
$$\mathrm{RHgX} + \mathrm{Co_2(CO)_8} \xrightarrow{\text{THF}} \mathrm{R{-}\underset{\displaystyle \overset{\|}{O}}{C}{-}R}$$

Symmetrical ketones can be prepared in good yields by the reaction of organomercuric halides with dicobalt octacarbonyl in tetrahydrofuran,[234] or with nickel carbonyl in dimethylformamide or certain other solvents.[235] R may be aryl or alkyl. However, when R is alkyl, rearrangements may intervene in the $Co_2(CO)_8$ reaction, though the $Ni(CO)_4$ reaction seems to be free from such rearrangements.[235] Diaryl ketones have also been prepared in low to moderate yields by treatment of the substrate with CO and Pd or Rh halide catalysts.[236] Diarylmercury compounds Ar_2Hg give Ar_2CO when treated with CO and a small amount of $Co_2(CO)_8$ acting as a catalyst, providing the reaction vessel is irradiated with uv light.[237] When arylmercury halides are treated with nickel carbonyl in the presence of Ar′I, unsymmetrical diaryl ketones can be obtained.[235] Aryllithium reagents react with iron pentacarbonyl to give aldehydes ArCHO,[238] while alkyllithium reagents react with CO to give symmetrical ketones.[239]

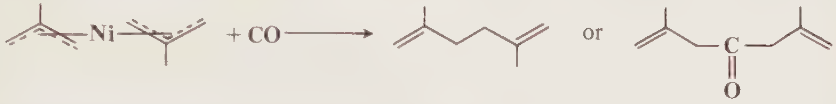
Aryl and vinyl halides react with a 1 : 1 CO–H_2 mixture at about 80 atm pressure in the presence of a tertiary amine and a complex such as $(PPh_3)_2PdBr_2$ to give the corresponding aldehyde.[240] An organopalladium complex is an intermediate. When the reaction is carried out at atmospheric pressure and 100 C, without H_2, and with an alcohol R′OH or a primary or a secondary amine $R'NH_2$ or R'_2NH added, the product is, respectively, an ester RCOOR′ or an amide RCONHR′ or $RCONR'_2$.[241] Dibutyl ketone can be prepared in good yield by treatment of dibutylcopperlithium with CO.[242] Alkyl Grignard reagents react with CO under pressure to give alkenes which contain one more carbon atom than the doubled R group,[243] e.g.,

$$2CH_3CH_2CH_2MgBr + CO \longrightarrow CH_3CH_2CH_2CH{=}CHCH_2CH_3$$

Treatment of bis-π-allylnickel complexes [which can be prepared from an allyl Grignard reagent and $NiBr_2$ or from a π-allylnickel bromide (p. 413)] with CO gives either a 1,5-hexadiene or a diallyl ketone, depending on the structure of the ligand.[244]



See also reactions **0-104**, **5-22**, **6-76**, and **8-27** to **8-29**.

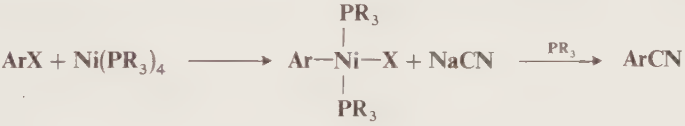
2-32 Cyanogenation of Organometallic Compounds

$$ArTl(OOCCF_3)_2 \xrightarrow[\text{aq. KCN}]{\text{excess}} ArTl(CN)_3^- \;\; K^+ \xrightarrow[\text{KCN}]{h\nu} ArCN$$

Arylthallium bis(trifluoroacetates) (reaction **2-20**) can be converted to aryl nitriles by treatment with excess aqueous KCN followed by photolysis of the resulting complex ion $ArTl(CN)_3^-$ in the presence of excess KCN.[199] Alternatively, arylthallium(III) salts react with $Cu(CN)_2$ or CuCN to give aryl nitriles without irradiation,[245] e.g.,

$$PhTl(OAc)(ClO_4) + Cu(CN)_2 \xrightarrow[\text{pyridine}]{\text{115 C, 5 hr}} 75\%\ PhCN$$

Yields from this procedure are variable, ranging from almost nothing to 90 or 100%. In another method, the arylnickel(0) complex **35** reacts with sodium cyanide to give aryl nitriles.[246] **35** are



$$ArX + Ni(PR_3)_4 \longrightarrow Ar{-}\underset{\underset{\displaystyle PR_3}{|}}{\overset{\overset{\displaystyle PR_3}{|}}{Ni}}{-}X + NaCN \xrightarrow{PR_3} ArCN$$

35

prepared by treatment of aryl halides with $Ni(PR_3)_4$ complexes.[247] In still another method, aryllithium reagents react with pentachlorobenzonitrile C_6Cl_5CN to give low to moderate yields of aryl nitriles.[248]

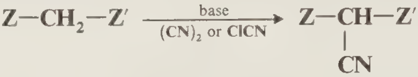
In some cases nitriles can be prepared by treatment of Grignard reagents with chlorocyanogen ClCN or with cyanogen NCCN, but these methods are limited in scope. For example, the reaction of ClCN with RMgX where R is aryl, alkynyl, or primary alkyl, gives mostly nitriles, but when R is secondary or tertiary alkyl, the principal products are alkyl chlorides. Other organometallic compounds may also give nitriles when treated with these reagents. Important examples are enolates derived from malonic ester, acetoacetic ester, and similar compounds. Primary and secondary Grignard reagents and certain other organometallic compounds react



$$\text{Z—CH}_2\text{—Z}' \xrightarrow[(\text{CN})_2 \text{ or ClCN}]{\text{base}} \text{Z—}\underset{\displaystyle\text{CN}}{\underset{|}{\text{CH}}}\text{—Z}'$$

with triphenylmethyl isocyanide Ph_3CNC to give nitriles in variable yields.[249]

Olefinic cyanides can be prepared from alkenes and palladium cyanide in a polar aprotic solvent. Yields are not high.[250]

$$CH_2{=}CHR \xrightarrow{Pd(CN)_2} CH_2{=}CR{-}CN$$

For other electrophilic substitutions of the type RM → RC, see reactions **0-86** to **0-109**, which are discussed under nucleophilic substitutions in Chapter 10. See also reaction **6-76**.

G. Metal Electrophiles

2-33 Replacement of a Metal with a Metal

$$RM + M' \rightleftharpoons RM' + M$$

Many organometallic compounds are best prepared by this reaction, which involves replacement of a metal in an organometallic compound by another metal.[251] RM′ can be successfully prepared only when M′ is above M in the electromotive series, unless some other way is found to shift the equilibrium. That is, RM is usually an unreactive compound, and M′ a metal more active than M. Most often, RM is R_2Hg, since mercury alkyls are easy to prepare and mercury is far down in the electromotive series.[252] Alkyls of Li, Na, K, Be, Mg, Al, Ga, Zn, Cd, Te, Sn, etc., have been prepared in this way. An important advantage of this method over reaction **2-37** is that it ensures that the organometallic compound will be prepared free of any possible halide. This method can be used for the isolation of solid sodium and potassium alkyls. If the metals lie too close together in the series, it may not be possible to shift the equilibrium. For example, alkylbismuth compounds cannot be prepared in this way from alkylmercury compounds.

OS V, 1116.

2-34 Replacement of a Metal with a Metal Halide

$$RM + M'X \rightleftharpoons RM' + MX$$

In contrast to reaction **2-33** the reaction between an organometallic compound and a metal *halide* is successful only when M′ is *below* M in the electromotive series.[253] The two reactions considered together therefore constitute a powerful tool for preparing all kinds of organometallic compounds. In this reaction the most common substrates are Grignard reagents. Among others, alkyls of Be, Zn, Cd, Hg, Al, Sn, Pb, Co, Pt, and Au have been prepared by treatment of Grignard reagents with the appropriate halide.[254] The reaction has been used to prepare alkyls of almost all nontransition metals and even of some transition metals. Alkyls of metalloids and of nonmetals, including Si, B, Ge, P, As, Sb, and Bi, can also be prepared in this manner.[255] Except for alkali-metal alkyls and Grignard reagents, the reaction between RM and M′X is the most common method for the preparation of organometallic compounds.[256]

[250] Odaira, Oishi, Yukawa, and Tsutsumi, *J. Am. Chem. Soc.* **88,** 4105 (1966).

[251] For a review, see Jones and Gilman, *Chem. Rev.* **54,** 835–890 (1954), pp. 841–845.

[252] For a review of the reaction when M is mercury, see Makarova, Ref. 191, pp. 190–226.

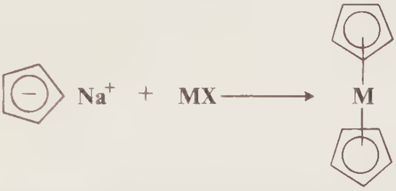
[253] For a review, see Ref. 251, pp. 847–856. Also see Schlosser, Ref. 188. For reviews of the mechanism, see Abraham, Ref. 2, pp. 39–106; Jensen and Rickborn, Ref. 2, pp. 100–192.

If M′ has a valence higher than 1, it is often possible to stop the reaction before all the halogens have been replaced, e.g.,

$$\mathrm{RMgX + SiCl_4 \longrightarrow RSiCl_3}$$

However, it is not always possible: RMgX + BF_3 gives only BR_3, although $BRCl_2$ can be prepared from R_2Zn and BCl_3.

Metallocenes (see p. 47) are usually made by this method:



Among others, metallocenes of Sc, Ti, V, Cr, Mn, Fe, Co, and Ni have been prepared in this manner.[257]

Metal nitrates are sometimes used instead of halides. For example, silver alkyls have been prepared from alkyllead compounds and silver nitrate.[258] Organosodium and organopotassium compounds can be prepared by the treatment of organolithium compounds with sodium and potassium alkoxides.[259]

OS **I,** 231, 550; **III,** 601; **IV,** 258, 473, 881; **V,** 211, 496, 727, 918, 1001; **55,** 127. Also see OS **IV,** 476.

2-35 Replacement of a Metal with an Organometallic Compound

$$\mathrm{RM + R'M' \rightleftharpoons RM' + R'M}$$

This type of metallic exchange is used much less often than reactions **2-33** and **2-34.** It is an equilibrium reaction and is useful only if the equilibrium lies in the desired direction. Usually the goal is to prepare a lithium compound which is not prepared easily in other ways, for example, vinyl- or allyllithium.[260] Examples are the preparation of vinyllithium from phenyllithium and tetravinyltin and the formation of α-dimethylamino organolithium compounds from the corresponding organotin compounds[261]

$$\mathrm{RR'NCH_2SnBu_3 + BuLi \xrightarrow{0^\circ C} RR'NCH_2Li + Bu_4Sn}$$

In general, the equilibrium lies in the direction in which the more electropositive metal is bonded to that alkyl or aryl group which is the more stable carbanion (p. 161). The reaction proceeds with retention of configuration;[262] an SEi mechanism is likely.[263]

OS **V**, 452; **51,** 17.

Halogen as Leaving Group

A. Hydrogen as the Electrophile

2-36 Reduction of Alkyl Halides

Although this reaction can proceed by an electrophilic substitution mechanism, it is considered in Chapter 10 (reaction **0-77**).

B. Metal Electrophiles

2-37 Replacement of a Halogen with a Metal

$$\mathbf{RX + M \longrightarrow RM}$$

Alkyl halides react directly with certain metals to give organometallic compounds. The most common metal is magnesium, and of course this is by far the most common method for the preparation of Grignard reagents.[264] The order of halide activity is I > Br > Cl. The reaction may be applied to many alkyl halides—primary, secondary, and tertiary—and to aryl halides, though aryl *chlorides* require the use of tetrahydrofuran or another higher-boiling solvent instead of the usual ether, or the use of special entrainment methods.[265] Aryl iodides and bromides can be treated in the usual manner. Allyl Grignard reagents can also be prepared in the usual manner (or in tetrahydrofuran),[266] though in the presence of excess halide these may give Wurtz-type coupling products (see reaction **0-87**). Like aryl chlorides, vinyl halides require higher-boiling solvents (see OS **IV**, 258), and ethynyl Grignard reagents are not generally prepared by this method at all. For these, reaction **2-19** is used. Dihalides[267] can be converted to Grignard reagents if the halogens are different and are at least three carbons apart. If the halogens are the same, it is possible to obtain dimagnesium compounds, e.g., $BrMg(CH_2)_4MgBr$.[268] 1,2-Dihalides give elimination instead of Grignard reagent formation (reaction **7-27**), and the reaction is seldom successful with 1,1-dihalides, though the preparation of *gem*-disubstituted compounds, such as $CH_2(MgBr)_2$, has been accomplished with these substrates.[269] α-Halo Grignard reagents and α-halolithium reagents can be prepared by the method given in reaction **2-38.**[270] Alkylmagnesium fluorides can be prepared by refluxing alkyl fluorides with Mg in the presence of appropriate catalysts (e.g., I_2 or EtBr) in tetrahydrofuran for several days.[271]

The presence of other functional groups in the halide usually affects the preparation of the Grignard reagent. Groups which contain active hydrogen (as defined on p. 557), such as OH, NH_2, and COOH, may be present in the molecule, but only if they are converted to the salt form (O^-, NH^-, COO^-, respectively). Groups which react with Grignard reagents, such as

---

[267] For reviews of the preparation of Grignard reagents from dihalides, see Heaney, *Organomet. Chem. Rev.* **1,** 27–42 (1966); Millar and Heaney, *Q. Rev., Chem. Soc.* **11,** 109–120 (1957).

[268] For example, see Denise, Ducom, and Fauvarque, *Bull. Soc. Chim. Fr.* 990 (1972).

[269] For example, see Bertini, Grasselli, Zubiani, and Cainelli, *Tetrahedron* **26,** 1281 (1970).

[270] For a review of compounds containing both carbon-halogen and carbon-metal bonds, see Chivers, *Organomet. Chem. Rev., Sect. A* **6,** 1–64 (1970).

[271] Yu and Ashby, *J. Org. Chem.* **36,** 2123 (1971). See also Ashby and Nackashi, *J. Organomet. Chem.* **24,** C17 (1970).

C=O, C≡N, NO_2, COOR, etc., inhibit Grignard formation entirely. In general, the only functional groups which may be present in the halide molecule without any interference at all are double and triple bonds (except terminal triple bonds) and OR and NR_2 groups. However, β-halo ethers generally give β-elimination when treated with magnesium (see reaction **7-29**), and Grignard reagents from α-halo ethers[272] can only be formed in tetrahydrofuran or methylal at a low temperature, e.g.,[273]

$$\mathrm{EtOCH_2Cl + Mg \xrightarrow[-30^\circ C]{THF\ or\ CH_2(OMe)_2} EtOCH_2MgCl}$$

because such reagents immediately undergo α elimination (see reaction **2-38**) at room temperature in ether solution.

Because Grignard reagents react with water (reaction **2-21**) and with oxygen (reaction **2-22**), it is generally best to prepare them in an anhydrous nitrogen atmosphere. Grignard reagents are generally neither isolated nor stored; but solutions of Grignard reagents are used directly for the required synthesis. Grignard reagents can also be prepared in benzene or toluene, if a tertiary amine is added to complex with the RMgX.[274] This method eliminates the need for an ether solvent. With certain primary alkyl halides it is even possible to prepare alkylmagnesium compounds in hydrocarbon solvents in the absence of an organic base.[275]

Next to the formation of Grignard reagents, the most important application of this reaction is the conversion of alkyl and aryl halides to organolithium compounds, but it has also been carried out with many other metals, e.g., Na, Be, Zn, Hg, As, Sb, and Sn.[276] With sodium, the Wurtz reaction (**0-86**) is an important side reaction. The reaction is not successful for potassium, complex mixtures being obtained in which RK is an unimportant constituent.[277] In some cases where the reaction between a halide and a metal is too slow, an alloy of the metal with potassium or sodium can be used instead. The most important example is the preparation of tetraethyllead from ethyl bromide and a Pb–Na alloy. In another example it has been shown that in the treatment of an alkyl halide with lithium it is necessary that a small amount of sodium be alloyed with the lithium in order to obtain a good yield of alkyllithium.[278]

The mechanism of Grignard reagent formation is not well known, though much work has been done in the area.[279] There is evidence from CIDNP[280] (p. 171) and from stereochemical, rate, and product studies[281] that free radicals are intermediates, and the following mechanism has been proposed:[280]

$$\begin{aligned}
\mathrm{R{-}X} + \overline{\mathrm{Mg}} &\longrightarrow \mathrm{R{-}X}^{\dot{-}} + \mathrm{Mg}_s^{\dot{+}} \\
\mathrm{R{-}X}^{\dot{-}} &\longrightarrow \mathrm{R}\cdot + \mathrm{X}^- \\
\mathrm{X}^- + \mathrm{Mg}_s^{\dot{+}} &\longrightarrow \mathrm{XMg}_s^{\boldsymbol{\cdot}} \\
\mathrm{R}\cdot + \mathrm{XMg}_s^{\boldsymbol{\cdot}} &\longrightarrow \mathrm{RMgX}
\end{aligned}$$

The species $R{-}X^{\dot{-}}$ and $Mg^{\dot{+}}$ are radical ions. The subscript "s" is meant to indicate that the species so marked are bound to the surface of the magnesium.

There are too many preparations of Grignard reagents in *Organic Syntheses* for us to list here. Use of the reaction to prepare other organometallic compounds can be found in OS **I,** 228; **II,** 184, 517, 607; **III,** 413, 757; **52,** 19; **55,** 103. The preparation of unsolvated butylmagnesium bromide is described at OS **V,** 1141.

2-38 Replacement of a Halogen by a Metal from an Organometallic Compound

$$\mathbf{RX + R'M \longrightarrow RM + R'X}$$

The exchange reaction between alkyl halides and organometallic compounds is almost entirely limited to the cases where M is lithium and X is bromide or iodide,[282] though it has been shown to occur with magnesium.[283] R′ is usually, though not always, alkyl, and often butyl; R is usually aromatic. Of course, the R which becomes bonded to the halogen is the one for which RH is the weaker acid. The reaction can be used to prepare α-halo organolithium and α-halo organomagnesium compounds,[284] e.g.,[285]

$$\mathbf{CCl_4 + BuLi \xrightarrow[-105^\circ C]{THF} Cl_3C{-}Li}$$

Such compounds can also be prepared by hydrogen-metal exchange, e.g.,[286]

$$\mathbf{Br_3CH + iso\text{-}PrMgCl \xrightarrow[-95^\circ C]{THF-HMPT} Br_3C{-}MgCl + C_3H_8}$$

This is an example of reaction **2-19.** However, these α-halo organometallic compounds are stable only at low temperatures (~ −100°C) and only in tetrahydrofuran or mixtures of tetrahydrofuran and other solvents (e.g., HMPT). At ordinary temperatures they lose MX (α elimination) to give carbenes (which then react further) or carbenoid reactions. The α-chloro-α-magnesio sulfones $ArSO_2CH(Cl)MgBr$ are exceptions, being stable in solution at room temperature and even under reflux.[287]

When the substrate has a halogen and a hydrogen on the same carbon, halogen-metal exchange is usually more rapid than hydrogen-metal exchange (the reaction of bromoform under the conditions shown above is an exception).[288] α-Halo sodium and α-halo potassium compounds have also been prepared by a hydrogen-metal exchange reaction.[289]

The mechanism in the reaction of alkyllithium compounds with alkyl and aryl iodides has been shown to involve free radicals:[290]

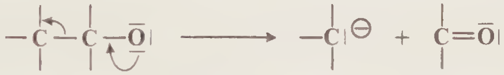
$$\mathbf{RX + R'M \rightleftharpoons \underset{\text{Solvent cage}}{[R\cdot, X, M, R'\cdot]} \rightleftharpoons RM + R'X}$$

Evidence for this mechanism is the obtention of coupling and disproportionation products from R• and R′•, and the observation of CIDNP (p. 171).[291]

Carbon Leaving Groups

In these reactions (**2-39** to **2-47**) a carbon-carbon bond cleaves.[292] We regard as the substrate that side which retains the electron pair; hence the reactions are considered electrophilic substitutions. The incoming group is hydrogen in all but one (reaction **2-41**) of the cases. The reactions in groups A and B are sometimes called *anionic cleavages*, though they do not always occur by mechanisms involving free carbanions (SE1). When they do, the reactions are facilitated by increasing stability of the carbanion.

A. Carbonyl-forming Cleavages These reactions follow the pattern



The leaving group is stabilized because the electron deficiency at its carbon is satisfied by a pair of electrons from the oxygen. With respect to the leaving group the reaction is elimination to form a C=O bond. Retrograde aldol condensations (reaction **6-40**) and cleavage of cyanohydrins (reaction **6-50**) belong to this classification but are treated in Chapter 16 under their more important reverse reactions. Other eliminations to form C=O bonds are discussed in Chapter 17 (reactions **7-44** to **7-46**).

2-39 Decarboxylation of Aliphatic Acids

$$\mathbf{RCOOH \longrightarrow RH + CO_2}$$

Many carboxylic acids can be successfully decarboxylated, either as the free acid or in the salt form, but not simple fatty acids.[293] An exception is acetic acid, which as the acetate, heated with base, gives good yields of methane. Aliphatic acids which do undergo successful decarboxylation have certain functional groups or double or triple bonds in the α or β position. Some of these are shown in Table 1. For decarboxylation of aromatic acids, see reaction **1-43.** Decarboxylation of an α-cyano acid may give a nitrile or a carboxylic acid, since the cyano group may or may not be hydrolyzed in the course of the reaction. In addition to the compounds listed in Table 1, decarboxylation can also be carried out on α,β-unsaturated and α,β-acetylenic acids, acids with a positive sulfur in the α position, for example, $Me_2\overset{+}{S}CH_2COOH\ Br^-$,[294] and certain acids with a

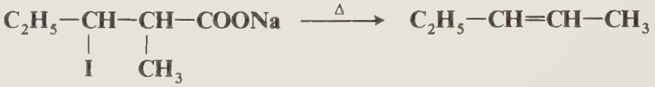
TABLE 1 Some acids which undergo decarboxylation fairly readily
Others are described in the text

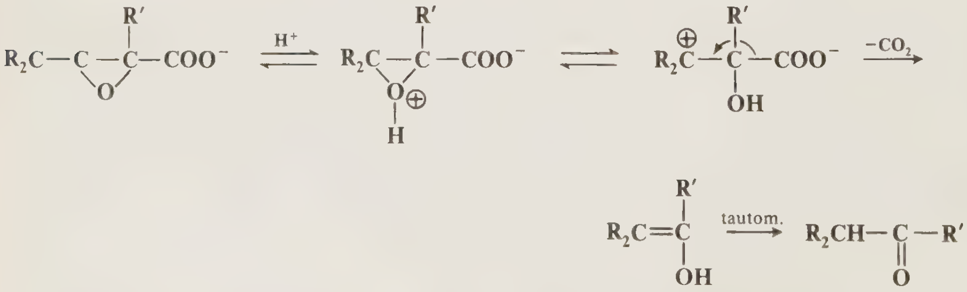
	Acid type	Decarboxylation product
Malonic	$HOOC-\overset{\mid}{\underset{\mid}{C}}-COOH$	$HOOC-\overset{\mid}{\underset{\mid}{C}}-H$
α-Cyano	$NC-\overset{\mid}{\underset{\mid}{C}}-COOH$	$NC-\overset{\mid}{\underset{\mid}{C}}-H$ or $HOOC-\overset{\mid}{\underset{\mid}{C}}-H$
α-Nitro	$O_2N-\overset{\mid}{\underset{\mid}{C}}-COOH$	$O_2N-\overset{\mid}{\underset{\mid}{C}}-H$
α-Aryl	$Ar-\overset{\mid}{\underset{\mid}{C}}-COOH$	$Ar-\overset{\mid}{\underset{\mid}{C}}-H$
α-Keto	$-\underset{\underset{O}{\Vert}}{C}-COOH$	$-\underset{\underset{O}{\Vert}}{C}-H$
α,α,α-Trihalo	$X_3C-COOH$	X_3CH
β-Keto	$-\underset{\underset{O}{\Vert}}{C}-\overset{\mid}{\underset{\mid}{C}}-COOH$	$-\underset{\underset{O}{\Vert}}{C}-\overset{\mid}{\underset{\mid}{C}}-H$
β,γ-Unsaturated	$-\underset{\mid}{C}=\underset{\mid}{C}-\overset{\mid}{\underset{\mid}{C}}-COOH$	$-\underset{\mid}{C}=\underset{\mid}{C}-\overset{\mid}{\underset{\mid}{C}}-H$

positive nitrogen in the α position.[295] β-Halo acids give decarboxylation accompanied by elimination:[296]



$$C_2H_5-\underset{I}{\underset{\mid}{CH}}-\underset{CH_3}{\underset{\mid}{CH}}-COONa \xrightarrow{\Delta} C_2H_5-CH=CH-CH_3$$

α,β-Unsaturated acids can also be decarboxylated with copper and quinoline in a manner similar to that discussed in reaction **1-43.** Glycidic acids give aldehydes on decarboxylation. The following mechanism has been suggested:[297]



---

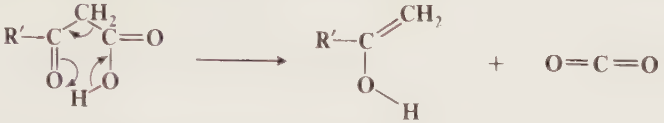
[295] Haake and Mantecon, *J. Am. Chem. Soc.* **86,** 5230 (1964).

[296] For a discussion of the mechanism of this elimination, see Vaughan, Cartwright, and Henzi, *J. Am. Chem. Soc.* **94,** 4978 (1972).

[297] Singh and Kagan, *J. Org. Chem.* **35,** 2203 (1970).

The direct product is an enol which tautomerizes to the aldehyde.[298] This is the usual last step in the Darzens reaction (reaction **6-45**).

Decarboxylations may be regarded as reversals of the addition of carbanions to carbon dioxide (reaction **6-34**), but free carbanions are not always involved.[299] When it is the carboxylate *ion* which is decarboxylated, the mechanism may be either SE1 or SE2. In the case of the SE1 mechanism, the reaction is of course aided by the presence of electron-withdrawing groups, which stabilize the carbanion.[300] Decarboxylations of carboxylate ions can be accelerated by the addition of a suitable crown ether, which in effect removes the metallic ion.[301] But some acids can also be decarboxylated directly, and in most of these cases there is a cyclic, six-center mechanism:



Here too there is an enol which tautomerizes to the product. The mechanism is illustrated for the case of β-keto acids,[302] but it is likely that malonic acids, α-cyano acids, α-nitro acids, and β,γ-unsaturated acids[303] behave similarly, since similar six-membered transition states can be written for them. Some α,β-unsaturated acids are also decarboxylated by this mechanism by isomerizing to the β,γ-isomers before they actually decarboxylate.[304] Evidence is that **36** and similar bicyclic β-keto acids resist decarboxylation.[305] In such compounds the six-membered cyclic transition state cannot form for steric reasons, and if it could, formation of the immediate enol product would violate Bredt's rule (p. 147). Some carboxylic acids which cannot form a six-membered transition state can still be decarboxylated, and these presumably react through an SE1 or SE2 mechanism.[306] Further evidence for the cyclic mechanism is that the reaction rate varies very little with a change from a nonpolar to a polar solvent (even from benzene to water[307]), and is not subject to acid catalysis.[308]

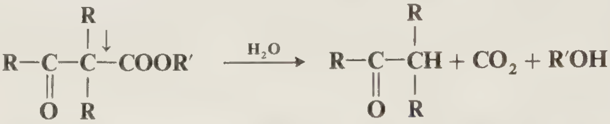
Although β-keto acids are easily decarboxylated, this reaction is seldom performed. The reason is that such acids are usually prepared from β-keto esters, and the esters are easily decarboxylated themselves on hydrolysis, without isolation of the acids. This decarboxylation of β-keto esters involving cleavage on the carboxyl side of the substituted methylene group (arrow) is carried out under acidic, neutral, or slightly basic conditions to yield a ketone. When strongly basic conditions are used, cleavage occurs on the other side of the CR_2 group (reaction **2-42**). β-Keto



$$\mathrm{R{-}\underset{\underset{O}{\|}}{C}{-}\overset{R}{\underset{R}{C}}{\downarrow}{-}COOR'} \xrightarrow{H_2O} \mathrm{R{-}\underset{\underset{O}{\|}}{C}{-}\overset{R}{\underset{R}{C}}H + CO_2 + R'OH}$$

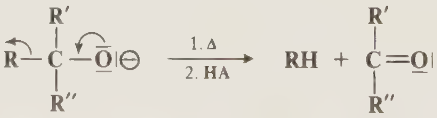
esters can be decarbalkoxylated without passing through the free-acid stage by treatment with boric anhydride B_2O_3 at 150°C.[309] The alkyl portion of the ester (R′) is converted to an alkene or, if it lacks a β-hydrogen, into an ether R′OR′. Another method for the decarbalkoxylation of β-keto esters, malonic esters, and α-cyano esters consists of heating the substrate in wet dimethyl sulfoxide containing NaCl, Na_3PO_4, or some other simple salt.[310] In this method too, the free acid is probably not an intermediate, but here the alkyl portion of the substrate is converted to the corresponding alcohol. Certain amides (e.g., Ph_3CCONH_2 and $Ph_2CHCONH_2$) can be decarboxaminated (to give, respectively, Ph_3CH and Ph_2CH_2) by treatment with butyllithium.[311] An SE1 mechanism is likely. Certain decarboxylations can also be accomplished photochemically.[312]

Some of the decarboxylations listed in *Organic Syntheses* are performed with concomitant ester or nitrile hydrolysis, and others are simple decarboxylations.

With ester or nitrile hydrolysis: OS **I,** 290, 451, 523; **II,** 200, 391; **III,** 281, 286, 317, 326, 510, 513, 591; **IV,** 55, 93, 176, 441, 664, 708, 790, 804; **V,** 76, 288, 572, 687, 989; **53,** 70, 98.

Simple decarboxylations: OS **I,** 351, 401, 440, 473, 475; **II,** 21, 61, 93, 229, 302, 333, 368, 416, 474, 512, 523; **III,** 213, 425, 495, 705, 733, 783; **IV,** 234, 254, 278, 337, 555, 560, 597, 630, 731, 857; **V,** 251, 585; **51,** 73, 136. Also see OS **IV,** 633.

2-40 Cleavage of Alkoxides



$$\mathrm{R{-}\overset{R'}{\underset{R''}{C}}{-}\overline{\underline{O}}|^{\ominus}} \xrightarrow[2.\ \mathrm{HA}]{1.\ \Delta} \mathrm{RH} + \mathrm{\overset{R'}{\underset{R''}{C}}{=}\underline{O}|}$$

Alkoxides of tertiary alcohols can be cleaved in a reaction which is essentially the reverse of addition of carbanions to ketones (reaction **6-31**).[313] The reaction is unsuccessful when the R groups are simple unbranched alkyl groups, e.g., the alkoxide of triethylcarbinol. Cleavage is accomplished with branched alkoxides such as the alkoxides of triisopropylcarbinol or diisopropylneopentylcarbinol. The reaction also takes place when R is aryl; for example, the alkoxide of triphenylcarbinol gives benzene and benzophenone. The reaction has been used for extensive mechanistic studies (see p. 525).

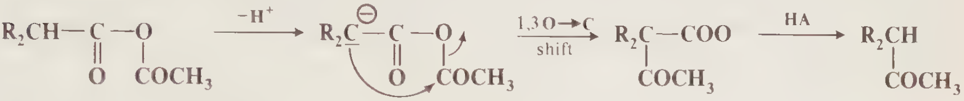
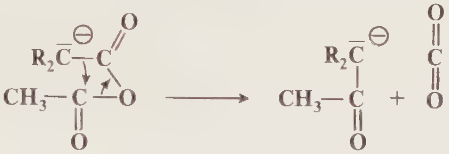
2-41 Replacement of a Carboxyl Group by an Acyl Group

$$R_2CHCOOH + (CH_3CO)_2O \longrightarrow R_2CHCOCH_3 + CO_2 + CH_3COOH$$

When a carboxylic acid containing at least one α-hydrogen is treated with an anhydride, it sometimes happens that decarboxylation occurs, accompanied by entrance of an acyl group. The reaction is aided by the presence of γ- and δ-NR_2 groups.[314] The first step is probably the formation of the mixed anhydride $R_2CHCOOCOCH_3$ by an acid-anhydride exchange (see reaction **0-30**). What happens next is not certain, but a 1,3 shift following loss of the α-proton has been proposed:[315]



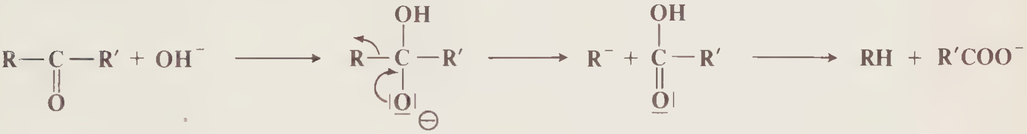
The 1,3 shift and the decarboxylation may occur in one step:[316]



This reaction was an important step in the total synthesis of strychnine.[317]

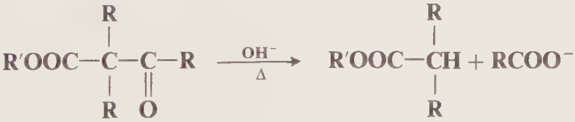
OS **IV**, 5; **V**, 27.

B. Acyl Cleavages In these reactions (**2-42** to **2-45**) a carbonyl group is attacked by a hydroxide ion (or amide ion), giving an intermediate which undergoes cleavage to a carboxylic acid (or a carboxylic acid amide). With respect to the leaving group, this is nucleophilic substitution at a carbonyl group, and the mechanism is the tetrahedral one discussed in Chapter 10 (p. 308).



With respect to R of course this is electrophilic substitution. Indications are that the mechanism is usually S_E1.

2-42 Basic Cleavage of β-Keto Esters and β-Diketones



$$R'OOC-\underset{R}{\overset{R}{C}}-\underset{O}{\overset{\|}{C}}-R \xrightarrow[\Delta]{OH^-} R'OOC-\underset{R}{\overset{R}{CH}} + RCOO^-$$

---

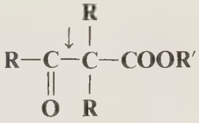
[314] Cruickshank and Sheehan, *J. Am. Chem. Soc.* **83**, 2891 (1961).

[315] Buchanan and McArole, *J. Chem. Soc.* 2944 (1952); Smith and Fahey, *J. Am. Chem. Soc.* **81**, 3391 (1959).

[316] Woodward, Cava, Ollis, Hunger, Daeniker, and Schenker, *Tetrahedron* **19**, 247 (1963).

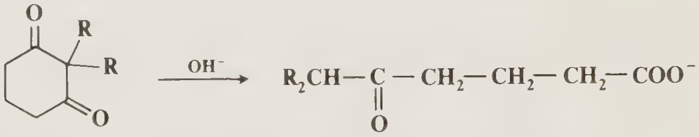
[317] Ref. 316, p. 260 (XXXIX → XL in that paper).

When β-keto esters are treated with concentrated base, cleavage occurs, but is on the keto side of the CR_2 group (arrow) in contrast to the acid cleavage mentioned on page 572. The products



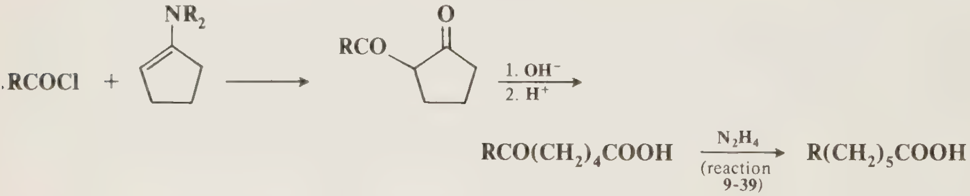
$$R-\underset{\underset{O}{\|}}{C}\overset{\downarrow}{-}\underset{\underset{R}{|}}{\overset{\overset{R}{|}}{C}}-COOR'$$

are an ester and the salt of an acid. However, the utility of the reaction is somewhat limited by the fact that decarboxylation is a side reaction, even under basic conditions. β-Diketones behave similarly to give a ketone and the salt of a carboxylic acid. The reaction has often been applied to cyclic β-diketones:[318]



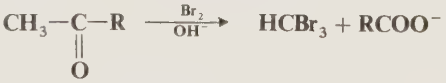
With both β-keto esters and β-diketones, OEt^- may be used instead of OH^-, in which case the ethyl esters of the corresponding acids are obtained instead of the salts. In the case of β-keto esters, this is the reverse of Claisen condensation (**0-111**).

A combination of reaction **2-17** and this reaction has been used as a method of extending a chain by 5, 6, or 12 carbons (illustrated for 5):[319]



OS **II**, 266, 531; **III**, 379; **IV**, 415, 957; **V**, 179, 187, 277, 533, 747, 767.

2-43 The Haloform Reaction



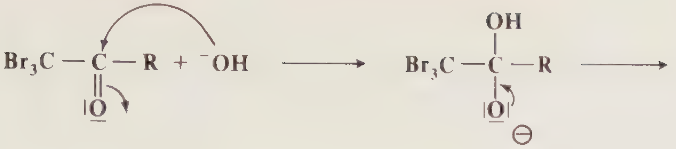
$$CH_3-\underset{\underset{O}{\|}}{C}-R \xrightarrow[OH^-]{Br_2} HCBr_3 + RCOO^-$$

In the *haloform reaction*, methyl ketones (and the only methyl aldehyde, acetaldehyde) are cleaved with halogen and a base. The halogen may be bromine, chlorine, or iodine. What takes place is actually a combination of two reactions. The first is an example of reaction **2-4**, in which, under the basic conditions employed, the methyl group is trihalogenated. Then the resulting trihalo ketone is attacked by hydroxide ion:

---

[318] For a review see Stetter, *Angew. Chem.* **67**, 769 (1955), *Newer Methods Prep. Org. Chem.* **2**, 51–99 (1963).

[319] Hünig and Lendle, *Chem. Ber.* **93**, 913 (1960); Hünig and Salzwedel, *Chem. Ber.* **99**, 823 (1966); Hünig and Buysch, *Chem. Ber.* **100**, 4010, 4017 (1967).

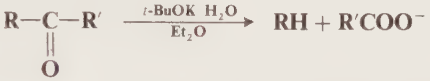


$$Br_3C^{\ominus} + RCOOH \longrightarrow Br_3CH + RCOO^-$$

Primary or secondary methylcarbinols also give the reaction, since they are oxidized to the carbonyl compounds under the conditions employed. As with reaction **2-4**, the rate-determining step is the preliminary enolization of the methyl ketone.[320] A side reaction is α halogenation of the nonmethyl R group. Sometimes these groups are also cleaved.[321] The reaction cannot be applied to F_2, but ketones of the form $RCOCF_3$ (R = alkyl or aryl) give fluoroform and $RCOO^-$ when treated with base.[322] The haloform reaction is often used as a test for methylcarbinols and methyl ketones. Iodine is most often used as the test reagent, since iodoform is an easily identifiable yellow solid. The reaction is also frequently used for synthetic purposes.

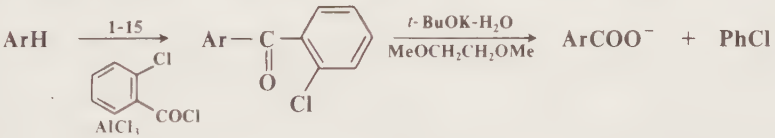
OS **I,** 526; **II,** 428; **III,** 302; **IV,** 345; **V,** 8. Also see OS **51,** 100.

2-44 Cleavage of Nonenolizable Ketones



$$R-\underset{\underset{O}{\|}}{C}-R' \xrightarrow[Et_2O]{t\text{-BuOK}\ H_2O} RH + R'COO^-$$

Ordinary ketones are generally much more difficult to cleave than trihalo ketones or β-diketones, since the carbanion intermediates in these cases are more stable than simple carbanions. However, nonenolizable ketones can be cleaved by treatment with a 10 : 3 mixture of t-BuOK–H_2O in an aprotic solvent such as ether, dimethyl sulfoxide, 1,2-dimethoxyethane (glyme), etc.[323] When the reaction is applied to monosubstituted diaryl ketones, that aryl group preferentially cleaves which comes off as the more stable carbanion, except that aryl groups substituted in the ortho position are more readily cleaved than otherwise because of the steric effect (relief of strain).[324] Combined with the preparation of diaryl ketones by Friedel-Crafts acylation (reaction **1-15**), this reaction provides an indirect method for introducing a carboxyl group into an aromatic ring:[325]



2-Chlorobenzoyl chloride is the preferred reagent here, because a 2-chlorophenyl group cleaves much more readily than most other aryl groups. In certain cases, cyclic ketones may be cleaved by base treatment, even if they are enolizable.[326]

In another application of this reaction, cyclobutanones substituted with electron-withdrawing groups such as SR may be cleaved with OR^- to give esters.[327] Since the cyclobutanones can be

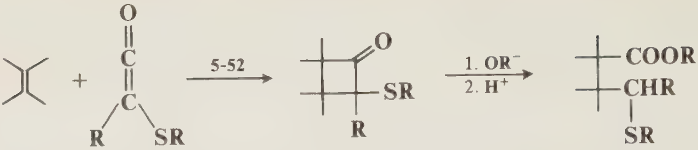
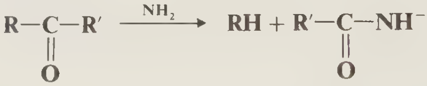
[326] For example, see Swaminathan and Newman, *Tetrahedron* **2,** 88 (1958); Hoffman and Cram, Ref. 22.

[327] Cossement, Binamé, and Ghosez, *Tetrahedron Lett.* 997 (1974).



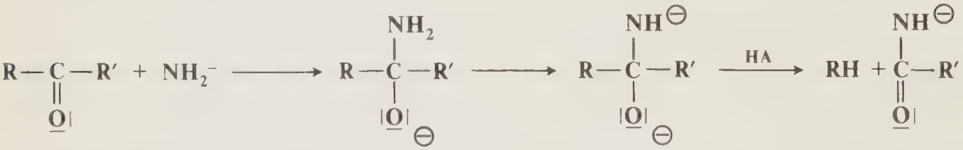
prepared by treatment of olefins with the appropriate ketenes (reaction **5-52**), this is an indirect method for the addition of two carbon moieties to a double bond (see also reactions **5-57, 5-58**).

2-45 The Haller-Bauer Reaction



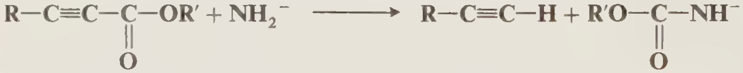
$$\underset{\substack{\| \\ \mathrm{O}}}{\mathrm{R{-}C{-}R'}} \xrightarrow{\mathrm{NH_2}} \mathrm{RH} + \underset{\substack{\| \\ \mathrm{O}}}{\mathrm{R'{-}C{-}NH^-}}$$

Cleavage of ketones with sodium amide is called the *Haller-Bauer reaction.*[328] As with reaction **2-44**, which is exactly analogous, the reaction is usually applied only to nonenolizable ketones. It is most often applied to ketones of the form $ArCOCR_3$, where the products R_3CCONH_2 are not easily attainable by other methods. However, many other ketones have been used, though benzophenone is virtually unaffected. It has been shown that the configuration of optically active R is retained.[329] The NH_2 loses its proton *before* the R is cleaved:[330]



$$\underset{\substack{\| \\ \underline{\mathrm{O}}|}}{\mathrm{R{-}C{-}R'}} + \mathrm{NH_2^-} \longrightarrow \overset{\substack{\mathrm{NH_2} \\ |}}{\underset{\substack{| \\ |\underline{\mathrm{O}}|^{\ominus}}}{\mathrm{R{-}C{-}R'}}} \longrightarrow \overset{\substack{\mathrm{NH}^{\ominus} \\ |}}{\underset{\substack{| \\ |\underline{\mathrm{O}}|^{\ominus}}}{\mathrm{R{-}C{-}R'}}} \xrightarrow{\mathrm{HA}} \mathrm{RH} + \overset{\substack{\mathrm{NH}^{\ominus} \\ |}}{\underset{\substack{\| \\ \underline{\mathrm{O}}|}}{\mathrm{C{-}R'}}}$$

A very similar reaction may be applied to esters and amides of α,β-acetylenic acids with no γ-hydrogen:[331]



$$\mathrm{R{-}C{\equiv}C{-}}\underset{\substack{\| \\ \mathrm{O}}}{\mathrm{C}}\mathrm{{-}OR'} + \mathrm{NH_2^-} \longrightarrow \mathrm{R{-}C{\equiv}C{-}H} + \mathrm{R'O{-}}\underset{\substack{\| \\ \mathrm{O}}}{\mathrm{C}}\mathrm{{-}NH^-}$$

Carbamates are obtained from esters, and ureas from amides.

OS V, 384, 1074.

C. Other Cleavages

2-46 The Cleavage of Alkanes in Super-acid Solutions

$$(CH_3)_4C \xrightarrow{FSO_3H\text{-}SbF_5} CH_4 + (CH_3)_3C^+$$

The C—C bonds of alkanes can be cleaved by treatment with super acids[43] (p. 226). The reaction may be called *alkylolysis*. For example, neopentane in FSO_3H–SbF_5 can cleave to give methane and the *t*-butyl cation. C—H cleavage (see reaction **2-1**) is a competing reaction, and, for example, neopentane can give H_2 and the *t*-pentyl cation (formed by rearrangement of the initially formed neopentyl cation) by this pathway. In general, the order of reactivity is tertiary C—H > C—C > secondary C—H ≫ primary C—H, though steric factors cause a shift in favor of C—C cleavage in such a hindered compound as tri-*t*-butylmethane. The mechanism is similar to that shown in reactions **2-1** and **2-16** and involves attack by H^+ on the C—C bond to give a pentavalent cation. The two major pathways for neopentane may therefore be shown as:

---

t-Pentyl cation

2-47 Decyanation of Alkyl Nitriles

$$\mathrm{RCN} \xrightarrow[\text{Na-Fe(acac)}_3]{\text{Na NH}_3 \text{ or}} \mathrm{RH}$$

The cyano group of alkyl nitriles can be removed by treatment with metallic sodium, either in liquid ammonia;[332] or together with tris(acetylacetonato)iron(III) $Fe(acac)_3$ [333] or, with lower yields, titanocene $C_{20}H_{20}Ti_2$. The two procedures are complementary. Although both can be used to decyanate many kinds of nitriles, the Na–NH_3 method gives high yields with R groups such as trityl, benzyl, phenyl, and tertiary alkyl, but lower yields (~35 to 50%) when R = primary or secondary alkyl. On the other hand, primary and secondary alkyl nitriles are decyanated in high yields by the Na–$Fe(acac)_3$ procedure. Sodium in liquid ammonia is known to be a source of solvated electrons, and the reaction may proceed through the free radical R• which would then be reduced to the carbanion R^-, which by abstraction of a proton from the solvent, would give RH. The mechanism with $Fe(acac)_3$ is presumably different. Another procedure, which is successful for R = primary, secondary, or tertiary, involves the use of Li, Na, or K in the solvent HMPT with or without an alcohol cosolvent at 0°C.[334] Best results were obtained with K, using *t*-BuOH as cosolvent. Nitriles can also be decyanated by solvated electrons produced electrochemically.[335]

α-Amino and α-amido nitriles $RCH(CN)NR'_2$ and $RCH(CN)NHCOR'$ can be decyanated in high yield by treatment with $NaBH_4$.[336]

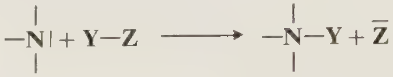
Electrophilic Substitution at Nitrogen

In most of the reactions in this section, an electrophile bonds with the unshared pair of a nitrogen atom. The electrophile may be a free positive ion or a positive species attached to a carrier which breaks off in the course of the attack or shortly after:



$$-\overset{|}{\underset{|}{\mathrm{N}}}| + \mathrm{Y{-}Z} \longrightarrow -\overset{|}{\underset{|}{\mathrm{N}}}\mathrm{{-}Y} + \overline{\mathrm{Z}}$$

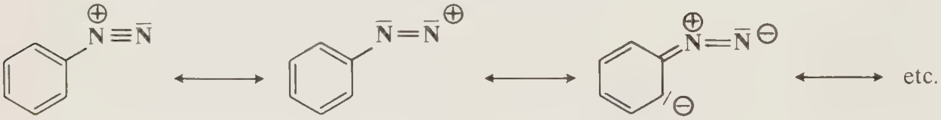
37

Further reaction of **37** depends on the nature of Y and of the other groups attached to the nitrogen.

2-48 Diazotization

$$\mathrm{Ar{-}NH_2} \quad + \quad \mathrm{HONO} \longrightarrow \mathrm{Ar{-}\overset{\oplus}{N}{\equiv}\overline{N}}$$

When primary aromatic amines are treated with nitrous acid, diazonium salts are formed.[337] The reaction also occurs with aliphatic primary amines, but aliphatic diazonium ions are extremely unstable, even in solution (see p. 327). Aromatic diazonium ions are more stable, because of resonance interaction between the nitrogens and the ring:



38 **39**

Incidentally, **38** contributes more to the hybrid than **39,** as shown by bond-distance measurements. In benzenediazonium chloride, the C—N distance is 1.42 Å, and the N—N distance 1.11 Å,[338] which values fit more closely to a single and a triple bond than to two double bonds (see p. 24). Even aromatic diazonium salts are stable only at low temperatures, usually only below 5°C, though more stable ones, such as the diazonium salt obtained from sulfanilic acid, are stable up to 10 or 15°C. Diazonium salts are usually prepared in aqueous solution and used without isolation, though it is possible to prepare solid diazonium salts if desired.[339]

For aromatic amines, the reaction is very general.[340] Halogen, nitro, alkyl, aldehyde, sulfonic acid, etc., groups do not interfere. Since aliphatic amines do not react with nitrous acid below a pH of about 3, it is even possible, by working at a pH of about 1, to diazotize an aromatic amine *without disturbing* an aliphatic amino group in the same molecule.[341]

If an aliphatic amino group is α to a COOR, CN, CHO, COR, etc., and has an α-hydrogen, then treatment with nitrous acid gives not a diazonium salt, but a *diazo compound.* Such diazo compounds can also be prepared, often more conveniently, by treatment of the substrate with

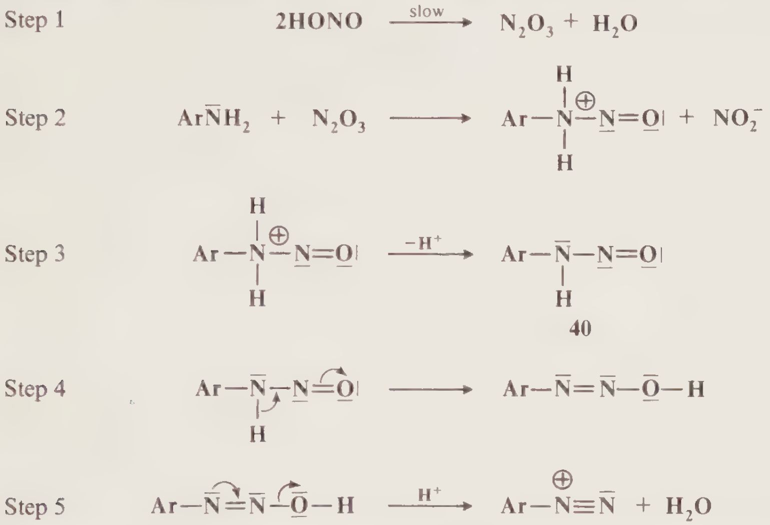
$$\mathrm{EtOOC{-}CH_2{-}NH_2 + HONO \longrightarrow EtOOC{-}CH{=}\overset{\oplus}{N}{=}\overset{\ominus}{\underline{N}}}$$

isoamyl nitrite and a small amount of acid.[342] Certain heterocyclic amines also give diazo compounds rather than diazonium salts.[340]

Despite the fact that diazotization takes place in acid solution, the actual species attacked is not the salt of the amine, but the small amount of free amine present.[343] It is because aliphatic amines are stronger bases than aromatic ones that at pH values below 3 there is not enough free amine present for the former to be diazotized, while the latter still undergo the reaction. In dilute acid the actual attacking species is N_2O_3, which acts as a carrier of NO^+. Evidence for this is that the reaction is second order in nitrous acid and, at sufficiently low acidities, the amine does not appear in the rate expression.[344] Under these conditions the mechanism is



40

There exists other evidence for this mechanism.[345] Other attacking species may be NOCl, $H_2NO_2^+$, and at high acidities even NO^+ itself.

There are many preparations of diazonium salts listed in *Organic Syntheses*, but they are always prepared for use in other reactions. We do not list them here, but under reactions in which they are used. The preparation of aliphatic diazo compounds can be found in OS **III**, 392; **IV**, 424. See also OS **52**, 53.

2-49 The Conversion of Hydrazines to Azides

$$\mathrm{RNHNH_2 + HONO \longrightarrow R{-}\overline{N}{=}\overset{\oplus}{N}{=}\overset{\ominus}{\underline{\overline{N}}}}$$

Monosubstituted hydrazines treated with nitrous acid give azides in a reaction which is exactly analogous to the formation of aliphatic diazo compounds mentioned in reaction **2-48**.

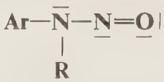
2-50 N-Nitrosation

$$R_2NH + HONO \longrightarrow R_2N{-}NO$$

When secondary amines are treated with nitrous acid, N-nitroso compounds are formed.[346] The reaction may be accomplished with dialkyl-, diaryl-, or alkylarylamines, and even with mono-N-substituted amides: $RCONHR' + HONO \rightarrow RCON(NO)R'$. Tertiary amines have also been N-nitrosated, but in these cases one group cleaves, so that the product is the nitroso derivative of a secondary amine.[347] The group which cleaves appears as an aldehyde or ketone. Other reagents have also been used, for example NOCl, which is useful for amines or amides which are not soluble in an acidic aqueous solution, or in cases where the N-nitroso compounds are highly reactive.

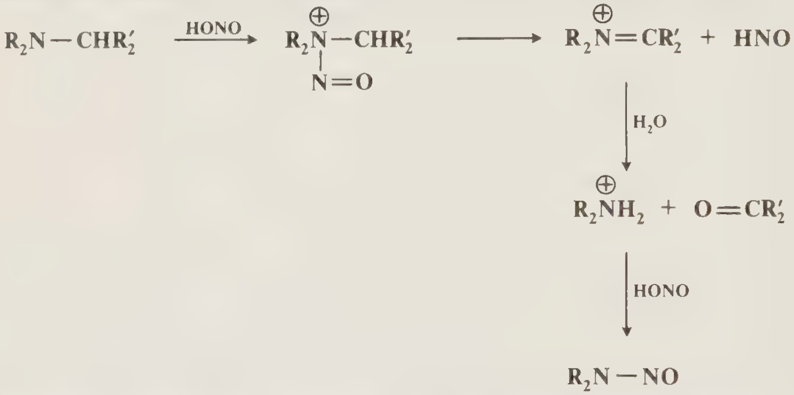
The mechanism of nitrosation is essentially the same as in reaction **2-48** up to the point where **41** (analogous to **40**) is formed. Since this species cannot lose a proton, it is stable and the



$$Ar{-}\underset{\displaystyle R}{\underset{|}{\bar{N}}}{-}\underline{N}{=}\underline{O}|$$

41

reaction ends there. The attacking entity may be any of those mentioned in reaction **2-48.** The following has been suggested as the mechanism for the reaction with tertiary amines:[348]



$R_2N{-}CHR'_2$
HONO
$R_2\overset{\oplus}{N}{-}CHR'_2$
$N{=}O$
$R_2\overset{\oplus}{N}{=}CR'_2$ + HNO
H_2O
$R_2\overset{\oplus}{N}H_2$ + $O{=}CR'_2$
HONO
$R_2N{-}NO$

The evidence for this mechanism includes the facts that nitrous oxide is a product (formed by $2HNO \rightarrow H_2O + N_2O$) and that quinuclidine, where the nitrogen is at a bridgehead and therefore cannot give elimination, does not react.[348]

Amines and amides can be N-*nitrated* with N_2O_5,[349] and aromatic amines can be converted to triazenes with diazonium salts. Aliphatic primary amines can also be converted to triazenes if the diazonium salts contain electron-withdrawing groups.[350] C-nitrosation is discussed in reactions **1-3** and **2-8.**

2-51 Conversion of Amines to Azides

$$\mathrm{RNH^-} \xrightarrow[\text{base}]{\mathrm{TsN_3}} \mathrm{RN_3}$$

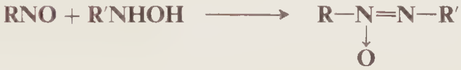
The treatment of the anion of a primary amine with tosyl azide produces the corresponding alkyl azide in low to moderate yields.[351] The reaction is analogous to the diazo transfer reaction (**2-9**) but takes place at a nitrogen rather than a carbon substrate. The conversion of amine anions to azides has also been effected with nitrous oxide N_2O.[352]

2-52 Conversion of Amines to Azo Compounds

$$\mathrm{ArNH_2 + Ar'NO} \xrightarrow{\mathrm{HOAc}} \mathrm{Ar{-}N{=}N{-}Ar'}$$

Aromatic nitroso compounds combine with primary arylamines in glacial acetic acid to give symmetrical or unsymmetrical azo compounds (the *Mills reaction*).[353] A wide variety of substituents may be present in both aryl groups. The mechanism under acidic or neutral conditions probably involves rate-determining attack of $ArNH_2$ on the nitroso compound.[354]

2-53 Conversion of Nitroso Compounds to Azoxy Compounds



$$\mathrm{RNO + R'NHOH} \longrightarrow \mathrm{R{-}\underset{\substack{\downarrow\\ O}}{N}{=}N{-}R'}$$

In a reaction similar to **2-52**, azoxy compounds can be prepared by the condensation of a nitroso compound with a hydroxylamine.[355] The position of the oxygen in the final product is determined by the nature of the R groups, and not by which R group came from which starting compound. Both R and R′ may be alkyl or aryl, but when two different aryl groups are involved, mixtures of azoxy compounds (ArNONAr, ArNONAr′, and Ar′NONAr′) are obtained,[356] and the unsymmetrical product (ArNONAr′) is likely to be formed in the smallest amount. This behavior is probably caused by an equilibration between the starting compounds prior to the actual reaction ($\mathrm{ArNO + Ar'NHOH \rightleftharpoons Ar'NO + ArNHOH}$).[357] The mechanism has been investigated in the presence of base. Under these conditions both reactants are converted to radical anions, which couple:

[353] For examples, see Faessinger and Brown, *J. Am. Chem. Soc.* **73,** 4606 (1950); Nutting, Jewell, and Rapoport, *J. Org. Chem.* **35,** 505 (1970). For a review, see Boyer, in Feuer, "The Chemistry of the Nitro and Nitroso Groups," pt. 1, pp. 278–283, Interscience Publishers, New York, 1969.

[354] Yunes, Terenzani, and do Amaral, *J. Am. Chem. Soc.* **97,** 368 (1975). For an investigation of the mechanism in basic solution, see Brown and Kipp, *J. Org. Chem.* **36,** 170 (1971).

[355] Boyer, Ref. 353.

[356] See for example, Ogata, Tsuchida, and Takagi, *J. Am. Chem. Soc.* **79,** 3397 (1957).

[357] Knight and Saville, *J. Chem. Soc., Perkin Trans. 2* 1550 (1973).

These radical anions have been detected by esr.[358] This mechanism is consistent with the following result: when nitrosobenzene and phenylhydroxylamine are coupled, ^{18}O and ^{15}N labeling show that the two nitrogens and the two oxygens become equivalent.[359] Unsymmetrical azoxy compounds can be prepared[360] by combination of a nitroso compound with an N,N-dichloroamine in the presence of CuCl or certain other promoters.

2-54 N-Halogenation

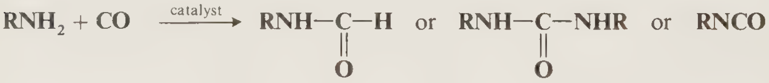
$$RNH_2 + NaOCl \longrightarrow RNHCl$$

Treatment with sodium hypochlorite or hypobromite converts primary amines into N-halo- or N,N-dihaloamines. Secondary amines may be converted to N-halo secondary amines. Similar reactions may be carried out on unsubstituted and N-substituted amides and on sulfonamides. With unsubstituted amides the N-halogen product is seldom isolated but usually rearranges (see reaction **8-17**); however, N-halo-N-alkyl amides and N-halo imides are quite stable. The important reagent N-bromosuccinimide is made in this manner. N-halogenation has also been accomplished with other reagents, for example, *t*-BuOCl.[361] Unsubstituted amides can be N-brominated or N,N-dibrominated by treatment with dibromoisocyanuric acid.[362] The mechanisms of these reactions involve attack by a positive halogen and are probably similar to those of reactions **2-48 and 2-50.**[363] N-Fluorination can be accomplished by direct treatment of amines[364] or amides[365] with F_2. Fluorination of N-alkyl-N-fluoro amides results in cleavage to N,N-difluoroamines.[366]

$$RNFCOR' \xrightarrow{F_2} RNF_2$$

OS **III,** 159; **IV,** 104, 157; **V,** 208, 663, 909.

2-55 The Reaction of Amines with Carbon Monoxide



$$RNH_2 + CO \xrightarrow{\text{catalyst}} RNH-\underset{\underset{O}{\|}}{C}-H \quad \text{or} \quad RNH-\underset{\underset{O}{\|}}{C}-NHR \quad \text{or} \quad RNCO$$

Three types of product can be obtained from the reaction of amines with carbon monoxide, depending on the catalyst. (1) Both primary and secondary amines react with CO in the presence of various catalysts [e.g., $Cu(CN)_2$, trimethylamine–hydrogen selenide, rhodium or ruthenium complexes] to give N-substituted and N,N-disubstituted formamides, respectively.[367] (2) Symmetrically substituted ureas can be prepared by treatment of a primary amine (or ammonia) with CO in the presence of selenium[368] or sulfur.[369] R may be alkyl or aryl. (3) When $PdCl_2$ is the catalyst, primary amines yield isocyanates.[370] Isocyanates can also be obtained by treatment of CO with azides: $RN_3 + CO \rightarrow RNCO$.[371] Thiocarbamates RNHCOSR′ are formed on treatment of primary aliphatic amines RNH_2 with CO and a disulfide R′SSR′ in the presence of selenium.[372]

Thirteen

Aromatic Nucleophilic Substitution

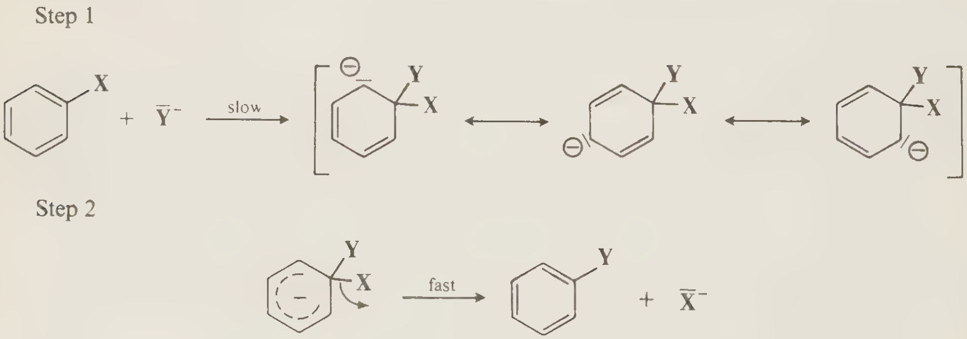
On p. 317 it was pointed out that nucleophilic substitutions proceed so slowly at an aromatic carbon that the reactions of Chapter 10 are not feasible for aromatic substrates. There are, however, exceptions to this statement, and it is these exceptions which form the subject of this chapter.[1] Reactions which *are* successful at an aromatic substrate are largely of three kinds: (1) reactions activated by electron-withdrawing groups ortho and para to the leaving group; (2) reactions catalyzed by very strong bases and proceeding through aryne intermediates; and (3) reactions in which the nitrogen of a diazonium salt is replaced by a nucleophile. However, not all the reactions discussed in this chapter fit into these categories.

MECHANISMS

Each of the three principal mechanisms is similar to one of the aliphatic nucleophilic substitution mechanisms discussed in Chapter 10.[2]

The SNAr Mechanism

By far the most important mechanism for nucleophilic aromatic substitution consists of two steps:



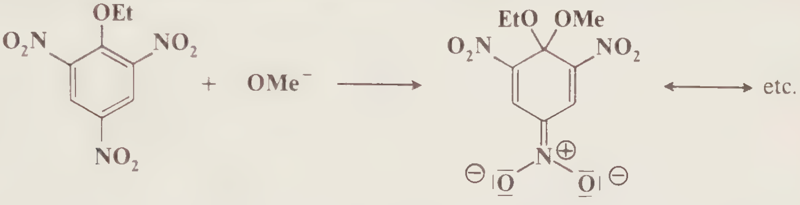
---

[1] For reviews of aromatic nucleophilic substitution, see Zoltewicz, *Top. Curr. Chem.* **59**, 33–64 (1975); Bunnett and Zahler, *Chem. Rev.* **49**, 273–412 (1951).

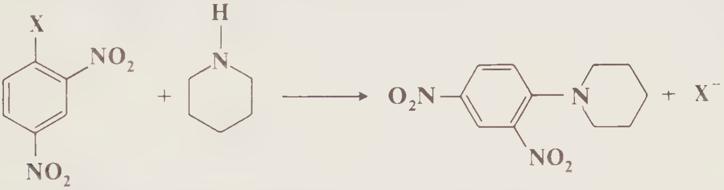
[2] For a monograph on aromatic-nucleophilic-substitution mechanisms, see Miller, "Aromatic Nucleophilic Substitution," American Elsevier Publishing Company, Inc., New York, 1968. For reviews, see Bunnett, *J. Chem. Educ.* **51**, 312–315 (1974), *Q. Rev., Chem. Soc.* **12**, 1–16 (1958); Bernasconi, *MTP Int. Rev. Sci.: Org. Chem. Ser. One*, **3** 33–63 (1973); Ross, in Bamford and Tipper, "Comprehensive Chemical Kinetics," vol. 13, pp. 407–431, American Elsevier Publishing Company, Inc., New York, 1972, *Prog. Phys. Org. Chem.* **1**, 31–74 (1963); Buck, *Angew. Chem. Int. Ed. Engl.* **8**, 120–131 (1969) [*Angew. Chem.* **81**, 136–148]; Buncel, Norris, and Russell, *Q. Rev., Chem. Soc.* **22**, 123–146 (1968); Sauer and Huisgen, *Angew. Chem.* **72**, 294–315 (1960); and Ref. 1.

The first step is usually, but not always, rate-determining. It can be seen that this mechanism greatly resembles the tetrahedral mechanism discussed in Chapter 10 (p. 308) and, in another way, the arenium-ion mechanism of electrophilic aromatic substitution (p. 453). In all three cases, the attacking species forms a bond with the substrate, giving an intermediate, and then the leaving group departs. This mechanism is sometimes called the SN2 mechanism because it is bimolecular, but in this book we reserve that name for nucleophilic substitutions in which attack and departure are simultaneous, so that there is no intermediate. We shall refer to this mechanism as the SNAr mechanism.[3]

There is a great deal of evidence for the mechanism, and we shall discuss only some of it.[2] Probably the most convincing evidence was the isolation, as long ago as 1902, of the intermediate **1** in the reaction between ethyl picrate and methoxide ion.[4] Intermediates of this type are stable salts, called *Meisenheimer salts*, and many more of them have been isolated since 1902.[5] The structures of several of these intermediates have been proved by nmr[6] and by x-ray crystallography.[7] Further evidence comes from studies of the effect of the leaving group on the reaction. If the mechanism were similar to either the SN1 or SN2 mechanisms described in Chapter 10, the Ar—X bond would be broken in the rate-determining step. In the SNAr mechanism this bond is not broken until after the rate-determining step (that is, if step 1 is rate-determining). We would predict from this that if the SNAr mechanism is operating, a change in leaving group should not have much effect on the rate of the reaction. In the reaction



1



when X was Cl, Br, I, SOPh, SO_2Ph, or *p*-nitrophenoxy, the rates differed only by a factor of about 5.[8] This behavior would not be expected in a reaction in which the Ar—X bond is broken in the rate-determining step. We do not expect the rates to be *identical*, because the nature of X affects the rate at which Y attacks. An increase in the electronegativity of X causes a decrease in the electron density around the substrate carbon, resulting in a faster attack by a nucleophile. Thus, in the reaction just mentioned, when X = F, the relative rate was 3300 (compared with I = 1). The very fact that fluoro is the best leaving group among the halogens in most aromatic nucleophilic substitutions is good evidence that the mechanism is different from the SN1 and the SN2 mechanisms, where fluoro is by far the poorest leaving group of the halogens. This is an example of the element effect (p. 312).

---

[3] The mechanism has also been called by other names, including the SN2Ar, the addition-elimination, and the intermediate complex mechanism.

2

The pattern of base catalysis of reactions with amine nucleophiles provides additional evidence. These reactions are catalyzed by bases only when a relatively poor leaving group (such as OR) is present (not Cl or Br) and only when relatively bulky amines are nucleophiles.[9] Bases could not catalyze step 1, but if amines are nucleophiles, bases can catalyze step 2. Base catalysis is found precisely in those cases where the amine moiety cleaves easily but X does not, so that k_{-1} is large and step 2 is rate-determining. This is evidence for the SNAr mechanism because it implies two steps. Furthermore, in cases where bases *are* catalysts, they catalyze only at low base concentrations: a plot of the rate against the base concentration shows that small increments of base rapidly increase the rate until a certain concentration of base is reached, after which further base addition no longer greatly affects the rate. This behavior, based on a partitioning effect (see p. 455), is also evidence for the SNAr mechanism. At low base concentration, each increment of base, by increasing the rate of step 2, increases the fraction of intermediate which goes to product rather than reverting to reactants. At high base concentration the process is virtually complete: there is very little reversion to reactants, and the rate becomes dependent on step 1. Just how bases catalyze step 2 has been investigated, and there is evidence that the mechanism for this process is as follows:[10]

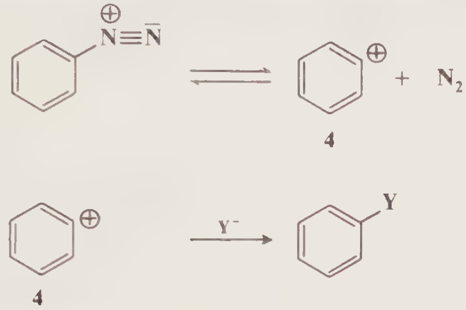
First, the base reversibly removes a proton from **2** to give its conjugate base **3** and BH$^+$. There follows rate-determining expulsion of X from **3** with general acid catalysis by BH$^+$. Further evidence for the SNAr mechanism has been obtained from $^{18}O/^{16}O$ and $^{15}N/^{14}N$ isotope effects.[11]

The SN1 Mechanism

For aryl halides, even active ones, a unimolecular SN1 mechanism has never been observed with certainty. It is with diazonium salts that this mechanism is important:[12]

Step 1

Step 2



4

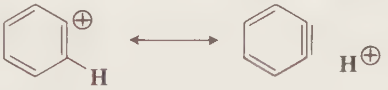
Among the evidence for the SN1 mechanism is the following:[13]

1. The reaction rate is first order in diazonium salt and independent of the concentration of Y.

2. When high concentrations of halide salts are added, the product is an aryl halide but the rate is independent of the concentration of the added salts.

3. The effects of ring substituents on the rate are consistent with a unimolecular rate-determining cleavage.[14]

4. When reactions were run with substrate deuterated in the ortho position, isotope effects of about 1.22 were obtained.[15] It is difficult to account for such high secondary isotope effects in any other way except that an incipient phenyl cation is stabilized by hyperconjugation, which is



reduced when hydrogen is replaced by deuterium.

5. That the first step is a reversible cleavage was demonstrated by the observation that when $Ar^{15}\overset{\oplus}{N}\equiv N$ was the reacting species, recovered starting material contained not only $Ar^{15}\overset{\oplus}{N}\equiv N$ but also $Ar\overset{\oplus}{N}\equiv {}^{15}N$.[16] This could arise only if the nitrogen breaks away from the ring and then returns. However, the rearrangement is very slow compared with the normal hydrolysis of the ArN_2^+.

[12] Aryl iodonium salts Ar_2I^+ also undergo substitutions by this mechanism (and by a free-radical mechanism).

[13] For discussions, see Swain, Sheats, and Harbison, *J. Am. Chem. Soc.* **97**, 783, 796 (1975); Burri, Wahl, and Zollinger, *Helv. Chim. Acta* **57**, 2099 (1974); Richey and Richey, in Olah and Schleyer, "Carbonium Ions," vol. 2, pp. 922–931, Interscience Publishers, New York, 1970; Zollinger, "Azo and Diazo Chemistry," pp. 138 142, Interscience Publishers, Inc., New York, 1961; Miller, Ref. 2, pp. 29–40.

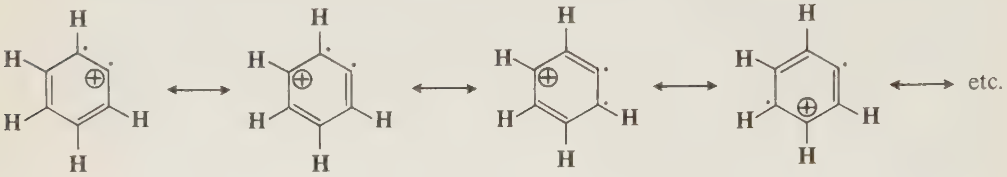
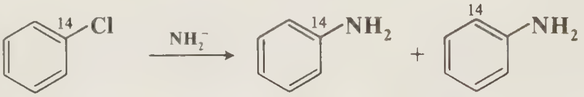
It is possible that the aryl cations formed in these reactions do not have the simple structure represented as **4**. The fact that esr spectra are obtained from these solutions indicates that the carbonium ion has unpaired electrons.[17] The simplest way to explain this is to assume that the ion has a diradical structure or that the diradical is in equilibrium with **4**.[18]



The Benzyne Mechanism[19]

Some aromatic nucleophilic substitutions are clearly different in character from those which occur by the SNAr mechanism (or the SN1 mechanism). These substitutions occur on aryl halides which have no activating groups; bases are required which are stronger than those normally used; and, most interesting of all, the incoming group does not always take the position vacated by the leaving group. That the latter statement is true was elegantly demonstrated by the reaction of 1-^{14}C-chlorobenzene with potassium amide:



The product consisted of almost equal amounts of aniline labeled in the 1 position and in the 2 position.[20]

A mechanism which can explain all these observations involves elimination followed by addition:

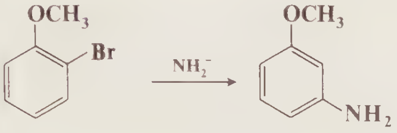
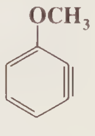
[20] Roberts, Semenow, Simmons, and Carlsmith, *J. Am. Chem. Soc.* **78**, 601 (1956).

The symmetrical intermediate **5** can be attacked by the nitrogen at either of two positions, explaining why about half of the aniline produced from the radioactive chlorobenzene was labeled at the 2 position. The fact that the 1 and 2 positions were not labeled equally is the result of a small isotope effect. Other evidence for this mechanism is the following:

1. If the aryl halide contains two ortho substituents, the reaction should not be able to occur. This is indeed the case.[20]

2. It had been known for many years before this mechanism was suggested that aromatic nucleophilic substitution occasionally results in substitution at a different position. This is called *cine substitution*[21] and can be illustrated by the conversion of *o*-bromoanisole to *m*-aminoanisole.[22] In this particular case, only the meta isomer is formed. The reason a 1 : 1 mixture is not formed is that the intermediate **6** is not symmetrical and the methoxy group directs the incoming group meta but not ortho (see p. 594). However, not all cine substitutions proceed by this kind of mechanism (see reaction **3-26**).[23]





6

3. The fact that the order of halide reactivity is $Br > I > Cl \gg F$ (when the reaction is performed with KNH_2 in liquid NH_3) shows that the SNAr mechanism is not operating here.[20]

In the conversion of the substrate to **6**, either proton removal or subsequent loss of halide ion may be rate-determining. In fact the unusual leaving-group order just mentioned ($Br > I > Cl$) stems from a change in the rate-determining step. When the leaving group is Br or I, proton removal is rate-determining and the rate order for this step is $F > Cl > Br > I$. When Cl or F is the leaving group, cleavage of the C—X bond is rate-determining and the order for this step is $I > Br > Cl > F$. Confirmation of the latter order was found in a direct competitive study. *meta*-Dihalobenzenes in which the two halogens are different were treated with NH_2^-.[24] In such compounds, the most acidic hydrogen is the one between the two halogens, and when it leaves, the anion which remains can lose either halogen. Therefore a study of which halogen is preferentially lost provides a direct measure of leaving-group ability. The order was found to be $I > Br > Cl$.[24]

Species such as **5** and **6** are called *benzynes* (sometimes *dehydrobenzenes*), or more generally *arynes*, and the mechanism is known as the *benzyne mechanism*. Benzynes differ from the species discussed in Chapter 5 in that each carbon has a valence of 4. However, they are very reactive, as are the species in that chapter. Neither benzyne nor any other aryne has yet been isolated under ordinary conditions, but stable benzyne has been isolated in an argon matrix at 8 K,[25] where its ir spectrum could be observed. In addition, spectra of transient benzynes have been detected,[26] and benzynes may be trapped; e.g., they undergo the Diels-Alder reaction (see reaction **5-51**). A stable solid complex of benzyne, π-benzyne diiodo-μ-carbonylnickel dimer (**7**)

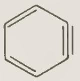
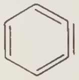
7

has been isolated.[27] That benzynes are highly reactive is indicated not only by the failure to isolate them (except in a matrix at 8 K) but also by their low selectivity. When bromobenzene is treated with amide ion in the presence of other nucleophiles, a considerable lack of selectivity is noted.[28] This reactivity is undoubtedly caused by the strain in a six-membered ring containing a triple bond. It should be noted that the extra pair of electrons does not affect the aromaticity. The original sextet still functions as a closed ring, and the two additional electrons are merely located in a π orbital which covers only two carbons. Benzynes do not have a formal triple bond, since two canonical forms (**A** and **B**) contribute to the hybrid. The infrared spectrum,



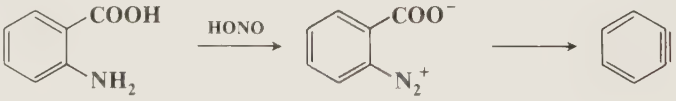
A



B

mentioned above, indicates that **A** contributes more than **B**. Not only benzene rings but other aromatic rings[29] and even nonaromatic rings (p. 314) can react through this kind of intermediate. Of course the nonaromatic rings do have a formal triple bond.

There are other ways to prepare benzyne intermediates.[30] Probably the most convenient method involves thermal or photolytic decomposition of the product of diazotization of anthranilic acid or its derivatives:[31]



8

The zwitterion (**8**) decomposes to give the highly reactive benzyne.

Other Mechanisms

There is no clear-cut proof that a one-step SN2 mechanism, so important at a saturated carbon, ever actually occurs with an aromatic substrate. Such a mechanism has been suggested[32] in cases where fluoro is a very poor leaving group, since this would be consistent with an SN2 process, but not with the SNAr mechanism as shown on p. 584. On the other hand, an SNAr mechanism in which the *second* step is rate-determining would be quite compatible with reactions in which fluoro is a poor leaving group, and some of them have been shown to operate by such a process.[33] The hypothetical aromatic SN2 process is sometimes called the *one-stage* mechanism to distinguish it from the *two-stage* SNAr mechanism.

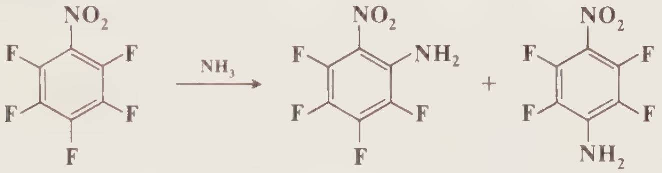
Some of the reactions in this chapter operate by still other mechanisms, among them an addition-elimination mechanism (see reaction **3-17**).

REACTIVITY

The Effect of Substrate Structure

In the discussion of electrophilic aromatic substitution (Chapter 11) equal attention was paid to the effect of substrate structure on reactivity (activation or deactivation) and on orientation. The question of orientation was important because in a typical substitution there are four or five hydrogens which could serve as leaving groups. This type of question is much less important for aromatic nucleophilic substitution, since in most cases there is only one potential leaving group in a molecule. Therefore attention is largely focused on the reactivity of one molecule compared with another and not on the comparison of the reactivity of different positions within the same molecule. However, there *have* been studies of the latter question.[34] For example, the nitro group has been shown to be ortho-para-directing by the observation that pentafluoronitrobenzene gave 95% of a mixture of 2-nitro-3,4,5,6-tetrafluoroaniline and 4-nitro-2,3,5,6-tetrafluoroaniline when treated with ammonia:[35]



Similarly, it was shown (for C_6F_5X) that the groups H, Me, CF_3, Cl, Br, I, SMe, and NMe_2 are mostly para-directing and NH_2 and O^- are largely meta-directing.[36]

Aromatic nucleophilic substitutions proceeding by the SNAr mechanism are accelerated by electron-withdrawing groups, especially in positions ortho and para to the leaving group, and are hindered by electron-attracting groups. This is, of course, opposite to the effects of these groups on electrophilic substitutions, and the reasons are similar to those discussed in Chapter 11 (p. 459). Table 1 contains a list of groups arranged approximately in order of activating or deactivating ability. Hetero nitrogen atoms are also strongly activating (especially to the α and γ positions)

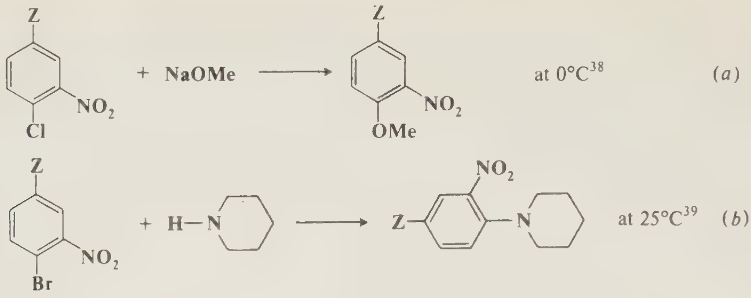
TABLE 1 Groups listed in approximate descending order of activating ability in the SNAr mechanism[37]



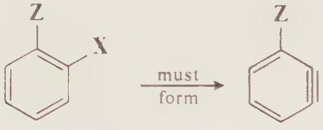
For reaction (a) the rates are relative to **H**, *but for reaction (b) they are relative to* **NH_2**

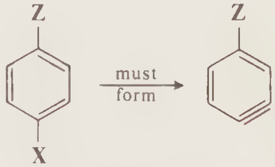
		Relative rate of reaction	
	Group Z	(*a*) **H** = 1[38]	(*b*) **NH_2** = 1[39]
Activates halide exchange at room temperature	**N_2^+**		
Activates reaction with strong nucleophiles at room temperature	$\overset{+}{\text{N}}$—R (heterocyclic)		
Activate reactions with strong nucleophiles at 80–100°C	**NO**	5.22×10^6	
	NO_2	6.73×10^5	Very fast
	N (heterocyclic)		
With nitro also present, activate reactions with strong nucleophiles at room temperature	**SO_2Me**		
	NMe_3^+		
	CF_3		
	CN	3.81×10^4	
	CHO	2.02×10^4	
With nitro also present, activate reactions with strong nucleophiles at 40–60°C	**COR**		
	COOH		
	SO_3^-		
	Br		6.31×10^4
	Cl		4.50×10^4
	I		4.36×10^4
	COO^-		2.02×10^4
	H	1	8.06×10^3
	F		2.10×10^3
	CMe_3		1.37×10^3
	Me		1.17×10^3
	OMe		145
	NMe_2		9.77
	OH		4.70
	NH_2		1

The comments on the left are from Bunnett and Zahler, Ref. 1, p. 308.

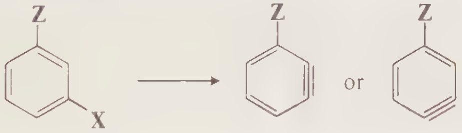
and are even more so when quaternized.[40] Thus 2- and 4-chloropyridine, for example, are often used as substrates. Heterocyclic N-oxides are readily attacked by nucleophiles in the 2 and 4 positions, but the oxygen is generally lost in these reactions.[41] The N_2^+ group is seldom deliberately used to activate a reaction, but it sometimes happens that in the diazotization of a compound such as *p*-nitroaniline or *p*-chloroaniline the group para to the diazonium group is replaced by OH from the solvent or by X from $ArN_2^+\ \ X^-$, to the surprise and chagrin of the investigator, who was trying only to replace the diazonium group and to leave the para group untouched.[42] By far the most common activating group is the nitro group, and the most common substrates are 2,4-dinitrophenyl halides and 2,4,6-trinitrophenyl halides (also called picryl halides).[43] Polyfluorobenzenes, e.g., C_6F_6, also undergo aromatic nucleophilic substitution quite well.[44] Benzene rings which lack activating substituents are generally not useful substrates for the SNAr mechanism.[45]

In reactions involving aryne intermediates, two factors affect the position of the incoming group, the first being the direction in which the benzyne forms.[46] When there are groups ortho or para to the leaving group, there is no choice:





but when a meta group is present, the benzyne may form in two different ways:



In such cases, the more acidic hydrogen is removed. Since acidity is related to the field effect of Z, it can be stated that an electron-attracting Z favors removal of the ortho hydrogen while an electron-donating Z favors removal of the para hydrogen. The second factor is that the benzyne, once formed, may be attacked at two positions. The favored position for nucleophilic attack is the one which leads to the more stable carbanion intermediate, and this in turn also depends on the field effect of Z. For $-I$ groups, the more stable carbanion is the one in which the negative

[42] In some cases this can be turned to good effect: the replacement of a *p*-fluoro substituent has been used to detect the presence of the N_2^+ group (or other group which causes the fluorine to be labile) during the course of a reaction: Suschitzky, *Angew. Chem. Int. Ed. Engl.* **6,** 596–607 (1967) [*Angew. Chem.* **79,** 636–648].

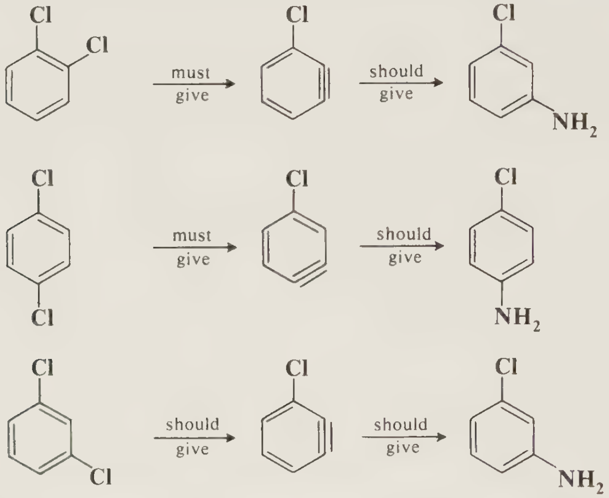
[43] For a review of the activating effect of nitro groups, see de Boer and Dirkx, in Feuer, Ref. 5, pt. 1, pp. 487–612.

[44] For a review, see Kobrina, *Fluorine Chem. Rev.* **7,** 1–114 (1974).

[45] It has been shown that such substrates can react by this mechanism but extremely slowly: Liotta and Pinholster, *Chem. Commun.* 1245 (1969).

[46] This analysis is from Roberts, Vaughan, Carlsmith, and Semenow, *J. Am. Chem. Soc.* **78,** 611 (1956). For a discussion, see Hoffmann, "Dehydrobenzene and Cycloalkynes," Ref. 19, pp. 134–150.

charge is closer to the substituent. These principles are illustrated by the reaction of the three dichlorobenzenes with alkali-metal amides. The predicted products are



In each case the predicted product was the one chiefly formed,[47] though the para isomer also gave 19% *m*-chloroaniline.[48] The obtention of *m*-methoxyaniline, mentioned on p. 589, is also in accord with these predictions.

Just as electrophilic aromatic substitutions were found more or less to follow the Hammett relationship (with σ^+ instead of σ; see p. 470), so do nucleophilic substitutions follow it, with σ^- instead of σ for electron-withdrawing groups.[49]

As pointed out on p. 467, the position of attack at alternant hydrocarbons is the same for electrophiles, nucleophiles, and free radicals.

The Effect of the Leaving Group[50]

The common leaving groups in aliphatic nucleophilic substitution (halide, sulfate, sulfonate, NR_3^+, etc.) are also common leaving groups in aromatic nucleophilic substitutions, but the groups NO_2, OR, OAr, SO_2R, and SR, which are not generally lost in aliphatic systems,[51] *are* leaving groups when attached to aromatic rings. Surprisingly, NO_2 is a particularly good leaving group.[52] An approximate order of leaving-group ability is[53] $F > NO_2 > OTs > SOPh > Cl, Br, I > N_3 > NR_3^+ > OAr, OR, SR, SO_2R, NH_2$. However, this depends greatly on the nature of the nucleophile, as illustrated by the fact that $C_6Cl_5OCH_3$ treated with NH_2^- gives mostly $C_6Cl_5NH_2$; i.e., one methoxy group is replaced in preference to five chlorines.[54] As usual, OH can be a leaving group if it is converted to an inorganic ester. Among the halogens, fluoro is generally a much better leaving group than the other halogens, which have reactivities fairly close together. The order is usually Cl > Br > I, but not always.[55] The leaving-group order is quite different from that for the SN1 or SN2 mechanisms. The most likely explanation is that the first step of the SNAr mechanism is usually rate-determining, and this step is promoted by groups with strong $-I$ effects. This would explain why fluoro and nitro are such good leaving groups when this mechanism is operating. An alternate explanation has been proposed for the leaving ability of fluorine. According to this, fluorine, the only one of the halogens which can form hydrogen bonds, does form such a bond with the nucleophile.[56] Of course, this can be possible only when the nucleophile contains a hydrogen. Fluoro is the poorest leaving group of the halogens when the second step of the SNAr mechanism is rate-determining (p. 591) or when the benzyne mechanism is operating. Of course, the only important leaving group in the SN1 mechanism is N_2^+.

The Effect of the Attacking Nucleophile[57]

It is not possible to construct a nucleophilicity order which is invariant, since different substrates and different conditions lead to different orders of nucleophilicity, but an overall approximate order is $NH_2^- > Ph_3C^- > PhNH^-$ (aryne mechanism) $> ArS^- > RO^- > R_2NH > ArO^- > OH^- > ArNH_2 > NH_3 > I^- > Br^- > Cl^- > H_2O > ROH$.[58] As with aliphatic nucleophilic substitution, nucleophilicity is generally dependent on base strength, and nucleophilicity increases as the attacking atom moves down a column of the periodic table, but there are some surprising exceptions; e.g., OH^-, a stronger base than ArO^-, is a poorer nucleophile. In a series of similar nucleophiles, such as substituted anilines,[59] nucleophilicity *is* correlated with base strength. Oddly, the cyanide ion is not a nucleophile for aromatic systems, except for sulfonic acid salts (reaction **3-12**) and in the von Richter (**3-26**) and Rosenmund–von Braun (**3-11**) reactions, which are special cases.

REACTIONS

In the first part of this section, reactions are classified according to attacking species, with all leaving groups considered together, except for hydrogen and N_2^+, which are treated subsequently. Finally, a few rearrangement reactions are discussed.

All Leaving Groups except Hydrogen and N_2^+

3-1 Replacement by OH

$$\mathbf{ArBr + OH^- \longrightarrow ArOH}$$

Aryl halides can be converted to phenols only if activating groups are present or if exceedingly strenuous conditions are employed.[60] Other leaving groups, including nitro,[61] azide, NR_3^+, etc., can also be replaced by OH groups. When the reaction is carried out at high temperatures, as in the commercial process for the preparation of phenol from chlorobenzene, cine substitution is observed, indicating a benzyne mechanism.[62] Phenols have been obtained from unactivated aryl halides by treatment with borane and a metal such as lithium, followed by oxidation with alkaline H_2O_2.[63] Nitro and OR groups can also be replaced by OH groups in photochemical reactions.[64] In some of these photochemical processes, electron-withdrawing (at least in the ground state) substituents activate the meta more than the ortho or para positions.

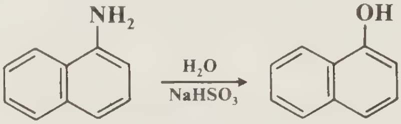
3-2 Replacement of an Amino Group by a Hydroxyl Group



The amino group of naphthylamines can be replaced by a hydroxyl group by treatment with aqueous bisulfite.[65] The scope is greatly limited: the amino group (which may be NH_2 or NHR) must be on a naphthalene ring, with very few exceptions. The reaction is reversible (see reaction **3-7**), and both the forward and reverse reactions are called the *Bucherer reaction.* The mechanism is completely different from any outlined in the first section of this chapter and is discussed at reaction **3-7.**

3-3 Alkali Fusion of Sulfonate Salts

$$ArSO_3^- \xrightarrow[300\text{–}320°C]{NaOH\ fus.} ArO^-$$

Aryl sulfonic acids can be converted, through their salts, to phenols, by alkali fusion. In spite of the extreme conditions, the reaction gives fairly good yields, except when the substrate contains other groups which are attacked by alkali at the fusion temperatures. Milder conditions may be used when the substrate contains activating groups, but the presence of deactivating groups hinders the reaction. The mechanism is obscure, but a benzyne intermediate has been ruled out by the finding that cine substitution does not occur.[66]

OS **I**, 175; **III**, 288.

3-4 Replacement by OR or OAr

$$ArBr + OR^- \longrightarrow ArOR$$

This reaction is similar to reaction **3-1** and, like that one, generally requires activated substrates.[60] With unactivated substrates, side reactions predominate, though aryl methyl ethers have been prepared from unactivated chlorides by treatment with MeO^- in HMPT.[66a] This reaction gives better yields than reaction **3-1** and is used more often. In addition to halides, leaving groups may be nitro, NR_3^+, other OR, etc., even OH.[67] The substrates Ar_2Br^+ are converted to ArOR in very high yields.[68] Acid salts, $RCOO^-$, are sometimes used as nucleophiles. Good yields of aryl benzoates can be obtained by the treatment of aryl halides with cuprous benzoate in diglyme or xylene at 140 to 160°C.[69]

---

[62] The benzyne mechanism for this reaction is also supported by ^{14}C labeling experiments: Bottini and Roberts, *J. Am. Chem. Soc.* **79,** 1458 (1957); Dalman and Neumann, *J. Am. Chem. Soc.* **90,** 1601 (1968).

[66a] Shaw, Kunerth, and Swanson, *J. Org. Chem.* **41,** 732 (1976).

For aroxide nucleophiles, the reaction is promoted by copper salts, and when these are used, activating groups need not be present. This method of preparation of diaryl ethers is called the *Ullmann ether synthesis*[69a] and should not be confused with the more important Ullmann coupling reaction (**3-16**). The reactivity order is typical of nucleophilic substitutions, despite the presence of the copper salts.[70] The Ullmann ether synthesis is best performed in pyridine or in certain other solvents containing hetero atoms.[71] Because aryloxycopper(I) reagents ArOCu react with aryl halides to give ethers, it has been suggested that they are intermediates in the Ullmann ether synthesis.[72] Indeed, high yields of ethers can be obtained by reaction of ROCu or ArOCu with aryl halides.[73]

OS **I,** 219; **II,** 445; **III,** 293, 566; **V,** 926; **51,** 82.

B. Sulfur Nucleophiles

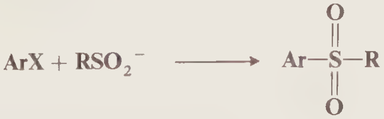
3-5 Replacement by SH or SR

$$\mathbf{ArBr + SH^- \longrightarrow ArSH}$$
$$\mathbf{ArBr + SR^- \longrightarrow ArSR}$$

Aryl thiols and thioethers can be prepared in reactions similar to **3-1** and **3-4**.[74] Activated aryl halides generally give good results, but side reactions are occasionally important. Diaryl sulfides can be prepared by the use of SAr^-. Sulfide salts, e.g., Na_2S, can also be used to prepare mercaptans, though yields are not high. Even unactivated aryl halides react with SAr^- if polar aprotic solvents, e.g., dimethylformamide[75] or dimethyl sulfoxide,[76] are used, though the mechanism is still nucleophilic substitution. Diaryl sulfides can also be prepared (in high yields) by treatment of unactivated aryl iodides with ArS^- in liquid ammonia under irradiation.[77] The mechanism in this case is probably SRN1 (see p. 599).

Other sulfur nucleophiles also react with activated aryl halides:

$$\mathbf{2ArX + S_2^{2-} \longrightarrow Ar{-}S{-}S{-}Ar}$$
$$\mathbf{ArX + SO_3^{2-} \longrightarrow Ar{-}SO_3^-}$$
$$\mathbf{ArX + SCN^- \longrightarrow ArSCN}$$



$$\mathbf{ArX + RSO_2^- \longrightarrow Ar{-}\overset{\overset{\textstyle O}{\|}}{\underset{\underset{\textstyle O}{\|}}{S}}{-}R}$$

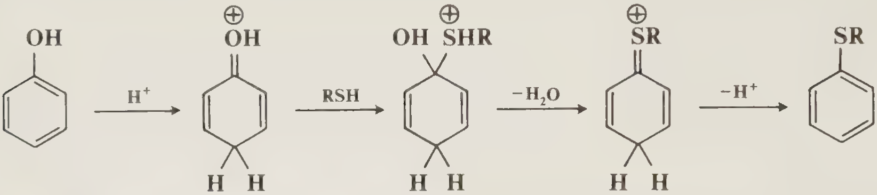
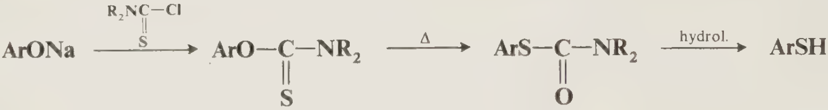
Hydroxyl groups can be replaced by SR groups in acid solution.[78] In this case the mechanism bears certain resemblances to that of the Bucherer reaction (**3-7**):



As with the Bucherer reaction, yields are highest with naphthols (50 to 60%), though in this case phenols also give the reaction (20 to 40% yields). Phenols can be converted to thiophenols by treatment of their salts with N,N-dimethylthiocarbamoyl chloride, pyrolysis of the resulting O-aryl dialkylthiocarbamate to the S-aryl dialkylthiocarbamate, and hydrolysis of this compound:[79]



$$\mathrm{ArONa} \xrightarrow{\mathrm{R_2N}\underset{\underset{\displaystyle \mathrm{S}}{\|}}{\mathrm{C}}\mathrm{-Cl}} \mathrm{ArO}-\underset{\underset{\displaystyle \mathrm{S}}{\|}}{\mathrm{C}}-\mathrm{NR_2} \xrightarrow{\Delta} \mathrm{ArS}-\underset{\underset{\displaystyle \mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{NR_2} \xrightarrow{\text{hydrol.}} \mathrm{ArSH}$$

C. Nitrogen Nucleophiles

3-6 Replacement by NH_2, NHR, or NR_2

$$\mathrm{ArBr} + \mathrm{NH_3} \longrightarrow \mathrm{ArNH_2}$$
$$\mathrm{ArBr} + \mathrm{RNH_2} \longrightarrow \mathrm{ArNHR}$$
$$\mathrm{ArBr} + \mathrm{R_2NH} \longrightarrow \mathrm{ArNR_2}$$

Activated aryl halides react quite well with ammonia and with primary and secondary amines to give the corresponding arylamines. Primary and secondary amines usually give better results than ammonia, with piperidine being especially reactive. Picryl chloride (2,4,6-trinitrochlorobenzene) is often used to form amine derivatives. 2,4-Dinitrofluorobenzene is used to tag the amino end of a peptide or protein chain. Other leaving groups in this reaction may be NO_2, N_3, OSO_2R, OR, and SR.

Nonactivated aryl halides can be converted to amines by the use of $NaNH_2$, NaNHR,[80] or $NaNR_2$.[81] With these reagents, the benzyne mechanism operates, and so cine substitution is often found. Ring closure has been effected by this type of reaction,[82] e.g.,

[80] See Biehl, Smith, and Reeves, *J. Org. Chem.* **36,** 1841 (1971).

[81] For a review, see Heaney, *Chem. Rev.* **62,** 81–97 (1962), pp. 83–89.

[82] Huisgen, König, and Lepley, *Chem. Ber.* **93,** 1496 (1960); Bunnett and Hrutfiord, *J. Am. Chem. Soc.* **83,** 1691 (1961). For a review of ring closures by the benzyne mechanism, see Hoffmann, "Dehydrobenzene and Cycloalkynes," Ref. 19, pp. 150–164.

It has proved possible to close larger rings too in this manner: eight- and even twelve-membered. Triarylamines have been prepared in a similar manner, from ArI and Ar'_2NLi, even with unactivated ArI.[83] Sulfonic acid salts can be fused with alkali-metal amides to give aromatic amines, a process similar to reaction **3-3.** With some substrates, the SNAr and benzyne mechanisms can run concurrently.[84]

The reaction with ammonia or amines, which undoubtedly proceeds by the SNAr mechanism, is catalyzed by copper and nickel[84a] salts, though these are normally used only with rather unreactive halides. The manner of catalysis is poorly understood.[85] Copper-ion catalysts (especially cuprous iodide) also permit the Gabriel synthesis (reaction **0-60**) to be applied to aromatic substrates. Aryl bromides or iodides are refluxed with potassium phthalimide and CuI in dimethylacetamide to give N-aryl phthalimides, which can be hydrolyzed to primary aryl amines.[86]

In certain reactions in which a benzyne mechanism would seem obvious, an analysis of the products has shown that another mechanism must intervene. For example, 5- and 6-iodo-1,2,4-trimethylbenzenes, treated with KNH_2 in NH_3, each gave a different ratio of 5- and 6-amino-1,2,4-trimethylbenzenes, though if a benzyne mechanism were the only one operating, the same benzyne intermediate (and consequently the same product ratio) should be present in both cases.[87] It has been proposed[87] that besides the benzyne mechanism, a free-radical mechanism (called SRN1) is also operating in these cases:

$$\mathbf{ArI} \xrightarrow[\text{donor}]{\text{electron}} [\mathbf{ArI}]\cdot^- \longrightarrow \mathbf{Ar}\cdot + \mathbf{I}^-$$

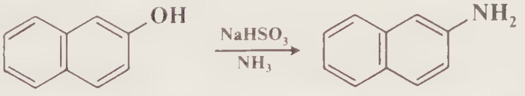
$$\mathbf{Ar}\cdot + \mathbf{NH_2} \longrightarrow \mathbf{ArNH_2}\cdot^- + \mathbf{ArI} \longrightarrow \mathbf{ArNH_2} + \mathbf{ArI}\cdot^-$$

Termination steps

The identity of the electron donor is not known, though if a known electron donor is added, e.g., K, the extent of the free-radical pathway is increased. For other examples of the SRN1 mechanism, see reactions **3-5, 3-7,** and **3-14.**[88]

OS **I,** 544; **II,** 15, 221, 228; **III,** 53, 307, 573; **IV,** 336, 364; **V,** 816, 1067.

3-7 Replacement of a Hydroxy Group by an Amino Group



The reaction of naphthols with ammonia and sodium bisulfite is the reverse of reaction **3-2** and has a similar scope.[65] It is also called the *Bucherer reaction.* Primary amines may be used instead of ammonia, in which case N-substituted naphthylamines are obtained. In addition, primary naphthylamines can be converted to secondary, by a transamination reaction:

$$\mathbf{ArNH_2} + \mathbf{RNH_2} \xrightarrow{\mathrm{NaHSO_3}} \mathbf{ArNHR}$$

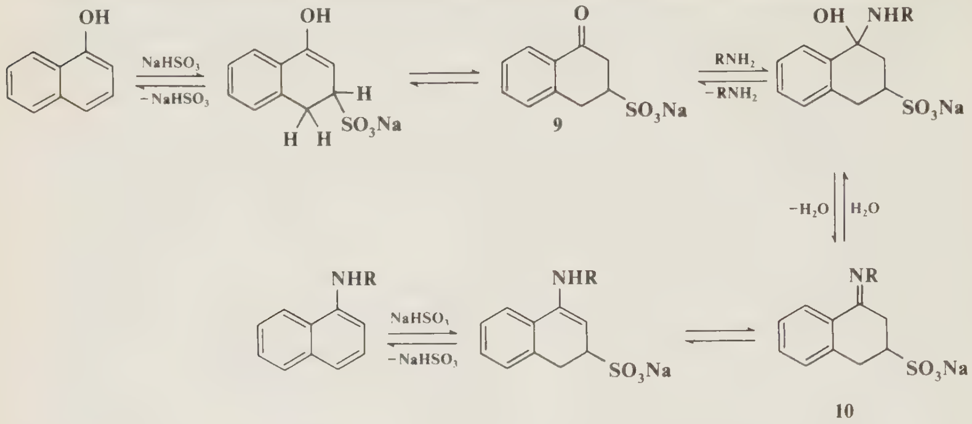
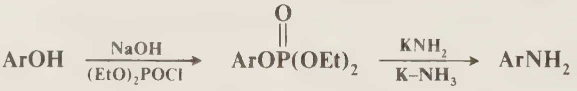
[88] For other examples, see Wolfe, Greene, and Hudlicky, *J. Org. Chem.* **37,** 3199 (1972).

The mechanism of the Bucherer reaction amounts to a kind of overall addition-elimination:[89]



The first step in either direction consists of addition of $NaHSO_3$ to one of the double bonds of the ring, giving an enol (or enamine), which tautomerizes to the keto (or imine) form. The conversion of **9** to **10** (or vice versa) is an example of reaction **6-15** (or **6-2**). Evidence for this mechanism was the isolation of **9**[90] and the demonstration that, for β-naphthol treated with ammonia and HSO_3^-, the rate of the reaction depends only on the substrate and on HSO_3^-, indicating that ammonia is not involved in the rate-determining step.[91] If the starting compound is a β-naphthol, the intermediate is a 2-keto-4-sulfonic acid compound, so that the sulfur of the bisulfite in either case attacks meta to the OH or NH_2.[92]

Hydroxy groups on benzene rings can be replaced by NH_2 groups if they are first converted to aryl diethyl phosphates. Treatment of these with KNH_2 and potassium metal in liquid ammonia



$$\mathrm{ArOH} \xrightarrow[(\mathrm{EtO})_2\mathrm{POCl}]{\mathrm{NaOH}} \mathrm{ArO}\overset{\overset{\displaystyle \mathrm{O}}{\|}}{\mathrm{P}}(\mathrm{OEt})_2 \xrightarrow[\mathrm{K\text{–}NH_3}]{\mathrm{KNH_2}} \mathrm{ArNH_2}$$

gives the corresponding primary aromatic amines.[93] The mechanism of the second step is SRN1 (see reaction **3-6**). Phenols can also be converted to amines by conversion to 4-aryloxy-2-phenylquinazolines; conversion of these (by heat) to 3-aryl-2-phenyl-4(3*H*)-quinazolinones; and hydrolysis of the latter.[94]

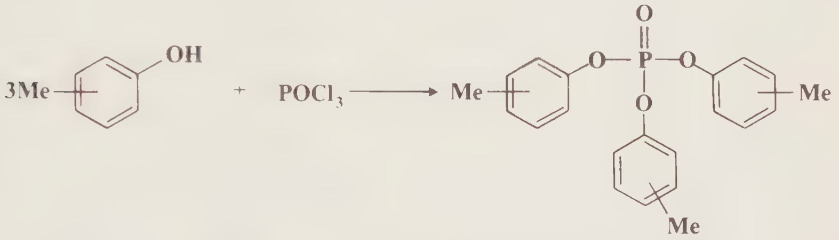
D. Halogen Nucleophiles

3-8 The Introduction of Halogens

$$\mathrm{Ar{-}X + X'^- \longrightarrow Ar{-}X' + X^-}$$

It is possible to replace a halogen on a ring by another halogen if the ring is activated. There is an equilibrium, but it is usually possible to shift this in the desired direction by the use of an excess of added halide ion.[95] Another common leaving group is nitro, which can be replaced with chloro by use of NH_4Cl, PCl_5, $SOCl_2$, HCl, Cl_2, or CCl_4. Some of these reagents operate only at high temperatures, and the mechanism is not always nucleophilic substitution. A phenolic hydroxy group can be replaced by chloro with PCl_5 or $POCl_3$, but only if activated. Unactivated phenols give phosphates when treated with $POCl_3$. An example is formation of tricresyl phosphate (TCP):



Phenols, even unactivated ones, can be converted to aryl bromides by treatment with Ph_3PBr_2[96] (see reaction **0-67**). However, when an ortho *t*-butyl group is present, this group may be cleaved.[97]

Halide exchange is particularly useful for putting fluorine into a ring, since there are fewer alternate ways of doing this than for the other halogens.[98] Activated aryl chlorides give fluorides when treated with KF in dimethylformamide, dimethyl sulfoxide, or dimethyl sulfone.[99] All six chlorines of hexachlorobenzene can be replaced by F by heating with KF at 450 to 500°C in the absence of a solvent.[100] Halide exchange can also be accomplished with copper halides. Since the leaving-group order in this case is $I > Br > Cl \gg F$, the SNAr mechanism is probably not operating.[101]

An indirect method for the replacement of OH or SH by F has been developed by Christie and Pavlath.[102] The method consists in the treatment of a phenol or thiophenol (or their salts) with COFCl to give a fluoroformate (or fluorothioformate), which is pyrolyzed to the product

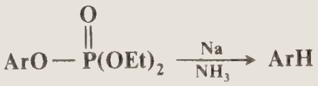
E. Hydrogen as Nucleophile

3-9 Reduction of Phenols and Phenolic Esters and Ethers

$$\mathrm{ArOH} \xrightarrow{\mathrm{Zn}} \mathrm{ArH}$$

Phenols can be reduced by distillation over zinc dust or with HI and red phosphorus, but these methods are quite poor and are seldom feasible. Catalytic hydrogenation has also been used, but the corresponding cyclohexanol (see reaction **5-13**) is a side product.[103]

Much better results have been obtained by conversion of phenols to certain esters or ethers, and reduction of the latter:



$$\mathrm{ArO{-}\overset{O}{\overset{\|}{P}}(OEt)_2} \xrightarrow[\mathrm{NH_3}]{\mathrm{Na}} \mathrm{ArH}$$

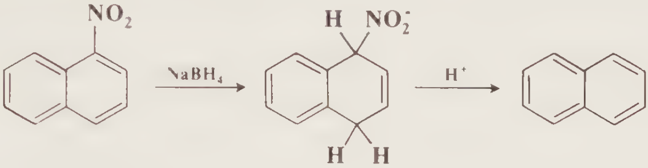
11 are prepared by treatment of phenols with 2,4-dinitrofluorobenzene (reaction **3-4**) and reduction of the dinitro product. **12** are prepared by treatment of phenols with 1-phenyl-5-chlorotetrazole in acetone containing K_2CO_3. See also reaction **1-46.**

OS **51,** 82.

