO})_3$ rings. The related complex $[\text{Sn}(\text{CH}_2)_6\text{Sn}](\text{ClCH}_2\text{CO}_2)_4(\text{OH})_2\text{O}_{10}$, prepared by the controlled hydrolysis of $[(\text{ClCH}_2\text{CO}_2)_3\text{SnCH}_2]_2\text{CH}_2$, has an almost planar array of all 12 tin atoms.²⁸² Prepared by an analogous route, $[(\text{Pr}^i\text{Sn})_9\text{O}_8(\text{OH})_6]^{5+}$ has a pyramidal cage structure with both *thp* and octahedral tin centers, linked by μ^3 oxo or μ^2 hydroxy ligands. The structure is further supported by intramolecular $\text{OH}\cdots\text{Cl}$ hydrogen bonds.^{283,284}

A different class of cluster with an octahedral frame is exemplified by $\text{Sn}_6(\mu^3\text{-O})_4(\mu^3\text{-OSiMe}_3)_4$, which has all eight oxygen ligands bridging the faces of the Sn_6 octahedron.²⁸⁵ The oxo cluster $\text{Sn}_6\text{O}_4(\text{MeO})_4$ shows luminescence at 77 K, with λ_{max} at 565 nm, probably due to a metal-centered *sp* excited state.²⁸⁶

The reaction of Me_2SnO with $\text{PhC}(\text{O})\text{CH}_2\text{C}(\text{O})\text{CF}_3$ in the presence of $\text{CF}_3\text{CO}_2\text{H}$ leads to the isolation of (111), a tetrameric complex in which the central $(\text{SnO})_2$ ring is planar and is itself almost coplanar with the chelate rings. The tin centers all have *thp* geometry with equatorial methyl groups. The complex displays the structural motif of a μ^3 oxo ligand, seen in the structures of a number of tin oxo species.²⁸⁷ The bridging $(\text{SnO})_2$ structure is also present in the hydroxy bridged dimer $[(\text{Bu}^t)_2\text{SnX}(\text{OH})]_2$.²⁸⁸

The nature of the species present in aqueous solutions of tin and lead salts has been the subject of much conjecture. Some information is now available following the crystallographic identification of two complexes from aqueous solutions of $\text{M}^{\text{II}}(\text{NO}_3)_2$. The open vertex cubane $[\text{Sn}_3(\text{OH})_4](\text{NO}_3)_2$ ($\text{Sn}-\text{O}_{\text{OH}}$ 2.149–2.345 Å) was crystallized from a solution of tin(II) nitrate²⁸⁹ and the cubane $[\{\text{Pb}(\text{OH})\}_4(\text{NO}_3)_4]$ from a solution of lead(II) nitrate ($\text{Pb}-\text{O}_{\text{OH}}$ 2.387 Å ave.).²⁹⁰ While these structures may not represent all the species present in solution under these conditions, it is an indication of the extent to which oligomerization can contribute in this speciation.

Lead also forms polynuclear assemblies supported by both monoanionic *O*-donor and oxo ligands. Lead alkoxides can be prepared by the alcoholysis of the labile amino complex $(\text{TMS}_2\text{N})_2\text{Pb}$ with a range of alcohols to give corresponding complexes of overall formula $(\text{RO})_2\text{Pb}$ ($\text{R} = \text{Pr}^i$, Bu^t , $\text{C}(\text{Me})_2\text{Et}$, $\text{C}(\text{Et})_3$, $\text{CH}(\text{Me})\text{CH}_2\text{NMe}_2$). The larger alcohols form linear trinuclear complexes $[(\text{RO})_2\text{Pb}]_3$ with each of the alcohol oxygens bridging two lead centers such as with Bu^tOH ²⁹¹ where the smaller form linear polymers with four-coordinate lead centers bridged by alcohol oxygens in a distorted *tbp* geometry.²⁹² By modifying the reaction conditions, higher nuclearity complexes can be obtained such that the alcoholysis of $(\text{TMS}_2\text{N})_2\text{Pb}$ by Bu^tOH also forms $(\text{Bu}^t\text{O})_6\text{OPb}_4$ (**112**) and by ROH ($\text{R} = \text{Et}$, Pr^i) gives $(\text{RO})_4\text{O}_4\text{Pb}_6$ (**113**). These complexes have structures that are related to adamantane.²⁹³

The reaction of $(\text{TMS}_2\text{N})_2\text{Pb}$ with Bu^tNCO gives both $[(\text{TMS}_2\text{N})\text{Pb}(\text{OSiMe}_3)]_2$ and $\text{Pb}_7(\mu^3\text{-O})(\mu^4\text{-O})(\mu\text{-OSiMe}_3)_{10}$.²⁹⁴ The heptanuclear product seems at first sight to be a rather unusual product, but does in fact have a strong resemblance to the product of the hydrolysis of $(\text{Pr}^i\text{O})_2\text{Pb}$.²⁹⁵

3.7.5.3 Complexes with Monoanionic Bidentate Oxygen Ligands

Monobasic bis-oxygen chelates offer the possibility of forming a variety of complexes with $\text{M}(14)$ ions. The complex anions $[\text{Ph}_2(\text{NO}_3)_3\text{Sn}]^-$ and $[\text{Ph}_2(\text{NO}_3)_2\text{ClSn}]^-$ co-crystallize and the molecular structure of these show bidentate coordination of the nitrate groups in all cases, leading to pentagonal and hexagonal bipyramidal geometries with apical phenyl groups.²⁹⁶ Cupferron, widely used as a chelating agent in analytical chemistry, forms complexes with tin that vary in nuclearity depending upon the starting material used. With tin(IV) chloride, an eight coordinate complex $(\text{PhN}(\text{O})\text{NO})_4\text{Sn}$ is formed, which has an irregular dodecahedral geometry in the crystal. With Me_3SnCl as the starting material, a tetrameric product $[\{\text{PhN}(\text{O})\text{NO}\}\text{Me}_3\text{Sn}]_4$ is formed, which has a central 20-membered $[\text{Sn}_4\text{O}_8\text{N}_8]$ ring.²⁹⁷

Six-coordinate tin complexes of benzoylacetonate are fluxional on the NMR timescale at ambient temperatures.²⁹⁸ The mechanism of interconversion of isomers of $\text{Ph}(\text{Cl})\text{Sn}(\text{Bzacac})_2$ has

been examined by one and two-dimensional NMR studies that show the isomerization can proceed by a Bailar twist, and that Ray-Dutt pathways and routes involving square planar intermediates can be excluded.²⁹⁹ Triorganotin(IV) halides react with the sodium salts of 2,4,6-heptanetrione, 1-Ph-1,3,5-hexanetrione, and 1,5-Ph₂-1,3,5-pentanetrione to form mono- and dinuclear complexes (114) and (115) (R = Me, Et, Prⁿ, Buⁿ, Ph).³⁰⁰ The acetylacetonate analogue 4-acyl-2,4-dihydro-5-Me-2-Ph-3-H-pyrazol-3-one reacts with Me₂SnCl₂ in the presence of sodium methoxide to form (116) or (117) depending upon stoichiometry.^{301,302} Homoleptic tropolonate complexes (trop)₄M (M = Ge, Sn) (trop = tropolonate) have been shown to comprise an ion pair in the case of germanium as [(trop)₃Ge](trop) and a genuine eight-coordinate tin in (trop)₄Sn.³⁰³

3.7.5.4 Complexes with Carboxylates or Phosphinates

Carboxylates can act as monodentate, chelating, or bridging ligands. Carboxylate complexes of Group 14 ions show all these coordination modes, depending upon the metal, the substitution on the metal, and the substitution on the carboxylate.

Triphenylgermanium chloride reacts with the sodium salts of carboxylates (2-furanyl, 2-furanyl vinyl, 2-(5-Bu¹)furanyl, 2-thiophenyl, 2-pyridinyl, 3-pyridinyl, 4-pyridinyl, 3-indinyl, 3-indolyl-methyl, and 3-indolylpropyl) to give in all cases four-coordinate germanium centers with monodentate carboxylate coordination. Interestingly the complexes all show high *in vitro* activity against human tumor cell lines MCF-7 and WiDr.³⁰⁴

Monodentate coordination is seen for the carboxylates in the complexes Ph₃Sn(O₂CC₆H₄X) (X = H, 2-Me, 2-NH₂, 2-NMe₂, 2-Cl, 4-Cl, 2-(OH), 4-(OH), 4-MeS, 2-MeO) in solution state by ¹¹⁹Sn NMR and Mössbauer spectroscopy. This persists in the solid with the exception of the 2-Cl and 2-(OH) derivatives that both show Mössbauer spectra consistent with bridging structures.³⁰⁵

A different monodentate carboxylate is found in the complex Ph₃SnCl(quinolinium-2-carboxylate), where the five coordinate tin is bound in a monodentate fashion to the carboxylate, the proton having migrated to the heterocyclic nitrogen, forming a Zwitterionic ligand.³⁰⁶ Picolinic acid and picolinic acid *N*-oxide also form complexes R₂Sn(pic)₂ and [R₂Sn(pic)]₂O (R = Me, Prⁱ, *n*-octyl, bn) (pic = picolinate) with monodentate carboxylate coordination supported by pyridine-*N* or pyridine *N*-oxide *O*-coordination.³⁰⁷ The structurally similar ligands nicotinic acid and nicotinic acid *N*-oxide form complexes R₂Sn(nic)₂ and [R₂Sn(nic)]₂O (nic = nicotinate) with chelated carboxylates seen in all cases³⁰⁸ and this chelating mode is by far the most commonly encountered in carboxylate complexes of tin. Other examples of substituted carboxylates that form complexes of this type include 2-BrC₆H₄CO₂H³⁰⁹ and 4-BrC₆H₄CO₂H.³¹⁰

The carboxylate ligands in Me₂Sn(OAc)₂ are all chelating, giving a distorted octahedral geometry to this prototypical tin carboxylate. Reaction with [N(Me)₄][OAc] gives the triacetate complex [N(Me)₄][Me₂Sn(OAc)₃], which is seven-coordinate with one monodentate acetate.

