**Coumarin** [91-64-5] **M** 146.2, **m** 68-69°, **b** 298°, **pK**<sup>25</sup> -4.97 (aqueous H<sub>2</sub>SO<sub>4</sub>). Coumarin crystallises from ethanol or water and sublimates *in vacuo* at 43° [Srinivasan & deLevie *J Phys Chem* 91 2904 1987]. [*Beilstein* 17/10 V 143.]

**Coumarin-3-carboxylic acid** [531-81-7] **M** 190.2, **m** 188°(dec), **pK**<sub>Est</sub> ~1.5. The acid crystallises from water. [*Beilstein* 18/8 V 323.]

**γ-Crotonolactone [2(5H)-furanone]** [497-23-4] **M** 84.1, **m** 3-4°, 76-77°/3.5mm, 90.5-91°/11.5mm, 92-93°/14mm, 107-109°/24mm, 212-214°/760mm, **d**<sub>4</sub><sup>20</sup> 1.197, **n**<sub>D</sub><sup>20</sup> 1.470. Fractionally distil the lactone under reduced pressure. Its IR(CCl<sub>4</sub>) has 1784 and 1742 cm<sup>-1</sup>, UV no max above 205nm (ε 1160 cm<sup>-1</sup> M<sup>-1</sup>) and <sup>1</sup>HNMR (CCl<sub>3</sub>) has τ at 2.15 (pair of triplets 1H), 3.85 (pair of triplets 1H) and 5.03 (triplet 2H). [Price & Judge *Org Synth Coll Vol V* 255 1973, Smith & Jones *Can J Chem* 37 2007, 2092 1959, *Beilstein* 17/9 V 112.]

**15-Crown-5** [33100-27-5] **M** 220.3, **b** 93-96°/0.1mm, **d**<sub>4</sub><sup>20</sup> 1.113, **n**<sub>D</sub><sup>20</sup> 1.465. Dry it over 3A molecular sieves and distil it in a high vacuum. [*Beilstein* 19/12 V 252.]

**18-Crown-6** [17455-13-9] **M** 264.3, **m** 37-39°. Recrystallise it from acetonitrile and dry it in a vacuum.

Purify it also by precipitating the 18-crown-6/nitromethane 1:2 complex with Et<sub>2</sub>O/nitromethane (10:1 mixture). The complex is decomposed in vacuum whereby 18-crown-6 distills off under the reduced pressure. [*Beilstein* 19/12 V 601.]

**Cryptopine** [482-74-6] M 369.4, m 220-221°, 220-223°, pK<sup>25</sup> 8.09. It crystallises from \*benzene, hot EtOH (0.25% cold, 1.2% at boiling), petroleum ether or methyl ethyl ketone. The *perchlorate* crystallises from aqueous MeOH with m 226-228°(dec). [Thomas et al. *Can J Chem* 33 570 1955, Howarth & Perkin *J Chem Soc* 1769 1926, *Beilstein* 27 III/IV 6652.]

**Cupreine (6'-hydroxycinchonidine)** [524-63-0] M 310.4, m 202°(anhydrous), [α]<sub>D</sub><sup>17</sup> -176° (c 0.5, MeOH), pK<sup>15</sup> 7.63. Cupreine crystallises from EtOH (*anhydrous* crystals) and wet Et<sub>2</sub>O (as *dihydrate* crystals). It has K<sub>b</sub> 2.7×10<sup>-7</sup> [Kolthoff *Biochem Z* 162 323]. The *sulfate* forms needles, m 257°(dec), from MeOH, amyl alcohol or H<sub>2</sub>O, with [α]<sub>D</sub><sup>20</sup> -197.9° (c 1.2, H<sub>2</sub>O). [*Beilstein* 22 I 165, 22 II 416.]

**5-Cyanoindole** [15861-24-2] M 142.2, m 106-108°, 107-108°, pK<sup>25</sup> <0. Dissolve the nitrile in 95% EtOH, boil it in the presence of charcoal, filter, evaporate to a small volume and add enough H<sub>2</sub>O to cause crystallisation and cool. Recrystallise it directly from aqueous EtOH and dry it in a vacuum. Its UV has λ<sub>max</sub> at 276 nm (log ε 3.6) in MeOH. [Lindwall & Mantell *J Org Chem* 18 345 1953, 20 1458 1955, Thesing at al. *Chem Ber* 95 2205 1962, NMR: Lallemand & Bernath *Bull Soc Chim Fr* 4091 1970, *Beilstein* 22/3 V 45.]

**3-Cyanopyridine** [100-54-9] M 104.1, m 50°, pK<sup>25</sup> 1.38. It is recrystallised to constant melting point from *o*-xylene/hexane. [*Beilstein* 22/2 V 115.]

**4-Cyanopyridine** [100-48-1] M 104.1, m 76-79°, pK<sup>25</sup> 1.86. It crystallises from dichloromethane/diethyl ether mixture. [*Beilstein* 22/2 V 214.]

**Cyanuric acid (2,4,6-trichloro-1,3,5-triazine)** [108-80-5] M 120.1, m >300°, pK<sup>25</sup> 6.78. It crystallises from water. Dry it at room temperature in a desiccator in a vacuum. [*Beilstein* 26 III/IV 632.]

**Cyanuric chloride (TCT, 2,4,6-trichloro-1,3,5-triazine)** [108-77-0] M 184.4, m 146-149°, 154°, b 190°. TCT crystallises from CCl<sub>4</sub> or petroleum ether (b 90-100°) and is dried under vacuum. It has also been recrystallised twice from anhydrous \*benzene immediately before use [Abuchowski et al. *J Biol Chem* 252 3582 1977]. [*Beilstein* 26 III/IV 66.]

**Cycloheximide (Actidione)** [66-81-9] M 281.4, m 119.5-121°, [α]<sub>D</sub><sup>20</sup> +9.5° (c 2, H<sub>2</sub>O). It crystallises from H<sub>2</sub>O/MeOH (4:1), amyl acetate, isopropyl acetate/isopropyl ether or H<sub>2</sub>O. [*Beilstein* 21/13 V 434.]

**1-Cyclohexyl-5-methyl-1H-tetrazole** [7707-57-5] M 166.2, m 124-124.5°. Crystallise it from absolute EtOH or H<sub>2</sub>O (heavy needles), then sublime it at 115°/3mm. [Harvill et al. *J Org Chem* 15 662, 668 1950, Billuber Inc USP 2507337 1946, *Beilstein* 26 III/IV 1661.]

**Cyclotrimethylenetrinitramine (RDX, Cyclonite, 1,3,5-trinitrohexahydro-1,3,5-triazine)** [121-82-4] M 222.2, m 203.8°(dec), 205-206°(dec). RDX crystallises from acetone. [Bachmann & Sheehan *J Am Chem Soc* 71 1842 1949, *Beilstein* 26 II 5, 26 III/IV 22.] **EXPLOSIVE.**

**Cytisine** (7*R*,9*S*-7,9,10,11,12,13-hexahydro-7,9-methano-12*H*-pyrido[1,2-*a*][1,5]diazocin-8-one, Laburnine, Ulexine) [485-35-8] M 190.3, m 152-153°, 155°, b 218°/2mm, [α]<sub>D</sub><sup>17</sup> -120° (H<sub>2</sub>O), [α]<sub>D</sub><sup>25</sup> -115° (c 1, H<sub>2</sub>O), pK<sup>15</sup> 1.20, pK<sup>15</sup> 8.12 [also stated are pK<sub>1</sub> 6.11, pK<sub>2</sub> 13.08]. Crystallise cytisine from acetone and sublime it in a vacuum. Its solubilities are: 77% (H<sub>2</sub>O), 7.7% (Me<sub>2</sub>CO), 28.6% (EtOH), 3.3% (\*C<sub>6</sub>H<sub>6</sub>), 50% (CHCl<sub>3</sub>) but it is insoluble in petroleum ether. The *tartrate* has m 206-207° [α]<sub>D</sub><sup>24</sup> +45.9°, the *N-tosylate* has m 206-207°, and the *N-acetate* has m 208°. [Bohlmann et al. *Angew Chem* 67 708 1955, van Tamelen & Baran *J Am Chem Soc* 77 4944 1955, Isolation: Ing *J Chem Soc* 2200 1931, Govindachari et al. *J Chem Soc* 3839 1957, Abs config: Okuda et al. *Chem Ind (London)* 1751 1961, *Beilstein* 24 H 134, 24 I 244, 24 II 70, 24 III/IV 321.] **TOXIC.**

**Cytosine (4-amino-2-hydroxypyrimidine)** See entry in “Miscellaneous Compounds”, Chapter 7.

***cis*-Decahydroisoquinoline** [2744-08-3] **M 139.2, b 97-98°/15mm, 208-209°/730mm, pK<sup>20</sup> 11.32.** The free base is treated with saturated aqueous picric acid, allowed to stand for 12 hours, filtered, washed with MeOH to remove the more soluble *trans* isomer and recrystallised from MeOH to give pure *cis-picric acid* **m** 149-150°. The picrate (~5g) is shaken with 5M aqueous NaOH (50ml) and Et<sub>2</sub>O (150ml) while H<sub>2</sub>O is added to the aqueous phase to dissolve insoluble Na picrate. The Et<sub>2</sub>O extract is dried over solid NaOH and then shaken with Al<sub>2</sub>O<sub>3</sub> (Merck for chromatography) until the yellow color of traces of picric acid disappears (this color cannot be removed by repeated shaking with 5-10 M aqueous NaOH). The extract is concentrated to 50ml and dry HCl is bubbled through until separation of the white crystals of the *cis-HCl* is complete. These are washed with Et<sub>2</sub>O, dried at 100° and recrystallised from EtOH/EtOAc to yield pure *cis-hydrochloride* **m** 182-183° (dried in a vacuum desiccator over KOH) with IR (KBr)  $\nu_{\max}$  2920, 2820, 1582, 1470, 1445, 1410, 1395, 1313, 1135, 1080, 990, 870 cm<sup>-1</sup>. The pure *free base* is prepared by dissolving the *hydrochloride* in 10 M aqueous NaOH, extracted with Et<sub>2</sub>O, dried over solid KOH, filtered and distilled in a vacuum. It has IR (film)  $\nu_{\max}$  2920, 2820, 2720, 2560, 1584, 1470, 1445, 1415, 1395, 1315, 1300, 1135, 1080, 1020, 990, 873 cm<sup>-1</sup>. The <sup>1</sup>HNMR in CDCl<sub>3</sub> is characteristically different from that of the *trans*-isomer. [Armarego *J Chem Soc (C)* 377 1967, Gray & Heitmeier *J Am Chem Soc* **80** 6274 1958, Witkop *J Am Chem Soc* **70** 2617 1948, Skita *Chem Ber* **57** 1982 1924, Helfer *Helv Chim Acta* **6** 799 1923, *Beilstein* **20** II 73, **20** III/IV 2026.]

***trans*-Decahydroisoquinoline** [2744-09-4] **M 139.2, b 106°/15mm, pK<sup>20</sup> 11.32.** This is purified as the *cis*-isomer above. The *trans-picric acid* has **m** 175-176°, and the *trans-hydrochloride* has **m** 221-222° and has IR (KBr) has  $\nu_{\max}$  at 2930, 3800, 1589, 1450, 1400, 1070, 952, 837 cm<sup>-1</sup>. The pure *free base* is prepared as above and had IR (film) with  $\nu_{\max}$  at 2920, 2820, 2720, 2560, 1584, 1470, 1445, 1415, 1395, 1315, 1300, 1135, 1080, 1020, 990, 873 cm<sup>-1</sup>. The <sup>1</sup>HNMR in CDCl<sub>3</sub> is characteristically different from that of the *cis*-isomer. (references as above and Helfer *Helv Chim Acta* **9** 818 1926). [*Beilstein* **20** II 73, **20** III/IV 2026.]

***cis*-Decahydroquinoline** [10343-99-4] **M 139.2, b 207-208°/708mm, pK<sup>20</sup> 11.29.** It is available as a *cis-trans*-mixture (**b** 70-73°/10mm, Aldrich, ~18% *cis*-isomer [2051-28-7]), but the isomers can be separated by fractionating in a spinning band column (1~1.5 metre, type E) at atmospheric pressure and collecting 2ml fractions with a distillation rate of 1 drop in 8-10 seconds. The lower boiling fraction solidifies and contains the *trans*-isomer (see below, **m** 48°). The higher boiling fraction **b** 207-208°/708mm remains liquid and is mostly pure *cis*-isomer. This is reacted with PhCOCl and M aqueous NaOH to yield the *N-benzoyl derivative* **m** 96° after recrystallisation from petroleum ether (**b** 80-100°). It is hydrolysed with 20% aqueous HCl by refluxing overnight. PhCO<sub>2</sub>H is filtered off, the filtrate is basified with 5M aqueous NaOH and extracted with Et<sub>2</sub>O. The dried extract (Na<sub>2</sub>SO<sub>4</sub>) is saturated with dry HCl gas, and the *cis-decahydroquinoline hydrochloride* which separates has **m** 222-224° after washing with Et<sub>2</sub>O and drying at 100°; and has IR (KBr) with  $\nu_{\max}$  at 2900, 2780, 2560, 1580, 1445, 1432, 1403, 1165, 1080, 1036, 990, 867 cm<sup>-1</sup>. The *free base* is obtained by dissolving the *hydrochloride* salt in 5M aqueous NaOH, extracting with Et<sub>2</sub>O and drying the extract (Na<sub>2</sub>SO<sub>4</sub>), evaporating and distilling the residue; it has IR (film) with  $\nu_{\max}$  at 2900, 2840, 2770, 1445, 1357, 1330, 1305, 1140, 1125, 1109, 1068, 844 cm<sup>-1</sup>. The <sup>1</sup>H NMR in CDCl<sub>3</sub> is characteristically different from that of the *trans*-isomer. [Armarego *J Chem Soc (C)* 377 1967, Hüchel & Stepf *Justus Liebigs Ann Chem* **453** 163 1927, Bailey & McElvain *J Am Chem Soc* **52** 4013 1930, *Beilstein* **20** H 157, **20** I 35, **20** II 72-73, **20** III/IV 2017.]

***trans*-Decahydroquinoline** [767-92-0] **M 139.2, m 48°, b 205-206°/708mm, pK<sup>20</sup> 11.29.** The lower boiling fraction from the preceding spinning band column fractionation of the commercial *cis-trans*-mixture (~ 20:60; see the *cis*-isomer above) solidifies readily (**m** 48°), and the receiver has to be kept hot with warm water. It is further purified by conversion to the *hydrochloride* **m** 285-286° after recrystallisation from EtOH/AcOEt. This has IR (KBr) with  $\nu_{\max}$  at 2920, 2760, 2578, 2520, 1580, 1455, 1070, 1050, 975, 950, 833 cm<sup>-1</sup>. The *free base* is prepared as for the *cis*-isomer above and distilled; and has IR (film, at ca 50°) with  $\nu_{\max}$  at 2905, 2840, 2780, 1447, 1335, 1305, 1240, 1177, 1125, 987, 900, 835 cm<sup>-1</sup>. The <sup>1</sup>HNMR in CDCl<sub>3</sub> is characteristically different from that of the *cis*-isomer. [Armarego *J Chem Soc (C)* 377 1967, Hüchel & Stepf *Justus Liebigs Ann Chem* **453** 163 1927, Bailey & McElvain *J Am Chem Soc* **52** 4013 1930, Prelog & Szpiflogel *Helv Chim Acta* **28** 1684 1945, *Beilstein* **20** H 157, **20** I 35, **20** II 72-73, **20** III/IV 2017.]

**Delphinine** [561-07-9] M 559.7, m 197-199°,  $[\alpha]_D^{20} +26^\circ$  (c 1, EtOH). It crystallises from EtOH with 198-200° uncorrected (187.5-188.5°) and from Et<sub>2</sub>O or Me<sub>2</sub>CO. Its solubility at ~25° in EtOH, CHCl<sub>3</sub> and Et<sub>2</sub>O is 4, 5 and 10% respectively. In c 1, EtOH, it has  $[\alpha]_D^{20} +22^\circ$  changing to +19° in 4 hours. [Markwood *J Am Chem Soc* **16** 931 1927.] The *hydrochloride* has m 214°(dec) from MeOH or MeOH/Et<sub>2</sub>O. [Weissner et al. *Can J Chem* **50** 1925 1972, Jacobs & Craig *J Biol Chem* **127** 363 1939, *Beilstein* **21** III/IV 2867.]

**3,6-Diaminoacridine hydrochloride** [952-23-8] M 245.7, m 270°(dec),  $\epsilon_{456} 4.3 \times 10^4$ ,  $pK_1^{20} 1.5$ ,  $pK_2^{20} 9.60$  (9.65 free base). It is first purified by precipitation of the free base by adding aqueous NH<sub>3</sub> solution to an aqueous solution of the hydrochloride or hydrogen sulfate (see below), drying the precipitate and subliming at 0.01mm Hg [Müller & Crothers *Eur J Biochem*, **54** 267 1975]. [*Beilstein* **22** H 487.]

**3,6-Diaminoacridine sulfate (proflavin sulfate)** [1811-28-5] M 516.6, m >300°(dec),  $\lambda_{max} 456nm$ . An aqueous solution, after treatment with charcoal, is concentrated, chilled overnight, filtered and the precipitate is rinsed with a little diethyl ether. The precipitate is dried in air, then overnight in a vacuum oven at 70°. [*Beilstein* **22** I 650, **22/11** V 323.]

**4,5-Diamino-2,6-dihydroxypyrimidine (diamino uracil) sulfate** [32014-70-3] M 382.3, m >300°,  $pK_1^{20} 1.7$ ,  $pK_2^{20} 3.20$ ,  $pK_3^{25} 4.56$ . The salt is quite insoluble in H<sub>2</sub>O but can be converted to the free base which is recrystallised from H<sub>2</sub>O and converted to the sulfate by addition of the required amount of H<sub>2</sub>SO<sub>4</sub>. The *hydrochloride* has m 300-305°(dec) and can be used to prepare the sulfate by addition of H<sub>2</sub>SO<sub>4</sub>; it is more soluble than the sulfate. The *perchlorate* has m 252-254°. The free base has  $\lambda_{max}$  at 260nm (log  $\epsilon$  4.24) in 0.1M HCl. [Bogert & Davidson *J Am Chem Soc* **86** 1668 1933, Bredereck et al. *Chem Ber* **86** 850 1953, Sherman & Taylor *Org Synth Coll Vol IV* 247 1963, Barlin & Pfeleiderer *J Chem Soc (B)* 1425 1971, *Beilstein* **25** II 382.]

**5,6-Diamino-1,3-dimethyluracil hydrate (5,6-diamino-1,3-dimethyl-2-pyrimidine-2,4-dione hydrate)** [5440-00-6] M 188.2, m 205-208°(dec), 209°(dec), 210°(dec),  $pK_1 1.7$ ,  $pK_2 4.6$ . It recrystallises from EtOH. The *hydrochloride* has m 310° (from MeOH), and the *perchlorate* has m 246-248°. [UV: Bredereck et al. *Chem Ber* **92** 583 1959, Taylor et al. *J Am Chem Soc* **77** 2243 1955, *Beilstein* **25** III/IV 4133.]

**6,9-Diamino-2-ethoxyacridine (Ethacridine)** [442-16-0] M 257.3, m 226°,  $pK^{20} 11.6$ . It crystallises from 50% EtOH or EtOH as orange-yellow crystals. It also crystallises as a *monohydrate* m 116-118°. It has a  $pK^{20}$  of 11.04 in 50% aqueous EtOH. The *methiodide* is soluble in H<sub>2</sub>O and has m 332-334° (dec) (from aqueous Me<sub>2</sub>CO). [Albert & Gledhill *J Soc Chem Ind* **61** 159 1942, Foye et al. *J Pharm Sci* **57** 1795 1968, Albert & Goldacre *J Chem Soc* 708 1946, *Beilstein* **22** II 458, **22** III/IV 6679, **22/12** V 243.]

**6,9-Diamino-2-ethoxyacridine dl-lactate monohydrate (Rivanol, Acrinol)** [6402-23-9] M 361.4, m 235° (dark at ~200°),  $pK^{20} 11.6$ . It forms yellow crystals from 90% EtOH/Et<sub>2</sub>O. Its solubility in H<sub>2</sub>O is ~15% at 25° and ~9% at 100°, and its solutions have a yellow fluorescence which is stable on boiling. It is an antiseptic. See ethacridine above, *Beilstein* **22** II 458, **22** III/IV 6680, **22/12** V 243.]

**2,4-Diamino-6-hydroxypyrimidine** [56-06-4] M 126.1, m 260-270°(dec),  $pK_1^{25} 1.34$ ,  $pK_2^{25} 3.27$ ,  $pK_3^{25} 10.83$ . It recrystallises from H<sub>2</sub>O. [*Beilstein* **25** III/IV 3642.]

**4,5-Diamino-6-hydroxypyrimidine hemisulfate** [102783-18-6] M 350.3, m 268°, 270°,  $pK_1^{25} 1.34$ ,  $pK_2^{25} 3.57$ ,  $pK_3^{25} 9.86$ . It recrystallises from H<sub>2</sub>O. The *free base* also crystallises from H<sub>2</sub>O (m 239°). [Mason *J Chem Soc* 2071 1954, Elion et al. *J Am Chem Soc* **74** 411 1952, *Beilstein* **25** III/IV 3645.]

**2,4-Diamino-5-phenylthiazole (Amiphenazole)** [490-55-1] M 191.3, m 163-164°(dec). The thiazole crystallises from aqueous EtOH or water. Store it in the dark under N<sub>2</sub>. The *hydrochloride* has m 273-274°(dec) (from MeOH/EtOAc), and the *picrate* has m 189-191°(dec) (from H<sub>2</sub>O). [Davies et al. *J Chem Soc* 3491 1950, Dodson & Turner *J Am Chem Soc* **73** 4517 1951, *Beilstein* **27** III/IV 5139.]

**2,3-Diaminopyridine** [452-58-4] M 109.1, m 116°,  $pK_1^{25} -0.50$ ,  $pK_2^{25} 6.92$ . It crystallises from \*benzene

and sublimes *in vacuo*. [Beilstein 22/11 V 241.]

**2,6-Diaminopyridine** [141-86-6] M 109.1, m 121.5° pK<sub>Est(1)</sub> <-6.0, pK<sub>Est(2)</sub> ~7.3. It crystallises from \*benzene and sublimes *in vacuo*. [Beilstein 22 III/IV 255.]

**3,4-Diaminopyridine** [54-96-6] M 109.1, m 218-219°, pK<sub>1</sub><sup>20</sup> 0.49, pK<sub>2</sub><sup>20</sup> 9.14. It crystallises from \*benzene and is stored under N<sub>2</sub> because it is *deliquescent* and absorbs CO<sub>2</sub>. [Beilstein 22/11 V 266.]

**3,5-Diamino-1,2,4-triazole (Guanazole)** [1455-77-2] M 99.1, m 206°, pK<sub>1</sub><sup>20</sup> 4.43, pK<sub>2</sub><sup>20</sup> 12.12. The triazole crystallises from water or EtOH. [Beilstein 26 III/IV 1161.]

**1,3-Diazaazulene (cycloheptimidazole)** [275-94-5] M 130.1, m 110-112°, 120°. It is recrystallised repeatedly from de-aerated cyclohexane in the dark or from petroleum ether/\*C<sub>6</sub>H<sub>6</sub> and forms yellow needles. It is soluble in H<sub>2</sub>O, EtOH and \*C<sub>6</sub>H<sub>6</sub>, and forms a *monohydrate* which loses H<sub>2</sub>O at 60°. The *picrate* has m 207°(dec). [Nozoe et al. *J Am Chem Soc* 76 3352 1954, Nukai et al. *Bull Chem Soc Jpn* 40 1967 1967, Beilstein 23 III/IV 1216.]

**1,5-Diazabicyclo[4.3.0]non-5-ene (DBN, 2,3,4,6,7,8-hexahydropyrrolo[1,2-*a*]-pyrimidine)** [3001-72-7] M 124.2, b 96-98°/11mm, 100-102°/12mm, 118-121°/32mm, d<sub>4</sub><sup>20</sup> 1.040, n<sub>D</sub><sup>20</sup> 1.520, pK<sup>25</sup> >13.0. Distil DBN from BaO. It forms a *hydroiodide* on addition of 47% HI; dry it and dissolve it in MeCN, evaporate and repeat; recrystallise from EtOH, dry at 25°/1mm for 5 hours, then at 80°/0.03mm for 12 hours and store and dispense it in a dry box, m 154-156° [Jaeger et al. *J Am Chem Soc* 101 717 1979]. The *methiodide* is recrystallised from CHCl<sub>3</sub>/Et<sub>2</sub>O, m 248-250°, and *hydrogen fumarate* has m 159-160° and is crystallised from *iso*-PrOH [Rokach et al. *J Med Chem* 22 237 1979, Oediger et al. *Chem Ber* 99 2012 1966, Reppe et al. *Justus Liebigs Ann Chem* 596 210 1955]. [Beilstein 23/5 V 239.]

**1,4-Diazabicyclo[2.2.2]octane (DABCO, triethylenediamine, TED)** [280-57-9] M 112.2, m 156-157° (sealed tube), pK<sub>1</sub><sup>25</sup> 2.97, pK<sub>2</sub><sup>25</sup> 8.82. DABCO crystallises from 95% EtOH, petroleum ether or MeOH/diethyl ether (1:1). Dry it under vacuum over CaCl<sub>2</sub> and BaO. It can be sublimed *in vacuo*, and readily at room temperature. It has also been purified by removal of water during azeotropic distillation of a \*benzene solution. It is then recrystallised twice from anhydrous diethyl ether under argon, and stored under argon [Blackstock et al. *J Org Chem* 52 1451 1987]. [Beilstein 23/3 V 487.]

**1,8-Diazabicyclo[5.4.0]undec-7-ene (DBU, 2,3,4,6,7,8,9,10-octahydropyrimidino[1,2-*a*]-azepine)** [6674-22-2] M 152.2, b 115°/11mm, d<sub>4</sub><sup>20</sup> 1.023, n<sub>D</sub><sup>20</sup> 1.522, pK<sub>Est</sub> ~ >13. Fractionally distil DBU under vacuum. Also purify it by chromatography on Kieselgel and eluting with CHCl<sub>3</sub>/EtOH/25% aqueous NH<sub>3</sub> (15:5:2) and checking by IR and MS. [Oediger et al. *Chem Ber* 99 2012 1962, *Angew Chem, Int Ed Engl* 6 76 1967, Guggisberg et al. *Helv Chim Acta* 61 1057 1978, Beilstein 23/5 V 271.]

**1,8-Diazabiphenylene** [259-84-7] M 154.2, m 156-158.5°, pK<sub>Est</sub> ~4.4. Recrystallise it from cyclohexane, then sublime it in a vacuum. [Barton & Walker *Tetrahedron Lett* 569 1975, Deroski & Marhgraf *Can J Chem* 62 2235 1984.]

**2,7-Diazabiphenylene** [31857-42-8] M 154.2, m 192-192.5°, pK<sub>Est</sub> ~4.5. It forms yellow crystals from cyclohexane, and sublimes in a vacuum. [MacBride *J Chem Soc, Chem Commun* 359 1974, Kramer & Berry *J Am Chem Soc* 94 8336 1972.]

**1,8-Diazafluorenone (cyclopenta[1.2-*b*:4,3-*b'*]dipyridin-9-one)** [54078-29-4] M 182.2, m 205°, 229-231°, pK<sub>Est</sub> ~2.6. Recrystallise it from Me<sub>2</sub>CO. The *oxime* has m 119-200°. [Druey & Schmid *Helv Chim Acta* 33 1080 1950, Beilstein 24 III/IV 622.]

**Dibenzo-18-crown-6** [14187-32-7] M 360.4, m 163-164°. Crystallise it from \*benzene, *n*-heptane or toluene and dry it under vacuum at room temperature for several days. [Szezygiel *J Phys Chem* 91 1252 1987, Vögtle ed. *Top Corr Chem (Host Guest Complex Chemistry)* 98 1981.]

**Dibenzo-18-crown-8** [14174-09-5] **M 448.5, m 103-106°**. Recrystallise it from EtOH, and dry in a vacuum at 60° over P<sub>2</sub>O<sub>5</sub> for 16 hours. [Delville et al. *J Am Chem Soc* **109** 7293 1987, Vögtle ed. *Top Corr Chem* (Host Guest Complex Chemistry) **98** 1981.]

**Dibenzofuran** [132-64-9] **M 168.2, m 82.4°**. Dissolve dibenzofuran in diethyl ether, then shake it with two portions of aqueous NaOH (2M), wash it with water, separate and dry (MgSO<sub>4</sub>) it. After evaporating the ether, dibenzofuran is crystallised from aqueous 80% EtOH and then dried under vacuum. [Cass et al. *J Chem Soc* 1406 1958.] High purity material is obtained by zone refining. [Beilstein **17** V 234.]

**Dibenzothiophene** [132-65-0] **M 184.3, m 99°**. Purify dibenzothiophene by chromatography on alumina with petroleum ether, in a darkened room. Recrystallise it from water or EtOH. [Beilstein **17** V 239.]

**1,3-Dibromo-5,5-dimethylhydantoin** [77-48-5] **M 285.9, m 190-192°(dec), 190-193°(dec)**. Recrystallise it from H<sub>2</sub>O. Its solubility in CCl<sub>4</sub> is 0.003 mol/L at 25° and 0.024 mol/L at 76.5°. [Beilstein **24** III/IV 1101.]

**4',5'-Dibromofluorescein** [596-03-2] **M 490.1, m 285°**. Crystallise it from aqueous 30% EtOH. [Beilstein **19/6** V 462.]

**5,7-Dibromo-8-hydroxyquinoline** [521-74-4] **M 303.0, m 196°, pK<sub>1</sub><sup>25</sup> 5.84, pK<sub>2</sub><sup>25</sup> 9.56**. Crystallise it from acetone/EtOH. It can be sublimed. [Beilstein **21/3** V 290.]

**2,6-Dibromopyridine** [626-05-1] **M 236.9, m 117-119°, 118.5-119°, b 249°/757.5mm, pK<sub>Est</sub> <0**. Purify 2,6-dibromopyridine by steam distillation, then recrystallise it twice from EtOH. It does not form an HgCl<sub>2</sub> salt. [den Hertog & Wibaut *Rec Trav Chim Pays Bas* **51** 381 1932, Beilstein **20/5** V 435.]

**3,4-Dibromothiophene** [3141-26-2] **M 241.9, m 4-5°, b 94-95°/12mm, 212-213° (atm), 221-222°(atm), d<sub>4</sub><sup>25</sup> 2.188, n<sub>D</sub><sup>20</sup> 1.640**. Distil it in a vacuum, but if it is discoloured then dissolve it in Et<sub>2</sub>O, wash it with 2M NaOH solution, separate the layers, filter, dry the Et<sub>2</sub>O layer over CaCl<sub>2</sub>, filter, evaporate, and distil the residual oil in a vacuum. Nitration with Ac<sub>2</sub>O/HNO<sub>3</sub> at 60° yields *3,4-dibromo-2-nitrothiophene* **m 115-116°** (from EtOH). [Steinkopf et al. *Justus Liebigs Ann Chem* **512** 149-151 1934, Beilstein **17** III/IV 248, **17/1** V 308.]

**2,6-Di-tert-butyl-4-methylpyridine** [38222-83-2] **M 205.4, m 31-32°, 33-36°, b 148-153°/ 95mm, 223°/760mm, n<sub>D</sub><sup>20</sup> 1.476, pK<sub>Est</sub> ~5.7**. A possible impurity is 2,6-di-tert-butyl-4-neopentylpyridine. Attempts to remove coloured impurities directly by distillation, acid-base extraction or treatment with activated charcoal were unsuccessful. Pure material is obtained by dissolving 0.3mole of the alkyipyridine in pentane (150ml) and introducing it at the top of a cold water jacketed chromatographic column (40 x 4.5cm) (cooling is necessary because the base in pentane reacts exothermically with alumina) containing activated and acidic alumina (300g). The column is eluted with pentane using a 1L constant pressure funnel fitted at the top of the column to provide slight pressure. All the pyridine is obtained in the first two litres of eluent (the progress of elution is monitored by spotting a fluorescent TLC plate and examining under short wave UV light—a dark blue spot is evidence for the presence of the alkyipyridine). Elution is complete in 1 hour. Pentane is removed on a rotovap with 90-93% recovery yielding a liquid which solidifies on cooling, **m 31-32°**, and the base can be distilled. The *H<sub>2</sub>PtCl<sub>6</sub>* salt has **m 213-314°(dec)**, and the *CF<sub>3</sub>SO<sub>3</sub>H* salt has **m 202.5-203.5°** (from CH<sub>2</sub>Cl<sub>2</sub>). [Anderson & Stang *Org Synth Coll Vol VII* 144 1981, Beilstein **20/6** V 190.]

**2,6-Di-tert-butylpyridine** [585-48-8] **M 191.3, b 100-101°/23mm, d<sub>4</sub><sup>25</sup> 0.852, n<sub>D</sub><sup>20</sup> 1.473, pK<sub>25</sub> 5.02**. Redistil it from KOH pellets. [Beilstein **20** III/IV 2868.]

§ Polystyrene supported version is commercially available [107054-29-5] 200-400 mesh, crosslinked with 1% divinylbenzene containing ~1.8mmol N/g polymer.

**3,5-Dicarbethoxy-1,4-dihydro-2,4,6-collidine** [632-93-9] **M 267.3, m 131-132°**. Crystallise the ester from hot EtOH/water mixture. [Beilstein **22** H 147, **22** I 529, **22** II 100, **22** III/IV 1594.]

(+) and (-) (8,8-Dichlorocamphorylsulfonyl)oxaziridine [127184-05-8] M 298.2, m 178-180°, 183-186°,  $[\alpha]_D^{20}$  (+) and (-) 88.3° (c 1.3, CHCl<sub>3</sub>), (+) and (-) 91° (c 5, CHCl<sub>3</sub>). Recrystallise the enantiomers from EtOH [Davis & Weismiller *J Org Chem* 55 3715 1990].

**1,3-Dichloro-5,5'-dimethylhydantoin** [118-52-5] M 197.0, m 132-134°, 136°. Purify it by dissolving in conc H<sub>2</sub>SO<sub>4</sub> and diluting with ice H<sub>2</sub>O, collect the solid, dry it in a vacuum and recrystallise it from CHCl<sub>3</sub>. It sublimes at 100° in a vacuum. It exhibits time-dependent hydrolysis at pH 9. [Pettersson & Grzeskowiak *J Org Chem* 24 1414 1959, *Beilstein* 24 III/IV 1100.]

**4,5-Dichloro-3H-1,2-dithiol-3-one** [1192-52-5] M 187.1, m 52-56°, 61°, b 87°/0.5mm, 125°/11mm. Dissolve it in CH<sub>2</sub>Cl<sub>2</sub> (1g in 250ml), filter, wash it twice with H<sub>2</sub>O, evaporate and distil the residue *in vacuo* and then recrystallise it from petroleum ether. Its IR has  $\nu_{\max}$  at 1650 cm<sup>-1</sup>. [Boberg *Justus Liebigs Ann Chem* 679 109 1964, Boberg *Justus Liebigs Ann Chem* 693 212 1966, *Beilstein* 19/4 V 72.]

**5,7-Dichloro-8-hydroxyquinoline** [773-76-2] M 214.1, m 180-181°, pK<sub>1</sub> 1.89, pK<sub>2</sub> 7.62. Crystallise the dichloro-oxine from acetone/EtOH. [*Beilstein* 21 H 95.]

**6,9-Dichloro-2-methoxyacridine (3,9-Dichloro-7-methoxyacridine)** [86-38-4] M 278.1, m 160-161°, 164°, 163-165°. Crystallise it from \*benzene or 1,2-dichloroethane (m 162-163°). [Hall & Turner *J Chem Soc* 697 1945, *Beilstein* 21 III/IV 1553.]

**5,7-Dichloro-2-methyl-8-hydroxyquinoline (5,7-dichloro-8-hydroxyquinaldine)** [72-80-0] M 228.1, m 114-115°, pK<sub>Est(1)</sub> ~2.0, pK<sub>Est(2)</sub> ~8.4. Crystallise it from EtOH. [*Beilstein* 21/3 V 346.]

**4,6-Dichloro-5-nitropyrimidine** [4316-93-2] M 194.0, m 100-103°, 101-102°, pK<sub>Est</sub> <0. If too impure, then dissolve it in Et<sub>2</sub>O, wash it with H<sub>2</sub>O, dry it over MgSO<sub>4</sub>, evaporate it to dryness and recrystallise it from petroleum ether (b 85-105°) to give a light tan solid. It is soluble in *ca* 8 parts of MeOH [Boon et al. *J Chem Soc* 96 1951, Montgomery et al. in *Synthetic Procedures in Nucleic Acid Chemistry* Zorbach & Tipson eds, Wiley & Sons, NY, p76 1968]. [*Beilstein* 23 III/IV 899.]

**2,6-Dichloropurine** [5451-40-1] M 189.0, m 180-181.5°, 181°, 185-195°(dec), 188-189°, pK<sub>1</sub><sup>20</sup> 1.16 (aqueous H<sub>2</sub>SO<sub>4</sub>), pK<sub>2</sub><sup>20</sup> 7.06. It can be recrystallised from 150 parts of boiling H<sub>2</sub>O and dried at 100° to constant weight. It is soluble in EtOAc. The HgCl<sub>2</sub> salt separates from EtOH solution. It has UV with  $\lambda_{\max}$  at 275nm ( $\epsilon$  8.9K) at pH 1; and 280nm ( $\epsilon$  8.5K) at pH 11 [Elion & Hitchings *J Am Chem Soc* 78 3508 1956, Schaeffer & Thomas *J Am Chem Soc* 80 3738 1958, Beaman & Robins *J Appl Chem (London)* 12 432 1962, Montgomery *J Am Chem Soc* 78 1928 1956]. [*Beilstein* 26 III/IV 1747.]

**2,6-Dichloropyridine** [2402-78-0] M 148.0, m 87-88°, pK<sup>25</sup> -2.86 (aqueous H<sub>2</sub>SO<sub>4</sub>). It crystallises from EtOH. [*Beilstein* 20/5 V 416.]

**3,5-Dichloropyridine** [2457-47-8] M 148.0, m 64-65°, 66-67°, b 178-178°/~760mm, pK<sup>25</sup> 0.67. Crystallise 3,5-dichloropyridine from EtOH, or distil it. [den Hertog et al. *Rec Trav Chim Pays Bas* 69 685 1950, *Beilstein* 20 H 23, 20 III/IV 2502, 20 V 417.]

**2,6-Dichloropyridine-3-carboxylic acid (2,6-dichloronicotinic acid)** [38496-18-3] M 192.0, m 146-148°, 147°, pK<sub>Est(1)</sub> ~-1. Purify the acid by recrystallisation from H<sub>2</sub>O or Et<sub>2</sub>O/petroleum ether (colourless needles), and the IR(KBr) has  $\nu_{\max}$  at 1738 cm<sup>-1</sup>, and  $\lambda_{\max}$  ( $\epsilon$ ) at 228.5(4700) and 273.5(8300)nm. The *acid chloride* [58584-83-1] M 210.4, b 72-74°/0.01mm, 117-118°/45mm, n<sub>D</sub><sup>20</sup> 1.5944, was obtained by treatment with SOCl<sub>2</sub>/DMF/\*C<sub>6</sub>H<sub>6</sub> and converted into the *amide* [70445-62-4] M 191.0, m 148-148.5°, or the *hydrazide* m 171-173° which crystallised from a large volume of MeCN. [Muterer et al. *Helv Chim Acta* 59 222 1976, Newcome et al. *J Org Chem* 44 2693 1979, *Beilstein* 22 H 44.] A pharmaceutical research building block acid of 90% grade is also available.

**2,6-Dichloropyridine-4-carboxylic acid (2,6-dichloroisonicotinic acid)** [5398-44-7] **M 192.0, m 210°, 209-212°, pK<sub>Est(1)</sub> ~ -1.** Purify the acid by crystallisation from H<sub>2</sub>O, and it forms needles or platelets from EtOH. The *methyl ester* crystallises from aqueous MeOH with **m 82°**, the *ethyl ester* from aqueous EtOH has **m 66°**, and the *amide* from H<sub>2</sub>O has **m 207-208°**. [Meyer et al. *Monatsh Chem* **36** 731 1915, Levelt & Wibaut *Rec Trav Chim Pays Bas* **48** 469 1929.]

**5,6-Dichloropyridine-3-carboxylic acid (5,6-dichloronicotinic acid)** [41667-95-2] **M 192.0, m 160-161°, 164-168°, 168°, pK<sub>Est(1)</sub> ~ 0.5.** Recrystallisation of the acid from H<sub>2</sub>O provides the *monohydrate* which becomes *anhydrous* (**m 161-162°**) on heating at 100°. The *acid chloride* distils at **125°/~24mm**, solidifies on cooling, and crystallises from petroleum ether with **m 48-49°**. The *methyl ester* has **m 67-68°** (from aqueous MeOH), and the *amide* forms colourless plates from aqueous EtOH with **m 218-220°**. [Räth & Schiffmann *Justus Liebigs Ann Chem* **487** 133 1931, Meyer & Graf *Chem Ber* **61** 2212 1928, *Beilstein* **22** H 44, **22** II 36, **22** III/IV 511, **22/2** V 80.]

**4,7-Dichloroquinoline** [86-98-6] **M 198.1, m 86.4-87.4°, b 148°/10mm, pK<sup>25</sup> 2.80.** Crystallise the dichloroquinoline from MeOH or 95% EtOH. [*Beilstein* **20/7** V 316.]

**2,3-Dichloroquinoxaline** [2213-63-0] **M 199.0, m 152-153°, 152-154°, pK<sub>Est</sub> < 0.** Recrystallise it from \*C<sub>6</sub>H<sub>6</sub> and dry it in a vacuum [Cheeseman *J Chem Soc* 1804 1955, *Beilstein* **23/7** V 144].

**cis-Dicyclohexyl-18-crown-6** [16069-36-6] **M 372.5, m 47-50°.** Purify it by chromatography on neutral alumina and elute with an ether/hexane mixture [see Izatt et al. *Inorg Chem* **14** 3132 1975]. Dissolve it in ether at *ca* 40°, and spectroscopic grade MeCN is added to the solution, which is then chilled. The crown ether precipitates and is filtered off. It is dried *in vacuo* at room temperature [Wallace *J Phys Chem* **89** 1357 1985]. [Vögtle ed. *Top Corr Chem* (Host Guest Complex Chemistry) **98** 1981.] **SKIN IRRITANT.**

**5,5-Diethylbarbituric acid (Barbital)** [57-44-3] **M 184.2, m 188-192°, pK<sub>1</sub><sup>25</sup> 8.02, pK<sub>2</sub><sup>25</sup> 12.7.** Crystallise barbital from water or EtOH and dry it in a vacuum over P<sub>2</sub>O<sub>5</sub>. [*Beilstein* **24** III/IV 1901.]

**1,1'-Diethyl-2,2'-cyanine iodide** [977-96-8] **M 454.4, m 274°(dec).** It crystallises from EtOH and is dried in a vacuum oven at 80° for 4 hours. [*Beilstein* **23** II 267.]

**2,3-Dihydrobenzofuran (coumaran)** [496-16-2] **M 120.2, m -21.5°, 72-73°/12mm, 84°/17mm, 188°/atm, d<sub>4</sub><sup>20</sup> 1.065, n<sub>D</sub><sup>20</sup> 1.5524.** Suspend coumaran in aqueous NaOH and steam distil it. Saturate the distillate with NaCl and extract it with Et<sub>2</sub>O, dry the extract (MgSO<sub>4</sub>), filter, evaporate and distil the residue. It gives a strong violet colour with FeCl<sub>3</sub> + H<sub>2</sub>SO<sub>4</sub> and forms a yellow *picrate*, **m 76°** (from EtOH or \*C<sub>6</sub>H<sub>6</sub>) which loses coumaran in a desiccator [Bennett & Hafez *J Chem Soc* 287 1941, Baddeley et al. *J Chem Soc* 2455 1956]. [*Beilstein* **17/1** V 581.]

**Dihydropyran (3,4-dihydro-2H-pyran)** [110-87-2] **M 84.1, b 84.4°/742mm, 85.4-85.6°/760mm, d<sub>4</sub><sup>20</sup> 0.9261, n<sub>D</sub><sup>20</sup> 1.4423, pK<sub>Est</sub> ~ 4.2.** Partially dry dihydropyran with Na<sub>2</sub>CO<sub>3</sub>, then fractionally distil it. The fraction **b 84-85°** is refluxed with Na until hydrogen no longer evolves when fresh Na is added. It is then dried, and distilled again through a 60 x 1.2cm column packed with glass rings [Brandon et al. *J Am Chem Soc* **72** 2120 1950, UV: Elington et al. *J Chem Soc* 2873 1952, NMR: Bushweller & O'Neil *Tetrahedron Lett* 4713 1969]. It has been characterised as the *2-(3,5-dinitrobenzoyloxy)tetrahydropyrane* derivative, **m 103°** [prepared by dissolving 3,4-dinitrobenzoic acid (3g) in 50% excess of dihydropyran with warming, cooling, adding Et<sub>2</sub>O (5ml), whereby the derivative crystallises out quantitatively] which forms pale yellow crystals from 80% dihydropyran/Et<sub>2</sub>O [Woods & Kramer *J Am Chem Soc* **69** 2246 1947]. [*Beilstein* **17/1** V 181.]

**3,4-Dihydro-2H-pyrido[1,2a]-pyrimidin-2-one** [5439-14-5] **M 148.2, m 185-187°, 187-188°, 191-191.5°.** Dissolve it in CHCl<sub>3</sub>, filter, evaporate, then recrystallise the residue from EtOH/Me<sub>2</sub>CO (needles) which can be washed with Et<sub>2</sub>O and dried. It can also be recrystallised from CHCl<sub>3</sub>/petroleum ether or CHCl<sub>3</sub>/hexane. The *hydrochloride* has **m 295-295°** (dec, from EtOH or MeOH/Et<sub>2</sub>O), the *hydrobromide* has **m 299-300°**(dec) (from

MeOH/Et<sub>2</sub>O) and the *picrate* has **m** 224-226°(corr), **m** 219-220° from EtOH. [Adams & Pachter *J Am Chem Soc* **74** 4906 1952, Lappin *J Org Chem* **23** 1358 1958, Hurd & Hayao *J Am Chem Soc* **77** 115 1955, *Beilstein* **24** III/IV 299.]

**7,8-Dihydroxycoumarin (Daphnetin)** [486-35-1] **M 178.2, m 256°(dec), pK<sub>Est(1)</sub> ~8.5, pK<sub>Est(2)</sub> ~12.3.** Crystallise it from aqueous EtOH. It can be sublimed. [*Beilstein* **18/3** V 202.]

**trans-2,3-Dihydroxy-1,4-dioxane** [4845-50-5] **M 120.1, m 91-95°, 100°.** Recrystallise it from Me<sub>2</sub>CO. With phenylhydrazine it gives *glyoxal phenylhydrazone* **m** 175° (from Me<sub>2</sub>CO/petroleum ether). The *diacetyl* derivative has **m** 105-106° [Head *J Chem Soc* 1036 1955, Raudnitz *Chem Ind (London)* 166 1956]. [*Beilstein* **1** IV 3627.]

**2,5-Dihydroxy-1,4-dithiane** [40018-26-6] **M 152.2, m (142-147°) 150-152°, 151°.** Recrystallise the dithiane from EtOH. *2,5-Diethoxy-dithiane* has **m** 91° (92-93°); it crystallises from petroleum ether and can be sublimed at 60°/0.001mm [Hormatka & Haber *Monatsh Chem* **85** 1088 1954, Thiel et al. *Justus Liebigs Ann Chem* **611** 121 1958, Hesse & Jøeder *Chem Ber* **85** 924 1952]. [*Beilstein* **1** IV 3966.]

**S(-)-4',7-Dihydroxyflavanone (3,4'-dihydroxyisoflavone, Liquiritigenin)** [578-86-9] **M 256.3, m 203-205°** [ $\alpha$ ]<sub>D</sub><sup>20</sup> -225° (c 0.95, 95%EtOH). It crystallises from aqueous 50% EtOH. [*Beilstein* **18** III/IV 1780, **18/4** V 82.]

**5,7-Dihydroxy-4'-methoxyflavone (Acacetin)** [480-44-4] **M 284.3, m 261°, 260-265°.** Acacetin crystallises from 95% EtOH or acetic acid as pale yellow needles (m 263°). It is an anti-inflammatory. [Zemplen & Bogner *Chem Ber* **76** 452 1943, Pillon *Bull Soc Chim Fr* 9 1954, UV: Gaydou & Bianchini *Bull Soc Chim Fr* Part II 43 1978, *Beilstein* **18** III/IV 2683, **18/4** V 575.]

**(±)-7-(2,3-Dihydroxypropyl)theophylline (Diprophylline, Dyphylline)** [479-18-5] **M 254.3, m 158°, 160-164°, 161°, 161-164°, pK<sub>Est</sub> ~8.7.** Recrystallise it from EtOH or H<sub>2</sub>O. Its solubility in H<sub>2</sub>O is 33% at 25°, in EtOH it is 2% and in CHCl<sub>3</sub> it is 1%. Its UV has  $\lambda_{\max}$  (H<sub>2</sub>O) at 273nm ( $\epsilon$  8,855). [Roth *Arch Pharm* **292** 234 1959.] The *4-nitrobenzoyl* derivative has **m** 178° [Oshay *J Chem Soc* 3975 1956]. [*Beilstein* **26** III/IV 2370.]

**1,3-Diiminoisindoline** [3468-11-9] **M 145.2, m 193-194°(dec), 196°(dec), pK<sup>25</sup> 8.27.** It crystallises from H<sub>2</sub>O, MeOH or MeOH/Et<sub>2</sub>O (charcoal) in colourless prisms that become green on heating. [Elvidge & Linstead *J Chem Soc* 5000 1952]. Its IR (nujol) has bands at 3150 and 690 cm<sup>-1</sup>, and the UV has  $\lambda_{\max}$  at 251nm ( $\epsilon$  12,500), 256nm ( $\epsilon$  12,500) and 303nm ( $\epsilon$  4,600) [Elvidge & Golden *J Chem Soc* 700 1957, Clark et al. *J Chem Soc* 3593 1953]. The *thiocyanate* has **m** 250-255° (dec), the *monohydrochloride* has **m** 300-301° (turns green), and the *dihydrochloride* has **m** 326-328° (turns green) and the *picrate* crystallises from EtOH with **m** 299° (dec). [*Beilstein* **22/13** V 5.]

**5,7-Diiodo-8-hydroxyquinoline** [83-73-8] **M 397.0, m 214-215°(dec) pK<sub>Est(1)</sub> ~3.2, pK<sub>Est(2)</sub> ~8.2.** It crystallises from xylene and is dried at 70° in a vacuum. [*Beilstein* **21** II 58.]

**6-Dimethylaminopurine** [938-55-6] **M 163.1, m 257.5-258.5°, 259-262°, 263-264°, pK<sub>1</sub><sup>25</sup> 3.87, pK<sub>2</sub><sup>25</sup> 10.5.** It is purified by recrystallisation from H<sub>2</sub>O, EtOH (0.32g in 10ml) or CHCl<sub>3</sub>. [Albert & Brown *J Chem Soc* 2060 1954, UV: Mason *J Chem Soc* 2071 1954.] The *monohydrochloride* crystallises from EtOH/Et<sub>2</sub>O, **m** 253°(dec) [Elion et al. *J Am Chem Soc* **74** 411 1952], the *dihydrochloride* has **m** 225°(dec) and the *picrate* has **m** 245° (235-236.5°) [Fryth et al. *J Am Chem Soc* **80** 2736 1958]. [*Beilstein* **26** III/IV 3566.]

**1,3-Dimethylbarbituric acid** [769-42-6] **M 156.1, m 123°, pK<sup>25</sup> 4.56.** Crystallise the acid from water and sublime it in a vacuum. Also purify it by dissolving 10g in 100ml of boiling CCl<sub>4</sub>/CHCl<sub>3</sub> (8:2) (1g charcoal), filtering and cooling to 25°. Dry it *in vacuo* [Kohn et al. *Anal Chem* **58** 3184 1986]. [*Beilstein* **24** III/IV 1875.]

**5,6-Dimethylbenzimidazole** [582-60-5] **M 146.2, m 205-206°, pK<sub>1</sub><sup>25</sup> 5.96, pK<sub>2</sub><sup>25</sup> 12.52.** Crystallise 5,6-dimethylbenzimidazole from diethyl ether. It sublimes at 140°/3mm. [*Beilstein* **23/6** V 454.]

**2,3-Dimethylbenzothiophene** [31317-17-6] M 212.3, m 69-70°, b 123-124°/10mm, n<sub>D</sub><sup>19</sup> 1.6171. Fractionate it through a 90cm Monel spiral column, or other efficient fractionating or spinning band column and collect the middle fraction. It has also been purified by chromatography on basic alumina using pentane as eluent. [Tedjanulia et al. *J Heterocycl Chem* **20** 1485 1983, *Beilstein* **17** III/IV 161.]

**4,4'-Dimethyl-2,2'-bipyridine** [1134-35-6] M 184.2, m 175-176°, pK<sub>Est(1)</sub> ~0.2, pK<sub>Est(2)</sub> ~4.9. Crystallise it from ethyl acetate. [Elliott et al. *J Am Chem Soc* **107** 4647 1985, *Beilstein* **23/8** V 79.]

**1,1'-Dimethyl-4,4'-bipyridylum dichloride (3H<sub>2</sub>O; Methyl Viologen Dichloride, paraquat dichloride)** [1910-42-5] M 311.2, m >300°(dec). Recrystallise the dichloride from MeOH/acetone mixture. It has also been recrystallised three times from absolute EtOH [Bancroft et al. *Anal Chem* **53** 1390 1981]. Dry it at 80° in a vacuum. [*Beilstein* **23/8** V 30.]

**1,3-Dimethylbutadiene sulfone (1,3-dimethylsulfolene, 2,5-dihydro-2,4-dimethylthiophene)** [10033-92-8] M 145.2, m 40.4-41.0°. Crystallise it from Et<sub>2</sub>O, Et<sub>2</sub>O/pentane or CCl<sub>4</sub>. [Grummitt et al. *J Am Chem Soc* **72** 5167 1950, Bartlett et al. *J Org Chem* **32** 1290 1967, *Beilstein* **17** III/IV 161.]

**2,2-Dimethyl-1,3-dioxan-4,6-dione (Meldrum's Acid)** [2033-24-1] M 144.1, m 92-96°, 94-95°, pK<sup>25</sup> 5.1, 7.32. Crystallise the dione from Me<sub>2</sub>CO/H<sub>2</sub>O. It is a useful synthon for the C3 malonic acid moiety. [Arnette et al. *J Am Chem Soc* **106** 6759 1984, Bihlmayer et al. *Monatsh Chem* **98** 564 1967, Review: McNab *Chem Soc, Rev* **7** 345 1978, Chan & Huang *Synthesis* 452 1982, *Beilstein* **19/5** V 8.] It is synthesised by a modified procedure in which concentrated H<sub>2</sub>SO<sub>4</sub> (1.5ml) is added to a stirred suspension of powdered malonic acid (52g, 0.5 mole) in acetic anhydride (60ml, 0.6 mole), whereby the malonic acid dissolves with spontaneous cooling. Acetone (40ml, 0.55 mole) is added to the mixture while keeping the temperature at 20-25°, then cooled in a refrigerator overnight, the crystals are filtered off, washed three times with ice-water (enough to cover the crystals) and air dried. The crude product (35g, 49%) is recrystallised without heating by dissolving it (10g) in Me<sub>2</sub>CO (20ml), filtering, and adding H<sub>2</sub>O (40ml), with ~70% recovery of material m 94-95°. [Pihlaja & Seilo *Acta Chem Scand* **22** 3053 1968.]

*Alternatively* concentrated H<sub>2</sub>SO<sub>4</sub> (0.5ml) is added dropwise to a stirred suspension of powdered malonic acid (52g, 0.5 mole) in redistilled isoprenyl acetate (62ml, 55g, [108-22-5]), when the temperature rose from 23° to 31° in 45 minutes and all the solid dissolved within 1 hour. Treatment of the reaction as above gave Meldrum's acid (37g, 50%). [Davidson & Bernhard *J Am Chem Soc* **70** 3426 1948]. Its <sup>1</sup>H NMR (CDCl<sub>3</sub>, TMS) has δ at 1.73 (s, 2-Me<sub>2</sub>) and 3.60 (s, 5-H) [Schuster & Schuster *Tetrahedron* **25** 199 1969].

**3,6-Dimethyl-1,4-dioxan-2,5-dione (Lactide)** [*cis-RS,RS*(±) 615-95-2, *cis-R,R*(+) 95-96-5, *cis-S,S*(-) 4511-42-6] M 144.1. This is the cyclic dilactone of lactic acid. The (±)-*cis-racemate* has been distilled with b 142°/8mm; the distillate which solidifies gives yellow needles on recrystallisation from EtOH with m 128°, from Et<sub>2</sub>O with m 129°, or CHCl<sub>3</sub> with m 126°, with IR ν<sub>max</sub> at 1720-1740 cm<sup>-1</sup>. It hydrolyses in cold H<sub>2</sub>O. [Carothers et al. *J Am Chem Soc* **54** 772 1932]. A *trans-form* (probably *RS,SR*) has been reported which crystallises from Et<sub>2</sub>O with m 42-43° [Hummel et al. *Acta Cryst (Sect B)* **38** 1679 1982]. The *R,R*(+)-*lactide* has b 150°/2mm and crystallises from Et<sub>2</sub>O with m 95°, or m 96.5-97.5° (from CHCl<sub>3</sub>) or m 97.7° (from EtOAc) and [α]<sub>D</sub><sup>22</sup> +297° (c 1.2, \*C<sub>6</sub>H<sub>6</sub>). The *S,S*(-)-*lactide* has b 150°/2.5mm and crystallises from EtOAc with m 98.7°, or m 95° (from CHCl<sub>3</sub>) or m 96.5-97.5° (from CCl<sub>4</sub>) and [α]<sub>D</sub><sup>22</sup> -297° (c 1.2, \*C<sub>6</sub>H<sub>6</sub>). [Toniolo et al. *J Org Chem* **35** 6 1970, *Beilstein* **19** H 154, **19** I 179, **19** II 176, **19** IV 1927, **19/5** V 10.]

**2,9-Dimethyl-4,7-diphenyl-1,10-phenanthroline (Bathocuproine)** [4733-39-5] M 360.5, m >280°, pK<sub>Est</sub> ~5.6. Purify it by recrystallisation from \*benzene. [Smith & Wilkins *Anal Chem* **25** 510 1953, *Beilstein* **23** III/IV 2160.]

**2,2-Dimethylethyleneimine (2,2-dimethylaziridine)** [2658-24-4] M 71.1, b 70.5-71.0°, 72°, n<sub>D</sub><sup>20</sup> 1.405, pK<sup>25</sup> 8.64. Dry the 2,2-dimethylaziridine over solid KOH, filter and freshly distil from sodium before use, and store it under dry nitrogen. The *N*-phenylthiocarbonyl derivative crystallises from petroleum ether containing a trace of Me<sub>2</sub>CO with m 92.5-93.5°. [Hassner et al. *J Am Chem Soc* **91** 5046 1969, Cairns *J Am Chem Soc* **63** 871 1941, Lamaty et al. *Justus Liebigs Ann Chem* **726** 77 1969, *Beilstein* **20** III/IV 280.]

**5,5-Dimethylhydantoin** [77-71-4] M 128.1, m 177-178° pK<sup>24</sup> 9.19. Crystallise the hydantoin from EtOH and sublime it *in vacuo*. [Beilstein 24 III/IV 1097.]

**4,6-Dimethyl-2-hydroxypyrimidine** [108-79-2] M 124.1, m 198-199°, 202-205°, pK<sub>1</sub><sup>20</sup> 3.77, pK<sub>2</sub><sup>20</sup> 10.50. Crystallise the pyrimidine from absolute EtOH (charcoal). [Beilstein 24/2 V 138.]

**1,2-Dimethyl-1H-imidazole** [1739-84-0] M 96.1, m 38-40°, b 206°/760mm, d<sub>4</sub><sup>20</sup> 1.084, pK<sub>Est</sub> ~8.1. Crystallise the imidazole from \*benzene, dry and store it at 0-4°. The *picrate* crystallises from H<sub>2</sub>O or EtOH with m 181°. [Balaban & Pymann *J Chem Soc* 125 1570 1924, Gorun et al. *J Am Chem Soc* 109 4244 1987, Beilstein 23 H 66, 23 II 56, 23 III/IV 594.]

**1,3-Dimethyl-2-imidazolinone (DMI, N,N'-dimethylethyleneurea, DMEU)** [80-73-9] M 114.2, m 8.2°, b 67-68°/2mm, 104°/5mm, 106-107°/17mm, 224-226°/atm, d<sub>4</sub><sup>25</sup> 1.056, n<sub>D</sub><sup>20</sup> 1.472. After preparation by reaction of N,N'-dimethylethylenediamine in toluene with phosgene in toluene below 15°, excess phosgene is removed by blowing air through the mixture. The hydrochloride salt that separates is removed by filtration, and washed with CHCl<sub>3</sub>. The combined filtrate and washings are evaporated off, and the residue is distilled (b 129°/39mm). The crude distillate is treated with H<sub>2</sub>O; K<sub>2</sub>CO<sub>3</sub> is added to saturate the solution, and extracted with CHCl<sub>3</sub>, the extract is dried (K<sub>2</sub>CO<sub>3</sub>), filtered, and pure 1,3-dimethylimidazolin-2-one distils at b 104°/5mm. It has been used as an alternative to HMPA [see 680-31-9] as a high dielectric solvent for reactions. [Boon *J Chem Soc* 307 1947, Lien & Kumler *J Med Chem* 11 241 1968, Kohn et al. *J Org Chem* 42 941 1977, Beilstein 24 III/IV 9.]

**3,3-Dimethyloxetane** [6921-35-3] M 86.1, b 79.2-80.3°/760mm, d<sub>4</sub><sup>20</sup> 0.836, n<sub>D</sub><sup>20</sup> 1.399. Purify 3,3-dimethyloxetane by gas chromatography using a 2m silicone oil column or distil it. Fractionate it at atmospheric pressure (preferably under N<sub>2</sub> or Ar). [Beilstein 17 II 21.]

**2,9-Dimethyl-1,10-phenanthroline (neocuproine hemihydrate)** [484-11-7] M 208.3, 217.3 (hemihydrate), m 162-164°, pK<sup>25</sup> 5.85. Purify it as the *hemihydrate* by crystallisation from water and as the *anhydrous* base from \*benzene. [Beilstein 23/8 V 527.]

**4,4-Dimethyl-2,6-piperidinedione (4,4-dimethylglutarimide)** [1123-40-6] M 141.2, m 144-146°, pK<sub>Est</sub> ~11.5. Recrystallise the imide from hot H<sub>2</sub>O or EtOH [Arnett & Harrelson *J Am Chem Soc* 109 809 1987]. [Beilstein 21 H 391, 21 I 331, 21 II 309, 21 III/IV 4601, 21/9 V 592.]

**2,5-Dimethylpyrazine** [123-32-0] M 108.1, b 156°, d<sub>4</sub><sup>20</sup> 0.990, n<sub>D</sub><sup>20</sup> 1.502, pK<sub>1</sub><sup>25</sup> -4.6 (aqueous H<sub>2</sub>SO<sub>4</sub>), pK<sub>2</sub><sup>25</sup> 1.85. Purify it *via its picrate* (m 150°) which is decomposed with a base (e.g. KOH) and distilled. [Wiggins and Wise *J Chem Soc* 4780 1956]. [Beilstein 23/5 V 403.]

**3,5-Dimethylpyrazole** [67-51-6] M 96.1, m 107-108°, pK<sup>20</sup> 4.16. Crystallise it from cyclohexane or water. [Barszcz et al. *J Chem Soc, Dalton Trans* 2025 1986, Beilstein 23/5 V 110.]

**2,3-Dimethylquinoxaline** [2379-55-7] M 158.2, m 106°, pK<sup>25</sup> -3.84 (aqueous H<sub>2</sub>SO<sub>4</sub>). It has been purified by steam distillation with the base crystallising in the distillate. Recrystallise it from distilled water or aqueous EtOH. The *sulfate* crystallises from EtOH with m 151-152°(dec). [Gibson *J Chem Soc* 343 1927, Beilstein 23 H 191, 23 II 197, 23 III/IV 1277.]

**2,4-Dimethylsulfolane** [1003-78-7] M 148.2, b 128°/77mm, d<sub>D</sub><sup>25</sup> 1.1314, n<sub>D</sub><sup>20</sup> 1.474. Distil the 2,4-dimethylsulfolane in a vacuum. [Beilstein 17/1 V 82.]

**1,3-Dimethyluracil** [874-14-6] M 140.1, m 121-122°, pK<sup>25</sup> -3.25 (aqueous H<sub>2</sub>SO<sub>4</sub>). Crystallise it from EtOH/ether. [Beilstein 24 III/IV 1196.]

**9,9-Dimethylxanthen (4,4-dimethyl-2,3:5,6-dibenzopyran)** [19814-75-6] M 210.3, m 36-38°, b 114-115°/0.6mm, n<sub>D</sub><sup>20</sup> 1.5973. It is prepared under argon (Schlenk equipment) by adding Me<sub>3</sub>Al solution (2.0M in

toluene, 320ml, 0.64mmol), *via* a septum over 50 minutes, to an ice-water cooled stirred suspension of 9-xanthone (50.0g, 0.255mol) in toluene (300ml) (exothermic reaction, no gas evolved). The dark red solution is allowed to warm to  $\sim 25^\circ$  over 3 hours, and stirred for a further 14 hours. (*Alternatively* it can be heated to  $60^\circ$  for  $\sim 0.5$  hours.) The mixture is transferred (*via* a cannula under argon pressure) to a stirred mixture of concentrated HCl (250ml) and ice (4 L). The organic phase is separated, dried ( $\text{MgSO}_4$ ), filtered, the solvent is evaporated *in vacuo* to give a yellow oil (51.5g, 96%) which distils at  $114\text{--}115^\circ/0.6\text{mm}$ , and solidifies on cooling. The  $^1\text{H NMR}$  ( $\text{CDCl}_3$ , TMS) has  $\delta$  at 1.63 (s, 6H,  $\text{CH}_3$ ), 7.0-7.6 (m, 8H, aromatic-H); MS has  $m/z$  at 210 ( $\text{M}^+$ ), 195 (base peak,  $\text{M}^+ - \text{CH}_3$ ). [Nowick et al. *J Am Chem Soc* **112** 8904 1990, Meisters & Mole *Aust J Chem* **27** 1655 1974, *Beilstein* **17** II 287.]

**1,3-Dioxolan-2-one (ethylene carbonate)** [96-49-1] **M 88.1, m  $37^\circ$ ,  $39^\circ$ ,  $40^\circ$ , b  $65\text{--}67^\circ/1\text{mm}$ ,  $126^\circ/17\text{mm}$ ,  $238^\circ/760\text{mm}$ ,  $d_4^{20}$  1.321,  $n_D^{40}$  1.4199.** Dry 1,3-dioxolan-2-one over  $\text{P}_2\text{O}_5$ , then fractionally distil it at low or atmospheric pressure. Recrystallise it from dry  $\text{Et}_2\text{O}$  (plates, **m  $36.5^\circ$ ,  $38.5\text{--}40^\circ$**  was also reported). It is soluble in  $\text{H}_2\text{O}$ . [*Beilstein* **19** II 135, **19 III/IV** 1556, **19/4 V** 6.]

**1,3-Dioxane** [505-22-6] **M 88.1, b  $104.5^\circ/751\text{mm}$ ,  $d_4^{20}$  1.040,  $n_D^{20}$  1.417.** Dry the dioxane with sodium and fractionally distil it. [*Beilstein* **19/1 V** 11.]

**1,4-Dioxane** [123-91-1] **M 88.1, f  $11.8^\circ$ , b  $101.3^\circ$ ,  $d_4^{25}$  1.0292,  $n_D^{15}$  1.4236,  $n_D^{25}$  1.42025.** It is prepared commercially either by dehydration of ethylene glycol with  $\text{H}_2\text{SO}_4$  and heating ethylene oxide or bis( $\beta$ -chloroethyl)ether with NaOH. The usual impurities are acetaldehyde, ethylene acetal, acetic acid, water and peroxides. Peroxides can be removed (and the aldehyde content decreased) by percolation through a column of activated alumina (80g per 100-200ml solvent), by refluxing with  $\text{NaBH}_4$  or anhydrous stannous chloride and distilling, or by acidification with conc HCl, shaking with ferrous sulfate and leaving in contact with it for 24 hours before filtering and purifying further.

Hess and Frahm [*Chem Ber* **71** 2627 1938] refluxed 2L of dioxane with 27ml conc HCl and 200ml water for 12 hours with slow passage of nitrogen to remove acetaldehyde. After cooling the solution, KOH pellets were added slowly and with shaking until no more would dissolve and a second layer had separated. The dioxane was decanted, treated with fresh KOH pellets to remove any aqueous phase, then transferred to a clean flask where it was refluxed for 6-12 hours with sodium, then distilled from it. *Alternatively*, Kraus and Vingee [*J Am Chem Soc* **56** 511 1934] heated it on a steam bath with solid KOH until fresh addition of KOH gave no more resin (due to acetaldehyde). After filtering through paper, the dioxane was refluxed over sodium until the surface of the metal was not further discoloured during several hours. It was then distilled from sodium.

The acetal (**b  $82.5^\circ$** ) is removed during fractional distillation. Traces of \*benzene, if present, can be removed as the \*benzene/MeOH azeotrope by distillation in the presence of MeOH. Distillation from  $\text{LiAlH}_4$  removes aldehydes, peroxides and water. Dioxane can be dried using Linde type 4X molecular sieves. Other purification procedures include distillation from excess  $\text{C}_2\text{H}_5\text{MgBr}$ , refluxing with  $\text{PbO}_2$  to remove peroxides, fractional crystallisation by partial freezing and the addition of KI to dioxane acidified with aqueous HCl. Dioxane should be stored out of contact with air, preferably under  $\text{N}_2$ .

*A detailed purification procedure is as follows:* Dioxane is stood over ferrous sulfate for at least 2 days, under nitrogen. Then water (100ml) and conc HCl (14ml)/ litre of dioxane are added (giving a pale yellow colour). After refluxing for 8-12 hours with vigorous  $\text{N}_2$  bubbling, pellets of KOH are added to the warm solution to form two layers and to discharge the colour. The solution is cooled rapidly with more KOH pellets being added (magnetic stirring) until no more dissolved in the cooled solution. After 4-12 hours, if the lower phase is not black, the upper phase is decanted rapidly into a clean flask containing sodium, and refluxed over sodium (until freshly added sodium remained bright) for 1 hour. The middle fraction is collected (and checked for minimum absorbency below 250nm). The distillate is fractionally frozen three times by cooling in a refrigerator, with occasional shaking or stirring. This material is stored in a refrigerator. Before use it is thawed, refluxed over sodium for 48 hours, and distilled into a container. All joints are clad with Teflon tape.

Coetzee and Chang [*Pure Appl Chem* **57** 633 1985] dried the solvent by passing it slowly through a column (20g/L) of 3A molecular sieves activated by heating at  $250^\circ$  for 24 hours. Impurities (including peroxides) are removed by passing the effluent slowly through a column packed with type NaX zeolite (pellets ground to

0.1mm size) activated by heating at 400° for 24 hours or chromatographic grade basic Al<sub>2</sub>O<sub>3</sub> activated by heating at 250° for 24 hours. After removal of peroxides the effluent is refluxed for several hours over sodium wire, excluding moisture, distilled under nitrogen or argon and stored in the dark.

One of the best tests of purity of dioxane is the formation of the purple disodium benzophenone complex during reflux and its persistence on cooling. (Benzophenone is better than fluorenone for this purpose and for the storing of the solvent.) [Carter et al. *Trans Faraday Soc* **56** 343 1960, *Beilstein* **19** V 16.] **TOXIC.**

**Rapid purification:** Check for peroxides (see Chapter 1 and Chapter 2 for test under ethers). Pre-dry with CaCl<sub>2</sub> or better over Na wire. Then reflux the pre-dried solvent over Na (1% w/v) and benzophenone (0.2% w/v) under an inert atmosphere until the blue colour of the benzophenone ketyl radical anion persists. Distil. and store it over 4A molecular sieves in the dark.

**1,3-Dioxolane** [646-06-0] **M** 74.1, **b** 75.0-75.2°, **d**<sub>4</sub><sup>20</sup> 1.0600, **n**<sub>D</sub><sup>21</sup> 1.3997. Dry it with solid NaOH, KOH or CaSO<sub>4</sub>, and distil it from sodium or sodium amalgam. Barker et al. [*J Chem Soc* 802 1959] heated 34ml of dioxolane under reflux with 3g of PbO<sub>2</sub> for 2 hours, then cooled and filtered. After adding xylene (40ml) and PbO<sub>2</sub> (2g) to the filtrate, the mixture is fractionally distilled. Addition of xylene (20ml) and sodium wire to the main fraction (**b** 70-71°) led to a vigorous reaction, following which the mixture was again fractionally distilled. Xylene and sodium additions are made to the main fraction (**b** 73-74°) before it is finally distilled. [*Beilstein* **19**/I V 6.]

**5,5-Diphenylhydantoin** [57-41-0] **M** 252.3, **m** 293-295°. Crystallise the hydantoin from EtOH. [*Beilstein* **24** III/IV 1748.]

**1,3-Diphenylisobenzofuran** [5471-63-6] **M** 270.3, **m** 129-130°. Recrystallise it from EtOH or EtOH CHCl<sub>3</sub> (1:1) under red light (as in photographic dark rooms) or from \*benzene in the dark. [*Beilstein* **17**/2 V 503.]

**2,5-Diphenyl-1,3,4-oxadiazole (PPD)** [725-12-2] **M** 222.3, **m** 70° (hydrate), 139-140° (anhydrous), **b** 231°/13mm, 248°/16mm. Its solubility in CHCl<sub>3</sub> is 10%. Crystallise it from EtOH and sublime it *in vacuo*. [*Beilstein* **27** III/IV 2712.]

**2,5-Diphenyloxazole (PPO)** [92-71-7] **M** 221.3, **m** 74°, **b** 360°/760mm. Distil it in steam and crystallise it from ligroin. [*Beilstein* **27** III/IV 1437.]

**2RS,5RS-(±)-2,5-Diphenylpyrrolidine (± trans isomer)** [22147-84-8] **M** 223.3, **b** 136°/0.3mm, **n**<sub>D</sub><sup>25</sup> 1.5866, **pK**<sub>Est</sub> ~8.0. A mixture of *cis*-(*meso*) and *trans*-(±) pyrrolidines (**b** ~130-145°/0.15-0.2mm, ~138g, 0.6mol) in EtOH (210ml) and concentrated HCl (100ml) was treated dropwise, during ~2 hours, with a solution of NaNO<sub>2</sub> (61.5g, 0.9mol) in H<sub>2</sub>O (100ml) at ~0° (ice-bath cooling). The mixture was poured into H<sub>2</sub>O (1L) and the precipitate (~160g) was collected, washed with H<sub>2</sub>O and fractionally recrystallised from Me<sub>2</sub>CO to give the *trans*-nitroso derivative (**m** 140-140.9°, 51%) [22147-82-6], and the *cis*-nitroso derivative (**m** 97-98°, 20%) [22147-81-5]. This *trans*-nitroso-pyrrolidine was de-nitrosated (HCl gas in Et<sub>2</sub>O) to the *trans*-hydrochloride **m** 196.5-180° which was recrystallised from EtOH/Et<sub>2</sub>O. The *trans*-free base was obtained by basifying an aqueous solution to pH 9-10 and extracting with Et<sub>2</sub>O (3 x 50ml), drying the extract (Mg<sub>2</sub>SO<sub>4</sub>), filtering, evaporating and distilling the residual oil (**b** 136°/0.3mm). The IR (film) has **v**<sub>max</sub> at 1110-1025 (three peaks, one is for C-N) and 3330 (N-H) cm<sup>-1</sup>. Similarly the *cis* (*meso*) *N*-nitroso derivative gave the *2RS,5SR*-diphenylpyrrolidine *meso*-hydrochloride which had **m** 224.7-225.5°, and the *meso*-free base [22147-83-7] had **b** 121-123.4°/0.2mm, **n**<sub>D</sub><sup>25</sup> 1.5850. The optically active *2R,5R*-(*-*)-diphenylpyrrolidine enantiomer [155155-73-0] had **m** 49-53°, [**α**]<sub>D</sub><sup>22</sup> +118° (c 1.0, CHCl<sub>3</sub>). [Overberger et al. *J Am Chem Soc* **91** 687 1969. Breuer & Melamed *J Org Chem* **37** 3949 1972.]

(±)-**α, α-Diphenyl-2-pyrrolidinemethanol (α, α-diphenyl-DL-prolinol)** [63401-04-7, 112022-88-55] **M** 253.3, **m** 82-83° (76° also reported), **pK**<sub>Est</sub> ~9.5. It is prepared as the (*±*)-hydrochloride [16226-54-3] **M** 289.8, **m** 267-269° (dec, 262-263° was also reported) by dissolving the amine in Et<sub>2</sub>O. Et<sub>2</sub>O MeOH or CH<sub>2</sub>Cl<sub>2</sub>, and dry HCl gas is bubbled through (avoid excess HCl as it may dissolve precipitated NH<sub>4</sub>Cl), filtering,

evaporating, and the residue is recrystallised from MeOH/Me<sub>2</sub>CO; and from which the *free base* is obtained by treatment with aqueous NaOH and extraction with Et<sub>2</sub>O. It has psychostimulating activity. [Enders et al. *Org Synth* **58** 113 1978, Enders et al. *Org Synth Coll Vol VI* 542 1988, Enders et al. *Synthesis* 548 1976, Likhosherstov et al. *Khim Farm Z* **1** 30 1967, *Chem Abstr* **67** 90642 1967, *Beilstein* **21** III IV 1519.]

*R*-(+)- $\alpha$ ,  $\alpha$ -Diphenyl-2-pyrrolidinemethanol ( $\alpha$ ,  $\alpha$ -Diphenyl-D-prolinol) [22348-32-0] **M253.3**, *m* 78-80°,  $[\alpha]_D^{20}$  +69° (c 3, CHCl<sub>3</sub>). It is purified by recrystallisation from EtOH or hexane. It was also purified via the (*R*)-hydrochloride [172152-19-1] as above.

*S*-(-)- $\alpha$ ,  $\alpha$ -Diphenyl-2-pyrrolidinemethanol ( $\alpha$ ,  $\alpha$ -diphenyl-L-prolinol) [112108-01-9] **M253.3**, *m* 79-9.5°, 83°,  $[\alpha]_D^{20}$  -68.1° (c 3.2, CHCl<sub>3</sub>),  $[\alpha]_D^{20}$  -87.5° (c 1.16, CH<sub>2</sub>Cl<sub>2</sub>). It is purified by recrystallisation from EtOH or hexane. The *S*-(-)-hydrochloride [148719-90-8] melts above 240°, and the *benzoyl* derivative *m* 183° crystallises from H<sub>2</sub>O, MeOH or EtOH. [Enders et al. *Bull Soc Chem Belg* **97** 691 1988, Kerrick & Beak *J Am Chem Soc* **113** 9708 1991, Corey & Bakshi *Tetrahedron Lett* **31** 611 1990, Mathre *J Org Chem* **58** 2880 1993, *Beilstein* **21** III IV 1519.]

Dipicolinic acid (pyridine-2,6-dicarboxylic acid) [490-83-2] **M 167.1**, *m* 255°(dec),  $\lambda_{\max}$  270nm,  $pK_1^{20}$  2.10,  $pK_2^{20}$  4.68. Crystallise the acid from water, and sublime it in a vacuum. [*Beilstein* **22/4 V** 128.]

Di-(4-pyridyl)hydrazine (*N,N'*-disonicolinoyl hydrazine) [4320-75-3] **M 246.2**, *m* 254-255°, 259-260°. Crystallise it from water, aqueous EtOH or propan-1-ol. [Albert & Rees *Biochem J* **61** 128 1955, *Beilstein* **22** III IV 663.]

2,2'-Dipyridylamine [1202-34-2] **M 171.2**, *m* 84° and remelts at 95° after solidifying, *b* 176-178°/13mm, 222°/50mm, 307-308°/60mm,  $pK^{25}$  6.69 (in 20% aqueous EtOH). Crystallise the amine from \*benzene or toluene [Blakley & De Armond *J Am Chem Soc* **109** 4895 1987]. The amine is also recrystallised from Me<sub>2</sub>CO (*m* 95.1°) or distilled in a vacuum. [*Beilstein* **22** I 630, **22** II 331, **22** III IV 3961.]

2,2'-Dipyridyl disulfide (2,2'-dithiopyridine, Aldrithiol-2) [2127-03-9] **M 220.3**, *m* 53°, 57-58°,  $pK_1^{25}$  0.35,  $pK_2^{25}$  2.45. Recrystallise the disulfide H<sub>2</sub>O from \*C<sub>6</sub>H<sub>6</sub>, petroleum ether (6:7), ligroin or \*C<sub>6</sub>H<sub>6</sub>. The *picrate* has *m* 119° (from EtOH). [Walter et al. *Justus Liebigs Ann Chem* **695** 7785 1966, Marckwald et al. *Chem Ber* **33** 1556 1900, Brocklehurst & Little *Biochem J* **133** 67.78 1973, *Beilstein* **21** III IV 48.] It has been used as a 1mM solution in EtOH for the spectrophotometric estimation of thiols. Essentially the thiol displaces half the disulfide molecule liberating the 2-mercaptopyridine anion, thereby shifting the  $\lambda_{\max}$  from 340nm (of the disulfide) to 268nm (of the anion) at pH 9, or 278nm in H<sub>2</sub>O. (Compare with 4,4'-dipyridyl disulfide (below) which has been used for the same purpose [Humphrey et al. *Anal Chem* **40** 698 1970].

4,4'-Dipyridyl disulfide (4,4'-dithiopyridine, Aldrithiol-4) [2645-22-9] **M 220.3**, *m* 74-76°,  $pK_{\text{Est}(1)}$  ~1.5,  $pK_{\text{Est}(2)}$  ~4.5. Recrystallise the disulfide from H<sub>2</sub>O, EtOH, Me<sub>2</sub>CO, \*C<sub>6</sub>H<sub>6</sub> or petroleum ether. It has been used as a 1mM solution in EtOH for the spectrophotometric estimation of thiols. Essentially the thiol displaces half the disulfide molecule liberating the 4-mercaptopyridine (4-pyridinethiol) anion, thereby shifting the  $\lambda_{\max}$  from 324nm (of the disulfide) to 285nm (of the anion) at pH 9. (Compare with 2,2' dipyridyl disulfide above which has been used for the same purpose.) [Humphrey et al. *Anal Chem* **40** 698 1970, Cheng & Ritchie *Aust J Chem* **26** 1785 1973.] [*Beilstein* **21** II 35, for review see Aldrich in *Aldrichimica Acta* **4** 33 1971.]

1,2-Di-(4-pyridyl)-ethane [4916-57-8] **M 184.2**, *m* 110.9-111.2°, 114.5-116°, *b* 167-174°/3mm,  $pK_{\text{Est}(1)}$  ~3.8,  $pK_{\text{Est}(2)}$  ~5.4. Crystallise the ethane from cyclohexane/\*benzene (3:1, solubility is ~7.5g/100ml). The *dihydrochloride* crystallises from EtOH with *m* 329-330°(dec). [Bergmann et al. *J Am Chem Soc* **74** 5981 1952, Thayer & Carson *J Am Chem Soc* **70** 2331 1948, Jampolsky et al. *J Am Chem Soc* **74** 5222 1952, Chow & Fouss *J Am Chem Soc* **80** 1095 1958, *Beilstein* **23** III IV 1389.]

*trans*-1,2-Di-(4-pyridyl)-ethylene [13362-78-2] **M 182.2**, *m* 153-154°, 155.5-156.5°,  $pK_1^{25}$  3.65,  $pK_2^{25}$  5.6. Crystallise the ethylene from water (1.6g/100ml at 100°). The *di-hydrochloride* has *m* 347°, from EtOH.

[*Beilstein* 23/8 V 239.]

**1,3-Di-(4-pyridyl)-propane** [17252-5]-6] *M* 198.3, *m* 60.5-61.5°, 62-65°,  $pK_{\text{Est}(1)} \sim 4.5$ ,  $pK_{\text{Est}(2)} \sim 5.5$ . Crystallise the propane from *n*-hexane \*benzene (5:1) or Me<sub>2</sub>CO. The *picrate* has *m* 185-185°. [Jampolsky et al. *J Am Chem Soc* 74 5222 1952, Chow & Fouss *J Am Chem Soc* 80 1095 1958, *Beilstein* 23 III/IV 1400.]

**2,5-Distyrylpyrazine** [14990-02-4] *M* 284.3, *m* 219°. Recrystallise it from xylene; chromatograph it on basic silica gel (60-80 mesh) using CH<sub>2</sub>Cl<sub>2</sub> as eluent, then sublime it in a vacuum on to a cold surface at 10<sup>-3</sup> torr [Ebied *J Chem Soc, Faraday Trans 1* 78 3213 1982]. All operations should be carried out in the dark.

**1,3-Dithiane** [505-23-7] *M* 120.2, *m* 54°. Crystallise the 1,3-dithiane from 1.5 times its weight of MeOH at 0°, and sublime it at 40-50°/0.1mm. [Gröbel & Seebach *Synthesis* 357 1977, *Beilstein* 19/1 V 13.]

**2,2'-Dithiobis(benzothiazole)** [120-78-8] *M* 332.2, *m* 180°, 182.5-183.5°. Crystallise it from \*benzene. [*Beilstein* 27 H 109, 27 III/IV 1862.]

**4,4'-Dithiodimorpholine (S,S'-di-N,N'-dimorpholine, dimorpholine-N,N'-disulfide)** [103-34-4] *M* 236.2, *m* 124-125°. Crystallise it from hot aqueous dimethylformamide or EtOH. It is a fungicide. [Blake *J Am Chem Soc* 65 1267 1943.]

**1-Dodecylpyridinium chloride** [104-74-5] *M* 301.9, *m* 68-70°. Purify the chloride by repeated crystallisation from acetone (charcoal); then recrystallise it twice from EtOH [Chu & Thomas *J Am Chem Soc* 108 6270 1986]. It is *hygroscopic* and should be stored with a desiccant. [*Beilstein* 20 III/IV 2314.]

**Ellipticine (5,11-dimethylpyrido[4,3-*b*]carbazole)** [519-23-3] *M* 246.3, *m* 311-315°(dec), 312-314°(dec),  $pK_{25} 5.78$  (80% aqueous methoxyethanol). This DNA intercalator is purified by recrystallisation from CHCl<sub>3</sub> or MeOH and is dried *in vacuo*. The UV has  $\lambda_{\text{max}}$  values in aqueous EtOH/HCl at 241, 249, 307, 335 and 426nm. [Marini-Bettolo & Schmutz *Helv Chim Acta* 42 2146 1959.] The *methiodide* has *m* 360°(dec), with UV  $\lambda_{\text{max}}$  (EtOH/KOH) at 223, 242, 251, 311, 362 and 432nm. [Goodwin et al. *J Am Chem Soc* 81 1903 1959, *Beilstein* 23/9 V 417.]

**Elymoclavine (8,9-didehydro-6-methylergoline-8-methanol)** [548-43-6] *M* 254.3, *m* 249-253°(dec), 250-252°(dec),  $[\alpha]_{\text{D}}^{20} -109^{\circ}$  (c 0.4, EtOH). It crystallises from MeOH, CHCl<sub>3</sub>, Et<sub>2</sub>O, Me<sub>2</sub>CO or \*C<sub>6</sub>H<sub>6</sub>. [*Beilstein* 23 III/IV 2716.]

**Emetine hydrochloride hydrate** [316-42-7] *M* 553.6 + aq, *m* 235-240°, 235-250°, 240-250°, 248-250° (depending on H<sub>2</sub>O content),  $[\alpha]_{\text{D}}^{20} -49.2^{\circ}$  (free base, c 4, CHCl<sub>3</sub>), +18° (c 6, H<sub>2</sub>O, dry salt),  $pK_1 5.77$ ,  $pK_2 6.64$ . It crystallises from MeOH/Et<sub>2</sub>O, MeOH or Et<sub>2</sub>O/EtOAc. The *free base* has *m* 104-105°, and the (-)-*phen,thiourea* derivative has *m* 220-221° (from EtOAc petroleum ether,  $[\alpha]_{\text{D}}^{25} -29.3^{\circ}$  (CHCl<sub>3</sub>)). Its IR has  $\nu_{\text{max}}$  at 3413 (OH) and 2611 (NH<sup>+</sup>) cm<sup>-1</sup>; and UV  $\lambda_{\text{max}}$  at 230nm ( $\epsilon$  16 200) and 282nm ( $\epsilon$  6 890) [Brossi et al. *Helv Chim Acta* 42 1515 1959, Barash et al. *J Chem Soc* 3530 1959]. [*Beilstein* 23 III/IV 3419.]

**Ergocornine** [564-36-3] *M* 561.7, *m* 182-184°,  $[\alpha]_{\text{D}}^{20} -176^{\circ}$  (c 0.5, CHCl<sub>3</sub>). It crystallises with solvent of crystallisation from MeOH. [Stadler et al. *Helv Chim Acta* 52 1549 1969, *Beilstein* 25 III IV 963, 27 II 860.]

**Ergocristine** [511-08-0] *M* 573.7, *m* 165-170°,  $[\alpha]_{\text{D}}^{20} -183^{\circ}$  (c 0.5, CHCl<sub>3</sub>). It crystallises with 2 molecules of solvent of crystallisation from \*benzene. [Stadler et al. *Helv Chim Acta* 52 1549 1969, *Beilstein* 25 III IV 966, 27 II 860.]

**Ergocryptine** [511-09-1] *M* 575.7, *m* 212-214°,  $[\alpha]_{\text{D}}^{20} -180^{\circ}$  (c 0.5, CHCl<sub>3</sub>). It crystallises with solvent of crystallisation, from acetone, \*benzene or methanol. [Stadler et al. *Helv Chim Acta* 52 1549 1969, *Beilstein* 25 III/IV 964, 27 II 860.]

**Ergotamine** [113-15-5] M 581.6, m 212-214°(dec),  $[\alpha]_D^{20}$  -160° (c 0.5, CHCl<sub>3</sub>), pK<sup>25</sup> 6.40. Crystallise it from \*benzene, then dry it by prolonged heating in high vacuum. It is very *hygroscopic*. [Beilstein 25 III/IV 964.]

**Ergotamine tartrate** [379-79-3] M 657.1, m 203°(dec). It crystallises from MeOH. [Beilstein 25 III/IV 964.]

**Ergotaminine** [639-81-6] M 581.7, m 241-243°,  $[\alpha]_D^{20}$  +369° (c 0.5, CHCl<sub>3</sub>). It forms rhombic plates from MeOH which retain solvent unlike its isomer ergotamine (previous entry). It is less soluble than ergotamine, and its solubility is 0.1% in boiling ethanol and 0.07% in methanol. [Stoll *Helv Chim Acta* 28 1299 and 1306 1945, Beilstein 25 II 860, 862, 25 III/IV 966.]

**D-Erythronic acid (3R-3,4-dihydroxyfuran-2-one)** [15667-21-7] M 118.1, m 98-100°, 103-104°, 104-105°, 105°,  $[\alpha]_D^{20}$  -73.2° (c 0.5, H<sub>2</sub>O),  $[\alpha]_{546}^{20}$  -87.6° (c 4, H<sub>2</sub>O). Recrystallise it from EtOAc (20 parts) or isoPrOH (3 parts). [Baker & MacDonald *J Am Chem Soc* 82 230 1960, Glattfeld & Forbrich *J Am Chem Soc* 56 1209 1934, Weidenhagen & Wegner *Chem Ber* 72 2010 1939, Musich & Rapoport *J Am Chem Soc* 100 4865 1978, Beilstein 18/2 V 457.]

**Esculetin (cichorigenin, 6,7-dihydroycoumarin)** [305-01-1] M 178.2, m 272-275° (dec), 274° (dec), pK<sup>25</sup> 8.60 (70% aqueous EtOH), pK<sub>Est(1)</sub> ~8.7, pK<sub>Est(2)</sub> ~12.4. It forms prisms from AcOH, aqueous EtOH or aqueous MeOH, and provides leaflets on sublimation in a vacuum. [Kagan *J Am Chem Soc* 88 2617 1966, Marby et al. *Phytochemistry* 4 492 1965.] Esculin (the 6-glucoside) has m 215°(dec),  $[\alpha]_D^{20}$  -41° (c 5, pyridine). [Beilstein 18 III/IV 1322, 18/3 V 202.]

**Eserine (Physostigmine, Physostol, [(3aS-cis)-1,2,3,3a,8,8a-hexahydro-1,3a,8-trimethyl-pyrrolo[2,3-b]indol-5-ol methylcarbamate ester]** [57-47-6] M 275.4, m 102-104°, 105-106°,  $[\alpha]_D^{17}$  -67° (c 1.3, CHCl<sub>3</sub>),  $[\alpha]_D^{25}$  -120° (\*C<sub>6</sub>H<sub>6</sub>), pK<sub>1</sub><sup>25</sup> 1.96, pK<sub>2</sub><sup>25</sup> 8.08. Eserine crystallises from Et<sub>2</sub>O or \*C<sub>6</sub>H<sub>6</sub> and forms an unstable low melting form m 86-87° [Harley-Mason & Jackson *J Chem Soc* 3651 1954, Wijnberg & Speckamp *Tetrahedron* 34 2399 1978]. [Beilstein 23/11 V 401.]

**2-Ethoxy-1-ethoxycarbonyl-1,2-dihydroquinoline (EEDQ)** [16357-59-8] M 247.3, m 63.5-65°, 66-67°. Dissolve EEDQ (~180g) in CHCl<sub>3</sub>, evaporate to dryness in a vacuum. Add dry Et<sub>2</sub>O (20ml) and a white solid separates on standing. Set aside for a few hours, collect the solid, wash it thoroughly with cold Et<sub>2</sub>O and dry it in a vacuum (~140g, m 63.5-65°). A further crop of solid (~25g) is obtained from the filtrate on standing overnight. [Fieser & Fieser *Reagents for Organic Synthesis* 2 191 1969, Belleau et al. *J Am Chem Soc* 90 823 1968 and 90 1651 1968, Beilstein 21/3 V 28.]

**Ethoxyquin (1,2-dihydro-6-ethoxy-2,2,4-trimethylquinoline)** [91-53-2] M 217.3, b 169°/12-13mm, d<sub>4</sub><sup>20</sup> 1.000, pK<sub>Est</sub> ~5.8. Purify Ethoxyquin by fractional distillation *in vacuo* whereby the distillate solidifies to a glass. [Knoevenagel *Chem Ber* 54 1723, 1730 1921.] The *methiodide* has m 179° (from EtOH), and the *1-phenylcarbamoyl* derivative has m 146-147° (from EtOH). [Beaver et al. *J Am Chem Soc* 79 1236 1957, Beilstein 21 III/IV 95.]

**2-Ethyl-1,2-benzisoxazolium tetrafluoroborate** [4611-62-5] M 235.0, m 107-109°, 109.5-110.2°. Recrystallise it from MeCN/EtOAc to give magnificent crystals. It is not *hygroscopic* but on long exposure to moisture it etches glass. It is light-sensitive and should be stored in brown glass bottles and free from moisture. The UV (H<sub>2</sub>O), has  $\lambda_{\max}$  at 258nm ( $\epsilon$  13 100) and  $\lambda_{\max}$  297nm ( $\epsilon$  2 900); the IR (CH<sub>2</sub>Cl<sub>2</sub>) has  $\nu_{\max}$  at 1613 (C=N) and 1111-1000 (BF<sub>4</sub><sup>-</sup>) [UV, IR, NMR: Kemp & Woodward *Tetrahedron* 21 3019 1965].

**N-Ethylcarbazole** [86-28-2] M 195.3, m 69-70°, 69-71°, b 199-200°/15mm. Recrystallise it from MeOH, EtOH, EtOH/water or isopropanol and dry it below 55°. [Beilstein 20 H 436, 20 II 282, 20 III/IV 3829.]

**Ethyl 1,3-dithiane-2-carboxylate** [20462-00-4] M 192.3, b 75-77°/0.2mm, 96°/0.4mm, d<sub>4</sub><sup>20</sup> 1.220, n<sub>D</sub><sup>25</sup> 1.5379. Dissolve the ester in CHCl<sub>3</sub>, wash with aqueous K<sub>2</sub>CO<sub>3</sub>, twice with H<sub>2</sub>O, dry over MgSO<sub>4</sub>, filter,

evaporate and distil the residue. [Eliel & Hartman *J Org Chem* **37** 505 1972, Seebach *Synthesis* **1** 17 1969, *Beilstein* **19/7** V 227.]

**Ethyl 1,3-dithiolane-2-carboxylate** [20461-99-8] **M 178.3**, **b 85°/0.1mm**,  $d_4^{20}$  **1.250**,  $n_D^{20}$  **1.538**. Dissolve the ester in  $\text{CHCl}_3$ , wash it with aqueous  $\text{K}_2\text{CO}_3$ , twice with  $\text{H}_2\text{O}$ , dry it over  $\text{MgSO}_4$ , filter, evaporate and distil the residue *in vacuo*. [Hermann et al *Tetrahedron Lett* 2599 1973, Corey & Erickson *J Org Chem* **36** 3553 1971]. [*Beilstein* **19/7** V 225.]

**Ethylene oxide (oxirane)** [75-21-8] **M 44.0**, **b 13.5°/746mm**,  $d_4^{10}$  **0.882**,  $n_D^7$  **1.3597**. Dry oxirane with  $\text{CaSO}_4$ , then distil it from crushed  $\text{NaOH}$ . It has also been purified by passage, as a gas, through towers containing solid  $\text{NaOH}$ . [*Beilstein* **17/1** V 3.]

**Ethylene thiourea (2-imidazolidinethione)** [96-45-7] **M 102.2**, **m 203-204°**. Crystallise it from  $\text{EtOH}$  or amyl alcohol. [*Beilstein* **24** III/IV 22.]

**Ethylene urea (2-imidazolidone)** [120-93-4] **M 86.1**, **m 131°**. Crystallise it from  $\text{MeOH}$  (charcoal). [*Beilstein* **24** III/IV 6.]

**(±)-2-Ethylethylenimine (2-ethylaziridine)** [2549-67-9] **M 71.1**, **b 88.5-89°**,  $\text{pK}_{\text{a}}^{25}$  **8.31** ( $K_{\text{b}}$   $5.70 \times 10^{-7}$ ). Freshly distil the aziridine from sodium before use. The *picrate* has **m 103-104°**. **TOXIC**. [O'Rourke et al. *J Am Chem Soc* **78** 2159 1956, *Beilstein* **20** III/IV 280.]

**Ethyl hydrocupreine hydrochloride (Optochin)** [3413-58-9] **M 376.9**, **m 249-251°**,  $\text{pK}_{\text{a}}^{25}$  **5.50**,  $\text{pK}_{\text{a}}^{25}$  **9.95**. Recrystallise it from  $\text{H}_2\text{O}$  [UV: Heidt & Forbes *J Am Chem Soc* **55** 2701 1933]. [*Beilstein* **24** H 385, **24** III/IV 1446.]

**2-Ethyl-isothionicotinamide (ethionamide, 3-ethyl 4-pyridinecarbothioamide)** [536-33-4] **M 166.2**, **m 163-164°**, **164-166°(dec)**. It crystallises from  $\text{EtOH}$  as lemon yellow needles. The *hydrochloride* crystallises from  $\text{EtOH}$  (+ few drops of  $\text{HCl}$ ) as orange yellow needles with **m 212-214°**. [Kutscherowa et al. *J Gen Chem USSR* (English transl) **29** 915 1959, *Beilstein* **22** III/IV 737.] It causes peripheral and ocular **neuropathy** and is **carcinogenic** and **teratogenic**.

**(±)-3-Ethyl-5-phenylhydantoin (Ethotoin)** [86-35-1] **M 204.2**, **m 94°**. Crystallise it from water. It is an anticonvulsant and is used in epilepsy. [Dudley et al. *J Heterocycl Chem* **10** 173 1973, Pinner *Chem Ber* **21** 2320 1888, *Beilstein* **25** III/IV 963, **27** II 860.]

**N-Ethyl-5-phenylisoxazolinium-3'-sulfonate (Woodward's reagent K)** [4156-16-5] **M 253.3**, **m 220°(dec)**. Crystallise the reagent from diethyl ether or ethyl acetate/petroleum ether. [Lamas et al. *J Am Chem Soc* **108** 5543 1986.] It is best purified by dissolving in excess of aqueous  $\text{N HCl}$  and precipitating with  $\text{Me}_2\text{CO}$  to give a white fluffy solid. [Woodward et al. *Tetrahedron* **22** Suppl **8** 321 1966, Fieser & Fieser *Reagents for Organic Synthesis* **1** 385, **2** 198.]

**(±)-3-Ethyl-3-phenyl-2,6-piperidinedione (Glutethimide)** [77-21-4] **M 217.3**, **m 84°**. Crystallise glutethimide from diethyl ether or ethyl acetate/petroleum ether. It has **m 91-92°** (from aqueous  $\text{EtOH}$ ), **87-87.5°** (from  $\text{Et}_2\text{O}$ /petroleum ether), **84-87°** (from isopropanol), and **83-84°** (from  $\text{Et}_2\text{O}$ ). [Penprase & Biles *J Am Pharm Assoc* **47** 523 1958, Hofmann et al. *Helv Chim Acta* **40** 387, 393 1957, *Beilstein* **21** III/IV 5493.] The *R(+)-enantiomer* crystallises from  $\text{EtOAc}$ /petroleum ether with **m 103-104°**, and  $[\alpha]_D^{20} +184^\circ$  (c 1,  $\text{EtOH}$ ). [Branchini *Ricerche Scientifiche* **29** 2435 1959, Finch et al. *Experientia* **31** 1002 1975.]

**2-Ethylpyridine** [100-71-0] **M 107.2**, **b 148.6°**,  $d_4^{25}$  **0.942**,  $\text{pK}_{\text{a}}^{25}$  **5.89**. Dry 2-ethylpyridine with  $\text{BaO}$ , and fractionally distil it. Purify it further by conversion to the *picrate*, recrystallisation of the *picrate* and regeneration of the free base followed by distillation. [*Beilstein* **20/6** V 3.]

**4-Ethylpyridine** [536-75-4] **M 107.2, b 168.2-168.3°, d<sub>4</sub><sup>25</sup> 0.942, pK<sup>25</sup> 6.02.** Dry 4-ethylpyridine with BaO, and fractionally distil it. Also purified by converting to the *picrate*, recrystallising and the free base is regenerated and distilled. [Beilstein 20/6 V 10.]

**4-Ethylpyridine-1-oxide** [14906-55-9] **M 123.1, m 109-110°, pK<sub>Est</sub> ~1.1.** Crystallise the oxide from acetone/ether. [Beilstein 20/6 V 10.]

**Etioporphyrin I** See aetioporphyrin I above.

**Flavone (2-phenyl-4H-1-benzopyran-4-one)** [525-82-6] **M 222.3, m 100°.** Crystallise flavone from petroleum ether. [Beilstein 17/10 V 552.]

**Fluorescein [9-(*o*-carboxyphenyl-6-hydroxy-3H-xanthene-3-one)]** [2321-07-5] **M 320.0, ε<sub>495nm</sub> 7.84 x 10<sup>4</sup> (in 10<sup>-3</sup>M NaOH), pK<sub>1</sub> 2.2, pK<sub>2</sub> 4.4, pK<sub>3</sub> 6.7.** Dissolve it in dilute aqueous NaOH, filter and precipitate it by adding dilute (1:1) HCl. The process is repeated twice more, and the fluorescein is dried at 100°. *Alternatively*, it has been crystallised from acetone by allowing the solution to evaporate at 37° in an open beaker. It has also been recrystallised from EtOH and dried in a vacuum oven. [Beilstein 19 I 721, 19 II 248, 19 III/IV 2904, 19/8 V 456.]

**Fluoresceinamine (mixture of 5- and 6-aminofluorescein)** [27599-63-9] **M 347.3, m 215-220°(dec, 5-amino) and m 314-316°(dec, 6-amino).** Dissolve it in EtOH, treat with charcoal, filter, evaporate and dry the residue in a vacuum at 100° overnight. Also recrystallise it from 6% HCl, then dissolve it in 0.5% aqueous NaOH and precipitate it by acidifying with acetic acid. The separate amines are made from the respective nitro compounds, which are best separated *via* their acetate salts. They have similar R<sub>F</sub> of 0.26 on Silica Gel Merck F<sub>254</sub> in 5 ml MeOH + 150 ml Et<sub>2</sub>O saturated with H<sub>2</sub>O. The IR (Me<sub>2</sub>SO) has a band at ν<sub>max</sub> 1690 cm<sup>-1</sup> (CO<sub>2</sub><sup>-</sup>) and sometimes a weak band at ν<sub>max</sub> 1750 cm<sup>-1</sup> due to the lactone. The UV (EtOH) of the 6-isomer has λ<sub>max</sub> at 222nm (ε 60,000) and the 5-isomer at λ<sub>max</sub> 222nm (ε 60,000) and 285nm (ε 20,600). [IR: McKinney & Churchill *J Chem Soc (C)* 654 1970, McKinney et al. *J Org Chem* 27 3986 1962, UV: Verbiscar *J Org Chem* 29 490 1964, Beilstein 19 III/IV 4337, 19/8 V 713.]

**Fluorescein isothiocyanate isomer I (5-isothiocyanato isomer)** [3326-32-7; 27072-45-3 *mixture of 5- and 6-isomers*] **M 389.4, m >160°(slow dec).** It is made from the pure 5-amino isomer. Purify it by dissolving it in boiling Me<sub>2</sub>CO, filtering and adding petroleum ether (b 60-70°) until it becomes turbid. If an oil separates, then decant it and add more petroleum ether to the supernatant and cool. Orange-yellow crystals separate, collect and dry them *in vacuo*. It should give one spot on TLC (silica gel) in EtOAc/pyridine/AcOH (50:1:1) and in Me<sub>2</sub>NCHO/CHCl<sub>3</sub>/28% NH<sub>4</sub>OH (10:5:4). Its IR (Me<sub>2</sub>SO) has ν<sub>max</sub> at 2110 (NCS) and 1760 (C=O) cm<sup>-1</sup>. The <sup>1</sup>HNMR spectra in Me<sub>2</sub>CO-d<sub>6</sub> of the 5- and 6-isomers are distinctly different for the protons in the \*benzene ring; the UV in phosphate buffer pH 8.0 shows a λ<sub>max</sub> at ~490nm. [Sinsheimer et al. *Anal Biochem* 57 227 1974, McKinney et al. *Anal Biochem* 7 74 1964, Beilstein 19 III/IV 4337.]

**3-Fluoro-4-iodopyridine** [22282-75-3] **M 223.0, m 80-81°, 85-89°, pK<sub>Est</sub> ~1.7.** Crystallise it from petroleum ether and/or sublime it *in vacuo* (m 87°). The *picrate* [22282-76-4] has m 140° (from EtOH). [Gribble & Saulnier *Tetrahedron Lett* 4137 1980.]

**4-Fluoro-7-nitrobenzofurazan (4-fluoro-7-nitrobenzo-2-oxa-1,3-diazole)** [29270-56-2] **M 183.1, m 52.5-53.5°, 53-56°, 53.5-54.5°.** Purify it by repeated recrystallisation from petroleum ether (b 40-60°). On treatment with MeONa in MeOH it gives *4-methoxy-7-nitrobenzo-2-oxa-1,3-diazole* m 115-116°. [Nunno et al. *J Chem Soc (C)* 1433 1970.] It is a very good fluorophore for amino acids [Imai & Watanabe *Analyt Chim Acta* 130 377 1981], as it reacts with primary and secondary amines to form fluorescent adducts with λ<sub>ex</sub> 470nm and λ<sub>em</sub> 530nm. It gives a *glycine* derivative with m 185-187° [Miyano et al. *Anal Chim Acta* 170 81 1985].

**5-Fluorouracil (5-fluoropyrimidinedi-2,4-[1H,3H]-one, 5-FU)** [51-21-8] **M 130.1, m 282-283° (dec),**

**282-286°(dec), pK<sub>1</sub><sup>25</sup> 8.04, pK<sub>2</sub><sup>25</sup> 13.0.** Recrystallise it from H<sub>2</sub>O or MeOH/Et<sub>2</sub>O and sublime it at 190-200°/0.1mm or 210-230°/0.5mm. UV: λ<sub>max</sub> at 265-266nm (ε 7070). [Barton et al. *J Org Chem* **37** 329 1972, Duschinsky & Plevin *J Am Chem Soc* **79** 4559 1957, *Beilstein* **24** III/IV 1229.]

**Fluram (Fluorescamine, 4-phenyl-spiro[furan-2(3H)-1-phthalan]-3,3'-dione)** [38183-12-9] **M 278.3, m 153-155°, 154-155°.** Fluram is a non-fluorescent reagent that reacts with primary amines to form highly fluorescent compounds. Purify it by dissolving (~1g) in Et<sub>2</sub>O/\*C<sub>6</sub>H<sub>6</sub> (1:1, 180 ml), washing with 1% aqueous NaHCO<sub>3</sub> (50ml), drying (Na<sub>2</sub>SO<sub>4</sub>), and evaporating in a vacuum. Dissolve the residue in warm CH<sub>2</sub>Cl<sub>2</sub> (5ml), dilute with Et<sub>2</sub>O (12ml) and refrigerate. Collect the solid and dry it in a vacuum. Its IR (CHCl<sub>3</sub>) has ν<sub>max</sub> at 1810, 1745, 1722, 1625 and 1600 cm<sup>-1</sup>, and <sup>1</sup>HNMR (CDCl<sub>3</sub>) with δ at 8.71 (s, -OHC=). [Weigele et al. *J Am Chem Soc* **94** 5927 1972, Weigele et al. *J Org Chem* **41** 388 1976, *Lai Methods Enzymol* **47** 236 1977.]

**Forskolin (Colforsin, Coleonol, 5-[acetyloxy]-3-ethenyldodecahydro-6,10,10b-trihydroxy-3,4a,7,7, 10a-penta-methyl-[3R-{3α-4aβ, 5β, 6β, 6α, 10α, 10 aβ, 10bα}-1H-naphtho[2,1-b]pyran-1-one)** [66575-29-9] **M 410.5, m 230-232°, 228-233°, [α]<sub>D</sub><sup>25</sup> -96.2° (c 1.7, CHCl<sub>3</sub>).** Recrystallise it from \*C<sub>6</sub>H<sub>6</sub>/petroleum ether, EtOAc/petroleum ether. It is an antihypertensive, a positive inotropic, a platelet aggregation inhibitor, and it has adenylate cyclase activating properties [*Chem Abstr* **89** 244150 1978, de Souza et al. *Med Res Rev* **3** 201 1983, X-ray: Tandon et al. *Indian J Chem* **15B** 880 1977]. [*Beilstein* **18/5** V 55.]

**Fumagillin {2.4.6.8-decatetraene-1,10-dioic acid mono[4-(1,2-epoxy-1,5-dimethyl-4-hexenyl)-5-methoxy-1-oxaspiro[2.5]oct-6-yl] ester}** [23110-15-8] **M 458.5, m 194-195°, [α]<sub>D</sub><sup>20</sup> -26.2° (in 95% EtOH), pK<sub>Est</sub> ~4.5.** Forty grams of a commercial sample containing 42% fumagillin, 45% sucrose, 10% antifoam agent and 3% of other impurities are digested with 150ml of CHCl<sub>3</sub>. The insoluble sucrose is filtered off and washed with CHCl<sub>3</sub>. The combined CHCl<sub>3</sub> extracts are evaporated almost to dryness at room temperature under reduced pressure. The residue is triturated with 20ml of MeOH, and the fumagillin is filtered off by suction. It is crystallised twice from 500ml of hot MeOH by standing overnight in a refrigerator (yellow needles). (The long-chain fatty ester used as antifoam agent is still present, but is then removed by repeated digestion, on a steam bath, with 100ml of diethyl ether.) For further purification, the fumagillin (10g) is dissolved in 150ml of 0.2M ammonia, and the insoluble residue is filtered off. The ammonia solution (cooled in running cold water) is then brought to pH 4 by careful addition of M HCl with constant shaking in the presence of 150ml of CHCl<sub>3</sub>. (Fumagillin is acid-labile and must be removed rapidly from the aqueous acid solution.) The CHCl<sub>3</sub> extract is washed several times with distilled water, dried (Na<sub>2</sub>SO<sub>4</sub>) and evaporated under reduced pressure. The solid residue is washed with 20ml of MeOH. The fumagillin is filtered off by suction, then crystallised from 200ml of hot MeOH. [Tarbell et al. *J Am Chem Soc* **77** 5610 1955.]

*Alternatively*, 10g of fumagillin in 100ml CHCl<sub>3</sub> is passed through a silica gel (5g) column to remove tarry material, and the CHCl<sub>3</sub> is evaporated to leave an oil which gives fumagillin on crystallisation from amyl acetate. It recrystallises from MeOH (charcoal) or Me<sub>2</sub>CO/MeOH. The fumagillin is stored in dark bottles in the absence of oxygen and at low temperatures. [Schenk et al. *J Am Chem Soc* **77** 5606 1955, *Beilstein* **19** III/IV 1012.]

**Furan** [110-00-9] **M 68.1, b 31.3°, d<sub>4</sub><sup>20</sup> 1.42, n<sub>D</sub><sup>20</sup> 1.4214.** Shake it with aqueous 5% KOH, dry it with CaSO<sub>4</sub> or Na<sub>2</sub>SO<sub>4</sub>, then distil it under nitrogen, from KOH or sodium, immediately before use. A trace of hydroquinone could be added as an inhibitor of oxidation. [*Beilstein* **17** H 27, **17** I 16, **17** II 34, **17** I V 291.]

**Furan-2-carboxylic (2-furoic) acid** [88-14-2] **M 112.1, m 133-134°, b 141-144°/20mm, 230-232°/760mm, pK<sub>1</sub><sup>25</sup> -7.3 (O-protonation), pK<sub>2</sub><sup>25</sup> 3.32.** Crystallise the acid from hot water (charcoal), dry it at 120° for 2 hours, then recrystallise it from CHCl<sub>3</sub>, and again dry it at 120° for 2 hours. For use as a standard in volumetric analysis, good quality commercial acid should be crystallised from CHCl<sub>3</sub> and dried as above or sublimed at 130-140°/50-60mm or less. [*Beilstein* **18** I 438, **18** II 265, **18** III/IV 3914, **18/6** V 102.]

**Furan-3-carboxylic (3-furoic) acid** [488-93-7] **M 112.1, m 122-123°, 123°.5, pK<sub>25</sub> 4.03.** Crystallise the acid from water or aqueous EtOH, and sublime it in a vacuum. [*Beilstein* **18** I 439, **18** III/IV 4052, **18/6** V 196.]

**Furan-3,4-dicarboxylic acid** [3387-26-6] **M 156.1, m 217-218°, 221.5-222.5°, pK<sub>1</sub><sup>25</sup> 1.44, pK<sub>2</sub><sup>25</sup> 7.84.**

Crystallise it from water or Et<sub>2</sub>O/petroleum ether, and sublime it in a vacuum. [*Beilstein* 18 III/IV 4497.]

**Furan-2,5-dione (maleic anhydride)** [108-31-6] **M 98.1, m 54°, b 94-96°/20mm, 199°/760mm.** Crystallise it from \*benzene, CHCl<sub>3</sub>, CH<sub>2</sub>Cl<sub>2</sub> or CCl<sub>4</sub>. Sublime it under reduced pressure. [Skell et al. *J Am Chem Soc* 108 6300 1986, *Beilstein* 17 III/IV 5897, 17/11 V 55.]

**3-(2-Furanyl)acrylic acid** [539-47-9] **M 138.1, (cis-isomer) m 106-108°, pK<sup>25</sup> 3.5; (trans-isomer) m 141°, 143-144°, b 285°, pK<sup>25</sup> 4.5 (H<sub>2</sub>O), 5.76 (50% aqueous EtOH), 6.65 (ethoxyethanol/H<sub>2</sub>O—80:20).** Crystallise the *cis*-isomer from \*C<sub>6</sub>H<sub>6</sub> and the *trans*-isomer from H<sub>2</sub>O, \*C<sub>6</sub>H<sub>6</sub> or petroleum ether (b 80-100°)(charcoal). [*Beilstein* 18 H 301, 18 III/IV 4143, 18/6 V 306.]

**Furfural (2-furfuraldehyde)** [98-01-1] **M 96.1, b 54-56°/11mm, 59-60°/15mm, 67.8°/20mm, 90°/65mm, 161°/760mm, d<sub>4</sub><sup>20</sup> 1.159, n<sub>D</sub><sup>20</sup> 1.52608, pK<sup>25</sup> -6.5 (O-protonation).** Furfural is unstable to air, light and acids. Impurities include formic acid, β-formylacrylic acid and furan-2-carboxylic acid. Distil it in an oil bath from 7% (w/w) Na<sub>2</sub>CO<sub>3</sub> (added to neutralise acids, especially pyromucic acid). Redistil it from 2% (w/w) Na<sub>2</sub>CO<sub>3</sub>, and then, finally fractionally distil it under vacuum. It is stored in the dark. [Evans & Aylesworth *Ind Eng Chem (Anal ed)* 18 24 1926.]

Impurities resulting from storage can be removed by passage through chromatographic grade alumina. Furfural can be separated from impurities other than carbonyl compounds by the bisulfite addition compound. The aldehyde is steam volatile.

It has been purified by distillation (using a Claisen head) under reduced pressure. This is essential as is the use of an oil bath with temperatures of no higher than 130° which is highly recommended. When furfural is distilled at atmospheric pressure (in a stream of N<sub>2</sub>), or under reduced pressure with a free flame (caution: because the aldehyde is flammable), an almost colourless oil is obtained. After a few days and sometimes a few hours, the oil gradually darkens and finally becomes black. This change is accelerated by light and occurs more slowly when it is kept in a brown bottle. However, when the aldehyde is distilled under vacuum and the bath temperature kept below 130° during the distillation, the oil develops only a slight colour when exposed to direct sunlight during several days. The distillation of very impure material should NOT be attempted at atmospheric pressure; otherwise the product darkens very rapidly. After one distillation under vacuum, a distillation at atmospheric pressure can be carried out without too much decomposition and darkening. The liquid **irritates mucous membranes**. Store it in dark containers under N<sub>2</sub>, preferably in sealed ampoules. [Adams & Voorhees *Org Synth Coll Vol I* 280 1941, *Beilstein* 17/9 V 292.]

**Furfuryl alcohol (2-furyl-methanol)** [98-00-0] **M 98.1, b 68-69°/20mm, 170.0°/750mm, d<sub>4</sub><sup>20</sup> 1.132, n<sub>D</sub><sup>20</sup> 1.4873, n<sub>D</sub><sup>30</sup> 1.4801, pK<sup>25</sup> 2.61.** Distil it under reduced pressure to remove tarry material, shake with aqueous NaHCO<sub>3</sub>, dry it with Na<sub>2</sub>SO<sub>4</sub> and fractionally distil it under reduced pressure from Na<sub>2</sub>CO<sub>3</sub>. It can be further dried by shaking with Linde 5A molecular sieves. [*Beilstein* 17/3 V 338.]

**Furfurylamine (2-aminomethylfuran)** [617-89-0] **M 97.1, b 54-56°/17mm, 142.5-143°/735mm, d<sub>4</sub><sup>20</sup> 1.059, n<sub>D</sub><sup>20</sup> 1.489, pK<sup>30</sup> 8.89.** Distil it under nitrogen from KOH through a column packed with glass helices, preferably under vacuum. The *picrate* has **m** 184-184°(dec), the *hydrochloride* has **m** 147-149°, and the *oxalate* has **m** 145-147°. [*Beilstein* 18 H 584, 18 II 416, 18 III/IV 3068, 18/9 V 541.]

**6-Furfurylaminopurine (Kinetin)** [525-79-1] **M 215.2, m 266-267°, 269-271°, 270-272°, 272° (sealed capillary), pK<sub>1</sub> <1, pK<sub>2</sub> 3.8, pK<sub>3</sub> 10.** It forms platelets from EtOH and sublimes at 220°, but is best done at lower temperatures in a good vacuum. It has been extracted from neutral aqueous solutions with Et<sub>2</sub>O. [Miller et al *J Am Chem Soc* 78 1375 1956, Bullock et al. *J Am Chem Soc* 78 3693 1956, *Beilstein* 26 III/IV 3586.]

**Furil** [492-94-4] **M 190.2, m 165-166°.** Furil crystallises from MeOH or \*benzene (charcoal). [*Beilstein* 19 III/IV 2008.]

**(±)-Furoin [1,2-di-(2-furyl)-2-hydroxyethanone]** [552-86-3] **M 192.2, m 135-136°, 138-139°, 158-162°/9mm.** It crystallises from MeOH (charcoal) and distils in a vacuum. [Hartman & Dickey *J Am Chem Soc* 55 1228 1933.] The (-)-*enantiomer* crystallises from toluene or EtOH with **m** 131-131°, and [α]<sub>D</sub><sup>20</sup> -4.9°

(dioxane) [Neuberg et al. *Arch Biochem* **1** 393 1943, *Beilstein* **19** H 204, **19** I 710, **19** II 224, **19** III/IV 2543.]

**Fusaric acid (5-*n*-butylpyridine-2-carboxylic acid)** [536-69-6] **M 179.2, m 96-98°**, **98°**, **98-100°**, **101-103°**, **pK<sub>1</sub> 5.7, pK<sub>2</sub> 6.16 (80% aqueous methoxyethanol)**. Dissolve it in CHCl<sub>3</sub>, dry (Na<sub>2</sub>SO<sub>4</sub>), filter, evaporate and recrystallise the residue from 50 parts of petroleum ether (b 40-60°), CHCl<sub>3</sub>/petroleum ether or EtOAc, then sublime it *in vacuo*. The *amide* crystallises from MeOH with **m 128.2-129.0°**. The *copper salt* forms bluish violet crystals from H<sub>2</sub>O and has **m 258-259°**. [Hardegger & Nikles *Helv Chim Acta* **39** 505 1956, Schreiber & Adam *Chem Ber* **93** 1848 1960, NMR and MS: Tschesche & Führer *Chem Ber* **111** 3500 1978, *Beilstein* **22** III/IV 764, **22/2** V 384.]

**Fuschin (Magenta I)** See rosaniline hydrochloride in "Aromatic Compounds" [632-99-2] in this Chapter.

**Glycidol (oxirane-2-methanol)** [*RS*-(±)- 556-52-5; *R*-(+)- 57044-25-4; *S*-(-)- 60456-23-7] **M 74.1, (R,S) b 61-62°/15mm, d<sub>4</sub><sup>20</sup> 1.117, n<sub>D</sub><sup>20</sup> 1.433, [S(-)-isomer, § also available on polymer support, has b 49-50°/7mm, 66-67°/19mm, [α]<sub>D</sub><sup>20</sup> -15°(neat)], [R(+)-isomer has b 56-56.5°/11mm, d<sub>4</sub><sup>20</sup> 1.117, n<sub>D</sub><sup>20</sup> 1.429, [α]<sub>D</sub><sup>20</sup> +15°(neat)]**. Purify glycidol by fractional distillation. The *4-nitrobenzoates* have **m 56°(±)**; **m 60-62°**, [α]<sub>D</sub><sup>20</sup> -37.9° (c 3.38 CHCl<sub>3</sub>) for *R*-(-)-isomer [106268-95-5]; **m 60-62°**, [α]<sub>D</sub><sup>20</sup> +38° (c 1 CHCl<sub>3</sub>) for the *S*-(+)-isomer [115459-65-9] and are recrystallised from Et<sub>2</sub>O or Et<sub>2</sub>O/petroleum ether (b 40-60°) [*S*-isomer: Burgos et al. *J Org Chem* **52** 4973 1987, Sowden & Fischer *J Am Chem Soc* **64** 1291 1942.] [*Beilstein* **17** I 50, **17** III/IV 985, **17/3** V 9.]

**Gramine (3-dimethylaminoethylindole)** [87-52-5] **M 174.3, m 134°**, **pK<sub>25</sub> 16.00 (NH acidic)**, **basic pK<sub>25</sub> 9.2 (50% aqueous EtOH)**. Crystallise gramine from diethyl ether, ethanol or acetone. It sublimes at 59°/0.001mm. The *hydrochloride* crystallises from EtOH/Et<sub>2</sub>O with **m 190.5-191.0°(dec)**. [Culvenor et al. *Aust J Chem* **17** 1301 1964, *Beilstein* **22** III/IV 4302, **22/10** V 25.]

**(2*S*,6'*R*)(+)-Griseofulvin** [126-07-8] **M 352.8, m 220°**, [α]<sub>D</sub><sup>22</sup> +365° (c 1, acetone). Crystallise it from \*benzene or EtOH. Purify 2g of griseofulvin by chromatography on Alumina (40 x 1.5cm) and elute with \*C<sub>6</sub>H<sub>6</sub>/MeOH (199:1) and follow the UV blue fluorescent band. [MacMillan *J Chem Soc* 1823 1959, *Beilstein* **18** III/IV 3160, **18/5** V 150.]

**Guanosine (H<sub>2</sub>O)** [118-00-3] **M 283.2, m 237-237.5°(dec)**, **239°(dec)**, [α]<sub>546</sub><sup>20</sup> -86° (c 1, 0.1M NaOH), **pK<sub>1</sub><sup>25</sup> 1.9, pK<sub>2</sub><sup>25</sup> 9.24, pK<sub>3</sub><sup>25</sup> 12.33**. It crystallises from water as a *dihydrate*. Dry it at 110°. [*Beilstein* **26/18** V 81.]

**Guanylic acid (guanosine-5'-monophosphoric acid)** [85-32-5] **M 363.2, m 208°(dec)**, **pK<sub>2</sub><sup>25</sup> 2.4, pK<sub>3</sub><sup>25</sup> 6.66 (6.1), pK<sub>4</sub><sup>25</sup> 9.4**. Crystallise it from water and dry it at 110°. [*Beilstein* **26** III/IV 3910.]

**Harmaline (7-methoxy-1-methyl-4,9-dihydro-3*H*-β-carboline, 4,9-dihydro-7-methoxy-1-methyl-3*H*-pyrido[3,4-*b*]indole)** [304-21-2] **M 214.3, m 229-230°**, **229-231°**, **235-237° (after distillation at 120-140°/10<sup>-3</sup>)**, **pK<sub>1</sub> 4.2**. Recrystallise harmaline from MeOH and sublime it at high vacuum. It has UV in MeOH with λ<sub>max</sub> at 218, 260 and 376nm (log ε 4.27, 3.90 and 4.02, respectively); IR (Nujol) with ν<sub>max</sub> at 1620, 1600, 1570 and 1535cm<sup>-1</sup> and in CHCl<sub>3</sub> ν<sub>max</sub> at 1470 and 1629cm<sup>-1</sup>. [Spenser *Can J Chem* **37** 1851 1959, Marion et al. *J Am Chem Soc* **73** 305 1951, UV Prukner & Witkop *Justus Liebigs Ann Chem* **554** 127 1942.] The *hydrochloride dihydrate* has **m 234-236°(dec)**, the *picrate* has **m 228-229°** (sinters at 215°) from aqueous EtOH, and the *N-acetate* forms needles **m 204-205°**. [*Beilstein* **23** H 396, **23** I 119, **23** II 345, **23** III/IV 2666, **23/12** V 148.]

**Harmane (2-methyl-β-carboline, 1-methyl-9*H*-pyrido[3,4-*b*]indole, Aribine)** [486-84-0] **M 182.2, m 235-238°**, **237-238°**, **pK<sub>1</sub> 7.37 (basic, Pry N)**, **pK<sub>2</sub> 14.7 (acidic, NH)**. Crystallise it from heptane/cyclohexane. It is insoluble in H<sub>2</sub>O, but soluble in dilute HCl or H<sub>2</sub>SO<sub>4</sub>. Solutions show a blue fluorescence. Its UV (MeOH) has λ<sub>max</sub> nm (log ε) at 234 (4.57), 287 (4.21) and 347 (3.66). The *hydrochloride* forms needles from EtOH/dil HCl which sublimes at **m 120-130°**. It is an imidazoline binding site agonist. [Wolfbeis *Monatsh Chem* **113** 509 1982, *Beilstein* **23/12** 237.]

**Harmine (7-methoxy-1-methyl-9H-pyrido[3,4-b]indole)** [442-51-3] M 212.3, m 261°(dec), 265°, pK<sup>20</sup> 7.61. Crystallise harmine from MeOH and sublime it in a vacuum. Its UV (MeOH) has  $\lambda_{\text{max}}$  nm (log  $\epsilon$ ) at 241 (4.61), 301 (4.21) and 336 (3.69). It is a CNS stimulant. See *hydrochloride* below. [Beilstein 23 II 348, 23 III/IV 2702, 23/12 V 237.]

**Harmine hydrochloride (hydrate)** [343-27-1] M 248.7, m 262°(dec, hydrate), 280°(dec). The *hydrate* crystallises as fluorescent crystals from water. Freely soluble in hot water, but only 2.5% in cold water. The *anhydrous* salt has m 319°. [Beilstein 23/12 V 237.]

**Hesperetin (3',5,7-trihydroxy-4'-methoxyflavanone)** [520-33-2] M 302.3, (R,S) m 227-228°, pK<sub>Est</sub> ~8.5-10.5 (phenolic). Crystallise it from EtOAc or ethanol. The natural S(-) form crystallises from EtOH and has m 216-218° and  $[\alpha]_{\text{D}}^{20}$  -37.6° (c 2, EtOH). Note that C2 is chiral. [Beilstein 18 II 204, 18 III/IV 3215, 18/5 V 214.]

**Hesperidin (hesperetin 7-rhamnoside)** [520-26-3] M 610.6, m 258-262°, 261-263°(dec),  $[\alpha]_{546}^{20}$  -82° (c 2, pyridine). Dissolve hesperidine in dilute aqueous alkali and precipitate it by adjusting the pH to 6-7. [Beilstein 18 III/IV 3219, 18/5 V 218.]

**Hexahydro-1H-azepine (hexamethyleneimine, Azepane)** [111-49-9] M 99.2, b 70-72°/30mm, 135-138°/atm,  $d_4^{20}$  0.879,  $n_{\text{D}}^{20}$  1.466, pK<sup>25</sup> 11.10 (pK<sup>0</sup> 9.71, pK<sup>75</sup> 9.71). Purify azepane by dissolving in Et<sub>2</sub>O and adding ethanolic HCl until all the base separates as the white *hydrochloride*, filter, wash with Et<sub>2</sub>O and dry it (m 236°). The salt is dissolved in the minimum volume of H<sub>2</sub>O and basified to pH ~14 with 10N KOH. The solution is extracted with Et<sub>2</sub>O, the extract is dried over KOH, evaporated and distilled. The free base is a **FLAMMABLE** and **TOXIC** liquid, and best kept as the salt. The *nitrate* has m 120-123°, the *picrate* has m 145-147°, and the *tosylate* has m 76.5° (ligroin). [Müller & Sauerwald *Monatsh Chem* 48 727 1027, Hjelt & Agback *Acta Chem Scand* 18 194 1964, Beilstein 20 II 1406, 20 III/IV 1406, 20/4 V 3.]

**Hexamethylenetetramine (Urotropine, hexamine, HMTA)** [100-97-0] M 140.1, m 280° (subln), 290-292° (sealed tube, CARE),  $d_4^{20}$  1.331, pK<sup>25</sup> 4.85 (6.30). It is soluble in H<sub>2</sub>O (67%), CHCl<sub>3</sub> (10%), EtOH (8%) and Et<sub>2</sub>O (0.3%), and a 0.2M solution has a pH of 8.4. Dissolve it in hot absolute EtOH (reflux, Norit), filter using a heated funnel, cool at room temperature first, then in ice. Wash the crystals with cold Et<sub>2</sub>O, dry them in air or under a vacuum. A further crop can be obtained by adding Et<sub>2</sub>O to the filtrate. It sublimes above 260° without melting. The *picrate* has m 179°(dec). [pK<sup>20</sup> 4.85: Reilley & Schmid *Anal Chem* 30 947 1958, pK<sup>20</sup> 6.30: Pummerer & Hofmann *Chem Ber* 56 1255 1923.] [Beilstein 26 I 306, 26 II 200, 26 III/IV 1680.]

**R-(+)-2-Hexyloxirane [R-(+)-1,2-epoxyoctane, R-(+)-octene oxide]** [77495-66-0] M 128.2, b 51-54°/10mm, 60-62°/15mm, 157°/atm,  $d_4^{25}$  0.839,  $n_{\text{D}}^{20}$  1.418,  $[\alpha]_{\text{D}}^{20}$  +14° (neat), the S(-)- enantiomer has [50418-68-3]  $[\alpha]_{\text{D}}^{20}$  -14.5° (c 2.5, EtOH),  $n_{\text{D}}^{20}$  1.412. The enantiomeric oxiranes have been purified by passage through a silica gel column in pentane and eluted with pentane/Et<sub>2</sub>O. The eluate is evaporated and subjected to bulb-to-bulb distillation in a vacuum. The enantiomeric purity is checked by HPLC. [White & Emmons *Tetrahedron* 17 31 1962, Johnson & Rogers *J Org Chem* 38 1793 1973, Beilstein 17 H 17, 17 I 11, 17 III/IV 111, 17/1 V 138.]

**Histamine** [51-45-6] M 111.2, m 86° (sealed tube), b 167°/0.8mm, 209°/18mm, pK<sub>1</sub><sup>25</sup> 6.02, pK<sub>2</sub><sup>25</sup> 9.70. It crystallises from \*benzene or chloroform. [Beilstein 25 I 628, 25 II 302, 25 III/IV 2049.]

**Histamine dihydrochloride** [56-92-8] M 184.1, m 249-252° (244-245°). The dihydrochloride crystallises from aqueous EtOH. The *phosphate* (2H<sub>3</sub>PO<sub>4</sub>) [51-74-1] has m 132-133° (from H<sub>2</sub>O). [Beilstein 25 III/IV 2049.]

**Homopiperazine (1,4-diazepane)** [505-66-8] **M 100.2, m 38-40°, 43°, b 60°/10mm, 92°/50mm, 169°/atm, pK<sub>1</sub><sup>20</sup> 6.70, pK<sub>2</sub><sup>20</sup> 10.41.** Purify it by fractionation through a column of 10 theoretical plates with a reflux ratio of 3:1. It boils at 169°, and the cool distillate crystallises in plates **m 43°**. [Poppelsdorf and Myerly *J Org Chem* **26** 131 1961.] Its pKa values are 6.67 and 10.09 at 29.7°, and 6.28 and 9.86 at 40° [Pagano et al. *J Phys Chem* **65** 1062 1961]. The 1,4-bis(4-bromobenzoyl) derivative has **m 194-198°** (from EtOH); the hydrochloride has **m 270-290°** (from EtOH) and the picrate has **m 265°(dec)** [Lloyd et al. *J Chem Soc (C)* 780 1966]. [Beilstein **23** III/IV 388, **23/3** V 240.]

**1-Hydrazinophthalazine (hydralazine)** [86-54-4] **M 160.1, m 172-173°(dec), pK<sub>1</sub><sup>25</sup> 2.90, pK<sub>2</sub><sup>25</sup> 7.25 (NNH<sub>2</sub>).** It crystallises from MeOH. Its UV has  $\lambda_{\max}$  at 656nm at pH ~11. It complexes with Bi<sup>3+</sup>, Zn<sup>2+</sup>, Fe<sup>2+</sup> and Co<sup>2+</sup>. The hydrochloride (hydralazine hydrochloride) [304-20-1] **M 196.6**, also crystallises from MeOH and has **m 172-173°(dec)**. [Druey et al. *Helv Chim Acta* **34** 195 1951, *Beilstein* **25** III/IV 4552.] It is an antihypertensive.

**2-Hydrazinopyridine** [4930-98-7] **M 109.1, m 41-44°, 46-47°, 49-50°, b 105°/0.5mm, 128-135°/13mm.** Purify it by distillation under a vacuum and by recrystallisation from Et<sub>2</sub>O/hexane. [Kauffmann et al. *Justus Liebigs Ann Chem* **656** 103 1962, Potts & Burton *J Org Chem* **31** 251 1966.] The mono-hydrochloride has **m 183°(dec)** from aqueous HCl, and the di-hydrochloride has **m 214-215°**. [Beilstein **22** II 487, **22** III/IV 7025, **22/14** V 486.]

**4-Hydroxyacridine (4-acridinol, neo-oxine)** [18123-20-1] **M 195.2, m 116.5°, 122-123°, pK<sub>1</sub><sup>15</sup> 5.28, pK<sub>2</sub><sup>15</sup> 9.75.** Crystallise neo-oxine from EtOH or aqueous EtOH. It complexes with Zn<sup>2+</sup>, Cd<sup>2+</sup>, Ga<sup>2+</sup>, Pb<sup>2+</sup>, Cr<sup>2+</sup>, Mn<sup>2+</sup>, Fe<sup>2+</sup>, Co<sup>2+</sup> and Ni<sup>2+</sup>. The hydrochloride crystallises from EtOH with **m 242°**. [Beilstein **21** II 78, **21** III/IV 1562, **21/4** V 90.]

**1-Hydroxy-1,2-benziodoxol-3(1H)-one (IBX, 2-iodoxybenzoic acid)** [61717-82-6] **M 280.0, m 224-225°, 226-234°, 232-233°(dec), 233°(dec), pK <4.** IBX prepared by the Dess-Martin procedure (KBrO<sub>3</sub>/H<sub>2</sub>SO<sub>4</sub>) [Dess & Martin *J Am Chem Soc* **113** 7277 1991] has been reported as being explosive and comparable to TNT [Hartman & Meyer *Chem Ber* **26** 1727 1893, Plumb & Harper *Chem Eng News* (July 16) 3 1990] when apparently the iodine content was below 43.5% (theoretical value is 45.32%). In an attempt to avoid this, IBX has been washed with H<sub>2</sub>O and EtOH to render it non-explosive. Although deliberate attempts to detonate it on several occasions have been unsuccessful; operators should exercise CAUTION when working with IBX particularly with large scale preparations. This is among the substances for which it may be difficult to obtain permission to transport it, so detailed preparations are described here.

*Dess-Martin method:* To a vigorously stirred mixture of 2-iodobenzoic acid (85.2g, 340mmol, see [88-67-5]) and 0.73 M H<sub>2</sub>SO<sub>4</sub> (730ml) in a bath at 55° is added KBrO<sub>3</sub> (76.0g, 450mmol) over 1 hour. The mixture is stirred further for 3.6 hours at 65°, cooled in an ice bath, and the solid is filtered off, washed with H<sub>2</sub>O (1000ml) then EtOH (2 x 50ml) and dried *in vacuo* to give BTX (89.1g, 320mmol, 93%) of analytical purity. [Dess & Martin *J Am Chem Soc* **113** 7277 1991]

*Santagostino et al.'s method:* To oxone (181.0g, 290mmol, see [70693-62-8] 2KHSO<sub>5</sub>—KHSO<sub>4</sub>—K<sub>2</sub>SO<sub>4</sub> triple salt) in deionised H<sub>2</sub>O (650ml, 450mmol) is added rapidly 2-iodobenzoic acid (50.0g, 200mmol), and kept at 70-73° for 20 minutes then stirred mechanically at 70-73° for 3 hours. Initially a thick slurry coating along the walls of the container is formed which gradually becomes finely dispersed and the now easily stirred suspension readily sediments if stirring is interrupted. The mixture is then stirred slowly at 5° for 1.5 hours, the white crystalline solid is collected onto a medium porosity sintered-glass funnel, washed with H<sub>2</sub>O (6 x 100ml) and Me<sub>2</sub>CO (2 x 100ml) then Et<sub>2</sub>O, and left in dry air for 16 hours to give IBX (44.8-45.7g, ~80%). The filtrates are disposed of by treating with solid Na<sub>2</sub>SO<sub>3</sub> (70g, 55mmol) and neutralising with M aqueous NaOH. Analysis indicated that the purity was ≥95% (judging by the <sup>1</sup>H NMR integrals of the triplets at 7.84 and 7.47 ppm, and elemental analysis), and it contained 2-iodosobenzoic acid (~4%) and 2-iodobenzoic acid (~0.5%). IBX of analytical purity (≥99%) is similarly obtained on a small scale by adding 2-iodobenzoic acid (5.0g, 20mmol) to a solution of oxone in deionised H<sub>2</sub>O (37.2g, 61mmol, in 200ml), and the suspension is kept at 70° for 1 hour when it becomes clear. After 0.5 hours at 0-5° the white crystals that separate are collected, washed and dried as before to give analytically pure IBX (4.4g, 77%), **m 233° (dec)**. This procedure is more environmentally friendly than the Dess-Martin procedure. [Frigerio et al. *J Org Chem* **64** 4537 1999.] It has IR

(film) with a  $\nu_{\max}$  at  $1640\text{ cm}^{-1}$ ; the  $^1\text{H NMR}$  ( $\text{DMSO-}d_6$ , TMS) has  $\delta$  at 8.15 (d, 1H), 8.01 (d, 1H), 7.89 (t, 1H), and 7.84 (t, 1H); and the  $^{13}\text{C NMR}$  ( $\text{DMSO-}d_6$ , TMS) has  $\delta$  at 167.49, 146.59, 133.39, 132.97, 131.36, 130.10 and 124.99 [Frigerio & Santagostino *Tetrahedron Lett* **43** 8019 1994].

**SIBX** is an even more stabilised, non-explosive formulation that has all the oxidative characteristics of IBX. It is prepared as follows: 2-iodobenzoic acid (200g) and isophthalic acid (133g, see [121-91-5]) are added into a solution of oxone (625g) in  $\text{H}_2\text{O}$  (2000ml) and kept at  $70^\circ$  for 3 hours, then sodium benzoate (128g) in  $\text{H}_2\text{O}$  (500ml) is added at  $40^\circ$ . The precipitate that is formed on cooling to  $20^\circ$  is filtered off, washed with  $\text{H}_2\text{O}$  (700ml) and dried in a ventilated oven at  $60^\circ$  to give **SBTX** (420g, 90%) containing 49% w/w of active IBX. [Ozanne et al. *Org Lett* **5** 2903 2003.]

**SIBX** and/or **IBX** are water tolerant, inexpensive to prepare and easy to use. They oxidise primary and secondary alcohols smoothly to aldehydes and ketones, and vicinal diols are oxidised to mono and/or dicarbonyl compounds without C-C cleavage [Frigerio & Santagostino *Tetrahedron Lett* **43** 8019 1994], as well as allylic and benzylic alcohols to respective aldehydes [Ozanne et al. *Org Lett* **5** 2903 2003.], amino alcohols to amino carbonyls without amino protection, and sensitive heterocyclic substituents are not affected [Frigeio et al. *J Org Chem* **60** 7272 1995]. The structure and kinetics of the reactive intermediates in the oxidation have been studied in detail [Munari et al. *J Org Chem* **61** 9272 1961]. The reagents are generally sparingly soluble in organic solvents such as EtOAc, THF,  $\text{Me}_2\text{CO}$ , MeCN, toluene, DMSO and *N*-methylpyrrolidine, but the reactions usually proceed in these solvents, or mixtures of them, with ease and in good to excellent yields either at room temperature or at as high as reflux temperatures.

**2-Hydroxybenzothiazole (benzothiazol-2(3H)-one)** [934-34-9] **M 183.1, m 140-141 $^\circ$** . Crystallise it from aqueous EtOH or water. [Hoggarth *J Chem Soc* 3314 1949, Hunter *J Chem Soc* 135 1930, *Beilstein* **27** H 182, **27** I 270, **27** II 225, **27** III/IV 2693.]

**1-Hydroxybenzotriazole hydrate (HOBt)** [2592-95-2; 123333-53-9 ( $\text{H}_2\text{O}$ )] **M 135.1, m 157 $^\circ$ , 159-160 $^\circ$ , pK $^{20}$  7.88**. Crystallise HOBt from hot aqueous EtOH or water (charcoal). It is prepared from *o*-nitrophenylhydrazine or its hydrochloride dissolved in a small volume of  $\text{H}_2\text{O}$  by treating with 25% of aqueous KOH or aqueous ammonia whereby the mixture warms up immediately and discolours. After the mixture cools to room temperature it is acidified with hydrochloric acid and the *hydroxybenzotriazole* separates as colourless needles. It is soluble in hot  $\text{H}_2\text{O}$ , EtOH and AcOH, but much less soluble in  $\text{Et}_2\text{O}$ , petroleum ether,  $^*\text{C}_6\text{H}_6$  and  $\text{CHCl}_3$ . It is an acid and forms metal salts such the **Pb salt** which crystallises from hot  $\text{H}_2\text{O}$  in glistening leaflets with **m 270 $^\circ$** . In aqueous solution it exists mainly as the zwitterionic N-oxide tautomer with  $\text{H}^+$  on N-2. [Nietzki & Braunschweig *Chem Ber* **27** 3381 1894, Zincke & Schwartz *Justus Liebigs Ann Chem* **329** 329 1900, Boyle & Jones *J Chem Soc Perkin Trans II* 160 1973, Tomita & Ikawa *J Pharm Soc Jpn* **75** 449 1955, *Beilstein* **26** III/IV 95.] It is a useful reagent for peptide synthesis [Heusel et al. *Angew Chem Int Ed* **16** 642 1977].

§ A polystyrene supported version is available. For use in solid phase peptide synthesis, see Dryland & Sheppard *J Chem Soc Perkin Trans I* 125 1986.

**4-Hydroxycoumarin (4-hydroxy-1-benzopyran-2-one)** [1076-38-6] **M 162.1, m 206 $^\circ$ , 211-213 $^\circ$ , pK $_{\text{Est}}$  ~9.0**. Crystallise 4-hydroxycoumarin from water and dry it in a vacuum desiccator over Sicapent. [*Beilstein* **18/1** V 378.]

***N*-2-Hydroxyethylpiperazine-*N'*-2-ethanesulfonic acid (HEPES)** [7365-45-9] **M 238.3, pK $^{20}$  7.55**. Crystallise the acid from hot EtOH and water. It is a useful buffer. [*Beilstein* **23** V 376.]

**3-Hydroxyflavone (Flavanol)** [577-85-5] **M 238.2, m 169-170 $^\circ$ , 171-172 $^\circ$** . Recrystallise it from MeOH (**m** 169.5-170 $^\circ$ ), EtOH, aqueous EtOH (**m** 167 $^\circ$ ) or hexane. It has also been purified by repeated sublimation under high vacuum, and dried at high vacuum pumping for at least one hour [Bruker & Kelly *J Phys Chem* **91** 2856 1987]. [*Beilstein* **17** H 527, **17** I 268, **17** II 498, **17** III/IV 6428.]

**7-Hydroxy-4-methylcoumarin (4-methylumbelliferone( $\beta$ ) hydrate)** [90-33-5] **M 194.2, m 185-186 $^\circ$ , 188-188.5 $^\circ$ , 194-195 $^\circ$ , pK $^{25}$  7.80 (phenolic OH)**. Purify it by recrystallisation from EtOH. It is very slightly soluble in cold  $\text{H}_2\text{O}$  (solubility at  $37^\circ$  is 0.22%), slightly soluble in  $\text{Et}_2\text{O}$  and  $\text{CHCl}_3$ , but soluble in MeOH and

AcOH. It has a blue fluorescence in aqueous EtOH and has UV with  $\lambda_{\text{max}}$  at 221, 251 and 322.5nm (MeOH). The IR has  $\nu_{\text{max}}$  at 3077 br, 1667, 1592, 1385, 1267, 1156, 1130 and 1066  $\text{cm}^{-1}$ . The *acetate* has **m** 153-154°. [Woods & Sapp *J Org Chem* **27** 3703 1962, *Beilstein* **18** III/IV 332, **18/1** V 439.]

**2-Hydroxymethyl-12-crown-4** [75507-26-5] **M 206.2, b 115°/0.04mm, d**<sub>4</sub><sup>20</sup> **1.186, n**<sub>D</sub><sup>20</sup> **1.480**. Purify it by chromatography on Al<sub>2</sub>O<sub>3</sub> with EtOAc as eluent to give a *hygroscopic* colourless oil, which is distilled under high vacuum and is distilled *in vacuo*. It has IR with  $\nu_{\text{max}}$  at 3418 (OH) and 1103 (COC)  $\text{cm}^{-1}$ , and NMR:  $\delta$  3.70s. [Kimura et al. *J Chem Soc, Chem Commun* 492 1983, Pugia et al. *J Org Chem* **52** 2617 1987.]

**S-(-)-5-Hydroxymethyl-2(5H)-furanone** [78508-96-0] **M 114.1, 39-42°, 40-44°, b 130°/0.3mm, [** $\alpha$ <sub>D</sub><sup>20</sup> **-180°, [** $\alpha$ <sub>D</sub><sup>20</sup> **-148° (c 1.4, H<sub>2</sub>O)**. It is purified by chromatography on Silica gel using hexane/EtOAc (1:1) to give a colourless oil which is distilled using a Kügelrohr apparatus, and the distillate crystallises on cooling. It has R<sub>F</sub> 0.51 on Whatman No 1 paper using pentan-1-ol and 85% formic acid (1:1) and developing with ammoniacal AgNO<sub>3</sub>. [Boll *Acta Chem Scand* **22** 3245 1968, NMR: Oppolzer et al. *Helv Chim Acta* **68** 2100 1985, *Beilstein* **18** III/IV 56, **18/1** V 54.]

**5-(Hydroxymethyl)furfural** [67-47-0] **M 126.1, m 33.5°, b 114-116°/1mm, d**<sub>25</sub><sup>25</sup> **1.2620, n**<sub>D</sub><sup>25</sup> **1.5533**. Crystallise it from diethyl ether/petroleum ether. [*Beilstein* **18** III/IV 100, **18/1** V 130.]

**dl-3-Hydroxy-N-methylmorphinan** [297-90-5] **M 257.4, m 251-253°**. Crystallise it from MeOH or aqueous EtOH. The *hydrochloride* has **m** 176-177°. The *hydrobromide* has **m** 200-201° when recrystallised from EtOH/Et<sub>2</sub>O. [Sneider & Hellerbach *Helv Chim Acta* **33** 1446 1950, *Beilstein* **21** III/IV 100.]

**8-Hydroxy-2-methylquinoline** [826-81-3] **M 159.2, m 74-75°, b 266-267°, pK**<sub>1</sub><sup>25</sup> **5.61, pK**<sub>2</sub><sup>25</sup> **10.16**. Crystallise the quinoline from EtOH or aqueous EtOH. Its solubility at 20° in H<sub>2</sub>O is 0.366g/L, and in CHCl<sub>3</sub> it is 466g/L. It complexes with many metals. [*Beilstein* **21** H 106, **21** III/IV 2132.]

**4-Hydroxy-2-n-nonylquinoline N-oxide** [316-66-5] **M 287.4, m 148-149°, pK**<sub>Est</sub> **~6.0**. Crystallise the *N*-oxide from EtOH. Its UV has  $\lambda_{\text{max}}$  at 220-230nm in 0.001N NaOH. [Cornforth & James *Biochem J* **63** 124 1956, *Beilstein* **21** III/IV 3834.]

**1-Hydroxyphenazine (Hemipyocyanine)** [528-71-2] **M 196.2, m 157-158°, 165-166°, pK**<sub>1</sub><sup>15</sup> **1.61, pK**<sub>2</sub><sup>15</sup> **8.33 (10% aqueous MeOH)**. Purify the hydroxyphenazine by chromatography on acidic alumina with \*benzene/ether, and recrystallise it from aqueous EtOH, \*benzene/heptane, then sublime it at 140°/1.5mm. [UV, IR: Badger et al. *J Chem Soc* 3204 1951, Hegedüs *Helv Chim Acta* **33** 746 1950, *Beilstein* **23** II 360, **23** III/IV 2753.]

**2-(2-Hydroxyphenyl)benzothiazole** [3411-95-8] **M 227.2, m 132-133°, b 173-179°/3mm**. Recrystallise it several times from aqueous EtOH or dilute AcOH and sublime it. [Itoh & Fujiwara *J Am Chem Soc* **107** 1561 1985, Bogert & Corbitt *J Am Chem Soc* **48** 786 1926, *Beilstein* **27** II 91.]

**2-(2-Hydroxyphenyl)benzoxazole** [835-64-3] **M 211.2, m 127°, b 338°/760mm**. Recrystallise it several times from aqueous EtOH or dilute AcOH and sublime it. An aqueous alkaline solution containing EtOH has a blue fluorescence. [Itoh & Fujiwara *J Am Chem Soc* **107** 1561 1985, *Beilstein* **27** II 91.]

**3-Hydroxy-2-phenylcinchoninic acid (Oxycincophen)** [485-89-2] **M 265.3, m 206-207°(dec)**. It is precipitated from alkaline solution on acidification and crystallises from EtOH or AcOH in yellow crystals. [Marshall & Blanchard *J Pharmacol* **95** 186 1949, *Beilstein* **22** H 245, **22** II 183, **22** III/IV 2383.]

**(±)-2-( $\alpha$ -Hydroxypropyl)piperidine [2-piperidinepropanol, *RS*-1-(*RS*-2-piperidyl)propan-1-ol, ( $\pm$ )- $\alpha$ -conhydrine] [3238-62-8, 63401-12-7, 24448-89-3] **M 143.2, m 99-100°, pK**<sub>Est</sub> **~10.2**. Crystallise it from ether. The [*RS*-1-(*SR*-2)]-isomer also crystallises from ether and has **m** 98-98.5°. The *methiodide* crystallises from Me<sub>2</sub>CO/MeOH with **m** 127-130.5°. **POISONOUS** [Sicher & Tichy *Col Czech Chem Commun* **23** 2081 1958, Govindachari & Rajappa *J Chem Soc* 1306 1958, Stereochemistry: Hill *J Am Chem Soc* **80** 1609 1958,**

*Beilstein* 21 II 21, 21 III/IV 122.]

(+)-2-( $\alpha$ -Hydroxypropyl)piperidine [2-piperidinepropanol, *R*-1-(*S*-2-piperidyl)propan-1-ol, (+)- $\alpha$ -conhydrine] [495-20-5] M 143.2, m 121°, b 224-5°/720mm,  $[\alpha]_D^{20}$  -9.8° (c 4, EtOH), pK<sub>Est</sub> ~10.2. This very POISONOUS alkaloid from hemlock crystallises in leaflets from ether. The *O,N*-dibenzoyl derivative has m 133-134° and  $[\alpha]_D^{24}$  -13° (c 3, CHCl<sub>3</sub>). [Sicher & Tichy *Col Czech Chem Commun* 23 2081 1958, Stereochemistry: Hill *J Am Chem Soc* 80 1609 1958, Absolute config & ORD: Fodor et al. *Canad J Chem* 47 4393 1969, *Beilstein* 21 I 191, 21 II 21, 21 III/IV 122.]

(-)-2-( $\alpha$ -Hydroxypropyl)piperidine [2-piperidinepropanol, *R*-1-(*R*-2-piperidyl)propan-1-ol, (-)- $\alpha$ -conhydrine] [495-20-5] M 143.2, m 121°, b 224-5°/720mm,  $[\alpha]_D^{20}$  +10° (c 10, EtOH), pK<sub>Est</sub> ~10.2. Crystallise the piperidine from ether. POISONOUS. [Galinovskiy & Mulley *Monatsh Chem* 79 426 1948, *Beilstein* 21 I 191, 21 II 21, 21 III/IV 122.]

( $\pm$ )-7-(2-Hydroxypropyl)theophylline (Proxophylline, 1,3-dimethyl-3*H*,7*H*-purine-2,6-dione) [603-00-9] M 238.2, m 135-136°. Crystallise it from EtOH, aqueous MeOH or EtOAc. Roth *Archiv Pharmazie* 292 234 1959, Zelnik et al. *Bull Soc Chim Fr* 1733 1956, *Beilstein* 26 III/IV 2366.]

6-Hydroxypurine (hypoxanthine) [68-94-0] M 136.1, m 150°(dec), pK<sub>1</sub><sup>20</sup> 1.98, pK<sub>2</sub><sup>20</sup> 8.96, pK<sub>3</sub><sup>20</sup> 12.18. Crystallise it from hot water and dry it at 105°. [*Beilstein* 26 II 252, 26 III/IV 2081.]

2-Hydroxypyridine (2-pyridone) [142-08-5] M 95.1, m 105-107°, b 181-185°/24mm,  $\epsilon_{293\text{nm}}$  5900 (H<sub>2</sub>O) pK<sub>1</sub><sup>25</sup> 1.25, pK<sub>2</sub><sup>25</sup> 11.99. Distil the pyridone under vacuum to remove coloured impurity, then recrystallise from \*benzene, CCl<sub>4</sub>, EtOH or CHCl<sub>3</sub>/diethyl ether. It can be sublimed under high vacuum. [DePue et al. *J Am Chem Soc* 107 2131 1985, *Beilstein* 21/7 V 106.]

3-Hydroxypyridine [109-00-2] M 95.1, m 129°, 130°, pK<sub>1</sub><sup>25</sup> 5.10, pK<sub>2</sub><sup>25</sup> 8.6. Crystallise 3-hydroxypyridine from \*C<sub>6</sub>H<sub>6</sub>, water or EtOH. [*Beilstein* 21 III/IV 402, 21/2 V 68.]

4-Hydroxypyridine (4-pyridone) [626-64-2] M 95.1, m 65°, 68° (hydrate), 148.5°, 151-152° (anhydr), b >350°/760mm, pK<sub>1</sub><sup>20</sup> 3.20, pK<sub>2</sub><sup>20</sup> 11.12. Crystallise 4-pyridone from H<sub>2</sub>O or wet CHCl<sub>3</sub> as the *monohydrate*. It loses H<sub>2</sub>O on drying *in vacuo* over H<sub>2</sub>SO<sub>4</sub>. Store it over KOH because it is *hygroscopic*. [*Beilstein* 21 III/IV 446, 21/7 V 152.]

2(6)-Hydroxypyridine-5(3)-carboxylic acid (6-hydroxynicotinic acid) [5006-66-6] M 139.1, m 304°(dec), pK<sub>1</sub><sup>20</sup> 3.82 and pK<sub>2</sub><sup>20</sup> 9.92. It crystallises from water with m 303.4-303.7°(dec), or with m 325°(dec) from aqueous EtOH. The *methyl ester* crystallises from Me<sub>2</sub>CO with m 166° and pK<sup>20</sup> 9.92. [Albert *J Chem Soc* 1020 1960, *Beilstein* 22 III/IV 2147, 22/6 V 119.]

4-Hydroxypyridine-2,6-dicarboxylic acid (chelidamic acid) [134.828-60-3] M 183.1, m 248°(dec, 1 H<sub>2</sub>O), 254°(dec), 263°(dec), pK<sub>1</sub><sup>22</sup> 1.9, pK<sub>2</sub><sup>22</sup> 3.18, pK<sub>3</sub><sup>22</sup> 10.85; pK<sub>1</sub> 3.62, pK<sub>2</sub> 4.82 (80% aqueous methoxyethanol). It crystallises from water. The *dimethyl ester* crystallises from MeOH with m 167° (*monohydrate*, from H<sub>2</sub>O), m 170-171° (*anhydrous*, from MeOH), and pK<sup>25</sup> 6.25. [Bensaude et al. *J Am Chem Soc* 99 4438 1972, *Beilstein* 22 III/IV 2583, 22/7 V 164.]

2-Hydroxypyrimidine [557-01-7] M 96.1, m 179-180°, pK<sub>1</sub><sup>20</sup> 2.24, pK<sub>2</sub><sup>20</sup> 9.17. It crystallises from EtOH or ethyl acetate. Its solubility in H<sub>2</sub>O at 20° is 1g/2.2ml. [Albert *J Chem Soc* 4219 1952, *Beilstein* 24 III/IV 194.], 2-Hydroxypyrimidine hydrochloride [38353-09-2] M 132.5, has m 203-205.5°(dec) and crystallises from EtOH. [*Beilstein* 24 III/IV 173.] The *picrate* has m 199° and crystallises from EtOH. [Brown et al. *J Chem Soc* 211 1955.]

4-Hydroxypyrimidine [4562-27-0] M 96.1, m 164-165°, pK<sub>1</sub><sup>20</sup> 1.66, pK<sub>2</sub><sup>20</sup> 8.63. It crystallises from \*benzene or ethyl acetate. The *picrate* has m 164-166° and crystallises from EtOH [Brown et al. *J Chem Soc* 4035 1955, *Beilstein* 24 III/IV 171.]

**R-(+)-3-Hydroxypyrrolidine** [ $(\pm)$  2799-21-5 and 104706-47-0,  $R(+)$  40499-83-0,  $S(-)$  100243-39-8] **M 87.1**, **b 215-216°/atm**,  $d_4^{20}$  **1.078**,  $n_D^{20}$  **1.490**,  $[\alpha]_D^{20}$  **+6.5°** (c 1.5, MeOH),  $pK_{Est}$  **~10.1**. The  $(\pm)$ -isomer is purified by repeated distillation (**b** 102-104°/12mm, 108-110°/18mm), and the  $(\pm)$ -picrate crystallises from EtOH with **m** 140-141°. The  $R(+)$ -enantiomer has **b** 70°/0.6mm and  $[\alpha]_D^{20}$  **+5.6°** (c 3.63, MeOH). Its *hydrochloride* has a negative rotation and its *dimethiodide* has **m** 230° and  $[\alpha]_D^{24}$  **-8.02°**. [Suyama & Kanno *Yakugaku Zasshi (J Pharm Soc Japan)* **85** 531 1965, Uno et al. *J Heterocycl Chem* **24** 1025 1987, Flanagan & Joullie *Heterocycles* **26** 2247 1987, *Beilstein* **21** III/IV 44.]

**2-Hydroxyquinoline (carbostyryl)** [59-31-4] **M 145.2**, **m 199-200°**,  $pK_1^{20}$  **-0.31**,  $pK_2^{20}$  **11.76**. Crystallise it from MeOH. It has **m** 200-201° after sublimation in a vacuum. The *picrate* has **m** 132° after crystallisation from Et<sub>2</sub>O. [Gibson et al. *J Chem Soc* 4340 1955, *Beilstein* **21** III/IV 1057, **21/8** V 217.]

**8-Hydroxyquinoline (oxine, 8-quinolinol)** [148-24-3] **M 145.2**, **m 71-73°, 75-76°, 76°**, **b 122°/0.1mm**, **~267°/atm**,  $pK_1^{25}$  **4.91**,  $pK_2^{25}$  **9.81**. Crystallise oxine from hot EtOH, acetone, petroleum ether (b 60-80°) or water. Crude oxine can be purified by precipitation of copper oxinate, followed by liberation of free oxine with H<sub>2</sub>S or by steam distillation after acidification with H<sub>2</sub>SO<sub>4</sub>. Store it in the dark. It forms complexes with many metals. [Manske et al. *Can J Research* **27F** 359 1949, Phillips *Chem Rev* **56** 271 1956, *Beilstein* **21** III/IV 1135, **21/3** V 252.]

**8-Hydroxyquinoline-5-sulfonic acid (H<sub>2</sub>O)** [84-88-8] **M 243.3**, **m 322-323°(sintering at ~305°), >310°**,  $pK_1^{25}$  **4.09**,  $pK_2^{25}$  **8.66**. Crystallise the acid from water (as the 1.5 *hydrate*, **m** 316-317°) or dilute HCl (ca 2% by weight). [*Beilstein* **22** I 620, **22** II 313, **22** III/IV 3493.]

**4-Hydroxy-2,2,6,6-tetramethylpiperidine** [2403-88-5] **M 157.3**, **m 130-131°**,  $pK^{20}$  **10.05**. The piperidine crystallises from water as a *hydrate* and crystallises from dry ether or \*C<sub>6</sub>H<sub>6</sub> as the *anhydrous* base. The *hydrochloride* has **m** 282-284° (from EtOH/H<sub>2</sub>O), and the *formate* has **m** 207°(dec, from EtOH/EtOAc). [Mailey & Day *J Org Chem* **22** 1061 1957, *Beilstein* **21** I 195, **21** III/IV 146, **21/1** V 159.]

**4(6)-Hydroxy-2,5,6(2,4,5)-triaminopyrimidine sulfate** [35011-47-3] **M 257.22**, **m >340°**,  $pK_1$  **2.0**,  $pK_2$  **5.1**,  $pK_3$  **10.1**. This salt has very low solubility in H<sub>2</sub>O. It is best purified by conversion into the dihydrochloride salt, which is then re-converted to the insoluble sulfate salt. The sulfate salt (2.57g, 10mmoles) is suspended in H<sub>2</sub>O (20ml) containing BaCl<sub>2</sub> (10mmoles) and stirred in a boiling water bath for 15 minutes. After cooling, the insoluble BaSO<sub>4</sub> is filtered off and washed with boiling H<sub>2</sub>O (10ml). The combined filtrate and washings are made acidic with HCl and evaporated to dryness. The residual hydrochloride salt is recrystallised from H<sub>2</sub>O by adding conc HCl whereby the *dihydrochloride salt* separates as clusters which darken at 260° and dec > 300°[darkening > 360°]. [Baugh & Shaw *J Org Chem* **29** 3610 1964, King & Spengley *J Chem Soc* 2144 1952]. The hydrochloride is then dissolved in H<sub>2</sub>O, and while hot an equivalent of H<sub>2</sub>SO<sub>4</sub> is added when the sulfate separates as a white microcrystalline solid which is filtered off washed liberally with H<sub>2</sub>O and dried in vacuum over P<sub>2</sub>O<sub>5</sub>. [Albert & Wood *J Appl Chem London* **3** 521 1953, UV: Cavalieri et al. *J Am Chem Soc* **70** 3875 1948; see also Pfeleiderer *Chem Ber* **90** 2272 1957, Traube *Chem Ber* **33** 1371 1900.] The *hydrochloride* has **m** > 300°. [*Beilstein* **25** II 384, **25** III/IV 3648.]

**3-Hydroxyxanthone** [3722-51-8] **M 212.2**, **m 246°, 249-250°**. Purify the xanthone by chromatography on SiO<sub>2</sub> gel with petroleum ether/\*benzene as eluent. Recrystallise it from \*benzene or EtOH. The *acetate* has **m** 157-158°. [Itoh et al. *J Am Chem Soc* **107** 4819 1985, Davies et al. *J Org Chem* **23** 307 1958]. [*Beilstein* **18** H 46, **18** I 315, **18** II 29, **21** III/IV 601.]

**Ibogaine (12-methoxybogamine)** [83-74-9] **M 300.3**, **m 152-153°**,  $[\alpha]_D^{20}$  **-54°** (EtOH),  $pK^{25}$  **8.1** (**80% aqueous MeOCH<sub>2</sub>CH<sub>2</sub>OH**). Crystallise this alkaloid from EtOH or aqueous EtOH and sublime it at 150°/0.01mm. It is soluble in organic solvents but insoluble in H<sub>2</sub>O. The *hydrochloride*, **m** 299-300°(dec), is soluble in H<sub>2</sub>O and alcohols. [Büchi et al. *J Am Chem Soc* **88** 3099 1866, Rosenmund *Chem Ber* **108** 1871 1975, *Beilstein* **23** III/IV 2742.]

**Imidazole (glyoxaline)** [288-32-4] **M 68.1, m 89.5-91°, 89-90°, b 140-145°/15mm, 256°/atm, 262-264°/atm, pK<sub>1</sub><sup>25</sup> 6.99, pK<sub>2</sub><sup>25</sup> 14.44.** Crystallise imidazole from \*benzene, CCl<sub>4</sub>, CH<sub>2</sub>Cl<sub>2</sub>, EtOH, petroleum ether, acetone/petroleum ether and distilled de-ionized water. Dry it at 40° under vacuum over P<sub>2</sub>O<sub>5</sub>. Distil it at low pressure. It is also purified by sublimation or by zone melting. [Snyder et al. *Org Synth Coll Vol III* 471 1955, Bredereck et al. *Chem Ber* **97** 827 1964, Caswell & Spiro *J Am Chem Soc* **108** 6470 1986.] <sup>15</sup>N-imidazole crystallises from \*benzene [Scholes et al. *J Am Chem Soc* **108** 1660 1986]. [*Beilstein* **23** II 34, **23** III/IV 564, **23/4** V 191.]

**1H-Indazole-3-carboxylic acid** [4498-67-3] **M 162.2, m 265-265.5°, 268-268.5°, pK<sub>Est(1)</sub> ~4.5.** Purify the acid by recrystallisation from glacial acetic acid (charcoal), and dry the yellow crystals *in vacuo*. Alternatively, dissolve the acid in boiling H<sub>2</sub>O, concentrate the solution to one third its volume, cool and collect the yellow powder. Its UV has λ<sub>max</sub> (H<sub>2</sub>O) at 295 (log<sub>e</sub> 3.88) nm. The *ethyl ester* (prepared via the acid chloride) has **m 139°** (from EtOH) and has λ<sub>max</sub> (MeOH) at 393 nm, and the *N-methylamide* crystallises in tan needles from MeNO<sub>2</sub> with **m 191-191° (187-188.5°** was also reported). [Rousseau & Lindwall *J Am Chem Soc* **72** 3048 1950, Snyder et al. *J Am Chem Soc* **74** 2009 1952, *Beilstein* **25** H 129, **25** I 238, **25** II 128, **25** IV 808.]

**1H, 2H-Indazol-3-one (3-hydroxy-1H-indazole)** [7364-25-2] **M 134.1, m 250-252°, 253-254°, pK<sub>Est(1)</sub> ~6.0.** Purify indazol-3-one by recrystallisation from MeNO<sub>2</sub> or aqueous MeOH, and sublimation at 220°/0.1mm. In the UV it has λ<sub>max</sub> in MeOH at 215 and 306 nm, and it is in the 3-OH form in ethanolic solution. There appears to be some controversy regarding the tautomeric form in the solid state, but the IR peak at ν<sub>max</sub> 1627 cm<sup>-1</sup> (KBr) supports the keto form. [Ainsworth *J Am Chem Soc* **79** 524 1957, Elguero et al. *Adv Heterocycl Chem, Suppl* **1** 354 1976, Chernokal'skii et al. *Khim Geterotsikl Soedin* **96** 1966, *Beilstein* **24** H 111, **24** II 59, **24** III/IV 270.]

**4'-(Imidazol-1-yl)acetophenone** [10041-06-2] **M 186.2, m 104-107°, pK<sup>25</sup> 4.54.** Recrystallise it twice from CH<sub>2</sub>Cl<sub>2</sub>/hexane [Collman et al. *J Am Chem Soc* **108** 2588 1986].

**2-Iminothiolane hydrochloride (2-iminotetrahydrothiophene, Traut's reagent)** [4781-83-3] **M 137.6, m 187-192°, 190-195°, 192-193°, 193-194°, 202-203°, pK<sup>25</sup> <2 (free base).** Recrystallise the hydrochloride from MeOH/Et<sub>2</sub>O (**m 187-192°**) or (MeOH/Me<sub>2</sub>CO), but after sublimation at ~180°/0.2mm the melting point rises to 202-203°. It has <sup>1</sup>HNMR with δ 2.27 (2H, t), 3.25 (2H, t) and 3.52 (2H, t) in -(CD<sub>3</sub>)<sub>2</sub>SO. [King et al. *Biochemistry* **17** 1499 1978.] The *free base* is purified by vacuum distillation (**b 71-72°/6mm**), has IR (film) with ν<sub>max</sub> at 1700 (C=N)cm<sup>-1</sup> and <sup>1</sup>HNMR (CDCl<sub>3</sub>) with δ at 3.58 (2H, t) and 2.10-2.8 (4H, m). The *free base* is stable on storage but slowly hydrolyses in aqueous solutions with half-lives at 25° of 390 hours at pH 9.1, 210 hours at pH 10 and 18 hours at pH 11. [Traut et al. *Biochemistry* **12** 3266 1973, *Biochemistry* **17** 399 1978, Alagon & King *Biochemistry* **19** 4343 1980, *Beilstein* **17/9** V 12.]

**Indanthrene (N,N'-dihydro-1,2,1',2'-anthraquinonazine)** [81-77-6] **M 442.4, m 470-500°(dec).** Crystallise indanthrene repeatedly from 1,2,4-trichlorobenzene to give a blue powder. It is soluble in alkali and conc H<sub>2</sub>SO<sub>4</sub>. [Weinstein & Merritt *J Am Chem Soc* **81** 3759 1959, *Beilstein* **24** II 317, **24** III/IV 2193.]

**Indazole** [271-44-3] **M 118.1, m 147°, 150°, pK<sub>1</sub><sup>20</sup> 1.32, pK<sub>2</sub><sup>20</sup> 13.80 (acidic NH).** Crystallise indazole from water, sublime it *in vacuo*, then recrystallise it from petroleum ether (**b 60-80°**). The *picrate* crystallises from Et<sub>2</sub>O with **m 136°**. [Ainsworth *Org Synth Coll Vol IV* 536 1963, *Beilstein* **23** III/IV 1055, **23/6** V 156.]

**Indigo** [482-89-3] **M 262.3, sublimes at ~300°, m 390°(dec), and halogen-substituted indigo dyes.** First reduce indigo in alkaline solution with sodium hydrosulfite, and filter. The filtrate is then oxidised by air, and the resulting precipitate is filtered off, dried at 65-70°, ground to a fine powder, and extracted with CHCl<sub>3</sub> in a Soxhlet extractor. Evaporation of the CHCl<sub>3</sub> extract gives the purified dye. [Brode et al. *J Am Chem Soc* **76** 1034 1954; spectral characteristics are listed, *Beilstein* **24** II 233, **24** III/IV 1791.]

**Indole** [120-72-9] **M 117.2, m 52°, 54.5°, b 124°/5mm, 253-254°/760mm, pK<sub>1</sub><sup>25</sup> -2.47 (H<sub>0</sub> scale), pK<sub>2</sub><sup>25</sup> 16.97 (acidic NH).** Crystallise indole from \*benzene, hexane, petroleum ether, water or EtOH/water (1:10). It can be further purified by sublimation in a vacuum or by zone melting. The *picrate* forms orange crystals from

EtOH and has  $m$  175°. [*Beilstein* 20 II 196, 20 III/IV 3176, 20/7 V 5.]

**Indole-3-acetic acid (heteroauxin)** [87-51-4]  $M$  175.2,  $m$  167-169°(dec),  $pK_i^{25}$  -6.13 (aqueous  $H_2SO_4$ ),  $pK_2^{25}$  4.54 ( $CO_2H$ ). Recrystallise heteroauxin from EtOH/water [James & Ware *J Phys Chem* 89 5450 1985]. [*Beilstein* 22 III/IV 65.] Alternatively, recrystallise 30g of the acid with 10g of charcoal in 1L of hot water, filter and cool when 22g of colourless acid separate. Dry it and store it in a dark bottle away from direct sunlight [Johnson & Jacoby *Org Synth Coll Vol V* 654 1973]. The *picrate* has  $m$  178-180°. [*Beilstein* 22 H 66, 22 I 508, 22 II 50, 22 III/IV 1088.] It is a plant growth substance.

**3-Indoleacetonitrile** [771-51-7]  $M$  156.2,  $m$  33-36°, 36-38°,  $b$  157°/0.2mm, 158-160°/0.1mm, viscous oil  $n_D^{20}$  1.6097. Distil the nitrile at very high vacuum, and the viscous distillate crystallises on standing after a few days; the *picrate* has  $m$  127-128° (from EtOH) [Coker et al. *J Org Chem* 27 850 1962, Thesing & Schülde *Chem Ber* 85 324 1952]. Store it away from light. The *N-acetate* has  $m$  118° (from MeOH) and has  $R_F = 0.8$ , on Silica Gel F<sub>254</sub> in  $CHCl_2/MeOH$  19:1 [Buzas et al. *Synthesis* 129 1977]. [*Beilstein* 22 III/IV 1097, 22/3 V 74.] It is a plant growth substance.

**Indole-2-carboxaldehyde** [19005-93-7]  $M$  145.2,  $m$  138°, 140-141°, 138-142°,  $pK_{Est} < 1$ . Recrystallise the indole from aqueous MeOH ( $m$  141-142°),  $Et_2O$  ( $m$  138°) or sublime it *in vacuo* ( $m$  138°). The *N,N*-dimethylhydrazone [127280-17-5] has  $m$  105-106° (from hexane/\* $C_6H_6$ ). The *thiosemicarbazone* has  $m$  229° (dec) (from 50% aqueous EtOH) [Doyle et al. *J Chem Soc* 2854 1956]. The *2,4-dinitrophenylhydrazone* has  $m$  315-320° (dec) (from pyridine/MeOH). [Suzuki et al. *Chem Pharm Bull Jpn* 39 2170 1991, *Beilstein* 21 III/IV 3754.]

**Indole-3-propionic acid** [830-96-6]  $M$  189.2,  $m$  134-135°,  $pK^{25}$  4.95. Recrystallise it from EtOH/water [James & Ware *J Phys Chem* 89 5450 1985]. The *picrate* has  $m$  143-144°, and the *methyl ester* crystallises from \* $C_6H_6$  or MeOH with  $m$  81-83°. [*Beilstein* 22 III/IV 1113, 22/3 V 114.]

(±)-**Indoline-2-carboxylic acid (2,3-dihydro-1H-indole-2-carboxylic acid)** [78348-24-0]  $M$  163.2,  $m$  168°(dec),  $pK_{Est(1)} \sim 2.1$ ,  $pK_{Est(2)} \sim 3.8$ . Dissolve the acid in hot EtOH, add excess of dry  $Et_2O$  and cool to yield colourless plates that decompose in the range of 120-150°. The *amide* ( $m$  208-209°) crystallises as colourless plates which sublime at 150°/1.0mm and has  $\nu_{max}$  at 1625 $cm^{-1}$  (paraffin mull) [Hudson & Robertson *Aust J Chem* 20 1935 1967]. [*Beilstein* 22/2 V 421.] See Chapter 6, Catalysts-Part 1 for optical isomers

**Indolizine [pyrrocoline, pyrrolo(1,2-a)pyridine]** [274-40-8]  $M$  117,  $m$  73-74°, 75°,  $pK^{20}$  3.94 (**C-protonation**). Purify indolizine through an alumina column in \* $C_6H_6$  and elute with \* $C_6H_6$  (toluene could be used instead). The eluate contained in the fluorescent band (using UV light  $\lambda$  365nm) is collected, evaporated and the crystalline residue is sublimed twice at 40-50°/0.2-0.5mm. The colourless crystals have a *naphthalene* odour, darken on standing and should be stored in dark sealed containers. If the original sample is dark in color then it should be covered with water and steam distilled. The colourless crystals in the distillate are collected and dried between filter paper and sublimed. It protonates on C3 in aqueous acid. It should give one fluorescent spot on paper chromatography (Whatman 1) in 3% aqueous ammonia and in *n*-BuOH/AcOH/ $H_2O$  (4:1:1). The *picrate* has  $m$  101° from EtOH. [Armarego *J Chem Soc* 226 1964, Armarego *J Chem Soc (B)* 191 1966, Scholtz *Chem Ber* 45 734 1912, *Beilstein* 20 II 200, 20 III/IV 3195.]

**trans-Indol-3-ylacrylic acid** [1204-06-4]  $M$  187.2,  $m$  190-195°(dec), 195°(dec), 196°(dec), 195-196°(dec),  $pK_{Est} \sim 4.2$ . Recrystallise the acid from AcOH,  $H_2O$  or EtOAc/cyclohexane. UV in MeOH has  $\lambda_{max}$  at 225, 274 and 325nm. [Shaw et al. *J Org Chem* 23 1171 1958, constitution: Rappe *Acta Chem Scand* 18 818 1964, Moffatt *J Chem Soc* 1442 1957, Kimming et al. *Hoppe Seyler's Z Physiol Chem* 371 234 1958, *Beilstein* 22 V 249.]

**3-Indolylbutyric acid** [133-32-4]  $M$  203.2,  $m$  120-123°, 123-125°, 124°,  $pK^{25}$  4.84. Recrystallise the acid from  $H_2O$ . It is soluble in EtOH,  $Et_2O$  and  $Me_2CO$  but insoluble in  $CHCl_3$ . [Bowman & Islip *Chem Ind London* 154 1971, Jackson & Manske *J Am Chem Soc* 52 5029 1930, Albaum & Kaiser *Am J Bot* 24 420 1937.] It has also been recrystallised from EtOH/water [James & Ware *J Phys Chem* 89 5450 1985]. Its UV

has  $\lambda_{\max}$  at 278 and 320nm in isoPrOH [Elvidge *Quart J Pharm Pharmacol* **13** 219 1940]. The *methyl ester* has **m** 73-74° (from \*C<sub>6</sub>H<sub>6</sub>/petroleum ether) and **b** 230°/6mm [Bullock & Hand *J Am Chem Soc* **78** 5854 1951]. [Beilstein **22** III/IV 1128, **22/3** V 140.]

**3-Indolylpyruvic acid** [392-12-1] **M** 203.2, **m** ~210°(dec), **208-210°(dec)**, **219°(dec)**, **pK<sub>Est</sub>** ~2.4. Recrystallise the acid from Me<sub>2</sub>CO/\*C<sub>6</sub>H<sub>6</sub>, EtOAc/CHCl<sub>3</sub>, Me<sub>2</sub>CO/AcOH (crystals have 1 molecule of AcOH) and dioxane/\*C<sub>6</sub>H<sub>6</sub> (with 0.5 molecule of dioxane) [Shaw et al. *J Org Chem* **23** 1171 1958, Kaper & Veldstra *Biochim Biophys Acta* **30** 401 1958]. The *ethyl ester* has **m** 133° (from Et<sub>2</sub>O), and its *2,4-dinitrophenylhydrazone* has **m** 255° (from Me<sub>2</sub>CO). [Baker *J Chem Soc* 461 1946.] The *oxime* has **m** 157°(dec, from EtOAc/Et<sub>2</sub>O) and **pK<sup>20</sup>** 3.40 [Ahmad & Spenser *Canad J Chem* **39** 1340 1961]. [Beilstein **22** II 250, **22** III/IV 3080, **22/6** V 324.]

**7-Iodoindole** [89976-15-8] **M** 243.0, **m** 52-56°, **pK<sub>Est</sub>** <1. Purify 7-iodoindole by chromatography through a silica gel column and eluting with CH<sub>2</sub>Cl<sub>2</sub>/hexane (1:3, v/v) followed by recrystallisation from hexane (colourless plates, **m** 55-56°). [Somei et al. *Chem Pharm Bull Jpn* **35** 3146 1987, Somei & Saida *Heterocycles* **23** 3114 1985.]

**Iodinine (1,6-dihydroxyphenazine-5,10-dioxide)** [68-81-5] **M** 244.1, **m** 236°(dec), **pK<sup>25</sup>** 12.5. Purify iodinine through a column of silica gel and elute with Me<sub>2</sub>CO/CHCl<sub>3</sub>, then recrystallise it from CHCl<sub>3</sub> to give purple crystals with a copper-coloured luster. [Clemons & Dalgleish *J Chem Soc* 1481 1950, Gerber & Lechevalier *Biochemistry* **3** 598 1964, Beilstein **23** III/IV 3227,]

**Iodonitrotetrazolium chloride (2[4-iodophenyl]-3-[4-nitrophenyl]-5-phenyl-2H-tetrazolium chloride)** [146-68-9] **M** 505.7, **m** 229°(dec), ~245°(dec). Recrystallise the chloride from H<sub>2</sub>O, aqueous EtOH or EtOH/Et<sub>2</sub>O. Alternatively, dissolve it in the minimum volume of EtOH and add Et<sub>2</sub>O; or dissolve it in hot H<sub>2</sub>O (charcoal), filter and precipitate it by adding conc HCl. Filter the solid off and dry it at 100°. Its solubility in H<sub>2</sub>O at 25° is 0.5%, and in hot MeOH/H<sub>2</sub>O (1:1) it is 5%. [Fox & Atkinson *J Am Chem Soc* **72** 3629 1950, Beilstein **26** III/IV 1776.]

**Iodonitrotetrazolium violet-Formazan** [7781-49-9] **M** 471.3, **m** 185-186°. Dissolve it in boiling dioxane (20g in 300ml), add H<sub>2</sub>O (100ml) slowly, cool, filter and dry it *in vacuo* at 100°. Its solubility in CHCl<sub>3</sub> is ~1%. [UV: Fox & Atkinson *J Am Chem Soc* **72** 3629 1950, Beilstein **26** III/IV 1776.]

**Isatin (indole-2,3-dione)** [91-56-5] **M** 147.1, **m** 201-203°, 205°, **pK<sup>25</sup>** >12 (acidic NH). Crystallise isatin from amyl alcohol and sublime it at 180°/1mm. In aqueous NaOH the ring opens to yield sodium *o*-aminobenzoylformate. [Beilstein **21** II 327, 567, **21** III/IV 4981, **21/10** V 221.]

**Isatoic anhydride (3,1-benzoxazin-2,4[1-H]-dione)** [118-48-9] **M** 163.1, **m** 235-240°, 240-243°, 243°, 243-245°. Recrystallise it from EtOH or 95% EtOH (30ml/g) or dioxane (10ml/g) and dry it in a vacuum. [Wagner & Fegley *Org Synth Coll Vol III* 488 1955, Ben-Ishai & Katchalski *J Am Chem Soc* **74** 3688 1952, UV: Zentmyer & Wagner *J Org Chem* **14** 967 1949, Beilstein **27** II 299, **27** III/IV 3330.]

**3-Isobutyl-1-methylxanthine (3-isobutyl-1-methylpurine-2,6-dione)** [28822-58-4] **M** 222.3, **m** 199-210°, 202-203°, **pK<sub>Est</sub>** ~ 6.7 (acidic NH). Recrystallise it from aqueous EtOH. [Beilstein **26** III/IV 2350.]

**(+)-Isolysergic acid** [478-95-5] **M** 268.3, **m** 218°(dec),  $[\alpha]_{\text{D}}^{20}$  +281° (c 1, pyridine) **pK<sub>1</sub><sup>24</sup>** 3.33, **pK<sub>2</sub><sup>24</sup>** 8.46. It crystallises from water as the *dihydrate*. The *methyl ester* has **m** 172-174° (from MeOH or \*C<sub>6</sub>H<sub>6</sub>) and  $[\alpha]_{\text{D}}^{20}$  +179° (c 0.5 CHCl<sub>3</sub>). [Smith & Timmis *J Chem Soc* 1440 1936, Craig et al. *J Biochem* **125** 289 1938, Stenlake *J Chem Soc* 1626 1955, Leemann & Fabbri *Helv Chim Acta* **4** 2696 1959, Beilstein **25** III/IV 935.]

**Isonicotinamide** [1453-82-3] **M** 122.1, **m** 155.5-156°, **pK<sub>1</sub><sup>20</sup>** -1.0 (protonation of CONH<sub>2</sub>), **pK<sub>2</sub><sup>20</sup>** 3.61, **pK<sub>3</sub><sup>25</sup>** 11.47 (acidic CONH<sub>2</sub>). Recrystallise isonicotinamide from hot water or isopropanol (158.5-159°), and dry it in a vacuum at 100°. The *picrate* crystallises from aqueous EtOH or H<sub>2</sub>O and has **m** 217-218° (214-215°). [Beilstein **22** III/IV 527, **22/2** V 195.]

**Isonicotinic acid (pyridine-4-carboxylic acid)** [55-22-1] M 123.1, m 320°, 323-325°(dec), pK<sub>1</sub><sup>25</sup> 1.70, pK<sub>2</sub><sup>25</sup> 4.89. Crystallise the acid repeatedly from water and dry it under vacuum at 110° or sublime it at 260°/15mm (m 319°). [Beilstein 22 III/IV 518, 22/2 V 188.]

**Isonicotinic acid hydrazide (isoniazide)** [54-85-3] M 137.1, m 172°, pK<sub>1</sub> 1.75 (NHNH<sub>2</sub>), pK<sub>2</sub> 3.57 (=N-), pK<sub>3</sub> 10.75 (-NH). Crystallise isoniazide from 95% EtOH and dry it in a vacuum. [Beilstein 22 III/IV 545, 22/2 V 219.]

**1-Isonicotinyl-2-isopropylhydrazide (Iproniazid)** [54-92-2] M 179.2, m 112.5-113.5°, 114-115°, pK<sub>Est</sub> ~3.5. Crystallise it from \*benzene or \*benzene/petroleum ether and dry it in a vacuum. It is soluble in H<sub>2</sub>O and EtOH. [Fox & Gibas *J Org Chem* 18 994 1953.] The *dihydrochloride* has m 227-228° (from EtOH). [Beilstein 22 III/IV 551.] It is an antidepressant.

**1-Isonicotinyl-2-isopropylhydrazide phosphate (Iproniazid phosphate, Marsilide)** [305-33-9] M 277.2, m 178-179°, 180-184°, pK<sub>Est</sub> ~3.5 (free base). Crystallise it from H<sub>2</sub>O and Me<sub>2</sub>CO. The *free base* (see above) has m 113-114° from \*C<sub>6</sub>H<sub>6</sub>/petroleum ether and is soluble in H<sub>2</sub>O and EtOH. [Fox & Gibas *J Org Chem* 18 994 1953, Beilstein 22 III/IV 551.]

**1-Isonicotinyl-2-salicylidenehydrazide** [495-84-1] M 241.2, m 232-233°. Crystallise it from EtOH (m 265-266° or 244-245°), aqueous EtOH or MeOH (252-253°) and dry it in a vacuum at 100°. [Beilstein 22 III/IV 584.]

**5-Isonitrosobarbituric acid (violuric acid)** [26851-19-9] M 175.1, m 221-223°, 245-250°, pK<sub>1</sub> 4.41, pK<sub>2</sub> 9.66 (10.1). Crystallise violuric acid from water or EtOH. *1,1-Dimethylvioluric acid*, m 144-147° has pK<sub>25</sub> 4.72 [Taylor & Robinson *Talanta* 8 518 1961]. [Beilstein 24 III/IV 2142.]

**N-Isopropylcarbazole** [1484-09-9] M 209.3, m 120°. Crystallise it from isopropanol. It sublimes under vacuum. It was also purified by zone refining. The *picrate* has m 143° after recrystallisation from EtOH. [Beilstein 20 I 164.]

**Isoquinoline** [119-65-3] M 129.2, m 24°, 25.5-26°, b 120°/18mm, 243.25°/760mm, d<sub>4</sub><sup>20</sup> 1.0986, n<sub>D</sub><sup>20</sup> 1.6148, pK<sub>25</sub> 5.40. Dry isoquinoline with Linde type 5A molecular sieves or Na<sub>2</sub>SO<sub>4</sub> and fractionally distil at reduced pressure. *Alternatively*, it can be refluxed with, and distilled from, BaO. It is also purified by fractional crystallisation from the melt and distilled from zinc dust. It forms a *phosphate* (m 135°) and a *picrate* (m 223°), which are purified by crystallisation, and the free base can be recovered and distilled. [Packer et al. *J Am Chem Soc* 80 905 1958.] The procedure for purification *via* the picrate comprises the addition of quinoline to picric acid dissolved in the minimum volume of 95% EtOH to yield yellow crystals which are washed with EtOH and air dried before recrystallising from acetonitrile. The crystals are dissolved in dimethyl sulfoxide (previously dried over 4A molecular sieves) and passed through a basic alumina column, on which picric acid is adsorbed. The free base in the effluent is extracted with *n*-pentane and distilled under vacuum. Traces of solvent from small quantities are removed by vapour phase chromatography. The *hydrochloride* crystallises from EtOH with m 193°. [Mooman & Anton *J Phys Chem* 80 2243 1976, Beilstein 20 II 236, 20 III/IV 3410, 20/7 V 333.]

**Isoxanthopterin (2-amino-4,7-dihydroxypteridine)** [529-69-1] M 179.4, m >300°, pK<sub>1</sub><sup>20</sup> -0.5 (basic), pK<sub>2</sub><sup>20</sup> 7.34 (acidic), pK<sub>3</sub><sup>20</sup> 10.06 (acidic). Purify it by repeated precipitation from alkaline solution with acid (preferably AcOH or formic acid), filter, wash well with H<sub>2</sub>O, then EtOH and dry at 100°. The purity is checked by paper chromatography [R<sub>F</sub> 0.15 (*n*-BuOH/AcOH/H<sub>2</sub>O, 4:1:1); 0.33 (3% aqueous NH<sub>4</sub>OH)]. [Goto et al. *Arch Biochem Biophys* 111 8 1965.] [For biochemistry see Blakley *Biochemistry of Folic Acid and Related Pteridines* North Holland Publ Co, Amsterdam 1969.] [Beilstein 26 III/IV 3999.]

**Janus Green B (3-dimethylamino-7-[4-dimethylaminoazo]-5-phenylphenazonium chloride)** [2869-83-2] M 511.1, m >200°, CI 11050. The dye dissolves in H<sub>2</sub>O to give a bluish violet solution which becomes colourless when made 10M in NaOH. It dissolves in EtOH to give a blue-violet colour, filter from insoluble

material, then add dry Et<sub>2</sub>O whereby the dye separates out leaving a small amount of blue colour in solution. Filter off the solid and dry it in a vacuum. Store it in a dark bottle. [Colour Index Vol 4, 3<sup>rd</sup> edn, 4015 1971.]

**Jervine** (3β,23β-17,23-epoxy-2-hydroxyvertraman-11-one, a steroidal alkaloid) [469-59-0] M 425.6, m 243-245°, 247-248°, [α]<sub>D</sub><sup>20</sup> -150° (in EtOH), pK<sub>Est</sub>~9.4. Crystallise Jervine from MeOH/H<sub>2</sub>O or Me<sub>2</sub>O. The *hydrochloride* has m 300-302° (from MeOH/Et<sub>2</sub>O), and the *picrate* has m 262.5° (from aqueous MeOH). [Kutney et al. *Can J Chem* 53 1796 1975, *Beilstein* 27 III/IV 3590.] It is **teratogenic**.

**Julolidine** (2,3,6,7-tetrahydro-1H,5H-benzo[*ij*]quinolizidine) [479-59-4] M 173.3, m 34-36°, 40°, b 105-110°/1mm, 155-156°/17mm, 280°(dec), pK<sub>Est</sub>~7.0. Purify julolidine by dissolving it in dilute HCl, steam is bubbled through the solution and the residual acidic solution is basified with 10N NaOH, extracted with Et<sub>2</sub>O, washed with H<sub>2</sub>O, dried (NaOH pellets), filtered, evaporated and distilled *in vacuo*. The distillate crystallises on cooling (m 39-40°). It develops a red colour on standing in contact with air for several days. The colour can be removed by distilling or dissolving in 2-3 parts of hexane, adding charcoal, filtering and cooling in an Me<sub>2</sub>CO/Dry-ice bath when julolidine crystallises out (85-90% yield m 39-40°). The *hydrobromide* [83646-41-7] has m 218° (239-242°), the *picrate* has m 174°(165°) and the *methiodide* crystallises from MeOH, with m 186° [Glass & Weisberger *Org Synth Coll Vol III* 504 1955, Smith & Yu *J Org Chem* 17 1285 1952, *Beilstein* 20 H 332, 20 I 133, 20 II 214, 20 III/IV 3281.] **Highly TOXIC**.

**Kainic acid H<sub>2</sub>O** (2S,3S,4S-2-carboxy-4-isoprenyl-3-pyrrolidine- acetic acid) [487-79-6] M 231.4, m 235-245°(dec), 251°(dec), [α]<sub>D</sub><sup>20</sup> -14.6° (c 1.46, H<sub>2</sub>O), pK<sub>1</sub> 2.09, pK<sub>2</sub> 4.58, pK<sub>3</sub> 10.21. Purify the acid by adsorbing on to a strongly acidic ion-exchange resin (Merck), elute the diacid with aqueous M NaOH, the eluate is evaporated, H<sub>2</sub>O is added, and filtered through a weakly acidic ion-exchange resin (Merck). The filtrate is then evaporated and recrystallised from EtOH. Its solubility is 0.1g in 1ml of 0.5N HCl. (±)-α-Kainic acid is recrystallised from H<sub>2</sub>O with m 230-260°. Its UV (MeOH) has λ<sub>max</sub> at 219 (log ε 3.9); the <sup>1</sup>HNMR (CCl<sub>4</sub>, 100MHz, Me<sub>4</sub>Si standard) has δ at 1.64 (s 1H), 1.70 (s 3H), 3.24 (d J = 7.5, 2H), 3.3-4.2 (1H), 3.70 (s 3H), 3.83 (s 3H), 4.35 (dd J = 7.5, 14.5, 1H), 5.21 (t J = 7.5, 1H), 7.26 (t J = 7.5, 1H). [Oppolzer & Andres *Helv Chim Acta* 62 2282 1979, *Beilstein* 22 III/IV 1523.]

**Ketanserin** [3(4-*p*-fluorobenzoylpiperidinyl)-*N*-ethylquinazolin-2,4-dione] [74050-98-9] M 395.4, m 227-235°, pK<sup>25</sup> 7.5. Its solubility is 0.001% in H<sub>2</sub>O, 0.038% in EtOH and 2.34% in Me<sub>2</sub>NCHO. It has been purified by recrystallisation from 4-methyl-3-pentanone [Peeters et al. *Cryst Structure Commun* 11 375 1982, Kacprowicz et al. *J Chromatogr* 272 417 1983, Davies et al. *J Chromatogr* 275 232 1983]. It is an antihypertensive.

**Khellin** (4,9-dimethoxy-7-methyl-5-oxofuro[3,2-*g*]-1,2-chromene) [82-02-0] M 260.3, m 154-155°, b 180-200°/0.05mm. Crystallise khellin from H<sub>2</sub>O, MeOH, petroleum ether or Et<sub>2</sub>O. The *hydrochloride* has m 98°(dec) (from EtOH/HCl). [*Beilstein* 19 II 236, 19 III/IV 2816, 19/6 V 320.]

**Kojic acid** [(5-hydroxy-2-hydroxymethyl)-4H-pyran-4-one] [501-30-4] M 142.1, m 152°, 154-155°, pK<sub>1</sub><sup>25</sup> -1.38, pK<sub>2</sub><sup>25</sup> 7.66. Crystallise the acid from MeOH (charcoal) by adding Et<sub>2</sub>O. It sublimes at 150-200°/0.1 torr. [*Beilstein* 18 II 57, 18 III/IV 1145, 18/2 V 516.]

**Kynurenic acid** (4-hydroxyquinoline-2-carboxylic acid) [492-27-3] M 189.1, m 282-283°, 285°, pK<sub>Est(1)</sub>~2, pK<sub>Est(2)</sub>~10. Crystallise the acid from absolute EtOH. The *methyl ester* crystallises from MeOH with m 224-226°. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 p2723 1961., *Beilstein* 22 II 174, 22 III/IV 2245, 22/6 V 280.]

**L-Kynurenine** [343-65-7] M 208.2, m 190°(dec), 210°(dec), [α]<sub>D</sub><sup>20</sup> -30° (c 0.4, H<sub>2</sub>O), pK<sub>Est(1)</sub>~2.3, pK<sub>Est(2)</sub>~3.5, pK<sub>Est(3)</sub>~9.2. Crystallise it from H<sub>2</sub>O or aqueous AcOH. The *picrate* has m 188.5-189°(dec) after crystallisation from H<sub>2</sub>O. (±)-Kynurenine has m 218°. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 p2726 1961, *Beilstein* 14 III 1657, 14 IV 2562.]

**L-Kynurenine sulfate** [16055-80-4] **M 306.3, m 194°**, monohydrate **m 178°**,  $[\alpha]_{\text{D}}^{25} +9.6^{\circ}$  ( $\text{H}_2\text{O}$ ). Crystallise the sulfate from water by addition of EtOH. The ( $\pm$ )-sulfate has **m 173°**. [Beilstein 14 IV 2562.]

**dl- and l-Laudanosine** {1-[(3,4-dimethoxyphenyl)methyl]-1,2,3,4-tetrahydro-6,7-dimethoxy-2-methylisoquinoline} [(+)-1699-51-0, (-)-2688-77-9] **M 357.4, m 114-115°, 118°**. Crystallise these from EtOH. The ( $\pm$ )-picrate crystallises from EtOH with **m 177-178°**. The (-)-isomer has **m 83-85°** and  $[\alpha]_{\text{D}}^{24} -110^{\circ}$  (c 0.3, EtOH). The hydrobromide tetrahydrate [303136-74-5] **M 436.3** has **m 232-234°**. [Frydman et al. *Tetrahedron* 4 342 1958, Elliott *J Heterocycl Chem* 9 853 1972, *Beilstein* 21 II 183, 21 III/IV 2704.]

**Lumichrome (7,8-dimethylalloxazine)** [1086-80-2] **M 242.2, m >290°, pK<sub>Est(1)</sub> ~0.1 (basic), pK<sub>Est(2)</sub> ~9.9 (acidic)**. Recrystallise lumichrome twice from glacial AcOH and dry it at 100° in a vacuum. [Cresswell & Wood *J Chem Soc* 4768 1960, *Beilstein* 26 III/IV 2538.]

**Luminol (5-aminophthalazin-1,4-dione)** [521-31-3] **M 177.2, m 329-332°, pK<sub>1</sub> 3.37, pK<sub>2</sub> 6.35**. Dissolve luminol in KOH solution, treat with Norit (charcoal), filter and precipitate it with conc HCl. [Hardy et al. *Talanta* 24 297 1977.] Store it in the dark in an inert atmosphere, because its structure changes during its luminescence. It has been recrystallised from 0.1M KOH [Merenyi et al. *J Am Chem Soc* 108 77716 1986]. [Beilstein 25 II 389, 25 III/IV 4192.]

**dl-Lupinine (1-hydroxymethyloctahydroquinolizine, 1-hydroxymethylquinolizidine)** [10248-30-3] **M 169.3, m 57-58°, 59°, 107°/1mm, pK<sub>Est</sub> ~7.0**. It crystallises from Me<sub>2</sub>CO, pentane and petroleum ether (b. 40-60°) and can be sublimed or distilled in high vacuum. The picrate has **m 127°**(from Et<sub>2</sub>O), the picrolonate has **m 203-204°**, and the methiodide has **m 203°**(dec, from EtOH). [Clemo et al. *J Chem Soc* 969 1937, Boekelheide & Lodge *J Am Chem Soc* 73 3684 1951, *Beilstein* 21 II 28, 21 III/IV 291.]

**Lutidine (mixture)**. For the preparation of pure 2,3-, 2,4- and 2,5-lutidine from commercial “2,4- and 2,5-lutidine” see Coulson et al. *J Chem Soc* 1934 1959, and Kyte, Jeffery and Vogel *J Chem Soc* 4454 1960.

**2,3-Lutidine** [583-61-9] **M 107.2, f -14.8°, b 160.6°, d<sub>4</sub><sup>20</sup> 0.9464, n<sub>D</sub><sup>20</sup> 1.50857, pK<sup>25</sup> 6.57**. Steam distil it from a solution containing about 1.2 equivalents of 20% H<sub>2</sub>SO<sub>4</sub>, until ca 10% of the base has been carried over with the non-basic impurities. The acidic solution is then made alkaline, and the base is separated, dried over NaOH or BaO, and fractionally distilled. The distilled lutidine is converted to its urea complex by stirring 100g with 40g of urea in 75ml of H<sub>2</sub>O, cooling to 5°, filtering at the pump, and washing with 75ml of H<sub>2</sub>O. The complex, dissolved in 300ml of H<sub>2</sub>O, is steam distilled until the distillate gives no turbidity with a little solid NaOH. The distillate is then treated with excess solid NaOH, and the upper layer is removed: the aqueous layer is then extracted with diethyl ether. The upper layer and the ether extract are combined, dried (K<sub>2</sub>CO<sub>3</sub>), and distilled through a short column. Final purification is by fractional crystallisation using partial freezing. The picrate crystallises from EtOH with **m 187-188°**. [Kyte et al. *J Chem Soc* 4454 1960, *Beilstein* 20 H 243, 20 II 159, 20 III/IV 2765, 20/6 V 15.]

**2,4-Lutidine** [108-47-4] **M 107.2, b 157.8°, d<sub>4</sub><sup>20</sup> 0.9305, n<sub>D</sub><sup>20</sup> 1.50087, n<sub>D</sub><sup>25</sup> 1.4985, pK<sup>25</sup> 6.77**. Dry it with Linde type 5A molecular sieves, BaO (*do not use Na, see picolines below*), and fractionally distil it. The distillate (200g) is heated with \*benzene (500ml) and conc HCl (150ml) in a Dean and Stark apparatus on a water bath until water no longer separates, and the temperature just below the liquid reaches 80°. When cold, the supernatant \*benzene is decanted, and the 2,4-lutidine hydrochloride, after washing with a little \*benzene, is dissolved in water (350ml). After removing any \*benzene by steam distillation, an aqueous solution of NaOH (80g) is added, and the free lutidine is steam distilled. It is isolated by saturating the distillate with solid NaOH and distilling it through a short column. The precipitation cycle is repeated, then the final distillate is partly frozen in an apparatus at -67.8-68.5° (cooled by acetone/CO<sub>2</sub>). The crystals are collected, then melted and distilled. [Kyte et al. *J Chem Soc* 4454 1960.] *Alternative purifications are via the picrate m 183-184°* (from H<sub>2</sub>O). [Clarke & Rothwell *J Chem Soc* 1885 1960], or the hydrobromide [Warnhoff *J Org Chem* 27 4587 1962]. The latter is precipitated from a solution of lutidine in \*benzene by passing dry HBr gas: the salt is recrystallised from CHCl<sub>3</sub>/methyl ethyl ketone, then decomposed with NaOH, and the free base is extracted

into Et<sub>2</sub>O, dried, evaporated and the residue is distilled. [*Beilstein* 20 II 180, 20 III/IV 2718, 20/6 V 19.]

**2,5-Lutidine** [589-93-5] M 107.2, m -15.3°, b 156.7°/759mm, d<sub>4</sub><sup>20</sup> 0.927, n<sub>D</sub><sup>25</sup> 1.4982, pK<sup>25</sup> 6.40. Steam distil the lutidine from a solution containing 1-2 equivalents of 20% H<sub>2</sub>SO<sub>4</sub> until about 10% of the base has been carried over with the non-basic impurities, then the acidic solution is made alkaline, and the base is separated, dried with NaOH and fractionally distilled twice. Dry the distillate with Na and fractionally distil it through a Todd column packed with glass helices. The *hydrochloride* has m 219°(dec), and the *picrate* has m 170.5° (from EtOH or H<sub>2</sub>O). [*Beilstein* 20 H 244, 20 II 160, 20 III/IV 2774, 20/6 V 27.]

**2,6-Lutidine** [108-48-5] M 107.2, m -59°, b 144.0°, d<sub>4</sub><sup>20</sup> 0.92257, n<sub>D</sub><sup>20</sup> 1.49779, pK<sup>25</sup> 6.72. Likely contaminants include 3- and 4-picoline (similar boiling points). However, they are removed by using BF<sub>3</sub>, with which they react preferentially, by adding 4ml of BF<sub>3</sub> to 100ml of dry fractionally distilled 2,6-lutidine and redistilling. Distillation of commercial material from AlCl<sub>3</sub> (14g per 100ml) can also be used to remove picolines (and water). *Alternatively*, lutidine (100m) can be refluxed with ethyl benzenesulfonate (20g) or ethyl *p*-toluenesulfonate (20g) for 1 hour, then the upper layer is cooled, separated and distilled. The distillate is refluxed with BaO or CaH<sub>2</sub>, then fractionally distilled through a glass helices-packed column.

2,6-Lutidine can be dried with KOH (do not use Na, see picolines below) or by refluxing with (and distilling from) BaO, prior to distillation. For purification *via* its *picrate*, 2,6-lutidine, dissolved in absolute EtOH, is treated with an excess of warm ethanolic picric acid. The precipitate is filtered off, recrystallised from acetone (to give m 163-164.5° (166-167°), and partitioned between ammonia and CHCl<sub>3</sub>/diethyl ether. The organic layer, after washing with dilute aqueous KOH, is dried with Na<sub>2</sub>SO<sub>4</sub> and fractionally distilled. [Warnhoff *J Org Chem* 27 4587 1962.] *Alternatively*, 2,6-lutidine can be purified *via* its urea complex, as described under 2,3-lutidine. Other purification procedures include azeotropic distillation with phenol [Coulson et al. *J Appl Chem (London)* 2 71 1952], fractional crystallisation by partial freezing, and vapour-phase chromatography using a 180-cm column of polyethylene glycol-400 (Shell, 5%) on Embacel (May and Baker) at 100°, with argon as carrier gas [Bamford & Block *J Chem Soc* 4989 1961]. The *hydrochloride* has m 235-237°, 239° (from EtOH). [*Beilstein* 20 II 160, 20 III/IV 2776, 20/6 V 32.]

**3,5-Lutidine** [591-22-0] M 107.2, f -6.3°, b 172.0°/767mm, d<sub>4</sub><sup>20</sup> 0.9419, n<sub>D</sub><sup>20</sup> 1.50613, n<sub>D</sub><sup>25</sup> 1.5035, pK<sup>25</sup> 6.15. Dry 3,5-lutidine with CaH<sub>2</sub> and fractionally distil it through a Todd column packed with glass helices. Dissolve (100ml) in dilute HCl (1:4) and steam distil this until 1L of distillate is collected. Excess conc NaOH is added to the residue which is again steam distilled. The base is extracted from the distillate, using diethyl ether. The extract is dried over K<sub>2</sub>CO<sub>3</sub>, and distilled. It is then fractionally crystallised by partial freezing. The *hydrochloride* has m 229°(sublimes at 190-231°), and the *picrate* has m 242-243°(dec, from H<sub>2</sub>O), 249-250°(dec, from AcOH). [*Beilstein* 20 II 161, 20 III/IV 2788, 20/6 V 60.]

**Lycorine** [476-28-8] M 552.9, m 275-280°(dec), b 175-185°/0.002mm. [α]<sub>D</sub><sup>20</sup> -91° (c 0.16, EtOH), pK<sup>25</sup> 6.9 (30% aqueous dimethylformamide). It crystallises as orange crystals from MeOH (m 281-283°), CHCl<sub>3</sub>/EtOH (m 272-274°), pyridine or from EtOH (m 277° dec). It has been distilled under high vacuum. The *hydrochloride* has m 288° (from MeOH/HCl), and the *picrate* has m 196-197°(from EtOH), [Cook et al. *J Chem Soc* 4176 1954, Martin & Tu *J Org Chem* 46 3763 1981, *Beilstein* 27 II 547, 27 III/IV 6463.]

(+)-Lysergic acid [82-58-6] M 268.3, m 240°(dec), [α]<sub>D</sub><sup>20</sup> +40° (pyridine), pK<sub>1</sub><sup>25</sup> 3.32, pK<sub>2</sub><sup>25</sup> 8.66, pK<sup>20</sup> 8.50, pK<sup>40</sup> 8.27. It crystallises from water as a *hydrate*. The *methyl ester* crystallises from \*C<sub>6</sub>H<sub>6</sub> and has m 168°; the *amide* [478-94-4] has m 242°(dec) (from MeOH) and [α]<sub>546</sub> +15° (c 0.5, pyridine). The (-)-*hydrochloride* has m 208-210°(dec, from MeOH). [Kornfeld et al. *J Am Chem Soc* 76 5256 1954, Kornfeld et al. *J Am Chem Soc* 78 3087 1956, *Beilstein* 25 III/IV 934.]

**Maltol (3-hydroxy-2-methyl-4-pyrone)** [118-71-8] M 126.1, m 161-162°, 162-162.5°. It crystallises from CHCl<sub>3</sub>, toluene, aqueous 50% EtOH or H<sub>2</sub>O, and is volatile in steam. It can be readily sublimed in a vacuum. It forms a Cu<sup>2+</sup> complex. [*Beilstein* 17 III/IV 5916, 18/1 V 114.]

**Meconic acid (3-hydroxy-γ-pyrone-2,6-dicarboxylic acid)** [497-59-6] M 200.1, m 100° (loses H<sub>2</sub>O), pK<sub>1</sub><sup>25</sup>

**1.83, pK<sub>2</sub><sup>25</sup> 2.3, pK<sub>3</sub><sup>20</sup> 10.10.** Crystallise the acid from water (0.25g/ml) and dry it at 100° for 20 minutes to dehydrate the *mono* or *dihydrate*. It decarboxylates above 120° or in boiling H<sub>2</sub>O. It is soluble in MeOH (2%), EtOAc (2%) and Me<sub>2</sub>CO (1%). The *picrate* has **m** 206.5-208.5°(dec, from H<sub>2</sub>O). [Wibaut & Kleinpool *Rec Trav Chim Pays Bas* **66** 24 1947, *Beilstein* **18** H 409, **18** I 523, **18** II 367, **18** III/IV 6136.]

**Melamine (2,4,6-triamino-1,3,5-triazine)** [108-78-1] **M 126.1, m 353°**, **pK<sup>25</sup> 5.00.** Crystallise Melamine from water or dilute aqueous NaOH. It sublimes at ~240° on prolonged heating. [*Beilstein* **26** I 74, **26** II 132, **26** III/IV 1253.]

**(±)-Mellein [(±)-3,4-dihydro-8-hydroxy-3-methyl-2-benzopyran-1-one, 8-hydroxy-3-methylisochroman-1-one]** [1200-93-7] **M 178.2, m 37-39°, 39°, pK<sub>Est</sub> ~9.5.** Purify it by recrystallisation from H<sub>2</sub>O or aqueous EtOH. It has UV with λ<sub>max</sub> at 247 and 314nm. [Arakawa et al. *Justus Liebigs Ann Chem* **728** 152 1969, Blair & Newbold *Chem Ind (London)* 93 1955, *J Chem Soc* 2871 1955.] The *methyl ether* has **m** 66-67° and UV with λ<sub>max</sub> at 242nm (ε 7,400) and 305nm (ε 4,600). *R(-)-Mellein* has **m** 56°(aqueous Me<sub>2</sub>CO), [α]<sub>D</sub><sup>25</sup> -102.5° (c 1, CHCl<sub>3</sub>) and *R(+)-mellein* has **m** 56-57°(hexane), [α]<sub>D</sub><sup>25</sup> +102° (c 1, CHCl<sub>3</sub>) or [α]<sub>D</sub><sup>25</sup> +88° (c 1, MeOH). [*Beilstein* **18** III/IV 188, **18**/I V 274.]

**2-Mercaptobenzimidazole** [583-39-1] **M 150.2, m 302-304°, 312°, pK<sup>20</sup> 10.24.** Crystallise it from aqueous EtOH, AcOH or aqueous ammonia. It complexes with many metals. [Brown *J Chem Soc* 1976 1958, *Beilstein* **24** II 65, **24** III/IV 287.]

**2-Mercaptobenzothiazole** [149-30-4] **M 167.2, m 182°, pK<sup>25</sup> 7.5 (50% aqueous AcOH).** Crystallise it repeatedly from 95% EtOH, or purify it by incomplete precipitation by dilute H<sub>2</sub>SO<sub>4</sub> from a basic solution, followed by several crystallisations from acetone/H<sub>2</sub>O or \*benzene. It complexes with Ag, Au, Bi, Cd, Hg, Ir, Pt, and Tl. [*Beilstein* **27** II 233, **27** III/IV 2709.]

**2-Mercaptoimidazole** [872-35-5] **M 100.1, m 221-222°, 226-228°(monohydrate), pK<sub>1</sub><sup>20</sup> -1.6, pK<sub>2</sub><sup>20</sup> 11.6.** Crystallise 2-mercaptoimidazole from Me<sub>2</sub>CO or H<sub>2</sub>O. Its UV has λ<sub>max</sub> at 208 and 252nm (H<sub>2</sub>O). [Fox et al. *J Am Chem Soc* **67** 496 1947, *Beilstein* **24** II 7, **24** III/IV 61.]

**2-Mercapto-1-methylimidazole** [60-56-0] **M 114.2, m 145-147°, 146-148°, pK<sub>1</sub><sup>20</sup> -2.0, pK<sub>2</sub><sup>20</sup> 11.9.** Crystallise it from EtOH. Its UV has λ<sub>max</sub> at 251nm (H<sub>2</sub>O), 260nm (EtOH) and 267nm (CHCl<sub>3</sub>). [Lawson & Morley *J Chem Soc* 1103 1956, *Beilstein* **24** H 17, **24** III/IV 61.]

**6-Mercaptopurine monohydrate** [6112-76-1] **M 170.2, m 314-315°(dec), ~315°(dec), 313-315°(dec), pK<sub>1</sub><sup>20</sup> 0.5, pK<sub>2</sub><sup>20</sup> 7.77, pK<sub>3</sub><sup>20</sup> 10.84.** Crystallise 6-mercaptoquinoline from pyridine (30ml/g), wash it with pyridine, then triturate with water (25ml/g) and adjust to pH 5 by adding M HCl. Recrystallise it by heating, then cooling, the solution. Filter off the solid, wash it with water and dry it at 110°. It has also been crystallised from water (charcoal) as yellow crystals of the *monohydrate* which become *anhydrous* on drying at 140°. It has UV with λ<sub>max</sub> at 230 and 312nm (ε 14,000 and 19,600) in 0.1N NaOH; 222 and 327nm (ε 9,2400 and 21,300), and 216 and 329nm (ε 8,740 and 19,300) in MeOH. It forms a 1:1 complex with Zn<sup>2+</sup>, Pb<sup>2+</sup>, Co<sup>2+</sup>, and Ni<sup>2+</sup> in aqueous dioxan. It is an antineoplastic. [Albert & Brown *J Chem Soc* 2060 1954, IR: Brown & Mason *J Chem Soc* 682 1957, UV: Fox et al. *J Am Chem Soc* **80** 1669 1958, UV: Mason *J Chem Soc* 2071 1954, *Beilstein* **26** III/IV 2097.]

**8-Mercaptoquinoline (2H<sub>2</sub>O, thioxine)** [491-33-8] **M 197.3, m 58-59°, pK<sub>1</sub><sup>25</sup> 2.0, pK<sub>2</sub><sup>25</sup> 8.40.** Thioxine readily oxidises in air to give diquinolyl-8,8'-disulfide (which is stable). It is more convenient to make 8-mercaptoquinoline by reduction of the disulfide. [Nakamura & Sekido *Talanta* **17** 515 1970.] The *hydrochloride* (see thioxine hydrochloride below) is more stable. [*Beilstein* **21** III/IV 1197, **21**/3 V 30.]

**3-Methoxycarbonyl-2,5-dihydrothiophen-1,1-dioxide (methyl 3-sulfolene-3-carboxylate)** [67488-50-0] **M 176.1, m 57-58°, 60-62°.** If the IR shows OH bands, then dissolve the dioxide in CHCl<sub>2</sub>, wash it with aqueous Na<sub>2</sub>CO<sub>3</sub> and H<sub>2</sub>O, dry it over MgSO<sub>4</sub>, filter, evaporate and wash the residue with cold Et<sub>2</sub>O and dry *in vacuo*. Its <sup>1</sup>HNMR (CDCl<sub>3</sub>) has δ at 7.00 (m 1H), 3.98 (bs 4H) and 3.80 (s Me). [McIntoch & Sieber *J Org Chem* **43**

4431 1978, *Beilstein* **18/6** V 5.]

**5-Methoxyindole** [1006-94-6] **M 147.2**, **m 55°, 57°**, **b 176-178°/17mm**, **pK<sub>Est</sub> ~0**. Crystallise 5-methoxyindole from cyclohexane petroleum ether or petroleum ether/Et<sub>2</sub>O. [Saito & Kikugawa *J Heterocycl Chem* **16** 1325 1979, *Beilstein* **21** III/IV 765, **21/3** V 18.]

**5-(*p*-Methoxyphenyl)-1,2-dithiole-3-thione** [42766-10-9] **M 240.2**, **m 111°**. Crystallise the thione from EtOAc, BuOAc or EtOH. It sublimes at 90°/0.001mm and complexes with Sb<sup>3+</sup>, Sb<sup>5+</sup>, Bi<sup>3+</sup>, Sn<sup>4+</sup>, Ag<sup>+</sup>, Au<sup>3+</sup> and Hg<sup>2+</sup>. [*Beilstein* **19** III/IV 2538.]

**8-Methoxypsoralen (Methoxsalen)** See xanthotoxin in “Miscellaneous Compounds” in Chapter 7.

**6-Methylaminopurine** [443-72-1] **M 149.2**, **m >300°, 312-314° (dec)**, **pK<sub>1</sub><sup>20</sup> <1**, **pK<sub>2</sub><sup>20</sup> 4.15**, **pK<sub>3</sub><sup>20</sup> 10.02**. The purine is best purified by recrystallising 2g from 50ml of H<sub>2</sub>O and 1.2g of charcoal. [UV: Albert & Brown *J Chem Soc* 2060 1954; UV: Mason *J Chem Soc* 2071 1954; see also Elion et al. *J Am Chem Soc* **74** 411 1952.] The *picrate* has **m 265°(257°)** [Bredereck et al. *Chem Ber* **81** 307 1948]. [*Beilstein* **26** III/IV 3565.]

**Methyl 3-aminopyrazine-2-carboxylate** [16298-03-6] **M 153.1**, **m 169-172°, 172°**. The ester forms yellow needles from H<sub>2</sub>O (100 parts using charcoal). If it contains the free acid (see IR), then dissolve it in CH<sub>2</sub>Cl<sub>2</sub>, wash it with saturated aqueous Na<sub>2</sub>CO<sub>3</sub>, brine, dry over MgSO<sub>4</sub> filter, evaporate and recrystallise the residue. The *free acid* has **m 203-204° (dec)** [UV: Brown & Mason *J Chem Soc* 3443 1956] with **pK<sub>1</sub> <1** and **pK<sub>2</sub> 3.70**. The *ammonium salt* has **m 232°(dec)** (from aqueous Me<sub>2</sub>CO) and the *amide* has **m 239.2°** (from H<sub>2</sub>O) [Ellingson et al. *J Am Chem Soc* **67** 1711 1945]. [*Beilstein* **25** III/IV 4412.]

**9-Methylcarbazole (*N*-methylcarbazole)** [1484-12-4] **M 181.2**, **m 87°, 89°**. Purify *N*-methylcarbazole by chromatography on silica gel and eluting with CHCl<sub>3</sub>/Me<sub>2</sub>CO/Et<sub>2</sub>O (100:5:1 v/v), or by flash chromatography using petroleum ether, or by zone melting followed by recrystallisation from petroleum ether or EtOH. [Flo & Pindus *Annalen* 509 1987, Kashima et al. *J Heterocycl Chem* **24** 913 1987, UV: Armarego *Physical Methods in Heterocyclic Chemistry* (Ed Katritzky, Academic Press) **Vol III** 158 1971, *Beilstein* **20** H 436.]

**5-Methylcytosine [4-amino-5-methylpyrimidin-2(1*H*)-one]** [554-01-8] **M 125.1**, **m 270°(dec)**, **pK<sub>1</sub> 4.6**, **pK<sub>2</sub> 12.4**. Crystallise it from water (solubility is 3.4%). The *hydrochloride* has **m 299-301°** (sintering at 280°) (from aqueous HCl/Me<sub>2</sub>CO). [Hitchings et al. *J Biol Chem* **177** 537 1949, Cohn *J Am Chem Soc* **73** 1539 1951, *Beilstein* **25** II 183, **25** III/IV 3727.]

**2-Methyl-1,3-dithiane** [6007-26-7] **M 134.3**, **b 53-54°/1.1mm**, **66°/5mm**, **79-80°/8-10mm**, **85°/12mm**, **d<sub>4</sub><sup>20</sup> 1.121**, **n<sub>D</sub><sup>20</sup> 1.560**. Wash the dithiane with H<sub>2</sub>O, 2.5 M aqueous NaOH, H<sub>2</sub>O, brine, dry over K<sub>2</sub>CO<sub>3</sub> (use toluene as solvent if the volume of reagent is small), filter, evaporate and distil the colourless residue. Its IR film has  $\nu_{\max}$  at 1455, 1371 and 1060 (all medium and CH<sub>3</sub>), 1451m, 1422s, 1412m, 1275m, 1236m, 1190m, 1171w, 918m and 866w (all dithiane) cm<sup>-1</sup> [Corey & Erickson *J Org Chem* **36** 3553 1971, Seebach & Corey *J Org Chem* **40** 231 1975]. [*Beilstein* **19** III/IV 49, **19/1** V 53.]

**Methylene Blue [3,7-bis-(dimethylamino)phenothiazin-5-ium chloride]** [61-73-4] **M 319.9**, **CI 52015**,  $\epsilon_{654}$  **94,000 (EtOH)**,  $\epsilon_{664}$  **81,000 (H<sub>2</sub>O)**, **pK<sup>25</sup> 3.8**. Crystallise the chloride from 0.1M HCl (16ml/g), the crystals are separated by centrifugation, washed with chilled EtOH and diethyl ether, and dried under vacuum. Crystallise it from 50% aqueous EtOH, wash it with absolute EtOH, and dry it at 50-55° for 24 hours. It has also been crystallised from \*benzene/MeOH (3:1). It has been salted out with NaCl from a commercial concentrated aqueous solution, then crystallised from water, and dried at 100° in an oven for 8-10 hours. [*Beilstein* **27** III/IV 5152.]

**Methylene Green [3,7-bis-(dimethylamino)-4-nitrophenothiazin-5-ium chloride]** [2679-01-8] **M 364.9**, **m >200°(dec)**, **CI 52020**, **pK<sup>25</sup> 3.2**. Crystallise the dye three times from water (18ml/g). [*Beilstein* **27** H 399.] The *ZnCl<sub>2</sub> double salt* [6722-15-2] **M 866.0** has the same **CI**. [*Beilstein* **27** III/IV 5157.]

**2-Methylene-oxetan-2-one (diketene)** [674-82-8] M 84.1, m  $-7^{\circ}$ , b  $41^{\circ}/50.5\text{mm}$ ,  $66-68^{\circ}/90\text{mm}$ ,  $127^{\circ}/760\text{mm}$ ,  $d_4^{20}$  1.440,  $n_D^{20}$  1.4376,  $n_D^{25}$  1.4348. Diketene polymerises violently in the presence of alkali. Distil it under reduced pressure, then fractionally crystallise it by partial freezing (using as a cooling bath made from a 1:1 solution of  $\text{Na}_2\text{S}_2\text{O}_3$  in water, cool with Dry-ice until slushy, and store it in a Dewar flask). Freezing proceeds slowly, and takes about a day for half completion. The crystals are separated and stored in a refrigerator under  $\text{N}_2$ . [Miller & Carlson *J Am Chem Soc* 79 3995 1957, Andreades & Carlson *Org Synth Coll Vol V* 679 1973, *Beilstein* 7 H 552, 7 I 309, 7 II 525, 1 III 2947, 17 III/IV 4297, 17/9 V 115.] See ketene [463-51-4] in “Aliphatic Compounds”, in this Chapter.

**2-Methylfuran (Silvan)** [534-22-5] M 82.1, f  $-90.19^{\circ}$ , b  $62.7-62.8^{\circ}/731\text{mm}$ ,  $d_4^{20}$  0.917,  $n_D^{20}$  1.436. Wash it with acidified saturated ferrous sulfate solution (to remove peroxides), separate, dry with  $\text{CaSO}_4$  or  $\text{CaCl}_2$ , and fractionally distil it from KOH immediately before use. To reduce the possibility of spontaneous polymerisation, addition of about one-third of its volume of heavy mineral oil to 2-methylfuran prior to distillation has been recommended. [*Beilstein* 17 H 36, 17 I 18, 17 II 39, 17 III/IV 265.]

**1-Methylguanidine** [938-85-2] M 165.2, m  $>300^{\circ}(\text{dec})$ ,  $\text{pK}_1^{20} \sim 0$ ,  $\text{pK}_2^{20}$  3.13,  $\text{pK}_3^{20}$  10.54. Crystallise it from  $\text{H}_2\text{O}$  or 50% aqueous acetic acid. [*Beilstein* 26 III/IV 3892.]

**7-Methylguanidine** [578-76-7] M 165.2,  $\text{pK}_1^{20} \sim 0$ ,  $\text{pK}_2^{20}$  3.50,  $\text{pK}_3^{20}$  9.95. Crystallise it from water. It has UV with  $\lambda_{\text{max}}$  at 280nm (pH 2.1). The *picrate* has m  $267^{\circ}$  ( $270-272^{\circ}$  dec, also reported). [*Beilstein* 26 H 455, 26 I 134, 26 II 263, 26 III/IV 3890.]

**N-Methylimidazole** [616-47-7] M 82.1, b  $81-84^{\circ}/27\text{mm}$ ,  $197-198^{\circ}/760\text{mm}$ ,  $d_4^{20}$  1.032,  $n_D^{20}$  1.496,  $\text{pK}^{25}$  7.25. Dry it with sodium metal and then distil it. Store it at  $0^{\circ}$  under dry argon. The *picrate* has m  $159.5-160.5^{\circ}$  (from  $\text{H}_2\text{O}$ ). [*Beilstein* 23 III/IV 568.]

**2-Methylimidazole (2-methylglyoxaline)** [693-98-1] M 82.1, m  $140-141^{\circ}$ ,  $144.5-145.5^{\circ}$ , b  $267^{\circ}/760\text{mm}$ ,  $\text{pK}^{25}$  7.86. Recrystallise 2-methylimidazole from \*benzene or petroleum ether. The *picrate* has m  $215^{\circ}$  (from  $\text{H}_2\text{O}$ ). [*Beilstein* 23 III/IV 594, 23/5 V 35.]

**4-Methylimidazole** [822-36-6] M 82.1, m  $47-48^{\circ}$ , b  $263^{\circ}/760\text{mm}$ ,  $\text{pK}^{25}$  7.61. Recrystallise 4-methylimidazole from \*benzene or petroleum ether. It has m  $56^{\circ}$  after sublimation. The *picrate* has m  $162-163.5^{\circ}$  (from EtOH). [*Beilstein* 23 II 60, 23 III/IV 597, 23/5 V 89.]

**2-Methylindole** [95-20-5] M 131.2, m  $61^{\circ}$ ,  $\text{pK}^{25}$   $-0.28$  (C-3 protonation, aqueous  $\text{H}_2\text{SO}_4$ ). Crystallise it from \*benzene. It has also been purified by zone melting. The *picrate* has m  $139^{\circ}$  (from  $\text{Et}_2\text{O}$  or  $\text{Et}_2\text{O}/\text{MeOH}$ ). [Cohen et al. *J Am Chem Soc* 82 2184 1960, *Beilstein* 20 III/IV 3202, 20/7 V 59.]

**3-Methylindole (skatole)** [83-34-1] M 131.2, m  $95^{\circ}$ ,  $\text{pK}^{25}$   $-4.55$  (C-3-protonation, aqueous  $\text{H}_2\text{SO}_4$ ). Crystallise skatole from \*benzene or petroleum ether (m  $96.5^{\circ}$ ). It has also been purified by zone melting. The *picrate* has m  $182^{\circ}$  (from  $\text{Et}_2\text{O}$  or  $\text{Et}_2\text{O}/\text{MeOH}$ ). [*Beilstein* 20 III/IV 3206, 20/7 V 69.]

**N-Methylmorpholine (4-methylmorpholine)** [109-02-4] M 101.2, b  $116-117^{\circ}/764\text{mm}$ ,  $d_4^{20}$  0.919,  $n_D^{20}$  1.436,  $\text{pK}^{25}$  7.41. Dry it by refluxing with BaO or sodium, then fractionally distil it through a helices-packed column. The *picrate* has m  $227^{\circ}$ , the *thiocyanate salt* has m  $103^{\circ}$  (from butanone). [Hall *J Phys Chem* 60 63 1956, *Beilstein* 27 I 203, 27 III/IV 22.]

**4-Methylmorpholine-4-oxide monohydrate** [7529-22-8] M 135.2, m  $71-73^{\circ}$ . When the oxide is dried for 2-3 hours at high vacuum, it dehydrates. Add MeOH to the oxide and distil off the solvent under vacuum until the temperature is *ca*  $95^{\circ}$ . Then add  $\text{Me}_2\text{CO}$  at reflux and cool to  $20^{\circ}$ . The crystals are filtered off, washed with  $\text{Me}_2\text{CO}$  and dried. The degree of hydration may vary and may be important for the desired reactions. [van Rheen et al. *Tetrahedron Lett* 1973 1076, Schneider & Hanze *US Pat* 2 769 823; see also Sharpless et al. *Tetrahedron Lett* 2503 1976.]

**3-Methyl-2-oxazolidone** [19836-78-3] M 101.1, m 15°, b 88-91°/1mm,  $d_4^{20}$  1.172,  $n_D^{20}$  1.455. Purify the oxazolidone by successive fractional freezing, then dry it in a dry-box over 4A molecular sieves for 2 days. Distil it under high vacuum and store it dry as before. [Beilstein 27 III/IV 2517.]

**3-Methyl-3-oxetanemethanol (3-hydroxymethyl-3-methyloxetane)** [3143-02-0] M 102.1, b 80°/4mm, 92-93°/12mm,  $d_4^{20}$  1.033,  $n_D^{25}$  1.4449. Purify the oxetane by fractionation through a glass column [Pattison *J Am Chem Soc* 79 3455 1957, Corey et al. *J Am Chem Soc* 106 2736 1984]. [Beilstein 17 III/IV 1128.]

**5-Methyl-1,10-phenanthroline** [3002-78-6] M 194.2, m 67°(monohydrate), 113°(anhydrous),  $pK^{25}$  5.28. Crystallise it from \*benzene/petroleum ether or from H<sub>2</sub>O as the monohydrate. It complexes with many metals. [Beilstein 23 III/IV 1714.]

**5-Methylphenazinium methyl sulfate** [299-11-6] M 306.3, m 155-157° (198°dec by rapid heating),  $pK^{25}$  -3.5. It forms yellow-brown prisms from EtOH (charcoal), or EtOH/Et<sub>2</sub>O. Its solubility in H<sub>2</sub>O at 20° is 10%. In the presence of aqueous KI it forms a *semiquinone* which crystallises as blue leaflets from EtOH. [Wieland & Roseen *Chem Ber* 48 1117 1913, Voriskova *Col Czech Chem Commun* 12 607 1947, Bülow *Chem Ber* 57 1431 1924, Campbell et al. *J Chem Soc* 404 1938, Morley *J Chem Soc* 4008 1952, Beilstein 23 I 59, 23 II 234, 23 III/IV 1658, 23/8 V 395.]

**N-Methylphenothiazine (10-methylphenothiazine)** [1207-72-3] M 213.2,  $\alpha$ -form m 99.3°, 100-102°, and b 360-365°,  $\beta$ -form m 78-79°. Recrystallise it (three times) from EtOH to give the  $\alpha$ -form (prisms). Recrystallisation from EtOH/\*benzene gives the  $\beta$ -form (needles). It has also been purified by vacuum sublimation and is carefully dried in a vacuum line. It has been crystallised from toluene or MeOH and stored in the dark [Guarr et al. *J Am Chem Soc* 107 5104 1985, Olmsted et al. *J Am Chem Soc* 109 3297 1987]. Its solubility in H<sub>2</sub>O (pH 6.5) is 0.0544mg/100ml, and in hexane it is 2083mg/100ml. Its UV has  $\lambda_{max}$  at 255nm (log $\epsilon$  4.60) (pH 6.3) and 255nm in hexane. [Cymerman-Craig & Warburton *Aust J Chem* 9 294 1956, Beilstein 27 II 33, 27 III/IV 1215.]

**3-Methyl-1-phenyl-5-pyrazolone** [89-25-8] M 174.2, m 127°, 129°,  $pK^{25}$  2.7. Crystallise the pyrazolone from hot H<sub>2</sub>O, EtOH or EtOH/water (1:1). It complexes with metals. [Veibel et al. *Acta Chim Scand* 6 1066 1952, Beilstein 24 II 9, 24 III/IV 71.]

**1-Methyl-4-phenyl-1,2,3,6-tetrahydropyridine hydrochloride (MPTP)** [23007-85-4] M 209.7, m 196-198°,  $pK_{Est}$  ~9.3,  $pK_a$  8.07 (50% aqueous EtOH). Purify MPTP by recrystallisation from Me<sub>2</sub>CO/isoPrOH. The *free base* has m 40-42° (from heptane), b 99-100°/1.3mm, 128-132°/12mm, (137-142°/0.8mm),  $n_D^{25}$  1.5347. The *hydrochloride* has m 251-252° (from Me<sub>2</sub>CO/isoPrOH) [Schmidle & Mansfield *J Am Chem Soc* 78 425 1956, Defeudis *Drug Dev Res* 15 1 1988, Beilstein 20 III/IV 3240, 20/7 V 121.]

**(±)-2-Methylpiperazine** [109-07-9] M 100.2, m 61-62°, 66°, b 147-150°/739mm,  $pK_1^{25}$  5.46,  $pK_2^{25}$  9.90. Purify it by zone melting and by distillation. It is *hygroscopic*. The *picrate* has m 275-276°. [Beilstein 23 II 16, 23 III/IV 393, 23/3 V 267.]

**(±)-3-Methylpiperidine** [626-56-2] M 99.2, b 125°/763mm,  $d_4^{20}$  0.846,  $n_D^{25}$  1.4448,  $pK^{25}$  10.92. Purify it *via* the *hydrochloride* (m 172°). The *hydrobromide* has m 162-163° (from iso-PrOH). [Chapman et al. *J Chem Soc* 1925 1959, Beilstein 20 III/IV 1499, 20/4 V 100.]

**4-Methylpiperidine** [626-58-4] M 99.2, b 124.4°/755mm,  $d_4^{20}$  0.839,  $n_D^{25}$  1.4430,  $pK^{25}$  10.78. Purify it *via* the *hydrochloride* (m 189°). It is freed from 3-methylpyridine by zone melting. The *hydrobromide* has m 173° (from butanone/\*C<sub>6</sub>H<sub>6</sub>). [Beilstein 20 III/IV 1511, 20/4 V 116.]

**1-Methyl-4-piperidone** [1445-73-4] M 113.2, b 53-56°/0.5mm, 54-56°/9mm, 68-71°/17mm, 85-87°/45mm,  $d_4^{20}$  0.972,  $n_D^{25}$  1.4588,  $pK^{25}$  7.9. It is best purified by fractional distillation. The *hydrochloride* of the hydrate (4-diol) has m 94.7-95.5°, but the anhydrous *hydrochloride* which crystallises from CHCl<sub>3</sub>/Et<sub>2</sub>O has m 165-168° (164-167°), and can also be obtained by sublimation at 120°/2mm. The *oxime* has m 130-132° (from

Me<sub>2</sub>CO). The *methiodide* crystallises from MeOH, the crystals with 1MeOH have **m** 189-190°, and the solvent-free *iodide* has **m** 202-204°(dec). [Lyle et al. *J Org Chem* **24** 342 1959, Bowden & Green *J Chem Soc* 1164 1952, Tomita *Yakugaku Zasshi (J Pharm Soc Japan)* **71** 1053 1951, *Beilstein* **21** III/IV 3183, **21/6** V 419.]

**2-Methylpyrazine** [109-08-0] **M** 94.1, **f** -28.8°, **b** 136-137°, **d**<sub>4</sub><sup>20</sup> 1.025, **n**<sub>D</sub><sup>20</sup> 1.505, **pK**<sub>1</sub><sup>25</sup> -5.25 (aqueous H<sub>2</sub>SO<sub>4</sub>), **pK**<sub>2</sub><sup>25</sup> 1.47. Purify it *via* the picrate and distil the *free base*. The *picrate* has **m** 133-134°(from EtOH). [Wiggins & Wise *J Chem Soc* 4780 1956, *Beilstein* **23** III/IV 911, **23/5** V 386.]

**2-Methylpyridine (2-picoline)** [109-06-8] **M** 93.1, **b** 129.4°, **d**<sub>4</sub><sup>20</sup> 0.9444, **n**<sub>D</sub><sup>20</sup> 1.50102, **pK**<sup>25</sup> 5.96. Biddiscombe and Handley [*J Chem Soc* 1957 1954] steam distilled a boiling solution of the base in 1.2 equivalents of 20% H<sub>2</sub>SO<sub>4</sub> until about 10% of the base had been carried over, along with non-basic impurities. Excess aqueous NaOH is then added to the residue, the free base is separated, dried with solid NaOH and fractionally distilled.

2-Methylpyridine can also be dried with BaO, CaO, CaH<sub>2</sub>, LiAlH<sub>4</sub>, or Linde type 5A molecular sieves. An alternative purification is *via* the ZnCl<sub>2</sub> adduct, which is formed by adding 2-methylpyridine (90ml) to a solution of anhydrous ZnCl<sub>2</sub> (168g) and 42ml conc HCl in absolute EtOH (200ml). Crystals of the complex are filtered off, recrystallised twice from absolute EtOH (to give **m** 118.5-119.5°), and the free base is liberated by addition of excess aqueous NaOH. It is steam distilled, and solid NaOH is added to the distillate to form two layers, the upper one of which is then dried with KOH pellets, stored for several days with BaO and fractionally distilled. Instead of ZnCl<sub>2</sub>, HgCl<sub>2</sub> (430g in 2.4L of hot water) can be used. The complex, which separates on cooling, can be dried at 110° and recrystallised from 1% HCl (to **m** 156-157°). *The alkali metals, Na, Li or Cs should NOT be used for drying pyridine, and pyridine derivatives, as they form coloured pyridine radical anions leading to bipyridyls.* [see Schmulback et al. *J Am Chem Soc* **90** 6600 1968].

The *hydrochloride* has **m** 78-79°, and the *picrate* has **m** 165.5°(from EtOH) and 180°(from H<sub>2</sub>O). [*Beilstein* **20** III/IV 2679, **20/5** V 464.]

**3-Methylpyridine (3-picoline)** [108-99-6] **M** 93.1, **m** -18.5°, **b** 144°/767mm, **d**<sub>4</sub><sup>20</sup> 0.957, **n**<sub>D</sub><sup>20</sup> 1.5069, **pK**<sup>25</sup> 5.70. In general, the same methods of purification that are described for *2-methylpyridine* can be used. However, 3-methylpyridine often contains 4-methylpyridine and 2,6-lutidine, neither of which can be removed satisfactorily by drying and fractionation, or by using the ZnCl<sub>2</sub> complex. Biddiscombe and Handley [*J Chem Soc* 1957 1954], after steam distillation as for *2-methylpyridine*, treated the residue with urea to remove 2,6-lutidine, then azeotropically distilled with acetic acid (the azeotrope had **b** 114.5°/712mm), and recovered the base by adding excess of aqueous 30% NaOH, drying with solid NaOH and carefully fractionally distilling. The distillate is then fractionally crystallised by slow partial freezing. An alternative treatment [Reithoff et al. *Ind Eng Chem (Anal Edn)* **18** 458 1946] is to reflux the crude base (500ml) for 20-24 hours with a mixture of acetic anhydride (125g) and phthalic anhydride (125g) followed by distillation until phthalic anhydride begins to pass over. The distillate is treated with NaOH (250g in 1.5L of water) and then steam distilled. Addition of solid NaOH (250g) to this distillate (*ca* 2L) led to the separation of 3-methylpyridine which is removed, dried (K<sub>2</sub>CO<sub>3</sub>, then BaO) and fractionally distilled. (Subsequent fractional freezing would probably be advantageous.) *The alkali metals, Na, Li or Cs should NOT be used for drying pyridine, and pyridine derivatives, as they form coloured pyridine radical anions leading to bipyridyls.* [see Schmulback et al. *J Am Chem Soc* **90** 6600 1968]. The *hydrochloride* has **m** 85°, and the *picrate* has **m** 153°(from Me<sub>2</sub>CO, EtOH or H<sub>2</sub>O). [*Beilstein* **20** III/IV 2710, **20/5** V 506.]

**4-Methylpyridine (4-picoline)** [108-89-4] **M** 93.1, **m** 4.25°, **b** 145.0°/765mm, **d**<sub>4</sub><sup>20</sup> 0.955, **n**<sub>D</sub><sup>20</sup> 1.5058, **pK**<sup>25</sup> 4.99. It can be purified as for *2-methylpyridine*. Biddiscombe and Handley's method (above) for 3-methylpyridine is also applicable. Lidstone [*J Chem Soc* 242 1940] purified it *via* the *oxalate* (**m** 137-138°) by heating 100ml of 4-methylpyridine to 80° and adding slowly 110g of anhydrous oxalic acid, followed by 150ml of boiling EtOH. After cooling and filtering, the precipitate is washed with a little EtOH, then recrystallised from EtOH, dissolved in the minimum quantity of water and distilled with excess 50% KOH. The distillate is dried with solid KOH and again distilled. Hydrocarbons can be removed from 4-methylpyridine by converting the latter to its hydrochloride, crystallising from EtOH/diethyl ether, regenerating the free base by adding alkali and distilling. As a final purification step, 4-methylpyridine can be fractionally crystallised by partial freezing

to effect a separation from 3-methylpyridine. Contamination with 2,6-lutidine is detected by its strong absorption at 270nm. *The alkali metals, Na, Li or Cs should NOT be used for drying pyridine, and pyridine derivatives, as they form coloured pyridine radical anions leading to bipyridyls.* [see Schmulback et al. *J Am Chem Soc* **90** 6600 1968]. The *hydrochloride* has *m* 161°, and the *picrate* has *m* 167°(from Me<sub>2</sub>CO, EtOH or H<sub>2</sub>O). [*Beilstein* **20** III/IV 2732, **20/5** V 543.]

**2-Methylpyridin-5-yl trifluoromethanesulfonate (2-methyl-5-pyridine triflate)** [111770-91-3] *M* **241.2**, *b* **80-82°/1.9mm**, *d*<sub>4</sub><sup>25</sup> **1.412**, *n*<sub>D</sub><sup>20</sup> **1.442**. Distil the triflate under vacuum, or if it is discoloured dissolve it in CH<sub>2</sub>Cl<sub>2</sub>, wash it with N NaOH and half saturated K<sub>2</sub>CO<sub>3</sub>, dry it over solid K<sub>2</sub>CO<sub>3</sub>, filter, evaporate, and distil by bulb-to-bulb distillation at 65-70°/0.1mm, then redistil *in vacuo*. Its <sup>1</sup>H NMR [(CD<sub>3</sub>)<sub>2</sub>SO] has δ at 2.50 (s, 3H, Me), 7.45 (d, *J* = 9.2 Hz, 1H), 7.90 (dd, *J* = 9.2, 2.3 Hz, 1H) and 8.60 (d, *J* = 2.3 Hz, 1H). [Tilley & Zawoiski *J Org Chem* **53** 386 1988, Ellingboe et al. *J Med Chem* **37** 542 1994.] When stirred with *m*-chloroperbenzoic acid in CH<sub>2</sub>Cl<sub>2</sub> (16 hours, 25°), filtered, concentrated and purified by flash chromatography (2% MeOH/ CH<sub>2</sub>Cl<sub>2</sub>), the triflate gave colourless crystals of the *triflate N-oxide m* **47-48°** with <sup>1</sup>H NMR [(CD<sub>3</sub>)<sub>2</sub>SO] with δ at 2.36 (s, 3H, Me), 7.56 (dd, *J* = 8.9, 2.3 Hz, 1H), 7.69 (d, *J* = 8.9 Hz, 1H) and 8.84 (d, *J* = 2.3 Hz, 1H), Ellingboe et al. *J Med Chem* **37** 542 1994.]

***N*-Methylpyrrole** [96-54-8] *M* **81.1**, *b* **115-116°/756mm**, *d*<sub>4</sub><sup>20</sup> **0.908**, *n*<sub>D</sub><sup>20</sup> **1.487**, *pK*<sup>25</sup> **-3.4 (-2.90)**. Dry *N*-methylpyrrole with CaSO<sub>4</sub>, then fractionally distil it from KOH immediately before use. [*Beilstein* **20** III/IV 2080, **20/5** V 8.]

**1-Methyl-2-pyrrolidinone (1-methyl-2-pyrrolidone)** [872-50-4] *M* **99.1**, *f* **-24.4**, *b* **65-76°/1mm**, **78-79°/12mm**, **94-96°/20mm**, **202°/760mm**, *d*<sub>4</sub><sup>20</sup> **1.0328**, *n*<sub>D</sub><sup>20</sup> **1.4678**, *pK*<sup>25</sup> **-0.17 (also -0.92, and 0.2)**. Dry the pyrrolidone by removing water as the \*benzene azeotrope. Fractionally distil at 10 torr through a 100-cm column packed with glass helices. [Adelman *J Org Chem* **29** 1837 1964, McElvain & Voza *J Am Chem Soc* **71** 896 1949.] The *hydrochloride* has *m* 86-88° (from EtOH or Me<sub>2</sub>CO/EtOH) [Reppe et al. *Justus Liebigs Ann Chem* **596** 1 1955]. [*Beilstein* **21** II 213, **21** III/IV 3145, **21/6** V 321.]

**2-Methylquinoline (quinaldine)** [91-63-4] *M* **143.2**, *b* **86-87°/1mm**, **155°/14mm**, **246-247°/760mm**, *d*<sub>4</sub><sup>20</sup> **1.058**, *n*<sub>D</sub><sup>20</sup> **1.6126**, *pK*<sup>25</sup> **5.65**. Dry it with Na<sub>2</sub>SO<sub>4</sub> or by refluxing with BaO, then fractionally distil it under reduced pressure and redistil it from zinc dust. Purify it further by conversion to its *phosphate* (*m* 220°) or *picrate* (*m* 192°) from which after recrystallisation, the free base is regenerated. [Packer et al. *J Am Chem Soc* **80** 905 1958.] Its ZnCl<sub>2</sub> complex can be used for the same purpose. [*Beilstein* **20** III/IV 3454, **20** V 375.]

**4-Methylquinoline (lepidine)** [491-35-0] *M* **143.2**, *b* **265.5°**, *d*<sub>4</sub><sup>20</sup> **1.084**, *n*<sub>D</sub><sup>20</sup> **1.61995**, *pK*<sup>25</sup> **5.59**. Reflux lepidine with BaO, then fractionally distil it. Further purify it *via* its recrystallised *dichromate salt* (*m* 138°) (from H<sub>2</sub>O). [Cumper et al. *J Chem Soc* 1176 1962.] [*Beilstein* **20** III/IV 3477, **20/7** V 389.]

**6-Methylquinoline** [91-62-3] *M* **143.2**, *b* **258.6°**, *d*<sub>4</sub><sup>20</sup> **1.067**, *n*<sub>D</sub><sup>20</sup> **1.61606**, *pK*<sup>25</sup> **4.92**. Reflux it with BaO, then fractionally distil it. Further purified *via* its recrystallised *ZnCl<sub>2</sub> complex* (*m* 190°). [Cumper et al. *J Chem Soc* 1176 1962, *Beilstein* **20** III/IV 3498, **20/7** V 400.]

**7-Methylquinoline** [612-60-2] *M* **143.2**, *m* **38°**, *b* **255-260°**, *d*<sub>4</sub><sup>20</sup> **1.052**, *n*<sub>D</sub><sup>20</sup> **1.61481**, *pK*<sup>25</sup> **5.29**. Purify it *via* its *dichromate complex* (*m* 149°, after five recrystallisations from water). [Cumper et al. *J Chem Soc* 1176 1962, *Beilstein* **20** III/IV 3497, **20/7** V 402.]

**8-Methylquinoline** [611-32-5] *M* **143.2**, *b* **122.5°/16mm**, **247.8°/760mm**, *d*<sub>4</sub><sup>20</sup> **1.703**, *n*<sub>D</sub><sup>20</sup> **1.61631**, *pK*<sup>25</sup> **4.60**. Purify it as for 2-methylquinoline. The *phosphate* and *picrate* have *m* 158° and *m* 201°, respectively. [*Beilstein* **20** III/IV 3500, **20/7** V 405.]

**(±)-3-Methylsulfolane (3-methyl-tetrahydrothiophene-1,1-dioxide)** [872-93-5] *M* **134.2**, *m* **0.5°**, *b* **101°/2mm**, **125-130°/12mm**, **278-282°/763.5mm**, *d*<sub>4</sub><sup>20</sup> **1.1885**, *n*<sub>D</sub><sup>20</sup> **1.4770**. Distil the sulfolane under vacuum and recrystallise it from Et<sub>2</sub>O at -60° to -70°. An IR film has strong bands at 570 and 500 cm<sup>-1</sup>. [Eigenberger *J Prakt Chem* [2] **131** 289 1931, Freaheller & Katon *Spectrochim Acta* **20** 1099 1964, Whitehead et al. *J Am*

*Chem Soc* **73** 3632 1951, *Beilstein* **17** I 8, **17** III/IV 64.]

(±)-2-Methyltetrahydrofuran [96-47-9] **M 86.1, b 80.0°, d<sub>4</sub><sup>20</sup> 0.856, n<sub>D</sub><sup>20</sup> 1.4053.** Likely impurities are 2-methylfuran, methyl-dihydrofurans and hydroquinone (stabiliser, which is removed by distillation under reduced pressures). It is washed with 10% aqueous NaOH, dried, vacuum distilled from CaH<sub>2</sub>, passed through freshly activated alumina under nitrogen, and refluxed over sodium metal under vacuum. Store it over sodium. [Ling & Kevan *J Phys Chem* **80** 592 1976.] Distil it from sodium under vacuum, and store it with sodium-potassium alloy (this treatment removes water and prevents the formation of peroxides). *Alternatively*, it can be freed from peroxides by treatment with ferrous sulfate and sodium bisulfate, then solid KOH, followed by drying with, and distilling from, sodium, or type 4A molecular sieves under argon. It may be difficult to remove \*benzene if it is present as an impurity (can be readily detected by its ultraviolet absorption in the 249-268nm region). [Ichikawa & Yoshida *J Phys Chem* **88** 3199 1984.] It has also been purified by percolating through Al<sub>2</sub>O<sub>3</sub> and fractionated collecting fraction **b 79.5-80°**. After degassing, the material is distilled onto degassed molecular sieves, then distilled onto anthracene and a sodium mirror. The solvent is then distilled from the green solution onto potassium mirror or sodium-potassium alloy, from which it is distilled again. [Mohammad & Kosower *J Am Chem Soc* **93** 2713 1971.] It should be stored in the presence of 0.1% of hydroquinone or 2,6-di-*tert*-butyl-*p*-cresol as stabiliser. The *R*(+)-*enantiomer* has **b 78-80°/atm** and  $[\alpha]_D^{20} +27.5^\circ$  (neat), and the *S*(-)-*enantiomer* has **b 86°/atm** and  $[\alpha]_D^{20} -27.0^\circ$  (neat) [Iffland & Davis *J Org Chem* **42** 4150 1977, Gagnaire & Butt *Bull Soc Chim Fr* 312 1961, *Beilstein* **17** III/IV 60, **17**/I V 78.] **HARMFUL VAPOURS.**

**3-Methylthiophene** [616-44-4] **M 98.2, b 60°/116mm, 111-113°/atm, 115.5°/atm, d<sub>4</sub><sup>20</sup> 1.024, n<sub>D</sub><sup>20</sup> 1.531.** Dry it with Na<sub>2</sub>SO<sub>4</sub>, then distil it from sodium. [*Beilstein* **17** III/IV 277, **17**/I V 331.]

**6(4)-Methyl-2-thiouracil** [56-04-2] **M 142.2, m 330°(dec), 299-303°(dec), 323-324°(dec), pK<sup>25</sup> 8.1.** Crystallise the thiouracil from a large volume of H<sub>2</sub>O. Purify it further by dissolving in base, adding charcoal, filtering and acidifying with AcOH. Suspend the wet solid (*ca* 100g) in boiling H<sub>2</sub>O (1L), stir and add AcOH (20ml), stir and refrigerate. Collect the product, wash it with cold H<sub>2</sub>O (4 x 200ml), drain it for several hours then place it in an oven at 70° to constant weight. [IR: Short & Thompson *J Chem Soc* 168 1952, Foster & Snyder *Org Synth Coll Vol* **IV** 638 1063, *Beilstein* **24** III/IV 1289.]

**4-Methyl-1,2,4-triazoline-3,5-dione (MTAD)** [13274-43-6] **M 113.1, m 103-104°, m 107-109°.** MTAD is obtained as pink needles by sublimation at 40-50°/0.1mm (see 4-phenyl-1,2,4-triazoline-3,5-dione, PTAD below). [Cookson et al. *Org Synth* **51** 121 1971, Cheng et al. *J Org Chem* **49** 2910 1984, *Beilstein* **26** III/IV 538.]

**2-Methyltricycloquinazoline** [2642-52-6] **M 334.4, m >300°.** Purify it by crystallisation from \*C<sub>6</sub>H<sub>6</sub>, toluene or xylene followed by vacuum sublimation. [*cf.* *Beilstein* **26** III/IV 1932.] **CARCINOGEN.**

**5-Methyltryptamine hydrochloride (3-[2-aminoethyl]-5-methylindole hydrochloride)** [1010-95-3] **M 210.7, m 289-291°(dec), 290-292°, pK<sub>Est(1)</sub> ~ -3 (protonation of ring NH), pK<sub>Est(2)</sub> ~ 9.0 (CH<sub>2</sub>NH<sub>2</sub>), pK<sub>Est(3)</sub> ~ 10.9 (acidic indole NH).** Recrystallise the hydrochloride from H<sub>2</sub>O. The *free base* has **m 96-98°** (from \*C<sub>6</sub>H<sub>6</sub>/cyclohexane) or **m 99-100°** (from petroleum ether), and the *picrate* has **m 243°(dec)** (from EtOH). [Young *J Chem Soc* 3493 1958, Gaddum et al. *Quart J Exp Physiol* **40** 49 1955, Röhm *Hoppe Seyler's Z Physiol Chem* **297** 229 1954, *Beilstein* **22** III/IV 4364, **22**/10 V 167.]

**6-Methyluracil** [626-48-2] **M 126.1, m 270-280°(dec), λ<sub>max</sub> 260nm log<sub>e</sub> 3.97, pK<sub>1</sub> ~1.1, pK<sub>2</sub> 9.8.** Crystallise 6-methyluracil from EtOH or acetic acid. [*Beilstein* **24** III/IV 1281.]

**1-Methyluric acid** [708-79-2] **M 182.1, m >350°, pK<sub>1</sub> 5.75 (basic), pK<sub>2</sub> 10.6 (acidic).** Recrystallise it from H<sub>2</sub>O. Its solubility at 17.5° is 1g in 353ml of H<sub>2</sub>O. [Bergmann & Dikstein *J Am Chem Soc* **77** 691 1955.] It has UV with λ<sub>max</sub> at 231 and 283nm (pH 3), and 217.5 and 292.5nm (pH >12) [Johnson *Biochem J* **5** 133 1952]. [*Beilstein* **26** II 299, **26** III/IV 2621.]

**3-Methyluric acid** [39717-48-1] **M 182.1, m >350°**, **pK<sub>1</sub> 5.75 (6.2), pK<sub>2</sub> >12**. Crystallise it from water. Its solubility at 17.5° is 1g in 19.7L of H<sub>2</sub>O. It has UV with  $\lambda_{\max}$  at 232 and 287 nm (pH 3), and 214 and 292.5nm (pH >12). [Beilstein 26 II 299, 26 III/IV 2621.]

**7-Methyluric acid** [612-37-3; 30409-21-3] **M 182.1, m >380°**, **pK<sub>1</sub> 5.6, pK<sub>2</sub> 10.3**. Crystallise it from water. It has UV with  $\lambda_{\max}$  at 234 and 286nm (pH 3), 237 and 293nm (8.5), and 222 and 296.5nm (pH >12) [Beilstein 26 H 525, 26 II 299, 26 III/IV 2622.]

**9-Methyluric acid** [30345-24-5] **M 182.1, m 385-400°(dec), >400°**. Crystallise it from water. [Beilstein 26 II 299, 26 III/IV 2622.]

**1-Methylxanthine (1-methyl-purin-2,6(3-*H*,7-*H*)-dione)** [6136-37-4] **M 166.1, m >360°** **pK<sub>1</sub><sup>20</sup> 1.3, pK<sub>2</sub><sup>20</sup> 7.9, pK<sub>3</sub><sup>20</sup> 11.8**. Crystallise it from water. It has UV with  $\lambda_{\max}$  at 266nm (pH 2.08), 242.5 and 276nm (pH 9). [Beilstein 26 II 263, 26 III/IV 2329.]

**3-Methylxanthine** [1076-22-8] **M 166.1, m >360°** **pK<sub>1</sub><sup>20</sup> 8.45, pK<sub>2</sub><sup>20</sup> 11.92**. Crystallise it from water. [Beilstein 26 II 263, 26 III/IV 2329.]

**7-Methylxanthine** [552-62-5] **M 166.1, m >380°(dec)** **pK<sub>1</sub><sup>20</sup> 8.42, pK<sub>2</sub><sup>20</sup> >13**. Crystallise it from water. [Beilstein 26 II 263, 26 III/IV 2330.]

**8-Methylxanthine** [17338-96-4] **M 166.1, m 292-293°(dec)**. Crystallise it from water. [Beilstein 26 III/IV 2330.]

**9-Methylxanthine** [1198-33-0] **M 166.1, m 384°(dec)**, **pK<sub>1</sub><sup>20</sup> 2.0, pK<sub>2</sub><sup>20</sup> 6.12, pK<sub>3</sub><sup>20</sup> 10.5 (>13)**. Crystallise it from water. [Beilstein 26 II 263, 26 III/IV 2330.]

**Metrazol (Cardiazol, Leptazol, 3a,4,5,6,7,8-hexahydro-1,2,3,3a-tetraaza-azulene, 1,5-pentamethylene-1,2,3,4-tetrazole)** [54-95-5] **M 138.2, m 61°, b 194°/12mm, pK<sub>Est</sub> ~<0**. Crystallise metrazol from diethyl ether and dry it under vacuum over P<sub>2</sub>O<sub>5</sub>, or distil it. [Schmidt *Chem Ber* 57 704 1924, Beilstein 26 II 213.]

**Morin (hydrate) (2',3,4',5,7-pentahydroxyflavone)** [480-16-0] **M 302.2, m 289-292°, CI 75660, pK<sub>1</sub> 5.3, pK<sub>2</sub> 8.74**. Stir morin at room temperature with ten times its weight of absolute EtOH, then leave overnight to settle. Filter it off, and evaporate under a heat lamp to one-tenth its volume. An equal volume of water is added, and the precipitated morin is filtered off, dissolved in the minimum amount of EtOH and again precipitated with an equal volume of water. The precipitate is filtered off, washed with water and dried at 110° for 1 hour (yield *ca* 2.5%). [Perkins & Kalkwarf *Anal Chem* 28 1989 1956.] It complexes with W and Zr. [Beilstein 18 H 239, 18 III/IV 3468, 18/5 V 492.]

**(-)-Morphine (H<sub>2</sub>O)** [57-27-2] **M 302.2, m 230°(dec), 254°(dec, rapid heating), 260°(Kofler block), [α]<sub>D</sub><sup>23</sup> -130.9° (MeOH), pK<sub>1</sub> 8.31, pK<sub>2</sub> 9.51**. Crystallise the narcotic from MeOH or anisole. It dehydrates at 130°. Its solubility in H<sub>2</sub>O is 0.2g/L at 20° and 0.9g/L at 100°, and in EtOH it is 5g/L at 20° and 10g/L on boiling. The *stypnate* has **m 189°** (from aqueous EtOH). [Beilstein 27 II 118, 27 III/IV 2223.]

**Morpholine** [110-91-8] **M 87.1, f -4.9°, b 128.9°, d<sub>4</sub><sup>20</sup> 1.0007, n<sub>D</sub><sup>20</sup> 1.4540, n<sub>D</sub><sup>25</sup> 1.4533, pK<sup>25</sup> 8.33**. Dry morpholine with KOH, fractionally distil it, then reflux it with Na, and again fractionally distil it. Dermer & Dermer [*J Am Chem Soc* 59 1148 1937] precipitated it as the *oxalate* by adding slowly to slightly more than 1<sup>\*</sup> molar equivalent of oxalic acid in EtOH. The precipitate is filtered off and recrystallised twice from 60% EtOH [1:1 salt has **m 190-195°(dec)**]. Addition of the *oxalate* to concentrated aqueous NaOH regenerated the base, which is separated and dried with solid KOH, then sodium, before being fractionally distilled. The *hydrochloride* has **m 178-179°** (from MeOH/Et<sub>2</sub>O), and the *picrate* has **m 151.6°** (from aqueous EtOH). [Beilstein 27 II 3, 27 III/IV 15.]

§ A polystyrene supported morpholine is commercially available.

**2-(*N*-Morpholino)ethanesulfonic acid (MES)** [4432-31-9] **M 213.3, m >300°(dec), pK<sup>20</sup> 6.15.** Crystallise MES from hot EtOH containing a little water. The *picrate* crystallises from EtOH and has **m 178.8-182°.** [Malkiel & Mason *J Org Chem* **8** 199 1943, *Beilstein* **27** III/IV 370.]

**Murexide (ammonium purpurate)** [3051-09-0] **M 284.2, m >300°, λ<sub>max</sub> 520nm (ε 12,000), pK<sub>2</sub> 9.2, pK<sub>3</sub> 10.9.** The sample may be grossly contaminated with uramil, alloxanthine, etc., and may be difficult to purify. It is better to synthesise it from pure alloxanthine [Davidson *J Am Chem Soc* **58** 1821 1936]. Recrystallise it from water. [Kuhn & Lyman *Chem Ber* **69** 1547 1936, *Beilstein* **25** I 709, **25** III/IV 4236.]

**α-Naphthoflavone (7,8-benzoflavone)** [604-59-1] **M 272.3, m 153-155°, 155°, pK<sup>25</sup> 8-9 (phenolic OH).** Recrystallise the flavone from EtOH or aqueous EtOH. [IR: Cramer & Windel *Chem Ber* **89** 354 1956, UV Pillon & Massicot *Bull Soc Chim Fr* 26 1954, Smith *J Chem Soc* 542 1946, Mahal & Venkataraman *J Chem Soc* 1767 1934.] It is a competitive inhibitor of human estrogen synthase. [Kellis & Vickery *Science* **225** 1032 1984, *Beilstein* **17** III/IV 5550.]

**Naphthol AS-acetate (3-acetoxynaphthoic acid anilide)** [1163-67-3] **M 305.3, m 152°, 160°.** Recrystallise it from hot MeOH and dry *in vacuo* over P<sub>2</sub>O<sub>5</sub>. It has **m 252°** after sublimation at 210-215°. It is slightly soluble in AcOH, EtOH, CHCl<sub>3</sub> or \*C<sub>6</sub>H<sub>6</sub>. It is a fluorogenic substrate for albumin esterase activity. [Chen & Scott *Anal Lett* **17** 857 1984.] At λ<sub>ex</sub> 320nm it has fluorescence at λ<sub>em</sub> 500nm. [Brass & Sommer *Chem Ber* **61** 1000 1928, *Beilstein* **12** II 260, **12** III 960, **12** IV 923.]

**1,5-Naphthyridine** [254-79-5] **M 130.1, m 75°, b 112°/15mm, pK<sup>20</sup> 2.84.** Purify 1,5-naphthyridine by repeated sublimation. The *picrate* crystallises from EtOH with **m 200°(dec).** [UV: Armarego *Physical Methods in Heterocyclic Chemistry* (Ed Katritzky, Academic Press) **Vol III** 133 1971, *Beilstein* **23** II 178, **23** III/IV 1235.]

**1,8-Naphthyridine** [254-60-4] **M 130.1, m 98-99°, pK<sup>20</sup> 3.36.** Purify 1,8-naphthyridine through an Al<sub>2</sub>O<sub>3</sub> column and elute with toluene and petroleum ether, evaporate the eluate, crystallise the residue from petroleum ether (b 60-80°), and sublime it at 80°/13mm. The *picrate* [15936-16-0] has **m 207-208°** (from EtOH), and the *methiodide* has **m 180-181°** (from EtOH). [Hawes & Wibberley *J Chem Soc (C)* 1564 1967, UV: Armarego *Physical Methods in Heterocyclic Chemistry* (Ed Katritzky, Academic Press) **Vol III** 134 1971, *Beilstein* **23** II 178, **23** III/IV 1237.]

**(±)-Naringenin (4',5,7-trihydroxyflavanone)** [480-41-1] **M 272.3, m 251° (phenolic pKs ~8-11).** Crystallise it from EtOH or aqueous EtOH. It has UV with λ<sub>max</sub> at 290nm (EtOH). The *S*(-)-*enantiomer* (natural form) has **m 255-256°** (from EtOH) and [α]<sub>D</sub><sup>20</sup> -28.0° (c 2, EtOH), [α]<sub>D</sub><sup>20</sup> -35.2° (c 1, pyridine). [*Beilstein* **18** H 503, **18** II 164, **18** III/IV 2630.] **Genistein (4',5,7-trihydroxyisoflavone)** [446-72-0] **M 270.2** crystallises from 60% aqueous EtOH or water with **m 297-298°** and [α]<sub>D</sub><sup>20</sup> -28° (c 0.6, 20mM NaOH). [*Beilstein* **18/4** V 594.]

For **Naringin (naringenin 7-rhamnoglucoside)**. See “Carbohydrates” in Chapter 7.

**Neutral Red (2-amino-8-dimethylamino-3-methylphenazine HCl, Basic Red 5, CI 50040)** [553-24-2] **M 288.8, m 290°(dec), pK<sup>25</sup> 6.5.** Crystallise the dye from \*benzene/MeOH (1:1). In aqueous solution it is red at pH 6.8 and yellow at pH 8.0. [*Beilstein* **25** III/IV 3054.]

**Nicotinaldehyde thiosemicarbazone** [3608-75-1] **M 180.2, m 222-223°.** Crystallise the derivative from EtOH, BuOH or water. Its *hydrochloride* crystallises from aqueous EtOH with **m 237-239° (dec).** [*Beilstein* **21** III/IV 3542 **21/7** V 342.]

**Nicotinamide (Niacin, Vitamin B<sub>3</sub>, vitamin PP)** [98-92-0] **M 122.1, m 128-131°, b ~150-160°/high vac, pK<sub>1</sub><sup>20</sup> 0.5, pK<sub>2</sub><sup>20</sup> 3.33.** Crystallise niacin from \*benzene. It has solubility in g/ml: H<sub>2</sub>O (1), EtOH (0.7) and glycerol (0.1). [*Methods in Enzymology* **66** 23 1980, UV: Armarego *Physical Methods in Heterocyclic Chemistry* (Ed Katritzky, Academic Press) **Vol III** 83 1971, *Beilstein* **22** III/IV 389, **22/2** V 80.]

**Nicotinic acid (Niacin is also used for the acid, pyridine-3-carboxylic acid)** [59-67-6] **M 123.1, m 232-234°**, **pK<sub>1</sub><sup>25</sup> 2.00, pK<sub>2</sub><sup>25</sup> 4.82**. Crystallise the acid from \*benzene, EtOH or H<sub>2</sub>O. It sublimes without decomposition. [McElvain *Org Synth Coll Vol I* 385 1941, *Beilstein* **22** III/IV 439, **22/2** V 57.]

**Nicotinic acid hydrazide** [553-53-7] **M 137.1, m 158-159°**, **pK<sub>1</sub><sup>25</sup> 2.2, pK<sub>2</sub><sup>25</sup> 3.63, pK<sub>3</sub><sup>25</sup> 11.49(NH)**. Crystallise it from aqueous EtOH or \*benzene. [*Beilstein* **22** III/IV 439, **22/2** V 121.]

**Nile Blue A (a benzophenoxazinium sulfate dye)** [3625-57-8] **M 415.5, m >300°(dec)**, **CI 51180, pK<sup>25</sup> 2.4**. Crystallise the dye from aqueous AcOH. It has UV with  $\lambda_{\max}$  at 630nm (96% aqueous EtOH) and 635nm (H<sub>2</sub>O). The *betaine* has UV with  $\lambda_{\max}$  at 513nm (EtOH). [Crossley et al. *J Am Chem Soc* **74** 57, 578 1952, Merill & Spencer *J Am Chem Soc* **70** 3683 1948, *Beilstein* **27** II 457, **27** III/IV 5166.]

**5-Nitrobarbituric acid (dilituric acid)** [480-68-2] **M 173.1, m 176°, 176-183°(dec)**, **pK<sup>20</sup> 10.25**. Crystallise dilituric acid from water as the *trihydrate* (**m 180-181°** (dec)). Drying over 70% H<sub>2</sub>SO<sub>4</sub> converts the trihydrate to the *dihydrate* [Loeffler & Moore *J Am Chem Soc* **70** 3650 1948]. [*Beilstein* **24** H 474, **24** II 273, **24** III/IV 1882.]

**4'-Nitrobenzo-15-crown-5** [60835-69-0] **M 313.3, m 84-85°, 93-95°**. Recrystallise the crown ether from EtOH, MeOH or \*C<sub>6</sub>H<sub>6</sub>/hexane as for the 18-crown-6 compound below. It complexes with Na<sup>+</sup>, K<sup>+</sup>, NH<sub>4</sub><sup>+</sup>, Ca<sup>2+</sup>, Mg<sup>2+</sup> and Cd<sup>2+</sup>. The <sup>1</sup>HNMR spectrum (CDCl<sub>3</sub>) has  $\delta$  (ppm) at 3.6-4.4 (m 16CH<sub>2</sub>), 6.8 (d 1H arom), 7.65 (d 1H arom), 7.80 (dd 1H arom  $J_{ab} = 9\text{Hz}$  and  $J_{bc} = 3\text{Hz}$ ) [Schmid et al. *J Am Chem Soc* **98** 5198 1976, Kikukawa et al. *Bull Chem Soc Jpn* **50** 2207 1977, Toke et al. *Justus Liebigs Ann Chem* **349** 349, 761 1988, Lindner et al. *Z Anal Chem* **322** 157 1985].

**4'-Nitrobenzo-18-crown-6** [53408-96-1] **M 357.4, m 83-84°, 83-84°**. If impure and discoloured, then chromatograph it through Al<sub>2</sub>O<sub>3</sub> and elute with \*C<sub>6</sub>H<sub>6</sub>/hexane (1:1) containing 1% MeOH. The fractions are followed by TLC on Al<sub>2</sub>O<sub>3</sub> (with Dragendorff's reagent for detection: R<sub>F</sub> 0.6 in the above solvent system). Recrystallise the residues from the required fractions from \*C<sub>6</sub>H<sub>6</sub>/hexane to give yellowish leaflets. It complexes with Na or K ions with logK<sub>Na</sub> 3.95 and logK<sub>K</sub> 4.71. [Petranek & Ryba *Col Chem Czech Chem Commun* **39** 2033 1974.]

**4-(4-Nitrobenzyl)pyridine (PNBP)** [1083-48-3] **M 214.2, m 70-71°, 74°, pK<sub>Est</sub> ~5.0**. Crystallise PNBP from aqueous EtOH or cyclohexane. The *hydrochloride* has **m 194-196°(dec)**, from EtOH, and the *picrate* has **m 168°(dec)**, from EtOH/EtOAc. [*Beilstein* **20** II 272, **20/7** V 564.]

**5-Nitroindole** [6146-52-7] **M 162.1, m 141-142°, pK<sup>25</sup> -7.4 (aqueous H<sub>2</sub>SO<sub>4</sub>)**. Decolourise (charcoal) 5-nitroindole and recrystallise it twice from aqueous EtOH or recrystallise it from octane. It has UV has  $\lambda_{\max}$  at 265 and 324nm (EtOH). [*Beilstein* **20** III/IV 3194, **20/7** V 41.]

**Nitron [1,4-diphenyl-3-phenylamino-(1H)-1,2,4-triazolium (hydroxide) inner salt]** [2218-94-2] **M 312.4, m 189°(dec)**. Crystallise it from EtOH, chloroform or EtOH/\*C<sub>6</sub>H<sub>6</sub>. [*Beilstein* **25** III/IV 1075.]

**5-Nitro-1,10-phenanthroline** [4199-88-6] **M 225.2, m 197-198°, pK<sup>25</sup> 3.33**. Crystallise the phenanthroline from \*benzene/petroleum ether, until anhydrous. It also crystallises from H<sub>2</sub>O with **m 202°**, and EtOAc with **m 203°**. Its pK<sup>25</sup> varies from 3.20 to 2.69 with varying MeOH/H<sub>2</sub>O ratios from 0 to 0.95 moles/L, and from 3.20 to 1.95 in varying EtOH/H<sub>2</sub>O ratios from 0 to 0.94 moles/L [Ram et al. *J Prakt Chem* **319** 719 1977]. It forms complexes with Cu<sup>2+</sup>, Zn<sup>2+</sup>, In<sup>2+</sup>, Fe<sup>2+</sup>, Co<sup>2+</sup>, Ni<sup>2+</sup>. [*Beilstein* **23** III/IV 1682, **23/8** V 425.]

**3-Nitro-2-pyridinesulfonyl chloride** [68206-45-1] **M 190.2, m 217-222°(dec)**. The chloride crystallises as yellow needles from CH<sub>2</sub>Cl<sub>2</sub>. When pure, it is stable for several weeks at room temperature, and no decomposition was observed after 6 months at <0°. It is moisture sensitive. Its UV (MeCN) has  $\lambda_{\max}$  at 231nm ( $\epsilon$  12,988), 264nm ( $\epsilon$  5,784) and 372nm ( $\epsilon$  3,117). [NMR and UV: Matsuda & Aiba *Chem Lett* 951 1978, Wagner et al. *Chem Ber* **75** 935 1942.]

**5-Nitroquinoline** [607-34-1] M 174.2, m 70°, pK<sup>20</sup> 2.69. Crystallise 5-nitroquinoline from pentane, then from \*benzene. The *hydrochloride* has m 224° and the *picrate* has m 206°, 214°(from MeOH). [Beilstein 20 H 371, 20 II 235, 20 III/IV 3397.]

**8-Nitroquinoline** [706-35-2] M 174.2, m 88-89°, 91-92°, pK<sup>20</sup> 2.55. Crystallise 8-nitroquinoline from hot water, MeOH, EtOH or EtOH/diethyl ether (3:1). It sublimes at 70°/2mm. [Beilstein 20 H 373, 20 III/IV 3399.]

**4-Nitroquinoline 1-oxide** [56-57-5] M 190.2, m 154-155°, 157°. The *N*-oxide recrystallises from aqueous acetone as yellow needles or platelets. [Ochiai *J Org Chem* 18 534 1953, Seki et al. *J Phys Chem* 91 126 1987, Beilstein 20 III/IV 3396.]

**5-Nitouracil (2,4-dihydroxy-5-nitropyrimidine)** [611-08-5] M 157.1, m 280-285°, >300°, pK<sup>20</sup><sub>1</sub> 0.03, pK<sup>20</sup><sub>2</sub> 5.55, pK<sup>20</sup><sub>3</sub> 11.3. The uracil recrystallises in prisms from boiling H<sub>2</sub>O as the *monohydrate* and loses H<sub>2</sub>O on drying *in vacuo*. [UV: Brown *J Chem Soc* 3647 1959, Brown *J Appl Chem* 2 239 1952, Johnson *J Am Chem Soc* 63 263 1941, Beilstein 24 I 313, 24 II 171, 24 III/IV 1236.]

**4-Nonadecylpyridine (hydrogen ionophore II [ETH 1907] - Proton ionophore)** [70268-36-9] M 345.6, b 180°/0.07mm, pK<sub>Est</sub> ~6.0. Dissolve the waxy ionophore (ca 60g) in CHCl<sub>3</sub> (200ml), wash it with H<sub>2</sub>O (3 x 200ml), dry it and evaporate it to dryness, then distil it in a vacuum. A waxy solid is formed on cooling the distillate. Its UV has λ<sub>max</sub> at 257nm (ε 1.86 x 10<sup>3</sup> M<sup>-1</sup>cm<sup>-1</sup>), 308nm (ε 1.7 x 10<sup>2</sup> M<sup>-1</sup>cm<sup>-1</sup>). [IR, NMR UV: Valenty et al. *Inorg Chem* 18 2160 1979.]

**Norcodeine** [467-15-2] M 285.3, m 185°, 186°, pK<sup>20</sup> 9.10. It crystallises from acetone or ethyl acetate. [Speyer & Walther *Chem Ber* 63 822 1930.] The *hydrochloride* has m 309°(dec) when crystallised from H<sub>2</sub>O. [Beilstein 18 III/IV 8091.]

**Octadecyl isonicotinate (hydrogen ionophore IV ETH 1778)** [103225-02-1] M 375.6, m 57.5°, pK<sub>Est</sub> ~3.5. Dissolve it in Et<sub>2</sub>O and wash it 3 times with H<sub>2</sub>O. Dry the extract (MgSO<sub>4</sub>), evaporate, and recrystallise the residue from EtOAc/hexane (4:1). [Oesch et al. *Anal Chem* 58 2285 1986.]

**Orotic acid (H<sub>2</sub>O)** [50887-69-9] M 174.1, m 334°(dec), 235-346°(dec), pK<sup>25</sup><sub>1</sub> 1.8, pK<sup>25</sup><sub>2</sub> 9.55. It crystallises from water. The *anhydrous acid* [65-86-1] M 156.1 has m 245-246°(dec). [Nye & Mitchell *J Am Chem Soc* 69 1382 1947, Beilstein 25 III/IV 1759.]

**Orotic acid Li salt H<sub>2</sub>O (1-carboxy-4,6-dihydroxypyrimidine Li salt H<sub>2</sub>O)** [5266-20-6] M 180.0, m >300°, pK<sub>1</sub> 2.8 (CO<sub>2</sub>H), pK<sub>2</sub> 9.4 (OH), pK<sub>3</sub> >13 (OH) (for free acid). The salt is soluble in H<sub>2</sub>O at 17° and 100°. Best to acidify an aqueous solution of the salt, isolate the *free acid* (see above) which is recrystallised from H<sub>2</sub>O (as *monohydrate*) m 345-347° (345-346°), then dissolve it in EtOH, add an equivalent amount of LiOH in EtOH and evaporate. Its solubility in H<sub>2</sub>O is 1.28% (17°) and 2.34% (100°). [Bachstsz *Chem Ber* 63 1000 1930, Johnson & Shroeder *J Am Chem Soc* 54 2941 1932, UV: Shugar & Fox *Biochim Biophys Acta* 9 199 1952, Beilstein 25 III/IV 1759.]

**Oxalylindigo** [2533-00-8] M 316.3. It crystallises twice from nitrobenzene as small yellow crystals and is dried by heating *in vacuo* for several hours. [Schanze et al. *J Am Chem Soc* 108 2646 1986.]

**2-Oxazolidinone (ethylene carbamate)** [497-25-6] M 87.1, m 88-90°, 89-90°, 91°, b 152°/0.4mm, 200°/12mm. It is prepared by reaction of ethanolamine with phosgene or diethylcarbonate. It can be prepared from ethanolamine (2g) in CHCl<sub>3</sub> (200ml, EtOH free by passing through an Al<sub>2</sub>O<sub>3</sub> column) by bubbling COCl<sub>2</sub> through the solution which is allowed to stand for 3 hours, the acid is neutralised with powdered PbCO<sub>3</sub>, filtered, evaporated to dryness and the solid residue is recrystallised from CHCl<sub>3</sub>. *Alternatively*, ethanolamine (61g), Et<sub>2</sub>CO<sub>3</sub> (150ml) and NaOMe (0.5g) are heated in an oil bath; and after the EtOH (~112ml) has distilled off, the residue solidifies on cooling and is recrystallised from CHCl<sub>3</sub> (100ml) to give the *oxazolidinone* (57g).

65%), m 87-89°. Its IR (film) has  $\nu_{\max}$  at 3000, 2920 (CH), 1766 (carbamate, C=O), 1690 (amide, C=O), 1465, 1382 and 1357 (CH<sub>2</sub>), 1298 (C-N), 1212, 1140 and 1030 (COC, C-O), 953 cm<sup>-1</sup>; and <sup>1</sup>H NMR (CDCl<sub>3</sub>) with  $\delta$  at 6.68 (NH, br s, 1H), 4.47 (H<sub>5</sub>, t, <sup>3</sup>J = 8Hz, 2H), 3.63 (H<sub>4</sub>, t, <sup>3</sup>J = 8Hz, 2H); and <sup>13</sup>C NMR (CDCl<sub>3</sub>) with  $\delta$  at 161.2 (C<sub>2</sub>), 65.1 (C<sub>5</sub>), 40.8 (C<sub>4</sub>); and <sup>13</sup>C NMR (D<sub>2</sub>O) with  $\delta$  at 165.1 (C<sub>2</sub>), 68.8 (C<sub>5</sub>), 43.1 (C<sub>4</sub>). [Hammer et al. *J Org Chem* **46** 1521 1981.] [Homeyer US Pat 2,399,118 1964, *Chem Abs* **40** 4084 1964.] It can be recrystallised from \*benzene, dichloroethane, CHCl<sub>3</sub> or EtOH. It is a cyclic urethane, and as such it is not very stable in aqueous solvents. The *N*-acetyl derivative [1432-43-5] **M 129.1, m 69-70°**, is obtained by boiling 2-oxazolidinone (3g) with Ac<sub>2</sub>O (20ml) and NaOAc (1g) for 1.5 hours, and is recrystallised from \*C<sub>6</sub>H<sub>6</sub>/Et<sub>2</sub>O or sublimed at 65° *in vacuo*. [Homeyer US Pat 2,399,118 1964, *Chem Abs* **40** 4084 1964.] The *N*-methyl derivative [19836-78-3] **M 101.1, b 120°/0.1mm**, is prepared from *N*-methyl ethanolamine with COCl<sub>2</sub>/CHCl<sub>3</sub>/PbCO<sub>3</sub> or as for the preparation of the parent compound [with (EtO)<sub>2</sub>CO], and distilled in a vacuum. It is **TOXIC**. The yellow *picrolonate* has **m 137-138°**. [*cf.* Fränkel & Cornelius *Chem Ber* **51** 1662 1918, Ben-Ishai *J Am Chem Soc* **78** 4962 1956, *Beilstein* **27** H 135, **27** I 259, **27** III/IV 2516.]

**Oxetane (1,3-trimethylene oxide)** [503-30-0] **M 58.1, b 45-46°/736mm, 47-49°/atm, 48°/760mm, d<sub>4</sub><sup>20</sup> 0.892, n<sub>D</sub><sup>20</sup> 1.395**. Distil oxetane twice from sodium metal and then fractionate it through a small column at atmospheric pressure, **b 47.0-47.2°**. It can also be purified by preparative gas chromatography using a 2m silica gel column. *Alternatively*, add KOH pellets (50g for 100g of oxetane) and distil it through an efficient column or a column packed with 1/4in Berl Saddles with the main portion boiling at 45-50° being collected and redistilled over fused KOH. [Noller *Org Synth Coll Vol III* 835 1955, Dittmer et al. *J Am Chem Soc* **79** 4431 1957, *Beilstein* **17** H 6, **17** I 3, **17** II 12, **17** III/IV 13, **17** I V 11.]

**Oxetan-2-one (β-propiolactone, propan-3-olide)** [57-57-8] **M 72.1, m -31.2°, -35°, b 51°/10mm, 83°/45mm, d<sub>4</sub><sup>20</sup> 1.1460, n<sub>D</sub><sup>25</sup> 1.4117**. Fractionally distil the lactone from sodium under reduced pressure. It gives an acidic solution in H<sub>2</sub>O. It irritates the skin and is a possible **carcinogen**. [*Beilstein* **17** I 130, **17** III/IV 4157.]

**Oxine Blue [3-(4-hydroxyphenyl)-3-(8-hydroxy-6-quiniliny)-1(3H)-isobenzofuranone]** [3733-85-5] **M 369.4, m 134-135°**. Recrystallise the dye from EtOH and dry it in a desiccator over H<sub>2</sub>SO<sub>4</sub>.

**Oxolinic acid (5-ethyl-5,8-dihydro-8-oxo-1,3-dioxolo[4,5-g]quinoline-3-carboxylic acid)** [14698-29-4] **M 261.2, m 313-314°(dec), 314-316°(dec), pK<sub>Est</sub> ~ 2.3**. Purify the acid by recrystallisation from aqueous Me<sub>2</sub>CO, 95% EtOH or dimethylformamide. It has UV with  $\lambda_{\max}$  at 220, (255.5sh), 259.5, 268, (298sh, 311sh), 321 and 326nm [ $\epsilon$  14.8, (36.8sh), 38.4, 38.4, (6.4sh, 9.2sh), 10.8 and 11.2 x 10<sup>3</sup>]. [Kaminsky & Metzger *J Med Chem* **11** 160 1968, *Beilstein* **17** H 6, **17** I 3, **17** II 202, **17** III/IV 13, **17** I V 11.]

**Papaverine hydrochloride (6,7-dimethoxy-1-veratrylisoquinoline hydrochloride)** [61-25-6] **M 375.9, m 215-220°, 222.5-223.5°(dec), 231°, pK<sub>25</sub> 6.41**. Recrystallise it from H<sub>2</sub>O. It sublimes at 140°/0.1mm. Its solubility in H<sub>2</sub>O is 5%. [Saunders & Srivastava *J Pharm Pharmacol* **3** 78 1951, Biggs *Trans Faraday Soc* **50** 800 1954.] The *free base* has **m 148-150°**. The *picrate* has **m 186-189°(dec), 186-186.5°(dec)** [Bobbitt *J Org Chem* **22** 1729 1957]. [*Beilstein* **21** II 202, **21** III/IV 2788, **21**/6 V 182.]

**Paraldehyde (acetaldehyde trimer, 2r,4c,6c-trimethyl-1,3,5-trioxane, all-cis)** [123-63-7] **M 132.2, m 12.5°, b 124°/751mm, d<sub>4</sub><sup>20</sup> 0.995, n<sub>D</sub><sup>20</sup> 1.407**. Wash paraldehyde with water and fractionally distil it. *Alternatively*, it is purified by drying with anhydrous Na<sub>2</sub>SO<sub>4</sub>, then cooled to 5°, and the frozen material is separated by decantation. The solid is distilled (**b 121-124°/atm**), the distillate is collected, stored over anhydrous Na<sub>2</sub>SO<sub>4</sub> for several days and re-distilled at atmospheric pressure before use [Le Fevre et al. *J Chem Soc* 290 1950]. The *2r,4c,6t-trimethyl-1,3,5-trioxane* has **m 14.5°, b 125°/760mm**. [*Beilstein* **19** II 394, **19** III/IV 4715, **19**/9 V 112.]

**Patulin [4-hydroxy-4H-furo(3,2-c)pyran-2(6H)-one, Clavatin]** [149-29-1] **M 154.1, m 110°, 111-112°**. Crystallise patulin from \*C<sub>6</sub>H<sub>6</sub>, Et<sub>2</sub>O, EtOH or chloroform. It sublimes at 90°/high vacuum [Bergel et al. *J Chem Soc* 415 1944]. [*Beilstein* **18** III/IV 1184, **18**/3 V 5.] (*Highly TOXIC*).

**Pentachloropyridine** [2176-62-7] **M** 251.3, **m** 122-124°, 123°, 124°, 124-125°, 125-126°, **b** 279-280°/atm, **pK**<sup>20</sup> -6.02 (aqueous H<sub>2</sub>SO<sub>4</sub>). Purify it by recrystallisation from EtOH or aqueous EtOH. It sublimes at 150°/3mm. [den Hertog et al. *Rec Trav Chim Pays Bas* **69** 673 1950, Schikh et al. *Chem Ber* **69** 2604 1936, *Beilstein* **20** I 81, **20** III/IV 2503, **20/5** V 422.]

**Pentafluoropyridine** [700-16-3] **M** 169.1, **m** -41.5°, **b** 83.5°, 84°, 83-85°, **d**<sub>4</sub><sup>20</sup> 1.609, **n**<sub>D</sub><sup>20</sup> 1.3818, **pK**<sub>Est</sub> <0. Distil it through a concentric tube column; it has λ<sub>max</sub> in cyclohexane at 256.8nm. [Chambers et al. *J Chem Soc* 3573 1964, <sup>19</sup>F NMR: Bell et al. *J Fluorine Chem* **1** 51 1971.] The *hexafluoroantimonate* has **m** 98-102°(dec) after crystallisation from liquid SO<sub>2</sub>. [*Beilstein* **20/5** V 401.]

**3,3,6,9,9-Pentamethyl-2,10-diazabicyclo[4.4.0]dec-1-ene (PMDBD, 1,2,3,4,4a,5,6,7-octahydro-2,2,4a,7,7-pentamethylnaphthyridine)** [69340-58-5] **M** 208.3, **m** 15°, **b** 65°/0.07mm, **d**<sub>4</sub><sup>20</sup> 0.924, **n**<sub>D</sub><sup>4</sup> 1.4840, **pK** >11 (MeOCH<sub>2</sub>CH<sub>2</sub>OH/H<sub>2</sub>O, 1:1). The pentamethylhydronaphthyridine is obtained by intramolecular cyclisation of 5-amidino-2,5,8-trimethylnona-2-7-diene [190.0g, 0.914mol, prepared from 2mols BuLi, one mol of propionitrile and 2mols of 3-methylbut-2-enyl bromide (isoprenehydrobromide) in THF at -78°, followed by NaNH<sub>2</sub> in boiling \*C<sub>6</sub>H<sub>6</sub>] in CH<sub>2</sub>Cl<sub>2</sub> (500ml) solution at 0°, by bubbling dry HCl gas through it until the pH is 4. The solution is evaporated *in vacuo* until free from HCl vapour to give a dark hygroscopic hydrochloride which is heated in a flask (protected from air with a CaCl<sub>2</sub> tube) at 200°, whereby excess of HCl is released after 30 minutes (cyclisation begins at *ca* 125°), and heating is continued for 18 hours. The dark brown residue is treated with H<sub>2</sub>O (1.0L), acidified with 2N H<sub>2</sub>SO<sub>4</sub> (500ml) and the aqueous phase is extracted with Et<sub>2</sub>O (2 x 100ml), the aqueous phase is basified (cooling is necessary) with NaOH (*ca* 100g) to pH >10. The brown oil that separates is extracted with Et<sub>2</sub>O (2 x 500ml), dried over K<sub>2</sub>CO<sub>3</sub>, filtered, and evaporated to give a viscous oil (190g) which is distilled through a Vigreux column at 0.05mm, and after a small fore run (3.8g), a colourless viscous oil of the *naphthyridine* distils (156.6g, 80% yield, **b** 60-67°). An analytical sample has **m** ~15° and **b** 65°/0.07mm. Store it in an inert dry atmosphere as it absorbs CO<sub>2</sub> in the presence of moisture to form a *bicarbonate* (see below). Its UV/VIS has λ<sub>max</sub> (ε) at 219 (11,600) nm; the IR (7.5% in CHCl<sub>3</sub>) has ν<sub>max</sub> at 3660w, 3350w, 2970s, 2930s, 2860s, 2500w, 1630s, 1475m/sh, 1460m, 1415w, 1385s, 1375m, 1365m, 1360m, 1335m, 1325m, 1250m, 1235m, 1180m, 1150s, 1130m, 1065w, 1000w, 875w, 840w, 655m, 630w, with the immonium band of the hydrochloride in CHCl<sub>3</sub> at 2500 cm<sup>-1</sup>; the <sup>1</sup>H NMR (CCl<sub>4</sub>) of the free base has δ at 1.08-1.13 (2s, 12H, 4CH<sub>3</sub>), 1.19 (s, 3H, CH<sub>3</sub>), 1.2-2.0 (m, 8H), 3.38 (s, NH); MS (200°) has *m/z* at 209 (4), 208 (*M*<sup>+</sup> 25), 194 (25), 193 (100).

The *hydrochloride*, when recrystallised twice from CH<sub>2</sub>Cl<sub>2</sub>/Et<sub>2</sub>O (15 hours at 0°), has **m** 195-196°, and the <sup>1</sup>H NMR (CCl<sub>4</sub>) has δ at 1.34-1.13 (2s, 9H, 3CH<sub>3</sub>), 1.42 (s, 6H, 2CH<sub>3</sub>), 1.6-2.3 (m, 8H), 9.78 (br s, 2H NH).

The *hydrogen carbonate salt* is formed from the free base and moist CO<sub>2</sub> in 2 minutes, then by extraction with CH<sub>2</sub>Cl<sub>2</sub>, drying (K<sub>2</sub>CO<sub>3</sub>) and evaporating gives a labile salt decomposing at 122-125°, and the <sup>1</sup>H NMR has δ at 1.28 (s, 6H, 2CH<sub>3</sub>), 1.30 (s, 3H, CH<sub>3</sub>), 1.36 (s, 6H, 2CH<sub>3</sub>), 1.4-2.2 (m, 8H), and **no** NH/OH signals except in CHCl<sub>3</sub> where an intense singlet appears at 7.25.

The *benzoate* crystallises from CH<sub>2</sub>Cl<sub>2</sub> with **m** 183-185°, the *hydrogen sulfate* crystallises from CH<sub>2</sub>Cl<sub>2</sub>/hexane with **m** 208-209°, the *tosylate* has **m** 114°, and the *dihydrogen phosphate* crystallises from MeOH/Et<sub>2</sub>O with **m** 225-228°. [Heinzer, Soukup and Eschenmoser *Helv Chim Acta* **61** 2851 1978, Sternbach et al. *Angew Chem* **91** 670 1979, *Beilstein* **23/5** V 302.] The strong basicity, proximity of the nitrogen atoms, and the steric hinderance from methyl groups around them, confer remarkable coordination properties to this amidine without the usual nucleophilic behaviour of nitrogen bases [Eschenmoser et al. *Angew Chem* **91** 670 1979, Boyle et al. *J Chem Soc, Chem Commun* 239 1992, *Denmark J Org Chem* **46** 3144 1981].

**Pentaquine monophosphate (1,4-pentanediamine, *n*-[6-methoxy-8-quinolinyl]-*N'*-[1-methylethyl] (1:1) phosphate)** [5428-64-8] **M** 399.4, **m** 189-190°, **pK**<sup>70</sup> 8.22. Crystallise it from H<sub>2</sub>O or 95% EtOH. The *free base* has **b** 165-170°/0.05mm, **n**<sub>D</sub><sup>25</sup> 1.5785. The *picrate* crystallises from Me<sub>2</sub>CO/EtOH with **m** 164.5-165.5°. [Drake et al. *J Am Chem Soc* **68** 1529 1946, *Beilstein* **22** III/IV 5814.]

**(±)-Pentobarbital (5-ethyl-5-1'-methylbutyl barbituric acid, Nembutal is the Na salt)** [76-74-4] **M** 226.4, **m** ~127°(dec), **pK**<sub>Est(1)</sub> ~8.0, **pK**<sub>Est(2)</sub> ~12.7. A solution of the sodium salt in 10% HCl is prepared, and the acid is extracted with ether. Evaporation of the extract gives a solid which is then purified by repeated crystallisation

from  $\text{CHCl}_3$ . It sublimes at  $95\text{--}105^\circ/10\text{--}12\text{mm}$ . [Bucket & Sandorfy *J Phys Chem* **88** 3274 1984.] The (+)- and (-)-*enantiomers* crystallise from 50% aqueous EtOH with *m*  $120\text{--}121^\circ$  and have  $[\alpha]_D^{25} +4.73^\circ$  to  $-4.93^\circ$  (EtOH) [Kleiderer & Shonle *J Am Chem Soc* **56** 1772 1934]. [Beilstein **24** I 419, **24** II 287, **24** III/IV 1951.]

**Pericyazine** [10-{3-(4-hydroxy-1-piperidinyl)-propyl}-10*H*-phenothiazine-2-carbonitrile, **Propericiazine**] [2622-26-6] *M* **365.4**, *m* **116-117°**. It recrystallises from a saturated solution in cyclohexane. It is antipsychotic and is a sensitive reagent for Pd, Va, Ru, Rh and Au. [Gowda et al. *Anal Chem* **55** 1816 1983, *Anal Chim Acta* **154** 347 1983, *Beilstein* **27** III/IV 4110.]

**Phenanthridine** (benzo[*c*]quinoline, 3,4-benzoquinoline) [229-87-8] *M* **179.2**, *m* **106.5°**, **108-109°**, **b** **350°/760mm**, **pK<sup>20</sup> 4.61 (4.48)**. Purify it *via* the  $\text{HgCl}_2$  addition compound formed when phenanthridine (20g) in 1:1 HCl (100ml) is added to aqueous  $\text{HgCl}_2$  (60g in 3L), and the mixture is heated to boiling. The  $\text{HgCl}_2$  complex separates as yellow red crystals with *m*  $195\text{--}198^\circ$  [Arcus & Mesley *J Chem Soc* 1780 1953]. Conc HCl is then added until all of the solid has dissolved. The compound separates on cooling and is decomposed with aqueous NaOH (*ca* 5M). Phenanthridine is extracted into  $\text{Et}_2\text{O}$ , evaporated, and the residue is crystallised from petroleum ether (*b*  $80\text{--}100^\circ$ ) or EtOAc. [Cumper et al. *J Chem Soc* 45218 1962.] It is also purified by chromatography on activated alumina from \*benzene solution, with diethyl ether as eluent. Evaporation of ether gives crystalline material which is freed from residual solvent under vacuum, then further purified by fractional crystallisation, under  $\text{N}_2$ , from its melt. It was purified by zone melting and sublimes in a vacuum. The *picrate* has *m*  $218.5\text{--}219.5^\circ$  (from *iso*-PrOH) (also reported are *m*  $244\text{--}245^\circ$  and  $247\text{--}248^\circ$ , from EtOH or  $\text{H}_2\text{O}$ ). [Slough & Ubbelohde *J Chem Soc* 911 1957.] [Beilstein **20** H 466, **20** III/IV 4016, **20/8** V 223.]

**1,10-Phenanthroline** (*o*-phenanthroline) [66-71-7 (*anhydr*); 5144-89-8 ( $\text{H}_2\text{O}$ )] *M* **198.2**, *m* **98-101°**, **108-110° (hydrate)**, **118° (anhydrous)**, **b** **>300°**, **pK<sub>1</sub><sup>25</sup> -0.7 (aqueous  $\text{HClO}_4$ )**, **pK<sub>2</sub><sup>25</sup> 4.86 (4.96)**. Crystallise its *picrate* (*m*  $191^\circ$ ) from EtOH; then the free base is liberated with aqueous alkali, dried at  $78^\circ/8\text{mm}$  over  $\text{P}_2\text{O}_5$  and crystallised from petroleum ether (*b*  $80\text{--}100^\circ$ ). [Cumper et al. *J Chem Soc* 1188 1962.] It can be purified by zone melting. It has also been crystallised from hexane, \*benzene/petroleum ether (*b*  $40\text{--}60^\circ$ ) or sodium-dried \*benzene, dried and stored over  $\text{H}_2\text{SO}_4$ . The *monohydrate* is obtained by crystallisation from aqueous EtOH or ethyl acetate. It has been crystallised from  $\text{H}_2\text{O}$  (300 parts) to give the *monohydrate* *m*  $102\text{--}103^\circ$  which sublimes at  $10^{-3}\text{mm}$  [Fielding & LeFevre *J Chem Soc* 1811 1951.] The *anhydrous* compound has *m*  $118^\circ$  (after drying at high vacuum at  $80^\circ$ ) and is also obtained by recrystallisation from petroleum ether or \* $\text{C}_6\text{H}_6$  (70 parts) and drying at  $78^\circ/8\text{mm}$ . [UV: Badger et al. *J Chem Soc* 3199 1951.] It has a pKa in  $\text{H}_2\text{O}$  of 4.857 ( $25^\circ$ ) or 5.02 ( $20^\circ$ ) and 4.27 in 50% aqueous EtOH ( $20^\circ$ ). [Albert et al. *J Chem Soc* 2240 1948]. [Beilstein **23** H 227, **23** II 235, **23/8** V 419.]

**1,10-Phenanthroline hydrochloride** (*o*-phenanthroline hydrochloride) [3829-86-5] *M* **243.7**, *m* **212-219°**. The hydrochloride crystallises from 95% EtOH, *m*  $212\text{--}219^\circ$  as the *monohydrate*; the *half hydrate* has *m*  $217^\circ$ . The *3HCl* has *m*  $143\text{--}145^\circ$  (sinters at  $128^\circ$ ). [Thevenet et al. *Acta Cryst Sect B* **33** 2526 1977]. [Beilstein **23** II 235, **23/8** V 421.]

**4,7-Phenanthroline-5,6-dione** [84-12-8] *M* **210.2**, *m* **295°(dec)**. The dione crystallises from MeOH. The *mono-oxime* forms yellow crystals from MeOH with *m*  $250^\circ(\text{dec})$ , the *di-oxime* forms yellow crystals from MeOH with *m*  $300^\circ(\text{dec})$  and the *mono-semihydrazone* forms yellow crystals from MeOH with *m*  $195^\circ(\text{dec})$ . [Druey & Schmidt *Helv Chim Acta* **33** 1080 1950, *Beilstein* **24** III/IV 1741.]

**Phenazine** [92-82-0] *M* **180.2**, *m* **171°**, **pK<sub>1</sub><sup>20</sup> -4.9 (aqueous  $\text{H}_2\text{SO}_4$ )**, **pK<sub>2</sub><sup>20</sup> 1.21**. Phenazine crystallises from EtOH,  $\text{CHCl}_3$  or ethyl acetate, after pre-treatment with activated charcoal. It can be sublimed *in vacuo* and purified by zone refining. [Beilstein **23/8** V 389.]

**Phenosafranine** (3,7-diamino-5-phenylphenazinium chloride) [81-93-6] *M* **322.8**, *m* **>300°**,  $\lambda_{\text{max}}$  **530nm ( $\text{H}_2\text{O}$ )**. Crystallise the chloride from dilute HCl. It has UV with  $\lambda_{\text{max}}$  at 530nm in  $\text{H}_2\text{O}$ . The *picrate* decomposes on heating and has a solubility of 0.0048% in  $\text{H}_2\text{O}$  at  $18^\circ$ . [Beilstein **23** H 395, *Beilstein* **25** H 394, **25** I 654, **25** II 338, **25** III/IV 3050.]

**Phenothiazine** [92-84-2] **M 199.3, m 184-185°**. Crystallise it from \*benzene, toluene, hexane or Me<sub>2</sub>CO (charcoal) after boiling for 10 minutes under reflux. Filter the crystals off and dry them in an oven at 100°, then in a vacuum desiccator over paraffin chips. Also recrystallise it twice from water and dry it in an oven at 100° for 8-10 hours. It sublimes at 130°/1mm and has UV with  $\lambda_{\text{max}}$  at 253nm in heptane. [Beilstein 27 I 225, 27 II 32, 27 III/IV 1214.]

**Phenoxazine** [135-67-1] **M 199.2, m 156°, 156-158°, 158-159°, b 215°/4mm**. Crystallise phenoxazine from EtOH and sublime it *in vacuo*. If too impure then extract it in a Soxhlet extractor using toluene. Evaporate the solvent and dissolve the residue (*ca* 100g) in \*C<sub>6</sub>H<sub>6</sub> (1L), **CARCINOGEN** (use an efficient fume cupboard) and chromatograph it through an Al<sub>2</sub>O<sub>3</sub> column (50 x 450 mm) using \*C<sub>6</sub>H<sub>6</sub>. The eluent (*ca* 3L) is evaporated to *ca* 150ml and cooled when *ca* 103g of phenoxazine **m 149-153°** are obtained. Sublimation yields platelets **m 158-159°**. It forms a green *picrate* **m 141.5-142°**. [Gilman & Moore *J Am Chem Soc* 79 3485 1957, Müller et al. *J Org Chem* 24 37 1959, Beilstein 27 I 223, 27 III/IV 1209.]

**2-Phenyl-1-azaindolizine** [4105-21-9] **M 194.2, m 140°, pK<sub>Est</sub> ~1.9**. Crystallise the indolizine from EtOH, \*benzene/petroleum ether, hexane (**m 135-136°**) or cyclohexane (**m 136-137°**). The *hydrochloride 2H<sub>2</sub>O* has **m 114-116°** (from H<sub>2</sub>O) and the *picrate* has **m 228-229°** (from AcOH) and 236-238° (from Me<sub>2</sub>CO). [Adams & Dix *J Am Chem Soc* 80 4618 1958, Beilstein 23 III/IV 1705.]

**Phenylbutazone (4-butyl-1,2-diphenylpyrazolidin-3,5-dione)** [50-33-9] **M 308.4, m 105°, 106-108°**. Crystallise the dione from EtOH. Its pK<sup>23</sup> is 4.52 (in H<sub>2</sub>O), 4.89 (in 50% aqueous EtOH) and 5.25 (80% 2-methoxyethanol). It complexes with Hg<sup>2+</sup>, Cd<sup>2+</sup> and Zn<sup>2+</sup>. It has UV with  $\lambda_{\text{max}}$  at 239.5nm in MeOH+50% aqueous HClO<sub>4</sub> and 264nm in aqueous 0.1N NaOH. [Beilstein 24 III/IV 1123.]

**2-Phenyl-1,3-diazahexahydroazulene** [2161-31-1] **M 212.3**. Recrystallise the azulene three times from de-aerated cyclohexane in the dark.

**2-Phenylindolizine** [25379-20-8] **M 193.2, m 214°(dec), pK<sub>Est</sub> ~4.4**. Crystallise 2-phenylindolizine from EtOH. The *0.25HCl* crystallises from MeCN with **m 109°**, and the *picrate* has **m 161°** when crystallised from EtOAc. [Beilstein 20 II 304, 20 III/IV 4033, 20/8 V 244.]

**1-Phenyl-5-mercaptotetrazole** [86-93-1] **M 178.2, m 150° (dec), 155° (dec), 157-158°, pK<sup>25</sup> 3.65 (5% aqueous EtOH)**. Purify the tetrazole by recrystallisation from EtOH or CHCl<sub>3</sub> (**m 152°**) [Tautomerism: Kauer & Sheppard *J Org Chem* 32 3580 1967, UV: Leiber et al. *Can J Chem* 37 563 1959]. The *ammonium salt* crystallises from EtOH and decomposes at 176°. The *sodium salt* crystallises from EtOH/\*C<sub>6</sub>H<sub>6</sub>, melts at 96° and decomposes at 145° [Stollé *J Prakt Chem* [2] 133 60 1932]. It is used for the determination of Bi and Pd. [Fresenius *Z Anal Chem* 261 151 1972, Beilstein 26 III/IV 2065.]

**4-(3-Phenylpropyl)pyridine [1-phenyl-3(4-pyridyl)propane]** [2057-49-0] **M 197.3, b 150-152°/5mm, 322°/atm, d<sub>4</sub><sup>25</sup> 1.03, n<sub>D</sub><sup>20</sup> 1.563, pK<sub>Est</sub> ~6.0**. This is prepared from the potassium salt of 4-picoline [obtained by dissolving K metal (1 mol) and a few mg of ferric oxide as catalyst in liquid NH<sub>3</sub> until the blue colour is discharged, indicating the formation of KNH<sub>2</sub>, to which is added 4-picoline (1 mol) rapidly forming a reddish-amber solution] and phenethyl bromide (1 mol, see [103-63-9]), allowing the NH<sub>3</sub> to evaporate (6-10 hours, in an efficient fume cupboard), adding H<sub>2</sub>O, the mixture is extracted into Et<sub>2</sub>O, evaporated to dryness and the residual oil is distilled, preferably under a vacuum to give the desired *phenylpropylpyridine*, **b 150-152°/5-6mm**, in 56% yield. The *hydrochloride*, obtained by evaporating a concentrated HCl solution of the base on a steam bath and the residual solid, recrystallised from EtOH/Et<sub>2</sub>O, has **m 143.5°** and is hygroscopic. [Bergstrom et al. *J Org Chem* 10 452 1945, Beilstein 20 III/IV 3687.]

**4-Phenylpyridine-2-carbonitrile** [18714-16-4] **M 180.1, m 97-101°, pK<sub>Est</sub> <0**. Purify the nitrile by recrystallisation from petroleum ether (**m 99-100°**). [Case & Gasper *J Am Chem Soc* 78 5842 1956, Beilstein 22 III/IV 1261.]

**Phenyl 2-pyridyl ketoxime** [1826-28-4] M 198.2, m 151-152°, 154-156°, pK<sub>1</sub><sup>25</sup> 3.84, pK<sub>2</sub><sup>25</sup> 10.71 for *E*-isomer. The *E*-isomer crystallises from EtOH (charcoal). It isomerises to the *Z*-isomer on melting or in boiling *o*-xylene, and crystallises from EtOH or cyclohexanol with m 166-168°. [Beilstein 21 H 330, 21 III/IV 4120, 21/8 V 568.]

**6-Phenylquinoline** [612-95-3] M 205.3, m 110.5-111.5°, pK<sub>Est</sub> ~5.2. Crystallise 6-phenylquinoline from EtOH (charcoal). The *picrate* has m 105° (from Me<sub>2</sub>CO). It has UV with λ<sub>max</sub> at 253nm in aqueous EtOH and 263 and 325nm in aqueous HCl. [Beilstein 20 H 483, 20 III/IV 4151.]

**2-Phenylquinoline-4-carboxylic acid (Cinchophen, Atophen)** [132-60-5] M 249.3, m 215°, pK<sub>Est(1)</sub> ~0.5 (CO<sub>2</sub>H), pK<sub>Est(2)</sub> ~5.1 (N). It crystallises from EtOH (ca 20ml/g), in several modifications with m 196° and 216°(subliming at 65°). [Beilstein 22 H 103, 22 II 518, 22 II 70, 22 III/IV 1358.]

**1-Phenyl-5-sulfanilamidopyrazole** [526-08-9] M 314.3, m 177-178°, 178-179°. Crystallise it from EtOH or aqueous EtOH. [Schmidt & Druey *Helv Chim Acta* 41 309 1958, Beilstein 25 III/IV 2029.]

**4-Phenyl-1,2,4-triazole-3,5-diol (4-phenylurazole)** [15988-11-1] M 175.2, m 207-209°. Crystallise 4-phenylurazole from water or 95% EtOH. Dissolve 35g in 80ml of boiling 95% EtOH and on cooling 90-95% is recovered with m 209-210°. It has IR with ν<sub>max</sub> at 1685 and 3120cm<sup>-1</sup>. [Cookson et al. *Org Synth* 51 121 1971, Beilstein 26 I 64, 26 III/IV 540.]

**4-Phenyl-1,2,4-triazoline-3,5-dione (PTAD)** [4233-33-4] M 175.2, m 165-170°(dec), 170-177°(dec). PTAD forms carmine red needles by sublimation (ice cold finger) at 100°/0.1mm, and/or by recrystallisation from EtOH. Its IR has ν<sub>max</sub> at 1760 and 1780 cm<sup>-1</sup>. [Cookson et al. *Org Synth* 51 121 1971, Moore et al. *J Org Chem* 39 3700 1974, Beilstein 26 I 57, 26 III/IV 540.]

**9-Phenyl-9-xanthenol (hydroxypixyl)** [596-38-3] M 274.3, m 158-161°, 158.5-159°, 159°. Dissolve hydroxypixyl in AcOH and add H<sub>2</sub>O whereby it separates as colourless prisms. It is slightly soluble in CHCl<sub>3</sub>, soluble in \*C<sub>6</sub>H<sub>6</sub> but insoluble in petroleum ether. It sublimes on heating. Its UV in H<sub>2</sub>SO<sub>4</sub> has λ<sub>max</sub> at 450nm (ε 5620) and 370nm (ε 24,900) and the HClO<sub>4</sub> salt in CHCl<sub>3</sub> has λ<sub>max</sub> at 450 (ε 404) and 375nm (ε 2420). [Sharp *J Chem Soc* 2558 1958, Bünzly & Decker *Chem Ber* 37 2983 1904, Chattopadhyaya & Reece *J Chem Soc, Chem Commun* 639 1978, Gomberg & Cone *Justus Liebigs Ann Chem* 370 142 1909, Beilstein 17 I 80, 17 II 161, 17 III/IV 1704, 17/4 V 675.]

**“Phosphine” [dye CI 793, Chrysaniline mononitrate, 3-amino-9-(4-aminophenyl)-acridinium mononitrate]** [10181-37-0] M 348.4, m >250°(dec), pK<sup>20</sup> 7.71 (50% aqueous EtOH). Crystallise the dye from \*benzene/EtOH. The *free base* crystallises from \*C<sub>6</sub>H<sub>6</sub> in yellow crystals m 229-230°. [Albert & Goldacre *J Chem Soc* 709 1946, Beilstein 22 H 91, 22 I 651, 22 II 403, 22 III/IV 5513.]

**Phthalazine** [253-52-1] M 130.2, m 90-91°, b 190°/30mm, 175°/17mm, pK<sup>20</sup> 3.47. Phthalazine crystallises from diethyl ether or \*benzene, and sublimes under a vacuum. The *hydrochloride* forms needles from EtOH with m 235-236°(dec) and the *picrate* has m 208-210°. [Armarego *J Appl Chem* 11 70 1961, Beilstein 23 H 174, 23 III/IV 1233.]

**Phthalazine-1,4-dione (phthalhydrazide)** [1445-69-8] M 162.2, m 330-333°, 336°, 346°, pK<sub>1</sub><sup>20</sup> -3.29 pK<sub>2</sub><sup>20</sup> -0.99, pK<sub>3</sub><sup>20</sup> 5.67, pK<sub>4</sub><sup>20</sup> 13.0. Recrystallise it twice from 0.1M KOH [Merenyi et al. *J Am Chem Soc* 108 7716 1986], EtOH or dimethylformamide and it sublimes >300°. [Beilstein 24 H 371, 24 II 194.]

**Phthalazone (1-hydroxyphthalazine)** [119-39-1] M 146.2, m 183-184°, 186-188°, b 337°/760mm, pK<sub>1</sub><sup>20</sup> -2.2, pK<sub>2</sub><sup>20</sup> -1.4, pK<sub>3</sub><sup>20</sup> 11.99. Phthalazone crystallises from H<sub>2</sub>O or EtOH and sublimes *in vacuo*. [Beilstein 24 H 142, 24 III/IV 400.]

**2-Picoline-*N*-oxide (2-methylpyridine-1-oxide)** [931-19-1] M 109.1, m 41-45°, b 89-90°/0.8-0.9mm, 90-100°/1mm, 110°/4mm, 135°/5mm, 123°/9mm, 123-124°/15mm, 259-261°/atm, n<sub>D</sub><sup>25</sup> 1.5854 (supercooled),

**pK<sup>25</sup> 1.10.** Purify the *N*-oxide by fractional distillation, and it can be recrystallised from \*C<sub>6</sub>H<sub>6</sub>/hexane but is *hygroscopic*. [Bullitt & Maynard *J Am Chem Soc* **76** 1370 1954, Ross et al. *J Am Chem Soc* **78** 3625 1956, IR: Wiley & Slaym Aker *J Am Chem Soc* **79** 2233 1957.] The *picrate* has **m** 125-126.5° (from EtOH) [Boekelheide & Linn *J Am Chem Soc* **76** 1286 1954]. The *phthalate* has **m** 115-116° (from EtOH) [den Hertog et al. *Rec Trav Chim Pays Bas* **70** 591 1951]. [Beilstein **20** III/IV 2689, **20/5** V 479.]

**3-Picoline-*N*-oxide (3-methylpyridine-1-oxide)** [1003-73-2] **M 109.1, m 37-39°, 37-38° (evacuated capillary), 84-85°/0.3mm, 101-103°/0.7-0.8mm, 114-115°/1.5mm, 118°/2mm, pK<sup>25</sup> 1.08.** Purify the *N*-oxide by careful fractionation *in vacuo*. The distillate remains supercooled for several days before solidifying. It is a slightly *hygroscopic* solid which could melt in the hand. The *picrate* has **m** 149-151° (from EtOH). [Taylor & Corvetti *Org Synth Coll Vol IV* 654 1963, IR: Katritzky et al. *J Chem Soc* 3680 1959, Jaffé & Doak *J Am Chem Soc* **77** 4441, 4481 1955, Boekelheide & Linn *J Am Chem Soc* **76** 1286 1954]. [Beilstein **20** III/IV 2719, **20/5** V 517.]

**4-Picoline-*N*-oxide (4-methylpyridine-1-oxide)** [1003-67-4] **M 109.1, m 182-184°, 185-186°, 186-188°, pK<sup>25</sup> 1.29.** Recrystallise the *N*-oxide from EtOH/EtOAc, Me<sub>2</sub>CO/Et<sub>2</sub>O or \*C<sub>6</sub>H<sub>6</sub>. [Bullitt & Maynard *J Am Chem Soc* **76** 1370 1954, Boekelheide & Linn *J Am Chem Soc* **76** 1286 1954]. [Beilstein **20** III/IV 2741, **20/5** V 558.]

**Picolinic acid (pyridine-2-carboxylic acid)** [98-98-6] **M 123.1, m 138°, pK<sub>1</sub><sup>25</sup> 1.03 (1.36), pK<sub>2</sub><sup>25</sup> 5.30 (5.80).** Crystallise the acid from water or \*benzene. The *picrate* has **m** 185-187° (from MeOH). [Beilstein **22** H 33, **22** I 502, **22** II 30, **22** III/IV 303, **22/2** V 3.]

**α-Picolinium chloride** [14401-91-3] **M 129.6, m 77-78°, 85°, b 229°/atm.** A 1:1 mixture of α-picoline and HCl is distilled at 275°, then sublimed in a vacuum at 91-91.5°. [Beilstein **20** H 236, **20** III/IV 2685, **20/5** V 474.]

***N*-4-Picolinoylbenzimidazole** [100312-29-6] **M 173.3, m 105-107°.** Recrystallise the imidazole three times from hexane [Fife & Przystas *J Am Chem Soc* **108** 4631 1986].

**Picrolic acid [3-methyl-4-nitro-1-(4-nitrophenyl)-2-pyrazolin-5-one, picrolonic acid]** [550-74-3] **M 264.2, m 120°(dec), 116.5°(dec at 125°) 125°.** Crystallise picrolic acid from water or EtOH (solubility is 0.123% at 15° and 1.203% at 100° in H<sub>2</sub>O; and 1.107% at 0° and 11.68% at 81° in EtOH). It forms Ca, Cu Hg, Mg, Na, Sr, Pb and many other metal complexes [Maquestian et al *Bull Soc Chim Belg* **82** 233 1973, Isaki et al. *Chem Ber* **74** 1420 1941]. [Beilstein **24** H 51, **24** I 218, **24** II 25, **22** III/IV 105.]

**Pinacyanol chloride (Quinaldine Blue)** [2768-90-3] **M 388.9, CI 808, m 270°(dec).** Crystallise the dye from EtOH/diethyl ether. The *iodide* [605-91-4] crystallises from MeOH or EtOH with **m** 298-299°(dec). [Beilstein **23** H 320, **23** I 89, II 282, III/IV 2064, **23/10** V 129.]

***dl*-Pipicolinic acid (piperidine-2-carboxylic acid)** [4043-87-2] **M 129.1, m 264°, 280°(dec), pK<sub>1</sub><sup>25</sup> 2.29, pK<sub>2</sub><sup>25</sup> 10.77.** It crystallises from water. The (±)-*picrate* has **m** 158-159° (from EtOH or \*C<sub>6</sub>H<sub>6</sub>). [Beilstein **22** H 7, **22** III/IV 97, **22/1** V 220.] The *R*(+)-*enantiomer* [1723-00-8] has **m** 277°(dec) and [α]<sub>D</sub><sup>20</sup> +27° (c 4, H<sub>2</sub>O), and the *S*(-)-*enantiomer* [3105-95-1] has **m** 277°(dec) and [α]<sub>D</sub><sup>20</sup> -26° (c 4, H<sub>2</sub>O). [cf p 603, Beilstein **22** III/IV 96, **22/1** V 220.]

**Piperazine** [110-85-0] **M 86.1, m 110-112°, 44° (hexahydrate 142-63-2) b 125-130°/760mm, pK<sub>1</sub><sup>25</sup> 5.33, pK<sub>2</sub><sup>25</sup> 9.73.** Piperazine crystallises from EtOH or anhydrous \*benzene and is dried at 0.01mm. It can be sublimed under vacuum and purified by zone melting. The *hydrochloride* has **m** 172-174° (from EtOH), and the *dihydrochloride* crystallises from aqueous EtOH and has **m** 318-320° (dec, sublimes at 295-315°). The *picrate* has **m** ~200°, and the *picrolonate* crystallises from dimethylformamide (**m** 259-261°). [Beilstein **23** H 4, **23** I 4, **23** II 3, **23** III/IV 15, **23/1** V 30.]

§ Piperazine on polystyrene support is commercially available.

**Piperazine-*N,N'*-bis(2-ethanesulfonic acid) (PIPES)** [5625-37-6] **M 302.4**,  $\text{pK}_1^{25} < 3$ ,  $\text{pK}_2^{25} 6.82$  (7.82). Purify PIPES from boiling water (maximum solubility is about 1g/L) or as described for ADA (see [26239-55-4] in "Aliphatic Compounds" in this Chapter). [Good et al. *Biochemistry* 5 469 1966, *Beilstein* 23/12 V 380.]

**Piperazine dihydrochloride (H<sub>2</sub>O)** [142-64-3 (2HCl); 6094-40-2 (xHCl)] **M 177.1**, **m 82.5-83.5°**. Crystallise the salt from aqueous EtOH and dry it at 110°. [*Beilstein* 23 III/IV 17, 23/1 V 30.]

**Piperazine phosphate (H<sub>2</sub>O)** [18534-18-4] **M 197.6**. Crystallise it twice from water, air-dry and store for several days over Drierite. The salt dehydrates slowly if heated at 70°. [*Beilstein* 23 III/IV 18, 23/1 V 30.]

**Piperidine** [110-89-4] **M 85.2**, **f -9°**, **b 35.4°/40mm**, **106°/760mm**,  $d_4^{20} 0.862$ ,  $n_D^{20} 1.4535$ ,  $n_D^{25} 1.4500$ ,  $\text{pK}^{25} 11.20$  (**basic**). Dry piperidine with BaO, KOH, CaH<sub>2</sub>, or sodium, and fractionally distil (optionally from sodium, CaH<sub>2</sub>, or P<sub>2</sub>O<sub>5</sub>). Purify from pyridine by zone melting. [*Beilstein* 22 H 6, 22 I 5, 22 II 3, 22 III/IV 287, 22/2 V 3.]

§ Piperidine on polystyrene support is commercially available.

**Piperidine-2,6-dione (glutarimide)** [1121-89-7] **M 113.1**, **m 163-165°**, **155-157°**, **154°**, **152-154°**,  $\text{pK}^{25} 11.43$  (**acidic**). Purify it by dissolving 75g in 200ml of H<sub>2</sub>O, boil for 30 minutes with 2g of charcoal, filter, evaporate to dryness and recrystallise the residue from 125m L of 95% EtOH to give 70g of white crystals, **m 152-154°**. It also crystallises from Me<sub>2</sub>CO (**m 163-165°**) or EtOH (**m 153-154°**). The *N*-bromo derivative (a brominating agent) crystallises from H<sub>2</sub>O with **m 180-185°**. [Paris et al. *Org Synth Coll Vol IV* 496 1963, *Beilstein* 21 H 382, 21 I 331, 21 II 307, 21 III/IV 4582.]

**Piperidinium chloride** [6091-44-7] **M 121.6**, **m 244-245**, **247-248°**. Crystallise the salt from EtOH/diethyl ether in the presence of a small amount of HCl. [*Beilstein* 20 H 6, 20 II 10, 20 III/IV 295, 20/2 V 13.]

**Piperidinium nitrate** [6091-45-8] **M 145.2**, **m 141°**, (**155-157° from EtOH**). The nitrate crystallises from acetone/ethyl acetate or EtOH. [*Beilstein* 20 H 12, 20 II 10, 20 III/IV 295, 20/2 V 14.]

**4-Piperidone [piperidin-4(1H)-one,  $\gamma$ -]** [41661-47-6] **M 99.1** (**anhydrous**), **cannot be distilled**,  $\text{pK}^{25} 8.6$  (**acidic**). It is a yellow irritating oil which is an alkaloid in the leaves and branches of *Dichilus* species (leguminosae), e.g. *D. strictus*, *D. gracilis*, *D. lebeckioides*, *D. pilosus* and *D. reflexus*. It decomposes on distillation and is purified and stored as the *monohydrate monohydrochloride* [*anhydrous* 41979-39-9; *hydrate* 40064-34-4], **M 135.6** (*anhydrous salt*), which is in fact *4,4-dihydroxy-piperidinium chloride* that recrystallises from H<sub>2</sub>O with **m 94-96°**, **97-100°** (+ 1 H<sub>2</sub>O), or from EtOH/Et<sub>2</sub>O with **m 139-141°** (+ 1.5 EtOH); and the *anhydrous salt* has **m 147-149°**. See above for the *N*-acetyl, *N*-benzyl and *N*-methyl derivatives. The *N*-benzoyl derivative [24686-78-0], **M 203.2**, has **m 49-50°** and **b 158-160°/0.2mm**, and the *oxime* [79858-41-6], **M 114.1**, crystallises from dry \*C<sub>6</sub>H<sub>6</sub> in needles **m 117-118°** (anhydrous), and is hygroscopic. [*Beilstein* 21/6 V 419.]

**Piperine (1-piperoylpiperidine)** [94-62-2] **M 285.4**, **m 129-129.5°**,  $\text{pK}^{15} 1.98$ . Piperine crystallises as light yellow crystals from EtOH or EtOAc (**m 132°**), aqueous EtOH (**m 128-129°**), Et<sub>2</sub>O (**m 129°**), or \*benzene/ligroin. [*Beilstein* 20 H 79, 20 I 23, 20 II 53, 20 III/IV 1341, 20/3 V 469.]

**Poly(*N*-vinylcarbazole)** [25067-59-8]. Precipitate it seven times from tetrahydrofuran with MeOH, with final freeze-drying from \*benzene. Dry it under vacuum.

**Poly(4-vinylpyridine)** [25232-41-1] **M (105.1)<sub>n</sub>**. Purify it by repeated precipitation from solutions in EtOH and dioxane, and then EtOH and ethyl acetate. Finally, freeze-dry a *tert*-butanol solution.

**Poly(*N*-vinylpyrrolidone)** [9003-39-8] **M (111.1)<sub>n</sub>**, **crosslinked** [25249-54-1] **m >300°**. Purify it by dialysis, and freeze-drying. Also by precipitation from CHCl<sub>3</sub> solution by pouring into ether. Dry it in a vacuum over P<sub>2</sub>O<sub>5</sub>. For the crosslinked polymer, purification is by boiling for 10 minutes in 10% HCl and then washing with glass-distilled water until free from Cl ions. Finally, Cl ions are removed more readily by neutralising with

KOH and continued washing.

**(±)-Primaquine diphosphate** (*RS*- 8-[4-amino-1-methylbutylamino]-6-methoxyquinoline di-phosphate) [63-45-6] **M** 455.4, **m** 197-198°, 204-206°(dec),  $\text{pK}_{\text{Est}(1)} \sim 3.38$  (ring  $\text{N}^+$ ),  $\text{pK}_{\text{Est}(2)} \sim 10.8$  ( $\text{NH}_3^+$ ). It forms yellow crystals from 90% aqueous EtOH and is moderately soluble in  $\text{H}_2\text{O}$ . The *oxalate salt* has **m** 182.5-185° (from 80% aqueous EtOH), and the *free base* is a viscous liquid **b** 165-170°/0.002mm, 175-177°/2mm. [Elderfield et al. *J Am Chem Soc* **68** 1526 1964, Elderfield et al. *J Am Chem Soc* **77** 4817 1955, *Beilstein* **22** III/IV 5817.]

**Proclavine (3,6-diaminoacridine)** [92-62-6] **M** 209.2, **m** 284-286°,  $\text{pK}_1^{25} -2.7$ ,  $\text{pK}_2^{25} 0.55$ ,  $\text{pK}_3^{25} 9.49$ . It crystallises from aqueous MeOH. The *picrate* crystallises from aqueous pyridine with **m**  $\sim 185^\circ$ . [*Beilstein* **22** H 487, **22** I 649, **22** II 397, **22** III/IV 5487, **22/11** V 322.] For proflavin see 3,6-diaminoacridine hydrochloride.

**Propidium iodide (3,8-diamino-5-(3-diethylaminopropyl)-6-phenylphenanthridinium iodide methiodide)** [25535-16-4] **M** 668.4, **m** 210-230°(dec),  $\text{pK}_{\text{Est}(1)} \sim 4$  (aniline  $\text{NH}_2$ ),  $\text{pK}_{\text{Est}(2)} \sim 8.5$  ( $\text{EtN}_2$ ). It crystallises as red crystals from  $\text{H}_2\text{O}$  containing a little KI. It fluoresces strongly with nucleic acids. [Watkins *J Chem Soc* 3064 1952, *Beilstein* **22** III/IV 5519.] **TOXIC.**

**(±)-Propylene carbonate (4-methyl-1,3-dioxolan-2-one)** [108-32-7] **M** 102.1, **b** 79-80°/0.08mm, 110°/0.5-1mm, 112-114°/2mm, 241°/760mm,  $d_4^{20} 1.204$ ,  $n_D^{20} 1.423$ . It is manufactured by reaction of 1,2-propylene oxide with  $\text{CO}_2$  in the presence of a catalyst (quaternary ammonium halide). Contaminants include propylene oxide, carbon dioxide, 1,2- and 1,3-propanediols, allyl alcohol and ethylene carbonate. It can be purified by percolation through molecular sieves (Linde 5A, dried at 350° for 14 hours under a stream of argon), followed by distillation under a vacuum. [Jasinski & Kirkland *Anal Chem* **39** 163 1967.] It can be stored over molecular sieves under an inert gas atmosphere. When purified in this way it contains less than 2 ppm of water. Activated alumina and dried CaO have also been used as drying agents prior to fractional distillation under reduced pressure. It has been dried with 3A molecular sieves and distilled under nitrogen in the presence of *p*-toluenesulfonic acid, then redistilled and the middle fraction collected. [*Beilstein* **19** III/IV 1564, **19/4** V 21.]

**dl-Propylene oxide** [75-56-9] **M** 58.1, **b** 34.5°,  $d_4^{20} 0.829$ ,  $n_D^{20} 1.3664$ . Dry the oxide with  $\text{Na}_2\text{SO}_4$  or  $\text{CaH}_2$  and fractionally distil it through a packed column (glass helices), after refluxing with Na,  $\text{CaH}_2$ , or KOH pellets. [*Beilstein* **17** I 4, **17** II 131, **17** III/IV 17, **17/1** V 17.] The *R*(+)-enantiomer [15448-47-2] and the *S*(-)-enantiomer [16088-62-3] have **b** 33-34°/atm and  $[\alpha]_D^{20}$  (+)14.6° and (-)14.6° (neat). [*Beilstein* **17/1** V 17.]

**6-Propyl-2-thiouracil (propacil, propylail)** [51-52-5] **M** 170.2, **m** 218-220°, 218-220°,  $\text{pK}_1^{21} -6.54$  (aqueous  $\text{H}_2\text{SO}_4$ ),  $\text{pK}_2^{21} -4.22$  (aqueous  $\text{H}_2\text{SO}_4$ ),  $\text{pK}_3^{21} 8.25$  (4% aqueous EtOH). Purify propacil by recrystallisation from  $\text{H}_2\text{O}$  (soluble in 900 parts at 20°, and 100 parts at 100°). Its UV (MeOH) has  $\lambda_{\text{max}}$  at 277nm. [Anderson et al. *J Am Chem Soc* **67** 2197 1945, Vanderhaegue *Bull Soc Chim Belg* **59** 689 1950, *Beilstein* **24** III/IV 1333.]

**Protopine [fumarine, macleyine, 4,6,7,14-tetrahydro-5-methyl-bis[1,3]-benzodioxolo[4,5-*c*:5',6'-*g*]azecine-13(5*H*)-one]** [130-86-9] **M** 353.4, **m** 208°, 209°, 211°,  $\text{pK}^{25} 5.99$ . It crystallises from EtOH/ $\text{CHCl}_3$ . The *picrate* has **m**  $\sim 240^\circ$ (dec). [*Beilstein* **27** H 558, **17** I 568, **17** II 620, **17** III/IV 6881.]

**Pteridine** [91-18-9] **M** 132.2, **m** 139.5-140°,  $\text{pK}_1^{20} 4.05$  (equilibrium, hydrate),  $\text{pK}_2^{20} 11.90$  (OH of hydrate). It crystallises from EtOH, \*benzene, *n*-hexane, *n*-heptane or petroleum ether. It is best purified by sublimation at 120-130°/20mm. Store at 0°, in the dark. The yellow crystalline solid turns green in the presence of light and on long standing in the dark, and sublimation leaves the dark-coloured material behind. [Albert et al. *J Chem Soc* 474 1951; see Albert & Armarego *Adv Heterocycl Chem* **4** 1 1965, *Beilstein* **26** III/IV 1770.]

**2,4-(1*H*,3*H*)-Pteridinedione  $\text{H}_2\text{O}$  (lumazine)** [487-21-8] **M** 182.1, **m**  $>350^\circ$ ,  $\text{pK}_1^{20} <1.0$ ,  $\text{pK}_2^{20} 7.94$ . Crystallise the dione from water. It has also been purified as for pterin [2236-60-4] below. [Dallacker & Steiner *Justus Liebigs Ann Chem* **660** 98 1962, *Beilstein* **26** III/IV 2489.]

**Pterin (2-aminopteridin-4(3H)-one)** [2236-60-4] **M 163.1, m >300°**,  $\text{pK}_1^{20}$  2.27 (basic),  $\text{pK}_2^{20}$  7.96 (acidic). It is dissolved in hot 1% aqueous ammonia, filtered, and an equal volume of hot 1M aqueous formic acid is added. The solution is allowed to cool at 0-2° overnight. The solid is collected and washed with distilled water several times by centrifugation and dried *in vacuo* over P<sub>2</sub>O<sub>5</sub> overnight, and then at 100° overnight (any ammonium formate in the sample evaporates off). [Beilstein 26 III/IV 3936.]

**Pterocarpin** {(6a*R*-*cis*)-6a,12a-dihydro-3-methoxy-6*H*-[1,3]dioxolo[5,6]benzofuro[3,2*c*][1]-benzopyran} [524-97-0] **M 298.3, m 165°, 165-166°,  $[\alpha]_{546}^{20}$  -215° (c 0.5, CHCl<sub>3</sub>)**. Crystallise it from EtOH, or petroleum ether. [Fukui & Nakayama *Bull Chem Soc Jpn* 42 1408 1969, Packler & Underwood *Tetrahedron* 23 1817 1967, Beilstein 19 II 459, 19 III/IV 5789.]

**Pterioic acid (2-amino-6-*p*-carboxyanilinomethylpteridin-4(3H)-one)** [119-24-4] **M 312.3, m >300°(dec)**,  $\text{pK}_{\text{Est}(1)} \sim 2.3$  (basic, N1),  $\text{pK}_{\text{Est}(2)} \sim 2.6$  (basic, CH<sub>2</sub>NH),  $\text{pK}_{\text{Est}(3)} \sim 4.5$  (COOH),  $\text{pK}_{\text{Est}(4)} \sim 7.9$  (acidic 4-OH). Crystallise it from dilute HCl. Dry it *in vacuo*. Hygroscopic **IRRITANT**. [Nair et al. *J Org Chem* 46 3152 1981, Beilstein 26 III/IV 3942.]

**Purine** [120-73-0] **M 120.1, m 216-217°,  $\text{pK}_1^{20}$  2.30,  $\text{pK}_2^{20}$  9.86**. It crystallises from toluene or EtOH, and sublimes at 100-150°/0.1mm or 160°/10<sup>-4</sup>mm. The *picrate* has **m 207-209°** after crystallisation from 20 volumes of H<sub>2</sub>O. [Beilstein 26 H 354, 26 III/IV 1736.]

**Pyocyanine (1-hydroxy-5-methylphenazinium zwitterion)** [85-66-5] **M 210.2, m 133° (sublimes and decomposes on further heating),  $\text{pK}^{25} -3.5$** . It crystallises from H<sub>2</sub>O as dark blue needles. The *picrate* has **m 190° (dec)**. [Beilstein 23 H 395, 23 I 59, 23 II 234, 23/8 V 395.]

**Pyrazine** [290-37-9] **M 80.1, m 47°, 57°, b 115.5-115.8°,  $\text{pK}_1^{20}$  -6.25 (aqueous H<sub>2</sub>SO<sub>4</sub>),  $\text{pK}_2^{20}$  1.1 (0.51 at 20°)**. Distil pyrazine in steam and crystallise it from water. Purify also by zone melting. [Beilstein 23 H 91, 23 II 80, 23 III/IV 899, 23/5 V 351.]

**Pyrazinecarboxamide** [98-96-4] **M 123.1, m 189-191° (sublimes slowly at 159°),  $\text{pK}^{25} -0.5$** . The amide crystallises from water, EtOH or 1:1 hexane/EtOH in four modifications *viz* α-form, β-form, δ-form and γ-form. [Rø & Sørum *Acta Cryst* 28B 1677 1972, Beilstein 25 III/IV 772.]

**Pyrazinecarboxylic acid** [98-97-5] **M 124.1, m 225-229°(dec),  $\text{pK}_1^{25} -3.0$ ,  $\text{pK}_2^{25} -0.7$ ,  $\text{pK}_3^{25} 2.70$** . It crystallises from water. The *methyl ester* has **m 62°** (from petroleum ether). [Sauville & Spoerri *J Am Chem Soc* 63 3153 1941, Beilstein 25 III/IV 771.]

**Pyrazine-2,3-dicarboxylic acid** [89-01-0] **M 168.1, m 183-185°(dec), 187°(dec),  $\text{pK}_1 < -2.0$ ,  $\text{pK}_2$  0.9,  $\text{pK}_3$  2.77 (2.20)**. Crystallise the dicarboxylic acid from water and dry it at 100°. The *dimethyl ester* has **m 62-63°** (from Et<sub>2</sub>O or Et<sub>2</sub>O/petroleum ether). [Beilstein 25 H 168, 25 II 164, 25 III/IV 1064.]

**Pyrazine-1,4-dioxide** [2423-65-6] **M 112.1, m 285-286°,  $\text{pK}_{\text{Est}} < 0$** . If the sample contains pyrazine-1-oxide, then place it in a Soxhlet extractor and extract it with hot petroleum ether (b 60-68°) in which the mono-oxide is soluble. Collect the dioxide from the thimble and recrystallise it from MeOH. It is dried *in vacuo*. It has  $\nu_{\text{max}}$  at 1270cm<sup>-1</sup>. [Koelsch & Gumprecht *J Org Chem* 23 1605 1958.]

**Pyrazine-1-oxide** [2433-84-9] **M 96.1, m 113-114°,  $\text{pK}_{\text{Est}} < 0$** . Recrystallise the oxide from \*C<sub>6</sub>H<sub>6</sub>. It is soluble in hot petroleum ether (b 60-68°, see pyrazine-1,4-dioxide above). Dry it *in vacuo*. It has  $\nu_{\text{max}}$  at 1305cm<sup>-1</sup>. [Koelsch & Gumprecht *J Org Chem* 23 1605 1958.]

**Pyrazole** [288-13-1] **M 68.1, m 70°, b 96°/16mm,  $\text{pK}^{25} 2.48$** . Crystallise pyrazole from petroleum ether, cyclohexane, or water. Its solubility in H<sub>2</sub>O at 9.6° is 2.7moles/L, and at 24.8° it is 19.4moles/L; in cyclohexane at 31.8° it is 0.577moles/L, and at 56.2° it is 5.86moles/L; and in benzene at 5.2° it is 0.31moles/L, and at 46.5° it is 16.8moles/1000ml. [Barszcz et al. *J Chem Soc, Dalton Trans* 2025 1986, Beilstein 23 H 39, 23 I 15, 23 II 33, 23 III/IV 550, 23/4 V 122.]

**Pyrazole-*N*-1-carboximidine hydrochloride (Praxadine, 1-amidinopyrazole hydrochloride, 1*H*-pyrazole-1-carboximidine hydrochloride)** [4023-02-3] **M 146.6, m 165-166°**, 167-168°, 167-168.5°, 167-170°, **pK<sub>Est</sub> ~8.5**. The white crystalline hydrochloride, which can be prepared from pyrazole and cyanamide in *p*-dioxane containing HCl, is purified by recrystallisation from dioxane/H<sub>2</sub>O. It is a good guanylation agent for primary and secondary amines [Bernatowicz et al. *J Org Chem* **57** 2497 1992, Bernatowicz et al. *Tetrahedron Lett* **34** 3389 1993]. The *free base* can be obtained by suspending the hydrochloride in CHCl<sub>3</sub> and bubbling NH<sub>3</sub> gas through, whereby NH<sub>4</sub>Cl separates and is filtered off. CHCl<sub>3</sub> is then distilled off and the residue is washed with a little EtOH and dried *in vacuo*. It crystallises from \*C<sub>6</sub>H<sub>6</sub> and has **m 93-96° (94-98.5° and 97-101°** have also been reported). The *picrate* has **m 202-203° (208°** has also been reported). [Bredereck et al. *Chem Ber* **98** 3178 1965, Jones et al. *J Org Chem* **19** 1428 1954, 2497 1992, *Beilstein* **23/4** V131.]

**1*H*-Pyrazole-3-carboxylic acid** [1621-91-6] **M 112.1, m 208-210°, 210-214° (decarboxylates)**, **pK<sub>25</sub> 3.74, pK<sub>Est(2)</sub> ~12 (acidic NH)**. Purify the acid by precipitation from an alkaline solution with mineral acid, and recrystallise it from H<sub>2</sub>O. On heating, it decarboxylates (to pyrazole *m* 70°) more readily than the 4-carboxylic acid below. The *N*-2-*methyl derivative* has **m 222° (from H<sub>2</sub>O)** and **pK<sub>25</sub> 3.27**. [Habraken et al. *Rec Trav Chim Pays Bas* **85** 1194 1966, Jones et al. *J Org Chem* **19** 1428 1954, Allen & Shirley *J Am Chem Soc* **80** 6273 1958, Knorr *Justus Liebigs Ann Chem* **273** 231 1893, Knorr *Justus Liebigs Ann Chem* **279** 217 1894.]

**1*H*-Pyrazole-4-carboxylic acid** [37718-11-9] **M 112.1, m 282° (decarboxylates)**, **pK<sub>Est(1)</sub> ~3.6, pK<sub>Est(2)</sub> ~12 (acidic NH)**. This acid, also obtained by decarboxylating the more water soluble 3,4,5-tricarboxylic acid, crystallises in yellow prisms from H<sub>2</sub>O. [Buchner & Fritsch *Justus Liebigs Ann Chem* **273** 253 1893, Knorr & Rothenburg *Chem Ber* **28** 693 1895, *Beilstein* **25** H 116.]

**Pyrazole-3,5-dicarboxylic acid** [3112-31-0] **M 174.1, m 287-289°(dec), 295-297°(dec)**, **pK<sub>Est(1)</sub> ~1.2 (CO<sub>2</sub>H), pK<sub>Est(2)</sub> ~3.7 (CO<sub>2</sub>H), pK<sub>Est(3)</sub> ~12 (NH)**. It crystallises from water as a *monohydrate*, or EtOH. Dry it in a vacuum at 100°. The *dimethyl ester* crystallises from \*C<sub>6</sub>H<sub>6</sub> with **m 155°**. [*Beilstein* **25** III/IV 1047.]

**Pyridazine *N*-oxide (pyridazine 1-oxide)** [1457-42-7] **M 96.1, m 38-39°, b 138-140°/4mm, pK<sub>Est</sub> <1**. Purify the oxide by distillation in a vacuum and by sublimation *in vacuo*. When a solution of the oxide in MeOH is treated with an aqueous solution of CuCl<sub>2</sub>, the [C<sub>4</sub>H<sub>4</sub>N<sub>2</sub>O]<sub>2</sub>-CuCl<sub>2</sub>-2H<sub>2</sub>O-*complex* (**m 182-183°**) is formed from which the oxide can be recovered. [Pollak et al. *J Org Chem* **35** 2478 1970, Klinge et al. *Rec Trav Chim Pays Bas* **95** 21 1976, Ohsawa et al. *Tetrahedron Lett* 1979 1978, Koelsch & Gumprecht *J Org Chem* **23** 1605 1958, *Beilstein* **23** III/IV 890.]

**Pyridine** [110-86-1] **M 79.1, f -41.8°, b 115.6°, d<sub>4</sub><sup>20</sup> 0.9831, n<sub>D</sub><sup>20</sup> 1.51021, pK<sub>25</sub> 5.23**. Likely impurities are H<sub>2</sub>O and amines such as the picolines and lutidines. Pyridine is *hygroscopic* and is miscible with H<sub>2</sub>O and organic solvents. It can be dried with solid KOH, NaOH, CaO, or BaO, followed by fractional distillation. Other methods of drying include standing with Linde type 4A molecular sieves, CaH<sub>2</sub> or LiAlH<sub>4</sub>, azeotropic distillation of the H<sub>2</sub>O with toluene or \*benzene, or treated with phenylmagnesium bromide in ether, followed by evaporation of the ether and distillation of the pyridine. A recommended [Lindauer & Mukherjee *Pure Appl Chem* **27** 267 1971] method dries pyridine over solid KOH (20g/Kg) for 2 weeks and fractionally distills the supernatant over Linde type 5A molecular sieves and solid KOH. The product is stored under CO<sub>2</sub>-free nitrogen. Pyridine can be stored in contact with BaO, CaH<sub>2</sub> or molecular sieves. Non-basic materials can be removed by steam distilling a solution containing 1.2 equivalents of 20% H<sub>2</sub>SO<sub>4</sub> or 17% HCl until about 10% of the base has been carried over along with the non-basic impurities. The residue is then made alkaline, and the base is separated, dried with NaOH and fractionally distilled. *The alkali metals, Na, Li or Cs should NOT be used for drying pyridine, and pyridine derivatives, as they form coloured pyridine radical anions leading to bipyridyls.* [see Schmulback et al. *J Am Chem Soc* **90** 6600 1968].

*Alternatively*, pyridine can be treated with oxidising agents. Thus pyridine (800ml) has been stirred for 24 hours with a mixture of ceric sulfate (20g) and anhydrous K<sub>2</sub>CO<sub>3</sub> (15g), then filtered and fractionally distilled. Hurd and Simon [*J Am Chem Soc* **84** 4519 1962] stirred pyridine (135ml), water (2.5L) and KMnO<sub>4</sub> (90g) for 2 hours at 100°, then set aside for 15 hours before filtering off the precipitated manganese oxides. Addition of solid KOH (*ca* 500g) caused pyridine to separate. It was decanted, refluxed with CaO for 3 hours and distilled.

Separation of pyridine from some of its homologues can be achieved by crystallisation of the oxalates. Pyridine is precipitated as its *oxalate* by adding it to the stirred solution of oxalic acid in acetone. The precipitate is filtered, washed with cold acetone, and pyridine is regenerated and isolated. Other methods are based on complex formation with  $\text{ZnCl}_2$  or  $\text{HgCl}_2$ . Heap, Jones and Speakman [*J Am Chem Soc* **43** 1936 1921] added crude pyridine (1L) to a solution of  $\text{ZnCl}_2$  (848g) in 730ml of water, 346ml of conc HCl and 690ml of 95% EtOH. The crystalline precipitate of  $\text{ZnCl}_2 \cdot (\text{pyridine})_2$  was filtered off, recrystallised twice from absolute EtOH, then treated with a conc NaOH solution, using 26.7g of solid NaOH to 100g of the complex. The precipitate was filtered off, and the pyridine was dried with NaOH pellets and distilled. Similarly, Kyte, Jeffery and Vogel [*J Chem Soc* 4454 1960] added pyridine (60ml) in 300ml of 10% (v/v) HCl to a solution of  $\text{HgCl}_2$  (405g) in hot water (2.3l). On cooling, crystals of pyridine- $\text{HgCl}_2$  (1:1) complex separated and were filtered off, crystallised from 1% HCl (to *m* 178.5-179°), washed with a little EtOH and dried at 110°. The free base was liberated by addition of excess aqueous NaOH and separated by steam distillation. The distillate was saturated with solid KOH, and the upper layer was removed, dried further with KOH, then BaO and distilled. Another possible purification step is fractional crystallisation by partial freezing.

Small amounts of pyridine have been purified by vapour-phase chromatography, using a 180-cm column of polyethyleneglycol-400 (Shell 5%) on Embacel at 100°, with argon as carrier gas. The Karl Fischer titration can be used for determining water content. A colour test for pyrrole as a contaminant is described by Biddiscombe et al. [*J Chem Soc* 1957 1954]. The 1:1-hydrochloride crystallises from EtOH with *m* 144°, *b* 218-219°/760mm (see below) and is hygroscopic. The 1:2-hydrochloride has *m* 46° [58888-58-7] and the *picrate* has *m* 165-166° [1152-90-5]. [*Beilstein* **20** H 181, **20** I 54, **20** II 96, **20** III/IV 2205, **20/5** V 160.]

§ Polystyrene-supported pyridine is commercially available.

**Pyridine-2-aldehyde** [1121-60-4] *M* 107.1, *b* 81.5°/25mm, *d*<sub>4</sub><sup>20</sup> 1.121, *n*<sub>D</sub><sup>20</sup> 1.535, *pK*<sub>1</sub><sup>25</sup> 3.84, *pK*<sub>2</sub><sup>25</sup> 12.68. Purification is achieved by bubbling sulfur dioxide into a solution of 50g of the aldehyde in 250ml of boiled water, under nitrogen, at 0°, until precipitation is complete. The bisulfite addition compound is filtered off rapidly and, after washing with a little water, is refluxed in 17% HCl (200ml) under nitrogen until a clear solution is obtained. Neutralisation with  $\text{NaHCO}_3$  and extraction with ether separated the aldehyde which is recovered by drying the extract, then distilling twice, under nitrogen. [Kyte et al. *J Chem Soc* 4454 1960, *Beilstein* **21** I 287, **21** III/IV 3495, **21/7** V 293.]

**Pyridine-3-aldehyde** [500-22-1] *M* 107.1, *b* 89.5°/14mm, *d*<sub>4</sub><sup>20</sup> 1.141, *n*<sub>D</sub><sup>20</sup> 1.549, *pK*<sub>1</sub><sup>20</sup> 3.80, *pK*<sub>2</sub><sup>20</sup> 13.10. Purified as for pyridine-2-aldehyde. [*Beilstein* **21** I 288, **21** III/IV 3517, **21/7** V 334.]

**Pyridine-4-aldehyde** [872-85-5] *M* 107.1, *b* 79.5°/12mm, *d*<sub>4</sub><sup>20</sup> 1.137, *n*<sub>D</sub><sup>20</sup> 1.544, *pK*<sub>1</sub><sup>20</sup> 4.77, *pK*<sub>2</sub><sup>20</sup> 12.20. Purified as for pyridine-2-aldehyde. [*Beilstein* **21** III/IV 2529, **21/7** V 351.]

**Pyridine-2-aldoxime (pyridine-2-carboxaldoxime)** [873-69-8] *M* 122.1, *m* 111-113°, 114°, *pK*<sub>1</sub><sup>25</sup> 3.56, *pK*<sub>2</sub><sup>25</sup> 10.17. Recrystallise it from  $\text{Et}_2\text{O}$ /petroleum ether or  $\text{H}_2\text{O}$ . The *picrate* has *m* 169-171° (from aqueous EtOH). It is used in peptide synthesis. [UV: Grammaticakis *Bull Chem Soc Fr* 109, 116 1956, Ginsberg & Wilson *J Am Chem Soc* **79** 481 1957, Hanania & Irvine *Nature* **183** 40 1959, Green & Saville *J Chem Soc* 3887 1956, *Beilstein E-isomer* **21** I 288, **21** III/IV 3504, **21/7** V 305.]

It has also been purified *via* the *dimethyl ester* which is distilled (**b** 95-100°/1.5mm) and hydrolysed with 3.5N HCl, evaporated and recrystallised. [Armarego & Evans *J Appl Chem* **12** 45 1962, Foye et al. *J Med Chem* **9** 61 1966, *Beilstein* **22** H 155, **22** I 534, **22** II 106, **22** III/IV 1641, **22/4** V 135.]

**Pyridine hydrobromide perbromide (pyridinium bromide perbromide)** [39416-48-3] **M 319.9, m 130° (dec), 132-134°(dec), 135°(dec).** It is a very good brominating agent-liberating one mol of Br<sub>2</sub>. Purify it by recrystallisation from glacial acetic acid (33g from 100ml of AcOH) to give orange-red crystals. [Fieser & Fieser's *Reagents for Organic Chemistry* **1** 967 1967, Englert & McElvain *J Am Chem Soc* **51** 865 1929, *Beilstein* **20** II 103, **20/5** V 181.]

**Pyridine hydrochloride** [628-13-7] **M 115.6, m 144°, b 218°/760mm.** Crystallise the salt from CHCl<sub>3</sub>/EtOAc and wash it with Et<sub>2</sub>O. It is *hygroscopic*. [*Beilstein* **20** H 185, **20** I 57, **20** II 103, **20** III/IV 2230, **20/5** V 180.]

**Pyridine N-oxide** [694-59-7] **M 95.1, m 67°, 68-69°, pK<sub>24</sub> 0.79.** Purify the *N-oxide* by crystallisation from Et<sub>2</sub>O and by vacuum sublimation. The *picrolonate* has **m** 182-184°. [Katritzky *J Chem Soc* 2407 1956, *Beilstein* **20** III/IV 2305, **20/5** V 217.]

**Pyridine 3-sulfonic acid** [636-73-7] **M 159.2, m 365-366°(dec), 357°, pK<sub>25</sub> 2.89 (12% aqueous EtOH), 3.22 (H<sub>2</sub>O)(protonation on N).** Purify the acid by recrystallisation from H<sub>2</sub>O or aqueous EtOH as needles or plates. [pKa: Evans & Brown *J Org Chem* **27** 3127 1962, IR: Arnett & Chawla *J Am Chem Soc* **100** 214 1978.] Its UV in 50% aqueous EtOH has  $\lambda_{\text{max}}$  at 208 and 262nm. The *ammonium salt* has **m** 243° (from H<sub>2</sub>O), the *sulfonyl chloride* has **m** 133-134° (from petroleum ether), the *amide* has **m** 110-111° (from H<sub>2</sub>O), the *hydrochloride* has **m** >300°(dec), and the *N-methyl betaine* has **m** 130° (from H<sub>2</sub>O). [Gastel & Wibaut *Rec Trav Chim Pays Bas* **53** 1031 1934, McElvain & Goese *J Am Chem Soc* **65** 2233 1943, Machek *Monatsh Chem* **72** 77 1938, *Beilstein* **22** I 616, **22** II 309, **22/7** V 552.]

**2-Pyridinethiol (2-mercaptopyridine)** [2637-34-5; 73018-10-7] **M 111.2, m 127.4°, 127-130°, 130-132°, pK<sub>1</sub><sup>20</sup> -1.07, pK<sub>2</sub><sup>20</sup> 9.97.** If impure, dissolve it in CHCl<sub>3</sub>, wash it with dilute AcOH, H<sub>2</sub>O, dry (MgSO<sub>4</sub>), evaporate under reduced pressure and recrystallise the residue from \*C<sub>6</sub>H<sub>6</sub> or H<sub>2</sub>O. *2-Methylmercaptopyridine* (**b** 100-104°/33mm, pK<sub>20</sub> 3.59) was formed by treatment with MeI/NaOH. [Albert & Barlin *J Chem Soc* 2394 1959, Phillips & Shapiro *J Chem Soc* 584 1942, *Beilstein* **21** H 45, **21** III/IV 373, **21/7** V 147.]

**4-Pyridinethiol (4-mercaptopyridine)** [4556-23-4] **M 111.2, m 177°, 179-189°, 186°, pK<sub>1</sub><sup>20</sup> 1.43, pK<sub>2</sub><sup>20</sup> 8.86.** Purify the thiol by dissolving ~45g in boiling H<sub>2</sub>O (100ml) (charcoal), filter and precipitate it by adding 50% aqueous NaOH (~80ml) to pH ~6. Dissolve the precipitate in EtOH, evaporate it to dryness, then crystallise it from boiling EtOH (~100ml, charcoal) to give yellow flat hexagonal plates (**m** 186°). It sublimes readily *in vacuo*. [King & Ware *J Chem Soc* 873 1939.] The *picrate* forms yellow needles from H<sub>2</sub>O with **m** 222°(dec). The *4-methylmercaptopyridine* derivative crystallises from petroleum ether (**m** 47°, also **44-45°** was reported, with a pK<sub>20</sub> of **5.97**) and was prepared by treatment with MeI/NaOH. Its *picrate* has **m** 245° (from H<sub>2</sub>O, MeOH or EtOH). The *N-methyl-4-pyridinethiol* derivative has **m** 168.5-170° (from EtOH), a pK<sub>20</sub> of **1.30** and is soluble in CHCl<sub>3</sub>. [Albert & Barlin *J Chem Soc* 2384 1959, *Beilstein* **21** II 35, **22** III/IV 373, **22/7** V 147.]

**Pyridoxal hydrochloride, pyridoxamine hydrochloride and pyridoxine hydrochloride (vitamin B<sub>6</sub>).** See entries in "Miscellaneous Compounds" in Chapter 7.

**1-(2-Pyridylazo)-2-naphthol (PAN)** [85-85-8] **M 249.3, m 140-142°, 142°, pK<sub>1</sub><sup>30-36</sup> 2.9, pK<sub>2</sub><sup>30-36</sup> 11.2.** Purify PAN by repeated crystallisation from EtOH or MeOH. It can also be purified by sublimation under vacuum. Purity can be checked by TLC using a mixed solvent (petroleum ether/Et<sub>2</sub>O/EtOH; 10:10:1) on a silica gel plate. It has pK<sub>1</sub> 1.9 and pK<sub>2</sub> 12.2 in 20% aqueous ethoxyethanol. It chelates with copper [Pease & Williams *Anal Chem* **31** 1046 1959]. [*Beilstein* **22** I 694, **22** III/IV 7073, **22/4** V 618.]

**4-(2-Pyridylazo)-resorcinol (PAR)** [1141-59-9] M 215.2, m >195°(dec),  $\lambda_{\max}$  415nm,  $\epsilon$  2.59 x 10<sup>4</sup> (pH 6-12), pK<sub>1</sub><sup>25</sup> 2.69 (3.1), pK<sub>2</sub><sup>25</sup> 5.50 (5.8), pK<sub>3</sub><sup>25</sup> 12.5 (11.9). Purify PAR as the sodium salt by recrystallisation from 1:1 EtOH/water. Purity can be checked by TLC using a silica gel plate and a mixed solvent (*n*-BuOH:EtOH:2M NH<sub>3</sub>; 6:2:2). [Beilstein 22 I 694, 22 III/IV 7074, 22/14 V 619.]

**3-(2-Pyridyl)-5,6-diphenyl-1,2,4-triazine** [1046-56-6] M 310.4, m 191-192°. Purify it by repeated recrystallisation from EtOH/dimethylformamide. It is a reagent for estimating Fe(II) and Ru(II). [Chriswell & Schilt *Anal Chem* 46 992 1974, Kamra & Ayers *Anal Chem* 78 423 1975.]

**1-(4-Pyridyl)ethanol** [*R*(+) 27854-88-2; *S*(-) 54656-96-1] M 123.2, m 63-65°, 67-69°, b 138-140°/30mm, 254°/760mm,  $[\alpha]_{\text{D}}^{20}$  *R*(+) +49.8° and *S*(-) -49.8° (c 0.5, EtOH), pK<sub>Est</sub> ~5.4. Purify it by recrystallisation from petroleum ether. The *m* recorded after sublimation was 59.9-60.2°, and 55° after crystallisation from \*C<sub>6</sub>H<sub>6</sub>/petroleum ether or petroleum ether/\*C<sub>6</sub>H<sub>6</sub>. The (-)-*di-O-benzoyl tartrate salt* has *m* 146-148° (from EtOH). [UV, ORD: Harelli & Samori *J Chem Soc Perkin Trans 2* 1462 1974.] The *racemate* recrystallises from Et<sub>2</sub>O with *m* 74-76°, b 90-94°/1mm. The *picrate* has *m* 125-126° (from \*C<sub>6</sub>H<sub>6</sub>). [Ferles & Attia *Col Czech Chem Commun* 38 611 1973, UV, NMR: Nielson et al. *J Org Chem* 29 2898 1964, Beilstein 21 III/IV 522, 21/2 V 217.]

**5-(3-Pyridyl)-4H-1,2,4-triazole-3-thiol** [1,2-dihydro-5-(3-pyridinyl)-3H-1,2,4-triazole-3-thione] [32362-88-2] M 178.2, , m 285-286°, 296-302°, pK<sub>Est(1)</sub> ~3.0 (py N), pK<sub>Est(2)</sub> ~9 (SH). This thio-1,2,4-triazole was prepared by fusing nicotinoylhydrazide with thiourea at ~150° then at 160-165° (30 minutes), cooled, EtOH was added and the white solid was filtered off [Beyerman et al. *Rec Trav Chim Pays Bas* 73 109 1954]; or by heating 1-nicotinoyl-3-thiosemicarbazide in 5% aqueous NaOH at 100° (4 hours), cooled, acidified with AcOH, and filtered off [Yale & Piala *J Med Chem* 9 42 1966]. It was recrystallised from 95% EtOH, *n*-BuOH/H<sub>2</sub>O, H<sub>2</sub>O, and 0.5% aqueous HCl provides the *hydrochloride*, which is dried *in vacuo* [over P<sub>2</sub>O<sub>5</sub> or H<sub>2</sub>SO<sub>4</sub>]. [Yoshida & Asai *J Pharm Soc Jpn* 74 948 1954, *Chem Abstr* 49 10937 1955, Beilstein 26 IV 2129].

**5-(4-Pyridyl)-4H-1,2,4-triazole-3-thiol** [1,2-Dihydro-5-(4-pyridinyl)-3H-1,2,4-triazole-3-thione] [14910-06-6] M 178.2, , m 301-303° (dec), 305-308° (dec), 308-313°, 320-322° (dec), 321-322° (dec), pK<sub>Est(1)</sub> ~3.5 (py N), pK<sub>Est(2)</sub> ~9 (SH). This thio-1,2,4-triazole was prepared and purified as for the 3-pyridyl-isomer above but by using isonicotinic acid derivatives. It has mild diuretic and natriuretic activity. [Blackman et al. *J Chem Soc C* 661 1967, Beyerman et al. *Rec Trav Chim Pays Bas* 73 109 1954, Yale & Piala *J Med Chem* 9 42 1966, Yoshida & Asai *J Pharm Soc Jpn* 74 948 1954, *Chem Abstr* 49 10937 1955, Beilstein 26 IV 2129]. **5-(4-Pyridyl)-4H-1,2,4-triazole-3-sulfonic acid hydrate** was obtained by oxidising the 3-thiol with saturated aqueous KMnO<sub>4</sub> 25° (1 hour), decomposed with EtOH, filtered, precipitated as the Ag salt, filtered off, and decomposed with 5% HCl, then evaporated, and the residue was recrystallised from H<sub>2</sub>O. It decomposed on heating. [Blackman et al. *J Chem Soc C* 661 1967.]

**$\alpha$ -Pyrone (2H-pyran-2-one, coumalin)** [504-31-4] M 96.1, m 5°, 8-9°, b 103-111°/19-22mm, 110°/26mm, 104°/ 30mm, 115-118°/37mm, 206-207°/atm,  $d_4^{20}$  1.1972,  $n_{\text{D}}^{20}$  1.5298, pK<sup>25</sup> -1.14 (aqueous H<sub>2</sub>SO<sub>4</sub>). Dissolve  $\alpha$ -pyrone in Et<sub>2</sub>O, wash it with brine, dry (Na<sub>2</sub>SO<sub>4</sub>), filter, evaporate, distil the residue under vacuum and redistil it. It is a colourless liquid. Its IR has  $\nu_{\max}$  at 1622 and 1752cm<sup>-1</sup> (CHCl<sub>3</sub>). [Zimmermann et al. *Org Synth Coll Vol V* 982 1973, Nakagawa & Saegusa *Org Synth* 56 49 1977, Elderfield *J Org Chem* 6 566 1941.] The *picrate* has *m* 106-107° (from EtOH). [Beilstein 17 H 271, 17 II 305, 17 III/IV 4399, 17/9 V 288.]

**$\gamma$ -Pyrone (4H-pyran-4-one)** [108-97-4] M 96.1, m 32.5-32.6°, 33°, 32-34°, b 88.5°/7mm, 91-91.5°/9mm, 95-97°/13mm, 105°/23mm, 215°/atm, pK<sup>25</sup> 0.10. Purify  $\gamma$ -pyrone by vacuum distillation; the distillate crystallises and is *hygroscopic*. It is non-steam volatile. The *hydrochloride* has *m* 139° (from EtOH), and the *picrate* has *m* 130.2-130.3° (from EtOH or H<sub>2</sub>O). [Mayer *Chem Ber* 90 2362 1957, IR: Jones et al. *Can J Chem* 37 2007 1959, Neelakatan *J Org Chem* 22 1584 1957, Beilstein 17 H 271, 17 I 145, 17 II 305, 17 III/IV 4399, 17/9 V 290.]

**Pyronin G [3,6-bis(dimethylamino)xanthylium chloride]** [92-32-0] **M 302.8, m 250-260°, CI 45005,  $\lambda_{\max}$  522nm,  $pK_{\text{Est}} \sim 7.6$ .** Commercial material may contain a large quantity of zinc. Purify it by dissolving 1g in 50ml of hot water containing 5g NaEDTA. Cool to 0°, filter, evaporate to dryness and the residue is extracted with EtOH. The solution is evaporated to 5-10ml, filtered, and the dye is precipitated by addition of excess of dry diethyl ether. It is centrifuged, and the crystals are washed with dry ether. The procedure is repeated, then the product is dissolved in  $\text{CHCl}_3$ , filtered and evaporated. The dye is stored in a vacuum. [Beilstein 18 H 596, 18 III/IV 7361, 18/10 V 181.]

**Pyrrrol-2,5-dione (maleimide)** [541-59-3] **M 97.1, m 91-93°, 92.6-93°,  $d_{\text{D}}^{105.5}$  1.2493,  $n_{\text{D}}^{110.7}$  1.49256.** Purify it by sublimation in a vacuum. The UV has  $\lambda_{\max}$  at 216 and 280nm in EtOH. [de Wolf & van de Straete *Bull Soc Chim Belg* 44 288 1935, UV: Rondestvedt et al. *J Am Chem Soc* 78 6115 1956, IR: Chiorboli & Mirone *Ann Chim (Rome)* 42 681 1952, Beilstein 21/10 V 3.]

**Pyrrrole** [109-97-7] **M 67.1, m 23.4°, b 66°/80mm, 129-130°/atm,  $d_4^{20}$  0.966,  $n_{\text{D}}^{20}$  1.5097,  $pK_1^{25}$  -4.4 (Protonation on carbon),  $pK_2^{25}$  17.51 (aqueous KOH, H<sub>2</sub> scale).** Dry pyrrole with NaOH,  $\text{CaH}_2$  or  $\text{CaSO}_4$ . Fractionally distil it under reduced pressure from  $\text{CaH}_2$ . Store it under nitrogen as it turns brown in air. Redistil it immediately before use. The *picrate* forms orange-red crystals with **m 69°(dec)**. [Beilstein 20 H 4, 20 I 3, 20 II 3, 20 III/IV 61, 20/5 V 3.]

**1H-Pyrrole-1-propanoic acid (3-[pyrrol-1-yl]propionic acid)** [89059-06-3] **M 139.2, m 59-64°, 62.5°,  $pK_{\text{Est}} \sim 4.5$ .** Recrystallise the acid from petroleum ether (b 80-100°) and dry it *in vacuo*. The *ethyl ester* has **b 122°/23mm**. The *amide* forms colourless needles from  $^*\text{C}_6\text{H}_6$  with **m 81°** and is soluble in cold  $\text{H}_2\text{O}$ . [Clemo & Ramage *J Chem Soc* 49 1931, Jefford & Johncock *Helv Chim Acta* 66 2666 1983.]

**Pyrrrolidine** [123-75-1] **M 71.1, b 87.5-88.5°,  $d_4^{20}$  0.860,  $n_{\text{D}}^{20}$  1.443,  $pK^{25}$  11.31.** Dry pyrrolidine with BaO or sodium, then fractionally distil it, under  $\text{N}_2$ , through a Todd column packed with glass helices. [Beilstein 20 H 159, 20 I 36, 20 II 79, 20 III/IV 2072, 20/1 V 162.]

**Pyrrrolidine-1-carbodithioic acid ammonium salt** [5108-96-3] **M 164.3, m 128-130°,  $pK^{25}$  3.25 (free acid).** Purify the salt by recrystallising twice by dissolving in MeOH and adding  $\text{Et}_2\text{O}$ . It has also been purified by recrystallisation from EtOH. It is used for the precipitation of As, Bi, Cd, Co, Cu, Fe, Mn, Ni, Pb, Sb, Su, V and Zn from acidic solutions [Kinrade & van Loon *Anal Chem* 46 1894 1974]. The *ethyl ester* has **b 87-89°/0.01mm**. [Synthesis and Polarography: Kitagawa & Taku *Bull Chem Soc Jpn* 64 2151 1973, Malissa & Schöffmann *Mikrochim Acta* 187 1955, Beilstein 20 III/IV 195, 20/1 V 331.]

**Quercetin (2H<sub>2</sub>O) (3,3',4',5,6-pentahydroxyflavone)** [6151-25-3 (2H<sub>2</sub>O); 117-39-3 (anhydrous)] **M 338.3, m ca 315°(dec), 317.4-317.9°(dec), (phenolic  $pK_s$  7—10).** Crystallise the flavone from aqueous EtOH and dry at 100°. It also sublimes in a vacuum. Its IR has  $\nu_{\max}$  at 2.5 $\mu$  and 16.7 $\mu$  (KBr). It complexes with  $\text{Cu}^{2+}$ ,  $\text{Al}^{3+}$ ,  $\text{Ca}^{2+}$ ,  $\text{Ge}^{4+}$ ,  $\text{Zn}^{2+}$ ,  $\text{Ti}^{4+}$ ,  $\text{Zr}^{4+}$ ,  $\text{Th}^{4+}$ ,  $\text{UO}^{4+}$ . [Beilstein 18 H 242, 18 I 242, 18 II 236, 18 III/IV 3470, 18/5 V 494.]

(±)-**Quinacrine [Atebrine, Mepacrine, 3-chloro-9(4-diethylamino-1-methyl)butylamino-7-methoxy-acridine] dihydrochloride.** [69-05-6] **M 472.9, m 248-250°(dec),  $pK_1^{30}$  -6.49 (aq  $\text{H}_2\text{SO}_4$ ),  $pK_2^{30}$  7.73 (ring  $\text{NH}^+$ ),  $pK_3^{30}$  10.18 ( $\text{Et}_2\text{N}$ ).** It crystallises from  $\text{H}_2\text{O}$  (solubility is 2.8% at room temperature) as yellow crystals. It is slightly soluble in MeOH and EtOH. The *free base* crystallises from  $\text{Me}_2\text{CO}$  or petroleum ether with **m 86-88°**, or aqueous EtOH with 85-87.5°. The *bismethiodide* has **m 224°** (from MeOH/EtOAc/ $\text{Et}_3\text{N}$ ), and the *picrate* has **m 207-208°(dec)** when crystallised from  $\text{Me}_2\text{CO}$ /EtOH. It is an antimalarial, antiprotozoal and intercalates DNA. [Wolfe *Antibiot* 3 (Springer-Verlag) 203 1975, Beilstein 22 III/IV 6247, 22/12 V 235.]

**Quinaldic (quinoline-2-carboxylic) acid** [93-10-7] **M 173.2, m 156-157°,  $pK_1^{25}$  1.45,  $pK_2^{25}$  2.49 (2.97).** Crystallise quinaldic acid from  $^*\text{C}_6\text{H}_6$  or AcOH. It is used for the estimation of many metals. The *methyl ester* has **m 86-87°** (from hexane) and  $pK^{25}$  1.76. [Chaudhuri et al. *Frez Z Anal Chem* 281 361 1976, Beilstein 22 H 71, 22 II 55, 22 III/IV 1149, 22/3 V 183.]

**Quinazoline** [253-82-7] **M** 130.2, **m** 48.0-48.5°, **b** 120-121°/17-18mm, **pK**<sub>1</sub><sup>20</sup> -4.51 (aqueous H<sub>2</sub>SO<sub>4</sub>, anhydrous dication), **pK**<sub>2</sub><sup>20</sup> 2.01 (anhydrous monocation), **pK**<sub>3</sub><sup>20</sup> 4.3 (equilibrium with 3,4-hydrated species), **pK**<sub>4</sub><sup>20</sup> 12.1 (hydrated anion). Purify quinazoline by passage through an activated alumina column in \*C<sub>6</sub>H<sub>6</sub> or petroleum ether (b 40-60°). Distil it under reduced pressure, sublime it under vacuum and crystallise it from petroleum ether. The *picrate* has **m** 188-189° (from MeOH). [Armarego *J Appl Chem* **11** 70 1961, Armarego *Quinazolines, Fused Pyrimidines Part I* Brown Ed, Wiley-Interscience 1967, Brown *Quinazolines Supplement I* Taylor Ed, Wiley-Interscience 1996, ISBN 0-471-14565-3; for covalent hydration see Albert & Armarego *Adv Heterocycl Chem* **4** 1 1965, *Beilstein* **23** H 175, **23** II 177, **23** III/IV 1221.]

**S(+)-Quinidine** [56-54-2] **M** 324.4, **m** 171°,  $[\alpha]_{546}^{20}$  +301.1° (CHCl<sub>3</sub> containing 2.5% (v/v) EtOH), **pK**<sub>1</sub><sup>15</sup> 4.13, **pK**<sub>2</sub><sup>15</sup> 8.77. Crystallise it from \*C<sub>6</sub>H<sub>6</sub> or dry CHCl<sub>3</sub>/petroleum ether (b 40-60°), discarding the initial, oily crop of crystals. Dry it under vacuum at 100° over P<sub>2</sub>O<sub>5</sub>. It has been used as a chiral catalyst [Wynberg & Staring *J Am Chem Soc* **104** 166 1982, *J Org Chem* **50** 1977 1985]. [*Beilstein* **23** H 506, **23** I 164, **23** II 414, **23** III/IV 3261, **23/13** V 395.]

**8S,9R-Quinine** [130-95-0] **M** 324.4, **m** 177°(dec),  $[\alpha]_{546}^{20}$  -160° (c 1, CHCl<sub>3</sub>), **pK**<sub>1</sub><sup>20</sup> 4.13 (quinoline N), **pK**<sub>2</sub><sup>20</sup> 8.52 (piperidine N). Crystallise the quinine from absolute EtOH. It has been used as a chiral catalyst (see previous entry). [*Beilstein* **23** H 511, **23** I 166, **23** II 416, **23** III/IV 3265, **23/13** V 395.]

**Quinine bisulfate** [6183-68-2 (7H<sub>2</sub>O), 549-56-4 (anhydrous)] **M** 422.4, **m** 160° (anhydrous). Crystallise the bisulfate from 0.1M H<sub>2</sub>SO<sub>4</sub>, and recrystallise it from water to give the *heptahydrate*. [*Beilstein* **23** III/IV 3270, **23/13** V 396.]

**Quinine sulfate (2H<sub>2</sub>O)** [6119-70-6 (H<sub>2</sub>O), 804-63-7 (anhydrous)] **M** 783.0, **m** 205° (219°). Crystallise it from water and dry it at 110°. [*Beilstein* **23** H 522, **23** I 168, **23** II 420, **23** III/IV 3269, **23** V 396.]

**Quinoline** [91-22-5] **M** 129.2, **m** -20°, -16°, **b** 113-114°/17mm, 236°/758mm, **d**<sub>4</sub><sup>20</sup> 1.0937, **n**<sub>D</sub><sup>20</sup> 1.625, **pK**<sup>25</sup> 4.80 (4.93). Dry quinoline with Na<sub>2</sub>SO<sub>4</sub> and distil it from zinc dust in a vacuum. It has also been dried by boiling with acetic anhydride, then fractionally distilled. Calvin and Wilmarth [*J Am Chem Soc* **78** 1301 1956] cooled redistilled quinoline in ice and added enough HCl to form its hydrochloride. Diazotization removed aniline, the diazo compound being broken down by warming the solution to 60°. Non-basic impurities were removed by ether extraction. Quinoline was then liberated by neutralising the hydrochloride with NaOH, then dried with KOH and fractionally distilled at low pressure. Addition of cuprous acetate (7g/L of quinoline) and shaking under hydrogen for 12 hours at 100° removed impurities due to the nitrous acid treatment. Finally the hydrogen was pumped off, and the quinoline was distilled. Other purification procedures depend on conversion to the *phosphate* (**m** 159°, precipitated from MeOH solution, filtered, washed with MeOH, then dried at 55°) or the *picrate* (**m** 201°) which, after recrystallisation, were reconverted to quinoline.

The method using the *picrate* [Packer et al. *J Am Chem Soc* **80** 905 1958] is as follows: quinoline is added to picric acid dissolved in the minimum volume of 95% EtOH, giving yellow crystals which are washed with EtOH, air-dried and crystallised from acetonitrile. These are dissolved in dimethyl sulfoxide (previously dried over 4A molecular sieves) and passed through a basic alumina column, onto which the picric acid is adsorbed. The free base in the effluent is extracted with *n*-pentane and distilled under vacuum. Traces of solvent can be removed by vapour-phase chromatography. [Moonaw & Anton *J Phys Chem* **80** 2243 1976.] The ZnCl<sub>2</sub> and dichromate complexes have also been used [Cumper et al. *J Chem Soc* 1176 1962]. [*Beilstein* **20** H 339, **20** I 134, **20** II 222, **20** III/IV 3334, **20/7** V 276.]

**2-Quinolinealdehyde** [5470-96-2] **M** 157.2, **m** 71°, **pK**<sub>Est</sub> ~3.3. Distil it in steam and recrystallise it from H<sub>2</sub>O. Protect it from light. The *semicarbazone* has **m** 254° (from aqueous EtOH), and the *picrate* has **m** 197-199°. [*Beilstein* **21** H 322, **21** III/IV 4034, **21/8** V 442.]

**8-Quinolinecarboxylic acid** [86-59-9] **M** 173.2, **m** 186-187.5°, **pK**<sub>1</sub><sup>25</sup> 1.82, **pK**<sub>2</sub><sup>25</sup> 6.87. Crystallise the acid from water, aqueous EtOH, EtOH or \*C<sub>6</sub>H<sub>6</sub>. The *ethyl ester* has **m** 45° and **b** 194-197°/13mm. [*Beilstein* **22** H 81, **22** III/IV 1200, **22/3** V 217.]

Quinoline ethiodide (1-ethylquinolinium iodide) [634-57-5] M 285.1, m 158-159°. Crystallise it from aqueous EtOH or EtOH peroxide free Et<sub>2</sub>O. [Beilstein 20 H 352, 20 I 139, 20 II 231, 20 III/IV 3357, 20/7 V 276.]

Quinoxaline [91-19-0] M 130.2, m 28° (anhydrous), 37°(H<sub>2</sub>O), b 108-110°/0.1mm, 140°/40mm, pK<sub>1</sub><sup>20</sup> -5.52 (-5.8, dication), pK<sub>2</sub><sup>20</sup> 0.56 (c 0.5), 0.72 (c 1.0) (monocation). Crystallise quinoxaline from petroleum ether. It crystallises as the *monohydrate* on addition of water to a petroleum ether solution. It has UV with  $\lambda_{\max}$  at 242 and 331nm (H<sup>+</sup> -2); 234 and 316nm (pH 7.1). The *picrate* has m 161-162°. [Albert & Phillips *J Chem Soc* 1294 1956, *Beilstein* 23 H 176, 23 II 177, 23 III/IV 1226, 23/7 V 135.]

Quinoxaline-2,3-dithiol [1199-07-7] M 194.1, m 345°(dec), pK<sub>1</sub> 6.9, pK<sub>2</sub> 9.9. Purify the dithiol by repeated dissolution in alkali and re-precipitation by acetic acid. It complexes with Ag<sup>+</sup>, Cd<sup>2+</sup>, Pb<sup>2+</sup>, Bi<sup>3+</sup> and Ni<sup>2+</sup> in aqueous NH<sub>3</sub>. [*Beilstein* 24 III/IV 1428.]

Quinuclidine (1-azabicyclo[2.2.2]octane) [100-76-5] M 111.2, m 158°(sublimes), pK<sup>25</sup> 10.95. Crystallise it from diethyl ether. The *hydrochloride* has m 364-365°(dec) (from EtOH or n-BuOH), and the *picrate* has m 225° (from aqueous EtOH). [*Beilstein* 20 H 144, 20 II 71, 20 III/IV 1966, 20/4 V 335.]

**Rescinnamine** (Anaprel, Apoterin, a  $\beta$ -carboline alkaloid) [24815-24-5] M 634.7, m 238-239°(vacuum), 240°,  $[\alpha]_{\text{D}}^{20}$  -97° (c 1, CHCl<sub>3</sub>), pK<sub>EST(1)</sub> <0 (carbazole N), pK<sub>EST(2)</sub> ~7.0 (quinolizidine N), pK<sup>25</sup> 6.4 (75% aqueous HCONMe<sub>2</sub>). Crystallise it from \*benzene, MeOH or aqueous Me<sub>2</sub>CO. The *hydrochloride* has m 232°(dec) (from MeOH) and  $[\alpha]_{\text{D}}^{25}$  -74° (MeOH). It is an antihypertensive. [Klohs et al. *J Am Chem Soc* 77 2241 1955, *Beilstein* 25 III/IV 1323.]

(-)-Reserpine acid [83-60-3] M 400.5, m 241-243°,  $[\alpha]_{\text{D}}^{24}$  -70° (c 1, H<sub>2</sub>O), pK<sub>EST(1)</sub> <0 (carbazole N), pK<sub>EST(2)</sub> -4.0 (C<sub>2</sub>H<sub>4</sub>), pK<sub>EST(3)</sub> -7.4 (quinolizidine N), pK<sub>1</sub> 6.2, pK<sub>2</sub> 8.2 (66% aqueous HCONMe<sub>2</sub>). Crystallise the acid from MeOH. It has UV with  $\lambda_{\max}$  at 222, 268 and 294nm (EtOH). The *hydrochloride 0.5H<sub>2</sub>O* has m 257-259° (from EtOH/Et<sub>2</sub>O),  $[\alpha]_{\text{D}}^{23}$  -81° (H<sub>2</sub>O). [Dorfman et al. *Helv Chim Acta* 77 59 1954, *Beilstein* 25 III/IV 1305.]

Reserpine [50-55-5] M 608.7, m 262-263°,  $[\alpha]_{\text{D}}^{20}$  -148° (c 1, CHCl<sub>3</sub>), pK<sub>EST(1)</sub> <0 (carbazole N), pK<sub>2</sub> 6.6 (7.4)(quinolizidine N). Crystallise reserpine from aqueous Me<sub>2</sub>CO or Et<sub>2</sub>O. [Woodward et al. *Tetrahedron* 2 155 1958, *Beilstein* 25 III/IV 1319.]

Rhamnetin (3,3'-4',5-tetrahydroxy-7-methoxy flavone, 7-methyl quercetin) [90-19-7] M 316.3, m >300°(dec), several phenolic pKs -7-10.5. Crystallise rhamnetin from EtOH (m 292-293°), aqueous EtOH (m 294-296°) or MeOH (m 290-294°), or Me<sub>2</sub>CO/MeOH. [Kuhn & Low *Chem Ber* 77 211 1944, Jurd *J Am Chem Soc* 80 5531 1958.] The *tetra-acetate* has m 189-190° (from Me<sub>2</sub>CO/MeOH). [*Beilstein* 18 H 245, 18 II 237, 18 III/IV 3474.]

Rhodamine 3B chloride [3,5-bis-(diethylamino)-9-(2-carboxyphenyl)xanthylium chloride] [81-88-9] M 479.0, m 210-211°(dec), CI 45170,  $\lambda_{\max}$  543nm, {Free base [509-34-2] CI 749}, pK<sup>25</sup> 5.53. Major impurities are partially dealkylated compounds not removed by recrystallisation. Purify the dye by chromatography, using ethyl acetate/isopropanol/ammonia (conc) 9:7:4, R<sub>f</sub> 0.75 on Kieselgel G). It has also been crystallised from a concentrated solution in MeOH by slow addition of dry diethyl ether; or from EtOH containing a drop of conc HCl by slow addition of ten volumes of dry diethyl ether. The solid is washed with ether and air dried. The dried material has also been extracted with \*benzene to remove oil-soluble material prior to recrystallisation. Store it in the dark. [*Beilstein* 18 II 486, 18 III/IV 8246, 19/8 V 669.]

Rhodamine 6G [Basic Red 1, 3,5-bis-(ethylamino)-9-(2-ethoxycarbonylphenyl)-2,7-dimethylxanthylium chloride] [989-38-8] M 479.3, CI 45160,  $\lambda_{\max}$  524nm, pK<sup>25</sup> 5.58. Crystallise the dye from MeOH or EtOH, and dry it in a vacuum oven. [*Beilstein* 18 III/IV 8244, 18/12 V 283.]

**Rhodanine (2-mercaptothiazolidin-4-one)** [141-84-4] **M 133.2, m 168.5° (capillary), pK<sup>20</sup> 5.18.** Crystallise rhodanine from glacial acetic acid or water. It is used to estimate Ag and gallic acid [Thies & Fischer *Microchimica Acta* 809 1973]. [Beilstein 27 H 242, 27 I 309, 27 II 288, 27 III/IV 3188.]

**Riboflavin, riboflavin-5'-phosphate (Na salt, 2H<sub>2</sub>O).** See entries in “Miscellaneous Compounds” and for **ribonucleic acids** see entry in “Proteins, Enzymes, DNA and RNA” in Chapter 7.

**Saccharin (1,2-benzisothiazol-3(2H)-one 1,1-dioxide, *o*-benzoic acid sulfimide)** [81-07-2] **M 183.2, m 227-229°, 229°, 228.8-229.7°, pK<sub>1</sub><sup>25</sup> 1.31, pK<sub>2</sub><sup>25</sup> 12.8.** Purify saccharin by recrystallisation from Me<sub>2</sub>CO [solubility 7.14% at 0°, 14.4% at 50°], or aqueous isoPrOH to give a fluorescent solution. It sublimes *in vacuo*. It is an artificial sweetener and is 500 times sweeter than sucrose. [DeGarmo et al. *J Am Pharm Assoc (Sci Ed)* 41 17 1952, Beilstein 27 H 168, 870, 27 I 266, 27 II 214, 27 III/IV 2649.]

**Safranine O (Safranine T, 3,7-diamino-2,8-dimethyl-5-phenylphenazinium chloride)** [477-73-6] **M 350.9, λ<sub>max</sub> 530nm, pK<sup>25</sup> 6.4.** Crystallise it from \*benzene/MeOH (1:1) or water. Dry it *in vacuo* over H<sub>2</sub>SO<sub>4</sub>. It has UV: λ<sub>max</sub> at 520nm (H<sub>2</sub>O) and 530nm (EtOH). [Beilstein 25 H 403, 25 I 657, 25 III/IV 3056.]

**Safrole (5-allyl-1,3-benzodioxole, 4-allyl-1,2-methylenedioxybenzene)** [94-59-7] **M 162.1, m~ 11°, b 69-70°/1.5mm, 104-105°/6mm, 231.5-232°/atm, 235-237°/atm, d<sub>4</sub><sup>20</sup> 1.0993, n<sub>D</sub><sup>20</sup> 1.53738.** Safrole has been purified by fractional distillation, although it has also been recrystallised from low boiling petroleum ether at low temperatures. [IR: Briggs et al. *Anal Chem* 29 904 1957, UV: Patterson & Hibbert *J Am Chem Soc* 65 1962 1943.] The *maleic anhydride adduct* forms yellow crystals from toluene **m 257°** [Hickey *J Org Chem* 13 443 1948], and the *picrate* forms orange-red crystals from CHCl<sub>3</sub> [Baril & Magrdichian *J Am Chem Soc* 58 1415 1936]. [Beilstein 19 H 39, 19 I 617, 19 II 29, 19 III/IV 275, 19/1 V 553.]

**Scopolamine (hyoscine, atropine, 6β,7β-epoxy-3-α-tropanyl *S*-(-)-tropate)** [51-34-3] **M 321.4, m 59°, [α]<sub>D</sub><sup>20</sup> -18° (c 5, EtOH), -28° (c 2, H<sub>2</sub>O), [α]<sub>D</sub><sup>20</sup> -30° (c 5, CHCl<sub>3</sub>), pK<sup>25</sup> 7.55.** Crystallise it from \*benzene/petroleum ether, EtOH or H<sub>2</sub>O. It is polymorphic with **m 165-166° and 190-191°.** The *racemate* has **m 56-57° (H<sub>2</sub>O), 37-38° (2H<sub>2</sub>O),** syrup (anhydrous), *l* and *d* isomers can separate as syrups when anhydrous. [Beilstein 27 H 99, 102, 27 I 247-248, 27 II 43-44, 27 III/IV 1790.]

**Scopoletin (7-hydroxy-6-methoxycoumarin)** [92-61-5] **M 192.2, m 206°, 208-209°, pK<sup>25</sup> 8.96 (70%aqueous EtOH).** Crystallise it from water, acetic acid or \*C<sub>6</sub>H<sub>6</sub>/MeOH. It is dimorphic with a second **m** at 193-195°. It sublimes at 120-130°/12mm. [Beilstein 18 H 99, 18 I 348, 18 II 68, 18 III/IV 1323, 18/3 V 203.]

**Secobarbital (5-allyl-5-1'-methylbutylbarbituric acid)** [76-73-3] **M 260.3, m 100°, pK<sub>1</sub><sup>25</sup> 8.08, pK<sub>2</sub><sup>25</sup> 12.6.** It is purified by dissolving the *sodium salt* [309-43-3] in 10% HCl which precipitates the acid form that is extracted into Et<sub>2</sub>O. The extract is dried (Na<sub>2</sub>SO<sub>4</sub>) and evaporated. The residue is then purified by repeated crystallisation from CHCl<sub>3</sub>. [Buchet & Sandorfy *J Phys Chem* 88 3274 1984, Beilstein 24 III/IV 2013.]

**Serotonin creatinine sulfate (H<sub>2</sub>O)** [971-74-4] **M 405.4, m 220°(dec), pK<sub>1</sub> 10.1, pK<sub>2</sub> 11.1, pK<sub>3</sub> 18.25 (NH) for serotonin, pK<sup>25</sup> 4.9 for creatinine.** It crystallises as the monohydrate from water. [Beilstein 22 III/IV 5667, 22/12 V 18.]

**Sinomenine hydrochloride (7,8-didehydro-4-hydroxy-3,7-dimethoxy-17-methyl-9α,13α,14α-morphan-6-one HCl)** [6080-33-7] **M 365.9, m 231°, [α]<sub>D</sub><sup>17</sup> -83° (c 4, H<sub>2</sub>O), pK<sub>Est(1)</sub>~10.0 (N), pK<sub>Est(2)</sub>~10.4 (OH).** Crystallise the salt from water (1g/1.5ml) or EtOH. The *free base* [115-53-7] **M 329.4,** has **m 161°** (from EtOH) (and again at 182°) after crystallisation from \*C<sub>6</sub>H<sub>6</sub>, and [α]<sub>D</sub><sup>20</sup> -78.9° (c 1, EtOH). The *picrate* has **m 159-162°(dec)** (from H<sub>2</sub>O). [Beilstein 21 II 470, 21 III/IV 6670.]

**(-)-Sparteine sulfate pentahydrate** [6160-12-9] **M 422.5, m loses H<sub>2</sub>O at 100° and turns brown at 136° (dec), [α]<sub>D</sub><sup>20</sup> -22° (c 5, H<sub>2</sub>O), [α]<sub>D</sub><sup>21</sup> -16° (c 10, EtOH for free base), pK<sub>1</sub><sup>20</sup> 2.24, pK<sub>2</sub><sup>20</sup> 9.46.** Recrystallise the

sulfate from aqueous EtOH or H<sub>2</sub>O, although the solubility in the latter is high. The *free (-)-base* has **b** 173°/8mm and is steam volatile but resinifies in air. The *dipicrate* forms yellow needles from EtOH/Me<sub>2</sub>CO, **m** 205-206° [Clemo et al. *J Chem Soc* 429 1931; see also Bolnmann & Schuman *The Alkaloids* (Ed Manske) Vol 9 175 1967]. The *free (±)-base* has **m** 71-72.5° [van Tamelen & Foltz *J Am Chem Soc* 82 2400 1960]. [Beilstein 23 II 99, 23 III/IV 18.]

**(-)-Strychnine** [57-24-9] **M** 334.4, **m** 268°, 278-279.5°,  $[\alpha]_{546}^{20}$  -139° (c 1, CHCl<sub>3</sub>), **pK<sub>1</sub><sup>20</sup>** 2.50, **pK<sub>2</sub><sup>20</sup>** 8.2, **pK<sub>1</sub><sup>20</sup>** 7.37 [80% aqueous MeO(CH<sub>2</sub>)<sub>2</sub>OH]. It crystallises from CHCl<sub>3</sub>/Et<sub>2</sub>O and sublimes at 125°/0.01mm. It can also be purified by conversion to the *hydrochloride* [**m** 275-295° (dec),  $[\alpha]_{D}^{20}$  -44° (0.03N HCl)] with aqueous HCl, then neutralisation with ammonia. [Beilstein 27 II 723, 27 III/IV 7530.] It is POISONOUS.

**Sulfamethazine (Sulfadimidine, N'-[4,6-dimethyl-2-pyrimidinyl]sulfanilamide)** [57-68-1] **M** 278.3, **m** 178-179°, 198-200°, 205-207°, **pK<sub>1</sub>** 2.65, **pK<sub>2</sub>** 7.4. Crystallise it from dioxane or aqueous dioxane. [Caldwell et al. *J Am Chem Soc* 63 2188 1941, Roblin et al. *J Am Chem Soc* 64 567 1942, Beilstein 25 III/IV 2215.]

**Sulfapyridine** [144-83-2] **M** 349.2, **m** 193°, **pK<sup>20</sup>** 8.64. Crystallise sulfapyridine from 90% acetone and dry it at 90°. Its solubility in Me<sub>2</sub>CO, EtOH and H<sub>2</sub>O is 1.5%, 0.22% and 0.02%, respectively. [Winterbottom *J Am Chem Soc* 62 160 1940, Beilstein 22 III/IV 3978.]

**2-Sulfobenzoic cyclic anhydride (2,1-benzoxathiazol-3-one-1,1-dioxide)** [81-08-3] **M** 184.2, **m** 126-127°, 129.5°, 130°, **b** 184-186°/18mm. The anhydride is purified by distillation in a vacuum and readily solidifies to a crystalline mass on cooling. [Heitman *J Am Chem Soc* 34 1594 1912.] Alternatively, purify it by dissolving it in the minimum volume of toluene and refluxing for 2 hours using a Dean-Stark trap. Evaporate under reduced pressure and distil the anhydride at 18mm. It is then recrystallised three times from its own weight of dry \*C<sub>6</sub>H<sub>6</sub>. It is sensitive to moisture and should be stored in the dark in a dry atmosphere. The *O-methyloxime* has **m** 110-112° [Levy *Tetrahedron Lett* 3289 1972]. If the sample has hydrolysed extensively (presence of OH band in the IR) then treat with an equal bulk of SOCl<sub>2</sub>, reflux it for 3 hours (CaCl<sub>2</sub> tube), evaporate and distil the residue in a vacuum, then recrystallise it from \*C<sub>6</sub>H<sub>6</sub>, Et<sub>2</sub>O/\*C<sub>6</sub>H<sub>6</sub> or CHCl<sub>3</sub> (EtOH free by passing through Al<sub>2</sub>O<sub>3</sub>, or standing over CaCl<sub>2</sub>). [Clarke & Dreger *Org Synth Coll Vol I* 495 1941.] It is used for modifying ζ-amino functions of lysyl residues in proteins [Bagree et al. *FEBS Lett* 120 275 1980]. [Beilstein 19 I 659, 19 II 137, 19 III/IV 1641, 19/4 V 215.]

**Sulfolane (tetramethylenesulfone)** [126-33-0] **M** 120.2, **m** 28.5°, **b** 153-154°/18mm, 285°/760mm, **d<sub>4</sub><sup>20</sup>** 1.263, **n<sub>D</sub><sup>30</sup>** 1.4820. It is prepared commercially by a Diels-Alder reaction of between 1,3-butadiene and sulfur dioxide, followed by Raney nickel hydrogenation. The principal impurities are water, 3-sulfolene, 2-sulfolene and 2-isopropyl sulfolanyl ether. It is dried by passage through a column of molecular sieves. Distil it under reduced pressure through a column packed with stainless steel helices. Again dry it with molecular sieves and distil. [Cram et al. *J Am Chem Soc* 83 3678 1961, Coetzee *Pure Appl Chem* 49 211 1977.] Alternatively, it is stirred at 50°, and small portions of solid KMnO<sub>4</sub> are added until the colour persists during 1 hour. Dropwise addition of MeOH then destroys the excess KMnO<sub>4</sub>; the solution is filtered, freed from potassium ions by passage through an ion-exchange column and dried under vacuum. It has also been distilled in a vacuum from KOH pellets. It is *hygroscopic*. [See Sacco et al. *J Phys Chem* 80 749 1976, *J Chem Soc, Faraday Trans 1* 73 1936 1977, 74 2070 1978, *Trans Faraday Soc* 62 2738 1966.] Coetzee has reviewed the methods of purification of sulfolane, and also the removal of impurities. [Coetzee in *Recommended Methods of Purification of Solvents and Tests for Impurities*, Coetzee Ed. Pergamon Press, 1982, Beilstein 17 I 5, 17 III/IV 37, 17/1 V 39.]

**2,2':6',2''-Terpyridyl** [1148-79-4] **M** 233.3, **m** 91-92°, **pK<sub>1</sub><sup>23</sup>** 2.64, **pK<sub>2</sub><sup>23</sup>** 4.33. Crystallise it from diethyl ether, toluene or from petroleum ether, then aqueous MeOH, followed by sublimation in a vacuum at 90°. It is used for estimating Ag and Ru. [Kamra et al. *Anal Chim Acta* 81 177 1976, Beilstein 26 III/IV 258.]

**Terthiophene (2,5-di[thienyl]thiophene; α-terthienyl)** [1081-34-1] **M** 248.4, **m** 94-95.5°, 94-96°. Possible impurities are bithienyl and polythienyls. Suspend it in H<sub>2</sub>O and steam distil it to remove bithienyl.

The residue is cooled and extracted with  $\text{CHCl}_3$ , dried ( $\text{MgSO}_4$ ), filtered, evaporated and the residue chromatographed on  $\text{Al}_2\text{O}_3$  using petroleum ether/3%  $\text{Me}_2\text{CO}$  as eluent. The terphenyl zone is then eluted from the  $\text{Al}_2\text{O}_3$  with  $\text{Et}_2\text{O}$ , the extract is evaporated and the residue is recrystallised from  $\text{MeOH}$  (40ml per g). The platelets are washed with cold  $\text{MeOH}$  and dried in air. [UV: Sease & Zechmeister *J Am Chem Soc* **69** 270 1947; Uhlenbroek & Bijloo *Rec Trav Chim Pays Bas* **79** 1181 1960.]

It has also been recrystallised from  $\text{MeOH}$ ,  $^*\text{C}_6\text{H}_6$ , petroleum ether or  $\text{AcOH}$ . [UV: Zechmeister & Sease *J Am Chem Soc* **69** 273 1947, Steinkopf et al. *Justus Liebigs Ann Chem* **546** 180 1941.] It is a phototoxic nematocide [Cooper & Nitsche *Bioorg Chem* **13** 36 1985, Chan et al. *Phytochem* **14** 2295 1975]. [*Beilstein* **19** III/IV 4763, **19/9** V 226.]

**2,4,5,6-Tetraaminopyrimidine sulfate** [5392-28-9] **M 238.2, m 255° (dec), >300°, >350° (dec), pK<sup>20</sup> 6.82.** Purify the salt by recrystallisation from  $\text{H}_2\text{O}$ , 2N  $\text{H}_2\text{SO}_4$  (20 parts, 67% recovery) or 0.1N  $\text{H}_2\text{SO}_4$  (40 parts, 62% recovery), and dried in air. [UV: Konrad & Pfeleiderer *Chem Ber* **103** 722 1970, Malletta et al. *J Am Chem Soc* **69** 1814 1947, Cavalieri et al. *J Am Chem Soc* **70** 3875 1948, *Beilstein* **25** H 423, **25** III/IV 3106.]

**1,4,8,11-Tetraazacyclotetradecane (cyclam)** [295-37-4] **M 200.33, m 173° (closed capillary and sublimes at 125°), 183-185°, 185°, pK<sub>Est(1)</sub> ~3.8, pK<sub>Est(2)</sub> ~6.0, pK<sub>Est(3)</sub> ~9.0, pK<sub>Est(4)</sub> ~9.6.** Purify cyclam by recrystallisation from dioxane (white needles), and it sublimes above 120°. It has been distilled, **b 132-140°/4-8mm**. It forms complexes with metals and gives a sparingly soluble *nitrate salt*, **m 205°(dec)**, which crystallises from  $\text{H}_2\text{O}$  and is dried at 150°. [UV: Bosnich et al. *Inorg Chem* **4** 1102 1963, van Alphen *Rec Trav Chim Pays Bas* **56** 343 1937, *Beilstein* **26** III/IV 1647.]

**Tetrabenazine (2-oxo-3-isobutyl-9,10-dimethoxy-1,2,3,4,6,7-hexahydro-11bH-benzo[a]-quinolizine)** [58-46-8] **M 317.4, m 127-128°, pK<sub>Est</sub> ~8.** Crystallise it from  $\text{MeOH}$ . The *hydrochloride* has **m 208-210°**, and the *oxime* has **m 158° (from EtOH)**. [*Beilstein* **21** III/IV 6488.]

**2,3,4,6-Tetrachloropyridine** [14121-36-9] **M 216.9, m 74-75°, (? 37-38°), b 130-135°/16-20mm, 248.5-249.5°/760mm, pK<sub>Est</sub> ~ -5.7.** Crystallise it from 50%  $\text{EtOH}$  and/or distil it. The *N-oxide* has **m 210° (from EtOH/CHCl<sub>3</sub>)**. [Chivers & Suschitzky *J Chem Soc* 2870 1971, *Beilstein* **20** III/IV 6488, **20/5** V 421.]

**Tetrahydrofuran (oxalane, THF)** [109-99-9] **M 72.1, b 25°/176mm, 66°/760mm, d<sub>4</sub><sup>20</sup> 0.889, n<sub>D</sub><sup>20</sup> 1.4070, pK<sup>25</sup> -2.48 (aqueous  $\text{H}_2\text{SO}_4$ ).** It is obtained commercially by catalytic hydrogenation of furan from pentosan-containing agricultural residues. It was purified by refluxing with, and distilling from  $\text{LiAlH}_4$  which removes water, peroxides, inhibitors and other impurities [Jaeger et al. *J Am Chem Soc* **101** 717 1979]. Peroxides can also be removed by passage through a column of activated alumina, or by treatment with aqueous ferrous sulfate and sodium bisulfate, followed by solid  $\text{KOH}$ . In both cases, the solvent is then dried and fractionally distilled from sodium. Lithium wire or vigorously stirred molten potassium have also been used for this purpose.  $\text{CaH}_2$  has also been used as a drying agent.

Several methods are available for obtaining the solvent almost anhydrous. Ware [*J Am Chem Soc* **83** 1296 1961] dried it vigorously with sodium-potassium alloy until a characteristic blue colour was evident in the solvent at Dry-ice/cellosolve temperatures. The solvent is kept in contact with the alloy until distilled for use. Worsfold and Bywater [*J Chem Soc* 5234 1960], after refluxing and distilling from  $\text{P}_2\text{O}_5$  and  $\text{KOH}$ , in turn, refluxed the solvent with sodium-potassium alloy and fluorenone until the green colour of the disodium salt of fluorenone was well established. [Alternatively, instead of fluorenone, benzophenone, which forms a blue ketyl, can be used.] The tetrahydrofuran was then fractionally distilled, degassed and stored above  $\text{CaH}_2$ . *p*-Cresol or hydroquinone inhibit peroxide formation. The method described by Coetzee and Chang [*Pure Appl Chem* **57** 633 1985] for 1,4-dioxane also applies here. Distillations should always be done in the presence of a reducing agent, e.g.  $\text{FeSO}_4$ . [*Beilstein* **17** H 10, **17** I 5, **17** II 15, **17** III/IV 24, **17**/I V 27.] **It irritates the skin, eyes and mucous membranes, and the vapour should never be inhaled. It is HIGHLY FLAMMABLE, and the necessary precautions should be taken.**

**Rapid purification:** Purification as for diethyl ether.

**l-Tetrahydropalmitine (2,3,9,10-tetramethoxy-6H-dibenzo[a,g]quinolizidine)** [10097-84-4] **M 355.4, m 148-149°, [α]<sub>D</sub><sup>20</sup> -291° (EtOH).** Crystallise it from  $\text{MeOH}$  or  $\text{EtOH}$  by addition of water [see Kametani & Ihara

*J Chem Soc (C)* 530 1967, Bradsher & Dutta *J Org Chem* **26** 2231 1961]. When crystallised from Me<sub>2</sub>CO/Et<sub>2</sub>O, it has **m** 142°. The *hydrate* has **m** 115°(effervescence). The *picrate* has **m** 188°(dec) (from aqueous EtOH). [Bradsher & Datta *J Org Chem* **26** 2231 1961, *Beilstein* **21** II 196, **21** III/IV 2769.]

**Tetrahydropyran (oxane, THP)** [142-68-7] **M 86.1, b 88.0°, d<sub>4</sub><sup>20</sup> 0.885, n<sub>D</sub><sup>20</sup> 1.4202, pK<sup>25</sup> -2.79 (aqueous H<sub>2</sub>SO<sub>4</sub>)**. Dry oxane with CaH<sub>2</sub>, then pass it through a column of silica gel to remove olefinic impurities and fractionally distil it. Free it from peroxides and moisture by refluxing with sodium, then distil it from LiAlH<sub>4</sub>. *Alternatively*, peroxides can be removed by treatment with aqueous ferrous sulfate and sodium bisulfate, followed by solid KOH, and fractional distillation from sodium. [*Beilstein* **17** H 12, **17** I 6, **17** II 18, **17** III/IV 51, **17**/I V 64.]

**Tetrahydro-4H-pyran-4-one** {29943-42-8} **M 100.1, b 57-59°/11mm, 65-66°/15mm, 67-68°/18mm, 73°/20mm, 164.7°/atm, 166-166.5°/atm, d<sub>4</sub><sup>20</sup> 1.0844, n<sub>D</sub><sup>20</sup> 1.4551**. Purify the pyrone by repeated distillation, preferably in a vacuum. [Baker *J Chem Soc* 296 1944, IR: Olsen & Bredoch *Chem Ber* **91** 1589 1958.] The *oxime* has **m** 87-88° and **b** 110-111°/13mm [Cornubert et al. *Bull Soc Chim Fr* 36 1950]. The *4-nitrophenylhydrazone* forms orange-brown needles from EtOH, **m** 186° [Cawley & Plant *J Chem Soc* 1214 1938]. [*Beilstein* **17** I 131, **17** II 287, **17** III/IV 4171, **17**/9 V 21.]

**Tetrahydrothiophene (thiophane)** [110-01-0] **M 88.2, m -96°, b 14.5°/10mm, 40.3°/39.7mm, 120.9°/760mm, d<sub>4</sub><sup>20</sup> 0.997, n<sub>D</sub><sup>20</sup> 1.5289**. The crude material is purified by crystallisation of the mercuric chloride complex to a constant melting point. It is then regenerated, washed, dried, and fractionally distilled. [Whitehead et al. *J Am Chem Soc* **73** 3632 1951.] It has been dried over Na<sub>2</sub>SO<sub>4</sub> and distilled in a vacuum [Roberts & Friend *J Am Chem Soc* **108** 7204 1986]. [*Beilstein* **17** I 5, **17** II 15, **17** III/IV 34, **17**/I V 36.]

**Tetrahydro-4H-thiopyran-4-one** [1072-72-6] **M 116.2, m 60-62°, 61-62°, 64-65°, 65-67°**. Purify it by recrystallisation from diisopropyl ether or petroleum ether and dry it in air. If too impure, then dissolve it in Et<sub>2</sub>O, wash with aqueous NaHCO<sub>3</sub>, then H<sub>2</sub>O, dry (MgSO<sub>4</sub>), filter, evaporate and the residue is recrystallised as before. [Cardwell *J Chem Soc* 715 1949.] The *oxime* can be recrystallised from CHCl<sub>3</sub>/petroleum ether (at -20°) and has **m** 84-85° [Barkenbus et al. *J Org Chem* **20** 871 1955]. The *2,4-dinitrophenylhydrazone* has **m** 186° (from EtOAc) [Barkenbus et al. *J Org Chem* **16** 232 1951]. The *S-dioxide* is recrystallised from AcOH, **m** 173-174° [Fehnel & Carmack *J Am Chem Soc* **70** 1813 1948, *Beilstein* **17** II 287, **17** III/IV 4172, **17**/I V 21].

**Tetramethylene sulfoxide (tetrahydrothiophen 1-oxide)** [1600-44-8] **M 104.2, b 235-237°, d<sub>4</sub><sup>20</sup> 1.175, n<sub>D</sub><sup>20</sup> 1.525**. Shake the oxide with BaO for 4 days, then distil it from CaH<sub>2</sub> under reduced pressure. [*Beilstein* **17** III/IV 36, **17**/I V 38.]

**2,2,6,6-Tetramethylpiperidinyl-1-oxy (TEMPO)** [2564-83-2] **M 156.3, m 36-38°**. Purify TEMPO by sublimation (33°, water aspirator) [Hay & Fincke *J Am Chem Soc* **109** 8012 1987, Keana *Chem Rev* **78** 37 1978].

**2,2,6,6-Tetramethyl-4-piperidone hydrochloride (triacetoneamine)** [33973-59-0] **M 191.7, m 190°(dec), 198-199°(dec), pK<sup>25</sup> 7.90**. Purify the salt by recrystallisation from EtOH/Et<sub>2</sub>O, MeCN or Me<sub>2</sub>CO/MeOH. The *free base* has **m** 37-39° (after sublimation), **b** 102-105°/18mm, and the *hydrate* has **m** 56-58° (wet Et<sub>2</sub>O); the *hydrobromide* has **m** 203° (from EtOH/Et<sub>2</sub>O), and the *picrate* has **m** 196° (from aqueous EtOH). [Sandris & Ourisson *Bull Soc Chim Fr* 345 1958, *Beilstein* **21** H 246, **21** I 273, **21** II 222, **21** III/IV 3278, **21**/6 V 538.]

**1,3,7,9-Tetramethyl uric acid** [2309-49-1] **M 224.2, m 225°, 228°, pK<sub>Est</sub> <0**. Crystallise the uric acid from H<sub>2</sub>O or MeOH. [*Beilstein* **26** H 532, **26** I 156, **26** II 302, **21** III/IV 2623.]

**1,3,5,5-Tetranitrohexahydropyrimidine** [81360-42-1] **M 270.1, m 153-154°**. Crystallise the nitropyrimidine from EtOH (5x) and sublime it (~65°/0.05mm) [Cichra & Adiolph *J Org Chem* **47** 2474 1982, *Labeled Comp Radiopharm* **29** 1197 1991].

**4,7,13,18-Tetraoxa-1,10-diazabicyclo[8.5.5]eicosane (Cryptand 211)** [31250-06-3] M 288.1, b 130°/0.002mm,  $d_4^{20}$  1.097,  $n_D^{20}$  1.505,  $pK_{Est}$  ~7.9. Redistil Cryptand 211, dry it under high vacuum over 24 hours, and store it under nitrogen.

**1,7,10,16-Tetraoxa-4,13-diazacyclooctadecane (4,13-diaza-18-crown-6)** [23978-55-4] M 262.3, m 118-116°,  $pK_{Est}$  ~8.8. Twice recrystallise it from \*benzene/*n*-heptane, and dry it for 24 hours under high vacuum [Weber & Vögtle *Top Curr Chem* (Springer Verlag, Berlin) **98** 1 1981, D'Aprano & Sesta *J Phys Chem* **91** 2415 1987].

**5,10,15,20-Tetraphenylporphyrin (TPP)** [917-23-7] M 614.7, m 450° (sublimes >400°),  $\lambda_{max}$  482nm. Purify TPP by chromatography on neutral (Grade I) alumina, and recrystallisation from CH<sub>2</sub>Cl<sub>2</sub>/MeOH or \*C<sub>6</sub>H<sub>6</sub>. It forms complexes with metals. [Yamashita et al. *J Phys Chem* **91** 3055 1987, *Beilstein* **26** III/IV 1958.]

**5,10,15,20-Tetra-4'-pyridinylporphyrin** [16834-13-2] M 618.7, m >300°(dec). Purify it by chromatography on alumina (neutral, Grade I), with CHCl<sub>3</sub>/MeOH (80:20) followed by recrystallisation from CH<sub>2</sub>Cl<sub>2</sub>/MeOH [Yamashita et al. *J Phys Chem* **91** 3055 1987]. [Kalyanasundaram *Inorg Chem* **23** 2453 1984, Okuno et al. *Synthesis* 537 1980.]

**Tetrathiafulvalene** [31366-25-3] M 204.4, m 122-124°. Recrystallise it from cyclohexane/hexane under an argon atmosphere [Kauzlarich et al. *J Am Chem Soc* **109** 4561 1987]. [*Beilstein* **19/11** V 380.]

**1,2,3,4-(1H)Tetrazole** [288-94-8] M 70.1, m 156°, 157.5-158°,  $pK^{25}$  4.89 (acidic). Crystallise the tetrazole from EtOH and sublime it under high vacuum at ca 120° (care should be taken due to possible **EXPLOSION**). [*Beilstein* **26** H 346, **26** I 108, **26** II 196, **26** III/IV 1652.]

**Thebaine** [115-37-7] M 311.4, m 193°,  $[\alpha]_D^{25}$  -219° (EtOH),  $pK^{20}$  8.15. Crystallise Thebaine from Et<sub>2</sub>O or EtOH. Sublime it at 170-180°. The *hydrochloride* decomposes >182° (from MeOH/Et<sub>2</sub>O). [*Beilstein* **27** II 177, **27** III/IV 2271.] It is a **NARCOTIC**.

**2-Thenoyltrifluoroacetone [1-(2-thienyl)-4,4,4-trifluorobutan-1,3-dione]** [326-91-0] M 222.2, m 42-44°, b 96-98°/9mm,  $pK^{25}$  6.4. Crystallise the dione from hexane or \*benzene. (An aqueous solutions slowly decomposes it). It has  $\nu_{max}$  at 1638(C=O), 1657(C=C)cm<sup>-1</sup>. The *oxime* crystallises from H<sub>2</sub>O or aqueous EtOH. It is used for the determination of Actinides and Lanthanides. [Chaston et al. *Aust J Chem* **18** 673 1956, Jeffrey et al. In *Vogel's Textbook of Quantitative Chemical Analysis* 5<sup>th</sup>edn J Wiley & Sons, p170 1989, *Beilstein* **17** III/IV 5989, **17/11** V 128.]

**2-Thenylamine (2-thiophenemethylamine)** [27757-85-3] M 113.1, b 78.5°/15mm,  $d_4^{20}$  1.137,  $n_D^{20}$  1.5643,  $pK^{30}$  8.92. Distil the amine under reduced pressure (nitrogen), from BaO, through a column packed with glass helices. The *hydrochloride* has m 193-194° (from EtOH/Me<sub>2</sub>CO) and the *picrate* has m 181-182°. [*Beilstein* **18** III/IV 7096.]

**Theobromine (3,7-dimethyl-2,6-dioxopurine)** [83-67-0] M 180.2, m 337° (sublimes slowly at 290° and finally melts at ~351°),  $pK_1^{40}$  -0.16,  $pK_2^{25}$  9.96. It crystallises from H<sub>2</sub>O. Its solubility in H<sub>2</sub>O is 0.06% at 15° and 1.25% at 100°, and it is poorly soluble in organic solvents. It forms salts with heavy metals and is a diuretic, vasodilator and a cardiac stimulant. [Lister *Purines Part II, Fused Pyrimidines* Brown Ed, Wiley-Interscience pp254-225 1971, ISBN 0-471-38205-1, *Beilstein* **26** H 457, **26** I 135, **26** II 264, **26** III/IV 2336.]

**Theophylline (1,3-dimethyl-2,6-dioxopurine, Theocin)** [58-55-9] M 180.2, m 272-274°,  $pK_1^{40}$  -0.24,  $pK_2^{40}$  8.79,  $pK_3$  11.5 (acidic). It crystallises from H<sub>2</sub>O as the *monohydrate* which becomes *anhydrous* above 100°. It is freely soluble in hot H<sub>2</sub>O, but its solubility at 15° is 0.44%. It complexes with heavy metals. It is a diuretic, vasodilator and a cardiac stimulant. [Lister *Purines Part II, Fused Pyrimidines* Brown Ed, Wiley-Interscience pp253-254 1971, ISBN 0-471-38205-1, *Beilstein* **26** H 455, **26** I 134, **26** II 263, **26** III/IV 2331.]

**Thianthrene** [92-85-3] **M 216.3, m 158°**. Crystallise thianthrene from Me<sub>2</sub>CO (charcoal), AcOH or EtOH. It sublimes in a vacuum. [Beilstein 19 H 45, 19 I 619, 19 II 34, 19 III/IV 347, 19/2 V 49.]

**5-Thiazolecarboxaldehyde** [1003-32-3] **M 113.1, b 92-94°/16mm, d<sub>4</sub><sup>20</sup> 1.304, n<sub>D</sub><sup>20</sup> 1.5874, pK<sub>Est</sub> ~0.6**. Dry the aldehyde over Na<sub>2</sub>SO<sub>4</sub> and fractionate it in a vacuum. The 2,4-dinitrophenylhydrazone forms red crystals from MeOH with **m 238-240°**, and the semicarbazone has **m 210-212°** (from MeOH). [Erne et al. *Helv Chim Acta* 34 148 1951, *Beilstein* 27 III/IV 2615.]

**Thiazoline-2-thiol** [96-53-7] **M 119.2, m 106-107°, 106-108°, pK<sub>Est</sub> ~13.0**. Purify the thiol by dissolution in aqueous alkali, precipitation by addition of HCl and then recrystallisation from H<sub>2</sub>O (as needles). [IR: Flett *J Chem Soc* 347 1953 and Mecke et al. *Chem Ber* 90 975 1957, Gabriel & Stelzner *Chem Ber* 28 2931 1895, *Beilstein* 27 III/IV 2540.]