3-10 Reduction of Halides and Nitro Compounds

The reaction ArX → ArH is treated in Chapter 11 (reaction **1-48**) though, depending on reagent and conditions, it may be nucleophilic[109] or free-radical[110] substitution, as well as electrophilic.

The nitro group of aromatic nitro compounds has been removed with sodium borohydride.[111] This reaction involves an addition-elimination mechanism, in which the addition is 1,4:



F. Carbon Nucleophiles

3-11 Replacement of Halides by Cyanide. The Rosenmund—von Braun reaction

$$ArBr + \text{anhyd. } CuCN \xrightarrow{200\text{ C}} ArCN$$

The reaction between aryl halides and cuprous cyanide is called the *Rosenmund–von Braun reaction.*[112] The mechanism may involve conversion of the aryl halide to an arylcopper intermediate.[69] Other cyanides, e.g., KCN and NaCN, do not react with aryl halides, even activated ones. However, KCN does convert aryl halides to nitriles in dimethylformamide in the presence of Pd(II) salts.[113] Also, in aprotic solvents (e.g., $CHCl_3$, dimethylformamide), CN^- reacts with 1,3-dinitrobenzene or 1,3,5-trinitrobenzene (at the 2 or 4 positions) to form Meisenheimer salts.[114] Aromatic ethers have been photochemically converted to nitriles (ArOR → ArCN) by irradiation of a mixture of the ether and sodium cyanide.[115] A similar photochemical process has been reported for some aromatic nitro compounds ($ArNO_2$ → ArCN).[116]

OS **III,** 212, 631.

3-12 Cyanide Fusion of Sulfonate Salts[117]

$$\mathrm{ArSO_3^-} \xrightarrow{\text{NaCN fus.}} \mathrm{ArCN}$$

This reaction is very similar to reaction **3-3.** Yields are usually low.

3-13 Coupling of Organometallic Compounds with Aryl Halides and Ethers

$$\mathrm{ArI + R_2CuLi} \longrightarrow \mathrm{ArR}$$

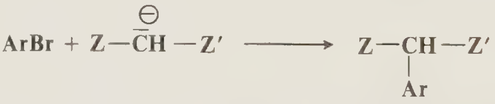
Aryl iodides, which need not be activated, couple with lithium dialkylcopper reagents. The reaction is discussed at reaction **0-87.** Aryl halides, even when activated, generally do not couple with Grignard reagents. The reaction proceeds better when OR can be the leaving group, providing that activating groups are present in the ring. Chloro-substituted nitrogen heterocycles can be alkylated indirectly by treatment with phosphorus ylides and subsequent hydrolysis:[118]

$$\mathrm{ArCl + RCH{=}PR'_3} \longrightarrow \mathrm{Ar{-}CR{=}PR'_3} \xrightarrow{\mathrm{OH^-}} \mathrm{ArCH_2R}$$

Unactivated aryl halides couple with alkyllithium reagents in tetrahydrofuran to give moderate to good yields of alkyl arenes.[119]

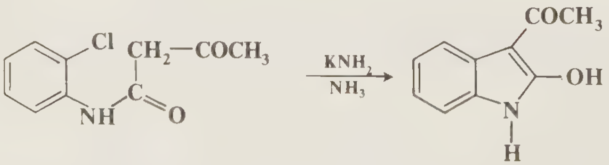
OS **52,** 128.

3-14 Arylation at a Carbon Containing an Active Hydrogen



$$\mathrm{ArBr} + \mathrm{Z{-}}\overset{\ominus}{\underline{\mathrm{C}}}\mathrm{H{-}Z'} \longrightarrow \mathrm{Z{-}}\underset{\substack{|\\ \mathrm{Ar}}}{\mathrm{CH}}\mathrm{{-}Z'}$$

The arylation of compounds of the form $\mathrm{ZCH_2Z'}$ is analogous to reaction **0-96,** and Z is as defined there. Activated aryl halides generally give good results. Even unactivated aryl halides can be employed if the reaction is carried out in the presence of excess sodium amide.[120] Compounds of the form $\mathrm{ZCH_2Z'}$ and even simple ketones[121] and esters have been arylated in this manner. The reaction with unactivated halides proceeds by the benzyne mechanism and represents a method for extending the malonic ester (and similar) syntheses to aromatic compounds. The base performs two functions: it removes a proton from $\mathrm{ZCH_2Z'}$ and catalyzes the benzyne mechanism. The reaction has been used for ring closure:[122]



---

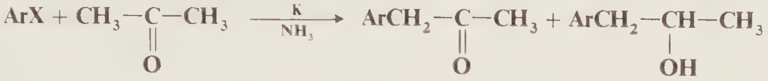
[119] Merrill and Negishi, *J. Org. Chem.* **39,** 3452 (1974).

[120] Leake and Levine, *J. Am. Chem. Soc.* **81,** 1169, 1627 (1959).

[121] For example, see Caubere and Guillaumet, *Bull. Soc. Chim. Fr.* 4643, 4649 (1972).

[122] Bunnett and Hrutfiord, *J. Am. Chem. Soc.* **83,** 1691 (1961); Bunnett, Kato, Flynn, and Skorcz, *J. Org. Chem.* **28,** 1 (1963). For a review, see Hoffmann, Ref. 82, pp. 150–164.

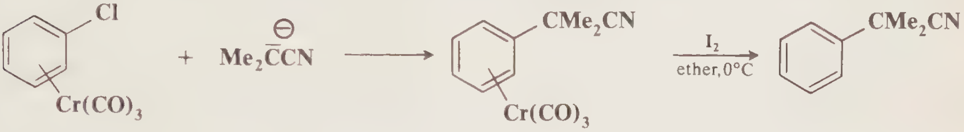
Compounds of the form CH_3Z can be arylated by treatment with an aryl halide in liquid ammonia containing Na or K, e.g.,[123]



$$ArX + CH_3-\underset{\underset{O}{\|}}{C}-CH_3 \xrightarrow[NH_3]{K} ArCH_2-\underset{\underset{O}{\|}}{C}-CH_3 + ArCH_2-\underset{\underset{OH}{|}}{CH}-CH_3$$

The same products are obtained (though in different proportions) when Na or K is omitted but the solution is irradiated with near-uv light.[124] In either case other leaving groups may be used instead of halogens (e.g. NR_3^+, SAr), and the mechanism is the SRN1 mechanism (see reaction **3-6**).

Another method for achieving the coupling of an aryl halide with certain carbanions involves the use of aryl halides activated by conversion to chromium carbonyl complexes.[125] For example,



13 **14**

13 couples with the anion of isobutyronitrile to give **14.** The chromium tricarbonyl group can be quantitatively removed from **14** by treatment with iodine and ether at 0°C.

Diaryliodonium salts have also been used to arylate ZCH_2Z', but the mechanism is apparently free-radical.[126]

Aryl iodides (even unactivated) react with copper acetylides to give arylacetylenes.[127] The mechanism in this case may also be free-radical.

OS V, 12, 263; **51,** 128.

3-15 Carbalkoxylation and Carboxylation

$$ArI \xrightarrow[Ni(CO)_4]{ROH} ArCOOR$$

Aryl iodides can be converted directly to esters by treatment with nickel carbonyl in ROH as solvent[128] (see reaction **0-105**). The yields are nearly quantitative. In aprotic solvents, such as tetrahydrofuran, the products are benzils, ArCOCOAr. The reaction is not successful for aryl chlorides, bromides, or fluorides. Aryl bromides can be carboxylated ($\text{ArBr} \rightarrow \text{ArCOOH}$) in high yields by treatment with CO in the presence of water and a catalytic amount of Ni(CO)_4 provided that a salt such as KOAc is present to neutralize the HBr formed.[129]

3-16 The Ullmann Reaction

$$2\text{ArI} \xrightarrow[\Delta]{\text{Cu}} \text{Ar—Ar}$$

The coupling of aryl halides with copper is called the *Ullmann reaction*.[130] The reaction is of broad scope and has been used to prepare many symmetrical and unsymmetrical biaryls. When a mixture of two different aryl halides is used, there are three possible products, but often only one of these is obtained. For example, picryl chloride and iodobenzene gave only 2,4,6-trinitrobiphenyl.[131] The best leaving group is iodo, and the reaction is most often done on aryl iodides, but bromides, chlorides, and even thiocyanates have been used. The reaction rate can be increased by the use of copper which has been activated by a complexing agent, e.g., the sodium salt of ethylenediaminetetraacetic acid.[132]

The effects of other groups on the ring are unusual. The nitro group is strongly activating, but only in the ortho (not meta or para) position.[133] R and OR activate in all positions. Not only do OH, NH_2, NHR, and NHCOR inhibit the reaction, as would be expected for aromatic nucleophilic substitution, but so do COOH (but not COOR), SO_2NH_2, and similar groups, for which the reaction fails completely. These groups inhibit the coupling reaction by causing side reactions.

The mechanism is not known with certainty. It seems likely that it is basically a two-step process, similar to that of the Wurtz reaction (**0-86**):

Step 1 $\quad \text{ArI} + \text{Cu} \longrightarrow \text{ArCu}$

Step 2 $\quad \text{ArCu} + \text{ArI} \longrightarrow \text{ArAr}$

The species represented as ArCu may not actually have this structure, but some kind of a complex is formed. Organocopper compounds have been trapped by coordination with organic bases.[134] In addition, arylcopper compounds (ArCu) have been independently prepared and shown to give biaryls (ArAr′) when treated with aryl iodides Ar′I.[135] An alternate possible second step is $2\text{ArCu} \rightarrow \text{ArAr}$, and indeed arylcopper compounds are known to dimerize in this fashion.[136] The mechanisms of steps 1 and 2 are in doubt. It has been suggested[137] that step 1 is a free-radical reaction

$$\text{ArI} + \text{Cu} \longrightarrow \text{Ar}\bullet \xrightarrow{\text{Cu}} \text{ArCu}$$

and that step 2 is a nucleophilic attack by ArCu on ArI. Evidence for the latter is that a Meisenheimer salt could be isolated from treatment of 1,3,5-trinitrobenzene with an arylcopper compound[138] (in this case the leaving group is hydrogen).

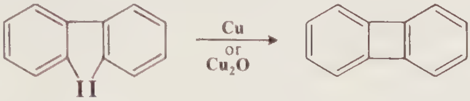
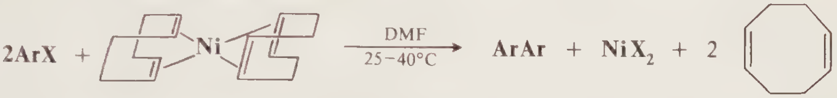
A similar reaction has been used for ring closure:



Either copper[139] or copper oxide[140] may be used in this ring-closure reaction, though the former gives better yields.[139]

Aryl halides can also be coupled by treatment with the complex bis(1,5-cyclooctadiene)-nickel(0) at 25 to 40°C in dimethylformamide.[141]

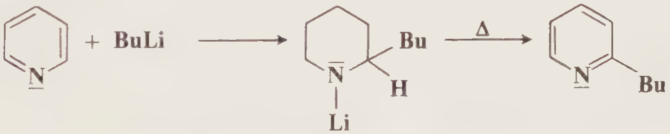


Ullmann-type coupling has also been carried out with ArNa and Ar′Cl. This proceeds by the benzyne mechanism.[142] For other methods of coupling of aromatic rings, see reactions **4-16, 4-19,** and **4-20.**

OS III, 339; 1120.

Hydrogen as Leaving Group

3-17 Alkylation and Arylation



The alkylation of heterocyclic nitrogen compounds with alkyllithiums is called *Ziegler alkylation.* Aryllithiums give arylation. The reaction occurs by an addition-elimination mechanism, and the adduct can be isolated.[143] Upon heating of the adduct, elimination of LiH occurs (see reaction **7-18**) and an alkylated product is obtained. With respect to the 2-carbon the first step is the same as that of the SNAr mechanism. The difference is that the unshared pair of electrons on the nitrogen combines with the lithium, so that the extra pair of ring electrons has a place to go: it becomes the new unshared pair on the nitrogen.

The reaction has been applied to nonheterocyclic aromatic compounds: benzene, naphthalene, and phenanthrene have been alkylated with alkyllithiums, though the usual reaction with these reagents is **2-19,**[144] and Grignard reagents have been used to alkylate naphthalene.[145] The addition-elimination mechanism apparently applies in these cases also. Aryl azo compounds can also be arylated (in ortho positions) with aryl Grignard reagents.[146]

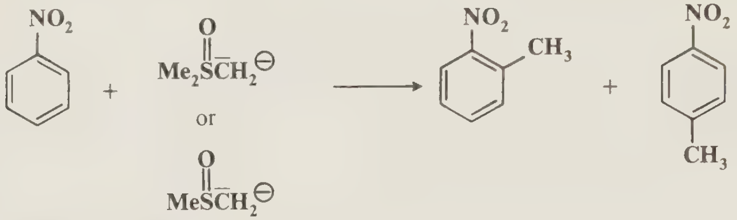
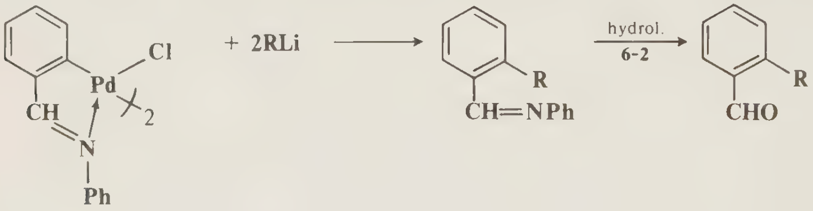
Aromatic nitro compounds can be methylated by treatment with dimethyloxosulfonium methylide[147] or the methylsulfinyl carbanion (obtained by treatment of dimethyl sulfoxide with a strong base):[148]



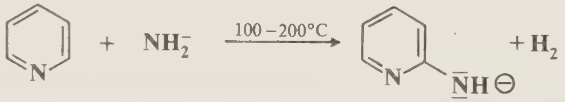
The latter reagent also methylates certain heterocyclic compounds, e.g., quinoline, and certain fused aromatic compounds, e.g., anthracene, phenanthrene.[149] The reactions with the sulfur carbanions are especially useful, since none of these substrates can be methylated by the Friedel-Crafts procedure (reaction **1-13**). For the introduction of CH_2SR groups into phenols, see reaction **1-29.**

Alkyl and aryl groups can be introduced into the ortho positions of aromatic aldehydes indirectly by reaction of palladium complexes of the corresponding Schiff bases with alkyl- or aryllithiums.[150]



OS **II**, 517.

3-18 Amination of Heterocyclic Nitrogen Compounds



Pyridine and other heterocyclic nitrogen compounds can be aminated with alkali-metal amides, in a process called the *Chichibabin reaction.*[151] The attack is always in the 2 position unless both such positions are filled, in which case the 4 position is attacked. Nitro compounds do not give the reaction.[151a]

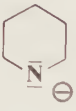
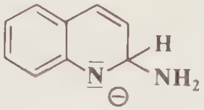
[151a] See for example, Levitt and Levitt, *Chem. Ind.* (*London*) 520 (1975).

Substituted alkali-metal amides, e.g., sodium piperidide (**15**), have also been used. Free amines may give the reaction, but only in the presence of bases like KOH.[152] Very likely the amide ion is the actual nucleophile in these cases. Apparently the hydride ion which is the leaving group combines with a proton from the initial $ArNH_2$ product to give H_2. At lower temperatures, in ammonia, potassium nitrate is sometimes necessary to oxidize the hydride ion. The mechanism is probably similar to that of reaction **3-17.** The existence of intermediate ions such as **16** (from quinoline) has been demonstrated by nmr spectra.[153] A pyridyne type of intermediate was ruled out by the observations that deuterium is not lost from pyridine-3-*d*[154] and that 3-ethylpyridine gave 2-amino-3-ethylpyridine.[155]



15

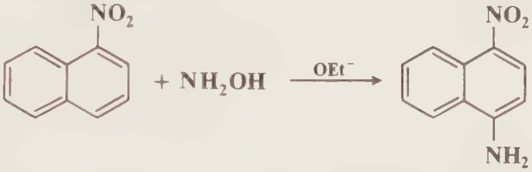


16

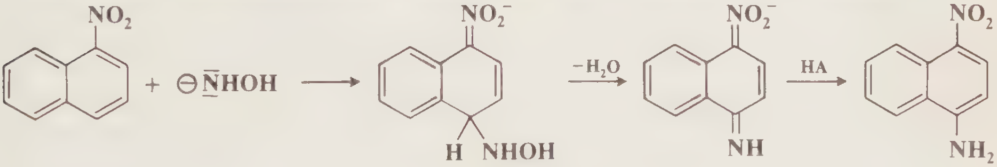
Analogous reactions have been carried out with hydrazide ions, $R_2N\bar{N}H^-$.[156] For other methods of aminating aromatic rings, see reactions **1-6, 3-19,** and **3-20.**

There are no *Organic Syntheses* references, but see OS **V**, 977, for a related reaction.

3-19 Amination by Hydroxylamine



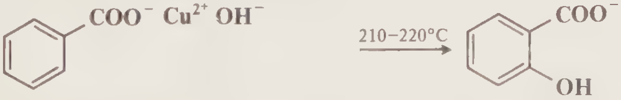
Activated aromatic compounds can be directly aminated with hydroxylamine in the presence of strong bases. Conditions are mild, and yields are high. Ions of the type **17** are intermediates:



17

OS **III**, 664.

3-20 Hydroxylation and Amination of Aromatic Acids



When basic copper salts of aromatic acids are heated, hydroxylation occurs in the ortho position.[157]

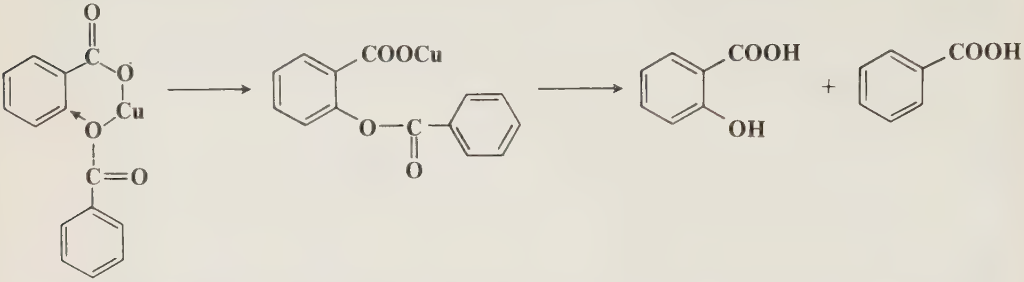
Better results are obtained by heating cupric carboxylates in protic solvents.[158] In the latter case there is a cyclic process leading to an ester intermediate:



Phenols are also produced, by concomitant decarboxylation of the salicylic acids or their esters.[159] In an analogous reaction, aromatic amines are produced by heating copper salts of aromatic acids with ammonia at 220°C under pressure.[160] See also reactions **1-32, 4-5,** and **4-10.**

N_2^+ as Leaving Group

The diazonium group can be replaced by a number of groups. Most of these are nucleophilic substitutions, with SN1 mechanisms (p. 587), but some are free-radical reactions and are treated in Chapter 14. (For *formation* of diazonium ions, see reaction **2-48.**) The N_2^+ group can be replaced by Cl^-, Br^-, and CN^-, by a nucleophilic mechanism (see OS **IV,** 182), but the Sandmeyer reaction is much more useful (reactions **4-25** and **4-28**). As mentioned on p. 593, it must always be kept in mind that the N_2^+ group may activate the removal of another group on the ring.

3-21 Replacement by OH

$$ArN_2^+ + H_2O \longrightarrow ArOH$$

Water is usually present whenever diazonium salts are made, but at these temperatures (0 to 5°C) the reaction proceeds very slowly. When it is *desired* to have OH replace the diazonium group, the excess nitrous acid is destroyed and the solution is usually boiled. Some diazonium salts require even more vigorous treatment, e.g., boiling with aqueous sulfuric acid or with trifluoroacetic acid containing potassium trifluoroacetate.[161] The reaction can be performed on solutions of any diazonium salts, but hydrogen sulfates are preferred to chlorides or nitrates, since in these cases there is competition from the nucleophiles Cl^- or NO_3^-. Phenols can also be prepared by treatment of aryl diazonium fluoborates with water and copper salts.[162] In this case the attacking species is a free radical, probably the $H_2O\cdot^+$ radical ion.

OS **I,** 404; **III,** 130, 453, 564; **V,** 1130.

3-22 Replacement by Sulfur-containing Groups

$$ArN_2^+ + HS^- \longrightarrow ArSH$$
$$ArN_2^+ + S^{2-} \longrightarrow ArSAr$$
$$ArN_2^+ + RS^- \longrightarrow ArSR$$
$$ArN_2^+ + SCN^- \longrightarrow ArSCN + ArNCS$$

---

[158] Kaeding and Collins, *J. Org. Chem.* **30,** 3750 (1965).
[159] See Oae, Watabe, and Furukawa, *Bull. Chem. Soc. Jpn.* **39,** 1329 (1966).
[160] Arzoumanidis and Rauch, *J. Chem. Soc., Chem. Commun.* 666 (1973).
[161] Horning, Ross, and Muchowski, *Can. J. Chem.* **51,** 2347 (1973).
[162] Lewin and Cohen, *J. Org. Chem.* **32,** 3844 (1967).

These reactions represent a convenient method of putting sulfur-containing groups onto an aromatic ring. With $Ar'S^-$ attack at the nitrogen takes precedence, so that the product is a diazosulfide ($Ar{-}N{=}N{-}S{-}Ar'$).[163] Thiophenols can be made as shown above, but more often the diazonium ion is treated with $EtO{-}CSS^-$ or S_2^{2-}, which give the expected products, and these are easily convertible to thiophenols. See also reaction **4-27**.

OS **II**, 580; **III**, 809 (but see OS **V**, 1050). Also see OS **II**, 238.

3-23 Replacement by the Azido Group

$$ArN_2^+ + N_3^- \longrightarrow ArN_3$$

Diazonium salts can be converted to aryl azides by the addition of sodium azide to the acidic diazonium salt solution.[164]

OS **IV**, 75; **V**, 829.

3-24 Replacement by Iodine

$$ArN_2^+ + I^- \longrightarrow ArI$$

One of the best methods for the introduction of iodine into aromatic rings is the reaction of diazonium salts with iodide ions. Analogous reactions with chloride, bromide, and fluoride ions give poorer results, and reactions **4-25** and **3-25** are preferred for the preparation of aryl chlorides, bromides, and fluorides. However, when other diazonium reactions are carried out in the presence of these ions, halides are usually side products.

The actual attacking species is probably not only I^-, if it is that at all. The iodide ion is oxidized (by the diazonium ion, nitrous acid, or some other oxidizing agent) to iodine, which in a solution containing iodide ions is converted to I_3^-, and this is the actual attacking species, at least partly. This was shown by isolation of $ArN_2^+\ I_3^-$ salts, which, on standing, gave ArI.[165] From this, it can be inferred that the reason the other halide ions give poor results is not that they are poor nucleophiles but that they are poor reducing agents (compared with iodide). A free-radical mechanism has also been proposed.[166]

OS **II**, 351, 355, 604; **V**, 1120.

3-25 Replacement by Fluorine. The Schiemann Reaction

$$ArN_2^+\ BF_4^- \xrightarrow{\Delta} ArF + N_2 + BF_3$$

Heating of diazonium fluoborates (the *Schiemann reaction*) is by far the best way of introducing fluorine into an aromatic ring.[167] In the most common procedure, the fluoborate salts are prepared by diazotizing as usual with nitrous acid and HCl and then adding a cold aqueous solution of $NaBF_4$, HBF_4, or NH_4BF_4. A precipitate forms, which is then dried, and the salt is heated in the dry state. These salts are unusually stable for diazonium salts, and the reaction is usually quite successful. In general, any aromatic amine which can be diazotized will form a BF_4^- salt, usually with high yields. The diazonium fluoborates can be formed directly from primary aromatic amines and $NOBF_4$.[168] The reaction has also been carried out on $ArN_2^+\ PF_6^-$, $ArN_2^+\ SbF_6^-$, and $ArN_2^+\ AsF_6^-$ salts, in many cases with better yields.[169] The reaction has been extended to

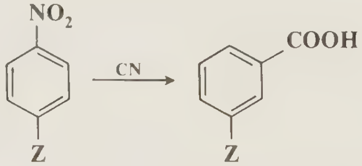
$ArN_2^+\ BCl_4^-$ and $ArN_2^+\ BBr_4^-$,[170] but aryl chlorides and bromides are more commonly prepared by the Sandmeyer reaction (**4-25**).

The mechanism is of the S_N1 type. That phenyl cations are intermediates was shown by the following experiments:[171] aryl diazonium chlorides are known to arylate other aromatic rings by a free-radical mechanism (see reaction **4-16**). In radical arylation it does not matter whether the other ring contains electron-withdrawing or electron-donating groups; in either case a mixture of isomers is obtained, since the attack is not by a charged species. If a phenyl free radical were an intermediate in the Schiemann reaction and the reaction were run in the presence of other rings, it should not matter what kinds of groups were on these other rings: mixtures of biaryls should be obtained in all cases. But if a phenyl cation is an intermediate in the Schiemann reaction, compounds containing meta-directing groups, i.e., meta-directing for *electrophilic* substitutions, should be meta-arylated and those containing ortho-para-directing groups should be ortho- and para-arylated, since a phenyl cation should behave in this respect like any electrophile (see Chapter 11). Experiments have shown[172] that such orientation is observed, demonstrating that the Schiemann reaction has a positively charged intermediate. The attacking species, in at least some instances, is not F^- but BF_4^-.[173]

OS **II**, 188, 295, 299; **V**, 133.

Rearrangements

3-26 The von Richter Rearrangement



When aromatic nitro compounds are treated with cyanide ion, the nitro group is displaced and a carboxyl group enters but does not take the place vacated by the nitro, as determined by analyses of products obtained from substituted nitrobenzenes. The carboxyl group always appears ortho to the displaced nitro group, never meta or para. This is thus a cine substitution (p. 589). The scope of this reaction, called the *von Richter rearrangement*, is variable.[174] As with other nucleophilic aromatic substitutions, the reaction gives best results when electron-withdrawing groups are in ortho and para positions, but yields are low, usually less than 20% and never more than 50%.

For many years, it was believed that a nitrile, ArCN, was an intermediate, since cyanide is the reagent and nitriles are hydrolyzable to carboxylic acids under the reaction conditions (reaction **6-5**). However, a remarkable series of results have shown this belief to be in error. Bunnett and Rauhut demonstrated[175] that α-naphthyl cyanide is *not* hydrolyzable to α-naphthoic acid under conditions at which β-nitronaphthalene undergoes the von Richter rearrangement to give α-naphthoic acid. This proved that the nitrile cannot be an intermediate in this case and cast doubt on all other cases, since it is unlikely that different mechanisms would be operating. It was subsequently demonstrated that *elemental nitrogen* is a major product of the reaction.[176] It had previously been assumed that all the nitrogen in the reaction was converted to ammonia, which would be compatible with a nitrile intermediate, since ammonia is a hydrolysis product of nitriles. At the same time it was shown that NO_2^- is not a major product. The discovery of nitrogen indicated that a nitrogen-nitrogen bond must be formed during the course of the reaction. A mechanism in accord with all the facts was proposed by Rosenblum:[176]

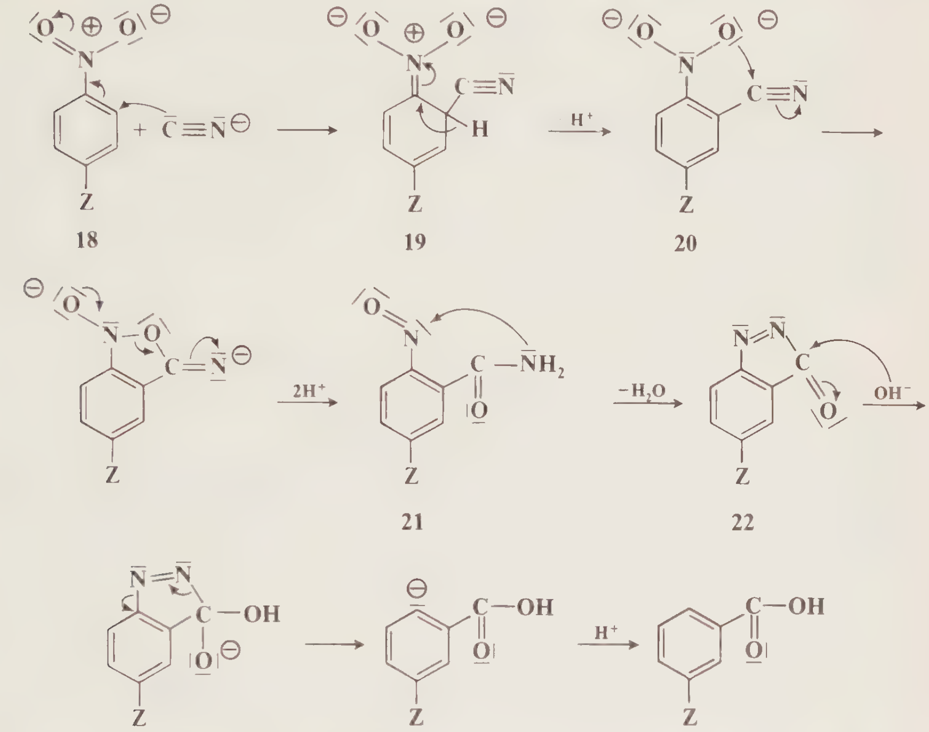
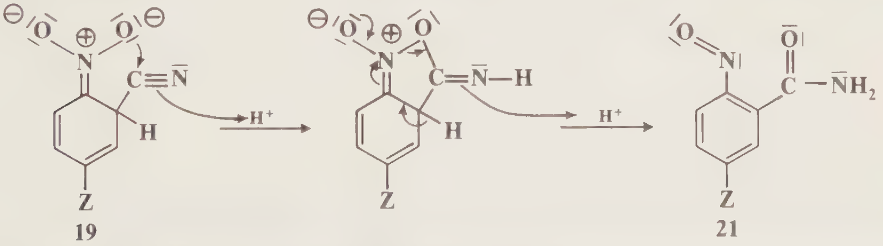
[175] Bunnett and Rauhut, *J. Org. Chem.* **21**, 934, 944 (1956).



It may be remarked that this mechanism postulates as an intermediate at least one stable compound, **21**, and perhaps another (**22**). It also postulates the existence of **20**, which has the unusual functional group $-NO_2^{2-}$. It is possible that **21** could be formed without going through **20**[177]



if the attack of the oxygen at the cyano carbon occurs *before* the proton leaves the ring and if another proton attacks the nitrogen as the ring proton is leaving. Since **21** are stable compounds, it should be possible to prepare them independently and subject them to the conditions of the von Richter rearrangement. This has been done, and the correct products are obtained.[178] Further evidence for the mechanism is as follows: among the side products isolated from reaction of **18** (Z = Cl) was **23**, which could arise from reduction of **21**;[179] **22** (Z = H) was prepared, though

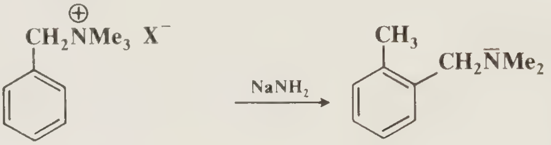
23

not isolated, and treatment with cyanide gave nitrogen and benzoic acid;[180] and when **18** (Z = Cl or Br) was treated with cyanide in $H_2{}^{18}O$, one-half of the oxygen in the product was labeled, showing that one of the oxygens of the carboxyl group came from the nitro group and one from the solvent, as required by this mechanism.[181]

OS **IV**, 114.

3-27 The Sommelet-Hauser Rearrangement



Benzyl quaternary ammonium salts, when treated with alkali-metal amides, undergo a rearrangement which some call the *Sommelet rearrangement* and others the *Hauser rearrangement*.[182] Since both of these men were important in our present knowledge of this reaction, we shall use the joint name, adopted by Bumgardner.[183] Since the product is a benzyl tertiary amine, it can be further alkylated and the product again subjected to the rearrangement. This process can be continued around the ring until an ortho position is blocked.[184]

The rearrangement occurs with high yields and can be performed with various groups present in the ring.[185] The reaction is most often carried out with three methyl groups on the nitrogen, but other groups can also be used, though if a β-hydrogen is present, Hofmann elimination (reaction **7-6**) can and often does compete. When the three groups are not the same, competing products may be obtained, e.g.,[183]

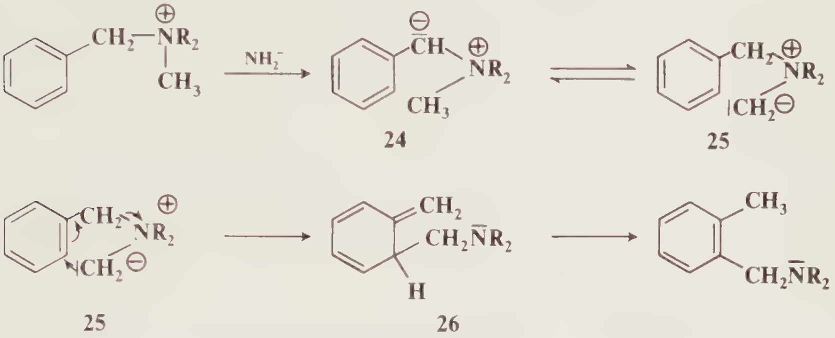
In any case, the Stevens rearrangement (reaction **8-25**) is a competing process. When both rearrangements are possible, the Stevens is favored at high temperatures and the Sommelet-Hauser at low temperatures.[186] When the migrating group carries an α-SR′ group, the Sommelet-Hauser product is an aromatic aldehyde, formed by hydrolysis during the workup of the $ArCH(SR')NR_2$ product.[187]

The mechanism is



The benzyl hydrogen is most acidic and is the one which first loses a proton to give the ylide **24.** However, **25,** which is present in smaller amount, is the species which undergoes the rearrangement, shifting the equilibrium in its favor. This mechanism is an example of a [2,3] sigmatropic rearrangement (see reaction **8-40**). Another mechanism which might be proposed is one in which a methyl group actually breaks away (in some form) from the nitrogen and then attaches itself to the ring. That this is not so was shown by a product study and by labeling experiments. If the second mechanism were true, **27** should give **28,** but the former mechanism predicts the formation of **29,** which is what was actually obtained.[188] In the labeling experiments, benzyltrimethylamine, labeled with ^{14}C in the α position of the benzyl group, gave a product labeled in the ring methyl group, as predicted by the first mechanism, and not in the methylene, as required by

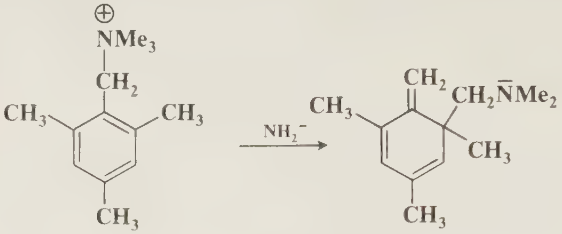
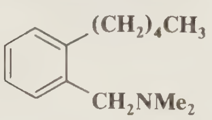
the second.[189] Further evidence for the cyclic mechanism was the isolation of **31** from reaction of **30**.[190] Since **30** is substituted in both ortho positions, it could not give the normal rearrangement



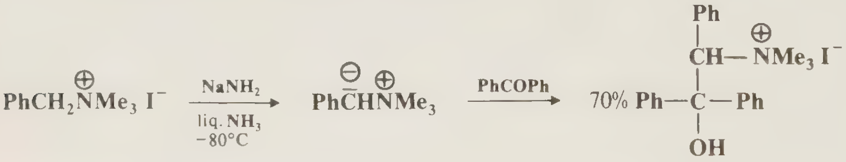
30 **31**

product, but the first step of the mechanism *has* occurred. The intermediate **26** has been shown to exist even when no ortho group is present by the obtention of **32** when the reaction was



32

carried out with BuLi as the base. **32** is formed by addition of BuLi to **26**.[191] The intermediate **24** has been trapped at −80°C by treatment with benzophenone:[192]

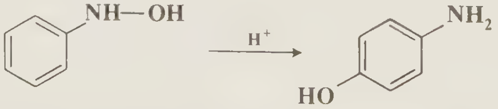


$$Ph\overset{\oplus}{CH_2NMe_3}\ I^- \xrightarrow[\substack{\text{liq. } NH_3\\ -80^\circ C}]{NaNH_2} Ph\overset{\ominus}{\underline{C}}H\overset{\oplus}{N}Me_3 \xrightarrow{PhCOPh} 70\%\ Ph-\underset{\substack{|\\ OH}}{\overset{\substack{Ph\\ |\\ CH-\overset{\oplus}{N}Me_3\,I^-\\ |}}{C}}-Ph$$

The mechanism as we have pictured it can lead only to an ortho product. However, a small amount of para product has been obtained in some cases.[193] A mechanism[183] in which there is a dissociation of the ArC—N bond (similar to the ion-pair mechanism of the Stevens rearrangement, p. 1014) has been invoked to explain the obtention of the para products.

OS **IV**, 585.

3-28 Rearrangement of Aryl Hydroxylamines



Aryl hydroxylamines treated with acids rearrange to aminophenols.[194] Although this reaction (known as the *Bamberger rearrangement*) is similar in appearance to reactions **1-36** to **1-40**, the attack on the ring is not electrophilic but nucleophilic. The rearrangement is intermolecular, with the following mechanism:

---

[189] Jones and Hauser, *J. Org. Chem.* **26**, 2979 (1961).

[190] Hauser and Van Eenam, *J. Am. Chem. Soc.* **79**, 5512 (1957).

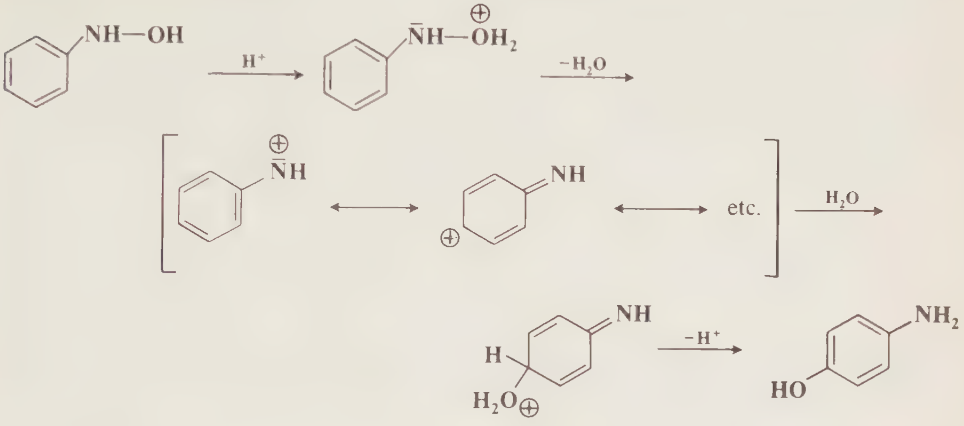
[192] Puterbaugh and Hauser, *J. Am. Chem. Soc.* **86**, 1105 (1964).

[193] Pine, *Tetrahedron Lett.* 3393 (1967); Pine, Ref. 182, p. 418.

[194] For reviews, see Ref. 174, pp. 182–190; Hughes and Ingold, *Q. Rev., Chem. Soc.* **6**, 34–62 (1952); pp. 45–48.

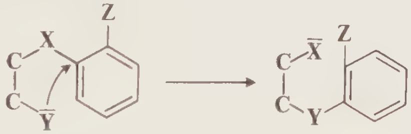


33

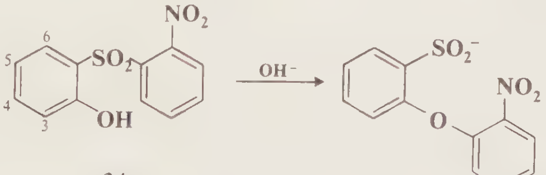
Among the evidence for this mechanism are the facts that other products are obtained when the reaction is run in the presence of competing nucleophiles, e.g., *p*-ethoxyaniline when ethanol is present, and that when the para position is blocked, compounds similar to **33** are isolated.

OS **IV**, 148.

3-29 The Smiles Rearrangement



The *Smiles rearrangement* actually comprises a group of rearrangements which follow the pattern given above.[195] A specific example is



34

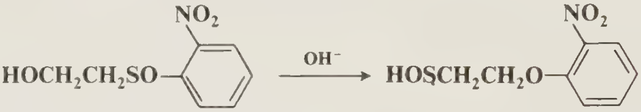
Smiles rearrangements are simply intramolecular nucleophilic substitutions. In the example given, SO_2Ar is the leaving group and ArO^- the nucleophile, and the nitro group serves to activate its ortho position. The ring at which the substitution takes place is nearly always activated, usually by ortho or para nitro groups. X is usually S, SO, SO_2,[196] O, or COO. Y is usually the conjugate base of OH, NH_2, NHR, or SH. The reaction has even been carried out with

---

[195] For reviews, see Truce, Kreider, and Brand, *Org. React.* **18,** 99–215 (1971); Shine, Ref. 174, pp. 307–316; Stevens and Watts, Ref. 182, pp. 120–126; Bunnett and Zahler, Ref. 1, pp. 362–372.

[196] For a review for the case of $X = SO_2$, see Cerfontain, "Mechanistic Aspects in Aromatic Sulfonation and Desulfonation," pp. 262–274, Interscience Publishers, New York, 1968.

$Y = CH_2^-$ (phenyllithium was the base here).[197] The reaction rate is greatly enhanced by substitution in the 6 position of the attacking ring, for steric reasons. For example, a methyl, chloro, or bromo group in the 6 position of **34** caused the rate to be about 10^5 times faster than when the same groups were in the 4 position,[198] though electrical effects should be similar at these positions. The enhanced rate comes about because the most favorable conformation the molecule can adopt to suit the bulk of the 6-substituent is also the conformation required for the rearrangement. Thus, less entropy of activation is required. Although the Smiles rearrangement is usually carried out on compounds containing two rings, this need not be the case; e.g.,[199]



35

In this case the sulfenic acid (**35**) is unstable, and the actual products isolated were the corresponding sulfinic acid (RSO_2H) and disulfide (R_2S_2).

Fourteen
Free-Radical Substitution

MECHANISMS

Free-Radical Mechanisms in General[1]

Any free-radical process must consist of at least two steps. The first step involves the *formation* of free radicals, nearly always by homolytic cleavage of a bond, i.e., a cleavage in which each fragment retains one electron:

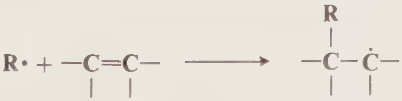
$$\mathbf{A{-}B} \longrightarrow \mathbf{A\cdot + B\cdot}$$

This is called an *initiation* step, and it may happen spontaneously or may have to be induced by heat or light (see the discussion on p. 176), depending on the type of bond. Peroxides, including hydrogen peroxide, dialkyl, diacyl, and alkyl acyl peroxides, and peracids are the most common source of free radicals induced spontaneously or by heat, but other organic compounds with low-energy bonds, such as azo compounds, are also used. Molecules which are cleaved by light are most often chlorine, bromine, and various ketones (see Chapter 7).

The second necessary step involves the *destruction* of free radicals, and this usually happens by a process opposite to the first, namely, a combination of two like or unlike radicals to form a new bond:

$$\mathbf{A\cdot + B\cdot} \longrightarrow \mathbf{A{-}B}$$

This type of step is called *termination*,[2] and it ends the reaction as far as these particular radicals are concerned unless the bond is broken once again and a new round begins.[3] However, it is not often that termination follows *directly* upon initiation. The reason for this is that most radicals are very reactive and will react with the first available species with which they come in contact, and in the usual situation, in which the concentration of radicals is low, this is much more likely to be a molecule than another radical. When a radical (which has an odd number of electrons) reacts with a molecule (which has an even number), the products must have a total number of electrons which is odd. The product in a particular step of this kind may be one particle, e.g.,



$$\mathbf{R\cdot + -\underset{|}{C}=\underset{|}{C}- \longrightarrow -\overset{\overset{R}{|}}{\underset{|}{C}}-\underset{|}{\dot{C}}-}$$

---

[1] For books on free-radical mechanisms, see Nonhebel and Walton, "Free-Radical Chemistry," Cambridge University Press, London, 1974; Huyser, "Free-Radical Chain Reactions," Interscience Publishers, New York, 1970; *MTP Int. Rev. Sci.: Org. Chem., Ser. One* **10** (1973); Pryor, "Free Radicals," McGraw-Hill Book Company, New York, 1966; Walling, "Free Radicals in Solution," John Wiley & Sons, Inc., New York, 1957. For reviews, see Huyser, in McManus, "Organic Reactive Intermediates," pp. 1–59, Academic Press, New York, 1973; Lloyd, *Chem. Technol.* 176–180, 371–381, 687–696 (1971), 182–188 (1972).

[2] Another type of termination is disproportionation (see p. 177).

[3] For a review of termination reactions, see Lapporte, *Angew. Chem.* **72,** 759–766 (1960).

in which case it must be another free radical; or it may consist of two particles, e.g.,

$$\mathrm{R\cdot + R'H \longrightarrow RH + R'\cdot}$$

in which case one must be a molecule and one a free radical, but in any case *a new radical is generated.* This type of step is called *propagation*, since the newly formed radical can now react with another molecule and produce another radical, and so on, until two radicals do meet each other and terminate the process. The process just described is called a *chain reaction*, and there may be hundreds or thousands of propagation steps between an initiation and a termination. Two other types of propagation reactions do not involve a molecule at all. These are (1) cleavage of a radical into, necessarily, a radical and a molecule and (2) rearrangement of one radical to another (see Chapter 18). When free radicals are highly reactive, e.g., alkyl radicals, chains are long, since reactions occur with many molecules; but with radicals of low reactivity, e.g., aryl radicals, the radical may be unable to react with anything until it meets another radical, so that chains are short, or the reaction may be a nonchain process. In any particular chain process there is usually a wide variety of propagation and termination steps. Because of this, these reactions lead to many products and are often difficult to treat kinetically.[4]

The following are some general characteristics of free-radical reactions:

1. Reactions are fairly similar whether they are occurring in the vapor or liquid phase, though solvation of free radicals in solution does cause some differences.[5]

2. They are largely unaffected by the presence of acids or bases or by changes in the polarity of solvents, except that nonpolar solvents may suppress competing ionic reactions.

3. They are initiated or accelerated by typical free-radical sources, such as the peroxides referred to, or by light. In the latter case the concept of quantum yield applies (p. 224). Quantum yields may be quite high, e.g., 1000%, if each quantum generates a long chain, or low, in the case of nonchain processes.

4. Their rates are decreased or the reactions are suppressed entirely by substances which scavenge free radicals, e.g., nitric oxide, molecular oxygen, or benzoquinone. These substances are called *inhibitors*.

In this chapter are discussed free-radical substitution reactions. Free-radical additions to unsaturated compounds and rearrangements are discussed in Chapters 15 and 18, respectively. In addition, many of the oxidation-reduction reactions considered in Chapter 19 involve free-radical mechanisms. Several important types of free-radical reactions do not usually lead to reasonable yields of pure products and are not generally treated in this book. Among these are polymerizations and high-temperature pyrolyses.

Free-Radical Substitution Mechanisms

In a free-radical substitution reaction

$$\mathrm{R{-}X \longrightarrow R{-}Y} \tag{1}$$

there must first be a cleavage of the substrate RX so that R· radicals are produced. This may happen by a spontaneous cleavage

$$\mathrm{R{-}X \longrightarrow R\cdot + X\cdot} \tag{2}$$

---

[4] For a discussion of kinetic aspects of free-radical chain reactions, see Huyser, "Free-Radical Chain Reactions," Ref. 1, pp. 39–65.

[5] For a discussion, see Mayo, *J. Am. Chem. Soc.* **89**, 2654 (1967).

it may be caused by light or heat, or, more often, there is no actual cleavage, but R• is produced by an *abstraction*

$$\mathrm{R{-}X + W\cdot \longrightarrow R\cdot + W{-}X} \tag{3}$$

W• is produced by adding a compound, such as a peroxide, which spontaneously forms free radicals. Such a compound is called an *initiator*. Once R• is formed, it may go to product in two ways, by abstraction

$$\mathrm{R\cdot + Y{-}W \longrightarrow R{-}Y + W\cdot} \tag{4}$$

or by coupling with another radical

$$\mathrm{R\cdot + Y\cdot \longrightarrow R{-}Y} \tag{5}$$

In a reaction with a moderately long chain, much more of the product will be produced by abstraction (4) than by coupling (5). Cleavage steps like (2) have been called SH1 (H for homolytic), and abstraction steps like (3) and (4) have been called SH2; reactions can be classified as SH1 or SH2 on the basis of whether RX is converted to R by (2) or (3).[6] Most chain substitution mechanisms follow the pattern of (3), (4), (3), (4),.... Chains are long and reactions go well where both (3) and (4) are energetically favored (no worse than slightly endothermic, see pp. 626, 635).

It would be interesting to know just how abstraction steps like (3) [and for that matter (4)] occur. Does the radical make a frontside attack, as in most SE2 reactions or a backside attack as in SN2 reactions? The details of these steps are not known, despite much work,[7] except for the special case where X is a carbon atom which is part of a cyclopropane ring (see p. 694).

It is known that with certain radicals the transition state in an abstraction reaction has some polar character. For example, consider the abstraction of hydrogen from the methyl group of toluene by a bromine atom. We can represent the transition state (assuming it is linear) as

$$\mathrm{PhCH_2\cdots\cdots H\cdots\cdots Br}$$

Since bromine is more electronegative than carbon, it is reasonable to assume that in the transition state there is a separation of charge, with a partial negative charge on the halogen and a partial positive charge on the carbon. Another way of representing this is to draw canonical forms for the transition state. Evidence for the polar character of the transition state is that

$$\mathrm{Ph\overset{\delta+}{C}H_2\overset{\cdot}{\vphantom{x}}\cdots\cdots H\cdots\cdots \overset{\delta-}{Br}} \qquad \text{or} \qquad \mathrm{PhCH_2{-}H\cdot Br \leftrightarrow PhCH_2\cdot H{-}Br \leftrightarrow Ph\overset{+}{C}H_2\quad \dot{H}\quad \bar{Br}}$$

electron-withdrawing groups in the para position of toluene (which would destabilize a positive charge) decrease the rate of hydrogen abstraction by bromine while electron-donating groups increase it.[8] However, as we might expect, substituents have a smaller effect here ($\rho \approx 1.4$) than they do in reactions where a completely ionic intermediate is involved, e.g., the SN1 mechanism (see p. 320). Other evidence for polar transition states in radical abstraction reactions is mentioned on p. 627. For abstraction by radicals such as methyl or phenyl, polar effects are very small or completely absent. For example, rates of hydrogen abstraction from ring-substituted toluenes by the methyl radical were relatively unaffected by the presence of electron-donating or electron-withdrawing substituents.[9] When the abstracting radical is *t*-butyl, the ρ value is positive ($\rho = +0.99$),[10] indicating that in this case the direction of the dipole is reversed:[11]

[7] Pryor and Pickering, *J. Am. Chem. Soc.* **84**, 2705 (1962). For a discussion of the transition state of radical-abstraction steps, see Szwarc, in "The Transition State," *Chem. Soc. Spec. Publ.* no. 16, 91–117, 1962.

[8] For example, see Pearson and Martin, *J. Am. Chem. Soc.* **85**, 354, 3142 (1963).

$$\overset{\delta-}{\mathrm{PhCH_2}}\text{-----}\mathrm{H}\text{-----}\overset{\delta+}{\mathrm{CMe_3}}$$

When the reaction step $\mathrm{R{-}X \rightarrow R\cdot}$ takes place at a chiral carbon, racemization is almost always observed because free radicals do not retain configuration. Exceptions to this rule are found at cyclopropyl substrates, where both inversion[12] and retention[13] of configuration have been reported, and in the reactions mentioned on p. 624.

Mechanisms at an Aromatic Substrate[14]

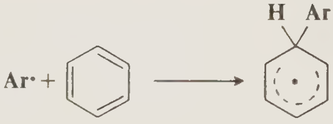
When the R in reaction (1) is aromatic, the simple abstraction mechanism just discussed may be operating, especially in gas-phase reactions. However, mechanisms of this type cannot account for all reactions of aromatic substrates. In processes such as the following (see reactions **4-16, 4-19,** and **4-20**):

$$\mathrm{Ar\cdot + ArH \longrightarrow Ar{-}Ar} \tag{6}$$

which occur in solution, the coupling of two rings cannot be explained on the basis of a simple abstraction

$$\mathrm{Ar\cdot + ArH \longrightarrow Ar{-}Ar + H\cdot} \tag{7}$$

since, as discussed on p. 625, abstraction of an entire group such as phenyl by a free radical is very unlikely. The products can be explained by a mechanism similar to that of electrophilic and nucleophilic aromatic substitution. In the first step, the radical attacks the ring in much the same way as would an electrophile or a nucleophile:



(8)

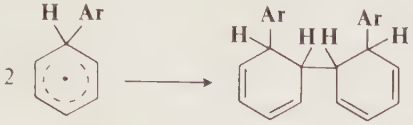
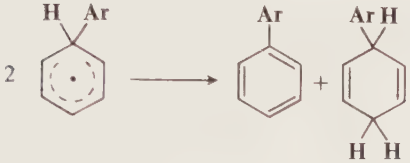
The intermediate is relatively stable because of the resonance. The reaction may terminate in three ways: by simple coupling, or by disproportionation



(9)

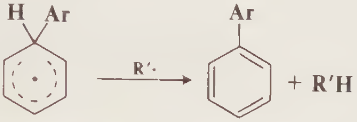
2



(10)

3

or, if a species (R′•) is present which abstracts hydrogen, by abstraction



(11)

2 is a partially hydrogenated quaterphenyl. Of course, the coupling need not be ortho-ortho, and other isomers may also be formed. Among the evidence for steps (9) and (10) was isolation of compounds of types **2** and **3**,[15] although normally under the reaction conditions dihydrobiphenyls like **3** are oxidized to the corresponding biphenyls. Other evidence for this mechanism is the detection of the intermediate **1** by CIDNP[16] (see p. 171) and the absence of isotope effects, which would be expected if the rate-determining step were (7), which involves cleavage of the Ar—H bond. In the mechanism just given, the rate-determining step (8) does not involve loss of hydrogen. A similar mechanism has been shown where the attacking radical was HO• (reaction **4-5**).

Neighboring-Group Assistance in Free-Radical Reactions

In a few cases it has been shown that cleavage steps (2) and abstraction steps (3) have been accelerated by the presence of neighboring groups. Photolytic halogenation (reaction **4-1**) is a process which normally leads to mixtures of many products. However, bromination of carbon chains containing a bromine atom occurs with high regiospecificity. Bromination of alkyl bromides gave 84 to 94% substitution at the carbon adjacent to the bromine already in the molecule.[17] This result is especially surprising because, as we shall see (p. 627), positions close to a polar group such as bromine should actually be *deactivated* by the electron-withdrawing field effect of the bromine. The unusual regiospecificity is explained by a mechanism in which abstraction (2) is assisted by a neighboring bromine atom:[18]

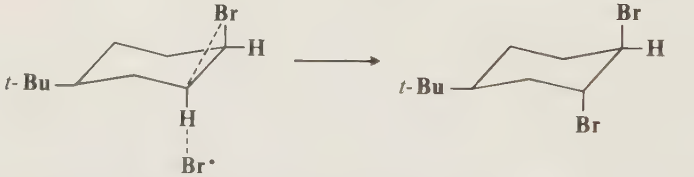
(12)

In the normal mechanism, Br• abstracts a hydrogen from RH, leaving R•. When a bromine is present in the proper position, it assists this process, giving a cyclic intermediate (a *bridged free radical*, **4**).[19] In the final step (very similar to R• + $Br_2 \rightarrow$ RBr + Br•) the ring is broken. If this mechanism is correct, the configuration at the substituted carbon (marked *) should be retained. This has been shown to be the case: optically active 1-bromo-2-methylbutane gave 1,2-dibromo-2-methylbutane with retention of configuration.[18] Furthermore, when this reaction was carried out in the presence of DBr, the "recovered" 1-bromo-2-methylbutane was found to be deuterated regiospecifically in the 2 position, and its configuration was retained.[20] This is just what would be predicted if some of the **4** present abstracted D from DBr. Additional evidence for this mechanism was shown in bromination of *cis*-4-bromo-*t*-butylcyclohexane. In this compound the bromo group is forced to be axial by the presence of the *t*-butyl group (see p. 131). Substitution occurred in the 3 position and was trans, as would be expected by the neighboring-group mechanism:[21]



(13)

The trans isomer, in which the bromine is equatorial and therefore in a much poorer position to be a neighboring group, was both less reactive and less selective than the cis. Low reactivity is normally associated with high selectivity, but in this case neighboring bromine (in the cis isomer) both accelerates the reaction and makes the attack both regiospecific and stereoselective. Other evidence is that chlorination with *t*-BuOCl (see p. 633 for the mechanism) of optically active *sec*-butyl bromide gave (along with other products) about 3% of 1-bromo-2-chlorobutane, *which was optically active.*[22] Such a product could have arisen only via a bridged intermediate:

[22] Skell, Pavlis, Lewis, and Shea, *J. Am. Chem. Soc.* **95,** 6735 (1973); for a similar result, see Juneja and Hodnett, *J. Am. Chem. Soc.* **89,** 5685 (1967).

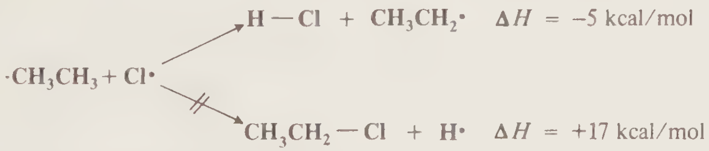
What took place here was a migration of Br arising from attack by *t*-BuOCl at C-2 rather than at C-1. We have previously seen similar behavior in the case of the neighboring-group mechanism for nucleophilic substitution (p. 281). Evidence that Cl can form bridged radicals comes from esr spectra, which show that the bridging is not necessarily symmetrical.[23] Still more evidence for bridging by Br has been found in isotope-effect and other kinetic studies.[24] However, evidence from CIDNP (p. 171) shows that the methylene protons of the β-bromoethyl radical are not equivalent, at least while the radical is present in the radical pair [$PhCOO\cdot \quad \cdot CH_2CH_2Br$] within a solvent cage.[25] This evidence indicates that under these conditions $BrCH_2CH_2\cdot$ is not a symmetrically bridged radical, but it could be unsymmetrically bridged. A bridged intermediate has also been invoked, when a bromo group is in the proper position, in the Hunsdiecker reaction[26] (**4-39**), and in abstraction of iodine atoms by the phenyl radical.[27] Neighboring-group participation in cleavage reactions (2) has also been shown, in the case of decomposition of *t*-butyl peresters.[28] The neighboring group in this case was SR.

The above facts support the neighboring-group mechanism for certain free-radical substitutions. However, the concept of anchimeric assistance in these reactions has been challenged by Tedder and coworkers[29] on the basis of results obtained in brominations in the gas phase. These workers distinguish between (1) interaction between a neighboring group and the half-filled orbital at the adjacent carbon (bridging) and (2) accelerated attack resulting from this bridging; they believe that bridging may be an important factor but that anchimeric assistance is not. However, anchimeric assistance approaching 10^3 in magnitude has been demonstrated in the bromination of alkyl bromides.[30] No such assistance was found in bromination of alkyl fluorides or chlorides.

REACTIVITY

Reactivity for Aliphatic Substrates

In a chain reaction, the step that determines what the product will be is most often an abstraction step. What is abstracted by a free radical is almost never a tetra- or trivalent atom and not often a divalent one.[31] Nearly always it is univalent, and so, for organic compounds, it is hydrogen or halogen. For example, a reaction between a chlorine atom and ethane gives an ethyl radical and not a hydrogen atom:



$$CH_3CH_3 + Cl\cdot \longrightarrow H{-}Cl + CH_3CH_2\cdot \qquad \Delta H = -5 \text{ kcal/mol}$$

$$CH_3CH_3 + Cl\cdot \not\longrightarrow CH_3CH_2{-}Cl + H\cdot \qquad \Delta H = +17 \text{ kcal/mol}$$

TABLE 1 Relative susceptibility to attack by Cl• of primary, secondary, and tertiary positions at 100 and 600°C in the gas phase[36]

Temp., °C	Primary	Secondary	Tertiary
100	1	4.3	7.0
600	1	2.1	2.6

The principal reason for this is *steric*. A univalent atom is much more exposed to attack by the incoming radical than an atom with a higher valence. Another reason is that in many cases abstraction of a univalent atom is energetically more favored. For example, in the reaction given above, a C_2H_5—H bond is broken ($D = 98$ kcal/mol, from Table 2, Chapter 5, p. 175) whichever pathway is taken, but in the former case an H—Cl bond is formed ($D = 103$ kcal/mol) while in the latter case it is a C_2H_5—Cl bond ($D = 81$ kcal/mol). Thus the first reaction is favored because it is exothermic by 5 kcal/mol (98 − 103), while the latter is endothermic by 17 kcal/mol (98 − 81).[32] However, the steric reason is clearly more important, because even in cases where ΔH is not very different for the two possibilities, the univalent atom is chosen.

Most studies of aliphatic reactivity have been made with hydrogen as the atom which is replaced and chlorine atoms as the abstracting species.[33] In these reactions, every hydrogen in the substrate is potentially replaceable, and mixtures are usually obtained. However, the abstracting radical is not totally unselective, and some positions on a molecule lose hydrogen more easily than others. We discuss the position of attack under several headings:[34]

1. *Alkanes*. The tertiary hydrogens of an alkane are the ones that are preferentially abstracted by almost any radical, with secondary hydrogens being next preferred. This is in the same order as D values for these types of C—H bonds (Table 2 in Chapter 5) although this agreement is partly fortuitous, since D values are not always in agreement with position of abstraction.[35] The extent of the preference depends upon the reactivity (hence selectivity) of the abstracting radical and upon the temperature. Table 1 shows[36] that at high temperatures selectivity decreases, as might be expected. An example of the effect of radical reactivity may be noted in a comparison of the selectivity of fluorine atoms with that of bromine atoms. For the former, the ratio of primary to tertiary abstraction (of hydrogen) is 1 : 1.4, while for the less reactive bromine atom this ratio is 1 : 1600.[34] With certain large radicals there is a steric factor which may change the selectivity pattern. For example, in the photochemical chlorination of isopentane in H_2SO_4 with N-chloro-di-*t*-butylamine and N-chloro-*t*-butyl-*t*-pentylamine, the primary hydrogens are abstracted 1.7 times *faster* than the tertiary hydrogen.[37] In this case the attacking radicals (the radical ions $R_2NH\cdot^+$, see p. 634) are bulky enough for steric hindrance to become a major factor.

2. *Olefins*. When the substrate molecule contains a double bond, treatment with chlorine or bromine usually leads to addition rather than substitution. However, for other free radicals (and

---

[32] ΔH for a free-radical abstraction reaction may be regarded simply as the difference in D values for the bond being broken and the one formed.

[33] For a review which lists many rate constants for abstraction of hydrogen at various positions of many molecules, see Hendry, Mill, Piszkiewicz, Howard, and Eigenmann, *J. Phys. Chem. Ref. Data* **3**, 937–978 (1974).

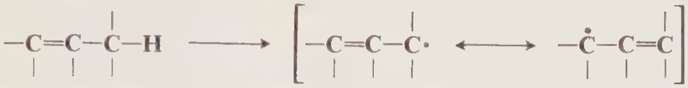
[36] Hass, McBee, and Weber, *Ind. Eng. Chem.* **28**, 333 (1936).

[37] Deno, Fishbein, and Wyckoff, *J. Am. Chem. Soc.* **93**, 2065 (1971).

even for chlorine or bromine atoms when they do abstract a hydrogen) the position of attack is perfectly clear. Vinylic hydrogens are practically never abstracted, and allylic hydrogens are greatly preferred to other positions of the molecule. This is hardly surprising, since the resulting allylic radicals are stabilized by resonance:



$$-\underset{|}{C}=\underset{|}{C}-\overset{|}{\underset{|}{C}}-H \longrightarrow \left[-\underset{|}{C}=\underset{|}{C}-\overset{|}{\underset{|}{C}}\cdot \longleftrightarrow -\overset{\bullet}{\underset{|}{C}}-\underset{|}{C}=\overset{|}{\underset{|}{C}}\right]$$

Also unsurprising is the fact that allylic rearrangements (see p. 303) are common in these cases.[38]

3. *Alkyl side chains of aromatic rings.* The preferential position of attack on a side chain is usually the one α to the ring. Both for active radicals such as chlorine and phenyl and for less active ones like bromine such attack is faster than that at a primary carbon, but for the active radicals benzylic attack is slower than for tertiary positions, while for the inactive ones it is faster. Two or three aryl groups on a carbon activate its hydrogens even more, as would be expected from the resonance involved. These statements can be illustrated by the following abstraction ratios:[39]

	$Me-H$	$MeCH_2-H$	Me_2CH-H	Me_3C-H	$PhCH_2-H$	Ph_2CH-H	Ph_3C-H
Br	0.0007	1	220	19,400	64,000	1.1×10^6	6.4×10^6
Cl	0.004	1	4.3	6.0	1.3	2.6	9.5

However, many anomalous results have been reported for these substrates. The benzylic position is not always the most favored. One thing which is certain is that *aromatic* hydrogens are seldom abstracted if there are aliphatic ones to compete (note from Table 2, Chapter 5, p. 175, that D for Ph—H is higher than that for any alkyl—H bond which might be present in the same molecule).

4. *Compounds containing electron-withdrawing substituents.* In halogenations electron-withdrawing groups greatly deactivate adjacent positions. Compounds of the type $Z-CH_2-CH_3$ are attacked predominantly or exclusively at the β position when Z is COOH, COCl, CN, COOR, SO_2Cl, or CX_3. Such compounds as acetic acid and acetyl chloride are not attacked at all. This is in sharp contrast to electrophilic halogenations (reactions **2-4** to **2-6**), where *only* the α position is substituted. This deactivation of α positions is also at variance with the expected stability of the resulting radicals, since they would be expected to be stabilized by resonance similar to that for allylic and benzylic radicals. This behavior is a result of the polar transition states discussed on p. 621. Halogen atoms are *electrophilic radicals* and look for positions of high electron density. Positions next to electron-withdrawing groups have low electron densities (because of the field effect of Z) and are therefore shunned. Radicals which are not electrophilic do not display this behavior. For example, the methyl radical is essentially nonpolar and does not avoid positions next to electron-withdrawing groups; relative rates of abstraction at the α and β carbons of propionic acid are:[40]

	CH_3-CH_2-COOH	
Me·	1	7.8
Cl·	1	0.03

---

[38] For reviews, see Wilt, in Kochi, Ref. 34, pp. 458-466; Walling, in Mayo, "Molecular Rearrangements," pp. 431-438, Interscience Publishers, New York, 1963.

[39] Russell, Ref. 34, p. 289.

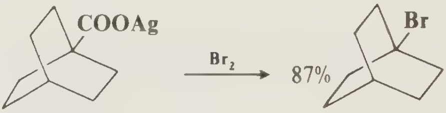
[40] Russell, Ref. 34, p. 311.

Some free radicals, e.g., *t*-butyl (see p. 622), benzyl,[41] 3-heptyl,[10] cyclopropyl,[42] and undecyl,[10] are *nucleophilic*. The phenyl radical appears to have a very small degree of nucleophilic character.[43] For longer chains, the field effect continues, and the β position is also deactivated to attack by halogen, though much less so than the α position. We have already mentioned (p. 621) that abstraction of an α hydrogen atom from ring-substituted toluenes can be correlated by the Hammett equation. A similar correlation with Taft σ_I values (p. 255) has been found for abstraction of hydrogen from substituted adamantanes by the electrophilic radical $\cdot CCl_3$.[44]

Abstraction of a halogen has been studied much less,[45] but the order of reactivity is $RI > RBr > RCl \gg RF$.

Reactivity at a Bridgehead[46]

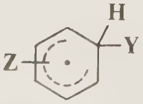
Many free-radical reactions have been observed to occur at bridgehead carbons, e.g. (see reaction **4-39**),[47]



demonstrating that the free radical need not be planar. However, treatment of norbornane with sulfuryl chloride and benzoyl peroxide gave mostly 2-chloronorbornane, although the bridgehead position is tertiary.[48] So, while bridgehead free-radical substitution is possible, it is not preferred, presumably because of the strain involved.[49] It is interesting that the 2-substituted norbornanes formed by free-radical substitutions consist mostly of the exo isomers (see p. 295).

Reactivity in Aromatic Substrates

Free-radical substitution at an aromatic carbon seldom takes place by a mechanism in which a hydrogen is abstracted to give an aryl radical. Reactivity considerations here are similar to those in Chapters 11 and 12; i.e., we need to know which position on the ring will be attacked to give the intermediate



The obvious way to obtain this information is to carry out reactions with various Z groups and to analyze the products for percent ortho, meta, and para isomers, as is so often done for electrophilic substitution. However, this procedure is much less accurate in the case of free-radical

MeO	5.6	1.23	2.31

substitutions because of the many side reactions. It may be, for example, that in a given case the ortho position is more reactive than the para but the intermediate from the para attack may go on to product while that from ortho attack gives a side reaction. In such a case, analysis of the three products will not give a true picture of which position is most susceptible to attack. The following generalizations can nevertheless be drawn, although there has been much controversy over just how meaningful such conclusions are:[50]

1. All substituents increase reactivity at ortho and para positions over that of benzene. There is no great difference between electron-donating and electron-withdrawing groups.

2. Reactivity at meta positions is usually similar to that of benzene, perhaps slightly higher or lower. This fact, coupled with the preceding one, means that all substituents are activating and ortho-para-directing; none are deactivating or (chiefly) meta-directing.

3. Reactivity at ortho positions is usually somewhat greater than at para positions, except where a large group decreases ortho reactivity for steric reasons.

4. In direct competition, electron-withdrawing groups exert a somewhat greater influence than electron-donating groups. Arylation of para-disubstituted compounds XC_6H_4Y showed that substitution ortho to the group X became increasingly preferred as the electron-withdrawing character of X increases (with Y held constant).[51] The increase could be correlated with the Hammett σ_p values for X.

5. Substituents have much less effect than in electrophilic or nucleophilic substitution; hence the partial rate factors (see p. 468) are not great. Partial rate factors for a few groups are given in Table 2.[52]

It should be remembered that in *alternant hydrocarbons*, the position of attack is the same for electrophilic, nucleophilic, and free-radical substitution (see p. 467).[53]

Reactivity in the Attacking Radical[54]

We have already seen that less active radicals are much more selective than active radicals (p. 626). The bromine atom is so selective that when only primary hydrogens are available, as in neopentane or *t*-butylbenzene, the reaction is slow or nonexistent; and isobutane can be selectively brominated to give *t*-butyl bromide in high yields. However, toluene reacts with bromine atoms instantly. Bromination of other alkylbenzenes, e.g., ethylbenzene and cumene, takes place exclusively at the α position,[55] emphasizing the selectivity of Br•. The dissociation energy *D* of the C—H bond is more important for radicals of low reactivity than for highly reactive radicals, since bond breaking in the transition state is greater. Thus, bromine shows a greater tendency than chlorine to attack α to an electron-withdrawing group because the energy of the C—H bond there is lower than in other places in the molecule.

Some free radicals, e.g., triphenylmethyl, are so unreactive that they abstract hydrogens very poorly if at all. Table 3 lists some common free radicals in approximate order of reactivity.[56]

It has been mentioned that some free radicals, e.g., chloro, are electrophilic and some, e.g., *t*-butyl, are nucleophilic. It must be borne in mind that these tendencies are relatively slight compared with the electrophilicity of a positive ion or the nucleophilicity of a negative ion. The predominant character of a free radical is neutral, whether it has slight electrophilic or nucleophilic tendencies.

The Effect of Solvent on Reactivity[58]

As has been noted earlier, the solvent usually has little effect on free-radical substitutions, in contrast to ionic ones: indeed, reactions in solution are often quite similar in character to those in the gas phase, where there is no solvent at all. However, in certain cases the solvent *can* make an appreciable difference. The chlorination of 2,3-dimethylbutane in aliphatic solvents gave about 60% **5** and 40% **6**, while in aromatic solvents the ratio became about 10 : 90:[59]

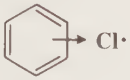
This result is attributed to complex formation between the aromatic solvent and the chlorine atom



7

which makes the chlorine less reactive and more selective.[60] This type of effect is not found in cases where the differences in abstractability are caused by field effects of electron-withdrawing groups (p. 627). In such cases aromatic solvents make little difference.[61] The complex **7** has been detected as a very short-lived species by observation of its visible spectrum in the pulse radiolysis of a solution of benzene in CCl_4.[62] Differences caused by solvents have also been reported in reactions of benzyloxy and *t*-butoxy radicals.[63] Some of the anomalous results obtained in the chlorination of aromatic side chains (p. 627) can also be explained by this type of complexing, in this case not with the solvent but with the reacting species.[64]

REACTIONS

The reactions in this chapter are classified according to leaving group. The most common leaving groups are hydrogen and nitrogen (from the diazonium ion), and these are considered first.[65]

Hydrogen as Leaving Group

A. Substitution by Halogen

4-1 Halogenation at an Alkyl Carbon

$$\mathrm{R{-}H + Cl_2 \xrightarrow{h\nu} R{-}Cl}$$

Alkanes can be chlorinated or brominated by treatment with chlorine or bromine in the presence of visible or uv light.[66] The reaction also can be applied to alkyl chains containing many functional

Mack Library
Bob Jones University

groups. The reaction is usually not useful for preparative purposes precisely because it is so general: not only does substitution take place at virtually every alkyl carbon in the molecule, but di- and polyhalogen substitution almost invariably occurs also, even if there is a large molar ratio of substrate to halogen. Thus methane always gives chloro-, dichloro-, trichloro-, and tetrachloromethane, in ratios which differ depending on the initial molar ratio of methane to chlorine, but all four products are always obtained. When functional groups are present, the principles are those outlined on p. 627: favored positions are those α to aromatic rings, while positions α to electron-withdrawing groups are least likely to be substituted. Tertiary carbons are most likely to be attacked and primary least. Positions α to an OR group are very readily attacked. Nevertheless, mixtures are nearly always obtained. This can be contrasted to the specificity of electrophilic halogenation (reactions **2-4** to **2-6**), which always takes place α to a carbonyl group (except when the reaction is catalyzed by $AgSbF_6$; see following). Of course, if a *mixture* of halides is wanted, the reaction is usually quite satisfactory and indeed it is of considerable industrial importance. For obtaining pure compounds, the chlorination reaction is essentially limited to substrates which have only one type of replaceable hydrogen, e.g., ethane, cyclohexane, neopentane. The most common of these are substrates which have methyl groups on aromatic rings, e.g., toluene and the xylenes, since few cases are known where halogen atoms substitute at an aromatic position.[67] Of course, ring substitution *does* take place in the presence of a positive-ion-forming catalyst (reaction **1-12**). In addition to mixtures of various alkyl halides, traces of other products are obtained. These include hydrogen gas, olefins, higher alkanes, lower alkanes, and halogen derivatives of *them.*

Since the bromine atom is less reactive than the chlorine atom, it would be expected that greater specificity would be obtained in brominations, and this is true. As indicated on p. 630, it is often possible to brominate tertiary positions selectively.[68] High specificity may also be obtained where the neighboring-group mechanism (p. 623) can operate.

As already mentioned, halogenation can be performed with chlorine or bromine. Fluorine has also been used,[69] but seldom, because it is too reactive and hard to control.[70] It often breaks carbon chains down into smaller units, a side reaction which sometimes becomes troublesome in chlorinations too. Fluorination has been achieved by the use of fluoroxytrifluoromethane CF_3OF and uv light.[71] For example, cyclohexane gave 44% fluorocyclohexane ($CFCl_3$ solvent, $-78°C$). CF_3OF without uv light fluorinates tertiary positions of certain molecules in good yields with high regiospecificity.[71a] For example, adamantane gave 75% 1-fluoroadamantane. F_2 at $-78°C$, diluted with N_2, gives the same result. These reactions probably have electrophilic (see p. 635) and not free-radical mechanisms.

Iodine can be used if the activating light has a wavelength of 1849 Å,[72] but iodinations are seldom attempted, largely because the HI formed reduces the alkyl iodide. Iodinations have been accomplished in low to moderate yields with "*t*-BuOI," generated in situ from HgI_2 and *t*-BuOCl.[73]

[73] Tanner and Gidley, *J. Am. Chem. Soc.* **90,** 808 (1968).

Many other halogenation agents have been employed, the most common of which is sulfuryl chloride SO_2Cl_2. The reaction in this case is more rapid and convenient than the one with chlorine itself. A mixture of Br_2 and HgO is a more active brominating agent than bromine alone.[74] The actual brominating agent in this case is believed to be bromine monoxide Br_2O. Other agents used have been N-bromosuccinimide (see reaction **4-2**), CCl_4, oxalyl chloride, $BrCCl_3$,[75] PCl_5,[76] phosgene, *t*-butyl hypobromite[77] and hypochlorite[78] (see also reaction **4-42**), N-haloamines and sulfuric acid,[79] and trichloromethanesulfonyl chloride and bromide.[80] In all these cases a chain-initiating catalyst is required, usually peroxides or uv light.

When chlorination is carried out with N-haloamines and sulfuric acid (catalyzed by either uv light or metal ions), selectivity is much greater than with other reagents.[79] In particular, alkyl chains are chlorinated with high regioselectivity at the position next to the end of the chain (the $\omega - 1$ position). Some typical selectivity values are[81]

$$\underset{1}{CH_3}-\underset{56}{CH_2}-\underset{29}{CH_2}-\underset{14}{CH_2}-CH_2-CH_2-CH_3 \qquad \text{Ref. 82}$$

$$\underset{1}{CH_3}-\underset{92}{CH_2}-\underset{3}{CH_2}-\underset{1}{CH_2}-\underset{1}{CH_2}-\underset{2}{CH_2}-\underset{0}{CH_2}-\underset{0}{CH_2}-OH \qquad \text{Ref. 83}$$

$$\underset{3}{CH_3}-\underset{72}{CH_2}-\underset{20}{CH_2}-\underset{4}{CH_2}-\underset{1}{CH_2}-\underset{0}{CH_2}-COOMe \qquad \text{Ref. 84}$$

Furthermore, di- and polychlorination are much less prevalent. Adamantane and bicyclo[2.2.2]-octane are predominantly chlorinated at the bridgeheads by this procedure.[85] The reasons for the high $\omega - 1$ specificity are not clearly understood.[81] Alkyl bromides can be regiospecifically chlorinated one carbon away from the bromine (to give *vic*-bromochlorides) by treatment with PCl_5.[86] Alkyl chlorides can be converted to *vic*-dichlorides by treatment with $MoCl_5$.[86a] For regiospecific chlorination at certain positions of the steroid nucleus, see reaction **9-3.**

In almost all cases, the mechanism involves a free-radical chain:[87]

$$\text{Initiation} \qquad X_2 \xrightarrow{h\nu} 2X\cdot$$

$$\text{Propagation} \qquad RH + X\cdot \longrightarrow R\cdot + XH$$

$$R\cdot + X_2 \longrightarrow RX + X\cdot$$

$$\text{Termination} \qquad R\cdot + X\cdot \longrightarrow RX$$

When the reagent is halogen, initiation occurs as shown above. When it is another reagent, a similar cleavage occurs (catalyzed by light or, more commonly, peroxides), followed by propagation steps which do not necessarily involve abstraction by halogen. For example, the propagation steps for chlorination by *t*-BuOCl are[88]

$$\begin{aligned} RH + t\text{-BuO}\cdot &\longrightarrow R\cdot + t\text{-BuOH} \\ R\cdot + t\text{-BuOCl} &\longrightarrow RCl + t\text{-BuO}\cdot \end{aligned}$$

and the abstracting radicals in the case of N-haloamines are the radical cations $R_2NH\cdot^+$, with the following mechanism (in the case of initiation by Fe^{2+}):[79]

$$\begin{aligned} &\text{Initiation} \qquad R_2NCl \xrightarrow{H^+} R_2\overset{\oplus}{N}HCl \xrightarrow{Fe^{2+}} R_2NH\cdot^+ + FeCl^{2+} \\ &\text{Propagation} \qquad R_2NH\cdot^+ + RH \longrightarrow R_2\overset{\oplus}{N}H_2 + R\cdot \\ &\qquad\qquad\qquad R\cdot + R_2\overset{\oplus}{N}HCl \longrightarrow RCl + R_2NH\cdot^+ \end{aligned}$$

This mechanism is similar to that of the Hofmann-Löffler reaction (**8-46**).

The two propagation steps shown above for X_2 are those which lead directly to the principal products (RX and HX), but many other propagation steps are possible and many occur. Similarly, the only termination step shown is the one that leads to RX, but any two radicals may combine. Thus, products like hydrogen, higher alkanes, and alkyl halides can be accounted for by steps like these (these are for chlorination of methane, but analogous steps can be written for other substrates):

$$\begin{aligned} Cl\cdot + HCl &\longrightarrow Cl{-}Cl + H\cdot \\ H\cdot + H\cdot &\longrightarrow H{-}H \\ CH_3\cdot + CH_3\cdot &\longrightarrow CH_3CH_3 \\ CH_3CH_3 + Cl\cdot &\longrightarrow CH_3CH_2\cdot + HCl \\ CH_3CH_2\cdot + Cl_2 &\longrightarrow CH_3CH_2Cl + Cl\cdot \\ CH_3CH_2\cdot + CH_3CH_2\cdot &\longrightarrow CH_3CH_3 + CH_2{=}CH_2 \\ CH_3CH_2\cdot + CH_3CH_2\cdot &\longrightarrow CH_3CH_2CH_2CH_3 \\ CH_3CH_2\cdot + HCl &\longrightarrow CH_3CH_3 + Cl\cdot \end{aligned}$$

etc.

At least when methane is the substrate, the rate-determining step is

$$CH_4 + Cl\cdot \longrightarrow CH_3\cdot + HCl$$

since an isotope effect of 12.1 was observed at 0°C.[89] For chlorinations, chains are very long, typically 10^4 to 10^6 propagations before a termination step takes place.

[89] Wiberg and Motell, *Tetrahedron* **19**, 2009 (1963).

TABLE 4 Some *D* values[90]

Bond	*D*, kcal/mol	Bond	*D*, kcal/mol	Bond	*D*, kcal/mol
H—F	135	F—F	37	CH_3—F	108
H—Cl	103	Cl—Cl	58	CH_3—Cl	84
H—Br	87	Br—Br	46	CH_3—Br	70
H—I	71	I—I	37	CH_3—I	56

The order of reactivity of the halogens can be explained by energy considerations. For the substrate methane, ΔH values for the two principal propagation steps are:

	kcal/mol			
	F_2	Cl_2	Br_2	I_2
$CH_4 + X\cdot \rightarrow CH_3\cdot + HX$	−31	+1	+17	+33
$CH_3\cdot + X_2 \rightarrow CH_3X + X\cdot$	−71	−26	−24	−19

In each case *D* for CH_3—H is 104 kcal mol, while *D* values for the other bonds involved are given in Table 4.[90] F_2 is so reactive that neither uv light nor any other initiation is needed (total $\Delta H = -102$ kcal mol);[91] while Br_2 and I_2 essentially do not react with methane. The second step is exothermic in all four cases, but it cannot take place before the first, and it is this step which is very unfavorable for Br_2 and I_2. It is apparent that the most important single factor causing the order of halogen reactivity to be $F_2 > Cl_2 > Br_2 > I_2$ is the decreasing strength of the HX bond in the order HF > HCl > HBr > HI. The increased reactivity of secondary and tertiary positions is in accord with the decrease in *D* values for R—H in the order primary > secondary > tertiary (Table 2 in Chapter 5, p. 175). (Note that for chlorination step 1 is exothermic for practically all substrates other than CH_4, since most other C—H bonds are weaker than those in CH_4.)

Bromination and chlorination of alkanes and cycloalkanes can also take place by an electrophilic mechanism if the reaction is catalyzed by $AgSbF_6$.[92] As with free-radical halogenation, mixtures of alkyl halides and other products are obtained. The most reactive positions are tertiary (e.g., *n*-alkanes give no reaction with Br_2 or Cl_2 and $AgSbF_6$), but the chief products are not necessarily the tertiary halides. For example, reaction of Br_2, $AgSbF_6$, and isobutane in a 5 : 1 : 10 ratio at −15°C gave 84% isobutyl bromide and 11% *t*-butyl bromide.[92] The isobutyl bromide is not the initial product but is probably formed by the pathway isobutane → *t*-butyl bromide → isobutene →

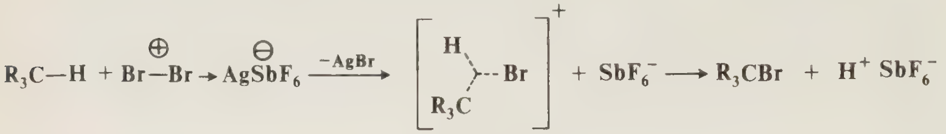
---

[90] Kerr, *Chem. Rev.* **66**, 465–500 (1966); Trotman-Dickenson and Kerr, in Weast, "Handbook of Chemistry and Physics," 51st ed., p. F158 (1970).

[91] For F_2 the following initiation step is possible: $F_2 + RH \rightarrow R\cdot + F\cdot + HF$ [first demonstrated by Miller, Koch, and McLafferty, *J. Am. Chem. Soc.* **78**, 4992 (1956)]. ΔH for this reaction is equal to the small positive value of 4 kcal/mol. The possibility of this reaction (which does not require an initiator) explains why fluorination can take place without uv light (which would otherwise be needed to furnish the 37 kcal/mol necessary to break the F—F bond). Once the reaction has been initiated, the large amount of energy given off by the propagation steps is ample to cleave additional F_2 molecules. Indeed, it is the magnitude of this energy which is responsible for the cleavage of carbon chains by F_2.

[92] Olah and Schilling, *J. Am. Chem. Soc.* **95**, 7680 (1973); Olah, Renner, Schilling, and Mo, *J. Am. Chem. Soc.* **95**, 7686 (1973); See also Olah, Schilling, Renner, and Kerekes, *J. Org. Chem.* **39**, 3472 (1974).

1,2-dibromo-2-methylpropane → isobutyl bromide. The following mechanism, similar to that of reaction **2-16,** has been proposed for the initial reaction:[92]



Electrophilic fluorination has already been mentioned (p. 632).

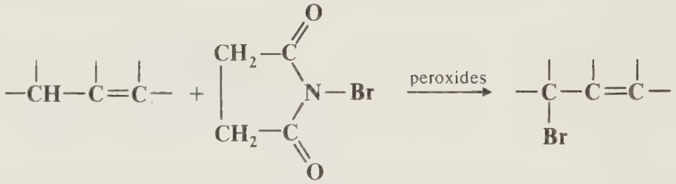
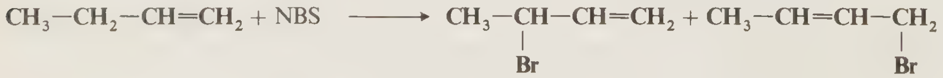
4-2 Allylic Halogenation



This reaction is actually a special case of reaction **4-1,** but it is important enough to be treated separately.[93] Olefins can be halogenated in the allylic position by a number of reagents, of which N-bromosuccinimide (NBS) is by far the most common. When this reagent is used, the reaction is known as *Wohl-Ziegler bromination.* A nonpolar solvent is used, most often CCl_4. Other N-bromo amides, including various N-bromohydantoins and N-bromocaprolactam,[94] have also been used, as have N-bromo-*t*-butylamine,[95] 1,2-dibromo-1,2,3,4-tetrachloroethane[96] (the latter is a *brominating* agent), and 4-bromo-2,4,6-tri-*t*-butyl-2,5-cyclohexadienone.[97] To a much lesser extent, allylic chlorination has been carried out, with N-chlorosuccinimide, N-chloro-N-cyclohexylbenzenesulfonamide,[98] or *t*-butyl hypochlorite.[99] With any reagent an initiator is needed, and this is usually a peroxide or, less often, uv light. When the reagent is NBS and the solvent CCl_4, the progress of the reaction is easily monitored. Both NBS and the reaction by-product (succinimide) are insoluble in CCl_4, but the NBS is denser than the solvent, while succinimide is less dense. Thus the solid at the bottom of the reaction mixture disappears during the course of the reaction and is replaced by solid floating on the surface.

The reaction is usually quite specific at the allylic position, and good yields are obtained. However, when the allylic radical intermediate is unsymmetrical, allylic shifts can take place, so that mixtures of both possible products are obtained, e.g.,



$$CH_3{-}CH_2{-}CH{=}CH_2 + NBS \longrightarrow CH_3{-}\underset{\displaystyle Br}{\underset{|}{CH}}{-}CH{=}CH_2 + CH_3{-}CH{=}CH{-}\underset{\displaystyle Br}{\underset{|}{CH_2}}$$

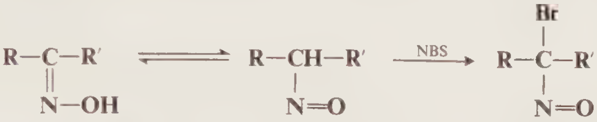
When a double bond has two different α positions, e.g., $CH_3CH{=}CHCH_2CH_3$, a secondary position is substituted more readily than a primary. The relative reactivity of tertiary hydrogen is not clear, though many substitutions at allylic tertiary positions have been performed.[100] It is possible to brominate both sides of the double bond.[101] Because of the electron-withdrawing nature of bromine, the second bromine substitutes on the other side of the double bond rather than α to the first bromine.

NBS is also a highly specific brominating agent at other positions, including positions α to a carbonyl group, to a C≡C triple bond, to a boron atom[102] (see p. 1018), and to an aromatic ring (benzylic position). When both a double and a triple bond are in the same molecule, the preferred position is α to the triple bond.[103] Allylic bromination can also be carried out on oximes, in which case it is the tautomeric nitroso form which is brominated:



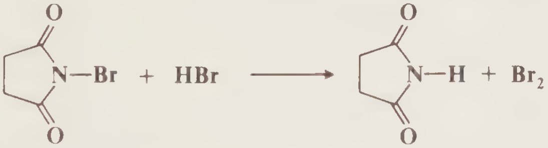
$$\underset{\displaystyle N{-}OH}{R{-}\overset{\|}{C}{-}R'} \rightleftharpoons \underset{\displaystyle N{=}O}{R{-}\overset{|}{CH}{-}R'} \xrightarrow{NBS} \overset{\displaystyle Br}{\underset{\displaystyle N{=}O}{R{-}C{-}R'}}$$

That the mechanism of allylic bromination is of the free-radical type was demonstrated by Dauben and McCoy,[104] who showed that the reaction is very sensitive to free-radical initiators and inhibitors and indeed does not proceed at all unless at least a trace of initiator is present. Subsequent work indicated that the species which actually abstracts hydrogen from the substrate is the bromine atom. The reaction is initiated by small amounts of Br•. Once it is formed, the main propagation steps are

Step 1 $Br\bullet + RH \longrightarrow R\bullet + HBr$

Step 2 $R\bullet + Br_2 \longrightarrow RBr + Br\bullet$

The source of the Br_2 is a fast ionic reaction between NBS and the HBr liberated in step 1:



The function of the NBS is therefore to provide a source of Br_2, in a low, steady-state concentration, and to use up the HBr liberated in step 1.[105] The main evidence for this mechanism is that NBS and Br_2 show similar selectivity[106] and that the various N-bromo amides also show similar selectivity,[107] which is consistent with the hypothesis that the same species is abstracting in each case.[108]

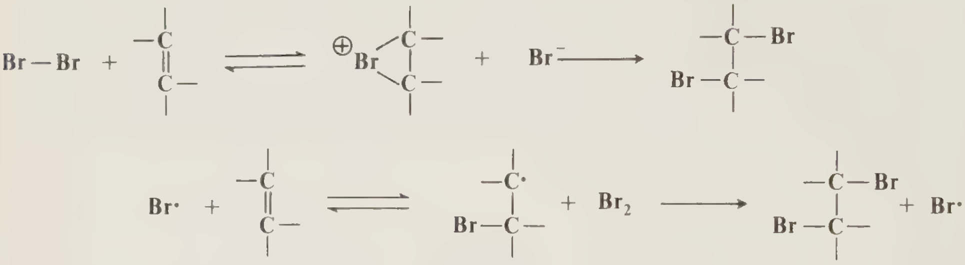
It may be asked why, if Br_2 is the reacting species, it does not add to the double bond, either by an ionic or by a free-radical mechanism (see reaction **5-30**). Apparently the concentration is too low. In bromination of a double bond, only one atom of an attacking bromine molecule becomes attached to the substrate, whether the addition is electrophilic or free-radical:



The other bromine comes from another bromine-containing molecule or ion. If the concentration is sufficiently low, there will not be a high probability that the proper species will be in the vicinity once the intermediate forms and the equilibrium will lie to the left. This slows the rate of addition so that allylic substitution can compete successfully. If this is true, it should be possible to brominate an olefin in the allylic position without competition from addition, even in the absence of NBS or a similar compound, if a very low concentration of bromine is used and if the HBr is removed as it is formed so that it is not available to complete the addition step. This has indeed been demonstrated.[109]

In polar solvents, the mechanism may be entirely different, involving electrophilic attack by Br^+. In protonating solvents the protonated radical **8** may be the abstracting species:[110]

OS **IV**, 108; **V**, 825.

4-3 Halogenation of Aldehydes

$$\mathbf{RCHO + Cl_2 \longrightarrow RCOCl}$$

Aldehydes can be directly converted to acyl chlorides by treatment with chlorine; however, the reaction operates only when the aldehyde does not contain an α hydrogen and even then is not very useful. When there is an α hydrogen, α halogenation (reaction **2-4**) occurs instead. Other sources of chlorine have also been used, among them SO_2Cl_2 [111] and *t*-BuOCl.[112] The mechanisms are probably of the free-radical type.

OS **I**, 155.

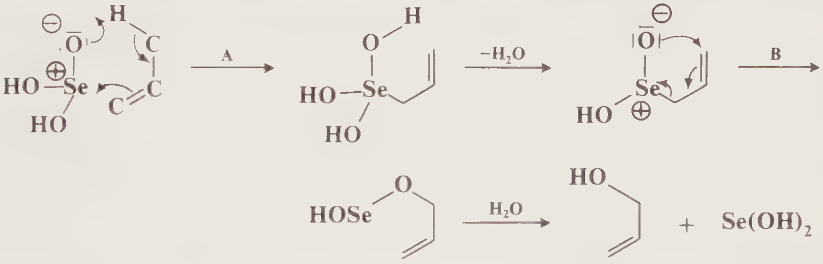
B. Substitution by Oxygen

4-4 Hydroxylation at an Aliphatic Carbon

$$R_3CH \xrightarrow[HOAc\text{-}H_2SO_4]{Na_2Cr_2O_7} R_3COH$$

Compounds containing susceptible C—H bonds can be oxidized to alcohols, though yields are often low.[113] Nearly always, the C—H bond involved is tertiary, so that the product is a tertiary alcohol. This is partly because tertiary C—H bonds are more susceptible to free-radical attack than primary and secondary bonds and partly because the reagents involved would oxidize primary and secondary alcohols further. The reagents may be chromic acid,[114] alkaline permanganate,[115] peracetic acid and uv light,[116] O_3, or H_2O_2 with nitrates or nitrites.[117] Best yields (as high as 99%) are obtained with O_3 when the substrate is adsorbed on silica gel.[117a] When chromic acid is the reagent, the mechanism is probably as follows: a Cr^{6+} species abstracts a hydrogen to give $R_3C\cdot$, which is held in a solvent cage near the resulting Cr^{5+} species. The two species then combine to give R_3COCr^{4+}, which is hydrolyzed to the alcohol. This mechanism predicts retention of configuration; this is largely observed.[118] The oxidation by permanganate also involves predominant retention of configuration, and a similar mechanism has been proposed.[119] The reaction is particularly useful for hydroxylation at bridgeheads, provided that the bridgehead system is large enough; e.g., bicyclo[3.3.1]nonane oxidized with chromic acid gave a 40 to 50% yield of 1-bicyclo[3.3.1]nonanol, but bridged bicyclooctanes gave no significant bridgehead substitution.[120]

Treatment of double-bond compounds with selenium dioxide introduces an OH group into the allylic position (see also reaction **9-16**).[121] Allylic rearrangements are common. There is evidence that the mechanism does not involve free radicals but includes two pericyclic steps (**A** and **B**):[122]



The step marked **A** is similar to the ene synthesis (reaction **5-18**). The step marked **B** is a [2,3]sigmatropic rearrangement (see reaction **8-40**).

Ketones and esters can be α-hydroxylated by treatment of their enolate forms (prepared by adding the ketone or ester to lithium diisopropylamide) with a molybdenum peroxide reagent (MoO_5–pyridine–HMPT) in tetrahydrofuran-hexane at −70°C[123] or by oxidation of their trimethylsilyl enol ethers with *m*-chloroperbenzoic acid.[123a] Yields in both methods are moderate to high. The enolate forms of amides and esters can similarly be converted to their α-hydroxy derivatives by reaction with molecular oxygen.[124] The MoO_5 method can also be applied to certain nitriles.[123]

OS **IV**, 23.

4-5 Hydroxylation at an Aromatic Carbon[124a]

$$\mathbf{ArH + H_2O_2 + FeSO_4 \longrightarrow ArOH}$$

A mixture of hydrogen peroxide and ferrous sulfate,[125] called *Fenton's reagent*,[126] can be used to hydroxylate aromatic rings, though yields are usually not high. Biaryls are usually side products. Among other reagents used have been H_2O_2 and titanous ion; a mixture of ferrous ion, oxygen, ascorbic acid, and ethylenetetraaminetetraacetic acid (*Udenfriend's reagent*);[127] and peracids such as pernitrous and trifluoroperacetic acids. Hydroxylation has also been accomplished by photochemical methods[128] and by exposure of aqueous solutions of aromatic substrates to ionizing radiation, e.g., γ-rays and x-rays, but these methods are seldom used for synthetic purposes.

Much work has been done on the mechanism of the reaction with Fenton's reagent, and it is known that free aryl radicals (formed by a process such as $HO\cdot + ArH \rightarrow Ar\cdot + H_2O$) are not intermediates. The mechanism is essentially that outlined on p. 622, with HO• as the attacking species,[129] formed by

$$\mathbf{Fe^{2+} + H_2O_2 \longrightarrow Fe^{3+} + OH^- + HO\cdot}$$

The rate-determining step is formation of HO• and not its reaction with the aromatic substrate.

Another hydroxylation reaction is the *Elbs reaction*.[130] In this method phenols can be oxidized to *para*-diphenols with $K_2S_2O_8$ in alkaline solution. Primary, secondary, or tertiary aromatic amines give predominant or exclusive ortho substitution unless both ortho positions are blocked, in which case para substitution is found. The reaction with amines is called the *Boyland-Sims oxidation*. Yields are low with either phenols or amines, generally under 50%. The mechanisms are not clear but may involve attack by $S_2O_8^{2-}$ at the oxygen or nitrogen, followed by rearrangement to the products.[131]

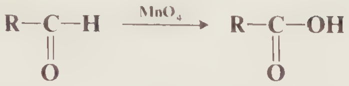
4-6 Oxidation of Aldehydes to Carboxylic Acids



$$\mathrm{R{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}H \xrightarrow{MnO_4} R{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}OH}$$

Oxidation of aldehydes to carboxylic acids is one of the most common oxidation reactions in organic chemistry[132] and has been carried out with many oxidizing agents, the most popular of which is permanganate in acid, basic, or neutral solution. Chromic acid and bromine are other reagents frequently employed. Silver oxide is a fairly specific oxidizing agent for aldehydes and does not readily attack other groups. Benedict's and Fehling's solutions oxidize aldehydes,[133] and a test for aldehydes depends on this reaction, but the method is seldom used for preparative purposes and in any case gives very poor results with aromatic aldehydes. Aldehydes are also oxidized to carboxylic acids by atmospheric oxygen, but the actual direct oxidation product in this case is the peracid RCO_3H,[134] which with another molecule of aldehyde disproportionates to give two molecules of acid (see reaction **4-8**).[135] The disproportionation evidently takes place by formation of an adduct between the perester and the aldehyde, which then decomposes to the products.[136] The structure of the adduct, which can be isolated, has been shown by nmr to be RC(=O)—O—O—CH(OH)R.[137]

Mechanisms of aldehyde oxidation[138] are not firmly established, but there seem to be at least two main types, a free-radical mechanism and an ionic one. In the free-radical process, the aldehydic hydrogen is abstracted to leave an acyl radical, which obtains OH from the oxidizing agent. In the ionic process, the first step is addition of a species OZ^- to the carbonyl bond, to give **9** in alkaline solution and **10** in acid or neutral solution. The aldehydic hydrogen of **9** or **10** is then lost as a proton, to a base, while Z leaves with its electron pair.

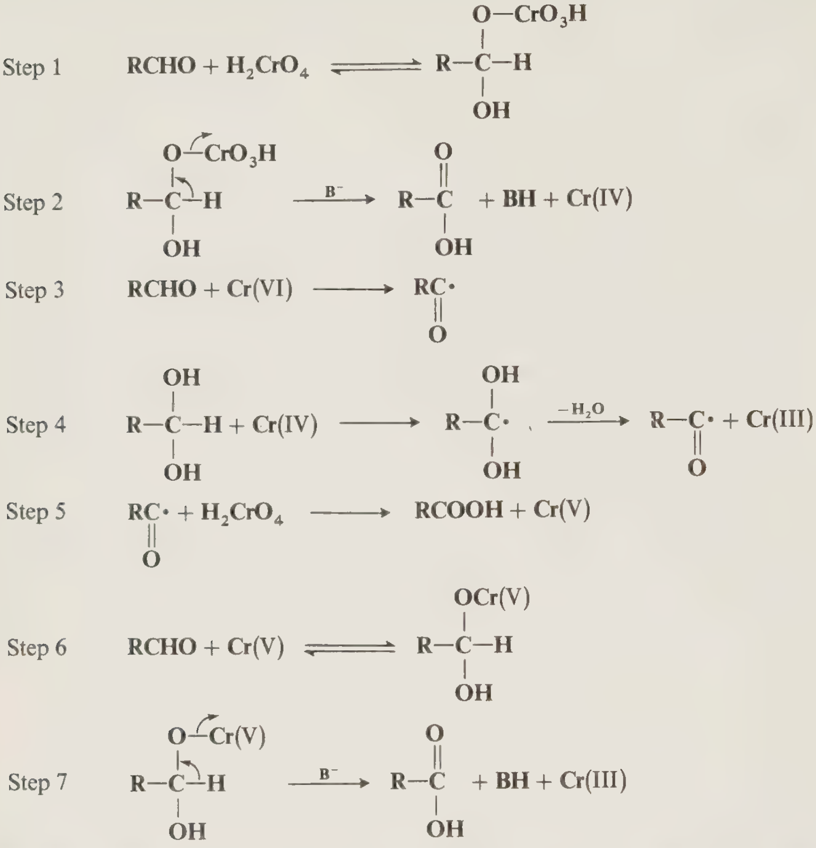
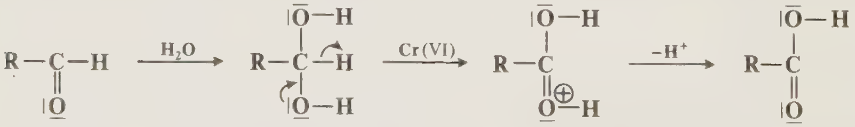
[138] For a review, see Roček, in Patai, "The Chemistry of the Carbonyl Group," vol. 1, pp. 461–505, Interscience Publishers, New York, 1966.

For oxidations with acid dichromate the picture seems to be quite complex, with several processes of both types going on:[139]



Steps 1 and 2 represent an oxidation by the ionic pathway by Cr(VI), and steps 6 and 7 a similar oxidation by Cr(V), which is produced in a free-radical process. Either Cr(VI) (step 3) or Cr(IV) (step 4) [Cr(IV) is produced in step 2] may abstract a hydrogen, and the resulting acyl radical is converted to carboxylic acid in step 5. Thus, chromium in three oxidation states is instrumental in oxidizing aldehydes. Still another possible process has been proposed in which the aldehydic hydrogen of a hydrated aldehyde molecule is removed by the dichromate as a *hydride ion:*[140]



This process is essentially nucleophilic substitution by the tetrahedral mechanism (see p. 308).

The mechanism with permanganate is less well known, but an ionic mechanism has been proposed for neutral and acid permanganate, similar to steps 1 and 2 for dichromate:

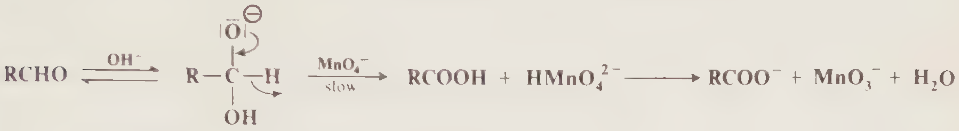
$$\mathrm{RCHO} + \mathrm{HMnO_4} \longrightarrow \mathrm{R{-}\overset{\overset{\large O-MnO_3}{|}}{\underset{\underset{\large OH}{|}}{C}}{-}H} \xrightarrow{B^-} \mathrm{R{-}\overset{\overset{\large O}{\|}}{\underset{\underset{\large OH}{|}}{C}}} + \mathrm{MnO_3^-} + \mathrm{BH}$$

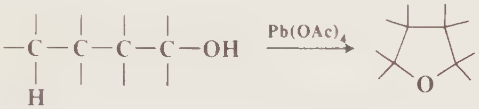
For alkaline permanganate, the following mechanism has been proposed:[141]



$$\mathrm{Mn(V)} + \mathrm{Mn(VII)} \longrightarrow \mathrm{2Mn(VI)}$$

OS **I**, 166; **II**, 302, 315, 538; **III**, 745; **IV**, 302, 493, 499, 919, 972, 974.

4-7 Formation of Cyclic Ethers



Alcohols which have a hydrogen in the δ position can be cyclized with lead tetraacetate.[142] The reaction is usually carried out at about 80 C (most often in refluxing benzene) but can also be done at room temperature if the reaction mixture is irradiated with uv light. Tetrahydrofurans are formed in high yields. Little or no four- and six-membered cyclic ethers (oxetanes and tetrahydropyrans, respectively) are obtained even when γ and ε hydrogens are present. The reaction has also been carried out with a mixture of halogen (Br_2 or I_2) and a salt or oxide of silver or mercury (especially HgO or AgOAc),[143] and with ceric ammonium nitrate.[143a] The following mechanism is likely for the lead tetraacetate reaction:[144]

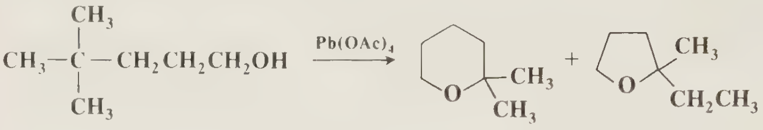
For a review, see Kalvoda and Heusler, *Synthesis* 501–526 (1971).

[143a] See for example, Trahanovsky, Young, and Nave, *Tetrahedron Lett.* 2501 (1969); Doyle, Zuidema, and Bade, *J. Org. Chem.* **40,** 1454 (1975).

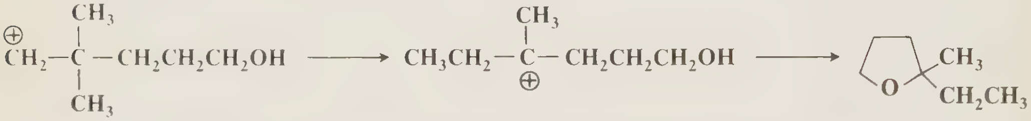
[144] Mihailović, Čeković, Maksimović, Jeremić, Lorenc, and Mamuzić, *Tetrahedron* **21,** 2799 (1965).

although **11** has never been isolated. The step marked **A** is a photochemical cleavage if irradiation is used; otherwise it is a thermal cleavage. The step marked **B** is a 1,5 internal hydrogen abstraction. Such abstractions are well known (see p. 1068) and are greatly favored over 1,4 or 1,6 abstractions (the small amounts of tetrahydropyran formed result from 1,6 abstractions). Evidence for the intermediacy of a carbonium ion is that 4,4-dimethylpentanol, which cannot give a normal product since it has no δ hydrogen, gave 1% of the rearranged product 2-methyl-2-ethyltetrahydrofuran (**12**) in addition to 4 to 6% of the tetrahydropyran:[145]



4–6% **12** 1%

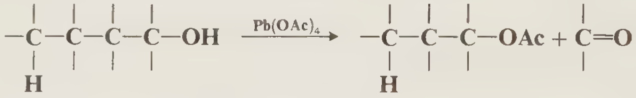
In this case the initial abstraction was 1,6, since a 1,5 abstraction was impossible. **12** was formed by a 1,2 shift of methyl:



12

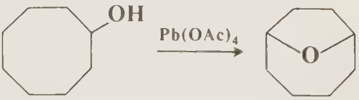
Carbonium ions, but not free radicals, commonly rearrange in this manner (see Chapter 18).

Reactions which sometimes compete are oxidation to the aldehyde or acid (reactions **9-4** and **9-22**) and fragmentation:



$$\underset{\mathrm{H}}{\overset{|}{\underset{|}{-\mathrm{C}}}}-\overset{|}{\underset{|}{\mathrm{C}}}-\overset{|}{\underset{|}{\mathrm{C}}}-\overset{|}{\underset{|}{\mathrm{C}}}-\mathrm{OH} \xrightarrow{\mathrm{Pb(OAc)_4}} \underset{\mathrm{H}}{\overset{|}{\underset{|}{-\mathrm{C}}}}-\overset{|}{\underset{|}{\mathrm{C}}}-\overset{|}{\underset{|}{\mathrm{C}}}-\mathrm{OAc} + \overset{|}{\underset{|}{\mathrm{C}}}{=}\mathrm{O}$$

Tetrahydrofuran formation decreases and fragmentation increases in the order primary, secondary, tertiary alcohol, and in the order β-unsubstituted, β-monomethyl-substituted, β,β-dimethyl-substituted alcohol.[146] When the OH group is on a ring of at least seven members, a transannular product may be formed, e.g.,[147]



There are no references in *Organic Syntheses*, but see OS **V**, 692, for a related reaction.