At ambient temperatures, the anion is fluxional with rapid exchange between the mono- and bidentate acetates.³¹¹

The factors that influence the denticity of carboxylates are complex. As an illustration of the variation of coordination behavior, the reaction of amino acid derivatives *N*-benzyl glycinate (**1**) or *N*-benzoylglycylglycinate (**2**) with R_2SnO forms complexes $R_2Sn(L)_2$ and $[R_2Sn(L)]_2O$ ($R = Me, Et, Pr^n, Bu^n, n\text{-octyl}$). The mononuclear complexes have a distorted octahedral geometry when R is Me, Pr^n , L is 1, and R is *n*-octyl, L is 2. In all of the other $R_2Sn(L)_2$ complexes, the tin is four coordinate with monodentate carboxylate ligands. The dinuclear complexes have chelated carboxylates when R is Me, Pr^n , L is 1 or R is Me or *n*-octyl, L is 2, but have bidentate coordination of L through a monodentate carboxylate and monodentate amide carbonyl in all other cases. The ligands 1 and 2 react with Ph_3SnCl to form five coordinate complexes $Ph_3Sn(L)$ with bidentate coordination of L through monodentate carboxylate and the amide carbonyl.^{312,313}

The influence of the size of the substituents of the tin and the carboxylic acid have been investigated using the series of complexes prepared from R_2SnO and R^1CO_2H ($R = Bu^n, Bu^s, Bu^i, Bu^t$; $R^1 = Me, Et, Pr^i, Bu^i$). In each case a reaction of stoichiometry tin:acid of 1:2 yielded the expected $R_2Sn(\kappa^2-O_2CR^1)_2$, and stoichiometry 1:1 gave $[R_2Sn(\kappa^2-O_2CR^1)]_2O$ except for the case where all R groups are Bu^i , where the product was $[Bu^i_2Sn(\kappa^2-O_2CBu^i)(OH)]_2$, with a central $[Sn(OH)]_2$ ring. These data seem to suggest that there is little steric influence over the course of these reactions except in the most extreme cases.³¹⁴

The dicarboxylic acids $HO_2C(R)CO_2H$ ($R = (CH_2)_{0-8}, trans\text{-CHCH}, 1,4\text{-C}_6\text{H}_4$) react with Bu_2SnO to form complexes of general formula $Bu_2Sn(O_2CRCO_2)_2$ and have, by solution ^{119}Sn and ^{13}C NMR, oligo- and polymeric structures in which each tin is chelated by two carboxylates from two different molecules of the diacid.³¹⁵

Complexes $[R_2Sn(L)]_2O$ and $R_2Sn(L)_2$ ($R = Me, Et, Pr^n, Bu^n$, $L = \text{anion of 2-MeO-benzoic acid}$; ³¹⁶ $R = Et, Bu^n$, $L = \text{anion of 2-MeS-nicotinic acid}$ ³¹⁷ or 2-NH₂-benzoic acid³¹⁸ prepared from R_2SnO and LH in 1:1 and 1:2 stoichiometry, respectively, show distinct structural features. The dinuclear complex (**118**) has a structure often seen for such carboxylates whereas the mononuclear complexes have a distorted octahedral geometry. Other examples of *ortho*-substituted benzoic acids that form complexes $R_2Sn(L)_2$ are 2-(OH) $C_6H_4CO_2H$ and 2-Cl $C_6H_4CO_2H$, the first of which shows intermolecular hydrogen-bonding, forming dimers, and both of which show asymmetric chelation of the carboxylate. The structures are described in terms of bicapped tetrahedral geometry, with short Sn—C and two short Sn—O bonds and two long Sn—O bonds.³¹⁹ Thiophene-2-carboxylic acid also forms both 1:1 and 1:2 complexes ($R = Me, Et, Pr^n, Bu^n, n\text{-octyl}$) where the coordination of the ligand is exclusively through bidentate carboxylate groups, with no participation from the neighboring thiophene.³²⁰

Bridging ($\mu^2-\kappa^1\kappa^1$) carboxylates are a feature of polymeric $R_3Sn(O_2CR)$ species which tend to have extended linear oligo- or polymeric structures.³²¹ An example of a dinuclear complex with a bridging carboxylate that is not supported by other bridging groups is given by $[Ph_2Sn(O_2CCX_3)]_2$ ($X = H, F, Cl$) where the separation Sn—Sn is in the range 2.69–3.77 Å for these complexes.³²²

Higher nuclearity complexes of this type can be prepared from the reaction of organostannoic acids with carboxylic acids. The hexanuclear (**119**) is prepared from $PhSn(O)OH$ and $cyCO_2H$,

(118)

(119)

and was the first example of a drum-shaped tin(IV) molecule of this class, although this structural type is found for other main group metals.³²³ The molecule comprises two $(\text{SnO})_3$ rings linked by carboxylate bridges between six-coordinate tin centers.³²⁴ This drum structure can be prepared using a wide range of carboxylic acids and the same structure is also seen in the product of the corresponding reactions with phosphinic and phosphoric acids. The structures of $(\text{MeSn}(\text{O})\text{O}_2\text{CMe})_6$, $[(\text{MeSn}(\text{O})\text{O}_2\text{CMe}_3)(\text{MeSn}(\text{O})\text{O}_2\text{P}^t\text{Bu}_2)]_3$, and $[\text{Bu}^n\text{Sn}(\text{O})\text{O}_2\text{P}(\text{OPh})_2]_6$ all exhibit the hexanuclear $(\text{Sn}_3\text{O}_3)_2$ core.³²⁵

The ladder structure is also a common structural motif for higher nuclearity tin carboxylate clusters and can be seen as an unrolled drum structure, and this structural type (**120**), seen in such complexes as $[(\text{Bu}^n\text{Sn}(\text{O})\text{O}_2\text{CPh})_2(\text{Bu}^n\text{SnClO}_2\text{CPh})_2]_2$ ³²⁶ and $\{[\text{Bu}_2\text{SnO}(\text{R})]_2\text{O}\}_2$ ($\text{R} = \text{C}(\text{O})\text{CH}_2\text{SC}(\text{O})\text{N}(\text{CH}_2\text{CH}_2)_2\text{O}$) is commonly found. The latter compound was more active than *cis* platinum against a number of cancer cell lines.³²⁷

Other complexes with different geometries can be prepared by varying the acid used, and though there are no known examples of the drum structure for polynuclear tin complexes of phosphinic acids, other structural types such as cubes $[\{\text{Bu}^n\text{Sn}(\text{O})\text{O}_2\text{P}^t\text{Bu}_2\}_4]$ and butterflies $[\{\text{Bu}^n\text{Sn}(\text{OH})\text{O}_2\text{P}(\text{OPh})_2\}\{(\text{PhO})\text{PO}_2\}]$ have been observed.^{328,329} Mixed complexes of phosphinic and thiophosphinic acids show yet further structural types, as shown by the linear tetramer (**121**), prepared from $\text{Bu}^n\text{Sn}(\text{O})\text{OH}$, $\text{Ph}_2\text{PO}_2\text{H}$ and $\text{Ph}_2\text{P}(\text{S})\text{OH}$ ³³⁰ and the double cube (**122**) prepared from the reaction of $\text{Bu}^n\text{Sn}(\text{O})(\text{OH})$ and $\text{Ph}_2\text{PO}_2\text{H}$ in the presence of elemental sulfur.³³¹ Triphenylmetal monothiophosphinato complexes $\text{Ph}_3\text{M}(\text{OSPR}_2)$ ($\text{M} = \text{Ge}, \text{Sn}; \text{R} = \text{Me}, \text{Et}, \text{Ph}$) show monodentate coordination of the monothiophosphinate through oxygen to form the four-coordinate germanium complexes and five-coordinate tbp tin complexes $[\{\text{R}_2\text{P}(\text{S})\text{O}\}\text{Ph}_2\text{SnOH}]_2$ with bridging hydroxy groups.³³²

Carbon dioxide reversibly inserts into the $\text{Sn}-\text{O}$ bond of compounds Bu^n_3SnOR ($\text{R} = \text{Me}, \text{Pr}^i, \text{Bu}^t, \text{SnBu}^n_3$) to give $\text{Ph}_3\text{SnOCO}_2\text{R}$. Treating these insertion products with caesium fluoride and methyl iodide yields Bu^n_3SnF and dimethyl carbonate.³³³

Lead(IV) carboxylates exhibit a less diverse coordination behavior, so that complexes of *N*-protected amino acids $\text{Ph}_2\text{Pb}(\text{L})_2$ ($\text{L} = \text{R-LLeu-OH}$), $\text{ClCH}_2\text{CO-X-OH}$ ($\text{X} = \text{Gly}, \text{DLAla}, \text{LLeu}$), $\text{Cl}_3\text{CC}(\text{O})\text{-DLAla-OH}$, $\text{F}_3\text{CC}(\text{O})\text{-X-OH}$ ($\text{X} = \text{DLAla}, \text{LPhe}$) are polymeric six-coordinate and $\text{Ph}_3\text{Pb}(\text{L})$ five coordinate with tbp chain structures, showing bidentate carboxylates in both cases.^{334,335} The pentanuclear $\{2,4,6\text{-(CF}_3)_3\text{C}_6\text{H}_2\text{S}\}_8(\text{O})\text{Pb}_5$, (**123**) was isolated after adventitious oxidation of the thiol complex $[2,4,6\text{-(CF}_3)_3\text{C}_6\text{H}_2\text{S}]_2\text{Pb}$ during isolation.³³⁶

Tin(II) carboxylates $\text{M}_2\text{Sn}(\text{C}_2\text{O}_4)_2 \cdot n\text{H}_2\text{O}$ ($\text{M} = \text{NH}_4, \text{Na}, \text{K}, \text{Rb}, \text{Cs}; n = 0, 1$) all exhibit distorted square planar geometry as determined by Mössbauer spectroscopy. The molecular structure of $\text{K}_2[\text{Sn}(\text{O}_2\text{C})_2\text{CH}_2]_3 \cdot \text{H}_2\text{O}$ is polymeric with malonates that bridge tin centers (**124**).³³⁷ Partial oxidation of $(\text{CF}_3\text{CO}_2)_2\text{Sn}$ allows isolation of the mixed oxidation state pentanuclear assembly $\text{Sn}^{\text{IV}}_4\text{Sn}^{\text{II}}(\text{O})_3(\text{CF}_3\text{CO}_2)_8$.³³⁸

(123)

(124)

3.7.5.5 Complexes with Dianionic Bidentate Oxygen Ligands

Germanium powder reacts with 3,5-Bu^t₂benzoquinone in refluxing toluene to give products that comprise corresponding 3,5-Bu^t₂catecholato complexes of germanium(IV). With an initial ratio Ge:benzoquinone of 1:2, the product isolated is a neutral oligomeric species [Ge(3,5-Bu^t₂cat₂)]_n (cat = dianion of catechol). Addition of the chelating ligand bipy allows isolation of the mono-nuclear (bipy)Ge(3,5-Bu^t₂cat)₂. If the ratio of metal: ligand is 3:1, the product is the six-coordinate diradical species Ge(3,5-Bu^t₂cat)₂(3,5-Bu^t₂cat).³³⁹ Other complexes (3,5-Bu^t₂cat)GeX₂ can be prepared from the reaction of the benzoquinone with GeX₂ (X₂ = F₂, Cl₂, OMe₂, Cl(OMe), F(OMe), Et₂, Ph₂) or from either R₂GeX₂ or Ge(OMe)₄ with the catechol.³⁴⁰ Dimethyl germanium(II), generated by the thermolysis of 7-germanabornadienes³⁴¹ reacts with linear, acyclic, or orthoquinone diketones to form the corresponding complexes Me₂Ge(diol) (125)–(129).³⁴²

Catechol, tetrachlorocatechol, or 3,4-Me₂-thiocatechol reacts with RGeCl₃ (R = Me, Ph) to form the five coordinate anions [R(κ²-L-E₂)₂Ge][−] with geometries close to tbp.³⁴³ The related ethane-1,2-dithioate (edt) containing anion [Ph(edt)₂Ge][−] has also been prepared³⁴⁴ as have the mixed catechol-thiocatecholate complexes [NR₄][X(C₆H₄SO)₂Ge] (X = F, Cl, Br) prepared from (C₆H₄SO)₂Ge and [NR₄]X. The geometries of these complexes are distorted from tbp toward square pyramidal and the extent of distortion is dependent upon the nature of the chelate ring. Square pyramidal geometry seems to be stabilized in the cases where there are two unsaturated five-membered chelate rings comprising like atoms within each ring.³⁴⁵ An X-ray crystallographic study of K₂[Ge(cat)₃] has shown the geometry at the germanium to be close to octahedral.³⁴⁶