**4-(2-Thiazolylazo)-resorcinol** [2246-46-0] **M 221.2, m 200-202°(dec), 218-219°, λ<sub>max</sub> 500 nm, pK<sub>1</sub><sup>25</sup> 1.25, pK<sub>2</sub><sup>25</sup> 6.53, pK<sub>3</sub><sup>25</sup> 10.76**. Dissolve it in aqueous alkali, extract it with diethyl ether, and re-precipitate it with dilute HCl. The purity is checked by TLC on silica gel using petroleum ether/diethyl ether/EtOH (10:10:1) as the mobile phase. It complexes with Cu<sup>2+</sup> (pH 3-4), Co<sup>2+</sup> and Ni<sup>2+</sup> (pH 7) and Zn<sup>2+</sup>, and Cd<sup>2+</sup> (pH 8.4). [Beilstein 27 III/IV 5988.]

**Thiazolyl blue tetrazolium bromide (MTT, 3-[4,5-dimethyl-2-thiazolyl]-2,5-diphenyl-2H-tetrazolium bromide)** [298-93-1, 2348-71-2] **M 414.3, m 171°**. It is recrystallised by dissolving in MeOH containing a few drops of HBr and then adding dry Et<sub>2</sub>O to complete the crystallisation, wash the needles with Et<sub>2</sub>O and dry them in a vacuum desiccator over KOH. [Beyer & Pyl *Chem Ber* 87 1505 1954, *Beilstein* 27 III/IV 6045.]

**Thietane (trimethylene sulfide)** [287-27-4] **M 74.1, m -64°, -73.2°, b 93.8-94.2°/752mm, 95°/atm, d<sub>4</sub><sup>20</sup> 1.0200, n<sub>D</sub><sup>20</sup> 1.5020**. Purify thietane by preparative gas chromatography on a dinonyl phthalate column. It has also been purified by drying over anhydrous K<sub>2</sub>CO<sub>3</sub>, and distilling through a 25cm glass helices-packed column (for 14g of thietane), then drying over CaSO<sub>4</sub> before sealing it in a vacuum. [Haines et al. *J Phys Chem* 58 270 1954.] It is characterised as the dimethylsulfonium iodide **m 97-98°** [Bennett & Hock *J Chem Soc* 2496 1927]. The *S*-oxide has **b 102°/25mm, n<sub>D</sub><sup>21</sup> 1.5075** [Tamres & Searles *J Am Chem Soc* 81 2100 1959]. [Beilstein 17 I 3, 17 II 12, 17 III/IV 14, 17/1 V 14.]

**2-Thiobarbituric acid** [504-17-6] **M 144.2, m 235°(dec), pK<sub>1</sub><sup>25</sup> 2.25, pK<sub>2</sub><sup>25</sup> 10.72 (2% aqueous EtOH)**. Crystallise it from water. [Beilstein 24 H 476, 24 I 414, 24 II 275, 24 III/IV 1884.]

**1,1'-Thiocarbonyldiimidazole** [6160-65-2] **M 178.1, m 100-102°, 105-106°**. It forms yellow crystals on recrystallisation from tetrahydrofuran or by sublimation at 10<sup>-3</sup> torr (bath temperature 70-80°). It is hydrolysed by H<sub>2</sub>O and should be stored dry. [Staab & Walther *Justus Liebigs Ann Chem* 657 98 1962; Pullukat et al. *Tetrahedron Lett* 1953 1967, Hanessian et al. *Can J Chem* 65 1859 1987, Rajanbabu et al. *J Am Chem Soc* 111 1759 1989.]

**Thiochrome** {2,7-dimethyl-5H-thiachromine-8-ethanol; 3,8-dimethyl-2-hydroxyethyl-5H-thiazolo-[2,3:1',2']pyrimido[4',5'-d]pyrimidine} [92-35-3] **M 262.3, m 227-228°, pK<sub>1</sub><sup>20</sup> 8.11, pK<sub>2</sub><sup>20</sup> 12.6**. Crystallise thiochrome from chloroform. The monohydrochloride has **m 235-236°(dec)** (from EtOH) and the dihydrochloride has **m 237°(dec)**. [Beilstein 27 III/IV 9599.]

**2-Thiocytosine (4-amino-2-mercaptopyrimidine)** [333-49-3] **M 127.2, m 236-237°(dec), 285-290°(dec), pK<sub>1</sub><sup>20</sup> 3.90 (NH<sub>2</sub>), pK<sub>2</sub><sup>20</sup> 11.10 (SH)**. It is recrystallised from hot H<sub>2</sub>O and dried at 100° to constant weight. [Brown *J Appl Chem (London)* 9 203 1959, Russell et al. *J Am Chem Soc* 71 2279 1949.] It is used in transcription and translation studies [Rachwitz & Scheit *Eur J Biochem* 72 191 1977].

**Thioflavine T [2-(4-dimethylaminophenyl)-3,6-dimethylbenzothiazolium chloride]** [2390-54-7] **M 318.9, pK<sub>25</sub> 2.7**. Crystallise the chloride from \*benzene/EtOH (1:1). [Beilstein 27 III/IV 5052.]

**1-Thioflavone (2-phenylthiochromen-4-one)** [784-62-3] **M 238.3, m 129-130°**. This yellow solid is purified by passage through a silica gel column, eluting with \*C<sub>6</sub>H<sub>6</sub>/Me<sub>6</sub>CO, evaporating and crystallising the residue from EtOH. The *sulfoxide* [65373-82-2] has **m 133-135°**, and the *sulfone* [22810-82-2] has **m 136.5-137°** (from EtOH). The *dimethylhydrazone* has **m 111-113°** (from BuOH). It forms easily hydrolysable salts. [Nakazumi et al. *J Heterocycl Chem* **21** 193 1984, Chen et al. *J Org Chem* **51** 3282 1986, Van Allen & Reynolds *J Heterocycl Chem* **8** 807 1971, *Beilstein* **17** I 204, **17** III/IV 5420, **17/10** V 560.]

**6-Thioguanine** [154-42-7] **M 167.2, m >300°, pK<sub>1</sub><sup>23</sup> 8.2 (SH), pK<sub>2</sub><sup>23</sup> 11.6 (acidic, 9-NH)**. It crystallises from H<sub>2</sub>O as needles. It has UV with  $\lambda_{\max}$  at 258 and 347nm (H<sub>2</sub>O, pH 1) and 242, 270 and 322nm (H<sub>2</sub>O, pH 11). [Elion & Hitchings *J Am Chem Soc* **77** 1676 1955, Fox et al. *J Am Chem Soc* **80** 1669 1958.] It is an antineoplastic agent [Kataoka et al. *Cancer Res* **44** 519 1984]. [*Beilstein* **26** III/IV 3926.]

**Thioindigo** [522-75-8] **M 296.2, m >280°**. Adsorb it on silica gel from CCl<sub>4</sub>/\*benzene (3:1), elute with \*benzene, evaporate, crystallise the residue from CHCl<sub>3</sub> and dry it at 60-65° [Wyman & Brode *J Am Chem Soc* **73** 1487 1951; this paper also gives details of purification of other thioindigo dyes]. [*Beilstein* **19** H 137, **19** I 690, **19** II 192, **19** III/IV 2091.]

**Thiomorpholine (tetrahydro-2H-1,4-thiazine)** [123-90-0] **M 103.2, b 110°/100mm, 169°/atm, d<sub>4</sub><sup>20</sup> 1.026, n<sub>D</sub><sup>20</sup> 1.540, pK<sup>25</sup> 9.00**. Purify it by vacuum distillation. The *hydrochloride* has **m 179°** (from isoPrOH or EtOH/Et<sub>2</sub>O/HCl). [Davies *J Chem Soc* 306 1920, *Beilstein* **27** II 4, **2** III/IV 636.]

**Thionine (3,7-diaminophenothiazine, Lauth's violet)** [135-59-1, 581-64-6 (HCl), 78338-22-4 (acetate)] **M 263.7,  $\epsilon_{590}$  6.2 x 10<sup>4</sup> M<sup>-1</sup> cm<sup>-1</sup>, pK<sup>15</sup> 6.9**. The standard biological stain is usually highly pure. It can be crystallised from water or 50% EtOH, then chromatographed on alumina using CHCl<sub>3</sub> as eluent [Shepp et al. *J Phys Chem* **66** 2563 1962]. Dry it overnight at 100° and store it in a vacuum. The *hydrochloride* can be crystallised from 50% EtOH or dilute HCl and aqueous *n*-butanol. Purify it also by column chromatography and washed with CHCl<sub>3</sub> and acetone. Dry it *in vacuo* at room temperature. [*Beilstein* **27** H 391, **27** I 412, **27** II 447, **27** III/IV 5149.]

**Thiooxine hydrochloride (8-mercaptoquinoline hydrochloride)** [34006-16-1] **M 197.7, m 170-175° (dec), pK<sub>1</sub><sup>25</sup> 2.16, pK<sub>2</sub><sup>25</sup> 8.38**. It forms yellow crystals from EtOH. It has pK<sub>a</sub><sup>20</sup> values of 2.05 and 8.29 in H<sub>2</sub>O. It is more stable than thiooxine. [UV: Albert & Barlin *J Chem Soc* 2384 1959]. [*Beilstein* **21** H 99, **21** III/IV 1197, **21/3** V 30.]

**Thiophene** [110-02-1] **M 84.1, f -38.5°, b 84.2°, d<sub>4</sub><sup>20</sup> 1.525, n<sub>D</sub><sup>20</sup> 1.52890, n<sub>D</sub><sup>30</sup> 1.5223**. The simplest purification procedure is to dry thiophene with solid KOH, or reflux it with sodium, and fractionally distil it through a glass-helices-packed column. More extensive treatments include an initial wash with aqueous HCl, then water, drying with CaSO<sub>4</sub> or KOH, and passage through columns of activated silica gel or alumina. Fawcett and Rasmussen [*J Am Chem Soc* **67** 1705 1945] washed thiophene successively with 7M HCl, 4M NaOH, and distilled water, dried with CaCl<sub>2</sub> and fractionally distilled it. \*Benzene was removed by fractional crystallisation by partial freezing, and the thiophene was degassed and sealed in Pyrex flasks. [Also a method is described for recovering the thiophene from the \*benzene-enriched portion.] [*Beilstein* **17** H 29, **17** I 17, **17** II 35, **17** III/IV 234, **17/1** V 297.]

**Thiophene-2-acetic acid** [1918-77-0] **M 142.2, m 63-64°, 76°, b 160°/22mm, pK<sup>25</sup> 3.89, pK<sup>25</sup> 6.43 [MeO(CH<sub>2</sub>)<sub>2</sub>OH-H<sub>2</sub>O/80:20]**. Crystallise the acid from ligroin, hexane and/or distil it in a vacuum. The *amide* has **m 148°** (from H<sub>2</sub>O or petroleum ether). [*Beilstein* **18** H 293, **18** III/IV 4062, **18/6** V 207.]

**Thiophene-3-acetic acid** [6964-21-2] **M 142.2, m 79-80°, pK<sub>Est</sub> ~3.1**. Crystallise the acid from ligroin or H<sub>2</sub>O. [*Beilstein* **18** III/IV 4066.]

**2-Thiophenecarboxaldehyde** [98-03-3] **M 112.2, b 75-77°/11mm, 106°/30mm, 198°/756mm, d<sub>4</sub><sup>20</sup> 1.593, n<sub>D</sub><sup>20</sup> 1.222**. Wash it with 50% HCl and distil it under reduced pressure just before use. It has UV with  $\lambda_{\max}$  234nm (hexane). The *Z-oxime* has **m 144°, 136-138° and 142° (H<sub>2</sub>O)**. [*Beilstein* **17** H 285, **17** I 148, **17** II 313, **17** III/IV 4477, **17/9** V 349.]

**Thiophene-2-carboxylic acid** [527-72-0] **M 128.2, m 129-130°, pK<sup>25</sup> 3.59.** Crystallise the acid from water and dry it in a vacuum. The *amide* has **m 181°(from H<sub>2</sub>O)** and **pK<sup>25</sup> 10.54** (50% aqueous dioxane). [*Beilstein* **18 H 289, 18 I 438, 18 II 269, 18 III/IV 4011, 18/6 V 158.**]

**Thiophene-3-carboxylic acid** [88-31-1] **M 128.1, m 138-139°, pK<sup>25</sup> 6.23(4.11).** Crystallise the acid from water and dry it in a vacuum. [*Beilstein* **18 H 292, 18 III/IV 4053, 18/6 V 199.**] The *amide* has **m 179-180°** (from H<sub>2</sub>O) [*Beilstein* **18 III/IV 4056.**]

**Thiophene-2,5-dicarbonyl dichloride [2,5-bis(chlorocarbonyl)thiophene]** [3857-36-1] **M 209.5, b 102-103°/2mm, 150-152°/11mm, m 43-47°, 45-46°.** Purify it by distillation in a vacuum; or if discoloured, then heat it with SOCl<sub>2</sub> or oxalyl chloride, and distil it in a vacuum. It solidifies on cooling, and can be recrystallised from \*C<sub>6</sub>H<sub>6</sub>/heptane. It provides the *di-phenyl ester* (**m 136-137°**), when treated with phenol at 200° or phenol/pyridine at 100°, followed by adding to cold H<sub>2</sub>O, filtering, drying, and recrystallising from EtOH. [Griffing & Salisbury *J Am Chem Soc* **70** 3416 1968, *Beilstein* **18 H 330, 18 III/IV 4496.**]

**Thiophene-2,5-dicarboxylic acid (2,5-dicarboxythiophene)** [4282-31-4] **M 172.2, m 332-333°(sealed capillary), 358.5-359.5°(corrected, sealed tube), 360°, pK<sub>Est(1)</sub> ~3.3, pK<sub>Est(2)</sub> ~7.4.** It can be precipitated from alkaline solution with acid, filtered and recrystallised from H<sub>2</sub>O, dried and sublimed at 0.0001 mm. Its *mono-methyl ester* crystallises from aqueous MeOH (**m 187-190°, pK<sub>Est(1)</sub> ~3.2**) or petroleum ether (**m 192°**), and sublimes in a vacuum unchanged. With diazomethane/Et<sub>2</sub>O it provides the *di-methyl ester* (**m 148.5-149.5°; m's 146-147° and 152°** were also reported) which crystallises from MeOH or 1:1 aqueous MeOH in flattened needles, and sublimes at 80-95° in high vacuum. This ester has λ<sub>max</sub>(logε) at 275(4.27) in EtOH. [Hartough & Kosak *J Am Chem Soc* **68** 1012 1947, Birkinshaw & Chaplen *Biochem J* **60** 255 1955, Griffing & Salisbury *J Am Chem Soc* **70** 3416 1968, *Beilstein* **18 H 330, 18 III/IV 4496.**]

**Thiopyronine (2,7-dimethylaminothioxanthene chloride hydrochloride)** [2412-14-8] **M 318.9, λ<sub>max</sub> 564nm (ε 78,500) H<sub>2</sub>O, pK<sub>Est</sub> ~ 7.** Purify it as the hydrochloride by recrystallisation from hydrochloric acid forming needles **m 245°** (dec) and UV with λ<sub>max</sub> at 564nm (ε 78,500, H<sub>2</sub>O). [Fanghanel et al. *J Phys Chem* **91** 3700 1987, *Beilstein* **18 H 596, 18 III/IV 7291.**]

**Thiothienoyltrifluoroacetone [1-(2-thienyl)-4,4,4-trifluorobutan-3-one-1-thione]** [4552-64-1] **M 228.2, m 61-62°, 64.5-65°, 73-74°, 74°.** It is easily oxidised and has to be purified before use. This is achieved by recrystallisation from \*benzene or by dissolution in petroleum ether, extraction into 1M NaOH solution, acidification of the aqueous phase with 1-6M HCl solution, back extraction into petroleum ether and final evaporation of the solvent. The purity can be checked by TLC. It is stored in ampoules under nitrogen at 0° in the dark. It crystallises in red crystals from petroleum ether. Its IR has ν<sub>max</sub> at 815m(C-S, C-H), 1260m(C-S), 1570sh(C=C) and 1612s(C=O)cm<sup>-1</sup>. [Müller & Rother *Anal Chim Acta* **66** 49 1973, Chaston et al. *Aust J Chem* **18** 673 1965.]

**2-Thiouracil** [141-90-2] **M 128.2, m 240°(dec), 315°(dec), pK<sub>1</sub><sup>25</sup> 7.75, pK<sub>2</sub><sup>25</sup> 12.7.** Crystallise 2-thiouracil from water or EtOH. [*Beilstein* **24 H 323, 24 I 315, 24 II 171, 24 III/IV 1237.**]

**9H-Thioxanthene-9-one (thioxanthone, thionanthone)** [492-22-8] **M 212.3, m 200-202°, 209°, 212-214°, b 371-373°/712mm.** It forms yellow needles from CHCl<sub>3</sub> or EtOH and sublimes *in vacuo*. It is soluble in CS<sub>2</sub>, hot AcOH, and dissolves in conc H<sub>2</sub>SO<sub>4</sub> to give a yellow colour with green fluorescence in VIS light. The *sulfone* has **m 187°** (from EtOH), and the *hydrazone* has **m 115°** (yellow leaflets from EtOH/\*C<sub>6</sub>H<sub>6</sub>). The *oxime* has **m 194-196°** (from petroleum ether). [Szmant et al. *J Org Chem* **18** 745 1953, Ullmann et al. *Chem Ber* **49** 2509 1916, NMR: Sharpless et al. *Org Magn Res* **6** 115 1974, *Beilstein* **17 H 357, 17 I 191, 17 III/IV 5302, 17/10 V 437.**]

**$\beta$ -Thymidine** [50-89-5] M 242.2, m 185°, 186-188°,  $[\alpha]_D^{20} +19^\circ$  (c 1, H<sub>2</sub>O), pK<sub>2</sub><sup>25</sup> 9.65. Crystallise  $\beta$ -thymidine from ethyl acetate, MeOH/Et<sub>2</sub>O (m 188°) or H<sub>2</sub>O (as 2H<sub>2</sub>O m 189°). It is soluble in water and hot organic solvents. The *picrate* has m 230° (from EtOH). [Beilstein 24 III/IV 1297.]

**Thymine (5-methylpyrimidin-2,4-dione)** [65-71-4] M 126.1, m 326°(dec), pK<sub>1</sub><sup>25</sup> 9.90 (9.82) pK<sub>2</sub><sup>25</sup> >13.0. Crystallise thymine from EtOAc, 10% aqueous EtOH or water. It has m 318-320° after sublimation at 200°/12mm. Purify it by preparative (2mm thick) TLC plates of silica gel, eluting with ethyl acetate/isopropanol/water (75:16:9, v/v; R<sub>F</sub> 0.75). The desired spot is located with a uv lamp, cut the band from the plate, place it in MeOH, shake and filter it through a millipore filter, then evaporate. [Infante et al. *J Chem Soc, Faraday Trans 1* 68 1586 1973, *Beilstein* 24 H 353, 24 I 330, 24 II 183, 24 III/IV 1292.]

**Tinuvin P (2-[2H-benzotriazol-2-yl]-*p*-cresol)** [50936-05-5] M 225.3, m 131-133°, pK<sub>Est(1)</sub>~1.6 (N protonation), pK<sub>Est(2)</sub>~8 (phenolic OH). Recrystallise it from *n*-heptane or Me<sub>2</sub>CO/pentane. [Woessner et al. *J Phys Chem* 81 3629 1985.]

**Toluidine Blue O** [93-31-9] M 305.8, CI 52040,  $\lambda_{\max}$  626nm, pK<sup>25</sup> 7.5. Crystallise the dye from hot water (18ml/g) by adding one and a half volume of alcohol and chilling on ice. Dry it at 100° in an oven for 8-10 hours. [Merrill & Spencer *J Am Chem Soc* 70 3683 1948, *Beilstein* 27 I 417, 27 II 454, 27 III/IV 5161.]

**1,5,7-Triazabicyclo[4.4.0]dec-5-ene (TBD, 1,3,4,6,7,8-hexahydro-2H-pyrimido[1,2-a]pyrimidine)** [5807-14-7] M 139.2, m 125-130°, pK<sup>25</sup> ~16. It crystallises from Et<sub>2</sub>O but readily forms white crystals of the carbonate. It is a strong base (see pK, i.e. about 100 times more basic than tetramethylguanidine). The *picrate* has m 220.5-222° (from EtOH). It forms the 5-nitro derivative m 145-160° that gives a 5-nitro nitrate salt m 100-101° (from EtOH/Et<sub>2</sub>O) and a 5-nitro *picrate* m 144-145° (from H<sub>2</sub>O) [McKay & Kreling *Can J Chem* 35 1438 1957, Schwesinger *Chimia* 39 369 1985, Hilpert et al. *J Chem Soc, Chem Commun* 1401 1983, Kamfen & Eschenmoser *Helv Chim Acta* 72 185 1989]. [*Beilstein* 26 III/IV 60.]

**1,2,4(1H)-Triazole** [288-88-0] M 69.1, m 121°, 260°, pK<sub>1</sub><sup>25</sup> 2.27 (basic), pK<sub>2</sub><sup>25</sup> 10.26 (acidic). Crystallise 1,2,4-triazole from EtOH, H<sub>2</sub>O, EtOAc (m 120.5-121°), or EtOH/\*C<sub>6</sub>H<sub>6</sub>. The *hydrochloride* has m 170°, and the *picrate* has m 163-164° (from H<sub>2</sub>O or CHCl<sub>3</sub>). [Barszcz et al. *J Chem Soc, Dalton Trans* 2025 1986]. [*Beilstein* 26 H 13, 26 II 6, 26 III/IV 35.]

**Tricycloquinazoline** [195-84-6] M 230.3, m 322-323°. Crystallise it repeatedly from toluene, xylene or these solvents mixed with \*C<sub>6</sub>H<sub>6</sub>. It can also be crystallised from CHCl<sub>3</sub> or cymene (m 308-310°), followed by sublimation at 210°/0.15-0.3 Torr in subdued light. [*Beilstein* 26 III/IV 1932.]

**Trifluoperazine dihydrochloride (10-[3-{4-methyl-1-piperazinyl}propyl]-2-trifluoro-methyl-phenothiazine 2HCl)** [440-17-5] M 480.4, m 240-243°, 242-243°, pK<sub>1</sub> 3.9, pK<sub>2</sub> 8.1. Recrystallise the salt from absolute EtOH, filter the crystals, dry them *in vacuo* and store them in tightly stoppered bottles because it is *hygroscopic*. It is soluble in H<sub>2</sub>O but insoluble in \*C<sub>6</sub>H<sub>6</sub>, Et<sub>2</sub>O and alkaline aqueous solution. It has UV with  $\lambda_{\max}$  at 258 and 307.5nm (log  $\epsilon$  4.50 and 3.50) in EtOH (neutral species). [Craig et al. *J Org Chem* 22 709 1957.] It is a calmodulin inhibitor [Levene & Weiss *J Pharmacol Exptl Ther* 208 454 1978] and is a psychotropic agent [Fowler *Arzneim.-Forsch* 27 866 1977]. [*Beilstein* 27 III/IV 1353.]

**Trigonelline (1-methylnicotinic acid zwitterion)** [535-83-1] M 137.1, m 218°(dec), pK<sub>1</sub><sup>25</sup> 2.10. Crystallise trigonelline (as *monohydrate*) from aqueous EtOH, then dry it at 100°. It also crystallises from H<sub>2</sub>O as the monohydrate with m 230-233°(dec). It has been crystallised from EtOH with m 214-215°(dec). The *hydrochloride* [6138-41-6] M 173.6 has m 258-259°(dec) (from EtOH) [Smisson & Hite *J Am Chem Soc* 81 1201 1959]. The *picrate* crystallises from EtOH with m 204-206°. [Green & Tong *J Am Chem Soc* 78 4896 1956, Kosower & Patton *J Org Chem* 26 1319 1961, *Beilstein* 22 I 504, 22 II 35, 22 III/IV 462, 22/2 V 143.]

**4',5,7-Trihydroxyflavone (apigenin)** [520-36-5] M 270.2, m 296-298°, 300-305°, 345-350° (pK's 7-10, for phenolic OH). Crystallise it from aqueous pyridine or aqueous EtOH. It dyes wool yellow when mixed with Cr ions. [*Beilstein* 18 H 181, 18 I 396, 18 II 178, 18 III/IV 2682, 18/4 V 574.]

**2,2,5-Trimethyl-1,3-dioxane-4,6-dione (Methyl Meldrum's Acid, methylmalonic acid cyclic isopropylidene ester)** [3709-18-0] **M 158.2, m 111-114°, 113-114°, 115°, pK<sup>25</sup> 4.77.** This 'acid' is synthesised and purified in the same way as *Meldrum's acid* [2033-24-1], except that malonic acid is replaced by methylmalonic acid, in 58% yield. [Pihlaja & Seilo *Acta Chim Scand* **22** 3053 1968, Davidson & Bernhard *J Am Chem Soc* **70** 3426 1948]. Its <sup>1</sup>H NMR (CDCl<sub>3</sub>, TMS) has δ at 1.77 (m, isopropylidene Me, *J* = 0.6Hz), 1.85 (m, isopropylidene Me, *J* = 0.6Hz), 1.52 (d, 5-Me, *J* = 7Hz) and 3.81 (q, 5-H, *J* = 7.0Hz) ppm [Schuster & Schuster *Tetrahedron* **25** 199 1969], and the proportion of *enol-form* is apparently not seriously altered by the polarity of the solvent, i.e. MeOH (55.7%), EtOH (1.2%), CDCl<sub>3</sub> (60.8%) and \*C<sub>6</sub>H<sub>6</sub> (58.9%) [Kabachnik et al. *Tetrahedron* **1** 317 1967]. The uncatalysed and acid-catalysed aqueous hydrolysis has been studied in detail with the 5,5-dimethyl-dione (not described here) hydrolysing slightly faster than the 5-methyl-4,6-dione (described here) and the unmethylated acid [Meldrum's acid, 2033-24-1] because, unlike the 5,5-dimethyl-4,6-dione, the latter two can enolise [Pihlaja & Seilo *Acta Chim Scand* **22** 3053 1968.] [*Beilstein* **18** I 480, **19** III/IV 1928, **19/5** V 11.]

**2,2,6-Trimethyl-4H-1,3-dioxin-4-one (diketene acetone adduct)** [5394-63-8] **M 142.2, m 12-13°, b 40°/0.03mm, 65-67°/2mm, 275°/atm, d<sub>4</sub><sup>20</sup> 1.0879, n<sub>D</sub><sup>20</sup> 1.4678.** The reactions of this dioxinone are very similar to those of diketene and it acts as a β-keto-ester synthon. Its purity can be easily assessed by <sup>1</sup>H NMR spectroscopy as it has only three characteristic peaks (see below). Purify it by fractional distillation, preferably under a vacuum. It is a pleasant smelling liquid that is quite stable in the **absence** of alkali. It is slightly soluble in H<sub>2</sub>O that becomes faintly acidic, it gives a red colour with FeCl<sub>3</sub>, and it rapidly reduces alkaline permanganate in alcoholic solution. It is readily prepared by refluxing a mixture of dry acetone (100ml), diketene (100ml, 109g, 1.3moles, see [674-82-8] **toxic**) and *p*-toluenesulfonic acid (0.5g, amount is critical) for 3 hours when the odour of diketene disappears. Excess of acetone is distilled off first followed by the *adduct* (168g, 1.18moles, 91% based on diketene). This procedure should be carried out in an efficient fume cupboard as diketene is **TOXIC**. [Carroll & Bader *J Am Chem Soc* **75** 5400 1953, Naylor (uses ZnCl<sub>2</sub> as catalyst) *J Chem Soc* 244 1945, Dehmlow & Shamout (using quaternary ammonium salts as catalysts) *Justus Liebigs Ann Chem* 1783 1982.] The structure of the adduct has been determined with certainty [Bader et al. *J Org Chem* **21** 821 1956]. Its FT-IR (film) has ν<sub>max</sub> at 1738.7, 1640.0, 1392.8, 1272.6, 1205.3, 1031.5, 901.2, 805.1 and 548.3 cm<sup>-1</sup>; the <sup>1</sup>H NMR (CDCl<sub>3</sub>, TMS) has δ at 1.69 [s, 6H, gem (CH<sub>3</sub>)<sub>2</sub>], 2.00 (s, but d at very high resolution with *J* ~1 Hz, 3H, allyl CH<sub>3</sub>) and 5.21 (s, but q at very high resolution with *J* ~1 Hz, 1H, vinyl H); and the <sup>13</sup>C NMR (CDCl<sub>3</sub>) has δ at 168.65, 161.06, 106.32, 93.81, 25.02 and 19.92. Labelling experiments with (CD<sub>3</sub>)<sub>2</sub>CO showed that isoprenyl acetoacetate may be the key intermediate in the synthesis [Hyatt *J Org Chem* **49** 5102 1984]. In addition to reacting as a diketene reagent, it has been functionalised, e.g. to 6-bromomethyl-2,2-dimethyl-4H-1,3-dioxin-4-one and 6-methylene-4-diethylphosphoryl-2,2-dimethyl-1,3-dioxinane, for the synthesis of natural products such as ikarugamycin and tirandamycin [Boeckman & Thomas *J Org Chem* **47** 2823 1982]. [*Beilstein* **19** IV 1604]

**1',3',3'-Trimethyl-6-nitrospiro[2H-benzopyran-2,2'-indoline]** [1498-88-0] **M 322.4, m 180°.** This photochromic dye crystallises from absolute EtOH [Hinnen et al. *Bull Soc Chim Fr* 2066 1968, Ramesh & Labes *J Am Chem Soc* **109** 3228 1987, Berman et al. *J Am Chem Soc* **81** 5607 1959]. [*Beilstein* **27** III/IV 1460.]

**2,2,4-Trimethyl-6-phenyl-1,2-dihydroquinoline** [3562-69-4] **M 249.3, m 102°.** It is the principal ingredient in Santoflex. Crystallise it three times from absolute EtOH. The 1-phenylcarbamoyl derivative has **m** 148-149.6° (from EtOH). [Hively et al. *Anal Chem* **27** 100 1955, *Beilstein* **20** III/IV 4116.]

**2,4,6-Trimethylpyridine (sym-collidine)** [108-75-8] **M 121.2, m -46°, b 10°/2.7mm, 36-37°/2mm, 60.7°/13mm, 65°/31mm, 170.4°/760mm, 175-178°/atm, d<sub>4</sub><sup>25</sup> 0.9100, n<sub>D</sub><sup>20</sup> 1.4939, 1.4981, n<sub>D</sub><sup>25</sup> 1.4959, pK<sup>25</sup> 6.69(7.45).** Commercial samples may be grossly impure. Likely contaminants include 3,5-dimethylpyridine, 2,3,6-trimethylpyridine and water. Brown, Johnson and Podall [*J Am Chem Soc* **76** 5556 1954] fractionally distilled 2,4,6-trimethylpyridine under reduced pressure through a 40cm Vigreux column and added to 430ml of the distillate slowly, with cooling to 0°, 45g of BF<sub>3</sub>-diethyl etherate. The mixture was again distilled, and an equal volume of dry \*benzene was added to the distillate. Dry HCl was passed into the solution, which was

kept cold in an ice-bath, and the hydrochloride was filtered off. It was recrystallised from absolute EtOH (1.5ml/g) to **m** 286-287° [**m** 256° (sealed tube), also **m** 293-294° subliming slowly]. The free base was regenerated by treatment with aqueous NaOH, then extracted with \*benzene, dried (MgSO<sub>4</sub>) and distilled under reduced pressure. Sisler et al. [*J Am Chem Soc* **75** 446 1953] precipitated trimethylpyridine as its phosphate salt from a solution of the base in MeOH by adding 85% H<sub>3</sub>PO<sub>4</sub>, shaking and cooling. The free base was then regenerated as above. Garrett and Smythe [*J Chem Soc* 763 1903] purified the trimethylpyridine *via* the HgCl<sub>2</sub> complex. It is more soluble in cold than hot H<sub>2</sub>O [the solubility is 20.8% at 6°, 3.5% at 20°, 1.8% at 100°].

*Alternatively*, purify it by dissolving it in CHCl<sub>3</sub>, adding solid K<sub>2</sub>CO<sub>3</sub> and Drierite, filtering and fractionally distilling through an 8in helix-packed column. *The alkali metals, Na, Li or Cs should NOT be used for drying pyridine, and pyridine derivatives, as they form coloured pyridine radical anions leading to bipyridyls.* [see Schmulback et al. *J Am Chem Soc* **90** 6600 1968]. The *sulfate* has **m** 205°, and the *picrate* (from hot H<sub>2</sub>O) has **m** 155-156°. [Frank & Meikle *J Am Chem Soc* **72** 4184 1950, *Beilstein* **20** H 250, **20** I 87, **20** II 164, **20** III/IV 2810, **20/6** V 93.]

**1,3,7-Trimethyluric acid** [5415-44-1] **M 210.2, m 345°(dec), pK<sup>25</sup> 6.0.** Crystallise it from water and dry it at 100° in a vacuum. It has UV with  $\lambda_{\max}$  at 289nm (pH 2.5). [*Beilstein* **26** III/IV 2623.]

**1,3,9-Trimethyluric acid** [7464-93-9] **M 210.2, m 340°(dec), 347°, pK<sup>20</sup> 9.39.** Crystallise it from water and dry it at 100° in a vacuum. [*Beilstein* **26** H 530, **26** II 301, **26** III/IV 2623.]

**1,7,9-Trimethyluric acid** [55441-82-2] **M 210.2, m 316-318°, 345°, pK<sub>Est</sub> ~9.0.** Crystallise the uric acid from water or EtOH, and sublime it *in vacuo*. [*Beilstein* **26** H 530, **26** II 302, **26** III/IV 2623.]

**3,7,9-Trimethyluric acid** [55441-72-0] **M 210.2, m 373-375°(dec), pK<sup>20</sup> 9.39.** Crystallise the uric acid from water and dry it at 100° in a vacuum. It has UV with  $\lambda_{\max}$  at 294nm (pH 2.5). [Bergmann & Dikstein *J Am Chem Soc* **77** 691 1955, *Beilstein* **26** H 530, **26** I 156, **26** II 301, **26** III/IV 2623.]

**1,3,5-Trioxane** [110-88-3] **M 90.1, m 64°, b 114.5°/759mm.** Crystallise 1,3,4-trioxane from sodium-dried diethyl ether or water, and dry it over CaCl<sub>2</sub>. It can also be purified by zone refining. [*Beilstein* **19** H 381, **19** II 392, **19** III/IV 4710, **19/9** V 103.]

**Trioxsalen (2,5,9-trimethyl-7H-furo[3,2-g]benzopyran-7-one)** [3902-71-4] **M 228.3, m 233-235°, 234.5-235°.** Purify trioxsalen by recrystallisation from CHCl<sub>3</sub>. If too impure, it is fractionally crystallised from CHCl<sub>3</sub>/petroleum ether (b 30-60°) using Norit, and finally crystallised from CHCl<sub>3</sub> alone to give colourless prisms, **m** 234.5-235°. It is a photosensitiser so it should be stored in the dark. [UV: Kaufmann *J Org Chem* **26** 117 1961, Baeme et al. *J Chem Soc* 2976 1949, *Beilstein* **19/4** V 472.]

**2,3,5-Triphenyltetrazolium chloride (TTC, TTZ)** [298-96-4] **M 334.8, m 243°(dec).** Crystallise TTZ from EtOH or CHCl<sub>3</sub>, and dry it at 105°. [*Beilstein* **26** H 363, **26** II 216, **26** III/IV 1774.]

**Tripyridyl triazine** [3682-35-7] **M 312.3, m 245-248°, 248-250°.** Purify it by repeated crystallisation from aqueous EtOH. It is a reagent for the determination of Fe(II) and total Fe [Collins et al. *Anal Chem* **31** 1862 1959]. [*Beilstein* **26** III/IV 4192.]

**1,1,1-Tris(acetyloxy)-1,1-dihydro-1,2-benziodoxol-3-(1H)-one (Dess-Martin periodinane, DMP)** [87413-09-0] **M 424.1, m 130-133°, 133-134° (dec).** DMP is essentially the acetylated form of IBX (see above) that renders the latter more soluble in organic solvents. Unlike IBX, it is not explosive on melting or upon hard impact. However, it is subject to hydrolysis in the presence of moisture that may give rise to explosive impurities. It is important that it should be stored in a dry atmosphere and that care should be taken when using it. The original Dess-Martin preparation [Dess-Martin *J Am Chem Soc* **113** 7277 1991] has been improved and is reported here.

1-Hydroxy-1,2-benziodoxol-3(1H)-one (100g, 360mmol, see IBX [61717-82-6]) is added to Ac<sub>2</sub>O (400ml, ~4mol) and TsOH.H<sub>2</sub>O (0.5g), and stirred under N<sub>2</sub> at 80° for 2 hours, then cooled in an ice-water bath. The

white solid that separates in the cold mixture is filtered off onto a fritted glass funnel, rinsed with anhydrous Et<sub>2</sub>O (5 x 50ml), and the crystalline solid (138g, 91%, m 134°) is rapidly transferred to an argon filled amber-glass bottle and stored in a freezer. When exposed to light for several weeks some decomposition occurs so it should be kept away from light. [Ireland & Liu *J Org Chem* **58** 2899 1993.] Its IR (CH<sub>2</sub>Cl<sub>2</sub>) has  $\nu_{\max}$  at 1726.9 (s) and 1707.5 cm<sup>-1</sup>; the <sup>1</sup>H NMR (CDCl<sub>3</sub>, TMS) has  $\delta$  at 2.01 (s, 6H, COCH<sub>3</sub>), 2.33 (s, 3H, COCH<sub>3</sub>), 7.80 (t, 1H,  $J_{\text{HH}} = 7.3$  and 8.5 Hz) and 8.07 (t, 1H,  $J_{\text{HH}} = 7.3$  and 8.5 Hz) (C-4 and C-5), 8.29 (d, 1H,  $J_{\text{HH}} = 8.5$  Hz) and 8.31 (d, 1H,  $J_{\text{HH}} = 8.5$  Hz) (C-3 and C-6); and the <sup>13</sup>C NMR (CDCl<sub>3</sub>) has  $\delta$  at 20.29 (2 COCH<sub>3</sub>), 20.43 (1 COCH<sub>3</sub>), 126.01 (C-2), 126.51, 131.79, 133.81, 135.76, 142.36 (C-1), 166.08 (endocyclic C=O), 173.96 (1 acetate C=O), 175.66 and (2 acetate C=O's). A 0.3M solution of DMP in CH<sub>2</sub>Cl<sub>2</sub> is available commercially.

**DMP** is an extremely useful reagent for the oxidation of primary and secondary alcohols to aldehydes and ketones to completion, without further oxidation to the acids, within ~2 hours at 20°; allylic and benzylic alcohols require ~30 minutes. The reaction is increased rapidly on addition of an alcohol. Furan rings or sulfides and vinyl ethers are unreactive. Geraniol is oxidised to geranial without rearrangement to nerol, and it oxidises *N*-benzylbenzamide to benzaldehyde. The reagent is usually added in an appropriate anhydrous solvent (e.g. CHCl<sub>3</sub>, CH<sub>2</sub>Cl<sub>2</sub>, MeCN, etc.) followed by the substrate. Workup can be by adding Et<sub>2</sub>O followed by aqueous NaOH which decomposes the reagent to iodobenzoate, or for base-sensitive substrates NaHCO<sub>3</sub> and sodium thiosulfate (Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>) are added, which also remove iodine. A pyridine buffer can be used to keep near-neutral conditions throughout the entire oxidation followed by a thiosulfate work up procedure. [see Dess-Martin *J Am Chem Soc* **113** 7277 1991, and papers cited in this reference.] In the peptide field, substances like *N*-Fmoc phenylglycinol are oxidised to *N*-Fmoc phenylglycinal almost quantitatively in water-saturated CH<sub>2</sub>Cl<sub>2</sub> with this reagent [Myers et al. *Tetrahedron Lett* **41** 1359 2000].

**1,3,5-Trithiane (trithioformaldehyde)** [291-21-4] **M 138.3, m 216-218°(dec)**. Crystallise it from AcOH or toluene, after Soxhlet extraction with toluene (30g/300ml) [*Beilstein* **19** III/IV 4711, **19/9** V 105.]

**3-Tropanol (Tropine)** [120-29-6] **M 141.2, m 63°, 64-66°, b 229°/760mm, pK<sup>15</sup> 3.80**. Distil 3-tropanol in steam and crystallise it from Et<sub>2</sub>O or toluene/petroleum ether. It is soluble in H<sub>2</sub>O, EtOH, CHCl<sub>3</sub>, and sublimes at 60°/0.1mm. *Hygroscopic*. A 0.05M solution in H<sub>2</sub>O has a pH of 11.5. The *hydrochloride* has **m 280°** (from EtOH/Et<sub>2</sub>O). [*Beilstein* **21** H 16, **21** I 197, **21** II 17, **21** III/IV 168, **21/1** V 219.]

**Tryptamine [3-(2-aminoethyl)indole]** [61-54-1] **M 160.1, m 116°, pK<sub>1</sub><sup>25</sup> -6.31 (aqueous H<sub>2</sub>SO<sub>4</sub>, diprotonation), pK<sub>Est(2)</sub>~4.9, pK<sub>3</sub><sup>25</sup> 16.60 (acidic indole NH)**. Crystallise tryptamine from \*benzene, Et<sub>2</sub>O (m 114°) or petroleum ether (m 118°). It has UV with  $\lambda_{\max}$  at 222, 276, 282 and 291nm (EtOH) and 226, 275, 281 and 290nm (HCl). [*Beilstein* **22** II 346, **22** III/IV 4319, **22/10** V 45.]

**Tryptamine hydrochloride** [343-94-2] **M 196.7, m 252-253°**. Crystallise the salt from EtOH/water or EtOH/Et<sub>2</sub>O. See previous entry for UV. [*Beilstein* **22** II 347, **22** III/IV 4319, **22/10** V 46.]

**Tryptophol [3-(2-hydroxyethyl)indole]** [526-55-6] **M 161.2, m 59°, b 174°/2mm**. Crystallise it from diethyl ether/petroleum ether, \*C<sub>6</sub>H<sub>6</sub>, \*C<sub>6</sub>H<sub>6</sub>/petroleum ether. The *picrate* has **m 100-101°** (from \*C<sub>6</sub>H<sub>6</sub>). [*Beilstein* **21** I 218, **21** II 49, **21** III/IV 788, **21/3** V 61.]

**(+)-Tubocurarine chloride (5H<sub>2</sub>O)** [57-94-3] **M 771.7, m 274-275°(dec) (anhydrous), [α]<sub>D</sub><sup>20</sup> +235° (c 0.5, H<sub>2</sub>O), pK<sub>Est(1)</sub>~8.5, pK<sub>Est(2)</sub>~8.8**. Crystallise this chloride from water. It forms various hydrates. The *hydrochloride pentahydrate* has **m 268-269°** (from H<sub>2</sub>O) and [α]<sub>D</sub><sup>21</sup> +190° (0.5, H<sub>2</sub>O). Its solubility in H<sub>2</sub>O at 25° is 50mg/ml. [*Beilstein* **27** II 897, **27** III/IV 8727.]

**Umbelliferone (7-hydroxycoumarin)** [93-35-6] **M 162.2, m 225-228°, 230-233°, pK<sub>Est</sub> ~8.0**. It crystallises from water (m 232-232.2°) or EtOH (m 232°). It sublimes at 160°/0.001mm. Fluorescence: Em<sub>max</sub> 452nm/Exc<sub>max</sub> 325nm in 50% EtOH. [*Beilstein* **18** H 27, **18** I 306, **18** II 16, **18** III/IV 294, **18/1** V 386.]

**Uracil (pyrimidine-2,4(1*H*)-dione)** [66-22-8] **M 122.1, m 335°(dec), pK<sub>1</sub><sup>25</sup> 9.43, pK<sub>2</sub><sup>25</sup> 13.3-14.2.** Uracil crystallises from water (**m** 339-341°) and **m** 338° after sublimation in high vacuum. Its solubility in H<sub>2</sub>O at 20° is 1g/300ml. [*Beilstein* 24 H 312, 24 I 312, 24 II 169, 24 III/IV 1193.]

**Uramil (5-aminobarbituric acid)** [118-78-5] **M 143.1, m 310-312°, 320°, >400°(dec), pK<sub>Est(1)</sub>~3.9, pK<sub>Est(2)</sub>~8.0, pK<sub>Est(3)</sub>~12.5.** It crystallises from water. It has also been purified by dissolving it in aqueous ammonia and precipitating it by dropwise addition of formic acid. The solid is collected and dried in a vacuum at 100°. [Hartman & Sheppard *Org Synth Coll Vol II* 617 1943, *Beilstein* 25 H 492, 25 I 704, 25 III/IV 4228.]

**Uric acid** [69-93-2] **M 168.1, m >300° (dec) pK<sub>1</sub> 5.75, pK<sub>2</sub> 10.3.** Crystallise uric acid from hot distilled H<sub>2</sub>O (the solubility in H<sub>2</sub>O is 1part/39,000parts at 18° and 1part/2,000parts at 100°). It is best purified by dissolving in an alkaline solution and acidifying with dilute HCl and drying it at 100° in a vacuum. [Bergmann & Dikstein *J Am Chem Soc* 77 691 1955, Lister *Purines Part II, Fused Pyrimidines* Brown Ed, Wiley-Interscience pp256-257 1971, ISBN 0-471-38205-1, *Beilstein* 26 H 513, 26 I 151, 26 II 293, 26 III/IV 2619.]

**β-Uridine** [58-96-8] **M 244.2, m 165°, [α]<sub>D</sub><sup>20</sup> +10.0° (c 1.6, H<sub>2</sub>O), pK<sub>25</sub> 9.51 (9.25).** Crystallise β-uridine from aqueous 75% MeOH or EtOH (**m** 165-166°). [*Beilstein* 24 III/IV 1202.]

**Urocanic acid (4-imidazolylacrylic acid)** [104-98-3] **M 138.1, m 225°, 226-228°, pK<sub>Est(1)</sub>~2.5, pK<sub>Est(2)</sub>~6, pK<sub>Est(3)</sub>~11.** Crystallise the acid from water and dry it at 100°. The *trans-isomer* [3465-72-3] has **m** 225° (229-230°, 230-231° or 231°(dec, from H<sub>2</sub>O) and pK<sub>1</sub> 3.5 and pK<sub>2</sub> 5.6, and the *picrate* has **m** 225°(dec, from H<sub>2</sub>O). The *cis-isomer* [7699-35-6] has **m** 175-176° (178-179° or 180-184° dec, from H<sub>2</sub>O) and pK<sub>1</sub> 3.0 and pK<sub>2</sub> 6.7, and the *picrate* has **m** 204° (from H<sub>2</sub>O). [*Beilstein* 25 H 124, 25 I 536, 25 II 121, 25 III/IV 786.]

**δ-Valerolactam (2-piperidone)** [675-20-7] **M 99.1, m 38.5-39.5°, 39-40°, 40°, b 81-82°/0.1mm, 136-137°/15mm, pK<sub>25</sub> 0.75 (in AcOH).** Purify it by repeated fractional distillation. [Cowley *J Org Chem* 23 1330 1958, Reppe et al. *Justus Liebigs Ann Chem* 596 198 1955, IR: Huisgen et al. *Chem Ber* 90 1437 1957.] The *hydrochloride* [5174-67-4] has **m** 183-184° (from isoPrOH or EtOH/Et<sub>2</sub>O) [Hurd et al. *J Org Chem* 17 865 1952], and the *oxime* has **m** 122.5° (from petroleum ether) [Behringer & Meier *Justus Liebigs Ann Chem* 607 67 1957]. The *N-benzoyl* derivative [4252-56-6] has **m** 115° (from CHCl<sub>3</sub>/petroleum ether), the *N-methyl* derivative [931-20-4] is a water soluble hygroscopic liquid with **b** 115°/14mm, and the *N-methyl hydrochloride* [87243-73-0] crystallises from from EtOH/Et<sub>2</sub>O with **m** 115°. The *picrate* has **m** 92-93°. [*Beilstein* 21 H 239, 21 III/IV 3170, 21/6 V 396.]

**δ-Valerolactone (tetrahydro-2*H*-pyran-2-one)** [542-28-9] **M 100.1, m -13°, -12°, b 88°/4mm, 97°/10mm, 124°/24mm, 145-146°/40mm, 229-229.5°/atm, d<sub>4</sub><sup>20</sup> 1.1081, n<sub>D</sub><sup>20</sup> 1.4568.** Purify the δ-lactone by repeated fractional distillation. Its IR has **v<sub>max</sub>** at 1750 (in CS<sub>2</sub>), 1732 (in CHCl<sub>3</sub>), 1748 (in CCl<sub>4</sub>) and 1733 (in MeOH) cm<sup>-1</sup> [Huisgen & Ott *Tetrahedron* 6 253 1959, Linstead & Rydon *J Chem Soc* 580 1933, Jones et al. *Can J Chem* 37 2007 1959]. [*Beilstein* 17 H 235, 17 II 287, 17 III/IV 4169, 17/9 V 17.]

**γ-Valerolactone (± 4,5-dihydro-5-methyl-2(3*H*)-furanone)** [108-29-2] **M 100.1, m -37°, 36°, b 82-85°/10mm, 102-103°/28mm, 125.3°/68mm, 136°/100mm, 205.75-206.25°/ 754mm, d<sub>4</sub><sup>20</sup> 1.072, n<sub>D</sub><sup>20</sup> 1.4322.** Purify the γ-lactone by repeated fractional distillation [Boorman & Linstead *J Chem Soc* 577, 580 1933]. Its IR has **v<sub>max</sub>** at 1790 (CS<sub>2</sub>), 1775 (CHCl<sub>3</sub>) cm<sup>-1</sup> [Jones et al. *Can J Chem* 37 2007 1959]. The BF<sub>3</sub>-complex distils at 110-111°/20mm [Reppe et al. *Justus Liebigs Ann Chem* 596 179 1955]. It is characterised by conversion to γ-hydroxy-*n*-valeramide on treatment with NH<sub>3</sub>, which has **m** 51.5-52° (by slow evaporation of a CHCl<sub>3</sub> solution). [*Beilstein* 17 H 235, 17 I 131, 17 II 288, 17 III/IV 4176, 17/9 V 24.]

**(±)-Vinclozolin [3-(3,5-dichlorophenyl)-5-methyl-5-vinylloxazolidine-2,4-dione]** [50471-44-8] **M 286.1, m 108°.** Crystallise the fungicide from Me<sub>2</sub>CO/H<sub>2</sub>O. Its solubility at 20° (w/w%) is 44 (Me<sub>2</sub>CO), 32 (CHCl<sub>3</sub>), 25 (EtOAc) and 10 (H<sub>2</sub>O). It irritates the eyes and skin. [GP 2,207,576 1973, *Chem Abstr* 79 137120 1973.]

**N-Vinylcaprolactam** [2235-00-9] **M 139.2, m 35-38°(polym), b 95-95.5°/4mm, 128°/21mm,  $d_4^{20}$  1.0287,  $n_D^{20}$  1.5133.** Distil it under vacuum and with 0.0015% of 4-*tert*-butylcatechol as stabilizer. [Beilstein 21 III/IV 3207.]

**N-Vinylcarbazole** [1484-13-5] **M 193.3, m 66°.** Crystallise *N*-vinylcarbazole repeatedly from MeOH in amber glassware. It sublimes in a vacuum. [Beilstein 20 II 282, 20 III/IV 3830, 20/8 V 19.]

**Vinylene carbonate (1,3-dioxol-2-one)** [872-36-6] **M 86.1, m 22°, b 76-78°/37mm, 165°/~760mm.** Purify it by zone melting, or distillation, and stabilise it with 0.5% of 2,6-di-*tert*-butyl-*p*-cresol. [Beilstein 19 III/IV 1597, 19/4 V 72.]

**2-Vinylpyridine monomer** [100-69-6] **M 105.1, b 79-82°/29mm, d 0.974, n 1.550,  $pK^{25}$  4.92(4.98).** Steam distil it, then dry it with  $MgSO_4$  and distil it in a vacuum. [Beilstein 20 H 256, 20 III/IV 2884, 20/6 V 211.]

**4-Vinylpyridine monomer** [100-43-6] **M 105.1, b 40-41°/1.4mm, 54°/5mm, 58-61°/12mm, 68°/18mm, 79°/33mm,  $d_4^{20}$  0.9836,  $n_D^{20}$  1.5486,  $pK^{25}$  5.62.** Purify the monomer by fractional distillation under a good vacuum and in a  $N_2$  atmosphere; store it in sealed ampoules under  $N_2$ , and keep it in the dark at -20°. The *picrate* has **m 175-176°.** [UV: Coleman & Fuoss *J Am Chem Soc* 77 5472 1955, Overberger et al. *J Polymer Sci* 27 381 1958, Petro & Smyth *J Am Chem Soc* 79 6142 1957.] It is used for alkylating SH groups in peptides [Anderson & Friedman *Can J Biochem* 49 1042 1971, Cawins & Friedman *Anal Biochem* 35 489 1970]. [Beilstein 20 II 170, 20 III/IV 2887, 20/6 V 213.]

**Viologen (4,4'-dipyridyl dihydrochloride)** [27926-72-3] **M 229.1, m 278° (also reported m 302-306°, >300°, with sublimation),  $pK_1^{20}$  3.17,  $pK_2^{20}$  4.82.** Purify viologen by precipitation on adding excess of acetone to a concentrated solution of it in aqueous MeOH. It has also been recrystallised several times from MeOH or *iso*-propanol and dried at 70° under vacuum for 24 hours [Prasad et al. *J Am Chem Soc* 108 5135 1986], and recrystallised three times from MeOH/*isopropanol* [Stramel & Thomas *J Chem Soc, Faraday Trans* 82 799 1986, Michaelis & Hill *J Am Chem Soc* 55 1481 1933, Tilford et al. *J Am Chem Soc* 70 4005 1948]. [Beilstein 23 I 49.]

**Visnagin (4-methoxy-7-methyl-5H-furo[3,2-g][1]benzopyran-5-one)** [82-57-5] **M 230.2, m 142-145°.** Crystallise visnagin from water. It is soluble in  $CHCl_3$  but slightly soluble in EtOH. [Aneja et al. *Tetrahedron* 3 230 1958, Beilstein 19 III/IV 2640.]

**9H-Xanthene (dibenzopyran)** [92-83-1] **M 182.2, m 100.5°, 101-102.5°, b 310-312°/760mm.** Crystallise dibenzopyran from \*benzene, MeOH or EtOH. [Beilstein 17 H 73, 17 I 30, 17 II 72, 17 III/IV 614, 17/2 V 252.]

**Xanthine (2,6-dihydroxypurine, purine-2,6(1H,3H)dione)** [69-89-6] **M 152.1,  $pK_1$  0.8 [protonation of imidazole 7(9)NH],  $pK_2$  7.44 [monoanion 1(3)NH],  $pK_3$  11.12 [dianion 1,3-N<sup>2-</sup>].** The *monohydrate* separates in a microcrystalline form on slow acidification with acetic acid of a solution of xanthine in dilute NaOH. It is also precipitated by addition of conc  $NH_3$  to its solution in hot 2N HCl (charcoal). After washing with  $H_2O$  and EtOH, it is dehydrated by heating above 125°. Its solubility in  $H_2O$  is 1 in 14,000 parts at 16° and 1 in 1,500 parts of boiling  $H_2O$ , and separates as plates. It has no **m**, but the *perchlorate* has **m 262-264°** [Lister *Purines Part II, Fused Pyrimidines* Brown Ed, Wiley-Interscience pp 252-253 1971, ISBN 0-471-38205-1]. [Beilstein 26 H 447, 26 I 131, 26 II 260, 26 III/IV 2327.]

**9-Xanthone (9-xanthenone)** [90-47-1] **M 196.2, m 175.6-175.4°.** Crystallise xanthone from EtOH (25ml/g) and dry it at 100°. It has also been recrystallised from *n*-hexane three times and sublimed *in vacuo*. [Saltiel *J Am Chem Soc* 108 2674 1986]. [Beilstein 17 H 354, 17 I 190, 17 II 378, 17 III/IV 5292, 17/10 V 430.]

**Xanthosine (2H<sub>2</sub>O) [9-(β-D-ribose)purin-2,6(1H,3H)-dione]** [5968-90-1] **M 320.3,  $[\alpha]_D^{20}$  -53° (c 8, 0.3M NaOH),  $pK_1^{25}$  <2.5,  $pK_2^{25}$  5.67,  $pK_3^{25}$  12.85.** It crystallises from EtOH (anhydrous) or water (as dihydrate).

[Howard et al. *J Chem Soc* 232 1949, *Beilstein* 31 H 28, 26 III/IV 2428.]

**Xanthurenic acid (5,8-dihydroxyquinoline-2-carboxylic acid)** [59-00-7] **M 205.2, m 286<sup>o</sup>, 290-295<sup>o</sup>(dec), 297-29<sup>o</sup>(dec), pK<sub>Est(1)</sub>~ 1.5, pK<sub>Est(2)</sub>~ 4.9, pK<sub>Est(3)</sub>~ 9.8.** It is precipitated by the addition of 2N formic acid to its solution in hot 2M ammonia (charcoal). The solid is filtered off, dried in a vacuum at ~80<sup>o</sup> in the dark. Its UV (H<sub>2</sub>O) has  $\lambda_{\max}$  nm ( $\epsilon$  M<sup>-1</sup>cm<sup>-1</sup>) at 243 (30,000) and 342 (6,500). The *methyl ester* has **m 262<sup>o</sup>** (from MeOH). It forms Cu<sup>2+</sup>, Zn<sup>2+</sup>, Fe<sup>2+</sup> and Fe<sup>3+</sup> salts. [*Beilstein* 22 III/IV 2513.]

**Xanthydrol** [90-46-0] **M 198.2, m 122-123<sup>o</sup>, 123-124<sup>o</sup>, 124-126<sup>o</sup>.** Crystallise xanthydrol from EtOH and dry it at 40-50<sup>o</sup>. [*Beilstein* 17 H 129, 17 I 72, 17 II 146, 17 III/IV 1602, 17/4 V 502.]

**Xylenol Orange {3H-2,1-benzoxathiol-3-ylidene-bis-[(6-hydroxy-5-methyl-*m*-phenylene)-methylnitrilo]-tetraacetic acid, S,S-dioxide}** [1611-35-4] **M 672.6, m 210<sup>o</sup>(dec),  $\epsilon_{578}$  6.09 x 10<sup>4</sup> (pH 14),  $\epsilon_{435}$  2.62 x 10<sup>4</sup> (pH 3.1), pK<sub>1</sub> -1.74, pK<sub>2</sub> -1.09 (aqueous H<sub>2</sub>SO<sub>4</sub>-HNO<sub>3</sub>), pK<sub>3</sub> 2.58, pK<sub>4</sub> 3.23, pK<sub>5</sub> 6.46, pK<sub>6</sub> 10.46, pK<sub>7</sub> 12.28.** It is generally contaminated with starting material (cresol red) and semi-xylenol orange. Purify it by ion-exchange chromatography using DEAE-cellulose, eluting with 0.1M NaCl solution, which will give the sodium salt [3618-43-7]. Cresol Red, semi-xylenol orange and iminodiacetic acid bands elute first. This procedure will give the sodium salt of the dye.

To obtain the *free acid*, dissolve the salt in H<sub>2</sub>O and acidify it with AcOH. Filter it off, wash it with H<sub>2</sub>O and dry it first in air and then in a vacuum desiccator over P<sub>2</sub>O<sub>5</sub> in the dark [Sato et al. *Anal Chim Acta* 94 317 1977]. [*Beilstein* 19 II 111, 19 III/IV 1135, 19/3 V 461.]

**$\alpha$ -Yohimbine (17 $\alpha$ -Hydroxy-20 $\alpha$ -yohimban-16 $\alpha$ -carboxylic acid methyl ester, Rauwolscine)** [146-48-5] **M 354.5, m 234<sup>o</sup>, 235-237<sup>o</sup>(dec), 278<sup>o</sup>(dec),  $[\alpha]_D^{20}$  +55.6<sup>o</sup> (c 2, EtOH), +108<sup>o</sup> (pyridine), pK<sub>1</sub><sup>22</sup> 3.0, pK<sub>2</sub><sup>22</sup> 7.45.** Crystallise the *Rauwolfia* alkaloid from EtOH or dilute EtOH (needles), and dry it in a vacuum to remove EtOH of crystallisation. It is soluble in MeOH, CHCl<sub>3</sub>, warm \*C<sub>6</sub>H<sub>6</sub>, moderately soluble in Et<sub>2</sub>O but difficultly soluble in H<sub>2</sub>O. Its has UV (MeOH) with  $\lambda_{\max}$  nm(log $\epsilon$ ) at 226(4.56), 280(3.88) and 291(380). The *hydrochloride* [45-19-0] crystallises in plates or prisms from EtOH with **m 302<sup>o</sup>(dec),  $[\alpha]_D^{20}$  +105<sup>o</sup> (H<sub>2</sub>O).** Its solubility in H<sub>2</sub>O is 83% (giving a neutral solution), and 0.25% in EtOH. [Van Tamelen et al. *J Am Chem Soc* 91 7315 1969, Stork & Guthikonda *J Am Chem Soc* 94 5109 1972, Wenkert et al. *J Am Chem Soc* 100 4894 1978 and *J Am Chem Soc* 101 5370 1982, *Beilstein* 25 II 201, 25 III/IV 1234.], It is pharmacologically active being a 5-HT<sub>1A</sub> serotonin receptor agonist and an  $\alpha_2$ -adrenoceptor antagonist.

For  $\delta$ -yohimbine and  $\gamma$ -yohimbine see ajmalicine [483-04-5] and ajmaline [4360-12-7] above.

## MISCELLANEOUS As, B, P, Si, S, Se and Te COMPOUNDS.

This section contains miscellaneous organic compounds of As, B, P, Si, S, Se, Te, and ammonium and metal salts of their acids, and salts of their bases. See other sections and chapters for further entries of sulfur, phosphorous and silicon compounds; and for sulfur heterocyclic compounds see section on "Heterocyclic Compounds",

**Acetyltriphenylphosphonium chloride** [1235-21-8] **M 354.8, m 237-238°, 244-246°(dec)**. Recrystallise it from  $\text{CHCl}_3$ / $\text{C}_6\text{H}_6$ /petroleum ether (b 60-80°) or by dissolving it in  $\text{CHCl}_3$  and pouring it into dry  $\text{Et}_2\text{O}$ . It has UV(EtOH) with  $\lambda_{\text{max}}$  nm( $\epsilon$ ) at 255(3,600), 262(3,700), 268(4,000) and 275(3,100). The *iodide salt* crystallises from  $\text{H}_2\text{O}$  and has **m** 207-209°. [Ramirez & Dershowitz *J Org Chem* **22** 41 1957.] It is an **IRRITANT** and is *hygroscopic*. When shaken with a 10% aqueous solution of  $\text{Na}_2\text{CO}_3$  (8 hours) it gives *acetylmethylene triphenyl phosphorane* which is recrystallised from  $\text{MeOH}/\text{H}_2\text{O}$ , and after drying at 70°/0.1mm has **m** 205-206°. It has UV with  $\lambda_{\text{max}}$  nm( $\epsilon$ ) at 268 (6600), 275 (6500) and 288 (5700), and its IR has  $\nu_{\text{max}}$  at 1529(s), 1470(m), 1425(s), 1374(m), 1105(s) and 978(s) ( $\text{cm}^{-1}$ ). [Ramirez & Dershowitz *J Org Chem* **22** 41, 44 1957, *Beilstein* **16** H 761, **16** II 373.]

**3R,4R,1'R-4-Acetoxy-3-[1-(tert-butylmethylsilyloxy)ethyl]-2-azetinone** [76855-69-1] **M 287.4, m 107-108°,  $[\alpha]_{\text{D}}^{20} +55^\circ$  (c 0.5, toluene),  $[\alpha]_{\text{D}}^{20} +53.7^\circ$  (c 1.04,  $\text{CHCl}_3$ )**. Purify it by chromatography on silica gel (3 x 14cm) for 50g of ester using 20% EtOAc in *n*-hexane. The eluate is evaporated, and the residue is recrystallised from hexane (white fluffy crystals). [Leanza et al. *Tetrahedron* **39** 2505 1983.]

**N-Acetyl-4-hydroxy-*m*-arsanilic acid (Acetarsol, 3-acetamido-4-hydroxyphenylarsonic acid)** [97-44-9] **M 275.1, m 240-250°,  $\text{pK}_1$  3.73,  $\text{pK}_2$  7.9,  $\text{pK}_3$  9.3**. It crystallises from water in colourless prisms. It decomposes slowly on prolonged boiling in  $\text{H}_2\text{O}$  or dilute alkalis. The *N*-propionyl derivative recrystallises from  $\text{H}_2\text{O}$  with **m** 228-229°(dec). [Raiziss & Fisher *J Am Chem Soc* **48** 1323 1926, Hewitt & King *J Chem Soc* 823 1926, *Beilstein* **16** I 491, **16** II 521, **16** III 1129.]

**Alizarin Red S (3,4-dihydroxy-9,10-dioxo-2-anthracene sulfonic acid, Na salt.  $\text{H}_2\text{O}$ )** [130-22-3] **M 360.4,  $\text{pK}_1^{25} <1$ ,  $\text{pK}_2^{25} 5.49$ ,  $\text{pK}_3^{25} 10.85$  (11.01)**. Commercial samples contain large amounts of sodium and potassium chlorides and sulfates. It is purified by passing through a Sephadex G-10 column (size exclusion column), followed by elution with water, then 50% aqueous EtOH [King & Pruden *Analyst (London)* **93** 601 1968]. Finally dissolve it in EtOH and precipitate it with  $\text{Et}_2\text{O}$  several times [Sacconi *J Phys Chem* **54** 829 1950, polarography: Furnam & Stone *J Am Chem Soc* **70** 3055 1948, *Beilstein* **11** IV 682.]

**Allyl trimethylsilane (2-propenyltrimethylsilane)** [762-72-1] **M 114.3, b 83.0-84.5°, 84-88°, 85.5-86.0°,  $d_4^{20} 0.713$ ,  $n_{\text{D}}^{20} 1.405$** . Fractionate it through an efficient column at atmospheric pressure. If impure, dissolve it in THF, shake it with  $\text{H}_2\text{O}$  (2x), dry ( $\text{Na}_2\text{SO}_4$ ), filter and fractionate it. [Cudlin & Chvalovský *Col Czech Chem Commun* **27** 1658 1962, *Beilstein* **4** IV 3927.]

**Ammonium dodecylsulfate (ammonium laurylsulfate)** [2235-54-3] **M 283.4**. Recrystallise it first from 90% EtOH and then twice from absolute EtOH, and finally dry it in a vacuum. [*Beilstein* **1** III 1786.]

**Ammonium tetraphenylborate** [14637-34-4] **M 337.3, m ca 220°(dec)**. Dissolve it in aqueous  $\text{Me}_2\text{CO}$  and allow crystallisation to proceed slowly; otherwise very small crystals are formed. No trace of  $\text{Me}_2\text{CO}$  is left in the crystals after drying at 120° [Davies & Staveley *Trans Faraday Soc* **53** 19 1957]. Also, the salt can be precipitated from a dilute AcOH solution of sodium tetraphenylborane in the presence of  $\text{NH}_4^+$  ions. After standing for 5 minutes, the precipitate is filtered off onto a sintered porcelain crucible, washed with very dilute AcOH and dried at room temperature for at least 24 hours [Vendlandt *Anal Chem* **28** 1001 1956]. Alternatively, a solution of sodium tetraphenylborane (5% excess) in  $\text{H}_2\text{O}$  is added to  $\text{NH}_4\text{Cl}$  solution. After 5 minutes the precipitate is collected, washed several times with  $\text{H}_2\text{O}$  and recrystallised from aqueous  $\text{Me}_2\text{CO}$ . [Howick & Pflaum *Analyt Chim Acta* **19** 342 1958, *Beilstein* **16** IV 1625.]

**9-Anthraceneboronic acid** [100622-34-2] M 222.0, m 203-250°. Crystallise the boronic acid from dilute HCl (m 180-184°). The *disodium salt* has m 209-213°. [Beilstein 16 IV 1679.]

**Anthraquinone Blue B (Acid Blue 45, 1,5-diamino-4,8-dihydroxy-9,10-anthraquinone-3,7-disulfonic acid di-Na salt)** [2861-02-1] M 474.3, m >300°, CI 63010,  $\lambda_{\max}$  595nm,  $\text{pK}_{\text{Est}(1)} \sim <0$ ,  $\text{pK}_{\text{Est}(2)} \sim 2$ ,  $\text{pK}_{\text{Est}(3)} \sim 9$ . Purify it by salting out an aqueous solution three times with sodium acetate, followed by repeated extraction with EtOH [McGrew & Schneider *J Am Chem Soc* 72 2547 1950, Beilstein 14 H 706, 725].

**Anthraquinone Blue RXO** [4403-89-8] M 445.5. Purify the dye by salting out an aqueous solution three times with sodium acetate, followed by repeated extraction with EtOH [McGrew & Schneider *J Am Chem Soc* 72 2547 1950]. [Beilstein 14 H 706, 725.]

**Anthraquinone Green G [Acid Green 25, Alizarin Cyanine Green F, 1,4-bis-(4-methyl-2-sulfophenyl-1-amino)-9,10-anthraquinone di-Na salt]** [4403-90-1] M 624.6, m 235-238°, CI 61570,  $\lambda_{\max}$  642nm,  $\text{pK}^{25} >0$ . Purify it by salting out three times from an aqueous solution with sodium acetate, followed by repeated extraction with EtOH [McGrew & Schneider *J Am Chem Soc* 72 2547 1950]. It is a green powder that is slightly soluble in  $\text{Me}_2\text{CO}$ , EtOH and pyridine. It is soluble in conc  $\text{H}_2\text{SO}_4$  to give a blue solution that becomes turquoise in colour on dilution. [Allen et al. *J Org Chem* 7 63 1942, Beilstein 14 H 725.]

**9,10-Anthraquinone-2,6-disulfonic acid (disodium salt)** [853-68-9] M 412.3, m >325°,  $\text{pK}_{\text{Est}} \sim <0$  (for  $\text{SO}_3\text{H}$ ). Crystallise it three times from water, in the dark [Moore et al. *J Chem Soc. Faraday Trans 1* 82 745 1986]. [Beilstein 11 IV 673.]

***o*-Arsanilic acid** [2045-00-3] M 216.1, m 153°,  $\text{pK}_1^{22}$  3.77 ( $\text{AsO}_3\text{H}_2$ ),  $\text{pK}_2^{22}$  8.66 ( $\text{AsO}_3\text{H}^-$ ). Crystallise it from water or ethanol/ether. **POISONOUS.** [Beilstein 16 I 463.]

***p*-Arsanilic acid** [98-50-0] M 216.1, m 232°,  $\text{pK}_1^{22}$  4.05 ( $\text{AsO}_3\text{H}_2$ ),  $\text{pK}_2^{22}$  8.66 ( $\text{AsO}_3\text{H}^-$ ). Crystallise it from water or ethanol/ether. **POISONOUS.** [Beilstein 16 I 466.]

**Arsenazo I [3(2-arsonophenylazo)-4,5-dihydroxy-2,7-naphthalenedisulfonic acid di Na salt]** [66019-20-3] M 614.3,  $\epsilon$   $2.6 \times 10^4$  at 500nm, pH 8.0,  $\text{pK}_1$  0.6(0.8),  $\text{pK}_2$  3.52,  $\text{pK}_3$  2.97( $\text{AsO}_3\text{H}_2$ ),  $\text{pK}_4$  8.20( $\text{AsO}_3\text{H}^-$ ),  $\text{pK}_5$  9.98(OH),  $\text{pK}_6$  15.0. A saturated aqueous solution of the free acid is slowly added to an equal volume of conc HCl. The orange precipitate is filtered off, washed with acetonitrile and dried for 1-2 hours at 110° [Fritz & Bradford *Anal Chem* 30 1021 1958]. It is then titrated with NaOH to form the di or tri Na salt as set out below.

**Arsenazo III [3,6-bis(2-arsonophenylazo)-4,5-dihydroxy-2,7-naphthalenedisulfonic acid di Na salt]** [62337-00-2] M 776.4,  $\text{pK}_1$  -2.7,  $\text{pK}_2$  -2.7,  $\text{pK}_3$  0.6,  $\text{pK}_4$  0.8,  $\text{pK}_5$  1.6,  $\text{pK}_6$  3.4,  $\text{pK}_7$  6.27,  $\text{pK}_8$  9.05,  $\text{pK}_9$  11.98,  $\text{pK}_{10}$  15.1. Contaminants include monoazo derivatives, starting materials for synthesis and by-products. It is partially purified by precipitation of the dye from aqueous alkali on addition of HCl. More thorough purification is achieved by taking a 2g sample in 15-25ml of 5% aqueous  $\text{NH}_3$  and filter. Add 10ml HCl (1:1) to the filtrate to precipitate the dye. Repeat the procedure and dissolve the solid dye (0.5g) in 7ml of a 1:1:1 mixture of *n*-propanol/conc  $\text{NH}_3$ /water at 50°. After cooling, filter the solution and chromatograph the filtrate through a cellulose column using a 3:1:1 mixture of *n*-propanol/conc  $\text{NH}_3$ /water as eluent. Collect the blue band and evaporate it to 10-15ml below 80°, then add 10ml of conc HCl to precipitate pure Arsenazo III. Wash it with EtOH and dry it in air [Borak et al. *Talanta* 17 215 1970]. The sodium salt is then obtained by dissolving it in the equivalent amount of dilute NaOH and freeze-drying. The purity of the dye can be checked by paper chromatography using M HCl as eluent. It is used for the estimation of Th, U, Zr, Cd and Zn [Michaylova & Yuroukova *Anal Chim Acta* 68 73 1974.]

**Benzaldehyde-2-sulfonic acid sodium salt** [1008-72-6] M 208.2, m decomposes on heating. It forms prisms or plates by extracting with boiling EtOH, filtering, evaporating to dryness and recrystallising the Na salt from a small volume of  $\text{H}_2\text{O}$ . The *N*-phenylhydrazone sodium salt recrystallises from  $\text{H}_2\text{O}$  with m 174.5°. [Gnehm & Schüle *Justus Liebigs Ann Chem* 299 363 1898, Beilstein 11 IV 652.]

**Benzeneselenenyl bromide (phenylselenenyl bromide)** [34837-55-3] **M 236.0, m 58-62°, 60°, 62°, b 107-108°/15mm, 134°/35mm.** Distil it in a vacuum, recrystallise it from petroleum ether, CHCl<sub>3</sub> (EtOH free), or Et<sub>2</sub>O (cooling mixture) to give dark red or orange crystals. These sublime at 25°/0.001mm [Behaghel et al. *Chem Ber* **65** 815 1932, Pitteloud & Petrzilka *Helv Chim Acta* **62** 1319 1979]. [Beilstein **6** III 1111.] **HIGHLY TOXIC.**

**Benzeneselenenyl chloride (benzeneselenyl chloride, phenylselenenyl chloride)** [5707-04-0] **M 191.5, m 59-60°, 64-65°, b 92°/5mm, 120°/20mm.** Purify it by distillation in a vacuum, and recrystallisation (orange needles) from hexane [Foster *J Am Chem Soc* **55** 822 1933, Foster et al. *Rec Trav Chim Pays Bas* **53** 405, 408 1934, Behaghel & Seibert *Chem Ber* **66** 714 1933]. [Beilstein **6** III 1110.] **HIGHLY TOXIC.**

**Benzeneseleninic acid** [6996-92-5] **M 189.1, m 122-124°, pK<sup>25</sup> 4.70.** Add 10% excess of 15M NH<sub>3</sub> to the solid acid and stir until the solid dissolves, filter, decolorise with charcoal (2x, Norite) and acidify by slow addition of 6M HCl, filter the solid off and wash it with H<sub>2</sub>O. Dissolve the acid in the minimum volume of MeOH, and this solution is added dropwise to boiling H<sub>2</sub>O until cloudiness appears. At this point add 25% more boiling H<sub>2</sub>O, filter hot (decolorise if necessary) and cool rapidly, with scratching, to 0°. After 30 minutes the solid is filtered off and recrystallised as before but with very slow cooling. The colourless needles are filtered off and dried in a vacuum desiccator (CaCl<sub>2</sub>) before the melting point is measured [McCullough & Gould *J Am Chem Soc* **71** 674 1949]. The HNO<sub>3</sub> complex has **m 112°.** [Beilstein **11** H 422, **11** I 110, **11** III 716.]

**Benzeneseleninic anhydride** [17697-12-0] **M 360.1, m 124-126°, 164-165°, 170-173°.** When the anhydride is recrystallised from \*C<sub>6</sub>H<sub>6</sub> it has **m 124-126°**, but when this is heated at 140°/1 hour in a vacuum or at 90°/2 hours it has **m 164-165°** and gives a solid **m 124-126°** when then recrystallised from \*C<sub>6</sub>H<sub>6</sub>. Both depress the melting point of the acid PhSeO<sub>2</sub>H. If the high melting anhydride is dissolved in \*C<sub>6</sub>H<sub>6</sub> and seeded with the high melting anhydride, the high melting anhydride crystallises out. It readily absorbs H<sub>2</sub>O to form the acid (PhSeO<sub>2</sub>H, **m 122-124°**). Because of this, the commercial anhydride could contain up to 30% of the acid. It is best purified by converting to the HNO<sub>3</sub> complex (**m 112°**) and heating this *in vacuo* at 120°/72 hours to give the anhydride as a white powder **m 164-165°.** *Alternatively,* heat the anhydride *in vacuo* at 120°/72 hours until the IR shows no OH band. [Ayvrey et al. *J Chem Soc* 2089 1962, Barton et al. *J Chem Soc, Perkin Trans 1* 567 1977, Beilstein **11** H 422, **11** I 110, **11** III 716, **11** IV 708.] **TOXIC** solid.

**Benzeneselenol (phenylselenol, selenophenol)** [645-96-5] **M 157.1, b 57-59°/8mm, 71-72°/18mm, 84-86°/25mm, d<sub>4</sub><sup>20</sup> 1.480, n<sub>D</sub><sup>20</sup> 1.616.** Dissolve it in aqueous N NaOH, acidify this with conc HCl and extract with Et<sub>2</sub>O, dry over CaCl<sub>2</sub>, filter, evaporate on a steam bath and distil the residue from a Claisen flask or through a short column collecting the middle fraction, and seal immediately in a glass vial, otherwise the colourless liquid becomes yellow. The alkali insoluble materials consist of diphenylselenide (**b 167°/16mm**) and diphenyldiselenide, **m 63°** (from EtOH). **TOXIC**, use rubber gloves. It has a foul odour. [Foster *Org Synth Coll Vol III* 771 1955, Beilstein **6** III 1104, 1110, **6** IV 1777.]

**Benzeneselenonic acid (benzeneselenoic acid)** [39254-48-3] **M 205.1, m 64°, pK<sup>25</sup> 4.79.** Purify it by dissolving in H<sub>2</sub>O and passing through a strong cation exchange resin (H<sup>+</sup> form). Evaporate the effluent under reduced pressure and dry the residue in a high vacuum to give colourless hygroscopic crystals [Dostal et al. *Z Chem* **6** 153 1966 and IR: Dostál et al. *Chem Ber* **104** 2044 1971]. [Beilstein **11** H 422, **11** I 111.]

**Benzenestibonic acid** [535-46-6] **M 248.9, m >285°(dec).** It crystallises from acetic acid (needles), or from EtOH/CHCl<sub>3</sub> mixture on addition of water. [Schmidt *Justus Liebigs Ann Chem* **542** 288 1939, May *J Chem Soc* **101** 1033 1912.]

**Benzopurpurin 4B** {3,3'-(3,3'-dimethyl[1,1'-biphenyl]-4,4'-diyl)bis(azo)]bis[4-amino-1-naphthalene-

sulfonic acid] di-Na salt, Direct red 2} [992-59-6] M 724.7,  $\lambda_{\max}$  500nm, CI 23500,  $\text{pK}^{25} < 0$ . It crystallises from  $\text{H}_2\text{O}$ . It is a biological stain that is violet at pH 1.2 and red at pH 4.0 and is used for detecting Al, Mg, Hg, Au and U. [Beilstein 16 H 411, 16 II 224, 16 III 474, 16 IV 601.]

**Benzotriazol-1-yloxytris(dimethylamino)phosphonium hexafluorophosphate (BOP, Castro's Reagent)** [56602-33-6] M 442.29,  $m > 130^\circ(\text{dec})$ , 147-149 $^\circ(\text{dec})$ . Dissolve it in  $\text{CH}_2\text{Cl}_2$ , dry ( $\text{MgSO}_4$ ), filter, concentrate it under a vacuum, then add dry  $\text{Et}_2\text{O}$  and filter off the first crop. Add  $\text{CH}_2\text{Cl}_2$  to the filtrate and concentrate again to obtain a second crop. The solid is washed with dry  $\text{Et}_2\text{O}$  and dried in a vacuum. Also recrystallise it from dry  $\text{Me}_2\text{CO}/\text{Et}_2\text{O}$  and check the purity by NMR. Store it in the dark. [Castro et al. *Synthesis* 751 1976, Nguyen et al *J Chem Soc, Perkin Trans I* 1915 1987, Coste et al. *Tetrahedron Lett* 36 4253 1995.]

**Benzyl Orange [4-(4-benzylaminophenylazo)benzenesulfonic acid potassium salt]** [589-02-6] M 405.5,  $\text{pK}_{\text{Est}(1)} \sim < 0$ ,  $\text{pK}_{\text{Est}(2)} \sim 3.8$ . Crystallise it from  $\text{H}_2\text{O}$ .

**Benzyltriphenylphosphonium chloride** [1100-88-5] M 388.9,  $m 280^\circ$  (sintering), 287-288 $^\circ$ . Wash it with  $\text{Et}_2\text{O}$  and crystallise it from  $\text{EtOH}$  (six-sided plates). It is *hygroscopic* and forms crystals with one molecule of  $\text{H}_2\text{O}$ . [Michaelis & Soden *Justus Liebigs Ann Chem* 229 320 1885, Kröhnke *Chem Ber* 83 291 1950, Beilstein 16 IV 994.]

**Biphenyl-2-yl diphenyl phosphate** [132-29-6] M 302.4,  $b 280-290^\circ/9\text{mm}$ ,  $d_{25}^{25} 1.184$ ,  $n_D^{25} 1.5925$ . Distil the ester in a vacuum, then percolate it through an alumina column. Pass the ester through a packed column maintained at  $150^\circ$  to remove residual traces of volatile materials by a counter-current stream of nitrogen at reduced pressure. [Dobry & Keller *J Phys Chem* 61 1448 1957, Beilstein 6 III 3295, 6 IV 4585.]

**Bis(*p*-tert-butylphenyl)phenyl phosphate** [115-87-7] M 438.5,  $b 281^\circ/5.5\text{mm}$ ,  $d_4^{25} 1.108$ ,  $n_D^{25} 1.5412$ . Purify as for biphenyl-2-yl diphenyl phosphate (above). [Beilstein 6 III 1871, 6 IV 3310.]

**Bis(2-chlorophenyl) phenyl phosphate** [597-80-8] M 395,  $b 254^\circ/4\text{mm}$ ,  $n_D^{25} 1.5767$ . Purify as for biphenyl-2-yl diphenyl phosphate above. [Fox et al. *J Phys Chem* 59 1097 1955, Beilstein 6 III 680, 6 IV 807.]

**Bis(2-ethylhexyl) 2-ethylhexyl phosphonate** [25103-23-5] M 434.6,  $n_D^{25} 1.4473$ . Purify it by stirring a 0.4M solution in \*benzene with an equal volume of 6M  $\text{HCl}$  at *ca*  $60^\circ$  for 8 hours. The \*benzene layer is then shaken successively with equal volumes of water (twice), aqueous 5%  $\text{Na}_2\text{CO}_3$  (three times), and water (eight times), followed by evaporation of the \*benzene and distillation of the residue under reduced pressure at room temperature (using a rotating evacuated flask). It should be stored dry and in the dark [Peppard et al. *J Inorg Nucl Chem* 24 1387 1962]. Distil it in a vacuum, then percolate it through an alumina column before finally passing it through a packed column maintained at  $150^\circ$  where residual traces of volatile materials are removed by a counter-current stream of  $\text{N}_2$  under reduced pressure [Dobry & Keller *J Phys Chem* 61 1448 1957].

**Bis(2-ethylhexyl) phosphoric acid ('diisooctyl' phosphate)** [298-07-7, 27215-10-7] M 322.4,  $m -60^\circ$ ,  $b 209^\circ/10\text{mm}$ ,  $d_4^{20} 0.965$ ,  $\text{pK}_{\text{Est}} \sim 1.7$ . Contaminants of commercial samples include the monoester, polyphosphates, pyrophosphate, 2-ethylhexanol and metal impurities. Dissolve the acid in *n*-hexane to give an 0.8M solution. Wash this with an equal volume of M  $\text{HNO}_3$ , then with saturated  $(\text{NH}_4)_2\text{CO}_3$  solution, with 3M  $\text{HNO}_3$ , and twice with water [Petrow & Allen *Anal Chem* 33 1303 1961]. Similarly, the impure sodium salt, after scrubbing with petroleum ether, is acidified with  $\text{HCl}$  and the free organic acid is extracted into petroleum ether and purified as above [Peppard et al. *J Inorg Nucl Chem* 7 231 1958], or as described by Stewart & Crandall [*J Am Chem Soc* 73 1377 1951]. It can be purified *via* its copper salt [McDowell et al. *J Inorg Nucl Chem* 38 2127 1976]. [Beilstein 1 IV 1796.]

**2,4-Bis(methylthio)-1,3,2 $\lambda^5$ ,4 $\lambda^5$ -dithiadiphosphetane-2,4-dithione (Davy's reagent methyl)** [82737-61-9] M 284.4,  $m 160^\circ$ . It crystallises from \* $\text{C}_6\text{H}_6$  in yellow plates or from hot trichlorobenzene. The low melting point reported in the literature ( $112^\circ$  with gradual softening at  $68-102^\circ$ ) has been attributed to the presence of elemental sulfur in the crystals. It has a **foul odour** and is a *suspected carcinogen*. [Yousif et al. *Tetrahedron*

40 2663 1984, Scott et al. *J Org Chem* 22 789 1957.]

**Bismuthiol I (2,5-dimercapto-1,3,4-thiadiazole) potassium salt** [4628-94-8] **M 226.4, m 275-276°(dec), ~294°(dec), pK<sub>Est(1)</sub>~4.1.** Usually contaminated with disulfide. Purify it by recrystallisation from EtOH. It is a reagent for the detection of Bi, Cu, Pb and Sb. [Najumdar & Chacraborty *Anal Chim Acta* 19 372 1958, Fries *Z Anal Chem* 165 100, 1959, Beilstein 27 IV 7725.]

**Bis[4-(1,1,3,3-tetramethylbutyl)phenyl]phosphate calcium salt (Selectophore)** [40835-97-0] **M 987.3.** The Ca diester salt is washed with H<sub>2</sub>O (x3) and MeOH (x3) alternately and dried in a vacuum oven at 50°. If the Ca salt is contaminated with much Ca salt of the monoester, then it (10g) is converted to the free acid by adding 6N HCl (*ca* 10 volumes) and Et<sub>2</sub>O (> 50 volumes) is added to it and stirred vigorously to form the free acids. When no white precipitate remains (*ca* 5 minutes), the Et<sub>2</sub>O is separated, washed with H<sub>2</sub>O (2 >50 ml) and dried by filtering through a bed of anhydrous Na<sub>2</sub>SO<sub>4</sub> (11 x 5 cm) which is then washed with Et<sub>2</sub>O (2 >50 ml). Evaporation gives an oil (TLC R<sub>F</sub> 0.81 for diester and 0.50 for monoester). The oil is dissolved in \*benzene (*ca* 25ml) and extracted with ethane-1,2-diol (25ml, 10x). After ten washings, a small sample of the \*benzene layer is washed twice with H<sub>2</sub>O to remove the diol and showed that it is pure *bis*-[4-(1,1,3,3-tetramethylbutyl)-phenyl]phosphoric acid by TLC, i.e. no monophosphate. To form the Ca salt, the oil is dissolved in MeOH and to it is added the equivalent amount of CaCl<sub>2</sub> together with aqueous NaOH to keep the pH >10. The resulting white precipitate is collected, washed alternately with 3 batches of H<sub>2</sub>O and MeOH and dried in a vacuum oven at 50°. [Craggs et al. *J Inorg Nucl Chem* 40 1483 1978, Morton & Chung *Anal Biochem* 157 345 1986.]

**2,4-Bis(*p*-tolylthio)-1,3,2λ<sup>5</sup>,4λ<sup>5</sup>-dithiadiphosphetane-2,4-dithione (Heimgartner's reagent or Davy's reagent *p*-tolyl)** [114234-09-2] **M 436.6, m 175-176°.** Recrystallise it from toluene (light yellow solid), wash it with Et<sub>2</sub>O and dry *in vacuo*. [Jennt & Heimgartner *Helv Chim Acta* 70 1001 1987.]

***N,O*-Bis(trimethylsilyl)acetamide (BSA)** [10416-59-8] **M 203.4, b 71-73°/35mm, d<sub>4</sub><sup>20</sup> 0.836, n<sub>D</sub><sup>20</sup> 1.4150.** Fractionate it through a spinning band column and collect liquid **b** 71-73°/35mm, and not higher because the main impurity MeCONHSiMe<sub>3</sub> distils at **b** 105-107°/35mm. It is used for derivatising alcohols and sugars [Klebe et al. *J Am Chem Soc* 88 3390 1966, see Matsuo et al. *Carbohydr Res* 241 209 1993, Johnson *Carbohydr Res* 237 313 1992]. It is **FLAMMABLE** and **TOXIC**.

**Bis(trimethylsilyl)acetylene (BTMSA)** [14630-40-1] **M 170.4, m 26°, b 134-136°/atm.** Dissolve it in petroleum ether and wash it with ice-cold dilute HCl. The petroleum ether extract is dried (MgSO<sub>4</sub>), evaporated and fractionated at 760mm. [Walton & Waugh *J Organomet Chem* 37 45 1972, Beilstein 4 IV 3950.]

**Bis(trimethylsilyl) sulfide (hexamethyldisilathiane)** [3385-94-2] **M 178.5, b 65-67°/16mm, 162.5-163.5°/750mm, 164°/760mm, d<sub>4</sub><sup>20</sup> 0.85, n<sub>D</sub><sup>20</sup> 1.4598.** Dissolve it in petroleum ether (*b ca* 40°), remove the solvent and distil it. Redistil it under atmospheric pressure of dry N<sub>2</sub>. It is collected as a colourless liquid which solidifies to a white solid in Dry-ice. On standing for several days it turns yellow possibly due to liberation of sulfur. Store it below 4° under dry N<sub>2</sub>. [Eaborn *J Chem Soc* 3077 1950, Beilstein 4 IV 4033.]

**9-Borabicyclo[3.3.1]nonane (9BBN)** [*monomer* 280-64-8] [*dimer* 21205-91-4 or 70658-61-6] [*1:1 coordination compound with tetrahydrofuran* 76422-63-4] **M 122.0 (monomer), 244.0 (dimer), m 141-143° (monomer), 150-152°, 154-155° (dimer), b 195°/12mm.** It is available as the solid dimer or in tetrahydrofuran solution. The solid is relatively stable and can be purified by distillation in a vacuum (as dimer) and by recrystallisation from tetrahydrofuran (solubility at room temperature is 9.5%, 0.78M), filter off the solid under N<sub>2</sub>, wash it with dry pentane and dry it *in vacuo* at *ca* 100°. The solid is a dimer (IR 1567cm<sup>-1</sup>), stable in air (for *ca* 2 months), and can be heated for 24 hours at 200° in an inert atmosphere without loss of hydride activity. It is a dimer in tetrahydrofuran solution also (IR 1567cm<sup>-1</sup>). It is sensitive to H<sub>2</sub>O and air (O<sub>2</sub>) in solution. Its concentration in solution can be determined by reaction with MeOH and measuring the volume of H<sub>2</sub> liberated, or it can be oxidised to *cis*-cyclooctane-1,5-diol (**m** 73.5-74.5°). [IR: Knights & Brown *J Am Chem Soc* 90 5280 1968, Brown et al. *J Am Chem Soc* 96 7765 1974, Brown et al. *J Org Chem* 41 1778 1976, Brown & Chen *J Org*

*Chem* **46** 3978 1981, Fieser & Fieser's *Reagents for Org Synth* **2** 31, **3** 24, **10** 48, **15** 43, **17**, 49.]

**Borane pyridine complex** [110-51-0] **M 92.9, m 8-10°, 10-11°, b 86°/7mm, 100-101°/12mm,  $d_4^{20}$  0.785.** Dissolve it in Et<sub>2</sub>O and wash it with H<sub>2</sub>O in which it is insoluble. Evaporate the Et<sub>2</sub>O and distil the residual oil to gives better than 99.8% purity. Its vapour pressure is less than 0.1mm at room temperature. [Taylor et al. *J Am Chem Soc* **77** 1506 1955, *Beilstein* **20** IV 2235.]

**Borane triethylamine complex** [1722-26-5] **M 115.0, b 76°/4mm, 8°/7mm, 100-101°/12mm,  $d_4^{20}$  0.78.** Distil it in a vacuum using a 60cm glass helices-packed column. [Brown et al. *J Am Chem Soc* **64** 325 1942, Ashby & Foster *J Am Chem Soc* **84** 3407 1962, Matsuura & Tolcura *Tetrahedron Lett* 4703 1968, *Beilstein* **4** IV 329.]

**Borane trimethylamine complex** [75-22-9] **M 73.0, m 94-94.5°, b 171°/atm.** It is sublimed using equipment described in Burg and Schlesinger [*J Am Chem Soc* **59** 780 1937]. Its vapour pressure is 86mm at 100°. It forms colourless hexagonal crystals varying from needles to short lumps, which are slightly soluble in H<sub>2</sub>O (1.48% at 30°), EtOH (1%), hexane (0.74%), but very soluble in Et<sub>2</sub>O, \*C<sub>6</sub>H<sub>6</sub> and AcOH. It is stable at 125°. [Burg & Schlesinger *J Am Chem Soc* **59** 780 1937, Brown et al. *J Am Chem Soc* **104** 325 1942, *Beilstein* **4** IV 140.]

**2-Bromoallyltrimethylsilane** [81790-10-5] **M 193.2, b 64-66°/10mm, 82-85°/58-60mm,  $d_4^{25}$  1.13.** It is fractionally distilled through an efficient column. It is **flammable**. [Trost & Chan *J Am Chem Soc* **104** 3733 1982, Trost & Coppola *J Am Chem Soc* **104** 6879 1982.]

**2-Bromo-1,3,2-benzodioxaborole** [51901-85-0] **M 198.8, m 47°, 51-53°, b 76°/9mm.** Keep at 20°/15mm for some time and then fractionally distil. [Gerrard *J Chem Soc* 1529 1959, *Beilstein* **6** IV 5612.]

**IR(endo, anti)-3-Bromocamphor-8-sulfonic acid ammonium salt** [55870-50-3] **M 328.2, m 284-285°(dec),  $[\alpha]_D^{25} +84.8^\circ$  (c 4, H<sub>2</sub>O).** Pass a hot aqueous solution of it through an alumina column to remove water-soluble coloured impurities which remain on the column when the ammonium salt is eluted with hot water. The salt is crystallised from water and is dried over CaCl<sub>2</sub> in a desiccator [Craddock & Jones *J Am Chem Soc* **84** 1098 1962, Kauffmann *J Prakt Chem* **33** 295 1966]. [*Beilstein* **11** H 319, **11** I 77, **11**, II 183, **11** III 595.]

**Bromopyrogallol Red.** See in "Aromatic Compounds", in this Chapter.

**Bromosulfalein (phenoltetrabromophthalein 3',3'-disulfonic acid disodium salt)** [71-67-0] **M 838.0.** Purify it by TLC on silica Gel G (Merck 250 $\mu$  particle size) in two solvent systems (BuOH/AcOH/H<sub>2</sub>O 30:7.5:12.5 v/v, and BuOH/propionic acid/H<sub>2</sub>O 30:20:7.5 v/v). When the solvent reaches a height of ~10cm, the plate is removed, dried in air and developed with NH<sub>3</sub> vapour giving blue-coloured spots. Also, the dye can be chromatographed on MN Silica Gel with *t*-BuOH/H<sub>2</sub>O/*n*-BuOH (32:10:5 v/v) as eluent and visualised with a dilute KOH (or NaOH if the Na salt is required) spray. The product corresponding to bromosulfalein is scraped off and eluted with H<sub>2</sub>O, filtered and evaporated to dryness in a vacuum. It is then dissolved in H<sub>2</sub>O, filtered through Sephadex G-25 and evaporated to dryness. [UV and IR identification: Barbier & DeVeerd *J Pharm Sci* **57** 819 1968, NMR: Kato et al. *Chem Pharm Bull Jpn* **20** 581 1972, McGuire *Anal Biochem* **83** 75 1977, *Beilstein* **18/9** V 461.]

**Bromotrimethylsilane (trimethylbromosilane, trimethylsilyl bromide)** [2857-97-8] **M 153.1, m -43.5° to -43.2°, b 40.5°/200mm, 77.3°/735mm, 79°/744mm, 79.8-79.9°/754mm,  $d_4^{20}$  1.1805,  $n_D^{20}$  1.422.** Purify it by repeated fractional distillation and store it in sealed ampoules in the dark. [McCusker & Reilly *J Am Chem Soc* **75** 1583 1953.] Also fractionate it through a 15-plate column (0.8 x 32cm packed with 1/16in single turn helices of Pt-Ir wire). [Gilliam et al. *J Am Chem Soc* **68** 1161 1946, Pray et al. *J Am Chem Soc* **70** 433 1948, *Beilstein* **4** IV 4008.]

**But-3-enylboronic acid** [379669-72-4] **M 99.9, m 84-90°, pK<sub>Est</sub> 8.8.** Recrystallise the acid from toluene and dry it *in vacuo*. [*cf* Letsinger & Skoog *J Org Chem* **18** 895 1953.]

**Butylboronic acid (1-butanedihydroxyborane)** [4426-47-5] M 101.9, m 90-92°, 94-96°, pK<sub>Est</sub> ~8.8. Purify the acid by recrystallisation from \*C<sub>6</sub>H<sub>6</sub>/petroleum ether and dry it *in vacuo*. [Corey et al. *J Am Chem Soc* **116** 3151 1994, Quallich et al. *J Am Chem Soc* **116** 8515 1994, Seerden *Tetrahedron Lett* **35** 4419 1994, *Beilstein* **4** IV 4383.]

**(±)-sec-Butylboronic acid ([sec-butyl]-dihydroxyborane)** [88496-88-2] M 101.9, m 86-89°, 87-88°, pK<sub>Est</sub> ~8.8. Purify the acid by recrystallisation from \*C<sub>6</sub>H<sub>6</sub>/petroleum ether and dry *in vacuo*. [McCusker et al. *J Am Chem Soc* **79** 5179 1957, *Beilstein* **4** IV 4386.]

**tert-Butyldicyclohexylphosphine (dicyclohexyl-tert-butylphosphine, Cy<sub>2</sub>P<sup>t</sup>Bu)** [93634-87-8] M 254.4, m ~22-25°, d<sub>4</sub><sup>25</sup> 1.094, pK<sub>Est</sub> ~8.7. This phosphine was prepared by adding *t*-BuLi (18ml, 27.2mmol, 1.5M in pentane) dropwise to a solution of chloro-dicyclohexylphosphine (5.75g, 24.7mmol, [16523-54-9] see above) in THF (20ml) at -78° and the yellow suspension was allowed to warm to ~25° and stirred overnight. The mixture was evaporated to dryness, extracted with pentane (2 x 20ml), filtered through Celite, concentrated to 20ml, cooled to -78° and after 2 hours the Cy<sub>2</sub>P<sup>t</sup>Bu crystallised in white crystals (5.6g, 89%) which were filtered off and washed with cold pentane under N<sub>2</sub> or Ar. It is highly air sensitive, flammable and should be stored under N<sub>2</sub> or Ar. It melts at room temperature. The <sup>1</sup>H NMR (CDCl<sub>3</sub>) has peaks at δ: 1.90-1.05 (m, 22H, C<sub>6</sub>H<sub>11</sub>), 1.10 (d, 9H, C(CH<sub>3</sub>)<sub>3</sub>, <sup>3</sup>J<sub>H-P</sub> = 10.8Hz); the <sup>13</sup>C NMR (CDCl<sub>3</sub>) has peaks at δ: 33.11 (d, CMe<sub>3</sub>, <sup>1</sup>J<sub>C-P</sub> = 19.4Hz), 33.61 (d, C<sub>1</sub> C<sub>6</sub>H<sub>11</sub>, <sup>1</sup>J<sub>C-P</sub> = 16.2Hz), 30.96, 27.82 (2d, C<sub>2</sub> C<sub>6</sub>H<sub>11</sub>, <sup>2</sup>J<sub>C-P</sub> = 9.7Hz), 30.33 (d, CH<sub>3</sub>)<sub>3</sub>, <sup>2</sup>J<sub>C-P</sub> = 13.2Hz), 27.69, 27.61 (2s, C<sub>3</sub> C<sub>6</sub>H<sub>11</sub>), 26.41 (s, C<sub>4</sub> C<sub>6</sub>H<sub>11</sub>); and <sup>31</sup>P NMR (CDCl<sub>3</sub>) has a peak at δ 28.58. [Jan et al. *J Organomet Chem* **55** 606 2000.]

**tert-Butyldimethylsilyl chloride (TBDMSCl)** [18162-48-6] M 150.7, m 87-89°, 92.5°, b 125°/760mm. Fractionally distil it at atmospheric pressure. [Sommer & Tyler *J Am Chem Soc* **76** 1030 1954, Corey & Venkateswarlu *J Am Chem Soc* **94** 6190 1972, *Beilstein* **4** IV 4076.]

**tert-Butyldiphenylchlorosilane (TBDPSCl, tert-butylchlorodiphenylsilane)** [58479-61-1] M 274.9, b 90°/0.015mm, d<sub>4</sub><sup>20</sup> 1.057, n<sub>D</sub><sup>20</sup> 1.568. Purify it by repeated fractional distillation. It is soluble in DMF and pentane [Hanessian & Lavalee *Can J Chem* **53** 2975 1975, Robl et al. *J Med Chem* **34** 2804 1991]. [*Beilstein* **4** IV 4076 for *tert-butylchlorodimethylsilane*.]

***n*-Butylphenyl *n*-butylphosphonate** [36411-99-1] M 270.3. Crystallise it three times from hexane as its compound with uranyl nitrate. See *tri-n-butyl phosphate* below.

***p*-tert-Butylphenyl diphenyl phosphate** [981-40-8] M 382.4, b 261°/6mm, n<sub>D</sub><sup>25</sup> 1.5522. Purify it by vacuum distillation, and percolation through an alumina column, followed by passage through a packed column maintained at 150° to remove residual traces of volatile materials in a counter-current stream of N<sub>2</sub> at reduced pressure [Dobry & Keller *J Phys Chem* **61** 1448 1957].

**Cacodylic acid (dimethylarsinic acid)** [75-60-5] M 138.0, m 195-196°, pK<sub>1</sub><sup>25</sup> 1.57, pK<sub>2</sub><sup>25</sup> 6.27 [Me<sub>2</sub>As(O)OH]. Recrystallise it from warm EtOH (3ml/g) by cooling and filtering. Dry it in a vacuum desiccator over CaCl<sub>2</sub>. It has also been recrystallised twice from propan-2-ol. [Kilpatrick *J Am Chem Soc* **71** 2608 1949, Nichol *J Am Chem Soc* **72** 2367 1950, Koller & Hawkrigde *J Am Chem Soc* **107** 7412 1985, *Beilstein* **4** H 610, **4** I 567, **4** II 993, **4** III 1818, **4** IV 3681.]

**Cadion [1-(4-nitrophenyl)-3-(4-phenylazophenyl)-triazene]** [5392-67-6] M 346, m 189°(dec). Commercial cadion is purified by recrystallisation from 95% EtOH and is dried *in vacuo*. It is stable in 0.2 N KOH (in 20% aqueous EtOH) at 25°. It is a sensitive reagent for Cd, and the Cd complex has λ<sub>max</sub> (EtOH) 475nm. [Chavanne & Geronimi *Anal Chim Acta* **19** 377 1958, *Beilstein* **16** III 664.]

**(4-Carbamylphenylarsylenedithio)diacetic acid** [531-72-6] M 345.1, pK<sub>Est</sub> ~3.5. Recrystallise it from MeOH or EtOH.

**Catecholborane (1,3,2-Benzodioxaborole)** [274-07-7] M 119.2, b 50°/50mm, 66°/80mm, 76-77°/100mm, 88°/165mm,  $d_4^{20}$  1.125,  $n_D^{20}$  1.507 (also available as a 1.0M solution in THF or toluene). It is a moisture-sensitive flammable liquid which is purified by distillation in a vacuum under a N<sub>2</sub> atmosphere and stored under N<sub>2</sub> at 0-4°. It liberates H<sub>2</sub> when added to H<sub>2</sub>O or MeOH. A solution in THF, after 25 hours at 25°, has residual hydride of 95% (under N<sub>2</sub>) and 80% (under air) [Brown & Gupta *J Am Chem Soc* 97 5249 1975].

**Chloramine-T (N-chloro-p-toluenesulfonamide sodium salt) 3H<sub>2</sub>O** [7080-50-4] M 281.7, m 168-170°(dec). Recrystallise it from hot water (2ml/g). Dry it in a desiccator over CaCl<sub>2</sub> where it loses water. Protect it from sunlight. It is used for the detection of bromate and halogens, and Co, Cr, Fe, Hg, Mn, Ni and Sb ions. [Campbell & Johnson *Chem Rev* 78 65 1978, Bremner *Synthetic Reagents* 6 9 1985, Chattaway *J Chem Soc* 87 145 11905, Inglis *J Soc Chem Ind (Lond)* 37 288 1918, *Beilstein* 11 H 107, 11 I 29, 11 II 62, 11 III 300, 2 IV 457.]

**Chlorazol Sky Blue FF {6,6'-[(3,3'-dimethoxy[1,1'-biphenyl]-4,4'-diyl)bis(azo)bis(4-amino-5-hydroxy-1,3-naphthylenedisulfonic acid) tetra-Na salt** [2610-05-1] M 996.9, m >300°(dec). Free it from other electrolytes by adding aqueous sodium acetate to a boiling solution of the dye in distilled water. After standing, the salted-out dye is filtered on a Büchner funnel, the process being repeated several times. Finally, the precipitated dye is boiled several times with absolute EtOH to wash out any sodium acetate, then dried (as the sodium salt) at 105°. [McGregor et al. *Trans Faraday Soc* 58 1045 1962, *Beilstein* 16 II 259.]

**Chlorodicyclohexylphosphine [Cy<sub>2</sub>PCI]** [16523-54-9] M 232.7, b 132-138°/3mm, 165°/12mm, 173-174°/17mm, 182-183°/23mm,  $d_4^{25}$  1.054,  $n_D^{20}$  1.533. Cy<sub>2</sub>PCI can be obtained as a colourless oil from cyclohexyldichloro-phosphine and cyclohexylmagnesium chloride, also from dicyclohexyldiethylamino-phosphine and HCl in the presence of NH<sub>4</sub>Cl in petroleum ether (b 70-90°) followed by fractional distillation. Alternatively, reaction of cyclohexylmagnesium chloride (from 12.6g of Mg and 62g of cyclohexyl chloride) in Et<sub>2</sub>O (250ml) and PCl<sub>3</sub> (35g) in Et<sub>2</sub>O (300ml) under N<sub>2</sub> followed by fractional distillation gives (22g, 37.2%) of Cy<sub>2</sub>PCI. [Issleib & Seidel *Chem Ber* 92 2681 1959, *Beilstein* 16 IV 968.]

**Chlorodiphenylphosphine (diphenylphosphinous chloride)** [1079-66-9] M 220.6, m 15-16°, b 124-126°/0.6mm, 174°/5mm, 320°/atm,  $d_4^{20}$  1.229,  $n_D^{20}$  1.636. This air-sensitive, pale yellow lachrymatory liquid is purified by careful fractional distillation and discarding the lower boiling fraction which contains the main impurity PhPCl<sub>2</sub> (b 48-51°/0.7mm), and checking for impurities by NMR. [Weinberg *J Org Chem* 40 3586 1975, Honer et al. *Chem Ber* 94 2122 1961, *Beilstein* 16 IV 969.]

**Chlorodi(o-tolyl)phosphine** [36042-94-1] M 248.7, m 36-37°, b 120-122°/0.03mm, 146-147°/1.1mm. It is purified by fractional distillation in a vacuum (b 179-183°/7mm, 253-257°/15mm) and the distillate solidifies (m 36°, also reported is m 37°). [Weinberg *J Org Chem* 40 3586 1975, McEwen et al. *J Am Chem Soc* 100 7304 1978, *Beilstein* 16 H 769, 16 IV 970 for chlorodi(p-tolyl)phosphine.]

**(Chloromethyl)dimethylvinylsilane** [16709-86-7] M 134.7, b 122-126°/atm,  $d_4^{25}$  0.908,  $n_D^{20}$  1.440. Distil the silane in a vacuum, but if it is suspect then dissolve it in Et<sub>2</sub>O, shake it with saturated aqueous NH<sub>4</sub>Cl, dry the Et<sub>2</sub>O layer (anhydrous Na<sub>2</sub>SO<sub>4</sub>), filter evaporate and fractionate in a vacuum. [Altamura et al. *J Org Chem* 60 8403 1995.]

**Chloromethylphosphonic acid dichloride** [1983-26-2] M 167.4, b 50°/0.5mm, 52-53(59)°/2mm, 63-65°/3mm, 78-79°/10mm, 87-88°/15mm, 102-103°/30mm,  $d_4^{20}$  1.638,  $n_D^{20}$  1.4971. It is fractionally distilled using a short Claisen column and redistilled. The aniline salt has m 199-201°. The <sup>31</sup>P NMR has a single peak at -38±2 ppm from 85% H<sub>3</sub>PO<sub>4</sub>. [Kinnear & Perren *J Chem Soc* 3437 1952, NMR: van Wazer et al. *J Am Chem Soc* 78 5715 1956, McConnell et al. *J Org Chem* 22 462 1957, *Beilstein* 1 III 2593, 1 IV 3068.]

**2-Chloro-2-oxo-1,3,2-dioxaphospholane** [6609-64-9] M 142.5, m 12-14°, b 89-91°/0.8mm,  $d_4^{20}$  1.549,  $n_D^{20}$

**1.448.** It should be distilled under high vacuum as some polymerisation occurs at atmospheric pressure. It has IR bands at 3012, 2933, 1477, 1366, 1325, 1040, 924 and 858  $\text{cm}^{-1}$ . It is hydrolysed to  $\text{HOCH}_2\text{CH}_2\text{OPO}_3\text{H}_2$  in 30 minutes in  $\text{H}_2\text{O}$  at  $100^\circ$  [IR: Cox & Westheimer *J Am Chem Soc* **80** 5441 1958]. [Beilstein **1** IV 2419.]

**2-Chlorophenyl diphenyl phosphate** [115-85-5] **M 360.7, b 236<sup>o</sup>/4mm, n<sub>D</sub><sup>25</sup> 1.5707.** Purify it by vacuum distillation, percolate it through a column of alumina, then pass it through a packed column maintained by a countercurrent stream of  $\text{N}_2$  at reduced pressure [Dobry & Keller *J Phys Chem* **61** 1448 1957].

**Chlorosulfonic (chlorosulfuric) acid** [7790-94-5] **M 116.5, b 151-152<sup>o</sup>/750mm, d<sub>4</sub><sup>20</sup> 1.753, n<sub>D</sub><sup>25</sup> 1.4929, pK<sup>25</sup> -5.9 (aqueous  $\text{H}_2\text{SO}_4$ ).** Distil it in an all-glass apparatus, taking the fraction boiling at 156-158<sup>o</sup>. It reacts **EXPLOSIVELY** with water [Cremlyn *Chlorosulfonic acid: A Versatile Reagent*, Royal Society of Chemistry UK, 2002, 308 pp, ISBN 0854044981]. **LACHRYMATORY and CORROSIVE, wear gloves and face shield.**

**Chlorotriphenylsilane (triphenylchlorosilane)** [76-86-8] **M 294.9, m 90-92<sup>o</sup>, 91-93<sup>o</sup>, 94-95<sup>o</sup>, 97-99<sup>o</sup>, b 156<sup>o</sup>/1mm, 161<sup>o</sup>/0.6mm.** Likely impurities are tetraphenylsilane, small amounts of hexaphenyldisiloxane and traces of triphenylsilanol. Purify it by distillation at 2mm, then crystallise it from EtOH-free  $\text{CHCl}_3$ , and from petroleum ether (b 30-60<sup>o</sup>) or hexane by cooling in a Dry-ice/acetone bath. [Allen & Modena *J Chem Soc* 3671 1957, Curran et al. *J Am Chem Soc* **72** 4471 1950, Speier & Zimmerman *J Am Chem Soc* **77** 6395 1955, Thomas & Rochow *J Am Chem Soc* **79** 1843 1957, Beilstein **16** IV 1484.]

**Chromazurol S (Mordant Blue 29)** [1667-99-8] **M 539.3,  $\lambda_{\text{max}}$  540nm,  $\epsilon$  7.80 x 10<sup>4</sup> (10M HCl), CI 43825, pK<sub>1</sub><sup>25</sup> <0, pK<sub>2</sub><sup>25</sup> 2.25, pK<sub>3</sub><sup>25</sup> 4.88, pK<sub>4</sub><sup>25</sup> 11.75.** The crude *phenolic triphenylmethanecarboxysulfonic acid triNa salt* (40g) is dissolved in water (250ml) and filtered. Then conc HCl (50ml) is added to the filtrate, with stirring. The precipitate is filtered off, washed with HCl (2M) and dried. It is redissolved in water (250ml), and precipitation is repeated twice more in a water bath at 70<sup>o</sup>. It is dried under vacuum over solid KOH (first), then  $\text{P}_2\text{O}_5$  [Martynov et al. *Zh Analyt Khim* **32** 519 1977]. It has also been purified by paper chromatography using *n*-butanol, acetic acid and water (7:3:1). First and second spots were extracted. It chelates Al and Be. It is used also for estimating fluoride. [Beilstein **11** IV 707.]

**Copper (I) thiophenolate** [1192-40-1] **M 172.7, m ca 280<sup>o</sup>, pK<sub>1</sub><sup>25</sup> 6.62 (for  $\text{PhS}^-$ ).** The Cu salt can be extracted from a thimble (Soxhlet) with boiling MeOH. It is a green-brown powder that gives a yellow-green solution in pyridine. Wash it with EtOH and dry it in a vacuum. It can be precipitated from a pyridine solution by adding  $\text{H}_2\text{O}$ , collecting the precipitate, washing it with EtOH and drying in a vacuum. [Posner et al. *Synthesis* 662 1974, Krebs et al. *Chem Ber* **90** 425 1957, Beilstein **6** IV 1465.]

**Cupferron ammonium salt (N-nitroso-N-phenylhydroxylamine ammonium salt)** [135-20-6] **M 155.2, m 150-155<sup>o</sup>(dec), 162.5-163.5<sup>o</sup>, 163-164<sup>o</sup>, pK<sup>25</sup> 4.16 (free base).** Recrystallise it twice from EtOH after treatment with Norite and finally once with EtOH. The crystals are washed with diethyl ether and air dried, then stored in the dark over solid ammonium carbonate. A standard solution (ca 0.05M prepared in air-free  $\text{H}_2\text{O}$ ) is prepared daily from this material for analytical work and is essentially 100% pure. [Olsen & Elving *Anal Chem* **26** 1747 1954.] It can also be washed with  $\text{Et}_2\text{O}$ , dried and stored as stated. In a sealed, dark container it can be stored for at least 12 months without deterioration. The UV has  $\lambda_{\text{max}}$  at 260nm ( $\text{CHCl}_3$ ). [Marvel *Org Synth Coll Vol I* 177 1941, Elving & Olson *J Am Chem Soc* **78** 4206 1956, Beilstein **16** IV 891.] Possible **CARCINOGEN**.

**Cupric trifluoromethylsulfonate (copper II triflate)** [34946-82-2] **M 361.7, pK<sup>25</sup> <-3.0 (for triflic acid).** Dissolve it in MeCN, add dry  $\text{Et}_2\text{O}$  until cloudy and cool at -20<sup>o</sup> in a freezer. The light blue precipitate is collected and dried in a vacuum oven at 130<sup>o</sup>/20mm for 8 hours. It has  $\lambda_{\text{max}}$  at 737nm ( $\epsilon$  22.4  $\text{M}^1\text{cm}^{-1}$ ) in AcOH. [Salomon & Kochi *J Am Chem Soc* **95** 330 1973]. It has also been dried in a vessel at 0.1Torr by heating with a Fischer burner [Andrist et al. *J Org Chem* **43** 3422 1978]. It has been dried at 110-120<sup>o</sup>/5mm for 1 hour before use and forms a \*benzene complex which should be handled in a dry box because it is air sensitive [Kobayashi et al. *Chem Pharm Bull Jpn* **28** 262 1980, Salomon & Kochi *J Am Chem Soc* **95** 330 1973]. [Beilstein **3** IV 34.]

**Cuprous (I) bromide dimethylsulfide complex** [54678-23-8] **M 205.6, m ca 135°(dec)**. Purify it by recrystallisation in the presence of Me<sub>2</sub>S. A solution of the complex (1.02g) in Me<sub>2</sub>S (5ml) is slowly diluted with hexane (20ml), and the pure colourless prisms of the complex (0.96g) separate and are collected and dried, **m 124-129°(dec)**. The complex is insoluble in hexane, Et<sub>2</sub>O, Me<sub>2</sub>CO, CHCl<sub>3</sub> and CCl<sub>4</sub>. It dissolves in DMF and DMSO, but the solution becomes hot and green indicating decomposition. It dissolves in \*C<sub>6</sub>H<sub>6</sub>, Et<sub>2</sub>O, MeOH and CHCl<sub>3</sub> if excess of Me<sub>2</sub>S is added and a colourless solution is obtained. [House et al. *J Org Chem* **40** 1460 1975.] Prior to use, the complex is dissolved in Me<sub>2</sub>S and evaporated to dryness in the weighed reaction flask [Bourgain-Commerçon et al. *J Organomet Chem* **228** 321 1983]. If this reagent is to assist in methylations with MeMgBr (e.g. of fullerenes) it is always best to make a fresh preparation. CuBr (25g) is washed with MeOH (4 x 50ml) to remove coloured impurities and dried *in vacuo* for 1 hour. This white green-tinged CuBr is dissolved in Me<sub>2</sub>S (60ml, redistilled b 38°, use efficient fume cupboard) and insoluble impurities are filtered off. Hexane (200ml) is added and the precipitated light-sensitive white crystalline complex is filtered off and washed with hexane (5 times) under suction and N<sub>2</sub>. It should be dried under a stream of dry N<sub>2</sub>, and should not be kept or stored under reduced pressure as it will lose the some of the disulfide ligand and its efficiency. [Wuts *Synth Commun* **11** 139 1981, Nakamura et al. *Org Synth* **83** 80, 2006.]

**Cuprous iodide trimethylphosphite** [34836-53-8] **M 314.5, m 175-177°, 192-193°**. Cuprous iodide dissolves in a \*C<sub>6</sub>H<sub>6</sub> solution containing trimethylphosphite to form the complex. The complex crystallises from \*C<sub>6</sub>H<sub>6</sub> or petroleum ether. [Arbusoff *Chem Ber* **38** 1171 1905, Nishizawa *Bull Chem Soc Jpn* **34** 1170, 1177 1961.]

**Decaborane (14) (B<sub>10</sub>H<sub>14</sub>)** [17702-41-9] **M 122.2, m 99.6-99.7°, 99.7-100°, b 100°/19mm, 213°/atm, d<sub>4</sub><sup>25</sup> 0.94**. Purify decaborane by vacuum sublimation at 80°/0.1mm, followed by crystallisation from methylcyclohexane, CH<sub>2</sub>Cl<sub>2</sub>, or dry olefin-free-*n*-pentane, the solvent being subsequently removed by storing the crystals in a vacuum desiccator containing CaCl<sub>2</sub>. It is soluble in H<sub>2</sub>O but is slowly decomposed to give H<sub>2</sub>. It is soluble in alkali, and on acidification it liberates H<sub>2</sub>. **TOXIC**. [Greenwood in *Comprehensive Chemistry (Ed Bailer et al.)* Pergamon Press Vol **1** pp 818-837 1973.]

**Di-*n*-amyl *n*-amylphosphonate** [6418-56-0] **M 292.4, b 150-151°/2mm, n<sub>D</sub><sup>20</sup> 1.4378**. Purify it by three crystallisations of its uranyl nitrate complex from hexane (see *tributyl phosphate*). It extracts Zr<sup>2+</sup> from NaCl solutions.

**Di-*n*-butyl boron triflate (di-*n*-butylboryl trifluoromethanesulfonate)** [60669-69-4] **M 274.1, b 37°/0.12mm, 60°/2mm, pK<sup>25</sup> <-3.0 (for triflic acid)**. Distil it in a vacuum under argon and store it under argon. It should be used within 2 weeks of purchase or after redistillation. Use a short path distillation system. It has IR bands in CCl<sub>4</sub> with  $\nu_{\max}$  at 1405, 1380, 1320, 1200 and 1550cm<sup>-1</sup>, and <sup>13</sup>C NMR (CDCl<sub>3</sub>) with  $\delta$  at 118.1, 25.1, 21.5 and 13.6. [Gage & Evans *Org Synth* **68** 83 1990, Evans et al. *J Am Chem Soc* **103**, 3099 1981.] **TOXIC**

**Di-*n*-butyl *n*-butylphosphonate** [78-46-6] **M 250.3, b 150-151°/10mm, 160-162°/20mm, n<sup>25</sup> 1.4302**. Purify by three recrystallisations of its compound with uranyl nitrate, from hexane. For method, see *tributyl phosphate*.

**Di-*n*-butyl cyclohexylphosphonate** [1085-92-3] **M 245.4**. The compound with uranyl nitrate is recrystallised three times from hexane. For method see *tributyl phosphate*.

**Di-*tert*-butyl dichlorosilane (DTBCl<sub>2</sub>)** [18395-90-9] **M 213.2, m -15°, b 190°/729mm, 195-197°/atm, d<sub>4</sub><sup>20</sup> 1.01**. Purify it by fractional distillation. It is a colourless liquid with a pleasant odour and does not fume in moist air, but does not titrate quantitatively with excess of dilute alkali. [Tyler et al. *J Am Chem Soc* **70** 2877 1948.]

**Di-*tert*-butylphosphine** [819-19-2] **M 146.2, b 34-35°/2mm, 38-40°/13mm, d<sub>4</sub><sup>25</sup> 0.951, pK<sub>Est</sub> ~8.7**. It is prepared by reaction of *tert*-butylmagnesium bromide with PCl<sub>3</sub> in the presence of LiAlH<sub>4</sub>, and purified by distillation in a vacuum. *Alternatively*, the intermediate *di-tert-butylchlorophosphine* [13716-10-4] is reduced separately and the product is purified by fractional distillation *in vacuo*. [Hoffmann & Schellenbeck *Chem Ber*

99 1134 1966, Hoffmann & Schellenbeck *Chem Ber* **100** 692 1967, Crofts et al. *J Chem Soc C* 331 1970.]

**Di-tert-butyl silyl bis(trifluoromethanesulfonate)** [85272-31-7] **M 440.5, b 73.5-74.5°/0.35mm, d<sub>4</sub><sup>20</sup> 1.36** (see **pK** for triflic acid). Purify it by fractional distillation at high vacuum. It is a pale yellow liquid that should be stored under argon. It is less reactive than the diisopropyl analogue. The presence of the intermediate monochloro compound can be detected by <sup>1</sup>H NMR, (CHCl<sub>3</sub>): *tert*-Bu<sub>2</sub>Si(OTf)<sub>2</sub> [δ 1.25s], but impurities have δ 1.12s for *tert*-Bu<sub>2</sub>Si(H)OTf and δ 1.19s for *tert*-Bu<sub>2</sub>HSi(Cl)OTf. [Deslongchamps *Tetrahedron Lett* **23** 4871 1982, Deslongchamps *Aldrichimica Acta* **17** 72 1984.] **TOXIC.**

**2,6-Dichlorophenol-indophenol sodium salt (2H<sub>2</sub>O)** [620-45-1] **M 326.1, ε 2.1 x 10<sup>4</sup> at 600nm and pH 8, pK<sup>30</sup> 5.7 (oxidised form), pK<sub>1</sub><sup>30</sup> 7.0, pK<sub>2</sub><sup>30</sup> 10.1 (reduced form).** Dissolve it in 0.001M phosphate buffer, pH 7.5 (alternatively, about 2g of the dye is dissolved in 80ml of M HCl), and extracted into diethyl ether. The extract is washed with water, extracted with aqueous 2% NaHCO<sub>3</sub>, and the sodium salt of the dye is precipitated by adding NaCl (30g/100ml of NaHCO<sub>3</sub> solution), then filtered off, washed with dilute NaCl solution and dried. It has λ<sub>max</sub> at 605nm. [Hiromi et al. *Anal Biochem* **101** 421 1980.] The *acetate* [24857-20-3] **M 310.1** has m 101-103° (from Et<sub>2</sub>O/petroleum ether) and 99.5-100.5° (from Et<sub>2</sub>O). [Beilstein **13** IV 1078-1079.]

**Dicyclopentylphosphine** [39864-68-1] **M 170.2, b 76-78°/0.8mm, d<sub>4</sub><sup>25</sup> 0.933, pK<sub>Est</sub> ~4.5.** Purify dicyclopentylphosphine by distillation in a vacuum in a stream of N<sub>2</sub> or Ar as it is air sensitive and must be stored in an inert atmosphere. [cf Neidergall *Chem Ber* **95** 64 1962, Beilstein **16** IV 947 for *dicyclohexylphosphine*.]

**O,O-Diethyl-S-2-diethylaminoethyl phosphorothiolate** [78-53-5] **M 269.3, m 98-99°.** Recrystallise it from isopropanol/diethyl ether. [Ailman & Magee in *Organo Phosphorus Compound* (Kosolapoff & Maier eds) Wiley Vol 7 pp 487-871 1976.]

**Diethylmethylsilane** [760-32-7] **M 102.3, b 78.4°/760mm, 77.2-77.6°/atm, d<sub>4</sub><sup>20</sup> 0.71.** Fractionally distil it through a *ca* 20-plate column, and the fraction boiling within a range of less than 0.5° is collected. It is a **flammable irritating** liquid. [Price *J Am Chem Soc* **69** 2600 1947, Beilstein **4** III 1847.]

**N,N-Diethyltrimethylsilylamine** [996-50-9] **M 145.3, b 33°/26mm, 126.8-127.1°/738mm, 126.1-126.4°, d<sub>4</sub><sup>20</sup> 0.763, n<sub>D</sub><sup>20</sup> 1.411.** Fractionate it through a 2ft vacuum-jacketed column containing Helipak packing with a reflux ratio of 10:1. [Sauer & Hasek *J Am Chem Soc* **68** 241 1946, Langer et al. *J Org Chem* **23** 50 1958, Rühlmann *J Prakt Chem* **9** 315 1959, Beilstein **4** IV 4010.]

**Diethyl trimethylsilyl phosphite** [13716-45-5] **M 210.3, b 61°/10mm, 66°/15mm, d<sub>4</sub><sup>20</sup> 0.9476, n<sub>D</sub><sup>20</sup> 1.4113.** Fractionate it under reduced pressure and has <sup>31</sup>PMR: δ<sub>P</sub> -128ppm relative to H<sub>3</sub>PO<sub>4</sub>. [Sekine et al. *J Org Chem* **46** 2097 1981, Chernyshev et al. *J Gen Chem USSR (Engl Transl)* **45** 231 1975.]

**Dihexadecyl phosphate (DHP)** [2197-63-9] **M 546.9, m 75°, pK<sub>Est</sub> ~1.2.** Recrystallise it from MeOH. Solutions of DHP were made in CHCl<sub>3</sub> or CH<sub>2</sub>Cl<sub>2</sub> for making vesicles. It has been used for making surfactant vesicles in studies of the viscosity-dependent variations of the fluorescence yield ϕ<sub>F</sub> and the polarity induced shift of the emission band maximum λ<sub>F(max)</sub> of a derivative of a [*p*-(dialkylamino)benzylidene]malononitrile [74677-08-0] fluorescence probe. [Lukac *J Am Chem Soc* **106** 4387 1984]. [Beilstein **1** IV 1880.]

**1,2-Dihydroxybenzene-3,5-disulfonic acid, di-Na salt (TIRON)** [149-45-1] **M 332.2, ε 6.9 x 10<sup>4</sup> at 260nm, pH 10.8, pK<sub>1</sub> and pK<sub>2</sub> <2 (for SO<sub>3</sub><sup>-</sup>), pK<sub>3</sub> 7.7, pK<sub>4</sub> 12.6 (for OHs of disulfonate dianion).** Recrystallise it from water [Hamaguchi et al. *Anal Chim Acta* **9** 563 1962]. It is an indicator colour reagent for Fe, Mn, Ti and Mo ions and complexes with Al, Cd, Co, Co, Fe (III), Mn, Pd, UO<sub>2</sub><sup>2+</sup>, VO<sub>2</sub><sup>2+</sup> and Zn. [Beilstein **11** IV 630.]

**(±)-Diisooctyl phenylphosphonate (bis[2-ethylhexyl] phenylphosphonate)** [49637-59-4] **M 378.5, b 204-207°/4mm, d<sub>4</sub><sup>20</sup> 0.970, n<sub>D</sub><sup>25</sup> 1.4780.** Distil it in a vacuum, percolate it through a column of alumina, then pass it through a packed column maintained at 150° to remove residual traces of volatile materials in a countercurrent

stream of N<sub>2</sub> under reduced pressure [Dobry & Keller *J Phys Chem* **61** 1448 1957]. [*Beilstein* **16** III 884.]

**Diisopropyl chlorosilane (chlorodiisopropylsilane)** [2227-29-4] **M 150.7, b 59°/8mm, 80°/10mm, 200°/738mm, d<sub>4</sub><sup>20</sup> 0.9008, n<sub>D</sub><sup>20</sup> 1.4518.** Impurities can be readily detected by <sup>1</sup>H NMR spectroscopy. Purify it by fractional distillation [Gilman & Clark *J Am Chem Soc* **69** 1499 1947, Allen et al. *J Chem Soc* 3668 1957].

**Dilongifolyl borane** [77882-24-7] **M 422.6, m 169-172°.** Wash it with dry Et<sub>2</sub>O and dry it in a vacuum under N<sub>2</sub>. It has **m 160-161°** in a sealed evacuated capillary. It is sparingly soluble in pentane, tetrahydrofuran, carbon tetrachloride, dichloromethane, and chloroform, but the suspended material is capable of causing asymmetric hydroboration. Disappearance of solid indicates that the reaction has proceeded. [Jadhav & Brown *J Org Chem* **46** 2988 1981.]

**Dimethyldichlorosilane** [75-78-5] **M 129.1, m -75.5°, b 68.5-68.7°/750mm, 70.5°/760mm, d<sub>4</sub><sup>20</sup> 1.0885, n<sub>D</sub><sup>20</sup> 1.4108.** Other impurities are chlorinated silanes and methylsilanes. Fractionate it through a 3/8in diameter 7ft Stedman column rated at 100 theoretical plates at almost total reflux. See purification of MeSiCl<sub>2</sub>. Solutions in heptane, 1,1,1-trichloroethane or 1-chloronaphthalene are used for the silanization of glassware and pipettes. [Sauer & Hadsell *J Am Chem Soc* **70** 3590 1948, *Beilstein* **4** IV 4110.]

**2,6-Dimethyl-1,10-phenanthrolinedisulfonic acid, di-Na salt (H<sub>2</sub>O) (bathocuproine-disulfonic acid di-Na salt)** [52698-84-7] **M 564.5, m ~300°, pK<sub>Est</sub> ~0 (for free acid).** Inorganic salts and some coloured species can be removed by dissolving the crude material in the minimum volume of water and precipitating by adding EtOH. The purified reagent can be obtained by careful evaporation of the filtrate. Recrystallise it from EtOH and dry it in a vacuum at room temperature in the dark. [Lorenzo et al. *J Electroanalyt Chem* **356** 43 1993, Watkins et al. *Microchem J* **16** 14 1971.]

**Dimethylphenylsilyl chloride (DMPSiCl, chlorodimethylphenylsilane, phenyl dimethyl chlorosilane)** [768-33-2] **M 170.7, b 79°/15mm, 85-87°/32mm, 196°/760mm, d<sub>4</sub><sup>20</sup> 1.017, n<sub>D</sub><sup>20</sup> 1.509.** Fractionate it through a 1.5 x 18inch column packed with stainless steel helices, or a spinning band column. [Daudt & Hyde *J Am Chem Soc* **74** 386 1952, Lewis et al. *J Am Chem Soc* **70** 1115 1948, Eaborn *J Chem Soc* 494 1953.] It is used for standardising MeLi or MeMgBr that form Me<sub>3</sub>PhSi which is estimated by GC. [Maienthal et al. *J Am Chem Soc* **76** 6392 1954, House & Respass *J Organomet Chem* **4** 95 1965, *Beilstein* **16** IV 1475.] **TOXIC and MOISTURE SENSITIVE.**

**Dimethyl thiophosphonate (dimethyl hydrogen phosphonothiolate)** [5930-72-3] **M 126.1, b 53-53.5°/16.5mm, 56-59°/9mm, 59°/16mm, d<sub>4</sub><sup>25</sup> 1.1892, n<sub>D</sub><sup>20</sup> 1.4768.** Fractionally distil the ester in a stream of dry N<sub>2</sub> or Ar at as high a vacuum as possible. Store in a sealed ampoule under Ar as it has a foul odour. The IR (film) has  $\nu_{\max}$  at ~800 cm<sup>-1</sup> (12.6 μ, P-S). [IR: McIvor et al. *Canad J Chem* **34** 1611 1956, McIvor et al. *Canad J Chem* **36** 820, 1818 1958, Tongcharoensirikul et al. *J Org Chem* **69** 2322 2004, *Beilstein* **1** IV 1258.]

**Diocetyl phenylphosphonate** [1754-47-8] **M 378.8, b 207°/4mm, d<sub>4</sub><sup>20</sup> 1.485, n<sub>D</sub><sup>25</sup> 1.4780.** Purify it as described for diisooctyl phenylphosphonate and distil under high vacuum. [*Beilstein* **16** IV 1069.]

**(1,3-Dioxalan-2-ylmethyl)triphenylphosphonium bromide** [52509-14-5] **M 429.3, m 191.5-193°, 193-195°.** Wash the crystals with Et<sub>2</sub>O, dry them in a vacuum and recrystallise them from CH<sub>2</sub>Cl<sub>2</sub>/dry Et<sub>2</sub>O to give prisnts with **m 172-174°**, which is raised to 191.5-193° on drying at 56°/0.5mm. [Cresp et al. *J Chem Soc, Perkin Trans I* 37 1974.]

**Diphenyldiselenide** [1666-13-3] **M 312.1, m 62-64.** Crystallise it twice from hexane [Kice & Purkiss *J Org Chem* **52** 3448 1987]. [*Beilstein* **6** IV 1781.]

**Diphenyl hydrogen phosphate (diphenyl phosphate)** [838-85-7] **M 250.2, m 99.5°, pK<sup>20</sup> 0.26.** Crystallise it from CHCl<sub>3</sub>/petroleum ether. [Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol 6 pp 211-577 1973, *Beilstein* 6 IV 714.]

**4,7-Diphenyl-1,10-phenanthrolinedisulfonic acid, di-Na salt 3H<sub>2</sub>O (bathophenanthroline-disulfonic acid di-Na salt)** [52746-49-3] **M 590.6, m 300°, pK<sub>Est</sub>~0 (for free acid).** Dissolve crude sample in the minimum volume of water and add EtOH to precipitate the contaminants. Carefully evaporate the filtrate to obtain pure material. It forms a dark red complex with Fe<sup>2+</sup> with  $\lambda_{\max}$  535nm ( $\epsilon$  2.23 x 10<sup>4</sup>mol<sup>-1</sup> cm<sup>-1</sup>) [Imasaka et al. *Anal Chim Acta* 115 407 1980]. It is prepared by sulfonating bathophenanthroline with ClSO<sub>3</sub>H: to 100g of bathophenanthroline is added 0.5ml of Fe free ClSO<sub>3</sub>H and heated over a flame for 30 seconds (**CARE**). Cool and carefully add 10ml of pure distilled H<sub>2</sub>O and warm on a water bath with stirring till all solid dissolves. A stock solution is made by diluting 3ml of this reagent to 100ml with 45% aqueous NaOAc, filter off the solid and store in a dark bottle. In this way it is stable for several months. [Landers & Bennie *Am J Clinical Pathology* 29 590 1958.]

**Diphenylphosphinic acid** [1707-03-5] **M 218.2, m 194-195°, pK<sup>20</sup> 1.72.** Recrystallise it from 95% EtOH and dry it under vacuum at room temperature. [see Kosolapoff *Organophosphorus Compounds* J Wiley, NY, 1950, Kosolapoff and Maier *Organic Phosphorus Compounds* Wiley-Interscience, NY, 1972-1976, *Beilstein* 16 IV 1036.]

**Diphenyl phosphorazidate (DPPA, diphenyl phosphoryl azide, phosphoric acid diphenyl ester azide)** [26386-88-9] **M 275.2, b 134-136°/0.2mm, 137°/0.17mm, d<sub>4</sub><sup>25</sup> 1.277, n<sub>D</sub><sup>20</sup> 1.551.** This azide and nitrene source is prepared by stirring a mixture of diphenyl phosphorochloridate (56.8g, 210mmol, freshly distilled at 165-168°/5mm, see [2524-64-3]), sodium azide (16.3g, 250mmol) and anhydrous Me<sub>2</sub>CO (300ml, dried over K<sub>2</sub>CO<sub>3</sub> and freshly distilled) in a dry atmosphere at 20-25° for 21 hours. The *lachrymatory* mixture is filtered in a fume cupboard, and the filtrate is concentrated in vacuum. The residue is purified by distillation through a short Vigreux column keeping the bath temperature below 200° to avoid decomposition of the *azidate*, and collecting the fraction with b 134-136°/0.2mm (49-52g, 84-89%). It is a colourless non-explosive oil which can be stored for long periods if it is protected from moisture and light. It has IR (neat) with  $\nu_{\max}$  at 3060 (w, C-H), 2170 (s, -N<sub>3</sub>), 1590 (m), 1490 (s, arene C=C), 1270 (m, P=O) and 960 (s, P-O-aryl) cm<sup>-1</sup>; and the <sup>1</sup>H NMR (CDCl<sub>3</sub>) has  $\delta$  at 7.0-7.3 (br s, aryl-H). [Shioiri & Yamada *Org Synth Coll Vol VII* 206 1990.]

It is a useful activating agent and a versatile reagent in organic synthesis (see references cited in *Org Synth Coll Vol VII* 206 1990 above). It is commercially available on a 100-200 mesh, 1% cross-linked polydivinylbenzene support and bound (*via para* linkage) through one of its phenyl rings (PS-DPPA, 1.0-1.5mmol/g N<sub>3</sub> loading).

**Diphenyl phosphoro chloridate (diphenyl phosphoryl chloride)** [2524-64-3] **M 268.6, b 141°/1mm, 194°/13mm, 314-316°/272mm, d<sub>4</sub><sup>30</sup> 1.2960, n<sub>D</sub><sup>35</sup> 1.5490.** Fractionally distil it in a good vacuum; better use a spinning band column. [Walsh *J Am Chem Soc* 81 3023 1959, IR: Bellamy & Beecher *J Chem Soc* 475 1952, *Beilstein* 6 IV 737.]

**Diphenylsilane** [775-12-2] **M 184.3, b 75-76°/0.5mm, 113-114°/9mm, 124-126°/11mm, 134-135°/16mm, d<sub>4</sub><sup>20</sup> 1.0027, n<sub>D</sub><sup>20</sup> 1.5802.** Dissolve it in Et<sub>2</sub>O, mix slowly with ice-cold 10% AcOH. The Et<sub>2</sub>O layer is then shaken with H<sub>2</sub>O until the washings are neutral to litmus. Dry over Na<sub>2</sub>SO<sub>4</sub>, evaporate the Et<sub>2</sub>O and distil the residual oil under reduced pressure using a Claisen flask with the take-off head modified into a short column. Ph<sub>2</sub>SiH<sub>2</sub> boils at 257°/760mm, but it cannot be distilled at this temperature because exposure to air leads to flashing, decomposition and formation of silica. It is a colourless, odourless oil, miscible with organic solvents but not H<sub>2</sub>O. A possible impurity is Ph<sub>3</sub>SiH which has **m** 43-45° and would be found in the residue. [West & Rochow *J Org Chem* 18 303 1953, Benknesser et al. *J Am Chem Soc* 74 648 1952, Gilman & Zuech *J Am Chem Soc* 81 5925 1959, *Beilstein* 16 IV 1366.]

**Diphenylsilanediol** [947-42-2] **M 216.3, m 148°(dec).** Recrystallise it from CHCl<sub>3</sub>/methyl ethyl ketone. [*Beilstein* 16 IV 1523.]

**Diphenyl *p*-tolyl phosphate** [26444-49-5] **M 340.3, m 18-29°, b 156-158°/0.002mm, n<sub>D</sub><sup>25</sup> 1.5758.** Distil it in a vacuum, then percolate it through a column of alumina. Finally, pass it through a packed column maintained at 150° to remove traces of volatile impurities in a countercurrent stream of nitrogen under reduced pressure. [Dobry & Keller *J Phys Chem* **61** 1448 1947, *Beilstein* **6** IV 2130.]

**Disodium 4,5(1,8)-dihydroxynaphthalene-2,7(3,6)-disulfonate 2H<sub>2</sub>O (Chromotropic acid di-Na salt)** [5808-22-0] **M 400.3, m >300°, pK<sub>1</sub> 0.61(SO<sub>3</sub><sup>-</sup>), pK<sub>2</sub> 0.7(SO<sub>3</sub><sup>-</sup>), pK<sub>3</sub> 5.45(OH), pK<sub>4</sub> 15.5(OH).** Recrystallise it from H<sub>2</sub>O or H<sub>2</sub>O by adding EtOH. It complexes with Ag, ClO<sub>3</sub><sup>-</sup>, Cr, Hg, NO<sub>2</sub><sup>-</sup>, NO<sub>3</sub><sup>-</sup> and Ti. [*Beilstein* **11** H 72, **11** I 307, **11** II 174, **11** III 174, **11** IV 576.]

**Disodium ethylenebis(dithiocarbamate) (Nabam)** [142-59-6] **M 436.5, pK<sub>Est</sub> ~3.0.** It crystallises (as *hexahydrate*) from aqueous ethanol. It is a skin irritant. [*Beilstein* **4** III 149, **4** IV 234.]

**Disodium-β-glycerophosphate** [819-83-0 (4H<sub>2</sub>O), 13408-09-8 (5H<sub>2</sub>O)] **M 216.0, m 102-104°, pK<sub>2</sub><sup>25</sup> 6.66 (free acid).** Crystallise it from water. [Attwood et al. *Biochem J* **253** 389 1988, *Beilstein* **1** IV 2766.]

**Disodium naphthalene-1,5-disulfonate** [1655-29-4] **M 332.3, pK<sub>Est</sub> ~0.** Recrystallise it from aqueous acetone. It darkens at high temperatures. [Okahata et al. *J Am Chem Soc* **108** 2863 1986, *Beilstein* **11** IV 561.]

**Disodium 4-nitrophenylphosphate (6H<sub>2</sub>O)** [4264-83-9] **M 371.1.** Dissolve it in hot aqueous MeOH, filter and precipitate it by adding Me<sub>2</sub>CO. Wash the solid with Me<sub>2</sub>CO and repeat the purification. Aqueous MeOH and Et<sub>2</sub>O can also be used as solvents. The white fibrous crystals contain less than 1% of free 4-nitrophenol [assay: Axelrod *J Biol Chem* **167** 57 1947]. [*Beilstein* **6** IV 1327.]

**Disodium phenylphosphate (2H<sub>2</sub>O)** [3279-54-7, 66778-08-3 (2H<sub>2</sub>O)] **M 254.1, pK<sub>1</sub><sup>25</sup> 1.46, pK<sub>2</sub><sup>25</sup> 6.29 [for PhPO(OH)<sub>2</sub>].** Dissolve it in a minimum amount of methanol, filtering off any insoluble residue of inorganic phosphate, then precipitate it by adding an equal volume of Et<sub>2</sub>O. Wash the solid with Et<sub>2</sub>O and dry it in a vacuum [Tsuboi *Biochim Biophys Acta* **8** 173 1952]. [*Beilstein* **6** IV 708.]

**Di-*p*-tolyl phenylphosphonate** [94548-75-1] **M 388.3, n<sub>D</sub><sup>25</sup> 1.5758.** Purify as described under diisooctyl phenylphosphonate.

**1,3-Divinyl-1,1,3,3-tetramethyldisiloxane** [2627-95-4] **M 186.4, m -99.7°, b 128-129°/atm, 139°/760mm, d<sub>4</sub><sup>20</sup> 0.811, n<sub>D</sub><sup>20</sup> 1.4122.** Dissolve it in Et<sub>2</sub>O, wash it with H<sub>2</sub>O, dry it over CaCl<sub>2</sub>, evaporate the solvent and distil the residue. It is an IRRITANT. [Kantor et al. *J Am Chem Soc* **77** 1685 1955, Bazant & Matousek *Col Czech Chem Comm* **24** 3758 1959, *Beilstein* **4** IV 4080.]

**Eriochrome Black T [3-hydroxy-7-nitro-4-(1-hydroxy-2-naphthylazo)naphthalene-1-sulfonic acid Na salt]** [1787-61-7] **M 416.4. A<sub>1cm</sub><sup>%</sup> (λ<sub>max</sub>) 656(620nm) at pH 10, using the dimethylammonium salt, pK<sub>2</sub><sup>25</sup> 5.81, pK<sub>3</sub><sup>25</sup> 11.55.** The sodium salt (200g) is converted to the free acid by stirring with 500ml of 1.5M HCl, and, after several minutes, the slurry is filtered on a sintered-glass funnel. The process is repeated and the material is air dried after washing with acid. It is then extracted with \*benzene for 12 hours in a Soxhlet extractor, the \*benzene solution is evaporated and the residue is air dried. A further desalting with 1.5M HCl (1L) is followed by crystallisation from dimethylformamide (in which it is very soluble) by forming a saturated solution at the boiling point, and allowing to cool slowly. The crystalline dimethylammonium salt so obtained is washed with \*benzene and treated repeatedly with dilute HCl to give the insoluble *free acid* which, after air drying, is dissolved in alcohol, filtered and evaporated. The final material is air dried, then dried in a vacuum desiccator over Mg(ClO<sub>4</sub>)<sub>2</sub>. The purified acid is converted to the dimethylammonium salt with Me<sub>2</sub>NH. [Diehl & Lindstrom *Anal Chem* **31** 414 1959]. It is an indicator in the complexometry of alkaline earth metals. [*Beilstein* **16** IV 429.]

**Eriochrome Blue Black B (Mordant Black, 3, 3-hydroxy-4-(1-hydroxy-2-naphthylazo)-naphthalene-1-**

**sulfonic acid Na salt** [3564-14-5] M 416.4,  $pK_2^{25}$  7.0,  $pK_3^{25}$  13.5. Free it from metallic impurities by three precipitations from aqueous solution by addition of HCl. The precipitated dye is dried at 60° under vacuum and converted into the Na salt with the calculated amount of alkali. It is an indicator in the complexometry of Al, Fe and Zr. [Beilstein 16 III 319.]

**Eriochrome Blue Black R (Palatine Chrome Black 6BN, Mordant Black 17, 3-hydroxy-4-(2-hydroxy-1-naphthylazo)naphthalene-1-sulfonic acid Na salt** [2538-85-4] M 416.4,  $pK_2^{25}$  7.0,  $pK_3^{25}$  13.5. Free it from metallic impurities by three precipitations from aqueous solution by addition of HCl. The precipitated dye is dried at 60° under vacuum and converted into the Na salt with the calculated amount of alkali. It is an indicator in the complexometry of Al, Fe and Zr. [Beilstein 16 H 297, 16 IV 428.]

**Ethoxycarbonylmethylene triphenylphosphonium bromide** [1530-45-6] M 429.3, m 155-155.5°, 158°(dec). Wash it with petroleum ether (b 40-50°) and recrystallise it from  $CHCl_3/Et_2O$  and dry it in a high vacuum at 65°. [Isler et al. *Helv Chim Acta* 40 1242 1957, Wittig & Haag *Chem Ber* 88 1654, 1664 1955.]

**(Ethoxycarbonylmethylene)triphenylphosphorane [ethyl (triphenylphosphoranylidene)-acetate]** [1099-45-2] M 348.4, m 116-117°, 128-130°. Crystallise it by dissolving it in AcOH and adding petroleum ether (b 40-50°) to give colourless plates. Its UV has  $\lambda_{max}$  ( $A_{1\%}^{1\text{cm}}$ ) at 222nm (865) and 268nm (116) [Isler et al. *Helv Chim Acta* 40 1242 1957, Beilstein 16 IV 977.]

**Ethylarsonic acid** [507-32-4] M 154.0, m 94-95°, 99.5°,  $pK_1$  4.72 ( $As(OH)O^-$ ),  $pK_2$  8.00 [ $AsO_2^{2-}$ ]. Crystallise it from ethanol. Also it dissolves in excess EtOH, filter off the insoluble matter (salts?), evaporate the filtrate to dryness and recrystallise the residue from small volumes of EtOH or  $H_2O$ . [Quick & Adams *J Am Chem Soc* 44 805 1922, Banks et al. *J Am Chem Soc* 69 927 1947, Beilstein 4 H 614, 4 II 997, 4 III 1823, 4 IV 3682.]

**Ethyl Orange (sodium 4,4'-diethylaminophenylazobenzenesulfonate)** [62758-12-7] M 355.4,  $pK_{Est} \sim 3.8$ . Recrystallise it twice from water. [Beilstein 16 IV 511.]

**Ethyl trimethylsilylacetate** [4071-88-9] M 160.3, b 75.5°/42mm, 157°/730mm,  $d_4^{20}$  0.8762,  $n_D^{20}$  1.4149. Purify it by distilling ca 10g of reagent through a 15cm, Vigreux column and then redistilling it through a 21cm glass helices-packed column [Hauze & Hauser *J Am Chem Soc* 75 994 1953]. Alternatively, dissolve it in  $Et_2O$ , wash with  $H_2O$ , dilute  $Na_2CO_3$ , dry over  $Na_2CO_3$ , evaporate  $Et_2O$ , and distil it through a column of 15 theoretical plates. [Gold et al. *J Am Chem Soc* 70 2874 1948, Beilstein 4 IV 3974.]

**Ethyl 3-(trimethylsilyl)propionate** [17728-88-0] M 174.3, b 93°/40mm, 178°-180°/atm,  $d_4^{20}$  0.8763,  $n_D^{20}$  1.4198. Dissolve it in  $Et_2O$ , wash this with  $H_2O$ , dilute  $Na_2CO_3$ , dry ( $Na_2SO_4$ ), evaporate  $Et_2O$  and fractionally distil. [Sommer & Marans *J Am Chem Soc* 72 1935 1950, Beilstein 4 IV 3975.]

**Ethyl triphenylphosphonium bromide** [1530-32-1] M 371.3, m 203-205°. Recrystallise it from  $H_2O$  and dry it in high vacuum at 100°. Its IR has bands at 1449, 1431 and 997 $cm^{-1}$ . [Wittig & Wittenberg *Justus Liebigs Ann Chem* 606 1 1957, Bergmann & Dusza *J Org Chem* 23 1245 1958, Beilstein 16 IV 982.]

**Ethynyl trimethylsilane** [1066-54-2] M 98.2, b 53°/atm, 52.5°/atm,  $d_4^{20}$  0.71,  $n_D^{20}$  1.3871. Distil it through an efficient column. The IR has bands at  $\nu_{max}$  2041 ( $C\equiv C$ ) and 3289 ( $\equiv C-H$ )  $cm^{-1}$ . [Kröhnke & Goss *Chem Ber* 92 30 1959, Beilstein 4 IV 3937.]

**Fluorotrimethylsilane (trimethylsilyl fluoride, TMSF)** [420-56-4] M 92.2, m -74°, b 16°/760mm, 19°/730mm,  $d^0$  0.793. It is a FLAMMABLE gas which is purified by fractional distillation through a column at low temperature and with the exclusion of air. Preferably work in a vacuum line. [Booth & Suttle *J Am Chem Soc* 68 2658 1946, Reid & Wilkins *J Chem Soc* 4029 1955, Beilstein 4 IV 4007.]

**Hexaethylidisiloxane** [924-49-0] M 246.5, b 114-115°/16mm, 235.5°/760mm,  $d_4^{20}$  0.8443,  $n_D^{20}$  1.4330. Distil in a vacuum, but it can be distilled at atmospheric pressure without decomposition. It is characterised by completely dissolving in conc H<sub>2</sub>SO<sub>4</sub>. [Eaborn *J Chem Soc* 3077 1950, *Beilstein* 4 IV 4055.]

**2,2,4,4,6,6-Hexamethylcyclotrisiloxane** [1009-93-4] M 219.5, m -10°, b 81-82°/19mm, 111-112°/85mm, 188°/756mm,  $d_4^{20}$  0.9196,  $n_D^{20}$  1.448. Purify it by fractional distillation at atmospheric pressure until the temperature reaches 200°. It is *moisture sensitive*. The residue in the flask is mostly octamethylcyclotetrasilazane. [Brewer & Haber *J Am Chem Soc* 70 3888 1948, *Beilstein* 4 III 1887.]

**Hexamethyldisilane** [1450-14-2] M 164.4, m 9-12°, b 113.1°/750mm,  $d_4^{20}$  0.7272,  $n_D^{20}$  1.4229. The most likely impurity is trimethylchlorosilane (*cf* boiling point). Wash it with H<sub>2</sub>O, cold conc H<sub>2</sub>SO<sub>4</sub>, H<sub>2</sub>O again, then aqueous NaHCO<sub>3</sub>, dry over CaSO<sub>4</sub> and fractionate at atmospheric pressure. [Brown & Fowles *J Chem Soc* 2811 1958.] A grossly impure sample (25% impurities) was purified by repeated spinning band distillation. This lowered the impurity level to 500 ppm. The main impurity was identified as 1-hydroxypentamethyldisilane. [*Beilstein* 4 IV 4277.]

**Hexamethyldisilazane [HMDS, (Me<sub>3</sub>Si)<sub>2</sub>NH]** [999-97-3] M 161.4, b 125-125.6°/atm, 126°/760mm,  $d_4^{20}$  0.7747,  $n_D^{20}$  1.407. A possible impurity is Me<sub>3</sub>SiCl. Wash it well with petroleum ether and fractionate it through a vacuum jacketed column packed with Helipac using a reflux ratio of 10:1. [Langer et al. *J Org Chem* 23 50 1958, *Beilstein* 4 IV 4014.] It forms a lithium salt, (Me<sub>3</sub>Si)<sub>2</sub>NLi [4039-32-1], which is soluble in THF and hexane; and ~ 1M solutions in these solvents are available commercially.

**Hexamethyldisiloxane (HMDSO)** [107-46-0] M 162.4, m -59°, b 99.4°/760mm, 100.4°/764mm,  $d_4^{20}$  0.7633,  $n_D^{20}$  1.3777. Fractionally distil through a column packed with glass helices with *ca* 15 theoretical plates. It is highly **flammable** and is an **irritant**. [Mills & McKenzie *J Am Chem Soc* 76 2672 1954, Csakvari et al. *J Organometal Chem* 107 287 1976, *Beilstein* 4 IV 4018.]

**Hexamethylphosphoric triamide (HMPA)** [680-31-9] M 179.2, f 7.2°, b 68-70°/1mm, 235°/760mm,  $d_4^{20}$  1.024,  $n_D^{20}$  1.460. The industrial synthesis is usually by treatment of POCl<sub>3</sub> with excess of dimethylamine in isopropyl ether. Impurities are water, dimethylamine and its hydrochloride. It is purified by refluxing over BaO or CaO at about 4mm pressure in an atmosphere of nitrogen for several hours, then distilled from sodium at the same pressure. The middle fraction (b *ca* 90°) is collected, refluxed over sodium under reduced pressure under nitrogen and distilled. It is kept in the dark under nitrogen, and stored in solid CO<sub>2</sub>. It can also be stored over 4A molecular sieves.

*Alternatively*, it is distilled under vacuum from CaH<sub>2</sub> at 60° and is crystallised twice in a cold room at 0°, seeding the liquid with crystals obtained by cooling in liquid nitrogen. After about two-thirds are frozen, the remaining liquid is drained off [Fujinaga et al. *Pure Appl Chem* 44 117 1975]. For tests of purity see Fujinaga et al. in *Purification of Solvents*, Coetzee Ed., Pergamon Press, Oxford, 1982. For efficiency of desiccants in drying HMPA see Burfield and Smithers [*J Org Chem* 43 3966 1978, and Sammes et al. *J Chem Soc, Faraday Trans 1* 281 1986]. [*Beilstein* 4 IV 284.] **CARCINOGEN**.

**Hexamethylphosphorous triamide [HMPT, tris(dimethylamino)phosphine]** [1608-26-0] M 163.2, m 7.2°, b 49-51°/12mm, 162-164°/12mm,  $d_4^{20}$  0.989,  $n_D^{20}$  1.466. It may contain more than 1% of phosphoric triamide. The yellow oil is first distilled at atmospheric pressure, then under reduced pressure and stored under N<sub>2</sub>. It is air sensitive, **TOXIC**, and *should not be inhaled*. It is absorbed through the skin. [Mark *Org Synth Coll Vol V* 602 1973, *Beilstein* 4 IV 274.]

**Hydroquinone-2-sulfonic acid K salt** [21799-87-1] M 228.3, m 250°(dec),  $pK_{Est(1)} \sim 1$ ,  $pK_{Est(2)} \sim 8.5$ ,  $pK_{Est(3)} \sim 11$ . Recrystallise it from water or EtOH. [*Beilstein* 11 I 70, 11 II 170, 11 III 570.]

**Hydroxynaphthol Blue tri-Na salt** [63451-35-4] M 620.5, m dec on heating,  $pK_{Est} < 0$ . The crude material is treated with hot EtOH to remove soluble impurities, then dissolve in 20% aqueous MeOH and chromatographed on a cellulose powder column with propanol/EtOH/water (5:5:4) as eluent. The upper of three

zones are eluted to give the pure dye which is precipitated as the *monosodium salt trihydrate* by adding conc HCl to the concentrated eluate [Ito & Ueno *Analyst* **95** 583 1970]. It can be converted to the trisodium salt with the calculated amount of alkali.

**Indigocarmine** (2[1,3-dihydro-3-oxo-5-sulfo-2H-indol-2-ylidene]-2,3-dihydro-3-oxo-1H-indole-5-sulfonic acid di-Na salt) [860-22-0] **M 466.4**, **pK<sub>1</sub><sup>20</sup> 2.8**, **pK<sub>2</sub><sup>20</sup> 12.3**. Its solubility in H<sub>2</sub>O is 1g/100ml at 25°. It has been purified by dissolving in H<sub>2</sub>O, filtering and adding EtOH to cause the salt to separate. Wash the solid with EtOH, Et<sub>2</sub>O and dry *in vacuo*. [Vörlander & Schubert *Chem Ber* **34** 1860 1901, UV: Smit et al. *Anal Chem* **27** 1159 1955, Preisler et al. *J Am Chem Soc* **81** 1991 1959, *Beilstein* **25** IV 1975.]

**Iodomethyl trimethylsilane** [4206-67-1] **M 214.1**, **b 139.5°/744mm**, **d<sub>4</sub><sup>20</sup> 1.44**, **n<sub>D</sub><sup>25</sup> 1.4917**. If slightly violet in colour, wash it with aqueous 1% sodium metabisulfite, H<sub>2</sub>O, dry (Na<sub>2</sub>SO<sub>4</sub>) it and fractionally distil it at 760mm. [Whitmore & Sommer *J Am Chem Soc* **68** 481 1946, *Beilstein* **4** IV 3878.]

**Iodotrimethylsilane (trimethylsilyl iodide, TMSI)** [16029-98-4] **M 200.1**, **b 106.8°/742mm**, **107.5°/760mm**, **d<sub>4</sub><sup>20</sup> 1.470**. Add a little antimony powder and fractionate with this powder in the still. Stabilise the distillate with 1% wt of Cu powder. [Eaborn *J Chem Soc* 3077 1950, *Beilstein* **4** IV 4009.]

**Isopropylidimethyl chlorosilane** [3634-56-8] **M 140.7**, **b 109.8-110.0°/738mm**, **d<sub>4</sub><sup>20</sup> 0.88**, **n<sub>D</sub><sup>20</sup> 1.4158**. Probable impurity is Me<sub>3</sub>SiCl (**b 56.9°/783mm**) which can be removed by efficient fractional distillation. [Sommer et al. *J Am Chem Soc* **76** 801 1954, *Beilstein* **4** IV 4067.]

**N-Lauroyl-N-methyltaurine sodium salt (sodium N-decanoyl-N-methyl-2-aminoethane sulfonate)** [4337-75-1] **M 343.5**, **pK<sub>Est</sub> ~1.5**. It is prepared from methyldecanoate (at 180° under N<sub>2</sub>) or decanoyl chloride and sodium N-methylethane sulfonate and purified by dissolving it in H<sub>2</sub>O and precipitating by addition of Et<sub>2</sub>O. It decomposes on heating. [Desseigne & Mathian *Mém Services Chim Etat Paris* **31** 359 1944, cf. *Chem Abstr* **41** 705 1947.]

**Lawesson's Reagent** [LR, 2,4-bis(4-methoxyphenyl)1,3,2,4-dithiadiphosphetane 2,4-disulfide, *p*-methoxyphenylthiophosphonic acid cyclic di(thioanhydride)] [19172-47-5] **M 404.5**, **m 228-229.5° (sintering at 215°), 228-230°**. The reagent has been washed with anisole or C<sub>6</sub>H<sub>6</sub>\* and dried in a vacuum over paraffin wax and P<sub>2</sub>O<sub>5</sub>, and heated above room temperature. It does not lose the solvents completely (possibly due to formation of clathrates). It loses anisole on heating at ~230°. Analytically pure reagent was obtained by recrystallisation from *o*-dichlorobenzene, washing the crystals with C<sub>6</sub>H<sub>6</sub>\* and drying *in vacuo* at 150°. It is extremely moisture sensitive, liberating H<sub>2</sub>S, and should be stored in sealed containers, and preferably weighed in a dry-box. Its molecular weight is consistent with the formula (C<sub>7</sub>H<sub>7</sub>OPS<sub>2</sub>)<sub>2</sub> but slowly polymerises in solution at ~80-85°. Polymerisation is more rapid in polar than non-polar solvents. It is a very useful thiating reagent particularly for converting hydroxy to thiol substituents. [Nishio *J Chem Soc, Perkin Trans I* 1113 1993, *Tetrahedron Lett* **47** 9329 2006, *Beilstein* **16** IV 1113.]

**Lead diethyldithiocarbamate** [17549-30-3] **M 503.7**, **pK<sub>1</sub><sup>25</sup> 3.36 (for N,N-diethyldithio-carbamate)**. Wash it with H<sub>2</sub>O and dry it at 60-70°, or dissolve it in the minimum volume of CHCl<sub>3</sub> and add the same volume of EtOH. Collect the solid that separates and dry it as before. *Alternatively*, recrystallise it by slow evaporation of a CHCl<sub>3</sub> solution at 70-80°. Filter the crystals, wash them with H<sub>2</sub>O until all Pb<sup>2+</sup> ions are eluted (check by adding chromate) and then dry it at 60-70° for at least 10 hours. [Lo et al. *Analyt Chem* **49** 1146 1977.]

**Lissamine Green B {1-[bis-(4,4'-dimethylaminophenyl)methyl]-2-hydroxynaphthalene-3,6-disulfonic acid sodium salt, Acid Green 50}** [3087-16-9] **M 576.6**, **m >200°(dec)**, **CI 44090**, **λ<sub>max</sub> 633nm**. Crystallise it from EtOH/water (1:1, v/v). **Irritant**. [*Beilstein* **14** II 574.]

**Lissapal C (mainly sodium salt of 9-octadecene-1-sulfate)** [2425-51-6]. Reflux the salt with 95% EtOH, then

filter to remove insoluble inorganic electrolytes. The alcoholic solution is then concentrated, and the residue is poured into dry acetone. The precipitate is filtered off, washed in acetone and dried under vacuum [Biswas & Mukerji *J Phys Chem* **64** 1 1960].

**Lissapol LS (mainly sodium salt of anisidine sulfate)** [28903-20-0]. Reflux the salt with 95% EtOH, then filter to remove insoluble inorganic electrolytes. The alcoholic solution is then concentrated, and the residue is poured into dry acetone. The precipitate is filtered off, washed in acetone and dried under vacuum [Biswas & Mukerji *J Phys Chem* **64** 1 1960].

**Lithium dodecylsulfate** [2044-56-6] **M 272.3**. Recrystallise this detergent twice from absolute EtOH and dry it under vacuum. Critical Micellar Concentration (CMC) in H<sub>2</sub>O is 8.77 x 10<sup>-3</sup>M. [Mukerjee et al. *J Phys Chem* **71** 4166 1967, Mysels & Dulin *J Colloid Sci* **10** 461 1955, *Beilstein* **1** IV 1847.]

**Lithium trimethylsilanolate (trimethylsilanol Li salt)** [2004-14-0] **M 96.1, m 120°(dec in air)**. Wash it with Et<sub>2</sub>O and petroleum ether. It sublimes at 180°/1mm as fine transparent needles. [Tatlock & Rochnow *J Org Chem* **17** 1555 1952, *Beilstein* **4** IV 3992.] Suspected **CARCINOGEN**.

**Magnesium dodecylsulfate** [3097-08-3] **M 555.1**. Recrystallise it three times from EtOH and dry it in a vacuum. [*Beilstein* **1** I 1788, **1** IV 1849.]

**Magnesium trifluoromethanesulfonate** [60871-83-2] **M 322.4, m >300°**. Wash it with CH<sub>2</sub>Cl<sub>2</sub> and dry it at 125°/2 hour and 3mmHg. [Corey & Shimoji *Tetrahedron Lett* **24** 171 1983, *Beilstein* **3** IV 34.]

**Manganous ethylenebis(dithiocarbamate) (Maneb)** [12427-38-2] **M 265.3, pK<sub>Est</sub> ~3.0 (for —NCSSH)**. Crystallise this fungicide from EtOH. It is soluble in CHCl<sub>3</sub>. It is a skin irritant. [*Beilstein* **4** III 149, **4** IV 234.]

**1R,2S,5R-Menthyl phosphorochloridite (MenOPCl<sub>2</sub>)** [95456-31-8] **M 257.1, b 110-112°/2.0mm, (62°/150mm ? also reported)**. MenOPCl<sub>2</sub> is prepared by adding a solution (1R,2S,5R)(-)-menthol (78g, 0.50mol) in CH<sub>2</sub>Cl<sub>2</sub> (50ml, or THF) dropwise to a solution of PCl<sub>3</sub> (137.5g, 1.0mol) in CH<sub>2</sub>Cl<sub>2</sub> (50ml, or THF) during 30 minutes. The mixture is stirred for 1 hour under a N<sub>2</sub> atmosphere, the volatiles are removed at ~25°/100mm, pure MenOPCl<sub>2</sub> distilled at ~62°/150mm quantitatively. It has <sup>1</sup>H NMR (400MHz, C<sub>6</sub>D<sub>6</sub>, TMS) with δ at 0.64 (m, 1H, H-4), 0.77 (m, 10H, H-3, H-8, H-9, H-10), 1.15 (M, 3H, H-2, H-5, H-6), 1.44 (m, 2H, H-3, H-4), 1.98 (M, 1H, H-7), 2.30 (M, 1H, H-6), 4.40 (m, 1H, H-1); the <sup>13</sup>C{<sup>1</sup>H} NMR (100MHz, C<sub>6</sub>D<sub>6</sub>, TMS) with δ at 16.1 (s, C-8), 21.2 (s, C-9), 22.0 (s, C-10), 22.8 (s, C-3), 25.1 (s, C-7), 31.4 (s, C-5), 33.8 (s, C-4), 43.3 (s, C-6), 48.7 (s, C-2), 83.5 (d, <sup>2</sup>J<sub>PC</sub> = 9.8Hz, C-1); and the <sup>31</sup>P NMR (121.4MHz, THF, external ref 85% H<sub>3</sub>PO<sub>4</sub>) with δ at 175.6 or (at 162MHz, C<sub>6</sub>D<sub>6</sub>) with δ at 176.1 (d, <sup>3</sup>J<sub>PH</sub> = 13.5Hz). [Alexander et al. *Organometallics* **19** 2700 2000, Brunel & Buono *J Org Chem* **58** 7313 1993, Totland et al. *Macromolecules* **29** 6114 1996]. Note that Hey-Hawkins and co-workers found that a 5 molar excess of PCl<sub>3</sub> in a solvent-free system gave 98% of dichloridite; but when a 1:1 ratio of menthol to PCl<sub>3</sub> was used a mixture of mono- and di- menthyl phosphorochloridites were obtained [Hey-Hawkins et al. *Eur J Inorg Chem* 2776 2009].

**2-Mercaptopyridine N-oxide sodium salt (pyridinethione or pyrithione sodium salt)** [3811-73-2] **M 149.1, m ~250°(dec), pK<sub>1</sub> -1.95, pK<sub>2</sub> 4.65**. When recrystallised from water, it assayed as 98.7% based on AgNO<sub>3</sub> titration [Krivis et al. *Anal Chem* **35** 966 1963; see also Krivis et al. *Anal Chem* **48** 1001 1976, and Barton & Crich *J Chem Soc, Perkin Trans 1* 1603, 1613 1986]. [*Beilstein* **21**/7 V 151.]

**Metanil Yellow (3{4-phenylamino}phenylazo)-benzenesulfonic acid)** [587-98-4] **M 375.4, pK<sub>Est</sub> <0**. It can be salted out from water three times with sodium acetate, then repeatedly extracted with EtOH [McGrew & Schneider *J Am Chem Soc* **72** 2547 1950]. [*Beilstein* **16** II 168.]

**(Methoxycarbonylmethyl)triphenylphosphorane [methyl (triphenylphosphoranylidene)-acetate]** [2605-67-6] **M 334.4, m 162-163°, 169-171°**. Crystallise it by dissolving in it AcOH and adding petroleum ether (b

40-50°) to give colourless plates. Its UV has  $\lambda_{\max}$  ( $A_{1\text{mm}}^{1\%}$ ) at 222nm (865) and 268nm (116) [Isler et al. *Helv Chim Acta* **40** 1242 1957]. [Beilstein **16** IV 977.]

**Methoxycarbonylmethyltriphenylphosphonium bromide** [1779-58-4] **M 415.3, m 163°, 165-170°(dec)**. Wash it with petroleum ether (b 40-50°), recrystallise it from  $\text{CHCl}_3/\text{Et}_2\text{O}$  and dry it at high vacuum at 65°. [Isler et al. *Helv Chim Acta* **40** 1242 1957, Wittig & Haag *Chem Ber* **88** 1654, 1664 1955, Beilstein **16** IV 981.]

**Methoxymethyl trimethylsilane (trimethylsilylmethyl methyl ether)** [14704-14-4] **M 118.3, b 83°/740mm,  $d_4^{25}$  0.758,  $n_D^{25}$  1.3878**. It forms an azeotrope with MeOH (b 60°). If it contains MeOH (check IR for bands above  $3000\text{cm}^{-1}$ ), then wash with  $\text{H}_2\text{O}$  and fractionate. A possible impurity could be chloromethyl trimethylsilane (b 97°/740mm). [Speier *J Am Chem Soc* **70** 4142 1948, Beilstein **4** III 1844.] It is an IRRITATING FLAMMABLE liquid.

**1-Methoxy-2-methyl-1-trimethylsiloxypropene (dimethyl ketene methyl trimethylsilyl acetal)** [31469-15-5] **M 174.3, b 121-122°/0.35mm, 125-126°/0.4mm, 148-150°/atm,  $d_4^{20}$  0.86**. Add  $\text{Et}_2\text{O}$ , wash with cold  $\text{H}_2\text{O}$ , dry ( $\text{Na}_2\text{SO}_4$ ), filter, evaporate  $\text{Et}_2\text{O}$ , and distil the oily residue in a vacuum. [Ainsworth et al. *J Organometal Chem* **46** 59 1972.]

**trans-1-Methoxy-3-(trimethylsilyloxy)-1,3-butadiene (Danishefsky's diene)** [54125-02-9] **M 172.3, b 68-69°/14mm, 70-72°/16mm,  $d_4^{20}$  0.885,  $n_D^{20}$  1.4540**. It may contain up to 1% of the precursor 4-methoxybut-4-ene-2-one. It is easily purified by distilling through a Vigreux column in a vacuum and taking the middle fraction. [Danishefsky & Kitihara *J Am Chem Soc* **96** 7807 1974, Danishefsky *Acc Chem Res* **14** 400 1981.]

**Methylarsonic acid** [124-58-3] **M 139.9, m 159.8°, 161°,  $\text{pK}_1^{25}$  4.58,  $\text{pK}_2^{25}$  7.82** [ $\text{As}(\text{OH})_2$ ]. Recrystallise this herbicide from  $\text{Me}_2\text{CO}$  or absolute EtOH (white plates; its solubility is 28g/100ml EtOH). [Quick & Adams *J Am Chem Soc* **44** 809 1922, Beilstein **4** H 613, **4** I 577, **4** II 996, **4** III 1822, **4** IV 3682.]

**Methyl dichlorosilane (dichloro methylsilane)** [75-54-7] **M 115.0, m -92.5°, b 41°/748mm, 40.9°/760mm, 40-45°/atm,  $d_4^{27}$  1.105**. Impurities are generally other chloromethyl silanes. Distil it through a conventional Stedman column of 20 theoretical plates or more. It should be protected from  $\text{H}_2\text{O}$  by storing over  $\text{P}_2\text{O}_5$ . [Stock & Somieski *Chem Ber* **52** 695 1919, Sauer *J Am Chem Soc* **68** 962 1946, Beilstein **4** IV 4096.]

**Methyl Orange (sodium 4,4'-dimethylaminophenylazobenzenesulfonate)** [547-58-0] **M 327.3,  $\text{pK}_1^{25}$  3.56,  $\text{pK}_2^{25}$  6.49**. Recrystallise it twice from hot water, then wash it with a little EtOH followed by diethyl ether. It is an indicator: pH 3.1 (red) and pH 4.4 (yellow). [Beilstein **16** IV 510.]

**Methylphenyl dichlorosilane (dichloro methyl phenylsilane)** [149-74-6] **M 191.1, b 114-115°/50mm, 202-205°/atm,  $d_4^{20}$  1.17**. Purify it by fractionation using an efficient column. It hydrolyses *ca* ten times more slowly than methyltrichlorosilane and *ca* sixty times more slowly than phenyltrichlorosilane. [Shaffer & Flanigen *J Phys Chem* **61** 1591 1957, Beilstein **16** III 1211, **16** IV 1517.]

**Methylphosphonic acid** [993-13-5] **M 96.0, m 104-106°, 105-107°, 108°,  $\text{pK}_1^{25}$  2.12,  $\text{pK}_2^{25}$  7.29**. If it tests for  $\text{Cl}^-$ , then add  $\text{H}_2\text{O}$  and evaporate to dryness, repeat several times till free from  $\text{Cl}^-$ . The residue solidifies to a wax-like solid. *Alternatively*, dissolve the acid in the minimum volume of  $\text{H}_2\text{O}$ , add charcoal, warm, filter and evaporate to dryness in a vacuum over  $\text{P}_2\text{O}_5$ . [Kosolapoff *J Am Chem Soc* **75** 3379 1953.] The *di-Na salt* is prepared from 24g of acid in 50ml of dry EtOH, and a solution of 23g Na dissolved in 400ml EtOH is added. A white precipitate is formed, but the mixture is refluxed for 30 minutes to complete the reaction. Filter off the solid and recrystallise it from 50% EtOH. Dry the crystals in a vacuum desiccator. [Thompson *J Chem Soc* 3292 1952, Beilstein **4** IV 3498.]

**Methylphosphonic dichloride** [676-97-1] **M 132.9, m 33°, 33-37°, b 53-54°/10mm, 64-67°/20.5mm, 86°/44mm, 162°/760mm,  $d_4^{40}$  1.4382**. Fractionally redistil it until the purity as checked by hydrolysis and

acidimetry for Cl<sup>-</sup> is correct and the distillate should solidify on cooling. [Kinnear & Perren *J Chem Soc* 3437 1952, Crofts & Kosolapoff *J Am Chem Soc* 75 3379 1952, for IR see McIvor et al. *Can J Chem* 34 1611 1956, *Beilstein* 4 IV 3509.]

**Methyl Thymol Blue, sodium salt** {MTB, 3,3'-bis[*N,N'*-di(carboxymethyl)amino]thymolsulfonephthalein sodium salt} [1945-77-3] **M 844.8,  $\epsilon$  1.89 x 10<sup>4</sup> at 435nm, pH 5.5, pK<sub>1</sub><sup>25</sup> 3.0, pK<sub>2</sub><sup>25</sup> 3.3, pK<sub>3</sub><sup>25</sup> 3.8, pK<sub>4</sub><sup>25</sup> 7.4 (pK<sub>4</sub><sup>25</sup> 7.2), pK<sub>5</sub><sup>25</sup> 11.5 pK<sub>6</sub><sup>25</sup> 13.4.** The starting material for synthesis is Thymol Blue. Purify it as for Xylenol Orange in "Heterocyclic Compounds" in this Chapter. [Tereshin et al. *J Anal Chem USSR (Engl Trans)* 20 1138 1965, Körbl & Kakác *Col Czech Chem Commun* 23 889 1958, *Beilstein* 19/8 V 619.]

**Methyl trichlorosilane** [75-79-6] **M 149.5, b 13,7°/101mm, 64.3°/710.8mm, 65.5°/745mm, 66.1°/atm, d<sub>4</sub><sup>20</sup> 1.263, n<sub>D</sub><sup>20</sup> 1.4110.** If not very pure, distil it before use. The purity is checked by <sup>29</sup>Si NMR ( $\delta$  in MeCN is 13.14 ppm with respect to Me<sub>4</sub>Si). Possible contaminants are other silanes which can be removed by fractional distillation through a Stedman column of >72 theoretical plates with total reflux and 0.35% take-off. This apparatus should be under N<sub>2</sub> gas at a rate of 12 bubbles/minute fed into the line using an Hg manometer to control the pressure. It is sensitive to H<sub>2</sub>O. [Gillam et al. *J Am Chem Soc* 73 4252 1951, Olah et al. *J Org Chem* 48 3667 1983, *Beilstein* 4 IV 4212.]

**Methyl triethoxysilane** [2031-67-6] **M 178.31, b 142-144.5°/742mm, 141°/765mm, 141.5°/775mm, d<sub>4</sub><sup>20</sup> 0.8911, n<sub>D</sub><sup>20</sup> 1.3820.** Purify by fractionating it repeatedly in a stream of N<sub>2</sub> through a 3' Heligrid packed Todd column. It is hydrolysed by H<sub>2</sub>O and yields cyclic polysiloxanes on hydrolysis in the presence of acid in \*C<sub>6</sub>H<sub>6</sub>. [Bee et al. *J Am Chem Soc* 77 1292 1955, Sprung & Guenther *J Am Chem Soc* 77 3990 1955, *Beilstein* 4 IV 4204.]

**Methyl trimethoxysilane** [1185-55-3] **M 136.2, b 102°/760mm, d<sub>4</sub><sup>20</sup> 1.3687, n<sub>D</sub><sup>20</sup> 1.3711.** Likely impurities are 1,3-dimethyltetramethoxy disiloxane (b 31°/1mm) and cyclic polysiloxanes, see previous entry methyl triethoxysilane. [Tamborski & Post *J Org Chem* 16 1400 1952, Seyferth & Rochow *J Org Chem* 20 250 1955, *Beilstein* 4 IV 4203.]

***N*-Methyl-*N*-trimethylsilylacetamide** [7449-74-3] **M 145.3, b 48-49°/11mm, 84°/13mm, 105-107°/35mm (solid at room temperature), d<sub>4</sub><sup>20</sup> 0.90, n<sub>D</sub><sup>20</sup> 1.4379.** A likely impurity is Et<sub>3</sub>N.HCl which can be detected by its odour. If it is completely soluble in \*C<sub>6</sub>H<sub>6</sub>, then redistil; otherwise dissolve it in this solvent, filter and evaporate first in a vacuum at 12mm, then fractionate; all operations should be carried out in a dry N<sub>2</sub> atmosphere. [Klebe et al. *J Am Chem Soc* 88 3390 1966, Ried & Suarez-Rivero *Chem Ber* 96 1473 1963, *Beilstein* 4 IV 4011.]

**Methyl trimethylsilylacetate** [2916-76-9] **M 146.3, b 65-68°/50mm, d<sub>4</sub><sup>20</sup> 0.89.** Dissolve it in Et<sub>2</sub>O, shake with 1M HCl, wash with H<sub>2</sub>O, aqueous saturated NaHCO<sub>3</sub>, H<sub>2</sub>O again, and dry it (a precipitate may be formed in the NaHCO<sub>3</sub> solution and should be drawn off and discarded). The solvent is distilled off, and the residue is fractionated through a good column. The IR (CHCl<sub>3</sub>) has  $\nu_{\max}$  □□1728cm<sup>-1</sup>. [Fessenden & Fessenden *J Org Chem* 32 3535 1967, Matsuda et al. *J Org Chem* 45 237 1980, *Beilstein* 4 III 1855, 4 IV 3974 for Et ester.]

**Methyl 2-(trimethylsilyl)propionate** [55453-09-3] **M 160.3, b 155-157°/atm, d<sub>4</sub><sup>20</sup> 0.89.** Dissolve it in Et<sub>2</sub>O, wash it with aqueous NaHCO<sub>3</sub>, H<sub>2</sub>O, 0.1M HCl, H<sub>2</sub>O again, dry (MgSO<sub>4</sub>), evaporate and distil it. [Emde & Simchen *Synthesis* 867 1977, Oppolzer et al. *Tetrahedron* 39 3695 1983, Crimmin et al. *J Chem Soc Perkin Trans 1* 541 1985.]

***N*-Methyl-*N*-trimethylsilyl trifluoroacetamide** [24589-78-4] **M 199.3, b 78-79°/130mm.** Fractionate the amide through a 40mm Vigreux column. Usually it contains ca 1% of methyl trifluoroacetamide and 1% of other impurities which can be removed by gas chromatography or fractionating using a spinning band column. [Donike *J Chromatogr* 42 103 1969, Donike *J Chromatogr* 103 91 1975, *Beilstein* 4 IV 4011.]

**Methyl triphenoxyphosphonium iodide** [17579-99-6] **M 452.2, m 114° (sealed tube), 146°.** Gently heat the impure iodide with good grade Me<sub>2</sub>CO. The saturated solution obtained is decanted rapidly from undissolved

salt and treated with an equal volume of dry Et<sub>2</sub>O. The iodide separates as flat needles which are collected by centrifugation, washed several times with dry Et<sub>2</sub>O, and dried in a vacuum over P<sub>2</sub>O<sub>5</sub>. For this recrystallisation it is essential to minimise the time of contact with Me<sub>2</sub>CO and to work rapidly and with rigorous exclusion of moisture. If the crude material is to be used, it should be stored under dry Et<sub>2</sub>O, and dried and weighed *in vacuo* immediately before use. [Landauer & Rydon *J Chem Soc* 224 1953, Hudson et al. *J Chem Soc Perkin Trans I* 982 1974, *Beilstein* 6 IV 704.]

**Methyl triphenylphosphonium bromide** [1779-49-3] **M 357.3, m 229-230°(corr), 227-229°, 230-233°**. If the solid is sticky, wash it with \*C<sub>6</sub>H<sub>6</sub> and dry it in a vacuum over P<sub>2</sub>O<sub>5</sub>. [Marvel & Gall *J Org Chem* 24 1494 1959, *Chem Ber* 87 1318 1954, Milas & Priesing *J Am Chem Soc* 79 6295 1957, Wittig & Schöllkopf *Org Synth* 40 66 1960.] The *iodide*, on recrystallisation from H<sub>2</sub>O, has **m 187.5-188.5°** [Mann et al. *J Chem Soc* 1130 1953, Wittig & Geissler *Justus Liebigs Ann Chem* 580 44 1953]. [*Beilstein* 16 IV 981.]

**Methyl vinyl dichlorosilane (dichloro methyl vinyl silane)** [124-70-9] **M 141.1, b 43-45.5°/11-11.5mm, 91°/742mm, 92.5°/743.2mm, 92.5-93°/atm, d<sub>4</sub><sup>20</sup> 1.0917, n<sub>D</sub><sup>20</sup> 1.444**. Likely impurities are dichloromethylsilane, butadienyl-dichloromethylsilane. Fractionate the silane through a column packed with metal filings (20 theoretical plates) at atmospheric or reduced pressure. [*Izv Akad Nauk SSSR Ser Khim* 1474 1957 and 767 1958, *Beilstein* 4 III 1894, 4 IV 4184.]

**Milling Red SWB {1-[4-[4-[4-toluenesulfonyloxy]phenylazo](3,3'-dimethyl-1,1'-biphenyl)-4'-azo]-2-hydroxynaphthalene-6,8-disulfonic acid di-Na salt, Acid Red 114}** [6459-94-5] **M 830.8, m dec >250°, CI 23635, λ<sub>max</sub> ~514nm**. Salt out three times with sodium acetate, then repeatedly extract it with EtOH and dry the solid in air. [McGrew & Schneider *J Am Chem Soc* 72 2547 1950, *Beilstein* 16 II 140.] See Solochrome Violet R [2092-55-9] in "Aromatic compounds" in this Chapter.

**Milling Yellow G** [51569-18-7]. Salted out three times with sodium acetate, then repeatedly extracted with EtOH. [McGrew & Schneider *J Am Chem Soc* 72 2547 1950, *Beilstein* 16 II 125.] See Solochrome Violet R [2092-55-9] in "Aromatic compounds" in this Chapter.

**Naphthalene Scarlet Red 4R [1-(4-sulfonaphthalene-1-azo)-2-hydroxynaphthalene-6,8-disulfonic acid tri-Na salt, New Coccine, Acid Red 18]** [2611-82-7] **M 604.5, m >250°(dec), CI 16255, λ<sub>max</sub> 506nm**. Dissolve the dye in the minimum quantity of boiling water, filter and enough EtOH is added to precipitate *ca* 80% of the dye. This process is repeated until a solution of the dye in aqueous 20% pyridine has a constant extinction coefficient. [*Beilstein* 16 I 306.]

**Naphthol Yellow S (citronin A, flavianic acid sodium salt, 8-hydroxy-5,7-dinitro-2-naphthalene sulfonic acid disodium salt)** [846-70-8] **M 358.2, decomposes on heating**. It is a water-soluble greenish yellow powder. The *free sulfonic acid* can be recrystallised from dilute HCl (m 150°) or AcOH/EtOAc (m 148-149.5°). The disodium salt is then obtained by dissolving the acid in two equivalents of aqueous NaOH and evaporating to dryness and drying the residue in a vacuum desiccator. The sodium salt can be recrystallised from the minimum volume of H<sub>2</sub>O or from EtOH [Dermer & Dermer *J Am Chem Soc* 61 3302 1939]. [*Beilstein* 11 III 542.]

**1,2-Naphthoquinone-4-sulfonic acid sodium salt (3,4-dihydro-3,4-dioxo-1-naphthlene sulfonic acid sodium salt)** [521-24-4] **M 260.2, pK<sub>Est</sub> <0**. It forms yellow crystals from aqueous EtOH and should be dried at 80° *in vacuo*. Its solubility in H<sub>2</sub>O is 5% [Martin & Fieser *Org Synth Coll Vol III* 633 1955, Danielson *J Biol Chem* 101 507 1933, UV: Rosenblatt et al. *Anal Chem* 27 1290 1955]. [*Beilstein* 11 IV 668.]

**1-Naphthyl phosphate disodium salt** [2183-17-7] **M 268.1, pK<sub>1</sub><sup>25</sup> 0.97, pK<sub>2</sub><sup>25</sup> 5.85 (for free acid)**. The free acid has **m 157-158°** (from Me<sub>2</sub>CO/\*C<sub>6</sub>H<sub>6</sub>). The *free acid* is recrystallised several times by adding 20 parts of boiling \*C<sub>6</sub>H<sub>6</sub> to a hot solution of 1 part of *free acid* and 1.2 parts of Me<sub>2</sub>CO. It has **m 157-158°**. [Chanley & Ferguson *J Am Chem Soc* 77 4002 1955.] The *monosodium salt* is precipitated from a solution of the acid phosphate in MeOH by addition of an equivalent of MeONa in MeOH. [Friedman & Seligman *J Am Chem Soc*

72 624 1950, *Beilstein* 6 IV 4226.] See also entry on p 877 in Chapter 7.

**2-Naphthyl phosphate monosodium salt** [14463-68-4] M 246.1, m 203-205°, pK<sub>1</sub><sup>25</sup> 1.25, pK<sub>2</sub><sup>25</sup> 5.83 (for free acid). Recrystallise it from H<sub>2</sub>O (10ml) containing NaCl (0.4g). The salt is collected by centrifugation and dried in a vacuum desiccator, m 203-205° (partially resolidifies and re-melts at 244°). It crystallises from MeOH (m 222-223°). The free acid is recrystallised several times by addition of 2.5 parts of hot CHCl<sub>3</sub> to a hot solution of the free acid (1 part) in Me<sub>2</sub>CO (1.3 parts), m 177-178°. [Friedman & Seligmann *J Am Chem Soc* 73 5292 1951, Chanley & Feaggeson *J Am Chem Soc* 77 4002 1955, *Beilstein* 6 H 647, 6 III 2989, 6 IV 428.] See also entry on p 877 in Chapter 7.

**2-Nitrophenol-4-arsonic acid (4-hydroxy-3-nitrophenylarsonic acid)** [121-19-7] M 263.0, pK<sub>Est(1)</sub>~4.4 As(O)-(OH)-(O<sup>-</sup>), pK<sub>Est(2)</sub>~7.4 (phenolic OH), pK<sub>Est(3)</sub>~7.7 (As(O)-2(O<sup>-</sup>)). It crystallises from water and is used for the spectroscopic detection of Zn. [*Beilstein* 16 II 468, 16 III 1073, 16 IV 1188.]

**1-Nitroso-2-naphthol-3,6-disulfonic acid, di-Na salt, hydrate (Nitroso-R-salt)** [525-05-3] M 377.3, m >300°, pK<sub>Est(1)</sub><0 (SO<sub>3</sub><sup>-</sup>), pK<sub>Est(2)</sub>~7 (OH). Purify the salt by dissolution in aqueous alkali and precipitation by addition of HCl. The pKa is 7.13. [Oka & Miyamoto *J Chem Soc Jpn* (Pure Chem Sectn) 76 672 1955 (*Chem Abstr* 11882 1956I), *Beilstein* 11 IV 669.]

**Nuclear Fast Red (1-amino-2,4-dihydroxy-5,10-anthraquinone-3-sulfonic acid Na Salt)** [6409-77-4] M 357.3, m >290°(dec), λ<sub>max</sub> 518nm. A solution of 5g of the dye in 250ml of warm 50% EtOH is cooled to 15° for 36 hours, then filtered on a Büchner funnel, washed with EtOH until the washings are colourless, then with 100ml of Et<sub>2</sub>O and dry it over P<sub>2</sub>O<sub>5</sub> *in vacuo*. It is a biological stain that is also used for the estimation of Ca. [Kingsley & Robnett *Anal Chem* 33 552 1961.]

**Octadecyl trichlorosilane** [112-04-9] M 387.9, b 159-162°/13mm, 185-199°/2-3mm, d<sub>4</sub><sup>30</sup> 0.98. Purify it by fractional distillation at high vacuum. [Winstein & Seubold *J Am Chem Soc* 69 2916 1947, *Beilstein* 4 IV 4256.]

**Octamethyl cyclotetrasiloxane** [556-67-2] M 296.6, m 17-19°, 17.58°, 18.5°, b 74°/20mm, 176.4°/760mm, d<sub>4</sub><sup>29.3</sup> 0.9451, n<sub>D</sub><sup>30</sup> 1.3968. The solid exists in two forms, m 16.30° and 17.65°. Dry it over CaH<sub>2</sub> and distil it. Further fractionation can be effected by repeated partial freezing and discarding the liquid phase. [Osthoff & Grubb *J Am Chem Soc* 76 399 1954, Hoffman *J Am Chem Soc* 75 6313 1953, *Beilstein* 4 IV 4125.]

**Octamethyl trisiloxane** [107-51-7] M 236.5, m -80°, b 151.7°/747mm, 153°/760mm. Distil it twice, the middle fraction from the first distillation is again distilled, and the middle fraction of the second distillation is used. [Patnode & Wilcock *J Am Chem Soc* 68 358, Wolcock *J Am Chem Soc* 68 691 1946, Thompson *J Chem Soc* 1908 1953, *Beilstein* 4 IV 4115.]

**Octaphenyl cyclotetrasiloxane** [546-56-5] M 793.2, m 201-202°, 203-204°, b 330-340°/1mm. Recrystallise it from AcOH, EtOAc, \*C<sub>6</sub>H<sub>6</sub> or \*C<sub>6</sub>H<sub>6</sub>/EtOH. It forms two stable isomorphs and both forms, as well as the mixture, melt at 200-201°. There is a metastable form which melts at 187-189°. [Burkhard et al. *J Am Chem Soc* 67 2174 1945, Hyde et al. *J Am Chem Soc* 69 488 1947, *Beilstein* 16 IV 1530.]

**Octyl trichlorosilane** [5283-66-9] M 247.7, b 96.5°/10mm, 112°/15mm, 119°/28mm, 229°/760mm, d<sub>4</sub><sup>20</sup> 1.0744, n<sub>D</sub><sup>20</sup> 1.4453. Purify the silane by repeated fractionation using a 15-20 theoretical plate glass column packed with glass helices. This can be done more efficiently using a spinning band column. Its purity can be checked by analysing for HCl (*ca* 0.5-1g of sample is dissolved in 25ml of MeOH, diluted with H<sub>2</sub>O and the HCl formed by hydrolysis is titrated with standard alkali). It is moisture sensitive. [Whitmore *J Am Chem Soc* 68 475 1946, El-Abbadly & Anderson *J Am Chem Soc* 80 1737 1958, *Beilstein* 4 III 1907.]

**Orange I [tropaeolin 000 Nr1, 4-(4-hydroxy-1-naphthylazo)benzenesulfonic acid sodium salt]** [523-44-4] M 350.3, m >260°(dec). Purify the dye by dissolving it in the minimum volume of H<sub>2</sub>O, adding, with stirring, a

large excess of EtOH. The salt separates as orange needles. It is collected by centrifugation or filtration, washed with absolute EtOH (3x) and Et<sub>2</sub>O (2x) in the same way, and dried in a vacuum desiccator over KOH. The *free acid* can be recrystallised from EtOH. [Slotta & Franke *Chem Ber* **64** 86 1931, *Beilstein* **16** H 275, **16** II 117, **16** IV 410.] The purity can be checked by titration with titanium chloride [Klotz *J Am Chem Soc* **68** 2299 1946].

**Orange II [tropaeolin 000 Nr2, 4-(2-hydroxy-1-naphthylazo)benzenesulfonic acid sodium salt]** [633-96-5] **M 350.3**. Purification is as for Orange I. Its solubility in H<sub>2</sub>O is 40g/L at 25°. [Müller et al. *Helv Chim Acta* **35** 2579 1952.] Also purify it by extracting it with a small volume of cold water, then crystallising it by dissolving in boiling water, cooling to *ca* 80°, adding two volumes of EtOH and cooling. When cold, the precipitate is filtered off, washed with a little EtOH and dried in air. It can be salted out from aqueous solution with sodium acetate, then repeatedly extracted with EtOH. Meggy and Sims [*J Chem Soc* 2940 1956], after crystallising the sodium salt twice from water, dissolved it in cold water (11ml/g) and added conc HCl to precipitate the *acid dye* which was separated by centrifugation, redissolved and again precipitated with acid. After washing the precipitate three times with 0.5M acid, it was dried over NaOH, recrystallised twice from absolute EtOH, washed with a little Et<sub>2</sub>O, dried over NaOH and stored over conc H<sub>2</sub>SO<sub>4</sub> in the dark. It can then be converted to the pure salt with the calculated amount of NaOH or Na<sub>2</sub>CO<sub>3</sub>. [*Beilstein* **16** IV 408.]

**Orange G (1-phenylazo-2-naphthol-6,8-disulfonic acid di-Na salt)** [1936-15-8] **M 452.4**, **pK<sub>Est</sub>~9**. Recrystallise this dye from 75% EtOH, dry it for 3 hours at 110° and keep it in a vacuum desiccator over H<sub>2</sub>SO<sub>4</sub>. The *free acid* crystallises from EtOH or conc HCl in deep red needles with a green reflex. [Conant & Pratt *J Am Chem Soc* **48** 2483 1923, Drew & Landquist *J Chem Soc* 292 1938, *Beilstein* **16** H 301, **16** I 305, **16** II 141, **16** III 327.]

**Orange RO {acid orange 8, 1,8-[bis(4-*n*-propyl-3-sulfophenyl-1-amino)]anthra-9,10-quinone di-Na salt}** [5850-86-2] **M 364.4**, **CI 15575**, **λ<sub>max</sub> 490nm**. Salt it out three times with sodium acetate, then extract it repeatedly with EtOH and dry *in vacuo*.

**Pentafluorophenyl dimethylchlorosilane (Flopemesyl chloride)** [20082-71-7] **M 260.7**, **b 89-90°/10mm**, **d<sub>4</sub><sup>30</sup> 1.403**, **n<sub>D</sub><sup>30</sup> 1.447**. If it goes turbid on cooling due to separation of some LiCl, then dissolve it in Et<sub>2</sub>O, filter and fractionate it in a vacuum. [Morgan & Poole *J Chromatogr* **89** 225 1974, Birkinshaw et al. *J Chromatogr* **132** 548 1977.]

**Phenylarsonic acid (benzenearsonic acid)** [98-05-5] **M 202.2**, **m 155-158°(dec)**, **158-162°(dec)**, **pK<sub>1</sub><sup>25</sup> 3.65**, **pK<sub>2</sub><sup>25</sup> 8.77**. Crystallise it from H<sub>2</sub>O (3ml/g) between 90° and 0°. *Alternatively*, dissolve 600g of the acid in 500ml of boiling H<sub>2</sub>O, add 20g of Norite, filter hot, cool, filter off the crystals and dry them. On heating at ~154-160° it is converted to the *anhydride*. [Bullard & Dickery *Org Synth Coll Vol II* 494 1943, for the 4-nitro derivative see Ruddy & Starkey *Org Synth Coll Vol III* 665 1955, *Beilstein* **16** H 868, **16** I 448, **16** II 457, **16** III 1057, **16** IV 1183.]

**Phenylboronic acid (benzeneboronic acid)** [98-80-6] **M 121.9**, **m ~43°, 215-216° (anhydride)**, **217-220°**, **pK<sub>1</sub><sup>25</sup> 8.83**. It recrystallises from H<sub>2</sub>O, but it can convert spontaneously to *benzeneboronic anhydride* or phenylboroxide on standing in dry air. A possible impurity is dibenzeneborinic acid which can be removed by washing with petroleum ether. Heating in an oven at 110°/760mm for 1 hour converts it to the *anhydride* **m** 214-216°. Its solubility in H<sub>2</sub>O is 1.1% at 0° and 2.5% at 25°, and in EtOH it is 10% (w/v). [Gilman & Moore *J Am Chem Soc* **80** 3609 1958.] If the acid is required, not the anhydride, the acid (from recrystallisation in H<sub>2</sub>O) is dried in a slow stream of air saturated with H<sub>2</sub>O. The *anhydride* is converted to the acid by recrystallisation from H<sub>2</sub>O. The acid gradually dehydrates to the *anhydride* if left in air at room temperature with 30-40% relative humidity. The melting point is usually that of the anhydride because the acid dehydrates before it melts [Washburn et al. *Org Synth Coll Vol IV* 68 1963]. [*Beilstein* **16** IV 1654.]

**1,2-Phenylenephosphorochloridate (2-chloro-1,3,2-benzodioxaphosphole-2-oxide)** [1499-17-8] **M 190.5**, **m 52°, 58-59°, 59-61°**, **b 80-81°/1-2mm**, **118°/10mm**, **122°/12mm**, **125°/16mm**, **155°/33mm**. After distilling it in a vacuum, it sets to a colourless solid. It is soluble in petroleum ether, \*benzene and slightly soluble in Et<sub>2</sub>O.

[Khwaja et al. *J Chem Soc (C)* 2092 1970, Anschütz & Broeker *Justus Liebigs Ann Chem* **454** 109 1927, *Beilstein* **6** IV 5602.]

**Phenylphosphinic acid [benzenephosphinic acid, PhPH(O)(OH)]** [1779-48-2] **M 142.1, m 70°, 71°, 83-85°, 86°, pK<sub>1</sub><sup>25</sup> 1.75.** Crystallise it from H<sub>2</sub>O (solubility is 7.7% at 25°). Also purify it by placing the solid in a flask covered with dry Et<sub>2</sub>O, and allowed it to stand for 1 day with intermittent shaking. Et<sub>2</sub>O is decanted off and the process repeated. After filtration, excess Et<sub>2</sub>O is removed in a vacuum. It has also been recrystallised from \*C<sub>6</sub>H<sub>6</sub>. [Michaelis *Justus Liebigs Ann Chem* **181** 265 1876, Banks & Skoog *Anal Chem* **29** 109 1957, NMR: Van Wazer et al. *J Am Chem Soc* **78** 5715 1956, *Beilstein* **16** IV 1033.]

**Phenylphosphonic acid** [1571-33-1] **M 158.1, m 164.5-166°, pK<sub>2</sub><sup>25</sup> 7.43 (7.07).** It is best to recrystallise it from H<sub>2</sub>O by concentrating an aqueous solution to a small volume and allowing it to crystallise. Wash the crystals with ice cold H<sub>2</sub>O and dry them in a vacuum desiccator over H<sub>2</sub>SO<sub>4</sub>. [Lecher et al. *J Am Chem Soc* **76** 1045 1954.] pK<sub>2</sub><sup>25</sup> values in H<sub>2</sub>O are 7.07, and in 50% EtOH 8.26. [Jaffé et al. *J Am Chem Soc* **75** 2209 1953, IR: Daasch & Smith *Anal Chem* **23** 853 1951, *Beilstein* **16** IV 1068.]

**Phenylphosphonic dichloride (P,P-dichlorophenyl phosphine oxide)** [824-72-6] **M 195.0, m 3°, b 83-84°/1mm, 135-136°/23mm, d<sub>4</sub><sup>30</sup> 1.977, n<sub>D</sub><sup>30</sup> 1.5578.** Fractionally distil it using a very efficient or a spinning band column. [Lecher et al. *J Am Chem Soc* **76** 1045 1954, NMR: Müller et al. *J Am Chem Soc* **78** 3557 1956, Van Wazer et al. *J Am Chem Soc* **78** 5715 1956, IR: Daasch & Smith *Anal Chem* **23** 853 1951, *Beilstein* **16** IV 1074.]

**Phenylphosphonous acid [PhP(OH)<sub>2</sub>] [tautomer of phenylphosphinic acid – above]** [121-70-0] **M 141.1, m 71°, pK<sub>Est</sub> <0, pK<sub>17</sub> 2.1.** Crystallise it from hot H<sub>2</sub>O or \*C<sub>6</sub>H<sub>6</sub>. [*Beilstein* **16** IV 1033.]

**Phenylphosphonous dichloride (P,P-dichloro phenyl phosphine)** [644-97-3] **M 179.0, m -51°, b 68-70°/1mm, 224-226°/atm, d<sub>4</sub><sup>30</sup> 1.9317, n<sub>D</sub><sup>35</sup> 1.5962.** Distil it in a vacuum by fractionating through a 20cm column packed with glass helices (better to use a spinning band column) [Buchner & Lockhart *J Am Chem Soc* **73** 755 1951, NMR: Müller et al. *J Am Chem Soc* **78** 3557 1956, IR: Daasch & Smith *Anal Chem* **23** 853 1951]. It forms a yellow *Ni* complex: Ni(C<sub>6</sub>H<sub>5</sub>Cl<sub>2</sub>P)<sub>4</sub> (**m** 91-92°, from H<sub>2</sub>O) [Quin *J Am Chem Soc* **79** 3681 1957] and a yellow complex also with molybdenum carbonyl: Mo(CO)<sub>3</sub>.(C<sub>6</sub>H<sub>5</sub>Cl<sub>2</sub>P)<sub>3</sub> (**m** 106-110° dec) [Abel et al. *J Chem Soc* 2323 1959]. [*Beilstein* **16** IV 972.]

**Phenyl phosphoryl dichloride** [770-12-7] **M 211.0, m -1°, b 103-104°/2mm, 110-111°/10mm, 130-134°/21mm, 241-243°/atm, d<sub>4</sub><sup>30</sup> 1.4160, n<sub>D</sub><sup>30</sup> 1.5216.** Fractionally distil it under as high a vacuum as possible using an efficient fractionating column or a spinning band column. It should be redistilled if the IR is not very satisfactory [IR: Bellamy & Beecher *J Chem Soc* 475 1952, Freeman & Colver *J Am Chem Soc* **60** 750 1938, Orloff et al. *J Am Chem Soc* **80** 727 1958]. [*Beilstein* **6** IV 737.] **HARMFUL VAPOURS.**

**Phenylsilane (PhSiH<sub>3</sub>)** [694-53-1] **M 108.2, b 62°/100mm, 120°/atm, d<sub>4</sub><sup>25</sup> 0.877, n<sub>D</sub><sup>20</sup> 1.5125.** It is best prepared by reduction of PhSiCl<sub>3</sub> with LiAlH<sub>4</sub>/Et<sub>2</sub>O: stir at room temperature overnight, pour onto crushed ice, extract with Et<sub>2</sub>O, dry the extract (Drierite), filter, evaporate and distil the residual oil preferably in a vacuum [Beukesser et al. *J Am Chem Soc* **74** 648 1952, Koch et al. *Rec Trav Chim Pays Bas* **114** 206 1995, Finholt et al. *J Am Chem Soc* **69** 2692 1947].

It is a useful reagent for deoxygenating phosphine oxides to phosphines, and will reduced chiral phosphine oxides to chiral phosphines with retention of configuration [Marsi *J Org Chem* **39** 265 1974]. It is a reducing agent in radical reactions [Perez et al. *J Org Chem* **52** 5570 1967], and deoxygenates primary and secondary alcohols *via* their xanthate or thionocarbonate esters (prepared from aryl-OCSCl and an inhibitor, e.g benzoyl peroxide) in 60-100 minutes in >87% yields [Barton et al. *Synlett* 435 1991]. [*Beilstein* **16** III 1198, **16** IV 1360.]

**Phenylthio trimethylsilane (trimethyl phenylthio silane)** [4551-15-9] **M 182.4, b 95-99°/12mm, d<sub>4</sub><sup>30</sup> 0.97.** Purification is as for phenyl trimethylsilylmethyl sulfide.

**Phenyl trimethoxysilane (trimethoxysilyl benzene)** [2996-92-1] **M 198.3, b 103°/20mm, 130.5-131°/45mm,  $d_4^{35}$  1.022,  $n_D^{35}$  1.4698.** Fractionate it through an efficient column but note that it forms an azeotrope with MeOH which is a likely impurity. [Kantor *J Am Chem Soc* **75** 2712 1953 *Beilstein* **16** IV 1556.]

**Phenyl trimethylsilylmethyl sulfide [(phenylthiomethyl)trimethylsilane]** [17873-08-4] **M 196.4, b 48°/0.04mm, 113-115°/12mm, 158.5°/52mm,  $d_4^{30}$  0.9671,  $n_D^{30}$  1.5380.** If the sample is suspect, then add H<sub>2</sub>O, wash it with 10% aqueous NaOH, H<sub>2</sub>O again, dry (anhydrous CaCl<sub>2</sub>) and fractionally distil it through a 2ft column packed with glass helices. [Cooper *J Am Chem Soc* **76** 3713 1954.]

**Phosphine** [7803-51-2] **M 34.0, m -133°, b -87.5°/760mm, -87.7°/760mm, critical temperature 51.3°,  $d_4^{25}$  1.5307,  $pK^{25}$  ~ -14 (extremely weak base).** Phosphine is a gas with a very strong odour of fish and is **POISONOUS**. The gas is poorly soluble in H<sub>2</sub>O (0.26ml/ml at 20°), and ignites spontaneously in air with a luminous glow. It has been prepared in various ways. A convenient preparation is to make aluminium phosphide by mixing 2 parts of Al powder and 1 part of red P on a piece of paper. By igniting the paper, the mixture becomes white-hot resulting in a spongy mass of aluminium phosphide [Hoffman *J Am Chem Soc* **43** 1684 1921, Bodoux *Bull Soc Chim Fr* **27** (3) 568 1902]. This phosphide reacts with cold H<sub>2</sub>O to give a steady stream of PH<sub>3</sub>. [Use an efficient fume cupboard in these experiments.] Fortunately, the gas is available in metal cylinders, but all due precautions should be taken. [Klement in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 525-530 1963, Gokhale and Jolly *Inorg Synth* **9** 56 1967, for basicity see Henderson & Streuli *J Am Chem Soc* **82** 5791 1960.]

**Polystyrenesulfonic acid sodium salt (-CH<sub>2</sub>CH(C<sub>6</sub>H<sub>4</sub>SO<sub>3</sub>Na)-)** [25704-18-1]. Purify the polymer by repeated precipitation of the sodium salt from an aqueous solution by MeOH, with subsequent conversion to the free acid by passage through an Amberlite IR-120 ion-exchange resin. [Kotin & Nagasawa *J Am Chem Soc* **83** 1026 1961.] Recrystallise it from EtOH. *Alternatively*, purify it by passage through cation and anion exchange resins in series (Rexyn 101 cation exchange resin and Rexyn 203 anion exchange resin), then titrated it with NaOH to pH 7. The sodium form of polystyrenesulfonic acid is precipitated by addition of 2-propanol. Dry it in a vacuum oven at 80° for 24 hours, and finally increasing to 120° before to use. [Kowblansky & Ander *J Phys Chem* **80** 297 1976.]

**Pontacyl Carmine 2G (Acid Red 1, Amido Naphthol Red G, Azophloxine, 1-acetamido-8-hydroxy-7-phenylazonaphthalene-3,7-disulfonic acid di-Na salt)** [3734-67-6] **M 510.4, CI 18050,  $\lambda_{max}$  532nm.** Salt it out three times with sodium acetate, then repeatedly extract it with EtOH. See Solochrome Violet R [2092-55-9] in "Aromatic compounds" in this Chapter. [McGrew & Schneider *J Am Chem Soc* **72** 2547 1950.]

**Pontacyl Light Yellow GX [Acid Yellow 17, 1-(2,5-dichloro-4-sulfophenyl)-3-methyl-4-(4-sulfophenylazo)-5-hydroxypyrazole di-Na Salt]** [6359-98-4] **M 551.3, CI 18965,  $\lambda_{max}$  400nm.** Purify as for Pontacyl Carmine 2G above.

**Potassium 4-acetylphenyltrifluoroborate** [252726-24-2] **M 226.1, m >250°, 290°(dec).** The salt is prepared by adding an aqueous solution of KHF<sub>2</sub> (41ml, 4.5M solution, 185mmol) to a solution of 4-acetylphenylboronic acid (10g, 61mmol) in MeOH (40ml) at ~25°, when a heavy precipitate deposits, but the suspension is stirred for 1 hour at 25° and the solid is filtered off, washed with MeOH and recrystallised from the minimum volume of Me<sub>2</sub>CO to provide *p*-AcC<sub>6</sub>H<sub>4</sub>-BF<sub>3</sub><sup>-</sup> K<sup>+</sup> (12, 87%), m >250°. Its <sup>1</sup>H NMR [(CD<sub>3</sub>)<sub>3</sub>CO, 500MHz] has  $\delta$  at 7.74(d, *J* = 7.8Hz, 2H), 7.59 (d, *J* = 7.8Hz, 2H), 2.49 (s, 3H); the <sup>13</sup>C NMR [(CD<sub>3</sub>)<sub>3</sub>CO, 125MHz] has  $\delta$  at 198.1, 134.2, 131.3 (d, *J* = 1.5Hz), 126.2, 26.4; the <sup>19</sup>F NMR (DMSO-*d*<sub>6</sub>, 470MHz) has  $\delta$  at -140.3 (br s), and the <sup>11</sup>B NMR (DMSO-*d*<sub>6</sub>, 64MHz) has  $\delta$  at 3.27 (br s), and has the correct elemental analysis for C and H. It has been used for inserting a 4-acetylphenyl group into the position of a halogen or triflate group of various arenes and various heterocycles in Pd-catalysed Suzuki-Miyaura cross-coupling reactions [Molander & Biolatto *J Org Chem* **68** 4302 2003.]

**Potassium 3,5-bis(trifluoromethyl)phenyltrifluoroborate** [166328-09-2] **M 320.0, m >250°.** This salt was prepared by the same procedure as the preceding salt in 89% yield and recrystallised from the minimum volume of Me<sub>2</sub>CO. Its <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>, 500MHz) has  $\delta$  at 7.87(s, 2H), 7.71 (s, 1H), 2.49 (s, 3H); the <sup>13</sup>C NMR

(DMSO- $d_6$ , 125MHz) has  $\delta$  at 131.2, 128.1 (q,  $J = 31\text{Hz}$ ), 124.2 (q,  $J = 272\text{Hz}$ ), 118.6 (s); the  $^{19}\text{F}$  NMR (DMSO- $d_6$ , 470MHz) has  $\delta$  at -61.7, -141.6 (br d,  $J = 71\text{Hz}$ ), and the  $^{11}\text{B}$  NMR (DMSO- $d_6$ , 64MHz) has  $\delta$  at 2.57 (br s), and has the correct elemental analysis for C and H. It has been used for inserting a 3,5-bis(trifluoromethyl)phenyl group into the position of a halogen or triflate group of various arenes and various heterocycles in Pd-catalysed Suzuki-Miyaura cross-coupling reactions [Molander & Biolatto *J Org Chem* **68** 4302 2003, Vedejs et al. *J Org Chem* **60** 3020 1995.]

**Potassium 2,6-difluorophenyltrifluoroborate** [267006-25-7] **M 220.0, m <300°**. This salt was prepared by the same procedure as the preceding bis(trifluoromethyl) salt in 90% yield except that the crystalline precipitate was washed with  $\text{H}_2\text{O}$  then  $\text{Et}_2\text{O}$  and dried at high vacuum in a Schlenk line, and had  $m >250^\circ$ . Its  $^1\text{H}$  NMR (DMSO- $d_6$ , 500MHz) has  $\delta$  at 6.66 (m, 2H), 7.10 (m, 1H); the  $^{13}\text{C}$  NMR (DMSO- $d_6$ , 125MHz) has  $\delta$  at 168.7 (dd,  $J = 242\text{Hz}$ , 18H), 127.5 (t,  $J = 11\text{Hz}$ ), 110.0 (dd,  $J = 23\text{Hz}$ , 8H), 118.6 (s); the  $^{19}\text{F}$  NMR (DMSO- $d_6$ , 470MHz) has  $\delta$  at -103.7 (q,  $J = 9.4\text{Hz}$ ), -132.6 (qt,  $J = 43.9\text{Hz}$ ); and the  $^{11}\text{B}$  NMR (DMSO- $d_6$ , 64MHz) has  $\delta$  at 2.17 (q,  $J = 44\text{Hz}$ ), and has the correct elemental analysis for C and H. It has been used for inserting a 2,6-difluorophenyl group into the position of a halogen or triflate group of various arenes and various heterocycles in Pd-catalysed Suzuki-Miyaura cross-coupling reactions [Molander & Biolatto *J Org Chem* **68** 4302 2003.]

**Potassium 2,4-difluorophenyltrifluoroborate** [871231-41-3] **M 220.0, m >300°** can be prepared by the same procedure as above and applied in similar reactions.

**Potassium 2,6-dimethylphenyltrifluoroborate** [561328-67-4] **M 212.1, m >250°**. This salt was prepared by the same procedure as the preceding difluorophenyl salt in 88% yield except that the crystalline precipitate was washed with  $\text{H}_2\text{O}$  then  $\text{Et}_2\text{O}$  and dried at high vacuum in a Schlenk line and had  $m >250^\circ$ . Its  $^1\text{H}$  NMR (acetone- $d_6$ , 500MHz) has  $\delta$  at 6.83 (t,  $J = 7.4\text{Hz}$ , 1H), 6.75 (d,  $J = 7.4\text{Hz}$ , 2H), 2.40 (s, 6H); the  $^{13}\text{C}$  NMR (acetone- $d_6$ , 125MHz) has  $\delta$  at 142.5, 127.7, 125.9, 23.8; the  $^{19}\text{F}$  NMR (acetone- $d_6$ , 470MHz) has  $\delta$  at -132.5 (q,  $J = 48\text{Hz}$ ); and the  $^{11}\text{B}$  NMR (acetone- $d_6$ , 64MHz) has  $\delta$  at 4.94 (br d,  $J = 49\text{Hz}$ ), and has the correct elemental analysis for C and H. It has been used for inserting a 2,6-dimethylphenyl group into the position of a halogen or triflate group of various arenes and various heterocycles in Pd-catalysed Suzuki-Miyaura cross-coupling reactions [Molander & Biolatto *J Org Chem* **68** 4302 2003, cf Vedejs et al. *J Org Chem* **60** 3020 1995.] **Potassium 4-tert-butylphenyltrifluoroborate** [423118-47-2] **M 240.1, m >230°**, can be similarly prepared from 4-tert-butylphenylboronic acid and used in Pd catalysed Suzuki cross-coupling reactions.

**Potassium ethyl xanthate (potassium O-ethyl dithiocarbonate, potassium ethyl xanthogenate)** [140-89-6] **M 160.3, m ~210°(dec), > 215°(dec), pK<sup>25</sup> 2.16 (for -S<sup>-</sup>)**. It forms white to pale yellow crystals, prepared by adding ethanolic KOH dropwise to an ethanolic solution of  $\text{CS}_2$  to form the salt which can be coaxed further out of solution by adding  $\text{Et}_2\text{O}$ . Crystallise it from absolute EtOH, ligroin/ethanol or acetone by adding  $\text{Et}_2\text{O}$ . Wash it with ether, then dry it in a desiccator. Its solubility at  $56^\circ$  in EtOH is  $>1\%$  and in  $\text{Me}_2\text{CO}$  is 8% (the Na salt has 44%), and very high in  $\text{H}_2\text{O}$  at  $25^\circ$ . Dry it *in vacuo*, if it contains  $\text{H}_2\text{O}$ , and store it in a tightly stoppered bottle away from light. [Warren & Matthews *Anal Chem* **26** 1985 1954, *Beilstein* **3** H 209, **3** I 84 **3** II 152, **3** III 336, **3** IV 402.]

**Potassium 2-furantrifluoroborate** [166328-14-9] **M 174.0, m 200°(dec), >293-303°**. This salt has been prepared from furan (5.0ml, 68.7mmol, dried over 3Å Molecular Sieves) in dry THF (50ml) which was treated under  $\text{N}_2$  with BuLi (42.0ml, 1.64M in pentane, 68.9mmol) and stirred at  $-5^\circ$  for 3.5 hours to form furyllithium. The latter was treated with  $\text{B}(\text{iso-PrO})_3$  and allowed to warm to  $\sim 25^\circ$ , quenched with 10% aqueous HCl ( $\sim 50\text{ml}$ ), diluted with  $\text{Et}_2\text{O}$  (50ml) and the organic layer was extracted with 1N NaOH (2 X 50ml). The alkaline extracts were combined, acidified to pH 3 with 10% aqueous HCl, and the acid layer was then extracted with  $\text{Et}_2\text{O}$  (3 X 50ml). The combined  $\text{Et}_2\text{O}$  extracts were dried ( $\text{Na}_2\text{SO}_4$ ) and evaporated to dryness. The residual 2-furanboronic acid was dissolved in MeOH (200ml) and  $\text{H}_2\text{O}$  (40ml) was treated with 3 equivalents of  $\text{KHF}_2$  (16g, 206mmol), refluxed overnight and evaporated to dryness *in vacuo*. The residue was extracted with MeCN (2 X 30ml), filtered and the filtrate was evaporated to dryness, the residue was washed with  $\text{Et}_2\text{O}$ , dried and recrystallised from MeCN/EtOAc to give pure 2-furan- $\text{BF}_3^- \text{K}^+$  (5.8g, 48%) as yellow crystals. Attempted TLC on Silica Gel with EtOAc caused hydrolysis of the salt to 2-furylboronic acid. Its IR (KBr) had bands at  $\nu_{\text{max}}$  1575 (C=C), 1005 (B-F), 970 (B-F)  $\text{cm}^{-1}$ , the  $^1\text{H}$  NMR ( $\text{CD}_3\text{CN}$ , 200MHz) had  $\delta$  at 7.44-7.33 (m, 1H), 6.25-

6.17 (m, 1H), 6.17-6.10 (m, 1H); and the  $^{11}\text{B}$  NMR ( $\text{CD}_3\text{CN}$ , 160MHz) has  $\delta$  (from  $\text{BF}_3\cdot\text{OEt}_2$ , 0 ppm) 1.8 (q,  $J$  49Hz) and it had the correct elemental analysis for C and H. It is air stable and has been used successfully in Pd-catalysed Suzuki-Miyaura cross-coupling reactions [Vedejs et al. *J Org Chem* **60** 3020 1995].

**Potassium isoamyl xanthate (potassium *O*-isoamyl dithiocarbonate)** [61792-26-5] **M 202.4,  $\text{pK}^{25}$  1.82 ( $\text{pK}^0$  2.8 free acid)**. Crystallise it twice from acetone/diethyl ether. Dry it in a desiccator for two days and store it under refrigeration. Its solubility in  $\text{Me}_2\text{CO}$  is 2.3% at 56°. [See potassium ethyl xanthate above for storage, Warren & Matthews *Anal Chem* **26** 1985 1954, *Beilstein* **3** III 340, **3** IV 404.]

**Potassium 4-methoxyphenyltrifluoroborate** [192863-36-8] **M 214.0,  $m >300^\circ$** . The salt is prepared by mixing 4-methoxyphenylboronic acid (0.65g, 4.3mmol) and  $\text{KHF}_2$  (0.76g, 9.7mmol) in  $\text{H}_2\text{O}$  (1ml) and MeOH (1.8ml) at  $\sim 25^\circ$  for 2 hours and the resulting yellow slurry is taken up in  $\text{Me}_2\text{CO}$  (10ml) and evaporated under a vacuum. The residue is dissolved consecutively in hot  $\text{Me}_2\text{CO}$  and THF, filtered and  $\text{Et}_2\text{O}$  is added to give a yellow solid which is filtered off, washed with  $\text{Et}_2\text{O}$  until free from the yellow colour, and the crystalline material is dried in a Schlenk vacuum line to give *p*- $\text{MeOC}_6\text{H}_4\text{-BF}_3^- \text{K}^+$  (0.83g, 92%). Its  $^1\text{H}$  NMR (acetone- $d_6$ , 500MHz) has  $\delta$  at 7.38 (d,  $J = 8.2\text{Hz}$ , 2H), 7.69 (d,  $J = 8.2\text{Hz}$ , 2H), 3.70 (s, 3H); the  $^{13}\text{C}$  NMR (acetone- $d_6$ , 125MHz) has  $\delta$  at 158.9, 133.5, 112.8, 55.1; the  $^{19}\text{F}$  NMR (acetone- $d_6$ , 470MHz) has  $\delta$  (from  $\text{CFCl}_3$ , 0ppm) at -142.28 (br d,  $J = 66\text{Hz}$ ); and the  $^{11}\text{B}$  NMR (acetone- $d_6$ , 64MHz) has  $\delta$  (from  $\text{BF}_3\cdot\text{OEt}_2$ , 0ppm) at 4.8 (br s,  $J = 17\text{Hz}$ ), and it has the correct elemental analysis for C and H. It is air stable and has been used successfully in Pd-catalysed Suzuki-Miyaura cross-coupling reactions [Molander & Biolatto *Org Lett* **4** 1867 2002].

**Potassium 3-methoxyphenyltrifluoroborate** [438553-44-7] **M 214.0,  $m >300^\circ$**  was prepared in the same manner from 3-methoxyphenylboronic acid in 89% yield and had IR (KBr) with bands at  $\nu_{\text{max}}$  1241 (? C=C), 987 (B-F)  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (acetone- $d_6$ , N, 500MHz) had  $\delta$ : 7.03 (m, 3H), 6.61 (m, 1H), 3.67 (s, 3H); the  $^{13}\text{C}$  NMR (acetone- $d_6$ , 125MHz) had  $\delta$  at 159.6, 128.2, 124.9, 117.6, 112.0 55.0; the  $^{19}\text{F}$  NMR (acetone- $d_6$ , 470MHz) had  $\delta$  (from  $\text{CFCl}_3$ , 0ppm) at -142.8 (br d,  $J = 66\text{Hz}$ ); and the  $^{11}\text{B}$  NMR (acetone- $d_6$ , 64MHz) had  $\delta$  (from  $\text{BF}_3\cdot\text{OEt}_2$ , 0ppm) at 4.2 (br s,  $J$  43Hz), and it had the correct elemental analysis for C and H [Molander & Biolatto *Org Lett* **4** 1867 2002, cf Vedejs et al. *J Org Chem* **60** 3020 1995].

**Potassium 2-methoxyphenyltrifluoroborate** [236388-46-8] **M 214.0,  $m >300^\circ$**  can be prepared in the same manner from 2-methoxyphenylboronic acid and used successfully in Pd-catalysed Suzuki-Miyaura cross-coupling reactions.

**Potassium methyltrifluoroborate** [13862-28-7] **M 121.94,  $m$  168-183°, 183°**. This salt, which was used successfully in Pd-catalysed Suzuki-Miyaura cross-coupling is air stable, more robust and easier to handle than methylboronic acid. It is prepared by adding trimethyl boroxine (5.14g, 41mmol, 3 equivs, [823-96-1]) at room temperature to  $\text{KHF}_2$  (19.0g, 243mmol, 6 equivs) in MeCN (200ml), and the mixture is cooled to  $0^\circ$  and stirred for 30 minutes. Then  $\text{H}_2\text{O}$  (4.5ml) is added and after stirring for 3 hours the solvent is evaporated and the resulting solid is dried thoroughly *in vacuo*. The residue is triturated with  $\text{Me}_2\text{CO}/\text{MeOH}$  (1:1, 100ml), filtered off, washed with the same mixture of solvents (100ml) and once with  $\text{Me}_2\text{CO}/\text{MeOH}$  (1:2, 100ml), and the remaining insoluble white solid is dried at high vacuum in a Schlenk line to give  $\text{MeBF}_3^- \text{K}^+$  (12.0g, 80%) as a white powder  $m$  183°. Its  $^1\text{H}$  NMR ( $\text{D}_2\text{O}$ , 500MHz) has  $\delta$  at -0.15 (s), the  $^{13}\text{C}$  NMR ( $\text{D}_2\text{O}$ , 125MHz) has  $\delta$  at 1.40 to -1.14 (br s),  $^{19}\text{F}$  NMR ( $\text{D}_2\text{O}$ , 470MHz) has  $\delta$  at -132.3 (q,  $J = 64\text{Hz}$ ), and  $^{11}\text{B}$  NMR ( $\text{D}_2\text{O}$ , 64MHz) has  $\delta$  at 7.25 (q,  $J = 64\text{Hz}$ ). and has the correct elemental analysis for C and H. It has been used for inserting a methyl group in the position of a halogen or triflate group of various arenes. [Molander et al. *J Org Chem* **68** 5534 2003.]

**Potassium nonafluorobutane sulfonate** [29420-49-3] **M 338.2**. Wash it with  $\text{H}_2\text{O}$  and dry it *in vacuo*. When the K salt is distilled with 100%  $\text{H}_2\text{SO}_4$ , it gives the *free acid* which can be distilled (**b** 105°/22mm, 210-212°/760mm) and then converted to the pure K salt. [Gramstad & Haszeldine *J Chem Soc* 2640 1957, *Beilstein* **2** IV 818.]

**Potassium phenol-4-sulfonate (4-hydroxybenzene-1-sulfonic acid K salt)** [30145-40-5] **M 212.3**. Crystallise it several times from distilled water at  $90^\circ$ , after treatment with charcoal, and cooling to *ca*  $10^\circ$ . Dry it at  $90\text{-}100^\circ$ , *in vacuo*. [*Beilstein* **11** H 55, **11** I 242, **11** II 137, **11** III 498, **11** IV 582.]

**Potassium phenyltrifluoroborate** [329976-74-1] **M 212.1, m 290°, 296°(dec)**. The salt is obtained by adding excess of saturated aqueous  $\text{KHF}_2$  (125ml, ca 4.5M solution, 563mmol) dropwise to a solution of phenylboronic acid (20g, 169mmol, [98-80-6]) in MeOH (50ml) with vigorous stirring. The precipitate is collected after 15 minutes, washed with cold MeOH and recrystallised from the minimum volume of MeCN and dried *in vacuo* to give  $\text{Ph-BF}_3^- \text{K}^+$  (25.5g, 82%), m 296°(dec.). Its  $^1\text{H}$  NMR ( $\text{CD}_3\text{CN}$ , 200MHz) has  $\delta$  at 7.44-7.41 (m, 2H), 7.22-7.05 (m, 3H); the  $^{19}\text{F}$  NMR ( $\text{CD}_3\text{CN}$ , vs  $\text{CF}_3\text{C}_6\text{H}_5$ , 470MHz) has  $\delta$  at -79 (1:1:1:1 q,  $J = 57\text{Hz}$ ); and the  $^{11}\text{B}$  NMR ( $\text{CD}_3\text{CN}$ , 160MHz) has  $\delta$ : 4.1 (q,  $J = 57\text{Hz}$ ), and it has the correct elemental analysis for C and H. [Vedejs et al. *J Org Chem* **60** 3020 1995, Thierig & Umland *Naturwissenschaften* **54** 563 1967.] It is air stable and has been used successfully in Pd-catalysed Suzuki-Miyaura cross-coupling reactions [Vedejs et al. *J Org Chem* **60** 3020 1995, Molander & Biolatto *J Org Chem* **68** 4302 2003]. **Potassium 2-naphthalenetri-fluoroborate** [668984-08-5] **M 234.1, m >300°** can be prepared in the same manner from 2-naphthaleneboronic acid and used successfully in Pd-catalysed Suzuki-Miyaura cross-coupling reactions.

**Potassium pyridine-3-trifluoroborate** [561328-69-6] **M 185.0, m 228-232°**. The 3-pyridine salt is prepared under  $\text{N}_2$  from 3-bromopyridine (3.46g, 21.9mmol) and triisopropyl borate (6.1ml, 26.4mmol) in a mixture of dry toluene (40ml) and dry THF (10ml) at  $-60^\circ$  to which is added *n*-BuLi (39ml, 1.6M in hexane, 62mmol) dropwise, the mixture is stirred for 2 hours and allowed to warm to room temperature overnight. This mixture containing the pyridine-3-boronic lithium salt is cooled to  $0^\circ$  and an aqueous solution of  $\text{KHF}_2$  (4.5M, 58mmol) is added dropwise and stirred for 4 hours then the mixture is evaporated to dryness. The residue is dissolved in MeOH, filtered, evaporated to dryness and the residual oil gave a solid (90%) under high vacuum. Its  $^1\text{H}$  NMR ( $\text{MeOD-}d_3$ , 500MHz) has  $\delta$  at 8.57 (br s, 1H), 8.26 (br d,  $J = 4.6\text{Hz}$ , 1H), 7.90 (d,  $J = 7.3$ , 1H), 7.23 (dd,  $J = 5.5$ , 6.6Hz, 1H); the  $^{13}\text{C}$  NMR ( $\text{DMSO-}d_6$ , 125MHz) has  $\delta$ : 153.0, 145.7, 138.8, 122.0; the  $^{19}\text{F}$  NMR ( $\text{DMSO-}d_6$ , 470MHz) has  $\delta$ : -134.9 (s); and the  $^{11}\text{B}$  NMR ( $\text{MeOD-}d_3$ , 64MHz) has  $\delta$ : 4.0 (br s). It has been used for inserting a 2,6-dimethylphenyl group into the position of a halogen or triflate group of various arenes and various heterocycles in Pd-catalysed Suzuki-Miyaura cross-coupling reactions [Molander & Biolatto *J Org Chem* **68** 4302 2003.]

**Potassium tetraphenylborate** [3244-41-5] **M 358.3**. Precipitate it from a solution of KCl acidified with dilute HCl, then crystallise it twice from acetone, wash it thoroughly with water and dry it at  $110^\circ$  [Findeis & de Vries *Anal Chem* **28** 1899 1956]. It has also been recrystallised from conductivity water. [Beilstein **16** IV 1625.]

**Potassium 3-thiophenyltrifluoroborate** [192863-37-9] **M 190.0, m >260°(dec)**. This salt, which was used successfully in Pd-catalysed Suzuki-Miyaura cross-coupling is air stable, more robust and easier to handle than 3-thienyl boronic acid. 3-Thiophenylboronic acid (4.97g, 26.2mmol) and  $\text{KHF}_2$  (5.14g, 65.8mmol) in a Nalgene (polyethylene) bottle (100ml) are stirred vigorously with MeOH (7.5ml) and  $\text{H}_2\text{O}$  (14ml) for 2 hours, and the amber solid formed is set aside at  $4^\circ$  for 2 hours. The solid was collected washed with the minimum of cold MeOH and dissolved in hot  $\text{Me}_2\text{CO}$  filtered, and the filtrate was cooled to  $25^\circ$  and  $\text{Et}_2\text{O}$  was added in portions with stirring, until the supernatant showed no cloudiness. The mixture was set aside at  $4^\circ$  for 1 hour until crystallisation was complete. The crystals were collected washed with a little cold  $\text{Et}_2\text{O}$  and dried *in vacuo* to give  $\text{C}_4\text{H}_3\text{S-BF}_3^- \text{K}^+$  (4.68g, 94%). Its  $^1\text{H}$  NMR [ $(\text{CD}_3)_3\text{CO}$ , 500MHz] has  $\delta$  at 7.20 (s, 1H), 7.14 (m, 2H); the  $^{13}\text{C}$  NMR [ $(\text{CD}_3)_3\text{CO}$ , 125MHz] has  $\delta$  at 131.8, 125.2, 122.3; the  $^{19}\text{F}$  NMR [ $(\text{CD}_3)_3\text{CO}$ , 470MHz] has  $\delta$  at -139.5 (d,  $J = 75\text{Hz}$ ), and it has the correct elemental analysis for C and H. It has been used for inserting a thiophenyl group into the position of a halogen or triflate group of various arenes and various heterocycles. [Molander & Biolatto *J Org Chem* **68** 4302 2003.] **Potassium 5-methyl-2-thiophenyltrifluoroborate** [871231-40-2] **M 204.1, m >220°, >250° (dec also reported)** can be similarly prepared from 5-methylthiophenyl-2-boronic acid and used in Pd catalysed Suzuki cross-coupling reactions. •

**Potassium trimethylsilanolate (trimethylsilanol K salt)** [10519-96-7] **M 128.3, m 131-135° (cubic form),  $d^{25}$  1.11, 125°dec (orthorhombic form)**. Recrystallise it from  $\text{H}_2\text{O}$  and dry it at  $100^\circ/1\text{-}2\text{mm}$ . [Hyde et al. *J Am Chem Soc* **75** 5615 1953, IR: Tatlock & Rochow *J Org Chem* **17** 1555 1952, Beilstein **4** IV 3992.]

**Propargyl triphenyl phosphonium bromide** [2091-46-5] **M 381.4, m 179°**. It recrystallises from 2-propanol as white plates. It also crystallises from EtOH with m 156-158°. Its IR has  $\nu_{\text{max}}$  at 1440,  $1110\text{cm}^{-1}$  (P-C str). [Elter & Dediger *Justus Liebigs Ann Chem* **682** 62 1965, Schweizer et al. *J Org Chem* **42** 200 1977].

**Propenyloxy trimethylsilane** [1833-53-0] **M 130.3, b 93-95°/atm, d<sub>4</sub><sup>20</sup> 0.786.** Purify it by fractional distillation using a very efficient column at atmospheric pressure. It usually contains 5% of hexamethyl-disiloxane that boils at 99-101°, but is generally non-reactive and need not be removed. [Hauser & Hance *J Am Chem Soc* **71** 5091 1952.] It has been distilled under N<sub>2</sub> through a 15cm column packed with glass helices. Fraction **b** 99-104° is further purified by gas chromatography through a Carbowax column (Autoprep A 700) at a column temperature of 87°, and has a retention time of 9.5 minutes. [Krüger & Rochow *J Organomet Chem* **1** 476 1963-4.]

**1-Propenyltrimethylsilane (cis and trans mixture)** [17680-01-2] **M 114.3, b 85-88°, n<sub>D</sub><sup>20</sup> 1.4121.** Dissolve ~20g in THF (200ml), shake it with H<sub>2</sub>O (2x 300 ml), dry (Na<sub>2</sub>SO<sub>4</sub>) and fractionate. This is a mixture of *cis* and *trans* isomers which can be separated by gas chromatography on an AgNO<sub>3</sub> column (for preparation: see Seyferth & Vaughan *J Organomet Chem* **1** 138 1963) at 25° with He as carrier gas at 9 psi. The *cis*-isomer has **n<sub>D</sub><sup>25</sup> 1.4105**, and the *trans*-isomer has **n<sub>D</sub><sup>25</sup> 1.4062**. [Seyferth et al. *Pure Appl Chem* **13** 159 1966.]

**Propylphosphonic acid (1-propanephosphonic acid)** [4672-38-2] **M 124.1, m 73°, pK<sub>1</sub><sup>25</sup> 2.49, pK<sub>2</sub><sup>25</sup> 8.18 (H<sub>2</sub>O).** The phosphonic acid is purified by recrystallisation from hexane, heptane or \*C<sub>6</sub>H<sub>6</sub> to give long colourless needles, and is dried *in vacuo* over KOH. It is best prepared from di-*n*-butylphosphite (50mmol), which is converted into its sodium salt in dry hexane (150ml, by stirring under reflux until Na has dissolved, ~3-5 hours), treated with an equivalent of *n*-propylbromide and refluxed gently for 5-6 hours. After cooling, the mixture is washed thoroughly with H<sub>2</sub>O, the organic layer is dried by distillation under a vacuum, and the residual dibutyl *n*-propylphosphonate is refluxed with 50-70ml of concentrated HCl overnight, and distilled from an oil bath to remove, BuCl and BuOH until *ca* 30ml is left, then carefully evaporated *in vacuo* and the residual solid is recrystallised from \*C<sub>6</sub>H<sub>6</sub> and/or hexane to give *n*-propylphosphonic acid (~80% yield) **m 72.5-74.5°**. **Diethyl propanephosphonate** [18812-51-6] **M 180.2** has **b 88-89°/9mm, d<sub>4</sub><sup>25</sup> 1.010, n<sub>D</sub><sup>20</sup> 1.4172**, and its <sup>13</sup>C NMR (25MHz, MeCO *d*<sub>6</sub>, TMS) has δ<sub>C</sub> at 61.8 (ester CH<sub>3</sub>, <sup>3</sup>J<sub>P,C-3</sub> = 5.9 Hz), 61.3 (ester CH<sub>2</sub>, <sup>2</sup>J<sub>P,C-2</sub> = 6.2 Hz), 28.2 (P-CH<sub>2</sub>, <sup>1</sup>J<sub>P,C-1</sub> = 140.4 Hz), 16.7 (-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>3</sub>, <sup>2</sup>J<sub>P,C-2</sub> = 5.2 Hz) and 15.4 (propane CH<sub>3</sub>, <sup>3</sup>J<sub>P,C-3</sub> = 16.2 Hz) ppm [Ernst *Org Mag Res* **9** 35 1977]. [Kosolapoff *J Am Chem Soc* **67** 1180 1945, *Beilstein* **4** H 596.]

**Propylphosphonic anhydride (2,4,6-tripropyl-1,3,5,2,4,6-trioxatriphosphorinane-2,4,6-trioxide, T3P)** [68957-94-8] **M 318.2 (cyclic trimer), b 200°/0.3mm 200-350°/0.01-50mm.** This reagent is prepared by heating *n*-propylphosphonic acid with acetic anhydride at 70-100°, and the polymeric phosphonic acid anhydride intermediate gives the trimeric cyclic anhydride on distilling at 200-350°/0.01-50mm. The anhydride is immediately made into 50% w/w solutions in DMF, CH<sub>2</sub>Cl<sub>2</sub>, EtOAc or BuOAc, which are also commercially available. It was originally used as a peptide coupling reagent, but has found many applications which require removal of the elements of water from organic molecules. It allows the synthesis of a variety of heterocyclic compounds, acylation reactions which involves C-C coupling, in the presence of DMSO alcohols can be oxidised to ketones; and with NH<sub>2</sub>OH.HCl and Et<sub>3</sub>N in MeCN, TBDMSCl is a selective reagent for hydroxyamidation of carboxylic acids. [Llanes Garcia *Synlett* 1328 2007, Wehner et al. PCT Int. Appl. WO 2005014604 2005, *Chem Abstr* **142** 198208 2005, Wissmann & Kleiner *Angew Chem Int Ed Engl* **19** 133 1980, Escher & Bünning *Angew Chem Int Ed Engl* **25** 277 1986.]

**3-(2-Pyridyl)-5,6-diphenyl-1,2,4-triazine-*p,p'*-disulfonic acid, monosodium salt (H<sub>2</sub>O) [Ferrozine]** [63451-29-6] **M 510.5, m >350°(dec).** Purify it by recrystallisation from water or by dissolving it in the minimum volume of water, followed by addition of EtOH to precipitate the pure salt. It is light sensitive and complexes with Fe. [Stookey *Anal Chem* **42** 779 1970.]

**Pyrocatechol Violet (tetraphenolictriphenylmethanesulfonic acid Na salt)** [115-41-3] **M 386.4, ε 1.4 x 10<sup>4</sup> at 445nm in acetate buffer pH 5.2-5.4, pK<sub>Est(1)</sub>>0 (SO<sub>3</sub>H), pK<sub>Est(2)</sub>~9.4, pK<sub>Est(3)</sub>~13.** It is recrystallised from glacial acetic acid. It is very *hygroscopic* and is an indicator standard for metal complex titrations. [Mustafin et al. *Zh Anal Khim* **22** 1808 1967, *Beilstein* **19/3** V 703.]

**Pyrogallol Red (tetraphenolic xanthyliumphenylsulfonate)** [32638-88-3] **M 418.4, m >300°(dec), ε 4.3 x 10<sup>4</sup> at 542nm, pH 7.9-8.6, pK<sub>1</sub> 2.71, pK<sub>2</sub> 6.60, pK<sub>3</sub> 10.41, pK<sub>4</sub> 12.16 (5% aqueous EtOH).** It is recrystallised from aqueous alkaline solution (Na<sub>2</sub>CO<sub>3</sub> or NaOH) by precipitation on acidification. Filter the dye off and dry

it in a vacuum. [Suk *Col Czech Chem Commun* **31** 3127 1966, *Beilstein* **19** H 407, **19** II 417, **19** III/IV 599, **19/10** V 226.]

**Rose Bengal** [Acid Red 94, 4,5,6,7-tetrachloro-2'.4',5',7'-tetraiodofluorescein di-Na or di-K salt] [*di-Na salt* 632-69-9] **M 1017.7 (di-Na salt)** [*di-K salt* 11121-48-5] **M 1049.8 (di-K salt)**. This biological stain can be purified by chromatography on silica TLC using a 35:65 mix of EtOH/acetone as eluent. [*Beilstein* **19** II 261, **19** III/IV 2926.]

**Selenopyronine** [85051-91-8] **M 365.8**,  $\lambda_{\max}$  571nm ( $\epsilon$  81,000). Purify it as the hydrochloride from hydrochloric acid [Fanghanel et al. *J Phys Chem* **91** 3700 1987]. [*Beilstein* **18** II 434.]

**Selenourea** [630-10-4] **M 123.0**, **m 200°(slow heating)**, **202-205°**, **205-207°(dec)**, **214-215°(dec)**, **235°(dec)**. Recrystallise it from the least volume of H<sub>2</sub>O using Norite (preferably under N<sub>2</sub>) to form colourless needles which are dried over P<sub>2</sub>O<sub>5</sub>. It is air and light sensitive. It slowly turns moderately dark on storage even below 0°. [King & Hlavacek *J Am Chem Soc* **73** 1864 1951, Dunbar & Painter *J Am Chem Soc* **69** 1833 1947, Bacher & Bos *Rec Trav Chim Pays Bas* **62** 580 1943, Hope *Acta Chem Scand* **18** 1800 1964.] The *Se-methyl iodide* provides yellow crystals from EtOH/Et<sub>2</sub>O with **m 187-188°(dec)**. The *N,N-dimethyl* derivative crystallises from H<sub>2</sub>O or EtOH as colourless needles which slowly turn pink, then gray on standing, and although slightly soluble in \*benzene it can be recrystallised from it and has **m 167-170°(dec)** [Zingaro et al. *J Org Chem* **18** 292 1953, IR: Jensen & Nielsen *Acta Chem Scand* **20** 597 1966, *Beilstein* **3** IV 435.]

**Silicon tetraacetate** [562-90-3] **M 264.3**, **m 110-111°**, **b 148°/5-6mm**, **pK<sub>1</sub><sup>25</sup> 9.7**, **pK<sub>2</sub><sup>25</sup> 11.9 (for H<sub>4</sub>SiO<sub>4</sub> free acid)**. It can be crystallised from mixtures of CCl<sub>4</sub> and petroleum ether or Et<sub>2</sub>O, or from acetic anhydride and then dried in a vacuum desiccator over KOH. Ac<sub>2</sub>O adheres to the crystals and is removed first by drying at room temperature, then at 100° for several hours. It is soluble in Me<sub>2</sub>CO, is very *hygroscopic* and effervesces with H<sub>2</sub>O. It decomposes at 160-170°. [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 701 1963, *Beilstein* **2** H 171.]

**Silver diethyldithiocarbamate** [1470-61-7] **M 512.3**, **m 172°**, **174°**, **176-78°**, **pK<sub>1</sub><sup>25</sup> 3.36 (for *N,N*-diethyldithio-carbamate)**. Purify it by recrystallisation from pyridine or CO<sub>2</sub>. Store it in a desiccator in a cool and dark place. [*Beilstein* **4** III 224, **4** IV 391.]

**Silver tosylate** [16836-95-6] **M 279.1**. The anhydrous salt is obtained by recrystallisation from H<sub>2</sub>O. Store it in the dark. [Claesson & Wallin *Chem Ber* **12** 1851 1879, *Beilstein* **11** H 97, 99.]

**Silver trifluoromethanesulfonate** [2923-28-6] **M 256.9**. Recrystallise it twice from hot CCl<sub>4</sub> [Alo et al. *J Chem Soc, Perkin Trans 1* 805 1986]. Store it in the dark. [*Beilstein* **3** IV 34.]

**Sodium *n*-alkylsulfates**. Recrystallise these salts from EtOH/Me<sub>2</sub>CO [Hashimoto & Thomas *J Am Chem Soc* **107** 4655 1985].

**Sodium amylpenicillin** [575-47-3] **M 350.4**, **m 188°(dec, anhydrous)** [ $\alpha$ ]<sub>D</sub><sup>23</sup> +319° (c 1, H<sub>2</sub>O). The *monohydrate* crystallises from moist acetone or moist ethyl acetate. Dry it in a vacuum. [Wintersteiner in "The Chemistry of Penicillin", Clarke, Johnson and Robinson eds, Princeton University Press, p 470 1949.]

**Sodium 9,10-anthraquinone-1,5-disulfonate (H<sub>2</sub>O)** [853-35-0] **M 412.3**. Separate it from insoluble impurities by continuous extraction with water. Recrystallise it twice from hot water and dry it under vacuum. [*Beilstein* **11** II 195, **11** III 634.]

**Sodium 9,10-anthraquinone-1-sulfonate (H<sub>2</sub>O)** [107439-61-2] **M 328.3**. Recrystallise it from hot water (4ml/g) after treatment with active charcoal, or from water by addition of EtOH. Dry it under vacuum over CaCl<sub>2</sub>, or in an oven at 70°. Store it in the dark. [*Beilstein* **11** II 192, **11** III 626, **11** IV 670.]

**Sodium 9,10-anthraquinone-2-sulfonate (H<sub>2</sub>O) (9,10-anthraquinone-2-sulfonic acid [Na salt, H<sub>2</sub>O])** [131-08-8] **M 328.3, pK<sub>Est</sub> <0 (SO<sub>3</sub>H)**. It crystallises from H<sub>2</sub>O or MeOH (charcoal). [Costa and Bookfield *J Chem Soc, Faraday Trans 1* **82** 991 1986, *Beilstein* **11** IV 671.]

**Sodium benzenesulfinate (benzenesulfonic acid Na salt)** [873-55-2] **M 164.2, m >300°, pK<sub>25</sub> 2.16 (2.74, for PhSO<sub>2</sub>H)**. Dissolve it in the minimum volume of O<sub>2</sub> free H<sub>2</sub>O (prepared by bubbling N<sub>2</sub> through for 2 hours) and adding O<sub>2</sub> free EtOH (prepared as for H<sub>2</sub>O), set aside at 4° overnight under N<sub>2</sub>, filter, wash with EtOH, then Et<sub>2</sub>O and dry *in vacuo*. The Na salt is relatively stable to air oxidation, but is best kept under N<sub>2</sub> in the dark. Also recrystallise it from EtOH and dry it at 120° for 4 hours in a vacuum. [Kornblum & Wade *J Org Chem* **52** 5301 1987, *Beilstein* **11** II 2, **11** IV 3.]

**Sodium benzenesulfonate** [515-42-4] **M 150.1, pK<sub>1</sub><sup>25</sup> 0.70 (2.55) (for PhSO<sub>3</sub>H<sub>2</sub>)**. Crystallise it from EtOH or aqueous 70-100% MeOH, and dry it under a vacuum at 80-100°. [*Beilstein* **11** H 28, **11** I 10, **11** II 18, **11** III 33, **11** IV 27.]

**Sodium bis(trimethylsilyl)amide (hexamethyl disilazane sodium salt)** [1070-89-9] **M 183.4, m 165-167°(sintering at 140°)**. It can be sublimed at 170°/2mm (bath temperature 220-250°) onto a cold finger, and can be recrystallised from \*C<sub>6</sub>H<sub>6</sub> (its solubility is: 10g in 100ml at 60°). It is slightly soluble in Et<sub>2</sub>O and is decomposed by H<sub>2</sub>O. [Wannagat & Niederprüm *Chem Ber* **94** 1540 1961.] It is available commercially under N<sub>2</sub> in Sure/Seal bottles in tetrahydrofuran (various concentrations) and at ~0.6M in toluene. [*Beilstein* **4** IV 4014.]

**Sodium 4-bromobenzenesulfonate** [5015-75-8] **M 258.7**. Crystallise it from MeOH, EtOH or distilled water. [*Beilstein* **11** H 570, **11** I 14, **11** II 30, **11** III 97.]

**Sodium cacodylate (3H<sub>2</sub>O)** [124-65-2] **M 214.0, m 60°**. Recrystallise it from aqueous EtOH. [*Beilstein* **4** H 612, **4** I 576, **4** IV 1818, see cacodylic acid above.]

**Sodium 4-chlorobenzenesulfonate** [5138-90-9] **M 214.6, pK<sub>Est</sub> <0 (for SO<sub>3</sub>H)**. Crystallise it twice from MeOH and dry it under vacuum. [*Beilstein* **11** IV 107.]

**Sodium 3-chloro-5-methylbenzenesulfonate** [5138-92-1] **M 228.7, pK<sub>Est</sub> <0 (for SO<sub>3</sub>H)**. Crystallise it twice from MeOH and dry it under vacuum. [*Beilstein* **2** I 22.]

**Sodium *p*-cymenesulfonate** [77060-21-0] **M 236.3**. Dissolve the salt in water, filter and evaporate to dryness. Recrystallise it twice from absolute EtOH and dry it at 110°.

**Sodium 1-decanesulfonate** [13419-61-9] **M 244.33**. Recrystallise it from absolute EtOH and dry it over silica gel. [*Beilstein* **4** IV 62.]

**Sodium *n*-decylsulfate** [142-87-0] **M 239.3**. Rigorously purify it by continuous Et<sub>2</sub>O extraction of a 1% aqueous solution for two weeks. [*Beilstein* **1** IV 1818.]

**Sodium dibenzylthiocarbamate** [55310-46-8] **M 295.4, m 230°(dec), pK<sub>20</sub> 3.13 (for monobenzylthiocarbamic acid)**. The free acid, when recrystallised twice from dry Et<sub>2</sub>O, has **m** 80-82°. The Na salt is reprecipitated from aqueous EtOH or EtOH by addition of Et<sub>2</sub>O or Me<sub>2</sub>CO [Lindler *Anal Chem* **50** 896 1978]. The *NH<sub>4</sub>* salt has **m** 130-133°, the *Cu* salt (yellow crystals) has **m** 284-286°, and the *Ti* salt has **m** 64-70°. [*Beilstein* **12** IV 2275.]

**Sodium 2,5-dichlorobenzenesulfonate** [5138-93-2] **M 249.0, pK<sub>Est</sub> <0 (for SO<sub>3</sub>H)**. Crystallise it from MeOH, and dry it under vacuum. [*Beilstein* **11** III 93.]

**Sodium diethylthiocarbamate (3H<sub>2</sub>O)** [20624-25-3] **M 225.3, m 94-96°(anhydrous), 98°, pK<sub>20</sub> 3.65**

(diethyldithiocarbamic acid). Recrystallise it from water. [*Beilstein* 4 III 224, 4 IV 390.]

**Sodium di(ethylhexyl)sulfosuccinate (Aerosol-OT, sodium docosate)** [577-11-7] **M 444.6**. Dissolve it in MeOH and the inorganic salts which precipitate are filtered off. Water is added and the solution is extracted several times with hexane. The residue is evaporated to one-fifth its original volume, \*benzene is added and azeotropic distillation is continued until no water remains. The solvent is evaporated. The white residual solid is crushed and dried *in vacuo* over P<sub>2</sub>O<sub>5</sub> for 48 hours [El Seoud & Fendler *J Chem Soc, Faraday Trans 1* **71** 452 1975]. [*Beilstein* 4 IV 114.] It solubilises major myelin trans membrane proteolipids, and forms reverse micelles in hydrocarbon solvents.

**Sodium 2,2'-dihydroxy-1-naphthaleneazobenzene-5'-sulfonate**. See Solochrome Violet R [2092-55-9] in "Aromatic Compounds" in this Chapter.

**Sodium 2,4-dihydroxyphenylazobenzene-4'-sulfonate (Tropaeolin O, Acid Orange 6)** [547-57-9] **M 316.3**. Recrystallise it from absolute EtOH. It has  $\lambda_{\max}$  at 490nm and CI (colour index) 14270. [*Beilstein* 16 H 275.]

**Sodium *p*-(*p*-dimethylaminobenzeneazo)-benzenesulfonate** [23398-40-5] **M 327.3**. Recrystallise it from water and dry it *in vacuo*. [*Beilstein* 16 H 331, 16 I 317, 16 II 169, 16 III 370, 16 IV 510.]

**Sodium 2,4-dimethylbenzenesulfonate** [827-21-4] **M 208.2**. Crystallise it from MeOH and dry it under vacuum. [*Beilstein* 11 III 339.]

**Sodium 2,5-dimethylbenzenesulfonate (sodium *p*-xylenesulfonate)** [827-19-0] **M 208.2**. Dissolve it in distilled water, filter it, then evaporate it to dryness. Recrystallise it twice from absolute EtOH or MeOH and dry it at 110° under vacuum. [*Beilstein* 11 III 93, 11 IV 502.]

**Sodium dimethyldithiocarbamate hydrate** [128-04-1 (*hydrate*), 207233-95-2 (*anhydrous*)] **M 143.2, m 106-108°, 120-122°, pK<sup>25</sup> 3.36 (diethyldithiocarbamic acid)**. Crystallise it from a small volume of H<sub>2</sub>O, or dissolve it in the minimum volume of H<sub>2</sub>O and add cold Me<sub>2</sub>CO, collect it and dry it in air. The solubility in Me<sub>2</sub>CO is ~12.5g/100ml. The *dihydrate* loses H<sub>2</sub>O on heating at 115° to give the *hemi-hydrate* that decomposes on further heating [Kulka *Can J Chem* **34** 1096 1956]. [*Beilstein* 4 IV 233.]

**Sodium *N,N*-dimethylsulfanilate** [2244-40-8] **M 223.2, m >300°**. It crystallises from water. [See *Beilstein* 4 IV 270.]

**Sodium 1-dodecanesulfonate** [2386-53-0] **M 272.4, m >300°**. Recrystallise it twice from EtOH and dry it in an oven at 105° for 2 hours. It picks up moisture to form the 3.5H<sub>2</sub>O. Its *hydrate* crystallises in several phases. [Tartar & Wright *J Am Chem Soc* **61** 543 1939, Reed & Tartar *J Am Chem Soc I* **57** 571 1935, *Beilstein* 4 III 27, 4 IV 64.]

**Sodium 4-dodecylbenzenesulfonate** [25155-30-0] **M 348.5**. It crystallises from propan-2-ol or H<sub>2</sub>O. [Gray et al. *J Org Chem* **20** 515 1955, *Beilstein* 11 IV 514.]

**Sodium dodecylsulfate (SDS, sodium laurylsulfate)** [151-21-3] **M 288.4, m 204-207°**. Purify this detergent by Soxhlet extraction with petroleum ether for 24 hours, followed by dissolution in acetone/MeOH/H<sub>2</sub>O 90:5:5(v/v) and recrystallisation [Politi et al. *J Phys Chem* **89** 2345 1985]. It has been purified by two recrystallisations from absolute EtOH, aqueous 95% EtOH, MeOH, isopropanol or a 1:1 mixture of EtOH/isopropanol to remove dodecanol, and dried under vacuum [Ramesh & Labes *J Am Chem Soc* **109** 3228 1987]. SDS has also been purified by repeatedly foaming whereby a 0.15% aqueous solution is made to foam and the foam is discarded, then the H<sub>2</sub>O is removed *in vacuo* and the residue is diluted to the required concentrations [see Cockbain & McMullen *Trans Faraday Soc* **47** 322 1951], or by liquid-liquid extraction [see Harrold *J Colloid Sci* **15** 280 1960]. Dry it over silica gel. For DNA work it should be dissolved in excess MeOH passed through an activated charcoal column and evaporated until it crystallises out. It has also been purified by dissolving in hot 95% EtOH (14ml/g), filtering and cooling, then drying in a vacuum

desiccator. *Alternatively*, it is crystallised from H<sub>2</sub>O, vacuum dried, washed with anhydrous Et<sub>2</sub>O and dried in vacuum again. These operations are repeated five times [Maritato *J Phys Chem* **89** 1341 1985, Lennox and McClelland *J Am Chem Soc* **108** 3771 1986, Dressik *J Am Chem Soc* **108** 7567 1986]. [*Beilstein* **1** IV 1847.]

**Sodium ethylmercurithiosalicylate (Thimerosal)** [54-64-8] **M 404.8, m ~230°**. Recrystallise this antibacterial from EtOH/Et<sub>2</sub>O. **HIGHLY TOXIC**. [Trikojus *Nature* **158** 472 1940, *Beilstein* **10** III 213.]

**Sodium ethylsulfate** [546-74-7] **M 166.1**. Recrystallise it three times from MeOH/Et<sub>2</sub>O and dry it in a vacuum. [*Beilstein* **1** H 326, **1** I 164, **1** III 1317, **1** IV 1325.]

**Sodium formaldehyde sulfoxylate dihydrate (sodium hydroxymethylsulfinate, Rongalite)** [149-44-0] **M 134.1, m 63-64° (dihydrate)**. It crystallises from H<sub>2</sub>O as the *dihydrate* and decomposes at higher temperatures. Store it in a closed container in a cool place. It is insoluble in EtOH and Et<sub>2</sub>O and is a good reducing agent. [X-ray structure: Tuter *J Chem Soc* 3064 1955.] Note that this compound {HOCH<sub>2</sub>SO<sub>2</sub>Na} should not be confused with formaldehyde sodium bisulfite adduct {HOCH<sub>2</sub>SO<sub>3</sub>Na} from which it is prepared by reduction with Zn. [*Beilstein* **1** IV 3052.]

**Sodium hexadecylsulfate** [1120-01-0] **M 344.5**. Recrystallise it from absolute EtOH or MeOH and dry it in vacuum [Abu Hamdiyyah & Rahman *J Phys Chem* **91** 1531 1987].

**Sodium 2-hydroxy-4-methoxybenzophenone-5-sulfonate** [6628-37-1] **M 330.3**. Crystallise it from MeOH and dry it under vacuum.

**Sodium *p*-hydroxyphenylazobenzene-*p'*-sulfonate** [2623-36-1] **M 288.2**. Recrystallise it from 95% EtOH.

**Sodium 2-mercaptoethanesulfonate (MESNA)** [19767-45-4] **M 164.2, pK<sub>1</sub><sup>20</sup> <0 (SO<sub>3</sub><sup>-</sup>), pK<sub>2</sub><sup>20</sup> 9.53 (SH)**. It can be recrystallised from H<sub>2</sub>O and does not melt below 250°. It is purified further by converting to the free acid by passing a 2M solution through an ion-exchange (Amberlite IR-120) column in the acid form, evaporating the eluate in a vacuum to give the acid as a viscous oil (readily decomposes) which can be checked by acid and SH titration. It is then dissolved in H<sub>2</sub>O, carefully neutralised with aqueous NaOH, evaporated and the salt recrystallised from H<sub>2</sub>O [Schramm *J Am Chem Soc* **77** 6231 1955]. [*Beilstein* **4** IV 85.]

**Sodium metanilate** [1126-34-7] **M 195.2**. It crystallises from hot water. [*Beilstein* **14** H 688.]

**Sodium methanethiolate [sodium methylmercaptide]** [5188-07-8] **M 70.1, pK<sup>25</sup> 10.33 (MeS<sup>-</sup>)**. Dissolve the salt (10g) in EtOH (10ml) and add Et<sub>2</sub>O (100ml). Cool and collect the precipitate, wash it with Et<sub>2</sub>O and dry it in a vacuum. It is a white powder which is very soluble in EtOH and H<sub>2</sub>O. [Billmann & Jensen *Bull Soc Chim Fr* **3** 2318 1936, *Beilstein* **1** III 1212.]

**Sodium 3-methyl-1-butanesulfonate** [5343-41-9] **M 174.1**. It crystallises from 90% MeOH.

**Sodium 1-naphthalenesulfonate** [130-14-3] **M 230.2**. Recrystallise it from water or aqueous acetone [Okadata et al. *J Am Chem Soc* **108** 2863 1986]. [*Beilstein* **11** IV 521.]

**Sodium 2-naphthalenesulfonate** [532-02-5] **M 230.2**. It crystallises from hot 10% aqueous NaOH or water and is dried in a steam oven. [*Beilstein* **11** IV 521.]

**Sodium 2-naphthylamine-5,7-disulfonate (Amido-G-acid)** [79004-97-0] **M 235.4**. Crystallise it from water (charcoal) and dry it in a steam oven. [*Beilstein* **14** H 784, **14** II 473, **14** IV 2811.]

**Sodium 1-octanesulfonate H<sub>2</sub>O** [5324-84-5] **M 216.2**. Recrystallise it from absolute EtOH. [*Beilstein* **4** IV 58.]

**Sodium phenol-4-sulfonate (2H<sub>2</sub>O) (4-hydroxybenzenesulfonic acid Na salt)** [825-90-1] **M 232.2**. It crystallises from hot water (g/1m) by cooling to 0°, or from MeOH, and is dried in vacuum. [Beilstein 11 II 134.]

**Sodium piperazine-*N,N'*-bis(2-ethanesulfonate) H<sub>2</sub>O (PIPES-Na salt)** [76836-02-7] **M 364.3**. It crystallises from water and EtOH. [Beilstein 23/2 V 380.]

**Sodium isopropyl xanthate (sodium *O*-isopropylidithiocarbonate)** [140-93-2] **M 158.2, pK<sup>25</sup> 2.16 (for -S<sup>-</sup>)**. It crystallises from ligroin/ethanol.

**Sodium sulfanilate (sodium *p*-aminobenzenesulfonic acid)** [515-74-2] **M 195.2**. It crystallises from water. [Beilstein 14 IV 2655.]

**Sodium taurocholate [2-(3 $\alpha$ ,7 $\alpha$ ,12 $\alpha$ -trihydroxy-24-oxo-5- $\beta$ -cholan-24-ylamino)ethanesulfonic acid sodium salt monohydrate]** [145-42-6; 312693-83-7; 345909-26-4 (*x* H<sub>2</sub>O)] **M 555.7 (monohydrate), m 168°dec (hydrate), [ $\alpha$ ]<sub>D</sub><sup>20</sup> +23.9° (c 2.5, H<sub>2</sub>O), pK of acid is 1.4**. The non-sulfated bile salt has been synthesised from *ethyl cholate* (**m 162-163°**, crystallised from EtOAc/petroleum ether b 30-60° 2:8) *via* the *hydrazide* (**m 210°**, sintering at 202°), which was diazotised to the *azide* (NaNO<sub>2</sub>/HCl at 0-2°) and condensed with taurine in aqueous N NaOH at 8-14°/45 minutes. The acidified product was converted to *Na taurocholate* which was prepared and purified by precipitation with saturated aqueous NaCl and Et<sub>2</sub>O (84% recovery; note that crystallisation does not occur unless enough H<sub>2</sub>O is present) [Cortese *J Am Chem Soc* 59 2532 1937]. It was also purified by recrystallisation from aqueous EtOH/Et<sub>2</sub>O, or by gel chromatography using Sephadex LH-20. It is a useful anionic detergent for solubilising proteins and bilirubin [Wosiewicz & Schroebler *Experientia* 35 717 1979]. It has a CMC of 3-11 mM at 20-25°, with an average micellar weight of 2100. It is hydrolysed by mineral acids to cholic acid and taurine. [Tanaka *Z physiol Chem* 220 39 1933, Beilstein 10 III 1655, 10 IV 2078.]

**Sodium tetradecylsulfate (sodium myristyl sulfate)** [1191-50-0] **M 316.4**. It recrystallises from absolute EtOH [Abu Hamdiyyah & Rahman *J Phys Chem* 91 1531 1987]. It is *hygroscopic*. [Beilstein 1 H 716, 1 IV 1866.]

**Sodium tetrakis-(4-fluorophenyl)borate hydrate** [207683-22-5] **M 450.2**. This gravimetric reagent for Cs is purified by passing a solution (10g in 100ml H<sub>2</sub>O) through a column of Dowex 50Wx4 (Na form) and eluting with dilute NaCl. Extract the 250-275ml eluate with Et<sub>2</sub>O (3 x 50ml), add dry xylene (200ml), evaporate the Et<sub>2</sub>O off *in vacuo*, immerse the xylene in a bath at 50° and the salt crystallises out. It is *hygroscopic*. [Moore et al. *Anal Chim Acta* 35 1 1966, Tsubouci et al. *Anal Chem* 57 783 1985.]

**Sodium tetraphenylborate [tetraphenyl boron Na]** [143-66-8] **M 342.2**. Dissolve the borate in dry MeOH and add dry Et<sub>2</sub>O. Collect the solid and dry it in a vacuum at 80°/2mm for 4 hours. It can also be extracted (Soxhlet) using CHCl<sub>3</sub>, and it crystallises from CHCl<sub>3</sub> as snow-white needles. It is freely soluble in H<sub>2</sub>O, Me<sub>2</sub>CO but insoluble in petroleum ether and Et<sub>2</sub>O. An aqueous solution has pH ~5 and can be stored for days at 25° or lower, and for 5 days at 45° without deterioration. Its solubility in polar solvents increases with decrease in temperature [Wittig & Raff *Justus Liebigs Ann Chem* 573 204 1950]. The salt can also be recrystallised from acetone/hexane or CHCl<sub>3</sub>, or from Et<sub>2</sub>O/cyclohexane (3:2) by warming the solution to precipitate the compound. Dry it in a vacuum at 80°. It dissolves in Me<sub>2</sub>CO at 50-60° to give a clear solution. After standing at this temperature for 10 minutes the mixture is filtered rapidly through a pre-heated Büchner funnel, cooled and the crystals are collected and dried in a vacuum desiccator at room temperature for 3 days [Abraham et al. *J Chem Soc, Faraday Trans 1* 80 489 1984]. If the product gives a turbid aqueous solution, the turbidity can be removed by treating with freshly prepared alumina gel and filtering. [Beilstein 16 IV 1624.]

**Sodium thioglycolate** [367-51-1] **M 114.1**. It crystallises from 60% EtOH (charcoal). It is *hygroscopic*. [Beilstein 3 IV 600.]

**Sodium 4-toluenesulfinate** [824-79-3] **M 178.2, pK<sup>25</sup> 2.80 (1.99)(for -SO<sub>2</sub><sup>-</sup>)**. Recrystallise the salt from

water (to constant UV spectrum) and dry it under vacuum, or extract it with hot benzene, then dissolve it in EtOH/H<sub>2</sub>O and heat with decolorising charcoal. The solution is filtered and cooled to give crystals of the dihydrate. [Beilstein 11 I 718.]

**Sodium 4-toluenesulfonate** [657-84-1] **M 194.2, pK<sup>25</sup> -1.34 (for -SO<sub>3</sub><sup>-</sup>)**. Dissolve it in distilled water, filter it to remove insoluble impurities and evaporate it to dryness. Then recrystallise it from MeOH or EtOH, and dry it at 110°. Its solubility in EtOH is not high (maximum 2.5%), so that Soxhlet extraction with EtOH may be preferable. Sodium *p*-toluenesulfonate has also been crystallised from Et<sub>2</sub>O and dried under a vacuum at 50°. [Beilstein 11 I 4, 11 II 6, cf Gibson & Reid *J Chem Soc* 879 1923.]

**Sodium 2,2',4-trihydroxyazobenzene-5'-sulfonate** [3564-26-9] **M 295.3**. Purify the dye by precipitating the free acid from aqueous solution using concentrated HCl, then wash it and extract it with EtOH in a Soxhlet extractor. Evaporation of the EtOH leaves the purified acid which is converted to the sodium salt with an equivalent of NaOH or Na<sub>2</sub>CO<sub>3</sub>.

**Sodium 2,4,6-trimethylbenzenesulfonate** [6148-75-0] **M 222.1**. Crystallise it twice from MeOH and dry it under vacuum. [Beilstein 11 III 345.]

**Sodium trimethylsilanolate (sodium trimethylsilanol)** [18027-10-6] **M 112.2, m 230°(dec)**. It is very soluble in Et<sub>2</sub>O and C<sub>6</sub>H<sub>6</sub> but moderately soluble in petroleum ether. It is purified by sublimation at 130-150° in a high vacuum. [Hyde et al. *J Am Chem Soc* 75 5615 1953, Tatlock & Rochow *J Org Chem* 17 1555 1952, Beilstein 4 III 1856.]

**Sodium 3,5-xylenesulfonate** [30587-85-0] **M 208.2**. Dissolve it in distilled water, filter, then evaporate it to dryness and recrystallise it twice from absolute EtOH and then dry it at 110°. [Beilstein 11 H 126, 11 I 34.]

**Strontium thiosalicylate (5H<sub>2</sub>O)** [15123-90-7] **M 289.8**. It crystallises from hot water (0.5g/ml) by cooling to 0°. [Beilstein 10 IV 272.]

**Sulfur trioxide pyridine complex** [26412-87-3] **M 159.2, m 155-165°, 175°**. Wash the solid with a little CCl<sub>4</sub>, then H<sub>2</sub>O to remove traces of pyridine sulfate, and dry it over P<sub>2</sub>O<sub>5</sub>. [Baumgarten *Chem Ber* 59 1166 1926, Olah et al. *Synthesis* 59 1979, Beilstein 20/5 V 184.]

**Tetrabutylammonium borohydride** [33725-74-5] **M 257.3, m 128-129°**. Purify it by recrystallisation from EtOAc followed by careful drying under vacuum at 50-60°. Samples purified in this way showed no signs of loss of active H after storage at room temperature for more than 1 year. Nevertheless samples should be stored at ca 6° in tightly stoppered bottles if they are to be kept for long periods. It is soluble in CH<sub>2</sub>Cl<sub>2</sub>. [Raber & Guida *J Org Chem* 41 690 1976, Brändström et al. *Tetrahedron Lett* 3173 1972.]

**Tetrabutylammonium tetrafluoroborate** [429-42-5] **M 329.3, m 161.8°, 161-163°, pK<sup>25</sup> -4.9 (for HBF<sub>4</sub>)**. Recrystallise it from H<sub>2</sub>O, aqueous EtOH or from EtOAc by cooling in Dry-ice. Also recrystallise it from ethyl acetate/pentane or dry acetonitrile. Dry it at 80° under vacuum. [Detty & Jones *J Am Chem Soc* 109 5666 1987, Hartley & Faulkner *J Am Chem Soc* 107 3436 1985.] The acetate has m 118±2° (from BuCl), the bromide has m 118° (from EtOAc) and the nitrate has m 120° (from C<sub>6</sub>H<sub>6</sub>). [Witschonka & Kraus *J Am Chem Soc* 69 2472 1947, Wheeler & Sandstedt *J Am Chem Soc* 77 2024 1955, Beilstein 4 IV 558.]

**Tetraethoxysilane (tetraethyl orthosilicate)** [78-10-4] **M 208.3, m -77°, b 165-166°/atm, d<sub>4</sub><sup>20</sup> 0.933, n<sub>D</sub><sup>25</sup> 1.382**. Fractionate it through an 80cm Podbielniak type column with a heated jacket and partial take-off head. It is soluble in EtOH, and is slowly decomposed by H<sub>2</sub>O and. It is **flammable**—it irritates the eyes and mucous membranes. [Sumrell & Ham *J Am Chem Soc* 78 5573 1956, Bradley et al. *J Chem Soc* 5020 1952, Beilstein 1 IV 1360.]

**Tetraethylammonium hexafluorophosphate** [429-07-2] **M 275.2, m >300°, 331°(dec), pK<sub>1</sub><sup>25</sup> ~ 0.5, pK<sub>2</sub><sup>25</sup>**

**5.12 (for fluorophosphoric acid  $\text{H}_2\text{PO}_3\text{F}$ ).** Dissolve the salt (0.8g) in hot  $\text{H}_2\text{O}$  (3.3ml) and cool to crystallise. Yield of prisms is 0.5g. Its solubility in  $\text{H}_2\text{O}$  is 8.1g/L at  $19^\circ$  [Lange & Müller *Chem Ber* **63** 1067 1930]. [Beilstein **4** III 199.]

**Tetraethylammonium tetrafluoroborate** [429-06-1] **M 217.1, m 235°, 356-367°, 275-277°, 289-291°.  $\text{pK}^{25}_{\text{a}} -4.9$  (for  $\text{HBF}_4$ ).** Dissolve the salt in hot MeOH, filter and add  $\text{Et}_2\text{O}$ . It is soluble in ethylene chloride [Thompson & Kraus *J Am Chem Soc* **69** 1016 1947, Wheeler & Sandstadt *J Am Chem Soc* **77** 2025 1955]. It has also been recrystallised three times from a mixture of ethyl acetate/hexane (5:1) or MeOH/petroleum ether, then stored at  $95^\circ$  for 48 hours under vacuum [Henry & Faulkner *J Am Chem Soc* **107** 3436 1985, Huang et al. *Anal Chem* **58** 2889 1986]. It is used as a supporting electrolyte. [Beilstein **4** IV 333.]

**Tetraethylsilane** [631-36-7] **M 144.3, b 153.8°/760mm,  $d_4^{30}$  0.77,  $n_D^{30}$  1.427.** Fractionate it through a 3ft vacuum-jacketed column packed with 1/4" stainless steel saddles. The material is finally percolated through a 2ft column packed with alumina and maintained in an inert atmosphere. [Staveley et al. *J Chem Soc* 1992 1954, Altshaller & Rosenblum *J Am Chem Soc* **77** 272 1955, Beilstein **4** H 625.]

**1.1.3.3-Tetraisopropyldisiloxane** [18043-71-5] **M 246.5, b 129-130°/6mm,  $d_4^{30}$  0.89,  $n_D^{30}$  1.47.** Fractionate it under reduced pressure in a  $\text{N}_2$  atmosphere. [Gilman & Clark *J Am Chem Soc* **69** 1500 1947.]

**Tetrakis(hydroxymethyl)phosphonium chloride (THPC)** [124-64-1] **M 190.6, m 151°.** THPC is prepared in an efficient fume cupboard by placing a mixture of 40% formaldehyde (90ml) and concentrated aqueous HCl (40ml, sp. gr. 1.2) into a 100ml 3-bulb Ladenburg flask (filling about half of the neck of the flask), the latter is provided with a stopper through which is passed a gas delivery tube that reaches the bottom. The flask is inclined to an almost horizontal position, when  $\text{PH}_3$  (from a cylinder) is passed to displace the air, and the solution is heated to  $\sim 80^\circ$  [note that at lower temperatures the reaction is slower, and at higher temperatures the vapour pressure of the solution decreases gas absorption]. The bulbs of the flask help to hold back the gas which results in a more complete reaction. The complete reaction may take up to many hours. Some  $\text{H}_2$  and  $\text{PH}_3$  which escape from the side neck of the flask should be vented through the flue of the fume cupboard. The mixture is then evaporated with stirring on a steam bath or *in vacuo* ( $\sim 50$  to  $60^\circ$ ) until a white granular solid is obtained (50g  $\sim$  88%). Its purity is good enough for most purposes. However, it can be purified to analytical purity by recrystallising 1g of THPC from 50ml of AcOH. The low melting flat needles obtained which contain AcOH of crystallisation are converted to the pure substance, **m 151°**, by blowing dry air at  $100^\circ$  over the crystals, or by drying them at  $100^\circ$  *in vacuo* to give a constant weight. It can also be recrystallised from absolute EtOH. [For a Kg scale laboratory preparation see Reeves et al. *J Am Chem Soc* **77** 3923 1955.] It is very deliquescent and should be kept in the presence of a desiccant. It is readily soluble in MeOH, slightly soluble in  $\text{CHCl}_3$ , but insoluble in  $\text{Et}_2\text{O}$ . It is quite stable, its aqueous solutions can be boiled without decomposition, and it is unaffected by dilute acids. The  $^1\text{H}$  NMR (60MHz,  $\text{D}_2\text{O}$ , DSS) has  $\delta$  for  $4\text{CH}_2$  at 4.77 (s,  $J_{\text{PCH}} = 1.7\text{Hz}$  and  $J_{\text{HCH}} \sim 153\text{Hz}$ ), and the  $^{31}\text{P}$  NMR (40MHz,  $\text{D}_2\text{O}$ , external 85%  $\text{H}_3\text{PO}_4$ ) has  $\delta$  at -25.8. With the stoichiometric amount of alkali, the free *tris(hydroxymethyl)phosphine* (see [2767-80-8] above) is obtained as an oil together with formaldehyde. However with excess of alkali on THPC,  $\text{H}_2$  evolution occurs with the liberation of HCHO and formation of *tris(hydroxymethyl)phosphine oxide* (see [1067-12-5] below) **m 54-55°**. The reaction with alkali becomes more complicated when the mixture is heated, and *bis(hydroxymethyl)phosphinic acid* is formed. An 80% w/v aqueous solution of THPC with  $d_4^{20}$  1.33 is available commercially. Also a 70-75% aqueous solution of *bis[tetrakis(hydroxymethyl)phosphonium] sulfate* [55566-30-8] **M 406.3** is commercially available. [Hoffman *J Am Chem Soc* **43** 1684 1921, Hoffman *J Am Chem Soc* **52** 2995 1930, Beilstein **1** IV 3062.]

**Tetramethoxysilane (tetramethyl orthosilicate)** [681-84-5] **M 152.2, m 4.5°, b 122°/760mm.** Purification is as for tetraethoxysilane. It has a vapour pressure of 2.5mm at  $0^\circ$ . [IR: Sternbach & MacDiarmid *J Am Chem Soc* **81** 5109 1959, Beilstein **1** IV 1266.]

**Tetramethylammonium borohydride** [16883-45-7] **M 89.0.** Recrystallisation of the borohydride from  $\text{H}_2\text{O}$  three times yields *ca* 94% pure compound. Dry in high vacuum at  $100^\circ$  for 3 hours. The solubility in  $\text{H}_2\text{O}$  is 48% ( $20^\circ$ ), 61% ( $40^\circ$ ), in EtOH it is 0.5% ( $25^\circ$ ), and in MeCN it is 0.4% ( $25^\circ$ ). It decomposes slowly in a

vacuum at 150°, but rapidly at 250°. The rate of hydrolysis of Me<sub>4</sub>N.BH<sub>4</sub> (5.8M) in H<sub>2</sub>O at 40° is constant over a period of 100 hours at 0.04% of original wt/hour. The rate decreases to 0.02%/hour in the presence of Me<sub>4</sub>NOH (5% of the wt of Me<sub>4</sub>N.BH<sub>4</sub>). [Banus et al. *J Am Chem Soc* **74** 2346 1952, *Beilstein* **4** IV 148.]

**Tetramethylammonium hexafluorophosphate** [558-32-7] **M 219.1, m >300°, d<sub>4</sub><sup>25</sup> 1.617, pK<sub>1</sub><sup>25</sup> ~ 0.5, pK<sub>2</sub><sup>25</sup> 5.12 (for fluorophosphoric acid H<sub>2</sub>PO<sub>3</sub>F).** The salt (0.63g) is recrystallised from boiling H<sub>2</sub>O (76ml), yielding pure (0.45) Me<sub>4</sub>N.PF<sub>6</sub> after drying at 100°. It is a good supporting electrolyte. [Lange & Müller *Chem Ber* **63** 1067 1930, *Beilstein* **4** III 110.]

**Tetramethylammonium triacetoxyborohydride** [109704-53-2] **M 263.1, m 93-98°, 96.5-98°.** If impure, wash it with freshly distilled Et<sub>2</sub>O and dry it overnight in a vacuum to give a free flowing powder. Check <sup>1</sup>H NMR, and if still suspect prepare it freshly from Me<sub>4</sub>NBH<sub>4</sub> and AcOH in \*C<sub>6</sub>H<sub>6</sub> and store it away from moisture [Banus et al. *J Am Chem Soc* **74** 2346 1952, Evans & Chipman *Tetrahedron Lett* **27** 5939 1986]. It is an **IRRITANT** and **MOISTURE SENSITIVE**.

**Tetramethylammonium triphenylborofluoride** [437-11-6] **M 392.2.** Crystallise it from acetone or acetone/ethanol. [*Beilstein* **4** IV 15.]

**2,4,6,8-Tetramethylcyclotetrasiloxane (TMCTS)** [2370-88-9] **M 240.5, m -69°, b 134°/750mm, 134.5-134.9°/755mm, d<sub>4</sub><sup>20</sup> 0.99, n<sub>D</sub><sup>20</sup> 1.3872.** It is purified by repeated redistillation, and fractions with the required <sup>1</sup>H NMR data are collected. [Sokolov *J Gen Chem USSR (Engl Transl)* **29** 262 1959, Sauer et al. *J Am Chem Soc* **68** 962 1946]. [*Beilstein* **4** IV 4099.]

**1,1,3,3-Tetramethyldisiloxane** [3277-26-7] **M 134.3, b 70.5-71°/731mm, 71-72°/atm, d<sub>4</sub><sup>30</sup> 0.75, n<sub>D</sub><sup>25</sup> 11.367.** Possible impurity is 1,1,5,5-tetramethyl-3-trimethylsiloxytrisiloxane **b 154-155°/733mm.** Fractionate it, collect fractions boiling below 80° and re-fractionate it. Its purity can be analysed by alkaline hydrolysis and measuring the volume of H<sub>2</sub> liberated followed by gravimetric estimation of silica in the hydrolysate. It is unchanged when stored in glass containers in the absence of moisture for 2-3 weeks. Small amounts of H<sub>2</sub> are liberated on long storage. *Care should be taken when opening a container due to developed pressure.* [Speier et al. *J Am Chem Soc* **79** 974 1958, Emeléus & Smythe *J Chem Soc* 609 1958, IR: Kriegsmann *Z Anorg Chem* **299** 78 1959, *Beilstein* **4** IV 3991.]

**N,N,N',N'-Tetramethylphosphonic diamide (methylphosphonic bis-dimethylamide)** [2511-17-3] **M 150.2, b 60.5°/0.6mm, 138°/32mm, 230-230°/atm, d<sub>4</sub><sup>30</sup> 1.0157, n<sub>D</sub><sup>30</sup> 1.4539.** Dissolve it in heptane or ethylbenzene, shake this with 30% aqueous NaOH, stir for 1 hour, separate the organic layer and fractionate. [Kosolapoff & Payne *J Org Chem* **21** 413 1956.] Its IR (film) has ν<sub>□□□</sub> at 1480, 1460, 1300, 1184, 1065 and 988-970cm<sup>-1</sup> [Harvey & Mayhood *Can J Chem* **33** 1552 1955].

**Tetramethylsilane (TMS)** [75-76-3] **M 88.2, b 26.3°, d<sub>4</sub><sup>20</sup> 0.639, n<sub>D</sub><sup>20</sup> 1.359.** Distil it from conc H<sub>2</sub>SO<sub>4</sub> (after shaking with it) or LiAlH<sub>4</sub>, through a 5ft vacuum-jacketed column packed with glass helices into an ice-cooled condenser, then percolate it through silica gel to remove traces of halide. [For preparation on a 250g scale see Whitmore & Sommer *J Am Chem Soc* **68** 481 1946, *Beilstein* **4** IV 3875.]

**2,4,6,8-Tetramethyl tetra vinyl cyclotetrasiloxane** [2554-06-5] **M 344.7, m -43.5°, b 111-112°/10mm, 145-146°/13mm, 224-224.5°/758mm, d<sub>4</sub><sup>30</sup> 0.98, n<sub>D</sub><sup>30</sup> 1.434.** A 7ml sample can be distilled in a small Vigreux column at atmospheric pressure without polymerisation or decomposition. It is soluble in cyclohexane. [Kantor et al. *J Am Chem Soc* **77** 1685 1955, *Beilstein* **4** IV 4184.]

**Tetraphenylarsonium chloride hydrate** [507-28-8] **M 418.8, m 258-260°, 261-263°.** A neutralised aqueous solution is evaporated to dryness. The residue is extracted into absolute EtOH, evaporated to a small volume and precipitated by addition of absolute Et<sub>2</sub>O. It is again dissolved in a small volume of absolute EtOH or ethyl acetate and re-precipitated with Et<sub>2</sub>O. *Alternatively,* it is purified by adding conc HCl to precipitate the chloride dihydrate. Redissolve in water, neutralise with Na<sub>2</sub>CO<sub>3</sub> and evaporate to dryness. The residue is extracted with

$\text{CHCl}_3$  and finally crystallised from  $\text{CH}_2\text{Cl}_2$  or EtOH by adding  $\text{Et}_2\text{O}$ . If the aqueous layer is somewhat turbid treat it with Celite and filter it through filter paper. It can be dehydrated before use in a vacuum. The *tetrafluoroborate* salt has *m* 293-295° (needles from MeCN), and the *picrate* salt has *m* 203-204° (from EtOH). [Blicke et al. *J Am Chem Soc* **57** 702 1935, Duke & Brown *J Am Chem Soc* **76** 1443 1954, Popov & Humphrey *J Am Chem Soc* **81** 2043 1959, Singhal & Raj *Synth Inorg Met-org Chem* **23** 1011 1993, *Beilstein* **16** III 1006, **16** IV 1170.] **POISONOUS**.

**Tetraphenylarsonium iodide** [7422-32-4] **M 510.2**. It crystallises from MeOH. [Blicke et al. *J Am Chem Soc* **57** 702 1935, Chatt et al. *J Chem Soc* 1192 1940.] **POISONOUS**.

**Tetraphenylarsonium perchlorate** [3084-10-4] **M 482.8**, **pK<sup>25</sup> -2.4 to -3.1 (for HClO<sub>4</sub>)**. It crystallises from MeOH. [Horner et al. *Chem Ber* **101** 2903 1968.] **POISONOUS and possibly explosive**.

**Tetraphenylbiphosphine (Ph<sub>2</sub>P-PPh<sub>2</sub>)** [1101-41-3] **M 370.4**, **m 120.5° (evacuated tube)**, **120-122° (sealed tube)**, **b 258-260°/1mm**. **pK<sub>Est</sub> >0.0**. This useful precursor of diphenylphosphine compounds is made by heating a mixture of diphenylphosphine (6.0g, 32.5mmol, 829-85-6) and chlorodiphenylphosphine (7.1g, 32.5mmol, 1709-66-9) in petroleum ether (100ml, b 90-100°, freshly distilled over Na) under N<sub>2</sub> at reflux for 3.5 hours during which time all the HCl has evolved. The white crystalline biphosphine that separates (~80%) on cooling is collected, washed with ligroin, dried *in vacuo* and recrystallised or distilled at high vacuum, preferably in a N<sub>2</sub> atmosphere. It is soluble in \*C<sub>6</sub>H<sub>6</sub>, toluene, CCl<sub>4</sub>, and pyridine (yellow solution), and slightly soluble in Et<sub>2</sub>O, EtOH and ligroin. The determined molecular weight was 391.6, 374.9 (method of Rast). When it is heated for 3 hours at 250-300° under N<sub>2</sub>, phosphorus is liberated. The brown residue is boiled for 1 hour with dilute aqueous NaOH and 3% of H<sub>2</sub>O<sub>2</sub>, filtered, cooled, the solid that is collected gives Ph<sub>3</sub>PO (*m* 153° and mixed *m* with authentic Ph<sub>3</sub>PO) after crystallisation from petroleum ether (b 90-100°). *Diphenylphosphonic acid* [*m* 191-192° and mixed melting point with authentic Ph<sub>2</sub>P(O)OH] can be isolated from the mother liquors, making a total yield of products almost quantitative. Reaction of a suspension of the biphosphine (3.3g) in CCl<sub>4</sub> under N<sub>2</sub> with Br (1ml) in CCl<sub>4</sub> is decolourised as it becomes clear. The mixture is then distilled and the oily residue is redistilled to give *bromodiphenylphosphine* (**b 146.5-148°/2.5mm**) as a colourless oil in almost quantitative yield. Bubbling dry air through a suspension of the biphosphine (3.3g) in dry toluene (30ml) at ~0° for 3 hours causes the mixture to become yellow in colour, and after dilution with toluene (30ml) and boiling for a short period it becomes clear. On cooling, and recrystallising the solid that separates from fresh toluene provides the white *dioxide* Ph<sub>2</sub>P(O)-P(O)Ph<sub>2</sub> (**m 167°**, evacuated tube, 1.9g, 53%), with a molecular weight of 418.5, 409.8 (measured by the method of Rast; the required value is 402.4). [Kuchen & Buchwald *Chem Ber* **91** 2871 1958, *Beilstein* **16** H 2871.]

*Sodium dipenylphosphine (Ph<sub>2</sub>PNa)* is readily prepared by adding Na to a solution of the diphosphine in dry Et<sub>2</sub>O or THF (exothermic!), whereby the colour becomes yellow and the orange Na salt separates. It is sensitive to moisture (giving Ph<sub>2</sub>PH) and to CO<sub>2</sub> (giving Ph<sub>2</sub>PCOOH); and the necessary precautions have to be taken. It is a useful reagent for preparing a variety of Ph<sub>2</sub>P-R derivatives and it is best to prepare it freshly when required. [Kuchen & Buchwald *Chem Ber* **92** 227 1959.]

**Tetraphenylboron potassium** see potassium tetraphenylborate.

**Tetraphenylphosphonium chloride** [2001-45-8] **M 374.9**, **m 273-275°**. Crystallise the chloride from acetone and dry at 70° under vacuum. It can also be recrystallised from a mixture of 1:1 or 1:2 dichloromethane/petroleum ether, the solvents having been dried over anhydrous K<sub>2</sub>CO<sub>3</sub>. The purified salt is dried at room temperature under a vacuum for 3 days, and at 170° for a further 3 days. It also crystallises from isoPrOH/Et<sub>2</sub>O or EtOH/Et<sub>2</sub>O. *Extremely hygroscopic*. [Wittig & Geissler *Justus Liebigs Ann Chem* **580** 44, 50 1953, Willard et al. *J Am Chem Soc* **70** 737 1948, *Beilstein* **16** III 851, **16** IV 984.]

**Tetraphenylsilane** [1048-08-4] **M 336.4**, **m 231-233°, 234-235°, 236-238°**. It crystallises from \*benzene as clear colourless bladed needles. It decomposes at ~360°/~760mm on attempted distillation. [George et al. *J Am Chem Soc* **77** 6647 1955, Polis *Chem Ber* **98** 1540 1885, Drew & Landuist *J Chem Soc* 1480 1935, *s Beilstein* **16** H 901, **16** I 525, **16** II 606, **16** III 1199, **16** IV 1372.]

**Tetrasodium pyrene-1,3,6,8-tetrasulfonate** [59572-10-0] M 610.5. Recrystallise this salt from aqueous acetone [Okahata et al. *J Am Chem Soc* **108** 2863 1986].

**Thexyl dimethyl chlorosilane (dimethyl-[2,3-dimethyl-2-butyl] chlorosilane)** [67373-56-2] M 178.8, b 55-56°/10mm, 158-159°/720mm,  $d_4^{20}$  0.970,  $n_D^{20}$  1.428. Purify this chlorosilane by fractional distillation, and store it in small aliquots in sealed ampoules. It is very sensitive to moisture and is estimated by dissolving an aliquot in excess of 0.1M NaOH and titrating with 0.1M HCl using methyl red as indicator [Szabó et al. *Helv Chim Acta* **67** 2128 1984].

**N-(Thexyl dimethylsilyl)dimethylamine (N-[2,3-dimethyl-2-butyl]dimethylsilyl dimethyl-amine)** [81484-86-8] M 187.4, b 156-160°/720mm. Dissolve the amine in hexane, filter, evaporate and distil. It is a colourless oil which is extremely sensitive to moisture. It is best to store small quantities in sealed ampoules after distillation. For estimation of purity, crush an ampoule in excess 0.1N HCl and titrate the excess acid with 0.1M NaOH using methyl red as indicator. [Szabó et al. *Helv Chim Acta* **67** 2128 1984.]

**Tribenzyl chlorosilane** [18740-59-5] M 336.9, m 139-142°, 141-142°, b 300-360°/100mm. It is recrystallised three times from petroleum ether (in slender colourless needles, m 141°). It is sparingly soluble in cold petroleum ether but is soluble in Et<sub>2</sub>O. It does not fume in moist air but is decomposed by H<sub>2</sub>O to give *tribenzyl silanol* m 106° (from petroleum ether). [Robinson & Kipping *J Chem Soc* **93** 439 1908, Jenkins & Post *J Org Chem* **15** 556 1950, *Beilstein* **16** H 906, **16** IV 1498.]

**Tribenzyl phosphine** [76650-89-7] M 304.4, m 96-101°, b 203-210°/0.5mm, pK<sub>Est</sub> ~8.8. Dissolve it in Et<sub>2</sub>O, dry it over Na<sub>2</sub>SO<sub>4</sub>, evaporate and distil it in an inert atmosphere. The distillate solidifies on cooling and is sublimed at 140°/0.001mm. This has m 92-95° (evacuated capillary). When air is bubbled through an Et<sub>2</sub>O solution, it is oxidised to *tribenzyl phosphine oxide*, m 209-212° (evacuated capillary) (it crystallises from Me<sub>2</sub>CO). [Hinton & Mann *J Chem Soc* 2835 1959, *Beilstein* **16** H 771, **16** IV 961.]

**Tri-*n*-butyl borate** [688-74-4] M 230.2, b 110°/11mm, 136°/30mm, 232.4°,  $d_4^{20}$  0.857,  $n_D^{20}$  1.4092. The chief impurities are *n*-butyl alcohol and boric acid (from hydrolysis). It must be handled in a dry-box and can readily be purified by fractional distillation, under reduced pressure. [O'Brien *Aust J Chem* **10** 91 1957, Gerrard & Lappert *J Chem Soc* 2545, 2547 1951, *Beilstein* **1** IV 1544.]

**Tri-*n*-butyl chlorosilane** [995-45-9] M 234.9, b 93-94°/4.5mm, 134-139°/16mm, 250-252°/atm, 142-144°/29mm,  $d_4^{20}$  0.88,  $n_D^{20}$  1.447. Fractionally distil this silane, and store it in small aliquots in sealed ampoules. [Gilman et al. *J Am Chem Soc* **74** 1361 1952, Osthoff & Clark *J Org Chem* **24** 219 1959, *Beilstein* **4** IV 4072.]

**Tri-*n*-butyl phosphate (butyl phosphate)** [126-73-8] M 266.3, m -80°, b 47°/0.45mm, 98°/0.1mm, 121-124°/3mm, 136-137°/5.5mm, 166-167°/17mm, 177-178°/27mm, 289°/760mm (some dec),  $d_4^{20}$  0.980,  $n_D^{20}$  1.44249. The main contaminants in commercial samples are organic pyrophosphates, mono- and di- butyl phosphates and butanol. It is purified by washing successively with 0.2M HNO<sub>3</sub> (three times), 0.2M NaOH (three times) and water (three times), then fractionally distilled under vacuum. [Yoshida *J Inorg Nucl Chem* **24** 1257 1962.] It has also been purified *via* its uranyl nitrate addition compound, obtained by saturating the crude phosphate with uranyl nitrate. This compound is crystallised three times from *n*-hexane by cooling to -40°, and then decomposed by washing with Na<sub>2</sub>CO<sub>3</sub> and water. Hexane is removed by steam distillation; the water is then evaporated under reduced pressure, and the residue is distilled under reduced pressure. [Siddall & Dukes *J Am Chem Soc* **81** 790 1959.]

*Alternatively*, wash it with water, then with 1% NaOH or 5% Na<sub>2</sub>CO<sub>3</sub> for several hours, then finally with water. Dry it under reduced pressure and fractionate it carefully under vacuum. It is a stable colourless oil, sparingly soluble in H<sub>2</sub>O (1ml dissolves in 165ml of H<sub>2</sub>O), but freely miscible in organic solvents. [Kuivila & Masterton *J Am Chem Soc* **74** 4953 1952, Cox & Westheimer *J Am Chem Soc* **80** 5441 1958, <sup>31</sup>P NMR: Van Wazer *J Am Chem Soc* **78** 5715 1956, Fertig et al. *J Chem Soc* 1488 1957, *Beilstein* **1** IV 1531.]

**Tri-*n*-butyl phosphine (TBP)** [998-40-3] M 202.3, b 109-110°/10mm, 115-116°/12mm, 149.5°/50mm, 240.4-

**242.2°/atm,  $d_4^{20}$  0.822,  $n_D^{20}$  1.4463,  $pK_{Est}$  ~7.6.** Fractionally distil TBP under reduced pressure in an inert atmosphere ( $N_2$ ) through an 8 inch gauze-packed column (**b** 110-111°/10mm), and redistil it in a vacuum, then seal it in thin glass ampoules. It is easily oxidised by air to *tri-n-butylphosphine oxide*, **b** 293-296°/745mm. It has a characteristic odour, it is soluble in EtOH, Et<sub>2</sub>O, and \*C<sub>6</sub>H<sub>6</sub>, but is insoluble in H<sub>2</sub>O; and is less easily oxidised by air than the lower molecular weight phosphines. It forms complexes, e.g. with CS<sub>2</sub> (1:1) **m** 65.5° (from EtOH). [Davies & Jones *J Chem Soc* 33 1929, Chernick & Skinner *J Chem Soc* 1401 1956, *Beilstein* 4 IV 3436.] Unlike with Ph<sub>3</sub>P, (MeO)<sub>3</sub>P, (Me<sub>2</sub>N)<sub>3</sub>P or Me<sub>3</sub>P, when (*n*-Bu)<sub>3</sub>P is complexed with DEAD, best results are achieved in the Mitsunobu lactonisation of the final stage in the synthesis of the strained lactone (-)-Echinospurin (XK-213) [Smith et al. *J Am Chem Soc* 114 2567 1992].

**Tri-*tert*-butylphosphine** [13716-12-6] **M 202.3, m ~30-35°, 62.3°, b 103-103°/13mm,  $d_4^{20}$  0.834,  $pK^{25}$  11.4.** It is prepared from *tert*-butylmagnesium chloride and PCl<sub>3</sub> in Et<sub>2</sub>O and finally purified by vacuum fractionation and distillation. [Ger Pat, IG Farbenind DRP 730 638 1939, DRP *Org Chem* 3 1144.] A 1.0M solution in toluene is commercially available (**d<sup>25</sup> 0.861 g/l**). [*Beilstein* 4 III 1771.] It is used with Pd<sub>2</sub>(dba)<sub>3</sub> and Bu<sub>3</sub>SnF in the Pd-catalysed regiocontrolled  $\alpha$ -arylation of trimethylsilyl enol ethers with aryl halides [Iwama & Rawal *Org Lett* 8 5725 2006], is a useful ligand for Pd-catalysed Suzuki-type coupling of arylboronic acids with phenyliodonium ylides of hydroxyquinones [Kazantzi et al. *Synlett* 2597 2006] and is a good ligand for Ni(acac)<sub>2</sub> in catalysing the cross-coupling of aryl- and heteroaryl- halides with aryl Grignard reagents [Böhm et al. *Angew Chem. Int Ed* 39 1602 2000].

**Tri-*tert*-butylphosphine oxide** [6866-70-2] **M 218.3, m 64-69°, 70°, 77°.** The oxide has been prepared by treating *t*-Bu<sub>3</sub>P (1.7g, 85mmol) in Et<sub>2</sub>O (20ml) containing a catalytic amount of KI (0.1g) with 30% of H<sub>2</sub>O<sub>2</sub> until the colour of iodine disappears. The mixture is diluted with H<sub>2</sub>O, basified with aqueous NaOH, the ethereal layer is evaporated, and the phosphine oxide (1.5g, 81%, **m 77°**) is obtained by sublimation at 50°/0.1mm. It is a crystalline hygroscopic solid that is soluble in most organic solvents, and is stable to 250°. Its IR (Nujol) has  $\nu_{max}$  at 1160 (P=O, s) and 815 (P-C, br s) cm<sup>-1</sup>; the <sup>1</sup>H NMR (C<sub>6</sub>D<sub>6</sub>, TMS) has  $\delta_H$  at 0.59 (d, <sup>3</sup>J<sub>P-H</sub> = 12.1Hz, C-Me<sub>3</sub>); the <sup>13</sup>C NMR (C<sub>6</sub>D<sub>6</sub>, TMS) has  $\delta_C$  at 29.08 (s, CH<sub>3</sub>), 38.95 (d, <sup>1</sup>J<sub>P-C</sub> = 51.27, C), and its <sup>31</sup>P NMR (C<sub>6</sub>D<sub>6</sub>, external H<sub>3</sub>PO<sub>4</sub>) has  $\delta$  at 60.86. [Schmidbauer & Blaschke *Z Naturforsch* 33B 1556 1978, Rankin et al. *JCS Dalton Trans* 827 1985.]

**Tri-*n*-butyl phosphite** [102-85-2] **M 250.3, b 114-115°/5mm, 122°/12mm, 130°/17mm, 137°/26mm,  $d_4^{20}$  0.926,  $n_D^{20}$  1.4924.** Fractionate the phosphite through an efficient column. It is stable in air but is slowly hydrolysed by H<sub>2</sub>O. [Gerrard *J Chem Soc* 1464 1940, Fertig et al. *J Chem Soc* 1488 1957, Fields *J Am Chem Soc* 80 2358 1958, Gillis et al. *J Am Chem Soc* 80 2999 1958, *Beilstein* 1 IV 1527.]

**B-Trichloroborazine [B-trichloroborazole]** [933-18-6] **M 183.1, m 83.9-84.5°(sealed evacuated cappillary), 87°, b 88-92°/21mm,  $d_4^{25}$  1.58.** Purify the borazine by distillation from mineral oil. It sublimes at 70°/1mm. [Brown & Laubangayer *J Am Chem Soc* 77 3699 1955, Emelús & Videla *J Chem Soc* 1306 1959.] It is extremely sensitive to moisture and reacts with H<sub>2</sub>O exothermically to give boric acid and NH<sub>4</sub>Cl. Store it in sealed tubes. It is soluble in \*C<sub>6</sub>H<sub>6</sub>, cyclohexane, CS<sub>2</sub>, CHCl<sub>3</sub>, CCl<sub>4</sub>, and C<sub>6</sub>H<sub>5</sub>Cl without decomposition, but in MeOH or EtOH it reacts vigorously, liberating HCl. It is insoluble in pyridine and C<sub>6</sub>H<sub>5</sub>NO<sub>2</sub>. [*Beilstein* 4 III 174, 1 IV 305.]

**Trichloromethyl trimethylsilane (trimethylsilyl trichloromethane)** [5936-98-1] **M 191.6, m 130-132°, b 146-156°/749mm.** This silane distils at atmospheric pressure without decomposition and readily sublimes at 70°/10mm. It has one peak in the <sup>1</sup>H NMR spectrum (CD<sub>2</sub>Cl<sub>2</sub>) with  $\delta$  at 0.38. [Speier *J Am Chem Soc* 73 824 1951, Hergott & Simchen *Synthesis* 626 1980, *Beilstein* 4 IV 3892.]

**Trichlorosilane (SiHCl<sub>3</sub>, silicochloroform)** [10025-78-2] **M 135.4, m -126°, b 31.8°/atm, 32-34°/atm, 36.5°/atm,  $d_4^{25}$  1.342,  $n_D^{20}$  1.4020.** This volatile trichlorosilane can be obtained from silane and HCl in the presence of AlCl<sub>3</sub>, and is purified by fractional distillation at atmospheric pressure in the strict absence of moisture. However, SiHCl<sub>3</sub> is best prepared by placing finely powdered silicon (purified by boiling with HCl

and dilute HF) ground with *ca* 10% of CuCl<sub>2</sub> in a pyrex glass tube (fitted with an adapter and condenser which should extend into the middle of the distilling flask) and heating (carefully at first) in a furnace while a slow stream of absolutely dry HCl gas (from a gas cylinder, or generated from NaCl and concentrated H<sub>2</sub>SO<sub>4</sub>) is passed over the mixture with a furnace temperature of 300°. The receiver is cooled by an acetone/Dry-ice mixture, and the crude product is distilled from the receiver. HCl comes off first then SiHCl<sub>3</sub> distils over at 36.5° in 50% yield. With careful fractionation, the forerun SiH<sub>2</sub>Cl<sub>2</sub>, can be recovered. At 300°, AlCl<sub>3</sub> disproportionates SiHCl<sub>3</sub> to SiH<sub>2</sub>Cl<sub>2</sub> and SiCl<sub>4</sub>. [Note that by using an 4:1 mixture of H<sub>2</sub>/HCl the yield of SiH<sub>2</sub>Cl<sub>2</sub>, [4109-96-0] M 101.0, m -122°, b 8.5°/atm, d<sup>-122°</sup> 1.22, can be greatly improved; and SiH<sub>3</sub>Cl, has m -118°, b -30.5°/atm, d<sup>-113°</sup> 1.15. SiHCl<sub>3</sub> is a water clear, very volatile liquid which fumes in moist air as it is hydrolysed by H<sub>2</sub>O, but is remarkably inert towards metals even the alkali metals such as Na. It is a good reducing agent, is soluble in most organic solvents, e.g. \*C<sub>6</sub>H<sub>6</sub>, CHCl<sub>3</sub>, and CS<sub>2</sub>, but not in protic solvents in which it may decompose. It is **TOXIC, should not be inhaled**, and should be handled under an efficient fume hood. [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 691-692 1963, Fritz *Z Anorg Allg Chem* **280** 134 1955.]

**Tricyclohexylphosphine** [2622-14-2] M 280.4, m 82-83°, pK<sub>Est</sub>~9.5. It recrystallises from EtOH [Boert et al. *J Am Chem Soc* **109** 7781 1987]. [Beilstein **16** IV 947.]

**Triethoxysilane** [998-30-1] M 164.3, m -170°, b 131.2-131.8°/atm, 131.5°/760mm, d<sub>4</sub><sup>20</sup> 0.98753, n<sub>D</sub><sup>20</sup> 1.4377. Fractionate it using a column packed with glass helices of *ca* 15 theoretical plates in an inert atmosphere. Store it in aliquots in sealed ampoules because it is sensitive to moisture. [Spauschus et al. *J Am Chem Soc* **72** 1377 1950, MacKenzie et al. *J Am Chem Soc* **72** 2032 1950, Havill et al. *J Org Chem* **13** 280 1948, Beilstein **1** IV 1359.]

**Triethylborane** [97-94-9] M 146.0, m -92.5°, b 94-97°, 94-95°, n<sub>D</sub><sup>20</sup> 1.378, d<sub>4</sub><sup>20</sup> 0.678. This borane distils at 56-57°/220mm. It can also be purified *via* its *ammonia addition complex* which is distilled in a high vacuum, decomposed with dry HCl, and the Et<sub>3</sub>B is distilled out. It is commercially available as a 15% solution in hexane or as 1M solution in hexane. [Brown *J Am Chem Soc* **67** 376 1945, Bamford et al. *J Chem Soc* 471 1946, Lin et al. *J Organomet Chem* **312** 277 1986, Beilstein **4** III 1957, **4** IV 4359.]

**Triethyl borate** [150-46-9] M 146.0, b 44.5°/45mm, 118°, n<sub>D</sub><sup>20</sup> 1.378, d<sub>4</sub><sup>20</sup> 0.864. Dry the ester over sodium, then distil it. Also fractionate it through a gauze packed column. [Charnlet et al. *J Chem Soc* 2288 1952, as for tributyl borate Johnson & Tompkins *Org Synth Coll Vol II* 106 1943, Beilstein **1** III 1339, **1** IV 1365.]

**Triethyl phosphate** [78-40-0] M 182.2, b 40-42°/0.25-0.3mm, 98-98.5°/8-10mm, 90°/10mm, 130°/55mm, 204°/680mm, 215-216°/760mm, d<sub>4</sub><sup>25</sup> 1.608, n<sub>D</sub><sup>20</sup> 1.4053. Dry the phosphate by refluxing it with solid BaO and then fractionally distil it under reduced pressure. It is kept over Na and distilled. Store it in the receiver protected from light and moisture. *Alternatively*, it is dried over Na<sub>2</sub>SO<sub>4</sub> and distilled under reduced pressure. The middle fraction is stirred for several weeks over anhydrous Na<sub>2</sub>SO<sub>4</sub> and again fractionated under reduced pressure until the specific conductance reaches a constant low value of κ<sup>25</sup> 1.19 x 10<sup>8</sup>, κ<sup>40</sup> 1.68 x 10<sup>8</sup>, and κ<sup>55</sup> 2.89 x 10<sup>8</sup> ohm<sup>-1</sup> cm<sup>-1</sup>. It has also been fractionated carefully under reduced pressure through a glass helices-packed column. It is soluble in EtOH, Et<sub>2</sub>O and H<sub>2</sub>O (dec). [Estok & Wendlandt *J Am Chem Soc* **77** 4767 1955, Hoffmann et al. *J Am Chem Soc* **78** 6413 1956. (P NMR), Muller et al. *J Am Chem Soc* **78** 3557 1956, French et al. *J Chem Soc* 3582 1959, IR: Bellamy & Beecher *J Chem Soc* 475 1952 and McIvor *Can J Chem* **36** 820 1958, Kosolapoff *Organophosphorus Compounds*, Wiley p 258 1950, Beilstein **1** IV 1339.]

**Triethylphosphine** [554-70-1] M 118.2, b 100°/7mm, 127-128°/744mm, d<sub>4</sub><sup>15</sup> 0.812, n<sub>D</sub><sup>18</sup> 1.457, pK<sup>25</sup> 8.69 (also available as a 1.0M solution in THF). All operations should be carried out in an efficient fume cupboard because it is flammable, toxic and has a foul odour. Purify the phosphine by fractional distillation at atmospheric pressure in a stream of dry N<sub>2</sub>, as it is oxidised by air to the oxide. In 300% excess of CS<sub>2</sub> it forms Et<sub>3</sub>PCS<sub>2</sub> (m 118-120° crystallising from MeOH) which decomposes in CCl<sub>4</sub> to give Et<sub>3</sub>PS as a white solid m 94° when recrystallised from EtOH. [Sorettas & Isbell *J Org Chem* **27** 273 1962, Henderson & Streuli *J Am*

*Chem Soc* **82** 5791 1960, pK: Henderson & Streuli *J Am Chem Soc* **82** 5791 1960, see also trimethylphosphine.] Store it in sealed vials under N<sub>2</sub>.

Alternatively, dissolve it in Et<sub>2</sub>O and shake it with a solution of AgI and KI to form the insoluble complex. Filter off the complex, dry it over P<sub>2</sub>O<sub>5</sub> and the Et<sub>3</sub>P is regenerated by heating the silver iodide complex in a tube attached to a vacuum system. It has the odour of hyacinths. [Hewitt & Holliday *J Chem Soc* 530 1953, Schettas & Isbell *J Org Chem* **27** 2573 1962, Kosolapoff *Organophosphorus Compounds*, Wiley p 31 1950, *Beilstein* **4** IV 3431.]

**Triethyl phosphite** [122-52-1] **M 166.2, b 48-49°/11mm, b 52°/12mm, 57.5°/19mm, 157.9°/757mm, d<sub>4</sub><sup>20</sup> 0.9687, n<sub>D</sub><sup>20</sup> 1.4135.** Treat the ester with Na (to remove water and any dialkyl phosphonate), then decant and distil it under reduced pressure, with protection against moisture; or distil it in a vacuum through an efficient Vigreux column or a column packed with Penn State 0.16 x 0.16inch protruded nickel packing and a variable volume take-off head. [Ford-Moore & Perry *Org Synth Coll Vol IV* 955 1963, Kosolapoff *Organophosphorus Compounds*, Wiley p 203 1950, *Beilstein* **1** IV 1333.]

**Triethyl phosphonoacetate (triethyl carboxymethyl phosphonate)** [867-13-0] **M 224.2, b 83-84°/0.5mm, 103°/1.2mm, 143-144°/11mm, 260-262°/atm, d<sub>4</sub><sup>20</sup> 1.1215, n<sub>D</sub><sup>20</sup> 1.4310.** Purify the phosphono-acetate by fractional distillation, preferably *in vacuo*. The <sup>31</sup>P NMR has a P resonance at 19.5 relative to orthophosphate. [Kosolapoff & Powell *J Am Chem Soc* **68** 1103 1946, Kosolapoff & Powell *J Am Chem Soc* **72** 4198 1950, Speziale & Freeman *J Org Chem* **23** 1586 1958, *Beilstein* **4** IV 3613.]

**Triethyl phosphonofornate** [1474-78-8] **M 210.2, b 70-72°/0.1mm, 122.5-123°/8mm, 130-131°/10mm, 138.2°/12.5mm, d<sub>4</sub><sup>20</sup> 1.22, n<sub>D</sub><sup>20</sup> 1.423.** Dissolve it in Et<sub>2</sub>O, shake this with H<sub>2</sub>O (to remove any trace of NaCl impurity), dry (Na<sub>2</sub>SO<sub>4</sub>), evaporate and distil it using an efficient fractionating column. [Nylén *Chem Ber* **57** 1035 1924, Reetz et al. *J Am Chem Soc* **77** 3813 1955, Monson *Advanced Organic Synthesis* Academic Press p 89 1972, *Beilstein* **3** II 103.]

**Triethyl 2-phosphonopropionate [ethyl 2-(diethoxyphosphinyl)propionate]** [3699-66-9] **M 238.2, b 76-77°/0.2mm, 137-138.5°/17mm, d<sub>0</sub><sup>20</sup> 1.096, n<sub>D</sub><sup>20</sup> 1.432.** Purify the ester by fractional distillation with high reflux ratio, preferably using a spinning band column. [Kosolapoff & Powell *J Am Chem Soc* **72** 4198 1950, Kresze et al. *Justus Liebigs Ann Chem* **756** 112 1972, *Beilstein* **4** IV 3617.]

**Triethylsilane** [617-86-7] **M 116.3, b 105-107°, 107-108°, d<sub>0</sub><sup>20</sup> 0.734, n<sub>D</sub><sup>20</sup> 1.414.** Reflux triethylsilane over molecular sieves, then distil it. It is passed through neutral alumina before use [Randolph & Wrighton *J Am Chem Soc* **108** 3366 1986]. [*Beilstein* **4** IV 3895.]

**Triethylsilyl-1,4-pentadiene (1,4-pentadien-3-yloxy-trimethylsilane)** [62418-65-9] **M 198.4, b 72-74°/12mm, d<sub>4</sub><sup>20</sup> 0.842, n<sub>D</sub><sup>20</sup> 1.439.** Dissolve the diene in pentane, wash this with H<sub>2</sub>O, dry (Na<sub>2</sub>SO<sub>4</sub>), evaporate, and distil it under vacuum. R<sub>F</sub> values on Kieselgel 60 are 0.15 (pentane) and 0.60 (\*C<sub>6</sub>H<sub>6</sub>). [IR, NMR, MS: Oppolzer et al. *Helv Chim Acta* **64** 2002 1981.]

**Tri-*n*-hexylborane** [1188-92-7] **M 265.3, b 127°/1.5mm, b 185-188°/30mm.** Treat the borane with hex-1-ene and 10% anhydrous Et<sub>2</sub>O for 6 hours at gentle reflux under N<sub>2</sub>, then distil it in a vacuum through an 18 inch glass helices-packed column under N<sub>2</sub> taking the fraction **b** 130°/2.1mm to 137°/1.5mm. The distillate may still contain some di-*n*-hexylborane [Brown & Subba Rao *J Am Chem Soc* **81** 6423 1959, Mirviss *J Am Chem Soc* **83** 3051 1961]. [*Beilstein* **4** IV 4362.]

**Triisomyl phosphate** [919-62-0] **M 308.4, b 143°/3mm.** Purify the ester by repeated crystallisation of its addition compound with uranyl nitrate from hexane. Decompose the complex, and distil the ester at high vacuum. [Siddall *J Am Chem Soc* **81** 4176 1959.] [see *tributyl phosphate* and Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol **6** pp 211-577 1973.]

**Triisobutyl phosphate** [126-71-6] **M 266.3, b 119-129°/8-12mm, 192°/760mm, d<sub>4</sub><sup>20</sup> 0.962, n<sub>D</sub><sup>20</sup> 1.421.** Purify the phosphate by repeated crystallisation of its addition compound with uranyl nitrate from hexane. (see *tributyl*

phosphate.) [Siddall *J Am Chem Soc* **81** 4176 1959; see Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol **6** pp 211-577 1973.]

**Triisooctyl thiophosphate** [30108-39-5] **M 450.6**. Purify the ester by passing its solution in  $\text{CCl}_4$  through a column of activated alumina. [See Ailman & Magean in *Organo Phosphorus Compound* (Kosolapoff & Maier eds) Wiley Vol **7** pp 487-465 1973, and tri-*p*-tolyl phosphate below.]

**Tri-isopropyl borate** [(iso-PrO)<sub>3</sub>B, boric acid tri-isopropyl ester, Boron iso-propoxide] [5419-55-6] **M 188.1**, **b** 75°/76mm, 90°/120mm, 139-141°/760mm,  $d_4^{25}$  0.815,  $n_D^{20}$  1.376. The borate ester is prepared in 85% yield from *iso*-propanol (250ml) and  $\text{NaBH}_4$  (6.84g) followed by dropwise addition of AcOH (0.18g) over a period of 11 minutes, and then refluxing for 4 hours (fume cupboard and a "Dry-Ice" condenser as 16.15L of  $\text{H}_2$  are released, CARE due to its flammability). Then fractionate the ester through a Widmer column. [Brown et al. *J Am Chem Soc* **78** 3613 1956.] The ester is a good reagent for borylation, e.g. *ortho*-borylating 1-substituted naphthalenes, by reacting with 1-halo- or cyano- naphthalenes (after treatment with LiTMP) to form 2-boryl esters which are later used in Pd-catalysed cross-coupling reactions [Lysén et al. *Synthesis* 3478 2006]. [Beilstein **1** H 363, **1** II 382, **1** III 1468, **1** IV 1488.]

**Triisopropyl phosphite** [116-17-6] **M 208.2**, **b** 58-59°/7mm, 63-64°/7mm,  $n_D^{25}$  1.4082. Distil the phosphite from sodium, under vacuum, through a column packed with glass helices. (This removes any dialkyl phosphonate.) [Ford-Moore & Williams *J Chem Soc* 1465 1947, Arbuzov *Chem Ber* **38** 1171 1905, see Verkade & Coskren in *Organo Phosphorus Compound* (Kosolapoff & Maier eds) Wiley Vol **2** pp 1-187 1972, Beilstein **1** IV 1476.]

**Trimesitylphosphine** [23897-15-6] **M 388.5**, **m** 205-206°,  $pK_{\text{Est}} \sim 8.0$ . It recrystallises from EtOH [Boert et al. *J Am Chem Soc* **109** 7781 1987]. The *P*-methyl iodide has **m** 269° (yellow powder from EtOH or  $\text{H}_2\text{O}$ ). [Beilstein **16** H 774.]

**Trimethyllyl phosphate** [14019-81-9] **M 260.3**, **b** 134.5-140°/5mm,  $n^{25}$  1.4454. Purify it as for triisoamyl phosphate. [Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol **6** pp 211-577 1973.]

**Trimethoxysilane** [2487-90-3] **M 122.2**, **m** -114.8°, 81.1°/760mm, 84°/atm,  $d_4^{20}$  0.957,  $n_D^{20}$  1.359. Likely impurities are  $\text{Si}(\text{OMe})_4$  and  $\text{H}_2\text{Si}(\text{OMe})_2$ . Efficient fractionation is essential for removing these impurities [IR: Sternbach & MacDiarmid *J Am Chem Soc* **81** 5109 1959, Heilfrich & Hausen *Chem Ber* **57** 795 1924, Beilstein **1** IV 1266.]

**Trimethyl borate (methylborate, trimethoxyboron)** [121-43-7] **M 103.9**, **m** -34°, **b** 67-68°/742mm,  $d_4^{20}$  0.928,  $n_D^{20}$  1.3610. Carefully fractionate the borate through a gauze-packed column. Re-distil and collect it in weighed glass vials and seal them. Keep it away from moisture. It undergoes alkyl exchange with alcohols and forms azeotropes, e.g. with MeOH the azeotrope consists of 70%  $(\text{MeO})_3\text{B}$  and 30% MeOH with **b** 52-54°/760mm,  $d$  0.87. [Charnley et al. *J Chem Soc* 2288 1952, Gerrard & Lappert *Chem Ind (London)* 53 1952, Schlesinger et al. *J Am Chem Soc* **75** 213 1953.] It has also been dried with Na and then distilled. [Beilstein **1** IV 1269.]

**Trimethyl boroxine ( $\text{Me}_3\text{B}_3\text{O}_3$ )** [823-96-1] **M 125.5**, **m** -38°, **b** 80°/742mm, 79.3°/755mm,  $d_4^{20}$  0.902,  $n_D^{20}$  1.362. Possible impurity is methylboronic acid. If present, then add a few drops of conc  $\text{H}_2\text{SO}_4$  and distil it immediately, then fractionate it through an efficient column. [McCusker et al. *J Am Chem Soc* **79** 5179 1957, IR: Goubeau & Keller *Z Anorg Allgem Chem* **272** 303 1953, Beilstein **4** IV 4378.]

**Trimethylphenylsilane (phenyltrimethylsilane)** [768-32-1] **M 150.3**, **b** 67.3°/20mm, 98-99°/80mm, 170.6°/738mm,  $d_4^{25}$  0.8646,  $n_D^{20}$  1.491. Fractionally distil the silane at atmospheric or reduced pressure (Podbielniak column) and estimate it by GC with a column packed with Silicone Fluid No 710 on Chromosorb P support. [Gilman et al. *J Org Chem* **18** 1743 1953, Maienthal et al. *J Am Chem Soc* **76** 6392 1954, House & Respass *J Organomet Chem* **4** 95 1965, Roberts et al. *J Am Chem Soc* **71** 2923 1949, Freiser et al. *J Am Chem*

*Soc* 75 2821 1953, *Beilstein* 16 I 525, 16 II 605, 16 III 1198, 16 IV 1361.]

**Trimethyl phosphate** [512-56-1] **M 140.1**, **b** 77°/12mm, 94°/22mm, 110°/60mm, 197.2°/atm,  $d_4^{20}$  1.0213,  $n_D^{20}$  1.3961. Purify the phosphate by fractionation through an efficient column at high reflux ratio. It is quite soluble in H<sub>2</sub>O; the solubility is 1:1 at 25°. [Becker *J Am Chem Soc* 74 2923 1952, IR: Bergmann et al. *J Chem Soc* 847 1952, McIvor et al. *Can J Chem* 36 820 1958, Kosolapoff *Organophosphorus Compounds*, Wiley p 258 1950, and Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol 6 pp 211-577 1973, *Beilstein* 1 IV 1259.]

**Trimethylphosphine** [594-09-2] **M 76.1**, **m** -86°, **b** 38-39°/atm, **pK<sup>25</sup> 8.65**, (also available as a 1.0M solution in THF or toluene). **All operations should be carried out in an efficient fume cupboard because it is flammable, toxic and has a foul odour.** Distil trimethylphosphine at atmospheric pressure in a stream of dry N<sub>2</sub> (apparatus should be held together with springs to avoid loss of gas from increased pressure in the system) and the distillate run into a solution of AgI in aqueous KI whereby the silver complex [Me<sub>3</sub>PAGI]<sub>4</sub> separates steadily. Filter off the complex, wash it with saturated aqueous KI solution, then H<sub>2</sub>O and dry it in a vacuum desiccator over P<sub>2</sub>O<sub>5</sub>. The dry complex is heated in a flask (in a stream of dry N<sub>2</sub>) in an oil bath at 140°, when pure Me<sub>3</sub>P distils off (bath temperature can be raised up to 260°). The vapour pressure of Me<sub>3</sub>P at 20° is 466mm and the **b** is 37.8° [Thomas & Eriks *Inorg Synth* IX 59 1967]. Alternatively, freshly distilled Me<sub>3</sub>P (6g) is shaken with a solution of AgI (13.2g, 1.1mol) in saturated aqueous KI solution (50ml) for 2 hours. A white solid, not wetted with H<sub>2</sub>O, separates rapidly. It is collected, washed with the KI solution, H<sub>2</sub>O, and dried [Mann et al. *J Chem Soc* 1829 1937]. The silver complex is stable if kept dry in the dark, in which state it can be kept indefinitely. Me<sub>3</sub>P can be generated from the complex when required. Store it under N<sub>2</sub> in a sealed container. It has been distilled in a vacuum line at -78° *in vacuo* and condensed at -96° [IR and NMR: Crosbie & Sheldrick *J Inorg Nucl Chem* 31 3684 1969]. The pK<sup>22</sup> by NMR was 8.80 [Silver & Lutz *J Am Chem Soc* 83 786 1961, pK<sup>25</sup> 8.65: Henderson & Strueuli *J Am Chem Soc* 82 5791 1960].

The [Me<sub>2</sub>PAGI]<sub>4</sub> complex [12389-34-3] is a flammable solid which has **m** 140-142°. It is decomposed by heating gently in one arm of an inverted U tube. The other arm is kept in a freezing mixture. The complex dissociates, and pure Me<sub>3</sub>P collects in the cold arm and is used at once. It should not be allowed to come in contact with air [for AsMe<sub>3</sub> see Mann & Wells *J Chem Soc* 708 1938]. The CS<sub>2</sub> complex has **m** 119° (crystallising from 95% EtOH) and decomposes in CCl<sub>4</sub> to give Me<sub>3</sub>PS **m** 154° (from EtOH) [Soretas & Isbell *J Org Chem* 27 273 1962].

*Trimethylphosphine hydrochloride* is unstable and volatilises at 75°/0.4mm (120°/14mm). [Brown *J Am Chem Soc* 67 503 1945, IR: Wagstaffe & Thompson *Trans Faraday Soc* 40 41 1944, Kosolapoff *Organo-phosphorus Compounds*, Wiley p 31 1950, *Beilstein* 4 IV 3429.]

**Trimethyl phosphite** [121-45-9] **M 124.1**, **b** 22°/23mm, 86-86.5°/351mm, 111-112°/760mm, 111°/atm,  $d_4^{20}$  1.0495,  $n_D^{20}$  1.408. Treat the phosphite with Na (to remove water and any dialkyl phosphonate), then decant and distil it with protection against moisture. It has also been treated with sodium wire for 24 hours, then distilled in an inert atmosphere onto activated molecular sieves [Connor et al. *J Chem Soc, Dalton Trans* 511 1986]. It can be fractionally distilled using a spinning band column at high reflux ratio. It is a colourless liquid which is slowly hydrolysed by H<sub>2</sub>O. [Gillis et al. *J Am Chem Soc* 80 2999 1958, <sup>31</sup>P NMR: Callis et al. *J Am Chem Soc* 79 2719 1957, Kosolapoff *Organophosphorus Compounds*, Wiley p 203 1950, *Beilstein* 1 IV 1256.]

**Trimethylsilyl acetamide** [13435-12-6] **M 131.3**, **m** 38-43°, 52-54°, **b** 84°/13mm, 185-186°/atm. Distil the amide repeatedly in an inert atmosphere with all operations to be performed in an anhydrous atmosphere. In the presence of moisture, trimethylsilanol (**b** 31-34°/26mm) is formed and is a likely impurity (check by NMR). [Birkofer et al. *Chem Ber* 96 1473 1963, *Beilstein* 4 IV 4011.]

**Trimethylsilyl acetonitrile (TMSAN)** [18293-53-3] **M 113.2**, **b** 49-51°/10mm, 65-70°/20mm,  $d_4^{20}$  0.8729,  $n_D^{20}$  1.4420. Check if NMR and IR spectra show impurities; if present dissolve it in \*C<sub>6</sub>H<sub>6</sub> (10 volumes), wash it with buffer (AcOH/AcONa pH ca 7) several times, dry (CaCl<sub>2</sub>) it, filter, evaporate and distil it. Its IR (CCl<sub>4</sub>) has

$\nu_{\max}$  at 2215 (CN)  $\text{cm}^{-1}$ , and  $^1\text{H}$  NMR ( $\text{CCl}_4$ ) with  $\delta$  at 0.23 (s, 9H,  $\text{SiMe}_3$ ), and 1.53 (s, 2H,  $\text{CH}_2\text{CN}$ ). [Matsuda et al. *J Chem Soc, Perkin Trans 1* 26 1979, *Beilstein* 4 IV 3974.]

**Trimethylsilyl azide** [4648-54-8] **M 115.2, b 92-95°/atm, 95-99°/atm,  $d_4^{20}$  0.878,  $n_D^{20}$  1.441.** Distil the azide through a Vigreux column in a  $\text{N}_2$  atmosphere maintaining the oil bath temperature thermostat at 135-140°. Check the purity by  $^1\text{H}$  NMR [ $\text{CHCl}_3$ ,  $\delta$ : single peak at 13cps from  $\text{Me}_4\text{Si}$ ]. Likely impurities are siloxane hydrolysis products. The azide is thermally stable even at 200° when it decomposes slowly without explosive violence. All the same, it is advisable to carry out the distillation behind a thick safety screen in a fumehood because unforeseen **EXPLOSIVE** azides may be formed on long standing. [Birkofer & Wagner *Org Synth Coll Vol VI* 1030 1988.]

**Trimethylsilyl chloride (TMCS trimethyl chlorosilane, chlorotrimethylsilane)** [75-77-4] **M 108.6, b 56-57°/atm, 58°/760mm,  $d_4^{20}$  0.86,  $n_D^{20}$  1.388.** Likely impurities are other chlorinated methylsilanes and tetrachlorosilane (b 57.6°), some of which can form azeotropes. To avoid the latter, very efficient fractional distillation is required. It has been fractionated through a 12 plate glass helices-packed column with only the heart-cut material being used. It has also been fractionated through a 90cm, 19mm diameter Stedman column. Purify it by redistilling from  $\text{CaH}_2$  before use. [Sauer et al. *J Am Chem Soc* 70, 4254 1948, Sauer & Hadsell *J Am Chem Soc* 70 4258 1948, Langer et al. *J Org Chem* 23 50 1958, *Beilstein* 4 IV 4007.] **FLAMMABLE and CORROSIVE.**

**Trimethylsilyl chloroacetate** [18293-71-5] **M 166.7, m -20°, b 57-58°/14mm, 70-71°/30mm, 159°/760mm,  $d_4^{20}$  1.057,  $n_D^{20}$  1.4231.** Purify the chloroacetate by repeated fractionation, and taking the fractions with clean NMR spectra. [Anderson *J Am Chem Soc* 74 2371 1952, *Beilstein* 4 IV 4004.]

**Trimethylsilyl cyanide** [7677-24-9] **M 99.2, m 8-11°, 10.5-11.5°, 11-12°, 12-12.5°, b 54-55°/87mm, 67-71°/168mm, 114-117°/760mm, 118-119°/760mm,  $d_4^{20}$  0.79  $n_D^{20}$  1.43916.** The material should have only one sharp signal in the  $^1\text{H}$  NMR (in  $\text{CCl}_4$  with  $\text{CHCl}_3$  as internal standard) with  $\delta$  at 0.4, and the IR with  $\nu_{\max}$  at  $2210\text{cm}^{-1}$  (C≡) [McBride & Beachall *J Am Chem Soc* 74 5247 1952, Prober *J Am Chem Soc* 77 3224 1955]; otherwise purify it by fractionating through an 18 x 1/4inch column. [Evers et al. *J Am Chem Soc* 81 4493 1959.] It has also been carefully distilled using a 60cm vacuum jacketed column. If the volume of sample is small, the cyanide can be chased (in the distillation) with xylene that had been previously distilled over  $\text{P}_2\text{O}_5$ . It is **HIGHLY TOXIC** and **FLAMMABLE**. [Evans et al. *J Org Chem* 39 914 1974, *Beilstein* 4 IV 3893.]

**Trimethylsilyldiazomethane (diazomethyl)trimethylsilane** [18107-18-1] **M 114.2, distils between 0°/100mm and 40°/15mm.** This diazo-silane is non-explosive, and non-mutagenic [Aoyama & Shiori *Chem Pharm Bull Jpn* 29 3249 1981] and the careful precautions used in preparing diazomethane are not strictly necessary here. It is a good safe and stable substitute for diazomethane and excess of reagent can be evaporated off. It is available commercially as 2.0M solutions in  $\text{Et}_2\text{O}$  or hexane. Solutions in hexane can be stored for periods of more than 6 months at 0° in the absence of light without noticeable decomposition. Care should be taken, however, when opening a container, as it may become pressurised by  $\text{N}_2$  which may be released, and should be done at ~0°.

Several methods were used for preparing this diazo-silane and some start from trimethylsilylmethylmagnesium chloride, e.g. by reaction with diazomethane (7-74%, Lappert et al. *J Chem Soc (A)* 2954 1970, Martin *Synth Commun* 13 809 1983), or with  $\text{TsN}_3$  (~17%, Mori et al. *Chem Pharm Bull Jpn* 30 3380 1982, Barton & Hoekman *React Inorg. Met-Org Chem* 9 297 1979], but the transfer of the azo group is most practical, high yielding and used on a large scale when diphenyl phosphorazidate is used, and is described here.

Trimethylsilylmethylmagnesium chloride [13170-43-9] is prepared in an inert atmosphere (e.g. argon) under strictly anhydrous conditions from Mg turning (10.7g, 0.44g-atom), anhydrous  $\text{Et}_2\text{O}$  (40ml) and 1,2-dibromoethane (0.1ml to initiate reaction) which are stirred at ~25° for 15 minutes, then 10ml of a mixture of trimethylsilylmethyl chloride (45.4g, 370mmol, freshly distilled at 97°/atm, see [2344-80-1] below) in anhydrous  $\text{Et}_2\text{O}$  (100ml) is added with stirring all at once to start the reaction followed by the rest in a dropwise manner at such a rate as to maintain gently reflux during the addition (~2 hours). After the exothermic reaction subsides, reflux and stirring are continued for 1 hour then the mixture is cooled to ~25°, and this Grignard

reagent is used in the next step. Under strictly anhydrous conditions and in a maintained argon atmosphere, a solution of diphenyl phosphorazidate (91.2g, 330mmol, freshly distilled at 134-136°/0.2mm see [26386-88-9] above) in anhydrous Et<sub>2</sub>O (350ml) is cooled and stirred in an ice-NaCl bath until the temperature is -10°, and the preceding Grignard reagent is added dropwise (*via* a funnel or a cannula) at such a rate as to maintain the inner temperature of the solution below 0° (addition requires ~ 1.5 hours, forming a large amount of white precipitate when two-thirds of the reagent is added). After addition is complete, the ice-salt bath is replaced by an ice bath while stirring for 2 hours, then stirring is continued for 14-16 hours. The mixture is again cooled in an ice-salt bath until the inner temperature drops to -15°, and cold H<sub>2</sub>O (35ml) is added dropwise while keeping the inner temperature below 0° (requiring ~ 1 hour), and the resulting yellow silyldiazomethane mixture is stirred for a further 0.5 hours. The mixture is filtered, the white solid is washed with Et<sub>2</sub>O (3 x 100ml), the combined filtrate and washings are washed with cold H<sub>2</sub>O (2 x 100ml), dried (Na<sub>2</sub>SO<sub>4</sub>), and the filtrate is placed in a 1L flask equipped with a Teflon-coated magnetic stirrer bar and a 30cm Vigreux column (1.5cm diameter). The mixture is slowly concentrated to *ca* 200ml by distillation at ~760mm with a bath temperature below 45° during ~6 hours (the colour of the distilled Et<sub>2</sub>O is yellow due to some co-distillation of the diazo-silane. This rate of distillation is important as a faster rate results in decreased yields of the diazo-silane. The concentration time can be reduced to ~ 4 hours if a 30cm Widmer column is used. The remaining deep-yellow solution is then distilled, in the same equipment, by reducing the pressure to 100mm at 0° (bath temperature) and then at 15mm and 40° (bath temperature) while the distillate is collected in a receiver in a Dry-ice/Me<sub>2</sub>CO bath until distillation is complete. The distillate is dried (MgSO<sub>4</sub>), filtered and diluted with redistilled hexane (100ml). This solution is then concentrated again by distillation through the 30cm Vigreux column until the temperature of the vapour reaches 68° (with final oil bath temperature at 87°) which requires ~3 hours. About 80-110ml of the residual yellow hexane solution contains 220-230mmol of *trimethylsilyldiazomethane* (67-70% based on the phosphorazidate). Its IR (hexane) has  $\nu_{\max}$  at 2075, 1260 and 885 cm<sup>-1</sup>, the <sup>1</sup>H NMR (100MHz, hexane, CHCl<sub>3</sub> as internal standard) has  $\delta$  at 0.16 (s, 9H, -Si(CH<sub>3</sub>)<sub>3</sub>) and 2.58 (s, 1H, -CHN<sub>2</sub>), and the <sup>1</sup>H NMR (100MHz, \*C<sub>6</sub>H<sub>6</sub>) has  $\delta$  at -0.03 (s, 9H, -Si(CH<sub>3</sub>)<sub>3</sub>) and 2.23 (s, 1H, -CHN<sub>2</sub>).

The concentration of *trimethylsilyldiazo-methane* in hexane can be determined by adding 91mg (0.5mmol) of dibenzyl (see [103-29-7], Aromatic compounds) in 1ml of the hexane solution containing it, and measuring the <sup>1</sup>H NMR. The concentration of the azo-silane (*x* mmol/ml) is calculated from the formula:  $x = 2a/b$ , where *a* is the integral value (mm) of the methine proton ( $\delta$ : 2.58) of *trimethylsilyldiazomethane*, and *b* is the integral value (mm) of the methylene protons ( $\delta$ : 2.99) of dibenzyl. [Shioiri & Aoyama *Org Synth Coll Vol VIII* 612 1993, Mori et al. *Chem Pharm Bull Jpn* **30** 3380 1982].

It has been used for stereo and/or regio selective dipolar cycloadditions, e.g. with chiral acrylamides it produces <sup>2</sup> $\Delta$ -pyrazoline carboxylic acids (azaprolines) after protio-desilylation [Mish et al. *J Am Chem Soc* **119** 8379 1997], or with diethyl *trans*-glutaconate where the pyrazoline ester is oxidised to the respective pyrazole [Di & Rein *Tetrahedron Lett* **45** 4703 2004]. It also acts as a carbene source in stereoselective [1 + 4] annulation reactions with silylvinylketenes to form a variety of cyclopent-2-enones in good to excellent yields [Moser et al. *J Org Chem* **71** 6542 2006].

**2-Trimethylsilyl-1,3-dithiane** [13411-42-2] **M 192.2, b 54.5°/0.17mm, 100°/8mm,  $d_4^{20}$  1.04,  $n_D^{20}$  1.533.** Fractionally distil the dithiane through an efficient column and collect the fractions that have the correct NMR and IR spectra. Its <sup>1</sup>H NMR (CCl<sub>4</sub>) has  $\tau$  at 6.36 (SiMe<sub>3</sub>), 9.87 (SCHS) and dithiane H at 7 and 8 (ratio 1:9:4:2) from Me<sub>4</sub>Si; the UV has  $\lambda_{\max}$  at 244nm ( $\epsilon$  711), sh 227nm ( $\epsilon$  800). [Corey et al. *J Am Chem Soc* **89** 434 1967.]

**2-(Trimethylsilyl)ethanesulfonyl chloride (SES-Cl)** [106018-85-3] **M 200.8, b 60°/0.1mm, 146.8°/760mm,  $d_4^{25}$  1.059,  $n_D^{25}$  1.4444.** Check IR: if the bands at ~3200 (OH) cm<sup>-1</sup> are strong, then much of the SES-Cl had hydrolysed, and it should be treated with POCl<sub>3</sub> (with cooling) and stirred at ~25° for about 1 hour, poured into ice cold H<sub>2</sub>O, extracted with CH<sub>2</sub>Cl<sub>2</sub>, washed with NaHCO<sub>3</sub>, dried (Na<sub>2</sub>SO<sub>4</sub>), evaporated, and it distils as a yellow oil in a vacuum. This procedure is used for converting the Na salt [18143-30-1] to SES-Cl. It reacts with amines to form amides, e.g. SES-NRR', which on heating with CsF (i.e. F<sup>-</sup> ions) in DMF at 95° provide the amine (NHRR'), SO<sub>2</sub> and CH<sub>2</sub>=CH<sub>2</sub> [Weinreb et al. *Tetrahedron Lett* **27** 2099 1986]. [Ribiere et al. *Chem Rev*

106 2249 2006.]

**Trimethylsilyl ethanol** [2916-68-9] **M 118.3, b 53-55°/11mm, 75°/41mm, 95°/100mm,  $d_4^{25}$  0.8254,  $n_D^{25}$  1.4220.** If the NMR spectrum is not clean, then dissolve the alcohol in Et<sub>2</sub>O, wash it with aqueous NH<sub>4</sub>Cl solution, dry (Na<sub>2</sub>SO<sub>4</sub>), evaporate and distil it. The 3,4-dinitrobenzoyl derivative has **m 66°** (from EtOH). [NMR: Speier et al. *J Am Chem Soc* **79** 974 1957, *Z Naturforsch* **14b** 137 1959, *Beilstein* **4** IV 3951.]

**2-(Trimethylsilyl)ethoxymethyl chloride (SEMCl)** [76513-69-4] **M 166.7, b 57-59°/8mm,  $d_4^{20}$  0.942,  $n_D^{20}$  1.4350.** Dissolve SEMCl in pentane, dry it (MgSO<sub>4</sub>), evaporate and distil the residual oil in a vacuum. Stabilise it with 10 ppm of diisopropylamine. Store it under N<sub>2</sub> in a sealed container in a refrigerator. [Lipshutz & Pegram *Tetrahedron Lett* **21** 3343 1980.]

**2-(Trimethylsilyl)ethoxymethyltriphenylphosphonium chloride** [82495-75-8] **M 429.0, m 140-142°, 145-149°.** Wash the solid with AcOH and recrystallise it from CH<sub>2</sub>Cl<sub>2</sub>/EtOAc. Dry it in a vacuum desiccator. *Hygroscopic.* The <sup>1</sup>H NMR (CDCl<sub>3</sub>) has δ at -0.2 (s, Me<sub>3</sub>Si), 0.8 (t, 8Hz, CH<sub>2</sub>Si), 3.83 (t, 8Hz, OCH<sub>2</sub>), 5.77 (d, *J*<sub>PH</sub> = 4Hz, P<sup>+</sup>-CH<sub>2</sub>O) and 7.70 (m, aromatic H). [Schönauer & Zbiral *Justus Liebigs Ann Chem* 1039 1983.]

**Trimethylsilylethyl phenylsulfone (phenyl-2-trimethylsilylethylsulfone)** [73476-18-3] **M 242.4, m 52°.** Dissolve the sulfone in Et<sub>2</sub>O, wash it with saturated HCO<sub>3</sub> followed by saturated NaCl, H<sub>2</sub>O and dried (MgSO<sub>4</sub>). Filtration followed by evaporation leaves residual crystals with **m 52°**. [Hsiao & Shechter *Tetrahedron Lett* **23** 1963 1982, Bortolini et al. *J Org Chem* **53** 2688 1985.]

**Trimethylsilyl isocyanate** [1118-02-1] **M 115.2, b 90-92°/atm, b 91.3-91.6°/atm,  $d_4^{20}$  0.850  $n_D^{20}$  1.43943.** Purify it by repeated fractionation as for the isothiocyanate below. [Eaborn *J Chem Soc* 3077 1950, *Beilstein* **4** III 1861, **4** IV 4011.]

**Trimethylsilyl isothiocyanate** [2290-65-5] **M 131.3, m -33°, b 142.6-143.1°/759mm, 143.8°/760mm,  $n_D^{20}$  1.4809.** The <sup>1</sup>H NMR spectrum should have only one peak; if not, purify it by repeated fractionation in an all-glass system using a 50cm (4mm internal diameter) column without packing. [Anderson *J Am Chem Soc* **69** 3049 1947, Fehér & Blümcke *Chem Ber* **90** 1934 1957, Neidleim & Hege *Synthesis* 51 1975, *Beilstein* **4** III 1861, **4** IV 4011.]

**(Trimethylsilyl)methanol** [3219-63-4] **M 104.2, b 120-122°/754mm, 122-123°/768mm,  $d_4^{20}$  0.83  $n_D^{20}$  1.4176.** If the NMR indicates impurities (should have only two signals), then dissolve it in Et<sub>2</sub>O, shake this with aqueous 5N NaOH, M H<sub>2</sub>SO<sub>4</sub>, saturated aqueous NaCl, dry (MgSO<sub>4</sub>) and distil it using an efficient column at atmospheric pressure. The 3,5-dinitrobenzoate has **m 70-70.5°** (from 95% EtOH). [Huang & Wang *Acta Chem Sin* **23** 291 1957, cf. *Chem Abstr* **52** 19911 1958, Speier et al. *J Am Chem Soc* **81** 1844 1959 and Speier et al. *J Am Chem Soc* **70** 1117 1948, *Beilstein* **4** III 1844, **4** IV 2876.]

**(Trimethylsilyl)methylamine (aminomethyl trimethylsilane)** [18166-02-4] **M 103.2, b 101.6°/735mm,  $d_4^{20}$  0.77,  $n_D^{20}$  1.416.** A possible contaminant is hexamethyldisiloxane. It should have two <sup>1</sup>H NMR signals in CDCl<sub>3</sub>; if not, dissolve it in \*C<sub>6</sub>H<sub>6</sub>, shake it with 15% aqueous KOH, separate, dry (Na<sub>2</sub>SO<sub>4</sub>), filter, evaporate and distil it using a still of *ca* 10 theoretical plates. The water azeotrope has **b 83°/735mm**; hence it is important to dry the extract well. The *hydrochloride* has **m 198-199°** (from MeOH or Me<sub>2</sub>CO). [Noll et al. *J Am Chem Soc* **73** 3867 1951, *Beilstein* **4** IV 3878.]

**(Trimethylsilyl)methyl chloride (chloromethyltrimethylsilane, silico-neopentyl chloride)** [2344-80-1] **M 122.7, b 97.1°/734mm, 98.2-98.7°/747mm  $d_4^{25}$  0.979,  $n_D^{20}$  1.4180.** This chloride is prepared by stirring a mixture of TMS (174g, 2 moles, Me<sub>4</sub>Si see [75-76-3]) in dry CCl<sub>4</sub> (150ml) and PCl<sub>5</sub> (3g) [use suitably placed traps of Dry-ice/Me<sub>2</sub>CO to prevent loss of TMS] under a reflux condenser and irradiated with a 450 watt GE sunlight lamp while dry chlorine is bubbled through for 4 hours at a rate of 0.5 mole per hour (check weight of flask occasionally). The mixture is then fractionated using a 15-plate glass helix packed column to give the *trimethylsilylmethyl chloride* (53g, 0.44 mole), **b 97.1°/734mm**, *polychlorinated tetramethylsilane* (93g) and

recovered TMS (62g, 0.7 mole). The *chloride* can be analysed by placing ~0.2g in a gelatin capsule in a Parr bomb and fused with Na<sub>2</sub>O<sub>2</sub> (15g) and sucrose (1g). The melt is treated with H<sub>2</sub>O, acidified with HNO<sub>3</sub> and the chloride ion is determined by titration using the Volhard method. [Whitmore & Sommer *J Am Chem Soc* **68** 481 1946, *Beilstein* **4** IV 3877.] It has also been prepared by reaction of chloro-dimethyl-chloromethyl-silane and MeMgBr in Et<sub>2</sub>O [Whitmore et al. *J Am Chem Soc* **69** 1976 1947, Roedel *J Am Chem Soc* **71** 271 1949]. [*Beilstein* **4** III 1844, **4** IV 3877.]

It is readily converted to *trimethylsilylmethylmagnesium chloride* (see [13170-43-9] above) in ~90% yield. It reacts with *n*-BuLi in pentane to give *trimethylsilylmethylLi* [Sommer et al. *J Am Chem Soc* **71** 2750 1949], which reacts with anhydrous cerium (III) chloride to form *trimethylsilylmethyl cerium dichloride*. The latter reacts with acyl halides to provide bis-β-silylethyl tertiary alcohols that efficiently undergo a trimethylchlorosilane-promoted Peterson reaction to generate allylsilanes in high overall yields [Anderson & Fuchs *Synth Commun* **17** 621 1987]. It is useful also for Peterson olefination and homologation of aldehydes and ketones *via* 1,2-epoxysilanes [Lee et al. *Tetrahedron* **45** 5877 1989]. *Trimethylsilylmethyl bromide* [18243-41-9] has **M** 167.1, **b** 115.5°/atm, **d**<sub>4</sub><sup>25</sup> 1.17, **n**<sub>D</sub><sup>20</sup> 1.444 [*Beilstein* **4** IV 3878], and *trimethylsilylmethyl iodide* [4206-67-1] has **M** 214.1, **b** 139-141°/atm, **d**<sub>4</sub><sup>25</sup> 1.433, **n**<sub>D</sub><sup>20</sup> 1.491 [*Beilstein* **4** IV 3878], and both should be stored in the dark.

**Trimethylsilylmethyl phenylsulfone (phenyltrimethylsilylmethylsulfone)** [17872-92-3] **M** 228.4, **m** 28-32°, **b** 121°/0.01mm, 160°/6mm, **n**<sub>D</sub><sup>20</sup> 1.5250. Fractionate the sulfone at high vacuum and recrystallise it from pentane at -80°. If too impure (*cf* IR), dissolve it in CH<sub>2</sub>Cl<sub>2</sub> (*ca* 800ml for 100g), wash this with 2M aqueous NaOH (2 x 200ml), brine, dry, evaporate and distil it. [Craig et al. *J Chem Soc, Perkin Trans 1* 1949 1985, IR and NMR: Cooper *J Am Chem Soc* **76** 3713 1954.]

**1-Trimethylsilyloxy-1,3-butadiene** [6651-43-0] **M** 142.3, **b** 131°/760mm (mixture of isomers), 49.5°/25mm (*E*-isomer), **d**<sub>4</sub><sup>20</sup> 0.8237, **n**<sub>D</sub><sup>20</sup> 1.447. Purify the butadiene by fractional distillation, and collect the fractions with the required <sup>1</sup>H NMR. Store it under N<sub>2</sub> — it is a flammable and moisture-sensitive liquid. [Caseau et al. *Bull Soc Chim Fr* 16658 1972, Belge Patent 670,769, *Chem Abstr* **65** 5487d 1966.]

**1-(Trimethylsilyloxy)cyclopentene** [19980-43-9] **M** 156.3, **b** 45°/11mm, 75-80°/20-21mm, **d**<sub>4</sub><sup>20</sup> 0.878, **n**<sub>D</sub><sup>20</sup> 1.441. If too impure as seen by the NMR spectrum, then dissolve it in 10 volumes of pentane, shake with cold NaHCO<sub>3</sub> (3 x 500ml), then 1.5M HCl (200ml) and aqueous NaHCO<sub>3</sub> (200ml) again, dry (Na<sub>2</sub>SO<sub>4</sub>), filter, evaporate and distil it through a short Vigreux column. Its <sup>1</sup>H NMR (CDCl<sub>3</sub>) has δ at 0.21 (s, 9H), 1.55 (m, 2H), 1.69 (m, 2H), 2.05 (br d, 4H) and 4.88 (br s, 1H). GLPC in a 6ft x 1/8inch with 3% SP2100 on 100-120 mesh Supelcoport column should give one peak. Store dry. [For the cyclohexene analogue see Varghese et al. *Org Synth Coll Vol VIII* 460 1993.]

**2-(Trimethylsilyloxy)furan** [61550-02-5] **M** 156.3, **b** 34-35°/9-10mm, 42-50°/17mm, 40-42°/25mm, **d**<sub>4</sub><sup>20</sup> 0.950, **n**<sub>D</sub><sup>20</sup> 1.436. Fractionally distil the furan using a short path column. Its <sup>1</sup>H NMR in CCl<sub>4</sub> has δ at 4.90 (dd, *J* = 1.3Hz, 3H), 6.00 (t, *J* = 3Hz, 4H) and 6.60 (m, 5H). [Yoshii et al. *Heterocycles* **4** 1663 1976.]

**4-Trimethylsilyloxy-3-penten-2-one (cis) (acetylacetone enol trimethylsilyl ether)** [13257-81-3] **M** 172.3, **b** 66-68°/4mm, 61-63°/5mm, **d**<sub>4</sub><sup>20</sup> 0.917, **n**<sub>D</sub><sup>20</sup> 1.452. Fractionally distil the enone, and store it in glass ampoules which are sealed under N<sub>2</sub>. It hydrolyses readily in contact with moisture giving, as likely impurities, hexamethyldisiloxane and 2,4-pentanedione. [West *J Am Chem Soc* **80** 3246 1958, *Beilstein* **4** IV 4003.]

**1-(Trimethylsilyl)-2-phenylacetylene (1-phenyl-2-trimethylsilylacetylene)** [78905-09-6] **M** 174.3, **b**\* 45-46°/0.1mm, 67°/5mm, 87.5°/9mm, **d**<sub>4</sub><sup>20</sup> 0.8961, **n**<sub>D</sub><sup>20</sup> 1.5284. Dissolve the acetylene in Et<sub>2</sub>O, wash with H<sub>2</sub>O, dry and fractionate it through a Todd column. [Benkeser & Hicker *J Am Chem Soc* **80** 5298 1958.]

**3-(Trimethylsilyl)propyne** [13361-64-3] **M** 112.3, **b** 99-100°/760mm, **d**<sub>4</sub><sup>20</sup> 0.7581, **n**<sub>D</sub><sup>20</sup> 1.4091. Fractionally distil the propyne, and add 2,6-di-*tert*-butyl-*p*-cresol (~0.5%) to stabilise it. [Petrov et al. *Doklady Acad Nauk USSR* **93** 293 1953, *cf Chem Abstr* **48** 13616 1954, *Beilstein* **4** IV 3938.]

**2-Trimethylsilylpyridine** [13737-04-7] **M** 151.3, **b** 47-49°/5mm, 69°/14.5mm, 74°/21mm, **d**<sub>4</sub><sup>25</sup> 0.9113, **n**<sub>D</sub><sup>20</sup>

**1.489.** Purify it by distillation in a vacuum, but if it is discoloured then dissolve it in Et<sub>2</sub>O or \*C<sub>6</sub>H<sub>6</sub>, wash it with H<sub>2</sub>O, dry over Na<sub>2</sub>SO<sub>4</sub>, filter, evaporate and distil the residue. It is more readily hydrolysed than the 3- or 4-trimethylsilyl isomers and the relative rates of hydrolysis in H<sub>2</sub>O:MeOH:EtOH are 740:120:1; pyridine being liberated. Acids inhibit the reaction but bases have little effect. [Anderson et al. *J Chem Soc B* 450 1958, Effenberger & Häbich *Justus Liebigs Ann Chem* 512 149-151 1934, Itami *Tetrahedron* 57 5045 2001.]

**3-Trimethylsilylpyridine** [13779-37-2] **M151.3, b 94°/30mm, d<sub>4</sub><sup>25</sup> 0.9113, n<sub>D</sub><sup>20</sup> 1.4913.** Purify it as for the 1-isomer above except that less care needs to be taken as it hydrolyses more slowly. [Anderson et al. *J Chem Soc B* 450 1958.]

**4-Trimethylsilylpyridine** [18301-46-7] **M151.3, b 107°/48mm, d<sub>4</sub><sup>25</sup> 0.9113, n<sub>D</sub><sup>20</sup> 1.4868.** Purify it as for the 1-isomer above except that less care needs to be taken as it hydrolyses more slowly. [Anderson et al. *J Chem Soc B* 450 1958.]

**1-Trimethylsilyl-1,2,4-triazole** [18293-54-4] **M 141.3, b 74°/12mm, d<sub>4</sub><sup>20</sup> 0.99, n<sub>D</sub><sup>20</sup> 1.4604.** Fractionally distil it at atmospheric pressure in an inert atmosphere because it is moisture sensitive. [Birkofer et al. *Chem Ber* 93 2804 1960.]

**Trimethylsilyl trifluoromethane (trifluoromethyl trimethylsilane, Ruppert's reagent)** [81290-20-2] **M 142.2, b 54-55°, 55-55.5°, d<sub>4</sub><sup>20</sup> 0.962, n<sub>D</sub><sup>20</sup> 1.332.** Purify the silane by distilling it from trap to trap in a vacuum of 20mm using a bath at 45° and Dry-ice/Me<sub>2</sub>CO bath for the trap. The liquid in the trap is then washed with ice cold H<sub>2</sub>O (3x), the top layer is collected, dried (Na<sub>2</sub>SO<sub>4</sub>), and the liquid is decanted and fractionated through a helices-packed column at atmospheric pressure. <sup>1</sup>H, <sup>13</sup>C, <sup>19</sup>F, and <sup>29</sup>Si NMR can be used for assessing the purity of fractions. [Ruppert et al. *Tetrahedron Lett* 25 2195 1984, Krishnamurti et al. *J Org Chem* 56 984 199, Beilstein 4 IV 3892.]

**2,8,9-Trimethyl-2,5,8,9-tetraaza-1-phosphabicyclo[3.3.3]undecane (Verkade Superbase, 2,8,9-trimethyl-pro-azaphosphatrane)** [120666-13-9] **M 216.3, m 110-115°, pKa 26.8 (DMSO).** The free superbase can be prepared in three ways. When tris(dimethylamino)phosphine (8.8g, 54mmol, toxic see [1608-26-0]) and tris[2-(methylamino)-ethyl]amine (10.0g, 53mmol, see [65604-89-9]) are dissolved in dry xylene and refluxed for 21 days, then the solvent is removed *in vacuo*, a residual thick oil is obtained. On heating this oil at 105°/0.05mm the *pro-azaphosphatrane* (53g, 24.5mmol, 46%) sublimes out as a colourless waxy solid.

In a second preparation the *trimethyl-pro-azaphosphatrane hydrochloride* (0.87g, 3.4mmol, see [138800-17-6] below) dissolved in MeCN (10ml) is added dropwise to a suspension of freshly sublimed *tert*-BuOK (0.41g, 3.7mmol) in MeCN (20ml), stirred for 30 minutes, the solvent is removed *in vacuo*, the residue is extracted with hexane (2 x 30ml), evaporated, and the residue is sublimed at 60°/0.01mm to give the pure *superbase* (80%) as a white solid. [Schmidt et al. *Z Anorg Allg Chem* 578 75 1989.]

In a third preparation the *trimethyl-azaphosphatrane hydrochloride* is heated slowly with a large excess of anhydrous NaOH under vacuum. No reaction occurs below 200°, but above this temperature sudden sublimation of the free superbase occurs. Extraction of the sublimate, and/or the reaction mixture, with \*C<sub>6</sub>H<sub>6</sub> followed by evaporation of the solvent provided pure free base (53% yield). Sometimes charring occurs during this reaction resulting in lower yields. [Lensink et al. *J Am Chem Soc* 111 3478 1959.]

The *free base* is an unusually strong Lewis base. It deprotonates phenol (pKa 10), protonated "Proton Sponge" [1,8-(bismethylamino)naphthalene HI (pKa 12.3, Alder et al. *J C S, Chem Commun* 723 1968), diethyl malonate (pKa 13, Pearson & Dillon *J Am Chem Soc* 75 2439 1953), H<sub>2</sub>O (pKa 13.99, Harned & Robinson *Trans Farad Soc* 36 2747 1940; or ? pKa 15.74 Reeve et al. *Can J Chem* 57 2747 1979), but does not react with *tert*-BuOH (pKa 16.5, Reeve et al. *Can J Chem* 57 2747 1979), to give the protonated base as the only product. In the presence of 1 equivalent of H<sub>2</sub>O an equilibrium mixture of free base to cation of ca 4:1 is obtained (from NMR studies) [Lensink et al. *J Am Chem Soc* 111 3478 1989.] The un-methylated analogous free base is not very stable although its hydrochloride is quite stable and it is a *stronger base* than the 2,8,9-trimethyl- or the respective 2,8,9-tribenzyl- derivative. The upper limit of the pKa of the trimethyl compound in DMSO is ~26.8 (by <sup>13</sup>P NMR) [Laramay & Verkade *J Am Chem Soc* 112 9421 1990]. The *free base* has IR (Nujol) with ν<sub>max</sub> at 1332 s, 1303 m, 1244 s, 1226 s, 1197m, 1145 s, 1128 s, 1053 s, 1004 s, 960 w, 887m, 850s, 767w, 650s and 634 s

cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, CD<sub>3</sub>CN, TMS) has δ at 2.60 (d, 9H, <sup>3</sup>J<sub>PH</sub> = 11.0 Hz, CH<sub>3</sub>) and 2.76 (br s, 12H, CH<sub>2</sub>); the <sup>13</sup>C NMR (75MHz, C<sub>6</sub>D<sub>6</sub>, TMS) has δ at 37.2 (<sup>2</sup>J<sub>PC</sub> = 41.0 Hz, CH<sub>3</sub>), 49.4 (d, <sup>2</sup>J<sub>PC</sub> = 6.7 Hz, N<sub>eq</sub>CH<sub>2</sub>) and 51.3 (s, N<sub>ax</sub>CH<sub>2</sub>); the <sup>31</sup>P NMR (122MHz, C<sub>6</sub>D<sub>6</sub>, 85% H<sub>3</sub>PO<sub>4</sub>) has δ at 120.8; and the HRMS has *m/z* 216.15088 (calc for M is 216.15039). [Schmidt et al. *Z Anorg Allg Chem* **578** 75 1989, Lensink et al. *J Am Chem Soc* **111** 3478 1989, Laramay & Verkade *J Am Chem Soc* **112** 9421 1990, Laramay & Verkade *Z Anorg Allg Chem* **608** 163 1991, Schmidt et al. *Inorg Chem* **29** 2214 1990]. In addition to being easily protonated (see following entry), the free base has been readily converted to P-substituted adducts (*five-coordinated phosphatranes*), where the P-H is replaced by P-X, where -X is -O (by using Me<sub>3</sub>SiO<sub>2</sub>), -S (by using S<sub>8</sub>), -Se (by using Se), -N<sub>3</sub>P (by using PhN<sub>3</sub>), -NPh (by using PhN<sub>3</sub> and heating), -CS<sub>2</sub> (by using CS<sub>2</sub>) and -PtCl<sub>2</sub> [by using (Et<sub>2</sub>S)<sub>2</sub>-PtCl<sub>2</sub>] in 60 to >80% yields [Schmidt et al. *Z Anorg Allg Chem* **578** 75 1989]. **Note** that the difference between the *pro-phosphatranes* and the *phosphatranes* is that the latter possess an apical N<sup>+</sup>O<sup>-</sup> bond as evidenced by the shorter bond distance in X-Ray diffraction analyses and the large decrease in the δ <sup>31</sup>P chemical shifts in the NMR spectra.

**2,8,9-Trimethyl-2,5,8,9-tetraaza-1-phosphabicyclo[3.3.3]undecane hydrochloride (Verkade Superbase HCl, 2,8,9-trimethylazaphosphatrane HCl)** [138800-17-6] **M 252.7, m 132-136°**. Like the preceding free base it is prepared in different ways — two are described here. A solution of PCl<sub>3</sub> (1.22g, 8.85mmol) in CH<sub>2</sub>Cl<sub>2</sub> (5.0ml) is added to a solution of P(NMe) (2.89g, 17.7mmol, toxic see [1608-26-0]) in CH<sub>2</sub>Cl<sub>2</sub> (5.0ml), then cooled to 5°, and TREN (3.88g, 26.5mmol, see [4097-89-6]) in CH<sub>2</sub>Cl<sub>2</sub> (25ml) is added during ~15 minutes. The precipitate formed is filtered off, washed with CH<sub>2</sub>Cl<sub>2</sub> (25ml) and dried to give the pure *hydrochloride* (5.58g, ~100%). Crystals for X-Ray diffraction can be grown from concentrated MeOH solutions. The *2,8,9-tribenzyl hydrochloride* can be similarly prepared in 89% yield by using tris-(*N*-benzylaminoethyl)amine in place of TREN. [Laramay & Verkade *Z Anorg Allg Chem* **605** 163 1991].

In the second preparation tris[2-(methylamino)-ethyl]amine (1.67g, 11.4mmol), see [65604-89-9]) in CH<sub>2</sub>Cl<sub>2</sub> (20ml) is added with stirring to a mixture of ClP(NMe<sub>2</sub>)<sub>2</sub> (1.76g, 11.4mmol, TOXIC) and Et<sub>3</sub>N (1.5g, 15mmol) in CH<sub>2</sub>Cl<sub>2</sub> (30ml) during 5 minutes, then the mixture is stirred at ~25° for 1 hour, the volatiles are evaporated off *in vacuo* to give the *hydrochloride* quantitatively. It can be recrystallised from hexane/CHCl<sub>3</sub> (82% yield) in colourless crystals. When the hydrochloride salt is treated with AgBF<sub>4</sub> in CH<sub>2</sub>Cl<sub>2</sub> the *HBF<sub>4</sub> salt* is obtained quantitatively. The salts are very difficult to deprotonate (see preceding entry). The X-ray crystal structure shows a short intra-annular bond between the apical N atom and the P atom with a robust P—H bond, the positive charge being on the apical N atom. [Laramay & Verkade *J Am Chem Soc* **112** 9421 1990, Lensink et al. *J Am Chem Soc* **111** 3478 1989.] It has <sup>1</sup>H NMR (300MHz, CDCl<sub>3</sub>, TMS) with δ at 2.61 (d, 9H, <sup>3</sup>J<sub>PH</sub> = 17.4 Hz, CH<sub>3</sub>) and 3.03 (dt, 6H, N<sub>ax</sub>CH<sub>2</sub>, <sup>3</sup>J<sub>PH</sub> = 11.0 Hz, <sup>3</sup>J<sub>HH</sub> = 6.2 Hz), 3.58 (dt, 6H, N<sub>eq</sub>CH<sub>2</sub>, <sup>3</sup>J<sub>PH</sub> = 4.7 Hz, <sup>3</sup>J<sub>HH</sub> = 6.2 Hz), 5.20 (d, 1H, <sup>1</sup>J<sub>PH</sub> = 6.2 Hz); the <sup>13</sup>C NMR (75MHz, CDCl<sub>3</sub>) has δ at 34.4 (d, <sup>2</sup>J<sub>PC</sub> = 17.1 Hz, CH<sub>3</sub>), 41.3 (d, <sup>2</sup>J<sub>PC</sub> = 6.1 Hz, N<sub>ax</sub>CH<sub>2</sub>) and 47.3 (d, <sup>2</sup>J<sub>PC</sub> = 7.3 Hz, N<sub>eq</sub>CH<sub>2</sub>); the <sup>31</sup>P NMR (122MHz, CDCl<sub>3</sub>, 85% H<sub>3</sub>PO<sub>4</sub>) has δ at -10.6 [Lensink et al. *J Am Chem Soc* **111** 3478 1989].

**Trimethyl vinyl silane** [754-05-2] **M 100.2, b 54.4°/744mm, 55.5°/767mm, d<sub>4</sub><sup>25</sup> 0.6865, n<sub>D</sub><sup>25</sup> 1.3880**. If the <sup>1</sup>H NMR spectrum shows impurities, then dissolve it in Et<sub>2</sub>O, wash it with aqueous NH<sub>4</sub>Cl solution, dry over CaCl<sub>2</sub>, filter, evaporate and distil it at atmospheric pressure in an inert atmosphere. It is used as a co-polymer and may polymerise in the presence of free radicals. It is soluble in CH<sub>2</sub>Cl<sub>2</sub>. [Nagel & Post *J Org Chem* **17** 1379 1952, Beilstein **4** IV 3922.]

**Tri(4-nitrophenyl)phosphate** [3871-20-3] **M 461.3, m 155-156°, 156°, 156-158°, 157-159°**. This phosphate has been recrystallised from AcOH, dioxane, AcOEt and Me<sub>2</sub>CO and dried it in a vacuum over P<sub>2</sub>O<sub>5</sub>. [Katelaar & Gersmann *J Am Chem Soc* **72** 5777 1950, Moffatt & Khorana *J Am Chem Soc* **79** 3741 1957.]

**Tri(*n*-octyl)phosphine oxide** [78-50-2] **M 386.7, m 59.5-60°, pK<sub>Est</sub> <0**. Mason, McCarty and Peppard [*J Inorg Nuclear Chem* **24** 967 1962] purified the oxide by stirring a 0.1M solution in \*benzene with an equal volume of 6M HCl at 40° in a sealed flask for 48 hours, then washed the \*benzene solution successively with water (twice), 5% aqueous Na<sub>2</sub>CO<sub>3</sub> (three times) and water (six times). The \*benzene and water were then evaporated under reduced pressure at room temperature. Zingaro and White [*J Inorg Nucl Chem* **12** 315 1960]

treated a petroleum ether solution of the oxide with aqueous  $\text{KMnO}_4$  (to oxidise any phosphinous acids to phosphinic acids), then with sodium oxalate,  $\text{H}_2\text{SO}_4$  and  $\text{HCl}$  (to remove any manganese compounds). The petroleum ether solution was slurried with activated alumina (to remove phosphinic acids), filtered, evaporated and the residue was recrystallised from petroleum ether or cyclohexane at  $-20^\circ$ . It can also be recrystallised from  $\text{EtOH}$ . [*Beilstein* 4 IV 3466.]

**Tri(neo-pentyl) phosphate** [14540-59-1] **M 320.4**. Crystallise it from hexane. [See Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol 6 pp 211-577 1973.]

**Triphenylarsine** [603-32-7] **M 306.2, m 60-62°**. Recrystallise  $\text{Ph}_3\text{As}$  from  $\text{EtOH}$  or aqueous  $\text{EtOH}$  [Dahlinger et al. *J Chem Soc, Dalton Trans* 2145 1986, Boert et al. *J Am Chem Soc* 109 7781 1987]. [*Beilstein* 16 H 829, 16 I 431, 16 II 407, 16 III 921, 16 IV 1139.] **HIGHLY TOXIC**.

**Triphenylarsine oxide** [1153-05-5] **M 322.2, m 194-196° (anhydrous)**. The anhydrous oxide crystallises from  $^*\text{C}_6\text{H}_6$ , whereas the *monohydrate* separates from  $\text{EtOH}$  with **m 118° (m 114-117° was also reported)**. [*Beilstein* 16 H 846, 16 I 433, 16 II 433, 16 III 1022, 16 IV 1139.] **HIGHLY TOXIC**.

**Triphenyl borane (borane triphenyl, triphenyl boron)** [960-71-4] **M 242.1, m 134-140°, 137°, 139-141°, 142-142.5°, 147.5-148°, 151°, b 203°/15mm**. Recrystallise the borane three times from  $\text{Et}_2\text{O}$  or  $^*\text{C}_6\text{H}_6$  under  $\text{N}_2$  and dry it at  $130^\circ$ . It can be distilled in a high vacuum at  $300-350^\circ$  and has been distilled (**b 195-215°/-15mm**) in vacuum using a bath temperature of  $240-330^\circ$ .  $\text{N}_2$  is introduced into the apparatus before dismantling. It forms complexes with amines. [Nielsen et al. *Chem Ind (London)* 1069 1957, Wittig et al. *Justus Liebigs Ann Chem* 563 110 1949, Bent & Dorfman *J Am Chem Soc* 57 1259 1935, *Beilstein* 16 IV 1623.]

**Triphenyl phosphate** [115-86-6] **M 326.3, m 49.5-50°, b 245°/11mm**. Crystallise the phosphate from  $\text{EtOH}$  or petroleum ether (b 60-80°)/ $\text{EtOH}$ . [Cox & Westheimer *J Am Chem Soc* 80 5441 1958, Krishnakumar & Sharma *Synthesis* 558 1983, Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol 6 pp 211-577 1973, *Beilstein* 6 III 658, 6 IV 720.] It has been used as an effective ligand with phase transfer catalysts [Nakoji et al. *J Org Chem* 67 7418 2002].

**Triphenylphosphine** [603-35-0] **M 262.3, m 77-78°, 79°, 79-81°, 80.5°, 80-81°, b >360°(377°, in inert gas),  $d_4^{25}$  1.194,  $d_4^{80}$  1.075 (liq),  $\text{pK}^{25}$  2.73**. The phosphine crystallises from hexane,  $\text{MeOH}$ , diethyl ether,  $\text{CH}_2\text{Cl}_2$ /hexane or 95%  $\text{EtOH}$ . Dry it at  $65^\circ$ / $<1\text{mm}$  over  $\text{CaSO}_4$  or  $\text{P}_2\text{O}_5$ . Chromatograph it through alumina using (4:1)  $^*\text{benzene}/\text{CHCl}_3$  as eluent. [Blau & Espenson et al. *J Am Chem Soc* 108 1962 1986, Buchanan et al. *J Am Chem Soc* 108 1537 1986, Randolph & Wrighton *J Am Chem Soc* 108 3366 1986, Asali et al. *J Am Chem Soc* 109 5386 1987.] It has also been crystallised twice from petroleum ether and 5 times from  $\text{Et}_2\text{O}/\text{EtOH}$  to give crystals with **m 80.5°**. Alternatively, dissolve it in conc  $\text{HCl}$ , and upon dilution with  $\text{H}_2\text{O}$  it separates because it is weakly basic, it is then crystallised from  $\text{EtOH}/\text{Et}_2\text{O}$ . It recrystallises unchanged from  $\text{AcOH}$ . [Forward et al. *J Chem Soc Suppl.* p121 1949, Muller et al. *J Am Chem Soc* 78 3557 1956.]  $3\text{Ph}_3\text{P}\cdot 4\text{HCl}$  crystallises out when  $\text{HCl}$  gas is bubbled through an  $\text{Et}_2\text{O}$  solution, it has **m 70-73°**, but recrystallises very slowly and is deliquescent.  $\text{Ph}_3\text{P}\cdot\text{HBr}$  [6399-81-1] has **m 196° (dec)**. The *hydriodide*, made by adding  $\text{Ph}_3\text{P}$  to hydriodic acid, is not hygroscopic and decomposes at  $\sim 100^\circ$ . The *chlorate* (1:1) salt has **m 165-167°**, but decomposes slowly at  $100^\circ$ . All salts hydrolyse in  $\text{H}_2\text{O}$  to give  $\text{Ph}_3\text{P}$  [IR, UV: Sheldon & Tyree *J Am Chem Soc* 80 2117 1958,  $\text{pK}$ : Henderson & Streuli *J Am Chem Soc* 82 5791 1960, Kosolapoff, *Organophosphorus Compounds*, Wiley 1950]. [*Beilstein* 16 IV 951.]

§ It is also available commercially on a support of polystyrene cross-linked with 2% divinylbenzene as the free base [39319-11-4], loading of  $\sim 3.2$  nmol/g, 100-200 mesh], and as the *hydrobromide* [loading 2.5-3.0 mmol Br, 200-400 mesh].

**Triphenylphosphine dibromide** [1034-39-5] **M 422.1, m 235°, 245-255°(dec)**. The dibromide recrystallises from  $\text{MeCN}/\text{Et}_2\text{O}$ . Although it has been recrystallised from  $\text{EtOH}$ , this is not recommended as it converts alcohols to alkyl bromides as it has brominating power. It deteriorates on keeping, and it is best to prepare it afresh. [Anderson & Frenor *J Am Chem Soc* 86 5037 1964, Horner et al. *Justus Liebigs Ann Chem* 626 26 1959, *Beilstein* 16 III 864.]

**Triphenylphosphine oxide** [791-28-6] **M 278.3, m 152.0°, 156-157°, pK<sub>Est</sub> ~2.10 (aqueous H<sub>2</sub>SO<sub>4</sub>), pK<sup>25</sup> 2.9 (in MeNO<sub>2</sub>).** It crystallises from absolute EtOH and is dried *in vacuo*. The *gold chloride complex* has **m 177.5-178.5°**. [Addison & Sheldon *J Chem Soc* 2705 1956, Cox & Westheimer *J Am Chem Soc* **80** 5441 1958, Beilstein **16** III 864, **16** 1011.]

**Triphenyl phosphite** [101-02-0] **M 310.3, m 16-20°, 21-23°, b 181-189°/1mm, 183-184°/1mm, d<sub>4</sub><sup>20</sup> 1.183.** Its ethereal solution is washed successively with aqueous 5% NaOH, distilled water and saturated aqueous NaCl, then dried with Na<sub>2</sub>SO<sub>4</sub> and distilled under vacuum after evaporating the diethyl ether. [Walsh *J Am Chem Soc* **81** 3023 1959, Verkade & Coskren in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol 6 pp 211-577 1973, Beilstein **6** IV 695.] It has been used as an effective ligand with phase transfer catalysts [Nakoji et al. *J Org Chem* **67** 7418 2002].

**Triphenylphosphorylidene acetaldehyde (formylmethylenetriphenylphosphorane)** [2136-75-6] **M 304.3, m 185-187°, 186-187°(dec).** Recrystallise it from Me<sub>2</sub>CO, or dissolve it in \*C<sub>6</sub>H<sub>6</sub>, wash with N NaOH, dry (MgSO<sub>4</sub>), evaporate, and crystallise the residue from Me<sub>2</sub>CO. It can be prepared from its precursor, formylmethyltriphenylphosphonium chloride (which crystallises from CHCl<sub>3</sub>/EtOAc), by treatment with Et<sub>3</sub>N and extraction with \*C<sub>6</sub>H<sub>6</sub>. [Tripett & Walker *J Chem Soc* 1266 1961.]

**(Triphenylphosphoranylidene)ketene [Bestmann ylide (triphenylphosphoranylidene)ethenone, ketenylidene(triphenyl)phosphorane]** [15596-07-3] **M 302.3, m 167-173°, 173°.** This versatile reagent is prepared in a dry inert atmosphere (N<sub>2</sub> or argon) by first mixing NaNH<sub>2</sub> (19.5g, 0.5mole) in toluene (1.3L, dried by passage through alumina) and bis(trimethylsilyl)amine (81g, 105ml, 0.5mol, toxic and corrosive), and heated (70-80° bath temperature) under a reflux condenser until a clear and colourless solution of sodium hexamethyldisilazane (see hexamethyl disilazane sodium salt [1070-89-9]) is obtained, and evolution of NH<sub>2</sub> ceased (2-4 hours). Note that repeated purging with argon or N<sub>2</sub> reduces the reaction time. The condenser is removed and under argon or N<sub>2</sub>, (methoxycarbonylmethylene)triphenylphosphorane (167g, 0.5mol, [2605-67-6]) is added in large portions, and the mixture is again heated (70-80° bath temperature) with stirring for 24-30 hours until the colour of the solution assumes a bright yellow hue [and the IR band of a film of aliquots between KBr plates, with  $\nu_{\max}$  at 1616 cm<sup>-1</sup> of the starting ylide has disappeared, and is replaced by a strong band of the product with  $\nu_{\max}$  at 2090 cm<sup>-1</sup> of constant intensity, indicating completion of reaction]. While still hot, and under argon or N<sub>2</sub>, the mixture is filtered rapidly [through a 20/40 standard taper vacuum filtration adapter and a 350ml fritted funnel of coarse porosity open to the atmosphere through a 2 cm thick layer of basic Al<sub>2</sub>O<sub>3</sub> (III) and a 1cm Celite pad on top, and occasional scraping the top of the pad] into a 2L 24/40 single necked flask. The filtration requires 30-60 minutes and the funnel temperature should be kept between 30-50° to avoid crystallisation. The filtrate is flushed with inert gas and evaporated (rotavap) to dryness. The residue is recrystallised from hot dry toluene (1g/5ml) followed by cooling at -20° overnight. While the mixture is cold, the solids are filtered off, washed with cold toluene (3 x 100ml at 0°). The combined filtrates are evaporated in the same way at low temperature as before to give a second crop. The combined crops are dried to constant weight at high vacuum (0.01mm) to give pure (*triphenylphosphoranylidene*) ketene (106.8-114.9g, 74-76% and ~99.97% pure by <sup>1</sup>H NMR) as a pale yellow, flaky powder with m 173°. It is remarkably stable, it can be stored at ~25° under argon or N<sub>2</sub> for months and can be handled at ~25° without obvious deterioration. It has IR (KBr) with  $\nu_{\max}$  at 2090 (s), 1625 (m), 1436 (m) and 1110 (m) cm<sup>-1</sup>; the <sup>1</sup>H NMR (400MHz, CDCl<sub>3</sub>) has  $\delta$  at 7.44-7.54 (m, 6H), 7.55-7.63 (m, 3H) and 7.64-7.77 (m, 6H); the <sup>13</sup>C NMR (100MHz, CDCl<sub>3</sub>) has  $\delta$  at -10.5 (d, <sup>3</sup>J<sub>P-C</sub> = 185.4 Hz, C $\alpha$ ), 128.8 (d, <sup>3</sup>J<sub>P-C</sub> = 12.9 Hz, C-ortho), 129.6 (d, <sup>1</sup>J<sub>P-C</sub> = 98.5 Hz, C-*ipso*), 132.2 (s, C-*para*), 132.3 (s, C-*meta*) and 145.6 (d, <sup>2</sup>J<sub>P-C</sub> = 63.0 Hz, C $\beta$ ); and the <sup>31</sup>P NMR (162MHz, CDCl<sub>3</sub>) has  $\delta$  at 6.0. Possible detectable impurities are starting ester ylide and toluene detected by <sup>1</sup>H NMR spectroscopy which have singlets at  $\delta$  3.60 and 2.36 respectively. It is a nucleophilic-only C<sub>2</sub>-building block that reacts with a range of electrophiles in a variety of ways. It also undergoes cycloaddition reactions at the polar P-C $\alpha$  bond as well as at the C $\alpha$ =C $\beta$  double bond, and multi-component and domino reactions. [Schobert *Org Synth* **82** 140 2005.]

**Triphenyl silane** [789-25-3] M 260.4, m 45°, b 148-151°/1mm. Purify it by recrystallisation from MeOH. [Gilman & Zuech *J Am Chem Soc* **81** 5925 1959, Westermarck *Acta Chem Scand* **9** 947 1955, IR: Kaplan *J Am Chem Soc* **76** 5880 1954, *Beilstein* **16** II 605, **16** III 1199, **16** IV 1369.]

**Triphenylsilanol (hydroxytriphenylsilane)** [791-31-1] M 276.4, m 150-153°, 151-153°, 154-155°, 156°. It is purified by dissolving in petroleum ether, passing through an Al<sub>2</sub>O<sub>3</sub> column, eluting thoroughly with CCl<sub>4</sub> to remove impurities and then eluting the silanol with MeOH. Evaporation gives crystals with m 153-155°. It can be recrystallised from petroleum ether, CCl<sub>4</sub> or from \*benzene or Et<sub>2</sub>O/petroleum ether (1:1). It has also been recrystallised by partial freezing from the melt to constant melting point. [George & Gilman *J Am Chem Soc* **81** 3288 1959, IR: Tatlock & Rochow *J Org Chem* **17** 1555 1952 and Richards & Thompson *J Chem Soc* 124 1949, *Beilstein* **16** IV 1480.]

**Triphenyl vinyl silane** [18666-68-7] M 286.5, m 58-59°, 57-59.5°, 67-68°, b 190-210°/3mm. The vinylsilane has been recrystallised from EtOH, 95% EtOH, EtOH/\*C<sub>6</sub>H<sub>6</sub>, petroleum ether (b 30-60°) and Et<sub>2</sub>O, and has been distilled under reduced pressure. [Cason & Brooks *J Am Chem Soc* **74** 4582 1952, Nagel & Post *J Org Chem* **17** 1379 1952, *Beilstein* **16** IV 1371.]

**Tri(*n*-propyl) borate** [688-71-1] M 188.1, b 64°/9mm, 175-177°/atm, d<sub>4</sub><sup>20</sup> 0.857, n<sub>D</sub><sup>20</sup> 1.395. Dry the ester over sodium and then distil it, preferably in a vacuum. (cf tributyl borate.) [Charnley et al. *J Chem Soc* 2288 1952, *Beilstein* **1** IV 1436.]

**Tri(*iso*-propyl) borate [(*iso*-PrO)<sub>3</sub>B, boric acid tri-*iso*-propyl ester, Boron *iso*-propoxide]** [5419-55-6] M 188.1, b 75°/76mm, 90°/120mm, 139-141°/760mm, d<sub>4</sub><sup>25</sup> 0.815, n<sub>D</sub><sup>20</sup> 1.376. The borate ester is prepared in 85% yield from *iso*-propanol (250ml) and NaBH<sub>4</sub> (6.84g) followed by dropwise addition of AcOH (0.18g) over a period of 11 minutes, and then refluxing for 4 hours (fume cupboard and a “Dry-ice” condenser as 16.15L of H<sub>2</sub> are released, CARE due to its flammability). Then fractionate the ester through a Widmer column. [Brown et al. *J Am Chem Soc* **78** 3613 1956.] The ester is a good reagent for borylation, e.g. *ortho*-borylating 1-substituted naphthalenes, by reacting with 1-halo- or cyano- naphthalenes (after treatment with LiTMP) to form 2-boryl esters which are later used in Pd-catalysed cross-coupling reactions [Lysén et al. *Synthesis* 3478 2006]. [*Beilstein* **1** H 363, **1** II 382, **1** III 1468, **1** IV 1488.]

**Tri(quinol-8-yl) phosphate** [52429-99-9] M 479.4, m 193-197°, 202-203°. Purify the phosphate by recrystallisation from dimethylformamide. The purity is checked by paper chromatography, R<sub>F</sub> 0.90 [*i*-PrOH/saturated (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>/H<sub>2</sub>O, 2:79:19 as eluent], its IR (KBr) has ν<sub>max</sub> at 1620, 1570 (C=C, C=N) and 1253 (P=O) cm<sup>-1</sup>. [Takaku et al. *Bull Chem Soc Jpn* **47** 779 1974.]

**Tri-*o*-tolylphosphine** [6163-58-2] M 304.4, m 129-130°, pK<sub>Est</sub> ~1.0. Like PPh<sub>3</sub>, it crystallises from hexane, MeOH, diethyl ether, CH<sub>2</sub>Cl<sub>2</sub>/hexane or 95% EtOH. Dry it at 65°/1mm over CaSO<sub>4</sub> or P<sub>2</sub>O<sub>5</sub>. Purify further by chromatography through alumina using (4:1) \*benzene/CHCl<sub>3</sub> as eluent. Of the phosphine ligands studied, P(*o*-Tol)<sub>3</sub> (6 mol%) was the best in the Ru<sub>3</sub>(CO)<sub>12</sub> (2 mol%) catalysed *N*-alkylation of primary amines and secondary alcohols (e.g. hexylamine with 1-phenylethanol to give *N*-octyl 1-phenethylamine) in high yields at 90-110° [Tillack et al. *Tetrahedron Lett* **47** 8881 2006]. The Heck reaction between aryl halides and *n*-butyl acrylates to provide substituted styrenes in ~80 to >90% yields at ~120° is catalysed by Pd(OAc)<sub>2</sub> (2 mol%) and P(*o*-Tol)<sub>3</sub> (8 mol%) without extensive P-C bond cleavage [Herrmann et al. *J Mol Catal A: Chem* **103** 133 1995]. [*Beilstein* **16** III 835.]

**Tris(2-biphenyl) phosphate** [132-28-5] M 554.6, m 115.5-117.5°. Crystallise it from MeOH containing a little acetone. (cf triphenyl phosphate.)

**Tris(2,4-di-*tert*-butylphenyl)phosphite** [31570-04-4] M 646.9, m 181-184°. If the ester is suspect, e.g. partly hydrolysed, dissolve it in Et<sub>2</sub>O, wash the solution successively with aqueous 5% NaOH, H<sub>2</sub>O and saturated aqueous NaCl, then shake with charcoal, filter, dry with Na<sub>2</sub>SO<sub>4</sub>, filter again, evaporate and add petroleum ether when the volume has decreased considerably to crystallise the ester. [Verkade & Coskren in *Organophosphorus*

*Compounds* (Kosolapoff & Maier eds) Wiley Vol 6 pp 211-577 1973.] It is used as a processing stabiliser for polymers.

**Tris(1,2-dioxyphenyl)cyclotriphosphazine** {trispiro[1,3,5,2,4,6-triazatriphosphorine]-2,2':-2,4'':2,6'''-tris(1,3,2)benzodioxaphosphole} [311-03-5] **M 459.0, m 244-245°, 245°, 245-246°**. Recrystallise this phosphazine from \*C<sub>6</sub>H<sub>6</sub> or chlorobenzene, then triple sublime it (175°/0.1mm, 200°/0.1mm, 230°/0.05mm). Its UV has  $\lambda_{\max}$  nm (log  $\epsilon$ ) at 276 (3.72), 271 (3.79) 266sh (3.68) and 209 (4.38) in MeCN. Its IR has  $\nu_{\max}$  at 1270 (O-Ph), 1220 (P=N), 835 (P-O-Ph) and 745 (Ph) cm<sup>-1</sup>. [Alcock *J Am Chem Soc* **86** 2591 1964, Alcock et al. *J Am Chem Soc* **98** 5120 1976, Meirovitch *J Phys Chem* **88** 1522 1984.]

**(±)-Tris(2-ethylhexyl) phosphate (TEHP, tri-isooctylphosphate, "trioctyl" phosphate, [78-42-2, 25103-23-5]** **M 434.6, b 186°/1mm, 219°/5mm, d<sup>25</sup> 0.92042, n<sub>D</sub><sup>20</sup> 1.44464**. TEHP, in an equal volume of diethyl ether, is shaken with aqueous 5% HCl, and the organic phase is filtered to remove traces of pyridine (used as a solvent during manufacture) as its hydrochloride. This layer is shaken with aqueous Na<sub>2</sub>CO<sub>3</sub>, then water, and the ether is distilled off at room temperature. The ester is then filtered, dried for 12 hours at 100°/15mm, and again filtered, then shaken intermittently for 2 days with activated alumina (100g/L). It is decanted through a fine sintered-glass disc (with exclusion of moisture), and distilled under vacuum. [French & Muggleton *J Chem Soc* 5064 1957.] \*Benzene can be used as a solvent (to give 0.4M solution) instead of ether. Its IR has  $\nu_{\max}$  at 1702, 1701, 481 and 478cm<sup>-1</sup> [Bellamy & Becker *J Chem Soc* 475 1952]. The *uranyl nitrate* salt is purified by partial crystallisation from hexane [Siddall & Dukes *J Am Chem Soc* **81** 790 1959, Siddall *J Am Chem Soc* **81** 4176 1959]. [Beilstein 1 IV 1786.]

**Tris(hydroxymethyl)phosphine (phosphinidynetrimethanol) [2767-80-8]** **M 121.1, m 48-56°, 55°, b 111-113°/2.5mm, n<sub>D</sub><sup>20</sup> 1.5497, pK 5.5 (half neutralisation point, glass electrode)**. It is obtained in two ways by neutralising precisely the THPC (Tetrakis(hydroxymethyl)phosphonium chloride, [124-64-1]). In the *first* method, NaOH (1.6g, 40mmol) in H<sub>2</sub>O (25ml) is added rapidly to THPC (7.6g, 40mmol, see above [124-64-1]) in H<sub>2</sub>O (50ml) under N<sub>2</sub> at room temperature in a closed system connected to a glass buret. No evolution of gas should be observed on stirring for 20 hours indicating that the stoichiometric amount of alkali has been added. Any liberation of gas (H<sub>2</sub>) would indicate that excess of alkali had been added which would liberate H<sub>2</sub> with the formation of the corresponding phosphine oxide (see next entry, and Hoffman *J Am Chem Soc* **52** 2995 1930). The solvent is then removed *in vacuo* at 50-60°, EtOH (under N<sub>2</sub>) is added, the solid NaCl is filtered off, and the EtOH is removed *in vacuo* (45°) to give the *free base* (4.8g, 97%) as a clear viscous liquid which can be distilled at high vacuum in an atmosphere of N<sub>2</sub> (N<sub>2</sub> bleed). An IR (film) should indicate the absence of P=O and the presence of primary OH and P-CH<sub>2</sub> bands [Grayson *J Am Chem Soc* **85** 79 1963].

In the *second* method, under N<sub>2</sub> flushing and stirring, a solution of THPC (25g, 131mmol) in distilled H<sub>2</sub>O (100ml), into which is immersed a glass pH electrode, is treated with ~ 150ml (0.21 equivalents) of 20-50 mesh Dowex-1 x 8 resin (in the OH<sup>-</sup> form) during 45 minutes until the pH was ~8.3-8.5. The resin is filtered off, washed with H<sub>2</sub>O, the combined aqueous solutions are evaporated (rotavap) at 65-70°, then under high vacuum for 30 minutes, then further at -30° to give the *free base* as a viscous liquid which formed a waxy solid. Its IR (film between NaCl plates) should have no bands at  $\nu_{\max}$  1052 (of THPC), or 1043 or 1135 (for P=O), but intense broad absorption at 1010 cm<sup>-1</sup>. The <sup>1</sup>H NMR (60MHz, D<sub>2</sub>O, internal TMS, or DSS at 0) has  $\delta$  for CH<sub>2</sub> at 4.15 ( $J_{\text{PCH}} = 5.5\text{Hz}$ ,  $J_{\text{13CH}} = \sim 148\text{Hz}$ ); and the <sup>31</sup>P NMR (40MHz, D<sub>2</sub>O, external 85% H<sub>3</sub>PO<sub>4</sub>) has  $\delta$  at -25.8. [Ellzey et al. *J Org Chem* **37** 3453 1972.] With *n*-butyl iodide it formed *n*-butyl phosphonium iodide which gave, on treatment with sodium tetraphenylboron, the *n*-butyl tris(hydroxymethyl)phosphonium tetraphenylboron complex, **m 145-146°(dec)** after drying and recrystallising from Me<sub>2</sub>CO/\*C<sub>6</sub>H<sub>6</sub>; and the *methiodide* gave with Ph<sub>4</sub>BNa, the *methyl tris(hydroxymethyl)phosphonium tetraphenylboron complex*, **m 170-171°(dec)** after drying and recrystallising from Me<sub>2</sub>CO/\*C<sub>6</sub>H<sub>6</sub> [Grayson *J Am Chem Soc* **85** 79 1963.]

**Tris(hydroxymethyl)phosphine oxide [1067-12-5]** **M 137.1, m 50-52°, 54-55° (69° and 70° have also been reported)**. The oxide is prepared by slowly adding about 130% excess (over an equimolar amount) of 20-50 mesh Dowex-1 x 8 resin (in the OH<sup>-</sup> form) to an aqueous solution of tris(hydroxymethyl)phosphine (25.0g, see preceding entry) which led to vigorous evolution of H<sub>2</sub>. After standing overnight the resin is filtered off, and the filtrate is evaporated (rotavap, vacuum) to give the *oxide* (16.1g, 88%) which is recrystallised from absolute EtOH to yield hygroscopic crystals (11.9g). Store in a dry atmosphere. The IR has strong bands at  $\nu_{\max}$  1043

and  $1134\text{ cm}^{-1}$ ; the  $^1\text{H}$  NMR (60MHz,  $\text{D}_2\text{O}$ , internal TMS, or DSS at 0) has  $\delta$  for  $\text{CH}_2$  at 4.20 ( $J_{\text{PCH}} = 3.1\text{Hz}$ ,  $J_{^{13}\text{CH}} = \sim 146\text{Hz}$ ); and the  $^{31}\text{P}$  NMR (40MHz,  $\text{D}_2\text{O}$ , external 85%  $\text{H}_3\text{PO}_4$ ) has  $\delta$  at -48.7. [Ellzey et al. *J Org Chem* **37** 3453 1972, Anteunis et al. *Bull Soc Chim Belg* **74** 622 1965.] The *tribenzoate*, prepared by boiling THPC with excess of aqueous NaOH solution until no further evolution of  $\text{H}_2$  occurred followed by treatment with a slight excess of  $\text{PhCOCl}$ , gave fine needles **m 111**<sup>o</sup> upon recrystallisation from MeOH [Hoffman *J Am Chem Soc* **43** 1684 1921].

**Trisodium 8-hydroxy-1,3,6-pyrenetrisulfonate (Pyranine Solvent Green 7)** [6358-69-6] **M 524.4, m >300(dec), CI 59040,  $\lambda_{\text{max}}$  403nm**. Purify the salt by chromatography through an alumina column, and elute with *n*-propanol/water (3:1, v/v). Recrystallise it from aqueous acetone (5:95, v/v) using decolorising charcoal. [Beilstein **1** III 565.] **IRRITANT**.

**Trisodium 1,3,6-naphthalenetrisulfonate** [5182-30-9] **M 434.2**. The *free acid* is obtained by passing the salt through an ion-exchange column and converting it to the lanthanum salt by treatment with  $\text{La}_2\text{O}_3$ . This salt is crystallised twice from hot water. [The much lower solubility of  $\text{La}_2(\text{SO}_4)_3$  and its retrograde temperature dependence allows a good separation from sulfate impurity]. The lanthanum salt is then passed through an appropriate ion-exchange column to obtain the free acid, the sodium or potassium salt. (The sodium salt is *hygroscopic*.) [Atkinson et al. *J Am Chem Soc* **83** 1570 1961.] It can also be recrystallised from aqueous acetone [Okahata et al. *J Am Chem Soc* **108** 2863 1986].

**Tris(2,2,2-trifluoroethyl) phosphite** [370-69-4] **M 328.1, b 130-131<sup>o</sup>/743mm,  $d_4^{20}$  1.487,  $n_D^{20}$  1.324**. Fractionate the phosphite through a 10 inch Helipak column [Krogh et al. *J Org Chem* **19** 1124 1954].

**Tris(trimethylsilyl)silane (TTMSS)** [1873-77-4] **M 248.7, b 73<sup>o</sup>/5mm,  $d_4^{20}$  0.808,  $n_D^{20}$  1.49**. Purify it by fractional distillation and taking the middle cut. Store it under  $\text{N}_2$  or Ar as it is **PYROPHORIC** and is an **IRRITANT**. [Chatgililoglu et al. *J Org Chem* **53** 3641 1988, Balestri et al. *J Org Chem* **56** 678 1991, Chatgililoglu *Acc Chem Res* **25** 188 1992, NMR: Gilman et al. *J Organomet Chem* **4** 163 1965.]

**Tri(*p*-tolyl) phosphate** [20756-92-7, 1330-78-5 (*isomeric tritolyl phosphate mixture*)] **M 368.4, m 77<sup>o</sup>, b 232-234<sup>o</sup>,  $d_4^{25}$  1.16484,  $n_D^{20}$  1.56703**. Dry the ester with  $\text{CaCl}_2$ , percolate it through a column of alumina, then distil it under a vacuum. *Alternatively*, pass it through a packed column of alumina at 150<sup>o</sup>, with a counter-current stream of nitrogen, under reduced pressure, to remove residual traces of volatile impurities. It also crystallises from petroleum ether (b 60-80<sup>o</sup>). [Cherbuliez in *Organic Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley-Interscience Vol **6** pp 454-457 1973.]

**Tropaeolin 00 {4-[(4-anilinophenyl)azo]benzenesulfonic acid Na salt}** [554-73-4] **M 375.4,  $\text{pK}_{\text{Est}(1)} \sim 2.3$ ,  $\text{pK}_{\text{Est}(2)} \sim 5.8$ ,  $\text{pK}_{\text{Est}(3)} \sim 10.3$** . Recrystallise it twice from water [Kolthoff & Gus *J Am Chem Soc* **60** 2516 1938]. It is an indicator which is red at pH 1.4 and orange-yellow at pH 3.2. [Beilstein **16** II 171.]

**Vinyl chlorosilane** [75-94-5] **M 161.5, b 17.7<sup>o</sup>/46.3mm, 82.9<sup>o</sup>/599.4mm, 92<sup>o</sup>/742mm, 91-91.5<sup>o</sup>/atm,  $d_4^{20}$  0.1.2717,  $n_D^{20}$  1.435**. Fractionally distil the chlorosilane at atmospheric pressure. It is water sensitive and is stored in the dark and it is likely to polymerise. [Müller & Schnurrbusch *Chem Ber* **91** 1805 1958, Munkelt & Müller *Chem Ber* **92** 1012 1959, Polarography: Abrahamson & Reynolds *Anal Chem* **24** 1827 1952, Beilstein **4** IV 4258.]

**3-Vinylphenylboronic acid ([3-ethenylphenyl]-dihydroxyborane)** [15016-43-0] **M148.0, m 141-147<sup>o</sup>, 145-160<sup>o</sup>,  $\text{pK}_{\text{Est}(1)} \sim 8.8$** . This binder for paper or glass crystallises in white plates from  $\text{H}_2\text{O}$  (**m** 144-145<sup>o</sup>), and its IR has  $\nu_{\text{max}}$  at 919 and 995 ( $\text{CH}_2\text{CH}=\text{CH}_2$ ), 1350 (B-O) and 3220 (OH)  $\text{cm}^{-1}$ . The *dibromo* derivative crystallises in white needles from  $\text{H}_2\text{O}$  with **m** 196-197.5<sup>o</sup>. [Wesley & Rush *J Org Chem* **27** 2598 1962, Beilstein **16** III 1279, **16** IV 1677.]

**Vinylphosphonic acid** [1746-03-8] **M 108.0**, **m 41-45°**, **d**<sup>25</sup> **1.389**, **pK**<sub>1</sub><sup>20</sup> **3.48**, **pK**<sub>2</sub><sup>20</sup> **8.54** (50% EtOH). This fireproofing agent, and ingredient for making polymers, is obtained as a syrup on hydrolysing vinylphosphonyl dichloride with cold H<sub>2</sub>O and solidifies on prolonged drying over P<sub>2</sub>O<sub>5</sub>/KOH. When distilled at 235-240°/0.0006mm, it gives the *anhydride* (**d**<sub>4</sub><sup>20</sup> 1.304, **n**<sub>D</sub><sup>20</sup> 1.5874) [Kabachnik & Medvedi *Izvest Akad Nauk SSSR, Ser Khim* 868 1953, *Chem Abstr* 54 10834 1960]. It is best kept as the *sodium salt* (**m** 350°) which precipitates when a solution of EtOH containing NaOEt (from 2g of Na) is added to vinylphosphonic acid (3.2g), and is recrystallised from EtOH (5.1g, quantitative). The *p-anisidinium salt* forms mauve prisms **m** 250° (from EtOH/Et<sub>2</sub>O). The *dimethyl ester*, [4645-32-3] **M 136.1**, **d**<sub>4</sub><sup>20</sup> 1.1405, **n**<sub>D</sub><sup>20</sup> 1.4330, has **b** 72.5°/10mm and 197-202°/760mm. [Kabachnik et al. *J Gen Chem USSR (Engl Trans)* 33 375 1963, *Beilstein* 4 IV 3568.]

**Xylenol Orange (sodium salt)**. See entry in "Heterocyclic Compounds" in this Chapter.

**Zinc diethyldithiocarbamate** [14324-55-1] **M 561.7**, **m 178-181°**, **pK**<sup>25</sup> **3.04** (for Et<sub>2</sub>NCS<sub>2</sub><sup>-</sup>). Crystallise this herbicide several times from hot toluene or from hot CHCl<sub>3</sub> by addition of EtOH. It also crystallises from xylene, **m** 180°. [*Beilstein* 4 II 613.] **TOXIC**.

**Zinc dimethyldithiocarbamate** [137-30-4] **M 305.8**, **m 151-152°, 248-250°**, **pK**<sup>25</sup> **3.36** (for Me<sub>2</sub>NCS<sub>2</sub><sup>-</sup>). Crystallise this herbicide several times from hot toluene or from hot CHCl<sub>3</sub> by addition of EtOH. [*Beilstein* 4 III 149, 4 IV 234.]

**Zinc ethylenebis(dithiocarbamate) (Zineb)** [12122-67-7] **M 249.7**. Crystallise this herbicide several times from hot toluene or from hot CHCl<sub>3</sub> by addition of EtOH. It is a skin irritant. [*Beilstein* 4 III 149, 4 IV 234.]

**Zinc phenol-*o*-sulfonate (8H<sub>2</sub>O) (Phenozin)** [127-82-2] **M 555.8**. Phenozin crystallises from warm water by cooling to 0°. It effloresces in dry air, and loses all its H<sub>2</sub>O at 120°. Its solubility in H<sub>2</sub>O is 63% at 20° and 250% at boiling point, and in EtOH it is 55% at 50°. [*Beilstein* 11 H 53, 11 I 234, 11 IV 574.]

**Zinc trifluoromethanesulfonate** [54010-75-2] **M 363.5**, **m >300°**. This zinc salt should be dried at 125° for 2 hours at 3mm before use. It is soluble in CH<sub>2</sub>Cl<sub>2</sub> but insoluble in petroleum ether. [Corey & Shimoji *Tetrahedron Lett* 24 169 1983.]

# CHAPTER 5

## PURIFICATION OF INORGANIC AND METAL-ORGANIC CHEMICALS

### INTRODUCTION

The most common method of purification of inorganic species is by recrystallisation, usually from water. However, especially with salts of weak acids or of cations other than the alkaline and alkaline earth metals, care must be taken to minimise hydrolysis. This can be achieved, for example, by recrystallising acetates in the presence of dilute acetic acid. Nevertheless, there are many inorganic chemicals that are too insoluble or are hydrolysed by water so that no general purification method can be given. It is convenient that many inorganic substances have large temperature coefficients for their solubility in water, but in other cases recrystallisation is still possible by partial solvent evaporation.

Organo-metallic compounds, on the other hand, behave very much like organic compounds, e.g. they can be redistilled and may be soluble in organic solvents. A note of **caution** should be made about handling organo-metallic compounds, e.g. arsines, because of their **potential toxicities**, particularly when they are volatile. Generally the suppliers of such compounds provide details about their safe manipulation. These should be read carefully and adhered to closely. If in any doubt, always assume that the materials are lethal and treat them with utmost care. The same **safety precautions** about the handling of substances as stated in Chapter 4 should be followed here (see Chapter 1).

For information on **ionization (pK)** see Chapter 1, pp 34-36, and Chapter 4, p 103. In order to avoid repetition, the literature (or predicted) pK values of anionic and/or cationic species are usually reported at least once, and in several cases are entered for the free acid or free base; e.g.  $\text{Na}_2\text{SO}_4$  will have a pK value for  $\text{Na}^+$  at the entry for NaOH and the pK values for  $\text{SO}_4^{2-}$  at the entries for  $\text{H}_2\text{SO}_4$ . When the pK values of the organic counterions are not given in this chapter, as in the case of sodium benzoate, the reader is referred to the value(s) in Chapter 4, Aromatic Compounds, e.g. of benzoic acid.

**Abbreviations** of titles of periodicals are defined as in the Chemical Abstracts Service Source Index (CASSI).

**Benzene**, which has been used as a solvent successfully and extensively in the past for reactions and purification by chromatography and crystallization, is now considered a **very dangerous substance**, so it has to be used with extreme care. We emphasised that an alternative solvent to benzene (e.g. toluene, toluene-petroleum ether, or a petroleum ether to name a few) should be used first. However, if benzene has to be used, then all operations have to be performed in well-ventilated fumehoods and precautions taken to avoid inhalation and contact with skin and eyes. Whenever benzene is mentioned in the text, an asterisk, e.g.  $\text{*C}_6\text{H}_6$  or  $\text{*benzene}$ , is inserted to remind the user that special precaution should be adopted.

**Organic dyes** which are *not* complexed, or are salts of metals, are included in Chapter 4 (use the CAS Registry Numbers to find them). Commercially available polymer-supported reagents are indicated with § under the appropriate reagent.

This chapter is subdivided into two sections: the **Purification of Inorganic Compounds** and the **Purification of Metal-Organic Compounds** which includes ammonium and metal salts of organic acids.

## INORGANIC COMPOUNDS

**Alumina (aluminium oxide) (neutral)** [1344-28-1] **M 102.0 (anhydrous)**. Stir the oxide with hot 2M HNO<sub>3</sub>, either on a steam bath for 12 hours (changing the acid every hour) or three times for 30 minutes, then wash it with hot distilled water until the washings have pH 4, and follow by three washings with hot MeOH. The product is dried at 270° [Angyal & Young *J Am Chem Soc* **81** 5251 1959]. For the preparation of alumina for chromatography see Chapter 1. [For α, β and γ Al<sub>2</sub>O<sub>3</sub> see Becher in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **I** p 822-823 1963 and Wagner in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **II** p 1662 1965.]

**Aluminium ammonium sulfate decahydrate** [7784-26-1] **M 453.3, m 93°, m 95°, pK<sub>1</sub><sup>25</sup> 4.89, pK<sub>2</sub><sup>25</sup> 5.43, pK<sub>3</sub><sup>25</sup> 5.86 (Al<sup>3+</sup> aquo), pK<sub>4</sub><sup>25</sup> 11.22 [aluminate Al(OH)<sub>4</sub><sup>-</sup>]**. Crystallise it from hot H<sub>2</sub>O and cool in ice. When the melt is heated, it loses NH<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub>, and gives pure alumina at red heat. Solubility (%) in H<sub>2</sub>O is 3.9% (0°), 15.0 (20°) and 135 (100°).

**Aluminium bromide** [7727-15-3] **M 266.7, m 97°, b 114°/10mm, d<sub>4</sub><sup>18</sup> 3.205**. Reflux it and then distil it from pure aluminium chips in a stream of nitrogen into a flask containing more of the chips. It is then redistilled under vacuum into ampoules [Tipper & Walker *J Chem Soc* 1352 1959]. Anhydrous conditions are essential, and the white to very light brown solid distillate can be broken into lumps in a dry-box (under nitrogen). It fumes in moist air. [Becher in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **I** p 812-813 1963.]

**Aluminium caesium sulfate dodecahydrate** [7784-17-0 (12H<sub>2</sub>O), 14284-36-7] **M 568.2**. Recrystallise it from hot water (3ml/g).

**Aluminium chloride (anhydrous)** [7446-70-0] **M 133.3, m 192.6°, d<sub>4</sub><sup>17</sup> 2.465**. Sublime it several times in an all-glass system under nitrogen at 30-50mm pressure. It has also been sublimed in a stream of dry HCl and has been subjected to a preliminary sublimation through a section of granular aluminium metal [for manipulative details see Jensen *J Am Chem Soc* **79** 1226 1957]. It fumes in moist air. Used in Friedel-Crafts reaction.

**Aluminium fluoride (anhydrous)** [7784-18-4] **M 84.0, m 250°**. The technical material may contain up to 15% alumina, and minor impurities such as aluminium sulfate, cryolite, silica and iron oxide. Reagent grade AlF<sub>3</sub> (hydrated) contains only traces of impurities, but its water content is variable (and may be up to 40%). It can be dried by calcining at 600-800° in a stream of dry air (some hydrolysis occurs), followed by vacuum distillation at low pressure in a graphite system, heated to approximately 925° (condenser at 900°) [Henry & Dreisbach *J Am Chem Soc* **81** 5274 1959]. Its solubility in H<sub>2</sub>O is 0.5%. [Kwasnik in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **I** p 225-226 1963.]

**Aluminium nitrate nonahydrate** [7784-27-2 (9H<sub>2</sub>O); 13473-90-0] **M 375.1**. Crystallise the nitrate from dilute HNO<sub>3</sub>, and dry it by passing dry nitrogen through the crystals for several hours at 40°. After 2 recrystallisations of ACS grade, it had S, Na and Fe at 2.2, 0.01 and 0.02 ppm, respectively.

**Aluminium potassium sulfate dodecahydrate (alum)** [7784-24-9] **M 474.4, m 92°**. Crystallise it from weak aqueous H<sub>2</sub>SO<sub>4</sub> (ca 0.5ml/g). Its solubility (%) in H<sub>2</sub>O is 5.7 (0°), 12.0 (20°) and 136.9 (100°).

**Aluminium rubidium sulfate dodecahydrate** [7784-29-4] **M 496.2**. Crystallise the double salt from aqueous H<sub>2</sub>SO<sub>4</sub> (ca 2.5ml/g).

**Aluminium sulfate (anhydrous)** [10043-01-3] **M 342.2, m 765°(dec), Al<sub>2</sub>O<sub>3</sub> 14-18 H<sub>2</sub>O [17927-65-0], Al<sub>2</sub>O<sub>3</sub> 18 H<sub>2</sub>O [7784-31-8]**. It crystallises from hot dilute H<sub>2</sub>SO<sub>4</sub> (1 ml/g) on cooling in ice. When a solution of alumina (Al<sub>2</sub>O<sub>3</sub>) in conc H<sub>2</sub>SO<sub>4</sub> is slowly cooled, Al<sub>2</sub>SO<sub>4</sub> 17 or 18H<sub>2</sub>O deposits as a crystalline mass. Al<sub>2</sub>SO<sub>4</sub> 17H<sub>2</sub>O is the stable form in equilibrium with its saturated aqueous solution at 25° [Smith *J Am Chem Soc* **64** 41

1942]. This is purified by dissolving it in a small volume of H<sub>2</sub>O and adding EtOH until the sulfate readily crystallises from the oily supersaturated solution. It forms Al<sub>2</sub>O<sub>3</sub>·16H<sub>2</sub>O between 0–112°. On gradual heating, the hydrate melts, giving the anhydrous salt at ca 250°. Several hydrates up to 27H<sub>2</sub>O have been described. Further heating to red heat (~ 600–800°) causes decomposition to Al<sub>2</sub>O<sub>3</sub> + SO<sub>3</sub> + SO<sub>2</sub> and O<sub>2</sub> [Cobb *J Soc Chem Ind* **29** 250 1910]. The ACS reagent is Al<sub>2</sub>O<sub>3</sub>·18H<sub>2</sub>O (98+%).

**Ammonia (gas)** [7664-41-7] **M 17.0, pK<sup>25</sup> 9.25**. Major contaminants are water, oil and non-condensable gases. Most of these impurities are removed by passing the ammonia through a trap at -22° and condensing it at -176° under vacuum. Water is removed by distilling the ammonia into a tube containing a small lump of sodium. Also dry it by passage through porous BaO, or over alumina followed by glass wool impregnated with sodium (prepared by soaking the glass wool in a solution of sodium in liquid ammonia and evaporating off the ammonia). It can be rendered oxygen-free by passage through a solution of potassium in liquid ammonia. [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **I** p 460-463 1963.] **AMMONIA (gas, liquid or aqueous solution) is very irritating and should not be inhaled in any quantity as it can lead to olfactory paralysis (temporary or permanent).**

**Ammonia (liquid)** [7664-41-7] **M 17.0, m -77.8°, b -33.35°, n<sub>D</sub><sup>20</sup> 1.325, d<sub>4</sub><sup>20</sup> 0.597, d<sup>-79</sup> 0.817g/ml**. Dry the liquid, and store it, with sodium in a steel cylinder, then distil and condense it by means of liquid air, the non-condensable gases being pumped off. In order to obtain liquid NH<sub>3</sub> from a cylinder, turn the cylinder upside-down (i.e. with the valve at the bottom, use a metal stand to secure it in this position; a special stand can be constructed for it) and lead a plastic tube from the tap to a measuring cylinder placed in an efficient fume cupboard which is kept running. Turn the tap on and allow the ammonia to be released. At first, gas and liquid will splatter out (make sure that the plastic tube is secure), but soon the liquid will drip into the measuring cylinder. The high latent heat of evaporation will cool the ammonia so that the liquid will remain cool and not boil vigorously. If the ammonia is required dry, the necessary precautions should be taken, i.e. the gas is allowed to flow through tubes packed with coarse CaO pellets. **AMMONIA (gas, liquid or aqueous solution) is very irritating and should not be inhaled in any quantity as it can lead to olfactory paralysis (temporary or permanent).**

**Ammonia (aqueous)** [7664-41-7] **M 17.0 + H<sub>2</sub>O, d<sub>4</sub><sup>20</sup> 0.90 (saturated, 27% w/v, 14.3 N), pK<sup>25</sup> 9.25 (pK<sub>b</sub> at 25° = 4.75, i.e. 14.00-9.25, and K<sub>b</sub> = 1.81 x 10<sup>-5</sup>)**. Obtained metal-free by saturating distilled water, in a cooling bath, with ammonia (from a cylinder) gas. *Alternatively*, isothermal distillation can be used by placing a dish of concentrated aqueous ammonia and a dish of pure water in an empty desiccator and leaving to equilibrate for several days. **AMMONIA (gas, liquid or aqueous solution) is very irritating and should not be inhaled in any quantity as it can lead to olfactory paralysis (temporary or permanent).**

**Ammonium bisulfate (ammonium hydrogen sulfate (NH<sub>4</sub>)<sub>2</sub>HSO<sub>4</sub>)** [7803-63-6] **M 115.1, m ~147°, d<sub>4</sub><sup>20</sup> 1.79, pK<sup>25</sup> 1.96 (HSO<sub>4</sub><sup>-</sup>)**. It crystallises from water at room temperature (1ml/g) on adding EtOH and cooling. (NH<sub>4</sub>)HSO<sub>4</sub> is formed as deliquescent rhombic crystals on cooling a solution of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> in hot conc H<sub>2</sub>SO<sub>4</sub> but EtOH decomposes it to (NH<sub>4</sub>)<sub>3</sub>H(SO<sub>4</sub>)<sub>2</sub> [Dunncliff *J Chem Soc* **123** 476 1923]. When powdered (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> is heated below 100°, it loses NH<sub>3</sub>, and at 300° it is completely converted to fused (NH<sub>4</sub>)HSO<sub>4</sub>, **m** 140°, but >300° it decomposes to SO<sub>2</sub> and N<sub>2</sub> [Smith *J Chem Soc* **30** 253 1911].

**Ammonium bromide** [12124-97-9] **M 98.0, m 450°(sublimes), d<sub>4</sub><sup>20</sup> 2.43**. It crystallises from 95% EtOH and is slightly hygroscopic.

**Ammonium chloride** [12125-02-9] **M 53.5, m 338°(sublime point, without melting), d<sub>4</sub><sup>20</sup> 1.53**. Crystallise it several times from conductivity water (1.5ml/g) between 90° and 0°. It sublimes. The salt is fully ionised in aqueous solution, i.e. K ≈ ∞. A 1M aqueous solution of NH<sub>4</sub>Cl has a pH of ~4.7, i.e. is acidic. After one crystallisation, ACS grade has: metal(ppm) As (1.2), K (1), Sb (7.2), V (10.2). [Becher in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **I** p 812 1963.]

**Ammonium chromate** [7788-98-9] **M 152.1, m 185°(dec),  $d_4^{20}$  1.81,  $pK_1^{25}$  0.74,  $pK_2^{25}$  6.49 (for  $H_2CrO_4$ ).** Crystallise it from weak aqueous ammonia (ca 2.5ml/g) by cooling from room temperature. It loses  $NH_3$  on heating to form ammonium dichromate. **POISONOUS.**

**Ammonium dichromate** [7789-09-5] **M 252.1, m 170°(dec),  $d_4^{20}$  1.26.** It crystallises from weak aqueous HCl (ca 1ml/g). It decomposes rapidly on heating. (Possible carcinogen and is **POISONOUS**).

**Ammonium dihydrogen arsenate** [13462-93-6] **M 159.0, m 300°(dec).** Crystallise it from water (!ml/g). **POISONOUS.**

**Ammonium dihydrogen orthophosphate** [7722-76-1] **M 115.0, m 190°,  $d_4^{20}$  1.80.** Crystallise it from water (0.7ml/g) between 100° and 0°.

**Ammonium ferric sulfate dodecahydrate** [7783-83-7 (12 $H_2O$ ), 10138-04-2 (anhydrous)] **M 482.2, m ~37°,  $d_4^{20}$  1.71.** Crystallise it from aqueous ethanol.

**Ammonium ferrous sulfate hexahydrate [Mohr's salt]** [7783-85-9 (6 $H_2O$ ), 10045-89-3 (anhydrous)] **M 392.1, m 100°(dec),  $d_4^{20}$  1.86.** A solution in warm water (0.67g/ml) is cooled rapidly to 0°, and the resulting light bluish-green monoclinic crystals are filtered at the pump, washed with cold distilled water and pressed between sheets of filter paper to dry it. The solubility at 25° is 0.36g/ml. It separates as an almost white powder when a saturated aqueous solution is diluted with EtOH.

**Ammonium hexachloroiridate (IV)** [16940-92-4] **M 441.0.** It is precipitated several times from aqueous solution by saturation with ammonium chloride. This removes any palladium and rhodium. It is then washed with ice-cold water and dried over conc  $H_2SO_4$  in a vacuum desiccator. If osmium or ruthenium is present, it can be removed as the tetroxide by heating with conc  $HNO_3$ , followed by conc  $HClO_4$ , until most of the acid has been driven off. (This treatment is repeated.) The near-dry residue is dissolved in a small amount of water and added to excess  $NaHCO_3$  solution and bromine water. On boiling, iridic (but not platinic) hydroxide is precipitated. It is dissolved in HCl and precipitated several times, then dissolved in HBr and treated with  $HNO_3$  and HCl to convert the bromides to chlorides. Saturation with ammonium chloride and cooling precipitates ammonium hexachloroiridate which is filtered off and purified as above [Woo & Yost *J Am Chem Soc* **53** 884 1931].