4-8 Formation of Hydroperoxides

$$\mathrm{RH} + \mathrm{O_2} \longrightarrow \mathrm{R{-}O{-}O{-}H}$$

The slow atmospheric oxidation (*slow* meaning without combustion) of a C—H bond to a

---

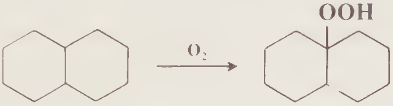
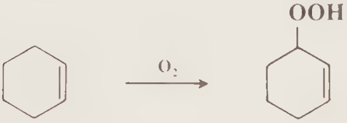
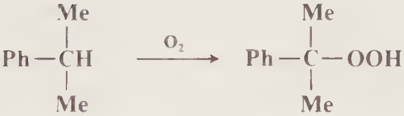
[147] Cope, Gordon, Moon, and Park, *J. Am. Chem. Soc.* **87**, 3119 (1965); Moriarty and Walsh, *Tetrahedron Lett.* 465 (1965); Mihailović, Čeković, Andrejević, Matić, and Jeremić, *Tetrahedron* **24**, 4947 (1968).

C—O—O—H group is called *autoxidation.*[148] The reaction occurs when compounds are allowed to stand in air and is catalyzed by light, so that unwanted autoxidations can be greatly slowed by keeping the compounds in dark places. The hydroperoxides produced often react further, to alcohols, ketones, and more complicated products, so that the reaction is not often used for preparative purposes, although in some cases hydroperoxides have been prepared in good yield. It is because of autoxidation that foods, rubber, paint, lubricating oils, etc., deteriorate on exposure to the atmosphere over periods of time. On the other hand, a useful application of autoxidation is the atmospheric drying of paints and varnishes. As with other free-radical reactions of C—H bonds, some bonds are attacked more readily than others,[149] and these are the ones we have seen before (pp. 626–628), although the selectivity is very low at high temperatures and in the gas phase. The reaction can be carried out successfully at tertiary (to a lesser extent, secondary), allylic (though allylic rearrangements are common), and benzylic R.[150] The following are actual examples:

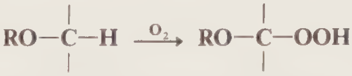






$$\mathrm{Ph{-}\overset{\displaystyle Me}{\underset{\displaystyle Me}{C}}H \xrightarrow{O_2} Ph{-}\overset{\displaystyle Me}{\underset{\displaystyle Me}{C}}{-}OOH}$$

Another susceptible position is aldehydic C—H, but the peracids so produced are not easily isolated[134] since they are converted to the corresponding carboxylic acids (reaction **4-6**). The α positions of ethers are also easily attacked by oxygen:



$$\mathrm{RO{-}\overset{|}{\underset{|}{C}}{-}H \xrightarrow{O_2} RO{-}\overset{|}{\underset{|}{C}}{-}OOH}$$

but the resulting hydroperoxides are almost never isolated. However, this reaction constitutes a hazard in the storage of ethers since solutions of these hydroperoxides and their rearrangement products in ethers are potential spontaneous explosives.[151]

---

[148] The term autoxidation actually applies to any slow oxidation with atmospheric oxygen. For reviews see Lloyd, *Methods Free-Radical Chem.* **4,** 1–131 (1973); Betts, *Q. Rev., Chem. Soc.* **25,** 265–288 (1971); Huyser, "Free-Radical Chain Reactions," Ref. 1, pp. 306–312; Chinn, Ref. 113, pp. 29–39, Ingold, *Acc. Chem. Res.* **2,** 1–9 (1969); Mayo, *Acc. Chem. Res.* **1,** 193–201 (1968); Waters, "Mechanisms of Oxidation of Organic Compounds," pp. 6–16, John Wiley & Sons, Inc., New York, 1964, *Prog. Org. Chem.* **5,** 1–46 (1961), pp. 17–26; Hock and Kropf, *Angew. Chem.* **69,** 313–321 (1957); Twigg, *Chem. Ind. (London)* 4–11 (1962); and Frank, *Chem. Rev.* **46,** 155–169 (1950).

[149] For a discussion, see Korcek, Chenier, Howard, and Ingold, *Can. J. Chem.* **50,** 2285 (1972); and previous papers in this series.

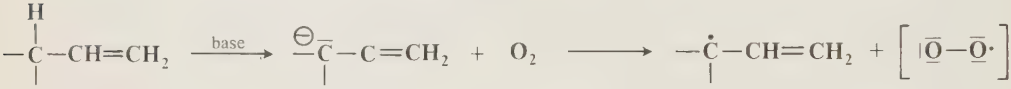
[150] For reviews of autoxidation at allylic and benzylic positions, see Voronenkov, Vinogradov, and Belyaev, *Russ. Chem. Rev.* **39,** 944–952 (1970); Bateman, *Q. Rev., Chem. Soc.* **8,** 147–167 (1954).

[151] For methods of detection and removal of peroxides from ether solvents, see Gordon and Ford, "The Chemist's Companion," p. 437, John Wiley & Sons, Inc., New York, 1972.

Oxygen itself (a diradical) is too unreactive to be the species which actually abstracts the hydrogen. But if a trace of free radical (say R′•) is produced by some initiating process, *it* reacts with oxygen to give R′—O—O•, and since this type of radical *does* abstract hydrogen, the chain is

$$\begin{aligned} R'OO\cdot + RH &\longrightarrow R\cdot + R'OOH \\ R\cdot + O_2 &\longrightarrow R\text{—}O\text{—}O\cdot \\ &\text{etc.} \end{aligned}$$

In at least some cases (in alkaline media)[152] the radical R• can be produced by formation of a carbanion and its oxidation (by O_2) to a radical, e.g.,[153]



$$\text{H—}\underset{|}{\overset{|}{C}}\text{—CH=CH}_2 \xrightarrow{\text{base}} {}^{\ominus}\underset{|}{\bar{C}}\text{—C=CH}_2 + O_2 \longrightarrow \text{—}\underset{|}{\dot{C}}\text{—CH=CH}_2 + \left[\,|\bar{O}\text{—}\bar{O}\cdot\,\right]^-$$

Autoxidations in alkaline media may also proceed by a different mechanism: R—H + base → $R^- + O_2 \rightarrow ROO^-$.[154]

When alkenes are treated with oxygen which has been photosensitized (p. 218), they are substituted by OOH in the allylic position.[155] Although superficially similar to autoxidation, this reaction is clearly different because 100% allylic rearrangement always takes place. The reagent here is not the ground-state oxygen (a triplet) but an excited singlet state[156] (in which all electrons are paired), and the function of the photosensitization is to promote the oxygen to this singlet state. Singlet oxygen can also be produced by nonphotochemical means, e.g., by the reaction between H_2O_2 and NaOCl[157] or between ozone and triphenyl phosphite.[158] The oxygen generated by either photochemical or nonphotochemical methods reacts with olefins in the same way,[159] and this is evidence that singlet oxygen is the reacting species in the photochemical reaction and not some hypothetical complex between triplet oxygen and the photosensitizer, as had previously been suggested. The fact that 100% allylic rearrangement always takes place is incompatible with a free-radical mechanism, and further evidence that free radicals are not involved comes from the treatment of optically active limonene (**13**) with singlet oxygen. Among

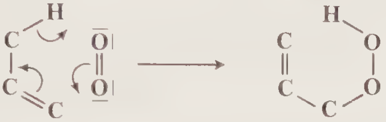
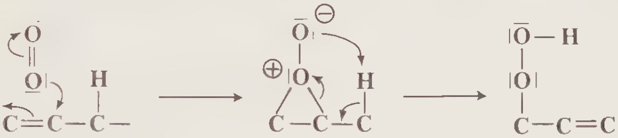
other products is the optically active hydroperoxide **14**, though if **15** were an intermediate, it could not give an optically active product since it possesses a plane of symmetry.[160] In contrast, autoxidation of **13** gave optically inactive **14** (a mixture of four diastereomers in which the two pairs of enantiomers are present as racemic mixtures). As this example shows, singlet oxygen reacts faster with more highly substituted than with less highly substituted alkenes (note that only the trisubstituted double bond of **13** was attacked). The order of alkene reactivity is tetrasubstituted > trisubstituted > disubstituted. Electron-withdrawing substituents deactivate the olefin.[161] Two mechanisms have been proposed for the reaction with singlet oxygen.[162] One of



these is a pericyclic mechanism, similar to that of the ene synthesis (**5-18**) and to the first step of the reaction between alkenes and SeO_2 (reaction **4-4**).[163] The other involves addition of singlet



16

oxygen to the double bond to give a peroxirane (**16**), followed by internal proton transfer.[164]

OS **IV**, 895.

4-9 Formation of Peroxides

$$\mathrm{RH + R'OOH \xrightarrow{CuCl} ROOR'}$$

Peroxy groups (ROO) can be introduced into susceptible organic molecules by treatment with a hydroperoxide in the presence of cuprous chloride or other catalysts, e.g., cobalt and manganese salts.[165] Very high yields may be obtained. The type of hydrogen replaced is similar to that with N-bromosuccinimide (reaction **4-2**), i.e., mainly benzylic, allylic, and tertiary. The mechanism is therefore of the free-radical type, involving ROO• formed from ROOH and the metal ion.

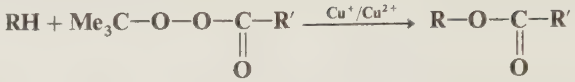
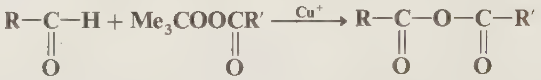
[165] For a review, see Sosnovsky and Rawlinson, Ref. 125, pp. 153–268.

4-10 Acyloxylation



$$\mathrm{RH} + \mathrm{Me_3C{-}O{-}O{-}}\underset{\mathrm{O}}{\underset{\|}{\mathrm{C}}}\mathrm{{-}R'} \xrightarrow{\mathrm{Cu^+/Cu^{2+}}} \mathrm{R{-}O{-}}\underset{\mathrm{O}}{\underset{\|}{\mathrm{C}}}\mathrm{{-}R'}$$

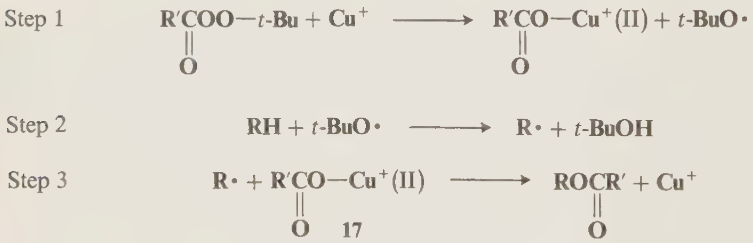
Susceptible positions of organic compounds can be directly acyloxylated by *t*-butyl peresters, the most frequently used being acetic and benzoic ($R' = Me$ or Ph).[166] The reaction requires a catalyst (cuprous ion is the actual catalyst, but a trace is all that is necessary, and such traces are usually present in cupric compounds, so that these are often used) and without it is not selective. Susceptible positions are similar to those in reaction **4-8:** benzylic, allylic, and the α position of ethers (and sulfides). Terminal olefins are substituted almost entirely in the 3 position, i.e., with only a small amount of allylic rearrangement, but internal olefins generally give mixtures containing a large amount of allylic-shift product. If the reaction with olefins is carried out in an excess of another acid R″COOH, the ester produced is of *that* acid ROCOR″. Aldehydes give anhydrides:



$$\mathrm{R{-}}\underset{\mathrm{O}}{\underset{\|}{\mathrm{C}}}\mathrm{{-}H} + \mathrm{Me_3COO}\underset{\mathrm{O}}{\underset{\|}{\mathrm{C}}}\mathrm{R'} \xrightarrow{\mathrm{Cu^+}} \mathrm{R{-}}\underset{\mathrm{O}}{\underset{\|}{\mathrm{C}}}\mathrm{{-}O{-}}\underset{\mathrm{O}}{\underset{\|}{\mathrm{C}}}\mathrm{{-}R'}$$

Acyloxylation has also been achieved with metallic acetates such as lead tetraacetate and mercuric acetate.[167] In this case not only does the reaction take place at allylic and benzylic positions and at those α to an OR or SR group but also at positions α to the carbonyl groups of aldehydes, ketones, or esters and at those α to two carbonyl groups (ZCH_2Z'). It is likely that in the latter cases the reaction takes place through the enol forms of these substrates. Ketones may be α-acetoxylated indirectly by conversion to the enamine (reaction **6-15**) and treatment of this with thallium triacetate.[168] Thallium triacetate also acyloxylates carboxylic acids in the α position.[169] Palladium acetate converts alkenes to vinyl and/or allylic acetates.[170]

Studies of the mechanism of the cuprous-catalyzed reaction show that the most common mechanism is the following:[171]



Step 1 $$\mathrm{R'}\underset{\mathrm{O}}{\underset{\|}{\mathrm{C}}}\mathrm{OO{-}}t\text{-}\mathrm{Bu} + \mathrm{Cu^+} \longrightarrow \mathrm{R'}\underset{\mathrm{O}}{\underset{\|}{\mathrm{C}}}\mathrm{O{-}Cu^+(II)} + t\text{-}\mathrm{BuO}\cdot$$

Step 2 $$\mathrm{RH} + t\text{-}\mathrm{BuO}\cdot \longrightarrow \mathrm{R}\cdot + t\text{-}\mathrm{BuOH}$$

Step 3 $$\mathrm{R}\cdot + \underset{17}{\mathrm{R'}\underset{\mathrm{O}}{\underset{\|}{\mathrm{C}}}\mathrm{O{-}Cu^+(II)}} \longrightarrow \mathrm{RO}\underset{\mathrm{O}}{\underset{\|}{\mathrm{C}}}\mathrm{R'} + \mathrm{Cu^+}$$

---

This mechanism, involving a free radical R•, is compatible with the allylic shifts found.[172] The finding that *t*-butyl peresters labeled with ^{18}O in the carbonyl oxygen gave ester with 50% of the label in each oxygen[173] is in accord with a combination of R• with the intermediate **17**, in which the copper is ionically bound, so that the oxygens are essentially equivalent. Other evidence is that *t*-butoxy radicals have been trapped with dienes.[174]

Free-radical acyloxylation of aromatic substrates has been accomplished by heating with cupric benzoate[175] (see also reaction **3-20**), with benzoyl peroxide iodine,[176] and with cobalt(III) trifluoroacetate.[177] Aromatic substrates can be converted to carbonate esters by treatment with diisopropyl peroxydicarbonate and ceric ammonium nitrate (CAN):[178]

$$\mathrm{ArH + (ROCOO)_2 \xrightarrow{CAN} ArOCOOR + ROH + CO_2} \qquad \mathrm{R = iso\text{-}Pr}$$

Both aromatic and aliphatic substrates can be acyloxylated with lead tetra(trifluoroacetate) $Pb(OOCCF_3)_4$.[179]

C. Substitution by Sulfur

4-11 Chlorosulfonation

$$\mathrm{RH + SO_2 + Cl_2 \xrightarrow{h\nu} RSO_2Cl}$$

The chlorosulfonation of organic molecules with chlorine and sulfur dioxide is called the *Reed reaction*.[180] In scope and in range of products obtained, the reaction is similar to reaction **4-1**. The mechanism is also similar, except that there are two additional main propagation steps:

$$\mathrm{R\cdot + SO_2 \longrightarrow R{-}SO_2\cdot}$$
$$\mathrm{R{-}SO_2\cdot + Cl_2 \longrightarrow R{-}SO_2Cl + Cl\cdot}$$

Chlorosulfenation can be accomplished by treatment with SCl_2 and uv light:[181]

$$\mathrm{RH + SCl_2 \xrightarrow{h\nu} RSCl}$$

D. Substitution by Nitrogen

4-12 Nitration of Paraffins

$$\mathrm{RH + HNO_3 \xrightarrow{400^\circ C} RNO_2}$$

Nitration of paraffins can be carried out in the gas phase, at about 400°C, or in the liquid phase.[182] The reaction is not practical for the production of pure products for any alkane except methane. For other alkanes, not only does the reaction produce mixtures of the mono-, di-, and polynitrated alkanes at every combination of positions, but extensive chain cleavage occurs[183] and to some extent the nitro products are further oxidized. As with reaction **4-1**, the order of preference is tertiary > secondary > primary, and allylic and benzylic positions are especially susceptible. The mechanism of the reaction has been the subject of considerable study. Titov has demonstrated[184] that nitric acid has no effect on paraffins in the absence of nitrogen dioxide (which is, of course, a free radical, since it has a total number of electrons which is odd). This suggests that the abstracting species is NO_2. The principal product-forming steps are

$$\mathrm{RH} + \cdot\mathrm{NO_2} \longrightarrow \mathrm{R}\cdot + \mathrm{HNO_2}$$
$$\mathrm{R}\cdot + \cdot\mathrm{NO_2} \longrightarrow \mathrm{RNO_2}$$

The only purpose of the nitric acid is to furnish a supply of nitrogen dioxide, perhaps by the reaction

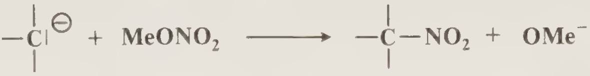
$$\mathrm{NO} + 2\mathrm{HNO_3} \longrightarrow 3\mathrm{NO_2} + \mathrm{H_2O}$$

The NO is presumed to arise by one of the following pathways:

$$\mathrm{N_2O_3} \longrightarrow \mathrm{NO_2} + \mathrm{NO}$$
$$\mathrm{HNO_2} \longrightarrow \mathrm{HO}\cdot + \mathrm{NO}$$

Other evidence for the radical character of the reaction (besides the conclusions drawn from the positions which are preferred) is the fact that racemization is found with optically active substrates.[185]

Activated positions (e.g., ZCH_2Z' compounds) can be nitrated by fuming nitric acid in acetic acid, by acetyl nitrate and an acid catalyst,[185a] or by alkyl nitrates under alkaline conditions.[186] In the latter case it is the carbanionic form of the substrate which is actually nitrated. What is



$$-\underset{|}{\overset{|}{\mathrm{C}}}|^{\ominus} + \mathrm{MeONO_2} \longrightarrow -\underset{|}{\overset{|}{\mathrm{C}}}-\mathrm{NO_2} + \mathrm{OMe^-}$$

isolated under these alkaline conditions is the conjugate base of the nitro compound. Yields are not high. Of course, the mechanism in this case is not of the free-radical type at all but is electrophilic substitution with respect to the carbon (similar to the mechanisms of reactions **2-7** and **2-8**). With respect to the nitrogen it is nucleophilic substitution. Positions activated by only one electron-withdrawing group, e.g., α positions of simple ketones, nitriles, sulfones, or N,N-dialkyl amides, can be nitrated with alkyl nitrates if a very strong base, e.g., *t*-BuOK or $NaNH_2$, is present to convert the substrate to the carbanionic form.[187] Electrophilic nitration of alkanes has been performed with nitronium salts, e.g., $NO_2^+ \; PF_6^-$, and with HNO_3-H_2SO_4 mixtures, but mixtures of nitration and cleavage products are obtained, and yields are generally low.[188]

4-13 The Direct Conversion of Aldehydes to Amides

$$\mathrm{ArCHO} \xrightarrow[\text{nickel peroxide}\ -20^\circ\mathrm{C}]{\mathrm{NH_3}} \mathrm{ArCONH_2}$$

Aromatic and α,β-unsaturated aldehydes can be directly converted to the corresponding amides by treatment with dry ammonia gas and nickel peroxide.[189] Best yields (80 to 90%) are obtained at -25 to -20°C. The reaction has also been performed with MnO_2 and NaCN along with ammonia or an amine at 0°C in isopropyl alcohol.[190] In the nickel peroxide reaction the corresponding alcohols ($ArCH_2OH$) have also been used as substrates.

E. Attack by Carbon In these reactions a new carbon-carbon bond is formed, and they may be given the collective title *coupling reactions.* In each case an alkyl or aryl radical is generated and then combines with another radical (a termination process) or attacks an aromatic ring or olefin to give the coupling product.

4-14 Simple Coupling at a Susceptible Position

$$2\mathrm{RH} \xrightarrow{\text{peroxides}} \mathrm{R{-}R}$$

In this reaction, the peroxide decomposes to give a radical which abstracts a hydrogen from RH to give R•, which dimerizes. Dialkyl and diacyl peroxides have been used, as well as Fenton's reagent (p. 640). This reaction is far from general, although in certain cases respectable yields have been obtained. Among susceptible positions are those at a tertiary carbon,[191] as well as those α to a phenyl group (especially if there is also an α-alkyl or α-chloro group),[192] an ether group,[193] a carbonyl group,[194] a cyano group,[195] a dialkylamino group,[196] or a carboxylic ester group, either the acid or alcohol side.[197]

OS **IV,** 367; **V,** 1026.

4-15 Coupling of Alkynes

$$2\mathrm{R{-}C{\equiv}C{-}H} \xrightarrow[\text{pyridine}]{\mathrm{CuX_2}} \mathrm{R{-}C{\equiv}C{-}C{\equiv}C{-}R}$$

Alkynes which have a hydrogen on one of the triple-bond carbons can be coupled by heating with stoichiometric amounts of cupric salts in pyridine or a similar base. This reaction, which produces symmetrical diynes in high yields, is called the *Eglinton reaction.*[198] The large-ring annulenes of Sondheimer et al. (see p. 64) were prepared by rearrangement and hydrogenation of cyclic polyynes, prepared by Eglinton coupling of terminal diynes, for example:[199]

18 is a cyclic trimer of 1,5-hexadiyne. The corresponding tetramers (C_{24}), pentamers (C_{30}), and hexamers (C_{36}) were also formed.

The Eglinton reaction is of wide scope. Many functional groups may be present on the alkyne. The oxidation is usually quite specific for triple-bond hydrogen. The cuprous ion is a necessary intermediate, but apparently there is always enough present in cupric salts to make the reaction possible. Another common procedure is the use of catalytic amounts of cuprous salts in the presence of ammonia or ammonium chloride (this method is called the *Glaser reaction*). Atmospheric oxygen or some other oxidizing agent such as permanganate or hydrogen peroxide is required in the latter procedure. This method is not satisfactory for cyclic coupling. Unsymmetrical diynes can be prepared by *Cadiot-Chodkiewicz* coupling:[200]

$$\mathrm{R{-}C{\equiv}C{-}H + R'{-}C{\equiv}C{-}Br \xrightarrow{Cu^+} R{-}C{\equiv}C{-}C{\equiv}C{-}R' + HBr}$$

This may be regarded as a variation of reaction **0-102** but must have a different mechanism since acetylenic halides give the reaction but ordinary alkyl halides do not, and this is hardly compatible with a nucleophilic mechanism. However, the mechanism is not fully understood. Propargyl halides also give the reaction.[201] A variation of the Cadiot-Chodkiewicz method consists of treating a haloalkyne ($R'C{\equiv}CX$) with a copper acetylide ($RC{\equiv}CCu$).[202] The Cadiot-Chodkiewicz procedure can be adapted to the preparation of diynes in which $R' = H$ by the use of $BrC{\equiv}CSiEt_3$ and subsequent cleavage of the $SiEt_3$ group.[203] This protecting group can also be used in the Eglinton or Glaser methods.[204]

The mechanism of the Eglinton and Glaser reactions probably begins with loss of a proton

$$\mathrm{R{-}C{\equiv}C{-}H \xrightarrow[Cu^+]{base} R{-}C{\equiv}C^- + Cu^+}$$

---

since there is a base present and acetylenic protons are acidic. The last step is probably the coupling of two free radicals:

$$2\text{R—C}{\equiv}\text{C}\cdot \longrightarrow \text{R—C}{\equiv}\text{C—C}{\equiv}\text{C—R}$$

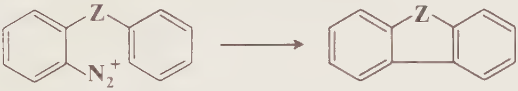
but just how the carbanion becomes oxidized to the radical and what part the cuprous ion plays (other than forming the acetylide salt) are matters of considerable speculation,[205] and depend on the oxidizing agent. It is known, of course, that cuprous ion can form complexes with triple bonds.

OS **V,** 517; **50,** 97; **54,** 1.

4-16 Arylation of Aromatic Compounds by Diazonium Salts

$$\text{ArH} + \text{Ar}'\text{N}_2{}^+ \ \ \text{X}^- \xrightarrow{\text{OH}^-} \text{Ar—Ar}'$$

When the normally acidic solution of a diazonium salt is made alkaline, the aryl portion of the diazonium salt can couple with another aromatic ring. Known as the *Gomberg* or *Gomberg-Bachmann reaction*,[206] it has been performed on several types of aromatic ring, including ferrocenes,[207] and on quinones. Yields are not high (usually under 40%) because of the many side reactions undergone by diazonium salts. The conditions of the Meerwein reaction (**4-17**), treatment of the solution with a copper-ion catalyst, have also been used, as has the addition of sodium nitrite in dimethyl sulfoxide (to benzene diazonium fluoborate in dimethyl sulfoxide).[208] When the Gomberg-Bachmann reaction is performed intramolecularly, either by the alkaline solution or by the copper-ion procedure, it is called the *Pschorr ring closure*[209] and yields are usually somewhat higher. Still higher yields have been obtained by carrying out the Pschorr reaction electrochemically.[210] The Pschorr reaction has been carried out for $\text{Z} = \text{CH}{=}\text{CH}$, CH_2CH_2, NH, $\text{C}{=}\text{O}$, CH_2, and quite a few others. A rapid and convenient way to carry out the Pschorr synthesis is to diazotize the amine substrate with isopropyl nitrite in the presence of sodium iodide, in which case the ring-closed product is formed in one step.[211]



Other compounds with nitrogen-nitrogen bonds have been used instead of diazonium salts. Among these are N-nitroso amides [Ar—N(NO)—COR], triazenes, and azo compounds. Still another method involves treatment of an aromatic primary amine directly with an alkyl nitrite in an aromatic substrate as solvent.[212]

In each case the mechanism involves generation of an aryl radical from a *covalent* azo compound. In acid solution diazonium salts are ionic, and their reactions are polar. When they cleave, the product is an aryl cation (see p. 587). However, in neutral or basic solution, diazonium ions are converted to covalent compounds, and these cleave to give free radicals:

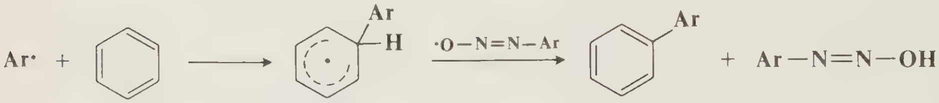
[212] Cadogan, *J. Chem. Soc.* 4257 (1962); Fillipi, Vernin, Dou, Metzger, and Perkins, *Bull. Soc. Chim. Fr.* 1075 (1974).

$$\mathrm{Ar{-}N{=}N{-}Z} \longrightarrow \mathrm{Ar{\cdot}} + \mathrm{N{\equiv}N} + \mathrm{Z{\cdot}}$$

Under Gomberg-Bachmann conditions, the species which cleaves is the anhydride Ar—N=N—O—N=N—Ar:[213]

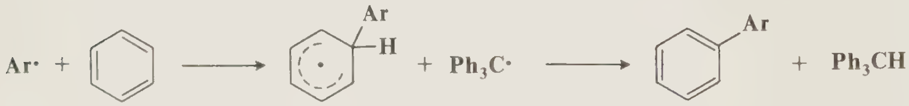
$$\mathrm{Ar{-}N{=}N{-}O{-}N{=}N{-}Ar} \longrightarrow \mathrm{Ar{\cdot}} + \mathrm{N_2} + \mathrm{{\cdot}O{-}N{=}N{-}Ar}$$



19

The aryl radical thus formed attacks the substrate to give the intermediate **19**, from which the radical Ar—N=N—O• abstracts hydrogen to give the product. When the reagent is phenylazotriphenylmethane ($\mathrm{Ph_3C{-}N{=}N{-}Ar}$), the latter cleaves directly and hydrogen is abstracted by the $\mathrm{Ph_3C{\cdot}}$ radical:[214]

$$\mathrm{Ar{-}N{=}N{-}CPh_3} \longrightarrow \mathrm{Ar{\cdot}} + \mathrm{N_2} + \mathrm{Ph_3C{\cdot}}$$



19

Although the triphenylmethyl radical is normally too unreactive to abstract hydrogens, it can do so in this case because of the favorable energy change in the conversion of the radical **19** to a fully aromatic compound. With N-nitroso amides the situation is much more complicated.[215] Here too a covalent azo compound decomposes to give aryl radicals, but several pathways seem to be involved. There is evidence that the reaction with alkyl nitrites also involves attack by aryl radicals.[216]

The Pschorr reaction may take place by two different mechanisms, depending on conditions: (1) attack by an aryl radical (as in the Gomberg-Bachmann reaction) or (2) attack by an aryl cation (similar to the SN1 mechanism discussed on p. 587).[217] Under certain conditions the ordinary Gomberg-Bachmann reaction can also involve attack by aryl cations.[218]

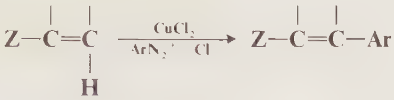
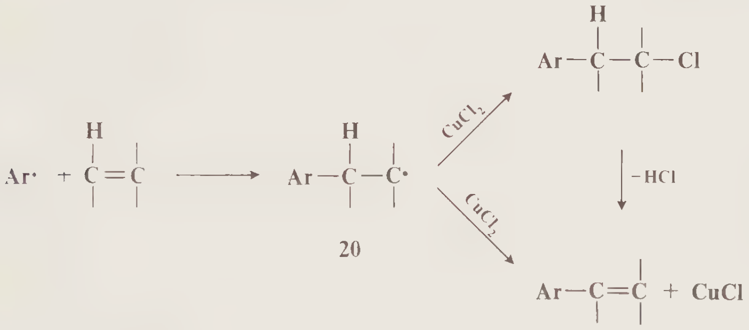
4-17 Arylation of Activated Olefins by Diazonium Salts. Meerwein Arylation



$$\mathrm{Z{-}\overset{|}{C}{=}\underset{H}{\overset{|}{\underset{|}{C}}}} \xrightarrow[\mathrm{ArN_2^+\ Cl^-}]{\mathrm{CuCl_2}} \mathrm{Z{-}\overset{|}{C}{=}\overset{|}{C}{-}Ar}$$

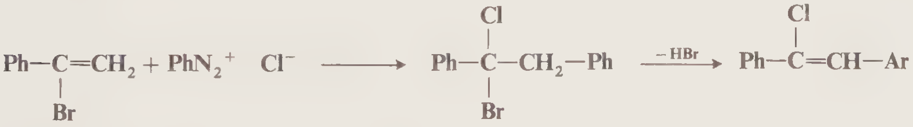
Olefins activated by an electron-withdrawing group (Z may be C=C, halogen, C=O, Ar, CN, etc.) can be arylated by treatment with a diazonium salt and a cupric chloride catalyst.[219] This is called the *Meerwein arylation reaction.* Addition of ArCl to the double bond (to give $\mathrm{Z{-}\overset{|}{\underset{Cl}{C}}{-}\overset{|}{\underset{H}{C}}{-}Ar}$) is a side reaction (reaction **5-37**). The reaction gives best results on quinones, cinnamic acid derivatives, and other activated olefins, but it has been performed even on unactivated compounds such as ethylene and acetylene. The reaction can be carried out without the catalyst, but yields are lower.

The mechanism is probably of the free-radical type, with Ar• forming as in reaction **4-25** and then[220]



20

The radical **20** may react with cupric chloride by two pathways, one of which leads to addition and the other to substitution. Even when the addition pathway is taken, however, the substitution product may still be formed by subsequent elimination of HCl.[221] In the reaction between diazonium chlorides and α-bromostyrene the substitution product was definitely formed by addition-elimination, since the product was α-*chloro*stilbene:[222]



$$\mathrm{Ph{-}\underset{Br}{C}{=}CH_2 + PhN_2^+\ \ Cl^-} \longrightarrow \mathrm{Ph{-}\overset{Cl}{\underset{Br}{C}}{-}CH_2{-}Ph} \xrightarrow{-\mathrm{HBr}} \mathrm{Ph{-}\overset{Cl}{C}{=}CH{-}Ar}$$

4-18 Arylation and Alkylation of Olefins by Organopalladium Compounds

$$R_2C{=}CH_2 + \text{“ArPdX”} \longrightarrow R_2C{=}CH{-}Ar$$

Arylation of olefins can also be achieved[223] by treatment with an “arylpalladium” reagent which can be generated in situ by three methods: (1) by treatment of an aryl iodide with palladium acetate in the presence of a base such as tributylamine or potassium acetate (ArI → “ArPdI”);[224] (2) by treatment of an arylmercury compound (either Ar_2Hg or ArHgX) with $LiPdCl_3$ (ArHgX → “ArPdX”)[225] (in some cases other group VIII metal salts have been used); or (3) by the reaction of an aromatic compound with palladium acetate or palladium metal and silver acetate in acetic acid; in this case an aryl *hydrogen* is replaced (ArH → “ArPdOAc”).[226]

Unlike reaction **4-17**, this reaction is not limited to activated substrates. The substrate may be a simple olefin, or it may contain a variety of functional groups, such as ester, keto, or cyano groups. Primary and secondary allylic alcohols give aldehydes or ketones which are products of double-bond migration,[226a] e.g.,

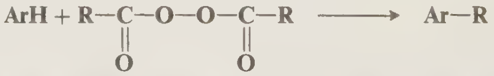
$$CH_2{=}CH{-}CH_2OH \xrightarrow{\text{“PhPdCl”}} PhCH_2CH_2CHO$$

Ethylene is the most reactive olefin. Increasing substitution lowers the reactivity. Substitution therefore takes place at the less highly substituted side of the double bond.[227] Alkylation can also be accomplished, but only if the alkyl group lacks a β-hydrogen; e.g., the reaction is successful for the introduction of methyl, benzyl, and neopentyl groups.[228] However, vinyl groups, even those possessing β-hydrogens, have been successfully introduced (to give 1,3-dienes) by the reaction of the olefin with a vinyl halide in the presence of a trialkylamine and a catalytic amount of $Pd(PPh_3)_2(OAc)_2$ at 100 to 150°C.[229]

The mechanisms are not completely known, but it is likely that in all three methods an addition-elimination reaction (addition of ArPdX followed by elimination of HPdX) is involved.[230] Methods 2 and 3 are stereospecific, yielding products expected from syn addition followed by syn elimination.[231]

OS **51,** 17.

4-19 Alkylation and Arylation of Aromatic Compounds by Peroxides



$$ArH + R{-}\underset{\underset{O}{\|}}{C}{-}O{-}O{-}\underset{\underset{O}{\|}}{C}{-}R \longrightarrow Ar{-}R$$

Arylation by peroxides is most often carried out with R = aryl, so that the net result is the same

[223] For reviews of this and related reactions, see Moritani and Fujiwara, *Synthesis* 524–533 (1973); Jira and Freiesleben, *Organomet. React.* 3, 1–190 (1972), pp. 84–105; Volkova, Levitin, and Vol'pin, *Russ. Chem. Rev.* **44,** 552 560 (1975).

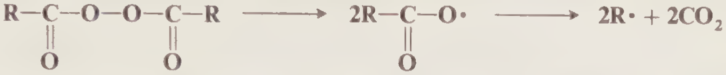
[229] Dieck and Heck, *J. Org. Chem.* **40,** 1083 (1975).

[230] Heck, *J. Am. Chem. Soc.* **91,** 6707 (1969); Shue, *J. Am. Chem. Soc.* **93,** 7116 (1971); Heck and Nolley, Ref. 224.

[231] Heck, Ref. 230; Moritani, Danno, Fujiwara, and Teranishi, *Bull. Chem. Soc. Jpn.* **44,** 578 (1971).

as in reaction **4-16**, though the reagent is different.[232] It is used less often than reaction **4-16**, but the scope is similar. When R = alkyl, the scope is more limited.[233] Only certain aromatic compounds, particularly benzene rings with two or more nitro groups, and fused ring systems, can be alkylated by this procedure. 1,4-Quinones can be alkylated with diacyl peroxides or with lead tetraacetate (methylation occurs with this reagent).

The mechanism involves attack on the substrate by free radicals formed by



$$\mathrm{R{-}\underset{\displaystyle \overset{\|}{O}}{C}{-}O{-}O{-}\underset{\displaystyle \overset{\|}{O}}{C}{-}R \longrightarrow 2R{-}\underset{\displaystyle \overset{\|}{O}}{C}{-}O\cdot \longrightarrow 2R\cdot + 2CO_2}$$

The attack is similar to that shown in reaction **4-16**, to give **19** (CIDNP has been observed[234]). However, in this case, there is no relatively stable free radical (such as Ph—N=N—O• or $Ph_3C\cdot$) present to abstract hydrogen from **19**, so that most of the product arises from dimerization and disproportionation, as shown on p. 623.[235] The addition of a small amount of nitrobenzene increases the yield of arylation product because the nitrobenzene is converted to diphenyl nitroxide, which abstracts the hydrogen from **19**, reducing the extent of side reactions.[236]

Aromatic compounds can also be arylated by aryllead tricarboxylates.[237] Best yields (~70 to 85%) are obtained when the substrate contains alkyl groups; an electrophilic mechanism is likely.

$$\mathrm{ArH + Ar'Pb(OAc)_3 \longrightarrow ArAr'}$$

OS V, 51. See also OS V, 952.

4-20 Photochemical Arylation of Aromatic Compounds

$$\mathrm{ArI + Ar'H \xrightarrow{h\nu} ArAr'}$$

Another free-radical arylation method consists of the photolysis of aryl iodides in an aromatic solvent.[238] Yields are generally higher than in reaction **4-16** or **4-19**. The aryl iodide may contain OH or COOH groups. The mechanism is similar to that of reaction **4-16**. Aryl radicals, generated by the photolytic cleavage ArI → Ar• + I•, attack the substrate to give **19**, from which hydrogen is abstracted by the I• atom. The reaction has been applied to intramolecular arylation (analogous to the Pschorr reaction).[239]

A similar reaction is photolysis of an arylthallium bis(trifluoroacetate) (reaction **2-20**) in an aromatic solvent. Here too, an unsymmetrical biaryl is produced in good yields.[240] In this case

$$\mathrm{ArTl(OCOCF_3)_2 \xrightarrow[Ar'H]{h\nu} ArAr'}$$

it is the C—Tl bond which is cleaved to give aryl radicals.

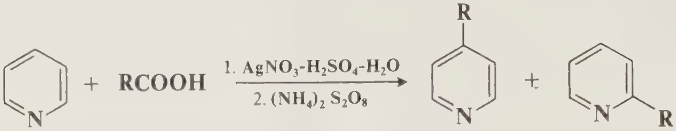
[239] See for example, Kupchan and Wormser, *J. Org. Chem.* **30**, 3792 (1965); Jeffs and Hansen, *J. Am. Chem. Soc.* **89**, 2798 (1967); Thyagarajan, Kharasch, Lewis, and Wolf, *Chem. Commun.* 614 (1967).

[240] Taylor, Kienzle, and McKillop, *J. Am. Chem. Soc.* **92**, 6088 (1970).

A PhC≡C group can be introduced into an aromatic ring by photolysis of 1-iodo-2-phenylacetylene in an aromatic solvent:[241]

$$\text{PhC}{\equiv}\text{CI} + \text{ArH} \xrightarrow{h\nu} \text{ArC}{\equiv}\text{CPh}$$

4-21 Alkylation and Acylation of Nitrogen Heterocycles[242]

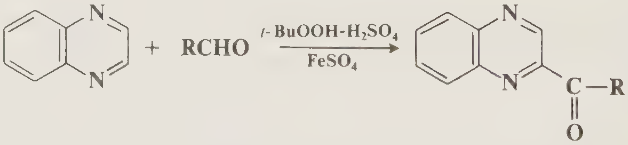


Alkylation of protonated nitrogen heterocycles (e.g., pyridines, quinolines) can be accomplished by treatment with a carboxylic acid, silver nitrate, sulfuric acid, and ammonium peroxydisulfate.[243] R may be primary, secondary, or tertiary. The attacking species is R•, formed by[244]

$$2\text{Ag}^+ + \text{S}_2\text{O}_8{}^{2-} \longrightarrow 2\text{Ag}^{2+} + 2\text{SO}_4{}^{2-}$$
$$\text{RCOOH} + \text{Ag}^{2+} \longrightarrow \text{RCOO}\cdot + \text{H}^+ + \text{Ag}^+$$
$$\text{RCOO}\cdot \longrightarrow \text{R}\cdot + \text{CO}_2$$

Similar alkylation can also be accomplished with other reagents, including hydroperoxides and FeSO_4;[245] and carboxylic acids and lead tetraacetate. Alcohols and ethers can be used instead of carboxylic acids to supply the free radicals, in this case α-hydroxy and α-alkoxy radicals.[246]

Protonated nitrogen heterocycles can be acylated by treatment with an aldehyde, *t*-butyl hydroperoxide, sulfuric acid, and ferrous sulfate, e.g.,[247]



A formyl group can be introduced indirectly (though yields are not high) by treating the substrate with trioxane, Fenton's reagent, and H_2SO_4 followed by hydrolysis; e.g.,[248]

[243] Minisci, Bernardi, Bertini, Galli, and Perchinunno, *Tetrahedron* **27**, 3575 (1971); Minisci, Mondelli, Gardini, and Porta, *Tetrahedron* **28**, 2403 (1972).

[244] Anderson and Kochi, *J. Am. Chem. Soc.* **92**, 1651 (1970).

[245] Minisci, Galli, Malatesta, and Caronna, *Tetrahedron* **26**, 4083 (1970); Minisci, Selva, Porta, Barilli, and Gardini, *Tetrahedron* **28**, 2415 (1972).

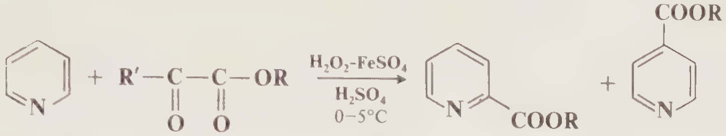
[246] Buratti, Gardini, Minisci, Bertini, Galli, and Perchinunno, *Tetrahedron* **27**, 3655 (1971).

[247] Caronna, Gardini, and Minisci, *Chem. Commun.* 201 (1969); Gardini and Minisci, *J. Chem. Soc. C* 929 (1970); Caronna, Galli, Malatesta, and Minisci, *J. Chem. Soc. C* 1747 (1971); Caronna, Fronza, Minisci, Porta, and Gardini, *J. Chem. Soc., Perkin Trans. 2* 1477 (1972).

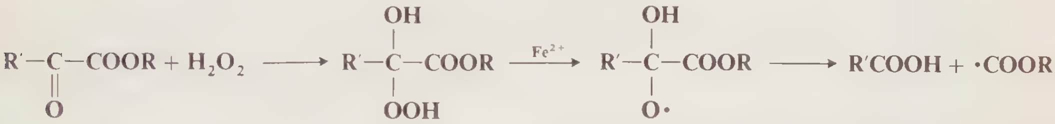
[248] Gardini, *Tetrahedron Lett.* 4113 (1972).

These alkylation and acylation reactions are important because Friedel-Crafts alkylation and acylation (reactions **1-13**, **1-15**) cannot be applied to most nitrogen heterocycles. See also reaction **3-17**.

4-22 Carbalkoxylation and Carboamidation of Nitrogen Heterocycles



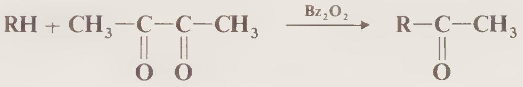
In a reaction related to **4-21**, protonated nitrogen heterocycles can be carbalkoxylated[249] by treatment with •COOR radicals generated from esters of α-keto acids:



$$R'\underset{\underset{O}{\|}}{C}{-}COOR + H_2O_2 \longrightarrow R'{-}\overset{\overset{OH}{|}}{\underset{\underset{OOH}{|}}{C}}{-}COOR \xrightarrow{Fe^{2+}} R'{-}\overset{\overset{OH}{|}}{\underset{\underset{O\cdot}{|}}{C}}{-}COOR \longrightarrow R'COOH + \cdot COOR$$

Similarly, a carbamoyl group can be introduced[250] by the use of the radicals $H_2N\underset{\underset{O}{\|}}{C}\cdot$ or $Me_2N\underset{\underset{O}{\|}}{C}\cdot$, generated from formamide or dimethylformamide and H_2SO_4, H_2O_2, and $FeSO_4$ or other oxidants.

4-23 Free-Radical Acylation and Chlorocarbonylation at an Aliphatic Carbon



$$RH + CH_3{-}\underset{\underset{O}{\|}}{C}{-}\underset{\underset{O}{\|}}{C}{-}CH_3 \xrightarrow{Bz_2O_2} R{-}\underset{\underset{O}{\|}}{C}{-}CH_3$$

Cyclohexane can be acylated by thermal decomposition of benzoyl peroxide in the presence of biacetyl.[251] The reaction has also been carried out with dioxane as substrate (to give 2-acetyldioxane), but the further scope of the reaction has not yet been established.

Chlorocarbonylation (RH →RCOCl) can be accomplished by treatment of the substrate (e.g., pentane, cyclohexane) with oxalyl chloride ClCOCOCl[252] or with CO and CCl_4.[253] using peroxides, uv light, or γ-radiation to initiate the chain.

N_2 as Leaving Group[254]

In these reactions diazonium salts are cleaved to aryl radicals,[255] in most cases with the assistance of copper salts. Reactions **4-16** and **4-17** may also be regarded as belonging to this category with respect to the attacking compound. For nucleophilic substitutions of diazonium salts, see reactions **3-21** to **3-25**.

4-24 Replacement of the Diazonium Group by Hydrogen. Dediazonation

$$\mathbf{ArN_2{}^+ + H_3PO_2 \longrightarrow ArH}$$

Reduction of the diazonium group (*dediazonation*) provides an indirect method for the removal of an amino group from a ring. The best and most common way of accomplishing this is by use of H_3PO_2,[256] although many other reducing agents have also been used, among them ethanol, sodium methoxide in methanol, hydroquinone,[257] alkaline formaldehyde, and sodium stannite. Ethanol was the earliest reagent used, and it frequently gives good yields, but often ethers (ArOEt) are side products. When hypophosphorous acid (H_3PO_2) is used, 5 to 15 mol of this reagent is required per mole of substrate. Diazonium salts can be reduced in nonaqueous media either by treatment with Bu_3SnH or Et_3SiH in ethers or MeCN[258] or by isolation as the $BF_4{}^-$ salt, and reduction of this with $NaBH_4$ in dimethylformamide.[259] Aromatic amines can be deaminated ($ArNH_2 \rightarrow ArH$) in one laboratory step by treatment with pentyl nitrite in boiling tetrahydrofuran.[260] The corresponding diazonium salt is an intermediate, but it is not necessary to isolate a solution of it.

Not many investigations of the mechanism have been carried out. It is generally assumed that the reaction of diazonium salts with ethanol to produce ethers takes place by an ionic (SN1) mechanism while the reduction to ArH proceeds by a free-radical process.[261] The reduction with H_3PO_2 is also believed to have a free-radical mechanism.[262] The mechanism with NaOMe in MeOH is free-radical at low NaOMe concentrations, but at high concentrations aryl carbanions are involved.[263] In the reduction with $NaBH_4$, an aryldiazene intermediate (ArN=NH) has been demonstrated,[264] arising from nucleophilic attack by $BH_4{}^-$ on the β-nitrogen. Such diazenes can be obtained as moderately stable (half-life of several hours) species in solution by the decarboxylation of aryldiazenecarboxylate ions ($ArN{=}NCOO^-$).[265] It is not entirely clear how the aryldiazene decomposes, but there are indications that either the aryl radical Ar• or the corresponding anion Ar^- may be involved.[266]

An important use of the dediazonation reaction is to remove an amino group after it has been used to direct one or more other groups to ortho and para positions. For example, the compound 1,3,5-tribromobenzene cannot be prepared by direct bromination of benzene because the bromo group is ortho-para-directing; however, this compound is easily prepared by the following sequence:

4-25 Replacement of the Diazonium Group by Chlorine or Bromine

$$\mathbf{ArN_2^+ + CuCl \longrightarrow ArCl}$$

Treatment of diazonium salts with cuprous chloride or bromide leads to aryl chlorides or bromides, respectively. In either case the reaction is called the *Sandmeyer reaction.* The reaction can also be carried out with copper and HBr or HCl, in which case it is called the *Gatterman reaction* (not to be confused with reaction **1-18**). The Sandmeyer reaction is not useful for the preparation of fluorides or iodides, but for bromides and chlorides it is of wide scope and is probably the best way of introducing bromine or chlorine into an aromatic ring. The yields are usually high.

The mechanism is by no means known with certainty but is believed to take the following course:[267]

$$\mathbf{ArN_2^+\ X^- + CuX \longrightarrow Ar\cdot + N_2 + CuX_2}$$
$$\mathbf{Ar\cdot + CuX_2 \longrightarrow ArX + CuX}$$

The first step involves a reduction of the diazonium ion by the cuprous ion, resulting in the formation of an aryl radical. In the second step, the aryl radical abstracts halogen from cupric chloride, reducing it. CuX is regenerated and is thus a true catalyst.

Aryl bromides can be prepared from primary aromatic amines in one step by two procedures: (1) by treatment of the amine with a complex of $CuBr_2$ and NO:[268]

$$\mathbf{ArNH_2 + CuBr_2NO \longrightarrow ArBr + H_2O + N_2 + CuBr}$$

(2) by treatment of the amine with pentyl nitrite in the presence of bromoform.[269] Procedure 1 is also applicable to the formation of chlorides, but procedure 2 gives low yields of chlorides when chloroform or carbon tetrachloride is used. Both procedures are, in effect, a combination of reaction **2-48** and the Sandmeyer reaction. A further advantage is that cooling is not needed. Procedure 1 proceeds at room temperature, while procedure 2 is carried out at 100°C.

4-26 Replacement of the Diazonium Group by Nitro

$$\mathbf{ArN_2^+ + NaNO_2 \xrightarrow{Cu^+} ArNO_2}$$

Nitro compounds can be formed in good yields by treatment of diazonium salts with sodium nitrite in the presence of cuprous ion. The reaction occurs only in neutral or alkaline solution. This is not usually called the Sandmeyer reaction, although, like reactions **4-25** and **4-28,** it was discovered by Sandmeyer. BF_4^- is often used as the negative ion, to avoid competition from the chloride ion. The mechanism is probably like that of reaction **4-25.**[270] If electron-donating groups are present, irradiation with uv light may be substituted for the cuprous ion catalyst.[271] If electron-withdrawing groups are present, neither the cuprous-ion catalyst nor irradiation is needed; $NaNO_2$ alone gives nitro compounds in high yields.[272]

OS **II,** 225; **III,** 341.

4-27 Replacement of the Diazonium Group by Sulfur-containing Groups

$$\mathbf{ArN_2^+ + SO_2 \xrightarrow[HCl]{CuCl_2} ArSO_2Cl}$$

Diazonium salts can be converted to sulfonyl chlorides by treatment with sulfur dioxide in the presence of cupric chloride.[273] The use of $FeSO_4$ and copper metal instead of $CuCl_2$ gives sulfinic acids $ArSO_2H$.[274] See also reaction **3-22.**

OS **V,** 60.

4-28 Replacement of the Diazonium Group by Cyano

$$\mathbf{ArN_2^+ + CuCN \longrightarrow ArCN}$$

This reaction, also called the *Sandmeyer reaction,* is similar to reaction **4-25** in scope and mechanism. It is usually conducted in neutral solution to avoid liberation of HCN.

OS **I,** 514.

4-29 Aryl Dimerization with Diazonium Salts

$$\mathbf{2ArN_2^+ \xrightarrow[\text{or } Cu + H^+]{Cu^+} Ar{-}Ar + 2N_2 \quad \text{or} \quad Ar{-}N{=}N{-}Ar + N_2}$$

When diazonium salts are treated with cuprous ion (or with copper and acid, in which case it is called the *Gatterman method*), two products are possible. If the ring contains electron-withdrawing groups, the main product is the biaryl, but the presence of electron-donating groups leads mainly to the azo compound. This reaction is different from reaction **4-16** (and from reaction **1-4**) in that *both* aryl groups in the product originate from ArN_2^+; i.e., hydrogen is not a leaving group in this reaction. The mechanism probably involves free radicals.[275]

OS **I,** 222; **IV,** 872. Also see OS **IV,** 273.

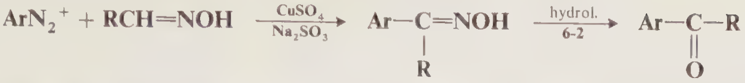
[275] See Cohen, Lewarchik, and Tarino, *J. Am. Chem. Soc.* **96,** 7753 (1974).

4-30 Conversion of Diazonium Salts to Aldehydes or Ketones



$$\mathrm{ArN_2^{\,+} + RCH{=}NOH \xrightarrow[\mathrm{Na_2SO_3}]{\mathrm{CuSO_4}} Ar{-}\underset{\displaystyle R}{\underset{|}{C}}{=}NOH \xrightarrow[6\text{-}2]{\text{hydrol.}} Ar{-}\underset{\displaystyle O}{\underset{\|}{C}}{-}R}$$

Diazonium salts react with oximes to give aryl oximes, which are easily hydrolyzed to aldehydes (R = H) or ketones.[276] A copper sulfate–sodium sulfite catalyst is essential. In most cases higher yields (40 to 60 %) are obtained when the reaction is used for aldehydes than for ketones.

OS **V**, 139.

4-31 Replacement of the Diazonium Group by a Metal

$$\mathrm{ArN_2^{\,+}\ \ BF_4^{\,-} + M \longrightarrow ArM}$$

Aromatic organometallic compounds can be prepared by the treatment of diazonium salts (most often fluoborates) with metals.[277] Among the metals used have been Hg, Tl, Sn, Pb, Sb, and Bi. Another method consists of treating the double salt of the diazonium salt and a metal chloride with a metallic powder, e.g.,

$$\mathrm{ArN_2Cl{\cdot}HgCl_2 \xrightarrow{Cu} ArHgCl + CuCl_2}$$

Organometallic compounds of Hg, Ge, Sn, and As have been among those prepared by this method. The mechanisms are not clear and may be either homolytic or heterolytic.

OS **II**, 381, 432, 494; **III**, 665.

Metals as Leaving Groups

4-32 The Conversion of Boranes to Iodides

$$\mathrm{R_3B + CH_2{=}CH{-}CH_2I \xrightarrow{air} RI + CH_2{=}CHCH_2CH_2CH{=}CH_2}$$

The reaction of trialkylboranes with allyl iodide in the presence of air converts the R group to an alkyl iodide,[278] in high yield. An equimolar amount of oxygen is required. The allyl group is dimerized to 1,5-hexadiene. If other iodides are used, dimerization products of these may be obtained; e.g., benzyl iodide gave bibenzyl. The reaction has a free-radical mechanism; the fact that an equimolar amount of oxygen is required indicates a nonchain process. See also reaction **2-28**.

4-33 The Conversion of Boranes to Sulfides

$$\mathrm{R_3B + R'SSR' \xrightarrow[\text{or } h\nu]{O_2} RSR' + R_2BSR'}$$

Unsymmetrical sulfides can be prepared in very high yields by treatment of a trialkylborane with a disulfide.[279] The reaction has been applied to R = primary or secondary alkyl and R′ = methyl or phenyl. The reaction rate is greatly accelerated by either light or air but totally inhibited by the addition of iodine, indicating a free-radical mechanism.

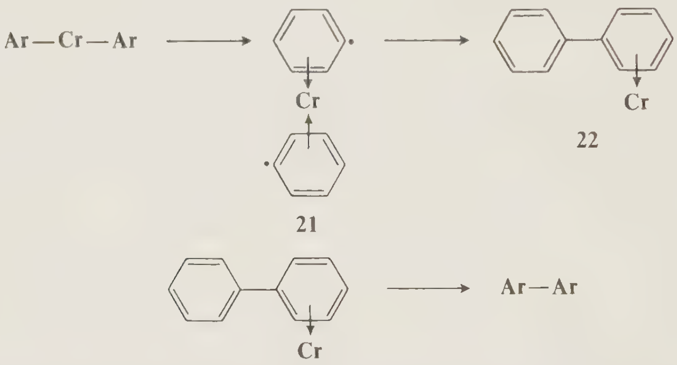
4-34 Coupling of Grignard Reagents

$$2RMgX \xrightarrow{TlBr} RR$$

Grignard reagents can be coupled, to give symmetrical dimers, by treatment with either thallium(I) bromide[280] or with a transition-metal halide such as $CrCl_2$, $CrCl_3$, $CoCl_2$, $CoBr_2$, or $CuCl_2$.[281] The metallic halide is an oxidizing agent and becomes reduced. Both aryl and alkyl Grignard reagents can be dimerized by either procedure, though the TlBr method cannot be applied to R = primary alkyl or to aryl groups with ortho substituents. Vinyl and alkynyl Grignard reagents can be coupled (to give 1,3-dienes and 1,3-diynes, respectively), by treatment with thionyl chloride.[282] Primary alkyl, vinyl, aryl, and benzylic Grignard reagents give symmetrical dimers in high yield ($\sim 90\%$) when treated with a silver(I) salt, e.g., $AgNO_3$, AgBr, $AgClO_4$, in the presence of a nitrogen-containing oxidizing agent such as lithium nitrate, methyl nitrate, or NO_2.[283]

The mechanisms of the reactions with metal halides, at least in some cases, probably begin with conversion of RMgX to the corresponding RM (reaction **2-34**), followed by its decomposition to free radicals.[284] For aryl Grignard reagents the following mechanism has been proposed:[285]

$$2ArMgBr + CrCl_2 \longrightarrow Ar{-}Cr{-}Ar$$



The first step of the reaction involves replacement of magnesium by the transition metal. The diaryl- transition-metal compound then rearranges to a sandwich diradical (**21**), which couples to give **22**, in which the chromium, now reduced to zero oxidation state, is still complexed to one ring. **22** is decomposed by boiling in benzene.

OS **55,** 48.

4-35 Coupling of Boranes

$$R{-}\underset{|}{B}{-} + R'{-}\underset{|}{B}{-} \xrightarrow[NaOH]{AgNO_3} R{-}R'$$

Alkylboranes can be coupled by treatment with silver nitrate and base.[286] Since alkylboranes are easily prepared from olefins (reaction **5-15**), this is essentially a way of coupling and reducing olefins; in fact, olefins can be hydroborated and coupled in the same flask. For symmetrical coupling ($R = R'$) yields range from 60 to 80% for terminal olefins and from 35 to 50% for those with the double bond not at the end of a chain. Unsymmetrical coupling has also been carried out,[286a] but with lower yields. Arylboranes react similarly, yielding biaryls.[287] Dienes have been coupled intramolecularly, to give cycloalkanes.[287a] The mechanism is probably of the free-radical type but has not yet been studied much.

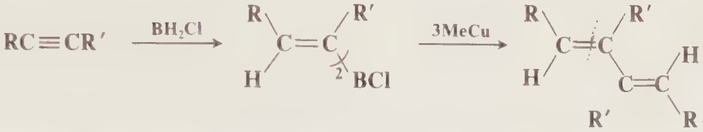
[286] Brown, Ref. 278, pp. 332–336; Snyder, *Intra-Sci. Chem. Rep.* **7** (2), 169–179 (1973).

Vinyl dimerization can be achieved by treatment of divinylchloroboranes (prepared by addition of BH_2Cl to alkynes; see reaction **5-15**) with methylcopper. (*E*,*E*)-1,3-Dienes are prepared in high yields:[288]



In a similar reaction, symmetrical conjugated diynes $RC{\equiv}C{-}C{\equiv}CR$ can be prepared by reaction of lithium dialkyldialkynylborates $Li^+ \quad [R'_2B(C{\equiv}CR)_2]^-$ with iodine.[288a]

4-36 Coupling of Other Organometallic Reagents

$$R_2CuLi \xrightarrow[-78^\circ C,\ THF]{O_2} RR$$

Lithium dialkylcopper reagents can be oxidized to symmetrical dimers by O_2 at $-78°C$ in tetrahydrofuran.[289] The reaction is successful for R = primary and secondary alkyl, vinyl, or aryl. Other oxidizing agents, e.g., nitrobenzene, can be used instead of O_2. Vinylcopper and vinylsilver reagents dimerize simply on standing at 0°C for several days or at 25°C for several hours, to yield 1,3-dienes.[290] The finding of retention of configuration for this reaction demonstrates that free-radical intermediates are not involved. Terminal vinylalanes (prepared by reaction **5-16**) can be dimerized to 1,3-dienes with cuprous chloride in tetrahydrofuran.[291] Diarylmercury compounds Ar_2Hg are converted to biaryls ArAr by heating with palladium or platinum metal.[292] Alkyl- and aryllithium compounds can be dimerized by transition-metal halides in a reaction similar to **4-34**.[293] Aryllithium compounds can also be converted to biaryls by uv irradiation.[294] Arylthallium(III) compounds (ArTlXY, where X and Y are such groups as Cl, OAc, ClO_4) give biaryls when treated with $PdCl_2$ in HOAc containing NaOAc.[295]

Halogen as Leaving Group

The conversion of RX to RH may occur by a free-radical mechanism but is treated at reaction **0-77**.

Sulfur as Leaving Group

4-37 Desulfurization with Raney Nickel

$$\mathrm{RSH} \xrightarrow[\mathrm{Ni}]{\mathrm{H_2}} \mathrm{RH}$$

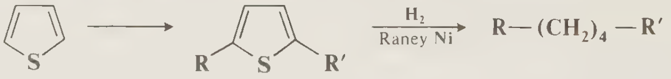
$$\mathrm{RSR'} \xrightarrow[\mathrm{Ni}]{\mathrm{H_2}} \mathrm{RH} + \mathrm{R'H}$$

Thiols and thioethers, both alkyl and aryl, can be desulfurized by hydrogenolysis with Raney nickel.[296] The hydrogen is usually not applied externally, since Raney nickel already contains enough hydrogen for the reaction. Other sulfur compounds can be similarly desulfurized, among them

Disulfides	$\mathrm{RSSR'}$	$\longrightarrow$	$\mathrm{RH} + \mathrm{R'H}$
Thioamides	$\mathrm{RCSNHR'}$	$\longrightarrow$	$\mathrm{RCH_2NHR'}$
Sulfoxides	$\mathrm{RSOR'}$	$\longrightarrow$	$\mathrm{RH} + \mathrm{R'H}$
Hemithioacetals	$\mathrm{RO}\overset{|}{\underset{|}{\mathrm{C}}}\mathrm{SR'}$	$\longrightarrow$	$\mathrm{RO}\overset{|}{\underset{|}{\mathrm{C}}}\mathrm{H}$
Dithioacetals	$\mathrm{RS}\overset{|}{\underset{|}{\mathrm{C}}}\mathrm{SR'}$	$\longrightarrow$	$\overset{|}{\underset{|}{\mathrm{C}}}\mathrm{H_2}$

The last reaction, which is an indirect way of accomplishing reduction of a carbonyl to a methylene group (see reaction **9-39**), can also give the olefin if an α-hydrogen is present.[297] In most of the examples given, R may also be aryl. Other reagents have also been used.[298]

An important special case is desulfurization of thiophene derivatives (a special case of RSR reduction). This proceeds with concomitant reduction of the double bonds. Many otherwise difficultly accessible compounds have been made by alkylation of thiophene, followed by reduction:



23

An example is the following, which was accomplished for $n = 8$ and 9:[299]

Soc.* **82,** 2872 (1960); the hydridotetracarbonylferrate ion $\mathrm{HFe(CO)_4^-}$, by Alper, *J. Org. Chem.* **40,** 2694 (1975).

[299] Gol'dfarb, Taits, and Belen'kii, *J. Gen. Chem. USSR* **29,** 3526 (1959).

Thiophenes can also be desulfurized to alkenes ($RCH_2CH{=}CHCH_2R'$ from **23**) with a nickel boride catalyst prepared from nickel(II) chloride and $NaBH_4$ in methanol.[300]

The exact mechanisms of the Raney nickel reactions are still in doubt, though they are probably of the free-radical type.[301] It has been shown that reduction of thiophene proceeds through butadiene and butene and not through butyl mercaptan or other sulfur compounds; i.e., the sulfur is removed before the double bonds are reduced. This was demonstrated by isolation of the olefins and the failure to isolate any potential sulfur-containing intermediates.[302]

OS **IV**, 638; **V**, 419.

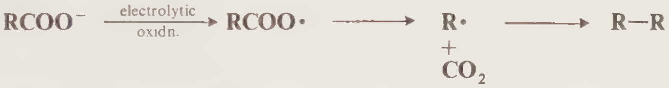
Carbon as Leaving Group

4-38 Decarboxylative Dimerization. The Kolbe Reaction

$$2RCOO^- \xrightarrow{\text{electrol}} R{-}R$$

Electrolysis of carboxylate ions, which results in decarboxylation and combination of the resulting radicals, is called the *Kolbe reaction.*[303] It is used to prepare symmetrical R—R, where R is straight- or branched-chained, except that little or no yield is obtained when there is a branching. When R is aryl, the reaction fails. Many functional groups may be present, though many others inhibit the reaction.[303] The position of the functional group is important, too. Thus $F(CH_2)_4COO^-$ gives 45% $F(CH_2)_8F$, but $F(CH_2)_3COO^-$ gives no reaction. Unsymmetrical R—R′ have been made by coupling mixtures of acid salts.

A free-radical mechanism is involved:



$$RCOO^- \xrightarrow[\text{oxidn.}]{\text{electrolytic}} RCOO\cdot \longrightarrow \underset{CO_2}{\underset{+}{R\cdot}} \longrightarrow R{-}R$$

Unlike many other organic oxidations, there is an actual loss of an electron, in an electrolytic process. There is much evidence for a free-radical mechanism, including the obtention of side products (RH, alkenes) which are characteristic of free-radical intermediates and the fact that electrolysis of acetate ion in the presence of styrene caused some of the styrene to polymerize to polystyrene (such polymerizations can be initiated by free radicals, see p. 681).

When the reaction is carried out in the presence of 1,3-dienes, additive dimerization may occur:[304]

$$2RCOO^- + CH_2{=}CH{-}CH{=}CH_2 \longrightarrow RCH_2CH{=}CHCH_2CH_2CH{=}CHCH_2R$$

The radical $R\cdot$ adds to the conjugated system to give $RCH_2CH{=}CHCH_2\cdot$, which dimerizes. Another possible product is $RCH_2CH{=}CHCH_2R$, from coupling of the two kinds of radicals.[305]

4-39 Decarboxylative Bromination. The Hunsdiecker Reaction

$$\mathrm{RCOOAg + Br_2 \longrightarrow RBr + CO_2 + AgBr}$$

Reaction of a silver salt of a carboxylic acid with bromine is called the *Hunsdiecker reaction* and is a way of decreasing the length of a carbon chain by one unit.[307] The reaction is of wide scope, giving good results for normal-alkyl R from 2 to 18 carbons and for many branched R too, giving primary, secondary, and tertiary bromides. Many functional groups may be present as long as they are not α-substituted. R may also be aryl. However, if R contains unsaturation, the reaction seldom gives good results. Although bromine is the most often used halogen, chlorine and iodine have also been used.

When iodine is the reagent, the ratio between the reactants is very important and determines the products. When a 1 : 1 ratio of salt to iodine is used, the product is the alkyl halide, as above. A 2 : 1 ratio, however, gives the ester RCOOR. This is called the *Simonini reaction* and is sometimes used to prepare esters. A 3 : 2 ratio gives both products: 1 mole of ester and 1 mole of halide from 3 moles of salt. The Simonini reaction can also be carried out with lead salts of acids.[308] A more convenient way to perform the Hunsdiecker reaction is by use of a mixture of the acid and mercuric oxide, instead of the salt, since the silver salt must be very pure and dry and such pure silver salts are often not easy to prepare.[309]

Other methods of accomplishing this reaction are: (1) treatment of thallium(I) carboxylates (which are easy to prepare and purify) with bromine;[310] (2) treatment of carboxylic acids with lead tetraacetate and halide *ions* ($\mathrm{Cl^-}$, $\mathrm{Br^-}$, or $\mathrm{I^-}$);[311] (3) reaction of the acids with lead tetraacetate and N-chlorosuccinimide, which gives tertiary and secondary chlorides in good yields but is not good for R = primary or phenyl;[312] and (4) the reaction between an acyl peroxide and $\mathrm{CuCl_2}$, $\mathrm{CuBr_2}$, or $\mathrm{CuI_2}$ [313] [this reaction also takes place with $\mathrm{Cu(SCN)_2}$, $\mathrm{Cu(N_3)_2}$, and $\mathrm{Cu(CN)_2}$]. The preparation of iodides has also been accomplished by treating the acid with iodine and lead tetraacetate in the presence of uv light.[314] Alkyl fluorides can be prepared in low yields by treating sodium or potassium salts of carboxylic acids with $\mathrm{F_2}$ [315]

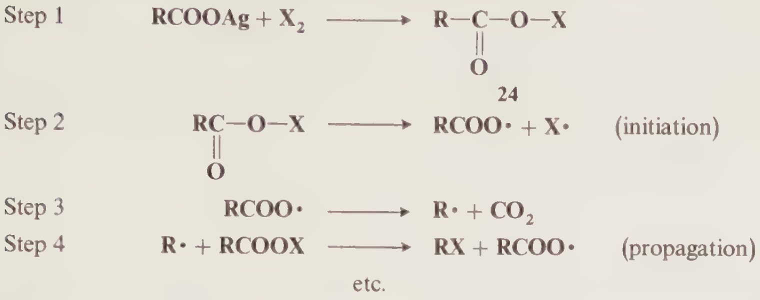
[315] Grakauskas, *J. Org. Chem.* **34**, 2446 (1969).

The mechanism of the Hunsdiecker reaction is believed to be as follows:



Step 1 $\mathrm{RCOOAg + X_2 \longrightarrow R{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}O{-}X}$ **24**

Step 2 $\mathrm{R\underset{\underset{\displaystyle O}{\|}}{C}{-}O{-}X \longrightarrow RCOO\cdot + X\cdot}$ (initiation)

Step 3 $\mathrm{RCOO\cdot \longrightarrow R\cdot + CO_2}$

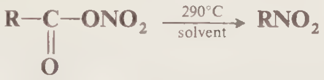
Step 4 $\mathrm{R\cdot + RCOOX \longrightarrow RX + RCOO\cdot}$ (propagation)

etc.

The first step is not a free-radical process, and its actual mechanism is not known. **24** is an acyl hypohalite and is presumed to be an intermediate, although it has never been isolated from the reaction mixture. Among the evidence for the mechanism outlined is that optical activity at R is lost (except when a neighboring bromine atom is present, see p. 625); if R is neopentyl, there is no rearrangement, which would certainly happen with a carbonium ion; and the side products, notably R—R, are consistent with a free-radical mechanism. There is evidence that the Simonini reaction involves the same mechanism as the Hunsdiecker reaction but that the alkyl halide formed then reacts with excess RCOOAg (reaction **0-26**) to give the ester.[316] See also reaction **9-14.**

OS **III,** 578; **V,** 126; **51,** 106. See also OS **50,** 31.

4-40 Decarboxylative Nitration



$$\mathrm{R{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}ONO_2 \xrightarrow[\text{solvent}]{290^\circ C} RNO_2}$$

Acyl nitrates can be smoothly decarboxylated by heating to give moderate yields of nitro compounds.[317] The reaction has been performed with R = primary, secondary, and tertiary alkyl, though only low yields have been obtained in the last case. A free-radical mechanism has been proposed, similar to that of the Hunsdiecker reaction.[317]

4-41 Decarbonylation of Aldehydes and Acyl Halides

$$\mathrm{RCHO \xrightarrow{RhCl(Ph_3P)_3} RH}$$

Aldehydes, both aliphatic and aromatic, can be decarbonylated[318] by heating with chlorotris(triphenylphosphine)rhodium[319] or other catalysts such as palladium.[320] $\mathrm{RhCl(Ph_3P)_3}$ is often called *Wilkinson's catalyst.* In an older reaction aliphatic (but not aromatic) aldehydes are decarbonylated by heating with di-*t*-butyl peroxide or other peroxides,[321] usually in a solution containing a hydrogen donor, such as a mercaptan. The reaction has also been initiated with light; and thermally (without an initiator) by heating at about 500°C.

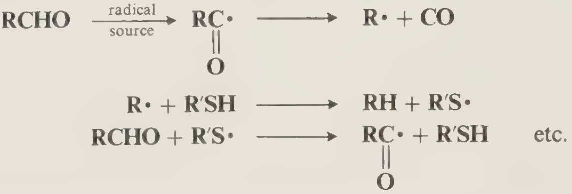
[320] For example, see Newman and Gill, *J. Org. Chem.* **31,** 3860 (1966); Wilt and Abegg, *J. Org. Chem.* **33,** 923 (1968). For a review, see Rylander, Ref. 170, pp. 260–267.

[321] For reviews of free-radical aldehyde decarbonylations, see Vinogradov and Nikishin, *Russ. Chem. Rev.* **40,** 916–932 (1971); Schubert and Kintner, in Patai, Ref. 138, pp. 711–735.

Wilkinson's catalyst also decarbonylates aromatic acyl halides (ArCOCl → ArCl).[322] This reaction has been carried out with acyl iodides[323] and fluorides,[324] as well as with bromides and chlorides.[322] Aliphatic acyl halides which lack an α-hydrogen also give this reaction,[325] but if an α-hydrogen is present, elimination takes place instead (see reaction **7-16**). Aromatic acyl cyanides give aryl cyanides (ArCOCN → ArCN).[326]

The mechanism of the peroxide- or light-induced reaction seems to be as follows (in the presence of mercaptans):[327]

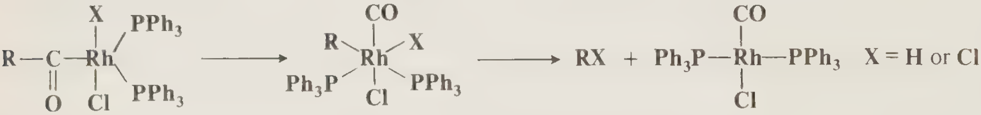


$$\mathrm{RCHO} \xrightarrow[\text{source}]{\text{radical}} \underset{\substack{\|\\ \mathrm{O}}}{\mathrm{RC}\cdot} \longrightarrow \mathrm{R}\cdot + \mathrm{CO}$$

$$\mathrm{R}\cdot + \mathrm{R'SH} \longrightarrow \mathrm{RH} + \mathrm{R'S}\cdot$$

$$\mathrm{RCHO} + \mathrm{R'S}\cdot \longrightarrow \underset{\substack{\|\\ \mathrm{O}}}{\mathrm{RC}\cdot} + \mathrm{R'SH} \qquad \text{etc.}$$

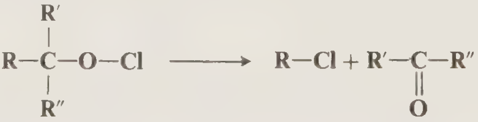
The reactions with Wilkinson's catalyst go through a complex of the form **25**, where X is H or halogen when the substrate is an aldehyde or an acyl halide, respectively. Both **25** and **26** (X = Cl)



25 **26**

have been isolated.[328] When X = H, the reaction with $\mathrm{RhCl(Ph_3P)_3}$ has been shown to give retention of configuration at a chiral R;[329] and deuterium labeling demonstrates that the reaction is intramolecular: RCOD gave RD.[330] For aldehyde decarbonylation by an electrophilic mechanism, see reaction **1-42**.

4-42 Decomposition of Tertiary Hypochlorites



$$\mathrm{R}-\overset{\substack{\mathrm{R'}\\ |}}{\underset{\substack{|\\ \mathrm{R''}}}{\mathrm{C}}}-\mathrm{O}-\mathrm{Cl} \longrightarrow \mathrm{R}-\mathrm{Cl} + \mathrm{R'}-\underset{\substack{\|\\ \mathrm{O}}}{\mathrm{C}}-\mathrm{R''}$$

When tertiary hypochlorites are heated, they spontaneously decompose to alkyl halides and ketones.[331] The reaction may be regarded as substitution at R (of $\mathrm{R_2COCl}$ by Cl). Primary and secondary hypochlorites give the reaction under much milder conditions, but the group which cleaves in these cases is always hydrogen, so that the products are HCl and an aldehyde or ketone, and the reaction is better regarded as an elimination (of HCl) rather than as a substitution. One of the R groups may be an acyl group, in which case acyl cleavage (to give an acyl halide) may take place and even predominate.[332]

[329] Walborsky and Allen, *J. Am. Chem. Soc.* **93**, 5465 (1971); see also Tsuji and Ohno, *Tetrahedron Lett.* 2173 (1967).

[330] Prince and Raspin, *J. Chem. Soc. A* 612 (1969); Walborsky and Allen, Ref. 329.

[331] Cairns and Englund, *J. Org. Chem.* **21**, 140 (1956); Denney and Beach, *J. Org. Chem.* **24**, 108 (1959).

The mechanism has been formulated as follows:[333]

$$\begin{aligned} R_3C{-}O{-}Cl &\longrightarrow R_3C{-}O\cdot + Cl\cdot \\ R_3CO\cdot &\longrightarrow R_2C{=}O + R\cdot \\ R\cdot + R_3C{-}O{-}Cl &\longrightarrow RCl + R_3CO\cdot \end{aligned}$$

It may be noted that these three steps are exactly analogous to steps 2 to 4 of the mechanism of the Hunsdiecker reaction (**4-39**). The evidence for this mechanism is similar to that for reaction **4-39:** racemization, formation of R—R, etc.

Fifteen

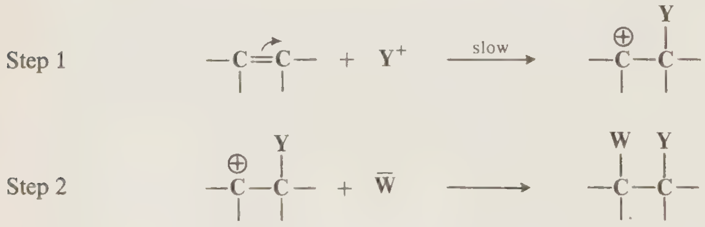
Addition to Carbon-Carbon Multiple Bonds

There are basically four ways in which addition to a double or triple bond can take place. Three of these are two-step processes, with initial attack by a nucleophile, an electrophile, or a free radical. The second step consists of combination of the resulting intermediate with, respectively, a positive species, a negative species, or a neutral entity. In the fourth type of mechanism, attack at the two carbon atoms of the double or triple bond is simultaneous. Which of the four mechanisms is operating in any given case is determined by the nature of the substrate, the reagent, and the reaction conditions. Some of the reactions in this chapter can take place by all four mechanisms.

MECHANISMS

Electrophilic Addition[1]

In this mechanism a positive species approaches the double or triple bond and in the first step forms a bond by converting the π pair of electrons into a σ pair:



Step 1

$$-\underset{|}{C}{=}\underset{|}{C}- \;+\; Y^+ \xrightarrow{\text{slow}} -\overset{\oplus}{\underset{|}{C}}-\overset{\overset{Y}{|}}{\underset{|}{C}}-$$

Step 2

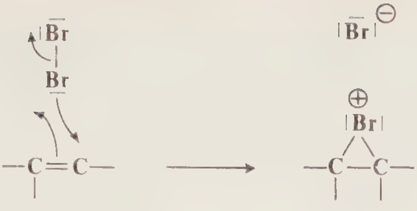
$$-\overset{\oplus}{\underset{|}{C}}-\overset{\overset{Y}{|}}{\underset{|}{C}}- \;+\; \overline{W} \longrightarrow -\overset{\overset{W}{|}}{\underset{|}{C}}-\overset{\overset{Y}{|}}{\underset{|}{C}}-$$

1

As in electrophilic substitution (p. 454), Y need not actually be a positive ion but may be the positive end of a dipole or an induced dipole, with the negative part breaking off either during the first step or shortly after. In any case, **1** has a positive charge on the other carbon. The second step, therefore, is a combination of **1** with a species carrying an electron pair and usually bearing a negative charge. This step is the same as the second step of the SN1 mechanism. There is evidence that **1** is not the actual intermediate ion in all cases. In many brominations it is fairly certain that **1**, if it is formed at all, very rapidly cyclizes to a bromonium ion (**2**):

---

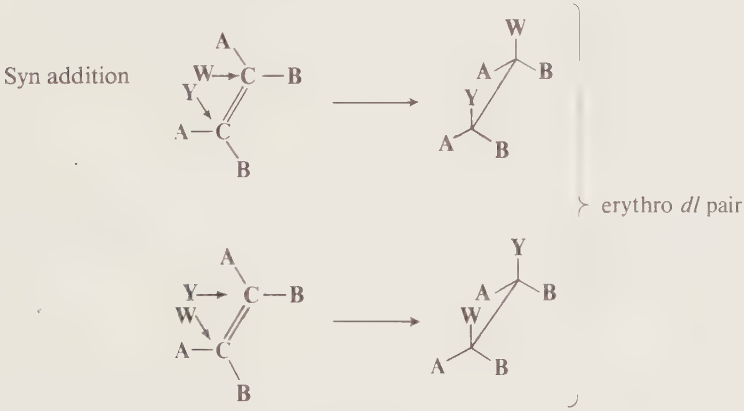
[1] For a monograph, see de la Mare and Bolton, "Electrophilic Additions to Unsaturated Systems," Elsevier Publishing Company, New York, 1966; For reviews, see Freeman, *Chem. Rev.* **75**, 439–490 (1975); Bolton, in Bamford and Tipper, "Comprehensive Chemical Kinetics," vol. 9, pp. 1–86, American Elsevier Publishing Company, Inc., New York, 1973; Dolbier, *J. Chem. Educ.* **46**, 342–344 (1969).



2

This intermediate is similar to those encountered in the neighboring-group mechanism of nucleophilic substitution, and it is likely that other potential neighboring groups (see p. 279) form similar intermediates. The attack of $\overline{W}$ on an intermediate like **2** is a nucleophilic substitution. As in the similar case of electrophilic substitution (p. 457), there has been speculation that the electrophile and the olefin might form an initial π complex,[2] which would then collapse to the open carbonium ion **1** or a cyclic intermediate like **2**. Evidence for such π complexes has been found in certain cases.[3]

In investigating the mechanism of addition to a double bond, perhaps the most useful type of information which can be obtained is the stereochemistry of the reaction.[4] The two carbons of the double bond and the four atoms immediately attached to them are all in a plane (p. 12), and there are thus three possibilities. Y and W may enter from the same side of the plane, in which case the addition is stereospecific and *syn*; they may enter from opposite sides for stereospecific *anti* addition; or the reaction may be nonstereospecific. In order to determine which of these possibilities is occurring in a given reaction, the following type of experiment is often done: YW is added to the cis and trans isomers of an olefin of the form ABC=CBA. We may use the cis olefin as an example. If the addition is syn, the product will be the erythro *dl* pair, because each carbon has a 50% chance of being attacked by Y:



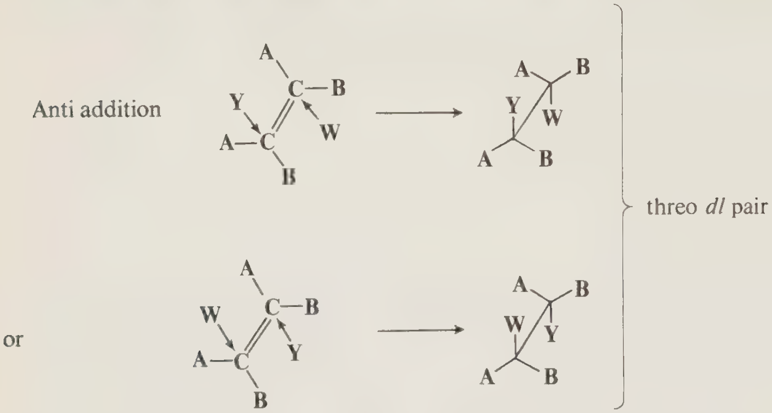
---

[2] For discussions, see Sergeev, Serguchev, and Smirnov, *Russ. Chem. Rev.* **42,** 697–712 (1973); Banthorpe, *Chem. Rev.* **70,** 295–322 (1970), pp. 304–308, 320–321.

[3] Olah and Hockswender, *J. Am. Chem. Soc.* **96,** 3574 (1974); Olah, Schilling, Westerman, and Lin, *J. Am. Chem. Soc.* **96,** 3581 (1974).

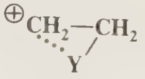
[4] For a review of the stereochemistry of electrophilic additions to double and triple bonds, see Fahey, *Top. Stereochem.* **3,** 237–342 (1968).

On the other hand, if the addition is anti, the threo *dl* pair will be formed:



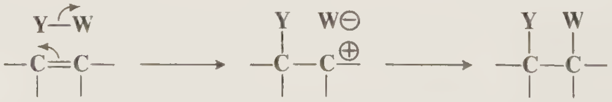
Of course, the trans isomer will give the threo pair if the addition is syn and the erythro pair if it is anti. As with the similar experiment discussed on p. 280, this experiment does not involve use of a polarimeter, and optical activity is not created, since none of the starting materials was optically active. The threo and erythro isomers have different physical properties. In the special case where Y = W (as in the addition of Br_2), the "erythro pair" becomes a meso compound. In addition to triple-bond compounds of the type AC≡CA, syn addition results in a cis olefin and anti addition in a trans olefin. By the definition given on p. 123, addition to triple bonds cannot be stereospecific, though it can be, and often is, stereoselective.

It can easily be seen that in reactions involving cyclic intermediates like **2** addition must be anti, since the second step must occur from the backside. It is not so easy to predict the stereochemistry for reactions involving **1**. If **1** has a relatively long life, the addition should be nonstereospecific, since there will be free rotation about the single bond. On the other hand there may be some factor which maintains the configuration, in which case W may come in from the same side or from the opposite side, depending on the circumstances. For example, the carbonium ion might be stabilized by an attraction for Y which does not involve a full bond:



3

The second group would then come in anti. A circumstance which would favor syn addition would be the formation of an ion pair after the addition of Y:[5]



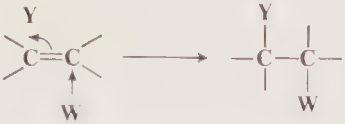
Since W is already on the same side of the plane as Y, collapse of the ion pair leads to syn addition. Another factor which might be responsible for anti addition is distortion of the substrate. It has been mentioned (p. 214) that ethylene, for example, in *excited* states is no longer planar. It has been suggested that anti addition may be the result of such distortion or of vibrational distortion of the substrate.[6]

---

[5] Dewar, *Angew. Chem. Int. Ed. Engl.* **3**, 245–249 (1964) [*Angew. Chem.* **76**, 320–325].

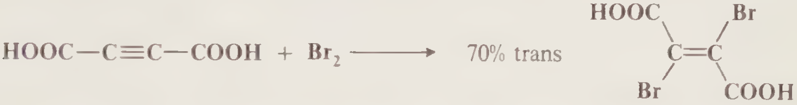
[6] Burnelle, *Tetrahedron* **20**, 2403 (1964), **21**, 49 (1965).

Another possibility is that anti addition might, at least in some cases, be caused by the operation of a mechanism in which attack by W and Y are essentially simultaneous but from opposite sides:[7]



This mechanism, which is called the Ad3 mechanism (*termolecular addition*), has the disadvantage that three molecules must come together in the transition state. However, it is the reverse of the E2 mechanism for elimination, for which the transition state is known to possess this geometry (p. 896).

There is much evidence that when the attack is by Br^+ (or a carrier of it), the bromonium ion **2** is often an intermediate, and the addition is anti. As long ago as 1912, McKenzie showed that treatment of maleic acid with bromine gave the *dl* pair of 2,3-dibromosuccinic acid, while fumaric acid (the trans isomer) gave the meso compound.[8] Many similar experiments have been performed since, with similar results. For triple bonds, stereoselective anti addition was shown even earlier. Bromination of dicarboxyacetylene gave 70% of the trans isomer:[9]



There is other evidence for mechanisms involving **2**. We have already mentioned (p. 283) that bromonium ions have been isolated in stable solutions in nucleophilic substitution reactions involving bromine as a neighboring group. Such ions have also been isolated in reactions involving addition of a Br^+ species to a double bond.[10] The following is further evidence. If the two bromines approach the double bond from opposite sides, it is very unlikely that they could come from the same bromine molecule. This means that if the reaction is performed in the presence of nucleophiles, some of these will compete in the second step with the bromide liberated from the bromine. It has been found, indeed, that treatment of ethylene with bromine in the presence of chloride ions gives some 1-chloro-2-bromoethane along with the dibromoethane.[11] Similar results are found when the reaction is carried out in the presence of nitrate ions and of water.

However, a number of examples have been found where addition of bromine is not stereospecifically anti. For example, the addition of Br_2 to *cis*- and *trans*-1-phenylpropenes in CCl_4 was nonstereospecific.[12] Furthermore, the stereospecificity of bromine addition to stilbene depends on the dielectric constant of the solvent. In solvents of low dielectric constant, the addition was 90 to 100% anti, but with an increase in dielectric constant, the reaction became less stereospecific, until, at a dielectric constant of about 35, the addition was completely nonstereospecific.[13] Likewise in the case of triple bonds, stereoselective anti addition was found in bromination of 3-hexyne, but both cis and trans products were obtained in bromination of phenylacetylene.[14] These results indicate that a bromonium ion is not formed where the open cation can be stabilized in other ways (e.g., addition of Br^+ to 1-phenylpropene gives the ion $Ph\overset{\oplus}{C}HCH_2CH_3$, which is a relatively stable benzylic cation) and that there is probably a spectrum of mechanisms between complete bromonium-ion (**2**, no rotation) formation and completely open-cation (**1**, free rotation) formation, with partially bridged bromonium ions (**3**, restricted rotation) in between.[15] We may recall (e.g., p. 288) that we have previously seen cases where cations required more stabilization from outside sources as they became intrinsically less stable themselves.

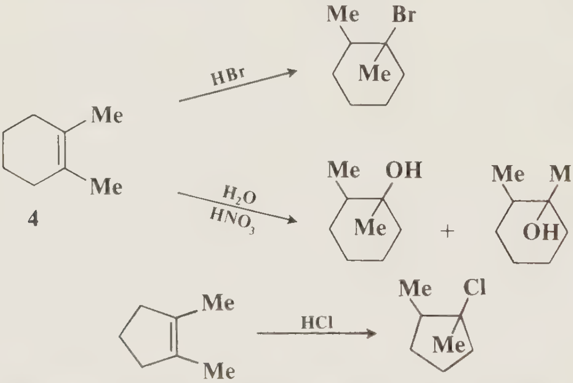
For electrophilic additions in which the electrophile is not Br^+ or a carrier of it, varying results have been reported. Attack by I^+ and RS^+ usually involves cyclic intermediates[16] and hence anti addition.[17] There is evidence that iodonium ions[18] and thiiranium ions[19] are less subject to competition from open cations than bromonium ions. When the electrophile is a proton, the cyclic intermediate is not possible. Examples are known of predominant syn, anti, and non-stereoselective addition of HX. It was found that treatment of 1,2-dimethylcyclohexene (**4**) with HBr and 1,2-dimethylcyclopentene with HCl gave predominant anti addition,[20] while addition of water to **4** gave equal amounts of the cis and trans alcohols:[21]



On the other hand, addition of DBr to acenaphthylene (**5**) and to indene and 1-phenylpropene gave predominant syn addition:[22]

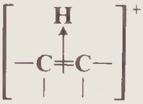
5

In fact it has been shown that the stereoselectivity of HCl addition can be controlled by changing the reaction conditions. Addition of HCl to **4** in CH_2Cl_2 at −98°C gave predominantly syn addition, while in ethyl ether at 0°C, the addition was mostly anti.[23]

In order to explain anti addition when the attack is by a proton, an initial complex[2] of the form



$$\left[-\overset{\overset{\displaystyle H}{\uparrow}}{C{=}C}- \right]^{+}$$

has been invoked, followed by rate-determining formation of an open cation.[24] However, there is much evidence against this concept,[25] including the fact that the addition of H^+ to double bonds is general-acid- and not specific-acid-catalyzed, implying rate-determining proton transfer from the acid to the double bond (p. 236). If there is a free carbonium-ion intermediate in additions of H_2O, it cannot be reversibly formed, since unreacted olefin recovered after treatment with D_2SO_4 contained no (or very little) deuterium.[26] This has led some investigators to doubt that a free carbonium ion is involved in hydrations.[26]

However, in order to show that free carbonium intermediates are formed in at least some reactions, we may cite the result of treatment of *trans*-1,2-di-*t*-butylethylene with chlorine. The product was not the simple addition product expected, but **6**, which arose by rearrangement of the carbonium ion initially formed:[27]

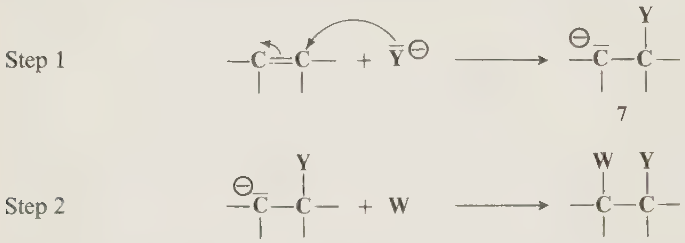
In all these cases (except for the Ad3 mechanisms) we have assumed that formation of the intermediate (**1**, **2**, or **3**) is the slow step and attack by the nucleophile on the intermediate is rapid, and this is probably true in most cases. However, some additions have been found in which the second step is rate-determining.[28]

Nucleophilic Addition[29]

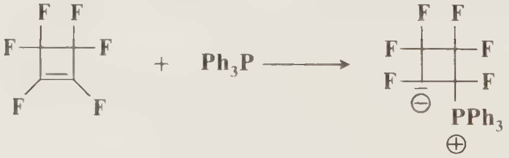
In the first step of nucleophilic addition a nucleophile brings its pair of electrons to one carbon atom of the double or triple bond, forcing the π electrons to become centered on the other carbon, creating a carbanion. The second step is combination of this carbanion with a positive species:



7

This mechanism is the same as the simple electrophilic one shown on page 672 except that the charges are reversed. When the olefin contains a good leaving group (as defined for nucleophilic substitution, p. 325), substitution is a side reaction (this is nucleophilic substitution at a vinyl substrate, see p. 311). There are at least five other types of side reactions which intermediates like **7** can undergo.[30]

In certain cases the intermediate carbanion **7** has been isolated. An example is the betaine **8**,



8

which was isolated as a white solid when perfluorocyclobutene was treated with triphenylphosphine.[31] In this case, **8** could not undergo the normal step 2 because no electrophile was available.

In the special case of addition of HY to a substrate of the form $-\underset{|}{C}=\underset{|}{C}-Z$, where Z = CHO, COR (including quinones[32]), COOR, $CONH_2$, CN, NO_2, SOR, SO_2R, etc., addition nearly always follows a nucleophilic mechanism, with Y^- bonding with the carbon *away* from the Z group, e.g.,

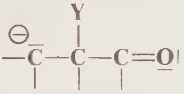
9

Protonation of the enolate ion is chiefly at the oxygen, which is more negative than the carbon, but this produces the enol **9**, which tautomerizes. So although the net result of the reaction is addition to a carbon-carbon double bond, the *mechanism* is 1,4 nucleophilic addition to the C=C—C=O (or similar) system and is thus very similar to the mechanism of addition to carbon-oxygen double and similar bonds (see Chapter 16). When Z is CN or a C=O group, it is also possible for Y to attack at *this* carbon, and this reaction sometimes competes. When it happens, it is called 1,2 addition. 1,4 addition to these substrates is also known as *conjugate addition.* Y^- never attacks at the 3 position, since the resulting carbanion would have no resonance stabilization:



$$-\overset{\ominus}{\underline{C}}-\overset{Y}{C}-C{=}\underline{O}|$$

Perhaps the most important substrate of this type is acrylonitrile, and 1,4 addition to it is called *cyanoethylation* because the Y is cyanoethylated:[33]

$$H_2C{=}CH{-}CN + HY \longrightarrow Y{-}CH_2{-}CH_2{-}CN$$

With any substrate, when Y is an ion of the type $Z{-}\overset{\ominus}{\bar{C}}R_2$ (Z is as defined above; R may be alkyl, aryl, hydrogen, or another Z), the reaction is called the *Michael reaction* (see reaction **5-1**). In this book we shall call all other reactions which follow this mechanism *Michael-type additions.* Systems of the type C=C—C=C—Z may give 1,2, 1,4, or 1,6 addition.[34] Even 1,8 addition has been found with suitable substrates. Michael-type reactions are reversible, and compounds of the type YCH_2CH_2Z can often be decomposed to YH and $CH_2{=}CHZ$ by heating, either with or without alkali.

If the mechanism for nucleophilic addition is the simple carbanion mechanism outlined on p. 678, the addition should be nonstereospecific, though it might well be stereoselective (see p. 123 for the distinction). For example, the cis and trans forms of an olefin ABC=CDE would give, respectively, **10** and **11**:

11

If the carbanion has even a short lifetime, **10** and **11** will assume the most favorable conformation before the attack of W. This is of course the same for both of them, and when W attacks, the same product will result from each. This will be one of two possible diastereomers, so the reaction will be stereoselective; but since the cis and trans isomers do not give rise to different isomers, it will not be stereospecific. Unfortunately, this prediction has not been tested on open-chain olefins. Except for Michael-type substrates, the stereochemistry of nucleophilic addition to double bonds has been studied only in cyclic systems, where only the cis isomer exists. In these cases the reaction has been shown to be stereoselective, with syn addition reported in some cases[35] and anti addition in others.[36] When the reaction is performed on a Michael-type substrate, C=C—Z, the hydrogen does not arrive at the carbon directly but only through a tautomeric equilibrium. The product will naturally assume the most thermodynamically stable configuration, without relation to the direction of original attack of Y. For obvious reasons, additions to triple bonds cannot be stereospecific.[37] As with electrophilic additions, nucleophilic additions to triple bonds are usually stereoselective and anti,[38] though syn addition[39] and non-stereoselective addition[40] have also been reported.

Free-Radical Addition[41]

The mechanism of free-radical addition follows the pattern discussed in Chapter 14 (pp. 619–620). A radical is generated by

$$\mathrm{YW} \xrightarrow[\text{dissociation}]{h\nu \text{ or spontaneous}} \mathrm{Y}\cdot + \mathrm{W}\cdot$$

or

$$\mathrm{R}\cdot \text{ (from some other source)} + \mathrm{YW} \longrightarrow \mathrm{RW} + \mathrm{Y}\cdot$$

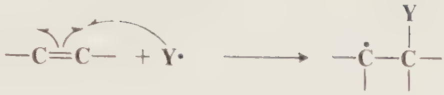
Propagation then occurs by

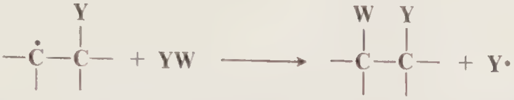
Step 1



$$-C{=}C- + Y\cdot \longrightarrow -\overset{\bullet}{C}-\overset{Y}{C}-$$

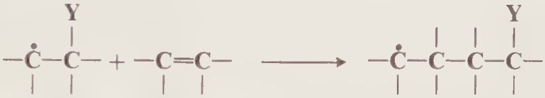
12

Step 2



$$-\overset{\bullet}{C}-\overset{Y}{C}- + YW \longrightarrow -\overset{W}{C}-\overset{Y}{C}- + Y\cdot$$

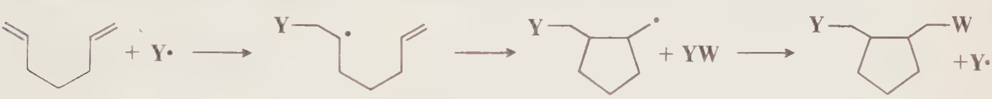
Step 2 is an abstraction, so that W is nearly always univalent, either hydrogen or halogen (p. 625). Termination of the chain may occur in any of the ways discussed in Chapter 14. If **12** adds to another olefin molecule,



$$-\overset{\bullet}{C}-\overset{Y}{C}- + -C{=}C- \longrightarrow -\overset{\bullet}{C}-C-C-\overset{Y}{C}-$$

a dimer is formed. This may now add to still another, and chains, long or short, may be built up. This is the mechanism of free-radical polymerization. Short polymeric molecules (called *telomers*), formed in this manner, are often troublesome side products in free-radical addition reactions.

When free radicals are added to 1,5- or 1,6-dienes, the initially formed radical can add intramolecularly to the other double bond, leading to a cyclic product, e.g.,[42]



13

Free radicals of the type **13**, generated in other ways, also undergo these cyclizations. Both five- and six-membered rings can be formed in these reactions (see p. 689).

The free-radical addition mechanism just outlined predicts that the addition should be nonstereospecific, at least if **12** has any but an extremely short lifetime. However, the reactions may be stereoselective, for reasons similar to those discussed for nucleophilic addition on p. 680.[43] Many free-radical additions have been found to be stereoselective, though not all. For example, addition of HBr to 1-bromocyclohexene gave only *cis*-1,2-dibromocyclohexane and none of the trans isomer (anti addition),[44] and propyne (at −78 to −60°C) gave only *cis*-1-bromopropene (anti addition).[45] However, stereospecificity has been found only in a few cases. The most important of these is addition of HBr to 2-bromo-2-butene under free-radical conditions at −80°C. Under these conditions, the cis isomer gave 92% of the meso addend, while the trans isomer gave mostly the *dl* pair.[46] This stereospecificity disappeared at room temperature, where both olefins gave the same mixture of products (about 78% of the *dl* pair and 22% of the meso compound), so that the addition was still stereoselective but no longer stereospecific. The stereospecificity at low temperatures is probably caused by a stabilization of the intermediate radical through the formation of a bridged bromine radical, of the type mentioned on p. 624:

---

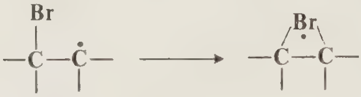
[45] Skell and Allen, *J. Am. Chem. Soc.* **80**, 5997 (1958).

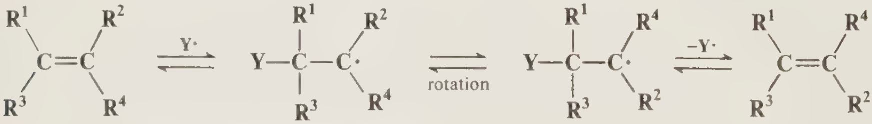
[46] Goering and Larsen, *J. Am. Chem. Soc.* **79**, 2653 (1957), **81**, 5937 (1959). Also see Skell and Allen, *J. Am. Chem. Soc.* **81**, 5383 (1959); Skell and Freeman, *J. Org. Chem.* **29**, 2524 (1964).



This species is similar to the bromonium ion, which is responsible for stereospecific anti addition in the electrophilic mechanism (p. 673). Further evidence for the existence of such bridged radicals was obtained by addition of Br• to olefins at 77 K. Esr spectra of the resulting species were consistent with bridged structures.[47] There is evidence that iodine may form similar bridges: free-radical addition of I_2 at $-42°C$ is stereospecific and anti.[48] However, addition of RSH to olefins, even at $-78°C$, is not stereospecific though it is stereoselective.[49]

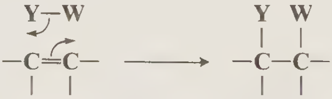
As mentioned previously, anti addition of HBr to triple bonds occurs at -78 to $-60°C$.[45] However, at room temperature this reaction, whether conducted in the liquid or in the vapor phase, is nonstereoselective. It has been shown that this is only apparent: the reaction is still stereoselective, but isomerization occurs after the initial product is formed.[50] Stereoselective syn addition has been demonstrated in the reaction between 1-bromopropyne and HBr.[51]

For many radicals step 1 (C=C + Y• → •C—C—Y) is reversible. In such cases free radicals can cause cis → trans isomerization of a double bond by the pathway[52] (see also p. 534)



Cyclic Mechanisms

There are some addition reactions where the initial attack is not at one carbon of the double bond, but both carbons are attacked simultaneously. Some of these are four-center mechanisms, which follow this pattern:



In others there is a five- or a six-membered transition state. In these cases the addition to the double or triple bond must be syn. The most important reaction of this type is the Diels-Alder reaction (**5-51**).

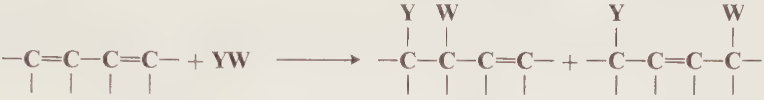
Addition to Conjugated Systems

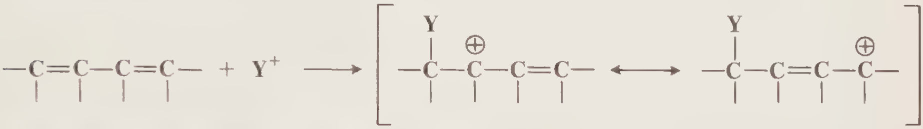
When electrophilic addition is carried out on a compound which has two double bonds in conjugation, a 1,2-addition product (**14**) is often obtained, but in most cases there is also a 1,4-addition product (**15**), often in much larger yield:



$$-\underset{|}{C}=\underset{|}{C}-\underset{|}{C}=\underset{|}{C}- + YW \longrightarrow -\underset{|}{\overset{Y}{C}}-\underset{|}{\overset{W}{C}}-\underset{|}{C}=\underset{|}{C}- + -\underset{|}{\overset{Y}{C}}-\underset{|}{C}=\underset{|}{C}-\underset{|}{\overset{W}{C}}-$$

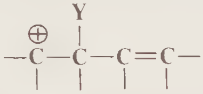
14 **15**

If the diene is unsymmetrical, there may be two 1,2-addition products. The competition between two types of addition product comes about because the carbonium ion resulting from attack by Y^+ is a resonance hybrid, with partial positive charges at the 2 and 4 positions:



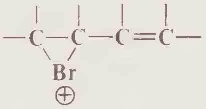
$$-\underset{|}{C}=\underset{|}{C}-\underset{|}{C}=\underset{|}{C}- + Y^+ \longrightarrow \left[-\underset{|}{\overset{Y}{C}}-\underset{|}{\overset{\oplus}{C}}-\underset{|}{C}=\underset{|}{C}- \longleftrightarrow -\underset{|}{\overset{Y}{C}}-\underset{|}{C}=\underset{|}{C}-\underset{|}{\overset{\oplus}{C}}-\right]$$

W^- may then attack either position. The original attack of Y^+ is always at the end of the conjugated system because an attack at a middle carbon would give a carbonium ion unstabilized by resonance:

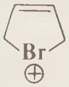


$$-\underset{|}{\overset{\oplus}{C}}-\underset{|}{\overset{Y}{C}}-\underset{|}{C}=\underset{|}{C}-$$

In the case of electrophiles like Br^+, which can form cyclic intermediates, both 1,2- and 1,4-addition products can be rationalized as stemming from an intermediate like **16**. Direct nucleophilic attack by W^- would give the 1,2-product, while the 1,4-product could be formed by attack at the 4 position, by an SN2′-type mechanism (see p. 304). Intermediates like **17** have been postulated but ruled out for Br and Cl by the observation that chlorination or bromination of butadiene gives trans 1,4-products.[53] If an ion like **17** were the intermediate, the 1,4-products would have to have the cis configuration.



16



17

In most cases more 1,4- than 1,2-addition product is obtained. This may be a consequence of thermodynamic control of products, as against kinetic. In most cases, under the reaction conditions, **14** is converted to a mixture of **14** and **15** which is richer in **15**. That is, either isomer gives the same mixture of both, which contains more **15**. It was found that at low temperatures, butadiene and HCl gave only 20 to 25% 1,4-adduct, while at high temperatures, where attainment of equilibrium is more likely, the mixture contained 75% 1,4 product.[54]

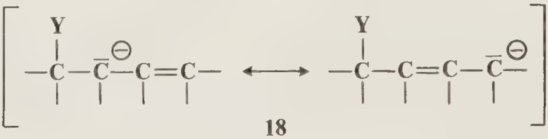
Another aspect of the stereochemistry of 1,4 addition, besides the configuration (cis or trans) of the new double bond, is the question of whether the groups Y and W both come in from the same side of the plane (of the conjugated system) or from opposite sides. This can be determined only for dienes of the type XZC=CR—CR=CUV (where X can be the same as U and Z can be the same as V but X ≠ Z and U ≠ V). Electrophilic bromination and chlorination of such systems has shown that the addition is primarily syn, with both bromines or chlorines entering mostly from the same side of the plane.[55]

---

[53] Mislow and Hellman, *J. Am. Chem. Soc.* **73,** 244 (1951); Mislow, *J. Am. Chem. Soc.* **75,** 2512 (1953).

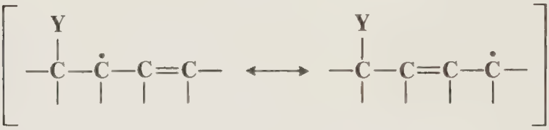
[54] Kharasch, Kritchevsky, and Mayo, *J. Org. Chem.* **2,** 489 (1938).

Addition to conjugated systems can also be accomplished by any of the other three mechanisms. In each case there is a competition between 1,2 and 1,4 addition. In the case of nucleophilic or free-radical attack,[56] the intermediates (**18** and **19**) are resonance hybrids and behave like the intermediate from electrophilic attack. Dienes may give 1,4 addition by a cyclic mechanism in this way:



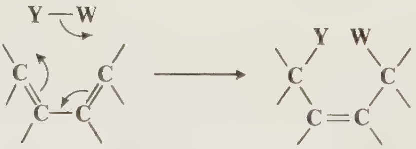
$$\left[-\underset{|}{\overset{\overset{\displaystyle Y}{|}}{C}}-\underset{|}{\overset{\ominus}{\bar{C}}}-\underset{|}{C}=\underset{|}{C}- \longleftrightarrow -\underset{|}{\overset{\overset{\displaystyle Y}{|}}{C}}-\underset{|}{C}=\underset{|}{C}-\underset{|}{\overset{\ominus}{\bar{C}}}-\right]$$

18

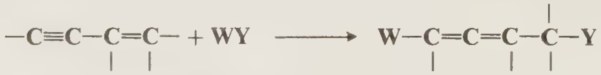


$$\left[-\underset{|}{\overset{\overset{\displaystyle Y}{|}}{C}}-\underset{|}{\dot{C}}-\underset{|}{C}=\underset{|}{C}- \longleftrightarrow -\underset{|}{\overset{\overset{\displaystyle Y}{|}}{C}}-\underset{|}{C}=\underset{|}{C}-\underset{|}{\dot{C}}-\right]$$

19



Other conjugated systems, including trienes, enynes, diynes, etc., have been studied much less but behave similarly.[57] 1,4 addition to enynes is an important way of making allenes:[58]



$$-C\equiv C-\underset{|}{C}=\underset{|}{C}- + WY \longrightarrow W-\underset{|}{C}=C=\underset{|}{C}-\underset{|}{\overset{|}{C}}-Y$$

ORIENTATION AND REACTIVITY

Reactivity

As with electrophilic aromatic substitution (Chapter 11), electron-donating groups increase the reactivity of a double bond toward electrophilic addition, and electron-withdrawing groups decrease it. This is illustrated in Tables 1 and 2.[59] As a further illustration it may be

[59] Table 1 is from de la Mare, *Q. Rev., Chem. Soc.* **3,** 126–145 (1949), p. 145. Table 2 is from Dubois and Mouvier, *Tetrahedron Lett.* 1325 (1963).