Six-coordinate (NH₄)₂[Sn(cat)₃] complexes with a range of substituted catechols have been prepared and characterized. The complexes are six-coordinate as determined by the value of δ in the ¹¹⁹Sn NMR. In the ¹H NMR it is possible to observe well resolved long range ⁴J¹¹⁹Sn–¹H and ⁵J¹¹⁹Sn–¹H couplings.³⁴⁷

Catecholato complexes of tin may also be prepared by the reaction of SnX₂ (X = Cl, Br, I) with tetrachlorobenzoquinone in the presence of phen, yielding (phen)SnX₂(C₆Cl₄O₂). If TMEDA is used in place of phen, a variety of products are formed, including the corresponding complexes and (C₆H₁₈N₂)[Sn(C₆Cl₄O₂)₃].³⁴⁸

Anodic oxidation of tin in the presence of catechol and derivatives (catH_2 , Br_4catH_2 , 2,3-(HO) $_2$ -naphth, 2,2'-(OH) $_2$ biphenyl) gives complexes $[\text{Sn}^{\text{II}}(\text{L})]_n$ which can be further converted to a range of tin(II) and tin(IV) diolate complexes.³⁴⁹ The structure of $[(4\text{-NO}_2\text{-cat})\text{Sn}\cdot\text{THF}]_n$ has been determined and the geometry at the tin shown to be distorted square pyramidal with chelation by one catechol ($\text{Sn}-\text{O}$ 2.112, 2.208 Å), two intermolecular tin-oxygen bonds with two different $[(4\text{-NO}_2\text{cat})\text{Sn}\cdot\text{THF}]$ units ($\text{Sn}-\text{O}$ 2.430 Å) and coordination of a molecule of THF through the ether oxygen ($\text{Sn}-\text{O}$ 2.535 Å).³⁵⁰

The structure of $(\text{Me}_3\text{Sn})_2\text{CO}_3$ is polymeric in the solid state arising from the tridentate coordination of the carbonate ion as (130). The C—O bonds show distinct differences in bond lengths (1.267, 1.264, and 1.315 Å) which suggests that there is some localization of the charge despite all three oxygens coordinating tin.³⁵¹

(130)

A number of examples of Zwitterionic five-coordinate germanium(IV) complexes with two dianionic chelating ligands and an alkyl group with a remote basic nitrogen have been isolated reported including mononuclear complexes with 2,3-(HO) $_2$ naphthalene³⁵² or 2-(HO)-carboxylates³⁵³ as the chelate.

Piperazine reacts with two equivalents of (chloromethyl)trimethoxygermanium(IV) to give [1,4-bis(trimethoxygermyl)methyl]piperazine, which is further reacted with 2-Me-2-HO-propionic acid to give the first dispirocyclic Zwitterionic germanium(IV) complex $\lambda^5\text{Ge}, \lambda^5\text{Ge}'$ -digermanate meso[1,4-piperaziniumdiylbis(methylene)-{bis[bis-2-Me-2-OH-propionate *O,O*]germanate}(131). The complex comprises two pentacoordinate germanium(IV) centers with formal negative charges and distorted *tbp* geometries with carboxylate oxygens in the axial positions (bond lengths $\text{Ge}-\text{O}$ 1.769–1.919 Å).³⁵⁴

(131)

The complexes (132) (Ge) and (133) (Sn) of the sterically demanding aryloxide react with oxidizing agents to form the oxo-bridged dimer (134) and with 3,5-Bu $_2$ benzoquinone to form the four coordinate (135) in which the chelate is acting as a catecholates (Scheme 23).³⁵⁵

Scheme 23

Germanium and tin complexes of 1,3-(SiMe₃)₂-4-Bu^t calix(4) arene can be prepared in both *exo* (Ge, Sn) and *endo* (Ge) forms. In the *endo* form, the metal is two coordinate, but the extent to which the ether oxygens are involved in bonding even in the *exo* forms is not clear. The distances M–O(SiMe₃) are not over long (Ge 2.421, 2.486; Sn 2.521, 2.532 Å) but their donating ability is in doubt. The *endo* isomer is thermodynamically preferred for germanium, and is converted to the *exo* form only on prolonged heating at >80 °C. The corresponding lead complex is unstable to light and has not been characterized thoroughly.^{356,357}

The general area of germanium and tin coordination by bidentate oxygen donor ligands has been reviewed.³⁵⁸

3.7.5.6 Complexes with Neutral Sulfur Ligands

Diorganotin nitrate readily forms cationic complexes with a range of neutral ligands upon dissociation of the nitrates. The thione Hmimt coordinates to tin giving the complexes [R₂Sn(Hmimt)₄](NO₃)₂ (R = Me,³⁵⁹ Et,³⁶⁰ or Ph³⁶¹ where all complexes have *trans* organic groups.

The sulfur ligands 1,4-dithiane and 6aneS₃ react with tin(IV) chloride or bromide to give complexes (κ²-1,4-dithiane)SnX₄, (κⁿ-6aneS₃)₂SnX₄,³⁶² and ligands 9aneS₃ and 18aneS₆ react with tin(IV) chloride to give [κ³-(9aneS₃)SnCl₃][SnCl₅] and (κ²,κ²-μ-18aneS₆)(SnCl₄)₂. In the ionic complex, the bond lengths Sn–Cl are 2.369 Å in the cation and 2.448 Å in the anion, and in the latter complex, the two tin centers are symmetrically bound to two thioether sulfurs giving overall six-coordinate tin centers.³⁶³ The larger thioether macrocycle 28aneS₈ forms a dinuclear complex [(28aneS₈)Pb₂](ClO₄)₄ with inclusion of the two lead(II) within the ligand leading to an [S₄O₄] coordination of each lead by the ligand and two chelating perchlorates.³⁶⁴

3.7.5.7 Complexes of Anionic Monodentate Sulfur, Selenium, or Tellurium Ligands

The sterically stabilized aryloxides (132) and (133) have been reported and for the germanium complex, shown to react with sulfur or gray selenium to afford the corresponding germathione or selenone. The tin complex did not react with either chalcogen. The germathione and selenone each react with 3,5-Bu^t-1,2-benzoquinone with extrusion of the sulfur or selenium to give the four-coordinate catecholato bis aryloxy germanium compound.³⁶⁵

Direct reaction of sulfur with [2,4,6-{CH(SiMe₃)₂}₃-C₆H₂](mes)MH₂ (M = Ge, Sn) gives the tetrasulfur ring compounds which are converted to the germa- or stannathione on heating.^{365–367} The germanium complex (R)(mes)GeS₄ reacts further with Ph₂CN₂ to give (R)(mes)Ge(S₄CPh₂) and two isomers of (R)(mes)Ge(S₄CPh₂).³⁶⁸ When [2,4,6-{CH(SiMe₃)₂}₃-C₆H₂](mes)GeBr₂ is treated with lithium naphthide and gray selenium (R)(mes)GeSe₄ is formed, comprising a five membered [GeSe₄] ring. The ring can be contracted by reaction with three equivalents of triphenylphosphine, forming triphenylphosphine selenide and the germaselenone R(mes)GeSe (136) (Ge–Se 2.180 Å). The germaselenone reacts with mesCNO or PhNCS to give products

with the corresponding (GeSeCNO) (**137**) and (GeSeCS) heterocycles (**138**) (Scheme 24).^{369–371} The tin selenones $[2,4,6\text{-}\{\text{CH}(\text{SiMe}_3)_2\}_3\text{C}_6\text{H}_2](\text{R})\text{SnSe}$ ($\text{R} = 2,4,6\text{-Pr}_3\text{C}_6\text{H}_2$, mes) (**139**) are available from the corresponding diaryl tin(II) and gray selenium³⁷² and these selenones each react with other chalcogen bearing molecules to yield products with tin-bound ring structures. Phenyl isothiocyanate gives a mixture of the phenyldiseleno- and dithiastannanes (**140**) and (**141**) rather than the expected mixed thiaselenastannane (Scheme 25). This is an intriguing reaction, which seems to require a bimolecular intermediate to give rise to the observed products. The same diaryl tin(II) reacts with carbon disulfide giving a product that is a symmetrical tetrathiaethylene-bridged dimer.³⁷³ The corresponding lead(II) aryls react with sulfur to form $\text{R}^1\text{R}^2\text{PbS}_4$ ³⁷⁴ whereas $(2,4,6\text{-Pr}_3\text{C}_6\text{H}_2)_2\text{Pb}$ gives R_2PbS_4 and both $[\text{R}_2\text{PbS}]_2$ and $\text{R}_4\text{Pb}_2\text{S}_3$ that have a central $[\text{Pb}_2\text{S}_3]$ ring. Interestingly, $[2,4,6\text{-}\{\text{CH}(\text{SiMe}_3)_2\}_3\text{C}_6\text{H}_2]_2\text{Pb}$ reacts with sulfur to give no products containing lead and sulfur but principally $\text{R}^1\text{S}_n\text{R}$ ($n = 6, 8$).³⁷⁵ The lead thione $\text{R}^1\text{R}^2\text{PbS}$ is stable at temperatures below -20°C , above which it dimerizes, forming a $(\text{PbS})_2$ ring. Reaction with phenyl isothiocyanate below -20°C gives the phenyldithiaplumbane (**142**).³⁷⁶

Scheme 24

Scheme 25

The tetraselenium ring in $[2,4,6\text{-}\{\text{CH}(\text{SiMe}_3)_2\}_3\text{C}_6\text{H}_2](\text{R})\text{SnSe}_4$ ($\text{R} = 2,4,6\text{-}(\text{Cy})_3\text{C}_6\text{H}_2$, $2,4,6\text{-(CH}_2\text{Et)}_2\text{C}_6\text{H}_2$, $2,6\text{-(2-Pr}^i\text{C}_6\text{H}_4)_2\text{C}_6\text{H}_3$) can be contracted to form the selenone again by reaction with three equivalents of triphenylphosphine. Unusual among such monochalcogenides, these complexes are monomeric under ambient conditions, presumably by virtue of the enormous ligands, where the other known examples all dimerize by forming $[\text{SnE}]_2$ bridges. By using only two equivalents of triphenylphosphine in the ring contracting deselenation, the remarkable perselenide $[2,4,6\text{-}\{\text{CH}(\text{SiMe}_3)_2\}_3\text{C}_6\text{H}_2](\text{R})\text{SnSe}_2$ can be isolated (Se—Se 2.524 Å, Sn—Se 2.530 (ave.) Å).³⁷⁷