**Ammonium hexacyanoferrate II hydrate** [14481-29-9] **M 284.1, m dec on heating.** The pale yellow trihydrate powder can be washed with 10% aqueous  $NH_3$ , filtered, then washed several times with EtOH and  $Et_2O$ , and dried at room temperature. It decomposes in a vacuum above 100° and should be stored away from light and under  $N_2$ . In light and air it decomposes by losing  $NH_3$ . [Lux in *Handbook of Preparative Inorganic Chem (Ed. Brauer)* Academic Press Vol II p 1509 1965.]

**Ammonium hexafluorophosphate** [16941-11-0] **M 163.0,  $d_4^{18}$  2.181,  $pK_1^{25}$  ~0.5,  $pK_2^{25}$  5.12 (for fluorophosphoric acid  $H_2PO_3F$ ).** It crystallises from  $H_2O$  in square plates and decomposes on heating before melting. Its solubility in  $H_2O$  at 20° is 74.8% w/v, and it is very soluble in  $Me_2CO$ , MeOH, EtOH and MeOAc, but is decomposed by boiling mineral acids. [Lange & Müller *Chem Ber* **63** 1063 1930, Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol I p 195 1963.]

**Ammonium hexafluorosilicate** [16919-19-0] **M 178.1,  $pK_2$  1.92 (for  $H_2SiF_6$ ).** Crystallise the salt from water (2ml/g). After 3 recrystallisations, the Technical grade salt has Li, Na, K and Fe at 0.3, 0.2, 0.1 and 1.0 ppm respectively.

**Ammonium hypophosphite** [7803-65-8] **M 83.0.** Crystallise it from hot EtOH.

**Ammonium iodate** [13446-09-8] **M 192.9,  $pK^{25}$  0.79 ( $IO_3^{3+}$ ).** Ammonium iodate crystallises from water (8ml/g) on cooling from 100° to 0°.

**Ammonium iodide** [12027-06-4] **M 144.9**, sublimes with dec  $\sim 405^\circ$ ,  $d_4^{20}$  2.51. The iodide crystallises from EtOH on addition of ethyl iodide, and is very *hygroscopic*. Store it in the dark. Its solubility is 177g in 100g of H<sub>2</sub>O at 25°. [Schmeisser in *Handbook of Preparative Inorganic Chem* (Ed. Brauer) Academic Press Vol I p 289-290 1963.]

**Ammonium magnesium chloride hexahydrate** [60314-43-4] **M 256.8**. It crystallises from water (6ml/g) by partial evaporation in a desiccator over KOH (deliquescent).

**Ammonium magnesium sulfate hexahydrate** [20861-69-2] **M 360.6**. It crystallises from water (1ml/g) between 100° and 0°.

**Ammonium manganous sulfate hexahydrate** [13566-22-8] **M 391.3**. It crystallises from water (2ml/g) by partial evaporation in a desiccator.

**Ammonium molybdate** [13106-76-8] **M 196.0**,  $pK_1^{25}$  0.9 (proton addition),  $pK_2^{25}$  3.57,  $pK_3^{25}$  4.08 (for H<sub>2</sub>MoO<sub>4</sub>). Crystallise the salt from water (2.5ml/g) by partial evaporation in a desiccator. When a solution of MoO<sub>3</sub> in excess of hot concentrated NH<sub>3</sub> is cooled, *normal* ammonium molybdate (NH<sub>4</sub>)<sub>2</sub>MoO<sub>4</sub> crystallises out. However, when this solution is made to evaporate which allows the pH to drop to 6, the *common* hydrated ammonium *paramolybdate* (NH<sub>4</sub>)<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub> · 4H<sub>2</sub>O {or 3[(NH<sub>4</sub>)<sub>2</sub>O], 7MoO<sub>3</sub>, 4H<sub>2</sub>O, [12054-85-2] **M 1235.9**} crystallises out. This was an old formula which was confirmed by Sturdivant. [Sturdivant *J Am Chem Soc* **59** 630 1937. Grüttner & Jauder in *Handbook of Preparative Inorganic Chem* (Ed. Brauer) Academic Press Vol II p 1711 1965.]

**Ammonium nickel sulfate hexahydrate** [7785-20-8 (6H<sub>2</sub>O), 15699-18-0 (anhydrous)] **M 395.0**,  $d_4^{20}$  1.923. Crystallise this salt from water (3ml/g) on cooling from 90° to 0°.

**Ammonium nitrate** [6484-52-2] **M 80.0**, **m 165°(moist salt), 210°(dec explosively)**,  $d_4^{20}$  1.72. It is crystallised twice from distilled water (1ml/g) by adding EtOH, or from warm water (0.5ml/g) by cooling in an ice-salt bath. Dry it in air, then under vacuum. After 3 recrystallisations of ACS grade, it contained Li and B at 0.03 and 0.74 ppm, respectively. It is deliquescent. [Early & Lowry *J Chem Soc* **115** 1387 1919, **121** 963 1922, Hendricks et al. *J Am Chem Soc* **54** 2766 1932.]

**Ammonium perchlorate** [7790-98-9] **M 117.5**,  $d_4^{20}$  1.95,  $pK^{25}$  -2.4 to -3.1 (for HClO<sub>4</sub>). It is recrystallised twice from distilled water (2.5ml/g) between 80° and 0°, and dried in a vacuum desiccator over P<sub>2</sub>O<sub>5</sub>. Drying at 110° might lead to slow decomposition to the chloride. **POTENTIALLY EXPLOSIVE.**

**Ammonium peroxydisulfate (ammonium persulfate)** [7727-54-0] **M 228.2**, **m dec when heated wet liberating oxygen**,  $d_4^{20}$  1.98. Recrystallise it at room temperature from EtOH/water. It gradually loses NH<sub>3</sub> on exposure to air. Its solubility is 0.5g/ml at 20°, and 2g/ml at 100°.

**Ammonium reineckate {Reineckate salt, NH<sub>4</sub>[Cr(NH<sub>3</sub>)<sub>2</sub>(SCN)<sub>4</sub>]}** [13573-16-5] **M 336.4 (anhydrous), m 270-273°(dec)**. Crystallise it from water, between 30° and 0°, while working under artificial light. Solutions of reineckate salt (aqueous or alcoholic) decompose slowly at room temperature in the dark (~2 weeks) and more rapidly at higher temperatures or in diffuse sunlight. The solutions are blue in colour and liberate HCN (**POISONOUS**). Store it dry in the dark under a vacuum. [Dakin *Org Synth Coll Vol II* 555 1943.]

**Ammonium selenate** [7783-21-3] **M 179.0**,  $d_4^{20}$  2.19, **m dec on heating**. Crystallise the selenate from water at room temperature by adding EtOH and cooling. Its solubility in H<sub>2</sub>O is 117% at 7° and 197% at 100°. [King *J Phys Chem* **41** 797 1937.]

**Ammonium sulfamate** [7773-06-0] **M 114.1**, **m 132-135°, dec at 160°**. Crystallise it from water at room temperature (1ml/g) by adding EtOH and cooling. [Sisler & Audrieth *Inorg Synth II* 180 1946.]

**Ammonium sulfate** [7783-20-2] **M 132.1**, **m 230°(dec), 280°(dec)**,  $d_4^{20}$  1.77. Crystallise it twice from hot

water containing 0.2% EDTA to remove metal ions, then finally from distilled water. Dry it in a desiccator for 2 weeks over  $\text{Mg}(\text{ClO}_4)_2$ . After 3 recrystallisations, ACS grade had Ti, K, Fe, Na at 11, 4.4, 4.4, 3.2 ppm respectively.

**Ammonium tetrafluoroborate** [13826-83-0] M 104.8,  $\text{pK}^{25}$  2.77 (for  $\text{HBF}_4$ ). Crystallise it from conductivity water (1m/g) between  $100^\circ$  and  $0^\circ$ .

**Ammonium thiocyanate** [1762-95-4] M 76.1, m  $138^\circ(\text{dec})$ ,  $149^\circ(\text{dec})$ ,  $\text{pK}^{25}$  -1.85 (for  $\text{HSCN}$ ), 149. Crystallise it three times from dilute  $\text{HClO}_4$  to give material optically transparent at wavelengths longer than 270nm. It has also been crystallised from absolute MeOH or from acetonitrile.

**Ammonium tungstate (VI)** [11120-25-5] M 283.9,  $\text{pK}_1^{25}$  2.20,  $\text{pK}_2^{25}$  3.70 (for tungstic acid,  $\text{H}_2\text{WO}_4$ ). It crystallises from warm water on adding EtOH and cooling.

**Ammonium (meta) vanadate** [7803-55-6] M 117.0,  $d_{10}^{20}$  2.326. Wash the salt with  $\text{H}_2\text{O}$  until free from  $\text{Cl}^-$  ions and dry it in air. It is soluble in  $\text{H}_2\text{O}$  (5.18g/100ml at  $15^\circ$ , 10.4g/100ml at  $32^\circ$ ) but is more soluble in dilute  $\text{NH}_3$ . It crystallises from conductivity water (20ml/g). When heated at relatively low temperature, it loses  $\text{H}_2\text{O}$  and  $\text{NH}_3$  to give vanadium oxide ( $\text{V}_2\text{O}_5$ ), and at  $210^\circ$  it forms lower oxides. [Baker et al. *Inorg Synth III* 117 1950.] Its solubility in  $\text{H}_2\text{O}$  is 0.52% ( $15^\circ$ ), 1% ( $32^\circ$ ) and 1.6% ( $50^\circ$ ). After washing the technical grade salt with  $\text{H}_2\text{O}$ , it had Na, Mn and U at 0.06, 0.2 and 0.1 ppm, respectively. [Brauer in *Handbook of Preparative Inorganic Chem (Ed. Brauer)* Academic Press Vol II p 1272-1273 1965.]

**Antimony (V) pentafluoride** [7783-70-2] M 216.7, m  $7.0^\circ$ ,  $8.3^\circ$ , b  $141^\circ$ ,  $150^\circ$ ,  $148-150^\circ$ ,  $d_4^{20}$  2.99,  $\text{pK}^{25}$  2.55 [for  $\text{HSb}(\text{OH})_6 = \text{Sb}(\text{OH})_6^- + \text{H}^+$ ]. Purify it by vacuum distillation, preferably in a quartz apparatus, and store it in quartz or aluminum bottles. It is a *hygroscopic* viscous liquid which reacts *violently* with  $\text{H}_2\text{O}$  and is hydrolysed by alkalis. It is **POISONOUS** and attacks the skin. [Woolf & Greenwood *J Chem Soc* 2200 1950, Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol I p 200 1965.]

**Antimony trichloride** [10025-91-9] M 228.1, m  $73^\circ$ , b  $283^\circ$ ,  $\text{pK}_1^{25}$  1.4,  $\text{pK}_2^{25}$  11.0 (11.8),  $\text{pK}_3^{25}$  12.95 (for  $\text{Sb}^{3+}$  aquo). Dry the trichloride over  $\text{P}_2\text{O}_5$  or by mixing it with toluene or xylene and distilling (water is carried off with the organic solvent), then distil it twice under dry nitrogen at 50mm, and sublime it twice in a vacuum into ampoules and seal. It can be crystallised from  $\text{CS}_2$  and is *deliquescent*. It fumes in moist air and is decomposed by  $\text{H}_2\text{O}$  with precipitation of the basic chloride, but forms a clear solution in dilute HCl.

**Antimony trifluoride** [7783-56-4] M 178.8, m  $292^\circ$ , b  $376^\circ$ ,  $d_4^{20}$  4.379. It crystallises from MeOH to remove oxide and oxyfluoride, then it is sublimed under vacuum in an aluminium cup on to a water-cooled copper condenser. Its solubility is 443g/100g in  $\text{H}_2\text{O}$  at  $20^\circ$  and 562g/100g in  $\text{H}_2\text{O}$  at  $30^\circ$  with partial hydrolysis. [Woolf *J Chem Soc* 279 1955, Kwasnik in *Handbook of Preparative Inorganic Chem (Ed. Brauer)* Academic Press Vol I p 199 1963].

**Antimony triiodide** [7790-44-5] M 502.5, m  $167^\circ$ ,  $170^\circ$ , b  $401^\circ$ . It sublimes under vacuum as a red solid with an orange vapour. It hydrolyses to the yellow oxyiodide with  $\text{H}_2\text{O}$ . [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol I p 614 1963.]

**Antimony trioxide** [1309-64-4] M 291.5, m  $656^\circ$ . Dissolve the trioxide in the minimum volume of dilute HCl, filter, and add six volumes of water to precipitate the basic antimonous chloride (free from Fe and  $\text{Sb}_2\text{O}_5$ ). The precipitate is redissolved in dilute HCl, and added slowly, with stirring, to a boiling solution (containing a slight excess) of  $\text{Na}_2\text{CO}_3$ . The oxide is filtered off, washed with hot water, then boiled and filtered. The process is repeated until the filtrate gives no test for chloride ions. The product is dried in a vacuum desiccator [Schuhmann *J Am Chem Soc* 46 52 1924]. After one crystallisation (precipitation?), the oxide from a Chinese source had: metal (ppm) Al (8), Ag (0.2), As (56), Cr (6), Ge (0.4), Mn (0.2), Na (16), Ni (2.2) Pb (2.4), Sn (0.4) and V (32). It sublimes in a vacuum at  $400^\circ$ , being yellow on heating and pale buff in colour on cooling. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol I p 615-616 1963.]

**Aqua regia.** This is prepared by slowly adding concentrated  $\text{HNO}_3$  (1 volume) to concentrated hydrochloric acid (3 volumes) in a glass container. This mixture is used to dissolve metals, including noble metals and alloys, as well as minerals and refractory substances. It is done by suspending the material and boiling (**EFFICIENT FUME CUPBOARD — EYE PROTECTION**) to dryness and repeating the process until the residue dissolves in  $\text{H}_2\text{O}$ . If the aqua regia is to be stored for long periods it is advisable to dilute it with one volume of  $\text{H}_2\text{O}$  which will prevent it from releasing chlorine and other chloro and nitrous compounds which are objectionable and toxic. Store it cool in a fume cupboard. However, it is good laboratory practice to prepare it freshly and dispose of it down the fume cupboard sink with copious amounts of water.

**Argon** [7440-37-1] **M 39.95, b -185.6°.** Argon is rendered oxygen-free by passage over reduced copper at  $450^\circ$ , or by bubbling through alkaline pyrogallol and  $\text{H}_2\text{SO}_4$ , then dried with  $\text{CaSO}_4$ ,  $\text{Mg}(\text{ClO}_4)_2$ , or Linde 5A molecular sieves. Other purification steps include passage through Ascarite (**CARE: asbestos** impregnated with sodium hydroxide), through finely divided uranium at about  $800^\circ$  and through a  $-78^\circ$  cold trap.

*Alternatively*, the gas is passed over  $\text{CuO}$  pellets at  $300^\circ$  to remove hydrogen and hydrocarbons, over Ca chips at  $600^\circ$  to remove oxygen and, finally, over titanium chips at  $700^\circ$  to remove nitrogen. It has also been purified by freeze-pump-thaw cycles and by passage over sputtered sodium [Arnold & Smith *J Chem Soc, Faraday Trans 2* 77 861 1981].

**Arsenic acid (arsenic pentoxide hydrate, arsenic V oxide hydrate, orthoarsenic acid)** [12044-50-7] **M 229.8 + xH<sub>2</sub>O, pK<sub>1</sub><sup>25</sup> 2.26, pK<sub>2</sub><sup>25</sup> 6.76, pK<sub>3</sub><sup>25</sup> 11.29 (H<sub>3</sub>AsO<sub>4</sub>).** The acid crystallises from concentrated solutions of boiling conc  $\text{HNO}_3$  as rhombic crystals. Dry it in a vacuum to give the *hemihydrate* (hygroscopic). Heating above  $300^\circ$  yields  $\text{As}_2\text{O}_5$ . [Thaler *Z Anorg Allgem Chem* 246 19 1941, Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 601 1963.] **POISONOUS.**

**Arsenic tribromide** [7784-33-0] **M 314.6, m 31.1°, b 89°/11mm, 221°/760mm, d<sub>4</sub><sup>20</sup> 3.67.** Distil it under vacuum. It hydrolyses in  $\text{H}_2\text{O}$ , but less readily than  $\text{AsCl}_3$ . **POISONOUS.** [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 597 1963.]

**Arsenic trichloride (butter of arsenic)** [7784-34-1] **M 181.3, m 31.2°, b 25°/11mm, 130.0°/atm, d<sub>4</sub><sup>20</sup> 2.2.** Reflux the trichloride with arsenic for 4 hours, then fractionally distil it. The middle fraction is stored with sodium wire for two days, then again distilled [Lewis & Sowerby *J Chem Soc* 336 1957]. It fumes in moist air forming the solid hydroxy-chloride [ $\text{AsCl}(\text{OH})_2$ ] and is readily hydrolysed by  $\text{H}_2\text{O}$  to form arsenious acid. **POISONOUS.** [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 596 1963.]

**Arsenic triiodide** [7784-45-4] **M 455.6, m 146°, b 400°/atm, d<sub>4</sub><sup>25</sup> 4.688.** It crystallises from acetone and sublimes below  $100^\circ$ . It is very slowly hydrolysed by  $\text{H}_2\text{O}$  (much more slowly than the chloride). **POISONOUS.** [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 597-598 1963.]

**Arsenic III oxide (arsenic trioxide, arsenious oxide)** [1327-53-3] **M 197.8, three forms: m ~200°(amorphous glass), m 275°(sealed tube, octahedral, common form, sublimes > 125° without fusion but melts under pressure), and m ~312°, pK<sub>1</sub><sup>20</sup> 9.27, pK<sub>2</sub><sup>20</sup> 13.54, pK<sub>3</sub><sup>20</sup> 13.99 (for H<sub>3</sub>AsO<sub>3</sub>).** It crystallises in an *octahedral form* (common form) from  $\text{H}_2\text{O}$  or from dilute  $\text{HCl}$  (1:2), and is then washed, dried and sublimed ( $193^\circ/760\text{mm}$ ). Analytical reagent grade material is suitable for use as an analytical standard after it has been dried at  $105^\circ$  for 1-2 hours or has been left in a desiccator for several hours over conc  $\text{H}_2\text{SO}_4$ .

*Alternatively*,  $\text{As}_2\text{O}_3$  (15g) is dissolved by heating in a mixture of  $\text{H}_2\text{O}$  (60ml) and  $\text{HCl}$  (90g, s.g. 1.1), and crystallisation occurs on cooling, accompanied by brilliant flashes of light [Bandrowski *Z Phys Chem* 17 234 1895].

The *amorphous* form is a colourless transparent glass (**m 200°**) which is obtained when the vapour is slowly condensed below the vaporisation temperature, and should be kept in a sealed tube because it changes to the *octahedral form* (**m 275°**) in the presence of moisture. [Rushton & Daniels *J Am Chem Soc* 48 384 1926.]

A third *monoclinic* form, is obtained by heating the oxide in a sealed tube at  $400^\circ$  (the vitreous, amorphous form

remains at the bottom of the tube) with the *monoclinic* form subliming onto the intermediate part of the tube at 200° (m 312°), and the *octahedral* form deposits at the top of the tube. The transition temperature between the last two forms is ~250°. **POISONOUS (particularly the vapour, handle in a ventilated fume cupboard).** [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 600 1963.]

**Barium (metal)** [7440-39-3] M 137.3, m 727°, b 1640°(1537°)/760mm,  $d_4^{20}$  3.56(3.76). Barium is cleaned by washing with diethyl ether to remove adhering paraffin, then filed in an argon-filled glove box, washed first with ethanol containing 2% conc HCl, then with dry ethanol. It is dried in a vacuum and stored under argon [Addison et al. *J Chem Soc* 3868 1962]. It has also been purified by double distillation under 10mm of argon pressure.

**Barium bromide dihydrate** [7791-28-8] M 333.2, m at 75° loses first H<sub>2</sub>O and at 120° it loses the second H<sub>2</sub>O and melts at 847°. It crystallises from H<sub>2</sub>O (1ml/g) by partial evaporation in a desiccator. [Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 930 1963.]

**Barium chlorate monohydrate** [10294-38-9 (hydrate), 13477-00-4 (anhydrous)] M 322.3, m 414°. It crystallises from H<sub>2</sub>O (1ml/g) between 100° and 0°, and loses 1H<sub>2</sub>O at 120°. [Schmeisser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 314 1963.]

**Barium chloride dihydrate** [10326-27-9] M 244.3, m ~120°(dec, hydrate), 963° (anhydrous). It is crystallised twice from water (2ml/g) and dried in an oven to constant weight. The solubilities of the hydrate (% of anhydrous wt) in H<sub>2</sub>O are 31.6 at 0°, 35.7 at 20° and 58.7 at 100°.

**Barium dithionate dihydrate** [13845-17-5] M 333.5, m >150° loses SO<sub>2</sub>, pK<sup>25</sup> 0.49 (for H<sub>2</sub>S<sub>2</sub>O<sub>6</sub>, theory pK<sub>1</sub> -3.4, pK<sub>2</sub> -0.2). It crystallises from water. Its solubility in H<sub>2</sub>O is 7.9% (0°), 15.7% (20°) and 19.9% (30°). [Pfanstiel *Inorg Synth II* 170 1946, Fehér in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 397 1963.]

**Barium ferrocyanide hexahydrate** [13821-06-2] M 594.8, m 80°(dec), pK<sub>3</sub><sup>25</sup> 2.57, pK<sub>4</sub><sup>25</sup> 4.35 (for ferrocyanide). It crystallises from hot water (100ml/g).

**Barium fluoride** [7787-32-8] M 175.3, m 1353°, 1368°, b 2260°,  $d_4^{20}$  4.83. Wash it well with distilled H<sub>2</sub>O and dry it in a vacuum. Its solubility in H<sub>2</sub>O is 1.6g (10°), 1.6g (20°) and 1.62g (30°) per L, and is soluble in mineral acids and aqueous NH<sub>4</sub>Cl. It may be stored in glass bottles. [Kwasnik in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 234 1963.]

**Barium hydroxide octahydrate** [12230-71-6] M 315.5, m 78°, pK<sub>1</sub><sup>25</sup> 13.13, pK<sub>2</sub><sup>25</sup> 13.36. It crystallises from water (1ml/g) and readily absorbs CO<sub>2</sub> from air. It effloresces to the *monohydrate*. It dehydrates to Ba(OH)<sub>2</sub> in dry air at 100°. An aqueous solution (*baryta water*) absorbs CO<sub>2</sub> to form a white precipitate of BaCO<sub>3</sub>.

**Barium hypophosphite monohydrate** [14871-79-5] M 285.4. It precipitates from aqueous solution (3ml/g) on adding EtOH. Its solubility in H<sub>2</sub>O is 28.6% at 17° and 33.3% at 100°. [Klement in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 557 1963.]

**Barium iodate monohydrate** [7787-34-0] M 487.1, m 130°(loses H<sub>2</sub>O), 476°(dec). It crystallises from a large volume of hot water on cooling. Its solubility in H<sub>2</sub>O is 1g/3.35L at 25° and 1g/0.625L at the boiling point. [Lambert & Yasada *Inorg Synth VII* 13 1963.]

**Barium iodide dihydrate** [7787-33-9 (2H<sub>2</sub>O), 13718-50-8 (anhydrous)] M 427.2, m 740°(dec). It crystallises from water (0.5ml/g) by partial evaporation in a desiccator. **POISONOUS.**

**Barium manganate (barium permanganate)** [7787-35-1] M 256.3,  $d_4^{20}$  3.77. Wash the salt with conductivity

H<sub>2</sub>O by decantation until the supernatant gives a faint test for Ba<sup>2+</sup>. Remove excess H<sub>2</sub>O in a vacuum (IMPORTANT), then heat at 100° and the last traces of H<sub>2</sub>O are removed in a vacuum desiccator over P<sub>2</sub>O<sub>5</sub>. Store it over KOH. It disproportionates in hot H<sub>2</sub>O or dilute acid into Ba(MnO<sub>2</sub>)<sub>2</sub> and MnO<sub>2</sub>, and is a mild oxidant. [Schlezinger & Siems *J Am Chem Soc* **46** 1965 1924, Nyholm & Woolliams *Inorg Synth XI* 56 1968.]

**Barium nitrate** [10022-31-8] **M 261.4, m 593°(dec)**. Crystallise it twice from water (4ml/g) and dry it overnight at 110°. It decomposes at higher temperatures to give mostly the oxide and the peroxide with only a little of the nitrite. **POISONOUS**. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 941 1963.]

**Barium nitrite monohydrate** [7787-38-4] **M 247.4, m 217°(dec)**. Barium nitrite crystallises from water (1ml/g) on cooling in an ice-salt bath. **POISONOUS**.

**Barium perchlorate** [13465-95-7] **M 336.2, m 505°, pK<sup>25</sup> -2.4 to -3.1 (for HClO<sub>4</sub>)**. Recrystallise the perchlorate twice from water. [Schmeisser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 320 1963.]

**Barium sulfate** [7722-43-7] **M 233.4, m >1580°**. Wash the sulfate five times by decantation with hot distilled water, dialyse it against distilled water for one week, then freeze-dry and dry in an oven at 105° to constant weight (~12 hours). It is almost insoluble in H<sub>2</sub>O (its solubility is 0.0024g/L at 25°).

**Barium tetrathionate** [82203-66-5] **M 361.6**. Purify the tetrathionate by dissolving it in a small volume of water and precipitating it with EtOH below 5°. After drying, the salt is stored in the dark at 0°. [see Fréhér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 399-401 1963 for potassium tetrathionate K<sub>2</sub>S<sub>4</sub>O<sub>4</sub>.]

**Barium thiocyanate dihydrate** [2092-17-3] **M 289.6, pK<sup>25</sup> -1.85 (for HSCN)**. It is crystallised from water (2.5ml/g) by partial evaporation in a desiccator. It is deliquescent. [Herstein *Inorg Synth III* 24 1950.]

**Barium thiosulfate** [35112-53-9] **M 249.5, m 220°(dec), pK<sub>1</sub><sup>25</sup> 0.6, pK<sub>2</sub><sup>25</sup> 1.74 (for H<sub>2</sub>S<sub>2</sub>O<sub>3</sub>)**. It is very slightly soluble in water and is washed repeatedly with chilled water and dried in air at 40°.

**Beryllium carbonate (BeCO<sub>3</sub>)** [744998-97-8] **M 69.0**. The commercial carbonate contains more than 1% of impurities. It is best purified by converting it to the basic acetate (see [1332-52-1]) which should be sublimed, converted into the nitrate with HNO<sub>3</sub> see below [13587-99-4]) and evaporated in a Pt dish until free from excess acid. The residual nitrate salt is dissolved in a small volume of H<sub>2</sub>O and enough ammonium carbonate solution is added to redissolve the beryllium carbonate that precipitates and gives a clear solution. This is then evaporated in a Pt dish until course BeCO<sub>3</sub> separates. It is washed thoroughly with pure H<sub>2</sub>O, then distilled EtOH and dried *in vacuo*. Be(OH)<sub>2</sub>, BeO and Be salts are generally insoluble in NH<sub>3</sub> but dissolve in **aqueous** (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> solution to form the carbonate. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 893 1963.] Beryllium compounds are potentially **carcinogenic**.

**Beryllium chloride (BeCl<sub>2</sub>)** [7787-47-5] **M 79.9, m 399°, 405°, b 488°/atm, d<sup>25</sup> 1.89**. The anhydrous chloride is obtained by heating Be powder or chips (or BeO + C) with Cl<sub>2</sub> gas in a furnace at 300-350° for *ca* 40 hours when anhydrous BeCl<sub>2</sub> sublimes out as a white to faintly yellow crystalline mass or orthorhombic crystals. It is purified further by sublimation at ~300° *in vacuo*. It is very hygroscopic and reacts exothermically with H<sub>2</sub>O which becomes acidic. The solid should be stored in a tightly stoppered vessel and handled in a dry atmosphere much like anhydrous AlCl<sub>3</sub> and has similar catalytic properties to it. It is insoluble in \*C<sub>6</sub>H<sub>6</sub> and toluene but is soluble EtOH, Et<sub>2</sub>O, pyridine and CS<sub>2</sub> with which it probably complexes. The conductivity of fused BeCl<sub>2</sub> is ~0.001 of that of fused NaCl implying that 1 molecule in 1000 is ionised. [Tannenbaum *Inorg Synth* **5** 22 1957, Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 889 1963.] Beryllium compounds are potentially **carcinogenic**.

**Beryllium hydroxide [Be(OH)<sub>2</sub>]** [13327-32-7] **M 43.0, d<sup>25</sup> 1.89**. The hydroxide exists in two forms, a meta-

stable  $\alpha$ -form and a stable  $\beta$ -form. The former is obtained in amorphous form by precipitating a Be salt with  $\text{NH}_3$  in the absence of  $\text{CO}_2$  and allowing it to age by prolonged heating (~24 hours) with  $\text{NH}_4\text{OH}$  solution.  $\beta$ - $\text{Be}(\text{OH})_2$  is made by boiling a saturated solution of the amorphous  $\alpha$ -form in 10N aqueous  $\text{NaOH}$  until a permanent turbidity is attained. On slow cooling fine crystals (regular double pyramids) of the  $\beta$ -form separate, and are purified by washing with warm  $\text{H}_2\text{O}$  until the washings are no longer alkaline, then drying at  $80^\circ$ . The mother liquors can be reused in the above process. It is very slightly soluble in  $\text{H}_2\text{O}$  and dilute  $\text{NaOH}$ , but both forms are amphoteric and are soluble in hot concentrated aqueous  $\text{NaOH}$  solutions and in acids. It dehydrates on strong heating to  $\text{BeO}$ . Several sodium beryllates are known. [Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 894, 895 1963.] Beryllium compounds are potentially **carcinogenic**.

**Beryllium nitrate** [ $\text{Be}(\text{NO}_3)_2$ ] [13587-99-4;  $3\text{H}_2\text{O}$  7787-55-5] M 133.0, m  $\sim 60^\circ$  (for  $3\text{H}_2\text{O}$ ). The nitrate does not crystallise easily and is very deliquescent. It can be prepared from the metal by digesting it with conc  $\text{HCl}$  until most of it has dissolved, filter any insoluble material through a 0.45 micron acetate filter. Then at low boil, add conc  $\text{HNO}_3$  with low heat to reduce to a slurry. Repeat with careful addition of  $\text{HNO}_3$  as many times as necessary (3-6 additions) until the slurry tests negative for chloride ions with 0.1N aqueous  $\text{AgNO}_3$ . Then isolate the nitrate as described below [J. Papa personal communication, 2011, see Chapter 1 p 38]. Alternatively, it is obtained by heating recrystallised, then sublimed, basic beryllium acetate  $\{\text{Be}_4\text{O}(\text{OAc})_6$ , see [1332-52-1]\}, with pure concentrated  $\text{HNO}_3$  in a degassed pyrex container until the volatiles are removed. Heat well below  $1100^\circ$ , so as not to decompose it to give pure  $\text{BeO}$ . It picks up moisture to give the white to pale yellow *trihydrate*. Store it in a well stoppered bottle in a cool place. [Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 893 1963.] Beryllium compounds are potentially **carcinogenic**.

**Beryllium oxide** [1304-56-9] M 25.0, m  $2530^\circ$ , d<sup>25</sup> 3.01. It is prepared by calcining the nitrate at  $1100^\circ$  {see  $\text{Be}(\text{NO}_3)_2$  above [13587-99-4]}, and this oxide always contains  $\sim 0.35\text{ml}$  of gas ( $\text{N}_2$ ,  $\text{O}_2$ ) per gram of oxide. Alternatively, freshly prepared beryllium carbonate is calcined in a Pt boat placed in an electric furnace at  $900^\circ$ .  $\text{BeO}$  is amphoteric, dissolving slowly in acids and in alkalis but if heated strongly it becomes refractory and difficult to dissolve except in hydrofluoric acid. Like ceramics it is a good electrical insulator, but it is a good conductor of heat like some metals. [Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 893 1963.] Beryllium compounds are potentially **carcinogenic**.

**Beryllium potassium fluoride** [7787-50-0] M 105.1, m  $\sim 350^\circ$ . It crystallises from hot water (25ml/g). Beryllium compounds are potentially **carcinogenic**.

**Beryllium sulfate tetrahydrate** [7787-56-6:] M 177.1, m  $\sim 100^\circ(\text{dec})$ , d<sup>25</sup> 1.713, pK<sub>1</sub><sup>25</sup> 3.2, pK<sub>2</sub><sup>25</sup>  $\sim 6.5$  ( $\text{Be}^{2+}$ ). It crystallises from a concentrated solution of weak aqueous  $\text{H}_2\text{SO}_4$  (with partial evaporation), and is dried in air. It is quite soluble in  $\text{H}_2\text{O}$ . The *tetrahydrate* loses  $\text{H}_2\text{O}$  at  $\sim 100^\circ$  to give the *dihydrate*. [cf Gmelin's *Beryllium* (8<sup>th</sup> edn) 26 169 1930.] Beryllium compounds are potentially **carcinogenic**.

**Bismuth** [7440-69-9] M 209.0, m  $271\text{-}273^\circ$ , b  $1450^\circ$ . Melt it in an atmosphere of dry helium, then filter it through dry Pyrex wool to remove any bismuth oxide present [Mayer et al. *J Phys Chem* 64 238 1960].

**Bismuth trichloride** [7787-60-2] M 315.3, m  $233.6^\circ$ , pK<sup>25</sup> 1.58 for hydrolysis ( $\text{Bi}_3^- = \text{BiOH}_2^+ + \text{H}^+$ ). Sublime the trichloride under high vacuum, or dry it under a current of  $\text{HCl}$  gas, followed by fractional distillation, once under  $\text{HCl}$  and once under argon. It is *deliquescent*. [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 621 1963.]

**Boric acid (orthoboric acid, boracic acid)** [10043-35-3] M 61.8, m  $171^\circ$ , pK<sup>25</sup> 9.23. Crystallise the acid three times from  $\text{H}_2\text{O}$  (3ml/g) between  $100^\circ$  and  $0^\circ$ , after filtering through sintered glass. Dry it to constant weight over metaboric acid in a desiccator. It is steam volatile. After two recrystallisations of ACS grade, it had Ag at 0.2 ppm. Its solubility (%) in  $\text{H}_2\text{O}$  is 2.66 at  $0^\circ$ , 4.0 at  $12^\circ$  and 24 at  $80^\circ$ . At  $100^\circ$  it loses  $\text{H}_2\text{O}$  to form *metaboric acid* ( $\text{HBO}_2$ ). When it is heated to redness or slowly to  $200^\circ$ , or over  $\text{P}_2\text{O}_5$  *in vacuo*, it dehydrates to *boric anhydride* ( $\text{B}_2\text{O}_3$ ) [1303-82-6] to give a white hard glass or crystals with m  $\sim 294^\circ$ . The glass softens on

heating and liquefies at red heat. It is an astringent, a fungicide and an antibacterial. [McCulloch *J Am Chem Soc* **59** 2650 1937, Kelly *J Am Chem Soc* **63** 1137 1941, Taylor & Cole *J Chem Soc* 70 1926, Conti *J Soc Chem Ind* **44** 343T 1925.]

**Boron trichloride (trichloroborane)** [10294-34-5] **M 117.2, m -107°, b 0°/476mm, 12.5°/atm, d<sup>0</sup> 1.3728, d<sub>4</sub><sup>12</sup> 1.35** (also available as a 1.0M solution in toluene, *p*-xylene, CH<sub>2</sub>Cl<sub>2</sub>, heptane or hexanes). Purify it (from chlorine) by passage through two mercury-filled bubblers, then fractionally distil it under a slight vacuum. In a more extensive purification the nitrobenzene addition compound is formed by passage of the gas over nitrobenzene in a vacuum system at 10°. Volatile impurities are removed from the crystalline yellow solid formed by pumping at -20°, and the BCl<sub>3</sub> is recovered by warming the addition compound at 50°. Passage through a trap at -78° removes entrained nitrobenzene, the BCl<sub>3</sub> finally condensing in a trap at -112° [Brown & Holmes *J Am Chem Soc* **78** 2173 1956]. Alternatively, purify it by condensing it into a trap cooled in acetone/Dry-ice, where it is pumped for 15 minutes to remove volatile impurities. It is then warmed, recondensed and again pumped. [Gamble *Inorg Synth III* 27 1950.]

It fumes in moist air. **TOXIC, do not breath in the vapours.** It forms addition compounds with Et<sub>2</sub>O; and with dimethyl sulfide it forms Me<sub>2</sub>S·BCl<sub>3</sub> [5523-19-3] **M 179.3**, which has **m 88-90°**, and is a convenient solid form of it (also commercially available as a 2.0M solution in CH<sub>2</sub>Cl<sub>2</sub>) — **beware** of the foul odour of Me<sub>2</sub>S; work in an efficient fume cupboard and absorb the sulfide vapours by flushing them with a stream of N<sub>2</sub> into lead acetate solution which will precipitate insoluble black PbS. [Gamble *Inorg Synth 3* 27 1950, Gerrard & Leppert *Chem Rev* **58** 1081 1958.]

**Boron trifluoride** [7637-07-2] **M 67.8, b -101°/760mm.** The usual impurities-bromine, BF<sub>5</sub>, HF and non-volatile fluorides-are readily separated by distillation. Brown and Johannesen [*J Am Chem Soc* **72** 2934 1950] passed BF<sub>3</sub> into benzonitrile at 0° until the latter was saturated. Evacuation to 10<sup>-5</sup>mm then removed all traces of SiF<sub>4</sub> and other gaseous impurities. [A small amount of the BF<sub>3</sub>-benzonitrile addition compound sublimes and is collected in a U-tube cooled to -80°]. The pressure is raised to 20mm by admitting dry air, and the flask containing the BF<sub>3</sub> addition compound is warmed with hot water. The BF<sub>3</sub> that evolves is passed through a -80° trap (to condense any benzonitrile) into a tube cooled in liquid air. The addition compound with anisole can also be used. BF<sub>3</sub> can be dried by passing it through H<sub>2</sub>SO<sub>4</sub> saturated with boric oxide. It fumes in moist air. [It is commercially available as a 1.3M solution in MeOH or PrOH.] [Booth & Wilson *Inorg Synth I* 21 1939, Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 219-222 1963.] **TOXIC.**

**Bromine** [7726-95-6] **M 159.8, m -7.2°, b 59°, d<sub>4</sub><sup>20</sup> 3.102, n<sub>D</sub><sup>20</sup> 1.661.** Reflux the brown liquid with solid KBr and distil; dry the distillate by shaking it with an equal volume of conc H<sub>2</sub>SO<sub>4</sub>, then redistil it. The H<sub>2</sub>SO<sub>4</sub> treatment can be replaced by direct distillation from BaO or P<sub>2</sub>O<sub>5</sub>. A more extensive purification [Hildenbrand et al. *J Am Chem Soc* **80** 4129 1958] is to reflux about 1L of bromine for 1 hour with a mixture of 16g of CrO<sub>3</sub> in 200ml of conc H<sub>2</sub>SO<sub>4</sub> (to remove organic material). The bromine is distilled into a clean, dry, glass-stoppered bottle, and chlorine is removed by dissolving *ca* 25g of freshly fused CsBr in 500ml of the bromine and standing overnight. To remove HBr and water, the bromine is then distilled back and forth through a train containing alternate tubes of MgO and P<sub>2</sub>O<sub>5</sub>. [Schmeisser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 275 1963.] **HIGHLY TOXIC.**

**Bromine pentafluoride** [7789-30-2] **M 174.9, m -60.5°, b 41.3°, d<sub>25</sub><sup>25</sup> 2.466.** Purify it *via* its KF complex, as described for chlorine trifluoride. [Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 158-159 1963.] **HIGHLY TOXIC.**

**Cadmium** [7440-43-9] **M 112.4, m 321.1°, b 767°, d<sub>4</sub><sup>20</sup> 8.642.** Any oxide contaminant is removed by filtering the molten metal, under vacuum, through quartz wool. Its solubility in Hg is 5.2% (18°), and it is soluble in mineral acids. [Wagenknecht & Juza in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1092 1965.]

**Cadmium bromide** [7789-42-6 (anhydrous), 13464-92-1 (4H<sub>2</sub>O)] **M 272.2, m 566°, b 863°, 963°, d<sub>4</sub><sup>20</sup> 5.192.**

Crystallise it from water (0.57g/ml at 10°, 1.26g/ml at 100°) between and 0°, and dry it at 110°. It forms the *monohydrate* below 36° and the *tetrahydrate* above 36°. It is hygroscopic. [Wagenknecht & Juza in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1096 1965.]

**Cadmium chloride** [10108-64-2] **M 183.3, m 568°, b 960°, d<sub>4</sub><sup>20</sup> 4.06.** Crystallise it from water (1ml/g) by addition of EtOH and cooling. [Pray *Inorg Synth* V 153 1957, Wagenknecht & Juza in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1093 1965.]

**Cadmium fluoride** [7790-79-6] **M 150.4, m >1000°, b 1748°, d<sub>4</sub><sup>20</sup> 6.35.** Crystallise it by dissolving it in hot water (25ml/g at room temperature) at 60°, filtering, then cooling. [Kwasnik in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 243 1963.]

**Cadmium iodide** [7790-80-9] **M 366.2, m 388°, b 787°, d<sub>4</sub><sup>20</sup> 5.66.** Crystallise it from ethanol (2ml/g) by partial evaporation. [Wagenknecht & Juza in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1096 1965.]

**Cadmium nitrate tetrahydrate** [10022-68-1] **M 308.5, m 59.5°.** Crystallise the nitrate from water (0.5ml/g) by cooling in ice-salt. [Gmelin's *Cadmium* (8th edn) 33 pp 76-78 1925, Suppl p 446 1959.]

**Cadmium potassium iodide** [13601-63-3] **M 532.2.** Crystallise it from ethanol by partial evaporation.

**Cadmium sulfate** [7790-84-3 (for 3CdSO<sub>4</sub> 8H<sub>2</sub>O), 10124-36-4 (anhydrous)] **M 208.4 (anhydrous), 769.5 (hydrate).** The sulfate crystallises from distilled water as a *hydrate* by partial evaporation in a desiccator. It gives the *monohydrate* on heating at 80°. It is insoluble in EtOH, Me<sub>2</sub>CO or EtOAc. It forms a white precipitate of Cd(OH)<sub>2</sub> with aqueous NH<sub>3</sub> which dissolves in excess of NH<sub>3</sub> to form soluble [Cd(NH<sub>3</sub>)<sub>4</sub>]SO<sub>4</sub>. [Gmelin's *Cadmium* (8th edn) 33 p 121 1925, Suppl pp 609-610 1959.]

**Calcium** [7440-70-2] **M 40.1, m 845°.** Clean the metal by washing it with ether to remove adhering paraffin, file the surface in an argon-filled glove box, and wash it with ethanol containing 2% of conc HCl. Then wash it with dry ethanol, dry it in a vacuum and store it under pure argon [Addison et al. *J Chem Soc* 3868 1962].

**Calcium bromide monohydrate** [62648-72-0, 71626-99-8 (xH<sub>2</sub>O), 7789-41-5 (anhydrous)] **M 217.9, d<sub>4</sub><sup>20</sup> 3.35.** Crystallise the bromide from EtOH or Me<sub>2</sub>CO. It loses H<sub>2</sub>O on heating, is anhydrous at 750°, then it loses Br at higher temperatures. It is *deliquescent*. [Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 930 1963.]

**Calcium chloride (anhydrous)** [10043-52-4] **M 111.0, m 772°, b >1600°, d<sub>4</sub><sup>15</sup> 2.15.** It is available as fused granules or cubic crystals. It is very *hygroscopic*, very soluble in H<sub>2</sub>O (exothermic), and EtOH. Store it in a tightly closed container. [Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 931 1963.]

**Calcium chloride dihydrate** [10035-04-8] **M 147.0, m 175°(dehydrates), 772°(dec).** Crystallise it from ethanol. It is *hygroscopic*. It loses H<sub>2</sub>O at 200° so it can be dried at high temperatures to dehydrate it. The *hexahydrate* [7774-34-7] has **m 30°** and **d 1.67**.

**Calcium dithionite** [13812-88-9] **M 168.2, m dec on heating.** Crystallise it from water, or water followed\* by acetone and dry it in air at room temperature.

**Calcium hexacyanoferrate (II) undecahydrate** [13821-08-4] **M 490.3.** Recrystallise it three times from conductivity H<sub>2</sub>O and dry it in air to constant weight over the partially dehydrated salt. [James *Trans Faraday Soc* 45 855 1949.] Alternatively, the Ca salt can be purified by precipitation with absolute EtOH in the cold (to avoid oxidation) from an air-free saturated aqueous solution. The pure lemon yellow crystals are centrifuged, dried in a vacuum desiccator first over dry charcoal for 24 hours, then over partly dehydrated salt and stored in a dark glass stoppered bottle. No deterioration occurs after 18 months. No trace of Na, K or NH<sub>4</sub> ions can be

detected in the salt from the residue after decomposition of the salt with conc  $\text{H}_2\text{SO}_4$ . Analyses indicate 11 mols of  $\text{H}_2\text{O}$  per mol of salt. The solubility in  $\text{H}_2\text{O}$  is 36.45g (24.9°) and 64.7g (44.7°) per 100g of solution. [Farrow *J Chem Soc* 50 1926.]

**Calcium hydroxide** [1305-62-0] **M 74.1, m loses  $\text{H}_2\text{O}$  on heating,  $\text{pK}^{25}$  12.7 (for  $\text{Ca}^{2+}$ ).** Heat analytical grade calcium carbonate at  $1000^\circ$  during 1 hour. Allow the resulting oxide to cool and add slowly to water. Heat the suspension to boiling, cool and filter through a sintered glass funnel of medium porosity (to remove soluble alkaline impurities). Dry the solid at  $110^\circ$  and crush it to a uniformly fine powder. [Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 934 1963.]

**Calcium iodate** [7789-80-2 ( $\text{H}_2\text{O}$ )] **M 389.9, m  $>540^\circ$ ,  $\text{pK}^{25}$  0.79 (for  $\text{HIO}_3$ ).** Crystallise it from water (100ml/g at  $100^\circ$  and 100ml/0.1g at  $0^\circ$ ). [Bahl & Singh *J Indian Chem Soc* 17 397 1940.]

**Calcium iodide x-hydrate** [71626-98-7 ( $x\text{H}_2\text{O}$ ), 10102-68-8 (anhydrous)] **M 293.9 (for  $4\text{H}_2\text{O}$ ), m  $740^\circ$ , b  $1100^\circ$ .** Dissolve the salt in acetone, which is then diluted and evaporated. This drying process is repeated twice, then the  $\text{CaI}_2$  is recrystallised from acetone/diethyl ether and stored over  $\text{P}_2\text{O}_5$ . It is very *hygroscopic* when anhydrous and is light sensitive [Cremlyn et al. *J Chem Soc* 528 1958]. The yellow *hexahydrate* has **m  $42^\circ$** . It is soluble in  $\text{H}_2\text{O}$ , MeOH, EtOH and  $\text{Me}_2\text{CO}$  but insoluble in  $\text{Et}_2\text{O}$ .

**Calcium nitrate tetrahydrate** [13477-34-4] **M 236.1, m  $45^\circ$ (hydrate),  $560^\circ$ (anhydrous).** Crystallise the nitrate four times from water (0.4ml/g) by cooling in a  $\text{CaCl}_2$ -ice freezing mixture. The *tetrahydrate* is dried over conc  $\text{H}_2\text{SO}_4$  and stored over  $\text{P}_2\text{O}_5$ , to give the *anhydrous salt*. It is *deliquescent*. After 3 recrystallisations of ACS grade salt, it had Co, Fe, Mg, Sr and Zn at 0.2, 1.0, 0.02, 10 and 0.02 ppm resp. [Bassett & Taylor *J Chem Soc* 105 1926 1914.]

**Calcium nitrite dihydrate** [13780-06-8 (30% w/w aqueous solution)] **M 150.1(hydrate), m dec on heating,  $d_4^{20}$  2.22.** Crystallise it from hot water (1.4ml/g) by adding ethanol and cooling to give the hydrate. It is *deliquescent*. [Ray & Ogg *J Am Chem Soc* 79 265 1957.]

**Calcium permanganate tetrahydrate** [10118-76-0 (anhydrous)] **M 350.0 (for  $4\text{H}_2\text{O}$ ).** Crystallise it from water (3.3ml/g) by partial evaporation in a desiccator. It is *deliquescent*. Note that it loses oxygen more readily than the potassium salt. It is an oxidising agent.

**Calcium sulfate dihydrate** [10101-41-4] **M 172.1, m 150(dec),  $d_4^{20}$  2.32.** It loses only part of its  $\text{H}_2\text{O}$  at  $100$ - $150^\circ$  (see below). It is soluble in  $\text{H}_2\text{O}$  and very slowly soluble in glycerol. It is insoluble in most organic solvents.

**Calcium sulfate hemihydrate** [10034-76-1] **M 145.2.** Its solubility in  $\text{H}_2\text{O}$  is 0.2parts/100 at  $18.75^\circ$ . It dehydrates completely  $>650^\circ$ . Dry it below  $300^\circ$  to give a solid with estimated pore size *ca* 38% of volume. *Anhydrous*  $\text{CaSO}_4$  (**Drierite**) has a high affinity for  $\text{H}_2\text{O}$  and will absorb 6.6% of its weight of  $\text{H}_2\text{O}$  to form the *hemihydrate* (gypsum). It sets to a hard mass with  $\text{H}_2\text{O}$ ; hence it should be kept in a tightly sealed container. The solubility of gypsum in  $\text{H}_2\text{O}$  is unusual: 0.176% at  $0^\circ$ , 0.209% at  $30^\circ$ , 0.210 at  $40^\circ$ , 0.204 at  $50^\circ$  and 0.200 at  $60^\circ$ . [Hulett *J Am Chem Soc* 27 49 1905, James & Partington *J Chem Soc* 107 1019 1915, Namba *J Soc Chem Ind* 40 2797 1920.]

**Calcium thiosulfate** [10124-41-1] **M 152.2, m  $43$ - $49^\circ$ ,  $\text{pK}_1^{25}$  0.6,  $\text{pK}_2^{25}$  1.74 (for  $\text{H}_2\text{S}_2\text{O}_3$ ).** Recrystallise the thiosulfate from water below  $60^\circ$  in a  $\text{N}_2$  atmosphere, followed by drying with EtOH and  $\text{Et}_2\text{O}$ . Store it in a refrigerator. The *hexahydrate* can decompose spontaneously at  $43$ - $49^\circ$ . Store it in a cool closed container. [Pethybridge & Taba *J Chem Soc, Faraday Trans 1* 78 1331 1982.]

**Carbon dioxide** [124-38-9] **M 44.0, sublimes at  $-78.5^\circ$ ,  $\text{pK}_1^{25}$  6.35,  $\text{pK}_2^{25}$  10.33 (for  $\text{H}_2\text{CO}_3$ ).** Pass the gas over CuO wire at  $800^\circ$  to oxidise CO and other reducing impurities (such as  $\text{H}_2$ ), then over copper dispersed on Kieselguhr at  $180^\circ$  to remove  $\text{O}_2$ . Drying it at  $-78^\circ$  removes the water vapour. Final purification is by vacuum

distillation at liquid nitrogen temperature to remove non-condensable gases [Anderson et al. *J Chem Soc* 3498 1962]. Sulfur dioxide contaminant can be removed at 450° using silver wool combined with a plug of platinised quartz wool. Halogens are removed by using Mg, Zn or Cu, heated to 450°. [Glemser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 647 1963.]

**Carbon disulfide** [75-15-0] **M 76.1, b 46.3°, d<sub>4</sub><sup>20</sup> 1.264, n<sub>D</sub><sup>20</sup> 1.627.** Shake it for 3 hours with three portions of KMnO<sub>4</sub> solution (5g/L), twice for 6 hours with mercury (to remove sulfide impurities) until no further darkening of the interface occurs, and finally with a solution of HgSO<sub>4</sub> (2.5g/L) or cold, saturated HgCl<sub>2</sub>. Dry it with CaCl<sub>2</sub>, MgSO<sub>4</sub>, or CaH<sub>2</sub> (with further drying by refluxing over P<sub>2</sub>O<sub>5</sub>), followed by fractional distillation in diffuse light. **Alkali metals cannot be used as drying agents.** It has also been purified by standing with bromine (0.5ml/L) for 3-4 hours, shaking rapidly with KOH solution, then copper turnings (to remove unreacted bromine), and drying with CaCl<sub>2</sub>. CS<sub>2</sub> is highly **TOXIC** has a **foul odour** and is highly **FLAMMABLE**. *Work in a good fumehood.*

Small quantities of CS<sub>2</sub> have been purified (including removal of hydrocarbons) by mechanical agitation of a 45-50g sample with a solution of 130g of sodium sulfide in 150ml of H<sub>2</sub>O for 24 hours at 35-40°. The aqueous sodium thiocarbonate solution is separated from unreacted CS<sub>2</sub>, then precipitated with 140g of copper sulfate in 350g of water, with cooling. After filtering off the copper thiocarbonate, it is decomposed by passing steam into it. The distillate is separated from H<sub>2</sub>O and distilled from P<sub>2</sub>O<sub>5</sub>. [Ruff & Golla *Z Anorg Chem* **138** 17 1924, *Beilstein* **3** IV 395.]

**Carbon monoxide** [630-08-0] **M 28.0, m -200°, b -191.5°.** Iron carbonyl is a likely impurity in CO stored under pressure in steel tanks. It can be decomposed by passing the gas through a hot porcelain tube at 350-400°. Passage through alkaline pyrogallol solution removes oxygen (and CO<sub>2</sub>). Removal of CO<sub>2</sub> and water are effected by passage through soda-lime followed by Mg(ClO<sub>4</sub>)<sub>2</sub> or P<sub>2</sub>O<sub>5</sub> and collected over Hg. Carbon monoxide can be condensed and distilled at -195°. It is sparingly soluble in H<sub>2</sub>O but is readily absorbed by a solution of CuCl in HCl to give the white crystalline adduct CuCl.CO.2H<sub>2</sub>O. It burns in air with a bright blue flame but a mixture of 2 volumes of CO and 1 volume of O<sub>2</sub> explode when kindled, although in a small jar the combustion is not violent. **HIGHLY POISONOUS gas** as it reacts with haemoglobin to form bright red carboxyhaemoglobin which is stable and not readily decomposed by oxygen. The **TOXIC LEVEL** of CO is 50ppm (~55mg/m<sup>3</sup>). **The ANTIDOTE should be at hand and always available in laboratories using CO; and staff should be trained to administer it.** [Gilliland & Blanchard *Inorg Synth* **II** 81 1946, Glemser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 645-646 1963.]

**Carbonyl bromide** [593-95-3] **M 187.8, b 64.5°/760mm.** Purify it by distillation from Hg and from powdered Sb to remove free bromine, then distil it in a slight vacuum to remove volatile SO<sub>2</sub> (the major impurity) [Carpenter et al. *J Chem Soc, Faraday Trans* **2** 384 1977]. **TOXIC.**

**Carbonyl sulfide (COS)** [463-58-1] **M 60.1, m -138°, b -47.5°, -50°.** Purify the gas by scrubbing it through three consecutive fritted washing flasks containing conc NaOH at 0° (to remove HCN), and then through conc H<sub>2</sub>SO<sub>4</sub> (to remove CS<sub>2</sub>) followed by a mixture of NaN<sub>3</sub> and NaOH solution; or passed through traps containing saturated aqueous lead acetate, then through a column of anhydrous CaSO<sub>4</sub>. Then it is freeze-pumped repeatedly and distilled through a trap packed with glass wool and cooled to -130° (using an *n*-pentane slurry). It liquefies at 0°/12.5mm. Use stainless steel containers. The gas is stored over conc H<sub>2</sub>SO<sub>4</sub>. [Glemser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 654 1963.] **TOXIC.**

**Ceric ammonium nitrate** [16774-21-3] **M 548.2, pK<sub>1</sub><sup>25</sup> -1.15, pK<sub>2</sub><sup>25</sup> -0.72, pK<sub>3</sub><sup>25</sup> 1.68, pK<sub>4</sub><sup>25</sup> 2.29 (for aquo Ce<sup>4+</sup>).** Ceric ammonium nitrate (125g) is warmed with 100ml of dilute HNO<sub>3</sub> (1:3 v/v) and 40g of NH<sub>4</sub>NO<sub>3</sub> until it dissolves, and filtered through a sintered-glass funnel. The solid which separates on cooling in ice is filtered off on a sintered funnel (at the pump) and air is sucked through the solid for 1-2 hours to remove most of the nitric acid. Finally, the solid is dried at 80-85°.

**Cerium(III) sulfate** [cerous sulfate, Ce<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>] [13454-94-9 anhydrous; 10450-59-6 8H<sub>2</sub>O; 13550-47-5 12 H<sub>2</sub>O] **M 568.4 (anhydr), d<sub>4</sub><sup>25</sup> 2.89, pK<sup>25</sup> 9.29 (for hydrolysis of Ce<sup>3+</sup>).** To prepare cerous sulfate, cerium

oxide [CeO<sub>2</sub>, 0.3g] or chloride is dissolved in hot 6N H<sub>2</sub>SO<sub>4</sub> (20ml), filtered through a sintered glass funnel and allowed to crystallise over concentrated H<sub>2</sub>SO<sub>4</sub> in a vacuum desiccator. The crystals are filtered off, washed twice with H<sub>2</sub>O (10ml) and once with EtOH (10ml), and dried in air for 4 hours to provide the *pentahydrate*. Alternatively, a neutral or slightly acidic (with H<sub>2</sub>SO<sub>4</sub>) aqueous solution of the sulfate is treated with ¾ of its volume of EtOH. The salt is thus obtained rapidly and quantitatively without the evaporation stage. The *anhydrous* sulfate is formed by heating any sulfate hydrate salt at 400-500°, but is hygroscopic. The hydrate loses most of its H<sub>2</sub>O at ca 250°, and above 650° it loses SO<sub>3</sub> also to give the basic salt. [Wendlandt *J Inorg Nucl Chem* 7 51 1958, Wetzell in *Handbook of Preparative Inorganic Chem (Ed. Brauer)* Academic Press Vol II p 1156 1965.] When a fairly concentrated solution of the anhydrous salt in ice H<sub>2</sub>O, is allowed to evaporate at 40-50°, the *octahydrate* salt separates as colourless rhombic pyramids [Koppel *Z Anorg Chem* 41 385 1904]. The *dodecahydrate* is obtained in fine needles when a clear fairly concentrated solution of cerous sulfate is allowed to evaporate over concentrated H<sub>2</sub>SO<sub>4</sub> in a desiccator in a refrigerator [Koppel *Z Anorg Chem* 41 385 1904]. [Vanino *Handbuch der Präparativen Chemie* Vol I, 3<sup>rd</sup> Edn, pp 754-755, Stuttgart 1925.]

**Cerium(IV) sulfate** [ceric sulfate, Ce(SO<sub>4</sub>)<sub>2</sub>] [13590-82-4 *anhydrous*] M 332.2, d<sub>4</sub><sup>25</sup> 3.01, pK<sub>1</sub><sup>25</sup>-1.15, pK<sub>2</sub><sup>25</sup>-0.72, pK<sub>3</sub><sup>25</sup>1.68, pK<sub>4</sub><sup>25</sup>2.29 (for hydrolysis of Ce<sup>4+</sup>). Ceric sulfate is prepared by heating pure ceric oxide (CeO<sub>2</sub>) with an excess of concentrated H<sub>2</sub>SO<sub>4</sub> for an hour, cooling, adding glacial acetic acid, stirring, allowing to settle and decanting off. The process is repeated several times and the yellow orthorhombic crystals of the sulfate are filtered off (sintered glass), washed with glacial acetic acid and dried in a vacuum desiccator over NaOH/KOH and/or soda lime. [Vanino *Handbuch der Präparativen Chemie* Vol I, 3<sup>rd</sup> Edn, pp 754-755, Stuttgart 1925, Meyer & Aufrecht *Chem Ber* 37 140 1904.] It is a strong oxidising agent (oxidation potential of a 1 to 8N H<sub>2</sub>SO<sub>4</sub> solution at 25° is 1.42 ±0.1 volts), and like ceric ammonium sulfate is used in volumetric analysis. Solutions in dilute H<sub>2</sub>SO<sub>4</sub> are standardised by titration with pure arsenious oxide, iron or ferrous ammonium sulfate. Although it is its own end-point indicator (Ce<sup>4+</sup> ions are yellow and Ce<sup>3+</sup> ions are colourless), the end point is not as sharp as that of permanganate, and it is best to use 0.005M *N*-phenylanthranilic acid as indicator (colour change from yellow-green to purple at end point) [J. Mendham, R.C. Denney, J.D. Barnes and M.J.K. Thomas, *Vogel's Quantitative Chemical Analysis*, 6th Edn, Prentice Hall, Harlow, 2000. ISBN 0582226287].

**Ceric sulfate tetrahydrate** is obtained thus: pure ceric ammonium nitrate [16774-21-3] in a small volume of H<sub>2</sub>O is treated with ammonia, Ce(OH)<sub>4</sub> separates, is collected and is dissolved in concentrated H<sub>2</sub>SO<sub>4</sub>. This solution is evaporated to dryness and the residue is crystallised from H<sub>2</sub>O (perhaps a small amount of H<sub>2</sub>SO<sub>4</sub> should be added to avoid hydrolysis). A small volume of H<sub>2</sub>O should be used as boiling with a large volume of H<sub>2</sub>O leads to separation of the basic salt. The yellow-orange powder or orthorhombic crystals lose H<sub>2</sub>O to give the anhydrous salt at 180-200°, but decomposes >350° to give the basic salt CeOSO<sub>4</sub>. [Vanino *Handbuch der Präparativen Chemie* Vol I, 3<sup>rd</sup> Edn, pp 755-756, Stuttgart 1925, Muthmann & Stützel *Chem Ber* 33 1763 1900.]

**Cesium bromide** [7787-69-1] M 212.8, m 636°, b ca 1300°, d<sub>4</sub><sup>20</sup> 4.44. It is very soluble in H<sub>2</sub>O, soluble in EtOH but insoluble in Me<sub>2</sub>CO. Dissolve it in the minimum volume of H<sub>2</sub>O, filter and precipitate it by adding Me<sub>2</sub>CO. Filter off the solid and dry it at 100°. Also recrystallise it from water (0.8ml/g) by partial evaporation in a desiccator.

**Cesium carbonate** [534-17-8] M 325.8, m 792°(at red heat). Crystallise it from ethanol (10ml/g) by partial evaporation. [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol I p 988 1963.]

**Cesium chloride** [7647-17-8] M 168.4, m 645°, b 1303°, d<sub>4</sub><sup>20</sup> 3.99. It is soluble in H<sub>2</sub>O but can be purified by crystallisation from H<sub>2</sub>O [solubility in g percent: 162.3(0.7°), 182.2(16.2°) and 290(at bp 119.4°)] and dried in a high vacuum. It is soluble in EtOH and is *deliquescent*; keep it in a tightly closed container. [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol I pp 951-955 1963.] For further purification of CsCl, a concentrated aqueous solution of the practically pure reagent is treated with an equivalent weight of I<sub>2</sub> and Cl<sub>2</sub> is bubbled into the solution until precipitation of CsCl<sub>2</sub>I is complete. Recrystallisation yields a salt that is free from other alkali metals. It is then decomposed to pure CsCl on heat-

ing. [Harned & Schupp *J Am Chem Soc* **52** 3886 1930.] It can also be recrystallised from acetone/water, or from water (0.5ml/g) by cooling in a CaCl<sub>2</sub>/ice bath. Dry it at 78° under vacuum.

**Cesium chromate** [56320-90-2] **M 381.8, pK<sub>1</sub><sup>25</sup> 0.74, pK<sub>2</sub><sup>25</sup> 6.49 (for H<sub>2</sub>CrO<sub>4</sub>).** Crystallise the chromate from water (1.4ml/g) by partial evaporation in a desiccator. [Boer et al. *Z Anorg Allgem Chem* **191** 113 1930, Hein & Herzog in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1389 1963.]

**Cesium fluoride** [13400-13-0] **M 151.9, m 703°.** Crystallise it from aqueous solution by adding ethanol.

**Cesium iodide** [7789-17-5] **M 259.8, m 621°, b~1280°, d<sub>4</sub><sup>20</sup> 4.5.** Crystallise it from warm water (1ml/g) by cooling to -5°.

**Cesium nitrate** [7789-18-6] **M 194.9, m 414°(dec), d<sub>4</sub><sup>20</sup> 3.65.** It crystallises from water (0.6ml/g) between 100° and 0°. After 1 crystallisation of 99.9% grade salt, it had K, Na and Se at 0.8, 0.4 and 0.2 ppm respectively.

**Cesium perchlorate** [13454-84-7] **M 232.4, pK<sup>25</sup> -2.4 to -3.1 (for HClO<sub>4</sub>).** Crystallise it from water (4ml/g) between 100° and 0°.

**Cesium sulfate** [10294-54-9] **M 361.9, m 1005°, d<sub>4</sub><sup>20</sup> 4.24.** Crystallise it from water (0.5ml/g) by adding ethanol and cooling.

**Chlorine** [7782-50-5] **M 70.9, m -101.5°, b -34.0°, d<sub>4</sub><sup>20</sup> 2.898.** Pass the gas in succession through aqueous KMnO<sub>4</sub>, dilute H<sub>2</sub>SO<sub>4</sub>, conc H<sub>2</sub>SO<sub>4</sub>, and a drying tower containing Mg(ClO<sub>4</sub>)<sub>2</sub>. Or bubble it through water, dry it over P<sub>2</sub>O<sub>5</sub> and distil it from bulb to bulb in a vacuum line. One volume of water dissolves 4.6 volumes of Cl<sub>2</sub> at 0°, 2.15 volumes at 20°, 1.22 volumes at 50° and 0.39 volumes at 90°. [Schmeisser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 272 1963.] **HIGHLY TOXIC.**

**Chlorine trifluoride** [7790-91-2] **M 92.5, b 12.1°.** Impurities include chloryl fluoride, chlorine dioxide and hydrogen fluoride. Pass it first through two U-tubes containing NaF to remove HF, then through a series of traps in which the liquid is fractionally distilled. It can be purified *via* the KF complex; KClF<sub>4</sub>, formed by adding excess ClF<sub>3</sub> to solid KF in a stainless steel cylinder in a dry-box and shaking overnight. After pumping out the volatile materials, pure ClF<sub>3</sub> is obtained by heating the bomb to 100-150° and condensing the evolved gas in a -196° trap [Schack et al. *Chem Ind (London)* 545 1967]. It attacks glass very vigorously. **HIGHLY TOXIC.**

**Chlorosulfonic (chlorosulfuric) acid** [7790-94-5] **M 116.5, b 151-152°/750mm, d<sub>4</sub><sup>20</sup> 1.753, n<sub>D</sub><sup>20</sup> 1.4929, pK<sup>25</sup> -5.9 (aqueous H<sub>2</sub>SO<sub>4</sub>).** Distil the acid at atmospheric pressure in an all-glass apparatus, taking the fraction boiling at 156-158°. It reacts **EXPLOSIVELY** with water. **wear gloves and face protection.** [Cremlyn *Chlorosulfonic acid: A Versatile Reagent*, Royal Society of Chemistry UK, 2002, p 308, ISBN 0854044981, Fehér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 385 1963].

**Chromic chloride (anhydrous)** [10025-73-7] **M 158.4, m 1152°, pK<sub>1</sub><sup>25</sup> 3.95, pK<sub>2</sub><sup>25</sup> 5.55, pK<sub>3</sub><sup>25</sup> 10.5 (for Cr<sup>3+</sup>).** Sublime the chloride in a stream of dry HCl. *Alternatively*, the impure chromic chloride (100g) is added to 1L of 10% aqueous K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and several millilitres of conc HCl and the mixture is brought to a gentle boil with constant stirring for 10 minutes. (This removes a reducing impurity.) The solid is separated and washed by boiling with successive 1L lots of distilled water until the wash water no longer gives a test for chloride ion, then dry it at 110° [Poulsen & Garner *J Am Chem Soc* **81** 2615 1959, Hein & Herzog in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1338 1965].

**Chromium ammonium sulfate dodecahydrate** [34275-72-4 (*hydrate*), 13548-43-1 (*anhydrous*)] **M 478.4, m 94° loses 9H<sub>2</sub>O then dehydrates at 300°, d<sub>4</sub><sup>20</sup> 1.72.** Crystallise the double salt from a saturated aqueous solution at 55° by cooling slowly with rapid mechanical stirring. The resulting fine crystals are filtered on a Büchner funnel, partly dried on a porous plate, then equilibrated for several months in a vacuum desiccator

over crude chromium ammonium sulfate (partially dehydrated by heating at 100° for several hours before use) [Johnson et al. *J Am Chem Soc* **75** 3922 1953].

**Chromium (II) chloride (anhydrous)** [10049-05-5] **M 122.9, m 824°, d<sub>4</sub><sup>14</sup> 2.75**. It is obtained from the *dihydrate* by heating *in vacuo* at 180°. It is a very *hygroscopic* white powder which dissolves in H<sub>2</sub>O to give a sky blue solution. It is stable in dry air but oxidises rapidly in moist air and should be stored in air tight containers. It sublimates at 800° in a current of HCl gas and should be cooled in the presence of HCl gas. *Alternatively*, it can be washed with air-free Et<sub>2</sub>O and dried at 110-120°. [Burg *Inorg Synth III* 150 1950, Balthis & Bailar (4 H<sub>2</sub>O) *Inorg Synth I* 125 1939, Hein & Herzog in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** pp 1336-1338 1965.]

**Chromium hexacarbonyl** [13007-92-6] **M 220.1, m 130°(dec), d<sub>4</sub><sup>20</sup> 1.77**. Wash the complex with cold EtOH, then Et<sub>2</sub>O, and allow it to dry in air. *Alternatively*, recrystallise it from dry Et<sub>2</sub>O. This is best accomplished by placing the hexacarbonyl in a Soxhlet extractor and extracting exhaustively with dry Et<sub>2</sub>O. Pure Cr(CO)<sub>6</sub> is filtered off and dried in air. Completely colourless refracting crystals are obtained by sublimation at 40-50°/0.5mm in an apparatus where the collecting finger is cooled by Dry-ice and in which there is a wide short bore between the hot and cold sections to prevent clogging by the crystals. Loss of product in the crystallisation and sublimation is slight. It is important not to overdo the drying as the solid is appreciably volatile and **TOXIC** [vapour pressure is 0.04(8°), 1.0(48°) and 66.5(100°) mm]. Also, do not allow the Et<sub>2</sub>O solutions to stand too long as a brown deposit is formed which is sensitive to light, and to avoid the possibility of violent decomposition. It sinters at 90°, decomposes at 130°, and **EXPLODES** at 210°. [Owen et al. *Inorg Synth III* 156 1950, Podall et al. *J Am Chem Soc* **83** 2057 1961.] **POISONOUS**.

**Chromium (III) nitrate nonahydrate** [7789-02-8] **M 400.2, m ~60° (dec >100°)**. The pure deep violet nonahydrate salt is best prepared freshly from pure recrystallised (3 times) chromium (VI) trioxide and pure nitric acid. A solution is prepared by dissolving 1g of CrO<sub>3</sub> in 3ml of H<sub>2</sub>O and 2ml of pure HNO<sub>3</sub>, and carefully, with stirring (behind a screen) pure MeOH (0.5-1.0ml) is added dropwise carefully (shield) with cooling to avoid a violent reaction. A bluish colour develops as Cr(VI) is reduced to Cr(III). When this solution is diluted to 130,000ppm of the salt, analysis detected by ICP/MS gave the following trace elements (ppm in brackets): Sr (33), Na (3.5), Mo, Ni, Cu, Si and Mg (0.13 each), Se, Zn, Al (0.026 each), Ti (1.5), Fe (4.9), Co (0.07), Sn (0.065), Ba (0.013 and W (0.078). Evaporation of the methanolic solution in high vacuum over CaCl<sub>2</sub> eventually yields pure deep violet rhombic crystals of chromium (III) nitrate *nonahydrate*. An aqueous solution of this salt becomes green on heating but reverts to the violet colour on cooling.

The pale green **anhydrous chromium (III) nitrate**, [13548-38-4] **M 238.0, m dec >60°**, is best obtained pure by mixing a solution of chromium hexacarbonyl in CCl<sub>4</sub> with excess of N<sub>2</sub>O<sub>5</sub> in CCl<sub>4</sub> under N<sub>2</sub> for 12 hours, whereby evolution of gases occurs. Filter off the salt and wash it with CCl<sub>4</sub> in a closed system under N<sub>2</sub>, and dry it *in vacuo*. It is very soluble in H<sub>2</sub>O, EtOAc and Me<sub>2</sub>SO but insoluble in \*C<sub>6</sub>H<sub>6</sub>, CCl<sub>4</sub> and CHCl<sub>3</sub>. The *deliquescent* powder reacts vigorously with Et<sub>2</sub>O. [Addison & Chapman *J Chem Soc* 539 1964.] **Cr(VI)** ions are **CARCINOGENIC** as they cause DNA breaks, and Cr(III) ions affect DNA synthesis.

**Chromium potassium sulfate dodecahydrate** [7788-99-0] **M 499.4, pK<sub>1</sub><sup>25</sup> 0.74, pK<sub>2</sub><sup>25</sup> 6.49 (for H<sub>2</sub>CrO<sub>4</sub>, chromic acid)**. Crystallise it from hot water (2ml/g) by cooling.

**Chromium trioxide (chromic anhydride)** [1333-82-0] **M 100.0, m 197°, dec at 250° to Cr<sub>2</sub>O<sub>3</sub>, d 2.70 (pK<sub>1</sub><sup>25</sup> 0.74, pK<sub>2</sub><sup>25</sup> 6.49, for H<sub>2</sub>CrO<sub>4</sub>, chromic acid)**. It forms red crystals from water (0.5ml/g) between 100° and -5°, or from water/conc HNO<sub>3</sub> (1:5). It separates when potassium or sodium dichromate are dissolved in conc H<sub>2</sub>SO<sub>4</sub>. Dry it in a vacuum desiccator over NaOH pellets. It is a *hygroscopic*, powerful oxidant and can ignite with organic compounds. It is a skin and pulmonary **IRRITANT**. [Keyes et al. *Industrial Chemicals* (Lowenheim & Moran eds.) 4<sup>th</sup> edn J. Wiley pp 270-274 1975.] **CANCER SUSPECT**.

**Chromyl chloride** [14977-61-8] **M 154.9, b 115.7°, d<sub>4</sub><sup>20</sup> 1.911**. Purify it by distillation under reduced pressure. It hydrolyses violently with H<sub>2</sub>O and is a powerful oxidant which explodes with P, and ignites in contact with S, NH<sub>3</sub>, EtOH and many organic compounds. **TOXIC**.

**Claisen alkali (alkali Claisen).** Prepare this from KOH (35g) in H<sub>2</sub>O (25ml) and dilute it to 100ml with MeOH. **STRONGLY CAUSTIC.**

**Cobaltous ammonium sulfate hexahydrate** [13596-46-8] **M 395.5, d<sub>4</sub><sup>20</sup> 1.90.** Crystallise it from boiling water (2ml/g) by cooling. Wash it with ethanol and dry it in a vacuum.

**Cobaltous bromide hexahydrate** [85017-77-2 (xH<sub>2</sub>O), 7789-43-7 (anhydrous)] **M 326.9 (6H<sub>2</sub>O), m 47<sup>o</sup>(dec), b 100<sup>o</sup>(dec), d<sub>4</sub><sup>20</sup> 4.9.** Crystallise it from water (1ml/g) by partial evaporation in a desiccator. The *anhydrous* salt is soluble in EtOH, Me<sub>2</sub>CO, MeOAc to form blue-coloured solutions. [Glemser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1517 1965.]

**Cobaltous hexahydrate** [7791-13-1 (6H<sub>2</sub>O), 7646-79-9 (anhydrous)] **M 237.9, m 87<sup>o</sup>(dec), d<sub>4</sub><sup>20</sup> 1.92.** A saturated aqueous solution at room temperature is fractionally crystallised by standing overnight. The first half of the material that crystallises in this way is used in the next crystallisation. The process is repeated several times, water being removed in a dry-box using air filtered through glass wool and dried over CaCl<sub>2</sub> [Hutchinson *J Am Chem Soc* 76 1022 1954]. It has also been crystallised from dilute aqueous HCl. The *hexahydrate* **m 86<sup>o</sup>** forms pink to red deliquescent crystals. It loses 4H<sub>2</sub>O on heating at 52-56<sup>o</sup> and forms the violet *dihydrate* which loses further H<sub>2</sub>O at 100<sup>o</sup> to form the violet *monohydrate* which loses the last H<sub>2</sub>O at 120-140<sup>o</sup> to give the pale blue *anhydrous* deliquescent salt **m 735<sup>o</sup>** and **b 1049<sup>o</sup>**. A pink solution of CoCl<sub>2</sub> in H<sub>2</sub>O becomes blue on heating to 50<sup>o</sup> or adding conc HCl which may precipitate the *mono* or *dihydrate*. The solid *dihydrate* gives a blue-purple solution with EtOH. Note: CoCl<sub>2</sub> in H<sub>2</sub>O is a "sympathetic ink", i.e. writing with an aqueous solution is almost invisible on paper, but becomes blue on warming the paper. On cooling or standing, the writing becomes invisible again. The *anhydrous* salt is soluble in H<sub>2</sub>O, EtOH, Et<sub>2</sub>O, Me<sub>2</sub>CO and pyridine. [Glemser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1515 1965.]

**Cobaltous nitrate hexahydrate** [10026-22-9] **M 291.0, m ~55<sup>o</sup>(6H<sub>2</sub>O), 100-105<sup>o</sup>(dec), d<sub>4</sub><sup>20</sup> 1.88.** Crystallise the nitrate from water (1ml/g), or ethanol (1ml/g), by partial evaporation. After 3 crystallisations from H<sub>2</sub>O it contains: metal (ppm) As (8), Fe (1.2), K (1), Mg (4), Mn (4), Mo (4), Na (0.6), Ni (18), Zn (1.6). The *hexahydrate* gives the pink *anhydrous* salt by the action of HNO<sub>3</sub> and N<sub>2</sub>O<sub>5</sub>. The *hexahydrate* melts at ~55<sup>o</sup> to give a red liquid which decomposes on further heating at 100-105<sup>o</sup> to form Co<sub>3</sub>O<sub>4</sub>.

**Cobaltous perchlorate hexahydrate** [13478-33-6] **M 365.9, pK<sup>25</sup> -2.4 to -3.1 (for HClO<sub>4</sub>).** Crystallise it from warm water (0.7ml/g) by cooling.

**Cobaltous potassium sulfate** [13596-22-0] **M 329.4.** Crystallise it from water (1ml/g) between 50<sup>o</sup> and 0<sup>o</sup>, and dry it in a vacuum desiccator over conc H<sub>2</sub>SO<sub>4</sub>.

**Cobaltous sulfate heptahydrate** [10026-24-1 (7H<sub>2</sub>O), 60459-08-7 (xH<sub>2</sub>O), 10124-43-3 (anhydrous)] **M 281.1, m (see text), d<sub>4</sub><sup>20</sup> 2.03.** Crystallise it three times from conductivity water (1.3ml/g) between 100<sup>o</sup> and 0<sup>o</sup> depending on which hydrate is required. The *heptahydrate* crystallises below 44<sup>o</sup> and is efflorescent with **m 97<sup>o</sup>**. Between 44<sup>o</sup> and 70<sup>o</sup> the monoclinic *hexahydrate* CoSO<sub>4</sub>·6H<sub>2</sub>O **m 41.5<sup>o</sup>** is formed, and above 70<sup>o</sup> the *monohydrate* CoSO<sub>4</sub>·H<sub>2</sub>O **m 71<sup>o</sup>** is obtained. The pale reddish or lavender-coloured *anhydrous* salt is obtained by heating the hydrate above 250<sup>o</sup>, boiling with conc H<sub>2</sub>SO<sub>4</sub> or by heating with (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>.

**Cupric ammonium chloride dihydrate** [10534-87-9 (hydrate), 15610-76-1 (anhydrous)] **M 277.5, m 110-120<sup>o</sup>(anhydrous) then dec at higher temperature, d<sub>4</sub><sup>20</sup> 2.0.** Crystallise it from weak aqueous HCl (1ml/g).<sup>\*</sup> It crystallises out of a hot solution of CuCl<sub>2</sub> saturated with NH<sub>3</sub> gas.

**Cupric bromide** [7789-45-9] **M 223.4, m 498<sup>o</sup>, b 900<sup>o</sup>, d<sub>4</sub><sup>20</sup> 4.7.** Crystallise it twice by dissolving it in water (140ml/g), filtering to remove any Cu<sub>2</sub>Br<sub>2</sub>, and concentrating under vacuum at 30<sup>o</sup> until crystals appear. The cupric bromide is then allowed to crystallise by leaving the solution in a vacuum desiccator containing P<sub>2</sub>O<sub>5</sub> [Hope et al. *J Chem Soc* 5226 1960, Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1009 1965].

**Cupric chloride** [7447-39-4] **M 134.4, m 498°, 630°(dec)**. Crystallise the chloride from hot dilute aqueous HCl (0.6ml/g) by cooling in a CaCl<sub>2</sub>-ice bath. It is dehydrated by heating on a steambath under vacuum. It is deliquescent in moist air but efflorescent in dry air. The *dihydrate* is emerald green but blue when free from solvent. Concentrated solutions are yellow-green in colour but are blue when free from solvent. Concentrated solutions are yellow-green and become yellow on adding conc HCl. A very dilute solution is pure blue due to Cu(H<sub>2</sub>O)<sub>4</sub><sup>2+</sup> [Donan & Bassett *J Chem Soc* **81** 939 1902]. CuCl<sub>2</sub> is very deliquescent and is soluble in MeOH or EtOH to give green crystals of Cu(ROH)<sub>2</sub>Cl<sub>2</sub>. [Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **II** p 1008 1965.]

**Cupric nitrate trihydrate** [10031-43-3 (3H<sub>2</sub>O), 3251-23-8 (anhydrous)] **M 241.6, m 114°, b 170°(dec), d<sub>4</sub><sup>20</sup> 2.0**. Crystallise it from weak aqueous HNO<sub>3</sub> (0.5ml/g) by cooling from room temperature. The *anhydrous* salt can be prepared by dissolving copper metal in a 1:1 mixture of liquid NO<sub>2</sub> and ethyl acetate and purified by sublimation [Evans et al. *J Chem Soc, Faraday Trans 1* **75** 1023 1979]. The *hexahydrate* dehydrates to the *trihydrate* at 26°, and the *anhydrous salt* sublimes between 150 and 225°, but melts at 255-256° and is *deliquescent*.

**Cupric perchlorate hexahydrate** [10294-46-9 (hydrate), 13770-18-8] **M 370.5, m 230-240°, pK<sup>25</sup> -2.4 to -3.1 (for HClO<sub>4</sub>)**. Crystallise it from distilled water. The *anhydrous salt* is hygroscopic.

**Cupric sulfate (blue vitriol, bluestone)** [7758-98-7] **M 159.6, m >560°**. After adding 0.02g of KOH to a litre of nearly saturated aqueous solution of the sulfate, it is left for two weeks, then the precipitate is filtered on to a fibreglass filter with pore diameter of 5-15 microns. The filtrate is heated to 90° and allowed to evaporate until some CuSO<sub>4</sub>.5H<sub>2</sub>O crystallises out. The solution is then filtered hot and cooled rapidly to give crystals which are freed from mother liquor by filtering under suction [Geballe & Giauque *J Am Chem Soc* **74** 3513 1952]. *Alternatively*, crystallise the sulfate from water (0.6ml/g) between 100 and 0°. The *pentahydrate* is slowly efflorescent, losing 2H<sub>2</sub>O at 30°, two more H<sub>2</sub>O are lost at 110° and a white anhydrous powder (desiccant) is obtained on heating above 250°.

**Cuprous bromide** [7787-70-4] **M 143.4, m 497°, b 1345°, d<sub>4</sub><sup>20</sup> 4.72**. Purify it as for cuprous iodide but using aqueous NaBr. [Keller & Wycoff *Inorg Synth* **II** 3 1946, Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **II** p 1006 1965.]

**Cuprous chloride** [7758-89-6] **M 99.0, m 430°, b~1400°**. Dissolve it in strong HCl, precipitate it by diluting with water and filter it off. Wash the solid with ethanol and diethyl ether, then dry it and store it in a vacuum desiccator [Österlöf *Acta Chem Scand* **4** 375 1950]. *Alternatively*, to an aqueous solution of CuCl<sub>2</sub>.2H<sub>2</sub>O is added, with stirring, an aqueous solution of anhydrous sodium sulfite. The colourless product is dried at 80° for 30 minutes and stored under N<sub>2</sub>. Cu<sub>2</sub>Cl<sub>2</sub> can be purified by zone-refining [Hall et al. *J Chem Soc, Faraday Trans 1* **79** 343 1983]. [Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **II** p 1005 1965.]

**Cuprous cyanide** [544-92-3] **M 89.6, m 474°**. Wash the cyanide thoroughly with boiling H<sub>2</sub>O, then with EtOH. Dry it at 100° to a fine soft powder. It dissolves in excess alkali cyanide solutions to form the very soluble complex ion Cu(CN)<sub>4</sub><sup>3-</sup>. [Bassett & Corbett *J Chem Soc* **125** 1660 1924, Barber *J Chem Soc* 79 1943.]

**Cuprous iodide** [7681-65-4] **M 190.5, m 605°, b 1336°, d<sub>4</sub><sup>25</sup> 5.63**. It can be freshly prepared by dissolving an appropriate quantity of CuI in boiling saturated aqueous NaI over 30 minutes. Pure CuI is obtained by cooling and diluting the solution with water, followed by filtering and washing sequentially with H<sub>2</sub>O, EtOH, EtOAc, Et<sub>2</sub>O and pentane, then drying *in vacuo* for 24 hours [Dieter, *J Am Chem Soc* **107** 4679 1985]. *Alternatively*, wash it with H<sub>2</sub>O, then EtOH and finally with Et<sub>2</sub>O containing a little iodine. Traces of H<sub>2</sub>O are best removed first by heating at 110° and then at 400°. Excess of I<sub>2</sub> is removed completely at 400°. It dissolves in Et<sub>2</sub>O if an amine is present to form the amine complex. On heating it becomes red, then black, but changes to white on cooling. It is sparingly soluble in H<sub>2</sub>O or alkali iodide solutions but readily soluble in NH<sub>3</sub> (which absorbs CO) and in cyanide or thiosulfate solutions. [Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **II** p 1007 1965, Bawn & Ledwith *Chem Ind (London)* 1180 1957.]

**Cuprous thiocyanate** [18223-42-2] **M 121.6, pK<sup>25</sup> -1.85 (for HSCN).** Purify it as for cuprous iodide but using aqueous NaSCN. [Demmerle et al. *Ind Eng Chem* **42** 2 1950, Newman *Analyst* **88** 500 1963.]

**Cyanamide** [420-04-2] **M 42.0, m 43°, 45°, 46°, b 85-87°/0.5mm, pK<sub>1</sub><sup>20</sup> -0.36 (1.1 at 29°), pK<sub>2</sub><sup>20</sup> 10.27.** Purify it by placing *ca* 15g in a Soxhlet thimble and extracting exhaustively (2-3 hours) with two successive portions of Et<sub>2</sub>O (400ml, saturated with H<sub>2</sub>O by shaking before use) containing two drops of 1N acetic acid. Two successive portions of Et<sub>2</sub>O are used so that the NH<sub>2</sub>CN is not heated for too long. Each extract is dried over Na<sub>2</sub>SO<sub>4</sub> (30g), then combined and evaporated under reduced pressure. The NH<sub>2</sub>CN may be stored unchanged at 0° in Et<sub>2</sub>O solution in the presence of a trace of AcOH. Extracts from several runs may be combined and evaporated together. The residue from evaporation of an Et<sub>2</sub>O solution is a colourless viscous oil which sets to a solid and can be recrystallised from a mixture of 2 parts of \*C<sub>6</sub>H<sub>6</sub> and 1 part of Et<sub>2</sub>O. Concentrating an aqueous solution of NH<sub>2</sub>CN at high temperatures causes **EXPLOSIVE** polymerisation. [Kurzer & Lawson *Org Synth Coll Vol IV* 645 1963, Pinck & Salisbury *Inorg Synth III* 39 1950, Soloway & Lipschitz *J Org Chem* **23** 613 1958.] *Hygroscopic.* [Beilstein **3** IV 145.]

**Cyanogen bromide** [506-68-3] **M 105.9, m 49-51°, b 60-62°/atm.** *All operations with this substance should be performed in a very efficient fume cupboard—it is very POISONOUS and should be handled in small amounts. Fresh commercial material is satisfactory for nearly all purposes and does not need to be purified. It is a white crystalline solid with a strong cyanide odour. If it is reddish in colour and partly liquid or paste-like, then it is too far gone to be purified, and fresh material should be sought.* It can be purified by distillation using small amounts at a time, and using a short wide-bore condenser because it readily solidifies to a crystalline white solid which may clog the condenser. *An appropriate gas mask should be used when transferring the molten solid from one container to another, and the operation should be done in an efficient fume cupboard.* The melting point (**m 49-51°**) should be measured in a sealed tube. [Hartman & Dreger *Org Synth Coll Vol II* 150 1948.]

**Cyanogen iodide** [506-78-5] **M 152.9, m 146-147°.** *This compound is POISONOUS, and the precautions for cyanogen bromide (above) apply here.* The reagent (*ca* 5.9g) is dissolved in boiling CHCl<sub>3</sub> (15ml), filtered through a plug of glass wool into a 25ml Erlenmeyer flask. Cool to room temperature for 15 minutes, then place it in an ice-salt bath and cool to -10°. This cooling causes a small aqueous layer to separate as ice. The ice is filtered with the CNI, but melts on the filter and is also removed with the CHCl<sub>3</sub> used as washing liquid. The CNI which is collected on a sintered glass funnel is washed 3x with CHCl<sub>3</sub> (1.5ml at 0°) and freed from last traces of solvent by placing it on a watch glass and exposing it to the atmosphere in a good fume cupboard at room temperature for 1 hour to give colourless needles (*ca* 4.5g), **m 146-147°** (sealed capillary totally immersed in the oil bath). The yield depends slightly on the rapidity of the operation; in this way loss by sublimation can be minimised. If desired, it can be sublimed under reduced pressure at temperatures at which CNI is only slowly decomposed into I<sub>2</sub> and (CN)<sub>2</sub>. The vacuum will need to be renewed constantly due to the volatility of CNI. [Bak & Hillebert *Org Synth Coll Vol IV* 207 1963.]

**Decaborane** [17702-41-9] **M 122.2, m 99.7-100°, b 100°/19mm, 213°/atm.** Purify decaborane by vacuum sublimation at 80°/0.1mm, followed by crystallisation from methylcyclohexane, CH<sub>2</sub>Cl<sub>2</sub>, or dry olefin-free-*n*-pentane, the solvent being subsequently removed by storing the crystals in a vacuum desiccator containing CaCl<sub>2</sub>. It is soluble in H<sub>2</sub>O but is slowly decomposed to give H<sub>2</sub>. It is soluble in alkali, and on acidification it liberates H<sub>2</sub>. **TOXIC.** [Greenwood in *Comprehensive Chemistry (Ed Bailar et al.)* Pergamon Press Vol **1** pp 818-837 1973.]

**Deuterium** [7782-39-0] **M 4.** Pass the gas over activated charcoal at -195° [MacIver & Tobin *J Phys Chem* **64** 451 1960]. Purify it also by diffusion through nickel [Pratt & Rogers, *J Chem Soc, Faraday Trans I* **92** 1589 1976]. Always check deuterium for radioactivity to determine the amount of tritium in it (see D<sub>2</sub>O below).

**Deuterium oxide** [7789-20-0] **M 20, f 3.8°/760mm, b 101.4°/760mm, d<sub>4</sub><sup>20</sup> 1.105.** Distil it from alkaline KMnO<sub>4</sub> [de Giovanni & Zamenhof *Biochem J* **92** 79 1963]. **NOTE that D<sub>2</sub>O invariably contains tritiated water and will therefore be RADIOACTIVE; always check the radioactivity level of D<sub>2</sub>O in a scintillation**

counter before using.

**cis-Diamminedichloroplatinum(II) (Cisplatin)** [15663-27-1] **M 300.1, m 270°(dec)**. Recrystallise it from dimethylformamide and check the purity by IR and UV-VIS spectroscopy. [Raudaschl et al. *Inorg Chim Acta* **78** 143 1983.] **HIGHLY TOXIC, SUSPECTED CARCINOGEN**.

**Diammonium hydrogen orthophosphate** [7783-28-0] **M 132.1**. Crystallise it from water (1ml/g) between 70 and 0°. Its solubility in H<sub>2</sub>O is 59% at room temperature and 200% at boiling point. It slowly evolves NH<sub>3</sub> and should be stored in a well-stoppered container. After one crystallisation, ACS grade salt had Fe, Mo, Na, Se and Ti at 1, 0.2, 1.4, 0.2 and 0.8ppm, respectively. [Gmelin's, Ammonium (8th edn) **23** pp422-426 1936.]

**Dinitrogen tetroxide (nitrogen dioxide, N<sub>2</sub>O<sub>4</sub>)** [10544-72-6] **M 92.0 m -11.2°, b 21.1°**. Purify it by oxidation at 0° in a stream of oxygen until the blue colour changes to red-brown. *Alternatively* distil it from P<sub>2</sub>O<sub>5</sub>, then solidify it by cooling in a deep-freeze (at -78°, giving nearly colourless crystals). Oxygen can be removed by alternate freezing and melting. **TOXIC VAPOUR**. [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 488-489 1963.]

**Disodium hydrogen orthophosphate (anhydrous)** [7558-79-4] **M 142.0 (see pK of H<sub>3</sub>PO<sub>4</sub>)**. Crystallise the salt twice from warm water, by cooling. Dry in air, then in an oven overnight at 130°. It should be dried before use as it is slightly *hygroscopic*. It forms di-, hepta- and deca- hydrates.

**Ferric Bromide** [10031-26-2] **M 395.6, m >130°(dec)**. Sublime it in a sealed tube with Br<sub>2</sub> at 120°-200°. [Lux in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1494 1965.]

**Ferric chloride (anhydrous)** [7705-08-0] **M 162.2, m >300°(dec)**. Sublime it at 200° in an atmosphere of chlorine. It is an "iron-black" coloured powder with green iridescence. It is soluble in \*C<sub>6</sub>H<sub>6</sub>, EtOH, Et<sub>2</sub>O, Me<sub>2</sub>CO and pyridine in which the monomeric species "FeCl<sub>3</sub>" exist whereas in the vapour state it exists in the dimeric "Fe<sub>2</sub>Cl<sub>6</sub>" form. Store it in a weighing bottle inside a desiccator as it absorbs moisture from air to form the yellow *hexahydrate* (see next entry). [Tarr *Inorg Synth* **III** 191 1950, Pray *Inorg Synth* **V** 153 1957, Epperson *Inorg Synth* **VII** 163 1963.]

**Ferric chloride hexahydrate** [10025-77-1] **M 270.3, m 37°(dec), pK<sub>1</sub><sup>25</sup> 2.83, pK<sub>2</sub><sup>25</sup> 4.59 (for hydrolysis of Fe<sup>3+</sup>)**. An aqueous solution, saturated with the salt at room temperature, is cooled to -20° for several hours. Separation of the crystals is slow, even with scratching and seeding, and it is generally necessary to stir this overnight. The presence of free HCl retards crystallisation. [Linke *J Phys Chem* **60** 91 1956].

**Ferric nitrate nonahydrate** [7782-61-8] **M 404.0, m 47°(dec)**. It crystallises from aqueous solutions of moderately strong HNO<sub>3</sub> as the pale violet *nonahydrate* **m 40°** and is soluble in EtOH and Me<sub>2</sub>CO. With more concentrated aqueous solutions (containing some HNO<sub>3</sub>), the *hexahydrate* crystallises out **m 60.5°**. The *anhydrous* salt is slightly deliquescent and decomposes at 47°. [Lambert & Thomson *J Chem Soc* **97** 2426 1920, Gmelin's, *Iron* (8th edn) **59** Part B pp 161-172 1932.]

**Ferric perchlorate nonahydrate** [13537-24-1] **M 516.3, pK<sub>1</sub><sup>25</sup> -2.4 to -3.1 (for HClO<sub>4</sub>)**. Crystallise it twice from conc HClO<sub>4</sub>, the first time in the presence of a small amount of H<sub>2</sub>O<sub>2</sub> to ensure that the iron is fully oxidised [Sullivan *J Am Chem Soc* **84** 4256 1962]. Extreme care should be taken with this preparation because it is potentially **EXPLOSIVE**.

**Ferric sulfate x-hydrate** [10028-22-5] **M 399.9 + xH<sub>2</sub>O**. Dissolve the sulfate in the minimum volume of dilute aqueous H<sub>2</sub>SO<sub>4</sub> and allow it to evaporate at room temperature until yellowish-white crystals start to form. Do not concentrate by boiling off the H<sub>2</sub>O as basic salts will be formed. Various *hydrates* are formed; the common ones are the dodeca and nona *hydrates* which are violet in colour. The *anhydrous salt* is colourless

and is quite *hygroscopic*, but it dissolves in H<sub>2</sub>O slowly unless ferrous sulfate is added. [*Gmelin's, Iron* (8th edn) pp 439-462 1932.]

**Ferrous bromide** [20049-65-4] **M 215.7 + xH<sub>2</sub>O, m 684°, d<sup>25</sup> 4.63.** It crystallises from air-free H<sub>2</sub>O to provide the *hexahydrate* as pale green to bluish-green rhombic prisms. On heating at 49° H<sub>2</sub>O is lost and the *tetrahydrate* is formed. On further heating at 83° more H<sub>2</sub>O is lost and the *dihydrate* is formed as a light yellow to dark brown *hygroscopic* powder. The ferrous iron in aqueous solutions of these salts readily oxidise to ferric iron. The salts should be stored over H<sub>2</sub>SO<sub>4</sub> under N<sub>2</sub> in tightly closed containers. They have some solubility in EtOH. [Baxter *Z Anorg Chem* **38** 236 1904, Kühn & Ernst *Z Anorg Allgem Chem* **317** 84 1962, Lux in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **II** p 1493 1965.]

**Ferrous chloride tetrahydrate** [13478-10-9] **M 198.8, m 105°(dec), pK<sub>1</sub><sup>25</sup> 6.7, pK<sub>2</sub><sup>25</sup> 9.3 (for aquo Fe<sup>2+</sup>).** A 550ml round-bottomed Pyrex flask is connected, *via* a glass tube fitted with a medium porosity sintered-glass disc, to a similar flask. To 240g of FeCl<sub>2</sub>·4H<sub>2</sub>O in the first flask is added conductivity water (200ml), 38% HCl (10ml), and pure electrolytic iron (8-10g). A stream of purified N<sub>2</sub> gas is passed through the assembly, escaping through a mercury trap. The salt is dissolved by heating which is continued until complete reduction has occurred. By inverting the apparatus and filtering (under N<sub>2</sub> pressure) through the sintered glass disc, unreacted iron is removed. After cooling and crystallisation, the unit is again inverted, and the crystals of ferrous chloride are filtered free from mother liquor by applied N<sub>2</sub> pressure. Partial drying by overnight evacuation at room temperature gives a mixed hydrate which, on further evacuation on a water bath at 80°, loses water of hydration and absorbed HCl (with vigorous effervescence) to give a white powder of FeCl<sub>2</sub>·2H<sub>2</sub>O (see below). [Gayer & Wootner *J Am Chem Soc* **78** 3944 1956, (2H<sub>2</sub>O) Gayer & Wootner *Inorg Synth* **V** 179 1957.]

**Ferrous chloride** [7758-94-3] **M 126.8, m 674°, b 1023°, d<sup>25</sup> 3.16.** It sublimes in a stream of HCl at *ca* 700°, or in H<sub>2</sub> below 300°. Its vapour pressure at 700° is 12mm. It forms white *hygroscopic* rhombohedral crystals with a green tint which oxidise in air to FeCl<sub>3</sub> and Fe<sub>2</sub>O<sub>3</sub>. It is soluble in H<sub>2</sub>O, EtOH Me<sub>2</sub>CO but insoluble in Et<sub>2</sub>O. The *tetrahydrate* is pale green to pale blue in colour and loses 2H<sub>2</sub>O at 105-115°. The *dihydrate* loses H<sub>2</sub>O at 120°. [Anhydrous FeBr<sub>2</sub> can be obtained by carefully dehydrating the *tetrahydrate* in a stream of HBr and N<sub>2</sub>, and it can be sublimed under N<sub>2</sub>.] The ferrous iron in aqueous solutions of these salts readily oxidises to ferric iron. (See above.) [Kovacuumic & Brace *Inorg Synth* **VI** 172 1960, Lux in *Handbook of Preparative Inorganic Chemistry* (Ed Brauer) Academic Press Vol **II** p 1491 1965.]

**Ferrous perchlorate hexahydrate** [13933-23-8] **M 362.9, pK<sup>25</sup> -2.4 to -3.1 (for HClO<sub>4</sub>).** Crystallise it from HClO<sub>4</sub>. [CARE, see ferric perchlorate above.]

**Ferrous sulfate heptahydrate (green vitriol)** [7782-63-0] **M 278.0, m ~60°(dec).** Crystallise the sulfate from 0.4M H<sub>2</sub>SO<sub>4</sub>, or precipitate it from an aqueous solution with EtOH. It is *efflorescent* in dry air, and is converted to the *tetrahydrate* at 57°, then to the *monohydrate* at 65° (or by heating the heptahydrate in a vacuum at 140°). It forms a brown-black complex, FeSO<sub>4</sub>·NO, with nitric oxide and is used in a qualitative test for nitrates ("brown ring" test).

**Fluorine** [7782-41-4] **M 38.0, b -129.2°.** Pass the gas through a bed of NaF at 100° to remove HF and SiF<sub>4</sub>. [For description of stills used in fractional distillation, see Greenberg et al. *J Phys Chem* **65** 1168 1961; Stein et al. *Purification of Fluorine by Distillation, Argonne National Laboratory, ANL-6364* 1961 (from Office of Technical Services, US Dept of Commerce, Washington 25).] **HIGHLY TOXIC.**

**Fluoroboric acid (tetrafluoroboric acid, fluoboric acid)** [16872-11-0] **M 87.8, b 130°(dec), pK<sup>25</sup> -4.9.** Crystallise fluoroboric acid several times from conductivity water. It can be stored in a glass vessel at room temperature. It is available commercially as ~48% aqueous solution. It is most useful for preparing *tetrafluoroborate salts* which are generally insoluble. For example, addition of the acid to aryldiazonium salt solutions precipitates the more stable aryldiazonium tetrafluoroborate salts which can be washed with H<sub>2</sub>O to remove impurities, followed by EtOH and Et<sub>2</sub>O, and stored for short periods of time before further use. It is a catalyst for preparing acetals. [Mathers et al. *J Am Chem Soc* **37** 1516 1915, Wamser & Christian *J Am Chem*

*Soc* 70 1209 1940, Kwasnik in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 221-222 1963.] **STRONG IRRITANT and is TOXIC.**

**Gallium** [7440-55-3] **M 69.7, m 29.78°, b 2403°, d<sup>29.6</sup> 5.904, d<sup>29.8</sup> 6.095.** Dissolve the metal in dilute HCl and extract it with Et<sub>2</sub>O. Bubbling H<sub>2</sub>S through the solution removes many metals, and a second extraction with Et<sub>2</sub>O frees Ga further from metal impurities, except for Mo, Th(III) and Fe which are largely removed by precipitation with NaOH. The solution is then electrolysed in 10% NaOH with a Pt anode and cathode (2-5A at 4-5V) to deposit Ga, In, Zn and Pb, from which Ga was obtained by fractional crystallisation of the melt [Hoffman *J Res Nat Bur Stand* 13 665 1934]. Ga is also purified by heating to boiling in 0.5-1M HCl, then heating to 40° in water and pouring the molten Ga with water under vacuum through a glass filter (30-50 μ pore size), to remove any unmelted metals or oxide film. The Ga is then fractionally crystallised from the melt under water. [Dönges in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 837 1963.]

**Gallium (III) Chloride** [13450-90-3] **M 176.1, m 77.8°, b 133°/100mm, 197.7°/700mm, d<sub>4</sub><sup>20</sup> 2.47, pK<sub>1</sub><sup>25</sup> 2.91, pK<sub>2</sub><sup>25</sup> 3.70, pK<sub>3</sub><sup>20</sup> 4.42 (for Ga<sup>3+</sup>).** The pure compound can be obtained by redistillation in a stream of Cl<sub>2</sub> or Cl<sub>2</sub>/N<sub>2</sub> followed by vacuum sublimation or zone refining. It forms colourless needles which give *gallium dichloride* [Ga(GaCl<sub>4</sub>), m 172.4°] on heating. It dissolves in H<sub>2</sub>O with liberation of heat. It is soluble in Et<sub>2</sub>O and can be extracted from an HCl solution with Et<sub>2</sub>O. [Laubengayer & Schirmer *J Am Chem Soc* 62 1579 1940, Dönges in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 846 1963.]

**Gallium (III) nitrate nonahydrate** [63462-65-7] **M 417.9, m ca 65°.** Recrystallise the nitrate from H<sub>2</sub>O (solubility is 295g/100ml at 20°). It forms a white *deliquescent*, colourless powder soluble in H<sub>2</sub>O, absolute EtOH and Et<sub>2</sub>O. It loses HNO<sub>3</sub> upon heating at 40°. Addition of Et<sub>2</sub>O to a warm ethanolic solution (40-50°) of Ga(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O precipitates Ga(OH)<sub>2</sub>NO<sub>3</sub>·Ga(OH)<sub>3</sub>·2H<sub>2</sub>O. If the salt has partly hydrolysed, dissolve it in conc HNO<sub>3</sub>, reflux, dilute with H<sub>2</sub>O and concentrate on a sand bath. Wash the solid several times by adding H<sub>2</sub>O and evaporating until there is no odour of acid. Dilute the residue to a Ga concentration of 26g/100ml. At this concentration, *spongy* Ga(NO<sub>3</sub>)<sub>3</sub>·xH<sub>2</sub>O separates from the viscous solution. After standing for several days the crystals are collected and dried in a stream of dry air first at room temperature, then at 40°. *Dehydration* is complete after 2 days. Recrystallise it from H<sub>2</sub>O and dry it at water pump vacuum at room temperature. [Reimmann & Tanner *Z Naturforsch* 20B 71 1965, Dönges in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 856 1963.]

**Gallium (III) sulfate** [13494-91-2 (*anhydrous*), 13780-42-2 (*hydrate*)] **M 427.6.** Recrystallisation from H<sub>2</sub>O gives the 16-18H<sub>2</sub>O hydrate (solubility at 20° is 170g/100ml). *Alternatively*, dissolve it in 50% H<sub>2</sub>SO<sub>4</sub> and evaporate (60-70°), cool and precipitate it by adding EtOH/Et<sub>2</sub>O. On heating at 165° it provides the *anhydrous* salt, which is a white *hygroscopic* solid. [Reimmann & Tanner *Z Naturforsch* 20B 71 1965.]

**Germanium** [7440-56-4] **M 72.6, m 937°, 925-975°, b 2700°, d<sub>4</sub><sup>20</sup> 5.3.** Copper contamination on the surface and in the bulk of single crystals of Ge can be removed by immersion in molten alkali cyanide under N<sub>2</sub>. The Ge is placed in dry K and/or Na cyanide powder in a graphite holder in a quartz or porcelain boat. The boat is then inserted into a heated furnace which, after a suitable time, is left to cool to room temperature. At 750°, a 1mm thickness of metal requires about 1 minute, whereas 0.5cm needs about half hour. The boat is removed from the furnace, and the solid samples are taken out with plastic-coated tweezers, carefully rinsed in hot water and dried in air [Wang *J Phys Chem* 60 45 1956, Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 712 1963]. **Care with the use of cyanide.**

**Germanium (IV) oxide** [1310-53-8] **M 104.6, m 1080°(soluble form), d<sup>25</sup> 6.239; m 1116°(insoluble form) d<sup>25</sup> 4.228, pK<sub>1</sub><sup>25</sup> 9.02, pK<sub>2</sub><sup>25</sup> 12.82 (for germanic acid H<sub>2</sub>GeO<sub>3</sub>).** The oxide (GeO<sub>2</sub>) is usually prepared by hydrolysing redistilled GeCl<sub>4</sub> and igniting it in order to remove H<sub>2</sub>O and chloride. It can be further purified by dissolving in hot H<sub>2</sub>O (solubility is 4g/L cold) evaporating and drying the residual crystalline solid. When the *soluble* form (which is produced in H<sub>2</sub>O at 355°) is heated for 100 hours, it is converted to the *insoluble* form.

This form is stable at temperatures up to 1033°, and fusion at 1080° for 4 hours causes complete de-vitrification and it reverts to the *soluble* form. [Müller & Blank *J Am Chem Soc* **46** 2358 1924, Dennis & Laubengayer *J Am Chem Soc* **47** 1945 1925, Laubengayer & Morton *J Am Chem Soc* **54** 2303 1932, Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 706 1963.]

**Germanium tetrabromide** [13450-92-5] M 392.2, m 26°, b 185.9°/atm,  $d_4^{29}$  3.123. Purify it by simple distillation or fractionation depending on purity. It is soluble in EtOH, CHCl<sub>3</sub>, \*C<sub>6</sub>H<sub>6</sub> and Et<sub>2</sub>O. It fumes in moist air and is readily hydrolysed by water. [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 718 1963]. **LACHRYMATORY.**

**Germanium tetrachloride** [10038-98-9] M 214.4, m -49.5° (α), -52.0° (β), b 83.1°/760mm, 86.5°/760mm corr,  $d_4^{20}$  1.84. Traces of Cl<sub>2</sub> and HCl can be removed from the liquid by blowing dry air through it for a few hours at room temperature or by shaking it with Hg or Hg<sub>2</sub>Cl<sub>2</sub> and then fractionating it in a vacuum. It decomposes on heating at 950°. It has a sharp penetrating odour and fumes in moist air to give a chalky coat of GeO<sub>2</sub>. It is slowly hydrolysed by H<sub>2</sub>O to give GeO<sub>2</sub>, but distils from conc HCl. [Foster et al. *Inorg Synth* **II** 109 1946, Dennis & Hance *J Am Chem Soc* **44** 304 1922, Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 715 1963.] **LACHRYMATORY.**

**Glass powder** (100-300 mesh). Washed with 10% HNO<sub>3</sub>, water and dry in air.

**Gold powder** [7440-57-5] M 196.97, m 1064.79°, b 2808° (2700°),  $d_4^{20}$  19.3, resistivity at 0° is 2.05 μΩ-cm. Massive gold reacts very slowly and it is best converted to the powder which is more readily reactive. While working in a well vented fume cupboard, solid gold (10g, 51mmol) is dissolved in *Aqua Regia*, made from concentrated hydrochloric acid (12M HCl, 50ml) and concentrated nitric acid (16M HNO<sub>3</sub>, 13ml), by heating to 90° which will hasten dissolution, but will require topping up with *Aqua Regia*. Alternatively, the suspension is allowed to stand at ~25° until the solid has dissolved. The solution is evaporated to ca 10ml, concentrated hydrochloric acid (30ml) is added and evaporation is repeated. The solution is diluted with H<sub>2</sub>O (20ml), filtered through a medium sintered-glass funnel, and the filter is washed with small volumes of H<sub>2</sub>O. The filtrate and washings, which contain HAuCl<sub>4</sub>, are heated to boiling and hydroquinone (10g, 91mmol) in hot H<sub>2</sub>O (100ml) is slowly added. The mixture is kept at 90° for 1 hour (sufficient time to reduce all the HAuCl<sub>4</sub> to Au), cooled and filtered through an extraction thimble. The thimble is placed in a Soxhlet apparatus and extracted with MeOH. After 15 minutes, when the circulating MeOH in the thimble is colourless, the thimble is removed and the contents are collected and dried in air to give Au powder quantitatively. [Block *Inorg Synth* **4** 15 1953.]

**Gold (III) bromide (gold tribromide)** [10294-28-7] M 436.7, m 150°(dec). Purify it by adding pure Br<sub>2</sub> to the dark powder, securely stopper the container, warm a little and shake while keeping away from light for ca 48 hours. Remove the stopper and place it over NaOH until free Br<sub>2</sub> is no longer in the apparatus (48-60 hours). The bright yellow needles of the tribromide are stable over NaOH in the dark. It is soluble in H<sub>2</sub>O and in EtOH where it is slowly reduced. Keep it in a cooled, closed container and protect it from light as decomposition causes free gold to be formed. *Auribromic acid* can be obtained by adding the calculated amount of conc HBr to AuBr<sub>3</sub> (actually Au<sub>2</sub>Br<sub>6</sub>) until all dissolves, whereby the acid crystallises out as HAuBr<sub>4</sub>·5H<sub>2</sub>O; a *deliquescent* solid soluble in EtOH with m ca 27°, and store it as above. [Gibson & Colles *J Chem Soc* 2411 1931, Burawoy & Gibson *J Chem Soc* 217 1935, Burawoy & Gibson *J Chem Soc* 219 1935.]

**Gold (I) chloride [aurous chloride, Au(I)Cl]** [10294-29-8] M 232.4, m 289°(dec),  $d^{25}$  7.4. It is best prepared by heating AuCl<sub>3</sub>·3H<sub>2</sub>O, or HAuCl<sub>4</sub> (see next entry) at 100° in a high vacuum until the vapour pressure drops considerably when most of the H<sub>2</sub>O has been expelled. As the HAuCl<sub>4</sub> liquefies again in this process much spluttering will occur. The solid residue (mostly anhydrous AuCl<sub>3</sub>) is then heated to 156° (bromobenzene bath) and further to 170-205° when decomposition to AuCl is complete. Another preparation includes heating AuCl<sub>3</sub> in air at 185° [Thomsen *J Prakt Chem* **13** 337 1876], but purer salt is obtained by heating AuCl<sub>3</sub> in a stream of dry HCl at 175° [Diemer *J Am Chem Soc* **35** 552 1913]. It forms pale yellow crystals which are not deliquescent, slightly soluble in cold EtOH, dissolve in alkali chloride solutions to form chloroaurates(I), e.g. KAuCl<sub>2</sub>, but it decompose in H<sub>2</sub>O to give gold and hydrolysed Au(III) species. [Blitz & Wein *Z Anor Allgem Chem* **148** 192 1925, Glemser & Sauer *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic

Press Vol II p 1055 1965.]

**Gold (III) chloride (hydrate)** [16903-35-8] **M 339.8 + xH<sub>2</sub>O, x ~3, m 229°, b 354°(dec), d<sub>4</sub><sup>20</sup> 3.9.** It is obtained as a dark red crystalline mass by dissolving Au in *aqua regia* and evaporating. When sublimed at 180°, the anhydrous crystals are ruby red. The anhydrous salt is *hygroscopic*, soluble in H<sub>2</sub>O but sparingly soluble in EtOH and Et<sub>2</sub>O. *Aurichloric acid* (chloroauric acid, HAuCl<sub>4</sub>) is formed when AuCl<sub>3</sub> is dissolved in HCl. [Diemer *J Am Chem Soc* **35** 553 1913, Block *Inorg Chem* **4** 14 1953, Glemser & Sauer *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1056 1965.]

**Gold (I) cyanide** [506-65-0] **M 223.0, m dec on heating.** The lemon yellow powder is sparingly soluble in H<sub>2</sub>O and EtOH but soluble in aqueous NH<sub>3</sub>. It is obtained by heating H[Au(CN)<sub>2</sub>] at 110°. Wash it well with H<sub>2</sub>O and EtOH and dry it at 110°. It has an IR band at  $\nu_{\max}$  2239 cm<sup>-1</sup> typical for C≡N stretching vibration. [Glemser & Sauer *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1064 1965.] **CARE:** may evolve HCN.

**Gold (I) iodide** [10294-31-2] **M 323.9, m 120°(dec), d<sub>4</sub><sup>20</sup> 8.25.** It has been prepared by heating gold and iodine in a tube at 120° for 4 months. Since it decomposes to Au and I<sub>2</sub> in the presence of UV light and heat, then the main impurity is Au. The salt is therefore purified by heating at 120° with I<sub>2</sub> for several weeks. The crystals should be kept dry and in a cool place in the dark. [Weiss & Weiss *Z Naturforsch* **11B** 604 1956.]

**Gold (III) oxide hydrate** [1303-58-8] **M 441.9 + xH<sub>2</sub>O, evolves O<sub>2</sub> at 110°, pK<sub>1</sub><sup>25</sup> <11.7, pK<sub>2</sub><sup>25</sup> 13.36, pK<sub>3</sub><sup>25</sup> >15.3 [for Au(OH)<sub>3</sub>].** The most probable impurities are SO<sub>4</sub><sup>2-</sup> and Cl<sup>-</sup> ions. Dissolve it in strong boiling KOH solution (*ca* 5M) and precipitate (**care**) with excess of 3N H<sub>2</sub>SO<sub>4</sub>. Then shake and centrifuge, resuspend in H<sub>2</sub>O and repeat the washing several times until free from SO<sub>4</sub> and Cl ions. This gives a *wet* oxide which is dried in air, but decomposes to free gold in sunlight. It is advisable to keep it wet as it decomposes on drying (analyse wet sample). Store it away from light in the presence of H<sub>2</sub>O vapour. It evolves O<sub>2</sub> at 110°. It is insoluble in H<sub>2</sub>O but soluble in HCl and conc HNO<sub>3</sub>. [Roseveare & Buehrer *J Am Chem Soc* **49** 1221 1927.]

**Graphite (black lead, mineral carbon, plumbago)** [7782-42-5] **m 3652-3697°, d<sup>25</sup> 2.09, 2.23.** This carbon allotrope is obtained by mining (e.g. in Shrilanka, Canada). It is normally soft, forms black/gray scales, and although even small crystals of it are rare it is composed of crystallised carbon containing traces of SiO<sub>2</sub>, Fe and other minerals. Treat graphite with hot 1:1 HCl. Then filter, wash and the dried powdered is heated in an evacuated quartz tube at 1000° until a high vacuum is obtained. Cool this and store it in an atmosphere of helium [Craig et al. *J Phys Chem* **60** 1225 1956]. See also entry in Chapter 8.

**Helium** [7440-59-7] **M 4.0, m -272.2°/26atm, b -268.9°, d<sup>-270.3</sup> 0.147.** Dry the gas by passing it through a column of Linde 5A molecular sieves and CaSO<sub>4</sub>, then through an activated-charcoal trap cooled in liquid N<sub>2</sub>, to adsorb N<sub>2</sub>, argon, xenon and krypton. Also pass it over CuO pellets at 300° to remove hydrogen and hydrocarbons, over Ca chips at 600° to remove oxygen, and then over titanium chips at 700° to remove N<sub>2</sub> [Arnold & Smith *J Chem Soc, Faraday Trans 2* **77** 861 1981]. Its solubility in 100ml of H<sub>2</sub>O is 0.94ml at 25°, 1.05ml at 50° and 1.21ml at 75°.

**Hexachloroplatinic acid hydrate (H<sub>2</sub>PtCl<sub>6</sub>, chloroplatinic acid, platinum IV chloride solution)** [16941-12-1] **M 409.8 + H<sub>2</sub>O, m 60° (deliquescent solid).** If it is to be purified, or regenerated from Pt recovered from catalytic hydrogenations, it should be dissolved in *aqua regia* followed by evaporation to dryness and dissolution in the minimum volume of H<sub>2</sub>O. Then the aqueous solution is treated with saturated ammonium chloride until all the ammonium hexachloroplatinate [16919-58-7] separates. The (NH<sub>4</sub>)<sub>2</sub>PtCl<sub>6</sub> is filtered off and dried at 100°. Igniting this salt gives **Pt sponge**; dissolve the Pt sponge in *aqua regia*, boil to dryness, dissolve the residue in concentrated HCl, boil to dryness again and repeat the process. Protect it from light. [Wickers *J Am Chem Soc* **43** 1268 1921, Adams et al. *Org Synth Coll Vol I* 463, 466 1941, Bruce *J Am Chem Soc* **58** 687 1936.]

**Hexammine cobalt(III) chloride** [10534-89-1] **M 267.5.** It crystallises from warm water (8ml/g) on cooling.

[Bjerrum & McReynolds *Inorg Synth* **II** 217 1946.]

**Hexammine ruthenium(III) chloride** [14282-91-8] **M 309.6**. Crystallise it twice from 1M HCl.

**Hexarhodium hexadecacarbonyl** [28407-51-4] **M 1065.6, m 220°(dec, in air),  $d_4^{20}$  2.87**. It slowly loses CO when heated in air, but may be regenerated by heating at 80-200° in the presence of CO at 200 atmospheres pressure for 15 hours, preferably in the presence of Cu. It forms black crystals which are insoluble in hexane. It has bands at 2073, 2026 and 1800  $\text{cm}^{-1}$  in the IR. [Hieber & Lagally *Z Anorg Allgem Chem* **251** 96 1963, Corey & Dahl *J Am Chem Soc* **85** 1202 1963, Doyle et al. *Tetrahedron Lett* **22** 1783 1981.] **POISONOUS**.

**Hydrazine monohydrate ( $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$ )** [7803-57-8] **M 50.1, m 198°, b 118-122°/atm,  $d_4^{20}$  1.03**. It is best obtained by heating hydrazine sulphate (200g), NaOH (160g) and  $\text{H}_2\text{O}$  (75ml, exothermic) in a copper flask under reflux for 1.5 hours then distilled off (using a flame to remove all the hydrazine). The distillate (175ml) is a clear liquid which contains ~40-45% of  $\text{N}_2\text{H}_4$ . Note that hydrazine attacks glass, rubber and cork, and stainless steel equipment should be used. The percentage of hydrazine is determined by titration with standard acid (methyl orange indicator) or against standard iodine (starch indicator). *Hydrazine monohydrate* should contain 64% of  $\text{N}_2\text{H}_4$ . The ~40-45% solution may be concentrated by mixing it (144ml) with xylene (230ml) and distilling it through an efficient fractionating column (e.g. Hempel column). All the xylene passes over with about 85ml of  $\text{H}_2\text{O}$ . On distilling the residue, hydrated hydrazine (50ml) is obtained containing 80-85% of  $\text{N}_2\text{H}_4$ . This can be diluted with conductivity  $\text{H}_2\text{O}$  to 64%  $\text{N}_2\text{H}_4$  to give the *monohydrate*. Hydrazine and its hydrates have **VERY IRRITATING** and **TOXIC** vapours and should be used in an efficient fume cupboard. [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **I** pp 469-472 1963.]

**Hydrazine hydrate ( $\text{N}_2\text{H}_4 \cdot x \text{H}_2\text{O}$ )** [10217-52-4] **M 32.05 + x 18.02**. Hydrated hydrazine can be obtained as above and diluted as required. Solutions containing various amounts of  $\text{H}_2\text{O}$  are available commercially.

**Hydrazine (anhydrous)** [302-01-2] **M 32.1, m 1.5-2.0°, b 47°/26mm, 56°/71mm, 113-113.5°/atm, n 1.470,  $d_4^{25}$  1.91,  $\text{pK}_1^{25}$  -0.88,  $\text{pK}_2^{25}$  8.11**. Hydrazine hydrate is dried by refluxing with an equal weight of KOH pellets for 3 hours, then distilled from fresh solid NaOH or BaO in a current of dry  $\text{N}_2$ . Use stainless steel or copper equipment. Hydrazine and its hydrates have **VERY IRRITATING** and **TOXIC** vapours and should be used in an efficient fume cupboard. Store in a well-stoppered vessel, preferably under  $\text{N}_2$ . It is a useful reducing agent. [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **I** pp 469-472 1963.]

**Hydrazine dihydrochloride** [5341-61-7] **M 105.0, m 198°,  $d_4^{20}$  1.42**. It is recrystallised from aqueous EtOH and dried under vacuum over  $\text{CaSO}_4$ .

**Hydrazine monohydrochloride** [2644-70-4] **M 68.5, m 89°**. Prepare it by dropwise addition of cold conc HCl to cold liquid hydrazine in equimolar amounts. The crystals are harvested from water and are twice recrystallised from absolute MeOH and dried under a vacuum. [Kovack et al. *J Am Chem Soc* **107** 7360 1985.]

**Hydrazine sulfate** [10034-93-2] **M 130.1, m 254°**. Crystallise it from  $\text{H}_2\text{O}$ . Its solubility in  $\text{H}_2\text{O}$  is 3% at room temperature, but is very soluble in hot  $\text{H}_2\text{O}$ . It is a suspected **carcinogen**. [Adams & Brown *Org Synth Coll Vol I* 309 1941, Audrieth & Nickles *Inorg Synth I* 90 1939.]

**Hydrazoic acid (hydrogen azide, triazoic acid)** [7782-79-8] **M 43.0, m -80°, b 37°/atm,  $\text{pK}^{25}$  4.72**. The free acid is **HIGHLY EXPLOSIVE** and **POISONOUS**, so it is prepared and used in solution, and in an **efficient fume cupboard**. It is a very useful reagent for Schmidt and related reactions [Wolff *Organic Reactions* **3** 307 1946]. Solutions in  $\text{C}_6\text{H}_6$  or  $\text{CHCl}_3$  are prepared by making a paste from  $\text{NaN}_3$  (65g, 1mole) in warm  $\text{H}_2\text{O}$  (65ml), and added to  $\text{C}_6\text{H}_6$  or  $\text{CHCl}_3$  (400ml), cooled to 0°, and concentrated  $\text{H}_2\text{SO}_4$  (26.6mls, 0.5mol) is dropped into the stirred mixture while carefully controlling the temperature between 0° and 5°. The organic layer is separated, dried ( $\text{Na}_2\text{SO}_4$ ), and stored in a cold room. Its concentration is determined by shaking a small

aliquot with ten times its volume of H<sub>2</sub>O in a glass-stoppered flask, and titrating it against standard alkali. It can then be diluted to the desired concentration. [Audrieth & Gibbs *Inorg Synth* **1** 77 1939, Frost et al. *J Am Chem Soc* **55** 3516 1933, Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 472-474 1963.] The pure acid is a mobile, pungent explosive liquid, and **poisonous**, causing irritation of membranes, headaches, palpitation, lowering blood pressure and ataxia — *handle with great care*.

**Hydriodic acid** [10034-85-2] **M 127.9, b 127°(aqueous azeotrope), d<sub>4</sub><sup>20</sup> 1.701, pK<sup>25</sup> -8.56**. Iodine can be removed from aqueous HI, probably as the amine hydrogen triiodide, by three successive extractions using a 4% solution of Amberlite LA-2 (a long-chain aliphatic amine) in CCl<sub>4</sub>, toluene or petroleum ether (10ml per 100ml of acid). [Davidson & Jameson *Chem Ind (London)* 1686 1963.] Extraction with tributyl phosphate in CHCl<sub>3</sub> or other organic solvents is also suitable. *Alternatively*, a De-acidite FF anion-exchange resin column in the OH<sup>-</sup> form using 2M NaOH, then into its I<sup>-</sup> form by passing dilute KI solution through, can be used. Passage of an HI solution under CO<sub>2</sub> through such a column removes polyiodide. The column can be regenerated with NaOH. [Irving & Wilson *Chem Ind (London)* 653 1964]. The earlier method was to reflux with red phosphorus and distil in a stream of N<sub>2</sub>. The colourless product is stored in ampoules in the dark [Bradbury *J Am Chem Soc* **74** 2709 1952, Heisig & Frykholm *Inorg Synth* **I** 157 1939]. It fumes in moist air. **HARMFUL VAPOURS**.

**Hydrobromic acid** [10035-10-6] **M 80.9, b 125°(aqueous azeotrope, 47.5% HBr)/atm, d<sub>4</sub><sup>20</sup> 1.38 (34% HBr), pK<sup>25</sup> -8.69**. A solution of aqueous HBr *ca* 48% (w/w, constant boiling) is purified by distilling twice with a little red phosphorus, and the middle half of the distillate is taken. (The azeotrope at 760mm contains 47.8% (w/w) HBr.) [Hetzer et al. *J Phys Chem* **66** 1423 1962]. Free bromine can be removed by Irvine and Wilson's method for HI (see above), except that the column is regenerated by washing with an ethanolic solution of aniline or styrene. Hydrobromic acid can also be purified by aerating with H<sub>2</sub>S, distilling and collecting the fraction boiling at 125-127°. [Heisig & Andur *Inorg Synth* **I** 155 1939.] **HARMFUL VAPOURS**.

**Hydrochloric acid (muriatic acid)** [7647-01-0] **M 36.5, b 108.6°(aqueous azeotrope, 20.2% HCl), d<sub>4</sub><sup>20</sup> 1.09(20%), pK<sup>25</sup> -6.1**. It is readily purified by fractional distillation as the constant boiling point acid, following dilution with H<sub>2</sub>O. The constant-boiling fraction contains 1 mole of HCl in the following weights of distillate at the stated pressures: 179.555g (730mm), 179.766g (740mm), 179.979 (750mm), 180.193 (760mm), 180.407 (770mm). [Foulk & Hollingsworth *J Am Chem Soc* **45** 1220 1923.] **HARMFUL VAPOURS**.

**Hydrofluoric acid** [7664-39-3] **M 20.0, b 112.2°(aqueous azeotrope, 38.2% HF), d<sub>4</sub><sup>20</sup> 1.15 (47-53% HF), pK<sup>25</sup> 3.21**. It is freed from lead (Pb *ca* 0.002ppm) by co-precipitation with SrF<sub>2</sub>, by addition of 10ml of 10% SrCl<sub>2</sub> solution per kilogram of the concentrated acid. After the precipitate has settled, the supernatant is decanted through a filter in a hard-rubber or paraffin lined-glass vessel [Rosenqvist *Am J Sci* **240** 358 1942]. Pure aqueous HF solutions (up to 25M) can be prepared by isothermal distillation in polyethylene, polypropylene or platinum apparatus [Kwestroo & Visser *Analyst* **90** 297 1965]. It attacks glass and is used for etching glass. **HIGHLY TOXIC**.

**Hydrogen** [1333-74-0] **M 2.0, m -259.1°, b -252.9°, d 0.0889g/L (gas), 0.070g/L (liquid)**. It is usually purified by passing through a suitable absorption train of tubes. Carbon dioxide is removed with KOH pellets, soda-lime or NaOH pellets. Oxygen is removed with a "De-oxo" unit or by passage over Cu heated to 450-500° and Cu on Kieselguhr at 250°. Passage over a mixture of MnO<sub>2</sub> and CuO (Hopcalite) oxidises any CO to CO<sub>2</sub> (which is removed as above). Hydrogen can be dried by passage through dried silica-alumina at -195°, through a dry-ice trap followed by a liquid-N<sub>2</sub> trap packed with glass wool, through CaCl<sub>2</sub> tubes, or through Mg(ClO<sub>4</sub>)<sub>2</sub> or P<sub>2</sub>O<sub>5</sub>. Other purification steps include passage through a hot palladium thimble [Masson *J Am Chem Soc* **74** 4731 1952], through an activated-charcoal trap at -195°, and through a non-absorbent cotton-wool filter or small glass spheres coated with a thin layer of silicone grease. *Potentially VERY EXPLOSIVE in air or with O<sub>2</sub>*.

**Hydrogen bromide (anhydrous)** [10035-10-6] **M 80.9, b -66.8°/atm**. Dry it by passing it through Mg(ClO<sub>4</sub>)<sub>2</sub> towers. This procedure is **hazardous** [Stoss & Zimmermann *Ind Eng Chem* **17** 70 1939]. *Alternatively*, shake it with mercury, distil it through a -78° trap and condense it at -195°/10<sup>-5</sup>mm. It fumes in moist air. **HARMFUL VAPOURS**. It is soluble in H<sub>2</sub>O. A constant boiling aqueous solution of HBr has **b 126°/760mm**, and its HBr concentration is 47.4% (see hydrobromic acid above). It is soluble in AcOH. [Schneider & Johnson *Inorg Synth*

I 152 1939, Schmeisser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 282-286 1963.]

**Hydrogen chloride** [7647-01-0] M 36.5, b -85°/760mm. Pass it through conc H<sub>2</sub>SO<sub>4</sub>, then over activated charcoal and silica gel. It fumes in moist air. Hydrogen chloride in gas cylinders contains ethylene, 1,1-dichloroethane and ethyl chloride. The latter two may be removed by fractionating the HCl through a trap cooled to -112°. Ethylene is difficult to remove. HCl fumes in moist air. **HARMFUL VAPOURS.** Its solubility in H<sub>2</sub>O is 82% at 0°. A constant boiling aqueous solution (azeotrope) has b 108.6°/760mm with an HCl concentration of ~20%, and is called *Hydrochloric acid* (*muriatic acid*) (see above). [Schmeisser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 280-282 1963.]

**Hydrogen cyanide (anhydrous)** [74-90-8] M 27.0, b 25.7°/760mm, pK<sup>25</sup> 9.21 (aqueous acid). HCN is prepared from NaCN and H<sub>2</sub>SO<sub>4</sub>, and dried by passage through H<sub>2</sub>SO<sub>4</sub> and over CaCl<sub>2</sub>, then distilled in a vacuum system and degassed at 77°K before use [Arnold & Smith *J Chem Soc, Faraday Trans 2* 77 861 1981]. Cylinder HCN may contain stabilisers against explosive polymerisation, together with small amounts of H<sub>3</sub>PO<sub>4</sub>, H<sub>2</sub>SO<sub>4</sub>, SO<sub>2</sub>, and water. It can be purified by distillation over P<sub>2</sub>O<sub>5</sub>, then frozen in Pyrex bottles at Dry-ice temperature for storage. [Zeigler *Org Synth Coll Vol I* 314 1941, Glemser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 658-660 1963.] Liquid HCN, like liquid ammonia, evaporates very slowly since the latent heat of evaporation is high and keeps it in the liquid state because the temperature of the liquid is lowered to below its boiling point. **EXTREMELY POISONOUS; all due precautions should be taken.**

**Hydrogen fluoride (anhydrous)** [7664-39-3] M 20.0, b 19.4°. It can be purified by trap-to-trap distillation, followed by drying over CoF<sub>2</sub> at room temperature and further distillation. *Alternatively*, it can be absorbed on NaF to form NaHF<sub>2</sub> which is then heated under vacuum at 150° to remove volatile impurities. The HF is regenerated by heating at 300° and is stored with CoF<sub>3</sub> in a nickel vessel, being distilled as required. (Water content should be *ca* 0.01%.) To avoid contact with base metal, use can be made of nickel, polychlorotrifluoroethylene and gold-lined fittings [Hyman et al. *J Am Chem Soc* 79 3668 1957]. An aqueous solution is *hydrofluoric acid* (see above). It is **HIGHLY TOXIC and attacks glass.**

**Hydrogen iodide (anhydrous)** [10034-85-2] M 127.9, b -35.5°. After removal of free iodine from aqueous HI, the solution is frozen, then covered with P<sub>2</sub>O<sub>5</sub> and allowed to melt under vacuum. The gas evolved is dried by passing through P<sub>2</sub>O<sub>5</sub> on glass wool. It can be freed from iodine contamination by repeated fractional distillation at low temperatures. It fumes in moist air, and an aqueous solution is *hydriodic acid* (see above). **HARMFUL VAPOURS.**

**Hydrogen peroxide** [7722-84-1] M 34.0, d<sub>4</sub><sup>20</sup> 1.110, pK<sup>25</sup> 11.65. The 30% material has been steam distilled using distilled water. Gross and Taylor [*J Am Chem Soc* 72 2075 1950] made 90% H<sub>2</sub>O<sub>2</sub> approximately 0.001M in NaOH and then distilled it under its own vapour pressure, keeping the temperature below 40°, the receiver being cooled with a Dry-ice/isopropyl alcohol slush. The 98% material has been rendered anhydrous by repeated fractional crystallisation in all-quartz vessels. **EXPLOSIVE IN CONTACT WITH ORGANIC MATERIAL.**

**Hydrogen peroxide urea adduct (UHP, urea hydrogen peroxide 1:1 complex, carbamide peroxide, Debrox, Hyperol)** [124-43-6] M 94.1, m. 85-90°(dec), 90°(dec). It is a safe alternative to H<sub>2</sub>O<sub>2</sub> in various oxidation reactions. It is commercially available in tablets ("rapidly soluble", equivalent to ~30% H<sub>2</sub>O<sub>2</sub>) or as a white powder (with 15-17% active oxygen). It is usually used without purification after assaying for active oxygen. This is done by titration with potassium permanganate or by iodometry, i.e. titration of liberated iodine when glacial acetic acid containing Fe<sup>3+</sup> and NaI are added. It can be recrystallised from 30% H<sub>2</sub>O<sub>2</sub> in a molar ratio of ~2:3 by heating in a pyrex dish for a few minutes at ~60°, cooling and allowed to crystallise slowly by evaporation in a crystallising dish. It forms elongated white needles, but if the solution is seeded just before crystallisation and shaken gently for a few seconds, then small plates are formed. Preferably collect the crystals by centrifugation at low temperature and dry them at 0° *in vacuo*. When dry, it is stable at room temperature and

it has been reported that the available oxygen content had not decreased noticeably after 12 months. However, it is best to store it dry at low temperature. It is soluble in organic solvents e.g. EtOH, Et<sub>2</sub>O, CHCl<sub>3</sub>, CH<sub>2</sub>Cl<sub>2</sub> and Me<sub>2</sub>CO with slow decomposition, and its solubility in H<sub>2</sub>O is 40% where it also decomposes slowly. It decomposes slowly at 40-60°/20mm and at 55-70°/760mm in air, but decomposition appears to accelerate above 80°. It is very useful (and in many cases superior to *p*-chloroperbenzoic acid) in the oxidation of alkenes, (epoxides), aromatic hydrocarbons (to phenols), ketones (Baeyer-Villiger), sulfides (to sulfones) and N-heterocycles (to N-oxides) when using 5 to 10 molar ratios of oxidant in the presence of acetic or trifluoroacetic anhydrides. Care should be used with this reagent as it is **potentially explosive**. [Lu et al. *J Am Chem Soc* **63** 1508 1941, Cooper et al. *Synlett* 533 1990, *Beilstein* **3** H 54, **3** I 25, **3** II 45, **3** III 105, **3** IV 102.]

**Hydrogen sulfide** [7783-06-4] **M 34.1, b -59.6°, pK<sub>1</sub><sup>25</sup> 7.05, pK<sub>2</sub><sup>25</sup> 12.89**. Wash it, then pass the gas through a train of tubes containing saturated Ba(OH)<sub>2</sub> (2x), water (2x), and dilute HCl [Goates et al. *J Am Chem Soc* **73** 707 1951]. It is available in gas cylinders. **HIGHLY POISONOUS**.

**Hydroxylamine** [7803-49-8] **M 33.0, m 33.1°, b 56.5°/22mm, d<sub>4</sub><sup>20</sup> 1.226, pK<sup>20</sup> 5.96 (7.97)**. Crystallise it from *n*-butanol at -10°, collect it by vacuum filtration and wash it with cold diethyl ether. **Harmful vapours**. [Hurd *Inorg Synth* **I** 87 1939, Semon in *Org Synth Coll Vol* **I** 318 1932.]

**Hydroxylamine hydrochloride** [5470-11-1] **M 69.5, m 151°**. Crystallise the salt from aqueous 75% ethanol or boiling methanol, and dry it under vacuum over CaSO<sub>4</sub> or P<sub>2</sub>O<sub>5</sub>. It has also been dissolved in a minimum of water and saturated with HCl; after three such crystallisations, it is dried under a vacuum over CaCl<sub>2</sub> and NaOH. Its solubility at 20° is 85% in H<sub>2</sub>O, 6% in EtOH and 12% in MeOH. [Hurd *Inorg Synth* **I** 87 1939, Semon in *Org Synth Coll Vol* **I** 318 1941.]

**Hydroxylamine sulfate** [10039-54-0] **M 164.1, m 170°(dec)**. Crystallise it from boiling water (1.6ml/g) by cooling to 0°.

**Hydroxylamine-O-sulfonic acid** [2950-43-8] **M 113.1, m 210-211°, 215°(dec), pK<sup>45</sup> 1.48**. Stir the solid vigorously with anhydrous Et<sub>2</sub>O and filter it off using large volumes of dry Et<sub>2</sub>O. Drain dry at the pump for 5 minutes and then for 12-14 hours in a vacuum. Store it in a vacuum desiccator over conc H<sub>2</sub>SO<sub>4</sub>. Determine the purity by oxidation of iodide to I<sub>2</sub>. It must be stored in a dry atmosphere at 0-4°. It decomposes slowly in H<sub>2</sub>O at 25° and more rapidly above this temperature. [Matsuguma & Andrieth *Inorg Synth* **V** 122 1957.]

**Hydroxyurea** [127-07-1] **M 76.1, m 70-72° (unstable form), m 133-136°, 141° (stable form), pK<sup>25</sup> 10.6**. Recrystallise hydroxyurea from absolute EtOH (10g in 150ml). Note that the rate of solution in boiling EtOH is slow (15-30 minutes). It should be stored in a cool dry place, but some decomposition could occur after several weeks. [Deghenghi *Org Synth Coll Vol* **V** 645 1973.] It is very soluble in H<sub>2</sub>O and can be crystallised from Et<sub>2</sub>O. [Kfod *Acta Chem Scand* **10** 256 1956, *Beilstein* **3** IV 170.]

**Hypophosphorous acid (Phosphinic acid)** [6303-21-5] **M 66.0, m 26.5°, d<sub>4</sub><sup>30</sup> 1.217, 1.13 and 1.04 for 50, 30-32, and 10% aqueous solutions resp, pK<sup>25</sup> 1.31 (H<sub>3</sub>PO<sub>2</sub>)**. Phosphorous acid is a common contaminant of commercial 50% hypophosphorous acid. Jenkins and Jones [*J Am Chem Soc* **74** 1353 1952] purified this material by evaporating about 600ml in a 1L flask at 40°, under reduced pressure (in N<sub>2</sub>), to a volume of about 300ml. After the solution was cooled, it was transferred to a wide-mouthed Erlenmeyer flask which was stoppered and left in a Dry-ice/acetone bath for several hours to freeze (if necessary, with scratching of the wall). When the flask was then left at *ca* 5° for 12 hours, about 30-40% of it liquefied, and was again filtered. This process was repeated, then the solid was stored over Mg(ClO<sub>4</sub>)<sub>2</sub> in a vacuum desiccator in the cold. Subsequent crystallisations from *n*-butanol by dissolving it at room temperature and then cooling in an ice-salt bath at -20° did not appear to purify it further. The free acid forms *deliquescent* crystals **m** 26.5° and is soluble in H<sub>2</sub>O and EtOH. The NaH<sub>2</sub>PO<sub>2</sub> salt can be purified through an anion exchange resin [Klement *Z Anorg Allgem Chem* **260** 267 1949.]

**Indium** [7440-74-6] **M 114.8, m 156.6°, b 2000°, d<sub>4</sub><sup>20</sup> 7.31.** Before use, the metal surface is cleaned with dilute HNO<sub>3</sub>, followed by thorough washing with water and an alcohol rinse. [Dönges in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 856 1963.]

**Indium (III) chloride** [10025-82-8] **M 211.2, m 586°, d<sub>4</sub><sup>20</sup> 4.0, pK<sub>1</sub><sup>25</sup> 3.54, pK<sub>2</sub><sup>25</sup> 4.28, pK<sub>3</sub><sup>25</sup> 5.16 (for aqueous In<sup>3+</sup>).** The anhydrous salt forms yellow deliquescent crystals which can be sublimed at 600° in the presence of Cl<sub>2</sub>/N<sub>2</sub> (1:1) [does not melt]. It is resublimed in the presence of Cl<sub>2</sub>/N<sub>2</sub> (1:10) and finally heated to 150° to expel excess Cl<sub>2</sub>. It is soluble in H<sub>2</sub>O and should be stored in a tightly closed container. [Baxter & Alter *J Am Chem Soc* **55** 1943 1933.]

**Indium (III) oxide** [1312-43-2] **M 277.6, d<sub>4</sub><sup>20</sup> 7.18, m sublimes at 850°.** Wash it with H<sub>2</sub>O and dry it below 850°. It volatilises at 850° and dissolves in hot mineral acids to form salts. Store it away from light because it darkens due to the formation of free In.

**Indium sulfate** [13464-82-9] **M 517.8.** Crystallise it from dilute aqueous H<sub>2</sub>SO<sub>4</sub>. It is *hygroscopic*; store it in a well-stoppered vessel.

**Indium (III) sulfate pentahydrate** [17069-79-3] **M 607.9, d<sub>4</sub><sup>20</sup> 3.44.** Dissolve the salt in strong H<sub>2</sub>SO<sub>4</sub> and slowly evaporate at *ca* 50°. Wash the crystals with glacial AcOH and then heat them in a furnace at a temperature of 450-500° for 6 hours. Its solubility in H<sub>2</sub>O is 5%. The *pentahydrate* is converted to an *anhydrous hygroscopic* powder on heating at 500° for 6 hours; but heating above this temperature over N<sub>2</sub> yields the oxide-sulfate. Evaporation of neutral aqueous solutions provides basic sulfates. [Baxter & Alter *J Am Chem Soc* **55** 1943 1933, Hattox & Vries *J Am Chem Soc* **58** 2126 1936.]

**Iodic acid** [7782-68-5] **M 175.9, m 118°(dec), d<sub>4</sub><sup>20</sup> 4.628, pK<sup>25</sup> 0.79.** Dissolve iodic acid in the minimum volume of hot dilute HNO<sub>3</sub>, filter and evaporate in a vacuum desiccator until crystals are formed. Collect the crystals and wash them with a little cold H<sub>2</sub>O and dry them in air in the dark. It is soluble in H<sub>2</sub>O: 269g/100ml at 20° and 295g/100ml at 40°. It is soluble in dilute EtOH and darkens on exposure to light. It is converted to HIO<sub>3</sub>.I<sub>2</sub>O<sub>5</sub> on heating at 70°, but at 220° complete conversion to HIO<sub>3</sub> occurs. [Lamb et al. *J Am Chem Soc* **42** 1636 1920, Bray & Caulkins *J Am Chem Soc* **53** 44 1931.]

**Iodine** [7553-56-2] **M 253.8, m 113.6°.** It is usually purified by vacuum sublimation. Preliminary purifications include grinding with 25% by weight of KI, blending with 10% BaO and subliming, subliming with CaO, grinding to a powder and treating with successive portions of H<sub>2</sub>O to remove dissolved salts, then drying, and recrystallising from \*benzene. Barrer and Wasilewski [*Trans Faraday Soc* **57** 1140 1961] dissolved I<sub>2</sub> in concentrated KI and distilled it, then steam distilled it three times and washed it with distilled H<sub>2</sub>O. Organic material is removed by sublimation in a current of O<sub>2</sub> over platinum at about 700°, the iodine being finally sublimed under vacuum. **HARMFUL VAPOURS.**

**Iodine monobromide** [7789-33-5] **M 206.8, m 42°.** The brown-black crystals are purified by repeated fractional crystallisation from its melt. The vapour dissociates on heating [Yost et al. *J Amer Chem Soc* **55** 552 1933, Schmeisser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 291-292 1963].

**Iodine monochloride** [7790-99-0] **M 162.4, m 27.2°(α-form), 13.9°(β-form).** Purify it by repeated fractional crystallisation from its melt at low temperatures. The black crystals melt to a red-brown liquid. [Cornøg & Karges *Inorg Synth* **I** 165 1939.]

**Iodine pentafluoride** [7783-66-6] **M 221.9, m -8.0°, b 97°.** Rogers et al. [*J Am Chem Soc* **76** 4843 1954] removed dissolved iodine from IF<sub>5</sub> by agitating with a mixture of dry air and ClF<sub>3</sub> in a Fluoroethene beaker using a magnetic stirrer. The mixture is transferred to a still, and the more volatile impurities are pumped off as the pressure is reduced below 40mm. The still is gradually heated (kept at 40mm) to remove the ClF<sub>3</sub> before IF<sub>5</sub> distilled. Stevens [*J Org Chem* **26** 3451 1961] pumped IF<sub>5</sub> under vacuum from its cylinder, trapping it at -78°, then allowing it to melt in a stream of dry N<sub>2</sub>. **HARMFUL VAPOURS.** [Kwasnik in *Handbook of Preparative*

*Inorganic Chemistry (Ed. Brauer) Academic Press Vol I pp 159-160 1963.]*

**Iodine trichloride** [865-44-1] **M 233.3, m 33°, b 77°(dec).** Purify  $\text{ICl}_3$  by sublimation at room temperature.  
**Irritant vapours.** [Booth & Morris *Inorg Synth I* 167 1939.]

**Iridium** [7439-88-5] **M 192.2, m 2450°, b ~4500°,  $d_4^{20}$  22.65.** Iridium is a silver white hard solid which oxidises on the surface in air. Scrape the outer tarnished layer until silver clear and store it under paraffin. It is stable to acids but dissolves in aqua regia. [Gilchrist *Chem Rev* 32 277 1943.]

**Iridium (IV) chloride hydrate (hexachloroiridic acid)** [16941-92-7 ( $6\text{H}_2\text{O}$ ), 207399-11-9 ( $x\text{H}_2\text{O}$ )] **M 334.0+ $\text{H}_2\text{O}$ .** If it contains nitrogen, then repeatedly concentrate a conc HCl solution until free from nitrogen, and dry free from HCl in a vacuum over CaO until crystals are formed. The olive-green solid (yellow at  $\sim 700^\circ$ ) is very *hygroscopic*. [Woo & Yost *J Am Chem Soc* 53 884 1931, Grube in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer) Academic Press Vol II* p1592 1965.]

**Iron (wire)** [7439-89-6] **M 55.9, m 1535°.** Clean it in conc HCl, rinse in de-ionised water, then reagent grade acetone and dry it under vacuum.

**Iron enneacarbonyl (di-iron nonacarbonyl)** [15321-51-4] **M 363.7, m 100°(dec).** Wash it with EtOH and  $\text{Et}_2\text{O}$ , then dry it in air. It sublimes at  $35^\circ$  in a high vacuum. It forms dark yellow plates which are stable for several days when kept in small amounts. Large amounts, especially when placed in a desiccator, spontaneously *ignite* in a period of one day. It decomposes in moist air. It is insoluble in hydrocarbon solvents but forms complexes with several organic compounds. [Sheline & Pitzer *J Am Chem Soc* 72 1107 1950, Speyer & Wolf *Chem Ber* 60 1424 1927.] **TOXIC.**

**Iron pentacarbonyl (pentacarbonyl iron)** [13463-40-6] **M 195.9, m  $-20^\circ$ , b  $102.8^\circ/749\text{mm}$ ,  $103^\circ/760\text{mm}$ , n 1.520, d 1.490.** It is a pale yellow viscous liquid that is **PYROPHORIC** and readily absorbed by the skin. **HIGHLY TOXIC (protect from light and air).** It should be purified in a vacuum line by distilling and collecting in a trap at  $-96^\circ$  (toluene-Dry-ice slush). It has been distilled at atmospheric pressure (use a very efficient fume cupboard). At  $180^\circ$ /atmospheric pressure it decomposes to give Fe and CO. In UV light in petroleum ether it forms  $\text{Fe}_2(\text{CO})_9$  (see previous entry). [Hagen et al. *Inorg Chem* 17 1369 1978, Ewens et al. *Trans Faraday Soc* 35 6811 1939.]

**Lanthanum** [7439-91-0] **M 138.9, m  $920^\circ$ , b  $3470^\circ$ ,  $d_4^{20}$  6.16.** It is a shiny metal that slowly tarnishes in air due to oxidation. It slowly decomposes by  $\text{H}_2\text{O}$  in the cold and more rapidly on heating to form the hydroxide. The metal is cleaned by scraping off the tarnished areas until the shiny metal is revealed and stored under oil or paraffin. It burns in air at  $450^\circ$ . It exists in three forms:  $\alpha$ -form,  $\beta$ -form and  $\gamma$ -form with transition temperatures of  $310^\circ$  and  $864^\circ$ , respectively. [Spedding et al. *Ind Eng Chem* 44 553 1952.]

**Lead (II) bromide** [10031-22-8] **M 367.0, m  $373^\circ$ .** Crystallise it from water containing a few drops of HBr (25ml of water per gram  $\text{PbBr}_2$ ) between  $100^\circ$  and  $0^\circ$ . A neutral solution is evaporated at  $110^\circ$ , and the crystals that separate are collected by rapid filtration at  $70^\circ$  and dried at  $105^\circ$  (to give the *monohydrate*). Its solubility in  $\text{H}_2\text{O}$  is 0.5% (at  $\sim 10^\circ$ ) and 5% (at  $\sim 100^\circ$ ). To prepare the *anhydrous* bromide, the hydrate is heated for several hours at  $170^\circ$  and then in a Pt boat at  $200^\circ$  in a stream of HBr and  $\text{H}_2$ . Finally it is fused [Clayton et al. *J Chem Soc, Faraday Trans 1* 76 2362 1980]. **POISONOUS.**

**Lead (II) chloride** [7758-95-4] **M 278.1, m  $501^\circ$ .** Crystallise it from distilled water at  $100^\circ$  (33ml/g) after filtering through sintered-glass and adding a few drops of HCl, by cooling. After three crystallisations the solid is dried under vacuum or under anhydrous HCl vapour by heating slowly to  $400^\circ$ . The solubility in  $\text{H}_2\text{O}$  is 0.07% at  $\sim 10^\circ$ , and 0.43% at  $\sim 100^\circ$ . **POISONOUS.**

**Lead (II) iodide** [10101-63-0] **M 461.0, m  $402^\circ$ .** It crystallises from a large volume of water. The solubility in

H<sub>2</sub>O is 1.1% at ~10°, and 3.3% at ~100°. **POISONOUS.**

**Lead monoxide** [1317-36-8] **M 223.2, m 886°.** Higher oxides are removed by heating under vacuum at 550° with subsequent cooling under vacuum. It is red at room temperature but becomes yellow at high temperatures (~480°) reversibly. [Ray & Ogg *J Am Chem Soc* **78** 5994 1956, Kwestroo et al. *J Inorg Nucl Chem* **29** 39 1967.] **POISONOUS.**

**Lead nitrate** [10099-74-8] **M 331.2, m 470°.** Precipitate it twice from a hot (60°) concentrated aqueous solution by adding HNO<sub>3</sub>. The precipitate is sucked dry on a sintered-glass funnel, then transferred to a crystallising dish which is covered by a clock glass and left in an electric oven at 110° for several hours [Beck et al. *Trans Faraday Soc* **55** 331 1959]. After two recrystallisations of ACS grade, no metals above 0.001ppm were detected. **POISONOUS.**

**Lithium (metal)** [7439-93-2] **M 6.9, m 180.5°, b 1342°, d<sub>4</sub><sup>20</sup> 0.534.** After washing with petroleum ether to remove storage oil, lithium is fused at 400° and then forced through a 10-micron stainless-steel filter with argon pressure. It is again melted in a dry-box, skimmed, and poured into an iron distillation pot. After heating under a vacuum to 500°, cooling and returning it to the dry-box for a further cleaning of its surface, the lithium is distilled at 600° using an all-iron distillation apparatus [Gunn & Green *J Am Chem Soc* **80** 4782 1958].

**Lithium aluminium hydride** [16853-85-3] **M 37.9, m 125°(dec).** Extract it with Et<sub>2</sub>O, and, after filtering, the solvent is removed under vacuum. The residue is dried at 60° for 3 hours, under high vacuum [Ruff *J Am Chem Soc* **83** 1788 1961]. It is a strong reducing agent. Store it in aliquots in a strictly dry atmosphere, and use in these aliquot quantities. **It IGNITES in the presence of a small amount of water and reacts with it EXPLOSIVELY.** [Becher in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 805 1963.]

**Lithium amide** [7782-89-0] **M 23.0, m 380-400°, d<sub>4</sub><sup>17.5</sup> 1.178.** Purify it by heating at 400° while NH<sub>3</sub> is passed over it in the upper of two crucibles (the upper crucible is perforated). The LiNH<sub>2</sub> will drip into the lower crucible through the holes in the upper crucible. The product is cooled in a stream of NH<sub>3</sub>. Protect it from air and moisture, store it under N<sub>2</sub> in a clear glass bottle sealed with paraffin. Store it in small quantities so that all the material is used once the bottle is opened. If the colour of the amide is yellow, it should be destroyed as it is likely to have oxidised and to **EXPLODE**. On heating above 450° it is decomposed to Li<sub>2</sub>NH, which is stable up to 750-800°. [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 463 1963, Greenlee & Henne *Inorg Synth* **II** 135 1953.]

**Lithium azide** [19597-69-4] **M 49.0, m 115-298° (dec), d<sub>4</sub><sup>20</sup> 1.008, pK<sup>25</sup> 4.72 (HN<sub>3</sub>).** Digest ~1g with 15ml of 96% EtOH at 35°, filter and dry it in air at temperatures below 80°. Store it in a cool place and treat it as potentially explosive. Its solubility in H<sub>2</sub>O is 66.4% at 16°, and 20.26% at 16° in EtOH. [Hofmann-Bang *Acta Chem Scand* **11** 581 1957, Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 581 1963.]

**Lithium borohydride** [16949-15-8] **M 21.8, m 268°, b 380°(dec), d<sub>4</sub><sup>20</sup> 0.66.** It is crystallised from Et<sub>2</sub>O, and pumped free of ether at 90-100° during 2 hours [Schaeffer et al. *J Am Chem Soc* **78** 729 1956]. Store it dry as it decomposes slowly in moist air. [Becher in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 775 1963.]

**Lithium bromide** [7550-35-8] **M 86.8, m 550°.** Crystallise it several times from water or EtOH, then dry it under high vacuum for 2 days at room temperature, followed by drying at 100°. Its solubility in H<sub>2</sub>O is 167% at ~20°, and 250% at ~100°. It is *deliquescent* and should be stored in a tightly stoppered vessel.

**Lithium carbonate** [554-13-2] **M 73.9, m 552°, 618°.** Crystallise it from water. Its solubility decreases as the temperature is raised. The solubility in H<sub>2</sub>O is 1.3% at ~10°, and 0.7% at ~100°. [Dönges in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 987 1963, Caley & Elving *Inorg Synth* **I** 1 1939.]

**Lithium chloride** [7447-41-8] **M 42.4, m 600°, 723°**. Crystallise it from water (1ml/g) or MeOH and dry it for several hours at 130°. Other metal ions can be removed by preliminary crystallisation from hot aqueous 0.01M disodium EDTA. It has also been crystallised from conc HCl, fused in an atmosphere of dry HCl gas, cooled under dry N<sub>2</sub> and pulverised in a dry-box. Kolthoff and Bruckenstein [*J Am Chem Soc* **74** 2529 1952] precipitated it with ammonium carbonate, washed it with Li<sub>2</sub>CO<sub>3</sub> five times by decantation and finally with suction, then dissolved it in HCl. The LiCl solution is evaporated slowly with continuous stirring in a large evaporating dish, the dry powder being stored (while still hot) in a desiccator over CaCl<sub>2</sub>.

**Lithium fluoride** [7789-24-4] **M 25.9, m 842°, 848°, b 1676°, 1681°, d<sub>4</sub><sup>20</sup> 2.640**. Possible impurities are LiCO<sub>3</sub>, H<sub>2</sub>O and HF. These can be removed by calcining it at red heat, then pulverizing it with a Pt pestle and storing it in a paraffin bottle. Its solubility in H<sub>2</sub>O is 0.27% at 18°. It volatilises between 1100-1200°. [Kwasnik in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 235 1963].

**Lithium hydride**. [7580-67-8] **M 7.95, m 680°, d<sub>4</sub><sup>20</sup> 0.76-0.77**. It should be a white powder; otherwise replace it. It darkens rapidly on exposure to air and is decomposed by H<sub>2</sub>O to give H<sub>2</sub> and LiOH, and reacts with lower alcohols. One gram in H<sub>2</sub>O liberates 2.8L of H<sub>2</sub> (could be explosive). [Dönges in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 987 1963.]

**Lithium hydroxide monohydrate** [1310-66-3 (H<sub>2</sub>O), 1310-65-2 (anhydrous)] **M 42.0, m 471°, d 1.51, pK<sup>25</sup> 13.82**. It crystallises from water (3ml/g) as the *monohydrate*. It *dehydrates* at 150° in a stream of CO<sub>2</sub>-free air, and sublimes at 220° with some decomposition [Cohen *Inorg Synth* **V** 3 1957, Bravo *Inorg Synth* **VII** 1 1963].

**Lithium iodate** [13765-03-2] **M 181.9**. Crystallise it from water and dry it in a vacuum oven at 60°.

**Lithium iodide** [10377-51-2] **M 133.8, m 73° (3H<sub>2</sub>O), 469°, b 1171°, d<sub>4</sub><sup>20</sup> 4.06**. Crystallise it from hot water (0.5ml/g) by cooling in a CaCl<sub>2</sub>-ice EtOH or from an acetone- Dry-ice bath. Dry it under a vacuum over P<sub>2</sub>O<sub>5</sub> for 1 hour at 60° and then at 120°. It is *deliquescent* and should be stored in dark tightly stoppered vessels.

**Lithium nitrate** [7790-69-4] **M 68.9, m 253°, d<sub>4</sub><sup>20</sup> 2.38**. It crystallises from water or EtOH. Dry it at 180° for several days by repeated melting under vacuum. If it is crystallised from water keeping the temperature above 70°, formation of *trihydrate* is avoided. The *anhydrous* salt is dried at 120° and stored in a vacuum desiccator over CaSO<sub>4</sub>. After the 99% pure salt was recrystallised 3 times, it contained: metal (ppm) Ca (1.6), K (1.1), Mo (0.4), Na (2.2). [Donnan & Burt *J Chem Soc* **83** 335 1903.]

**Lithium nitrite monohydrate** [13568-33-7] **M 71.0**. Crystallise it from water by cooling from room temperature.

**Lithium perchlorate** [7791-03-9] **M 106.4, m 236°, pK<sup>25</sup> -2.4 to -3.1 (for HClO<sub>4</sub>)**. Crystallise it from water or 50% aqueous MeOH. It is rendered *anhydrous* by heating the *trihydrate* at 170-180° in an air oven. It can then be recrystallised twice from acetonitrile and again dried under vacuum [Mohammad & Kosower *J Am Chem Soc* **93** 2713 1971]. **SKIN IRRITANT**.

**Lithium sulfate (anhydrous)** [10377-48-7] **M 109.9, loses H<sub>2</sub>O at 130° and m 859°, d<sub>D</sub><sup>20</sup> 2.21**. Crystallise it from H<sub>2</sub>O (4ml/g) by partial evaporation, and dry it above 130° *in vacuo*.

**Lithium tetrafluoroborate** [14283-07-9] **M 93.7, pK<sup>25</sup> 13.82 (Li<sup>+</sup>), pK<sup>25</sup> -4.9 (for HBF<sub>4</sub>)**. Dissolve it in THF just below its solubility, filter from insoluble material and evaporate it to dryness in a vacuum below 50°. Wash the residue with dry Et<sub>2</sub>O, and pass dry N<sub>2</sub> gas over the solid and finally heat it in an oven at 80-90°. Its solubility in Et<sub>2</sub>O is 1.3g in 100ml at 25°; in THF it is 71g in 100ml at 25°. It is *hygroscopic* and is an **IRRITANT**. [Elliott et al. *J Am Chem Soc* **74** 5211 1952, **75** 1753 1953.]

**Lithium thiocyanate (lithium rhodanide)** [556-65-0] **M 65.0, pK<sup>25</sup> -1.85 (for HSCN)**. It crystallises from H<sub>2</sub>O as the *dihydrate*, but on drying at 38-42° it gives the *monohydrate*. It can be purified by allowing an aqueous solution to crystallise in a vacuum over P<sub>2</sub>O<sub>5</sub>. The crystals are collected, dried out *in vacuo* at 80°/P<sub>2</sub>O<sub>5</sub>

in a stream of pure  $N_2$  at  $110^\circ$ . [Coates & Taylor *J Chem Soc* 1245 1936.]

**Magnesium** [7439-95-4] **M 24.3, m 651°**, **b 1100°**, **d<sub>4</sub><sup>20</sup> 1.739**. It slowly oxidises in moist air and tarnishes. If dark in colour, do not use. The shiny solid should be degreased by washing with dry  $Et_2O$ , dry it *in vacuo* and keep it in a  $N_2$  atmosphere. It can be activated by stirring it in  $Et_2O$  containing a crystal of  $I_2$  then filtering it off, before drying and storing. [Gmelin's Magnesium (8<sup>th</sup> edn) **27A** 121 1937.]

**Magnesium bromide (anhydrous)** [7789-48-2] **M 184.1, m 711°**, **d<sub>4</sub><sup>20</sup> 3.72**. Crystallise it from  $EtOH$  or  $H_2O$  (3.3g/ml). Dry it in a vacuum at  $\sim 150^\circ$ , or heat the *hydrate* in a stream of  $HCl$ . It is very *deliquescent*. [Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 909 1963.]

**Magnesium chloride hexahydrate** [7791-18-6] **M 203.3, m  $\sim 100^\circ$ (dec)**, **pK<sub>1</sub><sup>25</sup> 10.3, pK<sub>2</sub><sup>25</sup> 12.2 (for  $Mg^{2+}$  hydrolysis)**. Crystallise it from hot water (3.3g/ml) by cooling. Dry it in a vacuum at  $\sim 175^\circ$ , or heat the *hydrate* in a stream of  $HCl$ . When the hydrate is heated above  $180^\circ$  it is hydrolysed to the oxychloride ( $Mg_2OCl_2$ ). It is *deliquescent*; store it in a well-stoppered vessel. [Bryce-Smith *Inorg Synth* **VI** 9 1960, Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 908 1963.]

**Magnesium iodate tetrahydrate** [7790-32-1] **M 446.2**. Crystallise from water (0.2g/ml) between  $100^\circ$  and  $0^\circ$ .

**Magnesium iodide** [10377-58-9] **M 278.1, m 634°**. Crystallise it from water (0.8g/ml) by partial evaporation in a desiccator. It is *deliquescent* and should be stored in the dark. [Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 910 1963.]

**Magnesium nitrate hexahydrate** [13446-18-9] **M 256.4, m  $\sim 95^\circ$ (dec)**. Crystallise the nitrate from water (2.5mlg) by partial evaporation in a desiccator. It is *deliquescent* and is soluble in  $EtOH$ . After two recrystallisations, ACS grade salt has: metal (ppm) Ca (6.2), Fe (8.4), K (2), Mo (0.6), Na (0.8), Se (0.02).

**Magnesium perchlorate (Anhydrone, Dehydrite)** [10034-81-8 (anhydrous)] **M 259.2, m  $>250^\circ$** , **pK<sup>25</sup> -2.4 to -3.1 (for  $HClO_4$ )**. Crystallise it from water to give the *hexahydrate* **M 331.3** [13346-19-0]. Coll et al. [*J Am Chem Soc* **81** 1284 1959] removed traces of unspecified contaminants by washing it with small portions of  $Et_2O$  and drying in a vacuum (**CARE**). The anhydrous salt is commercially available as an ACS reagent, and is as efficient a dehydrating agent as  $P_2O_5$  and is known as "Dehydrite" or "Anhydrone". [Smith et al. *J Am Chem Soc* **44** 2255 1922 and *Ind Eng Chem* **16** 20 1924.] It is *hygroscopic*; keep it in a tightly closed container. It is **EXPLOSIVE in contact with organic materials, and is a SKIN IRRITANT**.

**Magnesium sulfate (anhydrous)** [7487-88-9] **M 120.4, m 1127°**. Crystallise it from warm  $H_2O$  (1g/ml) by cooling. Dry the *heptahydrate* (*Epsom salt*) at  $\sim 250^\circ$  until it loses 25% of its weight. Its solubility in  $H_2O$  is 36% at  $20^\circ$ , 55% at  $60^\circ$  and 74% at  $100^\circ$ ; above  $110^\circ$  the solubility decreases with rise of temperature. Store it in a sealed container.

**Manganese decacarbonyl  $Mn_2(CO)_{10}$**  [10170-69-1] **M 390.0, m 151-152°**, **154-155°(sealed tube)**, **d<sup>25</sup> 1.75**. Golden yellow crystals which in the absence of  $CO$  begin to decompose at  $110^\circ$ , and on further heating yield a metallic mirror. In the presence of 3000psi of  $CO$  it does not decompose on heating to  $250^\circ$ . It is soluble in common organic solvents, insoluble in  $H_2O$ , not very stable in air, to heat or UV light. It dissolves in a lot of  $*C_6H_6$  and can be crystallised from it. It distils with steam at  $92-100^\circ$ . It can be purified by sublimation under reduced pressure ( $<0.5mm$ ) at room temperature to give well-formed golden yellow crystals. If the sample is orange coloured, this sublimation leads to a mixture of golden-yellow and dark red crystals of the carbonyl and carbonyl iodide, respectively, which can be separated by hand picking under a microscope. Separation followed by resublimation provides the pure compounds. **POISONOUS**. [Brimm et al. *J Am Chem Soc* **76** 3831 1954, Closson et al. *J Am Chem Soc* **80** 6167 1958, **82** 1325 1960.]

**Manganous bromide (anhydrous)** [13446-03-2] **M 214.8, m 695° (4H<sub>2</sub>O)** [10031-20-6] **M 286.8, m 64°(dec)**. It forms rose-red *deliquescent* crystals which are soluble in  $EtOH$ . The  $H_2O$  is removed by heating at

100° then in HBr gas at 725°, or dry it in an atmosphere of N<sub>2</sub> at 200°.

**Manganous chloride tetrahydrate** [13446-34-9, 7773-01-5 (anhydrous)] **M 197.9, m 58°, 87.5°, 650° (anhydrous), b 1190° (anhydrous), d<sub>4</sub><sup>20</sup> 2.01.** It crystallises from water (0.3ml/g) on cooling. The red-rose *tetrahydrate* melts at ~52° and forms the *dihydrate salt* which loses all its H<sub>2</sub>O at 198° to give MnCl<sub>2</sub>. It is soluble in EtOH.

**Manganous sulfate monohydrate** [10034-96-5 (H<sub>2</sub>O), 15244-36-7 (xH<sub>2</sub>O)] **M 169.0, d<sub>4</sub><sup>20</sup> 2.75.** Crystallise it from water (0.9ml/g) at 54-55° by evaporating about two-thirds of the water. It *dehydrates* above 400°.

**Mercuric bromide** [7789-47-1] **M 360.4, m 238.1°, b 320°, d<sub>4</sub><sup>20</sup> 5.73.** Crystallise it from hot saturated ethanolic solution, dry and keep it at 100° for several hours under a vacuum, then sublime it. [Garrett *J Am Chem Soc* **61** 2744 1939.] Its solubility in H<sub>2</sub>O is 0.6% at 20°, and 22% at 100°; in EtOH it is 30% at 25°; and in MeOH it is 69.6% at 25°. [Wagenknecht & Juza *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **II** p 1109 1965.] **POISONOUS.**

**Mercuric chloride** [7487-94-7] **M 271.5, m 276°, b 304°, d<sub>4</sub><sup>20</sup> 5.6.** Crystallise it twice from distilled water, dry it at 70° and sublime it under high vacuum. Its solubility in H<sub>2</sub>O is 4.3% at ~0°, 6.6% at ~10° and 54% at ~100°. It is soluble in EtOH and is extracted into Et<sub>2</sub>O from an aqueous solution. It is **very POISONOUS** and 0.2-0.4g is fatal. The antidote is immediate administration of white of egg as an emetic.

**Mercuric cyanide** [592-04-1] **M 252.6, m 320°(dec), d<sub>4</sub><sup>20</sup> 4.00.** Crystallise it from water. The solubility in H<sub>2</sub>O is 8% at ~20° and 33% at ~100°; in EtOH it is 8% at ~20° and in MeOH it is 25% at ~20°. [Blitz *Z Anorg Allgem Chem* **170** 161 1928.] **POISONOUS.**

**Mercuric iodide (red)** [7774-29-0] **M 454.4, m 259°(yellow >130°), b ~350°(subl), d<sub>4</sub><sup>20</sup> 6.3.** Crystallise it from MeOH or EtOH and wash it repeatedly with distilled water (solubility is 0.006% at ~25°). It has also been mixed thoroughly with excess 0.001M iodine solution, filtered, washed with cold distilled water, rinsed with EtOH and Et<sub>2</sub>O, and dried in air. It changes colour reversibly to yellow at ~130°. [Friend *Nature* **109** 341 1922.] **POISONOUS.**

**Mercuric oxide (yellow)** [21908-53-2] **M 216.6, m 500°(dec).** Dissolve it in HClO<sub>4</sub> and precipitate it with NaOH solution. It is yellow when cold and changes to red at ~130° reversibly. **POISONOUS.**

**Mercuric thiocyanate** [592-85-8] **M 316.8, m 165°(dec), pK<sup>25</sup> -1.85 (for HSCN).** Recrystallise it from H<sub>2</sub>O, and it can give various crystal forms depending on conditions. Its solubility in H<sub>2</sub>O is 0.069% at 25°, but is more soluble at higher temperatures. It decomposes to Hg above 165°. **POISONOUS.** [Mason & Forgeng *J Phys Chem* **35** 1121 1931, Birckenbach & Kolb *Chem Ber* **68** 919 1935.]

**Mercurous nitrate dihydrate** [7782-86-7 (2H<sub>2</sub>O), 7783-34-8 (H<sub>2</sub>O), 10415-75-5 (anhydrous)] **M 561.2, m 70°(dec), d<sub>4</sub><sup>20</sup> 4.78, pK<sup>25</sup> 2.68 (for Hg<sub>2</sub><sup>2+</sup> hydrolysis).** Its solubility in H<sub>2</sub>O containing 1% HNO<sub>3</sub> is 7.7%. Recrystallise it from a warm saturated solution of dilute HNO<sub>3</sub> and cool to room temperature slowly to give elongated prisms. Rapid cooling gives plates. The colourless crystals should be stored in the dark. **POISONOUS.** [Grdenic *J Chem Soc* 1312 1956.]

**Mercurous sulfate** [7783-36-0] **M 497.3, d<sub>4</sub><sup>20</sup> 7.56.** The white-yellow powder is recrystallised from dilute H<sub>2</sub>SO<sub>4</sub>, dried in a vacuum under N<sub>2</sub>, and stored in the dark. Its solubility in H<sub>2</sub>O is 0.6% at 25°. It is hydrolysed by excessive washing with H<sub>2</sub>O to form the greenish-yellow *basic salt* Hg<sub>2</sub>SO<sub>4</sub>.Hg<sub>2</sub>O.H<sub>2</sub>O. **POISONOUS.**

**Mercury** [7439-97-6] **M 200.6, m -38.9°, b 126°/1mm, 184°/10mm, 261°/100mm, 356.9°/atm, d<sub>4</sub><sup>20</sup> 13.534.** After air has been bubbled through mercury for several hours to oxidise metallic impurities, it is filtered to remove coarser particles of oxide and dirt, then sprayed through a 4-ft column containing 10% HNO<sub>3</sub>. It is washed with distilled water, dried with filter paper and distilled under vacuum. [Schenk in *Handbook of*

*Preparative Inorganic Chemistry (Ed. Brauer) Academic Press Vol I p 8 1963.]*

**Molybdenum** [7439-98-7] **M 95.9, m 2622°, b ~4825°, d<sup>25</sup> 10.3g/ml, resistivity of 5.0 μΩ-cm at 20°.** The dark-gray metal is commercially available in varying degrees of purity from 98 to 99.99%, as foil with thickness from 0.025mm (5.8g 150 x 150mm) to 1.0mm (25.6g, 50mm x 50mm or 102.4g, 100mm x 100 mm), or black powder from <150μm to 1-2μm particle size as well in nanopowder form of <100nm (BET) size. It is also available as wire of 1.0mm in diameter. The metal is stable in air but is oxidised at red heat to MoO<sub>3</sub>; is unreactive towards dilute acids or alkalis but reacts with strong HNO<sub>3</sub>, H<sub>2</sub>SO<sub>4</sub>, fused KClO<sub>3</sub> or KNO<sub>3</sub>, F<sub>2</sub> (at ~ 25°), Cl<sub>2</sub> and Br<sub>2</sub> (at red heat). [**CARE:** it is potentially quite toxic—particularly the nano sized particles.]

**Molybdenum (VI) dichloride dioxide (MoO<sub>2</sub>Cl<sub>2</sub>)** [13637-68-8] **M 198.8, d<sup>25</sup> 6.31g/ml.** It is prepared from MoO<sub>2</sub> (40.0g, 313mmol) by placing it in a test tube with a wide side arm and a central tube which ends ~2cm above the surface of the oxide. The side arm is connected to a large round bottomed flask which vents through a bubbler containing H<sub>2</sub>SO<sub>4</sub>. The apparatus is flushed with argon, and the tube containing the oxide is immersed in an oil bath which is kept at 140° for 12 hours to dry the oxide. The temperature of the tube is then raised to 160° and a stream of Cl<sub>2</sub> gas (pre-dried by bubbling through two H<sub>2</sub>SO<sub>4</sub> traps) is allowed to flow over the hot oxide for 10 hours. The wide tube connecting the test tube and the flask is wrapped with a heating tape to encourage the MoO<sub>2</sub>Cl<sub>2</sub> to sublime into the flask as it is formed. Stirring the contents of the flask (magnetic stirrer bar) hinders the clogging entry and exit tubes. MoO<sub>2</sub>Cl<sub>2</sub> collects as ivory flakes that are quite pure for most purposes, but can be resublimed if necessary. All due **PRECAUTIONS** should be taken as chlorine is a **TOXIC GAS** and concentrated H<sub>2</sub>SO<sub>4</sub> is used in the bubblers. [Schrock et al. *J Am Chem Soc* **112** 3875 1990, Epperson et al. *Inorg Synth* **7** 168 1963.] Commercial fluffy MoO<sub>2</sub>Cl<sub>2</sub> gives poor yields of substitution products (e.g. with ArNHSiMe<sub>3</sub>), but the THF complex MoO<sub>2</sub>Cl<sub>2</sub>(THF)<sub>2</sub> [556907-19-8; 12081-12-8] is easier to handle, reacts in a similar way, and gives much higher yields of substitution products. It is readily prepared in solution by carefully adding solid MoO<sub>2</sub>Cl<sub>2</sub> to dry THF at -30°. Addition of THF to MoO<sub>2</sub>Cl<sub>2</sub> is too exothermic to keep under control. [Schrock et al. *J Am Chem Soc* **112** 3875 1990.] Krauss & Huber prepared it by adding MoO<sub>2</sub>Cl<sub>2</sub> (2.0g, 10mmol) in four portions to THF (7ml. 6.5g, 90mmol) while shaking. The yellow solution is diluted with light petroleum (5ml), filtered, the filtrate is diluted further with light petroleum (10ml) when the complex crystallises out. The supernatant is decanted off, the solid is washed several times with light petroleum (10ml lots), and dried at room temperature in a stream of N<sub>2</sub> to give analytically pure MoO<sub>2</sub>Cl<sub>2</sub>(THF)<sub>2</sub> (3.2g, 93%) as very pale yellow needles, **m > 50° (dec)**, that are soluble in THF, slightly soluble in Et<sub>2</sub>O but insoluble in light petroleum [Krauss & Huber *Chem Ber* **94** 2864 1961]. It is very useful for preparing a variety of Mo complexes and catalysts.

**Molybdenum hexacarbonyl** [13939-06-5] **M 264.0, m 150°(dec), b 156°.** Sublime it in a vacuum before use [Connor et al. *J Chem Soc, Dalton Trans* 511 1986]. **TOXIC.**

**Molybdenum hexafluoride** [7783-77-9] **M 209.9, m 17.5°, b 35°/760mm, d<sub>4</sub><sup>20</sup> 2.543.** Purify the hexafluoride by low-temperature trap-to-trap distillation over pre-dried NaF. It is *hygroscopic*, fumes in moist air and is hydrolysed readily by H<sub>2</sub>O. [Oppengard et al. *J Am Chem Soc* **82** 3825 1960, Anderson & Winfield *J Chem Soc, Dalton Trans* 337 1986, Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer) Academic Press Vol I p 259 1963.]* **Poisonous vapours.**

**Molybdenum (IV) oxide [molybdenum (IV) dioxide, MoO<sub>2</sub>]** [18868-43-4] **M 127.9, d<sup>25</sup> 6.47.** It is prepared by grinding together ~10-15g of a mixture in a 2:1 ratio of MoO<sub>3</sub> (dried by heating in at 500° for 1 hour) and Mo metal powder in a quartz combustion tube under argon, or in an evacuated tube (CARE when opening), at 800° for 70 hours. It forms a brown-violet powder, oblong needles or thick platelets with a metallic lustre. [Conroy & Ben-Dor *Inorg Synth* **14** 149 1973, **30** 105 1997, Herzog et al. in *Handbuch der Preparativen Anorganische Chemie (Ed. Brauer) Enke Verlag Stuttgart Vol 3 p 1542 1981.]* Beware of **TOXIC** vapours.

**Molybdenum trichloride** [13478-18-7] **M 202.3, m 1027°, d<sub>4</sub><sup>20</sup> 3.74.** Boil it with 12M HCl, wash it with absolute EtOH and dry it in a vacuum desiccator. It is a brown-red powder soluble in H<sub>2</sub>O, EtOH or Et<sub>2</sub>O and gives a blue solution in conc H<sub>2</sub>SO<sub>4</sub>. [Hein & Herzog *Handbook of Preparative Inorganic Chemistry (Ed. Brauer) Academic Press Vol II p 1404 1965.]*

**Molybdenum trioxide [molybdenum (VI) oxide, MoO<sub>3</sub>]** [1313-27-5] **M 143.9, m 795°, b 1155°, d<sub>4</sub><sup>20</sup> 4.60.** MoO<sub>3</sub> is prepared by adding HNO<sub>3</sub> to an aqueous solution of ammonium molybdate and stirring for several hours which precipitates H<sub>2</sub>MoO<sub>4</sub>. The acid is filtered off, washed with H<sub>2</sub>O, heated at 150° for 1-2 hours and the hydrated oxide is dried at 450°. It recrystallises in rhombs from water (1g/50ml) between 70° and 0°, and is dried in air at ~500° for 1 hour before use. Its solubility in H<sub>2</sub>O is 0.1% at 18°, and 2% at 70°. It is a white powder which turns yellow reversibly on heating. It sublimes readily at >780°/760mm in a quartz tube to give pure MoO<sub>3</sub>. [Hein & Herzog *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1412 1965, Herzog et al. in *Handbuch der Preparativen Anorganische Chemie* (Ed. Brauer) Enke Verlag Stuttgart Vol 3 p 1544 1981.] It is used in the synthesis of Mo compounds, and of the ternary reduced molybdenum oxide Pr<sub>4</sub>Mo<sub>9</sub>O<sub>18</sub>, which contains the previously unknown Mo<sub>7</sub>, Mo<sub>13</sub>, and Mo<sub>19</sub> clusters; and is a precursor for the preparation of fast ion conductors and superconductors [Arulraj *Chem Mater* 14 2492 2002, Lacorre *Nature* 404 856 2000]. The oxide forms hydrates and alcoholates which have different IR spectra [Krauss & Huber *Chem Ber* 94 2864 1961]. Beware of **TOXIC** vapours.

**Molybdic acid (H<sub>2</sub>MoO<sub>4</sub>)** [7782-91-4] **M 162.0, 180.0 (monohydrate), d<sup>25</sup> 3.124 (for monohydrate), pK<sub>1</sub><sup>25</sup> 0.9 (proton addition), pK<sub>2</sub><sup>20</sup> 4.00, pK<sub>3</sub><sup>20</sup> 4.21.** Treatment of an aqueous solution of 0.4N Na<sub>2</sub>MoO<sub>4</sub> [1L, or of (NH<sub>4</sub>)<sub>2</sub>MoO<sub>4</sub> as in the preceding entry] at 60° with 30% HNO<sub>3</sub> (1L, prepared from 300ml of concentrated acid, d 1.42, in 1L of H<sub>2</sub>O with cooling) and allowing to stand at 25° for several days deposited the theoretical amount of canary yellow monoclinic crystals which are collected, washed with ice water and dried *in vacuo* over H<sub>2</sub>SO<sub>4</sub> for 2 weeks to give H<sub>2</sub>MoO<sub>4</sub>·H<sub>2</sub>O. This is referred to as **α-molybdic acid** which on warming in H<sub>2</sub>O at 70° is transformed to the white anhydrous **β-molybdic acid**. These acids have different X-Ray spectra and vapour pressures. **Colloidal molybdic acid** is obtained by dialysing an aqueous solution of (NH<sub>4</sub>)<sub>2</sub>MoO<sub>4</sub> and HCl, and forms a gum on evaporation. By heating these acids, or the ammonium salts, provide white MoO<sub>3</sub> which on heating further at 500° in the presence of H<sub>2</sub> gives reddish-brown MoO<sub>2</sub>, and at 1200° a grey powder of metallic Mo is obtained (see preceding entries). Polymeric forms are known such as **tetramolybdic acid** [H<sub>2</sub>Mo<sub>4</sub>O<sub>16</sub>, pK<sub>1</sub> 1.4, pK<sub>2</sub> 1.2, Chauveau et al. *Bull Soc Chim Fr* 1190 1959] and **heptamolybdic acid** [H<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub>, pK<sub>5</sub><sup>25</sup> ~3.7, pK<sub>6</sub><sup>25</sup> 4.33, Sasaki et al *J Inorg Nucl Chem* 9 93 1959]. Note that in aqueous alkaline solution the main Mo(VI) acid species are MoO<sub>4</sub><sup>2-</sup>, but in neutral and acidic media polynuclear species exist [cf Sasaki & Sillén *Arkiv Kemi* 29 253 1968, and Sasaki et al *J Inorg Nucl Chem* 9 93 1959]. [Herzog et al. in *Handbuch der Preparativen Anorganische Chemie* (Ed. Brauer) Enke Verlag Stuttgart Vol 3 p 1544 1981, Rosenheim *Z Anorg Chem* 50 320 1906, Peters et al. *Z Anor Allgem Chem* 365 14 1969; and for pKs see also Sasaki & Sillén *Acta Chem Scand* 18 1014 1964, Rohwer & Cruywagen *J S African Chem Inst* 16 26 1963, Rohwer & Cruywagen *J S African Chem Inst* 17 145 1964.]

**Monocalcium phosphate dihydrate (monobasic)** [7789-77-7 (2H<sub>2</sub>O), 7757-93-9 (anhydrous)] **M 154.1, m 200°(dec, loses H<sub>2</sub>O at 100°), d<sub>4</sub><sup>20</sup> 2.2.** Crystallise it from a near-saturated solution in 50% aqueous reagent grade phosphoric acid at 100° by filtering through fritted glass and cooling to room temperature. The crystals are filtered off, and this process is repeated three times using fresh acid. For the final crystallisation the solution is cooled slowly with constant stirring to give thin plate crystals that are filtered off on a fritted glass funnel, washed free of acid with anhydrous acetone and dry in a vacuum desiccator [Egan et al. *J Am Chem Soc* 78 1811 1956].

**Neodymium chloride hexahydrate** [13477-89-9] **M 358.7, m 124°, pK<sub>1</sub><sup>25</sup> 8.43 (for Nd<sup>3+</sup> hydrolysis).** Neodymium chloride forms large purple prisms from concentrated solutions of dilute HCl. They are soluble in H<sub>2</sub>O (2.46 parts in 1 part of H<sub>2</sub>O) and EtOH, and lose H<sub>2</sub>O at 160°.

**Neodymium(II) iodide** [61393-36-0] **M 398.1.** This one electron reductant can be prepared in large quantities (~40g) by direct reaction of the metal and iodine at 600° [Evans et al. *Inorg Chem* 42 3097 2003]. The black solid NdI<sub>2</sub> can be kept at room temperature for months in the absence of solvent. Solutions can be stored under argon for several hours at -15° but should be used as soon as possible. The stability is considerably reduced if N<sub>2</sub> is used as inert atmosphere, instead of argon, even at -30°. In tetrahydrofuran under argon it promotes a pseudo-Barbier reaction, i.e. rapid reductive coupling of primary and secondary (but not tertiary) halides with ketones, e.g. butylchloride and cyclohexanone provide almost quantitative yield of 1-butylhexan-1-ol [Evans et

al. *Org Lett* **5** 2041 2003]. Thus behaving somewhat like a Grignard reagent. This solution also has Birch reduction-type reactivity, e.g. reduces naphthalene to 1,4-dihydronaphthalene.

**NdI<sub>2</sub> (THF)<sub>x</sub> solution** is prepared by transferring pre-cooled THF (45ml, at -15°) *via* a cannula into a septum-capped flask containing black NdI<sub>2</sub> (1.0g, 2.5mmol) and a magnetic stirrer bar at -15° whereby the colour of the solution becomes purple, and is stirred for 45 minutes. An aliquot should show the concentration to be 0.05M by complexometric titration [method of Evans & Allen *J Am Chem Soc* **122** 2118 2000]. This solution is used for reactions and should be performed under argon.

**Neodymium(III) iodide (anhydrous)** [13813-24-6] **M 524.7, m 775°, b 1370°**. It is an almost black crystalline powder (green when ground) that is soluble in hot and cold H<sub>2</sub>O. It can be prepared by the method of Bochkarev [Bochkarev & Fagin *Chem Eur J* **5** 2990 1999] where a small quantity of Nd metal is placed in a quartz crucible in a quartz reactor [see Evans et al. *Inorg Chem* **42** 3097 2003], heated to 600°, and I<sub>2</sub> is added, then small amounts of metal and I<sub>2</sub> are added alternately. Every addition of I<sub>2</sub> results in an orange glow in the mixture. When addition is complete (total ≥3 equivalents) the apparatus is cooled, and the crucible containing NdI<sub>3</sub> is transferred to an argon filled glovebox and the salt is ground (with a pestle and mortar) to a green powder. The metal content is analysed by titration (complexometric metal analysis is performed by dissolving the salt in H<sub>2</sub>O at ~25°, evaporating, ashing the residue at 500°, dissolving in HCl and the analysis is carried out in hexamethylenetetramine buffer with xylenol orange as indicator and EDTA as titrant: Schwarzenbach & Flaschka "Complexometric Titrations" Metheun, London p 194 1969; Evans et al. *J Am Chem Soc* **103** 6672 1981). It should contain at least 27.5% Nd (theoretical is 29.5% Nd). [Evans & Workman *Organometallics* **24** 1989 2005.]

**Potassium graphite KC<sub>8</sub> with NdI<sub>3</sub>** has also been used for reductive coupling and is prepared *in situ*. [Weitz & Rabinovitz *J Chem Soc, Perkin Trans I* 117 1993]. KC<sub>8</sub> can be prepared in a Schlenk line, or in a glove box, by adding K metal (0.541g, 13.8mmol) to a scintillating vial containing a Teflon stirbar then Graphite (1.242g, 12.9mmol), and the mixture is stirred and heated until a bronze-coloured powder results. The NdI<sub>3</sub>/KC<sub>8</sub>/THF is prepared by adding precooled (-15° *via* a cannula) THF into a septum-capped Schlenk flask (~25ml) containing NdI<sub>3</sub>, KC<sub>8</sub> and a Teflon stirbar thus producing a purple solution which is stirred at -15° for 40 minutes and is ready for the reaction. The alkyl halide is injected, stirred for 1 minute, and is followed by the aldehyde or ketone. [Evans & Workman *Organometallics* **24** 1989 2005.]

**Neodymium nitrate hexahydrate** [16454-60-7] **M 438.4, m 70-72°**. It crystallises with 5 and 6 molecules of H<sub>2</sub>O from concentrated solutions in dilute HNO<sub>3</sub> by slow evaporation; 1 part is soluble in 10 parts of H<sub>2</sub>O.

**Neodymium oxide** [1313-97-9] **M 336.5, m 2320°**. Dissolve it in HClO<sub>4</sub>, precipitate it as the oxalate with doubly recrystallised oxalic acid, wash it free of soluble impurities, dry it at room temperature and ignite it in a platinum crucible at higher than 850° in a stream of oxygen. It is a blue powder. [Tobias & Garrett *J Am Chem Soc* **80** 3532 1958.]

**Neon** [7440-01-9] **M 20.2**. Pass the gas through a copper coil packed with 60/80 mesh 13X molecular sieves which is cooled in liquid N<sub>2</sub>, or through a column of Ascarite (NaOH-coated silica/asbestos adsorbent).

**Nickel bromide** [13462-88-9] **M 218.5, m 963°(loses H<sub>2</sub>O at ~ 200°)**. Crystallise it from dilute HBr (0.5ml/g) by partial evaporation in a desiccator. The *anhydrous* salt is yellow, but the *trihydrate* is green.

**Nickel chloride hexahydrate** [7791-20-0 (6H<sub>2</sub>O), 69098-15-3 (xH<sub>2</sub>O), 7718-54-9 (*anhydrous*)] **M 237.7**. It crystallises from dilute HCl to form the green *hexahydrate*. At 70° this dehydrates to the *tetrahydrate*, and at higher temperatures it forms the *anhydrous* salt. It sublimes in yellow hexagonal scales in a stream of HCl. Store it in a desiccator as it is *deliquescent*. [Hart & Partington *J Chem Soc* 104 1943.]

**Nickel nitrate hexahydrate** [13478-00-7] **M 290.8, m 57°**. Crystallise it from water (3.3g/ml) by partial evaporation in a desiccator. Store it in a desiccator as it is *deliquescent*.

**Nickel(II) perchlorate hexahydrate** [Ni(ClO<sub>4</sub>)<sub>2</sub> · 6H<sub>2</sub>O] [13520-61-1] **M 365.7, m 140°, 200°, 209° (sealed tube), d<sup>0</sup> 1.570, d<sup>20</sup> 1.583, d<sup>40</sup> 1.597, d<sup>50</sup> 1.646, d<sup>60</sup> 1.597**. The greenish blue hexagonal prisms of this salt are

obtained by double decomposition between  $\text{NiSO}_4$  and  $\text{Ca}(\text{ClO}_4)_2$  in aqueous solution, filtering off the insoluble  $\text{BaSO}_4$ , and concentrating the filtrate. It recrystallises from  $\text{H}_2\text{O}$ , and drying the crystals in a vacuum desiccator over  $\text{H}_2\text{SO}_4$  or  $\text{CaCl}_2$  provides the *hexahydrate*. Alternatively, it is prepared from freshly precipitate  $\text{NiO}$  or  $\text{NiCO}_3$  and aqueous  $\text{HClO}_4$ , filtering off the excess of  $\text{NiCO}_3$  and concentrating the filtrate to crystallisation. The solubility of  $\text{Ni}(\text{ClO}_4)_2 \cdot 6\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  (g/100ml) is 217 ( $0^\circ$ ), 236 ( $10^\circ$ ), 245 ( $20^\circ$ ), 267 ( $30^\circ$ ), 280 ( $35^\circ$ ), 273 ( $40^\circ$ ), 311 ( $50^\circ$ ), 295 ( $55^\circ$ ), 280 ( $60^\circ$ ). The salt form hydrates with 2, 4, 5, 6, 7, and 9 molecules of  $\text{H}_2\text{O}$ . The *hexahydrate* is normally obtained by crystallisation from  $\text{H}_2\text{O}$  and is the more stable hydrate. It forms the *tetrahydrate* at  $110^\circ/760\text{mm}/36$  hours or  $70^\circ/1\text{mm}/66$  hours, which yields the *dihydrate* at  $130^\circ/760\text{mm}/42$  hours or  $100^\circ/1\text{mm}/72$  hours. It should be kept in a desiccator over  $\text{CaCl}_2$  as it is quite *hygroscopic*. The UV in EtOH has  $\lambda_{\text{max}}$  ( $\log \epsilon$ ) at 395 ( $\sim 0.68$ ), 660 ( $\sim 0.22$ ), 720 ( $\sim 0.25$ ) nm. Evaporation of a solution in ether with dry air gives  $\text{Ni}(\text{ClO}_4)_2 \cdot \text{Et}_2\text{O}$  as a yellow powder, and with dioxan it forms  $\text{Ni}(\text{ClO}_4)_2 \cdot 2\text{C}_4\text{H}_8\text{O}_2$ . A solution in  $\text{Me}_2\text{CO}$  at  $\sim 2 \times 10^{-4}\text{M}$  is green with a characteristic absorption at 410nm [Katzin *Nature* **182** 1013 1958]; it complexes also with acetylacetone [Fernelius et al. *J Chem Phys* **59** 235 1955], ethylene, trimethylenediamine [Cotton & Harris *J Phys Chem* **59** 1203 1955], DMF [Pflaum, & Popov *Anal Chim Acta* **13** 167, 169 1955], and with pyridine it forms blue crystals of  $[\text{Ni}(\text{C}_5\text{H}_5\text{N})_6](\text{ClO}_4)_2 \cdot 4\text{H}_2\text{O}$  [Weinland et al. *Arch Pharm* **265** 352 1927],  $\text{Ni}(\text{ClO}_4)_2 \cdot 4(\text{C}_5\text{H}_5\text{N})$  and  $\text{Ni}(\text{ClO}_4)_2 \cdot 6(\text{C}_5\text{H}_5\text{N})$  [Sinha *J Indian Chem Soc* **35** 865 1958, Sinha & Ray *J Indian Chem Soc* **20** 32 1943]. [Salvadori *Gazzetta* **42** I 458 1912, Veeraiah & Qureshi *J Indian Chem Soc* **21** 127 1944, Bernath et al. *J Prakt Chem* **143** [2] 302 1935, Freund & Schneider *J Am Chem Soc* **81** 4780 1959, Gmelin's *Handbuch der Anorganischen Chemie, Nickel Teil B-Lieferung 21*, Verlag Chemie GMBH Weinheim, System 57, pp 596-601 1966.]

**Nickel sulfate hexahydrate** [10101-97-0] **M 262.9, m loses  $5\text{H}_2\text{O}$  at  $100^\circ$ , becomes anhydrous at  $\sim 280^\circ$ ,  $d^{25}$  2.07.** It crystallises from  $\text{H}_2\text{O}$  in bluish-green tetragonal crystals of the  $\alpha$ -form which undergo a transition at  $53.3^\circ$  to the  $\beta$ -form that has green transparent monoclinic crystals. The crystals are stable at  $\sim 40^\circ$ , become blue in colour and then opaque in air due to slow efflorescence. Its solubility in  $\text{H}_2\text{O}$  is 0.6/ml at  $0^\circ$  and 3.4g/ml at  $100^\circ$ . It is sparingly soluble in EtOH, slightly more soluble in MeOH, soluble in aqueous NaOH, and very soluble in aqueous ammonia to give the bluish-green monoclinic  $(\text{NH}_4)_2\text{Ni}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$  double salt. The pH of an aqueous solution is about 4.5, i.e. weakly acidic. (See also the heptahydrate below.)

**Nickel sulfate heptahydrate** [10101-98-1, 7786-81-4 (anhydrous)] **M 280.9, m loses  $5\text{H}_2\text{O}$  at  $100^\circ$ , anhydrous m at  $\sim 280^\circ$ ,  $d^{25}$  1.948.** The sulfate crystallises from warm water (4g/ml) or dilute  $\text{H}_2\text{SO}_4$  as bright green monoclinic crystals on cooling. It is isomorphous with Epsom salt (see  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$  above). Prolonged exposure to air gives the blue *tetrahydrate*. On heating above  $118^\circ$ , it is converted to the *dihydrate*, which at  $>280^\circ$  is converted to the *yellow anhydrous*  $\text{NiSO}_4$  which does not react with HCl.

**Nickel(II) sulfide** **M 90.8 (NiS, mellirite, bronze-yellow,  $d^{25}$  5.3-5.6), 240.2 ( $\text{Ni}_3\text{S}_2$  [12035-72-2] Heazelwoodite,  $d^{25}$  5.8) and ( $\text{Ni}_3\text{S}_2/\text{NiS}$  black powder [16812-54-7]  $d^{25}$  5.3-5.6), m  $790^\circ$ ,  $797^\circ$ .** The sulfide is generally obtained as a highly insoluble black precipitate by adding  $\text{NH}_4\text{OH}$  and  $\text{NH}_4\text{SH}$  to a nickel salt. It dissolves slowly in excess of  $(\text{NH}_4)_2\text{S}_x$  and re-precipitates on boiling, exposure to air or addition of acid. A black dense sulfide is also obtained by boiling a nickel salt with  $\text{Na}_2\text{S}_2\text{O}_3$ . It is insoluble in dilute HCl, slowly soluble in concentrated HCl, readily in  $\text{HNO}_3$  and aqua regia. The sulfides should be washed well with  $\text{H}_2\text{O}$ , dried, and analysed for Ni. Various forms have been prepared [Dunn & Rideal *J Chem Soc* **123** 1242 1923.]

**Niobium (Colombium) (V) chloride** [10026-12-7] **M 270.2, m  $204.7-209.5^\circ$ , b  $\sim 250^\circ$  (begins to sublime at  $125^\circ$ ),  $d_4^{20}$  2.75.** It forms yellow, very deliquescent crystals which decompose in moist air to liberate HCl. Keep it in a dry box flushed with  $\text{N}_2$  in the presence of  $\text{P}_2\text{O}_5$ . Wash it with  $\text{CCl}_4$  and dry it over  $\text{P}_2\text{O}_5$ . The yellow crystals can contain a few small, dirty white pellets among the yellow needles. These should be easily picked out. Upon grinding in a dry box, however, they turn yellow.  $\text{NbCl}_5$  has been sublimed and fractionated in an electric furnace. [Epperson *Inorg Synth* **VII** 163 1963, Alexander & Fairbrother *J Chem Soc* suppl 233 1949.]

**Nitric acid (Aqua fortis)** [7697-37-2] **M 63.0, m  $-42^\circ$ , b  $83^\circ$ ,  $d^{25}$  1.5027, [Constant boiling acid has composition w/w of 68%  $\text{HNO}_3$  + 32%  $\text{H}_2\text{O}$ , b  $120.5^\circ$ ,  $d_4^{20}$  1.41],  $\text{pK}^{25}$  -1.27 (1.19).** The acid is obtained

colourless (approx. 92%) by direct distillation of fuming  $\text{HNO}_3$  under reduced pressure at 40-50° with an air leak at the head of the fractionating column. **Concentrated nitric acid** is an aqueous solution containing 70-71% of  $\text{HNO}_3$  ( $d_4^{20}$  1.4134). Store it in a desiccator that is kept in a refrigerator away from light which causes the formation of  $\text{NO}_2$ . Nitrite-free  $\text{HNO}_3$  can be obtained by vacuum distillation from urea. [Ward et al. *Inorg Synth III* 13 1950, Kaplan & Schechter *Inorg Synth IV* 53 1953.] If “fuming nitric acid” (90%) is yellow in colour (due to the presence of oxides of nitrogen), then treat 100mls with urea (0.5g) and bubble dry air through it until it is colourless (~20 minutes) [Freeman & Shepard *Org Synth* 43 84 1932]. Acid that is free from oxides does not discolour drops of 1N  $\text{KMnO}_4$ . **Anhydrous  $\text{HNO}_3$**  (100%,  $d_4^{20}$  1.5129) is obtained on distilling a mixture of equal volumes of “fuming nitric acid” and concentrated  $\text{H}_2\text{SO}_4$  [Liang *Org Synth Coll Vol III* 804 1955]. It is an oxidising agent, its vapours irritate and cauterise tissues, and cause the skin to turn yellow in colour. The “fuming acid” is particularly dangerous, should be handled in an efficient fume cupboard, and is used more as an oxidant than for acidification — use EYE PROTECTION.

**Nitric oxide** [10102-43-9] **M 30.0, b -151.8°**. Bubble the gas through 10M  $\text{NaOH}$  which removes  $\text{NO}_2$ . It can also be freed from  $\text{NO}_2$  by passage through a column of Ascarite followed by a column of silica gel held at -197°K. The gas is dried with solid  $\text{NaOH}$  pellets or by passing through silica gel cooled at -78°, followed by fractional distillation from a liquid  $\text{N}_2$  trap. This purification does not eliminate nitrous oxide. Other gas scrubbers sometimes used include one containing conc  $\text{H}_2\text{SO}_4$  and another containing mercury. It is freed from traces of  $\text{N}_2$  by the freeze and thaw method. [Blanchard *Inorg Synth II* 126 1946, Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 485-487 1963.] **TOXIC**.

**Nitrogen** [7727-37-9] **M 28.0, b -195.8°**. Cylinder  $\text{N}_2$  can be freed from oxygen by passage through **Fieser's solution** [which comprises 2g sodium anthraquinone-2-sulfonate and 15g sodium hydrosulfite dissolved in 100ml of 20%  $\text{KOH}$ ; see Fieser, *J Am Chem Soc* 46 2639 1924] followed by scrubbing with saturated lead acetate solution (to remove any  $\text{H}_2\text{S}$  generated by the Fieser solution), conc  $\text{H}_2\text{SO}_4$  (to remove moisture), then soda-lime (to remove any  $\text{H}_2\text{SO}_4$  and  $\text{CO}_2$ ). *Alternatively*, after passage through Fieser's solution,  $\text{N}_2$  can be dried by washing with a solution of the metal ketyl from benzophenone and  $\text{Na}$  wire in absolute diethyl ether. [If ether vapour in  $\text{N}_2$  is undesirable, the ketyl from liquid  $\text{Na-K}$  alloy under xylene can be used.]

Another method for removing  $\text{O}_2$  is to pass the nitrogen through a long, tightly packed column of  $\text{Cu}$  turnings, the surface of which is constantly renewed by scrubbing it with ammonia (sg 0.880) solution. The gas is then passed through a column packed with glass beads moistened with conc  $\text{H}_2\text{SO}_4$  (to remove ammonia), through a column of packed  $\text{KOH}$  pellets (to remove  $\text{H}_2\text{SO}_4$  and to dry the  $\text{N}_2$ ), and finally through a glass trap packed with chemically clean glass wool immersed in liquid  $\text{N}_2$ . Nitrogen has also been purified by passage over  $\text{Cu}$  wool at 723°K and  $\text{Cu(II)}$  oxide [prepared by heating  $\text{Cu(NO}_3)_2 \cdot 6\text{H}_2\text{O}$  at 903°K for 24 hours] and then into a cold trap at 77°K.

A typical dry purification method consists of a mercury bubbler (as trap), followed by a small column of silver and gold turnings to remove any mercury vapour, towers containing anhydrous  $\text{CaSO}_4$ , dry molecular sieves or  $\text{Mg(ClO}_4)_2$ , a tube filled with fine  $\text{Cu}$  turnings and heated to 400° by an electric furnace, a tower containing soda-lime, and finally a plug of glass wool as filter. Variations include tubes of silica gel, traps containing activated charcoal cooled in a Dry-ice bath, copper on Kieselguhr heated to 250°, and  $\text{Cu}$  and  $\text{Fe}$  filings at 400°. [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 458-460 1963.]

**Nitrosyl chloride** [2696-92-6] **M 65.5, m -64.5°. b -5.5°**. It is an orange gas with a suffocating odour. It has been fractionally distilled at atmospheric pressure in an all-glass, low-temperature still, taking the fraction boiling at -4° and storing it in sealed tubes. *Alternatively*, the gas is dried by  $\text{CaCl}_2$  and passed through  $\text{H}_2\text{SO}_4$  when  $\text{Cl}_2$  passes on, but  $\text{NOCl}$  is absorbed to form **nitrososulfuric acid** ( $\text{NO} \cdot \text{HSO}_4$ ) which on warming with  $\text{NaCl}$  evolves pure  $\text{NOCl}$  [Tilden *J Chem Soc* 27 630 1874.] It is decomposed by  $\text{H}_2\text{O}$  and alkali, and forms compounds with metal chlorides e.g.  $\text{FeCl}_3 \cdot \text{NOCl}$ . [Coleman *Inorg Synth I* 55 1939.]

**Nitrous oxide** (laughing gas) [10024-97-2] **M 44.0, b -88.5°**. Wash the gas with concentrated alkaline pyrogallol solution, to remove  $\text{O}_2$ ,  $\text{CO}_2$ , and  $\text{NO}_2$ , then dry it by passing it through columns of  $\text{P}_2\text{O}_5$  or Drierite, and collecting in a dry trap cooled in liquid  $\text{N}_2$ . It is further purified by freeze-pump-thaw and distillation cycles

under vacuum [Ryan & Freeman *J Phys Chem* **81** 1455 1977, Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 484-485 1963].

**Osmium tetroxide (osmic acid)** [20816-12-0] M 524.2, m 40.6°, b 59.4°/60mm, 71.5°/100mm, 109.3°/400mm, 130°/760mm,  $d_D^{20}$  5.10,  $pK_1^{25}$  7.2,  $pK_2^{25}$  12.2,  $pK_3^{25}$  13.95,  $pK_4^{25}$  14.17 (H<sub>4</sub>OsO<sub>6</sub>). It is **VERY TOXIC** and should be manipulated in a very efficient fume cupboard. It attacks the eyes severely (**use also eye and face protection**) and is a good oxidising agent. It is volatile and has a high vapour pressure (11mm) at room temperature. It sublimes and volatilises well below its boiling point. It is soluble in \*C<sub>6</sub>H<sub>6</sub>, H<sub>2</sub>O (7.24% at 25°), CCl<sub>4</sub> (375% at 25°), EtOH and Et<sub>2</sub>O. It is estimated by dissolving a sample in a glass-stoppered flask containing 25ml of a solution of KI (previously saturated with CO<sub>2</sub>) and acidified with 0.35M HCl. After gentle shaking in the dark for 30 minutes, the solution is diluted to 200ml with distilled H<sub>2</sub>O saturated with CO<sub>2</sub> and titrated with standard thiosulfate using starch as indicator. This method is not as good as the gravimetric method. Hydrazine hydrochloride (0.1 to 0.3g) is dissolved in 3M HCl (10ml) in a glass-stoppered bottle. After warming to 55-65°, a weighed sample of OsO<sub>4</sub> solution is introduced, and the mixture is digested on a water bath for 1 hour. The mixture is transferred to a weighed glazed crucible and evaporated to dryness on a hot plate. A stream of H<sub>2</sub> is started through the crucible, and the crucible is heated over a burner for 20-30 minutes. The stream of H<sub>2</sub> is continued until the crucible is cooled to room temperature, and then the H<sub>2</sub> is displaced by CO<sub>2</sub> in order to avoid rapid combustion of H<sub>2</sub>. Finally the crucible is weighed. [Grube in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II pp 1603 1965, Anderson & Yost *J Am Chem Soc* **60** 1822 1938.]

§ Available commercially on a polymer support.

**Oxygen** [7782-44-7] M 32.00, m -218.4°, b -182.96°,  $d^{-183}$  1.149,  $d^{-252.5}$  1.426. Purify it by passing the gas over finely divided platinum at 673°K and Cu(II) oxide (see under nitrogen) at 973°, then condensed in a liquid N<sub>2</sub>-cooled trap. **HIGHLY EXPLOSIVE in contact with organic matter.**

**Palladium (II) chloride** [7647-10-1] M 177.3, m 678-680°. The *anhydrous* salt is insoluble in H<sub>2</sub>O and dissolves in HCl with difficulty. The *dihydrate* forms red *hygroscopic* crystals that are readily reduced to Pd. Dissolve it in conc HCl through which dry Cl<sub>2</sub> is bubbled. Filter this solution which contains H<sub>2</sub>PdCl<sub>4</sub> and H<sub>2</sub>PdCl<sub>6</sub> and on evaporation it yields a residue of pure PdCl<sub>2</sub>. [Grube in *Handbook of Preparative Inorganic Chemistry* (Ed Brauer) Academic Press Vol II p 1582 1965, Mozingo *Org Synth Coll Vol III* 685 1955.] *Alternatively* (fume cupboard), Pd metal is dissolved in *aqua regia*, and converted to the chloride by repeated evaporation with concentrated HCl. The dark red palladous chloride is dried at 150-180° in a stream of dry chlorine gas to give the *anhydrous* salt. [Kharasch, Seyler and Mayo *J Am Chem Soc* **60** 882 1938.]

**Palladium (II) cyanide** [2035-66-7] M 158.1. The yellow solid should be washed well with H<sub>2</sub>O and dry in air. [Bigelow *Inorg Synth II* 245 1946]. **POISONOUS.**

**Perchloric acid** [7601-90-3] M 100.5,  $d_4^{20}$  1.665,  $pK^{25}$  -2.4 to -3.1 (HClO<sub>4</sub>). The 72% acid has been purified by double distillation from silver oxide under vacuum: this frees the acid from metal contamination. Distillation at atmospheric pressure is **dangerous and explosive**. The *anhydrous* acid is obtained by adding gradually 400-500ml of oleum (20% fuming H<sub>2</sub>SO<sub>4</sub>) to 100-120ml of 72% HClO<sub>4</sub> in a reaction flask cooled in an ice-bath. The pressure is reduced to 1mm (or less), with the reaction mixture at 20-25°. The temperature is gradually raised during 2 hours to 85°; the distillate is collected in a receiver cooled in Dry-ice. For further details of the distillation apparatus see Smith [*J Am Chem Soc* **75** 184 1953]. **It is HIGHLY EXPLOSIVE; a strong protective screen should be used at all times.** [Schmeisser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 318-320 1963.]

**Perrehenic acid (HRe<sub>2</sub>O<sub>4</sub>)** [13768-11-1] M 251.2,  $d^{25}$  2.16,  $pK^{25}$  -1.25. The acid is commercially available as a 65-70% w/w solution in H<sub>2</sub>O. It can be prepared freshly from a solution of pure finely powdered KRe<sub>2</sub>O<sub>4</sub> (10.0g, 35.6mmol) in hot H<sub>2</sub>O (120ml) at 100° which is placed on the top of a Dowex 50W-X1 cation exchange

resin column (40 x 20mm, 50g of 50-100 mesh with a 1cm layer of Pyrex wool). This resin is first washed with 6 M HCl (20ml) and flushed with pure hot H<sub>2</sub>O at 100° until the effluent is colourless and does not become turbid on addition of AgNO<sub>3</sub> solution (i.e. chloride free). The hot KRe<sub>2</sub>O<sub>4</sub> solution is applied to the resin in four 30ml portions (to keep the temperature high, boiling if necessary for the salt to remain in solution), and the hot column is rinsed with pure hot H<sub>2</sub>O. The rate of flow should be kept at 15-20ml/minute, the first effluent (*ca* 50ml) is discarded and the acidic fraction (to litmus, *ca* 150ml) is collected. This solution is concentrated to as small a volume as possible, preferably *in vacuo* over P<sub>2</sub>O<sub>5</sub>, and an aliquot is diluted and titrated against standard alkali to obtain the concentration of HRe<sub>2</sub>O<sub>4</sub> in the residue. It is a strong acid. It is then diluted with pure H<sub>2</sub>O as required. The theoretical amount of acid in the residue should be 8.68g. [Watt & Thompson *Inorg Synth* VII 187 1963.] It is also prepared by dissolving rhenium heptoxide (Re<sub>2</sub>O<sub>7</sub>, 1314-68-7) in H<sub>2</sub>O. [Smith & Long *J Am Chem Soc* 70 354 1948, Melaven et al. *Inorg Synth* III 188 1950.]

**Phosgene** [75-44-5] **M 98.9, m -118°, b 8.2°/756mm.** Dry the gas with Linde 4A molecular sieves, de-gas it and distil it under vacuum at low temperature. This should be done in a closed system such as a vacuum line. It is hydrolysed slowly by H<sub>2</sub>O, but does not fume in moist air. It is available in cylinders and as a ~20% solution in toluene. **It is HIGHLY TOXIC and should not be inhaled. If it is inhaled, the operator should lie still and, be made to breathe in ammonia vapour which reacts readily with phosgene to give urea.** [Pope et al. *J Chem Soc* 117 1410 1920, Beilstein 3 IV 41.]

**Phosphine** [7803-51-2] **M 34.0, m -133°, b -87.7°, pK<sup>25</sup> -14, pK<sub>b</sub> 28.** PH<sub>3</sub> is best purified in a gas line (in a vacuum) in an efficient fume cupboard. It is spontaneously flammable, has a strong odour of decayed fish and is **POISONOUS**. The gas is distilled through solid KOH towers (two), through a Dry ice-acetone trap (-78°, to remove H<sub>2</sub>O, and P<sub>2</sub>H<sub>4</sub> which spontaneously ignites with O<sub>2</sub>), then through two liquid N<sub>2</sub> traps (-196°), followed by distillation into a -126° trap (Dry-ice/methylcyclohexane slush), allowed to warm in the gas line and then sealed in ampoules preferably under N<sub>2</sub>. Its IR as  $\nu_{\max}$  at 327 (m), 1121 (m) and 900 (m) cm<sup>-1</sup>. [Klement in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 525-530 1963, Gokhale & Jolly *Inorg Synth* IX 56 1967.] PH<sub>3</sub> has also been absorbed into a solution of cuprous chloride in hydrochloric acid (when CuCl.PH<sub>3</sub> is formed). PH<sub>3</sub> gas is released when this solution is heated, and the gas is purified by passage through KOH pellets and then over P<sub>2</sub>O<sub>5</sub>. It ignites spontaneously in air with a luminous flame. Its solubility is 0.26ml/1 ml of H<sub>2</sub>O at 20°, and a crystalline *hydrate* is formed on releasing the pressure on an aqueous solution.

**Phosphonitrilic chloride (tetramer)** [1832-07-1] **M 463.9.** Purify it by zone melting, then recrystallise it from petroleum ether (b 40-60°) or *n*-hexane. [van der Huizen et al. *J Chem Soc, Dalton Trans* 1317 1986.]

**Phosphonitrilic chloride (trimer) (hexachlorocyclotriphosphazine)** [940-71-6] **M 347.7, m 112.8°, 113-114°.** Purify it by zone melting, by crystallisation from petroleum ether, *n*-hexane or \*benzene, and by sublimation. [van der Huizen et al. *J Chem Soc, Dalton Trans* 1311 1986, Meirovitch et al. *J Phys Chem* 88 1522 1984, Alcock et al. *J Am Chem Soc* 106 5561 1984; Winter & van de Grampel *J Chem Soc, Dalton Trans* 1269 1986.]

**Phosphonous acid (phosphonic acid, H-P=O(OH)<sub>2</sub>)** [13598-36-2] **M 82.0, m 73.6°, d<sub>4</sub><sup>25</sup> 1.651, pK<sub>1</sub> 1.43, pK<sub>2</sub> 6.67.** Phosphonous acid is best prepared by adding PCl<sub>3</sub> to concentrated HCl, when HCl gas is liberated and the solution is evaporated (fume-cupboard) until the temperature reaches 180° (all HCl gas is driven off). On cooling the acid separates as white hygroscopic (and deliquescent) crystals. It has a garlic taste, melts at 73.6°, and decomposes at 200° to give phosphine and phosphoric acid (note that PH<sub>3</sub> ignites in air with bright flashes, see above). It is a dibasic acid that slowly oxidises to phosphoric acid in air. Store it under dry N<sub>2</sub>, or as a 20% aqueous solution under N<sub>2</sub>. [Simon & Fehér *Z Anorg Allgem Chem* 230 298 1937, Voight & Gallais *Inorg Synth* IV 55 1953.]

**Tautomerism of phosphonous acid.** This acid is tautomeric with trihydroxyphosphine with the latter tautomer being in extremely small concentrations, e.g. 1 in 10<sup>12</sup>. The diester [e.g. (MeO)<sub>2</sub>P(H)=O] has the H linked to the P atom. The tautomerism is not like that of keto-enol tautomerism in carbon chemistry, and dialkylphosphites (RO)<sub>2</sub>P(H)=O do *not* react with sulfur to form the corresponding P-SH derivatives, but they do form solid salts such as (RO)<sub>2</sub>PONa which *do* add sulfur readily. Also this acid does form triesters such as (MeO)<sub>3</sub>P which is

trimethylphosphite or trimethoxyphosphine, and behave more like phosphines. [cf. F.A. Cotton, G. Wilkinson, C.A. Murillo and M. Bochmann, *Advanced Inorganic Chemistry*, 6<sup>th</sup> Edn, Interscience Publ, 1999, ISBN 0-471-19957-5.]

**Phosphoric acid** [7664-38-2] **M 98.0, m 42.3°, pK<sub>1</sub><sup>25</sup> 2.15, pK<sub>2</sub><sup>25</sup> 7.21, pK<sub>3</sub><sup>25</sup> 12.37.** Pyrophosphate can be removed from phosphoric acid by diluting with distilled H<sub>2</sub>O and refluxing overnight. By cooling to 11° and seeding with crystals obtained by cooling a few millilitres in a Dry-ice/acetone bath, 85% orthophosphoric acid crystallises as H<sub>3</sub>PO<sub>4</sub>·H<sub>2</sub>O. The crystals are collected on a sintered glass filter. [Weber & King *Inorg Synth I* 101 1939.]

**Phosphorus (red)** [7723-14-0] **M 31.0, m 590°/43atm, ignites at 200°, d<sub>4</sub><sup>20</sup> 2.34.** Heat it for 15 minutes in boiling distilled H<sub>2</sub>O, allow it to settle and wash it several times with boiling H<sub>2</sub>O. Transfer it to a Büchner funnel, wash it with hot H<sub>2</sub>O until the washings are neutral, then dry it at 100° and store it in a desiccator.

**Phosphorus (white)** [7723-14-0] **M 31.0, m 44.1°, b 287°, d<sub>4</sub><sup>20</sup> 1.82.** Purify white phosphorus by melting it under dilute H<sub>2</sub>SO<sub>4</sub>—dichromate (possible **carcinogen**) mixture and allow to stand for several days in the dark at room temperature. It remains liquid, and the initial milky appearance due to insoluble, oxidisable material gradually disappears. The phosphorus can then be distilled under vacuum in the dark [Holmes *Trans Faraday Soc* 58 1916 1962]. It sublimes *in vacuo*. Other methods of purification include extraction with dry CS<sub>2</sub> followed by evaporation of the solvent, or washing with 6M HNO<sub>3</sub>, then H<sub>2</sub>O, and drying under vacuum. It ignites in air at ~50°, or by friction if dry. Store and cut it under H<sub>2</sub>O. **POISONOUS, use gloves.**

**Phosphorus oxychloride** [10025-87-3] **M 153.3, b 105.5°, d<sub>4</sub><sup>20</sup> 1.675, n<sub>D</sub><sup>20</sup> 1.461.** Distil the liquid under reduced pressure to separate it from the bulk of the HCl and the phosphoric acid (from hydrolysis); the middle fraction is re-distilled into ampoules containing a little purified mercury. These ampoules are sealed and stored in the dark for 4–6 weeks with occasional shaking to facilitate reaction of any free chloride with the mercury. The POCl<sub>3</sub> is then again fractionally distilled and stored in sealed ampoules in the dark until required [Herber *J Am Chem Soc* 82 792 1960]. Lewis and Sowerby [*J Chem Soc* 336 1957] refluxed their distilled POCl<sub>3</sub> with Na wire for 4 hours, then removed the Na and again distilled. *Use Na only with almost pure POCl<sub>3</sub> to avoid explosions.* **HARMFUL VAPOURS; work in an efficient fume cupboard.**

**Phosphorus pentabromide** [7789-69-7] **M 430.6, m <100°, b 106°(dec).** Dissolve it in pure nitrobenzene at 60°, filtering off any insoluble residue on to sintered glass funnel, then allow it to crystallise by cooling. Wash the collected solid with dry Et<sub>2</sub>O and remove excess ether in a current of dry N<sub>2</sub>. (All manipulations should be performed in a dry-box.) [Harris & Payne *J Chem Soc* 3732 1958]. It fumes in moist air because of hydrolysis. **HARMFUL VAPOURS** (wash burning eyes with aqueous NaHCO<sub>3</sub>).

**Phosphorus pentachloride** [10026-13-8] **M 208.2, m 179-180°(sublimes).** [All operations should be carried out in an efficient fume cupboard.] Sublime it at 160-170° in an atmosphere of chlorine. Excess chlorine is then displaced by dry N<sub>2</sub> gas. All subsequent manipulations should be performed in a dry-box [Downs & Johnson *J Am Chem Soc* 77 2098 1955]. It fumes in moist air and attacks the eyes and the mucous membranes of the nose. It should not be breathed in and has very **HARMFUL VAPOURS** (wash burning eyes with aqueous NaHCO<sub>3</sub>).

**Phosphorus pentasulfide** [1314-80-3] **M 444.5, m 277-283°, 290°, b 513-515.** Purify P<sub>2</sub>S<sub>5</sub> by extraction and crystallisation with CS<sub>2</sub>, using a Soxhlet extractor, and is heated in a CO<sub>2</sub> atmosphere at 150° to remove solvent. It liberates H<sub>2</sub>S in moist air. **HARMFUL VAPOURS.** [Klements in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 568 1963.]

**Phosphorus pentoxide** [1314-56-3] **M 141.9, m 562°, b 605°.** It has been sublimed at 250° under vacuum into glass ampoules. It fumes in moist air and reacts violently with water. It is an excellent drying agent for use in desiccators. **HARMFUL VAPOURS and attacks skin, use gloves.** [Manley *J Chem Soc* 121 331 1922, Klements in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 541 1963.]

**Phosphorus sesquisulfide**  $P_4S_3$  [1314-85-8] **M 220.1, m 172°**. Extract  $P_4S_3$  with  $CS_2$ , filter it and evaporate it to dryness. *Alternatively*, place it in  $H_2O$ , and pass steam through it for an hour. The  $H_2O$  is then removed, the solid is dried, and recrystallised from  $CS_2$  (with the usual  $CS_2$  precautions) [Rogers & Gross *J Am Chem Soc* **74** 5294 1952].

**Phosphorus sulfochloride (phosphorus thiochloride)** [3982-91-0] **M 169.4, m -35°, b 122-124°, 125°(corr),  $d_4^{30}$  1.64,  $n_D^{30}$  1.556**. Possible impurities are  $PCl_5$ ,  $H_3PO_4$ ,  $HCl$  and  $AlCl_3$ . Gently mix it with  $H_2O$  to avoid a heavy emulsion; the product decolourises immediately and settles to the bottom layer. It is soluble in  $*C_6H_6$  and  $CCl_4$ . [Duval *Inorg Synth* **IV** 73 1953.] **HARMFUL VAPOURS**.

**Phosphorus tribromide** [7789-60-8] **M 270.7, m -41.5°, b 168-170°/725mm, 171-173°/atm, 172.9°/760mm(corr),  $d_4^{30}$  2.852**. It is decomposed by moisture, it should be kept dry and is *corrosive*. Purify it by distillation through an efficient fractionating column [see Whitmore & Lux *J Am Chem Soc* **54** 3451] in a slow stream of dry  $N_2$ , i.e. under strictly dry conditions. [Gay & Maxson *Inorg Synth* **II** 147 1946, *Org Synth Col Vol II* 358 1943.] Dissolve it in  $CCl_4$ , dry it over  $CaCl_2$ , filter and distil it. Store it in sealed ampoules under  $N_2$  and keep it away from light. It is also commercially available as a 1.0M solution in  $CH_2Cl_2$  ( $d^{25}$  1.488). **HARMFUL VAPOURS**.

**Phosphorus trichloride** [7719-12-2] **M 137.3, b 76°,  $d_4^{20}$  1.575, n 1.515**. Heat it under reflux to expel dissolved  $HCl$ , then distil it. It has been further purified by vacuum fractionation several times through a -45° trap into a receiver at -78°. [Forbes *Inorg Synth* **II** 145 1946.] **HARMFUL VAPOURS**.

**Phosphorus triiodide** [13455-01-1] **M 411.7, m 61°**. It decomposes in moist air and must be kept in a desiccator over  $CaCl_2$ . It is crystallised from sulfur-free  $CS_2$ ; otherwise the **m** decreases to *ca* 55°. It is best to prepare it freshly. [Germann & Traxler *J Am Chem Soc* **49** 307 1927, Klement in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **I** p 541 1963.] **HARMFUL VAPOURS**.

**12-Phosphotungstic acid** [12501-23-4] **M 2880.2, m ~96°**. A few drops of conc  $HNO_3$  are added to 100g of phosphotungstic acid dissolved in 75ml of water, in a separating funnel, and the solution is extracted with diethyl ether. The lowest of the three layers, which contains a phosphotungstic acid-ether complex, is separated, washed several times with 2M  $HCl$ , then with water and again extracted with ether. Evaporation of the ether under vacuum with mild heating on a water bath gives crystals which are dried under vacuum and ground [Matijevic & Kerker, *J Am Chem Soc* **81** 1307 1959].

**Platinum (IV) ammonium chloride [ammonium hexachloroplatinate (IV),  $(NH_4)_2 PtCl_6$ ]** [16919-58-7] **M 443.9**. This salt is a useful Pt compound and is a very good source for preparing many amine complexes. It provides spongy Pt at high temperature. It is prepared by dissolving the less expensive spongy Pt (9.76g, 50mmol) in *aqua regia* (200ml,  $1HNO_3:4HCl$  by volume, and allowed to stand for 30 minutes until orange-red in colour) by heating and concentrating in an evaporating dish (*use an efficient fume hood and care as it is a dangerous operation*) to a thick syrup which is then taken almost to dryness on a water bath. Avoid drying at higher temperatures as it becomes incompletely soluble in  $H_2O$ . The orange-red crusty residue is dissolved in  $H_2O$  (100ml), filtered; and to it is add slowly a solution of  $NH_4Cl$  (8g, 150mmol) in  $H_2O$  (100ml) with stirring, when a yellow finely crystalline precipitate separates. Set the mixture aside for 30 minutes in an ice bath. Filter off the platinate salt and wash it several times with 1% aqueous  $NH_4Cl$  (30ml portions), then with  $EtOH$  (which removes any corresponding Pd salt impurity) and  $Et_2O$ . Dry the salt first in air, powder the crystals and dry further at 120° for 1 hour to provide an almost quantitative yield. Note that although the filtrates may be yellow in colour they only contain minute traces of Pt as the colour can be imparted at as low concentrations as 1 part in 20,000 parts of  $H_2O$ . The salt is not hygroscopic. Its solubility (by weight) in  $H_2O$  is 0.5% at 20° and 3.37% at 100°, and it is still less soluble in 1M  $NH_4Cl$  (0.0028%). It decomposes above 185° and yields *spongy Pt* at higher temperatures. It is reduced to the metal by  $H_2$  at 120° and yields  $H_2PtCl_6$  with  $Cl_2$ . [Kauffman *Inorg Synth* **9** 182 1967.]

**Platinum (II) chloride** [10025-65-7] **M 266.0, d<sub>4</sub><sup>20</sup> 5.87**. It is purified by heating at 450° in a stream of Cl<sub>2</sub> for 2 hours. Some sublimation occurs because the PtCl<sub>2</sub> sublimes completely at 560° as red (almost black) needles. This sublimate can be combined to the bulk chloride, and while still at *ca* 450° it should be transferred to a container and cooled in a desiccator. A probable impurity is PtCl<sub>4</sub>. To test for this add a few drops of H<sub>2</sub>O (in which PtCl<sub>4</sub> is soluble) to the salt, filter and add an equal volume of saturated aqueous NH<sub>4</sub>Cl to the filtrate. If no precipitate is formed within 1 minute, then the product is pure. If a precipitate appears, then the whole material should be washed with small volumes of H<sub>2</sub>O until the soluble PtCl<sub>4</sub> is removed. The purified PtCl<sub>2</sub> is partly dried by suction and then dried in a vacuum desiccator over P<sub>2</sub>O<sub>5</sub>. It is insoluble in H<sub>2</sub>O, but soluble in HCl to form chloroplatinic acid (H<sub>2</sub>PtCl<sub>4</sub>) by disproportionation. [Cohen *Inorg Synth* VI 209 1960.]

**Potassium bicarbonate** [298-14-6] **M 100.1**. It is crystallised from water at 65-70° (1.25ml/g) by filtering and then cooling to 15° (~0.4ml/g). During all operations, CO<sub>2</sub> is passed through the stirred mixture. The crystals are sucked dry at the pump, washed with distilled water, dried in air and then over H<sub>2</sub>SO<sub>4</sub> in an atmosphere of CO<sub>2</sub>. It is much less soluble than the carbonate in H<sub>2</sub>O (see below).

**Potassium biiodate** [13455-24-8] **M 389.9**. Crystallise the biiodate three times from hot water (3ml/g), and stirring continuously during each cooling. After drying at 100° for several hours, the crystals are suitable for use in volumetric analysis.

**Potassium bisulfate** [7646-93-7] **M 136.2, m 214°, 218°**. Crystallise it from H<sub>2</sub>O (1ml/g) between 100° and 0°. It is also formed when a warm solution of K<sub>2</sub>SO<sub>4</sub> in conc H<sub>2</sub>SO<sub>4</sub> is cooled down.

**Potassium borohydride** [13762-51-1] **M 53.9, m ~500°(dec)**. Crystallise it from liquid ammonia. It is slowly hydrolysed by H<sub>2</sub>O. Its solubility at ~20° in H<sub>2</sub>O or liquid NH<sub>3</sub> is 20%, in MeOH it is 0.7%, in Me<sub>2</sub>NCHO it is 15% and in MeOH/H<sub>2</sub>O (1:4) it is 13%. [Jons & Wallbridge *Progr Inorg Chem* 11 99-231 1970.]

**Potassium bromate** [7758-01-2] **M 167.0, m 350°(dec at 370°), d<sub>4</sub><sup>20</sup> 3.27**. Crystallise KBrO<sub>3</sub> from distilled H<sub>2</sub>O (2ml/g) between 100° and 0°. To remove bromide contamination, a 5% solution in distilled H<sub>2</sub>O, cooled to 10°, is bubbled with gaseous chlorine for 2 hours, then filtered and extracted with reagent grade CCl<sub>4</sub> until colourless and odourless. After evaporating the aqueous phase to about half its volume, it is cooled again slowly to about 10°. The crystalline KBrO<sub>3</sub> that separates, is washed with 95% EtOH and dried in a vacuum [Boyd et al. *J Am Chem Soc* 74 237 1952]. Another way to remove Br<sup>-</sup> ions is by stirring several times in MeOH and then drying at 150° [Field & Boyd *J Phys Chem* 89 3767 1985].

**Potassium bromide** [7758-02-3] **M 119.0, m 734°, d<sub>4</sub><sup>20</sup> 2.75**. Crystallise the bromide from distilled water (1ml/g) between 100° and 0°. Wash it with 95% EtOH, followed by Et<sub>2</sub>O. Dry it in air, then heat it at 115° for 1 hour, pulverise it, then heat it in a vacuum oven at 130° for 4 hours. It has also been crystallised from aqueous 30% EtOH, or EtOH, and dried over P<sub>2</sub>O<sub>5</sub> under vacuum before heating in an oven.

**Potassium carbonate** [584-08-7] **M 138.2, m 898°, d<sub>4</sub><sup>20</sup> 2.3**. It crystallises from water between 100° and 0°. The solubility in H<sub>2</sub>O is 105% at 0°, 127% at 60° and 205% at 135° (**b** of saturated solution). After two recrystallisations of technical grade material, it had B, Li and Fe at 1.0, 0.04 and 0.01 ppm, respectively. [Dönges in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 987 1963.]

**Potassium chlorate** [3811-04-9] **M 122.6, m 368°**. It has been recrystallised from water (1.8ml/g) between 100° and 0°, and the crystals were filtered onto sintered glass. Keep away from organic material as it oxidises them readily.

**Potassium chloride** [7447-40-7] **M 74.6, m 771°, d<sub>4</sub><sup>20</sup> 1.98**. Dissolve it in conductivity water, filter it, and saturate it with chlorine (generated from conc HCl and KMnO<sub>4</sub>). Excess chlorine is boiled off, and the KCl is precipitated by HCl (generated by dropping conc HCl into conc H<sub>2</sub>SO<sub>4</sub>). The precipitate is washed with water, dissolved in conductivity water at 90-95°, and crystallised by cooling to about -5°. The crystals are drained at the centrifuge, dried in a vacuum desiccator at room temperature, then fused in a platinum dish under N<sub>2</sub>, cooled

and stored in a desiccator. Potassium chloride has also been sublimed in a stream of pre-purified  $N_2$  gas and collected by electrostatic discharge [Craig & McIntosh *Can J Chem* **30** 448 1952].

**Potassium chromate** [7789-00-6] **M 194.2, m 975°**,  $d_4^{20}$  2.72,  $pK_1^{25}$  0.74,  $pK_2^{25}$  6.49 (for  $H_2CrO_4$ ). Crystallise it from conductivity water (0.6g/ml at 20°), and dry it between 135° and 170°.

**Potassium cobalticyanide** [13963-58-1] **M 332.4, m dec on heating**,  $d_4^{25}$  1.878. Crystallise it from water to remove traces of HCN. Its solubility in 87-88% EtOH is 1 in 7500 at 20°. [Glemser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1542 1965.]

**Potassium cyanate** [590-28-3] **M 81.1,  $d_4^{20}$  2.05,  $pK^{25}$  3.46 (for HCNO)**. Common impurities include ammonia and bicarbonate ion (from hydrolysis). Purify it by preparing a saturated aqueous solution at 50°, neutralising with acetic acid, filtering, adding two volumes of EtOH and keeping for 3-4 hours in an ice bath. (More EtOH can lead to co-precipitation of  $KHCO_3$ .) Filter, wash it with EtOH and dry it rapidly in a vacuum desiccator ( $P_2O_5$ ). The process is repeated [Vanderzee & Meyers *J Chem Soc* **65** 153 1961].

**Potassium cyanide** [151-50-8] **M 65.1, m 634°**,  $d_4^{20}$  1.52. A saturated solution in  $H_2O$ -ethanol (1:3) at 60° is filtered and cooled to room temperature. Absolute EtOH is added, with stirring, until crystallisation ceases. The solution is again allowed to cool to room temperature (during 2-3 hours), then the crystals are filtered off, washed with absolute EtOH, and dried, first at 70-80° for 2-3 hours, then at 105° for 2 hours [Brown et al. *J Phys Chem* **66** 2426 1962]. It has also been purified by melting in a vacuum and by zone refining. Its solubility is 33% ( $H_2O$ ), 66% (boiling  $H_2O$ ), 33% (glycerol), 4% (MeOH) and 1% (EtOH). It hydrolyses in  $H_2O$ , and a 0.1M aqueous solution of KCN has a pH of 11, i.e.  $CO_2$  in the  $H_2O$  makes it acidic enough to liberate a lot of the more poisonous HCN. To keep the HCN in solution it must be made quite alkaline (pH <11).  $LD_{50}$  oral toxicity in rat is ~10mg/Kg. **HIGHLY POISONOUS work in an efficient fume cupboard.**

**Potassium dichromate** [7778-50-9] **M 294.2, m 398°(dec)**,  $d_4^{20}$  2.68. Crystallise it from water (g/ml) between 100° and 0° and dry it under vacuum at 156°. (Possible **CARCINOGEN**.)

**Potassium dihydrogen phosphate** [7778-77-0] **M 136.1**. Dissolve it in boiling distilled water (2ml/g), keep on a boiling water-bath for several hours, then filter it through paper pulp to remove any turbidity. Cool rapidly with constant stirring, and the crystals are collected on to hardened filter paper, using suction, washed twice with ice-cold water, once with 50% EtOH, and dried at 105°. Alternative crystallisations are from water, then 50% EtOH, and again water, or from concentrated aqueous solution by addition of EtOH. It is freed from traces of Cu by extracting its aqueous solution with diphenylthiocarbazon in  $CCl_4$ , followed by repeated extraction with  $CCl_4$  to remove traces of diphenylthiocarbazon.

**Potassium dithionate** [13455-20-4] **M 238.3,  $pK_{Est(1)}$  -3.4,  $pK_2^{25}$  0.49 (for dithionic acid)**. Crystallise it from water (1.5ml/g) between 100° and 0°.

**Potassium ferricyanide** [13746-66-2] **M 329.3,  $pK^{25}$  <1 (for ferricyanide)**. It has been recrystallised repeatedly from hot water (1.3ml/g) and dried under vacuum in a desiccator.

**Potassium ferrocyanide trihydrate** [14459-95-1] **M 422.4,  $pK_3^{25}$  2.57,  $pK_4^{25}$  4.35 (for ferrocyanide)**. It is purified by repeated crystallisation from distilled water, and never heating above 60°. The *anhydrous* salt is prepared by drying at 110° over  $P_2O_5$  in a vacuum desiccator. To obtain the *trihydrate*, it is necessary to equilibrate the salt in a desiccator over a saturated aqueous solution of sucrose and NaCl. It can also be precipitated from a saturated solution at 0° by adding an equal volume of cold 95% EtOH, setting aside for several hours, then centrifuge and wash with cold 95% EtOH. It is finally sucked air dry with water-pump vacuum. The *anhydrous* salt is obtained by drying the hydrate in a platinum boat at 90° in a slow stream of  $N_2$  [Loftfield & Swift *J Am Chem Soc* **60** 3083 1938].

**Potassium fluorosilicate** [16871-90-2] **M 220.3,  $d_4^{20}$  2.3,  $pK^{25}$  1.92 (for  $H_2SiF_6$ )**. Crystallise it several times from conductivity water (100ml/g) between 100° and 0°.

**Potassium hexachloroiridate (III) ( $K_3IrCl_6$ )** [14024-41-1] **M 483.1**. Crystallise it from hot aqueous solution, and the solution should be olive-green in colour. If it has a tinge of red, then some would have oxidised to ( $K_2IrCl_6$ ) [see following entry]. In this case make a concentrated solution in  $H_2O$ , and bubble  $H_2S$  through until the solution is clearly olive-green in colour due to Ir(III). Add KCl and  $K_3IrCl_6 \cdot 3H_2O$  deposits on evaporating under  $N_2$ . Filter it off, wash it with a little  $H_2O$ , then EtOH and dry it *in vacuo* away from air. [Grube in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II pp 1595 1965.]

**Potassium hexachloroiridate (IV) ( $K_2IrCl_6$ )** [16920-56-2] **M 522.2**. Crystallise it from hot aqueous solution containing a few drops of  $HNO_3$  to keep it in the oxidised state. It forms small shiny red-black octahedral crystals which are dried at  $100^\circ$  and give a red powder on grinding [Grube in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II pp 1593-1594 1965].

**Potassium hexachloroosmate (IV)** [16871-60-6] **M 481.1**. Crystallise it from hot dilute aqueous HCl. [Turner et al. *Anal Chem* **30** 1708 1958.]

**Potassium hexachloroplatinate (IV)** [16921-30-5] **M 486.0, m 250<sup>o</sup>(dec)**. It crystallises from water (20ml/g) between 100 and  $0^\circ$ . Its solubility in  $H_2O$  is 0.7% at  $0^\circ$ , 1.12% at  $20^\circ$ , 2.16% at  $50^\circ$  and 5.13% at  $100^\circ$ . [Grube in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1571 1965.]

**Potassium hexacyanochromate (III) ( $K_3[Cr(CN)_6] \cdot 3H_2O$ )** [13601-11-1] **M 418.5**. It forms yellow crystals from water. Recrystallise it two or three times from  $H_2O$  and dry it over  $H_2SO_4$ . Its solubility at  $20^\circ$  is 30.96g/100g  $H_2O$ , and it is insoluble in EtOH. Aqueous solutions tend to decompose especially in the presence of light or on heating when  $Cr(OH)_3$  separates. [Hein & Herzog in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II pp 1373-1374 1965.]

**Potassium hexafluorophosphate** [17084-13-8] **M 184.1,  $pK_1^{25} \sim 0.5$ ,  $pK_2^{25} 5.12$  (for fluoro-phosphoric acid  $H_2PO_3F$ )**. Crystallise it from alkaline aqueous solution, using polyethylene vessels, or from 95% EtOH, and dry it in a vacuum desiccator over KOH. [Kloditz *Z Anorg Allgem Chem* **284** 144 1956, Kwasnik in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 196 1963.]

**Potassium hexafluorozirconate ( $K_2ZrF_6$ )** [16923-95-8] **M 283.4,  $d_4^{20} 3.48$** . Recrystallise it from hot water (solubility is 0.78% at  $2^\circ$  and 25% at  $100^\circ$ ).

**Potassium hydrogen fluoride** [7789-29-9] **M 78.1, m 225<sup>o</sup>(dec)**. It crystallises from water. It is very soluble in hot  $H_2O$  and 41% at  $21^\circ$ . [Kwasnik in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 237 1963.]

**Potassium hydroxide (solution)** [1310-58-3] **M 56.1,  $pK^{25} 16$  (for aquo  $K^+$ )**. Its carbonate content can be reduced by rinsing KOH sticks rapidly with water prior to dissolving them in boiled out distilled water. Alternatively, a slight excess of saturated  $BaCl_2$  or  $Ba(OH)_2$  can be added to the solution which, after shaking well, is set aside so that the  $BaCO_3$  is allowed to separate out. Davies and Nancollas [*Nature* **165** 237 1950] rendered KOH solutions carbonate free by ion exchange using a column of Amberlite IR-100 in the  $OH^-$  form.

**Potassium iodate** [7758-05-6] **M 214.0,  $pK^{25} 0.80$  (for  $HIO_3$ )**. It has been crystallised twice from distilled water (3ml/g) between 100 and  $0^\circ$ , dried for 2 hours at  $140^\circ$  and cooled in a desiccator. Analytical reagent grade material dried in this way is suitable for use as an analytical standard.

**Potassium iodide** [7681-11-0] **M 166.0,  $pK^{25} -8.56$  (for HI)**. Crystallise it from distilled water (0.5ml/g) by filtering the near-boiling solution and cooling. To minimise oxidation to iodine, the process can be carried out under  $N_2$  and the salt is dried under a vacuum over  $P_2O_5$  at  $70-100^\circ$ . Before drying, the crystals can be washed with EtOH or with acetone followed by petroleum ether. It has also been recrystallised from water/ethanol. After 2 recrystallisations, ACS/USP grade had Li and Sb at  $<0.02$  and  $<0.01$  ppm respectively. [Lingane & Kolthoff *Inorg Synth* **I** 163 1939.]

**Potassium nickel sulfate hexahydrate** [13842-46-1] **M 437.1**. Crystallise it from H<sub>2</sub>O (1.7ml/g) between 75 and 0°.

**Potassium nitrate (saltpetre)** [7757-79-1] **M 101.1, m 336°**. It crystallises from hot H<sub>2</sub>O (0.5ml/g) on cooling (cf KNO<sub>2</sub> below). Dry it for 12 hours under vacuum at 70°. The solubility in H<sub>2</sub>O is 13.3% at 0°, 110% at 60°, and 246% at 100°. After two recrystallisations, technical grade salt had <0.001 ppm of metals. The fused salt is a powerful oxidising agent.

**Potassium nitrite** [7758-09-0] **M 85.1, m 350°(dec), pK<sup>20</sup> 3.20 (for HNO<sub>2</sub>)**. A saturated solution at 0° is warmed and partially evaporated under vacuum. The crystals so obtained are filtered off from the warm solution. (This procedure is designed to reduce the level of nitrate impurity and is based on the effects of temperature on solubility. The solubility of KNO<sub>3</sub> in water is 13g/100ml at 0°, 247g/100ml at 100°; for KNO<sub>2</sub> the corresponding figures are 280g/100ml and 413g/100ml.) *Alternatively*, dissolve it in H<sub>2</sub>O and precipitate by adding of EtOH.

**Potassium nitrosodisulfonate (Fremy's Salt)** [14293-70-0] **M 268.3**. It forms yellow needles (dimeric) which dissolve in H<sub>2</sub>O to give the violet monomeric free radical. It is purified by dissolving (~12g) in 2M KOH (600ml) at 45°, filtering the blue solution and keeping it in a refrigerator overnight. The golden yellow crystals (10g) are filtered off, washed with MeOH (3x), then Et<sub>2</sub>O and stored in a glass container in a vacuum over KOH. It is stable indefinitely when dry. [Cram & Reeves *J Org Chem* **80** 3094 1958, Schenk *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 505 1963.]

**Potassium osmate (VI) dihydrate** [19718-36-6] **M 368.4**. It forms *hygroscopic POISONOUS* crystals which are soluble in H<sub>2</sub>O but insoluble in EtOH and Et<sub>2</sub>O. It decomposes slowly in H<sub>2</sub>O to form the *tetroxide* which attacks the eyes. The solid should be kept dry and in this form it is relatively safe. [Lloyd et al. *Synthesis* 610 1972, Grube in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1604 1965.]

**Potassium perchlorate** [7778-74-7] **M 138.6, m 400(dec), d<sub>4</sub><sup>20</sup> 2.52, pK<sup>25</sup> -2.4 to -3.1 (for HClO<sub>4</sub>)**. It crystallises from boiling water (5ml/g) on cooling. Dry it under vacuum at 105°.

**Potassium periodate (potassium metaperiodate)** [7790-21-8] **M 230.0, m 582°, d<sub>4</sub><sup>20</sup> 3.62**. Crystallise it from distilled water. Its solubility in H<sub>2</sub>O is 0.2% at 0°, 0.4% at 20°, 4.4% at 80° and 7.9% at 100°. [Hill *Inorg Synth* I 171 1939, Schmeisser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 325 1963.]

**Potassium permanganate** [7722-64-7] **M 158.0, m 240(dec), d<sub>4</sub><sup>20</sup> 2.7, pK<sup>25</sup> -2.25 (for HMnO<sub>4</sub>)**. Crystallise it from hot water (19ml/g at 15°, 4ml/g at 65°), then dry it in a vacuum desiccator over CaSO<sub>4</sub>. Phillips and Taylor [*J Chem Soc* 4242 1962] cooled an aqueous solution of KMnO<sub>4</sub>, saturated at 60°, to room temperature in the dark, and filtered it through a No.4 porosity sintered-glass filter funnel. The solution was allowed to evaporate in air in the dark for 12 hours, and the supernatant liquid was decanted from the crystals, which were dried as quickly as possible with filter paper. It is a secondary analytical standard. It is a useful oxidant and is used as a topical antiseptic.

**Potassium peroxydisulfate (potassium persulfate, K<sub>2</sub>S<sub>2</sub>O<sub>8</sub>)** [7727-21-1] **M 270.3**. Crystallise the persulfate twice from distilled water (10ml/g) and dry it at 50° in a vacuum desiccator. Its solubility in H<sub>2</sub>O is 1.6% at 0°, 4.5% at 20°, and 7.2% at 30°. An aqueous solution decomposes on long standing with evolution of O<sub>2</sub> and formation of KHSO<sub>4</sub>. It is a powerful oxidising agent. Store it at ~10°. [Fehér in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 390 1963.]

**Potassium peroxymonosulfate (Oxone, potassium monopersulfate triple salt; 2KHSO<sub>5</sub>·KHSO<sub>4</sub>·K<sub>2</sub>SO<sub>4</sub>)**, [37222-66-5, 70693-62-8 (*triple salt*)] **M 614.8**. This is a stable form of Caro's acid and should contain >4.7% of active oxygen. It can be used in EtOH/H<sub>2</sub>O and EtOH/AcOH/H<sub>2</sub>O solutions. If active oxygen is too low, it is

best to prepare it afresh from 1mole of  $\text{KHSO}_5$ , 0.5mole of  $\text{KHSO}_4$  and 0.5mole of  $\text{K}_2\text{SO}_4$ . [Kennedy & Stock *J Org Chem* **25** 1901 1960, Stephenson US Patent 2,802,722 1957.] A rapid preparation of *Caro's acid* is made by stirring finely powdered potassium persulfate (M 270.3) into ice-cold conc  $\text{H}_2\text{SO}_4$  (7ml) and when homogeneous add ice (40-50g). It is stable for several days if kept cold. Keep away from organic matter as it is a **STRONG OXIDANT**. A detailed preparation of *Caro's acid* (*hypersulfuric acid*,  $\text{H}_2\text{SO}_5$ , [7722-86-3]) in crystalline form m  $-45^\circ$  from  $\text{H}_2\text{O}_2$  and chlorosulfonic acid was described by Fehér in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 388 1963.

**Potassium perrhenate ( $\text{KReO}_4$ )** [10466-65-6] M 289.3, m  $550^\circ$ , b 1360-1370 $^\circ$ , d<sub>4</sub><sup>25</sup> 4.887, n<sub>D</sub><sup>25</sup> 1.643. pK<sup>25</sup> -1.25 (for  $\text{HReO}_4$ ). It forms white tetrahedral crystals from  $\text{H}_2\text{O}$  where its solubility is 12.1g/L at  $20^\circ$  and 140g/L at  $100^\circ$ . The salt is then fused in a platinum crucible in air at  $750^\circ$ . [Smith & Long *J Am Chem Soc* **70** 354 1948, Watt & Thompson *Inorg Synth* **7** 187 1963.]

**Potassium reineckate** [34430-73-4] M 357.5. Crystallise it from  $\text{KNO}_3$  solution, then from warm water [Adamson *J Am Chem Soc* **80** 3183 1958].

**Potassium(VI) ruthenate** [31111-21-4] M 243.3. Dissolve the ruthenate in  $\text{H}_2\text{O}$  and evaporate until crystals are formed. The crystals are iridescent green prisms which appear red in thin films. A possible impurity is  $\text{RuO}_4$ ; in this case wash with  $\text{CCl}_4$  (which dissolves  $\text{RuO}_4$ ). The concentration of an aqueous solution of  $\text{RuO}_4^{2-}$  (orange colour) can be estimated from the absorbance at 385nm ( $\epsilon$  1030  $\text{M}^{-1} \text{cm}^{-1}$ ), or at 460nm ( $\epsilon$  1820  $\text{M}^{-1} \text{cm}^{-1}$ ). [Lee et al. *Can J Chem* **50** 3741 1972, Connic & Hurley *J Am Chem Soc* **74** 5012 1952, Grube et al. *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1600 1965].

**Potassium selenocyanate** [3425-46-5] M 144.1. Dissolve it in acetone, filter and precipitate it by adding  $\text{Et}_2\text{O}$ .

**Potassium sulfate** [7778-80-5] M 174.3, m  $1069^\circ$ , d<sub>4</sub><sup>20</sup> 2.67. It crystallised from distilled water (4ml/g at  $20^\circ$ ; 8ml/g at  $100^\circ$ ) between  $100^\circ$  and  $0^\circ$ .

**Potassium tetrachloroplatinate(II)** [10025-99-7] M 415.1, m  $500^\circ(\text{dec})$ . It forms crystals from aqueous 0.75M  $\text{HCl}$  (20ml/g) between  $100^\circ$  and  $0^\circ$ . Wash them with ice-cold water and dry.

**Potassium tetracyanopalladate (II) trihydrate** [10025-98-6] M 377.4. All operations should be carried out in an efficient fume cupboard. **Cyanide is very POISONOUS**. Dissolve the complex (ca 5g) in a solution of  $\text{KCN}$  (4g) in  $\text{H}_2\text{O}$  (75ml) with warming and stirring, and evaporate hot till crystals appear. Cool, filter off the crystals and wash them with a few drops of cold  $\text{H}_2\text{O}$ . Further concentration of the mother liquors provides more crystals. The complex is recrystallised from  $\text{H}_2\text{O}$  as the colourless *trihydrate*. It *effloresces* in dry air and dehydrates at  $100^\circ$  to the *monohydrate*. The *anhydrous salt* is obtained by heating at  $200^\circ$ , but at higher temperatures it decomposes to  $(\text{CN})_2$ , Pd and  $\text{KCN}$ . [Bigelow *Inorg Synth* **II** 245 1946.]

**Potassium tetrafluoroborate (potassium borofluoride)** [14075-53-7] M 125.9, m  $530^\circ$ , d<sub>4</sub><sup>30</sup> 2.505, pK<sup>25</sup> -4.9 (for  $\text{HBF}_4$ ). Crystallise it from  $\text{H}_2\text{O}$  (solubility% (temperature): 0.3 ( $3^\circ$ ), 0.45 ( $20^\circ$ ), 1.4 ( $40^\circ$ ), 6.27 ( $100^\circ$ ), and dry it under vacuum. It is a non-hygroscopic salt. A 10% solution is transparent blue at  $100^\circ$ , green at  $90^\circ$  and yellow at  $60^\circ$ . [Vörlander et al. *Chem Ber* **65** 535 1932, Kwasnik in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 223 1963.]

**Potassium thiocyanate** [333-20-0] M 97.2, m  $172^\circ$ , pK<sup>25</sup> -1.85 (for  $\text{HSCN}$ ). Crystallise it from  $\text{H}_2\text{O}$  if much chloride ion is present in the salt, otherwise from  $\text{EtOH}$  or  $\text{MeOH}$  (optionally by addition of  $\text{Et}_2\text{O}$ ). Filter off on a Büchner funnel without paper, and dry it in a desiccator at room temperature before heating for 1 hour at  $150^\circ$ , with a final 10-20 minutes at  $200^\circ$  to remove the last traces of solvent [Kolthoff & Lingane *J Am Chem Soc* **57** 126 1935]. Store it in the dark.

**Potassium thiosulfate hydrate** [13446-67-8, 10294-66-3 (75% aqueous solution)] **M 190.3**,  $\text{pK}_1^{25}$  **0.6**,  $\text{pK}_2^{25}$  **1.74** (for  $\text{H}_2\text{S}_2\text{O}_3$ ). Crystallise it from warm water (0.5ml/g) by cooling in an ice-salt mixture. It is a good reducing agent used in analytical chemistry. [Foerster & Mommen *Chem Ber* **57** 258 1924.]

**Potassium tungstate (ortho dihydrate)** [37349-36-3; 7790-60-5] **M 362.1**, **m 921°**,  $d_4^{20}$  **3.12**,  $\text{pK}_1^{25}$  **2.20**,  $\text{pK}_2^{25}$  **3.70** (for  $\text{H}_2\text{WO}_4$ ). Crystallise it from hot water (0.7ml/g).

**Praseodymium trichloride hexahydrate** [10361-79-2] **M 355.4**,  $\text{pK}_1^{25}$  **8.55** (for  $\text{Pr}^{3+}$  hydrol). Its 1M solution in 6M HCl is passed twice through a Dowex-1 anion-exchange column. The eluate is evaporated in a vacuum desiccator to half its volume and allowed to crystallise [Katzin & Gulyas *J Phys Chem* **66** 494 1962].

**Praseodymium oxide ( $\text{Pr}_6\text{O}_{11}$ )** [12037-29-5] **M 1021.4**. Dissolve the oxide in acid (perchloric acid), precipitate it as the oxalate and the salt is ignited at 650° to give the oxide.

**Reinecke salt.** See ammonium reineckate above.

**Rhodium (I) carbonyl chloride (di- $\mu$ -chloro-tetracarbonyl dirhodium I,  $[\text{Rh}(\text{CO})_2\text{Cl}]_2$ )** [14532-22-9] **M 388.8**, **m 121°**, **124-125°**. This catalyst is soluble in most organic solvents, but not petroleum ethers, and forms orange-red crystals from hexane. It sublimes at 80°/0.1mm to a red solid. It decomposes on exposure to air when in organic solvents but the solid is stable in dry air. It is moisture sensitive and should be stored in ampoules under  $\text{N}_2$  or argon. It catalyses ring-opening silylformylation of olefins. [McCleverty & Wilkinson *Inorg Synth* **8** 211 1966, Dahl et al. *J Am Chem Soc* **83** 1761 1961, Cramer *Inorg Synth* **15** 14 1974, Fukumoto et al. *J Org Chem* **58** 4187 1993, Colton et al. *Aust J Chem* **23** 1351 1970.]

**Rhodium (III) chloride** [10049-07-7] **M 209.3**, **m >100°(dec)**, **b 717°**. Probable impurities are KCl and HCl. Wash the chloride well with small volumes of  $\text{H}_2\text{O}$  to remove excess KCl and KOH and dissolve it in the minimum volume of conc HCl. Evaporate it to dryness on a steam bath to give wine-red coloured  $\text{RhCl}_3 \cdot 3\text{H}_2\text{O}$ . Leave it on the steam bath until the odour of HCl is lost – do not try to dry further as it begins to decompose above 100° to the oxide and HCl. It is not soluble in  $\text{H}_2\text{O}$  but soluble in alkalis or CN solutions and forms double salts with alkali chlorides. [Anderson & Basolo *Inorg Synth* **VII** 214 1963.]

**Rubidium bromide** [7789-39-1] **M 165.4**, **m 682°**, **b 1340°**,  $d_4^{20}$  **3.35**. The bromide is a white crystalline powder which crystallises from  $\text{H}_2\text{O}$  (solubility: 50% in cold and 67% in boiling  $\text{H}_2\text{O}$  to give a neutral solution). It also crystallises from near-boiling water (0.5ml/g) by cooling to 0°.

**Rubidium chlorate** [13446-71-4] **M 168.9**,  $d_4^{20}$  **3.19**. It crystallises from water (1.6ml/g) by cooling from 100°.

**Rubidium chloride** [7791-11-9] **M 120.9**, **m 715°**, **m 1383°**,  $d_4^{20}$  **2.80**. Crystallise it from water (0.7ml/g) by cooling to 0° from 100°. Its solubility in  $\text{H}_2\text{O}$  is 77.3% at 0.6°, 90.3% at 70° and 147% at boiling point. [Dönges in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **I** p 951-955 1963.]

**Rubidium nitrate** [13126-12-0] **M 147.5**, **m 305°**,  $d_4^{20}$  **3.11**. Crystallise the nitrate from hot water (0.25ml/g) by cooling to room temperature.

**Rubidium perchlorate** [13510-42-4] **M 184.9**,  $d_4^{20}$  **2.80**,  $\text{pK}^{25}$  **-2.4 to -3.1** (for  $\text{HClO}_4$ ). Crystallise the perchlorate from hot water (1.6ml/g) by cooling to 0°.

**Rubidium sulfate** [7488-54-2] **M 267.0**, **m 1050°**,  $d_4^{20}$  **6.31**. Crystallise the sulfate from water (1.2ml/g) between 100° and 0°.

**Ruthenium (III) chloride dihydrate ( $\beta$ -form)** [14898-67-0] **M 207.4 +  $\text{H}_2\text{O}$** , **m >500°(dec)**,  $d_4^{20}$  **3.11**,  $\text{pK}_1^{25}$  **3.40** (for aquo  $\text{Rh}^{3+}$  hydrolysis). Dissolve the salt in  $\text{H}_2\text{O}$ , filter and concentrate to crystallisation in the

absence of air to avoid oxidation. Evaporate the solution in a stream of HCl gas while being heated just below its boiling point until a syrup is formed and finally to dryness at 80-100° and dried in a vacuum over H<sub>2</sub>SO<sub>4</sub>. When heated at 700° in the presence of Cl<sub>2</sub> the insoluble  $\alpha$ -form is obtained [Grube in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1598 1965, Carlsen et al. *J Org Chem* **46** 3936 1981].

**Ruthenium (IV) oxide** [12036-10-1] M 133.1, d<sub>4</sub><sup>20</sup> 6.97. Free the oxide from nitrates by boiling in distilled water and filtering. A more complete purification is based on fusion in a KOH/KNO<sub>3</sub> mix to form the soluble ruthenate and perruthenate salts. The melt is dissolved in water, and filtered, then acetone is added to reduce the ruthenates to the insoluble hydrated oxide which, after making a slurry with paper pulp, is filtered and ignited in air to form the *anhydrous* oxide [Campbell et al. *Anal Chem* **33** 58 1961].

**Samarium (II) iodide (SmI<sub>2</sub>)** [32248-43-4] M 404.2, m 520°, b 1580. A possible impurity is SmI<sub>3</sub> from which it is made. If present, grind the solid to a powder and heat it in a stream of pure H<sub>2</sub>. The temperature (~ 500-600°) should be below the m (~628°) of SmI<sub>3</sub>, since the molten compounds react very slowly. [Wetzel in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II pp 1149, 1150 1965.] It promotes a pseudo-Barbier reaction between aldehydes and ketones with aliphatic or alicyclic halides (see NdI<sub>2</sub>) [Namy et al. *J Organomet Chem* **328** 81 1987.] It is a one-electron reducing agent [Brendt et al. *Aldrichim Acta* **24** 15 1991.]

**SmI<sub>2</sub> in THF** for reactions is prepared in a dry box, or dry gloves, filled with N<sub>2</sub> (not generally necessary for synthetic purposes, but should be used for Grignard-type conditions, i.e. exclusion of moisture) from samarium powder (3g, 20mmol, or distilled metal or ingot), placed in a flask fitted with a dropping funnel containing 1,2-diiodoethane (22.82g, 10mmol) in THF (250ml) which is added dropwise. The reaction has no induction period if the solvent is pure. [Excess metal can be re-used later.] An intense blue-green solution results with a SmI<sub>2</sub> concentration of 4 x 10<sup>-2</sup> M in THF that can be diluted to 10<sup>-1</sup> M. These solutions can be stored for a long time without loss of Sm<sup>2+</sup> concentration if kept in an inert atmosphere in the presence of a small amount of metal. However, it is best to use them within a few days to ensure reproducible results. In addition to promoting coupling reactions, it is also a powerful and selective reducing agent for olefins [Girard et al. *J Am Chem Soc* **102** 2693 1980, see also Asano et al. *Synthesis* 1309 2007], promotes the reaction of chlorofluoroacetonitrile [359-05-7] with aldehydes to form cyanofluorohydrins in the presence of HMPA [Asano et al. *Synthesis* 1309 2007], intramolecular cyclisation reactions [Molander & McKie *J Org Chem* **59** 3186 1994], and intermolecular ketone-olefin coupling reactions [Kawatsura et al. *J Org Chem* **59** 6900 1994].

**Selenious acid** [7783-00-8] M 129.0, m 70°(dec), d<sub>D</sub><sup>20</sup> 3.0, pK<sub>1</sub><sup>25</sup> 2.62, pK<sub>2</sub><sup>25</sup> 8.32 (H<sub>2</sub>SeO<sub>3</sub>). Recrystallise the acid from water. On heating it loses water and SeO<sub>2</sub> sublimes. [Waitkins & Clark *Chem Rev* **36** 235 1945.]

**Selenium** [7782-49-2] M 79.0, m 217.4°, d<sub>4</sub><sup>20</sup> 4.81. Dissolve selenium in small portions in hot conc HNO<sub>3</sub> (2ml/g), filter and evaporate to dryness to give selenious acid which is then dissolved in conc HCl. Pass SO<sub>2</sub> gas through the solution whereby selenium (but not tellurium) precipitates. It is filtered off and washed with conc HCl. This purification process is repeated. The selenium is then converted twice to the selenocyanate by treating with a 10% excess of 3M aqueous KCN (CARE), heated for half an hour on a sand-bath and filtered. Add an equal weight of crushed ice to the cold solution, followed by an excess of cold, conc HCl, with stirring (in an efficient fume cupboard as HCN is evolved) which precipitates selenium powder. This is washed with water until colourless, and then with MeOH and is heated in an oven at 105°. Finally it is fused for 2 hours *in vacuo*. It is cooled, crushed and stored in a desiccator [Tideswell & McCullough *J Am Chem Soc* **78** 3036 1956].

**Selenium dioxide** [7446-08-4] M 111.0, m 340°. Purify it by sublimation at 315°, or by solution in HNO<sub>3</sub>, precipitation of selenium which, after standing for several hours or boiling, is filtered off, then re-oxidised by HNO<sub>3</sub> and cautiously evaporated to dryness below 200°. The dioxide is dissolved in H<sub>2</sub>O and again evaporated to dryness. In H<sub>2</sub>O it forms selenious acid (see selenious acid above). Its solubility in H<sub>2</sub>O is 70%w/w at 20°, and it is soluble in EtOH. It is a useful and selective oxidant. [Waitkins & Clark *Chem Rev* **36** 235 1945, Fehér in *Handbook of Preparative Inorganic Chemistry* (Ed Brauer) Academic Press Vol I p 421 1963.]

**Silica** [7631-86-9 (*colloidal*), 60676-86-0 (*Quartz, Cristobalite, sand*), 112945-52-5 (*fumed*)]. Purification of silica for high technology applications uses isopiestic vapour distillation from concentrated volatile acids and is absorbed in high purity water. The impurities remain behind. Preliminary cleaning to remove surface contaminants uses dip etching in HF or a mixture of HCl, H<sub>2</sub>O<sub>2</sub> and deionised water [Phelan & Powell *Analyst* **109** 1299 1984].

**Silica gel** [63231-67-4, 112926-00-8]. Before use as a drying agent, silica gel is heated in an oven, then cooled in a desiccator. Conditions in the literature range from heating at 110° for 15 hours to 250° for 2-3 hours. Silica gel has been purified by washing with hot acid (in one case successively with *aqua regia*, conc HNO<sub>3</sub>, then conc HCl; in another case it was digested overnight with hot conc H<sub>2</sub>SO<sub>4</sub>), followed by exhaustive washing with distilled water (one week in a Soxhlet apparatus has also been used), and prolonged oven drying. *Alternatively*, silica gel has been extracted with acetone until all soluble material was removed, then dried in a current of air, washed with distilled water and oven dried. Silica gel has also been washed successively with water, M HCl, water, and acetone, then activated at 110° for 15 hours.

**Silicon monoxide** [10097-28-6] **M 44.1, m > 1700°, d<sub>4</sub><sup>20</sup> 2.18**. Purify the monoxide by sublimation in a porcelain tube in a furnace at 1250° (4 hours) in a high vacuum (10<sup>-4</sup>mm) in a stream of N<sub>2</sub>. It is obtained as brownish black scales. [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 696 1963.]

**Silicon tetrachloride** [10026-04-7] **M 169.9, m -70°, b 57.6°, d<sub>4</sub><sup>20</sup> 1.483**. Distil it under vacuum and store it in sealed ampoules under N<sub>2</sub>. It fumes in moist air and is very sensitive to moisture. It is soluble in organic solvents. It is a **strong irritant**. [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 682-683 1963.]

**12-Silicotungstic acid (tungstosilicic acid; H<sub>4</sub>SiW<sub>12</sub>O<sub>40</sub>)** [12027-43-9] **M 2914.5**. Extract the acid with diethyl ether from a solution acidified with HCl. The diethyl ether is evaporated under vacuum, and the free acid is crystallised twice [Matijevic & Kerker *J Phys Chem* **62** 1271 1958].

**Silver (metal)** [7440-22-4] **M 107.9, m 961.9°, b 2212°, d<sub>4</sub><sup>20</sup> 10.5**. For purification by electrolysis, see Craig et al. [*J Res Nat Bur Stand* **64A** 381 1960]. For purification of crude, or silver residues to pure silver see Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 1028-1030 1963, and for the preparation of *colloidal silver* see *ibid* (Ed. Brauer) p 1034.

**Silver acetate** [563-63-3] **M 166.9, dec on heating, d<sub>25</sub> 3.259**. The salt is a white (or slightly gray if exposed to light) crystalline powder or lustrous needles, which should not be exposed to light for long periods. It can be purified by recrystallisation from H<sub>2</sub>O (preferably containing a little AcOH) as its solubility (w/v) in cold H<sub>2</sub>O is 1% and in boiling H<sub>2</sub>O it is 35%. *Alternatively*, it is boiled with Ac<sub>2</sub>O, the insoluble salt is collected and recrystallised from glacial AcOH. It is freely soluble in dilute HNO<sub>3</sub>. Store in dark bottles away from light. [Beilstein **2 H** 110, **2 I** 48, **2 II** 116, **2 III** 189, **2 IV** 112.]

It oxidises a green solution of U(IV) acetate in liquid NH<sub>3</sub> to the yellow U(VI) in a few hours with the formation of the tris complex (NH<sub>4</sub>)U(VI)O<sub>2</sub>(AcO)<sub>3</sub> [isolated], acetamide and Ag metal [Kline & Kershner *Inorg Chem* **5** 932 1966].

At a 0.2-2 mole%, AgOAc catalyses efficient cycloaddition reactions of methyl isocyanoacetate with olefin Michael-acceptors at ambient temperature to produce Δ<sup>1</sup>- or Δ<sup>2</sup>-pyrrolines in good yields. Isocyanoacetates undergo AgOAc catalysed cyclodimerisation to imidazoles in excellent yields in the absence of a suitable olefin. Also, when combined with azomethine ylide, AgOAc catalyses a 1,3-dipolar cycloaddition reaction in a one-pot sequential cascade process to yield the 7-azabicyclo[2.2.1]heptane ring system which is characteristic of the naturally occurring potent non-opioid analgesic epibatidine [originally isolated from the skin of the Ecuadoran poison frog *Epipedobates tricolor*, Spande et al. *J Am Chem Soc* **114** 3475 1992]. [Grigg et al. *Tetrahedron* **55** 2025 1999.]

When combined with I<sub>2</sub>, AgOAc in aqueous or anhydrous AcOH reacts with olefins to form *vicinal diols* (glycols). The hydroxylations are not always *cis* [Woodward & Brucher *J Am Chem Soc* **80** 209 1958, Ginsberg *J Am Chem Soc* **75** 5746 1953, Barkley et al. *J Am Chem Soc* **76** 5014 1954, Klass et al. *J Am Chem Soc* **77** 2329

1955, Slates & Wendler *J Am Chem Soc* **78** 3749 1956, Jefferies & Milligan *J Chem Soc* 2363 1956, Gunstone & Morris *J Chem Soc* 487 1957, Ellington et al. *J Chem Soc* 1327 1966], but can produce *cis/trans* diol mixtures depending on the olefin [Bunton & Carr *J Chem Soc* 770 1963].

**Silver bromate** [7783-89-3] **M 235.8, m dec on heating,  $d_4^{20}$  5.21**. It crystallises from hot water (80ml/g). It reacts with bromine water to form bromic acid (HBrO<sub>3</sub>) which is a strong oxidising agent. Store it in the dark.

**Silver bromide** [7785-23-1] **M 187.8, m 432°,  $d_4^{20}$  6.47**. Purify it from Fe, Mn, Ni and Zn by zone melting in a quartz vessel under vacuum. It is insoluble in dilute HNO<sub>3</sub> or dilute NH<sub>3</sub> but is soluble in conc NH<sub>3</sub>. Store it in the dark.

**Silver chlorate** [7783-92-8] **M 191.3, m 230°, b 270°(dec),  $d_4^{20}$  4.43**. Recrystallise the chlorate three times from water (10ml/g at 15°; 2ml/g at 80°). Store it in the dark. [Nicholson & Holley *Inorg Synth II* 4 1946, Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol I p 1037 1963.]

**Silver chloride** [7783-90-6] **M 143.3, m 455°, b 1550°,  $d_4^{20}$  5.56**. Recrystallise it from conc NH<sub>3</sub> solution by acidifying with HCl, filtering off the solid, washing it with H<sub>2</sub>O and drying it in a vacuum. It is soluble in NH<sub>3</sub> and should be kept in the dark.

**Silver chromate** [7784-01-2] **M 331.8,  $d_4^{25}$  5.625,  $pK_1^{25}$  0.74,  $pK_2^{25}$  6.49 (for H<sub>2</sub>CrO<sub>4</sub>)**. Wash the red-brown powder with H<sub>2</sub>O, dry it in a vacuum, then powder well and dry again in a vacuum at 90°/5 hours. Its solubility in H<sub>2</sub>O is 0.0014% at 10°. Store it in the dark. [Cardillo & Shimizu *J Org Chem* **42** 4268 1977.]

**Silver cyanide** [506-64-9] **M 133.9, m dec at 320°,  $d_4^{20}$  3.95**. It is a **POISONOUS** white or grayish white powder. Stir it thoroughly with H<sub>2</sub>O, filter, wash well with EtOH and dry it in air in the dark. It is very insoluble in H<sub>2</sub>O (0.000023g in 100ml H<sub>2</sub>O), but is soluble in HCN or aqueous KCN to form the soluble Ag(CN)<sub>2</sub><sup>-</sup> complex. [Schnitz-Dumont *Chem Ber* **72** 298 1939, Randall & Halford *J Am Chem Soc* **52** 184 1930.]

**Silver difluoride** [7783-95-1] **M 145.9, m 690°,  $d_4^{20}$  4.7**. It is highly **TOXIC** because it liberates HF and F<sub>2</sub>. It is very *hygroscopic* and reacts violently with H<sub>2</sub>O. It is a powerful oxidising agent and liberates O<sub>3</sub> from dilute acids, and I<sub>2</sub> from I<sup>-</sup> solution. Store it in quartz or iron ampoules. It is white when pure; otherwise it is brown-tinged. It is thermally stable up to 700°. [Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol I p 241 1963.]

**Silver fluoride** [7775-41-9] **M 126.9, m 435°, b ca 1150°,  $d_4^{20}$  5.852**. The fluoride is a *hygroscopic* solid with a solubility of 135g/100ml of H<sub>2</sub>O at 15°, and forms an insoluble basic fluoride in moist air. Purify it by washing with AcOH and dry \*C<sub>6</sub>H<sub>6</sub>, then keep it in a vacuum desiccator at room temperature to remove \*C<sub>6</sub>H<sub>6</sub>, and store it in opaque glass bottles. The flaky *hygroscopic* crystals darken on exposure to light. It *attacks* bone and teeth. [Sharpe *J Chem Soc* 4538 1952, Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol I p 240 1963.]

**Silver iodate** [7783-97-3] **M 282.8, m >200°,  $d_4^{20}$  5.53**. Wash the iodate with warm dilute HNO<sub>3</sub>, then H<sub>2</sub>O and dry it at 100°, or recrystallise it from NH<sub>3</sub> solution by adding HNO<sub>3</sub>, filtering, washing with H<sub>2</sub>O and drying at 100°.

**Silver nitrate** [7761-88-8] **M 169.9, m 212°, b 444°(dec),  $d_4^{20}$  4.35**. Purify it by recrystallisation from hot water (solubility of AgNO<sub>3</sub> in water is 992g/100ml at 100° and 122g/100ml at 0°). It has also been purified by crystallisation from hot conductivity water by slow addition of freshly distilled EtOH.

**CAUTION: avoid using EtOH for washing the precipitate; and avoid concentrating the filtrate to obtain further crops of AgNO<sub>3</sub> owing to the risk of EXPLOSION (as has been reported to us) caused by the presence of silver fulminate. When using EtOH in the purification, the apparatus should be enveloped in a strong protective shield.** [Tully, *News Ed (Am Chem Soc)* **19** 3092 1941; Garin & Henderson *J Chem Educ*

47 741 1970, Bretherick, *Handbook of Reactive Chemical Hazards* 4th edn, Butterworths, London, 1985, pp 13-14.] Before being used as a standard in volumetric analysis, analytical reagent grade  $\text{AgNO}_3$  should be finely powdered, dried at  $120^\circ$  for 2 hours, then cooled in a desiccator.

Recovery of silver residues as  $\text{AgNO}_3$  [use protective shield during the whole of this procedure] can be achieved by washing with hot water and adding 16M  $\text{HNO}_3$  to dissolve the solid. Filter this through glass wool and concentrate the filtrate on a steam bath until precipitation commences. Cool the solution in an ice-bath and filter the precipitated  $\text{AgNO}_3$ . Dry it at  $120^\circ$  for 2 hours, then cool it in a desiccator in a vacuum. Store it over  $\text{P}_2\text{O}_5$  in a vacuum in the dark. *AVOID contact with hands due to formation of black stains.*

**Silver nitrite** [7783-99-5] **M 153.9, m  $141^\circ(\text{dec})$ ,  $d_4^{20}$  4.45.** Crystallise the salt from hot conductivity water (70ml/g) in the dark. Dry it in the dark under vacuum. [Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 1048 1963.]

**Silver(I) oxide** [20667-12-3] **M 231.7, m  $\sim 200^\circ(\text{dec})$ ,  $d_4^{20}$  7.13.** Leach the oxide with hot water in a Soxhlet apparatus for several hours to remove any entrained electrolytes. [Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1037 1965.]

**Silver (II) oxide** [1301-96-8] **M 123.9, m  $>100^\circ(\text{dec})$ ,  $d^{25}$  7.22.** It is soluble in 40,000 parts of  $\text{H}_2\text{O}$ , and should be protected from light. Stir it with an alkaline solution of potassium peroxy sulfate ( $\text{K}_2\text{S}_2\text{O}_8$ ) at  $85\text{--}90^\circ$ . The black  $\text{AgO}$  is collected, washed free from sulfate with  $\text{H}_2\text{O}$  made slightly alkaline and dried in air in the dark. [Hammer & Kleinberg *Inorg Synth* IV 12 1953.]

**Silver perchlorate monohydrate** [14242-05-8 ( $\text{H}_2\text{O}$ ), 7783-93-9 (anhydrous)] **M 207.3,  $\text{pK}^{25}$  -2.4 to -3.1 (for  $\text{HClO}_4$ ).** Reflux it with \*benzene (6ml/g) in a flask fitted with a Dean and Stark trap until all the water is removed azeotropically (ca 4 hours). The solution is cooled and diluted with dry pentane (4ml/g of  $\text{AgClO}_4$ ). The precipitated  $\text{AgClO}_4$  is filtered off and dried in a desiccator over  $\text{P}_2\text{O}_5$  at 1mm for 24 hours [Radell et al. *J Am Chem Soc* 83 3958 1961]. It has also been recrystallised from perchloric acid. [**Caution due to its EXPLOSIVE nature in the presence of organic matter.**] Store it in the dark.

**Silver permanganate** [7783-98-4] **M 226.8,  $d_4^{20}$  4.49.** The salt forms violet crystals which can be crystallised from hot  $\text{H}_2\text{O}$  (soluble is 9g/L at  $20^\circ$ ). Store it in the dark. This oxidising agent is decomposed by light. [Lux in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 1463 1963.]

**Silver sulfate** [10294-26-5] **M 311.8, m  $652^\circ$ , b  $1085^\circ(\text{dec})$ ,  $d_4^{20}$  5.45.** Crystallise the sulfate from hot conc  $\text{H}_2\text{SO}_4$  containing a trace of  $\text{HNO}_3$ , and dilute with  $\text{H}_2\text{O}$  while being strongly cooled. The precipitate is filtered off, washed with  $\text{H}_2\text{O}$  and dried at  $120^\circ$ . Its solubility in  $\text{H}_2\text{O}$  is 0.8% at  $17^\circ$ , and 1.46% at  $100^\circ$ . Store it in the dark. [Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1042 1965.]

**Silver tetraoxorhenate** [ $\text{Ag}(\text{ReO}_4)$ ] [7784-00-1] **M 358.1,  $\text{pK}_a$  -1.25.** It is prepared by adding slowly, with ice cooling,  $\text{H}_2\text{O}_2$  (35%, 100ml) to a stirred suspension of Re powder (10g, 54mmol) in  $\text{H}_2\text{O}$  (20ml) during 4 hours, stirring at  $\sim 25^\circ$  for 30 minutes, and then at  $80^\circ$  for 3 hours. The mixture is filtered from a small amount of insoluble material, and the clear solution is treated with  $\text{Ag}(\text{NO}_3)$  (10g, 59mmol), when  $\text{Ag}(\text{ReO}_4)$  immediately separates as a white precipitate which is filtered off, washed with  $\text{Et}_2\text{O}$  (3 x 25ml) to remove  $\text{H}_2\text{O}$  and  $\text{H}_2\text{O}_2$ , and dried *in vacuo* to give the silver salt (18.7g, 97%). [Herrmann & Kratzer *Inorg Synth* 33 111 2002, Herrmann et al. *Angew Chem, Int Ed. Engl* 36 2652 1997.]

**Silver thiocyanate** [1701-93-5] **M 165.9, m  $265^\circ(\text{dec})$ ,  $d_4^{20}$  3.746,  $\text{pK}^{25}$  -1.85 (for HSCN).** Digest the solid salt with dilute aqueous  $\text{NH}_4\text{NCS}$ , filter, wash it thoroughly with  $\text{H}_2\text{O}$  and dry it at  $110^\circ$  in the dark. It is soluble in dilute aqueous  $\text{NH}_3$ . *Alternatively*, dissolve it in strong aqueous  $\text{NH}_4\text{NCS}$  solution, filter and dilute with large volumes of  $\text{H}_2\text{O}$  when the Ag salt separates. The solid is washed with  $\text{H}_2\text{O}$  by decantation until free from  $\text{NCS}^-$  ions, collected, washed with  $\text{H}_2\text{O}$ ,  $\text{EtOH}$  and dried in an air oven at  $120^\circ$ . It has also been purified by dissolving in dilute aqueous  $\text{NH}_3$  when single crystals are formed by free evaporation of the solution in air. Store it in the

dark. [Garrick & Wilson *J Chem Soc* 835 1932, Occlshaw *J Chem Soc* 2405 1932, IR and Raman: *Acta Chem Scand* 13 1607 1957, Lindqvist *Acta Cryst* 10 29 1957.]

**Sodium (metal)** [7440-23-5] **M 23.0, m 97.5°, d<sub>4</sub><sup>20</sup> 0.97.** The metal is placed on a coarse grade of sintered-glass filter, melted under vacuum and forced through the filter using argon. The Pyrex apparatus is then re-evacuated and sealed off below the filter, so that the sodium could be distilled at 460° through a side arm and condenser into a receiver bulb which is then sealed off [Gunn & Green *J Am Chem Soc* 80 4782 1958]. **EXPLODES and IGNITES in water.**

**Sodium amide** [7782-92-5] **M 39.0, m 210°.** It reacts *violently* with H<sub>2</sub>O and is soluble in liquid NH<sub>3</sub> (1% at 20°). It should be stored in wax-sealed containers in small batches. It is very *hygroscopic* and absorbs CO<sub>2</sub> and H<sub>2</sub>O. If the solid is discoloured by being yellow or brown in colour, then it should be destroyed as it can be highly **EXPLOSIVE**. It should be replaced if discoloured. It is best destroyed by covering it with much toluene and slowly adding dilute EtOH with stirring until all the ammonia is liberated (FUME CUPBOARD). [Dennis & Bourne *Inorg Synth* I 74 1939, Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 465 1963, Bergstrom *Org Synth Coll Vol III* 778 1955.]

**Sodium ammonium hydrogen phosphate** [13011-54-6] **M 209.1, m 79°(dec), d<sub>4</sub><sup>20</sup> 1.55.** Crystallise it from hot water (1ml/g).

**Sodium arsenate heptahydrate** [10048-95-0] **M 312.0, m 50 (loses 5H<sub>2</sub>O), m 130°, d<sub>4</sub><sup>20</sup> 1.88 pK<sub>1</sub><sup>25</sup> 2.22, pK<sub>2</sub><sup>25</sup> 6.98 (for H<sub>3</sub>AsO<sub>4</sub>).** Crystallise it from water (2ml/g).

**Sodium azide** [26628-22-8] **M 65.0, m 300°(dec, explosive), pK<sub>25</sub> 4.72 (for HN<sub>3</sub>).** Crystallise sodium azide from hot water or from water by adding absolute EtOH or acetone. Also purify it by repeated crystallisation from an aqueous solution saturated at 90° by cooling it to 10°, and adding an equal volume of EtOH. The crystals are washed with acetone, and the azide is dried at room temperature under vacuum for several hours in an Abderhalden pistol. Its solubility in H<sub>2</sub>O is 42% at 18°, and in EtOH it is 0.22% at 0°. [Das et al. *J Chem Soc, Faraday Trans 1* 78 3485 1982, Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 474-475 1963, Browne *Inorg Synth* 1 79 1939, Frierson *Inorg Synth* II 139 1946.] **HIGHLY POISONOUS and potentially explosive.**

**Sodium bicarbonate** [144-55-8] **M 84.0, m ~50°(dec, -CO<sub>2</sub>).** Crystallise it from hot water (6ml/g). The solid should not be heated above 40° due to the formation of carbonate.

**Sodium bisulfite** [7631-90-5] **M 104.1, d<sub>4</sub><sup>20</sup> 1.48.** Crystallise it from hot H<sub>2</sub>O (1ml/g). Dry it at 100° under vacuum for 4 hours.

**Sodium borate (borax)** [1330-43-4] **M 201.2, m 741°, d<sub>4</sub><sup>20</sup> 2.37.** Most of the water of hydration is removed from the *decahydrate* (see below) by evacuation at 25° for three days, followed by heating to 100° and evacuation with a high-speed diffusion pump. The dried sample is then heated gradually to fusion (above 966°), allowed to cool gradually to 200°, then transferred to a desiccator containing P<sub>2</sub>O<sub>5</sub> [Grenier & Westrum *J Am Chem Soc* 78 6226 1956]. [Becher in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 794-795 1963.]

**Sodium borate (decahydrate, hydrated borax)** [1303-96-4] **M 381.2, m 75°(loses 5H<sub>2</sub>O at 60°), d<sub>4</sub><sup>20</sup> 1.73.** Crystallise the borate from water (3.3ml/g), keeping below 55° to avoid formation of the pentahydrate. Filter it off at the pump, wash it with water and equilibrate it for several days in a desiccator containing an aqueous solution saturated with respect to sucrose and NaCl. Borax can be prepared more quickly (but its water content is somewhat variable) by washing the recrystallised material at the pump with water, followed by 95% EtOH, then Et<sub>2</sub>O, and dried in air at room temperature for 12-18 hours on a clock glass. [Becher in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 794-795 1963.]

**Sodium borohydride** [16940-66-2] **M 37.8, m ~400°(dec), d<sub>4</sub><sup>20</sup> 1.07.** After adding NaBH<sub>4</sub> (10g) to freshly distilled diglyme (120ml) in a dry three-necked flask fitted with a stirrer, nitrogen inlet and outlet, the mixture is

stirred for 30 minutes at 50° until almost all of the solid has dissolved. Stirring is stopped, and, after the solid has settled, the supernatant liquid is forced under N<sub>2</sub> pressure through a sintered-glass filter into a dry flask. [The residue is centrifuged to obtain more of the solution which is added to the bulk.] The solution is cooled slowly to 0° and then decanted from the white needles that separated. The crystals are dried by evacuating for 4 hours to give anhydrous NaBH<sub>4</sub>. *Alternatively*, after the filtration at 50° the solution is heated at 80° for 2 hours to give a white precipitate of substantially anhydrous NaBH<sub>4</sub> which is collected on a sintered-glass filter under N<sub>2</sub>, then evacuated at 60° for 2 hours [Brown et al. *J Am Chem Soc* 77 6209 1955].

NaBH<sub>4</sub> has also been crystallised from isopropylamine by dissolving it in the solvent at reflux, cooling, filtering and allowing the solution to stand in a filter flask connected to a Dry-ice/acetone trap. After most of the solvent has passed over into the cold trap, crystals are removed with forceps, washed with dry diethyl ether and dried under vacuum. [Kim & Itoh *J Phys Chem* 91 126 1987.] Somewhat less pure crystals were obtained more rapidly by using Soxhlet extraction with only a small amount of solvent and extracting for about 8 hours. The crystals that formed in the flask are filtered off, then washed and dried as before. [Stockmayer et al. *J Am Chem Soc* 77 1980 1955.] Other solvents used for crystallisation include water and liquid ammonia.

**Sodium bromate** [7789-38-0] M 150.9, m 381°, d<sub>4</sub><sup>20</sup> 3.3. It is crystallised from hot water (1.1ml/g) to decrease contamination by NaBr, bromine and hypobromite. [Noszticzius et al. *J Am Chem Soc* 107 2314 1985.]

**Sodium bromide** [7647-15-6] M 102.9, m 747°, b 1390°, d<sub>4</sub><sup>20</sup> 3.2. Crystallise the bromide from water (0.86ml/g) between 50° and 0°, and dry it at 140° under vacuum (this purification may not eliminate chloride ion).

**Sodium carbonate** [497-19-8] M 106.0, m 858°, d<sub>4</sub><sup>20</sup> 2.5. It crystallises from water as the *decahydrate* which is redissolved in water to give a near-saturated solution. By bubbling CO<sub>2</sub>, NaHCO<sub>3</sub> is precipitated. It is filtered off, washed and ignited for 2 hours at 280° [MacLaren & Swinehart *J Am Chem Soc* 73 1822 1951]. Before being used as a volumetric standard, analytical grade material should be dried by heating at 260-270° for 0.5 hour and allowed to cool in a desiccator. It has a transition point at 450°, and its solubility in water is 21.58% at 20° (*decahydrate* in solid phase), 49.25% at 35° (*heptahydrate* in solid phase) and 44.88% at 75° (*monohydrate* in solid phase) [Dönges in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 987-988 1963]. After three recrystallisations, technical grade Na<sub>2</sub>CO<sub>3</sub> had Cr, Mg, K, P, Al, W, Sc and Ti at 32, 9.4, 6.6, 3.6, 2.4, 0.6, 0.2 and 0.2 ppm respectively; another technical source had Cr, Mg, Mo, P, Si, Sn and Ti at 2.6, 0.4, 4.2, 13.4, 32, 0.6, 0.8 ppm respectively.

**Sodium chlorate** [7775-09-9] M 106.4, m 248°, b >300°(dec), d<sub>4</sub><sup>20</sup> 2.5. It is crystallised from hot water (0.5ml/g). It is a strong oxidising agent, and should be kept clear from organic matter.

**Sodium chloride** [7647-14-5] M 58.4, m 800.7°, b 1413°, d<sub>4</sub><sup>20</sup> 2.17. It is recrystallised from a saturated aqueous solution (2.7ml/g) by passing in HCl gas, or by adding EtOH or acetone. It can be freed from bromide and iodide impurities by adding chlorine water to an aqueous solution and boiling it for some time to expel free bromine and iodine. Traces of iron can be removed by prolonged boiling of solid NaCl in 6M HCl; the crystals are then washed with EtOH and dried at *ca* 100°. Sodium chloride has been purified by sublimation in a stream of pre-purified N<sub>2</sub> and collected by electrostatic discharge [Ross & Winkler *J Am Chem Soc* 76 2637 1954]. For use as a primary analytical standard, analytical reagent grade NaCl should be finely ground, dried in an electric furnace at 500-600° in a platinum crucible, and allowed to cool in a desiccator. For most purposes, however, drying at 110-120° is satisfactory.

**Sodium chlorite** [7758-19-2] M 90.4, m ~180°(dec). Crystallise the chlorite from hot water and store it in a cool place. It has also been crystallised from MeOH by counter-current extraction with liquid ammonia [Curti & Locchi *Anal Chem* 29 534 1957]. A major impurity is chloride ion which can be removed by recrystallisation from 0.001M NaOH. [Schmeisser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 312 1963.]

**Sodium chromate tetrahydrate** [10034-82-9] M 234.0, m ~20°(for 10H<sub>2</sub>O), d<sub>4</sub><sup>20</sup> 2.7, pK<sub>1</sub><sup>25</sup> 0.74, pK<sub>2</sub><sup>25</sup> 6.49 (for H<sub>2</sub>CrO<sub>4</sub>). Crystallise the chromate from hot water (0.8ml/g). It is *deliquescent*.

**Sodium cyanate** [917-61-3] **M 65.0, m 550°, d<sub>4</sub><sup>20</sup> 1.893, pK<sup>25</sup> 3.47 (for HCNO).** It forms colourless needles from EtOH. Its solubility in EtOH is 0.22g/100g at 0°C. It is soluble in H<sub>2</sub>O but can be recrystallised from small volumes of it.

**Sodium cyanoborohydride** [25895-60-7] **M 62.8, m 240-242°(dec), d<sup>28</sup> 1.20.** It is a very *hygroscopic* solid, soluble in H<sub>2</sub>O (212% at 29°, 121% at 88°), tetrahydrofuran (37% at 28°, 42.2% at 62°), very soluble in MeOH, slightly soluble in EtOH, but insoluble in Et<sub>2</sub>O, \*C<sub>6</sub>H<sub>6</sub> and hexane. It is stable to acid up to pH 3 but is hydrolysed in 12N HCl. The rate of hydrolysis at pH 3 is 10<sup>-8</sup> times that of NaBH<sub>4</sub>. The fresh commercially available material is usually sufficiently pure. If very pure material is required, one of the following procedures can be used [Lane *Synthesis* 135 1975]: (a) The NaBH<sub>3</sub>CN is dissolved in tetrahydrofuran (20% w/v), filtered and the filtrate is treated with a fourfold volume of CH<sub>2</sub>Cl<sub>2</sub>. The solid is collected and dried in a vacuum [Wade et al. *Inorg Chem.* 9 2146 1970]. (b) NaBH<sub>3</sub>CN is dissolved in dry MeNO<sub>2</sub>, filtered, and the filtrate is poured into a 10-fold volume of CCl<sub>4</sub> with vigorous stirring; the white precipitate is collected, washed several times with CCl<sub>4</sub> and dried in a vacuum (yield 75%) [Berschied & Purcell *Inorg Chem* 9 624 1970]. (c) When the above procedures fail to give a clean product, then dissolve NaBH<sub>3</sub>CN (10g) in tetrahydrofuran (80ml) and add N MeOH/HCl until the pH is 9. Pour the solution with stirring into dioxane (250ml). The solution is filtered and heated to reflux. A further volume of dioxane (150ml) is added slowly with swirling. The solution is cooled slowly to room temperature, then chilled in ice and the crystalline dioxane complex is collected, dried in a vacuum for 4 hours at 25°, then 4 hours at 80° to yield the amorphous dioxane-free powder (6.7g) with purity >98% [Borch et al. *J Am Chem Soc* 93 2897 1971]. The purity can be checked by iodometric titration [Lyttle et al. *Anal Chem* 24 1843 1952].

**Sodium dichromate** [7789-12-0] **M 298.0, m 84.6° (2H<sub>2</sub>O), 356° (anhydrous); b 400°(dec), d<sub>4</sub><sup>25</sup> 2.348.** Crystallise the dichromate from small volumes of H<sub>2</sub>O by evaporation to crystallisation. Its solubility in H<sub>2</sub>O is 238% at 0° and 508% at boiling. The red *dihydrate* is slowly dehydrated by heating at 100° for long periods. It is *deliquescent* and is a powerful oxidising agent—*do not place it in contact with skin—wash immediately as it is caustic.* (Possible **carcinogen**.)

**Sodium dihydrogen orthophosphate dihydrate** [13472-35-0 (2H<sub>2</sub>O), 10049-21-5 (H<sub>2</sub>O), 7558-80-7 (anhydrous)] **M 156.0, m 60°(dec), d<sub>4</sub><sup>20</sup> 1.91.** Crystallise it from warm water (0.5ml/g) by chilling.

**Sodium dithionite dihydrate** [7631-94-9] **M 242.1, m 110°(loses 2H<sub>2</sub>O), 267°(dec), d<sub>4</sub><sup>20</sup> 2.19, pK<sub>Est(1)</sub><sup>25</sup> -3.4, pK<sub>2</sub><sup>25</sup> 0.49 (for dithionic acid).** Crystallise it from hot water (1.1ml/g) by cooling.

**Sodium ferricyanide monohydrate** [14217-21-1, 13601-19-9 (anhydrous)] **M 298.9, pK<sup>25</sup> <1 (for ferricyanide).** Crystallise the ferricyanide from hot water (1.5ml/g) or by precipitation from 95% EtOH.

**Sodium ferrocyanide decahydrate** [13601-19-9] **M 484.1, m 50-80° (loses 10H<sub>2</sub>O), 435°(dec), d<sub>4</sub><sup>20</sup> 1.46, pK<sub>3</sub><sup>25</sup> 2.57, pK<sub>4</sub><sup>25</sup> 4.35 (for ferrocyanide).** Crystallise it from hot water (0.7ml/g), until free of ferricyanide as shown by the absence of formation of Prussian Blue colour with ferrous sulfate solution.

**Sodium fluoride** [7681-49-4] **M 42.0, m 996°, b 1695°, d<sub>4</sub><sup>20</sup> 2.56.** Crystallise NaF from water by partial evaporation in a vacuum desiccator, or dissolve it in water, and precipitate *ca* half of it by adding EtOH. The precipitate is dried in an air oven at 130° for one day, and then stored in a desiccator over KOH. Its solubility in H<sub>2</sub>O is 4% at 15° and 4.3% at 25°. [Kwasnik in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 235 1963].

**Sodium fluoroborate** [13755-29-8] **M 109.8, m 384°, d<sub>4</sub><sup>20</sup> 2.47, pK<sup>25</sup> -4.9 (for fluoroboric acid H<sub>3</sub>O<sup>+</sup>BF<sub>4</sub><sup>-</sup>).** Crystallise the fluoroborate from hot water (50ml/g) by cooling to 0°. *Alternatively*, free it from insoluble material by dissolving it in a minimum amount of water; then fluoride ions are removed by adding concentrated lanthanum nitrate in excess. After removing lanthanum fluoride by centrifugation, the supernatant is passed through a cation-exchange column (Dowex 50, Na<sup>+</sup>-form) to remove any remaining lanthanum [Anbar & Guttman *J Phys Chem* 64 1896 1960]. It has also been recrystallised from anhydrous MeOH and dried in a vacuum at 70° for 16 hours. Keep it dry as it is *hygroscopic*. [Delville et al. *J Am Chem Soc* 109 7293 1987.]

**Sodium fluorosilicate** [16893-85-9] **M 188.1**. Crystallise it from hot water (40ml/g) by cooling.

**Sodium hexafluorophosphate** [21324-39-0] **M 167.9**,  $\text{pK}_1^{25} \sim 0.5$ ,  $\text{pK}_2^{25} 5.12$  (for fluoro-phosphoric acid  $\text{H}_2\text{PO}_3\text{F}$ ). Recrystallise it from acetonitrile and dry it in a vacuum for 2 days at room temperature. It is an irritant and is *hygroscopic*. [Delville et al. *J Am Chem Soc* **109** 7293 1987.]

**Sodium hexanitrocobaltate III** ( $\text{Na}_3[\text{Co}(\text{NO})_6]$ ) [13600-98-1] **M 403.9**. Dissolve the salt (*ca* 60g) in  $\text{H}_2\text{O}$  (300ml), filter to obtain a clear solution, add 96% EtOH (250ml) with vigorous stirring. Allow the precipitate to settle for 2 hours, filter it off, wash it with EtOH (4 x 25ml), twice with  $\text{Et}_2\text{O}$  and dry it in air [Glemser in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **II** p 1541 1965]. It forms yellow to brown crystals which are very soluble in  $\text{H}_2\text{O}$ , are decomposed by acid and form an insoluble K salt. Used for estimating potassium.

**Sodium hydride (NaH)** [7646-69-7] **M 24.00**,  $m \sim 425^\circ(\text{dec})$ ,  $800^\circ(\text{dec})$ , **d 1.396**. NaH is a granular gray powder which ignites in moist air and should be stored in an inert atmosphere. It is prepared in the laboratory by passing  $\text{H}_2$  through a dispersion of Na in an industrial white oil at *ca*  $250^\circ$  [Mattson & Whaley *Inorg Synth* **5** 10 1957]. Like sodium it is very reactive with  $\text{H}_2\text{O}$  liberating hydrogen and NaOH. Fortunately it is commercially available as a 50 to 60% (w/w) dispersion in oil, which protects the NaH from the atmosphere, moderates its reaction with moisture, and can be handled routinely without recourse to using dry box techniques. In this form its reaction with  $\text{H}_2\text{O}$  (and alcohols) can be controlled safely, unlike the dry solid. The oil is freely soluble in petroleum ethers, hexanes,  $\text{Et}_2\text{O}$ ,  $^*\text{C}_6\text{H}_6$ , toluene and THF without affecting NaH reactivity. Removal of the oil is achieved by adding any of these solvents, decanting them off, repeating the process, then adding the desired reaction solvent to cover the NaH. NaH is insoluble in inert organic solvents and in liquid  $\text{NH}_3$ . When the dispersion is kept for long periods, or if the lid of the container in which it is kept is removed a considerable number of times, the NaH may have deteriorated and the mixture will contain a high percentage of NaOH and/or  $\text{NaHCO}_3$  or  $\text{Na}_2\text{CO}_3$ . In this case a new batch should be used as laboratory purification is not practicable. The NaH content can, however, be determined by carefully adding  $\text{H}_2\text{O}$  to a known weight of the dispersion oil in a flask and measuring the volume of  $\text{H}_2$  released using a manometer. The aqueous solution can then be titrated with standard acid (phenolphthalein indicator) to provide the total Na content. [For numerous examples of the use of NaH in organic synthesis see the various volumes of Fieser and Fieser's *Reagents in Organic Synthesis*.]

**Sodium hydroxide (anhydrous)** [1310-73-2] **M 40.0**,  $m 323^\circ$ ,  $b 1390^\circ$ ,  $d_4^{20} 2.13$ . Common impurities are water and sodium carbonate. Sodium hydroxide can be purified by dissolving 100g in 1L of pure EtOH, filtering the solution under vacuum through a fine sintered-glass disc to remove insoluble carbonates and halides. (This and subsequent operations should be performed in a dry,  $\text{CO}_2$ -free box.) The solution is concentrated under vacuum, using mild heating, to give a thick slurry of the mono-alcoholate which is transferred to a coarse sintered-glass disc and evacuated free of mother liquor. After washing the crystals several times with purified alcohol to remove traces of water, they are dried in a vacuum, with mild heating, for about 30 hours to decompose the alcoholate, leaving a fine white crystalline powder [Kelly & Snyder *J Am Chem Soc* **73** 4114 1951]. **CAUSTIC.**

**Sodium hydroxide solutions (caustic)**,  $\text{pK}^{25} 14.77$ . Carbonate ion can be removed by passage through an anion-exchange column (such as Amberlite IRA-400;  $\text{OH}^-$ -form). The column should be freshly prepared from the chloride form by slow prior passage of sodium hydroxide solution until the effluent gives no test for chloride ions. After use, the column can be regenerated by washing with dilute HCl, then water. Similarly, other metal ions are removed when a 1M (or more dilute) NaOH solution is passed through a column of Dowex ion-exchange A-1 resin in its  $\text{Na}^+$ -form.

*Alternatively*, carbonate contamination can be reduced by rinsing sticks of NaOH (analytical reagent quality) rapidly with  $\text{H}_2\text{O}$ , then dissolving in distilled  $\text{H}_2\text{O}$ , or by preparing a concentrated aqueous solution of NaOH and drawing off the clear supernatant liquid. (Insoluble  $\text{Na}_2\text{CO}_3$  is left behind.) Carbonate contamination can be reduced by adding a slight excess of concentrated  $\text{BaCl}_2$  or  $\text{Ba}(\text{OH})_2$  to a NaOH solution, shaking well and allowing the  $\text{BaCO}_3$  precipitate to settle. If the presence of Ba in the solution is unacceptable, an electrolytic purification can be used. For example, sodium amalgam is prepared by the electrolysis of 3L of 30% NaOH

with 500ml of pure mercury for cathode, and a platinum anode, passing 15 Faradays at 4Amps, in a thick-walled polyethylene bottle. The bottle is then fitted with inlet and outlet tubes, the spent solution being flushed out by CO<sub>2</sub>-free N<sub>2</sub>. The amalgam is then washed thoroughly with a large volume of deionized water (with the electrolysis current switched on to minimise loss of Na). Finally, a clean steel rod is placed in contact in the solution with the amalgam (to facilitate hydrogen evolution), reaction being allowed to proceed until a suitable concentration is reached, before being transferred to a storage vessel and diluted as required [Marsh & Stokes *Aust J Chem* **17** 740 1964].

**Sodium hypophosphite monohydrate** [10039-56-2] **M 106.0** (see pK of hypophosphorous acid). Dissolve it in boiling EtOH, cool and add dry Et<sub>2</sub>O till all the salt separates. Collect and dry it in vacuum. It is soluble in 1 part of H<sub>2</sub>O. It liberates PH<sub>3</sub> on heating and can *ignite* spontaneously when heated. The anhydrous salt is soluble in ethylene glycol (33% w/w) and propylene glycol (9.7%) at 25°.

**Sodium iodate** [7681-55-2] **M 197.9, m dec on heating, d<sub>4</sub><sup>20</sup> 4.28**. Crystallise sodium iodate from water (3ml/g) by cooling.

**Sodium iodide** [7681-82-5] **M 149.9, m 660°, b 1304°, d<sub>4</sub><sup>20</sup> 3.67**. Crystallise NaI from water/ethanol solution and dry it for 12 hours under vacuum, at 70°. *Alternatively*, dissolve it in acetone, filter it and cool it to -20°; the resulting yellow crystals are filtered off and heated in a vacuum oven at 70° for 6 hours to remove acetone. The NaI is then crystallised from very dilute NaOH, dried under vacuum, and stored in a vacuum desiccator [Verdin *Trans Faraday Soc* **57** 484 1961].

**Sodium-mercury amalgam (sodium amalgam)** [11110-52-4] **M depends on Na%, m (Na-Hg/m): 0.5%/0°, 1.0%/50°, 1.5%/100°, 2.0%/130°, 2.5%/156°, 3.3%/250°, 4.0%/320°**. The composition of the amalgam depends on the amount of Na added to the Hg. The reaction is exothermic and can be violent on first mixing. Generally 1-3% of Na in Hg is used, but higher amalgams can be obtained or prepared. Amalgams with more than 1% are solids with melting points that increase with the percentage of Na reaching > 360° at > 5% Na. Unless it has been prepared recently, it is always best to prepare the amalgam afresh. Three general procedures can be adopted. Use a fume cupboard as Hg vapour is **TOXIC**.

*Method 1:* For a ~1.2% amalgam, clean dry Na (9g) is placed in a 500ml flask with a reflux condenser, covered with dry toluene (20ml), and warmed gently until the Na has melted. Hg is added dropwise (separating funnel) with swirling. The exothermic reaction during the addition of the first few mls of Hg will cause the toluene to reflux, and Hg is added at such a rate as to keep the toluene refluxing gently. When addition is complete, allow the solvent to evaporate and the amalgam will solidify. Note that it is low melting (~50°) but will solidify on cooling. The solid amalgam is pulverised in a mortar (under N<sub>2</sub>; to avoid spluttering of small quantities of solid Na-Hg, the mortar is covered with a thick filter paper, or cardboard, with a hole in the centre to allow the pestle to go through), and stored away from moisture in a tightly stoppered container. Up to a ~2%Na amalgam can be prepared by this method and using 15.2g Na and 750ml of Hg.

*Method 2:* To a flask with dry N<sub>2</sub> or Argon flushing continuously through it, clean freshly cut Na (22.8g) is added followed by Hg (10ml) from a separating funnel. The flask is warmed gently until the reaction commences then more Hg (total 750g) is added, with shaking, at such a rate as to keep the amalgam molten. After half the Hg is added, the amalgam begins to solidify and should be kept liquid by external heating. When addition is complete, the molten amalgam is poured (under N<sub>2</sub> or Argon) into a cold mortar and powdered (see Method 1 above). This provides a 3% amalgam. It should be stored as before. A 5%Na amalgam corresponds to a composition of NaHg<sub>2</sub>, and a 20% amalgam corresponds to a composition of Na<sub>2</sub>Hg.

*Method 3:* This method is convenient and commonly used. To the required volume of Hg in a wide-necked flask continuously flushed with N<sub>2</sub> or Argon, is added Na which is cut into small cubes, ca 5mm, and each cube is speared with a pointed glass rod and pushed into the liquid Hg. If traces of metal are not a concern, then it is better to use a stainless steel spike or a long tweezers to pick the Na cubes. A vigorous reaction occurs (perhaps with a flash of light occasionally) as each piece of Na dissolves into the Hg or amalgam. The temperature rises and the amalgam is kept in liquid form by the heat released on adding the Na. Do not allow the amalgam to solidify before all the Na is added. If it does, then heat the flask with a burner to keep the amalgam in a liquid state. To avoid damage from flying pieces of Na resulting from the vigorous reaction, the glass rod or metal pick spearing the Na cubes is inserted through a hole in the centre of a thick cardboard sheet which is placed over the mouth of the flask. The amalgam is then powdered and stored as above.

The amalgams are good reducing agents, and react with H<sub>2</sub>O releasing “nascent H” and H<sub>2</sub>, but much less vigorously than Na metal. [Brauer in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1802 1965, Audrieth *Inorg Synth* Vol I 5 1939, Babcock *Inorg Synth* I 10 1939, Holleman *Org Synth Coll Vol I* 555 1941, Renfrow & Hauser *Org Synth Coll Vol II* 609 1943, Deulofeu & Guerrero *Org Synth Coll Vol III* 589 1955.]

**Sodium metaperiodate (NaIO<sub>4</sub>)** [7790-28-5] M 213.9, m ~300°(dec), d<sub>4</sub><sup>20</sup> 4.17. Recrystallise it from hot water. [Willard *Inorg Synth* I 170 1939, Bernays *Inorg Synth* II 212 1946.]

**Sodium metasilicate pentahydrate** [6834-92-0] M 212.1, m 1088°, d<sub>4</sub><sup>20</sup> 2.4. Crystallise it from aqueous 5% NaOH solution. [Schwartz *Z Anorg Allgem Chem* 126 62 1923.]

**Sodium molybdate dihydrate** [10102-40-6] M 241.9, m 100°(loses 2H<sub>2</sub>O), 687°, d<sub>4</sub><sup>20</sup> 3.28, pK<sup>25</sup> 4.08 (for H<sub>2</sub>MoO<sub>4</sub>). Crystallise it from hot water (1ml/g) by cooling to 0°.

**Sodium nitrate** [7631-99-4] M 85.0, m 307°, b 380°, d<sub>4</sub><sup>20</sup> 2.26. Crystallise NaNO<sub>3</sub> from hot water (0.6ml/g) by cooling to 0°, or from a concentrated aqueous solution by adding MeOH. Dry it under a vacuum at 140°. After two recrystallisations, technical grade sodium nitrate had K, Mg, B, Fe Al, and Li at 100, 29, 0.6, 0.4, 0.2 and 0.2 ppm respectively. (See KNO<sub>3</sub>.)

**Sodium nitrite** [7632-00-0] M 69.0, m 271°, b 320°, d<sub>4</sub><sup>20</sup> 2.17. Crystallise NaNO<sub>2</sub> from hot water (0.7ml/g) by cooling to 0°, or from its own melt. Dry it over P<sub>2</sub>O<sub>5</sub>. (See KNO<sub>2</sub>.)

**Sodium oleate** [143-19-1] M 304.4, m 233-235°. It is recrystallised from EtOH, and is dried in an oven at 100°. [Beilstein 2 H 465, 2 I 201, 2 II 434, 2 III 1405, 2 IV 1645.]

**Sodium percarbonate (Na<sub>2</sub>CO<sub>3</sub>·1.5H<sub>2</sub>O<sub>2</sub>, hydrogen peroxide sodium carbonate adduct)** [15630-89-4] M 157.0, dec >120°. This is not a per-salt, but is crystalline Na<sub>2</sub>CO<sub>3</sub> with H<sub>2</sub>O<sub>2</sub> of crystallisation with a specific composition. The crystals are consistent in having 1.5 molecules of H<sub>2</sub>O<sub>2</sub> for each molecule of Na<sub>2</sub>CO<sub>3</sub>. It is a stable, inexpensive, a non-toxic source of H<sub>2</sub>O<sub>2</sub> that is easily handled in the laboratory. It is prepared by the addition of excess of H<sub>2</sub>O<sub>2</sub> (~3 to 15%) to a saturated aqueous solution of analytically pure Na<sub>2</sub>CO<sub>3</sub> or NaHCO<sub>3</sub> at room temperature, stirring for 30 minutes then absolute EtOH is added. The percarbonate separates as white needle-shaped crystals. These are filtered off, washed with EtOH then Et<sub>2</sub>O and dried in air. Its available oxygen content is determined by titration with standard KMnO<sub>4</sub> after acidification, and is ~13-15%. [Galwey & Hood *J Phys Chem* 83 1810 1979.] Its solubility in H<sub>2</sub>O at ~25° is ~1 mol/L and the pH is ~10.5. The kinetics of thermal decomposition have been studied in detail and are autocatalytic, and best represented by the equation Na<sub>2</sub>CO<sub>3</sub>·1.5H<sub>2</sub>O<sub>2</sub> = Na<sub>2</sub>CO<sub>3</sub> + 1.5 H<sub>2</sub>O + 0.75O<sub>2</sub>. [Galwey & Hood *J Chem Soc, Faraday Trans* 78 2815 1982.] It is a useful oxidising agent; converting nitriles to amides [Kabalka et al. *Synth Commun* 20 1445 1990], oxidises α-diketones to dicarboxylic acids [Yang et al. *Synth Commun* 23 1183 1993], it promotes the Baeyer-Villiger reaction in TFA at 0° [Olah et al. *Synthesis* 739 1991], forms epoxides with olefins, hydroxylates arenes, forms N-oxides, and converts sulfides into sulfones [Review: Muzart *Synthesis* 1325 1995], and converts selectively primary and secondary alcohols to their respective carbonyl compounds in the presence of catalytic amounts of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and Adogen 464 [see 72749-59-8] [Muzart et al. *Tetrahedron Lett* 35 1989 1994, Mohand & Muzart *Synth Commun* 25 2373 1995]. It is a useful disinfectant and antiseptic, and is best stored blow 10°. For X-ray crystallography, the crystals were prepared by slowly evaporating in air a solution of Na<sub>2</sub>CO<sub>3</sub> in 10% H<sub>2</sub>O<sub>2</sub>, or in an excess of 15% H<sub>2</sub>O<sub>2</sub> or D<sub>2</sub>O<sub>2</sub> by standing for 1 hour at -5° before precipitating with EtOH, washing with EtOH and Et<sub>2</sub>O, and drying in air. Na<sub>2</sub><sup>13</sup>C<sub>3</sub> was similarly used. The X-ray structure revealed the presence of H<sub>2</sub>O<sub>2</sub> molecules hydrogen bonded to the CO<sub>3</sub> ions in the crystal, with two types of H<sub>2</sub>O<sub>2</sub> molecules. The IR and Raman spectra of the normal, <sup>13</sup>C and <sup>2</sup>H isotopically substituted “percarbonates” are consistent with the X-ray data where the two H<sub>2</sub>O<sub>2</sub> sites are different. The IR (nujol, 25°) of Na<sub>2</sub>CO<sub>3</sub>·1.5H<sub>2</sub>O<sub>2</sub> has ν<sub>max</sub> at 3050w, 2900m, 2720sh, 2490s, 2350m, 1550m, 985m, 960s, 973vw, 868w cm<sup>-1</sup>, and Na<sub>2</sub>CO<sub>3</sub>·1.5<sup>2</sup>H<sub>2</sub>O<sub>2</sub> has ν<sub>max</sub> at 2470w, 2210m, 1940sh, 1890s, 1820m, 1130m, 1040s, 1035m, 873vw, 869w, 660m, 635s cm<sup>-1</sup> [Carrondo et al. *J Chem Soc, Dalton Trans* 2323 1977.]

**Sodium perchlorate (anhydrous)** [7601-89-0] **M 122.4, m 130°(for monohydrate),  $d_4^{20}$  2.02,  $pK_1^{25}$  -2.4 to -3.1 (for  $HClO_4$ ).** Because its solubility in water is high (2.1g/ml at 15°) and it has a rather low-temperature coefficient of solubility, sodium perchlorate is usually crystallised from acetone, MeOH, water/ethanol or dioxane/water (33g dissolved in 36ml of water and 200ml of dioxane is added). After filtering and recrystallising, the solid is dried under vacuum at 140-150° to remove solvent of crystallisation. Basic impurities can be removed by crystallisation from hot acetic acid, followed by heating at 150°. If  $NaClO_4$  is precipitated from distilled water by adding  $HClO_4$  to the chilled solution, the precipitate contains some free acid. **EXPLOSIVE.**

**Sodium phosphoamidate** [3076-34-4] **M 119.0.** Dissolve it in water below 10°, and acetic acid is added dropwise to pH 4.0 so that the monosodium salt is precipitated. The precipitate is washed with water and  $Et_2O$ , then dried in air. Addition of one equivalent of NaOH to the solution gives the sodium salt, the solution being adjusted to pH 6.0 before use [Rose & Heald *Biochem J* **81** 339 1961].

**Sodium-potassium alloy** [11135-81-2] **M depends on composition, liquid.** This is generally in the form of a liquid globule from which an aliquot can be pipetted under dry  $N_2$ . It is available commercially in two ratios, viz K (78wt%), Na (22 wt%) and K (56 wt%), Na (44 wt%), in ampoules. A fresh *ca* ~5:1  $NaK_{2.8}$  liquid alloy can be prepared from clean K metal (77g, 2.0mol) and clean Na (16g, 0.7mol) by heating gently in xylene (100ml, freshly distilled from Na) until the metals coalesce, then dry oxygen-free diglyme (50ml) is added in order to keep the alloy in one globule (stir with a glass rod). Small globules of the alloy can be united by adding a few drops of *iso*-PrOH to the mixture. Cool to room temperature, and this can be stored under dry  $N_2$  indefinitely. An aliquot can be safely pipetted out from the central globule by syringe equipped with a metal stopcock. The alloy can be more safely disposed of than the Na/Hg alloy, but must be handled carefully as it ignites in moist air. Residues are readily destroyed by a 1:1 mixture of *iso*-PrOH/petroleum ether (b 60-100°). [Ellis & Flom *J Organomet Chem* **99** 263 1975, Gilman & Young *J Org Chem* **1**, 315 1936.] When it reacts, e.g. in THF, to form metal carbonyl anions, and with some hydrocarbons, e.g. cyclopentadienes, diphenyl ether, it always forms the K-metallide, i.e. cyclopentadienylpotassium and  $C_6H_5K$ , and not the Na-metallide [Bryce-Smith & Turner *J Chem Soc* 861 1953, Ziegler & Schnell *Justus Liebigs Annalen Chemie* **437** 227 1924, Müller & Bunge *Chem Ber* **69** 2164 1936].

**Sodium pyrophosphate decahydrate** [13472-36-1] **M 446.1,  $d_4^{20}$  1.82,  $pK_1^{25}$  1.52,  $pK_2^{25}$  2.36,  $pK_3^{25}$  6.60,  $pK_4^{25}$  9.25 (for pyrophosphoric acid,  $H_4P_2O_7$ ).** Crystallise the salt from hot  $H_2O$  and dry it in air at room temperature.

**Sodium selenate** [13410-01-0] **M 188.9,  $d_4^{20}$  3.21,  $pK_1^{25}$  ~0,  $pK_2^{25}$  1.66 (for selenic acid,  $H_2SeO_4$ ).** Crystallise sodium selenate from hot water. [Fehér in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 433 1963].

**Sodium selenite** [10102-18-8] **M 172.9, m >350°,  $pK_1^{25}$  2.62,  $pK_2^{25}$  8.32 (for  $H_2SeO_3$ ).** Crystallise sodium selenite from a saturated aqueous solution where its solubility is 68% at 20° to give the *pentahydrate* salt. This yields the *anhydrous* salt on heating at 40°. [Fehér in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 431 1963].

**Sodium silicate solution** [1344-09-8]  **$pK_1^{25}$  9.51,  $pK_2^{25}$  11.77 (for silicic acid,  $H_4SiO_4$ )** Purify by contact filtration with activated charcoal.

**Sodium sulfate decahydrate** [7727-73-3 ( $10H_2O$ ), 7757-82-6 (*anhydrous*)] **M 322.2, m 32°(dec), 884° (anhydrous),  $d_4^{20}$  2.68 (anhydrous).** Crystallise sodium sulfate from water at 30° (1.1ml/g) by cooling to 0°. It becomes anhydrous at 32°.

**Sodium sulfide nonahydrate** [1313-84-4 ( $9H_2O$ ), 1313-82-2 (*anhydrous*)] **M 240.2, m ~50(loses  $H_2O$ ), 950(anhydrous),  $d_4^{20}$  1.43 ( $10H_2O$ ), 1.86 (anhydrous),  $pK_1^{25}$  7.04,  $pK_2^{25}$  11.96 (for  $H_2S$ ).** Some purification of the hydrated salt can be achieved by selecting large crystals and removing the surface layer (contaminated with oxidation products) by washing with distilled water. Other metal ions can be removed from  $Na_2S$  solutions

by passage through a column of Dowex ion-exchange A-1 resin, Na<sup>+</sup>-form. The hydrated salt can be rendered *anhydrous* by heating it in a stream of H<sub>2</sub> or N<sub>2</sub> until water is no longer evolved. (The resulting cake should not be heated to fusion because it is readily oxidised.) Recrystallise it from distilled water [Anderson & Azowlay *J Chem Soc, Dalton Trans* 469 1986]. Note that sodium sulfide hydrolyses in H<sub>2</sub>O to form NaHS + H<sub>2</sub>O, and is therefore alkaline. A 0.1N solution in H<sub>2</sub>O is 86% hydrolysed at room temperature. Its solubility in H<sub>2</sub>O is 8% at 0°, 12% at 20° and 30% at 50°. The *anhydrous* salt is obtained by allowing it to stand in a vacuum over conc H<sub>2</sub>SO<sub>4</sub> or P<sub>2</sub>O<sub>5</sub> at 45° to start with, then at 30-35° when the salt contains 4% of water. The last traces of water are removed by heating to 700° in a glass or porcelain tube in a stream of H<sub>2</sub> to give pure H<sub>2</sub>S. [Fehér in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 358-360 1963.]

**Sodium sulfite** [7757-83-7] M 126.0, d<sub>4</sub><sup>20</sup> 2.63. Crystallise the sulfite from warm water (0.5ml/g) by cooling to 0°. Also purify it by repeated crystallisation from deoxygenated water inside a glove-box, and finally drying it under vacuum. [Rhee & Dasgupta *J Phys Chem* 89 1799 1985.]

**Sodium tetrametaphosphate** [13396-41-3] M 429.9, pK<sub>1</sub><sup>25</sup> 2.60, pK<sub>2</sub><sup>25</sup> 6.4, pK<sub>3</sub><sup>25</sup> 8.22, pK<sub>4</sub><sup>25</sup> 11.4 (tetrametaphosphoric acid, H<sub>4</sub>P<sub>4</sub>O<sub>12</sub>). Crystallise it twice from water at room temperature by adding EtOH (300g of Na<sub>4</sub>P<sub>4</sub>O<sub>12</sub>·H<sub>2</sub>O, 2L of water, and 1L of EtOH), wash it first with 20% EtOH then with 50% EtOH and dry it in air [Quimby *J Phys Chem* 58 603 1954].

**Sodium thioantimonate (Na<sub>3</sub>SbS<sub>4</sub>·9H<sub>2</sub>O, Schlippe's salt)** [13776-84-6] M 481.1, m 87°, b 234°, d<sub>4</sub><sup>20</sup> 1.81. Crystallise it from warm water (2ml/g made weakly alkaline with a few drops of dilute aqueous NaOH) by cooling to 0°. It forms a yellow *nonhydrate* which readily *effloresces* in air. [Schenk in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 619 1963.]

**Sodium thiocyanate** [540-72-7] M 81.1, m 300°, pK<sup>25</sup> -1.85 (for HSCN). It is recrystallised from EtOH or Me<sub>2</sub>CO, and the mother liquor is removed from the crystals by centrifugation. It is very *deliquescent* and should be kept in an oven at 130° before use. It can be dried in a vacuum at 120°/P<sub>2</sub>O<sub>5</sub> [Partington & Winterton *Trans Faraday Soc* 30 1104 1934]. Its solubility in H<sub>2</sub>O is 113% at 10°, 178% at 46°, 225.6% at 101.4°; in MeOH 35% at 15.8°, 51% at 48°, 53.5% at 52.3°; in EtOH 18.4% at 18.8°, 24.4% at 70.9°; and in Me<sub>2</sub>CO 6.85% at 18.8° and 21.4% at 56° [Hughes & Mead *J Chem Soc* 2282 1929].

Sodium thiocyanate has also been recrystallised from water, acetonitrile or from MeOH using Et<sub>2</sub>O for washing, then dried at 130°, or dried under vacuum at 60° for 2 days. [Strasser et al. *J Am Chem Soc* 107 789 1985, Szezygiel et al. *J Am Chem Soc* 91 1252 1987.] (The latter purification removes material reacting with iodine.) Sodium thiocyanate solutions can be freed from traces of iron by repeated batch extractions with Et<sub>2</sub>O.

**Sodium thiosulfate pentahydrate** [10102-17-7 (*hydrate*), 7772-98-7 (*anhydrous*)] M 248.2 (*anhydrous*), m 48 (*rapid heat*), d<sub>4</sub><sup>20</sup> 1.69, pK<sub>1</sub><sup>25</sup> 0.6, pK<sub>2</sub><sup>25</sup> 1.74 (for H<sub>2</sub>S<sub>2</sub>O<sub>3</sub>). Crystallise it from EtOH/H<sub>2</sub>O solutions or from water (0.3ml/g) below 60° by cooling to 0°, and dry it at 35° over P<sub>2</sub>O<sub>5</sub> under vacuum. [Foerster & Mommsen *Chem Ber* 57 258 1924.] This salt is used as a secondary standard in volumetric analysis [Kilpatrick *J Am Chem Soc* 45 2132 1923], and is used as "Hypo" in photography [Hargreaves & Dunningham *J Soc Chem Ind* 42 147T 1923.]

**Sodium trimetaphosphate hexahydrate** [7785-84-4] M 320.2, m 53°, d<sub>4</sub><sup>20</sup> 1.79, pK<sub>2</sub><sup>25</sup> 1.64, pK<sub>3</sub><sup>25</sup> 2.07 (for trimetaphosphoric acid, H<sub>3</sub>P<sub>3</sub>O<sub>9</sub>). It is precipitated from an aqueous solution at 40° by adding EtOH. It is dried in air.

**Sodium tripolyphosphate** [7758-29-4] M 367.9, pK<sub>1</sub><sup>25</sup> ~1, pK<sub>2</sub><sup>25</sup> 2.0, pK<sub>3</sub><sup>25</sup> 2.13, pK<sub>4</sub><sup>25</sup> 5.78, pK<sub>5</sub><sup>25</sup> 8.56 (for tripolyphosphoric acid, H<sub>5</sub>P<sub>3</sub>O<sub>10</sub>). Purify it by repeated precipitation from aqueous solution by slow addition of MeOH and dried in air. Also a solution of anhydrous sodium tripolyphosphate (840g) in water (3.8L) is filtered, MeOH (1.4L) is added with vigorous stirring to precipitate Na<sub>5</sub>P<sub>3</sub>O<sub>10</sub>·6H<sub>2</sub>O. The precipitate is collected on a filter, air dried by suction, then left to dry in air overnight. It is crystallised twice more in this way, using a 13% aqueous solution (w/w), and leaching the crystals with 200ml portions of water [Watters et al. *J Am Chem Soc* 78 4855 1956]. Similarly, EtOH can be added to precipitate the salt from a filtered 12-15% aqueous solution, the final solution containing *ca* 25% EtOH (v/v). Air drying should be at a relative humidity of 40-

60%. Heat and vacuum drying should be avoided. [Quimby *J Phys Chem* **58** 603 1954, Klement in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 547 1963.]

**Sodium tungstate dihydrate** [10213-10-2] **M 329.9, m 698°, d<sub>4</sub><sup>20</sup> 4.18, pK<sub>1</sub><sup>25</sup> 2.20, pK<sub>2</sub><sup>25</sup> 3.70 (for tungstic acid, H<sub>2</sub>WO<sub>4</sub>).** The salt crystallises from hot water (0.8ml/g) on cooling to 0°. [Grüttner & Jender in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1727 1965].

**Stannic chloride (tin IV chloride, stannic tetrachloride)** [7646-78-8] **M 260.5, m -33°, -30.2°, b 114°/760mm, d<sub>4</sub><sup>20</sup> 2.23, pK<sub>25</sub> 14.15 (for aquo Sn<sup>4+</sup> hydrolysis).** SnCl<sub>4</sub> fumes in moist air due to formation of a hydrate. Fractionate it in a ground glass still and store it in the absence of air. Possible impurities are SO<sub>2</sub> and HCl [Baudler in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 729 1963]. It forms a solid *pentahydrate* [10026-06-9] which smells of HCl and is obtained when the *anhydrous* salt is dissolved in a small volume of H<sub>2</sub>O. Also reflux it with clean mercury or P<sub>2</sub>O<sub>5</sub> for several hours, then distil it under (reduced) N<sub>2</sub> pressure into a receiver containing P<sub>2</sub>O<sub>5</sub>. Finally redistil it. *Alternatively*, distil it from Sn metal under vacuum in an all-glass system and seal off in large ampoules. SnCl<sub>4</sub> is available commercially as 1M solutions in CH<sub>2</sub>Cl<sub>2</sub> or hexane. **HARMFUL VAPOURS.**

**Stannic iodide (SnI<sub>4</sub>)** [7790-47-8] **M 626.3, m 144°, b 340, d<sub>4</sub><sup>20</sup> 4.46.** It is recrystallised from anhydrous CHCl<sub>3</sub>, dry it under vacuum and store it in a vacuum desiccator. It sublimes at 180°.

**Stannic oxide (SnO<sub>2</sub>)** [18282-10-5] **M 150.7, m 1630°, d<sub>4</sub><sup>20</sup> 6.95.** Reflux it repeatedly with fresh HCl until the acid shows no tinge of yellow. The oxide is then dried at 110°.

**Stannous chloride (anhydrous)** [7772-99-8] **M 189.6, m 247°, b 606°, d<sub>4</sub><sup>20</sup> 3.95, pK<sub>1</sub><sup>25</sup> 1.7, pK<sub>2</sub><sup>25</sup> 3.7 (for aquo Sn<sup>2+</sup> hydrolysis).** Analytical reagent grade stannous chloride *dihydrate* is dehydrated by adding it slowly to vigorously stirred, redistilled acetic anhydride (120g salt per 100g of anhydride) in a fume cupboard. After *ca* an hour, the anhydrous SnCl<sub>2</sub> is filtered on to a sintered-glass or Büchner funnel, washed free from acetic acid with dry Et<sub>2</sub>O (2 x 30ml), and dried under vacuum. It is stored in a sealed container. [Stephen *J Chem Soc* 2786 1930, Williams *Org Synth Coll Vol III* 627 1955.]

**Strontium bromide** [10476-81-0] **M 247.4, m 643°, d<sub>4</sub><sup>20</sup> 4.22.** Crystallise the bromide from water (0.5ml/g). It is *deliquescent*. [Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 930 1963.]

**Strontium chloride hexahydrate** [1025-70-4] **M 266.6, m 61°(rapid heating), 114-150°(loses 5H<sub>2</sub>O), 868°(anhydrous).** It crystallises from warm water (0.5ml/g) on cooling to 0°. It dehydrates at 150-160° in a vacuum. [Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 930 1963.]

**Strontium chromate** [7789-06-2] **M 203.6, d<sub>4</sub><sup>20</sup> 3.9, pK<sub>1</sub><sup>25</sup> 0.74, pK<sub>2</sub><sup>25</sup> 6.49 (for H<sub>2</sub>CrO<sub>4</sub>).** Crystallise strontium chromate from water (40ml/g) by cooling.

**Strontium hydroxide octahydrate** [1311-10-0 (8H<sub>2</sub>O), 18480-07-4 (anhydrous)] **M 265.8, m 100° (loses H<sub>2</sub>O), d<sub>4</sub><sup>20</sup> 1.90, m 375 (anhydrous), d 3.63 (anhydrous).** Crystallise the hydroxide from hot water (2.2ml/g) by cooling to 0°.

**Strontium nitrate** [10042-76-9] **M 211.6, m 570°, b 645°, d<sub>4</sub><sup>20</sup> 2.99.** Crystallise it from hot water (0.5ml/g) by cooling to 0°.

**Sulfamic acid** [5329-14-6] **M 97.1, m 205°(dec), pK<sub>25</sub> 0.99 (NH<sub>2</sub>SO<sub>3</sub>H).** Crystallise NH<sub>2</sub>SO<sub>3</sub>H from water at 70° (300ml per 25g), after filtering, by cooling a little and discarding the first batch of crystals (about 2.5g) before standing in an ice-salt mixture for 20 minutes. The crystals are filtered off by suction, washed with a small quantity of ice cold water, then twice with cold EtOH and finally with Et<sub>2</sub>O. Dry it in air for 1 hour, then

store it in a desiccator over  $\text{Mg}(\text{ClO}_4)_2$  [Butler et al. *Ind Eng Chem (Anal Ed)* **10** 690 1938]. For the preparation of primary standard material see *Pure Appl Chem* **25** 459 1969.

**Sulfamide** [7803-58-9] **M 96.1, m 91.5°**. Crystallise sulfamide from absolute EtOH. It decomposes at 250°. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 482-483 1963.]

**Sulfur** [7704-34-9] **M 32.1, m between 112.8° and 120°, depending on form**. Murphy, Clabaugh & Gilchrist [*J Res Nat Bur Stand* **64A** 355 1960] have obtained sulfur of about 99.999% purity by the following procedure: Roll sulfur was melted and filtered through a coarse-porosity glass filter funnel into a 2L round-bottomed Pyrex flask with two necks. Conc  $\text{H}_2\text{SO}_4$  (300ml) was added to the sulfur (2.5kg), and the mixture was heated to 150°, stirring continuously for 2 hours. Over the next 6 hours, conc  $\text{HNO}_3$  was added in about 2ml portions at 10-15 minutes intervals to the heated mixture. It was then allowed to cool to room temperature and the acid was poured off. The sulfur was rinsed several times with distilled water, then remelted, cooled, and rinsed several times with distilled water again, this process being repeated four or five times to remove most of the acid entrapped in the sulfur. An air-cooled reflux tube (*ca* 40cm long) was attached to one of the necks of the flask, and a gas delivery tube (the lower end about 2.5cm above the bottom of the flask) was inserted into the other. While the sulfur was boiled under reflux, a stream of helium or  $\text{N}_2$  was passed through to remove any water,  $\text{HNO}_3$  or  $\text{H}_2\text{SO}_4$ , as vapours. After 4 hours, the sulfur was cooled so that the reflux tube could be replaced by a bent air-cooled condenser. The sulfur was then distilled, rejecting the first and the final 100ml portions, and transferred in 200ml portions to 400ml glass cylinder ampoules (which were placed on their sides during solidification). After adding about 80ml of water, displacing the air with  $\text{N}_2$ , the ampoule was cooled, and the water was titrated with 0.02M NaOH, the process being repeated until the acid content was negligible. Finally, entrapped water was removed by alternate evacuation to 10mm Hg and refilling with  $\text{N}_2$  while the sulfur was kept molten. The ampoules were then sealed. Other purifications include crystallisation from  $\text{CS}_2$  (which is less satisfactory because the sulfur retains appreciable amounts of organic material), \*benzene or \*benzene/acetone, followed by melting and degassing. It has also been boiled with 1% MgO, then decanted, and dried under a vacuum at 40° for 2days over  $\text{P}_2\text{O}_5$ . [For the purification of  $\text{S}_6$ , "recrystallised  $\text{S}_8$ " and "Bacon-Fanelli sulfur" see Bartlett et al. *J Am Chem Soc* **83** 103, 109 1961.]

**Sulfur dichloride (sulfur chloride,  $\text{SCl}_2$ )** [10545-99-0] **M 103.0, m -78°, b 59°/760mm(dec),  $d_4^{20}$  1.621**. Distil sulfur chloride twice in the presence of a small amount of  $\text{PCl}_3$  through a 12in Vigreux column, the fraction boiling between 55-61° being redistilled (in the presence of  $\text{PCl}_3$ ), and the fraction distilling between 58-61° retained. (The  $\text{PCl}_3$  is added to inhibit the decomposition of  $\text{SCl}_2$  into  $\text{S}_2\text{Cl}_2$  and  $\text{Cl}_2$ ). The  $\text{SCl}_2$  must be used as quickly as possible after distillation — within 1 hour at room temperature. The sample contains 4% of  $\text{S}_2\text{Cl}_2$ . On long standing this reaches 16-18%. [Fehér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 371-372 1963.] **HARMFUL VAPOURS.**

**Sulfur dioxide** [7446-09-5] **M 64.1, m -72°, b -10°**. Dry it by bubbling through conc  $\text{H}_2\text{SO}_4$  and by passage over  $\text{P}_2\text{O}_5$ , then through a glass-wool plug. Freeze it with liquid air and pump it to a high vacuum to remove dissolved gases. It is easily liquefied by compression (2.5 atmospheres at 15°), or by passing it through a glass spiral column in a freezing mixture of ice and salt. It is a colourless liquid with a density of 1.434 at 0°, which on rapid evaporation forms a snow white solid. It could be used as a solvent in certain reactions. **HARMFUL SUFFOCATING VAPOURS.**

**Sulfuric acid (oil of vitriol)** [7664-93-9] **M 98.08,  $d_4^{20}$  1.836 (96-98%), 1.805 (100%), m 3.0° (98%), 10.36° (100%), b 330.0 ± 0.5° (100%), dec > 340.0°, dihydrate M 134.11, m -38.9°, b 167°,  $\text{pK}_1^{25} \sim -8.3$ ,  $\text{pK}_2^{25} 1.99$** . Sulfuric acid, and also 30% fuming  $\text{H}_2\text{SO}_4$ , can be distilled in an all-Pyrex system, optionally from potassium persulfate. It has been purified by fractional crystallisation of the *monohydrate* from the liquid. It has a very strong dehydrating action and attacks skin—wash immediately with cold  $\text{H}_2\text{O}$  **and protect eyes**; otherwise the skin can be scarred for life **and could be blinding**. It is very *hygroscopic* and has been used as a desiccant in desiccators. Dilution with  $\text{H}_2\text{O}$  is highly exothermic, and because the concentrated acid is much more dense than  $\text{H}_2\text{O}$  it is diluted by running the concentrated acid down the side of the container of  $\text{H}_2\text{O}$  with slow stirring while cooling the outside of the container in an ice bath. If these precautions are not taken, the  $\text{H}_2\text{O}$  is likely to splatter and boil vigorously over. **CORROSIVE.**

**Sulfuric acid (fuming) (oleum)** [8014-95-7] **M 98.08 (+ x SO<sub>3</sub>)**. This is sulfuric acid with various amounts of SO<sub>3</sub> dissolved in it up to 80% free SO<sub>3</sub>. The specific gravities, **Sp gr**<sub>4</sub><sup>20</sup>, of oleums (% free SO<sub>3</sub>) are: 1.899 (15%), 1.915 (20%), 1.952 (30%), 2.001 (50%), 2.102 (60% maximum density) and 1.949 (80%). They are an almost colourless viscous liquids which emit choking fumes of SO<sub>3</sub>, and should be handled with great care: **use eye and body protection**. It reacts explosively with H<sub>2</sub>O to form strong sulfuric acid, and is a strong sulfonating agent.

**Sulfur monochloride (sulfur monochloride, S<sub>2</sub>Cl<sub>2</sub>)** [10025-67-9] **M 135.0, m -77°; b 19.1°, 29-30°/12mm, 72°/100mm, 138°/760mm, d**<sub>4</sub><sup>20</sup> **1.677, n**<sub>D</sub><sup>20</sup> **1.67**. It is a *pungent, irritating golden yellow liquid*. When impure its colour is orange to red due to SCl<sub>2</sub> formed. It fumes in moist air and liberates HCl, SO<sub>2</sub> and H<sub>2</sub>S in the presence of H<sub>2</sub>O. Distil it and collect the fraction boiling above 137° at atmospheric pressure. Fractionate this fraction over sulfur at *ca* 12mm using a ground glass apparatus (**b** 29-30°). *Alternatively*, purify it by distillation below 60° from a mixture containing sulfur (2%) and activated charcoal (1%), under reduced pressure (e.g. 50mm). It is soluble in EtOH, \*C<sub>6</sub>H<sub>6</sub>, Et<sub>2</sub>O, CS<sub>2</sub> and CCl<sub>4</sub>. Store it in a closed container in the dark in a refrigerator. [Fehér in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 371 1963.] **HARMFUL VAPOURS.**

**Sulfuryl chloride (SO<sub>2</sub>Cl<sub>2</sub>)** [7791-25-2] **M 135.0, m -54.1°, b 69.3°/760mm, d**<sub>4</sub><sup>20</sup> **1.67, n**<sub>D</sub><sup>20</sup> **1.44**. It is a *pungent, irritating colourless liquid*. It becomes yellow with time due to decomposition to SO<sub>2</sub> and HCl. Distil it and collect fraction boiling below 75°/atm which is mainly SO<sub>2</sub>Cl<sub>2</sub>. To remove HSO<sub>3</sub>Cl and H<sub>2</sub>SO<sub>4</sub> impurities, the distillate is poured into a separating funnel filled with crushed ice and *briefly* shaken. The lower cloudy layer is removed, dried for some time in a desiccator over P<sub>2</sub>O<sub>5</sub> and finally fractionate it at atmospheric pressure. The middle fraction boils at 69-70° and is pure SO<sub>2</sub>Cl<sub>2</sub>. It decomposes gradually in H<sub>2</sub>O to H<sub>2</sub>SO<sub>4</sub> and HCl. It reacts **violently** with EtOH and MeOH and is soluble in \*C<sub>6</sub>H<sub>6</sub>, toluene, Et<sub>2</sub>O and acetic acid. [Fehér in *Handbook of Preparative Inorganic Chemistry* (Ed Brauer) Academic Press Vol I p 383 1963, Allen & Maxson *Inorg Synth* I 114 1939]. **HARMFUL VAPOURS.**

**Tantalum (V) chloride (tantalum pentachloride)** [7721-01-9] **M 358.2, m 216.2°, 216.5-220°, b 239°/atm, d**<sub>4</sub><sup>20</sup> **3.68**. Purify it by sublimation in a stream of Cl<sub>2</sub>. It forms colourless needles when pure (yellow when contaminated with even less than 1% of NbCl<sub>5</sub>). It is sensitive to H<sub>2</sub>O; even in conc HCl it decomposes to tantalic acid. It is soluble in EtOH. [Rolsten *J Am Chem Soc* **80** 2952 1958, Brauer in *Handbook of Preparative Inorganic Chemistry* (Ed Brauer) Academic Press Vol II p 1302 1965.]

**Telluric acid** [7803-68-1] **M 229.6, pK**<sub>1</sub><sup>25</sup> **7.70, pK**<sub>2</sub><sup>25</sup> **11.04 (H<sub>6</sub>TaO<sub>6</sub>)**. Crystallise it once from nitric acid, then repeatedly from hot water (0.4ml/g). [Fehér in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I pp 451-453 1963.]

**Tellurium** [13494-80-9] **M 127.6, m 450°**. Purify tellurium by zone refining and repeated sublimation to an impurity of less than 1 part in 10<sup>8</sup> (except for surface contamination by TeO<sub>2</sub>). [Machol & Westrum *J Am Chem Soc* **80** 2950 1958.] Tellurium is volatile at 500°/0.2mm. It has also been purified by electrode deposition [Mathers & Turner *Trans Amer Electrochem Soc* **54** 293 1928].

**Tellurium dioxide** [7446-07-3] **M 159.6, m 733°, d**<sub>4</sub><sup>20</sup> **6.04**. Dissolve it in 5M NaOH, filter it and precipitate it by adding 10M HNO<sub>3</sub> (CARE) to the filtrate until the solution is acid to phenolphthalein. After decanting the supernatant, the precipitate is washed five times with distilled water, then dried for 24 hours at 110° [Horner & Leonhard *J Am Chem Soc* **74** 3694 1952].

**Terbium oxide** [12037-01-3] **M 747.7, pK**<sup>25</sup> **8.16 (for Tb<sup>3+</sup> hydrolysis)**. Dissolve it in acid (e.g. perchloric acid), precipitate it as its oxalate and ignite the oxalate at 650°.

**Thallium (III) nitrate trihydrate** [TTN, thallic nitrate trihydrate,  $\text{Tl}(\text{NO}_3)_3 \cdot 3\text{H}_2\text{O}$ ] [13453.38-8] **M 444.4, m 102-105°**. It is prepared from Tl(III)oxide (45g, [1314-32-5]) by stirring it in hot concentrated  $\text{HNO}_3$  (120ml) at  $\sim 50^\circ$  for 30 minutes when all the oxide dissolves to give a clear colourless solution. On cooling to  $0^\circ$ , a white solid crystallises out. It is filtered off, washed with a little cold  $\text{H}_2\text{O}$ , dilute  $\text{HNO}_3$ , dried in a vacuum desiccator over  $\text{P}_2\text{O}_5$  to give TTN (75g, 85%) as hard, colourless crystals which should be stored in a cold tightly sealed container. Treat carefully as it is **POISONOUS**. [McKillop et al. *J Am Chem Soc* **95** 3635 1973.]

**Thallos bromide** [7789-40-4] **M 284.3, m 460°**. Thallos bromide (20g) is purified by refluxing for 2-3 hours with water (200ml) containing 3ml of 47% HBr. It is then washed until acid-free, heated to  $300^\circ$  for 2-3 hours and stored in brown bottles. Its solubility in  $\text{H}_2\text{O}$  (w/w) is 0.034% at  $0^\circ$ , 0.048% at  $20^\circ$ , and 0.204% at  $100^\circ$ . [Dönges in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 870 1963]. **POISONOUS**.

**Thallos carbonate** [6533-73-9] **M 468.7, m 268-270°**. It crystallises from hot water (4ml/g) on cooling. **POISONOUS**.

**Thallos chlorate** [13453-30-0] **M 287.8,  $d_4^{20}$  5.05**. It crystallises from hot water (2ml/g) on cooling. Its solubility in  $\text{H}_2\text{O}$  (w/w) is 0.17% at  $0^\circ$ , 0.32% at  $20^\circ$ , and 2.4% at  $100^\circ$ . [Dönges in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 870 1963]. **POISONOUS**.

**Thallos chloride** [7791-12-0] **M 239.8, m 429.9°, b 806°,  $d_4^{20}$  7.0**. Recrystallise it from 1% HCl and wash it until acid-free, or crystallise it from hot water (50ml/g), then dry it at  $140^\circ$  and store it in brown bottles. Also purify it by subliming it in a vacuum, followed by treatment with dry HCl gas and filtering while molten. (It is soluble in 260 parts of cold water and 70 parts of boiling water). **POISONOUS**.

**Thallos hydroxide** [12026-06-1] **M 221.4, m 139°(dec),  $\text{pK}^{25}$  13.2 (for  $\text{Tl}^+$ )**. It crystallises from hot water (0.6ml/g) on cooling. **POISONOUS**.

**Thallos iodide** [7790-30-9] **M 331.3, m 441.8°, b 824°,  $d_4^{20}$  7.1**. Reflux it for 2-3 hours with water containing HI, then wash it until acid-free, and dry it at  $120^\circ$ . Store it in brown bottles. [Dönges in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 870 1963.] **POISONOUS**.

**Thallos nitrate** [10102-45-1] **M 266.4, m 206°, b 450°(dec),  $d_4^{20}$  5.55**. The nitrate crystallises from warm water (1ml/g) on cooling to  $0^\circ$ . **POISONOUS**.

**Thallos perchlorate** [13453-40-2] **M 303.8,  $\text{pK}^{25}$  -2.4 to -3.1 (for  $\text{HClO}_4$ )**. It crystallises from hot water (0.6ml/g) on cooling. Dry it under vacuum for 12 hours at  $100^\circ$  (protect from possible **EXPLOSION**).

**Thallos sulfate** [7446-18-6] **M 504.8, m 633°,  $d_4^{20}$  6.77**. The sulfate crystallises from hot water (7ml/g) by cooling; then dry it under vacuum over  $\text{P}_2\text{O}_5$ . It is **POISONOUS**.

**Thionyl chloride** [7719-09-7] **M 119.0, b 77°,  $d_4^{20}$  1.636**. Crude  $\text{SOCl}_2$  can be freed from sulfuryl chloride, sulfur monochloride and sulfur dichloride by refluxing it with sulfur and then fractionally distilling twice. [The  $\text{SOCl}_2$  is converted to  $\text{SO}_2$  and sulfur chlorides. The  $\text{S}_2\text{Cl}_2$  (**b** 135.6°) is left in the residue, whereas  $\text{SCl}_2$  (**b** 59°) passes over in the forerun.] The usual purification is to distil it from quinoline (50g  $\text{SOCl}_2$  to 10g quinoline) to remove acid impurities, followed by distillation from boiled linseed oil (50g  $\text{SOCl}_2$  to 20g of oil). Precautions must be taken to exclude moisture.

Thionyl chloride is used extensively in organic syntheses and can be prepared by distillation of technical  $\text{SOCl}_2$  in the presence of diterpene (12g/250ml  $\text{SOCl}_2$ ), and avoiding overheating. Further purification is achieved by redistillation from linseed oil (1-2%) [Rigby *Chem Ind (London)* 1508 1969]. Gas chromatographically pure material is obtained by distillation from 10% (w/w) triphenyl phosphite [Friedman & Wetter *J Chem Soc (A)* 36 1967, Larsen et al. *J Am Chem Soc* **108** 6950 1986]. **HARMFUL VAPOURS**.

**Thorium chloride** [10026-08-1] **M 373.8**,  $\text{pK}_1^{25}$  10.45,  $\text{pK}_2^{25}$  10.62,  $\text{pK}_3^{25}$  10.80,  $\text{pK}_4^{25}$  11.64 (for aquo  $\text{Th}^{4+}$ ). It is freed from anionic impurities by passing a 2M solution of  $\text{ThCl}_4$  in 3M HCl through a Dowex-1 anion-resin column. The eluate is partially evaporated to give crystals which are filtered off, washed with  $\text{Et}_2\text{O}$  and stored in a desiccator over  $\text{H}_2\text{SO}_4$  to dry. *Alternatively*, a saturated solution of  $\text{ThCl}_4$  in 6M HCl is filtered through quartz wool and extracted twice with ethyl, or isopropyl ether (to remove iron), then evaporated to a small volume on a hot plate. (Excess silica precipitates and is filtered off. The filtrate is cooled to  $0^\circ$  and saturated with dry HCl gas.) It is shaken with an equal volume of  $\text{Et}_2\text{O}$ , shaken with HCl gas, until the mixture becomes homogeneous. On standing,  $\text{ThCl}_4 \cdot 8\text{H}_2\text{O}$  precipitates out and is filtered off, washed with  $\text{Et}_2\text{O}$  and dried [Kremer *J Am Chem Soc* **64** 1009 1942].

**Thorium sulfate tetrahydrate** [10381-37-0] **M 496.2**, **m  $42^\circ$** (loses  $\text{H}_2\text{O}$ ),  $\text{d}_4^{20}$  2.8. Crystallise it from water. The solubility of the *decahydrate* increases with increase in temperature, whereas the solubility of the *tetrahydrate* decreases with increase of temperature.

**Tin** (powder) [7440-31-5] **M 118.7**. Tin powder is purified by adding it to about twice its weight of 10% aqueous NaOH and shaking vigorously for 10 minutes. (This removes oxide film and stearic acid or similar material that is sometimes added for pulverisation.) It is then filtered, washed with water until the washings are no longer alkaline to litmus, rinsed with MeOH and dried in air. [Sisido et al. *J Am Chem Soc* **83** 538 1961.]

**Titanium tetrabromide** [7789-68-6] **M 367.5**, **m  $28.3^\circ$** , **b  $233.5^\circ$** ,  $\text{d}_4^{20}$  3.3. Purify it by distillation. The distillate forms light orange hygroscopic crystals. Store it in the dark under  $\text{N}_2$  preferably in sealed brown glass ampules. [Olsen & Ryan *J Am Chem Soc* **54** 2215 1932.]

**Titanium tetrachloride** [7550-45-0] **M 189.7**, **b  $136.4^\circ$** ,  **$154^\circ$** , **d 1.730**,  $\text{pK}_1^{25}$  0.3,  $\text{pK}_2^{25}$  1.8,  $\text{pK}_3^{25}$  2.1,  $\text{pK}_4^{25}$  2.4 (for aquo  $\text{Ti}^{4+}$  hydrolysis). Reflux it with mercury or a small amount of pure copper turnings to remove the last traces of colour [due to  $\text{FeCl}_3$  and  $\text{VCl}_4$ ], then distil it under  $\text{N}_2$  in an all-glass system, taking precautions to exclude moisture. Clabaugh et al. [*J Res Nat Bur Stand* **55** 261 1955] removed organic material by adding aluminium chloride hexahydrate as a slurry with an equal amount of water (the slurry being *ca* one-fiftieth the weight of  $\text{TiCl}_4$ ), refluxed it for 2-6 hours while bubbling in chlorine, the excess of which is subsequently removed by passing a stream of clean dry air. The  $\text{TiCl}_4$  is then distilled, refluxed with copper and again distilled, taking precautions to exclude moisture. Volatile impurities are then removed using a technique of freezing, pumping and melting. The *titanium tetrachloride 2-tetrahydrofuran complex*,  $\text{TiCl}_4(\text{THF})_2$ , [31011-57-1] **M 333.9**, has **m  $126-128^\circ$**  and is easier to handle than  $\text{TiCl}_4$  [Hamilton et al. *Organometallics* **75** 2881 1953, Abrahamson et al. *Organometallics* **3** 1379 1984, Beilstein **17/1** V 33]. [Baxter & Fertig *J Am Chem Soc* **45** 1228 1923, Baxter & Butler *J Am Chem Soc* **48** 3117 1926.] **HARMFUL VAPOURS.**

**Titanium trichloride** [7705-07-9] **M 154.3**, **m  $>500^\circ$** ,  $\text{pK}_1^{25}$  2.55 (for hydrolysis of  $\text{Ti}^{3+}$  to  $\text{TiOH}^{2+}$ ). It is a brown purple powder that is very reactive to  $\text{H}_2\text{O}$  and pyrophoric when dry. It should be manipulated in a dry box. It is soluble in  $\text{CH}_2\text{Cl}_2$  and tetrahydrofuran, and is used as a M solution in these solvents in the ratio of 2:1, and stored under  $\text{N}_2$ . It is a powerful reducing agent. [Ingraham et al. *Inorg Synth* **VI** 52 1960.]

**Titanyl sulfate ( $\text{TiOSO}_4 \cdot 2\text{H}_2\text{O}$ )** [13825-74-6] **M 160.0**. Dissolve it in water, filter and crystallise it three times from boiling 45%  $\text{H}_2\text{SO}_4$ , washing with EtOH to remove excess acid, then with  $\text{Et}_2\text{O}$ . Dry it in air for several hours, then in an oven at  $105-110^\circ$ . [Hixson & Fredrickson *Ind Eng Chem* **37** 678 1945.]

**Triiron dodecacarbonyl** [17685-52-8] **M 503.7**, **m  $140^\circ$** (dec). It usually contains 10% by weight of MeOH as stabiliser. This can be removed by keeping it in a vacuum at 0.5mm for at least 5 hours. It can be sublimed slowly at high vacuum and is soluble in organic solvents. [Landesberg et al. *J Org Chem* **37** 930 1972, Case & Whiting *J Chem Soc* 4632 1960, King & Stone *Inorg Synth* **VII** 193 1963.] **TOXIC.**

**Trisodium orthophosphate dodecahydrate** [10101-89-0] **M 380.1**,  $\text{pK}_1^{25}$  2.15,  $\text{pK}_2^{25}$  7.21,  $\text{pK}_3^{25}$  12.33 (for  $\text{H}_3\text{PO}_4$ ). It crystallises from warm dilute aqueous NaOH (1ml/g) on cooling to  $0^\circ$ .

**Tritium** [10028-17-8] **M 6.0**. Purify tritium from hydrocarbons and  $^3\text{H}$  by diffusion through the wall of a hot nickel tube [Landecker & Gray *Rev Sci Instrum* **25** 1151 1954]. **RADIOACTIVE**.

**Tungsten** (rod) [7440-33-7] **M 183.6, m 3410°, b 5900°, d<sub>4</sub><sup>20</sup> 19.0**. Clean the solid with conc NaOH solution, rub it with very fine emery paper until its surface is bright, wash it with previously boiled and cooled conductivity water and dry it with filter paper. [Hein & Herzog in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **II** p 1417 1965.]

**Tungsten hexacarbonyl** [14040-11-0] **M 351.9, d<sub>4</sub><sup>20</sup> 2.650**. Sublime it *in vacuo* before use [Connoe et al. *J Chem Soc, Dalton Trans* 511 1986]. **TOXIC**.

**Tungsten (VI) trichloride** [13283-01-7] **M 396.6, m 265°(dec), 275°, b 346°, d<sub>4</sub><sup>25</sup> 3.520, pK<sub>1</sub><sup>25</sup> 2.20, pK<sub>2</sub><sup>25</sup> 3.70 (for tungstic acid, H<sub>2</sub>WO<sub>4</sub>)**. Sublime it in a stream of Cl<sub>2</sub> in a high temperature furnace and collect it in a receiver cooled in a Dry-ice/acetone bath in an inert atmosphere because it is sensitive to moisture. It is soluble in CS<sub>2</sub>, CCl<sub>4</sub>, CHCl<sub>3</sub>, POCl<sub>3</sub>, \*C<sub>6</sub>H<sub>6</sub>, petroleum ether and Me<sub>2</sub>CO. Its solutions decompose on standing. Good crystals can be obtained by heating WCl<sub>6</sub> in CCl<sub>4</sub> to 100° in a sealed tube, followed by slow cooling (tablets of four-sided prisms). Store it in a desiccator over H<sub>2</sub>SO<sub>4</sub> in the dark. [Leitzke & Holt *Inorg Synth* **III** 163 1950, Parterfield & Tyree *Inorg Synth* **IX** 133 1967, Hein & Herzog in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **II** p 1420 1965.]

**Uranium hexafluoride** [7783-81-5] **M 352.0, b 0°/17.4mm, 56.2°/765mm, m 64.8°, pK<sup>25</sup> 1.68 (for hydrolysis of U<sup>4+</sup> to UOH<sup>3+</sup>)**. Purify uranium hexafluoride by fractional distillation to remove HF. Also purify it by low-temperature trap-to-trap distillation over pre-dried NaF [Anderson & Winfield *J Chem Soc, Dalton Trans* 337 1986].

**Uranium trioxide** [1344-58-7] **M 286.0, d<sub>4</sub><sup>20</sup> 7.29**. The oxide is dissolved in HClO<sub>4</sub> (to give a uranium content of 5%), and the solution is adjusted to pH 2 by addition of dilute ammonia. Dropwise addition of 30% H<sub>2</sub>O<sub>2</sub>, with rapid stirring, precipitated U(VI) peroxide, the pH being held constant during the precipitation, by addition of small amounts of the ammonia solution. Then H<sub>2</sub>O<sub>2</sub> is added until further quantities caused no change in pH. After stirring for 1 hour, the slurry is filtered through coarse filter paper in a Büchner funnel, washed with 1% H<sub>2</sub>O<sub>2</sub> acidified to pH 2 with HClO<sub>4</sub>, then heated at 350° for three days in a large platinum dish [Baes *J Phys Chem* **60** 878 1956].

**Uranyl nitrate (UO<sub>2</sub>(NO<sub>3</sub>)<sub>2</sub> 6H<sub>2</sub>O)** [13520-83-7] **M 502.1, m 60.2°, b 118°, d<sub>4</sub><sup>25</sup> 2.807, pK<sup>25</sup> 5.82 (for aquo UO<sub>2</sub><sup>2+</sup>)**. Crystallise the nitrate from water by cooling to -5°, taking only the middle fraction of the solid which separates. Dry the *deliquescent* rhombic yellow crystals of the *hexahydrate* over 35-40% H<sub>2</sub>SO<sub>4</sub> in a vacuum desiccator. The crystals reflect a greenish lustre. They are remarkable because on crushing, rubbing or shaking they show *triboluminescence* with occasional detonation. They are very soluble in EtOH, and solutions of the nitrate in Et<sub>2</sub>O can explode in the presence of sunlight.

**Vanadium (metal)** [7440-62-2] **M 50.9, m 1910°, d<sub>4</sub><sup>20</sup> 6.0**. Clean the metal by rapid exposure consecutively to HNO<sub>3</sub>, HCl, HF, de-ionised water and reagent grade acetone, then dry it in a vacuum desiccator. [Brauer in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **II** pp 1252-1255 1965.]

**Vanadyl trichloride (VOCl<sub>3</sub>)** [7727-18-6] **M 173.3, m-79.5°, b 124.5-125.5°/744mm, 127.16°/760mm, d<sup>0</sup> 1.854, d<sup>32</sup> 1.811**. VOCl<sub>3</sub> should be lemon yellow in colour. If it is red, it may contain VCl<sub>4</sub> and Cl<sub>2</sub>. Fractionally distil it, and then redistil it over metallic Na, but be careful to leave some residue because the residue can become **EXPLOSIVE** in the presence of the metal. **USE A SAFETY SHIELD** and avoid contact with moisture. It readily hydrolyses to vanadic acid and HCl. Store it in a tightly closed container or in sealed ampoules under N<sub>2</sub>. [Brown & Griffiths *Inorg Synth* **I** 106 1939, Brown & Griffiths *Inorg Synth* **IV** 80 1953.]

**Water** [7732-18-5] **M 18.0, m 0<sup>0</sup>, b 100<sup>0</sup>, pK<sup>25</sup> 14.00.** Conductivity water (specific conductance *ca* 10<sup>-7</sup> mho) can be obtained by distilling water in a steam-heated tin-lined still, then, after adding 0.25% of solid NaOH and 0.05% of KMnO<sub>4</sub>, distilling once more from an electrically heated Barnstead-type still, taking the middle fraction into a Jena glass bottle. During these operations suitable traps must be used to protect against entry of CO<sub>2</sub> and NH<sub>3</sub>. Water, only a little less satisfactory for conductivity measurements (but containing traces of organic material) can be obtained by passing ordinary distilled water through a mixed bed ion-exchange column containing, for example, Amberlite resins IR 120 (cation exchange) and IRA 400 (anion exchange), or Amberlite MB-1. This treatment is also a convenient one for removing traces of heavy metals. (The metals Cu, Zn, Pb, Cd and Hg can be tested for by adding pure concentrated ammonia to 10ml of sample and shaking vigorously with 1.2ml of 0.001% dithizone in CCl<sub>4</sub>. Less than 0.1µg of metal ion will impart a faint colour to the CCl<sub>4</sub> layer.) For almost all laboratory purposes, simple distillation yields water of adequate purity, and most of the volatile contaminants such as ammonia and CO<sub>2</sub> are removed if the first fraction of distillate is discarded. Most laboratories have glass stills that “doubly” or “triple” distil water. [See “water” in Chapter 1.]

**Wood's Metal** [76093-98-6] **M ~1486, m ~75<sup>0</sup>, 73-77<sup>0</sup>.** It is a fusible alloy of Bi, Pb, Sn, Cd with the atomic composition of 4:2:1:1 (**m 71<sup>0</sup>**). It is commonly used as a metal bath for heating reaction flasks as it melts at a convenient temperature. Its temperature rises rather rapidly when heated with a Bunsen burner in a crucible (e.g. steel or nickel), so care should be taken when heating a reaction or distilling flask containing chemical reactants immersed into it. Heating should be applied slowly, and the temperature should be monitored continuously with a thermometer immersed in the molten metal. The temperature of the metal can be taken up to ~350<sup>0</sup>, and it is better to work in an efficient fume cupboard as the vapours are toxic. At higher temperature some oxidation of the metal takes place. A bath that has been heated at high temperatures and then the metal cooled back to the solid, and melted again has a solid scum of the oxides on its surface. These can be easily removed with a nickel spatula to leave a nice clean surface. The melting point of the re-used alloy is not seriously affected, and the alloy can be used over and over again without considerable loss in weight. It is commercially available in a granular form or as sticks with the composition of Bi(50 wt%), Pb (25 wt%), Sn (12.5 wt%) and Cd (12.5 wt%). Other such alloys are **Rose's metal (m 93.75<sup>0</sup>)** with the composition of Bi, Pb, Sn in the ratio of 2:1:1, and **Lipowitz alloy (m 60-65<sup>0</sup>)** with the composition of Bi, Pb, Sn, Cd in the ratio 15:8:4:3, but they are not commonly used in the laboratory. Alloys of Bi, Pb and Sn which melt slightly above 100<sup>0</sup> have been used as melting plugs in automatic sprinkler fire alarms.

**Zinc (dust)** [7440-66-6] **M 65.4.** Commercial zinc dust (1.2kg) is stirred with 2% HCl (3L) for 1 minute, then the acid is removed by filtration, and washed in a 4L beaker with a 3L portion of 2% HCl, three 1L portions of distilled water, two 2L portions of 95% EtOH, and finally with 2L of absolute Et<sub>2</sub>O. (The wash solutions were removed each time by filtration.) The material is then dried thoroughly, and if necessary, any lumps are broken up in a mortar. [Wagenknecht & Juza *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1067 1965.]

**Zinc (metal)** [7440-66-6] **M 65.4, m 420<sup>0</sup>, d<sub>4</sub><sup>20</sup> 7.141.** Fuse it under vacuum, cool it, then wash it with acid to remove the oxide.

**Zinc bromide** [7699-45-8] **M 225.2, m 384, b 697.** Heat ZnBr<sub>2</sub> to 300<sup>0</sup> under vacuum (2x10<sup>-2</sup> mm) for 1 hour, then sublime it. [Wagenknecht & Juza *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1072 1965.]

**Zinc chloride** [7646-85-7] **M 136.3, m 283<sup>0</sup>, 290<sup>0</sup>.** The anhydrous material can be sublimed under a stream of dry HCl, followed by heating to 400<sup>0</sup> in a stream of dry N<sub>2</sub>. It sublimes at high vacuum. Also purify it by refluxing (50g) in dioxane (400ml) with 5g zinc dust, filtering hot and cooling to precipitate ZnCl<sub>2</sub>. Crystallise it from dioxane and store it in a desiccator over P<sub>2</sub>O<sub>5</sub>. It has also been dried by refluxing in thionyl chloride. [Weberg et al. *J Am Chem Soc* **108** 6242 1986.] *Hygroscopic: minimal exposure to the atmosphere is necessary.* [Wagenknecht & Juza *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol II p 1070 1965.]

**Zinc-Copper Couple** [53801-63-1] **m 419-420°**. It is available in the form of a powder made of Zn and Cu. If the Zn contains some ZnO, then it should be treated with dilute HCl for a very short period, washed H<sub>2</sub>O, a little EtOH then Et<sub>2</sub>O, and dried *in vacuo* (see also zinc dust above). The *couple* can be prepared in either of the following ways. (1) Zinc dust (120g, MW of Zn is 65.4) and powdered copper oxide (10g, MW of Cu is 63.6) in a round-bottomed flask (~200ml) are heated gently over a flame in a current of H<sub>2</sub> and N<sub>2</sub> with stirring or rotating the flask until the CuO is reduced, and a uniformly gray mixture is obtained. The temperature should be maintained below the point of fusion during heating (~500°) and the mixture is stored in a desiccator. (2) Zinc powder (24.6g) is stirred with 3% aqueous HCl (20ml) for 1 minute, washed by decantation with 3% aqueous HCl (3 x 20ml), with H<sub>2</sub>O (5 x 20ml), with 2% aqueous CuSO<sub>4</sub> (2 x 40ml), distilled H<sub>2</sub>O (5 x 20ml), with EtOH (4 x 20ml), with Et<sub>2</sub>O (2 x 20ml), filtered off on a Büchner funnel, sucked dry then stored in a desiccator over P<sub>2</sub>O<sub>5</sub> overnight. [Corbin et al. *Org Synth* **44** 30 1964, Coll Vol **V** 328 1973; *Smith & Simmons Org Synth* **41** 72 1961, Coll Vol **V** 855 1973.] (3) A suitable zinc/copper alloy with 5—8% of Cu can be prepared by melting zinc (m 419.5°) with clean brass turnings (*ca* 2Cu/1Zn) and casting into bars, which can be turned into fine shavings prior to use. [Noller *Org Synth Coll Vol II* 185 1943.] Note that the couple loses activity in moist air, so it should be kept dry, and used as soon as possible after it is prepared for best results.

When it is required to reduce organic halides to the respective hydrocarbon or deuterated derivative, it is best to prepare the Zn-Cu couple in an oxygen-free system. Thus Zn dust (6.5g, 100mmol) suspended in H<sub>2</sub>O (10ml) is vigorously stirred with acidic cupric chloride solution (15ml of 0.15M in 5% hydrochloric acid) until evolution of gas ceases, the black solid is filtered off, and washed with H<sub>2</sub>O until the filtrate gives a negative chloride test with 6% AgNO<sub>3</sub> solution. The *couple* is washed twice with Me<sub>2</sub>CO, and in order to obtain the highest deuterium incorporation, the Me<sub>2</sub>CO wash should be followed by a D<sub>2</sub>O wash, two Me<sub>2</sub>CO washes, two Et<sub>2</sub>O washes and dried *in vacuo* at ~25°. This preparation of the *couple* is exceptional for replacing the halogen in a variety of organic halides by H or D in water-containing ether solvents, under mild conditions, and in reproducibly moderate to high yields (e.g. 1,4-dideuterobutadiene from 1,4-dichloro-1,3-butadiene, or 2-butanone-3-*d*<sub>1</sub> from 3-bromo-2-butanone). The deuterium derivatives provide a convenient <sup>13</sup>C NMR method for deuterium analysis. [Stephenson et al. *J Org Chem* **42** 212 1977.]

**Zinc cyanide** [557-21-1] **M 117.4, m 800°(dec), d<sub>4</sub><sup>20</sup> 1.852**. It is a **POISONOUS** white powder which becomes black on standing if Mg(OH)<sub>2</sub> and carbonate are not removed in the preparation. Thus, wash it well with H<sub>2</sub>O, then well with EtOH, Et<sub>2</sub>O and dry it in air at 50°. Analyse it by titrating the cyanide with standard AgNO<sub>3</sub>. Other likely impurities are ZnCl<sub>2</sub>, MgCl<sub>2</sub> and traces of basic zinc cyanide; the first two salts can be washed out. It is soluble in aqueous KCN solutions. However, if purified in this way Zn(CN)<sub>2</sub> is not reactive in the Gattermann synthesis. For this, the salt should contain at least 0.33 mols of KCl or NaCl which will allow the reaction to proceed faster. [Adams & Levine *J Am Chem Soc* **45** 2375 1923, Arnold & Sorung *J Am Chem Soc* **60** 1699 1938, Fuson et al. *Org Synth Coll Vol III* 549 1955.]

**Zinc fluoride** [7783-49-5] **M 103.4, m 872°, b 1500°, d<sub>4</sub><sup>25</sup> 5.00**. A possible impurity is H<sub>2</sub>O which can be removed by heating at 100° or by heating to 800° in a dry atmosphere. Heating in the presence of NH<sub>4</sub>F produces larger crystals. It is sparingly soluble in H<sub>2</sub>O (1.51g/100ml) but more soluble in HCl, HNO<sub>3</sub> and NH<sub>4</sub>OH. It can be stored in glass bottles. [Kwasnik in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **I** p 242 1963.]

**Zinc iodide** [10139-47-6] **M 319.2, m 446, b 624°(dec), d<sub>4</sub><sup>20</sup> 4.74**. Heat the iodide to 300°/2 x 10<sup>-2</sup>mm for 1 hour, then sublime it. Its solubility in H<sub>2</sub>O is 0.3ml/g, and it is soluble in EtOH. Store it in the dark.

**Zinc perchlorate hexahydrate** [13637-61-1] **M 372.4, m 105-107°, pK<sup>25</sup> -2.4 to -3.1 (for HClO<sub>4</sub>)**. Crystallise it from a small volume of H<sub>2</sub>O. It is soluble in EtOH. **Potentially EXPLOSIVE.**

**Zinc-Silver Couple** [37350-66-6]. It is best to prepare the couple fresh when used to replace a vinylic bromine atom in organic compounds by a hydrogen atom, deuterium atom or a tritium atom. The zinc dust to be used should first be cleaned from any zinc oxide or greasy material. Zinc dust (22g) is stirred under N<sub>2</sub> at ~25° as a suspension in 10% aqueous HCl (110ml) for 20 minutes. Acetone (50ml) is added to the mixture, the liquid is decanted from the metal, and the gray slurry is washed thoroughly with Me<sub>2</sub>CO (6 x 50ml) by decantation. The residual Zn is treated with a boiling suspension of AgOAc (~6.6g) in AcOH (125ml), stirred rapidly without

further heating, the liquid is decanted off and the black granular solid that is formed is washed with AcOH (2 x 60ml), Me<sub>2</sub>CO (2 x 20ml), and finally dry THF (2 x 50ml). Store it under N<sub>2</sub> in the dark. If it is used for deuterium replacement of bromine it is best to stir the couple with D<sub>2</sub>O (5ml) in dry THF (50ml) for 15 minutes, decant, repeat the process a second time and then wash the solid with dry THF (50ml). This reduces the amount of proton incorporation while maximising deuterium incorporation. [Fryzuk & Bosnich *J Am Chem Soc* **101** 3043 1979, Clark & Heathcock *J Org Chem* **41** 636 1976.]

**Zinc sulfate heptahydrate (white vitriol)** [7446-20-0 (7 H<sub>2</sub>O) 7446-19-7 (H<sub>2</sub>O), 7733-02-0 (anhydrous)] **M 287.5, m 100°(dec), 280°(loses all 7H<sub>2</sub>O), >500(anhydrous), d<sub>4</sub><sup>20</sup> 1.97.** Crystallise it from aqueous EtOH or dilute H<sub>2</sub>SO<sub>4</sub> below 39° when it forms the *heptahydrate*, and between 39° and 70° it forms the *hexahydrate*, and above 70° the *monohydrate* is stable. The *anhydrous salt* is obtained from the hydrates by heating at 280° or lower temperatures in a current of dry air. It decomposes to ZnO and SO<sub>2</sub> at 767°. The solubility of the *heptahydrate* in H<sub>2</sub>O is 5.88% at 0°, 61.92% at 30°, 66.61% at 35° and 70.05% at 39°.

**Zirconium tetrachloride** [10026-11-6] **M 233.0, m 300°(sublimes), pK<sub>1</sub><sup>25</sup> -0.32, pK<sub>2</sub><sup>25</sup> 0.06, pK<sub>3</sub><sup>25</sup> 0.35, pK<sub>4</sub><sup>25</sup> 0.46 (for hydrolysis of aquo Zr<sup>4+</sup>).** Crystallise it repeatedly from conc HCl. It is hydrolysed by H<sub>2</sub>O to form white ZrOCl<sub>2</sub> (see below) and HCl. [Krebs *Z Anorg Allgem Chem* **378** 263 1970.]

**Zirconyl chloride hexahydrate** [7699-43-6] **M 286.2, m 150°(loses 6H<sub>2</sub>O).** Crystallise it repeatedly from 8M HCl to give ZrOCl<sub>2</sub>·8H<sub>2</sub>O (see below). On drying, ZrOCl<sub>2</sub>·6H<sub>2</sub>O, **m 150°**, is formed. The product is not free from hafnium. [Blumenthal *J Chem Ed* **39** 607 1962.]

**Zirconyl chloride octahydrate** [13520-92-8] **M 322.3, m 150° (loses 6H<sub>2</sub>O), 210° (loses all H<sub>2</sub>O), 400° (anhydrous dec), d<sub>4</sub><sup>20</sup> 1.91.** Recrystallise the chloride several times from water [Ferragina et al. *J Chem Soc, Dalton Trans* 265 1986]. Recrystallisation from 8M HCl gives the *octahydrate* as white needles on concentrating. It is also formed by hydrolysing ZrCl<sub>4</sub> with water. After one recrystallisation from H<sub>2</sub>O, 99+% grade zirconyl chloride had Ag, Al, As, Cd, Cu, Hf, Mg, Na, Sc and V at 20, 1.8, 0.6, 0.6, 0.4, 8.4, 0.4, 2.4, 80 and 3 ppm, respectively. (See above.)

## METAL-ORGANIC COMPOUNDS

This section contains metal-organic compounds, ammonium and metal derivatives of organic alcohols, amines and carboxylic acids (salts), as well as ionophores that form complexes with metal ions. Note that there is a large number of metal-organic catalysts, and reagents for preparing some of these catalysts, in Chapter 6, and can be considered as an extension of this section. (For Introduction see p 555.)

**Acetylenedicarboxylic acid monopotassium salt** [928-04-1] **M 152.2**. It is very soluble in H<sub>2</sub>O, but can be crystallised from a small volume of H<sub>2</sub>O in small crystals. These are washed with EtOH and dried over H<sub>2</sub>SO<sub>4</sub> at 125°. [Bandrowski *Chem Ber* **10** 841 1877, Lossen *Justus Liebigs Ann Chem* **272** 133 1893, *Beilstein* **2** H 801, **2** I 317, **2** II 670, **2** III 1991, **2** IV 2290.]

**Acetylferrocene (ferrocenyl methylketone)** [1271-55-2] **M 228.1, m 86°, 86-87°**. Orange-red crystals are obtained when it is recrystallised from isooctane or \*C<sub>6</sub>H<sub>6</sub>, and then sublimed at 100°/1mm. The *oxime* has **m** 167-170° (from Et<sub>2</sub>O or aqueous EtOH). The *semicarbazone* has **m** 198-201° (from EtOH). [Richmond & Freiser *J Am Chem Soc* **77** 2022 1955, Weinmayer *J Am Chem Soc* **77** 3009 1955, Broadhead et al. *J Chem Soc* **650** 1958, *Beilstein* **16** IV 1798.]

**Allylpalladium(II) chloride dimer** [12012-95-2] **M 365.9, m ~160°**. It crystallises from benzene and is soluble in MeOH, Et<sub>2</sub>O and CHCl<sub>3</sub>. [Hüttel et al. *Chem Ber* **94** 766 1961, Dent et al. *J Chem Soc* 1585 1964, Armstrong *J Org Chem* **31** 618 1966.]

**Allyl tri-*n*-butylstannane (allyl tributyl tin)** [24850-33-7] **M 331.1, b 88-92°/0.2mm, 115°/17mm, d<sub>4</sub><sup>20</sup> 1.068, n<sub>D</sub><sup>20</sup> 1.487**. A possible impurity is tributylchlorostannane — test for Cl as Cl ion after hydrolysing. Dissolve it in \*C<sub>6</sub>H<sub>6</sub> (or toluene), shake this with dilute aqueous NaOH, dry (CaCl<sub>2</sub>), filter, evaporate and distil the residue in a vacuum [Jones et al. *J Chem Soc* 1446 1947, Bristow *Aldrichimica Acta* **17** 75 1984, Yamamoto *Aldrichimica Acta* **20** 45 1987]. [*Beilstein* **4** IV 4317.]

**Aluminum acetylacetonate (tris[2,4-pentandionate]aluminium)** [13963-57-0] **M 324.3, m 192-194°, 195°**. Recrystallise it several times from \*benzene or aqueous MeOH, λ<sub>max</sub> 216 and 286nm. [Charles & Pawlikowski *J Phys Chem* **62** 440 1958.] It can be purified by sublimation and has the following solubilities in g percent: \*C<sub>6</sub>H<sub>6</sub> 35.9 (20°), 47.6 (40°), toluene 15.9 (20°), 22.0 (40°) and acetylacetone 6.6 (20°), 10.4 (40°). [Fernelius & Bryant *Inorg Synth* **V** 105 1957, *Beilstein* **1** IV 3668.]

**Aluminum ethoxide** [555-75-9] **M 162.2, m 154-159°, 146-151°, b 187-190°/7mm, 210-214°/13mm**. Crystallise it from CS<sub>2</sub> [**m** 139°, CS<sub>2</sub> complex] and distil it in a vacuum. The molecular weight corresponds to [Al(OEt)<sub>3</sub>]<sub>4</sub> [Robinson & Peak *J Phys Chem* **39** 1127 1935, Vilani & Nord *J Am Chem Soc* **69** 2605 1947]. [*Beilstein* **1** H 313, **1** I 158, **1** II 3008, **1** III 1284, **1** IV 1289.]

**Aluminium isopropoxide** [555-31-7] **M 204.3, m 119°, b 94°/0.5mm, 135°/10mm**. Redistil it under vacuum. *Hygroscopic*. [Robinson & Peak *J Phys Chem* **39** 1127 1935, *Beilstein* **1** IV 1468.]

**Aluminum triethyl (triethyl aluminum)** [97-93-8] **M 114.2, b 69°/1.5mm, 76°/2.5mm, 129-131°/55mm, d<sub>4</sub><sup>20</sup> 0.695, n<sub>D</sub><sup>20</sup> 1.394**. Purify Al(Et)<sub>3</sub> by fractionation in an inert atmosphere under a vacuum in a 50cm column containing a heated nichrome spiral, taking the fraction **b** 112-114°/27mm. It is very sensitive to H<sub>2</sub>O and should be stored under N<sub>2</sub>. It should not contain chloride ions which can be shown by hydrolysis and testing with AgNO<sub>3</sub>. [Baker & Sisler *J Am Chem Soc* **75** 4828 5193 1953, NMR: Brownstein et al. *J Am Chem Soc* **81** 3826 1959, *Beilstein* **4** IV 4398.]

**Aluminium tri-*tert*-butoxide** [556-91-2] **M 246.3, m 208-210°(dec), >300°**. Crystallise Al(O-*t*Bu)<sub>3</sub> from \*C<sub>6</sub>H<sub>6</sub> and sublime it at 180°. [McElvain & Davie *J Am Chem Soc* **73** 1400 1951, *Beilstein* **1** IV 1612.]

**Aluminium trimethanide (trimethyl aluminium)** [75-24-1] **M 72.1, m 15.2°, b 111.5°/488.2mm, 124.5°/atm,  $d_4^{20}$  0.725.** Distil  $\text{Al}(\text{Me})_3$  through a 10-20 theoretical plates column under 1 atmosphere pressure of  $\text{N}_2$  (better with very slow take-off). It attacks grease (use glass joints). It has been distilled over Al in absence of grease, into small glass vials and sealed under  $\text{N}_2$ . The purity is measured by its freezing point. It reacts with  $\text{H}_2\text{O}$ , is non-conducting in  $\text{C}_6\text{H}_6$  and is **HIGHLY FLAMMABLE**. [Bamford et al. *J Chem Soc* 468 1946, Pitzer & Gutowsky *J Am Chem Soc* 68 2204 1946, *Beilstein* 4 IV 4397.]

**4-Aminophenylmercuric acetate** [6283-24-5] **M 371.8, m 168°, 175°(dec), 180°(dec).** Recrystallise it from hot dilute AcOH and dry it in air. Highly **TOXIC**. [Mahapatra et al. *J Indian Chem Soc* 32 613 1955, Albert & Schneider *Justus Liebigs Ann Chem* 465 269 1928, *Beilstein* 16 III 1411, 16 IV 1754.]

**Ammonium acetate** [631-61-8] **M 77.1, m 112-114°,  $d_4^{20}$  1.04.** Crystallise it twice from anhydrous acetic acid, and dry under vacuum for 24 hours at 100° [Proll & Sutcliffe *Trans Faraday Soc* 57 1078 1961].

**Ammonium benzoate** [1863-63-4] **M 139.2, m 198°, 200°(dec),  $d_4^{20}$  1.26.** Crystallise it from EtOH. [*Beilstein* 9 IV 273.]

**Ammonium dodecylsulfate (ammonium laurylsulfate)** [2235-54-3] **M 283.4.** Recrystallise it first from 90% EtOH and then twice from absolute EtOH, and finally dry it in a vacuum. [*Beilstein* 1 III 1786.]

**Ammonium ferric oxalate trihydrate** [13268-42-3] **M 428.1, m ~160°(dec),  $d_4^{20}$  1.77.** Crystallise it from hot water (0.5ml/g). [*Beilstein* 3 III 1103.]

**Ammonium formate** [540-69-2] **M 63.1, m 116°, 117.3°,  $d_4^{45}$  1.280.** Heat the solid in  $\text{NH}_3$  vapour and dry it in a vacuum till the  $\text{NH}_3$  odour is faint (note that it can evaporate completely in a vacuum). Recrystallise it from absolute EtOH and then keep it in a desiccator over 99%  $\text{H}_2\text{SO}_4$  *in vacuo*. It is very *hygroscopic*. It exists in two forms, stable needles and less stable plates. It also forms acid salts, i.e.  $\text{HCO}_2\text{NH}_4 \cdot 3\text{HCO}_2\text{H}$  and  $\text{HCO}_2\text{NH}_4 \cdot \text{HCO}_2\text{H}$ . [Kensall & Adler *J Am Chem Soc* 43 1473 1921, *Beilstein* 2 IV 18.]

**Ammonium ionophore I (Nonactin)** [6833-86-7] **M 736.9, m 147-148°,  $[\alpha]_D^{20}$  0° (c 1.2,  $\text{CHCl}_3$ ).** Crystallise it from MeOH (colourless needles), and it is dried at 20° in high a vacuum. It is a selectophore with high sensitivity for  $\text{NH}_4^+$  ions. [Corbaz et al. *Helv Chim Acta* 38 1445 1955, Domingues et al. *Helv Chim Acta* 45 129 1962, Nawata & Ando *Helv Chim Acta* 55 1371 1972, *Beilstein* 19/12 V 751.]

**Ammonium oxalate dihydrate** [6009-70-7] **M 142.1,  $d_4^{20}$  1.50.** Crystallise it from water (10ml/g) at 50°. [*Beilstein* 2 IV 1846.]

**Ammonium picrate** [131-74-8] **M 246.1, m EXPLODES above 200°.** Crystallise it from EtOH and acetone. [Mitchell & Bryant *J Am Chem Soc* 65 128 1943, *Beilstein* 6 II 262, 16 III 879, 16 IV 1392.]

***n*-Amylmercuric chloride** [544-15-0] **M 307.2, m 110°.** Crystallise it from EtOH. The *bromide* has **m 122°**. [Larock & Brown *J Am Chem Soc* 92 2467 1970, Marvel et al. *J Am Chem Soc* 47 3009 1925, *Beilstein* 14 H 706, 725.]

**Aurothioglucose (gold thioglucose)** [12192-57-3] **M 392.2.** Purify it by dissolving it in  $\text{H}_2\text{O}$  (0.05g in 1ml) and precipitating it by adding EtOH. It yields yellow crystals with a slight mercaptan odour. It decomposes slowly in  $\text{H}_2\text{O}$ , and is soluble in propylene glycol but insoluble in EtOH and other common organic solvents. [Cateron & Taylor *FEBS Lett* 98 351 1979, Cooney et al. *Biochem J* 259 651 1989.]

**Barium acetate** [543-80-6] **M 255.4.** Crystallise the salt twice from anhydrous acetic acid and dry it under vacuum for 24 hours at 100°. [*Beilstein* 2 I 49, 2 II 117, 2 III 192, 2 IV 114.]

**Barium ionophore I** [*N,N,N',N'*-tetracyclohexyloxy-bis-(*o*-phenyleneoxy)diacetamide] [96476-01-6] **M**

**644.9, m 156-158°.** Purify the ionophore by chromatography on a Kieselgel column, elute it with  $\text{CH}_2\text{Cl}_2/\text{EtOAc}$  (5:1), and recrystallise the residue from the evaporated effluent from  $\text{EtOH}/\text{Me}_2\text{CO}$  to give colourless crystals. It is an electrically neutral ionophore with high selectivity for  $\text{Ba}^{2+}$  ions and with high lipophilicity. [Kleiner et al. *Chem Ber* **118** 1071 1985, Läubli et al. *Anal Chem* **57** 2756 1985.]

**Barium propionate ( $\text{H}_2\text{O}$ )** [5908-77-0] **M 301.5,  $d_4^{27}$  1.44,  $\text{pK}^{24}$  4.88 (for propionic acid).** Crystallise it from warm water (50ml/g) by adding  $\text{EtOH}$  and cooling. [*Beilstein* **2** III 517, **2** IV 702.]

**Benzenechromium(0) tricarbonyl** [12082-08-5] **M 214.1, m 162-163°, 163-166°.** Purify the complex by sublimation *in vacuo*. A possible impurity is 2-picoline which can be removed by washing with pentane and drying. It is then purified further by sublimation at  $80\text{-}85^\circ/10^{-3}\text{mm}$ , or by recrystallisation from  $\text{Et}_2\text{O}$  to give yellow crystals.  $^1\text{H}$  NMR in  $\text{CDCl}_3$  should give a single peak at  $\tau$  4.68. [Rausch *J Org Chem* **39** 1787 1974, Pauson in Houben-Weyl *Meth Org Chem* V, E 18 Pt I p226 Theme Verlag, Stuttgart 1986, *Beilstein* **5** IV 625.]

**Beryllium acetate [ $\text{Be}(\text{OAc})_2$ ]** [543-81-7] **M 127.1, m 65-100° (slow heating), 155-180° (rapid heating).** It is obtained by dissolving the *basic acetate* (4g, see below) in boiling glacial  $\text{AcOH}$  containing acetyl chloride (4.5g) and refluxing for ~15 minutes. The  $\text{Be}(\text{OAc})_2$  which separates during this time, is filtered off, washed with  $\text{AcOH}$ , cold  $\text{CHCl}_3$  and dried *in vacuo* to give 90-94% yield of the salt. It is stable for several weeks in a tightly stoppered container at  $\sim 25^\circ$ . It slowly loses  $\text{Ac}_2\text{O}$ , and more rapidly on heating, to give the basic acetate which sublimes out. Strong heating partially decomposes it to give  $\text{Ac}_2\text{O}$  and  $\text{BeO}$ . It is not readily attacked by cold  $\text{H}_2\text{O}$  but forms a hydrate on warming, and is insoluble in most solvents. [Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **I** p 901 1963, Besson & Hardt *Z Anorg Allg Chem* **277** 188 1954.] Beryllium compounds are potentially **carcinogenic**.

**Beryllium acetate (basic) [ $\text{Be}_4\text{O}(\text{OAc})_6$ ]** [1332-52-1] **M 406.3, m 283°, 285-286°, b 330-331°/atm.** On evaporating  $\text{Be}(\text{OH})_2$  with  $\text{AcOH}$  this covalent basic acetate is produced. *Alternatively*,  $\text{BeCO}_3$  (40g, see [744998-97-8]) and  $\text{AcOH}$  (80ml) are heated with stirring until evolution of  $\text{CO}_2$  ceases. When the reaction is complete, white semi-translucent crystals separate. After cooling to  $\sim 25^\circ$ , the basic acetate crystals are filtered off and dried in air. These are treated with warm  $\text{CHCl}_3$  (60-80ml), any insoluble material is filtered off, and the colourless octahedral crystals of the basic acetate which separate on cooling (with partial evaporation) are collected and freed from any  $\text{CHCl}_3$  *in vacuo* to give pure basic salt (28g, ~47%, **m 284°**). It is readily volatile, it can be distilled, and it sublimes in a vacuum leaving a small residue of 0.3-0.5% of  $\text{BeO}$ . It is very soluble in  $\text{CHCl}_3$ , soluble in non-polar organic solvents such as boiling  $^*\text{C}_6\text{H}_6$ , toluene, xylene, tetralin, and in  $\text{AcOH}$ ; less so in  $\text{CCl}_4$ ,  $\text{Ac}_2\text{O}$  and  $\text{AcCl}$ , but is sparingly soluble ( $\sim 0.3\%$ ) in  $\text{Et}_2\text{O}$ . It dissolves in anhydrous boiling  $\text{MeOH}$  but soon liberates  $\text{Ac}_2\text{O}$  to form highly aggregated basic acetates. It is quite stable in cold  $\text{H}_2\text{O}$ , but is rapidly hydrolysed in hot  $\text{H}_2\text{O}$ . [Moeller et al. *Inorg Synth* **III** 9 1950, Ehrlich in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **I** p 901 1963, and for the basic formate or propionate salts see Besson & Hardt *Z Anorg Allg Chem* **277** 188 1954, Hendus & Hardt *Z Anorg Allg Chem* **277** 127 1954, Hendus & Hardt *Z Anorg Allg Chem* **286** 265 1956, and Hardt *Z Anorg Allg Chem* **286** 254 1956, *Beilstein* **2** H 111, **2** I 48, **2** II 116, **2** III 190, **2** IV 112.] The X-ray crystal structure shows that the four beryllium atoms are arranged at the corners of a regular tetrahedron with oxygen at the centre, and the six edges are occupied by acetate groups. Thus the four Be atoms at the apexes of the tetrahedron are coordinated to the carboxyl oxygen atoms of the six acetate groups, i.e. each Be atom is coordinated to three oxygen atoms. [Bragg & Morgan *Proc Roy Soc* **104** 437 1923, for partial structure see also F.A. Cotton and G. Wilkinson *Advanced Inorganic Chemistry (A Comprehensive Text)* p. 175, Interscience Publ. 1962, Library of Congress Catalog Number 62-14818.] Beryllium compounds are potentially **carcinogenic**.

**Beryllium acetylacetonate [ $\text{Be}(\text{acac})_2$ ]** [10210-64-7] **M 207.2, m 108°, 108.5-109°, b 270°,  $d^{20}$  1.168.** This complex has been prepared by adding 3M aqueous  $\text{NaOH}$  (100ml) to a solution of  $\text{BeSO}_4 \cdot 4\text{H}_2\text{O}$  (10g, see [7787-50-0]) in distilled  $\text{H}_2\text{O}$  (100ml) to give a strong basic solution to which is added freshly distilled acetylacetone (30ml) dropwise with stirring, and a white precipitate separates. This is collected, washed with  $\text{H}_2\text{O}$  and dried *in vacuo* to give the complex (5.1g 43%) which is recrystallised by dissolving in a small volume of  $^*\text{C}_6\text{H}_6$  and adding gradually petroleum ether until crystallisation is complete. The crystals are collected, washed with

petroleum ether and dried *in vacuo*. It can be recrystallised further from a small volume of \*C<sub>6</sub>H<sub>6</sub> or a large volume of petroleum ether. It has also been prepared in 70% yield from basic beryllium carbonate (3g) in H<sub>2</sub>O (45ml) by conversion to the chloride with 6N aqueous HCl (*ca* 20ml) until slightly acidic. To this is added dropwise a clear solution of acetylacetone (10g suspended in 45ml of H<sub>2</sub>O to which is added 6N ammonia until completely clear) and stirred until precipitation of the complex is complete (pH should be near neutral). The solid is collected washed with H<sub>2</sub>O, dried, and crystallised as before. It is also sublimed through a plug of glass wool at a vacuum of 0.1mm by heating in a bath at 80 to 100°. It is very soluble in most organic solvents such as EtOH, Et<sub>2</sub>O, Me<sub>2</sub>CO, \*C<sub>6</sub>H<sub>6</sub> and in CS<sub>2</sub> but considerably less in petroleum ethers. However, it is practically insoluble in H<sub>2</sub>O which hydrolyses it on boiling; and it is also hydrolysed by acids and alkalis. [Jones *J Am Chem Soc* **81**, 3188 1959, Arch & Young *Org Synth II* 17 1946.] Beryllium compounds are potentially carcinogenic.

**Bicyclo[2.2.1]hepta-2,5-diene rhodium (I) chloride dimer (norbornadiene rhodium chloride complex dimer)** [12257-42-0] **M 462, m 240°(dec)**. It recrystallises from hot CHCl<sub>3</sub>/petroleum ether as fine crystals soluble in CHCl<sub>3</sub> and \*C<sub>6</sub>H<sub>6</sub> but is almost insoluble in Et<sub>2</sub>O or petroleum ether. [Abel et al. *J Chem Soc* 3178 1959.]

**2,2'-Bipyridinium chlorochromate** [76899-34-8] **M 292.6**. Wash it with cold conc HCl, then H<sub>2</sub>O (sintered glass funnel) and dry it in a vacuum (CaCl<sub>2</sub>) to give a free-flowing yellow-brown powder. Store it in the dark. [Guziec & Luzzio *Synthesis* 691 1980, Chakraborty & Chandrasekaran *Synth Commun* **10** 951 1980.] **SUSPECTED CARCINOGEN.**

**2,2'-Biquinolin-4,4'-dicarboxylic acid dipotassium salt** [63451-34-3] **M 420.51**. Recrystallise it from H<sub>2</sub>O. The *Cu salt* has UV with  $\lambda_{\max}$  at 562nm. [Mopper & Gindler *Anal Biochem* **56** 440 1973, Beilstein **25** IV 1148.]

**Bis(1,2,3,4,5- $\eta$ -cyclooctadienyl)ruthenium [Ru(COD)<sub>2</sub>]** [63395-36-8] **M 315.4, m 89-90°, 113-114°**. The bis-complex is prepared by adding a solution of RuCl<sub>3</sub> · 3H<sub>2</sub>O (624mg, 1.33mol) in EtOH (20ml) under argon (or N<sub>2</sub>) slowly over 30 minutes to a stirred suspension of Zn powder (7g), EtOH (5ml) and redistilled 1,2-5,6-cyclooctadiene (11ml, 80mol), COD see [111-78-4, 1552-12-1], then stirring at room temperature for 2 hours, and filtering the mixture under N<sub>2</sub>. The filtrate is concentrated on a vacuum line to remove volatiles, and the residual brown oil is placed on top of an Al<sub>2</sub>O<sub>3</sub> column in hexane after flushing with N<sub>2</sub>. The yellow band is eluted with hexane, concentrated *in vacuo*, the eluate is evaporated, pentane is added to dissolve the residue and the solution is cooled at -78° for several hours, to provide very pale yellow (almost colourless) crystals of the analytically pure complex (283mg, 35%). The <sup>1</sup>H NMR (60MHz, C<sub>6</sub>D<sub>6</sub>, TMS) has  $\tau$  at 4.42 (t, 2H), 6.15 (dd, 4H), 6.45 (m, 4H) and 7.49-8.95 (m, 12H); and the <sup>13</sup>C NMR (22.6MHz, C<sub>6</sub>D<sub>6</sub>, TMS) has  $\delta$  at 22.5, 27.3, 36.7, 35.3, 38.9, 62.4, 76.7, 87.6. [Pertici et al. *J Chem Soc, Perkin Trans* 1961 1980 (gave m 89-90°), Itoh et al. *J Organomet Chem* **272** 179 1984 (gave m 113-114°)].

**Bis( $\eta^5$ -2,4-cyclopentadien-1-yl)samarium II [SmCp<sub>2</sub>, samarocene]** [80695-16-5] **M 280.5, decomposes at high temperatures**. Samarium dicyclopentadienyl can be prepared in Schlenk equipment under argon by adding SmI<sub>2</sub> (0.1M in THF, 60ml, 6mmol) to a 0.4M solution of sodium pentadienide in THF (30ml, 12mmol) when the complex separates immediately and is decanted within 1 hour. The red powder of SmCp<sub>2</sub> is collected, washed twice with THF to remove NaI, dried *in vacuo* and stored under argon. The red powder and the purple solid THF complex (**M 352.6**) are *pyrophoric* in air. SmCp<sub>2</sub> can also be stored for a few days in a Schlenk tube under THF without decomposition. Freshly prepared suspensions of SmCp<sub>2</sub> have been used in pseudo-Barbier couplings between carbonyl compounds and aliphatic or allylic halides and are more efficient than SmI<sub>2</sub> [Namy et al. *J Organometal Chem* **328** 81 1986].

**SmCp<sub>2</sub>-THF** has been prepared in one arm of a U-tube by stirring in an anhydrous oxygen-free helium atmosphere) tris(cyclopentadienyl)samarium III (SmCp<sub>3</sub>, 0.499g), K metal (0.527g, naphthalene (0.128g, 25% molar deficiency) and THF (25ml, freshly distilled under reduced pressure from Na-benzophenone) for 48 hours. Purple SmCp<sub>2</sub>-furanate was separated by decantation, washed by successive back-distillation with THF and the

solvent is removed at 24°/10<sup>-3</sup>mm during 18 hours. It is *pyrophoric* and should be handled in an anhydrous oxygen-free atmosphere. Its IR has  $\nu_{\max}$  (Nujol) at 3080 (C-H stretch), 1475, 1347, 1308, 1263, 1163, 1070, 1008 (C-H bend parallel), 775, 740 (C-H bend perpendicular) and 350 (antisym metal-ring vibration) cm<sup>-1</sup>, and other bands at 2980, 2880, 1375, 725 and 565 cm<sup>-1</sup> due to coordinated THF with intensities similar to the weaker metallocene bands. On exposure to traces of air this complex immediately changes in colour from deep purple to yellow-gray with drastic reduction in the paramagnetism. [Watt & Gillow *J Am Chem Soc* **91** 775 1969.]

**Bis(2,9-dimethyl-1,10-phenanthroline) copper(I) perchlorate (Cuproine)** [54816-44-5] **M 579.6, pK<sup>25</sup> -2.4 to -3.1 (for HClO<sub>4</sub>) and 6.15 (for dimethylphenanthroline).** Crystallise it from acetone. It has UV with  $\lambda_{\max}$  in isopentanol or hexan-1-ol at 454nm. [Smith & McCurdy *Anal Chem* **24** 371 1952, Gahler *Anal Chem* **26** 577 1954, *Beilstein* **23** III/IV 1737.]

**1,1'-Bis(diphenylphosphino)ferrocene** [12150-46-8] **M 554.4, m 181-183°, 184-194°.** Wash the ferrocene with distilled H<sub>2</sub>O and dry it in a vacuum. Dissolve it in *ca* 5 parts of hot dioxane and cool to give orange crystals **m** 181-183°. Recrystallisation from \*C<sub>6</sub>H<sub>6</sub>/heptane (1:2) gives a product with **m** 183-184°. [Bishop et al. *J Organomet Chem* **27** 241 1971.]

**Bis(ethyl)titanium(IV) chloride** [2247-00-9] **M 177.0.** Recrystallise it from boiling toluene. [See Marek (ed) *Titanium and Zirconium in Organic Synthesis* Wiley-VCH 2002 ISBN 3-527-304-28-2, Wailes et al. *Organometallic Chemistry of Titanium, Zirconium and Hafnium* Academic Press 1974 ISBN 0-127303502.]

**Bis(ethyl)zirconium(IV) chloride** [92212-70-9] **M 220.3.** Recrystallise it from boiling toluene. [See Marek (ed) *Titanium and Zirconium in Organic Synthesis* Wiley-VCH 2002 ISBN 3-527-304-28-2, Wailes et al. *Organometallic Chemistry of Titanium, Zirconium and Hafnium* Academic Press 1874 ISBN 0-127303502.]

**N,N'-Bis(salicylidene)ethylenediamine cobalt (II) [Co(SALEN)<sub>2</sub>, salcomine]** [14167-18-1] **M 325.2.** The powder should have an oxygen capacity of 4.7-4.8% as measured by the increase in weight under O<sub>2</sub> at 100 pounds pressure at *ca* 20°. The O<sub>2</sub> is expelled on heating the material to 65°. It crystallises from pyridine, CHCl<sub>3</sub> or \*C<sub>6</sub>H<sub>6</sub>, and the solvent may be removed by heating at 120° in a vacuum. However, this heating may mean reduced O<sub>2</sub> capacity. In the dry state it absorbs O<sub>2</sub>, turning from a maroon colour to black. [Diehl & Hack *Inorg Synth* **III** 196 1950.]

**Bis(tetrabutylammonium) dichromate** [56660-19-6] **M 700.9, m 139-142°.** Wash the dichromate with water and dry it in a vacuum. Recrystallise it from hexane (**m** 79-80°). [Santaniello & Ferraboschi *Synth Commun* **10** 75 1980, *Beilstein* **4** IV 556.] (Possible **CARCINOGEN**.)

**n-Butylmercuric chloride** [543-63-5] **M 293.1, m 130°.** Crystallise it from 95% EtOH. [Larock & Brown *J Am Chem Soc* **92** 2467 1970, Marvel et al. *J Am Chem Soc* **47** 3009 1925.]

**n-Butylstannoic acid [PhSn(OH)<sub>3</sub>, trihydroxy-n-butylstannane]** [22719-01-3] **M 208.8.** Purify it by adding excess KOH in CHCl<sub>3</sub> to remove *n*-BuSn(OH)Cl<sub>2</sub> and *n*-BuSn(OH)<sub>2</sub>Cl, and isolate it by acidification [Holmes et al. *J Am Chem Soc* **109** 1408 1987].

**Cadion [1-(4-nitrophenyl)-3-(4-phenylazophenyl)-triazene]** [5392-67-6] **M 346, m 189°(dec).** Commercial cadion is purified by recrystallisation from 95% EtOH and is dried *in vacuo*. It is stable in 0.2 N KOH (in 20% aqueous EtOH) at 25°. It is a sensitive reagent for Cd, and the Cd complex has UV with  $\lambda_{\max}$  (EtOH) at 475nm. [Chavanne & Geronimi *Anal Chim Acta* **19** 377 1958, *Beilstein* **16** III 664.]

**Cadmium acetate dihydrate** [5743-04-4] **M 230.5, m 255°(anhydrous), d<sub>4</sub><sup>20</sup> 2.01 (hydrate), 2.34 (anhydr), pK<sub>1</sub><sup>25</sup> 9.7, pK<sub>2</sub><sup>25</sup> ~11.0 (for Cd<sup>2+</sup>).** Recrystallise it twice from anhydrous acetic acid and dry it under vacuum for 24 hours at 100°. [*Beilstein* **2** IV 114.]

**Cadmium ionophore I [N,N,N',N'-tetramethyl-3,6-dioxooctanedi-(thioamide)]** [73487-00-0] **M 432.7, m**

**35-36°.** Wash it well with petroleum ether, then several times with 2N HCl (if it has a slight odour of pyridine), then H<sub>2</sub>O and dry it in a vacuum over H<sub>2</sub>SO<sub>4</sub>. It is a polar selectrophore for Cd. [Schneider *Helv Chim Acta* **63** 217 1980, Simon & Carafoli *Methods Enzymol* **56** 439 1977.]

**Cadmium lactate** [16039-55-7] **M 290.6.** Recrystallise the lactate from water (10ml/g) by partial evaporation in a desiccator. [Beilstein **3** H 277, **3** III 465, **2** IV 637.]

**Cadmium salicylate** [19010-79-8] **M 248.5, 242°(dec).** Recrystallise it from distilled H<sub>2</sub>O by evaporation in a desiccator. It is an antiseptic. [Prasad et al. *J Indian Chem Soc* **35** 267 1958, *Beilstein* **10** H 60, **10** I 25, **10** II 33, **10** III 94, **10** IV 128.]

**Calcein sodium salt** [2',7'-bis-{N,N-di(carboxymethyl)aminomethyl}fluorescein Na salt, **Fluorexon, Fluorescein Complexon**] [108750-13-6 diNa salt, 1461-15-0 free acid] **M 666.5, pK<sub>Est(1)</sub>~1.9, pK<sub>Est(2)</sub>~2.5, pK<sub>Est(3)</sub>~8.0, pK<sub>Est(4)</sub>~10.5 (all for N-CH<sub>2</sub>COOH), and pK<sub>Est(5)</sub>~3.5 (for benzoic COOH).** Dissolve it in distilled H<sub>2</sub>O and acidify with dilute HCl to pH 3.5. Filter off the solid acid and wash it well with H<sub>2</sub>O. Redissolve *ca* 10g in 300ml H<sub>2</sub>O containing 12g of NaOAc. Precipitate it again by adding HCl, filtering and washing with H<sub>2</sub>O. Add the solid to 200ml of EtOH stir for 1 hour and filter. Repeat the EtOH wash and dry the bright yellow solid in a vacuum. This acid decomposes on heating at *ca* 180°. See below for the preparation of the Na salt. [Diehl & Ellingboe *Anal Chem* **28** 882 1956].

*Alternatively*, dissolve it in H<sub>2</sub>O and acidify with 3N HCl to pH 3.5. Collect the solid and wash it with H<sub>2</sub>O. The air-dried precipitate is extracted with 70% aqueous EtOH, filtered hot and cooled slowly. Fine yellow needles of the acid crystallise out; they are filtered off and dissolved in the minimum quantity of 0.01N NaOH and re-precipitated by adding N HCl to pH 3.5. It is then recrystallised from 70% aqueous EtOH (3x). The final product (acid) is dried at 80° in a vacuum for 24 hours, **m >300°(dec)**. It contains one molecule of water per molecule of acid (C<sub>30</sub>H<sub>36</sub>N<sub>4</sub>O<sub>13</sub>·H<sub>2</sub>O). The product is pure as revealed by electrophoresis at pH 5.6 and 8.6, and by TLC in *i*-BuOH/*i*-PrOH/AcOH/H<sub>2</sub>O (60:60:5:5 by volume) or *i*-PrOH or pH 8.0 borate buffer. [Wallach et al. *Anal Chem* **31** 456 1959.]

The Na salt is prepared by dissolving the pure acid in H<sub>2</sub>O containing 2 mols of NaOH per mol of acid reagent and lyophilising. It complexes with Ca and Mg ions. [Beilstein **19** III/IV 4338.]

**Calcium acetate monohydrate** [5743-26-0 (H<sub>2</sub>O), 62-54-4 (xH<sub>2</sub>O)] **M 176.2 (H<sub>2</sub>O), m 150° (loses H<sub>2</sub>O), pK<sup>25</sup> 12.7 (for Ca<sub>2</sub><sup>+</sup>).** Recrystallise the acetate from water (3ml/g) by partial evaporation in a desiccator. [Beilstein **2** IV 113.]

**Calcium benzoate trihydrate** [2090-05-3] **M 336.4.** Recrystallise the benzoate from water (10ml/g) between 90° and 0°. [Beilstein **9** I 60, **9** H 85, **9** III 377, **9** IV 280.]

**Calcium butyrate** [5743-36-2] **M 248.2, d<sub>4</sub><sup>30</sup> 1.271.** Recrystallise the butyrate from water (5ml/g) by partial evaporation in a desiccator and dry it in a vacuum to constant weight. [Pathak & Bhide *J Indian Chem Soc* **30** 47, 48 1953.] Its dissociation constant at 25° is 0.29 [Colman-Porter & Monk *J Chem Soc* 4363 1952, *Beilstein* **2** IV 785].

**Calcium carbamate** [543-88-4] **M 160.1.** Recrystallise calcium carbamate from aqueous ethanol. [Beilstein **4** H 75, **4** I 336, **4** II 557, **4** III 149, **4** 234.]

**Calcium formate** [544-17-2] **M 130.1, m dec on heating, d<sub>4</sub><sup>20</sup> 2.01.** Recrystallise calcium formate from water (5ml/g) by partial evaporation in a desiccator. [Beilstein **2** IV 16.]

**Calcium D-gluconate monohydrate** [299-28-5, 18016-24-5] **M 448.4, m dec on heating, [α]<sub>D</sub><sup>20</sup> +11.0°, [α]<sub>D</sub><sup>20</sup> +9.0° (c 1.2, H<sub>2</sub>O).** Calcium gluconate is soluble in H<sub>2</sub>O (3.5g in 100g at 25°). Dissolve it in H<sub>2</sub>O, filter and precipitate it by adding MeOH. Filter off the solid and dry it in a vacuum at 85°. *Alternatively*, dissolve it in H<sub>2</sub>O, filter (from insoluble inorganic Ca) and evaporate it to dryness under vacuum at 85°. [March et al. *J Am Pharm Assoc* **41** 366 1952, *Beilstein* **3** IV 1255.]

**Calcium D-heptagluconate dihydrate** [17140-60-2] **M 526.4**,  $[\alpha]_{546}^{20} +5.2^{\circ}$ ,  $[\alpha]_{\text{D}}^{20} +4.4^{\circ}$  (c 5, H<sub>2</sub>O). Purify it in the same way as for calcium D-gluconate. [*Beilstein 3* III 1112.]

**Calcium ionophore I (ETH 1001)** [58801-34-6] **M 685.0**. This is a neutral Ca selectophore. It can be purified by thick layer (2mm) chromatography (Kieselgel F<sub>245</sub>) and eluted with Me<sub>2</sub>CO/CHCl<sub>3</sub> (2:1). [Ammann et al. *Helv Chim Acta* **56** 1780 1973, Simon & Carafoli *Methods Enzymol* **56** 439 1977.]

**Calcium ionophore II (ETH 129)** [74267-27-9] **M 460.7**, **m 153-154<sup>o</sup>**. Recrystallise it from Me<sub>2</sub>CO. It forms 1:2 and 1:3 metal/ligand complexes with Mg<sup>2+</sup> and Ca<sup>2+</sup> ions, respectively, and induces selectivity in membranes for Ca<sup>2+</sup> over Mg<sup>2+</sup> by a factor of *ca* 10<sup>4</sup>. [Pretsch et al. *Helv Chim Acta* **63** 191 1980, Simon & Carafoli *Methods Enzymol* **56** 439 1977.]

**Calcium ionophore III [A23187 calcimycin]** [52665-69-7] **M 523.6**, **m 181-182<sup>o</sup>**,  $[\alpha]_{\text{D}}^{25} -56.0^{\circ}$  (c 1, CHCl<sub>3</sub>). It recrystallises from Me<sub>2</sub>CO as colourless needles. Protect it from light and moisture, store in a refrigerator. It is soluble in Me<sub>2</sub>SO or EtOH and can be stored for 3 months without loss of activity. The Mg and Ca salts are soluble in organic solvents and cross biological membranes. It has a pK<sub>a</sub> of 6.9 in 90% Me<sub>2</sub>SO. The Ca complex crystallises from 50% EtOH as colourless prisms. It is *highly TOXIC*. [Pressman *Ann Rev Biochem* **45** 501 1976, Chaney et al. *J Am Chem Soc* **96** 1932 1974, Chaney et al. *J Antibiotics* **29** 124 1976, Suzuki et al. *Anal Biochem* **61** 382 1989, Simon & Carafoli *Methods Enzymol* **56** 439 1977.]

**Calcium isobutyrate** [533-90-4] **M 248.2**. Crystallise it from water (3ml/g) by partial evaporation in a desiccator. It forms a *pentahydrate* at low temperatures, but the crystals filtered from a saturated solution at 80<sup>o</sup> are the *monohydrate*; the transition temperature is 62.5<sup>o</sup>. [Lumsden *J Chem Soc* **81** 359 1902.] It has a dissociation constant of 0.31 [Colman-Porter & Monk *J Chem Soc* 4363 1952]. [*Beilstein 2* H 290, **2** II 290, **2** IV 845.]

**Calcium lactate (5H<sub>2</sub>O)** [814-80-2, 15743-47-5] **M 308.3**, **m anhydrous at 120<sup>o</sup>**,  $[\alpha]_{\text{D}}^{20} -4.2^{\circ}$  (c 5, H<sub>2</sub>O). Crystallise calcium lactate from warm water (10ml/g) by cooling to 0<sup>o</sup>. [*Beilstein 3* IV 636.]

**Calcium propionate** [4075-81-4] **M 186.2**, **m dec on heating**. Crystallise this antifungal salt from water (2ml/g) by partial evaporation in a desiccator. [*Beilstein 2* H 238, **2** II 218, **2** III 516.]

**Calcium salicylate (2H<sub>2</sub>O)** [824-35-1] **M 350.4**, **pK<sub>1</sub><sup>20</sup> 3.08**, **pK<sub>2</sub><sup>20</sup> 13.43 (for acid)**. Recrystallise calcium salicylate from water (3ml/g) between 90<sup>o</sup> and 0<sup>o</sup>. [*Beilstein 10* H 60, **10** II 33, **10** III 94, **10** IV 128.]

**Carbonate ionophore I [ETH 6010] (heptyl 4-trifluoroacetylbenzoate)** [129476-47-7] **M 316.3**, **b 170<sup>o</sup>/0.02mm**, **d<sub>4</sub><sup>20</sup> 0.909**. Purify the ionophore by flash chromatography (2g of reagent with 30g of Silica Gel 60) and elute with EtOAc/hexane (1:19). The fractions that absorb light at 260nm are pooled, evaporated and dried at room temperature (10.3 Torr). The oily residue is distilled in a bubble-tube apparatus (170<sup>o</sup>/0.02 Torr). Its IR (CHCl<sub>3</sub>) has peaks at 1720, 1280, 940cm<sup>-1</sup>, and its solubility in tetrahydrofuran is 50mg/0.5ml. It is a lipophilic neutral ionophore selective for carbonate as well as being an optical humidity sensor. [Behringer et al. *Anal Chim Acta* **233** 41 1990.]

**Cerous acetate** [537-00-8] **M 317.3**, **pK<sub>1</sub><sup>25</sup> 8.1 (9.29)**, **pK<sub>2</sub><sup>25</sup> 16.3**, **pK<sub>3</sub><sup>25</sup> 26.0 (for Ce<sup>3+</sup>)**. Recrystallise it twice from anhydrous acetic acid, then pumped dry under a vacuum at 100<sup>o</sup> for 8 hours. [*Beilstein 2* I 50, **2** II 119, **2** III 196, **2** IV 115.]

**Cesium oleate** [31642-12-3] **M 414.4**. Recrystallise cesium oleate from EtOAc, dry it in an oven at 40<sup>o</sup> and store it over P<sub>2</sub>O<sub>5</sub>. [Finkle et al. *J Am Chem Soc* **45** 2785 I1923, *Beilstein 2* II 437, **2** III 1405.]

**Cesium perfluoro-octanoate (Cesium pentadecafluorooctanoate)** [17125-60-9] **M 546.0**. Recrystallise it from a butanol/petroleum ether mixture, dry it in an oven at 40<sup>o</sup> and store it over P<sub>2</sub>O<sub>5</sub> under vacuum. [*Beilstein 2* IV 994.]

**Chloro-tri-isopropoxy titanium** [20717-86-6] **M 260.6, m 45-50°, b 61-65°/0.1mm**. When distilled under vacuum, the distillate sets slowly to a solid on standing. Stock reagents are made by dissolving the warm liquid in pentane, toluene, Et<sub>2</sub>O, THF, CH<sub>2</sub>Cl<sub>2</sub>, and can be stored in a pure state or in solution under dry N<sub>2</sub> for several months. The reagent is *hygroscopic* and is hydrolysed by H<sub>2</sub>O. [Reetz et al. *Chem Ber* **118** 1421 1985.]

**Chromocene [bis(cyclopentadienyl) chromium II]** [1271-24-5] **M 182.2, m 173°**. Chromocene forms *pyrophoric* red crystals on sublimation at 50°/0.1mm followed by resublimation at 75-90°/0.1mm. Although it is stable at least to 300°, it is readily oxidised in air, and effervesces slowly in H<sub>2</sub>O to give cyclopentadiene. All operations should be carried out in a dry box. It decomposes in CCl<sub>4</sub> or CS<sub>2</sub>, and for IR even grinding with nujol, KBr or KI causes some decomposition. [Wilkinson et al. *J Inorg Nucl Chem* **95** 109 1956, Wilkinson *J Am Chem Soc* **76** 209 1954, *Beilstein* **16** IV 1774.]

**Chromoionophore I [ETH 5294] [9-diethylamino-5-octadecanoyl-imino-5-H-benzo[a]-phenoxazine]** [125829-24-5] **M 583.9**. Purify it by flash chromatography (Silica Gel) and elute with EtOAc. The coloured fractions are pooled, evaporated and recrystallised from EtOAc. It is a lipophilic fluorescent chromoionophore and is a selectophore for K and Ca ions. [Morf et al. *Anal Chem* **62** 738 1990.]

**Cobalt (II) meso-5,10,15,20-tetraphenylporphine complex** [14172-90-8] **M 671.7**. It yields brown crystals from Et<sub>2</sub>O or CHCl<sub>3</sub>/MeOH (*cf iron chloride complex*). It crystallises on extraction (Soxhlet) with \*C<sub>6</sub>H<sub>6</sub>. It is soluble in most organic solvents except MeOH and petroleum ether. [UV, IR: Rothmund & Manott *J Am Chem Soc* **70** 1808 1948, Thomas & Martell *J Am Chem Soc* **81** 5111 1959.]

**Cobaltic acetylacetonate** [21679-46-9] **M 356.3**. Recrystallise it from \*C<sub>6</sub>H<sub>6</sub>/petroleum ether and dry it in a vacuum. [Charles & Pawlikowski *J Phys Chem* **62** 440 1938, *Beilstein* **1** H 783.]