TABLE 1 Relative reactivity of some olefins toward bromine in acetic acid at 24°C[59]

Olefin	Relative rate
$PhCH{=}CH_2$	Very fast
$PhCH{=}CHPh$	18
$CH_2{=}CHCH_2Cl$	1.6
$CH_2{=}CHCH_2Br$	1.0
$PhCH{=}CHBr$	0.11
$CH_2{=}CHBr$	0.0011

TABLE 2 Relative reactivity of some olefins toward bromine in methanol[59]

Olefin	Relative rate
$CH_2{=}CH_2$	3.0×10
$CH_3CH_2CH{=}CH_2$	2.9×10^3
cis-$CH_3CH_2CH{=}CHCH_3$	1.3×10^5
$(CH_3)_2C{=}C(CH_3)_2$	2.8×10^7

mentioned that the reactivity toward electrophilic addition of a group of olefins increased in the order $CCl_3CH{=}CH_2 < Cl_2CHCH{=}CH_2 < ClCH_2CH{=}CH_2 < CH_3CH_2{=}CH_2$.[60] For nucleophilic addition the situation is reversed. These reactions are best carried out on substrates containing three or four electron-withdrawing groups, two of the most common being $F_2C{=}CF_2$[61] and $(NC)_2C{=}C(CN)_2$.[62] The effect of substituents is so great that it is possible to make the statement that *simple olefins do not react by the nucleophilic mechanism and polyhalo or polycyano olefins do not generally react by the electrophilic mechanism.*[63] There are some reagents which attack only as nucleophiles, e.g., ammonia, and these add only to substrates susceptible to nucleophilic attack. Other reagents attack only as electrophiles, and, for example, $F_2C{=}CF_2$ does not react with these. In still other cases, the same reagent reacts with a simple olefin by the electrophilic mechanism and with a polyhalo olefin by a nucleophilic mechanism. For example, Cl_2 and HF are normally electrophilic reagents, but it has been shown that Cl_2 adds to $(NC)_2C{=}CHCN$ with an initial attack by Cl^- [64] and that HF adds to $F_2C{=}CClF$ with an initial attack by F^-.[65] Compounds which have a double bond conjugated with a Z group (as defined on p. 678) nearly always react by a nucleophilic mechanism. These are actually 1,4 additions, as discussed on p. 679. A number of studies have been made of the relative activating abilities of various Z groups.[66] On the basis of these studies, the following order of decreasing activating ability has been suggested: Z = NO_2, COAr, CHO, COR, SO_2Ar, CN, COOR, SOAr, $CONH_2$, CONHR.[67] When Michael-type reactions are performed on ZCH=CHZ′, then, in general, the more activating Z controls the position of attack[68] so that, for example, PhCOCH=CHCN is attacked at the carbon adjacent to the CN.[69] However, exceptions are known.

It seems obvious that electron-withdrawing groups enhance nucleophilic substitution and inhibit electrophilic substitution because they lower the electron density of the double bond. This is probably true, and yet similar reasoning does not apply to a comparison between double and triple bonds.[70] There is a higher concentration of electrons between the carbons of a triple bond than there is in a double bond, and yet triple bonds are *less* subject to electrophilic attack and *more* subject to nucleophilic attack than double bonds.[71] This statement is not universally true, but it does hold in most cases. In compounds containing both double and triple bonds (nonconjugated), bromine, an electrophilic reagent, always adds to the double bond.[72] On the other hand, addition of hydrogen halides gives results that are far from simple. In some cases (both conjugated and nonconjugated) the electrophilic H^+ predominantly attacks the double bond and in other cases the triple bond.[73] Which bond is attacked seems to depend on the state of alkylation. When the triple bond is of the form $HC{\equiv}C{-}$, it is the bond exclusively or predominantly attacked by H^+, but internal triple bonds are not so preferred. With conjugated enynes mixtures are commonly obtained. Thus bromination of vinylacetylene gives all possible dibromides.[72] The relative reactivity of double and triple bonds also depends on the solvent. It has been shown that in the gas phase and in nonpolar solvents, double bonds are far more reactive toward bromine than triple bonds (rate ratios were about 10^5), but in water the differences disappeared and the rates were about equal.[74]

[63] Such reactions can take place under severe conditions. For example electrophilic addition could be accomplished with $F_2C{=}CHF$ in super-acid solutions [Olah and Mo, *J. Org. Chem.* **37**, 1028 (1972)] although $F_2C{=}CF_2$ did not react under these conditions. For reviews of electrophilic additions to fluoroolefins, see Dyatkin, Mochalina, and Knunyants, *Russ. Chem. Rev.* **35**, 417–427 (1966), *Fluorine Chem. Rev.* **3**, 45–71 (1969); Ref. 61, pp. 77–81.

Still, it is true that in general triple bonds are more susceptible to nucleophilic and less to electrophilic attack than double bonds, in spite of their higher electron density. One explanation for this is that the electrons in the triple bond are held more tightly because of the smaller carbon-carbon distance, and it is thus harder for an attacking electrophile to pull out a pair. There is evidence from far-uv spectra to support this conclusion.[75] Another possible explanation lies in the fact that addition of an electrophile to a carbon-carbon triple bond gives a vinyl cation, and vinyl cations are somewhat less stable than the corresponding secondary alkyl cations[76] (p. 157). On the other hand, addition of a nucleophile gives a vinyl anion, and these are more stable than the corresponding alkyl anions. Where electrophilic addition involves bridged-ion intermediates, those arising from triple bonds (**20**) are more strained than the corresponding **21** and furthermore are antiaromatic systems (see p. 55), which **21** are not. This may be a reason why electrophilic addition by such electrophiles as Br, I, SR, etc., is slower for triple than for double bonds.[77] As might be expected, triple bonds connected to a Z group ($C{\equiv}C{-}Z$) undergo nucleophilic addition especially well.[78]

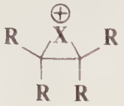
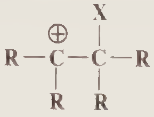
[76] For reviews of vinyl cations formed by addition of electrophiles to triple bonds and to allenes, see Stang, *Prog. Phys. Org. Chem.* **10**, 205–325 (1973); Modena and Tonellato, *Adv. Phys. Org. Chem.* **9**, 185–280 (1971), pp. 187–231; Richey and Richey, in Olah and Schleyer, "Carbonium Ions," vol. 2, pp. 906–922, Interscience Publishers, New York, 1970.

[77] Nevertheless, bridged ions **20** have been implicated in some additions to triple bonds. See, for example, Pincock and Yates, Ref. 14; Mauger and Berliner, *J. Am. Chem. Soc.* **94**, 194 (1972); Bassi and Tonellato, *J. Chem. Soc., Perkin Trans. 1* 669 (1973).

[78] For a review of additions to these substrates, see Winterfeldt, *Angew. Chem. Int. Ed. Engl.* **6**, 423–434 (1967) [*Angew. Chem.* **79**, 389–400], *Newer Methods Prep. Org. Chem.* **6**, 243–279 (1971).

Although alkyl groups in general increase the rates of electrophilic addition, there is a different pattern depending on whether the intermediate is a bridged ion or an open carbonium ion.[79] In the former case substitution of alkyl groups on $H_2C{=}CH_2$ causes a cumulative rate acceleration





$$R-\overset{\oplus}{\underset{R}{C}}-\overset{X}{\underset{R}{C}}-R$$

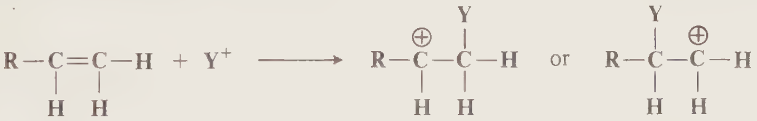
until all four hydrogens have been replaced by alkyl groups, because each group helps to stabilize the positive charge.[80] With the open ion the effect is not cumulative. Replacement of the two hydrogens on one carbon causes great rate increases (primary → secondary → tertiary carbonium ion), but additional substitution on the other carbon produces little or no acceleration.[81]

Free-radical additions may occur with any type of substrate. The determining factor is the presence of a free-radical attacking species. Some reagents, e.g., HBr, RSH, attack by ionic mechanisms if no initiator is present, but in the presence of a free-radical initiator, the mechanism changes and the addition is of the free-radical type. Nucleophilic radicals, like cyclopropyl (see p. 628), behave like nucleophiles, in that the rate is increased by the presence of electron-withdrawing groups in the substrate.[82] The reverse is true for electrophilic radicals.[83]

Steric influences are important in some cases. In catalytic hydrogenation, where the substrate must be adsorbed onto the catalyst surface, the reaction becomes more difficult with increasing substitution. It has been shown that alkyl groups affect the rate of electrophilic addition in accord with the σ_I and E_s values of Taft (pp. 255–258) so that only inductive and steric effects are important and not resonance (hyperconjugative) effects.[84]

Orientation

When an unsymmetrical reagent is added to an unsymmetrical substrate, the question arises: Which side of the reagent goes to which side of the double or triple bond? For electrophilic attack, the answer is given by *Markovnikov's rule: the positive portion of the reagent goes to the side of the double or triple bond which has more hydrogens.*[85] A number of explanations have been suggested for this regioselectivity, but the most probable is that Y^+ adds to that side which will give the more stable carbonium ion. Thus, when an alkyl group is present, secondary carbonium ions are more stable than primary:



$$R-\underset{H}{C}=\underset{H}{C}-H + Y^+ \longrightarrow R-\overset{\oplus}{\underset{H}{C}}-\overset{Y}{\underset{H}{C}}-H \quad \text{or} \quad R-\overset{Y}{\underset{H}{C}}-\overset{\oplus}{\underset{H}{C}}-H$$

More stable

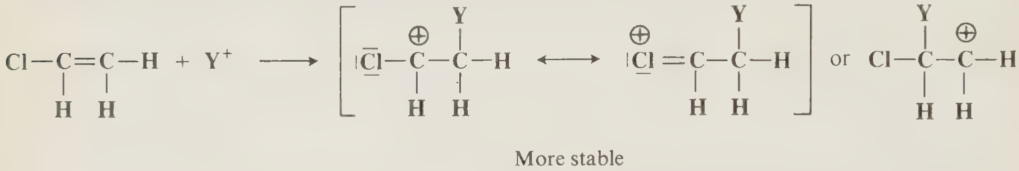
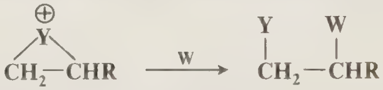
We may ask: How does Y^+ "know" which side will give the more stable carbonium ion? As in the similar case of electrophilic aromatic substitution (p. 459), we may invoke the Hammond postulate and say that that carbonium ion which has the lower energy is preceded by that transition state which has the lower energy. Markovnikov's rule also applies for halogen substituents because the halogen stabilizes the carbonium ion by resonance:



Markovnikov's rule is also usually followed where bromonium ions or other three-membered rings are intermediates. This means that in these cases attack by W must resemble the SN1

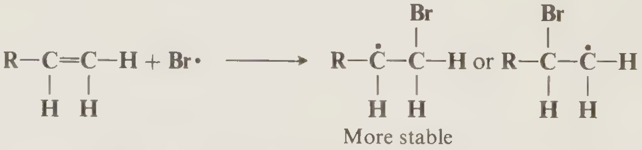


rather than the SN2 mechanism[86] (see p. 341), though the overall stereospecific anti addition in these reactions means that the nucleophilic substitution step is taking place with inversion of configuration.

Olefins containing strong electron-withdrawing groups may violate Markovnikov's rule. For example, attack at the Markovnikov position of $Me_3\overset{\oplus}{N}{-}CH{=}CH_2$ would give an ion with positive charges on adjacent atoms. The compound $CF_3CH{=}CH_2$ has been reported to give electrophilic addition with acids in an anti-Markovnikov direction, but it has been shown[87] that when treated with acids, this compound does not give simple electrophilic addition at all; the apparently anti-Markovnikov products are formed by other pathways.

For nucleophilic addition the direction of attack has been studied very little, except for Michael-type addition, with compounds of the type C=C—Z. Here the negative part of the reagent *always* attacks regiospecifically at the carbon which does not carry the Z (see p. 679).

In free-radical addition the radical attacks at that position which gives the more stable radical.[87a] This is usually the same position which would give the more stable carbonium ion, since the order of radical stability is the same as the order of carbonium-ion stability, namely, tertiary > secondary > primary. With a reagent such as HBr, this means that the addition is anti-Markovnikov, since it is Br• which is attacking:



Thus, the observed orientation in both kinds of HBr addition is caused by formation of the more stable intermediate, and in each case it is the secondary intermediate which is preferred to the primary (or the tertiary to the secondary or primary). The difference in orientation results from the fact that in electrophilic addition it is H^+ which attacks but in radical addition it is $Br\cdot$. Internal olefins with no groups present to stabilize the radical usually give approximately a 1 : 1 mixture. However, there are some differences in regioselectivity depending on how much electrophilic character the free radical has. For example, in additions to $FCH{=}CF_2$, the electrophilic $CCl_3\cdot$ radical attacked the FCH carbon, while the essentially nonpolar $CH_3\cdot$ radical preferred the CF_2 carbon.[88] Steric influences also play a part. A bulky radical shows a greater preference than a smaller radical[89] for the less hindered side. In *intramolecular* additions of

---

[86] SN2 attack would give anti-Markovnikov addition, and some examples of this have been found. For an example where Y^+ is RS^+, see Thaler, Mueller and Butler, *J. Am. Chem. Soc.* **90,** 2069 (1968); Mueller and Butler, *J. Am. Chem. Soc.* **90,** 2075 (1968).

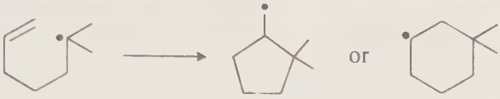
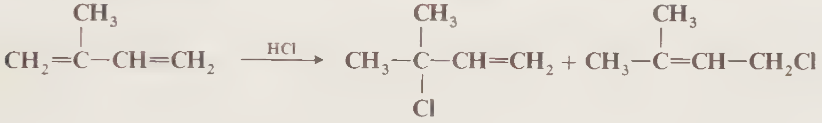
[87a] For a discussion of orientation in free-radical additions, see Tedder and Walton, *Acc. Chem. Res.* **9,** 183–191 (1976).



Favored

radicals containing a 5,6 double bond, both five- and six-membered rings may be formed, but in most cases the five-membered rings are greatly preferred, even (as in the case shown) where five-membered ring closure means generating a primary and six-membered ring closure a secondary radical. This phenomenon may be caused by more favorable entropy factors leading to a five-membered ring, but other explanations have also been offered.[90]

For conjugated dienes, attack by a positive ion, a negative ion, or a free radical is always at the *end* of the conjugated system, since in each case this gives an intermediate stabilized by resonance. In the case of an unsymmetrical diene, the more stable ion is the one that is formed. For example, isoprene treated with HCl gives only **22** and **23**, with none of the product arising from attack at the other end. $PhCH{=}CHCH{=}CH_2$ gives only $PhCH{=}CHCHClCH_3$ since it is

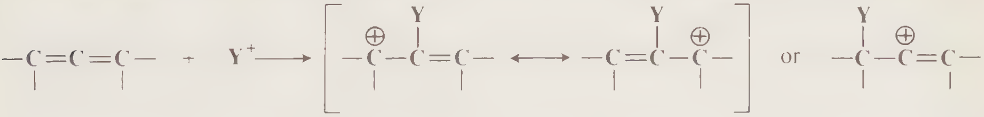


22 **23**

$$CH_2{=}\overset{\overset{CH_3}{|}}{C}{-}CH{=}CH_2 \xrightarrow{HCl} CH_3{-}\underset{\underset{Cl}{|}}{\overset{\overset{CH_3}{|}}{C}}{-}CH{=}CH_2 + CH_3{-}\overset{\overset{CH_3}{|}}{C}{=}CH{-}CH_2Cl$$

the only one of the eight possible products which has a double bond in conjugation with the ring and which results from attack by H^+ at an end of the conjugated system.

When allenes are attacked by electrophilic reagents,[91] Markovnikov's rule would predict that the attack should be at the end of the system, since there are no hydrogens in the middle. Attack



$$-\underset{|}{C}{=}C{=}\underset{|}{C}- \;+\; Y^+ \longrightarrow \left[-\underset{|}{\overset{\oplus}{C}}-\overset{\overset{Y}{|}}{C}{=}\underset{|}{C}- \longleftrightarrow -\underset{|}{C}{=}\overset{\overset{Y}{|}}{C}-\underset{|}{\overset{\oplus}{C}}- \right] \text{ or } -\underset{|}{\overset{\overset{Y}{|}}{C}}-\overset{\oplus}{C}{=}\underset{|}{C}-$$

at the center gives a carbonium ion which is stabilized by resonance, but not immediately, because in order for such stabilization to be in effect the three *p* orbitals must be parallel, and it requires a rotation about the C—C bond for this to happen.[92] Therefore, the stability of the allyl cation has no effect on the transition state, which still has a geometry similar to that of the original allene (p. 94). Probably because of this, attack on the unsubstituted $CH_2{=}C{=}CH_2$ is most often at the end carbon,[93] to give a vinyl cation,[76] though center attack has also been reported.[94] However, as alkyl or aryl groups are substituted on the allene carbons, attack at the middle carbon becomes more favorable because the resulting cation is stabilized by the alkyl or aryl groups (it is now a secondary, tertiary, or benzylic cation). For example, allenes of the form $RCH{=}C{=}CH_2$ are still attacked most often at the end, but with $RCH{=}C{=}CHR'$ center attack is more prevalent. Tetramethylallene is also attacked predominantly at the center carbon.[95] Free radicals attack allenes most often at the end,[96] though attack at the middle has also been reported.[97] It has been postulated that, at least in some of these cases, attack was actually at the end, but then isomerization occurred.[98] As with electrophilic attack, and for the same reason, the stability of the allyl radical has no effect on the transition state of the reaction between a free radical and an allene. Again, as with electrophilic attack, the presence of alkyl groups increases the extent of attack by a free radical at the middle carbon.[99]

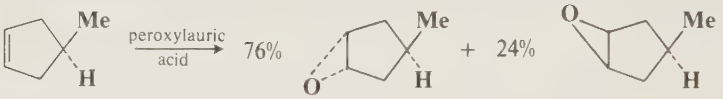
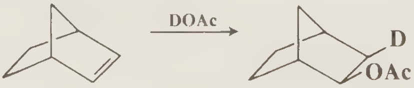
Stereochemical Orientation

It has already been pointed out that some additions are syn, with both groups approaching from the same side, and that others are anti, with the groups approaching from opposite sides of the double or triple bond. For cyclic compounds there are further aspects of steric orientation. In syn addition to an unsymmetrical cyclic olefin, the two groups can come in from the more hindered side or from the less hindered side of the double bond. The rule is that syn addition is usually, though not always, from the less hindered side.[100] For example, epoxidation of 4-methylcyclopentene gave 76% addition from the less hindered and 24% from the more hindered side:[101]



In anti addition to a cyclic substrate, the initial attack by the electrophile is also from the less hindered side. However, many (though not all) electrophilic additions to norbornene and similar strained bicycloalkenes are syn additions.[102] In these cases attack is always from the exo side, e.g.,[103]



unless the exo side is blocked by substituents in the 7 position, in which case endo attack may predominate; e.g., 7,7-dimethylnorbornene undergoes syn-endo epoxidation (**5-40**) and hydroboration[104] (**5-15**). However, addition of DCl and F_3CCOOD to, and oxymercuration (**5-2**) of,

7,7-dimethylnorbornene proceed syn-exo in spite of the methyl groups in the 7 position.[105] Similarly, free-radical additions to norbornene and similar molecules are often syn-exo, though anti additions and endo attacks are also known.[106]

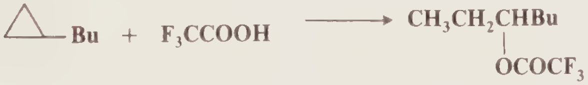
It has been mentioned that additions of Br_2 and HOBr are often anti because of formation of bromonium ions and that free-radical addition of HBr is also anti, presumably because of formation of the analogous cyclic-radical intermediates. When the substrate in any of these additions is a cyclohexene, the addition is not only anti but the initially formed product is conformationally specific too, being mostly diaxial.[107] This is so because diaxial opening of the three-membered ring preserves in the transition state a maximum coplanarity of the participating centers; indeed, on opening, epoxides also give diaxial products. However, the initial diaxial product may then pass over to the diequatorial conformer (see p. 129) unless other groups on the ring render the latter less stable than the former. Some cases have been found (in electrophilic addition of bromine) where the initial ring opening gave the diequatorial rather than the diaxial conformer.[108] Such behavior has been attributed to the second step of the reaction (ring opening) being rate-determining rather than the first (attack on the double bond by the electrophile).[109] In free-radical additions to cyclohexenes in which cyclic intermediates are not involved, the initial attack by the radical is also usually from the axial direction,[110] resulting in a diaxial initial product if the overall addition is anti.

Addition to Cyclopropane Rings[111]

We have previously seen (p. 141) that in some respects, cyclopropane rings resemble double bonds.[112] It is not surprising, therefore, that cyclopropanes undergo addition reactions analogous to those undergone by double-bond compounds, resulting in the opening of the three-membered ring; e.g. (the reaction numbers of the analogous addition reactions are given in parentheses),

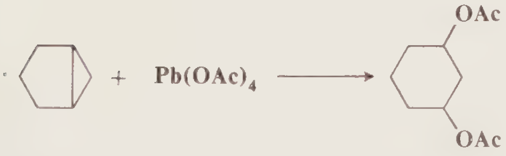
$$+ \ \mathrm{HBr} \longrightarrow \mathrm{CH_3CH_2CH_2Br}$$

(5-1)



$$\mathrm{Bu} + \mathrm{F_3CCOOH} \longrightarrow \mathrm{CH_3CH_2\underset{\displaystyle OCOCF_3}{\underset{|}{C}}HBu}$$

(5-6)[113]



$$+ \ \mathrm{Pb(OAc)_4} \longrightarrow$$

OAc

OAc

(5-39)[114]

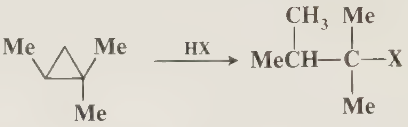
Other examples are discussed at reactions **5-14, 5-52,** and **5-53.**

Additions to cyclopropanes can take place by any of the four mechanisms already discussed in this chapter, but the most important type involves electrophilic attack.[115] For substituted cyclopropanes, these reactions usually follow Markovnikov's rule, though exceptions are known, and the degree of regioselectivity is often small. The application of Markovnikov's rule to these substrates can be illustrated by the reaction of 1,1,2-trimethylcyclopropane with HX.[116] The rule



predicts that the electrophile (in this case H^+) goes to the carbon with the most hydrogens and the nucleophile goes to the carbon which can best stabilize a positive charge (in this case the tertiary rather than the secondary carbon). The stereochemistry of the reaction can be investigated at two positions, the one which becomes connected to the electrophile and the one which becomes connected to the nucleophile. The results at the former position are mixed. Additions have been found to take place with 100% retention,[117] 100% inversion,[118] and with mixtures of retention and inversion.[119] At the carbon which becomes connected to the nucleophile the result is usually inversion, though retention has also been found,[120] and elimination, rearrangement, and racemization processes often compete, indicating that in many cases a positively charged carbon is generated at this position.

At least three mechanisms have been proposed for electrophilic addition (these mechanisms are shown for attack by HX, but analogous mechanisms can be written for other electrophiles).[121]

Mechanism *a*

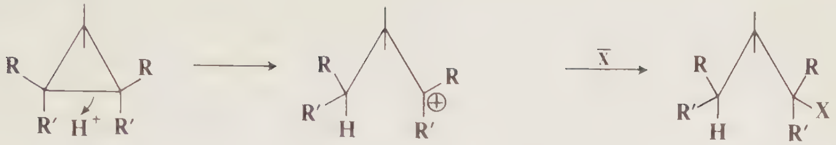
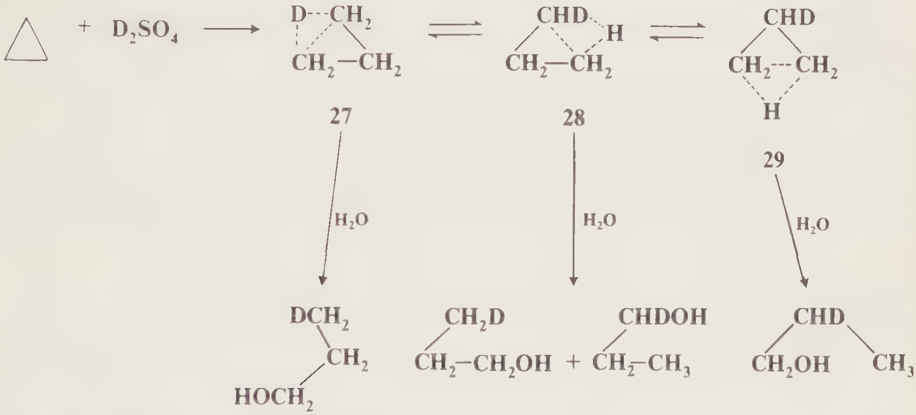
[121] Ref. 115, pp. 92–93.

Mechanism *c*



26

Mechanism *a* involves a corner-protonated cyclopropane[122] (**24**); we have already seen examples of such ions in the 2-norbornyl and 7-norbornenyl cations (pp. 296–297). Mechanism *b* involves an edge-protonated cyclopropane (**25**). Mechanism *c* consists of a one-step SE2-type attack by H^+ to give the classical carbonium ion **26**, which then reacts with the nucleophile. Although the three mechanisms as we have drawn them show retention of configuration at the carbon which becomes attached to the proton, mechanisms *a* and *c* at least can also lead to inversion at this carbon. Unfortunately, the evidence on hand at present does not allow us unequivocally to select any of these as the exclusive mechanism in all cases. Matters are complicated by the possibility that more than one edge-protonated cyclopropane is involved, at least in some cases. When cyclopropane was treated with D_2SO_4 (reaction **5-2**), the deuterium was found at all three carbons of the resulting 1-propanol.[123] This result can be explained by an equilibrium among the three edge-protonated species **27** to **29**. A similar equilibrium (with CH_3CO^+ instead of D^+) can



explain the reaction of cyclopropane with CH_3COCl to give $CH_3COCH_2CH_2CH_2Cl$, CH_3CO-$CHMeCH_2Cl$, and $CH_3COCHEtCl$ (as well as $CH_3COCMe{=}CH_2$, formed by elimination of HCl from $CH_3COCHMeCH_2Cl$).[124] There are also the possibilities that three corner-protonated cyclopropanes might be in equilibrium with each other (corner-to-corner hydrogen shifts) and with the edge-protonated species and that in some cases **24** or **25** might form first and then be converted to **26**. There is evidence that corner-protonated cyclopropanes may be somewhat more stable than the edge-protonated type.[125]

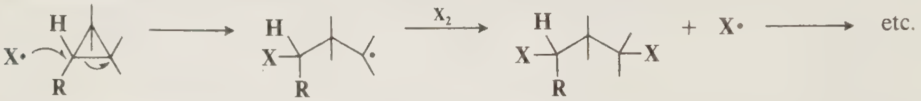
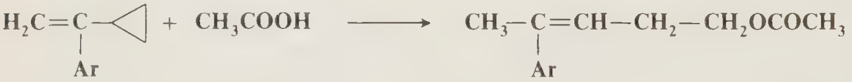
The mechanism of bromination seems to depend on the substrate. Cyclopropane itself does not react with bromine in the dark in the absence of a Lewis acid catalyst. However, when $AlCl_3$ or $FeBr_3$ is present, the product is a mixture of 1,1-, 1,2-, and 1,3-dibromopropanes,[126] which can be explained, as above, by the presence of an equilibrium among edge-protonated cyclopropanes (Br^+ instead of D^+). On the other hand, the pattern of products obtained (mostly derived from rearrangements) in the bromination of alkyl-substituted cyclopropanes indicates that in this case the reaction proceeds via open classical carbonium ions (mechanism *c*).[127] Mechanism *c* has also been proposed for bromination of aryl-substituted cyclopropanes.[128]

Free-radical additions to cyclopropanes have been studied much less, but it is known that Br_2 and Cl_2 add to cyclopropanes by a free-radical mechanism in the presence of uv light. The addition follows Markovnikov's rule, with the initial radical attacking the least substituted carbon and the second group going to the most substituted position. Several investigations have shown that the reaction is stereospecific at one carbon, taking place with inversion there, but non-stereospecific at the other carbon.[129] A mechanism which accounts for this behavior is



In some cases conjugate addition has been performed on systems where a double bond is "conjugated" with a cyclopropyl ring. An example is[130]



(5-6)

$$\underset{\mathrm{Ar}}{H_2C{=}\underset{|}{C}}\text{—}\triangleleft + CH_3COOH \longrightarrow CH_3\text{—}\underset{\substack{|\\ \mathrm{Ar}}}{C}{=}CH\text{—}CH_2\text{—}CH_2OCOCH_3 \qquad (5\text{-}6)$$

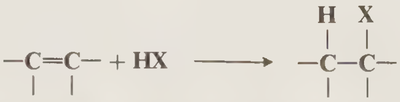
REACTIONS

Reactions are classified by type of reagent. All reactions where hydrogen adds to one side of the double bond, whether by electrophilic, nucleophilic, free-radical, or cyclic mechanisms, are treated first.

Reactions in Which Hydrogen Adds to One Side

A. Halogen on the Other Side

5-1 Addition of Hydrogen Halides



$$-\underset{|}{C}{=}\underset{|}{C}- + HX \longrightarrow -\underset{|}{\overset{\mathrm{H}}{\overset{|}{C}}}-\underset{|}{\overset{\mathrm{X}}{\overset{|}{C}}}-$$

Any of the four hydrogen halides may be added to double bonds. HI, HBr, and HF[131] add at room temperature. The addition of HCl usually requires heat. The reaction can be carried out with a large variety of double-bond compounds, including conjugated systems, where both 1,2 and 1,4 addition are possible. A convenient method for the addition of HF involves the use of a highly concentrated solution of HF in a tertiary amine such as pyridine or triethylamine, e.g., 70% HF–30% pyridine.[132] When the substrate is mixed with this solution in a solvent such as tetrahydrofuran at 0°C, alkyl fluorides are obtained in moderate to high yields.

The addition of hydrogen halides to simple olefins, in the absence of peroxides, takes place by an electrophilic mechanism, and the orientation is in accord with Markovnikov's rule.[133] When peroxides are added, the addition of HBr occurs by a free-radical mechanism and the orientation is anti-Markovnikov (p. 688).[134] It must be emphasized that this is true only for HBr. Free-radical addition of HF and HI has never been observed, even in the presence of peroxides, and of HCl only rarely. In the rare cases where free-radical addition of HCl was noted, the orientation was still Markovnikov, presumably because the more stable *product* was formed.[135] Free-radical addition of HF, HI, and HCl is energetically unfavorable (see the discussions on pp. 626, 635). It has often been found that anti-Markovnikov addition of HBr takes place even when peroxides have not been added. This happens because the substrate alkenes absorb oxygen from the air, forming small amounts of peroxides (reaction **4-8**). Markovnikov addition can be ensured by rigorous purification of the substrate, but in practice this is not easy to achieve, and it is more common to add inhibitors, e.g., phenols or quinones, which suppress the free-radical pathway. The presence of free-radical precursors such as peroxides does not inhibit the ionic mechanism, but the radical reaction, being a chain process, is much more rapid than the electrophilic reaction. In most cases it is possible to control the mechanism (and hence the orientation) by adding peroxides, to achieve complete free-radical addition, or inhibitors, to achieve complete electrophilic addition, though there are some cases where the ionic mechanism is fast enough to compete with the free-radical mechanism and complete control cannot be attained. For alternative methods of adding HBr (or HI) with anti-Markovnikov orientation, see reaction **2-28**.

It is also possible to add 1 or 2 moles of any of the four hydrogen halides to triple bonds.

$$-\mathrm{C{\equiv}C}- \xrightarrow{\mathrm{HX}} -\mathrm{CH{=}CX}- \xrightarrow{\mathrm{HX}} -\mathrm{CH_2}-\mathrm{CX_2}-$$

Markovnikov's rule ensures that *gem*-dihalides and not *vic*-dihalides are the products of the addition of 2 moles.

HX are electrophilic reagents, and many polyhalo and polycyano alkenes, e.g., $Cl_2C{=}CHCl$, do not react with them at all in the absence of free-radical conditions. When such reactions do occur, however, they take place by a nucleophilic addition mechanism; i.e., initial attack is by X^-. This type of mechanism also occurs with Michael-type substrates $C{=}C{-}Z$, where the orientation is always such that the halogen goes to the carbon which does not bear the Z, so that the product is of the form $X{-}C{-}CH{-}Z$, even in the presence of free-radical initiators. HI adds 1,4 to conjugated dienes in the gas phase by a pericyclic mechanism:[136]

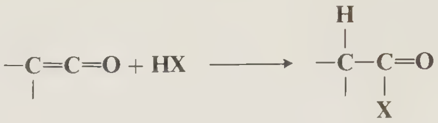
[135] Mayo, *J. Am. Chem. Soc.* **84,** 3964 (1962).

[136] Gorton and Walsh, *J. Chem. Soc., Chem. Commun.* 782 (1972).

HX can be added to ketenes[137] to give acyl halides:[137a]

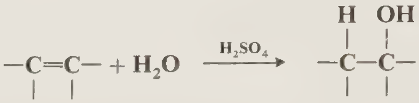


$$-\overset{}{\underset{|}{C}}=C=O + HX \longrightarrow -\overset{H}{\overset{|}{\underset{|}{C}}}-\underset{\underset{X}{|}}{C}=O$$

OS **I,** 166; **II,** 137, 336; **III,** 576; **IV,** 238, 543.

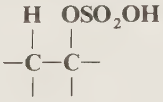
B. Oxygen on the Other Side

5-2 Hydration of Olefins



$$-\underset{|}{C}=\underset{|}{C}- + H_2O \xrightarrow{H_2SO_4} -\underset{|}{\overset{H}{\overset{|}{C}}}-\underset{|}{\overset{OH}{\overset{|}{C}}}-$$

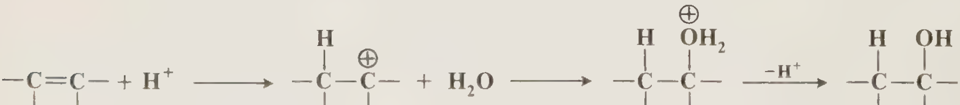
Olefins can be hydrated by treatment with water and an acid catalyst. The most common catalyst is sulfuric acid, but other acids, such as nitric or perchloric, may also be used. The mechanism is electrophilic and begins with attack by a proton (see p. 676). The negative attacking species may be HSO_4^- (or similar ion in the case of other acids) to give the initial product



$$-\underset{|}{\overset{H}{\overset{|}{C}}}-\underset{|}{\overset{OSO_2OH}{\overset{|}{C}}}-$$

30

which can be isolated (reaction **5-4**) but, under the conditions of the reaction, is usually hydrolyzed to the alcohol (reaction **0-4**). However, the conjugate base of the acid is not the only possible species which attacks the initial carbonium ion. The attack may also be by water:



$$-\underset{|}{C}=\underset{|}{C}- + H^+ \longrightarrow -\underset{|}{\overset{H}{\overset{|}{C}}}-\underset{|}{\overset{\oplus}{C}}- + H_2O \longrightarrow -\underset{|}{\overset{H}{\overset{|}{C}}}-\underset{|}{\overset{\overset{\oplus}{OH_2}}{\overset{|}{C}}}- \xrightarrow{-H^+} -\underset{|}{\overset{H}{\overset{|}{C}}}-\underset{|}{\overset{OH}{\overset{|}{C}}}-$$

When the reaction proceeds by this pathway, **30** and similar intermediates are not involved and the mechanism is exactly (by the principle of microscopic reversibility) the reverse of E1 elimination of alcohols (reaction **7-1**).[138] It is likely that the mechanism involves both pathways. Sometimes the initial carbonium ion rearranges to a more stable one. For example, hydration of $CH_2{=}CHCH(CH_3)_2$ gives $CH_3CH_2COH(CH_3)_2$. With ordinary olefins the addition predominantly follows Markovnikov's rule. For a method of anti-Markovnikov hydration, see reaction **5-15.** With substrates of the type C=C—Z (Z is as defined on p. 678) the product is always HO—C—CH—Z, and the mechanism is usually nucleophilic,[139] although electrophilic addition gives the same product[140] since a cation $CH{-}\overset{\oplus}{C}{-}Z$ would be destabilized by the positive charges (full or partial) on two adjacent atoms. Conjugated dienes are seldom hydrated.

---

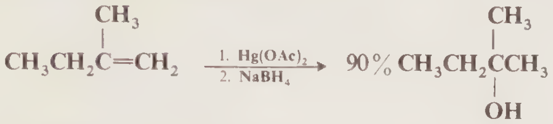
[137] For a review of the mechanisms of reactions of ketenes with HX, H_2O, ROH, RCOOH, and amines, see Satchell and Satchell, *Chem. Soc. Rev.* **4**, 231–250 (1975).

[137a] For a discussion of the mechanism, see Lillford and Satchell, *J. Chem. Soc. B* 897 (1968).

[138] For a discussion of the mechanism, see Liler, "Reaction Mechanisms in Sulphuric Acid," pp. 210–225, Academic Press, Inc., New York, 1971.

[139] For example, see Fedor, De, and Gurwara, *J. Am. Chem. Soc.* **95**, 2905 (1973); Jensen and Carré, *J. Org. Chem.* **39**, 2103 (1974).

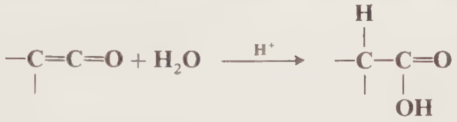
Olefins can be hydrated quickly, under mild conditions in high yields without rearrangement products, by the use of oxymercuration[141] (addition of oxygen and mercury) followed by in situ treatment with sodium borohydride[142] (reaction **2-21**). For example, 2-methyl-1-butene treated with mercuric acetate, followed by $NaBH_4$, gave 90% 2-methyl-2-butanol



$$CH_3CH_2\overset{CH_3}{\overset{|}{C}}{=}CH_2 \xrightarrow[2.\ NaBH_4]{1.\ Hg(OAc)_2} 90\%\ CH_3CH_2\underset{\underset{OH}{|}}{\overset{CH_3}{\overset{|}{C}}}CH_3$$

This method, which is applicable to mono-, di-, tri-, and tetraalkyl as well as phenyl-substituted olefins, gives almost complete Markovnikov addition.

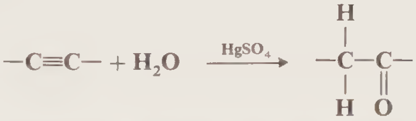
The addition of water to vinyl ethers causes hydrolysis to aldehydes or ketones (reaction **0-7**). Ketenes add water to give carboxylic acids in a reaction which is catalyzed by acids:[143]



$$-\underset{|}{C}{=}C{=}O + H_2O \xrightarrow{H^+} -\underset{|}{\overset{H}{\overset{|}{C}}}-\underset{\underset{OH}{|}}{C}{=}O$$

OS **IV**, 555, 560; **53**, 94. Also see OS **V**, 818.

5-3 Hydration of Alkynes



$$-C{\equiv}C- + H_2O \xrightarrow{HgSO_4} -\underset{\underset{H}{|}}{\overset{H}{\overset{|}{C}}}-\underset{\underset{O}{\|}}{C}-$$

Alkynes can be hydrated with mercuric ion salts (often the sulfate) as catalysts.[144] Thallium(III) salts can also be used.[145] Since the addition follows Markovnikov's rule, only acetylene gives an aldehyde. All other triple-bond compounds give ketones (for a method of reversing the orientation for terminal alkynes, see reaction **5-15**). With alkynes of the form $RC{\equiv}CH$ methyl ketones are formed almost exclusively, but with $RC{\equiv}CR'$ both possible products are usually obtained. However, if R is primary and R′ secondary or tertiary, the carbonyl group is formed preferentially next to the secondary or tertiary carbon.[146]

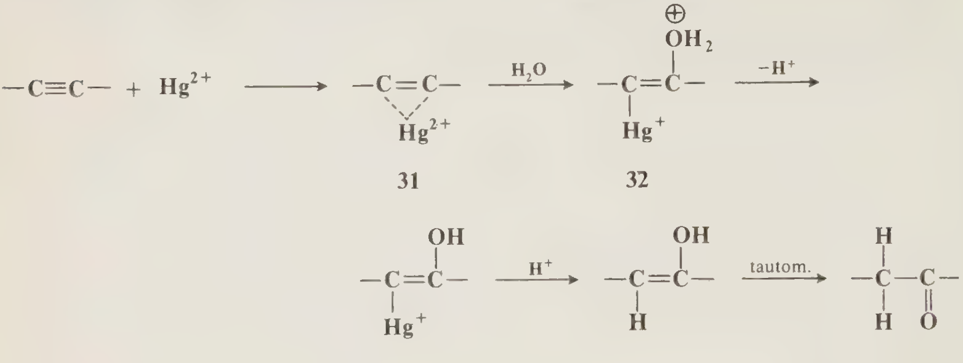
[143] For discussions of the mechanism, see Lillford and Satchell, *J. Chem. Soc. B* 889 (1968); Ref. 137.

[144] For reviews, see Khan and Martell, "Homogeneous Catalysis by Metal Complexes," vol. 2, pp. 91–95, Academic Press, Inc., New York, 1974; Miocque, Hung, and Yen, *Ann. Chim.* (*Paris*) [13] **8**, 157–174 (1963).

[145] Uemura, Kitoh, Fujita, and Ichikawa, *Bull. Chem. Soc. Jpn.* **40**, 1499 (1967).

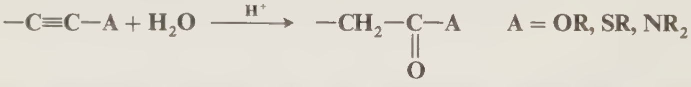
[146] Krupin and Petrov, *J. Gen. Chem. USSR* **33**, 3799 (1963).

The first step of the mechanism is probably formation of a complex (**31**), since ions like Hg^{2+} form complexes with alkynes (p. 79). Water then attacks in an SN2-type process to give the intermediate **32**, which loses a proton to give **33**. Hydrolysis of **33** (an example of reaction **2-21**) gives the enol, which tautomerizes to the product.[147] There is evidence that the mechanism is somewhat more complicated than this. A yellow color has been observed in the solution which, from spectral evidence, is attributed to a complex containing an Hg^{2+} ion and *two* acetylene molecules.[148] The isolation of **32** or **33** would be strong evidence in favor of the above mechanism. Such intermediates have not been isolated, but an analogous intermediate has been isolated from treatment of olefins with mercuric salts. Ions of the type **31** but with single C—C bonds instead of double have been prepared in stable solutions in super acids.[149]



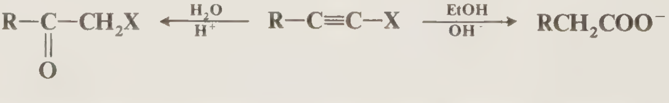
31 **32** **33**

Esters, thiol esters, and amides can be made, respectively, by acid-catalyzed hydration of acetylenic ethers, thioethers,[150] and ynamines, without a mercuric catalyst;[151]



$$-C\equiv C-A + H_2O \xrightarrow{H^+} -CH_2-\underset{\underset{O}{\|}}{C}-A \qquad A = OR, SR, NR_2$$

This is ordinary electrophilic addition, with rate-determining protonation as the first step.[152] Certain other alkynes have also been hydrated to ketones with strong acids in the absence of mercuric salts. These include $ArC\equiv CCOOH$,[153] $ArC\equiv CCH_3$,[154] and 3-hexyne.[155] When chloro or bromoalkynes are hydrolyzed in acid solution, they give the normal product, an α-halo ketone, but hydrolysis with ethanolic OH^- gives a carboxylic acid salt:[156]



$$R-\underset{\underset{O}{\|}}{C}-CH_2X \xleftarrow[H^+]{H_2O} R-C\equiv C-X \xrightarrow[OH^-]{EtOH} RCH_2COO^-$$

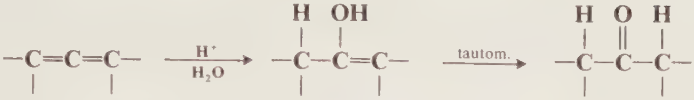
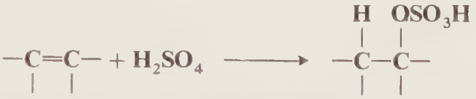
Allenes can also be hydrolyzed to ketones, with an acid catalyst:[157]



$$-\underset{|}{C}{=}C{=}\underset{|}{C}- \xrightarrow[H_2O]{H^+} -\overset{H}{\underset{|}{C}}-\overset{OH}{C}{=}\underset{|}{C}- \xrightarrow{\text{tautom.}} -\overset{H}{\underset{|}{C}}-\overset{O}{\overset{\|}{C}}-\overset{H}{\underset{|}{C}}-$$

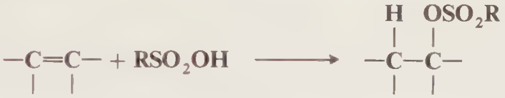
OS **III**, 22; **IV**, 13; **V**, 1024.

5-4 Formation of Inorganic Esters



$$-\underset{|}{C}{=}\underset{|}{C}- + H_2SO_4 \longrightarrow -\overset{H}{\underset{|}{C}}-\overset{OSO_3H}{\underset{|}{C}}-$$

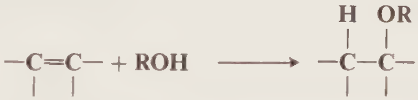
It is possible to prepare esters of sulfuric acid by treatment of olefins with H_2SO_4, but care must be taken that the esters do not hydrolyze to the alcohol (reaction **5-2**). It is also possible for the product to add to a second molecule of olefin to give a dialkyl sulfate. In practice, however, the reaction is seldom used for any olefin except ethylene. Esters of inorganic acids are most often prepared from alcohols (reaction **0-33**). Sulfonic acids add to many olefins, though not to ethylene, to give sulfonic esters:



$$-\underset{|}{C}{=}\underset{|}{C}- + RSO_2OH \longrightarrow -\overset{H}{\underset{|}{C}}-\overset{OSO_2R}{\underset{|}{C}}-$$

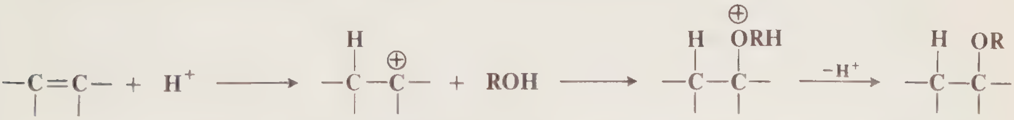
Alkyl fluorosulfates $ROSO_2F$ can be prepared by the treatment of olefins with fluorosulfuric acid HSO_3F at low temperatures.[158]

5-5 Addition of Alcohols and Phenols



$$-\underset{|}{C}{=}\underset{|}{C}- + ROH \longrightarrow -\overset{H}{\underset{|}{C}}-\overset{OR}{\underset{|}{C}}-$$

Alcohols and phenols add to olefins in reactions which are catalyzed by acids or bases. When the reactions are acid-catalyzed, the mechanism is electrophilic, with H^+ as the attacking species. The resulting carbonium ion combines with a molecule of alcohol:



$$-\underset{|}{C}{=}\underset{|}{C}- + H^+ \longrightarrow -\overset{H}{\underset{|}{C}}-\overset{\oplus}{\underset{|}{C}}- + ROH \longrightarrow -\overset{H}{\underset{|}{C}}-\overset{\overset{\oplus}{ORH}}{\underset{|}{C}}- \xrightarrow{-H^+} -\overset{H}{\underset{|}{C}}-\overset{OR}{\underset{|}{C}}-$$

The addition, therefore, follows Markovnikov's rule. Primary alcohols give better results than secondary, and tertiary alcohols are very inactive. This is a convenient method for the preparation of tertiary ethers by the use of a suitable olefin such as $Me_2C{=}CH_2$.

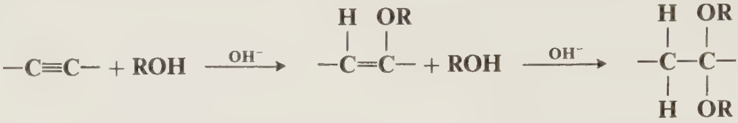
For those substrates which are more susceptible to nucleophilic attack, e.g., polyhalo olefins and olefins of the type C=C—Z, it is better to carry out the reaction in basic solution, where the attacking species is RO^-.[159] The reactions with C=C—Z are of the Michael type, and OR always goes to the side away from the Z.[160] Since triple bonds are more susceptible to nucleophilic attack than double bonds, it might be expected that bases would catalyze addition to triple bonds particularly well. This is the case, and vinyl ethers and acetals may be produced by this reaction:[161]

---

[157] For example, see Fedorova and Petrov, *J. Gen. Chem. USSR* **32**, 1740 (1962); Mühlstadt and Graefe, *Chem. Ber.* **100**, 223 (1967).

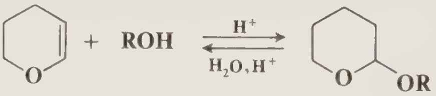
[158] See, for example, Olah, Nishimura, and Mo, *Synthesis* 661 (1973).

[159] For a review with respect to fluoroolefins, see Ref. 61, pp. 53–61.



$$-C\equiv C- + ROH \xrightarrow{OH^-} -\overset{H}{C}=\overset{OR}{C}- + ROH \xrightarrow{OH^-} -\overset{H}{\underset{H}{C}}-\overset{OR}{\underset{OR}{C}}-$$

Because vinyl ethers are more susceptible than triple bonds to electrophilic attack, the addition of alcohols to vinyl ethers can also be catalyzed by acids. One utilization of this reaction involves the compound dihydropyran (**34**), which is often used to protect the OH groups of primary and secondary alcohols and phenols. The acetal formed by this reaction (**35**) is stable to bases, Grignard reagents, $LiAlH_4$, and oxidizing agents, any of which may be used to react with functional groups located within the R group. When the reactions are completed, **35** is easily cleaved by treatment with dilute acids (reaction **0-7**).



34 **35**

In base-catalyzed addition to triple bonds the rate falls in going from a primary to a tertiary alcohol, and phenols require more severe conditions. Other catalysts, namely, BF_3 and mercuric salts, have also been used in addition of ROH to triple bonds. Similarly, the addition of alcohols to allenes (to give 3-alkoxyalkenes) is catalyzed by HgO–BF_3.[162]

Alcohols can be added to certain double-bond compounds (cyclohexenes, cycloheptenes) photochemically in the presence of a photosensitizer such as benzene. The mechanism is electrophilic, and Markovnikov orientation is found. The olefins react in their first excited triplet states.[163]

The oxymercuration-demercuration procedure mentioned in reaction **5-2** can be adapted to the preparation of ethers (Markovnikov orientation) if the oxymercuration is carried out in an alcohol ROH as solvent; e.g., 2-methyl-1-butene in ethanol gives $EtMe_2COEt$.[164] Primary and secondary alcohols give good yields when mercuric acetate is used, but for tertiary alcohols it is necessary to use mercuric trifluoroacetate. However, even with this reagent the method fails where the product would be a ditertiary ether. If the oxymercuration is carried out in the presence of a hydroperoxide instead of an alcohol, the product (after demercuration with $NaBH_4$) is an alkyl peroxide.[165] When either of the oxymercuration-demercuration procedures is applied to α-substituted-β-unsubstituted compounds of the form $CH_2{=}CR'{-}Z$ (Z = COOH, COOR, CHO, COPh), the products are the α-alkoxy compounds $CH_3CR'(OR){-}Z$ [or the corresponding peroxy compounds $CH_3CR'(OOR){-}Z$] which have the *opposite* orientation from that normal for Michael-type substrates.[166]

---

[160] For a review of addition of ROH to acrylonitrile (cyanoethylation of alcohols and phenols), see Bruson, *Org. React.* **5**, 79–135 (1949), pp. 89–95, 121–128.

[161] For reviews, see Shostakovskii, Trofimov, Atavin, and Lavrov, *Russ. Chem. Rev.* **37**, 907–919 (1968); Shostakovskii, Bogdanova, and Plotnikova, *Russ. Chem. Rev.* **33**, 66–77 (1964).

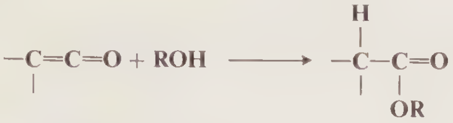
[162] Bach, *Tetrahedron Lett.* 5841 (1968).

[163] Marshall, *Acc. Chem. Res.* **2**, 33–40 (1969).

[164] Brown and Rei, *J. Am. Chem. Soc.* **91**, 5646 (1969).

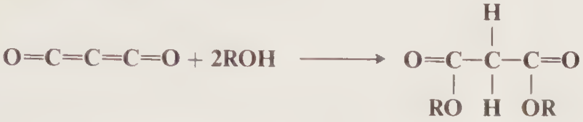
[165] Ballard and Bloodworth, *J. Chem. Soc. C* 945 (1971). See also Sokolov and Reutov, *J. Org. Chem. USSR* **5**, 168 (1969); Schmitz, Rieche, and Brede, *J. Prakt. Chem.* **312**, 30 (1970).

Both alcohols and phenols add to ketenes to give esters:[167]



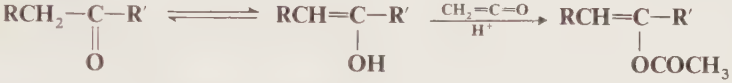
$$-\underset{|}{C}=C=O + ROH \longrightarrow -\overset{\overset{H}{|}}{\underset{|}{C}}-\underset{\underset{OR}{|}}{C}=O$$

Similarly, carbon suboxide gives malonic esters:[168]



$$O=C=C=C=O + 2ROH \longrightarrow O=\underset{\underset{RO}{|}}{C}-\overset{\overset{H}{|}}{\underset{\underset{H}{|}}{C}}-\underset{\underset{OR}{|}}{C}=O$$

In the presence of a strong acid, ketene reacts with aldehydes or ketones (in their enol forms) to give enol acetates:

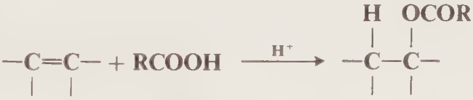


$$RCH_2-\underset{\underset{O}{\|}}{C}-R' \rightleftharpoons RCH=\underset{\underset{OH}{|}}{C}-R' \xrightarrow[H^+]{CH_2=C=O} RCH=\underset{\underset{OCOCH_3}{|}}{C}-R'$$

Alcohols can also add to olefins in a different way (see reaction **5-23**).

OS **III,** 371, 774, 813; **IV,** 184, 558; **52,** 128.

5-6 Addition of Carboxylic Acids



$$-\underset{|}{C}=\underset{|}{C}- + RCOOH \xrightarrow{H^+} -\overset{\overset{H}{|}}{\underset{|}{C}}-\overset{\overset{OCOR}{|}}{\underset{|}{C}}-$$

Esters are produced by the addition of carboxylic acids to olefins, a reaction which is usually acid-catalyzed (by proton or Lewis acids[169]) and similar in mechanism to reaction **5-5.** Since Markovnikov's rule is followed, hard-to-get esters of tertiary alcohols can be prepared by addition to olefins of the form $R_2C{=}CHR$.[170] *t*-Butyl alcohol is a particularly good solvent for this reaction.[171] When a carboxylic acid which contains a double bond in the chain is treated with a strong acid, the addition occurs internally and the product is a γ- and/or a δ-lactone, regardless of the original position of the double bond in the chain, since strong acids catalyze double-bond shifts (reaction **2-2**).[172] The double bond always migrates to a position favorable for the reaction, whether this has to be toward or away from the carboxyl group. However, another reaction competes, in which the product is a cyclopentenone or a cyclohexenone. This is essentially an example of reaction **2-15.** In either case, first the double bond migrates into the proper position, and then a proton from the catalyst may attack the acid in two ways. It either adds to the double bond or removes OH^- from the carboxyl group, leaving an acylonium ion:

---

[166] Normal orientation was observed for unsubstituted, β-only-substituted, and α,β-disubstituted substrates: Bloodworth and Bunce, *Chem. Commun.* 753 (1970), *J. Chem. Soc. C* 1453 (1971).

[167] Lacey, *Adv. Org. Chem.* **2,** 213–263 (1960), pp. 216–217; Quadbeck, *Angew. Chem.* **68,** 361 (1956), *Newer Methods Prep. Org. Chem.* **2,** 133–161 (1963). For discussions of the mechanism, see Tille and Pracejus, *Chem. Ber.* **100,** 196–210 (1967); Brady, Vaughn, and Hoff, *J. Org. Chem.* **34,** 843 (1969); Ref. 137.

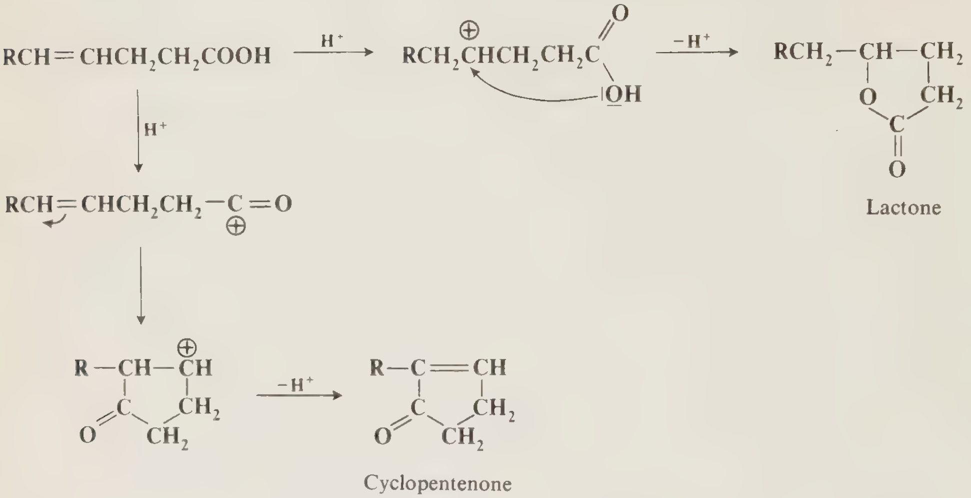
[168] For a review of carbon suboxide, see Kappe and Ziegler, *Angew. Chem. Int. Ed. Engl.* **13,** 491–504 (1974) [*Angew. Chem.* **86,** 529–542].

[169] See for example Guenzet and Camps, *Bull. Soc. Chim. Fr.* 3167 (1973), *Tetrahedron* **30,** 849 (1974).

[170] See for example Peterson and Tao, *J. Org. Chem.* **29,** 2322 (1964).

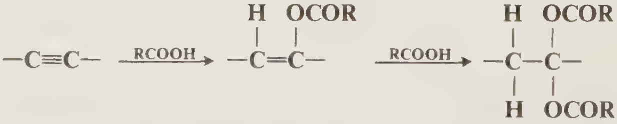
[171] Pavlov, Bogavac, and Arsenijevic, *Bull. Soc. Chim. Fr.* 2985 (1974).

[172] For a review of such lactonizations, see Ansell and Palmer, *Q. Rev., Chem. Soc.* **18,** 211–225 (1964).



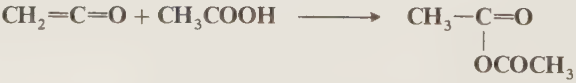
If it adds to the double bond, normal lactonization occurs, but if it creates an acylonium ion, *this* attacks the double bond and the ketone product is formed. Actually, the fact that anti addition is observed in the lactonization indicates that the two steps of this process are probably concerted or nearly so. Which type of reaction predominates depends mainly on which type of acid is used as catalyst. Proton-donating acids, e.g., H_2SO_4, HCOOH, and HF, give mostly lactones, while Lewis acids like acetic anhydride, $ZnCl_2$ in HOAc, P_2O_5, etc., are among those which give mostly ketones. Since carbonium ions are involved, rearrangements take place in both reactions.

Triple bonds may give alkenyl esters or acylals when treated with carboxylic acids. Mercuric salts are usually catalysts:



$$-C\equiv C- \xrightarrow{RCOOH} -\overset{\displaystyle H\ \ OCOR}{\overset{|\quad |}{C=C}}- \xrightarrow{RCOOH} -\underset{\underset{\displaystyle H\ \ OCOR}{|\quad |}}{\overset{\overset{\displaystyle H\ \ OCOR}{|\quad |}}{C-C}}-$$

With ketenes, carboxylic acids give anhydrides,[173] and acetic anhydride is prepared industrially in this manner:



$$CH_2{=}C{=}O + CH_3COOH \longrightarrow CH_3-\underset{\underset{\displaystyle OCOCH_3}{|}}{C}{=}O$$

Esters can also be obtained by the addition to olefins of acyl peroxides.[174] These reactions are catalyzed by copper and are free-radical processes.

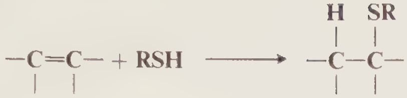
C. Sulfur on the Other Side

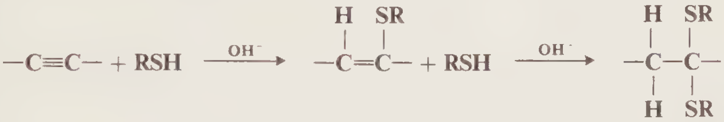
5-7 Addition of H_2S and Mercaptans



$$-\underset{|}{C}=\underset{|}{C}- + RSH \longrightarrow -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{|}{\overset{\overset{SR}{|}}{C}}-$$

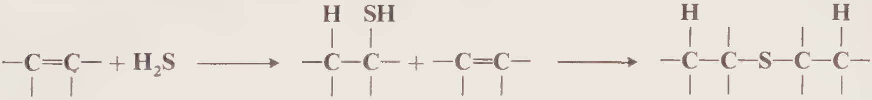
H_2S and mercaptans add to olefins by electrophilic, nucleophilic, or free-radical mechanisms.[175] In the absence of initiators the addition to simple olefins is by an electrophilic mechanism, similar to that in reaction **5-5**, and Markovnikov's rule is followed. However, this reaction is usually very slow and often cannot be done or requires very severe conditions unless an acid catalyst is used. For example, the reaction can be performed in concentrated H_2SO_4.[176] In the presence of free-radical initiators, H_2S and mercaptans add to double and triple bonds by a free-radical mechanism, and the orientation is anti-Markovnikov.[177] In fact the orientation can be used as a diagnostic tool to indicate which mechanism is operating. Free-radical addition can be done with H_2S, RSH (R may be primary, secondary, or tertiary), ArSH, RCOSH,[178] and even $(RO)_2PSSH$. R may contain various functional groups. The olefins may be terminal, internal, contain branching, be cyclic, and have various functional groups including OH, COOH, COOR, NO_2, RSO_2, etc. With acetylenes it is possible to add 1 or 2 moles of RSH.

When mercaptans are added to substrates susceptible to nucleophilic attack, bases catalyze the reaction and the mechanism is nucleophilic. These substrates may be of the Michael type[179] or may be polyhalo olefins or alkynes.[161] As with the free-radical mechanism, alkynes may give either vinyl thioethers or thioacetals:



$$-C\equiv C- + RSH \xrightarrow{OH^-} -\overset{\overset{H}{|}}{C}=\overset{\overset{SR}{|}}{C}- + RSH \xrightarrow{OH^-} -\underset{\underset{H}{|}}{\overset{\overset{H}{|}}{C}}-\underset{\underset{SR}{|}}{\overset{\overset{SR}{|}}{C}}-$$

By any mechanism, the initial product of addition of H_2S to a double bond is a mercaptan, which is capable of adding to a second molecule of olefin, so that sulfides are often produced:



$$-\underset{|}{C}=\underset{|}{C}- + H_2S \longrightarrow -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{|}{\overset{\overset{SH}{|}}{C}}- + -\underset{|}{C}=\underset{|}{C}- \longrightarrow -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{|}{\overset{|}{C}}-S-\underset{|}{\overset{|}{C}}-\underset{|}{\overset{\overset{H}{|}}{C}}-$$

Additions to conjugated dienes have been rare. For electrophilic (acid-catalyzed) conditions, 1,4 addition has been reported.[180] For free-radical addition, both 1,2[180] and 1,4 addition[181] have been demonstrated. Conjugated diynes, treated with H_2S, give thiophenes:[182]

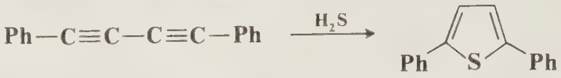
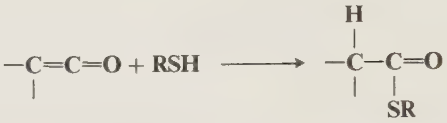
[179] For a review of additions to acrylonitrile, see Bruson, *Org. React.* **5,** 79–135 (1949), pp. 95–97, 129–130.

[180] Saville, *J. Chem. Soc.* 5040 (1962).

[181] Oswald, Griesbaum, Thaler, and Hudson, *J. Am. Chem. Soc.* **84,** 3897 (1962); Claisse and Davies, *J. Chem. Soc.* 4894 (1965), obtained both 1,2 and 1,4 products.

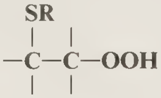


Conjugated triynes and tetraynes also give thiophenes. Ketenes add mercaptans to give thiol esters:



$$-\underset{|}{C}{=}C{=}O + RSH \longrightarrow -\overset{\overset{H}{|}}{\underset{|}{C}}-\underset{\underset{SR}{|}}{C}{=}O$$

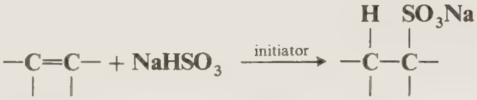
When mercaptans add to olefins by a free-radical mechanism in the presence of oxygen, β-hydroperoxy sulfides are side products:



$$-\overset{\overset{SR}{|}}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-OOH$$

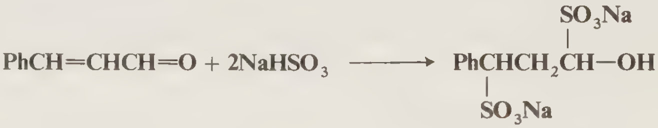
OS **III**, 458; **IV**, 669.

5-8 Addition of Sodium Bisulfite



$$-\underset{|}{C}{=}\underset{|}{C}- + NaHSO_3 \xrightarrow{\text{initiator}} -\overset{\overset{H}{|}}{\underset{|}{C}}-\overset{\overset{SO_3Na}{|}}{\underset{|}{C}}-$$

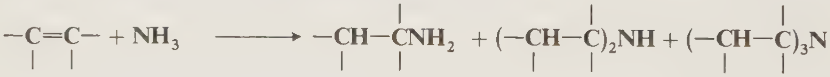
Salts of aliphatic sulfonic acids can be prepared by addition of bisulfite salts to olefins in the presence of free-radical initiators.[183] The orientation is anti-Markovnikov. On systems of the type C=C—C=O, bis addition may be observed:



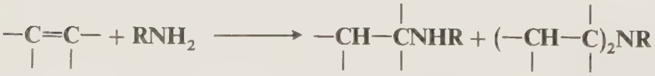
$$PhCH{=}CHCH{=}O + 2NaHSO_3 \longrightarrow Ph\underset{\underset{SO_3Na}{|}}{CH}CH_2\overset{\overset{SO_3Na}{|}}{CH}-OH$$

D. Nitrogen on the Other Side

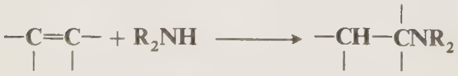
5-9 Addition of Ammonia and Amines



$$-\underset{|}{C}{=}\underset{|}{C}- + NH_3 \longrightarrow -\underset{|}{CH}-\overset{|}{\underset{|}{C}}NH_2 + (-\underset{|}{CH}-\overset{|}{\underset{|}{C}})_2NH + (-\underset{|}{CH}-\overset{|}{\underset{|}{C}})_3N$$



$$-\underset{|}{C}{=}\underset{|}{C}- + RNH_2 \longrightarrow -\underset{|}{CH}-\overset{|}{\underset{|}{C}}NHR + (-\underset{|}{CH}-\overset{|}{\underset{|}{C}})_2NR$$



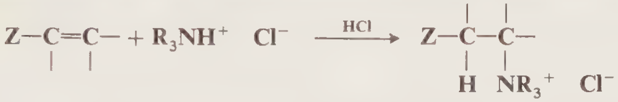
$$-\underset{|}{C}{=}\underset{|}{C}- + R_2NH \longrightarrow -\underset{|}{CH}-\overset{|}{\underset{|}{C}}NR_2$$

Ammonia and primary and secondary amines add to olefins which are susceptible to nucleophilic attack.[184] Ammonia gives three possible products, since the initial product is a primary amine, which may add to a second molecule of olefin, etc. Similarly, primary amines give both secondary and tertiary products. In practice it is usually possible to control which product predominates. Since ammonia and amines are much weaker acids than water, alcohols, and mercaptans (see reactions **5-2, 5-5, 5-7**), and since acids could hardly catalyze the reaction (because they would turn NH_3 into NH_4^+), this reaction does not occur by an electrophilic mechanism and so gives very low yields, if any, with ordinary olefins. The mechanism is nearly always nucleophilic, and the reaction is generally performed on polyhalo olefins,[185] Michael-type substrates, and alkynes. As expected, on Michael-type substrates the nitrogen goes to the carbon which does not carry the Z.[186] Other nitrogenous compounds, among them hydroxylamine, hydrazines, amides ($RCONH_2$ and RCONHR′ including imides and lactams), and sulfonamides, also add to olefins. In the case of amides, basic catalysts are required, since amides are not good enough nucleophiles for the reaction and must be converted to $RCONH^-$. Even with amines, basic catalysts are sometimes used, so that RNH^- or R_2N^- is the actual nucleophile. Tertiary amines (except those which are too bulky) add to Michael-type substrates in a reaction which is catalyzed by acids like HCl or HNO_3, to give the corresponding quaternary ammonium salts.[187]

---

[182] Schulte, Reisch, and Hörner, *Chem. Ber.* **95**, 1943 (1962).

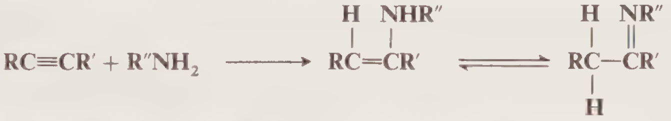
[183] For a review, see Gilbert, "Sulfonation and Related Reactions," pp. 148–156, Interscience Publishers, New York, 1965.



$$\mathrm{Z{-}\underset{|}{C}{=}\underset{|}{C}{-} + R_3NH^+\ \ Cl^- \xrightarrow{HCl} Z{-}\overset{|}{\underset{\underset{\displaystyle H}{|}}{C}}{-}\overset{|}{\underset{\underset{\displaystyle NR_3^+}{|}}{C}}{-}\ \ Cl^-}$$

The tertiary amine may be aliphatic, cycloalkyl, or heterocyclic (including pyridine).

Triple bonds are readily attacked.[188] Primary amines add to give enamines, which have a hydrogen on the nitrogen and (analogously to enols) tautomerize to the more stable imines:



$$\mathrm{RC{\equiv}CR' + R''NH_2 \longrightarrow \overset{\overset{\displaystyle H}{|}}{R C}{=}\overset{\overset{\displaystyle NHR''}{|}}{C}R' \rightleftharpoons R\underset{\underset{\displaystyle H}{|}}{\overset{\overset{\displaystyle H}{|}}{C}}{-}\overset{\overset{\displaystyle NR''}{\|}}{C}R'}$$

These are often stable enough for isolation.[189] When ammonia is used instead of a primary amine, the corresponding $\mathrm{RCH_2{-}\overset{\overset{\displaystyle NH}{\|}}{C}R'}$ is not stable enough for isolation, but polymerizes. Secondary amines give enamines $RCH{=}CR'NR''_2$, which, lacking a hydrogen on the nitrogen, are quite stable. It has been shown that triple bonds are more susceptible than even activated double bonds to attack by amines. Thus diethylamine added to the triple bonds of *both* $CH_3COCH{=}CHC{\equiv}CH$ and $CH_3COC{\equiv}CCH{=}CH_2$.[190] Ammonia and primary amines (aliphatic and aromatic) add to conjugated diynes to give pyrroles:[191]

[185] For a review with respect to fluoroolefins, see Chambers and Mobbs, *Adv. Fluorine Chem.* **4,** 51–112 (1965), pp. 62–68.

[186] For a review of cyanoethylation of ammonia and amines, see Bruson, *Org. React.* **5,** 79–135 (1949), pp. 79–89, 113–120.

[187] Le Berre and Delacroix, *Bull. Soc. Chim. Fr.* 640, 647 (1973).

[188] For a review of addition of ammonia and amines to triple bonds, see Chekulaeva and Kondrat'eva, *Russ. Chem. Rev.* **34,** 669–680 (1965).

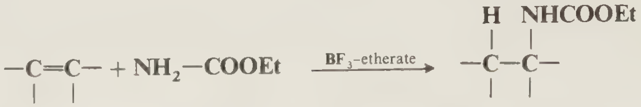
[189] For example, see Kruse and Kleinschmidt, *J. Am. Chem. Soc.* **83,** 213, 216 (1961).

[190] Bowden, Braude, Jones, and Weedon, *J. Chem. Soc.* 45 (1946).

[191] Schulte, Reisch, and Walker, *Chem. Ber.* **98,** 98 (1965).

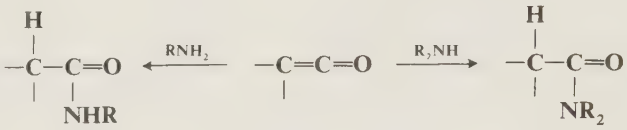
This is not 1,4 addition but 1,2 addition twice.

Carbamates add to olefins and conjugated dienes (which give 1,4 addition) in the presence of BF_3–etherate to give N-substituted carbamates:[192]



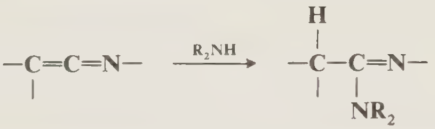
$$-\underset{|}{C}=\underset{|}{C}- + NH_2-COOEt \xrightarrow{BF_3\text{-etherate}} -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{|}{\overset{\overset{NHCOOEt}{|}}{C}}-$$

Primary and secondary amines add to ketenes, to give, respectively, N-substituted and N,N-disubstituted amides:[193]



$$-\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{\underset{NHR}{|}}{C}=O \xleftarrow{RNH_2} -\underset{|}{C}=C=O \xrightarrow{R_2NH} -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{\underset{NR_2}{|}}{C}=O$$

and to ketenimines to give amidines:[194]

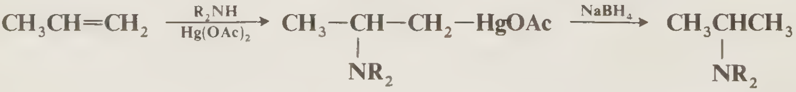


$$-\underset{|}{C}=C=N- \xrightarrow{R_2NH} -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{\underset{NR_2}{|}}{C}=N-$$

R = H or alkyl

Secondary amines can be added to certain nonactivated olefins if palladium(II) complexes are used as catalysts.[195] Markovnikov orientation is observed.

NH_3 can be added to double bonds (even ordinary double bonds) in an indirect manner by the use of hydroboration (**5-15**) followed by treatment with NH_2Cl or NH_2OSO_2OH (**2-29**). This produces a primary amine with anti-Markovnikov orientation. An indirect way of adding a primary or secondary amine to a double bond consists of aminomercuration followed by reduction (see **5-2** for the analogous oxymercuration-demercuration procedure), e.g.,[196]



$$CH_3CH=CH_2 \xrightarrow[Hg(OAc)_2]{R_2NH} CH_3-\underset{\underset{NR_2}{|}}{CH}-CH_2-HgOAc \xrightarrow{NaBH_4} CH_3\underset{\underset{NR_2}{|}}{CH}CH_3$$

The addition of a secondary amine (shown above) produces a tertiary amine, while addition of a primary amine gives a secondary amine. The overall orientation follows Markovnikov's rule. See also reaction **6-57**.

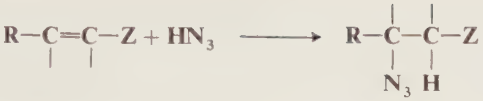
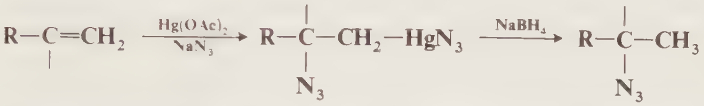
5-10 Addition of Hydrazoic Acid



$$R-\underset{|}{C}=\underset{|}{C}-Z + HN_3 \longrightarrow R-\underset{\underset{N_3}{|}}{\overset{|}{C}}-\underset{\underset{H}{|}}{\overset{|}{C}}-Z$$

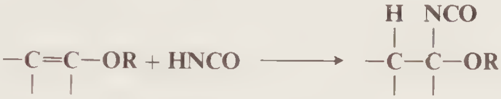
Hydrazoic acid can be added to certain Michael-type substrates (Z is as defined on p. 678) to give β-azido compounds.[197] The reaction apparently fails if R is phenyl. HN_3 can be added indirectly to ordinary olefins by azidomercuration, followed by demercuration,[198] analogous to the similar procedures mentioned in reactions **5-2**, **5-5**, and **5-9**. The method can be applied to



$$R-\underset{|}{C}=CH_2 \xrightarrow[NaN_3]{Hg(OAc)_2} R-\underset{\underset{N_3}{|}}{\overset{|}{C}}-CH_2-HgN_3 \xrightarrow{NaBH_4} R-\underset{\underset{N_3}{|}}{\overset{|}{C}}-CH_3$$

terminal alkenes or strained cycloalkenes (e.g., norbornene) but fails for unstrained internal alkenes.

5-11 Addition of HNCO to Vinyl Ethers

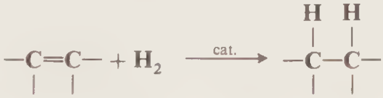


$$-\underset{|}{C}=\underset{|}{C}-OR + HNCO \longrightarrow -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{|}{\overset{\overset{NCO}{|}}{C}}-OR$$

α-Alkoxyisocyanates can be prepared by addition of cyanic acid to vinyl ethers.[199] The orientation is always as shown. Certain other olefins also undergo this reaction.[200]

E. Hydrogen on Both Sides

5-12 Hydrogenation of Double and Triple Bonds[201]



$$-\underset{|}{C}=\underset{|}{C}- + H_2 \xrightarrow{\text{cat.}} -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{|}{\overset{\overset{H}{|}}{C}}-$$

Most carbon-carbon double bonds, whether substituted by electron-donating or electron-withdrawing substituents, can be catalytically hydrogenated, usually in quantitative or near-quantitative yields.[202] According to the review of Adkins and Shriner, over 99% of all known alkenes add hydrogen at temperatures between 0 and 275 C. Many functional groups may be present in the molecule, e.g., OH, COOH, NH_2, CHO, COR, COOR, or CN. Some of these groups are also susceptible to catalytic reduction, but it is usually possible to find conditions under which double bonds can be reduced selectively[203] (see Table 2 in Chapter 19, p. 1116). The catalysts used can be divided into two broad classes both of which mainly consist of transition metals and their compounds: (1) catalysts which are insoluble in the reaction medium (*heterogeneous catalysts*). These have been the ones traditionally used. Among the most effective are Raney nickel,[204] $NaBH_4$-reduced nickel[205] (also called nickel boride), platinum metal or its oxide,[206] rhodium, ruthenium, zinc oxide,[207] and palladium-on-charcoal. (2) Catalysts which are soluble in the reaction medium (*homogeneous catalysts*).[208] These are of more recent discovery. The most important is chlorotris(triphenylphosphine)rhodium $RhCl(Ph_3P)_3$,[209] often called *Wilkinson's catalyst*, which catalyzes the hydrogenation of many olefinic compounds without disturbing such groups as COOR, NO_2, CN, or COR present in the same molecule.[210] Even unsaturated aldehydes can be reduced to saturated aldehydes,[211] though in this case decarbonylation (reaction **4-41**) may be a side reaction. Among other homogeneous catalysts are chlorotris(triphenylphosphine)-hydridoruthenium(II) $(Ph_3P)_3RuClH$,[212] which is specific for terminal double bonds (other double bonds are hydrogenated slowly or not at all), and pentacyanocobaltate(II) $Co(CN)_5{}^{3-}$, which is effective for double and triple bonds only when they are part of conjugated systems[213] (the conjugation may be with C=C, C=O, or an aromatic ring). Homogeneous catalysts often have the advantages of better catalyst reproducibility and better selectivity. They are also less susceptible to catalyst poisoning[214] (heterogeneous catalysts are usually poisoned by small amounts of sulfur, often found in rubber stoppers, or by sulfur-containing compounds such as mercaptans and sulfides). On the other hand, heterogeneous catalysts are usually easier to separate from the reaction mixture. Optically active homogeneous (as well as heterogeneous) catalysts have been used to achieve partially asymmetric hydrogenations.[215]

Hydrogenations in most cases are carried out at room temperature and just above atmospheric pressure, but some double bonds are more resistant and require higher temperatures and pressures. The resistance is usually a function of increasing substitution and is presumably caused by steric factors. Trisubstituted double bonds require, say, 25°C and 100 atm, while tetrasubstituted double bonds may require 275°C and 100 atm. Among the double bonds which are most difficult

to hydrogenate or which cannot be hydrogenated at all are those common to two rings, as in the steroid shown. Hydrogenations, even at about atmospheric pressure, are ordinarily performed in a special hydrogenator, but this is not always necessary. Both the catalyst and the hydrogen may be generated in situ, by treatment of H_2PtCl_6 or $RhCl_3$ with $NaBH_4$,[216] and then ordinary glassware may be used.

Although catalytic hydrogenation is the method which is most often used, double bonds can be reduced by other reagents as well. Among these are sodium in ethanol, sodium and *t*-butyl alcohol in HMPT,[217] lithium and aliphatic amines[218] (see also reaction **5-13**), chromous ion,[219] zinc and acids, water and precipitated nickel,[220] trifluoroacetic acid and triethylsilane Et_3SiH,[221] hydrazine (if a small amount of oxidizing agent, such as air, H_2O_2, or cupric ion is present),[222] and NH_2OSO_3H.[223] However, metallic hydrides, such as lithium aluminum hydride and sodium borohydride, do not in general reduce carbon-carbon double bonds,[224] although this can be done in special cases where the double bond is polar, as in fulvenes (p. 46). In addition, lithium aluminum hydride often reduces double bonds which are in conjugation with C=O bonds, as well as reducing the C=O bonds, e.g.,[225]

$$\mathbf{Ph{-}CH{=}CH{-}COOH} \xrightarrow{\text{LiAlH}_4} 85\%\ \mathbf{Ph{-}CH_2{-}CH_2{-}CH_2OH}$$

This double reduction can be avoided by the use of aluminum hydride[226] or diisobutylaluminum hydride,[227] which selectively reduce C=O groups in the presence of conjugated C=C bonds (see also p. 830). On the other hand, C=C bonds can be selectively reduced in the presence of conjugated C=O bonds by hydrogenation with $RhCl(PPh_3)_3$ as catalyst,[228] as well as by a number of other methods.[229] $LiAlH_4$ also reduces the double bonds of allylic alcohols.[230]

[227] Wilson, Seidner, and Masamune, *Chem. Commun.* 213 (1970).

The inertness of ordinary double bonds toward metallic hydrides is quite useful, since it permits reduction of, say, a carbonyl or nitro group, without effect on a double bond in the same molecule (see Chapter 19 for a discussion of selectivity in reduction reactions). Sodium in liquid ammonia also does not reduce ordinary double bonds, though it does reduce alkynes, allenes, conjugated dienes,[230a] certain nonconjugated dienes,[231] and aromatic rings (reaction **5-13**).

Another hydrogenation method is called *transfer hydrogenation.*[232] In this method the hydrogen comes from another organic molecule, which is itself oxidized. A transition-metal catalyst is frequently employed. A common reducing agent is cyclohexene, which, when a palladium catalyst is used, is oxidized to benzene, losing 2 moles of hydrogen.

Triple bonds can be reduced, either by catalytic hydrogenation or by the other methods mentioned. The comparative reactivity of triple and double bonds depends on the catalyst.[233] With most catalysts, e.g., Pd, triple bonds are hydrogenated more easily, and therefore it is possible to add just 1 mole of hydrogen and reduce a triple bond to a double bond (usually a stereoselective syn addition) or to reduce a triple bond without affecting a double bond present in the same molecule.[234] A particularly good catalyst for this purpose is the Lindlar catalyst ($Pd–CaCO_3–PbO$).[235] On the other hand, there are catalysts which selectively hydrogenate double bonds. Triple bonds can also be selectively reduced to double bonds with diisobutylaluminum hydride[236] (usually a stereoselective syn addition) or (internal triple bonds only) with alkali metals (Na, Li) in liquid ammonia or a low-molecular-weight amine (a stereoselective anti addition). Terminal alkynes are not reduced by the $Na–NH_3$ procedure because they are converted to acetylide ions under these conditions. However, terminal triple bonds can be reduced to double bonds by the addition to the $Na–NH_3$ solution of $(NH_4)_2SO_4$, which liberates the free ethynyl group.[237]

An indirect method[238] of double-bond reduction involves hydrolysis of boranes (prepared by reaction **5-15**). Trialkylboranes can be hydrolyzed by refluxing with carboxylic acids,[239] while

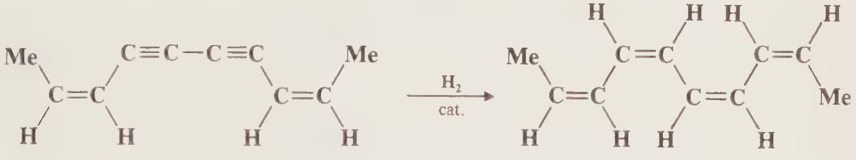
monoalkylboranes RBH_2 can be hydrolyzed with base.[240] Triple bonds can be similarly reduced, to cis olefins.[241]

Conjugated dienes may add hydrogen by 1,2 or 1,4 addition. Selective 1,4 addition can be achieved by hydrogenation in the presence of carbon monoxide, with bis(cyclopentadienyl)-chromium as catalyst.[242] With allenes catalytic hydrogenation usually reduces both double bonds, but reduction of just one double bond, to give an olefin, has been accomplished by treatment with Na NH_3[243] and by hydrogenation with $RhCl(PPh_3)_3$ as catalyst.[244]

Most catalytic reductions of double or triple bonds, whether heterogeneous or homogeneous, have been shown to be syn, with the hydrogens entering from the less hindered side of the molecule.[245] Stereospecificity can be investigated only for tetrasubstituted olefins (except when the reagent is D_2), which are the hardest to hydrogenate, but the results of these investigations show that the addition is usually 80 to 100% syn, though some of the anti addition product is normally also found and in some cases predominates. Catalytic hydrogenation of alkynes nearly always is stereoselective, giving the cis olefin (usually at least 80%), even when it is thermodynamically less stable. For example, **36** gave **37**, even though the steric hindrance is such that a planar molecule is impossible.[246] This is thus a useful method of preparing such cis olefins. However, when steric hindrance is too great, the trans olefin may be formed. One factor which complicates the study of the stereochemistry of heterogeneous catalytic hydrogenation is that exchange of hydrogens takes place, as can be shown by hydrogenation with deuterium. Thus deuterogenation of ethylene produced all the possible deuterated ethylenes and ethanes (including C_2H_6), as well as HD.[247] With 2-butene, it was found that double-bond migration, cis-trans isomerization, and even exchange of hydrogen with groups not on the double bond could occur; e.g., $C_4H_2D_8$ and C_4HD_9 were detected on treatment of *cis*-2-butene with deuterium and a catalyst.[248] Indeed, *alkanes* have been found to exchange with deuterium over a catalyst,[249] and even without deuterium, i.e.,



36 **37**

$$CH_4 + CD_4 \longrightarrow CHD_3 + CH_2D_2$$

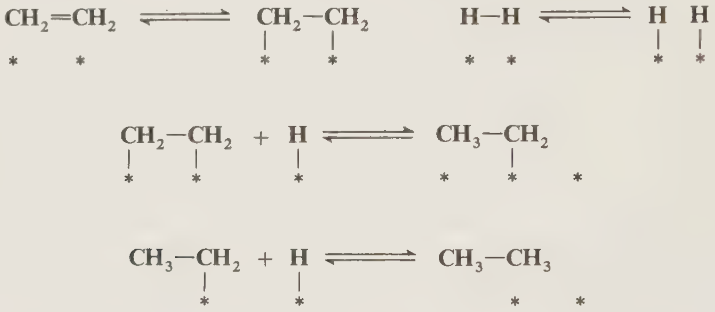
in the gas phase, with a catalyst. All this makes it difficult to investigate the stereochemistry of heterogeneous catalytic hydrogenation.

It was mentioned that catalytic hydrogenation of triple bonds and the reaction with diisobutylaluminum hydride usually give the cis olefin. Most of the other methods of triple-bond reduction lead to the more thermodynamically stable trans olefin. However, this is not the case with the method involving hydrolysis of boranes or with the reductions with hydrazine or NH_2OSO_3H, which also give the cis products.

The mechanism of the heterogeneous catalytic hydrogenation of double bonds is not thoroughly understood because it is a very difficult reaction to study.[250] Because the reaction is heterogeneous, kinetic data, though easy to obtain (measurement of decreasing hydrogen pressure), are difficult to interpret. Furthermore, there are the difficulties caused by the aforementioned hydrogen exchange. The currently accepted mechanism for the common two-phase reaction was originally proposed in 1934.[251] According to this, the olefin is adsorbed onto the surface of the metal, though the nature of the actual bonding is unknown[252] despite many attempts to elucidate it.[253] The metallic site is usually indicated by an asterisk. For steric reasons it is apparent that adsorption of the olefin takes place with its less hindered side attached to the catalyst surface. The fact that addition of hydrogen is generally also from the less hindered side indicates that the hydrogen too is probably adsorbed on the catalyst surface before it reacts with the olefin. It is likely that the H_2 molecule is cleaved to hydrogen atoms in the act of being adsorbed. It has been shown that platinum catalyzes homolytic cleavage of hydrogen molecules.[254] In the second step one of the adsorbed hydrogen atoms becomes attached to a carbon atom, creating, in effect, an alkyl radical (which is still bound to the catalyst though only by one bond) and two vacant catalyst sites. Finally, another hydrogen atom (not necessarily the one originally connected to the first hydrogen) combines with the radical to give the reaction product, freed from the catalyst surface, and two more vacant sites. All the various side reactions, including hydrogen exchange and isomerism, can be explained by this type of scheme. For example, these steps may be occurring in hydrogenation of 1-butene:[255]



$$\underset{*\qquad *}{CH_2{=}CH_2} \rightleftharpoons \underset{*\qquad *}{\overset{\vert\qquad\vert}{CH_2{-}CH_2}} \qquad \underset{*\quad *}{H{-}H} \rightleftharpoons \underset{*\quad *}{\overset{}{H\quad H}}$$

$$\underset{*\qquad *}{CH_2{-}CH_2} + \underset{*}{H} \rightleftharpoons \underset{*\qquad *}{CH_3{-}CH_2}\quad *$$

$$\underset{*}{CH_3{-}CH_2} + \underset{*}{H} \rightleftharpoons CH_3{-}CH_3 \quad *\quad *$$

In this scheme the normal reaction is represented by **38** → **39** → **40** → **41**, double-bond migration by **38** → **39** → **40** → **42** → **44**, cis-trans isomerization by **45** → **43** → **40** → **42** → **44**, and hydrogen exchange by **38** → **39** → **40** → **42** → **46** → **47**. Although this mechanism is satisfactory as far as it goes, there are still questions it does not answer, among them questions involving the nature of the asterisk, the nature of the bonding, and the differences caused by the differing nature of each catalyst. It is certain that the bond energy, and perhaps even the type of bonding, will be different for catalysts of different structure, but what effect this has on the mechanism is not known.[256] For example, there is evidence that metals such as platinum or nickel do not form π or π-allylic complexes with olefinic substrates[257] but that zinc oxide does form π-allylic complexes.[258]

The mechanism of homogeneous hydrogenation catalyzed by $RhCl(Ph_3P)_3$ [259] involves reaction of the catalyst with hydrogen to form a metal hydride $(PPh_3)_2RhH_2Cl$ (**48**), which rapidly transfers two hydrogen atoms to the alkene. The intermediate **48** can be isolated. If a mixture of H_2 and D_2 is used, the product contains only dideuterated and nondeuterated compounds; no monodeuterated products are found, indicating that (unlike the case of heterogeneous catalysis) H_2 or D_2 has been added to one olefin molecule and that no exchange takes place.[259] Although

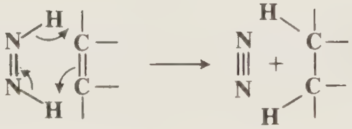
P = PPh$_3$
S = solvent

the addition is syn, there is evidence that the actual addition of the two hydrogens to the double bond (the step marked *A*) is not concerted but takes place in a stepwise fashion, at least in some cases.[260]

In the reactions with hydrazine and with NH_2OSO_3H the actual reducing species is diimide NH=NH, which is formed from the hydrazine by the oxidizing agent, and from NH_2OSO_3H by the intermediacy of NH, which dimerizes.[261] Although both the syn and anti forms of diimide are produced, only the syn form reduces the double bond,[262] by a cyclic mechanism:[263]



The addition is therefore stereospecifically syn[264] and, like catalytic hydrogenation, generally takes place from the less hindered side of a double bond, though not much discrimination in this respect is observed where the difference in bulk effects is small.[265] Diimide reductions are most successful with symmetrical multiple bonds (C=C, C≡C, N=N, O=O) and are more difficult for those inherently polar (C≡N, C=N, C=O, etc.). Diimide is not stable enough for isolation at ordinary temperatures, though it has been prepared[266] as a yellow solid at −196°C. Substituted diimides, e.g., MeN=NH and PhN=NH, have been prepared in solution and are somewhat more stable.[267] Diimide can also be generated by acid treatment of potassium azodicarboxylate (KOOC—N=N—COOK)[268] and by base-catalyzed or thermal elimination of a proton and the substituent from an acyl or sulfonyl hydrazide.[269]

When double bonds are reduced by lithium in ammonia or amines, the mechanism is similar to that of the Birch reduction (reaction **5-13**). The reduction with trifluoroacetic acid and Et_3SiH has an ionic mechanism, with H^+ coming in from the acid and H^- from the silane.[221] In accord with this mechanism, the reaction can be applied only to those olefins which when protonated can form a tertiary carbonium ion or one stabilized in some other way, e.g., by α-OR substitution.[270]

The occurrence of hydrogen exchange and double-bond migration in heterogeneous catalytic hydrogenation means that the hydrogenation does not necessarily take place by straightforward addition of two hydrogen atoms at the site of the original double bond. Consequently, this method is not synthetically useful for adding D_2 to a double or triple bond in a regiospecific or stereospecific manner. However, this objective can be achieved (with syn addition) by homogeneous catalytic hydrogenation, which usually adds D_2 without scrambling,[271] or by the use of one of the diimide methods.[264] Deuterium can also be regiospecifically added by the hydroboration-reduction procedure previously mentioned.

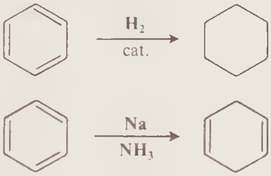
5-13 Hydrogenation of Aromatic Rings



Aromatic rings can be reduced by catalytic hydrogenation,[272] but higher temperatures (100 to 200°C) are required than for ordinary double bonds. Though the reaction is usually carried out with heterogeneous catalysts, homogeneous catalysts have also been used.[273] Many functional groups, such as OH, O^-, COOH, COOR, NH_2, etc., do not interfere with the reaction, but some groups may be preferentially reduced. Among these are CH_2OH groups, which undergo hydrogenolysis to CH_3 (reaction **0-79**). Phenols may be reduced to *cyclohexanones*, presumably through the enol. Heterocyclic compounds are often reduced. Thus furan gives tetrahydrofuran. With benzene rings it is usually impossible to stop the reaction after only one or two bonds have been reduced, since olefins are more easily reduced than aromatic rings. Thus, 1 mol of benzene, treated with 1 mol of hydrogen, gives no cyclohexadiene or cyclohexene but $\frac{1}{3}$ mol of cyclohexane and $\frac{2}{3}$ mol of recovered benzene. This is not true for all aromatic systems. With phenanthrene, for example, it is easy to stop after only the 9,10-bond has been reduced (see p. 43).

When aromatic rings are reduced by sodium (or potassium or lithium) in liquid ammonia (such reductions are known as *dissolving metal reductions*), usually in the presence of an alcohol

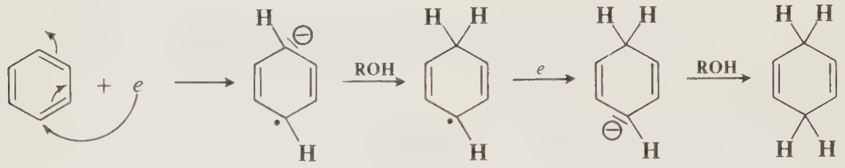
(often ethyl, isopropyl, or *t*-butyl alcohol), 1,4 addition of hydrogen takes place and nonconjugated cyclohexadienes are produced. This reaction is called the *Birch reduction.*[274] Ammonia obtained commercially often has iron salts as impurities which lower the yield in the Birch reduction. Therefore it is often necessary to distill the ammonia. When substituted aromatic compounds are subjected to the Birch reduction, electron-donating groups such as alkyl or alkoxyl decrease the rate of the reaction and are generally found on the nonreduced positions of the product. For example, anisole gives 1-methoxy-1,4-cyclohexadiene and not 3-methoxy-1,4-cyclohexadiene. On the other hand, electron-withdrawing groups such as COOH or $CONH_2$ increase the reaction rate and are found on the reduced positions of the product. The mechanism involves direct transfer of electrons from the metal:[275]



49 **50**

The sodium transfers an electron to the ring, becoming oxidized to Na^+ and creating a radical ion (**49**).[276] There is a great deal of evidence from esr spectra for these species.[277] The radical ion accepts a proton from the alcohol to give a radical, which is reduced to a carbanion by another sodium atom. Finally, **50** accepts another proton. Thus the function of the alcohol is to supply protons, since with most substrates ammonia is not acidic enough for this purpose. In the absence of the alcohol, products arising from dimerization of **49** are frequently obtained. There is evidence[278] at least with some substrates, e.g., biphenyl, that the radical ion corresponding to **49** is converted to the carbanion corresponding to **50** by a different pathway, in which the order of the steps is reversed: first a second electron is lost to give a dianion,[276] which then acquires a proton, producing the intermediate corresponding to **50**.

Ordinary olefins are usually unaffected by Birch-reduction conditions, and double bonds may be present in the molecule if they are not conjugated with the ring. However, phenylated olefins, internal alkynes (p. 710), and conjugated olefins (with C=C or C=O) are reduced under these conditions.

It may be noted that **50** is a resonance hybrid; i.e., we can write two additional canonical forms:

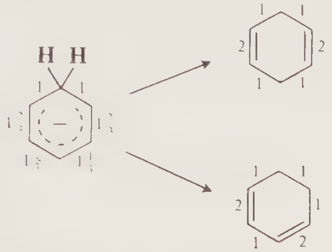
The question therefore arises: Why does the carbanion pick up a proton at the 6 position to give the 1,4-diene? Why not at the 2 position to give the 1,3-diene? An answer to this question has been proposed by Hine, who has suggested that this case is an illustration of the operation of the *principle of least motion*.[279] According to this principle, "those elementary reactions will be favored that involve the least change in atomic position and electronic configuration."[279] The principle can be applied to the case at hand in the following manner (simplified): The valence-bond bond orders (p. 29) for the six carbon-carbon bonds (on the assumption that each of the three forms contributes equally) are (going around the ring) $1\frac{2}{3}$, 1, 1, $1\frac{2}{3}$, $1\frac{1}{3}$, and $1\frac{1}{3}$. When the carbanion is converted to the diene, these bond orders change as follows:



It can be seen that the two bonds whose bond order is 1 are unchanged in the two products, but for the other four bonds there is a change. If the 1,4-diene is formed, the change is $\frac{1}{3}+\frac{1}{3}+\frac{1}{3}+\frac{1}{3}$, while formation of the 1,3-diene requires a change of $\frac{1}{3}+\frac{2}{3}+\frac{2}{3}+\frac{1}{3}$. Since a greater change is required to form the 1,3-diene, the principle of least motion predicts formation of the 1,4-diene. This may not be the only factor, because the ^{13}C nmr spectrum of **50** shows that the 6 position has a somewhat greater electron density than the 2 position, which presumably would make the former more attractive to a proton.[280]

Reduction of aromatic rings with lithium in amines (instead of ammonia) proceeds further, and cyclohexenes are obtained.[281] It is thus possible to reduce a benzene ring, by proper choice of reagent, so that one, two, or all three double bonds are reduced. It has been shown that it is possible to reduce either one or two double bonds by electrochemical reduction.[282]

5-14 Reductive Cleavage of Cyclopropanes

$\xrightarrow[\text{cat.}]{H_2}$ $CH_3CH_2CH_3$

Cyclopropanes can be cleaved by catalytic hydrogenolysis.[283] Among the catalysts used have been Ni, Pd, and Pt. The reaction can often be run under mild conditions.[284] Certain cyclopropane rings, especially cyclopropyl ketones and aryl-substituted cyclopropanes,[285] can be reductively cleaved by an alkali metal (generally Na or Li) in liquid ammonia.[286]

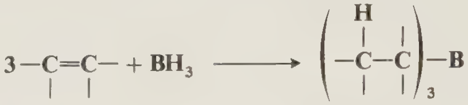
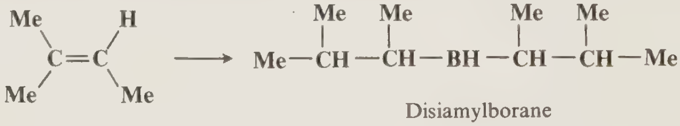
F. A Metal on the Other Side

5-15 Hydroboration

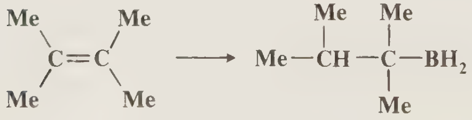


$$3\,-\overset{|}{\underset{|}{C}}=\overset{|}{\underset{|}{C}}-\;+\;BH_3 \longrightarrow \left(-\overset{H\;\;|}{\underset{|\;\;\,|}{C-C}}\right)_3\!-B$$

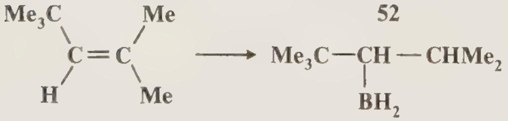
When olefins are treated with borane in ether solvents, BH_3 adds across the double bond.[287] Borane cannot be prepared as a stable pure compound[288] (it dimerizes to diborane B_2H_6), but it is commercially available in the form of complexes with tetrahydrofuran, dimethyl sulfide,[289] or tertiary amines, The olefins can be treated with a solution of one of these complexes (THF–BH_3 reacts at 0°C and is the most convenient to use; $R_3N–BH_3$ generally require temperatures of about 100°C; however, the latter can be prepared as air-stable liquids or solids, while the former can only be used as relatively dilute solutions in THF and are decomposed by the moisture in air) or with a mixture of $NaBH_4$ and BF_3 etherate (or $NaBH_4$ and acetic acid[290]), which generates borane in situ. Ordinarily, the process cannot be stopped with the addition of one molecule of BH_3 because the resulting RBH_2 adds to another molecule of olefin to give R_2BH, which in turn adds to a third olefin molecule, so that the isolated product is a trialkylborane R_3B. The reaction can be performed on alkenes with one to four substituents, including cyclic olefins, but when the olefin is highly hindered, the product *is* the dialkylborane R_2BH or even the monoalkylborane RBH_2.[291] For example, **51** (*disiamylborane*), **52** (*thexylborane*), and **54** have been prepared in this manner:



Disiamylborane
51



Thexylborane
52



53 **54**

---

[287] For books on this reaction and its manifold applications, see Brown, "Boranes in Organic Chemistry," Cornell University Press, Ithaca, N.Y., 1972, "Organic Syntheses Via Boranes," John Wiley & Sons, Inc., New York, 1975; "Hydroboration," W. A. Benjamin, Inc., New York, 1962; Cragg, "Organoboranes in Organic Synthesis," Marcel Dekker, Inc., New York, 1973. For reviews, see Zweifel and Brown, *Org. [288] Mappes and Fehlner, *J. Am. Chem. Soc.* **92,** 1562 (1970); Mappes, Fridmann, and Fehlner, *J. Phys. Chem.* **74,** 3307 (1970); Fehlner, *J. Am. Chem. Soc.* **93,** 6366 (1971).

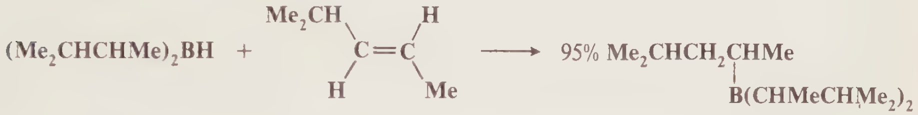
[289] Braun, Braun, Crissman, Opperman, and Adams, *J. Org. Chem.* **36,** 2388 (1971); Lane, *J. Org. Chem.* **39,** 1437 (1974).

[290] Hach, *Synthesis* 340 (1974).

[291] Unless coordinated with a strong Lewis base such as a tertiary amine, mono and dialkylboranes actually exist as dimers, e.g., $R_2B\overset{H}{\underset{H}{\langle\,\rangle}}BR_2$: Brown and Klender, *Inorg. Chem.* **1,** 204 (1962).

Monoalkylboranes RBH_2 (which can be prepared from hindered olefins, as above, or from simple olefins either by reaction **9-56** or by the method described below) and dialkylboranes R_2BH also add to olefins, to give the mixed trialkylboranes RR'_2B and $R_2R'B$, respectively. Mixed trialkylboranes $R_2R'B$ can also be prepared by addition to alkenes of dialkylthioboranes R_2BSR'', followed by treatment with $LiAlH_4$.[292]

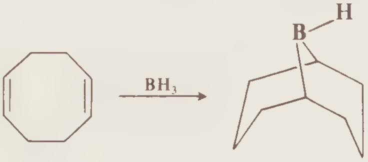
In all cases the boron goes to the side of the double bond which has more hydrogens, whether the substituents are aryl or alkyl.[293] Thus the reaction of **53** with BH_3 gives 98% **54** and only 2% of the other product. This actually follows Markovnikov's rule, since boron is more positive than hydrogen. However, the regioselectivity is caused mostly by steric factors, though electronic factors also play a part. Studies of the effect of ring substituents on rates and on the direction of attack in hydroboration of substituted styrenes showed that the attack by boron has electrophilic character.[294] When both sides of the double bond are monosubstituted or both disubstituted, about equal amounts of each isomer are obtained. However, it is possible in such cases to make the addition regioselective by the use of a large attacking molecule. For example, treatment of iso-PrCH=CHMe with borane gave 57% of product with boron on the methyl-bearing carbon and 43% of the other, while treatment with disiamylborane (**51**) gave 95% of **55** and only 5% of the other isomer:[295]



51

55

Another reagent with high regioselectivity is 9-borabicyclo[3.3.1]nonane (9-BBN), which is prepared by hydroboration of 1,5-cyclooctadiene:[296]



9-BBN

9-BBN has the advantage that it is stable in air. Borane is quite unselective and attacks all sorts of double bonds. Disiamylborane, 9-BBN, and similar molecules are far more selective and will preferentially attack less hindered bonds, so that it is often possible to hydroborate one double bond in a molecule selectively and leave others unaffected or to hydroborate one olefin in the presence of a less reactive olefin.[297] For example, 1-pentene can be removed from a mixture of 1- and 2-pentenes, and a cis olefin can be selectively hydroborated in a mixture of the cis and trans isomers.

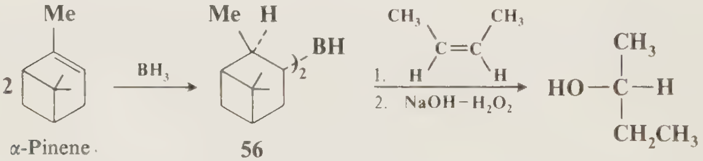
[297] Brown and Moerikofer, *J. Am. Chem. Soc.* **85,** 2063 (1963); Zweifel and Brown, *J. Am. Chem. Soc.* **85,** 2066 (1963); Zweifel, Ayyangar, and Brown, *J. Am. Chem. Soc.* **85,** 2072 (1963); Ref. 295.

Another hydroboration reagent with even greater regioselectivity than BH_3 (for terminal alkenes or those of the form $R_2C{=}CHR$) is monochloroborane BH_2Cl in ether (the hydroboration product is a dialkylchloroborane R_2BCl).[298] For example, 1-hexene gave 94% of the anti-Markovnikov product with BH_3–THF, but > 99.5% with BH_2Cl–OEt_2. This additional regioselectivity is caused by electronic rather than steric factors, so that alkenes with the same number of alkyl groups on both sides of the double bond give significant yields of both isomers. Treatment of alkenes with dichloroborane-etherate $BHCl_2$–OEt_2 in the presence of BCl_3 gives alkyldichloroboranes $RBCl_2$.[299]

An important use of the hydroboration reaction is that alkylboranes, when oxidized with hydrogen peroxide and NaOH, are converted to alcohols (reaction **2-26**). This thus becomes an indirect way of adding H_2O across a double bond in an anti-Markovnikov manner. However, boranes undergo other reactions as well. Among other things, they react with α-halo carbonyl compounds to give alkylated products (**0-101**), with α,β-unsaturated carbonyl compounds to give Michael-type addition of R and H (**5-21**), with CO to give alcohols and ketones (**8-27** to **8-29**); they can be reduced with carboxylic acids, providing an indirect method for reduction of double bonds (reaction **5-12**), or they can be oxidized with chromic acid to give ketones,[300] dimerized with silver nitrate and NaOH (**4-35**), isomerized (**8-14**), or converted to amines (**2-29**) or halides (**2-28**, **4-32**). They are thus useful intermediates for the preparation of a wide variety of compounds. In addition to alkyl and aryl groups, such functional groups as OR, OH, NH_2, SMe, halogen, and COOR may be present in the molecule,[301] but not groups which are reducible by borane.