The area of germanium sulfide cluster anions has been enriched by the publication of a number of new compounds. The structure of the quaternary germanium sulfide $\text{AgLa}_3\text{GeS}_9$ has been elucidated and shown to comprise La_3GeS_4 cubes linked through Ge—S bonds to form a three dimensional array.³⁷⁸ In contrast, the anion $[\text{CuGe}_2\text{S}_5]^-$ comprises $[\text{Ge}_4\text{S}_{10}]^{4-}$ units.³⁷⁹

The combination of germanium sulfide, silver acetate, and DABCO leads to the formation of the complex sulfide $[(\text{DABCO})_2(\text{H}_5\text{O}_2)]\text{AgGe}_4\text{S}_{10}$, which has a three dimensional array of Ge_4S_{10} clusters linked by triply bridging silver ions.³⁸⁰ Germanium, selenium, and silver acetate react in the presence of M_2CO_3 ($\text{M} = \text{Rb}, \text{Cs}$) to give $\text{M}_3\text{AgGe}_4\text{S}_{10}$. This structure is somewhat different, with a four-fold $\text{Ag-}[\text{Ge}_4\text{S}_{10}]$ interaction in the solid.³⁸¹ The nonadamantane [5.1.1.1] tetragermahexachalcogenanes (**143**) are prepared from the reaction of RGeCl_3 with the appropriate lithium chalcogenide³⁸² or $(\text{NH}_4)_2\text{S}_5$.³⁸³ These rearrange to the more stable [3.3.1.1] adamantane structure on heating. In reaction with hydrogen sulfide, Bu^iGeCl_3 forms the cyclic tetramer (**144**) which

again rearranges thermally to the adamantane structure.³⁸³ Adamantane $(RGe)_4E_6$ structures can also be prepared from the reactions of $RGeCl_3$ with $(H_3Si)_2E$ ($R = CF_3$, Et, $E = S$; $R = CF_3$, $E = Se$).³⁸⁴ Corresponding tin complexes $(RSn)_4S_6$ can be prepared from $RSnCl_3$ and either Na_2S or $(Me_3Si)_2S$, but using R_2SnCl_2 leads to the cyclotrimeric $(R_2SnS)_3$.³⁸⁵

(142)

(143)

(144)

The selenide or telluride Rb_2GeE_4 , prepared from Rb_2CO_3 , germanium, and the chalcogen, has been reported. When $E = Se$, the structure comprises tetrahedral $[GeSe_4]$ units with terminal (2.27–2.30 Å) and bridging (2.42–2.44 Å) Ge—Se bonds. Also isolated from the same reaction, $Rb_4Ge_4Se_{10}$ has an adamantane Ge_4S_{10} with terminal (2.25 Å) and cage (2.40–2.39 Å) Ge—Se bonds.³⁸⁶

Sodium sulfide reacts with $[PPh_4][SnCl_3]$ to give $[PPh_4]_2[Sn(S_4)_3]$ with discrete six-coordinate tin centers, whereas $\{NHMe_3\}[Sn_3S_7]$ comprises sheets of 24-membered rings having six $[Sn_3S_4]$ units connected through sulfide bridges at each tin.^{387,388} Hydrothermal reaction of caesium carbonate with tin(IV) sulfide at 130 °C gives $Cs_4Sn_5S_{12} \cdot 2H_2O$ which comprises polythiostannate(IV) sheet anions $[Sn_5S_{12}]^{4-}$ with octahedral $[SnS_6]$ and pyramidal $[SnS_5]$ units.³⁸⁹

Tin selenide $Bi_2Sn_3Se_6$ can be reduced by potassium in the presence of $[PPh_4]^+$ to give the anionic $[Sn_2Se_4Ph_2]^-$ which has a planar $(SnSe)_2$ ring, analogous to $(SnO)_2$, substituted with *trans* phenyl groups and selenides.³⁹⁰ The tin chalcogenides $[Sn_2E_6]^{4-}$ (145) and $[Sn_2E_7]^{4-}$ (146) ($E = Se, Te$) can be isolated by extracting the alloys $K_3Sn_2Se_6$ or $K_3Sn_2Te_5$ with alkaline solutions containing [2,2,2].³⁹¹ From the same reaction, the first mixed hydroxychalcogeno anion of tin was isolated $[(HO)Te_3Sn]^{3-}$. The telluride version of (145) can also be prepared from the reaction of the Zintl anion $[Sn_9]^{4-}$ with elemental tellurium.³⁹² The reaction of potassium or rubidium carbonate with tin and selenium in aqueous methanol gives $M_6^1Sn_4Se_{11} \cdot 8H_2O$, which comprises $[Sn_4Se_{11}]^{6-}$ ions where the corresponding reaction with caesium carbonate gives a product containing the $[Sn_2Se_5]^{2-}$ ion, which has a chair configuration. Chains of $[Sn_3Se_7]^{2-}$ are formed in the reaction using tetraethyl ammonium in place of an alkali metal ion.³⁹³

(145)

(146)

Cyclic trimeric $[Bu^n_2SnTe]_3$ is formed in the reaction of $[NH_4]_2Te$ and $Bu^n_2SnCl_2$ and can be used as a single source precursor to cubic tin selenide.³⁹⁴

3.7.5.8 Complexes of Anionic Bidentate Sulfur, Selenium, or Tellurium Ligands

Carbon disulfide inserts into the tin–carbon bonds of $(2,4,6-Bu^t_3C_6H_2)_2Sn$ to form both $(2,4,6-Bu^t_3C_6H_2)(\kappa^2-2,4,6-Bu^t_3C_6H_2CS_2S,S)Sn$ and $(\kappa^2-2,4,6-Bu^t_3C_6H_2CS_2S,S)_2Sn$.³⁹⁵ A similar insertion is also seen for $(RS)_2Pb$ complexes ($R = 2,6-CH(SiMe_3)_2-4-C(SiMe_3)_3C_6H_2$, $2,4,6-CH(SiMe_3)_3C_6H_2$, the first examples of thiocarbonate complexes of lead(II).³⁹⁶

Organotin complexes $R_3Sn(L)$ ($R = Me, Ph$; $L = S_2CNEt_2, S_2COEt, S_2P(OEt)_2$), $R_2Sn(L)_2$ ($R = Me, Bu^n, Bu^t, Ph$), and $R_2SnX(L)$ ($R = Me, Bu^n, Bu^t$, $X = Cl$; $R = Ph$, $X = Cl, Br$) were studied by NMR spectroscopy. For triorganotin derivatives, only dithiocarbamate shows spectra

consistent with a chelation by the sulfur ligand at ambient temperatures, the other ligands being involved in rapid interconversion between monodentate and chelate attachment. In solution, the dithiocarbamate ligands are chelating in $\text{Me}_2\text{Sn}(\text{S}_2\text{CNET}_2)_2$ but are monodentate in $(\text{Bu}^t)_2\text{Sn}(\text{S}_2\text{CNET}_2)_2$. The diorganotin derivatives are more effectively chelated, and the extent to which the molecule is nonrigid in solution is dependent upon the nature of the organic ligand, such that at -100°C $\text{Ph}_2\text{SnCl}(\text{S}_2\text{CNET}_2)$ is stereochemically rigid in solution and $(\text{Bu}^t)_2\text{SnCl}(\text{S}_2\text{CNET}_2)$ is not.³⁹⁷

Diorganotin bis(xanthates) $\text{R}_2\text{Sn}(\text{S}_2\text{COR}^2)_2$ ($\text{R}^1 = \text{Me, Et, Bu}^n, \text{Ph}$; $\text{R}^2 = \text{Et, CHMe}_2, \text{cy}$) also exhibit the asymmetric bonding of the two sulfur atoms to the extent that the six-coordinate complexes are skewed trapezoidal rather than octahedral in geometry.³⁹⁸ Dimethyl bis(ethoxy-xanthato)tin(IV) exhibits a solution ^{119}Sn NMR indicating that the complex is four-coordinate whereas the crystal structure shows a six-coordinate geometry albeit with markedly asymmetric Sn—S interactions.³⁹⁹ In a similar vein, the complex $\text{BuPhSn}(\text{S}_2\text{CNMe}_2)_2$ also shows an asymmetric coordination of the chelate with bond lengths Sn—S of 2.466 and 3.079 Å. The diethyldithiocarbamate complex has Sn—S bonds that are closer in length (2.454 and 3.764 Å) but still show an asymmetry.⁴⁰⁰ A useful qualitative discussion of the observed asymmetry in Sn—S bonds for tin(IV) dithiolates has appeared.⁴⁰¹ Thiocarboxylic acids form five-coordinate complexes with M(14) such as $(4\text{-MeC}_6\text{H}_4\text{CS}_2)\text{MPh}_3$ ($\text{M} = \text{Ge, Sn, Pb}$) that also show anisobidentate coordination of the $[\text{S}_2]$ donor set.⁴⁰²

With dimethyl dithiophosphinic acid, germanium(IV) chloride forms a tetrahedral complex (Ge—S 2.218–2.236 Å) with monodentate coordination of the ligand⁴⁰³ as do the organotin dithiophosphates $\text{Me}_3\text{Sn}(\text{S}_2\text{P}(\text{OEt})_2)$ and $\text{MeSn}(\text{S}_2\text{P}(\text{OEt})_2)_3$.⁴⁰⁴

Tin(II) complexes of dithiophosphates $[(\text{RO})_2\text{PS}_2]_2\text{Sn}$ ($\text{R} = \text{Me, Et, Pr}^i, \text{Ph}$) have a dimeric structure comprising five-coordinate tin centers, each coordinated by an approximately symmetrical chelating ligand (Sn—S 2.830, 2.623 Å) and one short and two long intermolecular bridging interactions (Sn—S 2.651, 3.042, 3.391 Å).⁴⁰⁵

Bis(diorganophosphorylchalcogeno)amides $[\{\text{R}_2\text{P}(\text{E})\}_2\text{N}]^-$ are compounds with excellent ligand properties and there are a correspondingly large number of complexes known. Complexes of the Group 14 metals are known mostly for the M^{II} state although $[\{\text{Ph}_2\text{P}(\text{S})\}_2\text{N}]_2\text{SnMe}_2$ has been reported.⁴⁰⁶ For M^{II} , the complexes $[\{\text{R}_2\text{P}(\text{E})\}_2\text{N}]_2\text{M}$ ($\text{R} = \text{Ph, E} = \text{O, M} = \text{Sn}$;⁴⁰⁷ $\text{R} = \text{Ph, E} = \text{S, M} = \text{Pb}$;⁴⁰⁸ $\text{R} = \text{Ph, E} = \text{Se, M} = \text{Sn, Pb}$ ⁴⁰⁹) a distorted *tbp* geometry is observed. The complex $[\{\text{Ph}_2\text{P}(\text{Se})\}_2\text{N}]\text{Sn}$ also crystallizes in a second form giving the first example of a square planar spiro tin(II) complex.⁴¹⁰ Unsymmetrical examples can also be prepared and can be used to form complexes such as $[\{\text{Ph}_2\text{P}(\text{S})\}\{\text{Ph}_2\text{P}(\text{O})\}\text{N}]_2\text{M}$ ($\text{M} = \text{Sn, Pb}$).⁴¹¹