**Cobaltous acetate tetrahydrate** [6147-53-1] **M 249.1, pK<sub>1</sub><sup>25</sup> 9.85 (for Co<sup>2+</sup>)**. Several recrystallisations from 50% aqueous acetic acid give the *tetrahydrate*. It is converted to the *anhydrous* salt by drying at 80°/1mm for 60 hours. [*Beilstein* **2** IV 120.]

**Cobaltous acetylacetonate** [14024-48-7, 123334-29-2 x H<sub>2</sub>O] **M 257.2, m 165-170°, 172°**. Recrystallise the complex from acetone or MeOH and dry it in a vacuum. [*Beilstein* **1** H 783.]

**12-Crown-4 (lithium ionophore V, 1,4,7,10-tetraoxacyclododecane)** [294-93-9] **M 176.2, m 17°**. The distilled crude ionophore has to be recrystallised from pentane at -20° to remove acyclic material. It is then dried over P<sub>2</sub>O<sub>5</sub>. It complexes Li. [Anet et al. *Acta Chem Scand* **27** 3395 1973, *Beilstein* **19/11** V 334.]

**Cupric acetate monohydrate** [6046-93-1 (H<sub>2</sub>O), 142-71-2 (anhydrous)] **M 199.7, m 115°, 240°(dec), d<sub>4</sub><sup>20</sup> 1.88, pK<sub>1</sub><sup>25</sup> 8.0, pK<sub>2</sub><sup>25</sup> 13.1 (for Cu<sup>2+</sup>)**. Recrystallise Cu(OAc)<sub>2</sub> twice from warm dilute acetic acid solutions (5ml/g) by cooling. [*Beilstein* **2** IV 111.]

**Cupric benzoate** [533-01-7] **M 305.8**. Recrystallise it from hot water. Its solubility in EtOH/\*C<sub>6</sub>H<sub>6</sub> (90%) at 25° is 0.1%. [Crawford & Stewart *J Chem Soc* 228, 289 1953, *Beilstein* **9** H 84, **9** I 60, **9** III 376, **9** IV 280.]

**Cupric lactate monohydrate** [814-81-3] **M 295.7**. The *monohydrate* crystallises from hot H<sub>2</sub>O (3ml/g) on cooling. [*Beilstein* **3** II 203, **3** III 465, **3** IV 636.]

**Cupric oleate** [1120-44-1] **M 626.5**. Crystallise cupric oleate from diethyl ether. [*Beilstein* **2** H 465, **2** I 196, **2** I 202, **2** II 436, **2** III 1404, **2** IV 1646.]

**Cupric phthalocyanine** [147-14-8] **M 576.1**. Precipitate it twice from conc H<sub>2</sub>SO<sub>4</sub> by slow dilution with water. It has also been purified by two or three sublimations at 580° in an argon flow at 300-400Pa. [*Beilstein* **26** III/IV 4256.]

**(1,5-Cyclooctadiene)(1,3,5-cyclooctatetraene)ruthenium [Ru(COD)(COT)]** [127382-91-6] **M 315.4, m 88-**

**94°**, **92-94°**. It can be prepared directly under argon and pressure equalisation, by adding freshly distilled cycloocta-1,5-diene (12.5ml, COD, see [111-78-4, 1552-12-1]) in MeOH (5ml) to Zn dust (6g) in a flask which is placed in an ultrasound bath (Branson, Bransonic Model B220) thermostated at 70°. A solution of RuCl<sub>3</sub>·3H<sub>2</sub>O (530mg) in MeOH (12ml) is slowly added during 20 minutes to the refluxing COD mixture under N<sub>2</sub> flow and ultrasound. After addition is complete the mixture is sonicated for a further 2 hours under reflux at 70°. The solids are filtered off and the filtrate is evaporated with a vacuum line. The residual brown oil is extracted with the minimum volumes of hexane (3 x, total ~70ml), placed on an Al<sub>2</sub>O<sub>3</sub> (Merck 1079, or Brockman Activity II-III) column under N<sub>2</sub> and eluted with hexane. The yellow band is collected, the volatiles are removed *in vacuo* to give orange crystals (590mg, 93%). Analytically pure **Ru(COD)(COT)** [C<sub>16</sub>H<sub>22</sub>Ru] is obtained as yellow crystals upon recrystallisation (70-90% recovery) from hexane at ~ -78°/-6 hours preferably under N<sub>2</sub> or argon. [Itoh et al. *J Organomet Chem* **272** 179 1984, Pertici et al. *J Chem Soc, Dalton Trans* 1961 1980.] The <sup>1</sup>H NMR (60MHz, \*C<sub>6</sub>D<sub>6</sub>, TMS) has τ at 4.78 (dd, 2H), 5.22 (m, 2H), 6.21 (m, 2H), 7.08 (m, 4H), 7.78 (m, 8H), 8.36 (m, 2H) and 9.10 (m, 2H); compare with the <sup>1</sup>H NMR (60MHz, \*C<sub>6</sub>D<sub>6</sub>, TMS) of **Ru(COD)<sub>2</sub>** (see below) which has τ at 4.42 (t, 2H), 6.15 (dd, 4H), 6.45 (m, 4H), and 7.49—8.95 (m, 12H).

**Alternatively**, thermal isomerisation of **Ru(COD)<sub>2</sub>** (75mg, see [63395-36-8]) in CDCl<sub>3</sub> (0.5ml) in an NMR tube filled with argon occurs when the sealed tube is heated at 70° for 12 minutes as observed by the spectrum. Evaporation of the solution and purification as above gave yellow-orange crystals of **Ru(COD)(COT)** in >85% yield with no deuterium incorporation as observed by NMR. Isomerisation in \*C<sub>6</sub>D<sub>6</sub> is very slow at 70° giving a mixture of three isomers after 5 hours [Itoh et al. *J Organomet Chem* **272** 179 1984, see also Petrici et al. *J Chem Soc, Dalton Trans* 1961 1980]. A synthesis *via* a Grignard reduction of [RuCl<sub>2</sub>(COD)]<sub>n</sub> has also been described [Pelzer et al. *Chem Mater* **16** 4937 2004]. For its catalytic activity see Chapter 7, Catalysts-Part 1. It is a key precursor for the preparation of stabilised Ru nanoparticles [Pan et al. *J Am Chem Soc* **123** 7584 2001, cf Chapter 8].

**Cyclopentadienyl iron(II) dicarbonyl dimer [di(cyclopentadienyl)tetracarbonyl-diiron, (C<sub>5</sub>H<sub>5</sub>Fe)<sub>2</sub>(CO)<sub>4</sub>] [38117-54-3] M 353.9, m 194° (dec) (sealed tube)**. This key precursor to a variety of cyclopentadienyl-carbonyl complexes is prepared from Fe(CO)<sub>5</sub> (10ml, [13463-40-6], **CARE**, poisonous, work in an efficient fume cupboard) by refluxing with an excess of dicyclopentadiene (10ml, cyclopentadiene dimer see 77-73-6) for *ca* 40 hours under a N<sub>2</sub> or argon atmosphere in the absence of light, removing the solvent, adding CHCl<sub>3</sub> (50ml), and removing any Fe<sub>2</sub>(CO)<sub>9</sub> and insoluble material by centrifugation. The decanted supernatant is cooled in a Dry-ice/Me<sub>2</sub>CO bath, the crystals are collected by centrifugation and recrystallised from CHCl<sub>3</sub> to give a ~30% yield (based on CO) of analytically pure dark reddish-purple crystals of (C<sub>5</sub>H<sub>5</sub>Fe)<sub>2</sub>(CO)<sub>4</sub>, **m 194° (dec)** (sealed tube). The solid is stable to air and light, but solutions deteriorate under these conditions. It forms ferrocene (in 75% yield based on C<sub>5</sub>H<sub>5</sub>) when heated at 210°. It is readily soluble in EtOH, CHCl<sub>3</sub>, pyridine, less soluble in CCl<sub>4</sub> and CS<sub>2</sub>, and sparingly soluble in light petroleum giving red solutions in each case. It is insoluble in H<sub>2</sub>O and is unaffected by it. The measured molecular weight by isothermal distillation is 368. The IR has strong bands at λ<sub>max</sub> at 4.95μ, 5.1μ and 5.6μ (in CCl<sub>4</sub>) and 12.1μ (CS<sub>2</sub>). In the presence of O<sub>2</sub> a solution of the complex in EtOH/CHCl<sub>3</sub>/concHCl/3hours provides red crystals of C<sub>5</sub>H<sub>5</sub>Fe(CO)<sub>2</sub>Cl (from CHCl<sub>3</sub>/petroleum ether 85:15, decomposing >87°). This chloride is not ionic but gives the orange cation C<sub>5</sub>H<sub>5</sub>Fe(CO)<sub>2</sub><sup>+</sup> with AgNO<sub>3</sub>/HNO<sub>3</sub>, and yellow crystals of C<sub>5</sub>H<sub>5</sub>Fe(CO)<sub>2</sub>CN (from CHCl<sub>3</sub>, decomposing >120°) by reaction with NaCN/MeOH/24 hours in 46% yield. [Piper, Cotton and Wilkinson *J Inorg Nucl Chem* **1** 165 1955, Beilstein **16** IV 1826.] When (C<sub>5</sub>H<sub>5</sub>Fe)<sub>2</sub>(CO)<sub>4</sub> is treated with NaHg it provides the anion C<sub>5</sub>H<sub>5</sub>Fe(CO)<sub>2</sub><sup>-</sup> that can be alkylated with MeI to furnish C<sub>5</sub>H<sub>5</sub>Fe(CO)<sub>2</sub>Me and related alkyl derivatives. [Aktogu et al. *J Organomet Chem* **262** 49 1984, R.B. King *Organometallic Synthesis Vol 1*, p 45, Academic Press, NY, 1965.]

**2,4-Cyclopentadien-1-yl lithium (lithium cyclopentadienide, CpLi)** [16733-97-4] **M 72.0**. CpLi is a white air and moisture sensitive solid which should be stored under N<sub>2</sub> preferably at low temperature. Like CpNa [4984-82-1] and CpK, it is handled in a dry box or Schlenk equipment in an inert atmosphere (compare with CpTi below). To avoid excessive manipulation, the reagents are sometimes prepared *in situ* in the reactions without being isolated. The solid is prepared in Schlenk equipment under a N<sub>2</sub> atmosphere by adding dropwise redistilled cyclopentadiene (2.34ml, 28.5mmol) to a solution of EtLi (28.5mmol) in \*benzene (50ml) and stirred magnetically until precipitation of a voluminous white solid is complete. This is filtered, or centrifuged, off

under N<sub>2</sub>, washed with dry Et<sub>2</sub>O and dried *in vacuo*. It is sparingly soluble in Et<sub>2</sub>O but is soluble in THF. [Wagner & Ebel *Tetrahedron* **26** 5155 1970.] For the preparation of a standard solution (use drybox, or Schlenk equipment under N<sub>2</sub>) cyclopentadiene (~10.0mmol) in dry THF (7ml) is refluxed with excess of lithium metal (see Ford *J Am Chem Soc* **82** 2857 1970) for 4 hours, filtered through a sintered glass funnel and diluted to a total volume of 10ml with THF which provides a 1.00M solution for further use. [Ford *J Organomet Chem* **32** 27 1971.] Its UV in THF has no maxima above 210nm, and its IR has  $\nu_{\max}$  (solid in Nujol) at 3048 (m), 2906 (w), 1742 (m), 1629 (m), 1548 (w), 1513 (w), 1426 (m), 1364 (sw), 1304 (w), 1258 (w), 1166 (w), 1110 (w), 1003 (s), 935 (sw), 887 (sw) and 746 (ss) cm<sup>-1</sup>; the <sup>1</sup>H NMR [100MHz, shift relative to β-CH<sub>2</sub> of THF (1.767ppm of 2% TMS in THF) at 27°] has a peak at δ 5.59 (at 1.0M) or 5.70 (at 0.01M) [Ford *J Organomet Chem* **32** 27 1971; the <sup>13</sup>C NMR (22.6MHz, MeOCH<sub>2</sub>CH<sub>2</sub>OMe/\*C<sub>6</sub>D<sub>6</sub> 3:1, under N<sub>2</sub> at 30°, TMS) has a multiplet with δ centered at 103.59 (m, <sup>1</sup>J<sub>C-H</sub> 159.4 and 6.9Hz). [Fischer et al. *J Organomet Chem* **116** 65 1976.]

**Cyclopentadienyl thallium [(η<sup>5</sup>-2,4-cyclopentadien-1-yl)thallium, thallium(I) cyclopentadienide, CpTI] [34822-90-7] M 269.5, blackens at ~60° in air and at ~230° in a sealed capillary, but does not melt below 270°.** CpTI is purified by repeated sublimation through a glass plug at ~80°/0.005mm, 75°/0.1mm or 100-110°/10mm to give pale yellow acicular (small pointed needles) crystals. It is moderately stable in air but darkens superficially after several months. As it is somewhat light sensitive, it should be stored in dark brown screw cap containers, and thus keeps for prolonged periods of time. It reacts with some solvents, e.g. CHCl<sub>3</sub> and CCl<sub>4</sub> (forming TlCl), and CS<sub>2</sub> (forming black and red materials), or is very poorly soluble, e.g. in THF, Et<sub>2</sub>O and \*C<sub>6</sub>H<sub>6</sub>. However, it is soluble enough in the latter solvents, even at low temperatures (e.g. -20°), to react almost completely to give high yields of products. *It is a more convenient reagent for cyclopentadienylation than CpNa, CpK or CpLi because it is less basic, can be prepared in aqueous medium, can be prepared on a large scale, and is stable in air at room temperature for long periods.* The cyclopentadiene ring of CpTI has IR in accord with C<sub>5v</sub> symmetry, exhibiting one C—H stretching band at  $\nu_{\max}$  3101 cm<sup>-1</sup> in the gas phase at 150° to 249° which compares with ferrocene (3109 cm<sup>-1</sup>), nickelocene (3107 cm<sup>-1</sup>), di-cyclopentadienylmanganese (3101 cm<sup>-1</sup>), di-cyclopentadienyl-magnesium(II) (3095 cm<sup>-1</sup>), and benzene (3099 cm<sup>-1</sup>), and is supported by theoretical considerations. The five membered ring is flat and ionic with the positive charge delocalised within it, and the Tl bears the counter negative charge and is centered on top of it. [Cotton & Raynolds *J Am Chem Soc* **80** 269 1958, Roberts et al. *J Mol Spectr* **35** 476 1970, Fritz *Chem Ber* **92** 780 1959.]

CpTI is conveniently prepared by dissolving or suspending a thallium(I) salt [TlCl 3.6g, TlBr 5.26g, TlI does not react, TlSCN 3.94g, TlNO<sub>3</sub> 4.00g or Tl(I) acetylacetonate 4.55g] in a solution of KOH (10g) in H<sub>2</sub>O (100ml) in a Waring Blender (900ml jar capacity), adding cyclopentadiene (2.0ml, freshly distilled [542-92-7]) and stirring for 30 seconds. Longer stirring gives a fine suspension that is difficult to collect. The white product is filtered off, washed with EtOH (2 x 10ml), dried in a desiccator over anhydrous CaSO<sub>4</sub> to give CpTI in 91, 93, 0, 99, 97 and 87% yields respectively which is usually used without purification. The preparation can be scaled up to give ~50g of CpTI, and the preferred salt is TlBr. If desired, further purification can be performed by high vacuum sublimation as described above. [Hunt & Doyle *Inorg Nucl Chem Lett* **2** 283 1966, Cotton & Raynolds *J Am Chem Soc* **80** 269 1958, Corey et al. *J Am Chem Soc* **93** 1489 1971.] **Note that all thallium compounds are POISONOUS and due precautions have to be exercised.**

CpTI is a source of the C<sub>5</sub>H<sub>5</sub> ligand, and reactions are performed under N<sub>2</sub> with highly purified solvents. The following are a few of the many reported reactions of CpTI. It has been used to prepare ferrocene, cobaltocene, nickelocene, also complexes such as Cp<sub>2</sub>TiCl<sub>2</sub> with TiCl<sub>4</sub> in \*C<sub>6</sub>H<sub>6</sub>, or of Cp(MeOCp<sub>2</sub>)Pd(II) from [CpPd(OMe)Cl]<sub>2</sub> with CpTI in \*C<sub>6</sub>H<sub>6</sub> [Hunt & Doyle *Inorg Nucl Chem Lett* **2** 283 1966], as well as compounds like the 1-methoxymethylcyclopenta-2,4-diene key intermediate for the synthesis of prostaglandins [Corey et al. *J Am Chem Soc* **93** 1489 1971]; it reacts with [CpMo(NO)I<sub>2</sub>]<sub>2</sub> in THF to give Cp<sub>2</sub>Mo(NO)I where the iodine can be replaced [King *Inorg Chem* **7** 90 1968], CpTI reacted with electrophilic olefins, e.g. tetracyanoethylene, in MeCN or THF to form compounds of the type Tl<sup>+</sup>[Cp(CN)C(CN)<sub>2</sub>]<sup>-</sup> [Freeman & Sneddon *Inorg Chem* **19** 1125 1980], and the reaction of CpTI (10-80% molar excess) with 7-chloronorbornadiene in dry diglyme at 150°/3-4 hours gave, after filtration of Tl salts, the hydrocarbon *hexahydro-3,4,7-methenocyclopenta[a]pentalene* in 8-12% yield from a one-step synthesis (a hydrocarbon which would have required several synthetic steps to prepare) [Battiste & Timberlake *J Org Chem* **42** 176 1977]. [Meister *Angew Chem* **69** 533 1957, Beilstein **16** IV 1690.]

**6,6-Dibenzyl-14-crown-4 (lithium ionophore VI, 6,6-dibenzyl-1,4,8,11-tetra-oxa-cyclo-tetradecane)** [106868-21-7] **M 384.5, m 102-103°**. Dissolve it in  $\text{CHCl}_3$ , wash this with saturated aqueous  $\text{NaCl}$ , dry ( $\text{MgSO}_4$ ), evaporate and purify it by chromatography on silica gel and gradient elution with  $^*\text{C}_6\text{H}_6/\text{MeOH}$  followed by preparative reverse phase HPLC on an octadecyl silanised silica (ODS) column and eluting with  $\text{MeOH}$ . It can be recrystallised from  $\text{MeOH}$  (IR has  $\nu_{\text{max}}$  at  $1120\text{ cm}^{-1}$ , C-O-C in  $\text{KBr}$ ). [Kimura et al. *Anal Chem* **59** 2331 1987, see also Maruyama et al. *J Chem Soc Perkin Trans 1* 2069 1986 and Tsukube et al. *J Chem Soc Perkin Trans 1* 1033 1986.] It complexes selectively with Li ions.

**Di-*n*-butyltin oxide** [818-08-6] **M 248.9, m >300°**. The oxide is prepared by hydrolysis of di-*n*-butyltin dichloride with  $\text{KOH}$ . Hence wash it with a little aqueous  $\text{M KOH}$ , then  $\text{H}_2\text{O}$  and dry at  $\sim 80^\circ/10\text{mm}$  until the IR is free from OH bands. [Cummings *Aust J Chem* **18** 98 1965, *Beilstein* **4** I 588.]

**Dicarbonyl(cyclopentadienyl)Co (I)** [12078-25-0] **M 180.1, b 75°/22mm, b 139-140°(dec)/710mm**. Best distilled in an atmosphere of  $\text{CO}$  in a vacuum. The red brown liquid decomposes slightly on distillation even in a vacuum to liberate some  $\text{CO}$ . Operations should be performed in an efficient fume cupboard. It is soluble in organic solvents and stable in air but decomposes slowly in sunlight and rapidly under UV. [Piper et al. *J Inorg Nucl Chem* **1** 165 1955, *Beilstein* **16** IV 1827.] **TOXIC**.

**Dichloro(2,2':6', 2''-terpyridine)platinum(II) dihydrate** [151120-25-1] **M 535.3, decomposes at 240-260°**. The aqueous filtrate from the reaction between terpyridyl (2.3g) and potassium platinumchloride (4.0g) in  $\text{H}_2\text{O}$  at  $90^\circ$  for 6 hours, is evaporated, cooled, and treated with  $\text{HCl}$  whereby the red chloride separates as the *dihydrate*, whereas the black *trihydrate* slowly crystallises from a cold aqueous solution and is air-dried. It is converted to the *dihydrate* in a desiccator over  $\text{H}_2\text{SO}_4$ , by washing with  $\text{EtOH}$ , heating in  $\text{H}_2\text{O}$  (slowly), or by precipitating from a warm aqueous solution with hydrochloric acid. This salt is not decomposed by boiling  $\text{HCl}$ , and is insoluble in most organic solvents. [Morgan & Burstall *J Chem Soc* 1498 1934, Lippard *Acc Chem Res* **118** 211 1987, *Beilstein* **26** IV 260.]

**Diethyl aluminium chloride** [96-10-6] **M 120.6, m -75.5°, b 106.5-108°/24.5mm,  $d_4^{20}$  0.96**. Distil it from excess dry  $\text{NaCl}$  (to remove ethyl aluminium dichloride) in a 50-cm column containing a heated nichrome spiral. [*Beilstein* **4** IV 4403.]

***N,N'*-Diheptyl-*N,N'*-5,5-tetramethyl-3,7-dioxanonanedi-*amide* [lithium ionophore I (ETH 149)]** [58821-96-8] **M 442.7**. Purify it by chromatography on Kieselgel using  $\text{CHCl}_3$  as eluent (IR has  $\nu_{\text{max}}$  at  $1640\text{cm}^{-1}$ ). [Kirsch et al. *Helv Chim Acta* **60** 2326 1977, Simon & Carafoli *Methods Enzymol* **56** 439 1977.]

**Diphenylmercury** [587-85-9] **M 354.8, m 125.5-126°, 128-129°**. Sublime  $\text{Ph}_2\text{Hg}$ , then crystallise it from nitromethane or ethanol. If phenylmercuric halides are present, they can be converted to phenylmercuric hydroxide which, being much more soluble, remain in the alcohol or  $^*\text{benzene}$  used for crystallisation. Thus, crude material (10g) is dissolved in warm ethanol (*ca* 150ml) and shaken with moist  $\text{Ag}_2\text{O}$  (*ca* 10g) for 30 minutes, then heated under reflux for 30 minutes and filtered hot. Concentrating the filtrate by evaporation gives diphenylmercury, which is then recrystallised from  $^*\text{benzene}$  [Blair et al. *J Chem Soc* 3174 1959]. [*Beilstein* **16** IV 1702.] **TOXIC**.

**Disodium calcium ethylenediaminetetraacetate** [39208-14-5] **M 374.3**, (see  $\text{pKs}$  for EDTA in entry below). Dissolve it in a small amount of water, filter it and precipitate it with excess  $\text{EtOH}$ . Dry it at  $80^\circ$ . [*Beilstein* **4** IV 2451.]

**Disodium dihydrogen ethylenediaminetetraacetic acid ( $2\text{H}_2\text{O}$ )** [6381-92-6] **M 372.2, m 248°(dec),  $\text{pK}_1^{25}$  0.26,  $\text{pK}_2^{25}$  0.96,  $\text{pK}_3^{25}$  2.60,  $\text{pK}_4^{25}$  2.67,  $\text{pK}_5^{25}$  6.16,  $\text{pK}_6^{25}$  10.26 (see EDTA)**. Analytical reagent grade material can be used as primary standard after drying at  $80^\circ$ . Commercial grade material can be purified by crystallisation from water or by preparing a 10% aqueous solution at room temperature, then adding ethanol slowly until a slight permanent precipitate is formed, filtering, and adding an equal volume of ethanol. The precipitate is filtered off onto a sintered-glass funnel, is washed with acetone, followed by diethyl ether, and

dried in air overnight to give the *dihydrate*. Drying at 80° for at least 24 hours converts it to the *anhydrous* form. [Beilstein 4 IV 2451.]

**Disodium magnesium ethylenediaminetetraacetate** [14402-88-1] M 358.5,  $\text{pK}_1^{25}$  0.26  $\text{pK}_2^{25}$  0.96,  $\text{pK}_3^{25}$  2.60,  $\text{pK}_4^{25}$  2.67,  $\text{pK}_5^{25}$  6.16,  $\text{pK}_6^{25}$  10.26 (see EDTA). Dissolve it in a small amount of water, filter and precipitate it with an excess of MeOH. Dry it at 80°. [Beilstein 4 IV 2450.]

**Disodium succinate** [150-90-3] M 162.1. Crystallise it twice from water (1.2ml/g) and dry it at 125°. It has been freed from other metal ions by passage of a 0.1M solution through a column of Dowex resin A-1 (Na form). It is *hygroscopic*. [Beilstein 2 H 606, 2 IV 1908.]

**Di-*p*-tolylmercury** [50696-65-6, 537-64-4] M 382.8, m 244-246°. Crystallise it from xylene. [Whitmore et al. *Org Synth Coll Vol I* 231 1941, *Beilstein* 16 H 947, 16 I 667, 16 III 1329, 16 IV 1705.]

**Di-*p*-tolyl phenylphosphonate** [94548-75-1] M 388.3,  $n_D^{25}$  1.5758. Purify as described under diisooctyl phenylphosphonate.

**Eosin B (Bluish, Eosin Scarlet, 4',5'-dibromo-2',7'-dinitrofluorescein disodium salt)** [548-24-3] M 624.1,  $\lambda_{\text{max}}$  514nm, CI 45400. Free it from inorganic halides by repeated crystallisation from butan-1-ol. [Beilstein 19/6 V 469.]

**Eosin Y (as di-Na salt) (2',4',5',7'-tetrabromofluorescein di-Na salt)** [17372-87-1] M 691.9. Dissolve it in water and precipitate it by adding dilute HCl. The precipitate is washed with water, crystallised from ethanol, then dissolved in the calculated amount of dilute NaOH solution and evaporated to dryness on a water-bath. The purified disodium salt is then crystallised twice from ethanol [Parker & Hatchard *Trans Faraday Soc* 57 1894 1961]. [Beilstein 19 III/IV 2917.] [Same as below.]

**Ethylmercuric chloride** [107-27-7] M 265.1, m 192.5°, 193-194°. Mercuric chloride can be removed by suspending ethylmercuric chloride in hot distilled water, filtering with suction onto a sintered-glass crucible and drying it. Then crystallise it from ethanol and sublime it under reduced pressure. It can also be crystallised from water. [Marvel et al. *J Am Chem Soc* 47 3009 1925.]

**Ethylmercuric iodide** [2440-42-8] M 356.6, m 182°, 186°. Crystallise it once from water (50ml/g). [See previous entry, Marvel et al. *J Am Chem Soc* 4 3009 1925.]

**Ethylzinc (zinc diethyl)** [557-20-0] M 123.5, m -28°, -33.8°, b 116.8°/761mm,  $d_4^{25}$  1.205,  $n_D^{20}$  1.498. The presence of EtI in the liquid can be detected by its absorption spectrum. This can be removed by 2 or 3 passages over a Zn/Cu couple at ~150°. Any hydrocarbon impurities are removed by distillation at ~760mm in an inert atmosphere as it is flammable. It is moisture sensitive, hydrolysing to give ethane so store it in sealed ampoules under N<sub>2</sub> or argon.

It is also available as a ~15% solution in toluene ( $d_4^{20}$  0.915) or ~1M *n*-hexane ( $d_4^{20}$  0.726). Solutions should be stored under dry N<sub>2</sub> or argon, and if they contain some precipitate, the solutions should be filtered through a sintered frit under inert gas pressure. *Alternatively*, siphon carefully the required volume of supernatant. [Noller *Org Synth Coll Vol II* 184 1943, Bamford et al. *J Chem Soc* 471 1946, *Beilstein* 4 H 672, 4 I 609, 4 II 1044, 4 III 1999, 4 IV 4423.]

**Ethynyl tributylstannane** [994-89-8] M 315.1, b 76°/0.2mm, 130-135°/0.7mm, 200°/2mm,  $d_4^{20}$  1.1113,  $n_D^{20}$  1.4770. Purify the stannane by dissolving the reagent (*ca* 50g) in heptane (250ml), washing it with H<sub>2</sub>O (100ml), drying (MgSO<sub>4</sub>), evaporating and distilling in a vacuum. It has IR with  $\nu_{\text{max}}$  at 3280 (≡C-H), 2950, 2850, 2005 (C≡C), 1455, 1065 and 865cm<sup>-1</sup>. [Bottaro et al. *J Org Chem* 46 5221 1981, Stille & Simpson *J Am Chem Soc* 109 2138 1987, Zavgorodnii et al. *J Gen Chem USSR (Engl Edn)* 37 1469 1967.]

**Europium (III) acetate dihydrate** [62667-64-5] **M 383.1, pK<sub>1</sub><sup>25</sup> 8.31 (for aquo Eu<sup>3+</sup>)**. Recrystallise it several times from water [Ganapathy et al. *J Am Chem Soc* **108** 3159 1986]. [Beilstein **2** II 119.] For europium shift reagents see lanthanide shift reagents in "Aliphatic Compounds", Chapter 4.

**Ferrocene** [102-54-5] **M 186.0, m 173-174°**. Purify ferrocene by crystallisation from pentane or cyclohexane (also \*C<sub>6</sub>H<sub>6</sub> or MeOH can be used). It is moderately soluble in Et<sub>2</sub>O and sublimes readily above 100°. Crystallisation from EtOH gave material **m 172.5-173°**. [Wilkinson *Org Synth Coll Vol IV* 473 1963, Miller *J Chem Soc* 632 1952.] It has also been crystallised from methanol and sublimed *in vacuo*. [Saltiel et al. *J Am Chem Soc* **109** 1209 1987, Beilstein **16** IV 1783.]

**Ferrocene carboxaldehyde** [12093-10-6] **M 214.1, m 117-120°, 118-120°, 121°, 124.5°**. The aldehyde forms red crystals from heptane/CH<sub>2</sub>Cl<sub>2</sub>, EtOH or petroleum ether and sublimes at 70°/1mm. The *cyanohydrin* has **m 104°** (from \*C<sub>6</sub>H<sub>6</sub>/EtOH). The *semicarbazone* has **m 217-219°(dec)** after recrystallisation from aqueous EtOH. The *oxime* provides two isomers from petroleum ether *viz* **m 96-99°** and **m 155°**. The *O-acetyloxime* has **m 80-81°** after recrystallisation from hexane [Lindsay & Hauser *J Org Chem* **22** 355 1957]. The *2,4-dinitrophenylhydrazone* has **m 248°(dec)**. [Beilstein **16** IV 1798, Graham et al. *J Am Chem Soc* **79** 3416 1957, Broadhead et al. *J Chem Soc* 650 1958.]

**Ferrocene carboxylic acid** [1271-42-7] **M 230.1, m 210°(dec), 225-230°(dec), pK<sub>20</sub> 4.4 (H<sub>2</sub>O), 6.29 (68% aqueous MeOH)**. The acid crystallises as yellow crystals from petroleum ether (**m 225-230°dec**), CHCl<sub>3</sub> (**m 208.5°dec**), toluene/petroleum ether (**m 195-205°dec**), or aqueous ethanol. [Matsue et al. *J Am Chem Soc* **107** 3411 1985.] The *acid chloride* **m 49°** crystallises from pentane, and has UV with λ<sub>max</sub> at 458nm [Lau & Hart *J Org Chem* **24** 280 1959]. The *methyl ester* crystallises from aqueous MeOH with **m 70-71°**. The *anhydride* has **m 143-145°** when recrystallised from petroleum ether [Acton & Silverstein *J Org Chem* **24** 1487 1959]. The *amide* has **m 168-170°** when crystallised from CHCl<sub>3</sub>/Et<sub>2</sub>O or **m 167-169°** when crystallised from \*C<sub>6</sub>H<sub>6</sub>/MeOH. [Reeves *Org Synth* **56** 28 1977, Arimoto & Haven *J Am Chem Soc* **77** 6295 1955, Benkeser et al. *J Am Chem Soc* **76** 4025 1954.] [Beilstein **16** IV 1807.]

**Ferrocene-1,1'-dicarboxylic acid** [1293-87-4] **M 274.1, m >250°(dec), >300°, pK<sub>1</sub><sup>25</sup> 3.9, pK<sub>2</sub><sup>25</sup> 5.3**. The dicarboxylic acid crystallises in orange-yellow crystals from AcOH and sublimes above 230°. The *monomethyl ester* has **m 147-149°** [Nesmeyanov & Reutov *Dokl Acad Nauk USSR* **115** 518 1957]. The *dimethyl ester* has **m 114-115°** [Woodward et al. *J Am Chem Soc* **74**, 3458 1953]. The *diacid chloride* has **m 92-93°** when recrystallised from petroleum ether. [Nesmeyanov & Reutov *Dokl Acad Nauk SSSR* **120** 1267 1958, Kazitsyna et al. *Dokl Acad Nauk SSSR* **127** 333 1959, Beilstein **16** IV 1811.]

**Ferrocene-1,1'-dimethanol** [1291-48-1] **M 246.1, m 107-108°**. The diol is obtained from the diacid by LiAlH<sub>4</sub> reduction and recrystallised from Et<sub>2</sub>O/petroleum ether. [Reinhart et al. *J Am Chem Soc* **82** 4111 1960, Beilstein **16** IV 1795.]

**1-(Ferrocenyl)ethanol (α-methylferrocenemethanol)** [1277-49-2] **M 230.1, m 73-75°, 76-77°, 76-79°**. This versatile reagent is obtained by reduction of acetylferrocene (22.8g, see [1271-55-2]) in dry Et<sub>2</sub>O (500ml) with LiAlH<sub>4</sub> (1.9g) solution in anhydrous Et<sub>2</sub>O and refluxing for 2 hours. Excess of hydride is destroyed with EtOAc, the mixture is treated with a solution of NH<sub>4</sub>Cl (28g) in H<sub>2</sub>O, stirred for 0.5 hours at 0°, filtered, the organic layer is washed twice with H<sub>2</sub>O, dried (MgSO<sub>4</sub>), and evaporated to dryness. The residue (20.5g, 89%) is recrystallised from Et<sub>2</sub>O/petroleum ether to give the *carbinol* as orange rods. It is free from a C=O band but has a strong broad OH band in the IR spectrum. The *acetyl derivative* (Ac<sub>2</sub>O/pyridine/0°/15 hours), after sublimation at 60°/0.2mm, has **m 67-68°** and an IR band at 5.78μ (s, C=O), but no band in the OH region. [Arimoto & Haven *J Am Chem Soc* **77** 6295, Beilstein **16** IV 1975.]

**Germanium tetraethoxide** [14165-55-0] M 252.8, m  $-72^{\circ}$ , b  $54.5^{\circ}/5\text{mm}$ ,  $71-72^{\circ}/11\text{mm}$ ,  $188-190^{\circ}/722\text{mm}$ ,  $d_{25}^{25}$  1.1288. Distil  $\text{Ge}(\text{OEt})_4$  through a 10cm Vigreux column under reduced pressure. Alternatively, distil it through a Fenske glass helices column fitted with a total condensation variable take-off stillhead. Fractionate it under reduced pressure using a reflux ratio of 10:1. [Johnson & Fritz *J Am Chem Soc* 75 718 1953, Bradley *J Chem Soc* 4916 1956, Beilstein 1 IV 1308.]

**Hexabutyl-distannane** {hexabutyl-ditin, bis[(tributyl)tin]} [813-19-4] M 580.4, b  $160-162^{\circ}/0.3\text{mm}$ ,  $d_4^{20}$  1.148,  $n_D^{20}$  1.512. Purify bis[(tributyl)tin] by distilling it in a vacuum and store it in the dark. [Shirai et al. *Yakugaku Zasshi* 90 59 1970, *Chem Abstr* 72 90593 1970, Beilstein 4 I 590.]

**Hexamethylditin** {hexamethyldistannane, bis[(trimethyl)tin]} [661-69-8] M 327.6, m  $23.5^{\circ}$ , b  $85-88^{\circ}/45\text{mm}$ ,  $182^{\circ}/756\text{mm}$ ,  $d_{25}^{25}$  1.57. Wash bis[(trimethyl)tin] with  $\text{H}_2\text{O}$  and extract with  $^*\text{C}_6\text{H}_6$ , dry by filtering through powdered  $\text{Na}_2\text{SO}_4$ , remove  $^*\text{C}_6\text{H}_6$  on a rotary evaporator and fractionally distil the oily residue under vacuum (b  $85-88^{\circ}/45\text{mm}$ ). It boils at ca  $182^{\circ}$  at atmospheric pressure, but it cannot be distilled in air because the hot vapours flash in the condenser. [Kraus & Session *J Am Chem Soc* 47 2361 1925, Morris & Selwood *J Am Chem Soc* 63 2509 1941, Pedley et al. *Trans Faraday Soc* 53 1612 1957, Beilstein 4 IV 4346.]

**Iron(II) acetylacetonate** [iron(II) bis(2,4-pentanedionato- $\kappa\text{O}2,\kappa\text{O}4$ ),  $\text{Fe}(2^+)(\text{acac})_2$ ] [14024-17-0] M 254.1, m  $175^{\circ}$ . The preparation and handling of this complex should be done in a dry box or Schlenk equipment under dry pre-purified  $\text{N}_2$ ; and solvents should be de-gassed prior to use.  $\text{Fe}(\text{acac})_2$  is prepared by adding  $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$  (25g) in degassed  $\text{H}_2\text{O}$  (50ml) containing a small amount of sodium dithionite to reduce any Fe(III) impurities, to a degassed aqueous solution (300ml) containing piperidine (27.3ml) and redistilled acetylacetonone (28.1ml, [123-54-6]). After 15 minutes the resulting precipitate is filtered off and washed with degassed  $\text{H}_2\text{O}$ , EtOH then  $\text{Et}_2\text{O}$  and the yellow-brown powder [presumed to be  $\text{Fe}(\text{acac})_2 \cdot 2\text{H}_2\text{O}$  Emmert & Jarczyński *Chem Ber* 64 1072 1931] is transferred into a sublimation apparatus with a large cold finger and pumped dry at  $10^{-3}$  mm for 6 hours; and the hydrated complex is then heated at  $90^{\circ}/10^{-3}\text{mm}$  for at least 12 hours to dehydrate it and the orange-brown solid is sublimed twice at  $165-175^{\circ}/10^{-3}\text{mm}$ . The small orange-brown crystals that sublime at first become darker as the crystals grow, giving finally larger black clusters which are analytically pure anhydrous solid. Note that the complex is very sensitive to  $\text{O}_2$  in air, darkens in colour upon oxidation, and great care should be exercised to avoid oxidation when using it. It maybe *pyrophoric* when dry. Its molecular weight (cryoscopic and ebullioscopic) in  $^*\text{C}_6\text{H}_6$  increases as the concentration increases reaching a maximum for a hexamer, and the data are supported by the UV absorption spectra. [Buckingham et al. *Aust J Chem* 20 281 1967, Dwyer & Sargeson *Pr J Soc NSWales* 90, 141, 142 1956; for the formation constant see Izatt et al. *J Phys Chem* 59 80 1955, Beilstein 1 III 3122, 1 IV 3675.] Note: iron(1+) bis(2,4-pentanedionato- $\kappa\text{O}2,\kappa\text{O}4$ ) has [20149-10-4], see Chapter 6, Catalysts-Part 1 for  $\text{Fe}(\text{III})(\text{acac})_3$ , [14024-18-1].

**Iron(II) bis(1,1,1,5,5,5-hexafluoropentan-2,4-dionate)** [iron(II) bis(1,1,1,5,5,5-hexafluoro-2,4-pentanedionato- $\kappa\text{O}2,\kappa\text{O}4$ ),  $\text{Fe}(2^+)(\text{facac})_2$ ,  $\text{Fe}(\text{hfacac})_2$ ] [28736-68-7] M 470.1, mp  $40^{\circ}$ . The preparation and handling of this complex [cf  $\text{Fe}(\text{acac})_2$  14024-17-0] should be carried out in a dry box or Schlenk equipment under dry pre-purified  $\text{N}_2$ ; and solvents should be de-gassed prior to use.  $\text{Fe}(\text{hfacac})_2$  is prepared by adding  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  (11.8g) in  $\text{H}_2\text{O}$  (50ml) slowly to a mixture of redistilled hexafluoroacetylacetonone (12.2ml, see [1522-22-1]) and piperidine (8.5ml), whereby a dark violet precipitate separates immediately. This solid is filtered off, washed with a large volume of  $\text{H}_2\text{O}$  (1000 ml), placed in a sublimation apparatus and evacuated at  $10^{-3}\text{mm}$  at  $\sim 25^{\circ}$  for hours. The temperature is slowly raised to  $40^{\circ}$  and kept at  $45-50^{\circ}$  and  $10^{-3}\text{mm}$  for 3 days, and the dark violet crystals that formed on the cold finger are collected, and if necessary are ground to a fine powder and re-sublimed to give analytically pure  $\text{Fe}(\text{hfacac})_2$  (IR is free of bands at  $3300-3500\text{ cm}^{-3}$ , i.e. absence of  $\text{H}_2\text{O}$ ). It requires a much longer period of evacuation than  $\text{Fe}(\text{acac})_2$  for dehydration. The strong electron withdrawing effects of the  $\text{CF}_3$  groups make this complex relatively more stable to aerial oxidation than  $\text{Fe}(\text{acac})_2$ . It can be recrystallised from very dry  $^*\text{C}_6\text{H}_6$  without alteration, where its molecular weight (cryoscopic and ebullioscopic) increases with increase in concentration up to a value of 1.7 (compare with 6 for  $\text{Fe}(\text{acac})_2$  above). [Buckingham et al. *Aust J Chem* 20 281 1967.]

**Iron(II) dicyanobis(2,2'-dipyridine) trihydrate**  $[\text{Fe}(\text{bpy})_2(\text{CN})_2 \cdot 3\text{H}_2\text{O}]$  [15603-10-8] **M 474.3, dec. on heating.** The iron complex is prepared from 2,2'-dipyridine (4.7g, 30mmol) and ferrous ammonium sulfate hexahydrate (3.9g, 10mmol) in  $\text{H}_2\text{O}$  (400ml) which are heated to just below boiling, and a freshly prepared solution of KCN (10g) in  $\text{H}_2\text{O}$  (20ml) is added all at once to it, stirred, and the hot mixture is allowed to cool to room temperature. The complex separates as very dark violet (almost black) fine crystals rapidly, but is allowed to stand for 1 hour. The solid is collected and washed liberally with  $\text{H}_2\text{O}$ . Unused bipyridine is recovered from the filtrate by extraction with  $\text{Et}_2\text{O}$ . The iron complex can be purified by dissolving it in concentrated  $\text{H}_2\text{SO}_4$  (25ml) and slowly diluting it with  $\text{H}_2\text{O}$  (800ml, CARE as it will warm up) with stirring. The crystalline solid is collected washed free from  $\text{H}_2\text{SO}_4$  with small volumes of  $\text{H}_2\text{O}$ , sucked dry, rinsed with  $\text{Me}_2\text{CO}$  and dried *in vacuo* to give analytically pure *trihydrated complex* (3.5g, 75%). It is soluble in  $\text{H}_2\text{O}$  to give a pale red solution, in  $\text{EtOH}$  to give a deep red-violet liquid, and in  $\text{CHCl}_3$  to give a deep blue colour; but is only very slightly soluble in basic solution. Large amounts can be dissolved in concentrated  $\text{H}_2\text{SO}_4$  to give the yellow di-protonated species which on gradual dilution with  $\text{H}_2\text{O}$  the solution changes its hue to orange then to red and finally to the dark violet colour of the original crystals. It is a diamagnetic Fe(II) complex which is readily oxidised to the corresponding Fe(III) complex and can be titrated with Ce(IV) sulfate in  $\text{H}_2\text{SO}_4$ . On titration with  $\text{HClO}_4$  in anhydrous  $\text{AcOH}$  (Care due to possible explosion; Schilt *J Am Chem Soc* **82** 5779 1960), the first equivalence point leads to a mono-protonated orange species, and at the second equivalence point (not quite as sharp as the first) it provides the yellow di-protonated species. The electronic (Schilt *J Am Chem Soc* **82** 3000 1960, Schilt *J Am Chem Soc* **82** 5779 1960, Madeja & König *J Inorg Nucl Chem* **25** 377 1963), and vibrational spectra (Schilt *Inorg Chem* **3** 1323 1964) have been reported, and the *cis*-configuration has been deduced from IR (Hamer & Orgel *Nature* **190** 439 1961, Schilt *Inorg Chem* **3** 1323 1964) and stereochemical (Madeja *Chem Zvesti* **19** 186 1965) considerations. [Schilt *Inorg Synth* **12** 249 1970.]

**Iron(III) ethoxide**  $[\text{Fe}(\text{OEt})_3]$  [5058-42-4] **M 91.0, m 120°, volatilities at 155°/0.1mm in a molecular still.** The ethoxide is prepared by adding excess of ammonia to a solution of anhydrous  $\text{FeCl}_3$  (15g) in  $^*\text{C}_6\text{H}_6$  (170ml) and  $\text{EtOH}$  (76ml), which results in an exothermic reaction at the end of which the mixture is evaporated to dryness *in vacuo*. The residue is extracted with  $^*\text{C}_6\text{H}_6$  (150ml), the  $\text{NH}_4\text{Cl}$  is filtered off, the filtrate is evaporated to dryness *in vacuo* to leave a viscous brown residue. This is dissolved in hot  $\text{EtOH}$  (30ml) and brown crystals of analytically pure *ferric ethoxide* (4.2g) deposit slowly. It is trimeric in  $^*\text{C}_6\text{H}_6$  solution (molecular weight by ebullioscopy) and is for preparing other useful ferric trialkoxides by alcohol exchange in benzene solution, e.g. with *n*- $\text{PrOH}$ , *n*- $\text{BuOH}$ , *iso*- $\text{BuOH}$  or *n*-amyl alcohol, via the azeotropic removal of  $\text{EtOH}$ . It is commercially available as a 1M solution in  $\text{EtOH}$ . [Bradley et al. *J Chem Soc* 126 1955, *Beilstein* **1** IV 1243.]

**Iron(III) meso-5,10,15,20-tetraphenylporphine chloride complex** [5,10,15,20-tetraphenyl-21H, 23H-porphine iron(III) chloride] [16456-81-8] **M 704.0,  $\lambda_{\text{max}}$  418nm.** Purify the complex by extraction from a thimble (Soxhlet) with  $\text{CHCl}_3$ . Concentrate the extract to *ca* 10ml and add *ca* 80ml of hot  $\text{MeOH}$ . Dark blue crystals separate on cooling. It can be recrystallised several times from  $\text{CHCl}_3/\text{MeOH}$ . Avoid prolonged heating. It is quite soluble in organic solvents but insoluble in petroleum ether. [Rothemund & Manotti *J Am Chem Soc* **70** 1808 1948, UV: Dorrough et al. *J Am Chem Soc* **73** 4315 1951, *Beilstein* **26** III 1960.] [As catalyst for silylation of OH groups see Firouzabadi et al. *Synth Commun* **27** 2709 1997.]

**Lanthanide shift reagents** See in "Aliphatic Compounds", Chapter 4, europium (III) acetate above and  $\text{Eu}(\text{tmc})_3$  and  $\text{Eu}(\text{tfc})_3$  below.

**Lead II acetate (sugar of lead)** [301-04-2 (anhydrous), 6080-56-4 ( $3\text{H}_2\text{O}$ )] **M 325.3, m 280°,  $\text{pK}_1^{25}$  7.1 (for  $\text{Pb}^{2+}$ ),  $\text{pK}_2^{25}$  10.1 ( $\text{HPbO}_2^-$ ),  $\text{pK}_3^{25}$  10.8 ( $\text{PbO}_2^{2-}$ ).** Crystallise  $\text{Pb}(\text{OAc})_2$  twice from anhydrous acetic acid and dry it under vacuum for 24 hours at 100°. The solubility in  $\text{H}_2\text{O}$  is 63% (at ~20°) and 200% (at boiling point). [*Beilstein* **2** IV 118.]

**Lead (bis-cyclopentadienyl) (plumbocene)** [1294-74-2] **M 337.4.** Purify it by vacuum sublimation. Handle and store it under  $\text{N}_2$ . [Dave et al. *J Chem Soc* 3686 1979, *Beilstein* **16** IV 1614.]

**Lead tetraacetate** [546-67-6] **M 443.2, m 175-180°**. Colourless prisms or needles purified by dissolving in hot glacial acetic acid containing a little acetic anhydride, treated with decolorising charcoal, collected on a hot water funnel or preheated Büchner funnel with minimum contact with moist air, and dried in a vacuum desiccator over KOH pellets. Store it in a well-stoppered vessel as it is decomposed by moisture to form brown PbO<sub>2</sub>. It attacks skin, is soluble in hot AcOH, \*C<sub>6</sub>H<sub>6</sub>, CHCl<sub>3</sub>, tetrachloroethane and is used as a powerful oxidising agent. [Bailar *Inorg Synth* **1** 42 1939, Baudler in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **I** p 767 1963, *Beilstein* **2** IV 118.] **TOXIC**.

**Lithium benzoate** [553-54-8] **M 128.1**. Crystallise the salt from EtOH (13ml/g) by partial evaporation. [*Beilstein* **9** I 107, **9** IV 279.]

**Lithium diisopropylamide** [4111-54-0] **M 107.1, b 82-84°/atm, 84°/atm, d<sup>22</sup> 0.722, flash point -6°**. LiN(*iso*-Pr)<sub>2</sub> is purified by refluxing over Na wire or NaH for 30 minutes and then distilled into a receiver under N<sub>2</sub>. Because of the low boiling point of the amide, a dispersion of NaH in mineral oil can also be used directly in this purification without prior removal of the oil. It is **HIGHLY FLAMMABLE**, and is decomposed by air and moisture. [Wittig & Hesse *Org Synth* **50** 69 1970, *Beilstein* **4** H 154, **4** I 369, **4** II 630, **4** III 274, **4** IV 510.]

**Lithium formate monohydrate** [6108-23-2 (H<sub>2</sub>O), 556-63-8 (anhydrous)] **M 70.0, d<sub>4</sub><sup>20</sup> 1.46**. Crystallise HCO<sub>2</sub>Li from hot water (0.5ml/g) by chilling. [*Beilstein* **2** III 22, **2** IV 13.]

**Lithium methylate (lithium methoxide)** [865-34-9] **M 38.0**. The most probable impurity is LiOH due to hydrolysis by moisture. It is important to keep the sample dry. It can be dried by keeping in a vacuum at 60-80° under dry N<sub>2</sub> using an oil pump for a few hours. Store it under N<sub>2</sub> in the cold. It should not have bands above 3000cm<sup>-1</sup>, and its IR (KBr) should have  $\nu_{\max}$  at 1078, 2790, 2840 and 2930cm<sup>-1</sup>. [Suebold *J Org Chem* **21** 156 1956, *Beilstein* **1** IV 1220, 1241.]

**Lithium pentamethylcyclopentadienide (LiCp', 1,2,3,4,5-pentamethyl-2,4-pentadiene-1-ylithium)** [51905-34-1] **M 142.2, m >230°**. In the necessary Schlenk equipment under argon or dry N<sub>2</sub> an equimolar amount of 4M *n*-BuLi in hexane is added dropwise to a stirred solution of equimolar pentamethylcyclopentadiene (Cp') in dry THF (30ml per g of Cp') at 0° which gives a pulpy pale yellow suspension. Magnetic stirring is continued for 2 hours while the temperature is allowed to rise to ~25°; and this can be used directly for coordinating a Cp' ligand to metals. If LiCp' is to be isolated, then the solvent to be used is petroleum ether (~15ml per g of Cp'), addition of the *n*-BuLi solution is done within a few minutes without cooling as the reaction is slower than in THF, and stirring is continued for 24 hours. The solvent is removed *in vacuo*, or the colourless to pale grey solid (>90% yield) is filtered off, washed with petroleum ether under N<sub>2</sub> and dried *in vacuo*. [Kohl et al. in *Organometallic Synthesis* (R. Bruce King and J.J. Eisch) **vol 3** 381, Elsevier Amsterdam 1986]. LiCp' is air and moisture sensitive, and should be stored and weighed in an inert atmosphere. [King & Bisnette *J Organomet Chem* **8** 287 1967.] This reagent has been prepared also *in situ* from Cp' with MeLi/THF at 0° [White et al. *Synth Commun* **3** 425 1973], with *n*-BuLi in dimethoxyethane [Manriques & Bercaw *J Am Chem Soc* **96** 6229 1974], or as a slurry of LiCp' in Et<sub>2</sub>O at ~25° [Beachley et al. *Organometallics* **4** 1675 1985]. The metal-Cp' bond in LiCp' has a more covalent nature than that in KCp' and NaCp' which are more ionic [Jutzi et al. *Chem Ber* **118** 1959 1985].

**Lithium picrate** [18390-55-1] **M 221.0**. Recrystallise the picrate three times from EtOH and dry it under vacuum at 45° for 48 hours [D'Aprano & Sesta *J Phys Chem* **91** 2415 1987]. [*Beilstein* **6** H 276, **6** II 263, **6** III 880, **6** IV 1390.] The necessary precautions should be taken in case of **EXPLOSION**.

**Lithium salicylate** [552-38-5] **M 144.1**. Recrystallise the salicylate from EtOH (2ml/g) by partial evaporation. [*Beilstein* **10** H 59, **10** II 32, **10** III 93, **10** IV 126.]

**Magnesium acetate** [142-72-3 (anhydrous), 16674-78-5 (4H<sub>2</sub>O)] **M 214.5, m 80°**. Crystallise it from anhydrous acetic acid, then dry it under vacuum for 24 hours at 100°. [Nencollas *J Chem Soc* 744 1956,

*Beilstein 2* IV 113.]

**Magnesium benzoate trihydrate** [553-70-8] **M 320.6, m ~200°**. Crystallise it from water (6ml/g) between 100° and 0°. [*Beilstein 9* III 376, **9** IV 280.]

**Magnesium ethylate (magnesium ethoxide)** [2414-98-4] **M 114.4**. Dissolve *ca* 1g of solid in 12.8ml of absolute EtOH and 20ml of dry xylene, and reflux in a dry atmosphere (use CaCl<sub>2</sub> in a drying tube at the top of the condenser). Add 10ml of absolute EtOH and cool. Filter the solid under dry N<sub>2</sub> and dry it in a vacuum. *Alternatively*, dissolve it in absolute EtOH and pass it through molecular sieves (40 mesh) under N<sub>2</sub>, evaporate under N<sub>2</sub>, and store it in a tightly stoppered container. [Smith & Wiley *J Am Chem Soc* **68** 889 1946, *Beilstein 1* III 1283.]

**Magnesium D-gluconate** [3632-91-5] **M 414.6, [α]<sub>D</sub><sup>20</sup> +13.5°, [α]<sub>D</sub><sup>20</sup> +11.3° (c 1, H<sub>2</sub>O)**. Crystallise it from dilute EtOH to give *ca trihydrate*, and then dry it at 98° in high vacuum. It is insoluble in EtOH, and the solubility in H<sub>2</sub>O is 16% at 25°. [Prescott et al. *Ind Eng Chem* **45** 338 1953, *Beilstein 3* IV 1256.]

**Magnesium ionophore I (ETH 1117), (N,N'-diheptyl-N,N'-dimethyl-1,4-butanediamide)** [75513-72-3] **M 340.6**. Purify it by flash chromatography (at 40 kPa) on silica and eluting with EtOH/hexane (4:1). Its IR (CHCl<sub>3</sub>) has  $\nu_{\max}$  at 1630 cm<sup>-1</sup>. [Eene et al. *Helv Chim Acta* **63** 2271 1980.] It is a good magnesium selectophore compared with Na, K and Ca [Lanter et al. *Anal Chem* **52** 2400 1980].

**Magnesium ionophore II (ETH 5214), [N,N]-octamethylene-bis(N'-heptyl-N-methyl methylmalonamide)** [119110-37-1] **M 538.8**. The reagent (*ca* 700mg) can be purified by flash chromatography on Silica Gel 60 (30g) and eluting with CH<sub>2</sub>Cl<sub>2</sub>/Me<sub>2</sub>CO (4:1). [Hu et al. *Anal Chem* **61** 574 1989.]

**Magnesium lactate** [18917-37-1] **M 113.4**. Recrystallise the salt from water (6ml/g) between 100° to 0°. [*Beilstein 3* IV 636.]

**Magnesium succinate** [556-32-1] **M 141.4**. Recrystallise the salt from water (0.5ml/g) between 100° and 0°. [*Beilstein 2* IV 1912.]

**Magon [3-hydroxy-4-(hydroxyphenylazo)-2-naphthoyl-2,4-dimethylanilide, Xylidyl Blue II]** [523-67-1] **M 411.5, m 246-247°**. Suspend it in H<sub>2</sub>O and add aqueous NaOH until it dissolves, filter and acidify with dilute HCl. Collect the dye, dissolve it in hot EtOH (solubility is 100mg/L at *ca* 25°) concentrate to a small volume and allow to cool. The solubility of the Na salt in H<sub>2</sub>O is 0.4mg/ml. [Mann & Yoe *Anal Chim Acta* **16** 155 1957, Mann & Yoe *Anal Chem* **28** 202 1956.]

**Manganese (II) acetylacetonate** [14024-58-9] **M 253.2, m ~250°, 261°(dec)**. Purify it by stirring 16g of reagent for a few minutes with 100ml absolute EtOH and filter by suction as rapidly as possible through coarse filter paper. Sufficient EtOH is added to the filtrate, to make up for the loss of EtOH and to redissolve any solid that separates. Water (15ml) is added to the filtrate, and the solution is evaporated with a stream of N<sub>2</sub> until reduced to half its volume. Cool for a few minutes and filter off the yellow crystals, dry them under a stream of N<sub>2</sub>, then in a vacuum at room temperature for 6-8 hours. These conditions are important for obtaining the *dihydrate*. A vacuum to several mm of Hg or much lower pressure for several days produces the *anhydrous complex*. The degree of hydration can be established by determining the loss in weight of 100g of sample after heating for 4 hours at 100° and <20mmHg. The theoretical loss in weight for 2H<sub>2</sub>O is 12.5%. The material sublimes at 200°/2mm. It is soluble in heptane, MeOH, EtOH or \*C<sub>6</sub>H<sub>6</sub> at 30°. [Charles *Inorg Synth* **VI** 164 1960, Fernelius & Biswas *Inorg Synth* **V** 105 1957, *Beilstein 3* II 3122.]

**Manganous acetate tetrahydrate** [6156-78-1 (4H<sub>2</sub>O), 638-38-0 (anhydrous)] **M 245.1, m 80°, d<sub>4</sub><sup>20</sup> 1.59, pK<sup>25</sup> 10.59 (for Mn<sup>2+</sup> hydrolysis)**. Crystallise it from water acidified with acetic acid. [*Beilstein 2* IV 120.]

**Manganous lactate trihydrate** [6505-50-6 3 H<sub>2</sub>O, 51877-53-3 (xH<sub>2</sub>O)] **M 287.1**. Recrystallise the lactate

from water. [IR: Ranade & Biswas *J Indian Chem Soc* **44** 314 1967, *Beilstein* **3** IV 637.]

**Mercuric(II) acetate** [ $\text{Hg}(\text{OAc})_2$ ] [1600-27-7] **M 318.7, m 178-180°, 179-182°, pK<sub>1</sub><sup>25</sup> 2.47, pK<sub>2</sub><sup>25</sup> 3.49 (for Hg<sup>2+</sup> hydrolysis).** It is prepared from HgO and acetic acid. Recrystallise it from glacial acetic acid. Its solubility in H<sub>2</sub>O is 1g/2.5ml at ~20° and 1g/ml at 100°, and it is soluble in EtOH. The solid is light sensitive and is hydrolysed slowly in H<sub>2</sub>O to yield a yellow oxide. Store it in a tightly stoppered bottle away from light. It is a reagent for mercuration of alkenes (and aromatic compounds, cf mercury trifluoroacetate below) [Larock *Tetrahedron* **38** 1713 1928]; de-mercuration being achieved with NaBH<sub>4</sub>. [Wagenknecht & Juza in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol **II** p 1120-1121 1965, *Beilstein* **2** IV 114.] **POISONOUS.**

**Mercury(II) bis(cyclopentadienyl)** [18263-08-6] **M 330.8 starts to dec at ~60° but melts at 83-85°.** The pale yellow crystals can be purified by low-temperature (-78°) recrystallisation from Et<sub>2</sub>O. Store it at low temperature in the dark as it decomposes slowly at room temperature even in the dark. It reacts with FeCl<sub>2</sub> in tetrahydrofuran to give ferrocene quantitatively. It is soluble in Et<sub>2</sub>O, \*C<sub>6</sub>H<sub>6</sub>, CHCl<sub>3</sub>, CCl<sub>4</sub>, and most organic solvents. [Campbell et al. *J Am Chem Soc* **94** 8387 1972, Wilkinson & Piper *J Inorg Nucl Chem* **2** 32, 36 1956, Piper & Wilkinson *J Inorg Nucl Chem* **3** 104,106 1956, *Beilstein* **16** IV 1702.]

**Mercury dibromofluorescein {mercurochrome, merobromin, [2',7'-dibromo-4'-(hydroxy-mercurio)-fluorescein di-Na salt]}** [129-16-8] **M 804.8, m>300°.** The Na salt is dissolved in the minimum volume of H<sub>2</sub>O, or the free acid suspended in H<sub>2</sub>O and dilute NaOH is added to cause it to dissolve, filter and acidify it with dilute HCl. Collect the precipitate, wash it with H<sub>2</sub>O by centrifugation and dry it in a vacuum. The di Na salt can be purified by dissolving it in the minimum volume of H<sub>2</sub>O and is precipitated by adding EtOH, filter, wash it with EtOH or Me<sub>2</sub>CO and dry it in a vacuum. Its solubility in 95% EtOH is 2% and in MeOH it is 16%. [White *J Am Chem Soc* **42** 2355 1920.]

**Mercury Orange [1-(4-chloromercuriophenylazo)-2-naphthol]** [3076-91-3] **M 483.3, m 291.5-293°(corr) with bleaching.** Wash it several times with boiling 50% EtOH and recrystallise it from 1-butanol (0.9g/l of boiling alcohol). The fine needles are insoluble in H<sub>2</sub>O but slightly soluble in cold alcohols, CHCl<sub>3</sub> and soluble in aqueous alkalis. [Chaikin *J Am Chem Soc* **70** 3522 1948.]

**Mercury(II) trifluoroacetate** [13257-51-7] **M 426.6, m 171-173°.** It is prepared from HgO and trifluoroacetic acid and is recrystallised from trifluoroacetic anhydride/trifluoroacetic acid. It is a useful reagent for mercuration of aromatic compounds [Lau & Kochi *J Am Chem Soc* **108** 6720 1986]. Store it in a tightly stoppered bottle away from light. [cf Aylett in *Comprehensive Inorganic Chemistry* (Bailer et al. eds) Vol **3** p187 1973, *Beilstein* **2** IV 458.] It is very **TOXIC** and *hygroscopic*.

**Methylmercuric chloride** [115-09-3] **M 251.1, m 167°, 170°.** Recrystallise it from absolute EtOH (20ml/g). Its UV has  $\lambda_{\text{max}}$  at 206nm ( $\epsilon$  1.37). [See EtHgCl above; Breitingner et al. *J Organomet Chem* **256** 217 1983, Slotta et al. *J Prakt Chem* **120** 249 1929, Waugh et al. *J Phys Chem* **59** 395 1955, *Beilstein* **16** IV 1729.]

**Milling Yellow G** [51569-18-7]. Salted out three times with sodium acetate, then repeatedly extracted with EtOH. [McGrew & Schneider *J Am Chem Soc* **72** 2547 1950, *Beilstein* **16** II 125.] See Solochrome Violet R [2092-55] in "Aromatic compounds", Chapter 4.

**Monoperoxyphthalic acid magnesium hexahydrate salt. (MMPP)** [84665-66-7] **M 494.7, m ~93°(dec).** MMPP is a safer reagent than *m*-chloroperbenzoic acid for oxidation reactions because it is not as explosive and has advantages of solubility. It is soluble in H<sub>2</sub>O, low-molecular-weight alcohols, *i*-PrOH and DMF. The product of reaction, Mg phthalate, is soluble in H<sub>2</sub>O. It has been used in aqueous phase to oxidise compounds in e.g. CHCl<sub>3</sub> and using a phase transfer catalyst, e.g. methyltrioctylammonium chloride [Brougham *Synthesis* 1015 1987]. The oxidising activity can be checked (as for perbenzoic acid in Silbert et al. *Org Synth Coll Vol V* 906 1973), and if found to be low it would be best to prepare afresh from phthalic anhydride (1mol), H<sub>2</sub>O<sub>2</sub> (1mol) and MgO at 20-25° to give MMPP. [Hignett, European Pat Appl 27 693 1981, *Chem Abstr* **95** 168810 1981, *Beilstein* **9** IV 3260.]

**Neopentoxo lithium** [3710-27-8] **M 94.1**. Recrystallise alkoxide from hexane [Kress & Osborn *J Am Chem Soc* **109** 3953 1987]. [*Beilstein* 1 H 406, 1 I 201, 1 II 435, 1 III 1448, 1 IV 1690, for alcohol and Al and Fe neopentoxides.]

**New Methylene Blue N (2,8-dimethyl-3,7-bis(ethylamino)phenothazinium chloride 0.5 ZnCl<sub>2</sub>)** [6586-05-6] **M 416.1**, **m >200°(dec)**, **pK<sub>1</sub> 3.54**, **pK<sub>2</sub> 4.82**. Crystallise the dye from \*benzene/MeOH (3:1). [*Beilstein* **27** IV 5163.]

**Nickel (II) acetate (4H<sub>2</sub>O)** [6018-89-9] **M 248.9**, **d<sub>4</sub><sup>20</sup> 1.744**, **pK<sub>1</sub><sup>25</sup> 8.94 (from Ni<sup>2+</sup> hydrolysis)**. The acetate crystallises from aqueous AcOH as the green *tetrahydrate salt*. It is soluble in 6 parts of H<sub>2</sub>O. It forms lower hydrates and should be kept in a well-sealed container. [Hardt & Pohlmann *Z Anorg Allgem Chem* **343** 92 1966, *Beilstein* **2** IV 120.]

**Nickelocene [bis-(cyclopentadienyl)nickel II]** [1271-28-9] **M 188.9**, **m 173-174°(under N<sub>2</sub>)**. Dissolve the complex in Et<sub>2</sub>O, filter and evaporate in a vacuum. Purify it rapidly by recrystallisation from petroleum ether using a solid CO<sub>2</sub>/Me<sub>2</sub>CO bath, and has **m 171-173°** (in an evacuated tube). Also purify it by vacuum sublimation. [Wilkinson et al. *J Am Chem Soc* **76** 1970 1954, *Beilstein* **16** IV 1831.]

**Nickel (II) phthalocyanine** [14055-02-8] **M 571.3**, **m >300°**. Wash it well with H<sub>2</sub>O and boiling EtOH and sublime it at high vacuum in a slow stream of CO<sub>2</sub>. A special apparatus is used (see reference), with the phthalocyanine being heated to red heat. The sublimate is in the form of needles with an extremely bright red lustre. The powder is dull greenish blue in colour. [Barrett et al. *J Chem Soc* 1719 1936, *Beilstein* **26** III/IV 4255.]

**Nickel 5,10,15,20-tetraphenylporphyrin** [14172-92-0] **M 671.4**, **λ<sub>max</sub> 414(525)nm**. Purify it by chromatography on neutral (Grade I) alumina, followed by recrystallisation from CH<sub>2</sub>Cl<sub>2</sub>/MeOH [Yamashita *J Phys Chem* **91** 3055 1987]. [*Beilstein* **26** III/IV 1960.]

**Octadecyl isonicotinate** See hydrogen ionophore IV, ETH 1778 in "Heterocyclic Compounds" [103225-02-1], Chapter 4.

**Phenylmercuric acetate (PhHgOAc)** [62-38-4] **M 336.7**, **m 148-151°, 149°, 151.8-152.8°**. This acetate forms small colourless lustrous prisms from EtOH. Its solubility in H<sub>2</sub>O is 0.17%, but it is more soluble in EtOH, Me<sub>2</sub>CO and \*C<sub>6</sub>H<sub>6</sub>. [Maynard *J Am Chem Soc* **46** 1510 1925, Coleman et al. *J Am Chem Soc* **59** 2703 1937, *J Am Pharm Assoc* **25** 752 1936, *Beilstein* **16** IV 1720.] See PhHgOH below.

**Phenylmercuric hydroxide (PhHgOH)** [100-57-2] **M 294.7**, **m 195-203°**, **pK<sub>25</sub> 10 (~4.5)**. Crystallise it from dilute aqueous NaOH. [Waugh et al. *J Phys Chem* **59** 395 1955, *Beilstein* **16** IV 1721.]

**Phenylmercuric nitrate (PhHgNO<sub>3</sub>)** [8003-05-2] **M 634.4**, **m 178-188°**. When recrystallised from water or aqueous EtOH, it has **m 191-191.5°**, and from 95% EtOH it has **m 186.5°** [Challanger & Rothstein *J Chem Soc I* 1258 1934]. When recrystallised from \*C<sub>6</sub>H<sub>6</sub> or CHCl<sub>3</sub>, it has **m 131-131.5°** [Morton et al. *J Am Chem Soc* **69** 908 1947]. [*Beilstein* **16** III 1348, **16** IV 1721.]

**Phthalocyanine** [574-93-6] **M 514.6**. Purify phthalocyanine by sublimation (two to three times) in an argon flow at 300-400Pa; and similarly for the Cu(II), Ni(II), Pb(II), VO(II) and Zn(II) phthalocyanine complexes. [*Beilstein* **26** III/IV 4255.]

**Platinum (II) acetate (diacetatoplatinum)** [38928-89-1] **M 313.2 (monomer)**, **m 245°dec**. Purify the purple crystals by dissolving them in CHCl<sub>3</sub>, filtering, mixing with half its volume of glacial acetic acid and set aside to evaporate at room temperature. The resulting large, almost black, crystals are collected, washed with H<sub>2</sub>O and

dried in air. It dissolves in  $\text{CHCl}_3$ ,  $^*\text{C}_6\text{H}_6$  and toluene to give purple solutions. Its molecular weights (ebullioscopically) in  $\text{CHCl}_3$ ,  $^*\text{C}_6\text{H}_6$  and chlorobenzene are 950 ( $\pm 2$ ), 937 and 888, respectively, indicate that it is trimeric in solution. [Stephenson et al. *J Chem Soc* 3632 1965.]

**Platinum (II) acetylacetonate** [15170-57-7] **M 393.3, m 249-252°**. It crystallises from  $^*\text{C}_6\text{H}_6$  as yellow crystals and is dried in air or in a vacuum desiccator. [Werner *Chem Ber* **34** 2584 1901, Fernelius & Bryant *Inorg Synth* **V** 105 1957, *Beilstein* **1** H 783, **1** IV 3678.]

**Potassium 4-aminobenzoate** [138-84-1] **M 175.2**. Crystallise the aminobenzoate from EtOH. [*Beilstein* **14** II 246, **14** IV 1128.]

**Potassium antimonytartrate monohydrate** [28300-74-5] **M 333.9,  $[\alpha]_D^{20} +141^\circ$  (c 2,  $\text{H}_2\text{O}$ )**. Crystallise "tartar emetic" from water (3ml/g) between 100° and 0°. Dry it at 100°. [Chinoporos & Papathanosopolos *J Phys Chem* **65** 1643 1961, *Beilstein* **3** III 1014, **3** IV 1227.]

**Potassium benzoate** [582-25-2] **M 160.2**. Crystallise it from water (1ml/g) between 100° and 0°. [*Beilstein* **9** III 375, **9** IV 279.]

**Potassium tert-butoxide** [865-47-4] **M 112.2**. It sublimes at 220°/1mm. The last traces of *tert*-BuOH are removed by heating at 150-160°/2mm for 1 hour. It is best prepared afresh as likely impurities are *tert*-BuOH, KOH and  $\text{K}_2\text{CO}_3$  depending on its exposure to air. Its solubility at 25-26° in hexane, toluene,  $\text{Et}_2\text{O}$ , and THF is 0.27, 2.27, 4.34 and 25.0%, respectively. [Feuer et al. *J Am Chem Soc* **78** 4364, Doering & Urban *J Am Chem Soc* **78** 5938 1956, *Beilstein* **1** IV 1612.]

**Potassium citrate tribasic monohydrate (tripotassium citrate monohydrate)** [6100-05-6] **M 324.4, m 275°(dec)**. Its solubility in  $\text{H}_2\text{O}$  is 154g/100ml and it loses  $\text{H}_2\text{O}$  at 180°. [*Beilstein* **3** III 1091.]

**Potassium dihydrogen citrate** [866-83-1] **M 230.2**. It crystallises from  $\text{H}_2\text{O}$  with a solubility of 11.5% at 100°. Dry it at 80°, or in a vacuum desiccator over Sicapent. [*Beilstein* **3** I 209, **3** III 336, **3** IV 402.]

**Potassium hydrogen D-glucurate (D-tetrahydroxyadipic acid mono K salt, D-glucosaccharic acid mono K salt)** [18404-47-2] **M 248.2, m 188°(dec),  $[\alpha]_D^{20} +4.95^\circ$  (c 1.2,  $\text{H}_2\text{O}$ ),  $\text{pK}_1^{25} 5.0$  (free acid)**. Crystallise it from water. [Wolfrom & Neely *J Am Chem Soc* **75** 2778 1953, *Beilstein* **3** H 579, **3** II 378, **3** III 1119, **3** IV 1291.]

**Potassium hydrogen malate** [4675-64-3] **M 172.2**. A saturated aqueous solution at 60° is decolorised with activated charcoal, and filtered. The filtrate is cooled in a water-ice bath, and the salt is precipitated by adding EtOH. After five recrystallisations from ethanol-water mixtures, it is dried overnight at 130° in air [Eden & Bates *J Res Nat Bur Stand* **62** 161 1959]. [*Beilstein* **3** H 419, **3** III 915, **3** IV 1123.]

**Potassium hydrogen oxalate ( $\text{H}_2\text{O}$ )** [127-95-7] **M 137.1, m ~300°(dec)**. Crystallise the acid oxalate from  $\text{H}_2\text{O}$  by dissolving 20g in 100ml  $\text{H}_2\text{O}$  at 60° containing 4g of potassium oxalate, filtering and allowing to cool to 25°. The crystals, after washing three or four times with water, are allowed to dry in air. [*Beilstein* **2** III 1552.]

**Potassium hydrogen phthalate** [877-24-7] **M 204.2**. Crystallise it first from a dilute aqueous solution of  $\text{K}_2\text{CO}_3$ , then  $\text{H}_2\text{O}$  (3ml/g) between 100° and 0°. Before being used as a standard in volumetric analysis, analytical grade potassium hydrogen phthalate should be dried at 120° for 2 hours, then allowed to cool in a desiccator. [*Beilstein* **9** IV 3169.]

**Potassium hydrogen d-tartrate** [868-14-4] **M 188.2,  $[\alpha]_{\text{D}}^{20} +37.5^\circ$  (c 10, M NaOH)**. It crystallises from water (17ml/g) between 100° and 0°. Dry it at 110°. [*Beilstein* **3** IV 1222.]

**Potassium ionophore I (valinomycin)** See valinomycin in "Miscellaneous Compounds", Chapter 7.

**Potassium laurate (potassium dodecanoate)** [10124-65-9] **M 338.4**. Recrystallise potassium laurate three times from EtOH [Neto & Helene *J Phys Chem* **91** 1466 1987]. [*Beilstein* **2** H 360, **2** I 156, **2** II 318, **2** III 880, **2** IV 186.] See purification of sodium dodecanoate below.

**Potassium nonafluorobutane sulfonate** [29420-49-3] **M 338.2**. Wash it with H<sub>2</sub>O and dry it *in vacuo*. When the K salt is distilled with 100% H<sub>2</sub>SO<sub>4</sub>, it gives the *free acid* which can be distilled (**b** 105°/22mm, 210-212°/760mm) and then converted back into the pure K salt. [Gramstad & Haszeldine *J Chem Soc* 2640 1957, *Beilstein* **2** IV 818.]

**Potassium oleate** [143-18-0] **M 320.6**. Recrystallise potassium oleate from EtOH (1g/ml). [*Beilstein* **2** H 465, **2** I 196, **2** I 202, **2** II 436, **2** III 1404, **2** IV 1646.]

**Potassium oxalate** [6487-48-5] **M 184.2, m 160°(dec), d<sub>4</sub><sup>20</sup> 2.13**. Recrystallise the oxalate from hot water. It forms various K + oxalic acid salts [e.g. potassium hydrogen oxalate KH(C<sub>2</sub>O<sub>4</sub>)—see above, and KH<sub>3</sub>(C<sub>2</sub>O<sub>4</sub>)<sub>2</sub> which is, surprisingly, called potassium tetraoxalate—see below]. [*Beilstein* **2** H 513, **2** I 224, **2** II, 485, **2** III 1552, **2** IV 1823.]

**Potassium pentamethylcyclopentadienide (KCp', 1,2,3,4,5-pentamethyl-2,4-pentadiene-1-ylpotassium)** [94348-92-2] **M 174.3, m >230°**. In an efficient fume cupboard, liquid NH<sub>3</sub> (1.3L) is condensed into a flask containing freshly cut K metal (11.7g, 300mg-atoms) under an argon or N<sub>2</sub> atmosphere, stirred at -78°, and a small crystal of Fe(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O is added to the blue coloured solution. The mixture is made to warm to room temperature allowing refluxing until the blue solution turns into a light grey suspension. Cp' (40.9g, 300mmol) is added *via* a syringe, the mixture is stirred at reflux (MeOH condenser cooled at -78°) for 4 hours, and the NH<sub>3</sub> is allowed to evaporate using a stream of N<sub>2</sub>. The residue is dried *in vacuo* and stored in a N<sub>2</sub> atmosphere as it is air and moisture sensitive, and unlike other Cp'Ms it can be spontaneously flammable in air. It is more soluble in THF than Cp'Li but less soluble than Cp'Na. It is a Cp' ligand source for complexing with a large number of metals and non-metal halides. [Kohl et al. in *Organometallic Synthesis* (R. Bruce King and J.J. Eisch eds) **vol 3** 381, Elsevier Amsterdam 1986].

**Potassium phthalimide (phthalimide K salt)** [1074-82-4] **M 185.2, m >300°**. The solid may contain phthalimide and K<sub>2</sub>CO<sub>3</sub> from hydrolysis. If too much hydrolysis has occurred (this can be checked by extraction with cold Me<sub>2</sub>CO in which the salt is insoluble, evaporate the Me<sub>2</sub>CO and weigh the residue), it would be better to prepare it afresh. If little hydrolysis has occurred, then recrystallise it from a large volume of EtOH, and wash the solid with a little Me<sub>2</sub>CO and dry it in a continuous vacuum to constant weight. [Salzerg & Supriawski *Org Synth Coll Vol I* 119 1941, Raman & IR: Hase *J Mol Struct* **48** 33 1978, Dykman *Chem Ind (London)* 40 1972, IR, NMR: Assef et al. *Bull Soc Chim Fr* II 167 1979, *Beilstein* **21/10** V 270.]

**Potassium picrate** [573-83-1] **M 267.2, m 250°**. Recrystallise it from water or 95% EtOH, and dry it at room temperature in vacuum. It is soluble in 200 parts of cold water and 4 parts of boiling water. [*Beilstein* **3** III 880, **3** IV 1390.] **THE DRY SOLID EXPLODES WHEN STRUCK OR HEATED.**

**Potassium propionate** [327-62-8] **M 112.2**. Recrystallise C<sub>2</sub>H<sub>5</sub>CO<sub>2</sub>K from water (30ml/g) or 95% EtOH. [*Beilstein* **2** II 217, **2** III 516, **2** IV 701.]

**Potassium sodium tartrate tetrahydrate** [6381-59-5 (4H<sub>2</sub>O), 304-59-6 (R,R)] **M 282.3**. Recrystallise the tartrate from distilled water (1.5ml/g) by cooling to 0°. [*Beilstein* **3** IV 1223.]

**Potassium *d*-tartrate monohydrate** [921-53-9, 6381-59-5] **M 235.3, m loses H<sub>2</sub>O at 150°, d<sub>4</sub><sup>20</sup> 1.98**. Recrystallise it from distilled water (solubility: 0.4ml/g at 100°, 0.7ml/g at 14°). [*Beilstein* **3** IV 1223.]

**Potassium tetraoxalate dihydrate [oxalic acid hemipotassium salt]** [6100-20-5 (2H<sub>2</sub>O), 127-96-8] **M 254.2**. Crystallise it from water below 50°. Dry it below 60° at 760mm. [See potassium oxalate above, *Beilstein* **2** IV 1823.]

**Potassium trifluoroacetate** [2923-16-2] **M 152.1, m 140-142°**, **pK<sup>25</sup> 0.52 (for CF<sub>3</sub>CO<sub>2</sub>H)**. To purify it, dissolve the salt in trifluoroacetic acid with *ca* 2% of trifluoroacetic anhydride, filter it and evaporate it carefully to dryness (avoid over heating), and finally dry it in a vacuum at 100°. It can be recrystallised from trifluoroacetic acid (solubility in the acid is *ca* 50.1%). [Simons & Lorentzen *J Am Chem Soc* **74** 4746 1952, Hara & Cady *J Am Chem Soc* **76** 4285 1954, Watt & Muga *J Inorg Nucl Chem* **9** 166 1959, *Beilstein* **2** IV 458.]

**Pyridinium chlorochromate** [26299-14-9] **M 215.6, m 205°(dec)**. Dry it in a vacuum for 1 hour. It is not hygroscopic and can be stored for extended periods at room temperature without change. If the purity is very suspect, it can be readily prepared. [Corey & Scuggs *Tetrahedron Lett* 2647 1975, Piancatelli et al. *Synthesis* 245 1982.] (Possible **CARCINOGEN**.)

§ Available commercially on a polymer support.

**Pyridinium dichromate** [20039-37-6] **M 376.2, m 145-148°, 152-153°**. Dissolve it in the minimum volume of H<sub>2</sub>O and add 5 volumes of cold Me<sub>2</sub>CO and cool to -20°. After 3 hours the orange crystals are collected, washed with a little cold Me<sub>2</sub>CO and dried in a vacuum. It is soluble in dimethylformamide (0.9g/ml at 25°), and in H<sub>2</sub>O, and has a characteristic IR with  $\nu_{\max}$  at 930, 875, 765, 730 and 730 cm<sup>-1</sup>. [Corey & Schmidt *Tetrahedron Lett* 399 1979, Coats & Corrigan *Chem Ind (London)* 1594 1969.] (Possible **CARCINOGEN**.)

§ Available commercially on a polymer support.

**Pyronin B [di-(3,6-bis(diethylamino)xanthylium chloride) diFeCl<sub>5</sub> complex]** [2150-48-3] **M 358.9 (Fe free), m 176-178° (diFe complex), CI 45010,  $\lambda_{\max}$  555nm, pK<sup>25</sup> 7.7**. Recrystallise it from EtOH. It forms an Fe stain. [*Beilstein* **18/10** V 182.]

**Quinolinium chlorochromate** [108703-35-1] **M 265.6, m 127-130°**. It is a yellow-brown solid which is stable in air for long periods. If it has deteriorated or been kept for too long, it is best to prepare it freshly. Add freshly distilled quinoline (13ml) to a mixture of chromic acid (CrO<sub>3</sub>) (10g) and ~5M HCl (11ml of conc HCl and 10ml of H<sub>2</sub>O) at 0°. A yellow-brown solid separates, it is filtered off on a sintered glass funnel, dried for 1 hour in a vacuum, and can be stored for extended periods without serious loss in activity. It is a good oxidant for primary alcohols in CH<sub>2</sub>Cl<sub>2</sub>. [Singh et al. *Chem Ind (London)* 751 1986, method of Corey & Suggs *Tetrahedron Lett* 2647 1975, *Beilstein* **20/7** V 276.]

**Resorufin (7-hydroxy-3H-phenoxazine-3-one Na salt)** [635-78-9] **M 213.2, pK<sub>1</sub><sup>30</sup> 6.93, pK<sub>2</sub><sup>30</sup> 9.26, pK<sub>3</sub><sup>30</sup> 10.0**. Wash Resorufin with water and recrystallise it several times from EtOH. [*Beilstein* **27** II 108, **27** III/IV 2263.]

**Rhodizonic acid sodium salt (5,6-dihydroxycyclohex-5-ene-1,2,3,4-tetraone di-Na salt)** [523-21-7] **M 214.0, pK<sub>1</sub><sup>30</sup> 4.1 (4.25), pK<sub>2</sub><sup>30</sup> 4.5 (4.72)**. The *free acid* is obtained by acidifying and extracting with Et<sub>2</sub>O, drying (MgSO<sub>4</sub>), filtering, evaporating and distilling in a vacuum (**b** 155-160°/14mm). The *free acid* solidifies on cooling, and the colourless crystals can be recrystallised from tetrahydrofuran/petroleum ether or \*C<sub>6</sub>H<sub>6</sub>. It forms a *dihydrate* **m** 130-140°. The pure di Na salt is formed by dissolving the acid in 2 equivalents of NaOH and evaporating in a vacuum. It forms violet crystals which give an orange solution in H<sub>2</sub>O that is unstable for extended periods even at 0°, and should be prepared freshly before use. Salts of rhodizonic acid **cannot** be purified by recrystallisation without great loss due to conversion to crotonate, so that the original material must be prepared anew if pure salt is required. It can be washed with NaOAc solution, then EtOH, to remove excess NaOAc, dried under vacuum and stored in the dark. [UV and tautomerism: Schwarzenbach & Suter *Helv Chim Acta* **24** 617 1941, Polarography: Preisler & Berger *J Am Chem Soc* **64** 67 1942, Souchay & Taibouet *J Chim Phys* **49** C108 1952, *Beilstein* **8** H 535, **8** II 572, **8** III 4214, **8** IV 3609.]

**Ruthenium (III) acetylacetonate** [14284-93-6] **M 398.4, m 240°(dec)**. Purify the complex by recrystallisation from \*benzene. [Wilkinson *J Am Chem Soc* **74** 6146 1952, *Beilstein* **1** IV 3677.]

**Ruthenocene [bis-( $\pi$ -cyclopentadienyl)ruthenium]** [1287-13-4] **M 231.2, m 195.5°, 199-210°**. If it has to

be prepared *ab initio*, then in a flask (500ml), under continuous flushing with N<sub>2</sub>, and stirring, dry 1,2-dimethoxyethane (300ml) is added followed by Na (7.2g, 0.312 g.atom) cut in small pieces then cyclopentadiene (31.0ml, 0.376 mole; see [542-92-7], prepared from the dimer, [cf. Wilkinson *Org Synth Coll Vol IV* 475 1963] is added dropwise. After H<sub>2</sub> evolution stops, the mixture is kept just below boiling for 1-2 hours until all the Na has dissolved. If some metal remains undissolved, cool, and add a few milliliters of cyclopentadiene, and heat again until complete dissolution of the metal occurs. To this solution of sodium pentadienide [see also 4989-82-1], under N<sub>2</sub> and stirring, is added a mixture of RuCl<sub>3</sub> (14.6g, 0.07 mole) and Ru metal (2.4g, 0.024 g.atom), and heated just below reflux for 80 hours. The solvent is removed under reduced pressure, the flask is filled with N<sub>2</sub>, the solid residue is transferred (use a dry-box) to a sublimator, and sublimed at 0.1mm and 130° (bath temperature). It is advantageous to use a Dry-ice sublimation finger. The sublimate is dissolved in \*C<sub>6</sub>H<sub>6</sub>, passed through a column of activated Al<sub>2</sub>O<sub>3</sub> (2.5 x 30cm), and evaporated to give pure *non-pyrophoric* ruthenocene (12.2-15.1g, 56-69%), m 199-200°. The residue from sublimation is, however, *pyrophoric*, but this residue can be destroyed by adding H<sub>2</sub>O under N<sub>2</sub>. It can be further sublimed in high vacuum at 120°. It forms yellow crystals which can be recrystallised from CCl<sub>4</sub> as transparent plates. [Bublitz et al. *Org Synth Coll Vol V* 1001 1973, Wilkinson *J Am Chem Soc* 74 6146 1952, *Beilstein* 16 IV 1833.] It is generally less reactive than ferrocene towards electrophiles.

Two other alternative syntheses have been adopted using Schlenk techniques in an atmosphere of N<sub>2</sub> or argon, with dry and de-oxygenated solvents. In the *first*, [Sn-*n*-Bu<sub>3</sub>(C<sub>5</sub>H<sub>5</sub>)] (32.0g, 90mmol, prepared from Sn-*n*-Bu<sub>3</sub>Cl, 1461-22-9, and LiC<sub>5</sub>H<sub>5</sub> as per Davison & Rakita *Inorg Chem* 9 289 1970) is added to a suspension of [RuCl<sub>2</sub>(COD)<sub>n</sub>] (8.4g, 30mmol, see [50982-12-2]) in EtOH (150ml), and the mixture is stirred and refluxed for 48 hours whereby the Ru polymer dissolved. The hot solution is filtered in air, and on cooling the pale yellow *ruthenocene* that crystallises out is filtered off, washed thoroughly with cold EtOH (2 x 20ml) then Et<sub>2</sub>O (2 x 20ml), and recrystallised to analytical purity (5.2g, 75%) from hot EtOH or Me<sub>2</sub>CO. Its <sup>1</sup>H NMR (500MHz, CDCl<sub>3</sub>) has δ at 4.55 (s, C<sub>5</sub>H<sub>5</sub>), and its <sup>13</sup>C NMR (125MHz, CDCl<sub>3</sub>) has δ at 20.1 (s, C<sub>5</sub>H<sub>5</sub>) (any *n*-butyl signals from impurities would be at their usual shifts). In the *second*, [RuCl<sub>2</sub>(COD)<sub>n</sub>] (1.4g, 50mmol) and cyclopentadienyl thallium (2.7g, 10mmol, see [34822-90-7]) in dimethoxyethane (~50ml) are refluxed for 1 hour, filtered hot (in air), the solvent is removed *in vacuo*, the residue is extracted with Et<sub>2</sub>O (4 x 20ml), filtered, evaporated, and the residue is recrystallised and/or sublimed, as above, to give pure *ruthenocene* (0.9g, 78%). [Albers et al. *Organometallics* 5 2321 1986.] The Raman spectrum of the melt has ν<sub>max</sub> at 160w, 325s(p), 396m, 590vw, 815m(p), 830w, 1060m, 1098s(p), 1195vw 1360w, 1410m cm<sup>-1</sup> (p is with polarized light) [Lokshin et al. *J Organomet Chem* 124 293 1977].

**Silver acetate** [563-63-3] M 166.9, pK<sup>25</sup> >11.1 (for aquo Ag<sup>+</sup> hydrolysis). Shake AgOAc with acetic acid for three days, and the process is repeated with fresh acid. The solid is then dried in a vacuum oven at 40° for 48 hours. It has also been recrystallised from water containing a trace of acetic acid, and dried in air. Store it in the dark. [*Beilstein* 2 IV 112.]

**Silver lactate** [128-00-7] M 196.9, m ~ 100°. Recrystallise it from H<sub>2</sub>O by adding EtOH. The solid is collected, washed with EtOH, then Et<sub>2</sub>O, and dried at 80° to give the *dihydrate*. It is a white powder soluble in 15 parts of H<sub>2</sub>O but only slightly soluble in EtOH. Store it in the dark. [Engelhardt & Maddrell *Justus Liebigs Ann Chem* 63 89 1847, Karrer et al. *Helv Chim Acta* 2 251 1919, *Beilstein* 3 III 464.]

**Silver tetrafluoroborate** [AgBF<sub>4</sub>] [14104-20-2] M 194.7, m 70-73°, dec >200° (to form a silver mirror). The anhydrous salt has been freshly prepared under dry N<sub>2</sub>, by suspending AgF (34g, 268mmol) in dry MeNO<sub>2</sub> (30.5ml) while BF<sub>3</sub> is passed through with stirring. The temperature rises to 60°, and is maintained by occasional dipping into an ice bath. After about 30 minutes most of the AgF dissolves and ~280mmoles of BF<sub>3</sub> will have dissolved. Excess BF<sub>3</sub> is removed by bubbling dry N<sub>2</sub> for 1 hour through the murky solution which is then filtered (through a sintered glass frit, under N<sub>2</sub>), and the MeNO<sub>2</sub> is distilled off at 70°/5mm into a liquid N<sub>2</sub> trap. The off-white solid is ground in a mortar under dry *n*-pentane in a glove box flushed with dry N<sub>2</sub>, and the solvent is evaporated under N<sub>2</sub> at ~25°. The residual salt (237mmole, 88.5%) is pumped dry at 70° and stored under *n*-pentane. [Olah & Quin *J Inorg Nucl Chem* 14 295 1960.] The synthesis has been carried out in \*C<sub>6</sub>H<sub>6</sub>

with which it forms a 1:2 complex [Heyns & Paulsen *Angew Chem* **72** 349 1960], although 1:1 [Meerwein et al. *Arch Pharm* **291** 541 1958] and 2:3 complexes [Sharp & Sharpe *J Chem Soc* 1855 1956] were reported.  $\text{AgBF}_4$  is very soluble in  $\text{H}_2\text{O}$ ,  $\text{Et}_2\text{O}$ , toluene,  $\text{MeNO}_3$ , moderately soluble in  $^*\text{C}_6\text{H}_6$ , cyclohexene but insoluble in pentane and cyclohexane. The solubility in unsaturated hydrocarbons is attributed to  $\pi$ -bond complexing. A solution obtained by dissolving  $\text{Ag}_2\text{O}$  (1.0g) in 45% fluoroboric acid (7.2g) has been used for the synthesis of a tropone [Birch & Keeton *J Chem Soc (C)* 09 1968].

The salt is used for making tetrafluoroborate salts of complexes and other salts (see examples in this chapter) by displacing chloride from precious metal complexes, e.g.  $\text{Ru}(\text{Me}_2\text{SO}_4)\text{Cl}_2$  with excess  $\text{AgBF}_4$  under  $\text{N}_2$  in refluxing  $\text{EtOH}$  (ca 1 hour) and repeatedly recrystallising from  $\text{H}_2\text{O}/\text{EtOH}$  to give a 60% yield of  $[\text{Ru}(\text{Me}_2\text{SO}_4)(\text{H}_2\text{O})_2]\text{BF}_4$ , which is used for the oxidation of alcohols by persulfate [Bressan et al. *J Mol Catal* **79** 85 1993]. It provides a silver-ion template for improved macrolactamisation of linear dipeptides, e.g. to form cyclohexadepsipeptides [Yanjie et al. *Synlett* 1901 2007].

**Silver trifluoroacetate** [2966-50-9] **M 220.9, m 251-255°**. Extract the salt (Soxhlet) with  $\text{Et}_2\text{O}$ . The extract is filtered and evaporated to dryness, then the powdered residue is completely dried in a vacuum desiccator over silica gel. Its solubility in  $\text{Et}_2\text{O}$  is 33.5g in 750ml. It can be recrystallised from  $^*\text{C}_6\text{H}_6$  (solubility is: 1.9g in 30ml of  $^*\text{C}_6\text{H}_6$ , and 33.5g will dissolve in 750ml of anhydrous  $\text{Et}_2\text{O}$ ). [Traynham & Dehn *J Org Chem* **23** 1545 1958, Haszeldine *J Chem Soc* 584 1951.] Store it in the dark. It is also soluble in trifluoroacetic acid (15.2% at 30°), toluene, *o*-xylene and dioxane [Hara & Cady *J Am Chem Soc* **76** 4285 1954]. [Beilstein **2** IV 461.]

**Sodium acetate** (anhydrous) [127-09-3] **M 82.0, m 324°, d<sub>4</sub><sup>20</sup> 1.53**. Crystallise it from acetic acid and keep it under vacuum for 10 hours at 120°. Alternatively, it crystallises from aqueous  $\text{EtOH}$  as the *trihydrate*. This material can be converted to *anhydrous* salt by heating slowly in a porcelain, nickel or iron dish, so that the salt liquefies. Steam is evolved and the mass again solidifies. Heating is now increased so that the salt melts again. (NB: if it is heated too strongly, the salt can char; avoid this.) After several minutes, the salt is allowed to solidify and is cooled to a convenient temperature (in a desiccator) before being powdered and bottled. The water content should now be less than 0.02%. [Beilstein **2** II 113, **2** III 184, **2** IV 109.]

**Sodium acetylacetonate** [ $\text{Na}(\text{acac})$ , 2,4-pentanedione ion (1-) sodium (1:1)] [15435-71-9] **M 122.1, m 217-219° and is quite stable to heating below 191°, d<sub>4</sub><sup>20</sup> 1.213**. It is prepared by two different procedures. In the *first*, 2,4-pentanedione (100g, 1.0 mole) in  $\text{H}_2\text{O}$  or  $\text{EtOH}$  is slowly added to  $\text{NaOH}$  (40g, 1.0 mole) in the minimum amount of  $\text{H}_2\text{O}$  while keeping the temperature below 70°. On cooling  $\text{Na}(\text{acac})$  (98g, 80%) crystallises out. Note that addition of solid  $\text{NaOH}$  resulted in a product containing  $\text{NaOH}$ . Recrystallisation from aqueous  $\text{EtOH}$ ,  $\text{Me}_2\text{CO}$  or  $\text{EtOAc}$  gives pearly plates of the *dihydrate* (most probably a coordinated compound) which is soluble  $\text{EtOAc}$  but not in toluene. It gives off  $\text{H}_2\text{O}$  on heating, and the anhydrous form (salt form ?) is no longer soluble in  $\text{EtOAc}$ .

In the *second* procedure, 2,4-pentanedione (50g, 0.5 mole) is added to  $\text{Na}$  metal (11.5g, 0.5 mole) in toluene (100ml) while the temperature is maintained at 100° to keep the metal in the molten state (CARE, as the experiment may be dangerous;  $\text{N}_2$  should be flushing through the apparatus until the metal has dissolved).  $\text{Na}(\text{acac})$  (101g, 83%) separates during the reaction. Note that using lower temperatures provide  $\text{Na}(\text{acac})$  contaminated with  $\text{Na}$ . The product can be recrystallised from  $\text{EtOH}$  (see above) or by dissolving in  $\text{EtOH}$  and adding  $^*\text{C}_6\text{H}_6$ . Its solubility in *n*-hexane, cyclohexane, or  $^*\text{C}_6\text{H}_6$  is less than 0.01% at 70°. However, although quite insoluble in  $^*\text{C}_6\text{H}_6$  or toluene, a suspension of  $\text{Na}(\text{acac})$  will dissolve in these solvents on warming if excess of 2,4-pentanedione, or other related dicarbonyl compounds, e.g. benzoylacetone or ethyl acetoacetate, are added. Note that on heating the anhydrous or hydrated material decomposition and charring occurs if the sample in a soft glass tube is used. However, if the tube is placed in a bath at ~212° and the temperature is raised slowly, a sharp and reproducible melting point (217-219°) can be obtained with very little decomposition. [Hatch & Sutherland *J Org Chem* **13** 249 1948, Sidgwick & Brewer *J Chem Soc* **127** 2379 1925.] The ratios of mole of decomposition product/mole of "salt" after 50 hours when heated under  $\text{N}_2$  at 27° and 191° are both 0.07, i.e. it is reasonably stable at high temperatures. [Charles & Pawlikowski *J Phys Chem* **62** 440 1958.] Its UV ( $\text{EtOH}$ ) has  $\lambda_{\text{max}}$  at 277 ( $\epsilon$  800 x 10<sup>3</sup>) nm [Hatch & Sutherland *J Org Chem* **13** 249 1948]; and its electrical molecular conductivities (dilution) are: 5.794 (8), 8.254 (16), 11.187 (32), 14.426 (64), 18.116 (128), 21.82 (256), 25.636 (512), 29.927 (1024), and do not approach complete dissociation when nearing maximum dilution as hydrolysis may well be occurring [White *J Chem Soc* 1413 1928]. Like  $\text{K}(\text{acac})$  and  $\text{Cs}(\text{acac})$ ,  $\text{Na}(\text{acac})$  is

unstable in aqueous solution or in moist conditions and is decomposed by hot H<sub>2</sub>O into Me<sub>2</sub>CO and the alkali acetate [Morgan & Moss *J Chem Soc* **105** 189 1914]. Store it in a dry atmosphere. [Marchi *Inorg Synth* **II** 10 1946, Frenelius & Bryant *Inorg Synth* **V** 105 1957.]

**Sodium acetylide** [1066-26-8] **M 48.0**. It disproportionates at *ca* 180° to sodium carbide. It sometimes contains diluents, e.g. xylene, butyl ether or dioxane that can be removed by filtration followed by a vacuum at 65-60°/5mm. *Alternatively*, the acetylide is purged with HC≡CH at 100-125° to remove diluent. NaC<sub>2</sub>H adsorbs 2.2x, 2.0x and 1.6x its wt of xylene, butyl ether and dioxane, respectively. Powdered NaC<sub>2</sub>H is yellow or yellow-gray in colour and is relatively stable. It can be heated to *ca* 300° in the absence of air. Although no explosion or evolution of gas occurs, it turns brown due to disproportionation. At 170-190° in air it ignites slowly and burns smoothly. At 215-235° in air it “flash-ignites” and burns quickly. It can be dropped into a *slight* excess of H<sub>2</sub>O without flashing or burning, but vigorous evolution of HC≡CH (**HIGHLY FLAMMABLE IN AIR**) occurs. A sample had been stored in the absence of air for one year without deterioration. Due to the high flammability of HC≡CH, the salt should be stored dry and should be treated with care. After long storage, NaC≡CH can be redissolved in liquid NH<sub>3</sub> and used for the same purposes as the fresh material. However, it may be slightly turbid due to the presence of moisture. [Rutledge *J Org Chem* **22** 649 1957, Greenlee & Henne *J Am Chem Soc* **77** 5013 1955, Campbell & Campbell *Inorg Synth* **II** 76, 81 1946, *Org Synth* **30** 15 1950, *Beilstein* **1 H** 238.] It is available commercially under N<sub>2</sub> in Sure/Seal bottles as an 18 wt% solution in xylene/mineral oil. See “Aliphatic Compounds”, Chapter 4, for its preparation.

**Sodium alginate (Algin)** [9005-38-3]. Free Algin from heavy metal impurities by treatment with ion-exchange resins (Na<sup>+</sup>-form), or with a dilute solution of the sodium salt of EDTA. *Alternatively*, dissolve it in 0.1M NaCl, centrifuge and fractionally precipitate it by gradual addition of EtOH or 4M NaCl. The resulting gels are centrifuged off, washed with aqueous EtOH or acetone, and dried under vacuum. [Büchner et al. *J Chem Soc* 3974 1961.]

**Sodium 4-aminobenzoate** [555-06-6] **M 159.1**. Recrystallise it from water. [Hermann *Helv Chim Acta* **9** 786 1926, *Beilstein* **14** II 247.]

**Sodium 4-aminosalicylate dihydrate** [6018-19-5] **M 175.1**. Recrystallise it from water at room temperature (2ml/g) by adding acetone and cooling. [*Beilstein* **14** III 1436, **14** IV 1969.]

**Sodium antimonyl tartrate** [34521-09-0] **M 308.8**. It crystallises from water. [*Beilstein* **3** III 1014, **3** IV 1227.]

**Sodium barbitone (sodium 5,5-diethylbarbiturate)** [144-02-5] **M 150.1**, pK<sub>1</sub><sup>25</sup> 3.99, pK<sub>2</sub><sup>25</sup> 12.5 (**barbituric acid**). Crystallise it from water (3ml/g) by adding an equal volume of EtOH and cooling to 5°. Dry it under vacuum over P<sub>2</sub>O<sub>5</sub>. [*Beilstein* **24** III/IV 1904.]

**Sodium benzoate** [532-32-1] **M 144.1**. Crystallise it from EtOH (12ml/g). [*Beilstein* **9** IV 27.]

**Sodium tert-butoxide** [865-48-5] **M 96.1**. It sublimes at 180°/1mm. Its solubility in *tert*-BuOH is 0.208M at 30.2° and 0.382M at 60°, and it is quite soluble in tetrahydrofuran (32g/100g). It should not be used if it has a brown colour. [Feuer *J Am Chem Soc* **78** 4364 1956, Hurd *Inorg Synth* **I** 87 1939, IR: Seubold *J Org Chem* **21** 156 1956, *Beilstein* **1** IV 1609.]

**Sodium butyrate** [156-54-7] **M 110.1**. Prepare it by neutralising the acid with Na<sub>2</sub>CO<sub>3</sub>, and recrystallising it from EtOH. [*Beilstein* **2** IV 779.]

**Sodium carboxymethylcellulose** [9004-32-4]. Dialyse it for 48 hours against distilled water and freeze-dry if a solid is required.

**Sodium decanoate (sodium caproate)** [1002-62-6] **M 194.2**. Neutralise sodium hydroxide by adding a slight excess of free decanoic acid and recovering the excess acid by Et<sub>2</sub>O extraction. The salt is recrystallised from

the aqueous solution by adding pure acetone and repeating the steps several times, then drying the salt in an oven at *ca* 110° [Chaudhury & Awuwallia *Trans Faraday Soc* 77 3119 1981]. [Beilstein 2 IV 1041.]

**Sodium deoxycholate monohydrate** [302-95-4, 145224-92-4] **M 432.6**,  $[\alpha]_D^{20} +48^\circ$  (c 1, EtOH). Recrystallise it from EtOH and dry it in an oven at 100°. The solution is freed from soluble components by repeated extraction with acid-washed charcoal. [Beilstein 10 IV 1608.]

**Sodium diethyloxaloacetate** [63277-17-8, 40876-98-0] **M 210.2**. Extract it several times with boiling Et<sub>2</sub>O (until the solvent remains colourless), and then the residue is dried in air. [Beilstein 3 H 789.]

**Sodium diformylamide** [18197-26-7] **M 95.0**. Grind the amide under dry tetrahydrofuran (fumehood), filter and wash it with this solvent, then dry it *in vacuo*. It is soluble in EtOH and H<sub>2</sub>O but insoluble in Et<sub>2</sub>O and petroleum ether. [IR and preparation: Rakshit *J Chem Soc* 103 1557 1913, Yinglin & Hongwen *Synthesis* 122 1990, Allenstein & Beyl *Chem Ber* 100 355 1967, Allenstein et al. *Chem Ber* 102 4089 1969, Beilstein 2 II 22.]

**Sodium p-dimethylaminoazobenzene-o'-carboxylate (Methyl Red)** [845-10-3] **M 291.2**. It can be precipitated from aqueous solution as the free acid which is recrystallised from 95% EtOH, then reconverted to the sodium salt. In H<sub>2</sub>O it is pink at pH 4.2 and yellow at pH 6.2 and has UV with  $\lambda_{\max}$  at 437nm. *Methyl Red Hydrochloride* [63451-28-5] has **M 305.8**, **m 175°(dec)** and UV with  $\lambda_{\max}$  at 493nm. [Beilstein 16 H 329.]

**Sodium p-dimethylaminoazobenzene-p'-carboxylate** [845-46-5] **M 219.2**. It has been precipitated from aqueous solution as the free acid which was recrystallised from 95% EtOH, then reconverted to the sodium salt. [Beilstein 16 H 329.]

**Sodium dodecanoate (sodium laurate)** [629-25-4] **M 222.3**, **pK<sup>20</sup> 5.3 (COOH)**. Neutralise it by adding a slight excess of dodecanoic acid and removing it by ether extraction. The salt is recrystallised from the aqueous solution by adding pure Me<sub>2</sub>CO and repeating the process (see sodium decanoate above). It has also been recrystallised from MeOH. [Beilstein 2 IV 1085.]

**Sodium ethoxide** [141-52-6] **M 68.1**. It is a *hygroscopic* powder which should be stored under N<sub>2</sub> in a cool place. A likely impurity is EtOH which can be removed by warming at 60-80° under high vacuum. It is hydrolysed by H<sub>2</sub>O to yield NaOH and EtOH. Other impurities, if kept in air for long periods are NaOH and Na<sub>2</sub>CO<sub>3</sub>. In this case the powder cannot be used if these impurities affect the reactivity, and a fresh sample would be acquired. It is prepared by adding Na to absolute EtOH under N<sub>2</sub> and evaporated *in vacuo*, or used *in situ*. [IR: Seubold *J Org Chem* 21 156 1956]. [Beilstein 1 H 311, 1 IV 1289.]

**Sodium ethylmercurithiosalicylate (Thimerosal)** [54-64-8] **sM 404.8**, **m ~230°**. Recrystallise this antibacterial from EtOH/Et<sub>2</sub>O. **HIGHLY TOXIC**. [Trikojus *Nature* 158 472 1940, Beilstein 10 III 213.]

**Sodium fluoroacetate (FCH<sub>2</sub>CO<sub>2</sub>Na)** [62-74-8] **M 100.0**, **m 200-205°(dec)**. It is a free-flowing white **HIGHLY POISONOUS** powder which is purified by dissolving it in *ca* 4 parts of H<sub>2</sub>O, and the pH is checked. If it is alkaline, add a few drops of FCH<sub>2</sub>CO<sub>2</sub>H to make the solution just acidic. Evaporate (fumehood) on a steam bath until crystals start to separate, cool and filter the solid off. More solid can be obtained by adding EtOH to the filtrate. Dry it at 100° *in vacuo*. The *p-nitrobenzyl ester* crystallises from EtOH with **m 76°**. The free acid interferes with the citric acid cycle. [Saunders & Stacey *J Chem Soc* 1778 1948, Beilstein 2 IV 446.]

**Sodium formate (anhydrous)** [141-53-7] **M 68.0**, **m 253°**, **d<sub>4</sub><sup>20</sup> 1.92**. A saturated aqueous solution at 90° (0.8ml water/g) is filtered and allowed to cool slowly. (The final temperature should be above 30° to prevent formation of the hydrate.) After two such crystallisations, the crystals are dried in an oven at 130°, then under high vacuum. [Westrum et al. *J Phys Chem* 64 1553 1960, Roecker & Meyer *J Am Chem Soc* 108 4066 1986.] The salt has also been recrystallised twice from 1mM DTPA (diethylenetriaminepentaacetic acid, which was recrystallised 4x from MilliQ water and dried in a vacuum), then twice from water [Bielski & Thomas *J Am Chem Soc* 109 7761 1987]. [Beilstein 2 IV 3.]

**Sodium D-gluconate** [527-07-1] M 218.1, m 200-205°dec,  $[\alpha]_{546}^{20} +14^{\circ}$ ,  $[\alpha]_{D}^{20} +12^{\circ}$  (c 20, H<sub>2</sub>O). Crystallise it from a small volume of H<sub>2</sub>O (solubility is 59g/100ml at 25°), or dissolve it in H<sub>2</sub>O and add EtOH since it is sparingly soluble in EtOH. It is insoluble in Et<sub>2</sub>O. It forms a Cu complex in alkaline solution and a complex with Fe in neutral solution. [Sawyer & Bagger *J Am Chem Soc* **81** 5302 1959, *Beilstein* **3** I 188.]

**Sodium glycochenodeoxycholate** [16564-43-5] M 472.6, m 245-250°,  $[\alpha]_{D}^{23} +41.2^{\circ}$  (c 1, H<sub>2</sub>O). Dissolve it in EtOH, filter it and concentrate it to crystallisation, and recrystallise from a little EtOH. It also recrystallises from EtOH/Et<sub>2</sub>O. [*Beilstein* **10** IV 1611.]

**Sodium glycocholate** [863-57-0] M 488.6, m 230-240°,  $[\alpha]_{D}^{23} +29.2^{\circ}$  (c 1, H<sub>2</sub>O). Dissolve it in EtOH, filter it and concentrated to crystallisation, and recrystallise from a little EtOH. It also crystallises from 95% EtOH/Et<sub>2</sub>O. [*Beilstein* **3** IV 573.]

**Sodium glycolate dehydrate (sodium hydroxyacetate)** [2836-32-0] M 98.0, pK<sup>25</sup> 3.83 (for acid). Precipitate it from aqueous solution by adding EtOH and dry it in air. Also recrystallise it from H<sub>2</sub>O, where its solubility is 38% at 0° and 61% at 100°. [*Beilstein* **3** III 370, **3** IV 573.]

**Sodium hydrogen diglycollate (2,2'-oxydiacetic acid monosodium salt)** [50795-24-9] M 156.1, pK<sub>1</sub><sup>20</sup> 2.70, pK<sub>2</sub><sup>20</sup> 4.22 (for acid). Crystallise it from hot water (7.5ml/g) by cooling to 0° with constant stirring. The crystals are filtered off on to a sintered-glass funnel and dried at 110° overnight. Its solubility in water is 2.6% (at 0°) and 20% (at 90°). [*Beilstein* **3** III 377, **3** IV 577.]

**Sodium hydrogen oxalate dihydrate** [1186-49-8] M 130.0, m 100°(loses H<sub>2</sub>O), b 200°(dec). Crystallise it from hot water (5ml/g) by cooling. Its solubility in H<sub>2</sub>O is 1.7% at 15.5° and 21.3% at boiling. [Souhay & Lensen *Justus Liebigs Ann Chem* **99** 34 1856, *Beilstein* **2** H 513, **2** I 223, IV 1817.]

**Sodium hydrogen succinate** [2922-54-5] M 140.0. Crystallise it from hot water and dry it at 110°. Its solubility in H<sub>2</sub>O is 17% at 0°, 40% at 25° and 86% at 75°. [Marshall & Bain *J Chem Soc* **97** [I] 1074, 1084 1910, Stokes **70** 1945 1948, *Beilstein* **2** H 606, **2** I 262, **2** III 16557, **2** IV 1911.]

**Sodium hydrogen d-tartrate** [526-94-3] M 190.1, m 100°(loses H<sub>2</sub>O), m 253°dec,  $[\alpha]_{546} +26^{\circ}$  (c 1, H<sub>2</sub>O) and  $[\alpha]_{D}^{20} +24^{\circ}$  (c 1, H<sub>2</sub>O). It crystallises from warm water (10ml/g) by cooling to 0°. [*Beilstein* **3** IV 1219.]

**Sodium 2-hydroxy-4-methoxybenzophenone-5-sulfonate** [6628-37-1] M 330.3. Crystallise it from MeOH and dry it under vacuum.

**Sodium p-hydroxyphenylazobenzene-p'-sulfonate** [2623-36-1] M 288.2. Recrystallise it from 95% EtOH.

**Sodium ionophore I (ETH 227) (N,N',N''-triheptyl-N,N',N''-trimethyl-4,4',4''-propylidyne-tris(3-oxabutamide)** [61183-76-4] M 642.0. It is purified (ca 200mg) by TLC on Kieselgel F<sub>254</sub> with CHCl<sub>3</sub>/Me<sub>2</sub>CO (1:1) as solvent, followed by HPLC (50mg) with an octadecyltrimethylsilane modified column (Mercksorb SI 100, 10µm) [IR, NMR, MS: Güggi et al. *Helv Chim Acta* **59** 2417 1976]. [See Simon & Carafoli *Methods Enzymol* **56** 439 1977.]

**Sodium ionophore V (ETH 4120) [4-octadecanoyloxymethyl-N,N,N',N''-tetraacyclohexyl-1,2-phenylenedioxydiacetamide]** [129880-73-5] M 849.3. Purify it by recrystallisation from EtOAc [Preparation and properties: Géhrig et al. *Anal Chim Acta* **233** 295 1990].

**Sodium ionophore VI {bis[(12-crown-4)methyl]dodecyl methyl malonate}** [80403-59-4] M 662.9. Purify it by gel permeation or column chromatography. [Preparation and NMR data: Shono et al. *J Electroanal Chem* **132** 99 1982, Cram & Cram *Science* **183** 803 1974.]

**Sodium RS-mandelate** [114-21-6] M 174.1, pK<sup>25</sup> 3.41 (for the acid). It crystallises from 95% EtOH and is dried in a vacuum. [Ross & Morrison *J Chem Soc* 1019 1933, Banks & Davies *J Chem Soc* 74 1938, *Beilstein* **10** III 450.]

**Sodium methoxide** [124-41-4] **M 54.0**. It behaves in the same way as sodium ethoxide. It is *hygroscopic* and is hydrolysed by moist air to NaOH and MeOH. Material that has been kept under N<sub>2</sub> should be used. If erratic results are obtained, even with recently purchased NaOMe, it should be freshly prepared thus: Clean Na (37g) cut in 1-3g pieces is added in small portions to stirred MeOH (800ml) in a 2L three-necked flask equipped with a stirrer and a condenser with a drying tube. After all the Na has dissolved, the MeOH is removed by distillation under vacuum, and the residual NaOMe is dried by heating at 150° under vacuum and kept under dry N<sub>2</sub> until required [Burness *Org Synth* **39** 51 1959]. [Beilstein **1** IV 1227.]

**Sodium monensin** [22373-78-0] **M 693.8**. Crystallise it from EtOH/H<sub>2</sub>O [Cox et al. *J Am Chem Soc* **107** 4297 1985].

**Sodium oleate** [143-19-1] **M 304.4, m 233-235°**. Sodium oleate crystallises from EtOH, and is dried in an oven at 100°. [Beilstein **2** H 465, **2** I 201, **2** II 434, **2** III 1405, **2** IV 1645.]

**Sodium oxalate** [62-76-0] **M 134.0, m 250-270°(dec), d<sub>4</sub><sup>20</sup> 2.34**. It crystallises from hot water (16ml/g) by cooling to 0°. Before use as a volumetric standard, analytical grade quality sodium oxalate should be dried for 2 hours at 120° and allowed to cool in a desiccator. [Beilstein **2** IV 1819.]

**Sodium palmitate** [408-35-5] **M 278.4, m , 270°, 285-201°**. It crystallises from EtOH and is dried in an oven. [Beilstein **2** IV 1157.]

**Sodium pentamethylcyclopentadienide (NaCp', 1,2,3,4,5-pentamethyl-2,4-pentadiene-1-ylsodium)** [40585-51-1] **M 158.2, m >230°**. It is prepared, handled and stored as for KCp' but is not as flammable. A 0.5M solution in THF is commercially available. It is a Cp' ligand source for complexing with a large number of metals and non-metal halides. [Kohl et al. in *Organometallic Synthesis* (R. Bruce King and J.J. Eisch eds) **Vol 3** 381, Elsevier Amsterdam 1986].

**Sodium phenoxide** [139-02-6, 156150-40-2 (3H<sub>2</sub>O)] **M 116.1, m 61-64°**. The ground powder is washed with Et<sub>2</sub>O, then heated at 60°/1mm for 12 to 24 hours to remove any free phenol and solvent. [Kornblum & Lurie *J Am Chem Soc* **81** 2710 1959, Beilstein **6** I 718.]

**Sodium phenylacetate** [114-70-5] **M 158.1**. Its aqueous solution is evaporated to crystallisation on a steam bath; the crystals are washed with absolute EtOH and dried under vacuum at 80°. [Beilstein **9** IV 1614.]

**Sodium o-phenylphenolate tetrahydrate** [132-27-4] **M 264.3**. Crystallise the salt from acetone and dry it under vacuum at room temperature. [Beilstein **16** IV 4600.]

**Sodium phenylpyruvate** [114-76-1] **M 186.1, m >300°**. The salt should have no OH broad bands in the IR at ~3000cm<sup>-1</sup>. If these are present, then they are due either to water contamination or to the presence of free acid. For the first case dry the solid thoroughly in a vacuum over P<sub>2</sub>O<sub>5</sub>, and in the latter case wash the salt well with Et<sub>2</sub>O *in vacuo* till free of acid. *Alternatively*, add a slight excess of the free acid (cf p 375, see[156-06-9]) in EtOH to ethanolic NaOH, evaporate to dryness and extract excess acid from the salt with dry Et<sub>2</sub>O. [Beilstein **10** I 325.]

**Sodium phytate monohydrate [myo-inositolhexakis(H<sub>2</sub>PO<sub>4</sub>) Na salt]** [14306-25-3] **M 857.9**. Crystallise sodium phytate from hot water. [Beilstein **6** IV 7927.]

**Sodium polyacrylate (NaPAA)** [9003-04-7]. Commercial polyacrylamide is first neutralised with an aqueous solution of NaOH, and the polymer is precipitated with acetone. The precipitate is redissolved in a small amount of water and freeze-dried. The polymer is then repeatedly washed with EtOH and water to remove traces of low-molecular-weight material, and finally dried in vacuum at 60° [Vink *J Chem Soc, Faraday Trans 1* **75** 1207 1979]. It has also been dialysed overnight against distilled water, then freeze-dried.

**Sodium poly ( $\alpha$ -L-glutamate).** Wash it with acetone, dry it in a vacuum, dissolve it in water and precipitate it with isopropanol at 5°. Impurities and low-molecular-weight fractions are removed by dialysis of the aqueous solution for 50 hours, followed by ultrafiltration through a filter impermeable to polymers of molecular weights greater than  $10^4$ . The polymer is recovered by freeze-drying. [Mori et al. *J Chem Soc, Faraday Trans 1* 2583 1978.]

**Sodium propionate** [137-40-6] **M 96.1, m 287-289°.** Recrystallise it from H<sub>2</sub>O (solubility 10%) and dry by heating at 100° for 4 hours. The solubility of the anhydrous salt in MeOH is 13% at 15° and 13.77% at 68°. It is insoluble in \*C<sub>6</sub>H<sub>6</sub> and Me<sub>2</sub>CO. [Henstock *J Chem Soc* 1341 1934, *Beilstein 2* IV 701.]

**Sodium stearate** [822-16-2] **M 306.6.** It is better to prepare it by adding a slight excess of octadecanoic acid to ethanolic NaOH, evaporating and extracting the residue with dry Et<sub>2</sub>O. [*Beilstein 2* III 1003.]

**Sodium R-tartrate dihydrate** [6106-24-7] **M 230.1, m 120°(loses H<sub>2</sub>O), d<sub>4</sub><sup>20</sup> 1.82, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +26° (c 1, H<sub>2</sub>O).** It crystallises from warm dilute aqueous NaOH on cooling. [*Beilstein 3* H 524.]

**Sodium trifluoroacetate** [2923-18-4] **M 136.0, m 206-210°(dec), pK<sup>25</sup> 0.52 (for CF<sub>3</sub>CO<sub>2</sub><sup>-</sup>).** A possible contaminant is NaCl. The solid is treated with CF<sub>3</sub>CO<sub>2</sub>H and evaporated twice. Its solubility in CF<sub>3</sub>CO<sub>2</sub>H is 13.1% at 29.8°. The residue is crystallised from dilute EtOH, and the solid is dried in vacuum at 100°. [Hara & Cady *J Am Chem Soc* 76 4285 1954.] It can be precipitated from EtOH by adding dioxane, then recrystallising several times from hot absolute EtOH. Dry it at 120-130°/1mm. [*Beilstein 2* IV 461.]

**Stannous bis-cyclopentadienyl** [26078-96-6] **M 248.9.** Purify it by vacuum sublimation. Handle and store it under dry N<sub>2</sub>. The related thallium and indium compounds are similarly purified.

**Strontium acetate** [543-94-2] **M 205.7, d 2.1, pK<sup>25</sup> 13.0 (for aquo Sr<sup>2+</sup> hydrolysis).** Crystallise it from AcOH, then dry it under vacuum for 24 hours at 100°. [*Beilstein 2* II 91.]

**Strontium lactate trihydrate** [29870-99-3] **M 319.8, m 120°(loses 3H<sub>2</sub>O).** It crystallises from aqueous EtOH. [*Beilstein 3* IV 633.]

**Strontium oxalate monohydrate** [814-95-9] **M 193.6, m 150°.** It crystallises from hot water on cooling. The solubility at ~25° in H<sub>2</sub>O is 1g/20L, and in 3.5% AcOH and 25% AcOH it is 1g/1.9L and 1g/1.1L respectively. **IRRITANT.** [*Beilstein 2* H 515, *2* IV 1826.]

**Strontium salicylate** [526-26-1] **M 224.7.** It crystallises from hot water (4ml/g) or EtOH. [*Beilstein 10* IV 125.]

**Strontium tartrate** [868-19-9] **M 237.7.** It crystallises from hot water. [*Beilstein 3* IV 1219.]

**Tantalum pentaethoxide** [6074-84-6] **M 406.3, b 147°/0.2mm, 202°/10mm, pK<sub>1</sub><sup>25</sup> 9.6, pK<sub>2</sub><sup>25</sup> 13.0 (for tantalic acid).** Purify it by distillation under reduced pressure. It aggregates in \*C<sub>6</sub>H<sub>6</sub>, EtOH, MeCN, pyridine and diisopropyl ether. [Bradley et al. *J Chem Soc* 726 1955, Bradley et al. *J Chem Soc* 5 1956, *Beilstein 1* IV 1312.]

**Tetraallyltin (tetraallylstannane)** [7393-43-3] **M 283.0, b 52°/0.2mm, 69-70°/15mm, d<sub>4</sub><sup>20</sup> 1.179, n<sub>D</sub><sup>20</sup> 1.536.** Possible contaminants are allyl chloride and allyltin chloride. Check the <sup>1</sup>H NMR and IR [Fishwick & Wallbridge *J Organomet Chem* 25 69 1970], and if impure, dissolve it in Et<sub>2</sub>O and shake it with a 5% aqueous solution of NaF which precipitates allyltin fluoride. Separate the Et<sub>2</sub>O layer, dry (MgSO<sub>4</sub>), and distil it at ~0.2mm. It decomposes slightly on repeated distillation. [O'Brien et al. *Inorg Synth XIII* 75 1972, Fishwick et al. *J Chem Soc (A)* 57 1971, *Beilstein 4* III 1922.]

**Tetrabutylammonium borohydride** [33725-74-5] **M 257.3, m 128-129°.** Purify it by recrystallisation from EtOAc followed by careful drying under vacuum at 50-60°. Samples purified in this way showed no signs

of loss of *active* H after storage at room temperature for more than 1 year. Nevertheless samples should be stored at *ca* 6° in tightly stoppered bottles if kept for long periods. It is soluble in CH<sub>2</sub>Cl<sub>2</sub>. [Raber & Guida *J Org Chem* **41** 690 1976, Brändström et al. *Tetrahedron Lett* 3173 1972.]

**Tetrabutyl orthotitanate monomer (titanium tetra-*n*-butoxide)** [5593-70-4] **M 340.4, b 142°/0.1mm, 134-136°/0.5mm, 160°/0.8mm, 174°/6mm, 189°/13mm, d<sub>4</sub><sup>35</sup> 0.993, n<sub>D</sub><sup>25</sup> 1.49.** Dissolve it in \*C<sub>6</sub>H<sub>6</sub>, filter if solid is present, evaporate and vacuum fractionate through a Widmer 24 inch column. The ester hydrolyses when exposed to air to give hydrated ortho-titanic acid. The titanium content can be determined thus: weigh a sample (*ca* 0.25g) into a weighed crucible and cover it with 10ml of H<sub>2</sub>O and a few drops of conc HNO<sub>3</sub>. Heat (hot plate) carefully till most of the H<sub>2</sub>O has evaporated. Cool and add more H<sub>2</sub>O (10ml) and conc HNO<sub>3</sub> (2ml), and evaporate carefully (no spillage) to dryness and ignite the residue at 600-650°/1 hour. Weigh the residual TiO<sub>2</sub>. [Bradley et al. *J Chem Soc* 2773 1952, Speer *J Org Chem* **14** 655 1949, *Beilstein* 1 II 398, 1 III 1515, 1 IV 1415.]

**Tetrabutyl tin (tin tetrabutyl)** [1461-25-2] **M 347.2, m -97°, b 94.5-96°/0.28mm, 145°/11mm, 245-247°/atm, d<sub>4</sub><sup>20</sup> 1.0559, n<sub>D</sub><sup>24</sup> 1.473.** Dissolve it in Et<sub>2</sub>O, dry it over MgSO<sub>4</sub>, filter, evaporate and distil it under reduced pressure. Although it does not crystallise easily, once the melt has crystallised, then it will recrystallise more easily. It is soluble in Et<sub>2</sub>O, Me<sub>2</sub>CO, EtOAc and EtOH, but insoluble in MeOH and H<sub>2</sub>O, and shows no apparent reaction with H<sub>2</sub>O. [Johnson & Fritz *J Org Chem* **19** 74 1954, Staveley *J Chem Soc* 1992 1954, Van der Kerk & Luitzen *Org Synth Coll Vol* **IV** 822 1963, *Beilstein* 4 III 1920, 4 IV 4312.]

**Tetraethyl lead** [78-00-2] **M 323.5, m -38°, b 84-85°/15mm, 200°, 227.7°(dec), d<sub>4</sub><sup>20</sup> 1.653, n<sub>D</sub><sup>20</sup> 1.5198.** Its more volatile contaminants can be removed by exposure to a low pressure (by continuous pumping) for 1 hour at 0°. Purify it by stirring with an equal volume of H<sub>2</sub>SO<sub>4</sub> (d 1.40), keeping the temperature below 30°, repeating this process until the acid layer is colourless. It is then washed with dilute Na<sub>2</sub>CO<sub>3</sub> and distilled water, dried with CaCl<sub>2</sub> and fractionally distilled at low pressure under H<sub>2</sub> or N<sub>2</sub> [Calingaert *Chem Rev* **2** 43 1926]. It prevents "knocking" in petrol combustion engines. [Milde & Beatty *Adv Chem Res* **23** 306-318 1959, *Beilstein* 4 H 639.] **VERY POISONOUS.**

**Tetraisopropyl orthotitanate (titanium tetraisopropoxide)** [546-68-9] **M 284.3, m 18.5°, 18-20°, b 80°/2mm, 78°/12mm, 228-229°/755mm.** Dissolve it in dry \*C<sub>6</sub>H<sub>6</sub>, filter if a solid separates, evaporate and fractionate. It is hydrolysed by H<sub>2</sub>O to give solid Ti<sub>2</sub>O(*iso*-OPr)<sub>2</sub> **m ca 48°.** [Bradley et al. *J Chem Soc* 2027, 1952, Bradley et al. *J Chem Soc* 469 1957, *Beilstein* 1 II 328, 1 IV 1469S.]

**Tetrakis(diethylamino) titanium [(titanium tetrakis(diethylamide))]** [4419-47-0] **M 336.4, b 85-90°/0.1mm, 112°/0.1mm, d<sub>4</sub><sup>30</sup> 0.93, n<sub>D</sub><sup>30</sup> 1.54.** Dissolve it in \*C<sub>6</sub>H<sub>6</sub>, filter if a solid separates, evaporate under reduced pressure and distil it. It is an orange liquid which reacts violently with alcohols. [Bradley et al. *J Chem Soc* 3857 1960, *Beilstein* 4 IV 313.]

**Tetramethyloxorhenium [(CH<sub>3</sub>)<sub>4</sub>ReO]** [53022-7-1] **M 262.4, m ~45° (no dec <150°).** It is best prepared by adding a 1M solution of MeLi in Et<sub>2</sub>O (80ml, 80mmol) slowly to a stirred suspension of ReOCl<sub>3</sub>(PPh<sub>3</sub>)<sub>2</sub> (8.32g, 10mmol, cf [17442-18-1]) in Et<sub>2</sub>O (120ml) at -78°, and the mixture is allowed to warm slowly to ~25° to form a dark brown solution which is stirred further for 0.5 hours. The excess of MeLi is destroyed by dropwise addition, at -78°, of H<sub>2</sub>O (~10ml), and allowed to warm to ~25°, and then cooled again, to -30°; and H<sub>2</sub>O<sub>2</sub> (2.5g, 30% diluted in 20ml of H<sub>2</sub>O) is added slowly dropwise with vigorous stirring. The colour of the solution changes to red rapidly and stirring is continued for 0.5 hours after the temperature has risen to ~25°. This mixture is then cooled to -78°, the Et<sub>2</sub>O layer is filtered free from ice, dried first with CaCl<sub>2</sub> at ~25° then with molecular sieves, cooled again to -78°, filtered, and the solvent is carefully evaporated at -50°. The red-purple (carmine) crystalline residue is sublimed onto a probe at -78°, in a 1mm vacuum, to give Me<sub>4</sub>ReO (1.26g, ~48%; but can be as high as 70% by very careful removal of solvent). Lower yields are obtained if due care is not taken during the removal of solvent *in vacuo*. The low melting solid is extremely volatile subliming readily even at -35°/10<sup>-3</sup>mm; it co-distils at low temperatures with Et<sub>2</sub>O or petroleum ether, and always occurs during removal of solvents (see earlier), hence the temperature has to be kept as low as possible, and a cold probe should be

included in the system to avoid losses. In an alternative method  $\text{ReOCl}_4$  (3mmol) is reacted with  $\text{MeLi}$  (12mmol) in  $\text{Et}_2\text{O}$  at  $-78^\circ$  to give a 20% yield of  $\text{Me}_4\text{ReO}$ , although this low yield may well be due to evaporative losses.

$\text{Me}_4\text{ReO}$  is thermally stable and can be stored indefinitely *in vacuo*. It is very soluble in petroleum ethers,  $\text{Et}_2\text{O}$ ,  $\text{CS}_2$ ,  $\text{CCl}_4$ , but these solutions slowly decompose with time even in the absence of air. However, solutions in THF and aromatic hydrocarbons are more stable. It is surprisingly unreactive at  $\sim 25^\circ$  in  $\text{Et}_2\text{O}$ ,  $\text{H}_2\text{O}$ , mineral acids, alcohols,  $\text{H}_2$ ,  $\text{CO}$ ,  $\text{CO}_2$ ,  $\text{SO}_2$ ,  $\text{HCl}$  gas, butadiene, tertiary phosphines, amines, tetramethylthiuram disulfide and 1,1-diphenyl-2-picrylhydrazyl. It is however, highly reactive with air and oxygen producing instantly white fumes and crystals of  $\text{MeReO}_3$  (methyltrioxorhenium, MTO, the carrier catalyst, see [70197-13-6]). In  $^*\text{C}_6\text{H}_6$  solution with air, it slowly oxidises to form yellow-orange products (cf yellow *cis*- $\text{Me}_3\text{ReO}_3$  [56090-01-8]). In the mass spectrum, ions of Re isotopes are identified ( $^{185}\text{Re}$  37%,  $^{187}\text{Re}$  63%) with the natural isotopic abundance. The solid state IR (at  $\sim -250^\circ$  co-condensed with argon) has  $\nu_{\text{max}}$  at 2974s(CH str), 1231s(CH def), 1018s(Re=O str), 1004sh,br, 746m(Me rock), 552m and 529s(ReC str)  $\text{cm}^{-1}$ , and IR (de-oxygenated  $\text{CS}_2$ ) has  $\nu_{\text{max}}$  at 2980s, 1370m, 1002s, 749w, 520m  $\text{cm}^{-1}$ . [Mertis, Williamson and Wilkinson *JCS, Dalton Trans* 607 1975, Mertis & Wilkinson *JCS, Dalton Trans* 1488 1976, Beattie & Jones *Inorg Chem* 18 2318 1979.]

**Tetramethyltin (tetramethylstannane, tin tetramethyl)** [594-27-4] **M 178.8, m  $-55^\circ$ , b 76.6 $^\circ$ /748mm, 74-75 $^\circ$ /atm, 78 $^\circ$ /atm,  $d^{25}$  1.291,  $n_D^{20}$  1.441.** Organotin compounds are **HIGHLY TOXIC**, and all due precautions should be taken when handling them.  $\text{Me}_4\text{Sn}$  is an ethereal smelling liquid that is highly flammable with a flash point of less than  $20^\circ$ , and should be stored at low temperatures. An improved preparation of  $\text{Me}_4\text{Sn}$  has been achieved by carrying out the reaction in the higher boiling di-*n*-butyl ether, and preparing the Grignard reagent *in situ*. Under strictly anhydrous conditions, to Mg turnings (50g, 2.06g.atoms) in dry *n*- $\text{Bu}_2\text{O}$  (600ml, containing a few crystals of  $\text{I}_2$ ) is added dropwise a solution of  $\text{MeI}$  (225g, 1.59moles, freshly distilled) in *n*- $\text{Bu}_2\text{O}$  (600ml) with gentle stirring. After the initial reaction has started, the  $\text{MeI}$  solution is added at such a rate as to keep the solution refluxing gently, requiring *ca* 3 hours. Cool the solution to  $\sim 25^\circ$  and add to it, dropwise, anhydrous  $\text{SnCl}_4$  (75g, 0.29 moles) while sustaining gentle reflux (*ca* 2-2.5 hours). The mixture is then refluxed steadily ( $85-95^\circ$ ) for 1 hour, and set aside at  $\sim 25^\circ$  for several hours. The reflux condenser is replaced by a Claisen head and the mixture is distilled; whereby  $\text{Me}_4\text{Sn}$  and *n*- $\text{Bu}_2\text{O}$  distil together at  $\sim 85-95^\circ/\text{atm}$ . It dissolves stopcock silicone greases. The  $\text{Me}_4\text{Sn}$  is purified by fractionation through a Todd column (35-40 plates) to give pure *stannane* with **b 76.6 $^\circ$ /748mm** in 91% yield. [Edgell & Ward *J Am Chem Soc* 76 1169 1954.] Its IR (liquid film) has  $\nu_{\text{max}}$  at 2920 (vs) and 3000 (vs) C-H str, 1443 (s) and 1198 (s)  $\text{CH}_3$  deformation, 770 (vs)  $\text{CH}_3$  rocking, **528 (s) C-Sn str**  $\text{cm}^{-1}$ , and from Raman spectrum 160 (vs) and 145 (vs)  $\text{cm}^{-1}$  for **C-Sn-C** bending [Taimsalu & Wood *Trans Farad Soc* 59 1754 1963, Edgell & Ward *J Am Chem Soc* 77 6486 1955]. The  $^{119}\text{Sn}$  NMR (15.5 MHz, at  $28^\circ\text{C}$ , 12mm tube not spinning, neat  $\text{SnCl}_4$  as external standard) has  $\delta$  at -147.8 ( $J_{\text{H-}^{119}\text{Sn}} = 54.0\text{Hz}$  from 60MHz proton spectrum) [Lassigne & Wells *Can J Chem* 55 927 1977, for  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra see Singh *J Organomet Chem* 99 251 1975.] [Beilstein 4 H 631, 4 I 583, 4 II 1010, 4 III 1917, 4 IV 4307.]

**Tetraphenyltin** [595-90-4] **M 427.1, m 224-225 $^\circ$ , 226 $^\circ$ .**  $\text{SnPh}_4$  forms yellow crystals from  $\text{CHCl}_3$ , petroleum ether (b 77-120 $^\circ$ ), xylene or \*benzene/cyclohexane, and is dried at  $75^\circ/20\text{mm}$ . [Gilman & Rosenberg *J Am Chem Soc* 74 531 1952, Beilstein 16 IV 1592.]

**Tetra-*n*-propylammonium perruthenate (TPAP, tetrapropyl tetraoxoruthenate)** [114615-82-6] **M 351.4, m 160 $^\circ$ (dec).** It is a dark green solid that is stable at  $\sim 25^\circ$  for long periods without much deterioration, and is best kept in a refrigerator. It is a strong oxidant, and should not be heated directly as it may explode. Small amounts decompose in a flame at  $\sim 155^\circ$  in air. It can be washed with aqueous *n*-propanol, then  $\text{H}_2\text{O}$  and dried over  $\text{KOH}$  in a vacuum. It is soluble in  $\text{CH}_2\text{Cl}_2$  and  $\text{MeCN}$ . Generally, at ambient temperatures in these solvents it is most useful, when in conjunction with *N*-methylmorpholine *N*-oxide, for the oxidation of primary and secondary alcohols, including allylic and benzylic alcohols, lactol oxidation, heteroatom oxidation, and some cleavage reactions. [Dengel et al. *Transition Met Chem* 10 98 1985, Griffith et al. *J Chem Soc, Chem Commun* 1625 1987, for a review see Ley et al. *Synthesis* 639 1994, and for its catalytic activity see chapter on "Catalysis".]

§ Polymer supported reagent is available commercially.

**Thallium (I) acetate (TIOAc)** [563-68-8] M 263.4, m 131°. Thallous (I) acetate crystallises from EtOH (needles) or Me<sub>2</sub>CO. The salt forms white deliquescent crystals (specific gravity 3.68) which are soluble in H<sub>2</sub>O and EtOH. Store it in sealed containers. It forms TIOAc·AcOH crystals which melt at 64°. [Beilstein 2 H 115, 2 II 119, 2 III 195.] **POISONOUS — HANDLE CAREFULLY WITH GLOVES, and work in a well-ventilated fume hood.**

**Thallium (III) triacetate [Tl(OAc)<sub>3</sub>]** [2570-63-0] M 381.5, m 182°(dec.). The salt is prepared by stirring thallic oxide (50g) in AcOH (300ml) at 65° until all the brown-black solid has dissolved (~24 hours), then filter and cool to obtain the salt as white crystals which are collected by decantation and dried over P<sub>2</sub>O<sub>5</sub> *in vacuo* as they turn brown in air. A second crop can be obtained by concentrating the filtrate (total yield 73g, 99%). On a large scale (457g) of the brown trioxide was treated with AcOH (2L) containing Ac<sub>2</sub>O (110ml) by stirring at 80-90°, the walls of the flask were washed down with a further volume of AcOH (500ml). Heating (90-100°) and stirring was continued for 2 hours (all the brown oxide had dissolved), the hot solution was filtered using a sintered glass funnel, cooled to ~20°, and collected onto a glass frit. The solid was dissolved in the minimum volume of AcOH (~800ml) at 80-90°, filtered through a glass frit and allowed to cool first to ~20° then to ~15°, and collected by filtration. The Tl(OAc)<sub>3</sub> was dried by spreading it in a large dish in a desiccator over KOH pellets overnight to give ~97% pure salt (467g, 61% yield). It promotes the quantitative photochemical decarboxylation of a variety of aliphatic acids to yield a high proportion of the corresponding alkanes with some alkenes, dialkyls and other minor products at wavelength 3500Å; whereas at wavelength 2537Å the alkyldimers are formed in high yields. [Kochi & Bethea *J Org Chem* 33 75 1968.] [Beilstein 2 H 115, 2 III 195.] **POISONOUS — HANDLE CAREFULLY WITH GLOVES, and work in a well-ventilated fume hood.**

**Thallium (III) trifluoroacetate [Tl(tfl)<sub>3</sub>, Tl(OCOCF<sub>3</sub>)<sub>3</sub>]** [23586-53-0] M 543.4, m dec slowly >100°, 213° (dec.). This thallation reagent is prepared in 90-100% yield by heating a suspension of thallium(III) oxide in TFA containing 10-20% of H<sub>2</sub>O until clear. This colourless solution can be used directly in thallation reactions or a granular solid salt can be isolated by evaporation *in vacuo*, and then used in inert solvents such as MeCN. The salt does not have a sharp melting point and decomposes slowly >100°. It is water sensitive but can be stored at ~25° in a stoppered container away from light without appreciable decomposition for long periods. A solution of the salt in TFA, however, can tolerate up to ~20% of H<sub>2</sub>O to give a 0.8M solution before serious hydrolysis of the salt occurs. It thallated aromatic rings (e.g. PhCl, PhF, toluene, xylene, *o*-benzoic acid) in TFA to produce the corresponding ArylTl(tfl)<sub>2</sub> at low temperatures which can be isolated in 70-100% yields, or reacted further (e.g. with KI) to displace the Tl(tfl)<sub>2</sub> group and form the respective iodides. [McKillop et al. *J Am Chem Soc* 93 4841 1971, Taylor et al. *Org Synth Coll Vol VI* 709 1988, see Fieser & Fieser's *Organic Reagents* for further applications, Beilstein 2 II 186.] **POISONOUS — HANDLE CAREFULLY WITH GLOVES, and work in a well-ventilated fume hood.**

**Thallic (I) ethoxide (TIOEt)** [20398-06-5] M 249.4, d<sub>4</sub><sup>25</sup> 3.522, n<sub>D</sub><sup>20</sup> 1.676. The alkoxide is prepared by refluxing dry EtOH in a modified Soxhlet extractor whereby the hot alcohol leaches thallium shot or turnings (see below) placed in the vapours of refluxing alcohol while oxygen flows through the apparatus which is protected from moisture with a soda lime drying tube at the top of the condenser. The apparatus devised by Fieser and Fieser can be used. Thallium shot (m 303°) is made by holding a clean piece of metal with tongs and heated with a blow torch allowing the molten metal to drip in ~2L of cold H<sub>2</sub>O. *Alternatively*, thallium turnings made with a pencil sharpener from thallium rods can be used. A Soxhlet flask (500ml) containing dry EtOH (300ml) is placed under Tl shot (100ml, dried by pressing with filter paper) in the crucible above, and the EtOH is refluxed while a rapid stream of dry O<sub>2</sub> is made to flow just beneath the metal. The volume of boiling EtOH in the flask is maintained at ~300ml by further addition of dry EtOH. When all the metal has been converted to TIOEt (12-16 hours), and all the oily alkoxide has run into the flask which will form a separate heavy oily liquid layer (note that TIOEt had d = 3.522), boiling is stopped and the volume of the alkoxide solution is adjusted to 300ml which would give a saturated solution containing 9g of TIOEt/100ml. Store away from moisture. *Alternatively*, the oily layer can be sucked out with a vacuum into a container, but great care should be taken to avoid contact with moisture. Thallium in the ethoxide solution can be determined as TIOH by cooling it in an ice bath without separating the excess of EtOH (to avoid partial conversion of TIOH to black Tl<sub>2</sub>OH), and adding an equal volume of boiled and re-cooled H<sub>2</sub>O (i.e. free from O<sub>2</sub>) and evaporating *in vacuo* to give yellow

adding an equal volume of boiled and re-cooled H<sub>2</sub>O (i.e. free from O<sub>2</sub>) and evaporating *in vacuo* to give yellow crystalline TIOH. [Fieser & Fieser's *Reagents for Organic Synthesis* 2 409 1969, Dönges in *Handbook of Preparative Inorganic Chemistry* (Ed. Brauer) Academic Press Vol I p 877-878 1963, Freudenberg & Uthemann *Chem Ber* 52 1508 1919.] **POISONOUS—handle with gloves, and work in a good fume hood.**

**Tin (II) acetate (stannous acetate)** [638-39-1] **M 236.8, m 180-182°, 182.55-183°, b 239-241° (some dec under N<sub>2</sub>), d 2.31.** It is prepared by dissolving blue-black SnO<sub>2</sub> (25g) in refluxing 50%v/v AcOH (200ml), evaporating *in vacuo* (over KOH) and subliming the white residue *in vacuo* at 150-155° (~96% yield of white orthorhombic crystals). *Alternatively*, finely divided Sn is refluxed in glacial AcOH for 80-90 hours [not less as Sn(OAc)<sub>2</sub>·2AcOH is formed] and isolated as before. It hydrolyses slowly in H<sub>2</sub>O to give blue Black SnO<sub>2</sub>, Me<sub>2</sub>CO, CO<sub>2</sub> and H<sub>2</sub>, can be stored for long periods under N<sub>2</sub>, and is soluble in EtOH (2.9%), Me<sub>2</sub>CO (1.4%) and 2N AcOH (33%). It is a useful reducing (and acetylating) agent. [Donaldson et al. *J Chem Soc* 5942 1964.]

**Titanium (IV) methoxide** [992-92-7] **M 172.0, m 200-210°, b 243°/52mm.** It is extremely sensitive to moisture. Dissolve it in H<sub>2</sub>O-free \*C<sub>6</sub>H<sub>6</sub>, filter, evaporate and distil it *in vacuo* under N<sub>2</sub>. It is **FLAMMABLE** and **TOXIC**. [Bradley et al. *Metal Alkoxides* Academic Press 1978, ISBN 0121242501.]

**Titanocene dichloride** [1271-19-8] **M 248.9, m 260-280°(dec), 289.2°, 298-291°, d<sub>4</sub><sup>20</sup> 1.60.** It forms bright red crystals from toluene or xylene/CHCl<sub>3</sub> (1:1) and sublimates at 190°/2mm. It is moderately soluble in EtOH and insoluble in Et<sub>2</sub>O, \*C<sub>6</sub>H<sub>6</sub>, CS<sub>2</sub>, CCl<sub>4</sub>, petroleum ether and H<sub>2</sub>O. The crystalline *dipicrate* explodes on melting at 139-140°. [Wilkinson et al. *J Am Chem Soc* 75 1011 1953, IR: Wilkinson & Birmingham *J Am Chem Soc* 76 4281 1954, NMR and X-ray: Glivicky & McCowan *Can J Chem* 51 2609 1973, Clearfield et al. *J Am Chem Soc* 53 1622 1975, *Beilstein* 16 IV 1769.]

**Tri-*n*-butyl tin chloride** [1461-22-9] **M 325.5, b 98-100°/0.4mm, 140-152°/10mm, 172°/25mm, d<sub>4</sub><sup>20</sup> 1.21, n<sub>D</sub><sup>20</sup> 1.492.** Fractionate it in an inert atmosphere and seal it in small aliquots in glass ampoules. It is sensitive to moisture. [Jones et al. *J Chem Soc* 1446 1947, Kocheshkov *J Gen Chem USSR* 4 1359 1934, Kocheshkov *J Gen Chem USSR* 5 211 1935, *J Appl Chem* 6 93 1936, *Beilstein* 4 III 1926, 4 IV 4330.]

**Tributyl tin hydride** [688-73-3] **M 291.1, b 76°/0.7mm, 81°/0.9mm, d<sub>4</sub><sup>20</sup> 1.098, n<sub>D</sub><sup>20</sup> 1.473.** Dissolve it in Et<sub>2</sub>O, add quinol (500mg for 300ml, to stabilise it), dry over Na<sub>2</sub>SO<sub>4</sub>, filter, evaporate and distil it under dry N<sub>2</sub>. It is a clear liquid if dry and decomposes very slowly. In the presence of H<sub>2</sub>O, traces of tributyl tin hydroxide are formed in a few days. Store it in sealed glass ampoules in small aliquots. It is estimated by reaction with aqueous NaOH when H<sub>2</sub> is liberated. **CARE:** stored samples may be under pressure due to liberated H<sub>2</sub>. [Van Der Kerk et al. *J Appl Chem* 7 366 1937, Ono et al. *Tetrahedron* 41 4013 1985, Neuman *Synthesis* 665 1987, *Curran Synthesis* 417 1988, *Beilstein* 4 IV 4312.]

**Triethyltin hydroxide** [994-32-1] **M 222.9, m 49-50°, b 153-155°/20mm.** Treat it with HCl, followed by KOH, and filter it to remove diethyltin oxide [Prince *J Chem Soc* 1783 1959]. [*Beilstein* 4 H 633, 4 I 585, 4 II 1012, 4 III 1924, 4 IV 4325.]

**Trimethyloxonium tetrafluoroborate** [420-37-1] **M 147.9, m 141-143°(sinters, open capillary), 179.6-180.0°(dec), 210-220°(dec).** The salt must be a white crystalline solid **m** ~179.6-180.0° (dec, sealed tube). Under a N<sub>2</sub> atmosphere (e.g. Dry Box), wash it twice with CH<sub>2</sub>Cl<sub>2</sub>, then twice with Na-dried Et<sub>2</sub>O, and dry by passing dry N<sub>2</sub> over the salt until free from Et<sub>2</sub>O [Curphey *Org Synth Coll Vol VI* 1019 1988]. The oxonium salt, purified in this way, can be handled in air for short periods. The sample kept in a desiccator (Drierite) for 1 month at -20° had an unaltered melting point, and samples stored in this way for >1 year are satisfactory for alkylations. <sup>1</sup>H NMR in liquid SO<sub>2</sub> in a sealed tube had a single peak at δ 4.54 (impurities have δ at 3.39). [Meerwein *Org Synth Coll Vol V* 1096 1973.] If the sample looks good, dry it in a vacuum desiccator for 2 hours (25°/1mm) and store it under N<sub>2</sub> at -20°. The melting point depends on heating rate. [*Beilstein* 1 IV 1248.]

**Cis-Trimethylrhenium dioxide** [*cis*-trimethyldioxorhenium(VII), *cis*-(CH<sub>3</sub>)<sub>3</sub>ReO<sub>2</sub>] [56090-01-8] **M 263.3, m 10-11°.** This yellow dioxide is best prepared, in ~60% yield, from Me<sub>4</sub>ReO (preceding oxide [53022-7-1],

e.g. 0.5g) in Et<sub>2</sub>O (e.g. 40ml) at -78° by exposing the solution to nitric oxide when the red colour disappears while allowing to warm to ~25° with stirring. After 1 hour (without isolating the nitroso intermediate), the Et<sub>2</sub>O is removed at -40° *in vacuo* and the yellow crystalline residue is sublimed at 10<sup>-3</sup>mm onto a probe at -78° to give *cis*-(CH<sub>3</sub>)<sub>3</sub>ReO<sub>2</sub>, which can be recrystallised from petroleum ether solution on cooling to -78°, or distilled *in vacuo*. It is reasonably stable at room temperature, and like the starting material it fumes in air forming needles of MTO, the carrier catalyst (see above). Store it under N<sub>2</sub> or argon in a sealed ampoule. Its IR spectrum is consistent with the trigonal bipyramidal structure, where bands due to methyl vibrations are present together with two strong bands at  $\nu_{\max}$  992 and 951 cm<sup>-1</sup> attributable to *cis*-ReO<sub>2</sub>. This structure is also consistent with the <sup>1</sup>H NMR in CS<sub>2</sub> or deuteriotoluene which has two sharp resonances at  $\delta$  2.07 and 2.50 in the ratio 1:2 in which the higher field band is assumed to be from the axial methyl group. The lines do not broaden on cooling to -78° or heating to 85° in toluene solution which is consistent with a rigid molecule. The MS is as predicted from the two isotopes of Re (see above). [Mertis & Wilkinson *JCS, Dalton Trans* 1488 1976, Beattie & Jones *Inorg Chem* 18 2318 1979.]

**Trimethyltin chloride (chlorotrimethylstannane)** [1066-45-1] **M 199.3, m 37.5-39.5°, 42°, b 45-47°/10mm, 152°/760mm, 154-156°/atm.** Me<sub>3</sub>SnCl forms colourless needles that have **HIGHLY TOXIC** vapours and is best purified by distillation at atmospheric pressure or in a vacuum. It has been prepared by dropwise addition of a solution of Et<sub>2</sub>O saturated with dry HCl (20ml) to freshly distilled (dimethylamino)trimethylstannane (2.21g, b 126°/atm,  $d_{25}^{25}$  1.274,  $n_D^{20}$  1.463 [993-50-0]) in dry Et<sub>2</sub>O (10ml). Me<sub>2</sub>NH.HCl precipitated out, was filtered, the solvent was evaporated at <20°/15mm, and the residue was distilled at 760mm providing the colourless crystalline solid Me<sub>3</sub>SnCl (1.80g, 89.7%). It sublimes slowly at ~25°/20mm. [Jones & Lappert *J Organomet Chem* 3 295 1965, for <sup>1</sup>H and <sup>13</sup>C NMR see Singh *J Organomet Chem* 99 251 1975.] It is also available commercially as 1.0M solutions in hexanes or THF. Like the reaction of Me<sub>2</sub>N-SnMe<sub>3</sub>, the Me<sub>3</sub>SnCl reacts with H<sub>2</sub>O on heating to give Me<sub>3</sub>SnOH (almost quantitatively, [56-24-6]) as white crystals **m 118°**, which sublime at their melting point. It has IR (Nujol mull) with  $\nu_{\max}$  at 3620 (m), 2985 (m), 2915 (m), 1405 (w), 1195 (m), 920 (s), 765 (s), **540** (s) **Sn-C** str, 370 (s) and 316 (w) cm<sup>-1</sup>; it exists as a *dimer* [Me<sub>3</sub>SnOH]<sub>2</sub> in the solid state (IR mull) and in \*C<sub>6</sub>H<sub>6</sub>, CCl<sub>4</sub> and in CHCl<sub>3</sub> solutions (ebullioscopy) [Okawara & Yasuda *J Organomet Chem* 1 356 1964].

**Triphenylantimony** [603-36-1] **M 353.1, m 52-54°.** Recrystallise Ph<sub>3</sub>Sb from acetonitrile [Hayes et al. *J Am Chem Soc* 107 1346 1985]. [Beilstein 16 H 891, 16 IV 1198.]

**Triphenylbismuth (bismuth triphenyl)** [603-33-8] **M 440.3, m 75-76°, 77-78°, 78.5°, b 124°/7mm,  $d_4^{98.5}$  1.6427(melt).** Dissolve Ph<sub>3</sub>Bi in EtOH, precipitate it with H<sub>2</sub>O, extract with Et<sub>2</sub>O, dry and evaporate till the residue crystallises. It has been recrystallised from EtOH and Et<sub>2</sub>O/EtOH and is a stable compound. [Forward et al. *J Chem Soc suppl* p121 1949, Pfeiffer et al. *Chem Ber* 37 4620 1904, Gilman & Yablunsky *J Am Chem Soc* 62 665 1940, UV: Jaffé *J Chem Phys* 22 1430 1954, Beilstein 4 III 1841.]

**Triphenyltin chloride (chlorotriphenylstannane, triphenylchlorostannane)** [639-58-7] **M 385.5, m 103-106°(dec), 108°(dec), b 240°/13.5mm.** Purify it by distillation, followed by recrystallisation from MeOH by adding petroleum ether (b 30-60°), **m 105-106°** [Kozeschow et al. *Chem Ber* 67 1348 1934], or by crystallisation from Et<sub>2</sub>O, or 5 parts of EtOH and a small volume of petroleum ether. [Krause *Chem Ber* 51 914 1918.] It sublimes in a vacuum. [Beilstein 16 H 914, 16 I 540, 16 II 625, 16 III 1240, 16 IV 1606.] **HIGHLY TOXIC.**

**Triphenyltin hydroxide** [76-87-9] **M 367.0, m 122-123.5°, 124-126°.** West, Baney and Powell [*J Am Chem Soc* 82 6269 1960] purified a sample which was grossly contaminated with tetraphenyltin and diphenyltin oxide by dissolving it in EtOH, most of the impurities remaining behind as an insoluble residue. Evaporation of the EtOH extract gave the crude hydroxide which was converted to *triphenyltin chloride* (above) by grinding in a mortar under 12M HCl, then evaporating the acidic solution. The chloride, after crystallisation from EtOH, had **m 104-105°**. It was dissolved in Et<sub>2</sub>O and converted to the hydroxide by stirring with excess aqueous ammonia. The ether layer was separated, dried, and evaporated to give triphenyltin hydroxide which, after crystallisation from EtOH (or MeCN) and drying under vacuum, was in the form of white crystals (**m 119-120°**), which retained some cloudiness in the melt above 120°. The hydroxide retains water (0.1-0.5 moles of water per mole)

tenaciously. [Glidewell & Liles *Acta Cryst* (B) **34** 129 1978, *Beilstein* **16** H 914, **16** I 540, **16** II 625, **16** III 1240, **16** IV 1606.]

**Tris(2,2'-bipyridine)ruthenium(II) dichloride (6H<sub>2</sub>O)** [50525-27-4] **M 748.6**. Recrystallise it from water, then from MeOH [Ikezawa et al. *J Am Chem Soc* **108** 1589 1986].

**Tris( $\eta^5$ -2,4-cyclopentadien-1-yl)samarium III [SmCp<sub>3</sub>]** [1298-55-1] **M 345.6, m 365°**. SmCp<sub>3</sub> was prepared by stirring SmCl<sub>3</sub> with cyclopentadienyl sodium [see 4989-82-1] in THF, the solvent is removed and the residue is heated at 200-250° in a high vacuum. Crystalline SmCp<sub>3</sub> is stable up to 400° and sublimes at 220°/10<sup>-4</sup>mm (also 145°/10<sup>-3</sup>mm) to give orange or yellow-orange crystals that are soluble in THF and are hydrolysed in H<sub>2</sub>O. The IR is similar to that of SmCp<sub>2</sub>. [Wilkinson & Birmingham *J Am Chem Soc* **76** 6210 1954, Birmingham & Wilkinson *J Am Chem Soc* **78** 42 1956, Watt & Gillow *J Am Chem Soc* **91** 775 1969.] It is used in the selective reduction of specific double bonds, i.e. has regioselectivity [Qian et al. *J Organomet Chem* **344** 175 1988].

The **acetonitrile SmCp<sub>3</sub> complex** [100439-84-7] **M 386.7** forms bright yellow crystals soluble in MeCN, the **cyclohexylisocyanide SmCp<sub>3</sub> complex** [37299-04-0] is soluble in \*C<sub>6</sub>H<sub>6</sub> and has **m 148°**, and the **pyridine SmCp<sub>3</sub> complex** [114269-11-3] **M 424.7** is obtained as a yellow crystalline solid by dissolving it in pyridine and evaporating to dryness and is soluble in pyridine and MeCN. [Deacon et al. *Aust J Chem* **40** 895 1987.]

**Tris(d,d-dicampholymethanato) europium (III) [Eu(dcm)<sub>3</sub>]** [52351-64-1] **M 108.5, m 220-227.5°, 229-232°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +28.6° (c 5.4, CCl<sub>4</sub>, and varies markedly with concentration)**. Dissolve it in pentane, filter it from any insoluble material, evaporate to dryness and dry the residue (white powder) at 100°/0.1mm for 36 hours. Its IR has  $\nu_{\max}$  at 1540cm<sup>-1</sup>. [McCreary et al. *J Am Chem Soc* **96** 1038 1974.]

**Trisodium citrate dihydrate** [68-04-2, 6132-04-3] **M 294.1, m 150°(loses H<sub>2</sub>O)**. Crystallise the salt from warm water by cooling to 0°. [*Beilstein* **3** III 1100, **3** IV 1274.]

**Tris-[(3-trifluoromethylhydroxymethylene)-d-camphorato] europium (III) [Eu(tfc)<sub>3</sub>]** [34830-11-0] **M 893.6, m 195-299° (dec), ~220°, [ $\alpha$ ]<sub>D</sub><sup>24</sup> +152° (c 2, CCl<sub>4</sub>, and varies markedly with concentration)**. Purify it by extraction with pentane, filter and the filtrate is evaporated and the residual bright yellow amorphous powder is dried at 100°/0.1mm for 36 hours. A sample purified by fractional molecular distillation at 180-200°/0.004mm gave a liquid which solidified and softened at ~130°, melted at ~180° and was analytically pure. Its IR (CCl<sub>4</sub>) has  $\nu_{\max}$  at  $\nu_{\max}$  1630-1680 cm<sup>-1</sup> and the <sup>1</sup>H NMR (CCl<sub>4</sub>) has  $\delta$  at -1.3 to 0.5 (br), -0.08 (s), 0.41 (s), 1.6-2.3 and 3.39 (s). [McCreary et al. *J Am Chem Soc* **96** 1038 1974, Goering et al. *J Am Chem Soc* **93** 5913 1971.]

**Vanadium (III) acetylacetonate (vanadyl tris[2,4-pentadienato-O,O'], V[AcAc]<sub>3</sub>)** [13476-99-8] **M 348.3, m 181-184°, 185-190°, pK<sub>1</sub><sup>25</sup> 2.92, pK<sub>2</sub><sup>25</sup> 3.5 (for aquo V<sup>3+</sup> hydrolysis)**. It crystallises from acetylacetonate in brown plates. It can be distilled in small quantities without decomposition. It is soluble in CHCl<sub>3</sub> and \*C<sub>6</sub>H<sub>6</sub>, and evaporation of a CHCl<sub>3</sub> solution yields brown crystals which are washed with cold EtOH and dried in vacuum or at 100° in a CO<sub>2</sub> atmosphere. Under moist conditions it readily oxidises [V(AcAc)<sub>3</sub> to V(AcAc)<sub>2</sub>O]. [Fernelius & Bryant *Inorg Synth* **V** 105 1957, McKaveney & Freiser *Anal Chem* **30** 526 1958, UV: *J Am Chem Soc* **80** 5686 1958, *Beilstein* **1** IV 3672.]

**Vanadyl (IV) acetylacetonate (vanadyloxa bis[2,4-pentadienato-O,O'], VO[AcAc]<sub>2</sub>)** [3153-26-2] **M 265.2, m 256-259°**. It crystallises from acetone. [cf Fernelius & Bryant *Inorg Synth* **V** 105 1957, *Beilstein* **1** IV 3672.]

**Vinylferrocene (ferrocenylethene)** [1271-51-8] **M 212.1, m 51-52.5°, b 80-85°/0.2mm**. Dissolve vinylferrocene in Et<sub>2</sub>O, wash it with H<sub>2</sub>O and brine, dry (Na<sub>2</sub>SO<sub>4</sub>), and evaporate to a small volume. Purify it through an Al<sub>2</sub>O<sub>3</sub> (Spence grade H) column by eluting the yellow band with petroleum ether (b 40-60°). The low melting orange crystals can be sublimed. The **tetracyanoethylene adduct** [49716-63-4] crystallises from \*C<sub>6</sub>H<sub>6</sub>/pentane and has **m 137-139°(dec)**. [Horspool & Sutherland *Can J Chem* **46** 3453 1968, Berger et al. *J Org Chem* **39** 377 1974, Rauch & Siegel *J Organomet Chem* **11** 317 1968, *Beilstein* **16** III 1787.]

**Vinyltributylstannane (vinyltributyltin)** [7486-35-3] M 317.1, b 104-106°/3.5mm,  $d_4^{20}$  1.081,  $n_D^{20}$  1.4751. Fractionate the stannane under reduced pressure and taking the middle fraction to remove impurities such as (*n*-Bu)<sub>3</sub>SnCl. [Seyferth & Stone *J Am Chem Soc* **79** 515 1957, *Beilstein* **16** III 1279.]

**Xylenol Orange (sodium salt)** See entry [1611-35-4] in "Heterocyclic Compounds", Chapter 4.

**Zinc acetate dihydrate** [5970-45-6] M 219.5, m 100° (loses 2H<sub>2</sub>O), 237°,  $d_4^{20}$  1.74, pK<sup>25</sup> 8.96 (for hydrolysis of Zn<sup>2+</sup> to ZnOH<sup>+</sup>). It crystallises (in poor yield) from hot water or, better, from EtOH. [*Beilstein* **2** III 193, **2** IV 114.]

**Zinc acetylacetonate** [14024-63-6, 108503-47-5 (*x* H<sub>2</sub>O)] M 263.6, m 138°. The zinc complex crystallises from hot 95% EtOH. [Fernelius & Bryant *Inorg Synth* **V** 105 1957, Wakita et al. *J Organometal Chem* **301** C17 1986, *Beilstein* **2** IV 144.]

**Zinc caprylate (zinc *n*-hexanoate)** [557-09-5] M 351.8, m 142°. It crystallises from EtOH in plates. [Howarth *J Chem Soc* 1406 1929, *Beilstein* **2** H 284.]

**Zinc formate dihydrate** [557-41-5] M 191.4, m 140°(loses H<sub>2</sub>O),  $d_4^{20}$  2.21. It crystallises from water (3ml/g). [*Beilstein* **2** H 16, **2** I 14, **2** II 21, **2** III 25, **2** IV 17.]

**Zinc *RS*-lactate trihydrate** [554-05-2, 16039-53-5 (*L*)] M 297.5. It crystallises from water (6ml/g). [*Beilstein* **3** I 107, **3** II 204, **3** III 464, **3** IV 637.]

**Zincon** (*o*-[1-(2-hydroxy-5-sulfo)-3-phenyl-5-formazono]-benzoic acid) [135-52-4] M 459.4. Main impurities are inorganic salts which can be removed by treatment with dilute acetic acid. Organic contaminants are removed by refluxing with ether. It can be recrystallised from dilute H<sub>2</sub>SO<sub>4</sub> and complexes with Zn ions (see below). [Fichter & Schiess *Chem Ber* **33** 751 1900, *Beilstein* **16** IV 421.]

**Zincon disodium salt** (*o*-[1-(2-hydroxy-5-sulfo)-3-phenyl-5-formazono]-benzoic acid di-Na salt) [135-52-4, 56484-13-0] M 484.4, m ~250-260° (dec). Zincon solution is prepared by dissolving 0.13g of the powder in aqueous N NaOH (2ml diluted to 100ml with H<sub>2</sub>O). This gives a deep red colour which is stable for one week. It is a good reagent for zinc ions but also forms stable complexes with transition metal ions. [UV-VIS: Bush & Yoe *Anal Chem* **26** 1345 1954, Hunter & Roberts *J Chem Soc* 820 1941, Platte & Marcy *Anal Chem* **31** 1226 1959] The *free acid* (see above) has been recrystallised from dilute H<sub>2</sub>SO<sub>4</sub>. [Fichter & Scheiss *Chem Ber* **33** 751 1900, *Beilstein* **16** IV 421.]

**Zinc phthalocyanine** [14320-04-8] M 580.9. Sublime it in oxygen-free N<sub>2</sub>. [*Beilstein* **26** III/IV 4257.]

**Zinc 5,10,15,20-tetraphenylporphyrin** [14074-80-7] M 678.1,  $\lambda_{\max}$  418(556)nm. Purify the porphyrin by chromatography on neutral (Grade I) alumina, followed by recrystallisation from CH<sub>2</sub>Cl<sub>2</sub>/MeOH [Yamashita et al. *J Phys Chem* **91** 3055 1987].

**Zirconium (IV) acetylacetonate** [17501-44-9] M 487.7, m 190-193° (sealed capillary) 194.5-195°. 192-195°. The zirconium complex crystallises from hot 95% EtOH (m 190-191°) or petroleum ether and sublimes *in vacuo* at 140° with slight decomposition. The *decahydrate* effloresces in air and dehydrates in a 0.1mm vacuum. Its solubility in 1L at 20° is 30g in CS<sub>2</sub>, 47g in CCl<sub>4</sub>, 44g in ethylene dibromide, 56g in acetylacetonate and 200g in \*C<sub>6</sub>H<sub>6</sub>. [Young & Arch *Inorg Synth* **II** 122 1964, *Beilstein* **1** H 782, **1** II 835, **1** III 3121, **1** IV 3672.]

**Zirconium (IV) propoxide** [23519-77-9] M 327.6, b 198°/0.03mm, 208°/0.1mm,  $d_4^{20}$  1.06,  $n_D^{20}$  1.454. Although it was reported that it could not be crystallised or sublimed even at 150°/10<sup>-4</sup>mm [Bradley & Wardlaw *J Chem Soc* 280 1951], the propoxide, when properly prepared, has been purified by distillation in a high vacuum [Bradley et al. *J Chem Soc* 2025 1953]. [*Beilstein* **1** IV 1420.]

# CHAPTER 6

## CATALYSTS

### INTRODUCTION

Catalysts, and the process of catalysis, are almost as old as the chemical and physical sciences. Over the centuries a large number of metals and their derivatives, and a large variety of organic compounds, have been found to catalyse reactions successfully. The importance of catalysis in the sciences can be judged by the number of Nobel Prizes that have been awarded over the years for discoveries in this field of research. During the past decade much research emphasis has concentrated on combining metals with organic ligands, by complexation, in order to achieve greater metal solubility in a variety of solvents, not only for more efficient catalysis but also, by using chiral ligands, to achieve high, if not almost complete, regioselectivity and/or stereoselectivity. This is evidenced by the award of the 2001, 2005 and 2010 Nobel Prizes for Chemistry respectively for *Catalytic Asymmetric Synthesis* (to W. S. Knowles, R. Nyori and K. B. Sharpless), for *Catalytic Olefin Metathesis* (to Y. Chauvin, R. H. Grubbs and R. R. Schrock) and for *Catalytic Cross-Coupling Reactions* (to R. Heck, E-I Negishi and A. Suzuki). In addition to the many recently published reviews and monographs on various aspects of catalysis, a journal entitled *ChemCatChem* began in 2009, and is published by Wiley-VCH on behalf of ChemPubSoc Europe [www.chempubsoc.eu]. Original research papers, and reviews, on “cutting edge” discoveries in homogeneous, heterogeneous and enzymes catalysis are published particularly in this periodical, allowing proximity and cross communication in these fields of work.

Commercial suppliers of chemicals have availed themselves of this surge in new catalysts, and are now providing a large variety of recently discovered catalysts to the scientific community. The present chapter addresses a selection of these commercially available catalysts. Generally they can be used as supplied. However, some samples may have been kept for too long, or their shelf life may not be long, or they may have partially deteriorated; so knowledge about their purification, or assessment of purity is essential. Purification details have been provided for these, and in many cases published details of their preparations have also been included. Knowledge of the methods of preparation can provide information about probable impurities, and dictate the best purification procedures. Since several catalysts (and some ligands) have high and/or not well defined melting points, spectroscopic details have been included; such as IR, <sup>1</sup>H NMR, <sup>13</sup>C NMR and <sup>11</sup>B NMR, <sup>31</sup>P NMR (when these elements are present), optical properties if they are chiral, and occasionally MS.

This chapter is divided into two sections. The first section is devoted to heterogeneous and homogeneous catalysts. The second section contains ligands and reagents used for the preparation of these catalysts and of these ligands, as well as sections on phase transfer catalysts, and a section containing a small number of chiral auxiliaries. There are a number of substances mentioned in this chapter, or could possibly have been included here, but whose purifications are described in chapters 4, 5 and 7, that are not repeated here. However, they are referred to *via* their Chemical Abstracts Registry Numbers (CASRN), and their place in the book can be located from the CASRN index which gives their respective page entry.

*It should be pointed out that great care should be taken to ascertain that the catalyst is indeed the metal or reagent used, and not some trace of unsuspected contaminating metal. This point has been clearly made in the article by J.M. Crow entitled “When is a catalyst not a catalyst” (Chemistry World 8 46 2011). He draws attention to the papers of Buchwald & Bolm Angew Chem, Int Ed 48 5586 2009, Larsson et al. Angew Chem, Int Ed 48 5691 2009, Leadbeater & Marco Angew Chem, Int Ed 42 1407 2003, Arvela et al. J Org Chem 70 161 2005, and the measurement of trace impurities at the ppb (parts per billion) and/or ppt (parts per trillion) levels in Gonda, Tolnai and Novák Chem Eur J 16 11822 2010, and the possibility of co-catalysis.*

## CATALYSTS—PART 1

### HETEROGENEOUS METAL CATALYSTS

**Copper Chromite (Lazier catalyst, copper chromium oxide,  $2\text{CuO}\cdot\text{Cr}_2\text{O}_3$ )** [12053-18-8] **M 311.1**. It is also known as **Adkins catalyst** (with very slight difference in preparation). The catalyst is prepared by adding  $\text{Cu}(\text{NO}_3)_2\cdot 3\text{H}_2\text{O}$  (109g) to a warm solution of  $\text{Ba}(\text{NO}_3)_2$  (13g) in  $\text{H}_2\text{O}$  (140ml) at  $70^\circ$  and stirring until clear. Ammonium chromate solution, made by dissolving ammonium dichromate (63g) in  $\text{H}_2\text{O}$  (300ml) and adding concentrated aqueous ammonia (75ml, sp.gr. 0.90), is stirred in a thin stream into the solution of the above nitrates, stirred for 5 minutes further and the red-brown precipitate of copper barium ammonium chromate is filtered off, washed with  $\text{H}_2\text{O}$ , drained well and dried at  $110^\circ$ . The salt is placed in a suitable container and heated in a muffle furnace at  $350\text{--}450^\circ$  for 1 hour. Note that a spontaneous exothermic reaction occurs on heating with evolution of gas. The ignited blue-black residue ( $\sim 80\text{g}$ ), composed of copper and barium chromates and  $\text{CuO}$ , is pulverised thoroughly, suspended in aqueous 10%  $\text{AcOH}$  (600ml), stirred for 10 minutes, allowed to settle during 15 minutes, the supernatant is decanted, and the process is repeated. Filter off the solid, dry it at  $110^\circ$  and grind it in a mortar to give the catalyst ( $\sim 70\text{g}$ ) as a fine black powder. It is not affected by air or moisture and no special storing precautions are necessary. Other than the use of  $\text{Na}_2\text{Cr}_2\text{O}_7$  (Adkin) instead of  $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$  (Lazier), there seems to be very little difference in the preparation procedure or the activity of the catalyst [see Fieser & Fieser's *Reagents for Organic Synthesis* 2 82 1969]. Note that the inclusion of barium is for protection against sulfate which is a catalyst poison, and stabilises it against reduction. If a barium free catalyst is required, then it is omitted in the preparation and the amount of  $\text{Cu}(\text{NO}_3)_2\cdot 3\text{H}_2\text{O}$  should be increased to 121g without altering the preparation procedure. [Lazier & Arnold *Org Synth Coll Vol II* 142 1943, Adkins et al. *J Am Chem Soc* 72 2626 1950]. It is an effective catalyst for the reduction of aldehydes, ketones and esters to the corresponding alcohols, aliphatic but not aromatic double bonds, the reduction of amides to amines, and for the decarboxylation of carboxylic acids [see Fieser & Fieser *Reagents for Organic Synthesis* 1 186 1967]. These reactions however may have to be carried out in stainless steel bombs or autoclaves as several reactions require high temperatures ( $100\text{--}260^\circ$ ) and pressures (up to 5000psi).

**Nickel** [7440-02-0] **M 58.7, m 1455<sup>o</sup>, b 2730<sup>o</sup>, d<sup>25</sup> 8.90**. The catalytic use of the metal can be divided into (a) the Raney nickel type and (b) the non-Raney nickel type.

**Raney Nickel type:** This catalyst was introduced by the Raney Catalyst Division of Grace & Co and is made from a Ni-Al alloy ( $\sim 1:1$ , e.g. by fusion at  $1200\text{--}1500^\circ$ ). The catalyst is prepared by treating the alloy with alkali, which dissolves the Al, and the alkali is washed off as thoroughly as possible. The method was developed by Adkins and coworkers at the University of Wisconsin (USA) and the catalyst was designated as **W-1** to **W-6** (chronological, not activity, order) [Billica & Atkins *Org Synth Coll Vol III* 176 1955, and for comparison of Ws see Adkins & Krsek *J Am Chem Soc* 70 412 1948]. The catalyst has been used very extensively for reduction reactions, as well as for replacing sulfur by hydrogen in compounds; and there is a large volume of literature on this subject [see Fieser & Fieser's *Reagents for Organic Synthesis* 1 440, 723, 2 289, 293, 4 267, 5 263, 381, 570, 736, 6 502, 7 321, 8 433, 9 405, 10 339, 11 457, 12 175, 218, 338, 422, 13 265, 14 270, 16 278, 17 296]. The reactions normally require stirring or shaking at ambient temperatures, and pressures of  $\text{H}_2$  not greater than 100psi. A variety of equipment for this purpose is available commercially. The catalyst is essentially prepared by adding the Ni-Al alloy (150g) in small portions to aqueous sodium hydroxide (190g in 750ml of  $\text{H}_2\text{O}$ ) with stirring in an ice bath at  $10^\circ$  at such a rate that the temperature is kept below  $25^\circ$ , ca 2 hours. *n*-Octanol may be added to prevent excessive foaming. This reaction should be carried out in an efficient fume cupboard as  $\text{H}_2$  is liberated during the reaction (with the possibility of igniting), and it is preferable to use magnetic stirring to avoid sparking from an electric motor. When addition of the alloy is complete, allow the temperature of the mixture to rise to  $\sim 25^\circ$ , and then heat it gradually (avoiding frothing over) on a boiling water bath until evolution of  $\text{H}_2$  is complete (8-12 hours). Add distilled  $\text{H}_2\text{O}$  to restore the original volume, stir, allow the Ni to settle down, then decant the supernatant liquid. Transfer the Ni to a graduated cylinder with  $\text{H}_2\text{O}$ , allow it to settle, decant the supernatant liquid, add aqueous NaOH (25g, in 250ml  $\text{H}_2\text{O}$ ), shake the mixture thoroughly, allow the Ni to settle again and decant off the supernatant alkaline liquid. Wash the Ni with  $\text{H}_2\text{O}$  ( $\sim 750\text{ml}$  each time) by shaking, allow it to settle and decant the supernatant  $\text{H}_2\text{O}$ . Repeat the process until the washings are neutral to litmus and then a further 10 times. This may require 30 to 40 washings. Repeat the washing process three times with 95%

EtOH, then again three times with absolute EtOH. Store the Ni catalyst in bottles which are filled with absolute EtOH to the brim and stopper them. Keep them in a cold store room. Yield of Raney Ni is usually ~75g. The metal should be kept moist, or under liquid, at all times because the dry solid is highly **pyrophoric**. The more active the catalyst, the more readily it ignites. For this reason it is best to spoon the catalyst out from the settled material. When prepared as above it contains ~0.6g of Ni per ml of settled solid, and a level tablespoonful contains ~3g of Ni. [Mozingo *Org Synth Coll Vol III* 181 1955]. The activity of Raney Ni deteriorates slowly with time, but if prepared properly and stored as above it should be quite active for about 6 months. Its activity can be enhanced immensely by addition of a very small amount of triethylamine and chloroplatinic [Levering & Lieber *J Am Chem Soc* **71** 1515 1949]. It has been used both as a catalytic oxidation catalyst (with an appropriate donor), as well as a reduction catalyst [Kleiderer & Kornfeld *J Org Chem* **13** 455 1948].

**Non-Raney Nickel type:** This includes a catalyst of the composition Ni/Al<sub>2</sub>O<sub>3</sub> formed by treating Ni-Al alloy with H<sub>2</sub>O at 70° [Tyman *Chem & Ind* 404 1964], and the commercially available Ni on silica (with 60 wt% loading on Kieselguhr) and Ni on silica/alumina (with ~65 wt% loading). All Ni coordination compounds which have catalytic activity can come under this heading.

**Palladium** [7440-05-3] **M 106.4, m 1555°**, **b 3167°/atm**, **d<sub>4</sub><sup>20</sup> 0.951**, **electrical resistivity at 0° is μΩ-cm**. Pd is a silver-white metal which also occurs as a black powder or in a compressible spongy form. It is reactive towards HNO<sub>3</sub>, H<sub>2</sub>SO<sub>4</sub>, HCl and HClO<sub>3</sub>, particularly in the presence of air or oxygen; and forms dihalides with halogen at high temperatures. It has the capacity of adsorbing and absorbing large volumes of H<sub>2</sub>. It is extremely useful in chemical reactions as displayed in a limited way in this chapter. Apart from its extensive value in metal coordination chemistry it has out-classed many related metals in the field of catalysis. As well as its use in catalysis as the free metal in precipitated form, pellet or granular form, it has found extensive use in catalysis when diluted with C [7440-44-0], BaSO<sub>4</sub>, CaSO<sub>4</sub>, SrSO<sub>4</sub>, Kieselguhr, and Al<sub>2</sub>O<sub>3</sub> (see below). The following catalyst preparations have been used for many decades:

**Palladium on charcoal (5% Pd)**— A clear solution of PdCl<sub>2</sub> (8.2g, 46mmol) in concentrated HCl (20ml, 240mmol) and H<sub>2</sub>O (50ml), obtained by heating on a steam bath for 2 hours or until complete dissolution, is added with stirring to a suspension of charcoal (93g, HNO<sub>3</sub>—washed)<sup>†</sup> in H<sub>2</sub>O (1.2L) at 80° followed by 37% formaldehyde solution (80ml, 100mmol). The solution is made slightly alkaline to litmus (pH ~8.0) by careful addition of aqueous 30% sodium hydroxide with stirring which is continued further for 5 minutes longer. The catalyst is filtered off and washed with H<sub>2</sub>O (10 x 250ml), drained well then dried at 25°, first in air then over KOH or CaCl<sub>2</sub> in a desiccator. The dry catalyst (93-98g), which is in a reduced state is stored in a tightly closed vessel. [Do not dry at high temperatures as ignition may occur.]

<sup>†</sup> *Darco G-60, Norit or other carbons can be used and should be heated on a steam bath with 10% aqueous HNO<sub>3</sub> for 2-3 hours, washed free from acid (check pH of washings), and dried at 100-110° before use (see chapter on Aliphatic Compounds).*

A comparison of the rates of hydrogenation with 5% Pd/C, 5% Pt/C, 5% Rh/C and 5% Ru/C catalysts towards reduction of C=C, C=O, C-OH and benzene rings in various solvents at 25° and initial H<sub>2</sub> pressure of 1 atmosphere were made by Breitner, Roginski & Rylander [*J Org Chem* **24** 1855 1959.]

Note that palladised charcoal has also been used for **dehydrogenation**. e.g. tetralin is converted to naphthalene by boiling for 4 hours in the presence of Pd/C in a slow stream of CO<sub>2</sub>, and α-tetralone is dehydrogenated to naphthalene by boiling (1 hour, with internal temperature of 235°) in the presence of Pd/C and a slow stream of CO<sub>2</sub> in 75% yield.

**Palladium on charcoal (10% Pd)**— A clear solution of PdCl<sub>2</sub> (8.3g) in concentrated HCl (5.5ml) and H<sub>2</sub>O (40ml), prepared as above, is poured into a solution of NaOAc.3H<sub>2</sub>O (135g) in H<sub>2</sub>O (500ml) in a hydrogenation bottle, and charcoal (45g, HNO<sub>3</sub>—washed, see above<sup>†</sup>) is added and the mixture is hydrogenated until absorption ceases (1-2 hours). The catalyst is collected on a filter funnel, washed with H<sub>2</sub>O (5 x 400ml), drained well, dried in air and then in a desiccator over KOH or CaCl<sub>2</sub>; and the reduced catalyst (48-50g) is stored as above.

**Palladium chloride on charcoal (5% Pd)**— A clear solution of PdCl<sub>2</sub> (8.2g, 46mmol) in concentrated HCl (20ml, 240mmol) and H<sub>2</sub>O (50ml), obtained by heating on a steam bath for 2 hours or until complete dissolution, is diluted with H<sub>2</sub>O (140ml) and poured over charcoal (92g, HNO<sub>3</sub>—washed, see above<sup>†</sup>) in a 20cm evaporating dish, thoroughly mixed and dried, firstly on a steam bath and then in an oven at 100° with occasional stirring until the catalyst (98-100g) is completely dry and is then stored in a stoppered bottle until required.

When required, the desired aliquot of catalyst is transferred to a hydrogenation bottle (or flask) and reduced in the solvent used for hydrogenation by shaking with  $H_2$  in the hydrogenation apparatus. When absorption of  $H_2$  is complete, the catalyst is filtered off, washed with fresh solvent to remove HCl, returned to the hydrogenation bottle (which should have been rinsed with the same fresh solvent), the material for reduction is added and hydrogenation is carried out in the usual way.

**Palladium on barium sulfate (5% Pd)**— To a rapidly stirred hot ( $80^\circ$ ) solution of reagent grade  $Ba(OH)_2 \cdot 8H_2O$  (126.2g, 400mmol) in  $H_2O$  (1.2L), 6N  $H_2SO_4$  (120ml, 360mol) is added all at once then more 6N  $H_2SO_4$  is added to the  $BaSO_4$  suspension that is formed in order to be just acidic to litmus (pH  $\sim 5$ ). A clear solution of  $PdCl_2$  (8.2g, 46mmol) in concentrated HCl (20ml, 240mmol) and  $H_2O$  (50ml), obtained by heating on a steam bath for 2 hours or until complete dissolution, is subsequently added to the hot ( $80^\circ$ ) stirred  $BaSO_4$  suspension<sup>#</sup> followed by 37% formaldehyde solution (8ml, 100mmol). The suspension is made alkaline to litmus (pH  $\sim 8.0$ ) by careful addition of aqueous 30% sodium hydroxide with stirring, which is continued further for 5 minutes longer, and allowed to settle. The clear colourless supernatant liquid is decanted off, replaced by  $H_2O$ , resuspended, and washed ten times by decantation. The catalyst is collected on a 90mm medium porosity sintered glass funnel, drained until the filter cake begins to crack, washed again with  $H_2O$  (95 x 250ml), drained as completely as possible and placed in an oven at  $80^\circ$  until a dry catalyst (93-98g) is obtained. Store it as above. [This catalyst is particularly useful for Rosenmund catalytic reductions of acid chlorides (RCOCl) to aldehydes (RCHO), cf Hersberg & Cason *Org Synth Coll Vol III* 627 1955.]

<sup>#</sup>An equivalent weight of precipitated  $BaCO_3$  (93g) may be used instead for  $BaSO_4$ ; but the volume of concentrated HCl in preparing the  $PdCl_2$  solution should be reduced to 8.2ml (to avoid decomposition of the carbonate) to give **5% Pd on calcium carbonate** catalyst. [Mozingo *Org Synth Coll Vol III* 685 1955.]

**Note** that at the completion of hydrogenations with these catalysts, the used catalysts that are filtered off should be kept moist with solvent or  $H_2O$  as they may be **pyrophoric** when dry. Also, with the catalysts that have been prepared using the formaldehyde (HCHO) procedure, the spent catalysts from reduction reactions in which MeOH is used as solvent are particularly flammable, possible because MeOH/HCHO form an oxidation-reduction couple since there is no guarantee that the catalyst is completely free from HCHO.

Other commonly used supports for Pd include **CaCO<sub>3</sub>** [Busch & Stöve *Chem Ber* **49** 1063 1916], **SrCO<sub>3</sub>** [Martin & Robinson *J Chem Soc* 4911943], **Al<sub>2</sub>O<sub>3</sub>** [Alan C. Johnson US pat 2,366,409, *Chem Abstr* **39** 2001 1945], **Kieselguhr** [Rosenmud & Langer *Chem Ber* **56** 2262 1923, Sabalitschka & Moses *Chem Ber* **60** 786 1927], **silica-gel** [Fester & Brude *Chem Ber* **56** 2247 1923], **asbestos** [Zelinsky & Borisoff *Chem Ber* **57** 150 1924, Zelinsky & Turowa-Pollak *Chem Ber* **58** 1295 1925] and **polyvinyl alcohol** [Kavanagh & Nord *J Am Chem Soc* **66** 2126 1944].

**Platinum** [7440-06-4] **M 195.1, m 1772<sup>o</sup>, b 3827<sup>o</sup>, d<sup>20</sup> 21.45.** Platinum, when used directly or on a carbon, alumina or silica support, or *via* its oxide, is generally an excellent catalyst for the reduction of compounds. Hydrogenations using Pt catalysts are usually carried out at ambient temperatures, and atmospheric pressure of  $H_2$ , and the reaction can be followed by using a manometer and noting the absorption of gas. They may require, as in the reduction of aromatic rings to alicyclic rings, somewhat elevated pressures (a few to several atmospheres) and temperatures. Specialised equipment is used in such cases (see Ni catalysts above).

**Platinum Black:** It is obtained by reducing a solution of chloroplatinic acid [16941-12-1] with alkaline formaldehyde and shaking vigorously to coagulate the colloidal metal formed [Feulgen *Chem Ber* **54** 360 1921]. In addition to its use as a catalyst, it destroys  $H_2O_2$  in liquids or solvents by shaking them with the metal until liberation of  $O_2$  ceases [Cope & Cignek *Org Syn Coll Vol IV* 612 1963].

**Platinum Sponge:** Ammonium hexachloroplatinate is precipitated when recovered Pt residues are dissolved in *aqua regia* (see below), evaporated to dryness then dissolved in the minimum volume of  $H_2O$  and treated with saturated ammonium chloride. The  $(NH_4)_2PtCl_6$  is filtered off and dried at  $100^\circ$ . Ignition of this salt gives Pt sponge. [Wickers *J Am Chem Soc* **43** 1268 1921.]

**Brown & Brown Catalyst:** This is usually prepared *in situ* by adding a solution of  $NaBH_4$  in EtOH stabilised with NaOH to a suspension of charcoal (see palladium catalysts above) in a solution of chloroplatinic acid in EtOH (or aqueous EtOH) to form the supported catalyst. Excess HCl is added, followed by the substrate for reduction, then  $NaBH_4$  in EtOH stabilised with NaOH is added dropwise at such a rate as to maintain atmospheric pressure of  $H_2$ . Here the supported catalyst and  $H_2$  are generated *in situ* resulting in more effective reductions. [Brown et al. *J Org Chem* **28** 214 1963.]

**Platinum on support:** The catalyst is prepared from a cooled solution of the metal (5.0g, or  $\text{PtCl}_4$  or  $\text{H}_2\text{PtCl}_6$ ) in  $\text{H}_2\text{O}$  (50ml) and concentrated  $\text{HCl}$  (5ml) and support [11g, acid washed charcoal (see Pd above), neutral alumina, silica or asbestos (Gooch asbestos, termolyte not chrysolite, boil with concentrated  $\text{HNO}_3$ , filter, wash free from acid with  $\text{H}_2\text{O}$  and dry at  $100^\circ$ )] in a freezing mixture and treat with formalin (50ml, 40% formaldehyde). The mixture is then stirred while aqueous  $\text{KOH}$  (50g in 50ml of  $\text{H}_2\text{O}$ ) solution is added slowly and keeping the temperature below  $5^\circ$ . The temperature is then allowed to rise to  $60^\circ$  in 15 minutes. The catalyst is washed thoroughly with  $\text{H}_2\text{O}$  by decantation, finally with dilute  $\text{AcOH}$ , collected onto a suction filter and washed with  $\text{H}_2\text{O}$  until free from chloride ions and alkali, and drained well. Dry the solid at  $100^\circ$  and store it in a desiccator. This method gives a catalyst containing *ca* 30-40% of metal, but the amount can be adjusted by varying the ratio of metal to support. [Brown & Brown *J Am Chem Soc* **28** 2827, 2829 1962.]

A comparison of the rates of hydrogenation with 5% Pd/C, 5% Pt/C, 5% Rh/C and 5% Ru/C catalysts towards reduction of C=C, C=O, C-OH and benzene rings in various solvents at  $25^\circ$  and initial  $\text{H}_2$  pressure of 1 atmosphere were made by Breitner, Roginski & Rylander [*J Org Chem* **24** 1855 1959.]

**Platinum (IV) oxide (Adams catalyst,  $\text{PtO}_2$ )** [*1H<sub>2</sub>O* 12137-21-2; *xH<sub>2</sub>O* 52785-06-5] **M 227.1, M 245.1 (1  $\text{H}_2\text{O}$ ), m >450°.** Adams catalyst can be prepared in three ways.

**Firstly**, from ammonium hexachloroplatinate (IV) [16919-58-7] [3.0g,  $(\text{NH}_4)_2\text{PtCl}_6$ ] and  $\text{KNO}_3$  (30g, Analytical Grade;  $\text{NaNO}_3$  yields slightly less active catalyst) which are thoroughly mixed in a porcelain dish (**fume cupboard, use a head shield for protection**) and heated gently at first until the rapid evolution of gas subsides, then strongly until the temperature reaches  $300^\circ$  (15 minutes, no splattering). The liquid mass is heated further at  $500\text{-}530^\circ$  for 30 minutes and allowed to cool. Add  $\text{H}_2\text{O}$  (50ml) to the residue, stir and allow the brown platinum oxide ( $\text{PtO}_2$ ,  $\text{H}_2\text{O}$ ) to settle. Wash it once or twice with  $\text{H}_2\text{O}$  by decantation, collect it on a filter, wash it free from nitrates (stop washing if the solid starts to become colloidal#; traces of  $\text{NaNO}_3$  do not affect catalytic activity) and dry the oxide in a desiccator. Store it in small aliquots.

# If colloidal Pt filters through, it can be checked by testing a small volume of the filtrate for Pt by acidifying it with  $\text{HCl}$ , adding a few drops of stannous chloride when a yellow or brown colour results depending on the amount of Pt present. The yellow colour is soluble in  $\text{Et}_2\text{O}$  rendering the test more sensitive. If Pt is present in the filtrate then heat the filtrate with excess formalin and aqueous  $\text{NaOH}$ , cool, and the platinum black which separates is filtered off and worked up with other Pt residues. The weight of  $\text{PtO}_2$  obtained is about equal to half the weight of  $(\text{NH}_4)_2\text{PtCl}_6$ .

**Secondly**, purest possible chloroplatinic acid [3.5g,  $\text{H}_2\text{PtCl}_6$ ] in  $\text{H}_2\text{O}$  (10ml) is mixed with  $\text{KNO}_3$  (35g, Analytical Grade;  $\text{NaNO}_3$  yields slightly less active catalyst) in a porcelain dish, evaporate gently to dryness and heat at  $350\text{-}370^\circ$  for 10 minutes (use a strong heat source. **fume cupboard, use a head shield for protection**) when brown oxides of nitrogen evolve and brown  $\text{PtO}_2$  separates. Stir more vigorously if frothing occurs and direct an additional burner at the top of the mixture. [Take care not to allow the top of the mixture to solidify, e.g. by removing the burner that is underneath, otherwise frothing over occurs]. The temperature is raised to  $400^\circ$  in the following 15 minutes, after which liberation of fumes decreases considerably, and the temperature is raised further to  $500\text{-}550^\circ$  (*ca* 2 minutes); at this stage evolution of brown gases practically ceases but there is still a gentle evolution of gas. Maintain at this temperature (with burner at full heat) for 30 minutes by which time fusion is complete. Allow the container to cool slowly to  $\sim 20\text{-}25^\circ$ , add  $\text{H}_2\text{O}$  (50ml) and isolate the catalyst as above.

**Thirdly**, Pt metal and or Pt metal residues are dissolved in *aqua regia* [**prepared by adding slowly concentrated  $\text{HNO}_3$  (1 volume) to concentrated hydrochloric acid (3 volumes) in a glass container in an efficient fume cupboard and head protection**] using gentle heat if necessary, evaporate several times almost to dryness with concentrated  $\text{HCl}$ , dissolve the final residue in a small volume of  $\text{H}_2\text{O}$  and precipitate the metal as  $(\text{NH}_4)_2\text{PtCl}_6$  with saturated aqueous  $\text{NH}_4\text{Cl}$ . Filter off the precipitate, dry it at  $100^\circ$  and continue as in the first procedure (see above). [Adams et al. *Org Synth Coll Vol I* 463, 466 1941, Bruce *J Am Chem Soc* **58** 687 1936.]

Reactions catalysed by Adams catalyst can be carried out in alcoholic solution which is sometimes enhanced by the presence of  $\text{HCl}$ ; a variety of other organic solvents have been used which include  $\text{EtOAc}$ ,  $\text{EtOAc}+15\%$   $\text{AcOH}$ ,  $\text{EtOAc}+8\%$   $\text{EtOH}$ , and glacial  $\text{AcOH}$ ; and neat  $\text{CF}_3\text{CO}_2\text{H}$  is a particularly good solvent for the reduction of C=N in heterocyclic compounds.

**$\text{PtO}_2$  on silicic acid** has been prepared in much the same way as above (**fume cupboard and head protection**)

from chloroplatinic acid (7g) in H<sub>2</sub>O (25ml) and silicic acid (20g, 200 mesh) in a borosilicate beaker (100ml) which are stirred into a smooth paste and heated on a burner until desiccated. Heat to ~360° and add powdered NaNO<sub>3</sub> (70g) in portions while stirring and mixing vigorously with a glass rod (evolution of brown fumes occurs at each addition with frothing) and heat until gas evolution ceases. Add further molten NaNO<sub>3</sub> (20g) to the beaker with heating while scratching its sides. Cool, and transfer to a 2L beaker containing H<sub>2</sub>O (1.5L), stir for 2 hours, allow to settle, decant the supernatant and collect on a medium porosity sintered glass funnel. Wash the solid well with H<sub>2</sub>O, then with 95% EtOH (2 x) and Et<sub>2</sub>O, dry it in air for 1 hour then in a vacuum desiccator (P<sub>2</sub>O<sub>5</sub>). The dry powder is then pulverised in a mortar and sieved (200 mesh) until all the solid has passed through (use a Camel's-hair brush to help the solid through) to give the catalyst as a light brown powder (21.0g) containing ~0.14g of Pt per gram of solid. Store it in screw capped vials. It can be exposed to light and air without loss of activity. It gives very reproducible hydrogenation results and has been used analytically for the estimation of reducible groups [Vandenheuevel *Anal Chem* **28** 362 1956.]; and for the hydrogenation of methyl esters in EtOH without causing trans-esterification [Ackman & Brugher *J Lipid Res* **5** 130 1964].

**Other applications:** Prior to the development of catalysts in which Pt is coordinated to a plethora of ligands in order to achieve particular specificities (e.g. Pt with phosphine ligands below), some specificities were obtained by manipulating the metal. Examples include a **platinum-tin chloride** catalyst made from **H<sub>2</sub>PtCl<sub>6</sub> and SnCl<sub>2</sub>** for specific reduction of olefins [Cramer et al. *J Am Chem Soc* **85** 1691 1963], **PtO<sub>2</sub>/Pt black+FeCl<sub>2</sub>/Zn(OAc)<sub>2</sub>** for reduction of unsaturated aldehydes to unsaturated alcohols, e.g. cinnamaldehyde to cinnamyl alcohol [Tulley & Adams *J Am Chem Soc* **47** 3061 1925], and **PtS<sub>2</sub>/C** which is less active than the oxide but is insensitive to poisons (e.g. sulfur compounds) and will reduce a nitro group without affecting halogen substituents, e.g. chloronitrobenzenes to chloroanilines [Dovell & Greenfield *J Am Chem Soc* **87** 2767 1965].

**Rhenium metal (Re) used in preparing the following catalysts has [7440-15-5] M 186.2, m 3180°, b 5596°, d<sup>20</sup> 21.02.**

**Rhenium(II) oxide (ReO.2H<sub>2</sub>O) [12143-03-2] M 238.2.** This catalyst is prepared in a fume cupboard by the reduction of ammonium perrhenate with either Na/liqNH<sub>3</sub>, Li/liqNH<sub>3</sub>, or Li/EtNH<sub>2</sub> which give consistently ReO.2H<sub>2</sub>O. In dried apparatus used typically for Na/liqNH<sub>3</sub> reduction, liquid NH<sub>3</sub> or EtNH<sub>2</sub> (50-75ml) and NH<sub>4</sub>ReO<sub>4</sub> (1-2g, weighed) are stirred in a dry atmosphere until the salt dissolves; then Na or Li (15-30g) are added in chunks as rapidly as possible. The colourless solution becomes typically blue-black and is stirred until the colour disappears (15 minutes to 2 hours). The NH<sub>3</sub> or EtNH<sub>2</sub> are allowed to evaporate while the total volume is kept constant by addition of EtOH. The residue is transferred to a fritted glass thimble in a Soxhlet apparatus and extracted with dilute HCl (~2N) for 24 hours (the pot acquiring a brown colour), then with EtOH for an equal time. When the brown acid extract, that decolorises aqueous KMnO<sub>4</sub>, is basified with aqueous NH<sub>4</sub>OH black ReO.2H<sub>2</sub>O precipitates, and the supernatant now does not decolorise aqueous KMnO<sub>4</sub>. The solid is collected, washed with cold EtOH, and dried at 100° *in vacuo* over P<sub>2</sub>O<sub>5</sub> (conditions under which it is stable and does not dehydrate) to provide the hydrated oxide (75-85%) as a very finely divided black powder. Note that any solid left in the thimble has the same composition as this oxide. It is stored as a suspension in EtOH which tends to settle rather readily, or as a suspension in distilled H<sub>2</sub>O which requires more than 24 hours to settle out completely. Aliquots of suspensions (with or without evaporating to dryness) are used as the heterogeneous catalyst. The amount of rhenium can be determined as described by Broadbent and Selin [*J Org Chem* **28** 2343 1963]. ReO.2H<sub>2</sub>O catalyses the hydrogenation of a wide variety of organic substrates in high yields with unusual selectivity, being particularly efficient for carboxylic acids. Hydrogenations are carried out in a rocking Parr reactor under pressures of ~200 atmospheres and temperatures varying from ~20° to ~200°, and reduction times from 0.5 to ~10 hours. The catalyst prepared by the Li/liqNH<sub>3</sub> method is only marginally better than by the other methods. [Broadbent & Seegmiller *J Org Chem* **28** 2347 1963.]

**Rhenium(III) oxide (Re<sub>2</sub>O<sub>3</sub>) [12060-05-8] M 420.5.** Re<sub>2</sub>O<sub>3</sub> is prepared from a mixture of ammonium perrhenate (2.04g, 160mmol, NH<sub>4</sub>ReO<sub>4</sub>), a solution of 8N NH<sub>4</sub>Ac (20ml, 160mmol) and glacial AcOH (2ml, 35mmol) in H<sub>2</sub>O (100ml) in an ice-water bath to which is added dropwise, with vigorous stirring, an ice-cold solution of NaBH<sub>4</sub> (3.4g, 90mmol) in H<sub>2</sub>O (100ml) over a 1 hour period. After half of the NaBH<sub>4</sub> solution is added, a further amount of AcOH (2ml, 35mmol) is added in one lot. Stirring is continued for 15 minutes and the solution is centrifuged at full speed in an ultracentrifuge, the supernatant is decanted off, the oxide is washed

twice by suspension in H<sub>2</sub>O and finally re-suspended in H<sub>2</sub>O, and stored as such before use. The fine solid remains in suspension for 12-24 hours. Analysis indicated that reduction was ~85% complete giving a yield of 70-90% (~1.35g). The activity is checked by its ability to effect hydrogenation of styrene at room temperature in 6-10 hours. It catalyses a range of substrates including aliphatic olefins, maleic acid, benzene, nitrobenzene, bromonitrobenzene, naphthalene, pyridine, ketones and nitriles mostly in yields approaching 100% with (e.g. H<sub>2</sub>O or EtOH), and without solvents. Typically the substrate (0.2mol, with or without solvent) and catalyst (0.2g of Re) in a 420ml rocking Parr bomb under hydrogen pressures up to 3000psi (204 atmospheres) are heated (40-50° increments) until the pressure starts to drop. Reductions occur in the temperature range of 25-250°. [Broadbent & Johnson *J Org Chem* **27** 4400 1962.]

**Rhenium(IV) oxide (ReO<sub>2</sub>·2.5H<sub>2</sub>O)** [12036-09-8] **M 218.2**. When a vigorously stirred mixture of a solution of ammonium perrhenate (1.2g) in H<sub>2</sub>O (150ml) and an excess of granular zinc (5-10g, previously treated with a little dilute acid, to remove any surface oxide, and washed thoroughly to clean the surface) is treated dropwise over a period of several hours with 3N H<sub>2</sub>SO<sub>4</sub> (64ml) at such a rate that black finely divided rhenium oxide is suspended into the solution which is periodically decanted from the zinc; the oxide is centrifuged off, the supernatant is returned to the reaction flask and addition of acid is resumed. The acid should not be added rapidly as the finely divided rhenium oxide coats the zinc and slows (or prevents) further reaction, and does not produce a Zn-free product. At the end of the reaction all the rhenium oxide residues from centrifugation are combined, washed with H<sub>2</sub>O by decantation until the washings are free from sulfate. Conversion from perrhenate to rhenium (IV) oxide is >60%, and nearer 100% if an excess of Zn is maintained in the reaction by further addition of the metal. ReO<sub>2</sub>·2.5H<sub>2</sub>O analyses as a hydrate, is very stable, resists dehydration at 95° *in vacuo* over P<sub>2</sub>O<sub>5</sub>, and loses H<sub>2</sub>O only very slowly at 250°; however when the hydrated oxide is heated at 250° in \*C<sub>6</sub>H<sub>6</sub> under hydrogenation conditions anhydrous ReO<sub>2</sub> can be isolated from the experiment. It exists in two crystallographic forms: the α-form is obtained when synthesised below 300° (Re + 2ReO<sub>3</sub> = 3ReO<sub>2</sub>), and is irreversibly transformed into the orthorhombic β-form which is obtained when synthesised above 300° [Rogers et al. *Inorg Synth* **XIII** 142-145 1972, Rogers et al. *Inorg Synth* **XXX** 102 1995].

ReO<sub>2</sub>·2.5H<sub>2</sub>O has catalytic activity for the hydrogenation of a variety of organic substrates, and although generally less active than Nickel or palladium catalysts (i.e. requires higher temperatures and/or pressures), it is however much more effective than these for the reduction of the carboxylic acid function. It has a potentially valuable selectivity, and very few other elements exhibit this characteristic to such a degree. [Broadbent & Selin *J Org Chem* **28** 2343 1963.]

**Rhenium(VI) oxide (ReO<sub>3</sub>)** [1314-28-9] **M 234.2, b 750°, d<sup>20</sup> 6.9-7.4**. ReO<sub>3</sub> is prepared from the heptoxide (1.0g, see below) by adding it directly to *p*-dioxane (10-25ml) or tetrahydrofuran and warming gently to produce a colourless to dark green solution, and the excess solvent is removed *in vacuo* to give a sticky, tarry, black complex. The complex decomposes when carefully heated to *ca* 145° to give gaseous products and a pure, red, crystalline residue of ReO<sub>3</sub> (84-95%yield). This is finely ground and stored dry in a screw-cap vial. It forms non-hygroscopic, red/maroon-coloured crystals (with a green luster) which are air stable below 100°, and disproportionates in a vacuum to rhenium(IV) and rhenium(VII) oxides at 400°. It is inert to H<sub>2</sub>O, dilute alkali, and is thus more convenient to handle and store than the hygroscopic heptoxide which also has high catalytic activity. Analysis showed it to have the formula of the anhydrous oxide ReO<sub>3</sub>. It is oxidised by HNO<sub>3</sub> to HReO<sub>4</sub>. It has catalytic activity when used as such or when prepared *in situ* by using Re<sub>2</sub>O<sub>7</sub> and allowing it to be reduced to ReO<sub>3</sub> during the hydrogenation process. This oxide, when used directly or prepared *in situ*, is the most effective hydrogenation catalyst of all the Re catalysts. It is very efficient in reducing carboxylic and carboxamide groups without reducing the aromatic ring, with the latter producing amines. Benzoic acid, ethyl benzoate, benzaldehyde, and *m*-nitrobenzaldehyde are reduced to the respective carbinols without hydrogenolysis to the toluenes as in most catalytic hydrogenations. Like the preceding rhenium oxide catalysts hydrogenations are carried out in shaking Parr-Bomb reactors under pressures of *ca* 200 atmospheres and temperatures ranging from ~100° to ~200° depending on when the substrates begin to absorb H<sub>2</sub> at a reasonable rate. [Broadbent & Bartley *J Org Chem* **28** 2345 1963, Nechamkin & Hiskey *Inorg Synth* **III** 186 1950.] It is also obtained in quant-

itative yield from  $\text{Re}_2\text{O}_7$  (purified by sublimation) in a CO atmosphere by heating at  $175^\circ$  until the oxide is blue, the temperature is raised slowly to  $225^\circ$ , then increased to  $280^\circ$  after the colour of the oxide has turned to red [Melaven et al. *Inorg Synth* **III** 187 1950].

**Rhenium(VII) oxide (rhenium heptoxide  $\text{Re}_2\text{O}_7$ )** [1314-68-7] **M 484.4, m 300.3°, b 360.3°, d<sup>20</sup> 6.103.**

Dirhenium heptoxide is prepared by heating the metal or its lower oxides in a stream of oxygen or air at  $400^\circ$  to  $425^\circ$ . It forms canary-yellow crystals which are as deliquescent as  $\text{P}_2\text{O}_5$ , and sublimates at  $250^\circ/760\text{mm}$  and melts at  $297^\circ$  in a sealed tube [Ogawa *Bull Chem Soc Jpn* **7** 265 1932]. Great care should be taken to avoid moisture during handling and storage. It is very soluble in  $\text{H}_2\text{O}$  to form perrhenic acid  $\text{HReO}_4$ . It is also soluble in most organic solvents such as ethers, esters, alcohols, dioxane and pyridine. [Melaven et al. *Inorg Synth* **III** 188 1950.] Reduction of  $\text{Re}_2\text{O}_7$  during hydrogenation reactions generates rhenium “blacks” which mainly consist of  $\text{ReO}_3$  and is among the best catalyst for reducing a variety of carboxylic acids to alcohols (at  $\sim 160^\circ/\text{ca}$  200 atmospheres/few hours) in very good yields. The alcohols are occasionally accompanied with esters; unreduced acids rarely survive, amides are reduced to the respective amines and the usual functional groups that are reduced by Ni and Pt catalysts are also reduced with this rhenium catalyst. [Broadbent et al. *J Org Chem* **24** 1847 1959.] It is a precursor for organorhenium oxides which catalyse olefin oxidation, metathesis and other transformations. It is a *Lewis-acidic metal oxide* which forms adducts of the formula  $\text{Re}_2\text{O}_7 \cdot n\text{L}$  with a variety of O, N and S ligands such as 1,2-dimethoxyethane, 4,4'-di-*tert*-butyl-2,2'-bipyridine, and 1,4,7-trithiacyclononane respectively [Herrmann et al. *Inorg Chem* **34** 4701 1995].

**Rhenium(VII) sulfide (rhenium heptasulfide,  $\text{Re}_2\text{S}_7$ )** [12038-67-4] **M 596.9.** The heptasulfide is obtained by bubbling  $\text{H}_2\text{S}$  through a 3% solution of potassium perrhenate in 5-6 N HCl maintained at the boiling point until precipitation is complete. The suspension is allowed to stand overnight, then it is filtered through a sintered glass funnel, the solid is washed with 1:4 aqueous HCl,  $\text{H}_2\text{O}$ , dried for several days in a desiccator over  $\text{CaCl}_2$ , powdered in a mortar and stored in a common screw capped vial. The catalyst is not adversely affected by occasional exposure to air, is prepared with high catalytic reproducibility, is insoluble in concentrated non-oxidising acids, is stable under all the conditions of hydrogenation used (1000-3600psi/ $25^\circ$  to  $335^\circ/0.5$  to 3 hours), and is not reduced to form  $\text{H}_2\text{S}$ . It is remarkably resistant to “poisoning”. It catalyses the reduction of a variety of organic substrates in high yields including sulfides, with desulfurisation [e.g. diphenylsulfide to benzene (94%), and thiophenol to a mixture of benzene (60%) and cyclohexane (40%)]; and without desulfurisation [e.g. allyl phenyl sulfide to propyl phenyl sulfide (100%), and of thiophene to thiophane (70%)]. [Broadbent et al. *J Am Chem Soc* **76** 1519 1954.] When the heptasulfide is heated for 16 hours at  $350\text{-}400^\circ$  in a tube furnace under a stream of  $\text{CO}_2$  to blow out sulfur vapours, and cooled in a desiccator, it gives **rhenium disulfide** [12038-63-0]. The catalytic activity of  $\text{ReS}_2$  parallels that of  $\text{Re}_2\text{S}_7$  but to a lesser extent, and is more active than related molybdenum or cobalt catalysts. [Broadbent et al. *J Am Chem Soc* **76** 1519 1954.]

**Rhodium metal (Rh) used in preparing the following catalysts has** [[7440-16-6] **M 102.9, m 1966°, b 3727°, d<sup>20</sup> 12.41**].

**Rhodium on alumina (5% Rh loading).**  $\text{Rh-Al}_2\text{O}_3$  has been used as a general catalyst for the complete reduction of the aromatic ring in phenols, e.g. gallic acid to *cis*-3,4,5-trihydroxycyclohexane carboxylic acid [Burgstahler & Bithos *Org Synth* **42** 62 1962] requiring high pressures (2200psi) and temperatures ( $\sim 100^\circ$ ) for 8-12 hours [see also Smith & Stump *J Am Chem Soc* **83** 2739 1961, Kaye & Matthews *J Org Chem* **28** 324 1963], the hydrogenation of 1-naphthol to *cis*-1-hydroxydecalin [6psi,  $25^\circ$ , 12 hours; Meyers et al. *J Org Chem* **29** 3427 1964], resorcinol gives cyclohexane-1,3-dione [50psi,  $25^\circ$ , 16-18 hours; Sircar & Meyers *J Org Chem* **30** 3206 1965], D-mandelic acid gives pure D-hexahydromandelic acid but L-mandelic acid gives ( $\pm$ )-hexahydromandelic acid [3-4 atmospheres,  $25^\circ$ , 1.5 hours, AcOH is mandatory; Stocker *J Org Chem* **27** 2288 1962], reduction of vinylic and allylic double bonds [500psi,  $100^\circ$ , 15 minutes; Ham & Coker *J Org Chem* **29** 194 1964], reduction of oximes or aliphatic nitriles to primary amines [1-2 atmospheres,  $\sim 25^\circ$ , 1-2 hours; Freifelder et al. *J Org Chem* **27** 2209 1962, Freifelder *J Am Chem Soc* **82** 2386 1960], hydrogenolysis of ketals to the corresponding dialkyl ethers [Howard & Brown *J Org Chem* **26** 1026 1961], hydrogenation of heterocyclic compounds e.g. 1,2,3,4-tetrahydroisoquinoline-3-carboxylic acid to *cis*-decahydroisoquinoline-3-carboxylic acid [40psi,  $\sim 25^\circ$ , 3 hours;

Rapala et al. *J Am Chem Soc* **79** 3770 1957], nicotinic acid to hexahydronicotinic (nipecotinic) acid without decarboxylation [2 atmospheres, ~25°, 4 hours; Freifelder *J Org Chem* **27** 4046 1962, Freifelder *J Org Chem* **28** 602, 1135 1963], complete hydrogenation of quinoxaline [Broadbent et al. *J Am Chem Soc* **82** 189 1960], reduction of the 4,5-double bond of pyrimidine nucleosides and nucleotides [Cohn & Doherty *J Am Chem Soc* **78** 2863 1956], dehydrogenation e.g. hydrogen transfer from hexahydrohexahelicene to benzene in order to provide hexahelicene and cyclohexane in 73% yield [Newman & Lednicer *J Am Chem Soc* **78** 4765 1956, cf also Anderson & Anderson *J Org Chem* **22** 1197 1957], and hydrogenation of anilines to cyclohexylamine with little hydrogenolysis [Freifelder et al. *J Org Chem* **30** 2485 1965].

**Rhodium on carbon (5% and 10% Rh loading).** A 10%-Rh, 0.1%Pd on carbon catalyst has been prepared from a mixture of  $\text{RhCl}_3 \cdot 3\text{H}_2\text{O}$  (5.26g),  $\text{PdCl}_2$  (0.34g) and carbon (18g, e.g. Darco G-60, or any acid washed charcoal can be used) in  $\text{H}_2\text{O}$  (200ml) is rapidly stirred and heated to 80°. Lithium hydroxide hydrate (2.7g) dissolved in  $\text{H}_2\text{O}$  (10ml) is added in one lot and heating is stopped but the mixture is stirred overnight, filtered, and washed with 0.5% v/v aqueous AcOH (100ml) then dried *in vacuo* at 65° to give 20.6-21g of catalyst. One gram of this catalyst will absorb 0.0022-0.0028 mole of  $\text{H}_2$  in aqueous suspension. It has been used, for example, in the reduction of *p*-aminobenzoic acid to a mixture of *cis*- and *trans*- 4-aminocyclohexanecarboxylic acid [at 50psi/~25°/~24 hours] which was converted to 2-azabicyclo[2.2.2]octan-3-one (3-isoquinuclidone) in 81-84% yield. *The point was made that when fresh catalyst is added to the reaction vessel, it should be moistened with the solvent; and that hydrogen should be removed by evacuation at the end of the reduction in order to avoid having a hydrogen-air atmosphere which could be explosive.* [Pearlman *Org Synth Coll Vol V* 670 1973, Pearlman *Tetrahedron Lett* 1663 1967.] It is a useful catalyst (even without the trace of Pd) for the reduction of nitriles to primary amines, and the hydrogenation of aromatic and pyridine rings, aldehydes and sugars. It is superior to  $\text{Rh-Al}_2\text{O}_3$  for reduction of the pyridine ring and larger amounts of catalyst have to be added to overcome the poisoning effect of the piperidine products [Freifelder et al. *J Org Chem* **27** 284 1962]. It is useful for the stepwise reduction of 3-*H*-pyrrolizine to 3,4-dihydropyrrolizine, and then to the fully reduced pyrrolizidine [Schweizer & Light *J Am Chem Soc* **86** 2963 1964]; and in boiling norbornadiene complete conversion to a mixture of dimers and trimers occurs [Mrowca & Katz *J Am Chem Soc* **88** 4012 1966]. A comparison of the rates of hydrogenation with 5% Pd/C, 5%Pt/C, 5% Rh/C and 5% Ru/C catalysts towards reduction of C=C, C=O, C-OH and benzene rings in various solvents at 25° and initial  $\text{H}_2$  pressure of 1 atmosphere were made by Breitner, Roginski & Rylander [*J Org Chem* **24** 1855 1959].

**Ruthenium (1,5-Cyclooctadiene)(1,3,5-cyclooctatetraene) [Ru(cod)(cot)]** [127382-91-6] **M 315.4, m 88-94°, 92-94°.** For preparation see Chapter 5, Metal-Organic Compounds. Purify the ruthenium complex (~ 0.3g) by dissolving it in *n*-pentane (~ 70ml) and filtering the solution through a column of alumina (Merck, Brockman activity II—III, 20cm). Collect the yellow band and reduce its volume to ~ 5ml then cool it at -70°, preferably under  $\text{N}_2$  or Ar. After ~ 6 hours collect the yellow solid (~ 0.2g) and dry it *in vacuo*. Recrystallisation from *n*-pentane results in a 75-85% recovery. [Itoh et al. *J Organomet Chem* **272** 179 1984, Petrici et al. *J Chem Soc, Dalton Trans* 1961 1980]. It is a highly selective catalyst for amine alkylations in which, unlike other ruthenium catalysts, alkylates the amino group of e.g., 2-, 3-, or 4- aminopyridines as well as 2-aminopyrimidine to give the respective monoethylamino derivatives by using EtOH in high yields with very little, if any, of diethylamino derivatives. Thus it stops almost exclusively at monoalkylation. [Watanabe et al. *J Org Chem* **61** 4214 1996]. It also catalyses the dimerisation of 2,5-norbornadiene *via* [2+2] cycloaddition reactions and eyne generation in the presence of dimethylfumarate in THF at 40° for 1 hour to form the “cup-shaped” molecule pentacyclo[6.6.0.0<sup>2,6</sup>.0<sup>3,13</sup>.0<sup>10,14</sup>]tetradeca-4,11-diene in 96% yield. An alicyclic compound which would otherwise require many steps to synthesis. [Mitsudo et al. *J Am Chem Soc* **121** 1839 1999.]

**Ruthenium metal (Ru) used in preparing the following catalysts has** [7440-18-8] **M 101.1, m 2310°, b 3900°, d<sup>20</sup> 12.5].**

**Ruthenium-aluminium oxide/hydroxide catalyst (~2.5wt% Ru loading).** The preparation of this catalyst is described in Chapter 8 because it consists of Ru(0) nanoparticles encapsulated in an aluminium oxy-hydroxide

matrix and is superior as a catalyst to the commercially available material. It is a recyclable catalyst for the efficient oxidant-free alcohol dehydrogenation (compare with  $\text{RuCl}_3 \cdot 3\text{H}_2\text{O}$  or  $x\text{H}_2\text{O}$  above) of a wide range of alcohols including benzylic alcohols, secondary long chain fatty alcohols, secondary allylic alcohols, 3-pyridylmethanol, 2-thiophenylmethanol and 4-methylthiobenzyl alcohol in dry toluene to the respective carbonyl compounds under argon at dehydrogenation temperatures of  $80^\circ$  to  $110^\circ$ , using 3-6 mol% of Ru, in yields of  $>90\%$ . It is 5 times superior to the commercial  $\text{Ru}/\text{Al}_2\text{O}_3$  catalyst and is re-usable, after washing with  $\text{Me}_2\text{CO}$  and drying in air, at least 10 times without loss of activity. [Kim, Park and Park *Org Lett* **8** 2543 2006.]

**Ruthenium on alumina (5% Ru reduced loading).**  $\text{Ru}/\text{Al}_2\text{O}_3$  can be freshly prepared by treating alumina powder with a ruthenium compound, e.g.  $\text{RuCl}_3 \cdot x\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ ,  $\text{Ru}(\text{acac})_3$  or  $\text{Ru}_3(\text{CO})_{12}$  in \*benzene (to give a solid that is  $\sim 5\text{wt}\%$  in Ru), followed by evaporating the solvent and reducing the solid in a stream of  $\text{H}_2$  at  $500^\circ$ . This catalyst will oxidise dibenzothiophene or dibenzothiophene oxide (Ru molar ratio 11:1) in \* $\text{C}_6\text{H}_6$  to dibenzothiophene sulfone at  $100^\circ$  in air (70 atmospheres) for 12 hours in 97% yield. Slow poisoning of Ru occurs during the oxidation. The activity of the catalyst depends on the preparation, but is much more active than the following catalysts in the sequence  $\text{Ru}_3(\text{CO})_{12} > \text{Ru}(\text{acac})_3 > \text{RuCl}_3 \cdot x\text{H}_2\text{O}$ .  $\text{Ru}/\text{C}$  or  $\text{Ru}/\text{SiO}_2$ , and the commercially available  $\text{Ru}/\text{Al}_2\text{O}_3$  are less active than the above preparation.  $\text{Pt}/\text{Al}_2\text{O}_3$  or  $\text{Ir}/\text{Al}_2\text{O}_3$  gives only a trace of the sulfone, and  $\text{Pd}/\text{Al}_2\text{O}_3$ ,  $\text{Rh}/\text{Al}_2\text{O}_3$ ,  $\text{Os}/\text{Al}_2\text{O}_3$  or  $\text{Cu}/\text{Al}_2\text{O}_3$  are totally inactive. It should be noted that with this catalyst oxidation of  $n\text{-Bu}_2\text{S}$  (0.2M in \* $\text{C}_6\text{H}_6$ ; in the ratio of Ru/sulfide 21:1) provides 44 and 9% molar yields of  $n\text{-Bu}_2\text{SO}$  and  $n\text{-Bu}_2\text{SO}_2$  respectively, with full recovery of unreacted  $n\text{-Bu}_2\text{S}$ . [Ledlie & Howell *Tetrahedron Lett* 785 1976.]

**Ruthenium on carbon (5% Ru loading).** A comparison of the rates of hydrogenation with 5%  $\text{Pd}/\text{C}$ , 5%  $\text{Pt}/\text{C}$ , 5%  $\text{Rh}/\text{C}$  and 5%  $\text{Ru}/\text{C}$  catalysts towards reduction of  $\text{C}=\text{C}$ ,  $\text{C}=\text{O}$ ,  $\text{C}-\text{OH}$  and benzene rings in various solvents at  $25^\circ$  and initial  $\text{H}_2$  pressure of 1 atmosphere were made by Breitner, Roginski & Rylander [*J Org Chem* **24** 1855 1959.]  $\text{Ru}/\text{C}$  is a superior catalyst than  $\text{Pd}/\text{C}$  and  $\text{Pt}/\text{C}$  for the hydrogenation of ketones in basic and neutral media and in some cases (e.g. tetramethylcyclobutan-1,3-dione at 1000-1500psi of  $\text{H}_2/125^\circ/1$  hour)  $>90\%$  yields of diols were obtained [Hseck et al. *J Org Chem* **27** 700 1961],  $\text{C}=\text{C}$  (with some selectivity), and acetylenes were reduced to alkanes [Berkowitz & Rylander *J Org Chem* **24** 708 1959], nitrobenzene was reduced to hydrazobenzene in alcoholic  $\text{KOH}$  in 80% yield without over-reduction to aniline [Peitra & Res *Ann Chim (Rome)* **48** 299 1958], and 10%  $\text{Ru}/\text{C}$  was better than other catalysts for reducing phenolic rings in polycyclic compounds [Walton et al. *J Am Chem Soc* **78** 4760 1956].

**Ruthenium(IV) oxide ( $\text{RuO}_2$ )** [12036-10-1] **M 133.1,  $d^{25}$  6.97.** The dioxide is prepared by heating Ru metal in a silica boat in a silica combustion tube placed horizontally in a furnace, and a slow stream of dry oxygen is allowed to flow over it while it is being heated at  $1000^\circ$  for 24 hours. During heating a little of the oxide volatilises and small crystals may condense on the walls at the downstream end of the tube. A 90-95% yield of polycrystalline  $\text{RuO}_2$  remains in the boat. It forms tetragonal dark blue crystals which are insoluble in organic solvents,  $\text{H}_2\text{O}$  and acids but soluble in fused alkali. [Schäfer & Heitland *Z Anorg Allgem Chem* **304** 249 1960, Schäfer et al. *Z Anorg Allgem Chem* **319** 327 1963, Rogers et al. *Inorg Synth* **XIII** 137 1972, **XXX** 96 1995.] It is a good catalyst, no doubt by being converted to the metal *in situ* which promotes catalysis. It has been used for the reduction of aromatic rings to cyclohexane rings [e.g. at 1350psi/147°/16 hours, or 70psi/90°/1 hour; Freifelder & Stone *J Am Chem Soc* **80** 5270 1958, Freifelder & Stone *J Org Chem* **26** 3805 1961, Freifelder & Stone *J Org Chem* **27** 3568 1962, Johnson et al. *J Am Chem Soc* **84** 2181 1962], and phenolic compounds to the respective cyclohexanols [Rapala & Farkas *J Org Chem* **23** 1404 1958, Counsel *Tetrahedron* **15** 202 1961, Ireland & Schiess *J Org Chem* **28** 6 1963]; but with some enones only the double bond was reduced without affecting the carbonyl function [Rapala & Farkas *J Am Chem Soc* **80** 1008 1958].

## HOMOGENEOUS METAL CATALYSTS

**Allylpalladium(II) chloride dimer {di- $\mu$ -chloro- $\eta^3$ -allylpalladium(II),  $[\text{Pd}(\eta^3\text{-C}_3\text{H}_5)\text{Cl}]_2$ }** [12012-95-2] **M 365.9, m 155-156°(dec.),  $\sim 160^\circ$ (dec.).** It is prepared from allyl chloride,  $\text{PdCl}_2$ , and  $\text{NaCl}$  in the presence of carbon monoxide and is extracted into  $\text{CHCl}_3$ , washed with  $\text{H}_2\text{O}$ , dried ( $\text{CaCl}_2$ ), filtered and evaporated to

dryness to give the complex as yellow crystals (use a very efficient fume cupboard). These can be used as such, but by recrystallisation from a mixture of  $\text{CH}_2\text{Cl}_2$  and hexane analytically pure catalyst can be obtained (**m 155-156° dec.**). It also crystallises from benzene and is soluble in MeOH,  $\text{Et}_2\text{O}$ ,  $\text{Me}_2\text{CO}$  and  $\text{CHCl}_3$ . The  $^1\text{H}$  NMR ( $\text{CDCl}_3$ ) has two doublets at  $\delta_{\text{H}}$  3.03 (anti  $\text{CH}_2$ ,  $J = 12.0\text{Hz}$ ) and 4.10 (syn  $\text{CH}_2$ ,  $J = 7.1\text{Hz}$ ), and a triplet at  $\delta_{\text{H}}$  5.48 (CH) 2:2:1. [Tatsuno et al. *Inorg Synth* **28** 342 1990, Shaw *Proc Chem Soc* 247 1960, Hüttel et al. *Chem Ber* **94** 766 1961, Dent et al. *J Chem Soc* 1585 1964.]

It is a labile Pd complex, but is very useful for preparing a variety of stable catalytic Pd(0) complexes with a wide selection of ligands to perform stereoselective reactions. A particularly useful ligand is *cis,cis,cis*-1,2,3,4-tetrakis(diphenylphosphinomethyl)cyclopentane [Tedicyp] [Laurenti et al. *J Org Chem* **66** 1633 2001]. The catalyst with this ligand is typically prepared under argon, in a Schlenk type system, by dissolving  $[\text{Pd}(\eta^3\text{-C}_3\text{H}_5)\text{Cl}]_2$  (4.2mg, 11.6 $\mu\text{mol}$ ) and Tedicyp (20mg, 23.2 $\mu\text{mol}$ , see [333380-86-2] in Part 2) in dry tetrahydrofuran (10ml) and stirring for 10 minutes before use. It gives a solution of 2.32 $\mu\text{mol}/\text{ml}$  of catalyst, which has  $^{31}\text{P}$  NMR (162MHz,  $\text{CDCl}_3$ ) with  $\delta$  at 25 (vbrs, width 80Hz), 19.4 (vbrs, width 110Hz). It is very efficient in catalysing allylic substitutions with high turnover numbers (up to 9,800,000) and frequencies (up to 190,000  $\text{h}^{-1}$ ).

$[\text{Pd}(\eta^3\text{-C}_3\text{H}_5)\text{Cl}]_2$  is used for cross-coupling reactions [Wallow & Novak *J Org Chem* **59** 5034 1994], the Heck reactions with olefins [Fall et al. *Synthesis* 1683 2007] and enol ethers [Battace et al. *Eur J Org Chem* 3122 2007], and the formation of ethyl cyclopropane carboxylates with ethyl diazoacetate and olefins [Armstrong *J Org Chem* **31** 618 1966] to name a few.

**Bis(acetonitrile)dichloropalladium(II)  $[\text{Pd(II)Cl}_2(\text{MeCN})_2$  complex]** [14592-56-4] **M 259.4, dec > 200°.** It is prepared by mixing anhydrous  $\text{PdCl}_2$  (1mol) and MeCN (2mols) until clear and precipitating the complex with petroleum ether. *Alternatively*, MeCN (3ml) is added to a solution of  $\text{K}_2\text{PdCl}_4$  (2g) in  $\text{H}_2\text{O}$  (40ml) and stirred at  $\sim 25^\circ$  until separation of yellow prisms is complete (could take up to 8 days). Filter these off, wash them with  $\text{H}_2\text{O}$ , EtOH,  $\text{Et}_2\text{O}$ , and dry them *in vacuo*. Further purification, if necessary, can be achieved by dissolving it in anhydrous solvents (which are not likely to displace the ligands) such as MeOH, toluene, THF, precipitating it with light petroleum, and drying the solid *in vacuo*. It is also soluble in  $^*\text{C}_6\text{H}_6$  to the extent of 100mg/4.0ml. In addition to its use as a source of metal for palladium complexes and catalysts such as  $\text{PdCl}_2(\text{R})\text{-BINAP}$  [115826-95-4] (see Ozawa et al. *Organometallics* **12** 4188 1993), it also catalyses Overman rearrangements (aza-Claisen rearrangement, Overman & Garpenher *Org React* **66** 1 2005, see below). A particularly interesting example of the rearrangement being the high diastereoselectivity which is directed by a  $\delta$ -methoxymethylether group in  $\delta$ -substituted allylic trichloroacetamides, where the ether oxygen atoms coordinate with Pd to direct the orientation of the reaction [Jamieson & Sutherland *Tetrahedron* **63** 2123 2007]. The IR spectrum shows, from the RCN and M-X vibrations, that the MeCN groups have a *trans*-planar configuration, unlike related Pt complexes which have the *cis*-configuration. The IR (Nujol) has  $\nu_{\text{max}}$  at 1417m, 1358m,  $\sim 1160\text{wbr}$ , 1030m, 970wbr  $\text{cm}^{-1}$  [Walton *Spectrochim Acta* **21** 1795 1965].

**Bis(benzonitrile)dichloropalladium(II)  $[\text{Pd(II)Cl}_2(\text{PhCN})_2$  complex]** [14220-64-5] **M 383.6, m 131°.** It is prepared and purified in the same manner as the  $\text{Pd(II)Cl}_2(\text{MeCN})_2$  complex above. *Alternatively*, anhydrous  $\text{PdCl}_2$  (2g) suspended in benzonitrile (50ml) is stirred at  $100^\circ$ . Most of the  $\text{PdCl}_2$  dissolves after 20 minutes to give a red solution which is filtered while hot, and the hot filtrate is poured slowly into petroleum ether (b 40-60°). The light yellow complex which crystallises out is collected, washed with petroleum ether and dried *in vacuo* (4.0g, 93%). It can be purified further by dissolving it in the minimum volume of  $^*\text{C}_6\text{H}_6$ , and the hot red solution is filtered and diluted with petroleum ether to allow the complex to crystallise out. [Doyle, Slade and Jonassen *Inorg Synth* **VI** 218 1960, Kharasch et al. *J Am Chem Soc* **60** 882 1938.]  $\text{Pd(II)Cl}_2(\text{PhCN})_2$  is an effective catalyst for the regiospecific cycloaddition cross-coupling reactions of aziridines with carbodiimides to form imidazolidin-2-imines in 40-94% yields [Baeg & Aler *J Org Chem* **57** 157 1992]. In the presence of a Buchwald ligand (e.g. 2-di-*t*-butyl-2'4'6'-tri-*i*-propylbiphenyl) in  $\text{CH}_2\text{Cl}_2$ , it catalyses the stereoselective formation of  $\alpha$ -*O*-glycosides from protected glycalimides with a variety of phenols or protected glycosides in high yields at room temperature [Schuff, Mercer and Nguyen *Org Lett* **9** 3174 2007]. Also, in the presence of Xantphos {4,5-bis(diphenylphospheno)-9,9-dimethylxanthene, see [161265-03-8]}, it promotes Stille-type cross coupling reactions between alkynyl- $\text{SnBu}_3$  and  $\alpha$ -halo esters or amides under neutral conditions in THF to provide 3-alkynoates or alkynoamides in high yields without homocoupling of the alkynyltin reagents [Shi et al.

*Chem Commun* 2342 2007]. The IR spectrum shows, from the RCN and M-X vibrations, that the PhCN groups have a *trans*-planar configuration, unlike related Pt complexes which have the *cis*-configuration. The IR (Nujol) has  $\nu_{\max}$  at 3096w, 3057w, 3033w, 3002vwm 2287s, 1480m-w, 1440s, 760s, 678s  $\text{cm}^{-1}$  [Walton *Spectrochim Acta* **21** 1795 1965].

**Bis(cyclopentadienyl)cobalt(II) (cobaltocene,  $\text{C}_5\text{H}_5\text{CoC}_5\text{H}_5$ ,  $\text{Cp}_2\text{Co}$ )** [1277-43-6] **M 189.1, m 173-174° (under  $\text{N}_2$ ), 176-180°(dec)**.  $\text{Cp}_2\text{Co}$  is prepared by adding anhydrous  $\text{CoCl}_2$  (0.5 mol, prepared by dehydrating the salt at 200° in a vacuum) to a cold solution of 1 mol of sodium cyclopentadienide [4984-82-1] in THF (see below), stirring for 2 hours, removing the solvent and subliming the product directly from the mixture at 150-200°/10<sup>-4</sup> mm in 75-80% yields; or by using  $\text{CoBr}_2$  and refluxing for 3 hours. *Alternatively* (method of Wi et al. *J Inorg Nucl Chem* **2** 110 1956), cyclopentadiene (42ml, 0.5mol) and  $\text{Et}_2\text{NH}$  (~100ml, 1mol) are added slowly to  $\text{CoBr}_2$  (0.25mol) with cooling, and then stirring at ~25° for 6-8 hours; the solvent is removed *in vacuo* and the residue is extracted with petroleum ether, filtered, and the solvent is evaporated to give dark violet monoclinic crystals m 171-173°.

When anhydrous *cobalticenium chloride* (5g, prepared from sodiocyclopentadienide and anhydrous  $\text{CoCl}_2$  in THF as above but stirring at the boiling point for 2 hours, evaporating the solvent and adding 1:1 hydrochloric acid) in dry 1,2-dimethoxyethane (150ml) is treated with excess of  $\text{NaBH}_4$  (5g, or LAH) in small portions while stirring ( $\text{H}_2$  is evolved), then warm to 60°, or add  $\text{H}_2\text{O}$  (2ml), the mixture becomes deep wine-red in colour. After 1 hour the solution is filtered, the solid is washed with  $\text{Et}_2\text{O}$  and the filtrate is evaporated to a few mls *in vacuo*, diluted with petroleum ether (b ~40-60°), concentrated again and applied on to an alumina column (20 x 2cm). The first red band that elutes with petroleum ether is evaporated, and the residue is sublimed *in vacuo* onto a cold finger at -70° to give wine-red crystals of  $\pi$ -cyclopentadienyl(cyclopentadiene)cobalt [ $\pi$ - $\text{C}_5\text{H}_5\text{CoC}_5\text{H}_6$ ] (yield 80%) with **m 98-99°**, has **M 193** (ebulioscopic in  $\text{C}_6\text{H}_6$ ), and a UV with  $\lambda_{\max}$  nm( $\epsilon$ ) at 263.8 (1.78 x 10<sup>5</sup>), 327 (9.27 x 10<sup>3</sup>), and 395 (5.27 x 10<sup>3</sup>). It has a camphorous odour and should be kept under argon as it is stable in air for only a few minutes, but for a few hours in degassed solutions of organic solvents. [Green et al. *J Chem Soc* 3753 1959.]

**Sodium cyclopentadienide** [4984-82-1] is prepared under  $\text{N}_2$  by slowly adding cyclopentadiene (37ml) to a cooled suspension of sodium (10g) in THF (150ml) when  $\text{H}_2$  evolves rapidly and a solution of sodium cyclopentadienide is formed. The colour of the solution depends on the purity of the solvent and the amount of air in the system. Clear pale orange or red solutions are obtained with good conditions, but dark red to purple colours are obtained in the presence of traces of air without, however, seriously decreasing the yields of the complexes formed. [Wilkinson et al. *J Inorg Nucl Chem* **2** 95 1956, Reynolds & Wilkinson *J Nuclear Chem* **9** 86 1959, *Beilstein* **16** IV 1698.] It is available commercially as a 2.0M solution in THF as sodium cyclopentadienylide. The dry solid is **pyrophoric**.

$\text{Cp}_2\text{Co}$  catalyses the condensation of acetylene and mono-substituted acetylenes (but not di-substituted acetylenes) with nitriles at 150° to give 30-70% yields of substituted pyridines [Wakatsuki & Yamazaki *Synthesis* **26** 1976]. This synthesis has been applied successfully in a 2+2+2 cycloaddition reaction between di(trimethylsilyl)propargyl ether and acetonitrile to prepare a pyridine intermediate which was used to obtain pyridoxine (vitamin B<sub>6</sub>) [Greiger et al. *Helv Chim Acta* **67** 1274 1984].

*The above are general procedures for preparing* **Bis(cyclopentadienyl)chromium (II) [ $\text{Cp}_2\text{Cr}$ ]** [1271-24-5] **M 182.2, m 168-170°** [*Beilstein* **16** IV 1774, Wilkinson et al. *J Inorg Nucl Chem* **2** 95 1956.], **Bis(cyclopentadienyl)magnesium(II) [ $\text{Cp}_2\text{Mg}$ ]** [1284-72-6] **M 154.5, m 176-178°, 180°(dec)** [*Beilstein* **16** IV 1695, Wilkinson et al. *J Inorg Nucl Chem* **2** 95 1956, Barber *J Inorg Nucl Chem* **4** 373 1957], and **Bis(cyclopentadienyl)vanadium(II) [ $\text{Cp}_2\text{V}$ ]** [1277-47-0] **M 181.1, m 165-167°** [*Beilstein* **16** IV 1771]. [Wilkinson et al. *J Inorg Nucl Chem* **2** 95 1956.]

**Bis(dibenzylideneacetone)palladium(0) [ $\text{Pd}(\text{dba})_2$ ]** [32005-36-0] **M 575.0**. The precise nature of this complex is not clear but a product with reproducible stoichiometry [ $\text{C}_{34}\text{H}_{28}\text{O}_2\text{Pd}$ ] is prepared first by stirring  $\text{PdCl}_2$  (8.87g, 50mmol) and  $\text{NaCl}$  (2.92g, 50mmol) in MeOH (250ml) at 25° for 16 hours, filtering through a cotton wool plug, diluting the filtrate to ~1.5L with MeOH, and heating to 60° to form  $\text{Na}_2[\text{PdCl}_6]$ . Dibenzylideneacetone (36.5g, 150mmol, see [538-58-9], cf Organic Compounds in Chapter 4) is then added to this warm solution stirred solution of  $\text{Na}_2[\text{PdCl}_6]$ , and stirring for a further 15 minutes and anhydrous  $\text{NaOAc}$  (75g) is added. The reaction begins immediately, heating is stopped but stirring is continued until the reaction

cools to room temperature. The dark brown precipitate that is formed is washed with MeOH (2 x 25ml), H<sub>2</sub>O (5 x 50ml), Me<sub>2</sub>CO (5 x 15ml) and dried in air to constant weight (923g, 80% yield) [Rettig & Maitlis *Inorg Synth* **17** 134 1977]. See the related complex **Pd(dm-dba)<sub>2</sub>** below for the structure of these complexes in CDCl<sub>3</sub> solution. Catalysis with these complexes occurs at room temperature in the presence the ligand DIPHOS [dpe, 1,2-bis-[diphenylphospheno]ethane (see [1663-45-2] in Metal-Organic Compounds in Chapter 5) which is more efficient than with the less stable Pd(PPh<sub>3</sub>)<sub>4</sub>. It is used for the synthesis of allylic substituted cyclopentadienes [Fiaud & Mallerson *Tetrahedron Lett* **21** 4437 1980] and is a homogeneous catalyst [Fiaud & Mallerson *Tetrahedron Lett* **22** 1399 1981, Black *Aldrichimica Acta* **15** 13 1982] which catalyses the alkylation of a variety of nucleophiles under mild conditions [Ferroud et al. *Tetrahedron Lett* **25** 4379 1984.] Together with cyclic thiourea ligands such as *1N,3N*-bis(1,4-di-*tert*-butylphen-2-yl)imidazoline-2-thione, it catalyses efficient aerobic oxidations of alcohols to aldehydes and ketones in toluene in yields >95% [Yang et al. *Synlett* 3057 2006.]

**Bis(3,5,3',5'-dimethoxybenzylideneacetone)palladium(0)** {**bis[1,3-bis(3',5'-methoxybenzylidene)acetone palladium(0), [Pd(dm-dba)<sub>2</sub>]**} [811862-77-8] **M 815.2, m 170-178°**. This Pd catalyst with the dimethoxy-dba ligand is prepared and purified as for Pd(dba)<sub>2</sub> above but using 1,5-bis(3',5'-dimethoxyphenyl)penta-1*E*,4*E*-diene-3-one (dm-dba, [39777-58-7]),\* instead of dba. *Alternatively*, Fairland's method can be used, whereby NaCl (3.3g, 56mmol) is added to PdCl<sub>2</sub> (5g, 28mmol) in MeOH (140ml) and stirred under argon at 25° for 24 hours, filtered and evaporated *in vacuo* to half its volume. To this solution at 60° is added dm-dba (20.6g, 88mmol), stirred at 60° for 15 minutes, anhydrous NaOAc (42.3g) is added and allowed to cool to 25°. The mixture is stirred at 25° for 2 hours as the dark red precipitate of the complex separates. The solid is collected, washed with MeOH (2 x 100ml), H<sub>2</sub>O (2 x 100ml) then Me<sub>2</sub>CO (2 x 20ml), partially dried by suction, placed in a Schlenk flask and stirred under a flow of N<sub>2</sub> overnight to give the complex as a maroon/purple microcrystalline solid (11g 68%). It was found to have higher activity than those of the complex with the unsubstituted ligand [i.e. Pd(dba)<sub>2</sub>] in Suzuki-Miyaura cross-coupling reactions of organic halides with arylboronic acids. *Note* that a solution of the complex, as in the case of Pd(dba)<sub>2</sub> above, in CDCl<sub>3</sub>, was found to contain one dm-dba ligand coordinated to Pd and one free in solution. Addition of two equivalents of Ph<sub>3</sub>P to the complex in THF and (CD<sub>3</sub>)<sub>2</sub>CO resulted in the formation of the  $\eta^2$ -(dm-dba)Pd<sup>(0)</sup>(Ph<sub>3</sub>P)<sub>2</sub> complex as shown by the presence of two phosphorous doublets in the <sup>31</sup>P NMR spectrum. [Fairlamb et al. *Org Lett* **6** 4435 2004, cf *Handbook of Organopalladium for Organic Synthesis* Negishi ed. Wiley, Hoboken NJ 2002, ISBN 0-471-31506-0.] For **Pd<sub>2</sub>(p,p'-dimethoxy-dba)<sub>3</sub>** see **Pd<sub>2</sub>(dba)<sub>3</sub>**(CDCl<sub>3</sub>) below.

**Bis(di-*tert*-butyl(4-dimethylaminophenyl)phosphine)dichloropalladium(II)** [(A-<sup>ta</sup>Phos)<sub>2</sub>PdCl<sub>2</sub>] [887919-35-9] **M 708.1**. The catalyst is prepared by mixing one equivalent of di-*tert*-butylphosphine, 1 equivalent of 4-dimethylaminophenyl bromide and 1 mol% of Pd<sub>2</sub>dba<sub>3</sub> at 90° for 12 hours. The mixture is cooled to 25°, filtered through a short silica gel plug, the plug is rinsed with toluene and the combined filtrate is evaporated under vacuum. The residue is dissolved in tetrahydrofuran and 0.35 equivalents of solid PdCl<sub>2</sub>(COD) are added followed by stirring at 25° for 12 hours. The product is filtered off, and the yellow solid collected is washed with pentane and dried *in vacuo* to give ~85% yield of (A-<sup>ta</sup>Phos)<sub>2</sub>PdCl<sub>2</sub> which provides the correct microanalysis for C and H. It has <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>) with  $\delta$  at 7.5 (s br, 4 H, ArH), 6.42 (d, *J* = 8.3Hz, 4H, ArH), 2.75 (s, 12H, NMe<sub>2</sub>), 1.38 (t, *J*<sub>PH</sub> = 6.6Hz, 36H, *tert*-Bu); and <sup>31</sup>P NMR (CDCl<sub>3</sub>) with  $\delta$  at 52.1. Similarly **bis[di-*tert*-butyl(*p*-trifluoromethylphenyl)phosphine)dichloropalladium(II)** can be prepared which has <sup>1</sup>H NMR (CDCl<sub>3</sub>) with  $\delta$  at 8.0 (s br, 4 H, ArH), 7.59 (d, *J* = 7.9Hz, 4H, ArH), 1.62 (t, *J*<sub>PH</sub> = 7.0Hz, 36H, *tert*-Bu); <sup>31</sup>P NMR (CDCl<sub>3</sub>) with  $\delta$  at 55.7; and <sup>19</sup>F NMR (CDCl<sub>3</sub>) with  $\delta$  at -63.4. Also **bis[di-*tert*-butyl(phenyl)phosphine)dichloro-palladium (II)** was prepared in the same way and has <sup>1</sup>H NMR (CDCl<sub>3</sub>) with  $\delta$  at 7.9-7.8 (m, 4 H, ArH), 7.36-7.30 (m, 6H, ArH), 1.56 (t, *J*<sub>PH</sub> = 6.9Hz, 36H, *tert*-Bu); <sup>31</sup>P NMR (CDCl<sub>3</sub>) with  $\delta$  at 54.4. These are air-stable active catalysts for Suzuki-Miyaura cross-coupling with aryl halides including 5- and 6-membered heteroaryl halides in the presence of bases such as K<sub>2</sub>CO<sub>3</sub>, Na<sub>2</sub>CO<sub>3</sub>, KOAc, K<sub>3</sub>PO<sub>4</sub> with high turn over numbers (TON) of 100 to 100,000 [Guram et al. *Org Lett* **8** 1787 2006].

**2-[Bis(2,4-di-*tert*-butylphenoxy)phosphinoxy]-3,5-di(*tert*-butyl)phenyl-palladium(II) chloride dimer {Bedford's Catalyst, 2[bis(2,4-di-*tert*-butylphenoxy)phosphino-κP-oxy]-3,5-di-*tert*-butylphenyl-κC]di-μ-chloro-dipalladium}** [217189-40-7] **M 1575.6**. The thoroughly characterised Bedford catalyst, an *ortho*-metallated dimer, is prepared in 96% yield from the bulky tris(2,4-di-*tert*-butylphenyl)phosphite and PdCl<sub>2</sub>. The catalyst is remarkably stable to moisture and air, showing no signs of deterioration after several weeks, can be kept in air for at least 6 months and is not decomposed on heating at 130° in toluene for 24 hours. It is very efficient for coupling aryl halides with either arylboronic acids (Suzuki reaction) or aryltin compounds (Stille reaction) in solvents such as toluene or tetrahydrofuran to form biaryls with very high turn over numbers (TONs up to 1,000,000 moles of product/mol of Pd) at even very low Pd catalyst concentrations, and in moderate to high yields [Albisson et al. *J Chem Soc, Chem Commun* 2095 1998]. Bedford's catalyst also proved to be extremely active in the arylation (with e.g. aryl bromides) of alkenes (e.g. acrylate, styrene) with turn over numbers of up to 5,750,000 (mole product/mol Pd), and turn over frequencies of 300,000 (mol product/mol Pd/hour) [Albisson et al. *Tetrahedron Lett* **39** 9793 1998].

***R,R*-(+) and *S,S*-(-) *N,N'*-Bis(3,5-di-*tert*-butylsalicylidene)-1,2-*trans*-cyclohexanediamine Manganese(III) Chloride [Jacobsen's catalyst] [*R,R*-138124-32-0, *S,S*-135620-04-1]** **M 635.2, m 330-332°, 324-326°, [α]<sub>D</sub><sup>20</sup> ±580° (c 0.01, EtOH)**. This complex is commonly referred to as the Mn(salen) catalyst. If this enantioselective catalyst for the epoxidation of olefins requires purification, the brown powder (*ca* 6g) is dissolved in CH<sub>2</sub>Cl<sub>2</sub> (100ml), extracted with H<sub>2</sub>O (2 x 100ml), the organic phase is dried (Na<sub>2</sub>SO<sub>4</sub>), filtered, evaporated to dryness and the solid residue is dried in a vacuum desiccator over CaSO<sub>4</sub>. [Jacobsen et al. *J Am Chem Soc* **113** 7063 1991]. For large scale preparation see Larrow et al. *J Org Chem* **59** 1939 1994, Deng & Jacobsen *J Org Chem* **57** 4320 1992. For epoxidation of indenenes see Hughes et al. *J Org Chem* **62** 2222 1997, and for the epoxidation of isoflavones see Adams et al. *Tetrahedron: Asymmetry* **9** 1121 1998, Chang et al. *Tetrahedron* **58** 6939 1993, Jacobsen et al. *Tetrahedron* **50** 4323 1994, Jacobsen's Asymmetric Catalytic Epoxidation of Unfunctionalized Olefins in *Catalytic Asymmetric Synthesis Vol I*, p. 159, Ojima Ed. VCH, NY 1993 (see also Bibliography in Part 2), and for enantioselective hydrolysis of epoxides see Furrow et al. *J Org Chem* **63** 6776 1998.

On a large scale, the brown *R,R*-(+)- catalyst (300-400g) is washed with hot H<sub>2</sub>O (2 x 800ml, at 50°), and dried on the filter for 2 hours then under vacuum (50-100mm) at 60-70° for 12 hours, m 324-326° (product of acceptable purity has m ~320°), [α]<sub>D</sub><sup>23</sup> +580° (c 0.01, EtOH), and IR with ν<sub>max</sub> (KBr) at 1535, 1612, 2950-2958 cm<sup>-1</sup>. [Larrow et al. *J Org Chem* **59** 1939 1994.]

The related chiral complexes of Al(II)-Cl [*R,R* 250611-13-3; *S,S* 307926-51-8], of Cr(III)-Cl [*R,R* 164931-83-3; *S,S* 219143-92-7] and of the Co(III)-Cl [*R,R*-(+) 176762-62-5; *S,S*-(-) 188264-84-8] (Tokunaga et al. *Science* **277** 936 1977, Jacobsen et al. *Tetrahedron Lett* **38** 733 1997) are similarly prepared and are available commercially.

NOTE: It was shown that addition of pyridine *N*-oxides, and particularly 4-(3-phenylpropyl)pyridine-1-oxide (P<sub>3</sub>NO, see [34122-28-6] in Part 2), stabilise and improve the catalytic activity of Mn(salen) catalysts [Larrow & Jacobsen *J Am Chem Soc* **116** 12129 1994, Srinivan et al. *J Am Chem Soc* **108** 2309 1986, Senanayake *Aldrichimica Acta* **31** 3 1998.] Thus in a typical epoxidation MnLCl (0.56mmol, salen Mn catalyst) and P<sub>3</sub>NO (2.32mmol) in chlorobenzene (10ml) are added to a 2M solution of NaOCl (26.5mmol) cooled to 0° under N<sub>2</sub>, and stirred at 0° for 15 minutes, followed by simultaneous addition of indene (10ml) and further NaOCl (79.5mmol) (syringe pumps) during 30 minutes. The reaction is complete within 1 hour at 0°, and can be performed on a multi-kilogram scale to provide indene epoxide in 89% yield and with an optical purity of 88% e.e. [Senanayake et al. *Tetrahedron Lett* **37** 3271 1996.]

A **dimeric Jacobsen ligand**, formed by linking two units with a methylene bridge has been prepared and crystallised from CH<sub>2</sub>Cl<sub>2</sub>/pentane. Its **bis-Mn catalyst** exhibited improved retention in a poly-dimethylsiloxane membrane for the asymmetric epoxidation of olefines [Janssen et al. *Tetrahedron: Asymmetry* **8** 3481 1997].

**[(*R*)-(+)-2,2'-Bis(diphenylphosphino)-1,1'-binaphthyl]palladium(II) dichloride ([*R*-BINAP]<sub>2</sub>PdCl<sub>2</sub>)** [115826-95-4] **M 800.0, m 255-260° (dec), [α]<sub>D</sub><sup>24</sup> +682° (c 0.5, CHCl<sub>3</sub>)**. This catalyst is prepared by dissolving a mixture of *R*-BINAP (500mg, 0.803mmol, see [76189-55-4]), η-allyl-η-cyclopentadienyl-Pd(II) (84.2mg, 0.396mmol, see [1271-03-0]), *cf* Tatsuno et al. *Inorg Synth* **19** 220 1979) in \*C<sub>6</sub>H<sub>6</sub> (5ml), in a Schlenk tube

under  $N_2$  (dried over  $P_2O_5$ ), and heated at  $80^\circ$  for 3 hours to give a deep red solution which is then evaporated to dryness. The red solid is then dissolved in  $CH_2Cl_2$  (10ml), filtered and the filtrate is evaporated *in vacuo* down to ca 4ml, diluted with  $Et_2O$  (40ml) and cooled to  $4^\circ$  whereby red-purple crystals of  $[R-BINAP]_2Pd(0)$  separate, which on washing with cold  $Et_2O$  and drying *in vacuo* give analytically pure  $[R-BINAP]_2Pd(0)-Et_2O$  (480mg, 90%). The 1:1 ratio of  $Et_2O$  to Pd is confirmed by  $^1H$  NMR spectroscopy. It has  $^1H$  NMR (90MHz,  $*C_6D_6$ , TMS) with  $\delta_H$  at 5.88 (t,  $J = 7.6Hz$ , 8H), 6.19 (t,  $J = 7.3Hz$ , 4H), 6.8-7.6 (m, 40H), 7.83 (d,  $J = 8.2Hz$ , 4H), 8.36 (brs, 8H); and the  $^{31}P\{^1H\}$  NMR (36MHz,  $*C_6D_6$ , referenced to external 85%  $H_3PO_4$  at  $\delta$  0.0) has  $\delta_P$  at 27.3. This Pd(0) complex catalyses asymmetric arylation in the Heck reaction.  $[R-BINAP]_2PdCl_2$  is obtained by stirring *R*-BINAP (249mg, 0.40mmol) in  $*C_6H_6$  (4.0ml) with  $PdCl_2(MeCN)_2$  (104mg, 0.40mmol) in  $*C_6H_6$  (4.0ml) overnight. The yellow precipitate is collected by filtration, washed with  $*C_6H_6$  and dried *in vacuo*. It is crystallised by dissolving in  $Me_2CO$ , layering with hexane and setting aside at  $\sim 25^\circ$  to give red crystals of  $[R-BINAP]_2PdCl_2$  (238mg, 75%, m 255-260 $^\circ$ ) of analytical purity, and suitable for X-ray crystallographic structure determination which confirmed its structure. [Ozawa et al. *Organometallics* **12** 4188 1993, cf review by Shimizu, Nagasaki & Saito *Tetrahedron* **61** 5405 2005].

**Bis(trifluoromethanesulfonyl)amine metal salts  $[NTf_2]$ , bis-(trifluoromethanesulfonyl)amide metal salts,  $(CF_3SO_2)_2N$ Metal** see [82113-65-3].  $NTf_2$  readily forms salts, e.g. with Li, Ba, Ca, Al, Zn, Al and lanthanides, which act as *Lewis Acids* in effectively catalysing Diels-Alder reactions [Kobayashi et al. *Chem Lett* 307 1995, Handy et al. *Synlett* 565 1995] and acylation reactions [Mikami et al. *Synlett* 171 1996]. It forms an *N*-trimethylsilyl derivative (TMSNTf<sub>2</sub> prepared from allylTMS and  $NTf_2$ , see above) which catalyses Diels-Alder reactions between methyl acrylate and various dienes [Mathieu & Ghosez *Tetrahedron Lett* **38** 5497 1997], as well as Friedel-Crafts acylation reactions of anisole, and allylation and bis-allylation of carbonyl derivatives [Oshii et al. *Synlett* 1145 1997].  $NTf_2$  is a weakly coordinating counter ion which confers stability to catalytic metal complexes such as the gold catalyst  $[Ph_3PAu(I)]^+ [NTf_2]^-$ , see [866395-16-6].

***R*(-)- and *S*(+)- 4,12-Bis(diphenylphosphino)-[2.2]-paracyclophane {*R*- and *S*- PHANEPhos, (*R*)- and (*S*)-5,11-bis(phenylphosphino)-tricyclo[8.2.2.2<sup>4,7</sup>]hexadeca-hexaene}** [*R*] 364732-88-7; [*S*] 192463-40-4] **M** 576.6, **m** 222-226 $^\circ$ , 224-276 $^\circ$ ,  $[\alpha]_D^{25}$  *R* -34 $^\circ$ , *S* +34 $^\circ$  (c 1,  $CHCl_3$ ). These are chiral ligands for the rhodium precatalysts  $(COD)Rh\{(R)-[2.2]PHANEPhos\}^+ OTf^-$  and  $(COD)Rh\{(S)-[2.2]PHANEPhos\}^+ OTf^-$  (see preparation and purification below) which are highly enantioselective in the hydrogenation of dehydroamino acid methyl esters generally, and also of methyl 1-Ac-4-Boc-1,4,5,6-tetrahydropyrazine-1-carboxylate which is difficult to reduce. When they are pre-reduced in MeOH, they form  $(MeOH)_2Rh\{(R)-[2.2]PHANEPhos\}^+ OTf^-$  whose activity is more pronounced and reduction is complete in less than 60 minutes by passing  $H_2$  gas through the MeOH solution at temperatures between  $-45^\circ$  to  $+50^\circ$ , with high substrate to catalyst ratios. The preparations of these ligands (described briefly here for convenience) involve di-bromination of *p*-cyclophane, separation of the *meso*- from the *racemic*-isomers (latter are more soluble in triglyme), reaction of the *rac*-isomer (1 equivalent) with *tert*-BuLi (4.2 equivalents), and  $MgBr_2 \cdot Et_2O$  (2.3 equivalents) in THF then diphenylphosphinyl chloride ( $Ph_2POCl$ , 2.2 equivalents) to give *rac*-4,12-bis(diphenylphosphinyl)-[2.2]-paracyclophane (76% yield). Optical resolution of this racemate (in  $CHCl_3$ ) with (+)-dibenzoyl-D-tartaric acid (in EtOAc) at  $60^\circ$ , then cooling to  $\sim 25^\circ$  over 18 hours, gave a white precipitate from which the *R*(-)-enantiomer (>99.5% ee) is isolated. The absolute configuration was obtained from the X-ray crystallographic structure determination of the *R*-dibenzoyl-D-tartrate salt (for definition of the chiral descriptor notation see R.S. Chan, C.K. Ingold and V. Prelog *Angew Chem Int Edn Engl* **5** 385 1966). From the mother liquors the *S*(+)-enantiomer (>99.5% ee) was isolated by washing the diastereomeric tartrate salt (in  $CHCl_3$ ) with 0.5M aqueous NaOH. They are white solids which are separated by SFC (supercritical fluid chromatography using a 25cm Hewlett Packard Chiracel AD column with 15% MeOH/supercritical  $CO_2$  at 1.0ml/minute) with retention times of 13.0 minutes for the *R*-isomer and 17.8 minutes for the *S*-isomer, and they have  $[\alpha]_D^{25}$  -104 $^\circ$  and  $[\alpha]_D^{25}$  +104 $^\circ$  (c 0.1, EtOH) respectively. When *R*-4,12-bis(diphenylphosphinyl)-[2.2]-paracyclophane (4.0g, 6.58mmol) is treated with  $Cl_3SiH$  (10ml, 99mmol, 10025-78-2) in *p*-xylene (80ml), and slowly heated to  $140^\circ$ , kept at this temperature for 18 hours, a further aliquot of  $Cl_3SiH$  (5ml, 49.5mmol) is added, and heating is continued for 24

hours, the reduction appears complete. The mixture is then cooled to  $-10^{\circ}$ , quenched with 30% aqueous NaOH (60ml, care violent reaction), extracted with EtOAc (3 x 80ml), the extract is dried ( $\text{MgSO}_4$ ), filtered and evaporated to dryness. Degassed MeOH (30ml, by sonication) is added to the residue which is filtered and dried to give the pure diphosphino *R*-[2.2]PHANEPhos as a white solid. It has  $^1\text{H}$  NMR (400MHz,  $\text{CDCl}_3$ , with residual  $\text{CHCl}_3$  as reference at  $\delta$  7.27) with  $\delta_{\text{H}}$  at 7.54, (m, 2H), 7.45 (m, 3H), 7.41 (m, 2H), 7.24 (m, 3H), 6.62 (*ortho and meta*, 2H), 6.58 (dd,  $J = 7.6$  and  $5.0\text{Hz}$ , 1H), 3.13 (m, 1H), 3.03 (*ortho and meta*, 2H), 2.65 (m, 1H); and  $^{13}\text{C}$  NMR (100MHz,  $\text{CDCl}_3$ , with residual  $\text{CHCl}_3$  as reference at  $\delta$  77.0) with  $\delta_{\text{C}}$  at 143.2 (d,  $J = 16.1\text{Hz}$ ), 139.6 (d,  $J = 11.2\text{Hz}$ ), 139.2 ( $J = 2.4\text{Hz}$ ), 137.4 (d,  $J = 12.0\text{Hz}$ ), 137.2 (d,  $J = 10.4\text{Hz}$ ), 135.8 (d,  $J = 22.5\text{Hz}$ ), 134.3 (d,  $J = 4.0\text{Hz}$ ), 133.3 (t,  $J = 4.0\text{Hz}$ ), 132.9 (d,  $J = 20.1\text{Hz}$ ), 132.7, 129.4, 128.44, 128.39 (d,  $J = 8.8\text{Hz}$ ), 128.2 (d,  $J = 8.0\text{Hz}$ ), 35.8, 33.2; and  $^{31}\text{P}$  NMR (160MHz,  $\text{CDCl}_3$ , referenced to external 85%  $\text{H}_3\text{PO}_4$  at  $\delta$  0.0) with  $\delta_{\text{P}}$  at  $-0.53$ . The enantiomeric *S*-[2.2]PHANEPhos is similarly obtained.

$\text{Rh}(\text{COD})\{(\text{R})\text{-[2.2]PHANEPhos}\}^+ \text{OTf}^-$  is prepared using Schlenk equipment under  $\text{N}_2$  from the red solution of *R*-[2.2]PHANEPhos (630mg, 1.09mmol) and  $[(\text{Rh COD})_2]^+ \text{OTf}^-$  (512mg, 1.09mmol, see 12092-47-6 for chloride), in  $\text{CH}_2\text{Cl}_2$  (10ml) which is stirred for 30 minutes, evaporated *in vacuo*, MeO-*t*-Bu (10ml) is added to the residue, sonicated for 30 minutes, stirred vigorously for 30 minutes, filtered and the solid is dried under  $\text{N}_2$  to give the orange *R*- precatalyst (860mg, 85%). It has  $^1\text{H}$  NMR (400MHz,  $\text{CDCl}_3$ , with residual  $\text{CHCl}_3$  as reference at  $\delta$  7.27) with  $\delta_{\text{H}}$  at 8.58 (m, 2H), 7.85 (m, 1H), 7.31 (m, 2H), 7.59 (m, 1H), 7.43 (m, 1H), 7.36 (m, 2H), 7.19 (m, 2H), 6.55 (br d,  $J = 8.0\text{Hz}$ , 1H), 6.43 (dd,  $J = 8.0$  and  $4.0\text{Hz}$ , 1H), 4.50 (br s, 2H), 2.77 (m, 1H), 2.67 (m, 1H), 2.54 (m, 1H), 2.48 (m, 1H), 2.20 (om, 3H), 2.03 (m, 1H); and  $^{13}\text{C}$  NMR (100MHz,  $\text{CDCl}_3$ , with residual  $\text{CHCl}_3$  as reference at  $\delta$  77.0), due to the non-equivalence of the P atoms, some carbon signals are second order multiplets which are noted as multiplets with  $\delta_{\text{C}}$  at 142.2, 139.9 (m), 139.3 (m), 139.0 (t,  $J = 4.0\text{Hz}$ ), 138.3 (m), 134.6, 133.7, 132.2 (t,  $J = 4.0\text{Hz}$ ), 131.2 (m), 130.8 (m), 130.59, 130.58 (m), 129.2 (t,  $J = 4.2\text{Hz}$ ), 128.9 (t,  $J = 4.4\text{Hz}$ ), 100.5 (dt,  $J = 8.8$  and  $3.2\text{Hz}$ ), 91.6 (dt,  $J = 8.0$  and  $7.0\text{Hz}$ ), 35.1, 34.5, 32.5, 28.8; and  $^{31}\text{P}$  NMR (160MHz,  $\text{CDCl}_3$ , referenced to external 85%  $\text{H}_3\text{PO}_4$  at  $\delta$  0.0) with  $\delta_{\text{P}}$  at 32.7 (d,  $J_{\text{P-Rh}} = 146.1\text{Hz}$ ). The enantiomeric  $\text{Rh}(\text{COD})\{(\text{S})\text{-[2.2]PHANEPhos}\}^+ \text{OTf}^-$  is similarly prepared. [Pye, Rossen et al. *J Am Chem Soc* **119** 6207 1997.] For the catalytic hydrogenation of  $\beta$ -keto esters to  $\beta$ -hydroxy esters using  $\text{Ru}(\text{II})\{[\text{2.2]PHANEPhos}\}(\text{trifluoroacetate})_2$  with up to 96% ee, see Pye, Rossen et al. *Tetrahedron Lett* **39** 4441 1998.

***R*(-)- and *S*(+)- 4,12-Bis[di(3,5-xylyl)phosphino]-[2.2]-paracyclophane {*R*- and *S*- xylyl-PHANEPhos, (*R*- and (*S*)-5,11-bis[di(3,5-xylyl)phenylphosphino]-tricyclo-[8.2.2.2<sup>4,7</sup>]hexadeca-hexaene} [(*R*) 325168-89-6; (*S*) 325168-88-5] M 688.9, m 234-238 $^{\circ}$ ,  $[\alpha]_{\text{D}}^{22}$  *R*  $-61.0^{\circ}$ , *S*  $+61.0$  (c 0.1, EtOH). These chiral ligands are prepared and purified in much the same way as for [2.2]PHANEPhos above except that 3,5-dimethylphenylphosphinyl chloride is used to introduce the phosphorous group into the *p*-cyclophane. When these enantiomers are complexed with ruthenium and chiral ethylenediamine-type bases, they form powerful precatalysts that in the presence of  $\text{H}_2$ , will catalyse the reduction of a range of simple aromatic, heteroaromatic as well as  $\alpha,\beta$ -unsaturated ketones with high ee values. Only one example, ***R*-{[xylyl-PHANEPhos]- $\text{Ru}_2\text{Cl}(\text{S,S})\text{-DPEN}$ }** is described here. It is prepared from the red solution of  $[(\text{C}_6\text{H}_6)\text{RuCl}_2]_2$  (218mg, 0.436mmol, see [37366-09-9]), *R*-xylyl-PHANEPhos (0.60mg, 0.871mmol) in dry DMF (6ml) by heating at  $100^{\circ}$  for 4 hours, to which is then added *S,S*-1,2-diphenylethylene-1,2-diamine (185mg, 0.871mmol, *S,S*-DPEN, [29841-69-8]), and heating, and stirring is continued at  $100^{\circ}$  for 1.5 hours. The mixture is filtered, the filtrate is evaporated *in vacuo*, treated with  $\text{Et}_2\text{O}$  (10ml) and MeOH (100), the yellow catalyst is filtered off, washed with MeOH (12ml) and dried (420mg, 45% yield). It has  $^1\text{H}$  NMR (400MHz,  $\text{CDCl}_3$ ) with  $\delta_{\text{H}}$  at 1.78 (ddd,  $J = 15.0, 10.5, 4.5\text{Hz}$ , 1H), 2.07 (s, 6H), 2.27 (s, 6H), 2.59 (s, 1H), 2.78 (m, 1H), 4.01 (m, 1H), 4.40 (m, 1H), 4.49 (m, 1H), 6.36 (d,  $J = 8.0\text{Hz}$ ), 6.42 (d,  $J = 8.0\text{Hz}$ ), 6.60 (m, 2H), 6.79 (m, 1H), 6.96 (m, 2H), 7.06 (s, 1H), 7.13 (m, 3H), 8.04 (m, 2H), 8.21 (m, 1H); and  $^{31}\text{P}$  NMR (162MHz,  $\text{CDCl}_3$ , referenced to external 85%  $\text{H}_3\text{PO}_4$  at  $\delta$  0.0) with  $\delta_{\text{P}}$  at  $+46.06$  (s). The crude catalysts performed equally as well as the purified precatalysts. [Burk et al. *Org Lett* **2** 4173 2000.]**

**{1,2-Bis[(4*S*)-4-isopropyl-2-oxazolin-2-yl]benzene}zinc(II) Chloride** [131380-93-3] M436.7, m 202 $^{\circ}$ . The zinc complex is obtained by adding a solution of the free ligand (300mg, 1mmol, see [131380-80-8]) in dry THF (5ml) to a solution of fused anhydrous  $\text{ZnCl}_2$  (136mg, 1mmol, dried by melting in high vacuum and cooling under argon) in dry THF (10ml) and collecting the crystals, but if crystals are not readily formed, evaporate to

dryness and recrystallise the residue from EtOH to give the colourless complex (420mg, 98%). It has IR (KBr) with  $\nu_{\max}$  at 1655 (C=N)  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (300MHz,  $\text{CD}_3\text{CN}$ ) has  $\delta$  at 0.84 (d,  $J = 6.9\text{Hz}$ , 6H,  $\text{CH}(\text{CH}_3)_2$ ), 0.95 (d,  $J = 7.1\text{Hz}$ , 6H,  $\text{CH}(\text{CH}_3)_2$ ), 2.52-2.62 (m, 2H,  $\text{CH}(\text{CH}_3)_2$ ), 4.50-4.62 (m, 6H,  $\text{OCH}_2\text{CHN}$ ), 7.77-7.81 (m, 2H, 4-H and 5-H), 7.85-7.89 (m, 2H, 3-H and 6-H) from TMS; and the  $^{13}\text{C}$  NMR (100MHz,  $\text{CD}_3\text{CN}$ ) has  $\delta$  at 14.85 (q), 18.59 (q), 30.92 (d), 71.08 (d), 71.39 (t), 126.57 (s), 132.25 (d), 134.05(d), 168.99 (s). [Bolm et al. *Chem Ber* **124** 1173 1991.] Like many chiral bis(oxazolin-2-yl) complexes it can be involved in a variety of metal catalysed asymmetric synthesis such as allylation, aziridination, cyclopropanation, Diels-Alder and retro Diels Alder, Mukaiyama aldol condensation and hydrosilylation [see reviews by Ghosh et al. *Tetrahedron: Asymmetry* **9** 1 1998, Pflatz *Acta Chem Scand* **50** 189 1996, Johnson & Evans *Acc Chem Res* **33** 325 2000, Jørgensen et al. *Acc Chem Res* **32** 605 1999.]

**1,3-Bis(2,4,6-trimethylphenyl)-imidazol-2-ylidene-gold(I) chloride (IMesAuCl)** [852445-81-9] **M 537.1, m ~280-286°**. The gold complex is prepared by adding  $\text{Ag}_2\text{O}$  (0.5mmol) to  $\text{IMes}^+ \text{Cl}^-$  (1mmol) in  $\text{CH}_2\text{Cl}_2$  and the suspension is stirred for 3 hours at  $\sim 25^\circ$  whereby it became clear; then a solution of  $\text{Au}(\text{Me}_2\text{S})\text{Cl}$  (1mmol, see [29892-37-3]) in  $\text{CH}_2\text{Cl}_2$  is added dropwise and stirred for a further 4 hours. After filtration through Celite, the filtrate is evaporated to a small volume and hexane is added to allow the complex to separate. It is collected and dried (49% yield). Its  $^1\text{H}$  NMR (400MHz,  $\text{CDCl}_3$ , TMS) has  $\delta_{\text{H}}$  at 7.08 (s, 2H), 6.97 (bs, 4H), 2.33 (s, 6H), 2.09 (s, 12H), and its  $^{13}\text{C}$  NMR (100MHz,  $\text{THF}-d_8$ , TMS) has  $\delta_{\text{C}}$  at 134.68, 129.49, 122.12, 21.13, and 17.75 (one signal is missing, coincident signals?). HRMS-FAB Calc for  $\text{C}_{21}\text{H}_{25}\text{AuN}_2\text{Cl}$  ( $\text{M}^+ + \text{H}$ ) is 537.1372; and found 537.1361. It catalyses the intramolecular [4+2] cycloadditions of 1-en-6-yne, or aralkynes with alkenes, in the presence of  $\text{AgSbF}_6$ ; also the related **1-methyl-3-(2,4,6-trimethylphenyl)-imidazol-2-ylgold(I) chloride** is almost equally effective [Nieto-Oberhuber *J Am Chem Soc* **127** 6178 2005].

The saturated 4,5-dihydro- analogue **1,3-bis(2,4,6-trimethylphenyl)-imidazolin-2-ylidene-gold(I) chloride (SMeAuCl)** [852445-82-0] **M 539.1**, behaves in much the same manner as  $\text{IMesAuCl}$ , chemically and catalytically. It has recently been shown that both  $\text{IMesAuCl}$  and  $\text{SMeAuCl}$  can be made by metal exchange from the cheaper respective  $\text{IMesCuCl}$  and  $\text{SMeCuCl}$  (see below) in 71-90% yields. Thus a mixture of  $[\text{AuCl}(\text{SMe}_2)]$  (0.4-0.47mmol, [29892-37-3]) and  $[\text{CuCl}(\text{NHC})]$  (1 equivalent) in  $\text{CH}_2\text{Cl}_2$  (5ml) is stirred at  $40^\circ$  for 1-2 hours, then filtered through Celite and the solvent is removed *in vacuo*.  $\text{CH}_2\text{Cl}_2$  (3ml) and petroleum ether (10ml) are added to the residue, the almost pure Au complex is filtered off, washed with petroleum ether (3 x 5ml) until colourless, and dried *in vacuo*. Their catalytic activities from these different preparations are the same. [Furst & Cazin *Chem Commun* **46** 6924 2010.]

**Chloro[(1,1'-biphenyl-2-yl)di-tert-butylphosphine]gold(I) (JohnPhos-gold(I) chloride, JohnPhos-AuCl)** [854045-93-5] **M 530.8, m 237-240°**. The gold complex is made from sodium tetrachloroaurate(III) dihydrate [13874-02-7] or hydrogen tetrachloroaurate(III) [see 16961-25-4] (1 mmol) in  $\text{H}_2\text{O}$  and the yellow solution is cooled in ice, to which is added bis(2-hydroxyethyl)sulfide [see 111-48-8] (3mmol) dropwise over  $\sim 45$  minutes with stirring. Then a solution of JohnPhos [224311-51-7] (1mmol) in EtOH is added dropwise, whereby the gold complex separates as a white solid which is filtered off (43% yield), washed with MeOH and dried *in vacuo*. The  $^1\text{H}$  NMR (400MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 7.87 (td,  $J = 7.7, 1.7\text{Hz}$ , 1H), 7.51 (m, 5H), 7.31 (m, 1H), 7.13 (dd,  $J = 8.0, 1.0\text{Hz}$ , 2H), 1.41 (d,  $J = 15.6\text{Hz}$ , 18H); the  $^{31}\text{P}$  NMR (160MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{P}}$  at 63.11; and the  $^{13}\text{C}$  NMR (100MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}$  at 150.16 (d,  $^2J_{(^{13}\text{C},^{31}\text{P})} = 13.5\text{Hz}$ ), 142.10 (d,  $^3J_{(^{13}\text{C},^{31}\text{P})} = 6.3\text{Hz}$ ), 133.46 (d,  $^4J_{(^{13}\text{C},^{31}\text{P})} = 3.0\text{Hz}$ ), 133.22 (d,  $^3J_{(^{13}\text{C},^{31}\text{P})} = 7.5\text{Hz}$ ), 129.19, 128.67, 128.22, 126.67 (d,  $^3J_{(^{13}\text{C},^{31}\text{P})} = 6.8\text{Hz}$ ), 126.06 (d,  $^1J_{(^{13}\text{C},^{31}\text{P})} = 45.3\text{Hz}$ ), 37.75 (d,  $^1J_{(^{13}\text{C},^{31}\text{P})} = 25.7\text{Hz}$ ), 30.84 (d,  $^2J_{(^{13}\text{C},^{31}\text{P})} = 6.7\text{Hz}$ ); HRMS-ESI calc for  $\text{CHAuNP}$  ( $\text{M} + \text{MeCN}\text{-Cl}$ ): 536.1781, found: 536.1779. [Nieto-Oberhuber et al. *J Am Chem Soc* **127** 6168 2005, Al-Sa'Ady et al. *Inorg Synth* 191 1985.]

The acetonitrile complex salt derivative (**acetonitrile**)-(2-biphenyl)-di-tert-butylphosphinogold(I) hexafluoroantimonate [866641-66-9] **M 772.1, has m 198-203°(dec)**. It catalyses a highly efficient intramolecular addition of  $\beta$ -ketoamide to unactivated olefins leading to highly substituted lactams in the presence of  $\text{AgOTf}$  (e.g. *N*-allyl *N*-benzyl benzoylacetamide to *cis*-3-benzoyl-1-benzyl-4-methylpyrrolidin-2-one in 99% yield) [Zhou & Che *J Am Chem Soc* **129** 5828 2007]. JohnPhos-AuCl and related complexes, in the presence of  $\text{AgSbF}_6$  (i.e. the  $\text{SbF}_6^-$  salts), catalyse intramolecular [4+2] cycloadditions of 1,3-enynes or arylalkynes and alkenes with high efficiency [Nieto-Oberhuber et al. *J Am Chem Soc* **127** 6168 2005].

**Chloro[2-dicyclohexyl(2',4',6'-tri-isopropylbiphenyl)phosphine]gold(I) [X-Phos-gold(I) chloride, X-Phos-**

**AuCl]** [854045-94-6] **M 709.1, m 243-250°**. This complex is prepared in much the same way as JohnPhos-AuCl but using a solution containing 1mmol of X-Phos [564483-18-7] in EtOH instead and giving a 61% yield of the X-Phos-AuCl as a white solid. The  $^1\text{H}$  NMR (400MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 7.57-7.55 (m, 2H), 7.23 (m, 1H), 7.05 (s, 2H), 2.95 (hept,  $J = 7.0\text{Hz}$ , 1H), 2.21 (hept,  $J = 6.7\text{Hz}$ , 2H), 2.05-2.01 (m, 4H), 1.83-1.71 (m, 6H), 1.67-1.61 (m, 2H), 1.53-1.42 (m, 3H), 1.35 (s, 3H), 1.34 (s, 3H), 1.28 (s, 3H), 1.26 (s, 3H), 1.23-1.13 (m, 7H), 0.92 (s, 3H), 0.91 (s, 3H); the  $^{31}\text{P}$  NMR (160MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{P}}$  at 38.48; and the  $^{13}\text{C}$  NMR (100MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}$  at 150.6, 145.48, 133.82 (d,  $^3J_{(^{13}\text{C},^{31}\text{P})} = 8.1\text{Hz}$ ), 132.04 (d,  $^1J_{(^{13}\text{C},^{31}\text{P})} = 3.2\text{Hz}$ ), 130.35 (d,  $^1J_{(^{13}\text{C},^{31}\text{P})} = 1.8\text{Hz}$ ), 127.08 (d,  $^1J_{(^{13}\text{C},^{31}\text{P})} = 7.1\text{Hz}$ ), 121.70, 37.23 (d,  $^1J_{(^{13}\text{C},^{31}\text{P})} = 33.5\text{Hz}$ ), 34.30, 30.93, 30.81, 27.01 (d,  $^1J_{(^{13}\text{C},^{31}\text{P})} = 13.5\text{Hz}$ ), 26.69 (d,  $^1J_{(^{13}\text{C},^{31}\text{P})} = 12.9\text{Hz}$ ), 24.36, 23.21 HRMS-ESI calc for  $\text{C}_{33}\text{H}_{49}\text{AuPNa}$  ( $\text{M}^+ + \text{Na}$ ): 731.2823, found: 731.2789. [Nieto-Oberhuber et al. *J Am Chem Soc* **127** 6168 2005, Al-Sa'Ady et al. *Inorg Synth* 191 1985.] Its catalytic activities are similar to those of JohnPhos-AuCl above.

**Chloro(triphenylphosphine)gold(I)** [14243-64-2] **M 495.7, m 240-241°, 242-243°**.  $\text{Ph}_3\text{PAuCl}$  is prepared under argon by adding a solution of hydrogen tetrachloroaurate (2.0g, 5.87mmol,  $\text{H}[\text{AuCl}_4] \cdot n\text{H}_2\text{O}$ ,  $n \sim 3$ , "brown gold chloride" see [16903-35-8]) in EtOH (10ml), which has been filtered to remove any insoluble Au-containing material, to a stirred solution of  $\text{Ph}_3\text{P}$  (3.08g, 11.7mmol) in absolute EtOH (50ml of 100%, warm if necessary to dissolve). The solution immediately becomes colourless and after stirring for 15 minutes the white microcrystalline solid is collected (fritted glass filter, porosity 4), washed with EtOH (2 x 5ml), then  $\text{Et}_2\text{O}$  (3 x 15ml), and dried *in vacuo* (0.1mm) to give the analytically pure complex (1.9-2.3g 67-80%, or up to 92% if equipment is thoroughly dried, solvents degassed, and working in a strict inert atmosphere). It (~1.g) crystallises from  $\text{CH}_2\text{Cl}_2$  (10ml) by slow addition of *n*-pentane (60ml) and cooling to  $-25^\circ$  to give small slender white needles within a few minutes, and it also crystallises from  $\text{CHCl}_3$  solution by addition of heptane. [Braunstein et al. *Inorg Synth* **27** 218 1990, Bruce et al. *Inorg Synth* **26** 324 1986, cf JohnPhos-AuCl above].  $\text{Ph}_3\text{PAuCl}$  has also been prepared by adding  $\text{Ph}_3\text{P}$  (1.5g) in  $\text{Me}_2\text{CO}$  (5ml) to a solution of  $\text{HAuCl}_4$  (1g, 0.5mol equivalents, "chlorogold(III) acid" see [16903-35-8]) in  $\text{Me}_2\text{CO}$  at  $20^\circ$ . The volume of the solution is reduced to *ca* 5ml and the complex that separates (1.2g, 83%) is collected and dried or crystallised as before [Burgess et al. *JCS, Dalton Trans* 1161 1983].

*Alternatively*, to the orange solution of sodium tetrachloroaurate(III). $2\text{H}_2\text{O}$  (1mmol, [13874-02-7]) dissolved in  $2\text{H}_2\text{O}$ , cooled in ice, is slowly added 2,2'-thiodiethanol {3mmol, i.e. bis(2-hydroxyethyl)sulfide [see 111-48-8]} at  $0^\circ$  during ~45 minutes, followed dropwise by a solution of the  $\text{Ph}_3\text{P}$  ligand (1mmol, or other  $\text{PX}_3$  ligand) in EtOH which causes a white solid to separate. This is filtered off, washed with MeOH, and dried *in vacuo* (0.1mm) to give  $\text{Ph}_3\text{PAuCl}$  (or other  $\text{PX}_3\text{AuCl}$ ) as a white solid in ~88% yield. It is recrystallised as described above. [Li et al. *J Org Chem* **73** 4323 2008,]. The  $^1\text{H}$  NMR (400MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 2.03-1.93 (m, 9H), 1.89-1.85 (m, 6H), 1.75-1.72 (m, 3H), 1.52-1.41 (m, 6H), 1.35-1.21 (m, 9H); the  $^{31}\text{P}$  NMR (160MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{P}}$  at 57.12 (34.224ppm reported also at 300MHz,  $\text{CDCl}_3$ , from external  $\text{H}_3\text{PO}_4$ ); and  $^{13}\text{C}$  NMR (100MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}$  at 33.28 (d,  $^1J_{(^{13}\text{C},^{31}\text{P})} = 31\text{Hz}$ ), 30/75, 26.96 (d,  $^2J_{(^{13}\text{C},^{31}\text{P})} = 12.2\text{Hz}$ ), 25.80 (d,  $^3J_{(^{13}\text{C},^{31}\text{P})} = 1.5\text{Hz}$ ), HRMS-ESI calc for  $\text{C}_{20}\text{H}_{36}\text{AuPNa}$  ( $\text{M}^+ + \text{MeCN}\cdot\text{Cl}$ ): 518.2251, found: 518.2241. [Nieto-Oberhuber et al. *J Am Chem Soc* **127** 6168 2005, Al-Sa'Ady et al. *Inorg Synth* 191 1985, Li et al. *J Org Chem* **73** 4323 2008.] Its catalytic activities are similar to those of JohnPhos-AuCl above. It has also been used in the cyclisation of *O*-propargyl carbamates to alkylideneoxazolidiones at room temperature, *via* a 5-exo-digonal pathway [Ritter et al. *Synlett* 3309 2006]. It is soluble in  $\text{Me}_3\text{CO}$ ,  $\text{CH}_2\text{Cl}_2$ ,  $\text{CHCl}_3$ ,  $^*\text{C}_6\text{H}_6$  and THF, but not in EtOH or hexane, and is used for the preparation of a variety of  $\text{Ph}_3\text{PAu}$  salts and cluster complexes. It is stable indefinitely in air, and note that  $^{31}\text{P}$  NMR studies of  $\text{Ph}_3\text{PAuCl}$  showed no change in the chemical shift (at 33.8ppm in THF) after bubbling  $\text{O}_2$  through the solution of 24 hours, indicating how stable it is compared with cationic  $\text{Ph}_3\text{PAu}^+$  species in the presence of  $\text{O}_2$  [Liu et al. *J Am Chem Soc* **128** 11332 2006]. X-Ray crystallography showed that the molecule of  $\text{Ph}_3\text{PAuCl}$  is linear with a P-Au-Cl angle of  $179.68^\circ$  and Au-P distance of  $2.235\text{\AA}$  [Baezinger et al. *Acta Cryst* **B32** 962 1976].

**Chlorotris(triphenylphosphine)rhodium(I) (Wilkinson's catalyst)** [14694-95-2] **M 925.2, m 138°(dec), 140°(dec), 157-158°(dec)**. It is prepared by adding  $\text{PPh}_3$  (12g, recrystallised from EtOH to remove any  $\text{PPh}_3\text{O}$ )

in hot EtOH (350ml) to  $\text{RhCl}_3 \cdot 3\text{H}_2\text{O}$  (2g) in 95% EtOH (70ml) in a flask purged with  $\text{N}_2$ , refluxed in the presence of  $\text{N}_2$  for 2 hours, and the red solid that is formed is collected on a sintered glass funnel and washed with small volumes of dry  $\text{Et}_2\text{O}$  (50ml) to give the catalyst (6.25g, 88%). It forms dark burgundy crystals from hot EtOH after refluxing for 30 minutes. When the solution is heated for only 5 minutes, orange crystals are formed. Heating the orange crystals in EtOH yields red crystals. Crystallisation from  $\text{Me}_2\text{CO}$  gives the orange crystals. The dimorphic forms have similar IR spectra, but the X-ray diffraction patterns are slightly different. Excess of  $\text{PPh}_3$  can be recovered by adding  $\text{H}_2\text{O}$  to the EtOH filtrates from recrystallisation and, collecting it after standing for 2-3 days. [Osborne et al. *J Chem Soc (A)* 1711 1966, Osborne & Wilkinson *Inorg Synth* **10** 67 1967, Bennett & Donaldson *Inorg Chem* **16** 655 1977.] The solubilities are as follows: in  $\text{CH}_2\text{Cl}_2$  ~2% (25°), in toluene 0.2% (25°), and less soluble in  $\text{Me}_2\text{CO}$ , MeOH, BuOH and AcOH, but insoluble in petroleum ethers and cyclohexane. It reacts with donor solvents such as pyridine, DMSO and MeCN. Solutions of  $\text{RhCl}[(\text{PPh}_3)_3]$  are air sensitive, absorb  $\text{O}_2$ , and as well as the solid should be stored under  $\text{O}_2$ -free  $\text{N}_2$  or argon. On heating solutions in  $^*\text{C}_6\text{H}_6$ , toluene or methyl ethyl ketone the chlorine-bridged *dimer*  $[(\text{PPh}_3)_3\text{RhCl}_2\text{Rh}(\text{PPh}_3)_3]$  is formed as salmon-red crystals which absorb oxygen even in the solid state, but can be converted to the *monomer* in refluxing EtOH containing  $\text{PPh}_3$ . Red solution of  $\text{RhCl}[(\text{PPh}_3)_3]$  absorb  $\text{H}_2$  reversibly at 760mm/25°, become yellow in colour, and are effective in catalysing the reduction of C-C double bonds and triple bonds, often in a selective manner. [Osborn & Wilkinson *Inorg Synth* **28** 77 1990.] The stoichiometric and catalytic reactions of  $\text{RhCl}[(\text{PPh}_3)_3]$  have been reviewed [Jardine *Prog Inorg Chem* **28** 63 1981]. In the presence of 1.5 mol of  $\text{Et}_2\text{Zn}$ , 1 mol of 4-phenylbut-3-ene-2-one (and related  $\alpha$ -ene-ones) reacts with 1.7mol of  $\text{CF}_3\text{Cl}$  in THF at 5° to give 4-phenyl-3-(trifluoromethyl)butan-2-one (and related ketones) in moderate yields in the presence of catalytic amounts of  $\text{RhCl}[(\text{PPh}_3)_3]$  (~0.02mol) [Sato, Omote, Ado and Kumadaki *Org Synth* **83** 177 2006].

**Chromium (III) acetylacetonate**  $[\text{Cr}(\text{acac})_3]$  [21679-31-2] **M 349.3, m 212-216°, 216°, b 340°, pK<sup>25</sup> 4.0** (see **chromic chloride**). Purify it by dissolving 6g in hot  $^*\text{C}_6\text{H}_6$  (20ml) and adding petroleum ether (75ml) slowly. Cool to room temperature then chill on ice, filter off and dry in air to give 2.9g. It also crystallises from EtOH. It is soluble in heptane,  $^*\text{C}_6\text{H}_6$ , toluene and pentane-2,4-dione at 20-40°. It forms a 1:2 complex with  $\text{CHCl}_3$ . [Fernelius & Blanch *Inorg Synth* **V** 130 1957, Steinbach & Burns *J Am Chem Soc* **80** 1839 1958, Beilstein **1** H 782, **1** II 836, **1** IV 3673.]  $\text{Cr}(\text{acac})_3$  catalyses the oxidation of methacrylic acid esters in the presence of  $\text{H}_2\text{O}_2$  which provides a new route to pyruvic esters [Inoue et al. *Chem Lett (Jpn)* **18** 99 1989]. **TOXIC** — potential carcinogen.

**Cobalt Oxazoline Palladacycles (COPs)** are organocobalt-palladium complexes which catalyse the asymmetric rearrangements of non-chiral allylic trichloroacetamidates with very high enantiomeric selectivity (>90%) to provide chiral allylic amines [it is an aza-Claisen rearrangement, '**The Overman Rearrangement**' Overman & Carpenter *Org React* **66** 2005, Kirsch, Overman and Watson *J Org Chem* **69** 8101 2004]; and in the presence of phenols stereospecific cross-coupling also occurs to provide chiral phenoxyallyl ethers with very high (>90%) enantiomeric selectivity [Kirsch, Overman and White *Org Lett* **9** 911 2007, Overman & Carpenter *Org React* **66** 2005].

**(S)-(+)-COP-OAc dimer catalyst**  $\{S(\text{COP-OAc})_2$ ; **di- $\mu$ -acetobis** $[\eta^5$ -**(S)**-**(pR)**-2-(2'-(4'-methyleneethyl)-oxazoliny)l)cyclopentadienyl, 1-C-3'-N)( $\eta^4$ -tetraphenylcyclobutadiene)cobalt} **dipalladium**  $\}$  [222400-03-5] **M 1512-2, m 189-194° (250-257° dec.),  $[\alpha]_D^{24} +942^\circ$  (c 0.215,  $\text{CHCl}_3$ )**. This COP is prepared in a Schlenk flask flushed with argon containing ( $\eta^5$ -**(S)**-2-(4'-methyleneethyl)-oxazoliny)l)cyclopentadienyl-( $\eta^4$ -tetraphenylcyclobutadiene)cobalt (9.6g, 16.2mmol, see 22240-02-4) in glacial acetic acid (96ml) to which is added palladium(II) acetate (3.6g, 16.2mmol, must be recrystallised from  $^*\text{C}_6\text{H}_6$ ), and the red solution is heated at 95° for 30 minutes when an orange precipitate separates. After cooling to ~25°, the solid is collected, washed with glacial acetic acid (50ml) and dried *in vacuo* to give almost analytically pure **S**-(COP-Ac)<sub>2</sub> (8.9g, 73%) as mustard coloured crystals. It has IR (thin film) with  $\nu_{\text{max}}$  at 3061, 2961, 1583 (C=N), 1501, 1417 (acetate bridge), 1366, 1181, 1069  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (500MHz,  $\text{CDCl}_3$ ) with  $\delta_{\text{H}}$  at -0.01 (d,  $J = 6.6\text{Hz}$ , 3H,  $\text{CH}_3$ ), 0.46 (d,  $J = 7.1\text{Hz}$ , 3H,  $\text{CH}_3$ ), 1.72-1.81 (m, 1H, CH), 1.96 (s, 3H,  $\text{CH}_3$ ), 2.98 (td,  $J = 9.0, 3.1\text{Hz}$ , 1H, CH), 3.36 (t,  $J = 9.0\text{Hz}$ , 1H,  $\text{CH}_2$ ), 4.08 (dd,  $J = 8.6, 3.9\text{Hz}$ , 1H,  $\text{CH}_2$ ), 4.23 (t,  $J = 2.4\text{Hz}$ , 1H, CH), 4.62 (d,  $J = 1.4\text{Hz}$ , 1H, CH), 4.68 (d,  $J = 2.0\text{Hz}$ , 1H,

CH), 7.20-7.29 (m, 12H, ArH), 7.64 (m, 8H, ArH); and the  $^{13}\text{C}$  NMR (125MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}$  at 13.3, 18.8, 24.2, 29.1, 65.0, 71.2, 76.2, 79.4, 85.0, 85.4, 86.8, 98.1, 126.2, 128.1, 129.5, 136.1, 170.8, and 180.9.

The **(R)-(-)-COP-OAc dimer enantiomer** [849592-74-1] **M 1512.2, m 241-251<sup>o</sup> dec.** is prepared in the same way but using the enantiomeric starting material. [Stevens & Richards *Organometallics* **18** 1346 1999, Anderson et al. *Org Synth* **84** 148 2007.] The reactions of trichloroacetimidate derivatives of *Z*-2-alken-1-ols with phenolic nucleophiles in the presence of chiral COP-OAc dimer catalysts yield 3-aryloxy-1-alkenes in high yield (63-90%) and high enantiomeric purity (90-97% ee); and are compatible with the presence of base-labile substituents in either reactant [Kirsch, Overman and White *Org Lett* **9** 911 2007].

**(S)-(+)-COP-Cl dimer catalyst** {**S(COP-Cl)<sub>2</sub>**; **di- $\mu$ -chlorobis[ $\eta^5$ -(*S*)-(p*R*)-2-(2'-(4'-methylethyl)-oxazoliny)cyclopentadienyl, 1-C-3'-N)( $\eta^4$ -tetraphenylcyclobutadiene)cobalt[dipalladium]**} [581093-92-7] **M 1464.98, m 204-205<sup>o</sup>, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +1201<sup>o</sup> (c 0.1,  $\text{CH}_2\text{Cl}_2$ ).** It is obtained from the above *S*-(COP-OAc)<sub>2</sub> (8.9g, 5.9mmol) in acetone (59ml) by stirring vigorously at ~25<sup>o</sup> with aqueous NaCl (2M, 30ml) to give a homogeneous mixture until the reaction is complete (~4 hours, checked periodically by sampling a filtered aliquot and examining the  $^1\text{H}$  NMR spectra). The yellow complex which separates is filtered off, washed with H<sub>2</sub>O (125ml) then Me<sub>2</sub>CO (20ml) and dried *in vacuo* to give almost pure (COP-Cl)<sub>2</sub> (8.2g, 95%) as a mustard coloured solid. It can be purified further by filtering a solution in CH<sub>2</sub>Cl<sub>2</sub> through a short plug of Celite and eluting with CH<sub>2</sub>Cl<sub>2</sub> to give an analytically pure orange solid (97% recovery) which exists as a 1.0:0.7 mixture of dimers. It has IR (thin film) with  $\nu_{\text{max}}$  at 3061, 2961, 1602, 1502, 1370, 1185 cm<sup>-1</sup>; the  $^1\text{H}$  NMR (500MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 0.70-0.74 (m, 6H, CH<sub>3</sub>), 0.76 (d, *J* = 6.8Hz, 3H, CH<sub>3</sub>), 0.80 (d, *J* = 7.0Hz, 3H, CH<sub>3</sub>), 2.20-2.33 (m, 2H, CH), 3.03-3.15 (m, 2H, CH), 3.34 (t, *J* = 9.0Hz, 1H, CH<sub>2</sub>), 3.43 (t, *J* = 8.9Hz, 1H, CH<sub>2</sub>), 4.16-4.22 (m, 2H, CH<sub>2</sub>), 4.28 (t, *J* = 2.5Hz, 1H, CH), 4.40 (t, *J* = 2.5Hz, 1H, CH), 4.70 (d, *J* = 2.0Hz, 1H, CH), 4.73 (d, *J* = 2.0Hz, 1H, CH), 4.98 (d, *J* = 1.5Hz, 1H, CH), 4.99 (d, *J* = 1.5Hz, 1H, CH), 7.16-7.22 (m, 12H, ArH), 7.23-7.30 (m, 12H, ArH), 7.58-7.62 (m, 8H, ArH), 7.66-7.71 (m, 8H, ArH); and the  $^{13}\text{C}$  NMR (125MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}$  at 14.3, 14.5, 19.0 (2C), 29.0, 29.2, 65.6, 66.0, 71.4, 71.5, 76.5, 76.8, 81.0, 84.2, 84.5, 84.8, 84.9, 85.7, 87.1, 98.6, 98.7, 126.4, 126.5, 128.2, 128.3, 129.4, 129.5, 135.5, 135.6, 171.1, 171.2. The enantiomeric purity was determined by conversion into the acetylacetonate derivative **COP-acac** (see below) and the enantiopurity was shown to be >99% by HPLC [Diacel Chiralpak AD-H (0.46cm x 25cm) column, with 1.0ml/minute flow rate and eluted with 95:5 hexanes:*iso*-PrOH]. The retention time for *S*-COP-acac is 5.1 minutes whereas that of *R*-COP-acac would have been ~3.1 minutes [Anderson, Kirsch and Overman *Org Synth* **84** 148 2007].

**(R)-(-)-COP-Cl dimer catalyst** {**R(COP-Cl)<sub>2</sub>**; **di- $\mu$ -chlorobis[ $\eta^5$ -(*R*)-(p*R*)-2-(2'-(4'-methylethyl)-oxazoliny)cyclopentadienyl, 1-C-3'-N)( $\eta^4$ -tetraphenylcyclobutadiene)cobalt[dipalladium]**} [612065-00-6] **M 1464.98, m 205-208<sup>o</sup>, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +1240<sup>o</sup> (c 0.1,  $\text{CH}_2\text{Cl}_2$ )** is obtained and purified as for its *S*-enantiomer above but using the *R*-enantiomeric intermediates. These planar chiral COP-Cl dimers catalyse the [3+3]-sigmatropic rearrangements of a wide range of non-chiral *E*-allylic trichloroacetimidates into the corresponding transposed chiral allylic trichloroacetamides (from which the free base can be obtained) in high yields and very high enantioselectivities [Anderson & Overman *J Am Chem Soc* **125** 12412 2003, Anderson, Overman and Watson *Org Synth* **82** 134 2005]. The reactions of trichloroacetimidate derivatives of *Z*-2-alken-1-ols with phenolic nucleophiles in the presence of chiral COP-Cl dimer catalysts yield 3-aryloxy-1-alkenes in high yield (63-90%) and high enantiomeric purity (90-97% ee); and are compatible with the presence of base-labile substituents in either reactant [Kirsch, Overman and White *Org Lett* **9** 911 2007].

**(S)-(+)-COP-acac monomer catalyst** {**acetylacetonato[ $\eta^5$ -(*S*)-(p*R*)-2-(2'-(4'-methylethyl)-oxazoliny)cyclopentadienyl, 1-C-3'-N)( $\eta^4$ -tetraphenylcyclobutadiene)cobalt[palladium]**} [805315-09-7] **M 796.1, m 100-104<sup>o</sup>(dec.), [ $\alpha$ ]<sub>D</sub><sup>28</sup> +246.1<sup>o</sup>, [ $\alpha$ ]<sub>577</sub><sup>28</sup> +250.2<sup>o</sup>, [ $\alpha$ ]<sub>546</sub><sup>28</sup> +175.5<sup>o</sup>, [ $\alpha$ ]<sub>435</sub><sup>28</sup> -59.8<sup>o</sup>, [ $\alpha$ ]<sub>405</sub><sup>28</sup> -91.4<sup>o</sup> (c 1.00,  $\text{CHCl}_3$ ).** *S*-(+)-COP-acac is obtained as a monomer from the above dimer *S*-(COP-OAc)<sub>2</sub> (1.0g, 0.66mmol), sodium acetylacetonate (954mg, 6.8mmol, see [15435-71-9]), Me<sub>2</sub>CO (6.6ml) and H<sub>2</sub>O (3.3ml) by stirring vigorously for 24 hours at ~25<sup>o</sup>. The mixture is then extracted with CH<sub>2</sub>Cl<sub>2</sub> (10ml), the extract is separated, dried (MgSO<sub>4</sub>), filtered and concentrated to give almost pure *S*-(+)-COP-acac (1.0g, quantitative) as an orange solid. It can be further purified by filtering through a silica-gel column and eluting with *iso*-PrOH:hexanes (5:95) and evaporating the orange band to give an analytically pure complex. See above *S*-(COP-Cl)<sub>2</sub> for HPLC data; and it has  $R_{\text{F}}$  0.59 (silica gel, hexanes-EtOAc, 80:20). It has IR (thin film) with  $\nu_{\text{max}}$  at 3058, 2960, 1597, 1579, 1508.

1399, 1265, 1183, 1067  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (400MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 7.64 (d,  $J = 7.6\text{Hz}$ , 8H), 7.20-7.30 (m, 12H), 5.26 (s, 1H), 5.17 (s, 1H), 4.89 (d,  $J = 1.6\text{Hz}$ , 1H), 4.47 (s, 1H), 4.27 (dd,  $J = 8.4, 5.6\text{Hz}$ , 1H), 3.67 (t,  $J = 9.0\text{Hz}$ , 1H), 3.29-3.31 (m, 1H), 2.26-2.27 (m, 1H), 2.00 (s, 3H), 1.94 (s, 3H), 0.84 (d,  $J = 7.6\text{Hz}$ , 3H), 0.82 (d,  $J = 8.0\text{Hz}$ , 3H); and the  $^{13}\text{C}$  NMR (100MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}$  at 14.8, 18.6, 27.2, 27.6, 29.0, 65.1, 71.6, 76.0, 80.0, 85.1, 85.8, 86.3, 99.4, 126.0, 127.8, 128.1, 129.2, 136.0, 172.0, 184.9, 186.3. [Kirsch et al. *J Org Chem* **69** 8101 2004, Anderson, Kirsh and Overman *Org Synth* **84** 148 2007].

The isomer **(R)-(-)-COP-acac monomer catalyst {acetylacetonato[ $\eta^5$ -(R)-(pR)-2-(2'-(4'-methyl-ethyl)-oxazoliny)cyclopentadienyl, 1-C-3'-N-( $\eta^4$ -tetraphenylcyclobutadiene)cobalt]palladium}** [CASRN is the same as preceding *S*-(+)-enantiomer] **M 796.1, m 100-104 $^\circ$ (dec),  $[\alpha]_{\text{D}}^{28} -246.1^\circ$ ,  $[\alpha]_{577}^{28} -250.2^\circ$ ,  $[\alpha]_{546}^{28} -175.5^\circ$ ,  $[\alpha]_{435}^{28} +59.8^\circ$ ,  $[\alpha]_{405}^{28} +91.4^\circ$  (c 1.00,  $\text{CHCl}_3$ )** can be obtained and purified as for its *S*-enantiomer above but using the *R*-enantiomeric intermediates. These monomeric COPs catalyse the asymmetric rearrangements of non-chiral allylic trichloro-acetimidates into chiral transposed allylic trichloroactamides in good yield with high asymmetric induction (>90% ee). These are more soluble catalysts than the COP dimers, and because they are soluble in a much wider variety of solvents, the reactions can be carried out at high substrate concentration (e.g. at ~2.6M) [Kirsch et al. *J Org Chem* **69** 8101 2004]. The reactions of trichloroacetimidate derivatives of *Z*-2-alken-1-ols with phenolic nucleophiles in the presence of chiral COP-acac monomer catalysts yield 3-aryloxy-1-alkenes in high yield (63-90%) and high enantiomeric purity (90-97% ee); and are compatible with the presence of base-labile substituents in either reactant [Kirsch, Overman and White *Org Lett* **9** 911 2007].

**(S)-(+)-COP-hfacac {hexafluoroacetylacetonato[ $\eta^5$ -(S)-(pR)-2-(2'-(4'-methyl-ethyl)oxazoliny)cyclopentadienyl, 1-C-3'-N-( $\eta^4$ -tetraphenylcyclobutadiene)cobalt]palladium}** [805315-08-6] **M 904.0, m 108-110 $^\circ$ (dec.)  $[\alpha]_{\text{D}}^{28} +271.2^\circ$ ,  $[\alpha]_{577}^{28} +277.6^\circ$ ,  $[\alpha]_{546}^{28} +214.8^\circ$ ,  $[\alpha]_{435}^{28} -57.7^\circ$ ,  $[\alpha]_{405}^{28} -86.8^\circ$  (c 1.02,  $\text{CHCl}_3$ )**. *(S)*-(+)-COP-hfacac is obtained as a monomer from the above dimer *S*-(COP-OAc)<sub>2</sub> (1.0g, 0.66mmol), sodium hexafluoroacetylacetonate (1.6g, 6.8mmol, see [22466-49-5]),  $\text{Me}_2\text{CO}$  (6.6ml) and  $\text{H}_2\text{O}$  (3.3ml) by stirring vigorously at ~25 $^\circ$  for 9-11 hours (check periodically by sampling a filtered aliquot and examining the  $^1\text{H}$  NMR spectra until completion). The solid that separates is filtered off, washed with  $\text{H}_2\text{O}$  (10-20ml) and dried *in vacuo* over  $\text{P}_2\text{O}_5$  to give *(S)*-(+)-COP-hfacac monomer (1.1g, 91%). A pure sample can be obtained by filtration through a short plug of silica gel with  $\text{CH}_2\text{Cl}_2$  as eluent (in an 89% yield). It has  $R_{\text{F}}$  0.63 (silica gel, hexanes-EtOAc, 80:20). It has IR (thin film) with  $\nu_{\text{max}}$  at 3061, 2964, 1629, 1598, 1509, 1475, 1258, 1208, 1150  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (500MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 7.54-7.56 (m, 8H, ArH), 7.19-7.29 (m, 12H, ArH), 5.95 (s, 1H, CH), 4.68 (d,  $J = 2.3\text{Hz}$ , 1H, CH), 4.90 (d,  $J = 2.3$ , 1H, CH), 4.53 (t,  $J = 2.3\text{Hz}$ , 1H, CH), 4.33 ( $J = 8.6, 5.3\text{Hz}$ , 1H,  $\text{CH}_2$ ), 3.72 (t,  $J = 9.4\text{Hz}$ , 1H,  $\text{CH}_2$ ), 3.45 (td,  $J = 9.4, 5.1\text{Hz}$ , 1H, CH), 2.05-2.08 (m, 1H, CH), 0.83 (d,  $J = 7.0\text{Hz}$ , 3H,  $\text{CH}_3$ ), 0.79 (d,  $J = 6.9\text{Hz}$ , 3H,  $\text{CH}_3$ ); and the  $^{13}\text{C}$  NMR (125MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}$  at 14.9, 18.4, 29.3, 65.3, 72.3, 76.7, 78.9, 84.1, 84.8, 87.7, 90.1, 97.6, 116.6, 118.8, 126.5, 127.9, 128.9, 135.5, 173.3, 173.6, 174.1. [Kirsch et al. *J Org Chem* **69** 8101 2004, Anderson et al. *Org Synth* **84** 148 2007].

Enantiomer **(R)-(-)-COP-hfacac {hexafluoroacetylacetonato[ $\eta^5$ -(R)-(pR)-2-(2'-(4'-methyl-ethyl)-oxazoliny)cyclopentadienyl, 1-C-3'-N-( $\eta^4$ -tetraphenylcyclobutadiene)cobalt]palladium}** [CASRN is the same as preceding *S*-(+)-enantiomer] **M 904.0, m 108-110 $^\circ$ (dec.)  $[\alpha]_{\text{D}}^{28} -271.2^\circ$ ,  $[\alpha]_{577}^{28} -277.6^\circ$ ,  $[\alpha]_{546}^{28} -214.8^\circ$ ,  $[\alpha]_{435}^{28} +57.7^\circ$ ,  $[\alpha]_{405}^{28} +86.8^\circ$  (c 1.02,  $\text{CHCl}_3$ )** can be obtained and purified as for its *S*-enantiomer above but using the *R*-enantiomeric intermediates. These COP-hfacac complexes, like the related COP-acac complexes, are monomeric and more soluble than the dimeric COPs above. They can be used in a variety of solvents, e.g. THF, MeCN, which allow catalytic asymmetric allylacetimidate rearrangements to be performed at high concentrations and using as little as 1 mole% of catalyst. [Anderson Kirsch and Overman *Org Synth* **84** 148 2007, Kirsch, Overman and Watson *J Org Chem* **69** 8101 2004]. The reactions of trichloroacetimidate derivatives of *Z*-2-alken-1-ols with phenolic nucleophiles in the presence of chiral COP-acac catalysts yield 3-aryloxy-1-alkenes in high yield (63-90%) and high enantiomeric purity (90-97% ee); and are compatible with the presence of base-labile substituents in either reactant [Kirsch, Overman and White *Org Lett* **9** 911 2007].

**Copper(I) [1,3-bis(2,6-di-*iso*-propylphenyl)imidazol-2-ylidene] chloride [1,3-bis(2,6-di-*iso*-propylphenyl)imidazol-2-ylidene copper(I) chloride, (IPr)=CuCl** [578743-87-0] **M 487.59, m >300 $^\circ$** . This NHC (N-heterocyclic carbene) precatalyst is readily prepared in analytical purity in a Schlenk flask and under an argon atmosphere. Dry THF (100ml) is added to a mixture of freshly prepared Cu(I)Cl (1.0g, 10.1mmol), 1,3-bis(2,6-

di-*iso*-propylphenyl)imidazolium chloride (4.29g, 10.1mmol, IPr.HCl see [250285-32-6]) and Na *tert*-butoxide (0.97g, 10.1mmol), and stirred mechanically under argon at  $\sim 25^\circ$  for 20 hours. The mixture is then filtered through a plug of Celite, and the filtrate is evaporated *in vacuo* to give the complex as a white powder (4.59g, 9.40mmol, 94%),  $m > 300^\circ$ . Suitable crystals were grown from  $\text{CH}_2\text{Cl}_2$ /hexane solutions and subjected to single-crystal diffraction studies. The molecular structure was as expected with the imidazole C2, Cu and Cl atoms in the same plane, with the C2-Cu bond length of 1.953Å, the Cu-Cl bond length 2.089Å, and the C2—Cu—Cl angle of  $180.00^\circ$ , i.e. is linear. [Kaur et al. *Organometallics* **23** 1157 1160]. It has IR (neat on a DiComp probe) with  $\nu_{\text{max}}$  at 2968, 2927, 2871, 1680, 1647, 1470, 1457, 809, 764, and 743  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (500MHz,  $\text{Me}_2\text{CO}-d_6$ , downfield from TMS) has  $\delta_{\text{H}}$  at 7.26 (s, 2H), 7.57-7.54 (dd,  $J = 15.5$  and  $8.0\text{Hz}$ , 2H), 7.43-7.41 (d,  $J = 8.0\text{Hz}$ , 4H), 2.70-2.65 (m, 4H), 1.32-1.31 (d,  $J = 7.0\text{Hz}$ , 12H), 1.27-1.25 (d,  $J = 6.5\text{Hz}$ , 12H); the  $^{13}\text{C}$  NMR (125MHz,  $\text{CDCl}_3$  with 77.23 ppm of  $\text{CDCl}_3$  reference) has  $\delta_{\text{C}}$  at 180.2, 146.0, 135.1, 130.6, 124.2, 24.4 and 23.3; and the HRMS (EI.  $m/z$ ) has: found 389.2962, and calculated for  $\text{C}_{14}\text{H}_{16}\text{O}$ : 389.2951 (M - CuCl) [Jurkauskas et al. *Org Lett* **5** 2417 2003.]

(IPr)=CuCl catalyses the conjugate reduction of  $\alpha,\beta$ -unsaturated carbonyl compounds with catalytic amounts of the Cu complex, Na *tert*-BuO and poly(methylhydrosiloxane) as the stoichiometric reductant in  $>81\%$  yields [Jurkauskas et al. *Org Lett* **5** 2417 2003], it catalyses the methenylation of a variety of aliphatic and aromatic aldehydes and ketones in the presence of trimethylsilyldiazomethane ( $\text{TMSCHN}_2$ ),  $\text{Ph}_3\text{P}$  and 2-propanol efficiently, and is a cheaper alternative to the corresponding rhodium catalyst [LeBel et al. *J Org Chem* **72** 144 2007], it catalyses the efficient hydrosilylation of ketones with  $\text{Et}_3\text{SiH}$  to yield the corresponding saturated triethylsilylethers [Kaur et al. *Organometallics* **23** 1157 1160], it catalyses the transfer of the ‘:CHCO<sub>2</sub>Et’ group (from ethyl diazoacetate) to saturated and unsaturated substrates, e.g. olefins, amines or alcohols, in very high yields [Fructos et al. *J Am Chem Soc* **126** 10846 2004], and has been used for the total synthesis of (-)-Angelastin A by catalysing the aziridiation (using  $\text{TsN}=\text{IPh}$ ) [55962-05-5] of a difficult rather electron-deficient cyclopentene intermediate [Trost & Dong *J Amer Chem Soc* **128** 6054 2006].

**NOTE:** More recently it has been shown that the above  $\text{IPr}=\text{CuCl}$  ( $\text{IPrCuCl}$ ) and its 4,5-dihydro-derivative  $\text{SIPrCuCl}$ , are readily prepared by refluxing  $\sim 1.9$ - $2.3\text{mmol}$  of 1,3-bis-(2,6-diisopropylphenyl)imidazolium chloride ( $\text{IPrCl}$ , see [250285-32-6]) or 1,3-bis-(2,6-diisopropylphenyl)imidazolium chloride ( $\text{SIPrCl}$ , see [25278-25-0]) with  $\text{Cu}_2\text{O}$  ( $\sim 1.4$ - $1.5\text{mmol}$ ,  $\sim 95\%$  purity, *ca* 0.65 equivalents) for 24 hours, then excess of  $\text{Cu}_2\text{O}$  is removed to provide the following respective yields in the solvents indicated:  $\text{IPrCuCl}$  (78% from toluene, 88% conversion; 94% from  $\text{H}_2\text{O}$  with 96% conversion; 74% from dioxan) or  $\text{SIPrCuCl}$  (88% from toluene, 99% conversion; 72% from  $\text{H}_2\text{O}$ , 78% conversion). [Cazin and coworkers: Citadella et al. *Dalton Trans* **39** 4489 2010, Son and coworkers: Chun et al. *Organometallics* **29** 1518 2010].

Similarly the analogous [1,3-bis(2,4,6-trimethylphenyl)imidazol-2-ylidene copper(I) chloride, [(IMes)=CuCl]] and the 4,5-dihydro derivative [1,3-bis(2,4,6-trimethylphenyl)imidazol-2-ylidene copper(I) chloride [(SIMes)=CuCl, S is for saturated] can be prepared from the respective *IMesCl* or *SIMesCl* with 0.65 equivalents of  $\text{Cu}_2\text{O}$  by refluxing in toluene for 24 hours (in 86% and 71% yields respectively, with 100% conversion), and by refluxing in  $\text{H}_2\text{O}$  for 24 hours (in 98% and 99% yields respectively, with 100% conversion). [Cazin and coworkers: Citadella et al. *Dalton Trans* **39** 4489 2010]. These are generally slightly less catalytically specific than their IPr counter-parts because the latter have slightly greater steric hindrance.

**Copper(I) bis-[1,3-bis(2,6-di-*iso*-propylphenyl)imidazol-2-ylidene] tetrafluoroborate [(IPr)<sub>2</sub>Cu<sup>+</sup> BF<sub>4</sub><sup>-</sup>] [886061-48-9] **M 927.5, m >300°**. This copper catalyst is prepared in an oven dried septum screw capped vial (in a glove box) by mixing tetrakis(acetonitrile)copper (I) tetrafluoroborate (186mg, 0.5mmol), IPr.Cl (157mg, 0.5mmol, see [250285-32-6]) and *ter*-BuONa (96mg, 1mmol), sealing, then injecting THF (10ml) and stirring outside the box at  $\sim 25^\circ$  for 6 hours. The mixture is filtered through a plug of Celite (THF), and the Cu complex salt is precipitated by adding excess hexane, filtered off, and dried *in vacuo* to give the pure white tetrafluoroborate (452mg, 92%). It has  $^1\text{H}$  NMR (400MHz,  $\text{Me}_2\text{CO}-d_6$ ) with  $\delta$  at 7.54 (t containing a singlet at 7.55,  $J = 7.5\text{Hz}$ , 8H, *p*-CH + NCH), 7.25 (d,  $J = 7.5\text{Hz}$ , 8H, *m*-CH), 2.40 (septet,  $J = 6.8\text{Hz}$ , 8H,  $\text{CH}(\text{CH}_3)_2$ ), 1.04 (d,  $J = 6.8\text{Hz}$ , 24H,  $\text{CH}_3$ ), 0.94 (d,  $J = 6.8\text{Hz}$ , 24H,  $\text{CH}_3$ ); and its  $^{13}\text{C}$  NMR (100MHz,  $\text{CDCl}_3$ ) has  $\delta$  at 177.4 (N-C-N), 145.0 (CH aromatic), 134.7 (C aromatic), 130.6 (C aromatic), 125.3 (=CH-N), 124.5 (CH aromatic), 28.6 ( $\text{CH}(\text{CH}_3)_2$ ), 24.3 ( $\text{CH}_3$ ), 24.2 ( $\text{CH}_3$ ). The hexafluorophosphate salt is similarly prepared in 96% yield starting from tetrakis(acetonitrile)copper (I) hexafluorophosphate [64443-05-6]. The structure of these salts was shown by X-ray crystal analysis (crystals grown from  $\text{CH}_2\text{Cl}_2$ -methyl *tert*-butyl ether solution) to consist of two *N*-heterocyclic carbenes attached to one Cu atom.**

These salts are air- and moisture- stable and are highly active catalysts for the hydroxysilylation of ketones with varying steric constraints, aldehydes and epolisable aldehydes, and esters in THF at  $\sim 25^\circ$ , in the presence of  $\text{Et}_3\text{SiH}$  and *ter*-BuONa in  $>90\%$  yields [Díez-González et al. *Organometallics* **25** 2355 2006].

**Diacetato[(*R*)-(+)- and (*S*)-(–)- 2,2'-Bis(diphenylphospheno)-1,1'-binaphthyl]ruthenium(II) [*R*- and *S*-(BINAP)<sub>2</sub> Ru(II) (OAc)<sub>2</sub>] [(*R*) 132071-87-5; (*S*) 261948-85-0, 104713-03-3] M 841.8, m 185-187°(dec.), 186-188°(dec.), 188-190°(dec.), *R*-  $\lambda_{\text{max}}$  335nm ( $\Delta\epsilon/\text{mol}^{-1}\cdot\text{dcm}^3\cdot\text{cm}^{-1}$  +4.5) and  $\lambda_{\text{max}}$  450nm ( $\Delta\epsilon/\text{mol}^{-1}\cdot\text{dcm}^3\cdot\text{cm}^{-1}$  +2.5); *S*-  $\lambda_{\text{max}}$  335nm ( $\Delta\epsilon/\text{mol}^{-1}\cdot\text{dcm}^3\cdot\text{cm}^{-1}$  -4.5) and  $\lambda_{\text{max}}$  450nm ( $\Delta\epsilon/\text{mol}^{-1}\cdot\text{dcm}^3\cdot\text{cm}^{-1}$  -2.5); ( $c$   $6.5 \times 10^{-5}$  M,  $\text{CH}_2\text{Cl}_2$ ). Typically, the *S*-enantiomer is prepared in a Schlenk tube under dry argon, by dissolving (*S*)-BINAP (1.37g, 2.20mmol, see [76189-56-5]) and  $[\text{RuCl}_2(\text{COD})]_n$  (0.56g, 2.0mmol, calc based on monomer weight, see [50982-12-2]) in dry toluene (55ml) containing  $\text{Et}_2\text{NH}$  (1.2ml, 8.6mmol), and the brown suspension is refluxed with stirring for 12 hours. The clear reddish brown solution is cooled to  $\sim 25^\circ$ , the solvent is removed *in vacuo* and the brown solid residue is dissolved in  $\text{CH}_2\text{Cl}_2$  (40ml), filtered through a Celite pad and the filtrate is evaporated *in vacuo*. A solution of anhydrous NaOAc (0.88g, 11mmol) in *t*-BuOH (107ml) is added to the residue, stirred under reflux for 12 hours in an argon atmosphere, the solvent is removed *in vacuo* and the residue is extracted with absolute  $\text{Et}_2\text{O}$  ( $3 \times 20\text{ml}$ ) and evaporated again *in vacuo*. The brown residue is extracted several times with absolute EtOH (70ml total) and evaporated *in vacuo* to give a yellow-brown solid (1.58g) which is recrystallised from toluene (12ml)/hexane (30ml) mixture to afford purer complex (1.23g, 68% yield). This sample is pure enough for providing good catalytic activity for asymmetric hydrogenations. Analytical purity (to give 0.9g, 50%, 188-190° dec.) can be achieved by further recrystallisation from toluene (14ml)/hexane (13ml), and another amount (0.3g, 17%) can be recovered from the mother liquors by evaporation and recrystallisation of the residue (from 8ml of toluene and 10ml of hexane). Crystals of analytical material were subjected to Xray structure determination that gave the required absolute configuration of the complex, and the circular dichroism spectrum of it and its enantiomer were consistent with the Xray structure. It has IR ( $\text{CH}_2\text{Cl}_2$ ) with  $\nu_{\text{max}}$  at 1452, 1518  $\text{cm}^{-1}$ ; and  $^1\text{H}$  NMR (400MHz,  $\text{CDCl}_3$ , TMS) with  $\delta_{\text{H}}$  at 1.80 (s, 2 OCOCH<sub>3</sub>), 6.47-7.84 (m, aromatic H); and  $^{13}\text{C}\{^1\text{H}\}$  NMR (100MHz,  $\text{CDCl}_3$ , TMS) with  $\delta$  at 23.5 (OCOCH<sub>3</sub>), 125.2-138.3 (aromatic C), 188.8 (OCOCH<sub>3</sub>). The *R*-enantiomer can be prepared and purified in the same way.**

The enantiomers of this complex catalyse the asymmetric hydrogenation of pro-chiral ketones and olefins in high yields and ee values. [Ohta, Takaya and Noyori *Inorg Chem* **27** 566 1988, Kumbobyashi et al. *Synlett* 1055 2001.] RhBINAP complexes with ligands other than acetate, e.g.  $\text{Cl}_2$ ,  $^*\text{C}_6\text{H}_6$ ,  $(\text{OCO-}t\text{-Bu})_2$ ,  $(\text{OCOCMe}=\text{CHMe})_2$  also catalyse asymmetric hydrogenations, isomerisations and asymmetric Heck reactions [Shimizu, Nagasaki and Saito *Tetrahedron* **61** 5405 2005.] An excellent asymmetric hydrogenation catalyst for  $\alpha$ -(acylimino)acrylic acids to give the corresponding chiral  $\alpha$ -aminoacylpropionic acids with high ee-ratios is (*S*)-[(BINAP)Rh<sup>+</sup>(OMe)<sub>2</sub>] ClO<sub>4</sub><sup>−</sup>. It is obtained (together with norbornane) when a solution of (*S*)-[(BINAP)Rh<sup>+</sup>(norbornadiene)] ClO<sub>4</sub><sup>−</sup> in MeOH is exposed to H<sub>2</sub> at room temperature. Exactly 2mols are absorbed, and it is isolated as deep red prisms [whose  $^1\text{H}$  NMR ( $\text{CD}_2\text{Cl}_2$ , TMS) has  $\delta_{\text{H}}$  at 7.50 (m) and 6.82 (BINAP), 3.42 (s, CH<sub>3</sub>O); and  $^{31}\text{P}$ NMR ( $\text{CD}_3\text{OD}$  with 5% H<sub>3</sub>PO<sub>4</sub> in  $\text{CD}_3\text{OD}$  as external standard) has  $\delta$  at 53.1 (d,  $J_{\text{Rh-P}} = 206\text{Hz}$ )]. It loses MeOH *in vacuo* to give an equally active catalyst. [Myashita et al. *J Am Chem Soc* **102** 7932 1980.]

**Dichloro(1,5-cyclooctadiene)palladium(II) [Pd(COD)Cl<sub>2</sub>] [12107-56-1] M 285.5, m 210° (dec).** This air-stable catalyst can be prepared by adding 1,5-cyclooctadiene (3ml, 2.2mol, [111-78-4]) to a cooled and filtered solution of PdCl<sub>2</sub> (2.0g, 1 mol) and concentrated HCl (150ml, warm) in EtOH (150ml), whereby the yellow complex separates immediately. After keeping for 10 minutes the solid is filtered off, washed with  $\text{Et}_2\text{O}$  ( $3 \times 30\text{ml}$ ) and dried *in vacuo* (3.1g, 96%). The yellow powder is recrystallised by boiling in  $\text{CH}_2\text{Cl}_2$  (200ml), and evaporating until the onset of crystals. **Dibromo(1,5-cyclooctadiene)palladium(II) [Pd(COD)Br<sub>2</sub>] [12145-47-0] M 374.4, m 213° (dec),** is obtained from the dichloride and NaBr in Me<sub>2</sub>CO, or as above from PdCl<sub>2</sub>/HCl in the presence of NaBr before adding the diene. [Drew & Doyle *Inorg Synthesis*, Coll Vol **28** 348 1990, **13** 52 1972.] *Alternatively*, a solution of sodium chloropalladite tetrahydrate (2g) in MeOH (75ml) and the diene (2ml) can be used, and the pale orange-yellow complex is collected after 1 hour and is recrystallised from glacial AcOH. [Pd(COD)Br<sub>2</sub>] can also be prepared from the dichloride (0.45g) and LiBr (0.1g) in Me<sub>2</sub>CO (20ml), boiled under

reflux for 2 hours, filtered and the filtrate is evaporated to dryness in a vacuum (15mm), the residue is washed with H<sub>2</sub>O, dried (0.22g) and is recrystallised from AcOH (orange-red needles). [Chatt et al. *J Chem Soc* 3413 1957.] The *dichloro-complex* is sparingly soluble in cold EtOH and \*C<sub>6</sub>H<sub>6</sub>, but is more soluble in hot \*C<sub>6</sub>H<sub>6</sub>, CHCl<sub>3</sub>, Me<sub>2</sub>CO, MeEtCO, (EtO)<sub>2</sub>CO, tetrahydrothiophene 1,1-dioxide (sulfolane) and nitrobenzene. It reacts with Me<sub>2</sub>SO to form *Pd(II)Cl<sub>2</sub>(Me<sub>2</sub>SO)<sub>2</sub>*. The IR (Nujol) has  $\nu_{\max}$  at 1489, 1419, 1337, 1088, 999, 867, 825, 794, 768 325 and 295 cm<sup>-1</sup>; and the <sup>1</sup>H NMR (CDCl<sub>3</sub>) has  $\delta$  at 2.69 (CH<sub>2</sub> protons) and 6.32 (CH=CH protons). The *dibromo-complex* is similarly air-stable and has similar solubility in solvents, and its IR (Nujol) has  $\nu_{\max}$  at 1472, 1417, 1333, 1172, 1083, 992, 905, 864, 823, 787, 764, 678, 310, 265, 221, 213, 178 and 126 cm<sup>-1</sup>; and the <sup>1</sup>H NMR (CDCl<sub>3</sub>) has  $\delta$  at 2.60 (CH<sub>2</sub> protons) and 6.32 (CH=CH protons). [Beilstein 5 IV 404.]

**Dichloro(1,5-cyclooctadiene)platinum(II) [Pt(COD)Cl<sub>2</sub>]\*** [12080-32-9] **M 374.2, m 220-278° (dec), 285° (dec).** The colourless air-stable dichloro-complex is obtained by adding 1,5-cyclooctadiene\* (6ml) to a warm solution (75°) of hydrated chloroplatinic acid (5g) in AcOH (15ml), stirring, and cooling to ~25° then diluting with H<sub>2</sub>O (50ml), and the black suspension is kept at ~25° for 1 hour. The black solid is collected, washed with H<sub>2</sub>O (50ml), Et<sub>2</sub>O (100ml), then suspended in CH<sub>2</sub>Cl<sub>2</sub> (400ml), heated to boiling and kept at this temperature for 5 minutes. The solution is cooled, mixed with chromatographic grade silica gel (5g) and allowed to settle. The supernatant should be colourless, otherwise portions (~1g) of silica gel should be added until the supernatant is colourless. The solid is filtered off, washed with CH<sub>2</sub>Cl<sub>2</sub> (2 x 50ml) and the combined CH<sub>2</sub>Cl<sub>2</sub> solutions (~500ml) are evaporated until crystallisation (75ml) occurs. The hot CH<sub>2</sub>Cl<sub>2</sub> solution is then poured into petroleum ether (b 60-70°) producing a fine white powder which is collected, washed with petroleum ether (50ml) and dried (2.55g, 80%). Recrystallisation in the same way (dissolving in boiling CH<sub>2</sub>Cl<sub>2</sub> and evaporating till crystallisation sets in) yields white macroscopic crystals. It also crystallises from AcOH (charcoal) as white needles. Its solubilities in solvents are similar to those of Pd(COD)Cl<sub>2</sub> above, i.e. being insoluble in most organic solvents except boiling CH<sub>2</sub>Cl<sub>2</sub>, CHCl<sub>3</sub> and AcOH, and decomposes slowly in Me<sub>2</sub>SO (cf related Pd compound above). Its IR (Nujol) has  $\nu_{\max}$  at 1334, 1179, 1333, 1009, 1083, 871, 834, and 782 cm<sup>-1</sup>; and the <sup>1</sup>H NMR (CDCl<sub>3</sub>) has  $\delta$  at 2.71 (CH<sub>2</sub> protons) and 5.62 (*J*<sub>Pt-H</sub> = 65Hz, CH=CH protons). [Drew & Doyle *Inorg Synthesis*, Coll Vol 28 346 1990, 13 47 1972.]

**Dibromo(1,5-cyclooctadiene)platinum(II) [Pt(COD)Br<sub>2</sub>]** [12145-48-1] **M 463.1, m 220-278° (dec)** can be obtained from sodium chloroplatinate hydrate (4g), diene (4ml) and LiBr (2g) in EtOH (80-100ml), kept at ~20° for 2 days, and the precipitate is crystallised from AcOH (charcoal) in pale yellow needles. It is slightly more soluble than the chloro-analogue in organic solvents. [Chatt et al. *J Chem Soc* 2496 1957, Beilstein 5 IV 404.]

\* *Dichloro(1,3,5,7-cyclooctatetraene)Platinum(II)*, *dichloro(dicyclopentadiene)Platinum(II)* and *dichloro(2,5-norbornadiene)Platinum(II)* have been prepared successfully by this procedure and using the respective olefins.

**Dichloro[(1,2,3,6,7,10,11,12- $\eta$  .  $\bar{1}$ )dodecatriene-1,12-diyl]ruthenium(IV), [(dichloro-2,6,10-dodecatrienylene-ruthenium(IV)]** [12170-97-7] **M 334.2, decomposes >200° with part melting at 220°.** This complex is much more stable than the corresponding Ni complex, and is prepared by bubbling butadiene for 7 hours through a solution of RuCl<sub>3</sub> · 3H<sub>2</sub>O (0.43g, [13815-94-6]) in 2-methoxyethanol (25ml) at 90° in a hot water bath. The deep red solution deposits yellow-brown prisms when cooled. These are filtered off and recrystallised from CH<sub>2</sub>Cl<sub>2</sub>/petroleum ether (b 40-60°) to give the analytically pure complex (0.30g, 54.5%) as orange crystals. The IR shows a medium intensity band at  $\nu$  = 1522 cm<sup>-1</sup> assigned to the *trans* C=C co-ordinated to the Ru atom; the <sup>1</sup>H NMR (60MHz, CDCl<sub>3</sub>/TMS) has  $\delta$  at ~5.4 (m, w = 65Hz, 6H, vinylic and non terminal allylic H), 4.9 (d, *J* = 7.5Hz, 2H, terminal allylic H), 3.76 (d, *J* = 11.2Hz, 2H, terminal allylic H), 3.1 (m, w = 20Hz, 4H, methylene H) and 2.37 (m, w = 35Hz, 4H, methylene H); and the measured molecular weight (osmometry in 1.45% \*C<sub>6</sub>H<sub>6</sub> solution) is 340. [Nicholson & Shaw *J Chem Soc (A)* 807 1966.] The <sup>1</sup>H NMR is consistent with a Ru atom enveloped by dodeca-2,6,10-triene and co-ordinated to the two terminal allylic double bonds, i.e. butadiene trimerised about the metal atom, and this structure is confirmed by an X-Ray determination. This showed that Ru is bipyramidal, with the Cl atoms at the apices of the pyramids with three co-ordinate bonds (to the allylic and the C6=C7 double bonds) in the central plane. [Lydon et al. *Proc Chem Soc* 421 1964.]

The *dichloro-dodecatriene-ruthenium* complex is a highly efficient catalyst for the *one-pot* internal redox process that converts allylic alcohols (RC=C-C(OH)) into carbonyl compounds (RC-C-C=O, ketones or aldehydes) in the presence of CsCO<sub>3</sub> under N<sub>2</sub> with high yields and turnover frequencies (TOF) in THF or H<sub>2</sub>O [Cadierno et al. *Chem Commun* 232 2004, see also van der Drift et al. *J Organomet Chem* 650 1 2002]. It is also an efficient catalyst for the de-protection of *N*-allylic and *N*-diallylic substrates (with ~3mol% of Ru) in aqueous solution at

90° under N<sub>2</sub> in very high yields (typically >95%) to give the free amine and propionaldehyde (allyl product); and can be carried out on a preparative scale [Cadierno et al. *Chem Commun* 4086 2005].

**Dichloro(η<sup>5</sup>-pentamethylcyclopentadienyl)iridium(III) dimer {di-μ-chloro-dichlorobis(η<sup>5</sup>-pentamethylcyclopentadienyl)diridium (III), [Rh(η<sup>5</sup>-C<sub>5</sub>Me<sub>5</sub>)Cl<sub>2</sub>]<sub>2</sub>}** [12354-84-6] **M 796.7, m >230°**. The complex is prepared by stirring IrCl<sub>3</sub>·xH<sub>2</sub>O (10g, 26mmol), pentamethylcyclopentadiene (5g, 36mmol, Cp' see [4045-44-7]) and MeOH (300ml), purging the apparatus with N<sub>2</sub> for 5 minutes then refluxing the solution also under N<sub>2</sub> for 48 hours. After cooling to room temperature the orange crystals are filtered off in air through a glass sinter, the filtrate is concentrated *in vacuo* to ~50ml and cooled to give a second crop of crystals which are combined with the first crop, washed with Et<sub>2</sub>O (3 x 50ml) and air dried. The *Ir-dimer* (10.7g, 85%) can be obtained as an orange microcrystalline solid in analytical purity by recrystallisation using the minimum volume of CHCl<sub>3</sub> to dissolve it, filtering off insoluble material if present, and adding slowly twice that volume of hexane. The complex is stable in air at room temperature without obvious decomposition for several years. It is soluble in chlorinated solvents, much less so in Me<sub>2</sub>CO, EtOH or hydrocarbon solvents, but is somewhat soluble in H<sub>2</sub>O. The halogen atoms undergo metathesis and can be replaced by PF<sub>6</sub> and MeCN to form complexes such as [Ir(η<sup>5</sup>-C<sub>5</sub>Me<sub>5</sub>)(NCMe)<sub>3</sub>][PF<sub>6</sub>]<sub>2</sub>. Its reactions can be studied by following the <sup>1</sup>H NMR (CDCl<sub>3</sub>) signal of the single C<sub>5</sub>Me<sub>5</sub> resonance at δ 1.73s. [White et al. *Inorg Synth* **29** 229 1992.] The *Ir-dimer* directly catalyses the C3 alkylation of a variety of indoles using aliphatic and benzylic alcohols in >80% yields [Grigg et al. *Tetrahedron* **65** 4375 2009]. It is used as a precursor of N-3-substituted-N-1-pyrimidyl-imidazolium-Ir-pentamethylcyclopentadiene which catalyses transfer hydrogenation from isoPrOH to ketones, e.g. cyclohexanone, and imines, e.g. benzylideneaniline, to form the respective alcohols and amines [Gnanamagri et al. *Organometallics* **28** 321 2009]. It has also been used as a precursor to efficient phosphine-free Ir-Cp' chiral catalysts, e.g. with *N*-sulfonyl *S,S*-1,2-diphenylethylenediamine, for the hydrogenation of 2-substituted quinolines to produce chiral 2-substituted 1,2,3,4-tetrahydroquinolines in >90% yields with up to 99% ee [Li et al. *Org Lett* **20** 5265 2008].

**Dichloro(η<sup>5</sup>-pentamethylcyclopentadienyl)rhodium(III) dimer {di-μ-chloro-dichlorobis(η<sup>5</sup>-pentamethylcyclopentadienyl)dirhodium (III), [Rh(η<sup>5</sup>-C<sub>5</sub>Me<sub>5</sub>)Cl<sub>2</sub>]<sub>2</sub>}** [12354-85-7] **M 618.1, m >230°**. The complex is readily prepared by stirring RhCl<sub>3</sub>·3H<sub>2</sub>O (10g, 42mmol), pentamethylcyclopentadiene (6g, 44mmol, Cp' see [4045-44-7]) and MeOH (300ml), purging the apparatus with N<sub>2</sub> for 5 minutes then refluxing the solution also under N<sub>2</sub> for 48 hours. After cooling to room temperature the dark red crystals are filtered off in air through a glass sinter, the filtrate is concentrated *in vacuo* to ~50ml and cooled to give a second crop of crystals which are combined with the first crop, washed with Et<sub>2</sub>O (3 x 50ml) and air dried to give the *Rh-dimer* (11.25g, 95%). It can be obtained in analytical purity by recrystallisation using the minimum volume of CHCl<sub>3</sub> to dissolve it, filtering off insoluble material if present, and adding slowly twice that volume of hexane. The complex is stable in air at room temperature without obvious decomposition for several years. It is soluble in chlorinated solvents, much less so in Me<sub>2</sub>CO, EtOH or hydrocarbon solvents, but is somewhat soluble in H<sub>2</sub>O. The halogen atoms undergo metathesis and can be replaced by PF<sub>6</sub> and MeCN to form complexes such as [Rh(η<sup>5</sup>-C<sub>5</sub>Me<sub>5</sub>)(NCMe)<sub>3</sub>][PF<sub>6</sub>]<sub>2</sub>. Its reactions can be studied by following the <sup>1</sup>H NMR (CDCl<sub>3</sub>) signal of the single C<sub>5</sub>Me<sub>5</sub> resonance at δ 1.60s. [White et al. *Inorg Synth* **29** 229 1992.] In the presence of base the rhodium dimer is a good catalyst for the hydrogenation of olefins [Gill et al. *J Chem Soc, Dalton Trans* 617 1978], for hydrosilylation of olefins [Millan et al. *J Mol Catal* **26** 89 1984, Millan et al. *J Chem Soc, Chem Commun* 673 1981], and for the disproportionation of aldehydes [Cook et al. *J Chem Soc, Dalton Trans* 2342 1981].

**Dicobalt octacarbonyl (cobalt carbonyl)** [10210-68-1] **M 341.9, m 51°, 51-52° (dec), d 1.87**. Co<sub>2</sub>(CO)<sub>8</sub> has been identified as the cobalt catalyst in hydroformylation, hydrogenation and homologation reactions involving H<sub>2</sub> and CO (synthesis gas). The earlier preparation [Glimont & Blanchard *Inorg Synth* **2** 238 1946] has been improved due to the availability of steel pressure vessels and CO under pressure. Thus Raney Co (4 to 6g) was placed with Et<sub>2</sub>O (145ml) under CO at 3200psi in a steel pressure bomb and heated with shaking for 5 or 6 hours at 150°. The pressure during the heating process dropped from 4900 to 4300psi and then to 2200psi when the bomb was cooled to ~25°. The insoluble material was removed by centrifugation, and the reddish-brown clear solution (160ml, which includes washings and transfers) contained 8.9g of Co<sub>2</sub>(CO)<sub>8</sub>. It is kept in a closed pressure-adjusted Pyrex bottle and aliquots siphoned as required because it decomposes slowly to liberate CO in an open vessel and should be stored in the cold. The solubility of the catalyst in Et<sub>2</sub>O at ambient temperature is 7.5g per 100ml of solution. Cobalt on Kieselguhr "Co-100 powder" which contains 12 to 15% of Co can be substituted for Raney Co. [Adkins & Kresk *J Am Chem Soc* **70** 383 1948.] The above preparation can also be

carried out in  $^*C_6H_6$  which has the advantage of being less volatile than  $Et_2O$ , and in which reactions could be carried out at lower temperatures. It has been kept at a concentration of  $1.0 \times 10^{-2}$  M in 50ml of  $^*C_6H_6$ . [Adkins & Kresk *J Am Chem Soc* **71** 3051 1949.] It forms orange-brown *air-sensitive* crystals on recrystallisation from *n*-hexane under a carbon monoxide atmosphere. It has been sublimed *in vacuo* (orange platelets), and is available commercially as a solid moistened with 5-10% of hexane. It is insoluble in  $H_2O$ , but soluble in organic solvents such as alcohols,  $Et_2O$ ,  $^*C_6H_6$ , CS, slowly decomposed by HCl, and  $H_2SO_4$ , but more rapidly by  $HNO_3$ . [Wender et al. *J Am Chem Soc* **71** 4160 1949, Ojima et al. *J Am Chem Soc* **109** 7714 1987; see also Hileman in *Preparative Inorganic Reactions*, Ed. Jolly, Vol 1 p 101 1987].

Carbon monoxide is **VERY POISONOUS** as it complexes with haemoglobin. Great care should be exercised when using the catalyst as well as CO, and all operations should be carried out in an efficient fume cupboard. The **TOXIC LEVEL** of CO is 50ppm ( $\sim 55\text{mg}/\text{m}^3$ ). **The ANTIDOTE should be at hand and always available in laboratories using CO; and staff should be trained to administer it.** On completion of reactions the autoclave should be filled with  $H_2$  at 1000-1300psi and heated at 110-135° for 45 minutes where cobalt compounds are transformed to the metal. If the product of reaction does not contain oxidisable compounds, the mixture is heated in air on a steam bath when copious evolution of CO occurs and the metal is deposited as a cobalt mirror. A third procedure to decompose  $Co_2(CO)_8$  and related CO compounds is to shake or stir the mixture with dilute  $H_2SO_4$  until evolution of gas ceases. [Wender et al. *J Am Chem Soc* **72** 4375 1950.]

**2,6-Di-iso-propylphenylimino-neophylidene[(S)-(-)-BIPHEN]molybdenum(VI)** **{(S)-Schrock-Hoveyda Catalyst; Mo(N-2,6-di-iso-Pr<sub>2</sub>C<sub>6</sub>H<sub>3</sub>)(CHCMe<sub>2</sub>Ph)(syn-(S)-(-)-tert-Bu<sub>2</sub>Me<sub>4</sub>(BIPHEN); molybdenum, [(S- or R-)** 3,3'-bis(1,1'-dimethylethyl)-5,5',6,6'-tetramethyl[1,1'-biphenyl]-2,2'-diolato(2-)-κO,κO'} [2,6-bis(1-methylethyl)benzenaminato(2-)](2-methyl-2-phenylpropylidene)- } [S- 205815-80-1; R- 329735-77-5; RS-300344-02-9] **M 755.9.** The key intermediate is **2,6-di-iso-propylphenylimino-neophylidene-bistriflate-dimethoxyethane-molybdenum (VI) complex** {molybdenum, [2,6-bis(1-methylethyl)benzenaminato(2-)] [1,2-dimethoxy-κO]ethane} [2-methyl-2-phenylpropylidene]bis(1,1,1-trifluoromethanesulfonato-κO)-; [Mo(=N-2,6-isoPr<sub>2</sub>C<sub>6</sub>H<sub>3</sub>)(=CHMePh)-(OTf)<sub>2</sub>-DME] [126949-63-1] which is prepared in three steps. **Firstly** (preferred method): A solution of  $MoO_2Cl_2(THF)_2$  (10.2g, 29.0mmol, see [13637-68-8, 556907-19-8; 12081-12-8]) in DME (200ml) at -30° is stirred vigorously while the following are added sequentially (i) a solution of 2,6-lutidine (12.4g, 116mmol) in DME (10ml at -30°) during 3-5 minutes, (ii) a solution of  $Me_3SiCl$  (31.5g, 290mmol, see [75-77-4]) in DME (40ml, at -30°) over a period of 3-5 minutes, and (iii) a solution of 2,6-di-iso-propylaniline (10.3g, 58mmol, see [24544-04-5]) in DME (15ml at -30°) during 15 minutes. The colour of the solution alters from pale yellow to bright red-orange to deep red-orange as a solid separated. The mixture is stirred as it warmed to room temperature during 6 hours. The mixture is then heated to 50° for 5 hours, filtered through Celite, to remove 2,6-lutidine hydrochloride, which is washed with  $Et_2O$  until the washings are clear; all filtrates are combined and evaporated *in vacuo* to give *bis(2,6-di-iso-propylphenylimino)dichloro-dimethoxyethane molybdenum* [Mo(=N-2,6-isoPr<sub>2</sub>C<sub>6</sub>H<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>DME] (16.7g, 27.5 mmol, 95%) as a brick red solid which is almost of analytical purity (elemental C, H, N and Cl for  $MoC_{28}H_{44}Cl_2N_2O_2$ ), and used in the next step. Its <sup>1</sup>H NMR (400MHz, C<sub>6</sub>D<sub>6</sub>, TMS) has δ at 7.01 (d, 4, arom H<sub>m</sub>), 6.89 (t, 2, arom H<sub>p</sub>), 4.29 (sept, 4, CHMe<sub>2</sub>), 3.44 (s, 6, MeOCH<sub>2</sub>CH<sub>2</sub>OMe), 3.18 (s, 4, MeOCH<sub>2</sub>CH<sub>2</sub>OMe), 1.25 (d, 24, CHMe<sub>2</sub>) and the <sup>13</sup>C NMR (100MHz, C<sub>6</sub>D<sub>6</sub>, TMS) has δ at 154.1 (arom C<sub>ipso</sub>), 145.5 (arom C<sub>p</sub>), 128.0 (arom C<sub>m</sub>), 123.9 (arom C<sub>o</sub>), 71.3 (MeOCH<sub>2</sub>CH<sub>2</sub>OMe), 62.8 (MeOCH<sub>2</sub>CH<sub>2</sub>OMe), 28.2 (CHMe<sub>2</sub>), 25.2 (CHMe<sub>2</sub>). **Secondly:** Neophyl magnesium chloride (100ml, 0.5M, 50mmol, see [35293-35-7]) in  $Et_2O$  is added dropwise to a stirred solution of the preceding complex [Mo(=N-2,6-isoPr<sub>2</sub>C<sub>6</sub>H<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>DME] (15.1g, 25mmol) in  $Et_2O$  (250ml) at -30° (all the complex need not have dissolved). The colour of the solution alters from red to orange as  $MgCl_2$  separates, the mixture is allowed to thaw to 25° and is stirred at this temperature for 3 hours. The mixture is filtered through Celite, the filtrate is concentrated *in vacuo*, kept at -40° to provide orange crystals (usually three crops) of almost analytically pure (elemental C, H and N for  $MoC_{44}H_{60}N_2$ ) *bis(2,6-di-iso-propylphenylimino)-bis(neophyl) molybdenum* [Mo(=N-2,6-isoPr<sub>2</sub>C<sub>6</sub>H<sub>3</sub>)<sub>2</sub>(-CH<sub>2</sub>C Me<sub>2</sub>Ph)<sub>2</sub>] (14.3g, 80%). Its <sup>1</sup>H NMR (400MHz, C<sub>6</sub>D<sub>6</sub>, TMS) has δ at 7.45 (d, 4H, aromatic), 7.24 (t, 4H, aromatic), 7.10 (t, 2H, aromatic), 7.00-6.92 (m, 6H, aromatic), 3.65 (sept, 4H, CHMe<sub>2</sub>), 1.72 (s, 4H, CH<sub>2</sub>CMe<sub>2</sub>Ph), 1.49 (s, 12H, CH<sub>2</sub>CMe<sub>2</sub>Ph), 1.11 (d, 24H, CHMe<sub>2</sub>) and the <sup>13</sup>C NMR (100MHz, C<sub>6</sub>D<sub>6</sub>, TMS) has δ at 153.3, 142.7, 128.6, 126.8, 126.4, 126.0, 123.2, 78.6, 39.5, 32.0, 27.9, 23.5. **Thirdly:** A solution of triflic acid (4.42g, 29.45mmol) in DME (15ml) is added slowly to an orange solution of the preceding

Mo(=N-2,6-isoPr<sub>2</sub>C<sub>6</sub>H<sub>3</sub>)<sub>2</sub>(-CH<sub>2</sub>CMe<sub>2</sub>Ph)<sub>2</sub> (14.2g, 20mmol) in DME (150ml) at -30°, then allowed to thaw to ~25°, stirred overnight, and the deep yellow solution is evaporated to dryness *in vacuo*. The yellow residue is extracted with chilled (~0°) toluene (100ml), filtered, evaporated *in vacuo*, and the dark yellow residue is recrystallised from Et<sub>2</sub>O to provide the desired almost analytically pure (elemental C, H, and N for MoC<sub>28</sub>H<sub>39</sub>F<sub>6</sub>NO<sub>8</sub>S<sub>2</sub>) key intermediate 2,6-di-iso-propylphenylimino-neophylidene-bis(triflate)-dimethoxyethane molybdenum(IV) complex [Mo(=N-2,6-isoPr<sub>2</sub>C<sub>6</sub>H<sub>3</sub>)(=CHMePh)(OTf)<sub>2</sub>DME] (5.94g, 76%, in three crops). Its <sup>1</sup>H NMR (400MHz, C<sub>6</sub>D<sub>6</sub>, TMS) has δ at 14.45 (s, 1H, CHCMe<sub>2</sub>Ph), 7.57 (d, 2H, aromatic), 7.18 (t, 2H, aromatic), 6.97-6.89 (m, 4H, aromatic), 3.84 (sept, 2H, CHMe<sub>2</sub>), 3.73 (s, 3H, OCH<sub>3</sub>), 3.18 (m, 2H, OCH<sub>2</sub>), 2.84-2.78 (m, 5H, OCH<sub>3</sub>, OCH<sub>2</sub>), 1.91 (s, 6H, CHCMe<sub>2</sub>Ph), 1.37 (d, 6H, CHMe<sub>2</sub>), 1.21 (d, 6H, CHMe<sub>2</sub>) and the <sup>13</sup>C NMR (100MHz, C<sub>6</sub>D<sub>6</sub>, TMS) has δ at 328.4, 152.1, 151.8, 148.7, 130.6, 128.7, 126.6, 124.3, 72.8, 70.0, 65.7, 61.9, 58.8, 31.1, 28.3, 25.6, 22.8. [Schrock et al. *J Am Chem Soc* **112** 3875 1990.]

The Schrock-Hoveyda catalyst is prepared in a glove box or in Schlenk equipment under an argon or N<sub>2</sub> atmosphere by adding solid KH (360mg, 9mmol, 3 equivalents) in portions to a stirred solution of H<sub>2</sub>[S-BIPHEN] (1.06g, 3mmol, see [R- 329735-68-4, S- 205927-03-3, RS- 101203-31-0] in Part 2) in THF (100ml), whereby H<sub>2</sub> gas evolves while the K<sub>2</sub>[BIPHEN] salt is being formed. After stirring for 18 hours at ~25°, the suspension is filtered through Celite to remove excess of KH, and the key intermediate above [Mo(=N-2,6-isoPr<sub>2</sub>C<sub>6</sub>H<sub>3</sub>)(=CHMePh)(OTf)<sub>2</sub>DME] (2.24g, 2.83mmol, 0.94 equivalents) is added as a solid during 2 minutes. The mixture is stirred for 3 hours at ~25°, the volatiles are removed *in vacuo*, and the residual red powder is treated with \*C<sub>6</sub>H<sub>6</sub> (40ml), and the slurry is filtered through Celite to remove insoluble CF<sub>3</sub>SO<sub>3</sub>K and washed with \*C<sub>6</sub>H<sub>6</sub> until the washings are no longer red in colour. The red \*C<sub>6</sub>H<sub>6</sub> solutions are combined, evaporated *in vacuo*, and the spongy red solid is recrystallised from Et<sub>2</sub>O (~4ml) to give the desired catalyst, mainly in the *syn* configuration at the alkylidene group, as dark orange red crystals (1.35g, 64%). Its <sup>1</sup>H NMR (400MHz, \*C<sub>6</sub>D<sub>6</sub>, TMS) has δ at 10.98 (s, 1H, J<sub>CH</sub> = 123Hz, *syn* alkylidene C=CHCMe<sub>2</sub>Ph), 7.42 (m, 3H, biphenyl and Ph CHs), 7.16 (m, 3H, biphenyl and Ph CHs), 7.05 (br t, J = 7.6Hz, 1H, aromatic), 6.92 (s, 3H, aromatic), 3.70 (heptet, J = 7.0Hz, 2H, *iso*-CHMe<sub>2</sub>), 2.13 (s, 3H), 2.15 (s, 3H), 1.85 (s, 3H), 1.74 (s, 3H), 1.66 (s, 3H) {these signals 2.13—1.66 ppm are from 4 biphenyl-Mes and one methyl from CMeMePh}, 1.59 (s, 9H, *tert*-CMe<sub>3</sub>), 1.54 (s, 9H, *tert*-CMe<sub>3</sub>), 1.14 (d, J = 7.0Hz, 6H, *iso*-CHMe<sub>2</sub>), 1.13 (s, 3H, CMeMePh), 0.90 (d, J = 7.0Hz, 6H, *iso*-CHMe<sub>2</sub>), and the <sup>13</sup>C{<sup>1</sup>H} NMR (100MHz, C<sub>6</sub>D<sub>6</sub>, TMS) has δ at 277.1 (d, J<sub>CH</sub> = 123Hz, *syn* alkylidene carbon), 155.4, 154.5, 154.3, 151.3, 146.8, 140.0, 138.0, 136.5, 135.7, 132.0, 131.1, 130.9, 130.6, 129.6, 128.2, 127.9, 126.3, 123.8, 53.7, 35.95, 35.7, 34.7, 33.1, 33.0, 30.9, 30.4, 29.2, 24.6, 23.0, 20.8, 20.7, 17.2, 16.7, 14.6. [Alexander et al. *J Am Chem Soc* **120** 4041 1998.] See also a slightly modified preparation in which the red spongy powder is dissolved in Et<sub>2</sub>O (18ml), transferred to a 20ml vial, kept uncapped in a well purged glovebox (with N<sub>2</sub>) until the volume decreased to 5ml, the red solution is decanted from the red crystal blocks which were washed with cold Et<sub>2</sub>O and dried *in vacuo* to provide a 72% yield of analytically pure (elemental C, H, and N for MoC<sub>46</sub>H<sub>61</sub>NO<sub>2</sub>) *syn*-(*S*)-catalyst. The X-ray crystal structure proved the absolute configuration of the biphenolate ligand. Related complexes in which the 2,6-di-iso-propylphenylimino ligand is replaced by various other ligands have been similarly prepared. [Alexander et al. *Organometallics* **19** 3700 2000.] Schrock-Hoveyda catalysts with *R*-BIPHEN and *racemic*-BIPHEN also form red crystals, and have been similarly prepared. All are *air* and *moisture sensitive*, and have to be stored cold and in the dark. NMR data revealed that the *syn*-alkylidene conformer predominates in solution with a *syn-anti* exchange rate of ~1 s<sup>-1</sup>. However, evidence from ROM (ring-opening metathesis) polymerisation suggests that reactions with the *anti* conformer are catalytically more active than with the *syn* conformer by some orders of magnitude [Oskam & Schrock *J Am Chem Soc* **115** 11831 1993].

The related catalyst where the *tert*-buyl groups in the biphenol ligand are replaced by 1-adamantyl groups Mo(*N*-2,6-di-iso-Pr<sub>2</sub>C<sub>6</sub>H<sub>3</sub>)(CHCMe<sub>2</sub>Ph)(*syn*-(*S*)-*tert*-Bu<sub>2</sub>Me<sub>4</sub>(BIAD)) has been prepared in 54% yield as orange crystals from the above key intermediate [Mo(=N-2,6-isoPr<sub>2</sub>C<sub>6</sub>H<sub>3</sub>)(=CHMePh)(OTf)<sub>2</sub>DME] and (*S*)-H<sub>2</sub>(BIAD) (see in Part 2) except that benzylpotassium was used instead of KH to prepare the phenolate salt. X-ray crystallography of the catalyst also confirmed the *S*-absolute configuration of (-)-H<sub>2</sub>(BIAD). [Alexander et al. *Organometallics* **19** 3700 2000; and for the X-ray crystallographic structures of related Mo-2,2'-dihydroxy-1,1'-

biaryls see Totland et al. *Macromolecules* **29** 6114 1996.]

These and related chiral molybdenum complexes are remarkable catalysts that effect efficient asymmetric enantioselective ring-closing olefin metathesis (RCM) [Alexander et al. *J Am Chem Soc* **120** 4041 1998, Weatherhead et al. *Tetrahedron Lett* **41** 9553 2000], ring-opening metathesis/cross metathesis (ROM/CM) [La et al. *J Am Chem Soc* **123** 7767 2001], as well as ring-opening olefin metathesis (ROM) polymerisation [Totland et al. *Macromolecules* **29** 6114 1996] reactions. These complexes catalyse olefin metathesis reactions in which the starting olefin is a racemic mixture, and in the reaction process *kinetic resolution* occurs, whereby the products, and any unreacted starting material, are of one chirality, i.e. the asymmetric centre in the racemic mixture is converted into one enantiomer at the expense of the other enantiomer. The above Mo-(S)-[BIPHEN] complex also catalyses efficient and enantioselective *desymmetrisation* reactions, e.g. ( $\pm$ )-3-allyloxy-2,4-dimethylpenta-1,4-diene and its 1,5-dimethyl derivative (4-allyloxy-3,5-dimethyl-hepta-2,5-diene) are cyclised to 2-(prop-2'-en-2'yl)-3(R)-methyl-2,5-dihydrofuran and 2-(but-2-en-2-yl)-3(R)-methyl-2,5-dihydro-furan in the absence of solvent, 1-2 mol% catalyst, at 22° in 5 minutes in 85% and 93% yields, and 93%ee and 99%ee respectively [La et al. *J Am Chem Soc* **120** 9720 1998]. [For a review on olefin metathesis see Grubbs *Tetrahedron* **60** 7117 2004, and R.H. Grubbs (Ed.), *Handbook of Metathesis*, Vols 1-3, Wiley-VCH, 2003. ISBN 3527306161.]

**Ferric (III) acetylacetonate [Fe(acac)<sub>3</sub>, iron(III) tris(2,4-pentadionate)]** [14024-18-1] **M 353.2, m 181.3-182.3°**. When recrystallised twice from \*benzene/petroleum ether, it has **m** 181.3-182.3° corr [Finn et al. *J Chem Soc* 1256 1938]. However, when recrystallised from EtOH or Et<sub>2</sub>O it has **m** 179° [Hantzsch & Desch *Justus Liebigs Ann Chem* **323** 13 1902]. Recrystallisation from absolute EtOH also gives material with **m** 159.5° [Emmert & Jacob *Chem Ber* **67** 286 1934]. Dry it for 1 hour at 120°. [*Beilstein* **1** I 404, **1** II 836, **1** IV 3675.]

Fe(acac)<sub>3</sub> catalyses a large variety of chemical reactions such as aromatic substitution, cross-coupling, Friedel-Crafts etc [see B. Pleitker (ed), *Iron Catalysis in Organic Chemistry* Wiley-VCH, 2008, ISBN 978-3-527-31927].

**Ferrous (II) acetylacetonate [Fe(acac)<sub>2</sub>, iron(II) bis(2,4-pentadionate)]** [14024-17-0] **M 254.1, m 175°**. For catalytic properties see B. Pleitker (ed), *Iron Catalysis in Organic Chemistry* Wiley-VCH, 2008, ISBN 978-3-527-31927, and for the preparation see Chapter 5, Metal-Organic Compounds. [*Beilstein* **1** III 3122, **1** IV 3676]

**Iridium(I) bis(1,5-cyclooctadiene) tetrafluoroborate complex [bis(1,5-cyclooctadiene)iridium (I) tetrafluoroborate, Ir(COD)<sub>2</sub><sup>+</sup>.BF<sub>4</sub><sup>-</sup>]** [35138-23-9] **M 495.4, m ~190° (dec)**. This iridium complex is prepared and purified exactly as for the corresponding Rh(COD)<sub>2</sub><sup>+</sup>.BF<sub>4</sub><sup>-</sup> [35138-22-8, below] from the dimer {[Ir(COD)Cl]<sub>2</sub> [12112-67-3] below, Herde et al. *Inorg Synth* **15** 18 1974]} with COD and AgBF<sub>4</sub> in 93% yield. [Schenck et al. *Inorg Chem* **24** 2334 1985.]

**Iridium(I) chloride 1,5-cyclooctadiene complex dimer {chloro(1,5-cyclooctadiene)iridium dimer, di- $\mu$ -chlorobis[(1,2,5,6- $\eta$ )-1,5-cyclooctadiene]diiridium (I), [Ir(COD)Cl]<sub>2</sub>}** [12112-67-3] **M 671.7, m 205°(dec)**. The complex is an orange-red, air-stable solid that is soluble in \*C<sub>6</sub>H<sub>6</sub> and CHCl<sub>3</sub>, less so in Me<sub>2</sub>CO and insoluble in Et<sub>2</sub>O. It can be prepared from IrCl<sub>3</sub>.3H<sub>2</sub>O (3g) in 95% EtOH (34ml), H<sub>2</sub>O (17ml) and cycloocta-1,5-diene (6ml), through which is bubbled (with magnetic stirring) a slow stream of N<sub>2</sub> while boiling under reflux for 24 hours, during which time a brick-red product precipitates. The mixture is cooled and Ir(COD)Cl<sub>2</sub> is filtered off, washed with ice-cold MeOH to remove unreacted COD and dried *in vacuo* at 25° for 8 hour (yield 1.5g, 72%, decomp >200°). [Herde et al. *Inorg Synth* **15** 18 1974.] Alternatively, to a mixture of H<sub>2</sub>O (100ml), isoPrOH (35ml) and 1,5-cyclooctadiene (18ml) is added (NH<sub>4</sub>)<sub>2</sub>IrCl<sub>6</sub> (20g), and the mixture is refluxed under N<sub>2</sub> for 18 hours when the colour changes to orange-red, and a red or orange solid separated on cooling. This is filtered off (frit), and washed with EtOH (2 x 5ml at 0°) to give the complex in high purity (14.0g, 92%). Recrystallisation (if required) is best carried out by slowly adding an equal volume of EtOH to a saturated stirred solution of the solid in CH<sub>2</sub>Cl<sub>2</sub>, followed by gentle removal of half of the mixed solvent under reduced pressure. The stirred solution is cooled spontaneously to -30° during the process and the complex is filtered off, washed with EtOH (2 x 5ml at 0°) and dried *in vacuo*. It is identified by the characteristic IR bands (Nujol) at 907, 970, 980 and 1002 cm<sup>-1</sup>; and the vinyl CH resonance in the <sup>1</sup>H NMR (CDCl<sub>3</sub>) spectrum at  $\delta$  4.3. [Crabtree et al. *Synth React Inorg Met-Org Chem* **12** 407 1982.]

It is the metal complex precursor with allyamines for asymmetric allylic substitutions; for resting state and kinetic studies [cf Markovic & Hartwig *J Am Chem Soc* **129** 11680 2007].

**Iridium(I) (1,5-cyclooctadiene)- $\eta^5$ -(indenyl) {(1,5-cyclooctadiene)- $\eta^5$ -(indenyl)iridium (I), [(COD)(C<sub>9</sub>H<sub>7</sub>)Ir(I)], [(Ind)Ir(I) (COD)]}** [102525-11-1] **M 414.5, m 126-131°**. The complex is obtained by adding solid indenyllithium (0.73g, 5.98mmol) to a solution of the preceding dimer [Ir(COD)Cl]<sub>2</sub> (2.0g, 2.98mmol) in THF (50ml) and stirring at ~20° for 1 hour. The solvent is removed *in vacuo*, extracted with pentane (6 x 50ml) and the combined extracts are slowly evaporated to deposit pale yellow crystals (2.15g, 86%). It has <sup>1</sup>H NMR (200MHz) with  $\delta$  at 1.65-1.86 (m, 8H, COD CH<sub>2</sub>), 3.99 (m, 4H, COD CH), 5.00 (d, 2H, indenyl H1/H3), 5.76 (t, 1H, indenyl H2), 6.98-7.16 (m, 4H, indenyl H4-H7); and <sup>13</sup>C NMR (50MHz) with  $\delta$  at 34.36 (COD CH<sub>2</sub>), 51.35 (COD CH), 72.80 (indenyl C1/C3), 85.15 (indenyl C2), 110.23 (indenyl C8/C9), 121.75 and 124.89 (indenyl C4-C7). [Merola & Kacmarcik *Oganometallics* **8** 778 1989, Abad *Inorg Chim Acta* **121** 213 1986, Crabtree et al. *Synth React Inorg Met-Org Chem* **12** 407 1982, Naderer Siebel *Organomet Chem* **518** 181 1996.] [Uson & Oro *Inorg Synth* **23** 126 1985.]

[(Ind)Ir(I) (COD)] is a powerful C-H activation catalyst for preparing phenols from arenes in the presence of pinacolborane and bis(diphenylphosphino)ethane that borylate arenes to the intermediate pinacol arylboryl esters which are then converted to the respective phenols by reaction with *oxone* [2KHSO<sub>5</sub>.KHSO<sub>4</sub>. K<sub>2</sub>SO<sub>4</sub>] in Me<sub>2</sub>CO at 25° within ~7 minutes in 51 to 88% yields depending on the substituents [Maleczka et al. *J Am Chem Soc* **125** 7792 2003.]

**Iridium(I)  $\mu$ -chloro-bis(cyclooctene) dimer {di- $\mu$ -chlorotetrakis(cyclooctene)diiridium(I), [Ir(COE)<sub>2</sub>Cl]<sub>2</sub>}** [12246-51-4] **M 967.2, m 150°(dec)**. This solid yellow iridium complex is air sensitive and decomposes to a dark green solid which eventually turns black. However, it can be stored *in vacuo* in a desiccator for prolonged periods of time. It is preferable to store it in aliquots in sealed ampoules under an inert atmosphere or in a vacuum. It is soluble in Me<sub>2</sub>CO, CHCl<sub>3</sub> and \*C<sub>6</sub>H<sub>6</sub>, but it oxidises more readily in solution than in the solid state, and the necessary precautions to strictly exclude air should be exercised.

It is prepared by stirring (stirrer bar) a mixture IrCl<sub>3</sub>.3H<sub>2</sub>O (2.0g), *iso*-propanol (22ml), H<sub>2</sub>O (8ml) and cyclooctene (40ml), while a slow stream of dry N<sub>2</sub> is bubbled through the solution, and refluxed at 78° for 3 hours. During this time the colour of the solution changes from dark red to orange-yellow and the complex separates from the solution which is cooled to ~25°. It is collected rapidly by filtration, washed rapidly with ice-cold MeOH to remove excess of cyclohexene (this is done preferably in a dry box under N<sub>2</sub>). Drying *in vacuo* at 25° for 4 hours gives pure di- $\mu$ -chlorotetrakis(cyclooctene)diiridium(I) (1.5g, 59%), which decomposes at 150° and has the correct elemental analysis for C, H, Cl and Ir. [Herde et al. *Inorg Synth* **15** 18 1974, Herde & Senoff *Inorg Nucl Chem Lett* **7** 1029 1971.] By using (NH<sub>4</sub>)<sub>3</sub>IrCl<sub>6</sub> (6g) suspended in an oxygen-free suspension of *iso*-PrOH (30ml) and H<sub>2</sub>O (90ml), and cyclooctene (12ml), and refluxing with stirring for 3-4 hours under N<sub>2</sub>, followed by cooling, provides an orange oil which solidifies, is collected, washed with cold EtOH, and allowed to crystallise from EtOH, collected, dried *in vacuo*, all under N<sub>2</sub>, to give of the [Ir(COE)<sub>2</sub>Cl]<sub>2</sub> (80-92% yield) as yellow needles. It should be stored under N<sub>2</sub> at room temperature. [van der Ent & Onderdelinden *Inorg Synth* **28** 91 1989.]

Although this compound is air sensitive, with the correct stoichiometry, it forms a less sensitive stable tris-boryl complex with pinacolborane (Bpin) and 4,4'-di-*tert*-butyl-2,2'-dipyridine (dtbpy) which has been crystallised, and its X-ray analysis shows that it has the composition [Ir(dtbpy)(COE)(Bpin)<sub>3</sub>]<sup>‡</sup>. These complexes are catalytically active in the C-H borylation of arenes. Thus dissolution of the latter complex in \*C<sub>6</sub>D<sub>6</sub> (or \*C<sub>6</sub>H<sub>6</sub>) provided \*C<sub>6</sub>D<sub>5</sub>-Bpin within minutes at room temperature and in 80% yield. Kinetic studies revealed a kinetic isotope effect *k<sub>H</sub>/k<sub>D</sub>* of 3.8. The iridium complexes containing dtbpy are easily prepared and are air-stable. The reaction of bis(pinacolato)diboron (B<sub>2</sub>pin<sub>2</sub>) and ½[IrCl(COE)<sub>2</sub>]<sub>2</sub>/dtbpy (5 mol% of Ir) in 60 equivalents of \*C<sub>6</sub>H<sub>6</sub> at 25° for 4.5 hours gives Ph-Bpin in 83% yield; and with ½[IrCl(COE)<sub>2</sub>]<sub>2</sub>/dtbpy (0.02 mol% of Ir) at 100° for 16 hours gives Ph-Bpin in 80% yield with 8000 turnovers. These catalysts provide a simple and direct route for the synthesis of arylboronates—which were previously obtained by transmetalation with aryl lithium or arylmagnesium reagents and trialkylborates. [Ishiyama et al. *J Am Chem Soc* **124** 390 2002, cf Ishiyama et al. *Angew Chem In Ed* **41** 3056 2002.]

<sup>‡</sup>[Ir(dtbpy)(COE)(Bpin)<sub>3</sub>] is prepared in a dry box under N<sub>2</sub>; a glass flask containing a mixture of [Ir(COE)<sub>2</sub>Cl]<sub>2</sub> (350mg, 390mmol), dtbpy (209mg, 778mmol) and B<sub>2</sub>pin<sub>2</sub> (494mg, 1.95mmol), to which is added mesitylene (or xylene) (50ml) and heated with very slow stirring at 50° for 5 hours. The solvent is evaporated off at ~25°, the residue is dissolved in Et<sub>2</sub>O and allowed to evaporate slowly at ~25° to afford red cubes (blocks) of the complex

in 28% yield (52mg). Its  $^1\text{H}$  NMR (400MHz, cyclohexane- $d_{12}$ ) has  $\delta$  at 1.15 (s, 12H), 1.17 (s, 12H), 1.18 (s, 12H), 1.33 (m, 12H), 1.41 (s, 18H), 3.74 (d, 2H,  $J = 10.8\text{Hz}$ ), 7.09 (dd, 2H,  $J = 6.4, 2.0\text{Hz}$ ), 7.93 (s, 2H), 9.45 (d, 2H,  $J = 6.4\text{Hz}$ ) from  $\text{Me}_4\text{Si}$ ; and its  $^{11}\text{B}$  NMR (128MHz,  $\text{CDCl}_3$ ) has  $\delta$  at 37 from external  $\text{BF}_3\text{OEt}_2$ . [Ishiyama et al. *J Am Chem Soc* **124** 390 2002.]

**Iridium(I) (methoxy)(1,5-cyclooctadiene) dimer {bis( $\eta^4$ -1,5-cyclooctadiene) di- $\mu$ -methoxy diiridium (I) dimer,  $[(\text{COD})(\text{OMe})\text{Ir}(\text{I})]_2$ } [12148-71-9] M 662.9, m 154-179° (dec). Deoxygenated solvents should be used and reactions should be carried out under  $\text{N}_2$  or argon. The methoxylated catalyst is prepared in Schlenk equipment in an inert atmosphere by adding a suspension of  $[\text{Ir}(\text{COD})\text{Cl}]_2$  (148mg, 222mmol, [12112-67-3]) in MeOH (10ml) to KOH (25mg, 445mmol) in MeOH (5ml), whereby the colour becomes orange-red and a yellow crystalline solid is formed. Stir for 30 minutes then add  $\text{H}_2\text{O}$  (40ml), collect the solid, wash it with  $\text{H}_2\text{O}$  (6 x 5ml), and dry it over  $\text{P}_2\text{O}_5$  *in vacuo* to give  $[\text{Ir}(\text{COD})(\text{OMe})]_2$  (124mg, 85%, decomposing at 145-155° becoming black at 155°) as a yellow air-stable solid. It is soluble in chlorinated solvents to give solutions which are air sensitive. It is soluble in MeOH,  $\text{Me}_2\text{CO}$ , hexane,  $^*\text{C}_6\text{H}_6$  and  $\text{Et}_2\text{O}$  but insoluble in  $\text{H}_2\text{O}$ . Its IR (Nujol) has  $\nu_{\text{max}}$  at 1325m, 1300m, 1232w, 1208m, 1172w, 1158w, 1060vs, 1005m, 972s, 913m, 824w, 827w, 811w, 783w, 574s, 560sh, 532m, 512w, 434w, 337m  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR ( $\text{CDCl}_3$ ) has  $\delta$  at 3.57 (8H, vinyl), 2.22 (8H, allylic H), 1.45 (8H, allylic H) and 3.28 (sharp singlet, 6H, MeO). [Uson et al. *Inorg Synth* **23** 127 1981.]**

Alternatively,  $[\text{Ir}(\text{COD})(\text{OMe})]_2$  can be prepared by boiling  $[\text{Ir}(\text{COD})\text{Cl}]_2$  (1g) in MeOH (40ml) under reflux with anhydrous  $\text{Na}_2\text{CO}_3$  (0.6g) for 1 hour, filtering hot, cooling, and the yellow plates of the desired complex are filtered off, washed with MeOH and dried *in vacuo*. [Chatt & Venanzi *J Chem Soc* 4735 1975.]

It has been used successfully, by preparing it *in situ*, on adding NaOMe to the solution containing  $[\text{Ir}(\text{COD})\text{Cl}]_2$  (see below).

$[\text{Ir}(\text{I})(\text{OMe})(\text{COD})]_2$ , like the preceding complex, is a powerful C-H activation catalyst for preparing phenols from arenes in the presence of pinacolborane and 3,3'-di-*tert*-butyl-1,1'-bipyridyl which borylates arenes to the intermediate pinacol arylboronate esters which are then converted to the respective phenols by reaction with *oxone* [ $2\text{KHSO}_5 \cdot \text{KHSO}_4 \cdot \text{K}_2\text{SO}_4$ ] in  $\text{Me}_2\text{CO}$  at 25° within 7 minutes in ~70% yields depending on the substituents [Maleczka et al. *J Am Chem Soc* **125** 7792 2003.] The catalyst, prepared *in situ*, in the presence of bipyridines has been used as in the previous reference for borylation of arenes in high yields and should be useful for preparing arylboronates [Ishiyama et al. *Angew Chem, Int Edn* **41** 3056 2002.]

**Iridium(III) (1,1,1,5,5,5-trifluoroacetylacetonato)(bis-cyclooctene) [(hfacac)(COE) $_2$ Ir]** [58616-58-3] M 620.5, m 96-97°. It is prepared by adding  $\text{Tl}(\text{hfacac})^\ddagger$  (600mg) to a suspension of  $[\text{Ir}(\text{COE})_2\text{Cl}]_2$  (920mg, see above) in pentane (100ml) at ~25°, and stirring for 3 hours then filtering. The red filtrate is concentrated to 10ml, kept at -30° for 24 hours and the red crystals of  $[(\text{hfacac})(\text{COE})_2\text{Ir}]$  (786.5g, 70%) are collected and dried *in vacuo* to give analytically pure complex (C and H). It is a monomeric complex in  $^*\text{C}_6\text{H}_6$  and has IR (KBr) with  $\nu_{\text{max}}$  at 2960m, 2910s, 2840s, 2660w, 1620m, 1580s, 1540s, 1500w, 1440s, 1340s, 1310w, 1250s, 1210w, 1140s, 1040w, 1015w, 970w, 950m, 945w, 910s, 895w, 875w, 860w, 850w, 810m, 795s, 740m, 680s, 630m, 590s, 570m, 545s, 435m  $\text{cm}^{-1}$ ; and the  $^1\text{H}$  NMR (60MHz,  $\text{CDCl}_3$ ) has  $\delta$  at 6.26 (s, 1H), 2.8-2.4 (br m, 4H), 2.3-1.8 (br m, 8H), 1.7-1.3 (br m, 16H) from TMS.

$(\text{Acac})(\text{COE})_2\text{Ir}$  is similarly prepared from  $\text{Tl}(\text{acac})^\ddagger$  {[25955-51-6]. M 303.5, m 134° obtained as for  $\text{Tl}(\text{hfacac})$  below} and  $[\text{Ir}(\text{COE})_2\text{Cl}]_2$  in 86% yield forming orange-yellow crystals with m 114-115°, M 512.6, and has IR (KBr) with  $\nu_{\text{max}}$  at 2970s, 2910s, 2890s, 2830s, 1620m, 1570s, 1540m, 1510s, 1460s, 1440m, 1410w, 1370m, 1340w, 1310w, 1270w, 1185w, 1140w, 1015s, 970w, 930w, 910w  $\text{cm}^{-1}$ ; and the  $^1\text{H}$  NMR (60MHz,  $\text{CDCl}_3$ ) has  $\delta$  at 5.43 (s, 1H), 1.92 (s, 6H), 2.4-1.7 (br m, 8H), 1.7-1.0 (br m, 20H) from TMS. [Diversi et al. *J Organomet Chem* **125** 253 1977.]

$^\ddagger$ Thallium 1,1,1,5,5,5-hexafluoroacetylacetonate  $[\text{Tl}(\text{hfacac})]$  is obtained when to a solution of thallos ethoxide (8g, prepared as in Fieser & Fieser's *Reagents for Organic Synthesis* **2** 407 1969, see [20398-06-5] in Chapter 5, Metal-Organic Compounds] in EtOH (60ml) is added hexafluoroacetylacetone (6.7g, [see 1522-22-1]) at ~25°, and after 30 minutes the solvent is removed *in vacuo* and the residue is washed with pentane and dried to give  $\text{Tl}(\text{hfacac})$  (11.8g, 95%) as a microcrystalline solid. [Ingrosso et al. *J Organomet Chem* **84** 75 1975.]

**Iron(0) 2,2'-bipyridine [bpyFe(0)]** [*bpyFe(1<sup>+</sup>)* 500295-31-8; *bpyFe(2<sup>+</sup>)* 73871-24-6; *bpyFe(3<sup>+</sup>)* 51232-88-3] **M 212.0**. This iron catalyst mediates *ene-carbocyclisations* such as formal [4+4] ene reaction of trienes [Takacs & Anderson *J Am Chem Soc* **109** 2200 1987, Takacs et al. *Tetrahedron* **46** 5507 1990], regio- and chemo-selective diene to olefin cross coupling reactions [Takacs et al. *Organometallics* **5** 2395 1986], stereoselective and regiocontrolled formation of substituted tetrahydropyrans [Takacs et al. *Tetrahedron Lett* **28** 5627 1987]. The “active bpyFe(0) catalyst” is prepared *in situ* from Fe(acac)<sub>2</sub> (see [14024-17-0]) generated by a minimum of 3.0 equivalents of Et<sub>3</sub>Al and Fe(acac)<sub>3</sub> (see [14024-18-1], in \*C<sub>6</sub>H<sub>6</sub> at 0°), and 2,2'-bipyridine (1:1 with respect to Fe, sublimed at 65°/0.01mm) to which is added the olefin(s) at or near room temperature. [The Fe(acac)<sub>3</sub> is recrystallised from EtOH or \*C<sub>6</sub>H<sub>6</sub>/hexanes, dried at 25°/0.01mm, or sublimed at 100°/0.05mm.] Prior to the reduction of the iron, 1.1 equivalents of 2,2'-bipyridine and 10 equivalents of “addend” (furan or 2-methylfuran) are added to the Fe(acac)<sub>3</sub> in \*C<sub>6</sub>H<sub>6</sub>. After reduction, the substrate(s) are added and the reaction is allowed to proceed at 25° and monitored. The “addend” is added mainly to slow down the disproportionation of the active bpyFe(0) into inactive bpy<sub>2</sub>Fe(0) and Fe<sub>metal</sub> [Takacs et al. *Tetrahedron* **46** 5507 1990]. **Note:** The catalytically active 1:1 complex bpyFe(0) has not been isolated, but is assumed to be in solution and is most probably stabilised in solution by coordinating with some entity such as ethylene (derived from Et<sub>3</sub>Al), or perhaps even furan or methylfuran as these are required for its stability (see below).

The reduction of FeCl<sub>3</sub> by 3.1 equivalents of *iso*-PrMgBr in the presence of 1.1 equivalents of 2,2'-bipyridine and 2,3-dimethylbutadiene yields an active catalyst by forming the **bpyFe(0)2,3-butadiene complex** [104714-94-5] in which the olefin may be involved in the reaction [Takacs et al. *Organometallics* **5** 2395 1986].

Carbocyclisations are also mediated by Pd, Ni, Co, and Rh complexes [for bibliography see Takacs et al. *Tetrahedron* **46** 5507 1990]. **Note:** the Fe(0) valence is dubious.

**(2,3-O-Isopropylidene)-2,3-dihydroxy-1,4-bis-(diphenylphosphino)butane (DIOP)** [*4R,5S(-)-* 32305-98-9, *4S,5R(+)-* 37002-48-5] **M 498.5, m 88-89°, 88-90°, [α]<sub>D</sub><sup>19</sup> (-) and (+) 26° (c 2.3, CHCl<sub>3</sub>), also 4R,5S- has [α]<sub>D</sub><sup>22</sup> (-) 12.3° (c 4.6, \*C<sub>6</sub>H<sub>6</sub>), pK<sub>Est</sub> ~0.0**. These are quite stable in air and have been recrystallised from \*C<sub>6</sub>H<sub>6</sub>/petroleum ether. After 2 recrystallisations from EtOH, they are generally pure by TLC on silica gel using Me<sub>2</sub>CO/hexane as solvent. The optical purity can be determined by GC [Chiral Select 1000 column 15m x 0.25mm using He carrier gas (1ml/minute); or Chirasil-L-Val fused silica 25m x 0.25mm] or by HPLC using an (S,S)-Whelk-01 column (5.0μm, 25cm x 0.46cm). [Details of the general preparation of DIOP are described under **3,4-O-isopropylidene-(3S,4S)-dihydroxy-(2R,5R)-bis(diphenylphosphino)hexane (RSSR-dimeDIOP)**, see [258873-45-9]] in Part 2. The rhodium(I) complexes described below catalyse the asymmetric hydrogenation of β-substituted α-acetamidoacrylic acids to the corresponding chiral α-amino acid derivatives with high stereoselectivity. [Kagan & Dang *J Am Chem Soc* **94** 6429 1972.]

The DIOP derived catalysts used are **Rh(I)<sup>+</sup>(DIOP)(COD) X<sup>-</sup>** where X<sup>-</sup> is Cl<sup>-</sup>, BF<sub>4</sub><sup>-</sup>, SbF<sub>6</sub><sup>-</sup> or PF<sub>6</sub><sup>-</sup> and are prepared *in situ* by reaction of Rh(I)<sup>+</sup>(COD)<sub>2</sub> X<sup>-</sup> with the DIOP ligand in a solvent (CH<sub>2</sub>Cl<sub>2</sub>, MeOH, PhCH<sub>3</sub>, THF or \*C<sub>6</sub>H<sub>6</sub>), using a DIOP/Rh ratio of <2 (preferably 1.1:1.0) to avoid the formation of Rh(I)<sup>+</sup>(DIOP)<sub>2</sub> which exhibits very little, if any, catalytic activity due to its inability to coordinate with the olefinic substrate. A **typical hydrogenation** is carried out in a Fisher-Porter tube which is filled (in a dry-box) with the enamide substrate (0.25mmol), the appropriate solvent (5ml), and pre-formed Rh(I)<sup>+</sup>(DIOP)(COD) X<sup>-</sup> [Rh precursor, Rh(I)<sup>+</sup>(COD)<sub>2</sub> X<sup>-</sup> (0.005mol) in the appropriate solvent (3ml), DIOP (0.055ml of 0.1M solution in, e.g. PhCH<sub>3</sub>, 0.0055mmol) and stir for 10 minutes]. After sealing, the tube is removed from the dry-box, placed behind a proper body shield, and *ca* five vacuum/refilling cycles of H<sub>2</sub> are performed. Hydrogenation is performed at room temperature, with the desired pressure of H<sub>2</sub> (1.1 to 50 bar, usually ~30psi), and is stirred vigorously for ~10 hours (but could be up to 60 hours). The reaction is completed by releasing the H<sub>2</sub>, the catalyst is filtered off through a short silica column, and the filtrate is worked up in the appropriate manner. [Kagan & Dang *J Am Chem Soc* **94** 6429 1972, Li & Zhang *J Org Chem* **65** 5871 2000, Yan & RajanBabu *Org Lett* **26** 4137 2000.] A variety of DIOP derivatives have been synthesised and tested with pre-Rh catalyst salts having different X<sup>-</sup> counter ions in several solvents. The combination which gave high yields and ee excesses of ~98% was the all-equatorial **3,4-O-isopropylidene-(3S,4S)-dihydroxy-(2R,5R)-bis(diphenylphosphino)hexane**, i.e. **RSSR-dimeDIOP**, X<sup>-</sup> = BF<sub>4</sub><sup>-</sup> and Rh(I)<sup>+</sup>(COD)<sub>2</sub> BF<sub>4</sub><sup>-</sup> [35138-22-8], in CH<sub>2</sub>Cl<sub>2</sub>, at 20-40psi and 10 hours [Yan & RajanBabu *Org Lett* **26** 4137 2000].

Other examples of the application of Rh-catalysed reactions requiring the DIOP ligand include regioselective hydroformylation of methyl *N*-aminoacrylate [and involving RhH(CO)(DOP)] [Gladiali & Pinna *Tetrahedron*:

*Asymmetry* **1** 693 1990], 1,4-disilylation of  $\alpha$ ,  $\beta$ -unsaturated ketones [Matsumoto & Hayashi *Tetrahedron* **50** 335 1994], the Heck reaction with alkenyl iodides [Sato et al. *Tetrahedron* **50** 371 1994], as well as the asymmetric hydrogenation of enamides [Morimoto et al. *Tetrahedron: Asymmetry* **6** 23 1995, Morimoto et al. *Tetrahedron Asymmetry* **6** 75 1995].

**Lanthanide trifluoromethanesulfonate (triflate) salts.** These behave mostly as water-tolerant *Lewis acids* which catalyse a variety of organic functional group transformations. The lanthanide triflates below have been prepared and purified by the general procedure described here unless otherwise stated. The salts are prepared by adding excess of lanthanide(III) or (IV) oxide (>99% purity, 30mmol) to an aqueous solution of trifluoromethanesulfonic acid (50% v/v, 21.2ml) and heating to boiling for 30 minutes to 1 hour (*alternatively*, at 100° for 2 hours). The mixture is filtered to remove the unreacted oxide. The water is then removed under a vacuum. The resulting hydrated salt is dried by heating under vacuum at 180 to 200° for 48 hours (200°/0.5mm for 40 hours was also reported). These salts are quite hygroscopic and all manipulations of reactions using these salts should be carried out using Schlenk equipment or glove boxes under an inert atmosphere (N<sub>2</sub>, He or Ar) to prevent contamination with H<sub>2</sub>O which will lead to the formation of insoluble lanthanide hydroxides, and to maximise the activity of the catalyst. [Forsberg et al. *J Org Chem* **52** 1017 1987, Kobayashi & Hachiya *J Org Chem* **59** 3590 1994.]

**Cerium(IV) trifluoromethanesulfonate [cerium triflate, Ce(OSO<sub>2</sub>CF<sub>3</sub>)<sub>4</sub> H<sub>2</sub>O, Ce(OTf)<sub>4</sub> H<sub>2</sub>O] [698999-65-4] M 736.4 (anhydrous), slowly decomposes above 120° to give trivalent cerium species.** Preparation of Ce(OTf)<sub>4</sub> from CeO<sub>4</sub> or Ce(OH)<sub>4</sub> and trifluoromethanesulfonic acid as above for lanthanide triflates is usually unsuccessful. It is best prepared by adding, with vigorous stirring, a solution of K<sub>2</sub>CO<sub>3</sub> (17.3g, 120mmol) in H<sub>2</sub>O (95ml) to a solution of cerium(IV) ammonium nitrate (27.4g, 50mmol) [16774-21-3] in H<sub>2</sub>O (80ml), whereupon a pale yellow carbonate separates. This is filtered off and washed several times with H<sub>2</sub>O. CF<sub>3</sub>SO<sub>3</sub>H (triflic acid, 17.7ml, 200mmol) is slowly added at 0° to this “wet” cerium(IV) carbonate whereby it dissolves, and the resulting orange coloured solution is evaporated under reduced pressure, and the residue is dried *in vacuo* at 70° for 10 hours to give Ce(OTf)<sub>4</sub> as a yellow powder (36.2g). [Note that a “wet” carbonate is important as very dry carbonate does not react readily with triflic acid at 0°.] The IR (KBr) has characteristic bands at  $\nu_{S=O}$  1230 and  $\nu_{C-F}$  1010 cm<sup>-1</sup> and it analyses as a *monohydrate* (by Karl Fischer). The salt is hygroscopic and should be stored under N<sub>2</sub> and preferably in aliquots in sealed containers. It is soluble in H<sub>2</sub>O, EtOH, THF, 1,2-dimethoxyethane and dioxane, but almost insoluble in hexane, \*C<sub>6</sub>H<sub>6</sub> and CHCl<sub>3</sub>. It has very good oxidising ability, thus converting benzylic alcohols to aldehydes or ketones, and benzylic type CH<sub>2</sub> to CO, e.g. substituted toluenes to their corresponding benzaldehydes, ethylbenzene to acetophenone and diphenylmethane to benzophenone in high yields. [Imamoto et al. *Chem Lett* 1445 1990]. Ce(OTf)<sub>4</sub> is an efficient catalyst for the ring opening of epoxides with high regio and stereo selectivity. Ring opening, e.g. of styrene oxides (phenyloxiranes), yields essentially *trans* products with the OH, OR or OAc entering groups (when H<sub>2</sub>O, alcohols or AcOH are used) attacking the ‘benzylic carbon’ atom and with high optical purity when the reaction is carried out at ~-10° [e.g. *R*(+)-styrene oxide provides *S*(+)-PhCH(OMe)CH<sub>2</sub>OH]. Ring opening of thiiranes with H<sub>2</sub>O, alcohols or AcOH also yield *trans* products which dimerise to the corresponding dithianes. [Iranpoor et al. *Synth Commun* **28** 347 1998, cf Vougiokas & Kagan *Tetrahedron Lett* **28** 6065 1987.]

**Gadolinium(III) trifluoromethanesulfonate [Gd(OTf)<sub>3</sub>] [52093-29-5] M 604.5, decomposes >120°.** Gd(OTf)<sub>3</sub> is prepared by the general method described above. If suspect, then add aqueous triflic acid (50% v/v) and proceed as above. It catalyses the aminolysis of epoxides in an extraordinarily efficient manner in aprotic solvents (e.g. toluene, CH<sub>2</sub>Cl<sub>2</sub>) with complete *trans* stereoselectivity and high regioselectivity [Chini et al. *Tetrahedron Lett* **35** 433 1994]. It also catalyses the reactions between nitriles and amines to yield a variety of amidines which, depending on the amine, can be used to prepare cyclic amidines, pyrimidines and *s*-triazines [Forsberg et al. *J Org Chem* **52** 1017 1987]. It is a water-tolerant *Lewis acid* used in aldol reactions of silyl enol-ethers and aldehydes in ~79-89% yields (see below) [Kobayashi & Hachiya *J Org Chem* **59** 3590 1994].

**Hafnium(IV) trifluoromethanesulfonate hydrate [Hf(OTf)<sub>4</sub>] [161337-67-3] M 774.8 (anhydrous),**

**m >350°.** Hf(OTf)<sub>4</sub> is prepared by the general method described above. If suspect, then add aqueous triflic acid (50% v/v) and proceed as in the general method above. It is an efficient catalyst in the Fries rearrangement of acyloxy benzene or naphthalene derivatives, and for the regioselective direct acylation of phenol and naphthol derivatives with acid chlorides [Kobayashi et al. *Tetrahedron Lett* **37** 2053 1996]. It is an excellent and recyclable catalyst for mono-nitration of *o*-nitrotoluene [Waller et al. *Tetrahedron Lett* **39** 1641 1998].

**Neodymium(III) trifluoromethanesulfonate [Nd(OTf)<sub>3</sub>] [34622-08-7] M 698.3, decomposes >120°.** Nd(OTf)<sub>3</sub> is prepared by the general method described above. If suspect, then add aqueous triflic acid (50% v/v) and proceed as above. It catalyses the aminolysis of epoxides in an extraordinarily efficient manner in aprotic solvents (e.g. toluene, CH<sub>2</sub>Cl<sub>2</sub>) with complete *trans* stereoselectivity and high regioselectivity [Chini et al. *Tetrahedron Lett* **35** 433 1994]. It also catalyses the reactions between nitriles and amines to yield a variety of amidines, which, depending on the amine, can be used to prepare cyclic amidines, pyrimidines and *s*-triazines [Forsberg et al. *J Org Chem* **52** 1017 1987]. It is a water-tolerant *Lewis acid* used in aldol reactions of silyl enol-ethers and aldehydes in ~83-85% yields (see below) [Kobayashi & Hachiya *J Org Chem* **59** 3590 1994].

**Ytterbium(III) trifluoromethanesulfonate hydrate [Yb(OTf)<sub>3</sub> · x H<sub>2</sub>O] [252976-51-5] M 620.3 (anhydr), decomposes >120°.** Yb(OTf)<sub>3</sub> is prepared by the general method described above. If suspect, then add aqueous triflic acid (50% v/v) and proceed as above. It can be recrystallised from MeCN/CH<sub>2</sub>Cl<sub>2</sub>. It has IR (KBr) bands at 3650, 3350, 2300, 1650, 1300, 1040 cm<sup>-1</sup>; and <sup>13</sup>C NMR (270MHz, D<sub>2</sub>O) at δ 122.4 (q, *J* = 317Hz) using sodium 2,2-dimethyl-2-silapentane-5-sulfonate as internal standard.

It catalyses the aminolysis of epoxides in an extraordinarily efficient manner in aprotic solvents (e.g. toluene, CH<sub>2</sub>Cl<sub>2</sub>) with complete *trans* stereoselectivity and high regioselectivity [Chini et al. *Tetrahedron Lett* **35** 433 1994]. It also catalyses the *trans* addition of indole (at position 3) to epoxides (e.g. to phenoxymethyloxirane) in >50% yields at 60° (42 hours) under pressure (10 Kbar) and was successfully applied for an enantioselective synthesis of (+)-diolmycin A2 [Kotsuki *Tetrahedron Lett* **37** 3727 1996]. Of the ten lanthanide triflates, Yb(OTf)<sub>3</sub> gave the highest yields (> 90%, see above) of condensation products by catalytically activating formaldehyde, and a variety of aldehydes, in hydroformylations and aldol reactions, respectively, with trimethylsilyl enol-ethers in THF at room temperature. All the lanthanide triflates can be recovered from these reactions for re-use. [Kobayashi & Hachiya *J Org Chem* **59** 3590 1994.]

**Methyltrioxorhenium (MTO, trimethylrhenium(VII) trioxide, Me<sub>3</sub>ReO<sub>3</sub>) [70197-13-6] M 249.2, m 110°, 111°, pK<sub>8</sub><sup>25</sup> 7.53.** MTO is an air-stable carbon-rhenium oxide which is prepared from tetramethylrhenium oxide (Me<sub>4</sub>ReO, [53022-70-1]) or trimethylrhenium dioxide (Me<sub>3</sub>ReO<sub>2</sub>, [56090-01-8]) (100mg) in a 1L evacuated bulb, and dry air is admitted up to a pressure of ~760mm (atmospheric). After a few days long needles of Me<sub>3</sub>ReO<sub>3</sub> are formed, and after 4 weeks in excess of 50% yields of the trioxide are obtained. These can be resublimed to analytical purity *in vacuo* (at ~25°/1mm or 65°/0.001mm), have a sharp melting point (110°), are not decomposed in the gas phase <300°. **Alternatively on a larger scale**, silver tetraoxorhenate (14.0g, 39mmol, AgReO<sub>4</sub> [7784-00-1]) is dissolved in MeCN (150ml) followed by addition of Me<sub>3</sub>SiCl (10.8ml, 85mmol, TMSCl [75-77-4]) whereby a white precipitate of AgCl separates and the solution becomes orange in colour. The suspension is treated with Me<sub>4</sub>Sn (6.0ml, 43mmol, [594-27-4]), stirred for 24 hours, filtered into a Schlenk sublimation tube (~0.75L) and evaporated in a vacuum (20mbar), using a liquid N<sub>2</sub> trap (for volatile Sn compounds). A cold finger is then inserted into the tube and the Me<sub>3</sub>SnCl [1066-45-1] is sublimed out at ~25°/20mbar; this compound is removed and the vacuum is increased to 0.01mbar when MTO sublimes out as a yellow-white crystalline solid. Traces of toxic Sn compounds may be present in this MTO (causing a pungent odour), but are removed by spreading it on filter paper in a fume hood for 1-3 hours, and the purity is checked by elemental analysis. MTO (7.8g) is thus obtained in 80% yield. Similar results are obtained on a 100g scale. The recovered Me<sub>3</sub>SnCl can be converted to SnMe<sub>4</sub> by methylating with MeMgCl (23% in THF). High-purity MTO can be obtained by recrystallisation from CH<sub>2</sub>Cl<sub>2</sub>/hexane (73%). The white solid turns gray on standing without alteration in its activity, but can be minimised by storing it away from light under N<sub>2</sub>. The Sn compounds are **HIGHLY TOXIC, and all work should be carried out in an efficient fume cupboard**. [Herrmann & Kratzer *Inorg Synth* **33** 111 2002, Herrmann et al. *Angew Chem, Int Ed. Engl* **36** 2652 1997.]

MTO forms colourless needles which develop a greyish tint on prolonged storage in light. It differs from methylperrhenate in being stable to hydrolysis by H<sub>2</sub>O. It is soluble in MeCN, \*C<sub>6</sub>H<sub>6</sub>, CHCl<sub>3</sub>, EtOH and H<sub>2</sub>O, but sparingly soluble in CS<sub>2</sub> and hexane. Its MS has parent ion peaks of MeReO<sub>3</sub><sup>+</sup> at 248 and 250 mass units for

the species containing  $^{185}\text{Re}$  and  $^{187}\text{Re}$  in a ratio consistent with the relative isotopic abundances. The UV/VIS ( $\text{Et}_2\text{O}$ ) has  $\lambda_{\text{max}}$  ( $\epsilon$ ) at 260nm (1400,  $\text{Lmol}^{-1}\text{cm}^{-1}$ ) and 232nm (1900,  $\text{Lmol}^{-1}\text{cm}^{-1}$ ).  $^1\text{H}$ ,  $^{13}\text{C}$  and  $^{17}\text{O}$  NMR ( $\text{CDCl}_3$ ,  $25^\circ$ ) spectroscopy shows signals with  $\delta_{\text{H}}$  at 2.61 (sharp),  $\delta_{\text{C}}$  at 19.03 ( $^2J = 138\text{Hz}$ , C-H) and  $\delta_{\text{O}}$  at 829 respectively; and the IR (hexachlorobutadiene mull) has  $\nu_{\text{max}}$  at 1360ms (*CH deformation*), 2895 and 2980 (*CH stretching*)  $\text{cm}^{-1}$ ; the IR in gaseous state (at  $70^\circ$ ) has  $\nu_{\text{max}}$  at 1003w(*ReO<sub>3</sub> sym str*), 985w, 975vs, 962vs(*ReO<sub>3</sub> antisym str*), 743mw(*CH<sub>3</sub>-rock*), 574w(*Re-C*), 324w(*ReO<sub>3</sub> deformation*)  $\text{cm}^{-1}$ , and the IR (argon matrix) 1000ms(*ReO<sub>3</sub> sym str*), 970vs and 966m(*ReO<sub>3</sub> antisym str*), 566w(*Re-C*)  $\text{cm}^{-1}$ . Its Raman spectrum in  $\text{CS}_2$  has  $\nu_{\text{max}}$  at 999s(*ReO<sub>3</sub> sym str*)  $\text{cm}^{-1}$ , and in the solid state it has  $\nu_{\text{max}}$  at 999s(*ReO<sub>3</sub> sym str*), 964m(*ReO<sub>3</sub> antisym str*), 530m(*Re-C*), 330m and 242m(*ReO<sub>3</sub> deformation*)  $\text{cm}^{-1}$ . [Beattie & Jones *Inorg Chem* **18** 2318 1979.]

**MTO** is a *catalytic oxygen carrier* in conjunction with an oxidant, e.g.  $\text{H}_2\text{O}_2$ , UHP (urea- $\text{H}_2\text{O}_2$  complex). For example 3.7mmol of 3,4,6-tri-*O*-acetyl-D-glucal in MeOH is oxidised by 7.4mmol of  $\text{H}_2\text{O}_2$  in the presence of a catalytic amount of MTO ( $3.6 \times 10^{-2}$ mmol) at  $\sim 25^\circ$  in 2 hours to give the corresponding  $\beta$ -D-*gluco*- and  $\alpha$ -D-*manno*- pyranosides (2:1) in 78% isolated yields *via* the intermediate epoxide. [Boyd et al. *Green Chem* **5** 679 2003.] **MTO** is a versatile oxidation catalyst and very effective in olefin epoxidation, olefin isomerisation, olefin metathesis, Baeyer-Villiger oxidation of ketones to lactones, aromatic oxidation to *p*-quinones, and in Diels-Alder reactions [Summarised in Herrmann *J Organomet Chem* **500** 149 1995]. It is a catalytic oxidant for the conversion of imines to nitrones [Soldaini et al. *Org Lett* **9** 473 2007, Baldwin & Long *Org Lett* **6** 1653 2004], and catalyses the efficient and stereospecific desulfurisation of thiirane (episulfides) by  $\text{Ph}_3\text{P}$  at  $\sim 25^\circ$ , and more so if MTO is pre-treated with  $\text{H}_2\text{S}$ , probably due to the formation of Re(V)S species as the active catalyst [Jacob & Espenson *JCS, Chem Commun* 1003 1999].

**Molybdenum dioxo bis(2,4-dipentandionato- $\kappa\text{O}_2,\kappa\text{O}_4$ ) [bis(acetylacetonato)dioxomolybdenum (IV), dioxobis(2,4-pentadionato)molybdenum (IV),  $\text{MoO}_2(\text{acac})_2$  [17524-05-9] M 326.2, m 179 $^\circ$ , 184-185 $^\circ$ , 184 $^\circ$  (dec).** This complex is readily prepared by dissolving powdered ammonium *paramolybdate*  $\{(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$ , 3.0g, 2.4mmol, see [12054-85-2]\} in 15% aqueous  $\text{NH}_3$  (6.0ml, or 6.0ml of 58%) with stirring. The clear solution (but if some solid remains undissolved, it will dissolve when nitric acid is finally added) is treated with 2,4-pentanedione (7.0ml, 6.8mmol) with stirring and the colour turns yellow. Concentrated  $\text{HNO}_3$  (5.0ml, d 1.42) is slowly added with stirring to the mixture which warms up and the colour turns greenish yellow. The yellow complex separates as the mixture is allowed to cool to room temperature. After  $\sim 0.5$  hours the solid is filtered off washed well with  $\text{H}_2\text{O}$ , then with EtOH, and dried *in vacuo* to give a 72% yield (4.0g) of the complex which can be increased to 93% if the hot solution is kept in a freezer at  $-10^\circ$  in 18 hours. It can be recrystallised by dissolving  $\sim 2.0$ g in hot 2,4-pentanedione (6.0ml) at  $\sim 90^\circ$  then keeping at  $-10^\circ$  in 18 hours. The yellow crystals are filtered off with suction, washed with EtOH and dried *in vacuo* to give 1.8g of product. Note that if all the 2,4-pentanedione is not removed the crystals slowly develop a reddish tint. It decomposes slowly when stored in air or under fluorescent light, and turns blue. However, it is stable when stored *in vacuo* or under  $\text{N}_2$ . It is insoluble in  $\text{H}_2\text{O}$ , but slightly soluble in EtOH,  $\text{CHCl}_3$ ,  $\text{CH}_2\text{Cl}_2$  and soluble in MeCN. [Chakravarti & Bandyopadhyay *Inorg Synth* **29** 130 1992, and from  $\text{MoO}_3$  and 2,4-pentanedione see Fernelius et al. *Inorg Synth* **6** 146 1960.] Its IR (KBr) has  $\nu_{\text{max}}$  at 1560, 1500, 1350, 1260, 1015, 930 (Mo=O *symm*), 900 (Mo=O *antisymm*), 795, 665, 570 and 445  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR ( $\text{CD}_2\text{Cl}_2$ , TMS) has  $\delta$  at 2.12, 2.14 and 5.83; and the  $^{13}\text{C}$  NMR ( $\text{CD}_2\text{Cl}_2$ , TMS) has  $\delta$  at 196.7, 185.2, 104.9, 28.0 and 25.7.

**$\text{MoO}_2(\text{acac})_2$**  catalyses: (a) the oxidation of primary (e.g. cinnamyl alcohol) or secondary alcohols (e.g. 1-phenylpropan-1-ol) to their respective aldehydes or ketones in high yields using sodium percarbonate (see [15630-89-4]) as oxidant and Adogen 464 (0.2 equivalents, as phase transfer catalyst see [72749-59-8]) in boiling (6-24 hours)  $\text{CH}_2\text{Cl}_2$  [Maignein et al. *Synlett* 439 1996]; (b) the mild and efficient deprotection of acetals (e.g. benzaldehyde dimethyl acetal, dodecanal dimethyl acetal) in  $> 70$ -95% yields using  $\sim 10\%$  of catalyst in MeCN under  $\text{N}_2$  for  $\sim 4$  hours [Kantam et al. *Synth Commun* **25** 2529 1995], (c) the oxidation of 3- $\beta$ -cholesteryl esters to the corresponding 5,6- $\beta$ -epoxides in the presence of isobutyraldehyde and  $\text{O}_2$  in  $\text{CH}_2\text{Cl}_2$  in yields  $> 75\%$  [Kantam et al. *Synth Commun* **24** 961 1994], and (d) the methoxymethylation of primary, secondary and tertiary alcohols (R-OH) to their corresponding methoxymethyl ethers (R-OCH<sub>2</sub>OCH<sub>3</sub>) in 75-95% yields using excess of methylal  $\{\text{CH}_2(\text{OMe})_2$  see [109-87-5]\} in refluxing  $\text{CHCl}_3$  [Kantam & Ssnthi *Synlett* 429 1993].

**(2S)-3-exo-(Morpholino)isborneol [(-)MIB] [287105-48-0] and (2R)-3-exo-(morpholino)iso-borneol [(+)MIB] (Nugent's reagent) M 239.4, m 60-65 $^\circ$ , 65-67 $^\circ$ ,  $[\alpha]_{\text{D}}^{25} \pm 6^\circ$  (c 1, MeOH).** The (2R)-enantiomer is prepared from (2R)(+)-*cis*-3-exo-(amino)isborneol (4.53g, 26.8mmol; Chittenden & Cooper *J Chem Soc C* 49

1970) in DMSO (25ml) and  $\text{Et}_3\text{N}$  (10ml), to which is added dropwise, with stirring, a solution of di(2-bromoethyl) ether (8.07g, ~90% pure, 31.3mmol) in DMSO (20ml). After 72 hours the mixture is poured into  $\text{H}_2\text{O}$  (250ml), basified with aqueous M NaOH (60ml), extracted with  $\text{Et}_2\text{O}$  (3 x 100ml), and the extract is evaporated *in vacuo*. The residue is then dissolved in  $\text{Et}_2\text{O}$ , extracted into aqueous M HCl (50ml), basified with aqueous NaOH and re-extracted into  $\text{Et}_2\text{O}$  which is dried ( $\text{MgSO}_4$ ), filtered, evaporated *in vacuo*, and the residue is dissolved in hot hexanes (4ml/g crude), filtered and cooled to  $-30^\circ$  to give analytically pure (C, H and N) (+)MIB (2.95g, 46%). It is a white crystalline solid, **m 65-67°**, that can be stored at ambient temperature for 3 months with no alteration in spectroscopic properties, or catalytic performance when compared with freshly prepared material. It has  $^1\text{H}$  NMR ( $^*\text{C}_6\text{D}_6$ ) with  $\delta_{\text{H}}$  at 0.69 (s, 3H), 0.73 (m, 1H), 0.88 (m, 1H), 1.04 (s, 3H), 1.31 (td, 1H), 1.52 (m, 1H), 1.67 (d, 1H), 1.99 (d, 1H), 2.13 (br, 2H), 2.31 (br, 2H), 3.32-3.42 (m, 5H total), 3.92 (br d, 1H); and the  $^{13}\text{C}$  NMR ( $^*\text{C}_6\text{D}_6$ ) has  $\delta_{\text{C}}$  at 11.88, 21.10, 22.19, 27.99, 32.56, 45.35, 46.64, 49.52, 66.82, 73.37, 79.03 (and one resonance is too broad to be observed at  $\sim 25^\circ$ ). [Nugent *J Chem Soc. Chem Commun* 1369 1999.]

MIB acts as an efficient catalyst for the enantioselective addition of the ethoxy vinyl zinc reagent to aldehydes providing hydroxy vinyl ethers, which in turn, are easily converted to chiral hydroxy aldehydes [Jeon et al. *Org Lett* 7 1729 2005]. It generally catalyses the addition of organo-zinc reagents (e.g. from transmetalation of allylic boranes with alkylZn compounds) to aldehydes with very high enantiomeric preference, *viz* (*R*)-MIB providing the (*R*)-alcohol from the corresponding aldehyde [Nugent *J Chem Soc. Chem Commun* 1369 1999, Jeon et al. *Org Lett* 7 1729 2005], and this catalytic method has been adopted for the preparation of  $\alpha$ -amino acids [Chen et al. *J Am Chem Soc* 124 12225 2002], of  $\gamma$ -unsubstituted  $\beta$ -amino acids [Lurain & Walsh *J Am Chem Soc* 125 10683 2003] and for epoxy-alcohols with up to three contiguous stereocentres [Lurain et al. *J Am Chem Soc* 126 10683 2004, Lurain et al. *J Org Chem* 70 1262 2005].

**Nickel(II) acetylacetonate**  $[\text{Ni}(\text{acac})_2]$  [3264-82-2] **M 256.9, m 229-230°, b 220-235°/11mm, d<sup>17</sup> 1.455**. It is obtained by adding a solution of acetylacetone (50g, 0.5mole) in MeOH (100ml) to  $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$  (59.4g, 0.25mole) in  $\text{H}_2\text{O}$  (250ml) with stirring, followed by a solution of  $\text{NaOAc} \cdot 3\text{H}_2\text{O}$  (68g, 0.5mole) in  $\text{H}_2\text{O}$  (150ml), heating briefly on a hot plate, cooling in a refrigerator for several hours, and filtering the crystals off. Wash the emerald green solid with  $\text{H}_2\text{O}$ , dry it in a vacuum desiccator and recrystallise it from MeOH. [Charles & Pawlikowski *J Phys Chem* 62 440 1958.] The complex can be conveniently dehydrated by azeotropic distillation with toluene, and the crystals can be isolated by concentrating the toluene solution. [Wilkinson et al. *J Am Chem Soc* 76 1970 1954, *Beilstein* 1 IV 3677.] It is soluble in organic solvents such as EtOH,  $\text{CHCl}_3$ , and  $^*\text{C}_6\text{H}_6$  but insoluble in  $\text{Et}_2\text{O}$  and hexanes. Its UV spectrum has  $\lambda_{\text{max}}$  nm(log $\epsilon$ ) at 265 (4.44) and 298 (4.34) ( $10^{-4}$  M in  $\text{CHCl}_3$ ). It is a *trimer* in the solid state and a *monomer* in the vapour phase. When the metal in  $\text{Ni}(\text{acac})_2$  is coordinated with the carbenes derived from IPr.Cl, IPr. $\text{BF}_4$ , (see below) or related 1,3-dimesityl-imidazolium chloride [141556-45-8], or with tri-*tert*-butylphosphine, it efficiently catalyses the cross-coupling of aryl- and heteroaryl-halides with aryl Grignard reagents [Böhm et al. *Angew Chem. Int Ed* 39 1602 2000].

**Nickel(II) bis(triphenylphosphine) dichloride** [**bis(triphenylphosphine)nickel(II) dichloride**] [14264-16-5] **M 654.2, m 247-250°(dec), 250°(dec)**. It is best prepared by adding  $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$  (2.38g, 10mmol) in  $\text{H}_2\text{O}$  (2ml) to a solution of  $\text{Ph}_3\text{P}$  (5.25g, 20mmol) in glacial AcOH (25ml) when an olive-green precipitate separates, but changes to dark blue crystals after standing in the mother liquors for 24 hours. These are filtered off washed with glacial AcOH and dried in a vacuum desiccator ( $\text{H}_2\text{SO}_4$  and KOH) until AcOH is removed to give 84% of dark blue crystals. [Venanzi *J Chem Soc* 719 1958, Cotton et al. *J Am Chem Soc* 83 344 1961, Kocienski et al. *J Org Chem* 54 1215 1989, *Beilstein* 16 IV 953]. With butyl chloride at 150-180° in a sealed tube followed by crystallisation from BuOH, it provides blue crystals with m 176° of  $[\text{Ni}(\text{BuCl})(\text{Ph}_3\text{P})_2\text{Cl}_2]$ . [Yamamoto *Bull Chem Soc Jpn* 27 501 1954, *Beilstein* 16 IV 953.]

In small amounts it catalyses the formation of terminal alkenes, e.g. from alkyl bromides or iodides in the presence of BuLi/DBU in THF at 25° in 50-80% yields [Jerapoulos & Smith *JCS Chem Commun* 1621 1986]. It also catalyses the replacement of OH groups in allyl alcohols with the alkyl group of alkylmagnesium bromide thus forming a C-C bond, and also causes dehydrohalogenation of alkylhalides to form the corresponding terminal olefin [Chuit et al. *JCS Chem Commun* 1604 1986].

**Nickel(0) bis(1,5-cyclooctadiene)** [**bis-(1,5-cyclooctadiene)nickel(0), Ni(COD)<sub>2</sub>**] [1295-35-8] **M 275.1, m 60°(dec), 142°(dec)**. It is available in sealed ampoules under  $\text{N}_2$ . All procedures should be carried out in a dry box

and in an atmosphere of N<sub>2</sub> or argon in subdued light because the complex is light and oxygen sensitive, and flammable. The solid is washed with dry Et<sub>2</sub>O (under argon) and separates from toluene as yellow crystals. Filter this under argon gas pressure, place the crystals in a container and dry them under a vacuum of 0.01mm to remove adhered toluene, flush with argon and seal them under argon or N<sub>2</sub> in glass ampoules. It catalyses cycloaddition reactions of 1,3-dienes [Semmelhack *Org Reactions* **19** 115 and 178 1972, Wilke et al. *Justus Liebigs Ann Chem* **699** 1 1966, Wender & Jenkins *J Am Chem Soc* **111** 6432 1989, Fieser & Fieser's *Reagents for Org Synth* **4** 33, 16 29, 17 32]. It also catalyses the addition of allyl phenyl sulfide to alkynes leading to 1,4-dienes. The reaction with acetylenes affords high yields, and in the presence of chiral phosphine ligands, with high stereoselectivity. The reaction tolerates a variety of functional groups [Hua et al. *Org Lett* **9** 263 2007].

**SUSPECTED CARCINOGEN.**

**Oxime Palladacycle dimers (Nájera Catalysts, OPs)** are Pd complexes of aromatic oximes, e.g. where palladium(II) is complexed with the oxime nitrogen atom and co-metalated with the *o*-position of the aromatic ring. They catalyse a variety of coupling reactions such as Suzuki-Miyaura, Heck, Stille, Sonogashira (all cross coupling) reactions and the Ullmann (homocoupling) reactions. *Note that the concentration of Pd in the products from Suzuki-Miyaura coupling reactions can be reduced from ~100ppm to 8000ppm by treating the reaction mixture with toluene and 20% aqueous NaHSO<sub>3</sub> at ~60° for ~1 hour* [Bullock, Mitchell and Toczko *Organic Process Research & Development* **12** 896 2008].