Use of the reagent diisopinocampheylborane **56** (prepared by treating optically active α-pinene with BH_3) results in asymmetric hydroboration-oxidation.[302] Alcohols with optical purities of 70 to 90% have been obtained in this way, making it one of the most efficient asymmetric syntheses known.



α-Pinene

56

Optically active

The double bonds in a conjugated diene are hydroborated separately; i.e., there is no 1,4 addition. However, it is not easy to hydroborate just one of a conjugated system, since conjugated double bonds are less reactive than isolated ones. Thexylborane[303] (**52**) is particularly useful for achieving the cyclic hydroboration of dienes, conjugated or nonconjugated,[304] e.g.,

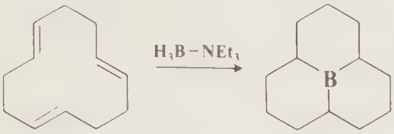
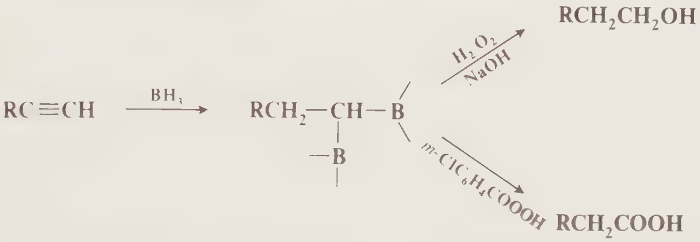
Rings of five, six, or seven members can be formed in this way. Similar cyclization can also be accomplished with other monoalkylboranes and, in some instances, with BH_3 itself.[305] One example is the formation of 9-BBN, shown above. Another is conversion of 1,5,9-cyclododecatriene to perhydro-9*b*-boraphenalene:[306]



Triple bonds can be monohydroborated to give unsaturated boranes, which can be reduced with carboxylic acids to cis alkenes or oxidized and hydrolyzed to aldehydes or ketones. Terminal alkynes give aldehydes by this method, in contrast to the mercuric or acid-catalyzed addition of water discussed at reaction **5-3**. However, terminal alkynes give unsaturated boranes (and hence aldehydes) only when treated with a hindered borane such as **51**, **52**, or catecholborane[307] (p. 560), or with $BH_2Cl\text{-}OEt_2$.[308] The reaction between terminal alkynes and BH_3 produces 1,1-dibora compounds, which can be oxidized either to primary alcohols (with $NaOH\text{-}H_2O_2$) or to carboxylic acids (with *m*-chloroperbenzoic acid).[309] Acetylenic acetals $RC{\equiv}CCH(OEt)_2$ (which can be prepared from ortho esters by reaction **0-92**) can be similarly hydroborated, with concomitant reduction of the acetal group (reaction **0-80**), to give alkenylborane ethers, which can be oxidized or hydrolyzed in situ to give α-keto ethers RCH_2COCH_2OEt or cis allylic ethers $RCH{=}CHCH_2OEt$, respectively.[310]



The addition in hydroboration has been shown to be stereospecific and syn, with attack taking place from the less hindered side.[311] Where the reaction rates are measurable (most are too fast), the reaction is second order.[312] The mechanism is probably a cyclic four-center one:[313]

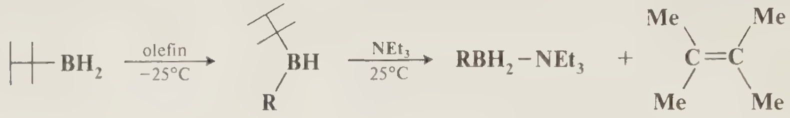
In the case of thexylmonoalkylboranes (**57**, prepared by addition of **52** to olefins), hydroboration can be reversed by treatment with triethylamine.[314] The monoalkylborane–triethylamine complexes **58** can be used to hydroborate olefins to give the trialkylboranes RR'_2B. **57** can also

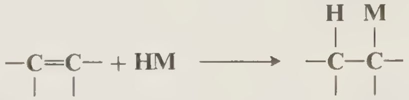


52 **57** **58**

be added to terminal alkenes to give trialkylboranes with three different R groups RR′R″B, one of which is the thexyl group.[315] However, if the terminal alkene is sufficiently hindered, a thexyl group is lost and again the product is RR'_2B.[315]

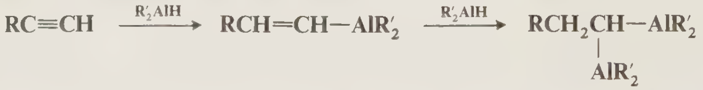
OS **50,** 88; **52,** 59; **53,** 77.

5-16 Other Hydrometalation



$$-\overset{|}{\underset{|}{C}}=\overset{|}{\underset{|}{C}}- + HM \longrightarrow -\overset{H}{\underset{|}{\overset{|}{C}}}-\overset{M}{\underset{|}{\overset{|}{C}}}-$$

Metal hydrides of groups IIIA and IVA of the periodic table (e.g., AlH_3, GaH_3) as well as many of their alkyl and aryl derivatives (e.g., R_2AlH, Ar_3SnH) add to double bonds to give organometallic compounds.[316] The hydroboration reaction (**5-15**) is an important example. The mechanism with group IIIA hydrides seems to be electrophilic (or four-centered pericyclic with some electrophilic characteristics) while with group IVA hydrides a mechanism involving free radicals seems more likely. With some reagents triple bonds can add 1 or 2 moles, e.g.,[317]



$$RC{\equiv}CH \xrightarrow{R'_2AlH} RCH{=}CH{-}AlR'_2 \xrightarrow{R'_2AlH} RCH_2\underset{\underset{\displaystyle AlR'_2}{|}}{CH}{-}AlR'_2$$

When 2 moles are added, electrophilic addition generally gives 1,1-dimetallic products (as with hydroboration), while free-radical addition usually gives the 1,2-dimetallic products. 1,1-Dialuminum compounds react with alkyllithium reagents or sodium methoxide to give the inter-

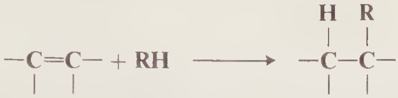
5-17 Addition of Alkanes and Alkenes



$$-\underset{|}{C}=\underset{|}{C}- + RH \longrightarrow -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{|}{\overset{\overset{R}{|}}{C}}-$$

There are two important ways of adding alkanes to olefins, the thermal method and the acid-catalysis method.[319] Both give chiefly mixtures, and neither is useful for the preparation of relatively pure compounds in reasonable yields. However, both are useful industrially. In the thermal method the reactants are heated to high temperatures (about 500°C) at high pressures (150 to 300 atm) without a catalyst. As an example, propane and ethylene gave 55.5% isopentane, 7.3% hexanes, 10.1% heptanes, and 7.4% alkenes.[320] The mechanism is undoubtedly of a free-radical type and can be illustrated by one possible sequence in the reaction between propane and ethylene:

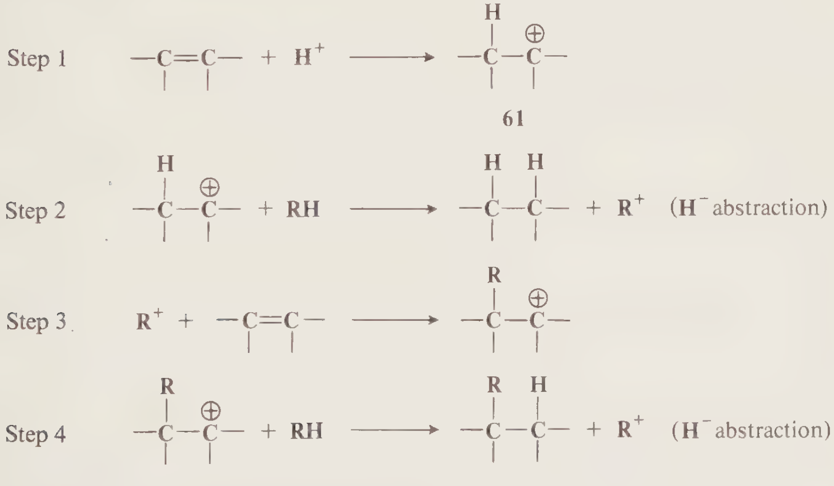
Step 1 $CH_3CH_2CH_3 \xrightarrow{\Delta} CH_3\cdot + CH_3CH_2\cdot$

Step 2 $CH_3\cdot + CH_3CH_2CH_3 \longrightarrow CH_4 + CH_3\underset{\bullet}{C}HCH_3$

Step 3 $CH_3\underset{\bullet}{C}HCH_3 + CH_2{=}CH_2 \longrightarrow (CH_3)_2CHCH_2CH_2\cdot$

Step 4 $(CH_3)_2CHCH_2CH_2\cdot + CH_3CH_2CH_3 \longrightarrow (CH_3)_2CHCH_2CH_3 + CH_3\underset{\bullet}{C}HCH_3$

In the acid-catalysis method, a proton or Lewis acid is used as the catalyst and the reaction is carried out at temperatures between −30 and 100°C. This is a Friedel-Crafts process with a carbonium-ion mechanism (illustrated for a proton acid catalyst):



Step 1 $$-\underset{|}{C}=\underset{|}{C}- + H^+ \longrightarrow -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{|}{\overset{\oplus}{C}}-$$

Step 2 $$-\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{|}{\overset{\oplus}{C}}- + RH \longrightarrow -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{|}{\overset{\overset{H}{|}}{C}}- + R^+ \quad (H^- \text{ abstraction})$$

Step 3 $$R^+ + -\underset{|}{C}=\underset{|}{C}- \longrightarrow -\underset{|}{\overset{\overset{R}{|}}{C}}-\underset{|}{\overset{\oplus}{C}}-$$

Step 4 $$-\underset{|}{\overset{\overset{R}{|}}{C}}-\underset{|}{\overset{\oplus}{C}}- + RH \longrightarrow -\underset{|}{\overset{\overset{R}{|}}{C}}-\underset{|}{\overset{\overset{H}{|}}{C}}- + R^+ \quad (H^- \text{ abstraction})$$

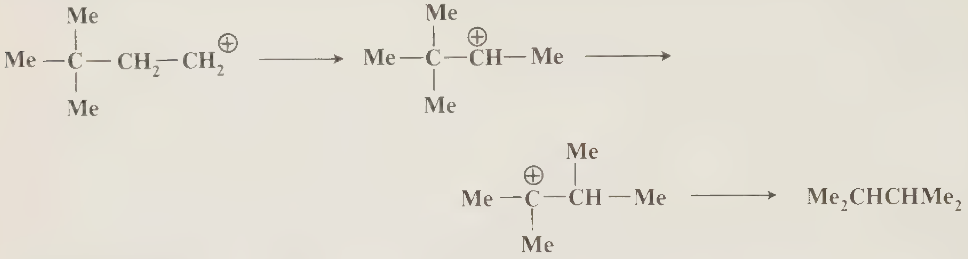
---

[318] Zweifel and Steele, *Tetrahedron Lett.* 6021 (1966).

[319] For reviews, see Shuikin and Lebedev, *Russ. Chem. Rev.* **35**, 448-455 (1966); Schmerling, in Olah, "Friedel-Crafts and Related Reactions," vol. 2, pp. 1075–1111, 1121–1122, Interscience Publishers, New York, 1964.

[320] Frey and Hepp, *Ind. Eng. Chem.* **28**, 1439 (1936).

62 often rearranges before it abstracts a hydride ion, explaining, for example, why the principal product from the reaction between isobutane and ethylene is 2,3-dimethylbutane:



$$Me_3C-CH_2-\overset{\oplus}{C}H_2 \longrightarrow Me_3C-\overset{\oplus}{C}H-Me \longrightarrow Me_2\overset{\oplus}{C}-CHMe-Me \longrightarrow Me_2CHCHMe_2$$

It is also possible for **61** (or **62**, for that matter), instead of abstracting a hydride ion, to add to another mole of olefin, so that not only rearrangement products but also dimeric and polymeric products are frequent.

The addition of secondary or tertiary carbonium ions (generated from the corresponding alcohols, esters, or alkenes) to 1,1-dichloroethene gives carboxylic acids by hydrolysis of the intermediate ions (see reaction **0-3**):[321]

$$R_3COH \xrightarrow{H^+} R_3C^+ + CH_2{=}CCl_2 \longrightarrow$$

$$R_3C-CH_2-\overset{\oplus}{C}Cl_2 \xrightarrow{H_2O} R_3CCH_2COOH$$

The reaction may also be base-catalyzed, in which case there is nucleophilic addition and a carbanion mechanism.[322] Carbanions most often used are those stabilized by one or more α-aryl groups. For example, toluene adds to styrene in the presence of sodium to give 1,3-diphenylpropane:[323]

$$PhCH_3 \xrightarrow{Na} Ph\overset{\ominus}{\bar{C}}H_2 + PhCH{=}CH_2 \longrightarrow$$

$$Ph\overset{\ominus}{\bar{C}}H-CH_2CH_2Ph \xrightarrow{\text{solvent}} PhCH_2CH_2CH_2Ph$$

Conjugated dienes give 1,4 addition.[324] This reaction has also been performed with salts of carboxylic acids in what amounts to a method of alkylation of carboxylic acids[325] (see also reaction **0-98**):

$$CH_3COOK \xrightarrow{NaNH_2} \overset{\ominus}{\bar{C}}H_2COOK + CH_2{=}CH_2 \longrightarrow \overset{\ominus}{\bar{C}}H_2-CH_2CH_2COOK$$

Two and even three alkyl groups can be put on this way.

---

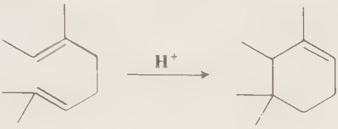
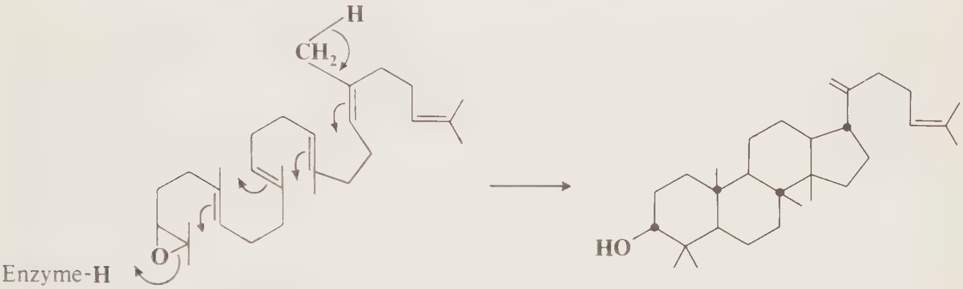
As pointed out above, it is possible in the acid-catalyzed process for an olefin to add to an olefin so that the product is a dimer which contains one double bond, e.g.,

$$CH_2{=}CH_2 + CH_2{=}CH_2 \longrightarrow CH_2{=}CH{-}CH_2{-}CH_3$$

This reaction has also been carried out internally, e.g.,



Processes of this kind are important in the biosynthesis of steroids and tetra- and pentacyclic terpenes. For example, squalene 2,3-oxide is converted by enzymic catalysis to dammaradienol.

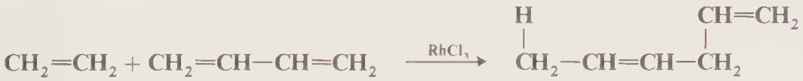


Squalene 2,3-oxide

Dammaradienol

The squalene → lanosterol biosynthesis (which is a key step in the biosynthesis of cholesterol) is similar.[326]

The addition of olefins to olefins can also be accomplished by bases[327] as well as by the use of catalyst systems[328] consisting of nickel complexes and alkylaluminum compounds (known as *Ziegler catalysts*)[329] and by catalysts derived from rhodium chloride.[330] These and similar catalysts also catalyze the 1,4 addition of olefins to dienes,[331] e.g.,



$$CH_2{=}CH_2 + CH_2{=}CH{-}CH{=}CH_2 \xrightarrow{RhCl_3} \overset{\overset{\displaystyle H}{|}}{C}H_2{-}CH{=}CH{-}\overset{\overset{\displaystyle CH{=}CH_2}{|}}{C}H_2$$

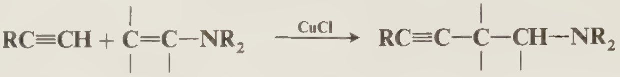
In the presence of cuprous chloride and ammonium chloride, acetylene adds to another molecule of itself to give vinylacetylene:

$$HC{\equiv}CH + HC{\equiv}CH \xrightarrow[NH_4Cl]{CuCl} HC{\equiv}C{-}CH{=}CH_2$$

Similarly, terminal alkynes add to the double bond of enamines:[332]

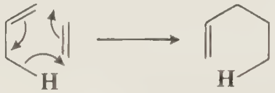


$$RC{\equiv}CH + \overset{|}{\underset{|}{C}}{=}\underset{|}{C}{-}NR_2 \xrightarrow{CuCl} RC{\equiv}C{-}\overset{|}{\underset{|}{C}}{-}\underset{|}{C}H{-}NR_2$$

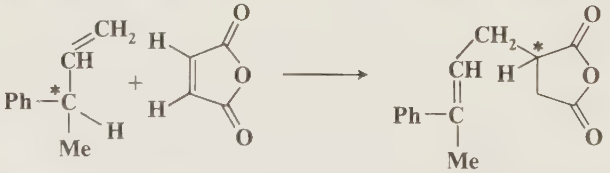
Olefins and alkynes may also add to each other to give cyclic products (see reactions **5-52** and **5-54**).

OS **I,** 229; **IV,** 665.

5-18 The Ene Synthesis

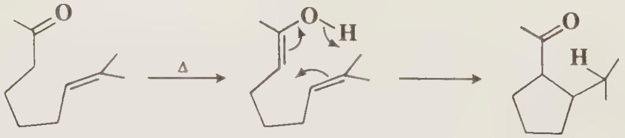


Olefins can add to double bonds in a reaction different from those discussed in **5-17,** which, however, is still formally the addition of RH to a double bond. This reaction is called the *ene synthesis*[333] and bears a certain similarity to the Diels-Alder reaction (**5-51**). One of the components must be a reactive dienophile[334] (see reaction **5-51** for a definition of this word) such as maleic anhydride, but the other (which supplies the hydrogen) may be a simple alkene such as propene. There has been much discussion of the mechanism of this reaction, and both concerted pericyclic (as shown above) and stepwise mechanisms have been suggested. The reaction between maleic anhydride and optically active PhCHMeCH=CH$_2$ gave an optically active product,[335]



which is strong evidence for a concerted rather than a stepwise mechanism. Incidentally, this is another case of asymmetric synthesis (p. 106).

6,7-Unsaturated ketones give internal ene reactions, which proceed through the enol forms, e.g.,[336]



OS **IV,** 766; **V,** 459.

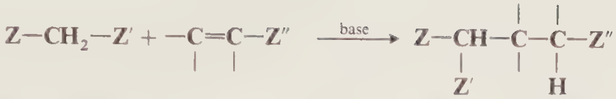
5-19 The Michael Reaction

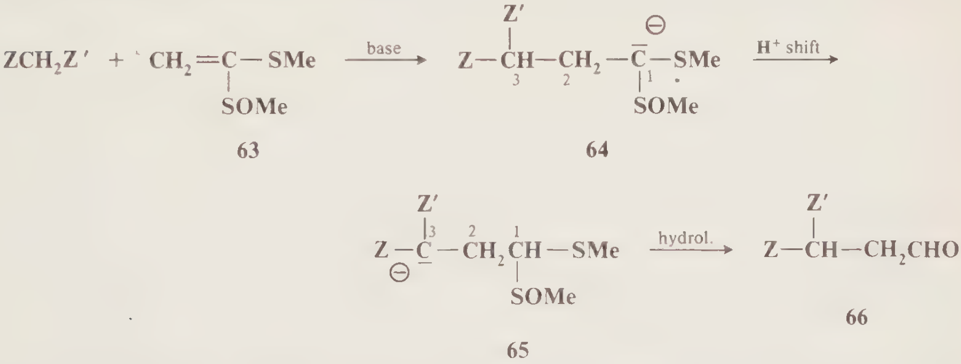


$$Z{-}CH_2{-}Z' + {-}C{=}C{-}Z'' \xrightarrow{\text{base}} Z{-}CH(Z'){-}C{-}CH{-}Z''$$

Compounds containing electron-withdrawing groups (Z is defined on p. 678) add, in the presence of bases, to olefins of the form C=C—Z (including quinones). This is called the *Michael reaction* and involves conjugate addition.[337] The base removes the acidic proton, and then the mechanism is as outlined on p. 679. The reaction has been carried out with malonates, cyanoacetates, acetoacetates, other β-keto esters, and compounds of the form $Z{-}CH_3$, ZCH_2R, $ZCHR_2$, and ZCHRZ', including esters, ketones, aldehydes, nitriles, nitro compounds,[338] and sulfones, as well as other compounds with relatively acidic hydrogens, such as indenes and fluorenes. These reagents do not add to ordinary double bonds, except in the presence of free-radical initiators (reaction **5-23**). 1,2 addition (to the C=O or C≡N group) often competes and sometimes predominates (reaction **6-42**).

Mannich bases (see reaction **6-17**) and β-halo carbonyl compounds may also be used as substrates; these are converted to the C=C—Z compounds in situ by the basic catalyst (reactions **6-17**, **7-13**).[339] Substrates of this kind are especially useful in cases where the C=C—Z compound is unstable. The reaction of C=C—Z compounds with enamines (**2-17**) can also be considered a Michael reaction. Michael reactions are reversible (**7-17**).

The ketene thioacetal monoxide **63** reacts with ZCH_2Z' compounds to give adducts which can be hydrolyzed to the substituted aldehydes **66**.[340] **63** is thus a synthon for the $-CH_2CHO$ group.



The reaction has been performed with Z, Z' = COR and COOR, as well as with simple esters $R'CH_2COOR$ and with enamines (see reaction **2-17**). When the reagent is ZCH_2Z', if an alkyl halide R″X is added to the reaction mixture before hydrolysis, the enolate ion **65** is alkylated at C-3, so that the product after hydrolysis is $ZCR''Z'CH_2CHO$.[341] On the other hand, if the reagent is a simple ester $R'CH_2COOR$, addition of R″X alkylates the more stable **64** (i.e., **65** does not form, and alkylation takes place at C-1), so that the product after hydrolysis is a γ-keto ester ROOCCHR′CH$_2$COR″.[341]

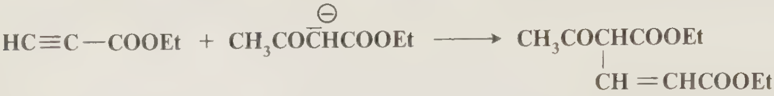
[338] For a review of Michael reactions where Z, Z', or Z″ is nitro, see Baer and Urbas, in Feuer, "The Chemistry of the Nitro and Nitroso Groups," pt. 2, pp. 130–148, Interscience Publishers, New York, 1970.

[339] Mannich bases react with ketones *without* basic catalysts to give 1,5-diketones, but this process, known as the *thermal-Michael reaction*, has a different mechanism: Brown, Buchanan, Curran, and McLay, *Tetrahedron* **24**, 4565 (1968); Gill, James, Lions, and Potts, *J. Am. Chem. Soc.* **74**, 4923 (1952).

[340] Herrmann, Kieczykowski, Romanet, Wepplo, and Schlessinger, *Tetrahedron Lett.* 4711 (1973).

[341] Herrmann, Kieczykowski, Romanet, and Schlessinger, *Tetrahedron Lett.* 4715 (1973).

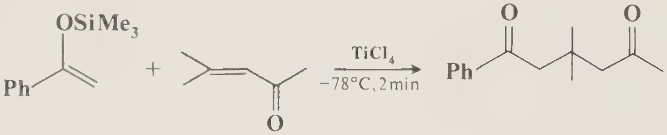
Michael reactions are sometimes applied to substrates of the type C≡C—Z, e.g.,



$$\mathrm{HC{\equiv}C{-}COOEt} + \mathrm{CH_3CO\overset{\ominus}{C}HCOOEt} \longrightarrow \mathrm{CH_3CO\underset{\substack{|\\ CH=CHCOOEt}}{C}HCOOEt}$$

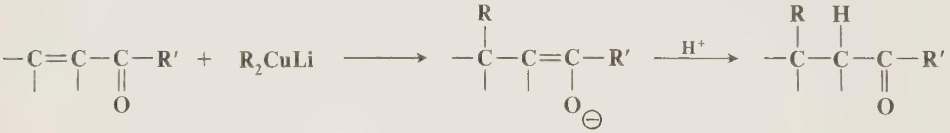
Indeed, because of the greater susceptibility of triple bonds to nucleophilic attack, it is even possible for nonactivated alkynes, e.g., acetylene, to be substrates in this reaction.[342]

In a closely related reaction, silyl enol ethers add to α,β-unsaturated ketones and esters when catalyzed by TiCl$_4$, e.g.,[342a]



OS **I**, 272; **II**, 200; **III**, 286; **IV**, 630, 652, 662, 776; **V**, 486, 1135; **53**, 1; **55**, 99.

5-20 1,4 Addition of Organometallic Compounds to Activated Double Bonds



$$-\underset{|}{C}=\underset{|}{C}-\underset{\parallel}{\underset{O}{C}}-R' + R_2CuLi \longrightarrow -\overset{\overset{R}{|}}{\underset{|}{C}}-\underset{|}{C}=\underset{\underset{O^{\ominus}}{|}}{C}-R' \xrightarrow{H^+} -\overset{\overset{R}{|}}{\underset{|}{C}}-\overset{\overset{H}{|}}{\underset{|}{C}}-\underset{\underset{O}{\parallel}}{C}-R'$$

67

Lithium dialkylcopper reagents (see reaction **0-87**) add to α,β-unsaturated aldehydes and ketones (R′ = H, R, Ar) to give conjugate addition products,[343] in a reaction which is closely related to the Michael reaction. α,β-Unsaturated esters are less reactive, and the corresponding acids do not react at all. R may be primary alkyl, vinyl, or aryl. Various functional groups such as OH and unconjugated C=O groups may be present in the substrate. A characteristic of the reaction is that only one of the R groups of R$_2$CuLi adds to the substrate; the other is wasted. This can be a limitation where the precursor (RLi or RCu, see p. 410) is expensive or available in limited amounts. The difficulty can be overcome by using one of the mixed reagents R(R′C≡C)-CuLi,[344] R(O—*t*-Bu)CuLi,[345] or R(PhS)CuLi,[346] each of which transfers only the R group. These reagents are easily prepared by the reaction of RLi with R′C≡CCu (R′ = *n*-Pr or *t*-Bu), *t*-BuOCu, or PhSCu, respectively. A further advantage of these mixed reagents is that good yields of addition product are achieved when R is tertiary, so that use of one of them permits the introduction of a tertiary alkyl group. The mixed reagent R(CN)CuLi, prepared from RLi and CuCN, also selectively transfers the R group.[347]

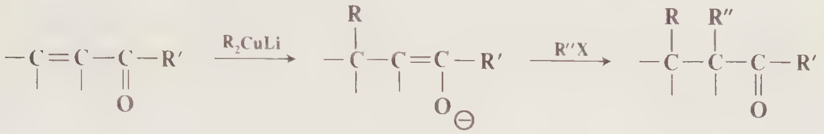
[347] Gorlier, Hamon, Levisalles, and Wagnon, *J. Chem. Soc., Chem. Commun*. 88 (1973).

There is generally little or no competition from 1,2 addition (to the C=O). However, when R is allyl, 1,4 addition is observed with some substrates and 1,2 addition with others.[348] R_2CuLi also add to α,β-unsaturated sulfones ($C{=}C{-}SO_2Ar$)[349] but not to simple α,β-unsaturated nitriles.[350] Organocopper reagents RCu (as well as certain R_2CuLi) add to α,β-unsaturated sulfoxides C=C—SOR.[351]

When the solvent is 1,2-dimethoxyethane, instead of hydrolyzing the enolate ion **67**, it is

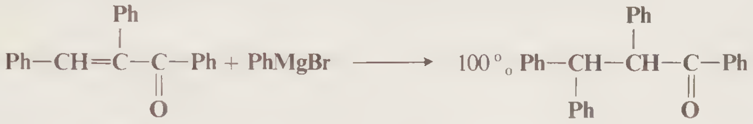


$$-\underset{|}{C}=\underset{|}{C}-\underset{\underset{O}{\|}}{C}-R' \xrightarrow{R_2CuLi} -\underset{|}{\overset{\overset{R}{|}}{C}}-\underset{|}{C}=\underset{\underset{O^{\ominus}}{|}}{C}-R' \xrightarrow{R''X} -\underset{|}{\overset{\overset{R}{|}}{C}}-\underset{|}{\overset{\overset{R''}{|}}{C}}-\underset{\underset{O}{\|}}{C}-R'$$

67

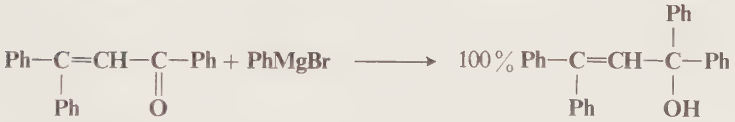
possible to alkylate it directly with an alkyl halide, where R″ is primary alkyl or allylic[352] (reaction **0-97**). Thus, by this method, both the α and β positions of a ketone are alkylated in one synthetic operation.

Grignard reagents also add to these substrates, but with these reagents, 1,2 addition may seriously compete: the product is often controlled by steric factors. Thus, **68** with phenylmagnesium bromide gives 100% 1,4 addition, while **69** gives 100% 1,2 addition:



$$Ph-CH=\overset{\overset{Ph}{|}}{C}-\underset{\underset{O}{\|}}{C}-Ph + PhMgBr \longrightarrow 100\%\ Ph-\underset{\underset{Ph}{|}}{CH}-\overset{\overset{Ph}{|}}{CH}-\underset{\underset{O}{\|}}{C}-Ph$$

68



$$Ph-\underset{\underset{Ph}{|}}{C}=CH-\underset{\underset{O}{\|}}{C}-Ph + PhMgBr \longrightarrow 100\%\ Ph-\underset{\underset{Ph}{|}}{C}=CH-\overset{\overset{Ph}{|}}{\underset{\underset{OH}{|}}{C}}-Ph$$

69

In general, substitution at the carbonyl group increases 1,4 addition, while substitution at the double bond increases 1,2 addition. In most cases both products are obtained, but α,β-unsaturated *aldehydes* nearly always give exclusive 1,2 addition when treated with Grignard reagents. However, the extent of 1,4 addition of Grignard reagents can be increased by the use of a copper-ion catalyst, e.g., CuCl, $Cu(OAc)_2$.[353] It is likely that alkylcopper reagents, formed from RMgX and Cu^+ (cupric acetate is reduced to cuprous ion by excess RMgX), are the actual attacking species in these cases.[343] Alkyllithiums, treated with compounds of the form $C{=}C{-}COCH_3$ and $C{=}C{-}COOC_2H_5$, gave only 1,2 addition.[354] In some cases, with Grignard reagents, it is possible to get a diaddition product (1,2 *and* 1,4).[355]

However, neither Grignard reagents nor lithium dialkylcopper reagents generally add to ordinary C=C double bonds. Grignard reagents in general add only to double bonds susceptible to nucleophilic attack, e.g., fluoroolefins, tetracyanoethylene,[355a] and fulvenes. However, active Grignard reagents (benzyl, allyl) also add to the double bonds of allylic amines[356] and of allylic and homoallylic alcohols[357] as well as to the triple bonds of propargyl alcohols and certain other alkynols.[358] It is likely that cyclic intermediates are involved in these cases, in which the magnesium coordinates with the hetero arom. Organolithium reagents (primary, secondary, and tertiary alkyl and in some cases aryl) also add to the double and triple bonds of allylic and propargylic alcohols[359] (in this case tetramethylethylenediamine is a catalyst) and to certain other olefins containing hetero groups such as OR, NR_2 or SR.[360] Allylic, benzylic, and tertiary Grignard reagents also add to 1-alkenes and to strained internal alkenes, e.g., norbornene, if the reaction is carried out not in ether but in a hydrocarbon solvent such as pentane or in the alkene itself as solvent, heated, under pressure if necessary, to 60 to 130°C.[361] Yields are variable. *Intramolecular* addition of RMgX to completely unactivated double and triple bonds has been demonstrated;[362] e.g., refluxing of 6-chloro-1-heptene with Mg for 5 hr gave, after hydrolysis, an 88% yield of 1,2-dimethylcyclopentane. Also, certain catalysts [e.g., tris(triphenylphosphine)-bromorhodium $(Ph_3P)_3RhBr$, bis(triphenylphosphine)dichloronickel $(Ph_3P)_2NiCl_2$] catalyze the addition of methylmagnesium bromide to diphenylacetylene.[363]

An alkynyl group can be added to the double bond of an α,β-unsaturated ketone by use of the diethylalkynylalane reagents $Et_2AlC{\equiv}CR$.[364] In a similar manner, the alkenyl reagents $R_2AlCH{=}CR'$ transfer an alkenyl group.[365] Trialkylalanes R_3Al also add 1,4 to such ketones in the presence of nickel acetylacetonate.[366]

In certain cases, Grignard reagents add 1,4 to *aromatic* systems, e.g.,[367]

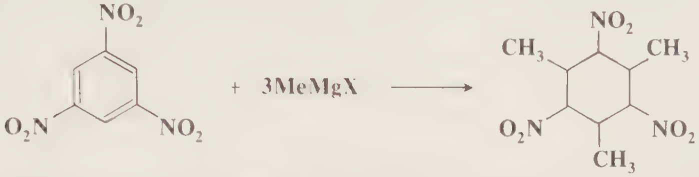
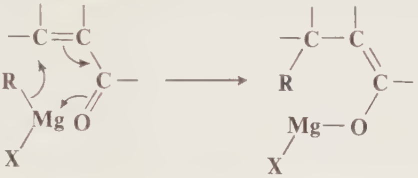
Such cyclohexadienes are easily oxidizable to benzenes (often by atmospheric oxygen), so that this reaction becomes a method of alkylating and arylating suitably substituted (usually hindered) aryl ketones. A similar reaction has been reported for aromatic nitro compounds:[368]



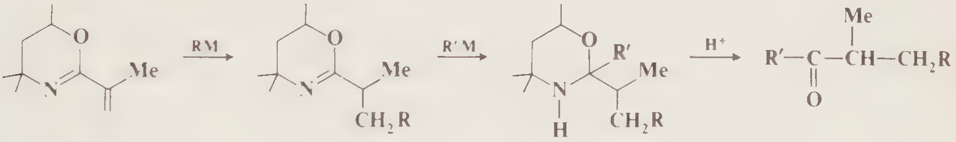
Both Grignard and R_2CuLi reagents[369] have also been added to triple-bond systems of the form C≡C—C=O.

The mechanisms of most of these reactions are not well known. The 1,4 uncatalyzed Grignard reaction has been postulated to proceed by a cyclic mechanism



but there is evidence against it.[370] The R_2CuLi and copper-catalyzed Grignard additions may involve a free-radical mechanism of some type,[371] though the fact that retention of configuration at R has been demonstrated in several cases rules out a completely free R• radical.[372] The addition of R_3Al takes place by a free-radical mechanism.[366]

Grignard reagents and alkyllithiums add to the double bond of the commercially available 2-isopropenyldihydro-1,3-oxazine **70** (see reaction **0-100**), and then without isolation of **71**, a second



70 71 72

mole of RM (the same or different) can be added to give **72**, which can be hydrolyzed to a ketone.[373] R may be aryl or primary, secondary, or tertiary alkyl, but R′ is limited to aryl and primary alkyl groups. Borohydride reduction of **71**, followed by hydrolysis (see reaction **0-100**), gives the α-alkyl aldehyde $RCH_2CHMeCHO$. Similar reactions have been carried out on 2-(1-phenyl-1-ethenyl)dihydro-1,3-oxazine, the phenyl analog of **70**. The addition of RM to **70** is not a simple 1,4-addition but involves ring opening to a ketenimine intermediate (similar to **162**, shown on p. 430), which then closes to give **71**.

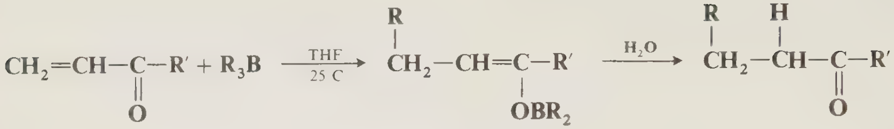
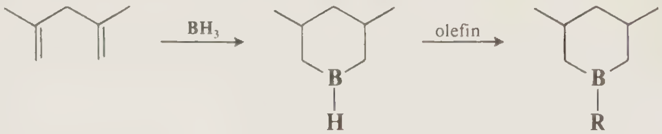
5-21 The Addition of Boranes to Activated Double Bonds



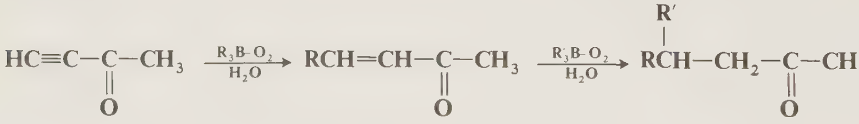
$$CH_2{=}CH{-}\underset{\underset{O}{\|}}{C}{-}R' + R_3B \xrightarrow[25\ C]{THF} \overset{\overset{R}{|}}{CH_2}{-}CH{=}\underset{\underset{OBR_2}{|}}{C}{-}R' \xrightarrow{H_2O} \overset{\overset{R}{|}}{CH_2}{-}\overset{\overset{H}{|}}{CH}{-}\underset{\underset{O}{\|}}{C}{-}R'$$

$R' = H, Me$

Trialkylboranes rapidly add to the double bonds of acrolein, methyl vinyl ketone, and certain of their derivatives, e.g., 2-bromo- and 2-methylacrolein, in tetrahydrofuran at 25°C, to give enol borinates, which can be hydrolyzed to aldehydes or ketones.[374] The water may be present from the beginning, so that the reaction can be run in one laboratory step. Since the boranes can be prepared from olefins (reaction **5-15**), this reaction provides a means of lengthening a carbon chain by three or four carbons, respectively. Compounds containing a terminal alkyl group, such as crotonaldehyde $CH_3CH{=}CHCHO$ and 3-penten-2-one, fail to react under these conditions, as does acrylonitrile, but these compounds can be induced to react by the slow and controlled addition of O_2 or by initiation with peroxides or uv light.[375] As in the Michael reaction, the α,β-unsaturated compound can be generated in situ from the corresponding Mannich base (reaction **6-17**).[376] A disadvantage is that only one of the three R groups of R_3B adds to the substrate, so that the other two are wasted. This difficulty is overcome by the use of a B-alkyl borinate such as **74**[377] (the reagents B-R-9-BBN are not useful here, since the R group of these reagents does not preferentially add to the substrate). **74** can be prepared by hydroboration of 2,4-dimethyl-1,4-pentadiene, followed by addition of the borinane **73** to an olefin. **74** (R = *t*-butyl) can be prepared by treatment of **74** (R = OMe) with *t*-BuLi. The use of this reagent permits *t*-butyl groups to be added. Like the three substrates mentioned above, 3-butyn-2-one fails to react in the absence of air but undergoes the reaction when exposed to a slow stream of air.[378]



73 **74**



$$HC{\equiv}C{-}\underset{\underset{O}{\|}}{C}{-}CH_3 \xrightarrow[H_2O]{R_3B{-}O_2} RCH{=}CH{-}\underset{\underset{O}{\|}}{C}{-}CH_3 \xrightarrow[H_2O]{R'_3B{-}O_2} \overset{\overset{R'}{|}}{RCH}{-}CH_2{-}\underset{\underset{O}{\|}}{C}{-}CH_3$$

75

Since the product is an α,β-unsaturated ketone, it can be made to react with another BR_3, the same or different, to produce a wide variety of ketones **75**. Similarly, the monoepoxides of

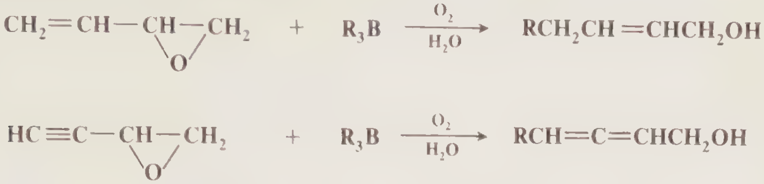
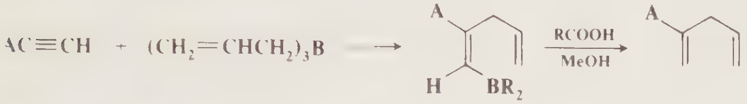
1,3-butadiene and butenyne react with BR_3 in the presence of oxygen to give 4-alkyl-2-buten-1-ols and 4-alkyl-2,3-butadien-1-ols, respectively:[379]



Triallylboranes add to unactivated triple bonds to give vinylboranes which can be hydrolyzed to 1,4-dienes:[380]



A = H, R, OR, Ar, vinyl, or Me_3Si

The fact that these reactions are catalyzed by free-radical initiators and inhibited by galvinoxyl[381] (a free-radical inhibitor) indicates that free-radical mechanisms are involved. The attacking species is R•, and the following mechanism[381] (shown for peroxide initiation) is likely:

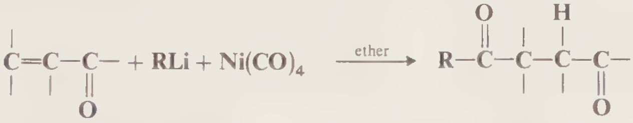
Initiation $\mathrm{R'OOR' \longrightarrow 2R'O\cdot}$

$$\mathrm{R'O\cdot + R_3B \longrightarrow R{-}\overset{\oplus}{\dot{O}}{-}\overset{\ominus}{\bar{B}}R_3 \longrightarrow R'O{-}BR_2 + R\cdot}$$

Propagation $\mathrm{R\cdot + C{=}C{-}C{=}O \longrightarrow R{-}C{-}C{=}C{-}O\cdot}$

$$\mathrm{R{-}C{-}C{=}C{-}O\cdot + R_3B \longrightarrow R{-}C{-}C{=}C{-}OBR_2 + R\cdot}$$

5-22 Acylation of Activated Double Bonds and of Triple Bonds



$$\overset{|}{\underset{|}{\mathrm{C}}}=\underset{|}{\mathrm{C}}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}- + \mathrm{RLi} + \mathrm{Ni(CO)_4} \xrightarrow{\text{ether}} \mathrm{R}-\overset{\overset{\mathrm{O}}{\|}}{\mathrm{C}}-\overset{|}{\underset{|}{\mathrm{C}}}-\overset{\overset{\mathrm{H}}{|}}{\underset{|}{\mathrm{C}}}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}-$$

76

An acyl group can be introduced into the 4 position of an α,β-unsaturated ketone by treatment with an organolithium compound and nickel carbonyl.[382] The product is a 1,4-diketone. R may be aryl or primary alkyl. The reaction can also be applied to alkynes (which need not be activated), in which case 2 moles add and the product is also a 1,4-diketone, e.g., $R'C{\equiv}CH \rightarrow RCOCHR'CH_2COR$.[383]

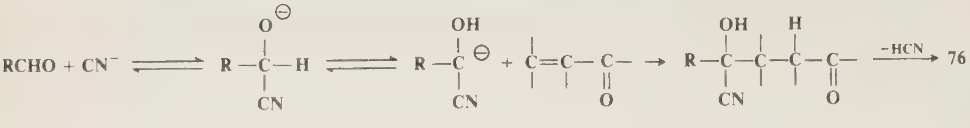
[382] Corey and Hegedus, *J. Am. Chem. Soc.* **91**, 4926 (1969).

[383] Sawa, Hashimoto, Ryang, and Tsutsumi, *J. Org. Chem.* **33**, 2159 (1968).

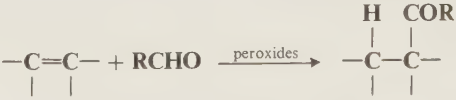
Another method involves treatment with an aldehyde and cyanide ion (see reaction **6-50**) in a polar aprotic solvent such as dimethylformamide or dimethyl sulfoxide[384]



77

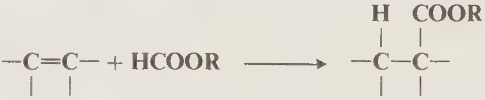
This method has been applied to α,β-unsaturated ketones, esters, and nitriles to give the corresponding 1,4-diketones, γ-keto esters, and γ-keto nitriles, respectively (see also reaction **6-56**). The ion **77** is a synthon for the unavailable $R\bar{C}\overset{\ominus}{=}O$ anion (see also p. 427); it may be considered a "masked" $\underset{\bigcirc}{R}\bar{C}\overset{\ominus}{=}O$ anion. Other masked carbanions which have been used in this reaction are the $EtS\underset{\ominus}{\bar{C}}RSOEt$ ion[385] (see p. 427), the $CH_2{=}\overset{\ominus}{\bar{C}}OEt$ ion,[385a] and the $R\overset{\ominus}{\bar{C}}$-(OCHMeOEt)CN ion[386] (see p. 423). In the last case, best results are obtained when R is a vinylic group. Anions of 1,3-dithianes (reaction **0-99**) do not give 1,4 addition to these substrates but instead add 1,2 to the C=O group (reaction **6-42**).

5-23 Addition of Alcohols, Amines, Esters, Aldehydes, etc.

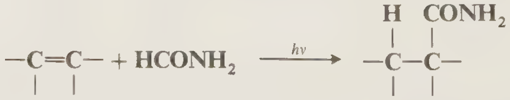


$$-\underset{|}{C}=\underset{|}{C}- + RCHO \xrightarrow{\text{peroxides}} -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{|}{\overset{\overset{COR}{|}}{C}}-$$

Aldehydes, formates, primary and secondary alcohols, amines, ethers,[387] alkyl halides,[388] compounds of the type $Z{-}CH_2{-}Z'$, and a few other compounds add to double bonds in the presence of free-radical initiators.[389] This is formally the addition of RH to a double bond, but the "R" is not just any carbon but one connected to an oxygen or a nitrogen, a halogen, or to two Z groups (defined as on p. 419). The addition of aldehydes is illustrated above. Formates and formamides[390] add similarly:



$$-\underset{|}{C}=\underset{|}{C}- + HCOOR \longrightarrow -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{|}{\overset{\overset{COOR}{|}}{C}}-$$



$$-\underset{|}{C}=\underset{|}{C}- + HCONH_2 \xrightarrow{h\nu} -\underset{|}{\overset{\overset{H}{|}}{C}}-\underset{|}{\overset{\overset{CONH_2}{|}}{C}}-$$

---

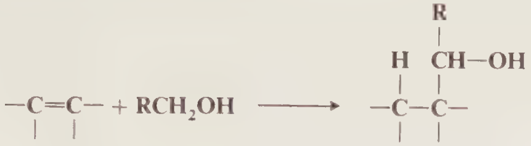
[387] Rosenthal and Elad, *Tetrahedron* **23,** 3193 (1967).

[388] Trecker and Henry, *Chem. Commun.* 258 (1966).

[389] For reviews, see Vogel, *Synthesis* 99–140 (1970); Huyser, Ref. 41, pp. 152–159; Elad, *Fortschr. Chem. Forsch.* **7,** 528–558 (1967); Walling and Huyser, Ref. 41, pp. 108–112, 132–146; Sosnovsky, Ref. 41, pp. 121–152; Walling, Ref. 41, pp. 273–289.

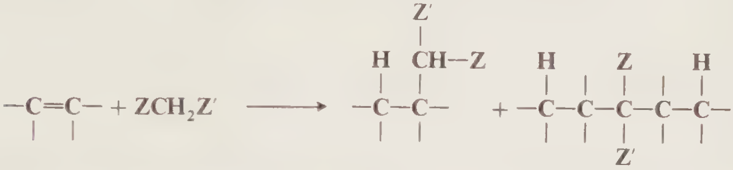
[390] Elad, Ref. 389, pp. 530–543.

Alcohols, ethers, amines, and alkyl halides add as follows (shown for alcohols):



$$-\underset{|}{\mathrm{C}}=\underset{|}{\mathrm{C}}- + \mathrm{RCH_2OH} \longrightarrow -\underset{|}{\overset{\overset{\mathrm{H}}{|}}{\mathrm{C}}}-\underset{|}{\overset{\overset{\overset{\overset{\mathrm{R}}{|}}{\mathrm{CH-OH}}}{|}}{\mathrm{C}}}-$$

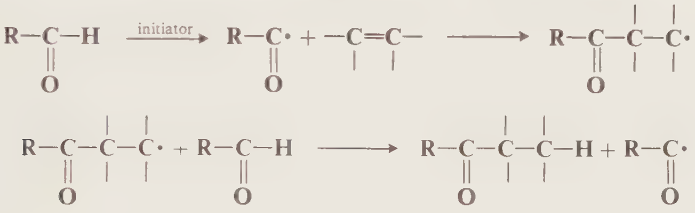
ZCH_2Z' compounds react at the carbon bearing the active hydrogen:[391]



$$-\underset{|}{\mathrm{C}}=\underset{|}{\mathrm{C}}- + \mathrm{ZCH_2Z'} \longrightarrow -\underset{|}{\overset{\overset{\mathrm{H}}{|}}{\mathrm{C}}}-\underset{|}{\overset{\overset{\overset{\overset{\mathrm{Z'}}{|}}{\mathrm{CH-Z}}}{|}}{\mathrm{C}}}- \quad + -\underset{|}{\overset{\overset{\mathrm{H}}{|}}{\mathrm{C}}}-\underset{|}{\overset{|}{\mathrm{C}}}-\underset{\underset{\mathrm{Z'}}{|}}{\overset{\overset{\mathrm{Z}}{|}}{\mathrm{C}}}-\underset{|}{\overset{|}{\mathrm{C}}}-\underset{|}{\overset{\overset{\mathrm{H}}{|}}{\mathrm{C}}}-$$

Similar additions have been successfully carried out with carboxylic acids, anhydrides,[392] acyl halides, esters, nitriles, and other types of compounds.[393]

These reactions are most successful when the olefin contains electron-withdrawing groups such as halo or carbonyl groups. A free-radical initiator is required, usually peroxides or uv light. The mechanism is illustrated for aldehydes but is similar for the other compounds:



$$\mathrm{R}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{H} \xrightarrow{\text{initiator}} \mathrm{R}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}\cdot + -\underset{|}{\mathrm{C}}=\underset{|}{\mathrm{C}}- \longrightarrow \mathrm{R}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}-\underset{|}{\overset{|}{\mathrm{C}}}-\underset{|}{\overset{|}{\mathrm{C}}}\cdot$$

$$\mathrm{R}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}-\underset{|}{\overset{|}{\mathrm{C}}}-\underset{|}{\overset{|}{\mathrm{C}}}\cdot + \mathrm{R}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{H} \longrightarrow \mathrm{R}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}-\underset{|}{\overset{|}{\mathrm{C}}}-\underset{|}{\overset{|}{\mathrm{C}}}-\mathrm{H} + \mathrm{R}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}\cdot$$

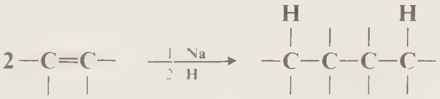
etc.

Polymers are often side products.

Similar reactions have been carried out on acetylene.[394]

OS **IV**, 430; **V**, 93; **55**, 57.

5-24 Reductive Coupling of Olefins



$$2\,-\underset{|}{\mathrm{C}}=\underset{|}{\mathrm{C}}- \xrightarrow[2.\ \mathrm{H}^{+}]{1.\ \mathrm{Na}} -\underset{|}{\overset{\overset{\mathrm{H}}{|}}{\mathrm{C}}}-\underset{|}{\overset{|}{\mathrm{C}}}-\underset{|}{\overset{|}{\mathrm{C}}}-\underset{|}{\overset{\overset{\mathrm{H}}{|}}{\mathrm{C}}}-$$

Certain olefins have been coupled by treatment with sodium, followed by acid. The reaction has been performed with styrene, 1,1-diphenylethylene, acrylonitrile, and butadiene, among others.[395]

---

[391] For example, see Allen, Cadogan, Harris, and Hey, *J. Chem. Soc.* 4468 (1962); Cadogan, Hey, and Sharp, *J. Chem. Soc. C* 1743 (1966), *J. Chem. Soc. B* 803 (1967).

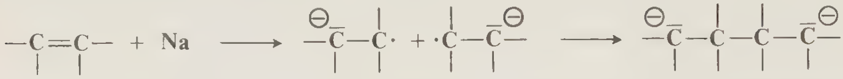
[392] de Klein, *Recl. Trav. Chim. Pays-Bas* **94**, 48 (1975).

[393] Allen, Cadogan, and Hey, *J. Chem. Soc.* 1918 (1965); Cadogan, *Pure Appl. Chem.* **15**, 153–165 (1967), pp. 153–158.

[394] For example, see Cywinski and Hepp, *J. Org. Chem.* **31**, 3814 (1965); DiPietro and Roberts, *Angew. Chem. Int. Ed. Engl.* **5**, 415 (1966) [*Angew. Chem.* **78**, 388].

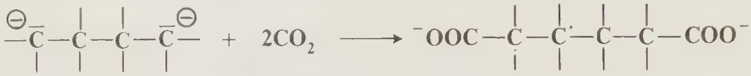
[395] Frank and Foster, *J. Org. Chem.* **26**, 303 (1961); Frank, Leebrick, Moormeier, Scheben, and Homberg, *J. Org. Chem.* **26**, 307 (1961); Suga, Watanabe, and Takahashi, *Bull. Chem. Soc. Jpn.* **40**, 2432 (1967).

The coupling is head to head. The first step is probably an electron transfer from the sodium, creating a radical ion, which dimerizes:



$$-\overset{|}{\underset{|}{C}}=\overset{|}{\underset{|}{C}}- + \text{Na} \longrightarrow \ominus\,-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}\cdot + \cdot\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-\,\ominus \longrightarrow \ominus\,-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-\,\ominus$$

That the dicarbanion is an intermediate may be shown by treatment of the mixture with carbon dioxide, instead of acid, whereupon a dicarboxylate ion is obtained:

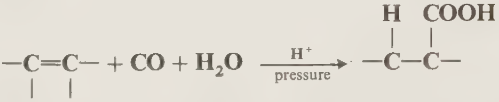


$$\ominus\,-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-\,\ominus + 2CO_2 \longrightarrow {}^{-}OOC-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-COO^{-}$$

Mixed coupling can be achieved in certain cases; e.g., a mixture of acrylonitrile and ethyl acrylate gave 80% ethyl δ-cyanovalerate.[396]

Similar reactions have been carried out electrolytically.[397]

5-25 Hydrocarboxylation



$$-\overset{|}{\underset{|}{C}}=\overset{|}{\underset{|}{C}}- + CO + H_2O \xrightarrow[\text{pressure}]{H^+} -\overset{H}{\overset{|}{C}}-\overset{COOH}{\overset{|}{C}}-$$

The acid-catalyzed hydrocarboxylation of olefins (the *Koch reaction*) can be performed in a number of ways.[398] In one method, the olefin is treated with carbon monoxide and water at 100 to 350°C and 500 to 1000 atm pressure, with a mineral-acid catalyst. However, the reaction can also be performed under milder conditions. If the olefin is first treated with CO and catalyst and then water added, the reaction can be accomplished at 0 to 50°C and 1 to 100 atm. If formic acid is used as the source of both the CO and the water, the reaction can be carried out at room temperature and atmospheric pressure.[399] The formic acid procedure is called the *Koch-Haaf reaction* (the Koch-Haaf reaction can also be applied to alcohols, see reaction **0-105**). Nearly all olefins can be hydrocarboxylated by one or more of these procedures. However, conjugated dienes are polymerized instead. If the olefin contains a functional group such as OH, NH_2, or $CONH_2$, the corresponding lactone (reaction **0-24**), lactam (reaction **0-56**), or cyclic imide may be the product.[400] Cyclic ketones can be produced from 1,5- and 1,6-dienes.

Hydrocarboxylation can also be accomplished under mild conditions (160°C and 50 atm) by the use of nickel carbonyl as catalyst. This is more often applied to triple bonds, to give α,β-unsaturated acids, in which cases the conditions are milder still. Acid catalysts are used along with the nickel carbonyl, but basic catalysts may also be employed.[401] Other metallic salts and complexes, e.g., bis(triphenylphosphine)palladium dichloride $(Ph_3P)_2PdCl_2$,[402] have also been used.

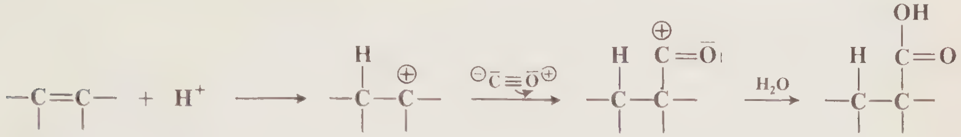
[402] For a review, see Bittler, Kutepow, Neubauer, and Reis, *Angew. Chem. Int. Ed. Engl.* **7,** 329–335 (1968) [*Angew. Chem.* **7,** 329–335]. See also Fenton, *J. Org. Chem.* **38,** 3192 (1973).

In another method, the palladium chloride complex of the olefin is treated with CO in ethanol at about 100°C.[403] The product in this case is the ethyl ester.

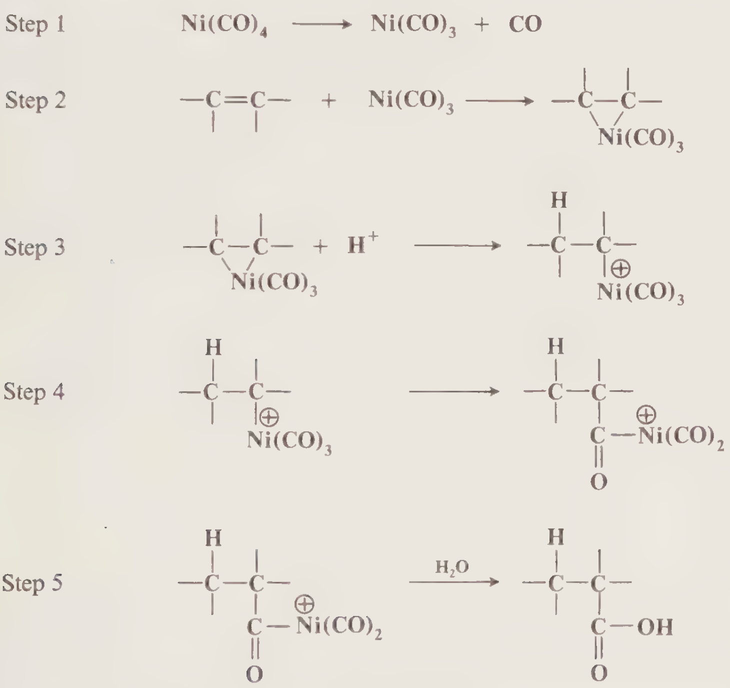
When acid catalysts are employed, in the absence of nickel carbonyl, the mechanism[404] involves initial attack by a proton, followed by attack of the resulting carbonium ion on carbon monoxide to give an acylonium ion, which, with water, gives the product:



H⁺
H
⊕
$^{\ominus}\bar{C}\equiv\bar{O}^{\oplus}$
H
⊕
C=O
H₂O
OH
H
C=O

Therefore, Markovnikov's rule is followed, and carbon skeleton rearrangements and double-bond isomerizations (prior to attack by CO) are frequent.

For the nickel carbonyl reaction, the addition is syn, for both alkenes and alkynes.[405] The following mechanism has been proposed:[405]



Step 1
$Ni(CO)_4 \longrightarrow Ni(CO)_3 + CO$
Step 2
$Ni(CO)_3$
$Ni(CO)_3$
Step 3
H⁺
$Ni(CO)_3$
H
⊕
$Ni(CO)_3$
Step 4
H
⊕
$Ni(CO)_3$
H
⊕
$Ni(CO)_2$
O
Step 5
H
⊕
$Ni(CO)_2$
O
H₂O
H
OH
O

Step 3 is an electrophilic substitution. The principal step of the mechanism, step 4, is a rearrangement.

In either the acid catalysis or the nickel carbonyl (or other metallic catalyst) method, if alcohols, mercaptans, amines, etc., are used instead of water, the product is the corresponding ester, thiol ester, or amide, instead of the carboxylic acid.

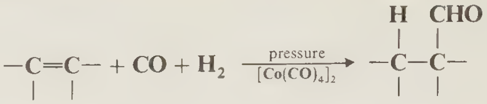
[404] For a review, see Hogeveen, *Adv. Phys. Org. Chem.* **10,** 29–52 (1973).

[405] Bird, Cookson, Hudec, and Williams, *J. Chem. Soc.* 410 (1963).

5-26 Hydroformylation

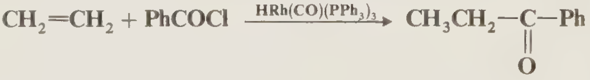


$$-\overset{|}{\underset{|}{C}}=\overset{|}{\underset{|}{C}}- + CO + H_2 \xrightarrow[{[Co(CO)_4]_2}]{\text{pressure}} -\overset{H}{\underset{|}{\overset{|}{C}}}-\overset{CHO}{\underset{|}{\overset{|}{C}}}-$$

Olefins can be hydroformylated[406] by treatment with carbon monoxide and hydrogen over a catalyst which is usually a cobalt carbonyl but may also be a rhodium complex[407] [e.g., hydridocarbonyltris(triphenylphosphine)rhodium] or another transition-metal compound. Commercially, this is called the *oxo process*, but it can be carried out in the laboratory in an ordinary hydrogenation apparatus. The order of reactivity is straight-chain terminal olefins > straight-chain internal olefins > branched-chain olefins. Conjugated dienes give dialdehydes when rhodium catalysts are used[408] but saturated monoaldehydes (the second double bond is reduced) with cobalt carbonyls. Many functional groups, e.g., OH, CHO, COOR, CN, may be present in the molecule, though halogens usually interfere. Hydroformylation of triple bonds proceeds very slowly, and few examples have been reported.[409] Among the side reactions are aldol condensation (**6-40**), acetal formation, the Tishchenko reaction (**9-75**), and polymerization.

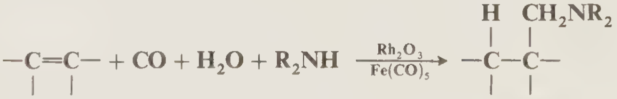
When dicobalt octacarbonyl $[Co(CO)_4]_2$ is the catalyst, the species which actually adds to the double bond[410] is tetracarbonylhydrocobalt $HCo(CO)_4$.[411] There then follows a rearrangement and a reduction of the C—Co bond, similar to steps 4 and 5 of the nickel carbonyl mechanism shown in reaction **5-25.** The reducing agent in the reduction step is either $HCo(CO)_4$ or, less likely, H_2. Alcohols can be obtained by allowing the reduction to continue after all the carbon monoxide is used up. It has been shown[412] that the formation of alcohols is a second step, occurring after the formation of aldehydes, and that $HCo(CO)_3$ is the reducing agent.

An indirect method for the hydroformylation of olefins involves formation of the trialkylborane (reaction **5-15**) and treatment of this with carbon monoxide and a reducing agent (see reaction **8-29**). *Hydroacylation* of alkenes has been accomplished, in variable yields, by treatment with an acyl halide and a rhodium complex catalyst, e.g.,[413]



$$CH_2=CH_2 + PhCOCl \xrightarrow{HRh(CO)(PPh_3)_3} CH_3CH_2-\underset{\underset{O}{\|}}{C}-Ph$$

5-27 Aminomethylation of Alkenes



$$-\overset{|}{\underset{|}{C}}=\overset{|}{\underset{|}{C}}- + CO + H_2O + R_2NH \xrightarrow[Fe(CO)_5]{Rh_2O_3} -\overset{H}{\underset{|}{\overset{|}{C}}}-\overset{CH_2NR_2}{\underset{|}{\overset{|}{C}}}-$$

[409] For examples with rhodium catalysts, see Fell and Beutler, *Tetrahedron Lett.* 3455 (1972); Botteghi and Salomon, *Tetrahedron Lett.* 4285 (1974).

[410] It is also possible that tricarbonylhydrocobalt $HCo(CO)_3$, formed by loss of CO from $HCo(CO)_4$, may be adding to the double bond.

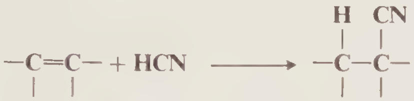
[411] Heck and Breslow, *Chem. Ind. (London)* 467 (1960), *J. Am. Chem. Soc.* **83,** 4023 (1961); Karapinka and Orchin, *J. Org. Chem.* **26,** 4187 (1961); Taylor and Orchin, *J. Am. Chem. Soc.* **93,** 6504 (1971); Clark, Terapane, and Orchin, *J. Org. Chem.* **39,** 2405 (1974); Whyman, *J. Organomet. Chem.* **81,** 97 (1974).

[412] Aldridge and Jonassen, *J. Am. Chem. Soc.* **85,** 886 (1963).

[413] Schwartz and Cannon, *J. Am. Chem. Soc.* **96,** 4721 (1974).

Alkenes react with carbon monoxide, water, and a secondary amine, to give the tertiary amines **78**.[414] Rhodium oxide may serve as a catalyst, but higher yields ($> 90\%$) are obtained when iron pentacarbonyl is also present.

5-28 Addition of HCN



$$-\underset{|}{\mathrm{C}}=\underset{|}{\mathrm{C}}- + \mathrm{HCN} \longrightarrow -\underset{|}{\overset{\overset{\mathrm{H}}{|}}{\mathrm{C}}}-\underset{|}{\overset{\overset{\mathrm{CN}}{|}}{\mathrm{C}}}-$$

Ordinary olefins do not react with HCN, but polyhalo olefins and olefins of the form C=C—Z add HCN to give nitriles.[415] The reaction is therefore a nucleophilic addition and is base-catalyzed. When Z is COR or, more especially, CHO, 1,2 addition (reaction **6-52**) is an important competing reaction and may be the only reaction. Triple bonds react very well when catalyzed by an aqueous solution of CuCl, NH_4Cl, and HCl. One or two moles of HCN may be added to a triple bond, since the initial product is a Michael-type substrate. Acrylonitrile is commercially prepared in this way, by the addition of HCN to acetylene. Alkylaluminum cyanides, e.g., Et_2AlCN, or mixtures of HCN and trialkylalanes R_3Al are especially good reagents for conjugate addition of HCN[416] to α,β-unsaturated ketones and α,β-unsaturated acyl halides. HCN may be added to ordinary olefins in the presence of either dicobalt octacarbonyl[417] or of tetrakis(triphenylphosphite)palladium(0) $Pd[P(OPh)_3]_4$ and triphenyl phosphite.[418]

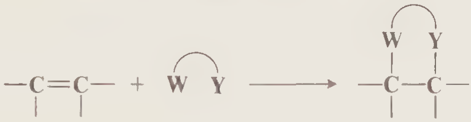
OS **I,** 451; **II,** 498; **III,** 615; **IV,** 392, 393, 804; **V,** 239, 572; **52,** 100.

5-29 Addition of ArH

See reaction **1-13** (Friedel-Crafts alkylation).

Reactions in Which Hydrogen Adds to Neither Side

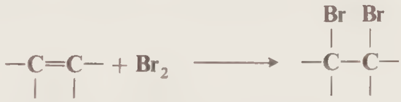
Some of these reactions are *cycloadditions* (reactions **5-40, 5-41, 5-45, 5-47,** and **5-50** to **5-55**). In such cases addition to the multiple bond closes a ring:



$$-\underset{|}{\mathrm{C}}=\underset{|}{\mathrm{C}}- + \overset{\frown}{\mathrm{W}\;\;\mathrm{Y}} \longrightarrow -\underset{|}{\overset{\overset{\mathrm{W}}{|}}{\mathrm{C}}}-\underset{|}{\overset{\overset{\mathrm{Y}}{|}}{\mathrm{C}}}-$$

A. Halogen on One or Both Sides

5-30 Halogenation of Double and Triple Bonds (Addition of Halogen, Halogen)



$$-\underset{|}{\mathrm{C}}=\underset{|}{\mathrm{C}}- + \mathrm{Br_2} \longrightarrow -\underset{|}{\overset{\overset{\mathrm{Br}}{|}}{\mathrm{C}}}-\underset{|}{\overset{\overset{\mathrm{Br}}{|}}{\mathrm{C}}}-$$

[418] Brown and Rick, *Chem. Commun.* 112 (1969).

Most double bonds are easily halogenated with bromine, chlorine, or interhalogen compounds.[419] Iodination has also been accomplished, but the reaction is slower.[420] Under free-radical conditions, iodination proceeds more easily.[421] However, *vic*-diiodides are generally unstable and tend to revert to iodine and the olefin. The order of activity for some of the reagents is $BrCl > ICl > Br_2 > IBr > I_2$.[422] Mixed halogenations have also been achieved by other methods. Mixtures of Br_2 and Cl_2 have been used to give bromochlorination;[423] iodochlorination has been achieved with $CuCl_2$ and either I_2, HI, CdI_2, or other iodine donors;[424] iodofluorination[425] with mixtures of AgF and I_2;[426] and mixtures of N-bromo amides in anhydrous HF give bromofluorination.[427] Bromo-, iodo-, and chlorofluorination have also been achieved by treatment of the substrate with a solution of Br_2, I_2, or an N-chloro-, N-bromo-, or N-iodo amide in 70% HF–30% pyridine.[428] Under ordinary conditions fluorine itself is too reactive to give simple addition; it attacks other bonds, and mixtures are obtained.[429] However, F_2 has been successfully added to certain double bonds in an inert solvent at low temperatures (−78°C).[430] Addition of fluorine has also been accomplished with other reagents, e.g., CoF_3;[431] XeF_2;[432] and a mixture of PbO_2 and SF_4.[433] XeF_4 has also been used for this purpose,[434] but isomerization takes place, so that ethylene gave 45% 1,2-difluoroethane but also 35% of the 1,1-difluoro isomer. With perfluoroethylene, where isomerization is not a factor, XeF_4 gave good yields of the normal addition product.

The reaction with bromine is very rapid and is easily carried out at room temperature. Bromine is often used as a test, qualitative or quantitative, for unsaturation.[435] The vast majority of double bonds can be successfully brominated. Even when aldehyde, ketone, amine, etc., functions are present in the molecule, they do not interfere, since the reaction with double bonds is faster.

Several other reagents add Cl_2 to double bonds, among them NCl_3,[436] SO_2Cl_2,[437] PCl_5,[438] $SbCl_5$,[439] $MoCl_5$,[440] and iodobenzene dichloride $PhICl_2$.[441] A convenient reagent for the addition of Br_2 to a double bond on a small scale is the commercially available pyridinium bromide perbromide $C_5H_5NH^+ \; Br_3^-$.[442] Br_2 or Cl_2 can also be added with $CuBr_2$ or $CuCl_2$ in the presence of a compound such as acetonitrile, methanol, or triphenylphosphine.[443]

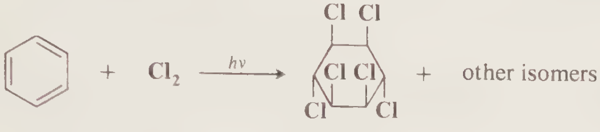
The mechanism is usually electrophilic (see p. 675), but when free-radical initiators (or uv light) are present, then addition may occur by a free-radical mechanism.[444] Once Br• or Cl• radicals are formed, however, substitution may compete (reactions **4-1** and **4-2**). This is especially important when the olefin has allylic hydrogens. Under free-radical conditions (uv light) bromine or chlorine adds to the benzene ring to give, respectively, hexabromo- and hexachlorocyclohexane. These are mixtures of stereoisomers (see p. 118). In the case of chlorination one of these isomers, which is called *gammexane* and constitutes about 10 to 12% of the mixture, is used as an insecticide. Toluene not only undergoes addition under these conditions but also α-halogenation[445] (reaction **4-1**).



Gammexane

Conjugated systems give both 1,2 and 1,4 addition.[446] Triple bonds add bromine, though generally more slowly than double bonds (see p. 686). Molecules that contain both double and triple bonds are preferentially attacked at the double bond. Two moles of bromine may be added to triple bonds to give tetrabromo products. There is evidence that the addition of the first mole of bromine to a triple bond may take place by a nucleophilic mechanism.[447] With allenes it is very easy to stop the reaction after only 1 mole has added, to give X—C—CX=C.[448] In most cases a second mole of halogen can be added only by forced treatment. Addition of halogen to ketenes gives α-halo acyl halides, but the yields are not good. When bromine was added to *cis*- and *trans*-cyclodecenes, the products were, respectively, *cis*- and *trans*-1,6-dibromocyclodecane.[449] In this case there was a transannular hydride shift.

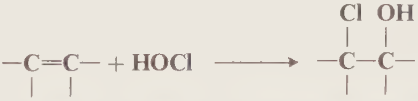
5-31 Addition of Hypohalous Acids and Hypohalites (Addition of Halogen, Oxygen)



$$-\underset{|}{C}=\underset{|}{C}- + HOCl \longrightarrow -\underset{|}{\overset{\overset{Cl}{|}}{C}}-\underset{|}{\overset{\overset{OH}{|}}{C}}-$$

HOCl, HOBr, and HOI can be added to olefins to produce halohydrins.[450] HOBr and HOCl are often generated in situ by the reaction between water and Br_2 or Cl_2, respectively. HOI can also be generated from I_2 and H_2O, but in this case an oxidizing agent such as HIO_3, HgO, or O_2 and HNO_2 must be present.[451] HOBr can also be conveniently added by the use of a reagent consisting of an N-bromo amide [e.g., N-bromosuccinimide (NBS) or N-bromoacetamide] and a small amount of water in a solvent such as dimethyl sulfoxide or dioxane.[452] The mechanism of HOX addition is electrophilic, with initial attack by the positive halogen end of the HOX dipole. Following Markovnikov's rule, the positive halogen goes to the side of the double bond which has more hydrogens. The resulting carbonium ion (or bromonium or iodonium ion) reacts with OH^- or H_2O to give the product. In the NBS–dimethyl sulfoxide method, the initial product is $\mathrm{Br{-}\overset{|}{\underset{|}{C}}{-}\overset{|}{\underset{|}{C}}{-}O\overset{\oplus}{S}Me_2}$, which is hydrolyzed by the water to the bromohydrin. If the substrate is treated with Br_2 or Cl_2 (or another source of positive halogen such as NBS or BrN_3[453]) in an alcohol or a carboxylic acid solvent, it is possible to obtain, directly, $\mathrm{X{-}\overset{|}{\underset{|}{C}}{-}\overset{|}{\underset{|}{C}}{-}OR}$ or $\mathrm{X{-}\overset{|}{\underset{|}{C}}{-}\overset{|}{\underset{|}{C}}{-}OCOR}$, respectively (also see reaction **5-39**). HOCl and HOBr can be added to triple bonds to give dihalo carbonyl compounds $—CX_2—CO—$.

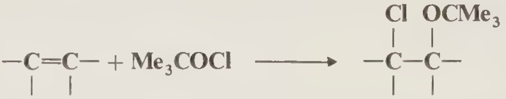
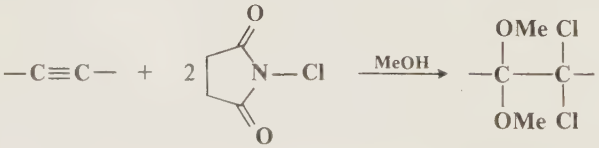
t-Butyl hypochlorite and hypobromite add to double bonds to give *t*-butyl ethers, e.g.,[454]



$$\mathrm{{-}\underset{|}{C}{=}\underset{|}{C}{-} + Me_3COCl \longrightarrow {-}\overset{Cl}{\underset{|}{\overset{|}{C}}}{-}\overset{OCMe_3}{\underset{|}{\overset{|}{C}}}{-}}$$

This is a convenient method for the preparation of tertiary ethers. Me_3COCl adds 1,2 to some conjugated dienes[454] and 1,4 to others.[455] When Me_3COCl or Me_3COBr is added to olefins in the presence of excess ROH, the ether produced is $\mathrm{X{-}\overset{|}{\underset{|}{C}}{-}\overset{|}{\underset{|}{C}}{-}OR}$.[456] Vinyl ethers give β-halo acetals.[457] Two moles of "MeOCl" can be added to triple bonds by treatment with N-chlorosuccinimide in methanol.[458]



These acetals can then be hydrolyzed to α,α-dichloro ketones. Alkenyl boronic acids RCH=CHB(OH)$_2$ (p. 560) react with bromine and NaOMe at −78°C to give α-bromo acetals RCHBrCH(OMe)$_2$.[459] Chlorine acetate [solutions of which are prepared by treating Cl_2 with

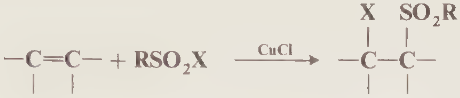
$Hg(OAc)_2$ in an appropriate solvent] adds to olefins to give acetoxy chlorides.[460] The latter are also produced by treatment of olefins with a mixture of $PdCl_2$ and $CuCl_2$ in acetic acid.[461]

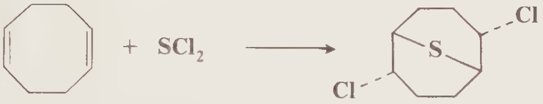
OS **I,** 158; **IV,** 130, 157.

5-32 Addition of Sulfur Compounds (Addition of Halogen, Sulfur)



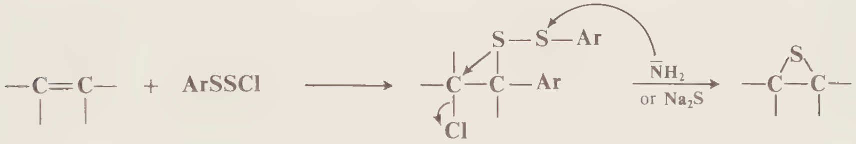
$$-\underset{|}{C}=\underset{|}{C}- + RSO_2X \xrightarrow{CuCl} -\underset{|}{\overset{X}{\overset{|}{C}}}-\underset{|}{\overset{SO_2R}{\overset{|}{C}}}-$$

Sulfonyl halides add to double bonds, to give β-halo sulfones, in the presence of free-radical initiators. A particularly good catalyst is cuprous chloride.[462] Triple bonds behave similarly, to give β-halo-α,β-unsaturated sulfones.[463] In a similar reaction, sulfenyl chlorides, RSCl, give β-halo thioethers,[464] $Cl-\underset{|}{\overset{|}{C}}-\underset{|}{\overset{|}{C}}-SR$. The latter may be free-radical or electrophilic additions, depending on conditions. Other sulfur compounds also add to double bonds by free-radical mechanisms.[465] Sulfur dichloride adds to cyclic dienes in a transannular fashion to give sulfur-bridged dichlorides,[466] e.g.,



Linear dienes undergo a similar reaction, to give sulfur heterocycles.[467]

β-Halo disulfides, formed by addition of arenethiosulfenyl chlorides to double-bond compounds, are easily converted to thiiranes by treatment with sodium amide or sodium sulfide.[468]



The overall episufidation is a stereospecific syn addition.

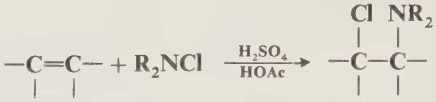
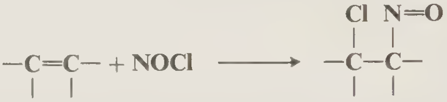
5-33 Addition of Halogen and an Amino Group (Addition of Halogen, Nitrogen)



$$-\overset{|}{\underset{|}{C}}=\overset{|}{\underset{|}{C}}- + R_2NCl \xrightarrow[HOAc]{H_2SO_4} -\overset{Cl}{\overset{|}{\underset{|}{C}}}-\overset{NR_2}{\overset{|}{\underset{|}{C}}}-$$

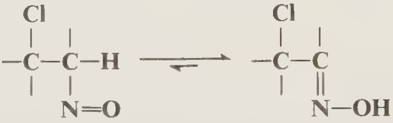
The groups R_2N and Cl can be added directly to olefins, allenes, conjugated dienes, and alkynes, by treatment with dialkyl-N-chloroamines and acids.[469] These are free-radical additions, with initial attack by the $R_2NH\cdot^+$ radical ion. N-Halo amides RCONHX add RCONH and X to double bonds under the influence of uv light.[470] For an indirect way of adding NH_2 and I to a double bond, see reaction **5-36.**

5-34 Addition of NOX and NO_2X (Addition of Halogen, Nitrogen)



$$-\overset{|}{\underset{|}{C}}=\overset{|}{\underset{|}{C}}- + NOCl \longrightarrow -\overset{Cl}{\overset{|}{\underset{|}{C}}}-\overset{N=O}{\overset{|}{\underset{|}{C}}}-$$

There are three possible products when NOCl is added to olefins.[471] The initial product is always the β-halo nitroso compound, but these are stable only if the carbon bearing the nitrogen has no hydrogen. If it has, the nitroso compound tautomerizes to the oxime:



$$-\overset{Cl}{\overset{|}{\underset{|}{C}}}-\underset{\underset{N=O}{|}}{\overset{|}{C}}-H \rightleftharpoons -\overset{Cl}{\overset{|}{\underset{|}{C}}}-\underset{\underset{N-OH}{\|}}{\overset{|}{C}}$$

With some olefins, the initial β-halo nitroso compound is oxidized by the NOCl to a β-halo nitro compound.[472] Many functional groups may be present without interference, e.g., COOH, COOR, CN, OR. In the past, the reaction was invaluable in the characterization of terpenes. The mechanism in most cases is probably simple electrophilic addition, and the addition is usually anti, although syn addition has been reported in some cases.[473] Markovnikov's rule is followed, the positive NO going to the carbon which has more hydrogens.

Nitryl chloride NO_2Cl also adds to olefins, to give β-halo nitro compounds, but this is a free-radical process. The NO_2 goes to the less substituted carbon.[474] Nitryl chloride also adds to triple bonds to give the expected 1-nitro-2-chloro olefins.[475] β-Halo nitro compounds can also be prepared by treatment of olefins with N_2O_4 and bromine (or iodine), but another possible product is the β-halo nitrate.[476] Which product is formed depends on the substrate. FNO_2 can be added to olefins[477] by treatment with HF in HNO_3[478] or by addition of the olefin to a solution of nitronium tetrafluoroborate $NO_2^+\ BF_4^-$ (see reaction **1-2**) in 70% HF–30% pyridine solution[479] (see also reaction **5-30**).

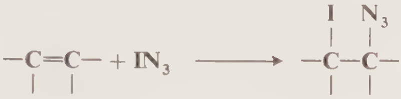
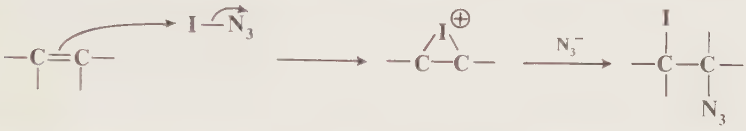
5-35 Addition of XN_3 (Addition of Halogen, Nitrogen)



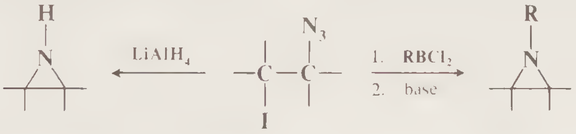
$$-\underset{|}{C}=\underset{|}{C}- + IN_3 \longrightarrow -\overset{\overset{I}{|}}{\underset{|}{C}}-\overset{\overset{N_3}{|}}{\underset{|}{C}}-$$

The addition of iodine azide to double bonds[480] gives β-iodo azides.[481] The addition is stereospecific and anti, suggesting that the mechanism involves a cyclic iodonium-ion intermediate



(see p. 676). The reaction has been performed on many double-bond compounds, including α,β-unsaturated ketones. Similar reactions can be performed with BrN_3 and ClN_3. 1,4 addition has been found with acyclic conjugated dienes.[482] In the case of BrN_3 both electrophilic and free-radical mechanisms are important,[483] while with ClN_3 the additions are chiefly free-radical.[484] Free-radical addition of ClN_3 can also be achieved by treatment of the alkene with NaN_3, $FeCl_3$, $FeSO_4$, and H_2O_2.[485] IN_3 also adds to triple bonds, to give β-iodo-α,β-unsaturated azides.[486]

β-iodo azides can be reduced to aziridines with $LiAlH_4$,[487] or converted to N-alkyl- or N-arylaziridines by treatment with an alkyl- or aryldichloroborane followed by a base.[488] In both



cases the azide is first reduced to the corresponding amine (primary or secondary, respectively) and ring closure (reaction **0-46**) follows. β-Iodo azides can also be converted to 1-azirines (reaction **5-46**).

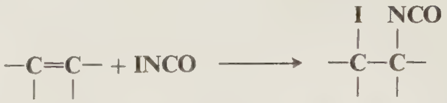
5-36 Addition of INCO (Addition of Halogen, Nitrogen)



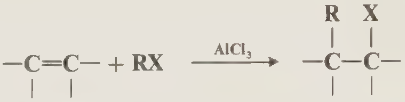
$$-\underset{|}{C}=\underset{|}{C}- + \text{INCO} \longrightarrow -\underset{|}{\overset{\overset{\text{I}}{|}}{C}}-\underset{|}{\overset{\overset{\text{NCO}}{|}}{C}}-$$

In a reaction similar to **5-35**, iodine isocyanate adds to double bonds to give β-iodo isocyanates.[489] The addition is stereospecific and anti, and the mechanism is similar to that shown in reaction **5-35.** The reaction has been applied to mono-, di-, and some trisubstituted olefins. The orientation generally follows Markovnikov's rule, the positive iodine adding to the less highly substituted side. α,β-Unsaturated carbonyl compounds do not react. Triple bonds give β-iodo-α,β-unsaturated isocyanates in low yields.[490] Allenes add 1 mole of INCO to give β-iodo-β,γ-unsaturated isocyanates.[491]

Since an isocyanate group can be hydrolyzed to an amino group ($RNCO \rightarrow RNH_2$, reaction **6-3**), the method is an indirect way of adding H_2N and I to double bonds.

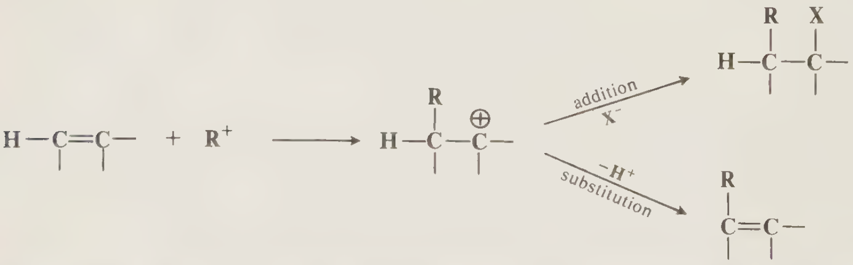
OS **51,** 112.

5-37 Addition of Alkyl Halides (Addition of Halogen, Carbon)



$$-\underset{|}{C}=\underset{|}{C}- + \text{RX} \xrightarrow{\text{AlCl}_3} -\underset{|}{\overset{\overset{\text{R}}{|}}{C}}-\underset{|}{\overset{\overset{\text{X}}{|}}{C}}-$$

Alkyl halides can be added to olefins in the presence of a Friedel-Crafts catalyst, most often $AlCl_3$.[492] The yields are best for tertiary R. Secondary R can also be used, but primary R give rearrangement products (as with reaction **1-13**). Methyl and ethyl halides, which cannot rearrange, give no reaction at all. The attacking species is the carbonium ion formed from the alkyl halide and the catalyst (see reaction **1-13**). The addition therefore follows Markovnikov's rule, with the carbonium ion going to the carbon with more hydrogens. Substitution is a side reaction, arising from loss of hydrogen from the carbonium ion formed when the original carbonium ion attacks the double bond:



Conjugated dienes can add 1,4.[493] Triple bonds also undergo the reaction, to give vinyl halides.[494]

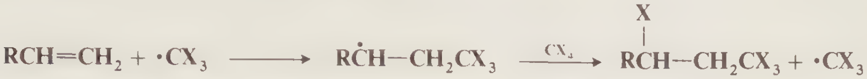
CCl_4, $BrCCl_3$, ICF_3, and similar simple polyhalo alkanes add to olefins in good yield.[495] These are free-radical additions and require initiation by peroxides, metal halides (e.g., $FeCl_2$, CuCl),[496] or uv light. The initial attack is by the carbon, and it goes to the carbon which has more hydrogens, as in most free-radical attack:

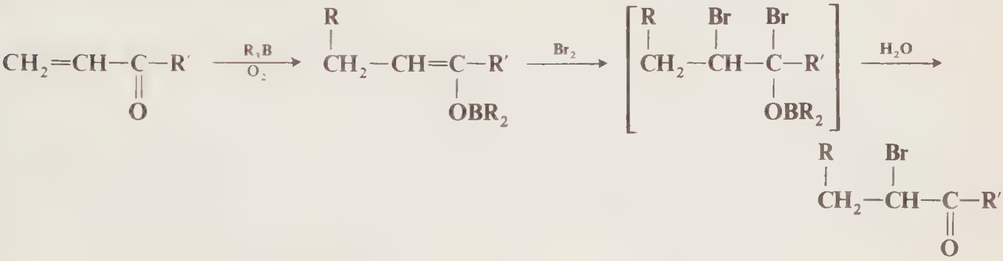


$$\mathrm{RCH{=}CH_2 + \cdot CX_3 \longrightarrow R\dot{C}H{-}CH_2CX_3 \xrightarrow{CX_4} R\overset{\overset{\textstyle X}{|}}{C}H{-}CH_2CX_3 + \cdot CX_3}$$

This type of polyhalo alkane adds to halogenated olefins in the presence of $AlCl_3$ by an electrophilic mechanism.[497] This is called the *Prins reaction* (not to be confused with the other Prins reaction, **6-54**).

ArX can be added across double bonds, in a free-radical process, by treatment of olefins with diazonium salts, though Meerwein arylation (substitution) (reaction **4-17**) competes.[498] This addition may be either 1,2 or 1,4 with conjugated dienes.[499] Addition of ArX can also be accomplished by treatment with an arylmercury halide ArHgX in the presence of CuX_2, LiX, and a palladium compound catalyst, usually Li_2PdCl_4.[500] In this case also, substitution (reaction **4-18**) is a side reaction. Yields of addition product are increased by increasing the concentration of CuX_2.

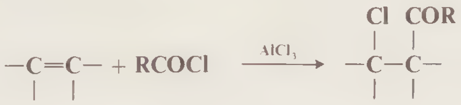
R and X can be added to double bonds of α,β-unsaturated ketones in an indirect manner. The substrate is treated with an organoboron compound (reaction **5-21**), and to the resulting enol borinate is added bromine, followed by hydrolysis.[501]



$$\mathrm{CH_2{=}CH{-}\underset{\underset{\textstyle O}{\|}}{C}{-}R' \xrightarrow[O_2]{R_3B} \overset{\overset{\textstyle R}{|}}{CH_2}{-}CH{=}\underset{\underset{\textstyle OBR_2}{|}}{C}{-}R' \xrightarrow{Br_2} \left[\overset{\overset{\textstyle R}{|}}{CH_2}{-}\overset{\overset{\textstyle Br}{|}}{CH}{-}\overset{\overset{\textstyle Br}{|}}{\underset{\underset{\textstyle OBR_2}{|}}{C}}{-}R'\right] \xrightarrow{H_2O} \overset{\overset{\textstyle R}{|}}{CH_2}{-}\overset{\overset{\textstyle Br}{|}}{CH}{-}\underset{\underset{\textstyle O}{\|}}{C}{-}R'}$$

OS **II,** 312; **IV,** 727; **V,** 1076; **51,** 1.

5-38 Addition of Acyl Halides (Addition of Halogen, Carbon)



$$\mathrm{{-}\underset{|}{C}{=}\underset{|}{C}{-} + RCOCl \xrightarrow{AlCl_3} {-}\underset{|}{\overset{\overset{\textstyle Cl}{|}}{C}}{-}\underset{|}{\overset{\overset{\textstyle COR}{|}}{C}}{-}}$$

Acyl halides have been added to many olefins, in the presence of Friedel-Crafts catalysts. The reaction has been applied to straight-chain, branched, and cyclic olefins, but to very few containing functional groups, except halogen.[502] The mechanism is similar to that of reaction **5-37**, and, as in that case, substitution competes (see reaction **2-15**). Increasing temperature favors substitution,[503] and good yields of addition products can be achieved if the temperature is kept under 0°C. The reaction usually fails with conjugated dienes, since polymerization predominates. The reaction can be performed on triple-bond compounds, producing compounds of the form $\text{RCO}-\underset{|}{\text{C}}=\underset{|}{\text{C}}-\text{Cl}$.[504] A *formyl* group and a halogen can be added to triple bonds by treatment with N,N-disubstituted formamides and $POCl_3$ (Vilsmeier conditions, see reaction **1-16**).[505]

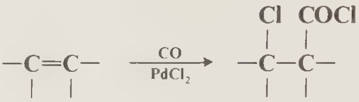
When olefins are treated with carbon monoxide in the presence of $PdCl_2$, β-chloro acyl halides are produced:[506]



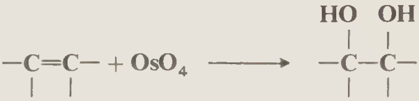
$$-\underset{|}{\text{C}}=\underset{|}{\text{C}}- \xrightarrow[\text{PdCl}_2]{\text{CO}} -\underset{|}{\overset{\text{Cl}}{\overset{|}{\text{C}}}}-\underset{|}{\overset{\text{COCl}}{\overset{|}{\text{C}}}}-$$

though not in high yield. The carbon goes to the side with more hydrogens.

OS **IV**, 186; **51,** 115.

B. Oxygen or Nitrogen on One or Both Sides

5-39 Hydroxylation (Addition of Oxygen, Oxygen)



$$-\underset{|}{\text{C}}=\underset{|}{\text{C}}- + \text{OsO}_4 \longrightarrow -\underset{|}{\overset{\text{HO}}{\overset{|}{\text{C}}}}-\underset{|}{\overset{\text{OH}}{\overset{|}{\text{C}}}}-$$

There are many reagents which add two OH groups to a double bond.[507] OsO_4 and alkaline $KMnO_4$ give syn addition, from the less hindered side of the double bond. Osmium tetroxide[508] adds rather slowly but almost quantitatively.[509] The cyclic ester **79** is an intermediate and can be isolated, but is usually decomposed in solution, with sodium sulfite in ethanol or other reagents. Bases catalyze the reaction by coordinating with the ester. The chief drawback to this reaction is that OsO_4 is expensive and highly toxic, so that its use has been limited to small-scale preparations of scarce materials. However, the same result (syn addition) can be accomplished more economically, by the use of H_2O_2, with OsO_4 present in catalytic amounts.[510] *t*-Butyl hydroperoxide in alkaline solution may be substituted for H_2O_2 in this procedure.[510a]

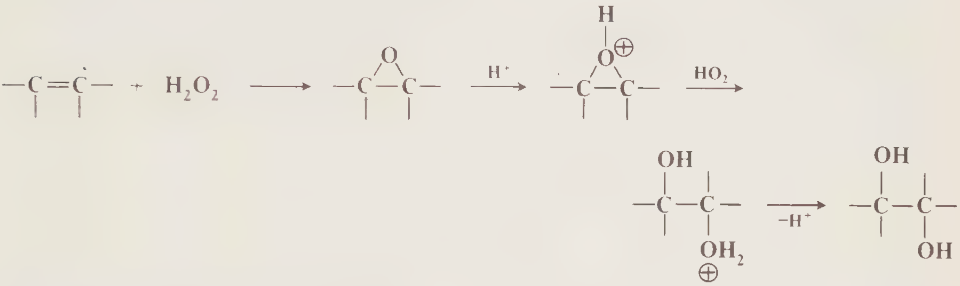
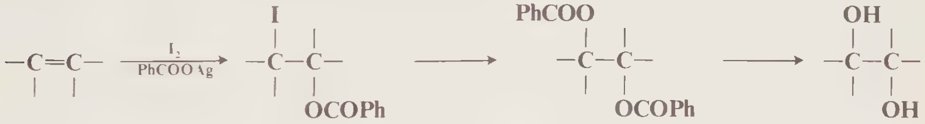
Potassium permanganate is a strong oxidizing agent and can oxidize the glycols which are the products of this reaction (see reactions **9-8** and **9-11**). In acid and neutral solution it always does so; hence it is not feasible to prepare glycols in this manner. Glycols can be prepared with alkaline permanganate, but the conditions must be mild. Even so, yields are seldom above 50%. As with OsO_4, it is likely that cyclic esters (**80**) are intermediates; species which are believed to be such intermediates have been detected spectrally.[511] This reaction is the basis of the *Baeyer test* for the presence of double bonds.

Anti hydroxylation can be achieved by treatment with H_2O_2 and formic acid. In this case, epoxidation (reaction **5-40**) occurs first, followed by an SN2 reaction, resulting in overall anti addition:



The same result can be achieved in one step with monopersuccinic acid.[512] Overall anti addition can also be achieved by the method of Prevost.[513] In this method the olefin is treated with iodine and silver benzoate in a 1 : 2 molar ratio. The initial addition is anti and results in a β-halo benzoate (**81**). These can be isolated, and this represents a method of addition of IOCOPh. However, under the normal reaction conditions, the iodine is replaced by a second PhCOO group. This is a nucleophilic substitution reaction, and it operates by the neighboring-group mechanism (p. 279), so that the groups are still anti:



81

Hydrolysis of the ester does not change the configuration. The method of Woodward is similar, but results in overall syn hydroxylation. The olefin is treated with iodine and silver acetate in a 1 : 1 molar ratio in acetic acid-containing water. Here again, the initial product is a β-halo ester; the addition is anti, and a nucleophilic replacement of the iodine occurs. However, in the presence of water, neighboring-group participation is prevented or greatly decreased by solvation of the ester function, and the mechanism is the normal SN2 process, so that the monoacetate is syn.

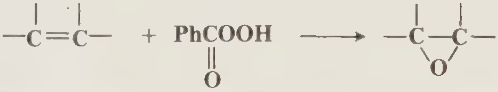
[513] For reviews of Prevost's and Woodward's methods, see Wilson, *Org. React.* **9,** 332-387 (1957), pp. 350 352.

Hydrolysis gives the glycol which is the product of overall syn addition. With cyclic trisubstituted olefins, both the Woodward and the Prevost methods may give allylic alcohols and ketones rather than the normal products.[514] Although the Woodward method results in overall syn addition, the product may be different from that with OsO_4 or $KMnO_4$, since the overall syn process is from the more hindered side of the olefin. Both the Prevost and the Woodward methods have also been carried out in high yields with thallium(I) acetate and thallium(I) benzoate instead of the silver carboxylates.[515] Addition of IOCOMe has also been accomplished with I_2 and peracetic acid[516] and with I_2 and potassium iodate in acetic acid.[517] The resulting β-iodo acetate can then be converted to the diol which is the product of syn addition by treatment with cupric acetate or potassium acetate. By a combination of the I_2–KIO_3 and $Cu(OAc)_2$ or KOAc methods, a double bond can be converted to the diol without the use of the expensive silver acetate.[517]

Olefins can also be oxidized with metallic acetates such as lead tetraacetate or thallium acetate to give bisacetates of glycols.[518]

OS **II,** 307; **III,** 217; **IV,** 317; **V,** 647; **50,** 24.

5-40 Epoxidation (Addition of Oxygen, Oxygen)



Olefins can be epoxidized with any of a number of peracids, of which perbenzoic is the most often used. The reaction, which is called the *Prilezhaev reaction*, has wide utility.[519] Alkyl, aryl, hydroxyl, ester, and other groups may be present, though not amino groups, since these are affected by the reagent. Electron-donating groups increase the rate, and the reaction is particularly rapid with tetraalkyl olefins. Conditions are mild, and yields are high. Other peracids, especially peracetic and *m*-chloroperbenzoic, are also used; trifluoroperacetic acid is a particularly reactive one.[520] Occasionally the reaction is performed with H_2O_2 and a carboxylic acid, so that the peracid is generated in situ. Glycols and glycol esters (reaction **5-39**) are side products.

The following one-step mechanism was proposed by Bartlett:[521]

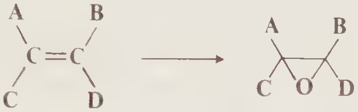
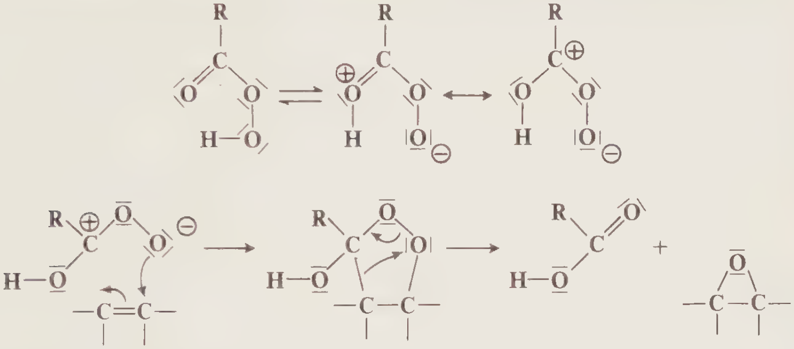
[520] Emmons and Pagano, *J. Am. Chem. Soc.* **77,** 89 (1955).

[521] Bartlett, *Rec. Chem. Prog.* **18,** 111 (1957).

Evidence for this mechanism is as follows:[522] (1) The reaction is second order. If ionization were the rate-determining step, it would be first order in peracid. (2) The reaction readily takes place in nonpolar solvents, where formation of ions is inhibited. (3) Measurements of the effect on the reaction rate of changes in the substrate structure show that there is no carbonium-ion character in the transition state.[523] (4) The addition is stereospecific; i.e., a trans olefin gives a trans epoxide and a cis olefin a cis epoxide:



Another mechanism, postulated more recently, is also in accord with the above facts:[524]



The key step of this mechanism is the 1,3-dipolar addition (see reaction **5-50**) of a tautomer of the peroxy acid. The five-membered cyclic adduct then rearranges to the products. Evidence against the 1,3-dipolar mechanism has been reported by Bingham and coworkers,[525] who found that the rates of epoxidation of cyclohexene and norbornene by perlauric acid were approximately the same, though in typical 1,3-dipolar additions norbornene reacts 10^3 to 10^4 times faster than cyclohexene.

Conjugated dienes can be epoxidized (1,2 addition), though the reaction is slower than for corresponding olefins, but α,β-unsaturated ketones do not generally give epoxides when treated with peracids.[526] However, α,β-unsaturated esters react normally, to give glycidic esters.[527] When a carbonyl group is in the molecule but not conjugated with the double bond, the Baeyer-Villiger reaction (**8-23**) may compete. It has been shown that 2-allylcyclohexanone treated with peracetic acid gives the Baeyer-Villiger reaction, but with H_2O_2 and benzonitrile it gives epoxidation.[528] Allenes are converted by peracids to allene oxides (**82**) or spiro dioxides (**83**),

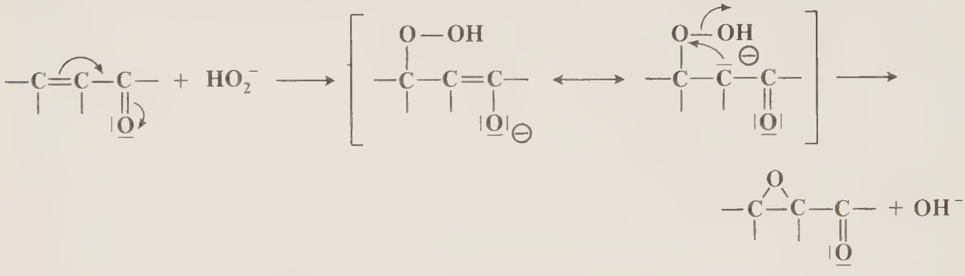
[528] Payne, *Tetrahedron* **18,** 763 (1962).

which in certain cases can be isolated[529] but more often are unstable under the reaction conditions and react further to give other products.[530]

α,β-Unsaturated ketones (including quinones), aldehydes, and sulfones can be epoxidized with alkaline H_2O_2,[531] but this is a nucleophilic addition by a Michael-type mechanism, involving attack by HO_2^-:[532]



Epoxides can also be prepared by treating olefins with oxygen or with an alkyl peroxide,[533] catalyzed by a complex of V or Mo. The reaction with oxygen, which can also be carried out without a catalyst, is probably a free-radical process.[534]

It would be useful if triple bonds could be simply epoxidized to give oxirenes (**84**). However, oxirenes are unknown. They probably form in the reaction[535] but react further before they can

84

be isolated. Note that oxirenes bear the same relationship to cyclobutadiene that furan does to benzene and may therefore be expected to be antiaromatic (see p. 55).

Peracids react with C=N bonds to give oxaziridines.[536]

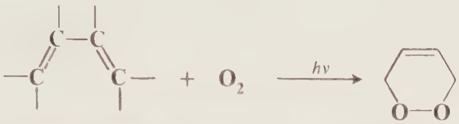
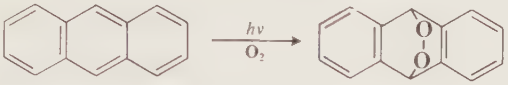
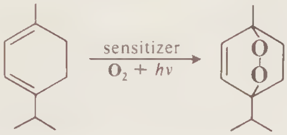
5-41 Photooxidation of Dienes (Addition of Oxygen, Oxygen)



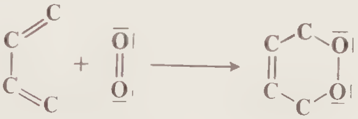
Conjugated dienes react with oxygen under the influence of light to give internal peroxides.[537] The reaction has mostly been applied to cyclic dienes. The scope extends to certain aromatic compounds,[538] e.g.,



In addition to those dienes and aromatic rings which can be photooxidized directly, there is a larger group which give the reaction in the presence of a photosensitizer such as eosin (see p. 218). Among these is α-terpinene, which is converted to ascaridole:



At first it may seem strange that oxygen, which is a diradical, needs photosensitization, either by light or a photosensitizer, to cause it to add to the conjugated system. But, as in reaction **4-8**, it is not the ground-state oxygen (the triplet) which reacts, and the purpose of the photosensitization is to elevate the oxygen to the singlet state,[539] so that the reaction is actually a Diels-Alder reaction (see **5-51**) with singlet oxygen as dienophile:[540]



Like reaction **5-51**, this reaction is reversible.

We have previously discussed the reaction of singlet oxygen with double-bond compounds to give hydroperoxides (reaction **4-8**), but singlet oxygen can also react with double bonds in another way, to give a dioxetane intermediate (**85**), which usually cleaves to aldehydes or ketones[541] but has been isolated in certain cases.[542]

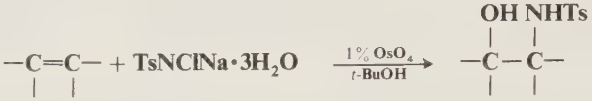
$$-\overset{|}{\underset{|}{C}}=\overset{|}{\underset{|}{C}}- + O_2 \longrightarrow \left[\begin{matrix} O-O \\ | \quad | \\ -C-C- \\ | \quad | \end{matrix}\right] \longrightarrow -\overset{O}{\overset{\|}{\underset{|}{C}}} + \overset{O}{\overset{\|}{\underset{|}{C}}}-$$

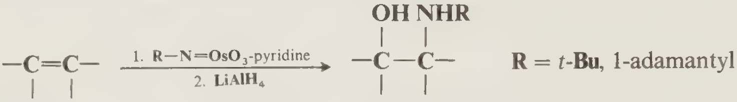
85

5-42 Oxyamination (Addition of Oxygen, Nitrogen)



$$-\underset{|}{C}=\underset{|}{C}- + \text{TsNClNa}\cdot 3H_2O \xrightarrow[t\text{-BuOH}]{1\%\ OsO_4} -\overset{OH}{\overset{|}{\underset{|}{C}}}-\overset{NHTs}{\overset{|}{\underset{|}{C}}}-$$

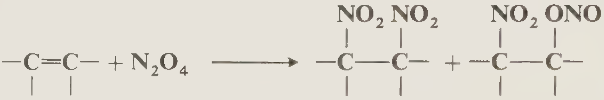
N-Tosylated β-hydroxy alkylamines (which can be easily hydrolyzed to β-hydroxyamines) can be prepared by treatment of alkenes with the trihydrate of Chloramine-T.[542a] In some cases $AgNO_3$ must be added. In another procedure, certain β-hydroxy secondary alkylamines can be prepared by treatment of alkenes with the osmium compounds $R{-}N{=}OsO_3$ (R = *t*-butyl or 1-adamantyl), followed by reductive cleavage with $LiAlH_4$ of the initially-formed osmic esters.[543] It is presumed



$$-\underset{|}{C}=\underset{|}{C}- \xrightarrow[2.\ LiAlH_4]{1.\ R-N=OsO_3\text{-pyridine}} -\overset{OH}{\overset{|}{\underset{|}{C}}}-\overset{NHR}{\overset{|}{\underset{|}{C}}}- \qquad R = t\text{-Bu, 1-adamantyl}$$

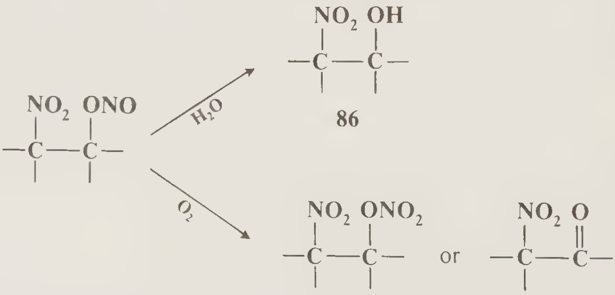
that $R{-}N{=}OsO_3$ (R = Ts) is an intermediate in the Chloramine-T reaction. Another oxyamination reaction involves treatment of a palladium complex of the olefin with a secondary amine, followed by lead tetraacetate.[543a]

5-43 Addition of N_2O_4 and Related Reactions (Addition of Nitrogen, Nitrogen or Nitrogen, Oxygen):



$$-\underset{|}{C}=\underset{|}{C}- + N_2O_4 \longrightarrow -\overset{NO_2}{\overset{|}{\underset{|}{C}}}-\overset{NO_2}{\overset{|}{\underset{|}{C}}}- + -\overset{NO_2}{\overset{|}{\underset{|}{C}}}-\overset{ONO}{\overset{|}{\underset{|}{C}}}-$$

When olefins are treated with N_2O_4 in an ether, ester, or alkane[544] as solvent, *vic*-dinitro compounds and β-nitro alkyl nitrites are produced.[545] The reaction may be successfully performed with all kinds of olefins and acetylenes. Generally, both products are produced. The dinitro compound is usually stable, but the ester is quite reactive. Upon addition of water or alcohol it is hydrolyzed to a β-nitro alcohol. If oxygen is added, it is oxidized to a β-nitro alkyl nitrate or an α-nitro aldehyde or ketone.



$$-\overset{NO_2}{\overset{|}{\underset{|}{C}}}-\overset{ONO}{\overset{|}{\underset{|}{C}}}- \xrightarrow{H_2O} -\overset{NO_2}{\overset{|}{\underset{|}{C}}}-\overset{OH}{\overset{|}{\underset{|}{C}}}-$$

86

$$-\overset{NO_2}{\overset{|}{\underset{|}{C}}}-\overset{ONO}{\overset{|}{\underset{|}{C}}}- \xrightarrow{O_2} -\overset{NO_2}{\overset{|}{\underset{|}{C}}}-\overset{ONO_2}{\overset{|}{\underset{|}{C}}}- \text{ or } -\overset{NO_2}{\overset{|}{\underset{|}{C}}}-\overset{O}{\overset{\|}{C}}-$$

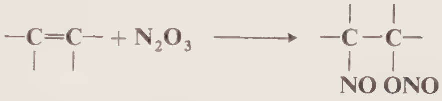
[545] For reviews, see Larson, in Feuer, Ref. 338, pt. 1, pp. 316–323 (1969); Stacey and Harris, *Org. React.* **13,** 150–376 (1963), pp. 224–229, 361–367; Shechter, *Rec. Chem. Prog.* **25,** 55–76 (1964); Sosnovsky, Ref. 41, pp. 252–269; Noble, Borgardt, and Reed, *Chem. Rev.* **64,** 19–57 (1964), pp. 20–22.