Alkyl and aryltin(IV) diphenyldithioarsenates $\text{R}_n\text{Sn}(\text{S}_2\text{AsPh}_2)_{4-n}$ ($n = 2, \text{R} = \text{Me, Bu}^n, \text{Ph}$; $n = 3, \text{R} = \text{Me, cy, Ph}$) are available from the organotin halides and the sodium salt of diphenyldithioarsenates. The dialkyl and trialkyltin species are four-coordinate by spectroscopy whereas the phenyl derivatives are six-coordinate. A structural study of $\text{Me}_2\text{Sn}(\text{S}_2\text{AsMe}_2)_2$ reveals a four-coordinate tin center with monodentate coordination of the dithioarsenate.⁴¹²

3.7.5.9 Complexes of Dianionic Bidentate Sulfur, Selenium, or Tellurium Ligands

Lawesson's reagent reacts with germanium amines to give products that vary according to the nature of the starting material. Germanium(II) amine $[\text{HCN}(\text{Pr}^i)]_2\text{Ge}$ gives the oxidized bis chelated product (147) whereas $(\text{TMS}_2\text{N})_2\text{Ge}$ gives (148), with the monodentate amines intact.⁴¹³

Germanium complexes $(\text{C}_2\text{H}_4\text{E}_2)\text{Ge}$ ($\text{E}_2 = \text{S}_2, \text{SO}$) react with 3,5- Bu^t_2 benzoquinone to give the mixed $(3,5\text{-Bu}^t_2\text{cat})\text{Ge}(\text{C}_2\text{H}_4\text{E}_2)$ complexes. These rearrange rapidly to give the homoleptic complexes $(3,5\text{-Bu}^t_2\text{cat})_2\text{Ge}$ and $(\text{C}_2\text{H}_4\text{E}_2)_2\text{Ge}$.⁴¹⁴ The reaction of $\text{K}_2[\text{edt}]$ with R_2SnCl_2 or tin(IV) chloride gives the complexes $\text{R}_2\text{Sn}(\text{edt})$ or $(\text{edt})_2\text{Sn}$, respectively. The complexes $\text{Bu}^n_2\text{Sn}(\text{edt})$ have a six-coordinate geometry in the solid state with two intermolecular $\text{Sn}\cdots\text{S}$ interactions completing the coordination sphere and forming a linear polymer. If the R group is smaller, the geometry at the tin is five-coordinate *tbp*, with only one strong intermolecular Sn—S interaction.⁴¹⁵ The dianion of toluene 3,4-dithiolate (*tdt*) forms analogous complexes $(\text{tdt})_2\text{Sn}$, which has a similar solid-state structure with intermolecular $\text{Sn}\cdots\text{S}$ interactions making a six-coordinate geometry at the tin. Addition of bases DMSO or triphenylphosphine oxide gives the mononuclear $(\text{tdt})_2\text{Sn}(\text{base})_2$ complexes with *trans* disposition of the monodentate ligands.⁴¹⁶ Anionic *edt* complexes $[\text{Et}_4\text{N}][(\text{edt})_2\text{SnR}]$ ($\text{R} = \text{Bu}^n, \text{Ph}$) and $[\text{Et}_4\text{N}]_2[(\text{edt})_2\text{R}(\text{Cl})\text{SnSCH}_2]_2$ show square pyramidal geometries for the mononuclear complexes and distorted *tbp* for the dimeric complexes.⁴¹⁷

The five-coordinate complexes $[A][(L)_2\text{Sn}X]$ ($A = \text{Ph}_3\text{MeP}$, $\text{H}_2\text{L} = 3,4\text{-tdt}$, $X = \text{Cl}$ (**149**); $A = \text{Et}_4\text{N}$, $\text{H}_2\text{L} = 2\text{-O-SC}_6\text{H}_4$, $X = \text{F}$ (**150**), Cl (**151**)) can be prepared by addition of $[\text{Ph}_3\text{MeP}]\text{Cl}$ to $\text{Sn}(3,4\text{-toluenedithiolate})_2$ or by direct reaction of tin(IV) acetate, 2-OH-thiophenol, and $[\text{Et}_4\text{N}]X$. The sulfur-coordinated (**149**) has a square pyramidal geometry at the tin, where the mixed oxygen-sulfur complexes (**150**) and (**151**) have *thp* geometries. These complexes can be hydrolyzed to form six-coordinate tin species, such as $[\text{Et}_4\text{N}][\text{H}_3](\text{L})_3\text{Sn}]$ from (**150**), which have distorted octahedral geometry.⁴¹⁸

Dithiolates $(\text{R}_3\text{M})_2(\text{L})$ ($\text{L} = 3,4\text{-tdt}$, $\text{M} = \text{Sn}, \text{Pb}$, $\text{R} = \text{Ph}$; $\text{L} = 1,2\text{-Me}_2\text{-bdt}$, $\text{M} = \text{Sn}$, $\text{R} = \text{Me}, \text{Ph}$; $\text{M} = \text{Pb}$, $\text{R} = \text{Ph}$), $\text{R}_2\text{M}(\text{L})$ ($\text{L} = 1,2\text{-bdt}$, $\text{M} = \text{Pb}$, $\text{R} = \text{Me}, \text{Et}, \text{Pb}$; $\text{L} = 3,4\text{-tdt}$, $\text{M} = \text{Sn}$, $\text{R} = \text{Me}, \text{Ph}$, $\text{M} = \text{Pb}$, $\text{R} = \text{Me}, \text{Et}, \text{Ph}$; $\text{L} = 2,3\text{-dithioquinoxaline}$, $\text{M} = \text{Pb}$, $\text{R} = \text{Ph}$), and $\text{Pb}(\text{L})_n$ ($\text{L} = 1,2\text{-bdt}$, $n = 2$; $\text{L} = 3,4\text{-tdt}$, $n = 2$; $\text{L} = 1,2\text{-Me}_2\text{-bdt}$, $n = 1$ or 2) all exhibit spectral properties consistent with mononuclear complexes having four-coordinate geometries.⁴¹⁹

In an attempt to prepare new dithiolate complexes Ph_2PbCl_2 was allowed to react with $(\text{NR}_4)_2[\text{Zn}(\text{MNT})_2]$, giving $\text{Ph}_2\text{Pb}(\text{MNT})_2$, which further reacts with $(\text{NR}_4)\text{I}$ to give $(\text{NR}_4)[\text{Ph}_2\text{Pb}(\text{MNT})_2\text{I}]$. Triphenyllead chloride reacts with $(\text{NR}_4)_2[\text{Zn}(\text{MNT})_2]$ to give $(\text{Ph}_3\text{Pb})_2(\text{MNT})$ which has symmetrical monodentate coordination of $[\text{MNT}]^{2-}$ ($\text{Pb-S } 2.523, 2.580 \text{ \AA}$).⁴²⁰

Lead(II) ethane-1,2-dithiolate is polymeric in the solid state with each lead is chelated by a dithiolate and has a further four close interactions with other neighboring sulfur atoms, giving an overall six-coordinate geometry.⁴²¹ The chelating ligands $\text{K}_2[\text{E}_2\text{C}_2(\text{CN})_2]$ ($\text{E} = \text{S}, \text{Se}$) react with lead to give the complexes $\text{M}^1_2\{[(\text{CN})_2\text{C}_2\text{E}_2]_2\text{Pb}\}$ ($\text{M}^1 = \text{K}$, $\text{E} = \text{S}$; $\text{M}^1 = \text{Ph}_4\text{As}$, $\text{E} = \text{Se}$).^{422,423}

3.7.6 COMPLEXES WITH GROUP 17 LIGANDS

Halide complexes of Group 14 metals continue to offer surprises in their structural chemistry. A new fluoro complex of germanium Ge_7F_{16} has been isolated from the decomposition of germanium(IV) fluoride and shown by crystallography to comprise sheets of $[\text{Ge}_6\text{F}_{10}]^{2+}$ clusters

interspersed by $[\text{GeF}_6]^{2-}$ anions.⁴²⁴ A different structural motif is seen in $[\text{Ge}_5\text{Cl}_{12} \cdot \text{GeCl}_4]$, a product isolated from the thermal decomposition of germanium(IV) chloride. The pentanuclear cluster has a neopentyl arrangement of germanium atoms and has Ge—Cl bond lengths that are longer than those in the GeCl_4 unit (2.119 cf. 2.081 Å).⁴²⁵

Addition of excess fluoride ions to aqueous or acetonitrile solutions of $(\text{CF}_3)_3\text{GeX}$ ($\text{X} = \text{F}, \text{Cl}, \text{Br}$) or $(\text{CF}_3)_4\text{Ge}$ gives the *thp* complex $[(\text{CF}_3)_3\text{GeF}_2]^-$, and octahedral *fac* $[(\text{CF}_3)_3\text{GeF}_3]^{2-}$ or *cis* $[(\text{CF}_3)_4\text{GeF}_2]^{2-}$, respectively. The structures of the anions have been elucidated by ^{19}F NMR and a crystallographic study of $[\text{N}(\text{Me})_4][(\text{CF}_3)_3\text{GeF}_2]$ shows the anion to have axial fluorides and equatorial CF_3 groups.⁴²⁶

Addition of $[\text{Et}_4\text{N}]\text{F}$ to a solution of Me_2SnF_2 leads to the formation of the organofluorostannate $[\text{Me}_4\text{Sn}_2\text{F}_5]^-$. The dimeric structure is derived from $[\text{Me}_2\text{SnF}_3]^-$, and even at low temperatures there is no evidence of coupling between the fluorine and tin nuclei, indicating a rapid fluxional process.⁴²⁷

Structural studies on anionic heptafluoro complexes $[\text{X}]^{3+}[\text{F}_7\text{M}]^{3-}$ ($\text{X} = (\text{NH}_4)_3$, $\text{M} = \text{Sn}$;^{428,429} $\text{X} = \text{Ln}$, Tl , $\text{M} = \text{Sn}, \text{Pb}$ ⁴³⁰) show that the complexes comprise octahedral $[\text{F}_6\text{M}]^{2-}$ ions and isolated fluoride ions rather than any seven-coordinate metals. Other tin fluorides have more complex structures, such as the dimeric $[\text{Sn}_2\text{F}_4]^{2-}$ ion present in $[\text{NH}_4]_4[\text{Sn}_2\text{F}_4](\text{NO}_3)_2$ ⁴³¹ and in mixed halide complexes, such as $\text{Cs}_2\text{Sn}_6\text{Br}_3\text{F}_{11}$ which has in the crystal three distinct tin sites, each of which has close contacts with the fluoride ions only.⁴³² The electronic effects of adduct formation of halides of germanium(IV) and tin(IV) have been reviewed with particular reference to the geometry of the complexes formed.⁴³³

Complexes of simple *N*-donor ligands with germanium(IV) fluoride have been studied at low temperatures by matrix isolation techniques. Complexes $\text{RCN} \cdot \text{GeF}_4$ ($\text{R} = \text{H}, \text{Me}$) and $\text{py} \cdot \text{GeF}_4$ give IR spectra consistent with simple complexation by coordination through the nitrogen, even in the case of HCN . For the pyridine complex, the shift in the bands associated with the pyridine were comparable with those seen in pyridine complexes of transition metal ions and are greater than those seen for the corresponding silicon complex, giving an indication of the acidity of the germanium in germanium(IV) fluoride.^{434,435}