**Oximes** are prepared by a common procedure: A solution of the required aryl-ketone (22mmol) in MeOH (10ml) is added to a solution of hydroxylamine hydrochloride (3.06g, 44mmol), anhydrous NaOAc (3.6g, 44mmol) in H<sub>2</sub>O pre-heated at 60° for 1 hour. If some solid separates, add enough MeOH to obtain a clear solution, then stir at this temperature overnight. On cooling to ~25°, the oximes that separate in >90% yield are filtered off, washed with H<sub>2</sub>O and recrystallised to <sup>1</sup>H NMR purity (>98%). *Acetophenone oxime* has **m 59.1-59.7°** (from MeOH then cyclohexane, Pearson & Ball *J Org Chem* **14** 125 1949), *4,4'-dichlorobenzophenone oxime* has **m 135.2-136.9°** (from MeOH, Sieger & Klein *J Org Chem* **22** 953 1957), *4,4'-dihydroxybenzophenone oxime* has **m 266-267°dec.** (from EtOH, Zigeuner & Ziegler *Monatsh für Chemie* **89** 359 1949), *4-hydroxyacetophenone oxime* has **m 144-145°** (from aqueous MeOH), *4-methoxyacetophenone oxime* has **87°** (from petroleum ether, v. Auwers et al. *Chem Ber* **58** 41 1925), *4-methylacetophenone oxime* has **m 87-88°** (from MeOH then cyclohexane, Pearson & Ball *J Org Chem* **14** 125 1949), and *9-fluorenone oxime* has **m 195°, 198°** (yellow crystals from \*C<sub>6</sub>H<sub>6</sub> or xylene, Anet et al. *Can J Chem* **35** 180 1957, Wislicenus & Waldmuller *Chem Ber* **41** 3335 1908).

**Oxime palladacycles** are generally dimers that can be prepared by a general procedure. A solution of the oxime (10mmol) in methanol (20ml) containing NaOAc.3H<sub>2</sub>O (1.63g, 10mmol) is added to a 0.5M solution of Li<sub>2</sub>PdCl<sub>4</sub> (20ml, i.e. 2.62g, 10mmol, see [123334-21-4] in this Chapter Part 2) and stirred at ~25° for 2 to 3 days. Small quantities of precipitate may form and the colour of the reddish black solution turns to yellow. This is filtered and H<sub>2</sub>O (10ml) is added to precipitate the palladacycles as yellow solids (~90% yields) that are filtered off, washed with a little MeOH and H<sub>2</sub>O, and dried *in vacuo*. [Botella & Nájera *J Organomet Chem* **663** 46 2002, Onoue, Minami and Nakagawa *Bull Chem Soc Jpn* **43** 3480 1970; for preparation *via* ligand exchange see Ryabov et al. *Inorg Chem* **31** 3083 1992.] They can be used directly to catalyse reactions, their solubilities vary with the complex, but some can be crystallised from CH<sub>2</sub>Cl<sub>2</sub>-*n*-hexane, \*C<sub>6</sub>H<sub>6</sub>-*n*-hexane or CHCl<sub>3</sub>. They catalyse Heck couplings (in *N*-methylpyrrolidone with Et<sub>3</sub>N as base), Heck couplings under Jeffrey's conditions (DMF with Bu<sub>4</sub>NBr), Sonogashira reactions (with acetylenes in pyrrolidine and CuI), Stille coupling (in toluene), Suzuki coupling (in toluene with K<sub>2</sub>CO<sub>3</sub> as base), and Ullmann-type homocoupling (in DMF, in the necessary presence of hydroquinone), and typical reaction conditions are described [Alonso, Nájera and Pacheco *Org Lett* **2** 1823 2000, Iyer & Ramesh *Tetrahedron Lett* **41** 8981 2000].

**Di-chloro-bis[5-chloro-2-[(4-chlorophenyl)(hydroxyimino)methyl]phenyl-C]-di-palladium {Nájera Catalyst I, di- $\mu$ -chlorobis[5-chloro-2-[(4-chlorophenyl)(hydroxyimino- $\kappa$ N)methyl]phenyl- $\kappa$ C]-palladium (II) dimer}** [287410-78-0] has **M 814.0** and **m 208-210°**. [Alonso, Nájera and Pacheco *Org Lett* **2** 1823 2000].

**Di-chloro-bis[5-hydroxy-2-[1-(hydroxyimino)ethyl]phenyl-C]-di-palladium {Nájera Catalyst II, di- $\mu$ -chlorobis[5-chloro-2-[1-(hydroxyimino- $\kappa$ N)ethyl]phenyl- $\kappa$ C]-palladium(II) dimer}** [419581-64-9] has **M 584.1** and **m >250°, 251-255°**. It has IR (KBr) with  $\nu_{\max}$  at 3425 (OH), 1662 (C=N) cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, DMF-*d*<sub>7</sub>, TMS) has  $\delta_{\text{H}}$  at 9.96 (brs, 2H, 2 x OH), 9.71(brs, 2H, 2 x OH), 7.20 (brs, 2H, ArH), 7.07 (d, *J* = 8.5Hz, 2H, ArH), 6.50 (dd, *J* = 7.9, 2.4 Hz, 2H, ArH), 2.24 (s, 6H, 2 x CH<sub>3</sub>); and its <sup>13</sup>C NMR (75MHz, DMF-*d*<sub>7</sub>, TMS) has  $\delta_{\text{C}}$  at 167.3, 157.4, 152.7, 134.2, 127.2, 123.4, 111.3, 111.1. Botella & Nájera [*J Organomet*

*Chem* **663** 46 2002] obtained high turnover numbers and turnover frequencies in Suzuki-Miyaura cross-coupling reactions at room temperature conditions with this catalyst. Botella & Nájera [*J Org Chem* **70** 4360 2005] also studied this catalyst for Mirozoki-Heck couplings in aqueous *N,N*-dimethylacetamide in air using *N*-methyldicyclohexylamine (see [7560-83-0]) as base with or without Bu<sub>4</sub>NBr.

**Di-chloro-bis[2-[1-(hydroxyimino)ethyl]phenyl-C]-di-palladium {di-μ-chlorobis[2-[1-(hydroxyimino-κN)ethyl]phenyl-κC]-palladium(II) dimer}** [32679-19-9] has **M 568.1** and **m 210°**, **209-212°**. It has IR (KBr) with  $\nu_{\max}$  at 3426 (OH), 1640 (C=N) cm<sup>-1</sup>. [Alonso, Nájera and Pacheco *Org Lett* **2** 1823 2000, Onoue, Minami and Nakagawa *Bull Chem Soc Jpn* **43** 3480 1970.]

**Di-chloro-bis[5-hydroxy-2-[(4-hydroxyphenyl)(hydroxyimino)methyl]phenyl-C]-di-palladium, {di-μ-chlorobis[5-hydroxy-2-[(4-hydroxyphenyl)(hydroxyimino-κN)methyl]phenyl-κC]-palladium(II) dimer}** [419581-64-9] has **M 777.0** and **m >250°**. It has IR (KBr) with  $\nu_{\max}$  at 3405 (OH), 1612 (C=N) cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, DMF-*d*<sub>7</sub>, TMS) has  $\delta_{\text{H}}$  at 10.50-9.40 (brs, 6H, 6 x OH), 7.41 (d, *J* = 8.5Hz, 4H, ArH), 7.26 (brs, 2H, 2 x OH), 7.20 (brs, 2H, ArH), 7.02 (d, *J* = 8.5Hz, 4H, ArH), 6.69 (d, *J* = 8.5Hz, 4H, ArH), 6.48 (dd, *J* = 7.9, 2.7 Hz, 2H, ArH); and its <sup>13</sup>C NMR (75MHz, DMF-*d*<sub>7</sub>, TMS) has  $\delta_{\text{C}}$  at 167.8, 160.0, 157.5, 152.9, 134.3, 131.5, 129.4, 123.7, 121.0, 115.8, 111.5. [Botella & Nájera *J Organomet Chem* **663** 46 2002.]

**Di-chloro-bis[5-chloro-2-[(4-phenyl)(hydroxyimino)methyl]phenyl-C]-di-palladium, {di-μ-chlorobis[5-chloro-2-[(4-phenyl)(hydroxyimino-κN)methyl]phenyl-κC]-palladium(II) dimer}** [1145982-32-6; 30471-18-2 for stereoisomer] has **M 743.0** and **m 139-141°**. It has IR (KBr) with  $\nu_{\max}$  at 3373 (OH), 1645 (C=N), 1569, 1435, 1340, 1024 cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, DMSO-*d*<sub>6</sub>, TMS) has  $\delta_{\text{H}}$  at 6.69 (m, 4H), 7.09 (m, 4H), 7.35-8.10 (m, 10H). [Alonso, Nájera and Pacheco *Org Lett* **2** 1823 2000, Onoue, Minami and Nakagawa *Bull Chem Soc Jpn* **43** 3480 1970.]

**Di-chloro-bis[5-methoxy-2-[(4-methoxyphenyl)(hydroxyimino)methyl]phenyl-C]-di-palladium {di-μ-chlorobis[5-methoxy-2-[(4-methoxyphenyl)(hydroxyimino-κN)methyl]phenyl-κC]-palladium(II) dimer}** [287410-79-1] has **M 803.0** and **m 135-137°**. It has IR (KBr) with  $\nu_{\max}$  at 3390 (OH), 1607 (C=N), 1579, 1559, 1253, 1233, 1177, 1026 cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, DMSO-*d*<sub>6</sub>, TMS) has  $\delta_{\text{H}}$  at 3.71 (s, 6H), 3.83 (s, 6H), 6.71 (m, 4H), 7.08-7.25 (m with d at 7.10, *J* = 8.6Hz, 5H), 7.30-7.55 (m with d at 7.43, *J* = 8.6Hz, 5H). [Alonso, Nájera and Pacheco *Org Lett* **2** 1823 2000].

**Palladium(II) acetate [Pd(OAc)<sub>2</sub>]** [3375-31-3] **M 244.5**, **m 205°(dec.)**, **pK<sub>1</sub><sup>25</sup> 1.0**, **pK<sub>2</sub><sup>25</sup> 1.2 (for Pd<sub>2</sub><sup>2+</sup>)**. It recrystallises from CHCl<sub>3</sub> as purple crystals. It can be washed with AcOH and H<sub>2</sub>O and dried in air. Large crystals are obtained by dissolving it in \*C<sub>6</sub>H<sub>6</sub>, adding half its volume of AcOH and allowing it to evaporate slowly at room temperature. It forms green adducts with nitrogen donors, it dissolves in KI solution to form solid PdI<sub>2</sub> and a red solution of PdI<sub>4</sub><sup>2-</sup>, but is insoluble in aqueous saturated NaCl, and NaOAc. It dissolves in HCl to form PdCl<sub>4</sub><sup>2-</sup>. It is soluble in CHCl<sub>3</sub>, CH<sub>2</sub>Cl<sub>2</sub>, Me<sub>2</sub>CO, MeCN, Et<sub>2</sub>O, but it is insoluble in H<sub>2</sub>O, and decomposes when warmed in alcohols in which it is also insoluble. [Morehouse et al. *Chem Ind (London)* 544 1964, Stephenson et al. *J Chem Soc* 3632 1965, Skapski & Smart *J Chem Soc (D)* 658 1970, Heck *Acc Chem Res* **12** 146 1979.] **Pd(OAc)<sub>2</sub>** should be an orange/red solid. Sometimes **commercial** samples, or old samples, give lower yields in catalytic reactions and it is found that good results are obtained after recrystallisation from \*C<sub>6</sub>H<sub>6</sub> [Anderson et al, *Org Synth* **84** 150 2007].

It is useful as a catalyst for coupling reactions [Kang et al. *J Am Chem Soc* **128** 6194 2006], and is a precursor for preparing heterogeneous and homogeneous catalysts [Jujjuri et al. *J Catal* **239** (2) 486 2006, Xu et al. *J Nano Res* **7** 449 2005].

**Palladium(II) acetylacetonate [Pd(acac)<sub>2</sub>]** [14024-61-4] **M 304.6**, **m 200-250°(dec)**. It can be recrystallised from \*C<sub>6</sub>H<sub>6</sub>/petroleum ether and sublimes *in vacuo*. It is soluble in heptane, \*C<sub>6</sub>H<sub>6</sub> (1.2% at 20°, 2.2 at 40°), toluene (0.56% at 20°, 1.4% at 40°) and acetylacetonate (1.2% at 20°, 0.05% at 40°). [West & Riley *J Inorg Nucl Chem* **5** 295 1957/8, Fernelius & Bryant *Inorg Synth* **V** 105 1957, *Beilstein* **1** IV 3676.] It is a soluble Pd source for the preparation of various soluble Pd catalysts by transferring the metal to a variety of phosphorus and other ligands for homogeneous catalysis [cf *Handbook of Organopalladium for Organic Synthesis* Negishi ed. Wiley, Hoboken NJ 2002, ISBN 0-471-31506-0.]

A complex consisting of Cu 1.10-phenanthroline [which mediates decarboxylation of arylcarboxylic acids with formation of aryl Cu species] and Pd(acac)<sub>2</sub> [for coupling] was made and used to catalyse the decarboxylative cross-coupling of the Cu species with aryl halides. This bimetallic system allows direct coupling of a variety of aryl, heteroaryl or vinyl carboxylic acids with aryl or heteroaryl bromides, chlorides or iodides at 160° in *N*-methylpyrrolidine in the presence of K<sub>2</sub>CO<sub>3</sub>. [Goossen et al. *J Am Chem Soc* **129** 4824 2007].

**Palladium EnCat.** Ley and co-workers [Ramarao et al. *J Chem Soc, Chem Commun* 1132 2002, Pears & Smith *Aldrichimica Acta* **38** 23 2005] have described a method of encapsulating Pd(OAc)<sub>2</sub> in the matrix of 20-250 μm microcapsules prepared from a dispersion of an aromatic polyfunctional isocyanate and Pd(OAc)<sub>2</sub> in CH<sub>2</sub>Cl<sub>2</sub> into H<sub>2</sub>O containing stabilisers and surfactants. At the point when the oily dispersion reaches the desired size, e.g. 20-250 μm, polymerisation is initiated (evolution of heat) whereby part of the isocyanate groups are hydrolyse to carbamate then to amino groups. The latter condense with the unhydrolysed isocyanate groups to form a crosslinked polyurea matrix entrapping the metal catalyst. After the necessary washing etc., polyurea microcapsules (MC average size ~150 μm) are formed which are hard, porous and highly crosslinked spheres. These beads are catalytically active, robust and recyclable and have been used in conventional and supercritical media (e.g. liquid CO<sub>2</sub>). They catalyse MC-[Pd] mediated Heck coupling (*p*-aryl and 4-heteroaryl nitro, methoxy and fluoro compounds with acrylic esters), carbonylation of 4-substituted arenes or heterocycles, Suzuki-type (ArB(OH)<sub>2</sub> + Ar to form crossed biaryls) and Stille couplings without requiring supplementary ligands [Ley et al. *J Chem Soc, Chem Commun* 1134 2002]. For **EnPd(OAc)<sub>2</sub>** [**Pd EnCat™**] and **Pd<sup>(0)</sup> EnCat™** see entries in Chapter 8.

Encapsulated Pd catalysts such as **Pd EnCat™** are available commercially. These particles are defined by their matrix content e.g. 30 or 40%, the latter having the smaller pore size. [See also Bremeyer et al. *Synlett* 1843 2002, Yu et al. *J C S Chem Commun* 678 2003, Vickerstaffe et al. *Org Biomol Chem* **1** 2419 2003.]

**Palladium(II) trifluoroacetate** [42196-31-6] **M 332.4, m ~210°(dec)**. Suspend it in trifluoroacetic acid and evaporate it on a steam bath a couple of times. The residue is then dried in vacuum (40-80°) to give a brown powder. It is *hygroscopic* and should be stored in a dry atmosphere, preferably aliquoted in sealed vials [Stephenson et al. *J Chem Soc* 3632 1965, Trost & Metzner *J Am Chem Soc* **102** 3572 1980.]

**Pd(CF<sub>3</sub>CO)<sub>2</sub>** catalyses the decarboxylation of electron-rich aromatic acids (e.g. with OMe groups) in DMSO/DMF at 70-90° (1 to 24 hours) in high yields and is not affected by steric hinderance [Dickstein et al. *Org Lett* **9** 2441 2007], and (in the presence of Cu(OAc)<sub>2</sub> with Cesium pivalate + 3-nitropyridine as additives at 110-140° in a microwave) it catalysed direct cross-coupling between unactivated arenes and *N*-acetylindoles with coupling mostly at C3 of indoles but with no homo-coupling [Stuart & Fangou *Science* **316** 1172 2007].

In the presence of AcOH, benzoquinone (as oxidant) and *o*-methoxyacetophenone or Ph<sub>3</sub>P as ligands, Pd(tfa)<sub>3</sub> catalyses selective allylic oxidation of olefins into their allyl acetates [McMurry & Kocovsky *Tetrahedron Lett* **25** 4187 1984].

**Phosferrox ligands and SK-Naud catalysts.** The ligands are (diphenylphosphinoferrrocenyl)oxazolines and are complexes where one of the cyclopentadienyl rings has two different substituents. These molecules have “**planar chirality**”, i.e. are asymmetric, and exist in two enantiomeric forms. The oxazolines are 4,5-dihydro-oxazoles which for this use have a 4-substituent, usually alkyl or aryl, thus introducing a chiral centre at C-4 of the heterocyclic ring. Phosferrox ligands are prepared by lithiation of chiral 4-alkyloxazolin-2-ylferrocene in which lithiation is directed predominantly to one of the *ipso* positions of the cyclopentadienyl ring, generating “**planar asymmetry**” in the ferrocene moiety. It is highly diastereoselective with *ortho*-lithiation yield of ~84-99% de, producing the *S*-stereochemistry at the ferrocene moiety as shown by X-ray analysis and CD spectra of the products. Reaction of the lithiated ferrocene with Ph<sub>2</sub>PCl furnishes the desired chiral phosferrox ligand. The stereochemistry of the reaction has been studied in detail [Sammakia et al. *J Org Chem* **60** 10 1995, Sammakia & Latham *J Org Chem* **60** 6002 1995, Richards & Mulvaney *Tetrahedron: Asym* **7** 1419 1996, Nishibayashi et al. *J Organomet Chem* **545-546** 381 1997]. Advantage is taken of the diastereoselectivity of the lithiation reaction in order to obtain the enantiomeric *R*-ferrocene. Thus, after lithiation, the lithium is displaced by a trimethylsilyl group (by reaction with Me<sub>3</sub>SiCl), the *S*-TMS derivative is lithiated again, but at the other *ipso* position of the same cyclopentadienyl ring, followed by reaction with Ph<sub>2</sub>PCl to form the 1-diphenylphosphino-3-TMS-2-(oxazolin-2-yl)ferrocene. Finally, removal of the TMS group, e.g. with *tetra-n-butylammonium fluoride* (TBAF, see [429-41-4; 3 H<sub>2</sub>O 87749-50-6]), provides the phosferrox where the stereochemistry at the ferrocene moiety is now *R*. Chiral phosferrox ligands react with RuCl<sub>2</sub>(Ph<sub>3</sub>P)<sub>3</sub> [15529-49-4] to form *Nauk catalysts* which are *phosferrox-RuCl<sub>2</sub>(Ph<sub>3</sub>P)* complexes that reduce aryl ketones in the presence of *i*-PrOH/*i*-PrOK to form the respective alcohols with high stereoselectivity [Sammakia & Stangeland *J Org Chem* **62** 6104 1997, Nishibayashi et al. *Organometallics* **18** 2291 1999].

**S-2-[(S)-2-(Diphenylphosphino)ferrocenyl]-4-(1-methylethyl)oxazoline (S,S-*i*-Pr-Phosferrox)** [163169-29-7] **M 481**, **m 157-158°**,  $[\alpha]_{\text{D}}^{24} +112^{\circ}$  (**c 0.1**, EtOH). This phosferrox is prepared in a Schlenk tube at  $-78^{\circ}$  under  $\text{N}_2$ , by adding dropwise *n*-BuLi (0.38ml, 0.7mmol) to a yellow-orange stirred solution of *S*-2-ferrocenyl-4-(1-methylethyl)oxazoline (0.158g, 0.53mmol) and TMEDA (0.10ml, 0.7mmol) in  $\text{Et}_2\text{O}$  (6ml) which had formed a yellow precipitate, and is stirred for 2 hours; the tube containing the orange non-homogeneous mixture is transferred to an ice-bath and stirred for 5 minutes further. To this now orange-red homogeneous solution is added  $\text{Ph}_2\text{PCl}$  (0.12ml, 0.7mmol, see [1079-66-9]), the mixture is allowed to warm to  $\sim 25^{\circ}$ , and after 15 minutes it is quenched with saturated aqueous  $\text{NaHCO}_3$  (10ml), the layers are separated, the aqueous layer is extracted with  $\text{Et}_2\text{O}$  (10ml), the combined  $\text{Et}_2\text{O}$  solutions are dried ( $\text{Mg SO}_4$ ), filtered, and evaporated to give an orange crystalline solid. This is purified by column chromatography (pre-adsorbed on silica, eluting with 10% EtOAc/petroleum ether) to give a yellow-orange crystalline solid (0.163g, 64%) that provided **S,S-*i*-Pr-Phosferrox** as an analytically pure single diastereomer upon recrystallisation from hexane. It has CD ( $\text{CHCl}_3$ )  $\lambda_{\text{max}}$  ( $\Delta\epsilon$ ) 456 (+2.20), 368 (+0.49), 342 (-1.00), 315 (+216) nm; the IR has  $\nu_{\text{max}}$  (nujol) at 1652 ( $\text{C}=\text{N}$ )  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (360Mz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 0.68 (3H, d,  $J = 7$  Hz,  $-\text{CH}_3$ ), 0.82 (3H, d,  $J = 7$  Hz,  $-\text{CH}_3$ ), 1.61-1.69 (1H, m,  $\text{CH}(\text{CH}_3)_2$ ), 3.61 (1H, brs, Fc), 3.67 (1H, t,  $J = 8$  Hz,  $-\text{OCHH}$ ), 3.83-3.90 (1H, m,  $-\text{NCH}$ -), 4.22 (5H, s,  $\text{C}_5\text{H}_5$ ), 4.22-4.30 (1H, m,  $-\text{OCHH}$ -), 4.37 (1H, brs, Fc), 4.99 (1H, brs, Fc), 7.18-7.24 (5H, m, Ph), 7.36-7.37 (3H, m, Ph), 7.46-7.51 (2H, m, Ph); the  $^{13}\text{C}$  NMR (90Mz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}\{^1\text{H}\}$  at 17.52 ( $-\text{CH}_3$ ), 18.61 ( $-\text{CH}_3$ ), 32.05 ( $\text{CH}(\text{CH}_3)_2$ ), 69.57 ( $-\text{OCH}_2$ -), 70.72 ( $\text{C}_5\text{H}_5$ ), 72.02, 72.14, 73.81, 73.85, 75.32 (d,  $J = 16$  Hz, Fc), 78.55 (d,  $J = 15$  Hz, Fc), 127.81 (Ph), 127.92 (Ph), 127.99 (Ph), 128.10 (Ph), 128.18 (Ph), 128.89 (Ph), 132.40 (d,  $J = 20$  Hz, Ph), 134.86 (d,  $J = 22$  Hz, Ph), 138.21 (d,  $J = 13$  Hz, Ph-*ipso*), 139.54 (d,  $J = 12$  Hz, Ph-*ipso*); the  $^{31}\text{P}$  NMR ( $\text{CDCl}_3$ ) has a single peak with  $\delta_{\text{P}}$  at -16.92, and the MS (EI) has  $m/z$  481 ( $\text{M}^+$ , 100%), 410 (68), 404 (44), 170 (38), 121 (76). [Richards & Mulvaney *Tetrahedron: Asym* 7 1419 1996].

**S-2-[(R)-2-(Diphenylphosphino)ferrocenyl]-4-(1-methylethyl)oxazoline [S-(R-*i*-Pr-Phosferrox)]** [163169-10-6] **M 481**, **m 132-132.5°**,  $[\alpha]_{\text{D}}^{20} -53^{\circ}$  (**c 0.15**, EtOH). This diastereomer is obtained by de-trimethylsilylation of *S*-2-[*R*-2-(diphenylphosphino)-5-(trimethylsilyl)ferrocenyl]-4-(1-methylethyl)oxazoline (0.14g 0.25mmol) with a yellow solution of 1M TBAF (see [429-41-4; 3  $\text{H}_2\text{O}$  87749-50-6], in Part 2) in THF (10ml) containing *ca* 5%  $\text{H}_2\text{O}$  by boiling for 4 hours, evaporating *in vacuo* to a small volume, shaking with  $\text{Et}_2\text{O}$  (10ml) and  $\text{H}_2\text{O}$  (10ml), separating, the aqueous layer is extracted with  $\text{Et}_2\text{O}$ , the ethereal layers are combined, dried ( $\text{Mg SO}_4$ ), filtered, evaporated *in vacuo*, and the residue is chromatographed in a silica column (eluted with 10% EtOAc/petroleum ether b 40-60°) to give **S-(R-*i*-Pr-Phosferrox)** as a yellow crystalline solid (0.090, 75%). Its CD ( $\text{CHCl}_3$ ) has  $\lambda_{\text{max}}$  ( $\Delta\epsilon$ ) 492 (+0.45), 434 (-0.43), 361 (-0.31), 344 (+0.35), 314 (-2.38) nm; the IR has  $\nu_{\text{max}}$  (nujol) at 1660 ( $\text{C}=\text{N}$ )  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (360Mz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 0.63 (3H, d,  $J = 7$  Hz,  $-\text{CH}_3$ ), 0.65 (3H, d,  $J = 7$  Hz,  $-\text{CH}_3$ ), 1.50-1.58 (1H, m,  $\text{CH}(\text{CH}_3)_2$ ), 3.62 (1H, brs, Fc), 3.89-4.08 (3H, m,  $-\text{OCH}_2\text{CH}$ -), 4.22 (5H, s,  $\text{C}_5\text{H}_5$ ), 4.36 (1H, brs, Fc), 4.94 (1H, brs, Fc), 7.19-7.23 (5H, m, Ph), 7.35-7.37 (3H, m, Ph), 7.48-7.53 (2H, m, Ph); the  $^{13}\text{C}$  NMR (90Mz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}\{^1\text{H}\}$  at 17.88 ( $\text{CH}_3$ ), 32.44 ( $-\text{CH}_3$ ), 69.47 ( $-\text{OCH}_2$ ), 70.44, 70.67 ( $\text{C}_5\text{H}_5$ ), 72.09, 72.41, 74.07, 74.95 (d,  $J = 16$  Hz, Fc), 78.12 (d,  $J = 14$  Hz, Fc), 127.71 (Ph), 127.83 (Ph), 127.90 (Ph), 128.07 (Ph), 128.15 (Ph), 128.55 (Ph), 128.86 (Ph), 132.38 (d,  $J = 19$  Hz, Ph), 134.98 (d,  $J = 22$  Hz, Ph), 138.31 (d,  $J = 13$  Hz, Ph-*ipso*), 139.37 (d,  $J = 12$  Hz, Ph-*ipso*), 164.62 ( $\text{C}=\text{N}$ ); the  $^{31}\text{P}$  NMR ( $\text{CDCl}_3$ ) has a single peak at  $\delta_{\text{P}}$  -18.03; and the MS (EI) has  $m/z$  481 ( $\text{M}^+$ , 32%), 410 (19), 170 (22), 121 (100). [Richards & Mulvaney *Tetrahedron: Asym* 7 1419 1996].

Among other phosferrox ligands that were prepared are *S,S*-4'*Me*-Phosferrox, *S,R*-4'*Me*-Phosferrox, *S,S*-4'*Et*-Phosferrox, *S,S*-4'*n*-Bu-Phosferrox, *S,S*-4'*iso*-Bu-Phosferrox, *S,S*-4'*t*-Bu-Phosferrox, *S,S*-4'*Ph*-Phosferrox, and *S,S*-4'*benzyl*-Phosferrox [Sammakia & Stangeland *J Org Chem* 62 6104 1997, Nishibayashi et al. *J Organomet Chem* 545-546 381 1997].

**S-2-[*S*<sub>p</sub>-2-(Diphenylphosphino)ferrocenyl]-4-*iso*-propyl-2-oxazoline triphenylphosphine ruthenium (II) dichloride complex [S,S-*i*-Pr-Phosferrox-Ru(II)  $\text{Ph}_3\text{PCl}_2$  complex, SK-Naud Catalyst-N003-2z]** [212133-11-4] **M 915.6**,  $[\alpha]_{\text{D}}^{20} -1100^{\circ}$  (**c 0.2**,  $\text{CHCl}_3$ ). This catalyst can be prepared *in situ* from the phosferrox and  $\text{RuCl}_2(\text{PhP}_3)_3$ , but it can also be isolated. Thus a mixture of  $\text{RuCl}_2(\text{PhP}_3)_3$  (480mg, 0.50mmol) and *S,S*-*i*-Pr-Phosferrox (0.50mmol) and toluene (15ml) are stirred under  $\text{N}_2$  at  $\sim 25^{\circ}$  for 20 hours when the original purple solution changes to a red suspension. Addition of *n*-hexane caused the crystalline catalyst to separate, and the red crystals are recrystallised to analytical purity from  $\text{CH}_2\text{Cl}_2$ /*n*-hexane ( $\sim 81\%$  yield). The  $^1\text{H}$  NMR (270Mz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 0.57 (3H, d,  $J = 7$  Hz,  $\text{CH}_3$ ), 0.97 (3H, d,  $J = 7$  Hz,  $\text{CH}_3$ ), 2.12 (1H, dd,  $J = 8$  and 8Hz), 3.21 (1H, m), 3.28 (1H, m), 3.80 (1H, dd,  $J = 3$  and 8Hz), 4.02 (5H, s), 4.59 (1H, m), 4.68 (1H, m), 4.84 (1H, m), 6.5-8.4 (25H, m); and the  $^{31}\text{P}$  NMR (107Mz,  $\text{CDCl}_3$ ) indicated a diastereomerically pure complex with  $\delta_{\text{P}}$  40.1 (d,  $J =$

45Hz) and 77.0 (d,  $J = 45\text{Hz}$ ). It causes a high conversion with high stereoselectivity (with 88- $<99\%$  ee) in the Ru-catalysed asymmetric transfer hydrogenation of ketones using *i*-PrOH as H source, as well as catalysing the asymmetric oxidation of *sec*-alcohols to ketones [Nishibayashi et al. *Organometallics* **18** 2291 1999].

**R-2-[R<sub>p</sub>-2-(Diphenylphosphino)ferrocenyl]-4-*iso*-propyl-2-oxazoline triphenylphosphine ruthenium(II) dichloride complex (SK-Naud Catalyst-N003-1z) [849921-25-1] M 915.6,  $[\alpha]_{\text{D}}^{20} +1100^{\circ}$  (c 0.5, CHCl<sub>3</sub>)** can be prepared and purified as in the preceding entry.

**S-2-[S<sub>p</sub>-2-(Diphenylphosphino)ferrocenyl]-4-phenyl-2-oxazoline triphenylphosphine ruthenium (II) dichloride complex [S,S-*Ph*-Phosferrox-Ru(II) Ph<sub>3</sub>P Cl<sub>2</sub> complex] [212210-73-6] M 949.6.** As above (SK-Naud catalyst-N003-2z) the catalyst can be prepared *in situ*, but can also be isolated in pure crystalline form, and its structure has been confirmed by X-ray crystallography. A mixture of **S,S-4'*Ph*-Phosferrox** [257mg, 0.50mol, red solid purified by flash chromatography with silica gel and eluting with hexanes the 10:1 hexanes/EtOAc, and recrystallisation from hexane, **m 184-185° dec.**,  $[\alpha]_{\text{D}}^{23} +25.6^{\circ}$  (c 0.67, CHCl<sub>3</sub>)] and RuCl<sub>2</sub>(PhP<sub>3</sub>)<sub>3</sub> (480mg, 0.50mmol) in toluene (15ml) are stirred under N<sub>2</sub> at  $-25^{\circ}$  for 20 hours when the original purple solution changes to a red suspension. Addition of *n*-hexane causes the crystalline catalyst to separate, and the red crystals are recrystallised to analytical purity from CH<sub>2</sub>Cl<sub>2</sub>/*n*-hexane to provide the catalyst (with 1 mol of CH<sub>2</sub>Cl<sub>2</sub>) in 80% yield. The <sup>1</sup>H NMR (270Mz, CDCl<sub>3</sub>) has  $\delta_{\text{H}}$  at 2.68 (1H, dd  $J = 8$  and 9Hz), 3.29 (1H, dd,  $J = 1$  and 9Hz), 4.12 (5H, s), 4.23 (1H, dd,  $J = 1$  and 8Hz), 4.71 (1H, m), 4.80 (1H, m), 5.04 (1H, m), 6.6-8.2 (30H, m); and the <sup>31</sup>P NMR (107Mz, CDCl<sub>3</sub>) indicated almost diastereomerically pure complex with  $\delta_{\text{P}}$  40.8 (d,  $J = 45\text{Hz}$ ) and 75.7 (d,  $J = 45\text{Hz}$ ). It has similar catalytic activity as the SK-Naud catalysts [Nishibayashi et al. *Organometallics* **18** 2291 1999, Sammakia & Stangeland *J Org Chem* **62** 6104 1997].

**Platinum(0) bis(1,5-cyclooctadiene) [Pt(COD)<sub>2</sub>, Pt bis(1,2,5,6- $\eta$ -1,5-octadiene)] [12130-66-4] M 411.6, **m** $\sim$ **200°**. Pt(COD)<sub>2</sub> is prepared in a dry, O<sub>2</sub>-free, N<sub>2</sub> atmosphere by adding dropwise an ethereal solution of Li<sub>2</sub>(C<sub>8</sub>H<sub>8</sub>) [*ca* 40ml of a 0.24mol dm<sup>-3</sup> of dilithium cyclooctatetraene [40698-91-7] in Et<sub>2</sub>O (Katz *J Am Chem Soc* **82** 3784 1960, see also below)] to a finely powdered suspension of Pt(COD)Cl<sub>2</sub> (3.7g, 10mmol, see above entry) in 1,5-cyclooctadiene at  $-30^{\circ}$ , stirring for 30 minutes as the temperature rises to  $-10^{\circ}$ ; and then the solvent is evaporated *in vacuo* to dryness. Extraction of the residue with toluene (6 x 50ml) gives a brown solution which is filtered through an Al<sub>2</sub>O<sub>3</sub> column (8 x 2.5cm, Brockman Activity III), the filtrate is evaporated to  $\sim$ 15ml and the supernatant is decanted from the off-white product which is washed with several small volumes of cold toluene until the washings are almost colourless. This Pt catalyst (1.6-2.4g, 40-60%) is useful for most purposes. Analytically pure (C and H) white crystals can be obtained by dissolving it in petroleum ether (b 40°-60°) ( $\sim$ 80ml for each mmol of catalyst), filtering through an Al<sub>2</sub>O<sub>3</sub> column (6 x 2.5cm) and cooling to  $-78^{\circ}$ . Its IR has  $\nu_{\text{max}}$  at 3020m, 3000sh, 2930m, 2910sh, 2965m, 2825m, 1475m, 1465m, 1433m, 1327s, 1306w, 1238m, 1212m, 1178w, 1158w, 1090vw, 1075w, 1009w, 998m, 970sh, 962w, 890vw, 865sh, 855m, 829sh, 823m, 810m, 788m, 769vw, 580vw, 510vw, and 465vw cm<sup>-1</sup>; the <sup>1</sup>H NMR (100MHz, \*C<sub>6</sub>D<sub>6</sub>) has  $\tau$  at 5.80 (m, 8H, CH=CH,  $J_{\text{Pt-H}} = 55\text{Hz}$ ) and 7.81 (m, 16H, CH<sub>2</sub>); and the <sup>13</sup>C NMR (25.15MHz, \*C<sub>6</sub>D<sub>6</sub>-<sup>1</sup>H decoupled) has <sup>13</sup>C shifts with  $\delta$  measured relative to SiMe<sub>4</sub> (positive values to high frequency) 73.3 (C=C,  $J_{\text{Pt-C}} = 143\text{Hz}$ ) and 33.2 (CH<sub>2</sub>,  $J_{\text{Pt-C}} = 15\text{Hz}$ ). The white crystalline complex is stable in air and can be handled without difficulty. [Spencer *Inorg Synth* **19** 214 1979, Crascall & Spencer *Inorg Synth* **28** 127 1990.] Note that attempts to prepare the corresponding Pd complex [Pd(COD)<sub>2</sub>] in a similar manner failed; however, it was obtained by the reaction of [Pd(COD)Cl<sub>2</sub>] with Li<sub>2</sub>[C<sub>8</sub>H<sub>8</sub>] in the presence of excess of propene as a white crystalline solid which was stable below  $-20^{\circ}$ , but decomposed rapidly to Pd and 1,5-cyclooctadiene at ambient temperatures. [Green et al. *J Chem Soc, Dalton Trans* 271 1977, Crascall & Spencer *Inorg Synth* **28** 128 1990.] Pt(COD)<sub>2</sub> catalyses the *cis*-diborylation of olefins in  $>80\%$  yields under ambient conditions with e.g. CatB-BCat (see below). [Iverson & Smith *Organometallics* **16** 2757 1997].**

**Platinum(0) bis(dibenzylideneacetone) [Pt(dba)<sub>2</sub>, bis(C<sup>3</sup>,O<sup>3</sup>- $\eta$ -1,5-diphenyl-1,4-pentadien-3-one)-platinum (0)] [33677-56-4] M 683.7, **m** $>$ **170° (to Pt and dba)**. Pt(dba)<sub>2</sub> is a deep purple air stable complex which is prepared in 41% yield from K<sub>2</sub>PtCl<sub>4</sub> with 3 mol equivalents of dba in refluxing EtOH under N<sub>2</sub> in the presence of NaOAc. It crystallises from Me<sub>2</sub>CO and is soluble in MeOH and CHCl<sub>3</sub>. It is useful for preparing complexes with (PPh<sub>3</sub>)<sub>2</sub>, (AsPh<sub>3</sub>)<sub>2</sub>, (PEt<sub>3</sub>)<sub>2</sub>, (AsEt<sub>3</sub>)<sub>2</sub>, as well as with other ligands. The *tris* complex Pt(dba)<sub>3</sub> is formed as a yellow microcrystalline solid in 40% yield by carrying out the above reaction in refluxing aqueous MeOH *in the presence of air or oxygen*. It is stable in the solid form, and is soluble in organic solvents but gives green solutions that rapidly turns purple, from which Pt(dba)<sub>2</sub> and dba (1:1) can be isolated. Physical properties showed**

that complete dissociation of  $\text{Pt}(\text{dba})_3$  had occurred. Both complexes decompose  $>170^\circ$  on heating to Pt and dba, on treatment with CO, or when solutions are set aside for long periods. The IR ( $\text{CHCl}_3$ ) of  $\text{Pt}(\text{dba})_2$  has  $\nu_{\text{max}}$  at 1656w(CO), 1613vs, br(C=C), 1579m(C=C aromatic), 1544m, br(CO)  $\text{cm}^{-1}$ ; and complex  $\text{Pt}(\text{dba})_3$  has  $\nu_{\text{max}}$  at 1652w(CO), 1624vs(C=C), 1593s, br(C=C aromatic), 1579m(C=C aromatic), 1527m br(CO)  $\text{cm}^{-1}$ . The UV-VIS ( $\text{CHCl}_3$ ) of  $\text{Pt}(\text{dba})_2$  has  $\lambda_{\text{max}}$  nm ( $\log \epsilon$ ) at 235 (4.48), 336 (4.54), 378sh(4.27) 538 (3.92, metal  $\rightarrow$  ligand:  $d \rightarrow \pi^*$ ); of  $\text{Pt}(\text{dba})_3$  has  $\lambda_{\text{max}}$  nm ( $\log \epsilon$ ) at 235 (4.27), 336 (4.48), 568 (3.51, metal  $\rightarrow$  ligand:  $d \rightarrow \pi^*$ ); and of dba has  $\lambda_{\text{max}}$  nm ( $\log \epsilon$ ) at 233 (3.90), 325 (4.38). The  $^1\text{H}$  NMR (100MHz,  $\text{CDCl}_3$ ) of  $\text{Pt}(\text{dba})_2$  and dba are surprisingly similar [see however: Müller & Gröser *Angew Chem. Int Edn* **6** 364 1967]. It is a useful catalyst for the oligomerisation of acetylenes [Moseley & Maitlis *J C S. Chem Commun* 982 1971, Cherwinski et al. *JCS, Dalton Trans* 1405 1974], and is used in the  $\text{Pt}(\text{dba})_2$ -catalysed selective *cis*-addition of bis(pinacolato)borane to terminal alkenes and cyclic alkenes with internal strain to form bis(boryl)alkanes in 76-86% yields at  $50^\circ$  [Ishiyama et al. *J C S, Chem Commun* 689 1997] among other uses in catalysis.

**Rhodium(II) acetate dimer ( $2\text{H}_2\text{O}$ ) [dirhodium tetraacetate, tetrakis(acetato)dirhodium(II)] [15956-28-2] M 478.0.** Dissolve 5g of the dimeric salt in boiling MeOH (*ca* 600ml) and filter. Concentrate the filtrate to 400ml and chill overnight at *ca*  $0^\circ$  to obtain dark green crystals of the MeOH adduct. Concentration of the mother liquors gives a further crop of  $[\text{Rh}(\text{OAc})_2]_2 \cdot 2\text{MeOH}$ . The adduct is then heated at  $45^\circ$  in a vacuum for 2 hours (all MeOH is lost) to leave the emerald green crystals of the acetate. [Legzdins et al. *J Chem Soc (A)* 3322 1970, Rempel et al. *Inorg Synth XIII* 90 1972.] Alternatively, dissolve the acetate in glacial AcOH and reflux for a few hours to give an emerald green solution. Evaporate most of the AcOH on a steam bath, then heat the residue at  $120^\circ/1$  hour. Extract the residue with boiling  $\text{Me}_2\text{CO}$ . Filter, concentrate to half its volume and keep at  $0^\circ/18$  hours. Collect the crystals, wash them with ice cold  $\text{Me}_2\text{CO}$  and dry them at  $110^\circ$ . It is moderately soluble  $\text{H}_2\text{O}$ , MeOH,  $\text{Me}_2\text{CO}$  (see above), and in many organic solvents to give green solutions. It forms adducts with MeOH,  $\text{Me}_3\text{N}$  and  $\text{Me}_2\text{S}$ , and gives solutions with different colours varying from green to orange and red depending on solvent and dilution. The IR(Nujol) has  $\nu_{\text{max}}$  at 1580s, 1425s, and 1350m  $\text{cm}^{-1}$ , and the IR (hexachlorobutadiene) has  $\nu_{\text{max}}$  at 1445s, 1415s and 1350m  $\text{cm}^{-1}$  among other bands. [UV: Johnson et al. *Inorg Chem* **2** 960 1963, Beilstein **1** H 124.]

It is a homogeneous catalyst [Black *Aldrichimica Acta* **15** 13 1982], is used in an efficient synthesis for  $\beta$ -hydroxy- $\alpha$ -acrylates involving the decomposition of diazoester intermediates with concomitant 1,2-arylmigration [Xiao et al. *Tetrahedron Lett* **48** 1147 2007], and is an effective catalyst for the formation of allylsulfonium ylides (e.g. from 3,3-dimethylallyl methyl sulfide and trimethylsilyldiazomethane) which undergo [2.3] sigmatropic rearrangement (e.g. to 2,2-dimethyl-1-methylthio-1-trimethylsilylbut-3,4-ene) [Carter & Van Vranken *Tetrahedron Lett* **40** 1617 1999]. The reaction of alkyl diazoacetates with carbodiimides (to form 2-imino-4-oxazolines) [Drapier et al. *Tetrahedron Lett* 559 1979], with acetylenes (to form cyclopropenes) [Petiniot et al. *Tetrahedron Lett* 1239 1978], and with ROH, HOH and  $\text{R}'\text{COOH}$  (replacing H to form the respective  $\text{O}-\text{CH}_2\text{CO}_2\text{Alkyl}$ ) [Paulissen et al. *Tetrahedron Lett* 2233 1973]; are all catalysed by  $[\text{Rh}(\text{OAc})_2]_2$  at about room temperature.

**Rhodium(III) acetylacetonate [2,4-pentanedione rhodium(III),  $\text{Rh}(\text{acac})_3$ ] [14284-92-5] M 400.2, m 263-264 $^\circ$ .** It is prepared from  $\text{Rh}(\text{NO}_3)_3$  solution (0.1g in Rh) in 0.2N  $\text{HNO}_3$  (10ml) which is neutralised with aqueous  $\text{NaHCO}_3$  (10%) to pH 4, whereby the light yellow hydroxide (or basic nitrate) begins to separate. Acetylacetonone (5ml) is added, the mixture is refluxed, and after a few minutes orange-yellow crystals begin to separate while the pH of the solution decreases. After 30 minutes reflux the pH of the solution is re-adjusted and reflux is continued for a further 15 minutes. The orange-yellow complex is collected and forms monoclinic plates (0.3g, 75%, m  $260^\circ$ ) upon recrystallisation from aqueous MeOH, and sublimes at  $240^\circ/1.0\text{mm}$ . It decomposes above  $280^\circ$  depositing a rhodium mirror. It is insoluble in  $\text{H}_2\text{O}$ , slightly soluble in EtOH and petroleum ether, but freely soluble in  $^*\text{C}_6\text{H}_6$  and  $\text{CHCl}_3$ . It is stable in boiling dilute acids and 10% aqueous NaOH. Molecular weight determination ( $\sim 490$ , by Rast in camphor) indicates that it is monomeric. [Dwyer & Sargeson *J Am Chem Soc* **75** 984 1953, Beilstein **1** IV 3677.]  $\text{Rh}(\text{acac})_3$  is a very effective catalyst ( $\sim 90\%$  yields) for the hydrogenation of monocarboxylic or  $\omega$ -dicarboxylic acids to the respective alcohols in DME at 100 atmospheres (16 hours at  $160^\circ$ ) when combined with  $\text{Re}(\text{CO})_{10}$  or  $\text{Mo}(\text{CO})_6$  [He et al. *Tetrahedron Lett* **36** 1059 1995].

**Rhodium(I) bis(1,5-cyclooctadiene) tetrafluoroborate complex [bis(1,5-cyclooctadiene)rhodium(I) tetra-**

**fluoroborate, Rh(COD)<sub>2</sub><sup>+</sup>.BF<sub>4</sub><sup>-</sup> [35138-22-8] M 406.1, m ~190° (dec), the xHydrate [207124-65-0] has m 165° (dec).** This complex is prepared from the dimer [Rh(COD)Cl]<sub>2</sub> (1.47g, 2.98mmol, cf [12092-47-6]) in CH<sub>2</sub>Cl<sub>2</sub> (20ml), to which is added COD (1.1ml, 8.97mmol) followed by AgBF<sub>4</sub> (1.33g, 6.83mmol) in Me<sub>2</sub>CO (10ml) which results in a deep red solution containing a white precipitate. The mixture is stirred for 20 minutes, filtered through Celite, THF (20ml) is then added and the volume is reduced on a Rotovap at 25° down to 10ml. The deep red crystals are filtered off, washed with THF (2 x 5ml), Et<sub>2</sub>O and dried in air (2.35g, 97%). [Schenck et al. *Inorg Chem* **24** 2334 1985.] A general purification procedure involves dissolving the complex in the minimum volume of CH<sub>2</sub>Cl<sub>2</sub>, adding an equal volume of EtOH and completing the crystallisation by dropwise addition of Et<sub>2</sub>O, filtration, and drying the solid *in vacuo*.

It is used for preparing cationic COD-Rh complexes with phosphine ligands for enantioselective [2+2+2] cycloaddition of unsymmetrical diynes with styrene and norbornene derivatives to yield bi- and tetra-cyclic products with good (~50%) to very good (>90%) enantiomeric enrichment [Shibata et al. *Tetrahedron* **63** 12853 2007], for hydrogenation [Nagel et al. *Chem Ber* **119** 3326 1986, Ojima et al. *Tetrahedron* **45** 6901 1989, Sawamura et al. *J Am Chem Soc* **117** 9602 1995], and for hydrosilylation [Takeuchi et al. *J Org Chem* **60** 3045 1995].

**[Rhodium(S,S-Chiraphos)(COD)] ClO<sub>4</sub>.THF {(1,2,5,6-η)-1,5-cyclooctadiene}[1,2-dimethyl-1,2-ethanediyl-(di-phenylphosphine)-P,P']rhodium(1<sup>+</sup>) perchlorate. THF, η<sup>4</sup>-1,5-cyclooctadiene[(2S,3S)-2,3-bis(diphenylphosphino)butane]rhodium(I) perchlorate.THF} [61886-03-1, 61886-02-0 THF-free] M 809.1, 737.0 (THF-free).** The S,S-catalyst is obtained by adding 70% perchloric acid (0.080g, 1 equivalent) in pure THF (1ml) under N<sub>2</sub> to a mixture of S,S-chiraphos (0.244g, see [64896-28-2]) and \*[Rh(COD)(acac)] (0.180) in THF (4ml); and the red mixture is allowed to stand at 25° for 14 hours. The bright orange block crystals are collected, washed with cold THF and dried in air to give analytically pure (C, H, P and Cl analysis) catalyst *perchlorate THF* (0.40g). The presence of solvent is confirmed by NMR. A single crystal X-ray (absolute) structural determination of this THF-pre-catalyst shows that it is as predicted, i.e. the chiral centres are S and the methyl groups are equatorial to give a δ-chelate ring [Ball & Payne *Inorg Chem* **16** 1187 1977]. The configuration in solution is assumed to be the same, being consistent with the stereochemistry of the catalytically produced products.

The above two complexes are efficient homogeneous catalysts for the hydrogenation of α-N-acylamioacrylic acids at room temperature and pressure in THF, dioxane or \*C<sub>6</sub>H<sub>6</sub>, EtOH or aqueous EtOH to provide the amino acid derivatives in very high optical purity [e.g. of alanine (91%), DOPA (83%) and tyrosine (92%)], and in almost quantitative chemical yields with turnover numbers ranging from 3 x 10<sup>-2</sup> to 6 x 10<sup>-4</sup> sec<sup>-1</sup>, from which essentially completely optically pure “non-natural” R-α-amino acids can be obtained by recrystallisation. [Fryzuk & Bosnich *J Am Chem Soc* **99** 6262 1977]. An ingenious application of this S,S-chiraphos catalyst using hydrogen, deuterium and tritium has been adopted for the asymmetric synthesis of chiral lactic acid in which the methyl group is chiral by virtue of its having a hydrogen, a deuterium and a tritium atom on the methyl carbon atom. [Fryzuk & Bosnich *J Am Chem Soc* **101** 3043 1979]. In the hydrogenation of selected Z-olefins with this pre-catalyst, addition of Et<sub>3</sub>N appears to give higher optical yields of products [Onuma et al. *Bull Chem Soc, Jpn* **53** 2012 1980].

\* **[Rh(COD)(acac)] [12245-39-5] M 310.2, m 138-140°**, is prepared from [Rh(COD)Cl]<sub>2</sub> (4.4g, 9 mmol, see [12092-47-6]) and acetylacetone (acacH, 0.9ml, 9 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (50ml) chilled to -80° by treating dropwise with a solution of Na<sub>2</sub>CO<sub>3</sub> (5.7g) in H<sub>2</sub>O (100ml) and shaking; then warming to 0° while shaking and more CH<sub>2</sub>Cl<sub>2</sub> (50ml) is added. The layers are separated, and the organic layer is evaporated *in vacuo* until the complex crystallises out. [Fryzuk & Bosnich *J Am Chem Soc* **99** 6262 1977].

**Rhodium(S,S-Chiraphos)(NBD)] ClO<sub>4</sub> {(bicyclo[2.2.1]heptadiene)[(2S,3S)-2,3-bis(diphenylphosphino)butane]-rhodium (I) perchlorate, [(1,2,5,6-η)bicyclo[2.2.1]hepta-2,5-diene][S,S-1,2-dimethyl-1,2-ethanediyl)-bis(diphenylphosphine)-P,P']rhodium(1<sup>+</sup>) perchlorate} [65012-74-0; 65012-73-9 for cation: Rh(S,S-chiraphos)(MeOH)<sub>2</sub><sup>+</sup> has 71264-71-6] M 720.97.** This catalyst can be prepared by two methods. In the first, 7% HClO<sub>4</sub> (0.173g, 1 equivalent) in THF (6ml) is added to a solution of the complex \*[Rh(NBD)(acac)] (0.356g) and S,S-chiraphos (0.516g, see [64896-28-2]) in dry, freshly distilled, THF (7.5ml) under N<sub>2</sub>, and the deep red coloured solution is allowed to stand at 25° for 24 hours. The orange-red crystals that separate are collected, washed with cold THF, dried at 40° *in vacuo* to give the catalyst *perchlorate* (0.6g), which should be

stored at 0° under N<sub>2</sub> in a sealed container. In the *second*, *S,S*-chiraphos (0.308g) and the complex **\*\*[Rh(NBD)<sub>2</sub>]ClO<sub>4</sub>** (0.290g) are dissolved in CH<sub>2</sub>Cl<sub>2</sub> (5ml) and THF (5ml) under N<sub>2</sub>, followed by addition of hexane (6ml), allowing to stand at 25° for 1 hour, then at 5° for 2 hours. The orange-red needles of the catalyst perchlorate (0.43g) are collected, dried and stored as in the first method. Note that it loses catalytic activity if stored in air. [Fryzuk & Bosnich *J Am Chem Soc* **99** 6262 1977.] Its <sup>31</sup>P NMR (CDCl<sub>3</sub>, with external H<sub>3</sub>PO<sub>4</sub> as reference) has δ at +56.9 (d, *J*<sub>Rh-P</sub> = 153Hz), i.e. downfield from H<sub>3</sub>PO<sub>4</sub> [Slack et al. *Inorg Chem* **18** 3125 1979]. The tetrafluoroborate **[79790-89-9] M 708.3** forms orange-red crystals from CH<sub>2</sub>Cl<sub>2</sub>/Et<sub>2</sub>O.

**\*[Rh(NBD)(acac)]** [32354-50-0] **M 294.2, m 176-177°**, is prepared from the dimer [Rh(NBD)Cl]<sub>2</sub> [12257-42-0] and Ti(acetylacetonate) ([25955-51-6]) as described for [(hfacac)(COE)<sub>2</sub>Ir] [58616-58-3] [see this chapter and Diversi et al. *J Organomet Chem* **125** 253 1977.]

**\*\* [Rh(NBD)<sub>2</sub>]<sup>+</sup>ClO<sub>4</sub><sup>-</sup>** [60576-59-1] **M 386.6**, is also prepared from the dimer [Rh(NBD)Cl]<sub>2</sub> (0.35g, [12257-42-0]) and NBD (0.14g) in CH<sub>2</sub>Cl<sub>2</sub> (15ml) under N<sub>2</sub>, adding AgClO<sub>4</sub> (0.315g), stirring for 1 hour, filtering and adding THF (15ml). When the CH<sub>2</sub>Cl<sub>2</sub> in the mixture is evaporated off under a vacuum, [Rh(NBD)<sub>2</sub>]ClO<sub>4</sub> separates as orange needles which are collected, washed with cold THF and dried *in vacuo* to give now orange-brown crystals (0.5g). *Alternatively*, add Et<sub>2</sub>O instead of THF (15ml), filter, wash with Et<sub>2</sub>O, and dry *in vacuo* (yield 90%). Its <sup>1</sup>H NMR in (CD<sub>3</sub>)<sub>2</sub>CO has δ at 5.23 (br, olefin H), 4.09 (bridgehead CH) and 1.50 (CH<sub>2</sub>). [Fryzuk & Bosnich *J Am Chem Soc* **99** 6262 1977; cf Cramer *J Am Chem Soc* **86** 217 1964, Uson et al. *Trans Metallorg Chem* **4** 55 1979.] **[Rh(NBD)<sub>2</sub>]<sup>+</sup>BF<sub>4</sub><sup>-</sup>** has [36620-11-8] **M 373.99, m 157-159°**, and is prepared as for the perchlorate, but replacing AgClO<sub>4</sub> by an equivalent of AgBF<sub>4</sub>, and recrystallising from CH<sub>2</sub>Cl<sub>2</sub>/Et<sub>2</sub>O. The cation **[Rh(NBD)<sub>2</sub>]<sup>+</sup>** has [35015-46-4] **M 287.2**. [Green et al. *J Chem Soc (A)* 2334 1971, Osborn et al. *J Am Chem Soc* **93** 3089 1971, Green et al. *JCS, Dalton Trans* 832 1972.]

**[Rhodium(*R,R*-Chiraphos)(NBD)]ClO<sub>4</sub> {(bicyclo[2.2.1]heptadiene)[(2*R*,3*R*)-2,3-bis(diphenylphosphino)butane]-rhodium (I) perchlorate}** [74892-62-9] **M 720.97**. This pre-catalyst is prepared and purified as its enantiomer above in 77% yield in orange-red crystals after recrystallising from CH<sub>2</sub>Cl<sub>2</sub>/hexane. Its catalytic properties are very similar to those of its enantiomer above except that optically pure “natural” *S*-α-amino acids are produced. [Köiiner & Gerber *Chem Ber* **113** 2323 1980.]

The mechanism of the above asymmetric hydrogenations has been studied in some detail [Brown & Chaloner *J Am Chem Soc* **102** 3040 1980, Brown et al. *J Organomet Chem* **216** 263 1981].

**[Rhodium (*R*-Prophos)(NBD)] ClO<sub>4</sub>. 0.5CH<sub>2</sub>Cl<sub>2</sub> {(bicyclo[2.2.1]heptadiene)[*R*(+)-1,2-bis(diphenylphosphino)butane]-rhodium(I) perchlorate. 0.5CH<sub>2</sub>Cl<sub>2</sub>, [(2,3,5,6-η)bicyclo[2.2.1]hepta-2,5-diene][(1-methyl-1,2-ethanediyl)bis(diphenylphosphine)-*P,P'*]rhodium(I<sup>+</sup>) perchlorate. 0.5CH<sub>2</sub>Cl<sub>2</sub>}** [67881-59-8; 67884-58-7 for the cation; *Rh*(*R*-prophos)(MeOH)<sub>2</sub><sup>+</sup> has 71264-72-7] **M 706.9, decomposes on heating**. The precatalyst is made from freshly recrystallised [Rh(NBD)<sub>2</sub>]ClO<sub>4</sub> (0.388g, 1mmol, [12257-42-0]) and *R*-prophos (0.437g, 1.106mmol) in a mixture of CH<sub>2</sub>Cl<sub>2</sub> (4ml) and pure THF (4ml) under N<sub>2</sub>; and to this orange red solution is added hexane (4ml) dropwise, and the mixture is then allowed to stand at 25° for 5 hours then at 5° for 12 hours.

The orange-red solid is filtered off quickly, washed with ice-cold THF then hexane, and dried under a stream of dry N<sub>2</sub> to give analytically pure [Rh(*R*-Prophos)(NBD)]ClO<sub>4</sub> (with 0.5CH<sub>2</sub>Cl<sub>2</sub> by NMR). It remains catalytically active indefinitely if kept at 0° under N<sub>2</sub>. Its <sup>31</sup>P NMR (CDCl<sub>3</sub>, with external H<sub>3</sub>PO<sub>4</sub> as reference) has δ at +60.5 (d, *J*<sub>Rh-P</sub> = 172Hz), +41.8 (q, *J*<sub>Rh-P</sub> = 139Hz, *J*<sub>P-P</sub> = 34Hz), i.e. downfield [Slack et al. *Inorg Chem* **18** 3125 1979]. Its absolute crystal X-ray structure has been determined and is the one predicted, i.e. the chelate ring is λ, the methyl group is equatorially disposed and the absolute configuration of the diphosphine is *R*. The configuration in solution is assumed to be the same, being consistent with the stereochemistry of the catalytically produced products.

Like the above rhodium complexes of *S,S*-chiraphos, this *R*-prophos rhodium complex is an efficient homogeneous catalyst for the production of α-amino acids, and the optical yields appear to be insensitive to the nature of the substituents on the substrates which provide the “natural” *S*-amino acids in 90±3% optical yields and high chemical yields (<87%) [compare with the *S,S*-chiraphos rhodium precatalysts above which gives the non-natural *R*-α-amino acids]. Furthermore, the catalyst *R*-prophos rhodium complex can breed its own chirality so that large quantities of *R*-prophos can be made from the catalytic hydrogenation of ethyl acetoxyacrylate, *via* ethyl *S*-(-)-O-acetyllactate, by the *R*-prophos catalyst itself. This procedure has been used to produce *S*-prophos

if the pre-catalyst used is  $[Rh(S,S\text{-chiraphos})(NBD)]ClO_4$ . [Fryzuk & Bosnich *J Am Chem Soc* **100** 5491 1978.] An ingenious application of this *R*-prophos rhodium pre-catalyst using hydrogen, deuterium and tritium has been adopted for the asymmetric synthesis of chiral lactic acid in which the methyl group is chiral by virtue of its having a hydrogen, a deuterium and a tritium atom on the methyl carbon atom. The orientations here being opposite to those obtained with the *S,S*-chiraphos rhodium precatalysts. [Fryzuk & Bosnich *J Am Chem Soc* **101** 3043 1979.]

Note that these rhodium catalysts are in fact *pre-catalysts* because in the presence of hydrogen their {e.g.  $[Rh(S,S\text{-chiraphos})(NBD)]^+$ } strong deep red-orange colours are reduced to a light straw yellow colour of the true catalyst {e.g.  $[Rh(S,S\text{-chiraphos})(H)_2]^+$ }. The mechanism of these asymmetric hydrogenations has been studied in some detail [Brown & Chaloner *J Am Chem Soc* **102** 3040 1980, Brown et al. *J Organomet Chem* **216** 263 1981].

**Rhodium(III) chloride**  $[RhCl_3 \pm x H_2O]$  [10049-07-7; 20765-98-4  $x H_2O$ ] **M 209.3 (anhydrous), m 100° (hydrate, dec)**. The anhydrous form is crystalline and is hydrophobic. It is a red powder insoluble in  $H_2O$ , but soluble in aqueous NaOH or cyanide solutions. The hydrate, however, is soluble in  $H_2O$ . [cf preparation of the trihydrate by Anderson & Basolo *Inorg Chem* **7** 214 1963.]

It catalyses the direct conversion of methane to AcOH [Sen et al. *Nature* **368** 613 1994], and is a catalyst for conjugate reduction of cinnamaldehydes followed by cross-coupling with arylboronic acids [Wang et al. *JCS, Chem Commun* 1192 2004]. It also catalyses the deuteration of saturated hydrocarbons [Takahashi et al. *J Am Chem Soc* **97** 7489 1975], and in the presence of  $Ph_3P$  (Wilkinson's catalyst) the trimethylsilylation of methacrylic esters to 1-alkoxy-1-trimethylsilyl oxyethylenes with rearrangement of a methyl group in the presence of  $Me_3SiH$  in THF is achieved [see Revis & Hilty *J Org Chem* **55** 2972 1990.]

**Rhodium(II) pentafluorobenzoate dimer [tetrakis(pentafluorobenzoato)dirhodium(II)]** [75863-37-5] **M 947.2**. This dimer is obtained from a solution of perfluorobenzoic acid (4.5g) and hydrated  $RhCl_3$  (1g) in EtOH (80ml), to which is added NaOH (0.8g), and heated under reflux for 3 hours, cooled and the solid is filtered off. The solid is refluxed for a further hour with fresh EtOH (80ml) and is filtered again. The combined EtOH solutions are evaporated *in vacuo*, the solid green residue is extracted with several volumes of  $Et_2O$  until the extracts are colourless; the  $Et_2O$  is concentrated and chromatographed on  $SiO_2$  (eluting with toluene/ $Et_2O$  9:1). Some of the complex (1g) is collected in one of the fractions, and dried *in vacuo* for 3 hours [ $150^\circ$  at  $10^{-2}$  mm] and is analytically pure. The IR(KBr) has  $\nu_{max}$  at 1655m, 1597s, 1525m, 1500s, 1433s, 1405s, 1297w, 1118m, 997s, 942w, 768m  $cm^{-1}$ . Like the triflate salt (following entry) it catalyses the addition of carbenes (drived from alkyl diazo diazoesters) to aromatic compounds, although its catalytic efficiency is unaffected by the bulk of the diazo ester alkoxy group [Anciaux et al. *J Org Chem* **46** 873 1981].

**Rhodium(II) trifluoroacetate dimer [dirhodium tetra-trifluoroacetate, tetrakis(trifluoroacetato)dirhodium(II),  $Rh_2(Tf)_4$ ]** [31126-95-1] **M 657.9**. It can be purified in much the same way as the preceding acetate dimer (see [15956-28-2]) and is recrystallised from  $*C_6H_6$  before use. It is a homogeneous catalyst [Black *Aldrichimica Acta* **15** 13 1982]. Tetrakis(perfluoroacetato)dirhodium(II) catalyses the addition of carbenes (generated from diazo esters) to aromatic compounds at room temperature to generate 1-carbalkoxycyclohepta-2,4,6-trienes (with high kinetic selectivity for the *nonconjugated* isomers) in very good yields. A competitive reduction of the catalyst occurs simultaneously causing the reaction to slow down, and should be taken onto account [Anciaux et al. *J Org Chem* **46** 873 1981].

**Ruthenium(III) acetylacetonate**  $[Ru(acac)_3]$  [14284-93-6] **M 398.4, m 240°(dec)**. Purify the complex by recrystallisation from  $*benzene$ . [Wilkinson *J Am Chem Soc* **74** 6146 1952, *Beilstein* **1** IV 3677.] It catalyses the hydrogenation of dimethyl oxalate to ethylene glycol under mild conditions [70bar  $H_2$  pressure at  $100^\circ$ ] and the best ligand is  $MeC(CH_2PPh_2)_3$  with a trace of Zn (0.07% of oxalate) in MeOH with yields of >84% and with turnover numbers of 875 (turnover frequency/hour of 53.5) [Teunissen & Elsevier *J Chem Soc, Chem Commun* 667 1997].

**Ruthenium (benzylidene)dichloro-bis-(tricyclohexylphosphine) [phenylmethylene-bis-(tricyclohexylphosphine) dichlororuthenium (Grubbs catalyst—first generation)]** [172222-30-9] **M 823.0, m 153° (dec)**. Wash

it repeatedly with Me<sub>2</sub>CO and MeOH and dry it in a vacuum. *Alternatively*, dissolve it in warm CH<sub>2</sub>Cl<sub>2</sub>, concentrate it to half its volume, filter, add MeOH to precipitate it as purple microcrystals. Filter these off, wash several times with Me<sub>2</sub>CO and MeOH and dry them in a vacuum for several hours. [Schwab et al. *J Am Chem Soc* **118** 100 1996, Miller et al. *J Am Chem Soc* **118** 9606 1996, Furstner & Langermann *J Am Chem Soc* **119** 9130 1997.] It is used to catalyse ring-closing metathesis [Schrodi & Pederson *Aldrichimica Acta* **40** 45 2007, Schmidt *Angew Chem. Int Ed* **42** 4997 2003], and promotes olefin metathesis with ruthenium based catalysts [Grubbs *Tetrahedron* **60** 7117 2004]

§ A polymer supported version is available [Schwab et al. *Angew Chem, Intl Edn* **34** 2039 1995].

**Ruthenium(III) chloride (RuCl<sub>3</sub>)** [*3H<sub>2</sub>O* 13815-94-6; *xH<sub>2</sub>O* 14898-67-0; *Anhydrous* 10049-08-8] **M 207.4 (anhydrous), 261.5 (3H<sub>2</sub>O), d<sup>20</sup> 3.11.** The anhydrous salt exists in two forms. The α-form is produced by the slow reaction of Cl<sub>2</sub> with Ru metal in siliceous containers at >600° to give black lustrous hexagonal crystals which are antiferromagnetic and insoluble in H<sub>2</sub>O or EtOH [Hill & Beamish *J Am Chem Soc* **72** 4855 1950]. The second β-form is prepared by heating Ru metal in a stream of CO and Cl<sub>2</sub> at 340°, to avoid the formation of carbonyl compounds such as Ru(CO)<sub>2</sub>Cl<sub>2</sub> and is free from the metal or α-RuCl<sub>3</sub>. It is formed in dark brown fluffy hexagonal crystals that are soluble in EtOH. It is the metastable form because at or about the transition temperature of 450° the β-form is slowly converted to the α-form (irreversibly, with *t*<sub>0.5</sub> ~1 hour), and is the best way to prepare the α-form. [Fletcher et al. *Nature* **199** α-form 1089 1963.]

**Hydrated RuCl<sub>3</sub>** is one of the most useful inorganic ruthenium compounds, and particularly for the preparation of Ru coordinated compounds. It is prepared by evaporating RuO<sub>4</sub> in concentrated hydrochloric acid in a stream of HCl gas. Unlike the anhydrous form, the hydrate is soluble in H<sub>2</sub>O, but a fresh aqueous solution (brown to brown-green colour) does not precipitate AgCl with AgNO<sub>3</sub> solution because the halogen atoms (as well as one molecule of H<sub>2</sub>O) are coordinated to the metal. However, on warming in H<sub>2</sub>O the halogen atoms are displaced by H<sub>2</sub>O molecules and the Cl<sup>-</sup> ions can be precipitated (or titrated) with AgNO<sub>3</sub> [Grube & Fromm *Z Electrochem* **45** 661 1940, cf Connick & Fine *J Am Chem Soc* **83** 3414 1961].

It is a soluble catalyst used for the oxidative cyclisation of 1,7-dienes to oxepane diols [Piccialli et al. *Tetrahedron Lett* **48** 5131 2007], and promotes a site-specific hydroxylation of tertiary carbon-hydrogen bonds of cyclic ethers in the presence of periodate or bromate [Lee et al. *J Org Chem* **72** 5820 2007].

It also catalyses oxidation reactions with an oxidant, e.g. the methylene group in cyclopropylmethyl-compounds to a carbonyl group in the presence of metaperiodate [Hasegawa et al. *Chem Lett (Jpn)* 1385 1985, Carlsen et al. *J Org Chem* **46** 3936 1981, cf Review Gore *Platinum Metals Rev* **27** 111 1983]. It catalyses the synthesis of 2-ethyl-3-methylquinolines from primary aromatic amines and triallylamine [Cho et al. *Tetrahedron Lett* **40** 1499 1999], and has been used for the selective hydrogenation of unsaturated aldehydes [Fujita et al. *J Catal* **255** 95 2004].

**Ruthenium [1,3-bis-(2,4,6-trimethylphenyl)-2-imidazolidinylidene] dichloro (benzylidene) (tri-cyclohexylphosphine) {Benzylidene-[1,3-bis(2,4,6-trimethylphenyl)-4,5-dihydro-2-imidazolinyldene]dichloro-(tri-cyclohexylphosphine)-ruthenium, [(1,3-Bis(2,4,6-trimethylphenyl)-2-imidazolinyldene) dichloro (phenyl-methylene)(tricyclophosphine)ruthenium, (Grubbs catalyst—second generation)}** [246047-72-3] **M 849.0, m 143.5-148.5°.** This catalyst is prepared by adding a solution of *tert*-BuOK (1.25g, 10.2mmol, 1.4 equiv) in dry THF (200ml) slowly to a suspension of 1,3-dimesityl-4,5-dihydroimidazolium tetrafluoroborate (4.2g, 10.2mmol, 1.4 equivalent) in dry THF (100ml) in a flame dried Schlenk flask (500ml) under N<sub>2</sub> (magnetic stirring) at ~20°. The BF<sub>4</sub><sup>-</sup> salt dissolves immediately, the cloudy yellow mixture is stirred at ~20° for 1 hour, and then transferred (cannula) to a larger Schlenk flask (twice size) under argon. To this is added RuCl<sub>2</sub>(=CHPh)(PCy<sub>3</sub>)<sub>2</sub> (7.29, 7.29mmol, 1.0 equivalents) in dry \*C<sub>6</sub>H<sub>6</sub> (400ml) and heated at 80° for 30 minutes when the reaction is complete (by <sup>1</sup>H NMR). The volatiles are removed *in vacuo* and the residue is washed with dry MeOH, or pentane (4 × 100ml) to provide the active catalyst as a pink-brown microcrystalline powder (4.64g, 75%). It has <sup>1</sup>H NMR (400MHz, CD<sub>2</sub>Cl<sub>2</sub>) with δ at 19.16 (s, 1H), 7.37-7.05 (m, 9H), 3.88 (s, 4H), 2.56—0.15 (m, 51H); <sup>31</sup>P NMR (161.9MHz, CD<sub>2</sub>Cl<sub>2</sub>) with δ at 31.41 and HRMS (FAB) at 848.3306 for M<sup>+</sup> [Scholl et al. *Org Lett* **1** 953 1999].

It is used in ruthenium catalysed ring closure metathesis (RCM) and olefin metathesis [Kulkarni & Diver *J Am Chem Soc* **126** 8110 2004, Schmidt *Angew Chem. Int Ed* **42** 4996 2003, Scholl et al. *Org Lett* **1** 953 1999], and generate unsaturated sultones (e.g. 2,7-3*H*-dihydro-[1,2]oxathiepine-2,2-dioxide) from olefinic sulfonates (e.g. but-3-enyl allylsulfonate) *via* ring closure metathesis [Le Flohic et al. *Tetrahedron* **62** 9017 2006].

**Ruthenium [(R-P-Phos)(acac)<sub>2</sub>] {Ruthenium [R-(+)-2,2',6,6'-tetramethoxy-4,4'-bis(diphenylphosphino)-3,3'-bipyridine)-bis(acetylacetonate)]** is prepared by mixing equimolar amounts of R-P-Phos (see R-(+)-[221012-82-4] in Part-2 below) with Ru(acac)<sub>3</sub> [14284-93-6] in the presence of a reducing agent (Zn powder) in refluxing EtOH to give the solid catalyst in 97% yield which was characterized by <sup>1</sup>H, <sup>31</sup>P NMR, elemental analysis and X-ray crystallographic structure determination. **Ru[(S-P-Phos)Cl<sub>2</sub>](DMF)<sub>n</sub>** is prepared in a similar manner with the appropriate ingredients (using S-(-)-P-Phos [362524-23-0]) in DMF. [Pai et al. *J Am Chem Soc* **122** 11513 2000.] These (see also below) atropisomeric bi-heteroaromatic diphosphine (P-Phos and its variants) complexes with transition metals are effective in catalysing asymmetric reactions including asymmetric hydrogenation of 2-arylacrylates, β-ketoesters, arylketones, hydrosilylation and C-C bond formation with high stereospecificity. [Wu & Chan *Acc Chem Res* **39** 711 2006, Au-Yeung & Chan *Coordination Chemistry Reviews* **248** 2151 2004, Pai et al. *J Am Chem Soc* **122** 11513 2000.]

**Ruthenium [(R-Xylyl-P-Phos)(C<sub>6</sub>H<sub>6</sub>)Cl<sub>2</sub>] {Ruthenium R-(+)-2,2',6,6'-tetramethoxy-4,4'-bis[di(3,5-xylyl)phosphino]-3,3'-bipyridine)(benzene) dichloride]** is prepared in 88% yield by mixing equimolar amounts of [RuCl<sub>2</sub>(C<sub>6</sub>H<sub>6</sub>)<sub>2</sub>] [37366-09-9] with R-Xylyl-P-Phos (see R-(+)- [442905-33-1] in Part-2 below) in EtOH/\*C<sub>6</sub>H<sub>6</sub> (8:1) and heating at 50-60° for 1 hour. This ruthenium complex is a highly active, enantioselective, air stable catalyst for the asymmetric hydrogenation of β-ketoesters (PH<sub>2</sub> = 200-350psi at 70-90° for 1-15 hours) to optically active β-hydroxyesters with ~100% conversion and >91% enantiomeric enrichment. It is very stable in the solid state in air; and a stirred solution for 10 hours under air showed no loss of activity or stereoselectivity; and its <sup>31</sup>P NMR (200MHz, CDCl<sub>3</sub>) is not different from that obtained for the original sample under N<sub>2</sub> which has an AB set of signals with δ<sub>p</sub> at 33.49 (d, J<sub>PA-PB</sub> = 62.9Hz) and 39.96 (d, J<sub>PA-PB</sub> = 62.5Hz). The coordination of ruthenium to benzene makes the phosphorus atoms non-equivalent. The resonance observed in the <sup>1</sup>H NMR (500MHz, CDCl<sub>3</sub>) at 5.65ppm is assignable to the 6H resonances of the η<sup>6</sup>-coordinated benzene moiety [Wu et al. *Tetrahedron Lett* **43** 1539 2002].

Other P-Phos related ligands, such as the chiral 4-bis(tolylphosphino) (**Tol-P-Phos**) and chiral 4-bis(cyclohexylphosphino) (**Cy-P-Phos**) ligands, were prepared and purified in a similar, or slightly modified, manner using the appropriate phosphines. They also form ruthenium complexes that have related catalytic activities [Wu & Chan *Acc Chem Res* **39** 711 2006, Au-Yeung & Chan *Coordination Chemistry Reviews* **248** 2151 2004].

**Ruthenium(II)-tris(triphenylphosphine) dichloride [tris(triphenylphosphine)ruthenium(II) dichloride] [15529-49-4] M 958.8; 433 (in Me<sub>2</sub>CO/N<sub>2</sub>), m 132-134°.** This catalyst is prepared by heating under reflux RuCl<sub>3</sub>·3H<sub>2</sub>O (0.26g, 1mmol) and Ph<sub>3</sub>P (1.57g, 6mmol) in MeOH (65ml) under N<sub>2</sub> for 3 hours, when the reddish-brown tris-complex separates. It is washed well with MeOH, then Et<sub>2</sub>O and dried *in vacuo* at 60° (yield 75%). It is soluble in CHCl<sub>3</sub>, Me<sub>2</sub>CO, \*C<sub>6</sub>H<sub>6</sub>, EtOAc and hot *i*-PrOH, but insoluble in H<sub>2</sub>O, Et<sub>2</sub>O and sparingly soluble in alcohol. When less Ph<sub>3</sub>P is used in e.g. MeOH, complexes such as Ru(III)-di(Ph<sub>3</sub>P)(MeOH)Cl<sub>2</sub> are formed. *Note that if the above mixture is shaken, not refluxed, Ru(II)-tetrakis(triphenylphosphine) dichloride is formed which turns green on exposure to air.* [Stephenson & Wilkinson *J Inorg Nucl Chem* **28** 945 1966, Sammakia & Stangeland *J Org Chem* **62** 6105 (footnote) 1997.]

The *tris-complex* catalyses a variety of reactions including hydrogen transfer [Sasson & Blum *Tetrahedron Lett* 2167 1971, Regen & Whitesides *J Org Chem* **37** 1832 1972], insertion of *t*-BuOO- into the carbon atom α to the N-atom of, e.g. *N*-methoxycarbonylpyrrolidine and 1,2,3,4-tetrahydroisoquinoline with *t*-BuOOH [Kondo et al. *J Org Chem* **56** 487 1991], intramolecular cyclisation of unsaturated α,α-dichloroesters or amides [Hayes et al. *J Org Chem* **51** 5501 1986], and the reduction of CHO by HCOOH/Et<sub>3</sub>N/THF without affecting NO<sub>2</sub>, RCOR', ester or *tert*-amide groups [Kai & Arcelli *Tetrahedron Lett* **26** 3365 1985]; and for other examples of catalysis by this Ru-complex see selected volumes of Fieser & Feiser's *Reagents in Organic Synthesis*, and *Angew Chem. Int Ed* **46** 1905 2007. When complexed further with chiral (phosphinoferrocenyl)oxazolines, hydrogen transfer is not only considerably enhanced but is also highly stereospecific [see further in this chapter].

**Samarium (II) iodide (SmI<sub>2</sub>)** **Samarium (II) iodide (SmI<sub>2</sub>)** see [32248-43-4], Chapter 5, Inorganic Compounds.

**Silver acetate (AgOAc)** see [563-63-3], Chapter 5, Inorganic Compounds.

**Silver tetrafluoroborate** [AgBF<sub>4</sub>] see [14104-20-2], Chapter 5, Inorganic Compounds.

**Tetrakis(triphenylphosphino)palladium(0)** [**palladium-tetrakis(triphenylphosphine)**] [14221-01-3] **M 1155.6, m 100-105°, 115°, ~116° (dec, sealed tube under N<sub>2</sub>), (m is unreliable and is not a criterion of purity because it varies).** This catalyst is prepared from PdCl<sub>2</sub> (5.9g, 0.1mol), Ph<sub>3</sub>P (43.7g, 0.5ml) in Me<sub>2</sub>SO (400ml) under a vacuum N<sub>2</sub> system with pressure release, and the yellow mixture is heated (oil bath) with stirring until dissolution (140°). The bath is removed, the mixture is stirred rapidly for 15 minutes and hydrazine hydrate (6.7g 0.4mol) is injected within 1 minute. A vigorous evolution of N<sub>2</sub> occurs and the dark solution is rapidly cooled with a cool water bath and crystallisation takes place (~125°). When the temperature reaches ~20° the solid is filtered off (coarse sintered glass) under N<sub>2</sub>, washed with EtOH (2 × 50ml), Et<sub>2</sub>O (2 × 50ml) and the yellow crystalline solid is dried by a slow stream of N<sub>2</sub> through the funnel overnight (37.4g 97%). *Alternatively*, it can be prepared freshly by mixing Pd(NO<sub>3</sub>)<sub>2</sub> (2mmols) and PPh<sub>3</sub>(2mmols) in hot \*C<sub>6</sub>H<sub>6</sub> when vigorous evolution of nitric oxide occurs (fume cupboard) and a solid mass separates. This is collected and crystallised from EtOH. It should not be heated excessively as it dissociates to Pd(PPh<sub>3</sub>)<sub>3</sub> and PPh<sub>3</sub>, and then further to Pd(PPh<sub>3</sub>)<sub>2</sub> and PPh<sub>3</sub>. It is also air sensitive as PPh<sub>3</sub> is oxidised to PPh<sub>3</sub>O. It is stable only for short periods because on exposure to heat or air it turns from yellow to orange and dissociates in solution, so the solutions should be used directly. Its cryoscopic constant in \*C<sub>6</sub>H<sub>6</sub> (at 0.601g/20ml) corresponds to **M 1156** [Malatesta & Angoletti *J Chem Soc* 1186 1957]. Molecular weight determination in \*C<sub>6</sub>H<sub>6</sub> indicates considerable dissociation, and the solution absorbs O<sub>2</sub> rapidly to give an insoluble green oxygen complex [Nyman et al. *J Chem Soc A* 561 1968]. It is moderately soluble in \*C<sub>6</sub>H<sub>6</sub> (5g/100ml), CH<sub>2</sub>Cl<sub>2</sub> and CHCl<sub>3</sub> but less soluble in Me<sub>2</sub>CO, THF and MeCN. Pd(Ph<sub>3</sub>P)<sub>4</sub> may be handled in air but it is best stored under N<sub>2</sub>. [Coulson *Inorg Synth* 28 121 1990, Malatesta & Angoletta *J Chem Soc* 1186 1990, *Beilstein* 16 IV 954.]

Pd(Ph<sub>3</sub>P)<sub>4</sub> is a very versatile catalyst for promoting the dimerisation of butadiene to 1,3,7-octatriene [Takahashi et al. *Bull Chem Soc Jpn* 41 454 1968], catalysing various coupling reactions, without homo-coupling occurring [Brocato et al. *Tetrahedron Lett* 33 7433 1992, Arcadi et al. *Tetrahedron Lett* 34 2813 1993, McClure & Danishefsky *J Am Chem Soc* 115 6093 1993, Paquette & Astles *J Org Chem* 58 165 1993, Schoo et al. *Org Lett* 8 4141 2006], including Suzuki coupling [Trost *Tetrahedron* 33 2615 1977]. [*Beilstein* 16 IV 954.]

This palladium catalyst bound to a polymer support (~0.06mmol/g) is also commercially available [*cf* Frnger & LeDrain *Tetrahedron Lett* 39 4287 2988].

**Tetra-*n*-propylammonium perruthenate (TPAP, tetrapropyl tetraoxoruthenate)** [114615-82-6] **M 351.4, m 160°(dec).** This stable dark green solid is a useful catalyst for a variety of oxidation reactions at about room temperature. It is used at a concentration of about 5 mol% with an equivalent of *N*-methylmorpholine *N*-oxide which provides the required oxygen with typical turnovers of about 250. The reactions are carried out in CH<sub>2</sub>Cl<sub>2</sub> and/or MeCN, although the latter assists the reactions in CH<sub>2</sub>Cl<sub>2</sub> considerably. Care should be taken to add TPAP slowly as the reaction can be vigorous. Addition of finely ground 4Å molecular sieves moderate the rate and efficiency of the reaction. The reactions usually proceed to completion within 5 minutes to one hour. Cooling and slow addition of TPAP is necessary with reactions on a large scale. Workup is simple, and is carried out by passing the solution through a short silica-gel column and eluting with EtOAc followed by evaporation and crystallisation or distillation of the product. When MeCN is the solvent, or is present in the solvent, it is advisable to evaporate the solvent prior to passage through the silica-gel column. [Ley et al. *Synthesis* 639 1994; see entry in the “Metal-Organic Compounds” chapter for further information].

**Triphenylphosphinegold(I) bis(trifluoromethanesulfonyl)imidate** ([Ph<sub>3</sub>PAu(I)]<sup>+</sup> [NTf<sub>2</sub>]<sup>-</sup>) [866395-16-6] **M 739.4, m >230°.** AgNTf<sub>2</sub> is first prepared by mixing Ag<sub>2</sub>CO<sub>3</sub> (276mg, 1.0mmol) and HNTf<sub>2</sub> (562mg, 2.0mmol, 2 equivalents [82113-65-3]) in H<sub>2</sub>O (10ml), and refluxing for 3 hours (to eliminate CO<sub>2</sub>); then evaporating to dryness *in vacuo*. It can be used as a solid or dissolved in dry CH<sub>2</sub>Cl<sub>2</sub> (5ml). [Li et al. *J Org Chem* 73 4323 2008.] The versatile catalyst is then prepared by dissolving Ph<sub>3</sub>PAuCl (2mmol, [14243-64-2]) in CH<sub>2</sub>Cl<sub>2</sub> (5ml) and adding to it solid AgNTf<sub>2</sub> (786mg, 2mmol) or the preceding CH<sub>2</sub>Cl<sub>2</sub> (5ml) solution. Immediate separation of AgCl occurs. After stirring for 15 minutes the <sup>31</sup>PMR reveals a single peak of the Au salt. The AgCl is removed by filtration through Celite, the pale coloured solution is evaporated *in vacuo*, and the residue is dried *in vacuo* to give a quantitative yield of the catalyst. It forms small white crystals which are air stable, but should be preferably stored in a dry inert atmosphere. It is soluble in Me<sub>2</sub>CO, CH<sub>2</sub>Cl<sub>2</sub>, and CHCl<sub>3</sub> but insoluble in petroleum ethers. Its IR (CCl<sub>4</sub>) has ν<sub>max</sub> at 1482, 1437, 1405, 1384, 1216, 1196, 1133, 1103 and 960, cm<sup>-1</sup>; the <sup>1</sup>H NMR (400MHz, CDCl<sub>3</sub>) has δ<sub>H</sub> at 7.47-7.55 (m, 12H, aromatic H) and 7.56-7.62 (m, 3H, aromatic H close to

Au); the  $^{13}\text{C}$  NMR (100MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}$  at 118.4 (q,  $J_{^{13}\text{C}-^{19}\text{F}} = 323.0\text{Hz}$ ), 126.3 (d,  $J_{^{13}\text{C}-^{31}\text{P}} = 65.8\text{Hz}$ ), 128.5 (d,  $J_{^{13}\text{C}-^{31}\text{P}} = 12.5\text{Hz}$ ), 133.5 (d,  $J_{^{13}\text{C}-^{31}\text{P}} = 2.5\text{Hz}$ ) and 133.1 (d,  $J_{^{13}\text{C}-^{31}\text{P}} = 13.7\text{Hz}$ ); and the  $^{31}\text{P}$  NMR (121.5MHz,  $\text{CD}_2\text{Cl}_2$ ) has  $\delta_{\text{P}}$  at 30.7. [Mésailles et al. *Org Lett* **7** 4133 2005.]  $\text{NTf}_2$  is a weakly coordinating counter ion which confers stability to the complex.  $^{31}\text{P}$  NMR spectra of pre-formed solutions of the complexes  $\text{Ph}_3\text{PAuBF}_4$ ,  $\text{Ph}_3\text{PAuPF}_6$  and  $\text{Ph}_3\text{PAuSbF}_6$ , using the respective Ag salts, showed that they were not very stable. Attempts to isolate the complexes were unsuccessful. [Mésailles et al. *Org Lett* **7** 4133 2005.]

At concentrations of 1-2mol% in  $\text{CH}_2\text{Cl}_2$  or  $\text{Me}_2\text{CO}$ ,  $\text{Ph}_3\text{PAu(I)}^+ [\text{NTf}_2]^-$  catalyses the stereoselective isomerisation of butynediol monobenzoates into functionalised 2,5-dihydrofurans (in a sequence of two steps) in high yields at room temperature and in 15 to ~30 minutes [Buzas et al. *Org Lett* **8** 1957 2006]. It is exceedingly active in catalysing a wide variety of *ene* cycloisomerisations [Mésailles et al. *Org Lett* **7** 4133 2005]. Also under similar mild conditions, in the presence of electrophilic bromine (from *N*-bromosuccinimide) or iodine (from *N*-iodosuccinimide), it catalyses the formation of linear  $\alpha$ -halo-enones from propargyl acetates [Yu et al. *Tetrahedron* **65** 1846 2009], and 4-haloalkylidene-1,3-dioxalane-2-ones with propargyl *tert*-butylcarbonates [Buzas et al. *Tetrahedron* **65** 1889 2009], products which are suitable substrates for Pd-catalysed cross coupling reactions. Like the following  $\text{OTf}^- \text{Au}$  catalyst, it promotes the glycosylation of 1,2-anhydrosugars as donors using protected sugars with one free sterically unhindered OH group [Li et al. *J Org Chem* **73** 4323 2008].

**Triphenylphosphinegold(I) trifluoromethanesulfonate** ( $[\text{Ph}_3\text{PAu(I)}]^+ [\text{OTf}]^-$ ) [156397-47-6] **M 608.2, m >230°**.  $\text{Ph}_3\text{PAu(I)}^+ [\text{OTf}]^-$  differs from the preceding catalyst in the counter anion, and is much less air and moisture sensitive. Due precautions need to be taken in use and storage. It is prepared by dissolving  $\text{Ph}_3\text{PAuCl}$  (0.1mmol, [14243-64-2]) and silver trifluoromethanesulfonate (0.1mol, [2923-28-6]) in dry  $\text{CH}_2\text{Cl}_2$  (1ml) and stirred for 5 minutes. Filtration from AgCl provides a 0.1M solution of catalyst in  $\text{CH}_2\text{Cl}_2$ . Generally the AgCl does not interfere in the catalytic process and so the catalyst can be prepared *in situ*. Colourless  $\text{Ph}_3\text{PAu(I)}^+ [\text{OTf}]^-$  can be obtained by evaporating the  $\text{CH}_2\text{Cl}_2$  solution and stored appropriately. It is a superior catalyst than anhydrous  $\text{ZnCl}_2$  for the well established glycosylation reactions with 1,2-anhydrosugars as donors [Li et al. *J Org Chem* **73** 4323 2008], and it catalyses the intramolecular hydroamination of terminal alkenes in high yields with 1-5mol% of catalyst by heating in toluene at 100° for 12-48 hours, or the intra- and inter- molecular hydroamination in  $\text{ClCH}_2\text{CH}_2\text{Cl}$  by microwave radiation as heat source in ~30 minutes in high yield [Liu et al. *Org Lett* **8** 2707 2006]. In a useful application, the catalyst  $\text{Ph}_3\text{PAu(I)}^+ [\text{OTf}]^-$  promotes a cascade cyclisation/oxidative cleavage of a carbon-carbon triple bond in *Z*-enynols, e.g. 5-Ph or 5-*n*-butyl-pent-2-ene-4-yne-1-ols, in the presence of molecular oxygen to give high yields of the corresponding 2,5-dihydrofuran-2-ones and releasing C-5 with its substituent as the aldehyde or acid. The reaction involves free radicals as it is completely suppressed in the presence of the radical scavenger 4-hydroxy-TEMPO [Liu et al. *J Am Chem Soc* **128** 11332 2006].

**Tris(dibenzylideneacetone)dipalladium(0) chloroform adduct**  $[\text{Pd}_2(\text{dba})_3(\text{CDCl}_3)]$  [52522-40-4] **M 1035.1, m 122-124°; solvent free  $\text{Pd}_2(\text{dba})_3$**  [51364-51-3] **M 95.7, m 152-155°**. When  $\text{PdCl}_2$  (1.05g, 5.92mmol) is added to a solution of dibenzylidene acetone (dba, 4.60g, 19.6mmol) and NaOAc (3.9g, 47.5mmol) in MeOH (150ml at 50°) and mixed at 40° for 4 hours then cooled, a reddish-purple precipitate separates. This is collected, washed with  $\text{H}_2\text{O}$  then  $\text{Me}_2\text{CO}$  and dried *in vacuo*. The precipitate (3.39g) is purified by dissolving it in hot  $\text{CDCl}_3$  (120ml), filtering, and to the deep violet filtrate is added slowly  $\text{Et}_2\text{O}$  (170ml) when the *chloroform adduct* separates as deep purple needles which are collected and dried *in vacuo* (80% yield, m 122-124°). Recrystallisation from  $^*\text{C}_6\text{H}_6$  instead of  $\text{CHCl}_3$  gives deep-violet needles of **tris(dibenzylideneacetone)-dipalladium(0) benzene adduct** (62.5% yield, m 141-142°). By using toluene instead of  $\text{CHCl}_3$ , deep-violet needles of **tris(dibenzylideneacetone) dipalladium(0) toluene adduct** (36% yield, m 140-141°) are obtained. The solvates can be exchanged with each other (i.e.  $\text{CDCl}_3$ ,  $^*\text{C}_6\text{H}_6$  or toluene) without affecting the coordinating reactivity of the complex with other ligands such as  $\text{Ph}_3\text{P}$ , Bipy, *o*-phen, olefins, *o*-quinones etc. [Ukai et al. *J Organomet Chem* **65** 253 1974, for applications see Fustero *Org Lett* **8** 4129 2006.]

If the procedure is used with bis(*p*-methoxybenzylidene)acetone and the complex crystallised from  $\text{CDCl}_3/\text{Et}_2\text{O}$ ,  **$\text{Pd}_2(p,p'$ -methoxy-dba) $_3$**  is obtained as deep violet needles (72.3% yield, m 141-143°) which do not complex with the solvent. [cf  **$\text{Pd}(\text{dba})_2$**  above.] [Ukai et al. *J Organomet Chem* **65** 253 1974.]

**Tris(dibenzylideneacetone)palladium**  $[\text{Pd}(\text{dba})_3]$ : When a fourfold excess of dba is added to solution of  $\text{Pd}(\text{dba})_2$  or  $\text{Pd}_2(\text{dba})_3$  in  $^*\text{C}_6\text{H}_6$ , heated and reduced in volume, the dark red colour of  $\text{Pd}(\text{dba})_2$  turns to brown,

and on complete evaporation, orange brown crystals of **Pd(dba)<sub>3</sub>** contaminated with yellow crystals of dba are obtained. Washing the crystals with \*C<sub>6</sub>H<sub>6</sub> leads to crystal decomposition. The IR of the complex has  $\nu_{\max}$  at 1651 (C=O) and olefine bands at 1598, 1580 and 1531 cm<sup>-1</sup>. X-ray analysis of the Pd(dba)<sub>3</sub>—\*C<sub>6</sub>H<sub>6</sub> crystals showed that each pentadienone ligand is coordinated through one olefin group, and the Pd atom is trigonal with  $\sim C_3$  symmetry [Mazza & Pierpont *Inorg Chem* **12** 2955 1973, cf *Handbook of Organopalladium for Organic Synthesis* Negishi ed. Wiley, Hoboken NJ 2002, ISBN 0-471-31506-0].

**Tris[triphenylphosphinegold(I)]oxonium tetrafluoroborate ([Ph<sub>3</sub>PAu(I)]<sub>3</sub>O<sup>+</sup> [BF<sub>4</sub>]<sup>-</sup>)** [53317-87-6] **M 1480.6, m 207° (dec), 207-208° (dec), 220-221° (dec)**. The catalytic oxonium salt is prepared by adding a solution of AgBF<sub>4</sub> (0.2g, 1.03mmol) in MeOH (5ml) to a solution of Ph<sub>3</sub>PAuCl (0.5g, 1.01mmol, [14243-64-2]) in THF (20ml) and the AgCl that precipitated is filtered off. A solution of KOH (0.1g, 1.78mmol) and NaBF<sub>4</sub> (0.5g, 4.55mmol) in MeOH (100ml) is added to the filtrate, stirred for 1 hour, the solvent is evaporated off *in vacuo*, the residue is extracted with CHCl<sub>3</sub> (2 x 30ml), the combined extract is filtered, and hexane (100ml) is added to precipitate the oxonium salt which gives analytically pure [Ph<sub>3</sub>PAu(I)]<sub>3</sub>O<sup>+</sup> [BF<sub>4</sub>]<sup>-</sup> (0.42g, 84%), **m 220-221° (dec)**, after recrystallisation from a saturated CHCl<sub>3</sub> solution on adding  $\sim 1.5$ -fold volume of Me<sub>2</sub>CO. **Alternatively**, Ag<sub>2</sub>O freshly prepared from AgNO<sub>3</sub> (5.0g, 29.5mmol), and NaBF<sub>4</sub> (5.0g, 45.5mmol, finely powdered) are added to a solution of Ph<sub>3</sub>PAuCl (4.0g, 8.08mmol) in Me<sub>2</sub>CO (600ml), stirred vigorously for 1 hour, and the solvent evaporated *in vacuo*. The residue is extracted with \*C<sub>6</sub>H<sub>6</sub> to removed unreacted Ph<sub>3</sub>PAuCl, and the oxonium salt is extracted with CHCl<sub>3</sub> (3 x 40ml), filtered, and hexane (400ml) is added to crystallise [Ph<sub>3</sub>PAu(I)]<sub>3</sub>O<sup>+</sup> [BF<sub>4</sub>]<sup>-</sup> (3.6g, 90%) out. It is soluble in CHCl<sub>3</sub> and CH<sub>2</sub>Cl<sub>2</sub> but insoluble in hexane and Et<sub>2</sub>O. Its IR (nujol mull) has  $\nu_{\max}$  at 1050-1070 (br, BF<sub>4</sub><sup>-</sup>) cm<sup>-1</sup>. It is a versatile air and moisture tolerant catalyst that has been used in a variety of reactions (see below). X-ray crystallography showed that in the crystals the oxonium ions are dimeric, with the two pyramidal monomeric (Ph<sub>3</sub>PAu)<sub>3</sub>( $\mu_3$ -O)<sup>+</sup> fragments interacting *via* Au—Au' bonds ( $\sim 3.16\text{\AA}$ ) involving two of the three Au atoms in each unit. The pyramidal structure has the O' atom centrally above the Au<sub>3</sub> triangular plane, and the resulting six-membered Au<sub>2</sub>O—Au<sub>2</sub>O heterocycle has a chair conformation. The **oxonium trifluoroacetate m 209-210° (dec)** from CHCl<sub>3</sub>/\*C<sub>6</sub>H<sub>6</sub>, and the **oxonium permanganate m 131-131.5° (dec)** from CHCl<sub>3</sub>/hexane (1.2:4.0 v/v) were prepared similarly. [Nesmeyanov et al. *J Organomet Chem* **201** 343 1980, cf Bruce et al. *Inorg Synth* **26** 326 1988.] Oxonium complexes with other phosphine ligands have been similarly prepared and if H<sub>2</sub><sup>17</sup>O is used in the preparations, then it is incorporated into the oxygen of the cation. [Ph<sub>3</sub>PAu(I)]<sub>3</sub><sup>17</sup>O<sup>+</sup> [BF<sub>4</sub>]<sup>-</sup> has <sup>31</sup>P NMR (36MHz, CD<sub>2</sub>Cl<sub>2</sub>, external 85% H<sub>3</sub>PO<sub>4</sub>) with  $\delta_P$  at 24.0, and <sup>17</sup>O NMR (CD<sub>2</sub>Cl<sub>2</sub> and external H<sub>2</sub>O) with  $\delta_{17O}$  at +19.7 (br s, w/2 = 152Hz). [Yang et al. *Inorg Chem* **32** 1946 1993.]

[Ph<sub>3</sub>PAu(I)]<sub>3</sub>O<sup>+</sup> [BF<sub>4</sub>]<sup>-</sup> catalyses the Claisen rearrangement of propargyl vinyl ethers, e.g. 1-phenylhept-2-yn-1-yl vinyl ether, to respective aldehydes which are usually reduced *in situ* with NaBH<sub>4</sub> to give the homoallylic alcohol, i.e. 1-phenyl-3-*n*-butyl-3-(2-hydroxyethyl)allene, in high yield with 1mole% of catalyst in CH<sub>2</sub>Cl<sub>2</sub> at room temperature. Chirality is efficiently transferred in the rearrangement. [Sherry & Toste *J Am Chem Soc* **126** 15978 2004]. In the presence of sterically hindered secondary amines, e.g. (iso-Pr)<sub>2</sub>NH or (iso-Pr)CyNH, it catalyses the 5-*exo-dig* cyclisation of formyl alkynes, e.g. 6-formyl-4,4-bis(methoxycarbonyl)hex-1-yne, to 1,1-(bismethoxycarbonyl)-3-formyl-4-exomethylenecyclopentane in CDCl<sub>3</sub>, 70°/3-24 hours, in  $\sim 70\%$  yields [Binder et al. *Org Lett* **10** 1025 2008]. In the presence of O<sub>2</sub> in THF at  $\sim 50^\circ$  [Ph<sub>3</sub>PAu(I)]<sub>3</sub>O<sup>+</sup> [BF<sub>4</sub>]<sup>-</sup> also catalyses the cascade cyclisation/oxidative cleavage of a carbon-carbon triple bond in Z-enynols efficiently [see Ph<sub>3</sub>PAu(I)]<sup>+</sup> [OTf]<sup>-</sup> above, Liu et al. *J Am Chem Soc* **128** 11332 2006].

**(Xantphos)Rh(H)(CO)(PPh<sub>3</sub>)** is prepared by stirring a solution of (PPh<sub>3</sub>)Rh(H)(CO) (100mg, 0.11mmol) and Xantphos (63.6mg, 0.11mmol, see [161265-03-8] in Catalysts—Part 2 below) in \*C<sub>6</sub>H<sub>6</sub> (10ml) at 30° for 4 hours, evaporating the solvent *in vacuo*, washing the residue with MeOH (1ml) and drying *in vacuo* to give the analytically pure complex with the formula C<sub>58</sub>H<sub>48</sub>O<sub>2</sub>P<sub>3</sub>Rh. The complex has IR (CHCl<sub>3</sub>) with  $\nu_{\max}$  at 1996.9vs, 1909.6m cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, C<sub>6</sub>D<sub>6</sub>) has  $\delta$  at 7.82 (apparent q, 4H,  $J = 4.8\text{Hz}$ , ar), 7.66 (m, 6H, ar), 7.53 (apparent q, 4H,  $J = 4.9\text{Hz}$ , ar), 7.11 (dd, 2H,  $J = 7.3, 1.3\text{Hz}$ , CHCHCC), 7.0-6.9 (ar), 6.79 ('d', 4H), 1.48 (s, 3H, CCH<sub>3</sub>), 1.38 (s, 3H, CCH<sub>3</sub>), -9.14 ( $J_{H-P} = 12.2\text{Hz}$ ,  $J_{H-P'} = 18.2\text{Hz}$ ,  $J_{H-Rh} = 1.7\text{Hz}$ ); the <sup>13</sup>C{<sup>1</sup>H}NMR (100MHz, C<sub>6</sub>D<sub>6</sub>) has  $\delta$  at 156.9 (t,  $J = 5.6\text{Hz}$ ), 141.9 (dt,  $J = 4.4, 31.1\text{Hz}$ ), 140.1 (t,  $J = 18.9\text{Hz}$ ), 137.6 (t,  $J = 18\text{Hz}$ ), 135.6 (s), 134.9 (ar), 134.8 (ar), 134.6 (ar), 134.5 (ar), 134.4 (ar), 134.2 (ar), 36.9 (s, C(CH<sub>3</sub>)<sub>2</sub>), 31.0 (s, CH<sub>3</sub>), 24.7 (s,

CH<sub>3</sub>); and the <sup>31</sup>P{<sup>1</sup>H}NMR (121.5MHz, C<sub>6</sub>D<sub>6</sub>, referenced to external 85% H<sub>3</sub>PO<sub>4</sub>) has δ at 42.67 (*J*<sub>P-Rh</sub> = 151.1Hz, *J*<sub>P-P</sub> = 119.1Hz, PPh<sub>3</sub>), 25.65 (*J*<sub>P-Rh</sub> = 127.9Hz, *J*<sub>P-P</sub> = 119.1Hz, Xantphos-P); and the MS has *m/z* at 961 (M-CO), 726 (M-PPh<sub>3</sub>-2H), 698 (M-PPh<sub>3</sub>-CO-2H); HR-MS found *M* is 578.1916 (calc for C<sub>39</sub>H<sub>32</sub>OP<sub>2</sub> is 578.1928). [Kranenburg, van der Burgt, Kramer and van Leewen *Organometallics* **14** 3081 1995.]

**Xantphos-Ru complex** formed *in situ* from equimolar amounts of Xantphos and Ru(PPh<sub>3</sub>)(CO)H<sub>2</sub> in refluxing toluene containing piperidinium acetate is a good catalyst for alkylating active methylene compounds, e.g. *t*-butyl cyanoacetate, and hydroxy compounds, e.g. PhCH<sub>2</sub>OH, to provide α-substituted cyanoacetates, e.g. *t*-butyl 2-cyano-3-phenylpropionate [Slatford, Whittlesey and Williams *Tetrahedron Lett* **47** 6787 2006].

**Xantphos-Pd complexes** formed *in situ* from xantphos and Pd(OAc)<sub>2</sub> or Pd<sub>2</sub>(dba)<sub>3</sub> catalyse the cross-coupling reactions between the amide nitrogen and aryl and heteroaryl halides [Manley & Bilodou *Org Lett* **14** 2433 2004] or *meso*-brominated porphyrins [Gao, Chen and Zhang *Org Lett* **11** 1837 2004] to form the corresponding aryl-N-CO- and *meso*-porphyrin-NCO- in high yields respectively in the presence of a base e.g. CsCO<sub>3</sub>. Similar cross-coupling catalysis with *in situ* Xantphos and Pd(OAc)<sub>2</sub> between thenylbromides and 2-aminopyridines or aminoquinolines has been achieved in high yields [Begouin et al. *Synthesis* 2794 2006]. It should be noted that a detailed study of the mixing of Xantphos and Pd<sub>2</sub>(dba)<sub>3</sub> identified the complexes (**Xantphos**)Pd(**dba**) and **Pd(Xantphos)**<sub>2</sub>. The former is a very active catalyst whereas the latter bis(xanthane based phosphine)<sub>2</sub>Pd(0) is less soluble and inherently less active. It is therefore important, when forming the pre-catalyst, to keep the ratio of xantphos to Pd source less than 1.5:1 for a more effective catalyst involving cross-coupling between a nitrogen atom and an organic halide. [Lingensmith, Strieter, Barder and Buchwald *Organometallics* **25** 82 2006.]

(**Xantphos**)<sub>2</sub> Pd is prepared, in flame dried Schlenk equipment, evacuated/backfilled with argon three times, by stirring xantphos (579mg, 1.00mmol) and Pd<sub>2</sub>(dba)<sub>3</sub> (229mg, 0.25mmol) in toluene (300ml) under argon for 4 hours. This is filtered *via* a cannula into a separate dry flask under argon, concentrated somewhat overnight and any palladium black which may have settled is filtered off and the filtrate is evaporated to dryness. The yellow residue is stirred overnight with toluene (100ml) to remove excess (or unused) dibenzylidene acetone and unreacted Xantphos. The remaining yellow Pd(Xantphos)<sub>2</sub> has **m 164° (dec.)**, is sparingly soluble in most common organic solvents, and is characterised by the correct elemental analyses for C<sub>78</sub>H<sub>64</sub>O<sub>2</sub>P<sub>4</sub>Pd. Its IR (KBr) has *v*<sub>max</sub> at 2924, 2854, 1461, 1398, 1377, 1222 cm<sup>-1</sup>; and MALDI-MS: calcd for C<sub>78</sub>H<sub>64</sub>O<sub>2</sub>P<sub>4</sub>Pd: *theoretical*: 1260.2894 (22.9%), 1262.2909 (63.4%), 1262.2911 (100.0%), 1263.2907 (64.6%), 1264.2914 (77.2%), 1265.2933 (47.5%), 1266.2931 (35.5%), 1267.2949 (25.1%); *Found*: 1260.3405 (24.0%), 1261.3285 (67.4%), 1262.3166 (100.0%), 1263.3162 (73.2%), 1264.3300 (79.3%), 1265.3424 (47.5%), 1266.3491 (35.5%), 1267.3104 (25.1%). [Lingensmith, Strieter, Barder and Buchwald *Organometallics* **25** 82 2006.]

**Zirconocene chloride hydride (bis[cyclopentadienyl]zirconium(IV) hydride chloride, Cp<sub>2</sub>ZrClH) (Schwartz' reagent) [37342-97-5] M 257.9.** It is moisture and light sensitive. Determine its purity by reaction with a slight excess of Me<sub>2</sub>CO whereby the active H reacts to produce Cp<sub>2</sub>ZrClOPr<sup>i</sup> and the integrals of the residual Me<sub>2</sub>CO in the <sup>1</sup>H NMR will show its purity. The presence of Cp<sub>2</sub>ZrH<sub>2</sub> can be determined because it forms Cp<sub>2</sub>Zr(OPr<sup>i</sup>)<sub>2</sub>. For a very active compound, it is best to prepare it freshly from the *dichloride*, see below by reduction with Vitride [LiAl(OCH<sub>2</sub>CH<sub>2</sub>OH)<sub>2</sub>H<sub>2</sub>], the white precipitate is filtered off, washed with tetrahydrofuran, then Et<sub>2</sub>O and dried in a vacuum. Store it dry in the dark. [Carr & Schwartz *J Am Chem Soc* **101** 3521 1979, Negishi & Takahashi *Aldrichimica Acta* **18** 31 1985, Buchwald et al. *Tetrahedron Lett* **28** 3895 1987, Negishi & Takahashi *Synthesis* 1 1988, *Beilstein* **16** IV 1770.] It has been used for functionalising olefins and alkyne [Sun et al. *Org Synth* **71** 83 1992, Negishi & Takahashi *Aldrichimica Acta* **18** 31 1985, Ganem & Franke *J Org Chem* **72** 3981 2007]. It has also been used for mild and selective hydrozirconation of amides to aldehydes [Spletstoser et al. *J Am Chem Soc* **129** 3408 2007].

**Zirconocene dichloride (bis[cyclopentadienyl]zirconium dichloride, Cp<sub>2</sub>ZrCl<sub>2</sub>) [1291-32-3] M 292.3, m 242-245°, 248°.** Recrystallise the dichloride from CHCl<sub>3</sub> or xylene and dry it in a vacuum. <sup>1</sup>H NMR (CDCl<sub>3</sub>) has δ at 6.52 from Me<sub>4</sub>Si. Store it dry in the dark under N<sub>2</sub>. [Reid et al. *Aust J Chem* **18** 173 1965, *Beilstein* **16** IV 1770.]. Together with Zn and CH<sub>2</sub>Cl<sub>2</sub> it is used for methylenation of carbonyl compounds [Tour et al.

*Tetrahedron Lett* **30** 3927 1989], and has been useful for the synthesis of a wide range of early transition-metal complexes and organometallic compounds [Negishi & Takahashi *Aldrichimica Acta* **18** 31 1985, see also selected volumes of Fieser & Fieser's *Reagents for Organic Synthesis*].

**NANO METAL CATALYSTS:** see section on Nano Metals in Chapter 8, "Nanomaterials and Nanotechnology".

## ORGANOCATALYSTS

Organocatalysis has already been discussed in general terms (see Chapter 3), and this section deals with some individual examples that have proved useful.

Organocatalysts are small metal-free organic molecules, or metal-containing compounds but where the metal is not involved in the catalytic process, which efficiently and selectively catalyse a large variety of chemical reactions when used in small non-stoichiometric amounts. Several are commercially available and the purification of some are described here; the preparations of some also are mentioned as these assist in devising methods of purification. The purification of a number of organocatalysts is also described in other chapters. Examples include (-)-*quinine* [see 130-95-0] and (+)-*quinidine* [see 56-54-2] used to catalyse  $\alpha$ -halogenation of carbonyl compounds, intramolecular Michael additions, cyclopropanation of enones, enolates etc,  $\beta$ -lactam synthesis from imines and ketenes,  $\beta$ -lactone synthesis from aldehydes and ketenes, Morita-Baylis-Hillman reactions, hydrophosphonylation of aldehydes, Diels-Alder reactions and desymmetrisation of *meso*-anhydrides; (-)-*cinchonidine* [see 405-71-2] and (+)-*cinchonine* [see 118-10-5] which catalyse additions to prochiral ketenes, desymmetrisation of *meso*-diols and of *meso*-epoxides; and their respective *N*-benzyl salts [see 69257-04-1, and 69221-14-3] are efficient chiral *phase transfer catalysts* (see below); *L*-*proline* [see 147-85-3] which catalyses intramolecular Michael addition, Mannich reactions, inter- and intra- molecular aldol reactions, addition to N=O ( $\alpha$ -aminoxylation/hydroxylation of C=O compounds), addition to nitrones and to N=N double bonds ( $\alpha$ -amination of C=O compounds); *L*-*phenylalanine* [see 63-91-2] which catalyses intramolecular aldol reactions; and the *metal-free Jacobsen's ligand N,N'*-Bis(3,5-di-*tert*-butylsalicylidene)-1,2-*trans*-cyclohexanediamine [see *R,R'*-135616-40-9 or *S,S'*-135616-36-3] which catalyses hydrocyanation (with TMS-CN) of aldehydes. It should be noted that the *Phase Transfer Catalysts* described in a later section of this Chapter are *organocatalysts*. [For further examples see: A. Berkessel and H. Gröger *Asymmetric Organocatalysis* Wiley-VCH, Weinheim 2005, ISBN-13 978-3-527-30517-9, ISBN-10 3-527-30517-3; B. List (Ed) *Topics in current chemistry Vol 291: Asymmetric Organocatalysis* Springer Verlag 2010, ISBN 9783642028144, 9783642028151; which include sections on *Noncovalent organocatalysis based on hydrogen bonding* (Etzenbach-Effers & Berkessel), *Enamine catalysis* (Pihko et al.), *Carbene catalysis* (Moore & Rovis) *Bronsted base catalysts* (Ting et al.), *Chiral ketone and iminium catalysts for olefin epoxidation* (Wong & Shi), *Amine, alcohol and phosphine catalysts for acyl transfer reactions* (Spivey & Arseniyadis), *Secondary and primary amine catalysts for iminium catalysis* (Brazier & Tomkinson), *Lewis acid organocatalysts* (Sereda et al.) and *Chiral Bronsted acids for asymmetric organocatalysis* (Kampen et al.); P.I. Willis, review on *Enantioselective desymmetrisation*, *J Chem Soc, Perkin Trans 1* 1765 1999.] A whole issue of *Chem Rev (ACS)* [107 513-5841 2007] devoted to *Organocatalysis* with B. List as introductory guest writer has appeared.

***RS*( $\pm$ )-1,1'-Bi(2-naphthol) ( $\pm$  1,1'-binaphthyl-2,2'-diol) [602-09-5] M 286.3, m 214-217 $^{\circ}$ , 216-218 $^{\circ}$ , 217-218 $^{\circ}$ , 218 $^{\circ}$ , pK<sub>Est(1)</sub><sup>20</sup> ~7.5, pK<sub>Est(2)</sub><sup>20</sup> ~11.8; *R*(+)-1,1'-bi(2-naphthol) (*R*(+)-BINOL) [18531-94-7] m 208-210 $^{\circ}$ , 207.5-208.5 $^{\circ}$ , [ $\alpha$ ]<sub>D</sub><sup>20</sup> 0 (c 1, THF), [ $\alpha$ ]<sub>546</sub><sup>25</sup> +50.9 $^{\circ}$  (c 1, THF); *S*(-)-1,1'-bi(2-naphthol) (*S*(-)-BINOL) [18531-99-2] m 207-208 $^{\circ}$ , 208-210 $^{\circ}$ , [ $\alpha$ ]<sub>D</sub><sup>22</sup> -34 $^{\circ}$  (c 1, THF), [ $\alpha$ ]<sub>546</sub><sup>25</sup> +51.3 $^{\circ}$  (c 1, THF). 1,1'-Bi(2-naphthol) is easily prepared by slowly adding a solution of FeCl<sub>3</sub>·6H<sub>2</sub>O (28g, 104mmol, see [10025-77-1]) in H<sub>2</sub>O (60ml) to a vigorously stirred and refluxing suspension of 2-naphthol (14.4g, 100mmol, see [135-19-3]) in H<sub>2</sub>O (600ml) and boiled until the oily drops of 2-naphthol disappear and the *binaphthol* separates out in flakes. Boiling is continued for 10 minutes, and the solid is filtered off, washed with boiling H<sub>2</sub>O and dried first in air then *in vacuo*, to give ( $\pm$ )-BINOL in almost quantitative yield. Recrystallisation from hot EtOH, toluene or \*C<sub>6</sub>H<sub>6</sub> (~150ml, using charcoal) gives colourless glistening plates m 218 $^{\circ}$ . The ( $\pm$ )-*dimethyl ether* [75640-87-8, 75685-**

01-7] has **m** 190° (from AcOH). [A.I.Vogel *Practical Organic Chemistry* Longmans, Green & Co, London, p 639 1948, Pummerer et al. *Ber* **59** 2159 1926, Walder *Ber* **15** 2166 1882.] The FT-IR (Nujol) has  $\nu_{\max}$  at 3486.6, 1617.9, 1508.8, 1322.7, 1252.4, 1177.2, 1126.4, 827.3 and 751.3  $\text{cm}^{-1}$  (note below how it is different from its enantiomers). [*Beilstein* **6 H** 1051, **6 I** 519, **6 II** 1026, **6 III** 5877, **6 IV** 7020.]

**R-** and **S-BINOL** have been obtained by a variety of ways which attest to their usefulness. They have been prepared by resolution of the ( $\pm$ )-BNP-acid (see below), the ( $\pm$ )-BINOL-boron ester (*via* the quinine salt), the ( $\pm$ )-BINOL dibenzoate (*via* pancreas acetone powder), or by oxidative coupling of 2-naphthol in the presence of chiral amines [see Zimmer & Suhrbier *J Prakt Chem* **339** 758 1997]. The preparations involving reduction of the ( $\pm$ )-BNP acid directly with  $\text{LiAlH}_4$ , or *via* the methyl phosphate derivative with  $\text{RedAl}$  [sodium bis(2-methoxyethoxy)aluminium hydride] in 3.4M toluene solution [Truesdale *Org Synth Coll Vol VIII* 46 1993] appear to be most convenient, and do not involve racemisation. The former is described here as it does not require an esterification step. Pure **R-(+)-BNP** acid (115.4g, 331mmol) in dry THF at 0° under  $\text{N}_2$ , is treated with  $\text{LiAlH}_4$  (31.4g, 830mmol) in small portions (exert extreme care here because of the large quantities used — fire hazard) during 1 hour with stirring. A further volume of dry THF (400ml) is added and the mixture is stirred at 25° under  $\text{N}_2$ , for 17 hours, cooled to 0° under  $\text{N}_2$ , and cold 6N aqueous HCl (250ml) is added very carefully. The upper phase is then decanted off, and the lower phase is mixed with 6N aqueous HCl (150ml) and THF (150ml), stirred, and is allowed to settle. The phases are separated and the lower phase is extracted with  $\text{Et}_2\text{O}$ . The combined organic phases are washed with brine, decolorised with charcoal and evaporated *in vacuo*. The residual oil is dissolved in  $^*\text{C}_6\text{H}_6$  (1L, toluene may be used) and evaporated until crystallisation sets in. The solid is collected (90.6g, 96%, **m** 202-207°), which upon crystallisation from  $^*\text{C}_6\text{H}_6$  or toluene gives optically pure BINOL (84.5g, 89%, **m** 207-208°) with (+) or (–)  $[\alpha]_{589}^{25}$  34.3°,  $[\alpha]_{578}^{25}$  37.8°,  $[\alpha]_{546}^{25}$  51.3°,  $[\alpha]_{436}^{25}$  228° (**c** 1.1, **THF**). The FT-IR (Nujol) of the BINOL enantiomers are identical, though different from that of the racemate (see above), and have  $\nu_{\max}$  at 3509.9, 1617.9, 1511.5, 1319.1, 1220.9, 1148.9, 815.6, 749.6 and 566.0  $\text{cm}^{-1}$ ; and the  $^1\text{H}$  NMR (1:1  $\text{CDCl}_3/\text{DMSO}-d_6$ , TMS) has  $\delta$  at 7.04 (d, 2H,  $J = 8.8\text{Hz}$ ), 7.20-7.35 (m, 4H), 7.40 (d, 2H,  $J = 8.8\text{Hz}$ ), 7.92 (d, 2H,  $J = 8.8\text{Hz}$ ) and 9.21 (s, 2H). **Racemisation studies** showed that: BINOL (0.1g) is optically stable in an  $\text{H}_2\text{O}$  (10ml)/dioxane (12ml) mixture at 100° under  $\text{N}_2$  during 26 hours; loses 44% and 66% of optical activity in BuOH (10ml) containing KOH (0.71mmol) per BINOL (0.33mmol) at 118° under  $\text{N}_2$  in 13 and 23 hours respectively; and loses 37% and 72% of optical activity of BINOL (100mg) in a 20% aqueous HCl (10ml)/dioxane (12ml) mixture at 100° under  $\text{N}_2$  during 7 and 26 hours respectively. [Kyba et al. *J Org Chem* **42** 4173 1977.]

BINOL and 3,3'-diaryl derivatives act as organocatalysts for Mirata-Baylis-Hillman reactions involving C-H activation, e.g. condensation of a variety of aldehyde with cyclohex-2-en-1-one to provide chiral 2-(1-substituted-1-hydroxymethyl)cyclohex-2-en-1-ones in 40 to 80% yields and “ee” values of ~90 in the presence of  $\text{Et}_3\text{P}$  [McDougal & Schaus *J Am Chem Soc* **125** 12094 2003], they catalyse hydrocyanation (with TMS-CN) of aldehydes with high “ee” at -78° [Holmes & Kagan *Tetrahedron Lett* **41** 7453 and 7457 2000], and the titanium complexes catalyse the stereoselective reduction [with  $(\text{MeO})_3\text{SiH}$ ] of carbonyl compounds [Schiffers & Kaga *Synlett* 1175 1997], as well as C-C forming reactions [Zimmer & Suhrbier *J Prakt Chem* **339** 758 1997] and Diels-Alder reactions [Mikami et al. *Tetrahedron: Asymmetry* **2** 643 1991]. The rare earth La-S-BINOL complex realises an asymmetric nitroaldol reaction with nitromethane in high product yield and enantiomeric enrichment [Sasai et al. *J Am Chem Soc* **115** 10372 1993].

**RS-( $\pm$ )-1,1'-Binaphthyl-2,2'-diylhydrogen phosphate (1,1'-binaphthyl-2,2'-phosphoric acid, BNP)** [36193-63-6] **M** 348.3, **m** 217°,  $\text{pK}^{20}$  0.74; **R-(–)-1,1'-binaphthyl-2,2'-diylhydrogen phosphate** [39648-67-4] **m** 217°,  $[\alpha]_{\text{D}}^{20}$  –608° (**c** 1, MeOH),  $[\alpha]_{\text{D}}^{22}$  –562.7° (**c** 0.97,  $\text{CHCl}_3$ ),  $[\alpha]_{546}^{22}$  –113° (**c** 0.95,  $\text{CHCl}_3$ ); **S-(+)-1,1'-binaphthyl-2,2'-diylhydrogen phosphate** [35193-64-7] **m** 217°,  $[\alpha]_{\text{D}}^{20}$  +608° (**c** 1, MeOH). Recrystallise it from EtOH. Reflux for 3 hours in N NaOH is required to hydrolyse the cyclic phosphate. The **R-enantiomer** has been prepared by a general procedure in which **R-(+)-1,1'-binaphthyl-2,2'-ol** (1.90mmol, see **R-BINOL** [18531-94-7]) in pyridine (7.8ml) is treated with  $\text{POCl}_3$  (250 $\mu\text{l}$ , 2.68mmol) and stirred at ~25° for 3 hours. The mixture is then quenched with  $\text{H}_2\text{O}$  (154 $\mu\text{l}$ ) at 0°, stirred for 1 hour at ~25°, evaporated *in vacuo*, the residue is acidified with 6N HCl (20ml) at 0° then refluxed for 2 hours. After cooling to 0°, the *phosphoric acid* separates, is filtered off, washed with  $\text{H}_2\text{O}$  and dried *in vacuo*. Recrystallisation by dissolving in  $\text{CH}_2\text{Cl}_2$  and pouring it into hexane provides pure crystals of the **R-(–)-acid** (1.58mmol, 83%). [Yamanaka et al. *J Am Chem Soc* **129** 6756 2007, for general procedure see Jacques & Fourquet *Org Synth* **67** 1 1989.] It has IR ( $\text{CHCl}_3$ ) with  $\nu_{\max}$  at 3024, 3015, 1231, 1215, 1203, 1020, 951, 797, 779, 773, 762, 748, 737, 723, 716, 700 and 673  $\text{cm}^{-1}$ ; its  $^1\text{H}$  NMR

(400MHz, CDCl<sub>3</sub>, TMS) has  $\delta$  at 8.01 (d, 2H,  $J = 8.8$  Hz), 7.94 (d, 2H,  $J = 8.2$  Hz), 7.55 (d, 2H,  $J = 8.8$  Hz), 7.49-7.44 (m, 2H), 7.38 (d, 2H,  $J = 8.2$  Hz), 7.32-7.27 (m, 2H) and 3.22 (s, 1H); and its <sup>13</sup>C NMR (100MHz, CDCl<sub>3</sub>, CDCl<sub>3</sub> as internal standard with  $\delta$  at 77.0) has  $\delta$  at 147.2, 147.1, 132.2, 131.6, 131.0, 128.3, 127.0, 126.5, 125.5, 121.4 and 120.5. [Jacques et al. *Tetrahedron Lett* 4617 1971, Arnold et al. *Tetrahedron* **24**, 343 1983, Beilstein 6 II 1027.] **Alternatively**, (and more useful as it can be carried out on a 100g scale), the *R*-(-) and *S*-(+)-BNP acids are obtained by optical resolution of the diastereoisomeric (+)-cinchonine salts of the (±)-BNP acid via recrystallisation from hot MeOH. The crude (+)-acid (+)-base salt [which contains 91% of (+)-acid (+)-base and 9% of (-)-acid (+)-base] has  $[\alpha]_{546}^{25} +424^{\circ}$  (c 0.99, MeOH) and the more soluble crude (-)-acid (+)-base salt obtained by evaporation of the mother liquors [which contains 81% of (-)-acid (+)-base and 19% of (+)-acid (+)-base] has  $[\alpha]_{546}^{25} -113^{\circ}$  (c 0.95, MeOH). Pure (+)-acid (+)-base salt  $[\alpha]_{546}^{25} +492^{\circ}$  (c 1, MeOH) and pure (-)-acid (+)-base salt,  $[\alpha]_{546}^{25} -256^{\circ}$  (c 1, MeOH) as obtained from the pure enantiomeric BNP acids and (+)-cinchonine are recrystallised from MeOH/EtOAc and MeOH/Me<sub>2</sub>CO/EtOAc respectively. The BNP acids are obtained from the respective salts (e.g. 77g) in boiling EtOH (e.g. 500ml) and adding 6N aqueous HCl (e.g. 570ml) with vigorous stirring during 30 minutes while keeping the temperature between 75° and 80°. After cooling the BNP acid is collected, washed with H<sub>2</sub>O (e.g. 5 x 90ml), and air dried to give (~50 yield of ~99% ee) almost pure acid (by NMR and HPLC). BNP acids from the filtrates can be purified by recrystallisation from hot MeOH or EtOH and are sparingly soluble in H<sub>2</sub>O. The solubilities at 25° in g/100ml are: 5.7±0.2 enantiomer (EtOH) and 10.3±0.5 racemate (EtOH); and 2.1±0.1 enantiomer (MeOH) and 2.5±0.1 racemate (MeOH). Two recrystallisations from EtOH of the BNP enantiomeric acids obtained did not alter the rotations at 25° which are (+) or (-): 595° ±7 (589nm), 624° ±7 (578nm), 720° ±8 (546nm), 1328 ±15 (436nm), 2050° ±25 (365nm) in MeOH; 574° ±16 (589nm), 602° ±17 (578nm), 694° ±20 (546nm), 1267 ±25 (436nm), 1828° ±40 (365nm) in EtOH. [Jacques & Fouquet *Org Synth Coll Vol VIII* 51 1993, see also Kyba et al. *J Org Chem* **42** 4172 1977].

The BNP acids, and their 3,3'-aryl derivatives, are useful asymmetric organocatalysts in being efficient *Bronsted acid catalysts* for enantioselective Mannich reactions. [Yamanaka et al. *J Am Chem Soc* **129** 6756 2007.]

**2,2'-Bis(diphenylphosphino)-1,1'-binaphthyl (BINAP)** [*RS* see 98327-87-8] **M 622.7, m 283-286°**. [*R*-(+)-see 76189-55-4] **m 241-242°**, [*S*-(-)-see 76189-56-5] **m 241-242°**. In addition to being ligands for Pd, Rh and Ru catalysts, *S*-BINAP also act as a organocatalysts for Mirata-Baylis-Hillman reactions involving C-H activation, e.g. in the condensation of 5-formylpyrimidine and derivatives with methyl acrylate to form methyl β-hydroxy-β-(pyrimidin-5-yl)-α-methylenepropionates with moderate enantiomeric excess at the chiral hydroxy centre [Hayase et al. *Chem Commun* 1271 1998].

### Bode-Rovis-Enders NHC precatalysts

These are a group of 3,4-fused-2-aryl substituted 1,2,4-triazolium salt pre-catalysts, which when converted into the corresponding NHCs (N-heterocyclic carbenes) where C-5 of the heterocyclic ring becomes a carbene carbon atom, are **organocatalysts** that promote a wide variety of organic reactions. The carbene is usually generated *in situ* on addition of diisopropylamine or BTU. Among the reactions that these NHCs catalyse are cyclocondensation reactions, enantioselective azadiene Diels-Alder reactions, aza-Claisen reactions, annulation reactions, formation of trisubstituted indanes *via* catalysed cascade annulations, desymmetrisation of cyclohexadienones, benzoin condensations, Stetter reaction, a<sup>3</sup> to d<sup>3</sup> Umpolung, transesterification, 1,2-additions, etc. [Bode *Speciality Chemicals Magazine* **27(6)** 28 pages 2007, Moor & Rovis *Top Curr Chem* **290** 77-144 2009, Enders, Niemeier and Henseler *Chem Rev* **107** 5606-5655 2007.] Described below are such four chiral organoprecatalysts whose carbenes catalyse highly stereospecific reactions in good to very good yields and with very high enantiomeric excess(e,e), and two related non-chiral salts which also catalyse non-chiral reactions in high yields.

**(4a*R*,9a*S*)-4,4a,9,9a-1-oxa-4-azafluorenone**, **(4a*R*,9a*S*)-indeno[2,1-*b*]-1,4-oxazin-3(2*H*)-one**, [862095-79-2] **M 189.2, m 180-183°(dec)**,  $[\alpha]_{\text{D}}^{23} -17.3^{\circ}$  (c 1.08, MeOH). This is the key chiral intermediate *fluorene-3-one* that uses (+)-*cis*-(1*R*,2*S*)-1-aminoindan-2-ol (see [136030-00-7]) for the preparation of chiral *indeno-triazolo-oxazinium* pre-catalysts. Details of its synthesis are not given here because they have been reported in great detail by Rovis and coworkers [Vora et al. *Org Synth* **87** 350 2010], but the physical and spectroscopic properties, and final purification procedures are provided in order to assess the purity of the commercial product and to purify it further if necessary. Thus the aminoindanol is converted to the -ONa salt with NaH/THF which is reacted with ClCH<sub>2</sub>CO<sub>2</sub>Et to form the *fluorenone*. The final purification is carried out by stirring vigorously the crude light brown solid with hexanes under a reflux condenser in an oil bath at 70° for

2 hours, cooling to  $\sim 25^\circ$ , filtering the solid off and drying it at  $70^\circ$  *in vacuo* (2mm Hg) for 1 hour to give the *fluorenone* as a white solid in 80-86% yield of almost analytical (C, H and N) purity. It has IR with  $\nu_{\max}$  at 3179, 3050, 2910, 1681, 1646, 1484, 1417  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (400MHz,  $\text{Me}_2\text{CO}-d_6$ ) with  $\delta$  at 2.97 (d,  $J = 16.8\text{Hz}$ , 1H), 3.23 (dd,  $J = 16.6, 4.9\text{Hz}$ , 1H), 3.89 (d,  $J = 16.2\text{Hz}$ , 1H), 4.05 (d,  $J = 16.2\text{Hz}$ , 1H), 4.57 (t,  $J = 4.6\text{Hz}$ , 1H), 4.82 (t,  $J = 4.0\text{Hz}$ , 1H), 7.23-7.29 (m, 3H), 7.46-7.49 (m, 1H), 8.21 (br s, 1H);  $^{13}\text{C}$  NMR (100MHz,  $\text{Me}_2\text{CO}-d_6$ ) with  $\delta$  at 38.2, 59.4, 67.1, 77.1, 124.7, 125.7, 127.6, 128.4, 140.8, 143.1, 168.5; and HRMS (APCI<sup>+</sup>) has  $m/z$  190.0862, and the calculated value for  $\text{C}_{11}\text{H}_{12}\text{NO}_2$  ( $\text{M}^+$ ) is 190.0863. The enantiomeric (**4aS,9aR**)-**4,4a,9,9a-1-oxa-4-azafluorenone** can be similarly prepared by starting from (-)-*cis*-(1*S*,2*R*)-1-*aminoindan-2-ol* (see [126456-43-7]) and differs only in the sign of the specific rotation.

(**5aR,10bS**)-**5a,10b-Dihydro-2-(2,4,6-trimethylphenyl)-4H,6H-indeno[2,1-b]-1,2,4-triazolo[4,3-d]-1,4-oxazinium chloride monohydrate** [903571-02-8 for anhydrous] **M 385.9, m 217-219 $^\circ$ , 226-230 $^\circ$**  (anhydrous ?),  $[\alpha]_{\text{D}}^{20} -133.5^\circ$  (c 1.00, EtOH),  $[\alpha]_{\text{D}}^{20} -156.0^\circ$  (c 1.00,  $\text{CHCl}_3$ ). Here also details of its synthesis are not given because they have been reported in great detail by Bode and coworkers [see Struble & Bode *Org Synth* **87** 362 2010], but the physical and spectroscopic properties, and final purification procedures are provided in order to assess the purity of the commercial products and to purify further if necessary. The preceding (**4aR,9aS**)-*fluorenone* is treated with  $\text{Me}_3\text{OBF}_4/\text{CH}_2\text{Cl}_2$  ( $\sim 25^\circ/16$  hours) then  $\text{NaHCO}_3$ , and dried in a high vacuum (12 hours) to give a 92-93% yield (95% purity) of (**4aR,9aS**)-**3-methoxy-2,4a,9,9a-tetrahydroindeno[2,1-b][1,4]oxazine** as a pale brown solid with **m 73-75 $^\circ$** ,  $[\alpha]_{\text{D}}^{20} -15.7^\circ$  (c 1.26, EtOH), and consistent IR, NMR and MS. This *methoxy-oxazine* is then added to a solution containing one equivalent of *2,4,6-trimethylphenylhydrazinium chloride*\* in MeOH and a catalytic amount of 4M HCl/dioxane (obligatory) and heated at  $60^\circ$  under a reflux condenser and  $\text{N}_2$  atmosphere for 48 hours. The solvent is removed *in vacuo* and the crude orange solid residue is suspended in EtOAc (must be absolutely dry for high yields; dry by passing through an  $\text{Al}_2\text{O}_3$  drying column in an argon atmosphere) with vigorous stirring at  $90^\circ$  (under  $\text{N}_2$ ) for 30 minutes, cooled to  $0^\circ$ , and the light yellow solid is filtered off, washed with EtOAc and dried at  $\sim 25^\circ$  ( $<1$  mbar, 12 hours) to provide an 81-82% yield of (**Z**)-**2-mesityl-1-[(4aR,9aS)-4,4a,9,9a-tetrahydroindeno-[2,1b][1,4]-oxazin-3-(2H)ylidene]hydrazinium chloride** as a light yellow powder which has **m 200-201 $^\circ$ (dec)**,  $[\alpha]_{\text{D}}^{20} +66.7^\circ$  (c 1.42, EtOH), and consistent IR, NMR and MS. The precatalyst is then obtained by cyclising the hydrazium chloride with triethylorthoformate (8 equivalents) in chlorobenzene (dried over 4Å molecular sieves) and anhydrous HCl (4M in dioxane, 1 equivalent) by stirring under  $\text{N}_2$  at  $120^\circ$  for 1 hour, and the clear brown solution is evaporated *in vacuo*. The brown residue is treated with toluene, heated at  $120^\circ$  for 5 minutes, cooled in ice/water, the white solid is filtered off and the filtrate is evaporated at  $60^\circ$  *in vacuo* and dried at high vacuum ( $<0.75\text{mm}$ ). The brown residue dissolves in toluene at  $60^\circ$  within 3-5 minutes then a white precipitate is formed rapidly. The cooled solution is filtered, the white solid is washed with a little toluene and dried at high vacuum ( $<1$  mbar) to constant weight ( $>24$  hours) to give a 60-64% yield of the desired (**5aR,10bS**)-*oxazinium chloride* pre-catalyst as an analytically pure (C, H and N) white powder with **m 217-219 $^\circ$** . It has IR with  $\nu_{\max}$  at 3435, 3482, 2904, 2853, 1580, 1466, 1222, 1097, 1083, 847, 749, 729, 662  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (400MHz,  $\text{DMSO}-d_6$ ) has  $\delta$  at 212 (s, 6H), 2.37 (s, 3H), 3.16 (d,  $J = 17.0\text{Hz}$ , 1H), 3.50 (dd,  $J = 16.9, 4.8\text{Hz}$ , 1H), 4.99 (t,  $J = 4.4\text{Hz}$ , 1H), 5.08 (d,  $J = 16.0\text{Hz}$ , 1H), 5.26 (d,  $J = 16.0\text{Hz}$ , 1H), 6.12 (d,  $J = 4.0\text{Hz}$ , 1H), 7.21 (s, 2H), 7.33-7.45 (m, 3H), 7.65 (d,  $J = 7.2\text{Hz}$ , 1H), 11.34 (s, 1H); the  $^{13}\text{C}$  NMR (100MHz,  $\text{DMSO}-d_6$ ) has  $\delta$  at 16.9, 20.6, 37.0, 59.7, 61.1, 76.8, 124.0, 125.3, 127.1, 129.2, 129.3, 131.2, 134.8, 136.1, 140.6, 141.3, 144.7, 150.0; and the HRMS (ESI) has  $m/z$  332.1756 and the calculated value for  $\text{C}_{21}\text{H}_{22}\text{N}_3\text{O}$  ( $\text{M}^+$ ) is 332.1757.

The enantiomeric (**5aS,10bR**)-**5a,10b-Dihydro-2-(2,4,6-trimethylphenyl)-4H,6H-indeno[2,1-b]-1,2,4-triazolo[4,3-d]-1,4-oxazinium chloride monohydrate** **M 385.9, m 212-216 $^\circ$ ,  $[\alpha]_{\text{D}}^{20} +158.0^\circ$**  (c 1.00,  $\text{CHCl}_3$ ) can be prepared similarly by starting from the enantiomeric (**4aS,9aR**)-**4,4a,9,9a-1-oxa-4-azafluorenone** and is purified in the same way.

\*The purity of **2,4,6-mesitylhydrazinium chloride** [76195-82-9] **M 186.7** is critical for obtaining pure mesityl-pre-catalysts. The preparation from 2,4,6-trimethylaniline is described in great detail by Struble and Bode [*Org Synth* **87** 362 2010] who emphasise that it is imperative for diazotisation and reduction to be strictly monitored. It is paramount that  $\text{NaNO}_2$  and  $\text{SnCl}_2$  solutions be added at such a rate that the internal temperature is carefully monitored at  $<5^\circ$ . The final purification is by suspending the salt ( $\sim 7.5\text{g}$ ) in absolute EtOH/Et<sub>2</sub>O (1:1, 15ml), and sonicating (85W) for 5 minutes while maintaining the temperature below  $30^\circ$ . The pale orange solid is filtered off using a fine porosity filter, washed with EtOH/Et<sub>2</sub>O (1:1, 3 x 5ml), and dried under high vacuum ( $\sim 25^\circ$ ,  $<0.75\text{mm}$ ) for 12 hours to give analytically pure (C, H and N) **2,4,6-mesitylhydrazinium chloride** (36-40% yield).

Note that the material may be very fine to filter in a short period, in which case it should be dissolved in dry MeOH and concentrated by evaporation to give a more crystalline product that can be filtered more easily. *Alternatively*, it should be collected by centrifugation, decantation of the supernatant, washed with EtOH/Et<sub>2</sub>O (1:1, 3 x 5ml) also by decantation and sonication in the same way in between washes. It has **m 195-197°(dec)** (**167-173°** also reported); it has IR with  $\nu_{\max}$  at 3296, 3002, 2964, 2911, 2691, 1564, 1515, 1479, 846, 830, 575 cm<sup>-1</sup>; the <sup>1</sup>H NMR (400MHz, DMSO-*d*<sub>6</sub>) has  $\delta$  at 2.20 (s, 3H), 2.35 (s, 6H), 6.60 (br s, 1H), 6.86 (s, 2H), 9.27 (variable br s, 3H, NH,NH<sub>2</sub>); the <sup>13</sup>C NMR (100MHz, DMSO-*d*<sub>6</sub>) has  $\delta$  at 17.8, 20.4, 129.0, 134.9, 136.1, 137.9; and HRMS (ESI) has *m/z* 151.1228, and the calculated value for C<sub>9</sub>H<sub>15</sub>N<sub>2</sub> (M<sup>+</sup>) is 151.1223. [Struble and Bode *Org Synth* **87** 362 2010]

**(5aR,10bS)-5a,10b-Dihydro-2-(pentafluorophenyl)-4H,6H-indeno[2,1-b]-1,2,4-triazolo[4,3-d]-1,4-oxazinium tetrafluoroborate** [740816-14-2] **M 467.1, m 223-226°, 235°(dec)**, [ $\alpha$ ]<sub>D</sub><sup>23</sup> -130.8° (c 1.28, MeCN). Details of its synthesis are not given here because they have been reported in great detail by Rovis and coworkers [Vora et al. *Org Synth* **87** 350 2010], but the physical and spectroscopic properties, and final purification procedures are provided in order to assess the purity of the commercial product and to purify it further if necessary. The common intermediate **(4aR,9aS)-4,4a,9,9a-1-oxa-4-azafluorenone** (1.0 equivalent see [862095-79-2] above) is added with stirring, and under anhydrous conditions in an argon atmosphere, to a mixture of Me<sub>3</sub>OBF<sub>4</sub> (1.0 equivalent *and no more*, care **Toxic**) in CH<sub>2</sub>Cl<sub>2</sub> (containing <20ppm of H<sub>2</sub>O, by filtering through activated Al<sub>2</sub>O<sub>3</sub> under argon) and stirred at ~25° until the homogeneous reaction is complete (1-2 hours by <sup>1</sup>H NMR). Pentafluorophenylhydrazine (1.0 equivalent) is then added to the mixture under argon, stirred until the reaction is complete (~4 hours, when <sup>1</sup>H NMR signals of activated amidate disappear), the mixture is evaporated *in vacuo*, dried at 100°/2mm; then chlorobenzene (as solvent) followed by triethyl orthoformate (2.5 equivalents) are added and heated under reflux to 130° with stirring (open to the atmosphere) for 24 hours. A second portion of triethyl orthoformate (2.5 equivalents, syringe) is added and the mixture is stirred for a further 24 hours, and this process is repeated once more. Excess of toluene is added, the slurry is filtered, and the solid is washed with toluene and hexanes. It is then triturated with EtOAc and MeOH (4:1), filtered through a medium frit funnel, washed with cold EtOAc to give the **oxazinium tetrafluoroborate** pre-catalyst which, when dried at 100°/2mm to constant weight (~1 hour, 61-64% yield), gave an off white solid that analysed as the ~0.5 hydrate. It has IR with  $\nu_{\max}$  at 3147, 3106, 3028, 2967, 1595, 1530, 1517, 1487, 1461, 1056, 1046, 998 cm<sup>-1</sup>; the <sup>1</sup>H NMR (400MHz, Me<sub>2</sub>CO-*d*<sub>6</sub>) has  $\delta$  at 3.28 (d, *J* = 17.2Hz, 1H), 3.55 (dd, *J* = 17.1, 4.9Hz, 1H), 5.19 (t, *J* = 4.5Hz, 1H), 5.25 (d, *J* = 16.4Hz, 1H), 5.39 (d, *J* = 16.4Hz, 1H), 6.33 (d, *J* = 4.0Hz, 1H), 7.34 (t, *J* = 7.3Hz, 1H), 7.43 (q, *J* = 7.4Hz, 2H), 7.63 (d, *J* = 7.6Hz, 1H), 11.09 (br s, 1H); the <sup>13</sup>C NMR (100MHz, Me<sub>2</sub>CO-*d*<sub>6</sub>) has  $\delta$  at 37.9, 60.8, 63.5, 78.2, 125.2, 126.4, 128.1, 130.4, 136.2, 141.7, 147.1, 152.5; and HRMS (APCI<sup>+</sup>) has *m/z* 380.0816, and the calculated value for C<sub>18</sub>H<sub>11</sub>N<sub>3</sub>OF<sub>5</sub> (M<sup>+</sup>) is 380.0817. [Vora et al. *Org Synth* **87** 350 2010].

The enantiomeric **(5aS,10bR)-5a,10b-Dihydro-2-(pentafluorophenyl)-4H,6H-indeno[2,1-b]-1,2,4-triazolo-[4,3-d]-1,4-oxazinium tetrafluoroborate** can be prepared and purified in a similar way but starting with the enantiomeric **(4aS,9aR)-4,4a,9,9a-1-oxa-4-azafluorenone**.

**2-Pentafluorophenyl-6,7-dihydro-5H-pyrrolo[2,1-c][1,2,4]triazol-2-ium tetrafluoroborate** (**2-pentafluoro-2,5,6,7-tetrahydro[2,1-c][1,2,4]-tetrazol-4-ium tetrafluoroborate**), [862095-91-8] **M 363.0, m 242-245°, 245°**. Details of its synthesis are not given here because they have been reported in great detail by Rovis and coworkers [Vora et al. *Org Synth* **87** 350 2010], but the physical and spectroscopic properties, and final purification procedures are provided in order to assess the purity of the commercial product and to purify it further if necessary. Starting with 2-pyrrolidinone (1.0 equivalent, [616-45-5]) which is converted into 2-methoxy-3,4-dihydro-5H-pyrrolidinium tetrafluoroborate by reaction with trimethyloxonium tetrafluoroborate (1.0 equivalent) in CH<sub>2</sub>Cl<sub>2</sub> under argon with stirring at ~25° until homogeneous, then pentafluorophenylhydrazine (1.0 equivalent, [828-73-9]) is added with stirring for 4 hours (when amidate signals disappear in the <sup>1</sup>H NMR spectrum), the mixture is evaporated *in vacuo*, chlorobenzene and triethyl orthoformate (2.0 equivalents, syringe) are added and heated at 130° for 24 hours under a reflux condenser open to the atmosphere. Addition of triethyl orthoformate (2.0 equivalents, syringe) and heating is repeated for 24 hours, followed by evaporation to dryness *in vacuo*, excess of toluene is added to the residue and the slurry is filtered, and the solid is washed with toluene and hexanes, then with EtOAc. Final purification is by washing well with

cold EtOAc, and the off-white solid is thoroughly dried at 100° *in vacuo* (2mm) to constant weight (~1 hour) to give the *pre-catalyst tetrafluoroborate* in 74-76% yield. It has IR with  $\nu_{\max}$  at 3145, 3097, 2983, 1655, 1604, 1524, 1499, 1028, 994, 875  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (400MHz,  $\text{Me}_2\text{CO}-d_6$ ) has  $\delta$  at 3.00 (ddd,  $J = 15.0, 7.7, 7.7\text{Hz}$ , 2H), 3.42 (t,  $J = 8.0\text{Hz}$ , 2H), 4.76 (t,  $J = 8.0\text{Hz}$ , 2H), 10.19 (s, 1H); the  $^{13}\text{C}$  NMR (100MHz,  $\text{Me}_2\text{CO}-d_6$ ) has  $\delta$  at 22.6, 27.6, 49.5, 137.8, 140.4, 142.9, 143.3, 144.5, 145.6, 145.8, 165.8; and HRMS (APCI+) has  $m/z$  276.0556, and the calculated value for  $\text{C}_{11}\text{H}_7\text{N}_3\text{F}_5$  ( $\text{M}^+$ ) is 276.0555. [Vora et al. *Org Synth* **87** 350 2010].

**2-Mesityl-6,7-dihydro-5H-pyrrolo[2,1-c][1,2,4]triazol-2-ium chloride (2-mesityl-2,5,6,7-tetrahydro[2,1-c][1,2,4]-tetrazol-4-ium chloride), M 263.8, m 202-205°.** This is prepared and purified in much the same way as the preceding salt except for using triethyloxonium chloride for preparing the ethoxy pyrrolidinium chloride followed by reaction with mesitylhydrazinium chloride instead of perfluorophenylhydrazine.

**Boron trifluoride diethyl etherate [109-63-7] M 141.9, m -58°, b 46°/10mm, 126-129°/atm,  $d_4^{25}$  1.15,  $n_D^{20}$  1.344.** If the liquid has darkened due to oxidation by air it can be redistilled to give a colourless liquid. It is recommended that excess dry  $\text{Et}_2\text{O}$  (10ml) be added to the etherate (500ml) and distilled from  $\text{CaH}_2$  (2g) in an all glass still at (b 46°/10mm) which removes volatile acids and avoids bumping [Zwiefel & Brown *Organic Reactions* **13** 28 1963]. It is a fuming liquid which hydrolyses in moist air forming highly toxic fluorides on decomposition. Store it under  $\text{N}_2$  or argon and work in an efficient fume cupboard. It is a versatile *Lewis acid* for catalysis, acetylation, alkylation, dehydration, condensations, Beckmann rearrangements and polymerisation reactions. It catalyses the synthesis of cyclopentyl- and cycloheptyl[*b*]indoles from aryl cyclopropyl ketones via [3+2] cycloaddition [Venkatesh et al. *Eur J Org Chem* 5378 2006], and is a mild and efficient catalyst for Beckmann rearrangement in anhydrous MeCN [An et al. *Chin J Chem* **29** 947 2011]. [Beilstein **1** IV 1321.]

#### CBS (Corey-Bakshi-Shibata) Catalysts:

***R*-(+)-2-Methyl-CBS-oxazaborolidine (R-1-methyl-3,3-diphenyltetrahydro-1H,3H-pyrrolo[1,2-c][1,3,2]-oxazaborole,  $\alpha,\alpha$ -diphenyl-D-prolinolmethylboronic acid cyclamide) [112022-83-0] M 277.2, m 74-87°, 79-81°, 85-95°,  $[\alpha]_D^{22} +76.8^\circ$  (c 1, toluene) and *S*-(-)-2-Methyl-CBS-oxazaborolidine [112022-81-8] M 277.2, m 85-95°.** These CBS (Corey-Bakshi-Shibata) catalysts effect the asymmetric reduction of *pro*-chiral ketones, the stereoselective synthesis of  $\alpha$ -amino acids and  $\alpha$ -hydroxy acids, the preparation of ferrocenyl diols and propargyl alcohols. The catalyst is usually best prepared *in situ* from the respective  $\alpha,\alpha$ -diphenyl- (*R* or *S*)-prolinol [22348-32-9 or 79815-20-6] and a slight excess of trimethylboroxine [823-96-1]. Their suitability is determined by capillary GC [DB-1, 200°, retention time 4.9 minutes] and  $^1\text{H}$  NMR, where possible impurities have signals at  $\delta$  ( $\text{CDCl}_3$ ) for starting prolinol at ~4.3(t), trimethylboroxine at 0.45(s), the B—OH intermediate at 0.35 to -0.50 multiple B-Me singlet's, and/or the ring-B-O-B(Me)-OH intermediate at -0.25 B-Me brs. An analytical sample is obtained by dissolving it in toluene, filtering, then evaporating at 50°/0.001mm to give the catalyst as a white solid. Store it under dry  $\text{N}_2$  or argon. The IR ( $\text{CCl}_4$ ) has  $\nu_{\max}$  at 1000, 1235, 1310, 1330, 1440, 2880, 2960  $\text{cm}^{-1}$ ; and the  $^1\text{H}$  NMR (0.2M in  $\text{CDCl}_3$ ) has  $\delta$  at 7.65-7.15 (m, 10 H, ArH), 4.4 (dd,  $J = 5.8, 10.0\text{Hz}$ , 1 H, C3a-H), 3.45-3.30 (m, 1 H, C6-H), 3.15-3.00 (m, 1 H, C6-H), 1.90-1.55 (m, 3 H, C4-H, C5-H<sub>2</sub>), 0.95-0.75 (m, 1 H, C4-H), 0.40 (s, 3 H, B-CH<sub>3</sub>). They are also available commercially as 1M solutions in toluene or tetrahydrofuran. [Mathre et al. *J Org Chem* **56** 571 1991, Corey et al. *J Am Chem Soc* **124** 3808 2002, Ryu & Corey *J Am Chem Soc* **126** 8106 2004, Ryu et al. *J Am Chem Soc* **124** 9992 2002, Hu et al. *J Am Chem Soc* **126** 13708 2004, Quallich & Woodall *Tetrahedron Lett* **34** 785 1993.]

***R*-(+)- and *S*-(-)-2-*o*-Tolyl-CBS-oxazaborolidine {*R*- and *S*-3,3-diphenyl-1-*o*-tolyltetrahydro-1H,3H-pyrrolo[1,2-c][1,3,2]-oxazaborole} [*R*-865812-10-8; *S* 463941-07-3] M 353.3,  $[\alpha]_D^{20} +18^\circ$  and  $-18^\circ$  (c 1, toluene).** These Corey-Bakshi-Shibata (CBS) oxazaborolidines are available commercially as 0.5M solutions in toluene ( $d_4^{25}$  0.9009g/ml). They produce chiral *Lewis acids* when protonated with trifluoromethanesulfonamide and are used in enantioselective Diels-Alder reactions. They are prepared and purified as for the 2-methyl-CBS-oxazaborolidines above except that they are obtained as liquids on evaporation of the toluene solutions. [For applications see Ryu & Corey *J Am Chem Soc* **125** 6388 2003, Stemmler *Synlett* 997 2007, Corey et al. *J Am Chem Soc* **109** 7925 1987, Cho & Kim *Tetrahedron: Asymmetry* **12** 2043 2001, Cho et al. *J Chem Soc, Perkin Trans I* 1204 2001, Lebsack et al. *J Am Chem Soc* **123** 4851 2001, and references therein.]

**2-Methyl-CBS-oxazaborolidines derived from 1*S*,2*R*-(-) [126456-43-7] and 1*R*,2*S*-(+)-*cis*-1-Amino-2-hydroxyindane [136030-00-7]** are best prepared *in situ* by reaction of *cis*-1-aminoindan-2-ol (1*S*,2*R*

see [126456-43-7]; 1*R*,2*S* see [136030-00-7]) with trimethylboroxine (see [823-96-1]) in a solvent (usually toluene), and they are sensitive to moisture and air. They catalyse the reduction of ketones and  $\alpha$ -haloketones to their respective alcohols by  $\text{BH}_3$  or some of its complexes, e.g.  $\text{BH}_3\text{-DMS}$ ,  $\text{BH}_3\text{-THF}$ , with high stereospecificities (ee above 80%) at room temperature or below because of the steric effects of the methyl and indane groups around the heterocyclic boron atom. In a typical preparation, trimethylboroxine (0.19ml, 1.34mmol) is added to a solution of pure 1*R*,2*S*-1-aminoindan-2-ol (2.01mmol) in dry toluene (10ml), stirred at  $\sim 25^\circ$  for 30 minutes, more toluene (10ml) is added and the solution is concentrated by distillation to *ca* 2ml. The procedure is repeated twice then the toluene is removed *in vacuo* to give the *CBS-catalyst* as a white solid. Dry THF ( $\sim 2$ ml) is added to produce an approximately 1.0M solution of the catalyst in THF for later reactions. The solution should be stored under dry  $\text{N}_2$  or argon and is stable for about 48 hours. For reduction reactions, the borane hydride (1.83mmol) is added to a solution of the chiral 2-methylaminoindanol (0.17ml, 0.166mmol) in the desired solvent (e.g. toluene) (2ml) stirred under  $\text{N}_2$  at  $\sim 25^\circ$  for 30 minutes, cooled to  $0^\circ$  and the ketone (1.67mmol) in the desired solvent (e.g. toluene, 1ml) is added *via* a cannula, stirred at  $\sim 25^\circ$  for 30 minutes, quenched with MeOH (5ml),  $\text{H}_2\text{O}$  (20ml) is added, the MeOH is removed *in vacuo*, and the resulting optically active alcohol is isolated from the aqueous solution. [Gilmore & Jones *Tetrahedron: Asymmetry* **14** 2115 2003, Hong et al. *Tetrahedron Lett* **36** 6631 1994

**4-Dimethylaminopyridine (DMAP)** [1122-58-3] **M 122.2, m 108-109 $^\circ$ , 112-113 $^\circ$ , b 191 $^\circ$ /atm (under  $\text{N}_2$ ),  $\text{pK}^{5.4}$  10.14,  $\text{pK}^{20}$  9.70,  $\text{pK}^{25}$  9.61,  $\text{pK}^{35}$  9.33 (in  $\text{H}_2\text{O}$ ).** Recrystallise DMAP from toluene [Sadownik et al. *J Am Chem Soc* **108** 7789 1986]. DMAP can also be purified by recrystallisation from EtOH or  $^*\text{C}_6\text{H}_6$  and dried *in vacuo*. It is prepared easily from suitable 4-substituted pyridines, e.g. 4-chloropyridine and  $\text{Me}_2\text{NH}$  in EtOH (2 hours at  $100^\circ$ , or in a sealed tube for 12 hours at  $100^\circ$ ,  $115\text{-}130^\circ$ , Wibaut & Brockman *Rec Trav Chim Pays Bas* **80** 309 1961), or in very high yield from 4-trimethylsilyloxy pyridine with  $\text{Me}_2\text{NH}/\text{HgCl}_2$  (48 hours at  $120^\circ$ , Vorbrüggen *Angew Chem Int Ed Engl* **11** 305 1972). This organocatalyst is a strong base and promotes a large variety of acylation reactions, e.g. of *m*-chloroaniline and of benzyl alcohol at relative rates that are  $3.14 \times 10^6$  and  $3.45 \times 10^8$  compared with those of the uncatalysed reactions. It is useful industrially. The acylating agent is an acid chloride or an acid anhydride. Typically, catalytic amounts of DMAP are used together with one equivalent of a tertiary base, e.g.  $\text{Me}_3\text{N}$ , to neutralise the anion formed, i.e.  $\text{Cl}^-$  from the acid chloride or  $\text{AcO}^-$  from the anhydride, and to avoid protonating the catalyst. [Scriven *Chem Soc Rev* **12** 129 1983.] Its *picrate* has **m 108 $^\circ$**  (EtOH), and its *tetrafluoroborate salt* has **m 126 $^\circ$**  (from  $\text{MeCN}/\text{Et}_2\text{O}$ ). The UV has  $\lambda_{\text{max}}$  ( $\epsilon$ ) at 261nm ( $18,300 \text{ cm}^2\text{.mole}^{-1}$ ) for free base at pH  $>12.0$ , and 280.5nm ( $19,600 \text{ cm}^2\text{.mole}^{-1}$ ) for the mono-cation at pH  $<7.0$  in  $\text{H}_2\text{O}$  (Essery & Schofield *J Chem Soc* 3939 1961); and the IR ( $\text{CHCl}_3$ ) has  $\nu_{\text{max}}$  ( $\epsilon_{\lambda}$ ) at 2840 (sh, 45), 1448 (95, Me bend), 1380 (155, CN str), 1346 (35), 1179 (35,  $\text{Me}_2$  rock), 1108 (30,  $\text{Me}_2$  rock), 1063 (35,  $\text{NMe}_2$ , C-N-C stretch) and 951 (55,  $\text{NMe}_2$ , C-N-C stretch)  $\text{cm}^{-1}$  (Katritzky & Jones *J Chem Soc* 3674 1959). [*Beilstein* **22** II 341, **22** III/IV 4101, **22/9** V 112.]

DMAP is an efficient *desymmetrisation* catalyst. [Willis *J Chem Soc, Perkin 1* 1765 1999.] Thus it allows the use of an achiral or *meso* molecule, e.g. 3-substituted glutaric anhydride to react with chiral alcohols e.g. *R*-1-(1'-naphthyl)ethanol to produce (1'*R*,3*R*)-1(1'-naphthyl)ethyl methyl 3-substituted-pentanoate di-esters (after treatment with diazomethane), which are now chiral at C-3. The achiral carbon atom at C-3 in the glutaric anhydride becomes chiral in the pentanoate (mono-ester of glutarate). [Theisen & Heathcock *J Org Chem* **53** 2374 1988, Theisen & Heathcock *J Org Chem* **58** 142 1993.]

§ It is commercially available in 0.04mmol impregnated tablets, and a polystyrene supported version (PS-DMAP) with a loading of  $\sim 3.0$ mmol/g is also available for recyclable acylation purposes.

***N,N'*-Dimethylethylenediamine [DMEDA, bis(methylamino)ethane]** [110-70-3] **M 88.2, b 110-112 $^\circ$ /750mm, 119 $^\circ$ /atm,  $d^{25}$  0.819,  $n_D^{20}$  1.431,  $\text{pK}_1^0$  8.30,  $\text{pK}_2^0$  10.89,  $\text{pK}_1^{25}$  6.80 (7.01),  $\text{pK}_2^{25}$  9.88 (10.03).** It has been prepared in several ways, but most commonly when ethylene dibromide (1mol),  $\text{MeNH}_2$  (5mols) and  $\text{H}_2\text{O}$  (*ca* 3mols) are boiled under reflux for 15 hours. A 32% aqueous solution of NaOH is added, excess  $\text{MeNH}_2$  is distilled out, and the rest of the liquid is distilled off. The diamine in the distillate is salted out with solid NaOH, dried ( $\text{Na}_2\text{CO}_3$ , or KOH), filtered and fractionally distilled (in *ca* 50% yield) until the NMR indicates that it is free from impurities. Store it in sealed containers under  $\text{N}_2$  or argon as it is a strong base. The *N,N'*-bis(*p*-toluenesulfonamide) has **m 164 $^\circ$**  (from AcOH), *N,N'*-bis(benzenesulfonamide) has **m 129-131 $^\circ$**  (from EtOH and AcOH, or EtOAc), the *N,N'*-bis(benzamide) has **m 177-178 $^\circ$**  (from  $^*\text{C}_6\text{H}_6$ ), the *monopicrate* has **m 140 $^\circ$**  (plates

from EtOH or Me<sub>2</sub>CO) and the *dihydrochloride* decomposes at **m 235°**. [Kermack & Wight *J Chem Soc* 1425 1935, Boon *J Chem Soc* 311 1947, Woodburn & O'Gee *J Org Chem* 17 1241 1953, Bauer *J Am Chem Soc* 78 1945 1956.]

In the presence of resublimed *tert*-BuOK (1.5mmol), DMEDA (0.1mmol) *catalyses* cross-coupling between aryl and substituted aryl halides (0.5mmol) with arenes, e.g. \*benzene, naphthalene (0.5mmol) at 80°/~4 hours, to provide the corresponding biaryls in high yields (~70 to >90%). *Ortho* substitution leads to decreased yields, and replacing KOBu<sup>t</sup> with other bases (e.g. KOH, Na<sub>2</sub>CO<sub>3</sub>, KOAc, *tert*-BuONa, or *tert*-BuOK, *tert*-BuOLi) results in no reaction or extremely low yields. Of the amines studied DMEDA is the most effective catalyst and evidence is presented that a radical reaction is involved. It is the first example of a cross-coupling reaction which does not require a metal. [Liu et al. *J Am Chem Soc* 132 16737 2010, *Beilstein* 4 H 250, 4 I 425, 4 II 689, 4 III 512, 4 IV 1171.]

***R*-(+)-Indoline-2-carboxylic acid** [98167-06 -7] **M 163.2, m 177°(dec)**, [α]<sub>D</sub><sup>20</sup> +11.0° (c 0.3, MeOH). Purify it as for the *S*-enantiomer below. The *R*-(+)-*hydrochloride* has [172152-19-1]. It is a proline based organocatalyst which promotes the enantioselective formation of cyclopropanes by reaction between 2-(dimethyl-λ<sup>4</sup>-sulfanylidene)-1-phenyl-ethanone (for stable sulfonium ylides see Ratts & Yao *J Org Chem* 31 1185 1966) and but-2-enals in high yields and very high stereoselectivity involving Direct Electrostatic Activation (DEA) [Kunz & Mac Millan *J Am Chem Soc* 127 3240 2005.]

***S*-(-)-Indoline-2-carboxylic acid** [79815-20-6] **M 163.2, m 177°(dec)**, [α]<sub>D</sub><sup>20</sup> -114° (c 1, N HCl). It is purified as the racemate (see [78348-24-0] in Heterocyclic Compound, Chapter 4). The *S*-(-)-*hydrochloride* [82923-76-0] **M 199.7, m 133°(dec)**, [α]<sub>D</sub><sup>20</sup> -70° (c 1, EtOH) crystallises from Et<sub>2</sub>O/propan-2-ol. It is a proline based organocatalyst which promotes the enantioselective formation of cyclopropanes by reaction between 2-(dimethyl-λ<sup>4</sup>-sulfanylidene)-1-phenyl-ethanone (for stable sulfonium ylides see Ratts & Yao *J Org Chem* 31 1185 1966) and but-2-enals in high yields and very high stereoselectivity involving Direct Electrostatic Activation (DEA) [Kunz & Mac Millan *J Am Chem Soc* 127 3240 2005.]

**α-Methyl-L-proline (*S*-2-methylproline)** [42856-71-3] **M 129.2, m 248-252°(dec)**, [α]<sub>D</sub><sup>25</sup> -75° (c 2.0, MeOH), **and (*R*-2-methylproline)** [58123-62-9]. This derivative catalyses reactions similar to those of proline. The general three-step synthesis from proline devised by Seebach and co-workers provides enantiomerically pure compound [*Helv Chim Acta* 64 2704 1981, *J Am Chem Soc* 105 5390 1983, *Org Synth* 72 62 1993]. It has been prepared on a 20-40g scale starting from *S*- or *R*- proline which is converted into **2*S*,5*S*- (or 2*R*,5*S*)- 2-*tert*-butyl-1-aza-3-oxabicyclo[3.3.0]octan-4-one** (*tert*-BuCHO, CF<sub>3</sub>CO<sub>2</sub>H as catalyst, pentane reflux for 114 hours with removal of H<sub>2</sub>O) in 67-74% yield, which is methylated to **2*S*,5*S*- (or 2*R*,5*S*)- 2-*tert*-butyl-5-methyl-1-aza-3-oxabicyclo[3.3.0]octan-4-one** [86046-11-9] (MeI, *iso*-Pr<sub>2</sub>NLi/THF/-78°) with complete retention of configuration at C-5 in 93-95% yield; and hydrolysed (1.3M HCl/reflux for 1 hour, or 15% aqueous HBr/~25° for 8 hours) to give the respective *2-methyl-proline hydrochloride* which is purified through a Dowex 50W x 8 (H<sup>+</sup> form) column by washing with H<sub>2</sub>O, then eluting with 3N aqueous NH<sub>3</sub> and evaporating to give the free *2-methylproline* in 85-90% yield. The last step is apparently quite tedious to carry out and is time consuming. The following procedure is more convenient and gives better than 90% yields of pure *2-methylproline*. The above butyl-methyl-aza-oxa-bicyclooctanone (13.4mmol) in MeOH/H<sub>2</sub>O (6:1, 35ml) is treated with Silica gel 200-400 mesh, 60Å (3.0g) and stirred overnight. The silica gel is filtered off, washed with MeOH, the combined washings and filtrate are evaporated *in vacuo*, the pale yellow residue is dissolved in CHCl<sub>3</sub>/MeOH (20:1), filtered through a 0.45μ filter disk (Acrodisk<sup>®</sup> CR PTFE), evaporated to dryness and the residue is triturated with Et<sub>2</sub>O and dried *in vacuo*. Although it may be yellow in colour, it is almost spectroscopically pure, and can be purified further by dissolving in MeOH, treating with activated charcoal (5% w/w), filtering the whole suspension through Celite and evaporating. It can be crystallised by slow evaporation of the CHCl<sub>3</sub>/MeOH solution, or from an MeOH/Et<sub>2</sub>O mixture to give a first crop (50-70% yield) of white crystals leaving remaining *2-methylproline* and traces of yellow impurities in the mother liquors. Additional product crystallisation can be achieved by vapour diffusion of the supernatant against Et<sub>2</sub>O in a closed desiccator. It also crystallises nicely from MeOH/EtOAc in colourless plates, unlike many α-amino acids. [Genin et al. *Tetrahedron Lett* 35 4967 1994.]

*S*-2-Methylproline with  $[\alpha]_D -72.1^\circ$  (c 1.0, MeOH) was shown to have an enantiomeric excess “ee” of  $99.0 \pm 0.5\%$  by chiral capillary gas chromatography. For this purpose the amino acid (5mg) is heated with *iso*-propyl isocyanate (0.3ml) in  $\text{CH}_2\text{Cl}_2$  (0.3ml) at  $100^\circ$  for 15 minutes, cooled, excess of volatiles are removed by a strong stream of dry air, the residue is dissolved in  $\text{Et}_2\text{O}$  (1ml), filtered through cotton wool and  $10\mu\text{l}$  applied to the chiral capillary column. A Chirasil-Val fused-silica capillary column of Machery-Nagel (25m, 0.4mm) in a Carlo-Erba-Frautovap 4160 HR GC unit has been used. The column was heated at  $160^\circ$  for 15 minutes then raised by  $2^\circ/\text{min}$  up to  $200^\circ$  (Argon as carrier gas ?). The amino acid has  $^1\text{H}$  NMR (200MHz,  $\text{D}_2\text{O}$ , HDO at d 4.80) with  $\delta$  at 1.52 (s, 3H,  $\text{CH}_3$ ), 1.75-2.40 (m, 4H, 3- $\text{CH}_2$  + 4- $\text{CH}_2$ ), and 3.20-3.45 (m, 2H, 5- $\text{CH}_2$ ); and its  $^{13}\text{C}\{^1\text{H}$  decoupled; NMR (50MHz,  $\text{D}_2\text{O}$ ) has  $\delta$  at 179.87 ( $\text{CO}_2\text{H}$ ), 73.2 (C-2), 48.06 ( $\text{CH}_3$ -2), 38.27 (N-C-5), 25-85 (C-3) and 23.99 (C-4). [Beck et al. *Org Synth* **72** 62 1993].

*S*-2-Methylproline hydrobromide [42856-71-3], prepared by hydrolysis with 15% aqueous HBr (see above) evaporating and triturating with dry  $\text{Et}_2\text{O}$  as colourless crystals (80%), has **m** 136-137<sup>o</sup>(dec),  $[\alpha]_D^{20} -28.9^\circ$  (c 1.0, MeOH) and its  $^1\text{H}$  NMR (200MHz,  $\text{D}_2\text{O}$ , HDO at d 4.70) has  $\delta$  at 1.60 (s, 3H,  $\text{CH}_3$ ), 1.80-2.45 (m, 4H, 3- $\text{CH}_2$  + 4- $\text{CH}_2$ ), and 3.36 (t, 2H, J = 7 Hz, 5- $\text{CH}_2$ ) [Seebach et al. *J Am Chem Soc* **105** 5390 1983, Overberger & Jon *J Polym Sci, Polym Sci Ed* **15** 1413 1977].

$\alpha$ -Methyl-DL-proline (*RS*-2-methylproline) [68078-09-1] **M** 129.2, **m** 263-264.5<sup>o</sup>. The racemic 2-methylproline was prepared by hydrolysing 5-(3-chloropropyl)-5-methylhydantoin (2g, 10mmol) with  $\text{Ba}(\text{OH})_2$  (6.3g, 20mmol) and  $\text{H}_2\text{O}$  (50ml) in a pressure bomb at  $160^\circ$  for 30 minutes, cooling, adjusting the pH to 6 with 6N  $\text{H}_2\text{SO}_4$ , filtering off the  $\text{BaSO}_4$ , applying the filtrate through a column of Amberlite IRC 120 ( $\text{H}^+$  form), washing with  $\text{H}_2\text{O}$ , eluting with 4N  $\text{NH}_4\text{OH}$ , and evaporating the eluate to give a white solid m 252-258<sup>o</sup> (1.2g, 90%). Recrystallisation of the solid from MeOH/ $\text{Et}_2\text{O}$  gave analytically pure *RS*-2-methylproline m 263-264.5<sup>o</sup>. It has IR (KBr) with  $\nu_{\text{max}}$  at 3450 and 3200 (OH and NH), and 1600 (C=O)  $\text{cm}^{-1}$ ; and its  $^1\text{H}$  NMR (60MHz,  $\text{CD}_3\text{OD}$ , TMS) has  $\delta$  at 1.6 (s, 3H,  $\text{CH}_3$ ), 1.9 (m, 4H, 3- $\text{CH}_2$  + 4- $\text{CH}_2$ ), and 3.3 (m, 2H, 5- $\text{CH}_2$ ). [Ellington & Honigberg *J Org Chem* **39** 104 1974]. It should be possible to prepare it by Seebach's procedure (see preceding entry) and starting with *RS*-proline.

Tetra-*n*-butylammonium fluoride (TBAF) [anhydrous, 1 M in THF 429-41-4; 3  $\text{H}_2\text{O}$  87749-50-6; hydrate 22206-57-1] **M** 261.5 (anhydrous), 315.5 (3  $\text{H}_2\text{O}$ ), **m** liquid (anhydrous), 62-63<sup>o</sup> (3  $\text{H}_2\text{O}$ ), 37<sup>o</sup> (18  $\text{H}_2\text{O}$ ). It is a powerful catalyst for the regioselective ring opening of epoxides with thiols [Albanese et al, *Synthesis* 34 1994], the addition reactions of trimethylallylsilane [Majetich et al. *J Org Chem* **51** 1745 1986], Michael, Knoevenagel, aldol condensations, and by acting as a base in organic synthesis [Clark *Chem Rev* **80** 429 1980]. It is a mild and highly efficient source of nucleophilic fluoride ions, causing substitution of halogen or tosyl groups by fluorine. TBAF is also used for cleaving silyl ethers and silyl protecting groups [cf T.W. Greene and P.G.M. Wuts *Protective Groups in Organic Synthesis*, J. Wiley, NY 1991]. When an aqueous solution of tetra-*n*-butylammonium hydroxide is titrated with hydrofluoric acid, a homogeneously melting octadecahydrate (m 37<sup>o</sup>) is obtained [Fowler et al. *J Am Chem Soc* **62** 1140 1940]. When the octadeca- or tri- hydrates are heated under high vacuum at temperatures of above  $80^\circ$ , decomposition occurs giving tetrabutylammonium bifluoride, tributylamine and 1-butene; with loss of a lot of its useful properties. When the trihydrate is warmed at  $40^\circ$  under high vacuum, almost “anhydrous” TBAF is obtained. This salt contained 0.1-0.3 molar equivalents of  $\text{H}_2\text{O}$  (by  $^1\text{H}$  NMR). It is an oil at room temperature [Cox et al. *J Org Chem* **49** 3216 1984]. Virtually anhydrous TBAF in DMF can be prepared without heating by using aliquots (~10 to 30mg) of the trihydrate and placing them under high vacuum (<0.1mm Hg) for 0.5 hour at  $\sim 25^\circ$ , the flask is flushed with  $\text{N}_2$ , and dry DMF (2ml) is added. The solution is transferred (syringe) to a round-bottomed flask (under  $\text{N}_2$ ), containing 4Å Molecular sieves (which had been activated by flame-drying for 5 minutes under high vacuum), and stirred with a micro stirrer bar for 30 minutes [Majetich et al. *J Org Chem* **51** 1745 1986]. This is then used for catalytic or other reactions in anhydrous media.

TBAF is also available commercially as a 1 M solution in THF, 75% solution in  $\text{H}_2\text{O}$ , on alumina support 15wt% loading [429-41-4], on silica gel at  $\sim 1.5\text{mmol/g F}^-$  as a non-hygroscopic support for use as a source of “naked” fluoride ions [Ricci et al. *Tetrahedron Lett* **23** 577 1982, Gambacorta et al. *Synth Commun* **19** 2441 1989]. [Beilstein **4** III 292, For further applications see selected volumes of Fieser & Fieser's *Reagents for Organic Synthesis*.]

## CATALYSTS—Part 2

## LIGANDS &amp; REAGENTS USED FOR MAKING LIGANDS THAT ASSIST CATALYSIS

*Ligands and reagents in this section are mainly ones that are used within this and the former section Catalysts-Part 1. Others will be found scattered in Chapters 4, 5 and 7, and can be identified by their CAS Registry Numbers through the index, or from their commonly used names.*

**( $\eta^3$ -Allyl)( $\eta^5$ -cyclopentadienyl)palladium(II) [(allyl)(cyclopentadienyl)palladium(II)] [1271-03-0] M 212.5, m 61° (dec).** This complex is volatile and should be handled in an efficient fume hood. Using Schlenk equipment under N<sub>2</sub> or argon and strictly dry conditions, a clear yellow solution of bis( $\eta^3$ -allyl)di- $\mu$ -chloro-dipalladium(II) (9.9g, 27mmol, see [12012-95-2]) in THF (100ml) and \*C<sub>6</sub>H<sub>6</sub> (100ml) is prepared, and cooled in an ice-NaCl bath to -20°. A solution of sodium cyclopentadienyl (54mmol in 28ml of THF, [4984-82-1]) in a N<sub>2</sub> flushed syringe is added dropwise to the yellow solution at -20° with stirring, whereby the colour changes to dark red. The ice bath is removed after stirring for 1 hour, the temperature is allowed to rise to ~25°, stirring is continued for 30 minutes and the solvents are removed by evaporation *in vacuo* (30-60 torr; no higher than 20° because the Pd complex will begin to sublime at ~25°) to yield a dark red solid. The residue is extracted with hexane (80ml), the extract is filtered under N<sub>2</sub> (use fluted filter paper as a glass frit is likely to become clogged). The filtrate is evaporated as before (*in vacuo* at 30-60 torr) to give red needles of the palladium(II) complex (9.2g, 80%). Note that by using mechanical stirring the yield can be improved to 98%. This product is satisfactory for most preparations of Pd(0) complexes, but an analytical sample is readily obtained as red needle-like crystals by subliming it at 40°/30mm. It has an unpleasant odour, is relatively stable in air, decomposes gradually in air at ~25° to form a black solid which is not soluble in hexane, and is best stored below -20° under N<sub>2</sub> or argon. The <sup>1</sup>H NMR (\*C<sub>6</sub>D<sub>6</sub>) has  $\delta$  at 2.14 (d, *J* = 11Hz, 2H), 3.11 (d, *J* = 6Hz, 6H) and 4.63 (m, 1H) complex for allyl protons and 8.1 (s, 5H, cyclopentadienyl protons). [Tatsuno et al. *Inorg Synth XIX* 221 1979]. The complex is useful for preparing Pd(0) complexes [Shaw *J Chem Soc* 247 1960] by reaction with hindered alkyl phosphines [Otsuka et al. *J Am Chem Soc* 98 5850 1976], reacts with isonitriles to form Pd(CNR)<sub>2</sub> complexes [Fischer & Werner *Chem Ber* 95 703 1962, Otsuka et al. *J Am Chem Soc* 91 6994 1969], and has been used to prepare BINAP complexes such as Pd[(*R*)-BINAP]<sub>2</sub> for asymmetric catalysis [Ozawa et al. *Organomet* 12 4188 1993].

**Ammonium perrhenate (NH<sub>4</sub>ReO<sub>4</sub>) [13598-65-7] M 268.2, m 365°(dec.), d<sub>4</sub><sup>25</sup> 3.97, pK<sup>25</sup> -1.25 (for HReO<sub>4</sub>).** The higher solubility of the ammonium salt in H<sub>2</sub>O (17g/L at 0°, and 162g/L at ~50°) compared to that of the potassium salt (see [10466-65-6]) has made this salt preferable for use in the preparation of a variety of rhenium compounds. It is prepared from perrhenic acid (see [13768-11-1]) which is obtained from KReO<sub>4</sub> (10.0g, 0.036mol) using the procedure of Watt & Thompson (*Inorg Synth* 7 187 1963) whereby a solution in H<sub>2</sub>O (100ml, solubility is 14% at 100°) at 90° is passed through a column of cation exchange resin (Dowex 50-Wx2, but not x8) held at 90° (preferably coated with "Instatherm", Ace Glass Co., Inc Vineland, NJ, USA, to withstand the temperature), washed with H<sub>2</sub>O, and the combined aqueous eluates are concentrated *in vacuo* down to the critical volume of 5ml. If it is concentrated further and the colour darkens, then one drop of 30% aqueous H<sub>2</sub>O<sub>2</sub> should be added to decolourise it. The solution is cooled to ~0°, and while being stirred, a chilled mixture of 2-propanol (15ml, saturated with gaseous NH<sub>3</sub>) and Et<sub>2</sub>O (50ml) is added. The cold mixture is allowed to stand for 1 hour, and the white hexagonal plates (~90% yield) are filtered onto a sintered-glass funnel, washed three times with 2-propanol/Et<sub>2</sub>O (1:9), dried *in vacuo*, then at 110° to give NH<sub>4</sub>ReO<sub>4</sub> (8.9g, 96% yield) that is 99.4-99.95% pure by microanalysis and by passage through a cation-exchange resin in H<sub>2</sub>O and titrating with standard base. [Thompson *Inorg Synth* 8 171 1966, see also Smith & Long *J Am Chem Soc* 70 354 1948.]

**Benzotriazol-1-yloxy-tris(dimethylamino)phosphonium hexafluorophosphate (BOP.PF<sub>6</sub>, Castro's reagent) [56602-33-6] M 442.3, m >130°, 147-148°, 130°.** Castro's reagent is prepared by adding dropwise hexamethylphosphoric triamide (180g, 1 mol, see [680-31-9]) to a vigorously stirred solution of phosgene in toluene (180ml, 20%) during 4 hours (use a bubbler to control the evolution of CO<sub>2</sub>). After stirring for 16 hours

at  $-25^{\circ}$ , excess of  $\text{COCl}_2$  is removed under reduced pressure.  $\text{CH}_2\text{Cl}_2$  (300ml) is added to ensure a homogeneous solution, and solid hydroxybenzotriazole monohydrate (153g, see [123333-53-9]) is added. The mixture is cooled to  $-5^{\circ}$  ( $\text{Me}_2\text{CO}/\text{Dry-ice}$ ) and  $\text{Et}_2\text{NH}$  (100ml, 1mol) is added during 15 minutes, and stirring is continued at  $0^{\circ}$  for 4 hours. The precipitated  $\text{Et}_2\text{NH}\cdot\text{HCl}$  is filtered off (sintered glass funnel), the solvent is evaporated *in vacuo*,  $\text{H}_2\text{O}$  (500ml) is added and the aqueous solution is extracted with  $\text{Et}_2\text{O}$  (3 x 100ml). This aqueous solution of BOP chloride is added to a filtered solution of  $\text{KPF}_6$  (200g) in  $\text{H}_2\text{O}$  (2L) and the precipitated  $\text{BOP}\cdot\text{PF}_6$  is extracted into  $\text{CH}_2\text{Cl}_2$ . The organic layer is dried ( $\text{MgSO}_4$ ), filtered and concentrated under reduced pressure. Addition of  $\text{Et}_2\text{O}$  causes the separation of the first crop of  $\text{BOP}\cdot\text{PF}_6$  which is collected, and further crops are obtained by addition of  $\text{CH}_2\text{Cl}_2$  to the mother liquors, concentrating and adding  $\text{Et}_2\text{O}$ . The combined crops are washed with  $\text{Et}_2\text{O}$  and dried *in vacuo* to give the salt (354g, m 147-149 $^{\circ}$ , 80%) which may be recrystallised further from  $\text{Me}_2\text{CO}/\text{Et}_2\text{O}$ . The reagent is usually pure enough for efficient coupling of peptides without this recrystallisation. Its IR(KBr) has  $\nu_{\text{max}}$  at 1010 (P-N), 840, 770, and 560 ( $\text{PF}_6^-$ )  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (acetone- $d_6$ ) has  $\delta_{\text{H}}$  at 3.0 (d, 18H,  $\text{N}(\text{CH}_3)_2$ ,  $J_{\text{H-P}} = 10\text{Hz}$ ), 7.9 (m,  $4\text{H}_{\text{arom}}$ ); and the  $^{31}\text{P}$  NMR ( $\text{CH}_2\text{Cl}_2/\text{D}_3\text{PO}_4$ ) has  $\delta$  at -43.7 (s,  $\text{P}^+$ ), +144.2 (septet,  $\text{PF}_6^-$ ). [Castro et al. *Synthesis* 751 1976.]

**Benzotriazol-1-yloxy(tripyrrolidino)phosphonium hexafluorophosphate (PyBOP)** [128625-52-5] **M 520.4, m 154-156 $^{\circ}$ , 156-157 $^{\circ}$** . It can be prepared and purified in a similar manner as for BOP except that pyrrolidine replaced  $\text{Et}_2\text{NH}$  [cf Castro's reagent above, see [56602-33-6] and Dormoy & Castro *Tetrahedron Lett* 3321 1979] by recrystallisation from  $\text{Me}_2\text{CO}/\text{Et}_2\text{O}$  and drying *in vacuo*. It is non-hygroscopic and can be stored at  $-25^{\circ}$ . It has  $^{31}\text{P}$  NMR ( $\text{CDCl}_3$ ) at  $\delta$ : 31.8 (s) and -143.7 (heptet,  $J = 713\text{Hz}$ ). It is an analogue of the BOP and a very good coupling agent which does not form the carcinogenic HMPA as byproduct [Coste *Tetrahedron Lett* 31 205 1990, Seebach *Helv Chim Acta* 77 1313 1994].

**(2-Biphenyl)-di-tert-butylphosphine [JohnPhos, 2-(di-tert-butylphosphino)biphenyl]** [224311-51-7] **M 298.4, m 86-88 $^{\circ}$** . This *Buchwald ligand* is prepared in Schlenk-type equipment under argon containing Mg turnings (617mg, 25.4mmol) and a small crystal of  $\text{I}_2$  (to activate the metal) at  $-25^{\circ}$ , which is treated with a solution of 2-bromobiphenyl (5.38g, 23.1mol, see [2052-07-5]) in THF (40ml), the mixture is refluxed for 2 hours and allowed to cool to  $25^{\circ}$ . Anhydrous  $\text{Cu(I)Cl}$  (2.40g, 24.2mmol) is added, the flask is capped with a septum, purged with argon for 2 minutes and di-tert-butylchlorophosphine (5.0g, 24.2mmol; see [13716-10-4]) is injected *via* a syringe, and the mixture is refluxed for 8 hours. The mixture is cooled to  $-25^{\circ}$ , diluted with 1:1 hexanes/ $\text{Et}_2\text{O}$  (200ml) and the suspension is filtered, the solids are washed with hexanes (60ml), and the solid material is added to 1:1 hexanes/ $\text{EtOAc}$  (150ml) followed by  $\text{H}_2\text{O}$  (100ml) and 30% aqueous  $\text{NH}_4\text{OH}$  (60ml). This slurry is stirred at  $-25^{\circ}$  for 5 minutes, the layers are separated and the organic layer is washed with brine (100ml), dried ( $\text{Na}_2\text{SO}_4$ ), filtered, evaporated *in vacuo* and the residue is recrystallised from  $\text{MeOH}$  (2 crops are collected) to provide *JohnPhos* as a white solid (4.46g, 67%) with **m 86-86.5 $^{\circ}$** . The IR (film) has  $\nu_{\text{max}}$  at 2956, 1459, 1362, 1173  $\text{cm}^{-1}$ . It has  $^1\text{H}$  NMR (300MHz,  $\text{CDCl}_3$ ) with  $\delta_{\text{H}}$  at 7.95-7.85 (m, 1H), 7.40-7.21 (m, 8H), 1.15 (d,  $J = 11.6\text{Hz}$ , 18H); the  $^{31}\text{P}$  NMR (121MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{P}}$  at -18.7; and  $^{13}\text{C}$  NMR (75MHz,  $\text{CDCl}_3$ ) at  $\delta_{\text{C}}$ : 151.4, 150.9, 143.6, 143.5, 135.6, 135.2, 135.0, 130.4, 130.1, 128.3, 127.0, 126.7, 126.5, 126.2, 126.0, 125.6, 32.7, 32.6, 30.8, 30.6 (observed complexity from P-C coupling not assigned).

This ligand with  $\text{Pd}(\text{OAc})_2$  catalyses Suzuki coupling at  $-25^{\circ}$  between aryl halides (Br and Cl) with arylboronic acids with 0.5-1.0mol%Pd in high yields [Wolfe et al. *J Am Chem Soc* 121 9550 1999, see cyclohexyl-JohnPhos below]. The ligand was used for the amination of aryl halides and aryltriflates [Wolfe et al. *J Org Chem* 65 1158 2000]. This bulky biarylphosphine ligand was also used in the Pd-catalysed Stille cross-coupling reaction [Artamkina et al. *Synlett* 2 235 2006] and in the Pd-catalysed 2,3-diarylation of  $\alpha,\alpha$ -disubstituted-3-thiophenemethanols *via* cleavage of C-H and C-C bonds [Nakano et al. *J Org Chem* 71 8309 2006].

**(2-Biphenyl)-dicyclohexylphosphine [cyclohexyl-JohnPhos, 2-(dicyclohexylphosphino)biphenyl]** [247940-06-3] **M 350.5, m 102-106 $^{\circ}$** . This *Buchwald ligand* is prepared in a way similar to the preceding JohnPhos except that 2-bromobiphenyl in THF is converted to 2-lithiobiphenyl with *n*-BuLi at  $-78^{\circ}/45$  minutes, and followed by reaction with dicyclohexylchlorophosphine at  $-78^{\circ}/15$  minutes. The desired product is recrystallised from  $\text{MeOH}$  to give cyclohexyl-JohnPhos (71%) as white crystals **m 103 $^{\circ}$** . The IR (film) has  $\nu_{\text{max}}$  at 2916, 1441, 749  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (300MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 7.62-7.51 (m, 1H), 7.40-7.10 (m, 8H), 1.95-1.45 (m, 13H), 1.35-0.95 (m, 9H); and the  $^{31}\text{P}$  NMR (121MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{P}}$  at -12.7; and the  $^{13}\text{C}$  NMR (75MHz,

CDCl<sub>3</sub>) has  $\delta_C$  at 150.7, 150.4, 142.9, 142.8, 134.1, 133.8, 132.8, 130.61, 130.55, 130.5, 130.2, 130.1, 128.1, 127.3, 127.14, 127.05, 126.7, 126.4, 34.7, 34.5, 30.5, 30.2, 29.3, 29.1, 27.3, 27.2, 27.1, 26.4 (observed complexity from P-C coupling not assigned).

This ligand with Pd(OAc)<sub>2</sub> allows Suzuki coupling at low catalyst loadings (0.000001-0.02mol%Pd) between aryl halides (Br and Cl) with arylboronic acids in high yields, and tolerates a wide range of functional groups and substrate combinations including sterically hindered substrates. It was the most active catalyst system in terms of temperature of reaction, turnover numbers and steric tolerance in 1999 [Wolfe et al. *J Am Chem Soc* **121** 9550 1999.] This ligand was also used for the amination of aryl halides and aryltriflates [Wolfe et al. *J Org Chem* **66** 2560 2001], and was employed in the Pd-catalysed synthesis of 1,3,5-tris(2'-aminophenyl)-benzene from *o*-aminophenylboronic acid and 1,3,5-triiodobenzene, which may be used as a three-directional core building block for potential ionic receptors [Piatek & Slomiany *Synlett* 2027 2006].

**2,2'-Bipyridine (2,2'-dipyridyl,  $\alpha,\alpha'$ -dipyridyl)** [366-18-7] **M 156.2, m 69.7°, b 272-273°/atm, pK<sup>25</sup> 4.50.**

The reaction of pyridine with Na produces a mixture of bipyridyls which can be separated by fractional distillation where the 2,2'-isomer distils at 272.5°/atm and solidifies on cooling (m 69.5°). The distilled oil can be purified further by dissolving in Et<sub>2</sub>O, adding an equal volume of petroleum ether then the 2,3'- and 3,3'-isomers are washed out with several portions of H<sub>2</sub>O. The organic layer is evaporated and the oily residue is recrystallised from aqueous EtOH. 2,2'-Bipyridyl also sublimes at 65°/0.01mm. Its solubility in H<sub>2</sub>O is 0.5%, and it is very soluble in organic solvents. Its UV spectrum has  $\lambda_{\max}$  nm( $\epsilon$ ) 233 (10,200) and 280 (13,300) for the neutral species in H<sub>2</sub>O. Unlike the other isomers it complexes with metals, e.g. it gives an intense red colour with ferrous salts. The *picrate* has **m 69.7°** (from aqueous EtOH). It is a metalloprotease inhibitor with high affinity for Fe<sup>2+</sup> containing enzymes at 10<sup>-8</sup> M. [Smith *J Am Chem Soc* **46** 414 1924; UV Krumholz *J Am Chem Soc* **73** 3487 1951, *Beilstein* **23/8** IV 28, **23/16** V 8.] [TOXIC]

**1,3-Bis(1-adamantyl)-1,3-dihydro-2H-imidazol-2-ylidene (IAd)** [131042-77-8] **M 336.3, m 240-241°.** This is a stable *N*-heterocyclic carbene (NHC) which has been prepared in 96% yield from IAdCl by de-protonation in THF with catalytic amounts of dismyl anion [CH<sub>3</sub>S(O)CH<sub>2</sub><sup>-</sup>] in the presence of 1 equivalent of NaH, or with *tert*-BuOK. In this reaction H<sub>2</sub> is liberated and NaCl is precipitated. The carbene is stable in the absence of oxygen and moisture and recrystallises from toluene to give clear, colourless rectangular prisms with a sharp melting point that is unaltered by melting and re-solidifying. The IR has (KBr) has  $\nu_{\max}$  at 2920, 1504, 1448, 1378, 1350, 1303, 1213, 1291, 833, 695 and 495 cm<sup>-1</sup>; the <sup>1</sup>H NMR (\*C<sub>6</sub>H<sub>6</sub>-d<sub>6</sub>) has  $\delta_H$  at 1.58 (s, Ad<sub>4',6',10'</sub>, 12H), 2.01 (s, Ad<sub>3',5',7'</sub>, 6H), 2.29 (s, Ad<sub>2',8',9'</sub>, 12H), 6.91 (s, 3,4-CH, 2H); the <sup>13</sup>C NMR (\*C<sub>6</sub>H<sub>6</sub>-d<sub>6</sub>) [<sup>1</sup>H] has  $\delta_C$  at 211.43 (s, C<sub>2</sub>), 113.88 (dd, <sup>1</sup>J<sub>CH</sub> = 185.6Hz, <sup>2</sup>J<sub>CH</sub> = 13.4Hz, C<sub>4',5'</sub>), 55.99 (s, Ad<sub>1'</sub>), 44.8 (tm, <sup>1</sup>J<sub>CH</sub> = 131.3Hz, Ad<sub>2',8',9'</sub>), 37.7 (tm, <sup>1</sup>J<sub>CH</sub> = 126.8Hz, Ad<sub>4',6',10'</sub>), 30.3 (dm, <sup>1</sup>J<sub>CH</sub> = 128.9Hz, Ad<sub>3',5',7'</sub>); the <sup>15</sup>N NMR (\*C<sub>6</sub>H<sub>6</sub>-d<sub>6</sub>, ref NH<sub>4</sub>NO<sub>3</sub>) has  $\delta$  -160.5, and the EI-MS has *m/z* = 336.26. The X-ray crystal structure has been determined and showed a small N-C-N angle at the carbene centre. [Arduengo et al. *J Am Chem Soc* **113** 361 1991, see also Arduengo 336.3 et al. *J Am Chem Soc* **114** 5530 1992.] It is as effective, if not better in some cases, in many of the metal mediated catalytic reactions as other NHCs (Nitrogen Heterocyclic Carbenes). For further detail see the entry on IPr.Cl [250285-32-6]. [Arduengo USPatent 5 077 414 1991, *Chem Abstr* **116** 106289 1002, Kantchev, O'Brien & Organ *Aldrichimica Acta* **39** 97 2006, Phillips, Chan & Scheidt *Aldrichimica Acta* **42** 55 2009].

**1,3-Bis(1-adamantyl)imidazolium tetrafluoroborate (IAd.BF<sub>4</sub>)** [286014-42-4] **M 424.3, m 277-282°.** This NHC (N-Heterocyclic Carbene) precursor is prepared by established procedures from 2 mols of amine, 1 mol of glyoxal and 1 mol of formaldehyde in toluene/H<sub>2</sub>O in the presence of HBF<sub>4</sub>. It is as effective, if not better in some cases, in many of the metal mediated catalytic reactions as other NHCs. For further detail see the entry on IPr.Cl [250285-32-6]. [Arduengo USPatent 5 077 414 1991, *Chem Abstr* **116** 106289 1002, Kantchev, O'Brien & Organ *Aldrichimica Acta* **39** 97 2006, Phillips, Chan & Scheidt *Aldrichimica Acta* **42** 55 2009].

**2,2'-Bis(1,3,2-benzodioxaborole) [bis(catcholato)diboron, Cat-BB-Cat]** [13826-27-2] **M 237.8, m 189-196°, 195-198°.** This borole is prepared by distilling B<sub>2</sub>Cl<sub>4</sub> (3.95mmol [Wartik et al. *J Am Chem Soc* **71** 3265 1949, Urry et al. *J Am Chem Soc* **76** 5293 1954]) and CH<sub>2</sub>Cl<sub>2</sub> (30ml) into a reaction vessel containing catechol (8.03mmol) at -196°, and then the reaction is allowed to proceed over the temperature range ~78 to 25° for 15 hours to give a clear solution (slightly less than 16mmol of HCl is liberated). CH<sub>2</sub>Cl<sub>2</sub> and HCl are distilled off

from the reaction vessel *in vacuo* leaving a white residue which is sublimed at 120-130°/10<sup>-4</sup>mm to give the pure borole in ~70% yield. A similar result is obtained by using B<sub>2</sub>[NMe<sub>2</sub>]<sub>4</sub> instead of B<sub>2</sub>Cl<sub>4</sub>. Cat-BB-Cat has one peak at -30.7ppm (from BF<sub>3</sub>OEt<sub>2</sub> external reference) in the <sup>11</sup>B NMR (19MHz, CH<sub>2</sub>Cl<sub>2</sub>), and one peak for the aromatic protons at 2.69ppm (from solvent reference) in the <sup>1</sup>H NMR (60MHz, CH<sub>2</sub>Cl<sub>2</sub>); and its IR (KBr) has  $\nu_{\max}$  at 3058vw, 1610vw, 1597w, 1481s, 1464s, 1422m, 1400s, 1368s, 1346m, 1337m, 1285w, 1271m, 1263w, 1232s, 1214sh, 1157m, 1148s, 1140s, 1132s, 1117s, 1083m, 1037w, 1000w, 940w, 930m, 901w, 892m, 861m, 851w, 811s, 766m, 754s, 740s, 732s, 554s, 475w, 457w, and 419s cm<sup>-1</sup>. Molecular weight determination in \*C<sub>6</sub>H<sub>6</sub> indicated that it is a *monomer*, and alkaline hydrolyses provided 0.96 mole of hydrogen per mole of B-B compound. [Welch & Shore *Inorg Chem* 7 225 1968.] Cat-BB-Cat is efficient in olefin diboration catalysed by base-free Pt complexes such as Pt(COD)<sub>2</sub> and Pt(norbornene)<sub>2</sub> [Iverson & Smith *Organometallics* 16 2757 1997], consequently producing useful synthons for cross-coupling reactions and related conversions to other functional groups [Miyaura & Suzuki *Chem Rev* 95 2457 1995].

**Bis[(*R,R,S*)-diazaphos-SPE] {2,2',2'',2'''-(1,2-phenylenebis(1*R*,3*R*)-tetrahydro-5,8-dioxo-1*H*-[1,2,4]-diazaphospholo[1,2-*a*]pyridazine-2,1,3(3*H*)-triylo)tetrakis(*N*-[(1*S*)-1-phenethyl]benzamide}** [851609-33-1] M 1311.40, m 183-195°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -82° (c 1, THF), and the diastereomeric bis[(*S,S,S*)-diazaphos-SPE] {2,2',2'',2'''-(1,2-phenylenebis(1*S*,3*S*)-tetrahydro-5,8-dioxo-1*H*-[1,2,4]-diazaphospholo[1,2-*a*]pyridazine-2,1,3(3*H*)-triylo)tetrakis(*N*-[(1*S*)-1-phenethyl]benzamide} [851770-14-4] M 1311.40, m 289-299°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +15° (c 1, THF). The central diazaphospholane tetracarboxylic acid in the two molecules are enantiomeric and these are converted to the phenethylamide using the same *S*-phenethylamine. Thus the two substances are diastereomeric. They are prepared by mixing the diazaphospholane tetracarboxylic acid (0.34mmol) with 5 equivalents of PyBOP [(benzotriazol-1-yloxy)tripyrrrolidinophosphonium hexafluorophosphate, m 154-156° cf [128625-52-5]] under N<sub>2</sub>, adding degassed CH<sub>2</sub>Cl<sub>2</sub> (100ml) followed by 5 equivalents of *N,N*-diisopropylethylamine and 5 equivalents of ( $\alpha$ *S*)- $\alpha$ -methylbenzylmethanamine (*S*-2-phenylethylamine), and stirring overnight. The solution is exposed to the atmosphere and washed with saturated NaHCO<sub>3</sub> (50ml), 2M HCl (50ml), saturated NaHCO<sub>3</sub> (50ml) again, then H<sub>2</sub>O (50ml). The organic layer is dried (MgSO<sub>4</sub>), filtered, and evaporated *in vacuo*. The residue is purified by flash chromatography (eluted with 2:1 CH<sub>2</sub>Cl<sub>2</sub>/EtOAc), and the separation of diastereoisomers is accomplished by liquid chromatography using a Zorbax Rx-Sil column (4.6 x 250 column). The *R,R,S*-diastereomer (21% yield) has <sup>1</sup>H NMR (500MHz, d-THF) with  $\delta_{\text{H}}$  at 1.37 (d, 6H, *J* = 6.7Hz, CH<sub>3</sub>), 1.56 (d, 6H, *J* = 6.7Hz, CH<sub>3</sub>), 2.2-2.7 (m, 6H, CH<sub>2</sub>CH<sub>2</sub>), 2.65-3.0 (m, 2H, CH<sub>2</sub>CH<sub>2</sub>), 5.06 (dq, 2H, *J* = 7.5, 6.9Hz, CHCH<sub>3</sub>), 5.41 (dq, 2H, *J* = 7.7, 6.9Hz, CHCH<sub>3</sub>), 6.39 (d, 2H, *J* = 7.3Hz), 6.5-6.9 (m, 10H), 7.06-7.36 (m, 26H), 7.51 (m, 2H), 7.60 (d, 4H, *J* = 7.4Hz), 7.97 (d, 2H, *J* = 8.3Hz, NHCH CH<sub>3</sub>), 9.23 (d, 2H, *J* = 7.8Hz, NHCH CH<sub>3</sub>); the <sup>13</sup>C NMR (125MHz, d-THF) has  $\delta_{\text{C}}$  at 23.2 (s, CH<sub>3</sub>), 23.7 (s, CH<sub>3</sub>), 29.6 (s, CH<sub>3</sub>), 30.6 (s, CH<sub>2</sub>), 50.0 (s, CHCH<sub>3</sub>), 50.3 (s, CHCH<sub>3</sub>), 56.9 (br, PCHN), 57.6 (t, br, PCHN), peaks at 125-150 have not been assigned, 166.7 (s, CO), 168.2 (s, CO), 168.4 (s, CO), 168.5 (s, CO); the <sup>31</sup>P NMR (202.4MHz, d-THF) has  $\delta_{\text{C}}$  at 11.0 (br). The NMR spectra of the *S,S,S*-diastereomer is similar but not identical. [Clark et al. *J Am Chem Soc* 127 5040 2005, Clark & Landis *J Am Chem Soc* 125 11792 2003.]

It is a diazaphospholane ligand which displays high conversion and selectivity in Rh catalysed asymmetric hydroformylation reactions [Axtel et al. *Angew Chem. Int Ed Engl* 44 5834 2005, Clark et al. *J Am Chem Soc* 127 5040 2005, US Pat 7.071.357B.]

***R,R*(-)- and *S,S*(+)- *N,N'*-Bis(3,5-di-*tert*-butylsalicylidene)-1,2-*trans*-cyclohexanediamine (Jacobsen's ligand)** [*R,R*- 135616-40-9, *S,S*- 135616-36-3] M 546.8, m 203-206°, 205-208°, 205-208°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> ±310° (c 1, CH<sub>2</sub>Cl<sub>2</sub>). If this general ligand is to be purified, dissolve it in boiling EtOH and while cooling add H<sub>2</sub>O to the yellow solution until a yellow solid separates. This is filtered off, washed with a little of 95% aqueous EtOH and dried *in vacuo*. It is the ligand for preparing Jacobsen's Catalysts [Jacobsen et al. *J Am Chem Soc* 113 7063 1991, Deng & Jacobsen *J Org Chem* 57 4320 1992].

On a large scale, the *R,R*-ligand (~60g) is dissolved in CH<sub>2</sub>Cl<sub>2</sub> (500ml), washed with H<sub>2</sub>O (2 x 300ml) and brine (100ml), dried (Na<sub>2</sub>SO<sub>4</sub>), and the solvent is removed to yield a yellow powder with m 200-203°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> ±315° (c 1, CH<sub>2</sub>Cl<sub>2</sub>), the required <sup>1</sup>H and <sup>13</sup>C NMR and IR with  $\nu_{\max}$  (KBr) at 1595, 1631, 2869, 2960 cm<sup>-1</sup>. However, if it is felt that the product is of insufficient purity then it should be crystallised in two crops from Me<sub>2</sub>CO (1:20 w/v with typical 86-93% recovery [Larrow et al. *J Org Chem* 59 1939 1994].

A **dimeric Jacobsen ligand**, formed by joining two units with a methylene bridge has been prepared and crystallised from CH<sub>2</sub>Cl<sub>2</sub>/pentane. Its **bis-Mn catalyst** exhibited improved retention in a poly-dimethylsiloxane

membrane for the asymmetric epoxidation of olefins [Janssen et al. *Tetrahedron Asymmetry* **8** 3481 1997].

**\*1,5-Bis(3',5'-dimethoxyphenyl)penta-1E,4E-dien-3-one (dm-dba)** [39777-58-7] **M 354.1, m 132-134°**. To a cooled (ice-water bath) solution of NaOH (1.8g, 2.5equivalents) in H<sub>2</sub>O (18ml) diluted with EtOH (15ml) is added slowly 3',5'-dimethoxybenzaldehyde (3g, 1equivalent) and analytical grade acetone (0.52g, 0.5equivalent) during 15 minutes, then it is stirred at 25° for 1 hour. A yellow solid separates, and after a further hour it is filtered off, then washed with Et<sub>2</sub>O (3 x 50ml) and dried *in vacuo*. Purification by flash chromatography (*ca* 150 mesh Al<sub>2</sub>O<sub>3</sub> deactivated with 6% v/w H<sub>2</sub>O prior to use) and elution with petroleum ether (b 40°—60°)/EtOAc (4/1 v/v) gives *dm-dba* as a yellow solid (2.2g, 69%) which is recrystallised by layering a concentrated solution of CD<sub>2</sub>Cl<sub>2</sub> with Et<sub>2</sub>O (CD<sub>2</sub>Cl<sub>2</sub>/Et<sub>2</sub>O, 1/3). The IR (CH<sub>2</sub>Cl<sub>2</sub>) has  $\nu_{\max}$  at 1652m (C=O), 1621vs (C=C), 1596w (C=C aromatic), 1572w (C=C aromatic) and 989m (CH trans) cm<sup>-1</sup>; the UV has  $\lambda_{\max}$  (THF) at 239 ( $\pi$ - $\pi^*$ ) and 371 (n- $\pi^*$ ) nm; the <sup>1</sup>H NMR (400MHz, CDCl<sub>3</sub>) has  $\delta_{\text{H}}$  at 6.48 (d, 1H, <sup>3</sup>J = 15.7Hz, H-2), 7.01 (1H, d, <sup>3</sup>J = 15.7Hz, H-1), 6.71 (2H, t, <sup>3</sup>J = 6.7Hz, 7.9Hz, H-6'), 7.62 (1H, d, <sup>3</sup>J = 8.2Hz, H-4'), 3.70 (s, 12H); and the <sup>13</sup>C NMR (100MHz, CDCl<sub>3</sub>) has  $\delta_{\text{C}}$  at 188.7 (4°), 160.9 (4°), 143.2 (CH), 136.5 (CH), 125.5 (CH), 106.1 (4°), 102.7 (4°) and 55.3 (CH<sub>3</sub>). [Fairlamb et al. *Org Lett* **6** 4435 2004, Beilstein **7** IV 1747.]

**2,2'-Bis(diphenylphosphino)-1,1'-binaphthyl (BINAP)** [RS 98327-87-8] **M 622.7, m 283-286°**, [*R*-(+)-76189-55-4] **m 241-242°**, [*S*-(-)-76189-56-5] **m 241-242°**, [ $\alpha$ ]<sub>D</sub><sup>20</sup> **R+ and S- 233° (c 0.3, toluene)**. It has been prepared from (±)-BINOL which is converted to (±)-2,2'-dibromo-1,1'-binaphthyl (with Ph<sub>3</sub>PBr<sub>2</sub>) then to (±)-2,2'-bis(diphenylphosphinyl)-1,1'-binaphthyl (BINAPO) [with Mg/Ph<sub>2</sub>P(O)Cl] which is resolved into *S*-(-)- and *R*-(+)- BINAPO *via* separation of the diastereoisomeric (-)-2,3-di-*O*-benzoyl-L-tartrate salts in CHCl<sub>3</sub>/EtOAc followed by treatment with 0.75N NaOH, extraction into CHCl<sub>3</sub>, and isolation. The chiral BINAPO enantiomers are reduced to the respective *S*-(-)- and *R*-(+)- BINAP with excess of Cl<sub>3</sub>SiH [see 10025-78-1] and Et<sub>3</sub>N in toluene (100-120°) followed by treatment with 30% aqueous NaOH, extraction into toluene, isolation and purification as follows. Dissolve the enantiomer in toluene, wash it with 30% aqueous NaOH, three times with H<sub>2</sub>O, dry (Na<sub>2</sub>SO<sub>4</sub>), evaporate to ~15% of its volume and add an equal volume of degassed MeOH. Collect the solid, wash it with MeOH and dry it at 80°/0.005mm for 6 hours. Recrystallise it from a 1:1 mixture of toluene/EtOH to optical purity (**m 241-242°**). Pure (99%) (*S*)-(-)-BINAP has <sup>1</sup>H NMR (300MHz, CDCl<sub>3</sub>, TMS) with  $\delta_{\text{H}}$  at 6.81 (d), 6.90 (t), 7.10 (m), 7.23 (s), 7.33 (t), 7.43 (dd), 7.82 (d) and 7.89 (d) where multiplicities are not necessarily coupled signals; and the <sup>13</sup>C NMR (75MHz, CDCl<sub>3</sub>, TMS) has  $\delta$  at 145.43, 145.38, 145.16, 144.93, 144.87, 137.93, 137.84, 137.77, 137.42, 137.35, 137.31, 137.24, 135.49, 135.46, 135.40, 135.38, 134.29, 134.23, 134.09, 133.94, 133.88, 133.31, 133.24, 133.12, 132.93, 132.89, 132.76, 132.63, 132.58, 130.44, 128.29, 127.99, 127.95, 127.91, 127.80, 127.57, 127.47, 127.39, 126.41 and 125.69 (40 signals of 44 carbons, i.e. 4 signals must overlap). The purity is determined by GLC analysis using an OV-101 5m capillary column at 200-280° (argon carrier gas ?). TLC analysis (Kieselgel 60 PF<sub>254</sub>, with MeOH/CHCl<sub>3</sub> 1:19) is used to identify BINAP (R<sub>f</sub> 0.83), BINAPO (R<sub>f</sub> 0.4.2) and BINAP-monooxide (R<sub>f</sub> 0.67). (±)-BINAPO [86632-33-9] crystallises from hot toluene (solubility is 3.6g/100ml at 110°) or from hexane/toluene, and analytically pure crystals have **m 304-306°** (299-300° also reported). *S*-(-)-BINAPO [94041-18-6] crystallises from a hexane/toluene mixture and has **m 261-262°**, [ $\alpha$ ]<sub>D</sub><sup>24</sup> **-396° (c 0.47, C<sub>6</sub>H<sub>6</sub>)**, [ $\alpha$ ]<sub>D</sub><sup>24</sup> **-168° (c 0.5, EtOH)**; and *R*-(+)-BINAPO [94041-16-4], similarly recrystallised, has **m 262-263°**, [ $\alpha$ ]<sub>D</sub><sup>24</sup> **+396° (c 0.5, C<sub>6</sub>H<sub>6</sub>)**. [Takaya et al. *Org Synth* **67** 20 1989, Coll Vol **VIII** 57 1993]. [Noyori & Takaya *Acc Chem Res* **23** 345 1990, Kitamura et al. *Org Synth* **71** 1 1993, Takaya et al. *Org Synth* **72** 74 1995, Kitamura et al. *J Org Chem* **57** 4053 1992.]

§ A polymer supported version of BINAP is available.

**2R,3R-(+)-2,3-Bis(diphenylphosphino)butane (R,R-CHIRAPHOS)** [74839-84-2] **2S,3S-(-)-2,3-bis(diphenylphosphino)butane (S,S-CHIRAPHOS)** [64896-28-2] **M 426.5, m 108-109°**, *R*- [ $\alpha$ ]<sub>D</sub><sup>20</sup> **(+)** and *S*- [ $\alpha$ ]<sub>D</sub><sup>20</sup> **(-)** **200° (c 1.5, CHCl<sub>3</sub>)**. For *S,S*-CHIRAPHOS: Ph<sub>2</sub>PLi [prepared *in situ* from Ph<sub>3</sub>P (95g) and Li (5g) in THF (300ml) under N<sub>2</sub> at ~55°/1 hour then at 25°/2 hours, and the PhLi formed is decomposed with *tert*-BuCl (33g) for 45 minutes; the clear orange solution is boiled for 5 minutes then cooled to -4°] solution is treated with (+)-(2R,3R)-butanediol bis(tosylate) (35g, [64896-27-1]) in dry THF (100ml) over 1 hour with stirring, the temperature is allowed to rise to 25° and stirring is continued for 30 minutes. N<sub>2</sub> purged H<sub>2</sub>O (100ml) is added, the THF layer is separated and evaporated *in vacuo* to give impure *S,S*-chiraphos (note inversion of configuration) as a colourless oil. The oil is extracted under N<sub>2</sub> with Et<sub>2</sub>O (2 x 150ml), dried (Na<sub>2</sub>SO<sub>4</sub>), and filtered (under N<sub>2</sub>) into a solution of Ni(ClO<sub>4</sub>)<sub>2</sub>·6H<sub>2</sub>O (15g) in EtOH. The Na<sub>2</sub>SO<sub>4</sub> is washed with Et<sub>2</sub>O which

is added to the Ni solution. The oily red-brown deposit of the *Ni-chiraphos* sometimes contains some yellow solid of the Ni-perchlorate complex which is discarded (pyrophoric?). To the brown-oily (or part crystalline) mixture is added NaCNS (15g) in hot EtOH and stirred vigorously until a homogenous yellow-brown crystalline  $[\text{Ni}(\text{S,S-chiraphos})_2\text{NCS}]\text{NCS}$  is obtained. It is collected, washed thoroughly with EtOH then finally Et<sub>2</sub>O.

The Ni-NCS complex (15g), suspended in 95% EtOH (150ml) under N<sub>2</sub> is stirred, brought to the boil, and NaCN (4g) in H<sub>2</sub>O (20ml) is added rapidly when the Ni complex slowly dissolves to give a clear blood-red solution which then turns cloudy beige in colour. The hot solution is stirred until all the complex which had dissolved is converted to the yellow slurry. After cooling in ice-water, the solid is collected, washed with H<sub>2</sub>O (2 x 25ml) then rapidly with ice-cold EtOH (25ml) to give impure beige coloured *S,S-chiraphos*. This solid is purified by drying at 25°, dissolving in boiling absolute EtOH (~125ml), filtering through a frit under N<sub>2</sub> and allowing to stand at ~25° for 12 hours, whereby *S,S-chiraphos* deposits as lustrous colourless plates. A second crystallisation from absolute EtOH (60ml) provides optically pure (-)-(2*S*,3*S*)-bis(diphenylphosphino)butane (**S,S-CHIRAPHOS**) (5.5g), *m* 108-109° (sealed tube under N<sub>2</sub>) as colourless plates with  $[\alpha]_{\text{D}}^{27} -211^\circ$  (c 1.5, CHCl<sub>3</sub>), which is unchanged on further recrystallisation [Fryzuk & Bosnich *J Am Chem Soc* **99** 6262 1977]. Its <sup>31</sup>P NMR (CDCl<sub>3</sub>, with external H<sub>3</sub>PO<sub>4</sub> as reference) has  $\delta$  at -10.7, i.e. upfield from H<sub>3</sub>PO<sub>4</sub> [Slack et al. *Inorg Chem* **18** 3125 1979].

**For R,R-CHIRAPHOS:** This enantiomeric ligand is obtained essentially by the same synthesis as its enantiomer above. The (-)-(2*S*,3*S*)-butanediol bis(tosylate) [74839-83-1] is prepared in 94% yield, and has *m* 63-64°,  $[\alpha]_{\text{D}}^{25} -36.8^\circ$  (c 2.1, CHCl<sub>3</sub>), and <sup>1</sup>H NMR (CDCl<sub>3</sub>) with  $\delta$  at 1.20 (d, *J* = 6Hz; 6H, CH<sub>3</sub>), 2.50 (s; 6H, tosyl-CH<sub>3</sub>), 4.70 (q, *J* ~ 7Hz; 2H, CH), 7.70 (m; 8H, aromatic-H). This is converted to bis[(2*R*,3*R*)-2,3-bis(diphenylphosphino)butan]thiocyanato-nickel(II) thiocyanate in 56% yield after washing with EtOH and Et<sub>2</sub>O, and decomposed with NaCN to give **R,R-CHIRAPHOS** in 32% yield with *m* 106-107°,  $[\alpha]_{\text{D}}^{27} +197^\circ$  (c 1.5, CHCl<sub>3</sub>), and <sup>1</sup>H NMR (CDCl<sub>3</sub>) with  $\delta$  at 1.10 (d, *J* = 7Hz; 3H, CH<sub>3</sub>), 1.40 (d, *J* = 6Hz; 6H, CH<sub>3</sub>), 2.60 (q, *J* ~ 7Hz; 2H, CH), 7.50 (m; 20H, aromatic-H). [Köiiner & Gerber *Chem Ber* **113** 2323 1980.]

**1,4-Bis-(diphenylphosphino)butane (dppb)** [7688-25-7] *M* 426.5, *m* 135-136°, 136-137°. Recrystallise it from EtOH [Trippett *J Chem Soc* 4263 1961]. [King *J Coord Chem* **1** 62 1971, Tolman *Chem Rev* **77** 313 1977.]

**1,2-Bis-(diphenylphosphino)ethane (DIPHOS, ethylene bis(diphenylphosphine))** [1663-45-2] *M* 398.4, *m* 139-140°, 140-142°, 143-144°, *pK*<sub>Est</sub> ~4.5. Recrystallise it from aqueous EtOH or \*C<sub>6</sub>H<sub>6</sub>. The dimethiodide, when recrystallised from MeOH has *m* 305-307°, and the dioxide when recrystallised from toluene or DMF (needles), or \*C<sub>6</sub>H<sub>6</sub> (plates) has *m* 252-254° (276-278°) [Isslieb et al. *Chem Ber* **92** 3175 1959, NMR: Aquiar et al. *J Org Chem* **29** 1660 1964, Bäckvall et al. *J Org Chem* **52** 5430 1987]. [Beilstein **16** IV 958.]

**R-(+)-1,2-Bis(diphenylphosphino)propane (R-PROPHOS)** [67884-32-6] *M* 412.4, *m* 68.5° (sealed tube under N<sub>2</sub>), 71-73°,  $[\alpha]_{\text{D}}^{26} R +186.0^\circ$ , *S* +61.0 (c 1.0, Me<sub>3</sub>CO). *S*-(-)-Propane-1,2-diol bis(*p*-toluenesulfonate) (51.9g, [60434-71-1]) in dry THF (75ml) is reacted with Ph<sub>2</sub>PLi to give the *R*-diol which is converted to its Ni-perchlorate salt and then converted into its NiNCS complex (45-55g) essentially as described for *chiraphos* above. This NCS complex (22g) is decomposed with NaCN essentially as described for *chiraphos* above, and finally the crude oily *R-prophos* (note change in absolute configuration) is dissolved in absolute EtOH at 50° under N<sub>2</sub>, allowed to cool to 25°, then held at 5° for 24 hours and the *diphosphine* (10g) that separated is collected and recrystallised from absolute EtOH (100ml) to give small colourless prisms of analytically pure *R-prophos* (7.5g) whose optical rotation is unchanged by further recrystallisation. [Fryzuk & Bosnich *J Am Chem Soc* **101** 3043 1979]. Its <sup>31</sup>P NMR (CDCl<sub>3</sub>, with external H<sub>3</sub>PO<sub>4</sub> as reference) has  $\delta$  at -20.6 (d, *J*<sub>P-P</sub> = 20.6Hz), i.e. upfield, and +1.7 ppm, i.e. downfield from H<sub>3</sub>PO<sub>4</sub> [Slack et al. *Inorg Chem* **18** 3125 1979]. Pure *R-prophos* can be prepared in a similar way.

**Bis(2-hydroxyethyl)sulfide (2,2'-thiodiglycol, thiodiglycol)** [111-48-8] *M* 112.2, *m* -16°, *b* 121-121.8°/0.01mm, 130°/2mm, 136-137°/3mm, 148°/4mm, 165°/20mm 168°/20mm, 185.5°/40mm, 194°/50mm, 282°/760mm, *d*<sub>4</sub><sup>0</sup> 1.1973, *d*<sub>4</sub><sup>25</sup> 1.1793, *n*<sub>D</sub><sup>20</sup> 1.5203, *n*<sub>D</sub><sup>26</sup> 1.5146. The sulfide has been prepared on large scales for

the manufacture of “Mustard Gas”. The thioglycol has been prepared from ethylene oxide and H<sub>2</sub>S, and the crude compound prepared from chlorohydrin contains considerable quantities of dithiane and polymeric impurities. These can be removed by distillation at 150°/8mm and the polymeric material breaks down at ~160° [Masson *J Chem Soc* **49** 236 1886]. The distillate is then diluted with H<sub>2</sub>O until its boiling point at atmospheric pressure is reduced to 165°, and superheated steam is passed through it. After evaporating off the H<sub>2</sub>O, the thiodiglycol is distilled at 147°/6mm. It is soluble in H<sub>2</sub>O, lower alcohols, CHCl<sub>3</sub>, EtOAc; and at 25° its solubility (w/w) in \*C<sub>6</sub>H<sub>6</sub> is 1.07%, in absolute Et<sub>2</sub>O it is 7.09 and in ligroin it is 0.06%. In organic acids, or alone, it is stable at 180° for many hours, but when heated at 100° with 2.5 parts of 0.1N aqueous NaOH for 30 minutes sulfide ions are formed, much more so (50%) with 1N NaOH at 140°/10 hours. Pb(OAc)<sub>2</sub>, and Cu(NO<sub>3</sub>)<sub>2</sub> decompose it at 100°, but it is stable with BaO, CaO and Al<sub>2</sub>O<sub>3</sub> even at 180°/10 hours, in unsuccessful attempts to dehydrate it to vinyl sulfide. Of the several esters of aliphatic alcohols that were reported, the *diacetate* had **b 139.5°/8mm**, the *dibutyrate* had **b 172°/8mm**, and the *dicaproate* had **b 207°/7mm** [Clayton & Reid *J Am Chem Soc* **64** 908 1942]. The *bis-3,4-diphenylcarbamoyl derivative* had **m 141.4-142.5°** (from EtOH) [Beaver et al. *J Am Chem Soc* **79** 1236 1957], and the *bis-4-nitrobenzoate ester* had **m 107.7°** (from EtOH) [Major *Bull Soc Chim Fr* **41** 634 1927]. [Nenitzescu & Scarlatescu *Chem Ber* **68** 587 1935, Beilstein **1 H** 470, **1 I** 244, **1 II** 525, **1 III** 2122, **1 IV** 2437.]

**1,2-Bis[(4*S*)-4-isopropyl-2-oxazolin-2-yl]benzene [(4*S*,4'*S*)-2,2'-(phen-1,2-diyl)bis(4-isopropyl-4,5-dihydro-oxazole)]** [131380-80-8] **M 300.4, b 175°/10<sup>-2</sup> mbar, [α]<sub>589</sub><sup>25</sup> -98.8° (c 2.13, CH<sub>2</sub>Cl<sub>2</sub>), [α]<sub>546</sub><sup>25</sup> -119.4° (c 2.13, CH<sub>2</sub>Cl<sub>2</sub>), [α]<sub>365</sub><sup>25</sup> -415.2° (c 2.13, CH<sub>2</sub>Cl<sub>2</sub>)**. This ligand is prepared by melting a small amount of anhydrous ZnCl<sub>2</sub> (68mg, 0.50mmol, m 293°) in high vacuum under argon, cooling to ~25°, adding chlorobenzene followed by *o*-phthalonitrile (1.28g, 10mmol) and *S*-valinol (3.09g, 30mmol), and boiling under reflux for 24 hours. The cooled solution is extracted with H<sub>2</sub>O (2 x 20ml), and the aqueous phase is extracted with CH<sub>2</sub>Cl<sub>2</sub> (30ml). The combined organic extracts are dried (Na<sub>2</sub>SO<sub>4</sub>), filtered, evaporated *in vacuo*, and the residual oil is purified by flash chromatography and MPLC (pentane/EtOAc 4:1); and distilled at high vacuum to provide optically (by NMR and chiral HPLC on CHIRACEL OD) and analytically pure (C, H and N) colourless *bis-oxazoline* (2.68g, 89%). It has IR(film) with  $\nu_{\max}$  at 1655 (C=N) and 1250 (C-O) cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, CDCl<sub>3</sub>) has  $\delta$  at 0.95 [d, *J* = 6.8Hz, 6H, CH(CH<sub>3</sub>)<sub>2</sub>], 1.04 [d, *J* = 6.8Hz, 6H, CH(CH<sub>3</sub>)<sub>2</sub>], 1.88 [sept, *J* = 6.8Hz, 2H, CH(CH<sub>3</sub>)<sub>2</sub>], 4.04-4.13 (m, 4H, OCH<sub>2</sub>), 4.34-4.42 (m, 2H, CHN), 7.45-7.50 (m, 2H, 4- and 5-H), 7.74-7.77 (m, 2H, 3- and 6-H) from TMS; and the <sup>13</sup>C NMR (400MHz, CDCl<sub>3</sub>) has  $\delta$  at 17.92 (q), 18.78 (q), 32.39 (d), 70.46 (t, C-5'), 72.87 (d, C-4'), 128.61 (s, C-1, C-2), 129.97 (d, C-4, C-5), 130.36 (d, C-3, C-6), 163.95 (s, C-2'). [Bolm et al. *Chem Ber* **124** 1173 1991.] Like many chiral bis(oxazolin-2-yl) ligands it complexes with metals such as Zn (see its crystalline Zn complex [131380-93-3] in Part 1 above) and Cu, being involved in a variety of metal catalysed asymmetric synthesis such as allylation, aziridination, cyclopropanation, Diels-Alder and retro Diels-Alder, Mukaiyama aldol condensation and hydrosilylation [see reviews by Ghosh et al. *Tetrahedron: Asymmetry* **9** 1 1998, Pflatz *Acta Chem Scand* **50** 189 1996, Johnson & Evans *Acc Chem Res* **33** 325 2000, Jørgensen et al. *Acc Chem Res* **32** 605 1999.]

**1,2-Bis[(4*S*)-4-isopropyl-2-oxazolin-2-yl]ethane [(4*S*,4'*S*)-2,2'-(ethane-1,2-diyl)bis(4-isopropyl-4,5-dihydro-oxazole)]** [131380-80-8] **M 252.4, b 150°/2.10<sup>-2</sup> mbar, [α]<sub>589</sub><sup>25</sup> -93.6° (c 2.28, CH<sub>2</sub>Cl<sub>2</sub>), [α]<sub>546</sub><sup>25</sup> -112.1° (c 2.28, CH<sub>2</sub>Cl<sub>2</sub>), [α]<sub>365</sub><sup>25</sup> -335.5° (c 2.28, CH<sub>2</sub>Cl<sub>2</sub>)**. This colourless bis-oxazolinylethane (1.49g, 59% yield) was prepared by the general method described in the preceding entry from anhydrous ZnCl<sub>2</sub> (68mg, 0.50mmol), 1,2-dicyanoethane (0.80g, 10mmol), and *S*-valinol (3.09g, 30mmol) in optical and analytical purity. It has IR(film) with  $\nu_{\max}$  at 1645 (C=N) cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, CDCl<sub>3</sub>) has  $\delta$  at 0.87 [d, *J* = 6.7Hz, 6H, CH(CH<sub>3</sub>)<sub>2</sub>], 0.95 [d, *J* = 6.7Hz, 6H, CH(CH<sub>3</sub>)<sub>2</sub>], 1.74 [sept, *J* = 6.7Hz, 2H, CH(CH<sub>3</sub>)<sub>2</sub>], 2.63 [s, 4H, CH<sub>2</sub>], 3.84-3.98 (m, 4H, OCH<sub>2</sub>), 4.22 (dd, *J* = 8.5, 8.5Hz, 2H, CHN) from TMS; and the <sup>13</sup>C NMR (100MHz, CDCl<sub>3</sub>) has  $\delta$  at 17.68 (q), 18.45 (q), 24.40 (t), 32.28 (d), 69.90 (t, C-5'), 71.92 (d, C-4'), 166.21 (s, C-2'). [Bolm et al. *Chem Ber* **124** 1173 1991.] Like many chiral bis(oxazolin-2-yl) ligands it complexes with metals such as Zn (see the crystalline Zn complex in Part 1 above) and Cu, being involved in a variety of metal catalysed asymmetric synthesis such as allylation, aziridination, cyclopropanation, Diels-Alder and retro Diels-Alder, Mukaiyama aldol condensation and hydrosilylation [see reviews by Ghosh et al. *Tetrahedron: Asymmetry* **9** 1 1998, Pflatz *Acta Chem Scand* **50** 189 1996, Johnson & Evans *Acc Chem Res* **33** 325 2000, Jørgensen et al. *Acc Chem Res* **32** 605 1999.]

**1,3-Bis[(4*S*)-4-isopropyl-2-oxazolin-2-yl]propane** [(4*S*,4'*S*)-2,2'-(propane-1,3-diyl)bis(4-isopropyl-4,5-dihydrooxazole)] [*131380-90-6*; **M 266.4, b 120<sup>0</sup>/2.10<sup>-2</sup> mbar**,  $[\alpha]_{589}^{25} -57.4^{\circ}$  (c 3.05, CH<sub>2</sub>Cl<sub>2</sub>),  $[\alpha]_{546}^{25} -68.4^{\circ}$  (c 3.05, CH<sub>2</sub>Cl<sub>2</sub>),  $[\alpha]_{365}^{25} -204.0^{\circ}$  (c 3.05, CH<sub>2</sub>Cl<sub>2</sub>). This colourless bis-oxazolinylpropane (1.12g, 42% yield) was prepared by the general method described in the preceding entries from anhydrous ZnCl<sub>2</sub> (68mg, 0.50mmol), 1,3-dicyanopropane (0.94g, 10mmol), and *S*-valinol (3.09g, 30mmol) in optical and analytical purity. It has IR(film) with  $\nu_{\max}$  at 1645 (C=N) cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, CDCl<sub>3</sub>) has  $\delta$  at 0.88 [d, *J* = 6.7Hz, 6H, CH(CH<sub>3</sub>)<sub>2</sub>], 0.95 [d, *J* = 6.7Hz, 6H, CH(CH<sub>3</sub>)<sub>2</sub>], 1.74 [sept, *J* = 6.7Hz, 2H, CH(CH<sub>3</sub>)<sub>2</sub>], 2.33-2.61 [m, 6H, CH<sub>2</sub>]<sub>3</sub>, 3.85-3.98 (m, 4H, OCH<sub>2</sub>CHN), 4.18-4.26 (m, 2H, NCHCH<sub>2</sub>O) ppm from TMS; and the <sup>13</sup>C NMR (100MHz, CDCl<sub>3</sub>) has  $\delta$  at 17.77 (q), 18.37 (q), 21.66 (t), 26.21 (t), 32.27 (d), 69.87 (t), 71.94 (d), 165.53 (s). [Bolm et al. *Chem Ber* **124** 1173 1991.] Like many chiral bis(oxazolin-2-yl) ligands it complexes with metals such as Zn (see the crystalline Zn complex in the "Catalyst" section above) and Cu, being involved in a variety of metal catalysed asymmetric synthesis such as allylation, aziridination, cyclopropanation, Diels-Alder and retro Diels-Alder, Mukaiyama aldol condensation and hydrosilylation [see reviews by Ghosh et al. *Tetrahedron: Asymmetry* **9** 1 1998, Pflatz *Acta Chem Scand* **50** 189 1996, Johnson & Evans *Acc Chem Res* **33** 325 2000, Jørgensen et al. *Acc Chem Res* **32** 605 1999.]

**2,2-Bis[(4*S*)-4-isopropyl-2-oxazolin-2-yl]propane** {4,5-dihydro-2-[2(4,5-dihydro-(4*S*)-4-isopropoxyloxazol-2-yl)propan-2-yl]-(4*S*)-4-isopropoxyloxazole, (4*S*,4'*S*)-2,2'-(propane-2,2-diyl)bis(4-isopropyl-4,5-dihydro-oxazole)} [*relative stereochemistry 929270-13-3; absolute stereochemistry 797757-81-4*] **M 266.4, b 95-100<sup>0</sup>/0.5 mm, d<sub>4</sub><sup>25</sup> 0.9864, n<sub>D</sub><sup>20</sup> 1.4665,  $[\alpha]_{D}^{24} -107.5^{\circ}$  (c 1, CH<sub>2</sub>Cl<sub>2</sub>). The propane ligand for metal assisted asymmetric catalysis is prepared in two steps. The *first* is the synthesis of the bis-oxazoline precursor (-)-(4*S*,4'*S*)-*N,N'*-bis(1-hydroxymethyl-2-methylpropyl),2,2-dimethylmalonamide which is prepared in a flask under nitrogen purge at 0<sup>0</sup> (ice bath) containing a mixture of *S*-valinol (5.13g, 50mmol) and dry EtNH<sub>2</sub> (17.4ml, 124mmol, distilled from CaH<sub>2</sub>) to which 2,2-dimethylmalondioyl chloride (3.3ml, 250mmol; Evans et al. *J Org Chem* **63** 4541 1998) is added dropwise during 25 minutes (temperature rising from 0<sup>0</sup> to 10<sup>0</sup>), then allowing to warm to ~25<sup>0</sup>. After stirring for 45 minutes the colourless precipitate in the mixture is dissolved by adding CH<sub>2</sub>Cl<sub>2</sub> (120ml). Aqueous N HCl (30ml) is then added, the mixture is extracted with CH<sub>2</sub>Cl<sub>2</sub> (3 x 13ml), the combined organic layers are washed with saturated aqueous NaHCO<sub>3</sub> (30ml), brine (30ml), dried (MgSO<sub>4</sub>), filtered and evaporated *in vacuo* to provide a yellow solid which is crystallised from EtOAc (~40ml) to give the malonamide (6.4g, 84% in three crops). The amide has m 98-99<sup>0</sup>,  $[\alpha]_{D}^{24} -6.0^{\circ}$  (c 0.5, CH<sub>2</sub>Cl<sub>2</sub>); it has IR(KBr) with  $\nu_{\max}$  at 3349, 3380, 2962, 2886, 1658, 1530, 1049, 1033 cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, CDCl<sub>3</sub>) has  $\delta$  at 0.92 (d, *J* = 6.8Hz, 6H), 0.96 (d, *J* = 6.8Hz, 6H), 1.50 (s, 6H), 1.82 (oct, *J* = 6.8Hz, 2H), 2.66 (br s, 2H), 3.52 (m, 2H), 3.69-2.86 (m, 4H), 6.41 (d, *J* = 8.6Hz, 2H); and the <sup>13</sup>C NMR (75MHz, CDCl<sub>3</sub>) has  $\delta$  at 18.8, 19.6, 23.7, 29.1, 50.2, 57.1, 63.5, 174.5; and correct elemental analysis for C, H and N.**

The *second* step is carried out, with stirring, under N<sub>2</sub> purge in a flask containing the preceding malondiamide (5.5g, 18.4mmol), 4-dimethylaminopyridine (204mg, 1.67mmol) in dry CH<sub>2</sub>Cl<sub>2</sub> (130ml, filtered through activated Al<sub>2</sub>O<sub>3</sub>) at ~25<sup>0</sup>, and dry EtNH<sub>2</sub> (10.25ml, 73.4mmol, distilled from CaH<sub>2</sub>) is added slowly (*via* syringe) followed by tosyl chloride (7.10g, 37mmol, 2 equivalents) dissolved in dry CH<sub>2</sub>Cl<sub>2</sub> (15ml) dropwise during 30 minutes *via* a funnel which is rinsed with CH<sub>2</sub>Cl<sub>2</sub> (2.5ml), and the mixture is stirred for 27 hours at ~25<sup>0</sup>. The mixture is then treated with saturated aqueous NH<sub>4</sub>Cl (70ml), H<sub>2</sub>O (40ml), the aqueous layer is separated, extracted with CH<sub>2</sub>Cl<sub>2</sub> (3 x 55ml), the combined organic layers are dried (MgSO<sub>4</sub>), filtered and evaporated. The oily residue is mixed with hot pentane (40ml), stirred for 5 minutes, the supernatant liquid is decanted, and the procedure repeated three times. The pentane layers are combined and evaporated *in vacuo* and the oily residue (4.05g 83%) is distilled (Kügelrohr) to give the analytically pure *bis-oxazole*. It has IR(film) with  $\nu_{\max}$  at 3308, 2960, 2874, 1746, 1525, 1353, 1303, 1037, 1017, 895, 815, 714 cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, CDCl<sub>3</sub>) has  $\delta$  at 0.95 (d, *J* = 6.8Hz, 6H), 0.91 (d, *J* = 6.8Hz, 6H), 1.51 (s, 6H), 1.88-1.73 (m, 2H), 4.06-3.93 (m, 4H), 4.26-4.15 (m, 2H); and the <sup>13</sup>C NMR (75MHz, CDCl<sub>3</sub>) has  $\delta$  at 17.3, 18.5, 24.4, 32.2, 38.5, 69.9, 71.5, 168.7. [Evans et al. *Org Synth* **83** 97 2006]. Like many chiral bis(oxazolin-2-yl) ligands it complexes with metals such as Zn (see the crystalline Zn complex [131380-93-3] in the "Catalyst" section above) Cu, Ir, Pd, W, being involved (with or without further ligands) in a variety of metal catalysed asymmetric synthesis such as allylation, aziridination, cyclopropanation, Diels-Alder and retro Diels-Alder, Mukaiyama aldol condensation and hydrosilylation [see reviews by Ghosh et al. *Tetrahedron: Asymmetry* **9** 1 1998, Pflatz *Acta Chem Scand* **50** 189 1996, Johnson & Evans *Acc Chem Res* **33** 325 2000, Jørgensen et al. *Acc Chem Res* **32** 605 1999.]

**1,3-Bis(2,6-isopropylphenyl)imidazolium chloride (IPr.Cl)** [250285-32-6] **M 425.1, m 278<sup>o</sup>(dec)**. IPr.Cl is a ligand precursor of an NHC (N-heterocyclic carbene — Kantchev, O'Brien & Organ *Aldrichimica Acta* **39** 97 2006, Phillips, Chan & Scheidt *Aldrichimica Acta* **42** 55 2009) which coordinates with transition metals to form soluble catalysts that promote a variety of reactions. IPr.Cl can be prepared in two steps. *1,4-Bis(2,6-diisopropylphenyl)diazabutadiene* [1,2-bis(2,6-diisopropylphenylimino)-ethane] is first prepared by dissolving 2,6-diisopropylaniline (100g, 560mmol) and glyoxal (31.5ml, 280mmol, in 40% H<sub>2</sub>O) in absolute EtOH (500ml), and adding a few drops of formic acid as catalyst. The yellow coloured solution produces a yellow precipitate after a few hours, the mixture is stirred for 2 days, and the yellow solid is collected, washed with cold MeOH, and dried *in vacuo* to give analytically pure *diazabutadiene-ethane* (81.7g, 77.5%). It has <sup>1</sup>H NMR (400MHz, CDCl<sub>3</sub>) with  $\delta$  at 1.28 (d,  $J = 7.6$  Hz, 24H, CH(CH<sub>3</sub>)<sub>2</sub>), 3.03 (sep,  $J = 6.4$ Hz, 4H, CH(CH<sub>3</sub>)<sub>2</sub>), 7.27 (m, 6H, CH(CH<sub>3</sub>)<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>), 8.19 (s, 2H, NCH). In the second step the *diazabutadiene-ethane* (25g, 66mmol) in toluene (500ml) is treated with solid paraformaldehyde (2.0g, 66mmol) with stirring under N<sub>2</sub>, heated to 100<sup>o</sup> until clear, then cooled to 40<sup>o</sup> and HCl (16.5ml, 66mmol, 4M in dioxane) is introduced with a syringe. The colour of the mixture turns to brown and a white precipitate separates within a few hours, but stirring is continued at ~25<sup>o</sup> for 36 hours. The solid is filtered off, washed with THF, and dried *in vacuo* to give off-white IPr.Cl (13.1g, 47%). It has <sup>1</sup>H NMR (400MHz, CD<sub>2</sub>Cl<sub>2</sub>) with  $\delta$  at 1.24 (d,  $J = 7.2$  Hz, 12H, CH(CH<sub>3</sub>)<sub>2</sub>), 1.27 (d,  $J = 7.2$  Hz, 12H, CH(CH<sub>3</sub>)<sub>2</sub>), 2.42 (sep,  $J = 6.8$ Hz, 4H, CH(CH<sub>3</sub>)<sub>2</sub>), 7.18 (t,  $J = 7.2$ Hz, 2H, *p*-C<sub>6</sub>H<sub>3</sub>), 7.4 (m, 4H, *m*-C<sub>6</sub>H<sub>3</sub>), 7.80 (s, 2H, NCH), 11.0 (s, 1H, NC(HCl)); and its <sup>13</sup>C NMR (100MHz, CD<sub>2</sub>Cl<sub>2</sub>) has  $\delta_C$ {H} at 23.9 (CH(CH<sub>3</sub>)<sub>2</sub>), 26.1 (CH(CH<sub>3</sub>)<sub>2</sub>), 86.4 (NCHCHN), 125.2 (q C, phenyl), 125.8 (CH, phenyl), 128.7 (quaternary C, phenyl), 129.5 (CH, phenyl), 145.7 (CHCl).

IPr.Cl has been used, in dioxane under argon, as a ligand with Pd<sub>2</sub>(dba)<sub>3</sub> (see above) to catalyse cross-coupling reactions between arylhalides and arylmagnesium bromides in a Kumada reaction to form diaryls efficiently [Huang & Nolan *J Am Chem Soc* **121** 9889 1999]; and in the presence of a base (*tert*-BuOK, or Cs<sub>2</sub>CO<sub>3</sub>) and Pd(OAc)<sub>2</sub> {or PdCl<sub>2</sub>, [Pd(allyl)Cl]<sub>2</sub>, PdCl<sub>2</sub>(PCy<sub>3</sub>)<sub>2</sub>} and CO under pressure it catalyses the carbonylative cross-coupling of bromopyridines with arylboronic acids to provide high yields of arylpyridylketones [Maerten et al. *Tetrahedron* **63** 682 2007].

When IPr.Cl is treated with a base (e.g. Bu'OK, Bu'ONa, K<sub>2</sub>CO<sub>3</sub> or Cs<sub>2</sub>CO<sub>3</sub>), the carbene **1,3-bis(2,6-diisopropylphenyl)-1,3-dihydro-2H-imidazol-2-ylidene** [244187-81-3] **M 388.6, m 213-217<sup>o</sup>**, is formed and is stable enough to be isolated, stored and is available commercially. The carbene-carbon atom at C2 coordinates with metals; and forms C-C bonds, by C-H insertion, with acetylene, MeCN, HCCl<sub>3</sub>, PhSOCH<sub>3</sub>, and the structures of some of the products have been confirmed by X-ray analysis [Arduengo et al. *Helv Chim Acta* **82** 2348 1999].

**Bis(pinacolato)diboron** [bis(pinacolyborane), **4, 4, 4', 4', 5, 5, 5', 5'-octamethyl-2,2'-bi-1,2,3-dioxaborolane, B<sub>2</sub>pin<sub>2</sub>**] [73183-34-3] **M 253.9, m 138<sup>o</sup>, 137-140<sup>o</sup>**. This versatile borylating agent is prepared in four steps\* from BBr<sub>3</sub> by conversion to tris(dimethylamino)borane {(Me<sub>2</sub>N)<sub>3</sub>B, m -16<sup>o</sup>, b 45<sup>o</sup>/12mm, 147-148<sup>o</sup>/atm [4375-83-1]} upon treatment with Me<sub>2</sub>NH/pentane, followed by further reaction with BBr<sub>3</sub>/pentane to give bromobis(dimethylamino)borane {(Me<sub>2</sub>N)<sub>2</sub>BBr, b 20-28<sup>o</sup>/0.5mm, 56-58<sup>o</sup>/12mm [6990-27-8]}, which on reaction with Na in toluene under reflux for ~3 hours provides tetrakis(dimethylamino)diboron [(Me<sub>2</sub>N)<sub>2</sub>B-B(Me<sub>2</sub>N)<sub>2</sub>, b 55-57<sup>o</sup>/2.5mm, 92<sup>o</sup>/12mm, Brotherton et al. *J Am Chem Soc* **82** 6242, 6245 1962] in 72% yield. Then a mixture of (Me<sub>2</sub>N)<sub>2</sub>B-B(Me<sub>2</sub>N)<sub>2</sub> [53.7g, 271mmol, one signal in the <sup>1</sup>H NMR at  $\delta$  2.67 (s, 24H) in CDCl<sub>3</sub>] in dry toluene (510ml) and pinacol (64.4g, 545mmol) in dry toluene (340ml) under dry N<sub>2</sub> is stirred in an ice-water bath, and 5.4M HCl in Et<sub>2</sub>O (203ml, 1.10 mol) is added dropwise during 2 hours. A white precipitate of Me<sub>2</sub>NH.HCl separates immediately but the mixture is stirred further for 4 hours at ~25<sup>o</sup>; the precipitate is filtered off and the filtrate is evaporated to dryness. The white residue is dissolved in pentane (~700ml), washed with H<sub>2</sub>O (3 x 500ml), dried (MgSO<sub>4</sub>), filtered and evaporated to ~150ml. This is warmed to dissolve any solid and chilled in a freezer (-30<sup>o</sup>). The first crop of **B<sub>2</sub>pin<sub>2</sub>** is collected and washed with cold pentane (2 x 30ml). The mother liquor is concentrated to give further crops of **B<sub>2</sub>pin<sub>2</sub>** which are combined with the first crop, and dried for 16 hours at ~25<sup>o</sup>/0.1mm to give colourless plates, m 138<sup>o</sup>, in 79-91% yield. The diboron is air stable and is stored in a capped container. Its IR (KBr) has  $\nu_{\max}$  at 2978, 2930, 1372, 1289, 1189, 1177, 1127, 960, 850, 744, 660, 547 cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, CDCl<sub>3</sub>) has  $\delta_H$  at 1.25 (s, 24H); the <sup>13</sup>C NMR (100MHz, CDCl<sub>3</sub>) has  $\delta_C$  at 83.4, 24.9; and the <sup>11</sup>B NMR (128.3MHz, toluene) has  $\delta_B$  at 30.61 (BF<sub>3</sub>, Et<sub>2</sub>O as external reference with  $\delta$  0.00). [Ishiyama et al. *Org Synth* **77** 176 2000, Nöth *Naturforsch B: Anorg Chem, Org Chem* **39B** 1463 1984.] It borates ethylenes, acetylenes, allenes, conjugated olefins, replaces the halogen atom or a

triflate group in arenes with a  $B(OR)_2$  group effectively in the presence of catalysts such as  $Pt(PPh_3)_4$ ,  $Pt(dba)_2$ , or  $PdCl_2(dppf)$ ,  $Pd(dba)_2$  [Ishiyama et al. *J Am Chem Soc* **115** 11018 1993, Lesley *Organometallics* **15** 5137 1996, Ishiyama et al. *J Chem Soc. Chem Commun* 689 1997, Iverson & Smith *Organometallics* **16** 2757 1997, Ishiyama et al. *J Chem Soc. Chem Commun* 2073 1996, Ishiyama et al. *Tetrahedron Lett* **39** 2357 1998, Ishiyama et al. *J Org Chem* **60** 7508 1995, Ishiyama et al. *Tetrahedron Lett* **38** 3447 1997].

\* Caution: All operations should be carried out under  $N_2$  in a well ventilated fume cupboard because bromoborane derivatives fume in air by hydrolysing rapidly with evolution of heat.

**Bis(trifluoromethanesulfonyl)amine** [ $NTf_2$ , **bis(trifluoromethanesulfonyl)amide**,  $(CF_3SO_2)_2NH$ ] [82113-65-3] **M 281.2, m 49-50°, 46-57°, b 90-91°/atm, has a pK of a superacid** [ $\Delta G_{acid} = 291.8$  kcal/mol].  $NTf_2$  is a very strong neutral *Brønsted acid* which is to be compared with  $CHF_2CO_2H$  ( $\Delta G_{acid} = 323.8$ ) <  $HBr$  ( $\Delta G_{acid} = 318.3$ ) <  $CF_3CO_2H$  ( $\Delta G_{acid} = 316.3$ ) and <  $CF_3SO_3H$  ( $\Delta G_{acid} = 299.5$ ) [Koppel et al. *J Am Chem Soc* **116** 3047 1994, see pK values in AcOH below]. For purification see at the end of its synthesis below.  $NTf_2$  is a white crystalline solid that should be handled in closed systems (Schlenk equipment), or under very efficient ventilation as it is quite volatile, fumes in moist air and is very corrosive. However, it is soluble in  $H_2O$ , and it is stable in aqueous solutions where it can be titrated with NaOH as a typical acid with a pKa of ~1.7. In glacial acetic acid, the pK value by measuring  $\delta(OH)$  chemical shifts in the  $^1H$  NMR spectra gives a value of 7.8 for  $NTf_2$ , as compared with  $CF_3CO_2H$  (11.4),  $HNO_3$  (10.1),  $H_2SO_4$  (7.0),  $HI$  (5.8),  $HClO_4$  (4.9) and  $CF_3SO_3H$  (4.2) measured in the same way. If these comparisons are valid then  $NTf_2$  is a remarkably strong acid. [Foropoulos & DesMarteau *Inorg Chem* **23** 3270 1984, cf also Rode et al. *Z Phys Org Chem (Leipzig)* **253** 17 1973.]

The preparation of  $NTf_2$  in several steps from  $CH_3SO_2Cl$  [Foropoulos & DesMarteau *Inorg Chem* **23** 2720 1984] has been improved from 48% to 80% overall yield [DesMarteau & Witz *J Fluorine Chem* **52** 7 1991], and is described here.

Methanesulfonyl chloride (286g, [124-63-0], b 60°/21mm, 161°/atm, redistilled from  $P_2O_5$ , Hearst & Noller *Org Synth Coll Vol IV* 571 1963) is added slowly to solid KF (170g) and stirred for 1 hour at 25°, then  $CH_3SO_2F$  is distilled off, fraction b 123-124° is collected and redistilled from  $P_2O_5$  to give pure acid fluoride (208g). Electrochemical fluorination of the methanesulfonyl fluoride in anhydrous HF at 4-5Volts and 7-9Amps continuously for 24 hours (as described by Gramstad & Haszeldine *J Chem Soc* 173 1956) gave  $CF_3SO_2F$  (~180g, [335-05-7]) is followed by isolation *via* condensation at -78° and redistillation at -21.7°.

$CF_3SO_2F$  (76g) is bubbled into semi-frozen  $NH_3$  (600ml, at ~-77°) with dry  $N_2$ , during 0.5 hours while stirring with external cooling at -78°. Excess of  $NH_3$  is allowed to evaporate under  $N_2$  flow into a fume cupboard; NaOMe (54g) in MeOH (500ml) is added to the residual slush and the mixture is heated to 60° for a few minutes, the NaF is filtered off, the filtrate is evaporated, the residue is dried in a high vacuum to give  $CF_3SO_2NHNa$  (81g, 95%, [91742-21-1]). This Na salt (81g) is refluxed with hexamethyldisilazane (645ml, 500g, HMDS see [999-97-3]) under  $N_2$  flow (oil bath temperature <145° to avoid excessive darkening) with strong mechanical stirring as the mixture thickens progressively. After release of  $NH_3$  is complete (~12 hours), HMDS is distilled off (while increasing the vacuum), and the residual moisture sensitive solid is dried under high vacuum (in the same flask) to give  $CF_3SO_2NNa(SiMe_3)$  (106g, 92%, [91742-20-0]). This salt (106g) in dry THF (370ml) is transferred to a stirrable stainless steel autoclave (~600ml) and gaseous  $CF_3SO_2F$  (67g, ~26% excess) is transferred under  $N_2$  pressure *via* a metal vacuum system, as it is not usually possible to cool the autoclave to below -50°. The autoclave is sealed and the mixture is stirred at 100° overnight, the volatile products are vented into an efficient hood, the autoclave is washed out with  $H_2O$ , the combined  $H_2O$ /THF mixture is washed with  $CH_2Cl_2$ , evaporated in a rotavap, and the residual solid is dried under high vacuum at 110° to give  $(CF_3SO_2)_2NNa$  (129g, 98%, [91742-21-1]). The Na salt (129g) and 96%  $H_2SO_4$  (150ml) are heated in a single necked flask at 60-90°/2 x 001mm and the  $(CF_3SO_2)_2NH$  ( $NTf_2$ ) (111g, 93%) is collected in an ascending tube cooled at -22°. If necessary (cf spectra below), it is sublimed twice at 60° and/or recrystallised from  $CFCl_3$  at -50°. The analytically pure crystalline white solid has m 49-50° and can be stored in a sealed container in a drybox.

$NTf_2$  has IR (gas in equilibrium with solid at 25°) with  $\nu_{max}$  at 3395 (m), 3320 (br), 1463 (m), 1440 (m), 1300 (w), 1240 (s), 1224 (s), 1138 (s), 860 (m), 643 (vw), 614 (m), 570 (vw) and 505 (w)  $cm^{-1}$ ; Raman (solid -180°) has  $\nu_{max}$  at 3205 (w), 1464 (vw), 1458 (w), 1450 (w), 1343 (w), 1263 (s), 1142 (m, 839 (w), 778 (s), 646 (w), 591 (w), 566 (w), 537 (w), 510 (w), 392 (m), 386 (m), 346 (s), 311 (s), 276 (s), 212 (w), 195 (w) and 128 (m)  $cm^{-1}$ ; the  $^1H$  NMR (60MHz, external TMS) has peaks at 10.42 (in  $Me_2CO$   $d_6$ ), 7.92 (in  $CFCl_3$ ) ppm; the  $^{19}F$  NMR (20MHz, in  $CFCl_3$  as solvent and internal standard) has a peak at -75.97 (s) ppm, i.e. is at high field

than that of  $\text{CFCl}_3$ ; the MS[EI] has  $m/z$  at 281 ( $\text{M}^+$ ), 211 ( $\text{CF}_3\text{SO}_2\text{NSO}_2^+$ ), 147 ( $\text{CF}_3\text{SO}_2\text{N}^+$ ), 133 ( $\text{CF}_3\text{SO}_2^+$ ) and 69 ( $\text{CF}_3^+$ ); and the MS[CI] has major  $m/z$  at 282 ( $\text{MH}^+$ ), 150 ( $\text{CF}_3\text{SO}_3\text{H}^+$  or  $\text{CF}_3\text{SO}_2\text{NH}_3^+$ ) and 115 ( $\text{CF}_2\text{SO}_2\text{H}^+$  or  $\text{CF}_2\text{SONH}_2^+$ ). [Foropoulos & DesMarteau *Inorg Chem* **23** 2720 1984.]

$\text{NTf}_2$  forms several derivatives including ( $\text{CF}_3\text{SO}_2$ )<sub>2</sub> $\text{NCl}$  (viscous acrid liquid, **m**  $-96^\circ$  to  $-93^\circ$ , [91742-17-5]), ( $\text{CF}_3\text{SO}_2$ )<sub>2</sub> $\text{NNO}$  (white solid, **m**  $\sim 118^\circ$ , [91742-19-7]), ( $\text{CF}_3\text{SO}_2$ )<sub>2</sub> $\text{NNO}_2$  (white crystals **dec**  $\sim 107^\circ$ , [91742-18-6]), ( $\text{CF}_3\text{SO}_2$ )<sub>2</sub> $\text{Si}(\text{Me})_3$  (low-volatile colourless liquid, [82113-18-5]), and with CsF in MeCN it gives the cesium salt ( $\text{CF}_3\text{SO}_2$ )<sub>2</sub> $\text{NCs}$  (white crystals **m**  $115^\circ$ , [91742-16-4]) [Foropoulos & DesMarteau *Inorg Chem* **23** 2720 1984]. It forms an *N*-trimethylsilyl derivative ( $\text{TMSNTf}_2$  prepared from allylTMS and  $\text{NTf}_2$ , see above) which catalyses Diels-Alder reactions between methyl acrylate and various dienes [Mathieu & Ghosez *Tetrahedron Lett* **38** 5497 1997], as well as Friedel-Crafts acylations of anisole, and allylation and bis-allylation of carbonyl derivatives [Oshii et al. *Synlett* 1145 1997]. It readily forms the silver salt,  $\text{AgNTf}_2$ , e.g. with  $\text{Ag}_2\text{CO}_3$ .

**1,3-Bis(2,4,6-trimethylphenyl)imidazolium chloride (IMes.Cl)** [141556-45-8] **M 340.9, m**  $>300^\circ$ . This NHC (N-Heterocyclic Carbene) precursor is prepared by established procedures from 2 mols of amine, 1 mol of glyoxal and one mol of formaldehyde [Arduengo US Patent 5 077 414 1991, *Chem Abstr* **116** 106289 1002, cf Hermann et al. *Chem Eur J* **2** 1627 1996] and washed with THF before use. It is useful for making  $\text{IMesCuCl}$  which in turn is used for making  $\text{IMesAuCl}$  and  $[\text{IMesPtCl}_2]$  [Furst & Casin *Chem Commun* **46** 6924 2010].

**1,3-Bis(2,4,6-trimethylphenyl)imidazol-2-ylidene (IMes)** [141556-42-5] **M 304.4, m**  $150-155^\circ(\text{dec})$ . By using Schlenk equipment and techniques under dry  $\text{N}_2$ , this NHC is prepared from the preceding  $\text{IMes.Cl}$  (10.0g, 29.3mmol) suspended in dry THF (80ml) and stirred for 15 minutes, then solid *tert*-BuOK (3.5g, 31.2mmol) is added at  $\sim 25^\circ$  in one portion, the dark grey solution is stirred for 20 minutes, and the volatiles are removed *in vacuo*. The residue is extracted into warm toluene (2 x 50ml), filtered through Celite and the solvent is removed *in vacuo* to provide small crystals of the carbene (7.55g, 84%). The crystals are recrystallised from hexane to yield colourless crystals, **m**  $150-155^\circ(\text{dec})$  which are analytically pure and suitable for X-ray structural analysis. Its  $^1\text{H}$  NMR (300MHz, THF-*d*<sub>8</sub>, TMS) has  $\delta_{\text{H}}$  at 2.02 (s, 2',6'-CH<sub>3</sub>, 12H), 2.30 (s, 4'-CH<sub>3</sub>, 6H), 6.94 (s, ArH, 4H), 7.04 (s, 4,5-CH, 2H); and its  $^{13}\text{C}$  NMR (75MHz, THF-*d*<sub>8</sub>, TMS) has  $\delta_{\text{C}}$  at 18.04 (s, 2',6'-CH<sub>3</sub>), 21.04 (s, 4'-CH<sub>3</sub>), 121.28 (s, C-4 and C-5), 129.69 (s, Mes C-3',5'), 135.73 (s, Mes C-2',6'), 137.55 (s, Mes C-4), 139.73 (s, Mes C-1), 219.69 (s, NCN carbene-C); and the  $^{15}\text{N}$  NMR (30MHz, THF-*d*<sub>8</sub>,  $\text{NH}_4^{15}\text{NO}_3$ ) has  $\delta$  at  $-178.85$ . [Arduengo et al. *J Am Chem Soc* **114** 5530 1992.] It is useful for making a variety metal complexes of ruthenium (among other metals) for catalysing olefin metathesis [Grubbs *Tetrahedron* **60** 7117 2004], and other metathesis reactions [Love et al. *Angew Chem. Int Ed* **41** 4035 2002, Schrodi & Pederson *Aldrichimica Acta* **40** 45 2007, Kanemitsu & Seeberger *Org Lett* **5** 4541 2003].

**4-Bromobiphenylboronic acid MIDA ester** {[2-(4-bromophenyl)-6-methyl-1,3,6,2-dioxazaborocane-4,8-dione], (4-bromophenyl)[*N*-[(carboxy- $\kappa\text{O}$ )methyl]-*N*-methylglycinato(2-)- $\kappa\text{N},\kappa\text{O}$ ] boron} [943552-04-3] **M 311.9, m**  $238-240^\circ$ ,  $248-253^\circ$ . This ester is obtained from 4-bromophenylboronic acid (24.99g, 124.4mmol) and MIDA (18.31g, 124.4mmol, see [4408-64-4]) to which is added a freshly prepared mixture of DMSO (6.3ml) and toluene (118.7ml) in a flask to give a white solid suspension in a clear colourless solution. The flask is fitted with a Dean-Stark trap and a reflux condenser, and the mixture is boiled under reflux with stirring (magnetic Teflon coated bar) for 6 hours during which time the mixture became clear and about 2.1ml of  $\text{H}_2\text{O}$  are collected in the trap. Heating is stopped and the reaction is allowed to cool, with stirring, to  $\sim 25^\circ$  during 1 hour; the apparatus is washed down with toluene and the combined liquids are evaporated ( $40^\circ/15\text{mm}$ ) to remove most of the toluene and give a crude tan, chunky, solid. Acetone (15ml) is added to the residue and swirled vigorously to give a white solid in a tan solution. To this mixture is added  $\text{Et}_2\text{O}$  (150ml, dried through neutral  $\text{Al}_2\text{O}_3$  columns) in small portions (25ml) with stirring each time to allow further separation of white solid, and is finally filtered onto a medium porosity glass frit. The solid is washed with  $\text{Et}_2\text{O}$  (3 x 50ml), dried by suction, and is dried further in a vacuum ( $\sim 25^\circ/1\text{mm}$ ) for 4 hours to give 4-bromophenylboronic acid MIDA ester as an air stable, free-flowing white powder (36.3g, 94%) with **m**  $238-240^\circ$ . Alternatively, the crude tan solid can be purified by silica gel chromatography to provide the white MIDA ester in almost quantitative yield. An analytical sample has IR (in  $\text{Me}_2\text{CO}$ , thin film) with  $\nu_{\text{max}}$  at 3012, 1745, 1584, 1459, 1339, 1294, 1237, 1216, 1187, 1037, 995, 867, 812, 707  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (400MHz,  $\text{CD}_3\text{CN}$ ) has  $\delta_{\text{H}}$  at 2.50 (s, 3H), 3.89 (d,  $J = 16.0\text{Hz}$ , 2H), 4.07 (d,  $J = 16.0\text{Hz}$ , 2H), 7.41 (d,  $J = 8.0\text{Hz}$ , 2H), 7.55 (d,  $J = 8.0\text{Hz}$ , 2H); the  $^{13}\text{C}$  NMR (100MHz,  $\text{CD}_3\text{CN}$ ) has  $\delta_{\text{C}}$  at

48.2, 62.5, 124.1, 131.6, 135.2, 169.2; the  $^{11}\text{B}$  NMR (100MHz,  $\text{CD}_3\text{CN}$ ) has  $\delta_{\text{B}}$  at 12.0; the LRMS ( $\text{EI}^+$ ) has  $m/z$  (relative intensity): 314.0 (97%), 313.0 (20%), 312.0 ( $\text{M}^+\text{H}$ , 100%), 311.0 (23%), 283.0 (16%), 255.9 (16%); and the HMRS ( $\text{EI}^+$ ) has found: 312.0035, and calculated for  $\text{C}_{11}\text{H}_{12}\text{BBrNO}_4$  [ $\text{M}+\text{H}$ ] $^+$ : 312.0037. [Ballmer, Gillis and Burke *Org Synth* **86** 344 2009.]

**trans-(2-Bromovinyl MIDA boronate** {**trans-2-bromovinylboronic acid MIDA ester 6-methyl-2-trans-bromovinyl-1,3,6,2-dioxazabronane-4,8-dione, [(1Z)-2-bromoethenyl]N-[(carboxy-κO)methyl]-N-methylglycinato(2-)-κN,κO]-boron**} [*trans E* 1104636-68-1; *cis Z* has 1105069-27-9] **M 261.9**. The ester is prepared using Schlenk equipment in subdued daylight under dry  $\text{N}_2$  by adding dropwise via a syringe freshly distilled (*E*)-(2-bromoethenyl)dibromoborane (21.0g, 75.9mmol, prepared from  $\text{BBr}_2$  and acetylene, Hyuga et al. *Chem Lett* 1757 1987) to a stirred mixture of MIDA (16.9g, 114mmol, 1.5 equivalents, see [4408-64-4]) and 2,6-lutidine (17.7g, 151.9mmol, 2 equivalents) in DMSO (250ml) at  $0^\circ$  over 15 minutes, and allowed to warm to  $\sim 25^\circ$  then kept at that temperature for 48 hours. The yellow mixture is treated with  $\text{H}_2\text{O}$  (300ml) and extracted with 1:1 THF:Et $_2\text{O}$  (3 x 500ml), the combined extracts are washed with brine (3 x 350ml), dried ( $\text{MgSO}_4$ ), filtered and evaporated *in vacuo*. The light yellow solid residue is purified by flash chromatography on silica gel and eluting with Et $_2\text{O}$ /petroleum ether (1:1), then EtOAc, then EtOAc/MeCN (9:1) to give the desired boronate as colourless crystals (12g, 60%). On TLC it has  $R_{\text{F}}$  0.46 (Merck silica gel plate grade 9385, 60Å, 230-400 mesh, eluting with EtOAc and visualised with  $\text{KMnO}_4$ ). [A preparation similar to the one for vinyl MIDA boronate (this chapter) using the MIDA-di Na salt gave similar yields [cf Uno, Gillis and Burke *Tetrahedron* **65** 3230 2009]. Material stored under air at room temperature for 1.5 years showed no signs of deterioration. Crystals grown by slow evaporation of an EtOAc solution at  $\sim 25^\circ$  were suitable for X-ray analysis which revealed a *trans* configuration while confirming the expected structure with a pyramidalised boron centre. Its IR (thin film) has  $\nu_{\text{max}}$  at 3006, 2962, 1755, 1589, 1451, 1338, 1286, 1196, 1152, 1118, 1080, 1025, 1009, 961, 893, 872, 773, 678  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (500MHz,  $\text{CD}_3\text{CN}$ ,  $\delta = 1.93$  centre line, TMS) has  $\delta_{\text{H}}$  at 6.69 (d,  $J = 15.0\text{Hz}$ , 1H), 6.63 (d,  $J = 14.5\text{Hz}$ , 1H), 3.97 (d,  $J = 17.0\text{Hz}$ , 2H), 3.82 (d,  $J = 17.0\text{Hz}$ , 2H), 2.80 (s, 3H); the  $^{13}\text{C}$  NMR (125MHz,  $\text{CD}_3\text{CN}$ ,  $\delta = 1.93$  centre line, TMS) has  $\delta_{\text{C}}$  at 169.0, 118.8, 62.6, 47.9; the  $^{11}\text{B}$  NMR (100MHz,  $\text{CD}_3\text{CN}$ ,  $\text{BF}_3\cdot\text{Et}_2\text{O}$  internal standard) has  $\delta$  at 10.5; and HRMS ( $\text{EI}^+$ ) found: 261.9874, calculated for  $\text{C}_7\text{H}_{10}\text{BBrNO}_4$  [ $\text{M}+\text{H}$ ] $^+$ : 261.9886. It is very useful in the reactions stated for vinyl MIDA boronate and for iterative cross-coupling. [Lee, Gray, Peak and Burke *J Am Chem Soc* **130** 466 2008, Uno, Gillis and Burke *Tetrahedron* **65** 3230 2009, Gillis & Burke *Aldrichimica Acta* **42** 17 2009].

**Chloro(dimethylsulfide)gold(I)** [(dimethylsulfide)gold(I) chloride, aurochloro dimethylsulfide, **AuCl.Me $_2$ S**] [29892-37-3] **M 295.6, m >100°(dec), 100-102°(dec), 120°(dec)**. All procedures for preparing this complex should be carried out in an efficient fume cupboard because  $\text{Me}_2\text{S}$  is **toxic** and has a **foul** odour. The gold complex has been prepared by adding  $\text{Me}_2\text{S}$  (1 mole, see [75-18-3]) slowly to a stirred solution of  $\text{NH}_4\text{AuCl}_4$  (1mole) in dilute *Aqua Regia* when the complex separates and is collected [Allen & Wilkinson *Spectrochimica Acta* **28B** 2257 1972]. Alternatively,  $\text{Me}_2\text{S}$  is added to a solution of auric chloride ( $\text{AuCl}_3$ ) in HCl [which forms *aurichloric acid* (*chloroauric acid*)  $\text{HAuCl}_4$  see [16903-35-8]] when much heat is evolved and a flocculent white precipitate of *AuCl.Me $_2$ S* separates. It is filtered off, washed with  $\text{H}_2\text{O}$  (in which it is insoluble) and a little EtOH (in which it is slightly soluble), and dried at room temperature in air in the dark. It is air stable and can be recrystallised from  $^*\text{C}_6\text{H}_6/\text{Me}_2\text{CO}$ . Clearly, the  $\text{Me}_2\text{S}$  reduces Au(III) to Au(I) before the complex separates. It is rapidly decomposed by sunlight to give metallic gold,  $\text{Me}_2\text{S}$  and HCl. In the absence of sunlight it can be kept in the solution in which it has been prepared for long periods, or in the presence of a slight excess of  $\text{Me}_2\text{S}$  in which colourless crystalline needles are formed. It is soluble in many organic solvents, e.g.  $\text{CH}_2\text{Cl}_2$ ,  $^*\text{C}_6\text{H}_6$ , but solutions deposit metallic gold in time. The gold content can be determined by exposing solutions to sunlight, and the gold that deposits can be collected and weighed. On heating in  $\text{N}_2$ ,  $\text{Me}_2\text{S}$  begins to evolve above  $100^\circ$  until  $200^\circ$ , after which a residue of gold is obtained. [Phillips *J Am Chem Soc* **23** 250 1901.] In a third synthesis, a suspension of freshly prepared Au(I)Cl (0.23g, 1mmol, [10294-29-8]) in dry  $^*\text{C}_6\text{H}_6$  (25ml) is treated with an excess of  $\text{Me}_2\text{S}$  which causes the solid to dissolve on stirring at  $20^\circ$ . After half an hour, the solution is evaporated *in vacuo*, and the crystalline residue is recrystallised from  $^*\text{C}_6\text{H}_6/\text{Me}_2\text{CO}$  (1:1) to give a 70% yield of the pure complex, **m 100-102°(dec)**. [Dash & Schmidbaur *Chem Ber* **106** 1221 1973.]

For the **Au(III) complex** aurochloric acid (10g) in  $\text{H}_2\text{O}$  (5ml) and a 1:1 v/v mixture of  $\text{HNO}_3$  (d 1.4) and HCl (d 1.2) (1ml) are cooled in an ice bath for 10 minutes, and then  $\text{Me}_2\text{S}$  (0.5g) in  $\text{Me}_2\text{CO}$  (5ml) is added gradually (1ml at a time, at 3-5 minutes interval), heat is evolved and a yellow oil separates which soon solidifies to an

orange yellow solid (some white *aurochloro dimethylsulfide* separates simultaneously). After allowing to stand in contact with a further quantity of acid mixture, all the solid is converted to *aurichloro dimethylsulfide* ( $\text{AuCl}_3 \cdot \text{Me}_2\text{S}$ ). This is filtered off, washed with a 1:1v/v mixture of N/10  $\text{HNO}_3$  and N/10  $\text{HCl}$  then  $\text{H}_2\text{O}$  and finally with  $\text{EtOH}$ , and dried in air. It is recrystallised from  $\text{CHCl}_3/\text{Et}_2\text{O}$  to give yellow prismatic crystals of analytically pure *auri complex*  $\text{AuCl}_3 \cdot \text{Me}_2\text{S}$  with **M 365.5** [29826-91-3] and **m 160°**, which is soluble in  $\text{CHCl}_3$ ,  $\text{Et}_2\text{O}$ ,  $\text{Me}_2\text{CO}$ , and warm  $^*\text{C}_6\text{H}_6$ . When this *auri complex* is warmed with  $\text{EtOH}$  on a water bath, it is converted into the *auro complex*  $\text{AuCl} \cdot \text{Me}_2\text{S}$  and the colour changes to white. The latter can be converted back to the former complex by treatment with aqua regia or chlorine water. [Ray & Sen *J Indian Chem Soc* **7** 67 1930.]

$\text{AuCl} \cdot \text{Me}_2\text{S}$  is monomeric with  $M^+$  at *m/e* at 294; its IR (Nujol mulls between polyethylene discs or CsI plates) has bands at 730vw ( $\text{SC}_2$  *asym*), 675vw ( $\text{SC}_2$  *sym*), 345s (Au-S, str), 326s and 319sh (Au-Cl str), 279m ( $\text{SC}_2$  *def*), 198s (CSAu *def*), 109m, 93m and 83m (SAuCl *bend and lattice modes*)  $\text{cm}^{-1}$  [Goggin et al. *J Chem Soc, Dalton* 1904 1972], the  $^1\text{H}$  NMR (100MHz,  $\text{CH}_2\text{Cl}_2$ , TMS) has one peak at  $\tau = 8.1$  ppm [Allen & Wilkinson *Spectrochim Acta* **28A** 2257 1972], and the  $^1\text{H}$  NMR (60MHz,  $\text{CHCl}_3$ , TMS) has one peak at  $\delta = -2.81$  [Dash & Schmidbaur *Chem Ber* **106** 1221 1973].

It is a very useful compound for preparing a variety of gold complexes and gold catalysts [e.g. IMesAuCl in Part 1 of this Chapter].

**Chlorotris(triphenylphosphine)cobalt** [ $\text{CoCl}(\text{PPh}_3)_3$ ] [26305-75-9] **M 881.2**, **m 135-139°(dec)**, **176-179°(dec)**, **177°(dec)**, **188°(dec)**. The complex is prepared under  $\text{N}_2$ , and preferably in Schlenck-type equipment.  $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$  (9.6, 40.3mmol),  $\text{PPh}_3$  (32g, 122mmol) and  $\text{EtOH}$  (600ml) are stirred while being purged with  $\text{N}_2$  for several minutes, then vigorously at 60-70° for 30 minutes to ensure complete formation of the blue-coloured fine powder of  $\text{CoCl}_2(\text{PPh}_3)_2$ . Then under vigorous stirring the mixture is cooled to ~30° and  $\text{NaBH}_4$  (1.28g, 33.9mmol) is added during ~10 minutes (in ~10 portions) whereby the colour of the solution changes from blue to green, then to brown. The green-brown precipitate is collected by filtration (in air), washed with portions of  $\text{EtOH}$  until the filtrate is no longer blue in colour, then with  $\text{H}_2\text{O}$ ,  $\text{EtOH}$  again and finally with hexane, and dried *in vacuo* to give  $\text{CoCl}(\text{PPh}_3)_3$  (24g, 67%). In the solid state it decomposes quite slowly in air, but is stable indefinitely under argon or  $\text{N}_2$  in a refrigerator. It is soluble in  $^*\text{C}_6\text{H}_6$  and  $\text{CH}_2\text{Cl}_2$  and the spectra in  $^*\text{C}_6\text{H}_6$  have  $\lambda_{\text{max}}$  at 745, ~940sh, 1100, 2200nm. [Wakatsuki & Yamazaki *Inorg Synth* **26** 190 1989, Aresta et al. *Inorg Chim Acta* **3** 227 1969.]

$\text{CoCl}(\text{PPh}_3)_3$  is a useful stoichiometric reagent for radical dimerisation of halogenated organic compounds as in the biomimetic synthesis of the bis-sesquiterpene lactones ( $\pm$ )-biatractylolide and ( $\pm$ )-biepiasterolide [Bagal et al. *J Org Chem* **69** 9100 2004], and alkaloid dimerisation in the total synthesis of the alkaloids (-)-calycanthine and (+)-chimonanthine [Movassaghi & Schmidt *Angew Chem Int Ed* **46** 3725 2007]. It is used for the preparation of COPs (cobalt oxazoline palladacycles) catalysts [see above, Stevens & Richard *Organometallics* **18** 1346 1999].

**(1,3,5,7-Cyclooctatetraene)dilithium (2,4,6-cyclooctatriene-1,2-diyl dilithium,  $\text{Li}_2\text{C}_8\text{H}_8$ )** [40698-91-7] **M 118.1**. It is prepared by suspending lithium foil (1.0g, 144mmol) under  $\text{N}_2$  in  $\text{Et}_2\text{O}$  (20ml) and stirring at 0° with 1,3,5,7-cyclooctatetraene (5.0g, 48mmol) for 16 hours. The small amount of white precipitate is allowed to settle, and an aliquot sample of the orange solution is sucked into a syringe, and the molarity of the solution is determined by hydrolysis with  $\text{H}_2\text{O}$  and titrating with standard acid. A saturated solution of  $\text{Li}_2\text{C}_8\text{H}_8$  in  $\text{Et}_2\text{O}$  is ~0.24M. Store in the cold and away from air and moisture. The solution is not more flammable than an  $\text{Et}_2\text{O}$  solution, but the dry solid  $\text{Li}_2\text{C}_8\text{H}_8$  is **pyrophoric** in air. [Spencer *Inorg Synth* **19** 214 1979, Craswell & Spencer *Inorg Synth* **28** 127 1990.]

**(1R,2R)-(+)-1,2-Diaminocyclohexane-*N,N'*-bis(2-diphenylphosphinobenzoyl)** [(*R,R*)-DACH-phenyl Trost ligand] [138517-61-0] and **(1S,2S)-(-)-1,2-diaminocyclohexane-*N,N'*-bis(2-diphenylphosphinobenzoyl)** [(*S,S*)-DACH-phenyl Trost ligand] [169689-05-8] **M 690.8**, **m 137-142°**,  $[\alpha]_{\text{D}}^{20}$  *R,R*- +134°, *S,S*- -134° (c 1.0, MeOH),  $[\alpha]_{\text{D}}^{20}$  *R,R*- +55.1°, *S,S*- -55.1° (c 2.85,  $\text{CH}_2\text{Cl}_2$ ). The (*1R,2R*)-enantiomer is prepared from (*1R,2R*)-1,2-diaminocyclohexane (0.535g, 4.68mmol), 2-(diphenylphosphino)benzoic acid (3.02g, 9.83mmol, [17261-28-8]), DMAP (61.0g, 0.5mmol) and DCC (2.13g, 10.3mmol) in  $\text{CH}_2\text{Cl}_2$  (30ml) for 6 hours. The residue is chromatographed on silica gel and eluted with a 15—30% gradient of  $\text{EtOAc}$ /hexanes followed by recrystallisation from  $\text{CH}_2\text{Cl}_2/\text{Et}_2\text{O}$  to give the (+)-DACH-phenyl Trost ligand (2.96g, 90%). It has an  $R_{\text{F}}$  of 0.43 on silica TLC (1:1  $\text{EtOAc}$ -pentanes) and its IR (neat film from  $\text{CDCl}_3$ ) has  $\nu_{\text{max}}$  at 3303, 3070, 2935, 2857,

1955w, 18877w, 1817w, 1645s, 1538, 1478, 1434, 1328, 1306, 1162, 1091, 909 cm<sup>-1</sup>; the <sup>1</sup>H NMR (200MHz, CDCl<sub>3</sub>) has δ at 7.57 (m, 2H), 7.15-7.26 (m, 24H), 6.91 (m, 2H), 6.31 (br d, *J* = 7.7Hz, 2H, N-H), 3.77 (m, 2H), 1.87 (m, 2H), 1.62 (m, 2H), 0.9-1.3 (m 6H); the <sup>13</sup>C NMR (50MHz, CDCl<sub>3</sub>) has δ at 169.46, 140.80 (d, *J* = 24.2Hz), 137.96 (d, *J* = 11.8Hz), 137.88 (d, *J* = 12.3Hz), 136.81 (d, *J* = 21.6Hz), 134.34, 133.97 (d, *J* = 20.3Hz), 130.23, 128.79, 128.66, 128.57, 128.51, 128.43, 127.63, 127.55, 53.58, 31.71, 24.4; and has correct elemental analyses for C, H, N and P. [Trost et al. *J Am Chem Soc* **114** 9327 1992.]

The Pd complexes have found extensive use in catalysing Asymmetric Allylic Alkylation (AAA) and palladium-catalysed Dynamic Kinetic Asymmetric Transformations (DKYATs), i.e. kinetic resolutions [Trost & Fandrick *Aldrichimica Acta* **40** 59 2007].

(-)-*N,N'*-(1*R*,2*R*)-1,2-Diaminocyclohexanediylbis(2-pyridinecarboxamide) [(*R,R*)-DACH-pyridyl Trost ligand] [218290-24-5] and (+)-*N,N'*-(1*S*,2*S*)-1,2-diaminocyclohexanediylbis(2-pyridinecarboxamide) [(*R,R*)-DACH-pyridyl Trost ligand] [172138-95-3] **M** 324.4, **m** 171-176°, 174-176°, [α]<sub>D</sub><sup>20</sup> *R,R* -97.0°, *S,S* +97.0° (**c** 1.0, MeOH). The (*RS,RS*)-1,2-diaminocyclohexanediylbis(2-pyridinecarboxamide) is readily prepared by treating a mixture of 1,2-diaminocyclohexane (5.7g, 50mmol) in pyridine (20ml) and pyridine-2-carboxylic acid (12.3g, 100mmol) in pyridine (40ml) with triphenylphosphite (31.0g, 100mmol), and heating on a steam bath for 12 hours. The resulting brown oil is extracted into CHCl<sub>3</sub>, washed twice with aqueous NaHCO<sub>3</sub>, and H<sub>2</sub>O, dried (MgSO<sub>4</sub>), filtered, evaporated to a small volume and set aside overnight whereby brown crystals of the product are obtained (7.6g, 47%). Recrystallisation from CHCl<sub>3</sub> gives analytically pure (±)-ligand as white crystals, **m** 201-202°, with IR (KBr)  $\nu_{\max}$  at 3300, 3050, 2940, 2850, 1655, 1535 cm<sup>-1</sup>; and the <sup>1</sup>H NMR (60MHz, CDCl<sub>3</sub>) has δ at 8.6 (m), 8.4 (br), 8.1 (m, combined 8H), 7.8 (m, 2H), 7.4 (m, 2H), 4.1 (br, 2H), 2.3 (br), 1.6 (br, combined 6H) downfield from TMS (peaks are not well separated at 60MHz). [Barnes et al. *J Chem Eng Data* **23** 349 1978.] (*1R,2R*)-DACH-pyridyl Trost ligand and [(1*S*,2*S*)-DACH-pyridyl Trost ligand are prepared similarly, but starting from (*1R,2R*)-(-)-[20439-47-8] and (*1S,2S*)(+)-[21436-03-3] 1,2-diaminocyclohexanes respectively [cf their resolution in Chapter 4, Alicyclic Compounds pp 242-243].

These ligands readily form complexes with Cu, Zn, Co, Pt and Pd [Mulqi et al. *Inorg Chim Acta* **53** L91c 1981, Adolfsen & Moberg *Tetrahedron:Asymmetry* **6** 2023 1995] and the Pd complexes have found extensive use in catalysing Asymmetric Allylic Alkylation (AAA) and palladium-catalysed Dynamic Kinetic Asymmetric Transformations (DKYATs), i.e. kinetic resolutions [Trost & Fandrick *Aldrichimica Acta* **40** 59 2007].

**Di-tert-butylchlorophosphine** [13716-10-4] **M** 180.7, **b** 48°/3mm, 72-73°/13mm, **d**<sub>4</sub><sup>25</sup> 0.951, **n**<sub>D</sub><sup>20</sup> 1.482. This chlorophosphine is prepared from two equivalents of *tert*-butylmagnesium bromide and PCl<sub>3</sub> followed by the usual workup and fractional distillation in a vacuum, and redistillation of the desired fraction. With MeLi it provides *di-tert-butylmethylphosphine* **b** 95-105°/3mm (170-172°/atm), which with MeI provides *di-tert-butyl-dimethylphosphonium iodide* **m** 95-105° (from EtOH). Hydrolysis of the chlorophosphine with H<sub>2</sub>O provides *di-tert-butylphosphine oxide* [684-19-5] **M** 162.2, **m** 55-59° (hygroscopic crystals), **b** 112°/9mm, with IR which has  $\nu_{\max}$  (CHCl<sub>3</sub>) 2950s, 2290, 1470s, 1394w, 1370, 1142s, 918, 815 (P-Bu<sup>t</sup>) and 656 cm<sup>-1</sup>; the <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>) has τ at 3.53 (d, *J*<sub>HP</sub> = 453Hz), 8.65 (d, *J*<sub>HCCP</sub> = 15Hz, Bu<sup>t</sup>). Note that this phosphine oxide is tautomeric with *di-tert-butylphosphinous acid*. [Hoffmann & Schellenbeck *Chem Ber* **99** 1134 1966, Hoffmann & Schellenbeck *Chem Ber* **100** 692 1967, Issleib & Krech *J Organometal Chem* **13** 283 1968, Crofts et al. *J Chem Soc C* 331 1970.]

The complex from Pd(OAc)<sub>2</sub> and this bulky *di-tert-butylchlorophosphine* ligand, after condensation with *P*-imino-azaphosphatane, catalyses efficiently the cross-coupling of arylboronic acids with aryl halides in the Suzuki-Miyaura reaction to provide specific unsymmetrical biphenyls in well over 90% yields [Kingston & Verkade *J Org Chem* **72** 2816 2007.]

**4,4'-Di-tert-butyl-2,2'-bipyridyl (dtbpy)** [72914-19-3] **M** 268.4, **b** 235°/32mm, **m** 159-160°, 159-161°, **pK**<sub>Est</sub> ~4.2. The bipyridyl has been prepared by reaction of *tert*-butylpyridine with NaNH<sub>2</sub> (ratio 2:1) in xylene at 144-218° during 26 hours, then cooled, hydrolysed with H<sub>2</sub>O, the organic layer is separated, dried, and distilled *in vacuo*. The bipyridyl solidified and can be sublimed. [McGill USP 4177349, *Chem Abstr* **92** 110871 1980, *Beilstein* **23/8** IV 181.] By coordinating with Ir(COD) and Ir(COE), complexes formed with **dtbpy** assist in C-H borylations [see Ir complexes above and Ishiyama et al. *Angew Chem. Int Edn* **41** 3056 2002, Ishiyama et al. *J Am Chem Soc* **124** 390 2002.]

**Di-tert-butylneopentylphosphine [DTBNpP, (PBU<sup>t</sup><sub>2</sub>(-CH<sub>2</sub>CMe<sub>3</sub>)]** [60633-21-8] **M 216.3, b 40°/0.1 mm, d<sup>25</sup> 0.839, n<sub>D</sub><sup>20</sup> 1.478.** This ligand, with increased steric bulk, can be obtained by adding a solution of di-tert-butylchlorophosphine (108.4g, 114.0ml, 0.6mol, see [13716-10-4]) in THF (250ml) to neopentylmagnesium chloride (from 16g, 0.67g-atom of Mg turnings, 74ml, 64g, 0.6mol of neopentyl chloride in 250ml of dry THF containing a small amount of 1,2-dibromoethane as initiator, and stirred until all the Mg has dissolved, then cooled to 0°) at 0° with stirring, allowing to warm to ~25°, boiling under reflux for *ca* 15 minutes, then the solvent is removed at ~40°/40mm). The residue is diluted with Et<sub>2</sub>O, the mixture is hydrolysed by stirring with saturated aqueous NH<sub>4</sub>Cl, the layers are separated and the organic phase is dried (MgSO<sub>4</sub>), filtered, the Et<sub>2</sub>O is removed at ~25°/50mm, and the residual phosphine is distilled at high vacuum. There are also alternative syntheses for DTBNpP. *Work with protective gloves, with eyes and face protection, and in an efficient fume cupboard.* [cf: King et al. *J Org Chem* **41** 972 1976.] It is, however, better to store and use it in the form of its salts, e.g. DTBNpP.HBF<sub>4</sub> (see below). In that case an equivalent amount of base, e.g. *t*-BuONa, must be added to the reaction mixture to liberate the free ligand. With a Pd source, e.g. Pd(OAc)<sub>2</sub> or Pd<sub>2</sub>(dba)<sub>3</sub>, H—B coupling (Hartwig—Buchwald) of various aryl halides with a variety of aromatic primary or secondary amines, or saturated heterocyclic amines, e.g. morpholine, is catalysed to form di- or tri-substituted amines in toluene solutions at 23° to 140° in high yields. [Hill et al. *J Org Chem* **71** 5117 2006.]

Unlike with Pd complexes, when DTBNpP is mixed with Pt(PhCN)<sub>2</sub>Cl<sub>2</sub> (1:1 mol per Pt atom) in CH<sub>2</sub>Cl<sub>2</sub> at 20° for a few minutes, a white binuclear complex is formed. It was characterised by spectroscopic and Xray diffraction methods to have the structure [PtCl(PBU<sup>t</sup><sub>2</sub>CH<sub>2</sub>CMe<sub>2</sub>CH<sub>2</sub>)]<sub>2</sub>, i.e. one of the methyl groups of the neopentyl moiety is folded back and is metallated by the Pt to form a five membered Pt heterocyclic ring — and the molecule is dimeric. Such metallation does not occur with PBU<sup>t</sup><sub>2</sub>Pr<sup>n</sup> under similar conditions, and in this case the monomeric *cis* and *trans* [PtCl<sub>2</sub>(PhCN)(PBU<sup>t</sup><sub>2</sub>Pr<sup>n</sup>)] square planar complexes are formed. [Mason et al. *JCS Chem Commun* 292 1976.]

**Di-tert-butylneopentylphosphonium tetrafluoroborate (DTBNpP<sup>+</sup>.HBF<sub>4</sub><sup>-</sup>)** [886059-84-3] **M 304.2, m 258-262°(dec).** This air stable salt is prepared in the same manner as [(*tert*-Bu)<sub>3</sub>PH<sup>+</sup> BF<sub>4</sub><sup>-</sup>, [131274-22-1] by mixing DTBNpP and aqueous HBF<sub>4</sub>. It is easier to handle [cf: Netherton & Fu *Org Lett* **3** 4295 2001], and is a useful ligand in Pd-catalysed cross-coupling amination reactions of aryl bromides and chlorides [Hill et al. *J Org Chem* **71** 5117 2006].

**3,3'-Di-tert-butyl-5,5',6,6'-tetramethyl-1,1'-biphenyl-2,2'-diol {H<sub>2</sub>[BIPHEN], 1,1'-biphenyl-2,2'-diol, 3,3'(1,1'-dimethylethyl)-5,5',6,6'-tetramethyl-}** [*R*- 329735-68-4, *S*- 205927-03-3, *RS*- 101203-31-0] **M 354.5, m 160.5-161.5°.** This biphenyl is prepared by the oxidation of 2-*tert*-butyl-4,5-dimethylphenol. The oxidation is carried out by slowly adding a solution of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> (130g, 0.442 mole, i.e. 1.02 equivalents being twice the theoretical amount to form the biphenyl) in a mixture of concentrated H<sub>2</sub>SO<sub>4</sub> (260ml) and H<sub>2</sub>O (780ml, CARE as much heat is evolved on mixing) at ~25°, to a solution of 2-*tert*-butyl-4,5-dimethylphenol (231.7g, 1.3 moles, see [1445-23-4]) in AcOH (1300ml) over 10 minutes at 55-60° and keeping at this temperature range. The colour of the solution changes from orange to green and a tan coloured solid separates during the reaction which is cooled to room temperature. It is collected, washed sequentially with H<sub>2</sub>O (2 x 250ml) and MeOH (3 x 200ml) until the solid is almost colourless, dried *in vacuo* and recrystallised from hot MeOH or dioxane/MeOH to give racemic 3,3'-di-tert-butyl-5,5',6,6'-tetramethyl-1,1'-biphenyl-2,2'-diol [101203-31-0] (~115g, ~50%) **m 160.5-161.5°** (m 140-142° before recrystallisation). Its <sup>1</sup>H NMR (400MHz, CDCl<sub>3</sub>, TMS) has δ at 7.12 (s, 2H, aromatic CH), 4.79 (s, 2H, OH), 2.24 (s, 6H, CH<sub>3</sub>), 1.80 (s, 6H, CH<sub>3</sub>), 1.38 (s, 18H, C(CH<sub>3</sub>)<sub>3</sub>); and its <sup>13</sup>C NMR (100MHz, C<sub>6</sub>D<sub>6</sub>, ref C<sub>6</sub>D<sub>6</sub> at δ = 128.4) has δ at 151.24, 134.60, 134.13, 127.73, 128.79, 121.64, 35.15, 30.19, 20.46, 16.35. [Albert *J Am Chem Soc* **76** 1983 1954, Alexander et al. *J Am Chem Soc* **120** 4041 1998, Alexander et al. *Organometallics* **19** 3700 2000.]

**Optical Resolution of H<sub>2</sub>[BIPHEN]:** Two procedures have been used: (i) preparation of the respective 2,2'-cyclic phosphoric acid (*via* reaction with POCl<sub>3</sub> with the di-Na salt in THF) followed by hydrolysis and recrystallisation of the (±)-acid (-)-Cinchonidine salt in EtOH, followed by hydrolysis of the optically salts, conversion of the optically active cyclic acids to their respective optically active cyclic methyl esters, and finally cleavage with “Red-Al” [Na AlH<sub>2</sub>(OCH<sub>2</sub>CH<sub>2</sub>OMe<sub>2</sub>)] in toluene to give optically pure H<sub>2</sub>[BIPHEN]*s*. [Alexander et al. *J Am Chem Soc* **120** 4041 1998.]; and (ii) which is described here in some detail as it can be used generally for the resolution of racemic 2,2'-dihydroxybiphenyls. **Firstly:** A solution of (1*R*,2*S*,5*R*)(-)-menthol (44g, 282mmol) in CH<sub>2</sub>Cl<sub>2</sub> (100ml) is added to a solution of PCl<sub>3</sub> (58g, 423mmol, 1.5

equivalents) in  $\text{CH}_2\text{Cl}_2$  (200ml) at  $0^\circ$  during 30 minutes. The cold bath is removed, the mixture is kept at  $\sim 25^\circ$  for 1 hour, and the volatiles are removed at  $<25^\circ/100\text{mm}$ . The residual oil, which consists of *menthyl phosphorochloridite* (see [95456-31-8] in Chapter 4, p 516), is dissolved in  $\text{CH}_2\text{Cl}_2$  (250ml), and a mixture of  $\text{Et}_3\text{N}$  (118ml, 847mmol, 3 equivalents) in  $\text{CH}_2\text{Cl}_2$  (400ml) and  $\text{H}_2[\text{Biphen}]$  (100g, 282mmol) is added during 30 minutes. After 2 hours the mixture is filtered;  $\text{H}_2\text{O}_2$  (30%, 200ml, *extremely violent reaction* take great CARE, wear body protection) is added very slowly with stirring, the biphasic mixture is then stirred vigorously for 2 hours, the layers are allowed to settle, the organic phase is washed with  $\text{H}_2\text{O}$  and brine (200ml), dried ( $\text{MgSO}_4$ ), filtered and evaporated *in vacuo* to give a mixture of (*R*)- and (*S*)-  $\text{BiphenP(O)(OMen)}$  (124g, 85%) with  $^{31}\text{P}$  NMR (121MHz, THF, external ref 85%  $\text{H}_3\text{PO}_4$ ) which has  $\delta$  at -4.89 and -3.37 respectively due to the diastereomeric menthyl phosphates. **Secondly:** The diastereomeric mixture of phosphates is dissolved in the minimum volume of refluxing  $\text{AcOH}$  ( $\sim 450\text{ml}$ ), allowed to cool, and after 16 hours white crystals were filtered off, washed with cold  $\text{AcOH}$  ( $2 \times 50\text{ml}$ ) and dried *in vacuo* to give (*S*)- $\text{BiphenP(O)(OMen)}$  (42g, 97-99% de). Recrystallisation from refluxing  $\text{AcOH}$  gives pure *S*-diastereomer (37.8g, >99%de, in 61% yield), The mother liquors from the first crystallisation are evaporated to give (*R*)- $\text{BiphenP(O)(OMen)}$  (26.8g, >99%de, 43% *R*-diastereomer) after two recrystallisations from refluxing  $\text{MeOH}$  and cooling to  $0^\circ$ . [Partly racemic ester from the mother liquors are re-used in subsequent resolution processes.] **Thirdly:** To the preceding (*S*)- $\text{biphenP(O)(OMen)}$  (37.83g, 70.3mmol) in toluene (500ml) in a 2L Schlenk flask at  $0^\circ$  is treated dropwise with Red-Al (53ml, 65%wt in toluene, introduced into the separating funnel *via* a cannula) at  $0^\circ$ , and stirred for 16 hours. The mixture is carefully quenched with  $\text{H}_2\text{O}$  (75ml) then bleach (75ml), the slurry is filtered through a Celite pad, the pad is washed with toluene (250ml), the combined filtrates are allowed to settle, the toluene layer is separated, washed with bleach (200ml), brine (200ml), dried ( $\text{MgSO}_4$ ), filtered, then the toluene is removed *in vacuo* at  $0^\circ$ , any menthol (minty odour) is removed by trituration with  $\text{MeOH}$  (50ml), to provide after drying, the resolved (*S*)- $\text{H}_2[\text{BIPHEN}]$  (17.5g, 70%, >99% ee) which has  $[\alpha]_{\text{D}}^{20} -53.0^\circ$  (c 0.352, THF). The absolute configuration of this diastereoisomer was deduced from the X-ray crystallographic structure of its *syn*- $\text{Mo}(N-2,6\text{-di-iso-PrC}_6\text{H}_3(\text{CHCMe}_2\text{Ph})[(\text{S})\text{-BIPHEN}]$  complex (see Schrock-Hoveyda catalyst [205815-80-1] in Part 1). (*R*)- $\text{H}_2[\text{BIPHEN}]$  is prepared from (*R*)- $\text{BiphenP(O)(OMen)}$  using an identical procedure and the optical purity is deduced from that of its precursor as no racemisation occurs in these reactions. Note that the NMR spectra of the *RS*- (see above), *R*- and *S*- $\text{H}_2[\text{BIPHENS}]$  are the same. About 20g each of the *R*- and *S*-  $\text{H}_2[\text{BIPHENS}]$  are usually obtained from 100g of *RS*- $\text{H}_2[\text{BIPHEN}]\text{Me}$ ; and  $\sim 60\text{g}$  of the latter are pooled from the mother liquors which can be recycled. [Alexander et al. *Organometallics* **19** 3700 2000, Alexander et al. *J Am Chem Soc* **120** 4041 1998.]

By using identical compounds and reactions, but in which the *tert*-butyl group is replaced by a 1-adamantyl group the corresponding *1-adamantyl* ( $\text{H}_2\text{BIAD}$ ) derivatives are obtained in almost similar yields and used to prepare related molybdenum catalysts. For example (*S*)-3,3'-bis(1-adamantyl)-5,5',6,6'-tetramethyl-1,1'-biphenyl-2,2'-diol  $\{(\text{S})\text{-H}_2(\text{BIAD}) \{(\text{S})\text{-}(-)\text{3,3'}\text{-biphenyl-2,2'}\text{-diol, 5,5',6,6'}\text{-tetramethyl-3,3'}\text{-bis(tricyclo-}[\text{3.3.1.13.7}]\text{dec-1-yl, [255728-57-5]}\}$  with  $[\alpha]_{\text{D}}^{20} -32.1^\circ$  (c 3.3, THF), whose absolute configuration was also deduced by X-Ray crystallography of its related respective Mo complex catalyst, was prepared starting from 2-(1-adamantyl)-4,5-dimethylphenol **m 135-138**<sup>o</sup>. [Alexander et al. *Organometallics* **19** 3700 2000.]

**Dicyclohexyl(2-methylphenyl)phosphine ( $\text{Cy}_2\text{P-}o\text{-Tol}$ )** [173593-25-4] **M 288.4, m 90-93<sup>o</sup>, pK<sub>Est</sub>  $\sim 4.0$** . This phosphine is prepared and purified in the same way as  $\text{Cy}_2\text{PPh}$  (following entry), and is used in the same manner as a phosphorus ligand for catalyst systems in coupling reactions. It has the advantage that it is less susceptible to oxidation, has a higher melting point and is easier to handle.

**Dicyclohexylphenylphosphine ( $\text{Cy}_2\text{PPh}$ )** [6476-37-5] **M 274.4, m 56-57<sup>o</sup>, 57-58<sup>o</sup>, pK<sub>25</sub> 3.40**.  $\text{Cy}_2\text{PPh}$  is a "foul smelling" solid which is a good ligand for Cr, Hg and Group VIII metals. It can be prepared by reaction of  $\text{PhPCl}_2$  with  $\text{CyMgCl}$  in 50% yield [Issleib & Völker *Chem Ber* **64** 392 1961], or in 90% yield from  $\text{PhPCl}_2$  and  $\text{CyLi}$  [Screttas & Isbell *J Org Chem* **27** 2573 1973], and is recrystallised from oxygen-free  $\text{Me}_2\text{CO}$  or  $\text{EtOH}$ . In detail: to the Grignard solution, at ice-salt bath temperature, made from Mg turnings (24.1g, 0.99mol) in dry  $\text{Et}_2\text{O}$  (350ml) and  $\text{CyBr}$  (162g, 122ml, 0.99mol) in dry  $\text{Et}_2\text{O}$  (130ml), is added dropwise (2 hours) to a solution of  $\text{PhPCl}_2$  (81g, 61.4ml, 0.45mol) in dry  $\text{Et}_2\text{O}$  (100ml). The mixture is then boiled under reflux for 30 minutes and hydrolysed by stirring with saturated, deoxygenated, aqueous  $\text{NH}_4\text{Cl}$ . The  $\text{Et}_2\text{O}$  layer is separated and evaporated at  $\sim 20^\circ/30\text{mm}$  leaving an oil that crystallises after all the solvent is removed. It may be recrystallised

by slowly cooling a hot, oxygen-free EtOH solution (1 ml/g), with gentle stirring to prevent formation of an oil, to give analytically pure (Cy<sub>2</sub>PPh) as white needles (98g, 79.5%). [Bianco & Doronzo *Inorg Synth* **18** 171 1978.] It is a phosphorus ligand used in catalytic systems for coupling reactions.

**Dicyclohexylphenylphosphine oxide** (Cy<sub>2</sub>PPhO), crystallises from petroleum ether, EtOH or Me<sub>2</sub>CO and melts at **157.5°** (m 165° was also reported).

**Dicyclohexylphosphine** (Cy<sub>2</sub>PH) [829-84-5] **M 198.3, b 105-108°/3mm, 128°/8mm, 281-283°/atm, n<sub>D</sub><sup>25</sup> 1.5142, pK<sub>a</sub> 4.55.** This phosphine is a useful air sensitive ligand and should be used preferably in an inert atmosphere. It has been prepared in 80% yield by heating Cy<sub>2</sub>PSSPCy<sub>2</sub> with excess Cu and distilling [Niederfeld & Langenfeld *Chem Ber* **95** 64 1962], or in 55% yield by the addition of PH<sub>3</sub> to cyclohexene under pressure in the presence of α, α-azobis(isobutyronitrile) followed by fractional distillation [Rauhut et al. *J Org Chem* **26** 5138 1961]. It is a phosphorus ligand in catalytic systems used in coupling reactions. It forms a pale yellow *Li salt* [19966-81-5] which is slightly soluble in dioxane but insoluble in Et<sub>2</sub>O, \*C<sub>6</sub>H<sub>6</sub> and petroleum ether. [cf Edmundson *Dictionary of Organophosphorus Compounds*, Chapman & Hall, London, 1988, p 221, ISBN 0-412-25790-4.]

**Dicyclohexylphosphine oxide** (Cy<sub>2</sub>PHO) [14717-29-4] **M 214.3, m 72.5-74.5°.** The oxide crystallises from hexane or \*C<sub>6</sub>H<sub>6</sub>. It is tautomeric with dicyclohexylphosphinous acid (Cy<sub>2</sub>P-OH), whose *Ethyl ester* ([80413-46-3] **M 242.3**, obtained from CyP<sub>2</sub>Cl [16523-54-9] and EtOH) distils at **111-113°/1mm, n<sub>D</sub><sup>20</sup> 1.4950.** [Kabachnik et al. *Izv Akad Nauk SSSR, Ser Khim*, 949, 923 (*Engl Trans*) 1967]; and the *trimethylsilyl ester*, **M 286.5**, distils at **108-110°/1mm, n<sub>D</sub><sup>20</sup> 1.4919** [Foss et al. *Zh Obshch Khim* **49** 2418, 2134 (*Engl Trans*) 1979, cf Edmundson *Dictionary of Organophosphorus Compounds*, Chapman & Hall, London, 1988, p 222, ISBN 0-412-25790-4.]

**2-Dicyclohexylphosphino-2',6'-dimethoxybiphenyl (S-Phos)** [657408-07-6] **M 410.5, m 162-162.5°, 164-166°.** This Buchwald phosphine can be synthesised in one pot under argon by adding *n*-BuLi (6.20ml, 2.5M solution in hexanes, 15.5mmol, 1.1 equivalents) *via* a syringe over 5 minutes to a cold (0°) solution of 1,3-dimethoxybenzene (2.00ml, 15.3mmol, 1.1 equivalents, [151-10-0]) in dry THF (35ml), allowing the temperature to rise to ~25°, then it is stirred for 3.5 hours. The mixture is re-cooled (0°) and 2-bromochlorobenzene (1.60ml, 13.7mmol, 1.0 equivalents, [694-80-4]) is added dropwise *via* a syringe over 15 minutes while stirring vigorously; and the burgundy coloured solution is stirred for a further 15 minutes at 0°. At this stage GC analysis of an aliquot quenched with Et<sub>2</sub>O/H<sub>2</sub>O should show that all the bromochlorobenzene has been used up and a clean conversion to 2-bromo-2',6'-dimethoxybiphenyl has occurred. The mixture is cooled to -78° and *n*-BuLi (6.20ml, 2.5M solution in hexanes, 15.5mmol, 1.1 equivalents) is added dropwise *via* a syringe during 5 minutes and stirred further (with swirling if necessary) at -78° for further 30 minutes. Neat chlorodicyclohexylphosphine (3.03ml, 13.7mmol, 1.0 equivalents [16523-54-9]) is then added dropwise *via* syringe, stirred at -78° for 1 hour and allowed to warm to ~25°. The mixture is filtered through a pad of Flash silica gel topped with a layer of Celite, eluted with EtOAc (400ml) and the combined filtrates are evaporated *in vacuo* to give a yellow solid residue which is recrystallised from Me<sub>2</sub>CO to give *S-Phos* (2.90g) as a white solid. A further crop can be obtained by concentrating the mother liquors and triturating with MeOH to provide a total yield of 3.32g (59%) as a white solid m 162-162.5°. Its IR (neat) has ν<sub>max</sub> at 2921, 2848, 1588, 1470, 1459, 1430, 1245, 1109, 909, 722 cm<sup>-1</sup>; and its <sup>1</sup>H NMR (300MHz, C<sub>6</sub>D<sub>6</sub>) has δ at 7.59 (dm, *J* for the doublet 7.2Hz, 1H), 7.39-7.42 (m, 1H), 7.15-7.25 (m, 3H), 6.43 (d, *J* = 8.5 Hz, 2H), 3.33 (s, 6H), 1.60-1.94 (m, 12H), 1.06-1.36 (m, 10H) from TMS; the <sup>13</sup>C NMR (75MHz, C<sub>6</sub>D<sub>6</sub>) has δ at 158.49, 158.48, 144.3, 143.9, 137.3, 137.3, 137.0, 132.82, 132.77, 132.4, 132.2, 129.2, 128.82, 128.81, 128.2, 126.8, 121.2, 121.1, 104.0, 55.2, 35.0, 34.8, 31.0, 30.8, 30.3, 30.1, 28.22, 28.15, 28.07, 28.05, 27.40, 27.39 (observed complexity due to P-C coupling; definitive assignment have not been made); the <sup>31</sup>P NMR (121MHz, C<sub>6</sub>D<sub>6</sub>) has δ at -8.6. [Barder et al. *J Am Chem Soc* **127** 4685 2005.]

Complexation of *S-Phos* to form a Pd-catalyst [e.g. with Pd(OAc)<sub>2</sub>] provides a system with unprecedented scope, reactivity and stability for Suzuki-Miyaura coupling processes, e.g. it generates truly hindered highly chiral biaryls and heterobiaryls [Walker et al. *Angew Chem. Int Ed* **43** 1879 2004, and quinine-quinidine syntheses: Raheem et al. *J Am Chem Soc* **126** 706 2004, Huang et al. *J Am Chem Soc* **125** 6653 2003, Nguyen et al. *J Am Chem Soc* **125** 11818 2003, Gelman & Buchwald *Angew Chem. Int Ed* **42** 5993 2003], and is useful for C-N bond formation [Strieter & Buchwald *Angew Chem. Int Ed* **45** 925 2006].

**2-Dicyclohexylphosphino-2',4',6'-triisopropylbiphenyl (X-Phos, 2,4,6-triisopropyl-2'-dicyclohexylphosphinobiphenyl)** [564483-18-7] **M 476.7, m 182-184°, 187-190°**. This *Buchwald ligand* is prepared by reacting 2,4,6-triisopropylphenylmagnesium bromide with *o*-bromochlorobenzene in the presence of CuCl, and the resulting biphenyl is condensed with dicyclohexylphosphorus chloride. X-Phos is purified by solubilising it in Et<sub>2</sub>O/CH<sub>2</sub>Cl<sub>2</sub> (2:1, *ca* 30ml/g) by sonication, seeding it, and setting aside at -40° for 24 hours to give a first crop which is collected and washed with cold Et<sub>2</sub>O. A second crop can be obtained by concentrating the mother liquors then mixing with hot MeOH (~10ml, at 65°), cooling and while sonicating Et<sub>2</sub>O/CH<sub>2</sub>Cl<sub>2</sub> is added until homogeneous and set aside as before. The combined crops are dried *in vacuo* for 24 hours to give white crystals **m 182-184°**. The IR (film) has  $\nu_{\max}$  at 2923, 1461, 1449, 876 and 768 cm<sup>-1</sup>. It has <sup>1</sup>H NMR (300MHz, C<sub>6</sub>D<sub>6</sub>) with  $\delta_{\text{H}}$  at 7.48-7.42 (m, 1H), 7.24-7.06 (m, 5H), 2.85 (septet, *J* = 6.9Hz, 1H), 2.71 (septet, *J* = 6.9Hz, 2H), 1.94-1.52 (m, 12H), 1.42 (d, *J* = 6.9Hz, 6H), 1.24 (d, *J* = 6.9Hz, 6H), 1.30-1.02 (m, 10H), 1.12 (d, *J* = 6.9Hz, 6H); the <sup>31</sup>P NMR (121MHz, C<sub>6</sub>D<sub>6</sub>) has  $\delta_{\text{P}}$  at -11.5; and the <sup>13</sup>C NMR (75MHz, C<sub>6</sub>D<sub>6</sub>) has  $\delta_{\text{C}}$  at 148.7, 148.6, 148.2, 147.01, 146.99, 137.8, 137.7, 137.60, 137.558, 132.92, 132.88, 132.3, 132.2, 128.2, 127.0, 121.0, 35.4, 35.3, 35.1, 32.1, 31.9, 31.68, 31.66, 30.3, 30.1, 28.6, 28.4, 28.3, 28.2, 27.4, 26.9, 25.0, 23.92, 23.90 (observed complexity from P-C coupling). [Huang et al. *J Am Chem Soc* **125** 6653 2003, Tomori et al. *J Org Chem* **65** 5334 2000.] X-Phos has been used for the amidation of arylsulfonates, in Pd catalysed Suzuki coupling [Johnson et al. *J Org Chem* **71** 7899 2006], annulation of *o*-haloanilines [Jia & Zhu *J Org Chem* **71** 7826 2006], and the synthesis of regioregular polythiophenes [Liversidge et al. *Tetrahedron Lett* **47** 5143 2006.]

***R*(+)- and *S*(-)- *N,N*-Dimethyl-1-ferrocenylethylamine ( $\alpha$ -ferrocenylethylidimethylamine)** [*R*] 31886-58-5; [*S*] 31886-57-4; [*RS*] 31904-34-4] **M 257.2, *R* or *S* b 120-121°/0.7mm,  $d_{25}^{25}$  1.222,  $n_{\text{D}}^{20}$  1.589, *RS* b 111°/0.65mm (part dec),  $n_{\text{D}}^{25}$  1.5883, *R* [ $\alpha$ ]<sub>D</sub><sup>25</sup> + 14.1° (c 1, EtOH), *S* [ $\alpha$ ]<sub>D</sub><sup>25</sup> -14.1° (c 1.6, EtOH)**. The *RS*-amine has been prepared from ferrocenyldimethylaminoacetonitrile and MeMgI [Hauser & Lindsay *J Org Chem* **22** 906 1957], but it is easily obtained by adding a solution of 1-ferrocenylethanol (23.0g, see [1277-49-2]) in toluene (150ml) at -20° dropwise to a stirred solution of phosgene (12.5g) in toluene (100ml) at -20° during ~30 minutes, then allowing to warm to ~20°; and without isolating the chloro-derivative, the mixture is added to a solution of Me<sub>2</sub>NH (22.5g) in propan-2-ol (200ml) at ~20°. The temperature is then allowed to rise to ~25°, the solution is filtered, evaporated to dryness, treated with \*C<sub>6</sub>H<sub>6</sub> which is washed with 8.5% aqueous H<sub>3</sub>PO<sub>4</sub>, more \*C<sub>6</sub>H<sub>6</sub> is added, neutralised with Na<sub>2</sub>CO<sub>3</sub>, the \*C<sub>6</sub>H<sub>6</sub> layer is dried (K<sub>2</sub>CO<sub>3</sub>), filtered and evaporated to give the *RS*-amine (24.2g, 95% crude), which after distillation (b 110°/0.45mm with some decomposition) gives the base as a clear amber oil (17.5g, 68%). Its *picrate* [39699-90-6] forms red plates **m 136-137°** from EtOH. The crude ( $\pm$ )-base is satisfactory for optical resolution. The **resolution** is carried out by stirring a solution of the ( $\pm$ )-base (51.4g) and *R*(+)-tartaric acid (30.0g) in MeOH (100ml) at 55°, seeding, lowering the temperature slowly (2°/hour), and after 24 hours the (-)-base-(+)-acid (30.0g) is obtained which gives the (-)-base (19.0g, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -11.0°, c 1.5, EtOH). This is purified further by mixing it again with the (+)-acid (11.1g), each in MeOH (50ml) at 55°, seeded, and cooled as before to give pure (-)-base-(+)-acid from which pure (-)-base (17.0g, b 120-121°/0.7mm, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -14.1°, c 1.6, EtOH) is isolated. From the mother liquors, the crude (+)-base is converted to the (+)base-(+)tartrate, recrystallised twice from Me<sub>2</sub>CO/H<sub>2</sub>O (10:1), from which pure (+)-base, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -14.1° is obtained as a clear amber oil. [Marquarding et al. *J Am Chem Soc* **92** 3589 1970.] The absolute configuration was determined by X-Ray analysis of the (*S,R,S*)-2-(*p*-methoxyphenyl)hydroxymethyl-*N,N*-dimethyl-1-ferrocenylethylamine [yellow powder from *n*-heptane has **m 110-111°**, [ $\alpha$ ]<sub>D</sub><sup>22</sup> -120.8° (c 1.6, EtOH)] which is obtained by lithiation of the (+)-base, which is highly stereoselective, followed by reaction with *p*-anisaldehyde. [Battelle et al. *J Am Chem Soc* **95** 482 1973.]

This ferrocene is a very useful compound for preparing a variety of chiral ferrocene derivatives [see Marquarding et al. *J Chem Res (S)* 82 1977 and (*M*) 0915 1977], and remarkable phosphine ligands for catalysts by virtue of its highly stereoselective lithiation (with BuLi) in the position *ortho* to the dimethylaminoethyl group that allows substitution to give chiral 2-phosphines [Hayashi et al. *Tetrahedron Lett* 4405 1974], 2—SiMe<sub>3</sub>, 2—CH<sub>2</sub>OH and 2—CPh<sub>2</sub>OH derivatives [Marquarding et al. *J Am Chem Soc* **92** 3589 1970]. The chiral 2-lithio derivative (prepared with *sec*-BuLi/Et<sub>2</sub>O) reacts with sulfur, selenium or tellurium to give the yellow, red or red-brown **dichalcogenides** (*R,S*)-{[E-C<sub>5</sub>H<sub>3</sub>-CHMe(NMe<sub>2</sub>)]Fe(C<sub>5</sub>H<sub>5</sub>)}<sub>2</sub> (from the *R*(+)-base) and (*S,R*)-{[E-C<sub>5</sub>H<sub>3</sub>-CHMe(NMe<sub>2</sub>)]Fe(C<sub>5</sub>H<sub>5</sub>)}<sub>2</sub> (from the *R*(+)-base), where E is S, Se or Te respectively. These dichalcogenides are effective chiral ligands for the rhodium(I) {using [Rh(COD)Cl]<sub>2</sub>}—catalysed asymmetric hydrosilylation of alkyl and aryl ketones with high enantiomeric excesses. The iridium(I) catalyst exhibits lower selectivity [Nishibayashi et al. *JCS Chem Commun* 1375 1994].

The tellurium dichalcogenide (*R,S*)-{Te-C<sub>5</sub>H<sub>3</sub>-CHMe(NMe<sub>2</sub>)]Fe(C<sub>5</sub>H<sub>5</sub>)}<sub>2</sub>, [*R,S*-(*-*)-(Fc\*Te)<sub>2</sub>] is prepared from lithiated *R*-(+)-*N,N*-dimethyl-1-ferrocenylethylamine (with *sec*-BuLi/Et<sub>2</sub>O) in Et<sub>2</sub>O under N<sub>2</sub> at 0° which is then treated with Te powder in portions, and the mixture is subjected to ultrasonic irradiation for 1 hour. The mixture is poured into H<sub>2</sub>O, and air is bubbled through it for 3 hours at ~25°. The solid is collected and purified by column chromatography on activated Al<sub>2</sub>O<sub>3</sub>, and eluting with EtOAc/hexane to give analytically pure [*R,S*-(*-*)-(Fc\*Te)<sub>2</sub>] as a red-brown solid (42%) with *m* 57-58°, [α]<sub>D</sub><sup>25</sup> -622° (c 1, CHCl<sub>3</sub>), the <sup>1</sup>H NMR (270MHz, CDCl<sub>3</sub>) has δ<sub>H</sub> at 1.25 (d, *J* = 6.9Hz, 6H), 2.18 (s, 12H), 4.01 (q, *J* = 6.9Hz, 2H), 4.06 (s, 10H), 4.18 (q, *J* = 1.3Hz, 2H), 4.23 (q, *J* = 1.1Hz, 2H), 4.48 (q, *J* = 1.3Hz, 2H); the <sup>13</sup>C NMR (67.8MHz, CDCl<sub>3</sub>) has δ<sub>C</sub> at 9.6 (q), 39.7 (q), 50.2 (q), 59.5 (q), 67.1 (d), 67.7 (d), 70.7 (d), 76.2 (d), 93.7 (s). [*S,R*-(+)-(Fc\*Te)<sub>2</sub>] is prepared similarly, but from *S*-(*-*)-*N,N*-dimethyl-1-ferrocenylethylamine in 47% yield and has identical physical properties except for [α]<sub>D</sub><sup>25</sup> +613° (c 1, CHCl<sub>3</sub>). After conversion into their anions (e.g. Te<sup>-</sup>Fc\*, with NaBH<sub>4</sub>/EtOH), they react with allylic bromides, e.g. geranyl bromide, to form allylic-TeF\*c which produce the corresponding allylic alcohols (on treatment with Bu<sup>t</sup>OOH/toluene) in 14-22% enantiomeric excess by chirality transfer, possibly *via* a [2,3]-sigmatropic rearrangement [Chiba et al. *Tetrahedron Lett* **36** 1519 1995].

Similarly, but using Se instead of Te, *R*-(+)- and *S*-(*-*)-*N,N*-dimethyl-1-ferrocenylethylamine provide [*R,S*-(Fc\*Se)<sub>2</sub>] (*m* 98-100° from hexane) and [*S,R*-(Fc\*Se)<sub>2</sub>] (*m* 103° from hexane) respectively as red solids, and these catalysts induce highly enantioselective selenoxide elimination to produce axially chiral allene carboxylic esters with high enantiomeric excess [Nishibayashi et al. *Tetrahedron Lett* **35** 3115 1994].

[*R,S*-(Fc\*S)<sub>2</sub>] (*m* 169-170° from hexane) is obtained as a yellow solid in the same way, but using S instead of Se or Te. [See above for the Rh(I)-catalysed asymmetric hydrosilylation reaction of ketones with these dichalcogenide ligands.]

(1*R*,2*R*)-(+)- and (1*S*,2*S*)-(-)-1,2-Diphenylethylenediamine [(1*R*,2*R*)-(+)- and (1*S*,2*S*)-(-)-1,2-diamino-1,2-diphenylenediamine, 1,2-diamino-1,2-diphenylethane, stilbenediamine, DPEN, STEIN] [(*R*) 35132-20-8]; (*S*) 29841-69-8; (*RS*±) 16635-95-3] *M* 212.3, *R* or *S* *m* 79-83°, *RS* *m* 82°, [α]<sub>D</sub><sup>20</sup> *R,R* +102°, *S,S* -102° (c 1, EtOH), [α]<sub>D</sub><sup>23</sup> *R,R* +106°, *S,S* -106° (c 1.1, MeOH), p*K*<sub>(Est1)</sub><sup>25</sup> ~5.86, p*K*<sub>(Est2)</sub><sup>25</sup> ~8.92. The racemate is prepared in two steps. In the first, a mixture of benzil (158g, 0.75mol, [134-81-6]), anhydrous NH<sub>4</sub>OAc (400g) and cyclohexanone (80ml, 0.77mol) in glacial AcOH (1.0L) are stirred and heated under reflux (colour changing from light yellow to dark green) for 1.5 hours, and while hot it is poured into H<sub>2</sub>O (3.0L) with vigorous stirring. After cooling to ~25° overnight, the crystals are collected, washed with H<sub>2</sub>O (4 x 300ml), and crushed in a mortar (*in vacuo*) to give 2,2-spirocyclohexane-4,5-diphenyl-2H-imidazole (2,3-diphenyl-1,4-diazaspiro-[4,5]deca-1,3-diene, [5396-98-5]) (~208g, 96%) as yellow-green crystals, *m* 107-108°, on recrystallisation from hexane or aqueous MeOH. Its <sup>1</sup>H NMR (400MHz, CDCl<sub>3</sub>, TMS) has δ<sub>H</sub> at 1.65-1.92 (m, 6H), 1.95-2.00 (m, 4H), 7.33-7.53 (m, 10H); and its <sup>13</sup>C NMR (100MHz, CDCl<sub>3</sub>) has δ at 24.1, 25.7, 34.7, 104.1, 128.3, 128.9, 129.9, 133.1, 164.0. In the second step, under argon and a Dry-ice condenser, the preceding crude spiroimidazole (72.0g, 0.25mol) in dry THF (400ml, distilled from Na/benzophenone) is stirred until clear, cooled to -78° (Dry-ice/Me<sub>2</sub>CO bath), a stream of gaseous NH<sub>3</sub> is passed through until the volume of homogeneous solution increases to 400ml. Lithium metal (6.94g, 1.0mol, *via* a powder funnel, from wire cut with scissors under a gentle stream of argon) is added at such a rate that the temperature is kept below -65°. The mixture is stirred for 30 minutes, absolute EtOH (30ml, 1.0mol) is added carefully, the mixture is stirred further for 20 minutes and NH<sub>4</sub>Cl (70g) is added. The cooling bath is removed, the reaction temperature is made to rise to 0°, H<sub>2</sub>O (400ml) is carefully added and the liquid phases are allowed to separate. The aqueous phase is extracted with Et<sub>2</sub>O (3 x 300ml), the combined organic phases are washed with saturated aqueous NaCl (brine), dried (Na<sub>2</sub>SO<sub>4</sub>), filtered, evaporated down (to 200ml), and while being kept at 0°, 2 N aqueous HCl (300ml) is added slowly, then the two phases are stirred vigorously for 1 hour at ~25°, H<sub>2</sub>O (500ml) is added and the phases are separated. The organic layer is treated with H<sub>2</sub>O (150ml) and extracted with CH<sub>2</sub>Cl<sub>2</sub> (to remove any cyclohexanone). All the aqueous acidic phases are combined, and carefully (cool if necessary) basified with 2N aqueous NaOH (300ml) and extracted with CH<sub>2</sub>Cl<sub>2</sub> (4 x 300ml); the combined extracts are washed with brine, dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and evaporated *in vacuo* to give crude ±STEIN (~40g, ~90%) as a light yellow solid *m* 81-82°. Its <sup>1</sup>H NMR (400MHz, CDCl<sub>3</sub>, TMS) has δ<sub>H</sub> at 1.59 (br s, 4H), 4.10 (s, 2H), 7.2-7.3 (m, 10H); and its <sup>13</sup>C NMR (100MHz, CDCl<sub>3</sub>) has δ at 61.9, 126.8, 126.9, 128.2, 143.4.

The optical resolution is carried out by adding carefully a hot (70°) homogeneous solution of (L)-(+)-tartaric acid (30.0g, 0.20mol) in EtOH (230ml) to a hot (70°) solution of ±STEIN (42.5g, 0.20mol) in EtOH (230ml)

(care exothermic, EtOH may boil) with stirring. The tartrate salts separate immediately and the mixture is cooled to  $\sim 25^\circ$ , the salts are filtered off, washed with EtOH (2 x 60ml), dried *in vacuo*, dissolved in boiling H<sub>2</sub>O (230ml), EtOH (230ml) is added and the clear solution is cooled slowly to  $\sim 25^\circ$ . The crystals are collected by filtration, washed with EtOH (40ml), dried *in vacuo*, and recrystallised twice as before [from boiling H<sub>2</sub>O (230ml), and EtOH (230ml)] to give the colourless (-)-*diamine*-(+)-*tartrate salt* ( $\sim 24\text{g}$ ,  $\sim 66\%$ ) with  $[\alpha]_{\text{D}}^{23} -10.8^\circ$  (c 1.2, H<sub>2</sub>O). To this (-)-(+)-salt suspended in H<sub>2</sub>O (300ml) and vigorously stirred at 0-5 $^\circ$ , is added dropwise an aqueous solution of 50% NaOH (23ml) followed by CH<sub>2</sub>Cl<sub>2</sub> (150ml), and is stirred for 30 minutes; the phases are separated, the aqueous phase is extracted with CH<sub>2</sub>Cl<sub>2</sub> (2 x 50ml), the organic layers are combined, washed with brine, dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and evaporated *in vacuo* to give a colourless solid that is recrystallised from hexane to provide  $>98\%$  optically pure *S,S*-(-)-*diphenylethylenediamine* as colourless crystals with the properties stated in the title and with NMR spectra same as the racemate.

To obtain the enantiomeric diamine, all the filtrates from above are combined, evaporated to dryness *in vacuo*, the residue is stirred vigorously in H<sub>2</sub>O (250ml), treated with aqueous 50% NaOH (25ml) then CH<sub>2</sub>Cl<sub>2</sub> (200ml), stirred further for 30 minutes, the phases are separated, the aqueous phase is extracted with CH<sub>2</sub>Cl<sub>2</sub> (2 x 50ml), the combined extracts are washed with brine, dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and evaporated *in vacuo* to give enriched *R,R*-(+)-*diamine* ( $\sim 26\text{g}$ ) as pale yellow crystals. This is treated with (D)-(-)-tartaric acid as in the above and gives relatively impure (+)-*diamine*-(-)-*tartrate salt* ( $\sim 31\text{g}$ ,  $\sim 85\%$ ,  $[\alpha]_{\text{D}}^{23} +4^\circ$  (c 1.2, H<sub>2</sub>O). However, recrystallisation of this salt did not improve its optical purity, but treatment with 50% NaOH and extraction as above etc, and crystallisation from hexane gave optically pure *R,R*-(+)-*diphenylethylenediamine* as colourless crystals with  $[\alpha]_{\text{D}}^{23} +106^\circ$  (c 1.1, MeOH), and NMR spectra as obtained with the racemate. The optical purity can be confirmed by the <sup>1</sup>H NMR of their (L)-mandelate salts (*cf* Benson et al. *J Org Chem* **53** 5335 1988). These diamines were used successfully in highly stereoselective epoxidation [Zhang et al. *J Am Chem Soc* **112** 2801 1990], aldol, Diels-Alder [Corey et al. *J Am Chem Soc* **111** 5493 1989], allylation [Corey et al. *J Am Chem Soc* **111** 5495 1989], osmylation [Corey et al. *J Am Chem Soc* **111** 2943 1989] reactions; as well as enantioselective Michael additions [Bruner & Hammer *Angew Chem Inter Ed Eng* **23** *J Am Chem Soc* **111** 5493 1989] 312 1984] and asymmetric hydrogenation [Fiorini & Giongo *J Mol Cat* **5** 303 1979]. [Corey et al. *J Am Chem Soc* **111** 5493 1989, Pikul & Corey *Org Synth* **71** 22 1993 and references herein.]

This diamine has been used successfully as a Trost ligand with Pd(dba)<sub>2</sub> to catalyse a Heck reaction, but it is not, albeit, as commonly used as DACH (*trans*-1,2-diaminocyclohexane) ligands.

***R*-(+) and *S*-(-)-2-[2-(Diphenylphosphino)phenyl]-4-isopropyl-2-oxazoline** [*R*-(+)- and *S*-(-)-2-[2-(diphenylphosphino)phenyl]-4,5-dihydro-4-isopropylloxazole [*R*- 164858-78-0; *S*- 148461-14-7] M 373.4, m 85-89 $^\circ$ ,  $[\alpha]_{\text{D}}^{20}$  *R* +48 $^\circ$  and *S* -48 $^\circ$  (c 1.4, CHCl<sub>3</sub>). The 4*S*-(-) enantiomer can be obtained by decomposing the 4*S*-(+)-Zinc II dichloride complex [crystallises from *tert*-butyl-methyl-ether/CHCl<sub>3</sub> as colourless crystals m 221-223 $^\circ$ ,  $[\alpha]_{\text{D}}^{20} +53^\circ$  (c 1.52, CHCl<sub>3</sub>)] (9.5g, 17.5mmol) in CHCl<sub>3</sub> (130ml) under argon with 2,2'-dipyridyl (2.72g, 1.74mmol) at  $\sim 25^\circ$  for 1 hour (stirring), then the mixture is applied directly onto a silica-gel column (6 x 7 cm), eluted with CHCl<sub>3</sub> or EtOAc (800ml), and the eluate is evaporated to yield the desired 4*S*-(-)-oxazoline (6.78g 95%) as a colourless solid which can be recrystallised from petroleum ether/Et<sub>2</sub>O. On TLC (silica gel 60 Merck, 0.25mm F245) it has R<sub>F</sub> 0.40 (hexane/EtOAc 6/1); the IR (CHCl<sub>3</sub>) has  $\nu_{\text{max}}$  at 3070w, 3060m, 3010m, 2965s, 2905m, 2875m, 1950w, 1885w, 1815w, 1650s, 1585w, 1480m, 1470w, 1435s, 1355m, 1310m, 1245m, 1090s, 1050m, 1030m, 965m cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, CDCl<sub>3</sub>) has  $\delta_{\text{H}}$  at 0.70 (d, *J* = 6.8Hz, 3H, CH(CH<sub>3</sub>)<sub>2</sub>), 0.81 (d, *J* = 6.8Hz, 3H, CH(CH<sub>3</sub>)<sub>2</sub>), 1.43-1.54 (m, 1H, CH(CH<sub>3</sub>)<sub>2</sub>), 3.80-3.90 (m, 2H, H<sub>2</sub>C(5)), 4.09-4.19 (m, 1H, HC(4)), 6.85-6.89 (m, 1H, HC(4')), 7.24-7.37 (m, 12 H, arom. H), 7.88-7.92 (m, 1H, HC(6')); the <sup>13</sup>C NMR (75MHz, CDCl<sub>3</sub>) has  $\delta_{\text{C}}$  at 18.3 (CH(CH<sub>3</sub>)<sub>2</sub>), 18.9 (CH(CH<sub>3</sub>)<sub>2</sub>), 32.7 (CH(CH<sub>3</sub>)<sub>2</sub>), 70.0 (H<sub>2</sub>C(5)), 73.1 (HC(4)), 127.8, 128.05, 128.16, 128.26, 128.27 (d, *J*<sub>PC</sub> = 15Hz), 129.6 (d, *J*<sub>PC</sub> = 3Hz), 130.1, 133.5 (d, *J*<sub>PC</sub> = 20Hz), 133.7, 134.1 (d, *J*<sub>PC</sub> = 21Hz)(arom CH), 131.7 (d, *J*<sub>PC</sub> = 19Hz), 137.9 (d, *J*<sub>PC</sub> = 10Hz), 138.1 (d, *J*<sub>PC</sub> = 12Hz), 138.8 (d, *J*<sub>PC</sub> = 25Hz)(arom. H), 162.7 (d, *J*<sub>PC</sub> = 3Hz, C(2)); and the <sup>31</sup>P NMR (121MHz, CDCl<sub>3</sub>, triphenyl phosphate external standard at -18ppm) has  $\delta$  at -5.8.

***S*-(+)-2-[2-(diphenylphosphino)phenyl]-4,5-dihydro-4-phenylloxazole** [148461-15-6] M 407.4, m 89-93 $^\circ$ ,  $[\alpha]_{\text{D}}^{20} +29.5^\circ$  (c 1, CHCl<sub>3</sub>) and ***R*-(-)-2-[2-(diphenylphosphino)phenyl]-4,5-dihydro-4-phenylloxazole** [167171-03-1] M 407.4, m 89-93 $^\circ$ ,  $[\alpha]_{\text{D}}^{20} -29.5^\circ$  (c 1, CHCl<sub>3</sub>) were prepared as for the 4-isopropylloxazole above and have R<sub>F</sub> 0.27 (hexane/EtOAc 5/1). [Koch et al. *Rec Trav Chim Pays Bas* **114** 206 1995.]

With an iridium catalyst they promote asymmetric alkylation [Janssen & Helchen *Tetrahedron Lett* **38** 8025

1997], and are chiral ligands for asymmetric reduction reactions [lightfoot et al. *Angew Chem Int Ed Engl* **110** 3047 1998]. These ligands, when complexed with Ni(COD)<sub>2</sub>, promote the regio and stereoselective addition of allylic sulfides to alkynes; a reaction which tolerates a variety of functional groups [Hua et al. *Org Lett* **9** 263 2007]. These types of ligands also promote Pd-catalysed allylic substitution reactions [von Matt & Pflatz *Angew Chem* **105** 614 1993, Williams et al. *Tetrahedron Lett* **34** 3149 1993].

**Diphenylphosphine** [829-85-6] **M 186.2, b 100-102°/1.5mm, 150-151°/12mm, 156-157°/16mm, 165°/25mm, 280°/atm, d<sup>25</sup> 1.07, n<sub>D</sub><sup>20</sup> 1.6269, pK 0.03.** This toxic and flammable phosphine is prepared under N<sub>2</sub> by adding dropwise a solution of chlorodiphenylphosphine (50g, [1079-66-9]) in dry Et<sub>2</sub>O (75ml) to a solution/suspension of LiAlH (2.6g) in absolute Et<sub>2</sub>O (75ml), then boiling the mixture under reflux for 1 hour, adding H<sub>2</sub>O (6ml, carefully and with cooling) and stirring for 2-3 hours. The Et<sub>2</sub>O layer is collected, dried (CaCl<sub>2</sub>), decanted, evaporated and the residue is distilled *in vacuo* to give the phosphine (70%) as a colourless oil [Kucken & Buchwald *Chem Ber* **91** 2871 1958]. Alternatively, Ph<sub>2</sub>ClP is reacted with Na in dry *n*-Bu<sub>2</sub>O under N<sub>2</sub> to give Ph<sub>2</sub>PNa which is treated with EtOH, boiled under reflux for 30 minutes, poured into H<sub>2</sub>O, extracted with Et<sub>2</sub>O which is separated, dried (CaCl<sub>2</sub>), decanted, evaporated and the residue is distilled *in vacuo* to give the phosphine (72%) [Kucken & Buchwald *Chem Ber* **92** 227 1959]. [Beilstein **16** H 758, **16** II 371, **16** III 833, **16** IV 950.]

**2-(Diphenylphosphino)benzoic acid [(2-carboxyphenyl)diphenylphosphine]** [17261-28-8] **M 306.3, m 174-177°, 175-176° (187-188°), pK<sub>Est</sub> ~2.7.** The benzoic acid is prepared by first adding Na (15.3g, 667mmol, cut in ~1g pieces) carefully to liquid NH<sub>3</sub> (1.5L) with stirring until a blue colour is persistent (**use an efficient fume cupboard**), then adding PPh<sub>3</sub> (87.4g, 330mmol) in small portions during 30-40 minutes with swirling to dissolve any Na on the sides of the flask. After 2.5 hours the red-orange colour of the solution of NaPPh<sub>2</sub> is treated with 2-chlorobenzoic acid (52.2g, 330mmol) in small portions over 30-40 minutes followed by anhydrous THF (500ml, using a syringe), and the resulting solution is allowed to warm to room temperature overnight under a blanket of argon. As the solution warms, the colour of the red solid turns to gold with mild evolution of heat results. The residue is dissolved in H<sub>2</sub>O (1.4L) and extracted with Et<sub>2</sub>O (400ml) which is discarded. The aqueous layer is acidified to pH 2 with concentrated HCl (~60ml), and extracted with CH<sub>2</sub>Cl<sub>2</sub> (3 x 200ml), the extract is washed with H<sub>2</sub>O (500ml), evaporated to *ca* 125ml, and MeOH (~50ml) is added to precipitate the pale-yellow crystalline acid (requiring inducement sometimes) which is collected and dried to give the phosphino-acid (50g, 49%) which provides analytically pure acid (C, H and P) on recrystallisation from a minimum amount of boiling MeOH. The air stable compound forms yellow needles from aqueous EtOH, is soluble in halogenated solvents and Et<sub>2</sub>O, but is less soluble in other solvents. Its IR (Nujol) has  $\nu_{\max}$  at 3200 (OH), 1690 (CO), 1275 cm<sup>-1</sup>. The *methiodide* crystallises from Me<sub>2</sub>CO/\*C<sub>6</sub>H<sub>6</sub> with **m 169-173°(dec)**, and the *phosphine oxide* [2572-40-9] **M 322.3 has m 262-264° (252-254° and 274-275° are also reported), pKa 5.06 and 5.37** (in 50% aqueous EtOH) and crystallises from EtOH, aqueous EtOH or aqueous AcOH. With diazomethane, *methyl 2-(diphenylphosphino)benzoate* is obtained in 85% yield; it forms colourless crystals from MeOH with **m 96-97°**, its IR (Nujol) has  $\nu_{\max}$  at 1712 (C=O) cm<sup>-1</sup>, and the <sup>1</sup>H NMR (90MHz, CDCl<sub>3</sub>) has  $\delta_{\text{H}}$  at 7.6-6.9 (m, 14H), 3.70 (s, 3H), and the <sup>31</sup>P NMR (40.5MHz, CDCl<sub>3</sub>) has  $\delta$  at 5.10 upfield of 85% H<sub>3</sub>PO<sub>4</sub>. [Rauchfuss et al. *J Am Chem Soc* **103** 6769 1981, Hoots et al. *Inorg Chem* **21** 178 1982.] It is used for preparing the DACH-Trost phenyl ligand above.

**S(-)-2-Ferrocenyl-4-(1-methylethyl)oxazoline [S(-)-4-isopropylxazo-2-yl ferrocene]** [162157-03-1] **M 297.0, m 71.5-72.5° (m 61-62°), [α]<sub>D</sub><sup>22</sup> -129° (c 1.5, EtOH), CD (CHCl<sub>3</sub>) λ<sub>max</sub> (Δε) 464 (-080), 358 (+1.0)nm.** This complex is prepared in three steps from ferrocenecarboxylic acid (1.33g, 4.49mmol, 1271-42-7), **firstly** by converting it into the acid chloride with oxalyl chloride (0.79g, 9mmol) in CH<sub>2</sub>Cl<sub>2</sub> (15ml) under N<sub>2</sub> at ~25° until gas evolution ceased (~10 minutes), stirring for 10 minutes further, and the solution is evaporated to dryness *in vacuo*. **Secondly** the crude dark red oily acid chloride (that solidified on standing) is dissolved in CH<sub>2</sub>Cl<sub>2</sub> (10ml) and added (syringe) to a solution of S(+)-valinol (0.554g, 5.37mmol) and Et<sub>3</sub>N (1.25ml, 9mmol) in CH<sub>2</sub>Cl<sub>2</sub> (7ml) under N<sub>2</sub> at ~25°. After standing overnight, the mixture is washed with H<sub>2</sub>O (2 x 20ml), dried (Na<sub>2</sub>SO<sub>4</sub>), filtered, and evaporated to dryness *in vacuo*. The residue is purified by column chromatography on SiO<sub>2</sub> (40-83mm), eluting with 3% MeOH/CH<sub>2</sub>Cl<sub>2</sub>, to give analytically pure **2S-N-(1-hydroxy-3-methylbutyl)-ferrocenamido** (1.184g, 84%) with **m 109-110°, [α]<sub>D</sub><sup>21</sup> -8° (c 1.34, EtOH)**. It has IR (nujol) with  $\nu_{\max}$  at 3284 (N-H), 3192 (O-H), 1611 (C=O amide I), 1551 (amide II) cm<sup>-1</sup>; the <sup>1</sup>H NMR (360MHz, CDCl<sub>3</sub>) has  $\delta_{\text{H}}$  at 0.97

(d, 3H,  $J = 6.8\text{Hz}$ ,  $-\text{CH}_3$ ), 0.98 (d, 3H,  $J = 6.8\text{Hz}$ ,  $-\text{CH}_3$ ), 1.93 (octet, 1H,  $J = 6.8\text{Hz}$ ,  $-\text{CH}(\text{CH}_3)_2$ ), 2.71 (brt, 1H,  $-\text{OH}$ ), 3.56-3.83 (m, 3H,  $-\text{CH}_2\text{OH}$  and  $-\text{NHCH}-$ ), 4.16 (s, 5H,  $\text{C}_5\text{H}_5$ ), 4.30 (brs, 2H, Fc), 4.60 (brs, 1H, Fc), 4.62 (brs, 1H, Fc), 5.80 (brd, 1H,  $-\text{NH}-$ ); the  $^{13}\text{C}$  NMR (90MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}\{^1\text{H}\}$  at 19.04 ( $-\text{CH}_3$ ), 19.69 ( $-\text{CH}_3$ ), 28.99 ( $-\text{CH}(\text{CH}_3)_2$ ), 57.01 ( $-\text{NHCH}-$ ), 63.87 ( $-\text{OCH}_2-$ ), 67.91 (Fc), 68.42 (Fc), 69.75 ( $\text{C}_5\text{H}_5$ ), 70.46 (Fc), 70.51 (Fc), 75.95 (Fc  $-\text{ipso}$ ), 171.37 (C=O); and the MS (EI) has  $m/z$  315 ( $\text{M}^+$ , 100%), 213 (81%). **Thirdly**, to a light orange solution of the preceding *S*-(-)-amide (0.817g, 2.59mmol) and  $\text{Ph}_3\text{P}$  (2.49g, 9.5mmol) in dry MeCN (60ml) is added  $\text{Et}_3\text{N}$  (1.6ml, 11.5mmol) followed by  $\text{CCl}_4$  (2.2ml, 22.8mmol), and the mixture is stirred at  $\sim 25^\circ$  overnight. Water (80ml) is added to the mixture which is extracted with petroleum ether (5 x 50ml), the combined organic layers are dried ( $\text{MgSO}_4$ ), filtered, and evaporated to dryness *in vacuo*. The residue is contaminated with  $\text{Ph}_3\text{PO}$ , and is purified through column chromatography ( $\text{SiO}_2$ , 40-83mm) and eluting with 30% EtOAc/petroleum ether (b 40-60 $^\circ$ ) to give analytically pure ferrocenyl oxazoline as dark yellow crystals (0.685g, 89%) with **m 71.5-72.5 $^\circ$** . Note that much lower yields of product are obtained if the solvent is removed from the reaction mixture before work-up. It has IR (nujol) with  $\nu_{\text{max}}$  at 1657 (C=N)  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (360MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 0.87 (d, 3H,  $J = 6.8\text{Hz}$ ,  $-\text{CH}_3$ ), 0.94 (d, 3H,  $J = 6.8\text{Hz}$ ,  $-\text{CH}_3$ ), 1.78 (hextet, 1H,  $J = 6.6\text{Hz}$ ,  $-\text{CH}(\text{CH}_3)_2$ ), 3.41 (q, 1H,  $J = 7.0\text{Hz}$ ,  $-\text{NHCH}-$ ), 3.89-3.95 (m, 1H,  $-\text{OCHH}-$ ), 4.00 (t, 1H,  $J = 7.7\text{Hz}$ ,  $-\text{OCHH}-$ ), 4.06 (s, 5H,  $\text{C}_5\text{H}_5$ ), 4.26 (brs, 2H, Fc), 4.66 (brs, 1H, Fc), 4.70 (brs, 1H, Fc); the  $^{13}\text{C}$  NMR (90MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}\{^1\text{H}\}$  at 17.79 ( $-\text{CH}_3$ ), 18.81 ( $-\text{CH}_3$ ), 32.27 ( $-\text{CH}(\text{CH}_3)_2$ ), 68.92, 68.95, 69.27, 69.51 ( $\text{C}_5\text{H}_5$ ), 70.06, 70.09, 70.60 (Fc  $-\text{ipso}$ ), 72.27, 165.56 (C=N); and the MS (EI) has  $m/z$  297 ( $\text{M}^+$ , 100%), 254 (64%), 211 (47%), 121 (92%). [Richards & Mulvaney *Tetrahedron Asymm* 7 1419 1996.] The *R*-enantiomer is prepared in the same way by using *R*(+)-valinol. Similarly prepared while using the respective chiral *S*-2-aminoethanols were *S*-(-)-4-methyloxazol-2-yl ferrocene [red solid, 96% yield, **m 84-85 $^\circ$** ,  $[\alpha]_{\text{D}}^{27} -60^\circ$  (c 0.2, EtOH), CD ( $\text{CHCl}_3$ )  $\lambda_{\text{max}}$  ( $\Delta\epsilon$ ) 461 (+0.34), 336 (-0.25)nm], *S*-(-)-4-ethyloxazol-2-yl ferrocene [orange solid, 34% yield, **m 47-48 $^\circ$** ], *S*-(-)-4-tert-butyloxazol-2-yl ferrocene [orange-red solid, 34% yield, **m 127-128 $^\circ$** ,  $[\alpha]_{\text{D}}^{24} -150^\circ$  (c 2.1,  $\text{CH}_2\text{Cl}_2$ )], and among others where the 4-alkyl group is replaced by isobutyl, *sec*-butyl, benzyl, phenyl, 4,5-diphenyl, 1-hydroxy-1-methylethyl, 1-methoxy-1-methylethyl, 1-hydroxy-1-ethylpropyl, 1-methoxy-1-ethylpropyl, hydroxymethyl, methoxymethyl, and several more [Sammakia et al. *J Org Chem* 60 10 1995, Nishibayashi et al. *J Organomet Chem* 545-546 381 1997, Richards & Mulvaney *Tetrahedron Asymm* 7 1419 1996.] An independent synthesis of the title compound from *S*-(-)-valinol,  $\text{ZnCl}_2$ , cyanoferrocene in refluxing chlorobenzene under  $\text{N}_2$  for 72 hours followed by column chromatography ( $\text{SiO}_2$ , eluting with hexane/EtOAc) gave a red solid (40% yield based on cyanoferrocene) **m 61-62 $^\circ$**  [note difference in m.p.] but with similar  $^1\text{H}$  and  $^{13}\text{C}$  NMR. Other chiral derivatives, some mentioned above, were also obtained in this way. [Nishibayashi et al. *J Organomet Chem* 545-546 381 1997.]

**Iridium(III) acetylacetonate [tris(pentane-2,4-dionato)iridium,  $\text{Ir}(\text{acac})_3$ ] [15635-87-7] M 489.5, m 269-271 $^\circ$** . Iridium sulfate solution is made from freshly precipitated iridium dioxide (from 1.0g of potassium hexachloridate) by heating it with 1N  $\text{H}_2\text{SO}_4$  (25ml) until the acid begins to fume. The solution is diluted to its original volume, and undissolved iridium oxide is removed by centrifugation. The light green solution is treated with 10% aqueous NaOH until the green iridium III hydroxide precipitate just begins to redissolve. This precipitation should be rapid in order to avoid oxidation; the pH of the solution is adjusted to 6, and the mixture is heated at 60 $^\circ$  with acetylacetone (2ml) for one hour. The solution becomes red and deposits a yellow crystalline precipitate. This iridium complex is collected and crystallises from aqueous MeOH in rhombic plates (0.1g, 10%, m 269 $^\circ$ ). It is insoluble in  $\text{H}_2\text{O}$ , slightly soluble in EtOH and petroleum ether, but freely soluble in  $^*\text{C}_6\text{H}_6$  and  $\text{CHCl}_3$ . It is stable in boiling dilute acids and 10% aqueous NaOH. It sublimes at 260 $^\circ$ /1mm, but decomposes above 290 $^\circ$  depositing an iridium mirror. Molecular weight determination ( $\sim 400$ , by Rast in camphor) indicates that it is monomeric. [Dwyer & Sargeson *J Am Chem Soc* 75 984 1953, Beilstein 1 IV 3678.] It is a useful precursor for making Iridium complexes.

**3,4-O-isopropylidene-(3*S*,4*S*)-dihydroxy-(2*R*,5*R*)-bis(diphenylphosphino)hexane (RSSR-dimeDIOP, or *R,S,S,R*-DIOP\*, DIOP starred, in dedication to Professor Kagan) [258873-45-9] M 526.2, low melting oil,  $[\alpha]_{\text{D}}^{24}$  (+) 41.8 $^\circ$  (c 0.88,  $\text{PhCH}_3$ ),  $\text{pK}_{\text{Est}} \sim 0.0$ . The starting material for this ligand is the readily available D-mannitol that is converted to the isopropylidene diepoxide, which in turn is converted to 3,4-*O*-isopropylidene-(3*S*,4*S*)-dihydroxy-(2*S*,5*S*)-hexane. The latter (2.2g, 11.6mmol), and  $\text{Et}_2\text{NH}$  (4.9ml, 34.8mmol) in  $\text{CH}_2\text{Cl}_2$  (30ml) is added dropwise to a solution of  $\text{MeSO}_2\text{Cl}$  (2.0ml, 25.8mmol) in  $\text{CH}_2\text{Cl}_2$  (10ml) at 0 $^\circ$ , kept at 0 $^\circ$  for 30 minutes, stirred at  $\sim 25^\circ$  for 30 minutes, and treated with saturated aqueous  $\text{NH}_4\text{Cl}$ . The layers are separated, the**

aqueous phase is extracted with  $\text{CH}_2\text{Cl}_2$ , the combined organic phases are dried ( $\text{Na}_2\text{SO}_4$ ), evaporated and the residue is purified by flash chromatography on silica gel, eluting with  $\text{CH}_2\text{Cl}_2/\text{Et}_2\text{O}$  (9/1) to give **3,4-O-isopropylidene-(3S,4S)-bis(mesyloxy)-(2S,5S)-hexane** (3.85g, 96%) as a colourless oil. This is a useful intermediate for making a variety of phosphine ligands and has  $[\alpha]_{\text{D}}^{24}$  (-) **1.3°** (c **1.04**,  $\text{CHCl}_3$ ); its  $^1\text{H}$  NMR (360MHz,  $\text{CDCl}_3$ ) has  $\delta$  at 4.82-4.76 (m, 2H), 3.99-3.96 (m, 2H), 3.03 (s, 6H), 1.45 (d,  $J = 6.6, 6.0\text{Hz}$ ), 1.37 (s, 6H); and the  $^{13}\text{C}$  NMR (90MHz,  $\text{CDCl}_3$ ) has  $\delta$  at 110.14, 78.19, 76.26, 38.53, 26.75, 17.63; and HRMS has found  $m/z$  347.0834, calcd for  $\text{C}_{11}\text{H}_{23}\text{O}_8\text{S}_2$  ( $\text{MH}^+$ ) is 347.0834. The preceding dimesylate (1.04g, 3.0mmol) in THF (20ml) is added to the orange solution at  $-78^\circ$  of  $\text{Ph}_2\text{PLi}$  [prepared under  $\text{N}_2$ , from  $\text{Ph}_2\text{PH}$  (1.15ml, 6.6mmol) in THF (50ml) to which is added *via* a syringe *n*-BuLi in hexane (4.0ml, 6.4mmol) at  $-78^\circ$  during 5 minutes, warmed to  $\sim 25^\circ$  while stirring for 1 hour, and cooling to  $-78^\circ$  again] during 20 minutes. The orange solution is warmed to  $\sim 25^\circ$ , stirred overnight, the resulting white suspension is hydrolysed with saturated aqueous  $\text{NH}_4\text{Cl}$ , the aqueous layer is extracted with  $\text{CH}_2\text{Cl}_2$ , the combined organic layers are dried ( $\text{Na}_2\text{SO}_2$ ), filtered, evaporated and the residue is purified by flash chromatography on silica gel, eluting with hexane/ $\text{Et}_2\text{OAc}$  (95/5), or hexane/ $\text{Et}_2\text{O}$  (95/5) to give (+)-RSSR-DIOP\* (1.06g, 67%) as a colourless oil or low melting white solid respectively. Its  $^1\text{H}$  NMR (360MHz,  $\text{CDCl}_3$ ) has  $\delta$  at 7.56-7.52 (m, 8H), 7.38-7.33 (m, 12H), 3.78-3.76 (m, 2H), 2.50-2.46 (m, 2H), 1.14 (s, 6H), 0.91 (d,  $J = 7.0\text{Hz}$ , 3H), 0.87 (d,  $J = 6.9\text{Hz}$ , 3H); the  $^{13}\text{C}$  NMR (90MHz,  $\text{CD}_2\text{Cl}_2$ ) has  $\delta$  at 137.46 (d,  $J = 15.9\text{Hz}$ ), 137.03 (d,  $J = 15.5\text{Hz}$ ), 134.14 (d,  $J = 3.7\text{Hz}$ ), 133.91 (d,  $J = 4.0\text{Hz}$ ), 129.30 (d,  $J = 8.6\text{Hz}$ ), 128.75 (d,  $J = 7.1\text{Hz}$ ), 108.27 (dd,  $J = 12.0, 6.8\text{Hz}$ ), 31.33 (d,  $J = 14.3\text{Hz}$ ), 27.05, 10.74 (d,  $J = 17.6\text{Hz}$ ); the  $^{31}\text{P}$  NMR ( $\text{CDCl}_3$ ) has  $\delta$  at -6.3 (-5.42); and the HRMS has found  $m/z$  527.2771, calculated for  $\text{C}_{33}\text{H}_{37}\text{O}_2\text{P}_2$  ( $\text{MH}^+$ ) is 527.2269. [Li & Zhang *J Org Chem* **65** 5871 2000, Yan & RajanBabu *Org Lett* **26** 4137 2000.]

**Lithium tetrachloropalladate(II) hydrate** ( $\text{Li}_2\text{PdCl}_4 \cdot x\text{H}_2\text{O}$ ) [123334-21-4] **M 262.1 (anhydrous)**. It is commercially available as a powder or in chunks. A 0.5M solution of water-free  $\text{Li}_2\text{PdCl}_4$  in dry MeOH for the preparation of Pd catalysts (e.g. see *Oxime Palladacycles* above) is made by stirring anhydrous LiCl (42.4g, 1 mole, dried at  $130^\circ$  to constant weight, several hours, see [7447-41-8]) and anhydrous  $\text{PdCl}_2$  (88.6g, 0.5 mole, see [7647-10-1]) in dry MeOH (1L) until the solution is homogeneous. Store the solution under  $\text{N}_2$  or argon. [Onue, Minami and Nakagawa *Bull Chem Soc Jpn* **43** 3480 1970.]

**$\eta^5$ -(S)-(pR)-2-(2'-(4'-Methylethyl)-oxazoliny)cyclopentadienyl,1-C-3'-N)( $\eta^4$ -tetraphenylcyclobutadiene) cobalt** [222400-02-4] **M 591.6, m 160-162°**,  $[\alpha]_{\text{D}}^{24}$  -55.2° (c **0.09**,  $\text{CHCl}_3$ ). This cobalt complex is the key intermediate for the preparation of all the cobalt oxazoline palladacycle (COP) catalysts described in Part 1. Although originally prepared in four distinct steps [Stevens & Richards *Organometallics* **18** 1346 1999], the synthesis has been slightly modified and can be completed in two steps without purifying intermediates. **Firstly**,  **$\eta^5$ -(carbomethoxycyclopentadienyl)-( $\eta^4$ -tetraphenylcyclobutadiene)cobalt** [182627-81-2] is prepared (using Schlenk equipment flushed with argon) in a triple-necked flask with two rubber septa containing sodium cyclopentadienide (20ml, 2.0M in THF, 40mmol, [4984-82-1], should be light red/orange in colour; discard if black or contains solid residues), anhydrous THF (20ml *via* a syringe, pre-filtered through activated  $\text{Al}_2\text{O}_3$ ), then dimethyl carbonate (10.2ml, 120mmol, *via* a syringe), and the mixture is stirred and boiled under reflux for 4 hours before cooling to  $\sim 25^\circ$ . [The intermediate can be isolated but this is not necessary.] To the cooled mixture is added dry toluene (160ml, *via* a syringe), followed by chlorotris(triphenylphosphine)cobalt(I) (30.8g, 34.8mmol, see above [26305-75-9], preferably freshly prepared for higher yields) and diphenylacetylene (14.2g, 80mmol, recrystallised from EtOH), and heated at reflux for 5 hours, cooled to  $\sim 25^\circ$  before transferring to a single-necked flask and evaporating to dryness *in vacuo*. The residue is suspended in hexanes (150ml), the solid is filtered off, washed with hexanes ( $\sim 3.5\text{L}$ ) until the filtrate is colourless. The dark mustard-coloured solid is dissolved from the filter by washing with  $\text{CH}_2\text{Cl}_2$  until the filtrate is colourless (discard any insoluble black solid) and evaporate the combined filtrates *in vacuo* to give the **Cobalt-ester** (12.7g, 67%) as a mustard-coloured solid. It can be purified by column chromatography on Matrix silica 60 (35-70 $\mu\text{m}$ , eluting with 20% EtOAc/petroleum ether b 40-60°) to give the **Cobalt-ester** as an orange crystalline solid **m 240-244°** [lit **m 246-248°** Mabrouk & Rauch *J Organomet Chem* **523** 111 1996]. It has IR (thin film) with  $\nu_{\text{max}}$  at 3058, 2953, 1713, 1596, 1498, 1467, 1281, 1140  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (500MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 3.23 (s, 3H), 4.79 (t,  $J = 2.0\text{Hz}$ , 2H), 5.21 (t,  $J = 2.0\text{Hz}$ , 2H), 7.22-7.30 (m, 12H), 7.43-7.45 (m, 8H); and the  $^{13}\text{C}$  NMR (125MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}$  at 51.4, 76.5, 84.7, 86.6, 86.8, 126.9, 128.2, 129.0, 135.3, 166.6. [Anderson, Overman, Richards, Watson and

White *Org Synth* **84** 139 2007.]

**Secondly**,  $\eta^5$ -(*S*)-(p*R*)-2-(2'-(4'-methyleneethyl)oxazoliny)cyclopentadienyl, 1-*C*-3'-*N*)( $\eta^4$ -tetraphenylcyclobutadiene)cobalt is prepared by stirring under argon the above crude *Cobalt-ester* (10g, 18.6mmol), lithium iodide (4.96g, 37.2mmol, see [10377-51-2]) and 2,4,6-collidine (100ml, b **175-178**<sup>o</sup>/atm, see [108-75-8]), then boiling under reflux (air condenser) for ~16 hours until the *Cobalt-ester* ( $R_F$  0.8, silica plate eluted with 20% EtOAc:hexanes) has completely reacted. The solution is cooled to ~25<sup>o</sup>, diluted with CH<sub>2</sub>Cl<sub>2</sub>, washed with 2N aqueous HCl (4 x 150ml), dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and evaporated *in vacuo* to give the solid orange coloured *Cobalt-acid* [<sup>1</sup>H NMR (500MHz, CDCl<sub>3</sub>) at  $\delta_H$ : 4.84 (2d,  $J = 2.0$ Hz, 2H), 5.23 (2d,  $J = 2.0$ Hz, 2H), 7.20-7.24 (m, 12H), 7.42-7.44 (m, 8H)] which is used further. Under argon, with stirring, the preceding *cobalt-acid* in CH<sub>2</sub>Cl<sub>2</sub> (124ml, pre-filtered through activated Al<sub>2</sub>O<sub>3</sub>), oxalyl chloride (3.25ml, 37.2mmol) followed by anhydrous DMF (3 drops sequentially, as evolution of gas occurs) are kept at ~25<sup>o</sup> for 30 minutes, evaporated *in vacuo*, CH<sub>2</sub>Cl<sub>2</sub> (100ml) is added to dissolve the residue, evaporate again *in vacuo* and the process is repeated three times to give dry *Cobalt-acid chloride* as a red-brown residue. A Schlenk flask with a rubber septum, flushed with argon *via* inlet and outlet needles, is loaded with *S*-valinol hydrochloride (3.6g, 26mmol, prepared from the free base, see [2026-48-4], by treating with 2N HCl in Et<sub>2</sub>O), then dry Et<sub>3</sub>N (15.5ml, 112mmol) and CH<sub>2</sub>Cl<sub>2</sub> (86ml) are added *via* the septum, followed, *via* a cannula, a solution of the preceding crude *Cobalt-acid chloride* in CH<sub>2</sub>Cl<sub>2</sub> (100ml). The mixture is stirred at ~25<sup>o</sup> for 2 hours and cooled to 0<sup>o</sup> in an ice-bath. MeSO<sub>2</sub>Cl (3.6ml, 47mmol, [124-63-0]) is then added to the mixture in one portion *via* a syringe and allowed to warm to ~25<sup>o</sup>. After 16 hours the mixture is washed with saturated aqueous NaHCO<sub>3</sub> (150ml), brine (150ml), the organic layer is dried (Na<sub>2</sub>SO<sub>4</sub>), filtered, and concentrated *in vacuo*. The residue is purified by dissolving it in the minimum volume of CH<sub>2</sub>Cl<sub>2</sub> (~50ml), adding it to a silica gel column and eluting with hexanes/EtOAc (9:1) to give  $\eta^5$ -(*S*)-(p*R*)-2-(2'-(4'-methyleneethyl)-oxazoliny)cyclopentadienyl, 1-*C*-3'-*N*)( $\eta^4$ -tetraphenylcyclobutadiene)cobalt (8.2g, 75%) as a yellow solid, which can be recrystallised to analytical purity from 10% EtOAc/petroleum ether to m 160-162<sup>o</sup>. It has IR (thin film) with  $\nu_{max}$  at 3058, 2958, 1652 (C=N), 1597, 1499, 1373, 1113, 1024 cm<sup>-1</sup>; the <sup>1</sup>H NMR (400MHz, CDCl<sub>3</sub>) has  $\delta_H$  at 0.77 (d,  $J = 6.7$ Hz, 6H, CH<sub>3</sub>), 0.97 (d,  $J = 6.7$ Hz, 3H, CH<sub>3</sub>), 1.40 (oct,  $J = 6.7$ Hz, 1H, CH(CH<sub>3</sub>)<sub>2</sub>), 3.41-3.56 (m, 3H, -CH-CH<sub>2</sub>-), 4.62 (brs, 1H, CpH), 4.80 (brs, 1H, CpH), 5.09 (brs, 1H, CpH), 5.20 (brs, 1H, CpH), 7.17-7.27 (m, 12H, *m+p*-PhH), 7.44-7.47 (m, 8H, *o*-PhH); and the <sup>13</sup>C NMR (100MHz, CDCl<sub>3</sub>) has  $\delta_C$ {<sup>1</sup>H} at 20.4 (CH<sub>3</sub>), 26.1 (CH<sub>3</sub>), 35.0 (CH(CH<sub>3</sub>)<sub>2</sub>), 71.5 (-CH-CH<sub>2</sub>-), 74.7 (-CH-CH<sub>2</sub>-), 78.9 (C<sub>4</sub>Ph<sub>4</sub>), 84.1 (*ipso*-CpC), 86.4 (CpC), 87.0 (CpC), 87.1 CpC), 88.4 CpC), 126.8 (*p*-PhC), 128.3 (PhC), 129.3 (PhC), 135.8 (*ipso*-PhC), 162.6 (C=N); and MS(EI) at  $m/z$  591 (M<sup>+</sup>, 100), 415 (82), 356 (8), 178 (60). The ***R*-enantiomer** is prepared in precisely the same way except that *R*-valinol hydrochloride is used, and it differs only in having optical rotation of opposite sign. [Stevens & Richards *Organometallics* **18** 1346 1999, Anderson, Overman, Richards, Watson and White *Org Synth* **84** 139 2007.]

***N*-Methyliminodiacetic acid (MIDA)** [4408-64-4] **M 147.1, m 220<sup>o</sup> (dec), 223-225<sup>o</sup> (dec), 226<sup>o</sup> (dec), pKa** (thermodynamic) **acidic: 2.138 (0<sup>o</sup>), 2.142 (10<sup>o</sup>), 2.146 (20<sup>o</sup>), 2.150 (30<sup>o</sup>), 2.154 (50<sup>o</sup>); basic: 10.474 (0<sup>o</sup>), 10.287 (10<sup>o</sup>), 10.088 (20<sup>o</sup>), 9.920 (30<sup>o</sup>), 9.730 (40<sup>o</sup>)**. It has been prepared from MeNH<sub>2</sub> and formaldehyde cyanohydrin followed by hydrolysis of the dinitrile formed [Eschweiler *Justus Liebigs Ann Chem* **279** 29 1894] and in 63-71% yield from chloroacetic acid and MeNH<sub>2</sub> [Berchet *Org Synth Coll Vol II* 397 1943]. However, a more convenient preparation is from iminodiacetic acid [142-73-4] (13.3g), formic acid (4.6g), aqueous formaldehyde (10ml, 36%) and H<sub>2</sub>O (5ml) at 100<sup>o</sup> until evolution of CO<sub>2</sub> ceases, and after 2 hours the mixture is refluxed for 10 minutes, diluted with excess EtOH, cooled and the precipitated acid is filtered off. Recrystallisation from aqueous EtOH (charcoal) provides pure colourless *MIDA* (14.7g, 90%). [Childs et al. *J Chem Soc* 2174 1948]. It has been purified *via* the Ba salt [Berchet *Org Synth Coll Vol II* 397 1943] and the stability constants of the complexes with Cu<sup>2+</sup>, Mg<sup>2+</sup>, Ca<sup>2+</sup>, Sr<sup>2+</sup>, Ba<sup>2+</sup>, Zn<sup>2+</sup>, Cd<sup>2+</sup>, Hg<sup>2+</sup>, and Ni<sup>2+</sup> have been determined [Swarzenbach et al. *Helv Chim Acta* **38** 1147 1955]. The **diethyl ester** has **b 92-94<sup>o</sup>/0.04mm** [Viscontini et al. *Helv Chim Acta* **35** 451 1952], and the **monoamide** has **m 168<sup>o</sup>** after crystallisation (needles) from aqueous EtOH [Eschweiler *Justus Liebigs Ann Chem* **279** 29 1894]. *MIDA* (**m 215-216<sup>o</sup> dec**) has been prepared on a ~100g scale by the method described by Childs et al. (above) with slight modification in 88% yield, and had IR (thin film) with  $\nu_{max}$  at 2998, 2955, 1682 (C=N), 1477, 1380, 1328, 1223, 1172, 1126, 1065, 1018, 982, 958, 903, 886, 723 cm<sup>-1</sup>; the <sup>1</sup>H NMR (400MHz, D<sub>2</sub>O) has  $\delta_H$  at 2.98 (s, 3H), 3.96 (s, 4H); the <sup>13</sup>C NMR (100MHz, 95:5 DMSO-*d*<sub>6</sub>: D<sub>2</sub>O, TMS) has  $\delta_C$  at 170.0, 56.7, 41.7; the LRMS (ESI<sup>+</sup>) has  $m/z$  (relative intensity) 219.1 (24%), 148.1 (M<sup>+</sup>, 100%), 102.1 (8%); and the HRMS (ESI<sup>+</sup>) for C<sub>5</sub>H<sub>10</sub>NO<sub>4</sub> [M+H<sup>+</sup>] has calculated 148.0604, and found 148.0603. [Ballmer, Gillis and Burke *Org Synth* **86** 344 2008]. [Beilstein 4 H

367, 4 II 800, 4 III 1177, 4 IV 2428].

**MIDA boronic esters:** MIDA is a very useful protecting group for boronic acids and forms stable (more stable than the free acid) *boronates* which are readily prepared from the boronic acid, MIDA in toluene-DMSO (2.5:1) under reflux using Dean-Stark conditions to eliminate H<sub>2</sub>O requiring ~3 hours. When these boronic acid surrogates are suitably substituted on boron they can be made to undergo Suzuki-Miyaura, Stille, Heck, Sonogashira and Negishi coupling, as well as Miyaura borylations. The boronates are easy to handle, stable in air, stable under cross-coupling conditions, surviving temperatures of up to 80°, and acidic reagents like trifluoromethanesulfonic, acetic acid and oxidizing agents such as Jones reagent. The MIDA group can be easily hydrolysed by mild aqueous base (see below) thus also allowing the use of controlled iterative cross-coupling (ICC) of protected haloboronic acids. [Gillis & Burke *Aldrichimica Acta* **42** 17 2009]. A variety of MIDA boronate synthons are available commercially.

**Hydrolysis of 4-(*p*-tolyl)phenylboronic acid MIDA ester (m 214-216°)** to the boronic acid is given here as a typical example for the hydrolysis procedure. The MIDA ester (10.1g, 31.3mmol, 1 equivalent) in THF (220ml), and aqueous 1M NaOH (93.5ml, 93.5mmol, 2.99 equivalents) gives a biphasic mixture with a clear colourless lower layer and a milky white upper layer. The container is capped, and the mixture is stirred vigorously at ~25° for 10 minutes whereby the lower colourless layer becomes clear and the upper layer becomes clear yellow. A saturated aqueous solution of NH<sub>4</sub>Cl (250ml) is added (to act as acidifier) and the mixture is stirred vigorously for 5 minutes, shaken with Et<sub>2</sub>O (4 x 50ml), and the aqueous layer is extracted with freshly prepared THF/Et<sub>2</sub>O (1:1, 400ml). The combined organic layers are dried (MgSO), filtered through Celite, and concentrated by rotary evaporation in a vacuum (40°/20mm), and residual solvent is removed by three azeotropic cycles with MeCN (3 x 50ml) in a rotary evaporator (40°/20mm), and then at higher vacuum (25°/1mm) for 12 hours to give the boronic acid as a fine off-white powder (6.24g, 94% yield, **m 136-138° dec**) with the expected IR, NMR and Mass spectra which indicate ~92% purity. [Ballmer, Gillis and Burke *Org Synth* **86** 344 2008].

**MIDA-disodium salt** is prepared from MIDA (147g, 1 mol), which is dissolved (caution: exothermic) in NaOH (120g, 3 mol) in H<sub>2</sub>O (300ml) to give a clear light yellow solution that is evaporated *in vacuo*. The residue is treated with MeOH (300ml), heated to reflux, filtered through a glass frit, heated to reflux and filtered again, and the process repeated once more. The filtrate is co-evaporated with MeCN (3 x) and lyophilised to give analytically pure **diNa salt** (173g, 91%) as a white powder with <sup>1</sup>H NMR (300MHz, CD<sub>3</sub>OD, TMS) δ<sub>H</sub> at 2.95 (s, 4H), 2.24 (s, 3H); and <sup>13</sup>C NMR (125MHz, CD<sub>3</sub>OD, TMS) δ<sub>C</sub> at 179.2, 63.7, 43.9. It is used for preparing MIDA-boronate esters [Uno et al. *Tetrahedron* **65** 3130 2009, cf also Coombs & Margerum *Inorg Chem* **9** 1711 1970, Davis & Richardson *Inorg Chem* **23** 184 1984, Stringfield & Shepherd *Inorg Chim Acta* **309** 28 2000].

**Norbornadiene (NBD, bicycle[2.2.1]hepta-2,5-diene) [121-46-0] M 92.1, m -19.1°, b 89.5-90°/atm, 90.3°/atm, d<sub>4</sub><sup>20</sup> 0.9064, n<sub>D</sub><sup>25</sup> 1.4684.** NBD is a versatile diene that coordinates with metals, helps in solubilising them in organic solvents, and is used for making a variety of pre-catalysts (see further in this chapter under “Homogeneous Catalysts” Part 1). It is prepared by a general method whereby *cis*- or *trans*- 1,2-*bis*(phenylsulfonyl)ethylene (0.22g, 0.714mmol; *trans* [963-16-6] M 308.4, m 221-223°, 226.5-227°, 229.5° from EtOH or AcOH; *cis*-isomer has m 89.5-90°, 101-101.5°, from EtOH, *Beilstein* **6** IV 1500, Truce & McManimie *J Am Chem Soc* **75** 1672 1953) and freshly distilled cyclopentadiene (1.6g, 2.42mmol) in toluene (5ml) are heated at 130° for 24 hours, evaporated to dryness *in vacuo*, and the residue is recrystallised from \*C<sub>6</sub>H<sub>6</sub>-EtOH (1:1) to give the Diels-Alder adduct 3,6-*methano*-4,5-*bis*(phenylsulfonyl)cyclohex-1,2-ene, m 257-258°, in good yield. Lower yields are obtained in \*C<sub>6</sub>H<sub>6</sub> (~25°/40 hours). Elimination of the β-disulfone groups is achieved by stirring a mixture of the *bis*(diphenylsulfonyl) compound (2.5mmol) and NaH<sub>2</sub>PO<sub>4</sub>·2 H<sub>2</sub>O (5g) in MeOH (~40ml) at room temperature overnight with freshly prepared sodium amalgam (from *ca* 0.4g, 17mmol of Na, [11110-52-4]). The mixture is extracted with pentane (b 36°/atm) and the extract is fractionated at atmospheric pressure to give NBD in 65% yield. Store and stabilise with 0.50.25% of BHT under N<sub>2</sub>. [De Lucchi & Modena *JCS Chem Commun* 914 1982, cf Parham & Heberling *J Am Chem Soc* **77** 1175 1955.] Industrially it is prepared from cyclopentadiene and acetylene at 340°/6atm [Shell Devel. Co., USP 2 875256 1953].

NBD has UV with λ<sub>max</sub> (logε) at 198.5 (3.78), 202infl (3.41), 213infl (3.24), 219infl (3.01), 227infl (2.41)nm (in EtOH), and 194.5 (3.53)nm (in cyclohexane) [Stich, Rotzler & Reichstein *Helv Chim Acta* **42** 1480 1959]; its IR (thin film) with ν<sub>max</sub> of the more intense bands at 2987, 1543, 1311, 1228, 875, 799, 727, 502 cm<sup>-1</sup>, and in CS<sub>2</sub>

and  $\text{CCl}_4$  it has  $\nu_{\text{max}}$  at 3080(s), 2960(vs), 2880(s), 1646(m), 1452(ms), 1335(ms), 1310(vs), 1271(m), 1229(s), 1206(s), 1150(s), 1105(ms), 1063(m), 1016(m), 935(s), 911(s), 885(sh), 870(vs), 795(sh), 715(vs), 650(s)  $\text{cm}^{-1}$  [Abel, Bennett and Wilkinson *J Chem Soc* 3178 1959]; the  $^1\text{H}$  NMR (60MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 1.99(s, 2H,  $\text{CH}_2$ ), 3.56(s, 2H, bridgehead H), 6.74(s, 4H, olefin H) from TMS, and the  $^{13}\text{C}$  NMR (15MHz,  $\text{CDCl}_3$ , TMS) has  $\delta_{\text{C}}$  at 143.3, 75.3, 50.2. The photoelectron spectrum shows intense bands at 8.69, 9.55, 11.26, 12.51—12.75, 14.24 and weak bands at 15.66—17.16 eV; and the interaction between the two non-conjugated  $\pi$ -bonds has been shown to be 0.85eV [Bischof et al. *Helv Chim. Acta* 52 1745 1969].

**NBD-silver nitrate** complex is formed by shaking for 5 minutes a mixture of  $\text{AgNO}_3$  (1.36g) in  $\text{H}_2\text{O}$  (10ml) and NBD (3ml). The white complex is collected and recrystallised from EtOH to give pure **NBD-(AgNO<sub>3</sub>)<sub>2</sub>** (0.95g) which decomposes in air, in  $\text{H}_2\text{O}$ , and on heating to give a strong odour of NBD. Store it cold and under  $\text{N}_2$ . It is soluble in warm MeOH, EtOH,  $\text{CCl}_4$ ,  $\text{CHCl}_3$ , and  $^*\text{C}_6\text{H}_6$ , but insoluble in  $\text{Me}_2\text{CO}$ ,  $\text{Et}_2\text{O}$  and light petroleum. Its IR (Nujol and hexachlorobutadiene mulls) has  $\nu_{\text{max}}$  at 3020(w), 2960(w), 2885(w), 1470(m), 1385(v, brs), 1325(s), 1310(s), 1243(m), 1189(m), 1046(m), 1014(w), 969(m), 950(vw), 929(m), 890(w), 877(w), 808(m), 795(w), 790(w), 725(ms)  $\text{cm}^{-1}$  [Abel, Bennett and Wilkinson *J Chem Soc* 3178 1959].

Similarly the **NBD-cuprous bromide** complex is formed by shaking for 5 minutes a mixture of anhydrous CuBr (2.6g) in EtOH (30ml) and NBD (5ml). The white crystalline complex is filtered off, and washed with EtOH (5ml) and  $\text{Et}_2\text{O}$  (5ml) to give **NBD-(CuBr)<sub>2</sub>** as fine white crystals which slowly become green in air. The complex, which is insoluble in most organic solvents, leaves CuBr under reduced pressure, and is decomposed by  $\text{H}_2\text{O}$  to give  $\text{Cu}_2\text{O}$ . Its IR (Nujol and hexachlorobutadiene mulls) has  $\nu_{\text{max}}$  at 3027(vw), 3000(vw), 2930(m), 2860(w), 1471(w), 1453(m), 1310(ms), 1265(w), 1245(vw), 1234(w), 1180—1080(br-w), 1050(vw), 993(m), 976(m), 950(w), 938(w), 918(ms), 889(w), 867(w), 777(w), 765(w), 739(m), 719(m)  $\text{cm}^{-1}$  [Abel, Bennett and Wilkinson *J Chem Soc* 3178 1959]. [*Beilstein* 5 IV 879.]

For the *bis(phenylsulfonyl)ethylenes* see also Truce & McManimie *J Am Chem Soc* 76 5745 1954, Montaniari *Gazetta* 86 429 1956, Parham & Heberling *J Am Chem Soc* 77 1175 1955, Modena & Montaniari *Gazetta* 86 436 1956, Adams & Ferretti *J Am Chem Soc* 81 4931 1959, and for UV see Angeletti & Montaniari *Boll Scient Fac Chim Ind Univ Bologna* 15 44, 45 1957; in EtOH the *cis-isomer* has  $\lambda_{\text{max}}$  at 241–243nm, and the *trans-isomer*  $\lambda_{\text{max}}$  at 246nm.

**Pentaphenylferrocenyl(di-tert-butyl)phosphine** [**P(C<sub>5</sub>H<sub>4</sub>FeC<sub>5</sub>Ph<sub>5</sub>)(t-butyl)<sub>2</sub>**, **Q-Phos**] [312959-24-3] **M 710.7, m 211-219°**. This catalyst ligand is prepared in two steps in high yield, and all reactions are performed in a drybox. Firstly (*di-tert-butylphosphino*)ferrocene is prepared by adding *t*-BuLi (31.6ml, 53.8mmol) in THF to a solution of  $\text{Cp}_2\text{Fe}$  (10.0g, 53.8mmol) in THF (25ml) during 5 minutes at 0°, stirred for 20 minutes and the solvent is removed *in vacuo*. The residue is dissolved in pentane (100ml) and THF (5ml), (*t*-Bu)<sub>2</sub>PCl (5.33g, 29.5mmol) is added and the mixture is stirred for 3 hours after which time degassed MeOH (1ml) is added, and most of the solvents are removed *in vacuo*. The residue is filtered through a plug of silica gel under  $\text{N}_2$  and unreacted  $\text{Cp}_2\text{Fe}$  is eluted with pentane first and then the phosphine is eluted all at once with  $\text{Et}_2\text{O}$ , the solvent is removed *in vacuo*, and the required *phosphine* is crystallised from pentane (yield 7.58g, 78%). In the second step this *phosphine* (1.00g, 3.03mmol),  $\text{Pd}(\text{OAc})_2$  (0.35g, 0.156mmol) and *t*-BuONa (2.93g, 30.5mmol) are dissolved in PhCl (34.10g, 303.0mmol) and heated at 110° for 18 hours. The mixture is filtered through Celite, the PhCl is removed *in vacuo*, and the residue is subjected to chromatography on Silica gel, and eluting with pentane/ $\text{Et}_2\text{O}$  (80:1), to give **P(C<sub>5</sub>H<sub>4</sub>FeC<sub>5</sub>Ph<sub>5</sub>)(t-butyl)<sub>2</sub>** (1.47g, 68%) as a pink-red solid. Its  $^1\text{H}$  NMR ( $\text{C}_6\text{D}_6^*$ ) has resonances at  $\delta$ : 1.07(d, 11.0Hz, 18H,  $\text{Me}_3$ ), 4.42(t, 1.7Hz, 2H,  $\text{C}_5\text{H}_4$ ), 4.67(d, 1.0Hz, 2H,  $\text{C}_5\text{H}_4$ ), 6.95–6.97(m, 15H, *m,p*- $\text{C}_6\text{H}_5$ ), 7.44–7.48(m, 10H, *o*- $\text{C}_6\text{H}_5$ ); the  $^{13}\text{C}\{^1\text{H}\}$  NMR ( $\text{C}_6\text{D}_6^*$ ) has resonances at  $\delta$ : 31.31(d, 13.8Hz,  $\text{CMe}_3$ ), 33.31(d, 24.8Hz,  $\text{CMe}_3$ ), 76.41(d, 2.6Hz,  $\text{C}_5\text{H}_4$ ), 78.58(d, 11.4Hz,  $\text{C}_5\text{H}_4$ ), 85.49(d, 41.6Hz, *ipso*- $\text{C}_5\text{H}_4$ ), 88.38(s,  $\text{C}_5\text{Ph}_5$ ), 126.67(s,  $\text{C}_5\text{Ph}_5$ ), 127.47(s,  $\text{C}_5\text{Ph}_5$ ), 133.23(s,  $\text{C}_5\text{Ph}_5$ ), 136.32(s,  $\text{C}_5\text{Ph}_5$ ); and the  $^{31}\text{P}\{^1\text{H}\}$  NMR ( $\text{C}_6\text{D}_6^*$ ) has a resonance at  $\delta$  25.49(s). Similarly prepared were **P[C<sub>5</sub>H<sub>4</sub>FeC<sub>5</sub>(C<sub>6</sub>H<sub>4</sub>*p*-CF<sub>3</sub>)<sub>5</sub>](t-butyl)<sub>2</sub>** (37.3% yield, from pentane), **P[C<sub>5</sub>H<sub>4</sub>FeC<sub>5</sub>(C<sub>6</sub>H<sub>4</sub>*p*-OMe)<sub>5</sub>](t-butyl)<sub>2</sub>** (36% yield, from  $\text{Et}_2\text{O}$  at -30°), **P(C<sub>5</sub>H<sub>4</sub>FeC<sub>5</sub>HPh<sub>4</sub>)(t-butyl)<sub>2</sub>** (47.4% yield, orange crystals from pentane at -35°), and **P[C<sub>5</sub>H<sub>4</sub>FeC<sub>5</sub>(3,5-Me<sub>2</sub>C<sub>6</sub>H<sub>3</sub>)<sub>5</sub>](t-butyl)<sub>2</sub>** (30% yield, red solid from pentane/ $\text{Et}_2\text{O}$ ) by using *p*-trifluoromethylchlorobenzene, *p*-methoxychlorobenzene, a limited amount of PhCl and 5-bromo-*m*-xylene respectively. These are air-stable ferrocenyl dialkylphosphines for palladium-catalysed C-C, C-N and C-O bonding-forming cross-coupling reactions. The ligand **P(C<sub>5</sub>H<sub>4</sub>FeC<sub>5</sub>Ph<sub>5</sub>)(t-butyl)<sub>2</sub>** exhibits turnovers of ~1000 for aminations with unactivated aryl bromides or chloride, catalysed the formation of selected aryl ethers under mild conditions, and aryl halides coupled with acyclic or cyclic secondary alkyl- and arylamines, and the latter amines coupled with aryl- and

primary alkylboronic acids. The ligand is air stable in the solid state and in solution, and produces highly active Pd catalysts which are stable in the solid state and react only slowly with oxygen in solution. [Kataoka et al. *J Org Chem* **67** 5553 2002, cf also Shelby et al. *J Am Chem Soc* **122** 10718 2000.]

**4-(3-Phenylpropyl)pyridine 1-oxide (P<sub>3</sub>NO)** [34122-28-6] **M 213.3, m 58-65°**, 60°, **pK<sub>Est</sub>~1.3**. The *N*-oxide is prepared by adding 4-(3-phenylpropyl)pyridine (12.5g, [2057-49-0]) during 5 minutes to a slurry of oxone (37.5g, [70693-62-8]), H<sub>2</sub>O (63.5ml) and MeOH (125ml) (pH ~1.4) under N<sub>2</sub>, and the stirred mixture is kept at pH 5.5 by addition of 5N aqueous NaOH while the temperature is kept at ≤ 35° (the temperature being controlled by external water cooling and by the rate of NaOH addition). The reaction is monitored by HPLC, and at completion, the salts are removed by filtration and the cake is washed with MeOH (50ml). The combined filtrate and washes are treated with 1M aqueous sodium metabisulfite solution (12ml), stirred for 0.5 hours and the pH is adjusted to 10.0 by addition of 5N aqueous NaOH, and set aside for 1 hour. The mixture is concentrated *in vacuo* (at 50°) to a final volume of ~75ml, cooled to 20°, the solid is filtered off, washed with H<sub>2</sub>O (50ml), and dried under N<sub>2</sub> to give the desired *l*-oxide in 93% yield. *Alternatively*, it can be prepared by the oxidation of the *phenylpropylpyridine* with 30% H<sub>2</sub>O<sub>2</sub>/AcOH using the standard method of Ochiai [*J Org Chem* **18** 534 1953, see also Boekelheide & Linn *J Am Chem Soc* **76** 1286 1954]. Its <sup>1</sup>H NMR (300MHz, CDCl<sub>3</sub>) has δ at 1.8-1.98 (m, 2H, 2'propyl-CH<sub>2</sub>), 2.3-2.6 (m, 4H, ph-CH<sub>2</sub>, py-CH<sub>2</sub>), 7.05 (m, 2H, 3,5-pyridine), 7.12-7.30 (m, 5H, benzene H), 8.11 (m, 2H, 2,6-pyridine H). [Senanayake et al. *Tetrahedron Lett* **37** 3271 1996.] This reagent stabilises and enhances Jacobsen Mn-salen catalysts and is more readily obtained in quantity than the commonly used 4-phenylpyridine 1-oxide [see Jacobsen et al. *J Am Chem Soc* **113** 7063 1991].

**Pinacolborane (4,4,5,5-tetramethyl-1,3,2-dioxaborolane)** [25015-63-8] **M 128.0, b 42-43°/50mm, d<sub>4</sub><sup>25</sup> 0.882, n<sub>D</sub><sup>20</sup> 1.396**. This borolane is prepared by stirring a cooled solution (at 0°) of pinacol (2.36g, 20mmol [76-09-5]) in CH<sub>2</sub>Cl<sub>2</sub> (2ml) to which is added, dropwise, BH<sub>3</sub>-SMe<sub>2</sub> (20mmol, 10.0M in SMe<sub>2</sub>) whereby effervescence occurs (use efficient fume hood, and gases have a foul odour, are flammable, and should be absorbed through alkaline solution or oxidising solutions containing H<sub>2</sub>O<sub>2</sub> or KMnO<sub>4</sub>). After stirring for ~1 hour at 0°, the mixture is warmed to ~25°, when evolution ceases (*ca* another 1 hour) and is distilled to give the borolane as a clear oil (1.61g, 63% yield). Its IR (CH<sub>2</sub>Cl<sub>2</sub>) has  $\nu_{\max}$  at 3272s, 2980s, 1530m, 1482s, 1333s, 1143s, 983s, 851s cm<sup>-1</sup>; and the <sup>1</sup>H NMR (300MHz, CDCl<sub>3</sub>) has δ at 1.27 (s, 12H); the <sup>13</sup>C NMR (75.5MHz, CDCl<sub>3</sub>) has δ at 83.1, 24.5; and the <sup>11</sup>B NMR (115.5MHz, CDCl<sub>3</sub>) has δ at 28.07. It is a very efficient hydroboration reagent, requires mild reaction conditions, has higher functional group tolerance, higher regio- and stereoselectivity, with excellent stability of the resulting pinacol boronic esters produced. [Tucker et al. *J Org Chem* **57** 3482 1992.]

**Rhodium(I) chloride 1,5-cyclooctadiene complex dimer {chloro(1,5-cyclooctadiene)rhodium dimer, di-μ,μ'-chlorobis[1,2,5,6-η]-1,5-cyclooctadiene}dirhodium (I), [Rh(COD)Cl]<sub>2</sub>}** [12092-47-6] **M 493.1, m ~243° (dec, see below)**. The complex is prepared by refluxing a solution of RhCl<sub>3</sub>·3H<sub>2</sub>O (1.93g, 7.3mmol), H<sub>2</sub>O (3ml), EtOH (35ml) and COD (6ml, 48mmol) overnight. After cooling, the crude solid is collected, washed with a little H<sub>2</sub>O, dried and recrystallised from CH<sub>2</sub>Cl<sub>2</sub>/hexane or acetic acid, then dried *in vacuo* to give 82% yield (1.5g) of dimer. On heating it darkens from about 220°, melts at ~256° and decomposes with effervescence at 258°. **M** by ebullioscopy in 0.9% CHCl<sub>3</sub> is ~513 confirming the dimeric structure. It is soluble in CH<sub>2</sub>Cl<sub>2</sub> and THF, moderately in CHCl<sub>3</sub>, AcOH and Me<sub>2</sub>CO, slightly soluble in hexane, Et<sub>2</sub>O, MeOH, EtOH, and \*C<sub>6</sub>H<sub>6</sub> but insoluble in H<sub>2</sub>O. Its magnetic susceptibility  $\chi$ , is -0.52 x 10<sup>-6</sup> ±4% per g. [Chatt & Venanzi *J Chem Soc* 4735 1957, Schenck et al. *Inorg Chem* **24** 2334 1985, cf Giordano & Crabtree *Inorg Synth* **19** 218 1979.]

**Rhodium(I) chloride norbornadiene complex dimer {bicyclo[2.2.1]hepta-2,5-diene-rhodium(I) chloride dimer, di-μ,μ'-chlorobis[2,5-norbornadiene]dirhodium(I), [Rh(NBD)Cl]<sub>2</sub>}** [dimer 12257-42-0; polymer 42740-82-9] **M 460.99, m ~240° (dec)**. The yellow dimer is obtained by shaking rhodium "trichloride" (0.7g, RhCl<sub>3</sub>·3H<sub>2</sub>O) and norbornadiene (2ml) in aqueous EtOH (10ml) for 2 days. It is collected and recrystallised from hot CHCl<sub>3</sub>/light petroleum to give analytically pure complex (0.62g). **M** by ebullioscopy in \*C<sub>6</sub>H<sub>6</sub> is 481 consistent with a dimeric structure. The fine yellow crystals are soluble in CHCl<sub>3</sub> and \*C<sub>6</sub>H<sub>6</sub>, but almost insoluble in light petroleum and Et<sub>2</sub>O. Its IR (CS<sub>2</sub>) has  $\nu_{\max}$  at 3060(m), 3000(m), 2960(m), 2920(m), 2855(m), 1307(s), 1171(m), 1157(w), 1068(w), 1029(w), 995(w), 932(m), 882(m), 721(w), 680(s), 630(s) cm<sup>-1</sup>. [Abel,

Bennett & Wilkinson *J Chem Soc* 3178 1959.]

**Ruthenium(II)benzenedichloride dimer {di- $\mu$ -chloro-bis[( $\eta$ -benzene)chlororuthenium(II)],  $\text{Ru}_2(\text{C}_6\text{H}_6)_2\text{Cl}_4$ ,  $[\text{Ru}(\text{C}_6\text{H}_6)\text{Cl}_2]_2$ } [37366-09-9] M 500.2, m 242°.** This versatile reagent is prepared by refluxing  $\text{RuCl}_3 \cdot 3\text{H}_2\text{O}$  (2.0g) in EtOH (100ml) with cyclohexadiene (10ml, of 1,3- or 1-4 prepared by reduction of \*benzene with Na/Liquid  $\text{NH}_3$ , Kaiser *Synthesis* 391 1972, Birch & Subba Rao *Adv Org Chem* 8 1 1972) for 4 hours. The brown precipitate is filtered off, washed with MeOH and dried *in vacuo* to give the complex (1.83g, 95%). The complex is diamagnetic, it is *dimeric* in freezing  $\text{CHBr}_3$ , and is sparingly soluble in organic solvents except  $\text{Me}_2\text{SO}$  with which it forms a red complex with the *monomeric* structure  $\text{RuCl}_2(\text{C}_6\text{H}_6)(\text{dmsO})$ . It dissolves in pyridine, tertiary phosphines, phosphites, tertiary arsines (L) which cleave the chlorine bridges of the dimer to form orange or red air stable complexes  $\text{RuCl}_2(\text{C}_6\text{H}_6)(\text{L})$  which are *monomeric* in  $\text{CHCl}_3$ . Large excess of the ligand L should be avoided in the reaction, otherwise the benzene rings may be displaced. Its IR has Ru—Cl stretching bands with  $\nu_{\text{max}}$  at 295, 259 and 248sh  $\text{cm}^{-1}$ ; and the  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , TMS) has a singlet at  $\tau_{\text{H}}$  4.02 which is *ca* 2.0 ppm upfield of the free benzene H resonance. It is a useful precursor for the preparation of Ru(II) complexes, some of which are catalysts. [Bennett & Smith *J Chem Soc, Dalton Trans* 233 1974, Bennett et al. in *Comprehensive Organometallic Chemistry* Wilkinson ed, Vol 4 pp 748-750 Pergamon Press Oxford 1982.]

The complex  $\text{Ru}_2(\text{C}_6\text{H}_6)_2$  has also been prepared by evaporating a coat of Ru powder (10-15%) in slow curing "Araldite" cement on a 1mm tungsten wire heated to  $\sim 2400^\circ$ . The Ru vapour thus produced is co-condensed with \*benzene to form thermally unstable orange-yellow crystals of  $\text{Ru}_2(\text{C}_6\text{H}_6)_2$  which decompose below  $0^\circ$ . The  $^1\text{H}$  NMR ( $\text{CFCl}_3$ ) of the orange crystals show H resonances at  $\tau$  4.22 (2H), 4.84 (6H), 5.10 (2H) and 7.11(2H) consistent with the 1—4- $\eta$ , 1—6- $\eta$  formulation of the  $\text{Ru}_2(\text{C}_6\text{H}_6)_2$  structure. [Timms & King *J C S, Chem Commun* 898 1978.]

**Ruthenium dichloride 1,5-cyclooctadiene complex [dichloro- $\mu$ -( $\eta^4$ -cycloocta-1,5-diene)ruthenium(II),  $\text{RuCl}_2(\text{COD})_n$ ] [50982-12-2] M 280.2 (monomer).** Analytically pure complex is obtained by heating a mixture of pure  $\text{RuCl}_3 \cdot 3\text{H}_2\text{O}$  (50.0g, 0.2mol) and cycloocta-1,5-diene (50ml, 0.4mol, use a fume hood) in absolute EtOH (400ml) under reflux for 24 hours whereby the brown complex precipitates. After cooling, the solid is filtered off, washed with  $\text{Et}_2\text{O}$  ((50ml) and dried *in vacuo* to give pure  $[\text{RuCl}_2(\text{COD})]$  ( $\sim 52\text{g}$ ,  $\sim 90\%$ ). It is stable in air, only slightly soluble in organic solvents, reacts by halogen-bridge cleavage and is a useful synthetic precursor of ruthenium(II) complexes. [Ohta, Takaya and Noyori *Inorg Chem* 27 566 1988, Alders, Singleton and Yates *Inorg Synth* 26 253 1989, Bennett et al. in *Comprehensive Organometallic Chemistry* Wilkinson ed., Vol 4 pp 748-750 Pergamon Press Oxford 1982.]

**Tetrakis(acetonitrile)copper(I) hexafluorophosphate  $[\text{Cu}(\text{MeCN})_4^+ \text{PF}_6^-]$  [64443-05-6] M 372.7, m 160°(dec).** In an efficient fume cupboard, 60-65% aqueous hexafluorophosphoric acid (10ml,  $\sim 113\text{mmol}$ , [16940-81-1], M 146.0) is added in 2ml portions to a stirred suspension of Cu(I) oxide (4.0g, 28mmol) in MeCN (80ml) when a very exothermic reaction occurs (use a reflux condenser), causing the solution to boil. After stirring for a further 3 minutes the solution is filtered (use a medium-porosity frit) from some black solid, and  $\text{Cu}(\text{MeCN})_4^+ \text{PF}_6^-$  may begin to crystallise out, and is complete on standing at  $-20^\circ$ , or by adding an equal volume of dry  $\text{Et}_2\text{O}$  and cooling to  $0^\circ$ . (If some white solid separates with the black solid it should be washed off with MeCN and the MeCN solutions combined and cooled at  $-20^\circ$ , or diluted with  $\text{Et}_2\text{O}$ .) The salt is collected by filtration, washed with  $\text{Et}_2\text{O}$  and immediately dissolved in MeCN (100ml), filter off any undissolved blue  $\text{Cu}^{2+}$  species, add  $\text{Et}_2\text{O}$  (100ml) and set aside at  $-20^\circ$  for several hours to crystallise out. The crystalline complex would need a second recrystallisation if it has a blue tinge. It may be recrystallised from MeCN (80ml) and  $\text{Et}_2\text{O}$  (80ml). The white complex salt is dried *in vacuo* for  $\sim 30$  minutes immediately after washing with  $\text{Et}_2\text{O}$  to give the analytically pure salt ( $\sim 12.5\text{g}$ ,  $\sim 60\%$  depending on crystallisation losses). It is a free-flowing white, microcrystalline powder which does not darken on long storage under  $\text{N}_2$  or argon. On exposure to air for  $>1$  hour minor surface oxidation occurs as it is slightly hygroscopic. The MeCN ligands are not removed easily *in vacuo* at  $\sim 25^\circ$  (but dissociation occurs at  $\sim 5$  torr/ $80^\circ$  and  $\sim 25$  torr/ $110^\circ$ ). The IR (Nujol) has  $\nu_{\text{max}}$  at 2277m and 2305m  $\text{cm}^{-1}$  (for MeCN), and 850vs and 557s  $\text{cm}^{-1}$  for  $\text{PF}_6^-$ . The related salt,

$\text{Cu}(\text{MeCN})_4^+ \text{BF}_4^-$ , can be prepared similarly by using an equivalent amount of  $\text{HBF}_4$  (as 48% aqueous acid [16872-11-0], M 87.9) instead of  $\text{HPF}_6$ . These complexes are suited for the non-aqueous-media synthesis of Cu(I) complexes [see  $(\text{IPr})_2\text{Cu}^+ \text{PF}_6^-$  and  $(\text{IPr})_2\text{Cu}^+ \text{BF}_4^-$  above]; as well as for preparing other complexes such as  $[\text{Rh}(\text{C}_2\text{H}_4)_3(\text{MeCN})_2]^+ + \text{CuCl}$  by reaction of  $\text{Cu}(\text{MeCN})_4^+$  with  $[\text{Rh}(\text{C}_2\text{H}_4)_2\text{Cl}]_2$  and  $\text{C}_2\text{H}_4$  in  $\text{CH}_2\text{Cl}_2$  [Maspero et al. *J Organomet Chem* **38** C43 1972]. The X-ray structure of the  $\text{ClO}_4^-$  salt showed that the copper is almost ideally tetrahedral with nearly linear MeCN molecules [Csoregh et al. *Acta Cryst* **B31** 314 1975]. [Kubas *Inorg Synth* **19** 90 1979, Kubas *Inorg Synth* **28** 68 1990.]

**cis-cis-cis-1,2,3,4-Tetrakis(diphenylphosphinomethyl)cyclopentane** [(1*R*\*,2*R*\*,3*S*\*,4*S*\*)-tetrakis(diphenylphosphinomethyl)cyclopentane, **Tedicyp**] [333380-86-2] **M 862.9, m 790**. The intermediate cis-cis-cis-1,2,3,4-tetrakis(boranatodiphenylphosphanyl)methyl)cyclopropane (white crystals **m 1490**, after chromatography on silica gel eluting with AcOEt/petroleum ether, 1:4) is obtained from  $\text{Ph}_2\text{PLi}$  (from  $\text{Ph}_2\text{PCl}$  see [1079-66-9] and Li) and cis-cis-cis-1,2,3,4-tetrakis(tosylloxymethyl)cyclopentane in THF under argon (~20°/5 hours), then borane in THF is added. This boranato intermediate formed is added to anhydrous  $\text{Et}_2\text{NH}$ , heated at 55-60° for 10 hours, evaporated to dryness, this process is repeated twice, and the residue is chromatographed on silica gel (eluted with  $\text{Et}_2\text{O}$ /petroleum ether, 1:4) to give white crystals of **Tedicyp** (98%) with **m 790**. It is not very stable in air and must be stored under argon. It has  $^1\text{H}$  NMR (400MHz, THF- $d_8$ ) with  $\delta$  at 7.71-7.23 (40H, m), 2.91-2.52 (2H, m), 2.38-1.72 (10H, m), 1.25 (2H, m); the  $^{13}\text{C}$  NMR (100MHz, THF- $d_8$ , TMS) has  $\delta$  at 141.6 (s,  $^1J_{\text{P,C}} = 15.1\text{Hz}$ ), 141.1 (s,  $^1J_{\text{P,C}} = 14.1\text{Hz}$ ), 140.0 (s,  $^1J_{\text{P,C}} = 15.1\text{Hz}$ ), 139.4 (s,  $^1J_{\text{P,C}} = 16.0\text{Hz}$ ), 134.6 (d,  $J_{\text{P,C}} = 20.1\text{Hz}$ ), 134.5 (d,  $J_{\text{P,C}} = 19.1\text{Hz}$ ), 133.5 (d,  $J_{\text{P,C}} = 17.0\text{Hz}$ ), 133.3 (d,  $J_{\text{P,C}} = 18.0\text{Hz}$ ), 129.6 (d,  $J_{\text{P,C}} = 14.0\text{Hz}$ ), 129.3-129.0 (d,  $J_{\text{P,C}} = 15.0\text{Hz}$ ), 45.4 (t,  $^2J_{\text{P,C}} = 8.6\text{Hz}$ ), 45.2 (d,  $^2J_{\text{P,C}} = 8.7\text{Hz}$ ), 40.4 (t,  $^2J_{\text{P,C}} = 8.75\text{Hz}$ ), 40.3 (t,  $^2J_{\text{P,C}} = 9.2\text{Hz}$ ), 3.91 (d,  $^2J_{\text{P,C}} = 13.3\text{Hz}$ ), 33.1 (d,  $^1J_{\text{P,C}} = 10\text{Hz}$ ), 26.5 (t,  $^1J_{\text{P,C}} = 12.9\text{Hz}$ ); the  $^{31}\text{P}$  NMR (162MHz, THF- $d_8$ ) has  $\delta$  at -16.3 and -17.7. It is used for preparing the Pd-Tedicyp catalyst with  $[\text{Pd}(\eta^3\text{-C}_3\text{H}_5)\text{Cl}]_2$  (see above) for promoting allylic alkylations [Laurenti et al. *J Org Chem* **66** 1633 2001], cross coupling reactions [Wallow & Novak *J Org Chem* **59** 5034 1994], and catalysing Heck reactions of  $\alpha$ - or  $\beta$ -substituted enol ethers with aryl bromides [Battace et al. *Eur J Org Chem* 3122 2007] with high efficiency.

The tetra-phosphine oxide of cis-cis-cis-1,2,3,4-tetrakis(diphenylphosphino)methyl)cyclopropane is obtained by oxidising **Tedicyp** in THF with excess  $\text{H}_2\text{O}_2$  (~20°/4 days) then purified by chromatography on silica gel (eluting with MeOH/ $\text{CH}_2\text{Cl}_2$ , 5:95) to yield (66%) white crystals of the *tetroxide* with **m 1650**. It has  $^1\text{H}$  NMR (400MHz,  $\text{CDCl}_3$ ) with  $\delta$  at 7.79-7.62 (16H, m), 7.32-7.28 (8H, m), 2.85 (2H, br t,  $J = 12.9\text{Hz}$ ), 2.28 (4H, d,  $J = 11.9\text{Hz}$ ), 2.26-2.15 (2H, m), 2.10-2.05 (2H, m), 1.88 (2H, br q,  $J = 12.9\text{Hz}$ ), 1.60 (1H, dt,  $J = 13.8, 7.5\text{Hz}$ ), 1.36 (1H, dt,  $J = 13.8, 10.2\text{Hz}$ ); the  $^{13}\text{C}$  NMR (100MHz,  $\text{CDCl}_3$ ) has  $\delta$  at 134.3 ( $^1J_{\text{P,C}} = 13.0\text{Hz}$ ), 133.3 (m), 131.94 ( $^1J_{\text{P,C}} = 5\text{Hz}$ ), 131.62 ( $^1J_{\text{P,C}} = 5\text{Hz}$ ), 131.27-131.0 (m), 129.0-128.6 (m), 41.9 (d,  $^2J_{\text{P,C}} = 10.0\text{Hz}$ ), 38.0 (t), 35.2 (d), 33.0 (t,  $^1J_{\text{P,C}} = 69.9\text{Hz}$ ), 27.1 (t,  $^1J_{\text{P,C}} = 70.0\text{Hz}$ ) relative to TMS; and the  $^{31}\text{P}$  NMR (162MHz,  $\text{CDCl}_3$ ) has  $\delta$  at 32.2. [Laurenti et al. *J Org Chem* **66** 1633 2001.]

**R-(+)- and S-(-)- 2,2',6,6'-Tetramethoxy-4,4'-bis(diphenylphosphino)-3,3'-bipyridine** (**R-(+)- P-Phos** and **S-(-)- P-Phos**) [*R*- 221012-82-4 and *S*- 362524-23-0] **M 644.6, m 261-2650**,  $[\alpha]_{\text{D}}^{20} +980$  and  $-980$  (c 1,  $\text{CHCl}_3$ ). This group of ligands have been prepared from (3-bromo-2,6-dimethoxy-pyrid-4-yl)(diphenyl)-phosphine oxide by an Ulmann reaction ( $\text{Cu}/\text{DMF}/140^\circ$ ) to give *RS*- 2,2',6,6'-tetramethoxy-3,3'-bipyridine-4,4'-diphenylphosphine dioxide (85%) which is resolved into the (+)- and (-)- enantiomers by HPLC on a preparative Diacel AD column (25m x 1.2m), eluting with 2-propanol/hexane (20:80) at a flow rate of 3.0ml/minute:  $t_{\text{R}} = 12.24$  minutes,  $t_{\text{S}} = 25.06$  minutes. The phosphine oxide groups are then each reduced by  $\text{Cl}_3\text{SiH}/\text{Et}_3\text{N}/\text{toluene}$  at  $140^\circ$  to give *R-(+)-* and *S-(-)-* **R-Phos** in 99% yields. Alternatively, the above *RS*- dioxide, which cannot be resolved easily, is converted into the 5,5'-dibromo derivative ( $\text{Br}_2/\text{NaOAc}/\text{AcOH}$ ;  $0^\circ$ - $60^\circ$ , 97%) which can now be resolved via the (+) and (-)-di-*O*-benzoyl tartrate salts (in  $\text{EtOAc}/\text{CHCl}_3$ , 1/1) to provide the enantiomeric 5,5'-dibromo-dioxides that are de-brominated, and reduced ( $\text{Cl}_3\text{SiH}/\text{Et}_3\text{N}/\text{toluene}$  during an extended period from  $25^\circ$  to  $140^\circ$ ) to give **R-(+)- and S-(-)- P-Phos** in 91% yields. [Pai et al. *J Am Chem Soc* **112** 11513 2000.]

**R-(+)- and S-(-)- 2,2',6,6'-Tetramethoxy-4,4'-bis(di(3,5-xylyl)phosphino)-3,3'-bipyridine** [**R-(+)- Xylyl-P-Phos** and **S-(-)- Xylyl-P-Phos**] [*R*- 442905-33-1 and *S*- 443347-10-2] **M 756.9, m (158-1620), 190-1940**,  $[\alpha]_{\text{D}}^{20} +1250$  and  $-1250$  (c 1,  $\text{CHCl}_3$ ). The Xylyl-P-Phos ligands are prepared in a slightly different way from P-Phos ligands above. Thus 3-bromo-2,6-dimethoxy-pyridine is converted into (3-bromo-2,6-dimethoxy-pyrid-4-yl)di(3,5-dimethylphenyl)phosphine [*a*:  $\text{LDA}/\text{THF}/-78^\circ$ ; *b*: (3,5-dimethylphenyl) $_2\text{PCl}/-78^\circ$ ] in 56% yield, then

oxidised ( $\text{H}_2\text{O}_2/\text{Me}_2\text{CO}/0^\circ$ ) to the *phosphine oxide* (99%), followed by an Ulmann reaction as above ( $\text{Cu}/\text{DMF}/140^\circ$ ) to give *RS-2,2',6,6'-tetramethoxy-3,3'-bipyridine-4,4'-di(3,5-dimethylphenyl)phosphine dioxide* (85% yield) that is resolved *via* (-)- and (+)- di-*O*-benzoyl tartrate salts (*a*: see above fractional crystallisation; *b*: 10% aqueous NaOH) to give the *R*- (75%) and *S*- (88%) *Xylyl-P-Phos dioxides* which are reduced ( $\text{Cl}_3\text{SiH}/\text{Et}_3\text{N}/\text{toluene}$ ) to *R*(+)- and *S*- *Xylyl-P-Phos* in >90% yields. The absolute configuration *S*- was determined from the X-ray crystal structure of the diastereoisometrically pure 1:1 salt of (-)-*Xylyl-P-Phos* and (+)-(*2S,3S*)-dibenzoyl-*O*-tartrate. The latter have  $^1\text{H}$  NMR (500MHz,  $\text{CDCl}_3$ ) with  $\delta_{\text{H}}$  at 2.20 (s, 12H,  $\text{PhCH}_3$ ), 2.25 (s, 12H,  $\text{PhCH}_3$ ), 3.37 (s, 6H, O  $\text{CH}_3$ ), 3.83 (s, 6H, O  $\text{CH}_3$ ), 6.06 (d,  $J = 1.5\text{Hz}$ , 2H,  $\text{PyH}$ ), 6.79-6.92 (m, 12H,  $\text{PhH}$ ); the  $^{13}\text{C}$  NMR (125MHz,  $\text{CDCl}_3$ ) with  $\delta_{\text{C}}$  at 21.54 (d,  $J = 4.78\text{Hz}$ ), 53.06, 53.43, 105.47, 115.39 (t,  $J = 37.07\text{Hz}$ ), 130.47 (d,  $J = 33.81\text{Hz}$ ), 131.46 (t,  $J = 20.99\text{Hz}$ ), 132.42 (t,  $J = 21.74\text{Hz}$ ), 135.69 (t,  $J = 10.05\text{Hz}$ ), 136.88 (t,  $J = 12.82\text{Hz}$ ), 137.39 (t,  $J = 8.04\text{Hz}$ ), 137.71 (t,  $J = 7.16\text{Hz}$ ), 154.64, 154.70, 154.75, 160.76 (t,  $J = 11.18\text{Hz}$ ), 162.30; the  $^{31}\text{P}$  NMR (200MHz,  $\text{CDCl}_3$ ) with  $\delta_{\text{P}}$  at -11.99; the LSMS [ $\text{M}^+$ ] found 757, calculated for  $\text{C}_{46}\text{H}_{50}\text{N}_2\text{O}_4\text{P}_2$  is 756.85; and the C, H and N elemental analyses fit for the latter empirical formula. [Wu et al. *Tetrahedron Lett* **43** 1539 2002.]

**6RS(±)-4,4,6-Trimethyl-2-vinyl-1,3,2-dioxaborinane (vinylboronic acid 2-methyl-2,4-pentanediol ester)** [4627-10-5] **M 154.0, b 50-55°/0.46mm,  $d_4^{25}$  0.893,  $n_D^{20}$  1.429**. It is prepared by a modification of a published method [Hoffmann & Landmann *Chem Ber* **119** 2013 1986] where *n*-octanol is replaced by 2-methylpentane-2,4-diol (MPD). To a solution of  $(\text{MeO})_3\text{B}$  (30ml, 270mmol) in dry  $\text{Et}_2\text{O}$  (125ml) at  $-78^\circ$  is added over 45 minutes a 2.1M solution of vinylmagnesium chloride (118ml, 248mmol) in THF with stirring, and allowing the temperature to rise to  $\sim 25^\circ$ . The mixture is then acidified, under cooling, with aqueous HCl (concentrated, 21ml, 0.25mol in 62.5ml of  $\text{H}_2\text{O}$ ), phenothiazine (0.1g, as stabiliser) is added, the phases are separated, the aqueous phase is extracted with MPD (3 x 50ml). The combined organic phases are evaporated *in vacuo* from a bath at  $80^\circ$  and the residual oil is distilled at high vacuum to give pure *borinane* in  $\sim 60\%$  yield. [Note that all the liquids in the reaction mixture distil at lower temperatures than the desired racemic vinyl-dioxaborinane.] It is superior to vinylboronic pinacol ester in preparation, storage, stability, and reactivity, providing improved selectivity for Heck *versus* Suzuki coupling with aryl and heteroaryl bromides and iodides [Lightfoot et al. *Tetrahedron Lett* **44** 7645 2003]. By adopting different reaction conditions with  $\text{Pd}(\text{PPh}_3)_4/t\text{-BuOK}$ , selective Suzuki-Miyaura coupling with a range of aryl and heteroaryl halides (Cl, Br and I) was achieved [Lightfoot et al. *Synlett* 259 2005, cf Lightfoot et al. *Org Biomol Chem* **3** 3167 2005].

**Tri-*tert*-butylphosphonium tetrafluoroborate [(*tert*-Bu) $_3\text{PH}^+\text{BF}_4^-$ ] [131274-22-1] **M 290.1, m 261°(dec),  $\text{pK}^{25}$  11.4 (phosphine)**. The salt is prepared by adding  $\text{HBF}_4$  (48% aqueous solution, 1.0ml, 7.6mmol) to a solution of pure (*tert*-Bu) $_3\text{P}$  (225mg, 1.1mmol, see above) in  $\text{CH}_2\text{Cl}_2$  (15ml), stirring vigorously for 5 minutes, the organic layer is separated, dried ( $\text{MgSO}_4$ ), filtered and evaporated to dryness to give analytically pure *salt* (302mg, 94%) as a white powder. It has  $\nu_{\text{max}}$  (KBr) at 3002, 2217, 1478, 1405, 1381, 1181, 1059, 886 (br)  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (400MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{H}}$  at 6.07 (d,  $^1J_{\text{PH}} = 465\text{Hz}$ , 1H), 1.65 (d,  $^3J_{\text{PH}} = 15.3\text{Hz}$ , 27H); the  $^{13}\text{C}$  NMR (75MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{C}}$  at 37.0 (d,  $^1J_{\text{PC}} = 29\text{Hz}$ , 1H), 30.1; and the  $^{31}\text{P}\{^1\text{H}\}$  NMR (121MHz,  $\text{CDCl}_3$ ) has  $\delta_{\text{P}}$  at 51.7. The salt is more air-stable than the free phosphine, and can be heated at  $120^\circ$  for 24 hours without decomposition (no change in NMR spectra), or loss of catalytic activity with transition metal complexes. It is *not hygroscopic*. In the presence of  $\text{Pd}_2(\text{dba})_3$  in THF it catalyses Suzuki cross-coupling reactions between aryl halides and arylboronic acids, Stille cross-coupling reactions between aryl halides and tributylSn compounds, and Heck reactions between aryl halides and olefines [Netherton & Fu *Org Lett* **3** 4295 2001]. The salt has also been used successfully in the Heck coupling [with  $\text{PdCl}_2(\text{COD})$ , LiCl,  $\text{C}_2\text{N}_2\text{Me}$ ] of non-activated alkenyl tosylates and phosphates as substrates with electron-poor alkenes and styrene derivatives [Hansen et al. *Angew Chem Int Ed* **45** 3349 2006].**

**Vinyl MIDA boronate {vinylboronic acid MIDA ester, 6-methyl-2-vinyl-1,3,6,2-dioxazaborocane-4,8-dione, [*N*-[(*carboxy-κO*)methyl]-*N*-methylglycinato(2-)-κN,κO]ethenyl boron}** [1104636-73-8] **M 183.0, m 152-156°**. The boronate is prepared in Schlenk equipment by adding dropwise vinyltrimethylsilane (4.49ml, 31.5mmol, freshly distilled see [754-05-2]) to a stirred solution of  $\text{BBr}_3$  (1.0M in  $\text{CH}_2\text{Cl}_2$ , 30mmol) at  $0^\circ$ , and maintained at this temperature for 20 minutes, then allowed to warm to  $\sim 25^\circ$  with stirring for a further 2 hours. This mixture is added *via* a cannula to a stirred suspension of MIDA sodium salt (5.73g, 30.0mmol, see above)

in MeCN (50ml) at 0°, at such a rate as to keep the temperature below 5°; then the temperature is allowed to warm to ~25° while stirring for 1 hour. The resulting white suspension is filtered through a pad of Celite and the filtrate cake is extracted 3 times with Me<sub>2</sub>CO. Et<sub>2</sub>O is added to the combined orange filtrates which allowed the colourless free flowing vinyl MIDA boronate (4.74g, 86%) to crystallise out. On TLC it has R<sub>F</sub> 0.26 (Merck silica gel plate grade 9385, 60Å, 230-400 mesh, with EtOAc). Its IR (thin film) has  $\nu_{\max}$  at 3063, 2997, 2960, 1755, 1617, 1455, 1420, 1345, 1312, 1251, 1175, 1155, 1134, 1117, 1090, 1033, 987, 964, 951, 865 cm<sup>-1</sup>; the <sup>1</sup>H NMR (500MHz, Me<sub>2</sub>CO-*d*<sub>6</sub>,  $\delta$  = 2.04 centre line) has  $\delta_{\text{H}}$  at 5.96 (dd,  $J$  = 19.0, 13.5Hz, 1H), 5.72-5.63 (m, 2H), 4.21 (d,  $J$  = 17.0Hz, 2H), 4.01 (d,  $J$  = 17.0Hz, 2H), 3.0 (s, 3H); the <sup>13</sup>C NMR (125MHz, Me<sub>2</sub>CO-*d*<sub>6</sub>,  $\delta$  = 29.80 centre line) has  $\delta_{\text{C}}$  at 168.3, 128.7, 61.6, 46.7; and the HMRS (EI+) has found  $m/z$  183.0700, calculated for C<sub>7</sub>H<sub>10</sub>BBrNO<sub>4</sub> [M]<sup>+</sup> is 183.0703.