The nitrate is stable. Even without deliberate addition of oxygen, it is not uncommon to find some nitrate or ketone. It is therefore possible to prepare four types of compound in this reaction, not counting the nitrite.

The mechanism is probably of the free-radical type,[546] with initial attack by NO_2 to give $-\underset{\bullet}{\overset{|}{C}}-\underset{|}{\overset{|}{C}}-NO_2$ as the intermediate for both products. In accord with this, the nitro group (in the nitrite derivatives) is found on the side with more hydrogens. There is evidence that a β-nitro alkyl peroxynitrate $O_2NCHRCHROONO_2$ is an intermediate in the formation of the α-nitro carbonyl compound.[547] When oxygen is completely absent, the product is a β-nitroso nitrate $O_2NOCR_2CR_2NO$, and it is likely that in this case N_2O_4 adds by a heterolytic mechanism.[548]

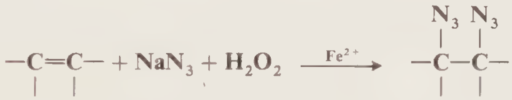
β-Nitro alcohols (**86**) can also be prepared indirectly, by addition of acetyl nitrate $AcONO_2$ to double bonds.[549] The resulting β-nitro acetate can be hydrolyzed to the alcohol. Side products of the addition of $AcONO_2$ are nitro olefins. The addition follows Markovnikov's rule, with the nitro group going to the carbon with more hydrogens.

N_2O_3 adds to olefins to give β-nitroso alkyl nitrites:[550]



$$-\underset{|}{C}=\underset{|}{C}- + N_2O_3 \longrightarrow -\underset{\underset{NO}{|}}{\overset{|}{C}}-\underset{\underset{ONO}{|}}{\overset{|}{C}}-$$

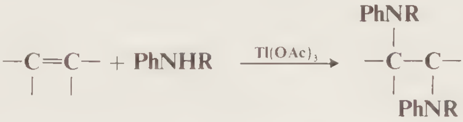
β-Nitroso formates can be prepared by treatment of alkenes with nitrosyl formate HCOONO, generated in situ from isoamyl nitrite and formic acid.[551] Two azide groups can be added to double bonds by treatment with sodium azide and hydrogen peroxide, in the presence of ferrous ion:[552]



$$-\underset{|}{C}=\underset{|}{C}- + NaN_3 + H_2O_2 \xrightarrow{Fe^{2+}} -\underset{|}{\overset{\overset{N_3}{|}}{C}}-\underset{|}{\overset{\overset{N_3}{|}}{C}}-$$

OS **50**, 84.

5-44 Bisamination (Addition of Nitrogen, Nitrogen)



$$-\underset{|}{C}=\underset{|}{C}- + PhNHR \xrightarrow{Tl(OAc)_3} -\underset{|}{\overset{\overset{PhNR}{|}}{C}}-\underset{\underset{PhNR}{|}}{C}-$$

Primary (R = H) and secondary aromatic amines react with alkenes in the presence of thallium(III) acetate to give *vic*-diamines in good yields.[553] The reaction is not successful for primary aliphatic amines.

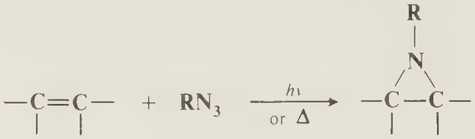
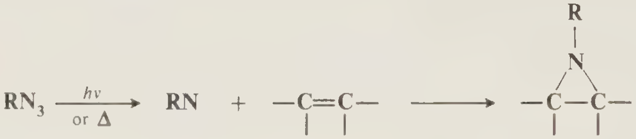
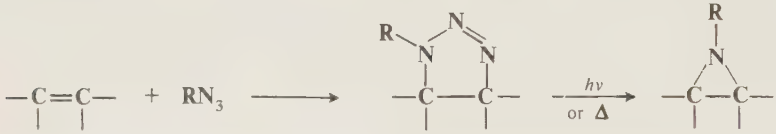
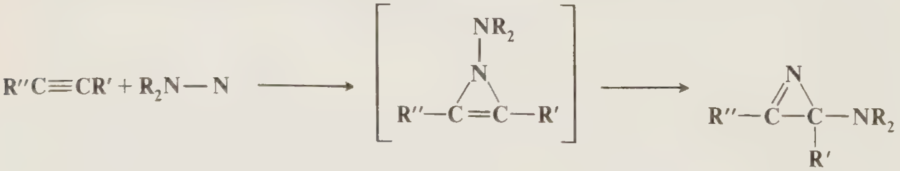
5-45 Formation of Aziridines (Addition of Nitrogen, Nitrogen)



Aziridines can be prepared directly from double-bond compounds by photolysis or thermolysis of a mixture of the substrate and an azide.[554] The reaction has been carried out with R = aryl, cyano, EtOOC, and RSO_2, as well as other groups. The reaction can take place by at least two pathways. In one, the azide is converted to a nitrene (p. 184), which adds to the double bond in a manner analogous to that of carbene addition (reaction **5-53**). In the other pathway a 1,3 dipolar addition (reaction **5-50**) takes place to give a triazoline (which can be isolated), followed by extrusion of nitrogen (reaction **7-48**). Evidence for the nitrene pathway is most compelling for R = acyl groups. As discussed on p. 184, singlet nitrenes add stereospecifically while triplet nitrenes do not. Aminonitrenes R_2NN have been shown to add to triple bonds to give 1-azirines, which arise from rearrangement of the initially formed 2-azirines.[555] Like oxirenes (p. 752), 2-azirines are unknown, probably because they are predicted to be antiaromatic.







Nitrenes can also add to aromatic rings to give ring-expansion products analogous to those mentioned in reaction **5-53**.[556] Nitrenoids can also add to C=N bonds and to C=O bonds, to give diaziridines and oxaziranes, respectively.[557]

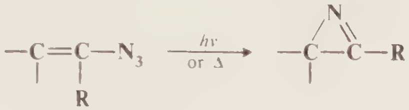
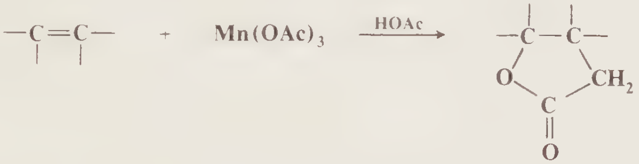
OS **55,** 114.

5-46 The Formation of 1-Azirines from Vinyl Azides



1-Azirines can be prepared by the photolysis or thermolysis of vinyl azides.[558] The thermolysis is catalyzed by tertiary amines.[559] The reaction may be regarded as a kind of addition of a nitrene to a double bond. R may be alkyl, aryl, or hydrogen,[560] though 1-azirines in which R = hydrogen are unstable and difficult to isolate. Vinyl azides are easily prepared from olefins in two steps: addition of iodine azide (reaction **5-35**) followed by elimination of HI (reaction **7-13**).

5-47 The Conversion of Olefins to γ-Lactones (Addition of Oxygen, Carbon)



Olefins react with manganese(III) acetate to give γ-lactones.[561] The mechanism is probably free-radical, involving addition of $\cdot CH_2COOH$ to the double bond. Similar lactone formation has also been accomplished with lead tetraacetate.[562]

Olefins can also be converted to γ-lactones by the following indirect route:[563] bromodicyano-

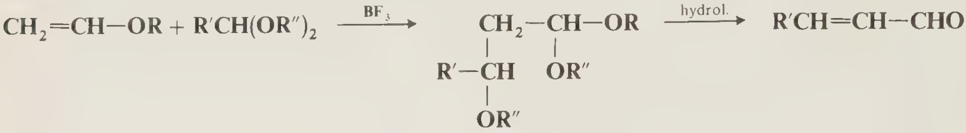
[562] Heiba, Dessau, and Koehl, *J. Am. Chem. Soc.* **90,** 2706 (1968).

[563] For another indirect route, see Das Gupta, Felix, Kempe, and Eschenmoser, *Helv. Chim. Acta* **55,** 2198 (1972).

methane adds to double bonds under the influence of uv light to give adducts (reaction **5-37**) which are easily hydrolyzed and decarboxylated. In the overall process a double-bond compound is converted to a γ-lactone.[564]

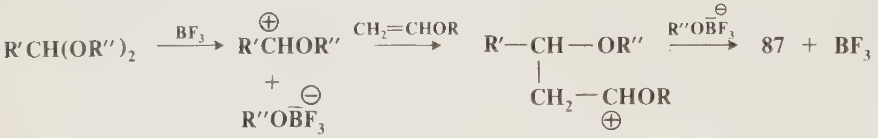
5-48 The Addition of Acetals to Vinyl Ethers (Addition of Oxygen, Carbon)



$$\mathrm{CH_2{=}CH{-}OR + R'CH(OR'')_2 \xrightarrow{BF_3} \begin{array}{ccc} & CH_2 & {-}CH{-}OR \\ & | & | \\ R'{-} & CH & OR'' \\ & | & \\ & OR'' & \end{array} \xrightarrow{hydrol.} R'CH{=}CH{-}CHO}$$

87

Acetals add to vinyl ethers in the presence of BF_3, to give alkoxy acetals which can be hydrolyzed to α,β-unsaturated aldehydes.[565] Other Lewis acids, e.g., $ZnCl_2$, $AlCl_3$, have also been used as catalysts. Because of transetherification (reaction **0-19**) the product acetal (when $R \neq R''$) may contain $R''OCHR'CH_2CH(OR'')_2$ as well as **87.** For this reason it is usually advisable to begin with an acetal and a vinyl ether in which $R = R''$. The mechanism of the addition reaction has been formulated as[566]

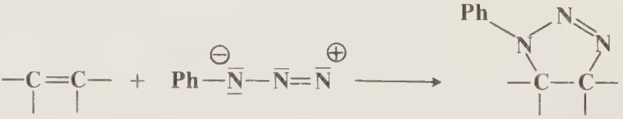


$$\mathrm{R'CH(OR'')_2 \xrightarrow{BF_3} \begin{array}{c} \overset{\oplus}{R'CHOR''} \\ + \\ R''O\overset{\ominus}{B}F_3 \end{array} \xrightarrow{CH_2{=}CHOR} \begin{array}{l} R'{-}CH{-}OR'' \\ \quad\ | \\ \quad CH_2{-}\overset{}{\underset{\oplus}{CHOR}} \end{array} \xrightarrow{R''O\overset{\ominus}{B}F_3} 87 + BF_3}$$

5-49 Addition of Aldehydes and Ketones (Addition of Oxygen, Carbon).

See the Prins reaction (**6-54**), reactions **6-55,** and **6-68** to **6-70.**

5-50 1,3-Dipolar Addition (Addition of Oxygen, Nitrogen, Carbon)



Azides add to double bonds to give triazolines. This is one example of a large group of reactions (2 + 3 cycloadditions) in which five-membered heterocyclic compounds are prepared by addition to double bonds of 1,3-dipolar compounds.[567] These are compounds which have a sequence of three atoms a—b—c, of which a has a sextet of electrons in the outer shell and c an octet with at least one unshared pair. The reaction can then be formulated as

For a review of intramolecular 1,3-dipolar additions, see Padwa, *Angew. Chem. Int. Ed. Engl.* **15,** 123–136 (1976) [*Angew. Chem.* **88,** 131–144].

Since compounds with six electrons in the outer shell of an atom are usually not stable, the a—b—c system is actually one canonical structure of a resonance hybrid, for which at least one other structure may be drawn, e.g., for azides

$$R-\overset{\ominus}{\underline{\overline{N}}}-\overline{N}=\overset{\oplus}{N} \longleftrightarrow R-\overset{\ominus}{\underline{\overline{N}}}-\overset{\oplus}{N}\equiv\overline{N}$$

1,3-Dipolar compounds can be divided into two main types:

1. Those in which the dipolar canonical form has a double bond on the sextet atom and the other canonical form a triple bond on that atom:

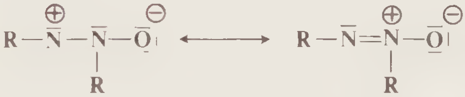
$$-\overset{\oplus}{a}=\underline{b}-\overset{\ominus}{\underline{c}} \longleftrightarrow -\overset{\oplus}{a}\equiv b-\overset{\ominus}{\underline{c}}$$

If we limit ourselves to the first row of the periodic table, b can only be nitrogen, a can be carbon or nitrogen, and c can be carbon, oxygen, or nitrogen; hence there are six types which fit this description. Among these are azides (a = b = c = N), illustrated above, and diazoalkanes ($R_2\overset{\ominus}{\overline{C}}-\overline{N}=\overset{\oplus}{\overline{N}}$).

2. Those in which the dipolar canonical form has a single bond on the sextet atom and the other form a double bond:

$$-\overset{\oplus}{a}-\underline{b}-\overset{\ominus}{\underline{c}} \longleftrightarrow -\overset{\oplus}{a}=b-\overset{\ominus}{\underline{c}}$$

Here b can be nitrogen or oxygen, and a and c can be nitrogen, oxygen, or carbon, but there are only 12 types, since, for example, N—N—C is only another form of C—N—N. Examples are azoxy compounds:



$$R-\overset{\oplus}{\overline{N}}-\overline{N}(R)-\overset{\ominus}{\underline{\overline{O}}}| \longleftrightarrow R-\overline{N}=\overset{\oplus}{N}(R)-\overset{\ominus}{\underline{\overline{O}}}|$$

Of the 18 systems, some of which are unstable and must be generated in situ, the reaction has been accomplished for at least 15, though not in all cases with a carbon-carbon double bond (the reaction also can be carried out with other double bonds). Not all olefins undergo 1,3-dipolar addition equally well. The reaction is most successful for those which are good dienophiles in the Diels-Alder reaction (**5-51**). The addition is stereoselective and syn, and the mechanism is probably a one-step synchronous process, as illustrated above.[568] As expected for this type of mechanism, the rates do not vary much with changes in solvent.[569] There are no simple rules covering orientation in 1,3-dipolar additions when both the reagent and the substrate are unsymmetrical. Regioselectivities are complicated but have been explained by molecular-orbital treatments.[570]

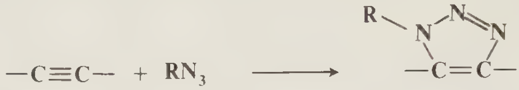
---

[568] For discussions, see Huisgen, *J. Org. Chem.* **33,** 2291 (1968), **41,** 403 (1976); Harcourt, *J. Mol. Struct.* **12,** 351–366 (1972); Firestone, *J. Org. Chem.* **33,** 2285 (1968).

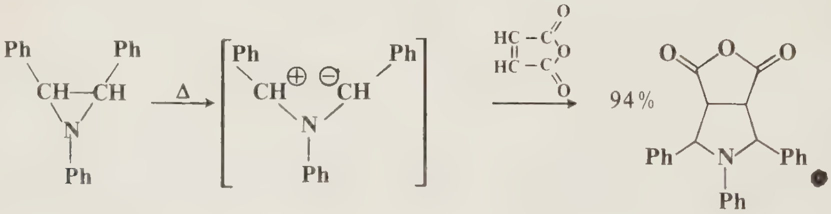
[569] For a review of the role of solvents in this reaction, see Kadaba, *Synthesis* 71–84 (1973).

[570] Sustmann, *Tetrahedron Lett.* 2717 (1971), *Pure Appl. Chem.* **40,** 569–593 (1974), Sustmann and Trill, *Angew. Chem. Int. Ed. Engl.* **11,** 838 (1972) [*Angew. Chem.* **84,** 887]; Houk, *J. Am. Chem. Soc.* **94,** 8953 (1972); Houk, Sims, Duke, Strozier, and George, *J. Am. Chem. Soc.* **95,** 7287 (1973); Houk, Sims, Watts, and Luskus, *J. Am. Chem. Soc.* **95,** 7301 (1973); Bastide, Ghandour and Henri-Rousseau, *Tetrahedron Lett.* 4225 (1972), *Bull. Soc. Chim. Fr.* 2290 (1973); Bastide and Henri-Rousseau, *Bull. Soc. Chim. Fr.* 2294 (1973), 1037 (1974); Caramella and Cellerino, *Tetrahedron Lett.* 229 (1974).

Carbon-carbon triple bonds may also undergo 1,3-dipolar addition.[571] For example, azides give triazoles:

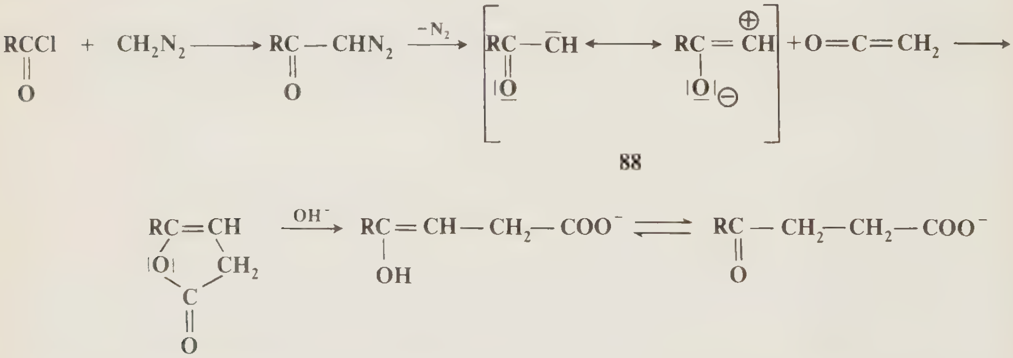


The 1,3-dipolar reagent can in some cases be generated by the in situ opening of a suitable three-membered ring system. For example, aziridines can add to activated double bonds to give pyrrolidines, e.g.,[572]



Aziridines also add to C≡C triple bonds as well as to other unsaturated linkages, including C=O, C=N, and C≡N.[573] In some of these reactions it is a C—N bond of the aziridine which opens rather than the C—C bond.

The 1,3-dipolar addition to ketene of a carbene derived from a diazo ketone provides a method of increasing the length of a carbon chain by three:[574]



88

The first step is an example of reaction **0-116.** In the last step the enol lactone (butenolide) formed by the 1,3-dipolar addition is hydrolyzed by base. It may be noted that the 1,3-dipolar species **88** does not fit into either of the two main categories mentioned above. Although **88** adds to the double bond of ketene, it normally undergoes rearrangement (reaction **8-9**) before it can add to most other double bonds.[575]

2 + 3 cycloadditions are also known in which the compound which adds to the double or triple bond is not a 1,3-dipolar compound but an anion with a partial negative charge at *both*

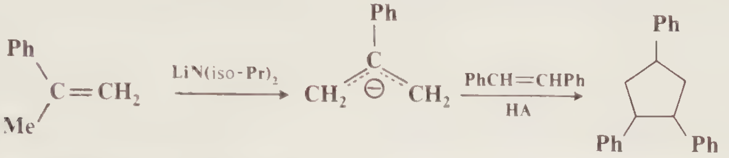
ends. Such reactions are called 1,3-*anionic cycloadditions*.[576] An important example is the case where the anion is an allyl carbanion and the product a cyclopentane. For example, α-methylstyrene adds to stilbene after being treated with the strong base lithium diisopropylamide.[577]

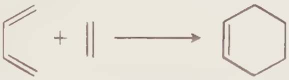


In this case the reagent is an allylic anion,[578] but similar 2 + 3 cycloadditions involving allylic cations have also been reported.[579]

OS V, 96, 127; **53,** 59. Also see OS **IV**, 380.

C. Carbon on Both Sides. Reactions **5-51** to **5-55** are cycloaddition reactions.[580]

5-51 The Diels-Alder Reaction



In the *Diels-Alder reaction* a double bond adds 1,4 to a conjugated diene (a 4 + 2 cycloaddition)[581] so that the product is always a six-membered ring. The double-bond compound is called a *dienophile*. The reaction is easy and rapid and of very broad scope. Ethylene and simple olefins make poor dienophiles, although the reaction has been carried out with these compounds. Most dienophiles are of the form $-\underset{|}{C}=\underset{|}{C}-Z$ or $Z-\underset{|}{C}=\underset{|}{C}-Z'$, where Z and Z′ are CHO, COR, COOH, COOR, COCl, COAr, CN,[582] NO_2,[583] Ar, CH_2OH, CH_2Cl, CH_2NH_2, CH_2CN, CH_2COOH, halogen, or C=C.[584] In the latter case, the dienophile is itself a diene:

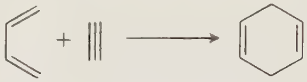
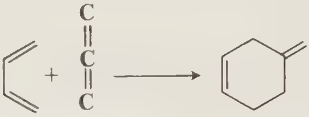
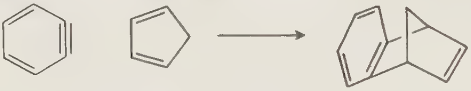
When two dienes react, mixtures are quite possible. Thus, butadiene and isoprene ($CH_2{=}CH{-}CMe{=}CH_2$) gave all nine possible Diels-Alder adducts, as well as eight-membered rings and trimers.[585] Particularly common dienophiles are maleic anhydride[586] and quinones.[587] Triple bonds ($-C{\equiv}C{-}Z$ or $Z{-}C{\equiv}C{-}Z'$) may be dienophiles[588]



as may allenes



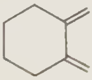
Benzynes, although not isolable, act as dienophiles, and can be trapped with dienes;[589] e.g.,



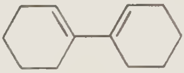
89

Besides carbon-carbon multiple bonds, other double- and triple-bond compounds may be dienophiles, giving rise to heterocyclic compounds. Among these are $N{\equiv}C{-}$, $-N{=}C{-}$, $-N{=}N{-}$, $O{=}N$, and $-C{=}O$ compounds[590] and, as we have seen (reaction **5-41**), even molecular oxygen.

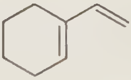
Dienes may be open-chain, inner-ring (e.g., **89**), outer-ring (e.g., **90**), across rings (e.g., **91**), or inner-outer (e.g., **92**), except that they may not be frozen into a transoid conformation (see p. 764). They need no special activating groups, and nearly all conjugated dienes undergo the reaction with suitable dienophiles.[591]



90



91



92

Aromatic compounds may also behave as dienes. Benzene is very unreactive toward dienophiles, and very few dienophiles (one of them is benzyne) have been reported to give Diels-Alder adducts with it.[592] Naphthalene and phenanthrene are also quite resistant, though naphthalene has given

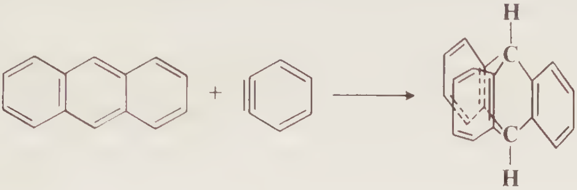
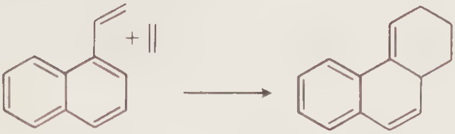
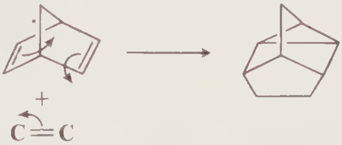
Diels-Alder addition at high pressures.[593] However, anthracene and other compounds with at least three linear benzene rings give Diels-Alder reactions readily. The interesting compound triptycene can be prepared by a Diels-Alder reaction between benzyne and anthracene:[594]



It is possible for a diene to have one double bond in an aromatic system and the other outside it, e.g.,

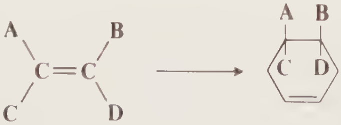


Even styrene has been shown to react in this manner.[595] Certain heterocyclic aromatic rings (among them furan) may also behave as dienes in the Diels-Alder reaction. Some hetero dienes which give the reaction are —C=C—C=O, O=C—C=O, and N=C—C=N.[590] For both all-carbon and hetero systems, the "diene" may be a conjugated enyne. If the geometry of the molecule is suitable, the diene may even be nonconjugated, e.g.,[596]



The stereochemistry of the Diels-Alder reaction can be considered from several aspects:[597]

1. With respect to the dienophile, the addition is almost always syn. Very few exceptions are known.[598] This means that groups which are cis in the olefin will be cis in the cyclohexene ring:



The addition is thus stereospecific.

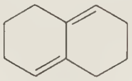
[597] For a review, see Martin and Hill, *Chem. Rev.* **61**, 537–562 (1961).

[598] For some exceptions, see Mark, *J. Org. Chem.* **39**, 3179, 3181 (1974).

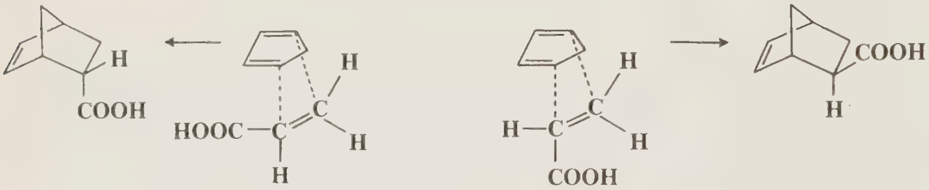
2. With respect to 1,4-disubstituted dienes, fewer cases have been investigated, but here too the reaction is stereospecific and syn. Thus, *trans,trans*-1,4-diphenylbutadiene gives *cis*-1,4-diphenylcyclohexene derivatives.

3. The diene must be in the cisoid conformation. If it is frozen into the transoid conformation, as in **93**, the reaction does not take place. For example, 7,9-cholestadiene has such a transoid system and is inert to maleic anhydride. The diene therefore either must be frozen into the cisoid conformation or must be able to achieve it during the reaction.



93

4. When the diene is cyclic, there are two possible ways in which addition can occur if the dienophile is not symmetrical. The larger side of the dienophile may be under the ring (*endo addition*), or it may be the smaller side (*exo addition*):

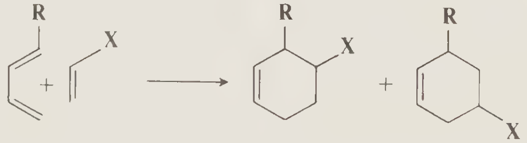


Endo addition

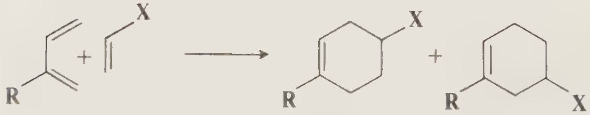
Exo addition

Most of the time, the addition is predominantly endo; i.e., the more bulky side of the olefin is under the ring, and this is probably true for open-chain dienes also. However, exceptions are known, and in many cases mixtures of exo and endo addition products are found.[599]

When an unsymmetrical diene adds to an unsymmetrical dienophile, there are two possible products (not counting stereoisomers):



Mostly



Mostly

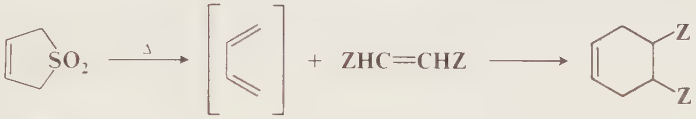
---

[599] See, for example, Alder and Günzl, *Chem. Ber.* **93**, 809 (1960); Stockmann, *J. Org. Chem.* **26**, 2025 (1961); Kobuke, Fueno, and Furukawa, *J. Am. Chem. Soc.* **92**, 6548 (1970); Jones and Wife, *J. Chem. Soc., Chem. Commun.* 421 (1973).

Although mixtures are often obtained, usually one predominates,[600] the one indicated above. This regioselectivity, in which the "ortho" or "para" product is favored over the "meta," has been explained by molecular-orbital considerations.[601]

Electron-donating substituents in the diene accelerate the reaction; electron-withdrawing groups retard it. For the dienophile it is just the reverse: donating groups decrease the rate, and withdrawing groups increase it. Cyclic dienes, in which the cisoid conformation is built in, usually react faster than the corresponding open-chain compounds, which have to achieve the cisoid conformation by rotation.[602]

As should be apparent from the foregoing, many interesting compounds can be prepared by the Diels-Alder reaction, some of which we would be hard put to make in any other way. It has thus been exceedingly useful. Competing reactions are polymerization of the diene or dienophile, or both, and 1,2 cycloaddition (reaction **5-52**). However, yields are usually quite high. No catalyst is needed, although it has been found that Lewis acids catalyze some Diels-Alder reactions,[603] usually those in which Z in the dienophile is a C=O or C=N group. A Lewis acid catalyst usually increases both the regioselectivity of the reaction (in the sense given above)[604] and the extent of endo addition.[605] The Diels-Alder reaction is usually reversible and has been used to protect double bonds.[606] A convenient substitute for butadiene in the Diels-Alder reaction is the compound 3-sulfolene (**94**), since the latter is a solid which is easy to handle while the former is a gas.[607] Butadiene is generated in situ by a reverse Diels-Alder reaction (see reaction **7-23**).



94

There are, broadly speaking, three possible mechanisms which have been considered for the Diels-Alder reaction.[608] In mechanism *a* there is a cyclic six-centered transition state and no intermediate. The reaction is concerted and occurs in one step. In mechanism *b* one end of the

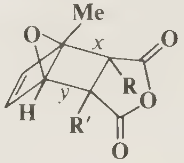
diene fastens to one end of the dienophile first to give a diradical, and then, in a second step, the other ends become fastened. A diradical formed in this manner must be a singlet; i.e., the two unpaired electrons must have opposite spins, by an argument similar to that outlined on p. 179. The third mechanism (*c*, not shown) is similar to mechanism *b*, but the initial bond and the subsequent bond are formed by movements of electron pairs and the intermediate is a diion. There have been many mechanistic investigations of the Diels-Alder reaction, and the bulk of the evidence suggests that most Diels-Alder reactions take place by the one-step cyclic mechanism *a*, although it is possible that a diradical or even a diion mechanism may be taking place in some cases. The main evidence in support of mechanism *a* is as follows: (1) The reaction is stereospecific in both the diene and dienophile. A completely free diradical or diion probably would not be able to retain its configuration. (2) In general, the rates of Diels-Alder reactions depend very little on the nature of the solvent. This would rule out a diion intermediate because polar solvents increase the rates of reactions which develop charges in the transition state. (3) It was shown that, in the decomposition of **95**, the isotope effect k_I/k_{II} was equal to 1.00 within experimental error.[609] If bond x broke before bond y, there should surely be a secondary isotope effect. This result strongly indicates that the bond breaking of x and y is simultaneous. This is the reverse of a Diels-Alder reaction, and by the principle of microscopic reversibility, the mechanism of the forward reaction should involve simultaneous formation of bonds x and y. Subsequently, a similar experiment was carried out on the forward reaction,[610] and the result was the same. There is also other evidence for mechanism *a*.[611] However, the fact that the mechanism is concerted does not necessarily mean that in the transition state both new σ bonds have been formed to the same extent. It could very well be that one bond has been formed to a greater degree than the other.[612]



95

I: R=H, R′=D
II: R=D, R′=H

In another aspect of the mechanism, the effects of electron-donating and electron-withdrawing substituents (p. 685) indicate that the diene is behaving as a nucleophile and the dienophile as an electrophile. However, this can be reversed. Perchlorocyclopentadiene reacts better with cyclopentene than with maleic anhydride and not at all with tetracyanoethylene, though the latter is normally the most reactive dienophile known. It is apparent, then, that this diene is the electrophile in its Diels-Alder reactions.[613]

We have emphasized that the Diels-Alder reaction generally takes place rapidly and conveniently. In sharp contrast, the apparently similar dimerization of olefins to cyclobutanes (reaction

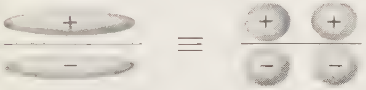
5-52) gives very poor results in most cases, except when photochemically induced. Woodward and Hoffmann have shown that these contrasting results can be explained by the *principle of conservation of orbital symmetry*,[614] which predicts that certain reactions are allowed and others forbidden. The orbital-symmetry rules (also called the Woodward-Hoffmann rules) apply *only to concerted reactions*, e.g., mechanism *a*, and are based on the principle that reactions take place in such a way as to maintain maximum bonding throughout the course of the reaction. There are several ways of applying the orbital-symmetry principle to cycloaddition reactions, of which we shall discuss two: the correlation-diagram method and the frontier-orbital method.[615]

The Correlation-Diagram Method[616]

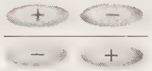
In this method we shall draw a correlation diagram for each reaction, in which the symmetry of the orbitals in the starting compounds will be compared with the symmetry of the orbitals of the products. First let us consider the dimerization of two ethylenes to give cyclobutane.

We shall ignore the σ bonds of the ethylenes and the two previously existing σ bonds of the cyclobutane and focus our attention on the two π bonds of the ethylenes and the two newly created σ bonds (marked ‡) in the cyclobutane. We recall (p. 12) that each ethylene has two π orbitals, one bonding and one antibonding. In this book we represent the bonding π orbital as shown on the left (**A**).



A **B**

Bonding orbital



Antibonding orbital

Note that many other books prefer to represent it as in **B**. The two methods of representation

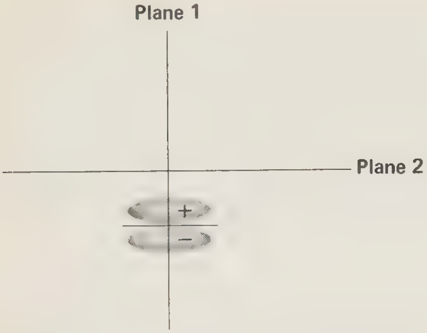

Figure 1 Cross section of the bonding π orbital of a single ethylene molecule.

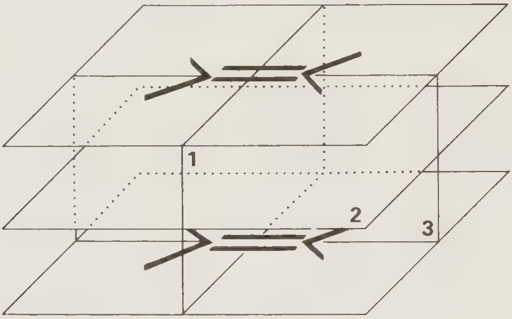
are completely equivalent. The most probable approach of the two ethylene molecules, in order for a concerted reaction to take place, is in two parallel planes[617]



In this configuration two planes of symmetry, marked 1 and 2 in the diagram, are present throughout the course of the reaction (plane 3 is also a plane of symmetry, but we ignore it because there is nothing to be learned from it). In order to construct a correlation diagram it is necessary to choose molecular orbitals *which are either symmetric or antisymmetric with respect to any plane of symmetry or other symmetry operation which may be present*. A choice of the bonding π orbital of a single ethylene molecule will not fulfill this condition, for the following reason. For an orbital to be symmetric with respect to a plane of symmetry, it must appear on both sides of the plane; and the signs of its lobes must be unchanged. To be antisymmetric with respect to a plane of symmetry, an orbital must also appear on both sides of the plane, but in this case the signs of all its lobes must be changed. It is obvious (Figure 1) that the bonding orbital of a single ethylene molecule is symmetric with respect to plane 1 but neither symmetric nor antisymmetric with respect to plane 2.[617a] Choosing the bonding orbital of the other ethylene molecule will not help either, because its symmetry properties are the same. We can fulfill the condition by examining the *interaction* of the orbitals in the transition state. As the two molecules approach each other, we can imagine the bonding orbital of one overlapping the bonding orbital of the other, to form two new transition-state orbitals which are the *sum* and the *difference* of the two original orbitals, respectively. In taking the sum of two orbitals, we simply merge them together. In taking the difference, we change the signs of one, and then merge them together. Likewise, the two antibonding orbitals interact in a similar fashion. Thus four orbitals arise (present in the transition state only), which can be represented in cross section as follows:

---

[617] This figure is adapted from Woodward and Hoffmann, Ref. 614.

[617a] The bonding π orbital of a single ethylene molecule is antisymmetric with respect to the plane of its own node, but this is irrelevant to the present case because this plane is not a plane of symmetry throughout the course of the reaction.

All four of these transition-state orbitals are either symmetric or antisymmetric with respect to planes 1 and 2 as shown above.

We now consider the two σ bonds (marked ‡) of the product. We may recall (p. 8, Figure 5) that a σ orbital consists of a single lobe, while a σ^* orbital has two lobes, of opposite signs. Once again we examine the interaction of the four orbitals involved (two σ and two σ^* orbitals). We take the sum and the difference of the two σ orbitals and the sum and the difference of the two σ^* orbitals. Note that we have shown the interaction of lowest energy as the sum of two + orbitals. We could just as easily have shown the sum of two − orbitals, which would have been equivalent. The important thing is that it is the sum of orbitals of the same sign.

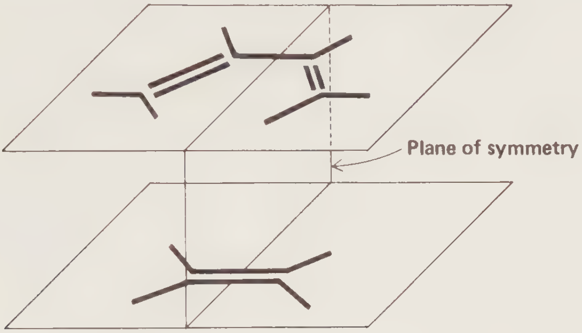
In an uncatalyzed reaction (called *thermal* to distinguish it from a photochemical, or light-induced reaction) the π electrons of the two ethylene molecules are in the bonding π orbitals (the π* orbitals are vacant). The principle of conservation of orbital symmetry says that orbital symmetry must be conserved for the reaction to be allowed. Therefore, the orbitals marked SS and SA in the starting compounds must convert into the orbitals marked SS and SA, respectively, in the product. This is no problem for the SS orbital, which in the product is a bonding orbital. But the SA orbital of the product is antibonding. Thus for the thermal reaction to take place, a bonding orbital *must*, in order to preserve its symmetry, be converted to an antibonding orbital; but the energy involved is unacceptably high, and the reaction is "forbidden." Note that this is true *in either direction*. Although thermal cleavage of cyclobutane to give two ethylene molecules is much more favored by entropy factors than is the reverse reaction, it too is forbidden to proceed by a cyclic mechanism.

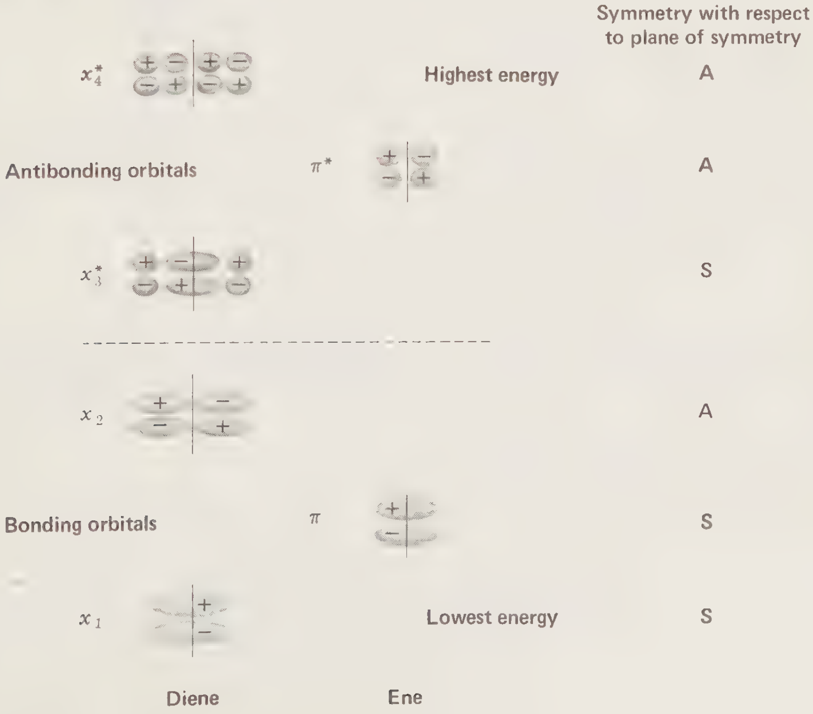
However, if the reaction, in either direction, is photochemically induced, *it becomes allowed.* The uv light promotes an electron from a bonding to an antibonding orbital, so that the orbitals marked SS, SA, and AS are all occupied. In this case conversion of starting material to product (in either direction) involves conversion of two bonding and one antibonding orbitals to two bonding and one antibonding orbitals, which, of course, does not involve a prohibitive energy cost.

Let us now analyze the Diels-Alder reaction in a similar manner. In this case, approach of the two molecules results in a configuration with only one plane of symmetry,[617]



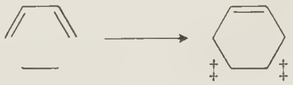
Plane of symmetry

and the orbitals involved are all symmetric or antisymmetric with respect to this plane, so that it is not necessary to consider the interaction of orbitals in the transition state. It will be sufficient to correlate the orbitals of the starting materials with those of the products. The orbitals of the starting compounds can be represented thus (see p. 33) for the orbitals of butadiene):

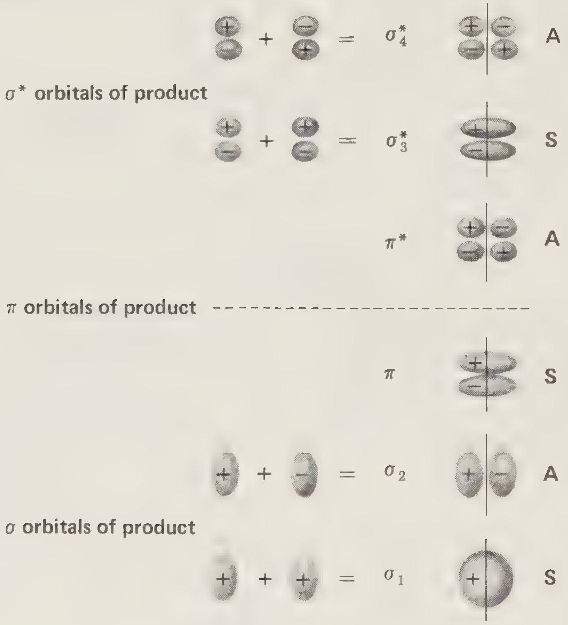


Symmetry with respect to plane of symmetry
x_4^*
Highest energy
A
Antibonding orbitals
π^*
A
x_3^*
S
x_2
A
Bonding orbitals
π
S
x_1
Lowest energy
S
Diene
Ene

The product in this case is a cyclohexene, and we need consider only the new π bond and the two new σ bonds (marked ‡). The two orbitals of the π bond can be considered individually,

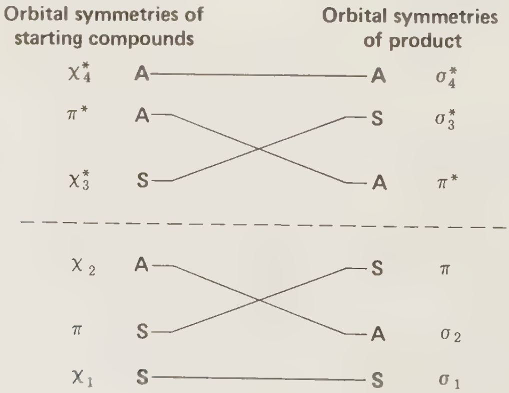


but the four σ orbitals interact as before. The orbitals of the product are therefore



σ* orbitals of product
σ_4^*
A
σ_3^*
S
π^*
A
π orbitals of product
π
S
σ_2
A
σ orbitals of product
σ_1
S

Drawing a correlation diagram as before, we have



Orbital symmetries of starting compounds
Orbital symmetries of product
χ_4^*
A
A
σ_4^*
π^*
A
S
σ_3^*
χ_3^*
S
A
π^*
χ_2
A

π
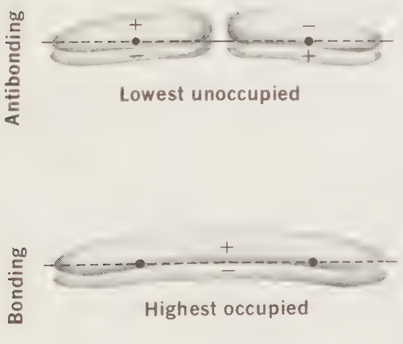
S
A
σ_2
χ_1
S
S
σ_1

Inspection of this correlation diagram shows us that the reaction can proceed by a cyclic transition state, in either direction, without any orbital going from a bonding to an antibonding condition. So the thermal reaction is *allowed*, in either direction. On the other hand, a photochemical reaction would require (for the forward direction) that a χ_3^* orbital convert to a σ_3^* orbital. Although both are antibonding, such a conversion bypasses the π^* orbital of the product and is therefore forbidden.[618] A photochemically induced reverse reaction is also forbidden for a similar reason: the π^* orbital of the cyclohexene would have to correlate with the π^* orbital of the ene component, bypassing the χ_3^* orbital of the diene.

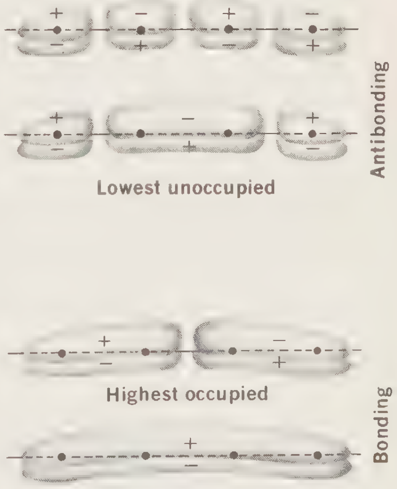
Note that, strictly speaking, the treatment we have given above applies only to cases possessing elements of symmetry and would not, strictly speaking, apply, say, to a reaction between ethylene and propylene to give methylcyclobutane because the presence of the extra methyl group destroys the symmetry of the reactants, transition state, and products. Nevertheless, we may make the reasonable assumption that the presence of substituents causes only small perturbations in the properties of the orbitals and does not greatly affect the reactions. Therefore, the principle of conservation of orbital symmetry covers these cases also. However, in some cases, where the olefin or diene contains hetero atoms (e.g., O=N—C=O) or is part of an aromatic ring, the symmetry of the orbitals involved may be so different that the general rules we have derived do not apply, and correlation diagrams must be individually drawn for each case.[618a]

The Frontier-Orbital Method[619]

As applied to cycloaddition reactions the rule is that *reactions are allowed only when all overlaps between the highest-occupied molecular orbital of one reactant and the lowest-unoccupied molecular orbital of the other are such that a positive lobe overlaps only with another positive lobe and a negative lobe only with another negative lobe*. For monoolefins and dienes these orbitals are



π orbitals of an isolated C=C bond



π orbitals of a conjugated diene

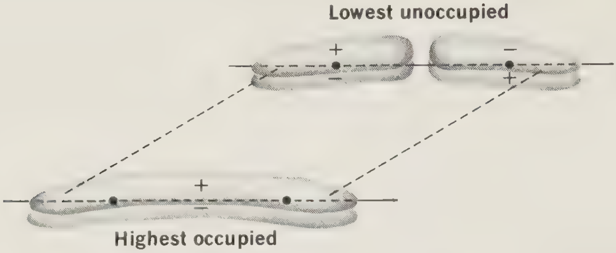
---

[618] For a discussion, see Epiotis and Yates, *J. Org. Chem.* **39**, 3150 (1974).

[618a] For a discussion, see Schilling and Snyder, *J. Am. Chem. Soc.* **97**, 4422 (1975).

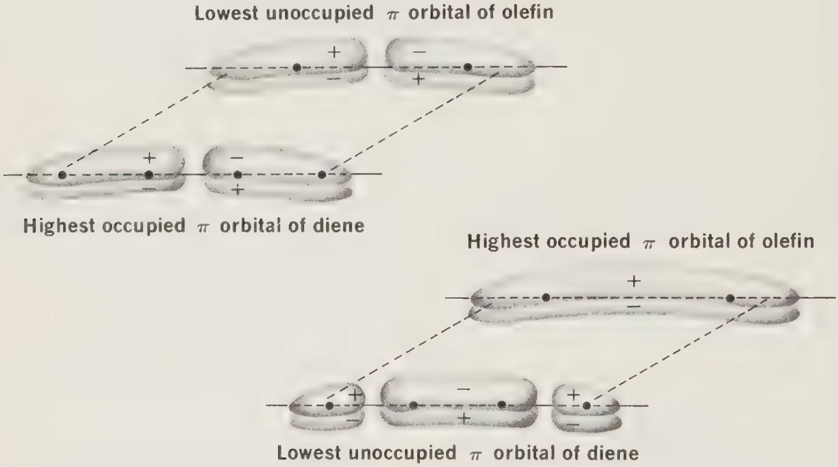
[619] Fukui and Fujimoto, *Bull. Chem. Soc. Jpn.* **40**, 2018 (1967), **42**, 3399 (1969); Fukui, *Fortschr. Chem. Forsch.* **15**, 1–85 (1970), *Acc. Chem. Res.* **4**, 57–64 (1971); Houk, *Acc. Chem. Res.* **8**, 361–369 (1975).

A concerted cyclization of two monoolefins (a 2 + 2 reaction) is not allowed because it would require that a positive lobe overlap with a negative lobe:



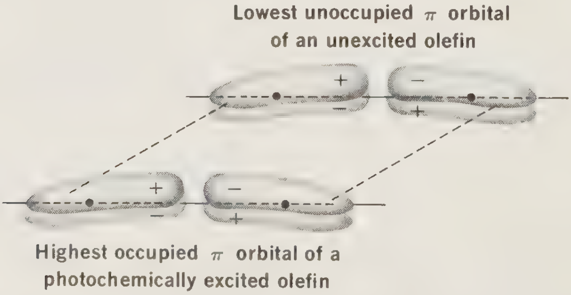
Lowest unoccupied
+
−
−
+
+
−
Highest occupied

On the other hand, the Diels-Alder reaction (a 4 + 2 reaction) is allowed, whether considered from either direction:



Lowest unoccupied π orbital of olefin
+
−
−
+
+
−
−
+
Highest occupied π orbital of diene
Highest occupied π orbital of olefin
+
−
+
−
−
+
+
−
Lowest unoccupied π orbital of diene

These considerations are reversed when the ring closures are photochemically induced since in such cases an electron is promoted to a vacant orbital before the reaction occurs. Obviously, the 2 + 2 reaction is now allowed:



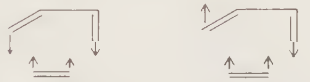
Lowest unoccupied π orbital
of an unexcited olefin
+
−
−
+
+
−
−
+
Highest occupied π orbital of a
photochemically excited olefin

and the 4 + 2 reaction disallowed. The reverse reactions follow the same rules, by the principle of microscopic reversibility. In fact, Diels-Alder adducts are usually cleaved quite readily, while cyclobutanes, despite the additional strain, require more strenuous conditions.

Thus, the correlation-diagram method and the frontier-orbital method lead to the same conclusions: thermal 2 + 4 cycloadditions and photochemical 2 + 2 cycloadditions (and the reverse ring openings) are allowed, while photochemical 2 + 4 and thermal 2 + 2 ring closings (and openings) are forbidden. Application of the same procedures to other ring closures shows that 4 + 4 and 6 + 2 ring closures and openings require photochemical induction while the 6 + 4 and 8 + 2 reactions can take place only thermally (see reaction **5-55**). In general cycloaddition reactions allowed thermally are those with $4n + 2$ electrons, while those allowed photochemically have $4n$ electrons.

It must be emphasized once again that the rules apply only to cycloaddition reactions which take place by cyclic mechanisms, i.e., where two σ bonds are formed (or broken) at about the same time. The rule does not apply to cases where one bond is clearly formed (or broken) before the other. It must further be emphasized that the fact that the thermal Diels-Alder reaction (mechanism *a*) is allowed by the principle of conservation of orbital symmetry does not constitute proof that any given Diels-Alder reaction proceeds by this mechanism. The principle merely says the mechanism is allowed, not that it must go by this pathway. However, the principle does say that thermal 2 + 2 cycloadditions in which the molecules assume the geometry we have pictured above cannot[620] take place by a cyclic mechanism (however, see below). As we shall see (**5-52**), such reactions largely occur by two-step mechanisms. Similarly, 4 + 2 photochemical cycloadditions are also known, but the fact that they are not stereospecific indicates that they also take place by the two-step diradical mechanism[621] (mechanism *b*[622]).

In all of the above discussion we have assumed that a given molecule forms both the new σ bonds from the same face of the π system. This manner of bond formation, called *suprafacial*, is certainly most reasonable and almost always takes place. The subscript s is used to designate this geometry, and a normal Diels-Alder reaction would be called a $[_{\pi}4_s + {}_{\pi}2_s]$ cycloaddition (the subscript π indicates that π electrons are involved in the cycloaddition.) However, we can conceive of another approach in which the newly forming bonds of the diene lie on *opposite* faces of the π system; i.e., they point in opposite directions.



Normal Diels-Alder reaction **$[4_s + 2_s]$**

Twisted Diels-Alder reaction **$[4_a + 2_s]$**

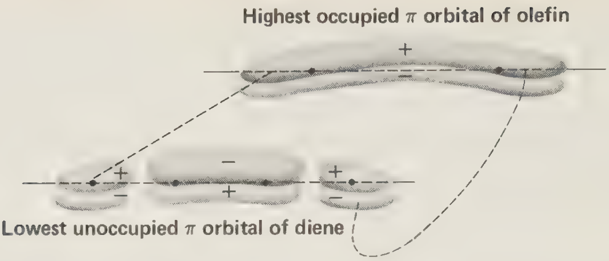
This type of orientation of the newly formed bonds is called *antarafacial*, and the reaction would be a $[_{\pi}4_a + {}_{\pi}2_s]$ cycloaddition (a stands for antarafacial). Formal correlation diagrams cannot be drawn in this case, but we can easily show by the frontier-orbital method that this reaction (and consequently the reverse ring-opening reaction) are thermally forbidden and photochemically allowed. Thus in order for a $[_{\pi}4_a + {}_{\pi}2_s]$ reaction to proceed, overlap between the highest occupied π orbital of the olefin and the lowest unoccupied π orbital of the diene would have to occur as follows, with a + lobe overlapping a − lobe:

---

[620] The possibility has been raised that some disallowed reactions may nevertheless proceed by concerted mechanisms: see Schmidt, *Helv. Chim. Acta* **54**, 862 (1971), *Tetrahedron Lett.* 581 (1972); Muszkat and Schmidt, *Helv. Chim. Acta* **54**, 1195 (1971); Baldwin, Andrist, and Pinschmidt, *Acc. Chem. Res.* **5**, 402–406 (1972); Berson, *Acc. Chem. Res.* **5**, 406–414 (1972); Berson and Salem, *J. Am. Chem. Soc.* **94**, 8917 (1972).

[621] It has been contended that 2 + 2 thermal and 2 + 4 photochemical cycloadditions occur by concerted mechanisms and the observed nonstereospecificity stems from completely concerted processes: Epiotis, *J. Am. Chem. Soc.* **95**, 1191, 1935, 1941 (1972).

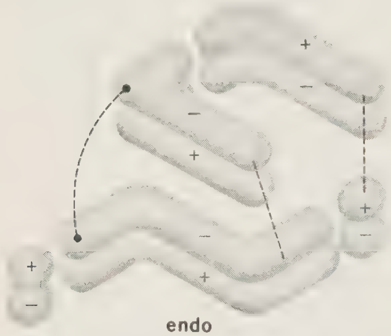
[622] For example, see Sieber, Heimgartner, Hansen, and Schmid, *Helv. Chim. Acta* **55**, 3005 (1972). For discussions, see Bartlett, Helgeson, and Wersel, *Pure Appl. Chem.* **16**, 187 200 (1968); Seeley, *J. Am. Chem. Soc.* **94**, 4378 (1972); Kaupp, *Angew. Chem. Int. Ed. Engl.* **11**, 313, 718 (1972) [*Angew. Chem.* **84**, 259, 718].



Highest occupied π orbital of olefin
Lowest unoccupied π orbital of diene

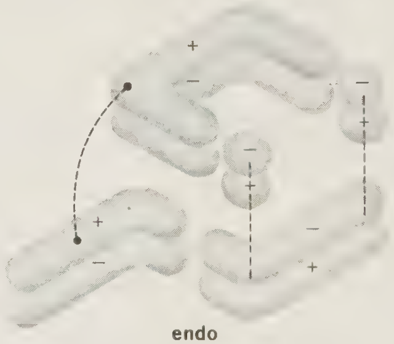
Since like signs are no longer overlapping, the thermal reaction is now forbidden. Similarly, thermal $[_\pi 4_s + {}_\pi 2_a]$ and $[_\pi 2_a + {}_\pi 2_a]$ cyclizations are forbidden, while thermal $[_\pi 4_a + {}_\pi 2_a]$ and $[_\pi 2_s + {}_\pi 2_a]$ cyclizations are allowed, and these considerations are reversed for the corresponding photochemical processes. Of course, an antarafacial approach is highly unlikely in a 2 + 4 cyclization,[623] but larger ring closures could take place by such a pathway, and 2 + 2 thermal cyclizations, where the $[_\pi 2_s + {}_\pi 2_s]$ pathway is forbidden, can also do so in certain cases (see reaction **5-52**). We therefore see that whether a given cycloaddition is allowed or forbidden depends on the geometry of approach of the two molecules involved, since each manner of approach gives rise to different symmetry elements.

Symmetry considerations have also been advanced to explain predominant endo addition.[624] In the case of 4 + 2 addition of butadiene to itself, the approach may be exo or endo:



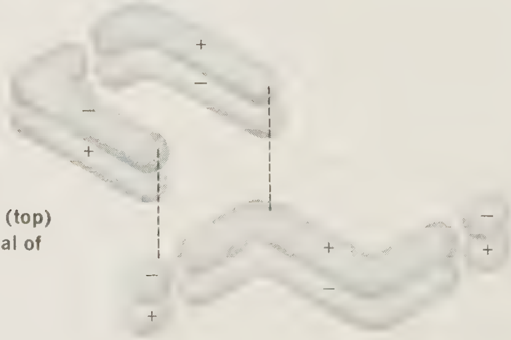
endo

Highest-occupied orbital of diene (top) overlaps lowest-unoccupied orbital of "olefin" (bottom)



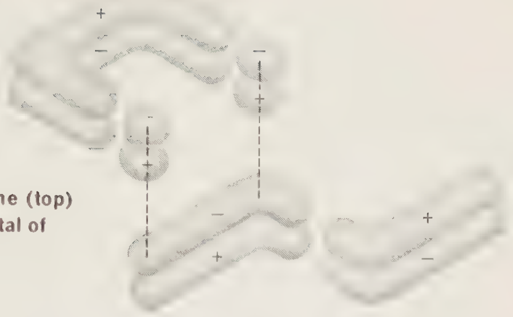
endo

Lowest-unoccupied orbital of diene (top) overlaps highest occupied orbital of "olefin" (bottom)



exo

Highest-occupied orbital of diene (top) overlaps lowest-unoccupied orbital of "olefin" (bottom)



exo

Lowest unoccupied orbital of diene (top) overlaps highest-occupied orbital of "olefin" (bottom)

It can be seen that whether the highest-occupied molecular orbital of the diene overlaps with the lowest-unoccupied molecular orbital of the olefin or vice versa, the endo orientation is stabilized by additional secondary overlap of orbitals of like sign (dashed lines between heavy dots). Addition from the exo direction has no such stabilization. Evidence for secondary orbital overlap as the cause of predominant endo orientation, at least in some cases, is that 6 + 4 cycloaddition is predicted by similar considerations to proceed with predominant exo orientation, and that is what is found.[625] However, this explanation does not account for endo orientation in cases where the dienophile does not possess additional π orbitals, and a number of alternative explanations have also been offered.[626]

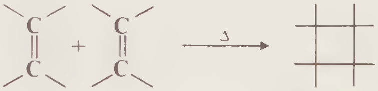
5-52 Dimerization of Olefins



The thermal reaction between two molecules of olefin to give cyclobutane derivatives (a 2 + 2 cycloaddition) can be carried out where the olefins are the same or different, but the reaction is not a general one for olefins.[627] Dimerization of like olefins occurs with the following compounds: $F_2C{=}CX_2$ (X = F or Cl) and certain other fluorinated alkenes, though not $F_2C{=}CH_2$, allenes (to give derivatives of **96**),[628] benzynes [to give biphenylene (**97**) derivatives], activated olefins

---

[623] A possible photochemical $[_{\pi}4_s + _{\pi}2_a]$ cycloaddition has been reported: Hart, Miyashi, Buchanan, and Sasson, *J. Am. Chem. Soc.* **96,** 4857 (1974).

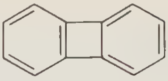
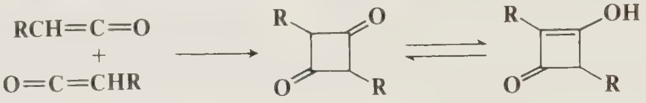
96



97

(e.g., styrene, acrylonitrile, butadiene), and certain methylenecyclopropanes.[629] Substituted ketenes dimerize to give cyclobutenone derivatives (**98**) as the major primary products, though ketene



98

itself dimerizes in a different manner, to give an unsaturated β-lactone (reaction **6-68**).[630]

Different olefins combine as follows:

1. $F_2C{=}CX_2$ (X = F or Cl), especially $F_2C{=}CF_2$, form cyclobutanes with many olefins. Compounds of this type even react with conjugated dienes to give four-membered rings rather than undergoing normal Diels-Alder reactions.[631]

2. Allenes[632] and ketenes[633] react with activated olefins and alkynes. Ketenes give 1,2 addition even with conjugated dienes.[634] Ketenes also add to unactivated olefins if sufficiently long reaction times are used.[635] A synthon for a ketene in this reaction is a ketenimmonium salt $R_2C{=}C{=}NR_2'^{+}\ ZnCl_3^{-}$.[636] The product is readily hydrolyzed (reaction **6-2**) to the same cyclobutanone which would be obtained from the corresponding ketene. Allenes and ketenes also add to each other.[637]

3. Benzynes react with certain olefins,[638] e.g.,

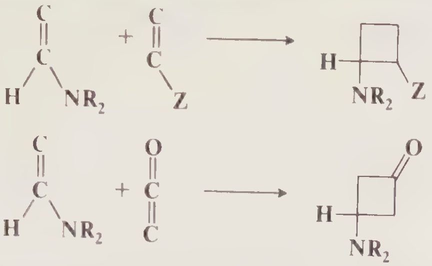
4. Enamines[639] form four-membered rings with Michael-type olefins[640] and with ketenes.[641] In both cases, only enamines from aldehydes give stable four-membered rings:



The reaction of enamines with ketenes can conveniently be carried out by generating the ketene in situ from an acyl halide and a tertiary amine. Ynamines react with ketenes to give the corresponding 3-dialkylaminocyclobutenones.[642]

5. Olefins with electron-withdrawing groups may form cyclobutanes with olefins containing electron-donating groups. The enamine reactions, mentioned above, are examples of this, but it has also been accomplished with tetracyanoethylene and similar molecules, which give substituted cyclobutanes when treated with olefins of the form C=C—A, where A may be OR, SR (enol and thioenol ethers),[643] cyclopropyl,[644] or certain aryl groups.[645]

Solvents are not necessary for 2 + 2 cycloadditions. They are usually carried out at 100 to 225°C under pressure, though the reactions in group 5 occur under milder conditions.

The reaction is similar to the Diels-Alder (in action, not in scope), and if dienes are involved, the latter reaction may compete, though most olefins react with a diene either entirely by 1,2 or entirely by 1,4 addition. We may propose three mechanisms,[646] analogous to those proposed for the Diels-Alder reaction. Mechanism *a* is a concerted pericyclic process, and mechanisms *b* and *c* are two-step reactions involving, respectively, a diradical and a diion intermediate. As in reaction 5-51, a diradical intermediate must be a singlet. In searching for ways to tell which mechanism is operating in a given case, we would expect mechanism *c* to be sensitive to changes in solvent

Mechanism *a*

Mechanism *b*

Mechanism *c*

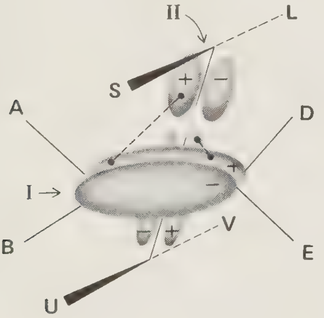
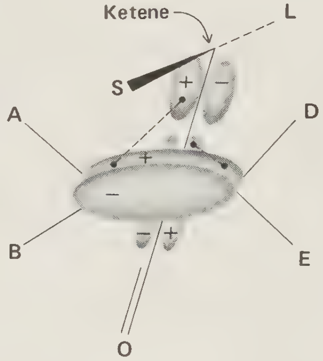
polarity, while mechanisms *a* and *b* should be insensitive, and we would expect mechanism *a* to be stereospecific, while mechanisms *b* and *c* probably would not be stereospecific, though if the second step of these processes takes place very rapidly, before the intermediate diradical or diion has a chance to rotate about the newly formed single bond, stereospecificity might be observed. Because of entropy considerations such rapid ring closure might be more likely here than in a $4 + 2$ cycloaddition.

There is evidence that the reactions can take place by all three mechanisms, depending on the structure of the reactants. A thermal $[{}_{\pi}2_{s} + {}_{\pi}2_{s}]$ mechanism is ruled out for most of these substrates by the principle of conservation of orbital symmetry, but a $[{}_{\pi}2_{s} + {}_{\pi}2_{a}]$ mechanism is allowed (p. 776), and there is much evidence that ketenes and certain other linear molecules in which the steric hindrance to such an approach is minimal can and often do react by this mechanism. In a $[{}_{\pi}2_{s} + {}_{\pi}2_{a}]$ cycloaddition the molecules must approach each other in such a way that the + lobe of the highest-occupied π orbital of one molecule (molecule I) overlaps with both + lobes of the lowest unoccupied π orbital of the other (molecule II), even though these lobes are on opposite sides of the nodal plane of molecule II.





The geometry of this approach requires that the groups S and U of molecule II project *into* the plane of molecule I. This has not been found to happen for ordinary alkenes,[647] but if molecule II is a ketene, the group marked U is not present and the $[{}_{\pi}2_{s} + {}_{\pi}2_{a}]$ reaction can take place. Among the evidence[648] for this mechanism is the following: (1) The reactions are stereospecific.[649] (2) The isomer which forms is the *more hindered one*. Thus methylketene plus cyclopentadiene gave only the endo product (**99**, A = H, R = CH_3).[650] Even more remarkably, when haloalkyl ketenes RXC=C=O were treated with cyclopentadiene, the endo-exo ratio of the product (**99**, **100**, A = halogen) actually *increased* substantially when R was changed from Me to

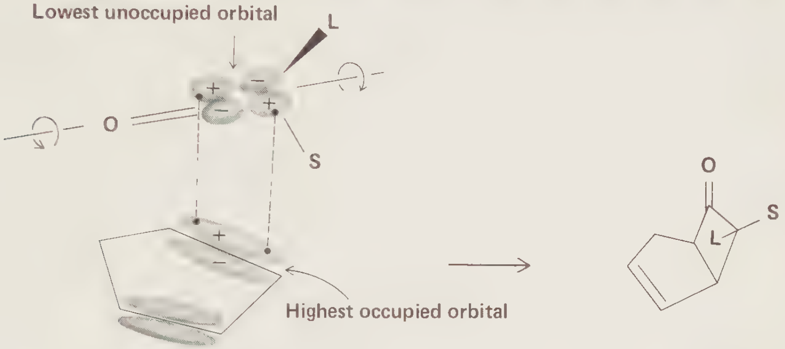
endo **99** exo **100**

iso-Pr to *t*-Bu![651] One would expect preferential formation of the exo products (**100**) from $[{}_{\pi}2_{s} + {}_{\pi}2_{s}]$ cycloadditions where the molecules approach each other as in the diagram on p. 768, but a $[{}_{\pi}2_{s} + {}_{\pi}2_{a}]$ process leads to endo products because the ketene molecule (which for steric reasons would approach with its smaller group directed toward the olefin) must twist as shown



(L = larger; S = smaller group) in order for the + lobes to interact and this swings the larger group into the endo position.[652] The experimental results in which the amount of endo isomer increases with the increasing size of the R group have been called *masochistic steric effects*, though, as we have seen, they are just what would be expected from a $[{}_{\pi}2_{s} + {}_{\pi}2_{a}]$ reaction. (3) There is only moderate polar solvent acceleration.[653] (4) The rate of the reaction is not very sensitive to the presence of electron-withdrawing or electron-donating substituents.[654] Because cycloadditions involving allenes are often stereospecific, it has been suggested that these also take place by the $[{}_{\pi}2_{s} + {}_{\pi}2_{a}]$ mechanism,[655] but the evidence in these cases is more consistent with the diradical mechanism *b*.[656]

The diradical mechanism *b* is most prominent in the reactions involving fluorinated alkenes. These reactions are generally not stereospecific[657] and are insensitive to solvent effects. Further evidence that a diion is not involved is that head-to-head coupling is found when an unsymmetrical molecule is dimerized. Thus dimerization of $F_2C{=}CFCl$ gives **101** and not **102.** If

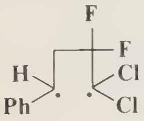
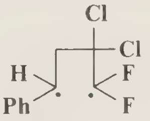
102 **101**

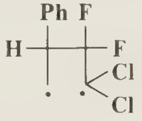
one pair of electrons moved before the other, the positive end of one molecule would be expected to attack the negative end of the other. Still more evidence is that when unsymmetrical olefins couple, the orientation of the product can almost always be predicted on the basis of the relative stability of the radicals; e.g., styrene and $F_2C{=}CCl_2$ can give four intermediates (**103** to **106**). On the basis of radical stability, **105** and **106** can be ruled out, since in **103** and **104**



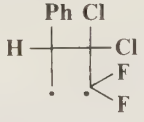
103



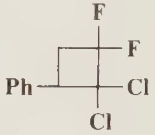
104



105



106



107

there is resonance of an unpaired electron with a phenyl group. **103** is more likely than **104,** since a dichloromethyl type of radical should be more stable than a difluoromethyl type. In accord with this prediction, the product is actually **107.**[658] Similarly, for an unsymmetrical diene, it is possible to predict which double bond will be attacked on the basis of which radical is more stable.[631]

The diion mechanism[659] *c* has been reported for at least some of the reactions in categories 4 and 5.[660] For example, the rate of the reaction between 1,2-bis(trifluoromethyl)-1,2-dicyanoethene and ethyl vinyl ether was strongly influenced by changes in solvent polarity.[661] Some of these reactions are nonstereospecific, but others are stereospecific.[662] As previously indicated, it is likely that in the latter cases the diionic intermediate closes before rotation can take place. Such rapid ring closure is more likely for a diion than for a diradical because of the attraction between the opposite charges. Other evidence for the diion mechanism in these cases is that reaction rates are greatly dependent on the presence of electron-donating and electron-withdrawing groups[663] and that it is possible to trap the diionic intermediates.[664]

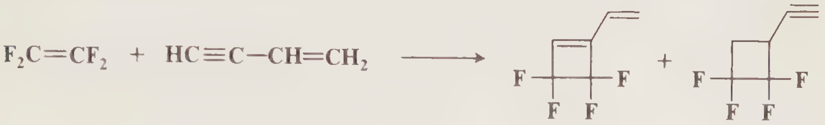
[663] Huisgen and Steiner, *Tetrahedron Lett.* 3763 (1973).

[664] Huisgen, Schug, and Steiner, *Angew. Chem. Int. Ed. Engl.* **13,** 80, 81 (1974) [*Angew. Chem.* **86,** 47, 48]. For additional evidence see Fleischmann and Kelm, *Tetrahedron Lett.* 3773 (1973); Ref. 646.

The reactions with benzynes are nonstereospecific,[665] ruling out a concerted mechanism, but there is doubt whether diradicals or diions are involved.[666]

Thermal cleavage of cyclobutanes[667] to give two olefin molecules (the reverse of 2 + 2 cycloaddition) operates by the diradical mechanism, and the $[{}_\sigma 2_s + {}_\sigma 2_a]$ pathway has not been found[668] (the subscripts σ indicate that σ bonds are involved in this reaction).

In some cases, double bonds add to triple bonds to give cyclobutenes, apparently at about the same rate that they add to double bonds; e.g.,



About equal amounts

The addition of triple bonds to triple bonds would give cyclobutadienes, and this has not been observed except where these rearrange before they can be isolated (see reaction **5-54**).[669]

Although thermal 2 + 2 cycloaddition reactions are essentially limited to the cases described above, many (though by no means all) double-bond compounds undergo such reactions *when photochemically excited* (either directly or by a photosensitizer—see p. 218) even if they are not in the above categories.[670] Simple alkenes absorb in the far uv (p. 212), which is difficult to reach experimentally, though this problem can sometimes be overcome by the use of suitable photosensitizers. The reaction has been applied to simple alkenes[671] (especially to strained compounds such as cyclopropenes and cyclobutenes), but more often the double-bond compounds involved are conjugated dienes,[672] α,β-unsaturated ketones,[673] acids or acid derivatives, or quinones, since these compounds, because they are conjugated, absorb at longer wavelengths (p. 211). Both dimerizations and mixed additions are common, some examples being (see also the example on p. 222)

Ref. 681

It is obvious that many molecules can be constructed in this way which would be difficult to make by other procedures. However, attempted cyclizations of this kind are not always successful. In many cases polymeric or other side products are obtained instead of the desired product.

It is possible that some of these photochemical cycloadditions take place by a $[_{\pi}2_s + {_{\pi}2_s}]$ mechanism (which is of course allowed by orbital symmetry); when and if they do, one of the molecules must be in the excited singlet state (S_1) and the other in the ground state.[682] The nonphotosensitized dimerizations of *cis*- and *trans*-2-butene are stereospecific,[683] making it likely that the $[_{\pi}2_s + {_{\pi}2_s}]$ mechanism is operating in these reactions. However, in most cases it is a triplet excited state which reacts with the ground-state molecule, and in these cases the diradical (or in certain cases the diionic) mechanism is taking place. Photosensitized $2\pi + 2\pi$ cycloadditions almost always involve the triplet state and hence a diradical (or diionic) mechanism.

The photochemical diradical mechanism is not quite the same as the thermal diradical mechanism. In the thermal mechanism the initially formed diradical must be a singlet, but in the photochemical process a triplet excited state is adding to a ground state (which is of course a singlet). Thus, in order to conserve spin,[684] the initially formed diradical must be a triplet; i.e., the two electrons must have the same spin. Consequently the second, or ring-closing, step of the mechanism cannot take place at once, because a new bond cannot form from a combination of two electrons with the same spin, and the diradical has a reasonably long lifetime before collisions with molecules in the environment allow a spin inversion to take place and the diradical to cyclize. We would therefore predict nonstereospecificity, and that is what is found.[685] At least some 2 + 2 photocycloadditions take place by way of exciplex intermediates[686] [an *exciplex* is an excited EDA complex (p. 79) which is dissociated in the ground state; in this case one double bond is the donor and the other the acceptor].

Many 2 + 2 photochemical cycloadditions are neither stereospecific nor regiospecific, though others display one or both of these characteristics. However, dimerizations which occur in the solid state are almost always both regiospecific and stereospecific. Since molecules in the solid state have no freedom, the only reactions which can occur are those where only a minimum of atomic or molecular motion is required. Only the electrons can move much. The dimerization of olefins is well suited to these limitations. In the solid state, closely related compounds may react quite differently. For example, $PhCH{=}CH{-}CH{=}C(COOH)_2$ gives a dimer where the two molecules are connected at the γ and δ positions, while $PhCH{=}CH{-}CH{=}CHCOOH$ gives a dimer where one molecule is connected by its α and β positions and the other by its γ and δ positions.[687] This result is found because the molecules are stacked differently in the lattice and

---

[681] Schenck and Steinmetz, *Chem. Ber.* **96**, 520 (1963).

[682] We have previously seen (p. 220) that reactions between two excited molecules are extremely rare.

[683] Yamazaki and Cvetanović, Ref. 671. For another likely example, see Lewis, Hoyle, and Johnson, *J. Am. Chem. Soc.* **97**, 3267 (1975).

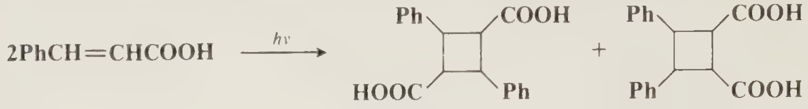
[684] This is an example of the Wigner spin conservation rule (p. 218). Note that spin conservation is something entirely different from symmetry conservation.

[685] See for example Liu and Hammond, *J. Am. Chem. Soc.* **89**, 4936 (1967); Kramer and Bartlett, *J. Am. Chem. Soc.* **94**, 3934 (1972).

[686] See for example Farid, Doty, and Williams, *J. Chem. Soc., Chem. Commun.* 711 (1972); Mizuno, Pac, and Sakurai, *J. Am. Chem. Soc.* **96**, 2993 (1974); Caldwell and Smith, *J. Am. Chem. Soc.* **96**, 2994 (1974); Creed and Caldwell, *J. Am. Chem. Soc.* **96**, 7369 (1974).

[687] Cohen and Schmidt, *J. Chem. Soc.* 1996 (1964).

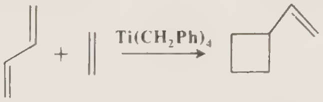
the principle of minimum motion is followed. A given compound may react one way in the solid phase and another way in freer phases. For example, the dimerization of *trans*-cinnamic acid



Truxillic acids Truxinic acids

occurs *only* in the solid state. Also different crystalline modifications of a compound may react differently, since the stacking is not the same. *trans*-Cinnamic acid supplies an example here too, since it is different crystalline forms which give rise to truxillic acid on the one hand and truxinic acid on the other (there are several stereoisomers of both truxillic and truxinic acid, but each crystalline form of *trans*-cinnamic acid produces just one stereoisomer). The study of reactions in the solid state is called *topochemistry*.[688]

It has been found that certain 2 + 2 cycloadditions which do not occur thermally can be made to take place without photochemical initiation by the use of certain catalysts, usually transition-metal compounds.[689] Examples are:



Ref. 690

Ref. 691

Among the catalysts used are Lewis acids[692] and phosphine-nickel complexes.[693] Certain of the reverse cyclobutane ring openings can also be catalytically induced (reaction **8-42**). The role of the catalyst is not certain and may well be different in each case. One possibility is that the presence of the catalyst causes a forbidden reaction to become allowed, through coordination of the catalyst to the π or σ bonds of the substrate.[694] In such a case the reaction would of course be a concerted $2_s + 2_s$ process. However, it is also possible that the catalysts cause the reactions to take place by nonconcerted mechanisms.[695] Evidence that the latter pathway has been followed in at least one case is the isolation of a metal-carbon σ-bonded intermediate in the dimerization of norbornadiene, catalyzed by iridium complexes.[696] Photodimerizations of olefins are catalyzed by copper(I) triflate.[697]

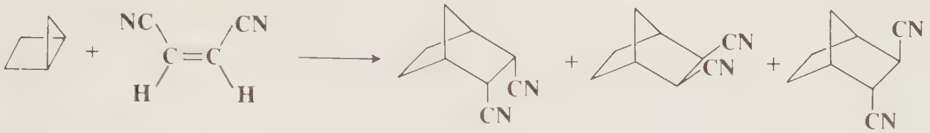
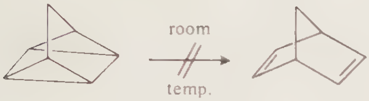
Thermal cycloadditions leading to four-membered rings can also take place between a cyclopropane ring and an alkene or alkyne[698] bearing electron-withdrawing groups.[699] These reactions are ${}_{\pi}2 + {}_{\sigma}2$ cycloadditions. Ordinary cyclopropanes do not undergo the reaction, but it has been accomplished with strained systems such as bicyclo[1.1.0]butanes[700] and bicyclo[2.1.0]pentanes.

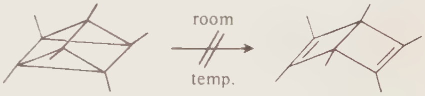


For example, bicyclo[2.1.0]pentane reacts with maleonitrile (or fumaronitrile) to give all three isomers of 2,3-dicyanonorbornane, as well as four other products.[701] The lack of stereospecificity and the negligible effect of solvent on the rate indicate a diradical mechanism. Photochemical[702] and metal-catalyzed[703] ${}_{\pi}2 + {}_{\sigma}2$ cycloadditions have also been reported.

In reaction **5-51** we used the principle of conservation of orbital symmetry to explain why certain reactions take place readily and others do not. The orbital-symmetry principle can also explain why certain molecules are stable though highly strained. For example, quadricyclane and hexamethylprismane[704] are thermodynamically much less stable (because much more strained) than their corresponding isomeric dienes, norbornadiene and hexamethylbicyclo[2.2.0]hexadiene (**108**).[705] Yet the former two compounds can be kept indefinitely at room temperature, although



Quadricyclane Norbornadiene



108

Hexamethylprismane (A Dewar benzene)

in the absence of orbital-symmetry considerations it is not easy to understand why the electrons simply do not move over, to give the more stable diene isomers. The reason is that both these reactions involve the conversion of a cyclobutane ring to a pair of double bonds (a ${}_{\sigma}2 + {}_{\sigma}2$ process) and, as we have seen, a thermal process of this sort is forbidden by the Woodward-Hoffmann rules. The process is allowed photochemically, and we are not surprised to find that both quadricyclane and hexamethylprismane can be photochemically converted to the respective dienes at room temperature or below.[706] It is also possible to conceive of simple bond rearrange-

ments whereby hexamethylprismane is converted to hexamethylbenzene, which of course is far more stable than either hexamethylprismane or **108.** It has been calculated that hexamethylbenzene is at least 90 kcal/mol more stable than hexamethylprismane. The fact that hexamethylprismane does not spontaneously undergo this reaction has prompted the observation[707] that the prismane has "the aspect of an angry tiger unable to break out of a paper cage." However, a correlation diagram for this reaction[707] discloses that it too is a symmetry-forbidden process. All three of these "forbidden" reactions do take place when the compounds are heated, but the diradical mechanism is likely under these conditions.[708]

Bicyclo[2.2.0]hexadienes and prismanes are *valence isomers* of benzenes.[709] These compounds actually have the structures which in the nineteenth century were proposed for benzenes. Prismanes have the Ladenburg formula, and bicyclo[2.2.0]hexadienes have the Dewar formula.[710] On p. 29 it was mentioned that Dewar formulas are canonical forms (though not very important) of benzenes. Yet they also exist as separate compounds in which the positions of the nuclei are different from those of benzenes.

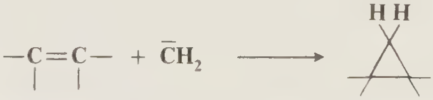
5-53 The Addition of Carbenes and Carbenoids to Double and Triple Bonds



Carbenes and substituted carbenes add to double bonds to give cyclopropane derivatives (2 + 1 cycloaddition).[711] Many derivatives of carbene, e.g., PhCH, ROCH,[712] $Me_2C{=}C$, $C(CN)_2$, have been added to double bonds, but the reaction is most often performed with CH_2 itself, with halo and dihalocarbenes,[713] and with carbalkoxycarbenes[714] (generated from diazoacetic esters). Alkylcarbenes HCR have been added to olefins,[715] but more often these rearrange to give olefins (p. 183). The carbene can be generated in any of the ways normally used (p. 181). However, not all reactions in which a cyclopropane is formed by treatment of an olefin with a carbene "precursor" actually involve free carbene intermediates. In some cases, e.g., the Simmons-Smith procedure, p. 793, it is certain that free carbenes are not involved, and in other cases there is doubt. Because of this, the term *carbene transfer* is often used to cover all reactions in which a double bond is converted to a cyclopropane, whether a carbene or a carbenoid (p. 182) is actually involved.

[714] For a review, see Dave and Warnhoff, *Org. React.* **18,** 217–401 (1970).

[715] For example, see Frey, *J. Chem. Soc.* 2293 (1962).

Carbene itself is extremely reactive and gives many side reactions, especially insertion reactions (**2-18**), which greatly reduce yields.[716] When it is desired to add CH_2 for preparative purposes, free carbene is not used, but the Simmons-Smith procedure or some other method which does not involve free carbenes is employed instead. Halocarbenes are less active than carbenes, and this reaction proceeds quite well, since insertion reactions do not interfere. The order of reactivity is $CH_2 > CHCl > CCl_2 > CBr_2 > CF_2$. A few of the many ways[717] in which halocarbenes or carbenoids are generated for this reaction are the following,[718] most of which involve formal α elimination (the first two steps of the SN1cB mechanism, p. 330):

$$\begin{array}{rcll}
CH_2Cl_2 + RLi & \longrightarrow & CHCl & \\
N_2CHBr & \xrightarrow{h\nu} & CHBr & \\
CHCl_3 + OH^- & \longrightarrow & CCl_2 & \\
CHCl_3 + LiOCEt_3 & \longrightarrow & CCl_2 & \text{(Ref. 719)} \\
PhHgCCl_2Br & \xrightarrow{\Delta} & CCl_2 & \text{(Ref. 720)} \\
PhHgCBr_3 & \xrightarrow{80^\circ C} & CBr_2 & \text{(Ref. 720)} \\
Me_3SnCF_3 + NaI & \longrightarrow & CF_2 & \text{(Ref. 721)} \\
CHBr_2F + RLi & \longrightarrow & CFBr & \text{(Ref. 721)}
\end{array}$$

It has been shown that the reaction between $PhCHCl_2$ and *t*-BuOK produces a carbenoid but when the reaction is run in the presence of a crown ether (p. 82), the free PhCCl is formed instead.[722] This is therefore a method for generating a free carbene.[723] Dihalocyclopropanes are very useful compounds[724] which can be reduced to cyclopropanes, treated with magnesium or sodium to give allenes (reaction **8-3**), or converted to a number of other products.

Olefins of all types can be converted to cyclopropane derivatives by this reaction. Even tetracyanoethylene, which responds very poorly to electrophilic attack, gives cyclopropane derivatives with carbenes.[725] Conjugated dienes give 1,2 addition:[726]

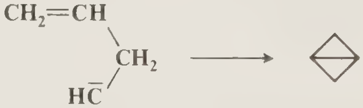
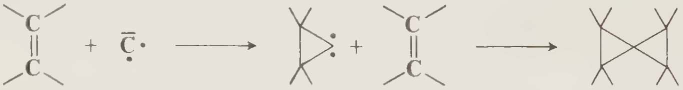
Addition of a second mole gives bicyclopropyl derivatives.[727] 1,4 addition is rare but has been reported for addition of $C(CN)_2$ to cyclooctatetraene.[728] In the addition of carbenes to unsymmetrical dienes, that double bond is attacked first which has a larger number of alkyl groups, since that makes it more susceptible to electrophilic attack. Carbene adds to ketene to give cyclopropanone.[729]

Allenes react with carbenes to give cyclopropanes with exocyclic unsaturation:[730]

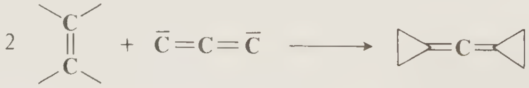
A second mole gives spiropentanes. In fact, any size ring with an exocyclic double bond can be converted by a carbene to a spiro compound.[731] Allylcarbene gives internal addition, forming bicyclobutane:[732]



Spiropentanes are also formed upon reaction of olefins with atomic carbon aged on a paraffin hydrocarbon surface at −196°C:[733]



The first addition is stereospecific and the second nonstereospecific, in accord with the $2s^22p_x{}^12p_y{}^1$ outer-shell configuration for the ground state of carbon. The C_3 species which is found in carbon vapor (p. 180) gives bisethanoallenes:[734]



Triple-bond compounds[735] react with carbenes to give cyclopropenes, except that in the case of acetylene itself, the cyclopropenes first formed cannot be isolated because they rearrange to allenes.[736] Cyclopropenones (p. 54) are obtained by hydrolysis of dihalocyclopropenes.[737] It has proved possible to add 2 moles of a carbene to an alkyne, to give a bicyclobutane:[738]

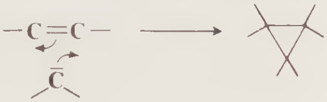
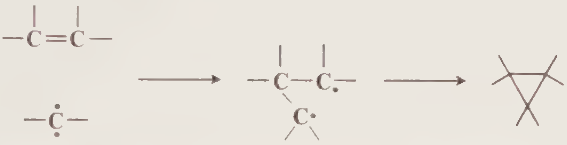
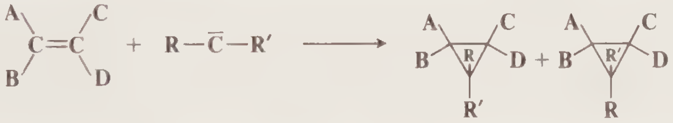
Carbenes are electrophiles, and, in accord with this, electron-donating substituents on the olefin increase the rate of the reaction, and electron-withdrawing groups decrease it,[739] though the range of relative rates is not very great.[740] As discussed on p. 179 carbenes in the singlet state (which is the most common state) react stereospecifically and syn,[741] probably by a one-step mechanism, similar to mechanism *a* of reactions **5-51** and **5-52:**



Carbenes in the triplet state react nonstereospecifically,[742] probably by a diradical mechanism, similar to mechanism *b* of reactions **5-51** and **5-52:**



For carbenes or carbenoids of the type R—C—R′ there is another aspect of stereochemistry.[743] When these species are added to all but symmetrical olefins, two isomers are possible, even if the four groups originally on the double-bond carbons maintain their configurations:



Which isomer is predominantly formed depends on R, R′, and on the method by which the carbene or carbenoid is generated. Most studies have been carried out on monosubstituted species (R′ = H), and in these studies it is found that aryl groups generally prefer the more substituted side (syn addition) while carbethoxy groups usually show anti stereoselectivity. When R = halogen, free halocarbenes show little or no stereochemical preference, while halocarbenoids exhibit a preference for syn addition. Beyond this, it is difficult to make simple generalizations.

Carbenes are so reactive that they add to the "double bonds" of aromatic rings. The products are usually not stable and rearrange to give ring expansion. Carbene reacts with benzene to give cycloheptatriene:[744]

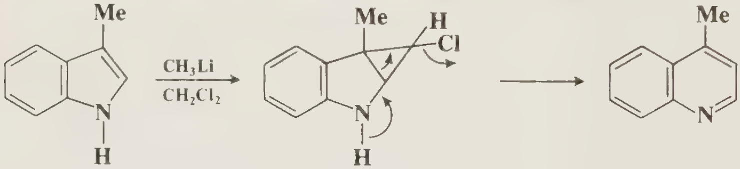
109

but not all carbenes are reactive enough to add to benzene. The norcaradiene intermediate (**109**) cannot be isolated in this case (it undergoes an electrocyclic rearrangement, p. 1024), though certain substituted norcaradienes, e.g., the product of addition of $C(CN)_2$ to benzene,[745] have been isolated.[746] With CH_2, insertion is a major side reaction, and, for example, benzene gives toluene as well as cycloheptatriene. A method of adding CH_2 to benzene rings without the use of free carbene is the catalytic decomposition of CH_2N_2 in the aromatic compound as solvent with CuCl or CuBr.[747] By this method better yields of cycloheptatrienes are obtained without insertion side products.[748] CHCl is active enough to add to benzene, but dihalocarbenes do not add to benzene or toluene, only to rings with greater electron density. Pyrroles and indoles can be expanded, respectively, to pyridines and quinolines, by treatment with halocarbenes,[749] e.g.,



110

The intermediate in this reaction (**110**) has not been isolated, but it has been trapped, as the N-acetate,[750] which with alcoholic KOH gives the quinoline product. In the reaction between indene and CCl_2, the intermediate has been isolated:[751]

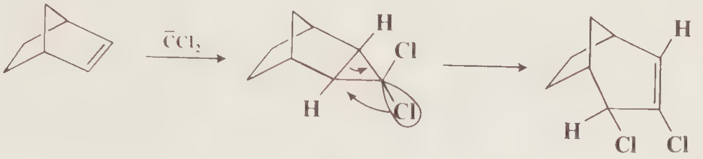
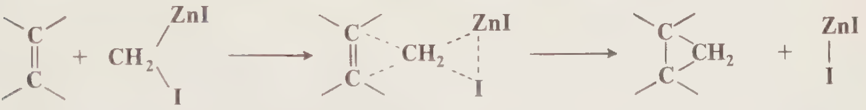
In such cases a side reaction which sometimes occurs is expansion of the *six-membered* ring. Ring expansion may occur even with nonaromatic compounds, when the driving force is supplied by relief of strain,[752] e.g.,



111

111 is so strained that it rearranges,[753] though it has been isolated.[754]

As previously mentioned, free carbene is not very useful for additions to double bonds since it gives too many side products. The *Simmons-Smith procedure* accomplishes the same result without a free carbene intermediate and without insertion side products.[755] This procedure involves treatment of the double-bond compound with CH_2I_2 and a Zn–Cu couple and leads to cyclopropane derivatives in good yields.[756] The Zn–Cu couple can be prepared in several ways,[757] of which heating Zn dust with CuCl in ether under nitrogen[758] is particularly convenient. The actual attacking species is an organozinc intermediate, probably $(ICH_2)_2Zn\cdot ZnI_2$. This intermediate is stable enough for solutions of it to be isolable.[759] These solutions give CH_2I_2 when treated with I_2 (reaction **2-28**). and CH_3I when treated with H_2O (reaction **2-21**). The addition is stereospecifically syn, and a concerted mechanism is likely, perhaps[760]



With the Simmons-Smith procedure, as with free carbenes, conjugated dienes give 1,2 addition,[761] and allenes give methylenecyclopropanes or spiropentanes. An alternative way of carrying out the Simmons-Smith reaction is by treatment of the substrate with CH_2I_2 or another dihalomethane and Et_2Zn in ether. This method can be adapted to the introduction of RCH and ArCH by the use of $RCHI_2$ or $ArCHI_2$ instead of the dihalomethane.[762] Another method uses a dihalo compound and copper.[762a]

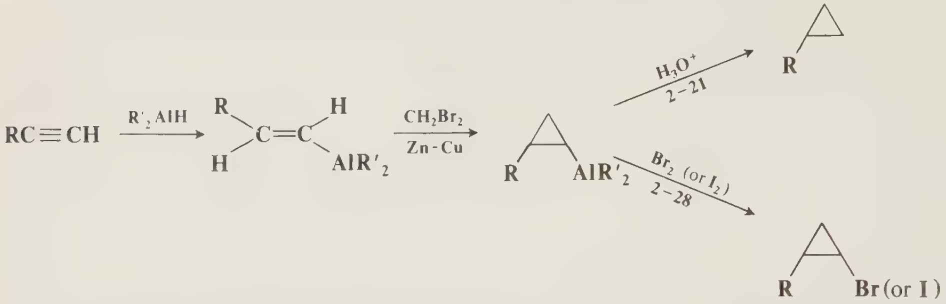
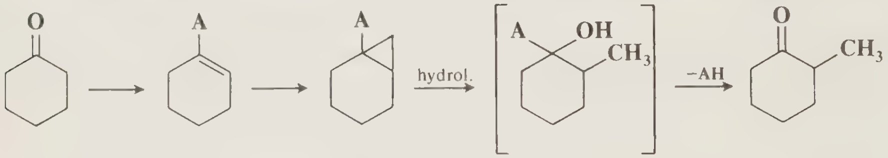
Alkynes can be converted to cyclopropanes or cyclopropyl halides by carbene transfer to the alkenylaluminum compound formed from the alkyne and a dialkylalane (reaction **5-16**):[763]

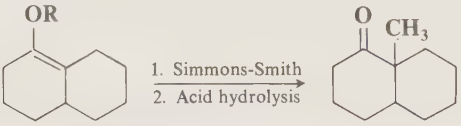


The Simmons-Smith reaction has been used as the basis of a method for the indirect α-methylation of a ketone.[764] The ketone (illustrated for cyclohexanone) is first converted to the enol ether, e.g., by reaction **6-6**, or to the enamine (reaction **6-15**) or silyl ether. Application of the Simmons-Smith reaction gives the cyclopropane compound **112**, which is then cleaved (addition of water to a cyclopropane ring) to an intermediate **113**, which loses ROH, RNH_2, or R_3SiH, producing the methylated ketone. Cleavage of **112** is carried out by acid hydrolysis if A is OR, by basic hydrolysis if A is SiR_3, and by neutral hydrolysis in aqueous methanol at 150 to 170°C if A is NR_2. If the double bond is at a bridgehead, the reaction is a means of angular methylation, e.g.,[765]



112 **113**

$A = OR, NR_2, SiR_3$



Olefins which undergo the Michael reaction (**5-19**) can be converted to cyclopropane derivatives with sulfur ylides.[765a] Among the most common of these is dimethyloxosulfonium methylide (**114**),[766] which is widely use to transfer CH_2 to activated double bonds, but other sulfur ylides,

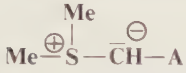
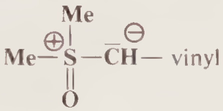
e.g., **115** (A = acyl,[767] carbethoxy[768]), **116**,[769] and **117**,[770] which transfer CHA, CH—vinyl, and CMe_2, respectively, have also been used. CHR and CR_2 can be added in a similar manner with



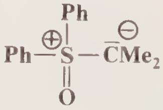
$\mathrm{Me_2\overset{\oplus}{S}{-}\overset{\ominus}{C}H{-}A}$

115



$\mathrm{Me_2\overset{\oplus}{S}(=O){-}\overset{\ominus}{C}H{-}vinyl}$

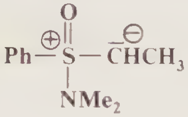
116



$\mathrm{Ph_2\overset{\oplus}{S}(=O){-}\overset{\ominus}{C}Me_2}$

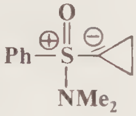
117

certain nitrogen-containing compounds. For example, the nitrogen ylides **118** and **119** and the carbanion **120** can be used, respectively, to add CHMe, cyclopropylidene, and CMe_2 to activated

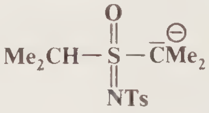


$\mathrm{Ph{-}\overset{\oplus}{S}(=O)(NMe_2){-}\overset{\ominus}{C}HCH_3}$

118



119



$\mathrm{Me_2CH{-}S(=O)(=NTs){-}\overset{\ominus}{C}Me_2}$

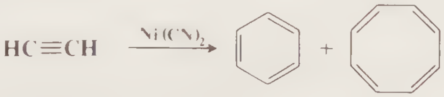
120

double bonds.[771] Similar reactions have been performed with phosphorus ylides.[772] The reactions with ylides are of course nucleophilic addition.

Many substituted cyclopropanes have been made by treatment of olefins with HCWZX, where W = H, R, Ar, Cl, or COOR; Z = COOR, CN, or COAr, and X = Cl or Br.[773] This is a syn addition.

OS **V**, 306, 855, 859, 874; **50**, 94; **51**, 60; **52**, 132; **54**, 11; **55**, 12.

5-54 Trimerization and Tetramerization of Alkynes



When acetylene is heated with nickel cyanide, other Ni(II) or Ni(0) compounds, or similar catalysts, it gives benzene and cyclooctatetraene.[774] It is possible to get more of either product by a proper choice of catalyst. Substituted acetylenes give substituted benzenes.[775] This reaction has been used to prepare very crowded molecules. Diisopropylacetylene was trimerized over $Co_2(CO)_8$ and over $Hg[Co(CO)_4]_2$ to hexaisopropylbenzene, which had previously been unknown.[776] The six isopropyl groups are not free to rotate but are lined up perpendicular to the plane of the benzene ring. Even more interesting was the *spontaneous* (no catalyst) trimerization of *t*-BuC≡CF to give 1,2,3-tri-*t*-butyl-4,5,6-trifluorobenzene (**122**), the first time three adjacent *t*-butyl groups had been put onto a benzene ring.[777] The fact that this is a head-to-head joining makes the following sequence likely:

R = *t*-butyl

121

122

The fact that **121** (a bicyclo[2.2.0]hexadiene) was also isolated lends support to this scheme.

In contrast to the spontaneous reaction, the catalyzed process seldom gives the 1,2,3-trisubstituted benzene isomer from an acetylene RC≡CH. The chief product is usually the 1,2,4-isomer, with lesser amounts of the 1,3,5-isomer also generally obtained but little if any of the 1,2,3-isomer. Mechanisms of the catalyzed reactions are not well established, although coordination of the metal with the triple bond is believed to be involved.[778] However, it has been shown that at least some of these reactions proceed through three- and five-membered heterocyclic intermediates (**123** and **124**). Such intermediates (where M = Rh, Ir, or Ni) have been isolated and

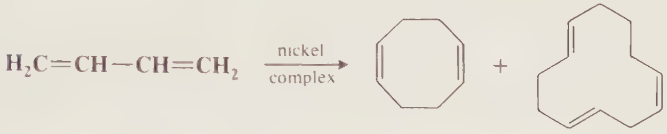
shown to give benzenes when treated with alkynes.[779] Note that this pathway accounts for the predominant formation of the 1,2,4-isomer.

For addition of triple bonds to triple bonds, but not with ring formation, see reaction **5-17.**

5-55 Other Cycloaddition Reactions



Conjugated dienes can be dimerized or trimerized at their 1,4 positions (formally, $4+4$ and $4+4+4$ cycloadditions) by treatment with certain nickel complexes or other transition-metal compounds.[780] Thus butadiene gives 1,5-cyclooctadiene and 1,5,9-cyclododecatriene.[781] The relative amount of each product can be controlled by use of the proper catalyst. For example, Ni : $P(OC_6H_4\text{-}o\text{-}Ph)_3$ gives predominant dimerization, while $Ni(cyclooctadiene)_2$ gives mostly trimerization. The products arise, not by direct 1,4 to 1,4 attack, but by stepwise mechanisms involving metal-olefin complexes.[782] Treatment of a mixture of ethylene and butadiene with the appropriate nickel compound gives 1,5-cyclodecadiene, formed from two molecules of the diene and one of the olefin[783] (a $4+4+2$ cycloaddition). In a similar manner, cocyclization of butadiene and triple-bond compounds gives 1,4,7-cyclodecatrienes.[784]

As we have seen in reaction **5-51,** the Woodward-Hoffmann rules allow suprafacial concerted cycloadditions to take place thermally if the total number of electrons is $4n+2$ and photochemically if the number is $4n$. Furthermore, forbidden reactions become allowed if one molecule reacts antarafacially. It would thus seem that syntheses of many large rings could easily be achieved. However, when the newly formed ring is eight-membered or greater, concerted mechanisms, though allowed by orbital symmetry for the cases stated, become difficult to achieve because of the entropy factor (the two ends of one system must simultaneously encounter the two ends of the other), unless one or both components are cyclic, in which case the molecule has many fewer possible conformations. There have been a number of reports of cycloaddition reactions leading to eight-membered and larger rings, some thermally and some photochemically induced, but (apart from the dimerization and trimerization of butadienes mentioned above, which are known not to involve direct 4 + 4 or 4 + 4 + 4 cycloaddition) in most cases evidence is lacking to indicate whether they are concerted or stepwise processes. Some examples are

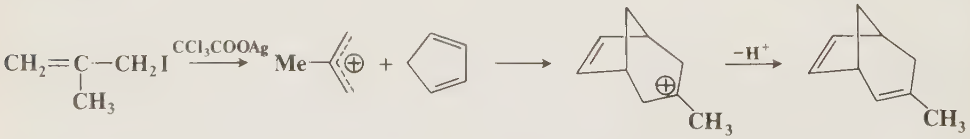
The suprafacial thermal addition of an allylic cation to a diene (a 4 + 3 cycloaddition[789]) is allowed by the Woodward-Hoffmann rules (note that the highest occupied molecular orbital of an allylic cation, p. 34, has the same symmetry as the highest occupied orbital of a simple alkene, so that this reaction would be expected to follow the same rules as the Diels-Alder reaction). Such cycloadditions can be carried out[790] by treatment of a diene with an allylic halide in the presence of a suitable silver salt, e.g.,[791]



This reaction has even been carried out with benzene assuming the role of the diene.[792]

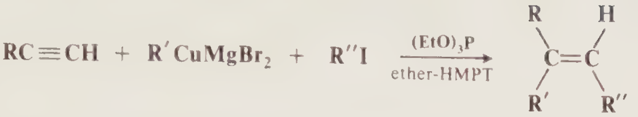
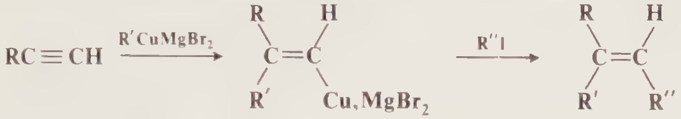
5-56 The Addition of Two Alkyl Groups to an Alkyne

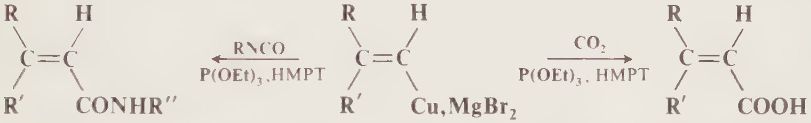


Two different alkyl groups can be added to a terminal alkyne in one laboratory step by treatment with an alkylcopper magnesium bromide reagent and an alkyl iodide in ether-HMPT containing triethyl phosphite.[793] The groups add stereoselectively syn. The reaction, which has been applied to primary R′ and to primary, allylic, benzylic, and α-alkoxyalkyl R″, involves initial addition of the alkylcopper reagent, followed by a coupling reaction (**0-87**):



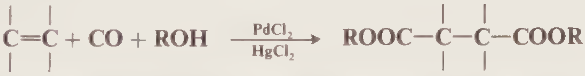
125

If the alkyl iodide is omitted, the vinylcopper intermediate **125** can be converted to a carboxylic acid by the addition of CO_2 (see reaction **6-35**) or to an amide by the addition of an isocyanate



(see reaction **6-37**), in either case in the presence of HMPT and a catalytic amount of triethyl phosphite.[794]

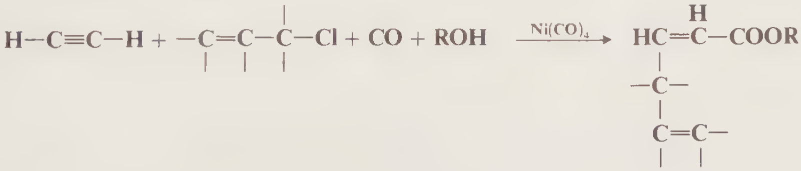
5-57 Dicarbalkoxylation of Olefins and Acetylenes



$$\text{C=C} + \text{CO} + \text{ROH} \xrightarrow[\text{HgCl}_2]{\text{PdCl}_2} \text{ROOC-C-C-COOR}$$

Alkenes can be converted to succinic esters by reaction with carbon monoxide, an alcohol, and palladium chloride in the presence of mercuric chloride.[795] The addition is mostly syn. In a similar reaction, both terminal and internal alkynes can be converted to esters of maleic acid. For an indirect method of adding two carbon groups to a double bond, see reaction **2-44.**

5-58 Carboxylation of Halides with Insertion of Acetylene



$$\text{H-C}\equiv\text{C-H} + \text{-C=C-C-Cl} + \text{CO} + \text{ROH} \xrightarrow{\text{Ni(CO)}_4} \text{HC=C(H)-COOR (with -C-C=C- on HC)}$$

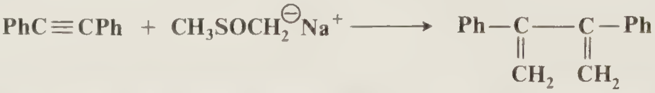
Treatment of acetylene at ordinary temperatures and pressures with an allylic halide, CO, an alcohol (or water), and a $Ni(CO)_4$ catalyst results in the preparation of an $\alpha,\beta{:}\delta,\varepsilon$-bis-unsaturated ester (or acid).[796] The use of ethylene instead of acetylene gives the corresponding δ,ε-unsaturated ester (or acid).[797] However, substituted acetylenes or ethylenes do not give the reaction; other products are formed instead.[798] The halide may be any of various primary or secondary allylic halides which do not have electron-withdrawing groups on the double-bond carbons. With respect to the halide, this is an SN1 reaction, and allylic shifts are found. Secondary allylic halides give almost exclusively the allylic-shift product. When ordinary alkyl or aryl halides are used (in the acetylene reaction), another CO is found in the product and the double bond is hydrogenated.[799]

$$\mathrm{HC{\equiv}CH + R'X + ROH \xrightarrow[H_2O]{Ni(CO)_4} R'COCH_2CH_2COOR}$$

5-59 The Conversion of Diphenylacetylene to a Butadiene



$$\mathrm{PhC{\equiv}CPh + CH_3SOCH_2^{\ominus}Na^+ \longrightarrow Ph{-}\underset{\underset{\textstyle CH_2}{\Vert}}{C}{-}\underset{\underset{\textstyle CH_2}{\Vert}}{C}{-}Ph}$$

Diphenylacetylene reacts with methylsulfinyl carbanion to give 2,3-diphenylbutadiene.[800] Neither the scope nor the mechanism of this reaction seems to have been investigated. .