Six-coordinate mixed halide complexes of tin(IV) supported by pyridine can be prepared from the addition of X_2 ($\text{X} = \text{Br}, \text{I}$) and $\text{XI} \cdot \text{py}$ ($\text{X} = \text{Cl}, \text{Br}$) to SnCl_2 in the presence of excess pyridine as $\text{SnCl}_2\text{X}_2\text{py}_2$ ($\text{X} = \text{Br}, \text{I}$), $\text{SnCl}_3\text{Ipy}_2$, and $\text{SnCl}_2\text{BrIpy}_2$. From the IR data of the complexes it is possible to extract a linear regression from the change in the values of the frequency of some of the bands arising from the pyridine ligands in the IR spectra and the electronegativity of the halides.⁴³⁶

Tin(II) difluoride oxidatively adds X_2 ($\text{X} = \text{Cl}, \text{Br}$) in acetonitrile solution to form the mixed monomeric halide $(\text{MeCN})_2\text{SnF}_2\text{X}_2$ and oligomeric $[(\text{MeCN})_2\text{SnF}_2\text{Br}_2]_n$. For the reaction with I_2 , the product obtained is $(\text{MeCN})_2\text{SnF}_4$, and as such represents a new and convenient route to the tetrafluoride, by the elimination of the solvent molecules. These may also be exchanged for a range of other ligands, and complexes with DMSO, DMF, THF, and pyridine were reported. In DMSO solution the same reactions lead to disproportionation products in preference to the mixed halides prepared in acetonitrile.⁴³⁷

Correlation of the ^{35}Cl and ^{79}Br NQR spectra of four- and five-coordinate organohalides of germanium and tin with structural studies on the same compounds has shown that NQR can be a rapid and effective method for determining the structure of such compounds.^{438,439}

The valuable report of a route to the important starting material $\text{GeCl}_2 \cdot \text{diox}$ and a range of other germanium(II) chloride adducts has appeared. Easy access to these useful compounds is very likely to increase their application in a range of reactions.⁴⁴⁰ Variable temperature solid-state NMR studies of PbF_2 have been used to probe the mechanism of fluoride mobility in the lattice. The pathway of the motion of the fluoride has been made on the basis of the lowest resistance to mobility associated with the largest lattice holes.⁴⁴¹ The reaction of $[\text{PPh}_4]\text{Cl}$ with PbCl_2 forms the trichloroplumbate(II) ion, which has a similar structure to the triiodoplumbate(II).⁴⁴²

The structural features of iodo complexes are somewhat more complex than those of the lighter halogens, and a range of new iodo complexes of M(IV) have been reported. The tin complex $[(\text{NH}_3)(\text{CH}_2)_3][\text{SnI}_4]$ has six six-coordinate tin ions in the asymmetric unit, four edge-sharing and two face-sharing,⁴⁴³ whereas the complex iodides $[(\text{Me}_2\text{NCH}_2)_2][\text{SnI}_4]$ and $[\text{PPh}_4][\text{Sn}_2\text{I}_6]$ comprise chains of weakly associated $[\text{SnI}_4]^{2-}$ and $[\text{SnI}_3]^-$ ions in the solid state.⁴⁴⁴

The complex $[(\text{Bu}_3\text{NCH}_2)_2][\text{Pb}_5\text{I}_{16}] \cdot 4\text{DMF}$ has in its crystal structure an iodoplumbate ion with D_{5h} symmetry. Five nearly octahedral $[\text{PbI}_6]$ units are disposed in a planar ring, each sharing a single iodide at the center of the ring and each having two sets of two bridging iodides that make up the central square plane. The coordination is completed by a single terminal iodide *trans* to the

central shared iodide.⁴⁴⁵ In $[\text{PPh}_4][\text{Pb}_2\text{I}_6]$ and $[\{\text{N}(\text{Bu}^n)_3\}_2(\text{CH}_2)_3][\text{PbI}_4]$ the lead ions are all four coordinate.⁴⁴⁶ The product of the reaction of lead(II) iodide, sodium iodide, and 1,1'-Me₂-4,4'-bipyridinium dichloride dihydrate in acetone comprises a linear polymer of face-sharing $[\text{PbI}_6]$ octahedra.⁴⁴⁷ The reaction of lead(II) iodide, sodium iodide, and $[(\text{Pr}^n)_3\text{N}]_2(\text{CH}_2)_3^{2+}$ in DMF leads to $[(\text{Pr}^n)_3\text{N}]_2(\text{CH}_2)_3[\text{Pb}_6\text{I}_{14}] \cdot 4(\text{DMF})$ and $[(\text{Pr}^n)_3\text{N}]_2(\text{CH}_2)_3[\{\text{Pb}(\text{DMF})_6\}\text{Pb}_5\text{I}_{14}] \cdot \text{DMF}$. The former comprises $[\text{PbI}_6]^{4-}$ and $[\text{PbI}_5(\text{DMF})]^{3-}$ octahedra sharing edges forming a one-dimensional polymeric structure, the latter comprises lead surrounded by either six bridging iodides, in $[\text{Pb}_5\text{I}_{16}]^{4-}$, or six DMF molecules. In the structure of $[(\text{Me}_3\text{N})_2(\text{CH}_2)_3][\text{Pb}_5\text{I}_7]$ there are layers of six-coordinate iodoplumbate ions interspersed with noncoordinating iodide ions.⁴⁴⁸ However, the giant of this family of compounds is the truly extraordinary $(\text{Bu}_4\text{N})_8[\text{Pb}_{18}\text{I}_{44}]$, characterized crystallographically and shown to comprise lead ions coordinated in six-coordinate environments by iodides in a structure reminiscent of an octahedral section of the NaCl lattice.⁴⁴⁹ The strategy of including hydrogen-bonding counterions or the inclusion of such solvents in order to partially influence the structure of polyhalo complexes has been discussed.⁴⁵⁰

Lead tetrafluorostannate has a range of useful conducting properties and has been much studied as a result. A crystallographic investigation reveals a structure in which there are two distinct sites for fluoride coordination to tin and a large number of partially occupied sites. These results suggest that the high fluoride mobility may be due to the existence of near-equivalent sites that serve to lower the energy barrier to ion mobility.⁴⁵¹

3.7.7 COMPLEXES OF HYDRIDE LIGANDS

There has been a marked increase in interest in the hydrides of Group 14 metals arising from the potential use of these metals, principally germanium, in the electronics industry, and the need to find routes to volatile pure compounds for vapor deposition processes. Accordingly, a number of new methods of preparation of both low molecular weight reactive germanes and stable primary germanes have appeared.

The copper-catalyzed reaction of germanium metal with dibromo- or dichloromethane gives mixtures of products depending upon the organohalide used (Scheme 26). All of these organo-germanium halides can be converted to germanes (Scheme 26) making this a very productive approach to germane synthesis.^{452,453} Similar reactions with suitable organohalosilanes gives access to mixed volatile germasilanes which are precursors to GeSi materials.⁴⁵⁴

Scheme 26

General routes to primary and secondary germanes have been developed, either by the oxidative addition of RX to $\text{GeCl}_2 \cdot \text{diox}$ followed by hydride reduction of the RGeCl_2X formed or by the reaction of Grignard reagents R^1MgX with $\text{Ge}(\text{OR}^2)_4$ compounds, and hydride reduction of the $\text{R}^1\text{Ge}(\text{OR}^2)_3$ (Scheme 27). For some of these germanes the ^{73}Ge NMR spectra show well-resolved spectra and $^1\text{J}^1\text{H}-^{73}\text{Ge}$ of ca. 100 Hz.⁴⁵⁵ Insertion of GeH_2 , prepared from the flash photolysis of 3,4-Me₂-germacyclopentane, into GeH_4 gives Ge_2H_6 in high yield.⁴⁵⁶

Scheme 27

The first stable crystalline primary germane (**152**) has been prepared. The complex is monomeric in the solid state.⁴⁵⁷ Primary germanes are also liable to dehydrocoupling in the presence of $\text{Cp}_2\text{ZrCl}_2/\text{Bu}^n\text{Li}$ forming poly(organogermanes) with moderate $(3 \times 10^4 - 7 \times 10^4)$ molecular weight.⁴⁵⁸

(152)

The first well-characterized tin(II) hydride has been prepared from the DIBAH reduction of [2,6-(trip)₂C₆H₃]₂SnCl. The hydride is isolated as orange crystals from a blue solution, and has a dimeric structure with a central (SnH)₂ ring. The geometry at the tin centers is distinctly pyramidal, indicating that the lone pair is stereochemically active.⁴⁵⁹

3.7.8 COMPLEXES OF LIGANDS WITH MIXED DONOR SETS

3.7.8.1 Complexes of Heterobidentate Ligands

An important group of compounds in this class are those with tethered [C,X] ligands, where an organic group bound to the metal comprises a functional group at an appropriate distance from the *ipso* carbon to allow the coordination of this group to the same metal center, forming a ring structure. In some cases, the tethered group supports the M(14)—C bond, and in some, the M(14)—C bond supports the coordination of an indifferent ligand.

Germanium—aryl bonds can be stabilized by intramolecular coordination of the germanium by secondary donor groups on the organic ligand, such as the methoxy substituent on the naphthalide (153). The supporting role played by this oxygen donor (Ge—O ca. 2.357 Å) seems to facilitate the formation of a range of stable complexes.⁴⁶⁰

(153)

A series of complexes of general formula [Me₂N(CH₂)₃]₂M^{IV}Ph_yX_z (M = Ge, Sn, Pb; y = 0–3; X = Cl, Br, I, OPh; z = 0–3) have been prepared and shown to exhibit intramolecular coordination of the dimethylamino group to the metal, forming a five-membered ring structure centered on a distorted t_{bp} metal. The complexes were studied by a range of spectroscopic techniques to establish the correlation between the electronegativity of the complementary ligand set and the strength of the metal to nitrogen interaction. The ¹³C NMR spectra are particularly useful in assessing the strength of this interaction because of the strong dependence of the value of δ for the α-methylene carbon upon the geometry of the ring formed by the intramolecular chelation.⁴⁶¹ A further example is given by the bicyclic complex (Me₂SnCH₂CH₂)₂P(O)Ph wherein the oxygen coordinates to both tin centers in chloroform solution but is displaced from one tin on addition of a coordinating solvent molecule such as pyridine.⁴⁶² In the same way, the complex ClMe₂Sn{CH₂—SiH₂CH₂P(O)(OEt)₂} shows intramolecular coordination of the phosphine oxide (Sn—O 2.371 Å), giving rise to a six membered ring with a chair conformation in the solid state⁴⁶³ and similarly the dimethyldithiocarbamate complex (MeCO₂CH₂CH₂)SnCl₂(S₂CNMe₂) has intramolecular coordination of the ester carbonyl.^{464,465} The rings remain intact in solution according

to NMR experiments.⁴⁶³ The γ -alkoxytin trichlorides $(\text{OH})(\text{CH}_2)_n\text{SnCl}_3$ ($n=3-5$) have five-coordinate tin centers. When n is 5 there is intermolecular $\text{Sn}(\text{OH})$ coordination, and the crystal structure shows a bond length $\text{Sn}-\text{O}$ of 2.365 Å. For the cases where n is three or four, the coordination is intramolecular, forming five- and six-membered rings.⁴⁶⁶