Single crystal X-ray analysis confirmed the predicted structure as having a pyramidalised boron centre. The vinylboronate shows no signs of deterioration when kept on the benchtop in air for more than 3 months. It is a versatile reagent that can be prepared on a multigram scale. It readily reacts with CH<sub>2</sub>N<sub>2</sub>/Pd(OAc)<sub>2</sub> to provide cyclopropyl MIDA boronate [Et<sub>2</sub>O, 0-23°, 1 hour, 93%], and with *m*-CPBA it yields oxiranyl MIDA boronate [CH<sub>2</sub>Cl<sub>2</sub>, 0-23°, 18 hours, 74%] [Uno, Gillis and Burke *Tetrahedron* **65** 3230 2009]; and can be used in Suzuki, Heck, Stille, Negishi and Sonogashira couplings and Miyaura borylations [Gillis & Burke *Aldrichimica Acta* **42** 17 2009].

**Xantphos [4,5-Bis(diphenylphosphino)-9,9-dimethylxanthene]** [161265-03-8] **M 578.2, m 221-222°, 224-228°**. Xantphos is prepared, using Schlenck techniques under N<sub>2</sub>, by adding *sec*-BuLi (13.6ml of 1.3M in 98/2 cyclohexane/hexane, 14.3mmol) dropwise to a stirred solution of 9,9-dimethylxanthene (1.0g, 4.76mmol, see [19814-75-6]) and TMEDA (2.3ml, 13.3mmol) in dry Et<sub>2</sub>O (54ml), and stirring for 16 hours at ~25° to form the 4,5-dilithium derivative. To this mixture is added a solution of chlorodiphenylphosphine (2.8ml, 14.3mmol, see [1079-66-9]) in hexane (16ml) dropwise, and stirring is continued for 16 hours, then the solvent is removed *in vacuo*. The residual thick oil is dissolved in CH<sub>2</sub>Cl<sub>2</sub>, washed with H<sub>2</sub>O, dried (MgSO<sub>4</sub>), filtered, the solvent is removed *in vacuo*, the residue is washed with hexanes, and recrystallised from propan-1-ol to give *xantphos* (2.05g, 74.6%) as an air stable yellow-white powder. Its IR (CHCl<sub>3</sub>) has  $\nu_{\max}$  at 3.073w, 2974w, 1435s, 1405vs, 1243m, 695m cm<sup>-1</sup>; the <sup>1</sup>H NMR (300MHz, CDCl<sub>3</sub>) has  $\delta$  at 7.4 (dd, 2H,  $J$  = 7.8, 1.0Hz, CPCHCH), 7.15-7.26 (aryl, 20H, [P(C<sub>6</sub>H<sub>5</sub>)<sub>2</sub>]<sub>2</sub>), 6.96 (t, 2H,  $J$  = 7.7Hz, CHCHCH), 6.54 (dd, 2H,  $J$  = 7.4, 1.4Hz, CHCHCC), 1.65 (s, 6H, CH<sub>3</sub>); the <sup>13</sup>C{<sup>1</sup>H}NMR (100MHz, CDCl<sub>3</sub>) has  $\delta$  at 137.2 (t,  $J$  = 5.3Hz) through space P-P coupling ~60Hz, 133.7 (t,  $J$  = 10.1Hz), 131.9, 129.7, 128.0 (ar), 126.1, 125.7 (t,  $J$  = 9.8Hz), 123.1, 67.8 (CMe<sub>2</sub>), 31.6 (CH<sub>3</sub>); the <sup>31</sup>P{<sup>1</sup>H}NMR (121.5MHz, CDCl<sub>3</sub>, referenced to external 85% H<sub>3</sub>PO<sub>4</sub>) has  $\delta$  at -17.5; and exact mass (MS) is found to be 578.1916 (calculated for C<sub>39</sub>H<sub>32</sub>OP<sub>2</sub> is 578.1928). Out of several diphenylphosphino ligands studied, *xantphos* induced the highest selectivity in rhodium-catalysed hydroformylation of 1-alkenes to form linear aldehydes. The hydroformylation is carried out in a stainless steel bomb under pressure of ~10 bars of CO/H<sub>2</sub> (1:1) in toluene with phosphorus ligand and Rh(acac)(CO)<sub>2</sub> as metal source. [Kranenburg, van der Burgt, Kramer and van Leewen *Organometallics* **14** 3081 1995.]

## PHASE TRANSFER CATALYSTS

Phase transfer catalysts (PTCs) are agents that are soluble in both lipophilic and hydrophilic solutions, i.e. soluble in aqueous solutions and in non-water soluble organic solvents, in varying degrees. They are mostly cationic species that assist the transfer of anions. e.g. CN<sup>-</sup>, from the aqueous phase into the non-aqueous phase, e.g. hexane, CHCl<sub>3</sub>, which would contain the reactive compound, e.g. 1-octyl chloride, to form the product, i.e. 1-octyl nitrile, in the non-aqueous phase in high yields. However, the catalysts can also be essentially neutral as with *crown ethers*, *cryptands* (tricyclic ethers containing nitrogen atoms at the bridgehead allowing formation of three rings) and *ionophores* which are useful for transferring metal ions through the bilayer interface. Some PTCs are polymer-bound making it easy for their removal and recycling. Other reactions that are phase transfer catalysed include:  $\beta$ -eliminations, *N*-alkylations, nucleophilic aromatic substitutions, metal-organic reactions, oxidation and reduction reactions. The reactions may proceed in either phase and/or at the interphase of the phases. They invariably occur in the organic phase, but in *Reverse Phase Transfer* reactions they occur in the aqueous phase. This section provides a selection of such agents, some of which are chiral and are capable of

promoting stereoselective, or stereospecific reactions. [Starks *J Am Chem Soc* **93** 195 1971, Brändström *Adv Phys Org Chem* **15** 267 1977, G.W. **Adogen 464 [methyl trialkyl(C8—C10)ammonium chloride]** [72749-59-8] **M 416.2, d<sup>25</sup> 0.898, n<sub>D</sub><sup>20</sup> 1.4665**. This is purified in the same way as Aliquat 336 in the following entry. [US Patent 3 992 432.]

**Aliquat 336 (methyltricaprylammonium chloride, tri-*n*-octylmethylammonium chloride)** [5137-55-3, a replacement product, Aliquat 128, has 63393-96-4] **M 404.2, d<sup>25</sup> 0.884, n<sub>D</sub><sup>20</sup> 1.4665**. A 30% (v/v) of Aliquat 336 solution in \*benzene is washed twice with an equal volume of 1.5M HBr. [Petrow & Allen, *Anal Chem* **33** 1303 1961.] It is purified by dissolving 50g in CHCl<sub>3</sub> (100ml) and shaking with 20% NaOH solution (200ml) for 10 minutes, and followed by 20% NaCl (200ml) for 10 minutes. It is then washed with a small volume of H<sub>2</sub>O, and filtered through a dry filter paper. [Starks *J Am Chem Soc* **93** 195 1971, Adam & Pribil *Talanta* **18** 733 1971.]

***N*-Anthracenylmethyl)cinchonidinium chloride** [199588-80-2] **M 521.1, m ~158-161°**. The salt can be purified by recrystallisation from CH<sub>2</sub>Cl<sub>2</sub>/Et<sub>2</sub>O and dried *in vacuo*. This chiral phase-transfer-catalyst (PTC) assists in the allyl alkylation of the α-carbon of glycine imino ester to yield finally α-allyl-substituted α-amino acids. Thus with a ratio of imino ester to allyl compound: achiral phosphines (e.g. 1,2-bis[diphenylphosphino]ethane DIPHOS, DPPE [1663-45-2], its oxide, triphenoxyphosphine or its oxide) : base (KOH) : [Pd(*p*-allyl)Cl]<sub>2</sub>: PTC of 100:200:150:3.5:10 produced the α-allyl imino ester in varying yields and stereoselectivity. However, the derivative ***N*-(9-anthracenylmethyl)-*O*(9)-methyl-cinchonidinium iodide** (prepared from the chloride with MeI/50% aqueous NaOH/20°/4 hours) was a more effective PTC, providing better yields and with up to ~94% enantiomeric excess. The orange *iodide*, which is soluble in CH<sub>2</sub>Cl<sub>2</sub>, is crystallised from CH<sub>2</sub>Cl<sub>2</sub>/Et<sub>2</sub>O and has [α]<sub>D</sub><sup>19</sup> -288° (c 1, CH<sub>2</sub>Cl<sub>2</sub>), IR with ν<sub>max</sub> (CDCl<sub>3</sub>) at 3686, 3014, 2952, 1598, 1515, 1456, 1075, 986 cm<sup>-1</sup>; the <sup>1</sup>H NMR (500MHz, CDCl<sub>3</sub>) has δ<sub>H</sub> at 1.38-1.55 (m, 2H), 1.95-2.03 (m, 1H), 2.12-2.21 (m, 1H), 2.35-2.43 (m, 1H), 2.64-2.72 (m, 1H), 3.09 (dd, 1H, *J* = 5.6, 5.6Hz), 3.83 (s, 3H), 4.42-4.51 (m, 1H), 4.84 (d, *J* = 4.8Hz, 1H), 5.07 (d, *J* = 5.2Hz, 1H), 5.19 (d, *J* = 8.5Hz, 1H), 5.25 (bs, 1H), 5.87-6.02 (m, 2H), 6.52 (bs, 1H), 6.97 (d, *J* = 6.9Hz, 1H), 7.54-7.60 (m, 3H), 7.69-7.73 (m, 2H), 7.82-7.89 (m, 2H), 7.97 (brs, 1H), 8.05 (d, *J* = 4.3Hz, 1H), 8.14 (d, *J* = 4.1Hz, 1H), 8.20 (d, *J* = 4.3Hz, 1H), 8.32 ((d, *J* = 4.6Hz, 1H), 8.65 (s, 1H), 9.06 (d, *J* = 2.3Hz, 2H), 9.65 (d, *J* = 4.4Hz, 1H); and the <sup>13</sup>C NMR (125MHz, CD<sub>3</sub>OD) has δ<sub>C</sub> at 150.9, 149.1, 143.0, 138.5, 134.7, 134.6, 133.8, 133.0, 132.9, 131.5, 131.2, 131.1, 130.4, 129.6, 129.4, 129.4, 127.2, 126.1, 126.57, 125.7, 124.8, 124.7, 121.8, 118.9, 117.8, 79.5, 70.0, 63.3, 57.7, 57.5, 53.7, 39.4, 27.2, 26.2, 23.2. This *iodide* in CH<sub>2</sub>Cl<sub>2</sub> was converted to another useful PTC ***N*-(9-anthracenylmethyl)-*O*(9)-methyl-cinchonidinium hexafluorophosphate** [by addition of NH<sub>4</sub>PF<sub>6</sub> in H<sub>2</sub>O at 25°/1 hour, dilution with CH<sub>2</sub>Cl<sub>2</sub> and H<sub>2</sub>O, drying the organic layer (MgSO<sub>4</sub>) and evaporating] which gave yellow crystals from CH<sub>2</sub>Cl<sub>2</sub>/CHCl<sub>3</sub> with **m 163-164°**, [α]<sub>D</sub><sup>23</sup> -314° (c 1.1, CH<sub>2</sub>Cl<sub>2</sub>), and IR and NMR quite similar to those of the *iodide*. [Nakoji et al *J Org Chem* **67** 7418 2002.]

**8*S*,9*R*-(-)-*N*-Benzylcinchonidinium chloride (BCDC)** [69257-04-1] **M 421.0, m 212-213° (dec), [α]<sub>D</sub><sup>20</sup> -180°, -183° (c 5, H<sub>2</sub>O), p*K*<sub>Est</sub> ~5**. Dissolve the chloride in the minimum volume of H<sub>2</sub>O and add absolute Me<sub>2</sub>CO. Filter it off and dry it in a vacuum. It can also be recrystallised from hot EtOH or EtOH/Et<sub>2</sub>O. It is a good chiral phase transfer catalyst producing the opposite enantiomer to the one using *N*-benzylcinchoninium chloride as catalyst — see below. [Colonna et al. *J Chem Soc, Perkin Trans 1* 547 1981, Imperali & Fisher *J Org Chem* **57** 757 1992.] [Beilstein **23** H 446.] See cinchonidine [485-71-2].

**8*R*,9*S*-(+)-*N*-Benzylcinchoninium chloride (BCNC, *N*-benzyl-9*S*-hydroxycinchoninium chloride)** [69221-14-3] **M 421.0, m 265° (dec), [α]<sub>D</sub><sup>20</sup> +169° (c 0.4, H<sub>2</sub>O), p*K*<sub>Est</sub> ~ 5**. Recrystallise the chloride from isoPrOH, toluene or small volumes of H<sub>2</sub>O. It is a good chiral phase transfer catalyst producing the opposite enantiomer to

the one using the above *N*-benzylcinchonidinium chloride as catalyst — see above. [Julia et al. *J Chem Soc, Perkin Trans 1* 574 1981, Hughes et al. *J Am Chem Soc* **106** 446 1984, Hughes et al. *J Org Chem* **52** 4745 1987, *Beilstein* **23** IV 2832.] See cinchonine [118-10-5].

**(11bR)-(–)- and (11bS)-(+)- 4,4-Dibutyl-4,5-dihydro-2,6-bis(3,4,5-trifluorophenyl)-3H-dinaphth[2,1-c:1',2'-e]azepinium bromide** [*R*- 887938-70-7; *S*- 851942-89-7] **M 748.6, m 223-228°**, **224-229°**,  $[\alpha]_{\text{D}}^{29} \pm 11.7^{\circ}$  (**c 1.01, CHCl<sub>3</sub>**). The precursor chiral 2,2'-bisbromomethyl -1,1'-binaphthyl (280mg, 0.4mmol), di-*n*-butylamine (140μl, 0.8mmol) and K<sub>2</sub>CO<sub>3</sub> (82mg, 0.6mmol) in MeCN (5ml) is refluxed with stirring for 10 hours. The mixture was poured into H<sub>2</sub>O, extracted with CH<sub>2</sub>Cl<sub>2</sub>, the extract is dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and evaporated to dryness. The residue is purified by column chromatography on silical gel (eluting with MeOH/CH<sub>2</sub>Cl<sub>2</sub>, 1:20) to give the bromide salt (275mg, 92%) which may be recrystallised from MeOH/Et<sub>2</sub>O. The *S*-enantiomer has IR with  $\nu_{\text{max}}$  (film) at 2965, 2936, 2876, 1614, 1524, 1470, 1447, 1360, 1242, 1047, 923, 908, 870, 725 cm<sup>-1</sup> and <sup>1</sup>H NMR (400MHz, CDCl<sub>3</sub>) with  $\delta_{\text{H}}$  at 7.97-7.95 (4H, m, Ar-H), 7.55-7.51 (2H, m, Ar-H), 7.27-7.23 (8H, m, Ar-H), 4.99 (2H, d, *J* = 14.1Hz, Ar-CH<sub>2</sub>), 3.74 (2H, d, *J* = 14.1Hz, Ar-CH<sub>2</sub>), 3.32 (2H, t, *J* = 12.5Hz, N-CH<sub>2</sub>-CH<sub>2</sub>), 2.56 (2H, t, *J* = 12.3Hz, N-CH<sub>2</sub>-CH<sub>2</sub>), 1.06-0.97 (6H, m, CH<sub>2</sub>), 0.71 (6H, t, *J* = 6.9Hz, CH<sub>3</sub>), 0.23 (2H, bs, CH<sub>2</sub>); the <sup>13</sup>C NMR (100MHz, CDCl<sub>3</sub>) has  $\delta_{\text{C}}$  at 151.03 (d, *J*<sub>C-F</sub> = 294.1Hz), 139.63 (ddd, *J*<sub>C-F</sub> = 254.1, 15.1, 15.1Hz), 138.30, 136.86, 134.63 (dd, *J*<sub>C-F</sub> = 12.7, 7.8Hz), 133.43, 131.13, 130.83, 128.30, 128.29, 127.68, 127.36, 123.32, 115.40-113.94 (m), 57.54, 57.34, 24.59, 19.32, 13.26. [Kitamura et al. *Angew Chem, Int Ed* **44** 1549 2005, Ooi et al. *J Org Chem* **68** 4576 2003.] These are potent phase transfer organocatalysts for asymmetric  $\alpha$ -alkylation of *N*-arylidene-glycine *tert*-butyl ester derivatives for the synthesis of chiral  $\alpha$ -substituted  $\alpha$ -amino acids at extremely low concentrations of catalyst [Ooi et al. *Tetrahedron Asymm* **17** 603 2006].

**Cetyltrimethylammonium bromide (cetrimonium bromide, CTAB)** [57-09-0] **M 364.5, m 227-235°(dec)**. Crystallise it from EtOH, EtOH/\*benzene or from wet acetone after extracting twice with petroleum ether. Shake it with anhydrous diethyl ether, filter and dissolve it in a little hot MeOH. After cooling in the refrigerator, the precipitate is filtered off at room temperature and re-dissolved in MeOH. Anhydrous ether is added and, after warming to obtain a clear solution, it is cooled and the crystalline material is collected. [Dearden & Wooley *J Phys Chem* **91** 2404 1987, Hakemi et al. *J Am Chem Soc* **91** 120 1987, *Beilstein* **4** IV 819.]

**Cetyltrimethylammonium chloride** [112-02-7] **M 320.0**. Crystallise the chloride from acetone/ether mixture, EtOH/ether, or from MeOH. [Moss et al. *J Am Chem Soc* **109** 4363 1987, *Beilstein* **4** IV 819.]

**Decyltrimethylammonium bromide** [2082-84-0] **M 280.3, m 239-242°**. Crystallise the salt from 50% (v/v) EtOH/Et<sub>2</sub>O, or from acetone and wash with ether. Dry it under vacuum at 60°. Also recrystallise it from EtOH and dry it over silica gel. [McDonnell & Kraus *J Am Chem Soc* **73** 2170 1952, Dearden & Wooley *J Phys Chem* **91** 2404 1987, *Beilstein* **4** IV 784.]

**Didodecyldimethylammonium bromide** [3282-73-3] **M 463.6, m 157-162°**. Recrystallise the salt from acetone, acetone/ether mixture, then from ethyl acetate, wash with ether and dry it in a vacuum oven at 60° [Chen et al. *J Phys Chem* **88** 1631 1984, Rupert et al. *J Am Chem Soc* **107** 2628 1985, Halpern et al. *J Am Chem Soc* **108** 3920 1986, Allen et al. *J Phys Chem* **91** 2320 1987]. [*Beilstein* **4** IV 801.]

**Diocetadecyldimethylammonium bromide** [3700-67-2] **M 630.9, m 161-163°**. Crystallise the bromide from acetone, then MeOH [Lukac *J Am Chem Soc* **106** 4387 1984]. Also purify it by chromatography on alumina by washing with \*C<sub>6</sub>H<sub>6</sub> and eluting with Me<sub>2</sub>CO, evaporating and crystallising from MeCN [Swain & Kreevoy *J Am Chem Soc* **77** 1126 1955]. [*Beilstein* **4** IV 829.]

***N,N*-Diocetadecyl methylamine (hydrogen ionophore III)** [4088-22-6] **M 536.0, m 40°, 44-46°, 48-49°, b 252-259°, pK<sub>Est</sub> ~10**. It can be distilled at high vacuum, but by dissolving in \*C<sub>6</sub>H<sub>6</sub>, filtering and evaporating, a waxy solid suitable for electrode use can be obtained. It recrystallises from Me<sub>2</sub>CO or MeCN. [Hoerr et al. *J Org Chem* **9** 201 1944, Wu & Yu *Talanta* **34** 577 1987, *Beilstein* **4** III 435.]

**Dodecyltrimethylammonium chloride** [112-00-5] **M 263.9, m 246<sup>o</sup>(dec)**. Dissolve the chloride in MeOH, treat with active charcoal, filter and dry it *in vacuo* [Waldenburg *J Phys Chem* **88** 1655 1984], or recrystallise it several times from 10% EtOH in acetone. It has also been repeatedly crystallised from EtOH/ether or MeOH. [Cella et al. *J Am Chem Soc* **74** 2062 1952, *Beilstein* **4** IV 79.]

**Hexyltrimethylammonium bromide** [2650-53-5] **M 224.3, m 186<sup>o</sup>**. Recrystallise it from acetone. It is extremely *hygroscopic*. [McDowell and Kraus *J Am Chem Soc* **73** 2170 1951, *Beilstein* **4** IV 710.]

**Octadecyl trimethylammonium bromide (stearyl trimethylammonium bromide)** [1120-02-1] **M 392.5, m ~250<sup>o</sup>dec, 230-240<sup>o</sup>(dec)**. Crystallise it from EtOH or H<sub>2</sub>O (solubility is 1 in 1000parts). It is very soluble in Me<sub>2</sub>CO. It is a bactericide. [Sheldon et al. *J Am Chem Soc* **68** 754 1946, Grieger & Kraus *J Am Chem Soc* **70** 3805, 38007, *Beilstein* **4** IV 827.]

**Tetra-*n*-amylammonium bromide (tetra-*n*-pentylammonium bromide)** [866-97-7] **M 378.5, m 100-101<sup>o</sup>**. Crystallise it from petroleum ether, \*benzene or acetone/ether mixtures and dry it *in vacuo* at 40-50<sup>o</sup> for 2 days. It is used in ion-paired chromatography. (Sagara et al. *J Chromatogr* **328** 289 1985). [*Beilstein* **4** IV 677.]

**Tetra-*n*-amylammonium iodide** [2498-20-6] **M 425.5, m 135-137<sup>o</sup>**. Crystallise the iodide from EtOH and dry it at 35<sup>o</sup> under a vacuum. It has also been purified by dissolving in acetone and precipitating by adding diethyl ether, and drying at 50<sup>o</sup> for 2 days. [*Beilstein* **4** IV 677.]

**Tetradecyltrimethylammonium bromide (myristyl trimethylammonium bromide)** [1119-97-7] **M 336.4, m 244-245<sup>o</sup>, 244-249<sup>o</sup>**. Crystallise the bromide from acetone or a mixture of Me<sub>2</sub>CO and >5% MeOH, or Me<sub>2</sub>CO/EtOH. Wash it with diethyl ether and dry it in a vacuum oven at 60<sup>o</sup>. It is a cationic detergent. Its solubility is 1g/5g H<sub>2</sub>O. [Dearden & Wooley *J Phys Chem* **91** 2404 1987, Shelton et al. *J Am Chem Soc* **68** 754 1946, *Beilstein* **4** III 419, **4** IV 813.]

**Tetra-*n*-heptylammonium iodide** [3535-83-9] **M 537.7, m 102-103<sup>o</sup>**. Crystallise the iodide from EtOH or aqueous EtOH. [Eriksen et al. *J Org Chem* **25** 849 1960, *Beilstein* **4** IV 736 for triheptylamine.]

**Tetra-*n*-hexylammonium bromide** [4328-13-6] **M 434.6, m 99-100<sup>o</sup>**. Wash the bromide with ether, and dry it in a vacuum at room temperature for 3 days.

**Tetra-*n*-hexylammonium chloride** [5922-92-9] **M 390.1**. Crystallise the chloride from EtOH.

**Tetra-*n*-hexylammonium iodide** [2138-24-1] **M 481.6, m 99-101<sup>o</sup>, 102-103<sup>o</sup>**. Wash the iodide with diethyl ether and dry it at room temperature *in vacuo* for 3 days. It is soluble in CH<sub>2</sub>Cl<sub>2</sub>. [Eriksen et al. *J Org Chem* **25** 849 1960, *Beilstein* **4** IV 711 for trihexylamine.]

**Tetrahexylammonium perchlorate** [4656-81-9] **M 454.1, m 104-106<sup>o</sup>**. Crystallise the salt from acetone and dry it *in vacuo* at 80<sup>o</sup> for 24 hours.

**Tetrapentylammonium bromide**. See tetra-*n*-amylammonium bromide above.

**Tetra-*n*-propylammonium bromide** [1941-30-6] **M 266.3, m >280<sup>o</sup>(dec)**. Crystallise it from ethyl acetate/EtOH (9:1), acetone or MeOH. Dry it at 110<sup>o</sup> under reduced pressure. [*Beilstein* **4** IV 471.]

**Tetra-*n*-propylammonium iodide** [631-40-3] **M 313.3, m >280<sup>o</sup>(dec)**. Purify the iodide by crystallising it from EtOH, EtOH diethyl ether (1:1), EtOH water or aqueous acetone. Dry it at 50<sup>o</sup> under a vacuum and store it over P<sub>2</sub>O<sub>5</sub> in a vacuum desiccator. Store it away from light. [*Beilstein* **4** IV 472.]

**Tri-*n*-butylhexadecylphosphonium bromide (TBHDTB, hexadecyltributylphosphonium bromide)** [14937-45-2] **M 507.7, m 54<sup>o</sup>, 56-58<sup>o</sup>**. It is made by heating 1-bromohexadecane (1 mol, 112-82-3) and tri-*n*-butylphosphine (1 mol, 998-40-3) at 65<sup>o</sup> for 3 days. The mixture solidifies on cooling, and the solid is recrystal-

lised from hexane and dried *in vacuo* to give 68% of the phosphonium salt. [Starks *J Am Chem Soc* **93** 195 1971, *cf* for preparing fluorides see Landini et al. *Synthesis* 37 and 428 1974, for preparing disulfides see Landini & Rolla *Synthesis* 565 1974.]

**Tri-*n*-dodecylamine (Hydrogen ionophore I)** [102-87-4] **M 522.0, m 15.7°, b 220-228°/0.03mm, d<sub>4</sub><sup>20</sup> 0.833, n<sub>D</sub><sup>20</sup> 1.4577, pK<sub>Est</sub> ~11.0.** Distil tridodecylamine under high vacuum and N<sub>2</sub>, and store it in the absence of CO<sub>2</sub>. It can be recrystallised from 95%EtOH/\*C<sub>6</sub>H<sub>6</sub> at low temperature under vacuum. The *hydrochloride* has **m 78-79°**. [Ra et al. *J Org Chem* **9** 259 1944, *Beilstein* **4** III 413, **4** IV 801.]

**Tri-*n*-dodecylammonium nitrate** [2305-34-2] **M 585.0.** Crystallise the salt from *n*-hexane/acetone (95:5) and keep it in a desiccator over P<sub>2</sub>O<sub>5</sub> under vacuum. [*Beilstein* **4** IV 801 for tridodecylamine.]

**Tri-*n*-dodecylammonium perchlorate** [5838-82-4] **M 622.4.** Recrystallise the salt from *n*-hexane or acetone and keep it in a desiccator over P<sub>2</sub>O<sub>5</sub>. (Potentially explosive.)

**Tri-*n*-octylammonium chloride** [1188-95-0] **M 384.2, m 78-79°, pK<sup>25</sup> 8.35 (in 70% aqueous EtOH).** Crystallise it from Et<sub>2</sub>O, then *n*-hexane (see above). [Burrows et al. *J Chem Soc* 200 1947, *Beilstein* **4** H 196.]

**Tri-*n*-octylammonium perchlorate** [2861-99-6] **M 454.2, m >300°(dec).** Crystallise the perchlorate from *n*-hexane. (Possibly explosive.) [*Beilstein* **4** IV 754.]

## IMIDAZOLIUM IONIC LIQUID CRYSTAL CATALYSTS

A general discussion on ionic liquid crystals has already been made (see Chapter 3), and this section includes some commercially available liquid crystal 1,3-dialkylimidazolium salts that participate in the catalytic process, i.e. by coordination with the metal component of catalysts, as well as assisting in other ways such as acting as a solvent, affecting the dielectric, and in phase transference of reagents. Depending on the *N*-alkyl substituents and the counter anion the salts may be more, or less, soluble in water or organic solvents. They are non-volatile (i.e. environmentally friendly), stable to water and air and many may be heated to temperatures as high as 300°, making it possible to distil off some products from them. They can be recovered for re-use. [See P. Wasserscheid and T. Welton, *Ionic Liquids in Synthesis* (2 volume set), Wiley VCH, Weinheim, 2008. ISBN-10: 3527312390, ISBN-13: 978-3527312399.]

*Preparation:* Alkylation of *N*-1 of imidazole can be carried out using alkyl halide and alkoxide as for 1-ethylimidazole [1072-62-4], and the second alkylation onto *N*-3 is performed by further reaction with the desired alkylbromide (slightly less than a molar equivalent) in a solvent, e.g. 1,1,1-trichloroethane, at reflux for 2 hours. The molten bromide salt is separated from the solvent, washed with trichloroethane, dried on a Rotavap at 70°/0.1mm to give the bromide salt as a white solid or a liquid in high yield (~90%) and high state of purity if the starting reagents are pure. Check purity by <sup>1</sup>H NMR and elemental analysis. The imidazolium bromide salts are most useful as they can be converted into other salts, e.g. AcO<sup>-</sup> with AgOAc, TfO<sup>-</sup> with AgOTf, bis(trifluoromethylsulfonyl)imide [NTf<sub>2</sub><sup>-</sup>] with NTf<sub>2</sub>Li, nonafluorobutanesulfonate [NfO<sup>-</sup>] with NfOK, etc. Generally the imidazolium bromide and the metal salt of the required anion are dissolved in the least volume of H<sub>2</sub>O at 70°, stirred for 1 hour (if silver halide precipitates it is filtered off), and the imidazolium salt can be extracted into an organic solvent, e.g. CH<sub>2</sub>Cl<sub>2</sub> or 1,1,1-trichloroethane, and the extract is then evaporated *in vacuo* and dried at 50°/0.1mm for 2 hours or until there is no further loss in weight. *Alternatively*, where possible, the 1-alkylimidazole is alkylated with e.g. alkyl toluene-*p*-sulfonate ester to provide the 1,3-dialkylimidazolium toluene-*p*-sulfonate directly. [Bonhôte et al. *Inorg Chem* **35** 1168 1996.]

The following liquid crystal salts can be readily prepared in small or large quantities:

**1-Butyl-3-methylimidazolium Salts (BMIM<sup>+</sup> X<sup>-</sup>,** see Park & Kazlauskas *J Org Chem* **66** 8395 2001 for improved preparation, purification and use at ambient temperature of some of the following ionic liquids in lipase-catalysed enantio- and regioselective acylation reactions:

**BMIM<sup>+</sup> AcO<sup>-</sup>** [284049-75-8] **M 198.6; BMIM<sup>+</sup> Ntf<sub>2</sub><sup>-</sup>** [174899-83-3] **M 419.4, n<sub>D</sub><sup>20</sup> 1.428,** [good synthetic activity of soluble *Candida antarctica* lipase B in this ionic liquid was obtained towards the enantioselective and operational stability for butyl butyrate synthesis and kinetic resolution of 1-phenylethanol in supercritical CO<sub>2</sub>,

Lozano et al. *JCS, Chem Commun* 692 2002]; **BMIM<sup>+</sup> Br<sup>-</sup>** [85100-77-2] **M 219.1**, [used in Heck reactions with Pd(OAc)<sub>2</sub> where Pd-Im bond is formed, Xu et al. *Organometallics* **19** 1123 2000]; **BMIM<sup>+</sup> Cl<sup>-</sup>** [79917-90-1] **M 174.7, m ~70°**, [used with AlCl<sub>3</sub> in Friedel-Crafts alkylation reactions, Chauvin et al. *J Mol Catal* **92** 155 1994]; **BMIM<sup>+</sup> (n-BuO)<sub>2</sub>P(O)O<sup>-</sup>** [663199-28-8] **M 348.4, n<sub>D</sub><sup>20</sup> 1.472**; **BMIM<sup>+</sup> (NC)<sub>2</sub>N<sup>-</sup>** [448245-52-1] **M 205.3**; **BMIM<sup>+</sup> SbF<sub>6</sub><sup>-</sup>** [174645-81-9] **M 375.0**; and **BMIM<sup>+</sup> PF<sub>6</sub><sup>-</sup>** [174501-64-5] **M 284.2, n<sub>D</sub><sup>20</sup> 1.411**, [used in allylation of RCHO with (Allyl)Sn, Gordon & McCluskey *JCS, Chem Commun* 1431 1999; in coupling of aryl halides by (Ph<sub>3</sub>)<sub>n</sub>Ni(0), Howarth et al. *Tetrahedron Lett* **41** 10319 2000; and catalyse the addition of CN (from TMSCN) to arylimines (from ArCHO + RNH<sub>2</sub>) to form α-aminonitriles, Yadav et al. *New J Chem* **27** 462 2003]; **BMIM<sup>+</sup> HCO<sub>3</sub><sup>-</sup>** [366491-15-8] **M 200.2, as 50% in 2:3 MeOH:H<sub>2</sub>O**; **BMIM<sup>+</sup> HSO<sub>4</sub><sup>-</sup>** (as **BASIONIC<sup>®</sup> AC 28**) [262297-13-2] **M 236.3**; **BMIM<sup>+</sup> MeSO<sub>3</sub><sup>-</sup>** (as **BASIONIC<sup>®</sup> ST 78**) [342789-81-5] **M 234.3**; and **BMIM<sup>+</sup> MeSO<sub>4</sub><sup>-</sup>** [401788-98-5] **M 250.3, n<sub>D</sub><sup>20</sup> 1.478**, [catalyse the addition of CN (from TMSCN) to arylimines (from ArCHO + RNH<sub>2</sub>) to form α-aminonitriles, Yadav et al. *New J Chem* **27** 462 2003]; **BMIM<sup>+</sup> BF<sub>4</sub><sup>-</sup>** [174501-65-6] **M 226.0**, {specifically catalyses the Biginelli reaction (formation of 3,4-dihydropyrimidin-2(1H)-ones from aldehydes + urea + MeCOCH<sub>2</sub>COR), Peng & Deng *Tetrahedron Lett* **42** 5917 2001; **BMIM<sup>+</sup> PF<sub>6</sub><sup>-</sup>** [174501-64-5] **M 284.2**, [catalyses the addition of CN (from TMSCN) to arylimines (from ArCHO + RNH<sub>2</sub>) to form α-aminonitriles, Yadav et al. *New J Chem* **27** 462 2003; assists in the bi-phasic hydrogenation of arenes at room temperature using a ruthenium cluster catalyst which coordinates with it, Dyson et al. *JCS, Chem Commun* 25 1999; and the molten salt catalyses the asymmetric hydrogenation of 2-arylacrylic acids by immobilised Ru-BINAP complex, Montiero et al. *Tetrahedron Asymmetry* **8** 177 1997; and is used in Palladium [Pd(Ph<sub>3</sub>)<sub>4</sub>] catalysed Suzuki cross-coupling (aryl halides and arylboronic acids) at ambient temperature, Mathews et al. *JCS, Chem Commun* 1249 2000; and it specifically catalyses the Biginelli reaction (formation of 3,4-dihydropyrimidin-2(1H)-ones from aldehydes + urea + MeCOCH<sub>2</sub>COR), Peng & Deng *Tetrahedron Lett* **42** 5917 2001; and **BMIM<sup>+</sup> CF<sub>3</sub>SO<sub>3</sub><sup>-</sup>** [174899-66-2] **M 288.3, n<sub>D</sub><sup>20</sup> 1.434**; **BMIM<sup>+</sup> octyOSO<sub>3</sub><sup>-</sup>** [445473-58-5] **M 348.5**, [this ionic liquid increases the yield and enzyme stability of β-galactosidase in enzyme-catalysed syntheses, Kaftzik et al. *Org Process Res Dev* **6** 553 2002].

**1-Ethyl-3-methylimidazolium Salts (EMIM<sup>+</sup> X<sup>-</sup>**, see Park & Kazlauskas *J Org Chem* **66** 8395 2001 for improved preparation and use of ambient temperature of some of the following ionic liquids in lipase-catalysed enantio- and regioselective acylation reactions):

**EMIM<sup>+</sup> Br<sup>-</sup>** [65039-08-9] **M 191.1**, [it is highly conductive at ~25° [Bonhôte et al. *Inorg Chem* **35** 1168 1996]; **EMIM<sup>+</sup> Cl<sup>-</sup>** [65039-09-0] **M 146.6, m 77-79°**; **EMIM<sup>+</sup> (n-BuO)<sub>2</sub>P(O)O<sup>-</sup>** [869858-84-4] **M 320.4, n<sub>D</sub><sup>20</sup> 1.469**; **EMIM<sup>+</sup> AcO<sup>-</sup>** [143314-17-4] **M 170.2, n<sub>D</sub><sup>20</sup> 1.502**; **EMIM<sup>+</sup> (CF<sub>3</sub>CF<sub>2</sub>-SO<sub>2</sub>)<sub>2</sub>N<sup>-</sup>** [216299-76-2] **M 491.3, m ≤1°**, [very stable fluorinated ionic liquids that are extremely hydrophobic]; **EMIM<sup>+</sup> Ntf<sub>2</sub><sup>-</sup>** [174899-82-2] **M 391.3, m ≥15°**, [it is a useful medium for the enantioselective cyclopropanation of styrene with ethyldiazoacetate, promoted by two different Cu-bis(oxazoline) complexes and its recovery, Fraile et al. *Tetrahedron Asymmetry* **12** 1891 2001; and good synthetic activity of soluble *Candida antarctica* lipase B in this ionic liquid was obtained towards the enantioselective and operational stability for butyl butyrate synthesis and kinetic resolution of 1-phenyl ethanol in supercritical CO<sub>2</sub>, Lozano et al. *JCS, Chem Commun* 692 2002]; **EMIM<sup>+</sup> (CN)<sub>2</sub>N<sup>-</sup>** [370865-89-7] **M 177.2**, [its conductivity is ~26,000 μS cm, and its electrochemical window is -2.4 to +3.3 V, cf Bonhôte et al. *Inorg Chem* **35** 1168 1996]; **EMIM<sup>+</sup> PF<sub>6</sub><sup>-</sup>** [155371-19-0] **M 256.1, m 58-62°**, [it is prepared by mixing EMIM<sup>+</sup> Cl<sup>-</sup> (29.3g, 200mmol) and 60% aqueous HPF<sub>6</sub> (9g, 200mmol) in H<sub>2</sub>O (300ml), the resulting mixture of white solid and liquid are cooled in an ice bath for 2 hours and the EMIM<sup>+</sup> PF<sub>6</sub><sup>-</sup> (31.8g 62%) is dried *in vacuo*. Recrystallisation from MeOH provides crystals for X-ray structural analysis. [Fuller et al. *JCS, Chem Commun* 299 1994]; and **EMIM<sup>+</sup> BF<sub>4</sub><sup>-</sup>** [143314-16-3] **M 198.0, m 15°, b >350°, d<sub>4</sub><sup>25</sup> 1.294, n<sub>D</sub><sup>20</sup> 1.413**, [its conductivity is ~11,500 μS cm, and its electrochemical window is -2.2 to +3.5 V, cf Bonhôte et al. *Inorg Chem* **35** 1168 1996]; the salt is prepared by stirring Ag<sub>2</sub>O (23.2g, 100mmol) with 48% aqueous HBF<sub>4</sub> (36.9g, 200mmol) in H<sub>2</sub>O (300ml) until the Ag<sub>2</sub>O has reacted completely to give a clear solution, then EMIM<sup>+</sup> Cl<sup>-</sup> (29.2g, 200mmol) dissolved in H<sub>2</sub>O is added and the mixture is stirred for 2 hours, the AgCl is filtered off, the filtrate is evaporated *in vacuo* and the colourless residue is dried in a vacuum oven at 60° to give the BF<sub>4</sub><sup>-</sup> salt (33.6g, 85%). [Fuller et al. *JCS, Chem Commun* 299 1994].

## CHIRAL AUXILIARIES

These compounds are involved in reactions, which direct stereospecificity and are decomposed, e.g. by

hydro-lysis, reduction, to generate the desired chiral products and the remains of the original auxiliary which can be recycled. Unlike the case of catalysis, the auxiliary is involved stoichiometrically and is not recycled during the reaction. It is one of the products of the reaction and can, *via* other reactions if necessary, be used to regenerate the original auxiliary. These have been used for decades and are of necessity chiral molecules themselves. The auxiliaries have to be linked to the molecule that has a reactive group which can be operated on, e.g. carbonyl, to generate an asymmetric centre, e.g. a chiral alcohol. This section includes more recently available auxiliaries, although many useful ones such as cinchonine, cinchonidine, borneols, camphors, menthol derivatives, substituted sugars, substituted chiral heterocycles (e.g. pyrrolidines), sterols etc. will be found scattered in Chapters 4, 5 and 7. [see Evans *Aldrichimica Acta* **15** 23 1982, Ager et al. *Chem Rev* **96** 835 1996, Ager et al. *Aldrichimica Acta* **30** 3 1997, Mukaiyama *Aldrichimica Acta* **29** 59 1996, K. Rück-Braun and H. Kunz *Chiral Auxiliaries in Cycloaddition Reactions* Wiley-VCH, Weinheim 1999, ISBN 3-527-29386-8.]

***R*-(–)- and *S*-(+)- Acetyl-cyclopentadienyl-ironcarbonyl triphenylphosphine complex [*R*- and *S*- ( $\eta^5$ -C<sub>5</sub>H<sub>5</sub>)Fe(CO)(CH<sub>3</sub>CO) (PPh<sub>3</sub>)]** [*R* 36548-61-5; *S* 36548-60-4; *RS* 12101-02-9] **M 454.3, m 142°**, (+), **140°** (–), **145°** ( $\pm$ ), ***R*-[ $\alpha$ ]<sub>436</sub><sup>27</sup> –288°, [ $\alpha$ ]<sub>546</sub><sup>22</sup> –288° (c 0.045, C<sub>6</sub>H<sub>6</sub>)**, ***S*- [ $\alpha$ ]<sub>546</sub><sup>22</sup> +288° (c 0.045, C<sub>6</sub>H<sub>6</sub>)**. This racemic “chiral” auxiliary can be made on a large scale from [ $\eta^5$ -(C<sub>5</sub>H<sub>5</sub>)Fe(CO)<sub>2</sub>]<sub>2</sub> [38117-54-3] which is cleaved with Na/Hg to give the anion [ $\eta^5$ -(C<sub>5</sub>H<sub>5</sub>)Fe(CO)<sub>2</sub>]<sup>–</sup> (Na<sup>+</sup>) that is methylated to  $\eta^5$ -(C<sub>5</sub>H<sub>5</sub>)Fe(CO)COMe (m **78–82°**, caramel coloured waxy crystals from sublimation *in vacuo* onto an ice-cooled glass finger) with MeI [Piper & Wilkinson *J Inorg Nucl Chem* **3** 104 1956, Aktogu et al. *J Organomet Chem* **262** 49 1984, King *Organometallic Synthesis Vol 1*, Academic Press, NY, p 145 1965]. This methyl complex provides the racemic title compound when treated with PPh<sub>3</sub>. Thus (C<sub>5</sub>H<sub>5</sub>)Fe(CO)<sub>2</sub>Me (1.0g, 5mmol) and PPh<sub>3</sub> (1.3g, 5mmol) in redistilled THF (10ml) are refluxed (65°) under N<sub>2</sub> until the Fe-Me band (IR: strong C-H deformation band at 1170 cm<sup>–1</sup> in CS<sub>2</sub>) disappears (~48 hours). The solution is filtered, the solvent is evaporated (to ~20mm), the residue is dissolved in pentane (10ml), passed through an Al<sub>2</sub>O<sub>3</sub> column (5 x 20cm), and only one band (yellow orange to orange) is eluted with pentane which, on evaporation (at ~20mm), provides the analytically pure orange ( $\pm$ )- $\eta^5$ -(C<sub>5</sub>H<sub>5</sub>)Fe(CO)(CH<sub>3</sub>CO)(PPh<sub>3</sub>), m 145° in ~98% yield. This reaction is solvent dependent, i.e. no reaction occurs in boiling hexane (68°), and is only 50% complete in boiling Et<sub>2</sub>O (34°) after 48 hours. The solid is stable in air, is soluble in organic solvents, e.g. pentane, hexane, Et<sub>2</sub>O, THF, CH<sub>2</sub>Cl<sub>2</sub>, CHCl<sub>3</sub>, and \*C<sub>6</sub>H<sub>6</sub>, but is insoluble in MeOH or H<sub>2</sub>O. Solutions in CHCl<sub>3</sub>, and \*C<sub>6</sub>H<sub>6</sub> decompose rapidly in air to produce brown intractable solids. Hence these solutions should be prepared and used under N<sub>2</sub> or argon. Its IR (CHCl<sub>3</sub>) has bands with  $\nu_{\max}$  at 1598 (s, MeC=O) and 1920 (vs, br, Fe carbonyl) cm<sup>–1</sup>; and the <sup>1</sup>H NMR (60MHz, CDCl<sub>3</sub>, external TMS) has  $\delta_{\text{H}}$  at 7.59 (m, Ph, 15H), 4.69 (s, C<sub>5</sub>H<sub>5</sub>, 5H) and 2.52 (s, COMe, 3H). [Bibler & Wojcicki *Inorg Chem* **5** 889 1966, Butler et al. *Inorg Chem* **6** 2074 1967.]

The versatility of this acetyl auxiliary has prompted its **optical resolution** into the pure enantiomers which proved to be very good chiral auxiliaries for preparing a variety of optically active molecules where high stereo control is achieved. Two independent resolutions were achieved, both involving 1*R*,2*S*,5*R*-(–)-2-isopropyl-5-methylcyclohexan-1-ol (*R*-(*l*-menthol). The first is from the reaction of sodium *R*-menthylate (NaOC<sub>10</sub>H<sub>19</sub>, *R*-menthyl refers to the radical produced by loss of the hydroxyl group) and ( $\pm$ )-( $\eta^5$ -C<sub>5</sub>H<sub>5</sub>)Fe(CO)<sub>2</sub>(PPh<sub>3</sub>)<sup>+</sup>PF<sub>6</sub><sup>–</sup> (see below) recovered from hydrolysis, decomplexation, of derivatives of the racemic title compound Aktogu et al. [*J Organomet Chem* **262** 49 1984] to give a diastereoisomeric mixture of (+)-(C<sub>5</sub>H<sub>5</sub>)Fe(CO)(PPh<sub>3</sub>)-(–)COOC<sub>10</sub>H<sub>19</sub> {[ $\alpha$ ]<sub>589</sub><sup>20</sup> +30°, [ $\alpha$ ]<sub>579</sub><sup>20</sup> +35°, [ $\alpha$ ]<sub>546</sub><sup>20</sup> +70°, [ $\alpha$ ]<sub>436</sub><sup>20</sup> 1450° (in 10<sup>–3</sup>M \*C<sub>6</sub>H<sub>6</sub>)}, and (–)-(C<sub>5</sub>H<sub>5</sub>)Fe(CO)(PPh<sub>3</sub>)-(–)COOC<sub>10</sub>H<sub>19</sub> {[ $\alpha$ ]<sub>589</sub><sup>20</sup> –75°, [ $\alpha$ ]<sub>579</sub><sup>20</sup> –80°, [ $\alpha$ ]<sub>546</sub><sup>20</sup> –120°, [ $\alpha$ ]<sub>436</sub><sup>20</sup> +1550° (in 10<sup>–3</sup>M \*C<sub>6</sub>H<sub>6</sub>)}, (together with NaPF<sub>6</sub>) which were separated by recrystallisation from pentane, with the latter being more soluble. [Brunner & Schmidt *J Organomet Chem* **21** P53 1970.] Then the ester with [ $\alpha$ ]<sub>546</sub><sup>20</sup> –120° (560mg, 0.93mmol) in THF (20ml) at –30°, is treated dropwise with MeLi (1ml of 1.5M Et<sub>2</sub>O solution), followed by stirring at –30°/1 hour, then at ~25°/1 hour. After quenching the reaction and evaporating, the brown residue is extracted into \*C<sub>6</sub>H<sub>6</sub>, and purified through a column of Al<sub>2</sub>O<sub>3</sub>/3% H<sub>2</sub>O and eluted with \*C<sub>6</sub>H<sub>6</sub>. The greenish zone gives a menthol-free yellow solid, which on sublimation provides analytically pure orange (+)- $\eta^5$ -(C<sub>5</sub>H<sub>5</sub>)Fe(CO)(CH<sub>3</sub>CO)(PPh<sub>3</sub>) (47mg, 11% yield), m 142°, [ $\alpha$ ]<sub>546</sub><sup>20</sup> –228° (in 10<sup>–3</sup>M \*C<sub>6</sub>H<sub>6</sub>), found M 465 (osmometry in \*C<sub>6</sub>H<sub>6</sub>). Similarly the menthyl ester with [ $\alpha$ ]<sub>546</sub><sup>20</sup> +70° gives pure (–)- $\eta^5$ -(C<sub>5</sub>H<sub>5</sub>)Fe(CO)(CH<sub>3</sub>CO)(PPh<sub>3</sub>) (80mg, 30% yield), m 140°, [ $\alpha$ ]<sub>546</sub><sup>20</sup> +227° (in 10<sup>–3</sup>M \*C<sub>6</sub>H<sub>6</sub>), found M 464 (osmometry in \*C<sub>6</sub>H<sub>6</sub>). From the CD and ORD spectra it was concluded that these reactions occurred with **inversion** of configuration at the tetrahedral iron centre [Brunner & Schmidt *J Organomet Chem* **36** C18 1972].

In the second resolution *R*-(-)-chloromethylmenthyl ether (*R*- is the configuration at 1-C-OH of menthol, see [26127-08-2]) was reacted with the lithium salt of  $(\pm)\text{-}\eta^5\text{-}(C_5H_5)Fe(CO)(CH_3CO)(PPh_3)$  (generated with *n*-BuLi) to give the diastereomeric ethers  $(-)\text{-}\eta^5\text{-}(C_5H_5)Fe(CO)(PPh_3)(COCH_2CH_2O(-)-C_{10}H_{19})$   $\{[\alpha]_D^{20} +65^\circ$  (c 0.4, \*C<sub>6</sub>H<sub>6</sub>) $\}$ , and  $(+)\text{-}\eta^5\text{-}(C_5H_5)Fe(CO)(PPh_3)(COCH_2CH_2O(-)-C_{10}H_{19})$   $\{[\alpha]_D^{20} -150^\circ$  (c 0.4, \*C<sub>6</sub>H<sub>6</sub>) $\}$  which are separable by chromatography and distinguishable by <sup>1</sup>H NMR (300MHz). Crystals of the latter diastereoisomer were subjected to x-ray crystallographic analysis which revealed that the absolute configuration at the tetrahedral Fe centre was *R* by virtue that the absolute configuration of the *R*-menthyl moiety had been established. Since the original formation of these ethers occurs with alteration in the configuration at the Fe centre, then the desired *S*(+)- and *R*(-)- configurations of  $(\pm)\text{-}\eta^5\text{-}(C_5H_5)Fe(CO)(CH_3CO)(PPh_3)$  are established. It was also shown that Brunner & Schmidt's reactions of the *R*-menthyl esters with *n*-BuLi to provide the title enantiomers occurred with *complete* inversion of configuration (as determined by 500MHz <sup>1</sup>H NMR spectroscopy). The enantiomers can be discriminated in solution (9mg in 700μl of CDCl<sub>3</sub>) containing the chiral shift reagent Eu(tfc) {tris[3-(trifluoromethylhydroxymethylene)-(+)-camphorato] europium (III), see [34834-11-0]} (0.48mg in 8μl) where a clear separation of the methyl singlets in the 300MHz <sup>1</sup>H NMR spectra occurs: the *S*(+)-enantiomer has δ at 2.66 and the *R*(-)-enantiomer has δ at 2.58 (from TMS). [Davies et al. *JCS Chem Commun* 607 1986.]

The chiral auxiliary properties of the complexes  $\eta^5\text{-}C_5H_5Fe(CO)(CH_3CO)(PPh_3)$  are displayed by deprotonation with *n*-BuLi (isoPr<sub>2</sub>NLi in THF has also been used) to give the blood-red enolate which undergoes a variety of reactions and sequences of reactions (homochiral synthesis) that are highly stereoselective. These include alkylation, homochiral succinylation, asymmetric aldol reactions, formation of α,β-unsaturated iron acyls and homochiral dienolates, asymmetric Michael addition reaction, asymmetric synthesis of β-amino acids and β-lactams, asymmetric synthesis of cyclopropanecarboxylic acids, asymmetric synthesis of chiral sulfoxides, and chirality recognition for homochiral synthesis. [Davies *Aldrichimica Acta* 23 31 1990.] Decomplexation at the end of the reactions can be achieved by oxidative cleavage (Br/MeOH, H<sub>2</sub>O or *n*-BuNH<sub>2</sub>, NBS/EtOH) to provide the acid, amide or ester, also by alcoholysis (to provide different esters) from which the products can be isolated. From the aqueous solution  $\eta^5\text{-}C_5H_5Fe(CO)_2(PPh_3)^+PF_6^-$  (evaporated to 20ml, from 1mmol of complex product) can be recovered by addition of NH<sub>4</sub>PF<sub>6</sub> (0.6g, 3.7mmol), stirring for 1 hour, evaporating to dryness, and the residue is extracted with CH<sub>2</sub>Cl<sub>2</sub> (3 x 10ml). The combined extracts are evaporated to 5ml and Et<sub>2</sub>O is added to give pale yellow crystals of the complex salt (0.38g, 65%, m 186°). It can also be recrystallised from Me<sub>2</sub>CO/Et<sub>2</sub>O or Me<sub>2</sub>CO/hexane. It has IR (Nujol) with ν<sub>max</sub> at 2055 and 2010 (terminal CO, in CHCl<sub>3</sub>) and 1435s, 1090s, 995w, 880m, 850-820vs, br, 740m, 700m, 685m, 605m, 575m, 555m, 525m, 500w cm<sup>-1</sup>; and the <sup>1</sup>H NMR (60MHz, Me<sub>2</sub>CO, TMS) has δ<sub>H</sub> at 5.62 (d, J<sub>P,H</sub> = 1.5Hz, C<sub>5</sub>H<sub>5</sub>) and 7.68 (m, Ph, 15H). [Aktogu et al. *J Organomet Chem* 262 49 1984, Treichel et al. *Inorg Chem* 5 1177 1966.]

***1R,2S,5R*(-)-Chloromethylmenthyl ether** [*R*(-)-chloromethylmenthyl ether] [26127-08-2] **M 204.7, b 62°/0.1mm, 160-162°/13-16mm, d 0.9821, d<sup>25</sup> 0.994, n<sub>D</sub><sup>20</sup> 1.467, n<sub>D</sub><sup>27</sup> 1.465, [α]<sub>D</sub><sup>24</sup> -177.0°** (c 1, CH<sub>2</sub>Cl<sub>2</sub>), and ***1S,2R,5S*(+)-chloromethylmenthyl ether** [*S*(+)-chloromethylmenthyl ether] [103128-76-3] **M 204.7, b 72°/0.4mm, d<sup>21</sup> 0.994, n<sub>D</sub><sup>20</sup> 1.467, [α]<sub>D</sub><sup>24</sup> +181.0°** (c 2, CH<sub>2</sub>Cl<sub>2</sub>). The chloro methyl derivatives of *R*(-)- and *S*(+)- menthol respectively are useful chiral auxiliary resolving agents (see previous entry) as they can be readily removed by mild hydrolysis and the recovered menthol can be recycled. The *R*(-)-enantiomer is prepared by melting *l*-menthol (100g, 0.64moles) on a water bath and stirring vigorously with 40% w/w aqueous formalin (50g, 0.67moles) while HCl gas is bubbled through. The mixture warms up at first and has to be cooled at 0° until no more gas dissolves. The clear mixture separates into two layers, the upper layer is removed and the lower layer is dried over Na<sub>2</sub>SO<sub>4</sub>. This is filtered and fractionated under reduced pressure from some unreacted menthol, formaldehyde trimer and HCl to give the *chloromethyl ether* (120-130g, 91-99%) as a slightly refracting oil which distils steadily at 160-162°/16mm (and 62°/0.1mm), but it decomposes at ca 230°/atm. The pure ether has [α]<sub>D</sub><sup>21</sup> -172.75° (c 6.78 CHCl<sub>3</sub>). On heating in EtOH/charcoal it forms the *dimethylmethylal* C<sub>10</sub>H<sub>19</sub>OCH<sub>2</sub>OC<sub>10</sub>H<sub>19</sub> which crystallises from aqueous EtOH in greasy looking scales or from Et<sub>2</sub>O in colourless needles m 57° (b 337°/atm), with [α]<sub>D</sub><sup>24</sup> -77.94° (c 0.8 EtOH). The *chloromethylmenthyl ethers* hydrolyse in H<sub>2</sub>O to menthol, HCHO and HCl so they should be stored in an inert atmosphere in the cold [Wedekind *Chem Ber* 34 813 1901, Deutsches Reichspatent No. 119008, D.R.P. 189331 *Chem Zentralblatt* 1 184 1908]. [Beilstein 6 H 32, 6 I 21.]

***4R*(+)-4-Isopropyl-5,5-dimethyl-2-oxazolidinone** (*4R*(+)-4-isopropyl-5,5-dimethyl-1,3-oxazolidin-2-one) [223906-38-5] and ***4S*(-)-4-isopropyl-5,5-dimethyl-2-oxazolidinone** (*4S*(-)-4-isopropyl-5,5-dimethyl-1,3-

**oxazolidin-2-one** [168297-86-7] **M 157.2, m 86-87°**,  $[\alpha]_D^{20} \pm 47^\circ$  (c 1, H<sub>2</sub>O). The starting chiral ethanolamine is prepared from the methyl esters of chiral  $\alpha$ -aminoacids (*R*- or *S*- valine in this case) by reaction with MeMgI/Et<sub>2</sub>O to give chiral 2,2-dimethylvalinol which is converted into the desired chiral 2-oxazolidinones with (EtO)<sub>2</sub>CO/K<sub>2</sub>CO<sub>3</sub> (as in the following entry), or by reaction with CCl<sub>3</sub>COCl (in pyridine) or carbonyl-diimidazole (in CH<sub>2</sub>Cl<sub>2</sub>) as carbonyl equivalents. Similarly by using the esters of chiral alanine, norleucine or  $\alpha$ -phenylglycine the respective optically active 5,5-dimethyl-2-oxazolidinones where the 4-isopropyl group is replaced by methyl, *n*-butyl and phenyl groups respectively can be prepared. These auxiliaries have been named "second series Quat auxiliaries", the first series being substituted 3,3-dimethyl-2-pyrrolidinones [Davies et al. *Tetrahedron Lett* **35** 2369, 2373 1994]. The present 2-oxazolidinones can be *N*-acylated, (e.g. with BuLi, then RCH<sub>2</sub>COCl or MeCH=CHCOCl), and the *N*-acyl moieties can be the targets for highly stereoselective enolate alkylation and conjugate addition reactions. The products can be hydrolysed (e.g. with LiOH, THF/H<sub>2</sub>O 3:1, 0° at ~25°) to provide the respective chiral acids and regenerated oxazolidin-2-one. The *gem*-dimethyl groups enhance the face-stereoselective shielding of the attached *N*-acyl moiety leading to very high diastereomeric excess in the products. [Davies & Sanganeer *Tetrahedron Asymm* **6** 671 1995, cf: review by Mukaiyama *Aldrichimica Acta* **29** 59 1996.]

**4R-(+)-4-Isopropyl-2-oxazolidinone (4R-(+)-4-isopropyl-1,3-oxazolidin-2-one)** [95530-58-8] and **4S-(-)-4-isopropyl-2-oxazolidinone (4S-(-)-4-isopropyl-1,3-oxazolidin-2-one)** [17016-83-0] **M 129.2, m 70-71.5°, 70-72°, 71-72°, R-  $[\alpha]_D^{20} +18^\circ$ , S-  $[\alpha]_D^{20} -18^\circ$ , (c 6, EtOH)**. These compounds are Evans' type of chiral auxiliaries. The *S*-enantiomer was prepared by stirring 1mol of *S*-valinol, 1.1mol of diethyl carbonate and 1mol of anhydrous K<sub>2</sub>CO<sub>3</sub> at 125-126° (internal temperature) until 2.0mols of EtOH had distilled off (4-6 hours). The cooled mixture (to 20°) is dissolved in Et<sub>2</sub>O, filtered through a pad of Celite to remove the K<sub>2</sub>CO<sub>3</sub>, evaporated to a small volume and cooled slowly to 0° when the oxazolinone crystallises as white needles (m 69-70°, 85-95% yield). It is soluble in CH<sub>2</sub>Cl<sub>2</sub> and recrystallises from hexanes/EtOAc (4:1, v/v) by allowing it to stand at 6° overnight. On TLC (0.25mm silica gel 60-F plates) it has R<sub>F</sub> 0.19 (hexanes/EtOAc 6:4,v/v). It has  $[\alpha]_{589} -16.6^\circ$ ,  $[\alpha]_{577} -17.3^\circ$ ,  $[\alpha]_{546} -20.2^\circ$ ,  $[\alpha]_{435} -37.3^\circ$ ,  $[\alpha]_{365} -63.7^\circ$  (c 5.81, EtOH); the IR (CH<sub>2</sub>Cl<sub>2</sub>) has  $\nu_{\max}$  at 1240, 1400, 1760, 2980, 3060, 3240-3340, 3480 cm<sup>-1</sup>; and the <sup>1</sup>H NMR (90MHz, CDCl<sub>3</sub>) has  $\delta$  at 6.7 (br s, 1H, NH), 4.42 (t, *J* = 8.6Hz, 1H, C<sub>5</sub>-H), 4.07 (d of d, *J* = 8.5, 6.5Hz, 1H, C<sub>5</sub>-H), 3.58 (d of t, *J* = 8.6, 6.5Hz, 1H, C<sub>4</sub>-H), 1.9-1.6 (m, 1H, C<sub>4</sub>-H), 0.95 (overlapping d's, *J* = 6.0Hz, 6H, CH(CH<sub>3</sub>)<sub>2</sub>). [Evans et al. *J Org Chem* **50** 1830 1985, Evans et al. *J Am Chem Soc* **103** 2127 1981.]

The **4S-(+)-4-isopropyl-3-propionyl-1:3-oxazolidine-2-one derivative** [77877-9-1] **M 185.2, has b 102-106°/0.75mm, d<sub>4</sub><sup>25</sup> 1.094, n<sub>D</sub><sup>20</sup> 1.464,  $[\alpha]_D^{25} +93^\circ$  (c 8.7, CH<sub>2</sub>Cl<sub>2</sub>)**. An auxiliary reagent also used as a chiral ligand in dirhodium (II) complexes [Doyle et al. *J Am Chem Soc* **115** 9968 1993], and in aldol addition reactions [Pridgen et al. *J Org Chem* **58** 5107 1993]. For a reviews on chiral auxiliaries for asymmetric synthesis see Ager et al. *Aldrichimica Acta* **30** 3 1997, and Mukaiyama *Aldrichimica Acta* **29** 59 1996.

**4R-(+)-4-Isopropyl-2-oxazolidinethione [4R-(+)-4-isopropyl-1,3-oxazolidin-2-thione, (4R)-4-(1-methyl-ethyl)-2-oxazolidinethione]** [1217463-35-8] and **4S-(-)-4-isopropyl-2-oxazolidinethione (4S-(-)-4-isopropyl-1,3-oxazolidin-2-thione)** [104499-08-3] **M 145.2, m 48-52°, 51-53°, R-  $[\alpha]_D^{20} +23.2^\circ$ , S-  $[\alpha]_D^{20} -23.2^\circ$ , (c 0.4, CHCl<sub>3</sub>)**. These compounds are Evans type of chiral auxiliaries. The *S*-(-)-enantiomer is synthesised by adding CS<sub>2</sub> (0.9ml, 15mmol) to a solution of *S*-valinol (10mmol [cf 2026-48-4]) in aqueous N Na<sub>2</sub>CO<sub>3</sub> (20ml) and stirring at 100° (bath at 110° under efficient reflux and fume-cupboard) for 15 minutes, cooling to 20° and extracting with CH<sub>2</sub>Cl<sub>2</sub> (2 x 50ml). The extract is dried (Na<sub>2</sub>SO<sub>4</sub>), filtered, evaporated to dryness and the residue is recrystallised from EtOAc/cyclohexane or EtOAc/hexane. It has UV (EtOH) with  $\lambda_{\max}$  at 244 nm ( $\epsilon$  18,800); the IR has  $\nu_{\max}$  (KBr) at 3160 and 1515 cm<sup>-1</sup>; and the <sup>1</sup>H NMR (300MHz, CDCl<sub>3</sub>) has  $\delta$  at 0.77 (d, 3H, *J* = 6.8Hz), 0.82 (d, 3H, *J* = 6.7Hz), 1.68 (m, 1H), 3.77 (d of t, 1H, *J* = 6.6 and 9.1Hz), 4.23 (d of d, 1H, *J* = 6.6 and 9.1Hz), 4.55 (t, 1H, *J* = 9.1Hz), 9.00 (br s, 1H); and the <sup>13</sup>C NMR (75.5MHz, CDCl<sub>3</sub>) has  $\delta$  at 189.54, 73.53, 62.52, 32.17, 18.04, 17.90. [Delaunay et al. *J Org Chem* **60** 6604 1995, Nagao et al. *J Chem Soc, Perkin Trans I* 2361 1985.] They are selective and efficient chiral auxiliaries [Velazquez & Olivio *Current Org Chem* **6** 303 2000] which can be directly reduced to their corresponding aldehydes and the chiral auxiliary by reductive cleavage with diisobutylaluminium hydride [Crimmins & Chaudhary *Org Lett* **2** 775 2000].

**4R-(+)-4-Isopropyl-2-thiazolidinethione (4R-(+)-4-isopropyl-1,3-thiazolidin-2-thione)** [110199-16-1] and **4S-(-)-4-isopropyl-2-thiazolidinethione (4S-(-)-4-isopropyl-1,3-thiazolidin-2-thione)** [76186-04-4] **M 161.3,**

**m** 66-67°, 67-68°, 69-71°, *R*- $[\alpha]_{\text{D}}^{20} +37^\circ$ , *S*- $[\alpha]_{\text{D}}^{20} -37^\circ$  (**c** 1,  $\text{CDCl}_3$ ). These compounds are efficient *Evans type* of chiral auxiliaries. The *S*-(-)-enantiomer was synthesised by adding  $\text{CS}_2$  (3ml, 50mmol) to a solution of *S*-valinol (10mmol (see [2026-48-4]) in aqueous  $\text{N KOH}$  (50ml) and stirring at 100° (bath at 110° under reflux and efficient fume-cupboard) for 16 hours, cooling to 20° and extracting with  $\text{CH}_2\text{Cl}_2$  (2 x 50ml). The extract is dried ( $\text{Na}_2\text{SO}_4$ ), filtered, evaporated to dryness and the residue is recrystallised from  $\text{CH}_2\text{Cl}_2$  (colourless needles) or  $\text{Et}_2\text{O}$ . *Note* that unlike the preparation of the 1,3-oxazolidine-2-thione above, the preparation of the 1,3-thiazolidine-2-thione required a larger excess of  $\text{CS}_2$ , stronger base and much longer heating time to replace the alcoholic O by S. It has  $^1\text{H NMR}$  (300MHz,  $\text{CDCl}_3$ ) with  $\delta$  at 1.00 (d, 3H,  $J = 7.2\text{Hz}$ ), 1.03 (d, 3H,  $J = 8.5\text{Hz}$ ), 2.01 (m, 1H), 3.32 (d of d, 1H,  $J = 8.2$  and  $11.0\text{Hz}$ ), 3.53 (d of d, 1H,  $J = 8.2$  and  $11.0\text{Hz}$ ), 4.11 (m, 1H), 9.05 (br s, 1H); and the  $^{13}\text{C NMR}$  (75.5MHz,  $\text{CDCl}_3$ ) has  $\delta$  at 200.78, 70.20, 35.73, 31.98, 18.78, 18.18. [Delaunay et al. *J Org Chem* **60** 6604 1995, Nagao et al. *J Chem Soc. Chem Commun* 1418 1985, Nagao et al. *J Org Chem* **51** 2391 1986, McKinnon & Meyer *J Org Chem* **58** 3568 1993.] They are selective and efficient chiral auxiliaries [Velazquez & Olivio *Current Org Chem* **6** 303 2000], and the condensation products can be directly reduced to the corresponding aldehyde and the chiral auxiliary by reductive cleavage with diisobutylaluminium hydride [Crimmins & Chaudhary *Org Lett* **2** 775 2000].

**1*R***(-)-Menthol [natural *l*(-)-, **1*R*,2*S*,5*R***(-)-1-hydroxy-2-isopropyl-5-methylcyclohexane] [2216-51-5] **M** 156.3, **m** 42-45°, 43°, 44-46.5°, 89°/2mm, 100-101°/7mm, 212°/atm,  $d_{25}^{25} 0.89$ ,  $n_{\text{D}}^{25} 1.458$ ,  $n_{\text{D}}^{60} 1.446$ ,  $[\alpha]_{\text{D}}^{20} -50^\circ$  (**c** 10, EtOH),  $[\alpha]_{546}^{18} -58.7^\circ$  (**c** 2, EtOH), and **1*S***(+)-menthol [synthetic *d*(+)-menthol, **1*S*,2*R*,5*S***(+)-1-hydroxy-2-isopropyl-5-methylcyclohexane] [15356-60-2] **m** 43-44°, 103-104°/9mm,  $d_{25}^{25} 0.89$ ,  $n_{\text{D}}^{25} 1.458$ ,  $n_{\text{D}}^{60} 1.446$ ,  $[\alpha]_{\text{D}}^{23} +48^\circ$  (**c** 10, EtOH),  $[\alpha]_{546}^{18} +58.6^\circ$  (**c** 2, EtOH). The natural *l*-isomer is present in peppermint oil and has a strong odour of peppermint, and is sometimes called peppermint camphor. Crystallise menthol from  $\text{CHCl}_3$ , petroleum ether or EtOH/water. It can be sublimed at 40° *in vacuo*, but distillation at 5-10mm is preferable with large quantities. It is best stored under  $\text{N}_2$  in the dark. It is soluble in most organic solvents but is slightly soluble in  $\text{H}_2\text{O}$ . [Barrow & Atkinson *J Chem Soc* 638 1939, *Beilstein* **6** III 133, **6** IV 150.] *l*(-)-Menthol is a very useful resolving agent for acids [Brunel & Buono *J Org Chem* **58** 7313 1993, see also resolution of the Fe complex [12101-02-9] above], and has been used in crystallisation-induced asymmetric transformation of malonate esters [Ihara et al. *J Chem Soc, Chem Commun* 9 1988]. It is a chiral auxiliary that can be recycled [Solladié et al. *Synthesis* 173 1987, Katagiri et al. *J Org Chem* **53** 227 1988]. Similar purification and applications are applicable for *non-natural d*(+)-menthol, with the advantage of producing the optical enantiomers of the products. The *racemic* form **1*R*,2*S*,5*R***(±)-1-hydroxy-2-isopropyl-5-methylcyclohexane (*hexahydro-thymol*) [1490-04-6] **M** 156.3, **m** 28° and 38° (dimorphic), **b** 216.5°/atm,  $d_{30}^{30} 0.8911$ ,  $n_{\text{D}}^{20} 1.4415$ ,  $n_{\text{D}}^{60} 1.4461$ , is obtained by catalytic hydrogenation of thymol [89-83-8] followed by distillation. [Huggett *J Soc Chem Ind* **60** 67 1941, Waters & Beal *J Am Pharm Assoc* **34** 52 1945, *Beilstein* **6** III 137, **6** IV 152.]

## LEWIS AND BRØNSTED/LOWRY ACIDS AND BASES

A few words are warranted here because these terms are frequently used in current literature. The definition of acids (which produce  $\text{H}^+$  ions) and bases (which produce  $\text{HO}^-$  ions) was adequate to explain reactions (e.g. salt formation) in aqueous solutions, and led to the concepts of pH (S.P.L. Sørensen *Biochem Z* **21** 131, 201 1909) and pK (ionisation, cf: Chapter 1 pp 34-36). The definition becomes unsatisfactory when applied to studies of reactions in non-aqueous media, particularly in the catalytic context. Independently, J.N. Brønsted [*Rec Trav Chim Pays Bas* **42** 718 1923, *Chem Rev* **5** 231 1928] and T.M. Lowry [*J Soc Chem Ind* (London) **42** 42 1923] developed the view that an acid is a substance that has a tendency to lose a proton, and a base is one that has a tendency to gain a proton. This led to the understanding of *conjugate* species, e.g.  $\text{R}_3\text{NH}^+$  as potential acids, and defining the equilibrium:  $\text{Base} + \text{H}^+ \rightleftharpoons \text{H-Base}^+$ . They pointed out that the differences in net charge is not as important as the chemical behaviour on which their definition is based. Basicity and acidity do not bear a simple relationship to the net respective charges, and both their properties depend much more on the complex electronic constitutions of the reagents. Later G.N. Lewis (1928 and later work) began with the classical concept of acids and bases, and progressed to a broader definition of an acid as a substance that is able to accept a pair of electrons, and a base as a substance capable of supplying a pair of electrons. This broader definition has been used extensively for reactions in non-aqueous solutions as well as in aqueous solutions. [Note that these concepts originated from extensive studies of catalytic reactions, e.g. mutarotation, hydrolysis, etc]. Thus a

Lewis acid is a substance that is electron deficient (e.g.  $\text{BF}_3$ ), and a Lewis base is a substance that can donate electrons (e.g. amines, phosphines, boranes, ethers, sulfides etc) to form bonds or complexes with Lewis acids.

In the *Bronsted/Lowry definition*, a base donates an electron pair to a proton to form a covalent B—H bond (a positive charge, if involved, will reside on B). In the *Lewis definition*, a base donates a pair of electrons to an electron deficient atom (other than a proton). An acid does not donate a proton but accepts a base to form a new bond. An electron pair is required for forming a covalent or a dative bond.

In the broadest form, an acid is an *electrophile* whereas a base is a *nucleophile*. When these species are regenerated during reactions then they become catalytic. For general reading see Michael B. Smith *Organic Chemistry: An Acid-Base Approach* CRC Press October 2010, ISBN 10: 1420079204, 13: 9781420079203.

## BIBLIOGRAPHY

### Earlier research papers on catalytic metal-mediated carbocyclisations:

**Cobalt-mediated:** Exon & Magnus *J Am Chem Soc* **105** 2477 1983; Billington & Willison *Tetrahedron Lett* **25** 4041 1984; Smit, Gybin, Shashkov, Strychkov, Kyz'mina, Mikaelian, Caple & Swanson *Tetrahedron Lett* **27** 1241 1986; Almansa, Moyano & Serratos *Tetrahedron* **44** 2657 1988; Schore & Rowley *J Am Chem Soc* **110** 5224 1988; Lautens & Crudden *Tetrahedron Lett* **30** 4803 1989; Harvey, Johnson, Ung & Vollhardt *Synlett* 15 1989.

# CHAPTER 7

## PURIFICATION OF BIOCHEMICALS AND RELATED PRODUCTS

### INTRODUCTION

Biochemicals are chemical substances produced by living organisms. They range widely in size, from simple molecules such as formic acid and glucose to macromolecules such as proteins and nucleic acids. Their *in vitro* synthesis is often impossibly difficult, and in such cases they are available (if at all) only as commercial tissue extracts which have been subjected to purification procedures of widely varying stringency. The desired chemical may be, initially, only a minor constituent of the source tissue which may vary considerably in its composition and complexity. Recent advances in molecular biology have made it possible to produce substantial amounts of biological materials, which are present in nature in extremely small amounts, by recombinant DNA technology and expression in bacteria, yeast, insect and mammalian cells. The genes for these substances can be engineered such that the gene products, e.g. polypeptides or proteins, can be readily obtained in very high states of purity, and in large amounts if necessary. However, many such products, which are still obtained from the original natural sources, are available commercially and may require further purification.

As a preliminary step the tissue might be separated into phases [e.g. whole egg into white and yolk, blood into plasma (or serum) and red cells], and the desired phase may be homogenised. Subsequent treatment usually comprises filtration, solvent extraction, salt fractionation, ultracentrifugation, chromatographic purification, gel filtration and dialysis. Fractional precipitation with ammonium sulfate gives crude protein species. Purification is finally judged by the formation of a single band of macromolecule (e.g. protein, DNA) on electrophoresis and/or analytical ultracentrifugation. Although these generally provide good evidence of high purity, nonetheless it does not follow that one band under one set of experimental conditions is an absolute indication of homogeneity [D.S. Vodopich and R. Moore, *Biology Laboratory Manual*, McGraw-Hill, 2007, ISBN 9780072995220].

During the past 20 or 30 years a wide range of methods for purifying substances of biological origin have become available. For small molecules (including many sugars and amino acids) reference should be made to Chapters 1 and 2. The more important methods used for large molecules, polypeptides and proteins in particular, comprise:

1. *Centrifugation*. In addition to centrifugation for sedimenting proteins after ammonium sulfate precipitation in dilute aqueous buffer, the technique has been used for fractionation of large molecules in a denser medium or a medium of varying density. By layering sugar solutions of increasing densities in a centrifuge tube, proteins can be separated in a sugar-density gradient by centrifugation. Smaller DNA molecules (e.g. plasmid DNA) can be separated from RNA or nuclear DNA by centrifugation in aqueous cesium chloride (ca 0.975g/ml of buffer) for a long time (e.g. 40 hours at 40,000 x g). The plasmid DNA band appears at about the middle of the centrifuge tube and is revealed by the fluorescent pink band formed by the binding of DNA to ethidium bromide which is added to the CsCl buffer. *Microfuges* are routinely used for centrifugation in Eppendorf tubes (1.2-2ml) and can run up to speeds of 12,000 x g. *Analytical centrifugation*, which is performed under specific conditions in an analytical ultracentrifuge is very useful for determining purity, aggregation of protein subunits and the molecular weight of macromolecules. [D. Rickwood, T.C. Ford and J. Steensgaard (Eds), *Centrifugation: Essential Data Series*, J Wiley & Sons, 1994, ISBN 9780471942719; L.L. Regel and W.R. Wilcox, *Processing by Centrifugation*, Springer, 2001, ISBN 9780306466546; J.M. Graham and D. Rickwood, *Biological Centrifugation*, Springer, 2001, 9781859960370; A. Records and K. Sutherland, *Decanter Centrifugation Handbook*, Elsevier, 2001, ISBN 1856173690].

2. *Gel filtration* with polyacrylamide (mol wt exclusion limit from 3000 to 300,000) and agarose gel (mol wt exclusion limit 0.5 to  $150 \times 10^6$ ) is useful for separating macromolecules. In this technique high-molecular-weight substances are too large to fit into the gel microapertures and pass rapidly through the matrix (with the void volume), whereas low-molecular-weight species enter these apertures and are held there for longer periods of time, being retarded by the column material in the equilibria, relative to the larger molecules. This method is also used for desalting solutions of macromolecules.
- Dry gels* and *crushed beads* are also useful in the gel filtration process. Selective retention of water and inorganic salts by the gels or beads (e.g. Sephadex G-25) results in increased concentration and purity of the protein fraction which moves with the void volume. (See also section on "Gel filtration" in Chapter 1.)
3. *Ion-exchange matrices* are microreticular polymers containing carboxylic acid (e.g. Bio-Rad 70) or phosphoric acid (Pharmacia, Amersham Biosciences, Mono-P) exchange functional groups for weak acidic cation exchangers, sulfonic acid groups (Dowex 50W) for strong acidic cation exchangers, diethylaminoethyl (DEAE) groups for weakly basic anion exchangers and quaternary ammonium (QEAE) groups for strong anion exchangers. The old cellulose matrices for ion exchanges have been replaced by Sephadex, Sepharose or Fractogel which have more even particle sizes with faster and more reproducible flow rates. Some can be obtained in fine, medium or coarse grades depending on particle size. These have been used extensively for the fractionation of peptides, proteins and enzymes. The use of pH buffers controls the strength with which the large molecules are bound to the support in the chromatographic process. Careful standardisation of experimental conditions and similarly the very uniform size distribution of Mono beads have led to high resolution in the purification of protein solutions. MonoQ is a useful strong anion exchanger, and MonoS is a useful strong cation exchanger, whereas MonoP is a weak cation exchanger (Pharmacia, Amersham Biosciences and alternative sources, see Chapter 1). These have been successful with medium pressure column chromatography (HPLC, see below in 7). Chelex 100 binds strongly and removes metal ions from macromolecules. [See sections on "HPLC", "Ion-exchange Resins" and "Ion-exchange Celluloses and Sephadex" in Chapter 1.]
4. *Hydroxylapatite* is used for the later stages of purification of enzymes. It consists essentially of hydrated calcium phosphate which has been precipitated in a specific manner. It combines the characteristics of gel and ionic chromatography. Crystalline hydroxylapatite is a structurally organised, highly polar material which, in aqueous solution (in buffers), strongly adsorbs macromolecules such as proteins and nucleic acids, permitting their separation by virtue of the interaction with charged phosphate groups and calcium ions, as well as by physical adsorption. The procedure therefore is not entirely ion-exchange in nature. Chromatographic separations of singly and doubly stranded DNA are readily achievable, whereas there is negligible adsorption of low-molecular-weight species.
5. *Affinity chromatography* is a chromatographic technique whereby the adsorbant has a particular and specific affinity for one of the components of the mixture to be purified. For example the adsorbant can be prepared by chemically binding an inhibitor of a specific enzyme (which is present in the crude complex mixture) to a matrix (e.g. Sepharose). When the mixture of impure enzyme is passed through the column containing the adsorbant, only the specific enzyme binds to the column. After adequate washing, the pure enzyme can be released from the column by either increasing the salt concentration (e.g. NaCl) in the eluting buffer or adding the inhibitor to the eluting buffer. The salt or inhibitor can then be removed by dialysis, gel filtration (above) or ultrafiltration (see below). [See W.H. Scouten, *Affinity Chromatography: Bioselective Adsorption on Inert Matrices*, J.Wiley & Sons, NY, 1981, ISBN 0471026492; H. Schott, *Affinity Chromatography: Template Chromatography of Nucleic Acids and Proteins*, Marcel Dekker, NY, 1984, ISBN 0824771117; P. Matejtschuk Ed. *Affinity Separations* Oxford University Press 1997 ISBN 0199635501 (paperback); M.A. Vijayalakshmi, *Biochromatography, Theory and Practice*, Taylor & Francis Publ, 2002, ISBN 0415269032; and the section on "Other Types of Chromatography" in Chapter 1.]
6. In the *Isoelectric focusing* of large charged molecules on polyacrylamide or agarose gels, slabs of these are prepared in buffer mixtures (e.g. ampholines) which have various pH ranges along the length of the gel. When a voltage is applied for some time, the buffers arrange themselves on the slabs in respective areas according to their pH ranges (prefocusing). Then the macromolecules are applied near the middle of the slab and allowed to migrate in the electric field until they reach the pH area similar to their isoelectric points and focus at that position. This technique can also be used in a chromatographic mode, *chromatofocusing*, whereby a gel in a column is run (also under HPLC conditions) in the presence of ampholines (narrow or wide pH ranges as required) and the macromolecules are then run through in a buffer. *Capillary electrophoresis* systems in which a current is applied to set the gradient are now available in which the columns are fine capillaries and are used for qualitative and quantitative purposes [See R. Kuhn and S. Hoffstetter-Kuhn, *Capillary Electrophoresis: Principles and Practice*, Springer-Verlag Inc, NY, 1993; P. Camilleri Ed. *Capillary Electrophoresis-Theory and Practice*, CRC Press, Boca Raton, Florida, 1993; D.R. Baker, *Capillary Electrophoresis*, J Wiley & Sons, NY, 1995; P.G. Righetti,

Henry, *Microchip Capillary Electrophoresis*, Humana, 2006, ISBN 9781588292933.] The bands are eluted according to their isoelectric points. Isoelectric focusing standards are available which can be used in a preliminary run in order to calibrate the effluent from the column, or alternatively the pH of the effluent is recorded using a glass electrode designed for the purpose. Several efficient commercial equipment are available for separating proteins on a preparative and semi-preparative scale.
7. *High performance liquid chromatography (HPLC)* is liquid chromatography in which the eluting liquid is sent through the column containing the packing (materials as in 2-6 above, which can withstand higher than atmospheric pressures) under pressure. On a routine basis this has been found useful for purifying proteins (including enzymes) and polypeptides after enzymic digestion of proteins or chemical cleavage (e.g. with CNBr) prior to sequencing (using reverse-phase columns such as  $\mu$ -Bondapak C18). Moderate pressures (50-300psi) have been found most satisfactory for large molecules (FPLC). [See *Scopes Anal Biochem* **114** 8 1981; *High Performance Liquid Chromatography and Its Application to Protein Chemistry*, Hearn in *Advances in Chromatography*, **20** 7 1982; B.A. Bidlingmeyer *Practical HPLC Methodology and Applications*, J Wiley & Sons, NY 1991; L.R. Snyder, J.L. Glajch and J.J. Kirkland *Practical HPLC Method Development*, J Wiley & Sons, NY 1988; ISBN 0471627828; R.W.A. Oliver, *HPLC of Macromolecules: A Practical Approach*, 2nd Edn, Oxford University Press, 1998, T. Hanai, *HPLC: A Practical Guide*, Royal Society of Chemistry (UK), 1999, ISBN 084045155; P. Millner *High Resolution Chromatography*, Oxford University Press, 1999 ISBN 0199636486; see also Chapter 1, Bibliography.]
  8. *Ultrafiltration (UF)* using a filter (e.g. Millipore) can remove water and low-molecular-weight substances without the application of heat. Filters with a variety of molecular-weight exclusion limits not only allow the concentration of a particular macromolecule to be determined, but also the removal (by washing during filtration) of smaller molecular-weight contaminants (e.g. salts, inhibitors or cofactors). This procedure has been useful for changing the buffer in which the macromolecule is present (e.g. from Tris-Cl to ammonium carbonate), and for desalting. Ultrafiltration can be carried out in a stirrer cell (Amicon) in which the buffer containing the macromolecule (particularly protein) is pressed through the filter, with stirring, under argon or nitrogen gas pressure (e.g. 20-60psi). During this filtration process the buffer can be changed. This is rapid (e.g. 2L of solution can be concentrated to a few mls in 1 to 2 hours depending on pressure and filter). A similar application uses a filter in a specially designed tube (Centricon tubes, Amicon) and filtration occurs under centrifugal force in a centrifuge (4-6000rpm at 0°/40min). The macromolecule (usually DNA) then rests on the filter and can be washed on the filter also by centrifugation. The macromolecule is recovered by inverting the filter, placing a conical receiver tube on the same side where the macromolecule rests, filling the other side of the filter tube with eluting solution (usually a very small volume e.g. 100  $\mu$ L), and during further centrifugation this solution passes through the filter and collects the macromolecule from the underside into the conical receiver tube. With the development of polymeric and ceramic nanofilters use can be made of nanofiltration (NF) in which particles or molecules of less than 2nm can be held back. This is to be compared with UF where the size limit is between 2nm and 0.1 $\mu$ m (see Chapter 8).
  9. *Partial precipitation* of a protein in solution can often be achieved by controlled addition of a strong salt solution, e.g. ammonium sulfate. This is commonly the first step in the purification process. Its simplicity is offset by possible denaturation of the desired protein and the (sometimes gross) contamination with other proteins. It should therefore be carried out by careful addition of small aliquots of the powdered salt or concentrated solution (below 4°, with gentle stirring) and allowing the salt to be evenly distributed in the solution before adding another small aliquot. Under carefully controlled conditions and using almost pure protein, it is sometimes possible to obtain the protein in crystalline form suitable for X-ray analysis (see below).
  10. *Dialysis*. This is a process by which small molecules, e.g. ammonium sulfate, sodium chloride, are removed from a solution containing the protein or DNA using a membrane which is porous to small molecules. The solution (e.g. 10ml) is placed in a dialysis bag or tube tied at both ends, and stirred in a large excess of dialysing solution (e.g. 1.5 to 2 L), usually a weak buffer at ca 4°. The dialysing buffer is replaced with fresh buffer several times, e.g. four times in 24 hours. This procedure is similar to ultrafiltration (above) and allows the replacement of buffer in which the protein, or DNA, is dissolved. It is also possible to concentrate the solutions by placing the dialysis tube or bag in Sephadex G25 which allows the passage of water and salts from the inside of the bag thus concentrating the protein (or DNA) solution. Dialysis tubing is available from various distributors, but "Spectra/por" tubing (from Spectrum Medical Industries, Inc, LA) is particularly effective because it retains macromolecules and allows small molecules to dialyse out very rapidly, thus reducing dialysing time considerably. This procedure is used when the buffer has to be changed so as to be compatible with the next purification or storage step, e.g. when the protein (or DNA) needs to be stored frozen in a particular buffer over

extended periods. UF and NF can also serve this purpose whereby the solvent can be completely replaced by washing with an alternative solvent.

11. *Gel Electrophoresis*. This is becoming a more commonly used procedure for purifying proteins, nucleic acids, nucleoproteins, polysaccharides and carbohydrates. The gels can be "electroblotted" onto membranes, and the modern procedures of identifying, sequencing (proteins and nucleic acids) and amplifying (nucleic acids) on sub-micro scales have made this technique a very important one. See below for polyacrylamide gel electrophoresis (PAGE). [D. Patel *Gel Electrophoresis*, J.Wiley-Liss, Inc., 1994; P. Jones and D. Rickwood, *Gel Electrophoresis: Nucleic Acids*, J. Wiley and Sons, 1999 (paperback) ISBN 0471960438; D.M. Gersten and D. Gersten, *Gel Electrophoresis: Proteins*, J. Wiley and Sons, 1996, ISBN 0471962651; R. Westermeier *Electrophoresis in Practice*, 4th Edn, Wiley-VCH Publishing, 2004 ISBN 9783527311811].
12. *Crystallisation*. The ultimate in purification of proteins or nucleic acids is crystallisation. This involves very specialised procedures and techniques and is best left to the experts in the field of X-ray crystallography who can provide a complete picture of the structure of these large molecules. [A. Ducruix and R. Giegé Eds, *Crystallisation of Nucleic Acids and Proteins: A Practical Approach*, 2nd Edition, 2000, Oxford University Press, ISBN 0199636788 (paperback); T.L. Blundell and L.N. Johnson *Protein Crystallisation*, Academic Press, NY, 1976; A. McPherson *Preparation and Analysis of Protein Crystals*, J.Wiley & Sons, NY, 1982; A. McPherson, *Crystallisation of Biological Macromolecules*, Cold Spring Harbour Laboratory Press, 2001 ISBN 0879696176, see also Bibliography in Chapter 1.]

Other details of the above can be found in Chapters 1 and 2 which also contain relevant references.

Several illustrations of the usefulness of the above methods are given in the *Methods Enzymol* series (Academic Press) in which 1000-fold purifications or more have been readily achieved. In applying these sensitive methods to macromolecules, reagent purity is essential. It is disconcerting, therefore, to find that some commercial samples of the widely used affinity chromatography ligand Cibacron Blue F3GA contained this dye only as a minor constituent. The major component appeared to be the dichlorotriazinyl precursor of this dye. Commercial samples of Procion Blue and Procion Blue MX-R were also highly heterogeneous [Hanggi and Cadd *Anal Biochem* **149** 91 1985]. Variations in composition of sample dyes can well account for differences in results reported by different workers. The purity of substances of biological origin should therefore be checked by one or more of the methods given above. Water of high purity should be used in all operations. Double glass distilled water or water purified by a MilliQ filtration system (see Chapter 2) is most satisfactory.

**Brief general procedures for the purification of polypeptides and proteins.** Polypeptides of up to *ca* 1-2000 (10-20 amino acid residues) are best purified by reverse phase HPLC. The desired fractions that are collected are either precipitated from solution with EtOH or lyophilised. The purity can be checked by HPLC and identified by microsequencing (1-30 picomoles) to ascertain that the correct polypeptide was in hand. Polypeptides larger than these are sometimes classified as proteins and are purified by one or more of the procedures described above. The purification of enzymes and functional proteins which can be identified by specific interactions is generally easier to follow because enzyme activities or specific protein interactions can be checked (by assaying) after each purification step. The commonly used procedures for purifying soluble proteins involve the isolation of an aqueous extract from homogenised tissues or extracts from ruptured cells from microorganisms or specifically cultured cells, for example, by sonication, freeze shocking or passage through a small orifice under pressure. Contaminating nucleic acids are removed by precipitation with a basic protein, e.g. protamine sulfate. The soluble supernatant is then subjected to fractionation with increasing concentrations of ammonium sulfate. The required fractions are then further purified by the procedures described in sections 2-9 above. If an affinity adsorbant has been identified, then affinity chromatography can provide an almost pure protein in one step sometimes even from the crude extract. The rule of thumb is that a solution with a protein concentration of 1mg/ml has an absorbance  $A_{1cm}$  at 280nm of 1.0 units. Membrane-bound proteins are usually insoluble in water or dilute aqueous buffer and are obtained from the insoluble fractions, e.g. the microsomal fractions from the  $>100,000 \times g$  ultracentrifugation supernatant. These are solubilised in appropriate detergents, e.g. Mega-10 (nonionic), Triton X-100 (ionic) detergents, and purified by methods 2 to 8 (previous section) in the presence of detergent in the buffer used. They are assayed also in the presence of detergent or membrane lipids.

The purity of proteins is best checked by *polyacrylamide gel electrophoresis* (PAGE). The gels are either made or purchased as pre-cast gels and can be with uniform or gradient gel composition. Proteins are applied onto the gels *via* wells set into the gels or by means of a comb, and travel along the gel surface by means of the current applied to the gel. When the buffer used contains sodium dodecylsulfate (SDS), the proteins are denatured and the denatured proteins (e.g. as protein subunits) separate on the gels mainly according to their molecular sizes. These can be identified by running marker proteins, with a range of molecular weights, simultaneously on a track alongside the proteins under study. The protein bands are visualised by fixing the gel (20% acetic acid) and staining with Coomassie blue followed by silver staining if higher sensitivity is required. An Amersham-Pharmacia “Phast Gel Electrophoresis” apparatus, or related equipment, is very useful for rapid analysis of proteins. It uses small pre-cast polyacrylamide gels (two gels can be run simultaneously) with various uniform or gradient polyacrylamide concentrations as well as gels for isoelectric focusing. The gels are usually run for 0.5-1.5 hours and can be stained and developed (1-1.5 hours) in the same apparatus. The equipment can be used to “electroblot” the protein bands onto a membrane from which the proteins can be isolated and sequenced or subjected to antibody or other identification procedures. It should be noted that all purification procedures are almost always carried out at *ca* 4° in order to avoid denaturation or inactivation of the protein being investigated.

There has been considerable necessity for, and interest in, the study of **Proteomics**. This involves the identification, quantitation and isolation of all the proteins produced by a cell or organism at a particular point in time. It provides information on the expression of **all** the proteins produced by particular cells at a desired stage of the cell's development, maturity, activation or condition. A sophisticated apparatus for this purpose is a flat bed polyacrylamide gel which is run electrophoretically in one direction according to the extent of polymerization of the acrylamide and then run at right angles along a pH gradient (isoelectric focusing). Hundreds of polypeptides and proteins are thus separated, collected and identified by various other techniques such as LC-MS-MS, capillary electrophoresis etc (T. Palzkill, *Proteomics*, Springer, 2001, ISBN 0792375653; T.D. Veenstra and R.D. Smith *Proteome Characterization and Proteomics*, Academic Press, 2003, ISBN 9780120342655; R. Westermeier, T. Naven and H-R. Höpker, *Proteomics in Practice: A Guide to Successful Experimental Design*. J. Wiley & Sons, 2008, ISBN 9783527319411; the *Journal of Proteomics* (ISSN: 1874-3919), which is the official journal of *The European Proteomics Association* published by Elsevier, has been running for several years and is but one of the many journals on Proteomics and Bioinformatics that are available and can be viewed on the internet; see also Bibliography in Chapter 1).

Another rapidly developing field is **metabolomics** where metabolites are screened and identified in the normal and diseased cell at specific time intervals. These cannot be identified from studies of *genomics*, *transcriptomics* or *proteomics*. The subject is now possible because of the highly improved power of HPLC, GC, MS, NMR and the interfacing of these instruments. Thus *metabolones* can be mapped for various biological systems (plant and animal). Publications that are available include the *Metabolomics Journal* published by SpringerLink and started in 2005, and *Journal of Metabolomics and Systems Biology (JMSB)*, published by Academic Journals which started in 2011. These periodicals publish original papers, reviews and conference reports.

Anyone contemplating the purification of a protein is referred to: Professor R.K. Scopes's monograph *Protein Purification*, 3rd Edn, Springer-Verlag, New York, 1994, ISBN 0387940723; M.L. **Brief general procedures for purifying DNA.** Oligo-deoxyribonucleotides (up to *ca* 60-mers) are conveniently purified by HPLC (e.g. using a Bio-Rad MA7Q anion exchange column and a Rainin Instrument Co, Madison, Dynamax-300A C<sub>8</sub> matrix column) and used for a variety of molecular biology experiments. Plasmid and chromosomal DNA can be isolated by centrifugation in cesium chloride buffer (see section 1, Centrifugation above), and then re-precipitated with 70% ethanol at -70° (18 hours), collected by centrifugation (microfuge) and dried in air before dissolving in TE (10mM TrisHCl, 1mM EDTA pH 8.0). The DNA is identified on an Agarose gel slab (0.5 to 1.0% DNA grade in 45mM Tris-borate + 1mM EDTA or 40mM Tris-acetate + 1mM EDTA pH 8.0 buffers) containing ethidium bromide which binds to the DNA and under UV light causes it to be visualised as pink fluorescent bands. Marker DNA (from  $\lambda$  phage DNA cut with the restriction enzymes Hind III and/or EcoRI ) with bands running from 72 to 353 base-pairs (bp) are run in a parallel track in order to estimate the size of the unknown DNA. Various other DNA markers are commercially available such as the step ladder ranging from 50bp to 800bp with bands at 50bp intervals, and the step ladder with bands ranging from 100bp to 4000bp with bands at 200bp intervals. The DNA can be isolated from the band on the gel by transfer onto nitro-acetate paper (e.g. NA 45) electrophoretically, by binding to silica or an ion-exchange resin, extracted from these adsorbents and precipitated with ethanol. The DNA pellet is then dissolved in TE buffer and its concentration determined. A solution of duplex DNA (or RNA) of 50 $\mu$ g/ml gives an absorbance of 1.0 unit at 260nm/1cm cuvette (single-stranded DNA or RNA gives a value of 1.3 absorbance units). DNA obtained in this way is suitable for molecular cloning.

Recombinant and chemically synthesised DNA and RNA are now routinely separated and purified by HPLC, and their structures are confirmed by sequencing an aliquot. A variety of commercially available HPLC systems are now available, and the desired system can be selected from them.

Brief mention must be made of the tremendous advances that have been made in recent years in the fields of DNA, RNA gene sequencing and synthesis. The development of instrumentation and analysers by the Illumina Company ([www.illumina.com/](http://www.illumina.com/)) and the “*Ion torrent*” semiconductor sequencing of DNA and RNA, using an ion PGM (personal genome machine) sequencer (see; <http://lifetech-it.hosted.jivesoftware.com/index.jspa>) have made it possible to sequence complete genomes in a matter of weeks or less.

For experimental details on the isolation, purification and manipulation of DNA and RNA the reader is referred to: J. Sambrook, E.F. Fritsch and T. Maniatis, *Molecular Cloning-A Laboratory Manual*, 2nd Edn (3 volumes), Cold Spring Harbor Laboratory Press (CSHL Press) NY, 1989, ISBN 0879693096 (paperback); P.D. Travers and M. Buckle, *DNA-Protein Interactions: A Practical Approach*, Oxford University Press, 2000, ISBN 0199636915 (paperback); R. Rapley and D.L. Manning Eds *RNA: Isolation and Characterisation Protocols*, Humana Press 1998 ISBN 0896034941; R. Rapley, *The Nucleic Acid Protocols Handbook*, Humana Press 2000 ISBN 0896038416 (paperback).

This chapter lists some representative examples of biochemicals and their origins, a brief indication of key techniques used in their purification, and literature references where further details may be found. Simpler low-molecular-weight organic compounds, particularly those that may have been prepared by chemical syntheses, e.g. acetic acid, will be found in Chapter 4. Only a small number of enzymes and proteins are included because of space limitations. The purification of the ones that have been included has been described only briefly. The reader is referred to comprehensive texts such as the *Methods Enzymology* (Academic Press, see below) series which currently runs to volume 489 in 2011, and *The Enzymes* (3rd Edn, Academic Press) which runs to 22 volumes for methods of preparation and purification of proteins and enzymes. Leading references on proteins will be found in *Advances in Protein Chemistry* which was incorporated with *Advances in Structural Biology* (84 volumes (2011), Elsevier Inc) and on enzymes will be found in *Advances in Enzymology* which then became *Advances in Enzymology and Related Areas of Molecular Biology*, J Wiley & Sons (up to volume 77 in 2011). The *Annual Reviews of Biochemistry* (Annual Reviews Inc. Patlo Alto California) is also an excellent source of

key references to the up-to-date information on known and new natural compounds, from small molecules, e.g. enzyme cofactors to proteins and nucleic acids. See also the *Springer Handbook of Enzymes* cited above.

**Abbreviations** of titles of periodical are defined as in the Chemical Abstracts Service Source Index (CASSI).

**Ionisation constants** of ionisable compounds are given as **pK** values (published from the literature) and refer to the **pKa** values at room temperature (~15°C to 25°C). The values at other temperatures are given as superscripts, e.g. **pK<sup>25</sup>** for 25°C. Estimated values are entered as **pK<sub>Est(1)</sub>** ~ (see section on “Ionisation Constants” in Chapter 1 for further information).

**Benzene**, which has been used as a solvent successfully and extensively in the past for reactions and purification by chromatography and crystallisation is now considered a **very dangerous substance**, so it has to be used with extreme care. We emphasise that an alternative solvent to benzene (e.g. toluene, toluene-petroleum ether, or a petroleum ether to name a few) should be used first. However, if benzene has to be used then all operations have to be performed in well-ventilated fumehoods and precautions taken to avoid inhalation and contact with skin and eyes. Whenever benzene is mentioned in the text, an asterisk e.g. \*C<sub>6</sub>H<sub>6</sub> or \*benzene, is inserted to remind the user that special precaution should be adopted.

*Selected Amino acids and peptides, Proteins Enzymes DNA and RNA, Carotenoids, Carbohydrates, Steroids, and Miscellaneous Compounds (which include Biochemical reagents, Cofactors, Coenzymes and Vitamins) are collected in the separate respective sections of this chapter.*

## AMINO ACIDS and PEPTIDES

This section includes amino acid derivatives and related compounds.

***N*-Acetyl-L-alaninamide** [15962-47-7] **M 130.2, m 162°**. Crystallise the amide repeatedly from EtOH/diethyl ether. The (±)-isomer crystallises from H<sub>2</sub>O and has **m 157-158°**. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 1838 1961, de Jong *Rec Trav Chim Pays Bas* **19** 288 1900, Fischer & Otto *Chem Ber* **36** 2106 1903, *Beilstein* **4** H 295.]

***N*-Acetyl-β-alanine** [3025-95-4] **M 127.2, m 78.3-80.3°, pK<sup>25</sup> 4.45**. The β-alanine crystallises from acetone. [King & King *J Am Chem Soc* **78** 1089 1956, *Beilstein* **4** IV 2526, 2548.]

***N*-Acetyl-L-alanyl-L-alaninamide** [30802-37-0] **M 201.2, m 250-251°**. Crystallise the dipeptide derivative repeatedly from EtOH/diethyl ether.

***N*-Acetyl-L-alanyl-L-alanyl-L-alaninamide** [29428-34-0] **M 272.3, m 295-300°**. Crystallise the tripeptide derivative from MeOH/diethyl ether.

***N*-Acetyl-L-alanylglycinamide** [76571-64-7] **M 187.2, m 148-149°**. Crystallise the dipeptide derivative repeatedly from EtOH/diethyl ether.

**Acetyl-α-amino-*n*-butyric acid** [34271-24-4] **M 145.2, pK<sup>25</sup> 3.72**. Crystallise the acid twice from water (charcoal) and dry it in air [King & King *J Am Chem Soc* **78** 1089 1956].

**Acetylcarnitine chloride (2-acetoxy-3-carboxy-*N,N,N*-trimethylpropanamine HCl)** [*S*(*D*)- 5080-50-2, *R*(*L*)- 5061-35-8, *RS* 2504-11-2] **M 239.7, m 181°, 187°(corr, dec), 197°(dec), [α]<sub>D</sub><sup>25</sup> -28° (c 2, H<sub>2</sub>O) for *S*-isomer, pK<sup>25</sup> 3.6**. Recrystallise the chloride from isopropanol. Dry it over P<sub>2</sub>O<sub>5</sub> under high vacuum. The *S*-betaine crystallises from EtOH/Et<sub>2</sub>O with **m 145°(dec)** and is hygroscopic; it has [α]<sub>D</sub><sup>20</sup> -19.5° (c 6, H<sub>2</sub>O). [Krimberg & Wittandt *Biochem Z* **251** 231 1932, Strack et al. *Z Physiol Chem* **238** 191 1936, *Beilstein* **4** III 1630, 1632.]

***R*(-)-*N*-Acetyl-L-cysteine methyl ester** [7652-46-2] **M 177.2, m 71-78°, 80°, [α]<sub>D</sub><sup>20</sup> -24.0° (c 1, MeOH)**. The ester is purified by converting into the cuprous mercaptide which is decomposed by dilute H<sub>2</sub>SO<sub>4</sub>, extracted into Et<sub>2</sub>O, dried (Na<sub>2</sub>SO<sub>4</sub>), filtered, evaporated and the residue recrystallised from H<sub>2</sub>O containing a little AcOH. The crystals are dried in a vacuum. These operations should be carried out in an inert atmosphere (N<sub>2</sub> or argon) to avoid oxidation to the disulfide cystin ester. Note that the cuprous salt is only stable when it is dry, but is readily oxidised when wet. It has been used as a sulfur transfer agent [Gilman & Spero *Tetrahedron Lett* **33** 1751 1993]. [Pirie *Biochem J* **25** 618 1931, *Beilstein* **4** III 1607.]

***N*-Acetylglutamic acid** [1188-37-0] **M 189.2, m 185° (*RS*), 201° (*S*), [α]<sub>D</sub><sup>25</sup> -16.6° (in H<sub>2</sub>O), [α]<sub>D</sub><sup>25</sup> -5.6° (c 4, MeOH) for *S*-enantiomer, pK<sub>Est(1)</sub> ~3.4, pK<sub>Est(2)</sub> ~4.3**. A likely impurity is glutamic acid. Crystallise it from boiling water. It inhibits *N*-acetyl-L-glutamate synthase. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 1948 1961, Shigesada & Tatibana *Eur J Biochem* **84** 285 1978, Coude *Biochem Biophys Res Commun* **102** 1016 1981, *Beilstein* **4** IV 3047.]

***N*-Acetylglycinamide** [2620-63-5] **M 116.1, m 139-139.5°**. Crystallise the amide repeatedly from EtOH/Et<sub>2</sub>O. Dry it in a vacuum desiccator over KOH. [Davis & Levy *J Chem Soc* 3485 1951, Fischer & Otto *Chem Ber* **36** 2106 1903, *Beilstein* **4** IV 2401.]

***N*-Acetylglycine** [543-24-8] **M 117.1, m 206-208°, pK<sub>1</sub><sup>25</sup> -1.92, pK<sub>2</sub><sup>25</sup> 3.69**. *N*-Acetylglycine is treated with acid-washed charcoal and recrystallised three times from water or EtOH/Et<sub>2</sub>O and is dried *in vacuo* over KOH [King & King *J Am Chem Soc* **78** 1089 1956]. [*Beilstein* **4** IV 2399.]

***N*-Acetylglycyl-L-alaninamide** [34017-20-4] **M 175.2**. Crystallise the dipeptide derivative repeatedly from EtOH/Et<sub>2</sub>O. Dry it in a vacuum desiccator over KOH.

***N*-Acetylglycylglycinamide** [27440-00-2] **M 173.2, m 207-208°**. Crystallise the dipeptide derivative repeatedly from EtOH/Et<sub>2</sub>O. Dry it in a vacuum desiccator over KOH.

***N*-Acetylglycylglycylglycinamide** [35455-24-4] **M 230.2, m 253-255°**. Crystallise the tripeptide derivative repeatedly from EtOH/Et<sub>2</sub>O. Dry it in a vacuum desiccator over KOH.

***N*-Acetylhistidine (H<sub>2</sub>O)** [39145-52-3] **M 171.2, m 148° (RS), 169° (S), [α]<sub>D</sub><sup>25</sup> +46.8° (c 1, H<sub>2</sub>O) for *S*-enantiomer**. A likely impurity is histidine. Crystallise it from water, then 4:1 acetone/water. [Marshall et al. *J Am Chem Soc* **78** 4636 1956, Bergmann & Zervas *Biochem Z* **203** 280 1928, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 p 1990 1961, Beilstein **25** IV 4359.]

***N*-Acetyl-*RS*-homocysteine thiolactone (Citolone)** [1195-16-0] [17896-21-8 for ±] **M 159.2, m 110°, 109-111°, 111.5-112.5°**. Dry Citolone in a vacuum desiccator. It recrystallises from toluene as needles. It is a ninhydrin -ve substance which gives a "slow" nitroprusside test. It has λ<sub>max</sub> at 238nm (ε 4,400 M<sup>-1</sup>cm<sup>-1</sup>); and ν<sub>max</sub> (nujol) 1789s and 851ms cm<sup>-1</sup>. [Benesch & Benesch *J Am Chem Soc* **78** 1597 1956, cf Laliberté *J Chem Soc* 2756 1963.]

***N*-Acetyl-L-leucinamide (2-acetamido-4-methylvaleramide)** [28529-34-2] **M 177.2, m 202°**. Recrystallise it from aqueous EtOH or CHCl<sub>3</sub>/petroleum ether (b 40-60°). [Gränacher *Helv Chim Acta* **8** 216 1925, Beilstein **4** II 864, for L, and Bergmann et al. *Justus Liebigs Ann Chem* **449** 301 1926, Beilstein **4** II 877 for DL.]

***N*-Acetyl-L-methionine** [65-82-7] **M 191.3, m 103.5-104.5°, 104°, [α]<sub>D</sub><sup>25</sup> -24.5° (c 1, in H<sub>2</sub>O), pK<sub>Est</sub> ~3.4**. Crystallise *N*-acetyl-L-methionine from Me<sub>2</sub>CO, H<sub>2</sub>O or EtOAc. Dry it in a vacuum over P<sub>2</sub>O<sub>5</sub>. Its solubility at 25° in H<sub>2</sub>O is 30.7%, and in Me<sub>2</sub>CO it is 29.5%. [Mitzi & Schueter *Biochim Biophys Acta* **27** 168 1958, Birnbaum et al. *J Biol Chem* **194** 455 1952, Beilstein **4** IV 3206.]

**Acetylmethionine nitrile** [538-14-7] **M 172.3, m 44-46°**. Crystallise the nitrile from diethyl ether. [Catch et al. *J Chem Soc* 1611 1947, Beilstein **4** III 1654.]

***N*-Acetyl-*N'*-methyl-L-alaninamide** [19701-83-8] **M 144.2, m 181.2-182° (sealed tube), [α]<sub>D</sub><sup>25</sup> -51.1° (c 2, EtOH)**. Crystallise the amide from EtOAc/Et<sub>2</sub>O, then from EtOH and Et<sub>2</sub>O. Also recrystallise it twice by dissolving ~2.5g in hot 200ml of toluene and cooling. It sublimes at ~170°, so its **m** is measured in a sealed tube. [Applewhite & Niemann *J Am Chem Soc* **81** 2212 1959, Beilstein **4** IV 2500.]

***N*-Acetyl-*N'*-methylglycinamide** [7606-79-3] **M 130.2, m 157.5-158°**. Recrystallise the amide from EtOH/Et<sub>2</sub>O mixture. Also recrystallise it twice from EtOAc/EtOH (16:1) and once from EtOAc. [Applewhite & Niemann *J Am Chem Soc* **81** 2212 1959.]

***N*-Acetyl-*N'*-methyl-L-leucine amide** [32483-15-1] **M 186.3, m 165.3-166.8° (sealed tube), [α]<sub>D</sub><sup>25</sup> -33.9° (c 1, H<sub>2</sub>O)**. Recrystallise the amide from EtOAc, EtOH/hexane mixture or toluene/hexane mixture. [Applewhite & Niemann *J Am Chem Soc* **81** 2212 1959.]

***N*-Acetyl-L-phenylalanine** [2018-61-3] **M 207.2, m 170-171°, 174-175°, [α]<sub>D</sub><sup>25</sup> +47.5° (c 4, EtOH), +52.5° (c 2, EtOH), (DL) m 152.5-153°, pK<sub>Est</sub> ~3.5**. *N*-Acetyl-L-phenylalanine is recrystallised from H<sub>2</sub>O, 20% MeOH/H<sub>2</sub>O, or CHCl<sub>3</sub>; dry and store it at 4°. The (*DL*)-isomer crystallises from H<sub>2</sub>O, Me<sub>2</sub>CO, EtOAc, or CHCl<sub>3</sub> with **m** 152-154° and the solubilities in w% at 25° are 0.73 (H<sub>2</sub>O), 4.3 (Me<sub>2</sub>CO), 0.79 (EtOAc) and 0.34 (CHCl<sub>3</sub>) [Kerr & Niemann *J Org Chem* **23** 893 1958, Overby & Ingersoll *J Am Chem Soc* **73** 3363 1951, L: Fu et al. *J Am Chem Soc* **76** 6057 1954, Bender & Glasson *J Am Chem Soc* **81** 1591 1959]. [Beilstein **14** I 238, **14** IV 1575.]

***N*-Acetyl-L-phenylalanine ethyl ester** [2361-96-8] **M 235.3, m 93-94°**. Crystallise the ester from aqueous

EtOH or H<sub>2</sub>O. [Izumiya & Fruton *J Biol Chem* **218** 59 1956.]

**N-Acetyltryptophan** [87-32-1] **M 246.3**, **m 206°**, **207-208° (RS)**, **pK<sub>Est</sub> ~3.8**, [1218-34-4] **m 188°, 189.5-190.5° (S)**, **[α]<sub>D</sub><sup>25</sup> +30.1° (aqueous NaOH)**, **+71.5° (dioxane/aqueous HCl)**. A likely impurity is tryptophan. Crystallise it from EtOH by adding water. [Cowgill *Biochim Biophys Acta* **200** 18 1970, DL: Berg *J Biol Chem* **100** 79 1933, *Beilstein* **22/14** V 40-50.]

**N-Acetyl-L-valine amide** [37933-88-3] **M 158.2**, **m 275°**. Recrystallise the amide from CH<sub>3</sub>OH/Et<sub>2</sub>O.

**Alamethicin (from *Tricoderma viridae*)**. [27061-78-5] **M 1964.3**, **m 259-260°, 275-270°**, **[α]<sub>D</sub><sup>22</sup> -45° (c 1.2, EtOH)**, **pK<sub>25</sub> 6.04 (aqueous EtOH)**. Recrystallise alamethicin from MeOH. [Panday et al. *J Am Chem Soc* **99** 8469 1977.] The *acetate* [64918-47-4] has **m 195-180°** from MeOH/Et<sub>2</sub>O, and the *acetate-methyl ester* [64936-53-4] has **m 145-140°** from aqueous MeOH.

**α-Alanine (RS)** [302-72-7] **M 89.1**, **m 295-296°**, **(S) [56-41-7] m 297°(dec)**, **[α]<sub>D</sub><sup>15</sup> +14.7° (in 1M HCl)**, **(R) [338-69-2] m 289-291°(dec)**, **[α]<sub>D</sub><sup>15</sup> -14.1° (c 0.9, 1M HCl)**, **pK<sub>1</sub><sup>25</sup> 2.34**, **pK<sub>2</sub><sup>25</sup> 9.87**. Crystallise alanine from H<sub>2</sub>O or aqueous EtOH, i.e. crystallise it from 25% EtOH in water, or recrystallise it from 62.5% EtOH, wash it with EtOH and dry it to constant weight *in vacuo* over P<sub>2</sub>O<sub>5</sub>. *RS-α-alanineamide* [20108-77-4] has **m 62°** (from CHCl<sub>3</sub>), **pKa 8.02**, the *hydrochloride* [80222-96-4] has **m 173°** (from EtOH) and the *acetate salt* has **m 136-137°**. *S-α-alanine methyl ester hydrochloride* [2491-20-5] has **m 109-111°**, **[α]<sub>D</sub><sup>15</sup> +8.0° (c 1.6, MeOH)**, and *S-α-alanine N-methylamide* [7324-05-2] has **m 78°** (hygroscopic, also **m 72°** reported, from CHCl<sub>3</sub>). [Gutter & Kegeles *J Am Chem Soc* **75** 3893 1953, Walsh *J Biol Chem* **264** 2394 1989.] 2,2'-Iminodipropionic acid is a likely impurity. [*Beilstein RS*: **4 H 387**, **4 I 491**, **4 II 814**, **4 III 1222**, **4 IV 2481**; *R*: **4 H 385**, **4 I 491**, **4 II 812**, **4 III 1219**, **4 IV 2480**; *S*: **4 H 381**, **4 I 489**, **4 II 809**, **4 III 1208**, **4 IV 2480**.]

**β-Alanine** [107-95-9] **M 89.1**, **m 197-198°(dec)**, **205°(dec)**, **205.5°(dec)**, **207°(dec, rapid heating)**, **pK<sub>1</sub><sup>25</sup> 3.55 (3.60, CO<sub>2</sub>H)**, **pK<sub>2</sub><sup>25</sup> 10.24 (10.36, NH<sub>3</sub><sup>+</sup>)**. Crystallise β-alanine by dissolving it in a hot saturated aqueous solution, filtering, adding four volumes of absolute EtOH and cooling in an ice-bath. Recrystallise it in the same way and then finally, crystallise it from a warm saturated solution in 50% EtOH and adding four volumes of absolute EtOH with cooling in an ice-bath. The crystals are dried in a vacuum desiccator over P<sub>2</sub>O<sub>5</sub>. It also crystallises from H<sub>2</sub>O, and sublimes at 170-180°/0.3mm. The *hydrochloride* [6057-90-5] forms plates with **m 123°**, its *methyl ester* has **b 69°/58mm**, the *methyl ester hydrochloride* [3196-73-4] has **m 107°** (from EtOH/Et<sub>2</sub>O), the *amide* has **m 41°** and the *amide hydrochloride* has **m 149°**. *N-Methyl β-alanine* crystallises from EtOH, the monohydrate forms plates with **m 99-100°** and its *hydrochloride* [2679-14-3] has **m 105°**. *N-Methyl β-alanine amide* [4874-17-3] **M 102.1** is a liquid with **d<sub>4</sub><sup>25</sup> 1.052**, **n<sub>D</sub><sup>20</sup> 1.458**, and is an antibacterial [Altamura et al. *J Med Chem* **38** 4244 1955]. [Donovan & Kegeles *J Am Chem Soc* **83** 255 1961, for pKa see Albert *Biochem J* **47** 531 1950, *Beilstein* **4 H 401**, **4 I 499**, **4 II 827**, **4 III 1258**, **4 IV 2526**.]

**S-Alaninol [S-2-aminopropan-1-ol]** [2749-11-3] **M 75.1**, **b 167-169°/760mm**, **d<sub>4</sub><sup>20</sup> 0.961**, **n<sub>D</sub><sup>20</sup> 1.456**, **[α]<sub>546</sub> +26.0° (c 2, EtOH)**, **pK<sub>25</sub> 9.43**. Purify it as for S-2-amino-3-methylbutan-1-ol below. [*Beilstein* **4 IV 1615**.]

**D-Allothreonine [2R,3R(-)-isomer]** [24830-94-2] **M 119.1**, **m 272-273°(dec)**, **276°(dec)**, **[α]<sub>D</sub><sup>25</sup> -9.1° (c 3.9, H<sub>2</sub>O)**, **pK<sub>1</sub><sup>25</sup> 2.11**, **pK<sub>2</sub><sup>25</sup> 9.10**. Recrystallise D-allothreonine from aqueous EtOH or 50% EtOH. [Elliot *J Chem Soc* **62** 1950, Birnbaum et al. *J Biol Chem* **194** 455 1952, IR: Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** 1961, *Beilstein* **4 IV 3170**.]

**RS-α-Allylglycine (2-aminopent-4-enoic acid)**. [7685-44-1] **M 115.1**, **m 250-255°(dec)**, **pK<sub>Est(1)</sub> ~2.3**, **pK<sub>Est(2)</sub> ~9.6**. Dissolve it in absolute EtOH and precipitate it with pyridine, then recrystallise it from aqueous EtOH [R<sub>F</sub> on paper in BuOH/EtOH/NH<sub>3</sub>/H<sub>2</sub>O (4:4:1:1) is 0.37]. The *hydrobromide* has **m 136-140°** (from EtOAc) and the *phenylureido* derivative has **m 159-161°**. [Schögl *Monatsh Chem* **89** 377 1958, *Beilstein* **4 IV 2852**.]

**Aminoacetic acid (Glycine)** [56-40-6] **M 75.1**, **m 262° (dec, goes brown at 226°, sublimes at 200°/0.1mm)**, **pK<sub>1</sub><sup>25</sup> 2.35**, **pK<sub>2</sub><sup>25</sup> 9.78**. Crystallise glycine from distilled water by dissolving at 90-95°, filtering, cooling to

about  $-5^{\circ}$ , and draining the crystals centrifugally. *Alternatively*, crystallise it from distilled water by addition of MeOH or EtOH (e.g. 50g dissolved in 100ml of warm water, and 400ml of MeOH is added). The crystals are washed with MeOH or EtOH, then with diethyl ether. Likely impurities are ammonium glycinate, iminodiacetic acid, nitrilotriacetic acid or/and ammonium chloride. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 p 1955 1961, *Beilstein* 4 IV 2349.]

**$\alpha$ -Amino acids.** All the  $\alpha$ -amino acids with the “natural” configuration [*S* (L), except for cysteine which is *R*(L)] at the  $\alpha$ - carbon atom are available commercially in a very high state of purity. Many of the “non-natural”  $\alpha$ -amino acids with the [*R*(D)] configuration as well as racemic mixtures are also available, and generally none require further purification before use unless they are of “Technical Grade” or were stored for a very long period. The *R* or *S* enantiomers are optically active except for glycine which has two hydrogen atoms on the  $\alpha$ -carbon atom, but these are *pro*-chiral and enzymes or proteins do distinguish between them, e.g. serine hydroxymethyltransferase successfully replaces the *pro*- $\alpha$ -hydrogen atom of glycine with  $\text{CH}_2\text{OH}$  (from formaldehyde) to make *S*-serine. The twenty common natural  $\alpha$ -amino acids are: **amino acid**, three-letter abbreviation, **one-letter abbreviation**, pK (-COOH) and pK ( $-\text{NH}_3^+$ ): **Alanine**, Ala, A, 2.34, 9.69; **Arginine**, Arg, R, 2.17, 9.04; **Asparagine**, Asn, N, 2.01, 8.80; **Aspartic acid**, Asp, D, 1.89, 9.60; **Cysteine**, Cys, C, 1.96, 8.18; **Glutamine**, Gln, Q, 2.17, 9.13; **Glutamic acid**, Glu, E, 2.19, 9.67; **Glycine**, Gly, G, 2.34, 9.60; **Histidine**, His, H, 1.8, 9.17; **Isoleucine**, Ile, I, 2.35, 9.68; **Leucine**, Leu, L, 2.36, 9.60; **Lysine**, Lys, K, 2.18, 8.95; **Methionine**, Met, M, 2.28, 9.20; **Phenylalanine**, Phe, F, 1.83, 9.12; **Proline**, Pro, P, 1.99, 10.96; **Serine**, Ser, S, 2.21, 9.15; **Threonine**, Thr, T, 2.11, 9.62; **Tryptophan**, Trp, W, 2.38, 9.39; **Tyrosine**, Tyr, Y, 2.2, 9.11, **Valine**, Val, V, 2.32, 9.61, respectively. Technical grade amino acids can be purified on ion-exchange resins (e.g. Dowex 50W and eluting with a gradient of HCl or AcOH), and the purity is checked by TLC in two dimensions and stained with ninhydrin. (J.P. Greenstein & M. Winitz, *Chemistry of the Amino Acids* (3 Volumes), J. Wiley & Sons, NY, 1961; C. Cooper, N. Packer and K. Williams, *Amino Acid Analysis Protocols*, Humana Press, 2001, ISBN 0896036561). Recently codons for a further two amino acids have been discovered which are involved in ribosome-mediated protein synthesis giving proteins containing these amino acids. The amino acids are *R*(L)-selenocysteine [Stadtman *Ann Rev Biochem* 65 83 1996] and pyrrolysine [(4*R*, 5*R*)-4-substituted (with Me,  $\text{NH}_2$  or OH) pyrroline-5-carboxylic acid] [Krzycki & Chan et al. *Science* 296 1459 and 1462 2002.] They are, however, rare at present and only found in a few microorganisms.

***dl*- $\alpha$ -Amino adipic acid (hydrate) (2-amino hexane-1,6-dioic acid) [542-32-5] M 161.2, m 196-198 $^{\circ}$ , 204 $^{\circ}$ , 205-206 $^{\circ}$ , pK<sub>Est(1)</sub> ~2.0, pK<sub>Est(2)</sub> ~4.5, pK<sub>Est(3)</sub> ~9.8.** Crystallise the acid from  $\text{H}_2\text{O}$ . *Alternatively*, purify it by precipitating the Cu salt and decomposing the Cu salt suspended in  $\text{H}_2\text{O}$  by bubbling  $\text{H}_2\text{S}$ , filtering off the CuS, evaporating, and recrystallising the residue from  $\text{H}_2\text{O}$ . Note that prolonged refluxing of an aqueous solution converts the acid to the lactone: *piperid-2-one-6-carboxylic acid* which has m 177-178 $^{\circ}$ . [Linstead & Wang *J Chem Soc* 810, 811 1937, Waelkes et al. *J Am Chem Soc* 72 5760 1950, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 p. 2408 1961, *Beilstein* 4 III 1555, 4 IV 3070.]

***N*-(*p*-Aminobenzoyl)-L-glutamic acid [4271-30-1] M 266.3, m 173 $^{\circ}$ , 174-175 $^{\circ}$  (L-form), [ $\alpha$ ]<sub>546</sub> -17.5 $^{\circ}$  (c 2, 0.1M HCl); 197 $^{\circ}$  (DL), pK<sub>1</sub><sup>25</sup> 2.61, pK<sub>2</sub><sup>25</sup> 3.76, pK<sub>3</sub><sup>25</sup> 4.83.** Crystallise the acid from  $\text{H}_2\text{O}$ . Also purify it by dissolving 2.7g in  $\text{H}_2\text{O}$  (130ml), adding aqueous NaOH to pH 5.5 and adding portionwise a solution of 0.5M  $\text{CuSO}_4$  to complete precipitation of the Cu salt. This salt is filtered off, suspended in  $\text{H}_2\text{O}$  and  $\text{H}_2\text{S}$  is bubbled through to precipitate CuS, filter, evaporate and recrystallise the residue from  $\text{H}_2\text{O}$ . It has  $\lambda_{\text{max}}$  ( $\text{H}_2\text{O}$ ) at 273nm. [Backer & Houtman *Rec Trav Chim Pays Bas* 70 738, 743 1951, *Beilstein* 14 IV 1153.]

***RS*-2-Aminobutyric acid [2835-81-6] M 103.1, m 287-288 $^{\circ}$ (dec), 303 $^{\circ}$ (dec), 303 $^{\circ}$ (dec, sealed tube), pK<sub>1</sub><sup>25</sup> 2.29, pK<sub>2</sub><sup>25</sup> 9.83.** Crystallise the acid from water. [Albertson & McKay *J Am Chem Soc* 81 505 1959, Perrin *J Chem Soc* 3125 1958, *Beilstein* 4 IV 2584.]

***S*-2-Aminobutyric acid (Butyrine) [1492-24-6] M 103.1, m 292 $^{\circ}$ (dec), [ $\alpha$ ]<sub>D</sub><sup>25</sup> + 20.6 $^{\circ}$  (c 2, 2.5N HCl), pK<sub>1</sub><sup>25</sup> 2.55, pK<sub>2</sub><sup>25</sup> 9.60.** Crystallise butyrine from aqueous EtOH, and the melting point depends on heating rate but has m 303 $^{\circ}$  in a sealed tube. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 p 2399 IR: 2401 1961, *Beilstein* 4 III 1294, 4 IV 2584.]

**RS-3-Aminobutyric acid** [2835-82-7] **M 103.1, m 193-194<sup>o</sup>, pK<sub>Est(1)</sub> ~3.5, pK<sub>Est(2)</sub> ~10.3.** Crystallise the acid from aqueous EtOH or MeOH/Et<sub>2</sub>O. Also crystallise it by heating a slightly diluted EtOH solution and adding Me<sub>2</sub>CO. It gives a purple spot with R<sub>F</sub> 0.89 on paper chromatography using 80% aqueous phenol (the α-amino acid has R<sub>F</sub> 0.74). [Zilka & Rivlin *J Org Chem* **23** 94 1958, Bruylants *Bull Soc Chim Belg* **32** 259 1923, Beilstein **4** IV 2595.]

**S-3-Aminobutyric acid** [3775-72-2] **M 103.1, m 212<sup>o</sup>, 210-212<sup>o</sup>, [α]<sub>D</sub><sup>20</sup> + 38.8<sup>o</sup> (c 0.5, H<sub>2</sub>O).** Purify the acid from absolute EtOH. It has also been crystallised from MeOH or MeOH/Et<sub>2</sub>O and dried in a vacuum. [Balenovic et al. *J Chem Soc* 3316 1952, Bruylants *Bull Soc Chim Belg* **32** 259 1923, Beilstein **4** IV 2595.]

**4-Aminobutyric acid (GABA)** [56-12-2] **M 103.1, m 202<sup>o</sup>(dec), 203<sup>o</sup>(dec), pK<sub>1</sub><sup>25</sup> 4.14, pK<sub>2</sub><sup>25</sup> 10.55.** Crystallise GABA from aqueous EtOH or MeOH/Et<sub>2</sub>O. Also crystallise it by dissolving it in the least volume of H<sub>2</sub>O and adding 5-7 volumes of absolute EtOH. [Sherman *Biochemical Preparations* **4** 91 1955, de Witt *Org Synth Coll Vol II* 25 1943, Beilstein **4** III 1316, **4** IV 2600.]

**1-Amino-1-cyclopentanecarboxylic acid (cycloleucine)** [52-52-8] **M 129.2, m 328-335<sup>o</sup>(dec), 328-329<sup>o</sup>, 330<sup>o</sup>(dec), pK<sub>1</sub><sup>20</sup> 2.4, pK<sub>2</sub><sup>20</sup> 10.3.** Any Cl<sup>-</sup> or other anions are removed by stirring with a strong cation exchange resin (Amberlite IR-120), filtering, and washing with distilled H<sub>2</sub>O until the filtrate is free from the anion. The resin is then stirred overnight with 6N NH<sub>4</sub>OH, filtered, the filtrate is decolourised (charcoal) and evaporated to dryness in a vacuum. The residue is recrystallised from H<sub>2</sub>O/EtOH. Also crystallise it from aqueous EtOH. The *hydrochloride* has **m 222-224<sup>o</sup>(dec)**. [Neelakantan & Hartung *J Org Chem* **23** 967 1958, Connors & Ross *J Chem Soc* 2119 1960, O'Donnell et al. *Synthesis* 127 1984, Beilstein **14** IV 974.]

**trans-(1RS,4RS)-4-Aminoethylcyclohexane-1-carboxylic acid (t-AMCHA, Tranexamic acid, Tranex, Transamin, Trasamlon, Ugurol, Frenolyse, Hexapromin, Abvitoff among other names)** [1197-18-8] **M 157.2, m 386-392<sup>o</sup> (dec), and cis-(1RS,4SR)-4-aminoethylcyclohexane-1-carboxylic acid** [1197-17-7] **M 157.2, m 236-238<sup>o</sup> (dec); cis- and trans- acids have the same pK<sub>1</sub><sup>25</sup> 4.51 (CO<sub>2</sub>H), pK<sub>2</sub><sup>25</sup> 10.72 (NH<sub>2</sub>).** A mixture of *cis*- and *trans*- acids (2:1) is obtained by catalytic reduction of 4-acetamidomethylbenzoic acid (3.9g, 20mmol, from acetylation of 4-aminomethylbenzoic acid see [56-91-7]) in aqueous NaOH (0.8g, 20mmol in 15ml of H<sub>2</sub>O) in the presence of Raney Ni (3ml of aqueous suspension) are shaken with H<sub>2</sub> in a bomb (100ml) at 170<sup>o</sup> and 82atm/cm<sup>2</sup> (1205psi). Reduction is complete after 2 hours, the catalyst is filtered off, the filtrate is acidified with 4N H<sub>2</sub>SO<sub>4</sub> and evaporated to dryness *in vacuo*; the residue is extracted with Me<sub>2</sub>CO, filtered and evaporated to dryness *in vacuo* to give crude 4-acetamidomethylcyclohexane-1-carboxylic acid (~3.9g). The acid is then refluxed with 20% HCl (20ml) for 3 hours (in an oil bath at 150<sup>o</sup>), evaporated to dryness *in vacuo*; the residue is dissolved in H<sub>2</sub>O (20ml) and freed from HCl by passage through a column of 'Amberlite IR-4B' (15ml, in OH<sup>-</sup> form) and eluted with H<sub>2</sub>O. Evaporation of the eluate *in vacuo* and crystallisation of the residue from aqueous Me<sub>2</sub>CO gives a 2:1 mixture of *cis*- and *trans*- **4-aminomethylcyclohexane-1-carboxylic acid** (2.24g, ~71%, **m ~232-236<sup>o</sup>, dec**). Both acids are symmetrical, i.e. mirror images are superimposable. The mixture (10g, 64mmol) is separated by refluxing with Cu(CO<sub>3</sub>)<sub>2</sub> (9.15g, 38mmol) in H<sub>2</sub>O (100ml) for 1 hour (turning deep blue in colour), cooled and the blue precipitate is filtered off, dissolved into 8% aqueous NH<sub>3</sub> (100ml), filtered from a little solid, and passed through a column of "Diaion SK#1 (NH<sub>4</sub><sup>+</sup> form)" and washed with H<sub>2</sub>O. The eluted solution is then passed through an "Amberlite IR-4B' (OH<sup>-</sup> form)" column and the effluent is evaporated to dryness. The residue (6.75g, **m ~221-223<sup>o</sup>, dec**.) is repeatedly recrystallised from H<sub>2</sub>O-Me<sub>2</sub>CO to give the pure *cis*-amino acid with **m 236-238<sup>o</sup>, dec**, and IR (KBr) peaks at ν<sub>max</sub> 2940, 2660, 1639 (1640), 1560 (1563), 1509 (1515), 1408 (1403), 1305 (1308), 930 and 904 cm<sup>-1</sup>, value in *italics* are from Meyer (see below). The combined filtrates from the recrystallisation are evaporated, the residue is dissolved in H<sub>2</sub>O and similarly de-ionised through the same columns. The final residue is recrystallised from H<sub>2</sub>O-Me<sub>2</sub>CO to give the pure *trans*-4-aminoethylcyclohexane-1-carboxylic acid (3.37g) with **m 286-292<sup>o</sup>, dec**, and IR (KBr) peaks at ν<sub>max</sub> 2940, 2610, 1637, 1535 (1528), 1383 (1381) (1325) and 920 cm<sup>-1</sup>, value in *italics* are from Meyer (see below). On TLC (Silica gel G, eluted with ascending *n*-PrOH/H<sub>2</sub>O, 65:35) the R<sub>F</sub> of the *cis*-isomer was always 1.2 times larger than that of the *trans*- isomer. [Note that the melting points of the isomers measured in the usual way vary somewhat, and by using a Du Pont Model 900 differential thermal analyzer the *cis*-acid had **m 252<sup>o</sup>**, and the *trans*-acid had **m 295-300<sup>o</sup>** as endotherms, Meyer *J Med Chem* **9** 641 1966]. The *cis*-hydrochloride has **m 195-197<sup>o</sup>, dec** (prisms from H<sub>2</sub>O-Me<sub>2</sub>CO), the *trans*-hydrochloride has **m 238-**

**241.5°**, **dec** (needles from H<sub>2</sub>O-Me<sub>2</sub>CO); the *cis*-hydrobromide has **m 205-208°**, **dec** (plates from Me<sub>2</sub>CO), the *trans*-hydrobromide has **m 227-229°**, **dec** (plates from H<sub>2</sub>O); the *cis*-*p*-toluenesulfonic acid salt has **m 177-178°** (plates from *n*-PrOH-Et<sub>2</sub>O), the *trans*-*p*-toluenesulfonic acid salt has **m 262-264°** (plates from H<sub>2</sub>O), the *cis*-HCl-AuCl<sub>3</sub> salt has **m 178-180°**, **dec** (yellow needles from H<sub>2</sub>O), the *trans*-HCl-AuCl<sub>3</sub> salt has **m 205-206°**, **dec** (yellow prisms from H<sub>2</sub>O), the *cis*-HCl-PtCl<sub>4</sub> salt has **m 233°**, **dec** (yellow needles from H<sub>2</sub>O), the *trans*-HCl-PtCl<sub>4</sub> salt has **m 254-255°**, **dec** (yellow-orange plates from H<sub>2</sub>O); the *cis*-*N*-acetamide has **m 189-190°** (prisms from EtOH), the *trans*-*N*-acetamide has **m 154-155°** (prisms from Me<sub>2</sub>CO); the *cis*-*N*-benzamide has **m 157-158°** (plates from EtOH/\*C<sub>6</sub>H<sub>6</sub>) and the *trans*-*N*-benzamide has **m 177-178°** (needles from EtOH/H<sub>2</sub>O).

The *cis*- and *trans*- acids are also readily separated from the mixture by recrystallisation of their *p*-toluenesulfonic acid salts which have very different solubility properties. **Isomerisation:** When a solution of the *cis*-acid (2g) in 0.5N NaOH (26ml) is heated in a silver vessel in an autoclave at 200° for 6 hours, and the cooled solution is passed through an "Amberlite IR-120" (NH<sub>4</sub><sup>+</sup> form) column and washed with H<sub>2</sub>O, and evaporation of the eluate *in vacuo* and four recrystallisations from aqueous MeOH, the *trans*-acid (0.8g, 40%), **m 384-390° dec**, is obtained [Naito et al. *Chem Pharm Bull Jpn* **16** 728 1968, Daiichi Seiyak Dutch Pat 6,414,942 1965, *Chem Abstr* **64** 3379 1966.] The width-at-half height of the peaks from the cyclohexane protons in the <sup>1</sup>H NMR spectra are larger from the *trans*-acid than the corresponding peaks from the *cis*-acid. The structure of the *cis*-acid was confirmed by conversion to a cyclic lactam on fusion. It has **m 104°** after recrystallisation from hexane followed by sublimation at 100°/2.5 x 10<sup>-2</sup>mm. [Note that this melting point was recorded at the point where, under crossed Nichol prisms, birefringence was lost. The crystal form, however, was only slowly lost thereafter over a wide range of temperatures]. The lactam has IR (KBr) peaks at  $\nu_{\max}$  1661 (amide I), 1421, 1325 and 1205 cm<sup>-1</sup> [Meyer *J Med Chem* **9** 641 1966].

These amino acids are haemostatic with antiplasmin activity. The *trans*-acid has potent antiplasmin activity (inhibiting the fibrinolytic enzyme system), being 50 times more active than the *cis*-acid, and 5-7 times more potent than  $\epsilon$ -aminocaproic acid [Naito et al. *Chem Pharm Bull Jpn* **16** 357 and 728 1968.] The antifibrinolytic activity is due to blocking of the lysine binding sites of plasminogen. *t*-AMCHA has been used as a lysine analogue to characterise binding sites in plasminogens. [Hoover et al. *Biochemistry* **32** 10936 1993, Marshall et al. *Biochemistry* **33** 3599 1994.]

**4-Amino hippuric acid** (*N*-*p*-aminobenzoylglycine) [61-78-9] **M 194.2**, **m 198-199°**, **200-202°**, **pK<sub>Est(1)</sub> ~1.7(NH<sub>2</sub>)**, **pK<sub>Est(2)</sub> ~3.4(CO<sub>2</sub>H)**. Crystallise the acid from H<sub>2</sub>O. It is soluble in organic solvents. [Cohen & McGilvery *J Biol Chem* **169** 119 1945, **171** 121 1947, Meunzen et al. *J Biol Chem* **26** 469 1926, *Beilstein* **14** III 1069, **14** IV 1152.]

***dl*-4-Amino-3-hydroxybutyric acid** [924-49-2] **M 119.1**, **m 218°(dec)**, **225°(dec)**, **pK<sub>25</sub> ~3.80(CO<sub>2</sub>H)**, **pK<sub>Est(2)</sub> ~9.3**. Crystallise the acid from H<sub>2</sub>O or aqueous EtOH. Recrystallise it by dissolving it in H<sub>2</sub>O and adding MeOH or EtOH. It is not very soluble in CHCl<sub>3</sub> or EtOAc. [Renaud & Seebach *Synthesis* 424 1986, *Beilstein* **4** IV 3187.]

***R* (L-)-4-Amino-3-hydroxybutyric acid (GABOB)** [352-21-6] **M 119.1**, **m 212°(dec)**, **213-214°(dec)**, **216-217°(dec)**, **[ $\alpha$ ]<sub>D</sub><sup>20</sup> -20.5° (c 1.75, H<sub>2</sub>O)**. Purify GABOB through a Dowex 50Wx8 resin, eluting with 1.3N NH<sub>4</sub>OH, evaporating and crystallising the residue by dissolving it in H<sub>2</sub>O and adding EtOH. It is an anticonvulsant. [Renaud & Seebach *Synthesis* 424 1986, Takano et al. *Tetrahedron Lett* **29** 795 1988, *Beilstein* **4** IV 3187.]

**$\alpha$ -Aminoisobutyric acid (2-amino-2-methylpropionic acid)** [62-57-7] **M 103.1**, **m sublimes at 280-281°**, **335° (sealed tube)**, **pK<sub>25</sub> 2.36**, **pK<sub>25</sub> 10.21**. Crystallise the acid from aqueous EtOH and dry it at 110°. [Zelinski & Stadnikoff *Chem Ber* **39** 1726 1906, *Beilstein* **4** IV 2616.]

***RS*- $\beta$ -Aminoisobutyric acid ( $\alpha$ -methyl- $\beta$ -alanine)** [10569-72-9] **M 103.1**, **m 176-178°**, **178-180°**, **181-182°**, ***R*-(-)- isomer [144-90-1] m 183°**, **[ $\alpha$ ]<sub>D</sub><sup>20</sup> -21° (c 0.43, H<sub>2</sub>O)**, **pK<sub>Est(1)</sub> ~3.7**, **pK<sub>Est(2)</sub> ~10.2**. *RS*- $\beta$ -Aminoisobutyric acid forms colourless prisms by crystallisation from hot H<sub>2</sub>O which are powdered and dried *in vacuo*. The purity is checked by paper chromatography (Whatman 1) using ninhydrin spray to visualise the amino acid; R<sub>F</sub> values in 95% MeOH and *n*-PrOH/5N HCOOH (8:2) are 0.36 and 0.50 respectively. [Kupiecki & Coon *Biochemical Preparations* **7** 20 1960, Pollack *J Am Chem Soc* **65** 1335 1943.] The *R*-enantiomer, isolated from

iris bulbs or human urine, crystallises from H<sub>2</sub>O and sublimes *in vacuo* [Asen et al. *J Biol Chem* **234** 343 1959]. The *RS*-hydrochloride crystallises from EtOH/Et<sub>2</sub>O with *m* 128-129° (also 130°) [Böhme et al. *Chem Ber* **92** 1258, 1260, 1261 1959]. [Beilstein **4** III 1330.]

**5-Aminolaevulinic acid hydrochloride (ALA-HCl,  $\delta$ -aminolaevulinic acid HCl)** [5451-09-2] *M* 167.6, *m* 148°(dec), 150-151°(dec), 156-158°(dec), *pK*<sub>1</sub><sup>22</sup> 4.05, *pK*<sub>2</sub><sup>22</sup> 8.90. Dry ALA-HCl in a vacuum desiccator over P<sub>2</sub>O<sub>5</sub> overnight, then crystallise it by dissolving it in cold EtOH and adding dry Et<sub>2</sub>O. Also crystallise it by dissolving in the minimum volume of MeOH, and placing in a desiccator containing dry Et<sub>2</sub>O (clamp the desiccator). During several days the Et<sub>2</sub>O slowly distils into the MeOH causing the hydrochloride to separate as long needles. Filter them off and dry them in a Fischer pistol. [Wynn & Corwin *J Org Chem* **15** 203, 207 1950, Neuberger & Scott *J Chem Soc* 1820, 1924 1954, Beilstein **4** IV 3265.]

**4-Aminomethylbenzoic acid ( $\alpha$ -amino-*p*-toluic acid)** [56-91-7] *M* 151.2, *m* 273-274°, 294-295°, >300°, 345°, 347-350° (sealed tube), *pK*<sub>1</sub><sup>20</sup> 3.59 (CO<sub>2</sub>H), *pK*<sub>2</sub><sup>20</sup> 9.64 (NH<sub>2</sub>). This acid has been prepared in two different ways from *p*-cyanobenzoic acid [Levine & Sedlecky *J Org Chem* **24** 115 1959, Albert & Magrath *J Chem Soc* 678 1944], and by reduction of *p*-carboxybenzaldehyde oxime [Nair & Baugh *J Org Chem* **38** 2189 1973]. A mixture of *p*-cyanobenzoic acid (14g, 619-65-8), Raney cobalt (2g, W-6 or W-7), 28% aqueous NH<sub>3</sub> (40ml) and H<sub>2</sub>O (150ml) are shaken in a Parr hydrogenator at 3 atm (initial pressure) and 25° for ~3 hours when the theoretical volume of H<sub>2</sub> is absorbed. The catalyst is filtered off, the filtrate is boiled to remove NH<sub>3</sub> and the solid that separated is collected, and recrystallised from H<sub>2</sub>O (charcoal) to give the amino acid (*m* 347-350°) in 80% yield. Alternatively, the oxime of *p*-carboxybenzaldehyde (1g, 619-66-9) in 95% EtOH (100ml) containing 5% Pd/C (100mg) is shaken with H<sub>2</sub> at 30 psi for 18 hours at 25°. The catalyst is filtered off and washed with hot glacial AcOH (2 x 20ml); the combined washings and filtrate are evaporated to dryness and the residue is recrystallised from H<sub>2</sub>O (charcoal) to give the white crystalline amino acid (850mg, *m* 294-295°). The melting point appears to vary with heating rate. UV has  $\lambda_{\text{max}}$  at 234nm (H<sub>2</sub>O), and the <sup>1</sup>H NMR [TFA] has  $\delta$  at 4.15 (q, *J* = 6Hz, benzylic H), 7.3 (d, *J* = 8Hz, two protons adjacent to H<sub>2</sub>NCH<sub>2</sub>) and 7.9 (d, *J* = 8Hz, two protons adjacent to CO<sub>2</sub>H). The *N*-acetyl derivative crystallises from a large volume of xylene and has *m* 199-200° (lit: Levine & Sedlecky state *m* 199-120°). [For *pK*<sub>a</sub> see Goldacre *Nature* **154** 796 1944, Beilstein **14** H 487, **14** III 1212, **14** IV 1362.]

***S*-2-Amino-3-methyl-1-butanol (*S*-valinol)** [2026-48-4] *M* 103.2, *m* 31-32°, *b* 88°/11mm, *d* 0.92, [ $\alpha$ ]<sub>546</sub> + 16.5° (*c* 6.32, *l* = 2 H<sub>2</sub>O), [ $\alpha$ ]<sub>D</sub> + 15.6° (EtOH), *pK*<sub>Est</sub> ~10.4. Purify *S*-valinol by vacuum distillation using a short Vigreux column. Alternatively, it is purified by steam distillation. The steam distillate is acidified with HCl; the aqueous layer is collected and evaporated. The residue is dissolved in butan-1-ol, filtered and dry Et<sub>2</sub>O added to crystallise the hydrochloride salt (*hygroscopic*), *m* 113°. The free base can be obtained by suspending the salt in Et<sub>2</sub>O and adding small volumes of saturated aqueous K<sub>2</sub>CO<sub>3</sub> until effervescence is complete and the mixture is distinctly alkaline. At this stage the aqueous layer should appear as a white sludge. The mixture is heated to boiling and refluxed for 30 minutes (more Et<sub>2</sub>O is added if necessary). The Et<sub>2</sub>O layer is decanted off from the white sludge, the sludge is extracted twice with Et<sub>2</sub>O (by boiling for a few minutes), the combined organic layers are dried (KOH pellets), evaporated and the residue is distilled in a vacuum. [Nagao et al. *J Org Chem* **55** 1148 1990, Beilstein **4** III 805.]

***S*-(+)-3-Aminopentanoic acid** [14389-77-6] and ***R*-(-)-3-aminopentanoic acid** [131347-76-7] *M* 115.1, *m* (175°), 185°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> (+) and (-) 43° (*c* 0.5, H<sub>2</sub>O), *pK*<sub>1</sub><sup>25</sup> 3.54, *pK*<sub>2</sub><sup>25</sup> 10.25. Crystallise the amino acid from EtOH/Et<sub>2</sub>O. [Beilstein **4** II 843, **4** III 1342, **4** IV 2635.]

**$\alpha$ -Aminothiophene-2-acetic acid [2-(2-thienyl)glycine]** [*R*(+) 65058-23-3, *S*(-) 4052-59-9, (-)- 43189-45-3, *RS*( $\pm$ ) 21124-40-3] *M* 57.2, *m* 236-237° (*R*), 235-236° (*S*), 208-210°, 223-224° (dec)(*RS*), [ $\alpha$ ]<sub>D</sub><sup>20</sup> (+) and (-) 84° (*c* 1, 1% aqueous HCl), [ $\alpha$ ]<sub>D</sub><sup>25</sup> (+) and (-) 71° (*c* 1 H<sub>2</sub>O), *pK*<sub>Est(1)</sub> ~ 1.5, *pK*<sub>Est(2)</sub> ~ 8.0. Recrystallise 2-(2-thienyl)glycine by dissolving it in H<sub>2</sub>O (1g in 3 ml), adjusting the pH to 5.5 with aqueous NH<sub>3</sub>, diluting with MeOH (20 ml), stirring, adjusting the pH to 5.5 and cooling to 0°. Also recrystallise it from small volumes of H<sub>2</sub>O. [*R*-isomer: Nishimura et al. *Nippon Kagaku Zasshi* **82** 1688 1961, *S*-isomer: Johnson & Panetta *Chem*

*Abstr* **63** 14869 1965, Johnson & Hardcastle *Chem Abstr* **66** 10930 1967, *RS*-isomer: LiBassi et al. *Gazz Chim Ital* **107** 253 1977.] The ( $\pm$ ) *N*-acetyl derivative has *m* 191° (from H<sub>2</sub>O) [Schouteenten et al. *Bull Soc Chim Fr* II 248, II 252 1978].

**5-Amino-*n*-valeric acid (5-aminopentanoic acid)** [660-88-8] *M* 117.2, *m* 157-158°, *pK*<sub>1</sub><sup>25</sup> 4.25, *pK*<sub>2</sub><sup>25</sup> 10.66. Crystallise it from H<sub>2</sub>O/EtOH. When heated above its melting point, it is converted to 2-piperidone with *m* 200°. [Wood & Colver *J Am Chem Soc* **67** 654 1945, *Beilstein* **4** IV 2636.]

**5-Amino-*n*-valeric acid hydrochloride** [627-95-2] *M* 153.6, *m* 92-94°, 103-104°. Crystallise the salt from CHCl<sub>3</sub>. Otherwise dissolve it in EtOH and add 2 volumes of Et<sub>2</sub>O and chill. [Schniepp & Marvel *J Am Chem Soc* **57** 1557 1935, Woods & Colver *J Am Chem Soc* **67** 654 1945, *Beilstein* **4** III 1343, **4** IV 2636.]

**Angiotensinogen (from human blood serum or porcine plasma)** [64315-16-8] *M* ~1762. A tetradecapeptide renin substrate which is purified by chromatography on Blue Sepharose, Phenyl-Sepharose, hydroxylapatite and immobilised 5-hydroxytryptamine [Campbell et al. *Biochem J* **243** 121 1987]. [*Beilstein* **25** III/IV 4390 for *angiotensin*.]

**Anserine [N, $\beta$ -alanyl-1-methyl-*S*-histidine]** [584-85-0] *M* 240.3, *m* 238-239°, [ $\alpha$ ]<sub>D</sub><sup>23</sup> +12.3° (c 5, H<sub>2</sub>O), *pK*<sub>1</sub><sup>25</sup> 2.64, *pK*<sub>2</sub><sup>25</sup> 7.04, *pK*<sub>3</sub><sup>25</sup> 9.49. Crystallise anserine from aqueous EtOH. It is *hygroscopic* and is best stored as the nitrate salt (see below). Purify it by shaking the nitrate salt with Dowex 3 (x4 free base) and washing with H<sub>2</sub>O, evaporating the filtrate and removing H<sub>2</sub>O by 3 distillations with 10ml of propan-2-ol. Dissolve the crystals in MeOH and add H<sub>2</sub>O dropwise until one phase is obtained and cool. Dry the crystals at 60° over P<sub>2</sub>O<sub>5</sub> in a vacuum. The *picrate* has *m* 145° (from H<sub>2</sub>O). [Rinderknecht et al. *J Org Chem* **29** 1968 1964, *Beilstein* **25** II 408, **25** IV 4383.]

***S*-Anserine nitrate** [5937-77-9] *M* 303.3, *m* 225°(dec), 226-228°(dec), [ $\alpha$ ]<sub>D</sub><sup>30</sup> +12.2°. Likely impurities are 1-methylimidazole-5-alanine and histidine. Crystallise the nitrate from aqueous MeOH or EtOH (needles). Also dissolve ~20g in 25ml of MeOH, add 2-propanol (150-200ml) and store the mixture at 5° overnight to give shiny needles. Recrystallise it by heating 12g of the nitrate in MeOH (300ml) and adding H<sub>2</sub>O (50-60ml) until one phase is obtained and refrigerating overnight. Filter and dry it at 60°/P<sub>2</sub>O<sub>5</sub> in a vacuum. [Rinderknecht et al. *J Org Chem* **29** 1968 1964, Behrens & duVigneaud *J Biol Chem* **120** 517 1937.]

***S*-Arginine** [74-79-3] *M* 174.2, *m* 205°(dec, anhydrous), 207°(dec, 2 H<sub>2</sub>O), [ $\alpha$ ]<sub>D</sub> +26.5° (c 5, in 5M HCl), [ $\alpha$ ]<sub>546</sub> +32° (c 5, in 5M HCl), *pK*<sub>1</sub><sup>25</sup> 2.18, *pK*<sub>2</sub><sup>25</sup> 9.36, *pK*<sub>3</sub><sup>25</sup> 11.5. *S*-Arginine crystallises from H<sub>2</sub>O as the *dihydrate* and as plates from EtOH. It also crystallises from 66% EtOH. Its solubility in H<sub>2</sub>O is 15% at 21°. Its isoelectric point is at pH 10.76. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 p 1841 1961, *Beilstein* **4** IV 817.]

***S*-Arginine hydrochloride** [1119-34-2] *M* 210.7, *m* 217°(dec), 222°(dec), [ $\alpha$ ]<sub>D</sub><sup>30</sup> +26.9° (c 6, M HCl). A likely impurity is ornithine. Crystallise the salt from H<sub>2</sub>O at pH 5-7, by adding EtOH to 80% (v/v). [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 p 1841 1961, *Beilstein* **4** IV 2649.]

***S*-Argininosuccinic acid** [2387-71-5] *M* 290.3, [ $\alpha$ ]<sub>D</sub><sup>23</sup> +16.4° (H<sub>2</sub>O). A likely impurity is fumaric acid. In neutral or alkaline solution it readily undergoes ring closure to the "anhydride" (see below). Crystallise it from water by adding 1.5 volumes of EtOH. The barium salt is stable at 0-5° if dry. [Westfall *Biochem J* **77** 135 1960, Ratner & Kunkemueller *Biochemistry* **5** 1821 1966.]

***S*-Argininosuccinic anhydride** [28643-94-9] *M* 272.3, [ $\alpha$ ]<sub>D</sub><sup>23</sup> -10° (H<sub>2</sub>O for anhydride formed at neutral pH). Crystallise the anhydride from H<sub>2</sub>O by adding two volumes of EtOH. An isomeric anhydride is formed if the free acid is allowed to stand at acid pH. In solution, the mixture of anhydride and free acid is formed [see above entry, Ratner & Kunkemueller *Biochemistry* **5** 1821 1966, Kowalsky & Ratner *Biochem J* **8** 899 1969].

***S*-Asparagine** [70-47-3] *M* 150.1, *m* 234-235° (monohydrate) [5794-13-8] [ $\alpha$ ]<sub>D</sub> +32.6° (0.1M HCl), *pK*<sub>1</sub><sup>25</sup>

**1.98, pK<sub>2</sub><sup>25</sup> 8.84.** Likely impurities are aspartic acid and tyrosine. Crystallise it from H<sub>2</sub>O or aqueous EtOH. It slowly effloresces in dry air. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 p 1856 1961, Beilstein 4 IV 3005.]

**Aspartic acid** M 133.1, m 338-339° (*RS*, [617-45-8]), m 271° (*S*, requires heating in a sealed tube [56-84-8]) [α]<sub>D</sub><sup>25</sup> +25.4° (3M HCl), pK<sub>1</sub><sup>25</sup> 1.99, pK<sub>2</sub><sup>25</sup> 3.90. Likely impurities are glutamic acid, cystine and asparagine. Crystallise the acid from water by adding 4 volumes of EtOH and dry it at 110°. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 p 1856 1961, Beilstein 4 IV 2998, 3000.]

**L-Aspartic acid β-methyl ester hydrochloride** [16856-13-6] M 183.6, m 194°, pK<sup>25</sup> 8.62. Recrystallise it from MeOH by adding anhydrous Et<sub>2</sub>O [Bach et al. *Biochemical Preparations* 13 20 1971].

**DL-Aspartic acid dimethyl ester hydrochloride** [14358-33-9] M 197.7, 116-117°. Crystallise it from absolute MeOH. [Kovach et al. *J Am Chem Soc* 107 7360 1985.] The *diethyl ester* has pK<sup>25</sup> 6.4.

**Azaserine** [115-02-6] M 173.1, m 146-162°(dec), [α]<sub>D</sub><sup>27.5</sup> -0.5° (c 8.5, H<sub>2</sub>O, pH 5.2), pK<sub>Est(1)</sub> ~4.53, pK<sub>Est(2)</sub> ~5.40. Crystallise azaserine from 90% EtOH. Also dissolve it in H<sub>2</sub>O, filter it through Supercel and add EtOH to give azaserine as pale yellow crystals. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 1 pp 75-76 1961, Curphey & David *J Org Chem* 43 4666 1978, Beilstein 4 IV 3124.]

**Benzoyl glycine (hippuric acid)** [495-69-2] M 179.2, m 188°, pK<sup>20</sup> 3.81, 3.59. pK<sup>40</sup> 3.59. Crystallise the acid from boiling H<sub>2</sub>O. Dry it over P<sub>2</sub>O<sub>5</sub>. Also purify it by dissolving 135-140g in 2L of boiling H<sub>2</sub>O, filtering through a steam-heated funnel and allowing to crystallise at ~20° (yield 115-122g first crop, m 186-187°). [Ingersoll & Babcock *Org Synth Coll Vol II* 328 1943, Beilstein 9 225, I 100.]

**N-Benzyloxycarbonylglycyl-L-alaninamide** [17331-79-2] M 279.3, m dec >200°. Recrystallise the dipeptide derivative from EtOH/Et<sub>2</sub>O.

**N-Benzyloxycarbonyl-N'-methyl-L-alaninamide** [33628-84-1] M 236.3, m dec >200°. Recrystallise the amide from EtOAc.

**Betaine (1-carboxymethyl-N,N,N-trimethylammonium zwitterion)** [107-43-7 (*anhydrous*), 590-47-6, 17146-86-0 (*monohydrate*)] M 117.1, m 294-294°(dec) (*monohydrate?*) 301-305°(dec) (*anhydrous*), ~319°(dec), pK<sup>25</sup> 1.83. Crystallise betaine from aqueous EtOH or EtOH/Et<sub>2</sub>O. The *monohydrate* loses H<sub>2</sub>O above 100°. Betaine undergoes internal alkylation to methyl dimethylaminoacetate above its melting point. It is also prepared by treating the hydrochloride (below) with silver oxide and recrystallising from EtOH/Et<sub>2</sub>O. [Edsall *J Am Chem Soc* 66 1767 1943, Leifer & Lippincott *J Am Chem Soc* 79 5098 1957, for pK see Grob et al. *Chem and Ind (London)* 1222 1955, Beilstein 4 III 1127, 4 IV 2369.]

**Betaine hydrochloride** [590-46-5] M 153.6, m 227-228°(dec), 232°(dec), 246-247°(dec). Recrystallise the salt from EtOH. Its solubility at 25° is 65% in H<sub>2</sub>O, and 5% in EtOH. [Edsall *J Am Chem Soc* 66 1767 1943, Kuhn & Ruelius *Chem Ber* 83 420 1950, Beilstein 4 III 1127, IV 2369.]

**Bis-N-tert-butylloxycarbonyl-L-cystine**, [10389-65-8] M 440.5, m 144.5-145°, [α]<sub>D</sub><sup>20</sup> -133.2° (c 1, MeOH), pK<sub>Est</sub> ~2.9. Crystallise the cystine derivative from EtOAc by adding hexane [Ferraro *Biochemical Preparations* 13 39 1971].

**Bombesin (2-L-glutamine-3,6-L-asparaginealytesin, a tetradecapeptide)** [31362-50-2] M 1619.9. Purify Bombesin by gel filtration on a small column of Sephadex G-10 and elute with 0.01 M AcOH. This procedure removes lower molecular weight contaminants which are retarded on the column. The procedure should be repeated twice, and the material should now be homogeneous on electrophoresis, and on chromatography it gives a single active spot which is negative to ninhydrin but positive to Cl<sub>2</sub> and iodoplatinate reagents. R<sub>F</sub> on paper chromatography (*n*-BuOH/pyridine/AcOH/H<sub>2</sub>O :: 37.5: 25:7.5:30) is 0.55 for Bombesin and 0.65 for

Alytin. [Bernardi et al. *Experientia* **Part 1** **27** 166 1971, Anastasi et al. **Part 2** **27** 873 1971.] The hydrochloride has  $m$  185°(dec) (from EtOH)  $[\alpha]_{\text{D}}^{25} -20.6^{\circ}$  [c 0.65, Me<sub>2</sub>NCHO/(Me<sub>2</sub>N)<sub>3</sub>PO (8:2)]. [For the stimulation of inositol phosphate see Lloyd et al. *Biochem J* **260** 813 1989.]

**Bradykinin** [ArgProProGlyPheSerProPheArg] [5979-11-3]  $M_r$  1,240.4. Purify Bradykinin by ion-exchange chromatography on CMC (*O*-carboxymethyl cellulose) and partition chromatography on Sephadex G-25. The purity is checked by paper chromatography using BuOH/AcOH/H<sub>2</sub>O (4:1:5) as eluent. [Park et al. *Can J Biochem* **56** 92 1978, ORD and CD: Bodanszky et al. *Experientia* **26** 948 1970, activity: Regoli & Barabé *Pharmacol Rev* **32** 1 1980, *Beilstein* **22** III/IV 91.]

**S-Canavanine** [2-amino-4-(guanidinoxy)butyric acid] [543-38-4]  $M$  176.2,  $m$  184°,  $[\alpha]_{\text{D}}^{17} +19.4^{\circ}$  (c 2, H<sub>2</sub>O),  $[\alpha]_{\text{D}}^{20} +7.9^{\circ}$  (c 3.2, EtOH),  $pK_1^{25}$  2.43,  $pK_2^{25}$  6.60,  $pK_3^{25}$  9.25. Crystallise *S*-canavanine from absolute EtOH or aqueous EtOH. [Tomiyama *J Biol Chem* **111** 48 1935 gave  $pK_1^{25}$  9.25 (COOH),  $pK_2^{25}$  7.4 (guanidinium),  $pK_3^{25}$  11.5 (NH<sub>4</sub><sup>+</sup>), Gulland & Morris *J Chem Soc* 763 1935, (±) Frankel et al. *J Chem Soc* 3127 1963, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2622-2628 1961, *Beilstein* **4** III 1636, **4** IV 3188.]

**S-Canavanine sulfate** (from jackbean, *O*-guanidino-*L*-homoserine) [2219-31-0]  $M$  274.3,  $m$  160-165°(dec), 172°(dec),  $[\alpha]_{\text{D}}^{18.5} +19.8^{\circ}$  (c 7, H<sub>2</sub>O),  $pK_1^{25}$  7.40 (CO<sub>2</sub>H),  $pK_2^{25}$  9.25 (α-NH<sub>2</sub>),  $pK_3^{25}$  11.5 (guanidinoxy). Recrystallise the sulfate by dissolving (~1g) in H<sub>2</sub>O (10ml), and adding with stirring 0.5 to 1.0 volumes of 95% EtOH whereby crystals separate. These are collected, washed with Me<sub>2</sub>CO/EtOH (1:1) and dried over P<sub>2</sub>O<sub>5</sub> in a vacuum. [Hunt & Thompson *Biochemical Preparations* **13** 416 1971, Feacon & Bell *Biochem J* **59** 221 1955, *Beilstein* **4** III 1636, **4** IV 3188.]

***N*-Carbamoylglycine** (hydantoic acid, *N*-carboxymethylurea, ureidoacetic acid) [462-60-2]  $M$  118.0,  $m$  169-170°(dec),  $m$  173-175°(dec), 178-180°(dec),  $pK_a$  (H<sub>2</sub>O) 3.91 (5°), 3.80 (20.3°), 3.87 (32.1°) and 3.89 (50°). Hydantoic acid is prepared by reaction of potassium cyanate (KNCO) with glycine in H<sub>2</sub>O, and is recrystallised from H<sub>2</sub>O or EtOH. [West *J Biol Chem* **34** 187 1918, Dakin *J Chem Soc* **107** 434 1915, King *J Am Chem Soc* **78** 6020 1956, Inouye & Watanabe *J Chem Soc, Perkin Trans I* 1911 1977.] It has UV  $\lambda_{\text{max}}$  (ε) at 215 (2800) and 240 (165)nm (neutral species: EtOH); 215 (2600) and 240 (105)nm (cation: EtOH + H<sup>+</sup>); 215 (2400) and 240 (80)nm (anion: EtOH + OH<sup>-</sup>) [Crombie & Hooper *J Chem Soc* 3010 1955]. The ethyl ester [6293-20-5]  $M$  146.0, crystallises from H<sub>2</sub>O as needles with  $m$  135°; and the amide [3530-79-8]  $M$  117.1, crystallises from H<sub>2</sub>O as prisms with  $m$  204° (180° has also been reported). [*Beilstein* **4** H 359, **4** I 477, **4** II 792, **4** III 1163, **4** IV 2411.]

**Carnitine** (α-hydroxy-β-*N,N,N*-trimethylaminopropionic acid) [*R*(+) 541-14-0, *S*(-) 541-15-1, *RS* 461-06-3]  $M$  161.2,  $m$  *R* or *S* isomer 197-198°(dec), 210-212°(dec), *RS* isomer 195-197°,  $[\alpha]_{\text{D}}^{20}$  (+) and (-) 36° (c 10, H<sub>2</sub>O),  $pK^{25}$  3.6. The *S*(*L*) isomer is levocarnitine, Vitamin B<sub>7</sub>. The *R* or *S* isomers crystallise from EtOH/Me<sub>2</sub>CO (hygroscopic). The *R* or *S* hydrochlorides crystallise from hot EtOH or EtOH/Et<sub>2</sub>O and have  $m$  142°(dec). The *RS*-isomer crystallises from hot EtOH (hygroscopic). The *RS* hydrochloride crystallises in needles from hot EtOH and has  $m$  196°(dec). [(±) Mazzetti & Lemmon *J Org Chem* **22** 228 1957, *Beilstein* **4** H 513, **4** I 548, **4** II 937-8, **4** III 1632-5, **4** IV 3185.]

**L-Carnosine** (β-alanyl-*L*-histidine) [305-84-0]  $M$  226.2,  $m$  258-260°(dec), 260°(capillary tube), 262°(dec),  $[\alpha]_{\text{D}}^{25} +20.5^{\circ}$  (c 1.5, H<sub>2</sub>O),  $pK_1^{25}$  2.64,  $pK_2^{25}$  6.83,  $pK_3^{25}$  9.51. Likely impurities are histidine and β-alanine. Crystallise *L*-carnosine from water by adding EtOH in excess. Recrystallise it from aqueous EtOH by slow addition of EtOH to a strong aqueous solution of the dipeptide. Its solubility in H<sub>2</sub>O is 33.3% at 25°. [Vinick & Jung *J Org Chem* **48** 392 1983, Turner *J Am Chem Soc* **75** 2388 1953, Sifford & du Vigneaud *J Biol Chem* **108** 753 1935, *Beilstein* **25** H 516, **25** I 717, **25** II 408.]

**S-Citrulline** (2-amino-5-ureidopentanoic acid) [372-75-8]  $M$  175.2,  $m$  222°,  $[\alpha]_{\text{D}}^{20} +24.2^{\circ}$  (in 5M HCl),  $pK^{25}$  2.43,  $pK_2^{25}$  9.41. Likely impurities are arginine and ornithine. Crystallise *S*-citrulline from water by adding 5 volumes of EtOH. Also crystallise it from water by addition of MeOH. [Ellenbogen *J Am Chem Soc*

74 5198 1952, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 2491-2494 1961, Beilstein 4 IV 2647.]

**Corticotropin** [92307-52-3] **polypeptide**  $M_r$  ~4697. The extract is purified by ion-exchange on CM-cellulose, desalted, evaporated and lyophilised. Then separate from impurities by gel filtration through Sephadex G-50. [Lande et al. *Biochemical Preparations* 13 45 1971, Esch et al. *Biochem Biophys Res Commun* 122 899 1984].

**Creatine (N-guanidino-N-methylglycine)** [6020-87-7 (*monohydrate*), 57-00-1 (*anhydrous*)] **M 131.1 (anhydrous), 149.1 (hydrate) m 303<sup>o</sup>, pK<sub>1</sub><sup>25</sup> 2.63, pK<sub>2</sub><sup>25</sup> 14.3.** Likely impurities are creatinine and other guanidino compounds. It crystallises from the minimum volume of boiling H<sub>2</sub>O as the *monohydrate*. The *hydrate* is also obtained by dissolving in H<sub>2</sub>O and adding Me<sub>2</sub>CO. Drying under vacuum over P<sub>2</sub>O<sub>5</sub> or drying at 100<sup>o</sup> gives the *anhydrous* base. The *anhydrous* base can be obtained also by dissolving the hydrate in H<sub>2</sub>O, seeding with the anhydrous base and cooling in ice. A **m of 258-268<sup>o</sup>(dec)** was reported. The *picrate* crystallises from 17 parts of H<sub>2</sub>O with **m of 218-220<sup>o</sup>(dec)**. [King *J Chem Soc* 2377 1930, Hoffmann et al. *J Am Chem Soc* 58 1730 1936, Mendel & Hodgkin *Acta Cryst* 7 443 1954, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 p 2750 1961, Beilstein 4 III 1170, 4 IV 2425.]

**Creatine phosphate di Na, 4H<sub>2</sub>O salt (phosphocreatine)** [922-32-7] **M 327.1, pK<sub>1</sub><sup>27</sup> 2.7, pK<sub>2</sub><sup>27</sup> 4.58, pK<sub>3</sub><sup>27</sup> ~12.** To 3-4g of the salt in H<sub>2</sub>O (220ml) is added 4 volumes of EtOH with thorough stirring and allowed to stand at 20<sup>o</sup> for 12 hours (this temperature is critical as crystals do not readily form at 23<sup>o</sup> or 25<sup>o</sup>). The salt first appears as oily droplets which slowly settle and crystallise. After 12 hours the supernatant is clear. Stirring and scratching the flask containing the filtrate brings out additional crystals (0.3-1g) if the salt is kept at 20<sup>o</sup> for 12 hours. Filter it off at room temperature, wash with 3 x 5ml of ice-cold 90% EtOH, then 5ml of absolute EtOH and dry it in a vacuum desiccator (Drierite or CaCl<sub>2</sub>) for 16-30 hours. The *hexahydrate* (plates) is converted to the *tetrahydrate* salt (needles) in a vacuum at -10<sup>o</sup>. [Ennor & Stocken *Biochemical Preparations* 5 9 1957, *Biochem J* 43 190 1958, Beilstein 4 III 1170, 4 IV 2425.]

**Creatinine [2-amino-1-methylimidazolidin-4-one, 2-imino-1-methyl-4(3H)-oxoimidazolidine]** [60-27-5] **M 113.1, m ~305<sup>o</sup>(dec), pK<sub>1</sub><sup>25</sup> 4.80, pK<sub>2</sub><sup>25</sup> 9.2.** Likely impurities are creatine and ammonium chloride. Dissolve it in dilute HCl, then neutralise with ammonia. Recrystallise it from H<sub>2</sub>O by adding excess of Me<sub>2</sub>CO. The *picrate* crystallises from 23 volumes of boiling H<sub>2</sub>O and has **m 220-221<sup>o</sup>(dec)**. [King *J Chem Soc* 2377 1930, Beilstein 25 III/IV 2543.]

**D-(R-natural) and L-(S-non-natural) Cycloserine (2-amino-3-isoxazolidone)** [R- 68-41-7 and S- 339-72-0] **M 102.1, m 145-150<sup>o</sup> (dec), 154-155<sup>o</sup>, 155-156<sup>o</sup> (dec), 156<sup>o</sup> (dec), [α]<sub>D</sub><sup>25</sup> (+) and (-) 137<sup>o</sup> (c 5, 2N NaOH), pK<sub>1</sub><sup>10</sup> 4.5, pK<sub>2</sub><sup>10</sup> 7.74, pK<sub>3</sub><sup>25</sup> 4.50, pK<sub>4</sub><sup>25</sup> 7.43, pK<sub>1</sub><sup>50</sup> 4.44, pK<sub>2</sub><sup>50</sup> 7.20.** Purify cycloserine by recrystallisation from aqueous EtOH or MeOH or aqueous NH<sub>3</sub>/EtOH or isoPrOH. Also recrystallise it from aqueous ammoniacal solution at pH 10.5 (100mg/ml) by diluting with 5 volumes of isopropanol and then adjusting to pH 6 with acetic acid. An aqueous solution, buffered to pH 10 with Na<sub>2</sub>CO<sub>3</sub>, can be stored in a refrigerator for 1 week without decomposition. Its UV has λ<sub>max</sub> at 226nm (*A*<sub>1cm</sub><sup>1%</sup> 4.02). The *tartrate salt* has **m 165-166<sup>o</sup> (dec), 166-168<sup>o</sup> (dec), and [α]<sub>D</sub><sup>24</sup> -41<sup>o</sup> (c 0.7, H<sub>2</sub>O)**. [Stammer et al. *J Am Chem Soc* 79 3236 1959, UV: Kuehl *J Am Chem Soc* 77 2344 1955, Beilstein 27 III/IV 5549.]

**Cystamine dihydrochloride [2,2'-diaminodiethylene disulfide dihydrochloride, 2,3'-dithio-bis(ethylamine) dihydrochloride]** [56-17-7] **M 225.2, m 219-220<sup>o</sup>(dec), pK<sub>1</sub><sup>30</sup> 8.82, pK<sub>2</sub><sup>30</sup> 9.58.** Recrystallise the salt by dissolving in EtOH containing a few drops of dry EtOH/HCl, filtering and adding dry Et<sub>2</sub>O. The solid is dried in a vacuum and stored in a dry and dark atmosphere. It has been recrystallised from EtOH (solubility: 1g in 60ml of boiling EtOH) or MeOH (plates). The *free base* has **b 90-100<sup>o</sup>/0.001mm, 106-108<sup>o</sup>/5mm and 135-136<sup>o</sup>/760mm, d<sub>4</sub><sup>20</sup> 1.1559, n<sub>D</sub><sup>20</sup> 1.5720.** [Verly & Koch *Biochem J* 58 663 1954, Gonick et al. *J Am Chem Soc* 76 4671 1954, Jackson & Block *J Biol Chem* 113 137 1936.] The *dihydrobromide* has **m 238-239<sup>o</sup> (from EtOH/Et<sub>2</sub>O)** [Viscontini *Helv Chim Acta* 36 835 1953]. [Beilstein 4 H 287, 4 IV 1578.]

**S,S-(L,L)-Cystathionine** (*S*-2-amino-2-carboxyethyl-L-homocysteine, L-2-amino-4[(2-amino-2-carboxyethyl)thio]butyric acid) [56-88-2] **M 222.3**, **m** >300°, **dec** at 312° with darkening at 270°,  $[\alpha]_D^{20} +23.9^\circ$  (c 1, **M HCl**). *S,S*-Cystathionine is purified by converting it to the *HCl* salt in 20% *HCl* and carefully basifying with aqueous  $\text{NH}_3$  until separation is complete. Filter it off and dry it in a vacuum. It forms prisms from  $\text{H}_2\text{O}$ . The *dibenzoyl* derivative has **m** 229° (from *EtOH*). [IR: Greenstein & Winitz *Chemistry of the Amino Acids* (*J Wiley*) **Vol 3** p2690 1961 and Tallan et al. *J Biol Chem* **230** 707 1958, Synthesis: du Vigneaud et al. *J Biol Chem* **143** 59 1942, Anslow et al. *J Biol Chem* **166** 39 1946.] [Prepn: Weiss & Stekol *J Am Chem Soc* **73** 2497 1951; see also du Vigneaud et al. *J Biol Chem* **143** 60 1942, Biological synthesis: Greenberg *Methods Enzymol* **5** 943 1962, *Beilstein* **4** IV 3197.]

**Cysteamine** (2-aminoethanethiol, 2-mercaptoethylamine) [60-23-1] **M 77.2**, **m** 97-98.5°, 98-99°, 99-100°, **pK<sub>1</sub><sup>0</sup> 9.15**, **pK<sub>2</sub><sup>0</sup> 11.93**, **pK<sub>1</sub><sup>30</sup> 8.42**, **pK<sub>2</sub><sup>30</sup> 10.83**. It is soluble in  $\text{H}_2\text{O}$  giving an alkaline reaction, and it has a disagreeable odour. A likely impurity is the disulfide *cystamine* which is not soluble in alkaline solution. Under a  $\text{N}_2$  atmosphere dissolve it in *EtOH*, evaporate to dryness and wash the white residue with dry petroleum ether, then sublime it at 0.1mm and store it under  $\text{N}_2$  at 0-10° in the dark. Its  $\text{HgCl}_2$  (2:3) complex has **m** 181-182° (from  $\text{H}_2\text{O}$ ), and its *picrate* has **m** 125-126°. [Mills & Bogert *J Am Chem Soc* **57** 2328 1935, **62** 1173 1940, Baddiley & Thain *J Chem Soc* 800 1952, Shirley *Preparation of Organic Intermediates* (*J. Wiley*) **Vol 3** 189 1951, Barkowski & Hedberg *J Am Chem Soc* **109** 6989 1987, *Beilstein* **4** IV 1570.]

**Cysteamine hydrochloride** [156-57-0] **M 113.6**, **m** 70.2-70.7°, 70-72°. Purify the salt by recrystallisation from *EtOH*. It is freely soluble in  $\text{H}_2\text{O}$  and should be stored in a dry atmosphere. [Mills & Bogert *J Am Chem Soc* **62** 1177 1940.] The *picrate* has **m** 125-126°; see previous entry for *free base*. [*Beilstein* **4** IV 1570.]

(±)-**Cysteic acid** (3-sulfoalanine, 1-amino-3-sulfopropionic acid) [13100-82-8, 3024-83-7] **M 169.2**, **m** 260°(dec). Likely impurities are cystine and oxides of cysteine. Crystallise the acid from water by adding 2 volumes of *EtOH*. It crystallises from  $\text{H}_2\text{O}$  as the *monohydrate*. When recrystallised from aqueous *MeOH* it has **m** 264-266°, and the *anhydrous* acid has **m** ~260°(dec). [Chapeville & Formageot *Biochim Biophys Acta* **26** 538 1957, Gortner & Hoffman *J Biol Chem* **72** 435 1927, Greenstein & Winitz *The Chemistry of the Amino Acids* *J. Wiley*, **Vol 3** p1908 1961.]

**R(L)-Cysteic acid (H<sub>2</sub>O)** [23537-25-9] **M 187.2**, **m** 275-280°(dec), 289°,  $[\alpha]_D^{20} +8.66^\circ$  (c 7.4,  $\text{H}_2\text{O}$ , **pH 1**) and +1.54° ( $\text{H}_2\text{O}$ , **pH 13**), **pK<sub>1</sub><sup>25</sup> 1.9** ( $\text{SO}_3\text{H}$ ), **pK<sub>2</sub><sup>25</sup> 8.7** ( $\text{CO}_2\text{H}$ ), **pK<sub>3</sub><sup>25</sup> 12.7** ( $\text{NH}_2$ ). Likely impurities are cystine and oxides of cysteine. Crystallise it from water by adding 2 volumes of *EtOH*. When recrystallised from aqueous *MeOH* it has **m** 264-266°, and the *anhydrous* acid has **m** ~260°(dec). [Chapeville & Formageot *Biochim Biophys Acta* **26** 538 1957, Riordan & Giese *Methods Enzymol* **47** 31 1977, *Beilstein* **4** IV 3296.]

**D-(S)- and L-(R)- Cysteine** (*S*- and *R*-2-amino-3-mercaptopropionic acid) [*S*(+) 921-01-7, *R*(-) 52-90-4] **M 121.2**, **m** 230°, 240° (dec),  $[\alpha]_D^{20} +$  and  $-7.6^\circ$  (c 2, **M HCl**), + and  $-10.1^\circ$  (c 2,  $\text{H}_2\text{O}$ , **pH 10**), **pK<sub>1</sub><sup>25</sup> 1.92** ( $\text{CO}_2$ ), **pK<sub>2</sub><sup>25</sup> 8.35** ( $\text{NH}_2$ ), **pK<sub>3</sub><sup>25</sup> 10.46** (**SH**). Purify it by recrystallisation from  $\text{H}_2\text{O}$  (free from metal ions) and dry it in a vacuum. It is soluble in  $\text{H}_2\text{O}$ , *EtOH*,  $\text{Me}_2\text{CO}$ , *EtOAc*, *AcOH*,  $\text{C}_6\text{H}_6$  and  $\text{CS}_2$ . Acidic solutions can be stored under  $\text{N}_2$  for a few days without deterioration. [For synthesis and spectra see Greenstein & Winitz *Chemistry of the Amino Acids* (*J. Wiley*) **Vol 3** p1879 1961, *Beilstein* **4** III 1618, **4** IV 3144.]

**L-Cysteine hydrochloride (H<sub>2</sub>O)** [52-89-1 (*anhydrous*), 7048-04-6 (*monohydrate*)] **M 175.6**, **m** 175-178° (dec),  $[\alpha]_D^{25} +6.53^\circ$  (**5M HCl**). Likely impurities are cystine and tyrosine. Crystallise the salt from *MeOH* by adding diethyl ether, or from hot 20% *HCl*. Dry it under vacuum over  $\text{P}_2\text{O}_5$ . *Hygroscopic*. [*Beilstein* **4** III 1580, 1600.]

(±)-**Cysteine hydrochloride** [10318-18-0 (*anhydrous*), 116797-51-5 (*monohydrate*)] **M 157.6**, **m** 140-141.5° (dec), **pK<sub>2</sub><sup>20</sup> 8.36** ( $\text{NH}_2$ ), **pK<sub>2</sub><sup>20</sup> 10.28** (**SH**). Crystallise the salt from hot 20% *HCl* and dry it under vacuum over  $\text{P}_2\text{O}_5$ . It also crystallises from *EtOH* with **m** 175° (hydrate?). When crystallised from absolute *EtOH* or *EtOH/Et<sub>2</sub>O*, it has **m** 140-141.5° (*anhydrous*?). [Rurner & Voitle *J Am Chem Soc* **72** 628 1950, Albert *Biochem J* **50** 690 1953, *Beilstein* **4** IV 3145.]

**L-Cystine** [56-89-3] M 240.3,  $[\alpha]_D^{25} -229^{\circ}$  (c 0.92 in M HCl),  $\text{pK}_1^{25} 1.04$  (1.65),  $\text{pK}_2^{25} 2.05$  (2.76),  $\text{pK}_3^{25} 8.00$  (7.85),  $\text{pK}_4^{25} 10.25$  (8.7, 9.85). Cystine disulfoxide impurity is removed by treating an aqueous suspension with  $\text{H}_2\text{S}$ . The cystine is filtered off, washed with distilled water and dried at  $100^{\circ}$  under a vacuum over  $\text{P}_2\text{O}_5$ . Crystallise it by dissolving in 1.5M HCl, then adjusting to neutral pH with ammonia. Likely impurities are D-cystine, meso-cystine and tyrosine. Also purify it by dissolving it in 10%  $\text{NH}_3$  and adding gradually dilute AcOH until the point of precipitation and cooling slowly [Dughton & Harrison *Acta Cryst* **12** 396, 402 1959.] Alternatively dissolve it in 6N  $\text{NH}_4\text{OH}$  and evaporate it at room temperature for crystallisation to occur. [Chaney & Steinrauf *Acta Cryst* **30** 711 1974, *Beilstein* **4** IV 3155.]

**meso-2,6-Diaminopimelic acid** [583-93-7] M 190.2, m 313-315 $^{\circ}$ (dec)  $\text{pK}_1^{25} 1.04$  (1.65, 1.8),  $\text{pK}_2^{25} 2.05$  (2.2, 2.76),  $\text{pK}_3^{25} 8.00$  (7.85, 8.8),  $\text{pK}_4^{25} 10.25$  (8.7, 9.85, 9.9), pI ~5.5. Crystallise the acid from  $\text{H}_2\text{O}$  or aqueous EtOH. Also purify it by dissolving it in hot  $\text{H}_2\text{O}$  and adding 5 volumes of EtOH, filter after 12 hours at  $-10^{\circ}$ . The acid has been recrystallised from 35% aqueous EtOH [Wade et al. *J Am Chem Soc* **79** 648, 651 1957]. [*Beilstein* **4** IV 3081.]

**L(S)-2,3-Diaminopropionic acid monohydrochloride (3-amino-L-alanine hydrochloride)** [1482-97-9] M 140.6, m 132-133 $^{\circ}$ (dec), 237 $^{\circ}$ (dec),  $[\alpha]_D^{25} +26.1^{\circ}$  (c 5.8, M HCl),  $\text{pK}_1^{25} 1.30$ ,  $\text{pK}_2^{25} 6.79$ ,  $\text{pK}_3^{25} 9.51$ . It forms needles from  $\text{H}_2\text{O}$  and can be recrystallised from aqueous EtOH. [Gmelin et al. *Z Physiol Chem.* **314** 28 1959, IR: Koegel et al. *J Am Chem Soc* **77** 5708 1977, *Beilstein* **4** IV 2501.]

**meso-2,3-Diaminosuccinic acid** [23220-52-2] M 148.1, m 305-306 $^{\circ}$ (dec, and sublimes),  $\text{pK}_{\text{Est}(1)} \sim 3.6$ ,  $\text{pK}_{\text{Est}(2)} \sim 9.8$ . Crystallise the acid from water. Also, dissolve it in dilute NaOH and add AcOH to pH 5-6 and allow it to crystallise (m 304 $^{\circ}$  dec). *Alternatively*, dissolve the acid in aqueous  $\text{NH}_3$  and boil; when the  $\text{NH}_3$  has evaporated, the acid separates, filter it off and dry it at room temperature in a vacuum. In another procedure 1g of acid is dissolved in 10ml of conc HCl + 15ml of  $\text{H}_2\text{O}$  at  $80^{\circ}$ , filter immediately, dilute with 20ml of  $\text{H}_2\text{O}$  and allow to stand for 24 hours. When the *monohydrochloride* (0.7g, m 175-156 $^{\circ}$  dec) crystallises out, filter and dry it. It has also been purified by dissolving it in the minimum volume of 10% HCl, filtering, and diluting with 5 volumes of  $\text{H}_2\text{O}$  when the crystals separate slowly on standing. The acid is filtered off after 24 hours and dried (m 306-306 $^{\circ}$  dec). Similar procedures were used for the *dl-isomer*. [Kenner *J Org Chem* **13** 28 1948, McKennis & Yard *J Org Chem* **23** 980 1958, *Beilstein* **4** III 1528, **4** IV 3025.]

**6-Diazo-5-oxo-L-norleucine** [157-03-9] M 171.2, m 140-150 $^{\circ}$ (dec), 145-155 $^{\circ}$ (dec),  $[\alpha]_D^{20} +21^{\circ}$  (c 5, EtOH),  $\text{pK}_1 2.1$ ,  $\text{pK}_2 8.95$ . Crystallise it from EtOH,  $\text{H}_2\text{O}/\text{EtOH}$ , MeOH, 95% aqueous MeOH or  $\text{H}_2\text{O}/\text{Me}_2\text{CO}$ . [DeWald & Moor *J Am Chem Soc* **80** 3944 1958, Dion et al. *J Am Chem Soc* **78** 3075 1956, *Beilstein* **4** IV 3278.]

**Diglycyl glycine (triglycine)** [556-33-2] M 189.2, m 246 $^{\circ}$ (dec),  $\text{pK}_1^{25} 3.30$ ,  $\text{pK}_2^{25} 7.96$ . Crystallise triglycine from  $\text{H}_2\text{O}$  or  $\text{H}_2\text{O}/\text{EtOH}$  and dry it at  $110^{\circ}$ . [Yakel & Hughes *Acta Cryst* **5** 847 1952, Lenel et al. *Acta Cryst* **3** 313 1952, Holley & Holley *J Am Chem Soc* **74** 3072 1952, *Beilstein* **4** III 1198, **4** IV 2469.]

**N,N-Di-(2-hydroxyethyl)glycine (BICINE, N,N-bis-(2-hydroxyethyl)glycine)** [150-25-4] M 163.2, m 193 $^{\circ}$ (dec), 193-195 $^{\circ}$ (dec),  $\text{pK}_1^{25} 2.50$ ,  $\text{pK}_2^{25} 8.11$ . Dissolve bicine in a small volume of hot water and precipitate it with EtOH, twice. Repeat once more but treat the aqueous solution with charcoal and filter before adding EtOH. Also crystallise it from concentrated aqueous solutions. [Torn & Kolthoff *J Am Chem Soc* **77** 2061 1955, Chaberek et al. *J Am Chem Soc* **75** 2185 1953, *Beilstein* **4** IV 2390.]

**3-(3,4-Dihydroxyphenyl)-L-alanine (DOPA, LEVODOPA, EUODOPA)** [59-92-7, 5796-17-8] M 197.2, m 275 $^{\circ}$ (dec), 267-268 $^{\circ}$ (dec), 284-286 $^{\circ}$ (dec), ~295 $^{\circ}$ (dec),  $[\alpha]_D^{15} -13.1^{\circ}$  (c 5.12, N HCl),  $\text{pK}_1^{25} 2.32$  ( $\text{CO}_2\text{H}$ ),  $\text{pK}_2^{25} 8.72$  ( $\text{NH}_2$ ),  $\text{pK}_3^{25} 9.96$  (OH),  $\text{pK}_4^{25} 11.79$  (OH). Likely impurities are vanillin, hippuric acid, 3-methoxytyrosine and 3-aminotyrosine. DOPA recrystallises from large volumes of  $\text{H}_2\text{O}$  forming colourless white needles; its solubility in  $\text{H}_2\text{O}$  is 0.165%, but it is insoluble in EtOH,  $^*\text{C}_6\text{H}_6$ ,  $\text{CHCl}_3$ , and EtOAc. Also crystallise it by dissolving it in dilute HCl and adding dilute ammonia to give pH 5, under  $\text{N}_2$ . *Alternatively*, crystallise it from dilute aqueous EtOH. It is rapidly oxidised in air when moist, and darkens, particularly in

alkaline solution. Dry it *in vacuo* at 70° in the dark, and store it in a dark container preferably under N<sub>2</sub>. It has  $\lambda_{\max}$  at 220.5nm (log  $\epsilon$  3.79) and 280nm (log  $\epsilon$  3.42) in 0.001N HCl. [Yamada et al. *Chem Pharm Bull Jpn* **10** 693 1962, Bretschneider et al. *Helv Chim Acta* **56** 2857 1973, NMR: Jardetzky & Jardetzky *J Biol Chem* **233** 383 1958, *Beilstein* **4** IV 2492, 2493.]

**3-(3,4-Dihydroxyphenyl)-2-methyl-L-alanine** [methyl dopa, **2-amino-3-(3,4-dihydroxy-phenyl)-2-methylpropionic acid**] [555-30-6, 41372-08-1 (*sesquihydrate*)] **M 238.2, m >300°, 300-301°(dec), pK<sub>1</sub><sup>25</sup> 2.2, pK<sub>2</sub><sup>25</sup> 9.2, pK<sub>3</sub><sup>25</sup> 10.6, pK<sub>4</sub><sup>25</sup> 12.0.** Recrystallise methyl dopa from H<sub>2</sub>O. [Reinhold et al. *J Org Chem* **33** 1209 1968.] The *L*-isomer forms a *sesquihydrate* from H<sub>2</sub>O **m 302-304° (dec)**, and the *anhydrous* crystals are *hygroscopic*,  $[\alpha]_{\text{D}}^{23}$  -4.0° (c 1, 0.1N HCl),  $[\alpha]_{546}$  +154.5° (c 5, CuSO<sub>4</sub> solution). It has  $\lambda_{\max}$  at 281nm ( $\epsilon$  2780). Its solubility in H<sub>2</sub>O at 25° is ~10mg/ml and the pH of an aqueous solution is ~5.0. It is insoluble in most organic solvents. [Stein et al. *J Am Chem Soc* **77** 700 1955, *Beilstein* **4** IV 2505.]

**3,5-Diiodo-L-thyronine (3,5-diiodo-4-[4-hydroxyphenoxy]-1-phenylalanine)** [1041-01-6] **M 525.1, m 255°(dec), 255-257°(dec),  $[\alpha]_{\text{D}}^{22}$  +26° [2N HCl-EtOH (1:2)], pK<sub>1</sub><sup>20</sup> 3.25, pK<sub>2</sub><sup>20</sup> 5.32, pK<sub>3</sub><sup>20</sup> 9.48.** Recrystallise it from EtOH. [Chambers et al. *J Chem Soc* 3424 1949, *Beilstein* **14** III 1565, **14** IV 2372.]

**3,5-Diiodo-L-tyrosine dihydrate** [300-39-0] **M 469.0, m 199-210°, 202°(dec), 204°(dec),  $[\alpha]_{\text{D}}^{20}$  +2.89° (c 4.9, 4% HCl), pK<sub>1</sub><sup>25</sup> 2.12, pK<sub>2</sub><sup>25</sup> 6.48, pK<sub>3</sub><sup>25</sup> 7.82.** It forms crystals from H<sub>2</sub>O [solubility (g/L): 0.204 at 0°, 1.86 at 50°, 5.6 at 75° and 17.0 at 100°]. Also recrystallise it from 50% or 70% EtOH. When boiled in EtOH the crystals swell, and on further boiling a gelatinous precipitate is formed [Harrington *Biochem J* **22** 1434 1928, Jurd *J Am Chem Soc* **77** 5747 1955]. It also crystallises from cold dilute ammonia on adding acetic acid to pH 6. [*Beilstein* **14** IV 2370.]

**dl-4-Dimethylamino-2,2-diphenylvaleramide (Dimevamide, Aminopentamide)** [60-46-8] **M 296.4, m 183-184°, pK<sub>Est</sub> ~9.8.** Crystallise dimevamide from aqueous EtOH. The *hydrochloride* forms leaflets from EtOH/Et<sub>2</sub>O with **m 190-191°** and is deliquescent. The *picrate* has **m 210-211°**. It is an antispasmodic. [Moffett et al. *J Am Chem Soc* **79** 4451, 4457 1957, Beckett *J Pharm Pharmacol* **8** 848 1956, *Beilstein* **14** III 1363, **14** IV 1865.]

**(-)-L-4-Dimethylamino-2,2-diphenylvaleramide** [6078-64-4] **M 296.4, m 134.5-135.5°, 136.5-137.5°,  $[\alpha]_{\text{D}}^{20}$  -112° (c 0.87, EtOH), -84.1° (c 0.9, 0.04N HCl), pK<sub>Est(1)}</sub> 8.3.** Crystallise the amide from petroleum ether, EtOH or as needles from aqueous EtOH. It is an analgesic. [Beckett et al. *J Chem Soc* 3076 1957.]

**N,N-Dimethylglycinehydrazide hydrochloride** [539-64-0] **M 153.6, m 181°.** Crystallise the salt by adding EtOH to a concentrated aqueous solution. [Viscontini & Meier *Helv Chim Acta* **33** 1773 1950, *Beilstein* **4** III 1127, **4** IV 2368.]

**Djenkolic acid (S,S'-methylene-bis-L-cysteine)** [498-59-9] **M 254.3, m 300-350°(dec),  $[\alpha]_{\text{D}}^{20}$  -65° (c 2, HCl) [See pK of S-methyl-L-cysteine].** Crystallise djenkolic acid from a large volume of water (solubility is 0.5g%). [du Vigneaud & Patterson *J Biol Chem* **114** 533 1936, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2682, 2687 1961, *Beilstein* **4** III 1591.] The *N,N'*-dibenzoyl derivative crystallises with 1H<sub>2</sub>O from aqueous EtOH with **m 87.5-89°** [*Beilstein* **9** III 1171.]

**S-Ethionine** [13073-35-3] **M 163.2, m 282°(dec),  $[\alpha]_{\text{D}}^{25}$  +23.7° (in 5M HCl), pK<sup>25</sup> 9.02 (for RS).** Likely impurities are *N*-acetyl-(*R* and *S*)-ethionine, *S*-methionine, and *R*-ethionine. Crystallise it from water by adding 4 volumes of EtOH or 85% aqueous EtOH. It sublimes at 196-216°/0.3mm with 99.1% recovery and unracemised [Gross & Gradsky *J Am Chem Soc* **77** 1678 1955]. [Weiss & Stekol *J Am Chem Soc* **73** 2399 1951, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2658, 2659 1961, *Beilstein* **4** IV 3194.]

**Ethylene N,N'-bis[(*o*-hydroxyphenyl)glycine]** [1170-02-1] **M 360.4, m 249°(dec), pK<sub>Est(1)}</sub> ~1.8, pK<sub>Est(2)}</sub> ~4.8, pK<sub>Est(3)}</sub> ~9.0.** Purify it by extensive Soxhlet extraction with acetone. [Bonadies & Carrano *J Am Chem*

*Soc* 108 4088 1986].

**2-Fluorophenylalanine** [*R*(+) 97731-02-7, *S*(-) 19883-78-4] **M 183.2, m 226-232°**, 231-234°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> (+) and (-) 15° (c 2, H<sub>2</sub>O pH 5.5), pK<sub>1</sub><sup>24</sup> 2.12, pK<sub>2</sub><sup>24</sup> 9.01. Recrystallise 2-fluorophenylalanine from aqueous EtOH. The *hydrochloride* has m 226-231°(dec), and the *N-acetyl* derivative has m 147-149° (aqueous EtOH). [Bennett & Nieman *J Am Chem Soc* 72 1800 1950, *Beilstein* 14 III 1268.]

**4-Fluorophenylalanine** [*R*(+) 18125-46-7, *S*(-) 1132-68-9] **M 183.2, m 227-232°**, [ $\alpha$ ]<sub>D</sub><sup>25</sup> + and -24° (c 2, H<sub>2</sub>O), pK<sub>1</sub><sup>24</sup> 2.13, pK<sub>2</sub><sup>24</sup> 9.05. It is recrystallised from aqueous EtOH. The (*R*)-*N-acetyl* derivative has m 142-145°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -38.6° (c 8, EtOH). [Bennett & Nieman *J Am Chem Soc* 72 1800 1950, *Beilstein* 14 III 1268.]

**L-5-Fluorotryptophan monohydrate** [16626-02-1; 154-08-5] **M 240.2, m reported for the L-enantiomer 158-163°(dec)**, (±)-isomer >250°(dec), 264-265°(also 238-239° dec reported), [ $\alpha$ ]<sub>D</sub><sup>20</sup> +5.5° (c 1, 0.1N HCl), pK<sub>Est(1)</sub>~2.5 (CO<sub>2</sub>H), pK<sub>Est(2)</sub>~9.4 (NH<sub>2</sub>), pK<sub>Est(3)</sub>~16 (indole-NH). Recrystallise it from EtOH, aqueous EtOH or AcOH. Also purify it by passage through a Dowex AG1x2 (acetate form) column and recrystallise the L-enantiomer (from enzymic enrichment) from H<sub>2</sub>O/EtOH, m 158-163°(dec), [ $\alpha$ ]<sub>D</sub><sup>23</sup> -8.3° (c 2.5, N NaOH). [Coy et al. *Biochemistry* 13 3550 1974, *Beilstein* 22/14 V 116.]

**L-Glutamic acid** [56-86-0] **M 147.1, m 224-225°(dec)**, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +31.4° (c 5, 5M HCl), pK<sub>1</sub><sup>20</sup> 2.06, pK<sub>2</sub><sup>20</sup> 4.35, pK<sub>3</sub><sup>20</sup> 9.85. Crystallise L-glutamic acid from H<sub>2</sub>O acidified to pH 3.2 by adding 4 volumes of EtOH, and drying at 110°. Likely impurities are aspartic acid and cysteine. It sublimes at 170-175°/10mm. It melts at 160° with cyclisation to L-pyrrolidone carboxylic acid. [Dunn & Brophy *J Biol Chem* 99 224 1958, Parikh et al. *J Am Chem Soc* 80 957 1958, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 1929-1952 1961, *Beilstein* 4 III 1530, 4 IV 3028.]

**L-Glutamic acid- $\gamma$ -benzyl ester** [1676-73-9] **M 237.3, m 179-181°**, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +19.3° (c 1, AcOH), pK<sub>1</sub><sup>25</sup> 2.17, pK<sub>2</sub><sup>25</sup> 9.00. Recrystallise the ester from H<sub>2</sub>O and store it at 0°. [Estrin *Biochemical Preparations* 13 25 1971, *Beilstein* 6 IV 2538.]

**L-Glutamine** [56-85-9] **M 146.2, m 184-185°**, 187°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +31.8° (M HCl), pK<sub>1</sub><sup>25</sup> 2.17, pK<sub>2</sub><sup>25</sup> 9.13. Likely impurities are glutamic acid, ammonium pyroglutamate, tyrosine, asparagine, isoglutamine, arginine. Crystallise it from water or aqueous EtOH. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 1929-1925 1961, *Beilstein* 4 IV 3038.]

**L-Glutathione (reduced form,  $\gamma$ -L-glutamyl-L-cysteinyl-glycine)** [70-18-8] **M 307.3, m 188-190°(dec)**, 195°(dec), [ $\alpha$ ]<sub>D</sub><sup>20</sup> -20.1° (c 1, H<sub>2</sub>O), pK<sub>1</sub><sup>25</sup> 2.12 (CO<sub>2</sub>H), pK<sub>2</sub><sup>25</sup> 3.59 (CO<sub>2</sub>H), pK<sub>3</sub><sup>25</sup> 8.75 (NH<sub>2</sub>), pK<sub>4</sub><sup>25</sup> 9.65 (10.0, SH). Crystallise L-glutathione from 50% aqueous EtOH, dry it in a vacuum and store it below 5°. Alternatively, recrystallise it from aqueous EtOH under N<sub>2</sub>, and store it dry in a sealed container below 4°. It is soluble in H<sub>2</sub>O. [Weygand & Geiger *Chem Ber* 90 634 1957, Martin & Edsall *Bull Soc Chim Fr* 40 1763 1958, du Vigneaud & Miller *Biochemical Preparations* 2 87 1952, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 2 p 1523 1961, *Beilstein* 4 IV 3165.]

**L-Glutathione (oxidised)** [27025-41-8] **M 612.6, m 175-195°**, 195°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -98° (c 2, H<sub>2</sub>O), pK<sub>1</sub> 3.15, pK<sub>2</sub> 4.03, pK<sub>3</sub> 8.75. Purify it by recrystallisation from 50% aqueous EtOH. Its solubility in H<sub>2</sub>O is 5%. Store it at 4°. [Li et al. *J Am Chem Soc* 76 225 1954, Berse et al. *Can J Chem* 37 1733 1959, *Beilstein* 4 IV 3168.]

**Glycinamide hydrochloride** [1668-10-6] **M 110.5, m 186-189°**, 203-205°, 207-208°, pK<sub>1</sub><sup>25</sup> -6.10, pK<sub>2</sub><sup>25</sup> -1.78, pK<sub>3</sub><sup>25</sup> 7.95. Crystallise the salt from EtOH, EtOH/H<sub>2</sub>O or MeOH. [Karmas & Spoerri *J Am Chem Soc* 74 1580 1952, *Beilstein* 4 IV 2358.]

**Glycine anhydride (2,5-diketopiperazine)** [106-57-0] **M 114.1, m 309-310°**, 311-312°(dec), ~315°(dec), pK<sub>1</sub> -4.45, pK<sub>2</sub> -2.16 (pK<sub>2</sub> -1.94 in AcOH). Recrystallise glycine anhydride from H<sub>2</sub>O (plates) and it can be

sublimed (slowly) at 260° or at 140-170°/0.5mm. The *dihydrochloride* has **m** 129-130° and is prepared by dissolving it in conc HCl and adding EtOH to crystallisation point; dry it in a vacuum. The *bis-1-naphthylurethane* has **m** 232°(dec), and the *diperchlorate* has **m** 117° (*hygroscopic*). [MS: Johnstone *J Chem Soc, Perkin Trans 1* 1297 1975, NMR: Blaha & Samek *Col Czech Chem Commun* 32 3780 1967, Sauborn *J Phys Chem* 36 179 1932, Corey *J Am Chem Soc* 60 1599 1938, *Beilstein* 24 IV 1070.]

**Glycine ethyl ester hydrochloride** [623-33-6] **M 136.9, m 145-146°, pK<sup>25</sup> 7.69**. Crystallise it from absolute EtOH or EtOH/Et<sub>2</sub>O. [Marvel *Org Synth Coll Vol II* 310 1943, *Beilstein* 4 II 780, 4 III 3 75.]

**Glycine tert-butyl ester (glycine 1,1-methylethyl ester)** [6456-742] **M 131.1, 65-67°/20mm, d<sub>D</sub><sup>20</sup> 1.4237, pK<sub>Est</sub> ~7.6**. The ester, prepared from *tert*-butyl azidoacetate by catalytic reduction (5% Pd/C and H<sub>2</sub>), has been purified *via* the phosphite salt. To the ester (23.6g, 0.18mole) in MeOH (150ml) is added phosphorous acid (15g, 0.18mole), the mixture is gently warmed to dissolve the latter and after cooling to 25°, Et<sub>2</sub>O (150ml) is added slowly and the stirred mixture is cooled at 0° for 12 hours. The *phosphite salt* is collected, filtered off, washed with Et<sub>2</sub>O and dried in an oven at 70° (32g, 82%, **m 144-147° dec.**). After recrystallisation from MeOH-isopropyl ether, the phosphite salt has **m 154-157° (dec)**. The phosphite salt (32g, 0.15mole) is added with stirring into aqueous 6N-sodium hydroxide solution (50ml) until all the solid has dissolved. The mixture is extracted with Et<sub>2</sub>O (2 x 20ml), the extract is dried (Na<sub>2</sub>SO<sub>4</sub>), filtered, evaporated and the residue is distilled under vacuum to give the *tert*-butyl ester as an oil (14g, 72%). The *tert*-butyl group is versatile and is labile under acidic conditions which do not affect the blocked amino grouping. *Glycine tert-butyl ester hydrochloride* [27532-96-3] **M 167.6, has m 143° (EtOH/Et<sub>2</sub>O)**. [Vollmar & Dunn *J Org Chem* 25 387 1960, More and Rydon *Org Synth Coll Vol V* 586 1973, *Beilstein* 6 IV 2489.]

**Glycine hydrochloride** [6000-43-7] **M 111.5, m 176-178°, 185°, 187°**. Crystallise the salt from absolute EtOH or 80% EtOH. *Monoglycine hydrochloride* has **m 176-177°**, and *diglycine monohydrochloride* has **m 187°**. [Frost *J Am Chem Soc* 64 1286 1942, *Beilstein* 4 III 1111, 4 IV 2353.]

**Glycine methyl ester hydrochloride** [5680-79-5] **M 125.6, m 174°(dec), 177°(corrected), pK<sup>25</sup> 7.66**. Crystallise the ester salt from MeOH. [Werbin & Spoerri *J Am Chem Soc* 69 1682 1947, *Beilstein* 4 H 340, 4 III 1116.]

**Glycine *p*-nitrophenyl ester hydrobromide**. [7413-60-7] **M 277.1, m 214° (dec)**. Recrystallise the ester salt from MeOH by adding diethyl ether. [Alners et al. *Biochemical Preparations* 13 22 1971].

**Glycocyanine (*N*-guanylglycine)** [352-97-6] **M 117.1, m 280-284°(dec), >300°, pK<sup>25</sup> 2.86 (NH<sub>3</sub><sup>+</sup>)**. Recrystallise it from 15 parts of hot H<sub>2</sub>O, or by dissolving it in slightly more than the calculated amount of 2N HCl and precipitating it by adding an equivalent of 2N NaOH, filtering, washing with cold H<sub>2</sub>O and drying first *in vacuo*, then at 60° *in vacuo*. The *hydrochloride* has **m 200°(dec)** after recrystallisation from aqueous HCl as plates. The *picrate* forms needles from hot H<sub>2</sub>O with **m 210°(dec)**. [Brand & Brand *Org Synth Coll Vol III* 440 1955, Failey & Brand *J Biol Chem* 102 768 1933, King *J Chem Soc* 2375 1930, *Beilstein* 4 H 359, 4 I 477, 4 II 793, 4 III 1165.]

***N*-Glycylanilide** [555-48-6] **M 150.2, m 62°, pK<sub>Est</sub> ~8.0**. *N*-Glycylanilide crystallises from water as needles (*dihydrate*) and is soluble in Et<sub>2</sub>O. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp1915-1970 1961, *Beilstein* 4 H 343.]

**Glycylglycine** [556-50-3] **M 132.1, m 260-262°(dec), pK<sup>20</sup> 8.40, pK<sup>30</sup> 8.04, pK<sup>15</sup> 3.19, pK<sub>2</sub><sup>25</sup> 8.40**. Crystallise glycylglycine from aqueous 50% EtOH or water at 50-60° by addition of EtOH. Dry it at 110°. It sublimes at 190-200°/0.3mm with 30% recovery [Gross & Gradsky *J Am Chem Soc* 77 1678 1955, King *J Am Chem Soc* 79 6153 1957]. [*Beilstein* 4 IV 2459.]

**Glycylglycine hydrochloride** [13059-60-4] **M 168.6, m 215-220°, 235-236°, 260-262°, pK<sub>1</sub><sup>25</sup> 3.12, pK<sub>2</sub><sup>25</sup> 8.17**. Crystallise the salt twice from 95% EtOH. Single crystals are formed by slow evaporation of an aqueous

solution. [Parthasarathy *Acta Cryst (B)* **25** 509 1969, Mellon & Hoover *J Am Chem Soc* **73** 3879 1951, Garfinkel & Edsall *J Am Chem Soc* **80** 3818 1958, Beilstein **4** IV 2469.]

**Glycyl-L-proline** [704-15-4] M 172.2, m 184°(dec), 185°, 204°, pK<sub>1</sub><sup>25</sup> 2.81, pK<sub>2</sub><sup>25</sup> 8.65. Crystallise glycyl-L-proline from water at 50–60° by addition of EtOH. [Saidel *J Am Chem Soc* **77** 3893 1955, Bergmann et al. *Z Physiol Chem* **212** 79 1932, Beilstein **22** IV 49.]

**dl-Glycylserine** [687-38-7] M 162.2, m 197–199°(dec, sealed tube), 207°(dec), pK<sub>1</sub><sup>25</sup> 2.92, pK<sub>2</sub><sup>25</sup> 8.10. Crystallise it from H<sub>2</sub>O (charcoal) by addition of EtOH. [Fölsch *Acta Chem Scand* **12** 561–566 1958, NSR: Bovey & Tiers *J Am Chem Soc* **81** 2876 1959, Beilstein **4** III 1572, **4** IV 3140.]

**Gramicidin A (a pentadecapeptide from *Bacillus brevis*)** [11029-61-1] m ~229–230°(dec). Purify gramicidin A by countercurrent distribution from \*C<sub>6</sub>H<sub>6</sub>/CHCl<sub>3</sub>, MeOH/H<sub>2</sub>O (15:15:23:7) with 5000 tubes. Fractions are examined by UV (280nm) of small aliquots. Separation from gramicidin C and other material occurred after 999 transfers. [Gross & Witkop *Biochemistry* **4** 2495 1965, Bauer et al. *Biochemistry* **11** 3266 1972.] Purify it finally by recrystallisation from EtOH/H<sub>2</sub>O and dry it at 100°/10<sup>-2</sup>mm over KOH. It forms platelets m 229–230°. It is almost insoluble in H<sub>2</sub>O (0.6%) but soluble in lower alcohols, dry Me<sub>2</sub>CO, dioxane, acetic acid and pyridine. The commercial material is more difficult to crystallise than the synthetic compound. [Sarges & Witkop *J Am Chem Soc* **86** 1861 1964, **87** 2011, 2020 1965.] It has characteristic [α]<sub>D</sub><sup>20</sup> +27.3° (c 1.3, MeOH) and UV with λ<sub>max</sub> at 282nm (ε 22,100). The *N*-carbamoyldeformyl gramicidine A precipitates from EtOAc/petroleum ether (b 40–60°). [Beilstein **26** III/IV 4273.]

**Gramicidin C (a pentadecapeptide from *Bacillus brevis*)** [9062-61-7]. Purify as for Gramicidin A since they are isolated together and separated. [Sarges & Witkop *Biochemistry* **4** 2491 1965, Hunter & Schwartz “Gramicidins” in *Antibiotics I* (Gotlieb and Shaw Eds) Springer-Verlag, NY, p. 642 1967, as well as references above for Gramicidin A.]

**Gramicidin S** [113-73-5] M 1141.4, m 268–270°, [α]<sub>D</sub><sup>25</sup> -290° (c 0.5, EtOH + 30mM aqueous HCl {7:3}). Gramicidin S crystallises from EtOH. The *di-HCl* [15207-30-4] crystallises from EtOH (+ few drops of HCl) with m 277–278° (see below). [NMR: Gibbons et al. *Nature* **227** 840 1970, Beilstein **26** III/IV 4273.]

**Gramicidin S 2HCl (from *Bacillus brevis* Nagano)** [15207-30-4] M 1214.4, m 277–278°(dec), [α]<sub>D</sub><sup>24</sup> -289° (c 0.4, 70% H<sub>2</sub>O+EtOH). It crystallises in prisms from EtOH+aqueous HCl.

***N*-Guanyltiramine hydrochloride** [60-20-8] M 215.7, m 218°, pK<sub>1</sub> 10.2 (phenolic OH), pK<sub>2</sub> 12.4 (guanidino N). Purify the salt on a phosphocellulose column and elute with a gradient of aqueous NH<sub>3</sub> (0–10%). The second major peak has the characteristic tryptamine spectrum and is collected, and lyophilised to give white crystals of the *dihydrate* which dehydrate at 100°. It has UV with λ<sub>max</sub> at 274.5nm (ε 1,310) in 0.1N NaOH and 274.5nm (ε 1,330) at pH 7.0. Excitation λ<sub>max</sub> is at 280nm and emission λ<sub>max</sub> is at 330nm. [Mekalanos et al. *J Biol Chem* **254** 5849 1979.]

***S*-Histidine** [71-00-1] M 155.2, m 287°(dec), [α]<sub>D</sub><sup>25</sup> -39.7° (c 1, H<sub>2</sub>O), +13.0° (6M HCl), pK<sub>1</sub><sup>25</sup> 1.96, pK<sub>2</sub><sup>25</sup> 6.12, pK<sub>3</sub><sup>25</sup> 9.17. A likely impurity is arginine. *S*-Histidine is adsorbed from aqueous solution onto a Dowex 50-H<sup>+</sup> ion-exchange resin, washed with 1.5M HCl (to remove other amino acids), then eluted with 4M HCl as the *dihydrochloride*. This purified *dihydrochloride* (see below) is finally dissolved in water, the pH adjusted to 7.0, and the *free zwitterionic base* crystallises out on addition of EtOH. Its solubility in H<sub>2</sub>O is 4.2% at 25°. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 1971–1993 1961, Beilstein **25** III/IV 4344.]

***S*-Histidine dihydrochloride** [1007-42-7] M 242.1, m 245°, [α]<sub>D</sub><sup>20</sup> +47.5° (c 2, H<sub>2</sub>O). The dihydrochloride crystallises from water or aqueous EtOH and is washed with acetone, then diethyl ether. *Alternatively*, convert it to the histidine *di-(3,4-dichlorobenzenesulfonate)* salt by dissolving 3,4-dichlorobenzenesulfonic acid (1.5g/10ml) in the aqueous histidine solution with warming, and then the solution is cooled in ice. The resulting crystals (m 280° dec) can be recrystallised from 5% aqueous 3,4-dichlorobenzenesulfonic acid, then dried over

CaCl<sub>2</sub> under vacuum, and washed with diethyl ether to remove excess reagent. The dihydrochloride can be regenerated by passing the solution through a Dowex-1 (Cl<sup>-</sup> form) ion-exchange column. The solid is obtained by evaporation of the solution on a steam bath or better in a vacuum. [Greenstein & Winitz, *The Amino Acids* Vol 3 p 1976 1961, *Beilstein* 25/16 V 366.]

**S-Histidine monohydrochloride (H<sub>2</sub>O)** [5934-29-2 (H<sub>2</sub>O), 7048-02-4] M 209.6, m 80° monohydrate, 254°(dec, anhydrous), [α]<sub>D</sub><sup>25</sup> +13.0° (6M HCl). Crystallise the mono-hydrochloride from aqueous EtOH or 60% aqueous EtOH (m 259°dec). Alternatively, dissolve 10g in 50ml of H<sub>2</sub>O, decolourise with Norite, filter, evaporate it in a vacuum to a syrup, cool to room temperature, add 95% EtOH with stirring until slightly turbid, scratch the sides of the vessel until crystals form, then add slowly 40ml of EtOH and keep at 0° overnight, filter the solid off, wash it several times with EtOH and dry it in a vacuum. [Cox *J Biol Chem* 78 475 1929, Cox et al. *J Biol Chem* 81 73 1929, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 1972, 2098 1961, *Beilstein* 25 II 407, 25 III/IV 4346.]

**L-Homocysteine (2-amino-4-mercaptoputyric acid)** [6027-13-0] M 135.2, m 232-233°, [α]<sub>D</sub><sup>25</sup> +153° (c 13, 5N HCl), pK<sub>1</sub><sup>25</sup> 2.22 (CO<sub>2</sub>H), pK<sub>2</sub><sup>25</sup> 8.87 (NH<sub>3</sub><sup>+</sup>), pK<sub>3</sub><sup>25</sup> 10.86 (SH). Crystallise L-homocysteine from aqueous EtOH. All operations should be carried out under N<sub>2</sub> as the thiol readily oxidizes in air. The acid (3g) is dissolved in freshly boiled H<sub>2</sub>O (30ml) under N<sub>2</sub>, cooled under N<sub>2</sub> (all operations should be under N<sub>2</sub>), add absolute EtOH (100ml), the acid is filtered off, and a second crop is obtained by diluting the filtrate to 500ml with absolute EtOH, kept overnight in a refrigerator, filtering, washing with EtOH and drying in a vacuum. Store it under N<sub>2</sub> or argon.

The S-benzyl derivative is repeatedly crystallised from H<sub>2</sub>O, or by dissolving it in HCl followed by slow addition of ammonia. It has m 240-241°, [α]<sub>D</sub><sup>25</sup> +27° (c 13, 5N HCl). [Riedel & du Vigneaud *J Biol Chem* 112 149 1935, du Vigneaud & Patterson *J Biol Chem* 109 101 1935, du Vigneaud *J Biol Chem* 126 217 1938, du Vigneaud & Brown *Biochemical Preparations* 5 93, 95 1975, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 2667-2670 1961, *Beilstein* 4 IV 3189, IR: Koegel et al. *J Am Chem Soc* 77 5708 1955.]

**dl-Homocysteine (2-amino-4-mercaptoputyric acid)** [454-29-5] M 135.2, m 234-235°(corr, dec). Purify it as for the L-isomer. [Allen & Steinmann *J Am Chem Soc* 74 3932 1952, and references for the L-isomer above, *Beilstein* 4 IV 3189.]

**dl-Homocystine** [462-10-2, 870-93-9 (±)] M 268.4, m 263-265°(dec), pK<sub>1</sub><sup>25</sup> 1.59 (CO<sub>2</sub>H), pK<sub>2</sub><sup>25</sup> 2.54 (CO<sub>2</sub>H), pK<sub>3</sub><sup>25</sup> 8.52 (NH<sub>3</sub><sup>+</sup>), pK<sub>4</sub><sup>25</sup> 9.44 (NH<sub>3</sub><sup>+</sup>). dl-Homocystine crystallises in platelets from water with 1H<sub>2</sub>O and m 258-260°(dec), all operations should be carried out under N<sub>2</sub>. [Sudo *J Chem Soc Jpn (Pure Chem Sect)* 79 81, 86, 87 1958, *Beilstein* 4 IV 3199.]

**L(S,S)-Homocystine** [626-72-2] M 268.4, m 281-284°(dec), [α]<sub>D</sub><sup>26</sup> +79° (c 1, M HCl), [α]<sub>D</sub><sup>21</sup> -16° (c 0.06, H<sub>2</sub>O), pK (see above). The acid (3g) is dissolved in freshly boiled H<sub>2</sub>O (30ml) under N<sub>2</sub>, cooled under N<sub>2</sub> (all operations should be under N<sub>2</sub>), absolute EtOH (100ml) is added, the acid is filtered off, and a second crop is obtained by diluting the filtrate to 500ml with absolute EtOH, kept overnight in a refrigerator, filtered, washed with EtOH and dried in a vacuum. The D(R,R)-form has similar properties but is -ve in M HCl and +ve in H<sub>2</sub>O. [du Vigneaud & Patterson *J Biol Chem* 109 101 1935, du Vigneaud & Brown *Biochemical Preparations* 5 93, 95 1975, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 2667-2670 1961, *Beilstein* 4 III 1643, 4 IV 3199, Koegel et al. *J Am Chem Soc* 77 5708 1955.]

**L-Homoserine (2-amino-4-hydroxybutyric acid)** [672-15-1] M 119.1, m 203°, [α]<sub>D</sub><sup>26</sup> +18.3° (in 2M HCl), pK<sub>Est(1)</sub> ~2.1, pK<sub>Est(2)</sub> ~9.3. Likely impurities are N-chloroacetyl-L-homoserine, N-chloroacetyl-D-homoserine, L-homoserine, homoserine lactone, homoserine anhydride (formed in strong solutions of homoserine if slightly acidic). It cyclises to the lactone in strongly acidic solution. It crystallises from water by adding 9 volumes of EtOH. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 2612-2616 1961, *Beilstein* 4 IV 3187.]

**erythro-3-Hydroxy-*RS*-aspartic acid** [6532-76-9] **M 149.1, pK<sub>1</sub><sup>25</sup> 1.91, pK<sub>2</sub><sup>25</sup> 3.51, pK<sub>3</sub><sup>25</sup> 9.11.** Likely impurities are 3-chloromalic acid, ammonium chloride, *threo*-3-hydroxyaspartic acid. Crystallise it from water. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 1** p 214, **Vol 3** p 2416 1961.]

**β-Hydroxyglutamic acid** [533-62-0] **M 163.1, m 100°(dec), pK<sub>1</sub><sup>25</sup> 2.27, pK<sub>2</sub><sup>25</sup> 4.29, pK<sub>3</sub><sup>25</sup> 9.66.** Crystallise the acid from water. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 1** pp 211-213, **Vol 3** p 2422 1961.]

**5-Hydroxy-L-lysine monohydrochloride** [32685-69-1; 13204-98-3] **M 198.7, m 225°(dec), [α]<sub>D</sub><sup>25</sup> +17.8° (6M HCl), pK<sub>2</sub><sup>25</sup> 8.85, pK<sub>3</sub><sup>25</sup> 9.83.** Likely impurities are 5-*allo*-hydroxy-(D and L)-lysine, histidine, lysine, ornithine. Crystallise the hydrochloride from water by adding 2-9 volumes of EtOH stepwise. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2000-2009 1961.]

**DL-erythro-3-Hydroxynorvaline (2-amino-3-hydroxypentanoic acid)** [34042-00-7] **M 133.2, m 257-259°(dec), 263°(dec), pK<sub>1</sub><sup>20</sup> 2.32, pK<sub>2</sub><sup>20</sup> 9.12.** Purify it by recrystallisation from aqueous EtOH. The *Cu* salt has **m 255-256° (dec)**, the *benzoyl* derivative has **m 181°**, and the *N*-phenylcarbamoyl derivative has **m 164°**. [Buston et al. *J Biol Chem* **204** 665 1953, *Beilstein* **4** IV 3220.]

***N*-(*p*-Hydroxyphenyl)glycine** [22818-40-2] **M 167.2, m >240°(dec), [α]<sub>D</sub><sup>20</sup> -156° (c 1, M HCl), pK<sub>Est(1)</sub>~2, pK<sub>Est(2)</sub>~4.5, pK<sub>Est(3)</sub>~10.3.** Crystallise it from water and dry it *in vacuo*. [*Beilstein* **14** I 659.]

***trans*-L-4-Hydroxyproline** [51-35-4] **M 131.1, m 274°, [α]<sub>D</sub><sup>20</sup> -76.0° (c 5, H<sub>2</sub>O), pK<sub>1</sub><sup>25</sup> 1.86, pK<sub>2</sub><sup>25</sup> 9.79.** Crystallise it from MeOH/EtOH (1:1). Separation from normal *allo*-isomer can be achieved by crystallisation of the copper salts [see Levine *Biochemical Preparations* **8** 114 1961]. Separation from proline is achieved via the crystalline picrate, CdCl<sub>2</sub>, or acid ammonium rhodanate salts [see Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2182 1961, Kapfhammer & Mohn *Z Physiol Chem* **306** 76 1956]. [*Beilstein* **22/5** V 7.]

**5-Hydroxy-L-tryptophan** [4350-09-8] **M 220.2, m 273°(dec), [α]<sub>D</sub><sup>22</sup> -32.5°, [α]<sub>D</sub><sup>20</sup> -73.5° (c 1, H<sub>2</sub>O), pK<sub>Est(1)</sub>~2.4, pK<sub>Est(2)</sub>~9.0, pK<sub>Est(3)</sub>~9.4, pK<sub>Est(4)</sub> 16 (NH).** Likely impurities are 5-hydroxy-D-tryptophan and 5-benzyloxytryptophan. Crystallise 5-hydroxy-L-tryptophan under nitrogen from water by adding EtOH. Store it under nitrogen. Also dissolve it in the minimum volume of hot H<sub>2</sub>O (~0.7g in 4ml) under nitrogen (charcoal) and allowed it to crystallise at 5°. The *picrolonate* crystallises from H<sub>2</sub>O with **m 184-186°(dec)**. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2732-2737 1961, Morris & Armstrong *J Org Chem* **22** 306 1957, *Beilstein* **22/14** V 278.]

**(±)-Ibotenic acid monohydrate (α-[3-hydroxy-5-isoxazolyl]-glycine, α-amino-3-hydroxy-5-isoxazoleacetic acid)** [2552-55-8] **M 176.1, m 144-146° (monohydrate), 151-152° (anhydrous), 148-151°, pK<sub>1</sub> 2, pK<sub>2</sub> 5.1, pK<sub>3</sub> 8.2.** It has been converted to the ammonium salt (**m 121-123° dec**) dissolved in H<sub>2</sub>O, passed through an Amberlite IR 120 resin (H<sup>+</sup> form) and eluted with H<sub>2</sub>O. The acidic fractions are collected, evaporated to dryness and the residue recrystallises from H<sub>2</sub>O as the *monohydrate* (**m 144-146°**). The anhydrous acid is obtained by making a slurry with MeOH, decanting and evaporating to dryness, and repeating the process twice more to give the *anhydrous acid* (**m 151-152°**). Recrystallisation from H<sub>2</sub>O gives the *monohydrate*. [Nakamura *Chem Pharm Bull Jpn* **19** 46 1971.] The *ethyl ester* forms needles when crystallised from a small volume of Et<sub>2</sub>O and has **m 78-79°** and IR (CHCl<sub>3</sub>) with  $\nu_{\max}$  □□ 3500-2300 (OH), 1742 (ester C=O), 1628, 1528cm<sup>-1</sup>, and UV with  $\lambda_{\max}$  □□ (EtOH) at 206nm (ε 7,080). The *hydrazide* has **m 174-175°** (from MeOH) with IR (KBr) 1656 (C=O)cm<sup>-1</sup>.

**Iminodiacetic acid** [142-73-4] **M 133.1, m 225°(dec), 240°(dec), 247.5°(dec), b 126-127°/14mm, pK<sub>1</sub><sup>25</sup> 2.50, pK<sub>2</sub><sup>25</sup> 9.40.** Crystallise the acid several times from water. The *N*-Methyl derivative **m 215°** is purified by dissolving it in an equal weight of warm H<sub>2</sub>O and adding 3 volumes of MeOH [Kiematsu et al. *Org Synth Coll Vol II* 397 1943]. [Laberek & Martell *J Am Chem Soc* **74** 5052 1952, *Beilstein* **4** III 2428, **4** IV 1176.]

**3-Iodo-L-tyrosine** [70-78-0] M 307.1, m 205-208°(dec),  $[\alpha]_{\text{D}}^{25} -4.4^{\circ}$  (c 5, 1M HCl),  $\text{pK}_{\text{Est}(2)} \sim 2.1$ ,  $\text{pK}_{\text{Est}(3)} \sim 6.4$ ,  $\text{pK}_{\text{I}}^{25} 8.7$ . Likely impurities are tyrosine, diiodotyrosine and iodide. Crystallise it by dissolving it in concentrated ammonia (~200mg in ~20ml), evaporate to ~5ml and  $\text{NH}_4\text{Cl}$  is added to pH4.5—5.0. After a few hours at 0°, the amino acid crystallises in needles. It is filtered off, washed with a little ice-cold  $\text{H}_2\text{O}$  and dried in a vacuum. *Alternatively*, dissolve it in dilute ammonia at room temperature, then add dilute acetic acid to pH 6. Store it at 0°. Recrystallisation of ~250mg from  $\text{H}_2\text{O}$  (~5ml) removes any diiodotyrosine. It is an inhibitor of tyrosine hydroxylase with a  $K_i$  of ~500nM. [Harrington & Rivers *Biochem J* 38 320 1944, Rivers *Chem & Ind (London)* 21 1956, *Beilstein* 14 III 1562, 14 IV 1562.]

**L-Isoleucine** [73-32-5] M 131.2, m 285-286°(dec),  $[\alpha]_{\text{D}}^{20} +40.6^{\circ}$  (6M HCl)  $\text{pK}_{\text{I}}^{25} 2.66$ ,  $\text{pK}_{\text{I}}^{25} 9.69$ . Crystallise L-isoleucine from  $\text{H}_2\text{O}$  by addition of 4 volumes of EtOH or from aqueous MeOH. It sublimes at 170-181°/0.3mm with 99.7% recovery, unracemised [Gross & Gradsky *J Am Chem Soc* 77 1678 1955]. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 1 p 183-191, Vol 3 pp 2043-2073 1961, Huffman & Ingersoll *J Am Chem Soc* 73 3366 1951, *Beilstein* 4 IV 2775.]

**DL-Isoserine** ( $\pm$ -3-amino-2-hydroxypropionic acid) [632-12-2] M 105.1, m 235°(dec), 237°(dec), 245°(dec), 250-252°(dec),  $\text{pK}_{\text{I}}^{25} 2.78$  (acidic),  $\text{pK}_{\text{I}}^{25} 9.27$  (basic). Recrystallise it from  $\text{H}_2\text{O}$  or 50% aqueous EtOH. It has an isoelectric pH of 6.02. [Rinderknecht & Niemann *J Am Chem Soc* 75 6322 1953, Gundermann & Holtmann *Chem Ber* 91 160 1958, Emerson et al. *J Biol Chem* 92 451 1931.] The *hydrobromide* has m 128-130° (from aqueous HBr) [Schöberl & Braun *Justus Liebigs Ann Chem* 542 288 1939]. [*Beilstein* 4 H 503, 4 IV 3116.]

**L-Isovaline** (2-amino-2-methylbutyric acid) [595-40-4] M 117.2, m ca 300° (sublimes in vac),  $[\alpha]_{\text{D}}^{25} +113.1^{\circ}$  (c 5,  $\text{H}_2\text{O}$ ),  $[\alpha]_{\text{D}}^{25} +10^{\circ}$  (5M HCl),  $\text{pK}_{\text{Est}(1)} \sim 2.4$ ,  $\text{pK}_{\text{Est}(2)} \sim 9.7$ . Crystallise it from aqueous  $\text{Me}_2\text{CO}$ , or better by dissolving in  $\text{H}_2\text{O}$  and adding excess  $\text{Me}_2\text{CO}$ . [Baker et al. *J Am Chem Soc* 74 4701 1952, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 p 2573-2577 1961.]

**L-Leucine** [61-90-5] M 131.2, m 293-295°(dec),  $[\alpha]_{\text{D}}^{25} +15.6^{\circ}$  (5M HCl),  $\text{pK}_{\text{I}}^{25} 2.33$ ,  $\text{pK}_{\text{I}}^{25} 9.74$ . Likely impurities are isoleucine, valine, and methionine. Crystallise L-leucine from water by adding 4 volumes of EtOH. It sublimes at 180-188°/0.3mm with 99.1% recovery, and unracemised [Gross & Gradsky *J Am Chem Soc* 77 1678 1955]. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 p 2075-2094 1961, Kameda et al. *J Pharm Soc Jpn* 78 763 1958, *Beilstein* 4 IV 2738.]

**L-Lysine** [56-87-1] M 146.2, [39665-12-8 monohydrate] M 164.2, m >210°(dec),  $[\alpha]_{\text{D}}^{20} +25^{\circ}$  (c 2, 6M HCl),  $\text{pK}_{\text{I}} 2.18$ ,  $\text{pK}_{\text{I}} 8.95$ ,  $\text{pK}_{\text{I}} 10.53$ . Crystallise L-lysine from aqueous EtOH. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 2097-2122 1961, Kearley & Ingersoll *J Am Chem Soc* 73 5783 1951, *Beilstein* 4 IV 2717.]

**L-Lysine dihydrochloride** [657-26-1] M 219.1, m 193°, 199-201°, 203-204°,  $[\alpha]_{\text{D}}^{25} +25.9^{\circ}$  (5M HCl). Crystallise it from MeOH, in the presence of excess HCl, by adding diethyl ether. [Yoneya *J Biochem (Tokyo)* 38 343 1951, Kearley & Ingersoll *J Am Chem Soc* 73 5783 1951, *Beilstein* 4 IV 2717.]

**L-Lysine monohydrochloride** [657-27-2] M 182.7, m 256°(dec),  $[\alpha]_{\text{D}}^{25} +20.5^{\circ}$  (c 5, 5M HCl). Likely impurities are arginine, D-lysine, 2,6-diaminoheptanedioic acid and glutamic acid. Crystallise the monohydrochloride from water at pH 4-6 by adding 4 volumes of EtOH. At above 60% relative humidity it forms a *dihydrate*. [Birhbaum et al. *J Biol Chem* 194 455, 468 1952, Kearley & Ingersoll *J Am Chem Soc* 73 5783 1951, *Beilstein* 4 IV 2717.]

**$\alpha$ -Melanotropin** [581-05-5] (a tridecapeptide,  $\alpha$ -MSH, melanocyte stimulating hormone), M 1664.9,  $[\alpha]_{\text{D}}^{25} -58.5^{\circ}$  (c 0.4, 10% aqueous AcOH). Its solubility in  $\text{H}_2\text{O}$  is 1mg/ml. It is separated from the extract by ion-exchange on carboxymethyl cellulose, desalted, evaporated and lyophilised, then chromatographed on

Sephadex G-25. [Lande et al. *Biochemical Preparations* **13** 45 1971.]

**$\beta$ -Melanotropin** [9034-42-8] (octadeca to docosa peptides), amorphous. An extract of  $\beta$ -melanotropin is purified by ion-exchange on carboxymethyl cellulose, desalted, evaporated and lyophilised, then chromatographed on Sephadex G-25. [Lande et al. *Biochemical Preparations* **13** 45 1971.]

**Melphalan** (4-[bis-{2-chloroethyl}amino]-L-phenylalanine) [148-82-3] **M 305.2, m 182-183° (dec), 183-185°,  $[\alpha]_D^{25} +7.5^\circ$  (c 1.33, 1.0 N HCl),  $[\alpha]_D^{20} -28^\circ$  (c 0.8, MeOH),  $pK_{Est} \sim 6.4$** . Purify melphalan by recrystallisation from MeOH, and its solubility is 5% in 95% EtOH containing one drop of 6N HCl. It is soluble in EtOH and propylene glycol but is almost insoluble in H<sub>2</sub>O. The *RS*-form has **m 180-181°**, and the *R*-form crystallises from MeOH with **m 181.5-182°** and  **$[\alpha]_D^{21} -7.5^\circ$  (c 1.26, 1.0 N HCl)**. [Bergel & Stock *J Chem Soc* 2409 1954, *Beilstein* **14** IV 1689.]

***dl*-Methionine** (*RS*-2-amino-4-methylthiobutyric acid) [59-51-8] **M 149.2, m 281°(dec),  $pK_1^{25} 2.28$ ,  $pK_2^{25} 9.21$** . Crystallise it from hot water or EtOH. Also purify it by dissolving it in H<sub>2</sub>O and passing through an Amberlite IR-120 resin (NH<sub>4</sub><sup>+</sup> form). The eluate is concentrated and then passed through Amberlite IR-4B resin, and this eluate is evaporated to dryness. The residue is washed with EtOH, then Me<sub>2</sub>CO, dried and recrystallised from aqueous EtOH (colourless plates) [Baddiley & Jamieson *J Chem Soc* 4283 1954]. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2125 1961, *Beilstein* **4** IV 3190.]

**L-Methionine** [63-68-3] **M 149.2, m 277-279°(dec), 283°(dec),  $[\alpha]_D^{25} +21.2^\circ$  (0.2M HCl),  $pK_1^{25} 2.13$ ,  $pK_2^{25} 9.73$** . Crystallise L-methionine from aqueous EtOH. Also purify it by dissolving ~0.5g of amino acid in ~10ml of hot H<sub>2</sub>O, filtering, adjusting the pH to 5.8 with 5N HCl, collecting the solid after addition of ~20ml of EtOH. It is recrystallised by dissolving in H<sub>2</sub>O and adding EtOH. It sublimes at 197-208°/0.3mm with 99.8% recovery and unracemised [Gross & Gradsky *J Am Chem Soc* **77** 1678 1955]. [Milne & Peng *J Am Chem Soc* **79** 647 1957, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2125-2152 1961, *Beilstein* **4** IV 3189.]

***dl*-Methionine sulfoxide** [454-41-1, 62697-73-8] **M 165.2, m >240°(dec), 241-242°(dec)**. Likely impurities are *dl*-methionine sulfone and *dl*-methionine. Crystallise the sulfoxide by dissolving it in hot H<sub>2</sub>O and adding excess EtOH. [Lepp & Dunn *Biochemical Preparations* **4** 80 1955, Micheel & Schmitz *Chem Ber* **72** 518 1939, *Beilstein* **4** III 1650, **4** IV 3192.]

**S-Methyl-L-cysteine** [1187-84-4] **M 135.2, m 207-211°, ~240°(dec), 267-270°,  $[\alpha]_D^{20} -32.0^\circ$  (-34.5°) (c 5, H<sub>2</sub>O),  $pK_1^{25} 1.94$  (COOH),  $pK_2^{25} 8.73$  (NH<sub>2</sub>, 8.97)**. Likely impurities are cysteine and S-methyl-*dl*-cysteine. Crystallise it from H<sub>2</sub>O by adding 4 volumes of EtOH. It also crystallises from MeOH with **m 234-236°(dec)**, but after sublimation it has **m 267-270°** and  **$[\alpha]_D^{27} -31.6^\circ$  (c 1, H<sub>2</sub>O)**. [Rinderknecht et al. *Helv Chim Acta* **41** 1, 10 1958, Theodoropoulos *Acta Chem Scand* **13** 383 1959, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 1904 1961, *Beilstein* **4** IV 3145.]

**$\alpha$ -Methylmethionine** [562-48-1] **M 163.0, m 283-284°,  $pK_{Est(1)} \sim 2.1$ ,  $pK^{30} 9.45$** . Crystallise  $\alpha$ -methylmethionine from aqueous EtOH or H<sub>2</sub>O. [Pfister et al. *J Am Chem Soc* **77** 697 1955, Potts *J Chem Soc* 1623 1955, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2566 1961.]

**S-Methyl-L-methionine chloride** See Vitamin U in "Miscellaneous Compounds", this chapter.

***N*-Methyltryptophan** (L-abrine) [526-31-8] **M 218.3, m 295°(dec with darkening and sintering),  $[\alpha]_D^{21} +44.4^\circ$  (c 2.8, 0.5M HCl),  $[\alpha]_D^{20} +65^\circ$  (c 1, 0.5N NaOH),  $pI 10.10$ ,  $pK_{Est(1)} \sim 2.3$ ,  $pK_{Est(2)} \sim 9.7$** . Crystallise L-abrine from H<sub>2</sub>O or EtOH/H<sub>2</sub>O mixture and dry it for 2 days at 60° in high vacuum; it has **m 275-290°(dec with browning at 230°)** and  **$[\alpha]_D^{21} +47.2^\circ$  (c 2, 0.5N HCl)** [Peter et al. *Helv Chim Acta* **46** 577 1963]. [Gregory & Morley *J Chem Soc* 913 1968, *Beilstein* **22/14** V 40.]

***dl*-5-Methyltryptophan** [951-55-3] **M 218.3, m 275°(dec) [ $pK$  see tryptophan]**. Crystallise *dl*-5-methyltryptophan from aqueous EtOH after dissolving it in aqueous NaOH, precipitating with AcOH, filtering

the solid off and drying for 24 hours at 50°. [Jackman & Archer *J Am Chem Soc* **68** 2105 1946, *Beilstein* **22** IV 6815.] The *picrate* crystallises from MeOH with **m** 202°(dec). The *N*-phenylcarbamoyl derivative crystallises from aqueous MeOH with **m** 202°. [Gordon & Jackson *J Biol Chem* **110** 151, 154 1935.]

**Nisin** [1414-45-5] **M 3354.2**. This polypeptide from *S. lactis* is purified by crystallisation from 80% (v/v) EtOH and by countercurrent distribution. The synthetic polypeptide antibiotic can also be purified by preparative HPLC and assayed by HPLC on a Nucleosil 3007C<sub>18</sub> (6 x 250mm) column using a MeCN—0.01M HCl gradient (30-50%), at 2%/minute, and flow rate of 1.5ml/minute to give a retention time of 8.1 minutes; or MeCN—0.3M guanidine-HCl gradient (30-50%), at 2%/minute, and flow rate of 1.5ml/minute to give a retention time of 10.9 minutes. FAB-MS gave the pseudomolecular ion *m/z* at 3352.7 (M + H)<sup>+</sup>. It is soluble in dilute acid and is stable even on boiling. [Berridge et al. *Biochem J* **52** 529 1952, synthesis by Fukase et al. *Tetrahedron Lett* **29** 795 1988.]

**Norleucine (α-amino-*n*-caproic acid)** [*R*(+) 327-56-0, *S*(-) 327-57-1] **M 117.2, m 301°**, [α]<sub>D</sub><sup>20</sup> (+) and (-) 28° (c 5, 5M HCl), [*RS*: 616-06-8] **m 297-300°** (sublimes partially at ~280°), **pK<sub>1</sub> 2.39, pK<sub>2</sub> 9.76** (for *RS*). Crystallise norleucine from water or aqueous MeOH. [Huffman & Ingersoll *J Am Chem Soc* **73** 3366 1951, *Beilstein* **4** III 1386, **4** IV 2628.]

**Norvaline (R-α-amino-*n*-valeric acid)** [*R*(+) 2031-12-9, *S*(-) 6600-40-4] **M 117.2, m 305°(dec)**, [α]<sub>D</sub><sup>20</sup> (+) and (-) 25° (c 10, 5M HCl), **pI 6.04, pK<sub>1</sub><sup>25</sup> 2.36, pK<sub>2</sub><sup>25</sup> 9.87** (9.72). Crystallise norvaline from aqueous EtOH or water. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2390-2399 1961, *Beilstein* **4** III 1331-1333, **4** IV 128, 2629.]

**L-Ornithine** [70-26-8] **M 132.2, m 140°**, [α]<sub>D</sub><sup>25</sup> +16° (c 0.5, H<sub>2</sub>O), **pK<sub>1</sub><sup>20</sup> 2.11, pK<sub>2</sub><sup>20</sup> 8.39, pK<sub>3</sub><sup>25</sup> 10.59**. Crystallise L-ornithine from water containing 1mM EDTA (to remove metal ions). [Perrin *J Chem Soc* 3125 1958, Rivard *Biochemical Preparations* **3** 97 1955, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2477-2491 1961, *Beilstein* **4** III 1346, **4** IV 2644.]

**L-Ornithine monohydrochloride** [3184-13-2] **M 168.6, m 230-232°(dec), 233°(dec), 236.5-237.5°(dec)**, [α]<sub>D</sub><sup>25</sup> +28.3° (5M HCl). Likely impurities are citrulline, arginine and D-ornithine. Crystallise the monohydrochloride from water by adding 4 volumes of EtOH and dry it in a vacuum desiccator over fused CaCl<sub>2</sub>. [Rivard *Biochemical Preparations* **3** 98 1955.] The *dihydrochloride* [6211-16-1] has **m 202-203°** and [α]<sub>D</sub><sup>20</sup> +18.4° (c 2.3, 6N HCl) after recrystallisation from MeOH/Et<sub>2</sub>O [Zaoral & Rudinger *Col Czech Chem Commun* **24** 2009 1959]. [*Beilstein* **4** IV 2644.]

**Oxytocin** [50-56-6] **M 1007.2, m dec on heating**, [α]<sub>D</sub><sup>22</sup> -26.2° (c 0.53, N AcOH). It is a cyclic nonapeptide which is purified by countercurrent distribution between solvent and buffer. It is soluble in H<sub>2</sub>O, *n*-BuOH and isoBuOH. [Bodanszky & du Vigneaud *J Am Chem Soc* **81** 2504 1959, Cash et al. *J Med Pharm Chem* **5** 413 1962, Sakakibara et al. *Bull Chem Soc Jpn* **38** 120 1965; solid phase synthesis: Bayer & Hagenmyer *Tetrahedron Lett* 2037 1968.] It was also synthesised on a solid phase matrix and finally purified as follows: A Sephadex G-25 column is equilibrated with the aqueous phase of a mixture of 3.5% AcOH (containing 1.5% of pyridine)/*n*-BuOH/\*C<sub>6</sub>H<sub>6</sub> (2:1:1) and then the organic phase of this mixture is run through. A solution of oxytocin (100mg) in H<sub>2</sub>O (2ml) is applied to the column which is then eluted with the organic layer of the above mixture. The fractions containing the major peak [as determined by the Folin-Lowry protein assay: Fryer et al. *Anal Biochem* **153** 262 1986] are pooled, diluted with twice their volume of H<sub>2</sub>O, evaporated to a small volume and lyophilised to give oxytocin as a pure white powder (20mg, 508 U/mg). [Ives *Can J Chem* **46** 2318 1968, *Beilstein* **22** III/IV 82.]

***dl*-Phenylalanine** [150-30-1] **M 165.2, m 265-266°(capillary, dec), 271-273°(dec), 282-284°(dec)**, **pK<sub>1</sub><sup>25</sup> 2.58, pK<sub>2</sub><sup>25</sup> 9.24**. *dl*-Phenylalanine crystallises from H<sub>2</sub>O or H<sub>2</sub>O/EtOH in large plates and is dried under vacuum over P<sub>2</sub>O<sub>5</sub>. *S*-Phenylalanine ethyl ester hydrochloride [3182-93-2] has **m 156-158°** and [α]<sub>D</sub><sup>20</sup> -7.8° (c

2, H<sub>2</sub>O) after crystallisation from EtOH/Et<sub>2</sub>O [Billimoria & Cook *J Chem Soc* 2328 1949, *Beilstein* 14 IV 1556]. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 2156-2175 1961, *Beilstein* 14 III 1229, 14 IV 1553.]

**L-Phenylalanine** [63-91-2] M 165.2, m 280°(dec), 281-183°(dec),  $[\alpha]_D^{25}$  -34.0° (c 2, H<sub>2</sub>O). Likely impurities are leucine, valine, methionine and tyrosine. Crystallise L-phenylalanine from water by adding 4 volumes of EtOH. Dry it *in vacuo* over P<sub>2</sub>O<sub>5</sub>. Also crystallise it from saturated refluxing aqueous solutions at neutral pH, or 1:1 (v/v) EtOH/water solution, or conc HCl. It sublimes at 176-184°/0.3mm with 98.7% recovery and unracemised [Gross & Gradsky *J Am Chem Soc* 77 1678 1955]. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 2156-2175 1961, *Beilstein* 14 IV 1552.]

**L- $\alpha$ -Phenylglycine** [2935-35-5] M 151.2, m 305-310°, 305-308°(capillary, dec),  $[\alpha]_{546}^{25}$  +188° (c 1, M HCl), pK<sub>1</sub><sup>25</sup> 1.83, pK<sub>2</sub><sup>25</sup> 4.39 (for *dl*). Crystallise it from EtOH. [Kaneko *J Chem Soc Jpn* 60 538 1939, Rudman et al. *J Am Chem Soc* 74 551 1952, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 2694-2697 1961, *Beilstein* 14 III 1187, 14 IV 1317.]

**Phenylglycine-*o*-carboxylic acid [N-(2-carboxyphenyl)glycine]** [612-42-0, 64241-57-2 Me Ester, 67990-19-6 mono-Na Salt, 71807-57-3 di-Na Salt] M 195.2, m 206°, 208°, 220°, pK<sub>1</sub><sup>20</sup> 5.44 (CO<sub>2</sub>H), pK<sub>2</sub><sup>20</sup> 6.96 (CO<sub>2</sub>H) (in 50% aqueous dioxane). Crystallise the acid from hot water (charcoal). It forms complexes with Cu<sup>2+</sup>, Zn<sup>2+</sup>, Cd<sup>2+</sup>, Co<sup>2+</sup> and Ni<sup>2+</sup> in aqueous dioxane. [Roileanu et al. *Rev Roumaine Chim* 12 105 1967, *Aldrich library of* <sup>13</sup>C, <sup>1</sup>H FTNMR Spectra, NMR 2 1181A, *Beilstein* 14 H 348, 14 I 544, 14 II 225, 14 III 938.]

**D-Pipecolinic acid (R-piperidine-2-carboxylic acid)** [1723-00-8] M 129.2, m 264°(dec), 267°(dec), ~280°(dec),  $[\alpha]_D^{25}$  +26.2° (c 2, H<sub>2</sub>O),  $[\alpha]_D^{25}$  +35.7° (H<sub>2</sub>O), pK<sub>1</sub><sup>20</sup> 2.29 (CO<sub>2</sub>H), pK<sub>2</sub><sup>20</sup> 10.77 (NH<sup>+</sup>). D-Pipecolinic acid recrystallises as platelets from EtOH and is soluble in H<sub>2</sub>O. The *hydrochloride* has m 256-257°(dec) from H<sub>2</sub>O and  $[\alpha]_D^{25}$  +10.8° (c 2, H<sub>2</sub>O). [*cf* p 422, Lukés et al. *Col Czech Chem Commun* 22 286 1957, Bayerman *Rec Trav Chim Pays Bas* 78 134 1959, Asher et al. *Tetrahedron Lett* 22 141 1981, *Beilstein* 22/1 V 220.]

**L-Pipecolinic acid (S-piperidine-2-carboxylic acid)** [3105-95-1] M 129.2, m 268°(dec), 271°(dec), ~280°(dec),  $[\alpha]_D^{20}$  -26° (c 4, H<sub>2</sub>O),  $[\alpha]_D^{25}$  -34.9° (H<sub>2</sub>O). Recrystallise L-pipecolinic acid from aqueous EtOH, and it sublimes as needles in a vacuum. It is sparingly soluble in absolute EtOH, Me<sub>2</sub>CO or CHCl<sub>3</sub> but insoluble in Et<sub>2</sub>O. The *hydrochloride* has m 258-259°(dec, from MeOH) and  $[\alpha]_D^{25}$  -10.8° (c 10, H<sub>2</sub>O). [Fuji & Myoshi *Bull Chem Soc Jpn* 48 1241 1975, *Beilstein* 22/1 V 220.]

**Piperidine-4-carboxylic acid (isonipecotic acid)** [498-94-2] M 129.2, m 336°(dec, darkens at ~300°), pK<sub>Est(1)</sub> ~ 4.3 (CO<sub>2</sub>H), pK<sub>Est(2)</sub> ~ 10.6 (NH<sup>+</sup>). It crystallises from H<sub>2</sub>O or EtOH as needles. The *hydrochloride* recrystallises from H<sub>2</sub>O or aqueous HCl with m 293°dec (also 298°dec, 300°dec). [Wibaut *Rec Trav Chim Pays Bas* 63 141 1944, IR: Zacharius et al. *J Am Chem Soc* 76 2908 1954, *Beilstein* 22/1 V 244.]

**Polypeptides.** These are strings of  $\alpha$ -amino acids usually with the natural *S*(L) [L-cysteine is an exception and has the *R* absolute configuration] or sometimes “unnatural” *R*(D) configuration at the  $\alpha$ -carbon atom. They generally have less than ~100 amino acid residues. They can be naturally occurring or, because of their small size, can be synthesised chemically from the desired amino acids. Their properties can be very similar to those of small proteins. Many are commercially available, and can be custom made commercially or locally with a peptide synthesiser. They are purified by HPLC and can be used without further purification. Their purity can be checked as described under proteins (Introduction).

**L-Proline** [147-85-3] M 115.1, m 215-220°(dec)(D-isomer), 220-222°(dec) (L-form), 205°(dec)(DL-isomer),  $[\alpha]_D^{20}$  -53° (c 0.6, 0.5N HCl), -93° (c 2.4, 6N KOH) for L-isomer, pl 6.3, pK<sub>1</sub><sup>25</sup> 1.95, pK<sub>2</sub><sup>25</sup> 10.64. A likely impurity is hydroxyproline. Purify L-proline *via* its *picrate* which is crystallised twice from water, then decomposed with 40% H<sub>2</sub>SO<sub>4</sub>. The *picric acid* is extracted with diethyl ether, the H<sub>2</sub>SO<sub>4</sub> in solution is precipitated with Ba(OH)<sub>2</sub>, and the filtrate is evaporated. The residue is crystallised from hot absolute EtOH [Mellan & Hoover *J Am Chem Soc* 73 3879 1951] or EtOH/Et<sub>2</sub>O. Its solubility in H<sub>2</sub>O is >100%. It sublimes

at 182-187°/0.3mm with 99.4% recovery and unracemised [Gross & Gradsky *J Am Chem Soc* **77** 1678 1955]. It is *hygroscopic* and is stored in a desiccator. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2178-2199 1961, *Beilstein* **22** III/IV 8, **22/1** V 31.]

**L-Prolylglycine** [2578-57-6] **M 172.2, m 236°**,  $[\alpha]_D^{20} +21.1^\circ$  (c 4, H<sub>2</sub>O), **pK<sub>1</sub><sup>25</sup> 3.19, pK<sub>2</sub><sup>25</sup> 8.97**. Recrystallise L-prolylglycine from water at 50-60° by addition of EtOH. [Appel et al. *Chem Ber* **108** 2680 1975, Rydon & Smith *J Chem Soc* 3642 1956.]

**L-Propargylglycine (S-2-aminopent-4-ynoic acid)** [23235-01-0] **M 113.1, m 230°(dec starting at 210°)**,  $[\alpha]_D^{20} -35^\circ$  (c 1, H<sub>2</sub>O),  $-4^\circ$  (c 5, 5N HCl), **pK<sub>Est(1)</sub>~ 2.3 (CO<sub>2</sub>H), pK<sub>Est(2)</sub>~ 9.8 (NH<sub>2</sub>)**. The acid crystallises readily when ~4g in 50ml H<sub>2</sub>O are treated with absolute EtOH at 4°/3 hours, and is collected, washed with cold absolute EtOH and Et<sub>2</sub>O and dried in a vacuum. Also, it recrystallises from aqueous Me<sub>2</sub>CO, R<sub>F</sub> on SiO<sub>2</sub> TLC plates with *n*-BuOH/H<sub>2</sub>O/AcOH (4:1:1) is 0.26. The *racemate* has **m 238-240°**. [Leukart et al. *Helv Chim Acta* **59** 2181 1976, Eberle & Zeller *Helv Chim Acta* **68** 1880 1985, Jansen et al. *Rec Trav Chim Pays-Bas* **88** 819 1969.] It is a suicide inhibitor of  $\gamma$ -cystathionase and other enzymes [Washtier & Abeles *Biochemistry* **16** 2485 1977, Shinozuka et al. *Eur J Biochem* **124** 377 1982].

**R-Pyroglutamic acid (5-oxo-D-proline, R-2-pyrrolidone-5-carboxylic acid)** [4042-36-8] **M 129.1, m 156-158°**,  $[\alpha]_D^{20} +11.2^\circ$  (c 1, H<sub>2</sub>O). Purify *R*-pyroglutamic acid by dissolving it in H<sub>2</sub>O, filtering, passing the filtrate through Dowex 50 (H<sup>+</sup> form), washing with H<sub>2</sub>O, pooling washings, evaporating, removing H<sub>2</sub>O azeotropically with Me<sub>2</sub>CO and \*C<sub>6</sub>H<sub>6</sub>, washing the residue with Et<sub>2</sub>O and recrystallising from EtOH/petroleum ether. [Pradeller et al. *Col Czech Chem Commun* **42** 79, 80 1977, *Beilstein* **22/6** V 7.]

**S-Pyroglutamic acid (5-oxo-L-proline)** [98-79-3] **M 129.1, m 156-158°, 162-164°**,  $[\alpha]_{546}^{20} -11^\circ$  (c 5, H<sub>2</sub>O), **pK<sup>25</sup> 12.7 (by electron spin resonance)**. Crystallise *S*-pyroglutamic acid by dissolving it in boiling EtOH (20g in 100ml), cooling and after a few minutes adding petroleum ether (b 40-60°, 120ml), then after 5 minutes adding a further 120ml, and cooling to room temperature with 90% recovery. This has **m 155.5-157.5°** and  $[\alpha]_D^{20} -11.4^\circ$  (c 4.4, H<sub>2</sub>O) [Hardy *Synthesis* 290 1978, Pellegata et al. *Synthesis* 614 1978]. The NH<sub>4</sub> salt has **m 184-186°** (from EtOH). [*Beilstein* **22/6** V 7.]

**Quisqualic acid (3-[3,5-dioxo-1,2,4-oxadiazolin-2-yl]-L-alanine)** [52809-07-1] **M 189.1, m 190-191°**,  $[\alpha]_D^{20} +17^\circ$  (c 2, 6M HCl), **pK<sub>Est(1)</sub>~ 2.1 (CO<sub>2</sub>H), pK<sub>Est(2)</sub>~ 8.9 (NH<sub>2</sub>)**. It has been purified by ion-exchange chromatography on Dowex 50W (x 8, H<sup>+</sup> form); the desired fractions are lyophilised and recrystallised from H<sub>2</sub>O/EtOH. It has IR (KBr) with  $\nu_{\max}$  at 3400-2750br, 1830s, 1775s, 1745s and 1605s cm<sup>-1</sup>; and <sup>1</sup>H NMR (NaOD/D<sub>2</sub>O, pH 13)  $\delta$ : 3.55-3.57 (1H m, X of ABX, H-2), 3.72-3.85 (2H, AB of ABX, H-3), <sup>13</sup>C NMR (D<sub>2</sub>O)  $\delta$ : 50.1(t), 53.4(d), 154.8(s), 159.7(s) and 171.3(s). [Baldwin et al. *J C S, Chem Commun* 256 1985.] It is a quisqualate receptor agonist [Joels et al. *Proc Natl Acad Sci USA* **86** 3404 1989].

**Sarcosine (N-methylglycine)** [107-97-1] **M 89.1, m 2 12-213°(dec)**, **pK<sub>1</sub><sup>20</sup> 2.12, pK<sub>2</sub><sup>20</sup> 10.19**. Crystallise sarcosine from absolute EtOH, 95% EtOH or H<sub>2</sub>O. It sublimes at 180-185°/0.3mm with 99.1% recovery [Gross & Gradsky *J Am Chem Soc* **77** 1678 1955]. [Cocker & Harris *J Chem Soc* 1291 1940, Cocker & Lapworth *J Chem Soc* 1897 1931, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2750 1961, *Beilstein* **4** III 1121, **4** IV 2363.]

**Sarcosine anhydride (1,4-dimethylpiperazin-2,5-dione)** [5076-82-4] **M 142.2, m 146-147°, 148°, pK<sub>Est(1)</sub>~ -4.2, pK<sub>Est(2)</sub>~ -1.9**. Crystallise the anhydride from H<sub>2</sub>O, EtOH or EtOAc. Dry it in a vacuum at room temperature. [Karrer et al. *Helv Chim Acta* **5** 140 1922, *Beilstein* **24** II 144, **24** IV 1072.]

**Seleno-DL-methionine ( $\pm$ 2-amino-4-methylselenylbutyric acid)** [1464-42-2, 2578-28-1 ( $\pm$ )] **M 196.1, m 265°(dec), 267-269°(dec), 270° (see pKs of methionine)**. It crystallises in hexagonal plates from MeOH and H<sub>2</sub>O. [Klosterman & Painter *J Am Chem Soc* **69** 2009 1949.] The *L*-isomer [3211-76-5] is purified by dissolving it in H<sub>2</sub>O, adjusting the pH to 5.5 with aqueous NH<sub>3</sub>, evaporating to near-dryness, and the residue is

washed several times with absolute EtOH till a solid is formed and then recrystallise from Me<sub>2</sub>CO. It has *m* 266-268°(dec) [also 275°(dec)], and  $[\alpha]_D^{25} +18.1^\circ$  (c 1, N HCl). [Pande et al. *J Org Chem* **35** 1440 1970, *Beilstein* **4** IV 3216.]

**L-Serine** [56-45-1] *M* 105.1, *m* 228°(dec), 233-235°(dec),  $[\alpha]_D^{25} +14.5^\circ$  (1M HCl),  $[\alpha]_{546}^{20} +16^\circ$  (c 5, 5M HCl), *pK*<sub>1</sub><sup>25</sup> 2.15, *pK*<sub>2</sub><sup>25</sup> 9.21. A likely impurity is glycine. Crystallise L-serine from H<sub>2</sub>O by adding 4 volumes of EtOH. Dry and store it in a desiccator. It sublimes at 160-170°/0.3mm with 99.7% recovery, and unracemised [Gross & Gradsky *J Am Chem Soc* **77** 1678 1955]. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2202-2235 1961, *Beilstein* **4** IV 3118.]

**Somatostatin** [38916-34-6] *M* 1637.9,  $[\alpha]_D^{25} -36^\circ$  (c 0.57, 1% AcOH). Somatostatin is a tetradecapeptide which is purified by gel filtration on Sephadex G-25, eluting with 2N AcOH, and then by liquid partition chromatography on Sephadex G-25 using *n*-BuOH/AcOH/H<sub>2</sub>O (4:1:5) and has *R*<sub>F</sub> = 0.4. It is a brain growth hormone releasing-inhibiting factor which has also been synthesised. [Burgus et al. *Proc Natl Acad Sci USA* **70** 684 1973, Sorantakis & McKinley *Biochem Biophys Res Commun* **54** 234 1973, Hartridt et al. *Pharmazie* **37** 403 1982.]

**L-Threonine** [72-19-5] *M* 119.1, *m* 251-253°, 254°(dec), 262-263°(dec),  $[\alpha]_D^{26} -28.4^\circ$  (H<sub>2</sub>O), *pK*<sub>1</sub><sup>25</sup> 2.17, *pK*<sub>2</sub><sup>25</sup> 9.00. Likely impurities are *allo*-threonine and glycine. Crystallise L-threonine from H<sub>2</sub>O by adding 4 volumes of EtOH. Dry and store it in a desiccator. It also crystallises from 80% EtOH to give hexagonal plates *m* 262-263°(dec). It sublimes at 200-226°/0.3mm with 99.6% recovery and unracemised [Gross & Gradsky *J Am Chem Soc* **77** 1678 1955]. [Elliot *J Chem Soc* **62** 1950, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 1** pp 176-183, **Vol 3** pp 2238-2257 1961, *Beilstein* **4** IV 3171.]

**L-Thyroxine sodium salt (5H<sub>2</sub>O)** [6106-07-6] *M* 888.9,  $[\alpha]_{546}^{20} +20^\circ$  (c 2, 1M HCl + EtOH, 1:4). Crystallise the sodium salt from absolute EtOH and dry it for 8 hours at 30°/1mm. [Canepa *Acta Cryst* **4** 283 1951, *Beilstein* **14** II 378, **14** III 1566, **14** IV 2374.]

**D-Thyroxine** {*O*-[3,5-diiodo-4-oxophenyl]-3,5-diiodo-D(-)-tyrosine, 3,3',5,5'-tetraiodo-D-thyronine} [51-49-0] *M* 776.9, *m* 235°(dec), 235-236°(dec), 340°(dec),  $[\alpha]_D^{20} +4.5^\circ$  (c 3, aqueous 0.2N NaOH in 70% EtOH),  $[\alpha]_D^{20} -17^\circ$  (c 2, aqueous N HCl + EtOH 1:4), *pK*<sub>1</sub><sup>25</sup> 2.2 (CO<sub>2</sub>H), *pK*<sub>2</sub><sup>25</sup> 8.40 (OH), *pK*<sub>3</sub><sup>25</sup> 10.1 (NH<sub>2</sub>). Recrystallise D-thyroxine from H<sub>2</sub>O (needles) or from an ammonical solution by dilution with H<sub>2</sub>O, MeOH or Me<sub>2</sub>CO. It has also been purified by dissolving ~6.5 g in a mixture of MeOH (200ml) and 2N HCl (20ml), adding charcoal, filtering then adding NaOAc solution to pH 6. On standing the thyroxine separates, it is filtered off, washed with MeOH then Me<sub>2</sub>CO and dried *in vacuo*. *N*-Formyl-D-thyroxine has *m* 210° and  $[\alpha]_{546}^{21} -26.9^\circ$  (c 5, EtOH). (±)-Thyroxine has *m* 256° and is purified in the same way. [Nahm & Siedel *Chem Ber* **96** 1 1963, Salter *Biochem J* **24** 471 1930, *Beilstein* **14** I 671, **14** II 384, **14** III 1566, **14** IV 2374.]

**L-Thyroxine** (*O*-[3,5-diiodo-4-oxophenyl]-3,5-diiodo-L-(+)-tyrosine, 3,3',5,5'-tetraiodo-L-thyronine) [51-48-9] *M* 776.9, *m* 229-230°(dec), ~235°(dec), 237°(dec),  $[\alpha]_D^{22} -5.1^\circ$  (c 2, aqueous N NaOH + EtOH 1:2),  $[\alpha]_D^{22} +15^\circ$  (c 5, aqueous N HCl in 95% EtOH 1:2),  $[\alpha]_D^{25} +26^\circ$  (EtOH/1M aqueous HCl, 1:1) (*pK*<sub>1</sub><sup>25</sup> 6.6). Purification is the same as for the D-isomer above. Likely impurities are tyrosine, iodotyrosine, iodothyroxines and iodide. Dissolve it in dilute ammonia at room temperature, then crystallise it by adding dilute acetic acid to pH 6. *N*-Formyl-L-thyroxine has *m* 214°(dec) and  $[\alpha]_{546}^{21} +27.8^\circ$  (c 5, EtOH). [Harrington et al. *Biochem J* **39** 164 1945, Nahm & Siedel *Chem Ber* **96** 1 1963, Reineke & Turner *J Biol Chem* **161** 613 1945, Chalmers et al. *J Chem Soc* 3424 1949, *Beilstein* **14** II 378, **14** III 1566, **14** IV 2373.]

***N*-Tosyl-L-lysine chloromethyl ketone (3*S*-1-chloro-3-tosylamino-7-amino-2-heptanone HCl)** [4272-74-6] *M* 369.3, *m* 150-153°(dec), 156-158°(dec), ~165°(dec),  $[\alpha]_D^{20} -7.3^\circ$  (c 2, H<sub>2</sub>O), *pK*<sub>Est</sub> ~ 10.6 (7-NH<sub>2</sub>). The hydrochloride slowly crystallises from a concentrated solution in absolute EtOH, thinned with EtOH/Et<sub>2</sub>O for collection and dried *in vacuo*. It is a suicide enzyme inhibitor of serine proteases, e.g. trypsin and clostripain. [Matsuda et al. *Chem Pharm Bull Jpn* **30** 2512 1982, Shaw et al. *Biochemistry* **4** 2219 1965].

**Triglycyl glycine (tetraglycine)** [637-84-3] M 246.2, m 270-275°(dec),  $pK_1^{25}$  3.21(CO<sub>2</sub>H),  $pK_2^{25}$  7.94(NH<sub>3</sub><sup>+</sup>). Crystallise it from H<sub>2</sub>O (optionally, by the addition of EtOH). [Li et al. *J Am Chem Soc* 79 5859 1957, Rising et al. *J Am Chem Soc* 56 1179 1934, *Beilstein* 4 II 807, 4 III 1201, 4 IV 2472.]

**Trigonellamide chloride (1-methylnicotinamide chloride)** [1005-24-9] M 172.6, m 240°(dec). It crystallises from MeOH, and is dried *in vacuo*. It is prepared from nicotinamide and MeI in refluxing MeOH then shaking with AgCl [Karrer et al. *Helv Chim Acta* 19 826 1936]. It is soluble in organic solvents but moderately in H<sub>2</sub>O. It is a metabolite of nicotinic acid in man, and was isolated from urine [Huff & Perizweig *J Biol Chem* 150 395 1943]. With ketones in aqueous alkali, it produces a green-blue fluorescence which turns blue on acidification and intensifies on heating. [*Beilstein* 22 III/IV 468, 22/2 V 80.]

**3,3',5-Triiodo-S-thyronine** [6893-02-3] M 651.0, m 236-237°(dec),  $[\alpha]_D^{29.5}$  +21.5° (EtOH/1M aqueous HCl, 2:1),  $pK_1^{25}$  6.48,  $pK_2^{25}$  7.62,  $pK_3^{25}$  7.82. Likely impurities are as in *thyroxine*. Purify it by dissolving in dilute NH<sub>3</sub> at ~20°, then crystallise it by addition of dilute acetic acid to pH 6. Alternatively, 35g are purified by dissolving it in a mixture of EtOH (250ml) and 2N NaOH (100ml), then hot 2N HCl is added to the boiling solution until the pH is 4-5. After cooling for a few hours, the solid is filtered off and dried in a vacuum [m 233-235°(dec)]. [Chambers et al. *J Chem Soc* 2433 1949, *Beilstein* 14 III 1566, 14 IV 2373.]

**N,N,N-Trimethyl glycinehydrazide chloride (Girard Reagent T, 2-hydrazino-N,N,N-trimethyl-2-oxoethanaminium chloride)** [123-46-6] M 167.6, m 192°. It is purified by crystallisation from absolute EtOH (slight decomposition) until it has only a slight odour. Store it in well-stoppered containers because it is very hygroscopic. It is very soluble in H<sub>2</sub>O, AcOH and glycerol but slightly soluble in EtOH (0.66%). It forms water-soluble hydrazones with carbonyl compounds. [*Beilstein* 4 III 1133.]

**N-Tris-(hydroxymethyl)methylglycine (TRICINE)** [5704-04-1] M 179.2, m 186-188°(dec),  $pK_1^{20}$  ~2.3,  $pK_2^{20}$  8.15. Crystallise Tricine from EtOH and water. [Good et al. *Methods Enzymol* 24B 53 1968, McGothlin & Jordan *Analyt Lett* 9 245 1976, *Beilstein* 18 III/IV 3454.]

**L-Tryptophan** [73-22-3] M 204.3, m 278°, 281-282°, 290°,  $[\alpha]_D^{20}$  -33.4° (EtOH),  $[\alpha]_{546}^{20}$  -36° (c 1, H<sub>2</sub>O),  $[\alpha]_D^{28}$  +28° (c 2.1, 10% HCl),  $pK_1^{25}$ -6.23 (aqueous H<sub>2</sub>SO<sub>4</sub>),  $pK_2^{25}$  2.46,  $pK_3^{25}$  9.41,  $pK_4^{25}$  14.82 (acidic NH, in aqueous NaOH). Crystallise L-tryptophan from H<sub>2</sub>O/EtOH, wash it with anhydrous diethyl ether and dry it at room temperature in a vacuum over P<sub>2</sub>O<sub>5</sub>. It sublimes at 220-230°/0.03mm with 99% recovery and unracemised [Gross & Gradsky *J Am Chem Soc* 77 1678 1955]. [Cox & King *Org Synth Coll Vol II* 612 1943, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 2316-2345 1961, *Beilstein* 22 IV 6765.]

**Tyrocidine A (cyclic decapeptide antibiotic with two D-Phe amino acids)** [1481-70-5] M 1268.8, m 240°(dec),  $[\alpha]_D^{25}$  -115° (c 0.91, MeOH). Crystallise tyrocidine A as the *hydrochloride* from MeOH or EtOH/HCl. [Paladin & Craig *J Am Chem Soc* 76 688 1954, King & Craig *J Am Chem Soc* 77 6624 1955, Okamoto et al. *Bull Chem Soc Jpn* 50 231 1977, *Beilstein* 26 III/IV 4280.]

**L-Tyrosine** [60-18-4] M 181.2, m 290-295°(dec), 294-300°(dec),  $[\alpha]_D^{25}$  -10.0° (5M HCl),  $pK_1^{25}$  2.18 (CO<sub>2</sub>H),  $pK_2^{25}$  9.21 (OH),  $pK_3^{25}$  10.47 (NH<sub>3</sub><sup>+</sup>). Likely impurities are L-cysteine and the ammonium salt. L-Tyrosine is dissolved in dilute ammonia, then crystallised by adding dilute acetic acid to pH 5. Also, crystallise it from H<sub>2</sub>O or EtOH/H<sub>2</sub>O, and dry it at room temperature in a vacuum over P<sub>2</sub>O<sub>5</sub>. It sublimes at 235-240°/0.03mm with 99.2% recovery and unracemised [Gross & Gradsky *J Am Chem Soc* 77 1678 1955]. [Albert *Biochem J* 50 690 1952, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 2348-2366 1961, *Beilstein* 14 IV 2264.]

**L-Valine** [72-18-4] M 117.2, m 305-308°(dec), 315°,  $[\alpha]_D^{17}$  +28.4° (c 2, 5M HCl),  $pK_1^{20}$  2.38 (CO<sub>2</sub>H),  $pK_2^{20}$  9.59 (NH<sub>3</sub><sup>+</sup>). Crystallise L-valine from water by addition of EtOH. It sublimes at 178-188°/0.03mm with 99.3% recovery and unracemised [Gross & Gradsky *J Am Chem Soc* 77 1678 1955]. [Perrin *J Chem Soc* 3125 1958, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, Vol 3 pp 2368-2377 1961, *Beilstein* 4 IV 2659.]

## PROTEINS, ENZYMES, DNA and RNA

**Abrin A and C (agglutinins from *Abrus seeds*)** [1393-62-0]  $M_r$  63,000-67,000. These are toxic lectins (proteins) from seeds of *Abrus precatorius*. The yellow-white powder is purified by successive chromatography on DEAE-Sephadex A-50, carboxymethylcellulose, and DEAE-cellulose. Abrin A is more positively charged on the DEAE-cellulose column and has been crystallised from  $(\text{NH}_4)_2\text{SO}_4$  by the free interface diffusion technique. Its molecular weight (by sedimentation equilibrium) is 60,000, whereas Abrin C has molecular weight of 63,800. Treatment of A with mercaptoethanol at 100°/2 hours followed by SDS-PAGE gave a main band with  $M_r$  32,000 and two very weak bands, whereas C (which is more toxic) gave two intense bands with  $M_r$  28,000 and 33,000. [Wei et al. *J Biol Chem* **249** 3061 1974.] Abrin C has been crystallised for X-ray analysis by the free interface diffusion technique described by Salemm [Arch Biochim Biophys **151** 533 1972]. The crystals were grown at 37° in Pyrex tubes (5 x 30 cm) by layering 50 $\mu$ l of protein solution (22mg/ml) over 100 $\mu$ l of unbuffered 70% saturated  $(\text{NH}_4)_2\text{SO}_4$  [Wei & Einstein *J Biol Chem* **249** 2985 1974.] [UV and CD: Herrmann & Behnke *Biochem Biophys Acta* **621** 43 1980, for physical and chemical properties see *Biochem Biophys Acta* **667** 397 1981, Beilstein **22** III/IV 6776.]

**Acetoin dehydrogenase [from beef liver, acetoin NAD oxidoreductase]** [9028-49-3]  $M_r$  76000 [EC 1.1.1.5]. Purify it via the acetone cake, then Ca-phosphate gel filtration (unabsorbed), lyophilised and then fractionated through a DEAE-22 cellulose column. The  $K_m$  for diacetyl is 40 $\mu$ M, and for NADH it is 100 $\mu$ M in phosphate buffer at pH 6.1. [Burgos & Martin *Biochim Biophys Acta* **268** 261 1972, **289** 13 1972.]

**$\beta$ -D-N-Acetylglucosaminidase [from *M sexta* insects]** [9012-33-3]  $M_r$  ~61,000 [EC 3.2.1.52]. Purify it by chromatography on DEAE-Biogel, hydroxylapatite chromatography and gel filtration through Sephacryl S200. Two isoforms: a hexosaminidase EI with  $K_m$  177 $\mu$ M ( $V_{max}$  328 sec<sup>-1</sup>) and EII a chitinase with  $K_m$  160 $\mu$ M ( $V_{max}$  103 sec<sup>-1</sup>) with 4-nitrophenyl- $\beta$ -acetylglucosamine as substrate. [Dziadil-Turner *Arch Biochim Biophys* **112** 546 1981.]

**$\beta$ -D-N-Acetylhexosaminidase A and B (from human placenta)** [9012-33-3]  $M_r$  ~61,000 [EC 3.2.1.52]. Purify it by Sephadex G-200 filtration and DEAE-cellulose column chromatography. The hexosaminidase A is further purified by DEAE-cellulose column chromatography, followed by an ECTEOLA-cellulose column, Sephadex-200 filtration, electrofocusing and Sephadex G-200 filtration. Hexosaminidase B is purified by a CM-cellulose column, electrofocusing and Sephadex G-200 filtration. [Srivastava et al. *J Biol Chem* **249** 2034 1974.]

**N-Acetyl neuraminic acid aldolase [from *Clostridium perfringens*, N-acetylneuraminic acid pyruvate lyase]** [9027-60-5]  $M_r$  32,000 [EC 4.1.3.3]. Purify the aldolase by extraction with H<sub>2</sub>O, protamine precipitation,  $(\text{NH}_4)_2\text{SO}_4$  fractionation, Me<sub>2</sub>CO precipitation, acid treatment at pH 5.7 and precipitation at pH 4.5. The equilibrium constant for pyruvate + *n*-acetyl-D-mannosamine  $\rightleftharpoons$  N-acetylneuraminidate at 37° is 0.64. The  $K_m$  for N-acetylneuraminic acid is 3.9mM in phosphate at pH 7.2 and 37°. [Comb & Roseman *Methods Enzymol* **5** 391 1962.] The enzyme from hog kidney (cortex) has been purified 1700-fold by extraction with H<sub>2</sub>O, protamine sulfate precipitation,  $(\text{NH}_4)_2\text{SO}_4$  fractionation, heating between 60-80°, a second  $(\text{NH}_4)_2\text{SO}_4$  fractionation and starch gel electrophoresis. The  $K_m$  for N-acetylneuraminic acid is 1.5mM. [Brunetti et al. *J Biol Chem* **237** 2447 1962.]

**Acyl-coenzyme A Synthase [from beef liver]** [9013-18-7]  $M_r$  57,000 [EC 6.2.1.2]. Purify the synthase by extraction with sucrose/HCO<sub>3</sub> buffer, protamine sulfate precipitation,  $(\text{NH}_4)_2\text{SO}_4$  (66-65%) fractionation (pH 4.35) and a second  $(\text{NH}_4)_2\text{SO}_4$  (35-60%) fractionation (pH 4.35). It has  $K_m$  0.15mM ( $V_{rel}$  1.0) for octanoate and 0.41mM ( $V_{rel}$  2.37) for heptanoate. The  $K_m$  for ATP is 0.5mM, all at pH 9.0 in ethylene glycol buffer at 38°. [Jencks et al. *J Biol Chem* **204** 453 1953, *Methods Enzymol* **5** 467 1962.]

**Acyl-coenzyme A Synthase (from yeast)** [9012-31-1]  $M_r$  ~151,000 [EC 6.2.1.1]. This enzyme has been purified by extraction into phosphate buffer pH 6.8-7.0 containing 2-mercaptoethanol and EDTA, protamine sulfate precipitation, polyethylene glycol fractionation, Alumina  $\gamma$  gel filtration, concentration by  $(\text{NH}_4)_2\text{SO}_4$

precipitation, Bio-Gel A-0.5m chromatography and DEAE-cellulose gradient chromatography. It has  $K_m$  (apparent) 0.24mM (for acetate) and 0.035mM (for CoA); 1.2 mM for ATP and  $Mg^{2+}$  4.0mM. [Frenkel & Kitchens *Methods Enzymol* **71** 317 1981.]

**ADP-Ribosyl transferase (adenyl transferase, polynucleotide, from human placenta)** [9026-30-6]  $M_r \sim 115,000$  [EC 2.4.2.30]. Purify the transferase by making an affinity absorbent for ADP-ribosyltransferase by coupling 3-aminobenzamide to Sepharose 4B. [Burtscher et al. *Anal Biochem* **152** 285 1986.]

**Agglutinin (from peanuts)** [*Arachis hypogaea*] [1393-62-0]  $M_r$  **134,900 (tetramer)**. Agglutinin is purified by affinity chromatography on Sepharose- $\zeta$ -aminocaproyl- $\beta$ -D-galactopyranosylamine. [Lotan et al. *J Biol Chem* **250** 8518 1974.]

**Albumin (bovine and human serum)** [9048-46-8 (bovine), 70024-90-7 (human)]  $M_r \sim 67,000$  (bovine), **69 000 (human)**, UV:  $A_{280nm}^{1\%}$  **6.6 (bovine) and 5.3 (human) in H<sub>2</sub>O**,  $[\alpha]_{546}^{25}$  **-78.2° (H<sub>2</sub>O)**. Albumin is purified by dissolving it in conductivity water and passage at 2-4° through two ion-exchange columns, each containing a 2:1 mixture of anionic and cationic resins (Amberlite IR-120, H-form, Amberlite IRA-400, OH<sup>-</sup> form). This treatment removes ions and lipid impurities. Care is taken to exclude CO<sub>2</sub>, and the solution is stored at -15°. [Möller et al. *Trans Faraday Soc* **57** 312 1961.] More complete lipid removal is achieved by lyophilising the deionised solution, covering the dried albumin (human serum) with a mixture of 5% glacial acetic acid (v/v) in iso-octane (previously dried with Na<sub>2</sub>SO<sub>4</sub>) and allowing it to stand at 0° (without agitation) for upwards of 6 hours before decanting and discarding the extraction mixture, washing with iso-octane, re-extracting, and finally washing twice with iso-octane. The purified albumin is dried under vacuum for several hours, then dialyzed against water for 12-24 hours at room temperature, lyophilised, and stored at -10°C [Goodman *Science* **125** 1296 1957]. It has been recrystallised in high (35%) and in low (22%) EtOH solutions from Cohn's Fraction V.

The **high EtOH recrystallisation** is as follows: To 1kg of Fraction V albumin paste at -5° is added 300ml of 0.4 M pH (pH 5.5) acetate buffer in 35% EtOH pre-cooled to -10° and 430 ml of 0.1 M NaOAc in 25% EtOH also at -10°. Best results are obtained by adding all of the buffer and about half of the NaOAc and stirring slowly for 1 hour. The rest of the NaOAc is added when all the lumps have disintegrated. The mixture is set aside at -5° for several days to crystallise. 35% EtOH (1 L) is then added to dilute the crystalline suspension and lower the ionic strength prior to centrifugation at -5° (yield 80%). The crystals are further dissolved in 1.5 volumes of 15% EtOH/0.02M NaCl at -5° and clarified by filtration through washed, calcined diatomaceous earth. This solution may be recrystallised by re-adjusting to the conditions in the first crystallisation, or it may be recrystallised at 22% EtOH with the aid of a very small amount of decanol (enough to give a final concentration of 0.02%). Note that crystallisation from lower EtOH concentration gave better purification (i.e. by removing globulins and carbohydrates) and producing a more stable product.

The **low EtOH recrystallisation** is as follows: To 1kg of Fraction V at -10° to -15° is added 500ml of 15% EtOH at -5°, stirred slowly until a uniform suspension is formed. To the 15% EtOH (500ml) is added sufficient 0.2M NaHCO<sub>3</sub> solution (125-150ml) at 0° to bring the pH (1:10 dilution) to 5.3. Some temperature rise occurs, and care must be taken to keep the temperature < -5°. If the albumin is incompletely dissolved a small amount of H<sub>2</sub>O is added (100ml at a time at 0°, allowing 15 minutes between additions). Undissolved albumin can be easily distinguished from small amounts of undissolved globulins, or as the last albumin dissolves, the appearance of the solution changes from milky white to hazy grey-green in colour. Keep the solution at -5° for 12 hours and filter by suspending in 15g of washed fine calcined diatomaceous earth, and filtering using a Büchner funnel precoated with coarser diatomaceous earth. The filtrate may require two or more similar filtrations to give a clear solution. To crystallise the filtrate, add through a capillary pipette, and with careful stirring, 1/100 volume of a solution containing 10% decanol and 60% EtOH (at -10°), and seed with the needle-type albumin crystals. After 2-3 days, crystallisation is complete. The crystals are centrifuged off. These are suspended with gentle mechanical stirring in one-third their weight of 0.005 M NaCl pre-cooled to 0°. With careful stirring, H<sub>2</sub>O (at 0°) is added slowly in an amount equal to 1.7 times the weight of the crystals. At this stage there is about 7% EtOH, and the temperature cannot be made lower than -2.5° to -1°. Clarify, and collect as above. [Cohn et al. *J Am Chem Soc* **69** 1753 1947.]

Human serum albumin has been purified similarly with 25% EtOH and 0.2% decanol. The isoelectric points of bovine and human serum albumins are 5.1 and 4.9, respectively.

**Angiotensin (from rat brain)** [70937-97-2]  $M_r$  1524.8. Angiotensin is purified using extraction, affinity chromatography and HPLC [Hermann et al. *Anal Biochem* **159** 295 1986].

**Angiotensin-converting enzyme (ACE, peptidyl peptide hydrolase) (from rabbit lung)** [9015-82-1]  $M$  129,000 Dal (equilibrium sedimentation),  $M_r$  ~140,000 (SDS-PAGE) [EC 3.14.15.1]. Purify ACE by fractionation on DEAE-cellulose, Ca phosphate gel chromatography, elution from Sephadex G-200 and lectin affinity chromatography. The MW varied with glycosidation and is higher by gel filtration. It contains one atom of Zn/mol and has  $K_m$  values for hydrolysis of hippurylhistidinylleucine and angiotensin I of 2.3 and 0.07 mM, and turnover of 15,430 and 792 mol/min/mol at 37°, respectively. The activity is inhibited by EDTA and increased amounts of Ca ions but required Ca ions. [Das & Soffer *J Biol Chem* **250** 6762 1975, Reviewed by Ehlers & Riordan *Biochemistry* **28** 5311 1989.]

**Angiotensinogen (from porcine plasma)** [64315-16-8]  $M_r$  59,400, 60,000, 62,600, 63,600 depending on sialic acid content. This rennin substrate is purified 390-fold from the serum by chromatography on Blue Sepharose, phenyl sepharose, hydroxyapatite and finally by affinity chromatography on 5-hydroxytryptamine (5-HT) sepharose to which it specifically binds to the 5-HT. It is applied to the latter column in 50mM sodium phosphate at pH 7 and after washing, it is eluted by increasing the ionic strength with 100mM sodium phosphate buffer containing 250mM NaCl. The multiple forms are separated by SDS-PAGE and have pI 4.40-4.82. [Campbell et al. *Biochem J* **243** 121 1987.]

**Avidin (from egg white)** [1405-69-2]  $M_r$  ~70,000. Avidin is purified by chromatography of an ammonium acetate solution on CM-cellulose [Green *Biochem J* **101** 774 1966]. It is also purified by affinity chromatography on 2-iminobiotin-6-aminoethyl-Sepharose 4B [Orr *J Biol Chem* **256** 761 1981]. It is a biotin-binding protein.

**Azurin (from *Pseudomonas aeruginosa*)** [12284-43-4]  $M_r$  30,000. Azurin with  $A_{625/280} = 0.56$  is purified by gel chromatography on G-25 Sephadex with 5mM phosphate pH 7 buffer as eluent [Cho et al. *J Phys Chem* **91** 3690 1987]. It is a blue Cu protein used in biological electron transport, and its reduced form is obtained by adding a slight excess of  $Na_2S_2O_4$ . [See *Structure and Bonding* Springer Verlag, Berlin **23** 1 1975.]

**Bromelain (anti-inflammatory Ananase from pineapple)** [37189-34-7]  $M_r$  ~33,000 [EC 3.4.33.4]. This protease has been purified *via* the acetone powder, G-75 Sephadex gel filtration and Bio-Rex 70 ion-exchange chromatography, and has  $A_{1cm}^{1\%}$  20.1 at 280nm. The protease from pineapple hydrolyses benzoyl glycine ethyl ester with a  $K_m$  (app) of 210mM and  $k_{cat}$  of 0.36 sec<sup>-1</sup>. [Murachi *Methods Enzymol* **19** 273 1970, Balls et al. *Ind Eng Chem* **33** 950 1941.]

**Carbonic anhydrase (carbonate hydrolase)** [9001-03-0]  $M_r$  31,000 [EC 4.2.1.1]. Purify carbonic anhydrase by hydroxylapatite and DEAE-cellulose chromatography [Tiselius et al. *Arch Biochem Biophys* **65** 132 1956, *Biochim Biophys Acta* **39** 218 1960], and is then dialysed for crystallisation. A 0.5 to 1% solution of the enzyme in 0.05 M Tris-HCl pH 8.5 is dialysed against 1.75M solution of  $(NH_4)_2SO_4$  in the same buffer, and this solution is slowly increased in salt concentration by periodic removal of small amounts of dialysate and replacing with an equal volume of 3.5M  $(NH_4)_2SO_4$ . The final salt concentration, in which the DEAE-cellulose fractions give beautiful birefringent suspensions of crystals, ranged from 2.4 to 2.7M and appeared first as fine crystals, then underwent transition to thin fragile plates. Carbonic anhydrase is a Zn enzyme which exists as several isoenzymes of varying degrees of activity [J *Biol Chem* **243** 6474 1968, crystal structure: *Nature, New Biology* **235** 131 1972; see also P.D. Boyer Ed. *The Enzymes* Academic Press NY, pp 587-665 1971].

**Carboxypeptidase A (from bovine pancreas, peptidyl-L-aminoacid lyase)** [11075-17-5]  $M_r$  34,600 [EC 3.4.17.1]. Carboxypeptidase A is purified by DEAE-cellulose chromatography, activation with trypsin and dialysed against 0.1M NaCl, yielding crystals. It is recrystallised by dissolving in 20 ml of M NaCl and dialysed for 24 hours each against the following salts present in 500ml of 0.02M sodium veronal pH 8.0, 0.5M NaCl, 0.2M NaCl and 0.15M NaCl. The last dialysate usually induces crystallisation. If it does not crystallise, then

dialyse the last solution against 0.02M sodium veronal containing 0.10M NaCl. Only 2 or 3 re-crystallisations are required to attain maximum activity. [Cox et al. *Biochemistry* **3** 44 1964.] Enzyme activity is measured by hydrolysing hippuryl-L-phenylalanine (or phenylacetic acid) and observing the rate of change of optical density at 254nm (reaction extinction coefficient is  $\sim 0.592 \text{ cm}^2/\mu\text{mole}$  at pH 7.5) [Bergmyer *Methods in Enzymatic Analysis* (Academic Press) **1** 436 1974].

**Cathepsin B (from human liver)** [9047-22-7]  $M_r$  27,500 [EC 3.4.22.1]. Cathepsin B is purified by affinity chromatography on the semicarbazone of Gly-Phe-glycinal-linked to Sepharose 4B, with elution by 2,2'-dipyridyl disulfide [Rich et al. *Biochem J* **235** 731 1986, *Methods Enzymol* **80** 551 1981].

**Cathepsin D (from bovine spleen)** [9025-26-7]  $M_r$  56,000 [EC 3.4.23.5]. Cathepsin D is purified on a CM column after  $(\text{NH}_4)_2\text{SO}_4$  fractionation and dialysis, then starch-gel electrophoresis and by ultracentrifugal analysis. Finally chromatograph on a DEAE column [Press et al. *Biochem J* **74** 501 1960].

**Ceruloplasmin (from human blood plasma)** [9031-37-2]  $M_r$  134,000. This blue protein is the principal Cu transporter (up to 90% of circulating Cu) and is purified by precipitation with polyethylene glycol 4000, batchwise adsorption and elution from QAE-Sephadex, and gradient elution from DEAE-Sepharose CL-6B. Ceruloplasmin is thus purified 1640-fold and is homogeneous on anionic polyacrylamide gel electrophoresis (PAGE), SDS-PAGE, isoelectric focusing and low-speed equilibrium centrifugation. It has  $\lambda_{\text{max}}$  at 280, 260nm ( $A_{1\text{cm}}^{1\%} \approx 0.68$ ). [Oesthuizen *Anal Biochem* **146** 1 1985, Cohn et al. *J Am Chem Soc* **68** 459 1946.]

**Chemokines.** These are small proteins formed from longer precursors and are chemo-attractants for lymphocytes and lymphoid organs. They are characterised by having cysteine groups in specific relative positions. The two largest families are the  $\alpha$  and  $\beta$  families that have four cysteine residues arranged (C-X-C) and (C-C) respectively. The mature chemokines have  $\sim 70$  amino acids with internal cys S-S bonds and attract myeloid type cells *in vitro*. The  $\gamma$ -family (Lymphotactin) has only two cys residues. The  $\delta$ -family (Neurotactin, Fractalkine) has the C-C-X-X-X-C sequence (*ca* 387 amino acids), binds to membrane and promotes adhesion of lymphocytes. The soluble domain of human Fractalkine "chemo-attracts" monocytes and T cells. Several chemokines are available commercially (some prepared by recombinant DNA techniques), including 6CKine/exodus/SLC which belongs to the  $\beta$ -family with 6 cysteines (110 amino acids, mature protein), as the name implies (C-C-C-C-X.....X-C-C) and homes lymphocytes to secondary lymphoid organs with lymphocyte adhesion antitumor properties. Other chemokines available are C10 ( $\beta$ CC) and Biotaxin. Several chemokine receptors and antibodies are available commercially and can generally be used without further purification. [Murphy "Molecular biology of lymphocyte chemo-attractant receptors" in *Ann Rev Immunol* **12** 593 1994.]

**Chirazymes.** These are commercially available enzymes, e.g. lipases, esterases, that can be used for the preparation of a variety of optically active carboxylic acids, alcohols and amines. They can cause regio and stereospecific hydrolysis and do not require cofactors. Some can be used also for esterification or transesterification in neat organic solvents. The proteases, amidases and oxidases are obtained from bacteria or fungi, whereas esterases are from pig liver and thermophilic bacteria. For preparative work the enzymes are covalently bound to a carrier and do not therefore contaminate the reaction products. Chirazymes are available from Roche Molecular Biochemicals and are used without further purification.

**$\alpha$ -Chymotrypsin** [9004-07-3]  $M_r$   $\sim 25000$  [EC 3.4.21.1].  $\alpha$ -Chymotrypsin is crystallised twice from four-tenths saturated ammonium sulfate solution, then dissolved in 1mM HCl and dialysed against 1mM HCl at 2-4°. The solution is stored at 2° [Lang et al. *J Am Chem Soc* **80** 4923 1958].

**Citric acid cycle components (from rat heart mitochondria).** These are resolved by anion-exchange chromatography [LaNoue et al. *J Biol Chem* **245** 102 1970].

**Clostripain** [9028-00-6]  $M_r$   $\sim 55,000$  [EC 3.4.22.8]. Clostripain is isolated from *Clostridium histolyticum* collagenase by extraction in pH 6.7 buffer, followed by hydroxylapatite chromatography with a 0.1-0.2 M phosphate gradient, then Sephadex G-75 gel filtration with 0.05M phosphate pH 6.7, dialysis and a second

hydroxylapatite chromatography (gradient elution with 0.1M  $\rightarrow$  0.3M phosphate, pH 6.7) purification. It has proteinase and esterase activity and is assayed by hydrolysing *N*-benzoyl-L-arginine methyl ester. [Mitchell & Harrington *J Biol Chem* **243** 4683 1968, *Methods Enzymol* **19** 635 1970.]

**Colicin E1 (from *E. coli*)** [11032-88-5].  $M_r$  56,000, pI 9.5. Colicin E1 is purified (8.6-fold to Specific Activity of  $1.5 \times 10^5$  units/mg) from *E. coli* JC411 by salt extraction of extracellular-bound colicin followed by  $(NH_4)_2SO_4$  (40-60% saturation) fractionation and ion-exchange chromatography on a DEAE-Sephadex A 50 column, and then by CM-Sephadex column chromatography [Schwartz & Helinski *J Biol Chem* **246** 6318 1971].

**Collagenase (from human polymorphonuclear leukocytes)** [9001-12-1]  $M_r$  68,000-125,000 [EC 3.4.24.3]. Collagenase is purified by using *N*-ethylmaleimide to activate the enzyme, and wheat germ agglutinin-agarose affinity chromatography [Callaway et al. *Biochemistry* **25** 4757 1986].

**Copper-zinc-superoxide dismutase (from blood cell haemolysis)** [9054-89-1]  $M_r$  ~32,000 [EC 1.15.1.1]. The dismutase is purified by DEAE-Sephadex and copper chelate affinity chromatography. The preparation is homogeneous by SDS-PAGE, by analytical gel filtration chromatography and by isoelectric focusing [Weselake et al. *Anal Biochem* **155** 193 1986, Fridovich *J Biol Chem* **244** 6049 1969].

**Cytochrome  $c_1$  (from horse, beef or fishes' heart, or pigeon breast muscle)** [9007-43-6]  $M_r$  ~13,000. Cytochrome  $c_1$  is purified by chromatography on CM-cellulose (CM-52 Whatman) [Brautigan et al. *Methods Enzymol* **53D** 131 1978]. It has a high PI (isoelectric point) and has been purified further by adsorption onto an acidic cation exchanger, e.g. Amberlite IRC-50 (polycarboxylic) or in ground form Amberlite XE-40 (100-200 mesh) or Decalco-F (aluminium silicate), where the non-cytochrome protein is not adsorbed and is readily removed. The cytochrome is eluted using a solution containing 0.25g ions/L of a univalent cation at pH 4.7 adsorbed onto the  $NH_4^+$  salt of Amberlite IRC-50 at pH 7, washed with  $H_2O$  and then with 0.12M  $NH_4OAc$  to remove non-cytochrome protein. When the cytochrome begins to appear in the eluate, then the  $NH_4OAc$  concentration is increased to 0.25 M. The fractions with  $ca$   $Fe = 0.465-0.467$  are collected, dialysed against  $H_2O$  and adsorbed onto a small IRC-50 column and eluted with 0.5M  $NH_3$ , then dialysed and lyophilised. (A second fraction II can be eluted from the first resin with 0.5M  $NH_3$  but is discarded). [Keilin & Hartree *Biochemical Preparations* **1** 1 1952, Margoliash *Biochemical Preparations* **8** 33 1957.]

*Cytochrome c has been recrystallised as follows:* The above eluate ( $ca$  100ml) is dialysed against  $H_2O$  (10 vols) at 4° for 24 hours (no more), then passed through an XE-40 column (2 x 1 cm above) which is equilibrated with 0.1M  $NH_4OAc$  pH 7.0. The column is washed with 0.1%  $(NH_4)_2SO_4$  pH 8.0, and the dark red resin in the upper part of the column is collected and in 0.1%  $(NH_4)_2SO_4$  pH 8.0 is transferred to another column (7mm diameter) and the cytochrome c is eluted with 5%  $(NH_4)_2SO_4$  pH 8.0. More than 98% of the red colour is collected in a volume of  $ca$  4ml in a weighed centrifuge tube. Add a drop of octanol and 0.43g of  $(NH_4)_2SO_4/g$  of solution. When the salt has dissolved, ascorbic acid (5mg) is added as well as a few drops of 30% aqueous  $NH_3$ , and it is kept at 10° for 10 minutes (turns lighter colour due to reduction). Then add finely powdered  $(NH_4)_2SO_4$  in small portions (stir with a glass rod) until the solution becomes turbid. Stopper the tube tightly, and set aside at 15-25° for 2 days while the cytochrome c separates as fine needles or rosettes. Further  $(NH_4)_2SO_4$  (20mg) are added per ml of suspension and kept in the cold for a few days to complete the crystallisation. The crystals are collected by centrifugation (5000xg), suspended in saturated  $(NH_4)_2SO_4$  (pH 8.0 at 10°), then centrifuged again. For recrystallisation the crystals are dissolved in the least volume of  $H_2O$ , one drop of ammonia and 1 mg of ascorbic acid are added and the above process is repeated. The yield of twice recrystallised cytochrome c from 2Kg of muscle is  $ca$  200 mg, but this varies with the source and freshness of the muscle used. The crystals are stored as a solid after dialysis against 0.08M NaCl or 0.1M sodium buffer and lyophilising, or as a suspension in saturated  $(NH_4)_2SO_4$  at 0°. [Hagihara et al. *Biochemical Preparations* **6** 1 1958.]

*Purity of cytochrome c:* This is checked by the ratio of the absorbance at 500nm (reduced form) to 280nm (oxidised form), i.e.  $\epsilon_{500}/\epsilon_{280}$  should be between 1.1 and 1.28, although values of up to 1.4 have been obtained for pure preparations.

For the preparation of the *reduced form* see Margoliash *Biochemical Preparations* **5** 33 1957 and Yonetani *Biochemical Preparations* **11** 19 1966.

Cytochrome from *Rhodospirillum rubrum* ( $\epsilon_{270}/\epsilon_{551}$  0.967) is purified by chromatography on a column of CM-Whatman cellulose [Paleus & Tuppy *Acta Chem Scand* **13** 641 1959].

**Cytochrome c oxidase (from bovine heart mitochondria).** [9001-16-5]  $M_r$  100,000/haeme [EC 1.9.3.1]. The oxidase is purified by selective solubilisation with Triton X-100 and subsequently with lauryl maltoside, finally by sucrose gradient centrifugation [Li et al. *Biochem J* **242** 417 1978].

It has also been purified by extraction in 0.02 M phosphate buffer (pH 7.4) containing 2% of cholic acid (an inhibitor which stabilises as well as solubilises the enzyme) and fractionated with  $(\text{NH}_4)_2\text{SO}_4$  collecting the 26-33% saturation cut and refractionating again and collecting the 26-33% saturation fraction. The pellet collected at 10,000x g appears as an oily paste. The cholate needs to be removed to activate the enzyme as follows: The precipitate is dissolved in 10ml of 0.1M phosphate buffer pH 7.4, containing 1% of Tween-80 and dialysed against 1L of 0.01 M  $\text{PO}_4$  buffer (pH 7.4) containing 1% of Tween-80 for 10 hours at 0° and aliquoted. The enzyme is stable at 0° for 2 weeks and at -15° for several months. It is assayed for purity (see reference) by oxidation of reduced cytochrome c ( $K_m$  10 $\mu\text{M}$ ). [Yonetani *Biochemical Preparations* **11** 14 1966, *J Biol Chem* **236** 1680 1961.]

**Cytokines** See chemokines, interferons, interleukins.

**Deoxyribonucleic acid (from plasmids).** These are purified by two buoyant density ultracentrifugations using ethidium bromide-CsCl. The ethidium bromide is extracted with  $\text{Et}_2\text{O}$ , and the DNA is dialysed against buffered EDTA and lyophilised. [Marmur & Doty *J Mol Biol* **5** 109 1962, Guerry et al. *J Bacteriol* **116** 1064 1973.] See “Introduction” in this chapter.

**Dermatan sulfate (chondroitin sulfate B from pig skin)**  $M_r$  20,000-36,000 [54328-33-5 (*Na salt*)]. Dermatan sulfate is purified by digestion with papain and hyaluronidase, and fractionation using aqueous  $\text{EtOH}$ . [Gifonelli & Roden *Biochemical Preparations* **12** 1 1968.]

**Dihydrofolate reductase (from *Mycobacterium phlei*)** [9002-03-3]  $M_r$  ~18,000 [EC 1.5.1.3]. Dihydrofolate reductase is purified by  $(\text{NH}_4)_2\text{SO}_4$  precipitation, then fractionation on a Sephadex G-75 column, applied to a Blue Sepharose column and eluted with 1mM dihydrofolate. [Al Rubeai & Dole *Biochem J* **235** 301 1986.]

**Dihydropteridine reductase (from sheep liver)** [9074-11-7]  $M_r$  52,000 [EC 1.6.99.7]. Dihydropteridine reductase is purified by fractionation with ammonium sulfate, dialysed against Tris buffer, adsorbed and eluted from hydroxylapatite gel. It is then run through a DEAE-cellulose column and also subjected to Sephadex G-100 filtration. [Craine et al. *J Biol Chem* **247** 6082 1972.]

**Dihydropteridine reductase (from human liver)** [9074-11-7]  $M_r$  52,000 [EC 1.6.99.7]. Dihydropteridine reductase is purified to homogeneity on a naphthoquinone affinity adsorbent, followed by DEAE-Sephadex and CM-Sephadex chromatography. [Firgaira, Cotton and Danks, *Biochem J* **197** 31 1981.] [For other dihydropteridine reductases see Armarego et al. *Med Res Rev* **4**(3) 267 1984.]

**3,4-Dihydroxyphenylalanine-containing proteins.** Boronate affinity chromatography is used in the selective binding of proteins containing 3,4-dihydroxyphenylalanine to a *m*-phenylboronate agarose column and eluted with 1M  $\text{NH}_4\text{OAc}$  at pH 10. [Hankus et al. *Anal Biochem* **150** 187 1986.]

**Dipeptidyl aminopeptidase (dipeptidyl peptidase IV, from rat brain)** [9031-94-1, 54249-88-6]  $M_r$  87,500 (monomer SDS-PAGE), (88,107 from nucleotide sequence), up to 4000,000 [EC 3.4.14.5]. The aminopeptidase is purified about 2000-fold by column chromatography on CM-cellulose, hydroxylapatite and Gly-Pro AH-Sepharose. [Imai et al. *J Biochem (Tokyo)* **93** 431 1983, Schomburg & Schomburg *Springer Handbook of Enzymes* 2nd Edn vol 6 p 286 2002.]

**DNA (deoxyribonucleic acids).** The essential structures of chromosomes are DNA and contain the genetic “blueprint” in the form of separate genes. They are made up of the four deoxyribonucleic acids (nucleotides): adenylic acid, guanylic acid, cytidylic acid and thymidylic acid (designated A, G, C, T respectively) linked together by their phosphate groups in ester bonds between the 3' and 5' hydroxy groups of the 2'-deoxy-D-ribose moiety of the nucleotides. The chains form a double-stranded spiral (helix) in which the two identical nucleotide

sequences run antiparallel with the heterocyclic bases hydrogen bonded (A...T, G...C) forming the “ladder” between the strands. Short sequences of DNA are available commercially, are commercially custom made or synthesised in a DNA synthesiser and purified by HPLC. Their purity can be checked by restriction enzyme cleavage followed by gel electrophoresis, or directly by gel electrophoresis or analytical HPLC. Commercial DNAs are usually pure enough for direct use but can be further purified using commercially available kits involving binding to silica or other matrices and eluting with Tris buffers. There are now rapid “throughput” techniques for sequencing DNA which are very accurate.

**Dopamine- $\beta$ -hydroxylase (from bovine adrenal medulla)** [9013-38-1]  $M_r \sim 290,000$  [EC 1.14.17.1]. The Cu-containing glycoprotein enzyme has been isolated by two procedures. The first is an elaborate method requiring extraction, two  $(\text{NH}_4)_2\text{SO}_4$  fractionations, calcium phosphate gel filtration, EtOH fractionation, DEAE-cellulose chromatography followed by two Sephadex-G200 gel filtrations giving enzyme with a specific activity of 65 Units/mg. [Friedman & Kaufman *J Biol Chem* **240** 4763 1965, Rush et al. *Biochem Biophys Res Commun* **61** 38 1974.] The second procedure is much gentler and provides good quality enzyme. Sedimented chromaffin vesicles are lysed in 10 volumes of 5mM K-phosphate buffer pH 6.5 using a loosely fitting Teflon-glass homogeniser. The mixture is centrifuged at 40,000xg/0.5 hours, and the supernatant is diluted with an equal volume of 100mM phosphate buffer (pH 6.5) containing 0.4M NaCl. This lysate is applied to a concanavalin A-Sepharose column (4 x 0.7cm) which had been equilibrated with 50 mM of phosphate buffer (pH 6.5 + 0.2M NaCl) with a flow rate of  $\sim 0.3$  ml/minute. The column is washed thoroughly with the buffer until  $\text{OD}_{280\text{nm}}$  is 0.005. The enzyme is then eluted with the same buffer containing 10%  $\alpha$ -methyl-D-mannoside (flow rate 0.1 ml/minute), and the enzyme is collected in 20-column volumes. The pooled eluate is concentrated by ultrafiltration in an Amicon Diaflo stirrer cell using an XM100A membrane. The concentrated enzyme is dialysed against 50mM phosphate buffer (pH 6.5) containing 0.1% NaCl. The enzyme gives one band (+ two very weak bands) on disc gel electrophoresis indicating better than 93% purity (67% fold purification) and has a specific activity of 5.4 Units/mg. [Rush et al. *Biochem Biophys Res Commun* **57** 1301 1974, Stewart & Klinman *Ann Rev Biochem* **57** 551 1988.]

**Exonucleases.** Like the endonucleases they are restriction enzymes which act at the 3' or 5' ends of linear DNA by hydrolysing off the nucleotides. Although they are highly specific for hydrolysing nucleotides at the 3' or 5' ends of linear DNA, the number of nucleotides cleaved is time dependent and usually has to be estimated from the time allocated for cleavage. Commercially available exonucleases are used without further purification.

**Ferritin (from human placenta)** [9007-73-2]  $M_r \sim 445,000$  (Fe free protein). The purification of this major iron-binding protein is achieved by homogenisation in water and precipitation with ammonium sulfate, repeating the cycle of ultracentrifugation, and molecular sieve chromatography through a Sephadex 4B column. Isoelectric focusing reveals a broad spectrum of impurities which can be separated by ion-exchange chromatography on Sephadex A-25 and stepwise elution. [Konijn et al. *Anal Biochem* **144** 423 1985.]

**Fibrinogen (from human plasma)** [9001-32-5]  $M_r$  341,000. This protein is made up of  $2\alpha_1, 2\beta$  and  $2\gamma$  subunits connected by disulfide bridges. A likely impurity is plasminogen. It is purified by glycine precipitation [Mosesson & Sherry *Biochemistry* **5** 2829 1966] to obtain fractions 1-2, then further purified [Blombäck & Blombäck *Arkiv Kemi* **10** 415 1956] and contaminating plasminogen is removed by passage through a lysine-Sepharose column. Such preparations are at least 95% clottable as determined by Mosesson and Sherry's method (above ref.) in which the  $\text{OD}_{280}$  is measured before and after clotting with 5 Units/ml of thrombin ( $>3000\text{U/mg}$ ). All fibrinogen preparations are treated with calf intestinal alkaline phosphatase to convert any fibrinogen peptide-AP to fibrinogen peptide-A by removing serine-bound phosphate. Solutions are then lyophilised and stored at  $-20^\circ$ . [Higgins & Shafer *J Biol Chem* **256** 12013 1981.] It is sparingly soluble in  $\text{H}_2\text{O}$ . Aqueous solutions are viscous with isoelectric point at pH 5.5. It is readily denatured by heating above  $56^\circ$  or by chemical agents, e.g. salicylaldehyde, naphthoquinone sulfonates, ninhydrin or alloxan. [Edsall et al. *J Am Chem Soc* **69** 2731 1947, Purification: Cama et al. *Naturwissenschaften* **48** 574 1961, Lorand & Middlebrook

*Science* **118** 515 1953, cf. Fuller in *Methods Enzymol* **163** 474 1988.]

For plasminogen-deficient fibrinogen from blood plasma, the anticoagulated blood is centrifuged and the plasma is frozen and washed with saline solution. It is treated with charcoal, freeze-thawed and dialysed *versus* Tris/NaCl buffer. [Maxwell & Nikel *Biochemical Preparations* **12** 16 1968.]

**Fibronectin (from human plasma)** [86088-83-7]  $M_r \sim 220,000$ . This glycoprotein contains 5-12% of carbohydrate. It has been purified by glycine fractionation and DEAE-cellulose chromatography. This material is dissolved in 0.25M Tris-phosphate buffer pH 7.0, diluted to 20% and glycine added gradually till 2.1M when the temperature falls to below 15°. The precipitate contains mainly fibrinogen. The supernatant is discarded, and the precipitate is treated with an equal volume of H<sub>2</sub>O, cooled (to 0°) and precipitated by adding EtOH to 16% (v/v) at -4°. The precipitate contains some CI (Cold Insoluble) globulin, fibronectin and small quantities of other proteins. To remove these the precipitate is dissolved in 0.25M Tris-phosphate buffer (pH 7.0) *ca* 0.5% and purified by DEAE-cellulose chromatography after diluting the buffer to 0.05M buffer. [Morrison et al. *J Am Chem Soc* **70** 3103 1948, Mosesson & Umfleet *J Biol Chem* **245** 5728 1970, Mosesson & Amrani *Blood* **56** 145 1980, Akiyama & Yamada *Adv Enzymol* **59** 51 1987.]

**Follicle Stimulating Hormone (FSH, follitropin)** [9002-68-0]  $M_r \sim 36,000$ . FSH is purified by Sephadex G100 gel filtration followed by carboxymethyl-cellulose with NH<sub>4</sub>OAc pH 5.5. The latter separates luteinising hormone from FSH. Its solubility in H<sub>2</sub>O is 0.5%. It has an isoelectric point of 4.5. A solution of 1mg in saline (100ml) can be kept at 60° for 0.5 hour. Activity is retained in a solution at pH 7-8 for 0.5 hour at 75°. The activity of a 50% aqueous EtOH solution is destroyed at 60° in 15 minutes. [Bloomfield et al. *Biochim Biophys Acta* **533** 371 1978, Hartree *Biochem J* **100** 754 1966, Pierce & Parsons *Ann Rev Biochem* **50** 465 1981.]

**β-Galactosidase (from bovine testes)** [9031-11-2]  $M_r$  510,000 [EC 3.2.1.23]. It is purified 600-fold by (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> precipitation, acetone fractionation and affinity chromatography on agarose substituted with terminal thio-β-galactopyranosyl residues. [Distlern & Jourdan *J Biol Chem* **248** 6772 1973.]

**Glucose oxidase (from *Aspergillus niger*)** [9001-37-0]  $M_r$  186,000, [EC 1.1.3.4]. The oxidase is purified by dialysis against deionized water at 6° for 48 hours and by molecular exclusion chromatography with Sephadex G-25 at room temperature. [Holt & Cotton *J Am Chem Soc* **109** 1841 1987.]

**Glucose-6-phosphate dehydrogenase** [9001-40-5]  $M_r$  128,000 (from Baker's yeast), 63,300 (from rat mammary gland) [EC 1.1.1.49]. The enzyme is useful for measuring pyridine nucleotides in enzyme recycling. The enzyme from Baker's yeast has been purified by (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> fractionation, Me<sub>2</sub>CO precipitation, a second (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> fractionation, concentration by DEAE-SF chromatography, a third (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> fractionation and recrystallisation. Crystallisation is induced by addition of its coenzyme NADP, which in its presence causes rapid separation of crystals at (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> concentration much below that required to precipitate the amorphous enzyme. To recrystallise, the crystals are dissolved in 0.01M NADP (pH 7.3) with (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> at 0.55 saturation, and the crystals appear within 10 to 60 minutes. After standing for 2-3 days (at 4°) the (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> is increased to 0.60 of saturation, and more than 80% of the activity in the original crystals is recovered in the fresh crystals. [Noltmann et al. *J Biol Chem* **236** 1255 1961]. Large amounts can be obtained from rat livers. The livers are extracted with 0.025M phosphate buffer (pH 7.5) and precipitated with 3M (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> (70% of activity). The precipitate is dissolved in 3 volumes of 0.025M phosphate (pH 7.5), dialysed against this buffer + 0.2mM EDTA at 4° for 5 hours, then diluted to 1% protein and the nucleic acids are precipitated by addition of 0.4 volumes of 1% protamine sulfate. (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> is added to a concentration of 2M (pH adjusted to 7.0 with NH<sub>3</sub>), the precipitate is discarded and the supernatant is adjusted to 2.8M (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, dialysed, and the protein is adjusted to 1% and treated with Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> gel. The gel is added in three steps (1.5ml of 0.4% gel/ml per step), and the gel is removed by centrifugation after each addition. The third gel adsorbed 50% of the activity. The gel is eluted with 0.2M phosphate buffer (pH 7.4, 40ml/g of gel; 60% recovery). The extract is precipitated in 3 volumes of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> (adjusted to 4M) to give enzyme with an activity of 30μmoles/mg of protein per hour. [Lowry et al. *J Biol Chem* **236** 2746 1961.] The  $K_m$  values for the yeast enzyme are 20μM for G-6P and

2 $\mu$ M for NADP (Tris pH 8.0, 10<sup>-2</sup> M MgCl<sub>2</sub>, 38°) [Noltmann & Kuby *The Enzymes* VII 223 1963].

**Glutathione S-transferase (human liver)** [50812-37-8]  $M_r$  25,000 [EC 2.5.1.18]. It is purified by affinity chromatography using a column prepared by coupling glutathione to epoxy-saturated Sepharose. After washing contaminating proteins, the pure transferase is eluted with buffer containing reduced glutathione. The solution is then concentrated by ultrafiltration, dialysed against phosphate buffer at pH ~7 and stored in the presence of dithiothreitol (2mM) in aliquots at < -20°. [Simons & Vander Jag *Anal Biochem* 52 334 1977.]

**Glyceraldehyde-3-phosphate dehydrogenase** [9001-50-7]  $M_r$  144,000 [EC 1.2.1.12]. Purify the dehydrogenase from rabbit muscle by extraction with 0.03N KOH and precipitate it with (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> (0.52 of saturation). The clear supernatant is adjusted to pH 7.5, and NH<sub>3</sub> is added dropwise to pH 8.2-8.4. Crystals appear sometimes even without seeding. The crystals are dissolved in H<sub>2</sub>O, filtered to remove suspended material and 2 volumes of saturated (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> at pH 8.2-8.4 is added. After 1 hour the crystals appear. Recrystallise it in the same way. [Cori et al. *J Biol Chem* 173 605 1948, Furfine & Velick *J Biol Chem* 240 844 1965, *The Enzymes* 7 243 1963, Lui & Huskey *Biochemistry* 31 6998 1992.] The Km values are: NADH (3.3 $\mu$ M) and 1,3-diphosphoglycerate (8x10<sup>-7</sup>M) in pH 7.4 imidazole buffer at 26°, NAD (13 $\mu$ M), glyceraldehyde-3-P (90 $\mu$ M), P<sub>i</sub> (2.9x10<sup>-4</sup>M), and arsenate (69 $\mu$ M) in 8.6 M NaHCO<sub>3</sub> buffer at 26°C. [Orsi & Cleland *Biochemistry* 11 102 1972.]

**Glycerol kinase (from *Candida mycoderma*, *E coli*, rat or pigeon liver glycerokinase)** [9030-66-4]  $M_r$  251,000 [EC 2.7.1.30]. Commercial enzyme has been dialysed against 2mM Hepes, 5mM dithiothreitol and 0.3mM EDTA, followed by several changes of 20mM Hepes and 5mM dithiothreitol prior to storage under N<sub>2</sub> at -20°. [Knight & Cleland *Biochemistry* 28 5728 1989.] The enzyme from pigeon liver is purified by acid-precipitation (acetate buffer at pH 5.1), (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> fractionation, heat treatment (60°/ 1 hour), calcium phosphate gel filtration, a second (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> fractionation, dialysis, elution of inert proteins and crystallisation. This is done by repeatedly extracting the precipitate from the last step with 0.05M sodium pyrophosphate (pH 7.5) containing 1mM EDTA and 0.2M (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> is added. Careful addition of solid (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> to this solution leads to crystallisation of the enzyme. Recrystallisation is repeated. The enzyme is activated by Mg<sup>2+</sup> and Mn<sup>2+</sup> ions and is most stable in solutions in the pH 4.5-5.5 range. The stability is greatly increased in the presence of glycerol. It has Km for glycerol of 60 $\mu$ M and for ATP 9 $\mu$ M in glycine buffer pH 9.8 and 25°. [Kennedy *Methods Enzymol* 5 476 1962.]

**L-Glycerol-3-phosphate dehydrogenase (GDH, from rabbit muscle)** [9075-65-4]  $M_r$  78,000 [EC 1.1.1.8]. The dehydrogenase is recrystallised by adding (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> to 0.45 saturation at pH 5.5 at 4°C, and the small amount of precipitate is removed, then a saturated solution of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> is added dropwise from time to time over several days in the cold room. The crystals are collected and recrystallised until they have maximum activity. The enzyme is stable in half-saturated (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> for several weeks at 4°. The equilibrium [dihydroxyacetone][NADH][H<sup>+</sup>]/[G-3-P][NAD] is 1.0 x 10<sup>-12</sup>M in Tris buffer at 25°. It uses NAD ten times more efficiently than NADP. The Km for G-3-P is 1.1 x 10<sup>-4</sup>M, for NAD it is 3.8 x 10<sup>-4</sup>M and for dihydroxyacetone it is 4.6 x 10<sup>-4</sup>M in phosphate buffer pH 7.0 and at 23.3°. Dihydroxyacetone phosphate and fructose-1,6-diphosphate are inhibitors. [Branowski *J Biol Chem* 180 515 1949, *The Enzymes* 7 85 1963, Young & Pace *Arch Biochem Biophys* 75 125 1958, Walsh & Sallach *Biochemistry* 4 1076 1965.]

**Glycogen synthase (from bovine heart)** [9014-56-6]  $M_r$  60,000 [EC 2.4.1.11]. Purify the synthase by precipitation in the presence of added glycogen by polyethylene glycol, chromatography on DEAE-Sephacel and high-speed centrifugation through a sucrose-containing buffer. [Dickey-Dunkirk & Kollilea *Anal Biochem* 146 199 1985.]

**Haemoglobin A (from normal human blood)** [9008-02-0]  $M_r$  ~64,500, amorphous. Purify it from blood using CM-32 cellulose column chromatography. [Matsukawa et al. *J Am Chem Soc* 107 1108 1985.] For the purification of the  $\alpha$  and  $\beta$  chains see Hill et al. *Biochemical Preparations* 10 55 1963.

**Histones (from S4A mouse lymphoma).** The purification of histones uses a macroprocess column, heptafluorobutyric acid as solubilising and ion-pairing agent and an acetonitrile gradient. [McCroskey et al. *Anal Biochem* **163** 427 1987.]

**Hyaluronidase** [9001-54-1, 37326-33-3]  $M_r$  **43,000 (bovine testes), 89,000 (bacterial)** [EC 3.2.1.35]. Hyaluronidase is purified by chromatography on DEAE-cellulose prior to use. [Distler & Jourdain *J Biol Chem* **248** 6772 1973.]

**D-Hydantoinase** [dihydropyrimidinase, also called 5,6-dihydropyrimidine amidohydrolase, from microorganisms e.g. *Pseudomonas*, *Bacillus*, *Agrobacterium* as well as from mammalian and human tissues] [9030-74-4]  $M$  **51,720 (monomer from amino acid sequence, usually dimer or tetramer)** [EC 3.5.2.2],  $pI$  **~6.5**. This cytosolic enzyme hydrolyses dihydropyrimidines and hydantoins to N-carbamoylamino acids, and with the appropriate substrates are useful for preparing D-amino acids. The enzyme from a recently isolated species of *Agrobacterium* was purified to homogeneity and found to possess hydantoinase activity that was free from dihydropyrimidinase activity. It had an estimated subunit molecular weight of ~66,500 and a theoretical molecular weight of 265,000. The preferred substrates were 5-mono-substituted hydantoins with aromatic groups as shown from the  $K_m$  values. 5,5-Dimethylhydantoin and thio analogues of 5-*p*-hydroxyphenylhydantoins were competitive inhibitors. [Runser & Meyer *Eur J Biochem* **213** 131 1993.]

A commercially available hydantoinase preparation from *Vigna angularis* from aduki bean with a minimum activity of 300U/g is commercially available. These enzymes are generally inhibited by N-carbamoylamino acids (reaction products) 8-hydroxyquinoline, EDTA,  $Sn^{2+}$  and  $Zn^{2+}$ , but are activated by uracil, 2-thiouracil,  $Co^{2+}$ ,  $Fe^{2+}$ ,  $Mg^{2+}$ ,  $Mn^{2+}$  and  $Ni^{2+}$ , with turnovers of ~27,000min<sup>-1</sup> for hydantoin. Their pH-range is 6—9.5, and the temperature range is ~4-60°. D-Hydantoinase genes have been cloned and expressed in *E coli* and the enzymes from several sources have been crystallised.

A unit of enzyme activity is defined as the amount that catalyses the formation of 1mmole of N-carbamoylglycine from hydantoin per minute at pH 9.0 and 40°. [Morin *Enz Microbiol Technol* **15** 208 1993, *Springer Handbook of Enzymes* D. Schonburg & I. Schonburg Eds (A. Chang co-Ed) Springer-Verlag, Berlin, Heidelberg.]

**3-Hydroxy butyrate dehydrogenase (from *Rhodopseudomonas spheroides*)** [9028-38-0]  $M_r$  **~85,000** [EC 1.1.1.30], **amorphous**. Purify the dehydrogenase by two sequential chromatography steps on two triazine dye-Sepharose matrices. [Scavan et al. *Biochem J* **203** 699 1982.]

**Interferons [ $\alpha$ IFN,  $\beta$ IFN and  $\gamma$ IFN].** Interferons are a family of glycosylated proteins and are cytokines which are produced a few hours after cells have been infected with a virus. Interferons protect cells from viral infections and have antiviral activities at very low concentrations (~3 x 10<sup>-4</sup> M; less than 50 molecules are apparently sufficient to protect a single cell). Double-stranded RNAs are very efficient inducers of IFNs. There are three main types of IFNs. The  $\alpha$ IFNs are synthesised in lymphocytes, and the  $\beta$ IFNs are formed in infected fibroblasts. The  $\alpha$  and  $\beta$  families are fairly similar, consisting of *ca* 166 to 169 amino acids. Although  $\gamma$ IFNs are also small glycosylated proteins (*ca* 146 amino acids), they are different because they are not synthesised after viral infections but are produced by lymphocytes when stimulated by **mitogens** (agents that induced cell division).

Several of these IFNs of mouse and human lymphocytes and fibroblasts are available commercially and have been best prepared in quantity by recombinant DNA procedures because they are produced in very small amounts by the cells. The commercial materials do not generally require further purification for their intended purposes. [Pestkas, Interferons and Interferon standards and general abbreviations, *Methods Enzymol*, Wiley & Sons, **119** 1986, ISBN 012182019X, Lengyel, Biochemistry of interferons and their actions, *Ann Rev Biochem* **51** 251-282 1982, De Maeyer & De Maeyer-Guignard, Interferons in *The Cytokine Handbook*, 3rd Edn, Thomson et al. Eds, pp. 491-516 1998 Academic Press, San Diego, ISBN 0126896623.]

**Interleukin (from human source).** Purify these using lyophilisation and desalting on a Bio-Rad P-6DC desalting gel, then two steps of HPLC, first with hydroxylapatite, followed by a TSK-125 size exclusion column. [Kock & Luger *J Chromatogr* **296** 293 1984.]

**Interleukin-2 (recombinant human)** [94218-72-1]  $M_r$  ~15,000, amorphous. Purify it by reverse phase HPLC. [Weir & Sparks *Biochem J* **245** 85 1987, Robb et al. *Proc Natl Acad Sci USA* **81** 6486 1984.]

**Interleukins (IL-1, IL-2 —IL18).** Interleukins are cytokines which cause a variety of effects including stimulation of cell growth and proliferation of specific cells, e.g. stem cells, mast cells, activated T cells, colony stimulating factors etc., as well as stimulating other ILs, prostaglandins release etc. They are small glycosylated proteins (ca 15 kD, 130-180 amino acids produced from longer precursors) and are sometimes referred to by other abbreviations, e.g. IL-2 as TCGF (T cell growth factor), IL-3 as multi-CSF (multilineage colony stimulating factor, also as BPA, HCSF, MCSF and PSF). They are produced in very small amounts and are commercially made by recombinant DNA techniques in bacteria or Sf21 insect cells. Interleukins for human (h-IL), mouse (m-IL) and rat (r-IL) are available, and up to IL-18 are available commercially in such purity that they can be used directly without further refinement, particularly those that have been obtained by recombinant DNA procedures which are specific. As well as the interleukins, a variety of antibodies for specific IL reactions are available for research or IL identification. [Symons et al. *Lymphokines and Interferons, A Practical Approach*, Clemens et al. Eds, p.272 1987, IRL Press, Oxford, ISBN 1852210354, 1852210362, Thomson et al. Eds, *The Cytokine Handbook*, 3rd Edn, 1998, Academic Press, San Diego, ISBN 0126896623.]

**Lactate dehydrogenase (from dogfish, Beef muscle)** [9001-60-9]  $M_r$  140,000 [EC 1.1.1.27]. A forty-fold purification of the dehydrogenase is effected by affinity chromatography using Sepharose 4B coupled to 8-(6-aminohexyl)amino-5'-AMP or -NAD<sup>+</sup>. [Lees et al. *Arch Biochem Biophys* **163** 561 1974, Pesce et al. *J Biol Chem* **239** 1753 1964.]

**Lactoferrin (from human whey)** [55599-62-7, Fe Salt]  $M_r$  ~90,000. This iron-binding protein is purified by direct adsorption on cellulose phosphate by batch extraction, then eluted by a stepped salt and pH gradient. The Fe bound protein forms red crystals with  $\lambda_{max}$  at 465nm (pH 8.2). [Foley & Bates *Anal Biochem* **162** 296 1987.]

**Lectins (proteins and/or glycoproteins of non-immune origin that agglutinate cells, e.g. from seeds of *Robinia pseudoacacia*),**  $M_r$  ~100,000. Lectins are purified by precipitation with (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> and dialysed, then chromatographed on DE-52 DEAE-cellulose anion-exchanger, hydroxylapatite and Sephacryl S-200. [Wantyghem et al. *Biochem J* **237** 483 1986.]

Lectins are a group of proteins that are classed as sugar-binding proteins or glycoproteins of non-immune origin and which agglutinate cells and/or precipitate glyco-conjugates. They are present in plants (seeds, roots, leaves or bark) and some invertebrates (snails, clams, crabs) and have  $M_r$  values of 10,000-400,000. They may contain Mn<sup>2+</sup> and/or Ca<sup>2+</sup>. Mono- or oligo- saccharides of appropriate specificity inhibit lectins. Some lectins are specific to human blood groups and induce mitosis in lymphocytes. [Goldstein *Nature* **286** 66 1980.]

**Lipoprotein lipase (from bovine skimmed milk)** [9004-02-8]  $M_r$  ~34,000 and 63,000 (SDSPAGE), 96,900 (sedimentation and diffusion), 100,000-120,000 (gel filtration) [EC 3.1.1.34]. Purify the lipase by affinity chromatography on heparin-Sepharose;  $K_i$  0.026mM for very low density lipoprotein. It is inhibited by 2-mercaptoethanol, Cys, Ca, Hg, Mg and Mn ions. Protamine sulfate, 1mg of bovine serum albumin/ml or in 50% glycerol at -70°, stabilises the lipase for several days. 60% loss of activity occurs at 0°/1hour in the presence of 1% of bovine serum albumin. [Shirai et al. *Biochim Biophys Acta* **665** 504 1981.]

**Lipoproteins (from human plasma).** Individual human plasma lipid peaks are removed from plasma by ultracentrifugation; then they are separated and purified by agarose-column chromatography. Fractions are characterised immunologically, chemically, electrophoretically and by electron microscopy. [Rudel et al. *Biochem J* **13** 89 1974.]

**Lipoteichoic acids (from gram-positive bacteria)** [56411-57-5]. The acids are extracted by hot phenol/water from disrupted cells. Nucleic acids are also extracted and are removed by treatment with nucleases. Nucleic resistant acids, proteins, polysaccharides and teichoic acids are separated from lipoteichoic acids by anion-exchange chromatography on DEAE-Sephacel or by hydrophobic interaction on octyl-Sepharose [Fischer et al. *Eur J Biochem* **133** 523 1983].

**Lysozyme (Muramidase, N-acetylmuramyl hydrolase, N-acetylmuramide, peptidoglycan N-acetylmuramoyl hydrolase, Globulin G<sub>1</sub>)** [human 174883-18-2, from human neutrophils 9001-63-2, from human milk 12671-19-1, from chicken egg white 126050-88-3, chloride from chicken egg white 9066-59-5] **M 14,400 ±100, E<sub>280nm</sub> 2.65 (c 1mg/ml) Isoelectric Point (IP) 10.5-11.0 [EC 3.2.1.17]**. Lysozymes from human and bird sources are 129 amino acid enzymes that contain four disulfide bonds. Hen lysozyme was isolated in quantity from chicken egg white, crystallised, and its X-ray crystalline structure was determined [Phillips *Proc Natl Acad Sci USA* **57** 484 1967]. Lysozyme occurs in many tissues of invertebrate and vertebrate animals. It is found in milk, blood serum and various secretions (saliva, nasal mucus and tears). It also occurs in some moulds and in the latex of certain plants. Lysozyme from human milk was studied in some detail and is very similar to the hen enzyme [Jolles & Jolles *Hely Chim Acta* **52** 2671 1969 and **54** 2668 1971]. Lysozyme is a glycosidase which dissolves various bacterial cell walls [particularly Gram-positive bacteria (which have surface lipoproteins) to give spheroblasts, and various Gram-negative bacteria in the presence of EDTA in hypotonic solutions, or non-ionic detergents]. Bacterial cell walls contain 1,4-β-N-acetylglucosaminyl oligosaccharides which are cleaved by the enzyme at the glycosidic C—O bond between the 4th and 5th sugar residues from the non-reducing end of the chain. The mechanism and kinetics of this hydrolysis have been studied extensively [cf Fersht *Enzyme Structure and Mechanism, 2nd edn*, W.H. Freeman & Co, Reading 1985, ISBN 0716716151]. Lysozyme was an extremely useful antibacterial in the pre-antibiotic era. It is a basic protein with 20-22 basic residues and only 3-4 acidic groups (see their isoelectric points); it forms soluble salts and is stable up to 55°. It is purified from egg white by chromatography through Amberlite IRC50 at pH 7.18 in 0.2M phosphate buffer followed by recrystallisation at pH 9.5 by adding NaCl to a concentration of 5%. Alternatively, ~1L of homogenised egg white in the absence of air (from 3 dozen eggs) is added to a 10% suspension of Bentonite [1302-78-9] (150ml, a native hydrated aluminium silicate) in 1% aqueous KCl, and stirred vigorously enough to avoid excessive foaming for ~5 minutes to give a smooth suspension. Separate the clay by centrifugation, wash it twice with 0.5M phosphate buffer (300ml each, pH 7.5) and three times with 5% aqueous pyridine (300ml each) while decanting from the clay and discarding inactive supernatants. From the combined washed clay, lysozyme is extracted out twice with 300ml of 5% aqueous pyridine (adjusted to pH5 with H<sub>2</sub>SO<sub>4</sub> using a glass electrode). The combined extracts are dialysed against running tap H<sub>2</sub>O (at 12-15°) until free from pyridine odour and dialysed further for 24 hours. Essentially pure amorphous lysozyme is obtained by lyophilising the dialysate below 25°. *Crystalline isoelectric lysozyme* is obtained from the amorphous powder by adding 0.5g of NaCl to a 5% aqueous solution of the enzyme (10ml), adjusting the pH to 9.5-10 (glass electrode) with aqueous NaOH and storing at 4°, whereby it crystallises out. *Crystalline lysozyme carbonate* is obtained from the amorphous powder by adding 0.5g of NaHCO<sub>3</sub> to a 5% aqueous solution of the enzyme (10ml), giving a final pH of 8.0-8.5 (glass electrode) with aqueous NaOH and allowing to stand at room temperature, whereby the carbonate crystallises out. *Crystalline lysozyme chloride* is obtained from a 5% solution of amorphous powder by adjusting the pH to 4.5 with hydrochloric acid (glass electrode) followed by solid NaCl to 5%, and storing at 4°, whereby the chloride crystallises out in 4 to 5 days. [Alderton & Fevold *J Biol Chem* **164** 1 1946, Fevold & Alderton *Biochemical Preparations* **I** 67 1949.] Other salts include the *L-ascorbate* [119189-24-1], the *lactate* [72497-48-4], the *phosphate* [72497-47-3] and the *2,3-dihydroxypropyl dihydrogen phosphate* [119189-23-0]. Dialysis and recrystallisation are simple and yield enzyme of high purity. Several forms of crystals are obtained depending on the pH of the crystallising solution. The activity of lysozyme is measured by the rate of decrease of turbidity (at 570nm) as hydrolysis of acetone-dried cell walls of the Gram-positive bacterium *Micrococcus lysodeikitus* (as substrate) occurs on addition of the enzyme [Hirs *Methods Enzymol* **I** 124 1968]. At high concentrations or in the presence of albumin, lysozyme can be lyophilised or desalted without loss of activity. Freezing and thawing does not inactivate it, and Na<sup>+</sup>, Mg<sup>2+</sup>, Ag<sup>+</sup>, Ca<sup>2+</sup>, and Cu<sup>2+</sup> exert an activating effect. It can be stored for several weeks at -20° without inactivation, and in the presence of 0.1% of bovine serum albumin it can be stored for months at -20° without inactivation. [Springer *Handbook of Enzymes* 2nd edn. Schonburg & Schonburg eds (A. Chang co-ed) Springer-Verlag Berlin, Heidelberg, **Volume 12** 2003 ISBN 3-540-00519-6.] Agarose-bound lysozyme from hen egg (5,000-10,000 Units/g of solid), a lysozyme Biotin-caproyl solution (20,000 U/mg) and a carboxymethylated-maleylated lysozyme (Lysozyme-RCM, reduced form), and lysozyme of up to 100,000 U/mg protein are commercially available.

A *T<sub>4</sub> bacteriophage lysozyme* (from phage grown on *E.coli* B<sup>1</sup>) [12585-29-4] was extracted and freed from

DNA, cell debris, intact cells and acidic proteins by precipitation with Rivanol (6,9-diamino-2-ethoxyacridine *dl*-lactate). The filtrate was purified by concentration through an Amberlite IRC50 column which was thoroughly washed with 0.1M phosphate buffer pH 6.5 containing  $10^{-3}$ M  $MgSO_4$  and eluted with the phosphate buffer at pH 5.8 containing a 0 to 0.5M NaCl gradient. This was repeated twice, followed by gel filtration through Sephadex G-75 in pH 5.8 phosphate buffer and eluted with 0.5M NaCl. The eluate was dialysed against  $H_2O$  and lyophilised to give a 1500-fold purification with 40% recovery. Like the hen lysozyme it is a basic protein but with 164 amino acid residues, and it is unstable  $>40^\circ$ . [Tsugita et al. *J Biol Chem* **243** 391 1968, Inouye et al. *J Biol Chem* **245** 3439, 3479 1970, Matthews *Biochim Biophys Acta* **405** 442 1975.]

**Metallothionein (from rabbit liver)** [9038-94-2]. Purify it by precipitation to give Zn- and Cd-containing protein fractions and running it on a Sephadex G-75 column, then isoelectric focusing to give two protein peaks [Nordberg et al. *Biochem J* **126** 491 1972, Comeau et al. *Prep Biochem* **22** 151 1992].

**Myoglobin (from sperm whale muscle)** [9047-17-0]  $M_r \sim 17,000$ . Myoglobin is purified by CM-cellulose chromatography and Sephadex G-50 followed by chromatography on Amberlite IRC-50 Type III or BioRex 70 ( $<400$ mesh). The crystalline product as a paste in saturated  $(NH_4)_2SO_4$  at pH 6.5-7.0 may be stored at  $4^\circ$  for at least 4 years unchanged, but must not be kept in a freezer. [Anres & Atassi *Biochemistry* **12** 942 1980, Edmundson *Biochemical Preparations* **12** 41 1968.]

**5'-Nucleotidase (from Electric ray, *Torpedo sp*)** [9027-73-0] [EC 3.1.3.5], **amorphous**. Purify it by dissolving it in Triton X-100 and deoxycholate, and by affinity chromatography on concanavalin A-Sepharose and AMP-Sepharose [Grondal & Zimmerman *Biochem J* **245** 805 1987].

**Orosomucoid (glycoprotein  $\alpha_1$  acid, from human plasma)** [66455-27-4]  $M_r$  **42000-44000**, **amorphous**. Purify the glycoprotein  $\alpha_1$  acid by passage through a carboxymethyl cellulose column, then through a Sephadex G-25 column. [Aronson et al. *J Biol Chem* **243** 4564 1968.]

**Papain** [9001-73-4]  $M_r \sim 21,000$  [EC 3.4.22.2], **amorphous**. A suspension of 50g of papain (freshly ground in a mortar) in 200ml of cold water is stirred at  $4^\circ$  for 4 hours, then filtered through a Whatman No 1 filter paper. The clear yellow filtrate is cooled in an ice-bath while a rapid stream of  $H_2S$  is passed through it for 3 hours, and the suspension is centrifuged at 2000rpm for 20 minutes. Sufficient cold MeOH is added slowly with stirring to the supernatant to give a final MeOH concentration of 70 vol%. The precipitate, collected by centrifugation for 20 minutes at 2000rpm, is then dissolved in 200ml of cold water, the solution is saturated with  $H_2S$ , centrifuged, and the enzyme is again precipitated with MeOH. The process is repeated four times. [Bennett & Niemann *J Am Chem Soc* **72** 1798 1950.] Papain has also been purified by affinity chromatography on a column of GlyGlyTyrArg-agarose [Stewart et al. *J Am Chem Soc* **109** 3480 1986].

**Pepsin** [9001-75-6]  $M_r$  **31,500(human), 6000(hog)** [EC 3.4.23.1]. Pepsin is re-chromatographed on a column of Amberlite CG-50 using a pH gradient prior to use. Crystallise it from EtOH. [Richmond et al. *Biochim Biophys Acta* **29** 453 1958, Huang & Tang, *J Biol Chem* **244** 1085 1969, **245** 2189 1970.]

**Pertussis toxin (from *Bordetella pertussis*)** [70323-44-3]  $M_r$  **117,000**. Purify the toxin by stepwise elution from 3 columns comprising Blue Sepharose, Phenyl Sepharose and hydroxylapatite, and the purity is checked by SDS-PAGE. [Svoboda et al. *Anal Biochem* **159** 402 1986, *Biochemistry* **21** 5516 1982, *Biochem J* **83** 295 1978.]

**Phosphatase alkaline (alkaline phosphatase)** [9001-78-9]  $M_r \sim 40,000$  (**bovine liver**),  $\sim 140,000$  (**bovine intestinal mucosa**), **80,000** (*E. coli*), [EC 3.1.3.1]. The *E. coli* supernatant in sucrose (20%, 33mM) in Tris-HCl pH 8.0 is purified through a DEAE-cellulose column and recrystallised. To the column eluates in 0.125M NaCl is added  $MgCl_2$  (to 0.01M) and brought to 50% saturation in  $(NH_4)_2SO_4$  by adding the solid (0.20g/ml). The mixture is centrifuged to remove bubbles and is adjusted to pH 8.0 (with 2N NaOH). Saturated  $(NH_4)_2SO_4$  at pH 8.0 is added dropwise until the solution becomes faintly turbid ( $\sim 61\%$  saturation). It is set aside at  $\sim 25^\circ$

for 1 hour (turbidity will increase). The mixture is placed in an ice bath for several minutes when turbidity

disappears and a clear solution is obtained. It is then placed in a large ice bath at 0° (~5L) and allowed to warm slowly to room temperature in a dark room whereby crystals are formed appearing as a silky sheen. The crystals are collected by centrifugation at 25° if necessary. The crystalline solutions are stable at ~25° for many months. They can be stored at 0°, but are unstable when frozen. Cysteine at 10<sup>-3</sup>M and thioglycolic acid at 10<sup>-4</sup>M are inhibitory. This is reversed on addition of Zn<sup>2+</sup> ions. Many organic phosphates are good substrates for this phosphatase. [Molamy & Horecker *Methods Enzymol* **9** 639 1966, Torriani et al. *Methods Enzymol* **12b** 212 1968, Engstrom *Biochim Biophys Acta* **92** 71 1964.]

Alkaline phosphatase from rat osteosarcoma has been purified by Me<sub>2</sub>CO precipitation and chromatography on DEAE-cellulose, Sephacryl S-200, and hydroxylapatite. [Nair et al. *Arch Biochem Biophys* **254** 18 1987.]

**Phosphoproteins (various).** These are purified by adsorbing onto an iminodiacetic acid substituted agarose column to which are bound ferric ions. This chelate complex acts as a selective immobilised metal affinity adsorbent for phosphoproteins. [Muszyfiska et al. *Biochemistry* **25** 6850 1986.]

**5'-Phosphoribosyl pyrophosphate synthetase (from human erythrocytes, or pigeon or chicken liver)** [9015-83-2]  $M_r$  60,000 [EC 2.7.6.1]. It is purified 5100-fold by elution from DEAE-cellulose, fractionation with (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, filtration on Sepharose 4B and ultrafiltration. [Fox & Kelley *J Biol Chem* **246** 5739 1971, Flaks *Methods Enzymol* **6** 158 1963, Kornberg et al. *J Biol Chem* **15** 389 1955.]

**Pituitary Growth Factor (from human pituitary gland)** [336096-71-0]. It is purified by heparin and copper affinity chromatography, followed by chromatography on carboxymethyl cellulose (Whatman 52). [Rowe et al. *Biochemistry* **25** 6421 1986.]

**Plasmids.** These are circular lengths of *double-stranded* DNA which invade bacteria or other cells, e.g. insect cells, yeast cells, and have sequences which are necessary for their replication using enzymes and other ingredients, e.g. nucleotides, present in the cells. They contain engineered, or already have, genes which produce enzymes that provide the cells with specific antibiotic resistance and are thus useful for selecting bacteria containing specific plasmids. Plasmids have been extremely useful in molecular biology since they can be very easily identified (from their size or the sizes of the DNA fragments derived from their restriction enzyme digests) and can be readily engineered *in vitro* (outside the cells). Genes coding for specific enzymes or other functional proteins can be inserted into these plasmids which have DNA sequences that allow the expression of large quantities of bacterial or non-bacterial (e.g. human) proteins. They have also been engineered in such a way as to produce “fusion proteins” (in which the desired protein is fused with a specific “reporter, marker or carrier protein” which will facilitate the isolation of the desired protein (e.g. by binding strongly to a nickel support), and then the desired protein can be cleaved from the eluted fusion protein and obtained in very pure form. A large number of plasmids with a variety of sequences for specific purposes are commercially available in very pure form. They can be used to infect cells and can be isolated and purified from cell extracts in large amounts using a number of available procedures. These procedures generally involve lysis of the cells (e.g. with alkaline sodium dodecylsulfate, SDS), separation from nuclear DNA, precipitation of plasmid DNA from the cell debris, adsorbing it on columns which specifically bind DNA, and then eluting the DNA from the column (e.g. with specific Tris buffers as recommended by the suppliers) and precipitating it (e.g. with Tris buffer in 70% EtOH at -70°C). The purity is checked on agarose gels (containing ethidium bromide to visualise the DNA) by electrophoresis. A large number of plasmids are now commercially available (see Clontech GmbH, <http://www.clontech.com>, Invitrogen <http://www.invitrogen.com>, among other suppliers) and used as vectors for bacterial, mammalian, yeast and insect cells, and for baculovirus expression.

**Protamine kinase (from rainbow trout testes)** [37278-10-7] [EC 2.7.1.70]. Partial purification of the kinase is achieved by chromatography through hydroxylapatite followed by biospecific chromatography on nucleotide coupled Sepharose 4B [the nucleotide is 8-(6-aminohexyl)amine coupled cyclic-AMP]. It requires Mg ions specifically but is inactivated by Ca, Mn, Cu, Zn ions and thiol compounds. [Jergil & Dixon *J Biol Chem* **245** 1425 1970, Jergil et al. *Biochem J* **139** 441 1974.]

**Protamine sulfate (from herring sperm)** [9007-31-2] [ $\alpha$ ]<sub>D</sub><sup>22</sup> -85.5° (saturated H<sub>2</sub>O), pK<sup>25</sup> 7.4-8.0.

Protamine sulfate is a strongly basic protein (white powder, see pK) used to precipitate nucleic acids from crude protein extracts. It dissolves to the extent of 1.25% in H<sub>2</sub>O. It is freely soluble in hot H<sub>2</sub>O but separates as an oil on cooling. It has been purified by chromatography on an IRA-400 ion-exchange resin in the SO<sub>4</sub><sup>2-</sup> form and is washed with dilute H<sub>2</sub>SO<sub>4</sub>. Eluates are freeze-dried under high vacuum below 20°. This method is used to convert proteamine and protamine hydrochloride to the sulfate. [UV: Rasmussen *Hoppe Seyler's Z Physiol Chem* **224** 97 1934, Ando & Sawada *J Biochem (Tokyo)* **49** 252 1961, Felix & Hashimoto *Hoppe Seyler's Z Physiol Chem* **330** 205 1963.]

**Protease nexin (from cultured human fibroblasts)** [148263-58-5]. It is purified by affinity binding of protease nexin to dextran sulfate-Sepharose. [Farrell et al. *Biochem J* **237** 707 1986.]

**Proteins.** These are usually naturally occurring (or deliberately synthesised in microorganisms, e.g. bacteria, insect cells, or animal tissues), and are composed of a large number of  $\alpha$ -S (L)amino acid residues (except for L-cysteine which has the R absolute configuration), selected from the 20 or so natural amino acids, in specific sequences and in which the  $\alpha$ -amino group forms an amide (peptide) bond with the  $\alpha$ -carboxyl group of the neighbouring amino acid. The number of residues is usually upwards of 100. Proteins with less than 100 amino acids are better referred to as **polypeptides**. Aqueous soluble proteins generally fold into ball-like structures mainly with hydrophilic residues on the outside of the "balls" and hydrophobic residues on the inside. Proteins can exist singly or can form dimers, trimers, tetramers etc., consisting of similar or different protein subunits. They are produced by cells for a large variety of functions, e.g. enzymology, reaction mediation as in regulation of DNA synthesis or chaperonins for aiding protein folding, formation of pores in membranes for transport of ions or organic molecules, or for intra or intercellular signalling etc. The purity of proteins can be checked in denaturing (SDS, sodium dodecylsulfate) or non-denaturing polyacrylamide gels using electrophoresis (PAGE), and staining appropriately (e.g. with Coomassie Blue, followed by silver staining for higher sensitivity). If the protein is partly impure, then it should be purified further according to the specific literature procedures for the individual protein (see specific proteins in the *Methods Enzymol*, Wiley series).

**Proteoglycans (from cultured human muscle cells).** These are separated by ion-exchange HPLC using a Bio-gel TSK-DEAE 5-PW analytical column. [Harper et al. *Anal Biochem* **159** 150 1986.]

**Prothrombin (Factor II, from equine blood plasma)** [9001-26-7] **M<sub>r</sub> 72,000**. Prothrombin is purified by two absorptions on a barium citrate adsorbent, followed by decomposition of the adsorbents with a weak carboxylic cation-exchanger (Amberlite IRF-97), isoelectric precipitation (pH 4.7-4.9) and further purification by chromatography on Sephadex G-200 or IRC-50. Finally it is recrystallised from a 1% solution adjusted to pH 6.0-7.0 and partial lyophilisation to ca 1/5 to 1/10th volume and set aside at 2-5° to crystallise. Occasionally seeding is required. [Miller *Biochemical Preparations* **13** 49 1971.]

**Prymnesin (toxic protein from phytoflagellate *Prymnesium parvum*)** [11025-94-8]. Prymnesin is purified by column chromatography, differential dissolution and precipitation in solvent mixtures and differential partition between diphasic mixtures. The product has at least 6 components as observed by TLC. [Ulitzur & Shilo *Biochim Biophys Acta* **301** 350 1970.]

**Pyruvate kinase isoenzymes (from *Salmonella typhimurium*)** [9001-59-6] **M<sub>r</sub> 64,000** [EC 2.7.1.40], **amorphous**. These are purified by (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> fractionation and gel filtration, ion-exchange and affinity chromatography. [Garcia-Olalla & Garrido-Pertierra *Biochem J* **241** 573 1987.]

**Renal dipeptidase (from porcine kidney cortex)** [9031-96-3] **M<sub>r</sub> 47,000** [EC 3.4.13.11]. The dipeptidase is purified 700-fold by homogenising the tissue, extracting with Triton X-100, elimination of insoluble material, and ion-exchange, size exclusion and affinity chromatography. [Hitchcock et al. *Anal Biochem* **163** 219 1987.]

**Restriction enzymes (endonucleases).** These are enzymes which cleave double-stranded DNA (linear or circular) at specific nucleotide sequences within the DNA strands which are then used for cloning (by ligating bits of DNA sequences together) or for identifying particular DNA materials, e.g. plasmids, genes etc. A very large number of restriction enzymes are now available commercially and are extensively used in molecular biology. They are highly specific for particular nucleotide arrangements and are sensitive to the reaction conditions, e.g. composition of the medium, pH, salt concentration, temperature etc, which have to be strictly adhered to.

Endonucleases are essentially of two types. One type cleaves the DNA producing *blunt ends*, i.e. the nucleotides are paired at each end. The second type cleaves the DNA leaving *hanging ends*, i.e. the nucleotides at the ends of each strand (usually four nucleotides) of the double strands protrude ahead of the paired nucleotides. The latter enzymes particularly allow ligation of the cleaved sequence to occur in a desired direction.

The enzymes do not require further purification, and the reaction conditions are also provided by the suppliers from which the necessary reaction media can also be purchased (see commercial catalogues).

**Reverse transcriptase (from avian or murine RNA tumour viruses)** [9068-38-6]  $M_r \sim 170,000$  [EC 2.7.7.49]. This enzyme produces the complementary DNA from the RNA (as template). These are purified by solubilising the virus with non-ionic detergents. Lysed virions are adsorbed on DEAE-cellulose or DEAE-Sephadex columns, and the enzymes are eluted with a salt gradient, then chromatographed on a phosphocellulose column and fractions with enzyme activity are eluted in a salt gradient. They are also purified from other viral proteins by affinity chromatography on a pyran-Sepharose column. [Verna *Biochim Biophys Acta* **473** 1 1977, Smith *Methods Enzymol* **65** 560 1980; see commercial catalogues for other transcriptases.]

**Ribonuclease (from human plasma)** [9001-99-4]  $M_r \sim 13,700$  [EC 3.1.27.5], **amorphous**. Purify it by  $(\text{NH}_4)_2\text{SO}_4$  fractionation, followed by PC cellulose chromatography and affinity chromatography (using Sepharose 4B to which  $(\text{G})_n$  is covalently bonded). [Schmukler et al. *J Biol Chem* **250** 2206 1975.]

**Ribozymes.** These are ribonucleic acids which act like protein enzyme in catalysing the making and breaking of peptide bonds as well as catalysing reactions and cleavage of DNA and RNA molecules. The short RNAs are being intensively studied (see RNAi below). MicroRNAs (miRNA, see also below) are ubiquitous and are also genetically produced. They are involved in numerous reactions from splicing RNA, e.g. mRNA (messenger RNA) to controlling transcription of DNA to RNA, and translation of RNA to protein. Each miRNA is capable of being involved in a small number to hundreds of interactions with nucleic acids and with proteins.

**Ricin (toxin from Castor bean *Ricinus communis*)** [A chain 96638-28-7, B chain 96638-29-8]  $M_r \sim 30,000$ , **amorphous**. Crude ricin, obtained by aqueous extraction and  $(\text{NH}_4)_2\text{SO}_4$  precipitation, is chromatographed on a galactosyl-Sepharose column with sequential elution of pure ricin. The second peak is due to ricin agglutinin. [Simmons & Russell *Anal Biochem* **146** 206 1985.] It is an inhibitor of protein synthesis. **EXTREMELY DANGEROUS, USE EXTREME CARE [instructions accompany product].**

**RNA (ribonucleic acids).** Ribonucleic acids are like DNA except that the 2'-deoxy-D-ribose moiety is replaced by a D-ribose moiety and the fourth nucleotide thymidylic acid (T) is replaced by uridylic acid (U). RNA does not generally form complete duplex molecules like DNA, i.e. it is generally monomeric, except in certain viruses. The two main classes of RNA are **messenger-RNA** (mRNA) and **transfer-RNA** (tRNA). Pre-mRNAs are transcribed from the DNA genes, and non-coding segments (the introns) are spliced out to give the mRNAs which code for specific proteins. There are many different tRNAs, at least one of which is linked to a specific  $\alpha$ -amino acid that binds to the mRNA *via* the ribosome (a set of proteins) to the RNA triplets (three nucleotides) which code for the particular  $\alpha$ -amino acids. An enzyme then joins the  $\alpha$ -amino acids of two adjacent tRNA- $\alpha$ -amino acid ribosome complexes bound to the mRNA to form a peptide bond. Thus peptide bonds and consequently polypeptides and proteins coded by the DNAs, *via* the respective mRNA, are produced. Martin et al. [*Biochem J* **89** 327 1963] purified RNA by dissolving it (5g) in 90ml of 0.1mM EDTA, then homogenised this with 90ml of 90% (w/v) phenol in water using a Teflon pestle. The suspension was stirred vigorously for 1 hour at  $\sim 20^\circ$ , then centrifuged for 1 hour at  $0^\circ$  at 25,000rpm. The lower (phenol) layer was extracted four times with 0.1mM EDTA, and the aqueous layers were combined, then made 2% (w/v) with respect to AcOK and 70% (v/v) with respect to EtOH. After standing overnight at  $-20^\circ$ , the precipitate was centrifuged down, dissolved in

50ml of 0.1mM EDTA, made 0.3M in NaCl and kept for 3 days at 0°. The purified RNA was then centrifuged down at 10000x g for 30 minutes, dissolved in 100ml of 0.1mM EDTA, dialysed at 4° against water, and freeze-dried. It was stored at -20° in a desiccator. Michelson [*J Chem Soc* 1371 1959] dissolved 10g of RNA in water, added 2M ammonia to adjust the pH to 7, then dialysed in Visking tubing against five volumes of water for 24 hours. The process was repeated three times; then the material after dialysis was treated with 2M HCl and EtOH to precipitate the RNA which was collected, washed with EtOH, ether and dried [see commercial catalogues for further examples]. RNAs are now routinely sequenced.

**RNAi (interfering RNA).** RNAi technology has exploded during the past five years and has become invaluable for exploring gene function, interaction and control. It has considerable potential in therapeutics. This came about from the discovery that a double-stranded RNA (**dsRNA**) complementary to the coding sequence of a muscle protein “turned off” the gene instead of enhancing the effect. It seemed that the dsRNA activated the cellular machinery to degrade the target mRNA. This led to the development and the use of interfering RNA (RNAi) to “silence” specific genes. This silencing of genes comes in various different forms. It can be brought about by *short interfering RNA (siRNA)*, *micro RNA (miRNA)* and *short-hairpin RNA (shRNA)*. RNA can be notoriously unstable in biological systems, e.g. its half-life in serum is ~6 minutes, but recently methods have been devised (using nanoparticle delivery systems) where they are more stable and can be used to target specific cancer cells.

About 50% of the human genome is apparently transcribed into mRNA and translated into protein or used to produce small RNA fragments. miRNAs are small molecules of about 23 or less ribonucleotides which are cleaved from larger fragments of RNA transcripts encoded from within genes, or large tracts of DNA between the genes. miRNAs are a special group of non-coding RNAs which work by blocking (silencing) gene expression. More than 400 have been discovered in the human genome so far and some appear to regulate many genes, as in embryonic development, e.g. cell growth, apoptosis. A cancer-causing miRNA was identified and called *onco-miRNA*. miRNA expression in particular cancers can now be quantified.

Single stranded RNAs consisting of 100s of bases fold back on themselves and undergo complementary base-pairing to form double-stranded “short-hairpin” RNA (shRNA). The loop of the hair-pin is excised by endonucleases, e.g. *Dicer*, to produce multiple functional miRNAs.

Many of the above RNAs for specific purposes are available commercially from several firms in high purity because they are synthetic. These firms will also synthesise particular RNAi’s to suit one’s requirements.

**Subtilisin (from *Bacillus subtilis*)** [9014-01-1]  $M_r$  27,000 (sedimentation equilibrium) [EC 3.4.21.62]. This alkaline protease is purified 211-fold by affinity chromatography using 4-(4-aminophenylazo)phenylarsonic acid complex to activated CH-Sepharose 4B. It is inhibited by 2-phenylethane boronic acid, PMSF, 3,4-dichloroisocoumarin, acetone and benzamide. [Chandraskaren & Dhar *Anal Biochem* 150 141 1985, Schomburg & Schomburg *Springer Handbook of Enzymes* 2nd Edn vol 7 p 286 2002.]

**Synexin (from bovine liver)**  $M$  47,000 Da. This Ca binding protein is purified by  $(NH_4)_2SO_4$  precipitation, then by a specific pH step elution from a chromatofocusing medium in the absence of ampholytes. The pI is 7.5. [Scott et al. *Anal Biochem* 149 163 1985.]

**Thrombin (from bovine blood plasma)** [9002-04-4]  $M_r$  32,600 [EC 3.4.4.13]. Thrombin is purified by chromatography on a DEAE-cellulose column, while eluting with 0.1M NaCl, pH 7.0, followed by chromatography on Sephadex G-200. The final preparation is free from plasminogen and plasmin. [Yin & Wessler *J Biol Chem* 243 112 1968.] Thrombin from bovine blood is also purified by chromatography using *p*-chlorobenzylamino- $\epsilon$ -aminocaproyl agarose, and gel filtration through Sephadex G-25. [Thompson & Davie *Biochim Biophys Acta* 250 210 1971.]

Thrombin from various species was purified initially by precipitation of impurities with Rivanol (see [6402-23-9]). [Miller *Nature* 184 450 1959.]

**Tissue inhibitor of metalloproteins (TIMP, from human blood plasma),**  $M_r$  ~30,000. These are purified by an [anti-human amniotic fluid-TIMP]-Sepharose immuno-affinity column and eluted with 50mM glycine/HCl

pH 3.0 buffer that is 0.5M in NaCl, and followed by gel filtration [Cawston et al. *Biochem J* **238** 677 1986].

**Transferrin (from human or bovine serum)** [11096-37-0]  $M_r$  ~80,000. This transferrin is purified by affinity chromatography on phenyl-boronate agarose followed by DEAE-Sepharcel chromatography. The product is free from haemopexin. [Cook et al. *Anal Biochem* **149** 349 1985, Aisen & Listowsky *Ann Rev Biochem* **49** 357 1980.]

**Trehalase (from kidney cortex,  $\alpha,\alpha$ -trehalose glycohydrolase)** [9025-52-9]  $M_r$  ~80,000 [EC 3.2.1.28]. This trehalase is purified by solubilising in Triton X-100 and sodium deoxycholate, and submitting to gel filtration, ion-exchange chromatography, conA-Sepharose chromatography, phenyl-Sepharose CL-4B hydrophobic interaction chromatography, Tris-Sepharose 6B affinity and hydrolyapatite chromatography. Activity is increased 3000-fold. [Yoneyama *Arch Biochem Biophys* **255** 168 1987.]

**T4-RNA ligase (from bacteriophage-infected *E. coli*)**  $M_r$  43,500, [EC 6.5.1.3 for RNA lyase]. This ligase is purified by differential centrifugation and separation on a Sephadex A-25 column, then through hydroxylapatite and DEAE-glycerol using Aff-Gel Blue to remove DNAase activity. (Greater than 90% of the protein in the enzyme preparation migrated as a single band on gradient polyacrylamide gels containing SDS during electrophoresis.) [McCoy et al. *Biochim Biophys Acta* **562** 149 1979.]

**Ubiquinol-cytochrome c reductase (from beef heart mitochondria)** [9027-03-6] [EC 1.10.2.2]. This reductase is purified by solubilising the crude enzyme with Triton X-100, followed by hydroxylapatite and gel chromatography. The minimum unit contains nine polypeptide subunits of  $M_r$  6000 – 49,000 kD. [Engel et al. *Biochim Biophys Acta* **592** 211 1980.]

**Uridine 5'-diphosphoglucose pyrophosphorylase (from rabbit skeletal muscle)** [9029-22-6]  $M_r$  350,000 [EC 2.7.7.9]. The pyrophosphorylase is purified by two hydrophobic chromatographic steps and gel filtration. [Bergamini et al. *Anal Biochem* **143** 35 1984.] It is also purified from calf liver by  $(\text{NH}_4)_2\text{SO}_4$  (40-58%) precipitation,  $\text{Ca}_3(\text{PO}_4)_2$  gel filtration, DEAE-cellulose chromatography and recrystallisation [by dialysis against concentrations of  $(\text{NH}_4)_2\text{SO}_4$  (from 10%) in 0.02M TEA, at 2.5% increments, until 20%  $(\text{NH}_4)_2\text{SO}_4$  when it crystallises out [Hansen et al. *Methods Enzymol* **8** 248 1966].

**Urokinase (from human urine)** [9039-53-6]  $M_r$  53,000 [EC 3.4.21.31]. Crystallisation of this enzyme is induced at pH 5.0 to 5.3 (4°) by careful addition of NaCl with gentle stirring until the solution becomes turbid (silky sheen). The NaCl concentration is increased gradually (over several days) until 98% of saturation is achieved whereby urokinase crystallises out as colourless thin brittle plates. It can be similarly recrystallised to maximum specific activity [104K CTA units/mg of protein (Sherry et al. *J Lab Clin Med* **64** 145 1964)]. [Lesuk et al. *Science* **147** 880 1965, NMR: Bogusky et al. *Biochemistry* **28** 6728 1989.] It is a plasminogen activator [Gold et al. *Biochem J* **262** 1989, de Bock & Wang *Med Res Rev* **24**(1) 13 2004].

**Xylanase (from *Streptomyces lividans*)** [37278-89-0]  $M_r$  43,000 [EC 3.2.1.8]. This xylanase is purified by anion-exchange chromatography on an Accell QMA column and finally by HPLC using a ProteinPak DEAE 5PW anion-exchange column. Solutions are stored frozen at -70°. [Morosoli et al. *Biochem J* **239** 587 1986, Wong et al. *Microbiol Rev* **52** 305 1988.]

## CARBOHYDRATES

This section includes natural and synthetic carbohydrates and glycosides.

### Z-O-(2-Acetamido-2-deoxy-D-glycopyranosylideneamino)-N-phenyl-carbamate

(PUGNAC) [132063-05-9] M 335.3, m 171-174° (dec), 174-180°(dec),  $[\alpha]_D^{20} +67.5^\circ$  (c 0.2, MeOH). Purify PUGNAC by flash chromatography (silica gel and elute with EtOAc/hexane 3:2), evaporate, and the foam is recrystallised from EtOAc/MeOH. The purity is checked by TLC on Merck SiO<sub>2</sub> gel 60 F<sub>254</sub> and the spots are detected by spraying with 0.025M I<sub>2</sub> in 10% aqueous H<sub>2</sub>SO<sub>4</sub> and heating at 200°. It has R<sub>F</sub> 0.21. The acetate is hydrolysed with NH<sub>3</sub>/MeOH. [*Helv Chim Acta* 68 2254 1985, *Helv Chim Acta* 73 1918 1990.]

**Acetobromo- $\alpha$ -D-galactose** [3068-32-4] M 411.2, m 87°,  $[\alpha]_{546}^{20} +255^\circ$ ,  $[\alpha]_D^{20} +210^\circ$  (c 3, CHCl<sub>3</sub>). Purify acetobromo- $\alpha$ -D-galactose as for the glucose analogue (next entry). If the compound melts lower than 87° or is highly coloured, then dissolve it in CHCl<sub>3</sub> (ca 3 volumes) and extract with H<sub>2</sub>O (2 volumes), 5% aqueous NaHCO<sub>3</sub>, and again with H<sub>2</sub>O and dry it over Na<sub>2</sub>SO<sub>4</sub>. Filter and evaporate it in a vacuum. The partially crystalline solid or syrup is dissolved in dry Et<sub>2</sub>O (must be very dry) and recrystallised by adding petroleum ether (b 40-60°) to give a white product. [McKellan & Horecker *Biochemical Preparations* 11 111 1960, *Beilstein* 17/6 V 369.]

**Acetobromo- $\alpha$ -D-glucose ( $\alpha$ -acetobromoglucose 2,3,4,6-tetraacetyl- $\alpha$ -D-glycopyranosyl bromide)** [572-09-8] M 411.2, m 87-88°, 88-89°,  $[\alpha]_{546}^{20} +230^\circ$ ,  $[\alpha]_D^{20} +195^\circ$  (c 3, CHCl<sub>3</sub>). If nicely crystalline, recrystallise it from Et<sub>2</sub>O/pentane or petroleum ether (b 40-60°). Alternatively, dissolve it in diisopropyl ether (dried over CaCl<sub>2</sub> for 24 hours, then over P<sub>2</sub>O<sub>5</sub> for 24 hours) by shaking and warming (for as short a period as possible), and filter warm. Cool to ca 45°, then slowly to room temperature and finally at 5° for more than 2 hours. Collect the solid, wash it with cold dry diisopropyl ether and dry it in a vacuum over Ca(OH)<sub>2</sub> and NaOH. Store it dry in a desiccator in the dark. Solutions can be stabilised with 2% CaCO<sub>3</sub>. [Redemann & Niemann *Org Synth* 65 236 1987, Coll Vol III 11 1955, *Beilstein* 17/6 V 368.]

**$\alpha$ -Acetyldigitoxin** [1111-39-3] M 807.0, m 153-180° (monohydrate, dec), 217-221°, 258°(dec),  $[\alpha]_D^{20} +5.0^\circ$  (c 0.7, pyridine), +24.5° (c 1, MeOH).  $\alpha$ -Acetyldigitoxin is obtained from the commercial mixture [ $\alpha$ : $\beta$  (2:1)] [25395-32-8]. The  $\alpha$ -form is obtained from the  $\beta$ -form by heating in anhydrous or aqueous organic solvent (e.g. aqueous MeOH) at pH 3.5—8. It crystallises from MeOH as plates, CHCl<sub>3</sub>/Et<sub>2</sub>O or Me<sub>2</sub>CO/Et<sub>2</sub>O. At 20° 1g dissolves in 16ml of MeOH, 66ml of Me<sub>2</sub>CO and ~880ml of EtOAc. [Stoll & Kreis *Helv Chim Acta* 35 1318, 1322 1952, *Beilstein* 18 III/IV 1479.] It is a cardenolide.

**$\beta$ -Acetyldigitoxin** [1264-51-3] M 807.0, m 225°,  $[\alpha]_D^{20} +18.7^\circ$  (c 0.7, pyridine), +24.3° (c 0.7, MeOH).  $\beta$ -Acetyldigitoxin crystallises from MeOH as a methanolate which loses MeOH in a vacuum desiccator. The solubility at room temperature is: H<sub>2</sub>O (0.0005%), EtOAc (0.4%), MeOH (0.6%), Me<sub>2</sub>CO (1.6%) and CHCl<sub>3</sub>(12%). [Stoll & Renz *Helv Chim Acta* 35 1310 1952, Kreis US 2776963, 1957 to Sandoz; *Beilstein* 18 III/IV 1479]. It is a cardenolide.

**N-Acetyl-D-lactosamine [2-acetyl-amino-O- $\beta$ -D-lactopyranosyl-2-deoxy-D-glucose]** [32181-59-2] M 383.4, m 169-171°, 170-171°,  $[\alpha]_D^{18} +51.5^\circ \rightarrow +28.8^\circ$  (in 3 hours, c 1, H<sub>2</sub>O). Purify N-acetyl-D-lactosamine by recrystallisation from MeOH (with 1 mol of MeOH) or from H<sub>2</sub>O. It is available commercially as a solution of 0.5g/ml of H<sub>2</sub>O. [Zilliken *J Biol Chem* 271 181 1955, *Beilstein* 17 IV 3452.]

**1-O-Acetyl-2,3,5-tri-O-benzoyl- $\beta$ -D-ribofuranose** [6974-32-9] M 504.5, m 128-130°, 130-131°, 131-132°,  $[\alpha]_D^{20} +44.2^\circ$  (c 1, CHCl<sub>3</sub>). Recrystallise it from EtOH or isoPrOH. [*Helv Chim Acta* 42 1171 1959, NMR: *J Org Chem* 33 1799 1968, IR: *Chem Pharm Bull Jpn* 11 188 1963, *Beilstein* 17/6 V 213.]

**N-Acetyl muramic acid [NAM]** See “Miscellaneous” in this Chapter.

**Alginic acid** [9005-32-7] **M 48,000-186000**. To 5g of acid in 550ml water containing 2.8g  $\text{KHCO}_3$  are added 0.3ml of acetic acid and 5g potassium acetate. EtOH is added to make the solution to 25% (v/v) in EtOH, and any insoluble material is discarded. Further addition of EtOH, to 37% (v/v), precipitated alginic acid. Collect the acid and dry it *in vacuo*. [Pal & Schubert *J Am Chem Soc* **84** 4384 1962.]

**Aloin [10-glucopyranosyl-1,8-dihydroxy-3-(hydroxymethyl)-9(10H)anthracenone, Barbaloin]** [8015-61-0, 5133-19-7, 1415-73-2] **M 418.4, m 148-148.5<sup>o</sup>, 148-150<sup>o</sup>**. Aloin forms the *monohydrate* as lemon yellow crystals on crystallisation from  $\text{H}_2\text{O}$  (450g/1.5l) which has a lower **m** ~70-80<sup>o</sup> than the anhydrous substance. [Cahn & Simonsen *J Chem Soc* 2573 1932, Hay & Haynes *J Chem Soc* 3141 1956.]

**D-Altrose** [1990-29-0] **M 180.2, m 103-105<sup>o</sup>,  $[\alpha]_{546} +35^{\circ}$  (c 7.6,  $\text{H}_2\text{O}$ )**. Crystallise D-altrose from aqueous EtOH. If it is obtained by the hydrolysis of the acetate, then it may contain sodium and acetate ions. Ions are best removed by dissolving in  $\text{H}_2\text{O}$ , passing through suitable columns of ion-exchange resins, e.g. Amberlite IR-120 and Duolite A, and concentrating in a vacuum to a syrup. This is dissolved in MeOH, filtered and evaporated in a vacuum desiccator over granular  $\text{CaCl}_2$ . The thick syrup is inoculated with seed crystals, stirred, and before it sets to a magma of crystals, transfer the crystals with MeOH to a Büchner funnel. Recrystallise them in the same way.  $\beta$ -D-Altrofuranside has initial  $[\alpha]_{20}^{\circ} \sim -69^{\circ}$  (c 4,  $\text{H}_2\text{O}$ ) which mutarotates to  $+33^{\circ}$ . [Richtmeyer *Methods in Carbohydrate Chemistry* **I** 107 Academic Press 1962, Beilstein **1** IV 4301, see Angyal *Adv Carbohydrate Chem Biochem* **42** 15 1984 for ratio of anomers in solution.]

**D-Amygdalin (D-mandelonitrile- $\beta$ -gentiobioside)** [29883-15-6] **M 457.4, m 214-216<sup>o</sup>,  $[\alpha]_{\text{D}}^{\circ} -38^{\circ}$  (c 1.2,  $\text{H}_2\text{O}$ )**. D-Amygdalin recrystallises from water as the *trihydrate*, or from EtOH. It is present in bitter almonds. [Smith *Chem Ber* **64** 1115 1931, Beilstein **17/8** V 188.]

**Amylose** [9005-82-7]  $(\text{C}_6\text{H}_{10}\text{O}_5)_n$  (*for use in iodine complex formation*). Amylopectin is removed from impure amylose by dispersing in aqueous 15% pyridine at 80-90<sup>o</sup> (concentration 0.6-0.7%) and allowing the solution to stand at 44-45<sup>o</sup> for 7 days. The precipitate is re-dispersed and recrystallises during 5 days. After a further dispersion in 15% pyridine, it is cooled to 45<sup>o</sup>, allowed to stand at this temperature for 12 hours, then cooled to 25<sup>o</sup> and left for a further 10 hours. The combined precipitates are dispersed in warm water, precipitated with EtOH, washed with absolute EtOH, and dried *in vacuo* [Foster & Paschall *J Am Chem Soc* **75** 1181 1953.]

**1,6-Anhydro- $\beta$ -D-glucose (levoglucosan,  $\beta$ -glucosan,  $\beta$ -D-pyranose-form)** [498-07-7] **M 162.1, m 177<sup>o</sup>, 179-180<sup>o</sup>, 182-184<sup>o</sup>, 184<sup>o</sup>,  $[\alpha]_{\text{D}} -66.3^{\circ}$  (c 2,  $\text{H}_2\text{O}$ )**. Levoglucosan is readily formed by pyrolysis (dry distillation) of starch, ash-free amylose, cellulose and  $\beta$ -D-glucose in a vacuum. Best results are obtained when the acidity of the distillate is least. The product is dissolved in MeOH, decolourised with charcoal and cooled to give the glucosan in good yields. Other  $\beta$ -D-glucosides such as Arbutin, Salicin and Phloridzin also yield levoglucosan, and is evidence for the  $\beta$ - linkage configuration because  $\alpha$ -glucose and  $\alpha$ -glucosides require more drastic conditions for pyrolysis, i.e. longer heating and higher temperatures since the  $\alpha$ -orientation at C-1 needs to be inverted to the  $\beta$ -orientation [Karrer *Helv Chim Acta* **3** 258 1920, Pictet & Cramer *Helv Chim Acta* **3** 640 1920, Ruchel & Schuerch *J Org Chem* **31** 2233 1966, Irvine & Oldham *J Chem Soc* 2903 1925, Carvalho et al. *J Am Chem Soc* **81** 4054 1959].

Another ready source of levoglucosan is  $\beta$ -phenylglucoside (2.0, see [1464-44-4]) which is dissolved 1.3N aqueous KOH (100ml), heated on boiling water bath for 9 hours, while monitoring the specific optical rotation until it is constant ( $-64.4^{\circ}$ ). The clear mixture is cooled, neutralised (to methyl orange, the slight colour of the cooled solution does not interfere) with 3N sulfuric acid, evaporated to dryness *in vacuo*, extracted from the  $\text{K}_2\text{SO}_4$  residue with warm EtOH, evaporated and the residue is recrystallised from EtOH (10ml) to give *levoglucosan*, m 179-180<sup>o</sup>,  $[\alpha]_{\text{D}} -66.3^{\circ}$  (c 2,  $\text{H}_2\text{O}$ ), in 88% yield. Other  $\beta$ -phenylglyco-pyrano-sides give anhydro-glycosans, but the  $\alpha$ -linked sugars require much longer heating (~20 hours or weeks) to give the anhydro-sugars. This alkaline reaction has been studied in detail, and similarly  $\beta$ -phenylgalactoside provided a 91% yield of **1,6-anhydro- $\beta$ -D-galactose (anhydroglactosan)** [644-76-8] **M 162.1, with m 226<sup>o</sup>** (plates from 50% aqueous EtOH) and  $[\alpha]_{\text{D}} -22.0^{\circ}$  (c 2,  $\text{H}_2\text{O}$ ). [Montgomery et al. *J Am Chem Soc* **65** 3 1943.]

Levoglucosan is one of the more important anhydro-sugars as it, and its 2-, 3- and 4-substituted derivatives, are readily hydrolysed by aqueous acid to give glucose and the respective derivatives [Peat *Adv Carbohydrate*

*Chem* **2** 29 1946]. Also at elevated temperature, in the presence of zinc dust, ZnCl<sub>2</sub>, or platinum black, levoglucosan polymerises to form a variety of oligomers described as *dextrans*, and these can be commonly 20,000 to 50,000 mers (but 300,000 mers in the extreme); and have found use in chromatographic purification of large molecules, e.g. proteins. The polymerisation process has been studied in detail [Carvalho et al. *J Am Chem Soc* **81** 4054 1959, Irvine & Oldham *J Chem Soc* 2903 1925, Ruchel & Schuerch *J Org Chem* **31** 2233 1966, see also Pictet & Sarasin *Helv Chim Acta* **1** 87 1918 and later papers]. The 2-, 3- and 4- OH groups are readily derivatised in the usual way, and the *triacetyl* derivative has [13242-55-2] M 288.2, **m** 109.5-110.5°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -50.8° (CHCl<sub>3</sub>), the *trifluoroacetyl* derivative has M 450.2, **m** 63.5-65.0°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -39.9° (**c** 2.1, CHCl<sub>3</sub>), the *tribenzoyl* derivative has [13567-05-7] M 474.4, **m** 202-203°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -36.4° (CHCl<sub>3</sub>), the *tri-O-methyl* derivative has M 204.2, **m** 57.5-58.5°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -63.7° (**c** 2, H<sub>2</sub>O), and the *tri-O-ethyl* derivative has M 246.3, **b** 90°/0.60mm, **d**<sup>28</sup> 1.081, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -51.5° (**c** 2.8, CHCl<sub>3</sub>), the *tri-O-benzyl* derivative has M 432.5, **m** 89.5-90.5°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -30.8° (**c** 2.7, CHCl<sub>3</sub>), and the *tri-O-methylsilyl* derivative has M 378.7, **b** 87-87.5°/0.05mm, [ $\alpha$ ]<sub>D</sub><sup>30</sup> -33.8° (**c** 3.6, CHCl<sub>3</sub>); all of which have been subjected to the polymerisation process with the “*ether*” derivatives being more successful than the “*ester*” derivatives in producing high polymers. [Ruckel & Scheurch *J Org Chem* **31** 2233 1966]. The <sup>1</sup>H NMR of levoglucosan and its derivatives in DMSO-*d*<sub>6</sub> and D<sub>2</sub>O have been reported in detail [Woolwage & Seib *J Chem Soc (C)* 3143 1971]. [*Beilstein* **19** H 894, **19** I 452, **19** III/V 1181, **19** V 498.]

**β-L-(+)-Arabinose (natural)** [87-72-9] M 150.1, **m** 158°, [ $\alpha$ ]<sub>D</sub> +104° (**c** 4, H<sub>2</sub>O after 24h), pK<sup>17</sup> 12.4. β-L-(+)-Arabinose is recrystallised slowly, twice, from 80% aqueous EtOH, then dried under vacuum over P<sub>2</sub>O<sub>5</sub>. It can also be purified by heating the arabinose (200g) with glacial acetic acid (300ml) on a boiling water bath for 45 minutes, cooling, filtering, washing with 95% EtOH (500ml) in four portions and drying at 56-60° over P<sub>2</sub>O<sub>5</sub>. It has been recrystallised from 5 times its weight of 76% EtOH using charcoal (10g) to yield 127g, **m** 155-157°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +190.6° and mutarotating to +104° (**c** 4, H<sub>2</sub>O). [Anderson & Sands *Org Synth Coll Vol I* 67 1941, Wolfrom & Christian *J Am Chem Soc* **48** 3172 1926, *Beilstein* **1** IV 4217.]

**D-(-)-Arabinose** [10323-20-3, 28697-53-2 (*pyranoside*)] M 150.1, **m** 164°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -104.5° (**c** 1, H<sub>2</sub>O), [ $\alpha$ ]<sub>546</sub> -123° (**c** 10, H<sub>2</sub>O after 24 hours), pK<sup>25</sup> 12.54. Crystallise D-(-)-arabinose three times from EtOH, dry it *in vacuo* at 60° for 24 hours and store it in a vacuum desiccator. It also crystallises from a mixture of H<sub>2</sub>O/MeOH/EtOH with **m** 158-160°, or H<sub>2</sub>O with **m** 160-161°. [Whistler & Schweiger *J Am Chem Soc* **81** 5190 1959, Fletcher et al. *J Am Chem Soc* **72** 4546 1950, *Beilstein* **1** IV 4215, see Angyal *Adv Carbohydrate Chem Biochem* **42** 15 1984 for ratio of anomers in solution.]

**D-Arabitol (D-arabinitol)** [488-82-4] M 152.2, **m** 103°, [ $\alpha$ ]<sub>546</sub><sup>20</sup> +13° (**c** 5, 8% borax solution). This pentol, which occurs in lichens and fungi, is purified by recrystallisation from 90% EtOH or MeOH. [Ashina & Yamagita *Chem Ber* **67** 801 1934, derivarives: Nakagawa et al. *Bull Chem Soc Jpn* **40** 2150 1967, Prince & Reichstein *Helv Chim Acta* **20** 101 1937, Hough & Theobald *Methods in Carbohydrate Chemistry* **I** 94 1962, Academic Press, *Beilstein* **1** IV 2832.]

**L-Arabitol (L-arabinitol)** [7643-75-6] M 152.2, **m** 102°, 103°, [ $\alpha$ ]<sub>546</sub> -13° (**c** 5, 8% borax solution). This pentol, which occurs in the urine of pentosuric subjects, is purified by recrystallisation from 90% EtOH or MeOH. It has a higher rotation in the presence of molybdate: [ $\alpha$ ]<sub>D</sub><sup>20</sup> -130° (**c** 0.16, acidified molybdate) [Richtmeyer & Hudson *J Am Chem Soc* **73** 2249 1957]. [Gätzi & Reichstein *Helv Chim Acta* **21** 197 1938, *Beilstein* **1** IV 2832.]

**DL-Arabitol (DL-arabinitol)** [2152-56-9] M 152.2, **m** 105-106°. This synthetic arabitol is purified by recrystallisation from 90% EtOH, MeOH or EtOH/Me<sub>2</sub>CO. [Raphael *J Chem Soc, Supplement*, 48 1949, Ashira & Yamagita *Chem Ber* **67** 802 1934, *Beilstein* **1** IV 2832.]

**p-Arbutin (p-hydroquinone-O-β-D-glucopyranoside)** [497-76-7] M 272.3, **m** 195-198°, 199°, 200°(sintering at 163-164°), [ $\alpha$ ]<sub>D</sub><sup>20</sup> -65° (**c** 2, H<sub>2</sub>O), pK<sub>Est</sub> ~10.0. The glycoside from *Protea exima* is purified by recrystallisation from H<sub>2</sub>O or moist EtOAc (as *monohydrate*), after chromatography through silica Gel using EtOAc/MeOH. Crystallisation from EtOH/CHCl<sub>3</sub> gives crystals **m** 199-200° with intermediate melting at 164° and resolidifying. The *pentaacetate* crystallises from EtOH in fine needles with **m** 145-146°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -28.2°

(c 2, Me<sub>2</sub>CO). [Robinson & Waters *J Chem Soc* 2729 1930, IR, NMR, MS: Perold et al. *J Chem Soc, Perkin Trans 1* 239 1979, *Beilstein* 17/7 V 110.]

**L(+)-Ascorbic acid** [50-81-7] **M 176.1, m 193°(dec), [α]<sub>546</sub> +23° (c 10, H<sub>2</sub>O), pK<sub>1</sub><sup>25</sup> 4.04, pK<sub>2</sub><sup>25</sup> 11.34.** Crystallise it from MeOH/Et<sub>2</sub>O/petroleum ether [Herbert et al. *J Chem Soc* 1270 1933]. [*Beilstein* 18/5 V 26.]

**6-Bromo-2-naphthyl-α-D-galactopyranoside** [25997-59-5] **M 385.2, m 178-180°, 224-226°, 225°, [α]<sub>D</sub><sup>28</sup> +60° (c 1.2, pyridine).** It is prepared from penta-*O*-acetyl-D-galactoside, 6-bromo-2-naphthol and ZnCl<sub>2</sub>. The resulting tetra-acetate (2g) is hydrolysed by dissolving in 0.3N KOH (100ml) and heating until the solution is clear, then filtering and cooling to give colourless crystals of the α-isomer which are collected and recrystallised twice from hot MeOH. The high specific rotation is characteristic of the α-isomer. The *tetraacetate* has **m 155-156°, [α]<sub>D</sub><sup>20</sup> +60° (c 1, CHCl<sub>3</sub>)** [Dey & Pridham *Biochem J* 115 47 1969] [reported **m 75-85°, [α]<sub>D</sub><sup>24</sup> +94° (c 1.3, dioxane)**, Monis et al. *J Histochem Cytochem* 11 653 1963]. [*Beilstein* 17 IV 2972.]

**λ-Carrageenan** [9064-57-7 (κ), 9000-07-1 (κ + little of λ)]. This D-galactose-anhydro-D or L-galactoside polysaccharide is precipitated from 4g of Carrageenan in 600ml of water containing 12g of KOAc by addition of EtOH. Collect the fraction that precipitates between 30 and 45% (v/v) of EtOH and dry them *in vacuo*. [Pal & Schubert *J Am Chem Soc* 84 4384 1962.]

**Colchicoside** [7S-7N-[3-(β-D-glucopyranosyloxy)-1,2,10-tetramethoxy-9-oxobenzo[*a*]-heptalen-7-yl-(7S)]-acetamide, 7-glucosylcolchicine] [477-29-2] **M 547.5, m 216-218° (block), [α]<sub>D</sub><sup>15</sup> -128.5° (c 1, CHCl<sub>3</sub>), [α]<sub>D</sub><sup>15</sup> -231° (c 1, MeOH), [α]<sub>D</sub><sup>15</sup> -355° (c 1, H<sub>2</sub>O).** Purify colchicoside by chromatography through alumina and eluting with CHCl<sub>3</sub>, then recrystallising from Me<sub>2</sub>CO, **m 275-280°** (after releasing solvent at 180°). It also crystallises from EtOH; see colchicine [64-86-8]. The *tetraacetate* has **m 175-177°, [α]<sub>D</sub><sup>15</sup> -57° (c 1, CHCl<sub>3</sub>).** [Bellet et al. *Ann Pharm Fr* 10 241 1952, *Chem Abstr* 47 3323 1953, *Beilstein* 14 IV 946 for colchicine.]

**Convallatoxin (α-cardenolide mannoside)** [508-75-8] **M 550.6, m 238-239°, 238-241° (dec), [α]<sub>D</sub><sup>20</sup> -9.4° (c 0.7, dioxane), [α]<sub>D</sub><sup>16</sup> -1.0 ±3° (c 0.7, EtOH).** Crystallise convallatoxin from EtOAc, CHCl<sub>3</sub>/EtOH (9:1) or MeOH/Et<sub>2</sub>O. The *tetraacetate* has **m 238-242°** (from MeOH/Et<sub>2</sub>O), [α]<sub>D</sub><sup>25</sup> -5° (CHCl<sub>3</sub>). [Reyle et al. *Helv Chim Acta* 33 1541 1950, Fieser & Jacobson *J Am Chem Soc* 59 2335 1937 *Beilstein* 18 III/IV 3142.]

**α-Cyclodextrin (H<sub>2</sub>O)** [10016-20-3] **M 972.9, m >280°(dec), [α]<sub>546</sub> +175° (c 10, H<sub>2</sub>O).** Recrystallise α-cyclodextrin from 60% aqueous EtOH, then twice from water, and dry it for 12 hours in a vacuum at 80°. It is also purified by precipitation from water with 1,1,2-trichloroethylene. The precipitate is collected, washed and resuspended in water. This is boiled to steam distil the trichloroethylene. The solution is then freeze-dried to recover the cyclodextrin. [Armstrong et al. *J Am Chem Soc* 108 1418 1986]. [*Beilstein* 19/12 V 789.]

**β-Cyclodextrin (H<sub>2</sub>O)** [7585-39-9, 68168-23-0] **M 1135.0, m >300°(dec), [α]<sub>546</sub> +170° (c 10, H<sub>2</sub>O).** Recrystallise β-cyclodextrin from water and dry it for 12 hours in a vacuum at 110°, or 24 hours in a vacuum at 70°. The purity is assessed by TLC on cellulose containing a fluorescent indicator. [Taguchi, *J Am Chem Soc* 108 2705 1986, Tabushi et al. *J Am Chem Soc* 108 4514 1986, Orstam & Ross *J Phys Chem* 91 2739 1987]. [*Beilstein* 19 IV 6287, 19/12 V 801.]

***N*-Decanoyl-*N*-methylglucamine (Mega-10, *N*-D-glucidyl-*N*-methyl deconamide)** [85261-20-7] **M 349.5, m 91-93°, 92°.** Possible impurities are decanoic acid and *N*-methylglycamine. The former is removed by grinding the solid with Et<sub>2</sub>O and then with petroleum ether and drying over P<sub>2</sub>O<sub>5</sub>. It is twice recrystallised from MeOH/Et<sub>2</sub>O by dissolving in the minimum volume of MeOH, adding Et<sub>2</sub>O and drying in a vacuum. To remove the glycamine, the solid (800mg) is dissolved in hot H<sub>2</sub>O (10ml) and set aside. Mega-10 crystallises as colourless needles. These are filtered off and dried in a vacuum to constant weight. It is a good non-ionic non-hygroscopic detergent with a critical micelle concentration (CMC) of 7.4mM (0.26%) in 0.1M Tris-HCl pH 7.4

at 25°. [Hildreth *Biochem J* **207** 363 1982.]

**Dehydro-L(+)-ascorbic acid** [490-83-5] **M 174.1, m 196°(dec),  $[\alpha]_{546}^{20} +42.5^\circ$  (c 1, H<sub>2</sub>O), pK<sup>25</sup> 3.90.** Crystallise dehydro-L(+)-ascorbic acid from MeOH. The *anhydrous acid* is formed by heating it in a vacuum at 100°/1 hour to give a crisp glassy product which when shaken with absolute EtOH and then kept at 0° for 2 days gives microcrystals of the anhydrous acid. This is then washed with absolute EtOH and dried in a vacuum. It has **m 225°(dec)** and is stable in acidic solution but decomposes rapidly in alkaline solution. A 1% solution of the anhydrous acid when dissolved in phthalate/HCl buffer pH 3.5 at 60° and cooled to 20° has  $[\alpha]_{\text{D}}^{20} +56^\circ$  (0 minutes), +53.5°(2 hours), +19°(3 days), -2°(5 days) and -6°(6 days); then it becomes orange in colour. A freshly prepared 1% solution in H<sub>2</sub>O has  $[\alpha]_{\text{D}}^{20} +50^\circ$  (0 minutes), +44°(2 hours), +16°(3 days) and 0°(5 days). [Herbert et al. *J Chem Soc* 1270 1933, Kenyon et al. *J Chem Soc* 158 1948, *Beilstein* **18/5** V 411.]

**2-Deoxy-D-allose (2-deoxy-D-ribo-hexose)** [6605-21-6] **M 164.2, m 140-142°,  $[\alpha]_{\text{D}}^{24} +57.5^\circ$  (c 1.2, H<sub>2</sub>O).** Purify 2-deoxy-D-allose by two recrystallisations from absolute EtOH. The *p-nitrophenylhydrazone* has **m 61-62°,  $[\alpha]_{\text{D}}^{16.5} -55^\circ$  (MeOH).** An equilibrium solution at 31° in D<sub>2</sub>O contains 15%  $\alpha$ -pyranose, 58%  $\beta$ -pyranose, 12%  $\alpha$ -furanose and 15%  $\beta$ -furanose forms as estimated by <sup>1</sup>HNMR spectroscopy. [see Angyal *Adv Carbohydrate Chem Biochem* **42** 15 1984 for ratio of anomers in solution, Zorbach & Ollapally *J Org Chem* **129** 1790 1964.] [*Beilstein* **1** IV 4283.]

**2-Deoxy- $\beta$ -D-galactose (2-deoxy-D-lyxo-hexose)** [1949-89-9] **M 164.2, m 110°, 120-121°, (126-128°),  $[\alpha]_{\text{D}}^{20} +60^\circ$  (c 2, H<sub>2</sub>O, 2 hours).** Crystallise 2-deoxy- $\beta$ -D-galactose from MeOH or diethyl ether. The *aniline derivative* has **m 142-143°,  $[\alpha]_{\text{D}}^{16.5} -149^\circ$  (c 0.8, pyridine).** [Overend et al. *J Chem Soc* 671, 675 1950 and 992 1951.] A 30% equilibrium solution at 31° in D<sub>2</sub>O contains 40%  $\alpha$ -pyranose, 44%  $\beta$ -pyranose, 8%  $\alpha$ -furanose and 8%  $\beta$ -furanose forms as estimated by <sup>1</sup>HNMR spectroscopy [Angyal & Pickles *Aust J Chem* **25** 1711 1972]. [*Beilstein* **1** IV 4283.]

**2-Deoxy- $\alpha$ -D-glucose (2-deoxy-D-arabino-hexose)** [154-17-6] **M 164.2, m 148-151°,  $[\alpha]_{\text{D}}^{20} +46^\circ$  (c 0.5, H<sub>2</sub>O after 45 hours).** Crystallise 2-deoxy- $\alpha$ -D-glucose from MeOH/Me<sub>2</sub>CO, Me<sub>2</sub>CO or butanone to give a mixture of  $\alpha$ - and  $\beta$ - anomers, **m 142-144°,  $[\alpha]_{\text{D}}^{18} +38^\circ$  (35 minutes) to +46° (c 0.5, H<sub>2</sub>O).** Recrystallisation from *iso*PrOH gives mainly the  $\alpha$ -anomer **m 134-136°,  $[\alpha]_{\text{D}}^{25} +156^\circ$  to +103° (c 0.9, pyridine).** <sup>1</sup>H NMR studies showed that at 44° in D<sub>2</sub>O the solution contained 36% of  $\alpha$ -pyranose and 64% of  $\beta$ -pyranose sugar, but furanose structures were undetectable. [Snowden & Fischer *J Am Chem Soc* **69** 1048 1947, derivatives: Bollinger & Schmidt *Helv Chim Acta* **34** 989 1951; see Angyal & Pickles *Aust J Chem* **25** 1711 1972 for ratio of isomers in solution, *Beilstein* **1** IV 4282.]

**6-Deoxy-D-glucose (D-quinovose)** [7658-08-4] **M 164.2, m 146°,  $[\alpha]_{\text{D}}^{20} +73^\circ$  (after 5 minutes) and +30° (final, after 3 hours) (c 8.3, H<sub>2</sub>O).** 6-Deoxy-D-glucose is purified by recrystallisation from EtOAc and is soluble in H<sub>2</sub>O, EtOH but insoluble in Et<sub>2</sub>O and Me<sub>2</sub>CO. [Srivastava & Lerner *Carbohydr Res* **64** 263 1978; NMR: Angyal & Pickles *Aust J Chem* **25** 1711 1972, *Beilstein* **1** IV 4260.]

**2-Deoxy- $\beta$ -L-ribose** [18546-37-7] **M 134.1, m 77°, 80°,  $[\alpha]_{\text{D}}^{25} +91.7^\circ$  (c 7, pyridine, +40° final).** Crystallise 2-deoxy- $\beta$ -L-ribose from diethyl ether. It can also be purified by dissolving the ribose (7.3g) in EtOAc (3L) by reflux, decanting from any insoluble material and evaporating at 50°/vacuum to 2.2L, setting aside for 1-2 hours, filtering, and concentrating to 840ml. The ribose separates as compact nodules during 3-5 days at 0° and has **m 87-93°, and after repeated recrystallisations it has m 92-95°.** Mutarotation is as follows:  $[\alpha]_{\text{D}}^{16.5} +80^\circ$  (0 minutes), +71°(6 minutes), +59°(21 minutes) and +59°(41 minutes) (c 1.14, H<sub>2</sub>O);  $[\alpha]_{\text{D}}^{20} +105^\circ$  (0 minutes), +71°(9.5 minutes), +67°(12.5 minutes), +49°(81 minutes), +49°(136 minutes) (c 0.9, MeOH). [Deriaz et al. *J Chem Soc* 1879 1949, *Beilstein* **1** IV 4181.]

**2-Deoxy- $\beta$ -D-ribose** [533-67-5] **M 134.1, m 86-87°, 87-90°,  $[\alpha]_{\text{D}}^{20} -56^\circ$  (c 1, H<sub>2</sub>O after 24 hours).** Dissolve 2-deoxy- $\beta$ -D-ribose in a little H<sub>2</sub>O, evaporate to a syrup (in a vacuum), and seed to crystallise. Triturate the crystals with a little EtOAc containing 5% MeOH, decant and dry in vacuum over P<sub>2</sub>O<sub>5</sub>. It is best purified *via* the *anilide* which separates from a mixture of the ribose (100-125g) in MeOH (100ml) and redistilled aniline (40ml) in a few minutes. After standing for 20 hours at room temperature, it is cooled to 0°, filtered, washed

with 50% aqueous MeOH and Et<sub>2</sub>O followed by recrystallisation from ethylene glycol monomethyl ether. The anilide has **m 172-173°**,  $[\alpha]_D^{25} +46^\circ$  (equilibrium in pyridine). The anilide (5g), benzaldehyde (5ml) and benzoic acid (0.5g) in H<sub>2</sub>O (150ml) are shaken mechanically for 20-24 hours. The aqueous phase is extracted with Et<sub>2</sub>O (3x), decolourised with a little charcoal and evaporated in a vacuum to a syrup. This is dried over P<sub>2</sub>O<sub>5</sub> in high vacuum. The syrupy sugar weighs 3.1g and crystallises in a few days, but more rapidly on seeding. Triturate it with a little EtOAc containing 5% MeOH, decant and dry it over P<sub>2</sub>O<sub>5</sub>. At this stage it has **m 78-82°**,  $[\alpha]_D^{25} -57^\circ$  (c 1, H<sub>2</sub>O final). This is a mixture of  $\alpha$ - and  $\beta$ - anomers. Pure  **$\beta$ -anomer** is obtained by recrystallisation from EtOAc. The  $\beta$ -anomer when recrystallised from EtOAc and isoPrOH has **m 96-98°**,  $[\alpha]_D^{25} -55^\circ$  (c 0.5, H<sub>2</sub>O final). [Sowden *Biochemical Preparations* 5 75 1957.] The mutarotation is as follows:  $[\alpha]_D^{20.5} +96.3^\circ$  (0 minutes),  $-76^\circ$  (33 minutes),  $-56^\circ$  (24 hours) (c 5.8 MeOH). It is moderately hygroscopic and should be kept in a well stoppered bottle. It also crystallises from diethyl ether. [Deriaz et al. *J Chem Soc* 1879 1949, *Beilstein* 1 IV 4181, Hauske & Rapoport *J Org Chem* 44 2472 1979.]

The **1,3,4-tribenzoate ( $\alpha$ - and  $\beta$ -mixture)**, obtained by benzylation, has **m 127°** (after crystallisation from EtOH),  $[\alpha]_D^{25} -65^\circ$  (c 1, CHCl<sub>3</sub>). The crude syrupy mixture in \*C<sub>6</sub>H<sub>6</sub> is applied to an acid-washed Alorco Al<sub>2</sub>O<sub>3</sub> column. Elution with \*C<sub>6</sub>H<sub>6</sub>/hexane (1:1) affords (after crystallisation from MeOH),  **$\beta$ -1,3,4-tri-O-benzoyl-2-deoxy-D-ribose**, **m 159-169°**,  $[\alpha]_D^{20} -196^\circ$  (c 1, CHCl<sub>3</sub>). Further elution with \*C<sub>6</sub>H<sub>6</sub> gives, after recrystallisation from MeOH pure  **$\alpha$ -1,3,4-tri-O-benzoyl-2-deoxy-D-ribose**, **m 151-152°**,  $[\alpha]_D^{20} +41.6^\circ$  (c 0.83, CHCl<sub>3</sub>). [Pedersen et al. *J Am Chem Soc* 82 3425 1960; see Angyal *Adv Carbohydrate Chem Biochem* 42 15 1984 for ratio of anomers and ring forms.]

**Dextran** [9004-54-0] **M<sub>r</sub> 6,000-220,000**. Solutions of dextran keep indefinitely at room temperature if 0.2ml of Roccal (10% alkyl dimethylbenzylammonium chloride) or 2mg phenyl mercuric acetate are added per 100ml solution. This inhibits mould growth. [Scott & Melvin *Anal Biochem* 25 1656 1953.]

**Diacetone-D-glucose (1,2:5,6-di-O-isopropylidene- $\alpha$ -D-glucofuranoside)** [582-52-5] **M 260.3, m 107-110°, 110.5°, 111-113°, 112°**,  $[\alpha]_D^{15} -18.4^\circ$  (c 1, H<sub>2</sub>O). Diacetone-D-glucose crystallises from Et<sub>2</sub>O, (needles), petroleum ether or \*C<sub>6</sub>H<sub>6</sub> and sublimes *in vacuo*. It is soluble in 7 volumes of H<sub>2</sub>O and 200 volumes of petroleum ether at their boiling points. The solubility in H<sub>2</sub>O at 17.5° is 4.3%. It precipitates from aqueous solutions on basification with NaOH. [Schmid & Karrer *Helv Chim Acta* 32 1371 1949, Fischer & Rund *Chem Ber* 49 90, 93 1916, IR: Kuhn *Anal Chem* 22 276 1950, *Beilstein* 19/12 V 318.]

***N,N'*-Diacetylchitobiose (2-acetyl-O<sup>4</sup>-[2-acetylamino-2-deoxy- $\beta$ -D-glucopyranosyl]-2-deoxy-D-glucose)** [35061-50-8] **M 424.4, m 245-247°(dec), 251.5-252.5°, 260-262°**,  $[\alpha]_D^{25} +39.5^\circ$  (extrapolated)  $\rightarrow +18.5^\circ$  (after 60 minutes, c 1, H<sub>2</sub>O). Recrystallise *N,N'*-Diacetylchitobiose from aqueous MeOH or aqueous EtOH/1,2-dimethoxyethane. [Zilliken et al. *J Chem Soc* 77 1296 1955, *Beilstein* 18/11 V 147.]

**1,3,4,6-Di-O-benzylidene-D-mannitol** [28224-73-9] **M 358.4, m 192-195°, 193°**,  $[\alpha]_D^{20} -11.9^\circ$  (c 0.7, Me<sub>2</sub>CO). 1,3,4,6-Di-O-benzylidene-D-mannitol recrystallises from Et<sub>2</sub>O in long fine needles with  $\lambda_{max}$  at 256nm ( $\epsilon$  435) in 95% EtOH, and R<sub>F</sub> 0.21 (1:1 CCl<sub>4</sub>/EtOAc) on TLC Silica Gel G. [Sinclair *Carbohydr Res* 12 150 1970, ORD, CD, NMR, IR, MS: Brecknell et al. *Aust J Chem* 29 1749 1976, *Beilstein* 19/11 V 640.]

**Digitonin** [11024-24-1] **M 1229.3, m >270°(dec)**,  $[\alpha]_{546}^{20} -63^\circ$  (c 3, MeOH). This digitoxin hexa-glycoside can be recrystallised from aqueous 85% EtOH or MeOH/diethyl ether. It is purified by preparative paper chromatography and developed with the upper phase of a mixture of nBuOH/H<sub>2</sub>O/AcOH (4:5:1), and the spot (R<sub>F</sub> 0.36) is eluted with 25% CCl<sub>3</sub>CO<sub>2</sub>H in CHCl<sub>3</sub>. It has also been purified by countercurrent distribution. It forms an ethanolate, and complexes with cholesterol and other sterols. [Ruhstroth-Bauer & Breitenfeld *Hoppe Seyler's Z Physiol Chem* 302 111 1955, Grisvold *J Am Pharm Assoc* 23 664 1934, *Beilstein* 19 IV 1243.]

**Digitoxin** [71-63-6] **M 764.9, m 256-257° (anhydrous)**,  $[\alpha]_D^{20} +16.7^\circ$  (c 1, CHCl<sub>3</sub>),  $+4.8^\circ$  (c 1, dioxane). Digitoxin crystallises from MeOH, aqueous EtOH with 0.5 to 1 H<sub>2</sub>O and from H<sub>2</sub>O as the *dihydrate*. It also crystallises from CHCl<sub>3</sub>/Et<sub>2</sub>O as *anhydrous* crystals. The hydrate dehydrates at 120°/vacuum. Its solubility is 2.5% in CHCl<sub>3</sub>, 1.7% in EtOH, 0.25% in EtOAc, and 0.001% in H<sub>2</sub>O; and has E<sub>1cm</sub><sup>1%</sup> 202.5 at 219-220nm (50% EtOH). [Stoll et al. *Helv Chim Acta* 37 1134 1954, Demoen & Janssen *J Am Pharm Assoc* 42 635 1953, *Beilstein* 18 IV 1478.]

**D(+)-Digitoxose (2,6-dideoxy-D-ribo-hexose)** [527-52-6] **M 148.2, m 110°**, 112°,  $[\alpha]_{546}^{20} +57^\circ$  (c 1, H<sub>2</sub>O). Crystallise D(+)-digitoxose from MeOH/Et<sub>2</sub>O, Et<sub>2</sub>O, EtOAc, EtOAc/Et<sub>2</sub>O/petroleum ether or Me<sub>2</sub>CO/Et<sub>2</sub>O and dry it over P<sub>2</sub>O<sub>5</sub>/vacuum. It has  $[\alpha]_{D}^{20} +45.2^\circ$  (6 minutes) mutarotating to +50.2° (16 hours constant) (c 1.65, H<sub>2</sub>O). [Gut & Prins *Helv Chim Acta* **20** 1229 1947, Bollinger & Ulrich *Helv Chim Acta* **35** 93 1952, NMR of derivs: Tsukamoto et al. *J Chem Soc, Perkin Trans 1* 2621 1988, *Beilstein* **1** IV 4191.]

**Digoxin** [5 $\beta$ ,20(22)-cardenolide-3 $\beta$ ,12 $\beta$ ,14 $\beta$ -triol-3-(O-2,6-dideoxy- $\beta$ -D-ribo-hexopyranosyl-(1 $\rightarrow$ 4)-O-2,6-dideoxy- $\beta$ -D-ribo-hexopyranosyl-(1 $\rightarrow$ 4)-O-2,6-dideoxy- $\beta$ -D-ribo-hexopyranosyl)-oxy-), **12 $\beta$ -isomer**] [20830-75-5] **M 781.0, m 265°(dec)**,  $[\alpha]_{546}^{20} +14.0^\circ$  (c 10, pyridine),  $[\alpha]_{546}^{25} +15.6^\circ$  (c 0.5, CHCl<sub>3</sub>/MeOH 1:1). Crystallise digoxin from aqueous EtOH, aqueous pyridine, EtOH/CHCl<sub>3</sub>, and dry it in a vacuum at 100°. The melting point depends on heating rate, but when placed in a bath at 260° and heated slowly it decomposes at 265°. In EtOH it has  $\lambda_{\max}$  at 220nm ( $\epsilon$  12,800). [Smith *J Chem Soc* 508 1930, X-ray: Go et al. *Cryst Struct Commun* **8** 149, 1031 1979, *Beilstein* **18/4** V 381.] **HIGHLY TOXIC.**

**(-)-2,3:4,6-Di-O-isopropylidene-2-keto-L-gulonic acid monohydrate (-DAG)** [18467-77-1] **M 292.3, m 100-101°**, 103°,  $[\alpha]_{D}^{25} -21.6^\circ$  (c 2.3, MeOH). Dissolve -DAG in Et<sub>2</sub>O, filter. dry (MgSO<sub>4</sub>) it, filter it again and evaporate to give a yellow oil. Addition of one drop of H<sub>2</sub>O induces crystallisation to the *monohydrate*, which also forms rhombic crystals on recrystallisation from 95% EtOH/H<sub>2</sub>O at room temperature. [Flatt et al. *Synthesis* 815 1979, Reichstein & Grussner *Helv Chim Acta* **17** 311 1934, Takagi & Jeffrey *Acta Crystallogr Sect B* **34** 2932 1978, cf *Org Synth* **55** 80 1976, *Beilstein* **19/12** V 520.]

**1,2:5,6-Di-O-isopropylidene-D-mannitol** [1707-77-3] **M 262.3, m 121-125°**, 122°,  $[\alpha]_{D}^{25} +1.2^\circ$  (c 3, H<sub>2</sub>O). Although quite soluble in H<sub>2</sub>O, it gives a purer product when crystallised from this solvent, forming needles [Baer *J Am Chem Soc* **67** 338 1945, NMR: Curtis et al. *J Chem Soc, Perkin Trans 1* 1756 1977]. [*Beilstein* **19/11** V 589.]

**Dulcitol (galactitol)** [608-66-2] **M 182.2, m 188-189°**, b 276-280°/1.1mm, **pK<sup>18</sup> 13.5**. Crystallise dulcitol from water by addition of EtOH. It is optically inactive and is prepared by reduction of D-galactose. Its *hexaacetate* crystallises from EtOH and has **m** 168-169°. [IR: Thompson et al. *Discuss Farad Soc* **9** 222 1950, Wolfrom & Thompson *Methods in Carbohydrate Chemistry* **II** 671963, Academic Press, *Beilstein* **1** IV 2844.]

**meso-Erythritol** [149-32-6] **M 122.1, m 122°**, b 329-331°, **pK<sup>18</sup> 13.9**. *meso*-Erythritol crystallises from distilled water or absolute EtOH and is dried at 60° in a vacuum oven. It sublimes at 110° in a high vacuum. It is optically inactive. [Jeans & Hudson *J Org Chem* **20** 1565 1955, IR: Kuhn *Anal Chem* **22** 276 1950, *Beilstein* **1** IV 2807.]

**Erythryl tetranitrate (Cordite)** [7297-25-8] **M 302.1, m 61°**. Crystallise cordite from EtOH. It explodes on percussion at ~220-460° and is a vasodilator. [*Beilstein* **1** III 2358, **1** IV 2809.]

**D(-)-Fructose** [57-48-7] **M 180.2, m 103-106°**,  $[\alpha]_{546}^{20} -190^\circ$  (after 1 hour, c 10, H<sub>2</sub>O), **pK<sup>25</sup> 12.03**. Dissolve D(-)-fructose in an equal weight of water (charcoal, previously washed with water to remove any soluble material), filter and evaporate under reduced pressure at 45-50° to give a syrup containing 90% of fructose. After cooling to 40°, the syrup is seeded and kept at this temperature for 20-30 hours with occasional stirring. The crystals are removed by centrifugation, washed with a small quantity of water and dried to constant weight under a vacuum over conc H<sub>2</sub>SO<sub>4</sub>. For higher purity, this material is recrystallised from 50% aqueous ethanol. [Tsunami et al. *J Am Chem Soc* **72** 1071 1950]. [*Beilstein* **31** H 321, **1** IV 4401.]

**D(+)-Fucose (6-deoxy-d-galactose)** [3615-37-0] **M 164.2, m 144°**,  $[\alpha]_{546}^{20} +89^\circ$  (after 24 hours, c 10 in H<sub>2</sub>O),  **$\alpha$ -form mutarotates:**  $[\alpha]_{D}^{20} +124^\circ$  (10 minutes) to +75.6° (24 hours) (c 9, EtOH). Crystallise D(+)-fucose from EtOH or 95% EtOH. Its *1,2:3,4-diisopropylidene* derivative has **b** 83-84°/0.45mm and crystallises on seeding with **m** 37° and  $[\alpha]_{D}^{20} -52^\circ$  (melt). [Schmidt *Methods in Carbohydrate Chemistry* **I** 191 1962, Academic Press, Haskett et al. *J Am Chem Soc* **61** 1658 1939, *Beilstein* **31** H 76, **1** IV 4265.]

**D-Galactal (1,5-anhydro-2-deoxy-D-lyxo-hex-1-enitol)** [21193-75-9] **M 146.2, m 100°, 100-102°, 104°, 103-106°,  $[\alpha]_D^{20}$  -21.3° (c 1, MeOH).** Recrystallise D-galactal from EtOAc, EtOH or EtOAc/MeOH. [Overend et al. *J Chem Soc* 675 1950, Wood & Fletcher *J Am Chem Soc* 79 3234 1957, Distler & Jourdan *J Biol Chem* 248 6772 1973, *Beilstein* 17 III/IV 2332.]

**Galactaric acid (mucic acid)** [526-99-6] **M 210.1, m 212-213°(dec)  $pK_{1}^{25}$  3.09 (3.29),  $pK_{2}^{25}$  3.63 (4.41).** Dissolve mucic acid (40g) in the minimum (calculated) volume of N aqueous NaOH (~335ml) without heating, decolorise this with charcoal, filter and precipitate it by adding 5N HCl (~57ml). Cool for 1 hour at 0°, filter off, wash with cold H<sub>2</sub>O and dry it *in vacuo*. All temperatures should be kept below 25°. It is optically inactive. [Barker et al. *J Chem Soc* 4128 1958, Lewis et al. *Methods in Carbohydrate Chemistry* II 39 1963, Academic Press, *Beilstein* 3 IV 1292.]

**D-Galactonic acid** [576-36-3] **M 196.2, m 141° (hydrate), 148° (anhydrous)  $pK_{Est}$  ~3.5.** Crystallise D-galactonic acid from EtOH or aqueous EtOH. It cyclises to *D-galactono-1,4-lactone*, **m 134-136°**, and mutarotates in 1 hour to  $[\alpha]_{346}^{30}$  -92° (c 5, H<sub>2</sub>O). It can also be obtained from the Na salt by adding 10 times its weight of acetic acid, warming till just brown, cooling, filtering off the crystals and drying them. It has **m 145-146°,  $[\alpha]_D^{25}$  -13.6° (c 1, H<sub>2</sub>O, 2 minutes and mutarotates to -57.6°).** [Blackburn & Upton *J Am Chem Soc* 55 2514 1933, *Beilstein* 3 IV 1257, and for the  $\gamma$ -lactone see below.]

**D(-)-Galactono-1,4-lactone** [2782-07-2] **M 178.1, m 134-135°, 134-137°,  $[\alpha]_D^{20}$  -78° (c 5, H<sub>2</sub>O, 1 hour).** Crystallise the lactone from EtOH, aqueous EtOH, MeOH or EtOAc. It is also purified by passage through a column of Amberlite IR-120 (H<sup>+</sup> form), and the effluent and washings are then freeze-dried [Wolfrom & Thompson *Methods in Carbohydrate Chemistry* I 67 1963, Academic Press]. The *5,6-O-isopropylidene-D-galactono-1,4-lactone* is purified by chromatography (EtOAc) and has **m 165-167° (from EtOH/hexane), and 167.5-168.5° (from Me<sub>2</sub>CO/\*C<sub>6</sub>H<sub>6</sub>)** [NMR: Copel & Stick *Aust J Chem* 31 1371 1978.] [*Beilstein* 18 III/IV 3026, 18/5 V 18.]

**D(+)-Galactosamine hydrochloride** [1772-03-8] **M 215.6, m 181-185°,  $[\alpha]_D^{25}$  +96.4° (after 24 hours, c 3.2 in H<sub>2</sub>O),  $pK_{Est}$  ~7.7 (free base).** Dissolve the hydrochloride in a small volume of H<sub>2</sub>O. Then add three volumes of EtOH, followed by acetone until faintly turbid and keep overnight in a refrigerator. [Roseman & Ludoweig *J Am Chem Soc* 76 301 1954, *Beilstein* 4 IV 2024.]

**$\alpha$ -D-Galactose** [59-23-4, 3646-73-9 pyranose] **M 180.2, m 167-168°,  $[\alpha]_D^{20}$  +80.4° (after 24 hours, c 4 in H<sub>2</sub>O),  $pK^{25}$  12.48.**  $\alpha$ -D-Galactose is crystallised twice from aqueous 80% EtOH at -10°, then dried in a vacuum oven at 90° over P<sub>2</sub>O<sub>5</sub> for 10 hours. [Link *Biochemical Preparations* 3 75 1953, Hansen et al. *Biochemical Preparations* 4 2 1955.] Also purify it by recrystallising the dried solid (150g) in hot H<sub>2</sub>O (150ml), then adding hot MeOH (250ml) and hot EtOH (500ml), stirring to mix, filtering through a bed of charcoal, and the clear filtrate is stirred to initiate crystallisation. After standing overnight at 10°, the crystals of the  $\alpha$ -anomer are filtered off by suction, washed with MeOH, then EtOH, and dried (yield 130g), and more can be obtained by evaporation of the filtrate and washing as before. [Wolfrom & Thompson *Methods in Carbohydrate Chemistry* I 120 1962, Academic Press, *Beilstein* 1 IV 4336.]

**$\beta$ -D-Galactose** [7296-64-2 (pyranose)] **M 180.2, m 167°,  $[\alpha]_D^{20}$  +52° (initial, c 4 in H<sub>2</sub>O).**  $\alpha$ -D-Galactose (40g) is dissolved in hot H<sub>2</sub>O to establish the equilibrium of  $\alpha$ - and  $\beta$ - anomers; then the solution is cooled to 0° and poured into absolute EtOH (500ml). Stir vigorously and crystallisation occurs within a few minutes, and more rapidly if seeded, filter the crystals immediately (7g,  $[\alpha]_D^{20}$  +65° initial, c 4 in H<sub>2</sub>O). This mixture of  $\alpha$ - and  $\beta$ - anomers is further separated by dissolving in an equal weight of cold H<sub>2</sub>O, filtering and adding to ice cold absolute EtOH (250ml) and stirring for 1 minute when crystals separate, then filter them off. After two such crystallisations, the initial  $[\alpha]_D^{20}$  is +53°. This can be further purified by shaking with 80% EtOH for 2 minutes, filtering, washing with EtOH and Et<sub>2</sub>O, and drying in a vacuum desiccator to give  $\beta$ -D-galactose (15g) with **m 167°,  $[\alpha]_D^{20}$  +52° (initial, c 4 in H<sub>2</sub>O) mutarotating to +80.4°.** Acetylation of D-galactose with hot NaOAc/Ac<sub>2</sub>O gives  **$\beta$ -D-galactopyranoside pentaacetate m 142°,  $[\alpha]_D^{25}$  +25 (c 4 in CHCl<sub>3</sub>).** [Wolfrom & Thompson *Methods in Carbohydrate Chemistry* I 120 1962, Academic Press, *Beilstein* 1 IV 4336.]