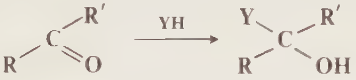
Addition to Carbon-Hetero Multiple Bonds

MECHANISM AND REACTIVITY

The reactions considered in this chapter involve addition to the carbon-oxygen, carbon-nitrogen, and carbon-sulfur double bonds and to the carbon-nitrogen triple bond. The mechanistic study of these reactions is much simpler than of the additions to carbon-carbon multiple bonds considered in Chapter 15.[1] Most of the questions which concerned us there either do not arise here or can be answered very simply. Since C═O, C═N, and C≡N bonds are strongly polar, with the carbon always the positive end (except for isonitriles, see p. 890), there is never any doubt about *orientation* of unsymmetrical addition to these bonds. Nucleophilic attacking species always go the carbon and electrophilic ones to the oxygen or nitrogen. Additions to C═S bonds are much less common, but in these cases the addition can be in the other direction. For example, thiobenzophenone $Ph_2C{=}S$, when treated with phenyllithium gives, after hydrolysis, benzhydryl phenyl sulfide Ph_2CHSPh.[2] The *stereochemistry* of addition is not generally a factor because it is not normally possible to determine whether the addition is syn or anti. In addition of YH to a ketone, for example,



the product has an asymmetric carbon, but unless there is asymmetry in R or R′ or unless YH is optically active, the product must be a racemic mixture and there is no way to tell from its steric nature whether the addition of Y and H was syn or anti. The same holds true for C═N and C═S bonds, since in none of these cases can asymmetry be present at the hetero atom. The stereochemistry of additions of a single YH to the carbon-nitrogen triple bond could be investigated, since the product can exist in syn and anti forms (p. 114), but these reactions are not very important. Of course if R or R′ *is* chiral, a racemic mixture will not always arise and the stereochemistry of addition can be studied in such cases. Cram's rule (p. 106) allows us to predict in many cases the direction of attack of Y. Another such rule is Prelog's rule.[3] However, even in this type of study, the relative directions of attack of Y and H are not determined but only the direction of attack of Y with respect to the rest of the substrate molecule.

Not only are questions of orientation and stereochemistry not of great importance in the study of these mechanisms, but the picture is further simplified by the fact that free-radical additions to carbon-hetero double bonds are rare.[4] The principal question remaining is which attacks first, the nucleophile or electrophile. In most cases it is the nucleophile, and these reactions are regarded as *nucleophilic additions*, which can be represented thus (for the C=O bond, analogously for the others):

---

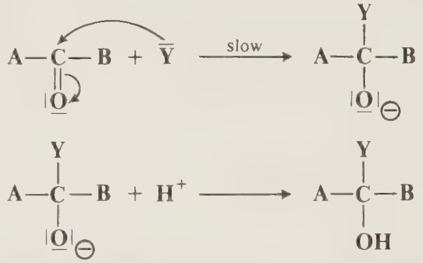
[3] Prelog, *Helv. Chim. Acta* **36,** 308 (1953); for a discussion of these rules, see Eliel, "The Stereochemistry of Carbon Compounds," pp. 68–74, McGraw-Hill Book Company, New York, 1962. For reviews of the stereochemistry of addition to carbonyl compounds, see Ashby and Laemmle, *Chem. Rev.* **75,** 521–546 (1975); Goller, *J. Chem. Educ.* **51,** 182–185 (1974); Toromanoff, *Top. Stereochem.* **2,** 157–198 (1967); Kamernitskii and Akhrem, *Russ. Chem. Rev.* **30,** 43–61 (1961) [the last review can also be found in *Tetrahedron* **18,** 705–750 (1962)].



Step 1

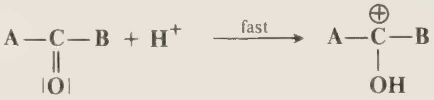
$$\mathrm{A{-}\underset{\overset{\|}{|\underline{O}}}{C}{-}B} + \overline{\mathrm{Y}} \xrightarrow{\text{slow}} \mathrm{A{-}\underset{|\underline{O}|^{\ominus}}{\overset{Y}{C}}{-}B}$$

Step 2

$$\mathrm{A{-}\underset{|\underline{O}|^{\ominus}}{\overset{Y}{C}}{-}B} + \mathrm{H}^+ \longrightarrow \mathrm{A{-}\underset{OH}{\overset{Y}{C}}{-}B}$$

The electrophile shown in step 2 is the proton. In almost all the reactions considered in this chapter the electrophilic attacking atom is either hydrogen or carbon. It may be noted that step 1 is exactly the same as step 1 of the tetrahedral mechanism of nucleophilic substitution at a carbonyl carbon (p. 308), and it might be expected that substitution would compete with addition. However, this is seldom the case. When A and B are H, R, or Ar, the substrate is an aldehyde or ketone and these almost never undergo substitution, owing to the extremely poor nature of H, R, and Ar as leaving groups. For acids and their derivatives (B = OH, OR, NH_2, etc.) addition is seldom found, because these are much better leaving groups. It is thus the nature of A and B which determines whether a nucleophilic attack at a carbon-hetero multiple bond will lead to substitution or addition.

As is the case in the tetrahedral mechanism, it is also possible for the electrophilic species to attack first, in which case it goes to the hetero atom. This species is most often a proton, and the mechanism is

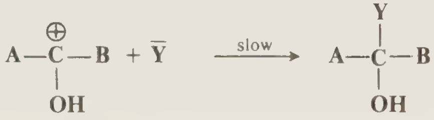


Step 1

1

2

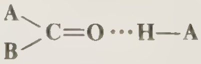
$$\mathrm{A{-}\underset{\overset{\|}{|O|}}{C}{-}B} + \mathrm{H}^+ \xrightarrow{\text{fast}} \mathrm{A{-}\underset{OH}{\overset{\oplus}{C}}{-}B}$$



Step 2

$$\mathrm{A{-}\underset{OH}{\overset{\oplus}{C}}{-}B} + \overline{\mathrm{Y}} \xrightarrow{\text{slow}} \mathrm{A{-}\underset{OH}{\overset{Y}{C}}{-}B}$$

The two mechanisms just mentioned are not usually regarded as being very different, and in each case the rate-determining step is usually the one involving nucleophilic attack. It may be observed that many of these reactions can be catalyzed by both acids and bases. Bases catalyze the reaction by converting a reagent of the form YH to the more powerful nucleophile Y^- (see p. 322). Acids catalyze it by converting the substrate, e.g., **1**, to an ion (**2**) in which the positive charge on the carbon is greatly increased, thus making it more attractive to nucleophilic attack. The latter type of catalysis may also take place with acids which are not so acidic that a proton is actually transferred to the substrate but which are able to form a hydrogen bond with it:



---

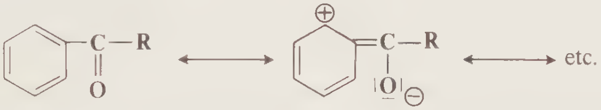
[4] For examples, see Kaplan, *J. Am. Chem. Soc.* **88**, 1833 (1966); Urry, Nishihara, and Niu, *J. Org. Chem.* **32**, 347 (1967); Maruyama, Taniuchi, and Oka, *Bull. Chem. Soc. Jpn.* **47**, 712 (1974).

TABLE 1 Percentage yields in the Perkin reaction (**6-44**) run on benzaldehydes substituted in the ring by methyl and chloro[7]

R in RCHO	Yield, %	R in RCHO	Yield, %
Phenyl	45–50	2-Chlorophenyl	71
2-Methylphenyl	15	3-Chlorophenyl	63
3-Methylphenyl	23	4-Chlorophenyl	52
4-Methylphenyl	33	2,6-Dichlorophenyl	82
2,6-Dimethylphenyl	0		

also resulting in a decreased electron density at the carbon. Similar catalysis can also be found with metallic ions, such as Ag^+, which may act here as Lewis acids.[5] We have mentioned before (p. 156) that ions of type **2** are comparatively stable carbonium ions because the positive charge is spread by resonance.

Reactivity factors in additions to carbon-hetero multiple bonds are similar to those for the tetrahedral mechanism of nucleophilic substitution.[6] If A and/or B are electron-donating groups, rates are decreased. Electron-attracting substituents increase rates. This means that aldehydes are more reactive than ketones. Table 1 illustrates these generalizations.[7] Aryl groups are somewhat deactivating compared to alkyl, because of resonance, which stabilizes the substrate molecule but is lost on going to the intermediate:

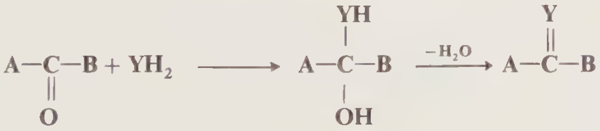


Double bonds in conjugation with the carbon-hetero multiple bond also lower addition rates, for similar reasons but, more important, may provide competition from 1,4 addition (p. 679). Steric factors are also quite important and contribute to the decreased reactivity of ketones compared with aldehydes. Highly hindered ketones like hexamethylacetone and dineopentyl ketone[8] either do not undergo many of these reactions or require extreme conditions.

REACTIONS

Many of the reactions in this chapter are simple additions to carbon-hetero multiple bonds, with the reaction ending as soon as the two groups have been added. But in many other cases subsequent reactions take place. We shall meet a number of such reactions, but most of them are of two types:

Type *A*



$$\mathrm{A}-\underset{\underset{\displaystyle \mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{B} + \mathrm{YH}_2 \longrightarrow \mathrm{A}-\overset{\overset{\displaystyle \mathrm{YH}}{|}}{\underset{\underset{\displaystyle \mathrm{OH}}{|}}{\mathrm{C}}}-\mathrm{B} \xrightarrow{-\mathrm{H_2O}} \mathrm{A}-\overset{\overset{\displaystyle \mathrm{Y}}{\|}}{\mathrm{C}}-\mathrm{B}$$

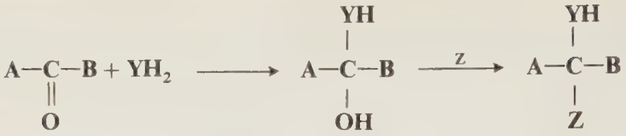
[6] For a review of the reactivity of nitriles, see Schaefer, in Rappoport, "The Chemistry of the Cyano Group," pp. 239–305, Interscience Publishers, New York, 1970.

[7] Böck, Lock, and Schmidt, *Monatsh. Chem.* **64**, 399 (1934).

[8] Liberman and Vasina, *J. Gen. Chem. USSR* **32**, 3179 (1962).

Type *B*



$$\underset{\substack{\| \\ \mathrm{O}}}{\mathrm{A{-}C{-}B}} + \mathrm{YH_2} \longrightarrow \mathrm{A{-}}\overset{\substack{\mathrm{YH} \\ |}}{\underset{\substack{| \\ \mathrm{OH}}}{\mathrm{C}}}\mathrm{{-}B} \xrightarrow{\mathrm{Z}} \mathrm{A{-}}\overset{\substack{\mathrm{YH} \\ |}}{\underset{\substack{| \\ \mathrm{Z}}}{\mathrm{C}}}\mathrm{{-}B}$$

In type *A*, the adduct loses water (or, in the case of addition to C=NH, ammonia, etc.), and the net result of the reaction is the substitution of C=Y for C=O (or C=NH, etc.). In type *B* there is a rapid substitution, and the OH (or NH_2, etc.) is replaced by another group Z, which is often another YH moiety. This substitution is in most cases nucleophilic, since Y usually has an unshared pair, and SN1 reactions occur very well on this type of compound (see p. 319), even when the leaving group is as poor as OH or NH_2. In this chapter we shall classify reactions according to what is initially adding to the carbon-hetero multiple bond, even if subsequent reactions take place so rapidly that it is not possible to isolate the initial adduct. It is true that this involves a certain danger, since we cannot always be sure just which reaction occurred first (e.g., reactions **6-7** and **6-17**). In such cases we shall make the assumptions which seem most reasonable from the mechanistic data at hand.

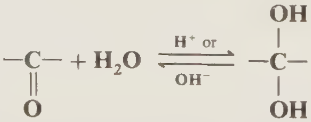
Most of the reactions considered in this chapter can be reversed. In many cases we shall consider the reverse reactions with the forward ones, in the same section. The reverses of some of the other reactions are considered in other chapters. In still other cases, one of the reactions in this chapter is the reverse of another, e.g., reactions **6-2** and **6-15.** For reactions which are reversible, the principle of microscopic reversibility (p. 195) applies.

We shall discuss first reactions in which hydrogen or a metallic ion (or in one case phosphorus or sulfur) adds to the hetero atom and then reactions in which carbon adds to the hetero atom. Within each group, the reactions are classified by the nature of the nucleophile. Additions to isonitriles, which are somewhat different in character, are treated at the end.

Reactions in Which Hydrogen or a Metallic Ion Adds to the Hetero Atom

A. Attack by OH (Addition of H_2O)

6-1 The Addition of Water to Aldehydes and Ketones. Formation of Hydrates



$$\underset{\substack{\| \\ \mathrm{O}}}{\mathrm{{-}C{-}}} + \mathrm{H_2O} \underset{\mathrm{OH^-}}{\overset{\mathrm{H^+\ or}}{\rightleftharpoons}} \mathrm{{-}}\overset{\substack{\mathrm{OH} \\ |}}{\underset{\substack{| \\ \mathrm{OH}}}{\mathrm{C}}}\mathrm{{-}}$$

The adduct formed upon addition of water to an aldehyde or ketone is called a hydrate or a *gem*-diol.[9] These compounds are usually stable only in water solution and decompose on distillation; i.e., the equilibrium shifts back toward the carbonyl compound. The position of the equilibrium is greatly dependent on the structure of the hydrate. Thus, formaldehyde in water at 20°C exists 99.99% in the hydrated form, while for acetaldehyde this figure is 58%, and for acetone the hydrate concentration is negligible.[10] It has been found, by exchange with ^{18}O, that the reaction with acetone is quite rapid when catalyzed by acid or base, but the equilibrium lies on the side of acetone and water.[11] Acetone hydrate *has* been shown to exist in the solid state (frozen mixtures of acetone and water).[12] Since methyl, a $+I$ group, inhibits hydrate formation, it may be expected that electron-attracting groups would have the opposite effect, and this is indeed the case. The hydrate of chloral[13] (**3**) is a stable crystalline substance. In order for **3** to revert to chloral, OH^- or H_2O must leave, and this is made difficult by the electron-withdrawing character of the Cl_3C group. Other polychlorinated and polyfluorinated aldehydes and ketones[14] and α-keto aldehydes also form stable hydrates, as do cyclopropanones. In the last case[15] formation of the hydrate (**4**) relieves some of the I strain (p. 250) of the parent ketone. Higher-molecular-weight aldehydes, e.g., C_7 and up, form solid hemihydrates (**5**), which are stable at low temperatures (near 0°C) but decompose to the aldehyde and water at about 40 to 50°C.[16]

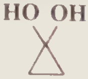
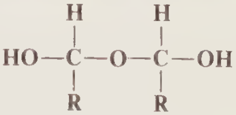
$$\mathrm{Cl{-}\overset{Cl}{\underset{Cl}{C}}{-}\overset{OH}{\underset{OH}{C}}{-}H}$$

3



4

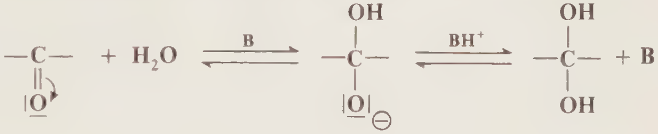


$$\mathrm{HO{-}\overset{H}{\underset{R}{C}}{-}O{-}\overset{H}{\underset{R}{C}}{-}OH}$$

5

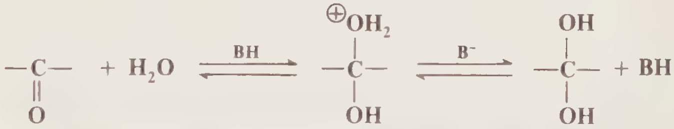
The reaction is subject to both general-acid and general-base catalysis; the following mechanisms can be written for basic (B) and acidic (BH) catalysis, respectively:[17]

Mechanism *a*



$$-\underset{\underline{|O|}}{\underset{\|}{C}}- + H_2O \overset{B}{\rightleftharpoons} -\overset{OH}{\underset{\underline{|O|}^{\ominus}}{C}}- \overset{BH^+}{\rightleftharpoons} -\overset{OH}{\underset{OH}{C}}- + B$$

Mechanism *b*

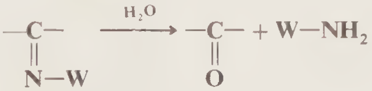


$$-\underset{O}{\underset{\|}{C}}- + H_2O \overset{BH}{\rightleftharpoons} -\overset{\oplus OH_2}{\underset{OH}{C}}- \overset{B^-}{\rightleftharpoons} -\overset{OH}{\underset{OH}{C}}- + BH$$

In mechanism *a*, as the H_2O attacks, the base pulls off a proton, and the net result is addition of OH^-. This can happen because the base is already hydrogen-bonded to the H_2O molecule before the attack. In mechanism *b*, because HB is already hydrogen-bonded to the oxygen of the carbonyl group, it gives up a proton to the oxygen as the water attacks. In this way B and HB accelerate the reaction even beyond the extent that they form OH^- or H_3O^+ by reaction with water.

For the reaction between ketones and H_2O_2, see reaction **7-51**.

6-2 Hydrolysis of the Carbon-Nitrogen Double Bond



$$-\underset{N-W}{\underset{\|}{C}}- \xrightarrow{H_2O} -\underset{O}{\underset{\|}{C}}- + W{-}NH_2$$

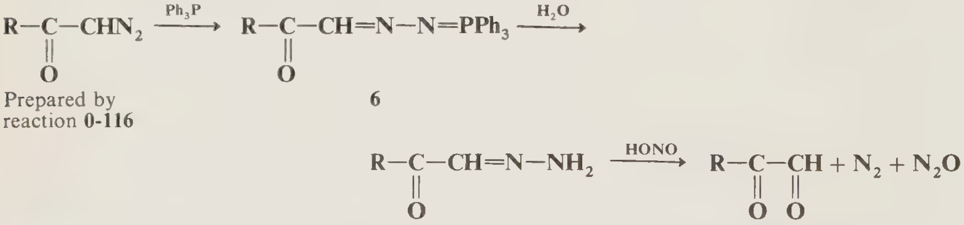
Compounds containing carbon-nitrogen double bonds can be hydrolyzed to the corresponding aldehydes or ketones. For imines (W = R or H) the hydrolysis is easy and can be carried out with water. When W = H, the imine is seldom stable enough for isolation, but hydrolysis is often done in situ, without isolation. The hydrolysis of Schiff bases (W = Ar) is more difficult and requires acid or basic catalysis. Oximes (W = OH), arylhydrazones (W = NHAr), and, most easily, semicarbazones (W = $NHCONH_2$) can also be hydrolyzed. Often a reactive aldehyde is added to combine with the liberated amine. Formaldehyde is generally used for this purpose, but levulinic acid is excellent for hydrolyzing oximes and arylhydrazones.[18]

A number of other reagents have been used to cleave C═N bonds, especially those which are not easily hydrolyzable with acidic or basic catalysts or which contain other functional groups which are attacked under these conditions. In particular, oximes have been converted to the corresponding aldehyde or ketone by treatment with, among other reagents, thallium(III) nitrate,[19] aqueous $TiCl_3$ and acetic acid,[20] aqueous $NaHSO_3$,[21] iron pentacarbonyl and BF_3,[22] aluminum isopropoxide in isopropyl alcohol,[23] lead tetraacetate,[24] cerium(IV) ions,[25] and by treatment of the O-acetate of the oxime with chromium(II) acetate.[26] Tosylhydrazones can be hydrolyzed to the corresponding ketones with NaOCl.[27] Among other reagents which have been used to cleave C═N bonds are nitrous acid (as well as nitrosonium salts such as $NO^+ \ BF_4^-$)[28] and ozone[29] (see reaction **9-10**). Aldehydes and ketones can be purified by conversion to the oxime, semicarbazone, or arylhydrazone derivative (reactions **6-21** and **6-22**), which is then recrystallized and hydrolyzed back to the starting compound. Conversion of a hydrazone to an aldehyde is the key step in the transformation of a carboxylic acid to an α-keto aldehyde, a method of increasing the carbon chain by 1:[30]



$$\text{R}-\underset{\underset{\text{O}}{\|}}{\text{C}}-\text{CHN}_2 \xrightarrow{\text{Ph}_3\text{P}} \text{R}-\underset{\underset{\text{O}}{\|}}{\text{C}}-\text{CH}=\text{N}-\text{N}=\text{PPh}_3 \xrightarrow{\text{H}_2\text{O}}$$

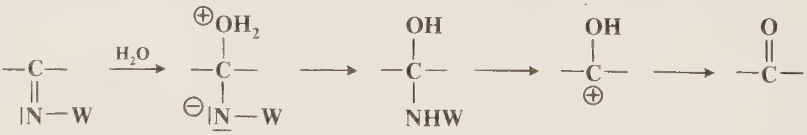
Prepared by
reaction **0-116**

6

$$\text{R}-\underset{\underset{\text{O}}{\|}}{\text{C}}-\text{CH}=\text{N}-\text{NH}_2 \xrightarrow{\text{HONO}} \text{R}-\underset{\underset{\text{O}}{\|}}{\text{C}}-\underset{\underset{\text{O}}{\|}}{\text{CH}} + \text{N}_2 + \text{N}_2\text{O}$$

Direct treatment of the α-ketotriphenylphosphazine (**6**) with HONO also gives the product.

The hydrolysis of carbon-nitrogen double bonds involves initial addition of water and elimination of a nitrogen moiety:



$$-\underset{\underset{|\text{N}-\text{W}}{\|}}{\text{C}}- \xrightarrow{\text{H}_2\text{O}} -\overset{\overset{\oplus\text{OH}_2}{|}}{\underset{\underset{\ominus|\underline{\text{N}}-\text{W}}{|}}{\text{C}}}- \longrightarrow -\overset{\overset{\text{OH}}{|}}{\underset{\underset{\text{NHW}}{|}}{\text{C}}}- \longrightarrow -\overset{\overset{\text{OH}}{|}}{\underset{\oplus}{\text{C}}}- \longrightarrow -\overset{\overset{\text{O}}{\|}}{\text{C}}-$$

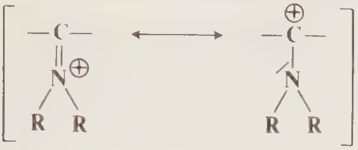
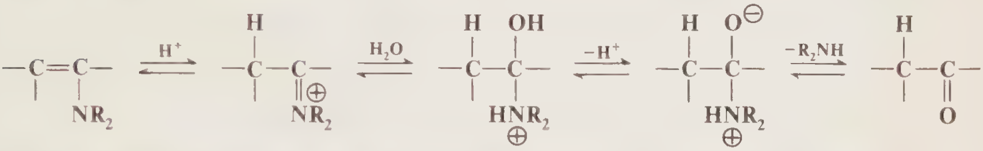
[30] Bestmann, Klein, Göthlich, and Buckschewski, *Chem. Ber.* **96,** 2259 (1963).

It is thus an example of reaction type *A* (p. 803). The sequence shown is generalized.[31] In specific cases there are variations in the order of the steps, depending on acid or basic catalysis or other conditions.[32] Which step is rate-determining also depends on acidity and on the nature of W and of the groups connected to the carbonyl.[33] Iminium ions (**7**) would be expected to undergo hydrolysis quite readily, since there is a contributing form with a positive charge on the carbon.



7

Indeed, they react with water at room temperature.[34] Acid-catalyzed hydrolysis of enamines (the last step of the Stork reaction, reaction **2-17**) involves conversion to iminium ions:[35]



The mechanism of enamine hydrolysis is thus similar to that of vinyl ether hydrolysis (**0-7**).

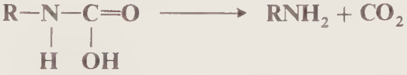
6-3 Hydrolysis of Isocyanates and Isothiocyanates

$$R\text{—}N\text{=}C\text{=}O + H_2O \xrightarrow{OH^- \text{ or } H^+} R\text{—}NH_2 + CO_2$$

A common method for the preparation of primary amines involves the hydrolysis of isocyanates or isothiocyanates.[36] The latter react more slowly, and more vigorous conditions are required. The reaction is catalyzed by acids or bases. In this case simple addition of water to the carbon-nitrogen double bond would give an N-substituted carbamic acid (**8**). Such compounds are unstable, however, and break down to carbon dioxide (or COS in the case of isothiocyanates) and the amine:



$$R\text{—}\underset{H}{\underset{|}{N}}\text{—}\underset{OH}{\underset{|}{C}}\text{=}O \longrightarrow RNH_2 + CO_2$$

8

In the absence of a basic catalyst, disubstituted ureas, RNHCONHR, can be obtained by a nucleophilic substitution of RNH_2 on the carbamic acid or by addition of RNH_2 to another mole of RNCO.[36a]

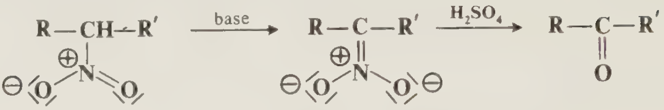
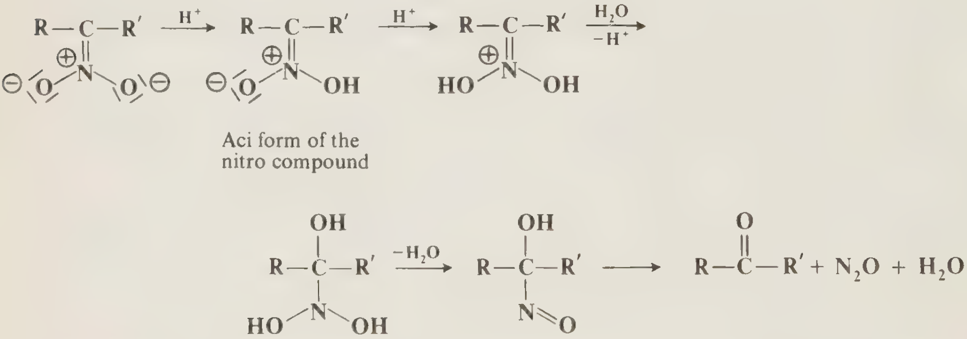
6-4 Hydrolysis of Aliphatic Nitro Compounds



Primary or secondary aliphatic nitro compounds can be hydrolyzed, respectively, to aldehydes or ketones, by treatment of their salts with sulfuric acid. This is called the *Nef reaction.*[37] Tertiary aliphatic nitro compounds do not give the reaction because they cannot be converted to the salt form. Like reaction **6-2**, this reaction involves hydrolysis of a carbon-nitrogen double bond. A possible mechanism is[38]



Aci form of the
nitro compound

The conversion of nitro compounds to aldehydes or ketones has been carried out with better yields and fewer side reactions by several alternative methods. Among these are treatment of the nitro compound with aqueous $TiCl_3$ [39] or with a mixture of $NaNO_2$ and an alkyl nitrite;[40] and treatment of the salt of the nitro compound with $KMnO_4$[41] or ozone.[42] When the Nef reaction is run with methanol instead of water, primary nitro compounds give high yields of the corresponding dimethyl acetals [$RCH_2NO_2 \rightarrow RCH(OMe)_2$].[43]

When *primary* nitro compounds are treated with sulfuric acid without previous conversion to the salt form, they give carboxylic acids. Hydroxamic acids are intermediates and can be isolated, so that this is also a method for preparing *them.* Both the Nef reaction and the hydroxamic acid process involve the aci form, and the difference in products arises from higher acidity; e.g., a difference in sulfuric acid concentration from 4 *N* to 31 *N* changes the product from the aldehyde to the hydroxamic acid.[44] The mechanism of the hydroxamic acid reaction is not known with certainty, but if higher acidity is required, it may be that the protonated aci form of the nitro compound is further protonated. The following rationalization has been proposed:[44]

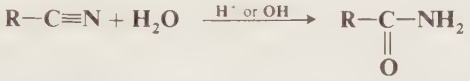
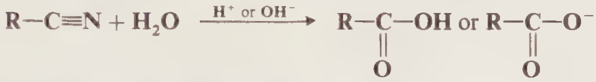
Hydrolysis of the hydroxamic acid produces the carboxylic acid.

There are no OS references, but see OS **IV**, 573, for a related reaction.

6-5 Hydrolysis of Nitriles



$$R{-}C{\equiv}N + H_2O \xrightarrow{H^+ \text{ or } OH^-} R{-}\underset{\underset{O}{\|}}{C}{-}NH_2$$



$$R{-}C{\equiv}N + H_2O \xrightarrow{H^+ \text{ or } OH^-} R{-}\underset{\underset{O}{\|}}{C}{-}OH \text{ or } R{-}\underset{\underset{O}{\|}}{C}{-}O^-$$

Nitriles can be hydrolyzed to give either amides or carboxylic acids.[45] The amide is the initial product, but since amides are also hydrolyzed with acid or basic treatment, the carboxylic acid is the more common product. When the carboxylic acid is desired, the reagent of choice is aqueous NaOH containing about 6 to 12% H_2O_2, though acid-catalyzed hydrolysis is also frequently carried out. However, there are a number of procedures for stopping at the amide stage,[46] among them the use of concentrated H_2SO_4; formic acid and HCl or HBr;[47] acetic acid and BF_3; H_2O_2 and OH^-; and dry HCl followed by H_2O. The same result can also be obtained by use of water and certain metal ions or complexes;[48] MnO_2 in methylene chloride;[49] or $TiCl_4$ and water,[50] in which cases no acid or base is used.

The hydrolysis of nitriles to carboxylic acids is one of the best methods for the preparation of these compounds. Nearly all nitriles give the reaction, with either acid or basic catalysts. The sequences

$$RX + NaCN \longrightarrow RCN \longrightarrow RCOOH \qquad (0\text{-}103)$$

$$RCHO + HCN \longrightarrow RCH(OH)CN \longrightarrow RCH(OH)COOH \qquad (6\text{-}50)$$

$$RCHO + NaCN + NH_4Cl \longrightarrow RCH(NH_2)CN \longrightarrow RCH(NH_2)COOH \qquad (6\text{-}51)$$

are very common. The last two sequences are often carried out without isolation of the cyanide intermediates.

[46] For a discussion, see Beckwith, in Zabicky, "The Chemistry of Amides," pp. 119–125, Interscience Publishers, New York, 1970.

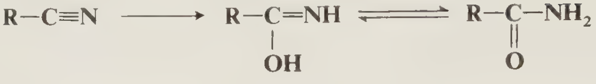
[47] Becke, Fleig, and Pässler, *Justus Liebigs Ann. Chem.* **749**, 198 (1971).

[48] For example see Watanabe, *Bull. Chem. Soc. Jpn.* **32**, 1280 (1959), **37**, 1325 (1964); Bennett and Yoshida, *J. Am. Chem. Soc.* **95**, 3030 (1973); Paraskewas, *Synthesis* 574 (1974). See also Diamond, Grant, Tom, and Taube, *Tetrahedron Lett.* 4025 (1974).

[49] Cook, Forbes, and Kahn, *Chem. Commun.* 121 (1966).

[50] Mukaiyama, Kamio, Kobayashi, and Takei, *Chem. Lett.* 357 (1973).

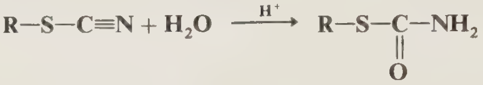
The first addition product is **9**, which tautomerizes to the amide.



$$R{-}C{\equiv}N \longrightarrow R{-}\underset{\displaystyle OH}{\underset{|}{C}}{=}NH \rightleftharpoons R{-}\underset{\displaystyle O}{\underset{\|}{C}}{-}NH_2$$

9

Thiocyanates can be converted to thiocarbamates, in a similar reaction:[51]



$$R{-}S{-}C{\equiv}N + H_2O \xrightarrow{H^+} R{-}S{-}\underset{\displaystyle O}{\underset{\|}{C}}{-}NH_2$$

Hydrolysis of cyanamides gives amines, produced by the breakdown of the unstable carbamic acid intermediates: $R_2NCN \rightarrow [R_2NCOOH] \rightarrow R_2NH$.

Nitriles exchange with carboxylic acids when heated together in an autoclave:[52]

$$RCN + R'COOH \xrightarrow{300°C} RCOOH + R'CN$$

The reaction proceeds as shown if RCOOH is a weaker acid (has a higher pK value) than R′COOH. Labeling studies have shown that it is nitrogen and oxygen which are being exchanged; i.e., the R—C and R′—C bonds are not broken.

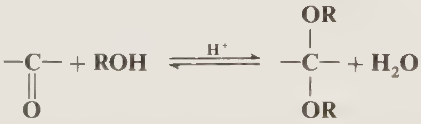
B. Attack by OR (Addition of ROH)

6-6 The Addition of Alcohols to Aldehydes and Ketones



$$-\underset{\displaystyle O}{\underset{\|}{C}}- + ROH \underset{}{\overset{H^+}{\rightleftharpoons}} -\overset{\displaystyle OR}{\overset{|}{\underset{\displaystyle OR}{\underset{|}{C}}}}- + H_2O$$

Acetals and ketals are formed by treatment of aldehydes and ketones, respectively, with alcohols in the presence of acid catalysts.[53] This is a reversible reaction, and acetals and ketals can be hydrolyzed by treatment with acid (reaction **0-7**). With small unbranched aldehydes the equilibrium lies to the right. If it is desired to prepare ketals, or acetals of larger molecules, the equilibrium must be shifted, usually by removal of water. One way of removing the water is by the use of molecular sieves.[54] The reaction in neither direction is catalyzed by bases, and so acetals and ketals are quite stable to bases, though they are easily hydrolyzed by acids. This makes this reaction a useful method of protection of aldehyde or ketone functions from attack by bases. The reaction is of wide scope. Most aldehydes are easily converted to acetals. With ketones the process is more difficult, presumably for steric reasons, and the reaction often fails, though many ketals, especially from cyclic ketones, have been made in this manner. Many functional groups may be present without being affected. 1,2-Glycols and 1,3-glycols form cyclic acetals and ketals, e.g.,

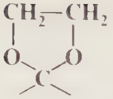
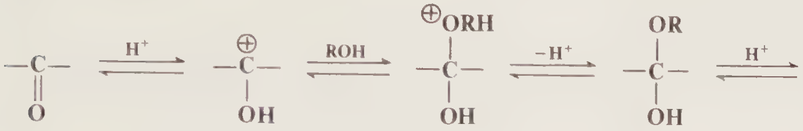
[53] For reviews, see Sandler and Karo, "Organic Functional Group Preparations," vol. 3, pp. 4–17, 34–42, Academic Press, Inc., New York, 1972; Ogata and Kawasaki, Ref. 17, pp. 14–20; Schmitz and Eichhorn, in Patai, "The Chemistry of the Ether Linkage," pp. 309–351, Interscience Publishers, New York, 1967.

[54] Roelofsen, Wils, and van Bekkum, *Recl. Trav. Chim. Pays-Bas* **90,** 1141 (1971).



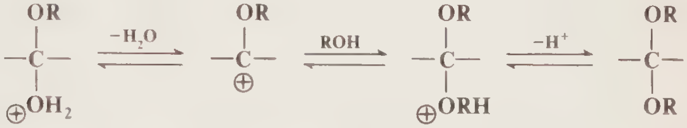
and these are often used to protect aldehydes and ketones.

The mechanism, which involves initial formation of a *hemiacetal*[55] **(10)**, is the reverse of that given for acetal hydrolysis **(0-7)**:



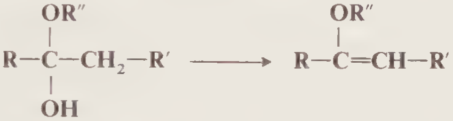
$$\underset{\text{O}}{\overset{}{\underset{\|}{-\text{C}-}}} \xrightleftharpoons{\text{H}^+} \underset{\text{OH}}{\underset{|}{\overset{\oplus}{-\text{C}-}}} \xrightleftharpoons{\text{ROH}} \underset{\text{OH}}{\underset{|}{\overset{\overset{\oplus}{\text{ORH}}}{\overset{|}{-\text{C}-}}}} \xrightleftharpoons{-\text{H}^+} \underset{\text{OH}}{\underset{|}{\overset{\text{OR}}{\overset{|}{-\text{C}-}}}} \xrightleftharpoons{\text{H}^+}$$

10



$$\underset{\oplus\text{OH}_2}{\underset{|}{\overset{\text{OR}}{\overset{|}{-\text{C}-}}}} \xrightleftharpoons{-\text{H}_2\text{O}} \underset{\oplus}{\overset{\text{OR}}{\overset{|}{-\text{C}-}}} \xrightleftharpoons{\text{ROH}} \underset{\oplus\text{ORH}}{\underset{|}{\overset{\text{OR}}{\overset{|}{-\text{C}-}}}} \xrightleftharpoons{-\text{H}^+} \underset{\text{OR}}{\underset{|}{\overset{\text{OR}}{\overset{|}{-\text{C}-}}}}$$

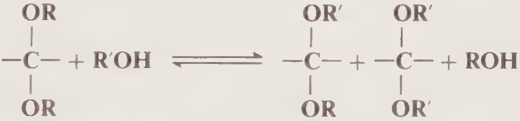
If the original aldehyde or ketone has an α-hydrogen, it is possible for water to split out in that way and enol ethers can be prepared in this manner:



$$\text{R}-\underset{\text{OH}}{\underset{|}{\overset{\text{OR}''}{\overset{|}{\text{C}}}}}-\text{CH}_2-\text{R}' \longrightarrow \text{R}-\overset{\text{OR}''}{\overset{|}{\text{C}}}=\text{CH}-\text{R}'$$

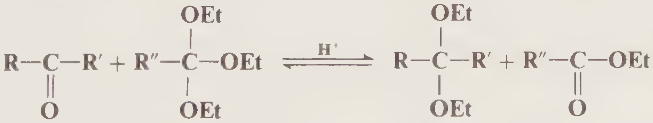
Hemiacetals themselves are no more stable than the corresponding hydrates (reaction **6-1**). As with hydrates, hemiacetals of polychloro and polyfluoro aldehydes and ketones may be quite stable.

When acetals or ketals are treated with an alcohol of higher molecular weight than the one already there, it is possible to get a *transacetalation* (reaction **0-19**):



$$\underset{\text{OR}}{\underset{|}{\overset{\text{OR}}{\overset{|}{-\text{C}-}}}} + \text{R}'\text{OH} \rightleftharpoons \underset{\text{OR}}{\underset{|}{\overset{\text{OR}'}{\overset{|}{-\text{C}-}}}} + \underset{\text{OR}'}{\underset{|}{\overset{\text{OR}'}{\overset{|}{-\text{C}-}}}} + \text{ROH}$$

In the equilibrium mixture are present three acetals and two alcohols, and in order for the reaction to be useful, a way must be found to shift the equilibria in the desired directions.[56] In another type of transacetalation, aldehydes or ketones can be converted to acetals or ketals by treatment with another acetal or ketal or with an ortho ester,[57] in the presence of an acid catalyst (shown for an ortho ester):



$$\text{R}-\underset{\text{O}}{\underset{\|}{\text{C}}}-\text{R}' + \text{R}''-\underset{\text{OEt}}{\underset{|}{\overset{\text{OEt}}{\overset{|}{\text{C}}}}}-\text{OEt} \xrightleftharpoons{\text{H}^+} \text{R}-\underset{\text{OEt}}{\underset{|}{\overset{\text{OEt}}{\overset{|}{\text{C}}}}}-\text{R}' + \text{R}''-\underset{\text{O}}{\underset{\|}{\text{C}}}-\text{OEt}$$

---

[55] For a review of hemiacetals, see Hurd, *J. Chem. Educ.* **43,** 527–531 (1966).

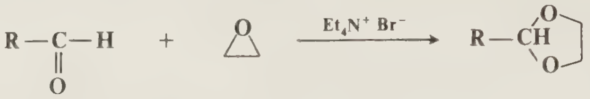
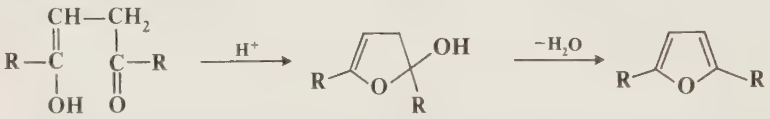
[57] For a review with respect to ortho esters, see DeWolfe, "Carboxylic Ortho Ester Derivatives," pp. 154–164, Academic Press, Inc., New York, 1970.

This method is especially useful for the conversion of ketones to ketals, since the direct reaction of a ketone with an alcohol often gives poor results. In a variation of this method, aldehydes are converted to cyclic acetals by heating in an autoclave with an epoxide and a quaternary ammonium salt:[58]



A feature of this method is that acid catalysts are not required.

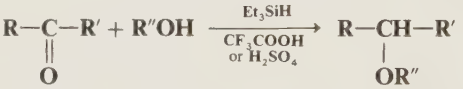
1,4-Diketones give furans when treated with acids. This is actually an example of an intramolecular addition of an alcohol to a ketone, since it is the enol form which adds:



Similarly, 1,5-diketones give pyrans. Formic acid reacts with alcohols to give orthoformates.

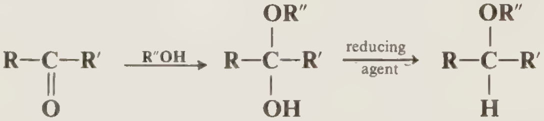
OS **I,** 1, 298, 364, 381; **II,** 137; **III,** 123, 387, 502, 536, 644, 731, 800; **IV,** 21, 479, 679; **V,** 5, 292, 303, 450, 539. Also see OS **IV,** 558, 588; **V,** 25.

6-7 Reductive Alkylation of Alcohols



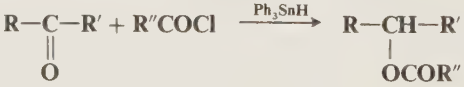
$$R-\underset{\underset{\displaystyle O}{\|}}{C}-R' + R''OH \xrightarrow[\text{or } H_2SO_4]{Et_3SiH \atop CF_3COOH} R-\underset{\underset{\displaystyle OR''}{|}}{CH}-R'$$

Aldehydes and ketones can be converted to ethers by treatment with an alcohol and triethylsilane in the presence of a strong acid[59] or by hydrogenation in alcoholic acid in the presence of platinum oxide.[60] The process can formally be regarded as addition of ROH to give a hemiacetal, followed by reduction of the OH:



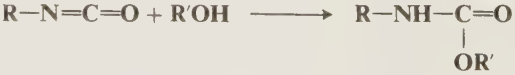
$$R-\underset{\underset{\displaystyle O}{\|}}{C}-R' \xrightarrow{R''OH} R-\overset{\overset{\displaystyle OR''}{|}}{\underset{\underset{\displaystyle OH}{|}}{C}}-R' \xrightarrow[\text{agent}]{\text{reducing}} R-\overset{\overset{\displaystyle OR''}{|}}{\underset{\underset{\displaystyle H}{|}}{C}}-R'$$

In this respect it is similar to reaction **6-16**. In a similar reaction, ketones can be converted to esters (reductive acylation of ketones) by treatment with an acyl chloride and triphenyltin hydride.[61]



$$R-\underset{\underset{\displaystyle O}{\|}}{C}-R' + R''COCl \xrightarrow{Ph_3SnH} R-\underset{\underset{\displaystyle OCOR''}{|}}{CH}-R'$$

6-8 The Addition of Alcohols to Isocyanates



$$R-N{=}C{=}O + R'OH \longrightarrow R-NH-\underset{\underset{\displaystyle OR'}{|}}{C}{=}O$$

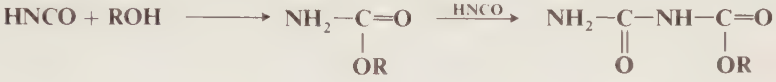
[59] Doyle, DeBruyn, and Kooistra, *J. Am. Chem. Soc.* **94,** 3659 (1972).

[60] Verzele, Acke, and Anteunis, *J. Chem. Soc.* 5598 (1963). For still another method, see Loim, Parnes, Vasil'eva, and Kursanov, *J. Org. Chem. USSR* **8,** 902 (1972).

[61] Kaplan, *J. Am. Chem. Soc.* **88,** 4970 (1966).

Substituted urethans (carbamates) are prepared when isocyanates are treated with alcohols.[36] This is an excellent reaction, of wide scope, and gives good yields. The carbamates are often used as derivatives of the alcohols. Cyanic acid HNCO gives unsubstituted carbamates. Addition of a second mole of HNCO gives *allophanates*, which make good derivatives for many alcohols.



$$\mathrm{HNCO + ROH \longrightarrow NH_2{-}\underset{\displaystyle OR}{\underset{|}{C}}{=}O \xrightarrow{HNCO} NH_2{-}\underset{\displaystyle O}{\underset{\|}{C}}{-}NH{-}\underset{\displaystyle OR}{\underset{|}{C}}{=}O}$$

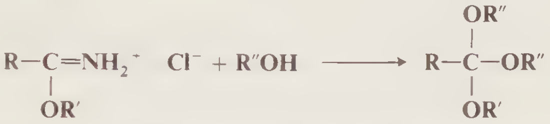
Allophanate

Polyurethans are made by combining compounds with two NCO groups with compounds containing two OH groups. Isothiocyanates similarly give thiocarbamates[62] RNHCSOR′, though they react slower than the corresponding isocyanates.

The details of the mechanism are poorly understood,[63] though the oxygen of the alcohol is certainly attacking the carbon of the isocyanate. Hydrogen bonding complicates the kinetic picture.[64] The addition of ROH to isocyanates can also be catalyzed by organometallic compounds.[65]

OS **I,** 140; **V,** 162; **51,** 112.

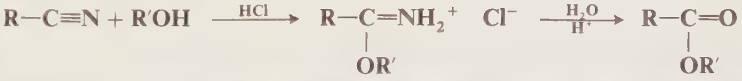
6-9 The Reaction between Imino Ester Salts and Alcohols



$$\mathrm{R{-}\underset{\displaystyle OR'}{\underset{|}{C}}{=}NH_2^+\ \ Cl^- + R''OH \longrightarrow R{-}\overset{\displaystyle OR''}{\overset{|}{\underset{\displaystyle OR'}{\underset{|}{C}}}}{-}OR''}$$

Imino ester salts (prepared by reaction **6-10**) react with alcohols to give ortho esters.[66] The reaction gives good yields.

6-10 Alcoholysis of Nitriles



$$\mathrm{R{-}C{\equiv}N + R'OH \xrightarrow{HCl} R{-}\underset{\displaystyle OR'}{\underset{|}{C}}{=}NH_2^+\ \ Cl^- \xrightarrow[H^+]{H_2O} R{-}\underset{\displaystyle OR'}{\underset{|}{C}}{=}O}$$

The addition of dry HCl to a mixture of a nitrile and an alcohol, in the absence of water, leads to the hydrochloride salt of an imino ester (imino esters are also called imidates and imino ethers). This reaction is called the *Pinner synthesis*.[67] The salt can be converted to the free imino ester by treatment with a weak base such as sodium bicarbonate, or it can be hydrolyzed with water and an acid catalyst to the corresponding carboxylic ester. If the latter is desired, water may be present from the beginning, in which case aqueous HCl can be used and the need for adding gaseous HCl is eliminated. Imino esters can also be prepared from nitriles with basic catalysts.[68]

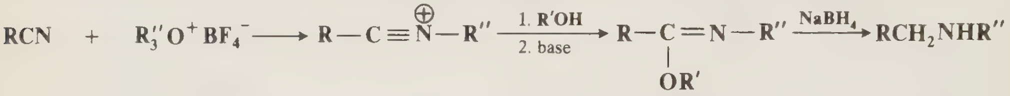
[68] Schaefer and Peters, *J. Org. Chem.* **26,** 412 (1961).

This reaction is of broad scope and is good for aliphatic, aromatic, and heterocyclic R and for nitriles with oxygen-containing functional groups. The application of the reaction to nitriles containing a carboxyl group constitutes a good method for the synthesis of mono esters of dicarboxylic acids with the desired group esterified and with no diester or diacid present. Addition of alcohols to nitrilium salts (prepared by treatment of nitriles with $R_3O^+ \quad BF_4^-$, see p. 373) gives



$$\mathrm{RCN} + \mathrm{R_3''O^+BF_4^-} \longrightarrow \mathrm{R{-}C{\equiv}\overset{\oplus}{N}{-}R''} \xrightarrow[\text{2. base}]{\text{1. R'OH}} \mathrm{R{-}\underset{\displaystyle OR'}{\underset{|}{C}}{=}N{-}R''} \xrightarrow{\mathrm{NaBH_4}} \mathrm{RCH_2NHR''}$$

N-alkylimino esters.[69] These imino esters can be reduced with $NaBH_4$ to yield secondary amines[70] (see also reactions **6-28, 6-29**).

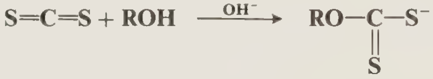
Cyanogen chloride reacts with alcohols in the presence of an acid catalyst such as dry HCl or $AlCl_3$ to give carbamates:[71]

$$\mathrm{ClCN + 2ROH \xrightarrow[\text{or } AlCl_3]{HCl} ROCONH_2 + RCl}$$

ROH can also be added to nitriles in another manner (reaction **6-57**).

OS **I**, 5, 270; **II**, 284, 310; **IV**, 645.

6-11 The Formation of Xanthates



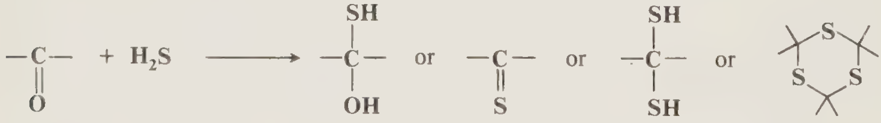
$$\mathrm{S{=}C{=}S + ROH \xrightarrow{OH^-} RO{-}\underset{\displaystyle S}{\underset{\|}{C}}{-}S^-}$$

The addition of alcohols to carbon disulfide in the presence of a base produces xanthates. The base is often OH^-, but in some cases better results can be obtained by using methylsulfinyl carbanion $MeSOCH_2^-$.[72] In a similar manner, alkoxide ions add to CO_2 to give carbonate ester salts $ROCOO^-$.

OS **V**, 439; **50**, 9.

C. Sulfur Nucleophiles

6-12 The Addition of H_2S and Mercaptans to Carbonyl Compounds



11 **12** **13** **14**

The addition of H_2S to an aldehyde or ketone may result in a variety of products.[73] The most usual product is the trithiane **14**.[74] α-Hydroxy thiols (**11**) can be prepared from polychloro and polyfluoro aldehydes and ketones.[75] Apparently **11** are stable only when prepared from these compounds, and not even for all of them. Thioketones[76] (**12**) can be prepared from certain ketones, such as diaryl ketones, by treatment with H_2S and an acid catalyst, usually HCl. They are often unstable and tend to trimerize (to **14**) or to react with air. Thioaldehydes are even less stable and apparently have never been prepared. Thioketones can also be prepared by treatment of ketones with P_4S_{10}.[77] *gem*-Dithiols (**13**) are much more stable than the corresponding hydrates or α-hydroxy thiols.[78] They have been prepared by the treatment of ketones with H_2S under pressure[79] and under mild conditions with HCl as a catalyst.[80] *gem*-Dithiols can also be prepared by the treatment of imines with H_2S,[81] and this can be accomplished without isolation of the imine if the aldehyde or ketone is treated with H_2S in the presence of ammonia or an amine.[82] In some cases *gem*-dithiols can be converted to thioketones by elimination of H_2S.[83]

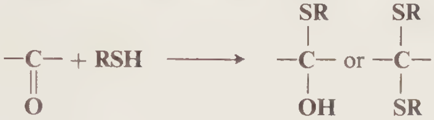
Mercaptans add to aldehydes and ketones to give hemimercaptals (**15**) and mercaptals[84] (**16**).[85] Hemimercaptals are ordinarily unstable[86] though they are more stable than the corresponding hemiacetals and can be isolated in certain cases.[87] Mercaptals, like acetals, are stable in the presence of bases, except that a strong base can remove the aldehyde proton, if there is one[88] (see reaction **0-99**). A common method for the protection of ketones involves treatment with ethanedithiol to give a cyclic thioketal.[88a] After subsequent reactions involving the R or R′ group, the protecting group can then be removed by reaction **0-7**. Alternatively, the thioketal can be desulfurized with Raney nickel (reaction **4-37**), giving the overall conversion C═O → CH_2. The C═O group of lactones and esters can be protected by a somewhat different, though related, procedure.[89] Mercaptals can also be prepared from aldehydes or ketones by treatment with orthothioborates



$$\underset{\Vert \atop \mathrm{O}}{-\mathrm{C}-} + \mathrm{RSH} \longrightarrow \underset{\mid \atop \mathrm{OH}}{\overset{\mathrm{SR} \atop \mid}{-\mathrm{C}-}} \text{ or } \underset{\mid \atop \mathrm{SR}}{\overset{\mathrm{SR} \atop \mid}{-\mathrm{C}-}}$$

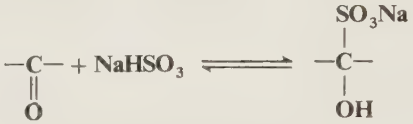
6-13 Formation of Bisulfite Addition Products



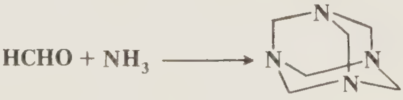
$$-\underset{\substack{\|\\ O}}{C}- + NaHSO_3 \rightleftharpoons -\overset{\substack{SO_3Na\\ |}}{\underset{\substack{|\\ OH}}{C}}-$$

Bisulfite addition products are formed from aldehydes, methyl ketones, cyclic ketones (generally seven-membered and smaller rings), α-keto esters, and isocyanates, upon treatment with sodium bisulfite. Most other ketones do not undergo the reaction, probably for steric reasons. The reaction is reversible (by treatment of the addition product with either acid or base) and is useful for the purification of the starting compounds, since the addition products are soluble in water and many of the impurities are not.

OS **I**, 241, 336; **III**, 438; **IV**, 903; **V**, 437.

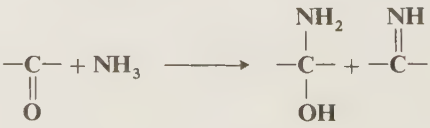
D. Attack by NH_2, NHR, or NR_2 (Addition of NH_3, RNH_2, R_2NH)

6-14 The Addition of Ammonia to Aldehydes and Ketones



17

The addition of ammonia to aldehydes or ketones does not generally give useful products. According to the pattern followed by analogous nucleophiles, the initial products would be expected to be *hemiaminals* (also called "aldehyde ammonias") (**18**) and/or imines (**19**):



$$-\underset{\substack{\|\\ O}}{C}- + NH_3 \longrightarrow -\overset{\substack{NH_2\\ |}}{\underset{\substack{|\\ OH}}{C}}- + -\overset{\substack{NH\\ \|}}{C}-$$

18 **19**

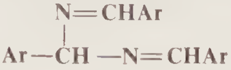
[93] Rinzema, Stoffelsma, and Arens, *Recl. Trav. Chim. Pays-Bas* **79**, 354 (1959).

However, these compounds are generally unstable. Imines with a hydrogen on the nitrogen spontaneously polymerize and have never been isolated in this reaction in the pure state, though cobalt complexes of such imines have been prepared and are stable enough to be storable under an inert-gas atmosphere at room temperature.[94] Stable hemiaminals can be prepared from polychlorinated and polyfluorinated aldehydes and ketones. Aside from these, when stable compounds *are* prepared in this reaction, they are the result of combinations and condensations of one or more molecules of **18** and or **19** with each other or with additional molecules of ammonia or carbonyl compound. The most important example of such a product is hexamethylenetetramine (**17**), prepared from ammonia and formaldehyde. Analogs of this compound have been prepared from aromatic aldehydes and ammonium carbonate.[95] Aromatic aldehydes give hydrobenzamides (**20**) derived from three molecules of aldehyde and two of ammonia.[96] Similar compounds can be prepared from aldehydes of the form R_2CHCHO and R_3CCHO.[97] Acetaldehyde and α,β-unsaturated aldehydes give alkylpyridine derivatives.[98] For example, 5-ethyl-2-picoline (**21**) can be obtained from acetaldehyde. Cyclic trimers of **19** can sometimes be isolated as crystalline compounds, but these are unstable in solution.[99]



$$\mathrm{Ar{-}\overset{\displaystyle N{=}CHAr}{\overset{|}{C}H}{-}N{=}CHAr}$$

20

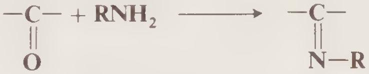
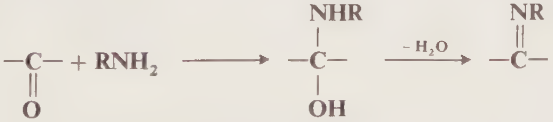
6-15 The Addition of Amines to Aldehydes and Ketones



$$\underset{\displaystyle O}{\underset{\|}{-C-}} + RNH_2 \longrightarrow \underset{\displaystyle N-R}{\underset{\|}{-C-}}$$

Primary, secondary, and tertiary amines can add to aldehydes[100] and ketones to give different kinds of products. Primary amines give imines.[101] In contrast to imines in which the nitrogen is attached to a hydrogen (reaction **6-14**), these imines are stable enough for isolation. However, in most cases they rapidly decompose or polymerize unless there is at least one aryl group on the nitrogen or the carbon. When there is an aryl group, the compounds are quite stable. They are usually called *Schiff bases*, and this reaction is the best way to prepare them. The reaction is straightforward and proceeds in high yields. The initial N-substituted hemiaminals lose water to give the stable Schiff bases:



$$\underset{\displaystyle O}{\underset{\|}{-C-}} + RNH_2 \longrightarrow \overset{\displaystyle NHR}{\overset{|}{\underset{\displaystyle OH}{\underset{|}{-C-}}}} \xrightarrow{-H_2O} \overset{\displaystyle NR}{\overset{\|}{-C-}}$$

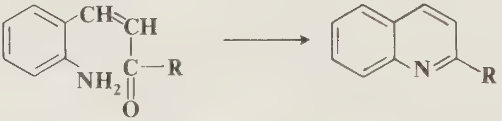
For a review of the chemistry of imines, see Layer, *Chem. Rev.* **63,** 489–510 (1963).

In general, ketones react more slowly than aldehydes, and higher temperatures and longer reaction times are often required. In addition, the equilibrium must often be shifted, usually by removal of the water, either azeotropically by distillation, or with a drying agent such as $TiCl_4$,[102] or with a molecular sieve.[103]

The reaction is often used to effect ring closure. The *Friedlander quinoline synthesis* is an example:



When secondary amines are added to aldehydes or ketones, the initially formed N,N-disubstituted hemiaminals (**22**) cannot lose water in the same way, and it is possible to isolate them.[104] However, they are generally unstable, and under the reaction conditions usually react further. If no α-hydrogen is present, **22** is converted to the more stable *aminal* (**23**). However, if an α-hydrogen is present, water (from **22**) or RNH_2 (from **23**) can be lost in that direction to give an enamine:[105]

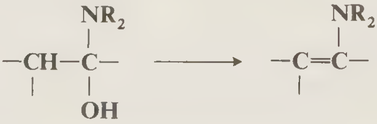
$$\begin{array}{c} NF_2 \\ | \\ -C- \\ | \\ NF_2 \end{array}$$

26



$$\begin{array}{c} \quad NR_2 \\ \quad | \\ -CH-C- \\ |\quad\ | \\ \quad OH \end{array} \longrightarrow \begin{array}{c} \quad NR_2 \\ \quad | \\ -C{=}C- \\ | \quad\ \ \end{array}$$

This is the most common method for the preparation of enamines and usually takes place when an aldehyde or ketone containing an α-hydrogen is treated with a secondary amine. The water is usually removed azeotropically or with a drying agent,[106] but molecular sieves can also be used.[107] Secondary amine perchlorates react with aldehydes and ketones to give iminium salts (**7**, p. 807).[108] Tertiary amines can only give salts (**24**). Difluoramine NF_2H adds to aldehydes and ketones to give stable α-difluoraminocarbinols (**25**)[109] or, if concentrated H_2SO_4 is present, *gem*-bis(difluoro)amines (**26**).[110]

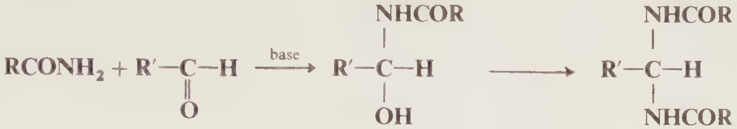
Amides can add to aldehydes in the presence of bases (so the nucleophile is actually $\mathrm{RCONH^-}$) or acids to give acylated amino alcohols, which often react further to give alkylidene or arylidene bisamides:[111]



$$\mathrm{RCONH_2 + R'-\underset{\underset{O}{\|}}{C}-H \xrightarrow{base} R'-\overset{\overset{NHCOR}{|}}{\underset{\underset{OH}{|}}{C}}-H \longrightarrow R'-\overset{\overset{NHCOR}{|}}{\underset{\underset{NHCOR}{|}}{C}}-H}$$

If the R′ group contains an α-hydrogen, water may split out.

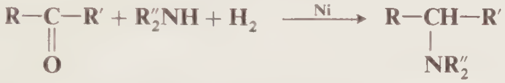
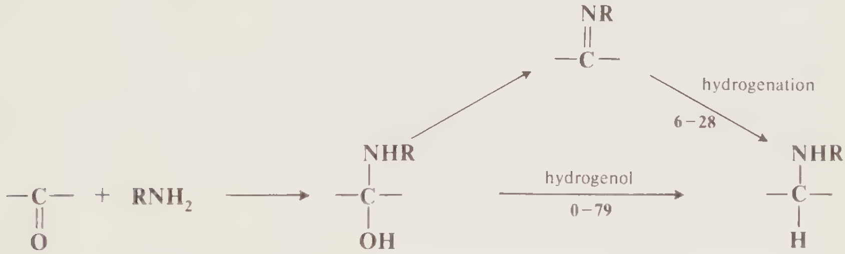
6-16 Reductive Alkylation of Ammonia or Amines



$$\mathrm{R-\underset{\underset{O}{\|}}{C}-R' + R''_2NH + H_2 \xrightarrow{Ni} R-\underset{\underset{NR''_2}{|}}{CH}-R'}$$

When an aldehyde or a ketone is treated with ammonia or a primary or secondary amine in the presence of hydrogen and a hydrogenation catalyst (heterogeneous or homogeneous[112]), *reductive alkylation* takes place.[113] The reaction can formally be regarded as occurring in the following manner (shown for a primary amine), which probably *does* correspond to the actual sequence of steps:[114]



For ammonia and primary amines there are thus two possible pathways, but when secondary amines are involved, only the hydrogenolysis pathway is possible. Other reducing agents can be used instead of hydrogen and a catalyst, among them zinc and HCl, sodium cyanoborohydride $\mathrm{NaBH_3CN}$,[115] sodium borohydride,[116] iron pentacarbonyl and alcoholic KOH,[117] and formic acid. When the last is used, the process is called the *Wallach reaction.* In the particular case where primary or secondary amines are reductively methylated with *formaldehyde* and formic acid, the method is called the *Eschweiler-Clarke procedure*. It is possible to use ammonium (or amine) salts of formic acid, or formamides, as a substitute for the Wallach conditions. This method is called the *Leuckart reaction*,[118] and in this case the products obtained are often the N-formyl derivatives of the amines instead of the free amines. Primary and secondary aromatic amines can be N-ethylated (e.g., ArNHR → ArNREt) by treatment with $NaBH_4$ in acetic acid.[119]

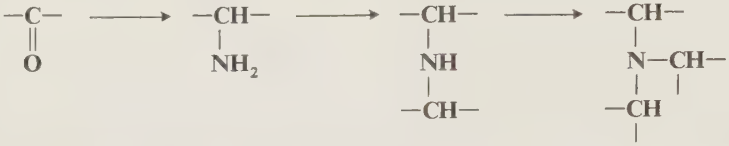
When the reagent is ammonia, it is possible for the initial product to react again and for this product to react again, so that secondary and tertiary amines are usually obtained as side products:



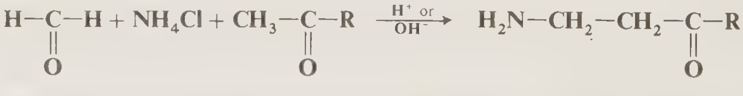
Similarly, primary amines give tertiary as well as secondary amines. In order to minimize this, the aldehyde or ketone is treated with an excess of ammonia or primary amine (unless of course the higher amine is desired).

Primary amines have been prepared from many aldehydes with at least five carbons and from many ketones by treatment with ammonia and a reducing agent. Smaller aldehydes are usually too reactive to permit isolation of the primary amine. Secondary amines have been prepared by both possible procedures: 2 moles of ammonia and 1 mole of aldehyde or ketone, and 1 mole of primary amine and 1 mole of carbonyl compound, the latter method being better for all but aromatic aldehydes. Tertiary amines can be prepared in three ways, but the method is seldom carried out with 3 moles of ammonia and 1 mole of carbonyl compound. Much more often they are prepared from primary or secondary amines.[120] The most common method for this purpose is the Eschweiler-Clarke procedure; i.e., treatment of the primary or secondary amine with formaldehyde and formic acid. Amines of the form $RNMe_2$ and R_2NMe are prepared in this manner.[121] Another method for accomplishing the conversions $RNH_2 \rightarrow RNMe_2$ and $R_2NH \rightarrow R_2NMe$ is to treat the amine with aqueous formaldehyde and $NaBH_4$[122] or $NaBH_3CN$.[123]

Reductive alkylation has also been carried out on nitro, nitroso, azo, and other compounds which are reduced in situ to primary or secondary amines.

OS **I,** 347, 528, 531; **II,** 503; **III,** 328, 501, 717, 723; **IV,** 603; **V,** 552; **52,** 124.

6-17 The Mannich Reaction



$$\underset{\displaystyle O}{\overset{}{H-\underset{\|}{C}-H}} + NH_4Cl + CH_3-\underset{\underset{\displaystyle O}{\|}}{C}-R \xrightarrow[OH^-]{H^+\text{ or}} H_2N-CH_2-CH_2-\underset{\underset{\displaystyle O}{\|}}{C}-R$$

In the *Mannich reaction*, formaldehyde (or sometimes another aldehyde) is condensed with ammonia, in the form of its salt, and a compound containing an active hydrogen.[124] This can formally be considered as an addition of ammonia to give H_2NCH_2OH, followed by a nucleophilic substitution (see the discussion of the mechanism on p. 822). Instead of ammonia, the reaction can be carried out with salts of primary or secondary amines, or with amides,[125] in which cases the product is substituted on the nitrogen with R, R_2, and RCO, respectively. Arylamines do not normally give the reaction. In any case, the product is referred to as a *Mannich base*. Many active hydrogen compounds give the reaction. Among these are the following types, with the active hydrogen underlined:

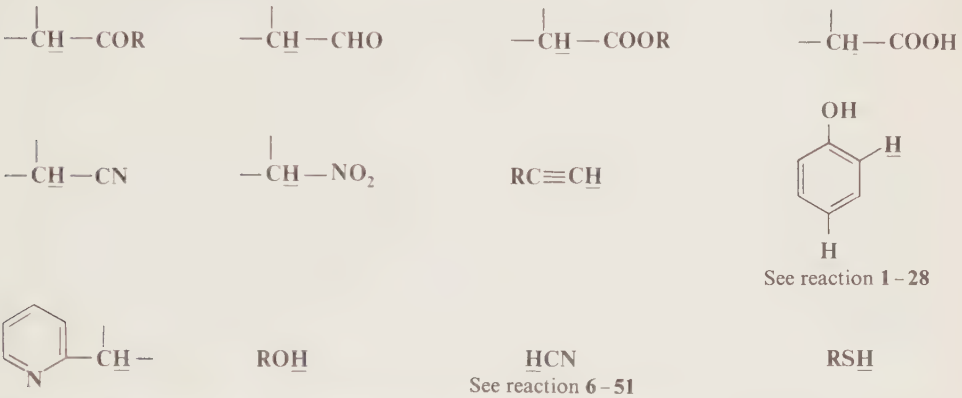
Benjamin, Inc., New York, 1972. For a review of Mannich reactions in which the active-hydrogen component is a nitro compound, see Baer and Urbas, in Feuer, "The Chemistry of the Nitro and Nitroso Groups," pp. 117–130, Interscience Publishers, New York, 1970.



$-\overset{|}{C}\underline{H}-COR$ $-\overset{|}{C}\underline{H}-CHO$ $-\overset{|}{C}\underline{H}-COOR$ $-\overset{|}{C}\underline{H}-COOH$

$-\overset{|}{C}\underline{H}-CN$ $-\overset{|}{C}\underline{H}-NO_2$ $RC{\equiv}C\underline{H}$

See reaction **1-28**

$RO\underline{H}$ $\underline{H}CN$ $RS\underline{H}$

See reaction **6-51**

The Mannich base can react further, in three ways. If it is a primary or secondary amine, then it may condense with one or two additional molecules of aldehyde and active compound, e.g.,

$$H_2NCH_2CH_2COR \xrightarrow[CH_3COR]{HCHO} HN(CH_2CH_2COR)_2 \xrightarrow[CH_3COR]{HCHO} N(CH_2CH_2COR)_3$$

If the active hydrogen compound has two or three active hydrogens, the Mannich base may condense with one or two additional molecules of aldehyde and ammonia or amine, e.g.,

$$H_2NCH_2CH_2COR \xrightarrow[NH_3]{HCHO} (H_2NCH_2)_2CHCOR \xrightarrow[NH_3]{HCHO} (H_2NCH_2)_3CCOR$$

Another further reaction consists of condensation of the Mannich base with excess formaldehyde:

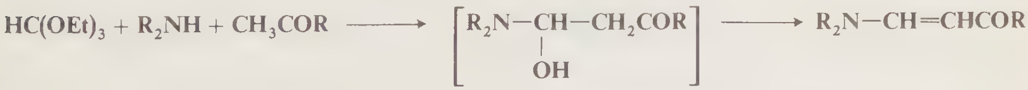
$$H_2NCH_2CH_2COR + HCHO \longrightarrow H_2C{=}NCH_2CH_2COR$$

Sometimes it is possible to obtain these products of further condensation as the main products of the reaction. At other times they are side products.

When the Mannich base contains an amino group β to a carbonyl (and it usually does), ammonia is easily eliminated and this is a route to α,β-unsaturated aldehydes, ketones, esters, etc.:

$$H_2NCH_2CH_2COR \xrightarrow{\Delta} H_2C{=}CHCOR$$

Enamines can be prepared by a Mannich reaction involving a secondary amine and formic acid (in the form of ethyl orthoformate) instead of formaldehyde, e.g.,

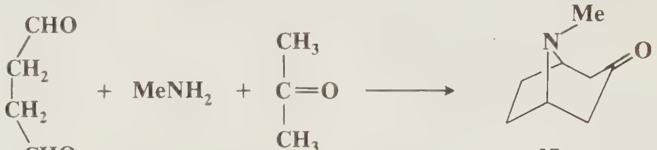


$$HC(OEt)_3 + R_2NH + CH_3COR \longrightarrow \left[R_2N-\underset{OH}{\underset{|}{C}H}-CH_2COR\right] \longrightarrow R_2N-CH{=}CHCOR$$

---

[125] Hellmann, *Angew. Chem.* **69,** 463 (1957), *Newer Methods Prep. Org. Chem.* **2,** 277–302 (1963).

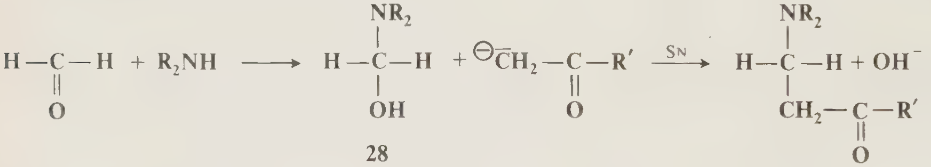
The Mannich reaction is an important biosynthetic route to natural products, mainly alkaloids, and some of these routes have been duplicated in the laboratory. A classic example is the synthesis of tropinone by Robinson in 1917. Atropine, a natural product, is an ester of tropic acid $\mathrm{PhCH(COOH)CH_2OH}$ and tropine. Tropine is a secondary alcohol which can be oxidized to the corresponding ketone, tropinone (**27**). Robinson synthesized tropinone by a Mannich reaction involving succindialdehyde, methylamine, and acetone:[126]



27

Over the years there has been much controversy about the mechanism of the Mannich reaction, especially whether the aldehyde is first attacked by the active hydrogen compound (as in reaction **6-40**) or by the ammonia or amine (as in reaction **6-15**). It is now generally agreed that the latter pathway is the correct one. Studies of the reaction kinetics have led to the following mechanistic proposals:[127]

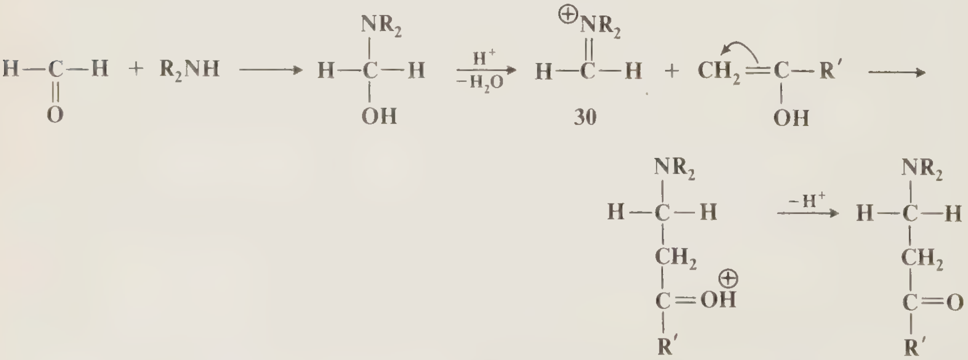
The base-catalyzed reaction



$$\underset{\overset{\|}{\mathrm{O}}}{\mathrm{H{-}C{-}H}} + \mathrm{R_2NH} \longrightarrow \underset{\underset{\mathbf{28}}{\mathrm{OH}}}{\overset{\mathrm{NR_2}}{\mathrm{H{-}C{-}H}}} + {}^{\ominus}\mathrm{CH_2{-}}\underset{\overset{\|}{\mathrm{O}}}{\mathrm{C}}\mathrm{{-}R'} \xrightarrow{\mathrm{S_N}} \underset{\mathrm{CH_2{-}}\underset{\overset{\|}{\mathrm{O}}}{\mathrm{C}}\mathrm{{-}R'}}{\overset{\mathrm{NR_2}}{\mathrm{H{-}C{-}H}}} + \mathrm{OH^-}$$

There is evidence that in basic media the intermediate which undergoes the nucleophilic substitution may be $\mathrm{H_2C(NR_2)_2}$ (**29**) instead of **28**,[128] but it has been shown that **28** are more reactive than **29** in this type of step.[129]

The acid-catalyzed reaction



$$\underset{\overset{\|}{\mathrm{O}}}{\mathrm{H{-}C{-}H}} + \mathrm{R_2NH} \longrightarrow \underset{\mathrm{OH}}{\overset{\mathrm{NR_2}}{\mathrm{H{-}C{-}H}}} \xrightarrow[-\mathrm{H_2O}]{\mathrm{H^+}} \underset{\mathbf{30}}{\overset{\overset{\oplus}{\mathrm{NR_2}}}{\overset{\|}{\mathrm{H{-}C{-}H}}}} + \mathrm{CH_2{=}}\underset{\mathrm{OH}}{\mathrm{C}}\mathrm{{-}R'} \longrightarrow$$

$$\underset{\underset{\underset{\mathrm{R'}}{\mathrm{C{=}\overset{\oplus}{O}H}}}{\mathrm{CH_2}}}{\overset{\mathrm{NR_2}}{\mathrm{H{-}C{-}H}}} \xrightarrow{-\mathrm{H^+}} \underset{\underset{\underset{\mathrm{R'}}{\mathrm{C{=}O}}}{\mathrm{CH_2}}}{\overset{\mathrm{NR_2}}{\mathrm{H{-}C{-}H}}}$$

According to this mechanism, it is the free amine and not the salt which reacts, even in acid solution; and the active-hydrogen compound (in the acid-catalyzed process) reacts as the enol when that is possible. This latter step is similar to that in reaction **2-4.** There is kinetic evidence for the intermediacy of the iminium ion (**30**).[130]

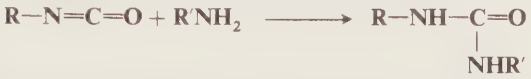
---

[126] Robinson, *J. Chem. Soc.* **111**, 762 (1917).
[127] Cummings and Shelton, *J. Org. Chem.* **25**, 419 (1960).
[128] Burckhalter, Wells, and Mayer, *Tetrahedron Lett.* 1353 (1964).
[129] Fernandez, *Tetrahedron Lett.* 2889 (1964).

When it is desired to use an unsymmetrical ketone as the active-hydrogen component, it is possible to get two products. Regioselectivity has been obtained by treatment of the ketone with preformed iminium ions:[131] the use of $Me_2\overset{\oplus}{N}{=}CH_2 \quad CF_3COO^-$ in CF_3COOH gives substitution at the more highly substituted position, while with iso-$Pr_2\overset{\oplus}{N}{=}CH_2 \quad ClO_4^-$ the reaction takes place at the less highly substituted position.[132] Regioselective synthesis of Mannich bases can also be carried out in an indirect manner (see reaction **6-36**). Also see reactions **6-51** and **1-28.**

OS **III,** 305; **IV,** 281, 515, 816.

6-18 The Addition of Amines to Isocyanates

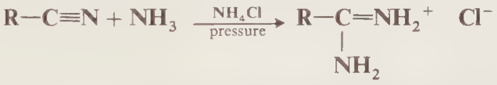


$$R{-}N{=}C{=}O + R'NH_2 \longrightarrow R{-}NH{-}\underset{\displaystyle NHR'}{\underset{|}{C}}{=}O$$

Ammonia and primary and secondary amines can be added to isocyanates to give substituted ureas.[36] Isothiocyanates give thioureas. This is an excellent method for the preparation of ureas and thioureas, and these compounds are often used as derivatives for primary and secondary amines. Cyanic acid HNCO also gives the reaction; usually its salts, e.g., NaNCO, are used. Wöhler's famous synthesis of urea involved the addition of ammonia to a salt of cyanic acid.[133]

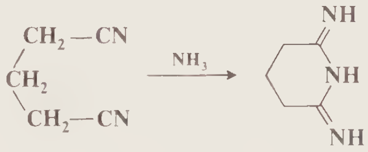
OS **II,** 79; **III,** 76, 617, 735; **IV,** 49, 180, 213, 515, 700; **V,** 555, 801, 802, 967; **51,** 121.

6-19 The Addition of Ammonia or Amines to Nitriles



$$R{-}C{\equiv}N + NH_3 \xrightarrow[\text{pressure}]{NH_4Cl} R{-}\underset{\displaystyle NH_2}{\underset{|}{C}}{=}NH_2^+ \quad Cl^-$$

Unsubstituted amidines (in the form of their salts) can be prepared by addition of ammonia to nitriles.[133a] Many amidines have been made in this way.[134] Dinitriles of suitable chain length may give imidines:[135]



Primary and secondary amines can be used instead of ammonia, to give substituted amidines, but only if the nitrile contains electron-withdrawing groups; e.g., Cl_3CCN gives the reaction. Ordinary nitriles do not react, and, in fact, acetonitrile is often used as a solvent in this reaction.[136] However, aniline can be added to benzonitrile with $AlCl_3$ as catalyst. The addition of ammonia to cyanamide NH_2CN gives guanidine $(NH_2)_2C{=}NH$.

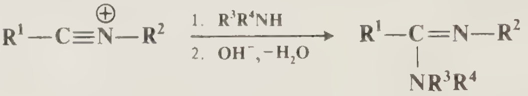
[135] Elvidge, Linstead, and Salaman, *J. Chem. Soc.* 208 (1959).

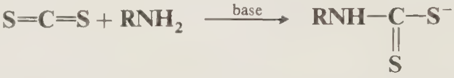
Ammonia and primary and secondary amines add to nitrilium salts to give substituted amidines (shown for secondary amines):[137]



$$R^1{-}C{\equiv}\overset{\oplus}{N}{-}R^2 \xrightarrow[2.\ OH^-,\ -H_2O]{1.\ R^3R^4NH} R^1{-}\underset{\displaystyle NR^3R^4}{\underset{|}{C}}{=}N{-}R^2$$

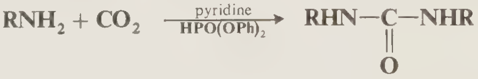
OS **I,** 302 [but also see OS **V,** 589]; **IV,** 245, 247, 515, 566, 769. See also OS **V,** 39.

6-20 The Addition of Amines to Carbon Disulfide and Carbon Dioxide



$$S{=}C{=}S + RNH_2 \xrightarrow{\text{base}} RNH{-}\underset{\displaystyle S}{\underset{\|}{C}}{-}S^-$$

Salts of dithiocarbamic acid can be prepared by the addition of primary amines to carbon disulfide. This reaction is similar to reaction **6-11.** H_2S can be eliminated from the product, directly or indirectly, to give isothiocyanates RNCS. Isothiocyanates can be obtained directly by the reaction of primary amines and CS_2 in pyridine in the presence of dicyclohexylcarbodiimide.[138] In the presence of diphenyl phosphite and pyridine, primary amines add to CO_2 and to CS_2 to give, respectively, symmetrically substituted ureas and thioureas:[139]

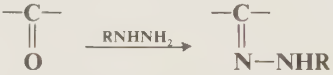


$$RNH_2 + CO_2 \xrightarrow[HPO(OPh)_2]{\text{pyridine}} RHN{-}\underset{\displaystyle O}{\underset{\|}{C}}{-}NHR$$

OS **I,** 447; **III,** 360, 394, 599, 763; **V,** 223.

E. Other Nitrogen Nucleophiles

6-21 The Addition of Hydrazine Derivatives to Carbonyl Compounds



$$-\underset{\displaystyle O}{\underset{\|}{C}}- \xrightarrow{RNHNH_2} -\underset{\displaystyle N{-}NHR}{\underset{\|}{C}}-$$

The product of condensation of a hydrazine and an aldehyde or ketone is called a *hydrazone*. Hydrazine itself gives hydrazones only with aryl ketones. With other aldehydes and ketones, either no useful product can be isolated, or the remaining NH_2 group condenses with a second mole of carbonyl compound to give an *azine*. This type of product is especially important for aromatic aldehydes:

$$ArCH{=}N{-}NH_2 + ArCHO \longrightarrow \underset{\text{An azine}}{ArCH{=}N{-}N{=}CHAr}$$

However, in some cases azines can be converted to hydrazones by treatment with excess hydrazine and NaOH.[140] Arylhydrazines, especially phenyl, *p*-nitrophenyl, and 2,4-dinitrophenyl, are used much more often and give the corresponding hydrazones with most aldehydes and ketones.[141]

[136] Grivas and Taurins, *Can. J. Chem.* **39,** 761 (1961).

[137] Fuks, *Tetrahedron Lett.* 2147, 2153 (1973).

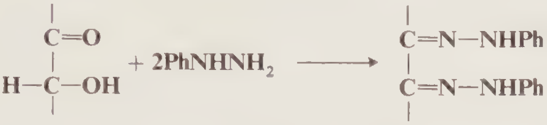
[138] Jochims and Seeliger, *Angew. Chem. Int. Ed. Engl.* **6,** 174 (1967) [*Angew. Chem.* **79,** 151]; Jochims, *Chem. Ber.* **101,** 1746 (1968). For another method, see Sakai, Aizawa, and Fujinami, *J. Org. Chem.* **39,** 1970 (1974).

[139] Yamazaki, Higashi, and Iguchi, *Tetrahedron Lett.* 1191 (1974).

[140] For example, see Day and Whiting, *Org. Synth.* **50,** 3 (1970).

[141] For a review of arylhydrazones, see Buckingham, *Q. Rev., Chem. Soc.* **23,** 37–56 (1969).

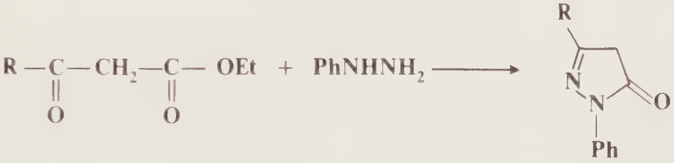
Since these are usually solids, they make excellent derivatives and are commonly employed for this purpose. α-Hydroxy aldehydes and ketones and α-dicarbonyl compounds give *osazones*, in which two adjacent carbons have carbon-nitrogen double bonds:



$$\begin{matrix} | \\ C{=}O \\ | \\ H{-}C{-}OH \\ | \end{matrix} + 2PhNHNH_2 \longrightarrow \begin{matrix} | \\ C{=}N{-}NHPh \\ | \\ C{=}N{-}NHPh \\ | \end{matrix}$$

An osazone

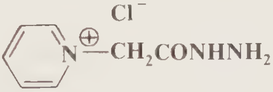
Osazones are particularly important in carbohydrate chemistry. In contrast to this behavior, β-diketones and β-keto esters give *pyrazoles* and *pyrazolones*, respectively (illustrated for β-keto esters):



Other hydrazine derivatives frequently used to prepare the corresponding hydrazone are semicarbazide $NH_2NHCONH_2$, in which case the hydrazone is called a semicarbazone, and *Girard's reagents T and P*, in which case the hydrazone is water-soluble because of the ionic group. Girard's reagents are often used for purification of carbonyl compounds.

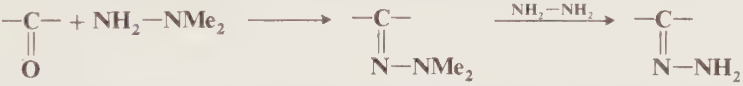
$Cl^- \quad Me_3NCH_2CONHNH_2$

Girard's reagent T



Girard's reagent P

Simple N-unsubstituted hydrazones can be obtained by an exchange reaction. The N,N-dimethylhydrazone is prepared first and then treated with hydrazine:[142]

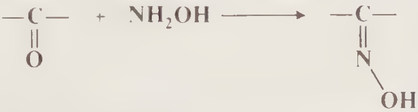


$$\underset{\displaystyle O}{\overset{}{\underset{\|}{-C-}}} + NH_2{-}NMe_2 \longrightarrow \underset{\displaystyle N{-}NMe_2}{\underset{\|}{-C-}} \xrightarrow{NH_2-NH_2} \underset{\displaystyle N{-}NH_2}{\underset{\|}{-C-}}$$

No azines are formed under these conditions.

OS **II,** 395; **III,** 96, 351; **IV,** 351, 377, 536, 884; **V,** 27, 258, 747, 929; **50,** 3, 102, **52,** 122; **55,** 52, 73. Also see OS **III,** 708; **50,** 6.

6-22 The Formation of Oximes



$$\underset{\displaystyle O}{\underset{\|}{-C-}} + NH_2OH \longrightarrow \underset{\displaystyle N{-}OH}{\underset{\|}{-C-}}$$

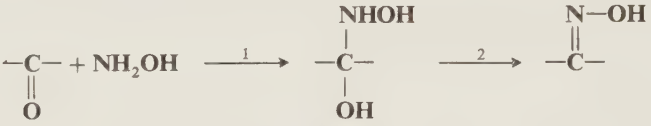
In a reaction very much like **6-21,** oximes can be prepared by the addition of hydroxylamine to aldehydes or ketones.[143] Derivatives of hydroxylamine, e.g., H_2NOSO_3H and $HON(SO_3Na)_2$, have also been used. For hindered ketones, such as hexamethylacetone, high pressures, e.g., 10,000 atm, may be necessary.[144] Another procedure, successful for hindered ketones, is to allow the ketone to stand with hydroxylamine and a strongly basic catalyst for 1 to 6 months. High yields of oximes are achieved in this way by those who have the patience to wait. Reactions which proceed over a long time but cannot be rushed by increase in temperature have been called *lethargic reactions*.[145]

---

[142] Newkome and Fishel, *J. Org. Chem.* **31,** 677 (1966).

[143] For a review, see Sandler and Karo, Ref. 53, vol. 3, pp. 372–381.

It has been shown[146] that the rate of formation of oximes is at a maximum at a pH which depends on the substrate but is usually about 4, and that the rate decreases as the pH is either raised or lowered from this point. We have previously seen (p. 309) that bell-shaped curves like this are often caused by changes in the rate-determining step. In this case, at low pH values step 2 is rapid (because it is acid-catalyzed), and step 1 is slow (and rate-determining) because under these acidic conditions most of the NH_2OH molecules have been converted to the conjugate NH_3OH^+ ions, which cannot attack the substrate. As the pH is slowly increased, the fraction of free NH_2OH molecules increases and consequently so does the reaction rate, until the maximum rate is reached at about pH = 4. As the rising pH has been causing an increase in the rate of step 1, it has also been causing a *decrease* in the rate of the acid-catalyzed step 2, although this latter process has not affected the overall rate since step 2 was still faster than step 1. However, when the pH goes above about 4, step 2 becomes rate-determining, and although the rate of step 1 is still increasing (as it will until essentially all the NH_2OH is unprotonated), it is now step 2 which determines the rate, and this step is slowed by the decrease in acid concentration. Thus the overall rate decreases as the pH rises beyond about 4. It is likely that similar considerations apply to the reaction of aldehydes and ketones with amines, hydrazines, and other nitrogen nucleophiles.[147] There is evidence that when the nucleophile is 2-methylthiosemicarbazide, there is a second change in the rate-determining step: above pH about 10 *basic* catalysis of step 2 has increased the rate of this step to the point where step 1 is again rate-determining.[148] Still a third change in rate-determining step has been found at about pH = 1, showing that at least in some cases step 1 actually consists of two steps: formation of a zwitterion, e.g., $HO\overset{\oplus}{N}H_2-\underset{|}{\overset{|}{C}}-O^{\ominus}$ in the case shown above, and conversion of this to **31**.[149] The intermediate **31** has been detected by nmr in the reaction between NH_2OH and acetaldehyde.[149a]



$$-\underset{\underset{O}{\|}}{C}- + NH_2OH \xrightarrow{1} -\underset{\underset{OH}{|}}{\overset{\overset{NHOH}{|}}{C}}- \xrightarrow{2} -\overset{\overset{N-OH}{\|}}{C}-$$

31

Ketones can also be converted to oximes by treatment with other oximes, in a transoximation reaction.[150]

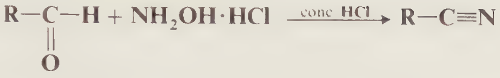
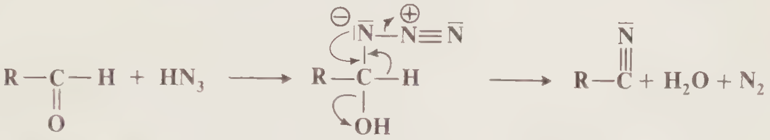
6-23 The Conversion of Aldehydes to Nitriles



$$\mathrm{R{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}H + NH_2OH{\cdot}HCl \xrightarrow{\text{conc HCl}} R{-}C{\equiv}N}$$

Aldehydes can be converted to nitriles in one step by refluxing with hydroxylamine hydrochloride and either concentrated HCl[151] or sodium formate in formic acid or sodium acetate in acetic acid.[152] The reaction is a combination of reactions **6-22** and **7-39.** Direct nitrile formation has also been accomplished with certain derivatives of NH_2OH, notably N,O-bistrifluoroacetylhydroxylamine $F_3CCONHOCOCF_3$[153] and NH_2OSO_2OH.[154] Another method involves treatment with hydrazoic acid, though the Schmidt reaction (**8-20**) may compete. A possible rationalization is the following:



Aromatic aldehydes have been converted to nitriles in good yield with $NH_4H_2PO_4$ and nitropropane in acetic acid[155] and with ammonia and iodine or lead tetraacetate.[156] Also see reaction **9-6.**

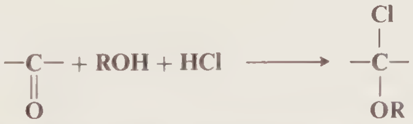
OS V, 656.

6-24 The Addition of Nitriles to Aldehydes

See reaction **6-61.**

F. Halogen Nucleophiles

6-25 The Formation of α-Halo Ethers



$$\mathrm{{-}\underset{\underset{\displaystyle O}{\|}}{C}{-} + ROH + HCl \longrightarrow {-}\overset{\displaystyle Cl}{\underset{\displaystyle OR}{C}}{-}}$$

α-Halo ethers can be prepared by treatment of aldehydes and ketones with an alcohol and HX, though α-halo ethers from simple aldehydes such as formaldehyde are unstable and the reaction tends to reverse. The reaction is applicable to aliphatic aldehydes and ketones and to primary and secondary alcohols. Aromatic aldehydes and ketones react poorly.[157]

The addition of HX to an aldehyde or ketone gives α-halo alcohols, which are usually unstable, though exceptions are known, especially with perfluoro and perchloro species. For example, **32** (X = any of the four halogens) were prepared in this way.[158] Unstable α-halo alcohols may be

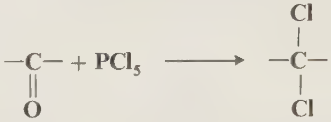
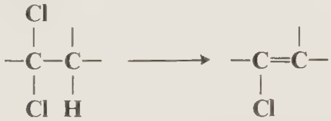
6-26 The Formation of *gem*-Dihalides from Aldehydes and Ketones



$$-\underset{\underset{O}{\|}}{C}- + PCl_5 \longrightarrow -\overset{\overset{Cl}{|}}{\underset{\underset{Cl}{|}}{C}}-$$

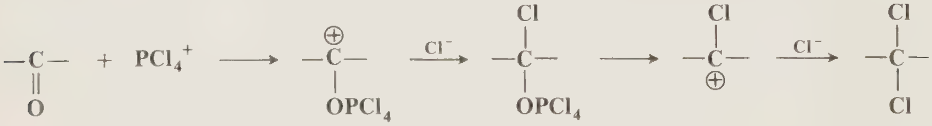
Aliphatic aldehydes and ketones can be converted to *gem*-dichlorides by treatment with PCl_5. The reaction fails for perhalo ketones.[159] If the aldehyde or ketone has an α-hydrogen, elimination of HCl may follow and a vinyl chloride is a frequent side product:[160]



$$-\overset{\overset{Cl}{|}}{\underset{\underset{Cl}{|}}{C}}-\overset{|}{\underset{\underset{H}{|}}{C}}- \longrightarrow -\underset{\underset{Cl}{|}}{C}=\overset{|}{C}-$$

These compounds may even become the main products.[161] PBr_5 does not give good yields of *gem*-dibromides.

The mechanism of *gem*-dichloride formation involves initial attack of PCl_4^+ (which is present in solid PCl_5) at the oxygen, followed by addition of Cl^- to the carbon:[162]



$$-\underset{\underset{O}{\|}}{C}- + PCl_4^+ \longrightarrow -\overset{\oplus}{\underset{\underset{OPCl_4}{|}}{C}}- \xrightarrow{Cl^-} -\overset{\overset{Cl}{|}}{\underset{\underset{OPCl_4}{|}}{C}}- \longrightarrow -\overset{\overset{Cl}{|}}{\underset{\oplus}{C}}- \xrightarrow{Cl^-} -\overset{\overset{Cl}{|}}{\underset{\underset{Cl}{|}}{C}}-$$

33 34 35

This chloride ion may come from PCl_6^- (which is also present in solid PCl_5). There follows a two-step S_N1 process. Alternatively, **33** can be converted to **35** without going through **34,** by an S_Ni process.

This reaction has sometimes been performed on esters, though these compounds very seldom undergo any addition to the C=O bond. An example is the conversion of $F_3CCOOPh$ to F_3CCCl_2OPh.[163] However, formates commonly give the reaction. PCl_5 converts hydrazides $RCONHNH_2$ to di- or trichlorides $RCHCl_2$ or $RCCl_3$.[164] R may be alkyl or aryl.

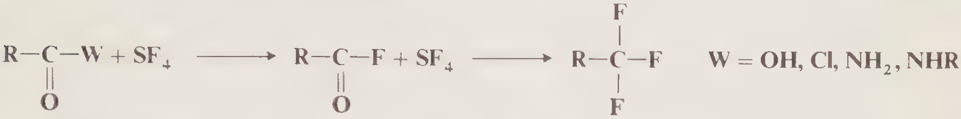
[163] Kirsanov and Molosnova, *J. Gen. Chem. USSR* **28,** 31 (1958); Clark and Simons, *J. Org. Chem.* **26,** 5197 (1961).

[164] Mikhailov, Matyushecheva, Derkach, and Yagupol'skii, *J. Org. Chem. USSR* **6,** 147 (1970); Yagupol'skii, Mikhailov, and Matyushecheva, *J. Org. Chem. USSR* **6,** 1658 (1970), **8,** 846 (1972); Mikhailov, Matyushecheva, and Yagupol'skii, *J. Org. Chem. USSR* **9,** 1847 (1973).

Many aldehydes and ketones have been converted to *gem*-difluoro compounds with sulfur tetrafluoride SF_4,[165] including quinones, which give 1,1,4,4-tetrafluorocyclohexadiene derivatives. Carboxylic acids, acyl chlorides, and amides react with SF_4 to give 1,1,1-trifluorides. In these cases the first product is the acyl fluoride, which then undergoes the *gem*-difluorination reaction:



$$R{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}W + SF_4 \longrightarrow R{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}F + SF_4 \longrightarrow R{-}CF_2{-}F \qquad W = OH, Cl, NH_2, NHR$$

The acyl fluoride can be isolated. Esters also give trifluorides, though more vigorous conditions are required, but in this case the carbonyl group of the ester is attacked first, and RCF_2OR' can be isolated from RCOOR′ and then converted to the trifluoride. Anhydrides can react in either manner, and both types of intermediate are isolable under the right conditions. SF_4 even converts carbon dioxide to CF_4. A disadvantage of reactions with SF_4 is that they require a pressure vessel lined with stainless steel. Selenium tetrafluoride SeF_4 gives similar reactions, but atmospheric pressure and ordinary glassware can be used.[166] Other reagents which have been used to convert aldehydes and ketones to *gem*-difluorides are phenylsulfur trifluoride $PhSF_3$,[167] carbonyl fluoride COF_2,[168] molybdenum hexafluoride MoF_6,[169] and dialkylaminosulfur trifluorides R_2NSF_3.[170]

The mechanism with SF_4 is probably similar in general nature, if not in specific detail, to that with PCl_5.

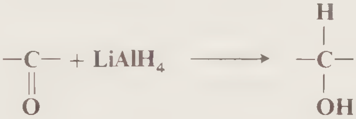
G. Attack by Hydrogen

6-27 Reduction of Aldehydes and Ketones to Alcohols



$$-\underset{\displaystyle O}{\underset{\|}{C}}- + LiAlH_4 \longrightarrow -\overset{\displaystyle H}{\overset{|}{\underset{\displaystyle OH}{\underset{|}{C}}}}-$$

Aldehydes can be reduced to primary alcohols and ketones to secondary alcohols by a number of reducing agents, of which lithium aluminum hydride and other metallic hydrides are the most commonly used.[171] These reagents have two main advantages over most of the reagents which were used before the discovery of $LiAlH_4$: they do not reduce carbon-carbon double (or triple) bonds, and they generally contain a lot of hydrogen in a small amount of reagent—with $LiAlH_4$, all four hydrogens are usable for reduction. The reaction is broad and general. $LiAlH_4$ easily reduces aliphatic, aromatic, alicyclic, and heterocyclic aldehydes, containing double or triple bonds and or nonreducible groups such as NR_3, OH, OR, F, etc. If the molecule contains a group reducible by $LiAlH_4$ (e.g., NO_2, CN, COOR), then it is reduced also. $LiAlH_4$ reacts readily with water and alcohols, so that these compounds must be rigorously excluded. Common solvents are ether and tetrahydrofuran. $NaBH_4$ has a similar scope but is more selective and so may be used with NO_2, Cl, COOR, CN, etc., in the molecule. Another advantage of $NaBH_4$ is that it can be used in water or alcoholic solvents and so reduces compounds such as sugars that are not soluble in ethers. The double bonds which are generally not affected by metallic hydrides may be isolated or conjugated, but double bonds which are conjugated with the C=O group may or may not be reduced depending on the substrate, reagent, and reaction conditions. For example, it has proved possible to reduce only the C=O bonds of α,β-unsaturated ketones with AlH_3 and with diisobutylaluminum hydride (p. 709). Also, examples are known where both $NaBH_4$[172] and $LiAlH_4$[173] predominantly reduce only the C=O bond of a C=C—C=O system. On the other hand, $LiAlH_4$ reduces both double bonds of cinnamaldehyde (p. 709), and $NaBH_4$ has been shown to give substantial amounts of fully saturated alcohol products in the reduction of a number of conjugated aldehydes and ketones.[173] The scope of these reagents with ketones is similar to that with aldehydes. $LiAlH_4$ reduces even sterically hindered ketones. With suitable hydrides a degree of selectivity is possible: the reagent tetrabutylammonium cyanoborohydride $Bu_4N^+\ \ BH_3CN^-$ in HMPT reduces both aldehydes and ketones when enough acid is added to the medium to bring the acid concentration to about 1.5 *N*, but at an acid concentration of about 0.1 *N* only aldehydes are reduced, while ketones are essentially unaffected.[174] Similarly, $NaBH_4$ in isopropyl alcohol,[175] sodium triacetoxyborohydride,[175a] and 2-propanol on dehydrated alumina[176] reduce aldehydes much faster than ketones. The reagent lithium N-dihydropyridylaluminum hydride reduces diaryl ketones much better than it does dialkyl or alkyl aryl ketones.[176a] Most other hydrides reduce diaryl ketones more slowly than other types of ketones. It is obvious that reagents can often be found to reduce one kind of carbonyl function in the presence of another. Aldehydes and ketones can often be reduced in the presence of other reducible groups if a suitable reagent is used. For a discussion of selectivity in reduction reactions, see p. 1116. Quinones are reduced to hydroquinones by $LiAlH_4$, $SnCl_2$–HCl, or sodium hydrosulfite $Na_2S_2O_4$, as well as by other reducing agents.

The reagent lithium tri-*sec*-butylborohydride $LiBH(sec\text{-}Bu)_3$, prepared by treatment of tri-*sec*-butylborane with lithium trimethoxyaluminum hydride $LiAlH(OMe)_3$, reduces cyclic and bicyclic ketones in a highly stereoselective manner, giving the less stable isomer.[177] For example, 2-methylcyclohexanone gave *cis*-2-methylcyclohexanol with an isomeric purity greater than 99%. The more usual reagents, e.g., $LiAlH_4$, $NaBH_4$, reduce relatively unhindered cyclic ketones either with little or no stereoselectivity or give predominant formation of the more stable isomer. The less stable axial alcohol is also predominantly formed when cyclohexanones are reduced with

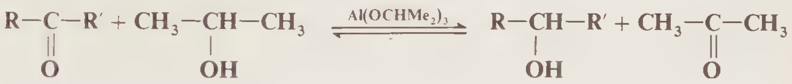
(among other reagents) AlH_3 in ether at $-70^\circ C$,[178] with triethyl phosphite and iridium tetrachloride in aqueous isopropyl alcohol,[179] with potassium triisopropoxyborohydride,[180] or with lithium dimesitylborohydride bis(dimethoxyethane).[181] Cyclohexanones which have a large degree of steric hindrance near the carbonyl group usually give predominant formation of the axial alcohol even with $LiAlH_4$ and $NaBH_4$.

Among other reagents which reduce aldehydes and ketones to alcohols are the following:

1. *Hydrogen and a catalyst.*[182] The most common catalysts are platinum and ruthenium, but homogeneous catalysts have also been used.[183] Before the discovery of the metal hydrides this was one of the most common ways of effecting this reduction, but it suffers from the fact that C=C, C≡C, C=N, and C≡N bonds are more susceptible to attack than C=O bonds. However, α,β-unsaturated aldehydes RCH=CHCHO (though not ketones) can be reduced to the corresponding unsaturated alcohols $RCH=CHCH_2OH$ by hydrogenation over reduced osmium supported on alumina or activated charcoal.[184] An iridium catalyst has also been used for this conversion.[185]

2. *Sodium in ethanol.*[186] This is called the *Bouveault-Blanc procedure* and was more popular for the reduction of esters (reaction **9-44**) than of aldehydes or ketones before the discovery of $LiAlH_4$.

3. *Isopropyl alcohol and aluminum isopropoxide.* This is called the *Meerwein-Ponndorf-Verley reduction.*[187] It is reversible, and the reverse reaction is known as the *Oppenauer oxidation* (reaction **9-4**).



$$R-\underset{\underset{\displaystyle O}{\|}}{C}-R' + CH_3-\underset{\underset{\displaystyle OH}{|}}{CH}-CH_3 \xrightleftharpoons{Al(OCHMe_2)_3} R-\underset{\underset{\displaystyle OH}{|}}{CH}-R' + CH_3-\underset{\underset{\displaystyle O}{\|}}{C}-CH_3$$

The equilibrium is shifted by removal of the acetone by distillation. The reaction takes place under very mild conditions and is highly specific for aldehydes and ketones, so that C=C bonds (including those conjugated with the C=O bonds) and many other functional groups may be present without themselves being reduced. This includes acetals, so that one of two carbonyl groups in a molecule may be specifically reduced if the other is first converted to an acetal. β-Keto esters, β-diketones, and other ketones and aldehydes with a relatively high enol content do not give this reaction.

4. Borane BH_3 and substituted boranes[188] reduce aldehydes and ketones in a manner similar to their addition to C=C bonds (reaction **5-15**).[189] That is, the boron adds to the oxygen and the hydrogen to the carbon:[190]

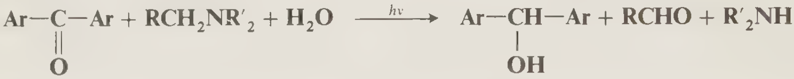
$$-\underset{\underset{\textstyle O}{\|}}{C}- \;+\; BH_3\text{-}THF \longrightarrow \left(-\overset{\overset{\textstyle H}{|}}{\underset{\underset{\textstyle O}{|}}{C}}-\right)_3\!\!-B$$

The borate is then hydrolyzed to the alcohol.

5. *Polymethylhydrosiloxane* $(MeHSiO)_n$, with an organotin catalyst, bis(dibutylacetoxytin) oxide, is a selective reducing agent for aldehydes and ketones under neutral conditions (refluxing 95% alcohol).[191] Under these conditions, carboxylic acids, esters, amides, alkyl halides, and nitro compounds are not reduced.

6. *Diimide* (N_2H_2, see p. 714) reduces aromatic aldehydes[192] and ketones, but aliphatic carbonyl compounds react very poorly.[193]

7. In certain cases ketones can be reduced to secondary alcohols by photochemical methods (see also p. 223). For example, diaryl ketones are reduced by irradiation in the presence of water and a tertiary amine (which is cleaved to a secondary amine and an aldehyde):[194]

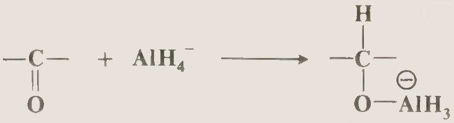


$$Ar-\underset{\underset{\textstyle O}{\|}}{C}-Ar + RCH_2NR'_2 + H_2O \xrightarrow{h\nu} Ar-\underset{\underset{\textstyle OH}{|}}{CH}-Ar + RCHO + R'_2NH$$

8. A single carbonyl group of an α-diketone can be reduced (to give an α-hydroxy ketone) by heating with zinc powder in aqueous dimethylformamide.[195]

9. In the Cannizzaro reaction (**9-74**) aldehydes without an α-hydrogen are reduced to alcohols.

With most reagents there is an initial attack on the carbon of the carbonyl group by H^- or some carrier of it, though with BH_3 the initial attack is on the oxygen. Detailed mechanisms are not known in most cases. With metallic hydrides of aluminum or boron, the attacking species is the AlH_4^- (or BH_4^-) ion, which, in effect, transfers H^- to the carbon.[196] The freed AlH_3



$$-\underset{\underset{\textstyle O}{\|}}{C}- \;+\; AlH_4^- \longrightarrow -\overset{\overset{\textstyle H}{|}}{\underset{\underset{\textstyle O-AlH_3}{|\;\ominus}}{C}}-$$

36

then complexes with the oxygen from the same molecule, or from a different one. However, it has been shown that in certain cases the cation plays an essential role. When the Li^+ was effectively removed from $LiAlH_4$ (by the addition of a crown ether, p. 82), the reaction did not take place.[197] The complex **36** must now be hydrolyzed to the alcohol. If the reaction is performed in a protic solvent, AlH_3 coordinates with the solvent instead and a proton from the solvent goes to the oxygen. Free H^- cannot be the attacking entity in most reductions with boron or aluminum hydrides because the reactions are frequently sensitive to the size of the MH_4^- [or $MR_mH_n^-$ or $M(OR)_mH_n^-$, etc.]. It has been shown that $NaBH_4$ *molecules* are not the attacking species either, since they react only in solvents in which they are ionized to Na^+ and BH_4^-.[198]

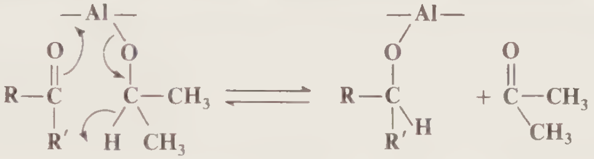
[198] Brown and Ichikawa, *J. Am. Chem. Soc.* **83**, 4372 (1961).

There has been much controversy about whether the initial complex (**36**) can reduce another carbonyl to give $(\mathrm{H{-}\overset{|}{\underset{|}{C}}{-}O})_2\mathrm{AlH}_2$, and so on. It has been shown[199] that this is probably not the case but that, more likely, **36** disproportionates to $(\mathrm{H{-}\overset{|}{\underset{|}{C}}{-}O})_4\mathrm{Al}$ and AlH_4^-, which is the only attacking species.