Dimeric intramolecularly coordinated organotin sulfides $[(\text{Me}_2\text{NCH}_2\text{CH}_2\text{CH}_2)_2\text{SnS}]_2$ have an octahedral *trans-cis* $[\text{C}_2\text{N}_2\text{S}_2]$ donor set in which the alkyl derivatives are *trans*, the bridging sulfur ligands are obliged to be *cis* and the dimethylamino nitrogens are necessarily *cis* to complete the octahedral geometry. The $(\text{SnS})_2$ ring is planar as is seen for all cases, and although the intramolecular coordination of the nitrogen is temperature dependent, the $(\text{SnS})_2$ ring remains intact in solution.⁴⁶⁷

Tin(IV) coordinates 2-thienyl pyridine not through a $[\text{N},\text{S}]$ chelate but rather a $[\text{C},\text{N}]$ donor set, with activation of the proton on the 2-thienyl position, such as bis[3-(2-pyridyl)-2-thienyl] Ph_2Sn , (154).⁴⁶⁸

Bis(lactamoylmethyl)germanium dichlorides react with TMSX ($\text{X} = \text{Br}, \text{I}, \text{TfO}$), LiZ ($\text{Z} = \text{Br}, \text{I}, \text{ClO}_4$), or AgA ($\text{A} = \text{F}, \text{BF}_4$) to yield products where the extent to which the halides are exchanged is dependent upon the nature of the anion rather than stoichiometry. For the noncoordinating anions TfO , ClO_4 , and BF_4 only one chloride is exchanged, giving products (155) with an all *trans* disposition of ligands. In reactions with the more coordinating anions, both chlorides may be exchanged giving products with the oxygens and monodentate ligands both *cis* and the carbons *trans*.⁴⁶⁹

Stable five-coordinate anionic complexes bis[α,α -bis(CF_3)benzenemethanolato]stannates (156) have been reported. Reaction of (156) ($\text{R} = \text{Ph}, 4\text{-MeC}_6\text{H}_4$) with SO_2Cl_2 gives the corresponding chlorostannates which were metathesized to the fluoro complexes with $[\text{Bu}_4\text{N}]\text{F}$.⁴⁷⁰

Lead(II) chloride reacts with lithiated dimethylamino(ferrocenyl)methane to give (157). In the solid state, the complex exists in the *meso* form, but in solution it rapidly converts to a mixture of both the *meso* and *rac* forms.⁴⁷¹ The general area of intramolecular coordination chemistry of tethered $[\text{C},\text{X}]$ donor ligands has been reviewed.⁴⁷²

Thioacetic acid reacts with Bu^tGeCl_3 to form the five-coordinate *tbp* (158), with one doubly and one singly deprotonated thioacetate ligand.⁴⁷³ The disodium salt of 2-thioethanol reacts with Bu^nSnCl_3 to give the trinuclear (159) in which the bridges are again of the $(\text{SnO})_2$ type. Attempts to replace the remaining chloro group by reaction with a Grignard reagent lead instead to the isolation of (160), which dimerizes in the solid state through $\text{Sn}\cdots\text{O}$ interactions.⁴⁷⁴ The structure of $\text{Me}_2\text{Sn}(\text{2-pyridinethiolato-}N\text{-oxide})_2$ exhibits very asymmetric chelation of the $[\text{S},\text{O}]$ donor and shows a skewed trapezoidal bipyramidal geometry with the methyl groups in axial positions.⁴⁷⁵

(159)

(160)

In the majority its complexes, 8-HO-quinoline (LH) is a chelating [N,O] donor, but in complexes $R_3Sn(L)$ ($R = Me, Et, Pr^i, Bu^n, Ph$) the ligand is coordinated in a monodentate fashion through the oxygen alone in solution according to ^{119}Sn NMR data⁴⁷⁶ while for tricyclohexylstannyl complexes of substituted 8-hydroxyquinolines chelation is observed.⁴⁷⁷ The substituted ligand in complexes (161) acts as a chelate.⁴⁷⁸

(161)

(162)

The Schiff-base salicylaldoximate forms two trinuclear complexes with tin upon refluxing with dimethyltin oxide (162). In both cases, the complex has a $[L_2Me_6Sn_3]$ unit with a bridging group X, which is either a fluoride or the oxygen of a second salicylaldoxime.⁴⁷⁹ Other bidentate [N,O] Schiff base ligands form stable complexes with tin that have antifungal activity.⁴⁸⁰

3.7.8.2 Complexes of Heterotridentate Ligands

The tolerance for diverse ligand type and coordination number makes the heavier members of Group 14 especially liable to coordinate ligands of higher denticity and with more varied donor atom type.

The dianions of *N*-substituted diethanolamines coordinate germanium through an $[NO_2]$ donor set in the five coordinate complex $\{RN(CH_2CH_2O)_2\}Ge(OH)_2$ ($R = H, Me$). The two hydroxy ligands are labile and readily displaced by bidentate ligands LH_2 (diols, α -hydroxy carboxylic acids, oxalic acid, 2- NH_2 phenol) to give the neutral five-coordinate complexes $HN(CH_2CH_2O)_2Ge(L)$. The coordination of nitrogen is confirmed by NMR data and in the case where LH_2 is $Ph_2C(OH)CO_2H$, by crystallography ($Ge-N$ 2.08 Å).⁴⁸¹

Five coordinate germanium(IV) complexes 1,1,5-trimethyl-2,8-dioxa-5-aza-1-germa-bicyclo [3.3.01,5]octane diones (163) can be prepared from the reaction of R_2GeX_2 ($R = Me, Ph$; $X = Cl, OR$) with $MeN(CH_2CO_2H)_2$.⁴⁸² Tridentate ligand 5-aza-2,2,8,8-tetramethylnonane-3,7-dione reacts with tin(IV) chloride to form (164), comprising a tin(II) center which is liable to oxidation by SO_2Cl_2 to form (165).⁴⁸³

The pyridine-based stannatrane (166) can be prepared from Bu^n_2SnO and 2,6- $(CH_2OH)_2$ pyridine.⁴⁸⁴ Aldimino alcohols react with $Bu^n_2Sn(NMe_2)_2$ to form initially *N,O*-chelated complexes that quickly dimerize to give five-coordinate geometries such as (167).⁴⁸⁵

The fluxional behavior of five-coordinate tin complexes of *N*-methyl diethanolamine and *N*-methyl diethylthiolate has been investigated. In the solid state, the structure of $Bu^t_2Sn(OCH_2CH_2)_2NMe$ has oxygen in the axial positions and equatorial alkyl and nitrogen ligands

(Sn—O 2.58 Å) where the sulfur analogue $\text{Me}_2\text{Sn}(\text{SCH}_2\text{CH}_2)_2\text{NMe}$ has equatorial sulfur coordination and an axial alkyl and nitrogen ligand (Sn—S 2.431 Å, ave.). This difference in disposition of ligands may arise from the change in electronegativity on going from oxygen to sulfur donors, or from the change in size of the alkyl ligand. The exchange of ligand positions in the fluxional processes in solution proceeds through a Berry pseudo-rotation process at low temperatures and by a dissociation-inversion pathway at higher temperatures.⁴⁸⁶

The complex $[\text{PhSn}(\text{SCH}_2\text{CH}_2)_2\text{NMe}]_2\text{CH}_2$ has two five-coordinate tin centers, each coordinated by a tridentate [N,S,S] and phenyl and the bridging methylene. In the solid state, the phenyl groups occupy axial positions, but in solution the molecule is fluxional, and NMR data indicate that the phenyl groups can symmetrically occupy axial or equatorial positions or asymmetric axial and equatorial isomers.⁴⁸⁷ Complexes $[\text{XSn}(\text{CH}_2\text{CH}_2\text{CH}_2)_2\text{NMe}]_2$ (X = Cl, Me) both have directly linked five-coordinate tin centers and are fluxional in solution. The fluxional processes that depend upon a rotation about the Sn—Sn bond are lower in energy for the methyl complex than for the chloro, a difference in behavior arising from the variation in the selectivity for apical positioning for the two ligands.⁴⁸⁸

The tridentate monobasic ligand 1-(2-pyridylazo)-2-naphtholate (pan) has been used to prepare seven-coordinate complexes $\text{R}_2(\text{pan})\text{M}(\text{L})$ (L = ACAC derivative, M = Sn, R = Bu, Me; M = Pb, R = Me). For both metals the difference in δ is distinct from lower coordination numbers, both showing an upfield shift in δ of ca. 200⁴⁸⁹ typical for such a change in coordination number.⁴⁹⁰ The dianionic tetracyclic ligand (168) is prepared from the lithiation of 2-Me-benzoxazole and reacts with tin(II) chloride to form (169).⁴⁹¹

Acetylacetonato complexes $\text{Sn}(\text{ACAC})_2\text{Cl}_2$ react with 2- $\text{NH}_2\text{C}_6\text{H}_4\text{OH}$, 2- $\text{NH}_2\text{C}_6\text{H}_4\text{SH}$, benzoylhydrazine, and thiobenzoylhydrazine gives the bis-tridentate complexes SnL_2 (L = acetylacetonato-*o*-iminophenol, -*o*-iminothiophenol, -benzoylhydrazine, and -thiobenzoylhydrazine) that exhibit distorted octahedral geometries.⁴⁹²

Tridentate Schiff-base ligands formed from the reaction of salicylaldehydes with either 2-(NH_2)-phenol^{493–495} anthranilic acid,⁴⁹⁶ or amino acids^{497,498} coordinate M^{IV} (M = Ge, Sn, Pb) as tridentate $[\text{NO}_2]$ donor ligands to form stable complexes that are either *tbp* or octahedral depending upon stoichiometry. The lead complex (170) is associated into a dimeric unit through $\text{Pb}\cdots\text{O}$ bridging interactions, forming a $[\text{PbO}]_2$ ring.⁴⁹⁴ Using salicylaldehyde-5-sulfonic acid and 2-(NH_2)-phenol-5-sulfonate, the water soluble version of the ligand can be prepared and used to form complexes of germanium in aqueous solution.⁴⁹⁹

(168)

(169)

(170)

The reaction of 3,5-Bu^tcatH₂ with ammonia under oxidizing conditions gives 3,5-Bu^t-1,2-quinone-1-(2-hydroxy-3,5-Bu^tphenyl)imine anion which acts as a tridentate [NO₂] ligand in reaction with MCl₂ (M = Sn, Pb). In these complexes, the ligand responds to the nature of the metal, such that the tin complex comprises tin(IV) and the lead complex comprises lead(II).⁵⁰⁰

Electrochemical oxidation of a tin anode in the presence of Schiff-base ligands derived from substituted salicylaldehydes and bis(2-aminophenyl)disulfide (L₂H₂) gives complexes SnL₂. The tin shows a distorted octahedral geometry for these complexes, and the structure of bis[2-(2-thiophenyl)imino-4,6-(MeO)₂C₆H₃O]tin(IV) has averaged bond lengths of Sn—N 2.17, Sn—O 2.07, and Sn—S 2.47 Å.⁵⁰¹