**D(+)-Galacturonic acid** [685-73-4, 91510-62-2 (H<sub>2</sub>O)] **M 194.1, m 159-161°**,  $[\alpha]_{\text{D}}^{20} +36^{\circ}$  (c 6, H<sub>2</sub>O, 2h), **pK<sub>Est</sub> ~4.8**. Crystallisation of the acid from 95% EtOH and drying it in a vacuum desiccator (12mm) over P<sub>2</sub>O<sub>5</sub> gives the *monohydrate* mixture of  $\alpha$ - and  $\beta$ - anomers (**mostly  $\alpha$ -**) as white micro needles, which sinter at ~100-111° and melt at 159-160°,  $[\alpha]_{\text{D}}^{20} +107^{\circ}$  (initial, c 4 in H<sub>2</sub>O mutarotating to +51°). [Link & Sell *Biochemical Preparations* 3 74, 78 1953, *Beilstein* 3 IV 2000.] The  **$\beta$ -anomer** is obtained by warming the  $\alpha$ -anomer in EtOH, AcOH or EtOAc and has **m 160° (165°, sinters at 140°)**,  $[\alpha]_{\text{D}}^{20} +27^{\circ}$  (initial, c 2 in H<sub>2</sub>O mutarotating to +55.3° in 24 hours). The *sodium salt* [14984-39-5] **M 216.1** has  $[\alpha]_{\text{D}}^{20} +27^{\circ}$  (c 10 in H<sub>2</sub>O after 5 hours). The *phenylhydrazone* has **m 141°** (from MeOH). [Ehrlich & Schubert *Chem Ber* 62 1974, 2014 1929, Anderson & King *J Chem Soc* 5333 1961, *Beilstein* 3 IV 2001.]

**Genistin (4',5,7-trihydroxyisoflavone-7-D-glucoside)** [529-59-9] **M 432.4, m 256°**,  $[\alpha]_{\text{D}}^{22} -28^{\circ}$  (c 0.6, 0.02N NaOH). Genistin is repeatedly crystallised from hot 80% EtOH/water and treated with charcoal (Nuchar) until free from saponin. The presence of saponin is detected by adding crystals to conc H<sub>2</sub>SO<sub>4</sub> when the citron yellow colour changes to red, then purple. Pure genistin does not change colour. Its UV in 85% EtOH has  $\lambda_{\text{max}}$  at 262.5nm. [Walter *J Am Chem Soc* 63 3273 1941, *Beilstein* 18 III/IV 2732.]

**$\alpha$ -Gentiobiose (amygdalose, 6-O- $\alpha$ -D-glucopyranosyl-D-glucopyranose)** [5995-99-5 (*bi-pyranose*)] **M 342.3, m 86° (2MeOH), 189-195°, 195-197° (anhydrous)**,  $[\alpha]_{\text{D}}^{20} +11^{\circ}$  (after 24 hours, c 4, H<sub>2</sub>O). Crystallise  $\alpha$ -gentiobiose from MeOH (retains solvent of crystallisation). It is best purified by conversion to the  *$\alpha$ -octaacetate*, **m 191-192°** (recrystallise from absolute EtOH or CHCl<sub>3</sub> and excess absolute EtOH),  $[\alpha]_{\text{D}}^{20} +51.6^{\circ}$  (c 4.3, CHCl<sub>3</sub>) [Goldstein & Whelan *Methods in Carbohydrate Chemistry* I 313/1962, Academic Press, Hudson & Johnson *J Am Chem Soc* 39 1271 1917] directly or from the  *$\beta$ -octaacetate* (see below) obtained by acetylation with Ac<sub>2</sub>O and ZnCl<sub>2</sub>, and hydrolysed (see below). It mutarotates from  $[\alpha]_{\text{D}}^{22} +16^{\circ}$  (3 minutes) to +9.5° (c 2, H<sub>2</sub>O). [Reynolds & Evans *J Am Chem Soc* 60 2559 1938, NMR of anomers: Bradbury et al. *Carbohydrate Research* 53 1970 1957, *Beilstein* 17/7 V 203.]

**$\beta$ -Gentiobiose (6-O- $\beta$ -D-glucopyranosyl-D-glucopyranose)** [5996-00-9 (*bi-pyranose*), 554-91-6 (*one open ring*)] **M 342.3, m 190-195°**,  $[\alpha]_{\text{D}}^{20} +8^{\circ}$  (after 6 hours, c 3, H<sub>2</sub>O).  $\beta$ -Gentiobiose is best purified *via* the *octaacetate* which is recrystallised from MeOH, EtOH or better from methyl cellosolve by heating at 80°. The octaacetate (15g) is hydrolysed by suspending it in dry 0.05N NaOMe in MeOH (180ml) for 1 hour with occasional shaking at room temperature. Dilute this with H<sub>2</sub>O to dissolve suspended matter, pass through Amberlite IR-120 and Duolite A-4 columns and the eluate is evaporated under reduced pressure to a syrup. Residual H<sub>2</sub>O is removed by repeated distillation with absolute EtOH under reduced pressure. The syrup is dissolved in methyl cellosolve (~40ml), filtered, nucleated and placed in an oven at 80°. The crystals are filtered off, washed with absolute EtOH (yield 6.7g, 89%), dried and have **m 187-189°**. Further recrystallisation from methyl cellosolve gives **m 190°**, and mutarotates from  $[\alpha]_{\text{D}}^{28} -1.5^{\circ}$  (initial) to +10.6° (final, c 4, H<sub>2</sub>O). The  *$\beta$ -octaacetate* has **m 193°** (crystallised from 95% EtOH) and has  $[\alpha]_{\text{D}}^{20} -5^{\circ}$  (c 1.8, CHCl<sub>3</sub>). [Goldstein & Whelan *Methods in Carbohydrate Chemistry* I 313 1962, Academic Press, *Beilstein* 17/7 V 203.]

**Glucamine (glycamine, 1-amino-1-deoxy-D-glucitol)** [488-43-7] **M 181.2, m 127°**,  $[\alpha]_{\text{D}}^{20} -8^{\circ}$  (c 10, H<sub>2</sub>O), **pK<sub>Est</sub> ~9.0**. Crystallise glucamine from MeOH or aqueous MeOH and store it in a CO<sub>2</sub>-free atmosphere. For the *N-methylglucamine* derivative see below. [Holly et al. *J Am Chem Soc* 72 5461 1950, Karrer et al. *Helv Chim Acta* 20 83 1937.]

**D-Gluconamide** [3118-85-2] **M 197.2, m 142-143°, 144°**,  $[\alpha]_{\text{D}}^{25} +31^{\circ}$  (c 2, H<sub>2</sub>O). Crystallise D-gluconamide from EtOH or 1,2-dimethoxyethane. It mutarotates slowly and hydrolytically in aqueous solution from +30.7° to +13.8° in 80 hours to give *ammonium D-gluconate* which recrystallises from 95% EtOH with **m 153-154°** and  $[\alpha]_{\text{D}}^{25} +11.8^{\circ}$  (c 3, H<sub>2</sub>O). [Wolfrom et al. *J Am Chem Soc* 80 944 1958, *Beilstein* 3 VI 1259.]

**D-Glucono- $\delta$ -lactone** [90-80-2] **M 178.1, m 152-153°**,  $[\alpha]_{\text{D}}^{20} +76^{\circ}$  (c 4, H<sub>2</sub>O). Crystallise D-glucono- $\delta$ -lactone from ethylene glycol monomethyl ether and dry for 1 hour at 110°. It can be freed from other sugars *via*

a column of Celite and charcoal (750g of each, 90 x 7.5cm) which is washed with 0.01N formic acid until the pH of the wash is equal to that of the entering acid. The lactone is applied in H<sub>2</sub>O and eluted with 0.01N formic acid (7L), then eluted with 7.5% EtOH/0.01N formic acid (8L), then 15% EtOH/0.01N formic acid (8L) which removes pentose and isomaltose (the optical rotation of the eluates are used for sugar detection) and finally elution with aqueous formic acid provides glucolactone which is obtained by evaporating or freeze drying. Its solubility in H<sub>2</sub>O is 60% and 1% in EtOH. A solution in H<sub>2</sub>O is slightly acidic, and the lactone dissolves in an equivalent of aqueous NaOH to form **sodium D-gluconate** [527-07-1] **M 218.1**, has **m 200-206°(dec)**,  $[\alpha]_{\text{D}}^{25} +12^{\circ}$  (c 10, H<sub>2</sub>O), **pK<sup>25</sup> 3.6**. [cf p 553, Smith & Whelan *Biochemical Preparations* 10 127 1963, Beilstein 3 IV 1255.]

**α- and β- Glucosamine (2-amino-2-deoxy-D-glucose)** [3416-24-8] **M 179.2**, **m 110°(dec)**,  $[\alpha]_{\text{D}}^{20} +28^{\circ}$  to  $+48^{\circ}$  (c 5, H<sub>2</sub>O), **pK<sup>24</sup> 7.71**. Crystallise the amines from MeOH. The free base has been obtained from the hydrochloride (21.5g, see below) in a mixture of Et<sub>3</sub>N (15ml) and EtOH (125ml) by shaking for 2 days at room temperature, and the solid Et<sub>3</sub>N.HCl is filtered off and the process repeated with more Et<sub>3</sub>N (3-4 times) until the **α-D-glucosamine** (15g) is free from Cl ions. It has **m 88°**,  $[\alpha]_{\text{D}}^{20} +100^{\circ}$  mutarotating to  $+47.5^{\circ}$  (c 1, H<sub>2</sub>O). When Et<sub>2</sub>NH is used as base, the α- to β- conversion is complete giving **β-D-glucosamine**. The *pentaacetate* is purified by dissolving in CHCl<sub>3</sub>, treating with charcoal, drying (MgSO<sub>4</sub>), evaporating the solvent, and adding a little dry Et<sub>2</sub>O to induce crystallisation. It has **m 124-126°**,  $[\alpha]_{\text{D}}^{20} +113^{\circ}$  (c 1, CHCl<sub>3</sub>) after 16 hours in a desiccator. [Leaback *Biochemical Preparations* 10 118 1963.] The *N-acetyl* derivative, **m 203-205°** from MeOH/Et<sub>2</sub>O (dry in vacuum P<sub>2</sub>O<sub>5</sub>) has  $[\alpha]_{\text{D}}^{20} +75^{\circ}$  to  $+41^{\circ}$  (c 2, H<sub>2</sub>O); this derivative can also be purified by dissolving in the minimum volume of H<sub>2</sub>O to which is added 7-8 volumes of EtOH followed by Et<sub>2</sub>O until turbid and keeping at ~20° to crystallise. Wash the crystals with MeOH then Et<sub>2</sub>O and dry *in vacuo* over P<sub>2</sub>O<sub>5</sub>. [Horton *Biochemical Preparations* 11 1 1966.]

**D-Glucosamine hydrochloride** [66-84-2] **M 215.6**, **m >300°**,  $[\alpha]_{\text{D}}^{25} +71.8^{\circ}$  (after 20 hours, c 4, H<sub>2</sub>O), **pK<sup>24</sup> 7.71**. Crystallise the hydrochloride from 3M HCl, water, and finally water/EtOH/acetone as for galactosamine hydrochloride. [Purchase & Braun *Org Synth* 26 36 1946, Stacey & Webber *Methods in Carbohydrate Chemistry* I 228 1962, Academic Press.] The salt has also been purified by dissolving in the minimum volume of boiling H<sub>2</sub>O (charcoal), filtering and adding a large excess of 95% EtOH (~4 volumes) and stirring vigorously for several hours. Collect the crystals after 4-6 hours to give **α-anomer** which mutarotates from  $[\alpha]_{\text{D}}^{25} +100^{\circ}$  to  $+72^{\circ}$  (equilibrium, c 1, H<sub>2</sub>O). A large amount of the **β-anomer** stays in solution. This can be precipitated from the filtrate by adding excess Et<sub>2</sub>O. The mixture of α- plus β-anomers has  $[\alpha]_{\text{D}}^{25.5} +68.8^{\circ}$  (c 4.75, H<sub>2</sub>O, mutarotating to  $+70.1^{\circ}$ ) [Leaback *Biochemical Preparations* 10 118 1963]. *Note that if Et<sub>2</sub>NH is used instead of Et<sub>3</sub>N, conversion to the β-anomer can be complete* (see above). [Stacey et al. *Methods in Carbohydrate Chemistry* I 306 1962, Academic Press, Beilstein 4 IV 2018.]

**α-D-Glucose** [492-62-6] **M 180.2**, **m 83° (monohydrate), 146° (anhydrous), mutarotates from  $[\alpha]_{\text{D}}^{20} +112^{\circ}$  to  $+52.5^{\circ}$  (after 24 hours, c 4, H<sub>2</sub>O), pK<sup>25</sup> 12.46**. Recrystallise α-D-glucose slowly from aqueous 80% EtOH, then dry it over P<sub>2</sub>O<sub>5</sub> *in vacuo*. *Alternatively*, crystallise it from water at 55°, then dry it for 6 hours in a vacuum oven between 60-70°/2mm. Its solubilities are: H<sub>2</sub>O (~50%), EtOH (1.7%). [Hendricks et al. *J Am Chem Soc* 56 99 1934, Beilstein 1 IV 4302.] [For equilibrium forms see Angyal *Adv Carbohydr Chem* 42 15 1984, Angyal & Pickles *Aust J Chem* 25 1711 1972.]

**β-D-Glucose** [50-99-7] **M 180.2**, **m 148-150°**, mutarotates from  $[\alpha]_{\text{D}}^{20} +18.7^{\circ}$  to  $+52.5^{\circ}$  (after 24 hours, c 4, H<sub>2</sub>O). Crystallise β-D-glucose from hot glacial acetic acid or pyridine. Traces of solvent are removed by drying in a vacuum oven at 75° for >3 hours. [Gottfried *Adv Carbohydr Chem* 5 127 1950, Kjaer & Lindberg *Acta Chem Scand* 13 1713 1959, Whistler & Miller *Methods in Carbohydrate Chemistry* I 130 1962, Academic Press, Beilstein 1 IV 4306.] [For equilibrium forms see Angyal *Adv Carbohydr Chem* 42 15 1984, Angyal & Pickles *Aust J Chem* 25 1711 1972.]

**α-D-Glucose pentaacetate** [604-68-2] **M 390.4**, **m 110-111°, 112-113°**,  $[\alpha]_{546}^{20} +119^{\circ}$ ,  $[\alpha]_{\text{D}}^{20} +102^{\circ}$  (c 5, CHCl<sub>3</sub>). Crystallise it from MeOH, EtOH or three recrystallisations from 95% EtOH. [Wolfrom & Thompson *Methods in Carbohydrate Chemistry* II 212 1963, Academic Press, Beilstein 17/7 V 318.]

**$\beta$ -D-Glucose pentaacetate** [604-69-3] **M 390.4, m 131-132<sup>o</sup>,  $[\alpha]_{546}^{20} +5^{\circ}$  (c 5, CHCl<sub>3</sub>).** Crystallise the pentaacetate from MeOH or EtOH. It is best purified by recrystallising 160g from 1L of hot 95% EtOH (charcoal) and filtering hot. It is important that as soon as the temperature of the filtrate cools to  $\sim 20^{\circ}$  it is filtered off. Note that some  $\alpha$ -D-isomer will crystallise out if a prolonged crystallisation period is allowed. Further crystallisation in this manner and drying in a vacuum over CaCl<sub>2</sub> will give pure  $\beta$ -D-anomer which has **m 132<sup>o</sup>,  $[\alpha]_{\text{D}}^{20} +4^{\circ}$  (c 5, CHCl<sub>3</sub>).** [Wolfrom & Thompson *Methods in Carbohydrate Chemistry* **II** 212 1963, Academic Press, Krahl & Cori *Biochemical Preparations* **1** 33 1955, *Beilstein* **17/7** V 319.]

**D-Glucose phenylhydrazone** [3713-25-5] **M 358.4, m three forms.** Crystallise the hydrazone from 70% aqueous EtOH or EtOH/Et<sub>2</sub>O. Three forms have been described: “ $\alpha$ ” form **m 159<sup>o</sup>, 160<sup>o</sup>** which mutarotates from  $[\alpha]_{\text{D}}^{20} -87^{\circ}$  to  $-50^{\circ}$  (H<sub>2</sub>O) [Fischer *Ber* **20** 821 1887, Behrends *Justus Liebigs Ann Chem* **353** 106 1907], “ $\beta$ ” form **m 140-141<sup>o</sup>, 142<sup>o</sup>** which mutarotates from  $[\alpha]_{\text{D}}^{20} -2^{\circ}$  to  $-50^{\circ}$  (H<sub>2</sub>O) [Behrends & Lohr *Justus Liebigs Ann Chem* **362** 78 1908], and Skraup’s form **m 115-116<sup>o</sup>** which mutarotates from  $[\alpha]_{\text{D}}^{20} -70^{\circ}$  to  $-47^{\circ}$  (H<sub>2</sub>O) [Skraup *Monatsh Chem* **10** 406 1889, Butler & Crechter *J Am Chem Soc* **51** 3161 1921]. These mutarotate to the **formazan**. [*Beilstein* **1** IV 4322, Mester & Major *J Am Chem Soc* **77** 4297 1955, Stanek et al. *The Monosaccharides*, Academic Press 1963, pp 539-541, 543.]

**D-Glucuronic acid** [6556-12-3] **M 194.1, m 159-161<sup>o</sup>, 165<sup>o</sup>,  $[\alpha]_{\text{D}}^{20} +36^{\circ}$  (c 6, H<sub>2</sub>O, 2 hours, mutarotating from +11.5<sup>o</sup>),  $\text{pK}_{\text{a}}^{20}$  3.18.** Crystallise the acid from EtOH or EtOAc, wash it with MeOH and dry it *in vacuo* to give the “ $\beta$ ” form. Heating converts it to the lactone (see below). The *sodium salt monohydrate* [207300-70-7] **M 234.1 has m  $\sim 136$ -138<sup>o</sup>(dec)  $[\alpha]_{\text{D}}^{20} +21^{\circ}$  (c 2, H<sub>2</sub>O after 2hours).** [Sutter & Reichstein *Helv Chim Acta* **21** 1210 1938, *Beilstein* **3** H 886, **3** IV 1997.]

**D-Glucurono-6,3-( $\delta$ )-lactone** [32449-92-6] **M 176.1, m 175-177<sup>o</sup>,  $[\alpha]_{546}^{20} +22^{\circ}$  (after 24 hours, c 10, H<sub>2</sub>O).** Dissolve the lactone or mixture of lactone and acid in H<sub>2</sub>O and concentrate on a steam bath until crystallisation begins. Cool rapidly to room temperature with stirring. After 2 hours the product is filtered off, washed with cold EtOH and dried to **m 174-175<sup>o</sup>** and  $[\alpha]_{\text{D}}^{25} +19.8^{\circ}$  (c 5.2, H<sub>2</sub>O). The amount of free acid can be obtained by titration of an ice-cold aqueous solution with standard alkali. It can be recrystallised from EtOH, EtOH/H<sub>2</sub>O or MeOH, and the highest recorded **m** is 180<sup>o</sup>. [Stacey *J Chem Soc* 1529 1939, Mehlretter et al. *J Am Chem Soc* **73** 2424 1951, *Beilstein* **18** III/IV 3055, **18/5** V 33.]

**D(+)-Glycogen** [9005-79-2] **M 25,000-100,000, m 270-280<sup>o</sup>(dec),  $[\alpha]_{546}^{20} +216^{\circ}$  (c 5, H<sub>2</sub>O).** A 5% aqueous solution (charcoal) of D(+)-glycogen is filtered, and an equal volume of EtOH is added. After standing overnight at 3<sup>o</sup> the precipitate is collected by centrifugation, washed with absolute EtOH, then EtOH/diethyl ether (1:1) and diethyl ether, and dried. [Sutherland & Wosilait *J Biol Chem* **218** 459 1956.]

**Glycyrrhizic acid ammonium salt (3H<sub>2</sub>O)** [53956-04-0] **M 823.0, m 210<sup>o</sup>(dec), 220<sup>o</sup>(dec, sintering at 170<sup>o</sup>),  $[\alpha]_{546}^{20} +60^{\circ}$  (c 1, 50% aqueous EtOH),  $\text{pK}_{\text{Est}} \sim 4.0$ .** Crystallise the ammonium salt from glacial acetic acid, then dissolve it in ethanolic ammonia and evaporate. The *pentahydrate* forms needles from 75% aqueous EtOH, **m 212-217<sup>o</sup>**. The free acid crystallises from glacial acetic acid. [Karrer et al. *Helv Chim Acta* **4** 100 1921, Lithgoe & Tripett *J Chem Soc* 1983, 1987 1950, *Beilstein* **18** IV 5156.]

**Heparin (from pig intestinal mucosa)** [9005-49-6] **M<sub>r</sub>  $\sim 3,000$ , amorphous,  $[\alpha]_{\text{D}}^{20} \sim +55^{\circ}$  (H<sub>2</sub>O).** Most likely contaminants are mucopolysaccharides including heparin sulfate and dermatan sulfate. Purify heparin by precipitation with cetylpyridinium chloride from saturated solutions of high ionic strength. [Cifonelli & Roden *Biochemical Preparations* **12** 12 1968, Wolfrom et al. *J Org Chem* **29** 540 1946, Huggard *Adv Carbohydr Chem* **10** 336-368 1955.]

**Heparin (sodium salt)** [9041-08-1] **M<sub>r</sub>  $\sim 3000$  (low Mol Wt, Bovine), amorphous,  $[\alpha]_{\text{D}}^{20} +47^{\circ}$  (c 1.5, H<sub>2</sub>O).** Dissolve the salt in 0.1M NaCl (1g/100ml) and precipitate it by adding EtOH (150ml). [Wolfrom et al. *J Org Chem* **29** 540 1946, Huggard *Adv Carbohydr Chem* **10** 336-368 1955.]

**Heptyl-β-D-glucopyranoside** [78617-12-6] M 278.4, m 74-77°, 76-77°,  $[\alpha]_D^{20}$  -34.2° (c 5, H<sub>2</sub>O). Purify the glucoside by repeated crystallisation from Me<sub>2</sub>CO which is a better solvent than EtOAc. The *acetate* has m 66-68.5° and  $[\alpha]_D^{20}$  -20.5° (c 4, CHCl<sub>3</sub>) [Pigman & Richtmyer *J Am Chem Soc* **64** 369 1942]. [Beilstein **17** IV 2936.]

**Heptyl-β-D-1-thioglucopyranoside** [85618-20-8] M 294.4, m 98-99°. The *tetraacetyl* derivative is purified by silica gel column chromatography and eluted with a \*C<sub>6</sub>H<sub>6</sub>/Me<sub>2</sub>CO gradient (up to 5% of Me<sub>2</sub>CO) and recrystallises from *n*-hexane as colourless needles m 72-74° (Erbing & Lindberg *Acta Chem Scand* **B30** 611 1976 gave m 69-70°). Hydrolysis with an equivalent of base in methanol gives the desired glucoside. This is a non-ionic detergent for reconstituting membrane proteins and has a critical micelle concentration of 30 mM. [Shimamoto et al. *J Biochem (Tokyo)* **97** 1807 1985; Saito & Tsuchiya *Chem Pharm Bull Jpn* **33** 503 1985.]

**D(-)-Isoascorbic acid (araboascorbic acid, 5R-[R-1,2-dihydroxyethyl-3,4-dihydroxy-5H-furan-2-one])** [89-65-6] M 176.1, m 169°, 174°(0.5 H<sub>2</sub>O, dec),  $[\alpha]_D^{25}$  -16.8° (c 2, H<sub>2</sub>O),  $[\alpha]_D^{20}$  +77° (c 2, Me<sub>2</sub>CO, acetonilidene derivative), pK<sup>18</sup> 3.99 (4.23). Crystallise D(-)-isoascorbic acid from H<sub>2</sub>O, EtOH or dioxane.  $\lambda_{\max}$  is at 245nm with  $\epsilon$  7500 (EtOH). [Reichstein et al. *Helv Chim Acta* **17** 510, 516 1934, Heslop et al. *J Chem Soc* 225 1944, Beilstein **18** III/IV 3037, **18/5** V 26.]

**2-Keto-L-gulonic acid (xylo-2-hexulonic acid)** [526-98-7] M 194.1, m 159-162°, 171°,  $[\alpha]_D^{20}$  -34.8° (c 2, MeOH),  $[\alpha]_D^{18}$  -48° (c 1, H<sub>2</sub>O), pK<sup>Est</sup> ~2.2. Crystallise 2-keto-L-gulonic acid from half its weight of water, wash it with Me<sub>2</sub>CO and dry it *in vacuo*. [Reichstein et al. *Helv Chim Acta* **17** 311 1934, NMR: Crawford et al. *J Am Chem Soc* **102** 2220 1980, Beilstein **3** IV 1985.]

**Lactobionic acid (4-O-β-D-galactopyranosyl-D-gulonic acid)** [96-82-2] M 358.3, m 128-130°, mutarotates from  $[\alpha]_D^{20}$  +53° to +22.6° (c 3, after 4 hours in H<sub>2</sub>O), pK<sup>25</sup> 3.6. Crystallise lactobionic acid from water by addition of EtOH. [NMR: Taga et al. *Bull Chem Soc Jpn* **51** 2278 1978, Beilstein **17** III/IV 3392, **17/7** V 436.]

**α-Lactose (H<sub>2</sub>O)** [63-42-3] M 360.3, m 220°(dec), 253-255° (252.4°),  $[\alpha]_D^{20}$  +52.3° (c 4.2, H<sub>2</sub>O), pK<sup>25</sup> 12.2 (OH). α-Lactose crystallises from water below 93.5° as the *hydrate* which can be dried at 80°/14mm. [Horst *Rec Trav Chim, Bas* **72** 878 1953, Beilstein **17** III/IV 3066.]

**Lactulose (4-O-β-D-galactopyranosyl-D-fructose)** [4618-18-2] M 342.2, m 168.5-169°(dec),  $[\alpha]_{D46}^{20}$  -57° (c 1, H<sub>2</sub>O). Crystallise lactulose from MeOH or 50% MeOH. It mutarotates from  $[\alpha]_D^{20}$  -11.9° to -50.7° (c 1, H<sub>2</sub>O). [Montgomery & Hudson *J Am Chem Soc* **32** 2101, 2104 1930, Beilstein **17** III/IV 3094, **17/7** V 214.] NMR in Me<sub>2</sub>SO at 24° shows 0% α-pyranose, 27% β-pyranose, 20% α-furanose and 52% β-furanose forms [Angyal *Adv Carbohydr Chem* **42** 15 1984].

**Lanatoside A (digitoxigenin nonoacetyl-tetraglycoside)** [17575-20-1] M 969.1, m 245-248°,  $[\alpha]_D^{20}$  +32° (EtOH). Crystallise lanatoside A from MeOH or 95% aqueous EtOH. Its solubility is 1/16000 (H<sub>2</sub>O), 1/20 (MeOH), 1/40 (EtOH) and 1/225 (CHCl<sub>3</sub>). [Stoll et al. *Helv Chim Acta* **16** 1049 1933, Kuhn et al. *Helv Chim Acta* **45** 881 1962, Beilstein **18** III/IV 1480.] It is **cardiotonic**.

**Lanatoside B (gitoxigenin nonoacetyl-tetraglycoside)** [17575-21-2] M 985.1, m 233°(dec), 245-248°(dec),  $[\alpha]_D^{20}$  +35° (MeOH). Crystallise lanatoside B from MeOH. Its solubility is: 1/20 (MeOH), 1/40 (EtOH), 1/5600 (CHCl<sub>3</sub>), and is insoluble in H<sub>2</sub>O. [Stoll et al. *Helv Chim Acta* **16** 1049 1933, Miyatake et al. *Chem Pharm Bull Jpn* **5** 171 1957, Beilstein **18** III/IV 2465.] It is **cardiotonic**.

**Lanatoside C (digoxigenin nonoacetyl-tetraglycoside)** [17575-22-3] M 297.1, m 246-248°,  $[\alpha]_D^{20}$  +33.5° (c

**1.85, 95% EtOH).** Crystallise lanatoside C from MeOH. Its solubility is : 1/17000 (H<sub>2</sub>O), 1/45 (EtOH) and 1/1500-2000 (CHCl<sub>3</sub>). [Stoll et al. *Helv Chim Acta* **16** 1049 1933, Stoll & Kreis *Helv Chim Acta* **35** 1318 1952, Okada et al. *Chem Pharm Bull Jpn* **23** 2039 1975, *Beilstein* **18** III/IV 2455.] It is **cardiotonic**.

**$\alpha$ -L(+)-Lyxose** [1949-78-6] **M 150.1, m 106-108<sup>o</sup>,  $[\alpha]_{\text{D}}^{20} +14^{\circ}$  after 1 hour (c 6, H<sub>2</sub>O).** The  $\alpha$ -anomer crystallises from propan-1-ol or EtOH, and the  $\beta$ -anomer crystallises from propan-2-ol. The *2,4-dinitrophenylhydrazone* has **m 171-172<sup>o</sup>** and  **$[\alpha]_{\text{D}}^{20} -31^{\circ}$**  (pyridine). In D<sub>2</sub>O it has 21% of the  $\alpha$ -pyranose form. The *2-methyl ether* has **m 120-121<sup>o</sup>** and  **$[\alpha]_{\text{D}}^{20} +6^{\circ}$**  (c 1, H<sub>2</sub>O). [Angyal *Adv Carbohydr Chem* **42** 15 1984, Bently *J Am Chem Soc* **79** 1720 1959, *Beilstein* **1** I 439, **1** IV 4232.]

**$\beta$ -D-Lyxose** [1114-34-7] **M 150.1, m 118-119<sup>o</sup>, 120-122<sup>o</sup>,  $[\alpha]_{\text{D}}^{20} -14^{\circ}$  (c 4, H<sub>2</sub>O),  $\alpha$ -anomer has m 105-107<sup>o</sup> mutarotates from  $[\alpha]_{\text{D}}^{20} +5.6^{\circ}$  to  $-18.8^{\circ}$  (c 4, H<sub>2</sub>O).** Crystallise  $\beta$ -D-lyxose from EtOH or aqueous 80% EtOH by slow crystallisation. Dry it under vacuum at 60<sup>o</sup>, and store it in a vacuum desiccator over P<sub>2</sub>O<sub>5</sub> or CaSO<sub>4</sub>. [*Beilstein* **1** IV 4230, Overend et al. *J Chem Soc* 3496 1961.] <sup>1</sup>H NMR in D<sub>2</sub>O has  $\delta$ :  $\alpha$ -H (pyranose) 5.39 (*J* 4.0 Hz),  $\beta$ -H (pyranose) 5.19 (*J* ~0 Hz),  $\alpha$ -H (furanose) 5.26 (*J* 4.0 Hz),  $\beta$ -H (furanose) 5.24 (*J* 4.5 Hz), and at 31<sup>o</sup> in D<sub>2</sub>O it consists of 70%  $\alpha$ -pyranose, 28%  $\beta$ -pyranose, 1.5%  $\alpha$ -furanose and 0.5%  $\beta$ -furanose [Angyal & Pickles *Aust J Chem* **25** 1711 1972].

**Maltose (H<sub>2</sub>O) (4-O- $\alpha$ -D-glucopyranosyl-D-glucose)** [6363-53-7] **M 360.3, m 109-110<sup>o</sup>, 118<sup>o</sup>, mutarotates from  $[\alpha]_{\text{D}}^{20} +111.7^{\circ}$  to  $+130.4^{\circ}$  (c 4, H<sub>2</sub>O).** Purify maltose by chromatography from aqueous solution on to a charcoal/Celite (1:1) column, wash it with water to remove glucose and other monosaccharides, then elute it with aqueous 75% EtOH. Crystallise it from water, aqueous EtOH or EtOH containing 1% nitric acid. Dry it as the *monohydrate* at room temperature under vacuum over H<sub>2</sub>SO<sub>4</sub> or P<sub>2</sub>O<sub>5</sub>. Also purify it by dissolving it in MeOH, evaporating to a syrup which on standing for 12 hours in contact with 1/10<sup>th</sup> its volume of H<sub>2</sub>O gives crystals of the *monohydrate*. Its iodine number is 55.5. The **osazone** has **m 200<sup>o</sup>(dec)** and  **$[\alpha]_{\text{D}}^{20} +58^{\circ}$**  (c 1.4, H<sub>2</sub>O). [Howarth et al. *J Chem Soc* 793 1937, *Beilstein* **17** III/IV 3057, **17** V 189.]

**D-Mannitol** [69-65-8] **M 182.2, m 166.1<sup>o</sup>, 168-170<sup>o</sup>,  $[\alpha]_{\text{D}}^{20} +29^{\circ}$  (c 10, after 1 hour in 8% borax solution),  $[\alpha]_{\text{D}}^{22} -4.0^{\circ}$  (c 0.5, DMF), pK<sup>18</sup> 13.5.** D-Mannitol is crystallised from EtOH, MeOH or H<sub>2</sub>O and dried at 100<sup>o</sup>. [Thomson *Acta Chem Scand* **6** 270, 279, 280 1952, *Beilstein* **1** IV 2841.]

**Mannitol hexanitrate** [15825-70-4] **M 452.2, m 112-113<sup>o</sup>,  $[\alpha]_{\text{D}}^{20} +45.8^{\circ}$  (c 1.4, EtOH).** The hexanitrate crystallises from EtOH or dilute EtOH as silky white needles. **EXPLOSIVE (on detonation).** [Hayward *J Am Chem Soc* **73** 1974 1951, Patterson & Todd *J Chem Soc* 2876 1929, *Beilstein* **1** IV 2841.]

**$\alpha$ -D(+)-Mannose** [3458-28-4] **M 180.2, m 132<sup>o</sup>,  $[\alpha]_{\text{D}}^{20}$  mutarotates from  $+29.9^{\circ}$  to  $+14^{\circ}$  (c 4, H<sub>2</sub>O).** Crystallise  $\alpha$ -D(+)-mannose repeatedly from EtOH, aqueous 80% EtOH, AcOH or MeOH/propan-2-ol and then dry it *in vacuo* over P<sub>2</sub>O<sub>5</sub> at 60<sup>o</sup>. [For <sup>1</sup>H NMR and equilibrium forms; Angyal *Adv Carbohydr Chem* **42** 15 1984, Angyal & Pickles *Aust J Chem* **25** 1711 1972, *Beilstein* **1** IV 4328.]

**D(+)-Melezitose (H<sub>2</sub>O) (O- $\alpha$ -D-glucopyranosyl-(1  $\rightarrow$  3)- $\beta$ -fructofuranosyl- $\alpha$ -D-glucopyranose** [597-12-6] **M 540.5, m 153-154<sup>o</sup>(dec), 2H<sub>2</sub>O, 160<sup>o</sup>(dec),  $[\alpha]_{\text{D}}^{20} +88^{\circ}$  (c 2, H<sub>2</sub>O for dihydrate) and  $[\alpha]_{\text{D}}^{20} +91.7^{\circ}$  (c 2, H<sub>2</sub>O for anhydrous).** D(+)-Melezitose crystallises from aqueous EtOH as the *monohydrate* and water as the *dihydrate*, and is then dried at 110<sup>o</sup> (anhydrous). It is also purified by dissolving in an equal volume of H<sub>2</sub>O, filtering into a crystallising dish and allowing to stand (loosely covered) for several weeks undisturbed at 20<sup>o</sup>. The crystals of clear prisms are wiped carefully and dried in air. They effloresce at once losing 3.35% of their weight, and after 3 days in air the loss is for 1H<sub>2</sub>O from the dihydrate. Drying at 110<sup>o</sup> for 6 hours *in vacuo* yields the *anhydrous* form which after 2 days in air it absorbs H<sub>2</sub>O to give the *monohydrate*. The *monohydrate* is also obtained by dissolving it in an equal weight of H<sub>2</sub>O at 60<sup>o</sup> and adding 4 volumes of 95% EtOH and drying in air overnight. [Richtmeyer & Hudson *J Org Chem* **11** 610 1946, *Beilstein* **17** III/IV 3815, **17** V 414.]

**D(+)-Melibiose (2H<sub>2</sub>O) (6-O- $\alpha$ -D-galactopyranosyl-D-glucose)** [585-99-9, *monohydrate* 66009-10-7] **M**

**360.3, m 84-85°, 178-181°, 184-185°,  $[\alpha]_D^{20} +135^\circ$  (c 5, after 10 hours H<sub>2</sub>O).** D(+)-Melibiose crystallises as a *hydrate* from water or aqueous EtOH. The  $\alpha$ -**anomer** is obtained by recrystallising 1g from a mixture of 0.35ml of H<sub>2</sub>O and 0.2ml of EtOH. It crystallises easily with **m** 179° and mutarotates from  $[\alpha]_D^{20} +166^\circ$  to  $+142.3^\circ$  (220 minutes, c 4, H<sub>2</sub>O). Crystallisation from MeOH gives the *anhydrous* form which hydrates to the monohydrate in air. The  $\beta$ -**anomer dihydrate** **m** 85-86° mutarotates from  $[\alpha]_D^{20} +123.5^\circ$  to  $+143.1^\circ$  (c 4, H<sub>2</sub>O for anhydrous). [Fletcher & Diehl *J Am Chem Soc* **74** 5774 1952, *Beilstein* **17** III/IV 3075, 17/7 V 206.]

**N-Methyl-D(-)-glucamine (Meglumine)** [6284-40-8] **M 195.2, m 128-129°,  $[\alpha]_{546}^{20} -19.5^\circ$  (c 2, H<sub>2</sub>O), pK<sup>28</sup> 9.62.** Crystallise N-methyl-D(-)-glucamine from MeOH. Its solubility in H<sub>2</sub>O is 10%. [Karrer & Herkenrath *Helv Chim Acta* **20** 83 1957 also for other N-alkyl derivatives, *Beilstein* **4** IV 1914.]

**N-Methyl  $\alpha$ -L-glucosamine** [42852-95-9] **M 193.2, m glass,  $[\alpha]_D^{25} -65^\circ$  (c 1, MeOH) pK<sub>Est</sub> ~9.** The *hydrochloride* crystallises from EtOH as hygroscopic needles with **m** 160-163°,  $[\alpha]_D^{25} +103^\circ$  mutarotating to  $-88^\circ$  after 24 hours (c 0.6, H<sub>2</sub>O), and gives the free base as a glass. The *Pentaacetate* crystallises from CHCl<sub>3</sub>/Et<sub>2</sub>O with **m** 160.5-161.5°,  $[\alpha]_D^{25} -100^\circ$  (c 0.7, CHCl<sub>3</sub>), and the *N-acetate* crystallises from CHCl<sub>3</sub>/MeOH with **m** 165-166°,  $[\alpha]_D^{25} -51^\circ$  (c 0.4, H<sub>2</sub>O). [Kuehl et al. *J Am Chem Soc* **68** 536 1946, **69** 3032 1947, Lemieux & Wolfrom *Adv Carbohydr Chem* **3** 337 1948, *Beilstein* **4** IV 2032.]

**Methyl  $\alpha$ -D-glucoside (methyl  $\alpha$ -D-glucopyranoside)** [97-30-3] **M 194.2, m 168°, 166-169°,  $[\alpha]_D^{20} +158.9^\circ$  (c 10, H<sub>2</sub>O), pK<sup>25</sup> 13.71.** Crystallise methyl  $\alpha$ -D-glucoside from MeOH or EtOH. Its solubility in H<sub>2</sub>O is 10%. [Ferrier et al. *Carbohydr Research* **27** 55, 59 1973, *Beilstein* **17/7** V 13.]

**Methyl  $\beta$ -D-glucoside (methyl  $\beta$ -D-glucopyranoside)** [7000-27-3] **M 203.2 (0.5 H<sub>2</sub>O), m 107-109°,  $[\alpha]_D^{20} -33^\circ$  (c 10, H<sub>2</sub>O).** Crystallise methyl  $\beta$ -D-glucoside from MeOH or EtOH. Its solubility in H<sub>2</sub>O is 10%. [Ferrier et al. *Carbohydr Research* **27** 55, 59 1973, *Beilstein* **17/7** V 10.]

**4-Methylumbellifer-7-yl- $\alpha$ -D-glucopyranoside** [17833-43-1] **M 338.3, m 209-210°, 221-222°,  $[\alpha]_D^{20} +162^\circ$  (c 0.5, pyridine).** Recrystallise 4-methylumbellifer-7-yl- $\alpha$ -D-glucopyranoside from hot H<sub>2</sub>O or EtOH. [Courtin-Duchateau & Veyrière *Carbohydr Research* **65** 23, 29 1978, *Beilstein* **18** IV 443.]

**4-Methylumbellifer-7-yl- $\beta$ -D-glucopyranoside** [18997-57-4] **M 338.3, m 211-213°, 211°,  $[\alpha]_D^{20} -68^\circ$  (c 0.5, pyridine),  $-89.5^\circ$  (c 0.5, H<sub>2</sub>O for half hydrate).** 4-Methylumbellifer-7-yl- $\beta$ -D-glucopyranoside crystallises as the half hydrate from hot H<sub>2</sub>O. [Constantzas & Kocourek *Col Czech Chem Commun* **24** 1099 1959, De Re et al. *Ann Chim (Rome)* **49** 2089 1959, Courtin-Duchateau & Veyrière *Carbohydr Research* **65** 23, 29 1978, *Beilstein* **18** III/IV 5152, **8** IV 433, **18/7** V 616.]

**Naringin (4',5,7-trihydroxyflavanone 7-rhamnoglucoside)** [10236-47-2] **M 580.5, m ~83° (6H<sub>2</sub>O), 171° (2H<sub>2</sub>O),  $[\alpha]_D^{19} -90^\circ$  (c 1, EtOH),  $[\alpha]_{546}^{20} -107^\circ$  (c 1, EtOH).** This bitter principle from grape juice crystallises from water to give the hydrate with 6-8 H<sub>2</sub>O which when dried at 110° gives the *dihydrate*. Its solubility in H<sub>2</sub>O is 0.1% at 40° and 10% at 75°. The *2,4-dinitrophenylhydrazone* crystallises from aqueous dioxane with **m** 246-247° [Douglass et al. *J Am Chem Soc* **73** 4023 1951]. [Pulley & von Loesecke *J Am Chem Soc* **61** 175 1939, *Beilstein* **18** III/IV 2637, **18** V 528.]

**2-Nitrophenyl- $\beta$ -D-galactopyranoside** [369-07-3] **M 301.3, m 185-190°, 193°, 193-194°,  $[\alpha]_D^{18} -51.9^\circ$  (c 1, H<sub>2</sub>O).** Purify 2-nitrophenyl- $\beta$ -D-galactopyranoside by recrystallisation from EtOH. [Seidman & Link *J Am Chem Soc* **72** 4324 1950, Snyder & Link *J Am Chem Soc* **75** 1758 1953]. It is a chromogenic substrate for  $\beta$ -galactosidases [Jagota et al. *J Food Sci* **46** 161 1981]. [*Beilstein* **17/7** V 52.]

**4-Nitrophenyl- $\alpha$ -D-galactopyranoside** [7493-95-0] **M 301.3, m 166-169°, 173°,  $[\alpha]_D^{25} +248^\circ$  (c 1, H<sub>2</sub>O).** Purify 4-nitrophenyl- $\alpha$ -D-galactopyranoside by recrystallisation from H<sub>2</sub>O or aqueous EtOH. The *monohydrate* has **m** 85° which resolidifies and melts again at 151-152° (the *hemihydrate*), then resolidifies again and melts at 173° to give the *anhydrous* form. Drying the monohydrate at 60° yields the hemihydrate, and drying at 100°

gives the anhydrous compound. The *tetraacetate* has *m* 147° after drying at 100°. [Jermyn *Aust J Chem* **15** 569 1962, Helfreich & Jung *Justus Liebigs Ann Chem* **589** 77 1954.] It is a substrate for  $\alpha$ -galactosidase [Dangelmaier & Holmsen *Anal Biochem* **104** 182 1980]. [Beilstein **17/7** V 55.]

**4-Nitrophenyl- $\beta$ -D-galactopyranoside** [3150-24-1] *M* 301.3, *m* 178°, 178-181°, 181-182°,  $[\alpha]_D^{20}$  -83° (c 1, H<sub>2</sub>O). Purify the galactoside by recrystallisation from EtOH. [Horikoshi *J Biochem (Tokyo)* **35** 39 1042, Goebel & Avery *J Exptl Medicine* **50** 521 1929, Snyder & Link *J Am Chem Soc* **75** 1758.] It is a chromogenic substrate for  $\beta$ -galactosidases [Buoncore et al. *J Appl Biochem* **2** 390 1980]. [Beilstein **17/7** V 55.]

**4-Nitrophenyl- $\alpha$ -D-glucopyranoside** [3767-28-0] *M* 301.3, *m* 206-212°, 216-217° (sinters at 210°),  $[\alpha]_D^{20}$  +215° (c 1, H<sub>2</sub>O). Purify 4-nitrophenyl- $\alpha$ -D-glucopyranoside by recrystallisation from H<sub>2</sub>O, MeOH or EtOH. [Jermyn *Aust J Chem* **7** 202 1954, Montgomery et al. *J Am Chem Soc* **64** 690 1942.] It is a chromogenic substrate from  $\alpha$ -glucosidases [Oliviera et al. *Anal Biochem* **113** 188 1981], and is a substrate for glucansucrases [Binder & Robyt *Carbohydr Research* **124** 287 1983]. [Beilstein **17/7** V 53.]

**4-Nitrophenyl- $\beta$ -D-glucopyranoside** [2492-87-7] *M* 301.2, *m* 164°, 164-165°, 165°,  $[\alpha]_D^{20}$  -107° (c 1, H<sub>2</sub>O). Purify 4-nitrophenyl- $\beta$ -D-glucopyranoside by recrystallisation from EtOH or H<sub>2</sub>O. [Montgomery et al. *J Am Chem Soc* **64** 690 1942, Snyder & Link *J Am Chem Soc* **75** 1758 1953.] It is a chromogenic substrate for  $\beta$ -glucosidases [Weber & Fink *J Biol Chem* **255** 9030 1980]. [Beilstein **17/7** V 53.]

***N*-Nonanoyl-*n*-methylglucamine (Mega-9)** [85261-19-4] *M* 335.4, *m* 87-89°. It is a non-ionic detergent which is purified as for *n*-decanoyl-*N*-methylglucamine above. [Hildreth *Biochem J* **207** 363 1982.]

**Nonyl- $\beta$ -D-glucopyranoside** [69984-73-2] *M* 306.4, *m* 67.5-70°, 70-71°,  $[\alpha]_D^{20}$  -34.4° (c 5, H<sub>2</sub>O),  $[\alpha]_D^{25}$  -28.8° (c 1, MeOH). Purify nonyl- $\beta$ -D-glucopyranoside by recrystallisation from Me<sub>2</sub>CO or hexane/Et<sub>2</sub>O and store it in well-stoppered containers as it is *hygroscopic*. [Pigman & Richtmyer *J Am Chem Soc* **64** 369 1942.] It is a UV transparent non-ionic detergent for solubilising membrane proteins [Schwendener et al. *Biochem Biophys Res Commun* **100** 1055 1981]. [Beilstein **17** III/IV 2937, 17/7 V 39.]

**Octyl- $\beta$ -D-glucopyranoside** [29836-26-8] *M* 292.4, *m* 62-65°, 63.8-65°,  $[\alpha]_D^{20}$  s-34° (c 4, H<sub>2</sub>O). Purify octyl- $\beta$ -D-glucopyranoside by recrystallisation from Me<sub>2</sub>CO. It is *hygroscopic* and should be stored in a well-stoppered container. [Noller & Rockwell *J Am Chem Soc* **60** 2076 1938, Pigman & Richtmyer *J Am Chem Soc* **64** 369 1942.] It is a UV transparent non-ionic dialysable detergent for solubilising membrane proteins. The  $\alpha$ -*D*-isomer with  $[\alpha]_D^{20}$  +118° (c 1, MeOH) has similar solubilising properties. [Lazo & Quinn *Anal Biochem* **102** 68 1980, Stubbs et al. *Biochim Biophys Acta* **426** 46 1976, Beilstein **17/7** V 38.]

**Pectic acid** [9046-40-6] *M<sub>r</sub>* (C<sub>6</sub>H<sub>8</sub>O<sub>6</sub>)<sub>n</sub> ~500,000, **amorphous**,  $[\alpha]_D$  +250° (c 1, 0.1M NaOH). Citrus pectic acid (500g) is refluxed for 18 hours with 1.5L of 70% EtOH, and the suspension is filtered hot. The residue is washed with hot 70% EtOH and finally with ether. It is dried in a current of air, ground and dried for 18 hours at 80° under vacuum. [Morell & Link *J Biol Chem* **100** 385 1933.] It can be further purified by dispersing it in water and adding just enough dilute NaOH to dissolve the pectic acid, then passing the solution through columns of cation- and anion-exchange resins [Williams & Johnson *Ind Eng Chem (Anal Ed)* **16** 23 1944], and precipitating with two volumes of 95% EtOH containing 0.01% HCl. The precipitate is worked with 95% EtOH, then Et<sub>2</sub>O, dried and ground. [Rees & Walsh *Angew Chem Int Edn* **16** 214 1977, Rees *Adv Carbohydr Chem* **24** 267 1969.]

**Pectin (1-4 linked)** [9000-69-5] *M<sub>r</sub>* 30,000-100,000, **amorphous**. Dissolve the pectin in hot water to give a 1% solution, then cool, and make it to about 0.05M in HCl by addition of conc HCl, and precipitate it by pouring it slowly, with vigorous stirring into two volumes of 95% EtOH. After standing for several hours, the pectin is filtered through a nylon cloth, then redispersed in 95% EtOH and stood overnight. The precipitate is filtered off, washed with EtOH/Et<sub>2</sub>O, then Et<sub>2</sub>O and dried in air. [Rees & Walsh *Angew Chem, Int Edn* **16** 214 1977, Rees *Adv Carbohydr Chem* **24** 267 1969.]

**Pentaerythritol (2,2-bis[hydroxymethyl]-1,3-propanediol)** [115-77-5] **M 136.2, m 260.5°, 268-269°**. Reflux pentaerythritol with an equal volume of MeOH, then cool, and the precipitate is collected and dried at 90°. It can also be crystallised from dilute aqueous HCl. After sublimation under high vacuum at 200° it has **m 265.5°**. Its solubility in H<sub>2</sub>O is 10%. [Beilstein **18** III 2361, **1** IV 2812.]

**Pentaerythritol tetraacetate** [597-71-7] **M 304.3, m 83-84°, 84-86°**. Crystallise pentaerythritol tetraacetate from hot water, then leach it with cold water until the odour of acetic acid is no longer detectable. It also crystallises from 95% EtOH after dissolving in CHCl<sub>3</sub>, washing with saturated NaHCO<sub>3</sub>, then H<sub>2</sub>O, drying over anhydrous CaCl<sub>2</sub> and evaporating. It has been prepared by acetolysis of the tetranitrate in 95% yield [Wolf from et al. *J Am Chem Soc* **73** 874 1951]. [Breusch & Oguzer *Chem Ber* **88** 1511 1955, LeFèvre et al. *J Chem Soc* **16** 1958, Beilstein **1** IV 1812, **2** IV 264.]

**Pentaerythrityl laurate (pentaerythrityl tetra-*n*-dodecanoate)** [13057-50-6] **M 864.6, m 50°**. Crystallise the laurate from Me<sub>2</sub>CO, Et<sub>2</sub>O or petroleum ether. [Breusch & Oguzer *Chem Ber* **88** 1511 1955.]

**Pentaerythritol tetranitrate** [78-11-5] **M 316.2, m 140.1°**. Crystallise pentaerythritol tetranitrate from acetone or acetone/EtOH. When crystallised from H<sub>2</sub>O at 0°, it may have **m 26-28°** (hydrate?). It detonates more easily than TNT on percussion. The *O*-acetate, when crystallised from EtOH, has **m 87-88°**. Although it has been distilled at 60°/2mm, distillation should **NOT** be attempted as it is **VERY EXPLOSIVE**. It is a vasodilator. [Marans et al. *J Am Chem Soc* **76** 1304 1954, Camp et al. *J Am Chem Soc* **77** 751 1955, Beilstein **1** IV 2816, **2** IV 264.]

**2-Phenylethyl-β-D-thiogalactoside** [63407-54-5] **M 300.4, m 108°, [α]<sub>D</sub><sup>25</sup> -32.2° (c 5, MeOH)**. Recrystallise the thiogalactoside from H<sub>2</sub>O and dry in air to give the 1.5.H<sub>2</sub>O which has **m 80°**. The anhydrous surfactant is obtained by drying it at 78° over P<sub>2</sub>O<sub>5</sub>. [Heilfrich & Türk *Chem Ber* **89** 2215 1856.]

**Phenyl-β-D-galactopyranoside** [2818-58-8] **M 256.3, m 153-154°, 146-148°, 155-156°(dried at 105°), [α]<sub>D</sub><sup>20</sup> -42° (c 1, H<sub>2</sub>O)**. Recrystallisation of phenyl-β-D-galactopyranoside from H<sub>2</sub>O gives the 0.5H<sub>2</sub>O. [Conchie & Hay *Biochem J* **73** 327 1959, IR: Whistler & House *Analyt Chem* **25** 1463 1953.] It is an acceptor substrate for fucosyltransferase [Chester et al. *Eur J Biochem* **69** 583 1976]. [Beilstein **17**/7 V 46.]

**Phenyl-β-D-glucopyranoside** [1464-44-4] **M 256.3, m 174-175°, 174-176°, 176°, 176-178°, [α]<sub>D</sub><sup>20</sup> -72.2° (c 1 for dihydrate, H<sub>2</sub>O)**. Phenyl-β-D-glucopyranoside recrystallises from H<sub>2</sub>O with 2H<sub>2</sub>O and can be dried *in vacuo* at 100°/P<sub>2</sub>O<sub>5</sub>. The dry preparation has [α]<sub>D</sub><sup>25</sup> -70.7° (c 2, H<sub>2</sub>O). [Robertson & Waters *J Chem Soc* 2729 1930, IR: Bunton et al. *J Chem Soc* 4419 1955, Takahashi *Yakugaku Zasshi (J Pharm Soc Jpn)* **74** 7436 1954, Whittler & House *Anal Chem* **25** 1463 1953, UV: Lewis *J Am Chem Soc* **57** 898 1935.] It is a substrate for β-D-glucosidase [deBryne *Eur J Biochem* **102** 257 1979]. [Beilstein **17** III/V 2946, **17**/7 V 46.]

**Phlorizin (2H<sub>2</sub>O) [phloretin 2'-O-β-D-glucoside]** [60-81-1] **M 472.5, m 110°, [α]<sub>D</sub><sup>20</sup> -62° (c 3.2, EtOH)**. Phlorizin crystallises as the *dihydrate* from water and causes glycosuria. [Brazy & Dennis *Am J Physiol* **234** 1279 1978, Zemplén & Bognár *Chem Ber* **17B** 1040 1943, Beilstein **17**/7 V 177.]

**D(+)-Raffinose (5H<sub>2</sub>O) (Melitose, 6-O-α-D-galactopyranosyl-D-glucopyranosyl-β-D-fructo-furanose** [17629-30-0 (5H<sub>2</sub>O), 512-69-6 (anhydrous)] **M 594.5, m 80°, 80-82°, [α]<sub>D</sub><sup>20</sup> +124° (c 10, H<sub>2</sub>O), [α]<sub>D</sub><sup>20</sup> +105° (c 1 for pentahydrate, H<sub>2</sub>O), pK<sub>1</sub><sup>25</sup> 12.40, pK<sub>2</sub><sup>25</sup> 13.44, pK<sub>3</sub><sup>25</sup> 13.52**. D(+)-Raffinose crystallises from H<sub>2</sub>O, 90% aqueous EtOH or MeOH as the *pentahydrate*. The *anhydrous* sugar has **m 132-135°**. It has R<sub>F</sub> 0.8 on TLC (Silica Gel, and 1:3:3 CHCl<sub>3</sub>/butanone:/MeOH). The *undecaacetate* has been purified through an alumina column by elution with CHCl<sub>3</sub>, and recrystallised from EtOH/MeOH/H<sub>2</sub>O (3:2:5), with **m 99-100°, [α]<sub>D</sub><sup>20</sup> +92.8° (c 5.14, EtOH)**. [pK : Coccioli & Vicedomini *Ann Chim (Rome)* **66** 269, 275 1976, <sup>1</sup>H NMR: Suami et al. *Carbohydr Research* **26** 234 1973, Beilstein **17** III/IV 3801, **17**/8 V 403.]

**L(+)-α-Rhamnose (H<sub>2</sub>O) (6-deoxy-L-mannose)** [10030-85-0 (H<sub>2</sub>O), 3615-41-6 (anhydrous)] **M 182.2, m 90-92°, 101°, 105°, [α]<sub>D</sub><sup>18</sup> -6.8° mutarotating to +9.1° (c 1, H<sub>2</sub>O)**. Crystallise the rhamnose from H<sub>2</sub>O or

EtOH. It crystallises easily as the *monohydrate* by evaporating a solution in MeOH (90%) and H<sub>2</sub>O (10%). It is also purified by dissolving in a small volume of EtOH, adding a few drops of H<sub>2</sub>O and cooling. <sup>1</sup>H NMR in D<sub>2</sub>O at 44° contains 60% α-pyranose and 40% β-pyranose forms [Angyal *Adv Carbohydr Chem* **42** 15 1984.] [Smith *J Chem Soc* 1035 1940, McGeachin & Beevers *Acta Cryst* **10** 227,230 197, Beilstein **1** IV 4261.]

**D-(+)-Ribonic acid-γ-lactone** [5336-08-3] **M 148.12, m 80°, 84-86°, [α]<sub>D</sub><sup>20</sup> +18.3° (c 5, H<sub>2</sub>O).** Purify D-(+)-ribonic acid-γ-lactone by recrystallisation from EtOAc. The *tribenzoate* has **m** 54-56° (from AcOH), [α]<sub>D</sub><sup>25</sup> +27° (c 2.37, Me<sub>2</sub>NCHO), and the *3,5-O-benzylidene* derivative has **m** 230-231.5° (needles from Me<sub>2</sub>CO-petroleum ether) and [α]<sub>D</sub><sup>25</sup> -177° (CHCl<sub>3</sub>). [Chen & Joulié *J Org Chem* **49** 2168 1984, Zinner & Voigt *J Carbohydr Research* **7** 38 1968.]

**α-D(-)-Ribose** [50-69-1] **M 150.1, m 90°, [α]<sub>D</sub><sup>20</sup> -24° (after 24hours, c 10, H<sub>2</sub>O), pK<sup>25</sup> 12.22.** Crystallise α-D(-)-ribose from aqueous 80% EtOH, dry it under vacuum at 60° over P<sub>2</sub>O<sub>5</sub> and store it in a vacuum desiccator. It exhibits a complex mutarotation with : [α]<sub>D</sub><sup>10</sup> -23.1° (1.5 minutes), -21.3° (5 minutes), -19.5° (10 minutes), -19.1° (30 minutes), -21.2° (60 minutes), -23.1° (120 minutes), -23.7° (300 minutes), (c 4.5, H<sub>2</sub>O) [Phelps et al. *J Am Chem Soc* **56** 748 1934]. <sup>1</sup>H NMR in D<sub>2</sub>O at 44° shows 17% α-pyranose, 59% β-pyranose, 9% α-furanose and 15% β-furanose forms with **furanose** α-H at 5.34ppm (*J* = 3.0Hz) and β-H at 5.31 (*J* = 1.7Hz) [Angyal *Adv Carbohydr Chem* **42** 15 1984, Angyal & Pickles *Aust J Chem* **25** 1711 1972]. The *phenylhydrazone* crystallises from aqueous pyridine in yellow needles, **m** 163-164°, and the *benzylphenylhydrazone* has **m** 127-128° [Snowden *J Am Chem Soc* **72** 808 1950]. [Beilstein **1** IV 4211.]

**(+)-Rutin (quercetin-3-rubinoside)** See Vitamin P in “Miscellaneous”, this chapter.

**Saccharides.** They are separated by anion-exchange chromatography. [Walberg & Kando *Anal Biochem* **37** 320 1970.]

**D(-)-Salicin [2-(hydroxymethyl)phenyl-β-D-glucopyranoside]** [138-52-3] **M 286.3, m 204-208°, [α]<sub>D</sub><sup>25</sup> -63.5° (c ca 3, H<sub>2</sub>O).** Crystallise D(-)-salicin from EtOAc, EtOH or water and sublime it at 190-195°/12mm. [Armour et al. *J Chem Soc* 412 1961, IR: Pearl & Darling *J Org Chem* **24** 731 1959, Beilstein **17** III/IV 2986, 17/7 V 113.]

**Sennoside A (bianthraquinonyl-bis-glucoside R,R-enantiomer)** [81-27-6] **M 862.7, m 220-240°(dec), [α]<sub>D</sub><sup>20</sup> -164° (c 0.1, Me<sub>2</sub>CO/H<sub>2</sub>O 6:4), [α]<sub>D</sub><sup>20</sup> -24° (c 0.2, 70% aqueous dioxane).** Sennoside A forms yellow crystals from aqueous acetone, 2-ethoxyethanol or large volumes of H<sub>2</sub>O. [Stoll et al. *Helv Chim Acta* **32** 1896 1900, Beilstein **17** III/IV 3403.]

**Sennoside B (bianthraquinonyl-bis-glucoside R,S-enantiomer)** [128-57-4] **M 862.7, m 209-212°(dec), [α]<sub>D</sub><sup>20</sup> -100° (c 2, Me<sub>2</sub>CO/H<sub>2</sub>O 7:1), [α]<sub>D</sub><sup>20</sup> -67° (c 0.2, 70% aqueous dioxane).** Sennoside B forms yellow crystals from aqueous acetone or large volumes of H<sub>2</sub>O. [Stoll et al. *Helv Chim Acta* **32** 1896 1900, Beilstein **17** III/IV 3402.]

**Sinigrin monohydrate (Myronate K, 1-thio-β-D-glucopyranose 1-[N-(sulfooxy)-3-butenimide] monopotassium salt)** [64550-88-5] **M 415.5, m 125-127°, 127-129°, 179°(anhydrous), [α]<sub>D</sub><sup>20</sup> -17° (c 0.2, H<sub>2</sub>O), pK<sub>Est</sub> <0.** Purify sinigrin by recrystallising it three times from EtOH and once from MeOH. The *tetraacetate* has **m** 193-195°, [α]<sub>D</sub><sup>20</sup> -16° (c 0.14, H<sub>2</sub>O). [Benn et al. *J Chem Soc, Chem Commun* 445 1965, Kjaær et al. *Acta Chem Scand* **10** 432 1956, Marsh et al. *Acta Cryst (Sect B)* **26** 1030 1970.] It is a β-D-thioglucopyranoside substrate for thiogluconidase [MacLeod & Rossiter *Phytochem* **25** 1047 1986]. [Beilstein **31** H 476, **17** III/IV 3738.]

**α-Solanine (solan-5-en-3β-yl-[O<sup>3</sup>-β-D-glucopyranosyl-O<sup>2</sup>-α-L-rhamnopyranosyl-β-D-galactopyranoside])** [20562-02-1] **M 868.1, m 285°(dec), 286°(dec) (sintering >190°), [α]<sub>D</sub><sup>20</sup> -58° (c 0.8, pyridine), pK<sup>15</sup> 6.66.** Recrystallise α-solanine from EtOH, 85% aqueous EtOH, MeOH or aqueous MeOH as *dihydrate* **m** 276-278°.

Its solubility in H<sub>2</sub>O is 25mg/l and 5% in pyridine, but it is very soluble in Et<sub>2</sub>O and CHCl<sub>3</sub>. The *hydrochloride* is gummy or amorphous but has been crystallised (**m** ~212° dec). It has insecticidal properties. [Kuhn et al. *Chem Ber* **88** 1492 1955, *Beilstein* **21** III/IV 1402.]

**Solasonine (solasodine-3-O-triglycoside)** [19121-58-5] **M 884.0, m 301-303° (sinters at ~296°), [α]<sub>D</sub><sup>20</sup> -75° (c 0.5, MeOH), pK<sub>Est</sub> ~ 7.7.** Solasonine crystallises from aqueous 80% dioxane or MeOH in needles. [Bell & Briggs *J Chem Soc* **1** 1942, Briggs et al. *J Chem Soc* **4645** 1961, Briggs et al. *J Chem Soc* **2848** 1963.] The *picrate* crystallises from 30% aqueous EtOH with **m** 197-198°(dec) [Briggs & Cambie *J Chem Soc* **1422** 1958]. [*Beilstein* **27** III/IV 2006.]

**D(-)-Sorbitol (D-glucitol)** [50-70-4] **M 182.2, m 89-93° (hemihydrate), 110-111° (anhydrous), [α]<sub>D</sub><sup>20</sup> -1.8° (c 10, H<sub>2</sub>O), pK<sup>60</sup> 13.00.** Crystallise D(-)-sorbitol (as hemihydrate) several times from EtOH/water (1:1), then dry it by fusing and storing over anhydrous MgSO<sub>4</sub>. [Koch et al. *J Am Chem Soc* **75** 953 1953, *Beilstein* **1** IV 2839.]

**Starch** [9005-84-9] **M (162.1)<sub>n</sub>.** Starch is de-fatted by Soxhlet extraction with Et<sub>2</sub>O or 95% EtOH. For fractionation of starch into “amylose” and “amylopectin” fractions, see Lansky et al. [*J Am Chem Soc* **71** 4066 1949].

**Streptozotocin (N-[methylnitrosocarbamoyl]-α-D-glucosamine, streptozocin)** [18883-66-4] **M 265.2, m 111-114°(dec), 114-115°(dec), 115°(dec with evolution of gas), [α]<sub>D</sub><sup>20</sup> ~+39° (H<sub>2</sub>O, may vary due to mutarotation).** Recrystallise streptozotocin from 95% EtOH. It is soluble in H<sub>2</sub>O, MeOH and Me<sub>2</sub>CO. It has UV with λ<sub>max</sub> at 228nm (ε 6360) in EtOH. The *tetraacetate* has **m** 111-114°(dec), and [α]<sub>D</sub><sup>25</sup> +41° (c 0.78, 95% EtOH) after recrystallisation from EtOAc. [Herr et al. *J Am Chem Soc* **89** 4808 1967, NMR: Wiley et al. *J Org Chem* **44** 9 1979.] It is a potent methylating agent for DNA [Bennett & Pegg *Cancer Res* **41** 2786 1981].

**D(+)-Sucrose (β-D-fructofuranosyl-α-D-glucopyranoside)** [57-50-1] **M 342.3, m 160-186°, 186-188°, [α]<sub>D</sub><sup>20</sup> +78° (c 10, H<sub>2</sub>O), [α]<sub>D</sub><sup>20</sup> + 66° (c 26, H<sub>2</sub>O), pK<sup>25</sup> 12.62.** Crystallise D(+)-sucrose from water (solubility: 1g in 0.5ml H<sub>2</sub>O at 20°, 1g in 0.2ml in boiling H<sub>2</sub>O). It is soluble in EtOH (0.6%) and MeOH (1%). *Sucrose diacetate hexaisobutyrate* is purified by melting and, while molten, treated with NaHCO<sub>3</sub> and charcoal, then filtered. [*Beilstein* **17/8** V 399.]

**D(+)-Sucrose octaacetate** [126-14-7] **M 678.6, m 83-85°, b 260°/1mm, [α]<sub>D</sub><sup>20</sup> +71° (c 2.5, EtOH).** After three recrystallisations from EtOH or 95% EtOH (charcoal), the **m** of the *octaacetate* rises to 88-90°, or Et<sub>2</sub>O with **m** 89° and [α]<sub>D</sub><sup>25</sup> +58.5° (c 2.6, EtOH). It has a bitter taste. [Linstead et al. *J Am Chem Soc* **62** 3260 1940, Lemieux & Huber *J Am Chem Soc* **78** 4117 1956, *Beilstein* **17/8** V 410.]

**D(-)-Tagatose** [87-81-0] **M 180.2, m 131-132°, 134-135°, [α]<sub>D</sub><sup>20</sup> -6.5° (c 1, H<sub>2</sub>O).** Crystallise D(-)-tagatose from EtOH/H<sub>2</sub>O (6:1). It mutarotates from [α]<sub>D</sub><sup>22</sup> +2° (2 minutes) to -5.0° (30 minutes) (c 4, H<sub>2</sub>O). The *phenylosazone* crystallises from aqueous EtOH with **m** 185-187°(dec), and [α]<sub>D</sub><sup>23</sup> +47° (c 0.82, 2-methoxyethanol). [Totton & Lardy *J Am Chem Soc* **71** 3076 1949, Gorin et al. *Canad J Chem* **33** 1116 1955, Reichstein & Bossard *Helv Chim Acta* **17** 753 1934, Wolfrom & Bennett *J Org Chem* **30** 1284 1965, *Beilstein* **1** IV 4414.] In D<sub>2</sub>O at 27° <sup>1</sup>H NMR showed the following ratios: α-pyranose (79), β-pyranose (16), α-furanose (1) and β-furanose (4) [Angyal *Adv Carbohydr Chem* **42** 15 1984, Angyal & Pickles *Aust J Chem* **25** 1711 1972].

**Thevetin A (cardenolide glycoside)** [37933-66-7] **M 858.9, m softens at 194°, m 208-210°, [α]<sub>D</sub><sup>26</sup> -72° (c 1.48, MeOH).** Crystallise Thevetin A from H<sub>2</sub>O. The *acetyl derivative* crystallises from MeOH/Et<sub>2</sub>O at -15° with **m** 145-149°, and [α]<sub>D</sub><sup>26</sup> -54.2° (c 1.86, CHCl<sub>3</sub>). [Block et al. *Helv Chim Acta* **43** 652 1960, <sup>13</sup>C NMR: Tori et al. *Tetrahedron Lett* 717 1977, *Beilstein* **18** III/IV 2552, **18/4** V 439.]

**Thevetin B (cardenolide glycoside)** [11018-93-2] **M 858.9, m 197-201°, [α]<sub>D</sub><sup>24</sup> -61.4° (c 1.5, MeOH).** It crystallises (as *trihydrate*) from isopropanol. Dry it at 100°/0.01mm to give the *hemihydrate* (*very hygroscopic*).

[Block et al. *Helv Chim Acta* **43** 652 1960,  $^{13}\text{C}$  NMR: Tori et al. *Tetrahedron Lett* 717 1977, *Beilstein* **18** III/IV 1493.]

**$\alpha,\alpha'$ -D(+)-Trehalose (2H<sub>2</sub>O)** [6138-23-4] **M 378.3, m 96.5-97.5<sup>o</sup>, 94-100<sup>o</sup> (dihydrate), 214-216<sup>o</sup> (anhydrous),  $[\alpha]_{\text{D}}^{20} +180^{\circ}$  (dihydrate, c 4, H<sub>2</sub>O),  $[\alpha]_{\text{D}}^{20} +199^{\circ}$  (anhydrous, c 4, H<sub>2</sub>O).**  $\alpha,\alpha'$ -D(+)-Trehalose crystallises (as the *dihydrate*) from aqueous EtOH. Dry it at 13<sup>o</sup>. For the *anhydrous* compound dissolve 10g in pyridine (200ml) and distil off this solvent at atmospheric pressure, and when the temperature rises to 115.3<sup>o</sup> all the H<sub>2</sub>O is removed and 73ml of distillate is collected. Most of the anhydrous material crystallises out at this stage. The crystals are collected (6.8g), washed with Et<sub>2</sub>O to give 6.1g of anhydrous product. Higher yields are obtained by slightly more prolonged distillation. [Birch *J Chem Soc* 3489 1965, X-ray cryst: Brown et al. *Acta Cryst* **28** 3145 1972, *Beilstein* **17/8** V 3.]

**D(+)-Turanose [3-O- $\alpha$ -D-glucosido]-D-fructose** [547-25-1] **M 342.3, m 168-170<sup>o</sup>,  $[\alpha]_{\text{D}}^{20} +88^{\circ}$  (c 4, H<sub>2</sub>O).** Crystallise D(+)-turanose from H<sub>2</sub>O by addition of EtOH (its solubility is 5.3% in 95% EtOH). Form **m 157<sup>o</sup>** is obtained by crystallisation from hot MeOH, and mutarotates from +27.3<sup>o</sup> to  $[\alpha]_{\text{D}}^{20} +88^{\circ}$  (c 4, H<sub>2</sub>O). The *phenylosazone* crystallises from 15 parts of 95% EtOH with **m 200-205<sup>o</sup>**,  $[\alpha]_{\text{D}}^{20} 24.5^{\circ}$  mutarotating to +33<sup>o</sup> [24hours, c 0.82, pyridine/EtOH (4:6)]. [Pascu *Methods in Carbohydrate Chemistry I* 353 1962, Academic Press, *Beilstein* **17/7** V 213.] In D<sub>2</sub>O at 36<sup>o</sup>  $^1\text{H}$  NMR showed the following ratios:  $\alpha$ -pyranose (<4),  $\beta$ -pyranose (39),  $\alpha$ -furanose (20) and  $\beta$ -furanose (41) [Angyal *Adv Carbohydr Chem* **42** 15 1984].

**Vicine (2,4-diamino-5- $\beta$ -D-glucopyranosidoxy-6-hydroxypyrimidine)** [152-93-2] **M 304.3, m 243-244<sup>o</sup>,  $[\alpha]_{\text{D}}^{20} -12^{\circ}$  (c 4, 0.2N NaOH).** Crystallise Vicine from water (1%) or aqueous 85% EtOH, and dry it at 135<sup>o</sup>. [Bendich & Clements *Biochim Biophys Acta* **12** 462 1953, *Beilstein* **31** H 163, **25** III/IV 4285.]

**Ustilagic acid (Ustizeain B, di-D-glucosyldihydroxyhexadecanoic acid)** [8002-36-6] **M ~780, m 146-147<sup>o</sup>,  $[\alpha]_{\text{D}}^{25} +7^{\circ}$  (c 1, pyridine),  $\text{pK}^{25} \sim 4.9$ .** Ustilagic acid is a mixture of partly acetylated di-D-glucosyldihydroxyhexadecanoic acid which crystallises from diethyl ether. It has also been purified from the culture by dissolving it in hot MeOH, filtering and concentrating by blowing a current of air until the solution becomes turbid, then heating to 50<sup>o</sup> and adding 4 volumes of H<sub>2</sub>O (also at 50<sup>o</sup>), and cooling very slowly. Filter off the white solid and dry it in air. It crystallises from Et<sub>2</sub>O, and is soluble in MeOH, butan-1,2-diol, poorly soluble in EtOH, *n*-BuOH, Me<sub>2</sub>CO and insoluble in H<sub>2</sub>O, EtOAc and \*C<sub>6</sub>H<sub>6</sub>. [Lemieux et al. *Can J Chem* **29** 409, 415 1951, Boothroyd et al. *Can J Biochem Physiol* **33** 289 1955.]

**Xanthorhamnin (xanthene rhamnoside)** [1324-63-6] **M 770.7, m 195<sup>o</sup>,  $[\alpha]_{\text{D}}^{20} +3.75^{\circ}$  (EtOH),  $\text{pK}_1^{24} 8.69$ ,  $\text{pK}_2^{24} 11.28$ ,  $\text{pK}_3^{24} 12.22$ .** Crystallise xanthorhamnin from a mixture of ethyl and isopropyl alcohols, dry it in air, then dry it further for several hours at 110<sup>o</sup>. The UV (EtOH) has  $\lambda_{\text{max}}$  at 258 and 362nm. [Nystrom et al. *J Org Chem* **22** 1272 1957, *Beilstein* **18** III/IV 3498.]

**$\alpha$ -D(+)-Xylose** [58-86-6] **M 150.1, m 146-147<sup>o</sup>, 153-154<sup>o</sup>,  $[\alpha]_{\text{D}}^{20} +92^{\circ}$  mutarotating to +18.8<sup>o</sup> (16 hours, c 10, H<sub>2</sub>O),  $\text{pK}^{18} 12.14$ .**  $\alpha$ -D(+)-Xylose forms needles or prisms (which have a very sweet taste) by slow crystallisation from aqueous 80% EtOH or absolute EtOH, which are then dried at 60<sup>o</sup> *in vacuo* over P<sub>2</sub>O<sub>5</sub>. Store it in a vacuum desiccator over CaSO<sub>4</sub>. 1Gram dissolves in 0.8ml H<sub>2</sub>O. [Bragg & Hough *J Chem Soc* 4347 1957, Hudson & Yanovsky *J Am Chem Soc* **39** 1029 1917, Monroe *J Am Chem Soc* **41** 1002 1919, *Beilstein* **1** IV 4223.] In D<sub>2</sub>O at 31<sup>o</sup>,  $^1\text{H}$  NMR showed the following ratios:  $\alpha$ -pyranose (36.5),  $\beta$ -pyranose (63),  $\alpha$ -furanose +  $\beta$ -furanose (~1) [Angyal *Adv Carbohydr Chem* **42** 15 1984, Angyal & Pickles *Aust J Chem* **25** 1711 1972].

## CAROTENOIDS

### General

Carotenoids are polyene pigments that are mostly naturally occurring in bacteria, plants and animals. They have been isolated from the natural sources and obtained first by extraction with solvents and then purified by column chromatography through  $\text{Al}_2\text{O}_3$  of various grades,  $\text{Ca}(\text{OH})_2$  alone or with  $\text{CaCO}_3$ ,  $\text{MgO}$  or Silica Gel and eluted with solvents of various polarities. The progress of separation can be followed visually because the bands of most carotenoids are of various colours. The bands can be collected by elution, or the column can be extruded and the bands cut out and extracted with a polar solvent, e.g. MeOH. This chromatography can be repeated with the separate bands, and finally the carotenoids are recrystallised to analytical purity. The purity can be checked by TLC on Silica Gel or  $\text{Al}_2\text{O}_3$  plates or paper chromatography and eluted in two dimensions. Gas-liquid or HPLC has been used for preparative work as well as for checking the purity and identifying them using internal standards such as tocopherol acetate (vitamin E acetate) and retinyl acetate.

Carotenoids are generally light sensitive, easily oxidised by air and are affected by traces of acid, e.g. in solvents. These cause the polyenes to bleach or polymerise. The necessary precautions are therefore required to minimise these effects during isolation, purification and storage. They are identified by their UV-VIS spectra, and their molar extinction coefficients at specific wavelengths ( $\lambda_{\text{max}}$ ) have been used for characterisation and for quantitation. More recently ORD, CD, NMR, IR and mass spectroscopy have been used extensively.

**Antheraxanthin (5,6-epoxy-zeaxanthin)** [68831-78-7] **M 584.8, m 205°,  $\lambda_{\text{max}}$  460.5, 490.5nm, in  $\text{CHCl}_3$ .**

Likely impurities are violaxanthin (see later) and mutatoxanthin (which contains a dihydrofuran ring derived from the epoxy group of antheraxanthin). Purify it by chromatography on columns of  $\text{Ca}(\text{OH})_2$  and of  $\text{ZnCO}_3$ . It crystallises from  $^*\text{C}_6\text{H}_6/\text{MeOH}$  as needles or thin plates. Store it in the dark, under  $\text{N}_2$  or argon at  $-20^\circ$ . In  $\text{CHCl}_3/\text{SbCl}_2$  it gives a blue colour with  $\lambda_{\text{max}}$  at 587nm and gives a stable blue colour with conc HCl. [Karrer & Oswald *Helv Chim Acta* **18** 1303 1935, Karrer & Jucker *Helv Chim Acta* **28** 300 1945.]

**$\beta$ -Apo-4'-carotenal** [12676-20-9] **M 414.7, m 139°,  $A_{1\text{cm}}^{1\%}$  2640 at 461nm.** Recrystallise the carotenal from  $\text{CHCl}_3/\text{EtOH}$  mixture or *n*-hexane. The  $\lambda_{\text{max}}$  of the absorption spectra of the radical anions and cations of such polyenals formed by pulse radiolysis are linearly dependent on the number of conjugated double bonds [Land et al. *JCS, Faraday Trans 1* **74** 538 1978, Bobrowski & Das *J Phys Chem* **91** 1210 1987, *Beilstein* **7** IV 1782.]

**trans- $\beta$ -Apo-8'-carotenal** [1107-26-2] M 414.7, m 136-139°. Recrystallise  $\beta$ -apo-8'-carotenal from  $\text{CHCl}_3/\text{EtOH}$  mixture or *n*-hexane. The absorption spectra of the radical anion of this  $\text{C}_{30}$  aldehyde in CTAB and Triton X100 micelles suggested an alcohol-like nature of the environment probed by the long-chain polyenal. For effect of conjugation on spectra see preceding entry [Bobrowski & Das *J Phys Chem* 91 1210 1987, Land et al. *JCS, Faraday Trans 1* 74 538 1978, *Beilstein* 7 III 2622, 7 IV 1782.]

**$\beta$ -Apo-8'-carotenoic acid ethyl ester** [1109-11-1] M 526.8, m 134-138°,  $A_{1\text{cm}}^{1\%}$  2550 at 449nm. Recrystallise the ester from petroleum ether or petroleum ether/EtOAc. Store it in the dark under  $\text{N}_2$  or argon at  $-20^\circ$ . [*Beilstein* 9 IV 2701 for Me ester.]

**$\beta$ -Apo-8'-carotenoic acid methyl ester** [16266-99-2] M 512.7, m 136-137°,  $A_{1\text{cm}}^{1\%}$  2575 at 446nm and 2160 at 471nm, in petroleum ether. Recrystallise the methyl ester from petroleum ether or petroleum ether/EtOAc. Store it in the dark in an inert atmosphere at  $-20^\circ$ . [*Beilstein* 9 IV 2701.]

**Astacin ( $\beta,\beta$ -carotene-3,3',4,4'-tetraone, Astacene)** [514-76-1] M 592.8, m 228°, 232-233°, 240-243°(evacuated tube),  $\epsilon_{1\text{cm}}^{1\%}$  550,000 at 498nm (pyridine). Astacin is a red pigment found in marine organisms (protozoa, algae, crustacians, sponges, fish, reptiles) together with astaxanthin (see below) from which it is possibly formed by autoxidation [Kuhn & Lederer *Chem Ber* 66 488 1933]. A probable impurity is astaxanthin (3,3'-dihydroxy- $\beta,\beta$ -carotene-4,4'-dione) which may be its precursor. It has been prepared by adding a solution of canthaxanthene (1.0g, see [514-78-3] below) in  $^*\text{C}_6\text{H}_6$  (15ml) to *t*-BuOK in *t*-BuOH (1.40N, 130ml) and shaken with  $\text{O}_2$  at  $20^\circ$  for 30 hours. Water (200ml) is added, then 0.5N HCl (800ml) and extracted with  $\text{CHCl}_3$  (300ml). The extract is washed with aqueous  $\text{NaHCO}_3$  (3 x 300ml),  $\text{H}_2\text{O}$  (2 x 200ml), diluted with  $^*\text{C}_6\text{H}_6$  (50ml) and the organic layer is evaporated *in vacuo*. The residue is recrystallised from  $\text{CHCl}_3$ -EtOH (1:5) to give *astacin* (450mg, ~90%) as deep purple leaflets m 232-233° with  $\lambda_{\text{max}}$  (pyridine) 498mm ( $\epsilon$  100 x 10<sup>3</sup>), ( $\text{CS}_2$ ) 513mm, (hexane) 477mm, (EtOH) 483mm, and (KOH-EtOH) 478mm; the IR ( $\text{CHCl}_3$ ) has  $\nu_{\text{max}}$  at 3410br ( $\epsilon$  ~90), 1610 ( $\epsilon$  1200), 1550, 1327 and 969 ( $\epsilon$  895)  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (60MHz,  $\text{CDCl}_3$ , TMS) has  $\delta$  at 1.30 (12H, C-1  $\text{Me}_2$  and C-1'  $\text{Me}_2$ ), 2.10 (6H, C-5 Me and C-5' Me), 2.02 (6H, C-9 Me and C-9' Me), 2.02 (6H, C-13 Me and C-13' Me), and 6.06 (C-2 H and C-2' H) (14 olefinic H-7,7', 8,8', 10,10', 11,11', 12,12', 14,14', and 15,15' are not included); and  $m/z$  592  $\text{M}^+$ . [Cooper et al. *J C S Perkin Trans I* 2195 1975.] Alternatively, purify astacin by chromatography on alumina/fibrous clay (1:4) or mixed chromatograms on sucrose using  $^*\text{C}_6\text{H}_6$ /light petroleum 1:4 as eluant; or by partition between petroleum ether and MeOH (alkaline). It crystallises from pyridine/water in purple leaflets or needles with a metallic lustre. Store it in the dark under  $\text{N}_2$  at  $-20^\circ$ . It is very soluble in pyridine, dioxane,  $\text{CS}_2$ ,  $\text{CHCl}_3$  and dilute aqueous NaOH, slightly soluble in AcOH, EtOAc and  $^*\text{C}_6\text{H}_6$ , but almost insoluble in  $\text{H}_2\text{O}$ ,  $\text{Et}_2\text{O}$ , petroleum ether and MeOH. Its *diacetate (enol-acetate)*, obtained by  $\text{Ac}_2\text{O}$ /pyridine treatment at  $25^\circ$  for 34 hours has m 232-233° (dec) (from  $\text{CHCl}_3/\text{EtOH}$ , 1:5) or 235° (dec) (from pyridine +  $\text{H}_2\text{O}$ ), and forms violet/black needles with  $\lambda_{\text{max}}$  (pyridine) at 497mm ( $\epsilon$  109 x 10<sup>3</sup>) and (EtOH) 474mm; the IR ( $\text{CHCl}_3$ ) has  $\nu_{\text{max}}$  at 1756 ( $\epsilon$  530), 1639 ( $\epsilon$  1150), 1555 and 972  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (60MHz,  $\text{CDCl}_3$ , TMS) has  $\delta$  at 1.35 (12H, C-1  $\text{Me}_2$  and C-1'  $\text{Me}_2$ ), 2.04 (6H, C-5 Me and C-5' Me), 2.04 (6H, C-9 Me and C-9' Me), 2.02 (6H, C-13 Me and C-13' Me), and 2.29 (2 OAc) (14 olefinic H-7,7', 8,8', 10,10', 11,11', 12,12', 14,14', and 15,15' are not included); and  $m/z$  576  $\text{M}^+$ . The *dipalmitate (enol-ester, Astacein)* has m 121°, and forms red square leaflets from petroleum ether. [Davis & Weedon *Proc Chem Soc* 182 1960, Widmer et al. *Helv Chim Acta* 65 671 1982, Karrer et al. *Helv Chim Acta* 17 412,745 1934, 18 96 1935, 19 479 1936, *Beilstein* H 30 102, 7 III 4797.]

**Astaxanthin (3,3'-dihydroxy- $\beta,\beta$ -carotene-4,4'-dione)** [472-61-7] M 596.84, m 182-183°. It is a potent antioxidant from marine alge, red yeast and other plant and marine animal sources. It was isolated from lobster eggs, is present in salmon, the red feathers of some birds (*Laniarius* spp, and flamingo), and occurs in flower petals of some *Ranunculaceae*. Racemic astaxanthin has been synthesised from astacene (see above) by reduction with  $\text{KBH}_4$  to  $\beta,\beta$ -carotene-3,4,3',4'-tetraol followed by oxidation with 2,3-dichloro-5,6-dicyano-*p*-benzoquinone and purification by preparative TLC on Kieselgel (20% $\text{Me}_2\text{CO}$ /light petroleum) to give ( $\pm$ )-*astaxanthin* m 182-183° as needles, after crystallisation from  $\text{Me}_2\text{CO}$ /light petroleum. It has  $\lambda_{\text{max}}$  (MeOH)

472mm, (hexane) 466-467mm, (CHCl<sub>3</sub>) 485 and (CS<sub>2</sub>) 503mm; the IR (CHCl<sub>3</sub>) has  $\nu_{\max}$  at 3620, 3510, 1660, 1610 and 975 cm<sup>-1</sup>; the <sup>1</sup>H NMR (60MHz, CDCl<sub>3</sub>, TMS) has  $\delta$  at 1.31 (6H, C-1 Me and C-1' Me), 1.20 (6H, C-1 Me and C-1' Me), 1.94 (6H, C-5 Me and C-5' Me), 1.98 (12H, C-9 Me, C-9' Me, C-13 Me and C-13' Me), (14 olefinic H-7,7', 8,8', 10,10', 11,11', 12,12', 14,14', and 15,15' are not included); and  $m/z$  592.386 M<sup>+</sup>. TLC in the above system or Micro-Cel did not separate it from natural (3*S*,3'*S*)-astaxanthin from the common lobster or sea water crayfish. Synthetic ( $\pm$ )-astaxanthin combined with the appropriate apoprotein to form  $\alpha$ -crustacyanin with  $\lambda_{\max}$  (MeOH) at 630mm. Its diacetate has **m 203-205**<sup>o</sup> (blue-black needles from pyridine/H<sub>2</sub>O, **m 189-191**<sup>o</sup> also reported),  $\lambda_{\max}$  (CHCl<sub>3</sub>) with 482mm, and is also indistinguishable by mixed TLC on Kieselgel, Micro-Cel or alumina from natural (3*S*,3'*S*)-astaxanthindiacetate, **m 187-189**<sup>o</sup>. All manipulations have to be carried out under argon to avoid their ready oxidation to astacin (see above). [Cooper et al *J C S Perkin Trans I* 2195 1975, Kienzel & Mayer *Acta Chim Acta* **61** 2609 1978.]

An efficient synthesis of natural (3*S*,3'*S*)-astaxanthin from (4*R*,4'*R*)-4-hydroxy-2,2,6-trimethylcyclohexanone in 67% yield and high optical purity has been described and was purified by recrystallisation from CH<sub>2</sub>Cl<sub>2</sub>/MeOH to give dark violet crystals, **m 216-218**<sup>o</sup>, with R<sub>F</sub> 0.30 on TLC with kieselgel (CH<sub>2</sub>Cl<sub>2</sub>/Me<sub>2</sub>CO/HCOOH, 95:5:3); its UV has  $\lambda_{\max}$  nm ( $\epsilon$ ), (CHCl<sub>3</sub>) at 492 (1920), 488 (125,000), and (CH<sub>2</sub>Cl<sub>2</sub>) 324(14,500), 298 (15,500), ~285sh (~14,000), 251 (14,500), ~225 (~15,000); and IR (KBr) has  $\nu_{\max}$  at 3486m (OH), 1664s (C=O, conjugated), 1607m, 1557s (C=O, conjugated), 1399w, 1390m, 1366w (gem Me<sub>2</sub>), 1076s, 1039m (OH) and 969s (CH=CH, *trans*) cm<sup>-1</sup>. [Widmer et al. *Helv Chim Acta* **64** 2405 1981]. Other high yielding syntheses have been achieved [Becher et al. *Helv Chim Acta* **64** 2419 1981, Kienzel & Mayer *Helv Chim Acta* **61** 2609 1978], and the absolute configuration of natural (3*S*,3'*S*)-astaxanthin, **m 219-220**<sup>o</sup> has been determined by X-ray analysis of a crystalline synthetic intermediate [Widmer et al. *Helv Chim Acta* **64** 2405 1981] and comparison of CD spectra [Englert et al. *Helv Chim Acta* **60** 1209 1977]. Its <sup>1</sup>H NMR (270MHz, CDCl<sub>3</sub>, TMS) has  $\delta$  for olefinic protons at 6.21 (H-7 and H-7'), 6.43 (H-8 and H-8'), 6.30 (H-10 and H-10'), 6.66 (H-11 and H-11'), 6.45 (H-12 and H-12'), ~6.30 (H-14 and H-14') and ~6.68 (H-15 and H-15') with  $J_{7,8}$  or  $J_{7,8'}$  = 16.3Hz,  $J_{10,11}$  or  $J_{10,11'}$  = 11.5Hz and  $J_{11,12}$  or  $J_{11',12'}$  = 14.7Hz;  $\delta$  for Me groups at 1.21 and 1.32 (6H, C-1 Me and C-1' Me), 1.95 (6H, C-5 Me and C-5' Me), 2.00 (6H, C-9 Me and C-9' Me), 1.99 (6H, C-13 Me and C-13' Me); and  $\delta$  for cyclohexenone protons at 1.82 (2H, axial H-2 and H-2'), 2.16 (2H, equatorial H-2 and H-2'), 4.32 (2H, H-3 and H-3'), and 3.70 (2H, 3-OH and 3'-OH,  $J$  = 1.8Hz,) with  $J_{2,2}$  (gem) or  $J_{2',2'}$  (gem) = 12.7Hz,  $J_{2e,3a}$  (vic) = 5.7Hz and  $J_{2a',3a'}$  (vic) = 14.0Hz,  $J_{2e',3a'}$  (vic) = 5.7Hz and  $J_{2a',3a'}$  (vic) = 14.0Hz; the <sup>13</sup>C NMR (23MHz, CDCl<sub>3</sub>, TMS) has  $\delta$  for methyl group carbons at 12.8 (13,13'), 12.6 (9,9'), 13.9 (5,5'), 26.2 (1 or 1'), 30.8 (1' or 1); for end group carbons 36.8 (1,1'), 45.6 (2,2'), 69.2 (3,3'), 200.3 (4,4'), 126.9 (5,5'), 162.4 (6,6'); and for olefinic carbons at 123.2 (7,7'), 142.2 (8,8'), 134.7 (9,9'), 135.1 (10,10'), 124.6 (11,11'), 139.7 (12,12'), 136.7 (13,13'), 133.8 (14,14') and 130.7 (15,15'); and the CD spectrum in CH<sub>2</sub>Cl<sub>2</sub> has  $\lambda_{\max}$  ( $\Delta\epsilon$ ) at 224 (+12.8), 249 (-14.4), 280 (+ 12.5), 323 (-23.1), 384 (+6.7) and 521 (-3.2, very broad) [Englert et al. *Helv Chim Acta* **60** 1209 1977].

It is the prosthetic group in many carotenoproteins, mainly in invertebrates, which vary from colourless to bright blue. It reduces blood glucose and improves some parameters in diabetic metabolism. It ameliorates blood flow and vascular tone in hypertension model and regulates *connexin* 43 in *in vitro* studies, and may be a cancer chemopreventive drug. It is obtained on a large scale from the heterobasidiomycetous yeast *Phaffia rhodozyma* and plays an important role in carotene biosynthesis [Schroeder & Johnson *J Biol Chem* **270** 18374 1995].

**Bixin (6,6'-diapo- $\psi,\psi$ -carotenedioic acid monomethyl ester)** [6983-79-5] **M 394.5, m 198<sup>o</sup>, 217<sup>o</sup>(dec)**,  $\lambda_{\max}$  (CHCl<sub>3</sub>) **209, 475 and 443nm**, **pK<sub>Est</sub> ~4.3**. Crystallise bixin from Me<sub>2</sub>CO (violet prisms) [Pattenden et al. *J Chem Soc (C)* 235 1970]. [Beilstein **2** III 2020, **2** IV 2455, H **30** 110.]

**Canthaxanthin (trans) ( $\beta$ ,  $\beta$ -carotene-4,4'-dione)** [514-78-3] **M 564.9, m 211-212<sup>o</sup>, 213<sup>o</sup>,  $\epsilon_{\text{mol}}$  124,100 (at 466nm, petroleum ether), 118,000 (at 484nm \*C<sub>6</sub>H<sub>6</sub>)**. Purify canthaxanthin by chromatography on a column of deactivated alumina or magnesium oxide, or on a thin layer plate of silica gel G (Merck), using dichloromethane/diethyl ether (9:1) to develop the chromatogram. Crystallise it from CH<sub>2</sub>Cl<sub>2</sub> or CH<sub>2</sub>Cl<sub>2</sub>/MeOH. Store in the dark and in an inert atmosphere at -20<sup>o</sup>. [Beilstein **7** III 4364, **7** IV 2680.]

**Capsanthin [(3*R*,3'*S*,5'*R*)-3,3'-dihydroxy- $\beta,\kappa$ -carotene-6-one]** [465-42-9] **M 584.9, m 170<sup>o</sup>,  $\lambda_{\max}$  484 ( $\epsilon_{\text{mol}}$  121,000), inflexion at 515 nm, in hexane**. Possible impurities are zeaxanthin and capsorubin (below). Purify

capsanthin by chromatography on a column of alumina (grade IV) and develop with 0.2% EtOH in \*C<sub>6</sub>H<sub>6</sub>. It crystallises from petroleum ether in red needles, IR has  $\nu_{\max}$  at 3600, 1664cm<sup>-1</sup>, and  $\epsilon_{1033}/\epsilon_{1664} \sim 4.1$ . [Baker et al. *J Chem Soc* 4019 1961, ORD & absolute config: Bartlett et al. *J Chem Soc (C)* 2527 1969.] The *di-O-acetate* is purified on an alumina (grade II) column in \*C<sub>6</sub>H<sub>6</sub> and it is recrystallised from MeOH with **m** 160-162°. [Faigle & Karrer *Helv Chim Acta* 44 1257 1961, *Beilstein* 8 II 415, 8 III 3047, 8 IV 2657.]

**Capsorubin (3,3'-dihydroxy- $\kappa,\kappa$ -carotene-6,6'dione)** [470-38-2] **M 604.9, m 218°,  $\lambda_{\max}$  443, 468, 503 nm, in hexane.** Possible impurities are zeaxanthin and capsanthin. Purify capsorubin by chromatography on a column of CaCO<sub>3</sub> or MgO. Crystallise it from \*benzene/petroleum ether or CS<sub>2</sub>. [*Beilstein* 1 III 3327, 8 III 3873, 8 IV 3304.]

**$\alpha$ -Carotene (6'R- $\alpha$ -carotene)** [7488-99-5] **M 536.9, m 184-188°, 187.5° (evacuated tube),  $[\alpha]_D^{20} +385^\circ$  (c 0.08, \*C<sub>6</sub>H<sub>6</sub>),  $[\alpha]_D^{25} +538^\circ$ ,  $\lambda_{\max}$  422, 446, 474 nm, in hexane,  $A_{1\text{cm}}^{1\%}$  2725 (at 446nm), 2490 (at 474nm),  $\epsilon_{\text{mol}}$  145,300 (at 455nm, hexane), and 456 (at 485nm, \*C<sub>6</sub>H<sub>6</sub>).** Purify  $\alpha$ -carotene by chromatography on columns of calcium hydroxide, alumina or magnesia. Crystallise it from CS<sub>2</sub>/MeOH, toluene/MeOH, diethyl ether/petroleum ether, or acetone/petroleum ether. Store it in the dark, under N<sub>2</sub> or Ar at -20°. It gives a blue colour with  $\lambda_{\max}$  at 542nm when mixed with SbCl<sub>3</sub> in CHCl<sub>3</sub>. [Karrer & Walker *Helv Chim Acta* 16 641 1933, Eugster et al. *Helv Chim Acta* 52 1729 1969, Eugster & Karrer *Helv Chim Acta* 38 610 1955, Strain *J Biol Chem* 105 523 1934, *Beilstein* 5 III 2457, 5 IV 2620.]

**all-trans- $\beta$ -Carotene** [7235-40-7] **M 536.9, m 178-179°, 179-180°, 180°, 181°, 183° (evacuated capillary),  $\epsilon_{\text{mol}}$  138,900 (at 450nm, petroleum ether), 124,300 (at 462nm, \*C<sub>6</sub>H<sub>6</sub>).** It forms purple prisms when crystallised from \*C<sub>6</sub>H<sub>6</sub>/MeOH and red rhombs from petroleum ether. Its solubility in hexane is 0.1% at 0°. It is **oxygen sensitive** and should be stored under N<sub>2</sub> at -20° in the dark. It gives a deep blue colour with  $\lambda_{\max}$  at 590nm when mixed with SbCl<sub>3</sub> in CHCl<sub>3</sub>. Its UV (\*C<sub>6</sub>H<sub>6</sub>) has  $\lambda_{\max}$  at 429infl, 454 and 484nm. The principal peak at 454nm has  $A_{1\text{cm}}^{1\%}$  2000. [Synthesis: Surmatis & Ofner *J Org Chem* 26 1171 1961; Milas et al. *J Am Chem Soc* 72 4844 1950.]  $\beta$ -Carotene is also purified by column chromatography (Al<sub>2</sub>O<sub>3</sub> activity I-II). It is dissolved in petroleum ether/\*C<sub>6</sub>H<sub>6</sub> (10:1), applied to the column and eluted with petroleum ether/EtOH; the desired fraction is evaporated and the residue is recrystallised from \*C<sub>6</sub>H<sub>6</sub>/MeOH (violet-red plates). [UV: Inhoffen et al. *Justus Liebigs Ann Chem* 570 54, 68 1950; Review: Fleming *Selected Organic Synthesis* (J Wiley, Lond) pp. 70-74 1973.] *Alternatively*, it can be purified by chromatography on a magnesia column, thin layer of Kieselguhr or magnesia. Crystallise it from CS<sub>2</sub>/MeOH, Et<sub>2</sub>O/petroleum ether, acetone/petroleum ether or toluene/MeOH. Store it in the dark, under an inert atmosphere, at -20°. Recrystallise it also from 1:1 EtOH/CHCl<sub>3</sub>. [Bobrowski & Das *J Phys Chem* 89 5079 1985, Johnston & Scaiano *J Am Chem Soc* 108 2349 1986, Strain *J Biol Chem* 105 523 1934, *Meth Biochem Anal* 4 1 1957, *Beilstein* 5 II 638, 5 III 2453, 5 IV 2617.]

**$\delta$ -Carotene (6R- $\epsilon,\psi$ -carotene)** [472-92-4] **M 536.9, m 140.4°, 142° (evacuated capillary)  $[\alpha]_D^{25} +352^\circ$  (c 16 hexane),  $[\alpha]_{\text{Cd}} +317^\circ$  (CS<sub>2</sub>),  $\lambda_{\max}$  430, 456, 486nm (hexane).**  $\delta$ -Carotene crystallises from CS<sub>2</sub>/hexane/EtOH as red needles. The **racemic** carotene is purified through an alumina (Grade II) column by elution with 15% \*C<sub>6</sub>H<sub>6</sub>/petroleum ether (b 60-80°), and the main band eluent is evaporated and the residue is crystallised from MeOH/petroleum ether (b 60-80°) to give  $\delta$ -carotene with **m** 150-151°. [Porter & Anderson *Arch Biochem* 32 21 1951, Synthesis: Manchand et al. *J Chem Soc* 2019 1965, Absolute Config: Buchecker & Eugster *Helv Chim Acta* 54 327 1971, 5 III 2453, 5 IV 2617.]

**$\gamma$ -Carotene ( $\beta,\psi$ -carotene)** [472-93-5, 10593-83-6] **M 536.9, m 152-153.5° (synthetic), 177.5° (polymorph),  $A_{1\text{m}}^{1\%}(\lambda_{\max})$  2055 (at 437nm), 3100 (at 462nm), 2720 (at 494nm) in hexane.** Purify  $\gamma$ -carotene by chromatography on alumina [Grade II in petroleum ether (b 60-80°) and elute with \*C<sub>6</sub>H<sub>6</sub>], or magnesia columns. When crystallised from \*C<sub>6</sub>H<sub>6</sub>/MeOH (2:1), it had **m** 177.5°. Store it in the dark, under an inert atmosphere at 0°, or in an evacuated tube at -20°. The purity is verified by TLC on Ca(OH)<sub>2</sub>/Kieselgel (8:2) using petroleum ether (b 60-80°) as eluant. [Manchand et al. *J Chem Soc* 2019 1965, *Beilstein* 5 III 2453, 5 IV 2617.]

**$\xi$ -Carotene** [38894-81-4] **M 536.9, m 38-42°,  $\lambda_{\max}$  378, 400, 425nm,  $A_{1\text{m}}^{1\%}(\lambda_{\max})$  2270 (400nm), in petroleum ether.** Purify  $\xi$ -carotene by chromatography on 50% magnesia-HyfloSupercel, developing with hexane and

eluting with 10% EtOH in hexane. It crystallises from toluene/MeOH. [Gorman et al. *J Am Chem Soc* **107** 4404 1985.] Store it in the dark under N<sub>2</sub> or argon at -20°. Also purify it like  $\gamma$ -Carotene. [Beilstein **5** IV 2623.]

**Citraxanthin** [5,9,14,18-tetramethyl-20-(2,6,6-trimethyl-1-cyclohex-1-enyl)- 3,5,7,9, 11,13,15,17,19-eicosanonen-2-one] [3604-90-8] **M 456.7, m 155-156°,  $A_{1m}^{1\%}(\lambda_{max})$  410 (349nm), 275 (466nm) in hexane.** Purify it by chromatography on a column of 1:1 MgO and HyfloSupercel (diatomaceous filter aid). Crystallise it from petroleum ether. Store it in the dark under N<sub>2</sub> or argon at 0°.

**Crocetin diethyl ester (8,8'-diapo- $\psi,\psi$ -carotenedioic acid diethyl ester)** [5056-14-4] **M 384.5, m 218-219°, 222.5°,  $A_{1m}^{1\%}(\lambda_{max})$  2340 (at 400nm), 3820 (at 422nm), 3850 (at 450nm) in petroleum ether.** Purify the diethyl ester by chromatography on a column of silica gel G. Recrystallise it from \*benzene. Store it in the dark, under N<sub>2</sub> or argon, at 0°. [Beilstein **2** III 2018, H **30** 106.]

**$\alpha$ -Cryptoxanthin (all-trans-3R,6R'- $\beta$ ,  $\epsilon$ -carotene-3-ol, zeinoxanthin, physoxanthin)** [24480-38-4] **M 552.9, m 175-176° (racemate 157.5-158.5°),  $[\alpha]_D^{25}$  -508° (c 0.4 Me<sub>2</sub>CO), CD<sub>max</sub>  $\Delta\epsilon$  -3.6 (218nm), +4.4 (245nm) and -9.0 (283nm),  $\lambda_{max}$  (hexane) 421, 446, 474nm,  $\epsilon_{mol}$  145,500 (at 446nm, hexane), 130,000 (at 459nm, \*C<sub>6</sub>H<sub>6</sub>).** It crystallises from \*C<sub>6</sub>H<sub>6</sub>/MeOH in red needles. The *racemate* is purified through an Al<sub>2</sub>O<sub>3</sub> column, eluting with \*C<sub>6</sub>H<sub>6</sub> and recrystallising from MeOH/Et<sub>2</sub>O. It has  $\lambda_{max}$  ( $\epsilon$  10<sup>-3</sup>) (hexane) at 421, 444, 471nm (90, 133, 122). [Loeber et al. *J Chem Soc (C)* 404 1971, Goodfellow et al. *J Chem Soc, Chem Commun* 1578 1970, Beilstein **6** IV 5113.]

**$\beta$ -Cryptoxanthin (all-trans-3R- $\beta,\beta$ -carotene-3-ol, caricaxanthin)** [472-70-8] **M 552.9, m 169° (natural), (racemate m 172-173°),  $\epsilon_{mol}$  131,900 (at 449nm, petroleum ether).** Purify it by chromatography on MgO, CaCO<sub>3</sub> or deactivated alumina, using EtOH or diethyl ether to develop the column. Crystallise it from \*C<sub>6</sub>H<sub>6</sub>/EtOH (metallic prisms), or needles from \*C<sub>6</sub>H<sub>6</sub>. Store it in the dark under N<sub>2</sub> or argon at -20°. The *acetate* has **m 117.5°**. The *racemate* is purified through a column of alumina (grade IV), eluted with \*C<sub>6</sub>H<sub>6</sub> then EtOAc/\*C<sub>6</sub>H<sub>6</sub> (1:9) and recrystallised from petroleum ether (b 60-80°) with **m 172-173°**. [Loeber et al. *J Chem Soc (C)* 404 1971, Goodfellow et al. *J Chem Soc Chem Commun* 1578 1970, Isler et al. *Helv Chim Acta* **40** 456 1957, Beilstein **6** III 3772, **6** IV 5111.]

**3,30-Diketospirilloxanthin (all-trans-2,31-dimethoxy-2,6,10,14,19,23,27,31-octamethyl-4,6,8,10,12,-14,16,18,20,22,24,26,28-dotriacontatridecene-3,30-dione)** [24009-17-4] **M 624.9, m 225-227°,  $\epsilon_{1m}^{1\%}(\lambda_{max})$  550 (at 349nm), 820 (at 422nm), 2125 (at 488nm), 2725(516nm), 2130(at 551nm) in hexane.** Purify it by chromatography on a column of partially deactivated alumina. Recrystallise it from acetone/petroleum ether. Store it in the dark, in an inert atmosphere at 0°. [cf Beilstein **1** III 2297, **1** IV 2750.]

**Echinenone ( $\beta,\beta$ -caroten-4-one)** [432-68-8] **M 550.8, m 178-179°,  $A_{1m}^{1\%}(\lambda_{max})$  2160 (at 458nm) in petroleum ether.** Purify  $\beta,\beta$ -caroten-4-one by chromatography on partially deactivated alumina or magnesia, or by using a thin layer plate of silica gel G with 4:1 cyclohexane/diethyl ether as the developing solvent. Recrystallise it from \*C<sub>6</sub>H<sub>6</sub>/MeOH. Store it in the dark at -20°. The *oxime* crystallises from \*C<sub>6</sub>H<sub>6</sub> with **m 208°**. [Beilstein **7** III 2858, **7** IV 1881.]

**Ethyl bixin (6,6'-diapo- $\Psi,\Psi$ -carotenedioic acid monomethyl ester monoethyl ester)** [6895-43-8] **M 436.6, m 138°.** Crystallise the ester from EtOH. [cf. Beilstein **2** III 2020, **2** IV 2356.]

**Lutein** See xanthophyll.

**Lycopene (all-trans- $\Psi,\Psi$ -carotene)** [502-65-8] **M 536.9, m 172-173°, 174°,  $\epsilon_{mol}$  184,900 (470nm petroleum ether), 180,600 (at 487nm \*C<sub>6</sub>H<sub>6</sub>).** Crystallise lycopene from CS<sub>2</sub>/MeOH, diethyl ether/petroleum ether, or

acetone/petroleum ether. Also purify it by column chromatography on deactivated alumina, CaCO<sub>3</sub>, calcium hydroxide or magnesia. It is oxygen sensitive and is stored in the dark, in an inert atmosphere. Also purified like  $\gamma$ -Carotene. [*Beilstein* 1 III 1076, 1 IV 1165.]

**Lycoxanthin (all-trans- $\Psi$ , $\Psi$ -carotene-16,16'-ol)** [19891-74-8] M 268.3, m 173-174°,  $\epsilon_{1\text{cm}}^{1\%}$  3360 (472.5nm), also  $\lambda_{\text{max}}$  444 and 503nm in petroleum ether. Crystallise lycoxanthin from diethyl ether/light petroleum, \*C<sub>6</sub>H<sub>6</sub>/petroleum ether or CS<sub>2</sub>. Purify it also by chromatography on columns of CaCO<sub>3</sub>, Ca(OH)<sub>2</sub> or deactivated alumina, and washing with \*benzene and eluting with 3:1 \*C<sub>6</sub>H<sub>6</sub>/MeOH. Store it in the dark, in an inert atmosphere, at -20°. The *dipalmitate ester* crystallises from \*C<sub>6</sub>H<sub>6</sub>/MeOH and has m 76°. [*Beilstein* 1 III 2051, 1 IV 2368.]

**Methylbixin (6,6'-diapo- $\Psi$ , $\Psi$ -carotenedioic acid dimethyl ester)** [26585-94-4] M 408.5, m stable *trans* form 203°, 205-206° (corr), unstable *cis* form 164°,  $\lambda_{\text{max}}$  405, 425, 450, 484nm in hexane. Crystallise the dimethyl ester from EtOH/CHCl<sub>3</sub>, or \*benzene. Also purify it by chromatography on alumina (Grade III) and eluting with 9:1 \*C<sub>6</sub>H<sub>6</sub>/petroleum ether (b 60-80°), and recrystallise it from EtOAc. [Pattenden et al. *J Chem Soc (C)* 235 1970, *Beilstein* 2 III 2020, 2 IV 2356.]

**Physalien (all-trans  $\beta$ -carotene-3,3'(R,R)-diol dipalmitate)** [144-67-2] M 1044, m 98.5-99.5°,  $A_{1\text{cm}}^{1\%}(\lambda_{\text{max}})$  1410 (at 449nm), 1255 (at 478nm) in hexane. Purify it by chromatography on water-deactivated alumina, using hexane/diethyl ether (19:1) to develop the column. It crystallises from \*benzene/EtOH in red needles. Store in the dark, in an inert atmosphere, at 0°. [See Zeaxanthin dipalmitate.] [*Beilstein* 6 III 5970.]

**Phytoene (7,7',8,8',11,11',12,12'-octahydro- $\psi$ , $\psi$ -carotene)** [540-04-5] M 544.9,  $A_{1\text{cm}}^{1\%}(\lambda_{\text{max}})$  850 (at 287nm) in hexane,  $\lambda_{\text{max}}$  275, 287 and 297nm. Purify phytoene by chromatography on columns of magnesium oxide-Supercel (a diatomaceous filter aid) or alumina [Rabourn et al. *Arch Biochem Biophys* 48 267 1954]. Store it as a solution in petroleum ether under nitrogen at -20°. [*Beilstein* 1 IV 1155.]

**Phytofluene (all-trans- 5,6,7,8,9,10,10',9',8',7',6',5'-dodecahydrolycopene)** [540-05-6] M 549.0, b 140-185°(bath temperature)/0.0001mm,  $A_{1\text{cm}}^{1\%}(\lambda_{\text{max}})$  1350 (at 348nm) in petroleum ether,  $\lambda_{\text{max}}$  331, 348, 267. Purify it by chromatography on partially deactivated alumina [Goodwin *Biochem J* 53 538 1953, Kushwaha et al. *J Biol Chem* 245 4708 1970]. Store it as a solution in petroleum ether under N<sub>2</sub> at -20°. [*Beilstein* 1 III 1072, 1 IV 1159.]

**Polycopene (all-cis [Z]- $\psi$ , $\psi$ -carotene or lycopene)** [2361-24-2] M 536.5, m 111°,  $\lambda_{\text{max}}$  443.5, 470nm in petroleum ether. Purify polycopene by chromatography on deactivated alumina [Kushwaha et al. *J Biol Chem* 245 4708 1970]. Crystallise it from petroleum ether. Store it in the dark, under N<sub>2</sub> or argon at -20°. [*Beilstein* 1 III 1079, 1 IV 1167.]

**Proneurosporene (3,4,7',8'-tetrahydrolycopene)** [10467-46-6] M 538.9,  $\lambda_{\text{max}}$  408, 432, 461 nm,  $\epsilon_{1\text{cm}}^{1\%}$  2040 (at 432nm) in hexane. Purify proneurosporene by chromatography on deactivated alumina [Kushwaha et al. *J Biol Chem* 245 4708 1970]. Store it in the dark, in an inert atmosphere at 0°. [*Beilstein* 1 IV 1156.]

**Retinol (vitamin A alcohol), retinoic acid (vitamin A acid), retinyl acetate (vitamin A acetate), retinal (vitamin A aldehyde) and retnyl palmitate (vitamin A palmitate).** See in "Miscellaneous", this chapter.

**Spirilloxanthin (rhodoviolascein)** [34255-08-8] M 596.9, m 216-218°, 218°,  $\lambda_{\text{max}}$  463, 493, 528 nm,  $\epsilon_{1\text{cm}}^{1\%}$  2680 (at 493nm) in petroleum ether (b 40-70°). Spirilloxanthin crystallises from CHCl<sub>3</sub>/petroleum ether, acetone/petroleum ether, \*C<sub>6</sub>H<sub>6</sub>/petroleum ether or \*C<sub>6</sub>H<sub>6</sub> as deep red spindle-like crystals. Purify it also by chromatography on a column of CaCO<sub>3</sub>/Ca(OH)<sub>2</sub> mixture, Ca(OH)<sub>2</sub> or deactivated alumina and elute it with a

\*C<sub>6</sub>H<sub>6</sub>/MeOH mixture. It gives a blue colour with SbCl<sub>3</sub> in CHCl<sub>3</sub> with  $\lambda_{\max}$  at 642nm. [Polgar et al. *Arch Biochem Biophys* **5** 243 1944, Synthesis: Surmatis & Ofner *J Org Chem* **28** 2735 1963, Karrer & Koenig *Helv Chim Acta* **23** 460 1940.] Store it in the dark in an inert atmosphere at -20°. [Beilstein **1** III 2297, **1** IV 2750.]

**Squalane** (Cosbiol, 2,6,10,15,19,23-hexamethyltetracosane, perhydrosqualene) [111-01-3] **M 422.8, m 7-38°**, **b 176°/0.05mm, 210-215°/1mm, 274°/10mm, ~350°/760mm,  $d_4^{20}$  0.80785,  $n_D^{20}$  1.416**. Purify squalane by fractional distillation *in vacuo* or evaporative distillation. It is soluble in petroleum ether, \*C<sub>6</sub>H<sub>6</sub>, Et<sub>2</sub>O and CHCl<sub>3</sub>, slightly soluble in alcohols, Me<sub>2</sub>CO and AcOH but insoluble in H<sub>2</sub>O. Small quantities can be purified by TLC as for squalene below. It is used as a marker in GLC and HPLC. [Staudinger & Leupold *Helv Chim Acta* **15** 223 1932, Sax & Stross *Anal Chem* **29** 1700 1951, Mandai et al. *Tetrahedron Lett* **22** 763 1981, Beilstein **1** IV 593.]

**Squalene** (all-*trans*-2,6,10,15,19,23-hexamethyl-2,6,10,14,18,22-tetracosahexaene) [111-02-4] **M 410.7, m ~75°**, **b 203°/0.1mm, 213°/1mm, 285°/25mm,  $d^{25}$  0.8670,  $n_D^{20}$  1.4905**. Crystallise squalene repeatedly from Me<sub>2</sub>CO (1.4ml/g) using a Dry-ice bath, wash the crystals with cold acetone, then freeze the squalene under vacuum. Squalene is further purified by passage through a column (or TLC plate) of silica gel or chromatographed on activated alumina, using petroleum ether as eluent and stored in a vacuum in the dark. Dauben et al. [*J Am Chem Soc* **74** 4321 1952] purified squalene *via* its hexachloride which is bactericidal. It is a key intermediate in sterol biosynthesis. [Capstack et al. *J Biol Chem* **240** 3258 1965, Krishna et al. *Arch Biochem Biophys* **114** 200 1966, Heilbron & Thompson *J Chem Soc* 883 1929, Karrer et al. *Helv Chim Acta* **13** 1084 1930, UV: Farmer et al. *J Chem Soc* 544 1943, Beilstein **1** III 1071.]

**Violaxanthin** (5*S*,6*S*,5'*S*,6'*S*-diepoxyzeaxanthin) [126-29-4] **M 600.9, m 200°, 207-208°,  $[\alpha]_{C_d}^{18}$  +35°** (c 0.1, CHCl<sub>3</sub>). Crystallise violaxanthin from MeOH (orange prisms) by adding a little Et<sub>2</sub>O in MeOH, or CS<sub>2</sub> (red brown crystals). Also purify it by column chromatography, and the purity is checked by TLC (see  $\delta$ -carotene). It has  $\lambda_{\max}$  at 415, 440 and 469nm. [Kuhn & Winterstein *Ber* **64** 326 1931, Karrer et al. *Helv Chim Acta* **14** 1044 1931, Absolute Config: Bartlett et al. *J Chem Soc (C)* 2527 1969, Beilstein **19** III/IV 1139.]

**Xanthophyll** (Lutein, 3*R*,3'*R*- $\alpha$ -carotene-3,3'-diol) [127-40-2] **M 568.9, m 183°, 193°, 196°,  $[\alpha]_{C_d}^{18}$  +165°** (c 0.7, \*C<sub>6</sub>H<sub>6</sub>)[NB: Cd I and II have  $\lambda$  533 & 537 nm],  $\epsilon_{1cm}^{1\%}$  ( $\lambda_{\max}$ ) **1750 (423nm), 2560 (446nm), 2340 (477.5nm) and  $\epsilon_{mol}$  144,800 (at 445nm) in EtOH;  $\lambda_{\max}$  in CS<sub>2</sub> 446, 479 and 511nm, and  $\epsilon_{mol}$  127,000 (at 458nm, \*C<sub>6</sub>H<sub>6</sub>)**. Crystallise lutein from MeOH (1g/700ml; copper-coloured prisms) or from diethyl ether by adding MeOH. Also purify it by chromatography on columns of magnesia or calcium hydroxide, and recrystallise it from CS<sub>2</sub>/EtOH. It may be purified *via* the dipalmitate ester which crystallises from EtOH with m 92°. Store it in the dark, in an inert atmosphere, e.g. Ar. [Buchecker et al. *Helv Chim Acta* **57** 631 1974, Karrer *Helv Chim Acta* **34** 2060 1951, Absolute Config: Goodfellow et al. *J Chem Soc, Chem Commun* 1578 1970, Beilstein **6** II 1026, **6** III 5871, **6** IV 7017.]

**Zeaxanthin** [all *trans*- $\beta$ -carotene-3,3'(R,R')-diol] [144-68-3] **M 568.9, m 205-206° (natural), 207°, 215.5°,  $[\alpha]_{C_d}^{18}$  -44°** (c 0.7, CHCl<sub>3</sub>), [NB: Cd I and II have  $\lambda$  533 & 537 nm],  $\lambda_{\max}$  **275nm (log  $\epsilon$  4.34), 450nm (log  $\epsilon$  5.14), 480nm (log  $\epsilon$  5.07) in EtOH,  $\epsilon_{mol}$  132,900 (at 452nm, Me<sub>2</sub>CO)**. Zeaxanthin forms yellow plates (with a blue lustre) from MeOH, EtOH and with 0.5 MeOH from \*C<sub>6</sub>H<sub>6</sub>/MeOH. The diacetate (from natural) has m 154-155° (from CH<sub>2</sub>Cl<sub>2</sub>/MeOH), the UV has  $\lambda_{\max}$  ( $\epsilon_{1cm}^{1\%}$ ) at 452, 480nm (2210, 1945). The dipalmitate (Physalein) (from natural source) has m 95-96° (from CH<sub>2</sub>Cl<sub>2</sub>/MeOH), the UV:  $\lambda_{\max}$  ( $\epsilon_{1cm}^{1\%}$ ) at 452, 480nm (1335, 1190). [Isler et al. *Helv Chim Acta* **31** 2041 1956, Hlubeck et al. *J Chem Soc, Perkin Trans I* 848 1974.] The racemate is purified by chromatography on an alumina (Grade IV) column by elution with a gradient of petroleum ether (b 60-80°), \*C<sub>6</sub>H<sub>6</sub> and EtOAc. The red band gives a solid which recrystallises from MeOH with m 211°, and the UV has  $\lambda_{\max}$  at 439infl, 462, 589nm ( $\epsilon$  10<sup>-3</sup>: 90, 126, 110 respectively). [Loeber et al. *J Chem Soc (C)* 404 1971, Beilstein **6** II 1026, **6** III 5865, **6** IV 7017.]

## STEROIDS

This section also includes steroidal hormones, steroidal alkaloids and cardenolides.

**(-)-3- $\beta$ -Acetoxy-5-etiolic acid** [**3- $\beta$ -acetoxy-5-etiocholonic acid, androst-5-ene-17- $\beta$ -carboxylic acid**] [51424-66-9] **M 306.5, m 238-240<sup>o</sup>, 241-242<sup>o</sup>, 243-245<sup>o</sup>, 246-247<sup>o</sup>,  $[\alpha]_D^{20}$  -19.9<sup>o</sup> (c 1, Me<sub>2</sub>CO), -36<sup>o</sup> (c 1, dioxane), -33.5<sup>o</sup> (CHCl<sub>3</sub>), pK<sub>Est</sub> ~ 4.7.** The acid is purified by recrystallisation from Me<sub>2</sub>CO, Et<sub>2</sub>O/pentane, or AcOH, dried in a vacuum oven (105<sup>o</sup>/20mm) and sublimed at high vacuum. [Staunton & Eisenbram *Org Synth* **42** 4 1962, Steiger & Reichstein *Helv Chim Acta* **20** 1404 1937.]

**21-Acetoxypregnenolone (3 $\beta$ -21-acetoxypregn-5-en-20-one)** [566-78-9] **M 374.5, m 184-185<sup>o</sup>.** Crystallise 21-acetoxypregnenolone from Me<sub>2</sub>CO by allowing the solvent to evaporate in a vacuum, then dry it *in vacuo*. The crystals become opaque on standing. [Steiger & Reichstein *Helv Chim Acta* **20** 1164 1937.]

**Adrenosterone (Reichstein's G, androst-4-ene-3,11,17-trione)** [382-45-6] **M 300.4, m 214-217<sup>o</sup>, 220-224<sup>o</sup>, 224-226<sup>o</sup>,  $[\alpha]_{546}^{20}$  +364<sup>o</sup> (c 0.18, EtOH).** Dissolve adrenosterone in Me<sub>2</sub>CO, decolorise it with charcoal, filter, add H<sub>2</sub>O, Me<sub>2</sub>CO evaporate and the solid is recrystallised from aqueous EtOH. Also recrystallise it from Et<sub>2</sub>O or Et<sub>2</sub>O/pentane and dry it at 110<sup>o</sup>/0.1mm for 2 hours. It can be sublimed under high vacuum. [Reichstein *Helv Chim Acta* **20** 953, 979 1937, Mason et al. *J Biol Chem* **116** 267 1936, Beilstein **7** III 4601.]

**Aldosterone (18-aldocorticosterone)** [52-39-1] **M 360.5, m 108-112<sup>o</sup>(hydrate), 164<sup>o</sup>(anhydrous),  $[\alpha]_D^{25}$  +161<sup>o</sup> (c 1, CHCl<sub>3</sub>).** Crystallise aldosterone from aqueous acetone. It exists in solution as an equilibrium mixture of free aldehyde and its cyclic hemiacetal, favouring the hemiacetal. The *21-acetate* crystallises from Me<sub>2</sub>CO/Et<sub>2</sub>O or CH<sub>2</sub>Cl<sub>2</sub>/EtOAc and has **m 198-199<sup>o</sup>,  $[\alpha]_D^{25}$  +121.7<sup>o</sup> (c 0.7, CHCl<sub>3</sub>).** [Barton et al. *J Chem Soc Perkin Trans 1* 2243 1975, Beilstein **8** IV 3491.]

**5 $\alpha$ -Androstane (etioallocholane)** [5 $\alpha$ - 438-22-2, 24887-75-0] **M 260.5, m 50-50.5<sup>o</sup>,  $[\alpha]_D$  +2<sup>o</sup> (c 0.12, CHCl<sub>3</sub>).** Purify 5 $\alpha$ -androstane by chromatography through Al<sub>2</sub>O<sub>3</sub> (grade III) and elute with petroleum ether and recrystallise from MeOH (2x) and Me<sub>2</sub>CO/MeOH. It sublimes at 60<sup>o</sup>/high vacuum. Also dissolve it in petroleum ether, filter it through silica gel, evaporate and recrystallise it. [Steiger & Reichstein *Helv Chim Acta* **20** 817 1937, Prelog et al. *Helv Chim Acta* **27** 66 1944, IR, NMR: Halkes & Havinga *Rec Trav Chim, Pays Bas* **84** 889 1965, Allinger et al. *Tetrahedron* **27** 5073 1971, Beilstein **5** III 1110, **5** IV 1211.]

**5 $\beta$ -Androstane (etiocholane, testane)** [438-23-3] **M 260.5, m 78-79<sup>o</sup>, 78-80<sup>o</sup>,  $[\alpha]_D^{20}$  +2.03<sup>o</sup>,  $[\alpha]_{546}^{18}$  +5<sup>o</sup> (c 1, CHCl<sub>3</sub>).** Crystallise etiocholane from acetone. The method of purification for 5 $\alpha$ -androstane (above) could be used here. [Shopee *Helv Chim Acta* **27** 246, 260 1944, Butenandt & Dannerbaum *Hoppe Seyler's Z Physiol Chem* **229** 192 1934, Beilstein **5** III 1110, **5** IV 1211.]

**4-Androstene-3,17-dione (androstenedione)** [63-05-8] **M 286.4, m 170-171<sup>o</sup>, 173-174<sup>o</sup>,  $[\alpha]_D^{20}$  +196<sup>o</sup> (c 0.13, EtOH).** Crystallise the dione from hexane. It is soluble in \*C<sub>6</sub>H<sub>6</sub>, CHCl<sub>3</sub> and EtOH. It has  $\lambda_{max}$  at 239nm. It is a precursor of estrone or testosterone and has androgenic activity. [Ruzicka & Wettstein *Helv Chim Acta* **18** 980 1935, Beilstein **7** III 3636, **7** IV 2381.]

**Androsterone (Cis) (3 $\alpha$ ,5 $\alpha$ -3-hydroxyandrost-17-one)** [53-41-8] **M 290.4, m 185-185.5<sup>o</sup>,  $[\alpha]_{546}$  +118<sup>o</sup> (c 1, EtOH),  $[\alpha]_D^{20}$  +94.6<sup>o</sup> (c 0.7, EtOH).** Crystallise androsterone from Me<sub>2</sub>CO/Et<sub>2</sub>O or Me<sub>2</sub>CO and sublime it in high vacuum. The *acetate* [1164-95-0] crystallises from Et<sub>2</sub>O, Me<sub>2</sub>CO/Et<sub>2</sub>O or aqueous EtOH and sublimes in high vacuum with **m 165-166<sup>o</sup>,  $[\alpha]_D^{25}$  +87<sup>o</sup> (c 2, EtOH).** [Ruzicka *Helv Chim Acta* **17** 1389 1934, Marker *J Am Chem Soc* **57** 1755 1935, Göndös & Orr *J Chem Soc Chem Commun* 1239 1982, Beilstein **8** IV 462.]

**epi-Androsterone (Trans)** [481-29-8] **M 290.4, m 172-173<sup>o</sup>, (161-162<sup>o</sup> dl-),  $[\alpha]_{546}$  +115<sup>o</sup> (c 1, MeOH),  $[\alpha]_D^{20}$  +44.4<sup>o</sup> (c 0.27, CHCl<sub>3</sub>).** Purify *epi*-androsterone *via* the acetate, hydrolyse this and recrystallise it from CHCl<sub>3</sub>/hexane or aqueous EtOH. The *acetate* [1239-31-2] is purified by chromatography and when crystallised

from petroleum ether has **m** 103-104°,  $[\alpha]_D^{20} +68.5^\circ$  (c 1, CHCl<sub>3</sub>). The *oxime* has **m** 194-196° (from MeOH),  $[\alpha]_D^{20} +17.5^\circ$  (c 6.2, CHCl<sub>3</sub>). The **racemic ketone** is sublimed at 130°/high vacuum and after two crystallisations from methylcyclohexane it gives prisms with **m** 161-162° (which changed crystal form at 140-145°). [Ruzicka & Wettstein *Helv Chim Acta* **18** 1264 1935, Johnson et al. *J Am Chem Soc* **75** 2275 1953, **78** 6331 1956, Cordwell et al. *J Chem. Soc* 361 1953, *Beilstein* **8** IV 462.]

**Betamethasone (9 $\alpha$ -fluoro-11 $\beta$ ,17 $\alpha$ ,21-trihydroxy-16 $\beta$ -methylpregna-1,4-diene-3,20-dione)** [378-44-9] **M** 392.5, **m** 231-136°(dec), 235-237°(dec),  $[\alpha]_D^{20} +108^\circ$  (c 1, Me<sub>2</sub>CO). Betamethasone crystallises from ethyl acetate, and has  $\lambda_{\max}$  at 238nm (log  $\epsilon$  4.18) in MeOH. The *21-acetate* [287-24-6] crystallises from Me<sub>2</sub>CO/Et<sub>2</sub>O (charcoal) **m** 196-201° (205-208°) and has  $[\alpha]_D^{20} +140^\circ$  (CHCl<sub>3</sub>). [Taub et al. *J Am Chem Soc* **82** 4012 1960, Olivetto et al. *J Am Chem Soc* **80** 6688 1958, *Beilstein* **8** IV 3501.]

**Bisnorcholeic acid (pregnane-20-carboxylic acid)** [28393-20-6] **M** 332.5, **m** 214° ( $\alpha$ -form), 242° ( $\beta$ -form), 210-211° ( $\gamma$ -form), 184° ( $\delta$ -form), 181° ( $\epsilon$ -form), **pK<sub>Est</sub>** ~5.0. Bisnorcholeic acid crystallises from EtOH ( $\alpha$ -form), or acetic acid (all forms). The  $\alpha$ -form has  $[\alpha]_D^{20} -7.5^\circ$  (c 0.8, EtOH), and its *ethyl ester* has **m** 106-107°; the  $\beta$ -form has  $[\alpha]_D^{20} +23.3^\circ$  (c 0.86, EtOH), and its *ethyl ester* is an oil; the  $\gamma$ -form has  $[\alpha]_D^{20} 0^\circ$ , and its *ethyl ester* has **m** 82-83°; the  $\delta$ -form has  $[\alpha]_D^{20} +31.7^\circ$  (c 0.76, EtOH), and its *methyl ester* has **m** 99°; the  $\epsilon$ -form has  $[\alpha]_D^{20} +14.3^\circ$  (c 0.8, EtOH), and its *methyl ester* has **m** 117°. [Wieland et al. *Hoppe Seyler's Z Physiol Chem* **161** 80 1926, *Beilstein* **9** III 2650.]

**Brassicasterol [24 $\beta$ (R)-methylcholesta-5,22E-dien-3 $\beta$ -ol, 5,22-cholestadien-24 $\beta$ (R)-methyl-3 $\beta$ -ol, 24R-Ergosta-5,22E-dien-3 $\beta$ -ol]** [474-67-9] **M** 398.7, **m** 148°, 149-150°, 157-158°,  $[\alpha]_D^{20} -60^\circ, -66^\circ$ , (c 1.2, CHCl<sub>3</sub>). It is purified from the 7,22E-isomer, which is formed during synthesis, by TLC on Silica Gel G-Celite (1:1) with 30% EtOAc/hexane as eluant and recrystallised from MeOH or EtOH [Anastasia et al. *J C S Perkin I* 379 1983]. In a different synthesis from enantiomeric 23,24-cyclopropane precursor 3 $\beta$ -acetates, [22E,24 $\beta$ (R)-3 $\beta$ -brassicasteryl acetate **m** 152-154°], is obtained and purified by HPLC [using two *Altex Ultrasphere*<sup>TM</sup> ODS columns 5 $\mu$ m (10mm id x 25cm) and MeOH mobile phase], has **t<sub>R</sub>** = 118 minutes and crystallises from MeOH. The *acetate* has the <sup>1</sup>H NMR (360MHz, CDCl<sub>3</sub>, TMS) with  $\delta$  at 5.37 (m, 1H, H-C6), 5.18 (m, 2H, H-C22 and H-C23), 4.60 (m, 1H, H-C3), 2.03 (s, 3H, OCOCH<sub>3</sub>), 1.02 (s, 3H, H<sub>3</sub>C19), 1.01 (d, 3H, *J* = 6.49Hz, H<sub>3</sub>C21), 0.91 (d, 3H, *J* = 6.80Hz, H<sub>3</sub>C28), 0.83 (d, 3H, *J* = 6.5Hz) and 0.83 (d, 3H, *J* = 6.5Hz, H<sub>3</sub>C26), 0.81 (d, 3H, *J* = 6.5Hz, H<sub>3</sub>C27), 0.69 (s, 3H, H<sub>3</sub>C18); and HRMS *m/z* 380.3452 (100, *M*-HOAc), C<sub>28</sub>H<sub>44</sub><sup>+</sup> requires 380.3443. [Lang & Djerassi *Helv Chim Acta* **65** 407 1982, Rubinstein et al. *Phytochemistry* **15** 195 1976.] The *acetate* (5mg) in dry Et<sub>2</sub>O is de-acetylated with LAH (4 fold) at -25°/30 minutes, excess LAH is decomposed with saturated aqueous Na<sub>2</sub>SO<sub>4</sub>, H<sub>2</sub>O is added and the free sterol is extracted into Et<sub>2</sub>O, dried (Mg<sub>2</sub>SO<sub>4</sub>), evaporated and the residue is recrystallised from MeOH to give pure (22,24R)-brassicasterol **m** 156-158°, with one peak in HPLC (as above but with an ODS-2 column) at **t<sub>R</sub>** = 55 minutes. Its <sup>1</sup>H NMR (360MHz, CDCl<sub>3</sub>, TMS) has  $\delta$  at 5.35 (m, 1H, H-C6), 5.181 (m, 2H, H-C22 and H-C23), 3.53 (m, 1H<sub>ax</sub>, H-C3), 1.011 (d, 3H, *J* = 6.34Hz, H<sub>3</sub>C21), 1.010 (s, 3H, H<sub>3</sub>C19), 0.910 (d, 3H, *J* = 6.84Hz, H<sub>3</sub>C28), 0.834 (d, 3H, *J* = 6.10Hz) and 0.817 (d, 3H, *J* = 6.22Hz, H<sub>3</sub>C26), 0.815 (d, 3H, *J* = 6.22Hz, H<sub>3</sub>C27), 0.693 (s, 3H, H<sub>3</sub>C18); and the HRMS has *m/z* at 398.3545 (*M*<sup>+</sup>), C<sub>28</sub>H<sub>46</sub>O requires 398.3549. [Lang & Djerassi *Helv Chim Acta* **65** 407 1982, Rubinstein et al. *Phytochemistry* **15** 195 1976, Sheikh & Djerassi *Steroids* **26** 129 1975.]

It is a plant sterol (phytosterol) present in canola oils and rape seed but is also found in some marine algae, diatoms and shellfish (oysters). It inhibits the enzyme  $\Delta^{24}$ -sterol reductase that is involved in mammalian cholesterol biosynthesis [Fernandez et al. *Biochem J* **336** 109 2002]. Brassino sterols have plant growth regulating activities [Anastasia et al. *J C S Perkin I* 379 1983.]

**Crinosterol [24 $\alpha$ (S)-methylcholesta-5,22E-dien-3 $\beta$ -ol, 5,22-cholestadien-24 $\alpha$ (S)-methyl-3 $\beta$ -ol, 24S-Campesta-5,22E-dien-3 $\beta$ -ol]** [17472-78-5] **M** 398.7, **m** 147-148°, 152-154°  $[\alpha]_D^{20} -47.2^\circ$  (c 1.2, CHCl<sub>3</sub>). Crinosterol occurs in sponges, oysters and in diatoms. It is the 24- $\alpha$ -methyl epimer of Brassicasterol (see [474-67-9] above). They sometimes occur together in Nature and sometimes are formed together in synthesis: purification of one invariably requires the removal of the other. *Crinosterol acetate* **m** 148-150°, when isolated from a synthesis was separated from the 24- $\beta$ -methyl epimer by HPLC (see brassicasterol above), had **t<sub>R</sub>** = 112 minutes, and was recrystallised from MeOH, or *alternatively*, it is prepared by acetylation of crinosterol, then

purified by TLC (10% w/w AgNO<sub>3</sub>/silica gel and developed with pure CHCl<sub>3</sub>) to give homogeneous (by GLC) acetate with **m 157-158°** (compare with above). Crinosteryl acetate has IR (Nujol) with  $\nu_{\max}$  at 1720, 970, 955 and 795 cm<sup>-1</sup>, and the <sup>1</sup>H NMR (360MHz, CDCl<sub>3</sub>, TMS) with  $\delta$  at 5.375 (m, 1H, H-C6), 5.160 (m, 2H, H-C22 and H-C23), 4.601 (m, 1H<sub>ax</sub>, H-C3), 2.033 (s, 3H, OCOCH<sub>3</sub>), 1.019 (s, 3H, H<sub>3</sub>C19), 1.002 (d, 3H,  $J = 6.68$ Hz, H<sub>3</sub>C21), 0.909 (d, 3H,  $J = 6.78$ Hz, H<sub>3</sub>C28), 0.835 (d, 3H,  $J = 6.52$ Hz) and 0.817 (d, 3H,  $J = 6.63$ Hz, H<sub>3</sub>C26), ~0.815 (d, 3H,  $J = 6.6$ Hz, H<sub>3</sub>C27), 0.690 (s, 3H, H<sub>3</sub>C18); and HRMS  $m/z$  380.3420 (100, M-HOAc), C<sub>28</sub>H<sub>44</sub> requires 380.3443. [Lang & Djerassi *Helv Chim Acta* **65** 407 1982, Anastasia et al. *J Chem Soc, Perkin I* 379 1983, Rubinstein et al. *Phytochemistry* **15** 195 1976]. Deacetylation with LAH (see brassicasterol above) gives **crinosterol** which is purified by TLC (silica gel developed with 2% v/v EtOH/CHCl<sub>3</sub>) has **m 152-154°** (reported twice, and **147-148°** reported twice, both recrystallised from MeOH or Me<sub>2</sub>CO), and has <sup>1</sup>H NMR (360MHz, CDCl<sub>3</sub>, TMS) has  $\delta$  at 5.349 (m, 1H, H-C6), 5.162 (m, 2H, H-C22 and H-C23), 3.53 (m, 1H<sub>ax</sub>, H-C3), 1.010 (s, 3H, H<sub>3</sub>C19), 1.001 (d, 3H,  $J = 6.21$ Hz, H<sub>3</sub>C21), 0.910 (d, 3H,  $J = 6.86$ Hz, H<sub>3</sub>C28), 0.836 (d, 3H,  $J = 6.45$ Hz) and 0.817 (d, 3H,  $J = 6.62$ Hz, H<sub>3</sub>C26), 0.815 (d, 3H,  $J = 6.62$ Hz, H<sub>3</sub>C27), 0.693 (s, 3H, H<sub>3</sub>C18); and HRMS  $m/z$  398.3551 (M<sup>+</sup>), C<sub>28</sub>H<sub>46</sub>O requires 398.3549. [Lang & Djerassi *Helv Chim Acta* **65** 407 1982, Anastasia et al. *J Chem Soc. Perkin I* 2365 1983, Rubinstein et al. *Phytochemistry* **13** 485 1974, Rubinstein et al. *Phytochemistry* **15** 195 1976]. Brassino steroids have plant growth regulating activities [Anastasia et al. *J C S Perkin I* 379 1983].

**Campesterol (24R-24-methylcholest-5-en-3 $\beta$ -ol)** [474-62-4] **M 400.7, m 156-159°, 157-158°, [ $\alpha$ ]<sub>D</sub><sup>24</sup> -35.1° (c 1.2, CHCl<sub>3</sub>)**. Campesterol is recrystallised twice from hexane and once from Me<sub>2</sub>CO. The *benzoyl* derivative has **m 158-160°** [ $\alpha$ ]<sub>D</sub><sup>23</sup> -8.6° (CHCl<sub>3</sub>), and the *acetyl* derivative has **m 137-138°** (EtOH) and [ $\alpha$ ]<sub>D</sub><sup>23</sup> -35.1° (c 2.9, CHCl<sub>3</sub>) [Fernholz & MacPhillamy *J Am Chem Soc* **63** 1155 1941]. [Beilstein **6** III 2680.]

**CHAPS (3-[(3-cholamidopropyl)dimethylammonio]-1-propanesulfonate betaine)** [75621-03-3 anhydrous], [313223-04-0 hydrate] **M 614.89, m 157°(dec), pK<sub>Est(1)</sub> ~<2 (acidic), pK<sub>Est(2)</sub> ~10 (basic)**. Triturate this zwitterionic detergent (~50g) with MeOH (200ml), then triturate it with Me<sub>2</sub>CO (500ml), collect it by vacuum filtration and dry it thoroughly at ~20°. Recrystallise it at 0° from absolute MeOH followed by drying *in vacuo* to constant weight. It should give one spot with R<sub>F</sub> 0.32 by TLC on silica gel G in 95% MeOH/5% NH<sub>4</sub>OH and visualised with iodine vapour; the tertiary amine precursor has R<sub>F</sub> 0.40. It has low UV absorption (1% in H<sub>2</sub>O: A280nm is 0.029 and A260nm is 0.035), and the CMC (critical micellar concentration) is 8mM. It is soluble in H<sub>2</sub>O, MeOH, Me<sub>2</sub>SO but insoluble in Me<sub>2</sub>CO, MeCN, hexane, toluene and xylene. [Hjelmeland et al. *Anal Biochem* **130** 72 1983, Matuo et al. *Methods Enzymol* **198** 155 1991.]

**CHAPSO (3-[(3-cholamidopropyl)dimethylammonio]-2-hydroxy-1-propanesulfonate betaine)** [82473-24-3] **M 630.89, m 184-196°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +19° (c 2, H<sub>2</sub>O), pK<sub>Est(1)</sub> ~<2 (acidic), pK<sub>Est(2)</sub> ~9 (basic)**. Dissolve this zwitterionic detergent (~ 60g) in 40% aqueous MeOH and stir it with the mixed-bed ion-exchange resin RG-501 x 8 (100g, Bio-Rad) until the pH of the supernatant is ~ 7. Filter off the resin and evaporate the filtrate to dryness under reduced pressure. Check for homogeneity by TLC on silica gel G in 95% MeOH/5% NH<sub>4</sub>OH and visualize the spot with iodine vapour (see CHAPS above). [Hjelmeland et al. *Anal Biochem* **130** 72 1983, Matuo et al. *Methods Enzymol* **198** 155 1991.]

**Chenodeoxycholic acid (chenodiol, 3 $\alpha$ ,7 $\alpha$ -dihydroxycholan-24-oic acid)** [474-25-9] **M 392.6, m (119°, 143°, 165-167°, [ $\alpha$ ]<sub>546</sub><sup>20</sup> +14° (c 2, EtOH), pK<sub>Est</sub> ~4.9**. This major bile acid in vertebrates (~80mg) is chromatographed on silica gel (5g) and eluted with CHCl<sub>3</sub>/EtOAc (3:2) and crystallised from EtOAc/hexane. It has IR with  $\nu_{\max}$  at 1705 cm<sup>-1</sup>(CHCl<sub>3</sub>). It also crystallises from EtOAc, EtOAc/heptane after purifying *via* the poorly soluble Na and K salt if necessary. [Kametani et al. *J Org Chem* **47** 2331 1982, Beilstein **10** IV 1604.]

**5 $\alpha$ -Cholanic acid (allocholanic acid)** [546-98-4] **M 360.6, m 170, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +22° (CHCl<sub>3</sub>), pK<sub>Est</sub> ~4.9**. Purify 5 $\alpha$ -cholanic acid by chromatography on silica gel and eluting with MeOH/EtOAc/hexane (1:5:10) and recrystallising from Et<sub>2</sub>O/hexane, MeOH or AcOH. The *methyl ester* has **m 91°** (from MeOH) and <sup>1</sup>H NMR (CDCl<sub>3</sub>) has  $\delta$  for C18 & C19 at 0.66 and 0.78 [see 5 $\beta$ -cholanic acid below, Mandava et al. *Steroids* **23** 357 1974]. [Demir et al. *Org Prepn Proced Int* **19** 197 1987, Stoll et al. *Helv Chim Acta* **18** 644 1935, Beilstein **9** III 2656, **9** IV 1992.]

**5 $\beta$ -Cholanic acid (ursocholanic acid)** [546-18-9, 25312-65-6] **M 360.6, m 164-165 $^{\circ}$ ,  $[\alpha]_{\text{D}}^{20}$  +21.7 $^{\circ}$  (CHCl<sub>3</sub>), pK<sub>Est</sub> ~4.9.** Crystallise 5 $\beta$ -cholanic acid from EtOH, Me<sub>2</sub>CO or AcOH. The *ethyl ester* has **m 93-94 $^{\circ}$**  (from 80% EtOH), **b 273 $^{\circ}$ /12mm,  $[\alpha]_{\text{D}}^{20}$  +21 $^{\circ}$  (CHCl<sub>3</sub>)**, and the *methyl ester* has **m 86-87 $^{\circ}$**  (from MeOH) after purification through Al<sub>2</sub>O<sub>3</sub> and eluting with \*C<sub>6</sub>H<sub>6</sub>, and  **$[\alpha]_{\text{D}}^{20}$  +21.2 $^{\circ}$  (CHCl<sub>3</sub>)**. The <sup>1</sup>H NMR (CDCl<sub>3</sub>) for the C18 & C19 protons has  $\delta$  at 0.65 and 0.92 [see 5 $\alpha$ -cholanic acid above, Mandava et al. *Steroids* **23** 357 1974]. [Stoll et al. *Helv Chim Acta* **18** 644 1935, Huang-Minlon *J Am Chem Soc* **71** 330 1949, Beilstein **9** III 2656, **9** IV 1992.]

**Cholesta-3,5-diene** [747-90-0] **M 368.6, m 77-78 $^{\circ}$ , 78 $^{\circ}$ , 78-79 $^{\circ}$ , 79-80 $^{\circ}$ , 79.5-80.5 $^{\circ}$ , 80-81 $^{\circ}$ ,  $[\alpha]_{\text{D}}^{16}$  -116 $^{\circ}$  (c 1.1, CHCl<sub>3</sub>).** This diene has been prepared in many ways but several of these are from solvolysis of epicholesteryl toluene-*p*-sulfonate using KOAc/Ac<sub>2</sub>O (38 hours at 75 $^{\circ}$ ), methanolic KOAc (reflux at 3.5 hours), LAH/Et<sub>2</sub>O (20 hours at 20 $^{\circ}$ ) in *ca* 60% yield [Schmid & Kägi *Helv Chim Acta* **35** 2194 1952], AgOAc/AcOH, KOAc/MeOH or KOAc/AcOH (reflux ~3 hours 92-99% yield), neutralised Al<sub>2</sub>O<sub>3</sub> at 20 $^{\circ}$  [Evans & Shoppee *J Chem Soc* 540 1953, Shoppee et al. *J Chem Soc* 2876 1955], KOAc/aqueous Me<sub>2</sub>CO [Becker & Wallis *J Org Chem* **20** 353 1955], and diphenylguanidinium salts accelerate solvolysis [Shoppee & Williams *J Chem Soc* 686 1955]. After the usual workup involving washing with NaHCO<sub>3</sub> and H<sub>2</sub>O, the diene is separated from other steroids and impurities by chromatography through Al<sub>2</sub>O<sub>3</sub> (various grades, including activity II-III, neutralised, basic or activated at 250-310 $^{\circ}$ ) and usually eluted with pentane, pentane/\*C<sub>6</sub>H<sub>6</sub> or Et<sub>2</sub>O/MeOH. It is then recrystallised from Me<sub>2</sub>CO, Et<sub>2</sub>O/MeOH or Et<sub>2</sub>O/EtOH, dried *in vacuo* and stored at -20 $^{\circ}$ . The UV has  $\lambda_{\text{max}}$  (log  $\epsilon$ ) at 228.5 (4.308), 235 (4.344) and 243 (4.163) nm.

**Cholesta-5,7-dien-3 $\beta$ -ol (7-dehydrocholesterol, 3 $\beta$ -hydroxy-5,7-cholestadiene, Provitamin D<sub>3</sub>)** [434-16-2] **M 384.6, m 150-151 $^{\circ}$  (anhydrous), 148-152 $^{\circ}$ ,  $[\alpha]_{\text{D}}^{20}$  -113.6 $^{\circ}$  (c 1, CHCl<sub>3</sub>),  $[\alpha]_{\text{D}}^{20}$  -127 $^{\circ}$  (\*C<sub>6</sub>H<sub>6</sub>).** It occurs in humans and higher animals, and has been isolated from pig skin or the horned snail (*Buccinum undatum*). It is purified by recrystallisation from MeOH, Et<sub>2</sub>O/MeOH or aqueous Et<sub>2</sub>O (plates) and holds to H<sub>2</sub>O tenaciously. It is insoluble in H<sub>2</sub>O but is soluble in most organic solvents. Store it at -20 $^{\circ}$  in the dark and absence of air which oxidises it slowly. Irradiation with UV light produces vitamin D<sub>3</sub> and like all provitamin D have  $\lambda_{\text{max}}$  at 260, 270, 281 and 293.5 nm. The *acetate* [1059-86-5] has **m 129-130 $^{\circ}$ ,  $[\alpha]_{\text{D}}^{20}$  -85.3 $^{\circ}$  (c 1.2, \*C<sub>6</sub>H<sub>6</sub>)**, crystallises from MeOH, and the *benzoate* has **m 139-140 $^{\circ}$ ,  $[\alpha]_{\text{D}}^{20}$  -53.2 $^{\circ}$  (c 1.2, CHCl<sub>3</sub>)**, and crystallises from CHCl<sub>3</sub>/Me<sub>2</sub>CO in plates. [Bernstein et al. *J Org Chem* **14** 443 1949, Beilstein **6** IV 4153].

**Cholesta-5,7-dien-3 $\alpha$ -ol,** [5765-84-0] **m 125-126 $^{\circ}$ ,  $[\alpha]_{\text{D}}^{20}$  -70.5 $^{\circ}$  (CHCl<sub>3</sub>),** crystallises from MeOH in needles, and its *acetate*, **m 114.5 $^{\circ}$ ,  $[\alpha]_{\text{D}}^{20}$  -35 $^{\circ}$  (CHCl<sub>3</sub>)**, also crystallises from MeOH in needles. [Aberhart et al. *J Org Chem* **41** 1067 1976]. [for NMR of steroids see Kirk et al. *J Chem Soc Perkin Trans 2* 1567 1990, and Anastasia et al. *Steroids* **49** 543 1987, and for ORD see Weiss et al. *Tetrahedron* **21** 3105 1965].

**Cholesta-5,24-dien-3 $\beta$ -ol (Desmosterol, 24-dehydrocholesterol, 3 $\beta$ -hydroxy-5,24-cholestadiene, natural 3 $\beta$ ,20*R*-form)** [313-04-2] **M 384.6, m 117-118 $^{\circ}$ , 119-119.5 $^{\circ}$ , 120.5-121 $^{\circ}$ , 121.5 $^{\circ}$ , 121.5-122.5 $^{\circ}$ ,  $[\alpha]_{\text{D}}^{20}$  -38.2 $^{\circ}$  (c 1.14, CHCl<sub>3</sub>).** It occurs in chick embryos, rat skins, red algae, barnacles and *Funtmia latifolia* seeds. This is a useful intermediate for the synthesis of vitamin D metabolites [Koreeda et al. *J Org Chem* **45** 1172 1980]. The sterol in hexane can be purified by chromatography on a AgNO<sub>3</sub>/silicic acid/Super-Cel column in \*C<sub>6</sub>H<sub>6</sub>, then rechromatographed on Alumina F20, eluting with \*C<sub>6</sub>H<sub>6</sub> followed by \*C<sub>6</sub>H<sub>6</sub>/EtOAc (1:1 v/v) and recrystallised from distilled MeOH or from Me<sub>2</sub>CO/MeOH. It has IR (KBr) with  $\nu_{\text{max}}$  at 1373, 1056, 1022, 959, 950, 835 and 800 cm<sup>-1</sup>; and HRMS has *m/z* 384.3421 (M<sup>+</sup>), C<sub>27</sub>H<sub>44</sub>O requires 384.3389 [Apfel *J Org Chem* **43** 2284 1978]. The *acetate* [2665-04-5] **m 99 $^{\circ}$ ,  $[\alpha]_{\text{D}}^{28}$  -44.8 $^{\circ}$  (c 1, CHCl<sub>3</sub>)**, can be obtained by refluxing 3-chlorocholesta-5,24-diene with AcOH/AcOK for 2.5 hours, cooling, adding H<sub>2</sub>O, extracting with Et<sub>2</sub>O, drying (MgSO<sub>4</sub>), evaporating the extract, followed by chromatography through silica gel, eluting with \*C<sub>6</sub>H<sub>6</sub>, evaporating and the white crystalline residue is recrystallised from Me<sub>2</sub>CO/MeOH. The acetate has <sup>1</sup>H NMR (60MHz, CCl<sub>4</sub>, TMS) with  $\delta$  at 0.68 (s, 3H, H<sub>3</sub>C18), 0.98 (s, 3H, H<sub>3</sub>C19), 1.00 (s, 3H, H<sub>3</sub>C21), 1.58 (s, 3H, H<sub>3</sub>C26 or H<sub>3</sub>C27), 1.65 (s, 3H, H<sub>3</sub>C27 or H<sub>3</sub>C26), 1.94 (s, 3H, 3-OCOCH<sub>3</sub>), 4.50 (m, 1H<sub>ax</sub>, H-C3), 5.00 (m, H, H-C24) and 5.35 (m, 1H, H-C5). Hydrolysis of the acetate with MeOH/KOH gave *desmosterol* with **m 119-120 $^{\circ}$ ,  $[\alpha]_{\text{D}}^{28}$  -41 $^{\circ}$  (CHCl<sub>3</sub>)**. [Ochi et al. *Steroids* **30** 795 1977]. *Desmosterol* has also been obtained from the readily available 3-hydroxy-bisnorcholenic acid in several synthetic steps and finally *via* the 3-tetrahydropyranyl ether which was hydrolysed in THF containing a few drops of concentrated HCl at 40 $^{\circ}$ /5 minutes to give the *sterol* **m 120-122 $^{\circ}$**  in 70% yield

after recrystallisation from MeOH. It has  $^1\text{H}$  NMR (60MHz,  $\text{CDCl}_3$ , TMS) with  $\delta$  at 0.41 (s,  $\text{H}_3\text{C18}$ ), 0.51 (d,  $J = 6\text{Hz}$ ,  $\text{H}_3\text{C21}$ ), 0.61 (s,  $\text{H}_3\text{C19}$ ), 1.97 and 1.02 (2s,  $\text{H}_3\text{C26}$ ,  $\text{H}_3\text{C27}$ ), 2.10 (1H<sub>ax</sub>, H-C3), 3.03 (24-H) and 3.20 (6-H). [Dasgupta et al. *J Org Chem* **39** 1658 1974.] Store it at  $-20^\circ$ .

**Cholesta-5,24-dien-3 $\alpha$ -ol** [67392-80-7] **M 384.6**, has **m 137-139 $^\circ$**  (from MeOH),  $[\alpha]_{\text{D}}^{28} -43.5^\circ$  ( $\text{CHCl}_3$ ), and its **acetate** [67383-62-4] **M 426.6**, has **m 112-115 $^\circ$**  (from MeOH),  $[\alpha]_{\text{D}}^{28} -47.5^\circ$  ( $\text{CHCl}_3$ ).

The **3 $\beta$ ,20S-form** [59532-46-6] **M 384.6**, has **m 125-127 $^\circ$**  (from MeOH), obtained by dehydration of 20S-3 $\beta$ ,25-dihydroxycholest-5-ene with dioxane/ $\text{H}_2\text{SO}_4$  (50% yield) has IR (KBr) with  $\nu_{\text{max}}$  at 3000 (OH)  $\text{cm}^{-1}$ , and  $^1\text{H}$  NMR (60MHz,  $\text{CDCl}_3$ , TMS) with  $\delta$  at 0.70 (s,  $\text{H}_3\text{C18}$ ), 0.84 (d,  $\text{H}_3\text{C21}$ ), 1.02 (s,  $\text{H}_3\text{C19}$ ), 1.62 and 1.70 (2s,  $\text{H}_3\text{C26}$ ,  $\text{H}_3\text{C27}$ ). It is an inhibitor of the cholesterol side-chain cleavage enzyme system in bovine adrenocortical preparations. [Bernstein et al. *Steroids* **27** 361 1976.]

**5 $\alpha$ -Cholestane** [481-21-0] **M 372.7**, **m 80 $^\circ$ , 80-80.5 $^\circ$** ,  $[\alpha]_{546}^{20} +29.5^\circ$ ,  $[\alpha]_{\text{D}}^{20} +24^\circ$ ,  $[\alpha]_{\text{D}}^{18} +30.2^\circ$ , (**c 2**,  $\text{CHCl}_3$ ). 5 $\alpha$ -Cholestane is prepared by catalytic reduction of cholestene  $\text{EtOAc}/\text{PtO}_2/\text{H}_2$ , and recrystallised from  $\text{EtOAc}$  or  $\text{Et}_2\text{O}/\text{EtOH}$ . Store at room temperature. The  $^1\text{H}$  NMR (100MHz,  $\text{CDCl}_3$ , TMS) signals of the methyl groups have  $\delta$  at 0.645 (s, 13-Me), 0.778 (s, 10-Me), 0.898 (,  $J = 6.0\text{Hz}$ , 20-Me) and 0.861 (d,  $J = 6.3\text{Hz}$ , 25-Me<sub>2</sub>) [Wittstruck et al. *J Chem Soc, Perkin Trans I* 1403 1977], and its CD in hexane has a  $\Delta\epsilon$  value of +0.5 at the longest wavelength of 183nm [Kirk et al. *Tetrahedron Lett* 1355 1973]. Note that catalytic hydrogenation of cholest-4-ene in acidic medium provides 5- $\alpha$ -cholestane whereas hydrogenation in neutral media results in 5- $\beta$ -cholestane [Windaus *Chem Ber* **52** 170 1919]. [Ruzicka et al. *Helv Chim Acta* **16** 327, 334 1933, *Beilstein* **5** III 1132, **5** IV 1227.]

**5 $\beta$ -Cholestane (coprostane,  $\psi$ -cholestane, pseudocholestane)** [481-20-9, 25269-18-5 + 21 other numbers + 105308-41-6] **M 372.7**, **m 70 $^\circ$ , 71-72 $^\circ$** ,  $[\alpha]_{\text{D}}^{20} +25^\circ$  (**c 2**,  $\text{CHCl}_3$ ). Catalytic hydrogenation ( $\text{Pt}_2\text{O}/\text{Et}_2\text{O}$ ) of 3-chlorocholest-4-ene followed by crystallisation from  $\text{Me}_2\text{CO}$  [Young et al. *J Am Chem Soc* **81** 1452 1959], or catalytic reduction ( $\text{Pt}_2\text{O}/\text{Et}_2\text{O}$ ) followed by chromatography through an  $\text{Al}_2\text{O}_3$  column and eluting with petroleum ether followed by recrystallisation of the residual oil from  $\text{Et}_2\text{O}/\text{EtOH}$  give high yields of coprostane [Nickson & Bagli *J Am Chem Soc* **83** 1498 1961] (see previous entry). It also recrystallises in needles from  $\text{EtOH}$ . Store it at room temperature. Its CD in hexane has a  $\Delta\epsilon$  value of +1.1 at the longest wavelength of 184nm (see previous entry) [Kirk et al. *Tetrahedron Lett* 1355 1973].

**5 $\alpha$ -Cholestan-3 $\beta$ -ol ( $\beta$ -cholestanol, dihydrocholesterol)** [80-97-7] **M 388.7**, **m 142-143 $^\circ$ (monohydrate)**,  $[\alpha]_{546}^{20} +28^\circ$  (**c 1**,  $\text{CHCl}_3$ ),  $[\alpha]_{\text{D}} +27.4^\circ$  (in  $\text{CHCl}_3$ ). Purify 5- $\alpha$ -cholestan-3 $\beta$ -ol via acetylation, crystallisation and de-acetylation, then recrystallisation from  $\text{EtOH}$  or slightly aqueous  $\text{EtOH}$ , or  $\text{MeOH}$ . Its solubility is: 0.5% ( $\text{MeOH}$ ) and 1% ( $\text{EtOH}$ ) at  $25^\circ$ . [Mizutani & Whitten *J Am Chem Soc* **107** 3621 1985.] The **acetate** has **m 114-115 $^\circ$**  from  $\text{EtOAc}/\text{MeOH}$  and  $[\alpha]_{\text{D}}^{20} +13^\circ$  (**c 2**,  $\text{CHCl}_3$ ). [Bruce & Ralls *Org Synth Col Vol II* 191 1943, *Beilstein* **6** IV 3577.]

**5 $\beta$ -Cholestan-3 $\alpha$ -ol (Epicoprostanol, epi-5 $\beta$ -cholestanol)** [516-88-7] **M 388.7**, **m 115-116 $^\circ$ , 116-117 $^\circ$ , 118 $^\circ$** ,  $[\alpha]_{\text{D}}^{20} +32^\circ$  (**c 1.8**,  $\text{CHCl}_3$ ). It is the main product from the acetolysis of 3 $\beta$ -chlorocoprostanol (KOAc/AcOH, reflux for 6 hours) involving a Walden inversion, and purified as in the following entry [Bridgewater & Shoppee *J Chem Soc* 1709 1953]. It has also been obtained by reduction of 5 $\beta$ -coprostan-3-one with LAH to give a 94% yield of epicoprostanol m 115-116 $^\circ$ , which did not form a precipitate with digitonin, and the small amount of digitonide formed gave a small quantity of coprostanol m 100 $^\circ$  (~4% yield and crystallised from  $\text{MeOH}$ , see below) [Shoppee & Summers *J Chem Soc* 687 1950]. Alternatively, the residue is purified as described in the succeeding entry or recrystallised from  $\text{Me}_2\text{CO}$  or  $\text{Et}_2\text{O}/\text{C}_6\text{H}_6$  to give the desired **3 $\alpha$ -ol**, after drying *in vacuo* at  $80^\circ$ . Note that crystals from  $\text{EtOH}$  have **m 115-116 $^\circ$** , and from  $\text{Me}_2\text{CO}$  have **m 117-118 $^\circ$** . Store it at room temperature. The **3 $\alpha$ -yl-acetate** (obtained by catalytic reduction of coprostan-3-one,  $\text{Et}_2\text{O}/\text{MeOH}/\text{PtO}_2/\text{H}_2$ , followed by chromatographic separation as below and acetylation) has **m 87-89 $^\circ$ , 89-91 $^\circ$** ,  $[\alpha]_{\text{D}}^{18} +42^\circ$  (**c 1.42**,  $\text{CHCl}_3$ ). [Shoppee & Summers *J Chem Soc* 687 1950, Ruzicka et al. *Helv Chim Acta* **17** 1407 1934.]

**5 $\beta$ -Cholestan-3 $\beta$ -ol (coprostan-3 $\beta$ -ol)** [360-68-9] **M 388.7**, **m 100-101 $^\circ$ , 101 $^\circ$** ,  $[\alpha]_{\text{D}}^{20} +28^\circ$  (**c 1.8**,  $\text{CHCl}_3$ ). It is the main product from the acetolysis of 3 $\alpha$ -chlorocoprostanol (KOAc/AcOH, reflux for 6 hours) involving a Walden inversion. Unlike epicoprostanol (above), coprostanol is precipitated by a 1.33% solution of digitonin in

95% EtOH, the digitonide can be collected, decomposed by dissolving in pyridine, precipitating the digitonin with excess of Et<sub>2</sub>O, filtering off digitonin and the coprostanol is obtained by evaporation of the organic solvent. A possible impurity is the 3 $\alpha$ -ol from which it can be separated by chromatography on Al<sub>2</sub>O<sub>3</sub> and eluting with Et<sub>2</sub>O/\*C<sub>6</sub>H<sub>6</sub> (1:24) whereby the 3 $\alpha$ -ol runs first (**m** 116-117°, see preceding entry) and further elution gives the pure 3 $\beta$ -coprosterol (**m** 99-101°). Crystallise it from MeOH (needles) or aqueous EtOH. Store it at room temperature. The 3 $\beta$ -yl-acetate from acetylation with Ac<sub>2</sub>O (also obtained by catalytic reduction of coprostan-3-one, AcOH/PtO<sub>2</sub>/H<sub>2</sub>, followed by chromatographic separation as above and acetylation) has **m** 91°, **90-91°**, [ $\alpha$ ]<sub>D</sub><sup>18</sup> +14.5° (**c** 1.8, CHCl<sub>3</sub>). Its solubility is 0.79% in H<sub>2</sub>O at 25°. [Bridgewater & Shoppee *J Chem Soc* 1709 1953, Shoppee & Summers *J Chem Soc* 687 1950, see Ruzicka et al. *Helv Chim Acta* 17 1407 1934.]

**Cholest-2-ene** [15910-23-3] **M** 370.6, **m** 75-76°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +66° (**c** 1.65, CHCl<sub>3</sub>). Purify cholest-2-ene by chromatography on Al<sub>2</sub>O<sub>3</sub> (Spence H) and elute with petroleum ether (b 40-60°), and recrystallise the residue from EtOAc/MeOH. Also recrystallise it from MeOH or diethyl ether/acetone. [Alt & Barton *J Chem Soc* 4284 1954, Bergbreiter & Chandran *J Am Chem Soc* 109 174 1987, *Beilstein* 5 III 1320, 5 IV 1507.]

**Cholesterol (cholest-5-en-3 $\beta$ -ol)** [57-88-5] **M** 386.7, **m** 148.9-149.4°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -35° (hexane). Crystallise cholesterol from ethyl acetate, EtOH or isopropyl ether/MeOH. [Hiromitsu & Kevan *J Am Chem Soc* 109 4501 1987.] For extensive details of purification through the dibromide, see Fieser [*J Am Chem Soc* 75 5421 1953] and Schwenk and Werthessen [*Arch Biochem Biophys* 40 334 1952], and by repeated crystallisation from acetic acid; see Fieser [*J Am Chem Soc* 75 4395 1953]. Like many sterols, cholesterol gives colour reactions with conc H<sub>2</sub>SO<sub>4</sub>: When cholesterol is dissolved in a small volume of CHCl<sub>3</sub> and mixed with conc H<sub>2</sub>SO<sub>4</sub>, the colour of the organic layer becomes crimson, then changes to purple and on further standing in air it turns to blue, then green and finally yellow. The H<sub>2</sub>SO<sub>4</sub> layer develops a green fluorescence. [*Beilstein* 6 III 2607, 6 IV 4000.]

**Cholesteryl acetate** [604-35-3] **M** 428.7, **m** 113-115°, 115-116°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -51° (**c** 5, CHCl<sub>3</sub>). Crystallise the acetate from *n*-pentanol or Me<sub>2</sub>CO. Also purify it by chromatography through silica gel and eluting with MeOH. [*Beilstein* 6 III 2607, 6 IV 4004.]

**Cholesteryl myristate** [1989-52-2] **M** 597.0, **m** 69-71°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -25.4° (**c** 1, CHCl<sub>3</sub>). Crystallise the myristate ester from Me<sub>2</sub>CO, EtOH/EtOAc or EtOH/Et<sub>2</sub>O or *n*-pentanol. Purify it also by column chromatography on silica gel and eluting with MeOH then evaporating to dryness. Recrystallise it and finally, dry it *in vacuo* over P<sub>2</sub>O<sub>5</sub> and store it at -20°. [Labarière et al. *Analyt Chem* 30 1466 1958, Malanik & Malat *Anal Chim Acta* 76 464 1975, *Beilstein* 6 III 2638].

**Cholesteryl oleate** [303-43-5] **M** 651.1, **m** 48.8-49.4°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -24° (**c** 1, CHCl<sub>3</sub>). Purify the oleate ester by chromatography on silica gel and eluting with MeOH. [*Beilstein* 6 III 2642.]

**3 $\alpha$ -5 $\beta$ -7 $\alpha$ -12 $\alpha$ -Cholic acid (3 $\alpha$ -7 $\alpha$ -12 $\alpha$ -trihydroxy-5 $\beta$ -cholan-24-oic acid, Cholalin)** [81-25-4] **M** 408.6 (anhydrous), 426.6 (hydrate) **m** 196-198°, 198-200°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +37°, [ $\alpha$ ]<sub>D</sub><sup>546</sup> +41° (**c** 0.6, EtOH), pK<sup>20</sup> 4.98. This bile acid crystallises from H<sub>2</sub>O, aqueous AcOH (as hydrate), wet Et<sub>2</sub>O (as hydrate) or EtOH (as alcoholate). Dry it under vacuum at 94° to give the *anhydrous acid* **m** 198°. Its solubility (w/v) at 15° is 0.028% in H<sub>2</sub>O, 3.06% in EtOH, 0.12% in Et<sub>2</sub>O, 0.51% in CHCl<sub>3</sub>, 0.036% in \*C<sub>6</sub>H<sub>6</sub>, 2.82% in Me<sub>2</sub>CO and 15.2% in AcOH. When an alcoholic solution of cholic acid + I<sub>2</sub> is added to aqueous KI, it forms a molecular compound (C<sub>24</sub>H<sub>40</sub>O<sub>5</sub>I)<sub>4</sub> KI. H<sub>2</sub>O. The *methyl ester* is dimorphic with **m** 155-156° and 162° (from 95% aqueous EtOH), and [ $\alpha$ ]<sub>D</sub><sup>20</sup> +25° (EtOH), and the *ethyl ester* has **m** 155° (162-163° after recrystallisation from EtOAc/petroleum ether b 30-60° 2:8, Cortese *J Am Chem Soc* 59 2532 1937). [Anderson et al. *Biochem J* 67 323 1957, 85 236 1962, Ekwall et al. *Acta Chem Scand* 11 50 1957.] The acid has been used as a non-denaturing ionic detergent, and for solubilising membrane-bound proteins in their native state [Hooper *Biochem Soc Trans* 14 586 1986]. It has also been used in liposome preparations [Yang & Lundahl *Anal Biochem* 218 210 1994.] [*Beilstein* 10 III 2162, 10 IV 2072.]

**4,5-Coprosten-3-ol (cholest-4-ene-3 $\beta$ -ol, allocholesterol)** [517-10-2] **M** 386.7, **m** 132°, [ $\alpha$ ]<sub>D</sub><sup>24</sup> +43.7°, (**c** 1, \*C<sub>6</sub>H<sub>6</sub>). Purify 4,5-coprosten-3-ol by dissolving it in Et<sub>2</sub>O, adding an equal volume of MeOH and removing the

Et<sub>2</sub>O with a stream of CO<sub>2</sub> until crystallisation begins. The sterol crystallises in needles when cooled in an ice-salt bath. Dry it *in vacuo*. The *acetate* crystallises from aqueous MeOH **m** 85°. [Schoenheimer & Evans *J Biol Chem* **114** 567 1936, Stoll *Hoppe Seyler's Z Physiol Chem* **246** 10 1937, *Beilstein* **6** IV 3577.]

**Corticosterone (11β, 21-dihydroxypregn-4-en-3,20-dione)** [50-22-6] **M 346.5, m 180-181°, 180-182°, 181-184°, [α]<sub>D</sub><sup>25</sup> +223° (c 1.1, EtOH), [α]<sub>D</sub><sup>23-25</sup> +194° (c 0.1, dioxane)**. Purify corticosterone by recrystallisation from Me<sub>2</sub>CO (trigonal plates), EtOH or isoPrOH. It has UV with λ<sub>max</sub> at 240nm, and gives an orange-yellow solution with strong fluorescence on treatment with concentrated H<sub>2</sub>SO<sub>4</sub>. It is insoluble in H<sub>2</sub>O but soluble in organic solvents. [Reichstein & Euw *Helv Chim Acta* **21** 1197 1938, **27** 1287 1944; Mason et al. *J Biol Chem* **114** 613 1936; ORD: Foltz et al. *J Am Chem Soc* **77** 4359 1955; NMR: Shoolery & Rogers *J Am Chem Soc* **80** 5121 1958.] The 21-*O*-*acetyl* derivative [1173-26-8] crystallises from Me<sub>2</sub>CO/Et<sub>2</sub>O with **m** 152.5-153°, [α]<sub>D</sub><sup>20</sup> +195° (c 0.6, Me<sub>2</sub>CO), and the 21-*O*-*benzoyl* derivative crystallises from AcOH/Et<sub>2</sub>O with **m** 201-202° [Reichstein *Helv Chim Acta* **20** 953 1937]. [*Beilstein* **8** IV 2907.]

**Cortisol** See hydrocortisone [50-23-7].

**Cortisone** [53-06-5] **M 360.5, m 230-231°, [α]<sub>D</sub><sup>20</sup> +225° (c 1, EtOH)**. Crystallise cortisone from 95% EtOH or acetone. The UV has ε 14,000 M<sup>-1</sup>cm<sup>-1</sup> at 237nm (EtOH). [Hems *J Pharm Pharmacol* **5** 409 1953, *Beilstein* **8** IV 3480.]

**Cortisone-21-acetate** [50-04-4] **M 402.5, m 242-243°, [α]<sub>D</sub><sup>20</sup> +227° (c 1, CHCl<sub>3</sub>)**. Crystallise cortisone-21-acetate from acetone or CHCl<sub>3</sub>. The UV has ε 15,800 M<sup>-1</sup>cm<sup>-1</sup> at 238nm in dioxane. [Sarett *J Biol Chem* **162** 601 1946, *Beilstein* **8** III 4058, **5** IV 3481.]

**Deoxycholic acid** [83-44-3] **M 392.6, m 171-174°, 176°, 176-178°, [α]<sub>D</sub><sup>20</sup> +64° (c 1, EtOH), [α]<sub>D</sub><sup>20</sup> +55° (c 2.5, EtOH), pK<sup>25</sup> 6.58**. Reflux the acid with CCl<sub>4</sub> (50ml/g), filter, evaporate under vacuum at 25°, recrystallise the residue from acetone and dry it under vacuum at 155° [Trenner et al. *J Am Chem Soc* **76** 1196 1954]. A solution of (cholic acid-free) material (100ml) in 500ml of hot EtOH is filtered, evaporate it to less than 500ml on a hot plate, and pour it into 1500ml of cold diethyl ether. The precipitate, filtered off by suction, is crystallised twice from 1-2 parts of absolute EtOH, to give an *alcoholate*, **m** 118-120°, which is dissolved in EtOH (100ml for 60g) and poured into boiling water. After boiling until free of the EtOH, the precipitate is filtered off, dried, ground and dried to constant weight *in vacuo* [Sobotka & Goldberg *Biochem J* **26** 555 1932]. Deoxycholic acid is also freed from fatty acids and cholic acid by silica gel chromatography and elution with 0.5% acetic acid in ethyl acetate [Tang et al. *J Am Chem Soc* **107** 4058 1985]. It can also be recrystallised from butanone. Its solubility in H<sub>2</sub>O at 15° is 0.24g/L, but in EtOH it is 22.07g/L. [*Beilstein* **10** IV 1608.]

**11-Deoxycorticosterone (21-hydroxyprogesterone)** [64-85-7] **M 330.5, m 141-142°, [α]<sub>D</sub><sup>20</sup> +178° and [α]<sub>D</sub><sup>546</sup> +223° (c 1, EtOH)**. Crystallise 11-deoxycorticosterone from diethyl ether. [Schindler et al. *Helv Chim Acta* **24** 360 1941, Steiger & Reichstein *Helv Chim Acta* **20** 1164 1937.]

**11-Deoxycorticosterone acetate (21-acetoxy-4-pregnen-3,20-dione)** [56-47-3] **M 372.5, m 154-159°, 154-160°, 155-157°, 155-161°, [α]<sub>D</sub><sup>20</sup> +174° (c 1, dioxane), [α]<sub>D</sub><sup>22-24</sup> +196° (c 1, CHCl<sub>3</sub>)**. 11-Deoxycorticosterone acetate recrystallises from EtOH as needles or Me<sub>2</sub>CO/hexane, and sublimes at high vacuum. It is partly soluble in MeOH, Me<sub>2</sub>CO, Et<sub>2</sub>O and dioxane but insoluble in H<sub>2</sub>O. [Reichstein & Euw *Helv Chim Acta* **23** 136 1940, Romo et al. *J Am Chem Soc* **79** 5034 1957; NMR: Shoolery & Rogers *J Am Chem Soc* **80** 5121 1959, *Beilstein* **8** IV 2195.]

**Dexamethasone (9-α-fluoro-16-α-methylprednisolone, prednisolone F)** [50-02-2] **M 392.5, m 262-264°, 268-271°, [α]<sub>D</sub><sup>25</sup> +77.5° (c 1, dioxane)**. Dexamethasone has been recrystallised from Et<sub>2</sub>O or small volumes of EtOAc. Its solubility in H<sub>2</sub>O is 10 mg/100ml at 25°; and is freely soluble in Me<sub>2</sub>CO, EtOH and CHCl<sub>3</sub>. Store it below 8°. It is a glucocorticoid steroidal anti-inflammatory agent. A stock solution of 20μg/ml is generally made by adding 1ml of absolute EtOH to 100μg of steroid, stir gently to dissolve then add 49ml of sterile medium while mixing. [Arth et al. *J Am Chem Soc* **80** 3161 1958; for the β-methyl isomer see Taub et al. *J Am*

*Chem Soc* **82** 4025 1960, see *Beilstein* **8** IV 3501.]

**Dexamethasone 21-acetate** (9- $\alpha$ -fluoro-16- $\alpha$ -methylprednisolone-21-acetate, prednisolone F acetate) [1177-87-3] **M 434.5, m 215-225<sup>o</sup>, 229-231<sup>o</sup>,  $[\alpha]_D^{25} +77.6^{\circ}$  (c 1, dioxane), +73<sup>o</sup> (c 1, CHCl<sub>3</sub>).** Dexamethasone 21-acetate is purified on neutral Al<sub>2</sub>O<sub>3</sub> using CHCl<sub>3</sub> as eluent, the fractions are evaporated, and the residue is recrystallised from CHCl<sub>3</sub>. Store it below 8<sup>o</sup>. It has  $\lambda_{\max}$  at 239nm ( $\epsilon$  14,900) in EtOH. It is a glucocorticoid steroidal anti-inflammatory agent. [Oliveto et al. *J Am Chem Soc* **80** 4431 1958]. [*Beilstein* **8** IV 3501.]

**Dexamethasone 21-phosphate disodium salt** (Baldex, Colvasone, Dexabene, Desone among many trade names) [2392-39-4] **M 516.4, m 233-255<sup>o</sup>,  $[\alpha]_D^{25} +74^{\circ}$  (for anhydrous salt, c 1, H<sub>2</sub>O).** Recrystallise it from EtOH and dry it *in vacuo*. It has  $\lambda_{\max}$  at 238-239nm ( $\epsilon$  14,000) in EtOH. Store it below 8<sup>o</sup>, but ethanolic solutions should be stored at ~0<sup>o</sup>.

Like the preceding two drugs it is also an anti-inflammatory drug, but is more soluble in H<sub>2</sub>O. It is a pro-drug and is converted to dexamethasone *in vivo*; it also stimulates glutamine uptake in the cerebral cortex.

**Digitoxigenin** (3 $\beta$ ,14 $\beta$ -dihydroxy-20(22)-norcholenic acid lactone) [143-62-4] **M 374.5, m 253<sup>o</sup>, 249-255<sup>o</sup>,  $[\alpha]_{546}^{20} +17^{\circ}$  (c 1, MeOH).** Dissolve digitoxigenin in EtOAc, wash it with H<sub>2</sub>O, dry it (Na<sub>2</sub>SO<sub>4</sub>), evaporate and recrystallise it from 40% aqueous EtOH or aqueous MeOH then EtOAc/Et<sub>2</sub>O. The UV has  $\lambda_{\max}$  at 218nm ( $\epsilon$  14,500 M<sup>-1</sup>cm<sup>-1</sup>). The 3-acetate crystallises from Me<sub>2</sub>CO/Et<sub>2</sub>O with **m 222-227<sup>o</sup>,  $[\alpha]_D^{20} +21^{\circ}$  (c 1, CHCl<sub>3</sub>).** [Wyss et al. *Helv Chim Acta* **43** 644 1960, Cruz et al. *J Org Chem* **42** 3580 1977, *Beilstein* **18** IV 1468.]

**Dihydrotachysterol** [67-96-9] **M 398.7, m 125-127<sup>o</sup>,  $[\alpha]_D^{20} +97^{\circ}$  (CHCl<sub>3</sub>).** Crystallise the sterol from 90% MeOH, and UV with  $\lambda_{\max}$  at 242, 251 and 261nm ( $E_{1\text{cm}}^{1\%}$  760, 1010 and 650) in EtOH. The acetate has **m 108-110<sup>o</sup>** and  $[\alpha]_D^{20} +32.8^{\circ}$  (CHCl<sub>3</sub>), and UV with  $\lambda_{\max}$  at 242, 251 and 261nm ( $E_{1\text{cm}}^{1\%}$  780, 910 and 600) in EtOH. The propionate has **m 97-98<sup>o</sup>** and  $[\alpha]_D^{20} +37^{\circ}$  (CHCl<sub>3</sub>), and UV with  $\lambda_{\max}$  242, 251 and 261nm ( $E_{1\text{cm}}^{1\%}$  750, 860 and 570) in EtOH. [Werder Hoppe Seyler's *Z Physiol Chem* **260** 119 1939, Windaus et al. *Justus Liebigs Ann Chem* **499** 1978 1932, *Beilstein* **6** III 2833, **6** IV 3994, 4161.]

**Diosgenin (25R-spirostaen-3 $\beta$ -ol)** [512-04-9] **M 294.5, m 204-207<sup>o</sup>,  $[\alpha]_D^{25} -129^{\circ}$  (in Me<sub>2</sub>CO).** Crystallise diosgenin from acetone, and chromatograph it on Al<sub>2</sub>O<sub>3</sub> and elute with \*C<sub>6</sub>H<sub>6</sub>/Et<sub>2</sub>O (9:1), then recrystallise it from MeOH. Its solubility is ~4% in H<sub>2</sub>O and 5% in CHCl<sub>3</sub>. The acetate crystallises from AcOH with **m 198<sup>o</sup>**; and has  $[\alpha]_D^{20} -119^{\circ}$  (pyridine). [Marker et al. *J Am Chem Soc* **65** 1199 1943. Mazur et al. *J Am Chem Soc* **82** 5889 1960, *Beilstein* **19** IV 862.]

**$\alpha$ -Ecdyson** [3604-87-3] **M 464.7, m 239-242<sup>o</sup>, 242<sup>o</sup>,  $[\alpha]_D^{20} +72^{\circ}$  (c 1, EtOH).** Recrystallise  $\alpha$ -ecdyson from tetrahydrofuran/petroleum ether and from H<sub>2</sub>O as a hydrate. It has been purified by chromatography on Al<sub>2</sub>O<sub>3</sub> and elution with EtOAc/MeOH. It has  $\lambda_{\max}$  at 242nm ( $\epsilon$  12,400). Its acetate has **m 214-216<sup>o</sup>** from EtOAc/petroleum ether, and the 2,4-dinitrophenylhydrazone has **m 170-175<sup>o</sup>(dec)** from EtOAc. [Karlson & Hoffmeister *Justus Liebigs Ann Chem* **662** 1 1963, Karlson *Pure Appl Chem* **14** 75 1967, *Beilstein* **8** IV 3613.]

**$\beta$ -Ecdyson** ( $\beta$ -echdysterone, crustecdyson, 20-hydroxyecdyson) [5289-74-7] **M 480.7, m 240-242<sup>o</sup>, 245-247<sup>o</sup>,  $[\alpha]_D^{20} +66^{\circ}$  (c 1, MeOH).** Crystallise  $\beta$ -ecdyson from water, tetrahydrofuran/petroleum ether, MeOH and EtOAc after chromatographic purification. It has  $\lambda_{\max}$  (EtOH) at 240nm ( $\epsilon$  12,670 M<sup>-1</sup>cm<sup>-1</sup>). [Also IR & NMR: Hüppi & Siddall *J Am Chem Soc* **89** 6799 1967, Kametani et al. *Tetrahedron Lett* **21** 4855 1980, *Beilstein* **8** IV 343.]

**(+)-Equilenin** [517-09-9] **M 266.3, m 258-259<sup>o</sup> (vac),  $[\alpha]_D^{16} +87^{\circ}$  (c 0.1, dioxane).** Crystallise (+)-equilenin from EtOH (solubility is 0.63% at 18<sup>o</sup>, 2.5% at 78<sup>o</sup>), aqueous EtOH or \*C<sub>6</sub>H<sub>6</sub> (Norite) and dry it in a vacuum. It sublimes on melting and at 170-180<sup>o</sup>/0.01mm. The acetate crystallises from MeOH with **m 165-167<sup>o</sup>** and  $[\alpha]_D^{20} +71^{\circ}$  (c 1, CHCl<sub>3</sub>). [Bachmann et al. *J Am Chem Soc* **62** 824 1940, *Beilstein* **8** III 1522, 1523, 1525, **8** IV 1420.]

**Ergosterol (Provitamin D<sub>2</sub>)** [57-87-4] M 396.7, m 165-166°, [ $\alpha$ ]<sub>546</sub><sup>20</sup> -171° (c 1, CHCl<sub>3</sub>), [ $\alpha$ ]<sub>D</sub><sup>20</sup> -135° (c 1, CHCl<sub>3</sub>). Crystallise ergosterol from EtOAc, then from ethylene dichloride or EtOH/\*C<sub>6</sub>H<sub>6</sub> (3:1). It has been purified by conversion to the *isobutyl ester* which crystallises from Et<sub>2</sub>O/Me<sub>2</sub>CO (1:3) with m: turbid at 148°, melts at 159° and becomes clear at 162°, followed by hydrolysis, [Bill & Honeywell *J Biol Chem* **80** 15 1938]. When crystallised from EtOH, it forms the *1,5-hydrate* m 168°. The water is difficult to remove giving an amorphous solid m 166-183°, b 250°/high vacuum. It is light sensitive. The *benzoate* has m 169-171°, after crystallisation from Me<sub>2</sub>CO/\*C<sub>6</sub>H<sub>6</sub> (4:1) after prolonged standing at 0° and becomes highly charged, with [ $\alpha$ ]<sub>D</sub><sup>20</sup> -177° (c 1, CHCl<sub>3</sub>). [UV of sterols: Hogness et al. *J Biol Chem* **120** 239 1937, *Beilstein* **6** IV 4407.]

**17 $\alpha$ -Estradiol** [57-91-0] M 272.3, m 223, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +57° (c 1, EtOH). 17 $\alpha$ -Estradiol recrystallises from aqueous EtOH (80%) as the *hemihydrate* and differs from the  $\beta$ -anomer (below) by not precipitating with digitonin in 80% aqueous EtOH. The *diacetate* [1474-52-8] crystallises from aqueous EtOH in needles with m 139-140°. The *3-benzoate* crystallises in three forms m 158°, 153° and 63°. [See references for 17 $\beta$ -Estradiol below.]

**17 $\beta$ -Estradiol (1,3,5-estratrien-3,17 $\beta$ -diol, 17- $\beta$ -estradiol was incorrectly called  $\alpha$ -estradiol)** [50-28-2] M 272.4, m 173-179°, 176-178°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +76° to +83° (c 1, dioxane). 17 $\beta$ -Estradiol (previously known as  $\alpha$ -estradiol) is purified by chromatography on SiO<sub>2</sub> (toluene/EtOAc 4:1) and recrystallised from CHCl<sub>3</sub>/hexane or 80% EtOH. It is stable in air, is insoluble in H<sub>2</sub>O, and is precipitated by digitonin. The UV has  $\lambda_{\max}$  at 225 and 280 nm. The *diacetate* [3434-88-6] has m 97-98° and forms leaflets from aqueous EtOH. The *3-benzoate* [50-50-0] crystallises from aqueous MeOH with m 193° and [ $\alpha$ ]<sub>D</sub><sup>25</sup> +58° to 63° (c 1, dioxane). [Meischer & Scholz *Helv Chim Acta* **20** 263, 1237 1937, *Biochem J* **32** 1273 1938, Oppolzer & Roberts *Helv Chim Acta* **63** 1703 1980, Inhoffen & Zühlendorf *Chem Ber* **74** 1914 1941, *Beilstein* **6** IV 6611.]

**$\beta$ -Estradiol-6-one (1,3,5-estratriene-3,17 $\beta$ -diol-6-one)** [571-92-6] M 359.4, m 278-280°, 281-283°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +4.2° (c 0.7, EtOH).  $\beta$ -Estradiol-6-one forms plates from EtOH. The *3,17-diacetate* has m 173-175° after recrystallisation from aqueous EtOH. [Longwell & Wintersteiner *J Biol Chem* **133** 219 1940.] The UV has  $\lambda_{\max}$  at 255 and 326nm in EtOH [Slaunwhite et al. *J Biol Chem* **191** 627 1951]. [*Beilstein* **8** IV 2398.]

**Estriol (1,3,5-estratrien-3 $\alpha$ ,16 $\alpha$ ,17 $\beta$ -triol)** [50-27-1] M 288.4, m 278.5-284°, 283°, [ $\alpha$ ]<sub>546</sub><sup>20</sup> +66° (c 1, dioxane). Crystallise estriol from EtOH/ethyl acetate. Also purify it by countercurrent distribution with cyclohexane/EtOAc (1:1) and EtOH/H<sub>2</sub>O (1:1). The UV (EtOH) has  $\lambda_{\max}$  at 280nm ( $\epsilon$  2,090 M<sup>-1</sup>cm<sup>-1</sup>). [Huffmann & Lott **71** 719 1949, Leeds et al. *J Am Chem Soc* **76** 2943 1954, *Beilstein* **6** IV 7550.]

**Estrone (1,3,5-Estratrien-3 $\beta$ -ol-17-one, Folliculin)** [53-16-7] M 270.4, m 260-261°, polymorphs have m 254° and 256°, [ $\alpha$ ]<sub>546</sub><sup>20</sup> +198° (c 1, dioxane), pK<sup>25</sup> 0.91. Purify estrone by chromatography on silica gel, eluting with 2:1 hexane/EtOAc and recrystallising from EtOH or Et<sub>2</sub>O/EtOH. [Danishefsky & Cain *J Am Chem Soc* **98** 4975 1976.] The *acetate* [901-93-9] crystallises from EtOH with m 125-127°. [*Beilstein* **8** III 1171.]

**Estrone 3-O-sulfamate** [148672-09-7] M 349.5. Estrone 3-O-sulfamate is purified by silica gel flash chromatography to give a product with one spot on TLC. It is an active site-directed inhibitor of estrone sulfatase, i.e. a time-dependent enzyme inactivator. [Woo et al. *J Med Chem* **39** 1349 1996, Purohit et al. *Biochemistry* **34** 11508 1995.]

**17- $\alpha$ -Ethinylestradiol** [57-63-6] M 296.4, m 141-146°, 145-146°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +4° (c 1, CHCl<sub>3</sub>). 17- $\alpha$ -Ethinylestradiol forms a *hemihydrate* on recrystallising from MeOH/H<sub>2</sub>O. It dehydrates on melting and re-melts on further heating at m 182-184°. The UV has  $\lambda_{\max}$  at 281nm ( $\epsilon$  2040) in EtOH. Its solubility is 17% in EtOH, 25% in Et<sub>2</sub>O, 20% in Me<sub>2</sub>CO, 25% in dioxane and 5% in CHCl<sub>3</sub>. [Petit & Muller *Bull Soc Chim Fr* 121 1951.] The *diacetyl* derivative has m 143-144° (from MeOH) and [ $\alpha$ ]<sub>D</sub><sup>20</sup> +1° (c 1, CHCl<sub>3</sub>) [Mills et al. *J Am Chem Soc* **80** 6118 1958]. [*Beilstein* **6** IV 6877.]

**Etiocolanic acid** [438-08-4] M 304.5, m 228-229°, pK<sub>Est</sub> ~4.7. Crystallise etiocholanic acid from glacial acetic acid and sublime it at 160°/0.002mm. The *ethyl ester* has m 77.5-78.5° (from EtOH) [ $\alpha$ ]<sub>546</sub><sup>20</sup> +52.5° (c 0.61, pyridine). [Jacobs & Elderfield *J Biol Chem* **108** 497 1935, Weiland et al. *Hoppe Seyler's Z Physiol Chem* **161** 80 1926, *Beilstein* **9** III 2644.]

**Gitoxigenin (3 $\beta$ ,14,16 $\beta$ ,21-tetrahydroxy-20(22)-norcholenic acid lactone)** [545-26-6] **M 390.5, m 223-226 $^{\circ}$ , 234 $^{\circ}$ , 239-240 $^{\circ}$  (anhydrous by drying at 60 $^{\circ}$ ),**  $[\alpha]_{\text{D}}^{20} +30^{\circ}$  (c 1, MeOH). Recrystallisation of gitoxigenin from aqueous EtOH produces plates of the *sesquihydrate* which dehydrate on drying at 100 $^{\circ}$  *in vacuo*. It also recrystallises from Me<sub>2</sub>CO/MeOH and from EtOAc (the crystals contain 1 mol of EtOAc) with  $[\alpha]_{\text{D}}^{21} +24.8^{\circ}$  (c 1, dioxane). It has UV with  $\lambda_{\text{max}}$  at 310, 485 and 520nm in 96% H<sub>2</sub>SO<sub>4</sub>. On heating with ethanolic HCl it yields *digitaligenin* with loss of H<sub>2</sub>O. [Smith *J Chem Soc* 23 1931, *Beilstein* 8 IV 2456.]

**Glycocholic acid (N-cholylglycine)** [475-31-0] **M 465.6, m 130 $^{\circ}$  (hydrate) 154-155 $^{\circ}$ , 165-168 $^{\circ}$ (anhydrous),**  $[\alpha]_{\text{D}}^{20} +37^{\circ}$  (c 1, EtOH), **pK<sup>25</sup> 4.4.** Glycocholic acid crystallises from hot water as the *sesquihydrate*. Dry it at 110 $^{\circ}$  *in vacuo*. An analytical sample is prepared by suspending the acid (4g) in H<sub>2</sub>O (400ml) at ~20 $^{\circ}$ , heating to boiling with slow stirring, filtering hot and allowing to cool to ~20 $^{\circ}$ . The acid is filtered off, washed with H<sub>2</sub>O, dried in air, recrystallised from 5% aqueous EtOH, washed well and dried over P<sub>2</sub>O<sub>5</sub> in a moderate vacuum to constant weight. Recrystallisation from EtOH/EtOAc, and drying, gave the *anhydrous* acid. [Cortese & Bauman *J Am Chem Soc* 57 1393 1935, Bergstrom & Norman *Acta Chem Scand* 7 1126 1953, *Beilstein* 10 IV 2077.]

**Glycodeoxycholic acid monohydrate (N-[3 $\alpha$ -12 $\alpha$ -dihydroxy-5 $\beta$ -cholan-24-oyl]glycine)** [360-65-6] **M 467.6, m 186-177 $^{\circ}$ (dec), 187-188 $^{\circ}$ ,**  $[\alpha]_{\text{D}}^{23} +45.9^{\circ}$  (c 1, EtOH), **pK<sub>Est</sub> ~4.4.** Glycodeoxycholic acid recrystallises from H<sub>2</sub>O or aqueous EtOH with 1 mol of H<sub>2</sub>O and is dried at 100 $^{\circ}$  *in vacuo*. Its solubility in EtOH is ~5%. [UV: Lindstedt & Sjövall *Acta Chem Scand* 11 421 1957.] The *Na* salt recrystallises from EtOH/Et<sub>2</sub>O with **m 245-250 $^{\circ}$**  and  $[\alpha]_{\text{D}}^{23} +41.2^{\circ}$  (c 1, H<sub>2</sub>O) [Wieland *Hoppe Seyler's Z Physiol Chem* 106 181 1919, Cortese *J Am Chem Soc* 59 2532 1937]. [*Beilstein* 10 IV 1611.]

**Hecogenin (25R-5 $\alpha$ -spirostan-3 $\beta$ -ol-12-one)** [467-55-0] **M 430.6, m 245-250 $^{\circ}$ , 253 $^{\circ}$ , 264-266 $^{\circ}$ , 268 $^{\circ}$ ,**  $[\alpha]_{\text{D}}^{23} +8^{\circ}$  (c 1, CHCl<sub>3</sub>). The saponin (~35 mg) in EtOAc is chromatographed on Al<sub>2</sub>O<sub>3</sub> and eluted with \*C<sub>6</sub>H<sub>6</sub>/Et<sub>2</sub>O, and the residue on evaporation is recrystallised from Me<sub>2</sub>CO. [Mazur et al. *J Am Chem Soc* 82 5889 1960, Marker et al. *J Am Chem Soc* 69 2167 1947, *Beilstein* 19 III/IV 2581.]

**Hecogenin acetate** [915-35-5] **M 472.7, m 265-268 $^{\circ}$ ,**  $[\alpha]_{\text{D}}^{20} -6.0^{\circ}$  (c 1, CHCl<sub>3</sub>). Crystallise the acetate from MeOH. [*Beilstein* 19 IV 2583.]

**Hydrocortisone (Cortisol, 11 $\beta$ ,17 $\alpha$ ,21-trihydroxypregn-4-ene-3,20-dione)** [50-23-7] **M 362.5, m 212-213 $^{\circ}$ , 214-217 $^{\circ}$ , 218-221 $^{\circ}$ , 220-222 $^{\circ}$ ,**  $[\alpha]_{\text{D}}^{22} +167^{\circ}$  (c 1, EtOH). Recrystallise hydrocortisone from EtOH or isoPrOH. It is bitter tasting and has UV with  $\lambda_{\text{max}}$  at 242 nm (log  $\epsilon$  4.20). Its solubility at 25 $^{\circ}$  is: H<sub>2</sub>O (0.28%), EtOH (1.5%), MeOH (0.62%), Me<sub>2</sub>CO (0.93%), CHCl<sub>3</sub> (0.16%), propylene glycol (1.3%) and Et<sub>2</sub>O (0.35%). It gives an intense green colour with conc H<sub>2</sub>SO<sub>4</sub>. [Wendler et al. *J Am Chem Soc* 72 5793 1950, *Beilstein* 8 IV 3422.]

**Hydrocortisone acetate (21-acetoxy-11 $\beta$ ,17 $\alpha$ -trihydroxypregn-4-ene-3,20-dione)** [50-03-3] **M 404.5, m 218-221.5 $^{\circ}$ , 221-223 $^{\circ}$ , 222-225 $^{\circ}$ ,**  $[\alpha]_{\text{D}}^{25} +166^{\circ}$  (c 0.4, dioxane), **+150.7 $^{\circ}$  (c 0.5, Me<sub>2</sub>CO).** The acetate recrystallises from Me<sub>2</sub>CO/Et<sub>2</sub>O or aqueous Me<sub>2</sub>CO as *hygroscopic* monoclinic crystals. Its UV has  $\lambda_{\text{max}}$  at 242 nm ( $A_{1\text{cm}}^{1\%}$  390) in MeOH. Its solubility at 25 $^{\circ}$  is: H<sub>2</sub>O (0.001%), EtOH (0.45%), MeOH (0.04%), Me<sub>2</sub>CO (1.1%), CHCl<sub>3</sub> (0.5%), Et<sub>2</sub>O (0.15%), and it is very soluble in Me<sub>2</sub>NCHO. [Wendler et al. *J Am Chem Soc* 74 3630 1952; Antonucci et al. *J Org Chem* 18 7081 1953, *Beilstein* 8 IV 3424.]

**19-Hydroxy-4-androsten-3,17-dione** [510-64-5] **M 302.4, m 167-169 $^{\circ}$ , 168-170 $^{\circ}$ , 169-170 $^{\circ}$ , 172-173 $^{\circ}$ ,**  $[\alpha]_{\text{D}}^{20} +190^{\circ}$  (c 1, CHCl<sub>3</sub>). Recrystallise 19-hydroxy-4-androsten-3,17-dione from Me<sub>2</sub>CO/hexane or Et<sub>2</sub>O/hexane. It has UV with  $\lambda_{\text{max}}$  at 242nm in EtOH or MeOH. The *19-acetoxy* derivative has  $[\alpha]_{\text{D}}^{25} +185^{\circ}$  (CHCl<sub>3</sub>) and  $\lambda_{\text{max}}$  with 237.5nm in EtOH. [Ehrenstein & Dünneberger *J Org Chem* 21 774 1956, *Beilstein* 8 IV2162.]

**25-Hydroxycholesterol (cholest-5-en-3 $\beta$ ,25-diol)** [2140-46-7] **M 402.7, m 177-179 $^{\circ}$ , 178-180 $^{\circ}$ , 181.5-182.5 $^{\circ}$ ,**  $[\alpha]_{\text{D}}^{25} -39^{\circ}$  (c 1.05, CHCl<sub>3</sub>). 25-Hydroxycholesterol forms colourless needles from MeOH [Schwartz *Tetrahedron Lett* 22 4655 1981]. The *3 $\beta$ -acetoxy* derivative has **m 142-142.8 $^{\circ}$**  (from Me<sub>2</sub>CO) and  $[\alpha]_{\text{D}}^{25} -40.4^{\circ}$

(c 2, CHCl<sub>3</sub>). The 3 $\beta$ ,25-diacetoxy derivative has **m** 119-120.5° (from MeOH) and  $[\alpha]_D^{25}$  -35.5° (CHCl<sub>3</sub>). [Dauben & Bradlow *J Am Chem Soc* 72 4248 1950, Ryer et al. *J Am Chem Soc* 72 4247 1950, Beilstein 6 IV 6437.]

**18-Hydroxy-11-deoxycorticosterone (18,21-dihydroxypregn-4-en-3,20-dione tautomeric with 18,20-epoxy-20,21-dihydroxypregn-4-en-3-one)** [379-68-0] **M 346.5, m 168-170°, 171-173°, 191-195°, 200-205°,  $[\alpha]_D^{20}$  +151° (c 1, CHCl<sub>3</sub>).** Recrystallise 18-hydroxy-11-deoxycorticosterone from Et<sub>2</sub>O/Me<sub>2</sub>CO to give crystals **m** 200-205°. When it is recrystallised from Me<sub>2</sub>CO, it has **m** 191-195°. It has UV with  $\lambda_{\max}$  at 240nm. The 21-O-acetoxy-18-hydroxy derivative has **m** 158-159° (from Et<sub>2</sub>O/\*C<sub>6</sub>H<sub>6</sub>), and the 21-O-acetoxy-18,20-epoxy derivative has **m** 149-154° (from Et<sub>2</sub>O). [Kahnt et al. *Helv Chim Acta* 38 1237 1955; Pappo *J Am Chem Soc* 81 1010 1959.]

**17 $\beta$ -Hydroxy-17 $\alpha$ -methyl-3-androsterone (Mestanolone)** [521-11-9] **M 304.5°, m 192-193°.** Dissolve mestanolone in Et<sub>2</sub>O, wash it with N NaOH, H<sub>2</sub>O, dry it (Na<sub>2</sub>SO<sub>4</sub>), evaporate and recrystallise it from EtOAc. The semicarbazone has **m** 235-236° (from EtOH). [Ruzicka et al. *Helv Chim Acta* 18 1487 1935.]

**17 $\alpha$ -Hydroxy-6 $\alpha$ -methylprogesterone (Medroxyprogesterone)** [520-85-4] **M 344.5, m 220°,  $[\alpha]_D^{25}$  +75° (CHCl<sub>3</sub>).** If it contains the *epi*-isomer (TLC), then dissolve it in CHCl<sub>3</sub>, bubble dry HCl gas to epimerise it, evaporate and recrystallise it from chloroform. The UV has  $\lambda_{\max}$  at 241nm ( $\epsilon$  16,150) in EtOH. The 17-acetate [71-58-9] crystallises from MeOH with **m** 207-208° and  $[\alpha]_D^{25}$  +61° (CHCl<sub>3</sub>). Its UV has  $\lambda_{\max}$  at 240nm ( $\epsilon$  15,950) in EtOH. [Babcock et al. *J Am Chem Soc* 80 2904 1958, Beilstein 8 IV 2212.]

**$\alpha$ -Hyodeoxycholic acid** [83-49-8] **M 392.6, m 196-197°,  $[\alpha]_{546}^{20}$  +8° (c 2, EtOH), pK<sub>Est</sub> ~4.9.** Crystallise  $\alpha$ -hyodeoxycholic acid from EtOAc or Me<sub>2</sub>CO. The K salt separates in needles from an alcoholic solution of the acid when an equivalent of KOMe is added (see lithocholic acid [434-13-9]). [Weiland & Gumlish *Hoppe Seyler's Z Physiol Chem* 215 18 1933, Windaus & Bohne *Justus Liebigs Ann Chem* 433 278 1923, Beilstein 10 III 1631.]

**Lanosterol** [79-63-0] **M 426.7, m 138-140°,  $[\alpha]_D^{20}$  +62.0° (c 1, CHCl<sub>3</sub>).** If very impure, then it should be acetylated, converted to the dibromide acetate [crystallised from EtOAc with slow cooling, **m** 168-170°,  $[\alpha]_D^{20}$  +214° (CHCl<sub>3</sub>)], de-brominated with Zn dust to give the acetate (below) which is recrystallised from 3-4 parts of Me<sub>2</sub>CO/MeOH (4:1) and hydrolysed as for stigmasterol (below). Recrystallise it from anhydrous MeOH. Dry it *in vacuo* over P<sub>2</sub>O<sub>5</sub> for 3 hours at 90°. The purity is checked by proton magnetic resonance. The acetate crystallises from MeOH with **m** 131-133°,  $[\alpha]_D^{25}$  +62° (c 1, CHCl<sub>3</sub>). [Block & Urech *Biochemical Preparations* 6 32 1958. van Tamelen et al. *J Am Chem Soc* 104 6479, 6480 1982, Beilstein 6 III 2880, 6 IV 4188.]

**Lithocholic acid (3 $\alpha$ -hydroxycholanic acid)** [434-13-9] **M 376.6, m 184-186°,  $[\alpha]_D^{25}$  +35° (c 1, EtOH), pK<sub>Est</sub> ~4.8.** Lithocholic acid can be purified by conversion to the rather insoluble Na or K salt by addition of the equivalent amount of aqueous NaOH or KOH, filtering off the alkali salt, washing it with ice cold H<sub>2</sub>O, dissolving it in the least volume of boiling H<sub>2</sub>O, acidifying with the dilute HCl (slight excess), filtering off the acid, washing with cold H<sub>2</sub>O and drying it thoroughly in a vacuum. Recrystallise it from Me<sub>2</sub>CO, EtOH or acetic acid. The methyl ester crystallises from MeOH, with 0.5 mol of MeOH, and has **m** 92-93°,  $[\alpha]_D^{25}$  +34° (MeOH). It has also been purified by recrystallisation from petroleum ether (b 40-60°) and, after chromatography on Al<sub>2</sub>O<sub>3</sub> in petroleum ether, gave a labile form **m** 92-93° which is transformed to the stable form **m** 125-126° after standing for 2 days in a vacuum desiccator. [Hoelm & Mason *J Am Chem Soc* 62 569 1940, Sarel & Yanuka *J Org Chem* 24 2018 1959, Beilstein 10 IV 785.]

**6- $\alpha$ -Methylprednisolone (Medrol, 11 $\beta$ ,17-21-trihydroxy-6 $\alpha$ -methylpregna-1,4-dien-3,20-dione)** [83-43-2] **M 347.5, m 226-237°, 228-237°, 240-242°,  $[\alpha]_D^{24}$  +91° (c 0.5, dioxane).** Recrystallise medrol from EtOAc. The UV has  $\lambda_{\max}$  at in 95% EtOH 243nm ( $\epsilon$  14,875). The 21-acetoxy derivative has **m** 205-208° (from EtOAc), and  $[\alpha]_D^{24}$  +95° (c 1, CHCl<sub>3</sub>). [Spero et al. *J Am Chem Soc* 78 6213 1956; Fried et al. *J Am Chem Soc* 81 1235 1959; <sup>1</sup>H NMR: Slomp & McGarvey *J Am Chem Soc* 81 2200 1959, Beilstein 8 IV 3498.]

**17 $\alpha$ -Methyltestosterone (Android, Mesterone)** [58-18-4] M 302.5, m 162-168 $^{\circ}$ , 164-165 $^{\circ}$ ,  $[\alpha]_{D}^{20} +87^{\circ}$  (c 1, dioxane),  $[\alpha]_{D}^{20} +82.3^{\circ}$  (c 1, EtOH)  $A_{1cm}^{1\%}$  241nm is 495-530 (EtOH). This anabolic steroid is crystallised from hexane or hexane/\*benzene. It has  $E_{1cm}^{1\%}$  495-530 at 241nm (EtOH). The colour reaction with 2,4-dinitrophenyl hydrazine is used for assaying it. [Gornall & Macdonald *J Biol Chem* **201** 279 1953.] In another colour reaction the sterone (1mg) in acetic acid (0.2ml) + 88% H<sub>3</sub>PO<sub>4</sub> (2ml) is allowed to stand for 1 hour when it becomes fluorescent. After 1 hour it is diluted with acetic acid (~3ml) and provides a strong yellow fluorescence with the intensity of 50-100 times that of estrone. [Stuart & Stuckey *J Pharm Pharmacol* **1** 130 1949, Openauer *Rec Trav Chim Pays Bas* **56** 137 137, *Beilstein* **8** IV 1010.]

**Norcholanic acid (5 $\beta$ -24-norcholan-23-oic acid)** [511-18-2] M 346.5, m 175.5-176.5 $^{\circ}$ , 186 $^{\circ}$ ,  $[\alpha]_{D}^{20} +32^{\circ}$  (EtOH), pK<sub>Est</sub> ~4.8. Recrystallise the acid from AcOH. The *methyl ester* has m 74 $^{\circ}$  (needles from MeOH), and the *ethyl ester* has m 65-66 $^{\circ}$ . [Yanuka et al. *Tetrahedron Lett* 1725 1968, *Beilstein* **9** III 2652, **10** IV 2083.]

**$\alpha$ -Oestradiol** See estradiol above [57-91-0].

**$\beta$ -Oestradiol-3-benzoate** See estradiol 3-benzoate above [50-50-0].

**Ouabain [3-{(6-deoxy- $\alpha$ -L-mannopyranosyl)oxy}-1,5,11a,14,19-pentahydroxycard-20(22)-enolide. G-Strophanthin, Acocantherine]** [630-60-4, 312619-45-7 (hydrate), 11018-89-6 (octahydrate)] M 728.8 (8 H<sub>2</sub>O), m 190 $^{\circ}$ (dec), 200-202 $^{\circ}$ (dec),  $[\alpha]_{546}^{20} -30^{\circ}$  (c 1, H<sub>2</sub>O). It crystallises from water as the *octahydrate*. Dry it at 130 $^{\circ}$ . It decomposes at 190 $^{\circ}$  when dry. Store it in the dark as it is light sensitive, but it is stable in air. Its solubility (g/100ml) in H<sub>2</sub>O is 1.3 (~25 $^{\circ}$ ), 20 (~100 $^{\circ}$ ), and in EtOH it is 1.0 (~25 $^{\circ}$ ) and 12.5 (~78 $^{\circ}$ ). It is highly **TOXIC** as it is an inhibitor of cation transport and of Na<sup>+</sup> and K<sup>+</sup> ATPase. [*Beilstein* **18/5** V 625.]

**Pancuronium bromide (2 $\beta$ ,16 $\beta$ -dipiperidino-5 $\alpha$ -androstan-3 $\alpha$ ,17 $\beta$ -diol diacetate dimetho-bromide)** [15500-66-0] M 732.7, m 212-215 $^{\circ}$ , 215 $^{\circ}$ . The bromide forms odourless crystals with a bitter taste which are purified through acid-washed Al<sub>2</sub>O<sub>3</sub> and eluted with isoPrOH/EtOAc (3:1) to remove impurities (e.g. the monomethobromide) and eluted with isoPrOH to give the pure dibromide which is recrystallised from CH<sub>2</sub>Cl<sub>2</sub>/Me<sub>2</sub>CO or isoPrOH/Me<sub>2</sub>CO. It is soluble in H<sub>2</sub>O (10%) and CHCl<sub>3</sub> (3.3%) at 20 $^{\circ}$ . It is a non-depolarising muscle relaxant. [Buckett et al. *J Med Chem* **16** 1116 1973.]

**Prednisolone acetate (21-acetoxypregna-1,4-diene-11 $\beta$ -17 $\alpha$ -diol-3,20-dione)** [52-21-1] M 402.5, m 237-239 $^{\circ}$ , 240-242 $^{\circ}$ , 240-243 $^{\circ}$ , 244 $^{\circ}$ ,  $[\alpha]_{D}^{20} +116^{\circ}$  (c 1, dioxane). Recrystallise prednisolone acetate from EtOH, Me<sub>2</sub>CO, Me<sub>2</sub>CO/hexane, and it has UV with  $\lambda_{max}$  at 243nm in EtOH. [Joly et al. *Bull Soc Chim Fr* 366 1958; Herzog et al. *J Am Chem Soc* **77** 4781 1955, *Beilstein* **8** IV 3468.]

**Prednisone (17,21-dihydroxypregna-1,4-diene-3,11,20-trione, deltacortisone)** [53-03-2] M 358.5, m 238 $^{\circ}$  (dec),  $[\alpha]_{D}^{20} +172^{\circ}$  (c 0.5, dioxane),  $\lambda_{max}$  238nm (log  $\epsilon$  4.18) in MeOH. Crystallise prednisone from acetone/hexane, then recrystallise it from Me<sub>2</sub>CO. The *monoacetate* crystallises from Me<sub>2</sub>CO/hexane with m 227-233 $^{\circ}$ (dec),  $[\alpha]_{D}^{25} +186^{\circ}$  (c 1, dioxane), and the *diacetate* crystallises from Me<sub>2</sub>CO/hexane with m 219-221 $^{\circ}$ (dec),  $[\alpha]_{D}^{25} +125^{\circ}$  (c 1, CHCl<sub>3</sub>). [Hertzog et al. *Tetrahedron* **18** 581 1962, *Beilstein* **8** IV 3531.]

**5 $\alpha$ -Pregnane (allopregnane)** [641-85-0] M 288.5, m 84.5-85 $^{\circ}$ ,  $[\alpha]_{D}^{20} +21.7^{\circ}$  (c 1.3, CHCl<sub>3</sub>). Recrystallise 5 $\alpha$ -pregnane several times from Me<sub>2</sub>CO. The melting point is lowered (e.g. to 50-71 $^{\circ}$ ) if it is contaminated with the 5 $\beta$ -isomer (see below). [Butenandt et al. *Chem Ber* **64** 2529 1931, Steiger & Reichstein *Helv Chim Acta* **21** 161 1938, *Beilstein* **5** III 1120, 1121, 1125.]

**5 $\beta$ -Pregnane** [481-26-5] M 288.5, m 82-83 $^{\circ}$ , 83.5 $^{\circ}$ ,  $[\alpha]_{D}^{20} +21.2^{\circ}$  (c 0.75, CHCl<sub>3</sub>). Crystallise 5 $\beta$ -pregnane from MeOH or Me<sub>2</sub>CO. The mixed melting point with allopregnane (above) is ~50-71 $^{\circ}$ . [Butenandt et al. *Chem*

*Ber* 64 2529 1931, Steiger & Reichstein *Helv Chim Acta* 21 161 1938.]

**5 $\alpha$ -Pregnane-3 $\alpha$ ,20 $\beta$ R-diol** [566-57-5] M 320.5, m 207-209°, [ $\alpha$ ]<sub>D</sub><sup>26</sup> +12° (c 1.1, CHCl<sub>3</sub>). Crystallise 5 $\alpha$ -pregnane-3 $\alpha$ ,20 $\alpha$ -diol from Me<sub>2</sub>CO. Its *diacetate* [6170-22-5] M 404.5, has two melting points 134-140° and 152.4°, and [ $\alpha$ ]<sub>D</sub><sup>26</sup> +40.5° (c 0.8, CHCl<sub>3</sub>). It is a progesterone metabolite in urine during pregnancy. [See references below.]

**5 $\alpha$ -Pregnane-3 $\alpha$ ,20 $\alpha$ S-diol** [566-58-5] M 320.5, m 248°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +17° (c 0.15, EtOH). Crystallise 5 $\alpha$ -pregnane-3 $\alpha$ ,20 $\alpha$ -diol from EtOH. Its *diacetate* [6003-18-5] has m 142° and [ $\alpha$ ]<sub>D</sub><sup>20</sup> +18° (c 0.4, \*C<sub>6</sub>H<sub>6</sub>). It is a progesterone metabolite in urine during pregnancy. [See references below.]

**5 $\beta$ -Pregnane-3 $\alpha$ ,20 $\beta$ R-diol** [80-91-1] M 320.5, m 239°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +10° (c 1, EtOH). Crystallise pregnane-diol (which is abundant in the urine of pregnant women) from EtOH or Me<sub>2</sub>CO and dry it *in vacuo*. It can be oxidised to progesterone (see below) and it is not precipitated by digitonin. Its *diacetate* [6100-28-3] has m 112-113° and [ $\alpha$ ]<sub>D</sub><sup>26</sup> +60° (c 1, CHCl<sub>3</sub>). It is a progesterone metabolite in urine during pregnancy. [Marian *Biochem J* 23 1090 1929, Johnson et al. *J Chem Soc* 1302 1954, Mattox et al. *J Org Chem* 32 708 1967, *Beilstein* 6 III 4778, 6 IV 6111.]

**5 $\beta$ -Pregnane-3 $\alpha$ ,20 $\alpha$ S-diol** [80-92-2] M 320.5, m 243-244°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +31° (c 1, EtOH). Crystallise the diol from acetone. The *diacetate* [1174-69-2] crystallises from petroleum ether with m 180° (also 182-183°) and [ $\alpha$ ]<sub>D</sub><sup>20</sup> +35° (c 1.1, CHCl<sub>3</sub>). [Marian *Biochem J* 23 1090 1929, Fish et al. *J Biol Chem* 143 716 1942, Hieschmann *J Biol Chem* 140 797 1941, Johnson et al. *J Chem Soc* 1302 1954, Glick et al. *J Org Chem* 27 3121 1962, *Beilstein* 6 III 4778, 6 IV 6111.]

**Progesterone** [57-83-0] M 314.5, m 128.5°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +230° (c 1, EtOH), +214.7° (c 1.3, Me<sub>2</sub>CO). The  $\alpha$ -form crystallises from EtOH with m 127-131°. The  $\beta$ -form crystallises from petroleum ether or aqueous petroleum ether/aqueous Et<sub>2</sub>O with m 119-120° or 121°. It also crystallises from Et<sub>2</sub>O, Me<sub>2</sub>CO/EtOAc, MeOH, aqueous Et<sub>2</sub>O, aqueous MeOH, wet petroleum ether, Et<sub>2</sub>O/petroleum ether, petroleum ether/\*C<sub>6</sub>H<sub>6</sub>, Et<sub>2</sub>O/pentane and isopropyl ether. The UV has  $\lambda_{\max}$  is at 240nm with log  $\epsilon$  4.25 (EtOH). [Wintersteiner & Allen *J Biol Chem* 107 321 1934, *Beilstein* 7 III 3648, 7 IV 2395.]

**Rubijervine (solanid-5-ene-3 $\beta$ -12 $\alpha$ -diol)** [79-58-3] M 413.6, m 242-244°, 240-246°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +19° (EtOH), [ $\alpha$ ]<sub>D</sub><sup>27.5</sup> +20° (c 1.04, MeOH), pK<sub>Est</sub> ~7.0. Rubijervine crystallises from 95% EtOH as colourless rods. It has solvent of crystallisation and is dried at 120°/2mm. It is precipitated by digitonin. The *hydrobromide* crystallises from MeOH/Me<sub>2</sub>CO with m 265-270°(dec). The *diacetate* crystallises from MeOH with m 160-163°. The *3-benzoate* gives colourless prisms from \*C<sub>6</sub>H<sub>6</sub> with m 156-159° and [ $\alpha$ ]<sub>D</sub><sup>27.5</sup> +22° (c 1.6, CHCl<sub>3</sub>). [Pelletier & Locke *J Am Chem Soc* 79 4531 1957, Jacobs & Craig *J Biol Chem* 148 41 1943, *Beilstein* 21 III/IV 2310.]

**$\beta$ -Sitosterol (stigmast-5-ene-3 $\beta$ -ol)** [83-46-5] M 414.7, m 136.5-137.5°, 140°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -42° (c 2, CHCl<sub>3</sub>). Crystallise  $\beta$ -sitosterol from EtOH, MeOH, Me<sub>2</sub>CO, Me<sub>2</sub>CO/EtOH or Me<sub>2</sub>CO/MeOH. It has also been purified by zone melting. The *acetate* crystallises from MeOH or EtOH as plates with m 127-128° and [ $\alpha$ ]<sub>D</sub><sup>20</sup> -41° (c 2, CHCl<sub>3</sub>). The *benzoate* crystallises from EtOH as needles with m 146-147° and [ $\alpha$ ]<sub>D</sub><sup>20</sup> -13.8° (c 2, CHCl<sub>3</sub>). [Fujimoto & Jacobson *J Org Chem* 29 3377, 3381 1964, Shoppee *J Chem Soc* 1043 1948, Heilbron et al. *J Chem Soc* 344, 347 1941, *Beilstein* 6 III 2696.]

**Smilagenin (25R-spirostan-3 $\beta$ -ol, isosarsapogenin)** [126-18-1] M 416.6, m 185°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -69°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -80° (c 0.3, CHCl<sub>3</sub>). Chromatograph smilagenin on active Al<sub>2</sub>O<sub>3</sub> and elute with \*C<sub>6</sub>H<sub>6</sub>, then recrystallise it from Me<sub>2</sub>CO, aqueous EtOH (m 187-188°) or MeOH. The *acetate* crystallises from MeOH with m 152° and [ $\alpha$ ]<sub>D</sub><sup>25</sup> -59.6°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -68.9° (c 0.25, CHCl<sub>3</sub>). [Askew *J Chem Soc* 1399 1936 and 1402 1936, Scheer et al. *J Am Chem Soc* 77 641 1955, *Beilstein* 19 III/IV 826.]

**Solanidine (solanid-5-en-3 $\beta$ -ol)** [80-78-4] M 397.6, m 218-219°(sublimes), [ $\alpha$ ]<sub>D</sub><sup>20</sup> -29° (c 0.5, CHCl<sub>3</sub>), pK<sup>15</sup>

**6.66.** Solanidine crystallises from  $\text{CHCl}_3/\text{MeOH}$ , aqueous EtOH or aqueous MeOH as needles. TLC on  $\text{Al}_2\text{O}_3$  plates using  $\text{CH}_2\text{Cl}_2/\text{MeOH}$  (98:2) gives a spot at  $R_F$  0.47. The *hydrochloride* crystallises from aqueous EtOH with **m** 345°(dec). The *acetate* crystallises from EtOH with **m** 208°. [Schreiber & Roensch *Tetrahedron* **21** 6451/965, Kessar et al. *Tetrahedron* **27** 2153 1971, Reichstein & Reich *Ann Rev Biochem* **15** 155 1946, Beilstein **21** III/IV 1398, **27** III/IV 2000.]

**$\alpha$ -Solanine (solan-5-en-3 $\beta$ -yl-[*O*<sup>3</sup>- $\beta$ -D-glucopyranosyl-*O*<sup>2</sup>- $\alpha$ -L-rhamnopyranosyl- $\beta$ -D-galactopyrano-side])**  
See “Carbohydrates” in this chapter.

**Solasodine (22 $\alpha$ ,25*R*-spirosol-5-en-3 $\beta$ -ol) [126-17-0] M 413.6, m 202°,  $[\alpha]_D^{25}$  -100° (c 2, MeOH), **pK**<sup>25</sup> 7.7.** Solasodine crystallises (as *monohydrate*) from MeOH as lustrous plates (on heating, the plates change to needles as they melt and resolidify in needles), or aqueous 80% EtOH, and sublimes at high vacuum. After recrystallisation from  $\text{H}_2\text{O}$ , **m** 198-199°, then from  $\text{Me}_2\text{CO}/\text{H}_2\text{O}$ , **m** 199-201°, it has  $[\alpha]_D^{25}$  -109.3° (c 0.581,  $\text{CHCl}_3$ ). On TLC with silica gel G ( $^*\text{C}_6\text{H}_6/\text{absolute EtOH}$ , 8:2) it has  $R_F$  0.45. The IR (KBr) has  $\nu_{\text{max}}$  at 10.3, 10.4, 11.2, 11.5 $\mu$  (azaooxaspirane bands). [Schreiber & Rönsh *Tetrahedron* **20** 1939 1964, Uhle *J Org Chem* **27** 656 1962, Kessar et al. *Tetrahedron* **27** 2153 1971, Beilstein **27** III/IV 2000.]

**Stigmasterol (3 $\beta$ -hydroxy-24-ethylcholesta-5,22-diene) [83-48-7] M 412.7, m 170°,  $[\alpha]_D^{25}$  -51° ( $\text{CHCl}_3$ ),  $[\alpha]_{546}^{20}$  -59° (c 2,  $\text{CHCl}_3$ ).** Stigmasterol is best purified *via* the *tetrabromide-acetate*. The impure sterol (3g) is acetylated with  $\text{Ac}_2\text{O}$  (60ml) by refluxing for 1.5 hour. The mixture is cooled at 20° for 1 hour, and the crude acetate is collected. The acetate (3g) in  $\text{Et}_2\text{O}$  (30ml) is then treated with  $\text{Br}_2/\text{AcOH}$  (38ml, from 5g  $\text{Br}_2$  in 100ml AcOH), and after cooling at 6° overnight, the tetrabromoacetate is filtered off and washed with  $\text{Et}_2\text{O}$ . After six recrystallisations from  $\text{CHCl}_3/\text{MeOH}$  the *tetrabromoacetate* has **m** 194-196°. This product (1g) in AcOH (12ml) and Zn dust (1g) is refluxed for 1.5 hours, filtered hot, diluted with  $\text{H}_2\text{O}$  (30m L) and extracted with  $\text{Et}_2\text{O}$ . The extract is washed with dilute aqueous sodium sulfite, then  $\text{H}_2\text{O}$ , the extract is dried ( $\text{Na}_2\text{SO}_4$ ) and the stigmasterol acetate (~550mg) is recrystallised (4x) from EtOH and twice from MeOH/ $\text{CHCl}_3$  (2:1) to give the *acetate* with **m** 139-148°. This acetate (400mg) is hydrolysed in boiling 10% alcoholic KOH (1ml) for 1 hour. Then  $\text{H}_2\text{O}$  (30ml) is added and the mixture is extracted with  $\text{Et}_2\text{O}$ . The extract is washed with aqueous  $\text{Na}_2\text{CO}_3$ , then  $\text{H}_2\text{O}$ , the solvent is distilled off and the residue is recrystallised (3x) from 95% EtOH to give ~110mg of pure stigmasterol. It is dried in a vacuum over  $\text{P}_2\text{O}_5$  for 3 hours at 90°. The purity is checked by NMR. The *acetate* crystallises from MeOH with **m** 145°,  $[\alpha]_D^{25}$  -56° (c 2,  $\text{CHCl}_3$ ). [Byerrum & Ball *Biochemical Preparations* **7** 86 1959, Thornton et al. *J Am Chem Soc* **62** 2006 1940, Colin et al. *Anal Chem* **51** 1661 1979, Beilstein **6** IV 4170.]

**Taurocholic acid (3 $\alpha$ , 7 $\alpha$ ,12 $\alpha$ -trihydroxy-5 $\beta$ -cholestan-24-oic acid *N*-(2-sulfoethyl) amide Na salt, *N*-coloyotaurine) [81-24-3] M 515.6, m ~125°(dec),  $[\alpha]_D$  +38.8° (c 2, EtOH), **pK**<sup>25</sup> 1.4.** The acid is present in bile and is isolated as an amorphous pale yellow powder. Crystallise it from EtOH/EtOAc/ $\text{Et}_2\text{O}$  (amorphous **m** 125°) or EtOH/ $\text{Et}_2\text{O}$  [Josephson *Biochem J* **29** 1484 1935]. The anhydrous acid is hygroscopic, freely soluble in  $\text{H}_2\text{O}$  and EtOH but insoluble in  $\text{H}_2\text{O}$  and EtOAc. It is hydrolysed by acids or alkalis to cholic acid and taurine. The *sodium salt (hydrate)* [312693-83-7, 345909-26-4 ( $x\text{H}_2\text{O}$ )] crystallises from aqueous EtOH/ $\text{Et}_2\text{O}$  with **m** 231-232°,  $[\alpha]_D^{23}$  +23.6° (c 2.5,  $\text{H}_2\text{O}$ ); and has the UV  $\lambda_{\text{max}}$  ( $\text{H}_2\text{SO}_4$ ) at 303, 389 and 480nm. [cf Cortese *J Am Chem Soc* **59** 2532 1937, Beilstein **10** III 2177, **10** IV 2078.]

**Taurodeoxycholic acid sodium salt monohydrate (3 $\alpha$ , 12 $\alpha$ -dihydroxy-5 $\beta$ -cholestan-24-oic acid *N*-(2-sulfoethyl) amide Na salt monohydrate, *N*-[desoxycholy]taurine Na salt  $\text{H}_2\text{O}$ ) [1180-95-6, 207737-97-1 (*x H}\_2\text{O}*)] M 539.7, m 171-175°,  $[\alpha]_D^{23}$  +37° (c 1,  $\text{H}_2\text{O}$ ), **pK**<sup>25</sup> 1.4 (free acid).** The Na salt is dissolved in the smallest volume of  $\text{H}_2\text{O}$ , a saturated solution of aqueous NaCl/ $\text{Et}_2\text{O}$  is added and the mixture is stored at 0° for 24 hours. Then shake the mixture well, keep it in the cold for another day and filter the crystals with gentle shaking, wash them with ice-cold saturated aqueous NaCl saturated with  $\text{Et}_2\text{O}$ , dry them over  $\text{CaCl}_2$  and extract them with absolute EtOH. Add ~10ml of  $\text{H}_2\text{O}$  to the solid followed by enough  $\text{Et}_2\text{O}$  to incipient cloudiness. Store it overnight at 0°. Add ice-cold  $\text{Et}_2\text{O}$  to make 250ml, collect the crystals, wash them with  $\text{Et}_2\text{O}$  then petroleum ether and dry them in air. The purification can be repeated with NaCl and  $\text{Et}_2\text{O}$  with ~85% recovery. NB: precipitation will not occur unless enough  $\text{H}_2\text{O}$  is present. Its solubility in  $\text{H}_2\text{O}$  is 10%. [Cortese *J Am*

*Chem Soc* **59** 2532 1937.] The *free acid* has **m** 141-144°. [Norman *Ark Kemi* **8** 331 1956.] It forms mixed micelles and solubilises some membrane proteins [Hajjar et al. *J Biol Chem* **258** 192 1983]. [*Beilstein* **10** IV 1611.]

**Testosterone (17- $\beta$ -hydroxyandrost-4-ene-3-one)** [58-22-0] **M 288.4, m 155°,  $[\alpha]_{546}^{20} +130^\circ$  (c 1, dioxane).** Crystallise testosterone from aqueous acetone, hexane or isoPrOH. The long needles that separated from EtOH/AcOH were used for X-ray crystallography [Roberts et al. *J Chem Soc Perkin Trans II* 1978 1973.] The *acetate* [1045-69-8] crystallises from MeOH or aqueous Me<sub>2</sub>CO, with **m** 140-141° and  $[\alpha]_{\text{D}}^{20} +87.8^\circ$  (c 1, EtOH). [Ruzicka et al. *Helv Chim Acta* **18** 1478 1935 and **19** 99, 842 1936, *Beilstein* **8** IV 974.]

**Testosterone propionate** [57-85-2] **M 344.5, m 118-122°,  $[\alpha]_{546}^{20} +102^\circ$  (c 2, dioxane).** Crystallise the propionate from aqueous EtOH, or Et<sub>2</sub>O/petroleum ether (**m** 121°), and its UV has  $\lambda_{\text{max}}$  at 240nm (EtOH), and  $[\alpha]_{546}^{20} +114^\circ$  (c 1, CHCl<sub>3</sub>). Also purify it by HPLC. [Ercol & de Ruggieri *J Am Chem Soc* **75** 650, 652 1953, polymorphism: Brandstätter-Kuhnert & Kofler *Microchim Acta* 847, 850 1959, *Beilstein* **8** IV 977.]

**Ursodiol (ursodeoxycholic acid, 3 $\alpha$ ,7 $\beta$ -dihydroxy-5 $\beta$ -cholan-24-oic acid, 7 $\beta$ -hydroxylithocholic acid, ursodeoxycholic acid)** [128-13-2] **M 392.5, m 203°,  $[\alpha]_{\text{D}}^{20} +60^\circ$  (c 0.2, EtOH),  $\text{pK}_{\text{Est}} \sim 4.8$ .** Recrystallise ursodiol from wet Et<sub>2</sub>O, EtOH or EtOH/MeOH. It is almost insoluble in H<sub>2</sub>O, sparingly soluble in Et<sub>2</sub>O, very slightly soluble in CHCl<sub>3</sub> but freely soluble in AcOH. The *diformate* has **m** 170°, and the *diacetate* has **m** 100-102°. It is an anticholelithogenic drug. [Iwasaki *Hoppe Seyler's Z Physiol Chem* **244** 181, 183 1936, Ward et al. *Drugs* **27** 95 1984, *Beilstein* **10** III 1635, **10** IV 1604.]

## MISCELLANEOUS COMPOUNDS (including biologically useful reagents, low-molecular-weight bioactive substances, antibiotics, coenzymes, vitamins, lipids, phospholipids, nucleosides, nucleotides and polynucleotides)

**Acetoacetyl coenzyme A trisodium salt trihydrate** [102029-52-7] **M 955.6, pK<sub>1</sub> 4.0 (NH<sub>2</sub>), pK<sub>2</sub> 6.4 (PO<sub>4</sub><sup>-</sup>)**. Purification can be carried out by passage through a DEAE-cellulose formate column, then through a Dowex 50 (H<sup>+</sup>) column to remove Na ions, concentrated by lyophilisation and redissolved in H<sub>2</sub>O. It is commercially available as a solution of 0.05g/ml of H<sub>2</sub>O. The concentration of acetoacetylcoenzyme A is determined by the method of Stern et al. [*J Biol Chem* **221** 15 1956]. It is stable at pH 7-7.5 for several hours at 0° (half-life *ca* 1-2 hours). At room temperature it is hydrolysed in *ca* 1-2 hours at pH 7-7.5. At pH 1.0/20° it is more stable than at neutrality. A solution of the trisodium salt (0.05g/ml H<sub>2</sub>O) adjusted to pH 5 with 2N NaOH can be stored frozen for several weeks. It is stable at pH 2-3/-17° for at least 6 months. [Hersch & Jencks *J Biol Chem* **242** 3468 1967, Clikenbeard et al. *J Biol Chem* **250** 3108 1975, Simon & Shemin *J Am Chem Soc* **75** 2520 1953, Moffatt & Khorana **81** 1265 1959, Salem et al. *Biochem J* **258** 563 1989, Beilstein **26** III/IV 3668.]

**Acetylcholine bromide** [66-23-9] **M 226.1, m 143°, 146°**. The bromide is a *hygroscopic* solid, but less so than the hydrochloride salt. It crystallises from EtOH as prisms. Some hydrolysis occurs in boiling EtOH, particularly if it contains some H<sub>2</sub>O. It can also be recrystallised from EtOH or MeOH by adding dry Et<sub>2</sub>O. [Heilbronn *Acta Chem Scand* **12** 1492 1958, Beilstein **4** IV 1446.]

**Acetylcholine chloride** [60-31-1] **M 181.7, m 148-150°, 151°**. It is very soluble in H<sub>2</sub>O (>10%), and is very *hygroscopic*. If pasty, dry it in a vacuum desiccator over H<sub>2</sub>SO<sub>4</sub> until a solid residue is obtained. Dissolve this in absolute EtOH, filter it and add dry Et<sub>2</sub>O, when the hydrochloride separates. Collect by filtration and store it under very dry conditions. [Jones & Major *J Am Chem Soc* **52** 307 1930.] The *chloroplatinate* crystallises from hot H<sub>2</sub>O in yellow needles and can be recrystallised from 50% EtOH, **m 242-244°** [Dudley *Biochem J* **23** 1069 1929]; other **m** given is 256-257°. The *perchlorate* crystallises from EtOH as prisms **m 116-117°**. [*J Am Pharm Assocn* **36** 272 1947, Beilstein **4** IV 1446.]

**N<sup>4</sup>-Acetylcytosine** [14631-20-0] **M 153.1, m >300°, 326-328°, pK<sub>Est(1)</sub> ~1.7, pK<sub>Est(2)</sub> ~10.0**. If TLC or paper chromatography shows that it contains unacetylated cytosine, then reflux it in Ac<sub>2</sub>O for 4 hours, cool at 3-4° for a few days, collect the crystals, wash them with cold H<sub>2</sub>O, then EtOH and dry at 100°. It is insoluble in EtOH and dissolves in H<sub>2</sub>O with difficulty, but crystallises in prisms from hot H<sub>2</sub>O. It is hydrolysed by 80% aqueous AcOH at 100°/1 hour. [UV: Brown et al. *J Chem Soc* 2384 1956, Codington et al. *J Am Chem Soc* **80** 5164 1958.] It forms an Hg salt [Fox et al. *J Am Chem Soc* **79** 5060 1957]. [Beilstein **25** III/IV 3657.]

**N-Acetylhistamine [N-(2-1{3}H-imidazol-4-yl)ethylacetamide]** [673-49-4] **M 153.2, m 147-148°, 148-149°, pK<sup>25</sup> 6.99**. It is purified by recrystallisation from Et<sub>2</sub>O/EtOH or EtOAc/EtOH (needles), and dried *in vacuo*. It sublimes at 148°/0.05mm. It is slightly soluble in H<sub>2</sub>O and EtOH, soluble in Me<sub>2</sub>CO and very soluble in Et<sub>2</sub>O. The *nitrate* has **m 170°**, the *picrate* is dimorphic with **m 169-171°** (from EtOH/Et<sub>2</sub>O) and **m 181-183°** (from EtOH). [Tabor & Mosettig *J Biol Chem* **80** 703 1949, Nagarajan et al. *Indian J Chem, Sect B* **16** 629, 633 1977, Beilstein **25** II 304, **25** III/IV 2053, **25/9** V 523.]

**O-Acetyl-β-methylcholine chloride [Methacholine chloride, Amechol, Provocholine, 2-acetoxypropylammonium chloride]** [62-51-1] **M 195.7, m 170-173°, 172-173°**. It forms white *hygroscopic* needles from Et<sub>2</sub>O and is soluble in H<sub>2</sub>O, EtOH and CHCl<sub>3</sub>. It decomposes readily in alkaline solutions and slowly in H<sub>2</sub>O. It should be handled and stored in a dry atmosphere. The *bromide* is less *hygroscopic*, and the *picrate* has **m 129.5-131°** (from EtOH). [racemate: Annis & Ely *Biochem J* **53** 34 1953, IR of iodide: Hansen *Acta Chem Scand* **13** 155 1959, Beilstein **4** IV 1670.]

**N-Acetyl neuraminic acid (NANA, O-Sialic acid, 5-acetamido-3,5-dideoxy-D-glycero-D-galacto-2-nonulosonic acid, lactaminic acid)** [131-48-6] **M 309.3, m 159°(dec), 181-183°(dec), 185-187°(dec), [α]<sub>D</sub><sup>25</sup> -33° (c 2, H<sub>2</sub>O), pK<sup>25</sup> 2.6**. A Dowex-1x8 (200-400 mesh) in the formate form is used, and is prepared by

washing with 0.1M NaOH, then 2N sodium formate; excess formate is removed by washing with H<sub>2</sub>O. *N*-Acetylneuraminic acid in H<sub>2</sub>O is applied to this column, washed with H<sub>2</sub>O, then eluted with 2N formic acid at a flow rate of 1ml/minute. Fractions (20ml) are collected and tested (Bial's orcinol reagent, *cf Biochemical Preparations* 7 1 1960). NANA elutes at a formic acid molarity of 0.38, and the Bial positive fractions are collected and lyophilised. The residue is recrystallised from aqueous AcOH: suspend 1.35g of residue in AcOH, heat rapidly to boiling, add H<sub>2</sub>O dropwise until the suspension dissolves (do not add excess H<sub>2</sub>O), filter hot and then keep at +5° for several hours until crystallisation is complete. Collect NANA and dry it in a vacuum over P<sub>2</sub>O<sub>5</sub>. *Alternatively*, dissolve 1.35g of NANA in 14ml of H<sub>2</sub>O, filter, add 160ml of MeOH followed by 360ml of Et<sub>2</sub>O. Then add petroleum ether (b 40-60°) until heavy turbidity. Cool at 20° overnight. The yield of NANA is *ca* 1.3g. Dry it over P<sub>2</sub>O<sub>5</sub> at 100°/1mm to constant weight. It mutarotates in Me<sub>2</sub>SO: [α]<sub>D</sub><sup>20</sup> -115° (after 7 minutes) to -32° (after 24 hours). It is commercially available as an aqueous solution (0.01g/ml). [IR and synthesis: Cornforth et al. *Biochem J* 68 57 1958; Zillikin & O'Brien *Biochemical Preparations* 7 1 1960; <sup>13</sup>C NMR and 1-<sup>13</sup>C synthesis: Nguyen & Perry *J Org Chem* 43 551 1978; Danishefski & DeNinno *J Org Chem* 51 2615 1986; Gottschalk, *The Chemistry and Biology of Sialic Acids and Related Substances*, Cambridge University Press, London, 1960, *Beilstein* 4 IV 3288.]

***N*-Acetyl penicillamine (*N*-acetyl-3-mercapto-D-valine)** [D -15537-71-0, DL -59-53-0] **M 191.3, m 183°, 186-187° (DL-form), 189-190° (D-form), D-form** [α]<sub>D</sub><sup>25</sup>+18° (c 1, 50% EtOH), pK<sub>Est(1)</sub> ~3.0 (CO<sub>2</sub>H), pK<sub>Est(2)</sub> ~8.0 (SH). Both forms are recrystallised from hot H<sub>2</sub>O. A pure sample of the D-form is obtained after five recrystallisations. [Crooks in *The Chemistry of Penicillin* Clarke, Johnson and Robinson eds, Princeton University Press, 470 1949, Review: Chain et al. *Antibiotics* (Oxford University Press) 2 1949, *Beilstein* 4 III 1662.]

***p*-Acetylphenyl sulfate potassium salt**, [38533-41-4] **M 254.3, m dec on heating, pK<sub>Est</sub> ~2.1**. Purify the salt by dissolving it in the minimum volume of hot water (60°) and adding EtOH, with stirring, then leave at 0° for 1 hour. The crystals are filtered off and recrystallised from H<sub>2</sub>O until free of Cl<sup>-</sup> and SO<sub>4</sub><sup>2-</sup> ions. Dry it in a vacuum over P<sub>2</sub>O<sub>5</sub> at room temperature. It is a specific substrate for arylsulfatases which hydrolyse it to *p*-acetylphenol [UV has λ<sub>max</sub> at 327nm (ε 21700 M<sup>-1</sup>cm<sup>-1</sup>)] [Milsom et al. *Biochem J* 128 331 1972].

**S-Acetylthiocholine bromide** [25025-59-6] **M 242.2, m 217-223°(dec)**. It is a *hygroscopic* solid which can be recrystallised from ligroin/EtOH (1:1), dried and kept in a vacuum desiccator. Crystallisation from \*C<sub>6</sub>H<sub>6</sub>/EtOH gives **m** 227° or from propan-1-ol the **m** is 213°. [Hansen *Acta Chem Scand* 11 537 1957, Heilbronn *Acta Chem Scand* 12 1481 1958, *Beilstein* 4 IV 1585.]

**S-Acetylthiocholine chloride** [6050-81-3] **M 197.7, m 172-173°**. The chloride can be purified in the same way as the bromide, and it can be prepared from the iodide. A few milligrams dissolved in H<sub>2</sub>O can be purified by applying onto a Dowex-1 Cl<sup>-</sup> resin column (prepared by washing with N HCl followed by CO<sub>3</sub><sup>2-</sup>-free H<sub>2</sub>O until the pH is 5.8). After equilibration for 10 minutes, elution is started with CO<sub>3</sub><sup>2-</sup>-free distilled H<sub>2</sub>O, and 3ml fractions are collected and their OD values at λ 229nm are measured. The fractions with appreciable absorption are pooled and lyophilised at 0-5°. Note that at higher temperatures decomposition of the ester is appreciable; hydrolysis is appreciable at pH >10.5/20°. The residue is dried *in vacuo* over P<sub>2</sub>O<sub>5</sub>, checked for traces of iodine (add conc H<sub>2</sub>SO<sub>4</sub> and heat, violet vapours are released), and recrystallise it from propan-1-ol. [Gal & Roth *Clin Chim Acta* 2 316 1957, *Beilstein* 4 IV 1585.]

**S-Acetylthiocholine iodide** [1866-15-5] **M 289.2, m 203-204°, 204°, 204-205°**. Recrystallise the iodide from propan-1-ol (or *iso*-PrOH, or EtOH/Et<sub>2</sub>O) until almost colourless and dry it in a vacuum desiccator over P<sub>2</sub>O<sub>5</sub>. Its solubility in H<sub>2</sub>O is 1% w/v. A 0.075M (21.7mg/ml) solution in 0.1M phosphate buffer pH 8.0 is stable for 10-15 days if kept refrigerated. Store it away from light. It is commercially available as a 1% solution in H<sub>2</sub>O. [Ellman et al. *Biochemical Pharmacology* 7, 88 1961, IR: Hansen *Acta Chem Scand* 13 151 1959, 11 537 1957, *Clin Chim Acta* 2 316 1957, Ivin *Zh Obshch Khim* 22 267 1952, *Beilstein* 4 III 726, 4 IV 1585.]

**Actinomycin C (Cactinomycin)** [8052-16-2] **M ~1255**. (A commercial mixture of Actinomycin C<sub>1</sub> ~5%, C<sub>2</sub> ~30% and C<sub>3</sub> ~65% is available). *Actinomycin C<sub>1</sub> (native)* crystallises from EtOAc as red crystals, is soluble in CHCl<sub>3</sub>, \*C<sub>6</sub>H<sub>6</sub> and Me<sub>2</sub>CO, and has **m** 246-247°(dec), [α]<sub>D</sub><sup>20</sup> -328° (0.22, MeOH) and λ<sub>max</sub> 443nm (ε 25,000)

and 240nm ( $\epsilon$  34,000). *Actinomycin C<sub>2</sub> (native)* crystallises as red needles from EtOAc and has **m** 244-246°(dec),  $[\alpha]_{\text{D}}^{20}$  -325° (c 0.2, MeOH),  $\lambda_{\text{max}}$  443nm ( $\epsilon$  25,300) and 240nm ( $\epsilon$  33,400). *Actinomycin C<sub>3</sub> (native)* recrystallises from cyclohexane, or \*C<sub>6</sub>H<sub>6</sub>/MeOH/cyclohexane as red needles with **m** 238-241° (dec),  $[\alpha]_{\text{D}}^{20}$  -321° (c 0.2, MeOH),  $\lambda_{\text{max}}$  443nm ( $\epsilon$  25,000) and 240nm ( $\epsilon$  33,300). [Brockman & Lackner, *Chem Ber* **101** 1312 1968.] It is *light sensitive*. [Beilstein **27** III/IV 9642.]

**Actinomycin D (Dactinomycin)** [50-76-0] **M 1255.5, m 241-243°(dec)**,  $[\alpha]_{\text{D}}^{22}$ -296° (c 0.22, MeOH). It crystallises as bright red rhombic crystals from absolute EtOH or from MeOH/EtOH (1:3). It will also crystallise from EtOAc/cyclohexane (**m** 246-247° dec), CHCl<sub>3</sub>/petroleum ether (**m** 245-246° dec), and EtOAc/MeOH/\*C<sub>6</sub>H<sub>6</sub> (**m** 241-243° dec). Its solubility in MeCN is 1mg/ml.  $[\alpha]_{\text{D}}^{20}$  varies from -296° to -327° (c 0.2, MeOH).  $\lambda_{\text{max}}$  (MeOH) 445, 240nm (log  $\epsilon$  4.43, 4.49),  $\lambda_{\text{max}}$  (MeOH, 10N HCl, 1:1) 477nm (log  $\epsilon$  4.21) and  $\lambda_{\text{max}}$  (MeOH, 0.1N NaOH) 458, 344, 285 (log  $\epsilon$  3.05, 4.28, 4.13). It is **HIGHLY TOXIC**, light sensitive and anti-neoplastic. [Bullock & Johnson, *J Chem Soc* 3280 1957, Beilstein **27** III/IV 9642.]

**Adenosine-5'-diphosphate [adenosine-5'-pyrophosphate, ADP]** [58-64-0] **M 427.2,  $[\alpha]_{\text{D}}^{25}$  -25.7° (c 2, H<sub>2</sub>O), pK<sub>1</sub><sup>25</sup> <2 (PO<sub>4</sub>H), pK<sub>2</sub><sup>25</sup> <2 (PO<sub>4</sub>H), pK<sub>3</sub><sup>25</sup> 3.95 (NH<sub>2</sub>), pK<sub>4</sub><sup>25</sup> 6.26 (PO<sub>4</sub>H)**. It is characterised by conversion to the *acridine salt* by addition of alcoholic acridine (1.1g in 50ml), filtering off the yellow salt and recrystallising from H<sub>2</sub>O. The salt has **m** 215°(dec), UV with  $\lambda_{\text{max}}$  at 259nm ( $\epsilon$  15,400) in H<sub>2</sub>O. [Baddiley & Todd *J Chem Soc* 648 1947, 582 1949, cf LePage *Biochemical Preparations* **1** 1 1949, Martell & Schwarzenbach *Helv Chim Acta* **39** 653 1956]. [Beilstein **26** III/IV 2369.]

**Adenosine-3'-monophosphoric acid hydrate [3'-adenylic acid, 3'-AMP]** [84-21-9] **M 347.3, m 197°(dec, as 2H<sub>2</sub>O), 210°(dec), m 210°(dec)**,  $[\alpha]_{546} -50°$  (c 0.5, 0.5M Na<sub>2</sub>HPO<sub>4</sub>), **pK<sub>1</sub><sup>25</sup> 3.65, pK<sub>2</sub><sup>25</sup> 6.05**. It crystallises from large volumes of H<sub>2</sub>O in needles as the *monohydrate*, but is not very soluble in boiling H<sub>2</sub>O. Under acidic conditions it forms an equilibrium mixture of 2' and 3' adenylic acids *via* the 2',3'-cyclic phosphate. When heated with 20% HCl, it gives a quantitative yield of furfural after 3 hours, unlike 5'-adenylic acid which only gives traces of furfural. The yellow *monoacridine salt* has **m** 175°(dec), and the *diacridine salt* has **m** 177° (225°)(dec). [Brown & Todd *J Chem Soc* 44 1952, Takaku et al. *Chem Pharm Bull Jpn* **21** 1844 1973, NMR: Ts' O et al. *Biochemistry* **8** 997 1969, Beilstein **26** III/IV 3607.]

**Adenosine-5'-monophosphoric acid monohydrate [5'-adenylic acid, 5'-AMP]** [18422-05-4] **M 365.2, m 178°, 196-200°, 200° (sintering at 181°)**,  $[\alpha]_{\text{D}}^{20}$  -47.5°,  $[\alpha]_{546} -56°$  (c 2, in 2% NaOH), -26.0° (c 2, 10% HCl), -38° (c 1, 0.5M Na<sub>2</sub>HPO<sub>4</sub>), **pK<sub>1</sub><sup>25</sup> 3.89, pK<sub>2</sub><sup>25</sup> 6.14, pK<sub>3</sub><sup>25</sup> 13.1**. The acid has been recrystallised from H<sub>2</sub>O (fine needles) and is freely soluble in boiling H<sub>2</sub>O. It crystallises also from H<sub>2</sub>O on addition of acetone. *Alternatively*, purify it by chromatography on Dowex 1 (in formate form), eluting with 0.25M formic acid. It is then adsorbed onto charcoal (which had been boiled for 15 minutes with M HCl, washed free of chloride and dried at 100°) and recovered by stirring three times with isoamyl alcohol/H<sub>2</sub>O (1:9 v/v). The aqueous layer from the combined extracts is evaporated to dryness under reduced pressure, and the product is crystallised twice from hot H<sub>2</sub>O. [Morrison & Doherty *Biochem J* **79** 433 1961]. It has UV with  $\lambda_{\text{max}}$  at 259nm ( $\epsilon$  15,400) in H<sub>2</sub>O at pH 7.0. [Alberty et al. *J Biol Chem* **193** 425 1951, Martell & Schwarzenbach *Helv Chim Acta* **39** 653 1956]. The *acridinium salt* has **m** 208° [Baddiley & Todd *J Chem Soc* 648 1947, Pettit *Synthetic Nucleotides*, van Nostrand-Reinhold, NY, **Vol 1** 252 1972, NMR: Sarma et al. *J Am Chem Soc* **96** 7337 1974, Norton et al. *J Am Chem Soc* **98** 1007 1976, IR of *diNa salt*: Miles *Biochem Biophys Acta* **27** 324 1958]. [Beilstein **26** III/IV 3615.]

**Adenosine 5'-[ $\beta$ -thio]diphosphate tri-lithium salt** [73536-95-5] **M 461.1**. Purify it by ion-exchange chromatography on DEAE-Sephadex A-25 using gradient elution with 0.1-0.5M triethylammonium bicarbonate. [Goody et al. *Biochem Biophys Acta* **276** 155 1972.]

**Adenosine 5'-[ $\alpha$ -thio]monophosphate di-lithium salt** [19341-57-2] **M 375.2**. Purify it as for the diNa salt [Murray & Atkinson *Biochemistry* **7** 4023 1968]. Dissolve 0.3g in dry MeOH (7ml) and 1M LiI (6ml) in dry Me<sub>2</sub>CO containing 1% of mercaptoethanol, and the Li salt is precipitated by adding Me<sub>2</sub>CO (75ml). The residue is washed with Me<sub>2</sub>CO (4 x 30ml) and dried at 55°/25mm. It has UV with  $\lambda_{\text{max}}$  at (HCl, pH 1.2) 257nm ( $\epsilon$  14,800); (0.015M NaOAc, pH 4.8) 259nm ( $\epsilon$  14,800); and (0.015M NH<sub>4</sub>OH, pH 10.1) 259nm ( $\epsilon$  15,300).

**Adenosine-5'-triphosphate (ATP)** [56-65-5] M 507.2,  $[\alpha]_{546}^{25} -35.5$  (c 1, 0.5 M Na<sub>2</sub>HPO<sub>4</sub>), pK<sub>1</sub><sup>25</sup> 4.00, pK<sub>2</sub><sup>25</sup> 6.48. ATP is purified by precipitating it as the barium salt on adding excess barium acetate solution to a 5% solution of ATP in water. The precipitate is filtered off, washed with distilled water, dissolved in 0.2M HNO<sub>3</sub> and again precipitated with barium acetate. The precipitate, after several washings with distilled water, is redissolved in 0.2M HNO<sub>3</sub>, and slightly more than an equivalent of 0.2M H<sub>2</sub>SO<sub>4</sub> is added to precipitate all the barium as BaSO<sub>4</sub> which is filtered off. The ATP is then precipitated by addition of a large excess of 95% ethanol. It is filtered off, washed several times with 100% EtOH and finally with dry diethyl ether. It is dried *in vacuo*. [Kashiwagi & Rabinovitch *J Phys Chem* 59 498 1955, *Beilstein* 26 III/IV 3654.]

**S-(5'-Adenosyl)-L-homocysteine** [979-92-0] M 384.4, m 202<sup>o</sup>(dec), 204<sup>o</sup>(dec), 205-207<sup>o</sup>(dec),  $[\alpha]_{D}^{25} +93^{\circ}$  (c 1, 0.2N HCl),  $[\alpha]_{D}^{23} +44^{\circ}$  (c 0.1, 0.05N HCl), (pK see SAM hydrochloride below). It has been recrystallised several times from aqueous EtOH or H<sub>2</sub>O to give small prisms and the UV has  $\lambda_{max}$  at 260nm in H<sub>2</sub>O. The *picrate* has m 170<sup>o</sup>(dec) from H<sub>2</sub>O. [Baddiley & Jamieson *J Chem Soc* 1085 1955, de la Haba & Cantoni *J Biol Chem* 234 603 1959, Borchardt et al. *J Org Chem* 41 565 1976, NMR: Follmann et al. *Eur J Biochem* 47 187 1974, *Beilstein* 26 III/IV 3676.]

**(-)-S-Adenosyl-L-methionine chloride (SAM hydrochloride)** [24346-00-7] M 439.9, pK<sub>Est(1)</sub>~ 2.13, pK<sub>Est(2)</sub>~ 4.12, pK<sub>Est(3)</sub>~ 9.28. Purify it by ion exchange on Amberlite IRC-150 and eluting with 0.1-4M HCl. [Stolowitz & Minch *J Am Chem Soc* 103 6015 1981.] It has been isolated as the tri-reineckate salt by adding 2 volumes of 1% solution of ammonium reineckate in 2% perchloric acid. The reineckate salt separates at once but is kept at 2<sup>o</sup> overnight. The salt is collected on a sintered glass funnel, washed with 0.5% of ammonium reineckate, dried (all operations at 2<sup>o</sup>) and stored at 2<sup>o</sup>. To obtain adenosylmethionine, the reineckate is dissolved in a small volume of methyl ethyl ketone (MEK) and centrifuged at room temperature to remove a small amount of solid. The clear dark red supernatant is extracted (in a separating funnel) with a slight excess of 0.1N H<sub>2</sub>SO<sub>4</sub>. The aqueous phase is re-extracted with fresh MEK until it is colourless. [Note that reineckates have UV absorption at 305nm ( $\epsilon$  15,000), and the optical density at 305nm is used to detect and estimate reineckate ions.] MEK is removed from the aqueous layer containing adenosylmethionine sulfate; the pH is adjusted to 5.6-6.0 and extracted with two volumes of Et<sub>2</sub>O. The *sulfate* is obtained by evaporating the aqueous layer *in vacuo*. The *hydrochloride* can be obtained in the same way but using HCl instead of H<sub>2</sub>SO<sub>4</sub>. SAM-HCl has a solubility of 10% in H<sub>2</sub>O. The salts are stable in the cold at pH 4-6 but decompose in alkaline media. [Cantoni *Biochemical Preparations* 5 58 1957.] The purity of SAM can be determined by paper chromatography [Cantoni *J Biol Chem* 204 403 1953, *Methods Enzymol* 3 601 1957], electrophoretic methods or enzymic analysis [Cantoni & Vignos *J Biol Chem* 209 647 1954]. [*Beilstein* 26 III/IV 3676.]

**L-Adrenaline** [*R*-(-)-epinephrine, L(-)-(3,4-dihydroxyphenyl)-2-methylaminoethanol] [51-43-4] M 183.2, m 210<sup>o</sup>(dec), 211<sup>o</sup>(dec), 211-212<sup>o</sup>(dec), 215<sup>o</sup>(dec),  $[\alpha]_{546}^{20} -61^{\circ}$  (c 5, 0.5M HCl),  $[\alpha]_{D}^{20} -52^{\circ}$  (c 2, 5% HCl), pK<sub>1</sub><sup>25</sup> 8.88 (8.75), pK<sub>2</sub><sup>25</sup> 9.90 (9.89), pK<sub>3</sub><sup>25</sup> 12.0 (~13). L-Adrenaline has been recrystallised from EtOH/AcOH/NH<sub>3</sub> [Jensen *J Am Chem Soc* 57 1765 1935]. It is sparingly soluble in H<sub>2</sub>O, readily in acidic or basic solutions but insoluble in aqueous NH<sub>3</sub>, alkali carbonate solutions, EtOH, CHCl<sub>3</sub>, Et<sub>2</sub>O or Me<sub>2</sub>CO. It has also been purified by dissolving in dilute aqueous acid, then precipitating it by adding dilute aqueous ammonia or alkali carbonates. It is readily oxidised in air and turns brown on exposure to light and air. (Epinephrine readily oxidises in neutral alkaline solution. This can be diminished if a little sulfite is added). Store it in the dark under N<sub>2</sub>. [Lewis *Br J Pharmacol Chemother* 9 488 1954]. The *hydrogen oxalate salt* has m 191-192<sup>o</sup>(dec, evacuated capillary) after recrystallisation from H<sub>2</sub>O or EtOH [Pickholz *J Chem Soc* 928 1945]. [*Beilstein* 13 H 830, 13 III/IV 2927.]

**Adrenolone hydrochloride** [3',4'-dihydroxy-2-methylaminoacetophenone hydrochloride] [62-13-5] M 217.7, m 244-249<sup>o</sup>(dec), 248<sup>o</sup>(dec), 256<sup>o</sup>(dec), pK<sub>25</sub> 5.5. It is purified by recrystallisation from EtOH or aqueous EtOH. [Gero *J Org Chem* 16 1222 1951, Kindler & Peschke *Arch Pharm* 269 581, 603 1931, *Beilstein* 14 IV 832.]

**Amethopterin (Methotrexate, 4-amino-4-deoxy-N<sup>10</sup>-methylpteroyl-L-glutamic acid)** [59-05-2] M 454.4, m 185-204<sup>o</sup>(dec),  $[\alpha]_{D}^{20} +19^{\circ}$  (c 2, 0.1N aqueous NaOH), pK<sub>1</sub> <0.5 (pyrimidine<sup>2+</sup>), pK<sub>2</sub> 2.5 (N5-Me<sup>+</sup>), pK<sub>3</sub> 3.49 ( $\alpha$ -CO<sub>2</sub>H), pK<sub>4</sub> 4.99 ( $\gamma$ -CO<sub>2</sub>H), pK<sub>5</sub> 5.50 (pyrimidine<sup>+</sup>). Most common impurities are 10-methylpteroyl-

glutamic acid, aminopterin and pteroylglutamic acid. Purify it by chromatography on Dowex-1 acetate, followed by filtration through a mixture of cellulose and charcoal. It has been recrystallised from aqueous HCl or by dissolution in the minimum volume of N NaOH and acidified until precipitation is complete, filter or *better* collect by centrifugation, wash with H<sub>2</sub>O (also by centrifugation) and dry at 100°/3mm. It has UV with  $\lambda_{\max}$  at 244 and 307nm ( $\epsilon$  17,300 and 19,700) in H<sub>2</sub>O at pH 1; 257, 302 and 370nm ( $\epsilon$  23,000, 22,000 and 7100) in H<sub>2</sub>O at pH 13. [Momle *Biochemical Preparations* **8** 20 1961, Seeger et al. *J Am Chem Soc* **71** 1753 1949.] It is a potent inhibitor of dihydrofolate reductase and is used in cancer chemotherapy. [Blakley *The Biochemistry of Folic Acid and Related Pteridines*, North-Holland Publ Co., Amsterdam, NY, pp157-163 1969, *Beilstein* **26** IV 3833.] It is **CARCINOGENIC; HANDLE WITH EXTREME CARE.**

**Aminopterin (4-amino-4-deoxypteroyl-L-glutamic acid)** [54-62-6] **M 440.4, m 231-235°(dec)**,  $[\alpha]_D^{20} +18^\circ$  (c 2, 0.1N aqueous NaOH), **pK<sub>1</sub> <0.5** (pyrimidine<sup>2+</sup>), **pK<sub>2</sub> 2.5** (N5-Me<sup>+</sup>), **pK<sub>3</sub> 3.49** ( $\alpha$ -CO<sub>2</sub>H), **pK<sub>4</sub> 4.65** ( $\gamma$ -CO<sub>2</sub>H), **pK<sub>5</sub> 5.50** (pyrimidine<sup>+</sup>). Purify aminopterin by recrystallisation from H<sub>2</sub>O. It has properties similar to those of methotrexate (above). It has UV at  $\lambda_{\max}$  244, 290 and 355nm ( $\epsilon$  18600, 21300 and 12000) in H<sub>2</sub>O at pH 1; 260, 284 and 370nm ( $\epsilon$  28500, 26400 and 8600) in H<sub>2</sub>O at pH 13. [Seeger et al. *J Am Chem Soc* **71** 1753 1949, Angier & Curran *J Am Chem Soc* **81** 2814 1959, Blakley *The Biochemistry of Folic Acid and Related Pteridines*, North-Holland Publ Co., Amsterdam, NY, pp 157-163 1969.] For small quantities, chromatograph it on DEAE cellulose with a linear gradient of ammonium bicarbonate pH 8 and increase the molarity from 0.1 to 0.4. Monitoring is by following the UV absorption of the fractions. For larger quantities, a near boiling solution of aminopterin (5g) in H<sub>2</sub>O (400ml) is slowly treated with small portions of MgO powder (~0.7g, calcined magnesia) with vigorous stirring until a small amount of MgO remained undissolved and the pH rises from 3-4 to 7-8. Charcoal (1g) is added to the hot solution and filtered immediately through a large sintered glass funnel of medium porosity and lined with a hot wet pad of Celite (~2-3 mm thick). The filtrate is cooled in ice, and the crystals of the Mg salt are collected by filtration and recrystallised from boiling H<sub>2</sub>O (200ml). The crystals are washed with EtOH and dried *in vacuo*. The Mg salt is redissolved in boiling H<sub>2</sub>O (200ml) and carefully acidified with vigorous agitation with AcOH (2ml). Pure aminopterin (3g) separates in fine yellow needles (dihydrate) which are easily filtered. The solid is washed with cold H<sub>2</sub>O, then Me<sub>2</sub>CO and dried *in vacuo*. If a trace of impurity is still present as shown by DEAE cellulose chromatography or TLC, repetition of the process will remove it; see UV above. [Loo *J Med Chem* **8** 139 1965, *Beilstein* **26** IV 3831.] **CARCINOGENIC.**

**3-Aminopyridine adenine dinucleotide** [21106-96-7] **M 635.4** (see **NAD for pK**). Purify it by ion-exchange chromatography as described [Fisher et al. *J Biol Chem* **248** 4293 1973, Anderson & Fisher *Methods Enzymol* **66** 81 1980].

**Anion exchange resins.** These should be conditioned before use by successive washing with water, EtOH and water, and taken through two OH<sup>-</sup>—H<sup>+</sup>—OH<sup>-</sup> cycles by successive treatment with N NaOH, water, N HCl, water and N NaOH, then washed with water until neutral to give the OH<sup>-</sup> form. (See commercial catalogues on ion-exchange resins.)

**Aniracetam (1-[4-methoxybenzyl]-2-pyrrolidinone)** [72432-10-1] **M 219.1, m 121-122°**. Purify aniracetam by recrystallisation from EtOH. It is a nootropic (Alzheimer) drug. [Gouliarov & Senning *Brain Research Rev* **19** 180 1994.]

**Apocodeine** [641-36-1] **M 281.3, m 124°, pK<sub>Est(1)</sub> ~ 7.0, pK<sub>Est(2)</sub> ~ 8.2**. Crystallise apocodeine from absolute EtOH by boiling and allowing to stand at 0° to give the alcoholate, **m 104.5-106.5°**; EtOH is lost slowly at 25°/2mm but readily at 78°/2mm, and the anhydrous base has **m 122.5-124.5°**. It is soluble in Et<sub>2</sub>O. [Folkers *J Am Chem Soc* **58** 1814 1936.] It has also been crystallised from MeOH or MeOH with a little CH<sub>2</sub>Cl<sub>2</sub> as a waxy solid and dried at 80°/2mm. It softens above 100° before melting and is sensitive to air and light. The *hydrochloride*, which is formed from the base in EtOH containing an equivalent amount of HCl followed by addition of Et<sub>2</sub>O, is recrystallised from 95% EtOH and adding Et<sub>2</sub>O until crystals separate. It melts at 260-263° (dec, with softening at 140°) and has  $[\alpha]_D^{20} -41.3^\circ$  to  $-43.3^\circ$  (c 0.81, H<sub>2</sub>O). [Neumyer et al. *J Med Chem* **16** 1223 1973.]

**R-Apomorphine** [58-00-4] M 267.3, m 195°(dec), pK<sub>1</sub><sup>15</sup> 7.20 (NH<sub>2</sub>), pK<sub>2</sub><sup>15</sup> 8.91 (phenolic OH). Crystallise R-apomorphine from CHCl<sub>3</sub> and a little petroleum ether, also from Et<sub>2</sub>O with 1 mol of Et<sub>2</sub>O which it loses at 100°. It sublimes in a high vacuum. It is white but turns green in moist air or in alkaline solution. Its UV has λ<sub>max</sub> at 336, 399 (98% EtOH). The *di-O-methylether* is an oil b 175°/high vacuum, whose *picrate* crystallises from MeOH and has m 140° (dec). The *di-O-acetate* crystallises from EtOAc/petroleum ether with m 127-128°, [α]<sub>D</sub><sup>25</sup> -88° (c 1, 0.1 N HCl). The *di-O-benzoyl* derivative has m 156-158° (from EtOH) and [α]<sub>D</sub><sup>18</sup> +43.44° (c 3.3, CHCl<sub>3</sub>). [Pachorr et al. *Chem Ber* 35 4377 1902, *Beilstein* 21 H 246.] **NARCOTIC.**

**R-Apomorphine hydrochloride** [41372-20-7] M 312.8, m 285-287°(dec), [α]<sub>D</sub><sup>20</sup> -48° (c 1, H<sub>2</sub>O). Crystallise the salt from H<sub>2</sub>O (*hemihydrate*) and from EtOH. Crystals turn green on exposure to light. (see previous entry). **NARCOTIC.**

**Aureomycin (7-chlorotetracycline)** [57-62-5] M 478.5, m 172-174°(dec), [α]<sub>D</sub><sup>23</sup> -275° (MeOH), pK<sub>1</sub> 3.3, pK<sub>2</sub> 7.44, pK<sub>3</sub> 9.27. Aureomycin is dehydrated by azeotropic distillation of its solution with toluene. On cooling, the anhydrous material crystallises out and is recrystallised from \*C<sub>6</sub>H<sub>6</sub>, then dried under vacuum at 100° over paraffin wax. (If it is crystallised from MeOH, it contains MeOH which is not removed on drying.) [Stephens et al. *J Am Chem Soc* 76 3568 1954, Laskin & Chan *Biochem Biophys Res Commun* 14 137 1964]. [*Beilstein* 14 IV 2631.]

**Aureomycin hydrochloride (7-chlorotetracycline hydrochloride)** [64-72-2] M 514.0, m 234-236°(dec), [α]<sub>D</sub><sup>25</sup> -23.5° (H<sub>2</sub>O). Purify the salt by dissolving 1g rapidly in 20ml of hot water, cooling rapidly to 40°, treating with 0.1ml of 2M HCl, and chilling in an ice-bath. The process is repeated twice. It is also recrystallised from Me<sub>2</sub>NCHO/Me<sub>2</sub>CO. [Stephens et al. *J Am Chem Soc* 76 3568 1954, UV: McCormick et al. *J Am Chem Soc* 79 2849 1957, *Beilstein* 14 IV 2631.]

**Bacitracin (Altracin, Topitracin)** [1405-87-4] M 1422.7, [α]<sub>D</sub><sup>23</sup> +5° (H<sub>2</sub>O). Bacitracin has been purified by carrier displacement using *n*-heptanol, *n*-octanol and *n*-nonanol as carriers and 50% EtOH in 0.1 N HCl. The pure material gives one spot with R<sub>F</sub> ~0.5 on paper chromatography using AcOH:*n*-BuOH:H<sub>2</sub>O (4:1:5). [Porath *Acta Chem Scand* 6 1237 1952.] It has also been purified by ion-exchange chromatography. It is a white powder soluble in H<sub>2</sub>O and EtOH but insoluble in Et<sub>2</sub>O, CHCl<sub>3</sub> and Me<sub>2</sub>CO. It is stable in acidic solution but unstable in base. It is a strong antibacterial. [Abraham & Bewton *Biochem J* 47 257 1950, Synthesis: Munekata et al. *Bull Chem Soc Jpn* 46 3187, 3835 1973, *Beilstein* 27 III/IV 5746.]

**N<sup>6</sup>-Benzyladenosine** [4294-16-0] M 357.4, m 177-179°, 185-187°, [α]<sub>D</sub><sup>25</sup> -68.6° (c 0.6, EtOH)(see pK of adenosine). Purify it by recrystallisation from EtOH. It has UV with λ<sub>max</sub> at 266nm (aqueous EtOH/HCl) and 269 nm (aqueous EtOH/NaOH). [Kissman & Weiss *J Org Chem* 21 1053 1956, *Beilstein* 26 III/IV 3682.]

**N-Benzylpenicillin sodium salt (penicillin G Na salt)** [69-57-8] M 356.37, m 215° (charring and dec), 225° (dec), [α]<sub>D</sub><sup>20</sup> +269° (c 0.7, MeOH), [α]<sub>D</sub><sup>25</sup> +305° (c 1, H<sub>2</sub>O), pK<sup>25</sup> 2.76 (4.84 in 80% aqueous EtOH)(for free acid). Purify the salt by dissolving it in a small volume of MeOH (in which it is more soluble than EtOH) and treating gradually with ~5 volumes of EtOAc. This gives an almost colourless crystalline solid (rosettes of clear-cut needles) and recrystallising twice more if slightly yellow in colour. The salt has also been conveniently recrystallised from the minimum volume of 90% Me<sub>2</sub>CO and adding an excess of absolute Me<sub>2</sub>CO. A similar procedure can be used with wet *n*-BuOH. If yellow in colour, then dissolve (~3.8g) in the minimum volume of H<sub>2</sub>O (3ml), add *n*-BuOH and filter through a bed of charcoal. The salt forms long white needles on standing in a refrigerator overnight. More crystals can be obtained on concentrating the mother liquors *in vacuo* at 40°. <sup>3</sup>A further recrystallisation (without charcoal) yields practically pure salt. A good preparation has ~600 Units/mg. The presence of H<sub>2</sub>O in the solvents increases the solubility considerably. The solubility in mg/100ml at 0° is 6.0 (Me<sub>2</sub>CO), 15.0 (Me<sub>2</sub>CO/0.5% H<sub>2</sub>O), 31.0 (Me<sub>2</sub>CO/1.0% H<sub>2</sub>O), 2.4 (methyl ethyl ketone), 81.0 (*n*-butanol) and 15.0 (dioxane at 14°). *Alternatively*, it is dissolved in H<sub>2</sub>O (solubility is ~10%), filtered if necessary and precipitated by addition of EtOH and dried in a vacuum over P<sub>2</sub>O<sub>5</sub>. A sample can be kept for 24 hours at 100° without loss of physiological activity. It also crystallises from MeOH/EtOAc. [IR: Barnes et al. *Anal Chem* 19 620 1947, *The Chemistry of Penicillin* (Clarke, Johnson and Robinson eds.) Princeton University Press,

Princeton NJ, Chapter V 85 1949, *Beilstein* 27 III/IV 5861.]

Other salts, e.g. the **potassium salt** (M 372.5 [113-58-4]) can be prepared from the Na salt by dissolving it (147mg) ice-cold in H<sub>2</sub>O acidified to pH 2, extracting with Et<sub>2</sub>O (~50ml), washing once with H<sub>2</sub>O, and extracting with 2ml portions of 0.3% KHCO<sub>3</sub> until the pH of the extract rises to ~6.5 (~7 extractions). The combined aqueous extracts are lyophilised, and the white residue is dissolved in *n*-BuOH (1ml, absolute) with the addition of enough H<sub>2</sub>O to effect solution. Remove insoluble material by centrifugation and add absolute *n*-BuOH to the supernatant. Crystals should separate on scratching, and after 2.5 hours in a refrigerator they are collected, washed with absolute *n*-BuOH and EtOAc and dried (yield 51.4mg). It also crystallises from aqueous Me<sub>2</sub>CO. The *potassium salt* has **m** 214-217° (dec) (block preincubated at 200°; heating rate of 3°/min) and  $[\alpha]_{\text{D}}^{22} +285^{\circ}$  (c 0.748, H<sub>2</sub>O). [*Beilstein* 27 III/IV 5861.]

The **free acid (penicillin G)** (M 334.5, [61-33-6]) has **m** 186-187° (MeOH/Me<sub>2</sub>CO), and **m** 190-191° (H<sub>2</sub>O)  $[\alpha]_{\text{D}}^{25} +282^{\circ}$  (EtOH). [Review: Sheehan & Henery-Logan *J Am Chem Soc* 84 2983 1962, Chain et al. *Antibiotics* (Oxford University Press) 2 1949, and Cook *Quarterly Reviews (Chemical Society)* 2 46 1948.]

**Bergapten (5-methoxypsoralen)** [484-20-8] **M 216.2, m 190-193°, 191-193°**. Crystallise it from EtOH or aqueous MeOH, and it sublimes *in vacuo*. Its properties are similar to those of its 9-methoxy isomer (xanthotoxin, see below). It is slightly soluble in \*C<sub>6</sub>H<sub>6</sub>, CHCl<sub>3</sub> and AcOH but insoluble in H<sub>2</sub>O. Its fluorescence has  $\lambda_{\text{ex}}$  at 352nm with  $\lambda_{\text{em}}$  at 480nm. It is a DNA intercalator and **possible carcinogen**. [Howell & Robertson *J Chem Soc* 293 1937, Boyer et al. *Biochemistry* 27 3011 1988, *Beilstein* 19/6 V 4.]

**(+)-Bicuculine** [*R*-6(5,6,7,8-tetrahydro-6-methyl-1,3-dioxolo[4,5-*g*]isoquinolin-5-yl)-furo-[3,4-*c*]-1,3-benzodioxolo-8(6*H*)-one] [485-49-4] **M 367.4, m 177°, 193-195°, 193-197°, 215°,  $[\alpha]_{\text{D}}^{20} +126^{\circ}$  (c 1, CHCl<sub>3</sub>),  $[\alpha]_{\text{D}}^{20} +159^{\circ}$  (c 1, CHCl<sub>3</sub>), pK<sup>25</sup> 4.84**. It crystallises from CHCl<sub>3</sub>/MeOH as plates. The crystals melt at 177°, then solidify and re-melt at 193-195° [Manske *Canad J Research* 21B 13 1943]. It is soluble in CHCl<sub>3</sub>, \*C<sub>6</sub>H<sub>6</sub>, EtOAc but sparingly soluble in EtOH, MeOH and Et<sub>2</sub>O. [Stereochem: Blaha et al. *Col Czech Chem Commun* 29 2328 1964, Snatzke et al. *Tetrahedron* 25 5059 1969, Pharmacol: Curtis et al. *Nature* 266 1222 1970, *Beilstein* 27 III/IV 1900].

**L-erythro-Biopterin** (2-amino-4-hydroxy-6-[(1*R*,2*S*)-1,2-dihydroxypropyl]pteridine) [22150-76-1] **M 237.2, m >300°(dec),  $[\alpha]_{\text{D}}^{20} -80^{\circ}$ ,  $[\alpha]_{\text{D}}^{20} -65^{\circ}$  (c 2.0, M HCl), pK<sup>25</sup> 2.23(2.45), pK<sup>25</sup> 7.89(8.05)**. Purify L-erythro-biopterin by chromatography on Florisil, which was washed thoroughly with 2M HCl, and elute with 2M HCl. The fractions with UV-fluorescence are pooled, evaporated *in vacuo* and the residue recrystallised. Biopterin is best recrystallised (90% recovery) by dissolving in 1% aqueous NH<sub>3</sub> (*ca* 100 parts), and adding this solution dropwise to an equal volume of M aqueous formic acid at 100° and allowing to cool at 4° overnight. It is dried at 20° to 50°/0.1mm in the presence of P<sub>2</sub>O<sub>5</sub>. [Schircks et al. *Helv Chim Acta* 60 211 1977, Armarego et al. *Aust J Chem* 35 785 1982.] It also crystallises from *ca* 50 parts of water or 100 parts of hot 3M aqueous HCl by adding hot 3M aqueous NH<sub>3</sub> and cooling. It has UV with  $\lambda_{\text{max}}$  at 212, 248 and 321nm (log  $\epsilon$  4.21, 4.09 and 3.94) in H<sub>2</sub>O at pH 0.0; 223infl, 235.5, 274.5 and 345nm (log  $\epsilon$  4.07infl, 4.10, 4.18 and 3.82) in H<sub>2</sub>O at pH 5.0; 221.5, 254.5 and 364nm (log  $\epsilon$  3.92, 4.38 and 3.84) in H<sub>2</sub>O at pH 10.0. [Sugimoto & Matsuura *Bull Chem Soc Jpn* 48 3767 1875, *Beilstein* 26 III/IV 4032.]

**D-(+)-Biotin (vitamin H, hexahydro-2-oxo-1*H*-thieno[3,4-*d*]imidazole-4-pentanoic acid)** [58-85-5] **M 244.3, m 229-231°, 230.2°(dec), 230-231°, 232-234°(dec),  $[\alpha]_{\text{D}}^{20} +108^{\circ}$ ,  $[\alpha]_{\text{D}}^{20} +91.3^{\circ}$  (c 1, 0.1N NaOH), pK<sub>Est</sub> ~ 4.8**. D-(+)-Biotin crystallises from hot water in fine long needles with a solubility of 22 mg/100ml at 25°. Its solubility in 95% EtOH is 80 mg/100 ml at 25°. Its isoelectric point is at pH 3.5. Store solid and solutions under sterile conditions because it is susceptible to mould growth. [Confalone *J Am Chem Soc* 97 5936 1975, Wolf et al. *J Am Chem Soc* 67 2100 1945, Synthesis: Ohuri & Emoto *Tetrahedron Lett* 2765 1975, Harris et al. *J Am Chem Soc* 66 1756 1944.] The (+)-*methyl ester* has **m** 166-167° (from MeOH/Et<sub>2</sub>O),  $[\alpha]_{\text{D}}^{22} +57^{\circ}$  (c 1, CHCl<sub>3</sub>) [du Vigneaud et al. *J Biol Chem* 140 643, 763 1941]; the (+)-*S-oxide* has **m** 200-203°,  $[\alpha]_{\text{D}}^{20} +130^{\circ}$  (c 1.2, 0.1N NaOH) [Melville *J Biol Chem* 208 495 1954]; the *SS-dioxide* has **m** 274-275°(dec, 268-270°), and the *SS-dioxide methyl ester* has **m** 239-241° (from MeOH/Et<sub>2</sub>O) [Hofmann et al. *J Biol Chem* 141 207, 213 1941]. [*Beilstein* 27 III/IV 7979.]

**D-(+)-Biotin hydrazide** [66640-86-6] M 258.4, m 238-240°, 245-247°,  $[\alpha]_D^{20} +66^\circ$  (c 1, Me<sub>2</sub>NCHO). Wash the hydrazide with H<sub>2</sub>O, dry it, wash it with MeOH then Et<sub>2</sub>O, and dry. Recrystallise it from hot H<sub>2</sub>O (clusters of prisms) [Hofmann et al. *J Biol Chem* **144** 513 1942]. [Beilstein **27** III/IV 7980.]

**D-(+)-Biotin N-hydroxysuccinimide ester (+-biotin N-succinimidyl ester)** [35013-72-0] M 342.4, m 210°, 212-214°,  $[\alpha]_D^{20} +53^\circ$  (c 1, Me<sub>2</sub>NCHO). Recrystallise the ester from refluxing isoPrOH and dry it in a vacuum over P<sub>2</sub>O<sub>5</sub> + KOH. [Jasiewicz et al. *Exp Cell Biol* **100** 213 1976.]

**D-(+)-Biotin 4-nitrophenyl ester** [33755-53-2] M 365.4, m 160-163°, 163-165°,  $[\alpha]_D^{25} +47^\circ$  (c 2, Me<sub>2</sub>NCHO containing 1% AcOH). The ester has been recrystallised by dissolving 2g in 95% EtOH (30ml), heated to dissolve, then cooled in an ice-water bath. The crystals are collected, washed with ice-cold 95% EtOH (5ml) and dried over P<sub>2</sub>O<sub>5</sub>. The R<sub>F</sub> on silica plates (CHCl<sub>3</sub>/MeOH 19:1) is 0.19 [Bodanszky & Fagan *J Am Chem Soc* **99** 235 1977].

**N-(+)-Biotinyl-4-aminobenzoic acid** [6929-40-4] M 363.4, m 295-297°, 295-300°,  $[\alpha]_D^{23} +56.55^\circ$  (c 0.5, 0.1N NaOH), pK<sub>Est</sub> ~4.0. Dissolve the acid in NaHCO<sub>3</sub> solution, cool and precipitate it by adding N HCl. Collect the solid, dry it at 100° and recrystallise it from MeOH. Note that it is hydrolysed by aqueous 3M, 1M and 0.2M HCl at 120°, but can be stored in 5% aqueous NaHCO<sub>3</sub> at -20° without appreciable hydrolysis [Knappe et al. *Biochem Zeitschrift* **338** 599 1963, Wolf et al. *J Am Chem Soc* **73** 4142 1951, Bayer & Wilchek *Methods Enzymol* **26** 1 1980]. [Beilstein **27** III/IV 7984.]

**N-Biotinyl-6-aminocaproic N-succinimidyl ester** [72040-63-2] M 454.5, m 149-152°. Dissolve ~400mg of the ester in dry propan-2-ol (~25ml) with gentle heating. Reduce the volume to ~10ml by gentle boiling and allow the solution to cool. Decant the supernatant carefully from the white crystals, dry the crystals in a vacuum over P<sub>2</sub>O<sub>5</sub> at 60° overnight. This material gives one spot on TLC. [Costello et al. *Clin Chem* **25** 1572 1979, Kincaid et al. *Methods Enzymol* **159** 619 1988.]

**N-(+)-Biotinyl-6-aminocaproyl hydrazide (biotin-6-aminohexanoic hydrazide)** [109276-34-8] M 371.5, m 189-191°, 210°,  $[\alpha]_D^{20} +23^\circ$  (c 1, Me<sub>2</sub>NCHO). Suspend the hydrazide in ice-water (100mg/ml), stand overnight at 4°, filter and dry the solid in a vacuum. Recrystallise it from isoPrOH. R<sub>F</sub> is 0.26 on SiO<sub>2</sub> plate using CHCl<sub>3</sub>/MeOH (7:3) as eluent. [O'Shannessy et al. *Anal Biochem* **163** 204 1987.]

**N-(+)-Biotinyl-L-lysine (Biocytin)** [576-19-2] M 372.5, m 228.5°, 228-230° (dec), 241-243°, 245-252° (dec, sintering at 227°),  $[\alpha]_D^{25} +53^\circ$  (c 1.05, 0.1 N NaOH). Recrystallise biocytin rapidly from dilute MeOH or Me<sub>2</sub>CO. It can also be recrystallised from H<sub>2</sub>O by slow evaporation or by dissolving in the minimum volume of H<sub>2</sub>O and adding Me<sub>2</sub>CO until solid separates. It is freely soluble in H<sub>2</sub>O and AcOH but insoluble in Me<sub>2</sub>CO. [Wolf et al. *J Am Chem Soc* **74** 2002 1952, **72** 1048 1950.] It has been purified by chromatography on superfiltrol-Celite, Al<sub>2</sub>O<sub>3</sub> and by countercurrent distribution and then recrystallised [IR: Peck et al. *J Am Chem Soc* **74** 1991 1952]. The *hydrochloride* recrystallises from aqueous Me<sub>2</sub>CO/HCl and has m 227° (dec). [Beilstein **27** III/IV 7984.]

**Brefeldin A [1-R-2c,15c-dihydroxy-7t-methyl-(1r,13t)-6-oxa-bicyclo[11.3.0]hexadeca-3t,11t-dien-5-one, Decumbin]** [20350-15-6] M 280.4, m 200-202°, 204°, 204-205°,  $[\alpha]_D^{22} +95^\circ$  (c 0.81, MeOH). Brefeldin A was isolated from *Penicillium brefeldianum* and recrystallised from aqueous MeOH/EtOAc or MeOH. Its solubility in H<sub>2</sub>O is 0.6mg/ml, 10mg/ml in MeOH and 24.9mg/ml in EtOH. The *O-acetate* recrystallises from Et<sub>2</sub>O/pentane and has m 130-131°,  $[\alpha]_D^{22} +17^\circ$  (c 0.95, MeOH). [Sigg *Helv Chim Acta* **47** 1401 1964, UV and IR: Härrri et al. *Helv Chim Acta* **46** 1235 1963, total synthesis: Kitahara et al. *Tetrahedron* 3021 1979, X-ray: Weber et al. *Helv Chim Acta* **54** 2763 1971, Beilstein **18** III/IV 1220.]

**5-Bromo-2'-deoxyuridine** [59-14-3] M 307.1, m 193-197°(dec), 217-218°,  $[\alpha]_D^{25} -4.1^\circ$  (c 0.1, H<sub>2</sub>O), pK<sup>25</sup> ~8.1. Recrystallise the uridine from EtOH or 96% EtOH. It has UV with  $\lambda_{max}$  at 279 nm at pH 7.0, and 279 nm (log  $\epsilon$  3.95) at pH 1.9. Its R<sub>F</sub> values are 0.49, 0.46 and 0.53 in *n*-BuOH/AcOH/H<sub>2</sub>O (4:1:1), *n*-BuOH/EtOH/H<sub>2</sub>O (40:11:19) and *i*-PrOH-25% aqueous NH<sub>3</sub>-H<sub>2</sub>O (7:1:1), respectively. [Nature **209** 230 1966, Prystās & Sorm *Col Czech Chem Comm* **29** 2956 1964, Beilstein **24** III/IV 1234.]

**5-Bromouridine** [957-75-5] **M 323.1, m 215-217°**, 217-218°,  $[\alpha]_D^{22}$  -24.1° (c 2, H<sub>2</sub>O), **pK<sup>25</sup> 8.1**. Recrystallise it from 96% EtOH. It has UV with  $\lambda_{\max}$  at 279nm (log  $\epsilon$  3.95) in H<sub>2</sub>O pH 1.9.  $R_F$  in *n*-BuOH/AcOH/H<sub>2</sub>O (4:4:1) is 0.49; in *n*-BuOH/EtOH/H<sub>2</sub>O (40:11:9) it is 0.46 and in isoPrOH/25%NH<sub>3</sub>/H<sub>2</sub>O (7:1:2) it is 0.53 using Whatman No 1 paper. [Prystās & Sorm *Col Czech Chem Commmun* **29** 2956 1964, *Beilstein* **31** H 24.]

**Brucine** [357-57-3 (anhydrous), 5892-11-5 (4H<sub>2</sub>O)] **M 394.5 (anhydrous), 430.5 (2H<sub>2</sub>O), 466.5 (4H<sub>2</sub>O), m 178-179°**,  $[\alpha]_{546}^{20}$  -149.9° (anhydrous; c 1, in CHCl<sub>3</sub>),  $[\alpha]_D^{20}$  -119° (anhydrous; c 2, in CHCl<sub>3</sub>), **pK<sub>1</sub><sup>15</sup> 2.50, pK<sub>2</sub><sup>15</sup> 8.16 (pK<sub>2</sub><sup>25</sup> 8.28)**. Crystallise brucine once from water or aqueous Me<sub>2</sub>CO (as the *tetrahydrate*), then suspend it in CHCl<sub>3</sub> and shake with anhydrous Na<sub>2</sub>SO<sub>4</sub> (to dehydrate the brucine, which then dissolves). Precipitate it by pouring the solution into a large bulk of dry petroleum ether (b 40-60°), filter and heat to 120° in a high vacuum [Turner *J Chem Soc* 842 1951]. The *tetrahydrate* crystallises from a mixture of EtOH and H<sub>2</sub>O as colourless elongated needles [Eeles *Acta Cryst* **6** 809 1953, *Beilstein* **27** III/IV 7875.] **VERY POISONOUS.**

**Brucine sulfate (hydrate)** [4845-99-2] **M 887.0, m ~180°(dec)**,  $[\alpha]_{546}^{20}$  -36° (dry; c 1, H<sub>2</sub>O). The *heptahydrate* crystallises from water as colourless laths. [Eeles *Acta Cryst* **6** 809 1953, *Beilstein* **27** III/IV 7875.]

**Butyryl choline iodide [(2-butyryloxyethyl)trimethyl ammonium iodide]** [2494-56-6] **M 301.7, m 85-89°, 87°, 93-94°**. Recrystallise the iodide from isoPrOH or Et<sub>2</sub>O. [Tammelin *Acta Chem Scand* **10** 145 1956.] The *perchlorate* has **m 72°** (from isoPrOH). [Aldridge *Biochem J* **53** 62 1953, *Beilstein* **4** IV 1448.]

**S-Butyryl thiocholine iodide [(2-butyrylmercaptoethyl)trimethyl ammonium iodide]** [1866-16-6] **M 317.2, m 173°, 173-176°**. Recrystallise S-butyryl thiocholine iodide from propan-1-ol and dry it *in vacuo*; store it in the dark under N<sub>2</sub>. The *bromide* has **m 150°** (from Me<sub>2</sub>CO) or **m 140-143°** (from butan-1-ol). [Gillis *Chem Ind (London)* 111 1957, Hansen *Acta Chem Scand* **11** 537 1957, *Beilstein* **4** IV 1586.]

**Carminic acid** (7- $\alpha$ -D-glucopyranosyl-9,10-dihydro-3,5,6,8-tetrahydroxy-1-methyl-9,10-dioxo-2-anthracene carboxylic acid, **Neutral Red 4: CI 75470**) [1260-17-9] **M 492.4, m 120°(dec)**,  $[\alpha]_{654}^{15}$  +51.6° (H<sub>2</sub>O), (several phenolic pKs). Carminic acid forms red prisms from EtOH. It gives a red colour in Ac<sub>2</sub>O and yellow to violet in acidic solution. Its UV has  $\lambda_{\max}$  (H<sub>2</sub>O) at 500nm ( $\epsilon$  6,800); (0.02N HCl) 490-500nm ( $\epsilon$  5,800) and (0.0001N NaOH) 540nm ( $\epsilon$  3,450). Its IR has  $\nu_{\max}$  at (Nujol) 1708s, 1693s, 1677m, 1648m, 1632m, 1606s, 1566s, 1509 cm<sup>-1</sup>. Periodate oxidation is complete after 4 hours at 0° with the consumption of 6.2 mols. The *tetra-O-methyl carminate* has **m 186-188°** (yellow needles from \*C<sub>6</sub>H<sub>6</sub>/petroleum ether). [IR: Ali & Haynes *J Chem Soc* 1033 1959, Bhatia & Venkataraman *Indian J Chem* **3** (2) 92 1965, Synthesis: Davis & Smith *Biochemical Preparations* **4** 38 1955, *Beilstein* **18** III/IV 6697.]

**Cation exchange resins.** These should be conditioned before use by successive washing with water, EtOH and water, and taken through two H<sup>+</sup>-OH<sup>-</sup>-H<sup>+</sup> cycles by successive treatment with M HCl, water, M NaOH, water and M HCl, then washed with water until neutral to give the H<sup>+</sup> form. (See commercial catalogues on ion exchange resins).

**Cephalosporin C potassium salt** [28240-09-7] **M 453.5,  $[\alpha]_D^{20}$  +103° (H<sub>2</sub>O), pK<sub>1</sub> <2.6, pK<sub>2</sub> 3.1, pK<sub>3</sub> 9.8**. Purify the salt by dissolving it in the minimum volume of H<sub>2</sub>O (filter) and adding EtOH until separation of solid is complete. A solution is stable in the pH range 2.5-8. It has UV with  $\lambda_{\max}$  at 260nm (log  $\epsilon$  3.95) in H<sub>2</sub>O. The **Ba salt** has  $[\alpha]_D^{20}$  +80° (c 0.57, H<sub>2</sub>O) [Woodward et al. *J Am Chem Soc* **88** 852 1966, Abraham & Newton *Biochem J* **79** 377 1961, Hodgkin & Maslen *Biochem J* **79** 402 1961; see also *Quart Reviews Chem Soc* London **21** 231 1967]. [*Beilstein* **27** III/IV 5902.]

**Chlorambucil** [4-{bis(2-chloroethyl)amino}-phenylbutyric acid] [305-03-3] **M 304.2, m 64-66°, pK<sub>1</sub> 5.8 (6.0 at 66°, 50% aqueous Me<sub>2</sub>CO), pK<sub>2</sub> 8.0**. Chlorambucil is recrystallised from petroleum ether (flat needles) and has a solubility at 20° of 66% in EtOH, 40% in CHCl<sub>3</sub>, 50% in Me<sub>2</sub>CO but is insoluble in H<sub>2</sub>O [Everett et al. *J Chem Soc* 2386 1953]. [*Beilstein* **14** IV 1715.] **CARCINOGEN.**

**Chloramphenicol** [Amphicol, 1R,2R(-)-2-{2,2-dichloroacetyl-amino}-1-{4-nitrophenyl}-propan-1,3-diol]

[56-75-7] **M 323.1, m 149-151°, 150-151°, 151-152°,  $[\alpha]_D^{20} +20.5^\circ$  (c 3, EtOH),  $[\alpha]_D^{25} -25.5^\circ$  (EtOAc).** Purify chloramphenicol by recrystallisation from H<sub>2</sub>O (solubility is 2.5mg/ml at 25°) or ethylene dichloride as needles or long plates, and by sublimation at high vacuum. It has  $A_{1\text{cm}}^{1\%}$  298 at  $\lambda_{\text{max}}$  278nm, and it is slightly soluble in H<sub>2</sub>O (0.25%) and propylene glycol (1.50%) at 25° but is freely soluble in MeOH, EtOH, BuOH, EtOAc and Me<sub>2</sub>CO. [Relstock et al. *J Am Chem Soc* **71** 2458 1949, Confroulis et al. *J Am Chem Soc* **71** 2463 1949, Long & Troutman *J Am Chem Soc* **71** 2469, 2473 1949, Ehrhart et al. *Chem Ber* **90** 2088 1957, *Beilstein* **13** IV 2742.]

**Chloramphenicol palmitate** [530-43-8] **M 561.5, m 90°,  $[\alpha]_D^{26} +24.6^\circ$  (c 5, EtOH).** The palmitate crystallises from \*benzene or xylene with **m** 105-106° and  $[\alpha]_D^{21} -39.5^\circ$  (c 2, Et<sub>2</sub>O),  $\lambda_{\text{max}}$  267.3nm. [Edgerton et al. *J Am Chem Soc* **77** 27 1955, *Beilstein* **13** IV 2753.]

**2-Chloroadenosine** [146-77-0] **M 301.7, m 145-146°(dec), 147-149°(dec),  $\text{pK}_{\text{Est}(1)} \sim 0.5$ ,  $\text{pK}_{\text{Est}(2)} \sim 7.6$ .** Purify 2-chloroadenosine by recrystallisation from H<sub>2</sub>O (~1% in cold), and it has UV with  $\lambda_{\text{max}}$  at 264 nm (pH 1 and 7) and 265 nm (pH 13) in H<sub>2</sub>O. [Brown & Weliky *J Org Chem* **23** 125 1958, Schaeffer & Thomas *J Am Chem Soc* **80** 3738 1958, IR: Davoll & Lewy *J Am Chem Soc* **74** 1563 1952, *Beilstein* **26** III/IV 3725.]

**Chlorophyll a** [479-61-8] **M 983.5, m 117-120°, 150-153°, 178-180° (sinters at ~150°),  $[\alpha]_D^{20} -262^\circ$  (Me<sub>2</sub>CO).** It forms green crystals from Me<sub>2</sub>CO, Et<sub>2</sub>O/H<sub>2</sub>O, Et<sub>2</sub>O/hexane/H<sub>2</sub>O or Et<sub>2</sub>O/pentane /H<sub>2</sub>O. It is sparingly soluble in MeOH and insoluble in petroleum ether. In alkaline solution it gives a blue-green colour with deep red fluorescence. A very crude chlorophyll mixture has been purified by chromatography on low melting polyethylene (MI 0.044; "Dow" melting index MI <2) and developed with 70% aqueous Me<sub>2</sub>CO. The order of effluent from the bottom of the column is: xanthophylls, chlorophyll *b*, chlorophyll *a*, phaeophytins and carotenes. A mixture of chlorophylls *a* and *b* is best separated by chromatography on sugar, and the order is chlorophyll *b* elutes first followed by chlorophyll *a*. To an Me<sub>2</sub>CO/H<sub>2</sub>O solution of chlorophylls 200ml of iso-octane are added, and the mixture shaken in a separating funnel and the H<sub>2</sub>O is carefully removed. The iso-octane layer is dried (Na<sub>2</sub>SO<sub>4</sub>) and applied onto a glass column (5cm diameter) dry packed with 1000ml of powdered sucrose which has been washed with 250ml of iso-octane. Elution with 0.5% of isopropanol in iso-octane gives chlorophyll *a*. Keeping the eluate overnight at 0° yields micro crystals which are collected by filtration or centrifugation (Yield 40mg). The UV<sub>EtOH</sub> has  $\lambda_{\text{max}}$  **660, 613, 577, 531, 498, 429** and 409 nm. *Note* that anhydrous chlorophylls can be easily enolised, epimerised or allomerised in dry polar organic solvents. [Anderson & Calvin *Nature* **194** 285 1962, Stoll & Weidemann *Helv Chim Acta* **16** 739 757 1933, NMR: Katz et al. *J Am Chem Soc* **90** 6841 1968, **85** 3809 1963 for *a* and *b*; ORD: Inhoffen et al. *Justus Liebigs Ann Chem* **704** 208 1967, Willstätter & Isler *Justus Liebigs Ann Chem* **390** 269, 233 1912, *Beilstein* **26** III/IV 3243.]

**Chlorophyll b** [519-62-0] **M 907.52, sinters at 86-92°, sinters at 170°, dec at 160-170°, m 183-185°, 190-195°,  $[\alpha]_D^{20} -267^\circ$  (Me<sub>2</sub>CO/MeOH),  $[\alpha]_{720}^{25} -133^\circ$  (MeOH/Pyridine 95:5).** See purification of chlorophyll *a*, and is separated from "*a*" by chromatography on sucrose [UV, IR: Stoll & Weidemann *Helv Chim Acta* **42** 679, 681 1959]. It forms red-black hexagonal bipyramids or four-sided plates from dilute EtOH and has been recrystallised from CHCl<sub>3</sub>/MeOH. It is soluble in MeOH, EtOH, EtOAc and insoluble in petroleum ether. [Dougherty et al. *J Am Chem Soc* **88** 5037 1966, *Beilstein* **26** III/IV 3787.]

**6-Chloropurine riboside (6-chloro-9-β-D-ribofuranosyl-9H-purine)** [2004-06-0] **M 286.7, m 158-162°(dec), 165-166°(sintering at 155°), 168-170°(dec),  $[\alpha]_D^{26} -45^\circ$  (c 0.8, H<sub>2</sub>O).** Purify the riboside by suspending the dry solid (~12 g) in hot MeOH (130 ml) and then adding enough hot H<sub>2</sub>O (~560ml) to cause solution, filter and set aside at 5° overnight. The colourless crystals of the riboside are filtered off, washed with Me<sub>2</sub>CO, Et<sub>2</sub>O and dried at 60°/0.1mm. More material can be obtained by evaporating the filtrate to dryness and recrystallisation of the residue from MeOH/H<sub>2</sub>O (2:1) (15ml/g). It has UV with  $\lambda_{\text{max}}$  at 264nm ( $\epsilon$  9140) in H<sub>2</sub>O. [Robins *Biochemical Preparations* **10** 145 1963, Baker et al. *J Org Chem* **22** 954 1957.]

**Chromomycin A<sub>3</sub>** [7059-24-7] **M 1183.3, m 185°dec,  $[\alpha]_D^{23} -57^\circ$  (c 1, EtOH).** Dissolve the antibiotic (10g) in EtOAc and add to a column of Silica Gel (Merck 0.05-0.2microns, 4x70cm) in EtOAc containing 1% oxalic acid. Elute with EtOAc+1% oxalic acid and check fractions by TLC. Pool fractions, wash with H<sub>2</sub>O thoroughly, dry and evaporate. Recrystallise the residue from EtOAc. The *heptaacetate* has **m** 214°,  $[\alpha]_D^{23} -20^\circ$  (c 1, EtOH). [Miyamoto et al. *Tetrahedron* **23** 421 1967, Harada et al. *J Am Chem Soc* **91** 5896 1969, *Beilstein* **17/5** V 673.]

**8*S*,9*R*-(-)-Cinchonidine** [485-71-2] **M 294.4, m 210.5°**,  $[\alpha]_{546}^{20} -127.5^{\circ}$  (c 0.5, EtOH),  $[\alpha]_{\text{D}}^{20} -109.2^{\circ}$  (EtOH), **pK<sub>1</sub><sup>15</sup> 4.17, pK<sub>2</sub><sup>15</sup> 8.4, pK<sub>1</sub><sup>20</sup> 5.80, pK<sub>2</sub><sup>20</sup> 10.03**. Crystallise cinchonidine from aqueous EtOH (prisms or plates). It is a strong base and readily forms a *mono- and di- hydrochloride* and other stable salts. It is slightly soluble in Et<sub>2</sub>O, but quite soluble in EtOH and CHCl<sub>3</sub>. For the *N-benzylcinchonidinium chloride* see [69257-04-1]. [Beilstein 23 III/IV 2824, 23/12 IV 406.]

**8*R*,9*S*-(+)-Cinchonine** [118-10-5] **M 294.4, m 265°**,  $[\alpha]_{546}^{20} +268^{\circ}$  (c 0.5, EtOH), **pK<sub>1</sub><sup>15</sup> 4.28, pK<sub>2</sub><sup>15</sup> 8.35, pK<sub>1</sub><sup>20</sup> 5.85, pK<sub>2</sub><sup>20</sup> 9.96**. Crystallise cinchonine from EtOH or diethyl ether (needles). Its solubility (w/v) is 1.7% in EtOH, 4% in boiling EtOH, 1% in CHCl<sub>3</sub> and is almost insoluble in H<sub>2</sub>O. It is a strong base and readily forms a *mono- and di- hydrochloride* and other stable salts. For the *N-benzylcinchoninium chloride* see [69221-14-3]. [Rabe *Justus Liebigs Ann Chem* 365 366, 371 1909, Beilstein 23 III/IV 2819, 2832.]

**Clonidine hydrochloride [Catapres, 2-(2,6-dichloroanilino)-2-imidazoline hydrochloride]** [4205-91-8] **M 266.6, m 305°, pK<sub>25</sub> 5.88 (free base)**. This antihypertensive is recrystallised from EtOH/Et<sub>2</sub>O and dried in a vacuum (solubility in H<sub>2</sub>O is 5%). The *free base* has **m 124-125°** and is recrystallised from hexane. [Jen et al. *J Med Chem* 18 90 1975, NMR: Jackman & Jen *J Am Chem Soc* 97 2811 1975.]

**Cloxacillin sodium salt (sodium 3-*o*-chlorophenyl-5-methyl-4-isoxazolyl penicillin monohydrate)** [642-78-4] **M 457.9, m 170°,  $[\alpha]_{\text{D}}^{20} +163^{\circ}$  (H<sub>2</sub>O pH 6.0-7.5), pK<sub>Est</sub> ~2.8 (COOH)**. Purify cloxacillin sodium salt by dissolving it in isoPrOH containing 20% of H<sub>2</sub>O, and diluting with isoPrOH to a water content of 5% and chilling. Recrystallise it again in this manner. The sodium salt is collected and dried at 40° in air to give the colourless *monohydrate*. It is soluble in H<sub>2</sub>O (5%), MeOH, EtOH, pyridine and ethylene glycol. [Doyle et al. *J Chem Soc* 5838 1963, Naylor et al. *Nature* 195 1264 1962.]

**(-)-Cocaine {ecogonine methyl ester benzoate, 2β-carbomethoxy-3-β-benzoxypyrane, methyl 1*R*-(*exo,exo*)-3-(benzoyloxy)-2-methyl-8-azabicyclo[3.2.1]octane-2-carboxylate}** [50-36-2] **M 303.4, m 98°, b 187-188°/0.1mm,  $[\alpha]_{\text{D}}^{20} -15.8^{\circ}$  (c 4, CHCl<sub>3</sub>),  $[\alpha]_{\text{D}}^{20} -35^{\circ}$  (50% EtOH), pK<sub>25</sub> 5.59 and 8.61 (8.39)**. (-)-Cocaine crystallises from EtOH and sublimes below 90° in a vacuum in an amorphous form. The *hydrochloride* crystallises from MeOH/Et<sub>2</sub>O with **m 195°** and  $[\alpha]_{\text{D}}^{20} -72^{\circ}$  (c 2 in H<sub>2</sub>O, pH 4.5), -78.5° (50% aqueous EtOH). [Sam & Reynolds *J Chem Soc* 97 1335 1910, Tufariello et al. *J Am Chem Soc* 101 2435 1979.] **α-Cocaine** is the (+) enantiomer. [Beilstein 22 I 547, 22 II 150.]

**Cocarboxylase tetrahydrate (aneurine pyrophosphoric acid tetrahydrate, thiamine pyrophosphoric acid tetrahydrate)** [136-09-4] **M 496.4, m 220-222°(sinters at 130-140°), 213-214°, pK<sub>Est(1)</sub> ~2, pK<sub>Est(2)</sub> ~6, pK<sub>Est(3)</sub> ~9**. Cocarboxylase tetrahydrate recrystallises from aqueous Me<sub>2</sub>CO. [Wenz et al. *Justus Liebigs Ann Chem* 618 210 1958, UV: Melnick *J Biol Chem* 131 615 1939, X-ray: Carlisle & Cook *Acta Cryst (B)* 25 1359 1969.] The *hydrochloride salt* has **m 242-244°(dec), 241-243°(dec) or 239-240°(dec)** and crystallises from aqueous HCl/EtOH, EtOH containing HCl or HCl/Me<sub>2</sub>CO. [Weijlard *J Am Chem Soc* 63 1160 1941, Synthesis: Weijlard & Tauber *J Am Chem Soc* 60 2263 1938, Beilstein 27 III/IV 1777.]

**Codeine** [76-57-3] **M 299.4, m 151-154°, 154-156°,  $[\alpha]_{\text{D}}^{20} -138^{\circ}$  (in EtOH), pK<sub>15</sub> 6.06(OH), pK<sub>25</sub> 8.21 (NMe)**. Codeine crystallises from water or aqueous EtOH. Dry it at 80°. Evaporation of a CHCl<sub>3</sub> extract gives a colourless glass which crystallises on scratching. It crystallises from H<sub>2</sub>O as the *monohydrate*, **m 157-158.5°**, and has  $[\alpha]_{\text{D}}^{25} -136^{\circ}$  (c 2.8, EtOH). The *hydrobromide* crystallises in needles from H<sub>2</sub>O, and effervesces at 151-160°, solidifies and remelts with extensive decomposition at 273-278°. It sublimes at 100°/0.03mm. [Gates *J Am Chem Soc* 75 4340 1953, Dauben et al. *J Org Chem* 44 1567 1979, Beilstein 27 II 136, 27 III/IV 2228.]

**Coenzyme A trihydrate** [85-61-0] **M 821.6, pK<sub>1</sub> 4.0 (adenine NH<sub>2</sub>), pK<sub>2</sub> 6.5 (PO<sub>4</sub>H), pK<sub>3</sub> 9.6 (SH)**. The white powder is best stored in an inert atmosphere in the dark in sealed ampoules after drying *in vacuo* over P<sub>2</sub>O<sub>5</sub> at 34°. It has UV with  $\lambda_{\text{max}}$  at 259 nm ( $\epsilon$  16,800) in H<sub>2</sub>O. [Buyske et al. *J Am Chem Soc* 76 3575 1954.] It is soluble in H<sub>2</sub>O but insoluble in EtOH, Et<sub>2</sub>O and Me<sub>2</sub>CO. It is readily oxidised in air and is best kept as the more stable *trilithium salt* [Moffat & Khorana *J Am Chem Soc* 83 663 1961; see also Beinert et al. *J Biol Chem* 200 384 1953, De Vries et al. *J Am Chem Soc* 72 4838 1950, Gregory et al. *J Am Chem Soc* 74 854 1952 and

Baddiley *Adv Enzymol* **16** 1 1955]. [*Beilstein* **26** III/IV 3663.]

**Coenzyme Q<sub>0</sub>** (2,3-dimethoxy-5-methyl-1,4-benzoquinone, 3,4-dimethoxy-2,5-tolu-quinone, fumigatin methyl ether) [605-94-7] **M 182.2, m 56-58°, 58-60°, 59°**. It crystallises in red needles from petroleum ether (b 40-60°) and sublimes at high vacuum at a bath temperature of 46-48° [Ashley et al. *J Chem Soc* 441 1938, UV in EtOH: Vischer *J Chem Soc* 815 1953, UV in cyclohexane: Morton et al. *Helv Chim Acta* **41** 2343 1858, Aghoramurthy et al. *Chem Ind (London)* 1327 1954]. [*Beilstein* **8** IV 2721.]

**Coenzyme Q<sub>4</sub>** (Ubiquinone-4, 2,3-dimethoxy-5-methyl-6-[3,7,11,15-tetramethyl-hexadeca-2*t*,6*t*,10*t*,14-tetraenyl]-1,4-benzoquinone) [4370-62-1] **M 454.7, m 30°, 33-45°**. It is a red oil which can be purified by chromatography on SiO<sub>2</sub> plates and eluted with Et<sub>2</sub>O/hexane. The purity is checked by HPLC (silica column using 7% Et<sub>2</sub>O/hexane). It has UV with  $\lambda_{\max}$  at 270 nm ( $\epsilon$  14,800) in petroleum ether. [NMR and MS: Naruta *J Org Chem* **45** 4097 1980, cf Morton *Biochemical Spectroscopy* (Adam Hilger, London, 1975) p 491]. It has also been dissolved in MeOH/EtOH (1:1 v/v) and kept at 5° until crystals appear [Lester & Crane *Biochim Biophys Acta* **32** 497 1958].

**Coenzyme Q<sub>9</sub>** (Ubiquinone-9, 2,3-dimethoxy-5-methyl-6-[3,7,11,15,19,23,27,31,35-nonamethyl-hexatriaconta-2*t*,6*t*,10*t*,14*t*,18*t*,22*t*,26*t*,30*t*,34-nonaenyl]-1,4-benzoquinone) [303-97-9] **M 795.3, m 40.5-42.5°, 44-45°, 45°**. The yellow crystals are purified by recrystallisation from petroleum ether and by chromatography on SiO<sub>2</sub> plates and eluted with Et<sub>2</sub>O/hexane. The purity can be checked by HPLC (silica column using 7% Et<sub>2</sub>O/hexane). It has UV with  $\lambda_{\max}$  at 270nm ( $\epsilon$  14,850) in petroleum ether. [NMR and MS: Naruta *J Org Chem* **45** 4097 1980, Le et al. *Biochem Biophys Acta* **32** 497 1958, cf Morton *Biochemical Spectroscopy* (Adam Hilger, London, 1975) p 491, IR: Lester et al. *Biochim Biophys Acta* **33** 169 1959, UV: Rüegg et al. *Helv Chim Acta* **42** 2616 1959, Shunk *J Am Chem Soc* **81** 5000 1959, *Beilstein* **8** IV 3313.]

**Coenzyme Q<sub>10</sub>** (Ubiquinone-10, 2,3-dimethoxy-5-methyl-6-[3,7,11,15,19,23,27,31,35,-39-decamethyl-tetraconta-2*t*,6*t*,10*t*,14*t*,18*t*,22*t*,26*t*,30*t*,34*t*,38-decaenyl]-1,4-benzoquinone) [303-98-0] **M 795.3, m 48-49°,49°, 49.5-50.5°, 50°**. Purify it by recrystallisation from EtOH, EtOH/Me<sub>2</sub>CO or Et<sub>2</sub>O/EtOH and by chromatography on silica gel using isoPrOH/Et<sub>2</sub>O (3:1) to give orange crystals. It has UV with  $\lambda_{\max}$  at 270nm ( $\epsilon$  15,170) in petroleum ether. [Terao et al. *J Org Chem* **44** 868 1979, NMR and MS: Naruta et al. *J Org Chem* **45** 4097 1980, IR: Lester et al. *Biochem Biophys Acta* **42** 1278 1959, NMR: Planta et al. *Helv Chim Acta* **42** 1278 1959; Morton *Biochemical Spectroscopy* (Adam Hilger, London, 1975) p 491].

**Colcemide (Demecocine)** [477-30-5] **M 371.4, m 182-185°, 183-185°, 186°,  $[\alpha]_{\text{D}}^{20}$  -129° (c 1, CHCl<sub>3</sub>)**. Colcemide is purified by chromatography on silica and eluting with CHCl<sub>3</sub>/MeOH (9:1), and by recrystallisation from EtOAc/Et<sub>2</sub>O to form yellow prisms. Its UV in EtOH has  $\lambda_{\max}$  at 243nm ( $\epsilon$  30,200) and 350nm ( $\epsilon$  16,300). [Synthesis, IR, NMR, MS: Capraro & Brossi *Helv Chim Acta* **62** 965 1979, *Beilstein* **8** IV 3319.]

**Colchicine** {*N*-[(7*S*)-1,2,3,10-tetramethoxy-5,6,7,9-tetrahydro-9-oxo-benzo[*a*]heptalen-7-yl]-acetamide} [64-86-8] **M 399.5, m 150-160° (dec), 155-157°(dec), 156-157°,  $[\alpha]_{\text{D}}^{20}$  -570° (c 1, H<sub>2</sub>O),  $[\alpha]_{\text{D}}^{20}$  -443° (c 1.7, H<sub>2</sub>O),  $[\alpha]_{\text{D}}^{20}$  -120° (c 1, CHCl<sub>3</sub>), pK<sup>20</sup> 1.85 and 12.4**. Commercial material contains up to 4% desmethylcolchicine. Purify colchicine by chromatography on alumina and eluting with CHCl<sub>3</sub> [Ashley & Harris *J Chem Soc* 677 1944]. Alternatively, an acetone solution on alkali-free alumina has been used, and eluting with acetone [Nicholls & Tarbell *J Am Chem Soc* **75** 1104 1953]. It crystallises as yellow needles from EtOAc or CHCl<sub>3</sub> with solvent of crystallisation which can be removed at ~70°. It is soluble in Et<sub>2</sub>O (0.5%), \*C<sub>6</sub>H<sub>6</sub> (1%) and H<sub>2</sub>O (4%). It is sold as “Colgout” for the treatment of gout and binds to tubulin. [Schreiber et al. *Helv Chim Acta* **44** 540 1961, Scott et al. *Tetrahedron* **21** 3605 1965, van Tamelen et al. *Tetrahedron* **14** 8 1961, *Beilstein* **14** IV 946.]

**Compactin (Mevastatin)** [73573-88-3] **M 390.5, m 151-153°, 152°,  $[\alpha]_{\text{D}}^{22}$  +283° (c 0.48, acetone)**. Purify compactin by recrystallisation from aqueous EtOH. Its UV (EtOH) has  $\lambda_{\max}$  at 230, 237 and 246nm (log  $\epsilon$  4.28, 4.30 and 4.11); and its IR (KBr) has  $\nu_{\max}$  3520, 1750 (lactone CO) and 1710 (CO ester) cm<sup>-1</sup>. [Clive et al. *J Am Chem Soc* **110** 6914 1988, Review: Rosen & Heathcock *Tetrahedron* **42** 4909 1986, IR, NMR, MS: Brown et al.

*J Chem Soc Perkin Trans I* 1165 1976.] It is a potent inhibitor of 3-hydroxy-3-methylglutaryl-CoA reductase (HMG-CoA reductase), is an enzyme in cholesterol biosynthesis, and lowers cholesterol levels [Brown et al. *J Biol Chem* **253** 1121 1978, Nakamura & Ableles *Biochemistry* **24** 1364 1985, *Beilstein* **18/3** V 145].

**Crotaline** (monocrotaline, 12,13-dihydroxy-(13 $\beta$ -14 $\beta$ H)-14,19-dihydro-20-norcrotalanan-11,15-dione) [315-22-0] **M 325.4**, **m 196-197<sup>o</sup>(dec)**, **197-198<sup>o</sup>(dec)**, **203<sup>o</sup>(dec)**,  $[\alpha]_D^{20}$  -55<sup>o</sup> (c 1, EtOH). Crotaline forms prisms from absolute EtOH and recrystallises also from CHCl<sub>3</sub>. Its UV(96% EtOH) has  $\lambda_{\max}$  at 217nm (log  $\epsilon$  3.32). [Adams et al. *J Am Chem Soc* **74** 5612 1952, Culvenor & Smith *Aust J Chem* **10** 474 1957.] The hydrochloride has **m 212-214<sup>o</sup>** (from MeOH/Et<sub>2</sub>O) and  $[\alpha]_D^{25}$  -38.4<sup>o</sup> (c 5, H<sub>2</sub>O) [Adams & Gianturco *J Am Chem Soc* **78** 1922 1956]. The picrate has **m 230-231.5<sup>o</sup>(dec)** [Adams et al. *J Am Chem Soc* **74** 5614 1952]. [*Beilstein* **27** III/IV 6660.]

**Curcumin** [bis(4-hydroxy-3-methoxycinnamoyl)methane, 1,7-bis(4-hydroxy-3-methoxyphenyl)(1E,6E)-1,6-heptadiene-3,5-one] [458-37-7] **M 368.4**, **m 182<sup>o</sup>**, **183<sup>o</sup>**, **184-195<sup>o</sup>**, **184-186<sup>o</sup>**, **pK<sub>1</sub> 7.80**, **pK<sub>2</sub> 8.5** and **pK<sub>3</sub> 9.0 (H<sub>2</sub>O)**. Purify curcumin by recrystallising it from MeOH, EtOH or acetic acid (yellow, orange-yellow prisms) and drying it *in vacuo*. It is best separated from related compounds by HPLC (see refs below). It is sparingly soluble in H<sub>2</sub>O but soluble in AcOH and in alkaline buffer. In solution at pH 1-7 the colour is yellow and at pH 7-9 the colour is brownish-red or deep red. It was commercialised as a pH indicator under the name of "curcuma paper". Curcumin is a phenolic substance which occurs naturally in *Curcuma domestica*, *C. xanthorrhiza*, *C. aromatica*, *C. longa*, and is used in Indian curry cooking as *turmeric*. It has many physiological properties including anti-oxidant, anti-inflammatory, potent anti-tumour, and is an inhibitor of several enzymes (EGFR tyrosine kinase, I $\kappa$ B kinase, nitric oxide synthase, cyclooxygenase, lipoxygenase). It penetrates cell membranes accumulating in plasma membranes, nuclear envelope and endoplasmic reticulum. Its UV-VIS has  $\lambda_{\max}$  (log $\epsilon$ )(EtOH) at 268 (4.09) and 430nm (4.74), (dioxane) at 265 (4.18) and 420nm (4.37) and (40% aqueous THF) at 429nm (4.780), with fluorescence maxima at  $\lambda_{\text{excit}}$  433nm and  $\lambda_{\text{emis}}$  511nm in 40% aqueous THF. Its IR (KBr) has  $\nu_{\max}$  at 3400 (br), 1625, 1600, 1500, 1275, 1025, 960 cm<sup>-1</sup>. The <sup>1</sup>H NMR [400MHz, CDCl<sub>3</sub>] has  $\delta$  at 6.06 (1H, s, H-4), 16.41 (1H, br s, OH), 7.57 (2H, d, *J* = 16.0Hz, H-2,6), 6.75 (2H, d, *J* = 16.0Hz, H-1,7), 7.32 (2H, d, *J* = 2.0Hz, H-2',2''), 9.64 (2H, s, OH-4',4''), 6.85 (2H, d, *J* = 8.1Hz, H-5',5''), 7.16 (2H, dd, *J* = 2.0, 8.1Hz, H-6',6''), 3.85 (6H, s, 3',3'' OMe) (from TMS); and the <sup>13</sup>C NMR [100MHz, CDCl<sub>3</sub>] has  $\delta$  at 100 (C-4), 183.2 (C-3,5), 121.1 (C-2,6), 140.7 (C-1,7), 126.4 (C-1',1''), 111.5 (C-2',2''), 148.0 (C-3',3''), 149.4 (C-4',4''), 115.8 (C-5',5''), 123.0 (C-6',6''), 55.7 (OCH<sub>3</sub>) (from TMS). It complexes strongly with boron, iron, copper and nickel, but weakly with calcium and magnesium. As a 0.1% solution in AcOH it is used for the spectrophotometric determination of Boron as a complex with  $\lambda_{\max}$  550nm ( $\epsilon$ 180,000). [Dyrssen et al. *Analyt Chim Acta* **60** 139 1972, Spicer & Strickland *Analyt Chim Acta* **18** 231 1958, Roughley & Whiting, *J Chem Soc, Perkin Trans I* 2379 1973, Zsila et al. *Tetrahedron Asymm* **14** 2433 2003, cf Cooke & Segal *Aust J Chem* **8** 107 1955, *Beilstein* **8** H 554, **8** I 757, **8** II 588, **8** III 4312, **8** IV 3697.]

The *diacetyl* derivative has **m 171-172<sup>o</sup>** (from EtOH) and the *dibenzoyl* derivative has **m 210<sup>o</sup>** (from EtOH or C<sub>6</sub>H<sub>6</sub>\*).

The *dimethyl* derivative [1,7-bis(3,4-dimethoxyphenyl)(1E, 6E)-1,6-heptadiene-3,5-one] has **m 128-130<sup>o</sup>**, **M 396.2**; the UV has  $\lambda_{\max}$  at 427nm, and the <sup>1</sup>H NMR [200MHz, CDCl<sub>3</sub>] has  $\delta$  at 3.92 (6H, s, 2 x CH<sub>3</sub>O-Ph), 3.93 (6H, s, 2 x CH<sub>3</sub>O-Ph), 5.82 (1H, s, H-4), 6.45 (2H, d, *J* = 13Hz, H-1,2), 6.86 (6H, m, Arom-H), 7.57 (2H, d, *J* = 13Hz, H-6,7) [Nurfina et al. *Eur J Med Chem* **32** 321 1997].

**5'-Methoxycurcumin** [1-(4-hydroxy-3,5-dimethoxyphenyl)-7-(4-hydroxy-3-methoxyphenyl)-(1E,6E)-1,6-heptadiene-3,5-one] **M 398.4**, has **m 145-146<sup>o</sup>** (from MeOH), and was isolated as a yellow powder from *C. xanthorrhiza* with UV  $\lambda_{\max}$  at 429nm in MeOH.

**1-Hydroxycurcumin** [1-hydroxy-1,7-bis(4-hydroxy-3-methoxyphenyl)-(6E-6-heptene-3,5-dione)] **m 84-88<sup>o</sup>** was isolated from the same source, had UV  $\lambda_{\max}$  at 372nm in MeOH and had a weaker antioxidant activity than the other curcumins towards the autoxidation of linoleic acid in a water-alcohol system [Masuda et al. *Phytochemistry* **31** 3645 1992]. An optically active form, **(1 $\xi$ )-1-hydroxy-1,7-bis(4-hydroxy-3-methoxyphenyl)-(1E,6E)-1,6-heptadiene-3,5-one**, has **m 92.0-96.0<sup>o</sup>**, with  $[\alpha]_D^{20}$  +12.2<sup>o</sup> (c 0.06, EtOH, configuration unknown), **M 386.4**. Its UV has  $\lambda_{\max}$  nm ( $\epsilon$ )(MeOH) at 230 (sh), 260 (21000), 283 (18000).

370 (56000); and its IR (CDCl<sub>3</sub>) has  $\nu_{\max}$  at 965, 1000, 1120, 1260, 1325, 1375, 1460, 1560, 1600, 1620, 1650, 2850, 2900, 3525 cm<sup>-1</sup>. Its <sup>1</sup>H NMR [270MHz, CDCl<sub>3</sub>] has  $\delta$  at 2.65(1H, dd,  $J = 17, 3.5$ Hz), 2.93 (1H, dd,  $J = 17, 14$ Hz), 3.93 (3H, s), 3.95 (3H, s), 5.39 (1H, dd,  $J = 14, 3.5$ Hz), 5.60 (1H, s), 5.80 (1H, br s, disappeared on addition of D<sub>2</sub>O), 5.86 (1H, br s, disappeared on addition of D<sub>2</sub>O), 6.44 (1H, d,  $J = 16$ Hz), 6.90 (1H, d,  $J = 8$ Hz), 7.00 (4H, br s), 7.03 (1H, dd,  $J = 8, 2$ Hz), 7.30 (1H, d,  $J = 16$ Hz) and  $R_F$  (Silica gel 60 F<sub>254</sub>, C<sub>6</sub>H<sub>6</sub>\*/EtOAc 1:1) of 0.2. When this *hydroxyheptadiene* was heated at 130°/15mmHg/10 hours it gave *curcumin* in 79% yield. (**3S,5S**) - **1, 7 - Bis (4 - hydroxy-3-methoxyphenyl) heptane-3, 5-diol** [colourless needles **m 132-134**°, with  $[\alpha]_D^{20} -18.5$ ° (c 0.26, EtOH),  $R_F$  0.1] was also isolated from the rhizomes of *C. xanthorrhiza* (Zingiberaceae) and characterised; and (**3R,5R**)-**1-(4-hydroxyphenyl)-7-phenylheptane-3,5-diol** [colourless needles **m 109-111**°, with  $[\alpha]_D^{20} +8.3$ ° (c 0.06, CDCl<sub>3</sub>),  $R_F$  0.3] was isolated from the rhizomes of *Alpinia officinarum* (Zingiberaceae) and characterised; the absolute configurations were determined from the circular dichroism (CD) spectra of the 3,5-bis-*p*-dimethylaminobenzoate esters of their methylated derivatives, and applying the *exciton chirality rule* [Uehara et al. *Chem Pharm Bull Jpn* **38** 3298 1987].

**Desmethoxycurcumin** [22608-11-3] **M 338.3, m 173-175**° (also reported are **168**° and **172**°) is a contaminant of curcumin, isolated from the same source as curcumin, best purified by HPLC and crystallises from EtOH as an orange-yellow powder. Its UV-VIS has  $\lambda_{\max}$  (log  $\epsilon$ ) (MeOH) at 419nm (4.706) and (40% aqueous THF) 425nm (4.806) with fluorescence maxima at  $\lambda_{\text{excit}}$  428nm and  $\lambda_{\text{emis}}$  505nm in 40% aqueous THF. The <sup>1</sup>H NMR [400MHz, CDCl<sub>3</sub>] has  $\delta$  at 5.97 (1H, s, H-4), 7.60 (2H, d,  $J = 16.0$ Hz, H-2,6), 6.69 (1H, d,  $J = 16.0$ Hz, H-1 or 7), 6.64 (1H, d,  $J = 16.0$ Hz, H-7 or 1), 7.34 (1H, d,  $J = 1.7$ Hz, H-2' or 2''), 6.90 (1H, d,  $J = 8.0$ Hz, H-2'' or 2'), 7.56 (1H, d,  $J = 8.0$ Hz, H-5'), 6.88 (1H, d,  $J = 8.0$ Hz, H-5''), 7.27 (1H, dd,  $J = 8, 1.7$ Hz, H-6'), 6.9 (1H, d,  $J = 8$ Hz, H-6''), 3.92 (3H, s, OCH<sub>3</sub>) (from TMS); and the <sup>13</sup>C NMR [100MHz, CDCl<sub>3</sub>] has  $\delta$  at 101.6 (C-4), 184.4 and 184.5 (C-3,5), 121.1 and 122.3 (C-2,6), 141.4 and 141.0 (C-1,7), 128.2 and 127.7 (C-1',1''), 111.5 and 130.9 (C-2',2''), 148.8 and 116.8 (C-3',3''), 150.0 and 160.5 (C-4',4''), 116.2 and 116.8 (C-5',5''), 123.8 and 130.9 (C-6',6''), 56.3 (OCH<sub>3</sub>) (from TMS).

Similarly **bis-desmethoxy-curcumin** [22608-12-4] **M 308.3, m 224**° (also reported are **216-218**° and **222**°) is a contaminant of curcumin, occurring in the same source, best purified by HPLC and crystallises as the *hydrate* in yellow plates from EtOH. Its UV has  $\lambda_{\max}$  (log  $\epsilon$ )(MeOH) at 414nm (4.675) and (40% aqueous THF) 420nm (4.702) with fluorescence maxima at  $\lambda_{\text{excit}}$  425nm and  $\lambda_{\text{emis}}$  501nm in 40% aqueous THF. The <sup>1</sup>H NMR [400MHz, CDCl<sub>3</sub>] has  $\delta$  at 6.03 (1H, s, H-4), 16.4 (1H, br s, 3-OH), 7.56 (2H, d,  $J = 15.9$ Hz, H-2,6), 7.56 (2H, d,  $J = 15.9$ Hz, H-1,7), 6.84 (2H, d,  $J = 8.2$ Hz, H-2',2''), 7.56 (2H, d,  $J = 8.2$ Hz, H-3',3''), 10.03 (2H, s, 4',4''-OH), 7.56 (2H, d,  $J = 8.2$ Hz, H-5',5''), 8.64 (2H, d,  $J = 8.2$ Hz, H-6',6'') (from TMS); and the <sup>13</sup>C NMR [100MHz, CDCl<sub>3</sub>] has  $\delta$  at 100.9 (C-4), 183.2 (C-3,5), 120.8 (C-2,6), 140.3 (C-1,7), 125.8 (C-1',1''), 130.3 (C-2',2''), 115.9 (C-3',3''), 159.8 (C-4',4''), 115.9 (C-5',5''), 130.3 (C-6',6'') (from TMS). [Jayaprakasha et al. *J Agric Food Chem* **50** 3668 2002, Inoue et al. *J Agric Food Chem* **56** 9328 2008, (HPLC, UV, fluorescence) Rouseff *J Food Sci* **53** 1823 1988, (MS) Jiang et al. *Rapid Commun Mass Spectrom* **20** 1001 2006, (HPLC, MS) Jiang et al. *J Chromatogr A* **1111** 21 2006, (HPLC, MS) Hiserodt et al. *J Chromatogr A* **740** 51 1996, (spectroscopy) Tonnesen et al. *Pharmazie* **50** H.10 1995, (IR) Tanaka et al. *J Agric Food Chem* **56** 9787 2008, (spectroscopy) Péret-Almeida et al. *Food Research International* **38** 1039 2005. (cytotoxicity) Ishida et al. *Bioorg Med Chem* **10** 3481 2002 (anti-inflammatory, antioxidant and anti-amyloid activity) Yang et al. *J Biol Chem* **280** 5892 2005.]

The keto-enol tautomerism of curcumin derivatives was shown to be a property that can be employed for amyloid detection in Alzheimer's disease, and may be exploited for the design of amyloid-binding agents for the therapy of the disease [Yanagisawa et al. *Biomaterials* **31** 4179 2010]. Over the years, curcumin derivatives have been screened for a variety of diseases (see above) including anti-HIV, and although few have displayed very potent anticancer activity, they are still being considered for development as future anticancer agents. A review on their potential as anticancer agents has been published recently. [Agrawal & Mishra *Med Res Rev* **30** 818 2010.] The above information under *Curcumin* was kindly supplied by Prof. Hiroyasu Taguchi, Shiga University of Medical Science, Molecular Neuroscience Research Centre, Japan.

**Cytidine** [65-46-3] **M 243.2, m 210-220**°(dec), **230**° (dec), **251-252**° (dec),  $[\alpha]_D^{20} +37$ ° (c 9, H<sub>2</sub>O),  $[\alpha]_D^{20} +29$ ° (c 9, H<sub>2</sub>O), **pK<sub>25</sub> 3.85**. Cytidine crystallises from 90% aqueous EtOH. It has also been converted to *sulfate* by dissolving (~200mg) in a solution of EtOH (10ml) containing H<sub>2</sub>SO<sub>4</sub> (50mg), whereby the salt crystallises out.

It is collected, washed with EtOH and dried for 5 hours at 120°/0.1mm. The *sulfate* has **m** 225°. The *free base* is obtained by shaking the salt solution with a weak ion-exchange resin, filtering, evaporating and recrystallising the residue from EtOH as before. [Fox & Goodman *J Am Chem Soc* **73** 3256 1956, Fox & Shugar *Biochim Biophys Acta* **9** 369 1952; see Prytsas & Sorm in *Synthetic Procedures in Nucleic Acid Chemistry* (Zorbach & Tipson Eds) **Vol 1** 404 1973.] [*Beilstein* **25** III/IV 3667.]

**Cytisine**, See entry in “Heterocyclic Compounds”, Chapter 4.

**Cytochalasin B (from dehydrated mould matter)** [14930-96-2] **M 479.6, m 218-221°**. Purify it by MeOH extraction, reverse phase C18 silica gel batch extraction by selective elution with 1:1 v/v hexane/tetrahydrofuran, crystallisation, subjected to TLC and recrystallisation [Lipski et al. *Anal Biochem* **161** 332 1987]. It is soluble in EtOH (3.6%), Me<sub>2</sub>CO (1%), Me<sub>2</sub>SO (37%) and Me<sub>2</sub>NCHO (49%) at 24°, and can be crystallised from the first two solvents. It interferes with cellular movement [Korm *Physiol Reviews* **62** 672 1982].

**Cytosine (4-amino-2-hydroxypyrimidine)** [71-30-7] **M 111.1, m 313° (hydrate, dec), 320-325° (anhydrous, dec), pK<sub>1</sub><sup>25</sup> 4.6, pK<sub>2</sub><sup>25</sup> 12.1**. Cytosine crystallises from H<sub>2</sub>O as the *monohydrate* which loses water on heating above 100°. Its solubility in H<sub>2</sub>O is 0.77%. Its UV has λ<sub>max</sub> at 267nm (ε 6,100) in H<sub>2</sub>O pH 8.8 and 275nm (ε 10,400) in 0.1N HCl. [Hilbert & Johnson *J Am Chem Soc* **52** 1152 1930, Hilbert et al. *J Am Chem Soc* **57** 552 1935, *Beilstein* **25** III/IV 3654.]

**Cytosine-1-β-O-arabinofuranoside (Cytarabin)** [147-94-4] **M 243.2, m ~220°(dec), 212-213.5°, [α]<sub>D</sub><sup>20</sup> +155° (c 1, H<sub>2</sub>O), pK<sub>1</sub><sup>25</sup> 4.3**. Purify cytarabin by recrystallisation from aqueous EtOH or a large volume of H<sub>2</sub>O (it solubility at ~20° is 5%). It has λ<sub>max</sub> at 212 and 279nm at pH 2 and 272nm at pH 12. It is an acute leukaemic agent. [Walwick et al. *Proc Chem Soc (London)* 84 1959, *Beilstein* **25** III/IV 3669.]

**Demeclocycline hydrochloride (7-chloro-6-demethyltetracycline hydrochloride, Clortetrin)** [64-73-3] **M 501.3, m 174-178°(dec, for sesquihydrate), [α]<sub>D</sub><sup>25</sup> -258° (c 0.5, 0.1N H<sub>2</sub>SO<sub>4</sub>), pK<sub>1</sub><sup>25</sup> 4.45 [H<sub>2</sub>O-Me<sub>2</sub>NCHO (1:1)]**. Crystallise the salt from EtOH/Et<sub>2</sub>O or H<sub>2</sub>O and dry it in air [McCormick et al. *J Am Chem Soc* **79** 4561 1957, Dobrynin et al. *Tetrahedron Lett* 901 1962]. [*Beilstein* **14** IV 2625.]

**2'-Deoxyadenosine (adenine 2'-deoxyriboside)** [16373-93-6] **M 269.3, m 187-189°, 189-191°, [α]<sub>D</sub><sup>20</sup> -25° (c 0.5, H<sub>2</sub>O), [α]<sub>589</sub><sup>25</sup> -26°, [α]<sub>310</sub><sup>25</sup> -206° (c 0.5, H<sub>2</sub>O), pK<sub>20</sub><sup>20</sup> 3.79**. Purify it by recrystallisation from H<sub>2</sub>O (hydrated crystals; solubility of the *monohydrate* is 1.1% in H<sub>2</sub>O at 20°). It has UV with λ<sub>max</sub> at 258nm (pH 1), 260nm (pH 7) and 261nm (pH 13). [Ness & Fletcher *J Am Chem Soc* **81** 4752 1959, Walker & Butler *Can J Chem* **34** 1168 1956.] The 3',5'-*O*-diacetyl derivative has **m** 151-152° (from EtOAc/petroleum ether). [*Beilstein* **26** III/IV 3589.]

**3'-Deoxyadenosine (Cordycepin, adenine 3'-deoxyriboside)** [73-03-0] **M 251.2, m 225-226°, 225-229°, [α]<sub>D</sub><sup>20</sup> -47° (H<sub>2</sub>O), pK<sub>Est</sub> ~4.8**. 3'-Deoxyadenosine forms needles from EtOH, *n*-BuOH and *n*-PrOH, and a *monohydrate* from H<sub>2</sub>O. It has UV with λ<sub>max</sub> at 260nm (ε 14,600) in EtOH. The *picrate* has **m** 195°(dec, yellow crystals from H<sub>2</sub>O). [Kaczka et al. *Biochim Biophys Acta* **14** 456 1964, Todd & Ulbricht *J Chem Soc* 3275 1960, Lee et al. *J Am Chem Soc* **83** 1906 1961, Walton et al. *J Am Chem Soc* **86** 2952 1964, *Beilstein* **26** III/IV 3594.]

**2'-Deoxycytidine monohydrate** [951-77-9, 652157-52-3 (*hydrate*), 207121-53-7] **M 245.2, m 119-200°, 207-209°, 213-215°, [α]<sub>D</sub><sup>25</sup> +78° (c 0.4, N NaOH), [α]<sub>D</sub><sup>23</sup> +57.6° (c 2, H<sub>2</sub>O), pK<sub>1</sub><sup>25</sup> 4.25**. Purify 2'-deoxycytidine by recrystallisation from MeOH/Et<sub>2</sub>O or EtOH and dry it in air. [NMR: Miles *J Am Chem Soc* **85** 1007 1963, UV: Fox & Shugar *Biochim Biophys Acta* **9** 369 1952.] The *hydrochloride* crystallises from H<sub>2</sub>O/EtOH and has **m** 174°(dec, 169-173°). [Walker & Butler *Can J Chem* **34** 1168 1956.] The *picrate* has **m** 208°(dec). [Fox et al. *J Am Chem Soc* **83** 4066 1961, *Beilstein* **25** III/IV 3662.]

**2'-Deoxycytidine 5'-monophosphoric acid (deoxycytidylic acid)** [1032-65-1] **M 307.2, m 170-172°(dec),**

183-184°(dec), 183-187°(dec),  $[\alpha]_D^{21} +35^\circ$  (c 0.2, H<sub>2</sub>O), pK<sub>1</sub> 4.6, pK<sub>2</sub> 6.6. Recrystallise the acid from H<sub>2</sub>O or aqueous EtOH and dry it in a vacuum. [Volkin et al. *J Am Chem Soc* **73** 1533 1951, UV: Fox et al. *J Am Chem Soc* **75** 4315 1953, IR: Michelson & Todd *J Chem Soc* 3438 1954, *Beilstein* **25** IV 3664.]

**2'-Deoxyguanosine monohydrate** (9-[2-deoxy-β-D-ribofuranosyl]guanidine) [961-07-9] M 285.3, m ca 200°(dec),  $[\alpha]_D^{20} +37.5^\circ$  (c 2, H<sub>2</sub>O),  $[\alpha]_D^{14} -47.7^\circ$  (c 0.9, N NaOH), pK<sub>Est(1)</sub>~ 3.3, pK<sub>Est(2)</sub>~ 9.2. 2'-Deoxyguanosine recrystallises from H<sub>2</sub>O as the monohydrate. [Brown & Lythgoe *J Chem Soc* 1990 1950, Levene & London *J Biol Chem* **81** 711 1929, **83** 793 1929, UV: Hotchkiss *J Biol Chem* **175** 315 1948, ORD: Levendahl & James *Biochim Biophys Acta* **26** 89 1957.] The 3',5'-di-O-acetyl derivative crystallises from aqueous EtOH with m 222°(dec), and  $[\alpha]_D^{18} -38^\circ$  (c 0.3, 10% aqueous EtOH) [Hayes et al. *J Chem Soc* 808, 813 1955]. [*Beilstein* **26** III/IV 3897.]

**2'-Deoxyinosine** [890-38-0] M 252.2, m 206°(dec), 218-220°(dec),  $[\alpha]_D^{25} -21^\circ$  (c 2, N NaOH),  $[\alpha]_D^{21.5} -21^\circ$  (c 1, H<sub>2</sub>O), pK<sub>Est(1)</sub>~8.9, pK<sub>Est(2)</sub>~12.4. Purify 2'-deoxyinosine by recrystallisation from H<sub>2</sub>O. [Brown & Lythgoe *J Chem Soc* 1990 1950, UV: MacNutt *Biochem J* **50** 384 1952, *Beilstein* **26** III/IV 2086.]

**5-Deoxy-5-(methylthio)adenosine** [2457-80-9] M 297.3, m 210-213°(dec), 211°, 212°, 213-214°.  $[\alpha]_D^{20} -23.7^\circ$  (c 0.02, pyridine),  $[\alpha]_D^{20} -8^\circ$  (c 1, 5% aqueous NaOH),  $[\alpha]_D^{25} +15^\circ$  (c 0.4-1.0, 0.3N aqueous AcOH), pK<sub>Est</sub>~3.5. Recrystallise it from H<sub>2</sub>O and sublime it at 200°/0.004mm. [v.Euler & Myrbäck *Hoppe Seyler's Z physiol Chem* **177** 237 1928, Weygand & Trauth *Chem Ber* **84** 633 1951, Baddiley et al. *J Chem Soc* 2662 1953.] The hydrochloride has m 161-162° [Kuhn & Henkel *Hoppe Seyler's Z Physiol Chem* **269** 41 1941]. The picrate has m 183°(dec) (from H<sub>2</sub>O). [*Beilstein* **26** III/IV 3675.]

**Deoxyribonucleic acid (from plasmids).** Purify plasmid DNA by two buoyant density ultracentrifugations using ethidium bromide-CsCl. The ethidium bromide is extracted with Et<sub>2</sub>O, and the DNA is dialysed against buffered EDTA and lyophilised. [Marmur & Doty *J Mol Biol* **5** 109 1962, Guerry et al. *J Bacteriol* **116** 1064 1973.] See "Introduction" in this Chapter.

**3'-Deoxythymidine** {2',3'-dideoxythymidine, 1-[(2*r*)-5*c*-hydroxymethyltetrahydro(2*r*)-furyl]-5-methylpyrimidine-2,4-dione} [3416-05-5] M 226.2, m 145°, 149-151°,  $[\alpha]_D^{26} +18^\circ$  (c 1, H<sub>2</sub>O), pK<sub>Est</sub>~ 9.2. Crystallise it from Me<sub>2</sub>CO/MeOH. [Michelson & Todd *J Chem Soc* 816 1955, *Beilstein* **24** III/IV 1297.]

**2'-Deoxyuridine** [1-(β-D-erythro-2-deoxypentofuranosyl)-1*H*-pyrimidine-2,4-dione] [951-78-0] M 228.2, m 163°, 163-163.5°, 165-167° 167°,  $[\alpha]_D^{26} +30^\circ$  (c 2, H<sub>2</sub>O),  $[\alpha]_D^{22} +50^\circ$  (c 1, N NaOH), pK<sub>25</sub> 9.3. 2'-Deoxyuridine forms needles from absolute EtOH or 95% EtOH. [Dekker & Todd *Nature* **166** 557 1950, Brown et al. *J Chem Soc* 3035 1958, NMR Jardetzky *J Am Chem Soc* **83** 2919 1961, Fox & Shugar *Biochim Biophys Acta* **9** 369 1952, UV: MacNutt *Biochem J* **50** 384 1952, *Beilstein* **24** III/IV 1200.]

**3'-Deoxyuridine** {1-[(2*R*)-5*c*-hydroxymethyltetrahydro(2*r*)furyl]-5-methylpyrimidin-2,4-dione, 2',3'-dideoxythymidine} [7057-27-4, 3416-05-5] M 226.2, m 149-151°,  $[\alpha]_D^{20} +18^\circ$  (c 1, H<sub>2</sub>O), pK<sub>Est</sub>~ 9.3. 3'-Deoxyuridine is recrystallised from Me<sub>2</sub>CO/MeOH and is dried in a vacuum. [Michelson & Todd *J Chem Soc* 816 1955.]

**Desthiobiotin (4*R*-cis-5-methyl-2-oxo-4-imidazolidinehexanoic acid)** [533-48-2] M 214.3, m 156-158°,  $[\alpha]_D^{20} +10.5^\circ$  (c 2, H<sub>2</sub>O), pK<sub>Est</sub>~2.8. Dissolve desthiobiotin in 0.5% Na<sub>2</sub>CO<sub>3</sub>, filter, acidify with HCl to Congo Red, concentrate to a small volume (2-3 ml) to give fine needles, filter it off and recrystallise it twice from H<sub>2</sub>O, m 157-158°. It also crystallises from 95% EtOH. The methyl ester crystallises from MeOH and sublimes at 100°/high vacuum, m 69-70°,  $[\alpha]_D^{27.5} +2.6^\circ$  (c 2, CHCl<sub>3</sub>). [Melville et al. *Science* **98** 497 1943, *J Am Chem Soc* **66** 1422 1944, *Beilstein* **25** III/IV 1543.]

**Di- and tri-carboxylic acids.** These are separated by anion-exchange chromatography. [Bengtsson & Samuelson *Anal Chim Acta* **44** 217b 1969.]

**7,8-Dihydrofolic acid (7,8-dihydropteroyl-L-glutamic acid, DHFA)** [4033-27-6] M 443.4, pK<sub>1</sub> 2.0 (basic

**10-NH), pK<sub>2</sub> 2.89 (2-NH<sub>2</sub>), pK<sub>3</sub> 3.45 (α-CO<sub>2</sub>H), pK<sub>4</sub> 4.0 (basic 5N), pK<sub>5</sub> 4.8 (γ-CO<sub>2</sub>H), pK<sub>6</sub> 9.54 (acidic 3NH).** DHFA is best purified by suspending (1g mostly dissolved) in ice-cold sodium ascorbate (300ml of 10% at pH 6.0, prepared by adjusting the pH of 30g of sodium ascorbate in 150ml of H<sub>2</sub>O by adding 1N NaOH dropwise using a glass electrode till the pH is 6.0). This gives a clear solution with pH ~5. While stirring at 0°, add N HCl dropwise slowly (0.1ml/min) until the pH drops to 2.8 when white birefringent crystals separate. These are collected by centrifugation (1000xg for 5 minutes), washed 3x with 0.001N HCl also by centrifugation and decantation. The residue is then dried in a vacuum (0.02mm) over P<sub>2</sub>O<sub>5</sub> (change the P<sub>2</sub>O<sub>5</sub> frequently at first) and KOH at 25° in the dark. After 24 hours the solid reaches constant weight.

For the assay of *dihydrofolate reductases* (see [9002-03-3] p 803): suspend ~66.5mg of DHFA in 10ml of 0.001M HCl containing 10mM dithiothreitol (DTT stock made from 154mg in 10ml H<sub>2</sub>O making 0.1M), shake well and freeze in 400μl aliquots. Before use, mix 400μl of this suspension with 0.1M DTT (200μl, also made in frozen aliquots), and the mixture is diluted with 200μl of 1.5M Tris-HCl pH 7.0 and 1.2ml of H<sub>2</sub>O (making a total volume of ~2ml) to give a clear solution. To estimate the concentration of DHFA in this solution, dilute 20μl of this solution to 1ml with 0.1M Tris-HCl pH 7.0 and read the OD at 282nm in a 1cm path length cuvette. ε at 282nm is 28,000M<sup>-1</sup>cm<sup>-1</sup>. [Futterman *Methods Enzymol* **6** 801 1963, Reyes & Rathod *Methods Enzymol* **122** 360 1986, *Beilstein* **26** III/IV 3934.]

**DL-erythro-Dihydrosphingosine (dl-erythro-2-amino-octadecan-1,3-diol) [3102-56-5] M 301.5, m 85-86°, 85-87°, pK<sub>Est</sub> ~ 8.8.** Purify it by recrystallisation from petroleum ether/EtOAc or CHCl<sub>3</sub>. The (±)-*N*-dichloroacetyl derivative has **m** 142-144° (from MeOH). [Shapiro et al. *J Am Chem Soc* **80** 2170 1958, Shapiro & Sheradsky *J Org Chem* **28** 2157 1963.] The D-isomer crystallises from petroleum ether/Et<sub>2</sub>O and has **m** 78.5-79°, [α]<sub>546</sub><sup>28</sup> +6° (CHCl<sub>3</sub>/MeOH, 10:1). [Grob & Jenny *Helv Chim Acta* **35** 2106 1953, Jenny & Grob *Helv Chim Acta* **36** 1454 1953, *Beilstein* **4** I 448, **4** II 757, **4** III 854, **4** IV 1887.]

**Dihydrostreptomycin sesquisulfate [5490-27-7] M 461.4, m 250°(dec), 255-265°(dec), [α]<sub>D</sub><sup>20</sup> -92.4° (c 1, H<sub>2</sub>O), pK<sub>Est(1)</sub> ~ 9.5 (NMe), pK<sub>Est(2,3)</sub> ~ 13.4 (guanidino).** It crystallises from H<sub>2</sub>O, MeOH, *n*-BuOH or methyl ethyl ketone. The crystals are not hygroscopic like the amorphous powder; however, both forms are soluble in H<sub>2</sub>O but the amorphous solid is about 10 times more soluble than the crystals. The *free base* also crystallises from H<sub>2</sub>O/Me<sub>2</sub>CO and has [α]<sub>D</sub><sup>26</sup> -92° (aqueous solution pH 7.0). [Solomons & Regina *Science* **109** 515 1949, Wolf et al. *Science* **109** 515 1949, McGilveray & Rinehart *J Am Chem Soc* **87** 4003 1956]. [*Beilstein* **18** III/IV 7538.]

**2,4-Dihydroxyimidazole (hydantoin, imidazolin-2,4-dione) [461-72-3] M 100.1, m 215°, 218-220°, 220°, pK<sup>25</sup> 9.15, pK<sup>18</sup> 9.16.** Well over the past hundred years many syntheses of hydantoin have been reported involving the reaction of alloxanic acid with HI [Baeyer *Justus Liebigs Ann Chem* **119** 127 1861 and **130** 159 1864], the cyclisation of urea derivatives [Harries & Weiss *Chem Ber* **33** 3418 1900 and *Justus Liebigs Ann Chem* **327** 366 1903], the cyclisation of ethyl *N*-carbamoylglycinate, accomplished with NaOMe in MeOH in 85% yield [Kavalek et al. *Col Czech Chem Commun* **51** 375 1986], and more recently by the acid catalysed condensation of glycine with KNCO [El-Deeb et al. *Eur J Med Chem* **45** 2516 2010]. In a later patent, glycine (75g, 1 mole) and urea (140g, 2.3 moles) were dissolved in H<sub>2</sub>O (120ml) and stirred under reflux for 12 hours. The mixture was acidified by careful addition of concentrated H<sub>2</sub>SO<sub>4</sub> while being cooled in an ice bath, then boiled for 1 hour, cooled to 0-5°, and the crystalline solid was filtered off, washed with cold H<sub>2</sub>O and dried. A further crop was obtained by evaporating the mother liquor. The combined solids were recrystallised from glacial AcOH (10 parts) to give pure *hydantoin* (71g, 70%) m 220-220°. [Alkaloida US patent 4647694 1987.] It can be purified by dissolving it in at least 2.5 parts of hot H<sub>2</sub>O (charcoal), filtering, acidifying to pH ~6, filtering again, collecting the solid, washing it with ice cold H<sub>2</sub>O, drying it, and recrystallising it from EtOH (needles) or from 10 parts of AcOH. Its solubility is 39.7g/L in H<sub>2</sub>O and 3.24g/L in EtOH at 25°. It has λ<sub>max</sub> (ε) at 215(400) and 245(60)nm in 0.01N EtOH/NaOH; 215(360) and 245(50)nm in EtOH/H<sup>+</sup>; and has ν<sub>max</sub> at 1697 (2CO) and 1776 (4CO) cm<sup>-1</sup> in a paraffin mull [West *J Biol Chem* **34** 187 1918, Crombie & Hooper *J Chem Soc* 3010 1955, *Beilstein* **24** H 242, **24** I 287, **24** II 127, **24** III/IV 1034].

**1,2-Dilauroyl-*sn*-glycero-3-phosphoethanolamine (±-dilauroyl-α-cephalin, 3-*sn*-phosphat-idylethanolamine 1,2-didodecanoyl) [59752-57-7] M 579.8, m 210°, pK<sub>Est(1)</sub> ~ 5.8 (PO<sub>4</sub>H), pK<sub>Est(2)</sub> ~ 10.5 (NH<sub>2</sub>).**

Recrystallise it from EtOH or tetrahydrofuran. [Bevan & Malkin *J Chem Soc* 2667 1951, IR: Bellamy & Beecher *J Chem Soc* 728 1953, *Beilstein* 4 IV 1417.]

**1,2-Dimyristoyl-sn-glycero-3-phosphocholine monohydrate (dimyristoyl-L- $\alpha$ -lecithin)** [18194-24-6 (1H<sub>2</sub>O)] **M 696.0**,  $[\alpha]_D^{24} +7.0$  (c 8, EtOH-CHCl<sub>3</sub> 1:1 for  $\alpha_1$  form), **pK<sub>Est</sub> ~ 5.8 (PO<sub>4</sub>)**. It has three forms  $\alpha_1$ ,  $\alpha_2$  and  $\beta'$ . Recrystallise it from aqueous EtOH or EtOH/Et<sub>2</sub>O. Its solubility at 22-23° in Et<sub>2</sub>O is 0.03%, in Me<sub>2</sub>CO it is 0.06% and in pyridine it is 1.3%. [Baer & Kates *J Am Chem Soc* 72 942 1950, Baer & Maurakas *J Am Chem Soc* 74 158 1952, IR: Marinetti & Stotz *J Am Chem Soc* 76 1347 1954.] The *S*-isomer with 1H<sub>2</sub>O is recrystallised from 2,6-dimethylheptan-4-one and has **m** 226-227° (sintering at 90-95°), and  $[\alpha]_D^{20} -7.0$  (c 6, MeOH/CHCl<sub>3</sub> 1:1). [Baer & Martin *J Biol Chem* 193 835 1951, *Beilstein* 4 IV 1463.]

**(±)-1,2-Dimyristoyl-sn-glycero-3-phosphoethanolamine (dimyristoyl- $\alpha$ -kephalin)** [998-07-2] **M 635.9**, **m 207°**, **pK<sub>Est(1)</sub> ~ 5.8 (PO<sub>4</sub>H)**, **pK<sub>Est(2)</sub> ~ 10.5 (NH<sub>2</sub>)**. Recrystallise the kephalin from EtOH [Bevan & Malkin *J Chem Soc* 2667 1951]. The *R*-isomer has **m** 195-196° (sintering at 130-135°) after recrystallisation from CHCl<sub>3</sub>/MeOH, and  $[\alpha]_D^{26} +6.7$  (c 8.5, CHCl<sub>3</sub>/AcOH 9:1). [Baer *Can J Biochem Physiol* 35 239 1957, Baer et al. *J Am Chem Soc* 74 152 1952, *Beilstein* 4 IV 1463.]

***S*(-)-1,2-Dipalmitin (*S*-1,2-dipalmitoyl-sn-glycerol)** [30334-71-5] **M 568.9**, **m 68-69°**  $[\alpha]_D^{20} -2.9$  (c 8, CHCl<sub>3</sub>), the ***R*(+)-isomer (2,3-dipalmitoyl-sn-glycerol)** [6076-30-8] has **m 67.5-68.2°**,  $[\alpha]_D^{20} -2.8$  (c 8, CHCl<sub>3</sub>). Crystallise *S*(-)-1,2-dipalmitin from chloroform/petroleum ether (b 40-60°) ~1:1.5. [*S*(-)-isomer: Baer & Kates *J Am Chem Soc* 72 942 1950, Hanahan & Vercamer *J Am Chem Soc* 76 1804 1954, *R*(+)-isomer: Tattrie et al. *Arch Biochem* 78 319 1958, *Beilstein* 2 IV 1173.] The *racemate* [40290-32-2] is polymorphic with different IR spectra. When crystallised from hexane, or other solvents, the higher melting form with **m** 71.5-72.5° is obtained. The melt then solidifies to give the lower melting  $\alpha$ -form with **m** 49.7-50°. The  $\beta$ -form has **m** 61° (65-66° is also reported). When the lower melting forms are kept at their melting temperatures for a while, they are converted to the higher melting form. [Howe & Malkin *J Chem Soc* 2663 1951, Baer & Kates *J Am Chem Soc* 72 942 1950, *Beilstein* 2 IV 1173.]

***R*-Dipalmitoyl-sn-glycero-3-phosphatidic acid** [7091-44-3] **M 648.9**,  $[\alpha]_D^{26} +4.0$  (c 10, CHCl<sub>3</sub>), **pK<sub>Est(1)</sub> ~1.6**, **pK<sub>Est(2)</sub> ~6.1**. Recrystallise the acid from Me<sub>2</sub>CO at low temperature. At 21° it is soluble in \*C<sub>6</sub>H<sub>6</sub> (4.2%), petroleum ether (0.01%), MeOH (2%), EtOH (2.5%), AcOH (1.3%), Me<sub>2</sub>CO (1.76%), and Et<sub>2</sub>O (1.5%). [Baer *J Biol Chem* 189 235 1951.]

***R*-1,2-Dipalmitoyl-sn-glycero-3-phosphocholine monohydrate (dipalmitoyl- $\alpha$ -L-lecithin)** [63-89-8] **M 752.1**, **m** sinters at 120°,  $[\alpha]_D^{25} +7.0$  (c 5.6, absolute CHCl<sub>3</sub>), **pK<sub>Est</sub> ~5.8 (PO<sub>4</sub>)**. It has three crystalline forms  $\alpha_1$ ,  $\alpha_2$  and  $\beta'$  which change at 60-70° and at 229°, respectively. In order to obtain a fine powder, ~2 g are dissolved in CHCl<sub>3</sub> (15ml) and petroleum ether (b 35-60°) is added; the solution is evaporated to dryness *in vacuo* at <20° and then dried at 0.1mm over CaCl<sub>2</sub>. [Baer & Maurukas *J Am Chem Soc* 74 158 1952, Baer & Kates *J Biol Chem* 185 615 1950, *Beilstein* 4 IV 1463.]

***dl*- $\beta\gamma$ -Dipalmitoylphosphatidyl choline** [2797-68-4] **M 734.1**, **m 230-233°**, **pK<sub>Est</sub> ~5.8 (PO<sub>4</sub>)**. Recrystallise the choline from chloroform and dry it for 48 hours at 10<sup>-5</sup> Torr [O'Leary & Levine *J Phys Chem* 88 1790 1984].

**1,2-Distearoyl-sn-glycerol** [1429-59-0] **M 625.0**. The *dl*-form recrystallises from CHCl<sub>3</sub>/petroleum ether (b 40-60°), **m** 59.5° ( $\alpha$  form) and 71.5-72.5° ( $\beta$  form). Recrystallisation from solvents such as EtOH, MeOH, toluene, Et<sub>2</sub>O gives the higher melting form, and resolidification gives the lower melting form. [IR: Chapman *J Chem Soc* 4680 1958, 2522 1956.] The *S*-isomer is recrystallised from CHCl<sub>3</sub>/petroleum ether and has **m** 76-77°,  $[\alpha]_D^{24} -2.8$  (c 6, CHCl<sub>3</sub>). [Baer & Kates *J Am Chem Soc* 72 942 1950, *Beilstein* 2 IV 1231.]

**1,2-Distearoyl-sn-glycero-3-phosphoethanolamine (distearoyl- $\alpha$ -kephalin)** [1069-79-0] **M 748.1**, **m 180-182° (*R*-form, sintering at 130-135°)**, **m 196° ( $\pm$  form)**, **pK<sub>Est(1)</sub> ~5.8 (PO<sub>4</sub>H)**, **pK<sub>Est(2)</sub> ~10.5 (NH<sub>2</sub>)**. The *R*-form is recrystallised from CHCl<sub>3</sub>/MeOH, and the  $\pm$ -form is recrystallised from EtOH. [Bevan & Malkin *J Chem Soc* 2667 1951, Baer *Can J Biochem Physiol* 81 1758 1959, *Beilstein* 4 IV 1420.]

**Dolichol (from pig liver)** [11029-02-0]  $C_{80}$ - $C_{105}$  **polyprenols**. Crystallise each dolichol 6 times from petroleum ether/EtOH at  $-20^{\circ}$ . The pure individual prenil should run as an entity on a chromatogram on paraffin impregnated paper, with acetone as the mobile phase. [Burgos *Biochem J* **88** 470 1963.]

**Domoic acid [4-(2-carboxyhexa-3,5-dienyl)-3-carboxymethylproline]** [14277-97-5] **M 311.3, m  $215^{\circ}$ ,  $217^{\circ}$ ,  $[\alpha]_D^{20} -108^{\circ}$  (c 1,  $H_2O$ ),  $pK_1$  2.20 ( $2-CO_2H$ ),  $pK_2$  3.72 ( $CO_2H$ ),  $pK_3$  4.93 ( $3-CH_2CO_2H$ ),  $pK_4$  9.82 (NH).** Domoic acid (~300 mg) is purified on a Dowex1 column (3.5 x 40 mm, 200-400 mesh, acetate form), washed with  $H_2O$  until neutral, then eluted with increasing concentrations of AcOH (8L) from 0 to 0.25M. The fraction containing domoic acid (in 50ml) is collected, evaporated to dryness under reduced pressure and recrystallised from aqueous EtOH. It is a glutamate and a Kainate receptor agonist. [Impellizzeri et al. *Phytochemistry* **14** 1549 1975, Takemoto & Diago *Arch Pharm* **293** 627 1960, *Beilstein* **22/4** V 371.]

**Enniatin A** [11113-62-5] **M 681.9, m  $122-122.5^{\circ}$ ,  $[\alpha]_D^{18} -92^{\circ}$  (c 0.9,  $CHCl_3$ ).** It is a cyclic peptidic ester antibiotic which is recrystallised from EtOH/water but is deactivated in alkaline solution. [Ovchinnikov & Ivanov in *The Proteins* (Neurath and Hill eds) Academic Press, NY, Vol V pp. 365 and 516 1982, Tomeda et al. *J Antibiot* **45** 1626 1992.]

**(-)-Ephedrine (1R,2S-2-methylamino-1-phenylpropanol)** [299-42-3] **M 165.2, m  $\sim 34^{\circ}$ ,  $36^{\circ}$ ,  $38.1^{\circ}$ ,  $40^{\circ}$ , b  $126-129^{\circ}/7mm$ ,  $225-227^{\circ}/760mm$ ,  $d^{22} 1.0085$ ,  $[\alpha]_{546}^{20} -47^{\circ}$  and  $[\alpha]_D^{26} -42^{\circ}$  (c 4, 3% HCl),  $[\alpha]_D^{22.5} +15.1^{\circ}$  (c 0.8,  $H_2O$ ),  $-9.36^{\circ}$  (c 3, MeOH),  $pK^{22} 9.58$  ( $pK^{25} 8.84$  in 80% aqueous methoxyethanol).** Purify (-)-ephedrine by vacuum distillation (dehydrates) and forms waxy crystals or granules, and may pick up 0.5  $H_2O$ . The presence of  $H_2O$  raises its melting point to  $40^{\circ}$ . [Moore & Taber *J Amer Pharm Soc* **24** 211 1935.] The *anhydrous base* crystallises from dry ether [Fleming & Saunders *J Chem Soc* 4150 1955]. It gradually decomposes on exposure to light and is best stored in an inert atmosphere in the dark (preferably at  $-20^{\circ}$ ). Its solubility in  $H_2O$  is 5%, in EtOH it is 1% and it is soluble in  $CHCl_3$ ,  $Et_2O$  and mineral oils. It has  $pK_a$  values in  $H_2O$  of 10.25 ( $0^{\circ}$ ) and 8.69 ( $60^{\circ}$ ) [Everett & Hyne *J Chem Soc* 1136 1958, Prelog & Häflinger *Helv Chim Acta* **33** 2021 1950] and  $pK_a^{23} 8.84$  in 80% aqueous methoxyethanol [Simon *Helv Chim Acta* **41** 1835 1958]. The *hydrochloride* has **m  $220^{\circ}$**  (from EtOH/ $Et_2O$ ) and  $[\alpha]_D^{20} -38.8^{\circ}$  (c 2, EtOH). [IR: Chatten & Levi *Anal Chem* **31** 1581 1959.] The *anhydrous base* crystallises from  $Et_2O$  [Fleming & Saunders *J Chem Soc* 4150 1955]. [*Beilstein* **13** H 373, **13**, III 1720, **13** IV 1879.]

**(+)-Ephedrine hydrochloride (1S-2R-2-methylamino-1-phenylpropan-1-ol hydrochloride)** [24221-86-1] **M 201.7, m  $216-219^{\circ}$ ,  $[\alpha]_D^{20} +34^{\circ}$  (c 11.5,  $H_2O$ ).** Recrystallise the hydrochloride from EtOH/ $Et_2O$ . The *free base* crystallises from  $*C_6H_6$  with **m  $40-41^{\circ}$**  (Skita et al. *Chem Ber* **66** 974 1933). [*Beilstein* **13** H 254, **13** II 375, **13** III 1721, **13** IV 1879.]

**(-)-Ephedrine hydrochloride** [50-98-6] **M 201.7, m  $218^{\circ}$ ,  $[\alpha]_{546}^{20} -48^{\circ}$  (c 5, 2M HCl).** It crystallises from water. [*Beilstein* **13** H 254.]

**$\alpha$ -Erythroidine (3R,5S,12S)** [466-80-8] **M 273.3, m  $52-55^{\circ}$ ,  $58-60^{\circ}$ ,  $[\alpha]_D^{27} +136^{\circ}$  (c 0.5,  $H_2O$ ),  $pK_{Est(3)} \sim 7.4$**  Recrystallise  $\alpha$ -erythroidine from pentane. It is best prepared freshly from the more stable hydrochloride. The hydrochloride (1.3g) in  $H_2O$  (20ml) is basified with  $NaHCO_3$  to pH  $\sim 8$  and extracted with  $*C_6H_6$  (6 x 10ml). The combined extracts are evaporated to a small volume and refrigerated. The free base separates as white hygroscopic crystals **m  $52-55^{\circ}$** , which are recrystallised from pentane. Although stable in solution, the crystals turn brown on exposure to air.

**$\alpha$ -Erythroidine hydrochloride** is best purified by dissolving 10g in  $H_2O$  (100ml), adjusting the pH to 8 with aqueous  $NaHCO_3$ , extracting with  $*C_6H_6$  (4 x 20ml), evaporating to 20ml, passing through activated  $Al_2O_3$  and eluting with  $*C_6H_6$ . The eluate is evaporated to a small volume and the crystals are collected, dissolved in EtOH and dry HCl gas passed through to give the pure hydrochloride. When recrystallised from EtOH, it has **m  $226-228^{\circ}(dec)$** , and  $[\alpha]_D^{32} +118^{\circ}$  (c 0.5,  $H_2O$ ). It has  $\lambda_{max}$  at 224nm ( $\epsilon$  35, 500); compare with  $\beta$ -erythroidine hydrochloride below. [Boelkeleide & Grundon *J Am Chem Soc* **75** 2563 1953, Boelkeleide & Morrison *J Am*

*Chem Soc* **80** 3905 1958, abs config: Hill & Shearer *J Org Chem* **27** 3342 1955, *Beilstein* **27** III/IV 3569.]

**$\beta$ -Erythroidine (3*R*,5*S*)** [466-81-9] **M 273.3, m 97-99°, 99.5-100°,  $[\alpha]_D^{25} +89^\circ$  (c 0.5, H<sub>2</sub>O).** Purify it like the  $\alpha$ -isomer but recrystallise it from EtOH. The *free base* is unstable in air and light, but the hydrochloride is more stable and best stored as such. The *methiodide* has **m 211°** (prisms from EtOH).

**$\beta$ -Erythroidine hydrochloride** can be obtained from the  $\alpha$ -isomeric salt as follows: The  $\alpha$ -hydrochloride (1.2g) in 10% aqueous NaOH (12ml) is refluxed for 3 hours under N<sub>2</sub>, cooled in ice and conc HCl added to pH 2. After standing for 3 hours, NaHCO<sub>3</sub> is carefully added to pH 7, the solution is extracted with CHCl<sub>3</sub> (5x), and the extracts are dried, filtered, and concentrated to give an oil which on seeding gives  $\beta$ -erythroidine **m 97-99°**. When dissolved in EtOH and dry HCl gas is passed through the solution, the pure  $\beta$ -erythroidine hydrochloride crystallises out with **m 230.5-231.5°,  $[\alpha]_D^{25} +10^\circ$  (c 0.5, H<sub>2</sub>O).** It is a muscle relaxant with a curare-like-action and is more active than the  $\alpha$ -isomer. [Koniuszy & Folkers *J Am Chem Soc* **72** 519 1950, Boekelheide et al. *J Am Chem Soc* **75** 2550 1953, Boekelheide & Morrison *J Am Chem Soc* **80** 3905 1958, Wenzinger & Boekelheide *J Org Chem* **29** 1307 1964, Berger & Schwartz *J Pharmacol Exp Therap* **93** 362 1948, *Beilstein* **4** IV 3568.]

**Erythromycin A** [114-07-8] **M 733.9, m 133-135°(dec), 135-140°, 137-140°,  $[\alpha]_D^{20} -75^\circ$  (c 2, EtOH), pK<sup>25</sup> 8.9.** It recrystallises from H<sub>2</sub>O to form hydrated crystals which melt at *ca* 135-140°, resolidifies and melts again at 190-193°. The melting point after drying at 56°/8mm is that of the *anhydrous* material and is at 137-140°. Its solubility in H<sub>2</sub>O is ~2mg/ml. The *hydrochloride* has **m 170°, 173°** (from aqueous EtOH, EtOH/Et<sub>2</sub>O). [Flynn et al. *J Am Chem Soc* **76** 3121 1954, constitution: Wiley et al. *J Am Chem Soc* **79** 6062 1957]. [*Beilstein* **18/10** V 398.]

**Ethidium bromide** [1239-45-8] **M 384.3, m 260-262°.** Crystallise it from MeOH or EtOH [Lamos et al. *J Am Chem Soc* **108** 4278 1986]. Its solubility in H<sub>2</sub>O is 1%. [*Beilstein* **22/11** V 352.] **POSSIBLE CARCINOGEN.**

**Ethyl 7-acetoxycoumarin-3-carboxylate** [13207-77-3] **M 276.3, m 147-148°, 152°, 152-154°, pK<sup>25</sup> 7.04.** Purify the ester by recrystallisation from EtOH or aqueous EtOH, dry it *in vacuo* and store it at 2-8°. It is a good fluorogenic substrate for esterases that hydrolyse it to the acid, which acts as an indicator. The fluorescence has  $\lambda_{ex}$  386nm,  $\lambda_{em}$  445nm in 0.1 M Tris buffer pH 8.0. It has been prepared by refluxing 2-imino-3-ethoxycarbonyl-7-hydroxy-2*H*-chromene with Ac<sub>2</sub>O for 1 hour, evaporating and recrystallising the residue from aqueous MeOH [Yasuda & Midorikawa *Bull Chem Soc Jpn* **39** 1754 1966]. *Alternatively*, it can be prepared by acetylation of 7-hydroxy-3-carbethoxycoumarin by the Ac<sub>2</sub>O/pyridine method, and crystallises from EtOH in plates, **m 152°**. An attempted Fries rearrangement by heating the ester with anhydrous AlCl<sub>3</sub> at 16-170° failed, but gave **7-hydroxy-3-carboxycoumarin, m 271° (dec)** (from H<sub>2</sub>O). [Shah & Shah *J Org Chem* **13** 1681 1954, see also Boehm *Archiv der Pharmazie (Weinheim)* **271** 490 1933.]

**Farnesol (trans-trans-3,7,11-trimethyl-2,6,10-dodecatrien-1-ol)** [106-28-5, 4602-84-0 (*trans-trans, E,E*)] **M 222.4, b 111°/0.35mm, 126-127°/0.5mm, 142-143°/2mm,  $d_4^{20}$  0.8871,  $n_D^{20}$  1.4870.** The main impurity is the *cis-trans* isomer. Purify it by gas chromatography using a 4ft x 0.125in 3%OV-1 column at 150°. [Corey et al. *J Am Chem Soc* **92** 6637 1970, Popjak et al. *J Biol Chem* **237** 56 1962.] It has also been fractionated through a 14-in Podbielniak column at 11°/0.35mm. *Alternatively*, it has been purified by gas chromatography using SF96 silicone on Fluoropak columns or Carbowax 20M on Fluoropak or base-washed 30:60 firebrick (to avoid decomposition, prepared by treating the firebrick with 5N NaOH in MeOH and washed with MeOH to pH 8) at 210° with Helium carrier gas at 60 ml/min flow rate. The *diphenylcarbamoyl* derivative has **m 61-63°** (from MeOH) and has an IR band at 3500 cm<sup>-1</sup>. [Bates et al. *J Org Chem* **28** 1086 1963, *Beilstein* **1** IV 2335.]

**Farnesyl acetate (trans-trans-3,7,11-trimethyl-2,6,10-dodecatrien-1-yl acetate)** [4128-17-0 (*trans-trans, E,E*): 29548-30-9 (*isomeric mixture*)] **M 264.4, b 115-125°/0.3mm, 167-169°/0.3mm,  $d_4^{20}$  0.91,  $n_D^{20}$  1.4870.** Purify farnesyl acetate in the same way as the alcohol above. [*Beilstein* **2** I 66, **2** II 154, **2** III 303.]

**Farnesyl pyrophosphate** [13058-04-3, *E,E*: 372-97-4] **M 382.3, pK<sub>Est(1)</sub> ~<2, pK<sub>Est(2)</sub> ~<2, pK<sub>Est(3)</sub> ~3.95, pK<sub>Est(4)</sub> ~6.26.** Purify the pyrophosphate by chromatography on Whatman No3 MM paper in a system of isopropanol-isobutanol/ammonia/water (40:20:1:30) (v/v). Store it as the Li or NH<sub>4</sub> salt at 0°. See geranyl-

geranyl pyrophosphate below.

**Flavin adenine dinucleotide (di-Na, 2H<sub>2</sub>O salt, FAD)** [146-14-5, 84366-81-4 (anhydrous)] **M 865.6**,  $[\alpha]_{546}^{-540}$  (**c 1, H<sub>2</sub>O**). Small quantities of FAD are purified by paper chromatography using *tert*-butyl alcohol/water, cutting out the main spot and eluting with water. Larger amounts can be precipitated from water as the uranyl complex by adding a slight excess of uranyl acetate to a solution at pH 6.0, dropwise and with gentle stirring. The solution is set aside overnight in the cold, and the precipitate is centrifuged off, washed with small portions of cold EtOH, then with cold peroxide-free diethyl ether. It is dried in the dark under vacuum over P<sub>2</sub>O<sub>5</sub> at 50-60°. The uranyl complex is suspended in water, and, after adding sufficient 0.01M NaOH to adjust the pH to 7, the precipitate of uranyl hydroxide is removed by centrifugation [Huennekens & Felton *Methods Enzymol* **3** 954 1957]. It can also be crystallised from water. It should be kept in the dark. More recently it was purified by elution from a DEAE-cellulose (Whatman DE 23) column with 0.1M phosphate buffer pH 7, and the purity was checked by TLC. [Holt & Cotton, *J Am Chem Soc* **109** 1841 1987, *Beilstein* **26** III/IV 3632.]

**Flavin mononucleotide (Na, 2H<sub>2</sub>O salt, riboflavin-5'-phosphate [Na salt, 2H<sub>2</sub>O], FMN)** [130-40-5, 6184-17-4 (Na salt)] **M 514.4**, **pK<sub>1</sub> 2.1 (PO<sub>4</sub>H<sub>2</sub>)**, **pK<sub>2</sub> 6.5 (PO<sub>4</sub>H<sup>-</sup>)**, **pK<sub>3</sub> 10.3 (CONH)**, **fluorescence  $\lambda_{\max}$  530nm (870nm for reduced form)**. Purify FMN by paper chromatography using *tert*-butanol/water, cutting out the main spot and eluting it with water. It can also be purified by adsorption onto an apo-flavodoxin column, followed by elution and freeze drying. It crystallises from aqueous acidic solution. [Mayhew & Strating *Eur J Biochem* **59** 539 1976, *Beilstein* **26** III/IV 2555.]

**5-Fluorouridine (5-fluoro-1- $\beta$ -D-ribofuranosyl-1H-pyrimidine-2,4-dione)** [316-46-1] **M 262.2**, **m 180-182°, 182-184°**,  $[\alpha]_{\text{D}}^{20} +18^{\circ}$  (**c 1, H<sub>2</sub>O**), **pK<sub>Est(1)</sub> ~ 8.0**, **pK<sub>Est(2)</sub> ~ 13**. 5-Fluorouridine is recrystallised from EtOH/Et<sub>2</sub>O and dried at 100° in a vacuum. It has UV with  $\lambda_{\max}$  at 269nm (pH 7.2, H<sub>2</sub>O), 270nm (pH 14, H<sub>2</sub>O). [Liang et al. *Mol Pharmacol* **21** 224 1982, *Beilstein* **24** III/IV 1231.]

**Folic acid (FA, pteroyl-S-glutamic acid)** [59-30-3, 75708-92-8 (2H<sub>2</sub>O)] **M 441.4**, **m >250°(dec)**,  $[\alpha]_{\text{D}}^{25} +23^{\circ}$  (**c 0.5, 0.1N NaOH**), **pK<sub>1</sub> 2.35 (protonation N10)**, **pK<sub>2</sub> 2.75 (protonation N1)**, **pK<sub>3</sub> 3.49 ( $\alpha$ -CO<sub>2</sub>H)**, **pK<sub>4</sub> 4.65 ( $\gamma$ -CO<sub>2</sub>H)**, **pK<sub>5</sub> 8.80 (acidic N3)**. If paper chromatography indicates impurities, then recrystallise it from hot H<sub>2</sub>O or from dilute acid [Walker et al. *J Am Chem Soc* **70** 19 1948]. Impurities may be removed by repeated extraction with *n*-BuOH of a neutral aqueous solution of folic acid (by suspending in H<sub>2</sub>O and adding N NaOH dropwise till the solid dissolves, then adjusting the pH to ~7.0-7.5) followed by precipitation with acid, filtration, or *better* collected by centrifugation and recrystallised from hot H<sub>2</sub>O. [Blakley *Biochem J* **65** 331 1975, Kalifa et al. *Helv Chim Acta* **61** 2739 1978.] Chromatography on cellulose followed by filtration through charcoal has also been used to obtain pure acid. [Sakami & Knowles *Science* **129** 274 1959.] UV:  $\lambda_{\max}$  247 and 296nm ( $\epsilon$  12,800 and 18,700) in H<sub>2</sub>O pH 1.0; 282 and 346nm ( $\epsilon$  27,600 and 7,200) in H<sub>2</sub>O pH 7.0; 256, 284 and 366nm ( $\epsilon$  24600, 24,500 and 86,00) in H<sub>2</sub>O pH 13 [Rabinowitz in *The Enzymes* (Boyer et al. Eds), **2** 185 1960]. [*Beilstein* **26** III/IV 3944.]

**3-Formylchromone (4-oxo-4H-1-benzopyran-3-carbaldehyde)** [17422-74-1] **M 174.2**, **m 151-153°, 152°, 152-153°**. This useful precursor for heterocyclic compounds [Sabitha *Aldrichim Acta* **29** 12 1996] is best prepared by a Vilsmeier-Haack reaction. Tetrachloropyrophosphate (80ml) is added dropwise to a solution of *o*-hydroxyacetophenone (25g, 0.184mole) in DMF (80ml) at -20° to 20° during 10 minutes. The mixture is stirred at ~25° for 13 hours, poured into ice-water and the solid is filtered off, washed with H<sub>2</sub>O, then EtOH, dried *in vacuo*, and recrystallised from Me<sub>2</sub>CO to give white crystals of 3-formylchromone (19.6g, 61%). *Alternatively*, DMF/POCl<sub>3</sub> is used. It has IR bands with  $\nu_{\max}$  at 1605 (CHO), 1650 (C=O) and 1620 (C=C) cm<sup>-1</sup>, the <sup>1</sup>H NMR [60MHz, DMSO-*d*<sub>6</sub>, TMS] has  $\delta$  at 10.16 (s, CHO), 8.9 (s, H-2) and 8.3-7.4 (m, H-5,6,7 and 8), and the MS *m/z*(%) has peaks at 174(4), 147(10), **146(100)**, 121(8), 120(24), 118(3), 105(6), **104(34)**, 92(17), 90(13), 89(11), **76(13)**, 64(12), 63(18), 53(24), fragments in bold are characteristic of the 4-oxo-4H-1-benzopyran-3-carbaldehyde molecule. A large number of substituted derivatives have been prepared in this way and some, particularly the 6-bromoderivative, showed relatively strong anti-anaphylactic activity with low LD<sub>50</sub>, and decreased gastric acid volume. [Nohara et al *Tetrahedron* **30** 3553 1974, Klutchko et al. US Pat 4,098,799 1978, *Chem Abs* **90** 22803 1979.]

**Fructose-1,6-diphosphate (trisodium salt)** [38099-82-0] **M 406.1, pK<sub>1</sub><sup>25</sup> 1.48, pK<sub>2</sub><sup>25</sup> 6.14, pK<sub>3</sub><sup>25</sup> 6.29, pK<sub>4</sub><sup>25</sup> 6.93 (free acid).** Fructose-1,6-diphosphate is best purified *via* the acid strychnine salt which is stable for several months. To remove the strychnine, dissolve 5g in H<sub>2</sub>O (150ml), and add 5N NaOH (or KOH to obtain the K salt) to pH 8.3 (phenolphthalein) with vigorous stirring. Remove the precipitate by centrifugation, wash with cold H<sub>2</sub>O (2x 25ml), extract with CHCl<sub>3</sub> until the extract is free of strychnine (*ca* 8 to 10 times, Mandelein spot test). Freeze-dry the aqueous solution to give the Na salt which is hygroscopic. It has been recrystallised from aqueous EtOH as the *octahydrate*, **m 125°**, **[α]<sub>D</sub><sup>20</sup> +2.6° (c 1, H<sub>2</sub>O).** A neutral solution of the salt keeps well in a frozen state for over several months. [Neuberg et al. *Arch Biochem* **3** 33 1943, Sable *Biochemical Preparations* **2** 52 1952, Stumpf *J Biol Chem* **182** 261 1950]. The *calcium salt* can be partially purified by dissolving in ice-cold N HCl (1g per 10ml) and re-precipitating by dropwise addition of 2N NaOH: the precipitate and supernatant are heated on a boiling water bath for a short time, then filtered, and the precipitate is washed with hot water. The *magnesium salt* can be precipitated from a cold aqueous solution by adding four volumes of EtOH. The *tetramethyl ester* is an oil with **n<sub>D</sub><sup>19</sup> 1.4648, [α]<sub>D</sub><sup>18</sup> +20.2 (c 0.4, MeOH).** [Schulbach & Rauchenberger *Chem Ber* **60** 1178 1927, *Beilstein* **1** IV 4424.]

**Fructose-6-phosphate** [643-13-0] **M 260.1, [α]<sub>D</sub><sup>21</sup> +2.5° (c 3, H<sub>2</sub>O), pK<sub>1</sub><sup>21</sup> 0.97, pK<sub>2</sub><sup>21</sup> 6.11, (pK<sub>2</sub><sup>25</sup> 5.84).** Crystallise fructose-6-phosphate as the barium salt from water by adding 4-volumes of EtOH. The barium can be removed by passage through the H<sup>+</sup> form of a cation exchange resin, and the free acid is collected by freeze-drying. *Alternatively*, the Ba salt is dissolved in H<sub>2</sub>O, and one equivalent of Na<sub>2</sub>SO<sub>4</sub> is added in small portions with stirring, filter off BaSO<sub>4</sub> and freeze dry to give the Na salt. The 6-phosphate hydrolyses more slowly than the 1-phosphate and considerably slower than pyrophosphoric acid (10<sup>2</sup> times) and triphosphoric acid (10<sup>3</sup> times). [Neuberg *Biochem Zeitschrift* **88** 432 1918, pKa: Meyerhof & Lohmann *Biochem Zeitschrift* **185** 113, 131 1927, Neuberg et al. *Arch Biochem* **3** 33, 40 1944, Hydrolysis: Friess *J Am Chem Soc* **74** 5521 1954, *Beilstein* **1** I 464, **1** IV 4423, **H** 31 537.]

**Gangcyclovir** [9-{(1,3-dihydroxy-2-propoxy)methyl}guanine; 2-amino-1,9-{(2-hydroxy-1-hydroxy-methyl)-ethoxymethyl}-6H-purin-6-one; Cytovene; Cymevea(e)n(e)] [82410-32-0] **M 255.2, m >290°(dec), >300°(dec), monohydrate m 248-249°(dec), pK<sub>Est(1)</sub>~1.1, pK<sub>Est(2)</sub>~4.1, pK<sub>Est(3)</sub>~9.7.** Recrystallise gangcyclovir from MeOH. *Alternatively*, dissolve ~90g of it in 700ml of H<sub>2</sub>O, filter and cool (*ca* 94% recovery). It has UV with λ<sub>max</sub> (MeOH) at 254nm (ε 12,880), 270sh nm (ε 9040); its solubility in H<sub>2</sub>O at 25° is 4.3mg/ml at pH 7.0. **ANTIVIRAL.** [Ogilvie et al. *Can J Chem* **60** 3005 1982, Ashton et al. *Biochem Biophys Res Commun* **108** 1716 1982, Martin et al. *J Med Chem* **26** 759 1983.]

**Geraniol** [*trans, E-form* 106-24-1] **M 145.2, b 114-115°/12mm, 229-230°/757mm, d<sub>4</sub><sup>20</sup> 0.889, n<sub>D</sub><sup>20</sup> 1.4628.** Purify geraniol by fractional distillation. It has a sweet rose odour when pure, and the UV has λ<sub>max</sub> at 190-195nm (ε 18,000). [See also p 146, *Beilstein* **1** H 457, **1** IV 2277.]

**Geranyl acetate** [*trans, E-form* 105-87-3; 16409-44-2] **M 196.3, b 118°/12mm, 138°/25mm, 236-242°/760mm(dec), d<sub>15</sub><sup>15</sup> 0.9174, n<sub>D</sub><sup>15</sup> 1.4766.** Purify the fragrant smelling geranyl acetate by fractional distillation at as high a vacuum as possible. It is very soluble in EtOH but insoluble in H<sub>2</sub>O. [*Beilstein* **2** H 140, **2** I 65, **2** II 153, **2** III 299, **2** IV 204.]

**Geranylgeranyl pyrophosphate** [6699-20-3 (NH<sub>4</sub> salt), 64732-91-8] **M 450.5, pK<sub>Est(1)</sub>~<2, pK<sub>Est(2)</sub>~<2, pK<sub>Est(3)</sub>~3.95, pK<sub>Est(4)</sub>~6.26.** Purify the pyrophosphate by countercurrent distribution between two phases of a butanol/isopropyl ether/ammonia/water mixture (15:5:1:19) (v/v), or by chromatography on DEAE-cellulose (linear gradient of 0.02M KCl in 1mM Tris buffer, pH 8.9). *Alternatively*, purify it through a column of Dowex 1-x8 (formate form previously washed with MeOH) and eluted with a linear gradient of 0.053—0.43M ammonium formate in a total volume of 300ml of MeOH. The purity can be checked by TLC on Silica gel G on buffered plates (pH 6.5), eluted with CHCl<sub>3</sub>/MeOH/H<sub>2</sub>O (60:40:9) and developed with I<sub>2</sub> vapour. Store it as a powder at 0°. [Altman et al. *J Am Chem Soc* **94** 3257 1972.] It is more stable as the di(tri-n-butylammonium)hydrogen phosphate salt which can be obtained from the acid by evaporation in a rotary evaporator below 32° [Upper & West *J Biol Chem* **242** 3285 1967]. [Gregonis & Rilling *Biochemistry* **13** 1538 1974, Gregonis & Rilling

*Biochem Biophys Res Commun* **54** 449 1973.]

**Geranyl pyrophosphate** [*E*-form 763-10-0 tri-(NH<sub>4</sub> salt), *Z*-form 16751-02-3] **M 314.2**, **pK<sub>Est(1)</sub> ~ 2**, **pK<sub>Est(2)</sub> ~ 2**, **pK<sub>Est(3)</sub> ~ 3.95**, **pK<sub>Est(4)</sub> ~ 6.26**. Purify the pyrophosphate by paper chromatography on Whatman No 3 MM paper in a system of isopropyl alcohol/isobutyl alcohol/ammonia/water (40:20:1:39), R<sub>F</sub> 0.77-0.82. Store it in the dark as the ammonium salt at 0°. The *E*-form crystallises in platelets from aqueous Me<sub>2</sub>CO, **m ~ 120°**. It dissolves in dry MeCN. *Alternatively*, purify it through a column of Dowex AG 1x8(200-400mesh) equilibrated with 50mM NH<sub>4</sub> formate, and elute with MeOH/H<sub>2</sub>O/NH<sub>4</sub>OH (95:5:05), then freeze-dry. [Dixit et al. *J Org Chem* **46** 1967 1981, *Beilstein* **1** IV 3580.]

**Gliotoxin (3*R*-6*t*-hydroxy-3-hydroxymethyl-2-methyl-(5*at*)-2,3,6,10-tetrahydro-5*aH*-3,10*ac*-epidissulfido-[1,2-*a*]-indol-1,4-dione)** [67-99-2] **M 326.4**, **m 191-218°(dec)**, **220°(dec)**, **221°(dec)**, **[α]<sub>D</sub><sup>20</sup> -254° (c 0.6, CHCl<sub>3</sub>)**, **[α]<sub>D</sub><sup>25</sup> -270° (c 1.7, pyridine)**. Purify gliotoxin by recrystallisation from MeOH. Its solubility in CHCl<sub>3</sub> is 1%. The *dibenzoyl* derivative has **m 202°** (from CHCl<sub>3</sub>/MeOH). [Glister & Williams *Nature* **153** 651 1944, Elvidge & Spring *J Chem Soc Suppl* **135** 1949, Johnson et al. *J Am Chem Soc* **65** 2005 1943, Bracken & Raistrick *Biochem J* **41** 569 1947.]

**Glucose-1-phosphate (G-1-P)** [59-56-3] **M 260.1**, **[α]<sub>D</sub><sup>25</sup> +120° (c 3, H<sub>2</sub>O)**, **[α]<sub>D</sub><sup>20</sup> +78° (c 4, H<sub>2</sub>O of di-K salt)**, **pK<sub>1</sub> 1.11**, **pK<sub>2</sub> 6.13** [**pK<sub>25</sub> 6.50**]. Two litres of a 5% aqueous solution of the phosphate are purified by adjusting the pH to 3.5 with glacial acetic acid (+ 3g of charcoal) and filtering. An equal volume of EtOH is added, the pH is adjusted to 8.0 (glass electrode) and the solution is stored at 3° overnight. The precipitate is filtered off, dissolved in 1.2L of distilled water, filtered and an equal volume of EtOH is added. After standing at 0° overnight, the crystals are collected at the centrifuge and washed with 95% EtOH, then absolute EtOH, ethanol/diethyl ether (1:1), and diethyl ether. [Sutherland & Wosilait, *J Biol Chem* **218** 459 1956.] Its barium salt can be crystallised from water and EtOH. Heavy metal impurities are removed by passage of an aqueous solution (*ca* 1%) through an Amberlite IR-120 column (in the appropriate H<sup>+</sup>, Na<sup>+</sup> or K<sup>+</sup> forms). *Di-K salt* crystallises as a *dihydrate* from EtOH. [see McGready *Biochemical Preparations* **4** 63 1955.] [*Beilstein* **17/8** V 247.]

**Glucose-6-phosphate (G-6-P)** [acid 156-73-5; Ba salt 58823-95-3; Na salt 54010-71-8] **M 260.1**, **m 205-207°(dec)** **mono Na salt**, **[α]<sub>D</sub><sup>20</sup> +41° (c 5, H<sub>2</sub>O)**, **pK<sub>1</sub> 1.65**, **pK<sub>2</sub> 6.11**, **pK<sub>3</sub><sup>25</sup> 11.71** [-C<sub>1</sub>(OH)O<sup>-</sup>]. It can be freed from metal impurities as described for glucose-1-phosphate. The solubility of the Na salt is 5% in H<sub>2</sub>O at 20°. Its *barium* salt can be purified by solution in dilute HCl and precipitation by neutralising the solution. The precipitate is washed with small volumes of cold water and dried in air. *Alternatively*, the barium salt is dissolved in H<sub>2</sub>O, 4 volumes of EtOH are added, the precipitate is collected, washed with 90% EtOH, absolute EtOH, 75% EtOH/25% Et<sub>2</sub>O, 25% EtOH/75% Et<sub>2</sub>O and finally dry Et<sub>2</sub>O. The dry Barium salt has **[α]<sub>D</sub><sup>25</sup> +17.9° (c 1, H<sub>2</sub>O)**. [*Beilstein* **1** IV.]

G-6-P is relatively more stable to hydrolysis (12% hydrolysis in N HCl/100° in 4 hours) than G-1-P (45% hydrolysis in N HCl/20° in 20 hours). [Lardy & Fischer *Biochemical Preparations* **2** 39 1952.]

**L-α-Glycerol phosphocholine (Cadmium Chloride)<sub>x</sub> complex** [64681-08-9] **M 257.2 + (183.3)<sub>x</sub>**, **pK<sub>Est</sub> ~ 5.5**. Glycerol phosphocholine is purified *via* the CdCl<sub>2</sub> complex which is recrystallised four times from 99% EtOH by standing at 0° for 1 hour. The white precipitate is collected, washed with EtOH, Et<sub>2</sub>O and dried in a vacuum. The amorphous Cd complex can be converted to the crystalline form [C<sub>8</sub>H<sub>20</sub>O<sub>6</sub>NP.CdCl<sub>2</sub>.3H<sub>2</sub>O] by dissolving 34.4g in H<sub>2</sub>O (410ml), and 99% EtOH (1650ml total) is added slowly with stirring and allowing the clear solution to stand at 25° for 12 hours, then at 5° for 12 hours. The crystalline complex is filtered off, washed with cold 80% EtOH and dried in air. Glycerol phosphocholine can be recovered from the complex by dissolving it in H<sub>2</sub>O (2% solution) and passing it through an ion-exchange column (4.9 x 100cm, of 1 volume IRC-50 and 2 volumes of IR-45). The effluent is concentrated to a thick syrup at 45°. It is dried further at 50°/P<sub>2</sub>O<sub>5</sub>/48 hours. The vitreous product (~8.25g) is then dissolved in 99% EtOH (50ml), and the clear solution is cooled to 5°, whereby crystals begin to appear, and crystallisation is completed at -15° after 16 hours. The crystals are filtered off, washed with 99% EtOH, and Et<sub>2</sub>O then dried at 50° *in vacuo* over P<sub>2</sub>O<sub>5</sub>. It can be recrystallised from 99.5% EtOH (long prisms). It is *hygroscopic* and must be handled in a H<sub>2</sub>O-free atmosphere [Tattie & McArthur *Biochemical Preparations* **6** 16 1958, Baer & Kates *J Am Chem Soc* **70** 1394 1948, *Acta*

*Cryst* 21 79, 87 1966].

**Hematin (ferrihaeme hydroxide)** [15489-90-4] **M 633.5, m 200°(dec), pK<sub>Est</sub> ~ 4.** Crystallise it from pyridine. Dry it at 40° *in vacuo*. [Beilstein 26 III/IV 3047.]

**Hematoporphyrin IX (8,13-bis(1-hydroxyethyl)-3,7,12,17-tetramethyl-21H-23H-porphin-2,18-dipropionic acid, 3,3'-[7,12-bis-(1-hydroxyethyl)-3,8,13,17-tetramethyl-porphyrin-2,18-diyl]-dipropionic acid)** [14459-29-1] **M 598.7, pK<sub>Est</sub> ~4.8.** Purify it by dissolving it in EtOH and adding H<sub>2</sub>O or Et<sub>2</sub>O to give deep red crystals. It has also been recrystallised from MeOH. Its UV has  $\lambda_{\text{max}}$  at 615.5, 565, 534.4 and 499.5nm in 0.1N NaOH, and 597, 619, 634, 653, 683 and 701nm in 2N HCl. [Falk *Porphyryns and Metalloporphyryns* Elsevier, NY, p 175 1964, LCCCN<sub>o</sub> 63-19821.] It is used in the affinity chromatographic purification of Heme proteins [Olsen *Methods Enzymol* 123 324 1986]. The *O*-methyl-dimethyl ester has **m 203-206°** (from CHCl<sub>3</sub>/MeOH), and the *O,O'*-dimethyl-dimethyl ester has **m 145°** (from CHCl<sub>3</sub>/MeOH). [Paul *Acta Chem Scand* 5 389 1951, Beilstein 26 III/IV 3157, and 3158 for the HCl.]

**Hematoporphyrin dimethyl ester** [33070-12-1] **M 626.7, m 212°.** It crystallises from CHCl<sub>3</sub>/MeOH. [Beilstein 26 III/IV 3157.]

**Hematoxylin ( $\pm$ -11bc-7,11b-dihydroindeno[2,1-c]-chromen-3,4-6ar-9,10-pentaol)** [517-28-2] **M 302.3, m 200°(dec), 210-212°(dec).** Hematoxylin recrystallises from H<sub>2</sub>O (as *trihydrate*) in white-yellow crystals which become red on exposure to light and then melt at 100-120°. It has been recrystallised from Me<sub>2</sub>CO/\*C<sub>6</sub>H<sub>6</sub>. It has been recrystallised as well from dilute aqueous NaHSO<sub>3</sub> until colourless and is soluble in alkali, borax and glycerol. Store it in the dark below 0°. [Morsingh & Robinson *Tetrahedron* 26 182 1970, Dann & Hofmann *Chem Ber* 98 1498 1955, Beilstein 17/8 V 469.]

**Hemin (ferriprotoporphyrin IX chloride)** [16009-13-5] **M 652.0, m sinters at 240°, pK<sub>Est</sub> ~4.8.** Hemin is purified by recrystallisation from AcOH. Also, hemin (5g) is shaken in pyridine (25ml) till it dissolves, then CHCl<sub>3</sub> (40ml) is added, the container is stoppered and shaken for 5 minutes (releasing the stopper occasionally). The solution is filtered under slight suction, and the flask and filter are washed with a little CHCl<sub>3</sub> (15ml). During this period, AcOH (300ml) is heated to boiling, and saturated aqueous NaCl (5ml) and conc HCl (4ml) are added. The CHCl<sub>3</sub> filtrate is poured in a steady stream, with stirring, into the hot AcOH mixture and set aside for 12 hours. The crystals are filtered off, washed with 50% aqueous AcOH (50ml), H<sub>2</sub>O (100ml), EtOH (25ml), Et<sub>2</sub>O and dried in air. [Fischer *Org Synth Coll Vol III* 442 1955, Beilstein 26 III/IV 3048.]

**(+)-Hydroquinidine anhydrous (9S-6'-methoxy-10,11-dihydrocinchonon-9-ol)** [1435-55-8] **M 326.4, m 168-169°, 169°, 169-170°, 171-172°, [α]<sub>D</sub><sup>20</sup> +231° (c 2, EtOH), +299° (c 0.82, 0.1N H<sub>2</sub>SO<sub>4</sub>), pK<sub>Est</sub> ~ 8.8.** (+)-Hydroquinidine forms needles from EtOH and plates from Et<sub>2</sub>O. It is slightly soluble in Et<sub>2</sub>O and H<sub>2</sub>O but readily soluble in hot EtOH. [Heidelberger & Jacobs *J Am Chem Soc* 41 826 1919, King *J Chem Soc* 523 1946.] The *hydrochloride* has **m 273-274°, [α]<sub>D</sub><sup>26</sup> +184° (c 1.3, MeOH)** and is very soluble in MeOH and CHCl<sub>3</sub>, but less soluble in H<sub>2</sub>O, EtOH and still less soluble in dry Me<sub>2</sub>CO. [Kyker & Lewis *J Biol Chem* 157 707 1945, Emde *Helv Chim Acta* 15 557 1932, Beilstein 23/13 V 340.]

**Hydroquinine** [522-66-7] **M 326.4, m 168-171°, 171.5°, [α]<sub>D</sub><sup>16</sup>-143° (c 1.087, EtOH), pK<sub>15</sub> 5.33 and 8.87.** Recrystallise hydroquinine from EtOH, Et<sub>2</sub>O or \*C<sub>6</sub>H<sub>6</sub>. [Rabe & Schultz *Chem Ber* 66 120 1933, Beilstein 23 III/IV 3193, 23/13 V 340.] The *racemate* has **m 175-175.5°** (from EtOH).

**5-Hydroxycreatinine (creatol, CTL, 2-amino-5-hydroxy-1-methylimidazolidin-4-one)** [133882-98-1] **M 129.1, m 190° (191°, dec) for the hydrochloride, pK<sub>25</sub> 4.2.** Creatol is one of three metabolites of creatinine [60-27-5] which was isolated from inflamed rabbit skin tissues [Ienaga et al. *Tetrahedron Lett* 28 4587 1987], and the urine of uraemic rats (adenine induced chronic renal failure) and uraemic patients. The other two metabolites are 1-methylhydantoin (1-methylimidazolidine-2,4-dione [616-04-6]) and 5-hydroxy-1-methylhydantoin [1-methyl-5-hydroxyimidazolidine-2,4-dione] [84210-26-4]. [Ienaga et al. *J C S, Chem Commun*

509 1991.] Urine from uraemic rats (44ml, collected after 24 hours of administration of creatinine) was applied onto a PK216 ion exchange column (H<sup>+</sup> form) that was washed with H<sub>2</sub>O, then eluted with aqueous NH<sub>3</sub> (2mol dm<sup>-3</sup>) and evaporated *in vacuo*. The residue, in H<sub>2</sub>O, was applied onto a Biolex-70 ion exchange column (H<sup>+</sup> form) that was washed with H<sub>2</sub>O, then eluted with aqueous AcOH (0.1mol dm<sup>-3</sup>), and the eluate was evaporated *in vacuo* to give *creatol* (0.66mg, 0.11%, purity checked by ODS reverse phase HPLC). [The H<sub>2</sub>O wash from the PK216 column gave the other two metabolites (1.5mg, 0.35 and 0.87mg, 0.15% respectively) which were separated on a silica gel column with EtOAc elution.] Creatol has <sup>1</sup>H NMR (D<sub>2</sub>O, *tert*-BuOH as internal standard) with δ at 3.11 (s, in N<sup>12</sup>CH<sub>3</sub> creatol; but d, in N<sup>13</sup>CH<sub>3</sub> labelled creatol with *J* = 143 Hz) and 5.11 (s, H-5); and <sup>13</sup>C NMR (D<sub>2</sub>O, dioxane as internal standard) with δ at 30 (NCH<sub>3</sub>), 81 (C-5), 160 (C-2) and 174 (C-4). [Ienaga et al. *J C S, Chem Commun* 509 1991.] The natural enantiomer most probably has the *S* configuration at C-5 [see Ienaga et al. *J C S, Chem Commun* 509 1991]. [Nakamura & Ienaga, Glycoyamidine derivatives, *Japanese Kokai Tokkyo Koho*, JP 2957217 1989, US patent 4957936 1990.] Data kindly supplied by Dr Kazu Ienaga, Nippon Zoki Pharmaceutical Co Ltd, Osaka, Japan.

***R*-(*-*)-2-Hydroxy-3,3-dimethyl-γ-butyrolactone (3-hydroxy-4,4-dimethyl-4,5-dihydrofuran-2-one, D-pantolactone) [599-04-2] M 130.1, m 89-91°, 90.5-91.5°, 91°, 92-93°, b 120-122°/15mm, [α]<sub>D</sub><sup>20</sup> -28° (c 5, MeOH), [α]<sub>D</sub><sup>20</sup> -51° (c 3, H<sub>2</sub>O). Recrystallise the lactone from Et<sub>2</sub>O/petroleum ether, diisopropyl ether or \*C<sub>6</sub>H<sub>6</sub>/petroleum ether and sublime it at 25°/0.0001mm. It hydrolyses readily to the hydroxy-acid and racemises when heated above 145°. The *Brucine salt* has m 211-212° (from EtOH). [Kuhn & Wieland *Chem Ber* 73 1134 1940, and Stiller et al. *J Am Chem Soc* 62 1779 1940, Bental & Tishler *J Am Chem Soc* 68 1463 1946, *Beilstein* 18/1 V 22.]**

(±)-5-Hydroxy-1-methyl-imidazolidine-2,4-dione (HMH) [84210-26-4] M 130.1, m 138°, pK 8.64. The racemic compound was obtained by oxidation of *N*-1-methylhydantoin with Pb(OAc)<sub>4</sub> in \*C<sub>6</sub>H<sub>6</sub> (60°, 24 hours), isolation of the 5-acetoxy derivative (*via* a short silica-gel column chromatography; eluting with \*C<sub>6</sub>H<sub>6</sub>/hexane), followed by hydrolysis with aqueous 0.3M H<sub>2</sub>SO<sub>4</sub> (~25°, 40 minutes). Neutralisation, followed by evaporation, and silica-gel TLC (EtOAc) provided pure racemate m 138°, (64% yield) with the expected <sup>1</sup>H NMR spectrum and EI MS and elemental analysis. It is a plant growth regulator affecting the flowering period of cut white chrysanthemums at concentrations as low as 10<sup>-6</sup> M. [Ienaga et al. *Tetrahedron Lett* 28 4587 1987.]

The natural metabolite *N*-1-methylhydantoin (MH [616-04-6], see below) was isolated from rabbit urine by diluting the urine two-fold with MeOH and evaporating. The residue was extracted with MeOH/EtOAc (1:6), filtered, the filtrate was concentrated, subjected to silica-gel column chromatography and eluted with MeOH/CHCl<sub>3</sub> (1:9). The first eluate gave the pure crystalline 5-hydroxy compound (HMH, 28% of total) that had m 147-150° and [α]<sub>D</sub><sup>25</sup> -5.1° (c 1.0, MeOH). The expected <sup>1</sup>H NMR [Eu(tfc)<sub>3</sub>] spectrum indicated that its enantiomeric excess was 56% (i.e. a 78:22 mixture). Some racemisation of the 5-hydroxy compound may well have occurred during isolation. The synthetic racemate was resolved by conversion into the diastereoisomeric Bz-*L*-proline ester (1:1, *R*:*S*) [with 1-(3-diethylaminopropyl)-3-ethylcarbodiimide HCl in the presence of DMAP in MeCN at 0°/2 hours) followed by purification through a silica-gel column and eluting with EtOAc/hexane (7:3)] in 56% yield. Fractional recrystallisation from Me<sub>2</sub>CO gave pure 5-(*R*)-(*N*-Bz-*L*-prolyloxy)-1-methylimidazolidine-2,4-dione (30%), m 189-192°, [α]<sub>D</sub><sup>25</sup> -2.1° (c 1.0, MeOH) {<sup>1</sup>H NMR, DMSO-*d*<sub>6</sub> has δ at 1.8-2.0 (m, 3H), 2.2-2.4 (m, 1 H), [2.52 (s) + 2.75 (s), 3H], 3.4-3.55 (m, 2 H), [4.35 (dd, *J* = 4, 9 Hz) + 4.46 (dd, *J* = 4, 9 Hz) 1H], [5.03 (s) + 5.10 (s) 2H], [6.90 (s) + 6.10 (s) 1H], 7.25-7.45 (m, 5H, aromatic) and 11.21 (br s, NH)}; and when these crystals were subjected to X-ray crystallography they revealed that the absolute configuration at C5 of the *imidazolidine-2,4-dione* part of the molecule was *R*, and that C5 of the *natural metabolite* was therefore *S* when a comparison of the HPLC of the mixture of prolyl-esters from the natural metabolite was made. The residue from evaporation of the mother liquors was recrystallised from EtOAc and gave the diastereoisomeric 5-(*S*)-*N*-Bz-*L*-prolyl ester (8%) with m 147-150°, [α]<sub>D</sub><sup>25</sup> -68.9° (c 1.0, MeOH) {<sup>1</sup>H NMR, DMSO-*d*<sub>6</sub> has δ at 1.7-2.0 (m, 3H), 2.2-2.4 (m, 1 H), [2.63 (s) + 2.73(s), 3H], 3.35-3.55 (m, 2 H), [4.36 (dd, *J* = 4, 9 Hz) + 4.47 (dd, *J* = 4, 9 Hz) 1H], [5.04 (d, *J* = 13Hz) + 5.07 (d, *J* = 13Hz) 1H], [5.07 (d, *J* = 13Hz) + 5.13 (d, *J* = 13Hz) 1H], [6.05 (s) + 6.12 (s) 1H], 7.25-7.45 (m, 5H, aromatic) and 11.25(br s, NH)}. Attempted hydrolysis of these esters gave racemic 5-hydroxyimidazolidine-2,4-dione, however, owing to facile racemisation. [Ienaga et al. *J Chem Soc, Perkin Trans I* 1153 1989.] The racemate and the optically active form of 5-hydroxy-1-methylhydantoin have the same <sup>1</sup>H NMR (400MHz, Me<sub>2</sub>CO-*d*<sub>6</sub>, TMS) with δ at ~5.1 (d, C-5) and ~5.9 (d, 1-NMe). Data kindly supplied by Dr Kazu Ienaga, Nippon Zoki Pharmaceutical Co Ltd, Osaka, Japan.

**(-)-Inosine** [58-63-9] M 268.2, m 90° (dihydrate), 218° (dec, anhydrous),  $[\alpha]_{546}^{20}$  -76° (c 1, 0.1M NaOH),  $pK_1^{25}$  1.06,  $pK_2^{25}$  8.96,  $pK_3^{25}$  11.36. (-)-Inosine forms *anhydrous* crystals from aqueous 80% EtOH but the *dihydrate* from H<sub>2</sub>O. [Beilstein 31 H 25, 26 III/IV 2087.]

**myo-Inositol** (cyclohexane[1*r*,2*c*,3*c*,4*t*,5*c*,6*t*]-hexol) [87-89-8] M 180.2, m 218° (di-hydrate), 225-227°, 226-230°. Recrystallise *myo*-inositol from aqueous 50% ethanol or H<sub>2</sub>O forming a *dihydrate*, or *anhydrous* crystals from AcOH. The dihydrate is efflorescent and becomes anhydrous when heated at 100°. The anhydrous crystals are not hygroscopic. Its solubility in H<sub>2</sub>O at 25° is 14%, at 60° it is 28%; it is slightly soluble in EtOH but insoluble in Et<sub>2</sub>O. [Ballou & Anderson *J Am Chem Soc* 75 748 1953, Anderson & Wallis *J Am Chem Soc* 70 2931 1948, Beilstein 6 II 1157, 6 IV 7919.]

**Inositol monophosphate** [15421-51-9] M 260.1, m 195-197°(dec). Crystallise the phosphate from water, and EtOH. Recrystallise 1g by dissolving it in 3ml of H<sub>2</sub>O and adding slowly 15ml of commercial EtOH, filter the crystals, wash with a little EtOH then Et<sub>2</sub>O and dry it in a vacuum. [McCormick & Carter *Biochemical Preparations* 2 65 1952.]

**5-Iodouridine** (5-iodo-1-[β-D-ribofuranosyl]-pyrimidine-2,4(1*H*)-dione) [1024-99-3] M 370.1, m 205-208°(dec), 210-215°(dec),  $[\alpha]_D^{20}$  -23.5° (c 1, H<sub>2</sub>O),  $pK^{20}$  8.5. Recrystallise 5-iodouridine from H<sub>2</sub>O and dry it *in vacuo* at 100°. It UV has  $\lambda_{max}$  at 289nm (0.01N HCl) and 278nm (0.01N NaOH). [Prusoff et al. *Cancer Res* 13 221 1953, Beilstein 24 III/IV 1235.]

**Isopentenyl pyrophosphate** [358-71-4] M 366.2,  $pK_{Est(1)} \sim 2$ ,  $pK_{Est(2)} \sim 2$ ,  $pK_{Est(3)} \sim 3.95$ ,  $pK_{Est(4)} \sim 6.26$ . Purify the pyrophosphate by chromatography on Whatman No 1 paper using *tert*-butyl alcohol/formic acid/water (20:5:8, R<sub>F</sub> 0.60) or 1-propanol/ammonia/water (6:3:1, R<sub>F</sub> 0.48). *Alternatively*, purify it by chromatography on a DEAE-cellulose column or a Dowex-1 (formate form) ion-exchanger using formic acid and ammonium formate as eluents. A further purification step is to convert it to the *monocyclohexylammonium salt* by passage through a column of Dowex-50 (cyclohexylammonium form) ion-exchange resin. It can also be converted into its lithium salt. (See geranyl pyrophosphate above.)

**Kanamycin B** (Bekanamycin, 4-*O*-[2,6-diamino-2,6-dideoxy-α-D-glucopyranosyl]-6-*O*-[3-amino-3-deoxy-α-D-glucopyranosyl]-2-deoxystreptamine) [4696-76-8, 29701-07-3 (sulfate salt)] M 483.5, m 170-179°(dec), 178-182°(dec),  $[\alpha]_D^{18}$  +130° (c 0.5, H<sub>2</sub>O),  $pK^{25}$  7.2. A small quantity of kanamycin B (24mg) can be purified on a small Dowex-1 x 2 column (6 x 50mm); the required fraction is evaporated to dryness and the residue crystallised from EtOH containing a small amount of H<sub>2</sub>O. [Umezawa et al. *Bull Chem Soc Jpn* 42 537 1969.] It has been crystallised from H<sub>2</sub>O by dissolving ~1g in H<sub>2</sub>O (3ml), adding Me<sub>2</sub>NCHO (3ml) and setting aside at 4° overnight. The needles are collected and dried to constant weight at 130°. It has also been recrystallised from aqueous EtOH. It is slightly soluble in CHCl<sub>3</sub> and isoPrOH. [IR: Wakazawa et al. *J Antibiot* 14A 180, 187 1961, Ito et al. *J Antibiot* 17 A 189 1964, Beilstein 18 III/IV 7631.]

**Lecithin** (1,2-diacylphosphatidylcholine mixture) [8002-43-5] M ~600-800, **amorphous**. Lecithin from hen egg white is purified by solvent extraction and chromatography on alumina. It is suspended in H<sub>2</sub>O and kept frozen until required [Lee & Hunt *J Am Chem Soc* 106 7411 1984, Singleton et al. *J Am Oil Chem Soc* 42 53 1965]. For purification of commercial egg lecithin, see Pangborn [*J Biol Chem* 188 471 1951].

**Leucopterin** (2-amino-5,8-dihydropteridine-4,6,7(1*H*)-trione) [492-11-5] M 195.1, m >300° (dec),  $pK_1^{20}$  -1.66,  $pK_2^{20}$  7.56,  $pK_3^{20}$  9.78,  $pK_4^{20}$  13.6. Leucopterin is purified by dissolving it in aqueous NaOH, stirring with charcoal, filtering and precipitating by adding aqueous HCl, then drying at 100° in a vacuum. It separates with 0.5 mole of H<sub>2</sub>O. Its solubility in H<sub>2</sub>O is 1g/750 litres [Albert et al. *J Chem Soc* 4219 1952, Albert & Wood *J Appl Chem (London)* 2 591 1952, Pfeleiderer *Chem Ber* 90 2631 1957]. [Beilstein 26 III/IV 4017.]