Nickel porphyrazineoctathiolate has four [S₂N] sites that can be used to coordinate further metal ions, and the crystal structure of (R₂Sn)₄S₈(porphyrazine)Ni^{II} (171) shows symmetrical coordination of the four tin centers onto the periphery of the ring.⁵⁰²

The flexibility in coordination number and geometry exhibited by M(14) in comparison to transition metal ions sometimes leads to the formation of complexes in which the coordination of a particular ligand takes an unexpected form. The ligand (172) H₂ would seem to present an [O₂] donor set, but in its complexes with germanium acts as a tridentate [O₂Se] ligand, coordinating in a *fac* configuration in both the tbp (172)GeMe₂ and octahedral (172)₂Ge. The complexes are configurationally stable in solution by NMR and they seem to be the first examples of selenoether coordination to neutral germanium(IV) centers.⁵⁰³

Tridentate ligands with pincer arrays have become popular subjects for study. The reaction of Li[2,6-(Me₂NCH₂)C₆H₃] with tin(II) chloride leads to the pincer complex [κ³-2,6-(Me₂NCH₂)C₆H₃-C,N,M]SnCl. The complex has a tbp geometry with a stereochemically active lone pair in an equatorial position and both axial positions taken by nitrogens. The complex is stereochemically nonrigid at temperatures above -70 °C but the nature of the fluxional process was not unambiguously determined. The chloro ligand is liable to substitution in reaction with aryllithium reagents.⁵⁰⁴ Another pincer stannylene (173) has been reported and again shown to be readily substituted with a range of ligands to form further stannylenes.⁵⁰⁵

(171)

(172)

(173)

3.7.8.3 Complexes of Heterotetradentate Ligands

Schiff-base ligands prepared from the condensation of salicylaldehyde with diamines offer $[N_2O_2]$ donor sets that are capable of coordinating a wide range of metals. Tin(IV) acetate reacts with $salenH_2$ ⁵⁰⁶ and R_2SnCl_2 reacts with either (3-MeO)salphen ($R = Ph, Bu^n, Me$)⁵⁰⁷ or the ligand prepared by the condensation of 1,2-(NH_2) $_2C_6H_4$ and 2-(HO)-1-naphthaldehyde ($R = Ph$)⁵⁰⁸ to give in all cases the corresponding six-coordinate products $(L)SnR_2$. Divalent $M(14)$ Schiff-base complexes can be prepared by the reaction of the amines $(TMS_2N)_2M$ ($M = Ge, Sn, Pb$) with the Schiff bases directly. These M^{II} complexes are prone to oxidation, by iodine to give the diiodide or by 3,5- Bu^t_2 -benzoquinone to give the catecholate.^{509,510} In these M^{II} complexes, the metals do not sit in the plane defined by the $[N_2O_4]$ donors but rather are displaced to one face of the ligand. With lead(II) perchlorate, $salenH_2$ forms a trinuclear complex $[(salen)_3Pb_3](ClO_4)_2$, with the same out of plane coordination of the two lead(II) centers within the ligand pockets and with the third lead linking the two $[(salen)Pb]$ monomers by coordinating in an *exo* fashion to all four phenolic oxygens.⁵¹¹ In the same paper, a four-coordinate complex of lead(II) with the potentially heptadentate ligand saltrenH₃ is also reported, where the lead(II) coordinates to the ligand through only four donor atoms.

Amine phenol (**174**) related to reduced salen reacts with R_2SnO ($R = Me, Bu^n, Bu^t, Ph$) to give six-coordinate complexes with $[N_2O_2]$ coordination of the ligand⁵¹² whereas reduced $salenH_2$ reacts with lead(II) acetate to give a dimeric complex $[(\kappa^2-HL-N,O)(\kappa^1-OAc)Pb]_2$ linked through bridging phenolic oxygens and reduced saltrenH₃ gives a dimeric complex $[(\kappa^4-HL-N,N,O)Pb]_2\mu-OAc(OAc)$.⁵¹³

(174)

Tripodal ligands $(CH_2CH_2OH)(CH_2CO_2H)_2N$ and $(CH_2CONH_2)(CH_2CO_2H)_2N$ react with R_2SnO ($R = Bu^n, n$ -octyl) to give complexes $(L)SnR_2$. The crystal structure of $[(CH_2CH_2OH)(CH_2CO_2)_2N]SnBu^n_2$ has a distorted octahedral geometry in which the hydroxy group is coordinated as an innocent ligand.⁵¹⁴ The unsubstituted iminodiacetate complexes $HN(CH_2CO_2)_2SnR_2$ ($R = Me, Bu^n$) prepared in the same way crystallizes as a dimer with a seven-coordinate tin center, in which the alkyl groups are in the *trans* positions.⁵¹⁵

Despite the proven depressant neurotropic influence of furan- or thiophene-substituted germatranes,⁵¹⁶ germatranes and stannatranes have been studied to develop routes for their synthesis, from triethanolamine^{517,518} or tristannyl ethers^{519–521} their substitution reactions,^{522,523} their structures,^{524,525} and iododestannation.⁵²⁶

The series of germatranes $RC_6H_4Ge(OCH_2CH_2)_3N$ ($R = H, 4-Me, 3-Me, 2-Me$) have been prepared by the insertion of germanium(II) bromide into a carbon-halide bond on the aryl group to give $RC_6H_4GeBr_3$, which can be converted to the alkoxy derivative $RC_6H_4Ge(OR)_3$. Reaction with triethanolamine gives a good yield of the phenyl germatranes, some of which were characterized by crystallography. Inclusion of a group in the ortho position decreases the angle $N-Ge-C_{ipso}$ from 177.5° in the unsubstituted complex to 144.2° , and for these complexes the transannular $Ge-N$ bond is found to be in the range 2.212 – 2.230 Å.⁵¹⁷

Unsymmetrical stannatranes $R_2Sn(XCH_2CH_2)_2Y$, $RSn(XCH_2CH_2)_2Y$, and $R_2Sn(OC(O)CH_2)_2Y$ ($X = O, NMe, S, Y = O, S, NR$) have been studied by Mössbauer spectroscopy to establish the coordination geometries. The preferred geometry is *thp* for all cases where the apical atom is nitrogen and distorted four-coordinate where the apical atom is a chalcogen, indicating that in these cases the apical group is not coordinated.⁵²⁷

3.7.8.4 Complexes of Heterodonor Ligands of Higher Denticity

Seven-coordinate complexes of tin are not unusual, and the structure of $Et_2Sn\{2,6\text{-diacetylpyridine bis}(2\text{-thienoyl})\}\text{hydrazone}$ is an example having a pentagonal bipyramidal geometry with axial alkyl groups where the pentagonal plane is defined by the pentadentate ligand.⁵²⁸

Diethylenetriaminepentaacetic acid (H_5dtpa) forms complexes $(\text{Hdtpa})\text{Sn}\cdot 3\text{H}_2\text{O}$, $(\text{Hdtpa})\text{Sn}$, and $\text{Na}[(\text{dtpa})\text{Sn}]$. The structure of $(\text{Hdtpa})\text{Sn}\cdot 3\text{H}_2\text{O}$ shows an eight-coordinate tin with an $[\text{N}_5\text{O}_3]$ donor set, one of the highest coordination numbers seen for tin(IV).⁵²⁹

The tripodal Schiff-base ligand 3-MeO-saltren H_3 reacts with lead(II) chloride to give a dinuclear complex $[(3\text{-MeO-satren})\text{Pb}_2]\text{Cl}$, crystallized as its perchlorate salt. The complex comprises two distinct lead(II) centers, one coordinated within the ligand cavity having an $[\text{N}_4\text{O}_3]$ donor set, the other coordinated in an *exo* fashion to the three phenolic oxygens, an example of the breadth of tolerance for coordination number and donor atom type even within a single complex.⁵³⁰

Lead complexes of a range of mixed $[\text{N},\text{O}]$ donor macrocycles and substituted macrocycles have been prepared. Schiff-base condensation of a range of amines with pyridine-2,6-dicarboxaldehyde gives the ligands (175)–(177). The mononuclear complex of lead with (175) comprises a 10-coordinate lead, bound to all six of the macrocycle donors and two chelating nitrates, whereas the complex of the reduced version (176) shows a different conformation associated with the greater degree of flexibility in the ring of the macrocycle.⁵³¹ Ligand (177) complexes lead to give a linear polymer⁵³² where the octadentate (178) forms mononuclear complexes.⁵³³ The structurally related (179) forms both mono- and dinuclear complexes depending upon the reaction stoichiometry.⁵³⁴

The substituted cyclam (180) forms a mononuclear lead complex that has a six-coordinate geometry in the solid state and is fluxional in solution. A ^{13}C NMR study shows that the four ring donors stay coordinated throughout and that all four pendant groups are involved in coordinating the lead.^{535,536}

In order to investigate preferences for ligand configuration and donor atom type, families of related complexes have been prepared and their complexes compared. For the family of

complexants (**181**) the most successful ligand for lead(II) was found to be the smallest example⁵³⁷ and for the complexes (**182**), the most successful was that with an all-nitrogen donor set.^{538,539}

(180)

(181)

(182)

Introduction of even a single nitrogen donor enhances the stability of complexes of lead(II) with macrocycles such as aza crown ethers (**183**) and (**184**), which both form lead(II) complexes that show markedly higher stability than those of the corresponding oxygen donors 15-C-5 and 18-C-6. Structurally, the complexes are distinct, with the former showing a nine-coordinate lead with *cis* coordination of two chelating nitrates and the coordination of the macrocycle on the opposite face of the lead, and the latter 10-coordinate with an equatorial macrocycle and *trans* disposed chelating nitrates.⁵⁴⁰⁻⁵⁴² The mixed donor substituted macrocycles (**185**) and the related macrobicycles (**186**) all complex lead(II) by coordination within the ligand ring. The structure of the complexes with (**185**) $a=b=1$ comprises a six-coordinate lead, with one primary amine nitrogen, two tertiary amine nitrogens and three ether oxygens coordinating, whereas the complex with (**186**) has donor set made up of a pyridine nitrogen, one imine nitrogen, two tertiary amine nitrogens, two ether oxygens, and a monodentate perchlorate.⁵⁴³

(183)

(184)

Mixed nitrogen–sulfur donor macrocycles show relatively low affinities for lead(II) despite assumptions based upon hard–soft arguments. The ligands (187) and (188) complex lead with moderate efficiency.⁵⁴⁴

3.8

Appendix to Volume 3

JON A. McCLEVERTY

University of Bristol, Bristol, UK

and

THOMAS J. MEYER

Los Alamos National University, Los Alamos, New Mexico, USA

This appendix provides access to original chapters from Comprehensive Coordination Chemistry (published in 1987) that are relevant to this volume of Comprehensive Coordination Chemistry II (CCC2) but that are not cited by a specific chapter in CCC2.

For further details please see the end of the Preface under the General Information tab.

PDF 1. Chapter 24 Boron

PDF 2. Chapter 29 Sulfur, Selenium, Tellurium and Polonium

PDF 3. Chapter 30 Halogenium Species and Noble Gases