**DL-α-Lipoamide** (±-6,8-thioctic acid amide, 5-[1,2]-dithiolan-3-ylvaleric acid amide) [940-69-2; 3206-73-

3] **M 205.3, m 124-126°, 126-129°, 130-131°.** DL- $\alpha$ -Lipoamide is recrystallised from EtOH and has UV with  $\lambda_{\max}$  at 331nm in MeOH. [Reed et al. *J Biol Chem* **232** 143 1958, IR: Wagner et al. *J Am Chem Soc* **78** 5079 1956, *Beilstein* **19/7** V 238.]

**DL- $\alpha$ -Lipoic acid ( $\pm$ -6,8-thioctic acid, 5-[1,2]-dithiolan-3-ylvaleric acid)** [1077-28-7] **M 206.3, m 59-61°, 60.5-61.5° and 62-63°, b 90°/10<sup>-4</sup>mm, 150°/0.1mm, pK<sup>25</sup> 4.7.** It forms yellow needles from cyclohexane or hexane and has been distilled at high vacuum: and sublimes at  $\sim$ 90° and very high vacuum. It is insoluble in H<sub>2</sub>O but dissolves in alkaline solution. [Lewis & Raphael *J Chem Soc* 4263 1962, Soper et al. *J Am Chem Soc* **76** 4109, Reed & Niu *J Am Chem Soc* **77** 416 1955, Tsuji et al. *J Org Chem* **43** 3606 1978, Calvin *Fed Proc USA* **13** 703 1954.] The *S*-benzylisothiuronium salt has **m** 153-154° (evacuated capillary, from MeOH), 132-134°, 135-137° (from EtOH). The *d*- and *l*- forms have **m** 45-47.5° and  $[\alpha]_{\text{D}}^{25} \pm 113^{\circ}$  (c 1.88, \*C<sub>6</sub>H<sub>6</sub>) and have UV in MeOH with  $\lambda_{\max}$  at 330nm ( $\epsilon$  140). [*Beilstein* **19/7** V 237.] The reduced form, ( $\pm$ )-6,8-dimercaptooctanoic acid, [7516-48-5] **M 208.3**, is a light yellow liquid which is sold in sealed ampoules.

**D-Luciferin (firefly luciferin, S-2[6-hydroxybenzothiazol-2-yl]-4,5-dihydrothiazol-4-carboxylic acid)**, [2591-17-5] **M 280.3, m 189.5-190°(dec), 196°(dec), 201-204°, 205-210°(dec, browning at 170°),  $[\alpha]_{\text{D}}^{22}$  -36° (c 1.2, DMF), pK<sub>Est(1)}<sup>~</sup> 1.2 (benzothiazole-N), pK<sub>Est(2)}<sup>~</sup> 1.6 (thiazolidine-N), pK<sub>Est(3)}<sup>~</sup> 6.0 (CO<sub>2</sub>H), pK<sub>Est(4)} 8.5 (6OH).</sub></sub></sub></sub>** D-Luciferin crystallises as pale yellow needles from H<sub>2</sub>O, or MeOH (83mg/7ml). It has UV with  $\lambda_{\max}$  at 263 and 327nm (log  $\epsilon$  3.88 and 4.27) in 95% EtOH. The Na salt has a solubility of 4mg in 1 ml of 0.05M glycine. [White et al. *J Am Chem Soc* **83** 2402 1961, **85** 337 1963, UV and IR: Bitler & McElroy *Arch Biochem* **72** 358 1957, Review: Cormier et al. *Fortschr Chem Org Naturst* **30** 1 1973, *Beilstein* **27** III/IV 8934.]

**Lumiflavin (7,8,10-trimethylbenzo[g]pteridine-2,4(3H,10H)-dione)** [1088-56-8] **M 256.3, m 330°(dec), 340°(dec), pK<sup>25</sup> 10.2.** Lumiflavin forms orange crystals upon recrystallisation from 12% aqueous AcOH, or from formic acid. It sublimes at high vacuum. It is freely soluble in CHCl<sub>3</sub>, but not very soluble in H<sub>2</sub>O and most organic solvents. In H<sub>2</sub>O and CHCl<sub>3</sub> solution it has a green fluorescence. Its UV has  $\lambda_{\max}$  at 269, 355 and 445nm ( $\epsilon$  38,800, 11,700 and 11,800, respectively) in 0.1N NaOH and 264, 373 and 440nm ( $\epsilon$  34,700, 11,400 and 10,400, respectively) in 0.1N HCl, while the UV in CHCl<sub>3</sub> has  $\lambda_{\max}$  at 270, 312, 341, 360, 420, 445 and 470nm. [Hemmerich et al. *Helv Chim Acta* **39** 1242 1956, Holiday & Stern *Chem Ber* **67** 1352 1834, Yoneda et al. *Chem Pharm Bull Jpn* **20** 1832 1972, Birch & Moyer *J Chem Soc* 2622 1958, Fluorescence: Kuhn & Moruzzi *Chem Ber* **67** 888 1934, *Beilstein* **26** III/IV 2539.]

**Magnesium protoporphyrin dimethyl ester** [14724-63-1] **M 580.7, m 214-217° (others found m 228-230°).** The Mg complex can be prepared from protoporphyrin dimethyl ester (see below) and Mg(ClO<sub>4</sub>)<sub>2</sub> in boiling pyridine under N<sub>2</sub> for 3-4 hours until the band at 630nm (free porphyrin) is absent. Filter, wash the insolubles with Et<sub>2</sub>O until the filtrate is colourless. Evaporate the solvent *in vacuo* at 50-60° to a very small volume, then add excess peroxide free Et<sub>2</sub>O in a separating funnel, shake with H<sub>2</sub>O (2x), evaporate the Et<sub>2</sub>O, and remove the H<sub>2</sub>O and pyridine by evaporating (azeotropically) with \*C<sub>6</sub>H<sub>6</sub> (4x). Purify the residue by dissolving the Mg complex in as little hot \*C<sub>6</sub>H<sub>6</sub> (50ml for 800mg) as possible, and add cold petroleum ether (b 30-60°), leave at room temperature until crystallisation begins, then further in a refrigerator to give twinned prisms, **m** >330°. Its IR has  $\nu_{\max}$  at 3080(w CH=CH<sub>2</sub>), 1610, 1698, 1740 (s CO<sub>2</sub>Me) cm<sup>-1</sup>, but no NH. Its UV (Et<sub>2</sub>O) has  $\lambda_{\max}$  ( $\epsilon$ ) at 588nm (19,000), 550nm (19,300), 417nm (Soret, 252,000). [Ramsey *Biochemical Preparations* **3** 39 1953, Fuhrhop & Graniek *Biochemical Preparations* **13** 55 1971.]

**6-Mercaptopurine-9- $\beta$ -D-ribofuranoside** [574-25-4] **M 284.3, m 208-210°(dec), 210-211°(dec), 220-223°(dec), 222-224°(dec),  $[\alpha]_{\text{D}}^{25}$  -73° (c 1, 0.1N NaOH), pK<sup>25</sup> 7.56.** Recrystallise the riboside from H<sub>2</sub>O or EtOH. It has UV with  $\lambda_{\max}$  (H<sub>2</sub>O) at 322nm (pH 1), 320 nm (pH 6.7) and 310nm (pH 13). [IR: Johnson et al. *J Am Chem Soc* **80** 699 1958, UV: Fox et al. *J Am Chem Soc* **80** 1669 1958, *Beilstein* **26** III/IV 2100.]

**R(-)-Methadone (Levomethadone, 6-dimethylamino-4,4-diphenylheptan-3-one)** [125-58-6] **M 309.4, m 98-100°,  $[\alpha]_{\text{D}}^{20}$  -32° (c 1.8, EtOH), see below for pKa.** This pharmacologically active (against narcotic addiction)

enantiomer was obtained by optical resolution (using D-tartaric acid) of the racemate, and was purified by precipitation of the hydrochloride from aqueous solution at pH >6, dried and recrystallised from propan-2-ol. The *R*-hydrochloride [5967-73-7], when recrystallised from propan-2-ol, has *m* 245-246°,  $[\alpha]_{\text{D}}^{20}$  -169° (c 2, EtOH). The *S*-(+)-enantiomer [5653-8-5] also recrystallises from propan-2-ol and has recorded *m* of 100-101°,  $[\alpha]_{\text{D}}^{25}$  +26° (c 1.2, H<sub>2</sub>O). The *S*-hydrochloride [15284-15-8], when crystallised from propan-2-ol, has *m* 243-244°,  $[\alpha]_{\text{D}}^{20}$  +169° (c 2, EtOH). [Larsen et al. *J Am Chem Soc* **70** 4194 1948, Brode & Hill *J Org Chem* **13** 191 1948, Schultz et al. *J Am Chem Soc* **69** 2454 1947, Easton et al. *J Am Chem Soc* **69** 2941 1947, Winter & Flataker *J Pharmacol Exp Ther* **98** 305 1950, Beilstein **14** III 278, **14** III/IV 300.]

(±)-Methadone hydrochloride (6-dimethylamino-4,4-diphenylheptan-3-one HCl) [1095-90-5] *M* 345.9, *m* 241-242°,  $\text{pK}_{\text{I}}^{25}$  8.94,  $\text{pK}_{\text{2}}^{20}$  10.12 (free base). The salt (see above) crystallises from EtOH, or EtOH/Et<sub>2</sub>O. [See methadone references in the above entry.]

Methoxantin coenzyme (PQQ, pyrrolo quinoline quinone, 2,7,9-tricarboxy-1*H*-pyrrolo-[2,3-*f*]-quinoline-4,5-dione, 4,5-dihydro-4,5-dioxo-1*H*-pyrrolo[2,3-*f*]quinoline-2,7,9-tri-carboxylic acid) [72909-34-3] *M* 330.2, *m* 220°(dec). Efflorescent yellow-orange needles of PQQ are formed on recrystallising from H<sub>2</sub>O by addition of Me<sub>2</sub>CO, or better from a supersaturated aqueous solution, as it forms an acetone adduct. [Forrest et al. *Nature* **280** 843 1979.] It has also been purified by passage through a C-18 reverse phase silica cartridge or a silanised silica gel column in aqueous solution whereby methoxantin remains behind as a red-orange band at the origin. This band is collected and washed thoroughly with dilute aqueous HCl (pH 2) and is then eluted with MeOH/H<sub>2</sub>O (7:3) and evaporated *in vacuo* to give the coenzyme as a red solid. It has also been purified by dissolving it in aqueous 0.5M K<sub>2</sub>CO<sub>3</sub> and acidified to pH 2.5 whereby PQQ precipitates as a deep red solid which is collected and dried *in vacuo*. Methoxantin elutes at 3.55 retention volumes from a C18 μBondapak column using H<sub>2</sub>O/MeOH (95:5) + 0.1% AcOH pH 4.5. It has UV with  $\lambda_{\text{max}}$  at 247 and 330nm (shoulder at 270nm) in H<sub>2</sub>O and with  $\lambda_{\text{max}}$  at 250 and 340nm in H<sub>2</sub>O at pH 2.5. With excitation at  $\lambda_{\text{ex}}$  365nm it has a  $\lambda_{\text{em}}$  at 483nm. The <sup>13</sup>C NMR has  $\delta$ : 113.86, 122.76, 125.97, 127.71, 130.68, 137.60, 144.63, 146.41, 147.62, 161.25, 165.48, 166.45, 173.30 and 180.00.

When a solution in 10% aqueous MeCO is adjusted to pH 9 with aqueous NH<sub>3</sub> and kept at 25° for 30 minutes, the *acetone adduct* is formed, which has UV with  $\lambda_{\text{max}}$  at 250, 317 and 360nm (H<sub>2</sub>O, pH 5.5), and with  $\lambda_{\text{ex}}$  at 360nm it fluoresces with  $\lambda_{\text{em}}$  at 465nm; and the <sup>13</sup>C NMR [(CD<sub>3</sub>)<sub>2</sub>SO, TMS] has  $\delta$ : 29.77, 51.06, 74.82, 111.96, 120.75, 121.13, 125.59, 126.88, 135.21, 139.19, 144.92, 161.01, 161.47, 165.17, 168.61, 190.16 and 207.03. It also forms a *methanol adduct*.

When it is reacted with Me<sub>2</sub>SO<sub>4</sub>/K<sub>2</sub>CO<sub>3</sub> in dry Me<sub>2</sub>NCHO at 80° for 4 hours, it forms the *trimethyl ester* which has *m* 265-267°(dec) [260-263°(dec) also reported] after recrystallisation from hot MeCN it forms orange crystals with UV that has  $\lambda_{\text{max}}$  at 252 and 344nm (H<sub>2</sub>O) and 251, 321 and 373nm (in MeOH; MeOH adduct?). [Duine et al. *Eur J Biochem* **108** 187 1980, Duine et al. *Adv Enzymology* **59** 169 1987, Corey & Tramontano *J Am Chem Soc* **103** 5599 1981, Gainor & Weinreb *J Org Chem* **46** 4319 1981, Hendrickson & de Vries *J Org Chem* **17** 1148 1982, McKenzie et al. *J Chem Soc, Chem Commun* 1372 1983.]

Methyl benzylpenicillinate [653-89-4] *M* 348.3, *m* 97°,  $[\alpha]_{\text{D}}^{20}$  +328° (c 1, MeOH),  $[\alpha]_{\text{D}}^{20}$  +286° (c 1, CHCl<sub>3</sub>). Crystallise the ester from CCl<sub>4</sub> or EtOAc/hexane. [Sheehan et al. *J Am Chem Soc* **84** 2983 1962, Review: Chain et al. *Antibiotics* (Oxford University Press) **2** 1949.]

1-Methylimidazolidine-2,4-dione (1*N*-methylhydantoin, MH) [616-04-6] *M* 114.1, *m* 158°, 155-156°, 157-159°, and 184-185° (dimorphic ?),  $\text{pK}^{25}$  9.20. It is purified by dissolving it in the minimum volume of H<sub>2</sub>O, extracting with EtOAc, the extract is dried and evaporated to dryness. The residue, in EtOAc is subjected to column chromatography (silica gel with EtOAc as eluent), or silica gel TLC [MeOH/CHCl<sub>3</sub> (1:9)] and recrystallised from EtOH (elongated plates). It is identified by <sup>1</sup>H NMR and MS. The IR has  $\nu_{\text{max}}$  at 1712 (2CO) and 1761 (4CO) cm<sup>-1</sup>. The 3-*acetate* has *m* 134-135°. [Miller & Robson *J Chem Soc* 1910 1938, West *J Biol Chem* **34** 187 1918, Ienaga et al. *Tetrahedron Lett* **28** 4587 1987, Ienaga et al. *J Chem Soc, Perkin Trans I* 1153 1989, Beilstein **24** H 44.] Data kindly supplied by Dr Kazu Ienaga, Nippon Zoki Pharmaceutical Co Ltd, Osaka, Japan.

(±)-5-Methylimidazoline-2,4-dione (5-methylhydantoin) [616-03-5] *M* 114.1, *m* 145°, 148-152°, 149-151°,

**150°**, **pK<sup>25</sup> 9.07**. Purify it by recrystallisation from H<sub>2</sub>O, and dry it *in vacuo*. [Ienaga et al. *Tetrahedron Lett* **28** 4587 1987, Ienaga et al. *J Chem Soc, Perkin Trans I* 1153 1989, IR: Burland & Christian *Can J Chem* **35** 444 1957, *Beilstein* **24** H 279, **24** I 305, **24** II 155, **24** III/IV 1083.] Data supplied by Dr Kazu Ienaga (see above).

**5-Methyltetrahydrofolic acid disodium salt (prefolic A)** [68792-52-9] **M 503.4**, **pK<sub>1</sub> 2.4** (N10 protonation), **pK<sub>2</sub> 2.7** (pyrimidine N1 protonation), **pK<sub>3</sub> 3.5** ( $\alpha$ -CO<sub>2</sub>H), **pK<sub>4</sub> 4.9** ( $\gamma$ -CO<sub>2</sub>H), **pK<sub>5</sub> 5.6** (N5-Me), **pK<sub>6</sub> 8.5** (3NHCO acidic). First check the purity by measuring the UV at pH 7.0 (use phosphate buffer), and it should have  $\lambda_{\max}$  at 290nm and  $\lambda_{\min}$  at 245nm with a ratio of A<sub>290</sub>/A<sub>250</sub> of 3.7. This ratio goes down to 1.3 as oxidation to the dihydro derivative occurs. The latter can be reduced back to the tetrahydro compound by reaction with 2-mercaptoethanol at room temperature. If oxidation has occurred, then the compound should be chromatographed on DEAE-cellulose (~0.9 milliequiv/g, in AcO<sup>-</sup> form) in (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> (1.5 M) and washed with 1M NH<sub>4</sub>OAc containing 0.01M mercaptoethanol till free from UV absorption and then washed with 0.01M mercaptoethanol. All is done in a nitrogen atmosphere. The reduced folate is then eluted with a gradient between 0.01M mercaptoethanol and 1M NH<sub>4</sub>OAc containing 0.01M mercaptoethanol, and the fractions with absorption at 290nm are collected. These are evaporated under reduced pressure at 25°, and traces of NH<sub>4</sub>OAc and H<sub>2</sub>O are removed at high vacuum/25° (~24-48 hours). The residue is dissolved in the minimum volume of 0.01M mercaptoethanol, and an equivalent of NaOH is added to convert the acid to the diNa salt and evaporated to dryness at 25°/high vacuum. The pure product has  $\lambda_{\max}$  290nm ( $\epsilon$  32,000) in pH 7.0 buffer. [Sakami *Biochemical Preparations* **10** 103 1963.]

**Mevalonic acid lactone** [674-26-0] **M 130.2**, **m 28°**, **b 145-150°/5mm**. Purify the lactone *via* the *dibenzylethylenediammonium salt* (**m** 124-125°) [Hofmann et al. *J Am Chem Soc* **79** 2316 1957], or by chromatography on paper or on a Dowex-1 (formate) column. [Bloch et al. *J Biol Chem* **234** 2595 1959.] Store it as the *N,N'*-dibenzylethylenediamine (DBED) salt, or as the lactone in a sealed container at 0°. [*Beilstein* **18/1** V 19.]

**Mevalonic acid 5-phosphate** [1189-94-2] **M 228.1**, **pK<sub>Est(1)</sub> ~1.5** (PO<sub>4</sub>H<sub>2</sub>), **pK<sub>Est(2)</sub> ~4.4** (CO<sub>2</sub>H), **pK<sub>Est(3)</sub> ~6.31** (PO<sub>4</sub>H<sup>-</sup>). Purify the acid by conversion to the *tricyclohexylammonium salt* (**m** 154-156°) by treatment with cyclohexylamine. Recrystallise the salt from water/acetone at -15°. *Alternatively*, the phosphate is chromatographed through an ion-exchange resin or paper (Whatman No 1) in a system of isobutyric acid/ammonia/water (66:3:30; R<sub>F</sub> 0.42). Store it as the cyclohexylammonium salt.

**Mevalonic acid 5-pyrophosphate** [1492-08-6] **M 258.1**, **pK<sub>Est(1)</sub> ~2**, **pK<sub>Est(2)</sub> ~2**, **pK<sub>Est(3)</sub> ~3.95** (PO<sub>4</sub>), **pK<sub>Est(4)</sub> 4.4** (CO<sub>2</sub>H), **pK<sub>Est(5)</sub> ~6.26** (PO<sub>4</sub>). Purify the pyrophosphate by ion-exchange chromatography on Dowex-1 formate [Bloch et al. *J Biol Chem* **234** 2595 1959], DEAE-cellulose [Skilletar and Kekwick, *Anal Biochem* **20** 171 1967], or by paper chromatography [Rogers et al. *Biochem J* **99** 381 1966]. Likely impurities are ATP and mevalonic acid phosphate. Store it as a dry powder or in a slightly alkaline (pH 7-9) solution at -20°.

**Mithramycin A (Aureolic acid, Plicamycin)** [18378-89-7] **M 1085.2**, **m 180-183°**,  $[\alpha]_D^{20}$  -51° (c 0.3, EtOH), **pK<sub>Est</sub> ~9.2**. Purify mithramycin A by crystallisation from CHCl<sub>3</sub>. It is soluble in MeOH, EtOH, Me<sub>2</sub>CO, EtOAc, Me<sub>2</sub>SO and H<sub>2</sub>O, and moderately soluble in CHCl<sub>3</sub>, but is slightly soluble in \*C<sub>6</sub>H<sub>6</sub> and Et<sub>2</sub>O. It is a fluorescent antitumour agent used in flow cytometry. [Thiem & Meyer *Tetrahedron* **37** 551 1981, NMR: Yu et al. *Nature* **218** 193 1968, *Beilstein* **17/1** V 672.]

**Mitomycin C** [50-07-7] **M 334.4**, **m >360°**, **pK<sub>Est(2)</sub> ~8.0**. Mitomycin C forms blue-violet crystals from \*C<sub>6</sub>H<sub>6</sub>/petroleum ether. It is soluble in Me<sub>2</sub>CO, MeOH and H<sub>2</sub>O, moderately soluble in \*C<sub>6</sub>H<sub>6</sub>, CCl<sub>4</sub> and Et<sub>2</sub>O but insoluble in petroleum ether. It has UV with  $\lambda_{\max}$  at 216, 360 and a weak peak at 560nm in MeOH. [Stevens et al. *J Med Chem* **8** 1 1965, Shirahata & Hirayama *J Am Chem Soc* **105** 7199 1983, *Beilstein* **25** III/IV 516.]

**Muramic acid [R-2(2-amino-2-deoxy-D-glucose-3-yloxy)-propionic acid]** [1114-41-6] **M 251.2**, **m 145-150°(dec)**, **152-154°(dec)**, **155°(dec)**,  $[\alpha]_D^{25}$  +109° (c 2, H<sub>2</sub>O), +165.0° (extrapolated to 0 time) → +123° [after 3 hours (c 3, H<sub>2</sub>O)], **pK<sub>Est(1)</sub> ~3.8** (CO<sub>2</sub>), **pK<sub>Est(2)</sub> ~7.7** (NH<sub>2</sub>). Muramic acid crystallises from H<sub>2</sub>O or aqueous EtOH as the *monohydrate* which loses H<sub>2</sub>O at 80° *in vacuo* over P<sub>2</sub>O<sub>5</sub>. It sometimes contains some NaCl. It has

been purified by dissolving 2.2g in MeOH (75ml), filtering from some insoluble material, concentrating to ~10ml and refrigerating. The colourless crystals are washed with absolute MeOH. This process does not remove NaCl; to do so, the product is recrystallised from an equal weight of H<sub>2</sub>O to give a low recovery yield of very pure acid (0.12g). On paper chromatography 0.26µg give one ninhydrin positive spot after development with 75% phenol (R<sub>F</sub> 0.51) or with *sec*-BuOH/HCO<sub>2</sub>H/H<sub>2</sub>O (7:1:2) (R<sub>F</sub> 0.30). [Matsushima & Park *Biochemical Preparations* **10** 109 1963, *J Org Chem* **27** 3581 1962.] The acid has also been purified by dissolving 990mg in 50% aqueous EtOH (2ml), cooling, collecting the colourless needles on a sintered glass funnel and drying over P<sub>2</sub>O<sub>5</sub> at 80°/0.1mm to give the anhydrous acid. [Lambert & Zilliken *Chem Ber* **93** 2915 1960.] Alternatively the acid is dissolved in a small volume of H<sub>2</sub>O, neutralised to pH 7 with ion-exchange resin beads (IR4B in OH<sup>-</sup> form), filtered, evaporated and dried. The residue is recrystallised from 90% EtOH (v/v) and dried as above for 24 hours. [Strange & Kent *Biochem J* **71** 333 1959.] The *N*-acetyl derivative (**NAMA**, ***R*-2-(acetylamino)-3-*O*-(1-carboxyethyl)-2-deoxy-D-glucose, *R*-2(2-acetylamino-2-deoxy-D-glucose-3-yloxy)-propionic acid**) [10597-89-4], M 292.3, has *m* ~125° (dec) and [α]<sub>D</sub><sup>20</sup> +41.2° after 24 hours (c 1.5, H<sub>2</sub>O), pK<sub>Est</sub> ~ 3.6. [Watanabe & Saito *J Bacteriol* **144** 428 1980, *Beilstein* **4** IV 2029.]

**Muscimol (pantherine, 5-aminoethyl-3[2*h*]-isoxazolone)** [2763-96-4] M 114.1, *m* 170-172°(dec), 172-174°(dec), 172-175°, 175°, 176-178°(dec), pK<sub>Est(1)</sub> ~ 6 (acidic, ring 2-NH), pK<sub>Est(2)</sub> ~ 8 (CH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub>). Recrystallise muscimol from MeOH/tetrahydrofuran or EtOH and sublime it at 110-140° (bath) at 10<sup>-4</sup> mm to give a yellow spot with ninhydrin which slowly turns purple [NMR: Bowden et al. *J Chem Soc (C)* 172 1968]. It can also be purified by dissolving in the minimum volume of hot H<sub>2</sub>O and adding EtOH dropwise until cloudy, cool, and colourless crystals separate; its IR has ν<sub>□□□</sub> at 3445w, 3000-2560w br, 2156w, 1635s and 1475s cm<sup>-1</sup>. [NMR: Jager & Frey *Justus Liebigs Ann Chem* 817 1982.] Alternatively, it has been purified by two successive chromatographic treatments on Dowex-1 x 8, with the first elution with 2M AcOH and a second with a linear gradient between 0—2M AcOH, evaporating the desired fractions and recrystallising the residue from MeOH. [McCarry & Savard *Tetrahedron Lett* **22** 5153 1981, Nakamura *Chem Pharm Bull Jpn* **19** 46 1971.]

**Mycophenolic acid (6-[1,3-dihydro-7-hydroxy-5-methoxy-4-methyl-1-oxoisobenzofuran-6-yl]-4-methylhex-4-enoic acid)** [24280-93-1] M 320.3, *m* 141°, 141-143°, pK<sub>Est(1)</sub> ~ 2.5 (CO<sub>2</sub>H), pK<sub>Est(2)</sub> ~ 9.5 (phenolic OH). Purify the acid by dissolving it in the minimum volume of EtOAc, applying onto a silica gel column (0.05-0.2 mesh) and eluting with a mixture of EtOAc/CHCl<sub>3</sub>/AcOH (45:55:1) followed by recrystallisation from heptane/EtOAc, from aqueous EtOH or from hot H<sub>2</sub>O and drying *in vacuo*. It is a weak dibasic acid, moderately soluble in Et<sub>2</sub>O, CHCl<sub>3</sub> and hot H<sub>2</sub>O but weakly soluble in \*C<sub>6</sub>H<sub>6</sub> and toluene. [Birch & Wright *Aust J Chem* **22** 2635 1969, Canonica et al. *J Chem Soc, Perkin Trans 1* 2639 1972, Birkinshaw et al. *Biochem J* **50** 630 1952, *Beilstein* **18** II 393, **18** III/IV 6513.]

**Myricetin (Cannabiscetin, 3,3',4',5,5',7-hexahydroxyflavone)** [529-44-2] M 318.2, *m* >300°, 357°(dec) (polyphenolic pK<sub>Est</sub> ~ 8-11). Recrystallise myricetin from aqueous EtOH (*m* 357° dec, as *monohydrate*) or Me<sub>2</sub>CO (*m* 350° dec, with one mol of Me<sub>2</sub>CO) as yellow crystals. It is almost insoluble in CHCl<sub>3</sub> and AcOH. The *hexaacetate* has *m* 213°. [Hergert *J Org Chem* **21** 534 1956, Spada & Cameroni *Gazzetta* **86** 965, 975 1956, Kalf & Robinson *J Chem Soc* **127** 181 1925, *Beilstein* **18/5** V 670.]

**Nalidixic acid (1-ethyl-7-methyl-1,8-naphthyridin-4-one-3-carboxylic acid)** [389-08-2] M 232.3, *m* 226.8-230.2°, 228-230°, 229-230°, pK<sup>25</sup> 6.0. Nalidixic acid crystallises from H<sub>2</sub>O or EtOH as a pale buff powder. It is soluble at 23° in CHCl<sub>3</sub> (3.5%), toluene (0.16%), MeOH (0.13%), EtOH (0.09%), H<sub>2</sub>O (0.01%) and Et<sub>2</sub>O (0.01%). It inhibits nucleic acid and protein synthesis in yeast. [Leshner et al. *J Med & Pharm Chem* **5** 1063 1962.]

**Naloxone hydrochloride hydrate (Narcan, 1-*N*-propenyl-7,8-dihydro-14-hydroxymorphinan-6-one hydrochloride)** [51481-60-8] M 399.9, *m* 200-205°, [α]<sub>D</sub><sup>20</sup> -164° (c 2.5, H<sub>2</sub>O), pK<sub>Est(1)</sub> ~ 6 (*N*-propenyl), pK<sub>Est(2)</sub> ~ 9.6 (phenolic OH). This opiate antagonist has been recrystallised from EtOH/Et<sub>2</sub>O or H<sub>2</sub>O. It is soluble in H<sub>2</sub>O (5%) and EtOH but insoluble in Et<sub>2</sub>O. The *free base* has *m* 184° (177-178° also reported) after recrystallisation from EtOAc, and [α]<sub>D</sub><sup>20</sup> -194.5° (c 0.93, CHCl<sub>3</sub>). [Olofson et al. *Tetrahedron Lett* 1567 1977,

Gold et al. *Med Res Rev* 2 211 1982.]

**Naltrexone hydrochloride dihydrate (1-N-cyclopropylmethyl-7,8-dihydro-14-hydroxy-morphinan-6-one hydrochloride)** [16676-29-2] **M 413.9, m 274-276°**,  $[\alpha]_D^{20} -173^\circ$  (c 1, H<sub>2</sub>O), **pK<sub>Est(1)</sub> ~6 (N-cyclopropylmethyl), pK<sub>Est(2)</sub> ~9.6 (phenolic OH)**. This narcotic antagonist has been purified by recrystallisation from MeOH and dried in air. The *free base* has **m 168-170°** after recrystallisation from Me<sub>2</sub>CO. [Cone et al. *J Pharm Sci* 64 618 1975, Gold et al. *Med Res Rev* 2 211 1982.]

**1-Naphthyl phosphate disodium salt** [2183-17-7] **M 268.1, pK<sub>1</sub><sup>26</sup> 0.97, pK<sub>2</sub><sup>26</sup> 5.85 (for free acid)**. Purify the salt through an acid ion-exchange column (in H<sup>+</sup> form) to give the *free acid* [1136-89-6], **M 224.2**, which is obtained by freeze drying and recrystallising from Me<sub>2</sub>CO/\*C<sub>6</sub>H<sub>6</sub>, or by adding 2.5 volumes of hot CHCl<sub>3</sub> (or 20 parts of boiling \*C<sub>6</sub>H<sub>6</sub>) to a hot solution of 1 part acid and 1.2 parts Me<sub>2</sub>CO and cooling (**m 155-157°**, 157-158°). The acid is dissolved in the minimum volume of H<sub>2</sub>O to which 2 equivalents of NaOH are added and then freeze dried, or by adding the equivalent amount of MeONa in MeOH to a solution of the acid in MeOH and collecting the Na salt, washing with cold MeOH, then Et<sub>2</sub>O, and drying in a vacuum. [Friedman & Seligman *J Am Chem Soc* 72 624 1950, Chanley & Fegeason *J Am Chem Soc* 77 4002 1955.] The *monosodium salt* [1136-89-6] is similarly prepared but by using 1 equivalent of NaOH. The phosphate group is hydrolysed at pH 1.1-5.85 at 70°. [Beilstein 6 IV 4226.] It is a substrate for alkaline phosphatase [Gomori *Methods Enzymol* 4 381 1957, 128 212 1968], and prostatic phosphatase [Babson *Clin Chem* 30 1418 1984]. [See p 519 in "Miscellaneous As, B, P, Si, S, Se and Te Compounds", Chapter 4, *Beilstein* 6 IV 4226.]

**2-Naphthyl phosphate monosodium salt** [14463-68-4] **M 246.2, m 177-178°, 296° (sintering at 228°), pK<sub>1</sub><sup>26</sup> 1.28, pK<sub>2</sub><sup>26</sup> 5.53, pK<sub>3</sub><sup>26</sup> 6.57 (for free acid)**. The *free acid* [41845-15-2] is purified as for the preceding 1-isomer and has **m 176-177°** (also 177-178°) after several recrystallisations by adding 2.5 volumes of hot CHCl<sub>3</sub> to a hot solution of 1 part of acid in 1.3 volumes of Me<sub>2</sub>CO as for the 1-isomer above. It is neutralised with one equivalent of NaOH and freeze dried or prepared as the 1-isomer above. Its solubility in H<sub>2</sub>O is ~5%. It also forms a 0.5 Na.1 H<sub>2</sub>O salt which has **m 203-205°** (244° also reported). [Friedman & Seligman *J Am Chem Soc* 72 624 1950, Chanley & Fegeason *J Am Chem Soc* 77 4002 1955, See p 520 in "Miscellaneous As, B, P, Si, S, Se and Te Compounds", Chapter 4, *Beilstein* 6 IV 4285.]

**D(+)-Neopterin** [2009-64-5] **M 253.2, m >300°(dec)**,  $[\alpha]_{546}^{20} +64.5^\circ$  (c 0.14, 0.1M HCl),  $[\alpha]_D^{25} +50.1^\circ$  (c 0.3, 0.1N HCl), **pK<sub>1</sub> 2.23 (basic), pK<sub>2</sub> 7.89 (acidic)**. Purification is as for biopterin. Also purify it on a Dowex-1 x 8 (formate form) column and elute with 0.03M ammonium formate buffer pH 8.0 then pH 7.2. The fluorescent neopterin fraction is evaporated under reduced pressure, leaving neopterin and ammonium formate (the latter sublimes out at high vacuum) behind. Stir the residue for 24 hours with EtOH, collect the solid and recrystallise it from H<sub>2</sub>O. [Viscontini et al. *Helv Chim Acta* 53 1202 1970, cf Wachter et al. Eds *Neopterin* W de Gruyter, Berlin 1992, ISBN 9783110117905, *Beilstein* 26 IV 4038.]

**β-Nicotinamide adenine dinucleotide (diphosphopyridine nucleotide, NAD, DPN)** [53-84-9] **M 663.4,  $[\alpha]_D^{23} -34.8^\circ$  (c 1, H<sub>2</sub>O), pK<sub>1</sub> 2.2 (PO<sub>3</sub>H), pK<sub>2</sub> 4.0 (adenine NH<sub>2</sub>), pK<sub>3</sub> 6.1 (PO<sub>4</sub>)**. NAD is purified by paper chromatography or better on a Dowex-1 ion-exchange resin. The column is prepared by washing with 3M HCl until free of material absorbing at 260nm, then with water, 2M sodium formate until free of chloride ions and, finally, with water. NAD, as a 0.2% solution in water, is adjusted with NaOH to pH 8, and adsorbed onto the column, washed with water, and eluted with 0.1M formic acid. Fractions with strong absorption at 360nm are combined, acidified to pH 2.0 with 2M HCl, and cold acetone (*ca* 5L/g of NAD) is added slowly and with constant agitation. It is left overnight in the cold, then the precipitate is collected in a centrifuge, washed with pure acetone and dried under vacuum over CaCl<sub>2</sub> and paraffin wax shavings [Kornberg *Methods Enzymol* 3 876 1957]. It has been purified by anion-exchange chromatography [Dalziel & Dickinson *Biochemical Preparations* 11 84 1966.] The purity is checked by reduction to NADH (with EtOH and yeast alcohol dehydrogenase) which has  $\epsilon_{340\text{nm}} 6220 \text{ M}^{-1}\text{cm}^{-1}$ . [Todd et al. *J Chem Soc* 3727, 3733 1957.] [pKa, Lamborg et al. *J Biol Chem* 231 685 1958.] The *free acid* crystallises from aqueous Me<sub>2</sub>CO with 3H<sub>2</sub>O and has **m 140-142°**. It is stable in cold neutral aqueous solutions in a desiccator (CaCl<sub>2</sub>) at 25°, but decomposes at strong acid and alkaline pH. Its purity is checked by reduction with yeast alcohol dehydrogenase and EtOH to NADH and noting the OD at 340nm. Pure NADH (see below) has  $\epsilon_{340} 6.2 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$ , i.e. 0.1μmole of NADH in 3ml and in a 1cm path

length cell has an OD at 340nm of 0.207. [*Beilstein* 26 IV 3644.]

**$\beta$ -Nicotinamide adenine dinucleotide reduced di-Na salt trihydrate (reduced diphosphopyridine nucleotide sodium salt, NADH)** [606-68-8] **M 763.5, pKa as for NAD.** This coenzyme is available in high purity, and it is advisable to buy a fresh preparation rather than to purify an old sample as purification will invariably lead to a more impure sample contaminated with the oxidised form (NAD). It has UV with  $\lambda_{\max}$  at 340nm ( $\epsilon$  6,200 M<sup>-1</sup>cm<sup>-1</sup>) at which wavelength the oxidised form NAD has no absorption. At 340nm a 0.161mM solution in a 1cm (pathlength) cell has an absorbance of 1.0 unit. The purity is best checked by the ratio  $A_{280\text{nm}}/A_{340\text{nm}} \sim 2.1$ , a value which increases as oxidation proceeds. The dry powder is stable indefinitely at -20°. Solutions in aqueous buffers at pH  $\sim 7$  are stable for extended periods at -20° and for at least 8 hours at 0°, but are oxidised more rapidly at 4° in a cold room (e.g. almost completely oxidised overnight at 4°). [UV: Drabkin *J Biol Chem* 175 563 1945, Fluorescence: Boyer & Thorell *Acta Chem Scand* 10 447 1956, Redox: Rodkey *J Biol Chem* 234 188 1959, Schlenk in *The Enzymes* 2 250, 268 1951, Kaplan in *The Enzymes* 3 105, 112 1960.] Deuterated NADH, i.e. NADD, has been purified through the anion exchange resin AG-1 x 8 (100-200 mesh, formate form) and through a Bio-Gel P-2 column. [Viola et al. *Anal Biochem* 96 334 1979, *Beilstein* 26 III/IV 3639.]

**$\beta$ -Nicotinamide adenine dinucleotide phosphate (NADP, TPN)** [53-59-8] **M 743.4, pK<sub>1</sub> 1.1 (PO<sub>4</sub>H<sub>2</sub>), pK<sub>2</sub> 4.0 (adenine NH<sub>2</sub>), pK<sub>3</sub> 6.1 (PO<sub>4</sub> ).** Purify it by anion-exchange chromatography in much the same way as for NAD [Dalziel & Dickinson *Biochem J* 95 311 1965, *Biochemical Preparations* 11 87 1966]. Finally it is purified by dissolving in H<sub>2</sub>O and precipitating with 4 volumes of Me<sub>2</sub>CO and dried *in vacuo* over P<sub>2</sub>O<sub>5</sub>. It is unchanged by storing *in vacuo* at 2°. [Hughes et al. *J Chem Soc* 3733 1957, Schuster & Kaplan *J Biol Chem* 215 183 1955.] Deuterated NADPH, i.e. NADPD, has been purified through the anion exchange resin AG-1 x 8 (100-200 mesh, formate form) and through a Bio-Gel P-2 column.  $\lambda_{\min}$  259nm ( $\epsilon$  18.000) at pH 7.0. [Viola et al. *Anal Biochem* 96 334 1979, *Beilstein* 26 IV 3669, 3672.]

**$\beta$ -Nicotinamide adenine dinucleotide phosphate reduced tetrasodium salt (reduced diphosphopyridine nucleotide phosphate sodium salt, NADPH)** [2646-71-1] **M 833.4, pKa as for NADP.** Purification is mostly similar to that of NADH above. [*Beilstein* 26 III/IV 3671.]

**$\beta$ -Nicotinamide mononucleotide (NMN)** [1094-61-7] **M 334.2,  $[\alpha]_D^{23} -38.3^\circ$  (c 1, H<sub>2</sub>O), pK<sub>Est</sub>  $\sim 6.1$  (PO<sub>4</sub> ).** Purify NMN by passage through a column of Dowex-1 (Cl<sup>-</sup> form) and washing with H<sub>2</sub>O until no absorbance is observed at 260 nm. The tubes containing NMN are pooled, adjusted to pH 5.5-6 and evaporated *in vacuo* to a small volume. This is adjusted to pH 3 with dilute HNO<sub>3</sub> in an ice-bath and treated with 20 volumes of Me<sub>2</sub>CO at 0-5°. The heavy white precipitate is collected by centrifugation at 0°. It is best stored wet and frozen or it can be dried to give a gummy residue. It has  $\lambda_{\max}$  at 266nm ( $\epsilon$  4,600) and  $\lambda_{\min}$  at 249nm ( $\epsilon$  3600) at pH 7.0 (i.e. no absorption at 340nm). It can be estimated by reaction with CN<sup>-</sup> or hydrosulfite which form the 4-adducts (equivalent to NADH) which have UV with  $\lambda_{\max}$  at 340nm ( $\epsilon$  6,200). Thus after reaction, an OD<sub>340</sub> of "one" is obtained from a 0.1612mM solution in a 1cm path cuvette. [Plaut & Plaut *Biochemical Preparations* 5 56 1957, Maplan & Stolzenbach *Methods Enzymol* 3 899 1957, Kaplan et al. *J Am Chem Soc* 77 815 1955, *Beilstein* 22/2 V 168.]

**(-)-Nicotine ((2S)-1-methyl-2[3-pyridyl]-pyrrolidine)** [54-11-5] **M 162.2, b 123-125°/17mm, 243-248°/760mm (partial dec),  $d_4^{20}$  1.097,  $n_D^{20}$  1.5280,  $[\alpha]_D^{20} -169^\circ$  (c 1, Me<sub>2</sub>CO), pK<sub>1</sub><sup>15</sup> 6.16 (pyridine N<sup>+</sup>), pK<sub>2</sub><sup>15</sup> 10.96 (pyrrolidine N<sup>+</sup>).** (-)-Nicotine is a very pale yellow *hygroscopic* oil with a characteristic odour (tobacco extract) which turns brown in air on exposure to light. It is purified by fractional distillation under reduced pressure in an inert atmosphere. A freshly distilled sample should be stored in dark sealed containers under N<sub>2</sub>. It is a strong base; a 0.05 M aqueous solution has a pH of 10.2. It is very soluble in organic solvents. It is soluble in H<sub>2</sub>O and readily forms salts. [UV: Parvis *J Chem Soc* 97 1035 1910, Dobbie & Fox *J Chem Soc* 103 1194 1913.] The *hydrochlorides* (mono- and di-) form deliquescent crystals soluble in H<sub>2</sub>O and EtOH but insoluble in Et<sub>2</sub>O. It has also been purified *via* the ZnCl<sub>2</sub> double salt. [Ratz *Monatsh Chem* 26 1241 1905, Biosynthesis: Nakan & Hitchinson *J Org Chem* 43 3922 1978.] The *picrate* has **m** 218° (from EtOH). [*Beilstein* 23/6 V 64.] **POISONOUS.**

**(±)-Nicotine** [22083-74-5] **M 162.2, b 113-115°/10mm, 242.3°/atm,  $d_4^{20}$  1.082 (pKa see above).** It is purified

by fractional distillation. Its solubility in EtOH is ~5%. The *picrate* forms yellow needles from hot H<sub>2</sub>O and has **m** 219°. The *methiodide* has **m** 219° (from MeOH). [Craig *J Am Chem Soc* **55** 2854 1933, Nakane & Hutchinson *J Org Chem* **43** 3922 1978, *Beilstein* **23/6** V 64.] **POISONOUS.**

**Nonactin** [6833-84-7] **M** 737.0, **m** 147-148°,  $[\alpha]_{\text{D}}^{20}$  0° (±2°) (c 1.2, CHCl<sub>3</sub>). This macrotetrolide antibiotic crystallises from MeOH as colourless needles and is dried at 90°/20 hours/high vacuum. [Cordaz et al. *Helv Chim Acta* **38** 1445 1955, crystal structure: Dobler *Helv Chim Acta* **55** 1371 1972, Gambos et al. *Tetrahedron Lett* 3391 1975, *Beilstein* **19/12** V 751.]

**L-Noradrenaline (Adrenor, R-2-amino-1-[3,4-dihydroxyphenyl]ethan-1-ol, L-norepi-nephriene)** [51-41-2, 69815-49-2, 636-88-4 (*bitartrate salt*)] **M** 169.2, **m** 216.5-218°(dec), ~220-230°(dec),  $[\alpha]_{\text{D}}^{20}$  -45° (c 5, N HCl),  $[\alpha]_{\text{D}}^{25}$  -37.3° (c 5, 1 equivalent aqueous HCl), **pK**<sub>1</sub><sup>25</sup> 5.58 (phenolic OH), **pK**<sub>2</sub><sup>25</sup> 8.90 (phenolic OH), **pK**<sub>3</sub><sup>25</sup> 9.78 (NH<sub>2</sub>). Recrystallise adrenor from EtOH and store it in the dark under N<sub>2</sub>. [pKa, Lewis *Brit J Pharmacol Chemother* **9** 488 1954, UV: Bergström et al. *Acta Physiol Scand* **20** 101 1950, Fluorescence: Bowman et al. *Science NY* **122** 32 1955, Tullar *J Am Chem Soc* **70** 2067 1948.] The *L-tartrate salt monohydrate* has **m** 102-104.5°,  $[\alpha]_{\text{D}}^{25}$  -11° (c 1.6, H<sub>2</sub>O), after recrystallisation from H<sub>2</sub>O or EtOH. [*Beilstein* **13** III 2382.]

**L-Noradrenaline hydrochloride (Arterenol)** [329-56-6] **M** 205.6, **m** 145.2-146.4°, ~150°(dec),  $[\alpha]_{\text{D}}^{25}$  -40° (c 6, H<sub>2</sub>O), **pKa** see above. Recrystallise arterenol from isoPrOH and store it in the dark as it is oxidised under light (see preceding entry). [Tullar *J Am Chem Soc* **70** 2067 1948, *Beilstein* **13** III 2382.]

**1R,2S(-)-Norephedrine [L(-)-erythro-1R,2S-2-amino-1-phenyl-1-propanol]** [492-41-1] **M** 151.2, **m** ~49-53°, 50-52°,  $[\alpha]_{\text{D}}^{25}$  -14.6° (c 3.4, EtOH),  $[\alpha]_{\text{D}}^{20}$  -41° (c 7, M HCl), **pK**<sup>25</sup> 8.92. It crystallises in plates from H<sub>2</sub>O or Et<sub>2</sub>O/petroleum ether.

The *1R,2S(-) hydrochloride* **M** 187.7, has **m** 174-175°, crystallises from iso-PrOH, and has  $[\alpha]_{\text{D}}^{20}$  -33.0° (c 5, H<sub>2</sub>O). [cf Atkins & Cramer *J Am Chem Soc* **52** 4349 1930, *Beilstein* **13** II 370, **13** III 1717, **13** IV 1875.]

**1S,2R(+)-Norephedrine [D(+)-erythro-1R,2S-2-amino-1-phenyl-1-propanol]** [37577-28-9] **M** 151.2, **m** ~49-53°, 50-52°,  $[\alpha]_{\text{D}}^{27}$  +14.8° (c 4, EtOH),  $[\alpha]_{\text{D}}^{20}$  +40° (c 7, M HCl), **pK**<sup>25</sup> 8.92. Purify it by recrystallisation from H<sub>2</sub>O (plates), and it is soluble in Et<sub>2</sub>O. Lewis [*Brit J Pharmacol Chemother* **9** 488 1954] obtained **pK**<sub>2</sub><sup>20</sup> 9.44 (H<sub>2</sub>O).

The *hydrochloride* [1S,2R(+)] 40626-28-7] **M** 187.7, has **m** 172-175° (plates from EtOH) and  $[\alpha]_{\text{D}}^{20}$  +33.4° (c 6, H<sub>2</sub>O), and the *sulfate* (plates from H<sub>2</sub>O) has **m** 285-286° and  $[\alpha]_{\text{D}}^{20}$  +31.5° (H<sub>2</sub>O). [cf Atkins & Cramer *J Am Chem Soc* **52** 4349 1930, *Beilstein* **13** II 371, **13** III 1717, **13** IV 1875.]

**DL-(±)-Norephedrine hydrochloride [Propadrin, (±)-erythro-1RS,2SR-2-amino-1-phenyl-1-propanol hydrochloride]** [154-41-6] **m** 194-196° (also 194° was reported), **pK** 8.20. It crystallises in plates from absolute EtOH or isoPrOH, and the (±)-*oxalate* has **m** 245°(dec) (plates from H<sub>2</sub>O). The *2,4-dinitrobenzoate* has **m** 86-88° (from EtOH) and the *3,5-dinitrobenzoate* has **m** 78-79° (from EtOH). It is a mixed anti-sympathomimetic and used as a nasal anticongestant. [cf Atkins & Cramer *J Am Chem Soc* **52** 4349 1930, Krantz & Hartung *J Am Pharm Assoc* **19** 461 1930, Fischer & Plein *J Am Pharm Assoc* **44** 313 1955, *Beilstein* **13** I 252, **13** II 371, **13** III 1717, **13** IV 1875.]

**1R,2R(-)-Norpseudoephedrine [L(-)-threo-1R,2R-2-amino-1-phenyl-1-propanol]** [37577-07-4] **M** 151.2, **m** ~50°, 50-52°, 77°, 77.5-78°,  $[\alpha]_{\text{D}}^{20}$  -34° (c 3.5, EtOH), **pK**<sup>25</sup> 8.92. Purify (-)-nor-ψ-ephedrine by recrystallisation from H<sub>2</sub>O, MeOH, EtOH, Et<sub>2</sub>O/petroleum ether or \*C<sub>6</sub>H<sub>6</sub> (plates). The *mandelate salt* has **m** 163.5° (from EtOH/Et<sub>2</sub>O) and  $[\alpha]_{\text{D}}^{32}$  -41.3° (c 0.8, H<sub>2</sub>O) [Jarowski & Hartung *J Org Chem* **8** 564 566 567 1943]. The *hydrochloride* is purified by dissolving 1.44g in 96% EtOH (5ml), adding Et<sub>2</sub>O (16ml) and cooling; it has **m** 178-179° (**m**180-181° is also reported) and  $[\alpha]_{\text{D}}^{30}$  -42.9° (c 1.8, H<sub>2</sub>O) [Fles & Markovac-Prpic *Croat Chem Acta* **29** 186 1957]. EtOH), and is soluble in H<sub>2</sub>O with  $[\alpha]_D^{20} +42.5^\circ$ . It is a stimulant and is an anorexic substance. [Nagaai & Kanao *Justus Liebigs Ann Chem* **470** 157 1929, Sicher & Pankova *Col Czech Chem Commun* **20** 1409 1955, *Beilstein* **13** I 252, **13** II 370, **13** III 1716, **13** IV 1874.]

**Novobiocin** (7-[O<sup>3</sup>-carbamoyl-5-O<sup>4</sup>-dimethyl-β-L-lyso-6-desoxyhexahydropyranosyloxy]-4-hydroxy-3[4-hydroxy-3-{3-methylbut-2-enyl}-benzylamino]-8-methylcoumarin) [303-81-1] **M 612.6**, two forms **m 152-156°** and **m 172-174°, 174-178°, λ<sub>max</sub> at 330nm (acidic EtOH), 305nm (alkaline EtOH), [α]<sub>D</sub><sup>25</sup> -63° (c 1, EtOH), pK<sub>1</sub> 4.03 (4.2), pK<sub>2</sub> 9.16**. Crystallise novobiocin from EtOH and store it in the dark. It has also been recrystallised from Me<sub>2</sub>CO/H<sub>2</sub>O. [Hoeksema et al. *J Am Chem Soc* **77** 6710 1955, Kaczka et al. *J Am Chem Soc* **77** 9404 1955.]

The **sodium salt** [1476-53-5] **M 634.6**, **m 210-215°, 215-220°(dec), 222-229°, [α]<sub>D</sub><sup>25</sup> -38° (c 1, H<sub>2</sub>O)** has been recrystallised from MeOH, then dried at 60°/0.5mm. [Sensi et al. *Anal Chem* **29** 1611 1957, Kaczka et al. *J Am Chem Soc* **78** 4126 1956, *Beilstein* **18/8** IV 8125.]

**Nucleotide thiophosphate analogues.** The preparation and purification of [<sup>3</sup>H]ATPγS, [<sup>3</sup>H]GTPγS, S<sup>6</sup>ITPγS (6-thioinosine), Cl<sup>6</sup>ITPγS (6-chloroinosine) and [<sup>3</sup>H]ATPγS were described, and general purification was achieved by chromatography of the nucleotide thiophosphates in the minimum volume of H<sub>2</sub>O placed onto a DEAE-Sephadex A25 column and eluted with a linear gradient of triethylammonium bicarbonate (0.1 to 0.6M for G and I nucleotides and 0.2 to 0.5M for A nucleotides). [Googy et al. *Biochim Biophys Acta* **276** 155 1972.]

**Nystatin dihydrate (Mycostatin, Fungicidin)** [1400-61-9] **M 962.1**, **m dec>160° (without melting by 250°), [α]<sub>D</sub><sup>25</sup> -7° (0.1N HCl in MeOH), -10° (AcOH), +12° (Me<sub>2</sub>NCHO), +21° (pyridine)**. Nystatin is a light yellow powder with the following solubilities at ~28°: MeOH (1.1%), ethylene glycol (0.9%), H<sub>2</sub>O (0.4%), CCl<sub>4</sub> (0.12%), EtOH (0.12%), CHCl<sub>3</sub> (0.05%) and \*C<sub>6</sub>H<sub>6</sub> (0.03%). It has been precipitated from MeOH solution by addition of H<sub>2</sub>O. Aqueous suspensions of this macrolide antifungal antibiotic are stable at 100°/10minutes at pH 7.0 but decompose rapidly at pH <2 and >9, and in the presence of light and O<sub>2</sub>. [Birch et al. *Tetrahedron Lett* 1491, 1485 1964, Weiss et al. *Antibiot Chemother* **7** 374 1957.] It may contain a mixture of components A<sub>1</sub>, A<sub>2</sub> and A<sub>3</sub>. [*Beilstein* **18** III/IV 7480.]

**Oxacillin sodium salt (5-methyl-3-phenyl-4-isoxazolympenicillin sodium salt)** [1173-88-2] **M 423.4**, **m 188°(dec), [α]<sub>D</sub><sup>20</sup> +29° (c 1, H<sub>2</sub>O), pK<sub>Est</sub> ~2.7**. This antibiotic, which is stable to penicillinase, is purified by recrystallisation from isoPrOH and dried *in vacuo*. Its solubility in H<sub>2</sub>O at 25° is 5%. [Doyle et al. *Nature* **192** 1183 1961, Review: Chain et al. *Antibiotics* (Oxford University Press) **2** 1949.]

**Oxiracetam (4-hydroxy-2-oxo-1-pyrrolidine acetamide)** [62613-82-5 unspecified, 68567-97-5 racemate] **M 158.2**, **m 165-168°**. This nootropic (Alzheimer) drug is purified by recrystallisation from MeOH or aqueous Me<sub>2</sub>CO and dried *in vacuo*. [NMR, IR: Pifferi & Pinza *Farmaco Ed Sci* **32** 602 1977, Banfi et al. *Farmaco Ed Sci* **39** 16 1984, Gouilaev & Senning *Brain Research Rev* **19** 180 1994.]

**R-(+)-oxiracetam** [68252-28-8] **m 135-136°, [α]<sub>D</sub><sup>20</sup> +36° (c 1, H<sub>2</sub>O)**, and **S-(-)-oxiracetam** [88929-35-5] **m 135-136°, [α]<sub>D</sub><sup>20</sup> +36.5° (c 1, H<sub>2</sub>O)**, have been recrystallised from aqueous Me<sub>2</sub>CO. [Gouilaev & Senning *Brain Research Rev* **19** 180 1994.]

**Palmitoyl coenzyme A** [1763-10-6] **M 1005.9**. Possible impurities are palmitic acid, S-palmitoyl thioglycolic acid and S-palmitoyl glutathione. These are removed by placing *ca* 200mg in a centrifuge tube and extracting with Me<sub>2</sub>CO (20ml), followed by two successive extractions with Et<sub>2</sub>O (15ml) to remove S-palmitoyl thioglycolic acid and palmitic acid. The residue is dissolved in H<sub>2</sub>O (4 x 4 ml), adjusted to pH 5 and centrifuged to remove insoluble S-palmitoyl glutathione and other insoluble impurities. To the clear supernatant is added 5% HClO<sub>4</sub> (6ml) whereby S-palmitoyl CoA precipitates. The precipitate is washed with 0.8% HClO<sub>4</sub> (10ml) and finally with Me<sub>2</sub>CO (3x 5ml) and dried *in vacuo*. It is stable for at least one year in dry form at 0° in a desiccator (dark). Solutions are stable for several months at -15°. Its solubility in H<sub>2</sub>O is 4%. The adenine content is used as the basis of purity with λ<sub>max</sub> at 260 and 232nm (ε 6.4 x 10<sup>6</sup> and 9.4 x 10<sup>6</sup> cm<sup>2</sup>/mol, respectively). Higher

absorption at 232nm would indicate other thio ester impurities, e.g. S-palmitoyl glutathione, which absorb highly at this wavelength. Also the phosphate content should be determined, and acid phosphate can be titrated potentiometrically. [Seubert *Biochemical Preparations* 7 80 1960, Srer et al. *Biochim Biophys Acta* 33 31 1959, Kornberg & Pricer *J Biol Chem* 204 329, 345 1953, Beilstein 26 III/IV 3665.]

**3-Palmitoyl-*sn*-glycerol** (*R*-glycerol-1-palmitate, *L*- $\beta$ -palmitin) [32899-41-5] **M 330.5,  $d_{27.3}^{20}$  0.9014, m 66.5° ( $\alpha$ -form), 74° ( $\beta'$ -form) and 77° ( $\beta$ -form).** The stable  $\beta$ -form is obtained by crystallisation from EtOH or Skellysolve B, and recrystallisation from Et<sub>2</sub>O provides the  $\beta'$ -form. The  $\alpha$ -form is obtained on cooling the melt. [Malkin & el Sharbagy *J Chem Soc* 1631 1936, Chapman *J Chem Soc* 58 1956, Luton & Jackson *J Am Chem Soc* 70 2446 1948, Beilstein 2 III 966.]

**D-Panthenol** (Provitamin B, *R*-2,4-dihydroxy-3,3-dimethylbutyric acid 3-hydroxy-propylamide) [81-13-0] **M 205.3, b 118-120°/0.02mm,  $d_{20}^{20}$  1.2,  $n_D^{20}$  1.4935,  $[\alpha]_D^{20} +30^\circ$  (c 5, H<sub>2</sub>O).** Purify D-panthenol by distillation *in vacuo*. It is a slightly *hygroscopic* viscous oil and is soluble in H<sub>2</sub>O and organic solvents. It is hydrolysed by alkali and strong acid. [Rabin *J Am Pharm Assoc (Sci Ed)* 37 502 1948, Bonati & Pitre *Farmaco Ed Scient* 14 43 1959, Beilstein 4 IV 1652.]

***R*-(+)-Pantothenic acid sodium salt** (*N*-[2,4-dihydroxy-3,3-dimethylbutyryl]  $\beta$ -alanine Na salt) [867-81-2] **M 241.2,  $[\alpha]_D^{25} +27.1^\circ$  (c 2, H<sub>2</sub>O),  $pK_{25}^{25}$  4.4 (for free acid).** Crystallise the salt from absolute EtOH. It is very *hygroscopic* (keep in sealed ampoules). The *free acid* is a viscous *hygroscopic* oil with  $[\alpha]_D^{25} +37.5^\circ$  (c 5, H<sub>2</sub>O), easily destroyed by acids and bases. See next entry. [Beilstein 4 IV 2569.]

***R*-(+)-Pantothenic acid Ca salt** [(D(+)) 137-08-6, 63409-48-3] **M 476.5, m 195-196°, 200-201°,  $[\alpha]_D^{20} +28.2^\circ$  (c 5, H<sub>2</sub>O).** The salt crystallises as needles from MeOH, EtOH or isoPrOH (with 0.5mol of isoPrOH). It is moderately *hygroscopic*. The *S*-benzylisothiuronium salt has **m 151-152° (149° when crystallised from Me<sub>2</sub>CO).** [Kagan et al. *J Am Chem Soc* 79 3545 1957, Wilson et al. *J Am Chem Soc* 76 5177 1954, Stiller & Wiley *J Am Chem Soc* 63 1239 1941, Beilstein 4 IV 2569.]

**Paromomycin sulfate** {amminosidin, *O*-2,6-diamino-2,6-dideoxy- $\beta$ -*L*-idopyranosyl-(1 $\rightarrow$ 3)-*O*- $\beta$ -*D*-ribofuranosyl(1 $\rightarrow$ 5)-*O*-[2-amino-2-deoxy- $\alpha$ -*D*-glucopyranosyl-(1 $\rightarrow$ 4)]-2-deoxystrepta amine sulfate} [1263-89-4] **M 713.7, amorphous,  $[\alpha]_D^{25} +50^\circ$  (c 1.5, H<sub>2</sub>O pH6),  $pK_{Est} \sim 9$ .** Purify it by dissolving it in H<sub>2</sub>O (0.5g/10ml) and adding excess EtOH, filter or collect and wash with EtOH, then Et<sub>2</sub>O by centrifugation, and dry it *in vacuo*. An aqueous solution is stable at 37° for a week but longer at 0-5°. The *free base* [7542-37-2] is a white amorphous powder which should be stored under N<sub>2</sub> because it is strongly basic and can absorb CO<sub>2</sub> from the atmosphere. It is soluble in MeOH (less soluble in EtOH) and has  $[\alpha]_D^{25} +65^\circ$  (c 1.5, MeOH). It is an antimicrobial against Gram +ve and Gram -ve bacteria and is antiamoebic. It inhibits initiation and peptide elongation during protein synthesis. [Haskell et al. *J Am Chem Soc* 81, 3480, 3482 1959, Hichens & Rinehart *J Am Chem Soc* 85 1547 1963, Beilstein 18 III/IV 7534.]

**D(-)-Penicillamine** (*R*-3-mercapto-*D*-valine, 3,3-dimethyl-*D*-cysteine, from natural penicillin) [52-67-5] **M 149.2, m 202-206°, 214-217°,  $[\alpha]_D^{21} -63^\circ$  (c 1, N NaOH or pyridine).** The melting point of D(-)-penicillamine depends on the rate of heating (**m 202-206°** is obtained by starting at 195° and heating at 2°/minute). It is soluble in H<sub>2</sub>O and alcohols but insoluble in Et<sub>2</sub>O, CHCl<sub>3</sub>, CCl<sub>4</sub> and hydrocarbon solvents. Purify it by dissolving it in MeOH and adding Et<sub>2</sub>O slowly. Dry it *in vacuo* and store it under N<sub>2</sub>. [Weight et al. *Angew Chem, Int Ed (English)* 14 330 1975, Cornforth in *The Chemistry of Penicillin* (Clarke, Johnson and Robinson eds) Princeton Univ Press, 455 1949, Review: Chain et al. *Antibiotics* (Oxford University Press) 2 1949, Polymorphism: Vidler *J Pharm Pharmacol* 28 663 1976]. The *D*-*S*-benzyl derivative has **m 197-198° (from H<sub>2</sub>O),  $[\alpha]_D^{17} -20^\circ$  (c 1, N NaOH), -70° (N HCl).** [Beilstein 4 IV 3228.]

***L*-(-)-Penicillamine** [1113-41-3] **M 149.2, m 190-194°, 202-206°, 214-217°,  $[\alpha]_D^{21} +63^\circ$  (c 1, N NaOH or pyridine).** Same as the preceding entry for its enantiomer. [Beilstein 4 IV 3228.]  
***D*-Penicillamine disulfide hydrate** (*S,S'*-di-*D*-penicillamine) hydrate) [20902-45-8] **M 296.4 + aqueous, m 203-204°(dec), 204-205°(dec),  $[\alpha]_D^{23} +27^\circ$  (c 1.5, N HCl), -82° (c 0.8, N NaOH),  $pK_{Est(1)} \sim 2.4$  (CO<sub>2</sub>),  $pK_{Est(2)}$**

~ 10.7 (NH<sub>2</sub>). Purify it by recrystallisation from EtOH or aqueous EtOH. [Crooks in *The Chemistry of Penicillin* (Clarke, Johnson and Robinson Eds) Princeton University Press, 469 1949. Use as a thiol reagent for proteins: Garel *Eur J Biochem* **123** 513 1982, Süss *Justus Liebigs Ann Chem* **561** 31 1948, *Beilstein* **4** IV 3231.]

**Penicillic acid (5-hydroxy-5-isopropenyl-4-methoxy-2(5H)furanone)** [90-65-3] **M 158.2, m 58-64°, 64-65° (monohydrate, acid), 83-84°, 87° (anhydrous, lactone), pK<sup>25</sup> 5.9.** The lactone (furanone, *anhydrous*) hydrolyses to the acid (3-methoxy-4-oxo-hexa-2,5-dienoic acid, *hydrate*). It crystallises from water as the *monohydrate* (acid), or from petroleum ether as the *anhydrous* (lactone) compound. The free acid is in equilibrium with the lactone. Its UV has  $\lambda_{\max}$  at 221nm ( $\epsilon$  12,500) in 0.02M KOH; 228nm ( $\epsilon$  11,500) in 0.02M HCl [Raphael *J Chem Soc* 1508 1948]. [*Beilstein* **3** II 519, **3** III 1467.] It is a possible **antineoplastic**.

**3-sn-Phosphatidylethanolamine (L- $\alpha$ -cephalin, from Soya bean)** [39382-08-6] **M<sub>r</sub> ~600-800, amorphous, pK<sub>Est(1)</sub>~5.8 (PO<sub>4</sub><sup>-</sup>), pK<sub>Est(2)</sub>~10.5 (NH<sub>2</sub>).** Purify the cephalin by dissolving it in EtOH, adding Pb(OAc)<sub>2</sub>·3H<sub>2</sub>O (30g in 100ml H<sub>2</sub>O) until excess Pb<sup>2+</sup> is present. Filter off the solid. Pass CO<sub>2</sub> gas through the solution until precipitation of PbCO<sub>3</sub> ceases. Filter the solid off and evaporate (while bubbling CO<sub>2</sub>) under vacuum. An equal volume of H<sub>2</sub>O is added to the residual oil and extracted with hexane. The hexane extract is washed with H<sub>2</sub>O until the aqueous phase is free from Pb [test with dithizone (2 mg in 100 ml CCl<sub>4</sub>; Feigl *Spot Tests* Vol I, Elsevier p. 10 1954)]. The hexane is dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and evaporated to give a yellow waxy solid which should be dried to constant weight *in vacuo*. It is practically insoluble in H<sub>2</sub>O and Me<sub>2</sub>CO, but freely soluble in CHCl<sub>3</sub> (5%) and Et<sub>2</sub>O, and slightly soluble in EtOH. [Schofield & Dutton *Biochemical Preparations* **5** 5 1957.]

**O-Phosphocolamine (2-aminoethyl dihydrogen phosphate)** [1071-23-4] **M 141.1, m 237-240°, 242.3°, 234.5-244.5°, 244-245°(capillary), pK<sub>1</sub><sup>20</sup> <1.5 (PO<sub>4</sub>H<sub>2</sub>), pK<sub>2</sub><sup>20</sup> 5.77 (PO<sub>4</sub>H<sup>-</sup>), pK<sub>3</sub><sup>20</sup> 10.26 (NH<sup>+</sup>).** Purification by recrystallisation from aqueous EtOH gives a *hydrate* (**m** 140-141°). Its solubility in H<sub>2</sub>O is 17% and 0.003% in MeOH or EtOH at 22°. [Fölisch & Österberg *J Biol Chem* **234** 2298 1959, Baer & Stauber *Can J Chem* **34** 434 1956, Christensen *J Biol Chem* **135** 399 1940.] It is a potent inhibitor of ornithine decarboxylase [Gilad & Gilad *Biochem Biophys Res Commun* **122** 277 1984]. [*Beilstein* **4** IV 1415.]

**Phosphoenolpyruvic acid monopotassium salt (KPEP)** [4265-07-0] **M 206.1, pK<sub>1</sub><sup>25</sup> 3.4 (CO<sub>2</sub>), pK<sub>2</sub><sup>25</sup> 6.35 (PO<sub>4</sub>H<sup>-</sup>) (for free acid).** KPEP is purified *via* the monocyclohexylamine salt (see next entry). The salt (534mg) in H<sub>2</sub>O (10ml) is added to Dowex 50Wx4 H<sup>+</sup> form (200-400 mesh, 2ml, H<sub>2</sub>O washed) and stirred gently for 30 minutes and filtered. The resin is washed with H<sub>2</sub>O (6ml), and the combined solutions are adjusted to pH 7.4 with 3N KOH (~1.4ml) and the volume adjusted to 18.4ml with H<sub>2</sub>O to give a solution of 0.1M KPEP which can be lyophilised to a pure powder and is very good for enzyme work. It has been recrystallised from MeOH/Et<sub>2</sub>O. [Clark & Kirby *Biochemical Preparations* **11** 103 1966, Wold & Ballou *J Biol Chem* **227** 301 1957, Cherbuliez & Rabinowitz *Helv Chim Acta* **39** 1461 1956, *Beilstein* **3** IV 977.]

**The triNa salt** [5541-93-5] **M 360.0,** is purified as follows: the salt (1g) is dissolved in MeOH (40ml) and dry Et<sub>2</sub>O is added in excess. The white crystals are collected and dried over P<sub>2</sub>O<sub>5</sub> at 20°. [Cramer & Voges *Chem Ber* **92** 952 1959, *Beilstein* **3** IV 977.]

**Phosphoenolpyruvic acid tris(cyclohexylamine) salt** [35556-70-8] **M 465.6, m 155-180°(dec).** Recrystallise it from aqueous Me<sub>2</sub>CO and dry it in a vacuum. At 4° it is stable for >2 years and has IR at 1721cm<sup>-1</sup> (C=O). [Wold & Ballou *J Biol Chem* **227** 301 1957, Clark & Kirby *Biochemical Preparations* **11** 103 1966 for the monocyclohexylamine salt, *Beilstein* **12** IV 8.]

**D-3-Phosphoglyceric acid disodium salt (D-glycerate 3-phosphate di-Na salt)** [80731-10-8] **M 230.0, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +7.7° (c 5, H<sub>2</sub>O), -735° (in aqueous NH<sub>4</sub><sup>+</sup> molybdate), pK<sub>Est(1)</sub>~1.0 (PO<sub>4</sub>H<sub>2</sub>), pK<sub>Est(2)</sub>~6.66 (PO<sub>4</sub>H<sup>-</sup>) (for free acid).** It is best purified by conversion to the **Ba salt** by precipitation with BaCl<sub>2</sub>, which is recrystallised three times before conversion to the sodium salt. The **Ba salt** (9.5g) is shaken with 200ml of a 1:1 slurry of Dowex 50 (Na<sup>+</sup> form) for 2 hours. The mixture is filtered, and the resin is washed with H<sub>2</sub>O (2 x 25ml). The combined filtrates (150ml) are adjusted to pH 7.0 and concentrated *in vacuo* to 30-40ml and filtered if not clear. Absolute EtOH is added to make 100ml, and then *n*-hexane is added whereby a white solid and/or a second phase separates. When set aside at room temperature, complete precipitation of the Na salt as a solid occurs. The salt is

removed by centrifugation, washed with Me<sub>2</sub>CO, dried in air then in an oven at 55° to give a stable powder (4.5g). It did not lose weight when dried further over P<sub>2</sub>O<sub>5</sub> at 78°/8 hours. The high rotation in the presence of (NH<sub>4</sub>)<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub> is not very sensitive to the concentration of molybdate or pH as it did not alter appreciably in 1/3 volume between 2.5 to 25% (w/v) of molybdate or at pH values ranging between 4 and 7. [Cowgill *Biochim Biophys Acta* **16** 613 1955, Embdan et al. *Hoppe Seyler's Z Physiol Chem* **230** 20 1934, *Beilstein* **3** IV 1051.]

**Phospholipids.** For the removal of ionic contaminants from raw zwitterionic phospholipids, most lipids are purified twice by mixed-bed ionic exchange resins (Amberlite AB-2) of methanolic solutions. (About 1g of lipid in 10ml of MeOH). With both runs the first 1ml of the eluate is discarded. The main fraction of the solution is evaporated at 40°C under dry N<sub>2</sub> and recrystallised three times from *n*-pentane. The resulting white powder is dried for about 4 hours at 50° under reduced pressure and stored at 3°. Some samples are purified by mixed-bed ion exchange of aqueous suspensions of the crystal/liquid crystal phase. [Kaatze et al. *J Phys Chem* **89** 2565 1985.]

**O-Phospho-L-serine** [407-41-0] **M 185.1, m 175-176°**, [α]<sub>D</sub><sup>20</sup> +4.3° (c 3.2, H<sub>2</sub>O), +16.2° (c 3.2, 2N HCl), pK<sub>i</sub><sup>25</sup> <1 (PO<sub>4</sub>H<sub>2</sub>), pK<sub>2</sub><sup>25</sup> 2.08 (CO<sub>2</sub>H), pK<sub>3</sub><sup>25</sup> 5.65 (PO<sub>4</sub>H<sup>-</sup>), pK<sub>4</sub><sup>25</sup> 9.74 (NH<sub>3</sub><sup>+</sup>). Recrystallise the phosphoserine by dissolving 10g in H<sub>2</sub>O (150ml) at 25°, stirring for up to 20 minutes. Undissolved material is filtered off (Büchner), and 95% EtOH (85ml) is added dropwise during 4 minutes, and set aside at 25° for 3 hours, then at 3° overnight. The crystals are washed with 95% EtOH (100ml), then dry Et<sub>2</sub>O (50ml), and dried in a vacuum (yield 6.5g). A further quantity (1.5g) can be obtained by keeping the mother liquors and washings at -10° for 1 week. The *DL*-isomer has **m** 167-170°(dec) after recrystallisation from H<sub>2</sub>O/EtOH or MeOH. [Neuhaus & Korke *Biochemical Preparations* **6** 75 1958, Neuhaus & Byrne *J Biol Chem* **234** 113 1959, IR: Fölsch & Mellander *Acta Chem Scand* **11** 1232 1957, *Beilstein* **4** IV 3120.]

**O-Phospho-L-threonine (L-threonine-O-phosphate)** [1114-81-4] **M 199.1, m 194°(dec)**, [α]<sub>D</sub><sup>24</sup> -7.4° (c 2.8, H<sub>2</sub>O) (pKa as above). Dissolve the phosphate in the minimum volume of H<sub>2</sub>O, add charcoal, stir for a few minutes, filter and apply onto a column of Dowex 50W (H<sup>+</sup> form), then elute with 2N HCl. Evaporate the eluates under reduced pressure whereby the desired fraction produces crystals of the phosphate which can be recrystallised from H<sub>2</sub>O/MeOH mixtures and the crystals are then dried *in vacuo* over P<sub>2</sub>O<sub>5</sub> at ~80°. [de Verdier *Acta Chem Scand* **7** 196 1953, *Beilstein* **4** IV 3175.]

**O-Phospho-L-tyrosine (L-tyrosine-O-phosphate)** [21820-51-9] **M 261.2, m 225°, 227°, 253°**, [α]<sub>D</sub><sup>20</sup> -5.5° (c 1, H<sub>2</sub>O), -9.2° (c 1, 2N HCl), pK<sub>Est(1)</sub> ~1.6 (PO<sub>4</sub>H<sub>2</sub>), pK<sub>Est(2)</sub> ~2.02 (CO<sub>2</sub>H), pK<sub>Est(3)</sub> ~5.65 (PO<sub>4</sub>H<sup>-</sup>), pK<sub>Est(4)</sub> 9.2 (NH<sub>3</sub><sup>+</sup>). Purify it by recrystallisation from H<sub>2</sub>O or H<sub>2</sub>O/EtOH. [Levene & Schormüller *J Biol Chem* **100** 583 1933, Posternak & Graff *Helv Chim Acta* **28** 1258 1945, *Beilstein* **14** III 1510.]

**Phytol (d-2E-3,7R,11R,15-tetramethylhexadec-2-en-1-ol)** [150-86-7, 7541-49-93] **M 296.5, b 145°/0.03mm, 150-151°/0.06mm, 202-204°/10mm, d<sub>4</sub><sup>25</sup> 0.8497, n<sub>D</sub><sup>25</sup> 1.437, [α]<sub>D</sub><sup>22</sup> +0.06° (neat)**. It is commercially available as a mixture of isomers. Phytol is purified by distillation under high vacuum. It is almost insoluble in H<sub>2</sub>O but soluble in most organic solvents. It has UV with λ<sub>max</sub> at 212nm (log ε 3.04) in EtOH and IR has ν<sub>max</sub> at 3300 and 1670cm<sup>-1</sup>. [Demole & Lederer *Bull Soc Chim Fr* 1128 1958, Burrell *J Chem Soc (C)* 2144 1966, Bader *Helv Chim Acta* **34** 1632 1951, *Beilstein* **1** IV 2208.]

**Piracetamide (2-oxo-1-pyrrolidine acetamide)** [7491-74-9] **M 142.2, m 151.5-152.5°**. This typical nootropic (Alzheimer) drug modulates Na flux in AMPA receptors and is purified by recrystallisation from isoPrOH. [Gouilaev & Senning *Brain Research Rev* **19** 180 1994.]

**Podophylotoxin** [518-28-5] **M 414.4, m 181-181°, 183-184°, 188-189°**, [α]<sub>D</sub><sup>20</sup> -132° (c 1, CHCl<sub>3</sub>). The toxin recrystallises from \*C<sub>6</sub>H<sub>6</sub> (with 0.5C<sub>6</sub>H<sub>6</sub>), EtOH/\*C<sub>6</sub>H<sub>6</sub>, aqueous EtOH (with 1-1.5H<sub>2</sub>O, **m** 114-115°) and CH<sub>2</sub>Cl<sub>2</sub>/pentane. When dried at 100°/10mm it has **m** 183-184°. [UV: Stoll et al. *Helv Chim Acta* **37** 1747 1954, IR: Schecler et al. *J Org Chem* **21** 288 1956.] It is an inhibitor of microtubule assembly [Prasad et al. *Biochemistry* **25** 739 1986]. [*Beilstein* **19/10** V 666.]

**Polyethylene glycol** [25322-68-3] **M<sub>r</sub> various, from PEG ~200 to ~35,000**. PEG is available commercially as

a powder or as a solution in various degrees of polymerisation depending on the average molecular weight, e.g. PEG 400 and PEG 800 have average molecular weights of 400 and 800, respectively. They may be contaminated with aldehydes and peroxides. Solutions deteriorate in the presence of air due to the formation of these contaminants. Methods available for purification are as follows:

*Procedure A:* A 40% aqueous solution of PEG 400 (2L, average molecular weight 400) is de-aerated under vacuum and made 10mM in sodium thiosulfate. After standing for 1 hour at 25°, the solution is passed through a column (2.5x20cm) of mixed-bed R-208 resin which has a 5cm layer of Dowex 50-H<sup>+</sup> at the bottom of the column. The column was previously flushed with 30% aqueous MeOH, then thoroughly with H<sub>2</sub>O. A flow rate of 1ml/minute is maintained by adjusting the fluid head. The first 200ml are discarded, and the effluent is then collected at an increased flow rate. The concentration of PEG solution is checked by density measurement, and it is stored (preferably anaerobically) at 15°.

*Procedure B:* A solution of PEG 800 (500g in 805ml H<sub>2</sub>O) is made 1mM in H<sub>2</sub>SO<sub>4</sub> and stirred overnight at 25° with 10g of treated Dowex 50-H<sup>+</sup> (8% crosslinked, 20-50 mesh). The resin, after settling, is filtered off on a sintered glass funnel. The filtrate is treated at 25° with 1.5g of NaBH<sub>4</sub> (added over a period of 1 minute) in a beaker with tight but removable lid through which a propeller-type mechanical stirrer is inserted and continuously flushed with N<sub>2</sub>. After 15 minutes, 15g of fresh Dowex 50-H<sup>+</sup> are added, and the rate of stirring is adjusted to maintain the resin suspended. The addition of an equal quantity of Dowex 50-H<sup>+</sup> is repeated and the reaction times are 30 and 40 minutes. The pH of a 1 to 10 dilution of the reaction mixture should remain above pH 8 throughout. If it does not, more NaBH<sub>4</sub> is added or the addition of Dowex 50-H<sup>+</sup> is curtailed. (Some samples of PEG can be sufficiently acidic, at least after the hydrolysis treatment, to produce a pH that is too low for efficient reduction when the above ratio of NaBH<sub>4</sub> to Dowex 50-H<sup>+</sup> is used.) About 30 minutes after the last addition of NaBH<sub>4</sub>, small amounts of Dowex 50-H<sup>+</sup> (~0.2g) are added at 15 minute intervals until the pH of a 1 to 10 dilution of the solution is less than 8. After stirring for an additional 15 minutes the resin is allowed to settle, and the solution is transferred to a vacuum flask for brief de-gassing under a vacuum. The de-gassed solution is passed through a column of mixed-bed resin as in procedure A. The final PEG concentration would be about 40% w/v.

Assays for aldehydes by the purpural method and of peroxides are given in the reference below.

*Treatment of Dowex 50-H<sup>+</sup> (8% crosslinked, 20-50 mesh):* The Dowex (500g) is suspended in excess 2N NaOH, and 3ml of liquid Br<sub>2</sub> is stirred into the solution. After the Br<sub>2</sub> has dissolved, the treatment is repeated twice, and then the resin is washed with 1N NaOH on a sintered glass funnel until the filtrate is colourless. The resin is then converted to the acid form (with dilute HCl, H<sub>2</sub>SO<sub>4</sub> or AcOH as required) and washed thoroughly with H<sub>2</sub>O and sucked dry on the funnel. The treated resin can be converted to the Na salt and stored.

[Ray & Purathalingal *Anal Biochem* **146** 307 1985.]

**Porphobilinogen (5-amino-4-carboxymethyl-1H-pyrrole-3-propionic acid)** [487-90-1] **M 226.2, m 172-175°(dec), 175-180°(dec, darkening at 120-130°), pK<sub>1</sub> 3.70 (4-CH<sub>2</sub>CO<sub>2</sub>H), pK<sub>2</sub> 4.95 (3-CH<sub>2</sub>CH<sub>2</sub>CO<sub>2</sub>H), pK<sub>3</sub> 10.1 (NH<sup>+</sup>).** Porphobilinogen recrystallises as the *monohydrate* (pink crystals) from dilute NH<sub>4</sub>OAc solutions of pH 4, and is dried *in vacuo*. The *hydrochloride monohydrate* has **m 165-170°(dec)** (from dilute HCl). [Jackson & MacDonald *Can J Chem* **35** 715 1957, Westall *Nature* **170** 614 1952, Bogarad *J Am Chem Soc* **75** 3610 1953, Beilstein **22/14 V** 210.]

**Porphyrin a (from ox heart)** [5162-02-1] **M 799.0, m dec on heating.** It is purified on a cellulose powder column followed by extraction with 17% HCl and fractionated with HCl. [Morell et al. *Biochem J* **78** 793 1961.] It recrystallises from CHCl<sub>3</sub>/petroleum ether or Et<sub>2</sub>O/\*C<sub>6</sub>H<sub>6</sub> [detailed UV-VIS and NMR data: Caughey et al. *J Biol Chem* **250** 7602 1975, Lemberg *Adv Enzymol* **23** 265 1961].

**Prazosin hydrochloride (2[4-{(2-furoyl)piperazin-1-yl}4-amino-6,7-dimethoxyquinazoline hydrochloride)** [19237-84-4] **M 419.9, m 278-280°, 280-282°, pK<sub>25</sub> 6.5.** The salt is recrystallised by dissolving it in hot MeOH, adding a small volume of MeOH/HCl (dry MeOH saturated with dry HCl gas) followed by dry Et<sub>2</sub>O until crystallisation is complete. Dry it *in vacuo* over solid KOH till the odour of HCl is absent. It has been recrystallised from hot H<sub>2</sub>O, the crystals are washed with H<sub>2</sub>O, and the H<sub>2</sub>O is removed azeotropically with CH<sub>2</sub>Cl<sub>2</sub>, and dried in a vacuum. [NMR and IR: Honkanen et al. *J Heterocycl Chem* **17** 797 1980, cf Armarego & Reece *Aust J Chem* **34** 1561 1981.] It is an antihypertensive drug and is an α<sub>1</sub>-adrenergic antagonist [Brosman et al. *Proc Natl Acad Sci USA* **82** 5915 1985].

**Procaine hydrochloride** (Novocain, 2-diethylaminoethyl-4-aminobenzoate) [51-05-8] M 272.8, m 153-156°, 154-156°, 156°,  $\text{pK}_{\text{Est}(1)} \sim 2.52$  ( $\text{NH}_2^+$ )  $\text{pK}_2^{20}$  9.0 ( $\text{Et}_2\text{N}^+$ ). Novocain is recrystallised from aqueous EtOH. It is soluble at 25° in  $\text{H}_2\text{O}$  (86.3%), EtOH (2.6%) and  $\text{Me}_2\text{CO}$  (1%), it is slightly soluble in  $\text{CHCl}_3$ , but is almost insoluble in  $\text{Et}_2\text{O}$ . The anhydrous *free base* is recrystallised from ligroin or  $\text{Et}_2\text{O}$  and has m 61°. [Einhorn *Justus Liebigs Ann Chem* 371 125 1909, IR: Szymanski & Panzica *J Amer Pharm Assoc* 47 443 1958, *Beilstein* 14 IV 1138.]

**R-Propranalol hydrochloride** (*R*-1-isopropylamino-3-(1-naphthoxy)-2-propanol HCl) [13071-11-9] M 295.8, m 192°, 193-195°,  $[\alpha]_{\text{D}}^{20}$  -25° (c 1, EtOH),  $\text{pK}^{20}$  9.5 (for *free base*). The hydrochloride is recrystallised from *n*-PrOH or  $\text{Me}_2\text{CO}$ . It is soluble in  $\text{H}_2\text{O}$  and EtOH but is insoluble in  $\text{Et}_2\text{O}$ ,  $\text{C}_6\text{H}_6$  or EtOAc. The *racemate* has m 163-164°, and the *free base* recrystallises from cyclohexane with m 96°. [Howe & Shanks *Nature* 210 1336 1966.] The *S*-isomer (below) is the physiologically active isomer.

**S-Propranalol hydrochloride** (*S*-1-isopropylamino-3-(1-naphthoxy)-2-propanol HCl) [4199-10-4] M 295.8, m 192°, 193-195°,  $[\alpha]_{\text{D}}^{20}$  +25° (c 1, EtOH)  $\text{pK}^{20}$  9.5. See preceding entry for physical properties and purification. The (+)-salt is the active isomer which blocks isoprenaline tachycardia and is a  $\beta$ -adrenergic blocker. [Leclerc et al. *Trends Pharmacol Sci* 2 18 1981, Howe & Shanks *Nature* 210 1336 1966.]

**Protoporphyrin IX** (3,18-divinyl-2,7,13,17-tetramethylporphyrin-8,12-dipropionic acid, ooporphyrin) [553-12-8] M 562.7,  $\text{pK}_{\text{Est}} \sim 4.8$ . Protoporphyrin IX is purified by dissolving (4g) in 98-100%  $\text{HCOOH}$  (85ml), diluting with dry  $\text{Et}_2\text{O}$  (700ml) and keeping at 0° overnight. The precipitate is collected and washed with  $\text{Et}_2\text{O}$ , then  $\text{H}_2\text{O}$ , and dried in a vacuum at 50° over  $\text{P}_2\text{O}_5$ . It crystallises from aqueous pyridine and from  $\text{Et}_2\text{O}$  in monoclinic, brownish-yellow prisms. The UV has  $\lambda_{\text{max}}$  at values in 25% HCl are 557.2, 582.2 and 602.4nm. It is freely soluble in ethanolic HCl, AcOH,  $\text{CHCl}_3$ , and  $\text{Et}_2\text{O}$  containing AcOH. It forms sparingly soluble diNa and diK salts. [Ramsey *Biochemical Preparations* 3 39 1953, UV: Holden *Aust J. Exptl Biol and Med Sci* 15 412 1937, Garnick *J Biol Chem* 175 333 1948, IR: Falk & Willis *Aust J Sci Res [A]* 4 579 1951, *Beilstein* 26 IV 3042.]

**Protoporphyrin IX dimethylester** [5522-66-7] M 590.7, m 228-230°. The crude dimethyl ester (1g) in  $\text{CHCl}_3$  (200 ml) is mixed with petroleum ether (b 70-90°, 600ml), and any porphyrin (m > 260°) which is insoluble in this mixture is filtered off. The filtrate is passed through a column of  $\text{CaCO}_3$  [from  $\text{CaCO}_3$  (130g) which is kept overnight in a mixture of  $\text{CHCl}_3$ /petroleum ether (b 70-90°, 1:3), and the slurry is poured into a glass tube (2.5 x 26cm) to form the column]. After all the filtrate is applied, the column is eluted with a solution of  $\text{CHCl}_3$ /petroleum ether (b 70-90°, 1:3). All the coloured eluates are collected, evaporated at room temperature in a vacuum to give a residue (0.8g), m 208-211°. The residue (0.8g) in  $\text{CHCl}_3$  (66ml) is heated briefly to its boiling point, then boiling MeOH (198ml) is added immediately to it. The mixture is allowed to cool to room temperature, refrigerated for 2 days and the solid is filtered off. The solid is washed on the filter funnel with  $\text{CHCl}_3$ /MeOH (1:9, 50ml) and dried at 50°/vacuum (yield 0.62-0.66g). It can also be recrystallised by dissolving in as little hot dry  $\text{C}_6\text{H}_6$  as possible and left overnight at 20°, and has m 228-230°.

It has also been purified by dissolving (0.4g) in  $\text{CHCl}_3$  (33ml) by boiling for a few minutes, then diluting with boiling MeOH (100ml) and refrigerating for 2 days. The crystals are collected, washed with  $\text{CHCl}_3$ /MeOH (1:9) and dried at 50° in a vacuum (yield 0.3g). Its UV has  $\lambda_{\text{max}}$  at 631, 576, 541, 506 and 407nm in  $\text{CHCl}_3$  and 601, 556 and 406nm in 25% HCl. [Ramsey *Biochemical Preparations* 3 39 1953, *Beilstein* 26 III/IV 3052.]

**Pterin-6-carboxylic acid** (2-amino-4-oxo-3,4-dihydropteridine-6-carboxylic acid) [948-60-7] M 207.2, m >360°,  $\text{pK}_1^{20}$  1.43,  $\text{pK}_2^{20}$  2.88,  $\text{pK}_3^{20}$  7.72. The acid gives yellow crystals by repeated dissolution in aqueous NaOH and adding aqueous HCl. It has UV with  $\lambda_{\text{max}}$  at 235, 260 and 265nm ( $\epsilon$  11,000, 10,500 and 9,000) in 0.1N HCl and 263 and 365nm ( $\epsilon$  20,500 and 9000) in 0.1N NaOH. [UV: Pfeleiderer et al. *Justus Liebigs Ann Chem* 741 64 1970, Stockstad et al. *J Am Chem Soc* 70 5 1948, Fluorescence: Kavanagh & Goodwin *Arch Biochem* 20 315 1949, *Beilstein* 26 III/IV 4053.]

**Purine-9- $\beta$ -ribofuranoside** (Nebularin) [550-33-4] M 252.2, m 178-180°, 181-182°,  $[\alpha]_{\text{D}}^{25}$  -48.6° (c 1,  $\text{H}_2\text{O}$ ), -22° (c 0.8, 0.1N HCl) and -61° (c 0.8, 0.1N NaOH),  $\text{pK}^{25}$  2.05. Nebularin is recrystallised from butanone/Mebutanone/MeOH or EtOH and forms a MeOH photo-adduct. It is a strong inhibitor of adenosine

deaminase [EC 3.5.4.4]. [Nair & Weichert *Bioorg Chem* **9** 423 1980, Löfgren et al. *Acta Chem Scand* **7** 225 1953, UV: Brown & Weliky *J Biol Chem* **204** 1019 1953, *Beilstein* **26** III/IV 1740.]

**Puromycin dihydrochloride** (*O*-methyl-L-tyrosine[*N*<sup>6</sup>,*N*<sup>6</sup>-dimethylaminoadenosin-3'-yl-amide]) [58-58-2/ **M 616.5**, **m 174°**,  $[\alpha]_D^{25} -11^\circ$  (free base in EtOH), **pK<sub>1</sub> 6.8**, **pK<sub>2</sub> 7.2**. Puromycin dihydrochloride is purified by recrystallisation from H<sub>2</sub>O. The *free base*, [58-60-6] **M 294.3**, has **m 175.5-177°** (172-173°) (from H<sub>2</sub>O). The *sulfate* has **m 180-187°** dec (from H<sub>2</sub>O), and the *picrate monohydrate* has **m 146-149°** (from H<sub>2</sub>O). [Baker et al. *J Am Chem Soc* **77** 1 1955, Fryth et al. *J Am Chem Soc* **80** 3736 1958.] It is an inhibitor of aminopeptidase and terminates protein synthesis [Reboud et al. *Biochemistry* **20** 5281 1981]. [*Beilstein* **26** III/IV 3704.]

**Pyridoxal hydrochloride** [65-22-5] **M 203.6**, **m 176-180°(dec)**, **pK<sub>1</sub><sup>20</sup> 4.23** (3-OH), **pK<sub>2</sub><sup>20</sup> 8.7** (Pyridinium<sup>+</sup>), **pK<sub>3</sub><sup>20</sup> 13.04** (CH<sub>2</sub>OH?). Dissolve it in water and adjust the pH to 6 with NaOH. Set aside overnight to crystallise. The crystals are washed with cold water, dried in a vacuum desiccator over P<sub>2</sub>O<sub>5</sub>, and stored in a brown bottle at room temperature. The *free base* is then converted to the hydrochloride with one equivalent of HCl. [Fleck & Alberty *J Phys Chem* **66** 1678 1962, *Beilstein* **21/13** V 44.]

**Pyridoxal-5'-phosphate monohydrate** (PLP, codecarboxylase) [54-47-7] **M 265.2**, **pK<sub>1</sub><sup>25</sup> <2.5** (PO<sub>4</sub>), **pK<sub>2</sub><sup>25</sup> 4.14** (3-OH), **pK<sub>3</sub><sup>25</sup> 6.20** (PO<sub>4</sub>), **pK<sub>4</sub><sup>25</sup> 8.69** (pyridinium<sup>+</sup>). PLP has been purified by dissolving 2g in H<sub>2</sub>O (10-15ml, in a dialysis bag a third full) and dialysing with gentle stirring against 1L of H<sub>2</sub>O (+ two drops of toluene) for 15 hours in a cold room. The dialysate is evaporated to 80-100ml, then lyophilised. Lemon yellow microscopic needles of the monohydrate remain when all the ice crystals have been removed. The purity is checked by paper chromatography (in EtOH or *n*-PrOH/NH<sub>3</sub>) and the spot(s) visualised under UV light after reaction with a spray of *p*-phenylene diamine, NH<sub>3</sub> and molybdate. Solutions stored in a freezer are 2-3% hydrolysed in 3 weeks. At 25°, only 4-6% hydrolysis occurs even in N NaOH or HCl, and 2% is hydrolysed at 37° in 1 day—but is complete at 100° in 4 hours. It is best stored as a dry solid at -20°. In aqueous acid the solution is colourless but is yellow in alkaline solutions. It has UV with  $\lambda_{\max}$  at 305nm ( $\epsilon$  1100) and 380nm ( $\epsilon$  6550) in 0.1 N NaOH; 330nm ( $\epsilon$  2450) and 388nm ( $\epsilon$  4,900) in 0.05M phosphate buffer pH 7.0 and 295nm ( $\epsilon$  6700) in 0.1N HCl. [Peterson et al. *Biochemical Preparations* **3** 34, 119 1953.] The *oxime* decomposes at 229-230° and is practically insoluble in H<sub>2</sub>O, EtOH and Et<sub>2</sub>O. The *O-methylloxime* decomposes at 212-213°. [Heyl et al. *J Am Chem Soc* **73** 3430 1951.] It has also been purified by column chromatography through Amberlite IRC-50 (H<sup>+</sup>) [Peterson & Sober *J Am Chem Soc* **76** 169 1954]. [*Beilstein* **21/13** V 46.]

**Pyridoxamine hydrochloride** [5103-96-8, 524-36-7 (*free base*)] **M 241.2**, **m 226-227°(dec)**, **pK<sub>1</sub><sup>25</sup> 3.54** (3-OH), **pK<sub>2</sub><sup>25</sup> 8.21** (ring N<sup>+</sup>), **pK<sub>3</sub><sup>25</sup> 10.63** (NH<sub>2</sub>). The amine salt is recrystallised from hot MeOH. The *free base* crystallises from EtOH with **m 193-193.5°** [Harris et al. *J Biol Chem* **154** 315 1944, *J Am Chem Soc* **66** 2088 1944]. [*Beilstein* **22** IV 6064, **22/12** V 324.]

**Quizalofop ethyl** {[ethyl 2-[4-(6-chloro-2-quinoxalinyloxy)phenoxy]propionate} [(±) 76578-14-8; R- 100646-51-3, 100646-52-4, 100760-08-5, 100760-10-9] **M 372.8**, **m 92-93°**, **m 220°/0.2mm**. This (±)-herbicide forms white crystals from Me<sub>2</sub>CO/EtOH and sublimes *in vacuo*. Large quantities can be distilled at high vacuum. Its solubilities at 20° in g/10ml are 0.09 (EtOH), 1.1 (Me<sub>2</sub>CO), 1.2 (xylene), 2.9 (\*C<sub>6</sub>H<sub>6</sub>), and is nearly insoluble in H<sub>2</sub>O (0.3mg/l). The (±)-acid has [95977-28-9]. The *R-ester enantiomer* has **m 76-77°** (pale brown crystals from EtOH),  $[\alpha]_D^{20} +35.9^\circ$  (EtOH). It is the more active fatty acid synthase inhibitor (designated DPX-Y6202) used to control grassy weeds in broadleaf crops. The *R-acid* has [94051-08-8].

**Resorufin** (7-hydroxy-3H-phenoxazin-3-one Na salt) [34994-50-8] **M 252.2**, **decomposes on heating**, **pK<sup>25</sup> 5.8** (H<sub>2</sub>O), **6.10** (50% aqueous MeOH). The free acid is purified by dissolving it in conc H<sub>2</sub>SO<sub>4</sub> which on dilution precipitates resorufin and is filtered off, washed well with hot H<sub>2</sub>O and dried. [Eichler *J Prakt Chem* **139** 113 1934.] Detailed UV and IR studies were reported by Musso & Mattheis *Chem Ber* **90** 1814 1957]. [pKa: Musso & Rathjen *Chem Ber* **92** 751 1959, *Beilstein* **27** 1V 2263.]

The **monoacetate** [1152-14-3] **M 252.2**, **m 223°** is a fluorogenic substrate used for hydrolytic enzymes, and its fluorescence has  $E_{em}$  593nm ( $E_{ex}$  500nm, in 0.1M phosphate pH 8.0 with lipase) [Kitson & Kitson *Biochem J*

322 701 1997]. [*Beilstein* 27 IV 2263.]

The **O<sup>7</sup>-methylresorufin (7-methoxy-3*H*-phenoxazin-3-one)** [5735-89-3] **M 227.2, m >220°** has fluorescence at  $\lambda_{\text{em}}$  585nm ( $\lambda_{\text{ext}}$  571 nm in deacylase solution) and is used to differentiate isoenzymes of cytochrome P-450. It is insoluble in H<sub>2</sub>O and dilute alkali but is soluble in EtOH and CHCl<sub>3</sub> to give an orange yellow colour. [Kehrmann *Justus Liebigs Ann Chem* 372 352 1910, *Beilstein* 27 II 108.]

**Riboflavin.** See vitamin B<sub>2</sub> or lactoflavin below.

**Riboflavin-5'-phosphate (Na salt, 2H<sub>2</sub>O).** See flavin mononucleotide (FMN) above.

**Rifampicin (Rifampin)** [13292-46-1] **M 823.0, m 183-185°, pK<sub>1</sub> 1.7, pK<sub>2</sub> 7.9.** This macrolide antibiotic crystallises from Me<sub>2</sub>CO in red-orange plates. It has UV with  $\lambda_{\text{max}}$  at 237, 255, 334, and 475nm ( $\epsilon$  33,200, 32,100, 27,000 and 15,400) at pH 7.38. It is stable in Me<sub>2</sub>SO and H<sub>2</sub>O and is freely soluble in most organic solvents, but slightly soluble in H<sub>2</sub>O at pH <6. [Binda et al. *Arzneim.-Forsch* 21 1907 1971.] It inhibits cellular RNA synthesis without affecting DNA [Calvori et al. *Nature* 207 417 1965].

**Rifamycin B** [13929-35-6] **M 755.8, m 300° (darkening at 160-164°),  $[\alpha]_{\text{D}}^{20}$  -11° (MeOH), pK<sub>1</sub> 2.60, pK<sub>2</sub> 7.76.** Rifamycin B forms yellow needles from \*C<sub>6</sub>H<sub>6</sub>. Its solubilities are: H<sub>2</sub>O (0.027%), MeOH (2.62%) and EtOH (0.44%). It has UV with  $\lambda_{\text{max}}$  at 223, 304 and 245nm ( $A_{1\text{cm}}^{1\%}$  555, 275 and 220). [Oppolzer & Prelog *Helv Chim Acta* 56 2287 1973, Oppolzer et al. *Experientia* 20 336 1964, X-ray: Brufani et al. *Experientia* 20 339 1964.]

**Rifamycin SV** [6998-60-3] **M 697.8, m 300°(darkening >140°),  $[\alpha]_{\text{D}}^{20}$  -4° (MeOH), pK<sub>Est</sub> ~7.8.** Rifamycin SV gives yellow-orange crystals from Et<sub>2</sub>O/petroleum ether or aqueous EtOH, is very soluble in MeOH, EtOH, Me<sub>2</sub>CO and EtOAc, and is less soluble in Et<sub>2</sub>O and HCO<sub>3</sub><sup>-</sup>, but slightly soluble in H<sub>2</sub>O and petroleum ether. Its UV has  $\lambda_{\text{max}}$  at 223, 314 and 445nm ( $A_{1\text{cm}}^{1\%}$  586, 322 and 204) in phosphate buffer pH 7. [NMR: Bergamini & Fowst *Arzneim.-Forsch* 15 951 1965.]

**(-)-Scopolamine hydrobromide 3H<sub>2</sub>O (6 $\beta$ ,7 $\beta$ -epoxy-3 $\alpha$ -tropanyl *S*(-)-tropate HBr, hyoscine HBr)** [114-49-8] **M 438.3, m 193-194°, 195°, 195-199°,  $[\alpha]_{\text{D}}^{25}$  -25° (c 5, H<sub>2</sub>O), pK<sup>20</sup> 8.15.** The hydrobromide is recrystallised from Me<sub>2</sub>CO, H<sub>2</sub>O or EtOH/Et<sub>2</sub>O and dried. It is soluble in H<sub>2</sub>O (60%) and EtOH (5%) but insoluble in Et<sub>2</sub>O and slightly in CHCl<sub>3</sub>. The *hydrochloride* has **m 300°** (from Me<sub>2</sub>CO). The *free base* is a viscous liquid which forms a crystalline *hydrate* with **m 59°** and  $[\alpha]_{\text{D}}^{20}$  -28° (c 2.7, H<sub>2</sub>O). It hydrolyses in dilute acid or base. [Meinwald *J Chem Soc* 712 1953, Fodor *Tetrahedron* 1 86 1957, *Beilstein* 6 III 4185.]

**Serotonin hydrochloride (5-HT, 3-[2-aminoethyl]-5-hydroxyindole HCl)** [153-98-0] **M 212.7, m 167-168°, 178-180°, pK<sub>1</sub><sup>25</sup> 4.9, pK<sub>2</sub><sup>25</sup> 9.8 (10.0, NH<sub>2</sub>), pK<sub>3</sub><sup>25</sup> 11.1 (5-OH), pK<sub>4</sub><sup>25</sup> 18.25 (acidic indole NH).** 5-HT is purified by recrystallisation from EtOH/Et<sub>2</sub>O or Et<sub>2</sub>O to give the *hygroscopic* salt. Store it in the dark as it is light sensitive. The *free base* has **m 84-86°** (from Et<sub>2</sub>O). The *5-benzyloxy* derivative has **m 84-86°** (from Et<sub>2</sub>O). [Ek & Witkop *J Am Chem Soc* 76 5579 1954, Hamlin & Fischer *J Am Chem Soc* 73 5007 1951.] The *picrate* *1H<sub>2</sub>O* has **m 196-197.5°** (dec with sintering at 160-165°) after crystallisation from Et<sub>2</sub>O. Serotonin is a natural neurotransmitter [Chuang *Life Sci* 41 1051 1987]. [*Beilstein* 22/12 V 16.]

**Spectinomycin dihydrochloride pentahydrate (Actinospectacin)** [21736-83-4] **M 495.3, m 205-207°(dec),  $[\alpha]_{\text{D}}^{20}$  +14.8° (c 0.4, H<sub>2</sub>O), pK<sub>1</sub> 6.95, pK<sub>2</sub> 8.70.** The salt is purified by recrystallisation from aqueous Me<sub>2</sub>CO and is soluble in H<sub>2</sub>O, MeOH and dilute acid and base, but only slightly soluble in Me<sub>2</sub>CO, EtOH, CHCl<sub>3</sub> and \*C<sub>6</sub>H<sub>6</sub>. The *free base* is an amorphous solid, **m 184-194°** with  $[\alpha]_{\text{D}}^{20}$  -20° (H<sub>2</sub>O). [Wiley et al. *J Am Chem Soc* 93 2652 1963, X-ray: Cochran et al. *J Chem Soc Chem Commun* 494 1972.] It is an aminoglycoside antibiotic which interacts with 16S ribosomal RNA [Moazet & Noller *Nature* 327 389 1987] and is used for the treatment of gonorrhoea [Rinehart *J Infect Dis* 119 345 1969].

**D-Sphingosine (2*S*,3*S*-D-erythro-2-amino-octadec-4*t*-ene-1,3-diol from bovine brain)** [123-78-4] **M 299.5, m 79-82°, 82° 82.5° (softens at ~70°),  $[\alpha]_{\text{D}}^{22}$  -3.4° (c 2, CHCl<sub>3</sub>), pK<sub>Est</sub> ~8.8.** D-Sphingosine is purified by re-

crystallisation from EtOAc, Et<sub>2</sub>O or petroleum ether (60–80°). It is insoluble in H<sub>2</sub>O but is soluble in Me<sub>2</sub>CO, EtOH and MeOH. It has IR bands at 1590 and 875 cm<sup>-1</sup>, and is characterised as the *tribenzoate* **m** 122–123° (from 95% EtOH). [Tipton *Biochemical Preparations* **9** 127 1962.]

**Squalene** precursor of cholesterol. See “Carotenoids” in this chapter.

**Sterigmatocystin** (3a,12c-dihydro-8-hydroxy-6-methoxy-3*H*-furo[3',2':4,5]furo[2,3-*c*]xanthen-7-one) [10048-13-2] **M** 324.3, **m** 246°, 247–248°, [α]<sub>D</sub><sup>20</sup> -398° (c 0.1, CHCl<sub>3</sub>), pK<sub>Est</sub> ~ 8.0. It crystallises from amyl acetate, Me<sub>2</sub>CO or EtOH and sublimes *in vacuo*. It has UV with λ<sub>max</sub> at 208, 235, 249 and 329nm (log ε 4.28, 4.39, 4.44 and 4.12). [UV: Bullock et al. *J Chem Soc* 4179, 1962, UV, IR: Holker & Mulheim *J Chem Soc, Chem Commun* 1576, 1576 1968, Birkinshaw & Hammady *Biochem J* **65** 162 1957.] This mycotoxin induces bone marrow changes in mice [Curry et al. *Mutation Res* **137** 111 1984]. [Beilstein **19/10** V 575.]

**Stigmatellin A** (2-[4,6-dimethoxy-3,5,11-trimethyltridecatri-7*t*,9*t*,11*t*-enyl]-8-hydroxy-5,7-dimethoxy-3-methyl-4*H*-1-benzopyran-4-one) [91682-96-1] **M** 514.6, **m** 128–130°, [α]<sub>D</sub><sup>20</sup> +38.5° (c 2.3, MeOH), pK<sub>Est</sub> ~7 (phenolic OH). Stigmatellin A is stable in aqueous solution at neutral pH but decomposes at pH <5. It is purified by recrystallisation from toluene/hexane. It has UV with λ<sub>max</sub> nm (ε) at 248sh (4,100), 258 (59,500), 267 (65,500), 279 (1400) and 335 (5200) in MeOH; 249sh (45,600), 258 (60,000), 268 (72,700), 277 (54,100), 320 (2,500) and 370 (3000) in MeOH + 1 drop of N KOH; 243sh (29,300), 264 (63,200), 274 (64,100), 283sh (45,800), 329 (4800) and 420 (21,000) in MeOH + 6N HCl; and IR (CHCl<sub>3</sub>) with ν<sub>max</sub> at 3550m, 1645chs, 1635ss, 1620ss, 1590s, 1510m and 905m cm<sup>-1</sup>. It gives colour reactions at 110° with vanillin/H<sub>2</sub>SO<sub>4</sub> (grey), Ce(IV)/(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> (yellow) and phosphomolybdate (blue-grey). [Höfle et al. *Justus Liebigs Ann Chem* 1882 1984.] It inhibits electron transport [Jagow & Link *Methods Enzymol* **126** 253 1986, Robertson et al. *Biochemistry* **32** 1310 1933], and has antibiotic properties [Kunze et al. *J Antibiot* **37** 454 1984]. The 7*t*,9*t*,11*c*-isomer is *Stigmatellin B*.

**Streptomycin sulfate** [3810-74-0] **M** 1457.4, [α]<sub>D</sub><sup>20</sup> -84.3° (c 3, H<sub>2</sub>O), pK<sub>Est(1)</sub> ~ 9.5 (MeNH), pK<sub>Est(2,3)</sub> ~ 13.4 (guanidino). The sulfate is recrystallised from H<sub>2</sub>O/EtOH, washed with a little EtOH, Et<sub>2</sub>O and dried in a vacuum. [UV and IR: Grove & Randall *Antibiotics Monographs* **2** 163 1855, Heuser et al. *J Am Chem Soc* **75** 4013 1953, Kuehl et al. *J Am Chem Soc* **68** 1460 1946, Regna et al. *J Biol Chem* **165** 631 1946.] During protein synthesis it inhibits initiation and causes misreading of mRNA [Zierhut et al. *Eur J Biochem* **98** 577 1979, Chandra & Gray *Methods Enzymol* **184** 70 1990]. [Beilstein **18/11** V 82.]

**Streptonigrin (nigrin, 5-amino-6-[7-amino-5,8-dihydro-6-methoxy-5,8-dioxo-2-quinolinyl]-4-[2-hydroxy-3,4-dimethoxyphenyl]-3-methyl-2-pyridinecarboxylic acid)** [3930-19-6] **M** 506.5, **m** 262–263°, 275°(dec), pK<sub>25</sub> 6.3 (1:1 aqueous dioxane). Streptonigrin is purified by TLC on pH 7-buffered silica gel plates (made from a slurry of Silica Gel 60 and 400ml of 0.05M phosphate buffer pH 7.0) and eluted with 5% MeOH/CHCl<sub>3</sub>. Material from the extracted band recrystallises from Me<sub>2</sub>CO or dioxane as almost black plates or needles. It is soluble in pyridine, Me<sub>2</sub>NCHO, aqueous NaHCO<sub>3</sub> (some dec), and slightly soluble in MeOH, EtOH, EtOAc and H<sub>2</sub>O. It has UV with λ<sub>max</sub> at 248, 375–380nm (ε 38,400 and 17,400). [Weinreb et al. *J Am Chem Soc* **104** 536 1982, Rao et al. *J Am Chem Soc* **85** 2532 1963.] It is antineoplastic and causes severe bone marrow depression [Wilson et al. *Antibiot Chemother* **11** 147 1961].

**Succinyl coenzyme A trisodium salt** [108347-97-3] **M** 933.5. If it should be purified further, then it should be dissolved in H<sub>2</sub>O (0.05g/ml) adjusted to pH 1 with 2M H<sub>2</sub>SO<sub>4</sub> and extracted several times with Et<sub>2</sub>O. Excess Et<sub>2</sub>O is removed from the aqueous layer by bubbling N<sub>2</sub> through it and is stored frozen at pH 1. When required, the pH should be adjusted to 7 with dilute NaOH and used within 2 weeks (samples should be frozen). Succinyl coenzyme A is estimated by the hydroxamic acid method [Hersch & Jencks *J Biol Chem* **242** 3468 1967]. It is more stable in acidic than in neutral aqueous solutions, but neutral solutions can be stored at -15° with negligible decomposition. [Jordan & Laghai-Newton *Methods Enzymol* **123** 435 1986, Beilstein **26** III/IV 3666.]

**Terramycin (oxytetracycline)** [79-57-2; 6153-64-6 (2H<sub>2</sub>O)] **M** 460.4 (anhydrous), 496.5 (2H<sub>2</sub>O), sinters at 182°, melts at 184–185°(dec), [α]<sub>D</sub><sup>20</sup> -196.6° (equilibrium in 0.1M HCl), -2.1°(equilibrium in 0.1M NaOH).

Terramycin crystallises (as dihydrate) from water or aqueous EtOH and is soluble in MeOH, EtOH, Me<sub>2</sub>CO and H<sub>2</sub>O (0.25mg/ml at 25°) but insoluble in Et<sub>2</sub>O and petroleum ether. It is amphoteric, and an aqueous solution has pH 2.0-5.0. It has UV with  $\lambda_{\max}$  at 247, 275 and 353nm in 0.1 M phosphate (pH 4.5). [Finlay et al. *Science* **111** 85 1951.] The *hydrochloride*, [2058-46-0] M 496.9 [Beilstein **14** IV 2630], crystallises from MeOH in needles and from H<sub>2</sub>O at 50° it forms plates. Terramycin has also been purified *via* the *hydrochloride* by dissolving it in H<sub>2</sub>O, adjusting to pH 6, and the solid is filtered off after 1 hour. The crystals of the *dihydrate* are dried to constant weight in vacuum/CaCl<sub>2</sub>/25°. Drying at 60° *in vacuo* gives the *anhydrous base* m 184.5-185.5° (sintering at 180°). The *dihydrate* has m 181-182°. Its optical rotation in MeOH decreases from  $[\alpha]_{\text{D}}^{25} +2.6^{\circ}$  (c 0.5%) to  $[\alpha]_{\text{D}}^{25} +11.3^{\circ}$  after standing for 16 hours. It forms a *sodium salt* and a *CaCl<sub>2</sub> complex*. [Regna et al. *J Am Chem Soc* **73** 4211 1951, Beilstein **14** IV 2633.]

**Tetracycline** [60-54-8] M 444.4, m 172-174°(dec),  $[\alpha]_{\text{D}}^{20} -291^{\circ}$  (c 1, MeOH), pK<sub>1</sub><sup>25</sup> 3.30, pK<sub>2</sub><sup>25</sup> 7.68, pK<sub>3</sub><sup>25</sup> 9.69. Tetracycline crystallises from toluene or aqueous MeOH as the *trihydrate*. [Stephen et al. *J Am Chem Soc* **76** 3568 1954, Beilstein **14** IV 2625.]

**Tetracycline hydrochloride** [64-75-5] M 480.9, m 214°(dec), 215-220°,  $[\alpha]_{\text{D}}^{25} -258^{\circ}$  (c 0.5, 0.1N HCl),  $[\alpha]_{\text{D}}^{20} -245^{\circ}$  (c 1, MeOH),  $[\alpha]_{\text{D}}^{25} -257.9^{\circ}$  (c 0.5, aqueous HCl), pK<sub>1</sub> 1.4 (enolic OH), pK<sub>2</sub> 3.30, pK<sub>3</sub> 7.68 (phenolic OH), pK<sub>4</sub> 9.27 (Me<sub>2</sub>N). The hydrochloride is recrystallised from MeOH/*n*-BuOH or *n*-BuOH/HCl. It is insoluble in Et<sub>2</sub>O and petroleum ether. It has UV with  $\lambda_{\max}$  at 270 and 366nm in MeOH. [Gottstein et al. *J Am Chem Soc* **81** 1198 1959, Conover et al. *J Am Chem Soc* **84** 3222 1962, Stephen et al. *J Am Chem Soc* **78** 4155 1956, Beilstein **14** IV 2627.]

**6R-Tetrahydro-erythro-biopterin dihydrochloride** (BH<sub>4</sub>.2HCl, 6R-2-amino-4-hydroxy-6-{{1R,2S}-1,2-dihydroxypropyl}-5,6,7,8-tetrahydropteridine 2HCl) [69056-38-8] M 316.2, m 245-246°(dec),  $[\alpha]_{\text{D}}^{25} -6.8^{\circ}$  (c 0.67, 0.1N HCl), pK<sub>1</sub> 1.37 (pyrimidine<sup>+</sup>), pK<sub>2</sub> 5.6 (5-NH<sup>+</sup>), pK<sub>3</sub> 10.6 (acidic, 3NH). Recrystallisation of BH<sub>4</sub>.2HCl from HCl enriches BH<sub>4</sub> in the natural 6R isomer. Dissolve the salt (~6g) in conc HCl (15ml) under gentle warming, then add EtOH (30ml) dropwise, chill and collect the colourless needles (67%, up to 99% if the mother liquors are concentrated), and dry it *in vacuo* immediately over P<sub>2</sub>O<sub>5</sub> and KOH. It is stable indefinitely at -20° in a dry atmosphere. Better store it in sealed ampoules under dry N<sub>2</sub>. It can be recrystallised from 6N aqueous HCl. It has UV with  $\lambda_{\max}$  (in 2N HCl) at 264nm ( $\epsilon$  16,770; pH 3.5 phosphate buffer) 265nm ( $\epsilon$  13,900); (in pH 7.6) at 297nm ( $\epsilon$  9500) and 260nm sh ( $\epsilon$  4690). It has been separated from the 6S-isomer by HPLC on a Partisil-10SCX column using 30mM ammonium phosphate buffer (pH 3.0) containing 3mM NaHSO<sub>3</sub> (2ml/minute flow rate; 275nm detector) with retention times of 5.87 minutes (6R) and 8.45 minutes (6S). It is stable in acidic solutions and can be stored for extended periods at -20° in 0.04M HCl. Above pH 7 the neutral species are obtained, and these are readily oxidised by the oxygen in the solvent to the *quinonoid species*, and then further oxidation and degradation occurs at room temperature. These changes are slower at 0°. The *sulfate salt* can be obtained by recrystallisation from 2M H<sub>2</sub>SO<sub>4</sub> and is less soluble in water than the hydrochloride salt. The 6R-2,5,1',2'-tetraacetylbiopterin derivative has m 292°(dec) after recrystallisation from MeOH (100 parts) and  $[\alpha]_{\text{D}}^{20} -144^{\circ}$  (c 0.5, CHCl<sub>3</sub>),  $[\alpha]_{\text{D}}^{20} +12.8^{\circ}$  (c 0.39, Me<sub>2</sub>SO). [NMR, UV: Matsuura et al. *Heterocycles* **23** 3115 1985, Viscontini et al. *Helv Chim Acta* **62** 2577 1979, Armarego et al. *Aust J Chem* **37** 355 1984, Beilstein **26** III/IV 4032.]

**Tetrahydrofolic acid dihydrochloride 2H<sub>2</sub>O** (THFA, 6S- or 6RS- 5,6,7,8-tetrahydrofolic acid 2HCl 2H<sub>2</sub>O, 5,6,7,8-tetrahydropteroyl-L-glutamic acid 2HCl 2H<sub>2</sub>O) [135-16-0] M 544.4, m >200°(dec),  $[\alpha]_{\text{D}}^{27} +16.9^{\circ}$  (H<sub>2</sub>O pH 7.0 + 2-mercaptoethanol), pK<sub>1</sub> 1.7 (pyrimidine N<sup>+</sup>), pK<sub>2</sub> 2.4 (10N<sup>+</sup>), pK<sub>3</sub> 3.5 ( $\alpha$ -CO<sub>2</sub>H), pK<sub>4</sub> 4.9 ( $\gamma$ -CO<sub>2</sub>H), pK<sub>5</sub> 5.6 (5-NH<sup>+</sup>), pK<sub>6</sub> 10.4 (acidic, 3NH). Very high quality material is now available commercially, and it should be a white powder. It can be dried over P<sub>2</sub>O<sub>5</sub> in a vacuum desiccator and stored in weighed aliquots in sealed ampoules. It is stable at room temperature in sealed ampoules for many months and for much more extended periods at -10°. When moist, it is extremely sensitive to air whereby it oxidises to the yellow 7,8-dihydro derivative. In solution it turns yellow in colour as it oxidises, and then particularly in the presence of acids it turns dark reddish brown in colour. Hence aqueous solutions should be frozen immediately when not in use. It is always advisable to add 2-mercaptoethanol (if it does not interfere with the procedure for which it is used) which stabilises it by depleting the solution of O<sub>2</sub>. The *sulfate salt* is more stable but is much less soluble. The best way to prepare standard solutions of this acid is to dissolve it in the desired buffer and

estimate the concentration by UV absorption in pH 7 buffer at 297nm ( $\epsilon$  22,000 M<sup>-1</sup>cm<sup>-1</sup>). If a sample is suspect, it is not advisable to purify it because it is likely to deteriorate further as “dry box” conditions are necessary. Either a new sample is purchased or one is freshly prepared from folic acid. It has the above pKa values. [Hafeti et al. *Biochemical Preparations* 7 89 1960, UV: Mathews & Huennekens *J Biol Chem* 235 3304 1960, Osborn & Huennekens *J Biol Chem* 233 969 1958, O’Dell et al. *J Am Chem Soc* 69 250 1947, Blakley *Biochem J* 65 331 1957, Asahi *Yakugaku Zasshi (J Pharm Soc Jpn)* 79 1548 1959, Beilstein 26 III/IV 3879.]

**5,6,7,8-Tetrahydropterin sulfate (2-amino-5,6,7,8-tetrahydropteridin-4-one H<sub>2</sub>SO<sub>4</sub>)** [20350-44-1] **M 265, m >200°(dec), pK<sub>1</sub><sup>25</sup> 1.3 (pyrimidine<sup>+</sup>), pK<sub>2</sub><sup>25</sup> 5.6 (5-NH<sup>+</sup>), pK<sub>3</sub><sup>25</sup> 10.6 (acidic, 3NH).** If its colour has become strongly violet, then it will need to be reduced again. It is best to check the UV absorption in N HCl where it has a peak at ~265nm which drops sharply to zero having no absorption at ~340nm. The presence of absorption at 340nm indicates oxidation to quinonoid or 7,8-dihydropterin. If the absorption is weak, then dissolve it in the minimum volume of anhydrous trifluoroacetic acid (fume hood), add charcoal, filter, then add two drops of N H<sub>2</sub>SO<sub>4</sub> followed by dry Et<sub>2</sub>O at 0°, allow the white tetrahydro salt to settle, collect, and wash it with dry Et<sub>2</sub>O, by centrifugation. Dry the residue *in vacuo* over P<sub>2</sub>O<sub>5</sub> and KOH. Store it in aliquots in the dark at <0°. It has UV  $\lambda_{\max}$  at 265nm ( $\epsilon$  16,980) at pH -1.0 (dication); 219nm ( $\epsilon$  23,440) and 266nm ( $\epsilon$  12,880) at pH 3.5 (monocation); 220nm ( $\epsilon$  18,620), [260nm ( $\epsilon$  4270)sh] and 299nm ( $\epsilon$  9330) at pH 8.0 (neutral species); and 218nm ( $\epsilon$  10,000), [240nm ( $\epsilon$  5500)sh] and 287nm ( $\epsilon$  5500) at pH 13 (anion). [Blakley *Biochem J* 72 707 1959, Asahi *Yakugaku Zasshi (J Pharm Soc Jpn)* 79 1557 1959, Pfeleiderer in *Pterins and Folate* (Benkovic and Blakley Eds) J Wiley Vol 2 p 97 1985.]

**Thiamine monophosphate chloride 2H<sub>2</sub>O (Aneurine monophosphate chloride)** [532-40-1] **M 416.8, m 193°(dec), 200°(dec), 200-203°(dec), pK<sub>1</sub> 2.40, pK<sub>2</sub> 4.80, pK<sub>3</sub> 6.27, pK<sub>4</sub> 9.65, pK<sub>5</sub> 10.20.** Purify it by recrystallisation from aqueous HCl, EtOH slightly acidified with HCl, EtOH/Me<sub>2</sub>CO, H<sub>2</sub>O, or H<sub>2</sub>O/EtOH/Et<sub>2</sub>O. Dissolve it in a small volume of H<sub>2</sub>O and mix it with EtOH/Me<sub>2</sub>CO (1:1) to give the HCl.H<sub>2</sub>O as crystals. Filter it off, wash it with Et<sub>2</sub>O and dry it in a vacuum. The *chloride hydrochloride*, **m 215-217°(dec)** is obtained when it is crystallised from aqueous HCl. [Wenz et al. *Justus Liebigs Ann Chem* 618 2280 1958, Viscontini et al. *Helv Chim Acta* 34 1388 1951, Leichssenring & Schmidt *Chem Ber* 95 767 1962, McCormick & Wright *Methods Enzymol* 18A 141, 147 1970, Beilstein 27 III/IV 1766.]

**Thiamphenicol (Thycymetin, 1R,2R-2-[2,2-dichloroacetyl-amino]-1-[4-methanesulfonyl-phenyl]-propan-1,3-diol)** [15318-45-3 (*D-threo*), 90-91-5] **M 356.2, m 163-166°, 165.2-165.6°, 165-166°,  $[\alpha]_{\text{D}}^{25}$  +15.6° (c 2, EtOH), pK<sup>25</sup> 7.2.** Recrystallise thiamphenicol from H<sub>2</sub>O or CHCl<sub>3</sub>. The UV has  $\lambda_{\max}$  at 224, 266 and 274nm ( $\epsilon$  13,700, 800 and 700) in 95% EtOH. The *1S,2S-isomer* [14786-51-7] has **m 164.3-166.3°** (from H<sub>2</sub>O/EtOAc/petroleum ether) and  $[\alpha]_{\text{D}}^{25}$  -12.6° (c 1, EtOH); and the *racemate 1RS,2RS-Racefenical* [847-25-6] has **m 181-183° (dec)** from CHCl<sub>3</sub>/EtOAc/petroleum ether. [Cutler et al. *J Am Chem Soc* 74 5475, 5482 1952, UV: Nachod & Cutler *J Am Chem Soc* 74 1291 1952, Suter et al. *J Am Chem Soc* 75 4330 1953, Cutler et al. *J Am Pharm Assoc* 43 687 1954, Beilstein 13 IV 2957.]

**$\epsilon$ -[2-(4-Thiazolidinone)]hexanoic acid (Mycobacidin, Acidomycin, 6[4-oxothiazolidin-2-yl]hexanoic acid)** [539-35-5] **M 215.3, m 140°, pK<sup>25</sup> 5.1.** The *dl-form* is *dimorphic*; it crystallises from CHCl<sub>3</sub> with **m 116-117°**, and from H<sub>2</sub>O with **m 123°**. The *l(-)-enantiomer* (from Actinomyces) crystallises from H<sub>2</sub>O, MeOH (**m 139-140°**), aqueous EtOH (**m 140-141°**) or EtOAc, and has  $[\alpha]_{\text{D}}^{20}$  -54° (c 1, MeOH). The *d(+)-enantiomer* (from optical resolution of the brucine salt) has **m 138-139°** (from H<sub>2</sub>O) and  $[\alpha]_{\text{D}}^{25}$  +57° (c 1, MeOH). The optically active acids racemise in hot alkali. [McLamore et al. *J Am Chem Soc* 75 105 1953, Beilstein 27 III/IV 4281.]

**6-Thioguanosine (2-amino-6-mercapto-9- $\beta$ -D-ribofuranosylpurine)** [85-31-4] **M 299.3, m 224-227°(dec), 230-231°(dec),  $[\alpha]_{\text{D}}^{20}$  -64° (c 1.3, 0.1N NaOH), pK<sup>25</sup> 8.33.** Thioguanosine is crystallised (as *hemihydrate*) from hot H<sub>2</sub>O (charcoal) and cooled slowly to give tapered prisms. It also crystallises by dissolving in dilute NH<sub>3</sub> and acidifying with acetic acid, and then recrystallising from H<sub>2</sub>O. Its UV (pH 4-6) has  $\lambda_{\max}$  at 257nm ( $\epsilon$  8,820) and 342nm ( $\epsilon$  24,800), and at pH 10.4-12.0 it has  $\lambda_{\max}$  at 252nm ( $\epsilon$  14,700) and 319.5nm ( $\epsilon$  21,000). [Fox et al. *J Am Chem Soc* 80 1667 1958, Beilstein 26 III/IV 3927.]

***dl*- $\alpha$ -Tocopherol (see vitamin E)** [10191-41-0] **M 430.7,  $A_{1\text{cm}}^{1\%}$  74.2 at 292 nm in MeOH.** Dissolve *dl*- $\alpha$ -

tocopherol in anhydrous MeOH (15ml/g) cool to  $-6^{\circ}$  for 1 hour, then chill in a Dry-ice/acetone bath; crystallisation is induced by scratching with a glass rod. The *dl*- $\alpha$ -acetate [52225-20-4] (see *DL-vitamin E acetate* below) is a viscous yellow liquid with **m**  $-7^{\circ}$ , **b**  $184^{\circ}/0.01\text{mm}$ ,  $224^{\circ}/0.3\text{mm}$ ,  $d_4^{20}$  0.953,  $n_D^{20}$  1.496. It is used as a standard for Vitamin E activity where the unit of activity is attained with 1mg of pure *dl*- $\alpha$ -acetate. [Friedrich "Vitamins" Water de Guyter Publ, Berlin 1988, *Beilstein* 17/4 V 168.]

**$\gamma$ -Tocopherol (3,4-dihydro-2,7,8-trimethyl-2-(4,8,12-trimethyltridecyl)-2H-benzopyran-6-ol)** [54-28-4] **M 416.7**, **m**  $-30^{\circ}$ , **b**  $200-210^{\circ}/0.1\text{mm}$ ,  $d_4^{20}$  0.951,  $n_D^{20}$  1.505,  $[\alpha]_D^{20}$   $-2.4^{\circ}$  (EtOH).  $\gamma$ -Tocopherol is purified by distillation at high vacuum and stored in dark ampoules under  $N_2$ . Its UV has  $\lambda_{\text{max}}$  at 298nm ( $A_{1\text{cm}}^{1\%}$  92.8). It is insoluble in  $H_2O$  but soluble in organic solvents. The *allophanate* (used for separating it from its isomers) has **m**  $136-138^{\circ}$ ,  $[\alpha]_D^{18}$   $+3.4^{\circ}$  ( $CHCl_3$ ). [Baxter et al. *J Am Chem Soc* 65 918 1943, Emerson et al. *Science* 83 421 1936, *J Biol Chem* 113 319 1936, *Beilstein* 17/4 V 158.]

**Tomatidine (5 $\alpha$ ,20 $\beta$ ,22 $\alpha$ ,25 $\beta$ ,27-azaspirostan-3 $\beta$ -ol)** [77-59-8] **M 415.7**, **m**  $202-206^{\circ}$ ,  $[\alpha]_D^{20}$   $+5.9^{\circ}$  (c 1, MeOH),  $[\alpha]_D^{20}$   $+8^{\circ}$  ( $CHCl_3$ ). Tomatidine forms plates from EtOAc. It is also purified by dissolving 80mg in  $*C_6H_6$  and applying to an  $Al_2O_3$  column (3.0g) and eluting with  $*C_6H_6$ , evaporating and recrystallising the residue three times from EtOAc. The *hydrochloride* has **m**  $265-270^{\circ}$  from EtOH and  $[\alpha]_D^{25}$   $-5^{\circ}$  (MeOH). [IR: Uhle *J Am Chem Soc* 83 1460 1961, Kessar et al. *Tetrahedron* 27 2869 1971, Schreiber & Adams *Experientia* 17 13 1961, *Beilstein* 27 III/IV 1950.]

**Tomatine (22S,25S-3 $\beta$ , $\beta$ -lycotetraosyloxy-5 $\alpha$ -spirosolan)** [17406-45-0] **M 1034.2**, **m**  $263-268^{\circ}$ (dec),  $290-291^{\circ}$ (evacuated capillary),  $283.5-287^{\circ}$ (dec),  $272-277^{\circ}$ (dec),  $300-305^{\circ}$ (dec),  $[\alpha]_D^{20}$   $-18^{\circ}$  to  $-34^{\circ}$  (c 0.55, pyridine). Tomatine is recrystallised from MeOH, EtOH, aqueous EtOH or dioxane/ $NH_3$ . It is almost insoluble in petroleum ether,  $Et_2O$  or  $H_2O$ . [Reichstein *Angew Chem* 74 887 1962, *Beilstein* 27 III/IV 1954.]

**Tubercidin (7-deazaadenosine)** [69-33-0] **M 266.3**, **m**  $247-248^{\circ}$ ,  $[\alpha]_D^{17}$   $-67^{\circ}$  (50% aqueous AcOH), **pK<sup>10</sup> 5.2-5.3**. 7-Deazaadenosine forms needles from hot  $H_2O$ . It is soluble in  $H_2O$  (0.33%), MeOH (0.5%) and EtOH (0.05%). It has UV with  $\lambda_{\text{max}}$  at 270nm ( $\epsilon$  12,100) in 0.001N NaOH. The *picrate* has **m**  $229-231^{\circ}$ (dec). [Tolman et al. *J Am Chem Soc* 91 2102 1969, Mizuno et al. *J Org Chem* 28 3329 1963, IR: Anzai et al. *J Antibiot (Japan)* [9] 10 201 1957, *Beilstein* 26 IV 1117.]

**Tunicamycin** [11089-65-9] **M ~780**, **m**  $234-235^{\circ}$ (dec),  $[\alpha]_D^{20}$   $+52^{\circ}$  (c 0.5, pyridine), **pK<sub>Est</sub> ~ 9.4**. The components of this nucleotide antibiotic from *Streptomyces* sp. are purified by recrystallising 3 times from hot glass-distilled MeOH, and the white crystals are dissolved in 25% aqueous MeOH and separated on a Partisil ODS-10 $\mu$  column (9.4 x 25 cm) [Magnum-9 Whatman] using a 260nm detector. The column is eluted with MeOH/ $H_2O$  mixture adjusted to 1:4 (v/v) then to 2:4 (v/v). The individual components are recovered and lyophilised. Ten components have been isolated, and all were active (to varying extents) depending on the lengths of the aliphatic side-chains. The mixture has UV with  $\lambda_{\text{max}}$  at 205 and 260nm ( $A_{1\text{cm}}^{1\%}$  230 and 110). It is stable in  $H_2O$  at neutral pH but unstable in acidic solution. It inhibits protein glycosylation. [Mahoney & Duskin *J Biol Chem* 254 6572 1979, Elnein *Trends Biochem Sci* 6 219 1981, Takatsuki *J Antibiot* 24 215 1971.]

**Uracil, uridine and uridine nucleotides.** These are resolved by ion-exchange chromatography with AG1 (Cl form). [Lindsay et al. *Anal Biochem* 24 506 1968.]

**Uridine 5'-(1-thio) monophosphate** [15548-52-4, 18875-72-4 (*Absolute Stereochemistry specified*)] and **Uridine 5'-( $\alpha$ -thio) diphosphate** [*RS*( $\alpha$ -P) 27988-67-6; *R*( $\alpha$ -P) 72120-52-6], **pK<sub>Est(1)</sub> ~ 6.4**, **pK<sub>Est(2)</sub> ~ 9.5**. The  $Et_3N$  salts are purified by dissolving ~4g in 500ml of  $H_2O$  (adding a drop or two of  $Et_3N$  if they do not dissolve) and chromatograph by applying to a column (3 x 30cm) of DEAE-Sephadex A-25 and eluting with 1.4L of a linear gradient of  $Et_3NH.HCO_3$  from 0.05 to 0.55M, pH 7.8 and  $4^{\circ}$ . The product elutes between 0.2-0.3M  $Et_3NH.HCO_3$ . The pooled fractions are evaporated, and the residue is twice taken up in EtOH and evaporated to dryness to remove the last traces of  $Et_3NH.HCO_3$ .  $^{31}P$  NMR:  $P_{\alpha}$  is a doublet at  $-40.81$  and  $-40.33$ , and  $P_{\beta}$  at  $7.02\text{ppm}$ ,  $J_{\alpha,\beta}$  32.96Hz. [Sheu et al. *Biochemistry* 18 5548 1979.]

**Uridylic acid (di-Na salt)** [27821-45-0] **M 368.2, m 198.5°, pK<sub>3</sub><sup>25</sup> 6.63, pK<sub>4</sub><sup>20</sup> 9.71.** Crystallise it from MeOH. It may contain some Ba salt(s); hence stir it with Amberlite IR-120 cation exchanger (25ml, wet resin, 15-50 mesh in H<sup>+</sup> form) in H<sub>2</sub>O (50ml) until the nucleotide dissolves. Filter, wash resin with H<sub>2</sub>O until the eluate is neutral. Combine the filtrate and washings, and adjust the pH to 8.0 with 2.0 M aqueous NaOH. Concentrate it *in vacuo* to a small volume (~20ml), and add Me<sub>2</sub>CO dropwise until crystallisation begins. Cool to 0°, and the shiny plates of di Na uridine-5'-phosphate dihydrate are filtered off and dried over P<sub>2</sub>O<sub>5</sub> at 25°/0.1mm for 24 hours (>76% recovery). Its UV has λ<sub>max</sub> at 262nm (ε 10,000 M<sup>-1</sup>cm<sup>-1</sup>) in 0.1 M HCl. [Boon et al. *J Chem Soc* 408 1950, Smith *Biochemical Preparations* 8 130 1960.] [*Beilstein* 24 IV 1214.]

**(+)-Usnic acid (2,6-diacetyl-7,9-dihydroxy-8,9b-dimethyldibenzofuran-1,3(2H,9bH)-dione)** [7562-61-0, 125-46-2] **M 344.3, m 201-204°, 203-206°, [α]<sub>D</sub><sup>20</sup> +630° (c 0.7, CHCl<sub>3</sub>), pK<sub>1</sub> 4.4, pK<sub>2</sub> 8.8, pK<sub>3</sub> 10.7.** This very weak acid is the natural form which is recrystallised from Me<sub>2</sub>CO, MeOH or \*C<sub>6</sub>H<sub>6</sub>. At 25° it is soluble in H<sub>2</sub>O (<0.01%), Me<sub>2</sub>CO (0.77%), EtOAc (0.88%), MeOCH<sub>2</sub>CH<sub>2</sub>OH (0.22%), and furfural (7.32%). [Curd & Robertson *J Chem Soc* 894 1937, Barton & Brunn *J Chem Soc* 603 1953, resolution: Dean et al. *J Chem Soc* 1250 1953, synthesis: Barton et al. *J Chem Soc* 538 1956, *Beilstein* 18/5 V 586.]

**(-)-Usnic acid (2,6-diacetyl-7,9-dihydroxy-8,9b-dimethyldibenzofuran-1,3(2H,9bH)-dione)** [6159-66-6, 7562-61-0] **M 344.3, m 201-204°, 204°, [α]<sub>D</sub><sup>20</sup> -495° (c 0.9, CHCl<sub>3</sub>).** Its properties are similar to those of the acid in the preceding entry. [*Beilstein* 18 II 241, 18 III/IV 3522.]

**Valinomycin (Potassium ionophore I)** [2001-95-8] **M 111.3, m 186-187°, 190°, [α]<sub>D</sub><sup>20</sup> +31.0° (c 1.6, \*C<sub>6</sub>H<sub>6</sub>).** Recrystallise valinomycin from dibutyl ether or Et<sub>2</sub>O. It is dimorphic: modification A crystallises from *n*-octane, and modification B crystallises from EtOH/H<sub>2</sub>O. It is soluble in petroleum ether, CHCl<sub>3</sub>, AcOH, BuOAc and Me<sub>2</sub>CO. [Smith et al. *J Am Chem Soc* 97 7242 1975, UV, IR and NMR see Brockmann & Schmidt-Kastner *Chem Ber* 88 57 1955, *Beilstein* 27 I 9728, 17 IV 9728.]

**(±)-Verapamil hydrochloride (5-[N-{3,4-dimethoxyphenylethyl}methylamino]-2-[3,4-dimethoxyphenyl]-2-isopropylvaleronitrile HCl)** [23313-68-0] **M 491.1, m 138.5-140.5°, 142°(dec), pK<sub>Est</sub> ~10.6.** The salt is purified by dissolving it in EtOH, filtering (if insoluble particles are present) and adding Et<sub>2</sub>O, filtering the salt, washing it with Et<sub>2</sub>O and drying it *in vacuo*. It has the following solubilities: hexane (0.001%), CH<sub>2</sub>Cl<sub>2</sub> (~10%), MeOH (~10%), EtOH (20%) and H<sub>2</sub>O (8.3%). It has UV with λ<sub>max</sub> at 232 and 278nm. The *free base* is a viscous yellow oil **b** 243-246°/0.01mm (n<sub>D</sub><sup>25</sup> 1.5448) and is almost insoluble in H<sub>2</sub>O but soluble in organic solvents. It is a Ca channel antagonist and is a coronary vasodilator. [Ramuz *Helv Chim Acta* 58 2050 1975, Harvey et al. *Biochem J* 257 95 1989.]

**Veratridine (3-veratroylveracevine)** [71-62-5] **M 673.8, m ~180° (after drying at 130°, pK 9.54 (quinolizidine N), [α]<sub>D</sub><sup>20</sup> +8.0° (c ~5, EtOH).** It is an alkaloid neurotoxin which prevents inactivation of Na<sup>+</sup> channels. Its solubility in EtOH is ~5%; and it separates as a pale yellow powder from an ethanolic solution on addition of Et<sub>2</sub>O. It forms nitrate, sulfate and perchlorate salts. [McKinney et al. *Anal Biochem* 153 33 1986, *Beilstein* 21 V/13 709.]

**Vinblastine sulfate (VLB, vincalucoblastine sulfate)** [143-67-9] **M 909.5, m 284-285°(dec), 267°(dec), [α]<sub>D</sub><sup>20</sup> -28° (MeOH), pK<sub>1</sub> 5.5, pK<sub>2</sub> 7.4.** Crystallise the sulfate from MeOH or EtOH and dry it *in vacuo* over conc H<sub>2</sub>SO<sub>4</sub>. The *free base* crystallises from EtOH or MeOH **m** 211-216° (+ 2MeOH.1 H<sub>2</sub>O) and forms a stable etherate from Et<sub>2</sub>O with **m** 201-211°, and [α]<sub>D</sub><sup>25</sup> +42° (CHCl<sub>3</sub>), and its UV has λ<sub>max</sub> at 214 and 259nm (log ε 4.73 and 4.21). The *dihydrochloride* has **m** 244-246°(dec)(MeOH). It is a monoamine oxidase B inhibitor and induces microtubule aggregation. It is an antineoplastic drug for Hodgkin's lymphoma. [Neuss et al. *J Am Chem Soc* 81 4754 1959, Jong-KeunSon et al. *J Med Chem* 33 1845 1990, Warfield & Bouck *Science* 186 1219 1974, *Beilstein* 26 III/IV 3167.]

**Vincristine sulfate (22-oxovincalucoblastine sulfate)** [2068-78-2] **M 925.1, m 218-220°, [α]<sub>D</sub><sup>25</sup> +26.2° (CH<sub>2</sub>Cl<sub>2</sub>), pK<sub>1</sub> 5.0, pK<sub>2</sub> 7.4 (in 33% Me<sub>2</sub>NCHO/H<sub>2</sub>O).** The salt is recrystallised from MeOH. It has UV with λ<sub>max</sub> at 220, 255 and 296nm (log ε 4.65, 4.21 and 4.18). It is a monoamine oxidase inhibitor and is used in

cancer research [Son et al. *J Med Chem* **33** 1845 1990, Horio et al. *Proc Natl Acad Sci USA* **85** 3580 1988].

**Viomycin sulfate (Viocin, Tuberactinomycin B)** [37883-00-4] **M 685.7, m 266°(dec)**,  $[\alpha]_D^{17}$  **-29.5° (c 1, H<sub>2</sub>O)**, **pK<sub>1</sub> 7.2 (8.2), pK<sub>2</sub> 10.3**. Viocin crystallises from H<sub>2</sub>O/EtOH and is dried in a vacuum. The dry material is *hygroscopic* and should be stored dry. The UV has  $\lambda_{\max}$  at 268 and 285nm (log  $\epsilon$  4.4 and 4.2) in H<sub>2</sub>O. [Kitigawa et al. *Chem Pharm Bull Jpn* **20** 2176 1972.] The *hydrochloride* forms *hygroscopic* plates with **m 270°(dec)**,  $[\alpha]_D^{18}$  **-16.6° (c 1, H<sub>2</sub>O)**, with  $\lambda_{\max}$  at 268nm (log  $\epsilon$  4.5) in H<sub>2</sub>O; 268nm (log  $\epsilon$  4.4) in 0.1N HCl and at 285nm (log  $\epsilon$  4.3) in 0.1N NaOH. [*Beilstein* **26** III/IV 4245.]

**Vitamin A acetate (retinyl acetate)** [127-47-9] **M 328.5, m 57°**. The acetate is separated from retinol by column chromatography, then crystallised from MeOH. [Kofler and Rubin *Vitamins and Hormones (NY)* **18** 315 1960 for purification methods]. Store it in the dark, under N<sub>2</sub> or Ar, at 0°. [*Beilstein* **6** IV 4135.]

**Vitamin A acid [Retinoic acid, 3,7-dimethyl-9-(2,6,6-trimethyl-1-cyclohexenyl)-2,4,6,8-nonatetraen-1-oic acid]** [302-79-4] **M 300.4, m 180-181°, 180-182°, pK<sub>Est</sub> ~4.2**. Purify the acid by chromatography on silicic acid columns, and eluting it with a small amount of EtOH in hexane. Also dissolve it in Et<sub>2</sub>O, wash it with H<sub>2</sub>O, dry (Na<sub>2</sub>SO<sub>4</sub>), evaporate and the solid residue is recrystallised from MeOH (0.53g /3.5ml MeOH to give 0.14g) or EtOH. It also recrystallises from *i*-PrOH, or as the *methyl ester* from MeOH. Its UV(MeOH) has  $\lambda_{\max}$  at 351nm ( $\epsilon$  45,000). *9-Cis*-acid forms yellow needles from EtOH, with **m 189-190°**, and its UV(MeOH) has  $\lambda_{\max}$  at 343nm ( $\epsilon$  36,500); the *13-cis*-acid forms red-orange plates from *i*-PrOH with **m 174-175°**, and its UV has  $\lambda_{\max}$  at 345nm ( $\epsilon$  39,800). Store it in the dark, in an inert atmosphere, at 0° [Robeson et al. *J Am Chem Soc* **77** 4111 1955]. [*Beilstein* **9** IV 2387.]

**Vitamin A alcohol (retinol)** [68-26-8] **M 286.5, A<sub>1cm</sub><sup>1%</sup> (max) (all-trans) 1, 832 (325 nm), (13-cis) 1686 (328nm), (11-cis) 1230 319 nm), (9-cis) 1480 (323 nm), (9,13-di-cis) 1379 (324 nm), (11,13-di-cis) 908 (311 nm) in EtOH**. Purify retinol by chromatography on columns of water-deactivated alumina and elute with 3-5% acetone in hexane. Separate the isomers by TLC plates on silica gel G, developed with petroleum ether (low boiling)/methyl heptanone (11:2). Store it in the dark, under N<sub>2</sub>, at 0°, or in Et<sub>2</sub>O, Me<sub>2</sub>CO or EtOAc. [See Gunghaly et al. *Arch Biochem Biophys* **38** 75 1952, *Beilstein* **6** IV 4133.]

**Vitamin A aldehyde [all-trans-retinal; 3,7-dimethyl-9-(2,6,6-trimethyl-1-cyclohexenyl)-2,4,6,8-nonatetraen-1-al]** [116-31-4] **M 284.4, m 61-64°**. The aldehyde is separated from retinol by column chromatography on water-deactivated alumina. Elute with 1-2% acetone in hexane, or on TLC plates of silica gel G and using the same eluting solvent. It crystallises from petroleum ether or *n*-hexane as yellow-orange crystals, and the UV in hexane has  $\lambda_{\max}$  at 373nm ( $A_{1cm}^{1\%}$  1548) and 368nm ( $\epsilon$  48,000). It is an **irritant** and is light sensitive. Store it in sealed ampoules under N<sub>2</sub>. The *semicarbazone* forms yellow crystals from CHCl<sub>3</sub>/Et<sub>2</sub>O or EtOH, **m 199-201°(dec)**. The *9-cis-isomer* [514-85-2] and the *13-cis-isomer* [472-86-6] [ $\lambda_{\max}$  at 375nm ( $\epsilon$  1,250) in EtOH] are also available commercially. [*Beilstein* **7** III 1742.]

**Vitamin A palmitate (retinyl palmitate)** [79-81-2] **M 524.9, m 28-29°,  $\epsilon_{1cm}^{1\%}$  (all-trans) 1000 (325 nm) in EtOH**. The palmitate is separated from retinol by column chromatography on water-deactivated alumina with hexane containing a very small percentage of acetone. It is also chromatographed on TLC silica gel G, using petroleum ether/isopropyl ether/acetic acid/water (180:20:2:5) or petroleum ether/acetonitrile/acetic acid/water (190:10:1:15) to develop the chromatogram. It is then recrystallised from propylene at low temperature (below -47°). [*Beilstein* **6** IV 4135.]

**Vitamin B<sub>1</sub> Hydrochloride [Aneurine hydrochloride, Thiamine hydrochloride, 3{(4-amino-2-methyl-5-pyrimidinyl)methyl}-4-methylthiazolium chloride monohydrochloride]** [67-03-8] **M 337.3, m 248°(dec), 249-250°, monohydrate m 135°(dec), pK<sub>1</sub><sup>25</sup> 4.8, pK<sub>2</sub><sup>25</sup> 9.2**. The hydrochloride crystallises from 95% EtOH (solubility is *ca* 1%). The *monohydrate* is dehydrated at 100° *in vacuo* over H<sub>2</sub>SO<sub>4</sub>, but is *hygroscopic* and picks up one molecule of H<sub>2</sub>O readily. It can be sterilised at 100° if the pH of the solution is below 5.5. The *nitrate* has **m 196-200°(dec)** and is more stable than the hydrochloride. The *picrolonate* crystallises from H<sub>2</sub>O and is *dimorphic*, **m 164-165° and 228-229°(dec)**. [Todd & Bergel *J Chem Soc* 364, 367 1937, *J Am Chem Soc* **58** 1063, 1504 1936, **59** 526 1937, *Beilstein* **27** IV 1766.]

**Vitamin B<sub>2</sub>** [Riboflavin, Lactoflavin, 6,7-dimethyl-9-(D-1'-ribyl)isoalloxazine] [83-88-5] **M 376.4, m 278-282°**(dec with darkening at 240°), 281-282°,  $[\alpha]_{\text{D}}^{25} -9.8^{\circ}$  (H<sub>2</sub>O),  $[\alpha]_{\text{D}}^{25} -112^{\circ}$  to  $-125^{\circ}$  (c 2.5, 0.02N NaOH),  $[\alpha]_{\text{D}}^{20} -59^{\circ}$  (c 0.23, AcOH), **pK<sub>1</sub> 1.7, pK<sub>2</sub> 9.69 (10.2, acidic NH)**. It crystallises from H<sub>2</sub>O as a yellow-orange powder in three different forms with differing amounts of H<sub>2</sub>O. It melts if placed in an oil bath at 250°, but decomposes at 280° if heated at a rate of 5°/minute. It is also purified by crystallisation from 2M acetic acid, then extracted with CHCl<sub>3</sub> to remove lumichrome impurity. [Smith & Metzler *J Am Chem Soc* **85** 3285 1963.] Its solubility in H<sub>2</sub>O is 1g in 3-15L depending on the crystal structure. Its solubility in EtOH at 25° is 4.5mg in 100ml. Store it in the dark because it is decomposed to lumichrome by UV light. [Pearson *The Vitamins* **vol V** pp1-96 1967 and **vol VII** pp 1-96 1972, Gyögy and Pearson eds, Academic Press, *Beilstein* **26** IV 2542.]

**Vitamin B<sub>3</sub> (vitamin PP, Niacin)**. See nicotinamide in "Heterocyclic Compounds", Chapter 4.

**Vitamin B<sub>6</sub> hydrochloride** (adermine, pyridoxine HCl, 3-hydroxy-4,5-bis[hydroxymethyl]-2-methylpyridine HCl) [58-56-0] **M 205.6, m 208-208.5°, 208-209°(dec), 209-210°(dec), 205-212° (sublimes), pK<sub>1</sub><sup>25</sup> 5.0 (3-OH), pK<sub>2</sub><sup>25</sup> 8.96 (pyridinium<sup>+</sup>)**. Purify the vitamin by recrystallisation from EtOH/Me<sub>2</sub>CO, *n*-BuOH or MeOH/Et<sub>2</sub>O. Its solubility in H<sub>2</sub>O is 22%, and in EtOH it is 1.1%. It is insoluble in Et<sub>2</sub>O and CHCl<sub>3</sub>. Acidic aqueous solutions are stable at 120°/30minute. The *free base* has **m 159-160°** after recrystallisation from Me<sub>2</sub>CO and sublimation at 140-145°/0.0001mm. It has UV with  $\lambda_{\text{max}}$  at 290nm ( $\epsilon$  84,000), 253 and 325nm ( $\epsilon$  3700 and 7100) in 0.1N aqueous HCl. [Khua & Wendt *Chem Ber* **71** 780 1938, **72** 311 1939, Harris & Folkers *J Am Chem Soc* **61** 1242 1939, Harris et al. *J Am Chem Soc* **62** 3198 1940, *Beilstein* **21/5** V 492.] See also **Pyridoxal-5'-phosphate H<sub>2</sub>O** above.

**Vitamin B<sub>12</sub> (cyanocobalamine,  $\alpha$ -[5,6-dimethylbenzimidazolyl]cyano cobamide)** [68-19-9] **M 1355.4, m darkens at 210-220° and does not melt below 300°,  $[\alpha]_{\text{D}}^{23} -59^{\circ}$  (H<sub>2</sub>O)**. Vitamin B<sub>12</sub> crystallises from de-ionized H<sub>2</sub>O, with a solubility in H<sub>2</sub>O of 1g/80g, and is dried under vacuum over Mg(ClO<sub>4</sub>)<sub>2</sub>. The dry red crystals are *hygroscopic* and can absorb ~12% of H<sub>2</sub>O. A solution at pH 4.5-5 can be autoclaved for 20 minutes at 120° without decomposition. Aqueous solutions are stabilised by addition of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>. [Golding *Comprehensive Organic Chem* Vol 5 (Ed. Haslam; Pergamon Press, NY, 1979) pp 549-584.] *Alternatively*, an aqueous solution of the coenzyme can be concentrated, if necessary in a vacuum at 25° or less, until the concentration is 0.005 to 0.01M (as estimated by the OD at 522nm of an aliquot diluted with 0.01M K-phosphate buffer pH 7.0). If crystals begin to form on the walls of the container, they should be re-dissolved with a little H<sub>2</sub>O. The concentrated solution is placed in a glass stoppered flask and diluted with 5 volumes of Me<sub>2</sub>CO. After 2-3 hours at 3° it is centrifuged (10,000xg/10minutes) in Me<sub>2</sub>CO-insoluble plastic tubes to remove some amorphous precipitate. The clear supernatant is inoculated with a small crystal of the vitamin and allowed to crystallise overnight at 3°. Crystals are formed on the walls and the bottom of the container. A further 2 volumes of Me<sub>2</sub>CO are added and set aside at 3° to further crystallise. Crystallisation is followed by observing the OD<sub>522</sub> of the supernatant. When the OD falls to 0.27, then *ca* 94% of the crystals have separated. The supernatant is decanted (saved for obtaining a second crop), and the crystals are washed with a little cold 90% aqueous Me<sub>2</sub>CO (2x), 100% Me<sub>2</sub>CO (2x), Et<sub>2</sub>O (2x) at which time the crystals separate from the glass walls. Allow them to settle and remove residual Et<sub>2</sub>O with a stream of dry N<sub>2</sub>. The process can be repeated if necessary. The crystals can be dried in air or in a vacuum for 2 hours over silica gel at 100° with an 8-9% weight loss. [Barker et al. *Biochemical Preparations* **10** 33 1963.] This material gives a single spot on paper chromatography [see Weissbach et al. *J Biol Chem* **235** 1462 1960.] The vitamin is soluble in H<sub>2</sub>O (16.4mM at 24°, 6.4mM at 1°), in EtOH and PhOH but insoluble in Me<sub>2</sub>CO, Et<sub>2</sub>O, CH<sub>2</sub>Cl<sub>2</sub> and dioxane. Its UV has  $\lambda_{\text{max}}$  at 260, 375 and 522nm ( $\epsilon$  34.7 x 10<sup>6</sup>, 10.9 x 10<sup>6</sup> and 8.0 x 10<sup>6</sup>/mole) in H<sub>2</sub>O. The dry crystals are stable for months in the dark, but aqueous solutions decompose on exposure to VIS or UV light or alkaline CN<sup>-</sup>, but are stable in the dark at pH 6-7. The vitamin is inactivated by strong acids or alkalis. [Barker et al. *J Biol Chem* **235** 480 1960, see also *Vitamin B<sub>12</sub>* (Zagalak & Friedrich Eds) Walter de Gruyter, Berlin 1979, *Beilstein* **26** IV 3117.]

**Vitamin C**. See ascorbic acid entry in "Carbohydrates" in this chapter.

**Vitamin D<sub>2</sub>** [50-14-6] **M 396.7, m 114-116°,  $[\alpha]_{\text{D}}^{20} +122^{\circ}$  (c 4, EtOH)**. It is converted into its 3,5-dinitrobenzoyl ester and crystallised repeatedly from acetone. The ester is then saponified and the free vitamin is

isolated. [Laughland & Phillips *Anal Chem* **28** 817 1956, *Beilstein* **6** IV 4404.]

**Vitamin D<sub>3</sub>** (cholecalciferol, Calcitol, activated 7-dehydrocholesterol, (+)-vitamin D<sub>3</sub>) [67-97-0] **M 384.6, m 83-85°**,  $[\alpha]_{546}^{20} +126^{\circ}$  (c 2, EtOH). It is converted into its 3,5-dinitrobenzoyl ester and crystallised repeatedly from acetone. The ester is then saponified and the free vitamin is isolated. Store it in sealed ampoules under argon below 8°. It acts through a receptor which modulates differentiation and proliferation of normal and neoplastic cells. [Laughland & Phillips *Anal Chem* **28** 817 1956, DeLuca & Schones *Ann Rev Biochem* **52** 411 1983, *Beilstein* **6** III 2811, **6** IV 4149.]

**Vitamin E** (2*R*,4'*R*,8'*R*- $\alpha$ -tocopherol, natural active isomer) [59-02-9] **M 430.7, m 2.5-3.5°, b 200-220°/0.1mm, 200°/0.005mm, d<sub>4</sub><sup>25</sup> 0.950, n<sub>D</sub><sup>25</sup> 1.5045,  $[\alpha]_{D}^{25} +3.58^{\circ}$  (c 1, \*C<sub>6</sub>H<sub>6</sub>)**. Vitamin E is a viscous yellow oil which is distilled at high vacuum. It has  $\lambda_{max}$  at 294nm ( $E_{1cm}^{1\%}$  71). It is oxygen and light sensitive and is best stored as its stable *D*- $\alpha$ -acetate [58-95-7] which is purified by evaporative distillation at **b** 180-200°(bath temperature)/0.7mm, and has  $[\alpha]_{D}^{25} +3.3^{\circ}$  (c 5.1, EtOH). It forms needles at -30° and has **m** 26.5-27.5°,  $[\alpha]_{D}^{25} +0.25^{\circ}$  (c 10, CHCl<sub>3</sub>). [NMR: Cohen et al. *Helv Chim Acta* **64** 1158 1981, Burton & Ingold *Acc Chem Res* **19** 194 1986, Karrer et al. *Helv Chim Acta* **21** 520 1938, Robeson *J Am Chem Soc*, **64** 1487 1942, **65** 1660 1943.] Of the eight isomers the *D*- $\alpha$ -isomer is the most active. [See W. Friedrich "Vitamins" Walter de Guyter Publ, Berlin 1988.] [*Beilstein* **17/4** V 168.]

**DL-Vitamin E acetate** (DL- $\alpha$ -tocopheryl acetate) [7695-91-2] **M 472.8, m -27.5°, b 194-196°/0.01mm, 222-224°/0.3mm, d<sub>4</sub><sup>20</sup> 0.958, n<sub>D</sub><sup>20</sup> 1.4958**. It is a viscous liquid which is purified by distillation under high vacuum under N<sub>2</sub> or argon and stored in sealed ampoules in the dark. It is considerably more stable to light and air than the parent unacetylated vitamin. It is insoluble in H<sub>2</sub>O but freely soluble in organic solvents. All eight stereoisomers have been synthesised. The commercially pure *d*- $\alpha$ -tocopheryl acetate (2*R*,4'*R*,8'*R*) has **b** 180-200°/0.7mm and  $[\alpha]_{D}^{20} +3.9^{\circ}$  (c 5, EtOH); see above. [Cohen et al. *Helv Chim Acta* **64** 1158 1981, *Beilstein* **17/4** V 169.]

**Vitamin K<sub>1</sub>** (2-methyl-3-phytyl-1,4-naphthoquinone) [84-80-0] **M 450.7, m -20°, b 141-140/0.001mm, b 140-145°/10<sup>-3</sup> mm, d<sub>4</sub><sup>25</sup> 0.967, n<sub>D</sub><sup>25</sup> 1.527,  $[\alpha]_{D}^{20} -0.4^{\circ}$  (c 57.5, \*C<sub>6</sub>H<sub>6</sub>)**. Vitamin K<sub>1</sub> is a yellow viscous oil, which can be distilled at high vacuum practically unchanged. It is insoluble in H<sub>2</sub>O, but soluble in common organic solvents. Store it in the dark under N<sub>2</sub> as it is oxygen sensitive. It has  $A_{1cm}^{1\%}$  328 at 248nm. [Fieser et al. *J Am Chem Soc* **61** 2557 1939, Hirschmann et al. *J Am Chem Soc* **76** 4592 1954, Isler & Doebel *Helv Chim Acta* **27** 225 1954, *Beilstein* **7** IV 2496.]

**Vitamin K<sub>3</sub>** (2-methyl-1,4-naphthoquinone, Menadione, Menaphthone) [58-27-5] **M 172.2, m 105-106°, 105-107°**. Recrystallise it from 95% EtOH, or MeOH after filtration. It forms bright yellow crystals which are decomposed by light. Its solubility in EtOH is 1.7% and in \*C<sub>6</sub>H<sub>6</sub> it is 10%. It **IRRITATES** mucous membranes and skin. [Fieser *J Biol Chem* **133** 391 1940, *Beilstein* **7** IV 2430.]

**Vitamin K<sub>5</sub>** (4-Amino-2-methyl-1-naphthol hydrochloride) [130-24-5] **M 209.6, m 283°(dec), pK<sub>Est(1)</sub> ~5.6 (NH<sub>2</sub>), pK<sub>Est(2)</sub> ~10.4 (OH)**. Crystallise it from dilute HCl. [Sah *Rec Trav Chim Pays Bas* **59** 458 1941, Sah *Rec Trav Chim Pays Bas* **60** 373 1940, Veldstra & Wiardi *Rec Trav Chim Pays Bas* **61** 547 1942, Veldstra & Wiardi *Rec Trav Chim Pays Bas* **62** 75 1943, *Beilstein* **13** III 1921.]

**Vitamin P** [(+)-Rutin, quercetin-3-rubinoside] [153-18-4] **M 610.5, 664.5 (trihydrate), m 188-189°, 195-196°,  $[\alpha]_{546}^{20} +13^{\circ}$  (c 5, EtOH),  $[\alpha]_{D}^{24} -37.6^{\circ}$  (c 1.24, pyridine), (polyphenolic flavone pKs 7—10)**. The vitamin crystallises from MeOH or water/EtOH, dry it in air, then dry it further for several hours at 110° or in high vacuum at 120°. It forms yellow crystals from EtOH/Me<sub>2</sub>CO/H<sub>2</sub>O (2:1:1). It has also been purified by passing (0.5g) through a Kieselgel column (30 x 5cm) with EtOAc/MeOH/H<sub>2</sub>O (100:20:15), and after 750ml have passed through, the yellow fraction of 250ml gives the glycoside (0.3g) on evaporation. [Hörhammer et al. *Chem Ber* **101** 1183 1968, Marini-Bettòlo *Gazz Chim Ital* **80** 631 1950, *Beilstein* **18/5** V 519.]

**Vitamin U** (S-Methyl-L-methionine chloride) [*S*- 1115-84-0, *S*-ion- 6708-35-6, *RS*- 44901-24-8] **M 199.5, m 135° (dec), 139° (dec),  $[\alpha]_{D}^{23} +33^{\circ}$  (0.2M HCl), pK<sub>1</sub> 1.9, pK<sub>2</sub> 7.9**. Likely impurities are methionine, methionine

sulfoxide and methionine sulfone. Crystallise Vitamin U from water by adding a large excess of EtOH. It is *hygroscopic*. It should be stored in a cool, dry place and protected from light. It has also been purified on a column of Dowex 50 H<sup>+</sup> form, washed with H<sub>2</sub>O and eluted with 6N ammonia, lyophilised, the residue is dissolved in dilute HCl, lyophilised again and then it is obtained as colourless prisms by vapour diffusion of Et<sub>2</sub>O in a 1:1 (v/v) mixture of MeOH/EtOH in which the *hydrochloride* is dissolved [Del Re *Acta Cryst B* **33** 3289 1977]. The *iodide salt*, **m** ~150°(dec), is obtained by dissolving it in 50% aqueous EtOH and adding ~3.5 volumes of absolute EtOH. The *bromide salt* has **m** 140°(dec) [Toennies & Kolb *J Amer Chem Soc* **67** 849 1945].

***dl*-Warfarin (Coumafene, 4-hydroxy-3-(3-oxo-1-phenylbutyl)-2H-1-benzopyran-2-one)** [81-81-2] **M 308.3, m 162-164°, pK<sup>20</sup> 4.85 (the 4-mercapto derivative has pK<sup>20</sup> 6.60).** *dl*-Warfarin crystallises from EtOH or MeOH. Its UV has  $\lambda_{\max}$  at 308nm ( $\epsilon$  13,610) in H<sub>2</sub>O. The *acetate* has **m** 117-118°, the *O-triflate* has **m** 90-91°, and the *2,4-dinitrophenylhydrazone* has **m** 215-216°. It is an effective anticoagulant and rodenticide. [West et al. *J Am Chem Soc* **83** 2676 1961, HPLC: Banfield & Rowland *J Pharm Sci* **72** 921 1983, *Beilstein* **17** III/IV 6794.]

***R*(+)-Warfarin** has **m** 170-171°,  $[\alpha]_{\text{D}}^{25}$  +149° (c 1.2, in 0.5N NaOH), +25.5° (c 2, AcOH), +15.5° (c 2, MeCN) and -19° (c 1.1, propan-2-ol), and ***S*(-)-Warfarin (more active enantiomer)** has **m** 172-173°,  $[\alpha]_{\text{D}}^{25}$  -148° (c 1.2, in 0.5N NaOH), -25.5° (c 2, AcOH), -15.5° (c 2, MeCN) and +19° (c 1.1, propan-2-ol). *dl*-Warfarin is resolved *via* recrystallisation of the quinidine salt, and the free acids are recrystallised (70g) from 600ml of 80% aqueous Me<sub>2</sub>CO. Large prismatic crystals of the pure enantiomers are obtained by slow crystallisation from Me<sub>2</sub>CO or AcOH. The solubilities of the pure enantiomers at 25° are 11.2% in Me<sub>2</sub>CO and 2.6% in AcOH, whereas the racemate has solubilities of 6.5% in Me<sub>2</sub>CO and 2% in AcOH. The IR spectra are the same with  $\nu_{\max}$  (CHCl<sub>3</sub>) at 2.78 (w), 5.88, 6.16 and 6.38 $\mu$ . [West et al. *J Am Chem Soc* **83** 2676 1961, Cbz-proline diastereoisomeric esters were used for HPLC analysis: Banfield & Rowland *J Pharm Sci* **72** 921 1983.] **Poisonous, anticoagulant and rodenticide.**

**Xanthopterin monohydrate (2-amino-4,6-dihydroxypteridine, 2-aminopteridin-4,6(1*H*,5*H*)-dione)** [5979-01-1 (H<sub>2</sub>O), 119-48-8 (anhydrous)] **M 197.2, m <300°, pK<sub>1</sub> 1.6 (basic), pK<sub>2</sub> 6.59 (acidic), pK<sub>3</sub> 9.31 (acidic)(anhydrous species), and pK<sub>1</sub> 1.6 (basic), pK<sub>2</sub> 8.65 (acidic), pK<sub>3</sub> 9.99 (acidic)(7,8-hydrated species).** Purification is as for isoxanthopterin (see [529-69-1] "Heterocyclic Compounds", Chapter 4). It is crystallised by acidifying a hot ammoniacal solution with formic acid, and collecting the crystals by centrifugation followed by washing with EtOH, ether and drying at 100° *in vacuo*. Its R<sub>F</sub> values on paper chromatography are 0.15 (*n*-PrOH, 1% aqueous NH<sub>3</sub>, 2:1), 0.36 (*n*-BuOH/AcOH/H<sub>2</sub>O, 4:1:1) and 0.47 (3% aqueous NH<sub>3</sub>). [Inoue & Perrin *J Chem Soc* 260 1962, Inoue *Tetrahedron* **20** 243 1964, see also Blakley *Biochemistry of Folic Acid and Related Pteridines* North Holland Publ Co, Amsterdam 1969, *Beilstein* **26** II 313, **26** III/IV 4000.]

**Xanthotoxin (Methoxalen, 9-methoxypsoralen, Ammoidin, 9-methoxyfuro[3,2-*g*][1]benzopyran-7-one)** [298-81-7] **M 216.2, m 146-148°, 148°, 148-149°.** Purify xanthotoxin by recrystallisation from \*C<sub>6</sub>H<sub>6</sub>/petroleum ether (b 60-80°) to give silky needles, or from EtOH/Et<sub>2</sub>O to give rhombic prisms or from hot H<sub>2</sub>O to give needles. It is soluble in aqueous alkali due to ring opening of the cyclic lactone but recyclises upon acidification. It has UV with  $\lambda_{\max}$  (EtOH) at 219, 249 and 300nm (log  $\epsilon$  4.32, 4.35 and 4.06) and <sup>1</sup>H NMR in CDCl<sub>3</sub> with  $\delta$  at 7.76 (d, 1H, *J* = 10Hz), 7.71 (d, 1H, *J* = 2.5Hz), 7.38 (s, 1H), 6.84 (d, 1H, *J* = 2.5Hz), 6.39 (d, 1H, *J* = 10Hz) and 4.28 (s, 3H). [Nore & Honkanen *J Heterocycl Chem* **17** 985 1980.] It is a DNA intercalator, is used in the treatment of dermal diseases, and is a **human carcinogen** [Tessman et al. *Biochemistry* **24** 1669 1985]. [*Beilstein* **19** I 711, **19/6** V 15.]

**Zeatin (trans-*N*<sup>6</sup>-[4-hydroxy-3-methylbut-2-en-1-yl]adenine)** [1637-39-4] **M 219.3, m 207-208, 209-209.5°, pK<sub>1</sub> 4.4 (basic), pK<sub>2</sub> 9.8 (acidic).** Purify zeatin by recrystallisation from EtOH or H<sub>2</sub>O. Its UV has  $\lambda_{\max}$  at 207 and 275nm ( $\epsilon$  1400 and 14,650) in 0.1N aqueous HCl; 212 and 270nm ( $\epsilon$  17,050 and 16,150) in aqueous buffer pH 7.2; and 220 and 276nm ( $\epsilon$  15,900 and 14,650) in 0.1N aqueous NaOH. The *picrate* has **m** 192-194° (from H<sub>2</sub>O) from which zeatin can be recovered by treatment with Dowex-I x 8 (200-400 mesh, OH<sup>-</sup> form).

[Letham et al. *Aust J Chem* **22** 205 1969, *Proc Chem Soc (London)* 230 1964, Shaw & Wilson *Proc Chem Soc (London)* 231 1964.] It is a cell division factor (plant growth regulator) [Letham & Palni *Ann Rev Plant Physiol* **34** 163 1983] and inhibits mitochondrial function [Miller *Plant Physiol* **69** 1274 1982]. The commercially available *trans*-9-riboside derivative, [6025-53-2], **M 351.4**, is a cytokine which separates from aqueous AcOH with **m** 177-179°. Its solubility in AcOH is ~5%. [McDonald & Morris *Methods Enzymol* **100** 347 1985.]

## CHAPTER 8

### NANOMATERIALS AND NANOTECHNOLOGY

#### INTRODUCTION

*Nanomaterials* are substances that are, or have been, reduced in size to the range from 1nm to ~100nm (i.e. 1 to ~100 nanometers, or 1 to ~100 x 10<sup>-9</sup> meters). *Nanotechnology* is the science and applications of nanomaterials, and is growing at an ever increasing pace. At this particle size the properties of materials can be altered dramatically. Properties such as solubility, reactivity, spectroscopy, electrical and magnetic, transport through membranes etc. are generally different from those of the same materials with large particle size. The applications of materials of nano size have escalated in the last fifteen or so years and are currently gaining momentum. The technology has broad applications in performance materials, health, consumer products, water, information technology and energy. The discovery of *fullerenes* (1996 Nobel Prize for Chemistry to H.W. Kroto, R.E. Smalley and R.F. Curl) and of *Graphene* (2010 Nobel Prize for Physics to A. Geim and K. Novoselov) are very important factors in the development of nanotechnology. Not very many nanomaterials have so far been included in chemical catalogues of commercially available substances, e.g. as compared with catalysts (although some catalysts are now available as nanoparticles), hence the relatively smaller size of this chapter. Fullerenes and related materials such as carbon nanotubes have found applications in medicine for the transport of drugs and biological materials to targeted sites and some readily available derivatives are described in this chapter, together with other commercially available nanoparticulate substances, e.g. catalysts, magnetic and electrically conducting thin films. General safety aspects of handling nanomaterials have been briefly addressed.

#### IDENTIFICATION AND MEASUREMENT OF NANOMATERIALS

The 1 to ~ 100nm (10 to ~1000Å) particles are smaller than the wavelength of UV light, and thus the use of appropriate small particles e.g. electrons, or radiation e.g. X-rays is necessary to identify and measure these particles. Instrumentation for these purposes has been developed and the resolutions are continuously being improved. These instruments can measure very accurately, and depending on the physical principles of the machines, they measure different parameters of the nanoparticles, e.g. diameter (if spherical), length (if rod like), width (if bulky) etc, and not necessarily all parameters at the same time with one instrument. The commonly used instruments include the *Transmission Electron Microscope* (TEM) in which the electron beam runs past the particles placed on a transparent surface, and then through the surface giving a 2D image and magnifying one million times. In the *Scanning Electron Microscope* (SEM) and *Scanning Tunneling Microscope* (STM, or *Spectroscopy* STS) the electron beam scans the surface of the particles to provide a 3D picture, e.g. of hairs on a fly. *Dynamic Light Scattering* (DLS) uses light scattering through solutions of nanoparticles. Another technique, *Scattering Probe Microscopy* (SPM), allows scanning with a probe over a surface and includes *Atomic Force Microscopy* (AFM, or *non-contact atomic force microscopy* NC-AFM) where a ceramic or semiconductor tip scans the surface (much like a phonograph needle scans a record), and measures the atomic forces beneath it. The NC-AFM tip is attached to a very small tuning fork that oscillates at amplitudes of 0.2 to 0.5Å, smaller than the diameter of an atom. When the tip is brought very close to a molecule on a surface, this frequency alters slightly thus *detuning* due to the atomic forces between the tip and the molecule to give a complete picture of the molecule on the surface. By placing a CO (carbon monoxide) molecule at the tip, and keeping it there throughout the imaging process, very high resolution can be obtained. Gross and coworkers [Gross et al. *Science* **325** 1110 2009] obtained the complete image of pentacene on a copper surface in this way, and succeeded in imaging the amount of charge on a single atom [Gross et al. *Science* **324** 1428 2011]. The sensitivity of *Magnetic Resonance Imaging* (MRI) has been considerably increased (with a resolution of ~4nm), by Rugar and coworkers [Degen et al. *Proc Natl Acad Sci* **106** 1313 2009, cf H. Birch *MRI on the Nanoscale*, RSC Chemistry World **6**(2) 28 2009, J. M. Crow *Picture perfect pentacene*,

RSC *Chemistry World* 6(1) 462011] who have developed the *Magnetic Resonance Force Microscopy* (MRFM) technique. Here the sample is placed at the end of a tiny silicon cantilever to which is applied, *via* a magnetic tip, a radio frequency magnetic field. The spin of the nuclei alternate (*up* and *down*) when the frequency reaches their ‘wobbling’ frequencies making the cantilever vibrate. Photon density 3D images of the specimen (e.g. tobacco mosaic virus, *ca* 18 nanometers across) can be obtained by using a laser to detect the cantilever vibrations. The technique does not affect the sample and gives superior images to those from STM and AFM. [A.I. Kirkland and J. I. Hutchinson (eds) *Nanocharacterisation* RSC Publishing UK, 2007, ISBN 9781847557926, 1847557929; A. Turley *Sizing it up*, RSC *Chemistry World* 8(3) 50 2011; M. Thompson RSC *The Characterisation of Nanoparticles; Analytical Methods Committee Technical Briefs* 48, December 2010; ISSN 1757-5958, <http://bit.ly/AMCparticle>). Other techniques include *Near-Infrared Spectroscopy* (NIR) and solution phase NIR [Iktis et al. *Nano Lett* 3 309 2003], general *Electron Microscopy* (EM), *Field Emission Microscopy* (FEM), *FT-Raman Scattering Spectroscopy*, *Nuclear (proton) Magnetic Resonance Spectroscopy* (NMR for derivatised carbon nanotubes, CNTs), *Thermo Gravimetric Analysis* (TGA), *Energy Dispersive X-ray Spectroscopy* (EDX), as well as other optical techniques (see Bibliography at the end of this chapter).

Preparation of the specimen is very important since the atoms or/and molecules have to be spread over the surface in as close to one atom or molecule thick. Where thicknesses (*t*) of 7 to ~13nm need to be measured *Grazing Incident X-Ray Reflectometry* (GICRR/XRR) provides an initial measure of particle lengths (*l*) of 1 to 35nm. *Spectroscopic Ellipsometry* (SE, *t* = ~ 10.5 to 12.3nm, *l* = 1 to 10.5nm), *Scanning Ion Mass Spectrometry* (SIMS, *t* ~ 10.4 to 10.8nm, *l* = ~12 to 13 nm), *Transmission Electron Microscopy* (TEM, *t* ~ 7.5 to 12.5nm, *l* = 12.5 to 18.5 nm), *X-Ray Fluorescence Spectroscopy* (XFS, *t* ~ 7.5 to 9.3nm, *l* = 16.0 to 19.5 nm), *X-Ray Photoelectron Spectroscopy* (XPS, *t* ~ 9.2 to 11.7, *l* = 18.5 to 25.5 nm) and higher resolution *Grazing Incident X-Ray Reflectometry* (GIXRR/XRR, *t* ~ 9.2 to 11.7, *l* = 24.0 to 36.0 nm) provide the approximate *t* and *l* values stated in the brackets. It must be noted that these values are approximate as they do vary depending on the nature of the materials that are measured.

**Average particle size:** The accepted method for determining the primary particle size of nanomaterials is by TEM analysis. However, this is expensive and time-consuming. Studies have shown that an average primary particle size for spherical or cubic shaped dry nanoparticles of roughly uniform shape and size can be calculated from the equation:

$$\text{Average particle size (nanometers)} = (6/\text{BET surface area}^* \times \text{density}^{**}) \times 1000$$

Where surface area\* is in sq. m/g, and density\*\* is in g/cc. *Micromeritics Analytical Services* (MAS) will measure BET surface area by a gas absorption procedure and the real density by gas pycnometry. This gives a good estimate of average primary particle size. For further information see [www.micromeritics.com](http://www.micromeritics.com), Micromeritics Analytical Services Downloads.

## FULLERENES AND RELATED SUBSTANCES

Fullerenes and related substances are made by heating carbon (e.g. soot, graphite) to form nano-sized carbon ‘balls’. These nanoparticles look like ‘footballs’ in being constructed of five (pentagon) and/or six (hexagon) carbon rings. Their carbon ring sizes make for stable ‘ball-like’ molecules of 60 or more carbon atoms and have some solubility in organic solvents. These carbon allotropes have a variety of exotic properties including electrochemical [Echegoyen & Echegoyen *Acc Chem Res* 31 593 1998], ferromagnetism [Allemand et al. *Science* 253 301 1991], superconductivity [Hebard et al. *Nature* 350 600 1991], photophysical [Guldi *Chem Commun* 321 2000], anti-HIV bioactivity [Friedman et al. *J Am Chem Soc* 115 6506 1993], and their ‘aromatic’ nature allows them to react accordingly and be functionalised (see below) for further chemical reactions [Kordatos et al. *J Org Chem* 66 4915 2001]. New and useful applications are continually being found in nano science, medicine, pharmaceuticals, and nanotechnology [see references below].

### FULLERENES

**Fullerene C<sub>60</sub>** (Buckminsterfullerene C<sub>60</sub>, Footballene, Buckyball 60) [99685-96-8] M 720.66 and **Fullerene C<sub>70</sub>** [115383-22-7] M 840.77. **Purification procedures: (a)** This was purified from the soluble toluene extract (400mg) of the soot (Fullerite), formed from resistive heating of graphite, by adsorption on neutral alumina (100g, Brockmann I, 60 x 8cm). Elution with toluene/hexane (5:95 v/v) gives *ca* 250mg of quite pure C<sub>60</sub>. It has characteristic spectral properties (see below). Further elution with toluene/hexane (20:80

v/v, i.e. increased polarity of solvent) provides 50mg of "pure" C<sub>70</sub> [Allemand et al. *J Am Chem Soc* **113** 1050 1991].

Chromatography on alumina can be improved by using conditions which favour adsorption rather than crystallisation. Thus the residue from toluene extraction (1g) in CS<sub>2</sub> (ca 300ml) is adsorbed on alumina (375g, standard grade, neutral ca 150 mesh, Brockmann I) and loaded as a slurry in toluene/hexanes (5:95 v/v) to a 50 x 8cm column of alumina (1.5Kg) in the same solvent. To avoid crystallisation of the fullerenes, 10% of toluene in hexane is added quickly followed by 5% of toluene in hexane after the fullerenes had left the loading fraction (2-3 hours). With a flow rate of 15ml/minute the purple C<sub>60</sub> fraction is eluted during a 3-4 hour period. Evaporation of the eluates gives 550-630mg of product which, after recrystallisation from CS<sub>2</sub>/cyclohexane yields 520-600mg of C<sub>60</sub> which contains adsorbed solvent. On drying at 275<sup>o</sup>/10<sup>-3</sup>mm for 48 hours a 2% weight loss is observed although the C<sub>60</sub> still contains traces of solvent. Further elution of the column with 20% of toluene in hexane provides 130mg of C<sub>70</sub> containing 10-14% of C<sub>60</sub> (by <sup>13</sup>C NMR). This was re-chromatographed as above using a half scale column and adsorbing the 130mg in CS<sub>2</sub> (20ml) on alumina (24g) which gave 105mg of recrystallised C<sub>70</sub> (containing 2% of C<sub>60</sub>). The purity of C<sub>60</sub> can be improved further by washing the crystalline product with Et<sub>2</sub>O and Me<sub>2</sub>CO followed by recrystallisation from \*C<sub>6</sub>H<sub>6</sub> and vacuum drying at high temperatures.

(b) Carbon soot from resistive heating of a carbon rod in a partial helium atmosphere (0.3bar) under specified conditions is extracted with boiling \*C<sub>6</sub>H<sub>6</sub> or toluene, filtered and the red-brown solution is evaporated to give crystalline material in 14% yield which is mainly a mixture of fullerenes C<sub>60</sub> and C<sub>70</sub>. Chromatographic filtration of the 'crude' mixture with \*C<sub>6</sub>H<sub>6</sub> allows no separation of components, but some separation was observed on silica gel TLC with *n*-hexane or *n*-pentane, but not cyclohexane as eluents. Analytical HPLC with hexanes (5µm Econosphere silica) gave satisfactory separation of C<sub>60</sub> and C<sub>70</sub> (retention times of 6.64 and 6.93 minutes respectively) at a flow rate of 0.5ml/minute and using a detector at 256nm. HPLC indicated the presence of minor (<1.5% of total mass) unidentified C<sub>n</sub> species with retention times of 5.86 and 8.31 minutes. Column chromatography on flash silica gel with hexane gives a few fractions of C<sub>60</sub> with ≥95% purity, but later fractions contain mixtures of C<sub>60</sub> and C<sub>70</sub>. These can be obtained in 99.85 and >99% purity, respectively, by column chromatography on neutral alumina. [Ajie et al. *J Phys Chem* **94** 8630 1990.]

(c) Separation of C<sub>60</sub> and C<sub>70</sub> can be achieved by HPLC on a dinitroanilinopropyl (DNAP) silica (5µm pore size, 300Å pore diameter) column with a gradient from *n*-hexane to 50% CH<sub>2</sub>Cl<sub>2</sub> using a diode array detector at wavelengths 330nm (for C<sub>60</sub>) and 384nm (for C<sub>70</sub>). [Cox et al. *J Am Chem Soc* **113**, 2940, 1991.]

Soxhlet extraction of the "soot" is a good preliminary procedure, or if material of only ca 98% purity is required. Soxhlet extraction with toluene is run (20 minutes per cycle) until colourless solvent fills the upper part of the Soxhlet equipment (10 hours). One-third of the toluene remains in the pot. After cooling, the solution is filtered through a glass frit. This solid (purple in toluene) is ca 98% C<sub>60</sub>. This powder is again extracted in a Soxhlet using identical conditions as before, and the C<sub>60</sub> is recrystallised from toluene to give 99.5% pure C<sub>60</sub>. C<sub>70</sub> has greater affinity than C<sub>60</sub> for toluene. [Coustel et al. *J Chem Soc, Chem Commun* 1402 1992.]

(d) Purification of C<sub>60</sub> from a C<sub>60</sub>/C<sub>70</sub> mixture was also achieved by dissolving it in an aqueous solution of γ (but not β) cyclodextrin (0.02M) with refluxing. The rate of dissolution (as can be followed by UV spectroscopy) is quite slow and constant up to 10<sup>-5</sup>M of C<sub>60</sub>. The highest concentration of C<sub>60</sub> in H<sub>2</sub>O obtained was 8 x 10<sup>-5</sup>M and a 2 γ-cyclodextrin:1 C<sub>60</sub> clathrate is obtained. C<sub>60</sub> is extracted from this aqueous solution with toluene and C<sub>60</sub> of >99 purity is obtained by evaporation. With excess of γ-cyclodextrin more C<sub>60</sub> dissolves and the complex precipitates. The precipitate is insoluble in cold H<sub>2</sub>O but soluble in boiling H<sub>2</sub>O to give a yellow solution. [Andersson et al. *J Chem Soc, Chem Commun* 604 1992.]

(e) C<sub>60</sub> and C<sub>70</sub> can also be readily purified by inclusion complexes with *p*-*tert*-butylcalix[6] and [8]arenes. Fresh carbon-arc soot (7.5g) is stirred with toluene (250ml) for 1 hour and filtered. To the filtrate is added *p*-*tert*-butylcalix[8]arene, refluxed for 10 minutes and filtered. The filtrate is seeded and set aside overnight at 20°. The C<sub>60</sub> complex separates as yellow-brown plates and is recrystallised twice from toluene (1g from 80ml) to give a 90% yield. Addition of CHCl<sub>3</sub> (5ml) to the complex (0.85g) releases C<sub>60</sub> (0.28g, 92% from recrystallised complex).

*p*-*tert*-Butylcalix[6]arene-(C<sub>60</sub>)<sub>2</sub> complex is prepared by adding *p*-*tert*-butylcalix[6]arene (4.4mg) to a refluxing solution of C<sub>60</sub> (5mg) in toluene (5ml). The hot solution is filtered rapidly and cooled overnight to give prisms (5.5mg, 77% yield). Pure C<sub>60</sub> is obtained by decomposing the complex with CHCl<sub>3</sub> as above.

The *p*-*tert*-butylcalix[6]arene-(C<sub>70</sub>)<sub>2</sub> complex is obtained by adding *p*-*tert*-butylcalix[6]arene (5.8mg) to a refluxing solution of C<sub>70</sub> (5mg) in toluene (2ml), filtering hot and slowly cooling to give red-brown needles (2.5mg, 31% yield) of the complex. Pure C<sub>70</sub> is then recovered by decomposing the complex with CHCl<sub>3</sub>. Decomposition of these complexes can also be achieved by boiling a toluene solution over KOH pellets for *ca* 10 minutes. The calixarenes form Na salts which do not complex with the fullerenes. These appear to be the most satisfactory means at present for preparing large quantities of relatively pure fullerene C<sub>60</sub> and C<sub>70</sub> and is considerably cheaper than previous methods. [Atwood et al. *Nature* **368** 229 1994.]

**(f) Rapid and economical purification of C<sub>60</sub> fullerene** [22685-96-8, 99685-96-8] **M 720.6, m >280°, flash point 94°**. Crude soot enriched in fullerenes with ~5% of soluble fullerenes available from suppliers such as *Texas Fullerene Corporation* (8926 Kirby Drive, Houston, USA) and *Polygon Enterprises* (P.O.Box 5536, Waco) was used. A concentrated slurry of fullerene extract (containing *ca* 2.5g of solid) in toluene was prepared by *Soxhlet* extraction of enriched soot with toluene, and evaporated. It was applied onto a glass filter funnel (*D4* 10cm diameter frit) which was loaded with a slurry of silica gel (125g, 230-400 mesh, ~0.05mm, Merck) and acid washed activated charcoal (63g, *Darco G60*, Fluka) in toluene (800ml), and shaken for 5 minutes to give a 5.5 cm high plug which was not allowed to run dry. The plug is covered with 1cm of washed sea sand. The loading of the plug and washing were performed under low vacuum suction (~ 50mm) applied to the suction flask. The plug was rinsed with toluene (3.5L) and the eluate turned intensely purple on further elution with EtOH (300ml). The total separation took ~15 minutes. The purple solution was evaporated to dryness and the residue was washed with small volumes of Et<sub>2</sub>O on a *D4* frit. The yield of C<sub>60</sub> was ~1.5g (60% of the total 75% present in the fullerene soot). Analysis by HPLC should show absence of C<sub>70</sub> or higher fullerenes, but depending upon the original sample may show the presence of 1-3% of C<sub>60</sub>O.

**(g)** A higher purity C<sub>60</sub> can be obtained by using a glass filter funnel with a *D4* frit (diameter 6.5cm) on a suction flask filled with a slurry of silica gel (~84g, 230-400 mesh) and *Darco G60* charcoal (42g) in toluene to a plug height of 9cm; and covered with sea sand (1cm). A concentrated solution of 1.7g of soot extract in toluene (~500ml) was applied onto the plug which was washed with toluene (2.6L). The first fraction (1.4L) of deep purple eluate gave, after evaporation to dryness and washing with small portions of Et<sub>2</sub>O on a *D4* frit, ~690mg of C<sub>60</sub> (41% of the possible 75% of C<sub>60</sub> in the soot extract) which contained 99.75% pure C<sub>60</sub> by HPLC. A further fraction of 1.2L gave, after similar treatment, 143mg (14%) of C<sub>60</sub> of 99.2% purity plus 0.8% of C<sub>60</sub>O as the only other product. [For HPLC and NMR see Isaacs et al. *Helv Chim Acta* **76** 1231 1993].

**(h)** Tour and coworkers [Scrivens et al. *J Am Chem Soc* **114** 7917 1992] described another **gram-quantity purification procedure for C<sub>60</sub> fullerene** where a slurry of alkaline decolorising carbon Norit-A (36g) and silica gel (72g, flash chromatography grade 60 of 230-240 mesh ASTM, 0.040-0.063mm particle size) in toluene (200ml) was poured into a flash chromatography column (38mm in diameter and 45cm long, tape wrapped in case of cracking due to pressure and should be shielded) with a cotton plug at the bottom to form the stationary phase. The slurry was allowed to settle above the stationary phase and drained under a head of 7.5 psi of N<sub>2</sub> pressure applied at the top of the column which should not be allowed to dry out. A saturated solution of crude fullerenes (1.85g, extracted from carbon arc soot) in toluene (400ml, made homogeneous by sonication for ~30 minutes) was applied slowly at the top of the stationary phase. The pressure applied (7.5—10psi) provides a flow rate of ~16ml/minute. C<sub>60</sub> elutes as a purple coloured solution after ~37 minutes in a volume of ~600ml. The eluate, after further ~36 minutes, is colourless and after ~3 minutes further it turns to red-brown when the more strongly adsorbed C<sub>70</sub> fullerene begins to elute out. C<sub>60</sub> fullerene (1.16g, 63 of the 73% of extractable C<sub>60</sub> fullerene) is pure as shown by having one signal *only* in the <sup>13</sup>C NMR (125MHz, \*C<sub>6</sub>H<sub>6</sub>) at δ 143.29 (100%) (compare with the spectrum of C<sub>70</sub> fullerene below).

Repeated chromatography on neutral alumina yields minor quantities of solid samples of C<sub>76</sub>, C<sub>84</sub>, C<sub>90</sub> and C<sub>94</sub> believed to be higher fullerenes. A stable oxide C<sub>70</sub>O has been identified. These have been separated by repeated flash chromatography on alumina with gradient elution using hexane/toluene mixtures (starting from 95:5 and increasing proportions of toluene until the ratio of 50:50 was attained) [Diederich et al. *Science* **252** 548 1991].

**Physical properties of Fullerene C<sub>60</sub>:** C<sub>60</sub> fullerene [135105-52-1] **M 720.64, does not melt below 360°, and starts to sublime at 300° in vacuo**, and is now available commercially in a high state of purity. It is a mustard-coloured solid that appears brown or black with increasing film thickness. It is soluble in common organic solvents, particularly aromatic hydrocarbons which give a beautiful magenta colour. Toluene solutions are

purple in colour. It is soluble in  $^*C_6H_6$  (5mg/ml), but dissolves slowly.  $C_{60}$  crystallises in needles or plates. [Taylor *J Chem Soc, Chem Commun* 1423 1990.]

UV-Vis in hexanes:  $\lambda_{max}$  nm(log  $\epsilon$ ) 211(5.17), 227sh(4.91), 256(5.24), 328(4.71), 357sh(4.08), 368sh(3.91), 376sh(3.75), 390(3.52), 395sh(3.30), 403(3.48), 407(3.78), 492sh(2.72), 540(2.85), 568(2.78), 590(2.86), 598(2.87) and 620(2.60).

IR (KBr):  $\nu_{max}$  1429m, 1182m, 724m, 576m and 527s  $cm^{-1}$ .  $^{13}C$  NMR: one signal with  $\delta$  at 142.68.

$C_{60}$  fullerene is a nano-channel organic semiconductor [Newman et al. *Chem Mater* **16** 4436 2004].

**Purification of [5,6]  $C_{70}$  fullerene for derivatisation** [115383-22-7] **M 840.8, m >280°**. By using a toluene extract (845mg) of Norit A (Aldrich) and a single-column purification using activated charcoal and derivatised polystyrene as stationary phases with toluene/1,2-dichlorobenzene then pure 1,2-dichlorobenzene as eluents, the six fractions obtained (confirmed by HPLC) were: (i) 205mg of pure  $C_{60}$ , (ii) 231mg of 38:62  $C_{60}/C_{70}$ , (iii) 101mg of 88% pure  $C_{70}$ , (iv) 66mg of 92% pure  $C_{70}$ , (v) 131mg of 96% pure  $C_{70}$  and (vi) 57mg of 94% pure  $C_{70}$ . Fractions with >90% purity were satisfactory for the preparation of fullerene  $C_{70}$  derivatives. [Herrmann et al. *Helv Chim Acta* **78** 1673 1995; for column used see Tour above and below.] Fullerene  $C_{70}$  forms a nano adduct with 4,5-dimethoxy-1,2-quinonedimethane [Smith et al. *J Am Chem Soc* **117** 9359 1995, Tour *J Org Chem Perspective* **72** 7477 2007].

Tour and coworkers [Scrivens et al. *J Am Chem Soc* **114** 6939 1994] described a **gram-quantity purification procedure for  $C_{70}$  fullerene** where a slurry of alkaline decolourising carbon Norit-A (400g) and silica gel (800g, flash chromatography grade 60 of 230-240 mesh ASTM, 0.040-0.063mm particle size) in 1:1 toluene/ODCB (*o*-dichlorobenzene) was poured into a flash chromatography column (7cm in diameter and 120cm long, tape wrapped in case of cracking due to pressure and should be shielded) with a cotton plug at the bottom to form the stationary phase. The slurry was allowed to settle above the stationary phase and drained under a head of 15 psi of  $N_2$  pressure applied at the top of the column which should not be allowed to dry out. The stationary phase was 75cm long after settling. A solution of carbon arc soot-extracted [Scrivens & Tour *J Org Chem* **57** 6932 1992] crude fullerene (10.0g, 36%  $C_{70}$  by HPLC analysis) in 1:1 toluene/ODCB (666ml) was applied slowly at the top of the column and eluted with a 15 psi of  $N_2$  head pressure giving a flow rate of ~15ml/minute. Since more solvent was required, the tap at the bottom of the column was closed, the pressure was released, and more solvent was added. After the first colourless fraction (~2516ml), the second purple fraction (1520ml) of  $C_{60}$  fullerene was eluted and gave 5.97g of >99.9% pure  $C_{60}$  fullerene (by HPLC). Then the eluate became colourless again, but was followed by the red-brown colour of  $C_{70}$  fullerene when fraction 3 was collected and the mobile phase was replaced by pure ODCB. Fraction 3 (~750ml) contained a mixture of  $C_{60}/C_{70}$  (58:42, 1.3g) and was followed by a change of colour from red-brown to black indicating that pure ODCB had reached the bottom of the column. The black fraction 4 (750ml) was 90% enriched in  $C_{70}$  fullerene (0.65g), and the final fraction 5 (total 10L) contained 1.58g of  $C_{70}$  of >97% purity. The combined fractions weighed 9.5g (95% mass recovery). Additional column work of impure fractions could give ~3g of >97% pure  $C_{70}$  from 10g of crude material. The solubility of  $C_{70}$  in ODCB in saturated solutions appears to vary with temperature from 24mg/ml at 25° to >50mg/ml in hot ODCB which on standing overnight give an abundance of  $C_{70}$  as long crystals with 99.5% purity (by HPLC). The  $^{13}C$  NMR (125MHz,  $^*C_6H_6$ ) of  $C_{70}$  has  $\delta$  (relative peak heights) at 150.73 (4), 148.18 (11), 147.48 (5), 145.44 (9) and 130.94 (3) (compare with one peak at 142.68 for  $C_{60}$  fullerene previous entry).

**Physical properties of Fullerene  $C_{70}$ :  $C_{70}$  (5,6)-fullerene** [115383-22-7] **M 840.78, does not melt below 360°, and starts to sublime at 300° in vacuo**, and is now available commercially in a high state of purity. It is a reddish-brown solid but greenish black in thicker films. Solutions are port-wine red in colour. Mixtures of  $C_{60}$  and  $C_{70}$  are red due to  $C_{70}$  being more intensely coloured. It is less soluble than  $C_{60}$  in  $^*C_6H_6$  and also dissolves slowly.  $C_{70}$  gives orange-coloured solutions in toluene. Drying at 200-250° is not sufficient to remove all the solvent. Samples need to be sublimed to be free from solvent. [Taylor *J Chem Soc, Chem Commun* 1423 1990.] UV-Vis in hexanes:  $\lambda_{max}$  nm(log  $\epsilon$ ) 214(5.05), 235(5.06), 249sh(4.95), 268sh(4.78), 313(4.23), 330(4.38), 359(4.29), 377(4.45), 468(4.16), 542(3.78), 590sh(3.47), 599sh(3.38), 609(3.32), 623sh(3.09), 635sh(3.13) and 646sh(2.80).

IR (KBr):  $\nu_{max}$  1430 m, 1428m, 1420m, 1413m, 1133mw, 1087w, 795s, 674ms, 642ms, 5778s, 566m, 535ms and 458m  $cm^{-1}$ .

$^{13}C$  NMR [run in the presence of Cr(pentan-2,4-dione)<sub>3</sub> which induces a *ca* 0.12ppm shift in the spectrum]: Five signals with  $\delta$  at 150.07, 147.52, 146.82, 144.77 and 130.28, which are unaffected by proton decoupling.

$C_{70}$  fullerene is a nano-channel organic semiconductor [Newman et al. *Chem Mater* **16** 4436 2004].

**C<sub>76</sub> fullerene** [135113-15-4] **M 912.85, melts > 350°**. It is now available commercially. After the sequential removal of C<sub>60</sub> and C<sub>70</sub> fullerenes from soot extracts (see above) on gel permeation columns (e.g. Buckyclutcher 1 column), C<sub>76</sub> and higher fullerenes are obtained. These are further separated on a Trident-TriDNP functionalised silica column. After two HPLC runs on a C<sub>18</sub> reverse phase (Vydac 201 TP C<sub>18</sub>) column and eluting with 1:1 MeCN/toluene, pure C<sub>76</sub> fullerene is obtained. The identity is confirmed by HPLC/GPC system with Waters 600E UV/VIS detection, mass and NMR spectroscopy. [Seleque et al. In Kadish and Ruoff (Eds) *Fullerenes: Recent Advances in the Chemistry and Physics of Fullerenes and Related Materials* The Electrochemical Soc. Inc, Pennington, NJ, 1994 ISBN 1566770823, Diederich & Whetten *Acc Chem Res* **25** 119 1992, Diederich et al. *Science* **254** 1768 1991.]

**C<sub>78</sub> (C<sub>2v</sub>)-fullerene** [136316-32-0] **M 936.98, melts above 350°**. It is now available commercially. Pure material is obtained as in the previous purification and elutes after C<sub>76</sub> fullerene, followed by **C<sub>78</sub> (D<sub>3h</sub>)-fullerene**. The identities are confirmed by an HPLC/GPC system with Waters 600E UV/VIS detection, mass and NMR spectroscopy. [Seleque et al. In Kadish and Ruoff (Eds) *Fullerenes: Recent Advances in the Chemistry and Physics of Fullerenes and Related Materials* The Electrochemical Soc. Inc, Pennington, NJ, 1994 ISBN 1566770823, Diederich & Whetten *Acc Chem Res* **25** 119 1992, Diederich et al. *Science* **254** 1768 1991, MS and NMR: Taylor et al. *J Chem Soc, Chem Commun* 1043 1992.]

**C<sub>84</sub> fullerene** [135113-16-5] **M 1008.94, melts above 350°**. It is now available commercially. Pure material is obtained as in the previous purification and elutes after C<sub>78</sub> (D<sub>3h</sub>)-fullerene. It consists of at least two isomers. Common impurities are C<sub>82</sub> and C<sub>86</sub> fullerenes. The identities are confirmed by an HPLC/GPC system with Waters 600E UV/VIS detection, mass and NMR spectroscopy. [Seleque et al. In Kadish and Ruoff (Eds) *Fullerenes: Recent Advances in the Chemistry and Physics of Fullerenes and Related Materials* The Electrochemical Soc. Inc, Pennington, NJ, 1994 ISBN 1566770823, Diederich & Whetten *Acc Chem Res* **25** 119 1992, Diederich et al. *Science* **254** 1768 1991, Manolopoulos & Fowler *J Chem Phys* **96** 7603 1992.]

Higher Fullerenes, e.g. **C<sub>396</sub> fullerene** [175833-78-0] have also been isolated [*Chem Abstr* **124** 299339 1996.]

### FUNCTIONALISED FULLERENES.

A large number of functionalised fullerenes have been reported. They are synthesised by chemical reactions at the double bonds of the 'ball' to form anchors for further condensation with small or large molecules such as proteins, lipids, DNA etc. They find applications in a variety of industries including drugs and pharmaceutical industries and in medicine. They are of nano size, can circulate in the animal's body and can be used to deliver substances to targeted tissues. A few of these are commercially available in chemical catalogues and some are described here to show how fullerenes can be made to react with reagents.

**1,4-Bis(pentafluorobenzyl)[C<sub>60</sub>]fullerene {7,8-dihydro-7,8-bis(2,3,4,5,6-pentafluorophenyl)methyl}-[5,6]-fullerene-C60-I<sub>h</sub>}** [1260376-31-5] **M 914.6**. This bifunctional [C<sub>60</sub>]fullerene was prepared in an argon atmosphere by adding potassium metal (124mg, 3.19mmol) in one portion to a freeze-thawed degassed mixture of fullerene (1.0g, 1.93mmol) and 1-methylnaphthalene (5.93g, 4.1.7 mmol, 30 equivalents, see [90-12-0]) in THF (150ml). This produced a dark red solution after stirring at ~25° for 3 hours under argon. Pentafluorobenzyl bromide (3.63g, 13.9mmol, tenfold excess) is then added, stirring is continued for 8 hours, the reaction is stopped by addition of aqueous NH<sub>4</sub>Cl (0.5ml), the mixture is concentrated *in vacuo* down to ~10ml and the crude desired product is precipitated by addition of MeOH. It is purified by chromatography through silica gel and eluting first with CS<sub>2</sub>/hexane (1:1) then CS<sub>2</sub> to provide the *bis-perfluorobenzyl fullerene* (830mg, 55%) which is fully characterised by its spectroscopic properties. It is stable in air and in solution (e.g. CHCl<sub>3</sub>). For further purification preparative HPLC or GPC may be necessary. It is identified by investigations of dynamic light scattering (DLS), X-ray diffraction (XRD), differential scanning calorimetry (DSC), thermogravimetric analysis (TG-DTA), and of its electrochemical (OVP) properties. The data showed that the perfluoroaromatic rings interact in a face-to-face π-π manner with the [C<sub>60</sub>]fullerene surfaces and exhibit unique aggregation-deaggregation behaviour. These properties allow this fullerene to be used for high-performance organic photovoltaic devices. [see Y. Matsuo and coworkers in Li et al. *Chem Commun* **46** 8582 2010, Matsuo et al. *Synfacts* **2** 148 2011.] Note that the name within the chain brackets above is the name given by the *Chemical Abstract Service*.

**tert-Butyl (1,2-methanofullerene C<sub>60</sub>)-61-carboxylate [6,6-closed 1,2-dihydro-1,2-methanofullerene C<sub>60</sub>]-61-carboxylic acid tert-butyl ester** [150493-29-1] **M 834.8**. The crude *tert*-butyl ester was prepared as for the ethyl ester below and obtained in 25% yield as a 1:1:3 mixture of 6,6-closed, trans-5,6-open and cis-5,6-open esters. As for the diethyl ester below, the mixture (20mg) was equilibrated in boiling toluene to give pure 6,6-closed-*tert*-butyl ester (15mg 75%) which held toluene very strongly. It has UV/VIS with  $\lambda_{\max}$  nm( $\epsilon$ ) in toluene at 334 (40250), 406 (*sh* 3850), 429 (1800), 503 (1150), 593 (*br* 750); the IR (KBr) has strong bands at  $\nu_{\max}$  526, 1141, 1733 cm<sup>-1</sup> as well as 5 other medium-weaker bands; the <sup>1</sup>H NMR (500 MHz, in \*C<sub>6</sub>D<sub>6</sub>) has  $\delta$  at 4.38 (*s* 1 H), 1.51 (*s*, 9 H), and the <sup>13</sup>C NMR (125 MHz, CS<sub>2</sub>/(CD<sub>3</sub>)<sub>2</sub>CO 10:1) has  $\delta$  at 164.33(COO), 149.07—71.74 (32 fullerene resonance), 83.28 [COOC(CH<sub>3</sub>)<sub>3</sub>], 41.21 (CHCOO) and 28.58 [(CH<sub>3</sub>)<sub>3</sub>]. The FAB-MS has a peak at 834 (*M*<sup>+</sup>). [Isaacs et al. *Helv Chim Acta* **76** 1231 1993, Isaacs & Dieterich *Helv Chim Acta* **76** 2454 1993.]

**Diethyl (1,2-methanofullerene C<sub>60</sub>)-61,61-carboxylic acid [6,6-closed-1,2-dihydro-1,2-methanofullerene C<sub>60</sub>]-61,61-carboxylic acid diethyl ester** [155679-98-4] **M 878.8, m >270°**. If the <sup>1</sup>H NMR spectrum indicated the presence of isomeric esters then dissolve it in chlorobenzene (0.2g in 100ml) and heat it under reflux for 24 hours to convert the isomers to the more stable [6,6-closed]-ester. Column chromatography on silica and elution first with toluene/hexane (1:1) then toluene followed by recrystallisation from CHCl<sub>3</sub>/MeOH and drying (60°/0.1 Torr, 6 hours) provided the desired diester as a dark solid [*R*<sub>F</sub>: SiO<sub>2</sub> toluene is 0.50]. Store it at 2-8°. It has IR (KBr) with  $\nu_{\max}$  bands at 1061w, 1095m, 1186 (C<sub>60</sub>), 1206m, 1234s, 1266m, 1295m, 1428 (C<sub>60</sub>), 1745 (C=O) and 2979w cm<sup>-1</sup>. The <sup>1</sup>H NMR (200MHz; CDCl<sub>3</sub>) has  $\delta_{\text{H}}$  at 4.75 (q, *J* = 7Hz) and 1.53 (t, 6H, *J* = 7Hz); and the <sup>13</sup>C NMR (125MHz; CDCl<sub>3</sub>) has  $\delta_{\text{C}}$  at 163.61, 145.33—139.04 (16 peaks), 71.61, 63.42, 52.21, 14.22. The *di-tert-butyl ester* was similarly purified (see above). [Bingel *Chem Ber* **126** 1957 1993, Dieterich et al. *J Chem Soc, Perkin Trans II* 391 1994.]

**Diethyl (1,2-methanofullerene C<sub>70</sub>)-71,71-carboxylate [6,6-closed-1,2-dihydro-1,2-methanofullerene C<sub>70</sub>]-71,71-carboxylic acid diethyl ester** [153218-95-2] **M 998.9**. It was prepared by reaction of diethyl bromomalonate with fullerene C<sub>70</sub> in the presence of DBU in toluene (4 hours, ~25°), filtered and purified by chromatography through Kieselgel (0.063—0.2mm) by eluting with a gradient of toluene/*iso*-hexane (1/1 to 4/1). This gave the *diester* in 60% yield [*R*<sub>F</sub>: SiO<sub>2</sub> toluene is 0.50], with a 40% recovery of the fullerene. Store it at 2-8°. The <sup>1</sup>H NMR (360MHz; CDCl<sub>3</sub>) has  $\delta_{\text{H}}$  at 4.75 (q, *J* = 7.1Hz) and 1.46 (t, 6H, *J* = 7.1Hz); and the <sup>13</sup>C NMR (100MHz; CDCl<sub>3</sub>) has  $\delta_{\text{C}}$  at 163.45, 155.33—130.83 (34 peaks), 66.90, 66.24, 63.47, 37.22, 14.23. [Bingel *Chem Ber* **126** 1957 1993.]

**1,2-Dihydro-[1,2]fullereneC<sub>60</sub>[3,4]pyrrolidin-1-ylethoxyethoxyethylammonium bis-trifluoroacetate {2-[2-[2-(2'*H*-[5,6]fullereno-C<sub>60</sub>-I<sub>h</sub>-[1,9-*c*]pyrrol-1'(5'*H*)-yl)ethoxy]ethoxy]ethanamine bis-2,2,2-trifluoroacetate}** [C<sub>60</sub>=CH)<sub>2</sub>NH<sup>+</sup>-CH<sub>2</sub>CH<sub>2</sub>OCH<sub>2</sub>CH<sub>2</sub>OCH<sub>2</sub>CH<sub>2</sub>NH<sub>3</sub><sup>+</sup>. 2CF<sub>3</sub>COO<sup>-</sup>, C<sub>70</sub>H<sub>20</sub>O<sub>6</sub>N<sub>2</sub>F<sub>6</sub>] [356066-52-9 for mono(trifluoroacetate)] **M 1123.0**. *N*-Boc-aminoethoxyethoxyethylaminoacetic acid (423mg, 1.38mmol, see below in SWCNT[=CH)<sub>2</sub>N-CH<sub>2</sub>CH<sub>2</sub>O-CH<sub>2</sub>CH<sub>2</sub>O-CH<sub>2</sub>CH<sub>2</sub>NH<sub>3</sub><sup>+</sup>. HCl]<sub>n</sub>), paraldehyde (456mg, 3.45mmol) and fullerene C<sub>60</sub> (500mg, 0.69mmol) in toluene (300ml) are refluxed for 1 hour. After cooling to ~25° the mixture is applied onto a column of silica gel (NM Kieselgel 60, 70-320 mesh) and eluted with 9:1 toluene/EtOAc to give the analytically pure (elemental C, H, N) C<sub>60</sub>=*N*-Boc-pyrrolidinyl derivative (212mg, 0.29mmol, 31%). It has IR-DRIFT (KBr) with bands at  $\nu_{\max}$  545, 794, 1121, 1168, 1457, 1498, 1710, 2853, 2921, 3444 cm<sup>-1</sup>; the UV-VIS (cyclohexane) has  $\lambda_{\max}$  at 254, 309, 429, 466sh, 546sh, 703 nm; the <sup>1</sup>H NMR (200 MHz, CDCl<sub>3</sub>, TMS) has  $\delta$  at 5.08 (bs, 1H), 4.50 (s, 4H), 4.05 (t, *J* = 5.5Hz, 2H), 3.77 (m, 4H), 3.60 (t, *J* = 5.3Hz, 2H), 3.36 (m, 4H), 1.44 (s, 9H); the <sup>13</sup>C NMR (50 MHz, CDCl<sub>3</sub>, TMS) has  $\delta$  at 156.0, 155.1, 147.3, 146.3, 146.1, 145.7, 145.4, 145.3, 144.6, 143.1, 142.7, 142.3, 142.1, 141.9, 140.2, 136.2, 79.3, 70.9, 70.7, 70.6, 70.5, 68.6, 54.4, 28.6; and the ES-MS showed a peak at *m/z* 995 (MH<sup>+</sup>).

The *N*-Boc group is removed by treating the pure C<sub>60</sub>=*N*-Boc-pyrrolidinyl derivative (150mg, 0.14mmol) in CH<sub>2</sub>Cl<sub>2</sub> (3ml) with CF<sub>3</sub>COOH (3ml), and stirring for 3 hours. The solvent is removed *in vacuo*, the residue is washed with toluene and dried *in vacuo* to give the analytically pure (elemental C, H, N) functionalised title fullerene C<sub>60</sub>=*N*-pyrrolidinyl bis-trifluoroacetate salt (168mg, 0.15mmol, ~99%). This has IR-DRIFT (KBr) with bands at  $\nu_{\max}$  525, 715, 1130, 1190, 1480, 1515, 1680, 2890 cm<sup>-1</sup>; UV-VIS (cyclohexane) with  $\lambda_{\max}$  at 331, 430, 484sh, 684 254, 309, 429, 466sh, 546sh, 703 nm; the <sup>1</sup>H NMR (200 MHz, DMSO-*d*<sub>6</sub>, TMS) has  $\delta$  at

7.81 (brs, 3H), 4.58 (s, 4H), 3.93 (t,  $J = 5.5\text{Hz}$ , 2H), 3.71-3.43 (m, 6H), 3.32 (m, 2H), 2.95 (m, 2H); the  $^{13}\text{C}$  NMR (50 MHz, DMSO- $d_6$ , TMS) has  $\delta$  at 156.0, 147.4, 146.7, 146.4, 146.2, 146.0, 145.5, 145.4, 144.7, 143.3, 142.8, 142.5, 142.2, 142.0, 140.2, 136.4, 135.4, 71.5, 70.5, 70.1, 68.0, 67.5, 54.1; and the ES-MS showed a peak at  $m/z$  896 ( $\text{MH}^+$ ). Related compounds with a two carbon atoms and a thirteen carbon atom chain between the pyrrolidine nitrogen atom and the terminal amino nitrogen atom have also been prepared. The  $\omega$ -primary amino groups at the end of the chains were derivatised (e.g. with 12-acetylsulfanildodecanoic acid in the presence of EDCI and HOBt for self-assembled monolayers (SAMs) purposes, or various fluorescent indole-2-carboxylic acids) by standard procedures. Useful applications for nano materials science and nano medicinal chemistry (e.g. by linking to DNAs or other biological materials) have been made possible with such fullerene precursors by M. Prato and coworkers. [Kordatos et al. *J Org Chem* **66** 4915 2001.]

**Ethyl (1,2-methanofullerene  $\text{C}_{60}$ )-61-carboxylate [6,6-closed 1,2-dihydro-1,2-methanofullerene  $\text{C}_{60}$ ]-61-carboxylic acid ethyl ester** [50493-27-9] **M 806.8**. Fullerene  $\text{C}_{60}$  reacts with an equimolar amount of ethyl diazoacetate in boiling toluene for 7 hours to provide a 30% yield of a 1:1:3 mixture of 6,6-closed : trans-5,6-open : cis-5,6-open *tert*-butyl (1,2-methanofullerene  $\text{C}_{60}$ )-61-carboxylate. This mixture was isolated by applying the residual solid from the reaction onto a silica gel column which was first eluted with hexane to remove fullerene  $\text{C}_{60}$  then with toluene-hexane (1:1) to provide the mixture at  $R_F$  ca 0.43. The mixture was isomerised almost entirely to the more stable 6,6-close ester by refluxing it (35mg) in toluene (105ml) for 24 hours when the initial purple solution turned pink in colour. Chromatography on silica gel as before provided a pink-red product eluting at the same  $R_F$  ca 0.43 which was then evaporated to dryness. The black microcrystalline residue was washed with  $\text{Et}_2\text{O}$  and dried at  $25^\circ/0.1$  Torr (31mg, 89%). It holds residual toluene tenaciously. It has UV/VIS with  $\lambda_{\text{max}}$  nm( $\epsilon$ ) in toluene at 331 (40250), 395 (*sh* 5250), 404 (*sh* 3300), 417 (1900), 429 (2250), 495 (*br* 1250); the IR (KBr) has strong bands at  $\nu_{\text{max}}$  527, 1155, 1185, 1742  $\text{cm}^{-1}$  as well as 6 other medium to weak bands; the  $^1\text{H}$  NMR (400 MHz, in  $^*\text{C}_6\text{D}_6$ ) has  $\delta$  at 4.31 (*s* 1 H), 4.10 (*q*,  $J = 7.1\text{Hz}$ , 2 H), 1.06 (*t*,  $J = 7.1\text{Hz}$ , 3 H), and the  $^{13}\text{C}$  NMR (125 MHz,  $\text{CS}_2/(\text{CD}_3)_2\text{CO}$  10:1) has  $\delta$  at 165.44 ( $\text{COOEt}$ ), 149.07—71.59 (32 fullerene resonance), 62.70 ( $\text{CH}_3\text{CH}_2$ ), 40.01 ( $\text{CHCOOEt}$ ) and 14.99 ( $\text{CH}_3\text{CH}_2$ ). The FAB-MS has an  $m/z$  peak at 807 ( $M^+$ ), and the elemental analysis is consistent with  $\text{C}_{62}\text{H}_6\text{O}_2$ . [Isaacs et al. *Helv Chim Acta* **76** 1231 1993, Isaacs & Dieterich *Helv Chim Acta* **76** 2454 1993.]

**Fullerene  $\text{C}_{60}$ - $\gamma$ -lactone esters.** G-W. Wang and coworkers [Li et al. *Org Lett* **21** 4896 2010] have improved the condensation yields of diethyl malonate esters with [ $\text{C}_{60}$ ]fullerene to form the disubstituted fused  $\gamma$ -lactone esters by using  $\text{Fe}(\text{ClO}_4)_3$  instead of  $\text{Mn}(\text{OAc})_3$  for assistance (catalysis). Although the yields are still low, they are however, considerably higher when mediated by the iron perchlorate, and the products are cleaner. The solvent is *o*-dichlorobenzene and the ratios of reagents are 1:2:2:20 for [ $\text{C}_{60}$ ]fullerene:EtOCOCHR $\text{COOEt}$ : $\text{Fe}(\text{ClO}_4)_3$ : $\text{Ac}_2\text{O}$ . The following results were obtained: **R** ester (reaction temperature, reaction time, **yield** of  $\gamma$ -lactone ester, consumed fullerene): **Me** ( $80^\circ$ , 20 minutes, **34%**, 55%); **Et** ( $80^\circ$ , 20 minutes, **37%**, 71%); **PhCH<sub>2</sub>** ( $80^\circ$ , 30 minutes, **27%**, 61%); **Ph\*** ( $0^\circ$ , 180 minutes, **12%**, 67%); **Br** ( $80^\circ$ , 30 minutes, **22%**, 56%); and **EtOCO** ( $110^\circ$ , 20 minutes, **16%**, 53%); \* reactant ratio was 1:2:2:50. The structures of the lactones are consistent with their HRMS,  $^1\text{H}$  NMRs,  $^{13}\text{C}$  NMRs, FT-IRs and UVs. It should be possible to convert these lactones into hydrofullerenes, fullerene hemiacetals, fullerene hemiketals and fullerenols. [Li et al. *Synfacts* **1** 38 2011.]

**Fullerene  $\text{C}_{60}$ /Poly(bisphenol A)carbonate.**  $\text{C}_{60}$  is a known 'radical sponge' [Morton et al *J Am Chem Soc* **114** 5454 1992, McEwen et al. *J Am Chem Soc* **114** 4412 1992]. It reacts readily with free radicals and undergoes photolysis to generate  $\text{C}_{60}$  radical ions. Thus irradiating a mixture of  $\text{C}_{60}$  and poly(bisphenol A)carbonate polymer (PC, [25037-45-0]) at room temperature with a conventional UV lamp, or warming the mixture at  $60^\circ$  with AIBN (a radical initiator, see [78-61-1]) results in fullerenated-PC. By controlling the ratio of reagents (i.e. 5.4mg  $\text{C}_{60}$ /500mg PC in 1,1,2,2-tetrachloroethane), a  $\text{C}_{60}$ /PC can be obtained with a  $\text{C}_{60}$  content as high as 6.3% (i.e.  $>2$   $\text{C}_{60}$  per PC chain) in  $\sim 99\%$  yield. Multi-additions of PC did not lead to heavy cross-linking. The fullerenated polymer is a brown powder which is soluble in common organic solvents such as THF and  $\text{CHCl}_3$ . When the polymer is dissolved in THF (a solvent that does not dissolve  $\text{C}_{60}$ ) and the solution is precipitated into hexane through a filter, no particles are left on the filter, and the hexane supernatant is colourless. This shows that all the  $\text{C}_{60}$  is incorporated into the polymer. The precipitate is then collected and dried under high vacuum to constant weight. The  $\text{C}_{60}$  content is 1.16 wt%, has  $M_n \sim 27,000$ ; the UV (0.3mg/ml in THF) has  $\lambda_{\text{max}}$  at 238.9, 259.4, 262.0, 287.2, 329.5sh nm, and the IR (KBr) has  $\nu_{\text{max}}$  at 3040w, 2968s,

1778vs, 1602m, 1506s, 1410m, 1386w, 1364m, 1230vs, 1194s, 1162s, 1080s, 1014s, 888m, 830s, 768m, 556s, 528w  $\text{cm}^{-1}$ . This fullerenation provides a versatile synthetic tool for making processable fullerene polymers and opens opportunities for exploring fullerene-based speciality materials with properties not found in the unconjugated polymers. [Tang et al. *Macromolecules* **30** 2848 1997.]

**(1,2-Methanofullerene  $\text{C}_{60}$ )-61-carboxylic acid [6,6-closed-1,2-dihydro-1,2-methanofullerene  $\text{C}_{60}$ ]-61-carboxylic acid** [155116-19-1] **M 778.7**. Attempted hydrolysis of the ethyl ester (see [155679-98-4] above) was unsuccessful, however, treatment of the 6,6-closed-ethoxycarbonylmethyl ester with  $\text{BBr}_3$  in  $^*\text{C}_6\text{H}_6$  under  $\text{N}_2$  and stirring for 9 hours gave an 82% yield of the acid. Similarly the *tert*-butyl ester (see [150493-29-1] above), but in refluxing toluene for 8 hours, gave a 77% yield of the acid. After hydrolysis, the acid was purified by dissolving it in  $\text{CHCl}_3/\text{Me}_2\text{SO}$ , re-precipitating with hexane and drying overnight at  $25^\circ/0.1$  Torr, or at  $60^\circ/0.1$  Torr for 12 hours. The brown or black solid 6,6-closed-acid was mostly insoluble in common solvents and slightly soluble in bromobenzene and 1,2-dichlorobenzene. This 6,6-closed acid (i.e. cyclopropane acid) has IR (KBr) with strong bands  $\nu_{\text{max}}$  at 525, 699, 810, 847, 1013, 1426, 1785, 1794  $\text{cm}^{-1}$  and twenty other medium to weak bands. The  $^1\text{H}$  NMR (300 MHz, in  $\text{CHCl}_3/\text{Me}_2\text{SO}$ , 1:1) has one signal for the cyclopropane H at 5.13 ppm, the  $^{13}\text{C}$  NMR consists of 32 signals between  $\delta$  136 and 167, and signals at  $\delta$  40.34 and 71.66. Elemental analysis is consistent with the formula  $\text{C}_{62}\text{H}_2\text{O}_2 \cdot 0.5\text{Me}_2\text{SO}$ .

With alcohols in the presence of dicyclohexylcarbodiimide, 1-*H*-benzotriazol-1-ol and a base [e.g. 4-( $\text{Me}_2\text{N}$ ) $\text{C}_6\text{H}_4\text{N}$  or  $\text{Et}_3\text{N}$ ] in bromobenzene, the corresponding esters were obtained. Similarly peptides with *methyl glycinate* and *methyl-L-phenylalaninate* were obtained by using the corresponding amino acid esters. [Isaacs & Diederich *Helv Chim Acta* **76** 2454 1993, Diederich et al. *Chem Soc Rev* **23** 243 1994.]

**6,9,12,15,18-Pentamethyl-1,6,9,12,15,18-hexahydro( $\text{C}_{60}$ -I<sub>h</sub>)fullerene** [244229-54-7] **M 796.7**. Preparation of these substituted fullerenes should be carried out in Schlenk-type equipment under an inert atmosphere ( $\text{N}_2$  or argon), in dry solvents and reagents (at least in the early stages of the reactions), and any oxygen or air in solvents should be flushed out by bubbling dry inert gas through them. Microcrystalline [ $\text{C}_{60}$ ]fullerene (2.0g, 2.78mmol, [99685-96-8]) in 1,2-dichlorobenzene (90ml), cooled in an ice-water bath, stirred under reduced pressure (1mm) to remove dissolved  $\text{O}_2$ , and warmed to  $\sim 25^\circ$ , is added during 15 minutes to a stirred mixture of  $\text{CuBr} \cdot \text{SMe}_2$  (6.84g, 33.3mmol, use an efficient fume cupboard) in THF (47ml) at  $\sim 25^\circ$  to which is previously added  $\text{MeMgBr}$  in THF (3 M, 11.1ml, 33.3mmol) followed by DMI (3.62ml, 33.3mmol, see [80-73-9]) and rapidly warmed to  $\sim 35^\circ$  within 5 minutes. The colour of the white suspension soon turned to dark brown. After stirring at  $35^\circ$  for 40 minutes under a flow of  $\text{N}_2$  (note that some liberation of ethane may occur), a degassed saturated aqueous  $\text{NH}_4\text{Cl}$  solution (3.0ml) is added *via* a syringe, the colour of the solution changes from dark brown to red-brown and the mixture is stirred under a vacuum (*ca* 1mm) at  $\sim 25^\circ$  to remove THF and  $\text{Me}_2\text{S}$  and reduce it to half its volume. This is diluted with degassed toluene (200ml) and subjected to silica gel flash chromatography (45 x 200mm size, using 90g of silica gel 230-450 mesh) with toluene as eluent (total volume 100ml). It should be done as rapidly as possible, as care should be taken to avoid oxygen and formation of  $\text{C}_{60}\text{Me}_5\text{O}_n\text{H}$  ( $n = 2-3$ ). The vermilion eluate is evaporated at  $\sim 40^\circ/10\text{mm}$  then at  $80^\circ$  (to remove 1,2-dichlorobenzene) until solid begins to appear on the sides of the flask.  $\text{N}_2$  is allowed to enter the evacuated flask and degassed MeOH is added along the inside wall of the flask, whereby the mixture becomes cloudy, and MeOH ( $\sim 400\text{ml}$  total) is added until precipitation is complete. The solid is filtered off, washed with MeOH (5 x 10ml) and hexane (3 x 10ml) and dried *in vacuo* (1mm) to give red microcrystals of pentamethylfullerene (2.08g, 94%) of  $\sim 91\%$  purity. Purity and/or purification is carried out using a Buckyprep or ODS column (4.6 x 150mm, flow rate 1ml/minute) and eluting with toluene/*i*-PrOH (7:3) or (3:7) respectively. The solid should be stored in an inert atmosphere, as on storage in air it deteriorates slowly over several months, and in solution in the presence of air its purity decreases by 80% in 24 hours. It has IR (neat) with  $\nu_{\text{max}}$  bands at 2973, 2912, 2858, 1572, 1546, 1518, 1459, 1370, 1324, 1286, 1265, 1234, 1169, 1145, 1128, 792, 747, 684  $\text{cm}^{-1}$ ; the  $^1\text{H}$  NMR (500 MHz,  $\text{CS}_2/(\text{CD}_3)_2\text{CO}$  5%) has  $\delta$  at 2.34 (s, 6H), 2.35 (s, 6H), 2.46 (s, 3H), 4.50 (s, 1H,  $\text{C}_{60}\text{-H}$ ); and the  $^{13}\text{C}$  NMR (100 MHz,  $\text{CS}_2/(\text{CD}_3)_2\text{CO}$  5%) has  $\delta$  at 27.23 (2C), 27.61 (2C), 33.14 (1C), 51.37 (1C), 51.45 (2C), 53.51 (2C), 59.75 (1C), 143.61 (2C), 144.12 (2C), 144.48 (2C), 144.53 (2C), 144.77 (2C), 144.89 (4C), 145.20 (2C), 145.42 (2C), 145.87 (2C), 145.96 (2C), 146.98 (1C), 147.14 (2C), 147.24 (2C), 148.03 (2C), 148.12 (2C), 148.28 (3C), 148.54 (2C), 148.60 (2C), 148.91 (4C), 149.10 (2C), 150.12 (2C), 154.27 (2C), 154.37 (2C), 154.62 (2C), 157.76 (2C). [Matsuo, Mueamatsu, Tahara, Koide and Nakamura *Org Synth* **83** 80 2006, Matsuo et al. *Functional Organic Materials* 58-80 2007.]

The procedure described above is unique as all five substituents are symmetrically placed on the bridgehead carbons of five six-membered rings surrounded by a fused five membered cyclopentadiene ring (X-ray evidence). Similar reactions also produce very high yields of fullerenes with *five*  $C_6H_5$ , *five*  $4-CF_3C_6H_5$ , *five*  $4-MeOC_6H_4$ , *five*  $4-ClC_6H_5$ , *five*  $4-PhC_6H_5$ , *five* (*E*)-1-propenyl, *five* (*Z*)-1-propenyl and *five* (*E*)-2-phenylethenyl groups all symmetrically placed as in the pentamethyl derivative above. [see Matsuo, Mueamatsu, Tahara, Koide and Nakamura *Org Synth* **83** 80 2006 and references therein.]

The hydrogen atom of the central cyclopentadiene ring can be displaced by potassium with *t*-BuOK to form the  $K(C_{60}Me_5)$  complex in which the potassium atom can then be displaced to form iridium complexes such as  $Ir(\eta^5-C_{60}Me_5)(CO)_2$  [Matsuo, Iwashita and Nakamura *Organometallics* **24** 89 2005], and with rhodium to form  $Rh(\eta^5-C_{60}Me_5)(CO)_2$  [Sawamura, Kuninobu and Nakamura *J Am Chem Soc* **122** 12407 2000], structures which are supported by X-ray structure analyses. The same cyclopentadiene can complex with Fe and cyclopentadiene (Cp) to form a hybrid of 'buckyferrocene'  $Fe(C_{60}Me_5)Cp$  [Sawamura et al. *J Am Chem Soc* **124** 9354 2002, Nakamura *Pure Appl Chem* **75** 427 2003].

***N*-Tosyl[1,2]-aziridino[ $C_{60}$ ]fullerene {2a[(4-methylphenyl)sulfonyl]-2a-aza-1,2(2a)-homo[5,6]fullerene- $C_{60}$ -I<sub>h</sub> [226909-63-3] M 889.0.** This useful fullerene precursor is readily prepared. In a dry Schlenk flask with flushing argon is added CuCl (1.2mg, 12μmol), *o*-dichlorobenzene (40ml) and 2,6-toluidine (2.0 μL, 24 μmol), then stirring at ~25° for 30 minutes, followed by adding  $C_{60}$  fullerene (432mg, 600μmol) and TsN=IPh (224mg, 600μmol, see synthesis below\*). The mixture is stirred ~25° for 12 hours and purified by flash chromatography through silica gel (toluene/hexane 1.2 ~ 1.1) to provide the pure aziridinofullerene (228mg, 43%) as a dark brown solid [and recovered 185mg, 43%, of unreacted  $C_{60}$  fullerene]. It has <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>/CS<sub>2</sub> = 1:1, TMS) with δ at 2.56 (s, 3H), 7.50 (d, *J* = 8.3Hz, 2H), 8.19 (d, *J* = 8.3Hz, 2H); the <sup>13</sup>C NMR (100 MHz, CDCl<sub>3</sub>, CHCl<sub>3</sub> at δ 77.0 standard) has δ at 21.75, 79.69, 128.44, 129.93, 135.63, 140.75, 141.20, 141.71, 142.02, 142.63, 142.94, 142.99, 143.12, 143.74, 143.81, 144.01, 144.36, 144.83, 144.89, 144.97, 145.14, 145.34; and the HRMS (ESI-TOF; negative) showed a peak at *m/z* 889.0205, and 889.0203 is the calculated value for  $C_{67}H_7NO_2S$  (M<sup>-</sup>). Note that other Cu catalysts and other pyridine bases resulted in lower yields of this reaction. Itami and coworkers [Nambo et al. *J Am Chem Soc* **133** 2402 2011] developed the use of this aziridinofullerene as a versatile platform for preparing a variety of functionalised fullerenes. Thus it reacts with aryl and heteroaryl compounds (5% TfOH, 1,2-Cl<sub>2</sub>C<sub>6</sub>H<sub>4</sub>, 100°, 12 hours) to replace the 1,2-aziridine by two aryl or heteroaryl groups to form 1,4-disubstituted fullerenes in over 80% yields; it reacts with bifunctional nucleophiles of the type R-Z(H)=Y(X-H)-R' (10% TfOH, 1,2-Cl<sub>2</sub>C<sub>6</sub>H<sub>4</sub>, 100°, 12 hours) to form 1,2-disubstituted fullerenes (1,2-disubstituted fullerenes fused with a 5-membered ring where the H's are replaced by bonds with C1 and C2 of the fullerene), such as 2,3-furano, 2,3-pyrrolo, 2,3-thiazolo-, 1,2-cyclic [1,3,2]-dioxaborolan- fullerenes in over 60% yields; it reacts with 2,2'-bithiophenes in various ways, and undergoes formal [2+2] cycloaddition reactions with 1,2-[bis(*p*-methoxyphenyl)acetylene (10% TfOH, 1,2-Cl<sub>2</sub>C<sub>6</sub>H<sub>4</sub>, 100°, 12 hours) to form a 3,4-adduct (cyclobutene) which retains the 1,2-aziridino moiety in 81% yields. Some of the structures were supported by X-ray crystal structure analysis.

\*[*N*-(*p*-Toluenesulfonyl)imino]phenyliodinane (TsN=IPh) [55962-05-5] M 373.1. Toluene-*p*-sulfonamide (3.42g, 20mmol) and diacetoxyiodobenzene (6.4g, 20mmol, see [2340-34-4]) are added to a solution of KOH (2.8g, 50mmol) dissolved in MeOH (80ml) at 0°, and then stirred at 25° for 3 hours. The mixture is poured into distilled water at 0°, kept at 4° overnight, the solid is filtered off, drained and recrystallised from hot MeOH (20ml) to give TsN=IPh (2.6g, 35%). It has <sup>1</sup>H NMR (200 MHz, DMSO-*d*<sub>6</sub>, TMS) with δ at 7.80-7.73 (m, 2H), 7.56-7.48 (m, 3H), 7.40-7.31 (m, 2H), 7.15-7.10 (m, 2H), 2.34 (s, 3H). [Heuss et al. *Inorg Chim Acta* **342** 301 2003.]

**2,5,10-Triphenyl-2,5,6,10-tetrahydro( $C_{70}$ -I<sub>h</sub>)fullerene [ $C_{70}$ (4-PhC<sub>6</sub>H<sub>4</sub>)<sub>3</sub>H] [244237-40-9] M 1073.0.** When a procedure similar to the preparation of  $C_{60}Me_5H$  above is applied to fullerene- $C_{70}$  only three substituents are inserted. A suspension of CuBr.SMe<sub>2</sub> (374mg, 1.82mmol, 30 equivalents) in THF (23.0ml) is treated with PhMgBr (0.98M, 1.86ml, 1.82mmol, 30 equivalents) and stirred at 28° for 20 minutes. To the resulting yellow suspension is added a degassed solution of  $C_{70}$  (49.6mg, 59μmol) in 1,2-dichlorobenzene (25ml) and stirring is continued for 24 hours. The reaction is treated with 5% aqueous HCl, the organic layer is washed with H<sub>2</sub>O, brine, dried (MgSO<sub>4</sub>), evaporated to a small volume and diluted with MeOH to give a dark brown precipitate which is washed thoroughly with MeOH, Et<sub>2</sub>O, H<sub>2</sub>O again and dried *in vacuo* to give  $C_{70}Ph_3H$  (61.2mg, 95%,

96% purity, cf C<sub>60</sub>Me<sub>5</sub>H above). The <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>) has δ at 7.8-7.78 (m, 2H), 7.74-7.70 (m, 2H), 7.61-7.57 (m, 3H), 7.39-7.23 (m, 8H), 4.43 (s, 1H); and the <sup>13</sup>C NMR (100 MHz, CDCl<sub>3</sub>-CS<sub>2</sub>) has δ at 160.70, 155.67, 155.07, 153.80, 152.62, 153.14, 152.62, 152.19, 150.16, 149.87, 149.57, 149.42, 149.39, 149.17, 149.08, 148.95, 148.82, 148.68, 148.59, 148.30, 148.21, 148.09, 147.92, 147.88, 147.77, 147.68, 147.18, 147.06, 147.00, 146.65, 146.61, 146.44, 146.23, 146.18, 145.84, 145.64, 145.51, 145.32, 145.06, 145.03, 144.92, 144.88, 144.74, 144.48, 144.15, 143.97, 143.43, 142.99, 142.81, 142.21, 142.18, 140.50, 140.40, 139.54, 139.20, 138.33, 136.87, 133.08, 131.96, 131.93, 131.82, 131.72, 131.59, 131.43, 131.43, 131.41, 130.65, 128.96, 128.88, 128.78, 128.16, 128.04, 127.71, 127.60, 127.47, 127.27, 127.15, 126.70, 126.42, 56.23, 56.19, 55.5; and the APCI-MS has *m/z* 1072 [(M - H)<sup>-</sup>]. Similarly prepared are C<sub>70</sub>Me<sub>3</sub>H, C<sub>70</sub>(4-PhC<sub>6</sub>H<sub>4</sub>)<sub>3</sub>H, C<sub>70</sub>(4-ClC<sub>6</sub>H<sub>4</sub>)<sub>3</sub>H, and C<sub>70</sub>(1-naphthyl)<sub>3</sub>H. [Sawamura et al. *J Mater Chem* **12** 2109 2002, cf Matsuo, Mueamatsu, Tahara, Koide and Nakamura *Org Synth* **83** 80 2006 and references therein.] C<sub>70</sub>(4-CF<sub>3</sub>C<sub>6</sub>H<sub>4</sub>)<sub>3</sub>H is also prepared similarly and is believed to proceed by formation of [(4-CF<sub>3</sub>C<sub>6</sub>H<sub>4</sub>)<sub>2</sub>Cu<sup>-</sup>] from the reaction between the arylMgBr and CuBr.SMe<sub>2</sub> which attacks successively three six-membered rings around a cyclopentadiene ring to give the intermediate C<sub>70</sub>(4-CF<sub>3</sub>C<sub>6</sub>H<sub>4</sub>)<sub>3</sub>Cu-Ar which decomposes on addition of acid or NH<sub>4</sub>Cl to provide the desired C<sub>70</sub>(4-CF<sub>3</sub>C<sub>6</sub>H<sub>4</sub>)<sub>3</sub>H. When the latter, in THF-*d*<sub>8</sub>, is treated with 1 equivalent of *t*-BuOK or TIOEt at 25°, the colour changes from reddish-brown to dark red to provide K[η<sup>5</sup>-C<sub>70</sub>(4-CF<sub>3</sub>C<sub>6</sub>H<sub>4</sub>)<sub>3</sub>] {whose <sup>1</sup>H NMR (400 MHz, THF-*d*<sub>8</sub>) has δ at 8.07-8.05 (m, Ar-H, 6H), 7.57-7.54 (m, ArH, 6H); and the <sup>13</sup>C NMR (100 MHz, THF-*d*<sub>6</sub>) has δ at 166.18, 160.50, 153.30, 151.99, 151.04, 150.32, 149.79, 149.77, 149.17, 148.88, 148.82, 148.48, 148.44, 148.26, 147.14, 146.90, 146.81, 146.37, 146.19, 146.07, 145.72, 145.61, 145.43, 144.71, 142.53, 142.28, 137.87, 136.81, 143.54, 134.46, 133.24, 132.92, 132.60, 129.36-129.23 (m), 128.93, 125.80-125.77 (m), 125.6 (q, *J* = 271.19Hz), 121.07, 61.06, 59.11}, or Tl[η<sup>5</sup>-C<sub>70</sub>(4-CF<sub>3</sub>C<sub>6</sub>H<sub>4</sub>)<sub>3</sub>] {whose <sup>1</sup>H NMR (400 MHz, THF-*d*<sub>8</sub>) has δ at 8.09-8.07 (m, Ar-H, 6H), 7.59-7.53 (m, ArH, 6H)} respectively [Sawamura, Iikura, Hirai and Nakamura *J Am Chem Soc* **120** 8285 1998].

**1,4,11,15,30-Pentakis(4-hydroxyphenyldimethylsilylmethyl)-2H-1,2,4,11,15,30-hexahydro-(60)fullerene {4-HOC<sub>6</sub>H<sub>4</sub>Si(Me)<sub>2</sub>CH<sub>2</sub>]<sub>5</sub>-2H-1,2,4,11,15,30-hexahydro-(C<sub>60</sub>-I<sub>h</sub>)fullerene, 1,7,8,11,24,27-hexahydro-1,7-, 11,24,27-pentakis(dimethyl 4-hydroxyphenylsilyl)methyl-[5,6]fullerene-C<sub>60</sub>-I<sub>h</sub>}** [658080-04-7] **M 1549.1.**

This functionalised fullerene can be used as an example of a molecule to which long chains can be coupled for specialised purposes. Typically, using Schlenk equipment under N<sub>2</sub> or argon in strict absence of H<sub>2</sub>O, the protected Grignard compound Me<sub>2</sub>(4-tetrahydropyranyloC<sub>6</sub>H<sub>4</sub>)SiCH<sub>2</sub>MgCl (0.656M in THF, 13.0ml, 9.84mmol) is added to a purple suspension of a white powder of CuBr.SMe<sub>2</sub> (3.00g, 14.6mmol) and microcrystalline [C<sub>60</sub>]fullerene (400mg, 0.555mmol) in 1,2-dichlorobenzene (80ml), and stirred at 25° for 1 hour. The mixture is treated with saturated aqueous NH<sub>4</sub>Cl (0.5ml), concentrated *in vacuo* to ca 60ml and diluted with toluene. The brown mixture is applied onto a silica column and washed with toluene (~100ml, i.e. until the effluent becomes yellow), followed by EtOAc/toluene (3:97) and the effluent is collected until its colour is pale yellow. This is evaporated *in vacuo* to a small volume and MeOH is added rapidly to precipitate a brown powder which is collected under N<sub>2</sub>, dissolved in MeOH/toluene (1:1, 46ml) and TsOH.H<sub>2</sub>O (92mg, 0.48mmol) is added to it. After stirring for 1 hour at 25°, the mixture is neutralised with NaHCO<sub>3</sub>, the solvent is evaporated, the residue is dissolved in MeOH/toluene (1:9, ~30ml), filtered from some insoluble material and evaporated *in vacuo*. The crude residue is purified by preparative HPLC (Nomura Chemical RPFullerene, with toluene/MeOH 1:9 as eluant) to give on evaporation the desired fullerene as an orange powder (99.5mg, 0.064mmol, 12% yield). Its <sup>1</sup>H NMR (400 MHz, acetone-*d*<sub>6</sub>, TMS) has δ at 7.32-7.28 (m, 8H), 7.23 (d, *J* = 8.0Hz, 2H), 6.69-6.64 (m, 10H), 4.55 (s, 1H), 2.38 (s, 2H), 2.31 (d, *J* = 14.4Hz, 2H), 2.23 (d, *J* = 14.4Hz, 2H), 2.11 (d, *J* = 14.8Hz, 2H), 2.05 (d, *J* = 14.8Hz, 2H), 0.36 (s, 6H), 0.35 (s, 6H), 0.34 (s, 6H), 0.33 (s, 6H), 0.27 (s, 6H); and the <sup>13</sup>C NMR (100 MHz, acetone-*d*<sub>6</sub>) has δ at 159.84, 159.81, 158.36, 155.22, 155.18, 154.80, 150.53, 149.13, 149.19, 149.05, 148.74, 148.66, 148.41, 148.18, 148.70, 147.66, 147.30, 146.97, 146.52, 146.22, 145.93, 145.24, 144.07, 143.53, 143.49, 142.76, 136.07 (C<sub>6</sub>H<sub>4</sub>), 136.03 (C<sub>6</sub>H<sub>4</sub>), 127.99 (C<sub>6</sub>H<sub>4</sub>), 127.84 (C<sub>6</sub>H<sub>4</sub>), 118.89 (C<sub>6</sub>H<sub>4</sub>), 115.92 (C<sub>6</sub>H<sub>4</sub>), 115.87 (C<sub>6</sub>H<sub>4</sub>), 115.82 (C<sub>6</sub>H<sub>4</sub>), 55.66 (CCH<sub>2</sub>SiMe<sub>2</sub>), 54.11 (CCH<sub>2</sub>SiMe<sub>2</sub>), 53.69 (CCH<sub>2</sub>SiMe<sub>2</sub>), 31.20 (C<sub>60</sub>CCH<sub>2</sub>Si), 30.39 (C<sub>60</sub>CCH<sub>2</sub>Si), 30.35 (C<sub>60</sub>CCH<sub>2</sub>Si), -0.22 (SiMe<sub>2</sub>), -0.30 (SiMe<sub>2</sub>), -0.34 (SiMe<sub>2</sub>), -0.47 (SiMe<sub>2</sub>); the HRMS (APCI+) has calculated for C<sub>105</sub>H<sub>67</sub>Si<sub>5</sub>O<sub>5</sub> (M-2H)<sup>+</sup> 1547.3835, and the found mass is 1547.3840.

This fullerene now has five phenolic groups for condensation with lipid molecules. When a mixture of it (9.40mg, 6.07 $\mu$ mol) and 4-(dodecan-1-yloxy)benzoyl chloride (13.0mg, 9.81 $\mu$ mol) in THF (3.0ml) is treated with Et<sub>3</sub>N (5.8  $\mu$ L, 42mmol) and 4-dimethylaminopyridine (3.5mg, 29 $\mu$ mol), stirred at 25° for 3 hours, evaporated *in vacuo*, and the residue in toluene is filtered through a silica gel pad, and then purified by GPC (JAIGEL 3H, eluting with toluene), precipitated with MeOH/toluene as above and dried *in vacuo* (at 25° for 12 hours), it provided **1,4,11,15,30-pentakis{4-[4-(dodecan-1-yloxy)benzoyloxy]phenyldimethylsilylmethyl}-2H-1,2,4,11,15,30-hexahydro-(60)fullerene** (12.9mg, 71% yield). Similarly the [4-tetradecan-1-yloxy] (75% yield), [4-hexadecan-1-yloxy] (72% yield), [4-octadecan-1-yloxy] (61% yield) and [3,4-di(octadecan-1-yloxy)] (37% yield) *derivatives* were obtained in high purity and characterised by <sup>1</sup>H NMR, <sup>13</sup>C NMR and ACPI MS analysis. These form beautifully coloured liquid crystals and X-ray diffraction studies showed interesting stacking of these fullerene molecules. [Matsuo, Muramatsu, Hamasaki, Mizoshita, Kato and Nakamura *J Am Chem Soc* **126** 432 2004.]

## CARBON NANOTUBES (CNTs) AND RELATED MATERIALS

The development of carbon nanotubes (CNTs) since their discovery by Sumio Iijima [*Nature* **354** 56 1991] has been explosive, not only because of their mechanical, thermal and electronic properties but because they can be modified physically and chemically in a variety of ways to suit a plethora of applications. Structurally, they are made of rolled up sheets of carbon atoms forming fused hexagonal carbon rings just like a monolayer of graphite. The sides of the sheet are fused to form complete tubes. When one or both ends of a tube come together, like the bottom of a test tube, the round portion is more like half a 'fullerene ball'. The way that the carbon atoms in the half fullerene ball 'finger tip' structure are stable is by forming both hexagonal and pentagonal rings (see Marchand et al. *Nano Lett* **9** 2961 2009, FEM imaging below).

Many carbon nanotubes are now available commercially in chemical catalogues, and a selected number are entered here. Their chemical and biochemical applications include diagnostics, novel devices for rapid DNA sequencing, human personalised medicine, bio-labeling for cancer research, novel biomaterials for human implants, and for tissue engineering implants. The non-chemical applications have also been extended to attachments to surfaces with patterned and unpatterned textures to form conductors, and exciting applications as for nano-filters, in LEDs, nanostructured optical fibres, lasers, and solar cells. Carbon nanotubes are very strong materials and could be ~200 stronger than steel. When mixed with building materials, such as cement or aluminium composites, they not only increase their strength but make them much lighter. Carbon sheets such as graphene are conducting surfaces and have found extensive use in touch screens, i-Pods, mobile phones to name a few. [Haddon *Carbon Nanotubes (editorial)*, *Acc Chem Res* **35** 997 2002, see also P. Calvert *A recipe for strength*, *Nature* **399** 210 1999].

### PREPARATION OF CNTs (NTs)

**MWCNTs** (multi walled CNTs) were first prepared by the arc discharged evaporation method (as for fullerene synthesis) where the needles (nanotubes) grew at the negative end of the carbon electrode in an argon filled vessel (at 100Torr). TEM micrographs showed tubes of 5 concentric graphic sheets (6.7nm diameter), 2 concentric graphic sheets (5.5nm diameter, DWCNT, double walled CNTs), and 7 concentric sheets (2.2nm diameter MWCNT). Electron diffraction patterns show that the tubes were formed from rolled up graphite sheets of carbon hexagons in helical structures. [Iijima *Nature* **354** 56 1991.] In chemical arc deposition, acetylene (at partial pressure  $\sim 10^{-2}$ mbar, 0.0075mm Hg at 0°) is often used as the hydrocarbon gas. J-M Bonard and coworkers prepared CNTs by growing them on 0.3mm diameter wires of Kanthal (Fe-Al-Cr alloy) in the centre of the anode at the rather low temperatures of 700-900°, hence the name *Cold Atmosphere Chemical Vapour Deposition CVD* (CACVD, compare below). The technique produces homogeneous films of well-graphitised NTs allowing control of their length and density. [Crocetti et al. *Chem Vap Deposition* **8** 89 2002, Bonard et al. *Appl Phys Lett* **81** 2836 2002]. MWCNTs are generally formed to a smaller or larger extent in the procedures used together with small quantities of buckyballs and amorphous carbon which can be invariably sublimed out, annealed out, or separated by chromatography. Annealing at high temperatures ( $\sim 2500$ - $2700^\circ$ ) removes volatile carbon, metals (generally bound to the open end of the tubes) and improves the structural order of the tubes.

**SWCNTs** (single walled CNTs): Among the techniques that have been developed for making SWCNTs are EA (electric arc) methods which use a carbon source and catalytic amounts ( $\sim 1$  to 6 atom%) of transition metals, commonly Ni/Co, Ni/Y, Rh/Pt or Fe that are allowed to supersaturate the carbon [Kokai et al. *J Phys Chem B* **103** 4346 1999, Sen et al. *Chem Phys Lett* **349** 383 2001]. The methods have been studied in detail in order to optimise the sizes and yields of CNTs. The technique developed by R.C Haddon and co-workers [Itkiss et al. *J Phys Chem B* **108** 12770 2004], and the purity estimated by solution phase NIR [Itkiss et al. *Nano Lett* **3** 309 2003] adopts the EA method where an electric arc discharge is applied between a graphite cathode and composite anode containing catalytic amounts of metal(s), e.g. 4:1 atom% of Ni/Y, under He buffer gas at  $\sim 680$ Torr, and arc current 90A with a 10mm arc gap. These conditions produce high yields of AP-SWCNT (high purity, As-Prepared nanotubes). The purity can be assessed by Near-Infrared (NIR) spectroscopy. Large scale production of SWCNTs by the EA technique is achieved by using an arc generated between a graphite rod (16mm diameter, 40mm long) cathode and an anode of graphite (6mm diameter, 100mm long) in which a hole 3.5mm diameter, 40mm deep, is drilled and filled with a mixture of a metallic catalyst (Ni 4.2 atom%/Y1 atom% and graphite) in a He atmosphere (660mbar) formed by a current of 100A/30V and keeping a constant distance ( $\sim 3$ mm) between the electrodes. Within  $\sim 2$  minutes, the total carbon mass was in  $\sim 2$ g quantities consisting of  $\sim 70\%$  SWCNTs in highly crystalline bundles. The nature of the product(s) was assessed by SEM, high resolution TEM, Raman spectroscopy and X-ray diffraction. [Journet et al. *Nature* **388** 756 1997.]

Another technique developed by R.E. Smalley and coworkers is the laser ablation of carbon targets (*Carbon Vapour Deposition*, CVD), e.g. laser-vaporised carbon-Ni/Co mixture (e.g. 1:1 1.2 atom% in C) at high temperatures (e.g. 1200°C) and vacuum (e.g. 500Torr) and an argon stream. [Thess et al. *Science* **273** 483 1996, Sen et al. *Chem Phys Lett* **332** 467 2000, Koran et al. *J Vac Sci Technol A* **13** 1171 1995]. This CVD produces high yields ( $\sim 70\%$ ) of SWCNTs as assessed by X-ray diffraction and electron microscopy (EM) methods at a rate of  $\sim 80$ mg/day. The production of SWCNTs can be increased to  $\sim 1$ g/day by using a 2" tube and dual laser pulses. However, by modifying the apparatus, using up and down scanning of the laser pulses onto a rotating carbon-Ni/Co target in a 4" diameter tube, a lower temperature (1100°C) can be used to generate 20g of 40-50vol% SWCNT material in 48 hours of continuous (largely unattended) operation [Rinzler et al. *Appl Phys A* **67** 29 1998]. The high purity was checked by EM, XRD, Raman spectroscopy and TGA. Note that higher temperature operations produce tubes of larger diameters, albeit well within the nanometer scale.

In a more recent, essentially CVD procedure, S.T. Purcell and co-workers [Marchand et al. *Nano Lett* **9** 2961 2009 which provide an animated supplement, and summarised by H. Birch 'Nanotube growth on camera', *RSC Chemistry World* **6**(9) 26 2009] have demonstrated by *Field Emission Microscopy* (FEM) how the growth of SWCNTs takes place. They used a W-tip connected to the electrodes (at 1200°C) in a chamber at ultra high vacuum ( $5 \times 10^{-10}$  Torr base pressure). The W-tip (tip radius  $\sim 60$ nm) is first covered with a graphite diffusion barrier by heating in acetylene (at  $P_{C_2H_2} \sim 1 \times 10^{-4}$  Torr), and Ni nanoparticles are induced to grow directly onto the tip [by dewetting, from a circular Ni wire in the chamber using CVD in  $C_2H_2$  ( $\sim 1-2 \times 10^{-7}$  Torr during growth) at 800°C] while FEM imaging is performed. The images are collected on camera, and a frame-by-frame analysis of the video showed that the SWCNT grows at one end of the carbon tube at a time. The tube

rotates in discrete steps, ~24 per rotation (half of the number of carbon atoms on the circumference of a common SWCNT) with the CNT turning ~180 times during its 11 minutes growth (as in the 'screw-dislocation-like' model). Growth starts at the Ni atom (of the catalyst), the carbon attaches itself to the metal then it forms carbon rings (as hexagons, because these are the more stable configuration), and the molecule rotates as the tube is being formed. In the end, the tube is sealed by forming a semi-fullerene ball 'finger tip' structure, and produces a 'test-tube like' nano carbon structure with the metal atom at its mouth. The metal can then be removed by heating the SWCNT strongly (annealing).

The *HiPco* process for preparing SWCNTs developed by R.E. Smalley and co-workers [Nikolaev et al. *Chem Phys Lett* **313** 91 1999] involves formation of the catalysts by *in situ* thermal decomposition of Fe(CO)<sub>5</sub> in a heated flow of CO in the gas phase at 1-10atm and 800-1200°C. By adjusting the processing parameters (best at 1-10atm and 800-1200°C), SWCNTs were produced in high yields (79 mole%, i.e. 44 wt%) with narrowest tubes (as small as 0.7nm in diameter, same as in C<sub>60</sub> fullerene) at the rate of 1.24mg/hour. The structures were confirmed by TEM, SEM, EDX and TGA. An important advantage of this procedure is that it is a continuous-flow process which can be used for bulk production of narrow SWCNTs. See below for purification of HiPco tubes.

### PURIFICATION OF CNTs (NTs)

**MWCNTs:** Raw tubes, as prepared by the EA method, contain about one third of other nanomaterial. This material is best removed by oxidation. Pure tubes can thus be prepared, although the procedure is wasteful. The purest tubes are obtained when 99% is oxidised; but when 95% is oxidised only 10-20% of product contains pure nanotubes. A ground raw sample is placed in an oven and the temperature is raised to 750° in air or oxygen for ~30 minutes until ~1% is left. This consists mostly of pure tubes with length/diameter ratios that exceed 100, and traces of open cylinders with the ratio of 20. [Ebbesen et al. *Nature* **367** 519 1994, see also Chen et al. *Adv Mater* **8** 1012 1996.]

MWCNTs, prepared by the CVD procedure using ferrocene and xylene (0.75% Fe/C) as catalyst and precursor with argon/H<sub>2</sub> at ~700° [Andrews et al. *Chem Phys Lett* **303** 467 1999 (a step closer to commercialisation), Rao et al. *Appl Phys Lett* **76** 3813 2000], or acetylene as precursor and 2.5wt% Co-2.5wt% Fe/NaY zeolite as catalyst with argon/H<sub>2</sub> at ~700° [Bulusheva et al. *J Phys Chem B* **105** 4853 2001], were purified by heating the raw tubes (200mg) in 2.6M aqueous HNO<sub>3</sub> (40ml) for 48 hours. The cooled solution was centrifuged (use PTFE tubes, ~20,000g/30 minutes), the sediment was washed/re-centrifuged with de-ionised H<sub>2</sub>O until the supernatant was barely acidic and the MWCNT sediment was dried *in vacuo*. This material was satisfactory for functionalising [Lin et al. *J Phys Chem B* **106** 1294 2002]. Alternatively, to a dispersed suspension of MWCNTs (100mg), formed by sonication (1 minute), is added an acidic solution of KMnO<sub>4</sub> (4g in 120ml of 1N H<sub>2</sub>SO<sub>4</sub>) dropwise and refluxed for 12 hours, cooled, and centrifuged. The sediment is treated with concentrated HCl (20ml) and refluxed for 24 hours to dissolve the MnO<sub>2</sub>, cooled, centrifuged and the sediment is refluxed with 68% (azeotropic) HNO<sub>3</sub> (40ml) for 24 hours, cooled, centrifuged again, and the solids are washed repeatedly (using several centrifugation/washing cycles) with de-ionised H<sub>2</sub>O until almost neutral then dried in a vacuum oven. This procedure exposes the CO<sub>2</sub>H groups on the CNTs and can be used for conversion to COCl groups, and further reactions to make soluble MWCNTs. [Fu et al. *Nano Lett* **1** 439 2001.]

**SWCNTs: (i)** Mechanically ground cloth-like raw SWCNTs from the electric arc process (EA) can be purified in reproducibly high yields (optimally 25-30wt% and <1wt% of transition metal) in two steps. The first involves thermal annealing in air by rotating the powders at 470°C for 50 minutes in a quartz tube at 30rpm which burns the carbonaceous particles out, and the second is acid treatment which etches out the metals. The powder is immersed in aqueous 6M HCl for 24 hours, filtered (or centrifuged) several times until the colour of the acid is unaltered, and then washed with de-ionised H<sub>2</sub>O. The SWCNTs are then 'unbundled' by boiling in 30% aqueous HNO<sub>3</sub> for 4-6 hours, and the suspension is filtered with a polytetrafluoroethylene (PTFE) membrane in deionised H<sub>2</sub>O, rinsed and dried to give a grayish black, thin mat of SWCNTs. The purity at each stage can be observed by SEM, TEM, FT-Raman spectroscopy and TGA which usually show ~96% purity after HCl treatment. The HNO<sub>3</sub> treatment, however, appears to break down the CNTs into small pieces and sometimes forms MWCNTs. [Moon et al. *J Phys Chem B* **105** 5677 2001.]

**(ii)** A gas-phase purification procedure developed by Margrave and co-workers [Zimmerman et al. *Chem Mater* **12** 1361 2000] involved purging the CNT sample [prepared by the pulsed laser method (Rinzler et al. *Appl Phys A* **67** 29 1998), from Graphite (1-2mm), or from EA] in a quartz tube with a mixture of Cl<sub>2</sub> (7.2ml/min), H<sub>2</sub> (2.7ml/min) and argon (3.0ml/min) for 1 hour at ~25°, which is then lowered into a furnace at 500° while the evolving gases (CO, COCl<sub>2</sub>, CCl<sub>4</sub> and CO<sub>2</sub>) are monitored by IR. Purging is continued until the CO partial

pressure is  $<0.5$ Torr. The temperature of the sample is lowered to  $\sim 25^\circ$ , sonicated in DMF/0.6M HCl (1:1) to remove metals, then pure DMF, filtering, and washing with MeOH to form an SWCNT 'paper'. (*Alternatively*, the metals, if present, can be removed by sublimation in HCl gas at higher temperature.) The SWCNT 'paper' is dried at  $160^\circ$  and the purity assessed by SEM, TGA and UV-VIS. Any fullerenes present may be removed by a toluene reflux or by sonication. The yield is  $\sim 15$ wt% to give CNTs that are generally more reactive due to their larger curvature.

(iii) Raw HiPco SWCNTs can be purified in a multi-step process. Low density raw HiPco ( $\sim 100$ mg,  $d \sim 0.01$ g/cc) is compressed onto dry filter paper (vacuum), placed in a ceramic boat and inserted into a quartz tube furnace while a gas mixture of 20%  $O_2$  (or air) in argon (wetted by bubbling through  $H_2O$ ) is allowed to flow over the sample in the furnace at 100cc/sec. The nanotubes are heated at  $225^\circ$  for 18 hours, sonicated for  $\sim 15$  minutes (or stirring overnight) in concentrated HCl (yellow colour due to  $Fe^{3+}$  ions). The suspension is filtered onto a Teflon membrane (47mm,  $1.0\mu m$  pore size), washed several times with deionised  $H_2O$ , MeOH, and dried in a vacuum oven at  $100^\circ$  for 2 hours (weight loss 33.7%; 0.67% residual metal). This oxidation with wet  $O_2$  (or air) in argon, and extraction cycle is repeated at  $325^\circ$  for 1.5 hours (further weight loss 8.3%, 0.05% residual metal), and again at  $425^\circ$  for 1 hour (further weight loss 22.9%, 0.09% residual metal). After drying *in vacuo*, the HiPco tubes are annealed at  $800^\circ$  in argon for 1 hour (further weight loss 4.2%, 0.03% residual metal). Assessment of purity is by SEM, TEM, TGA, Raman and UV-VIS-NIR spectroscopy. The onset of oxidation of the smaller diameter HiPco SWCNTs is *ca*  $100^\circ$  lower than for the purification of large diameter tubes obtained in the laser-oven process, and is consistent with the greater steric strain present in small diameter SWCNTs. [Chiand et al. *J Phys Chem B* **105** 8297 2001.]

(iv) A general purification procedure for raw SWCNTs obtained by the EA process (reaching 2-3g, containing  $\sim 70\%$  SWCNTs) [Ebbesen & Ajayan *Nature* **358** 220 1992, Journet et al. *Nature* **388** 756 1996], or the laser ablation method (reaching  $\sim 20$ g, containing up to 50% SWCNTs) was developed by A. Hirsch and coworkers [Holzinger et al. *Appl Physics A* **70** 599 2000]. The process involves three steps. (a) Raw material (100mg) was refluxed with 65%  $HNO_3$  (150ml) for 3 hours, and centrifuged. The sediment was washed with  $H_2O$  and centrifuged repeatedly until the supernatant (first colourless then darkens, still contains some SWCNTs and was kept for further use) has pH  $\sim 1$ . The sediment is suspended in distilled  $H_2O$ , subjected to two and three 0.5 seconds of ultrasonic pulses when the liquid became weakly acidic (pH 3-4), almost free from metal catalyst, and contained  $\sim 1$ mg/ml  $H_2O$  of only SWCNTs and nanoparticles. For storage, the pH is adjusted to 8-9 with  $K_2CO_3$  which increased the repulsive interactions between the carboxylate groups of the SWCNTs. (b) The suspension is sonicated for 1 minute which reduces the nanoparticles to smaller pieces. The tubes and bundles were also smashed and the difference in size between the SWCNTs and degraded particles increases (as observed by AFM). (c) This most important step involved elution of the suspension through a column of potassium polyacrylate which was swollen (the cross-linked polymer particle size swells from  $<1\mu m$  to  $\sim 300\mu m$ ) creating pores large enough to entrap nanoparticles as well as SWCNTs and bundles of comparable size. [Optimum: 15ml of swollen polymer per 1ml of a 1g/L aqueous SWCNTs, and choosing a diameter to give a column height of 6-7cm held by a glass filter pore size 2]. A vacuum is applied at the bottom of the column which squeezes the swollen polymer particles. The SWCNTs are so large that they cannot now be entrapped and elute freely to give large quantities ( $> 40\%$  of the total mass) in the first fraction. The remaining material contains a large portion of SWCNT fraction of lesser quality which can be recycled. Most of the degraded material and smaller nanoparticles remain in the cavities. The purification can be followed by AFM and the purity can be assessed by Raman spectroscopy. In the Raman spectrum, *pristine* SWCNTs have a doublet at 1546 and 1575  $cm^{-1}$  (of about equal intensity — G-lines) and a less intense band (D-line, *ca*  $1/4.75$  th of the G-lines) at  $\sim 1342$   $cm^{-1}$ . The relative intensity of the G-lines increase as the purity increases. The broadness of the D-band may originate from disordered or carboxylated carbon formed by oxidation.

#### PREPARATION AND PURIFICATION OF FULLERENE PIPES (TUBES)

These are short SWCNTs of 100 to 300nm lengths and  $\sim 1.2$  to 1.4nm in diameter which are most useful for preparing functionalised SWCNTs. They are distinct from the above *fullerenes* which are "bucky balls" and are made up of tubes consisting of a network of hexagonal carbon rings like in CNTs. As prepared, the CNTs are long almost endless single walled highly convoluted, entangled, bundled tubes. R.E. Smalley and coworkers [Rinzler et al. *Appl Phys A* **67** 29 1998, Liu et al. *Science* **280** 1253 1998] have purified, and cut such material from large batches into small lengths of open-ended tubes, *Fullerene pipes*, which form stable colloidal suspensions in the presence of detergents. These can be made to react like ordinary organic molecules to form any variety of derivatives. In a typical preparation, the raw tubes (10g) in 2.6M  $HNO_3$  were refluxed for 45

hours, cooled, and the black solution was centrifuged in PTFE (Teflon) tubes (20,000g, 20 minutes, Sorvall R5C centrifuge). The supernatant was decanted off, the sediment was resuspended in de-ionised H<sub>2</sub>O by vigorous shaking and the centrifuging/washing cycle repeated 3 to 4 times until the supernatant was almost neutral, although black in colour. The acid treatment not only assists in separating the bundles, but also oxidises the material, thus producing carboxylic acid groups at the ends as well as at the sides of the tubes. This makes 'holes' in the sides of the tubes and causes them to be 'cut' [cf K. Kinoshita *Carbon Electrochemical and Physicochemical Properties* Wiley, New York 1988, ISBN 978047184802-8]. The sediment as examined by SEM and TEM contains carboxylated carbon tubes and other species such as fullerenes, polycyclic aromatic sheets and cross-linked sheets edged with CO<sub>2</sub>H groups which, by virtue of de-protonation allow mutual repulsion between the particles. The sediment (using 10g) was dispersed in aqueous NaOH (1.8L, pH 10) containing 0.5vol% of the non-ionic surfactant Triton X 100 by sonication for ~1 hour, and purified by *cross-flow-filtration* (CFF, cellulose ester M22M 600 01N, mini-Kros® Spectrum cartridge: 0.6mm diameter, 200nm pores and 0.56m<sup>2</sup> of surface area) against a buffer of aqueous NaOH (40L, pH 10) containing 0.2vol% of Triton X 100. At a head pressure of 5-6psi and flow rate of ~70ml/min the process was complete in ~10 hours. Salt was removed by washing with de-ionised H<sub>2</sub>O (10L). Clogging occasionally occurred and was overcome by momentarily reversing the flow before continuing. Clamping off the buffer line and opening a vent allowed concentration of the SWCNTs down to ~200ml of solution. When a portion of this solution was filtered through a PTFE membrane (Millipore LS 5µ pore) using a vacuum, it deposited a thick pad of SWCNTs on the membrane. After washing with MeOH, the pad can be easily peeled off to give a freestanding mat which was called 'Bucky Paper' and was estimated as typically 10 to 20% yield depending on the initial raw material. TEM images of the SWCNT 'paper' showed that the pipes still contained impurities which were removed by two further oxidising acid treatment which 'cut' (by reacting at the sides of the tubes) and 'polished' the tubes.

In a typical *cutting*, the purified SWCNT 'Bucky Paper' (10mg) was suspended in a 3:1 mixture of concentrated H<sub>2</sub>SO<sub>4</sub>/HNO<sub>3</sub> (40ml), sonicated (55kHz) at 35° to 40° for 24 hours. The suspension was diluted with H<sub>2</sub>O (200ml), larger tubes were collected onto a 100nm pore filter membrane (Millipore, VCTP type), and washed with 10mM NaOH solution. *Polishing* was performed by suspension in a 4:1 mixture of concentrated H<sub>2</sub>SO<sub>4</sub>/30% H<sub>2</sub>O<sub>2</sub>, stirring at 70° for 30 minutes, filtering and washing again on a 100nm filter, and re-suspending at 0.1mg/ml of 0.5wt% Triton X100 in H<sub>2</sub>O to avoid flocculation. On a larger scale CFF purification was carried out after each oxidation step. Finally, to obtain best purified 'Bucky Paper', annealing *in vacuo* at 1200° was necessary. Note that in 3:1 H<sub>2</sub>SO<sub>4</sub>/HNO<sub>3</sub> at 70° the average cutting was at a rate of ~130nm/hour, and in 4:1 H<sub>2</sub>SO<sub>4</sub>/30% H<sub>2</sub>O<sub>2</sub> the shortening rate was at ~200nm/hour.

*Characterisation* of these fullerene tubes was done by electro-deposition [developed by Smalley and coworkers, see above references] which drives the suspended tubes onto the surface of highly oriented pyrolytic graphite surface and are scanned by AFM. The molecular nature of the tubes was demonstrated by converting their CO<sub>2</sub>H groups to COCl, followed by reaction with H<sub>2</sub>N(CH<sub>2</sub>)<sub>11</sub>SH and exposure to 10nm gold particles. Gold (which reacts with SH) was only found on the carboxylated fullerene tubes.

### SOLUBILISATION OF CNTs

CNTs, whether MWCNTs or SWCNTs, readily form bundles, and attempts to separate the bundles by means such as sonication or use of detergents have been uniformly unattractive. The carbon material is 'non-wettable' and quite insoluble in polar and non-polar liquids. Considerable effort has been expended to find means of separating the bundles and much success has been achieved by functionalising the carbon matrices, which destabilise the interaction between the fibres, but also introduce bound groups which afford solubility in organic solvents as well as aqueous solutions. These provide opportunity for purification because the partly purified CNTs are not homogeneous. The non-homogeneity is not only in the length and/or diameter, but also in their nature since during the formation of the tubes, the row of hexagonal rings do not only align to form straight tubes (with parallel hexagonal rows), but can also form spiral tubes in which the row can be out of line by one and/or more than one hexagon while forming the tube. [For the *Dislocation theory of chirality-controlled nanotube growth* see B.I. Yakobsen and coworkers *Proc Natl Acad Sci USA* **106**(8) 2506 2009, and for a review see H. Birch *RSC Chemistry World* **6**(3) 25 2009.] This provides the opportunity for a variety of chiral CNTs. In his respect M Zheng and coworkers [Zheng & Semke *J Am Chem Soc* **129** 6084 2007, Tu et al. *Nature* **460** 250 2009, see also P. Broadwith *RSC Chemistry World* **6**(8) 28 2009] have selected short strands of DNA [8 to 12 mers, with repeating nucleotides e.g. (GTC)<sub>2</sub>, (GTC)<sub>2</sub>GT, (GTT)<sub>3</sub>G, (TAT)<sub>4</sub> etc] which entwine around the SWCNTs (e.g. produced from HiPco, see above) of *ca* 1nm diameter with different selectivities depending on the '*n,m* chirality' of the nanotubes [e.g. (8,6), (9,4), (7,6), (6,5) etc respectively] to form barrels around the

tubes. The mixture is dispersed in appropriate aqueous solutions (e.g. 0.1M NaCl, 0.1M NaCl/10% glycerol) by sonication (~60 minutes), incubated for a period of time, centrifuged (16,000g/90 minutes) and the supernatant is fractionated by Size Exclusion Chromatography (SEC) through an IEX resin (CNT-NS 1500, Biochrom, Terre Haute, IN, USA), and the various DNA-wrapped-SWCNTs are eluted with 2x(0.3M NaCl, 0.03M sodium citrate)/0.5mM EDTA/pH 7.0 and a 0 to 1M sodium benzoate gradient. The fractions are monitored at 300nm and 425nm. The DNA interaction is electrostatic and is easily removed by thermal treatment.

Strong acids solubilise SWCNT and MWCNT bundles by protonating them causing the strands to separate, but chlorosulfonic acid is by far (~1,000 times) the best acid as shown by M. Pasquali and the late R.E. Smalley [Davis et al. *Nature Nanotechnology* **4** 830 2009, summarised by P. Broadwith RSC *Chemistry World* **6**(12) 32 2009]. SWCNTs spontaneously dissolve in ClSO<sub>3</sub>H at a concentration of as low as 0.5wt%. The Phase Diagram in strong H<sub>2</sub>SO<sub>4</sub> exhibited true thermodynamic behaviour forming isotropic (I), liquid crystal (LC), crystal solvate (CS) and solid (S) phases at different concentrations of SWCNTs, ClSO<sub>3</sub>H and H<sub>2</sub>SO<sub>4</sub>. When an 8.5vol% of SWCNTs was coagulated in 96% aqueous H<sub>2</sub>SO<sub>4</sub> by extrusion through an orifice while co-flowing with CHCl<sub>3</sub> or CH<sub>2</sub>Cl<sub>2</sub>, the resulting nanotube bundles (10-100nm) combined into larger bundles to form macroscopic fibres which were easily spun into tens of meters of continuous fibres in a matter of minutes. These fibres can yield a strength in excess of 320 MPa. By sandwiching the dope between glass plates, long ribbons of material were produced, and possibly any shapes (e.g. coils) can be made. The technological applications are enormous.

For examples of some currently commercial CNTs and functionalised CNTs see the following paragraphs.

### CARBON NANOTUBES (CNTs)

**Carbon annealed nanodiscs/nanocones** [7440-44-0]. These are available as a black powder containing a mixture of 20% cones, 70% discs and 10% of carbon black impurities by weight. The carbon cones have a nearly perfect geometry. The five theoretically possible cones with apical angles of 19.2°, 38.9°, 60°, 84.6° and 112.9° are all present in the mixture with cone lengths of 0.3-0.8μ, maximum base diameter of 1-2μ and wall thickness of 20-50 nanometers. The diameter and thickness of the discs are 0.88-3.5μ and 20-50 nanometers respectively. A product of almost 100% carbon is obtained by annealing at 2500-2700° which increases the structural order and reduces the concentration of impurities particularly of metals (from catalyst). They are similar to multi-walled carbon nanotubes (MWCNTs).

**Carbon multi-walled nanotubes (MWCNTs or MWNTs)** [1333-86-4]. These are produced as a black powder by chemical vapour deposition (CVD) and contain >90% of nanotubes which are almost free from metal impurities. The tubes are ~7μ in length and ~140 nanometers in diameter. Multi-walled smaller nanotubes of ~1.5μ in length and ~20-25 nanometers in diameters are similarly prepared. When the multi-walled carbon nanotubes are 'arc-produced' they are even smaller in size with ~2μ in length and ~2-50 nanometers in diameter [308068-56-6]. This 'arc process' produces a mixture of 55-65wt% of straight multi-walled nanotubes and 35-45wt% of graphite nanoparticles. They contain almost 100% carbon. By growing the tubes at 3000-4000° using this process they contain less defects than by other procedures, and are purified in this way. They are stable in air up to 700°.

MWCNT arrays for nanoelectronics with nickel-carbide particle tips with same diameters as above are also available. Vertically aligned MWCNTs on a silicon wafer substrate with low resistivity (1-30 ohm-cm), as well as on a copper wafer substrate (1cm x 1cm x 0.05cm high conductivity low-oxygen copper) have been prepared. The latter are produced by plasma-enhanced chemical vapour deposition (PECVD). MWCNTs have also been made in 3-19, 7-13 and 5-15 graphene layers wall thicknesses. See below for breaking up the bundles and graphene.

**Carbon double-walled nanotubes (DWCNTs or DWNTs).** These have been prepared by the *Carbon Vapour Deposition (CVD)* method with >90% carbon content and 50-80% DWCNT. They can be prepared with approximately the following dimension 5nm OD, 1.3-2.0nm ID and 50μm length; and with 0.12-0.14g/ml bulk density and >600m<sup>2</sup>/g surface area. The rest (10-40%) consists of amorphous carbon and residual metal catalysts which are deliberately placed in the original carbon in order to synthesise the carbon tubes.

**Carbon single-walled nanotubes (SWCNTs or SWNTs)** [308068-56-6] **M 3652-3607, d<sup>25</sup> 1.7-1.9g/ml.** The SWCNTs are of particular use for derivatisation and the applications stated above. They can be prepared in various bundle dimensions, viz:  $d = 1.2-1.5\text{nm}$ ,  $l = 2-5\mu\text{m}$  (40-60% SWCNT, arc method);  $d = 1.1-0.5\text{nm}$ ,  $l =$

100 $\mu\text{m}$  (>50% SWCNT, Carbon Vapour Deposition, CVD, method);  $d = 2\text{-}10\text{nm}$ ,  $l = 1\text{-}5\mu\text{m}$  (50-70% SWCNT, arc method); individual short tubes  $d = 1\text{-}2\text{nm}$ ,  $l = 0.5\text{-}2\mu\text{m}$  (90% SWCNT, electric arc, EA, method), and individual long tubes  $d = 1.3\text{-}1.5\text{nm}$ ,  $l = 1\text{-}5\mu\text{m}$  (40-60% SWCNT, arc method, EA) and the HiPco process (see above).

### FUNCTIONALISED CNTs.

MWCNTs and SWCNTs have been successfully functionalised, and the products have found numerous applications. They are conducive to further chemical reactions as they are readily soluble, thus amenable to solution chemistry [see R.C. Haddon and coworkers in *Chemistry of Single-Walled Carbon Nanotubes*, Niyogi et al. *Acc Chem Res* **35** 1105 2002; and Sun and coworkers in *Functionalized Carbon Nanotubes: Properties and Chemistry*, Sun et al. *Acc Chem Res* **35** 1096 2002]. When purified by the acid and oxidising conditions the tubes invariably are oxidised to form CO<sub>2</sub>H or quinone groups, particularly at the ends of the tubes. Depending on the conditions, ‘cutting’ may occur leaving open-ended tubes (see fullerene tubes above). Annealing at high temperatures *in vacuo* causes some decarboxylation and closing up of the ends which form half fullerene tips (like the end of a glass test tube, see above). Because of the larger curvature at the tips than on the sides of the tubes, the tips are more readily functionalised (due to the easier conversion of sp<sup>2</sup> to sp<sup>3</sup> carbon atoms); but then again they would lose the added function more readily on annealing. The tips are also more easily cleaved by oxidants (KMnO<sub>4</sub>, OsO<sub>4</sub> and RuO<sub>4</sub>) at 100° under acidic conditions [Hwang *Chem Commun* 173 1995]. Functionalised SWCNTs dissolve in organic solvents (e.g. THF, CH<sub>2</sub>Cl<sub>2</sub>) and can be examined by optical spectroscopy. Tubes with CO<sub>2</sub>H groups on the sides are commonly formed, are readily converted to COCl groups, and can react with a variety of reagents possessing the appropriate functional group. Also by virtue of the double bonds in the hexagonal rings, the tubes condense with nitrenes (to form aziridino compounds with UV light), react with carbenes (to form cyclopropane derivatives), are reduced (by Birch reduction), form metal derivatives which can be reacted further, react with aryl diazonium compounds (arylation), undergo 1,3-dipolar cycloaddition reactions (e.g. to form pyrrolidine derivatives), undergo nucleophilic reactions, radical reactions, and halogenation. J.L. Musgrave and coworkers [Khabashesku et al. *Acc Chem Res* **35** 1087 2002] have prepared ‘fluoronanotubes’ by direct fluorination of SWCNTs, and the fluoronanotubes dispersed in THF reacted with alkyl-Li reagents, Grignard reagents, alkoxides, hydrazine and  $\omega$ -diamines to form a variety of useful functionalised tubes. Sun and coworkers [Fu et al. *Nano Lett* **1** 439 2001] functionalised SWCNTs with lipophilic and hydrophilic dendra and showed that they can be defunctionalised in homogeneous solutions by base- and acid- catalysed hydrolysis demonstrating the existence of ester linkages. Absorption in the UV/VIS spectra of these functionalised tubes obey Beer’s law demonstrating no aggregation effects, and SEM analysis was not successful due to the extent of substitution, whereas the de-functionalised SWCNTs and MWCNTs gave successful SEM imaging. SWCNTs attached to a silicon substrate can be used as very small highly sensitive chemical sensors or memristors for gases. They also adsorb chemicals such as alcohols, aromatics, amines and phosphonates, some of which do not readily desorb and slow the process down unless they are removed by other means such as high temperatures which tend to be time consuming and degrade the sensor. Masel and coworkers [Salehi-Khojin et al. *Science* **329** 1327 2010, reviewed by H. Birch, Electric shock resets nanotube sensor, *RSC Chemistry World* **7** (10) 2010] showed that current induced voltage above the Poole-Frenkel conduction threshold (>12V) desorbed most molecules effectively after 3 hours and the sensors returned rapidly to baseline.

**SWCNT—(CO<sub>2</sub>H)<sub>n</sub>, 89-90% SWCNT (carbonaceous purity), bundle dimension: diam 4-5nm x length 0.5-1.5 $\mu\text{m}$ .** The SWCNTs were produced by EA discharge [Journet et al. *Nature* **388** 756 1996, Itkis et al. *J Phys Chem B* **108** 12770 2004] or the HiPco procedure (see above). SWCNT-CO<sub>2</sub>H is prepared as follows: HiPco SWCNTs (0.2g) are sonicated in a 3:1 mixture of concentrated H<sub>2</sub>SO<sub>4</sub>/concentrated HNO<sub>3</sub> (80ml) for 4 hours, diluted with deionised H<sub>2</sub>O and filtered through a 0.2 $\mu\text{m}$  pore acid resistant membrane. The solid is dried at ~25°, then sonicated in a solution of 4:1 concentrated H<sub>2</sub>SO<sub>4</sub>/30% H<sub>2</sub>O<sub>2</sub> for 15 minutes, diluted with excess deionised H<sub>2</sub>O, filtered again and dried *in vacuo* at 25° to give 79w/w% of ‘shortened’ product (85% have length < 600nm, i.e. ~0.6 $\mu\text{m}$ ). [Zhao et al. *Adv Funct Mater* **14** 71 2004.] Solution phase NIR spectroscopy against a standard [see Itkis et al. *Nano Lett* **3** 309 2003], gave a carbonaceous purity of 80-90% and 3-6 atom% carboxylic acid. Its solubility is 1mg/ml in DMF, and 0.1mg/ml in H<sub>2</sub>O. Metal content is 5-10%. This is suitable for further reactions.

**SWCNT—(COCl)<sub>n</sub>.** The preceding shortened SWCNT-acid (100mg) [see also Liu et al. *Science* **280** 1253 1998] is stirred in SOCl<sub>2</sub> (20ml) containing DMF (1ml) at 70° for 2 hours, centrifuged, the brown coloured supernatant is decanted, the sediment is washed with anhydrous THF, centrifuged again; the pale yellow supernatant is decanted and the sedimented SWCNT-(COCl)<sub>n</sub> is dried at ~25° *in vacuo*. This product is reactive and should be used immediately. [Chen et al. *Science* **282** 95 1998]. Alternatively, the preceding acid (12mg) in dry DMF (20ml) is sonicated for 30 minutes to give a homogeneous suspension, to which is added redistilled oxalyl chloride (0.4ml) dropwise at 0° under N<sub>2</sub>. The mixture is stirred at 0° for 2 hours, then at 70° and stirred overnight to remove excess of oxalyl chloride, and dried *in vacuo*. This product is reactive and should be used immediately. [Itkis et al. *Nano Lett* **3** 309 2003.]

**SWCNT—(CONH<sub>2</sub>)<sub>n</sub>, 89-90% SWCNT (carbonaceous purity), bundle dimension: diam 4-6nm x length 0.7-1.0µm, average diameter of individual SWCNT being 1.4nm ±0.1nm.** The preceding cooled SWCNT-(COCl)<sub>n</sub> in dry DMF (~0°) is treated with liquid NH<sub>3</sub> (~0.5ml) and stirred while the temperature rose to ~25°, and kept there with stirring for 24 hours. Dry N<sub>2</sub> is bubbled through the mixture to remove excess of NH<sub>3</sub>, excess of dry THF is added and the mixture is centrifuged, the supernatant is decanted off, the sediment is washed with dry THF, centrifuged again and the SWCNT-NH<sub>2</sub> residue is dried *in vacuo* at ~25°. The extent of labeling is the same as the original acid, i.e. 3-6 atom % (amide groups) and metals ~6-8%. Their solubilities are 0.5 to 1.0mg/ml, in each of the alcohols, acetone and DMF; and can be functionalised with any reagent that will react with amide groups.

**SWCNT-(ODA)<sub>n</sub> {SWCNT-[CONHCH<sub>2</sub>(CH<sub>2</sub>)<sub>16</sub>CH<sub>3</sub>]<sub>n</sub>, octadecylamide functionalised}, 89-90% SWCNT (carbonaceous purity), bundle dimension: diam 2-10nm x length 0.5-2.0µm, average diameter of individual SWCNT being 1.4nm ±0.1nm.** It is prepared from the above SWCNT-(COCl)<sub>n</sub> (obtained from 100mg of the acid) by mixing with octadecylamine (ODA, 2g, m 55-57°) and heating at 90-100° for 96 hours under dry N<sub>2</sub>, and cooled. Excess of ODA is removed by washing with EtOH four times (5-10 minutes sonication at 40 KHz) by centrifugation/decantation, the sediment is dissolved in CH<sub>2</sub>Cl<sub>2</sub>, filtered, the black coloured filtrate is evaporated to dryness in a rotavap and the residue is dried *in vacuo* at ~25° to give >60% yield based on shortened SWCNTs. Note that the reaction of SWCNTs-(COCl)<sub>n</sub> and excess of ODA in toluene at ~25° for several days gives only traces of product and the success of the former procedure was attributed to expansion and defoliation of the SWCNTs bundles to give the more reactive individual nanotubes [Chen et al. *Science* **282** 95 1998]. The extent of labeling in the commercial sample is 30-40wt% (ODA) and contains 4% of metals. The amide is soluble in CHCl<sub>3</sub>, CH<sub>2</sub>Cl<sub>2</sub>, \*C<sub>6</sub>H<sub>6</sub>, toluene, and the solubility in CS<sub>2</sub> or THF is >1mg/ml.

The solubility of the ODA derivative made it amenable to purification, and R.C. Haddon and coworkers purified it by gel permeation chromatography (SEC) using Styragel HMW7 [Nyogi et al. *J Am Chem Soc* **123** 733 2001] and PLgel MIXED-A [Zhao et al. *J Am Chem Soc* **123** 11673 2001], both being polystyrene divinylbenzene resins. The latter proved to be a superior gel (300 x 7.5mm column), and using THF as eluent three bands were separated at a flow rate of 0.5ml/minute. The first band contained 74% of SWCNTs-ODA (as detected by AFM, UV and NIR) [MW range 2000 to 4 x 10<sup>7</sup>, particle size 15-20µm, retention time 8 minutes], the second band with retention time of 9 minutes contains mostly nanoparticles with traces of SWCNTs, and the third band with retention time of 19 minutes contained amorphous carbon. IR, Raman and UV spectra confirmed the ODA component, and <sup>1</sup>H NMR (200MHz, CDCl<sub>3</sub>) demonstrated bands characteristic of CH<sub>2</sub> groups and the terminal CH<sub>3</sub> group. The nature (e.g. such as broadness) of the bands was indicative that both ionic (charge transfer) and covalent interactions were occurring.

**SWCNT-{CONH-*p*-[C<sub>6</sub>H<sub>3</sub>(*m*-SO<sub>3</sub>H)-*p*-NHC<sub>6</sub>H<sub>3</sub>(*m*-SO<sub>3</sub>H)]<sub>m</sub> }<sub>n</sub> [SWCNT-*n*-poly-*p*-aminobenzene-*m*-sulfonic acid, SWCNT-(CO-PABS)<sub>n</sub>], 75-85% SWCNT (carbonaceous purity), average diameter of individual SWCNT being 1.4nm ±0.1nm, average PABS Mw ~400-600g/mol.** The PABS polymer was prepared by mixing *m*-aminobenzenesulfonic acid (ABS, 0.865g) and aniline (15-20mol% of ABS, as inhibitor of polymerisation) and 1M HCl with ammonium persulfate as oxidant, stirred at 0° for 6 hours, concentrated at ~25° (*in vacuo*), filtered and the solid was washed with Me<sub>2</sub>CO. This was dissolved in H<sub>2</sub>O, and the aqueous solution was slowly added to a large excess of Me<sub>2</sub>CO. The black solid was filtered off and dried at ~25° (*in vacuo*) to give PABS (340mg, 40%, Av M<sub>w</sub> ~400-600 g/mol), which was identified by its UV spectrum that has λ<sub>max</sub> at 290 and 510nm in aqueous 1N NaOH [Roy et al. *Synth Met* **100** 233 1999]. SWCNT-(CO-PABS)<sub>n</sub> was

obtained from SWCNT-(COCl)<sub>n</sub> [prepared as above by the oxaly] method from HiPco SWCNTs (12mg, Carbon Nanotechnologies Inc.) in dry DMF (~20ml) by mixing with PABS (120mg) in DMF (~50ml) and stirred at 100° for 5 days. After cooling to 25° the solid was filtered through a 0.2mm pore-size membrane and washed thoroughly with DMF and EtOH, and dried *in vacuo*. The black SWCNT-(CO-PABS)<sub>n</sub> (57mg) on the membrane was collected and dried *in vacuo* overnight. Its solubilities are 0.05mg/ml in EtOH, 0.1mg/ml in DMF and 5.0mg/ml in H<sub>2</sub>O. The commercial product has 65% (PABS) and 4% metals. The water soluble graft polymer had a much higher conductivity (5.6 x 10<sup>-3</sup> Scm<sup>-1</sup>) than PABS (5.4 x 10<sup>-7</sup> Scm<sup>-1</sup>), and IR spectrum consistent with an amide bond; the <sup>1</sup>H NMR (300MHz, D<sub>2</sub>O) exhibited a very weak broad spectrum compared with the sharp signals of PABS itself, characteristic of the effect of the ring currents in the nanotubes. The UV/VIS/MIR spectrum showed the presence of the interband transitions of the semiconducting SWCNTs and an absorption at 17,750 cm<sup>-1</sup> due to the PABS moiety. [Zhao et al. *Adv Funct Mater* **14** 71 2004.] Solution phase NIR spectroscopy against a standard, provided a carbonaceous purity of 80-90% — a procedure which has an accuracy of ~3% [see Itkis et al. *Nano Lett* **3** 309 2003].

**SWCNT-(PEG)<sub>n</sub> {SWCNT-[COO(CH<sub>2</sub>CH<sub>2</sub>-O)-<sub>m</sub>-H]<sub>n</sub>, polyethylene glycol functionalised}, 80-90% SWCNT (carbonaceous purity), bundle dimension: diam 4-5nm x length 0.5-0.6µm, average diameter of individual SWCNT being 1.4nm ±0.1nm, PEG Mw ~600g/mol.** The above SWCNT-(COCl)<sub>n</sub> prepared from 30mg of SWCNT-CO<sub>2</sub>H is mixed with PEG (250mg, m 20-25°) and heated under N<sub>2</sub> at 75° with vigorous stirring for 48 hours. The mixture is cooled to 25° extracted with CHCl<sub>3</sub> several times, filtered, and the dark coloured solution is repeatedly precipitated with EtOH to give SWCNT-(PEG)<sub>n</sub> which is collected (filtration or centrifugation) and dried *in vacuo*. Its solubility in H<sub>2</sub>O is high (5.0mg/ml) and has ~30wt% (PEG) and ~6% trace metals. The ester function can be identified by IR (ν<sub>max</sub> ~1700 cm<sup>-1</sup>), but the <sup>1</sup>H NMR signals are weak and broad (see above). The ester-free SWCNTs can be recovered by acid- and base- catalysed hydrolysis [see above Fu et al. *Nano Lett* **1** 439 2001]. Solution phase NIR spectroscopy against a standard, provides a carbonaceous purity of 80-90% — a procedure which has an accuracy of ~3% [see Itkis et al. *Nano Lett* **3** 309 2003].

**SWCNT-(*p*-C<sub>6</sub>H<sub>4</sub>-R; R = F, Cl, Br, I, SO<sub>3</sub>H, CO<sub>2</sub>H, NO<sub>2</sub>, *n*-butyl, *t*-Bu or CO<sub>2</sub>Me)<sub>n</sub>.** These were prepared by ‘on water’ functionalisation of bundled SWCNTs. The term ‘on water’ refers to the water-based reactions of water-insoluble organic substrates [see K.B. Sharpless and coworkers in Narayan et al. *Angew Chem, Int Ed* **44** 3275 2005 and Klijn & Engberts *Nature* **435** 746 2005]. This technically involves the reaction of *p*-substituted benzene diazonium compounds with the hexagonal rings on the walls of SWCNTs in aqueous medium and represents a “green” or “environmentally friendly” process. The following are optimal conditions for functionalisation. HiPco SWCNTs (10mg) and deionised H<sub>2</sub>O (30ml) were homogenised in a flask (100ml) by stirring at medium setting for 30 minutes, then heating at 80° with the substituted aniline (4 equivalents/SWCNT) and isoamyl nitrite (2 equivalents/SWCNT) with vigorous stirring (stirrer bar) under a reflux condenser overnight. The mixture is then cooled, filtered through a 0.45µm Teflon filter, the filter cake is washed with deionised H<sub>2</sub>O, and Me<sub>2</sub>CO until the filtrate is clear. The cake is collected, sonicated in DMF (25ml) to remove any remaining organic compounds, collected by filtration (0.45µm Teflon filter) and rinsed with Me<sub>2</sub>CO to give the desired functionalised SWCNTs as evidenced by 20-30% weight increases. TGA, Raman [elevated D (diamondoid, ν<sub>max</sub> at 1290 cm<sup>-1</sup>)/G (graphic, ν<sub>max</sub> 1590 cm<sup>-1</sup>) band ratios] and UV-VIS-NIR spectroscopy, XPS, AFM and TEM confirmed the structures. It is interesting that TEM images (on a carbon grid) showed that the SWCNT bundles have smooth edges, whereas functionalised SWCNT bundles have ‘bumps’ all along the edges. These functionalised nanotubes should be useful for further functionalisation reactions [Price & Tour *J Am Chem Soc* **128** 12899 2006].

By using the above procedure SWCNT-(*p*-C<sub>6</sub>H<sub>4</sub>-CH<sub>2</sub>NH<sub>2</sub>) and MWCNT-(*p*-C<sub>6</sub>H<sub>4</sub>-CH<sub>2</sub>NH<sub>2</sub>) were prepared and successfully coupled, *via* their terminal amino group to the carboxy group of *N*(1)-carboxymethyl-thymine, to form thymine ends. These functionalised CNTs readily form stable *double* hydrogen bonds with other thymine groups of these CNTs. This induces controlled non-covalent self-assembled supramolecular aggregation of the CNTs in solvents that do not break hydrogen bonds such as CH<sub>2</sub>Cl<sub>2</sub>, and can form good dispersions in polar aprotic solvents such as DMF. All characterisations were performed using spectroscopic, analytical and microscopic techniques. [Quintana & Prato *Chem Commun* 6005 2009, reviewed by K. Davies *RSC Chemistry World* **6**(11) 6005 2009.] These properties can be of importance in *nanoelectronics*, or in

biological applications such as making patterned active substrates for neuronal growth [Cellot et al. *Nat Nanotechnol* **4** 126 2009].

**I-SWCNT**,  $\mathbf{I} = \{-\text{COOCH}_2\text{-[3,5-di(hexadecyloxy)phenyl]}\}_n$  and **I<sub>PEG</sub>-SWCNT**,  $\mathbf{I}_{\text{PEG}} = \{-\text{COOCH}_2\text{-[3,5-di(methyltriglycoloxy)phenyl]}\}_n$ . These are respectively hydrophobic and hydrophilic SWCNTs which were prepared as described by Y.-P. Sun and coworkers [Fu et al. *Nano Lett* **1** 439 2001] by stirring vigorously SWCNT-(COCl)<sub>n</sub> (30mg, see above) and carefully dried **I** (250mg) under N<sub>2</sub> at 75°/48 hours. The cooled mixture is extracted several times with CHCl<sub>3</sub>, the combined dark-coloured extracts were repeatedly precipitated with EtOH to give **I-SWCNT** with <sup>1</sup>H NMR (500MHz, CDCl<sub>3</sub>) which had δ at 0.88 (t, *J* = 6.5Hz) and typically weak broad bands at 1.1-1.5, 1.6-1.8, 3.5-3.9, 4.0-4.2 and 6.0-6.5 caused by the effect of the CNT. **I<sub>PEG</sub>-SWCNT** was prepared in a similar manner except that its solubility in H<sub>2</sub>O allowed further purification by dialysis for several days against deionised H<sub>2</sub>O (dialysis tubing with Mr ~100,000 cut off to remove PEG). Dendron **I** was prepared by reaction of methyl 3,5-dihydroxybenzoate and hexabromodecane followed by reduction with LAH, and Dendron **I<sub>PEG</sub>** was obtained from the same benzoate and triethylene glycol monoethyl ether in the presence of Ph<sub>3</sub>P and diethyl azidodicarboxylate in THF, followed LAH reduction. The corresponding hydrophobic **I-MWCNT** and hydrophilic **I<sub>PEG</sub>-MWCNT** dendra were similarly prepared from reacting SWCNT-(COCl)<sub>n</sub> with the benzylic OH group in the dendra, and all were characterised by <sup>1</sup>H NMR, UV-Vis spectroscopy, TGA and SEM as well by defunctionalisation of homogeneous solutions under acid- and base- catalysed reaction conditions.

**MWCNT-(PPEI-EI)<sub>n</sub>**. These functionalised MWCNTs were prepared in two ways. *Firstly*, the MWCNTs (20mg) were refluxed with SOCl<sub>2</sub> (5ml) for 24 hours and evaporated *in vacuo*, then the co-polymer PPEI-EI [200mg, poly(propionylethylenimine-co-ethylenimine) [as prepared by Y.-P. Sun and coworkers *Macromolecules* **32** 8747 1999, *Photochem Photobiol* **66** 301 1997, *Chem Commun* 2699 1996]] was added and heated at 160-180° for 12 hours under N<sub>2</sub>, cooled, repeatedly extracted with CHCl<sub>3</sub> and the dark combined extracts were precipitated with hexane. The isolated solid was dissolved in deionised H<sub>2</sub>O and dialysed against fresh H<sub>2</sub>O (dialysis tubing with Mr ~100,000 cut off to remove PPEI-EI) for 3 days. Further purification was by re-precipitation from CHCl<sub>3</sub> solution into hexane, and drying the dark **MWCNT-(PPEI-EI)<sub>n</sub>** solid which had <sup>1</sup>H NMR (500MHz, CDCl<sub>3</sub>) with broad weak bands at δ 0.8-1.4, 1.9-2.6, 2.7-2.9, 3.1-4.3. *Secondly*, (without forming the COCl derivative) by directly heating the MWCNTs (20mg) with PPEI-EI (200mg) at 160-180° for 12 hours under N<sub>2</sub> and worked up as above provided **MWCNT-(PPEI-EI)<sub>n</sub>** which had <sup>1</sup>H NMR (500MHz, CDCl<sub>3</sub>) with broad weak bands at δ 0.8-1.4, 1.9-2.6, 2.7-2.9, 3.1-4.3. Raman, UV-VIS spectroscopy, SEM, TEM and TGA showed that both procedures were effective in producing functionalised MWCNTs which were readily soluble in common organic solvents and in H<sub>2</sub>O. The latter method may have caused amidation as well as ionic interaction between the amino-polymer and the CNT. [Lin et al. *J Phys Chem B* **106** 1294 2002.]

**SWCNT[=CH]<sub>2</sub>N-CH<sub>2</sub>CH<sub>2</sub>OCH<sub>2</sub>CH<sub>2</sub>OCH<sub>2</sub>CH<sub>2</sub>NH<sub>3</sub><sup>+</sup>. HCl]<sub>n</sub> and **MWCNT[=CH]<sub>2</sub>N-CH<sub>2</sub>CH<sub>2</sub>OCH<sub>2</sub>CH<sub>2</sub>-OCH<sub>2</sub>CH<sub>2</sub>NH<sub>3</sub><sup>+</sup>. HCl]<sub>n</sub>**. These salts are very soluble in H<sub>2</sub>O and solutions are stable for more than a month at concentrations of 20mg and 12mg per ml respectively. The free amino terminal group is a useful handle for attachment to physiologically active molecules (see below). They are formed in a 1,3-dipolar cycloaddition reaction between the C-C bonds of the CNTs with the N-glycine N atom and formaldehyde. The glycine in this case is BocNHCH<sub>2</sub>CH<sub>2</sub>O-CH<sub>2</sub>CH<sub>2</sub>OCH<sub>2</sub>CH<sub>2</sub>NHCH<sub>2</sub>CO<sub>2</sub>H and is prepared as follows: BocNHCH<sub>2</sub>CH<sub>2</sub>O-CH<sub>2</sub>CH<sub>2</sub>OCH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub> (30mmol) in dioxane (20ml) at 0° is treated dropwise with a solution of benzyl bromoacetate (2.3g, 10mmol) in dioxane (30ml) during 1 hour, and the mixture is stirred overnight. The solvent is evaporated off *in vacuo*, the residue is dissolved in H<sub>2</sub>O (70ml) and extracted with EtOAc (3 x 50ml), the combined organic phase is dried (Na<sub>2</sub>SO<sub>4</sub>), evaporated *in vacuo*, and the residue is purified by chromatography on Silica gel [NM Kieselgel 60 (70-230 mesh)] and eluted with 1:1 EtOAc/petroleum ether then pure EtOAc to give *N-Boc-aminoethoxyethoxyethylaminoacetic* as an oil. To a solution of this oil (5.05mmol) in MeOH (50ml) is added 10% Pd/C (50mg), the mixture is stirred under H<sub>2</sub> for 24 hours, the catalyst is filtered off (through Celite), the solvent is evaporated and the residue is triturated with dry Et<sub>2</sub>O to give *aminoethoxyethoxyethylaminoacetic acid* as a pure white solid (1.6g, 99%, 5.05mmol), **m 105-106°** with the expected elemental (C, H and N) analyses. The acid has IR-DRIFT (KBr) with  $\nu_{\text{max}}$  at 3250, 2970, 1706, 1620, 1540, 1365, 1115, 686, 590, 480 cm<sup>-1</sup>; the <sup>1</sup>H NMR (200MHz, CDCl<sub>3</sub>, TMS) has δ at 1.40 (s, 9H), 3.22 (m, 2H),**

3.49 (t,  $J = 5.1$  Hz, 2H), 3.64-3.53 (m, 8H), 3.79 (bt, 2H), 5.54 (bt, 1H), 6.23 (bs, 1H), 8.21 (bs, 1H); the  $^{13}\text{C}$  NMR (50MHz,  $\text{CDCl}_3$ , TMS) has  $\delta$  at 170.5, 156.2, 79.1, 70.4, 70.3, 70.1, 66.6, 49.8, 46.8, 40.4, 28.6; EI-MS found  $m/z$  306 ( $\text{M}^+$ ). [Kordatos et al. *J Org Chem* **66** 4915 2001.]

For **functionalisation**, a suspension of full length SWCNTs or MWCNTs [diameter 20-30nm, from Carbon Nanotechnologies, Inc USA ([www.cnanotech.com](http://www.cnanotech.com)), and Nanostructured & Amorphous Materials Inc USA, ([www.nanoamor.com](http://www.nanoamor.com)) respectively] in DMF is treated with the preceding acetic acid and paraformaldehyde, and the mixture is heated at  $130^\circ$  for 96 hours. Unreacted material is removed by filtration, the filtrate is evaporated, the residue is dissolved in  $\text{CHCl}_3$ , washed with  $\text{H}_2\text{O}$ , dried, evaporated, redissolved in  $\text{CHCl}_3$ , precipitated with  $\text{Et}_2\text{O}$ , collected (on a 0.45mm Teflon filter) and washed several times with  $\text{Et}_2\text{O}$  to give the functionalised CNTs in  $\sim 10\%$  yields based on the amount of starting CNTs. They are soluble in solvents such as  $\text{CH}_2\text{Cl}_2$ ,  $\text{CHCl}_3$ , toluene and  $\text{Me}_2\text{CO}$ . Removal of the *N*-Boc group is achieved by dissolving the previous functionalised SWCNTs or MWCNTs in  $\text{CH}_2\text{Cl}_2$ , dry HCl gas is bubbled through the solution whereby the **CNT-chloride hydrochloride salts** (desired materials) separate out. They are collected (or the solvent is evaporated), dissolved in MeOH and precipitated with dry  $\text{Et}_2\text{O}$ . The desired products, as identified by TEM showed that the functionalised SWCNTs and MWCNTs have 10-50nm and 20-30nm mean diameters respectively, their  $^1\text{H}$  NMR spectra are similar with the signals from the oligoethylene glycol chains appearing as broad peaks at  $\sim 3.6$  ppm, and absence of the Boc methyl groups which would have been at 1.2 ppm from TMS. [Georgakilas et al. *Chem Commun* 3050 2002.] These functionalised CNTs were successfully coupled *via* their terminal amino group to the carboxy group of *N*(1)-carboxymethyl-thymine to produce thymine ends. The thymine functionalised CNTs readily form stable double hydrogen bonds with other thymine groups of these CNTs. This induces controlled non-covalent self-assembled supramolecular aggregation on the CNTs in solvents that do not break hydrogen bonds such as  $\text{CH}_2\text{Cl}_2$ , and can form good dispersions in polar aprotic solvents such as DMF. All characterisations were performed using spectroscopic, analytical and microscopic techniques. [Quintana & Prato *Chem Commun* 6005 2009, reviewed by K. Davies *RSC Chemistry World* **6**(11) 6005 2009.] These properties can be of importance in *nanoelectronics* or in biological applications such as making patterned active substrates for neuronal growth [Cellot et al. *Nat Nanotechnol* **4** 126 2009.]

SWCNT[ $=(\text{CHR}')(\text{CH}_2\text{N-R}'')$ ], where  $\text{R}' = \text{H}$ , 4-MeOC<sub>6</sub>H<sub>4</sub>- or 2-pyrenyl-, and  $\text{R}'' = -(\text{CH}_2\text{CH}_2\text{O})_3\text{CH}_3$  or  $-(\text{CH}_2)_7\text{CH}_3$ ]<sub>*n*</sub> and MWCNT[ $=(\text{CHR}')(\text{CH}_2\text{N-R}'')$ ], where  $\text{R}' = \text{H}$ , 4-MeOC<sub>6</sub>H<sub>4</sub>- or 4-pyrenyl-, and  $\text{R}'' = -(\text{CH}_2\text{CH}_2\text{O})_3\text{CH}_3$  or  $-(\text{CH}_2)_7\text{CH}_3$ ]<sub>*n*</sub> were prepared by 1,3-dipolar cycloaddition reactions with short oxidised SWCNTs or purified MWCNTs as in the preceding entry and using paraformaldehyde, 4-methoxybenzaldehyde or 4-formylpyrene to form the substituted pyrrolidines with the double bond(s) of the CNTs. They were characterised by UV-VIS, Raman and  $^1\text{H}$  NMR spectroscopy and by TEM. The fluorescence of the pyrene derivatives were of interest, and all provide means for the preparation of nanocomposites. [Georgakilas et al. *J Am Chem Soc* **124** 760 2002, Calvert *Nature* **399** 210 1999.]

## GRAPHENE MATERIALS

**Graphene** is the name given to a flat monolayer of carbon atoms packed in a two-dimensional (2D) honeycombe lattice of six-membered carbon rings. It is the unit block (2D sheet) of graphitic materials which stack into multilayers to form graphite (3D), rolls to form nanotubes (1D) or wraps to form buckyballs (0D)[see above]. ‘Graphenes’ are defined as single-, double-, and few (3 to <10) carbon layers (2D), with characteristic electrical properties not found in graphite. *Graphene* is the accepted name for a single, or at most a double carbon thick layer which is  $\approx 5\text{\AA}$  thick. Single layer 2D crystals have been prepared (see below) that have high crystal quality where charge carriers can travel thousands of atomic distances without scattering. Its electrical behaviour includes a pronounced ambipolar electric field effect in which charged carriers could be tuned continuously between electrons and holes at concentrations  $n$  as high as  $10^{13}\text{ cm}^{-2}$ , with mobilities  $\mu$  greater than  $15,000\text{ cm}^2\text{ V}^{-1}\text{ s}^{-1}$  under laboratory conditions. Films of 5 layers would be considered as ‘bulk material’, and films with more than 100 layers are considered as thin films of 3D graphite (see graphite [7782-42-5] below). [Geim & Novosolov *The Rise of Graphene: Nat Mat* **6** 183 2007.]

Graphene films were obtained by mechanical exfoliation (repeated peeling) of highly oriented pyrolytic graphite. The 2D crystallites were collected from a fresh surface of a layered crystal using few-layered graphene, FLG, by rubbing against another surface (any solid is suitable, but an oxidised silicon wafer, i.e.  $\text{SiO}_2$  would be also useful later for identification). This allows flakes of graphene to be attached to the surface for characterisation. This approach was very reproducible, has also been used for preparing thicker films ( $\geq 3\text{nm}$ ) which were up to  $100\mu\text{m}$  across, as well as FLGs of up to  $10\mu\text{m}$  in size and visible to the naked eye.

Preliminary identification of single layer films among the resulting flakes was done with an optical microscope. These became visible when they were on top of an oxidised silicon wafer (see above) because even a monomolecular layer adds enough to the optical path of reflected light that the interference colour changes reveal the presence and contours of the film. The process is simple and the 2D crystallites can be identified in about half an hour. Further identification of selected single layers is then done by AFM. It was pointed out that only a small number of single films among the many thicker films were produced by this method, they could not be identified by TEM, but they were transparent to visible light on surfaces other than SiO<sub>2</sub> wafers, and thus require AFM and high resolution AFM imaging for definitive identification and are difficult to find by scanning surfaces at random. These atomically thin sheets, particularly very large 2D molecules, unprotected from the environment are stable in air under laboratory conditions, have high crystal quality and maintain macroscopic continuity. [Novoselov, Geim and coworkers, Electric field effects in atomically thin carbon films, *Science* **306** 666 2004, Two dimensional atomic crystals, *Proc Natl Acad Sci USA* **102** 10451 2005.]

The sp<sup>2</sup> character of all the C-C bonds of graphene confer remarkable electric conductivity to it due to the delocalisation of electrons, and it is difficult to stop the flowing current at will. Geim and Novoselov and their coworkers [Elias et al. Control of Graphene's properties by reversible hydrogenation: Evidence for Graphane, *Science* **323** 610 2009] have succeeded in hydrogenating the double bonds of graphene to make **graphane** which now has C-C bonds with sp<sup>3</sup> character. The reduction transforms graphene from the highly conductive zero-overlap semimetal into an insulator. Reduction was achieved with a hydrogen-helium mixture (10% H<sub>2</sub>) at low pressure (0.075mm Hg) and the direct current plasma ignited between two aluminium electrodes with the samples 30cm away from the discharge zone to avoid damage by energetic ions. Graphene and graphane have distinctly different Raman properties. The reaction is reversed by annealing graphane at 450° (higher temperatures damage graphene) in an argon atmosphere for 24 hours. Thus the original metallic state, lattice spacing, Raman and TEM properties, and even the quantum 'Hall effect' are restored. Note that when the thin film is on a substrate, reduction takes place on the upper face of the film, and for more effective reduction they used free-standing graphene membranes. If one can imagine a magic pencil which can remove hydrogen from graphane and drawing channels of graphene into it, better control of current flow can be achieved [see review by J. Urquart *RSC Chemistry World* **6** (3) 23 2009].

**Cutting of single-layer graphene** (SLG) by anisotropic etching using thermally activated Ni nanoparticles has been developed by Jarillo-Herrero and coworkers [Campos et al. *Nano Lett* **9** 2600 2009, reviewed by L. Brindley, Cutting Graphene to ribbons, *RSC Chemistry World* **9** (8) 2009]. Unlike previous methods for making graphene nanoribbons and the like, their procedure makes SLG nanoribbons and other SLG structures (e.g. triangles, rectangles) in which all cuts (sub-10nm width) are oriented with the same edge-chirality, i.e. aligned along a single crystallographic directions with no hanging edges. Thus the cuts are straight, and always at an angle of 60° and/or 120°. With graphite and FLGs, etching occurs with chirality changing angles of 30°, 90°, and 150°, as well as 60° and 120°. Their method is described here in some detail as it involves **purification procedures useful for SLG preparation**. To ensure reliable cuts in nanoparticle assisted etching, the SiO<sub>2</sub>/Si substrates (wafers, see above) have to be cleaned with Me<sub>2</sub>CO and *iso*-PrOH, and submitted to UV illumination for 5 minutes to remove organic material and for making the SiO<sub>2</sub>/Si surface more hydrophilic to ensure proper wetting during the spin-coating deposition of Ni from solution. Graphene is exfoliated on this clean surface using semiconductor grade tape. The SLG on the clean substrate is identified by optical spectroscopy (see above), AFM (typically SLGs are at a height of 0.8nm) and Raman spectroscopy (graphene's G' 2D peak, see above). The tape residue is removed by heating the SLGs in a quartz tube at 500° for 15 minutes under an argon:H<sub>2</sub> flow (850:150 sccm). After this heat 'cleaning', an aqueous solution of NiCl<sub>2</sub> (2.4mg/ml) is centrifuged onto this surface at 1800rpm for 60 seconds, then heated at 90° for 10 minutes on a hot plate to eliminate H<sub>2</sub>O. The NiCl<sub>2</sub> treated sample in an argon:H<sub>2</sub> flow (850:150 ratio) is firstly annealed at 500° for 20 minutes to convert the salt into Ni nanoparticles, and then the etching is carried out at 1000° for 25 minutes in the same gas flow. The best etching conditions require a slow heating/cooling rate of ~50°/minute. During the etching the Ni nanoparticle (with H<sub>2</sub> adsorbed) furrows through the SLG by catalytically hydrogenating the carbon atoms in its path and converting each atom into a molecule of methane. With SLGs, but not with FLGs or graphite, the cutting paths never cross each other; as soon as the Ni nanoparticle comes within a 10nm distance of a preformed path it changes direction at a 60° or 120° angle. The purification procedure and the Ni concentration stated are very critical if the formation of CNTs are to be avoided. This opens many future directions for studying SLG nanoribbons and other shapes, constrictions and quantum dots with crystallographic edges. H-H. Ahn and B.H Hong and coworkers [Bae, et al, *Nature Nanotechnology* **5** 574 2010] have pressed rectangular graphene films (76cm diagonal) with a roller against an adhesive polymer support and the copper

etched away. The graphene is pressed with rollers onto a polyethylene terephthalate substrate and the polymer adhesive is released on heating. In this way further layers of graphene can be added. When treated with  $\text{HNO}_3$ , the graphene sheet acts as a transparent electrode for touchscreen devices. It is tougher and has better transparency than indium-tin oxide (ITO) electrodes [see below, and review by S. Hadlington RSC *Chemistry World* 7 (8) 22 2010].

**Stacked Graphene Platelet Nanochips (stacked graphene nanofilms, SGNF heat treated) and Platelet Nanofibres (SGNF acid washed)** are commercially available as black powders with 40-50nm mean width, 0.1-10 $\mu$ m length, 0.3g/cm<sup>3</sup> density, and 120m<sup>2</sup> of surface area. The electrical resistivities are 55 $\mu$ Wcm and 120 $\mu$ Wcm for the chips and fibres respectively. These SGNFs are used in nanotechnology research. [US Patents 6,995,115 and 7,001,586.]

**Graphite** [7782-42-5] **m 3652-3697°**, **d<sup>25</sup> 2.09, 2.23**. It is available commercially in various forms such as *flakes* (mesh 75+), *rods* (6mm x 150mm, low density and high density, 3mm x 150mm low density), *powder* ( $\leq 20\mu\text{m}$ ,  $\leq 45\mu\text{m}$ , and  $150\leq\mu\text{m}$ ), *nanofibres* (I.D. 0.5-10nm x O.D 80-200nm x L. 0.5-20 $\mu\text{m}$ , bulk density 0.06-0.08g/ml), *graphitised nanopowder* (particle size <200nm with large mesopores, 10% graphite lattice content, surface area 70m<sup>2</sup>/g, average pore  $\sim 137\text{\AA}$  and d 1.818g/cm<sup>3</sup>) and *platelet nanofibres* (prepared by catalytic CVD then demineralised by HCl, with surface area 80m<sup>2</sup>/g, particle width  $\sim 100\text{nm}$  and particle length  $\sim 2.5\mu\text{m}$ , TEM). [For purification by acid treatment see entry [7782-42-5] in Chapter 5, Inorganic Compounds.] The applications of graphite include the manufacture of 'lead' pencils, lubricants, polishing, pigments, explosives, commutator brushes, carbon anodes, and arc-lamp carbon among many others. **Avoid breathing it** as it can cause coughing, decreased lung function and fibrosis, **use a mouth mask**. [See Holliday et al. in *Comprehensive Inorganic Chemistry* vol 1, Bailar Jr et al. Eds, Pergamon Press, Oxford, pp1250-1294 1973; ISBN 9780080172750.]

### SELF ASSEMBLED MONOLAYERS (SAMs).

SAMs have been of considerable interest for some time [see Chechik, Crooks and Stirling, Reactions and reactivity of self-assembled nanolayers, *Adv Mater* 12 1161 2001] and several useful ones have been prepared using a variety of materials and methods. Only a recent report will be described here, and it is of 2D carbon nanolayers prepared by Mo(IV) and Cu catalysed crosslinking of 1,4-bispropyne- (1), 1,4-bisacetylene- (2), and 1,4-bis(2,3,4-triacetylenephényl)propyne- (3) benzenes with each benzene ring further substituted with a 3-(triethoxysilyl)propylaminocarbonyloxymethyl— [(EtO)<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>-NH-COOCH<sub>2</sub>—] group which acts as a linker in the polymerisation process. These three organic compounds are connected by vacuum-driven Mo(IV) catalysed alkyne metathesis [cf Zhang & Moore *Adv Synth Catal* 349 93 2007], or oxidative Cu catalysed Hay-type coupling [cf Siemen et al. *Angew Chem Int Ed* 39 2633 2000] which polymerise them to form self-assembled monolayers on SiO<sub>2</sub>-, Si<sub>3</sub>N<sub>4</sub>- coated substrates (wafers) or quartz/glass slides when immersed in monomer solutions.

*Preparation and purification of substrates:* The freshly cleaned and dried SiO<sub>2</sub>-, Si<sub>3</sub>N<sub>4</sub>- coated substrates or quartz/glass slides are placed in a reaction tube containing a 15mM solution of (1) or (2), or (3) in toluene and Me<sub>3</sub>N (10mM) under N<sub>2</sub>, sealed and heated at 95-100° for 24 hours. The liquid is removed, the substrate is rinsed with toluene (1x), CH<sub>2</sub>Cl<sub>2</sub> (2x), and sonicated for 5 minutes in toluene. The rinse is repeated, the substrate is sonicated in MeOH for 5 minutes, the rinse is repeated again and the substrate is blown dried under a stream of N<sub>2</sub> ready for monolayer formation.

*Preparation and purification of polymerised coated substrate linked monolayers by Cu Coupling:* CuCl (20mg) and degassed Me<sub>2</sub>CO (3ml) in a reaction vial are treated with TMEDA (61 $\mu$ l), stirred under N<sub>2</sub> at 20° for 30 minutes and the preceding coated substrates are added. The mixture is purged with O<sub>2</sub> from a balloon and stirred under O<sub>2</sub> for 15 hours. The polymerised coated substrate is collected, rinsed with DMF (1x), with a solution of 0.1M sodium diethyldithiocarbamate in DMF (1x), with toluene (1x), with CH<sub>2</sub>Cl<sub>2</sub> (2x), sonicated in toluene for 5 minutes, the rinse is repeated, the substrate is finally sonicated for 5 minutes in MeOH, and the *polymerised linked substrate* blown dry with a stream of N<sub>2</sub>.

*Preparation and purification of polymerised coated substrate linked monolayers by alkyne metathesis:* A mixture of trisamidomolybdenum(IV) propylidyne (5.0mg) and *p*-nitrophenol (3.3mg) dissolved in trichlorobenzene (3.3ml, 1,2,4-) are placed in a vial, the coated substrate is added, the flask is sealed under a vacuum (5 Torr) for 22 hours. The substrate is collected. Rinsed with DMF (1x), 0.1M sodium diethyldithiocarbamate in DMF (1x), toluene (1x), CH<sub>2</sub>Cl<sub>2</sub> (2x), then sonicated in toluene for 5 minutes. The

rinse is repeated, the substrate is sonicated in MeOH for 5 minutes, the rinse repeated again and finally the *polymerised linked substrate* is blown dry in a stream of N<sub>2</sub>.

These monolayers (SAMs) are characterised by UV-Vis, fluorescence and Raman spectroscopy. This is made easy because of the presence of benzene cores within the acetylene and linker chains, these being made of poly(1,4-phenylene-1,3-butadiynylene) polymers. AFM then provides the topology, i.e. shapes (contours), thicknesses and aspect ratios (length and width), of the 2D SAMs. This is done at all stages including those described below.

*Lift-off and transfer of the SAMs:* The ‘lifting off’ is carried out by simple oxygen-reactive ion etching through a layer of ‘photoresist’ (e.g. 5µm x 5µm ‘aspect ratio’) patterned by photolithography. The ‘photoresist’ is placed on top of the monolayer which lies on top of the silicon substrates (support, i.e. the films of SiO<sub>2</sub>, or Si<sub>3</sub>N<sub>4</sub>, or glass). Selective etching from the support is done with concentrated HF which dissolves the silicon, leaving photoresist/SAM or photoresist/monolayer membrane hybrid which can be transferred onto other substrates and then freed from the ‘photoresist’ layer by sonication in Me<sub>2</sub>CO. Characterisation of the monolayers during these stages showed that very little, if any, changes in structure has occurred. The atomic force micrographs (AFMs) showed that the SAMs derived from (1) are monolayers with thicknesses of ≈ 1.5nm (average roughness of 0.18-0.27nm), and those from (2) and (3), unlike from (1), formed multilayers of 2.8nm and 4.7nm respectively (average roughness of 0.5nm and 0.3nm respectively). These SAMs, with aspect ratios being the same as the ‘photoresist’ can be transferred by contact onto a variety of surfaces such as films, pleated sheets, spheres, tubes, cones and any other shapes (followed by removal of the ‘photoresist’ by sonication in Me<sub>2</sub>CO). With a free-standing shape, a free standing silicon support can be used which is then removed by etching to give a free standing SAM. The monolayers are quite robust and can be stretched over ~440nm holes without tearing. This approach and these procedures that were developed by J.S. Moore, J.A. Rogers and coworkers [Schultz et al. *Poc Natl Acad Sci USA* **105** 7353 2008] have considerable merit for synthesising monolayer carbon networks of varying shapes which can be accessible for analysis and device applications.

## DIAMOND NANOMATERIALS

**Nanodiamond (ND)** [7782-40-3] **M 12.01** is commercially available in powder form with particle spherical size <10nm and ≥ 97% trace metal basis, bulk density 0.2-0.7g/ml with BET surface area of 200-450m<sup>2</sup>/g, and in powder form with particle spherical size <10nm and ≥ 95% trace metal, bulk density 0.17g/ml with BET surface area of 278-335m<sup>2</sup>/g. The diamond powder is made by *explosive detonation procedures* that are performed in stainless steel hermetic tanks (e.g. of 0.17m). Carbon condensed products [the HE (High Explosive) composite explosives] such as cast trotyl/cyclotrimethylene-trinitramine (TNT/RDX) in various proportions from 50/50 and increasing RDX, with various initial inert gas (N<sub>2</sub> or Ar) pressures were used to determine the best conditions to produce diamonds. Thirty minutes after the explosion, the pressure in the tank is slowly released, and the carbon product is washed out with water, allowed to settle (requiring quite a long period), the water is decanted off, and residual water is evaporated at 150°. This yielded solid carbonaceous soots which contain ultradispersed diamond (UDD, 2-15nm), together with amorphous carbon (4-25nm), graphite ribbons (<20nm), and spheres (2-4nm) as investigated by TEM, XRD, SAXS (small angle X-ray scattering) and Auger spectroscopy. Purification was carried out to remove amorphous and graphite-like carbon from the detonation soot by boiling with perchloric acid, and the maximum yield of diamond was identified by X-ray analysis. The best yield was ~7wt% obtained when TNT/RDX was 50/50 and initial pressure in the tank was ~7 atmospheres which optimised the yield of UDD. It was also shown that the UDD was thermally transformed to onion-like carbon (OLC) particles. [Kuznetsov et al. *Carbon* **32** 873 1994.] Annealing studies, in the temperature range of 750°—1900°, of detonation diamond (e.g. OLC) in an inert atmosphere (e.g. argon) affected the structure as shown by XRD and HRTEM as well as purified the material further. The IR showed that all the oxygenated groups (mainly OH, COOH and C=O) were removed, and that at the lower temperatures of ~700-800° a higher coverage of the diamond surface with π-bonds resulted. At higher temperatures the powder undergoes a phase transition from cubic diamond to graphite. [Chen et al. *Appl Phys Lett* **74** 3651 1999, Okotrub et al. *J Phys Chem A* **105** 9781 2001.] Previously, reactions of ND with free radicals lead to diamond alkylation [Nakamura et al. *Chem Commun* 900 2003]; and arylation with diazonium salts [Yeap et al. *Langmuir* **25** 185 2009, Liang et al. *ACS Nano* **3** 2288 2009] resulted in low yields of *functionalized nanodiamond*. However, with ND annealing at ~800°, the larger coverage of diamond surface with π-bonds allowed A. Kreuger and coworkers [Jarre et al. *Chem Commun* **47** 544 2011] to achieve stable covalent C-C bonding of aromatic groups using Diels-Alder reaction onto surface annealed ND. The key reaction involved the addition of *o*-quinodimethane [acting as diene, generated *in situ* from *o*-bis(bromomethyl)benzene and substituted

benzenes] to the  $\pi$ -bonds of ND in the presence of 18-crown-6 and KI in refluxing toluene for 72 hours. The substituent on the benzene ring can be *functionalised* further, e.g. an  $\text{SO}_3\text{H}$  group (formed by sulfonation of the benzene ring) can be converted into an SH group ( $\text{PPh}_3$ ,  $\text{I}_2$ ,  $^*\text{C}_6\text{H}_6$ , reflux, 24 hours) which can be made to react with *N*-dye substituted maleimide to form a condensed sulfide. The dye being fluorescent Oregon Green 488 which provided fluorescent diamond particles. The applications of such functionalisations are similar to those of functionalised fullerenes and CNTs including fluorescence labeling, drug delivery, magnetic sensing, electrochemistry, and composite materials among others.

### SOLVENT RESISTANT NANO FILTERS (SRNF)

During the past decade and a half considerable effort has been expended in developing filters for separating mixtures down to the molecular level. An alternative name to SRNF is organic solvent nanofiltration (OSN). This shows promise as an energy- and waste- efficient process. SRNF has been developed particularly for use with organic solvents but it also applies to aqueous media, with the *proviso* that the membranes may be different. The driving force is the pressure applied to the membranes which are classified as UF (ultrafiltration) with pressures of 1 to 5 bar, NF (nanofiltration) with pressures from 5 to 20 bar and RO (reverse osmosis) with pressures  $>10$  bar. In UF substances between 2nm and  $0.1\mu\text{m}$  are rejected, in NF particles or dissolved molecules smaller than 2nm are removed from solution, and in RO only solvents permeate.

SRNFs are essentially of two types, the organic polymer type or the ceramic type. The former are polymers which need to be cross-linked in order to increase their strength. A variety of polymers have been prepared and studied including the composites: PAN (polyacrylonitrile), PVDF [poly(vinylidene fluoride)], PI [polyimide (Matrimide) and (Lenzing P84)], PEI [poly(etherimide)], PA (polyamide), PAH [poly(amide hydrazide)], PSf (polysulfone), PES [poly(ethersulfone)], PEEK (polyether ether ketone), SPEEK (sulfonated PEEK), PPESK [poly(phthalazinone ether sulfone ketone)], SPPEEK (sulfonated PPESK), CA (cellulose acetate), and PBI (polybenzimidazole). The polymers are supported by an ultra-thin (submicron) barrier (TFC, thin film composite) on top of a chemically different polymer support. The TFCs are made of a variety of substances including PDMS (polydimethylsiloxane), PEI (polyethyleneimine), PAA (polyacrylic acid), PPz (polyphosphazene) among others. The TFCs cause the membranes to be quite strong, as the membranes need to be used and reused over again.

Ceramic membranes, which are much stronger than polymer membranes, are commonly made of Al, Si, Ti or Zr oxides and mixed oxides. The top layers of the membrane are prepared by sol-gel synthesis which converts a colloidal or polymeric solution of inorganic precursors (e.g. alkoxides or salts) to a gelatinous product. Viscous binders are usually added prior to layering followed by controlled calcination and finally sintering to form the ceramic membrane. The process can be controlled to provide membranes with specific MWCs (molecular weight cut-offs) and which can sustain defined solvents, temperatures and pressures.

Unfortunately at present not many of either type of membranes are available commercially, but undoubtedly many more will appear on the market in the near future. Commercially available SRNF include the *Se/RO membranes* (Koch Membrane Systems, USA), *Starmem membranes* (Membrane Extraction Technologies, UK), *SolSep membranes* (SolSep, The Netherlands), and *Desal-5 and Desal-5-DK membranes* (GE/Osmomics, USA) designed for aqueous applications, as well as for SRNF.

SRNFs have found applications in food chemistry, catalysis, chiral separations, petrochemical industry and pharmaceutical manufacturing. The preparation, practical considerations, and theoretical transport mechanisms of SRNFs have been critically reviewed by P. Vanezande, L.E.M. Gevers and I.F.J. Vankelecom [*Chem Soc Rev* **37** 365 2008].

### NANO METALS AND METAL DERIVATIVES

**Antimony (III) oxide nanopowder ( $\text{Sb}_2\text{O}_3$ )** [1309-64-4] **M 291.5, bulk density 0.5-0.6g/ml.** It is available in particle size of  $<250\text{nm}$  (BET). It is used in paints, pigments, enamels, glasses and flame-proofing canvas. It is toxic and should not be inhaled.

**Antimony-tin oxide nanopowder** [ATO,  $\sim(\text{SnO}_2)_{0.9}(\text{Sb}_2\text{O}_5)_{0.1}$ ] **M 167.0.** It is available in particle size of  $<50\text{nm}$  and has the alloy composition of 89-93% tin(IV) oxide and 7-11% antimony(V) pentoxide. The surface area is  $74\text{ m}^2/\text{g}$ . It is toxic and should not be inhaled.

**Cobalt** [7440-48-4] M 58.9, m 1495°, b 2870°, d<sup>20</sup> 8.71, resistivity 6.24 μΩcm/20°, Brinell hardness 125.

**Cobalt nanoparticles** for use in *magnetic fluids* (MFs) are available commercially with an average particle size of 10-12nm. It is in the form of a black powder and is prepared by a *thermolysis process* using a strict formula. Thus to dicobalt octacarbonyl {Co<sub>2</sub>(CO)<sub>8</sub>, 17.1g, 100mmol, see [10210-68-1]} under flowing argon is added Al(C<sub>8</sub>H<sub>17</sub>)<sub>3</sub> (4.4ml, 10mmol) [Co:Al = 10.1] dissolved in toluene (300ml) in one portion, and the mixture is stirred and heated at 110° under a reflux condenser for 18 hours. The reaction is carried out in an efficient fume cupboard because **POISONOUS** carbon monoxide evolution occurs. The colour of the solution changes to dark brown and a black precipitate separates from the clear solution. The mixture is cooled to 20°, and still under argon a further amount of Al(C<sub>8</sub>H<sub>17</sub>)<sub>3</sub> (1.2ml, ~30% of the initial quantity) is added, the temperature is raised to 110° and is heated for 3 hours more. The mixture is cooled to 20°, and stirred further for 16 hours. Smooth oxidation is carried out by bubbling (use a capillary) air through the mixture for 6 hours. The product is stirred overnight and the precipitated Co is allowed to settle during 2 hours. The supernatant is decanted and the solid is isolated in *toluene wet form*, or by drying *in vacuo* to give an air stable *Co nano-powder* (5.2g); both of which can be handled under laboratory conditions. The particle size of the Co, as determined by TEM and HRTEM is ~10±1.1nm (see further, however). The particle size is sensitive to the thermolysis conditions and to the Al(alkyl)<sub>3</sub>. With alkyl = Me, Et or *n*-octyl (C<sub>8</sub>H<sub>17</sub>) and a Co:Al ratio of 10:1 as above, the nanoparticle sizes are 3-4, 5-8 or ~10nm respectively. However with a Al(C<sub>8</sub>H<sub>17</sub>)<sub>3</sub> and Co:Al ratio of 1:2 the particle size was always ~5.4nm.

**Peptisation of Co nanoparticles:** The Co particles are suspended in toluene and peptised by adding 2ml of KorantinSH, oleic acid, LP-4 (a fatty acid condensation polymer, or AOT (sodium dioctylsulfosuccinate) as surfactants and sonicated in an ultrasound bath for 10 minutes to give a clear dark brown Co-MF. After drying a sample *in vacuo* elemental analysis indicated the presence 67.8% of Co and 0.98% of Al. These MFs were found to be stable for more than 5 months [by X-ray absorption near edge structure (XANES) measurements] under air. It should be pointed out that if the Al(C<sub>8</sub>H<sub>17</sub>)<sub>3</sub> is washed away from the Co particles immediately after the synthesis, the magnetic properties are markedly reduced after exposure to air. The chemical nature of the analysed nanoparticles shows that the stability of the local electronic and geometric structure is significantly affected by the surfactant used. Peptised Co nanoparticles can also be dispersed in kerosene or mineral oil as precursors for MFs.

**Cobalt nanoparticles (surface modified with L-cysteine ethyl ester) ethanol wet** are available as ~10nm black powder (wet with EtOH) which is best used within 3 months. The material can be easily transferred into stable aqueous suspensions, and can be used as a starting material for surface modifications (e.g. dextran coating) or the preparation of magnetic polymer microspheres.

**Copper-zinc alloy, 55-60% Cu** [12682-85-8] Cu/Zn, M 64.3. It has the composition of Cu (60% by wt) and Zn (40% by wt). The **nanopowder, has particle size <150 nm (TEM), 37-41% Zn basis**. It is a macro-agglomeration of ultra-fine particles, with sizes of *ca* 70 nm and is commercially available. It has trace Mn 1.5-2.5%, Sn 1.5-2.0% and Pb 0.5-2.5%.

**Copper zinc iron oxide, 98.5% trace metal basis (zinc copper ferrite, copper zinc ferrite)** [66402-68-4] M 416.3 (CuZnFe<sub>4</sub>O<sub>4</sub>), d<sub>4</sub><sup>25</sup> 5.5. It is a nano powder with particle size <100nm (BET). The actual particle size is <50nm (XRD) and is commercially available.

**Gold nanoparticles stabilised by gum Arabic (GA-AuNP).** AuNPs have been widely used for a variety of purposes and water soluble composites with gum Arabic (GA) are commercially available. Gum Arabic [9000-01-5] from *Acacia* gum is a branched polymer of galactose, rhamnose, arabinose and glucuronic acid as the Ca, Mg and K salts with M ~250,000, and is a non-toxic and physiologically compatible substance. GA-AuNP has been developed by Kannan, Katti and coworkers [Kattumiri et al. *Small* 3 333 2007]. It is prepared simply by mixing NaAuCl<sub>4</sub> with an aqueous solution of a non-toxic phosphine amino acid [P(CH<sub>2</sub>NHCHCH<sub>3</sub>COOH)<sub>3</sub> \*THPAL, see preparation below] reducing agent in the presence of a 0.2% aqueous solution of gum Arabic. This resulted in an immediate reaction which produced GA-labeled AuNPs in over 98% yield. The aqueous solutions are stable for months. Note that if GA is omitted, the reaction is also instantaneous but the solutions agglomerate within 4-6 hours. TEM images showed that the size of GA-AuNPs thus produced is 15-20nm. It is stable in the presence of cysteine, bovine and human serum albumins and does not agglomerate in 25% NaCl

solution. Formulations of it can be readily administered site specifically (*intravenously*), for diagnostic imaging (*computer tomography* CT), and is biocompatible for therapeutic applications in nanomedicine. GA-AuNPs are also suitable for nanoelectronics which include sensor design, MEMS applications, spin coating, self-assembly and formation of monolayers.

K.V. Katti and coworkers [Raghuraman et al. *J Am Chem Soc* **125** 6955 2003] prepared the reducing agent *\*tris[N-(R or S)-alaninylmethylene]phosphine* (\*THPAL) by adding tris(hydroxymethyl)phosphine (0.50g, 4.03mmol, see [2767-80-8]) in H<sub>2</sub>O (5ml) dropwise to R- or S- alanine (1.08g, 12mmol) in H<sub>2</sub>O (10ml) at 25° with stirring under N<sub>2</sub> for 1 hour. Evaporation *in vacuo* gave a white solid which, after washing with MeOH and drying *in vacuo* was pure product (90% yield). The <sup>1</sup>H NMR (300MHz, D<sub>2</sub>O) has δ at 1.38 (d, *J* = 6.0Hz, 9H, NCH(CH<sub>3</sub>)COOH), 3.47 (d, 6H, PCH<sub>2</sub>), 3.65 (m, 3H, NCH(CH<sub>3</sub>)COOH); the <sup>13</sup>C NMR (75MHz, D<sub>2</sub>O) has δ at 14.84 (s, NCH(CH<sub>3</sub>)COOH), 42.65 (d, *J*<sub>p-c</sub> = 12.82Hz, PCH<sub>2</sub>), 59.35 (d, *J*<sub>p-c</sub> = 5.77 Hz, NCH(CH<sub>3</sub>)COOH), 174.10 (s, NCH(CH<sub>3</sub>)COOH); and the <sup>31</sup>P NMR (121.5MHz, D<sub>2</sub>O) has δ at -39.9 (s); and the ESI-MS has calculated for C<sub>12</sub>H<sub>24</sub>N<sub>3</sub>O<sub>6</sub>P 337.3, found *m/z* 337.6. The X-ray crystal structure analysis of the S-enantiomer (4 H<sub>2</sub>O) revealed that the alanine portions were packed to form two-dimensional bilayers running parallel to (001). [See also Kannan et al. *J Am Chem Soc* **128** 11342 2006.]

**Gold nanoparticles stabilised by agarose (A-AuNP).** K.V. Katti and coworkers [Kattumuri et al. *Appl Phys Lett* **88** 153114 2006] prepared this similarly, but replacing GA by agarose. A-AuNPs were used for surface-enhanced Raman spectroscopic detection of DNA nucleosides as well as the other applications stated above.

**Gold (~1%) nanoparticles on titanium oxide extrudates (AUROLite Au/TiO<sub>2</sub>), on aluminium oxide extrudates (Au/Al<sub>2</sub>O<sub>3</sub>), on zinc oxide granulates (Au/ZnO), and on manganese oxide and carbon (Au/MnO<sub>x</sub>/C).** These are available commercially and used to catalyse some reactions. A 1% AuNP (~2nm) preparation on TiO<sub>2</sub> is used for catalytic purposes in 'Green' processes, e.g. in the presence of NaOMe in alcohols as solvents it catalyses the oxidation of aldehydes to esters using air as oxidant at ambient or lower temperatures [Marsden et al. *Green Chem* **10** 168 2008]. It also catalyses the oxidation of CO and H<sub>2</sub> using O or NO as oxidants [Walther et al. *J Catal* **260** 86 2008]. Au/Al<sub>2</sub>O<sub>3</sub>, Au/ZnO and Au/Mn<sub>x</sub>O/C are active catalysts for low temperature oxidation of CO and/or of CH<sub>4</sub> [Grisel & Nieuwenhuys *Catal Today* **64** 69 2001, Ma et al. *J Catal* **252** 119 2007, see also Freund *Catal Today* **117** 6 2006]. The preparations, properties and identification of these and related 'Gold on support' substances will be found in these references; and in Hugon et al. *Gold Bull* **41** 127 2008, Supansomboon et al. *Gold Bull* **41** 296 2008, and Steyn et al. *Gold Bull* **41** 318 2008.

**Indium-tin oxide nanopowder (ITO) [50926-11-9] M 264.9, surface resistivity of 100Ωcm.** Available in particle size <50nm. It is coated on glass for making transparent electrodes for screens (e.g. touch screens). However, graphene electrodes have better transparency and are tougher (see above) [Ahn et al. *Nature Nanotechnol* **5** 574 2010, DOI:10.1038/nnano.2010.132]

**Pd<sup>(0)</sup> EnCat™** is obtained by reducing the \*EnPd(OAc)<sub>2</sub> (0.4g, 0.4mmol/g, see below) in Et<sub>2</sub>O (8ml) with formic acid (8ml) at 45° for 2 hours. The mixture is cooled and the solid microcapsules are filtered through a polyethylene frit (20 micron porosity), washed with distilled H<sub>2</sub>O (3 x 30ml), Me<sub>2</sub>CO (3 x 30ml) and Et<sub>2</sub>O (3 x 30ml). The microcapsules are dried (at <0.5mm) at 45° for 5 hours to provide black **Pd<sup>(0)</sup> EnCat** microcapsules (0.35g, containing Pd nanoparticles of ~2nm size). It is an efficient catalyst for reductive ring-opening of epoxides to the respective alcohols which occurs in ~99% yields. The reaction requires either HCOOH/Et<sub>3</sub>N or H<sub>2</sub> as hydrogen donors, and the catalyst can be recycled ~10 times [Ley et al. *Org Lett* **5** 4665 2003].

**\*EnPd(OAc)<sub>2</sub> [Pd EnCat™]** is prepared from polymethylene polyphenylene di-isocyanate (SUPRASEC 5025, average functionality of 2.7) and Pd(OAc)<sub>2</sub> dissolved in CHCl<sub>3</sub> and then dispersed at 800rpm for 1 minute into an aqueous solution of Na lignosulfonate (Reax 100M), polyvinyl alcohol (Gohsenol GL 03) and the polyoxyethylene ether of butanol (Tergitol XD), using a mechanical overhead stirrer with a rotary blade. The resulting emulsion would have a particle size range of 20-250microns and the mixture is then gently shaken for 16 hours. The solid polyurea microcapsules formed are collected on a polyethylene frit (20 micron porosity), washed with de-ionised H<sub>2</sub>O (5 x 50ml), Me<sub>2</sub>CO (5 x 50ml), Et<sub>2</sub>O (3 x 50ml) and dried at room temperature.

Encapsulated Pd catalysts such as **Pd EnCat™** are available commercially. These particles are defined by their matrix content e.g. 30% or 40%, the latter having the smaller pore size. [See also Bremeyer et al. *Synlett* 1843 2002, Yu et al. *J C S Chem Commun* 678 2003, Vickerstaffe et al. *Org Biomol Chem* **1** 2419 2003.]

**Platinum nanoparticles on spherical polyelectrolyte brushes (SPB).** Pt crystals (2-3nm) were deposited on SPB using the procedure of M. Ballauff and coworkers [Schrinner et al. *Science* **323** 617 2009]. The SPB consists of a polystyrene core (~100nm diameter) onto which a cationic polyelectrolyte ( $^+H_3NCH_2CH_2OOC^-$ )<sub>n</sub> is attached [Schrinner et al. *Adv Mater* **20** 1928 2008]. A mixture of  $AuCl_4^-$  and  $PtCl_6^{2-}$  was reduced with  $NaBH_4$  on the surface of the cationic SPB to form alloy nanoparticles ( $Au_{45}Pt_{55}$  ratio) on the surface. The Au was removed with cyanide and  $O_2$ . Thus a solution of  $1.9 \times 10^{-5}$  M NaCN (4ml) was added dropwise within 25 minutes to a stirred suspension of AuPt-SPB (0.04 weight %) at room temperature under air. The high dilution of the cyanide is crucial for avoiding complete dissolution of the NPs and coagulation. Air was bubbled through the solution to remove completely the Au atoms. After 3 hours the colour of the solution was blue due to the formation of pure Pt NPs. [Schrinner et al. *Macromol Chem Phys* **208** 1542 2007.] Detailed examination of the composite particles by cryo-TEM, wide angle XRS and HR-TEM showed that the Pt NPs are well-defined faceted single crystals embedded in the SPB-chain layer. This composite system has excellent colloidal stability, and high catalytic activity with turn over numbers of as high as  $1580 \pm 50$  for the reduction of *p*-nitrophenol to *p*-aminophenol using  $NaBH_4$ , which is among the highest ever observed for this reaction. [For a review see H. Birch RSC *Chemistry World* **6** (3) 29 2009.]

**Rhodium nanoparticles entrapped in Rh/AlO(OH) matrix (~5wt% Rh loading).** The catalyst is prepared from a mixture of  $RhCl_3 \cdot xH_2O$ ,  $Al(secBuO)_3$  and 2-butanol (compare with Ru/AlO(OH) below) at  $100^\circ$  for 3 hours, aging in air for 1 day, filtering, washing the solid with  $Me_2CO$  and drying in air at  $25^\circ$ . It is estimated by high resolution transmission electron microscopy (HRTEM) and X-ray diffraction that the Rh particle sizes in the matrix are 2.5-3.0nm. It is an efficient catalyst for the hydrogenation of arenes, e.g. benzene, naphthalene, quinoline, at low pressures of  $H_2$  (~1 atmosphere) and room temperature in yields approaching 100% and with high turn over, with *ca* 1 mol% of Rh in the catalyst. [Park et al. *Chem Commun* 5667 2005].

**Ruthenium (nanoparticles) in aluminium oxide/hydroxide (~2.5wt% Ru loading).** In this catalyst, Ru is encapsulated in an aluminium oxy-hydroxide matrix where the metal has been shown by energy dispersive X-ray analysis (EDX) and X-ray photoelectron spectroscopy (XPS) to exist mainly as Rh(0) in the matrix. It is prepared in a one-pot synthesis through nanoparticle generation and gelation. Thus  $RuCl_3 \cdot xH_2O$  (52mg, 0.25mmol) and  $Al(secBuO)_3$  (2.5g, 10mmol) in EtOH (1.2ml, 20mmol) under a reflux condenser are heated, with stirring, at  $100^\circ$  for 1 hour, forming a black suspension to which  $H_2O$  (2.0ml) is rapidly added. The mixture is stirred for a further 30 minutes at  $100^\circ$ , filtered, the black solid is washed with  $Me_2CO$  and dried in air at  $25^\circ$  to give the catalyst as a grey powder (0.74g, 2.5wt% of Ru). It is used as a recyclable catalyst for the efficient oxidant-free alcohol dehydrogenation see Chapter 6, Catalysts-Part 1. [Kim, Park and Park *Org Lett* **8** 2543 2006.]

**Ruthenium nanoparticles stabilised in polymer ligands.** A general procedure was used for making these colloids (agglomerates) which involved introducing ruthenium (1,5-cyclooctadiene)(1,3,5-cyclooctatetraene) (158mg, 0.5mmol,  $[Ru(COD)(COT)]$  see [127382-91-6]) in a Fischer-Parr bottle and left *in vacuo* for 30 minutes, then THF (25ml, degassed by freeze-pump cycles) is added and the yellow solution is cooled to  $-80^\circ$ , after which the ligand (0.1mmol) in THF (~60ml) is introduced to the bottle. The bottle is pressurised under 3 bar of  $H_2$  and allowed to warm to room temperature. After ~20 hours a brown-black suspension was obtained. Complete decomposition of the Ru complex was checked by eliminating the  $H_2$  (e.g. by blowing  $N_2$  through) and taking a 3ml aliquot through a small  $Al_2O_3$  column when the filtrate should be colourless. The volume of the solution was then reduced to *ca* 15ml, pentane (50ml) was added, the resulting mixture was cooled to  $-80^\circ$  at which temperature a brown precipitate was formed. This was filtered off (or centrifuged), washed with pentane and dried *in vacuo*. The ligands used were PVP (poly vinylpyrrolidone), *n*-alkyl (C8, C12 and C16) amines and *n*-alkyl (C8, C12 and C16) thiols in varying amounts (from 0.2 to 1 equivalent) giving Ru percentages of ~55 to 80%. The colloids were characterised by microanalysis, IR after CO absorption, high resolution EM and wide-angle X-ray scattering. In THF and in a polymer matrix (Ru/polymer ~5%) crystalline particles of uniform mean size (1.1nm) and agglomerated particles (1.7nm) were obtained in PVP and cellulose acetate. The reaction with various concentration of alkyl amines and alkyl thiols lead to agglomerate particles or particles dispersed in solution both displaying mean size of 2-3nm. In the case with the amine ligands the particles were generally elongated with the tendency of forming worm or rod like structures at high amine concentrations, whereas  $^{13}C$  NMR studies showed that the stabilised particles were not fluxional, but thiol groups were oxidised to disulfide groups probably by the Ru surface. Because of their chemically reactive groups they are potentially very useful

in nanotechnology. [Pan et al. *J Am Chem Soc* **123** 7584 2001]. In a similar synthesis ruthenium nanoparticles were stabilised by organosilane fragments, by using *n*-octylsilane, giving particles of ~2.3nm diameter which is a very narrow distribution of size. They were characterised by TEM, as well as solid state <sup>13</sup>C MAS NMR. [Pelzer et al. *Chem Mater* **16** 4937 2004.]

**Silver acetate** [563-63-3] see also entry in Chapter 6, "Catalysis—Part I". Among the current intense activities in the synthesis of hybrid materials, where an inorganic phase is present as nanometer-sized particles dispersed throughout an organic matrix, is the preparation of a *ca* 190nm uniform film of exceptionally reflective and surface conductive silver "mirror" on a flexible poly(amic) matrix. The Ag-containing resin solutions are made first by dissolving AgOAc in a small volume of dimethylacetamide (DMAc, [127-19-5]) by adding 1.35 equivalents of 1,1,1-trifluoro-2,4-pentanedione (TFAH). As AgOAc is not very soluble in DMAc, addition of TFAH converts the acetate salt into the much more soluble AgTFAH complex. The poly(amic) matrix is prepared by co-polymerising 3,3',4,4'-benzophenonetetracarboxylic anhydride (BTDA, [2421-28-5]) with 4,4'-oxydianiline (APE, 4,4'-diaminodiphenyl ether, [101-80-4]), and making a 15%w/w solution in DMAc by stirring for 5 hours to give a viscosity of 1.7-1.8 dL/g at 35°. The poly(amic) solution is added to the Ag solution to give the desired Ag to BTDA/APE polymer ratio (10.7 to 13.0% Ag), cast into films (onto soda lime glass plates) to give cured films of 20-25 mm thickness. Air (10% relative humidity) is slowly flowed over the film for 18 hours, then thermally cured in a forced air oven with a cycle involving heating at 135° for 20 minutes, holding for 1 hour, heating at 300° for 4 hours, and holding at 300° for 7 hours. This process reduces Ag(I) to the metal and releases all the volatiles. Uniform nanometer thin films of Ag metal (see above) are thus formed in the polymer matrix. Characterisation by X-ray diffraction, transmission (TEM) and scanning (SEM) microscopy, tapping mode atomic force microscopy, X-ray photoelectron microscopy (XPS), and conductivity, reflectivity, thermal and mechanical measurements showed that the films have excellent properties, and are stable in air below 325°. This 'film-to-film' method minimises the amount of Ag used. The applications for this Ag-copolymer silvered films with exceptional reflectivity, thermal, and surface conductivity are immense, and include the fabrication of lightweight optical mirrors, sunshields (e.g. in space telescopes), radiofrequency antennas for management of electromagnetic signals in space, Ag coated tubing to deter catheter-induced urethritis, elastomeric devices, concentration of solar energy, flexible conductive patterned surfaces and tapes. [Southward et al. *Chem Mater* **11** 501 1999.]

**Silver nanoparticles on spherical electrolyte brushes (SPB).** Compare these with the above Pt NPs on SPB. They were also developed by M. Ballauff and coworkers [Lu et al. *J Phys Chem C* **111** 7676 2007]. In this case Ag nanoparticles were synthesised onto the polystyrene (PS) core—poly(acrylic acid) (PAA) SPB particles *in situ* by photoemulsion polymerisation. The PS core with a thin layer of photo initiator {2-[*p*-(2-hydroxy-2-methylpropiophenone)]-ethylene glycol-methacrylate} was made by standard emulsion polymerisation procedures also developed by M. Ballauff and coworkers [Gua et al. *Macromolecules* **32** 6043 1999]. The PS-PAA-Ag composite particles were prepared *in situ* by mixing diluted PS core solution (1 wt %) with a defined quantity of functional monomer silver acrylate (30 mol% of the amount of styrene), degassing and refilling with N<sub>2</sub> (5 times). Then the mixture was irradiated under N<sub>2</sub> with UV-VIS radiation at ~25° for 90 minutes while being vigorously stirred to keep the mixture homogeneous. Coagulum was removed by filtration through glass wool and the Ag nanocomposite particles were washed by dialysis against purified H<sub>2</sub>O using a cellulose nitrate membrane (100nm pore size). DLS showed that the polyelectrolyte brushes were on the PS core; TEM, Cryo-TEM, and wide-angle XRS revealed that the Ag NPs in the brushes were crystalline with a diameter of 3 ± 1.2nm.

This Ag-composite is stable and has very good catalytic activity. Reduction of *p*-nitrophenol using NaBH<sub>4</sub> is very fast, albeit slightly slower than with Pt or Pd immobilised on related carriers.

**Silver nanoparticles [AgNP], on gum Arabic, gelatin or starch.** Available as yellow-brownish liquids. They are water soluble in the form of 5-10nm spheres (10-15nm for starch) and have UV with λ<sub>max</sub> at 405-410nm. The gum Arabic (GA), gelatin and starch stabilise these particles and can be used for sensor design applications, for *in vitro* as well as *in vivo* antimicrobial and antifungal purposes.

**Silver-tin alloy nanoparticles, M 118.3.** These particles are available in <150nm in size and contain 3.5% Ag with the formula Ag<sub>0.035</sub>Sn<sub>0.965</sub>. They have a surface area >5.4 m<sup>2</sup>/g.

**Stannic oxide nanopowder (Sn(IV)O<sub>2</sub>)** [18582-10-5] **M 150.7**. It is available in particle size of <100nm. It is used for polishing metal or glass, used in coloured glass, enamels and as a mordant for colouring fabrics. It is toxic and should not be inhaled.

**Zinc nano metallic powder (ZnNP)** [7440-66-6] **M 65.4**. ZnNP is available as a gray powder of spherical particles of 75-125nm size. It is a very reactive form of the metal as it has a high surface area. The powder is particularly reactive with organo-halides to form organo-Zn compounds and in azo-coupling reactions. Sonication will de-agglomerise the nano Zn into particles of 35nm size. ZnNP with particle size <50nm is also available commercially with BET surface area of 35-50 (m<sup>2</sup>/g).

## SOME ORGANIC AND METAL-ORGANIC COMPOUNDS USED IN NANOTECHNOLOGY

**1-Adamantane thiol (tricyclo[3.3.1.1<sup>3,7</sup>]decane-1-thiol)** [34301-54-7] **M 168.3, m 95-97<sup>o</sup>, 100-102<sup>o</sup>, 99-106<sup>o</sup>, pK ~11.2**. This thiol was prepared by various methods namely by formation of 1-adamantylisothiourinium bromide from 1-adamanyl bromide followed by alkaline hydrolysis [Geigy A.-G. **Belg. Pat** 629,370 1963, *Chem Abstr* **60** 9167 1963], by refluxing 1-adamantanol with Lawesson's reagent (see [19172-47-5]) in toluene [Nishio *J Chem Soc, Perkin Trans I* 1113 1993], and by photolysis of *N*-(1-adamanylcarbonyloxy)pyridin-2-thione [Barton reaction: Barton et al. *Tetrahedron Lett* **35** 6057 1994]. The thiol is generally purified by drying over P<sub>2</sub>O<sub>5</sub>, dissolving in Skellysolve B (see Aliphatic Compounds, Chapter 4) or *n*-hexane, passing through a column of Alumina in *n*-hexane, and eluting with *n*-hexane/EtOAc (97:3). Store it dry under N<sub>2</sub> or argon. The IR (CCl<sub>4</sub>) has  $\nu_{\max}$  at 2190, 2850, 1450 and 2565 (S-H) cm<sup>-1</sup>, the <sup>1</sup>H NMR (CCl<sub>4</sub>) has  $\tau$  at 8.06 (s, 9,  $\beta$  and  $\gamma$  H), 8.29 (s, 6,  $\delta$  H) and 8.57 (s, 1 S-H); and the MS has *m/z* (peak height) 168 (14, M<sup>+</sup>), 136 (12), 135 (100), 93 (15), 79 (17). The *S*-2,4-dinitrophenylsulfenyl derivative gives yellow needles from MeOH with **m 159-160<sup>o</sup>**. [Tanner & Brownlee *J Canad Chem* **51** 3366 1973]. The *S*-CH<sub>2</sub>CO<sub>2</sub>Et derivative (from NaNH<sub>2</sub>/BrCH<sub>2</sub>CO<sub>2</sub>Et) has **b 117-118<sup>o</sup>/0.001mm**, and on hydrolysis (NaOH/EtOH, 5 hours) gave  $\alpha$ -(adamant-1-ylthio)acetic acid **m 68-70<sup>o</sup>** (hexane/pentane). Similarly obtained are  $\alpha$ -(adamant-1-ylthio)propionic acid **m 142-144<sup>o</sup>** (cyclohexane),  $\alpha$ -(adamant-1-ylthio)butyric acid **m 113-114<sup>o</sup>**,  $\alpha$ -(adamant-1-ylthio)isovaleric acid **m 134-145<sup>o</sup>** (cyclohexane),  $\alpha$ -(adamant-1-ylthio)caproic acid **m 74-76<sup>o</sup>**,  $\alpha$ -(adamant-1-ylthio)- $\alpha$ -phenylacetic acid **m 122-124<sup>o</sup>** (cyclohexane/hexane) as well as other acids that are reported [Geigy A.-G. **Belg. Pat** 629,370 1963, *Chem Abstr* **60** 9167 1963]. 1-Adamantane-thioether is a good novel sialoside protecting group which is also used for coupling with adequately protected sugars [Critch & Li *J Org Chem* **72** 7794 2007].

1-Adamantanethiolate molecules have been used in a new patterning technique (microdisplacement printing) to form self-assembled mono-layers (SAMs) on an Au(111) surface for contact printing. The attached thiolate molecular film hinders lateral surface diffusion of the patterning molecules allowing the use of such molecules which are too mobile to pattern by other methods. It is used for SAMs Cat 659452-5G molecular spacer in nanotechnology [ *J Org Chem* **72** 7794 2007, Dameron et al. *Nano Lett* **5** 1834 2005].

**Coronene (hexabenzobenzene, [6]circulene)** [191-07-1] **M 300.4, m 420<sup>o</sup>, 425-428<sup>o</sup>, 428<sup>o</sup>, 438-440<sup>o</sup>, 440<sup>o</sup> (uncorrected), 442<sup>o</sup> (sealed tube) b 525<sup>o</sup>/atm**. Purify coronene by passing a solution in \*C<sub>6</sub>H<sub>6</sub> through a short Al<sub>2</sub>O<sub>3</sub> column and eluting with \*C<sub>6</sub>H<sub>6</sub>, followed by evaporation and recrystallisation from \*C<sub>6</sub>H<sub>6</sub> or xylene (**m 245-248<sup>o</sup>**), and sublimation at 200-300<sup>o</sup>/20mm, or 420<sup>o</sup>/atm requiring ~2 hours. Crystallisation from \*C<sub>6</sub>H<sub>6</sub> yields amber-yellow needles (5—15mm long). Alternatively, coronene in \*C<sub>6</sub>H<sub>6</sub> is added to a saturated solution of picric acid in EtOH whereby the *picrate* (**m 310-325<sup>o</sup> dec**) separates as red needles. The *picrate* in \*C<sub>6</sub>H<sub>6</sub> is passed through an Al<sub>2</sub>O<sub>3</sub> column and eluted with \*C<sub>6</sub>H<sub>6</sub> when picric acid remains strongly adsorbed on the column. The eluate is evaporated and the residue recrystallised from toluene, and sublimed (yellow needles) at 250<sup>o</sup>/high vacuum. It has been distilled at atmospheric pressure using a naked flame. In concentrated H<sub>2</sub>SO<sub>4</sub> a green-yellow solution is obtained. The *picrate* forms bright red needles from \*C<sub>6</sub>H<sub>6</sub> with **m 310-325<sup>o</sup>**. The 1,3,5-trinitrobenzene adduct gives orange needles which decompose at high temperature. The UV spectrum in \*C<sub>6</sub>H<sub>6</sub> contains 16 sharp peaks between 290 and 428nm, but in EtOH it has  $\lambda_{\max}$  (log  $\epsilon$ ) at 228 (4.08), 252 (3.88) and 290 (5.10) nm. [Baker et al. *J Chem Soc* 1114 1951, Baker et al. *J Chem Soc* 1120 1951, Clar & Zander *J Chem Soc* 4616 1957, Hopff & Schweizer *Helv Chim Acta* **42** 2315 1959, *Beilstein* **5** III 2661, **5** IV 2830.] It is a nano-channel organic semiconductor [Newman et al. *Chem Mater* **16** 4436 2004] and is used to synthesise MBE-grown layered superconductors [*Japanese J Appl Phys, Part 1* **34** 3837-3845 1995].

**6-Mercaptohexylferrocene** [134029-92-8] **M 302.3, b 321-353°**. This thiol is prepared in four steps from ferrocene. Thus a mixture of 6-bromohexanoyl chloride (3.2g, 15mmol, see [22809-37-6]) and anhydrous  $\text{AlCl}_3$  (2.0g, 15mmol) in cold ( $0^\circ$ )  $\text{CH}_2\text{Cl}_2$  (40ml), which is stirred (20 minutes) under argon, is added dropwise with stirring to ferrocene (2.79g, 15mmol) in  $\text{CH}_2\text{Cl}_2$  (40ml) over a period of 20 minutes when the colour of the solution turns purple. After stirring for 2 hours, the stirring rate is increase while  $\text{H}_2\text{O}$  (20ml) is added slowly, and the solvent boils gently. The organic layer is collected after 10 minutes, washed with  $\text{H}_2\text{O}$  until the washings are neutral, dried ( $\text{MgSO}_4$ ), filtered, concentrated *in vacuo*, and the residue is subjected to chromatography on silica-gel (230-400 mesh) with hexane/EtOAc (100:1) as eluent. The second orange band (the first is ferrocene) is collected and gives *6-(ferrocenylcarbonyl)pentyl bromide* (4.5g, 85%) on evaporation. A part of it (1.61g, 7.4mmol) and Zn/Hg amalgam (freshly prepared from 7.4g of granulated Zn and 0.5g of  $\text{HgCl}_2$ ) in  $\text{H}_2\text{O}$  (25ml), 12M HCl (20ml) and toluene (30ml) are stirred vigorously so that the two liquid phases and the solids are in close contact, and are heated under reflux for 16 hours during which time 12M HCl (2 x 5ml) is added. The mixture is cooled to  $\sim 25^\circ$ , the organic layer is collected washed with  $\text{H}_2\text{O}$ , dried ( $\text{MgSO}_4$ ), filtered, concentrated, and the residue is purified through a silica-gel column as before. The yellow-brown band provides the required *6-ferrocenylhexyl bromide* (2.33g, 90%). The bromide (1.11g, 3.2mmol) and thiourea (0.24g, 3.5mmol) in absolute EtOH (20ml) is then boiled under reflux in an atmosphere of argon. After boiling for 18 hours, the solvent is removed *in vacuo*, treated with aqueous KOH (0.20g, 3.5mmol, in 20ml of  $\text{H}_2\text{O}$ ) and boiled under reflux in an atmosphere of argon for 2 hours. The orange-yellow oil that settles on cooling is extracted into  $\text{Et}_2\text{O}$  (3 x 50ml), the combined extracts are dried ( $\text{MgSO}_4$ ), concentrated, and chromatographed as before. The first yellow band gives the desired **6-ferrocenylhexanethiol** (0.68g, 62%) on evaporation. It is identified by its  $^1\text{H}$  NMR (300 MHz,  $\text{CDCl}_3$ ) which has  $\delta$  at 1.35 (t, 1H, SH), 1.39 (br, 4H,  $\text{FcCH}_2\text{CH}_2\text{CH}_2$ ), 1.52 (q, 2H,  $\text{CH}_2\text{CH}_2\text{CH}_2\text{SH}$ ), 1.63 (q, 2H,  $\text{CH}_2\text{CH}_2\text{SH}$ ), 2.34 (t, 2H,  $\text{FcCH}_2$ ), 2.53 (q, 2H,  $\text{CH}_2\text{SH}$ ), 4.06 (t, 2H,  $\text{C}_5\text{H}_4$ ), 4.07 (t, 2H,  $\text{C}_5\text{H}_4$ ), 4.11 (s, 5H,  $\text{C}_5\text{H}_5$ ); and EI-MS  $m/z$  at 302 ( $\text{M}^+$ ). The second yellow band contains the corresponding *disulfide* which can be reduced and used. [Creager & Rowe *J Electroanal Chem (Lausanne Switz)* **370** 203 1994, cf Yu et al. *J Org Chem* **66** 2937 2001.] This and other related ferrocenyl-alkane thiols have been synthesised and characterised electrochemically in solution and in self-assembled monolayer (SAM) films on gold electrodes. The affinities of these on the electrode surface have been described in detail. These red-ox active thiols can be used for selective electrochemical sensing and preparing a new type of thiol self-assembled sensing devices (SAMs). [Creager & Rowe *J Electroanal Chem (Lausanne Switz)* **370** 203 1994.] Gold nanoparticles covered fully with 6-ferrocenylhexanethiolate ligands, with average composition  $\text{Au}_{225}(\text{6-ferrocenylhexanethiolate})_{42}$ , were prepared, and had a unique combination of adsorption properties on Pt electrodes which were studied comprehensively. The adsorbed layers are so robust that sub, mono and multi nanoparticulate layers on the electrodes can be transferred to fresh electrolyte solutions in which they show stable ferrocene voltametry over long time periods. [Stiles et al. *J Am Chem Soc* **130** 1856 2008.]

**NPs for drug delivery** to tissues and particularly to brain, i.e. traverse the blood-brain-barrier, include conjugates of dextran, agarose, chitosan polyacetic acid (PLA), poly(lactic-co-glycolytic acid) (PLGA) and NPs with lipophilic moieties, e.g. polyethylene glycol (PEG) to which drugs can be bound have been explored by Fresta and co-workers [Celia et al. *Med Res Rev* **31** (3) 716-756 2011], and shown to be useful devices.

**Tetra-*n*-propylammonium perruthenate (TPAP, tetrapropyl tetraoxoruthenate)** [114615-82-6] **M 351.4, m 160°(dec)**. This oxidant (at 5 mol%) acts catalytically in oxidising 2-substituted *N*-1, *N*-3-dihydroxy-imidazolidines (1mol) in  $\text{CH}_2\text{Cl}_2$  at room temperature in 1-12 hours in the presence of *N*-methylmorpholine *N*-oxide (1.1mol) to provide the respective 2-substituted imidazoline-1-nitronyl-3-nitroxide radicals (NNRs) in 44-90% yields. NNRs have found applications in Physics, Chemistry and Nanotechnology for the development of organic molecular magnets [Palacio et al. *Phys Rev Lett* **79** 2336 1997] and single chain magnets [Caneschi et al. *Angew Chem Int Ed* **40** 1760 2001]. Gorini et al. *Synlett* 948 2006; for further reading see TPAP entries on p. 656 in Chapter 5, 'Metal-Organic Compounds', and on p. 708 Chapter 6, 'Catalysis-Part 1'.

## SAFETY ISSUES

Materials of nanometer size have been present on earth almost since its formation  $\sim 4.6$  billion (eon) years ago, as well as in the universe. Recently J. Cami, and coworkers have discovered large clouds in the planetary nebula Tc1 in which  $\text{C}_{60}$  and  $\text{C}_{70}$  fullerenes were identified by infra red spectroscopy. [*Science* **329** (Issue 5996) 1180

2010, reviewed by A. Extnance RSC *Chemistry World* 7 (9) 21 2010, and L. Howes RSC *Chemistry World* 8 (1) 34 2011.] During the past 30 years or so the development of nanomaterials and their wide ranging applications have avalanched, and progress is continuing. The safety aspects of nanomaterials have been of concern for many years, and it is generally accepted that conscious efforts have to be made to protect the individual workers in the field, the general public and the environment. Research on safety aspects is slowly gaining pace, and it has already been shown in mice that carbon nanotubes (CNTs) exhibit asbestos-like pathogenicity when inhaled. [K. Donaldson and coworkers: Poland et al. *Nature Nanotechnol* 3 423 2008, J.C. Bonner and coworkers: Ryman-Rasmussen et al. *Nature Nanotechnology* 4 747 2009, Reviewed by H. Birch RSC *Chemistry World* 6 (12) 24 2009.] The movement of nanomaterial from lungs to lymph nodes to the blood stream and clearance through the kidneys has been demonstrated by J.V. Frangioni and A. Tsuda and their coworkers [Choi et al. *Nature Biotechnol* 28 1300 2010, reviewed by L. Howes RSC *Chemistry World* 7 (12) 24 2010.] More recently W. Wohlleben and coworkers have subjected two thermoplastic materials and two cement materials infused with different nanoparticles (i.e. nanotubes and nanoparticle in polymers filters and in inorganic matrices) to gentle abrasion, high speed sanding and UV radiation. They did not find significant release of nanopowders into the atmosphere in which the sizes of the nanoparticles were very different from those in control powders. Moreover, rats exposed to the dust fared no worse than those exposed to dust that contained nanocomponents. However, further studies are in progress. [Wohlleben et al. *Small* 7 (16) 2384 2011, DOI: 10: 1002/smll.201002054; reported by K. McAlpine *Chemistry World* 8 (8) 28 2011.] Safety was rather slack in the early days, but it is being realised that nanomaterials should be treated differently from hazardous chemicals due to their unknown long-term effects. Nano-enabled hoods and nano-enabled-gear for personnel are being used, but only to a small extent. Safety protocols have been written and updated, but nano-regulation is only slowly creeping in [see special report by V. Gill RSC *Chemistry World* 6 (4) 10 2009.] A comprehensive report on nanosafety practices in research laboratories worldwide was compiled by J. Santamaria and coworkers recently, where they detail an up-to-date account of the present situation regarding to safety issues. [Balas et al. *Nature Nanotechnol* 5 93 2010; Reviewed by K. McAlpine RSC *Chemistry World* 7 (3) 15 2010.]

***Our advice is that in the manipulation and disposal of nanomaterials the same guidelines for asbestos handling should be used. In addition, further precautions should be exercised which should consider the known toxicity and the chemical nature of the nanomaterials in use.***

 Exaltone (Cyclopentadecanone) 234  
 Exonucleases 804

## F

FA folic acid (Pteroyl-*S*-glutamic acid) 877

facac (tfacac; 1,1,1-Trifluoro-2,4-pentanedione) 214, 937

FAD (Flavin Adenine Dinucleotide) 877

FEM (FluorescePAe Emission Microscopy) 909, 919, 920

Fenazox (Azoxybenzene) 271

Ferritin 804

Fibrinogen 804

Fibronectin 805

Fieser's solution 594

Filters, micro 44  
Whatman 43

Filtration 15

Flavanol (3-Hydroxyflavone) 446

Florisil 15

Flow chemistry 93

Fluoranthene (Benzo[*j,k*]fluorene) 334

Fluorescein [9-(*o*-Carboxyphenyl)-6-hydroxy-3*H*-xanthene-3-one] 53, 440

Fluoresceinamine (Mixture of 5- and 6-aminofluorescein) 53, 440

Fluorescein isothiocyanate isomer I (5-Isothiocyanato isomer) 53, 440

Fluorous chemistry 97, 102

Fluram (Fluorescamine, 4-phenyl-spiro-[furan-2(3*H*)-1-phthalan]-3,3'-dione) 53, 441

FMN (Flaniv adenine dinucleotide) 877

Fmoc (9-Fluorenylmethylcarbonyl-) 94

Fmoc-Cl (9-Fluorenylmethyl chloroformate) 335

Folliculin (1,3,5-Estratrien-3-ol-17-one) 850

Follitropin (Follicle stimulating hormone) 805

Forskolin, Colforsin 441

Forthane (2-Amino-4-methylhexane) 115

F-propene (Perfluoropropene) 145, 169

Fractogels 26, 49

Freeze-pump-thaw and purging 37

Fremy's Salt (Potassium nitroso sulfonate) 602

Freon 12 (Dichlorodifluoro-methane) 140

Freon 13B1 (Bromotrifluoro-methane) 121

FSH (Follicle Stimulating Hormone) 805

5FU (5-Fluorouracil) 440

Fullerene C<sub>60</sub>- $\gamma$ -lactone esters 915

Fullerene[60]/PC [Poly(bis-phenol A)carbonate] 915

Fullerenes 909-913

Fumagillin 441

Fumarine 475

Functionalised CNTs

Functionalised fullerenes 913-919

Fungicidin (Nystatin) 890

Fusaric acid (5-*n*-Butylpyridine-2-carboxylic acid) 443

Fuschin, rosaniline HCl 379

Fuming nitric acid 594

## G

GA (Gum Arabic) 934, 937

GABA (*S*-2-Aminobutyric acid) 776

GABOB [*R* (L-)-4-Amino-3-hydroxybutyric acid] 777

Galactitol 822

Galvinoxyl [2,6-Di-*tert*-butyl- $\alpha$ -(3,5-di-*tert*-butyl-4-oxo-2,5-cyclohexadiene-1-ylidene)-*p*-tolylxy] 336

Gangcyclovir 878

Gas chromatography 19, 47, 63

GDH (L-Glycerol-3-phosphate dehydrogenase) 806

Gel electrophoresis 768

Gel filtration 26, 63, 766

Gentian violet 305

Germanium tetroxide [14165-55-0] 638-639

GIXRR (Grazing Incident X-Ray Refractometry) 909

Girard Reagent T (*N,N,N*-Trimethylglycinehydrazide chloride) 797

Glass powder 578

Globulin G<sub>1</sub> 809

Glovebox techniques 37

D-Glucitol 824

Glycamine 824

Glycocyanine (*N*-Guanylglycine) 787

GA-AuNP (Au nano-particles stabilised by gum Arabic) 934

Graded adsorbents 21, 48

Gramicidin A, C, & S 788

Gramine (3-Dimethylamino-ethylindole) 443

Graphane 930

Graphene 929

Green chemistry 93, 97, 98

Green vitriol (Ferrous sulfate) 576

Griseofulvin 443

Grubbs catalyst 705, 706

Guaiaic acid [4,4'-(2,3-Dimethyl-1-butene-(1,4-diyl)-bis-(2-methoxyphenol)] 337

Guaiazulone (1,4-Dimethyl-7-isopropylazulene) 337

Guanabenz (1-[2,6-Dichlorobenzylideneamino]guanidine WY-8677) 337

Guanazole (3,5-Diamino-1,2,4-triazole) 427

Gypsum (Calcium sulfate) 567

## H

Hematin 880

Haemoglobin A 806

Haematoporphyrin IX 880

Hagemann's ester (4-Carboethoxy-3-methyl-2-cyclohexen-1-one) 226

Harmaline (7-Methoxy-1-methyl-4,9-dihydro-3*H*- $\beta$ -carboline) 443

Harmane (2-Methyl- $\beta$ -carboline) 443

Harmine (7-Methoxy-1-methyl-9*H*-pyrido[3,4-*b*]indole) 444

Hazards,  
Chemical 4-7  
Nano materials 939-94

HBTU (*O*-Benzotriazol-1-yl-*N,N,N,N'*-tetramethyluronium F<sub>6</sub>PO<sub>4</sub><sup>-</sup>) 410

Heating baths 43

HEDTA [*N*-(2-Hydroxyethyl)ethylene diaminetriacetic Acid] 172

Heimgartner's reagent [2,4-Bis(*p*-tolylthio)-1,3,2 $\lambda^5$ ,4 $\lambda^5$ -dithiadiphosphetane-2,4-dithio] 503

Hemimellitic acid (Benzene-1,2,3-tri-carboxylic) 274

Hesperetin (3',5,7-Trihydroxy-4'-methoxy-flavanone) 444

Hesperidin (Hesperetin 7-rhamnoside) 444

Heteroauxin (Indole-3-acetic acid) 451

HEPES [Na piperazine-*N,N'*-bis(2-ethane-sulfonate)] 72, 446

HETP, height equivalent to a theoretical plate 9

Hexesterol [3,4-Bis-(4-hydroxyphenyl)-hexane] 285

hfacac (1,1,1,5,5,5-Hexafluoro-2,4-pentanedione) 169

HFIP (1,1,1,3,3,3-Hexafluoropropan-2-ol) 170

HIMDA (*N*-Hydroxyiminodiacetic Acid) 172

HiPco (High Pressure Carbon Monoxide Disproportionation)

Hippuric acid (Benzoyl glycine) 780

Histones 807

HMDB [Hexamethyl(Dewar)-benzene] 249, 337-338

HMDS (Hexamethyldisilazane) 514

HMDSO (Hexamethyldisiloxane) 514

HMH (5-Hydroxy-1-methylimidazol-idine-2,4-dione) 881

HMPA (Hexamethylphosphoric triamide) 133, 433, 514

HMPT Hexamethylphosphorous triamide) 514

HOBt (1-Hydroxybenzotriazole) 95, 446, 915

HPLC, high performance liquid chromatography 27, 60, 64, 579  
gel filtration 26, 63  
reverse-phase 27

HPTLC (High performance thin layer chromatography) 20

5-HT [Serotonin HCl; 3-(2-aminoethyl)-5-hydroxyindole HCl] 897

Hünig's Base (Diisopropylethylamine) 147

Hyamine (1622) 275

Hydralazine (1-Hydrazino-phthalazine) 445

Hydranal 2, 30

Hydantoin (2,4-Dihydroxy-imidazole) 873

Hydrogen ionophore II 467

Hydrogen ionophore IV 467

Hydroxyamphetamine [4-(2-Aminopropyl)phenol] 267

Hydroxylapatite 26, 766

Hyflo-supercel 15

Hypo (Sodium thiosulfate) 616

Hypericin (4,5,7,4',5',7'-Hexahydroxy-2',2'-dimethylnaphthodianthrone) 342

Hyperol (see UHP) 582

## I

Ibotenic acid [ $\alpha$ -(3-Hydroxy-5-isoxazolyl)glycine] 790

Ibuprofen (4-*iso*Butyl- $\alpha$ -methylphenylacetic acid) 342

IBX [1-Hydroxy-1,2-benziodoxol-3(1*H*)-one; 2-iodoxybenzoic acid] 494

ICC (Iterative cross-coupling) 745

Impurities, sources of 3, 4

Ionic equilibria 34, 64

Ion-exchange 25, 65, 72  
bead form 24, 26, 49  
Cellex CM 26  
Cellex D 26  
celluloses 25, 26, 48  
Chelex 25, 48  
resins 24, 25, 43  
Sephadex 25, 26  
Sephacrose 26

Ionic liquids (ILs) 96, 97, 101, 755

Ionisation constants 8, 24, 34, 103, 555, 771  
pK and temperature 35  
pK and solvent 36

IPNBSH (*N*-Isopropylidene-*N'*-2-nitrobenzenesulfonyl hydrazide) 345

Interferons 807

Interleukins 807-808

Ionic liquids 96, 755

Iproniazid (1-Isonicotinyl-2-isopropylhydrazide) 453

Ishikawa's Reagent (PPDA) 145

Isoelectric focusing 766-767

Isoniazide (Isonicotinic acid hydrazide) 453

Isosarsasapogenin 854

isothermal distillation 14

Isoxanthopterin (2-Amino-4,7-dihydroxypteridine) 453

## J

Jacobsen's catalysts 675

Jacobsen's ligand 724

Janus Green B (3-Dimethylamino-[4-dimethylaminoazo]-5-phenylphenazonium chloride) 453

Janus Red B 345

Juglone (5-Hydroxy-1,4-naphthoquinone) 341

Julolidine (2,3,6,7-Tetrahydro-1*H*,5*H*-benzo[*ij*]quinolizidine) 454

## K

Kanamycin B (Beknamycin) 882

Kemp's acid (Trimethylcyclo-hexane-1,3,5-tricarboxylic acid) 256

Kerosene 177

Ketone Moschus (4-*tert*-Butyl-2,6-dimethyl-3,5-dinitroacetophenone) 345

Kinetin (6-Furfurylaminopurine) 442

Koser's reagent (Hydroxy(tosyloxy)-iodobenzene) 342

Koshland's reagent (2-Hydroxy-5-nitrobenzyl bromide) 341

KPEP (K Phosphoenolpyruvate) 892

## L

Laboratory techniques 65

Laburnine 424

Lactaminic acid (NANA) 857

Lactide (3,6-Dimethyl-1,4-dioxan-2,5-dione) 432

Lactoferrin 808

Lactoflavin (Vitamin B<sub>2</sub>) 904

LAH (Lithium aluminium hydride) 73, 586

Lanthanide (Europium) shift reagents 177, 660

- Laughing gas (Nitrous oxide) 594  
 Lauth's Violet 490  
 Lawesson's reagent (2,4-Bis(4-methoxyphenyl)1,3,2,4-dithia-diphosphetane-2,4-disulfide) 515  
 Lazier catalyst (Copper chromite) 663  
 Lectins 798, 808  
 Levallorphan [1-*N*-Allyl-3-hydroxy-morphinan] 402  
 Levocarnitine 781  
 Levomethadone 883  
 Lignoceric acid (Tetracosanoic acid) 204  
 Ligroin 17  
 Lipoproteins 808  
 Lipowitz alloy 623  
 Liquid crystal catalysts (Imidazolium salts) 755  
 Lithium aluminium hydride, in purification 73  
 Lithium hydride 587  
 D-Luciferin (from firefly) 883  
 Lumichrome (7,8-Dimethylalloxazine) 455  
 Lumiflavin (7,8,10-Trimethylbenzo[*g*]pteridine-2,4-(3*H*,10*H*)-dione) 883  
 Luminol (5-Aminophthalazin-1,4-dione) 455  
*dl*-Lupinine (1-Hydroxymethyl-octahydroquinolizine) 455  
 Lutein (Xanthophyll) 841  
 (+)-Lysergic acid 456  
 Lysozyme 809
- ## M
- MAAN (*N*-Methyleneamino-acetonitrile) 184  
 Macleyine (Protopine) 475  
 McLeod type gauge 12  
 Mafenide HCl (4-Aminomethylbenzenesulfonamide hydrochloride) 265  
 Magenta I 379  
 Magneson -I 359

 Metalphthalein (*o*-Cresolphthalein complexon) 304  
 Metals, trace analysis 90  
*R*(-)-Methadone (*levo*-6-Dimethylamino-4,4-diphenylheptan-3-one) 883  
 ( $\pm$ )-Methadone HCl 884  
 Methotrexate, amethopterin 860  
 Methoxalen (Xanthotoxin) 906  
 5-Methoxypsoralen (Bergapten) 863  
 9-Methoxypsoralen 906  
 Methylarenes 349  
 Methyl dopa [3-(3,4-Dihydroxyphenyl)-2-methyl-L-alanine] 785  
 Methylene Blue [3,7-Bis-(dimethylamino)phenothiazin-5-ium chloride] 458  
 Methylene Green [3,7-Bis-(dimethylamino)-4-nitrophenothiazin-5-ium chloride] 458  
 Methyl Meldrum's acid (2,2,5-Dimethyl-1,3-dioxane-4,6-dione) 493  
 Methyl Orange (Sodium 4,4'-dimethylaminophenylazobenzene-sulfonate) 517  
 Methyl Red (4-Dimethylaminoazobenzene-2'-carboxylic acid) 651  
 5-Methyltetrahydrofolic acid (prefolic acid) 885  
 Metol (*p*-Methylaminophenol sulfate) 348  
 Metrazol, Cardiazol (3a,4,5,6,7,8-Hexahydro-1,2,3,3a-tetraazaazulene) 464  
 Mevastatin (Compactin) 868  
 MF (Magnetic Fluid) 934  
 MH (1-Methylhydantoin; 1-methylimidazolidin-2,4-dione) 884  
 MIB (Nugent's reagent) [(2*S*)-3-exo-(Morpholino)isborneol] 695  
 Michler's ketone [4,4'-Bis(dimethylamino)benzophenone] 353  
 Michler's base 384  
 Microwave technologies 93  
 MIDA (*N*-Methylimino-diacetic acid) 731  
 MIDA boronic esters (Formation & hydrolysis) 745  
 MIDA-disodium salt 745  
 Mithramycin A 885

Mixed solvents **17, 21, 39, 45**  
 MMPP (Monoperphthalic acid mono Mg salt) **643**  
 Mohr's salt (Ammonium ferrous sulfate) **558**  
 Molecular sieves **32, 67**  
 MOMCl (Chloromethyl methyl ether) **133**  
 Monacrin (9-Aminoacridine HCl) **402**  
 Monocrotaline (Crotaline) **869**  
 Monolithic chromatography **28**  
 MONO-TRIS [2-Hydroxyethylimino-tris(hydroxymethyl)methane] **172**  
 Monuron [3-(4-Chlorophenyl)-1,1-dimethylurea] **302**  
 Morin (2',3,4',5,7-Pentahydroxyflavone) **464**  
 (-)-Morphine **464**  
 Mosher's acid ( $\alpha$ -Methoxy- $\alpha$ -trifluoromethylphenylacetic acid) **348**  
 MPD (*R,S*-2-Methyl-2,4-propanediol) **186, 750**  
 MPTP (1-Methyl-4-phenyl-1,2,3,6-tetrahydropyridine hydrochloride) **460**  
 MRFM (Magnetic Resonance Force Microscopy) **909**  
 MRI (Magnetic Resonance Imaging) **908**  
 $\alpha$ -MSH ( $\alpha$ -Melanotropin) **791**  
 $\beta$ -MSH ( $\beta$ -Melanotropin) **792**  
 MTAD (4-Methyl-1,2,4-triazoline-3,5-dione) **463**  
 MTB (Methyl thymol blue, Na) **518**  
 MTBE (Methyl *t*-butyl ether) **128**  
 MTO (Methyltrioxorhenium) **694**  
 MTPA ( $\alpha$ -Methoxy- $\alpha$ -trifluoromethylphenylacetic acid) **348**  
 MTT (Methyl thiazolyltetrazolium bromide blue) **489**  
 Muramic acid [*R*-2(2-Amino-2-deoxy-D-glucose-3-yloxy)-propionic acid] **885**  
 Muramidase (Lysozyme) **809**  
 Muriatic acid (conc HCl) **581, 582**  
 Muscimol (5-Aminoethyl-3[2*h*]-

isoxazolone) **886**  
 MWCNTs (MWNTs) (Multi Walled Carbon Nano Tubes) **920**  
 Mycobacinin  $\epsilon$ -[2-(4-Thiazolidinone)]hexanoic acid) **900**  
 Mycostatin (Nystatin) **890**  
 Myoglobin **810**  
 Myricetin (Cannabiscetin) **866**  
 Myronate K (Sinigrin) **832**

## N

Nabam [Na ethylenebis(dithiocarbamate)] **512**  
 NAD (DPN) ( $\beta$ -Nicotinamide adenine dinucleotide) **887**  
 NADH, reduced NAD **888**  
 NADP (TPN) ( $\beta$ -Nicotinamide adenine dinucleotide phosphate) **888**  
 NADPH, reduced NADP **888**  
 Nájera catalysts (Oxime palladacycles) **697**  
 Naloxone HCl **886**  
 Naltrexone HCl **887**  
 NAM (*N*-(9-Acridinyl)maleimide) **400**  
 NAMA (*N*-Acetylmuramic acid) **886**  
 NANA (*N*-Acetylneuraminic acid) **857**  
 NaPAA (Sodium polyacrylate) **653**  
 Naptalam **357**  
 Naphthazarin (5,8-Dihydroxy-1,4-naphthoquinone) **354**  
 Narcan (Naloxone HCl) **886**  
 Naringin (4',5,7-Trihydroxyflavone 7-rhamnoglucoside) **829**  
 NBD (2,5-Norbornadiene) **253, 745**  
 NBD-chloride (7-Chloro-4-nitrobenzoxadiazole) **421**  
 NBSH (*o*-Nitrobenzenesulfonyl hydrazide) **359**  
 NC-AFM (Non Contact-Atomic Force Microscopy) **908**  
 ND (Nanodiamond) **932**  
 NDELA (*N*-Nitrosodiethanolamine) **190**  
 Nebularin (Purine-9- $\beta$ -ribofuranoside) **895**  
 Nembutal (5-Ethyl-5-1'-methylbutyl barbituric acid, Na salt) **469**

Neocuproine (2,9-Dimethyl-1,10-phenanthroline) **433**  
 Neo-oxine (4-Hydroxyacridine) **445**  
 Neophyl chloride (2-Chloromethyl-2-phenylpropane) **299**  
 D(+)-Neopterin **887**  
*cis*-, *trans*-, *cis/trans*-Nerolidol **189**  
 Norephedrine [2-Amino-1-phenyl-1-propanol] **889**  
 NF (Nanofiltration) **767, 933**  
 Niacin (Nicotinamide) **465, 466**  
 Nile Blue A (a Benzophenoxazinium sulfate dye) **466**  
 Nigrin (Streptonigrin) **898**  
 Nioxime (Cyclohexane-1,2-dione dioxime) **231**  
 NIR (Near Infra Red) **909, 920, 922, 925, 927**  
 Nisin (Polypeptide) **793**  
 Nitric acid (anhydrous) **593**  
 Nitrin (2-Aminobenzaldehyde phenylhydrazone) **262**  
 Nitromethane **190**  
 Nitrososulfuric acid **594**  
 NMN ( $\beta$ -Nicotinamide mononucleotide) **888**  
 Nonactin (Ammonium ionophore I) **627**  
 Norpseudoephedrine **889**  
 Norspermidine (Bis-[3-amino-propyl]-amine) **137**  
 NPS-Cl (2-Nitrobenzenesulfonyl chloride) **359**  
 NTA [Nitrilotriacetic acid; tris-(carboxymethyl)amine] **190**  
 DTBNpP (Di-*tert*-butylneopentylphosphine) **735**  
 NTF<sub>2</sub> [Bis-(trifluoromethane-sulfon)amide] **708, 730, 755,**  
 Nucleotide thiophosphates **890**  
 Nylon powder **191**  
 Nystatin (Mycostatin, Fungicidin) **890**

## O

Octyl- $\beta$ -D-glucopyranoside **830**  
 ODA (Octadecylamine) **191, 926**  
 ODCB (*o*-Dichlorobenzene) **312, 912**  
 Oil of vitriol, H<sub>2</sub>SO<sub>4</sub> **618**  
 Oleum (Fuming H<sub>2</sub>SO<sub>4</sub>) **619**  
 OP catalysts (Oxime Palladacycle dimers) **697**  
 Optochin (Ethyl hydrocupreine hydrochloride) **439**  
 ORBO cartridges **23**  
 Orcine **365**  
 Organocatalysis **92, 712**  
 Ostwald coefficient **36**  
 (Table) **58**

- Ouabain 853  
 Overman Rearrangement 672, **680**  
 Oxacillin (5-Methyl-3-phenyl-4-isoxazolyl-penicillin sodium salt) 890  
 Oxine (8-Hydroxyquinoline) 449  
 Oximes (Preparation) 697  
 Oxiracetam 890  
 Oxone (Caro's acid, Potassium peroxymonosulfate) 602  
 Oxycinchophen (3-Hydroxy-2-phenyl-cinchonic acid) 447  
 Oxytetracycline (Terramycin) 898  
 Oxytocin 793
- ## P
- PABS (Poly-*p*-aminobenzene-*m*-sulfonic acid) 926  
 PAGE (Polyacrylamide gel electrophoresis) 768, 769  
 L- $\beta$ -Palmitin 891  
 PAN [4-(2-Pyridylazo)naphthol] 479  
 Pantothenic (Na and Ca Salt) 891  
 Paper chromatography 21  
 PAR [4-(2-Pyridylazo)resorcinol] 480  
 Paracetamol (4-Acetamidophenol) 258  
 Praxadine (1-Amidinopyrazole hydrochloride) 477  
 Paraffin wax 194  
 Paraquat 2HCl (1,1'-Dimethyl-4,4'-bi-pyridylum dichloride) 432  
 Patulin, Clavatin [4-Hydroxy-4*H*-furo(3,2-*c*)pyran-2(6*H*)-one] 468  
 PBN (*N*-*t*-Butyl  $\alpha$ -phenyl nitron; free radical trap) 294  
 Pectic acid 830  
 Pectin 830  
 PEG (Polyethylene glycol) 893-894  
 Penicillamine 891  
 Penicillin G 862-863  
 Pentadecanolide (1-oxacyclohexadecan-2-one) 194  
 Pentalin (Pentachloroethane) 194  
 Pentaphene (2,3,6,7-Dibenzphenanthrene) 309  
 Pentobarbital (5-Ethyl-5-1'-methylbutyl barbituric acid) 469  
 Perex test for peroxides 84  
 Pericyazine {10-[3-(4-Hydroxy-1-piperidinyl)-propyl]-10*H*-phenothiazine-2-carbonitrile} 470  
 Petroleum ether 17, 39, 45, **196**  
 Petroleum spirit 17  
 PFBHA HCl [*O*-(2,3,4,5,6-Pentafluorobenzyl)hydroxyl-amine hydrochloride] 366  
 Phenacetin (*p*-Methoxyacetanilide) 259  
 Phenamisol (Phenyl 4-amino-salicylate) 370  
 Phenozin (Zn phenol-*o*-aulfonate) 554  
 Phlorizin 831  
 Phloron (2,6-Dimethyl-1,4-benzoquinone) 322  
 Phosferrox ligands 699, 700  
 Phospholipids 893  
 Phosphoproteins 811  
 Phosphorus sesquisulfide P<sub>4</sub>S<sub>3</sub> 598  
 Photol (Metol) (*p*-Methylamino-phenol sulfate) 348  
 Physostigmine, Eserine 438  
 PIC, chromatography 23  
 Picrotoxin (cocculin) 255  
 Pinacolborane (4,4,5,5-Tetramethyl-1,3,2-dioxaborolane) 747  
 PIPES (Piperazine-*N,N'*-bis(2-ethanesulfonic acid) 474  
 PIPES-Na salt 532  
 Piracetamide (2-Oxo-1-pyrrolidine acetamide) 893  
 Pituitary Growth Factor 811  
 Pixyl chloride (9-Chloro-9-phenylxanthene) 421  
 pK 34, 103, 555, 771  
 pKa and pKb 35 and temperature 35 and solvent 36  
 Plasmids (DNA) 803, 811  
 Platinum (II) chloride 599  
 Platinum Sponge 579, 598  
 Plicamycin (Mithramycin A) 885  
 PLP, codocarboxylase 896  
 Plumbagin (5-Hydroxy-2-methyl-1,4-naphthaquinone) 340  
 PMDBD (3,3,6,9,9-Pentamethyl-2,10-diazabicyclo[4.4.0]dec-1-ene) 469  
 PMSF (Phenyl methanesulfonyl fluoride) 374  
 PNBP [4-(4-Nitrobenzyl)pyridine] 466  
 P<sub>3</sub>NO [4-(3-Phenylpropyl)pyridine 1-oxide] (cf 471), 675, **747**  
 Polybrene (1,5-Dimethyl-1,5-diazaundecamethylene polymethobromide) 149  
 Polyethylene glycol (PEG) 893  
 Polymer supported reactants 95  
 Polypeptides, purification 768  
 Polyprenols (Dolichols) 875  
 Polystyrene 377  
 Potassium borohydride, in purification 74  
 Potassium chromate 600  
 Potassium hexachloroiridate (III) (K<sub>3</sub>IrCl<sub>6</sub>) 601  
 Potassium nickel sulfate hexahydrate 602  
 Potassium nitrate (saltpetre) 602  
 Potassium thiosulfate hydrate (75% aqueous solution)] 604  
 PPDA (Perfluoropropyl-diethylamine) 145  
 PPD (2,5-Diphenyl-1,3,4-oxadiazole) 435  
 PPEI-EI [Poly(propionylethylenimine-co-ethylenimine)] 928  
 P-Phos [2,2',6,6'-Tetramethoxy-4,4'-bis(diphenylphosphino)-3,3'-bipyridine] 749  
 PPO (2,5-Diphenyloxazole) 435  
 PQQ (Methoxantin coenzyme) 884  
 Prazosin HCl 894  
 Prefixes for quantities 59  
 Prefolic A 885  
 Preparative GC 19, 63  
 Primaquine diphosphate 475  
 Pristane, norphytane (2,6,10,14-Tetramethylpentadecane) 208  
 Procaine HCl (Novocain, 2-diethylaminoethyl-4-aminobenzoate HCl) 895  
 Proclavine (3,6-Diaminoacridine) 475  
 Proflavin sulfate 426  
 Progesterone 854  
 Propacil (6-Propyl-2-thiouracil) 475  
 PROPHOS [1,2-Bis(diphenylphosphino)propane] 198, 726  
 Propylail (6-Propyl-2-thiouracil) 475  
 Proteins 812 purification 768  
 Proteoglycans 812

Proteomics 769  
 Proton ionophore (4-Nonadecylpyridine) 467  
 Proton sponge (*N,N,N',N'*-Tetramethyl-1,8-naphthalenediamine) 384  
 Protoporphyrin IX (& ester) 895  
 Protopine 475  
 Provitamin B, D-panthenol 891  
 Provocholine (*O*-Acetyl- $\beta$ -methylcholine chloride) 857  
 Proxyphylline [( $\pm$ )-7-(2-Hydroxypropyl)theophylline] 448  
 PS (Polystyrene) 377

 Squalane (2,6,10,15,19,23-Hexamethyl-tetracosane) 841  
 Squalene (all-*trans*-2,6,10,15,19,23-Hexamethyl-2,6,10,14,18,22-tetracosahexaene) 841  
 SRNF (Solvent resistant nanofilters) 933  
 STEIN (Stilbenediamine) 739  
 Stigmasterol (3 $\beta$ -Hydroxy-24-ethyl-cholesta-5,22-diene) 855  
 Stilbesterol (Diethylstilboesterol) 316  
 STM (Scanning Tunneling Microscope) 908, 909  
 Streptozocin (*N*-[Methylnitroso-carbamoyl]- $\alpha$ -D-glucosamine) 833  
 STS (Scanning Tunneling Spectroscopy) 908,  
 Sublimation 18  
 Sudan II (1,4-bis-(Butylamino)-9,10-dihydro-9,10-dioxoanthracene) 381  
 Sudan III [1-(*p*-Phenylazophenylazo)-2-naphthol] 381  
 Sudan IV [1-(4-*o*-Tolylazo-*o*-tolylazo)-2-naphthol] 381  
 Sudan orange G (2,4-Dihydroxy-

azobenzene) 317  
 Sugar of lead (Lead acetate) 640  
 Sulfacetamide (*N*-(4)-Acetylsulfanilamide) 261  
 Sulfuric acid (conc) for removal of alcohols 7  
 removal of ethers 7  
 removal of unsaturated hydrocarbons 7  
 Sulfuric acid (fuming) (oleum) 618–619  
 Supercritical CO<sub>2</sub> 96  
 Supercritical fluids (SCF) 96  
 Supelco columns 19, 23  
 SWCNTs (SWNTs) (Single Walled Carbon Nano Tubes) 920–924  
 SWCNT-(CO<sub>2</sub>H)<sub>n</sub> 925  
 SWCNT-functionalised 925–929  
 “Sympathetic Ink” (aqueous Cobaltous chloride) 572

## T

2,4,5-T (2,4,5-Trichlorophenoxyacetic acid) 931  
 T3P (Propylphosphonic anhydride) 527  
 Tartar emetic (Potassium antimonyl-tartrate) 645  
 TBA (Tri-*n*-butylamine) 210  
 TBAF (Tetra-*n*-butylammonium fluoride) 699, 720  
 TBD (1,5,7-Triazabicyclo[4.4.0]-dec-5-ene) 492  
 TBDMSCl (*tert*-Butyldimethylsilyl chloride) 505  
 TBDPSCl (*tert*-Butyldiphenylchlorosilane) 505  
 TBHDTB (Tri-*n*-butylhexadecylphosphonium bromide) 754  
 TBHP (*t*-Butyl hydroperoxide) 126  
 TBP (Tri-*n*-Butyl phosphine) 537  
 TCT (Cyanuric chloride) 424  
 TDM spray (4,4'-Tetramethyldiaminodiphenylmethane) 397  
 TED (DABCO, Triethylenediamine, (1,4-Diazabicyclo[2.2.2]-octane) 427  
 Tedicyp (*cis-cis-cis*-1,2,3,4-Tetrakis(diphenylphosphino-methyl)cyclopentane) 749  
 TEHP [(Tris(2-ethylhexyl)-phosphate) 552  
 TEM (Transmission Electron Microscope) 908, 909  
 TEMPO 2,2,6,6-Tetramethylpiperidin-yl-1-oxy 487  
 Terramycin (Oxytetracycline) 898  
 Terreic acid (2-Hydroxy-3-methyl-1,4-benzoquinone-5,6-epoxide) 382  
 TES [*N*-Tris(hydroxymethyl)methyl-2-aminomethane sulfonic acid] 72, 216  
 Testane (5 $\beta$ -Androstane) 842  
 Testosterone (17- $\beta$ -Hydroxy-androst-4-ene-3-one) 856  
 Tetracycline (& HCl) 899  
 6*R* and 6*S*-Tetrahydrobiopterin 2 HCl {6*R*- and 6*S*-2-Amino-4-hydroxy-6-[(1*R*,2*S*)-1,2-dihydroxypropyl]-5,6,7,8-tetrahydropteridine} 2HCl 899  
 Tetrahydrofolic acid 2HCl 899  
 Tetrahydropyran (Oxane) 487  
 Tetralone test 384  
 Tetraphene (1,2-Benzanthracene) 272  
 TFAH (tfacac; 1,1,1-Trifluoro-2,4-pentanedione) 214, 937  
 TGA (Thermo Gravimetric Analysis) 909, 920–922, 927, 928  
 Thallium (III) nitrate trihydrate [TTN, thallic nitrate trihydrate, Ti(NO<sub>3</sub>)<sub>3</sub>·3H<sub>2</sub>O] 620  
 Thaspic acid (1,14-Hexadecanedioic acid) 169  
 Theocin, theophylline (1,3-Dimethyl-2,6-dioxopurine) 488  
 Theophylline (1,3-Dimethyl-2,6-dioxopurine) 488  
 Theoretical discussion 65  
 Theoretical Plate 9

Thevetin A, and B (Cardenolide glycoside) 833  
 THF (Tetrahydrofuran) 486  
 THFA (5,6,7,8-Tetrahydrofolic acid) 899  
 Thiamine monophosphate 900  
 Thiazolsulfone (2-Amino-5-sulfanylthiazole) 268  
 Thimerosal (Sodium ethylmercuri-thiosalicylate) 531  
 6,8-Thioctic acid 882, 883  
 Thiosinamine (*N*-Allylthiourea) 114  
 Thiram (Tetramethylthiuram disulfide) 208  
 Thorium chloride 621  
 THPAL (Tris[*N*-alaninylmethylene]-phosphine) 934, 935  
 THPC (Tetrakis(hydroxymethyl)-phosphonium chloride) 552  
 Thycocymetin (Thiamphenicol) 900  
 Thyroxine {*O*-[3,5-Diiodo-4-oxyphenyl]-3,5-diiodo-D(-)-tyrosine} 796  
 Tiglic acid (*trans*-2,3-Dimethylacrylic acid) 209  
 Tibetolide (Pentadecanolide, 1-oxacyclohexadecan-2-one) 194  
 TIMP (Tissue inhibitor of metalloproteins) 814  
 TIRON (1,2-Dihydroxybenzene-3,5-disulfonic acid, di-Na salt) 509  
 TLG, thin layer gel filtration 20  
 TMCS (Trimethylsilyl chloride) 543  
 TMCTS (2,4,6,8-Tetramethylcyclo-tetrasiloxane) 535  
 TMED, TMEDA (*N,N,N',N'*-Tetramethylethylenediamine) 208  
 TMS (Tetramethylsilane) 535  
 TMSAN (Trimethylsilylacetone nitrile) 542  
 TMSF (Trimethylsilyl fluoride) 513  
 TMSI (Trimethylsilyliodide) 515  
 TMSNF<sub>2</sub> [Trimethylsilyl bis-(trifluoromethanesulfon)amide] 731  
 TNBS (2,4,6-Trinitrobenzenesulfonic acid) 393  
 TNT (2,4,6-Trinitrotoluene) 394, 932  
 Tolan (Diphenylacetylene) 328  
 Topitracin (Bacitracin) 862  
 TOSMIC [*p*-Tolylsulfonylmethyl isocyanide] 389  
 Toyopearl 26, 49  
 TPAP (Tetra-*n*-propylammonium perruthenate) 708, 939  
 THP (Oxane, Tetrahydropyran) 487  
 TPP 5,10,15,20-Tetraphenylporphyrin 488  
 Tranexamic acid (AMCHA) 776  
*trans*-Traumatic acid (2-Dodecene-1,12-dioic acid) 209  
 Traut's Reagent (2-Iminotetrahydrothiophene) 450  
 TREN [Tris(2-aminoethyl)amine] 216

Tricarballic acid (Propane-1,2,3-tricarboxylic acid) 210  
 TRICINE [*N*-Tris-(hydroxymethyl)methylglycine] 797  
 TRIEN (TETA) (Triethylene-tetramine, trientine) 212  
 TRIEN.HCl 213  
 Triglyme (Triethylene glycol dimethyl ether) 212  
 Trigonelline (1-Methylnicotinic acid zwitterion) 492  
 Trigonellamide chloride (1-Methyl nicotinamide chloride) 797  
 Trimellitic acid, trimesic acid (Benzene-1,3,5-tricarboxylic) 275  
 Triphosgene [Bis(trichloromethyl) carbonate] 119  
 TRIS [*N*-Tris(hydroxymethyl)methylamine] 72, 216  
 TRIS-HCl [*N*-Tris(hydroxymethyl)methyl amine HCl] 216  
 Tritium 621–622  
 Triton B (Benzyltrimethylammonium hydroxide) 283  
 Tropaeolin 0 530  
 Tropaeolin 00 553  
 Tropaeolin 000 520, 521  
 Tropine (3-Tropanol) 495  
 TTC (TTZ) (2,3,5-Triphenyltetrazolium chloride) 494  
 TTMSS [Tris(trimethylsilyl)silane] 553  
 TTN (Thallium III nitrate) 235, 620  
 Tungsten (rod) 621–622  
 Tunicamycin 901  
 Tuberactinomycin (Viomycin sulfate) 903  
 Tyrocidine A (Cyclic decapeptide) 797

## U

Ubiquinone, Coenzyme Q 868  
 UF (Ultrafiltration) 16, 767, 933

UHP (Hydrogen peroxide urea adduct) 582  
 Ulexine (Cytisine) 424  
 Ultrafiltration (UF) 16, 767, 933  
 Ultragels 26  
 Umbelliferone (7-Hydroxycoumarin) 495  
 UPLC (Ultraperformance liquid chromatography) 28  
 Uracil 496  
 Uramil (5-Aminobarbituric acid) 496  
 Urethane (Ethyl carbamate) 217  
 Uridine and uridine nucleotides 901  
 Uridine 5'-(1-thio) monophosphate 901  
 Urocanic acid (4-Imidazolylacrylic acid) 496  
 Urotropin, HMTA (Hexamethylenetetramine) 444  
 Ursocholic acid 845  
 Ursodeoxycholic acid (Ursodiol) 856  
 Ursodiol (3 $\alpha$ ,7 $\beta$ -Dihydroxy-5 $\beta$ -cholan-24-oic acid) 856  
 Usnic 902  
 Ustizeain B (Ustilagic acid, di-D-glucosyldihydroxyhexadecanoic acid) 834

## V

*cis*-Vaccenic acid (Octadec-11-enoic acid) 217  
 Vacuum lines 37  
*S*-Valinol (*S*-2-Amino-3-methyl-1-butanol) 778  
 Valinomycin 902  
 ( $\pm$ )-Verapamil HCl (5-[*N*-(3,4-Dimethoxyphenylethyl)methylamino]-2-[3,4-dimethoxyphenyl]-2-isopropylvaleronitrile HCl) 902  
 Veratridine (3-Veratroylveracevine) 902  
 Verkade Superbase (2,8,9-Trimethyl-*pro*-azaphosphatrane) 547  
 Verkade Superbase HCl 548  
 Vicine (2,4-Diamino-5- $\beta$ -D-glucopyranosidoxy-6-hydroxypyrimidine) 834

Vilsmeier Reagent [(Chloromethylene)dimethyliminium chloride] 324  
 Vinblastine sulfate (VLB) 902  
 ( $\pm$ )-Vinclozolin [3-(3,5-Dichlorophenyl)-5-methyl-5-vinylloxazolidine-2,4-dione] 496  
 Vincristine sulfate 902  
 Viocin (Viomycin sulfate) 903  
 Violanthrene (Dibenzanthrene) 396  
 Viologen (4,4'-Dipyridyl dihydrochloride) 497  
 Violuric acid (5-Isonitrosobarbituric acid) 453  
 Virofrol (1-Adamantylamine HCl) 221  
 Visnagin (4-Methoxy-7-methyl-5*H*-furo[3,2-*g*][1]benzopyran-5-one) 497  
 VPA (Valproic acid, 2-propylpentanoic Acid) 200  
 Vitamins (A, B<sub>1</sub>, B<sub>2</sub>, B<sub>3</sub>, B<sub>6</sub>, B<sub>12</sub>, D<sub>2</sub>, D<sub>3</sub>, E, K<sub>1</sub>, K<sub>3</sub>, K<sub>5</sub>, P, U) 903-905  
 VLB, vinblastine 902

## W

Wanzlick's Reagent (*N,N'*-Diphenylethylenediamine) 329  
 Warfarin (4-Hydroxy-3-(3-oxo-1-phenylbutyl)-2*H*-1-benzopyran-2-one) 906  
 Water 623  
 White vitriol (Zinc sulfate) 625  
 Wilkinson's catalyst [Chlorotris-(triphenylphosphine)rhodium(I)] 679  
 Wood's Metal 623  
 Woodward's Reagent K (*N*-Ethyl-5-phenylisoxazolinium-3'-sulfonate) 439  
 Wurster's reagent [*N,N,N',N'*-Tetramethyl-1,4-phenylenediamine dihydrochloride] 384

## X

XANES (X-ray Absorption Near Edge Structure) 934  
 9*H*-Xanthene (Dibenzopyran) 497  
 Xanthene rhamnoside 834  
 Xanthine (2,6-Dihydroxypurine) 497  
 Xanthone (9-Xanthenone) 497  
 Xanthophyll (Lutein) 841

- Xanthopterin 906  
Xanthotoxin 906  
Xanthurenic acid (5,8-Dihydroxy-quinoline-2-carboxylic acid) 498  
Xantphos [4,5-Bis(diphenylphosphino)-9,9-dimethylxanthene] 673, 710, 711, **751**  
XFS (X-ray Fluorescence Spectroscopy) 909  
X-Phos (2-Dicyclohexylphosphino-2',4',6'-triisopropylbiphenyl) 678, 679, **738**  
XPS (X-ray Photoelectron Spectroscopy) 909, 927, 936, 937  
Xylenol Orange 498  
Xylyl-P-Phos (2,2',6,6'-Tetra-methoxy-4,4'-bis[di(3,5-xylyl)phosphino]-3,3'-bipyridine) 677, 707, **749**

## Y

- $\alpha$ -Yohimbine 401, **498**  
 $\gamma$ -Yohimbine 401, 498

## Z

- Zeatin (*trans*-*N*<sup>6</sup>-[4-Hydroxy-3-methylbut-2-en-1-yl]adenine) 906  
Zeaxanthin [all*trans*- $\beta$ -Carotene-3,3'(*R,R'*)-diol] 841  
Zeinoxanthin (all-*trans*-3*R*,6*R'*- $\beta$ ,*e*-Carotene-3-ol) 839  
Zinc-copper alloy 934  
copper/iron oxide 934  
couple 623  
Zinc-Copper Couple 624  
Zinc nano metallic powder 938  
Zinc-Silver couple 624  
Zincon {*o*-[1-(2-Hydroxy-5-sulfo)-3-phenyl-5-formazono]-benzoic acid} 661

## CAS Registry Numbers Index

### HOW TO VALIDATE CHEMICAL ABSTRACTS SERVICE REGISTRY NUMBERS

**Almost** all chemical and biochemical entries in this book have CAS (Chemical Abstract Service) Registry Numbers to identify them and have been entered for each substance. The registry numbers are an efficient way for identifying substances and are independent of the nomenclature of substances. Unlike chemical names which may have more than one synonymous name, there is only one CAS Registry Number for each substance (with only a few exceptions, e.g. where a substance may have another number before purification, or before determination of absolute configuration).

The registry numbers are made up of three sets of digits separated by two hyphens with the general form:  $nN_n + \dots + 4N_4 + 3N_3 + 2N_2 + 1N_1 - R$  where the  $N$ s are sequential numbers and  $R$  is the *check digit*. The first set can be up to eight digits (at this point in time, but not less than two), and the second is made of two digits (zeros are included as a digits) and the third is a single digit which *checks* the validity of the sequential numbers, e.g. 379669-72-4 for *but-3-enylboronic acid* or 83-32-9 for *acenaphthene*. The validity of a registry number can be checked by the following formula (computer generated):

$$\frac{nN_n + \dots + 4N_4 + 3N_3 + 2N_2 + 1N_1}{10} = Q + R/10$$

where the  $N$ s include all numbers except the last *check digit*,  $Q$  represents an integer (fractions not included) which, although it is disregarded, does give the value of  $R$  equal to the *check digit* in a **valid** Registry Number.

The following three examples demonstrate the application of the formula and the validity of the Registry Number:

1. **1,5-Dihydroxynaphthalene 83-56-7**

$$\frac{(4 \times 8) + (3 \times 3) + (2 \times 5) + (1 \times 6)}{10} = \frac{57}{10} = 5 + \frac{7}{10} \quad [\text{Note: the last (check) digit of the CAS number 7 is not included.}]$$

When the value of  $Q$  is made to equal 5, the *check digit*  $R$  becomes equal to 7; thus the Registry Number is **valid**. In this case the value of  $Q$  is in fact the digit(s) (**5**), before the last *check digit* (**7**).

2. **4,5-Diamino-6-hydroxypyrimidine hemisulfate 102783-18-6**

$$\frac{(8 \times 1) + (7 \times 0) + (6 \times 2) + (5 \times 7) + (4 \times 8) + (3 \times 3) + (2 \times 1) + (1 \times 8)}{10} = \frac{106}{10} = 10 + \frac{6}{10}$$

When the value of  $Q$  is made to 10, the *check digit*  $R$  becomes equal to 6; thus the Registry Number is **valid**. In this case the value of  $Q$  is in fact the digit(s) (**10**), before the last *check digit* (**6**).

3. 1,4-Bis(pentafluorobenzyl)[C<sub>60</sub>]fullerene 1260376-31-5

$$\frac{(9 \times 1) + (8 \times 2) + (7 \times 6) + (6 \times 0) + (5 \times 3) + (4 \times 7) + (3 \times 6) + (2 \times 3) + (1 \times 1)}{10} = \frac{135}{10} = 13 + \frac{5}{10}$$

When the value of Q is made to 13, the check digit R becomes equal to 5; thus the Registry Number is **valid**. In this case the value of Q is in fact the digit(s) (**13**), before the last *check* digit (**5**).

The CAS Registry Handbook (Number Section) and supplements should be consulted for obtaining the substance name and elemental formula corresponding to a Registry Number.

To facilitate the method for locating the purification of a substance, a CAS Registry Number Index of the numbers of the entries with their respective page numbers is included here. This will also provide the reader with a rapid way to see if the purification of a particular substance has been reported in the book.

# PURIFICATION OF LABORATORY CHEMICALS

SEVENTH EDITION

- Improves efficiency, results and safety by providing critical information for day-to-day lab and processing work
- Searchable electronic database allows instant access to accurate, reliable information on processes and techniques of purification along with detailed physical properties
- New commercially available chemical products and processing techniques are covered; hazards and safety remain central to the book

A bestseller since 1966, Purification of Laboratory Chemicals keeps engineers, scientists, chemists, biochemists and students up-to-date with the processes for purification of the chemical reagents with which they work, and guides readers on critical safety and hazards for the safe handling of chemicals and processes. The 7th Edition is updated and provides expanded coverage of the latest chemical products and processing techniques, safety and hazards. The book has been reorganized, has a new chapter on Catalysts and one on Nanomaterials, and is fully indexed by CAS Registry Numbers. Compounds are now grouped to make navigation easier, and extensive literature references for all substances and techniques have been added.

#### About the authors

W.L.F. Armarego

Department of Structural Biology, The John Curtin School of Medical Research, Australian National University, Canberra

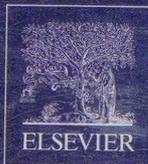

Wilfred L. F. Armarego graduated BSc (Special, Hons) in 1953 and PhD from the University of London in 1956 and came to Australia in that year. After two years at the Central Research Laboratories (ICIANZ) in Melbourne, where he worked on plant growth substances, and one year on potentially carcinogenic polycyclic aromatic hydrocarbons at the University of Melbourne as Senior Demonstrator in Organic Chemistry, he joined the Department of Medical Chemistry as a Research Fellow in 1960. He became a Fellow in 1963 and was awarded a DSc degree (London) in 1968. He was promoted to Senior Fellow in 1967 and began research work on the biochemistry and molecular biology of pteridine-requiring enzymes related to the inherited metabolic disease phenylketonuria and its variants. He was head of the Protein Biochemistry Group and Pteridine Biochemistry Laboratory. In addition to writing more than 100 original research papers and reviews in heterocyclic chemistry, enzymology and molecular cloning, he has written three other books as sole author. He is now a Visiting Fellow in the John Curtin School of Medical Research, and member of the editorial boards of 'Medicinal Research Reviews' and 'Pteridines' journals. He is a Chartered Chemist, a Fellow of the Royal Society of Chemistry and a Fellow of the Royal Australian Chemical Institute.

Christina L. L. Chai

Department of Pharmacy, National University of Singapore & Institute of Chemical and Engineering Sciences, Agency for Science Technology and Research (A\*STAR), Singapore

Christina Li Lin Chai obtained her BSc (Hons) from the University of Canterbury, Christchurch, New Zealand and her PhD in synthetic organic chemistry from the Research School of Chemistry, Australian National University, Canberra.

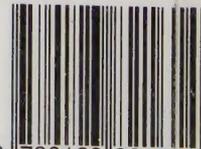

She joined the Institute of Chemical and Engineering Sciences as a Principal Scientist and Programme Manager of the New Synthesis Techniques and Applications (NSTA) Programme from 2004 till 2011. Since August 2011, Dr Chai holds a joint appointment as Associate Professor in the Department of Pharmacy, National University of Singapore and the Institute of Chemical and Engineering Sciences, A\*STAR. Dr Chai's professional achievements include the DAAD Fellowship and Alexander von Humboldt Fellowship and she is a member of the American Chemical Society, and the Singapore Institute of Chemistry. Her research interests are in the areas of medicinal chemistry, green technologies and synthesis of bioactive compounds and elucidation of their mechanisms.