36 is essentially LiAlH_4 with one of the hydrogens replaced by an alkoxy group, i.e., $\mathrm{LiAlH}_3\mathrm{OR}$. The fact that **36** and other alkoxy derivatives of LiAlH_4 are less reactive than LiAlH_4 itself has led to the use of such compounds as reducing agents which are less reactive and hence more selective than LiAlH_4.[200] We have already met some of these, e.g., $\mathrm{LiAlH(O\text{-}}t\mathrm{\text{-}Bu)}_3$ (reactions **0-83** to **0-85**; see also Table 5, Chapter 19, p. 1118). As an example of selectivity in this reaction it may be mentioned that $\mathrm{LiAlH(O\text{-}}t\mathrm{\text{-}Bu)}_3$ has been used to reduce only the keto group in a molecule containing both keto and ester groups.[201] However, the use of such reagents is sometimes complicated by the disproportionation mentioned above, which may cause LiAlH_4 to be the active species even if the reagent is an alkoxy derivative. Another highly selective reagent (reducing aldehydes and ketones, but not other functional groups), which does not disproportionate, is potassium triisopropoxyborohydride.[180] The use of tin hydrides, such as $\mathrm{Ph_2SnH_2}$, gives alcohols from aldehydes or ketones directly; i.e., both hydrogens come from the hydride, and no hydrolysis is needed.[202]

The Meerwein-Ponndorf-Verley reaction usually involves a cyclic transition state:



but in some cases 2 moles of aluminum alkoxide are involved, one attacking the carbon and the other the oxygen, a conclusion which stems from the finding that in these cases the reaction was 1.5 order in alkoxide.[203] It has been shown by deuterium labeling that it is the α-hydrogen of the alkoxide which appears at the carbonyl carbon of the starting aldehyde or ketone.[204] Although we have depicted a cyclic mechanism, it is possible to visualize it as occurring in three phases: (1) coordination of the ketone with the alkoxide, (2) hydride transfer, and (3) separation of the new complex. There is controversy over which step is rate-determining: some feel that it is hydride transfer,[205] and others claim that it is none of these but a subsequent step, in which the alkoxide is hydrolyzed.[206] Although, for simplicity, we have shown the alkoxide as a monomer, it actually exists as trimers and tetramers, and it is these which react.[207]

The mechanism of the reaction with sodium in ethanol is similar to that of the Birch reduction (**5-13**) and involves a ketyl intermediate, which can be isolated.

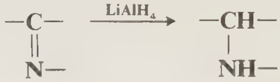
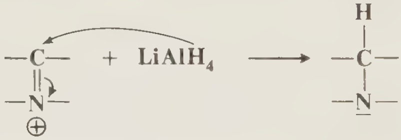
6-28 Reduction of the Carbon-Nitrogen Double Bond

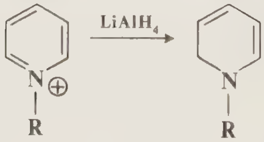


$$-\mathrm{C}(=\mathrm{N}-)- \xrightarrow{\mathrm{LiAlH_4}} -\mathrm{CH}(\mathrm{NH}-)-$$

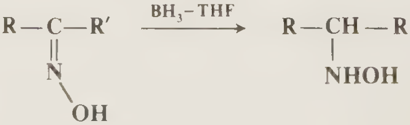
Imines, Schiff bases, hydrazones, and other C=N compounds can be reduced with $\mathrm{LiAlH_4}$, $\mathrm{NaBH_4}$, Na-EtOH, hydrogen and a catalyst, as well as with other reducing agents.[209] Iminium salts are also reduced by $\mathrm{LiAlH_4}$, though here there is no "addition" to the nitrogen:[210]



$\mathrm{LiAlH_4}$ similarly reduces N-alkylpyridinium salts to 1,2-dihydropyridines:



Oximes are generally reduced to amines (reaction **9-53**), but simple addition of H_2 to give hydroxylamines can be accomplished with borane at 25°C[211] or with sodium cyanoborohydride.[115]



$$\mathrm{R-C(=N-OH)-R'} \xrightarrow{\mathrm{BH_3-THF}} \mathrm{R-CH(NHOH)-R'}$$

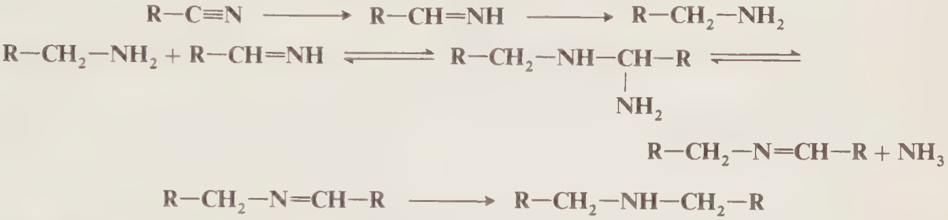
6-29 The Reduction of Nitriles to Amines

$$\mathrm{R{-}C{\equiv}N + LiAlH_4 \longrightarrow R{-}CH_2{-}NH_2}$$

Nitriles can be reduced to primary amines with many reducing agents,[212] including $LiAlH_4$, BH_3 THF, NaOEt, and hydrogen and a catalyst.[213] $NaBH_4$ does not generally reduce nitriles but does so in alcoholic solvents when a $CoCl_2$ catalyst is added[214] or in the presence of Raney nickel.[215] The reaction is of wide scope and has been applied to many nitriles. Secondary amines are often side products, arising from the following sequence of steps:



$$\mathrm{R{-}C{\equiv}N \longrightarrow R{-}CH{=}NH \longrightarrow R{-}CH_2{-}NH_2}$$

$$\mathrm{R{-}CH_2{-}NH_2 + R{-}CH{=}NH \rightleftharpoons R{-}CH_2{-}NH{-}\underset{\displaystyle NH_2}{\underset{|}{CH}}{-}R \rightleftharpoons R{-}CH_2{-}N{=}CH{-}R + NH_3}$$

$$\mathrm{R{-}CH_2{-}N{=}CH{-}R \longrightarrow R{-}CH_2{-}NH{-}CH_2{-}R}$$

These side products can be avoided by adding a compound such as acetic anhydride, which removes the primary amine as soon as it is formed,[216] or by the use of excess ammonia to drive the equilibria backward.[217]

It is not possible to stop with the addition of only 1 mole of hydrogen, i.e., to convert the nitrile to an imine, except where the imine is subsequently hydrolyzed (reaction **6-30**).

N-Alkylnitrilium ions are reduced to secondary amines by $NaBH_4$[218]

$$\mathrm{RCN \xrightarrow{R_3'O^+\ \ BF_4^-} R{-}C{\equiv}\overset{\oplus}{N}{-}R' \xrightarrow[\text{diglyme}]{NaBH_4} RCH_2{-}NH{-}R'}$$

Since nitrilium salts can be prepared by treatment of nitriles with trialkyloxonium salts (see reaction **6-10**), this is a method for the conversion of nitriles to secondary amines. In contrast, triethylsilane reduces nitrilium ions to imines: $\mathrm{R{-}C{\equiv}\overset{\oplus}{N}{-}R' \rightarrow R{-}CH{=}N{-}R'}$.[219] The imines can be hydrolyzed to aldehydes RCHO, making this an indirect method for the conversion of nitriles to aldehydes.

OS **III**, 229, 358, 720; **53**, 21.

6-30 The Reduction of Nitriles to Aldehydes

$$\mathrm{R{-}C{\equiv}N \xrightarrow[\text{2. hydrol.}]{\text{1. HCl, SnCl}_2} R{-}CH{=}O}$$

There are two principal methods for the reduction of nitriles to aldehydes.[220] In one of these, known as the *Stephen reduction*, the nitrile is treated with HCl to form

$$\mathrm{RCCl{=}NH_2^+\ \ Cl^-}$$

37

This is reduced with anhydrous $SnCl_2$ to RCH=NH, which precipitates as a complex with $SnCl_4$ and is then hydrolyzed (reaction **6-2**) to the aldehyde. The Stephen reduction is most successful when R is aromatic, but it can be done for aliphatic R up to about six carbons.[221] It is also possible to prepare **37** in a different way, by treating ArCONHPh with PCl_5. The **37** obtained in this way can then be converted to the aldehyde. This is known as the *Sonn-Müller method.*

The other way of reducing nitriles to aldehydes involves using a metal hydride reducing agent to add 1 mole of hydrogen and hydrolysis, in situ, of the resulting imine (which is undoubtedly coordinated to the metal). This has been carried out with $LiAlH_4$, $LiAlH(OEt)_3$,[222] $AlH(CH_2CHMe_2)_2$,[223] and $NaAlH_4$.[224] The metal hydride method is useful for aliphatic and aromatic nitriles. Reduction to the aldehyde has also been accomplished by treatment of the nitrile with sodium hypophosphate and Raney nickel in aqueous acetic acid-pyridine or formic acid;[225] with Raney nickel in aqueous tetrahydrofuran containing H_2SO_4;[226] and photochemically, by irradiation of the nitrile in 0.01 *M* NaOH solution.[227] Another method for the conversion of nitriles to aldehydes (by way of the nitrilium ion) was mentioned at reaction **6-29.**

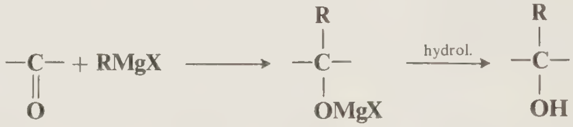
H. Carbon Attack by Organometallic Compounds

6-31 The Addition of Organometallic Compounds to Aldehydes and Ketones



$$\underset{\displaystyle \overset{\|}{O}}{-C-} + RMgX \longrightarrow -\overset{\displaystyle R}{\underset{\displaystyle OMgX}{C}}- \xrightarrow{\text{hydrol.}} -\overset{\displaystyle R}{\underset{\displaystyle OH}{C}}-$$

The addition of Grignard reagents to aldehydes and ketones is known as the *Grignard reaction.*[228] Formaldehyde gives primary alcohols; other aldehydes give secondary alcohols; and ketones give tertiary alcohols. The reaction is of very broad scope, and hundreds of alcohols have been prepared in this manner. R may be alkyl or aryl. In many cases the hydrolysis step is carried out with dilute HCl or H_2SO_4, but this cannot be done for tertiary alcohols in which at least one R group is alkyl because such alcohols are easily dehydrated under acidic conditions (reaction **7-1**). In such cases (and often for primary and secondary alcohols as well) an aqueous solution of ammonium chloride is used instead of a strong acid. Other organometallic compounds may also be used, but only if they are of active metals; e.g., alkylmercurys and alkylcadmiums do not react. In practice, the only organometallic compounds used to any extent, besides Grignard reagents, are alkyl- and aryllithiums, though alkylzinc reagents were used in the past.[228a] For the addition of acetylenic groups, sodium may be the metal used: RC≡CNa (reaction **6-42**); while vinylalanes (prepared as in reaction **5-16**) are the reagents of choice for the addition of vinyl groups.[229] The reaction with alkyl- and aryllithium reagents has also been carried out without preliminary formation of RLi: a mixture of RX and the carbonyl compound was added to a suspension of lithium pieces in tetrahydrofuran.[230] Yields were generally satisfactory. Lithium dimethylcopper Me_2CuLi reacts with aldehydes[230a] but not with ketones, though a reagent prepared from Me_2CuLi and MeLi does convert cyclohexanones stereoselectively to tertiary alcohols, with the axial alcohol preferred.[231]

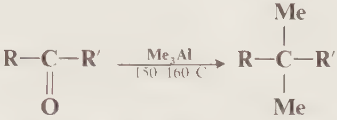
[229] Newman, *Tetrahedron Lett.* 4571 (1971).

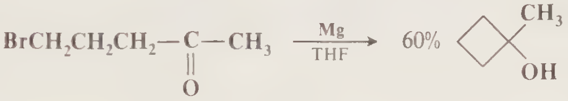
Trimethylaluminum exhaustively methylates ketones to give *gem*-dimethyl compounds[231a] (see also reaction **0-90**):



$$R-\underset{\underset{\textstyle O}{\|}}{C}-R' \xrightarrow[150-160^\circ C]{Me_3Al} R-\overset{\overset{\textstyle Me}{|}}{\underset{\underset{\textstyle Me}{|}}{C}}-R'$$

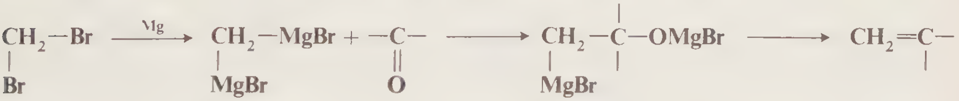
α,β-Unsaturated aldehydes or ketones can give 1,4 addition as well as normal 1,2 addition (see p. 729). In general, alkyllithiums give less 1,4 addition than the corresponding Grignard reagents.[232] Quinones may add Grignard reagents on one or both sides or give 1,4 addition. In a compound containing both an aldehydic and a ketonic carbonyl group it is possible to add RMgX selectively to the aldehydic function without significantly disturbing the ketonic group.[233]

The Grignard reaction can be performed intramolecularly. For example, treatment of 5-bromo-2-pentanone with magnesium and a small amount of mercuric chloride in tetrahydrofuran



produced 1-methyl-1-cyclobutanol in 60% yield.[234] Other four- and five-membered ring compounds were also prepared by this procedure. Similar closing of five- and six-membered rings was achieved by treatment of a δ- or ε-halocarbonyl compound, not with a metal, but with a dianion derived from nickel tetraphenylporphine.[235] The cyclization of a δ-halo γ,δ-unsaturated ketone (to give a cyclopentenol) was accomplished by treatment of the substrate with di-*n*-butylcopperlithium in pentane-ether at 0°C.[235]

The *gem*-disubstituted magnesium compounds formed from CH_2Br_2 or CH_2I_2 (reaction **2-37**) react with aldehydes or ketones to give olefins in moderate to good yields.[236] The reaction



$$\underset{\underset{\textstyle Br}{|}}{CH_2}-Br \xrightarrow{Mg} \underset{\underset{\textstyle MgBr}{|}}{CH_2}-MgBr + -\underset{\underset{\textstyle O}{\|}}{C}- \longrightarrow \underset{\underset{\textstyle MgBr}{|}}{CH_2}-\overset{|}{\underset{|}{C}}-OMgBr \longrightarrow CH_2=\underset{|}{C}-$$

could not be extended to other *gem*-dihalides. Similar reactions with *gem*-dimetallic compounds prepared with metals other than magnesium have also produced olefins, though usually with low yields.[237] However, exceptions are the α,α-dimetallic derivatives of phenyl sulfones $PhSO_2CM_2R$ ($M = Li$ or Mg), which react with aldehydes or ketones R′COR″ to give good yields of the α,β-unsaturated sulfones $PhSO_2CR{=}CR'R''$,[238] which can be reduced with aluminum amalgam (see reaction **0-96**) or with $LiAlH_4$-$CuCl_2$ to give the olefins $CHR{=}CR'R''$.[239] These reactions are closely related to the Wittig reaction (**6-47**) and, like it, provide a means of achieving the conversion $R_2C{=}O \rightarrow R_2C{=}R'_2$. On the other hand, *gem*-dihalides treated with a carbonyl compound and Li or BuLi give epoxides[240] (see also reaction **6-65**). In another use of *gem*-dihalo compounds, methylene halides add the CHX_2 group to aldehydes or ketones when treated with lithium dicyclohexylamide at low temperatures.[241]

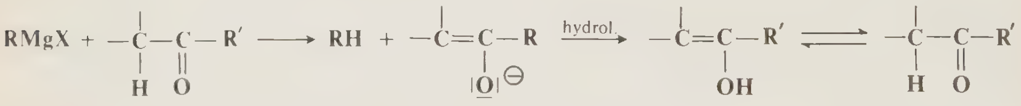
$$\mathrm{CH_2X_2} + -\underset{\underset{\displaystyle \mathrm{O}}{\|}}{\mathrm{C}}- \xrightarrow[2.\ \mathrm{H_2O}]{1.\ \mathrm{LiN(C_6H_{11})_2},\ -78^\circ\mathrm{C}} -\overset{|}{\underset{\underset{\displaystyle \mathrm{OH}}{|}}{\mathrm{C}}}-\mathrm{CHX_2} \qquad \mathrm{X = Cl, Br, I}$$

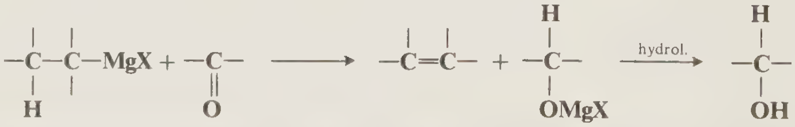
Although most aldehydes and ketones react very nicely with most Grignard reagents, there are several types of side reaction which occur mostly with hindered ketones and with bulky Grignard reagents. The two most important of these are *enolization* and *reduction*. The former requires that the aldehyde or ketone have an α-hydrogen, and the latter requires that the Grignard reagent have a β-hydrogen:

Enolization



$$\mathrm{RMgX} + -\overset{|}{\underset{\underset{\displaystyle \mathrm{H}}{|}}{\mathrm{C}}}-\underset{\underset{\displaystyle \mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{R'} \longrightarrow \mathrm{RH} + -\overset{|}{\mathrm{C}}{=}\underset{\underset{\displaystyle \mathrm{|\underline{O}|^{\ominus}}}{|}}{\mathrm{C}}-\mathrm{R} \xrightarrow{\text{hydrol.}} -\overset{|}{\mathrm{C}}{=}\underset{\underset{\displaystyle \mathrm{OH}}{|}}{\mathrm{C}}-\mathrm{R'} \rightleftharpoons -\overset{|}{\underset{\underset{\displaystyle \mathrm{H}}{|}}{\mathrm{C}}}-\underset{\underset{\displaystyle \mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{R'}$$

Reduction



$$-\overset{|}{\underset{\underset{\displaystyle \mathrm{H}}{|}}{\mathrm{C}}}-\overset{|}{\underset{|}{\mathrm{C}}}-\mathrm{MgX} + -\underset{\underset{\displaystyle \mathrm{O}}{\|}}{\mathrm{C}}- \longrightarrow -\overset{|}{\mathrm{C}}{=}\overset{|}{\mathrm{C}}- + -\overset{\overset{\displaystyle \mathrm{H}}{|}}{\underset{\underset{\displaystyle \mathrm{OMgX}}{|}}{\mathrm{C}}}- \xrightarrow{\text{hydrol.}} -\overset{\overset{\displaystyle \mathrm{H}}{|}}{\underset{\underset{\displaystyle \mathrm{OH}}{|}}{\mathrm{C}}}-$$

Enolization is an acid-base reaction (**2-21**) in which a proton is transferred from the α-carbon to the Grignard reagent. The Grignard reagent RMgX is converted to RH and the carbonyl compound to its enolate-ion form, which, on hydrolysis, is reconverted to original ketone or aldehyde. Enolization is important not only for hindered ketones but also for those which have a relatively high percentage of enol form, e.g., β-keto esters, etc. Another factor which affects enolization is the relative freedom of R in the organometallic compound. Thus, acetophenone gave addition with RMgX and RLi but enolization with RNa and RK, in which the R has greater carbonionic character.[242] In reduction, the carbonyl compound is reduced to an alcohol (reaction **6-27**) by the Grignard reagent, which itself undergoes elimination to give an olefin. Two other side reactions are condensation (between enolate ion and excess ketone) and Wurtz-type coupling (reaction **0-92**). Such highly hindered tertiary alcohols as triisopropylcarbinol, tri-*t*-butylcarbinol, and diisopropylneopentylcarbinol cannot be prepared (or can be prepared only in extremely low yields) by the addition of Grignard reagents to ketones, because reduction and/or enolization become prominent.[243] However, these carbinols can be prepared by the use of alkyllithiums at −80°C,[244] under which conditions enolization and reduction are much less important.[245] Another method of increasing the degree of addition at the expense of reduction consists in complexing the Grignard reagent with $LiClO_4$ or $Bu_4N^+ \quad Br^-$.[246]

There has been much controversy regarding the mechanism of addition of Grignard reagents to aldehydes and ketones.[247] The reaction is difficult to study because of the variable nature of the species present in the Grignard solution (p. 167) and because the presence of small amounts of impurities in the magnesium seems to have a great effect on the kinetics of the reaction, making reproducible experiments difficult.[248] Furthermore, the mechanism seems to be quite complicated, since both RMgX and R_2Mg can react with the ketone, since both of these species as well as Mg_2X form complexes (Chapter 3) with the ketone,[249] and since the products initially formed can then react further (as described below). A detailed mechanism for the reaction between methylmagnesium bromide and 2-methylbenzophenone has been proposed by Ashby and co-workers,[250] based on the discovery that this reaction proceeds by two paths, one first order in MeMgBr and the other first order in Me_2Mg.[251] The initial stages of this mechanism, which starts with the three complexes formed from MeMgBr, Me_2Mg, and $MgBr_2$ are [252]

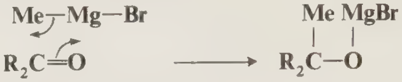
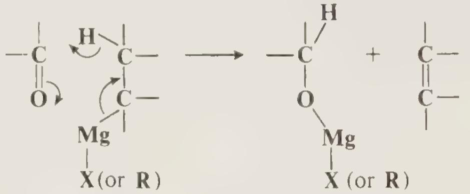
[252] The coefficient 2 in front of the MeMgBr refers only to the Schlenk equilibrium, presented horizontally, and not to the reactions between MeMgBr and the ketone, presented vertically.

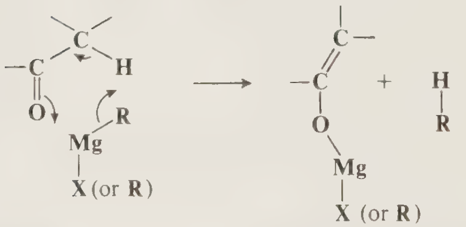
When excess Grignard reagent is present, the steps shown are essentially all that are required to describe the mechanism, but when the ketone-to-Grignard ratio is about 1 : 1, or when excess ketone is present, **38** and **39** react further—with each other and with additional molecules of RMgX and of ketone to give dimeric and trimeric species. Although the formation of these species complicates the mechanistic picture, they present no synthetic problem, since the hydrolysis step at the end of the reaction converts them all to the same alcohol, in this case R_2MeCOH. The exact nature of the step by which MeMgBr or Me_2Mg reacts with the substrate is not certain. One possibility is a four-centered cyclic transition state:[253]



The mechanism just outlined is probably not the only one. There are indications that in some cases, at least part of the reaction may go through a ketyl (p. 177) intermediate[254] [this pathway is called the *single-electron-transfer* (SET) *pathway*]. The SET pathway is favored by the presence of small amounts of transition metals[255] (which are often found as impurities in the magnesium).

There is general agreement that the mechanisms leading to reduction[256] and enolization are as follows:





Aromatic aldehydes and ketones can be alkylated and reduced in one reaction vessel by treatment with an alkyl- or aryllithium, followed by lithium and ammonia and then by ammonium chloride.[257]

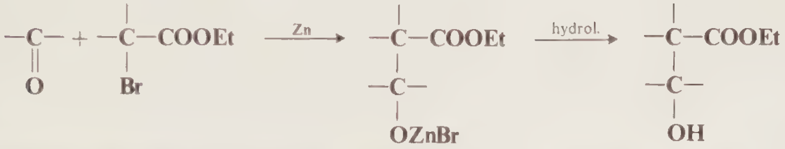
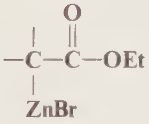
6-32 The Reformatsky Reaction



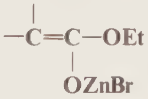
$$\mathrm{{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}} + \mathrm{{-}\overset{|}{\underset{\underset{\displaystyle Br}{|}}{C}}{-}COOEt} \xrightarrow{\mathrm{Zn}} \mathrm{{-}\overset{|}{\underset{\underset{\underset{\underset{\displaystyle OZnBr}{|}}{{-}C{-}}}{|}}{C}}{-}COOEt} \xrightarrow{\text{hydrol.}} \mathrm{{-}\overset{|}{\underset{\underset{\underset{\underset{\displaystyle OH}{|}}{{-}C{-}}}{|}}{C}}{-}COOEt}$$

The *Reformatsky reaction* is very similar to reaction **6-31.**[258] An aldehyde or ketone is treated with zinc and a halide;[259] the halide is nearly always an α-halo ester or a vinylog of an α-halo ester (e.g., RCHBrCH=CHCOOEt) though α-halo nitriles,[260] α-halo N,N-disubstituted amides, and the zinc salts of α-halo carboxylic acids[261] have also been used. With the last reagent the product is an α-hydroxy acid. The reaction has also been carried out with activated indium instead of zinc.[261a] The aldehyde or ketone may be aliphatic, aromatic, or heterocyclic or contain various functional groups. Formally, the reaction can be regarded as if it were analogous to the Grignard reaction (**6-31**), with **40** as an intermediate analogous to RMgX. There *is* an intermediate derived from zinc and the ester, but whether it has the structure **40** or the enolate structure **41** has been a matter of some controversy. There is some evidence for **40,**[262] but most of the evidence favors **41.**[263] The following pericyclic mechanism, involving **41,** has been proposed:[264]



$$\mathrm{{-}\overset{|}{\underset{\underset{\displaystyle ZnBr}{|}}{C}}{-}\overset{\overset{\displaystyle O}{\|}}{C}{-}OEt}$$

40



$$\mathrm{{-}\overset{|}{C}{=}\underset{\underset{\displaystyle OZnBr}{|}}{C}{-}OEt}$$

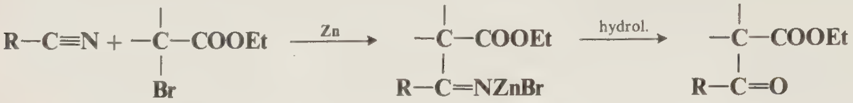
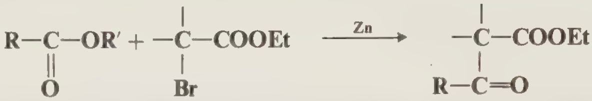
Usually, after hydrolysis, the alcohol is the product, but sometimes (especially with aryl aldehydes) elimination follows directly and the product is an olefin. Since Grignard reagents cannot be formed from α-halo esters, the method is quite useful, although there are competing reactions and yields are sometimes low. A similar reaction has been carried out on nitriles:[265]



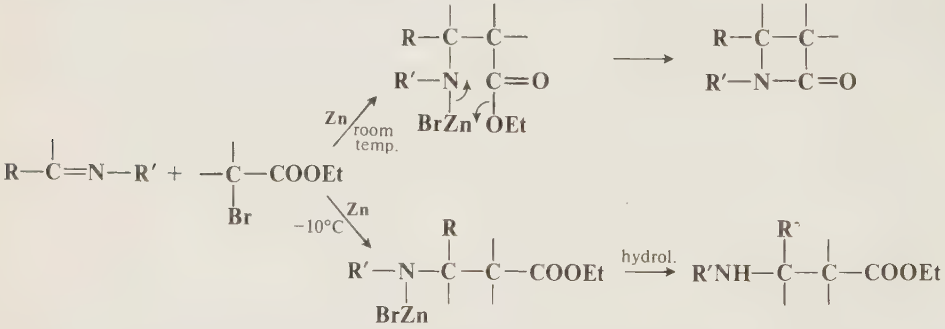
$$\mathrm{R{-}C{\equiv}N} + \underset{\mathrm{Br}}{\overset{|}{\underset{|}{-\mathrm{C}-}}}\mathrm{COOEt} \xrightarrow{\mathrm{Zn}} \underset{\mathrm{R-C=NZnBr}}{\overset{|}{\underset{|}{-\mathrm{C}-}}}\mathrm{COOEt} \xrightarrow{\text{hydrol.}} \underset{\mathrm{R-C=O}}{\overset{|}{\underset{|}{-\mathrm{C}-}}}\mathrm{COOEt}$$

Esters have also been used as substrates, but then, as might be expected (p. 802), the result is substitution and not addition:



$$\mathrm{R{-}\underset{\underset{O}{\|}}{C}{-}OR'} + \underset{\mathrm{Br}}{\overset{|}{\underset{|}{-\mathrm{C}-}}}\mathrm{COOEt} \xrightarrow{\mathrm{Zn}} \underset{\mathrm{R-C=O}}{\overset{|}{\underset{|}{-\mathrm{C}-}}}\mathrm{COOEt}$$

The product in this case is the same as with the corresponding nitrile, though the pathways are different. Imines give β-amino esters (after hydrolysis) when the reaction is carried out at −10°C,[266] but at room temperature the product is the corresponding β-lactam:[267]



Addition of *t*-butyl acetate to lithium diisopropylamide in hexane at −78°C gives the lithium salt of *t*-butyl acetate[268] (reaction **2-20**) as a stable white solid. The nmr and ir spectra of this salt in benzene show it to have the enolate structure **42**, similar to the structure **41** given above

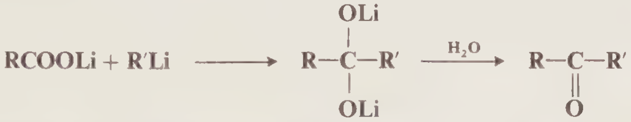
for the Reformatsky reagent. Reaction of **42** with a ketone provides a simple rapid alternative to the Reformatsky reaction as a means of preparing β-hydroxy *t*-butyl esters with the structure **43.** A similar reaction involves treatment of a ketone R_2CO with ethyl or *t*-butyl lithiotrimethylsilylacetate $Me_3SiCHLiCOOR'$, but in this case the product is the α,β-unsaturated ester $R_2C{=}CHCOOR'$.[269]

OS **III**, 408; **IV**, 120, 444.

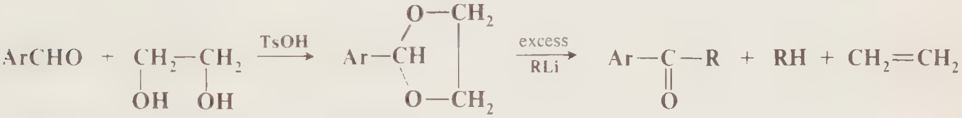
6-33 The Conversion of Carboxylic Acid Salts to Ketones with Organometallic Compounds



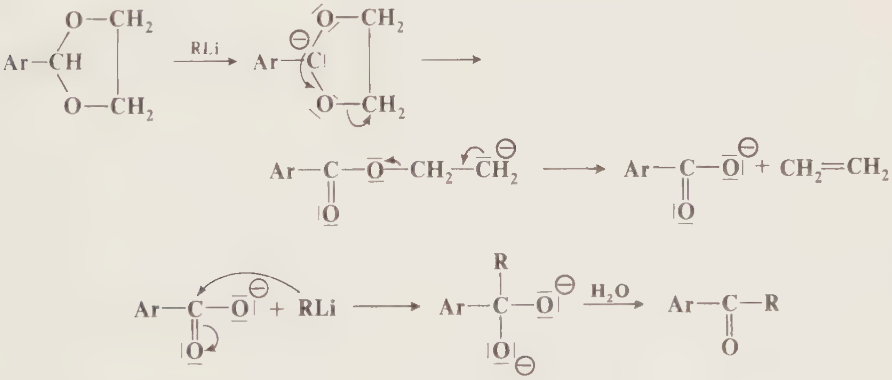
$$\text{RCOOLi} + \text{R'Li} \longrightarrow \text{R}-\underset{\text{OLi}}{\overset{\text{OLi}}{\text{C}}}-\text{R'} \xrightarrow{H_2O} \text{R}-\underset{\text{O}}{\overset{}{\text{C}}}-\text{R'}$$

Good yields of ketones can often be obtained by treatment of the lithium salt of a carboxylic acid with an alkyllithium reagent, followed by hydrolysis.[270] The reaction can be run in two ways: the acid can be treated with 2 moles of R′Li, or the lithium carboxylate can be independently prepared and treated with 1 mole of R′Li. R′ may be aryl or primary, secondary, or tertiary alkyl. MeLi and PhLi have been employed most often. R may be alkyl or aryl, though lithium acetate generally gives low yields. Tertiary alcohols are side products.

A reaction between ArCOOLi and RLi is one step in a conversion of an aromatic aldehyde to an alkyl aryl ketone. The aldehyde is converted to the corresponding cyclic acetal, which is treated with excess RLi.[271]



The mechanism is



OS **V**, 775.

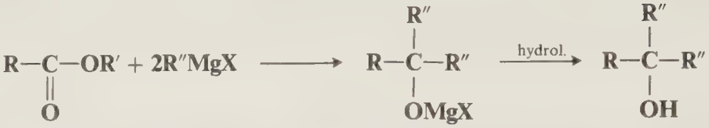
[270] For a review, see Jorgenson, *Org. React.* **18**, 1–97 (1970).

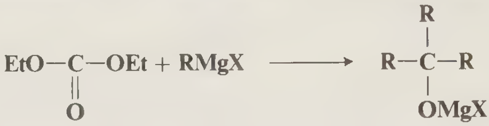
[271] Berlin, Rathore, and Peterson, *J. Org. Chem.* **30**, 226 (1965).

6-34 The Addition of Grignard Reagents to Acid Derivatives



$$R-\underset{\underset{O}{\|}}{C}-OR' + 2R''MgX \longrightarrow R-\overset{\overset{R''}{|}}{\underset{\underset{OMgX}{|}}{C}}-R'' \xrightarrow{\text{hydrol.}} R-\overset{\overset{R''}{|}}{\underset{\underset{OH}{|}}{C}}-R''$$

When esters are treated with Grignard reagents, there is usually concomitant addition to the carbonyl (reaction **6-31**) and substitution of R″ for OR′ (reaction **0-106**), so that tertiary alcohols are formed in which two R groups are the same. Formates give secondary alcohols, and carbonates give tertiary alcohols in which all three R groups are the same:

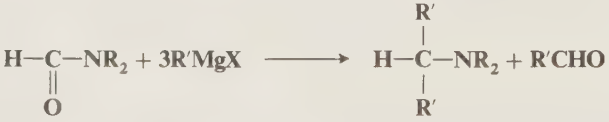


$$EtO-\underset{\underset{O}{\|}}{C}-OEt + RMgX \longrightarrow R-\overset{\overset{R}{|}}{\underset{\underset{OMgX}{|}}{C}}-R$$

Acyl halides and anhydrides behave similarly, though these substrates are employed less often.[272] There are many side reactions possible, especially when there is branching in the acid derivative or in the Grignard reagent: enolizations, reductions (not for esters, but for halides), condensations, and cleavages, but the most important is simple substitution (reaction **0-106**), which in some cases may be made to predominate. Trimethylaluminum, which exhaustively methylates ketones (reaction **6-31**), also exhaustively methylates carboxylic acids, to give *t*-butyl compounds[273] (see also reaction **0-90**):

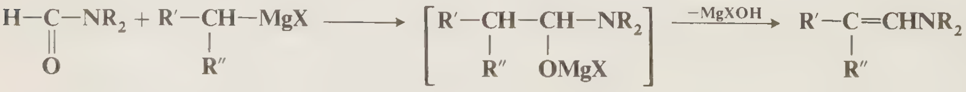
$$RCOOH + \text{excess } Me_3Al \xrightarrow{120\ C} RCOOAlMe_2 \xrightarrow{Me_3Al} RCMe_3$$

Disubstituted formamides can give addition of 2 moles of Grignard reagent.



$$H-\underset{\underset{O}{\|}}{C}-NR_2 + 3R'MgX \longrightarrow H-\overset{\overset{R'}{|}}{\underset{\underset{R'}{|}}{C}}-NR_2 + R'CHO$$

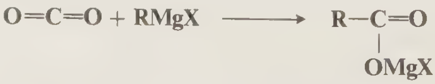
The products of this reaction (called the *Bouveault reaction*) are an aldehyde and a tertiary amine.[274] The use of an amide other than a formamide can give a ketone instead of an aldehyde, but yields are generally low. Alternatively, if R′ contains an α-hydrogen, the product may be an enamine, and enamines have been synthesized in good yields by this method.[275]



$$H-\underset{\underset{O}{\|}}{C}-NR_2 + R'-\underset{\underset{R''}{|}}{CH}-MgX \longrightarrow \left[R'-\underset{\underset{R''}{|}}{CH}-\underset{\underset{OMgX}{|}}{CH}-NR_2\right] \xrightarrow{-MgXOH} R'-\underset{\underset{R''}{|}}{C}=CHNR_2$$

OS **I,** 226; **II,** 179, 602; **III,** 237, 831, 839; **IV,** 601; **52,** 19; **55,** 39.

6-35 The Addition of Organometallic Compounds to CO_2



$$O=C=O + RMgX \longrightarrow R-\underset{\underset{OMgX}{|}}{C}=O$$

Grignard reagents add to one C=O bond of CO_2 exactly as they do to an aldehyde or a ketone.[276] Here, of course, the product is the salt of a carboxylic acid. The reaction is usually performed by adding the Grignard reagent to dry ice, but it is also possible to bubble CO_2 through a Grignard solution. However, the latter procedure usually gives lower yields, since the salt can react with additional molecules of Grignard reagent to give a ketone and a tertiary alcohol (reactions **6-31** and **6-34**). Sometimes this can be turned to preparative use; e.g., hexamethylacetone can be made in this way from CO_2 and *t*-butylmagnesium bromide.

---

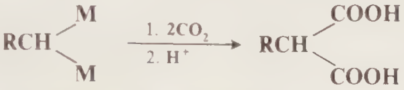
[272] For a review of these reactions, see Kharasch and Reinmuth, Ref. 228, pp. 549–766, 846–869.

[273] Meisters and Mole, *Aust. J. Chem.* 27, 1665 (1974).

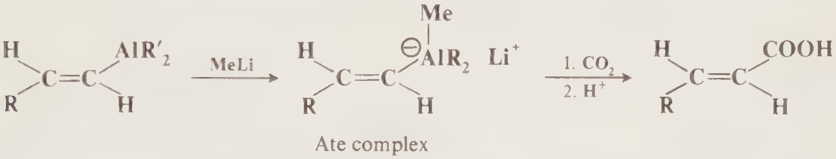
[274] For a review, see Ref. 120, pp. 59–63.

[275] Hansson and Wickberg, *J. Org. Chem.* **38,** 3074 (1973).

Many carboxylic acids have been prepared in this manner, and, along with the sequence **0-103–6-5** and reaction **8-9**, this constitutes an important way of increasing a carbon chain by one unit. Since labeled CO_2 is commercially available, this is a good method for the preparation of carboxylic acids labeled in the carboxyl group. Other organometallic compounds have also been used (RLi, RNa, RCaX, etc.) but much less often. The formation of the salt of a carboxylic acid after the addition of CO_2 to a reaction mixture is regarded as a positive test for the presence of a carbanion or of a reactive organometallic intermediate in that reaction mixture (see also reaction **6-43**). Addition of CO_2 to *gem*-dimetallic compounds gives replacement of both metal atoms, the product being a malonic acid.[277]



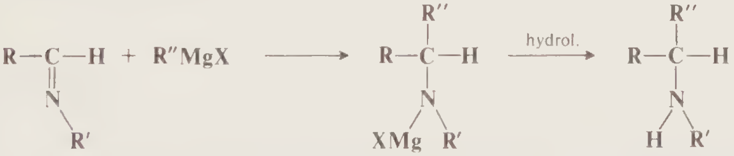
α,β-Unsaturated acids can be prepared by carbonation of an ate complex of a vinylalane.[278]



Vinylalanes can be prepared by addition of a dialkylalane to a triple bond (reaction **5-16**).

OS **I**, 361, 524; **II**, 425; **III**, 413, 553, 555; **V**, 890, 1043.

6-36 The Addition of Organometallic Compounds to Imines



Aldimines can be converted to secondary amines by treatment with Grignard reagents.[279] Ketimines generally give reduction instead of addition. However, organolithium compounds give the normal addition product with both aldimines and ketimines.[280] Many other C=N systems (phenylhydrazones, oxime ethers, etc.) give normal addition when treated with Grignard reagents;

---

[276] For reviews of the reaction between organometallic compounds and CO_2, see Volpin and Kolomnikov, *Organomet. React.* **5**, 313–386 (1975); Sneeden, in Patai, "The Chemistry of Carboxylic Acids and Esters," pp. 137–173, Interscience Publishers, New York, 1969; Kharasch and Reinmuth, Ref. 228, pp. 913–948.

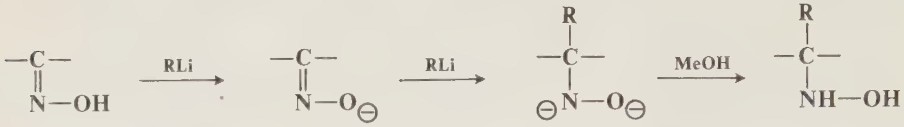
[277] For examples, see Cainelli, Dal Bello, and Zubiani, *Tetrahedron Lett.* 3429 (1965); Zweifel and Steele, Ref. 237; Bertini, Grasselli, Zubiani, and Cainelli, Ref. 236.

[278] Zweifel and Steele, *J. Am. Chem. Soc.* **89**, 2754, 5085 (1967).

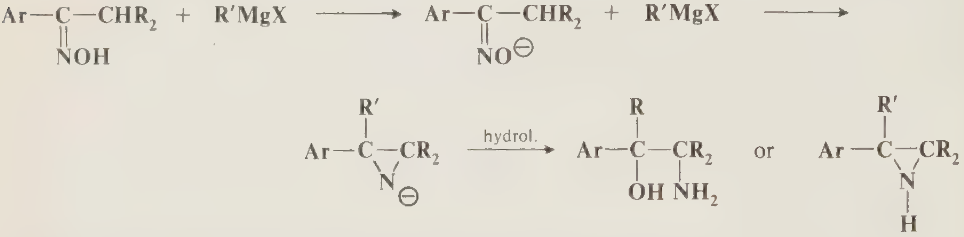
[279] For reviews of the addition of organometallic reagents to C=N bonds, see Harada, in Patai, "The Chemistry of the Carbon-Nitrogen Double Bond," Ref. 31, pp. 266–272; Kharasch and Reinmuth, Ref. 228, pp. 1204–1227.

[280] Huet, *Bull. Soc. Chim. Fr.* 952, 960, 967, 973 (1964).

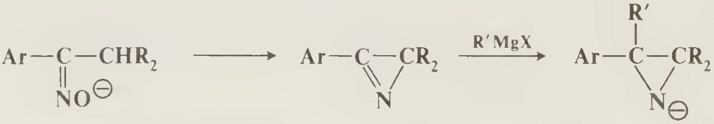
others give reduction; others (oximes) give an active hydrogen to the Grignard reagent; and still others give miscellaneous reactions. Oximes can be converted to hydroxylamines by treatment with two moles of an alkyllithium reagent, followed by methanol.[280a] Aryl alkyl oximes containing an α hydrogen react with 2 moles of Grignard reagent to give α-amino alcohols, with a net migration of N, or aziridines, depending on the method of hydrolysis.[281]



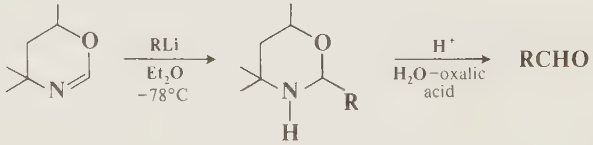
$$\underset{\substack{\| \\ \text{N—OH}}}{-\text{C}-} \xrightarrow{\text{RLi}} \underset{\substack{\| \\ \text{N—O}^{\ominus}}}{-\text{C}-} \xrightarrow{\text{RLi}} \overset{\substack{\text{R} \\ |}}{\underset{\substack{| \\ {}^{\ominus}\text{N—O}^{\ominus}}}{-\text{C}-}} \xrightarrow{\text{MeOH}} \overset{\substack{\text{R} \\ |}}{\underset{\substack{| \\ \text{NH—OH}}}{-\text{C}-}}$$



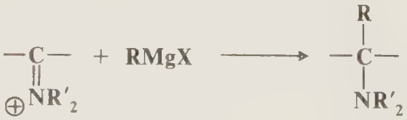
The mechanism involves initial formation of an azirine (see reaction **8-16**).[282]



Alkyllithium compounds add to the C=N bond of the dihydro-1,3-oxazine **44**.[283] Since the products **45** can be hydrolyzed to aldehydes, this is a method for the conversion of RLi to RCHO (see also reaction **2-31**).



Iminium salts[210] give tertiary amines directly, with just R adding:



$$\underset{\substack{\| \\ {}^{\oplus}\text{NR}'_2}}{-\text{C}-} + \text{RMgX} \longrightarrow \overset{\substack{\text{R} \\ |}}{\underset{\substack{| \\ \text{NR}'_2}}{-\text{C}-}}$$

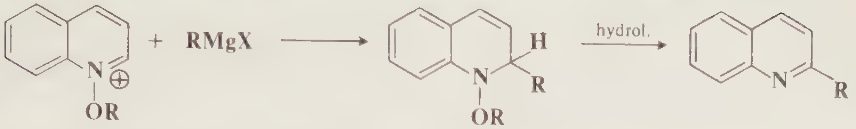
[280a] Richey, McLane, and Phillips, *Tetrahedron Lett.* 233 (1976).

[281] Campbell, Campbell, McKenna, and Chaput, *J. Org. Chem.* **8**, 103 (1943); Freeman, *Chem. Rev.* **73**, 283–292 (1973), pp. 288–190. See also Alvernhe, Arsenyiadis, Chaabouni, and Laurent, *Tetrahedron Lett.* 355 (1975).

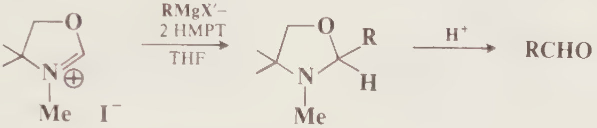
[282] Eguchi and Ishii, *Bull. Chem. Soc. Jpn.* **36**, 1434 (1963); Laurent and Muller, *Tetrahedron Lett.* 759 (1969); Alvernhe and Laurent, *Bull. Soc. Chim. Fr.* 3003 (1970).

[283] Meyers and Adickes, *Tetrahedron Lett.* 5151 (1969).

Salts of nitrogen heterocycles have also been alkylated in this manner, e.g.,[284]

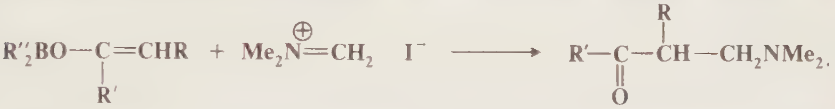


Application of this reaction to N-alkyl derivatives of 2-oxazolines (in the presence of HMPT) provides a means of conversion of an aryl, benzyl, or vinyl Grignard reagent RMgX to the corresponding aldehyde RCHO[285] (see reaction **0-100** for the similar conversion of Grignard reagents to ketones):



However, the method is not applicable to simple Grignard reagents.

Enol borinates react with iminium ions to give β-dialkylamino ketones (Mannich bases).[286]



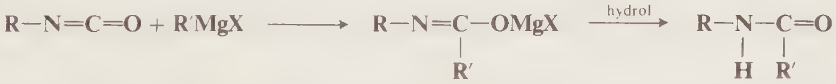
$$R''_2BO-\underset{R'}{\underset{|}{C}}=CHR + Me_2\overset{\oplus}{N}=CH_2 \quad I^- \longrightarrow R'-\underset{O}{\underset{\|}{C}}-\overset{R}{\overset{|}{C}}H-CH_2NMe_2.$$

This reaction provides a means of constructing a Mannich base from a given ketone in a regioselective manner, since either enol borinate can be prepared at will. The enol borinates (which need not be isolated) are prepared as in reaction **0-101.**

For the addition of alkyllithium compounds to the C═N bond of ketenimines, see reaction **2-17.**

OS **IV,** 605; **54,** 42. Also see OS **III,** 329.

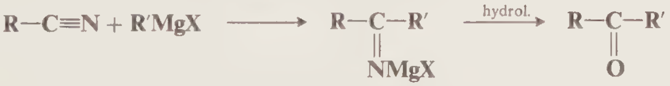
6-37 The Addition of Grignard Reagents to Isocyanates



$$R-N=C=O + R'MgX \longrightarrow R-N=\underset{R'}{\underset{|}{C}}-OMgX \xrightarrow{\text{hydrol}} R-\underset{H}{\underset{|}{N}}-\underset{R'}{\underset{|}{C}}=O$$

The addition of Grignard reagents to isocyanates gives, after hydrolysis, N-substituted amides. The reaction is written above as involving addition to C═O, but the ion is a resonance hybrid and the addition might just as well have been shown as occurring on the C═N. In any event, hydrolysis gives the amide. This is a very good reaction and may be used to prepare derivatives of alkyl and aryl halides. The reaction has also been performed with alkyllithium compounds.[287] Isothiocyanates give N-substituted thioamides.

6-38 The Addition of Grignard Reagents to Nitriles



$$R-C\equiv N + R'MgX \longrightarrow R-\underset{NMgX}{\underset{\|}{C}}-R' \xrightarrow{\text{hydrol.}} R-\underset{O}{\underset{\|}{C}}-R'$$

---

[284] Červinka, Fábryová, and Matouchová, *Collect. Czech. Chem. Commun.* **28,** 535 (1963).

[285] Meyers and Collington, *J. Am. Chem. Soc.* **92,** 6676 (1970).

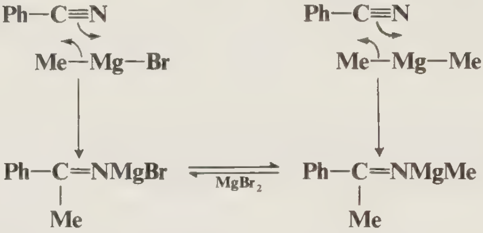
[287] LeBel, Cherluck, and Curtis, *Synthesis* 678 (1973).

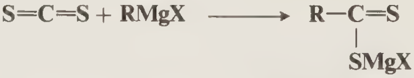
Ketones can be prepared by addition of Grignard reagents to nitriles and subsequent hydrolysis. Many ketones have been made in this manner, though when both R groups are alkyl, yields are not high.[288] The ketimine salt does not in general react with Grignard reagents; hence tertiary alcohols or tertiary alkyl amines are not often side products.[289] By careful hydrolysis of the salt it is sometimes possible to isolate ketimines $\mathrm{R{-}\underset{\underset{NH}{\|}}{C}{-}R'}$.[290] The addition of Grignard reagents to the C≡N group is normally slower than to the C=O group, and CN-containing aldehydes add the Grignard reagent without disturbing the CN group.[291] In a similar reaction, triethylaluminum[292] reacts with nitriles (in a 2 : 1 ratio) to give, after hydrolysis, ethyl ketones.[293]

The following mechanism has been proposed for the reaction of the methyl Grignard reagent with benzonitrile:[294]



OS **III,** 26, 562; **V,** 520.

6-39 The Addition of Grignard Reagents to CS_2



$$S{=}C{=}S + RMgX \longrightarrow \mathrm{R{-}\underset{\underset{SMgX}{|}}{C}{=}S}$$

This reaction is analogous to reaction **6-34.**[294a] See also reaction **6-43.**

I. Carbon Attack by Active Hydrogen Compounds. Reactions **6-40** through **6-49** are base-catalyzed condensations (although some of them are catalyzed by acids too).[295] In reaction **6-40** through **6-47,** a base removes a C—H proton to give a carbanion, which then adds to a C=O. The oxygen acquires a proton, and the resulting alcohol may or may not be dehydrated, depending on whether an α-hydrogen is present and on whether the new double bond would be in conjugation with double bonds already present:

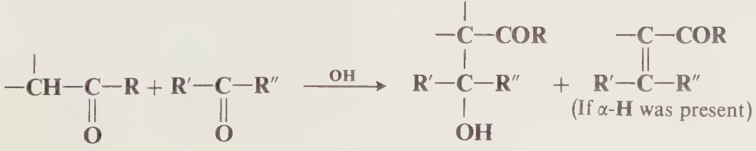
TABLE 2 Base-catalyzed condensations showing the active-hydrogen components and the carbonyl components

Reaction	Active-hydrogen component	Carbonyl component	Subsequent reactions
6-40 Aldol condensation	Aldehyde $-\overset{\vert}{\mathrm{C}}\mathrm{H}-\mathrm{CHO}$ Ketone $-\underset{\vert}{\mathrm{C}}\mathrm{H}-\mathrm{COR}$	Aldehyde, ketone	Dehydration may follow
6-41	Ester $-\overset{\vert}{\mathrm{C}}\mathrm{H}-\mathrm{COOR}$	Aldehyde, ketone (usually without α-hydrogens)	Dehydration may follow
6-42 Knoevenagel reaction	$\mathrm{Z}-\mathrm{CH_2}-\mathrm{Z'}$, $\mathrm{Z}-\mathrm{CHR}-\mathrm{Z'}$, and similar molecules	Aldehyde, ketone (usually without α-hydrogens)	Dehydration usually follows
6-43	$-\overset{\vert}{\mathrm{C}}\mathrm{H}-\mathrm{Z}$ $\quad \mathrm{Z} = \mathrm{COR, COOR, NO_2}$	$\mathrm{CO_2}$, $\mathrm{CS_2}$	
6-44 Perkin reaction	Anhydride $-\overset{\vert}{\mathrm{C}}\mathrm{H}-\mathrm{COOCOR}$	Aromatic aldehyde	Dehydration usually follows
6-45 Darzen's reaction	α-Halo ester $\mathrm{X}\overset{\vert}{\mathrm{C}}\mathrm{H}-\mathrm{COOR}$	Aldehyde, ketone	Epoxidation (SN reaction) follows
6-46 Tollens' reaction	Aldehyde $-\overset{\vert}{\mathrm{C}}\mathrm{H}-\mathrm{CHO}$ Ketone $-\overset{\vert}{\mathrm{C}}\mathrm{H}-\mathrm{COR}$	Formaldehyde	Crossed Cannizzaro reaction follows
6-47 Wittig reaction	Phosphorus ylide $\mathrm{Ph_3}\overset{\oplus}{\mathrm{P}}-\overset{\vert}{\underset{\ominus}{\underline{\mathrm{C}}}}-$	Aldehyde, ketone	"Dehydration" always follows
6-48 Thorpe reaction	Nitrile $-\overset{\vert}{\mathrm{C}}\mathrm{H}-\mathrm{CN}$	Nitrile	
6-49	Phosphorus ylide $\mathrm{Ph_3}\overset{\oplus}{\mathrm{P}}-\overset{\vert}{\underset{\ominus}{\underline{\mathrm{C}}}}-$	Nitrile	

The reactions differ in the nature of the active hydrogen component and of the carbonyl component. Table 2 illustrates the differences. Reactions **6-48** and **6-49** are analogous reactions involving addition to C≡N.

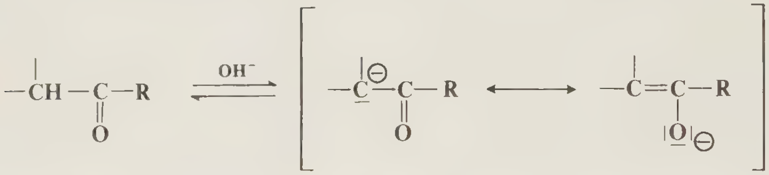
6-40 The Aldol Condensation



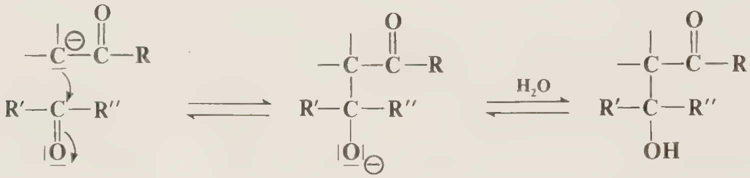
$$-\overset{|}{\mathrm{C}}\mathrm{H}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{R} + \mathrm{R'}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{R''} \xrightarrow{\mathrm{OH}} \mathrm{R'}-\overset{\overset{|}{-\mathrm{C}-\mathrm{COR}}}{\overset{|}{\underset{\underset{\mathrm{OH}}{|}}{\mathrm{C}}}}-\mathrm{R''} + \mathrm{R'}-\overset{-\mathrm{C}-\mathrm{COR}}{\overset{\|}{\mathrm{C}}}-\mathrm{R''}$$

(If α-H was present)

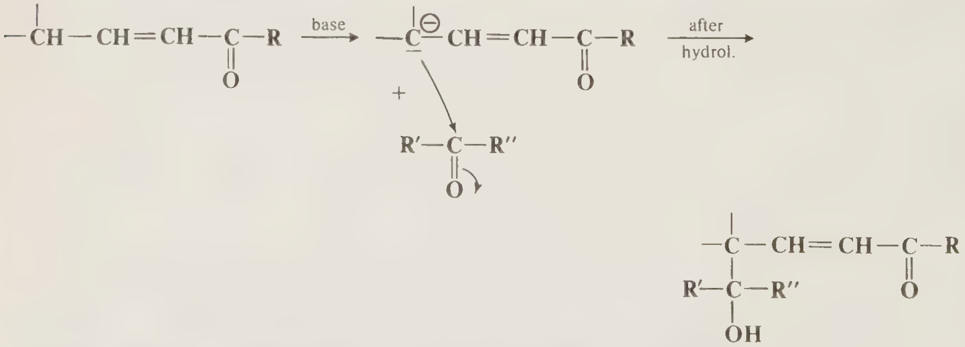
In the *aldol condensation* the α-carbon of one aldehyde or ketone molecule adds to the carbonyl carbon of another.[296] The base most often used is OH^-, though stronger bases, e.g., aluminum *t*-butoxide, are sometimes employed. Hydroxide ion is not a strong enough base to convert substantially all of an aldehyde or ketone molecule to the corresponding enolate ion; i.e., the equilibrium



lies well to the left, for both aldehydes and ketones. Nevertheless, enough enolate ion is present for the reaction to proceed:



The product is a β-hydroxy aldehyde (called an *aldol*) or ketone, which in some cases is dehydrated during the course of the reaction. Even if the dehydration is not spontaneous, it can usually easily be done, since the new double bond will be in conjugation with the C═O bond; so that this is a method of preparing α,β-unsaturated aldehydes and ketones as well as β-hydroxy aldehydes and ketones. The entire reaction is an equilibrium (including the dehydration step), and α,β-unsaturated and β-hydroxy aldehydes and ketones may be cleaved by treatment with OH^-. This reverse reaction is known as the *retrograde aldol reaction.* Under the principle of vinylogy, the active hydrogen may be one in the γ position of an α,β-unsaturated carbonyl compound:

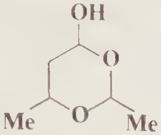


The scope of the aldol condensation may be discussed under five headings:

1. *Condensation between two molecules of the same aldehyde.* This equilibrium lies far over to the right, and the reaction is quite feasible. Many aldehydes have been converted to aldols and/or their dehydration products in this manner. The most effective catalysts are basic ion-exchange resins. Of course, the aldehyde must be one with an α-hydrogen. Aldol itself, the condensation product of acetaldehyde, is actually a trimer:[297]

---

[296] For a book-length review, see Nielsen and Houlihan, *Org. React.* **16,** 1–438 (1968).

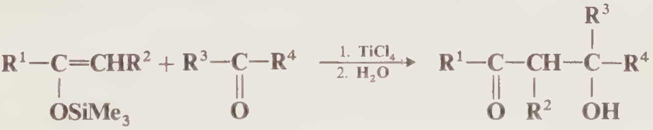


2. *Condensation between two molecules of the same ketone.* In this case the equilibrium lies well over to the left, and the reaction is feasible only if the equilibrium can be shifted. This can often be done by allowing the reaction to proceed in a Soxhlet extractor (for example, see OS **I,** 199). In this method the ketone is refluxed in such a way that the condensate drips into a separate chamber, in which the base is present. In this chamber the reaction proceeds to the small extent permitted by the unfavorable equilibrium. When the chamber is full, the mixture of the ketone and its dimer is siphoned back into the original flask, out of contact with the base. Since the boiling point of the dimer is higher than that of the ketone, only the ketone is volatilized back to the chamber containing the base, where a little more of it is converted to dimer, and the process is repeated until a reasonable yield of dimer is obtained. Two molecules of the same ketone can also be condensed without a Soxhlet extractor, by use of the reagent barium pernitride Ba_3N_4.[298] Unsymmetrical ketones condense on the side which has more hydrogens. (An exception is butanone, which with acid catalysts reacts at the CH_2 group, though with basic catalysts it too reacts at the CH_3 group.)

3. *Condensation between two different aldehydes.* In the most general case this will produce a mixture of four products (eight, if the olefins are counted). However, if one aldehyde does not have an α-hydrogen, only two aldols are possible, and in many cases the crossed product is the main one. The crossed aldol condensation is often called the *Claisen-Schmidt reaction.*

4. *Condensation between two different ketones.* This is seldom attempted, but similar considerations apply.

5. *Condensation between an aldehyde and a ketone.* This is usually feasible, especially when the aldehyde has no α-hydrogen, since there is no competition from ketone condensing with itself. This is also called the *Claisen-Schmidt reaction.* Even when the aldehyde has an α-hydrogen, it is the α-carbon of the ketone which adds to the carbonyl of the aldehyde, and not the other way around. The reaction is ordinarily carried out by adding a base to a mixture of the aldehyde and ketone, but it has been done by preparing the lithium enolate of the ketone separately (reaction **2-20**) and then adding this to the aldehyde in the presence of $ZnCl_2$,[299] a method which has the advantages that coupling will take place on the desired side of an unsymmetrical ketone, and that the aldol product is stabilized by chelation of its two oxygen atoms with the zinc ion. Another way to ensure coupling on the desired side of a ketone is to treat the silyl ether of the ketone (instead of the ketone itself) with an aldehyde or ketone, with $TiCl_4$ as catalyst.[300] This reaction



$$\underset{\displaystyle OSiMe_3}{R^1-\underset{|}{C}}{=}CHR^2 + R^3-\underset{\displaystyle O}{\underset{\|}{C}}-R^4 \xrightarrow[2.\ H_2O]{1.\ TiCl_4} R^1-\underset{\displaystyle O}{\underset{\|}{C}}-\underset{\displaystyle R^2}{\underset{|}{CH}}-\overset{\displaystyle R^3}{\overset{|}{\underset{\displaystyle OH}{\underset{|}{C}}}}-R^4$$

46

can also be run with the aldehyde or ketone in the form of its acetal $R^3R^4C(OR')_2$, in which case the product is the ether $RCOCHR^2CR^3R^4OR'$, instead of **46.**[301] Enol acetates also give this product when treated with acetals and $TiCl_4$ or a similar catalyst.[302]

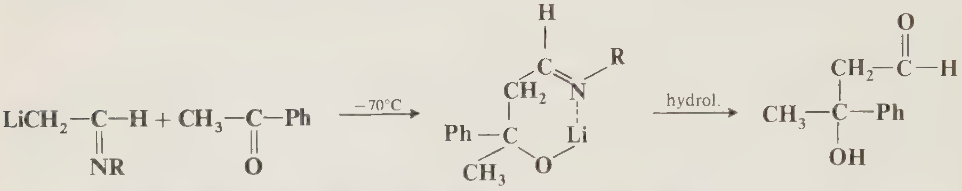
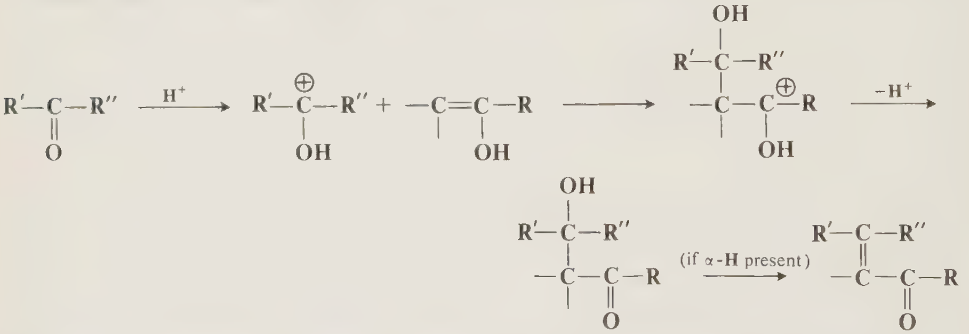
[300] Mukaiyama, Banno, and Narasaka, *J. Am. Chem. Soc.* **96,** 7503 (1974).

It is possible to make the α-carbon of the aldehyde add to the carbonyl carbon of the ketone, by using the Schiff base instead of the aldehyde, and $LiN(iso\text{-}Pr)_2$ as the base:[303]



The aldol condensation can also be performed with acid catalysts, in which case dehydration usually follows. Here there is initial protonation of the carbonyl group, which attacks the α-carbon of the *enol* form of the other molecule:



With respect to the enol, this mechanism is similar to that of α halogenation (reaction **2-4**).

A side reaction which is sometimes troublesome is further condensation, since the product of an aldol condensation is still an aldehyde or ketone.

Aldol condensations are often used to close five- and six-membered rings. Because of the favorable entropy (p. 193), such ring closures generally take place with ease, even where a ketone condenses with a ketone. An important example is the *Robinson annulation reaction*,[304] which has often been used in the synthesis of steroids and terpenes. In this reaction a cyclic ketone is converted to another cyclic ketone, with one additional six-membered ring containing a double bond. The substrate is treated with methyl vinyl ketone (or a simple derivative of methyl vinyl ketone) and a base.[305] The enolate ion of the substrate adds to the methyl vinyl ketone in a

Michael reaction (**5-19**) to give a diketone which undergoes or is made to undergo an internal aldol condensation and subsequent dehydration to give the product. Because methyl vinyl ketone has a tendency to polymerize, precursors are often used instead, i.e., compounds which will give methyl vinyl ketone when treated with a base. One common example, $MeCOCH_2CH_2NEt_2Me^+ I^-$ (see reaction **7-8**), is easily prepared by quaternization of $MeCOCH_2CH_2NEt_2$, which itself is prepared by a Mannich reaction (**6-17**) involving acetone, formaldehyde, and dimethylamine. The Robinson annulation reaction has also been carried out with 3-butyn-2-one, in which case the new ring of the product contains two double bonds.[306] α-Silylated vinyl ketones $RCOC(SiMe_3){=}CH_2$ have also been used successfully in annulation reactions.[307] The $SiMe_3$ group is easily removed. 1,5-Diketones prepared in other ways are also frequently cyclized by internal aldol condensations.

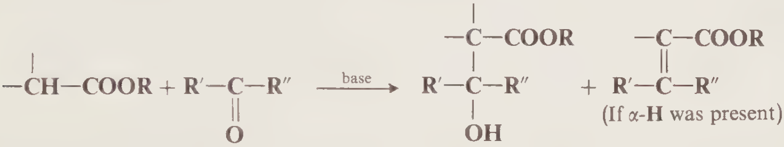
6-41 Condensations between Esters and Aldehydes or Ketones



In the presence of a strong base, the α-carbon of an ester may condense with the carbonyl carbon of an aldehyde or ketone to give a β-hydroxy ester, which may or may not be dehydrated to the α,β-unsaturated ester. This reaction is sometimes called the Claisen condensation,[308] an unfortunate usage since that name is more firmly connected to reaction **0-111.** It is also possible for the α-carbon of an aldehyde or ketone to add to the carbonyl carbon of an ester, but this is a different reaction (**0-112**) involving nucleophilic substitution and not addition to a C=O bond. It can, however, be a side reaction if the aldehyde or ketone has an α-hydrogen.

Besides ordinary esters (containing an α-hydrogen), the reaction can also be carried out with lactones and, as in reaction **6-40**, with the γ position of α,β-unsaturated esters (vinylology).

For most esters, a much stronger base is needed than for aldol condensations; Ph_3CNa and $LiNH_2$[309] are among those employed. However, one type of ester reacts more easily, and such strong bases are not needed: diethyl succinate and its derivatives condense with aldehydes and ketones in the presence of bases such as NaOEt, NaH, or $KOCMe_3$. This reaction is called the *Stobbe condensation.*[310] One of the ester groups (sometimes both) is hydrolyzed in the course of the reaction. The following mechanism accounts for (1) the fact that succinic esters react so much better than others; (2) one ester group is always cleaved; and (3) the alcohol is not the product but the olefin. In addition, intermediate lactones **47** have been isolated from the mixture:[311]

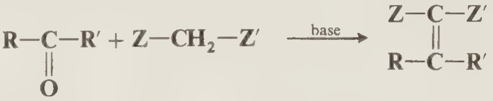
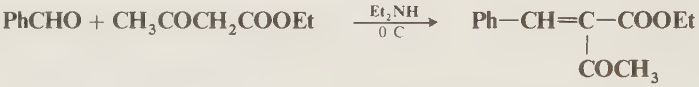
6-42 The Knoevenagel Condensation



$$\underset{\displaystyle\overset{\|}{\mathrm{O}}}{\mathrm{R{-}C{-}R'}} + \mathrm{Z{-}CH_2{-}Z'} \xrightarrow{\text{base}} \begin{array}{c}\mathrm{Z{-}C{-}Z'}\\ \|\\ \mathrm{R{-}C{-}R'}\end{array}$$

The condensation of aldehydes or ketones, usually not containing an α-hydrogen, with compounds of the form Z—CH$_2$—Z′ or Z—CHR—Z′ is usually called the *Knoevenagel reaction*,[313] although some limit the use of this name to only some of the active-hydrogen compounds which give the reaction. Z and Z′ may be CHO, COR, COOH, COOR, CN, NO$_2$,[314] SOR, SO$_2$R, SO$_2$OR, or similar groups. When Z = COOH, decarboxylation of the product often takes place in situ. If a strong enough base is used, the reaction can be performed on compounds possessing only a single Z; e.g., CH$_3$Z or RCH$_2$Z. Other active hydrogen compounds can also be employed, among them CHCl$_3$, 2-methylpyridines, terminal acetylenes, cyclopentadienes, etc.; in fact any compound which contains a C—H bond the hydrogen of which can be removed by a base. The following examples illustrate the wide scope of the reaction:



$$\mathrm{PhCHO + CH_3COCH_2COOEt \xrightarrow[0\ C]{Et_2NH} Ph{-}CH{=}\underset{\displaystyle\underset{\mathrm{COCH_3}}{|}}{C}{-}COOEt}$$

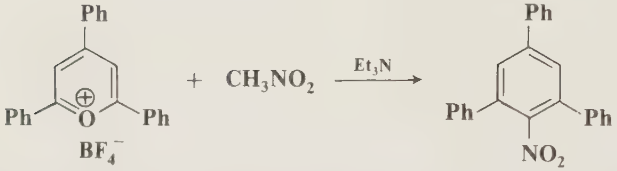
51 (Ref. 323)



(Ref. 324)

We see from these examples that many of the carbon nucleophiles we encountered in Chapter 10 are also nucleophiles toward aldehydes and ketones (compare reactions **0-96** through **0-100** and **0-102**). As we have seen in Chapter 10, the initial products in many of these cases, e.g., **48** through **51**, can be converted by relatively simple procedures (hydrolysis, reduction, decarboxylation, etc.) to various other products. In the reaction with terminal acetylenes,[325] sodium acetylides are the most common reagents (when they are used, the reaction is often called the *Nef reaction*), but lithium,[325a] magnesium, and other metallic acetylides have also been used. A particularly convenient reagent is lithium acetylide–ethylenediamine complex,[326] a stable, free-flowing powder which is commercially available. Alternatively, the substrate may be treated with the alkyne itself in the presence of a base, so that the acetylide is generated in situ. This procedure is called the *Favorskii reaction*, not to be confused with the Favorskii rearrangement (**8-8**). 1,4-Diols can be prepared by the treatment of aldehydes with dimetalloacetylenes MC≡CM.[327] The reaction with cyclopentadiene is a good method for the preparation of fulvenes.

With most of these reagents the alcohol is not isolated (but only the olefin) if the alcohol has a hydrogen in the proper position. However, in some cases it is the alcohol which is the major product. When the reactant is of the form ZCH_2Z', aldehydes react much better than ketones and few successful reactions with ketones have been reported. However, it is possible to get good yields of olefin from the condensation of ethyl malonate $CH_2(COOEt)_2$ with ketones, as well as with aldehydes, if the reaction is run with $TiCl_4$ and pyridine in tetrahydrofuran.[328] In reactions with ZCH_2Z', the catalyst is most often a secondary amine (piperidine is the most common), though many other catalysts have been used, among them certain amino acids, e.g., β-alanine, α-aminophenylacetic acid. When the catalyst is pyridine (to which piperidine may or may not be added) the reaction is known as the *Doebner modification* of the Knoevenagel reaction. In some cases amine salts make better catalysts than the free amines, but this is not always true. Alkoxides are also common catalysts. In some cases it is possible to get a second molecule of active compound to add to the initial product in a Michael reaction; e.g.,

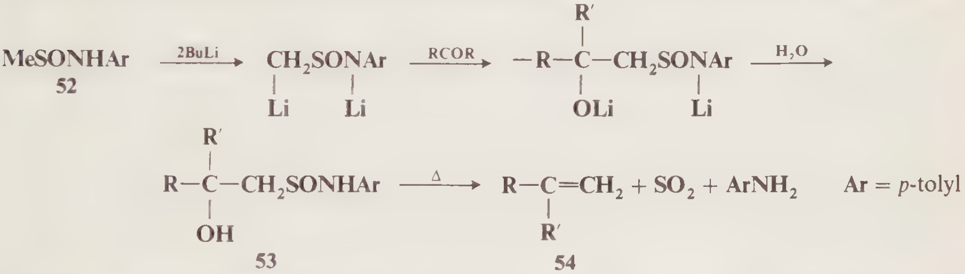
It has also proved possible to have one active hydrogen compound add to an aldehyde and then, in situ, to have a *different* one add to the olefin in the Michael manner.[329]

As with reaction **6-40**, these reactions have sometimes been performed with acid catalysts.[330]

Imines can be employed instead of aldehydes or ketones; the products are the same, an amine being lost instead of water.[331]

A number of special applications of the Knoevenagel reaction follow.

1. The dilithio derivative of N-methanesulfinyl-*p*-toluidine[332] (**52**) adds to aldehydes and ketones to give, after hydrolysis, the hydroxysulfinamides **53**, which, upon heating, undergo stereospecifically syn eliminations to give the olefins **54**.[333] The reaction is thus a method for achieving the conversion $\mathrm{RR'CO \rightarrow RR'C{=}CH_2}$ and represents an alternative to the Wittig reaction. In a similar reaction, the lithio derivatives of alkyl *t*-butyl sulfoxides add to aldehydes and ketones to give β-hydroxy sulfoxides, which eliminate SO_2 when treated with N-chlorosuccinimide or sulfuryl chloride.[333a] Another similar method involves treatment of the aldehyde or ketone with the sulfoximine derivative **55**, followed by reduction of the product with aluminum



$$\underset{\mathbf{52}}{\mathrm{MeSONHAr}} \xrightarrow{\mathrm{2BuLi}} \mathrm{\underset{Li}{CH_2}SON\underset{Li}{Ar}} \xrightarrow{\mathrm{RCOR}} \mathrm{R{-}\overset{R'}{\underset{OLi}{C}}{-}CH_2SO\underset{Li}{N}Ar} \xrightarrow{\mathrm{H_2O}}$$

$$\underset{\mathbf{53}}{\mathrm{R{-}\overset{R'}{\underset{OH}{C}}{-}CH_2SONHAr}} \xrightarrow{\Delta} \underset{\mathbf{54}}{\mathrm{R{-}\underset{R'}{C}{=}CH_2}} + \mathrm{SO_2 + ArNH_2} \qquad \mathrm{Ar} = p\text{-tolyl}$$

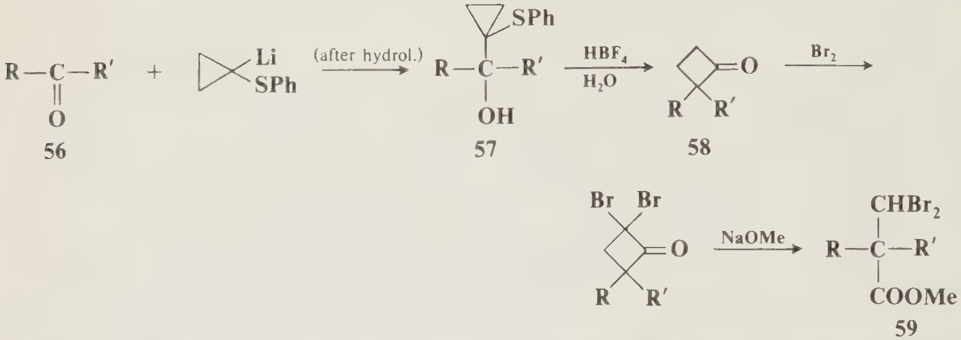
amalgam in aqueous tetrahydrofuran containing acetic acid.[334] Still other similar reactions have been reported in which a carbanion was generated α to a silicon rather than a sulfur atom.[335]

2. Another kind of conversion which can be realized with the aid of a type of Knoevenagel reaction is that of $C{=}O \rightarrow CR_2$.[336] Treatment of a ketone (**56**) with 1-lithiocyclopropyl phenyl sulfide gives the cyclopropylcarbinol **57**, which is rearranged (reaction **8-3**) to the cyclobutanone



56 **57** **58** **59**

58. Bromination of **58** (reaction **2-4**), followed by treatment with NaOMe, cleaves the cyclobutane ring (reaction **2-44**) to give compound **59**, which has two functional groups and so can be converted to a variety of other products. The conversion of **56** to **59** can also be accomplished by the use of a sulfur ylide (see reaction **6-65**). Other $C{=}O \rightarrow CR_2$ conversions are mentioned at reactions **6-31** (p. 837) and **6-47** (p. 871).

3. The reaction of ketones with tosylmethylisocyanide (**60**) gives different products[337] depending on the reaction conditions. When the reaction is run with potassium *t*-butoxide in tetrahydrofuran

[337] For a review of α-metalated isocyanides, see Hoppe, *Angew. Chem. Int. Ed. Engl.* **13**, 789–804 (1974) [*Angew. Chem.* **86**, 878–893].

at −5°C, one obtains (after hydrolysis) the normal Knoevenagel product **61**, except that the isonitrile group has been hydrated (reaction **6-71**).[338] With the same base but with 1,2-dimethoxyethane (DME) as solvent the product is the nitrile **62**.[339] When the ketone is treated with **60** and thallium(I) ethoxide in a 4 : 1 mixture of absolute ethanol and DME at room temperature, the product is a 4-ethoxy-2-oxazoline **63**.[340] Since **61** can be hydrolyzed[341] to a carboxylic acid[338] and **63** to an α-hydroxy aldehyde,[340] this versatile reaction provides a means for achieving the conversion of RCOR′ to RCHR′COOH, RCHR′CN, or RCR′(OH)CHO, as desired. The conversion to RCHR′COOH has also been carried out with certain aldehydes (R′ = H).[342]

4. Aldehydes and ketones RCOR′ react with α-methoxyvinyllithium $CH_2=C(Li)OMe$ to give hydroxy enol ethers $RR'C(OH)C(OMe)=CH_2$, which are easily hydrolyzed to acyloins RR′C(OH)COMe.[343] In this reaction, the $CH_2=C(Li)OMe$ is a synthon for the unavailable $CH_3-\overset{\ominus}{\bar{C}}=O$ ion. The reagent also reacts with esters RCOOR′ to give $RC(OH)(COMe=CH_2)_2$. A synthon for the $Ph-\overset{\ominus}{C}=O$ ion is $Ph\overset{\ominus}{\bar{C}}(CN)OSiMe_3$, which adds to aldehydes and ketones RCOR′ to give, after hydrolysis, the α-hydroxy ketones RR′C(OH)COPh.[343a]

5. A procedure for converting an aldehyde or ketone RR′CO to the homologous aldehyde RR′CHCHO consists of treating the substrate with lithium bis(ethylenedioxyboryl)methide, followed by oxidation with aqueous H_2O_2:[344]

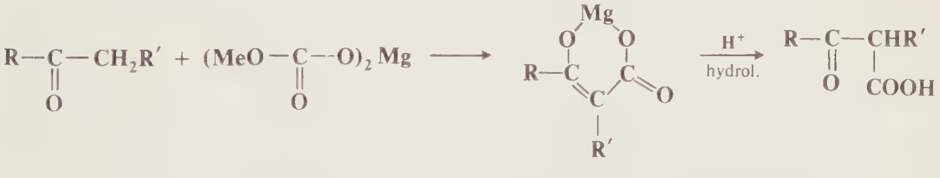
6-43 The Addition of Active Hydrogen Compounds to CO_2 and CS_2



64 65

Ketones of the form $RCOCH_3$ and $RCOCH_2R'$ can be carboxylated indirectly by treatment with magnesium methyl carbonate **64**.[344a] Because formation of the chelate **65** provides the driving force of the reaction, carboxylation cannot be achieved at a disubstituted α-position. The reaction has also been performed on CH_3NO_2 and compounds of the form RCH_2NO_2 [345] and on certain lactones[346] and hydantoins[347] (p. 861). Direct carboxylation has been reported in a number of instances. Various ketones, esters, and other active hydrogen compounds have been carboxylated in the α position with the aid of the base PhONa, though yields are generally low.[348] Malonic acid monoalkyl esters can be directly prepared from carboxylic esters of the form RCH_2COOR' and $R_2CHCOOR'$ by treatment of the lithium salt with carbon dioxide.[349] Best yields are obtained from anions which are rather severely crowded around the anionic carbon atom. In a similar reaction, ketones have been carboxylated in the α position to give β-keto acids.[350] The base here was lithium 4-methyl-2,6-di-*t*-butylphenoxide (**66**). This base has also been used in the addition

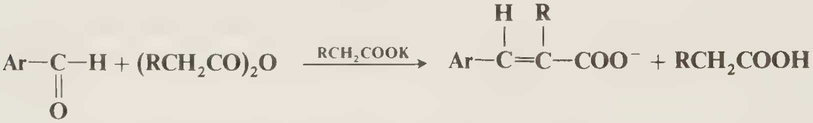
66 **67** **68**

of ketones to CS_2 to give dianions (**67**), which are easily alkylated to α-dithiomethylene ketones **68**.[351] Compounds of the form ZCH_2Z' also react with bases and CS_2 to give dianions analogous to **67**.[352]

6-44 The Perkin Reaction



$$\mathrm{Ar{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}H + (RCH_2CO)_2O \xrightarrow{RCH_2COOK} Ar{-}\overset{H}{\overset{|}{C}}{=}\overset{R}{\overset{|}{C}}{-}COO^- + RCH_2COOH}$$

The condensation of aromatic aldehydes with anhydrides is called the *Perkin reaction*.[353] When the anhydride has two α-hydrogens (as shown), dehydration always occurs; the β-hydroxy acid salt is never isolated. In some cases, anhydrides of the form $(R_2CHCO)_2O$ have been used, and then the hydroxy compound is the product since dehydration cannot take place. The base in the Perkin reaction is nearly always the sodium or potassium salt of the acid corresponding to the anhydride. Besides aromatic aldehydes, their vinylogs ArCH=CHCHO also give the reaction. Otherwise, the reaction is not suitable for aliphatic aldehydes.[354] There is a possible side reaction: decarboxylation of the initial β-hydroxy acid salt instead of simple dehydration. Sometimes this is the main reaction:

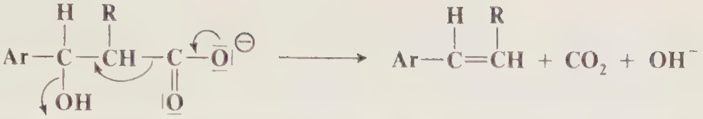
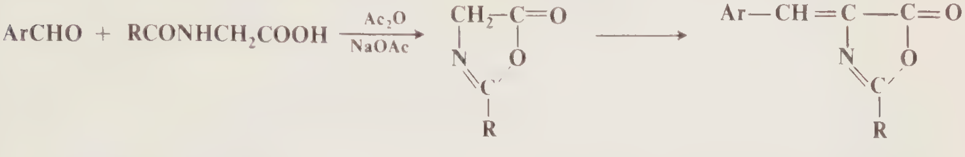
[354] Crawford and Little, *J. Chem. Soc.* 722 (1959).

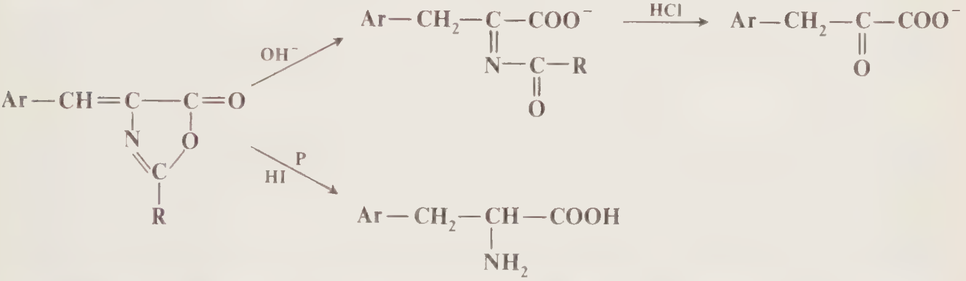


An important variation of the Perkin reaction is the *Erlenmeyer azlactone synthesis*.[355] In this reaction aromatic aldehydes are condensed with N-acyl derivatives of glycine, in the presence of acetic anhydride and sodium acetate. The product is an azlactone:



The intermediate **69** is formed first and then condenses with the aldehyde. When **69** was prepared independently, it reacted with aromatic aldehydes to give azlactones.[356] The Erlenmeyer reaction can be extended to aliphatic aldehydes by the use of tetrahydrofuran as solvent and replacement of NaOAc by $Pb(OAc)_2$.[357]

Azlactones are useful because they can be converted into other compounds. Treatment with NaOH, followed by HCl, gives arylpyruvic acids, the preparation of which represents a method of increasing the carbon chain by two (from the original aldehyde). Reduction of an azlactone by phosphorus and HI, or other reducing agents, produces an amino acid, also increasing the chain by two:



Further variations of the Perkin reaction involve condensation with hydantoin (**70**) and with rhodanine (**71**). The product from hydantoin condensation may also be reduced to an amino acid. The product from the rhodanine condensation may be converted, in high yield, by a three-step process to a nitrile with one more carbon than the original aldehyde:

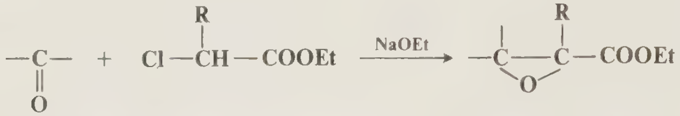
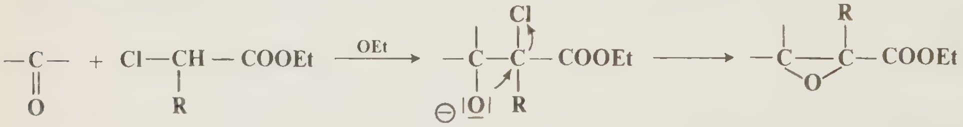
6-45 Darzen's Glycidic Ester Condensation



Aldehydes and ketones condense with α-halo esters in the presence of bases to give α,β-epoxy esters, called *glycidic esters.* This is called *Darzen's condensation.*[358] The reaction consists of an initial Knoevenagel-type condensation (**6-42**) followed by an internal SN2 reaction (**0-15**):[359]



Although the intermediate halo alkoxide is generally not isolated, it has been done, not only with α-fluoro esters (since fluorine is such a poor leaving group in nucleophilic substitutions) but also with α-chloro esters.[360] This is only one of several types of evidence that rule out a carbene intermediate.[361] Sodium ethoxide is often used as the base, although other bases, including sodium amide, are sometimes used. Aromatic aldehydes and ketones give good yields, but aliphatic aldehydes react poorly. However, the reaction can be made to give good yields (~80%) with simple aliphatic aldehydes as well as with aromatic aldehydes and ketones by treatment of the α-halo ester with the base lithium bis(trimethylsilyl)amide $LiN(SiMe_3)_2$ in tetrahydrofuran at −78°C (to form the conjugate base of the ester) and addition of the aldehyde or ketone to this solution.[362] The Darzen's reaction has also been carried out on α-halo ketones, α-halo nitriles,[363] α-halo sulfones,[364] α-halo N,N-disubstituted amides,[365] and even on benzylic halides. Glycidic esters can easily be converted to aldehydes (reaction **2-39**). The reaction has been extended to the formation of analogous aziridines by treatment of an imine with an α-halo ester or an α-halo N,N-disubstituted amide and *t*-BuOK in the solvent 1,2-dimethoxyethane.[366] However, yields were not high. Acid-catalyzed Darzen's reactions have also been reported.[367] See also reaction **6-65.**

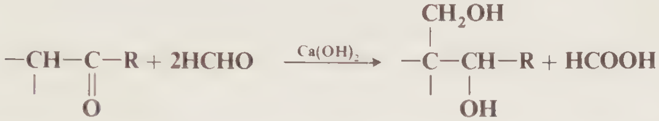
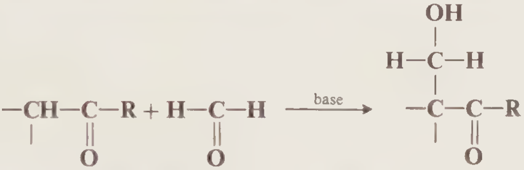
6-46 Tollens' Reaction



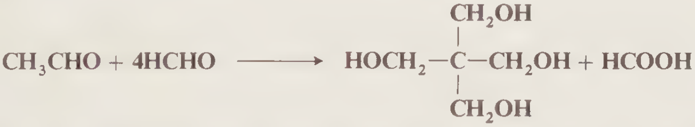
$$-\underset{|}{\mathrm{CH}}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{R}+2\mathrm{HCHO}\xrightarrow{\mathrm{Ca(OH)_2}}-\overset{\overset{\mathrm{CH_2OH}}{|}}{\underset{|}{\mathrm{C}}}-\underset{\underset{\mathrm{OH}}{|}}{\mathrm{CH}}-\mathrm{R}+\mathrm{HCOOH}$$

In *Tollens' reaction* an aldehyde or ketone containing an α-hydrogen is treated with formaldehyde in the presence of $Ca(OH)_2$ or a similar base. The first step is a mixed aldol condensation (**6-40**), in which the α-carbon of the aldehyde or ketone adds to the carbonyl carbon of formaldehyde:



$$-\underset{|}{\mathrm{CH}}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{R}+\mathrm{H}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{H}\xrightarrow{\text{base}}-\overset{\overset{\overset{\overset{\mathrm{OH}}{|}}{\mathrm{H}-\mathrm{C}-\mathrm{H}}}{|}}{\underset{|}{\mathrm{C}}}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{R}$$

The reaction can be stopped at this point, but more often a second mole of formaldehyde is permitted to reduce the newly formed aldol to a 1,3-glycol, in a crossed Cannizzaro reaction (**9-74**). If the aldehyde or ketone has several α-hydrogens, they can all be replaced. An important use of the reaction is to prepare pentaerythritol from acetaldehyde:

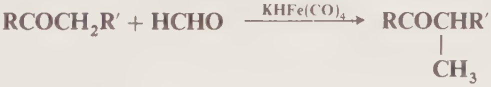


$$\mathrm{CH_3CHO}+4\mathrm{HCHO}\longrightarrow\mathrm{HOCH_2}-\overset{\overset{\mathrm{CH_2OH}}{|}}{\underset{\underset{\mathrm{CH_2OH}}{|}}{\mathrm{C}}}-\mathrm{CH_2OH}+\mathrm{HCOOH}$$

When aliphatic nitro compounds are used instead of aldehydes or ketones, no reduction occurs, and the reaction is essentially a Knoevenagel reaction, though it is usually also called a Tollens' reaction:

$$\mathrm{CH_3NO_2}+\mathrm{HCHO}\xrightarrow{\mathrm{OH^-}}\mathrm{HOCH_2CH_2NO_2}$$

When a ketone of the type $RCOCH_3$ or $RCOCH_2R'$ is treated with formaldehyde and $KHFe(CO)_4$ in ethanol or water, a CH_3 group is introduced in the α position:[368]



$$\mathrm{RCOCH_2R'}+\mathrm{HCHO}\xrightarrow{\mathrm{KHFe(CO)_4}}\mathrm{RCO}\underset{\underset{\mathrm{CH_3}}{|}}{\mathrm{CH}}\mathrm{R'}$$

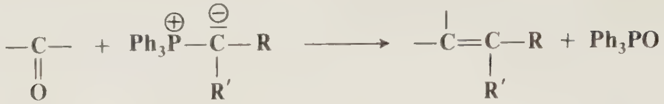
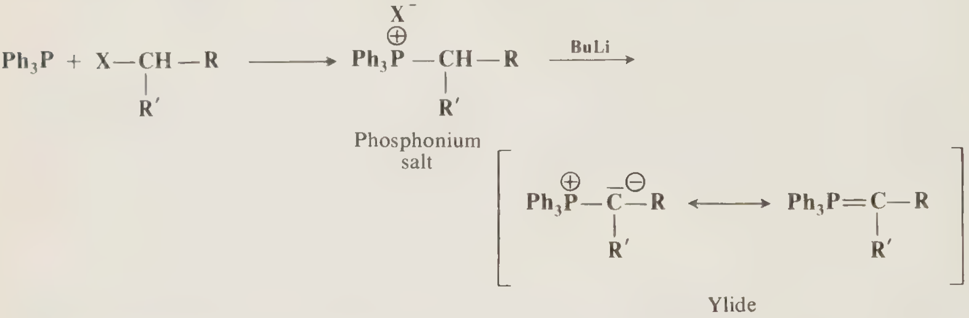
6-47 The Wittig Reaction



$$\underset{\overset{\|}{O}}{-C-} + Ph_3\overset{\oplus}{P}-\underset{R'}{\overset{\ominus}{C}}-R \longrightarrow -\overset{|}{C}=\underset{R'}{C}-R + Ph_3PO$$

In the *Wittig reaction* an aldehyde or ketone is treated with a *phosphorus ylide* (also called a *phosphorane*) to give an olefin.[369] Phosphorus ylides, which are hybrids of two canonical forms, are usually prepared by treatment of a phosphonium salt with a base, and phosphonium salts are usually prepared from the phosphine and an alkyl halide (reaction **0-46**):



$$Ph_3P + X-\underset{R'}{CH}-R \longrightarrow \overset{X^-}{\overset{\oplus}{Ph_3P}}-\underset{R'}{CH}-R \xrightarrow{BuLi} \left[Ph_3\overset{\oplus}{P}-\underset{R'}{\overset{\ominus}{C}}-R \longleftrightarrow Ph_3P=\underset{R'}{C}-R\right]$$

The overall sequence of three steps may be called the Wittig reaction, or only the final step.[370] Phosphonium salts are also prepared by addition of phosphines to Michael olefins (like reaction **5-9**) and in other ways. The phosphonium salts are most often converted to the ylides by treatment with a strong base such as butyllithium, sodium amide, sodium hydride, or a sodium alkoxide, though weaker bases may be used if the salt is acidic enough. For $(Ph_3P^+)_2CH_2$, sodium carbonate is a strong enough base.[371] Ethylene oxide has also been used as the base.[372] The conversion of phosphonium salts to ylides is apparently a simple acid-base reaction (**2-19**), but, at least with alkyllithiums, it must be more complicated than that, since, in addition to a simple proton abstraction, exchange of groups can occur. Thus, $Ph_3\overset{\oplus}{P}CH_3 \quad Br^-$ with methyllithium gave 26% *benzene*.[373] It is likely that an intermediate Ph_3PMe_2 was formed, which lost either methane or benzene to give an ylide. Phosphorus ylides can also be prepared by reaction **0-114** and by the addition of halocarbenes to phosphines in a Lewis acid-base reaction:

$$\overline{C}HCl + Ph_3P \longrightarrow Ph_3\overset{\oplus}{P}\overset{\ominus}{\underline{C}}HCl$$

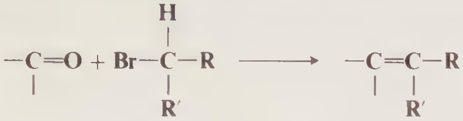
[373] Seyferth, Hughes, and Heeren, *J. Am. Chem. Soc.* **87**, 2847, 3467 (1965).

In the overall Wittig reaction, an olefin is formed from the aldehyde or ketone and an alkyl halide in which the halogen-bearing carbon contains at least one hydrogen:

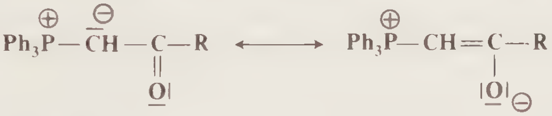


$$-\underset{|}{C}=O + Br-\overset{\overset{H}{|}}{\underset{\underset{R'}{|}}{C}}-R \longrightarrow -\underset{|}{C}=\underset{\underset{R'}{|}}{C}-R$$

This result is similar to that obtained in the Reformatsky reaction (**6-32**), but this is more general since no ester or other group is required to be α to the halogen. Another important advantage of the Wittig reaction is that the *position* of the new double bond is always certain, in contrast to the result in the Reformatsky reaction and in most of the base-catalyzed condensations (**6-40** to **6-46**).

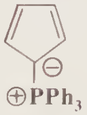
The reaction is very general. The aldehyde or ketone may be aliphatic, alicyclic, or aromatic (including diaryl ketones); it may contain double or triple bonds; it may contain various functional groups, such as OH, OR, NR_2, aromatic nitro or halo, acetal, or even ester groups. Although phosphorus ylides also react with esters (reaction **0-114**), that reaction is too slow to interfere.[374] Double or triple bonds *conjugated* with the carbonyl also do not interfere, the attack being at the C=O carbon.

The phosphorus ylide may also contain double or triple bonds and certain functional groups. Simple ylides (R, R′ = hydrogen or alkyl) are highly reactive, reacting with oxygen, water, hydrohalic acids, and alcohols, as well as carbonyl compounds and esters, so that the reaction must be run under conditions where these materials are absent. When an electron-withdrawing group, e.g., COR, CN, COOR, CHO, is present in the α position, the ylides are much more stable. The stability is increased because the charge on the carbon is spread by resonance:

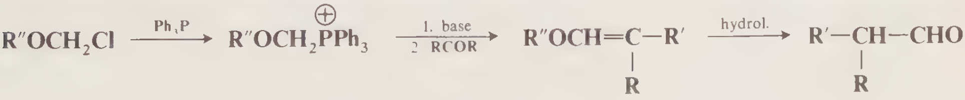


$$Ph_3\overset{\oplus}{P}-\overset{\ominus}{\bar{C}}H-\underset{\underset{\underline{O}|}{\|}}{C}-R \longleftrightarrow Ph_3\overset{\oplus}{P}-CH=\underset{\underset{|\underline{O}|^{\ominus}}{|}}{C}-R$$

These ylides react readily with aldehydes but slowly or not at all with ketones. In extreme cases, e.g., compound **72**, the ylide does not react with ketones *or* aldehydes. Besides these groups, the ylide may contain one or two α-halogens [these ylides can be prepared from halocarbenes and phosphines (p. 864) or in the normal manner][375] or an α-OR or α-OAr group. In the latter case



72



$$R''OCH_2Cl \xrightarrow{Ph_3P} R''OCH_2\overset{\oplus}{P}Ph_3 \xrightarrow[2.\ RCOR]{1.\ base} R''OCH=\underset{\underset{R}{|}}{C}-R' \xrightarrow{hydrol.} R'-\underset{\underset{R}{|}}{CH}-CHO$$

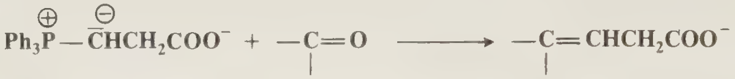
[374] Greenwald, Chaykovsky, and Corey, *J. Org. Chem.* **28,** 1128 (1963).

[375] Seyferth, Grim, and Read, *J. Am. Chem. Soc.* **82,** 1510 (1960), **83,** 1617 (1961); Seyferth, Heeren, Singh, Grim, and Hughes, *J. Organomet. Chem.* **5,** 267 (1966); Schlosser and Zimmermann, *Synthesis* 75 (1969); Burton and Greenlimb, *J. Fluorine Chem.* **3,** 447 (1974).

the product is a vinyl ether, which can be hydrolyzed (**0-7**) to an aldehyde,[376] so that this reaction is a means of achieving the conversion RCOR′ → RR′CHCHO. However, the ylide may not contain an α-nitro group. If the phosphonium salt contains a potential leaving group, such as Br or OMe, in the β position, treatment with a base gives elimination, instead of the ylide:

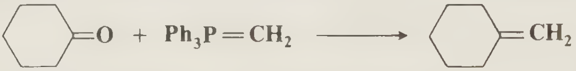
$$Ph_3\overset{\oplus}{P}CH_2CH_2Br \xrightarrow{\text{base}} Ph_3\overset{\oplus}{P}CH{=}CH_2$$

However, a β-COO⁻ group may be present, and the product is a β,γ-unsaturated acid:[377]

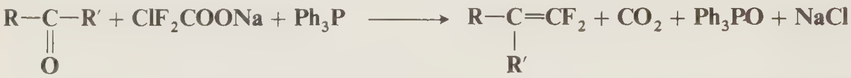


$$Ph_3\overset{\oplus}{P}-\overset{\ominus}{\bar{C}}HCH_2COO^- + -\underset{|}{C}{=}O \longrightarrow -\underset{|}{C}{=}CHCH_2COO^-$$

This is the only convenient way to make these compounds, since elimination by any other route gives the thermodynamically more stable α,β-unsaturated isomers. This is an illustration of the utility of the Wittig method for the specific location of a double bond. Another illustration is the conversion of cyclohexanones to olefins containing exocyclic double bonds, e.g.,[378]

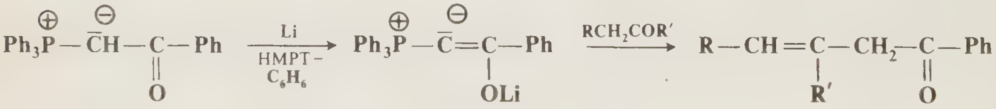


This is the only general method for the synthesis of these compounds. As indicated above, α,α′-dihalophosphoranes can be used to prepare 1,1-dihaloalkenes. Another way to prepare such compounds is to treat the carbonyl compound with a mixture of CBr_4 (or CCl_4) and triphenylphosphine, either with or without the addition of zinc dust (which allows less Ph_3P to be used).[379] Aldehydes and ketones can be converted to 1,1-difluoroalkenes by treatment with a salt of chlorodifluoroacetic acid in the presence of triphenylphosphine:[380]



$$R-\underset{\underset{O}{\|}}{C}-R' + ClF_2COONa + Ph_3P \longrightarrow R-\underset{\underset{R'}{|}}{C}{=}CF_2 + CO_2 + Ph_3PO + NaCl$$

When the phosphorane **73** is treated with lithium in HMPT-benzene, a second proton is removed to give the enolate ylide **74**. This ylide reacts with ketones of the form RCH_2COR' to



$$Ph_3\overset{\oplus}{P}-\overset{\ominus}{\bar{C}}H-\underset{\underset{O}{\|}}{C}-Ph \xrightarrow[\text{HMPT}-C_6H_6]{\text{Li}} Ph_3\overset{\oplus}{P}-\overset{\ominus}{\bar{C}}{=}\underset{\underset{OLi}{|}}{C}-Ph \xrightarrow{RCH_2COR'} R-CH{=}\underset{\underset{R'}{|}}{C}-CH_2-\underset{\underset{O}{\|}}{C}-Ph$$

73 **74** **75**

give the nonconjugated β,γ-unsaturated ketones **75**.[381] As mentioned above, ylides of the type **73** are too unreactive to react with the ketones themselves, but if **73** did react directly with RCH_2COR', the normal Wittig product would be the α,β-unsaturated ketone $RCH_2CR'{=}CHCOPh$.

[377] Corey, McCormick, and Swensen, *J. Am. Chem. Soc.* **86,** 1884 (1964).

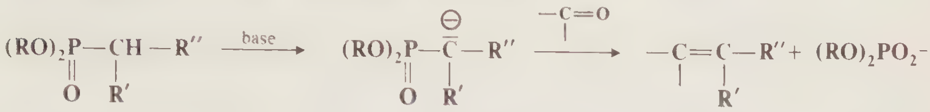
[378] Wittig and Schöllkopf, *Chem. Ber.* **87,** 1318 (1954).

[379] Rabinowitz and Marcus, *J. Am. Chem. Soc.* **84,** 1312 (1962); Ramirez, Desai, and McKelvie, *J. Am. Chem. Soc.* **84,** 1745 (1962); Raulet and Levas, *C. R. Acad. Sci., Ser. C* **270,** 1467 (1970); Corey and Fuchs, *Tetrahedron Lett.* 3769 (1972); Posner, Loomis, and Sawaya, *Tetrahedron Lett.* 1373 (1975).

[380] Fuqua, Duncan, and Silverstein, *J. Org. Chem.* **30,** 1027, 2543 (1965).

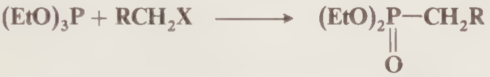
[381] Broquet, *Tetrahedron* **29,** 3595 (1973), **31,** 1331 (1975).

Ylides are usually prepared from triphenylphosphine, but other triarylphosphines,[382] trialkylphosphines,[383] and triphenylarsine have also been used. The Wittig reaction has also been carried out with other types of ylides, the most important being prepared from phosphonates:[384]



$$\underset{\text{O}}{\overset{\|}{(\text{RO})_2\text{P}}}-\underset{\text{R}'}{\overset{|}{\text{CH}}}-\text{R}'' \xrightarrow{\text{base}} \underset{\text{O}}{\overset{\|}{(\text{RO})_2\text{P}}}-\underset{\text{R}'}{\overset{\ominus}{\bar{\text{C}}}}-\text{R}'' \xrightarrow{-\overset{|}{\text{C}}=\text{O}} -\overset{|}{\text{C}}=\underset{\text{R}'}{\overset{|}{\text{C}}}-\text{R}'' + (\text{RO})_2\text{PO}_2^-$$

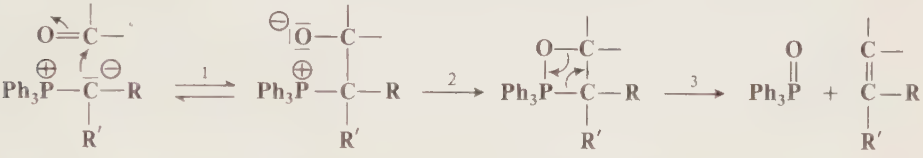
This method, sometimes called the *Horner-Emmons reaction*,[385] has several advantages over the use of phosphoranes. These ylides are more reactive than the corresponding phosphoranes, and when R′ is an electron-withdrawing group, these compounds often react with ketones which are inert to phosphoranes. In addition, the phosphorus product is a phosphate ester and hence soluble in water, unlike Ph_3PO, which makes it easy to separate it from the olefin product. Phosphonates are also cheaper than phosphonium salts and can easily be prepared by the *Arbuzov reaction*:[386]



$$(\text{EtO})_3\text{P} + \text{RCH}_2\text{X} \longrightarrow \underset{\text{O}}{\overset{\|}{(\text{EtO})_2\text{P}}}-\text{CH}_2\text{R}$$

Ylides formed from $\text{Ar}_2\underset{\text{O}}{\overset{\|}{\text{P}}}\text{CHRR}'$, phosphonic acid bisamides $(\text{R}''_2\text{N})_2\text{POCHRR}'$,[387] and alkyl phosphonothionates $(\text{MeO})_2\text{PSCHRR}'$[388] share some of these advantages.

The mechanism of the key step of the Wittig reaction consists of at least two and perhaps three steps:



Step 1 may or may not be an equilibrium reaction. Steps 2 and 3 constitute an elimination of Ph_3PO (see reaction **7-21**) and may be simultaneous. Either step 1 or steps 2-3 may be rate-determining. Step 1 has been shown to be reversible for stable ylides (those containing COR, CN, etc., groups) by the preparation in another way of the betaine and the demonstration that the ylide can be prepared from it.[389] With unstable ylides it has been suggested[390] that steps 1 and 2 may be simultaneous[391] (so that the betaine is not an intermediate[392]). Evidence for this is that

[390] Vedejs and Snoble, *J. Am. Chem. Soc.* **95**, 5778 (1973).

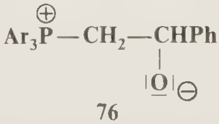
[391] Such a mechanism has been suggested for stable ylides as well: Nesmeyanov, Binshtok, and Reutov, Ref. 389.

[392] For kinetic evidence against a betaine intermediate, see Frøyen, *Acta Chem. Scand.* **26**, 2163 (1972).

^{31}P nmr spectra taken of the reaction mixture at low temperatures are compatible with an oxaphosphetane structure which persists for some time but not with a tetracoordinated phosphorus species. Since a betaine, an ylide, and a phosphine oxide all have tetracoordinated phosphorus, these species could not be causing the spectra, leading to the conclusion that an oxaphosphetane intermediate is present in the solution.[393] Under these conditions, steps 1 and 2 are obviously fast and step 3 rate-determining. According to any of these mechanisms, an optically active phosphonium salt $RR'R''\overset{\oplus}{P}CHR_2$ should retain its configuration all the way through the reaction, and it should be preserved in the phosphine oxide RR'R"PO. This has been shown to be the case.[394]

When ylides of the form $Ph_3P{=}CHR$ undergo the Wittig reaction in protic solvents, a different mechanism may compete with the one shown above, depending on the structure of the reactants and the reaction conditions. This mechanism involves protonation of the betaine and cleavage of the resulting β-hydroxy phosphonium salt.[395]

In reactions in which there is a betaine intermediate, we may examine the question of when step 1 is faster than steps 2-3 and vice versa. We have already seen that the ylide is increased in stability (and decreased in reactivity) by the presence of electron-withdrawing groups on the carbon. Another factor is the presence of electron-donating groups on the phosphorus. These groups stabilize the ylide canonical form (of the resonance hybrid) at the expense of the C=P form by decreasing the positive charge on the phosphorus. This increases the reactivity of the ylide and explains, for example, why trialkyl phosphorus ylides are more reactive than the triaryl variety. On the other hand, once the betaine is formed, these factors work in precisely the opposite direction. Electron-withdrawing groups on the carbon increase the reactivity of the betaine because they stabilize (by conjugation) the newly forming double bond; and electron-donating substituents on the phosphorus decrease the reactivity of the betaine since they decrease the positive charge on the phosphorus and make it less attractive to the negative oxygen. We see from all this that with ylides containing electron-donating groups on the phosphorus, the first step will be faster than the subsequent ones. In some cases, indeed, it has proved possible to isolate the betaine, an example being **76**.[396] However, if there are electron-withdrawing groups on the carbon, the first step will be slower than the subsequent ones and it should be much more difficult to isolate the betaine. Up to now, no such betaine has been isolated. We would also clearly not expect to be able to isolate a betaine in cases where steps 2 and 3 are simultaneous.



$$Ar_3\overset{\oplus}{P}{-}CH_2{-}\underset{\underset{\ominus}{|\underline{O}|}}{CHPh} \qquad Ar = p\text{-}MeOC_6H_4$$

76

These considerations make possible at least some conclusions about the stereochemistry of the reaction. If the betaine has two asymmetric carbons, there are two diastereomeric *dl* pairs. In cases where betaine formation is reversible, the thermodynamically more stable diastereomer will be predominantly formed before elimination (a syn process, in this case) occurs, and this diastereomer will normally give the trans olefin:

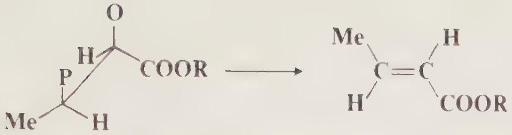
---

[393] In certain cases, oxaphosphetanes have been isolated: Birum and Matthews, *Chem. Commun.* 137 (1967); Mazhar-Ul-Haque, Caughlan, Ramirez, Pilot, and Smith, *J. Am. Chem. Soc.* **93**, 5229 (1971). See also Schlosser, Piskala, Tarchini, and Tuong, *Chimia* **29**, 341 (1975).

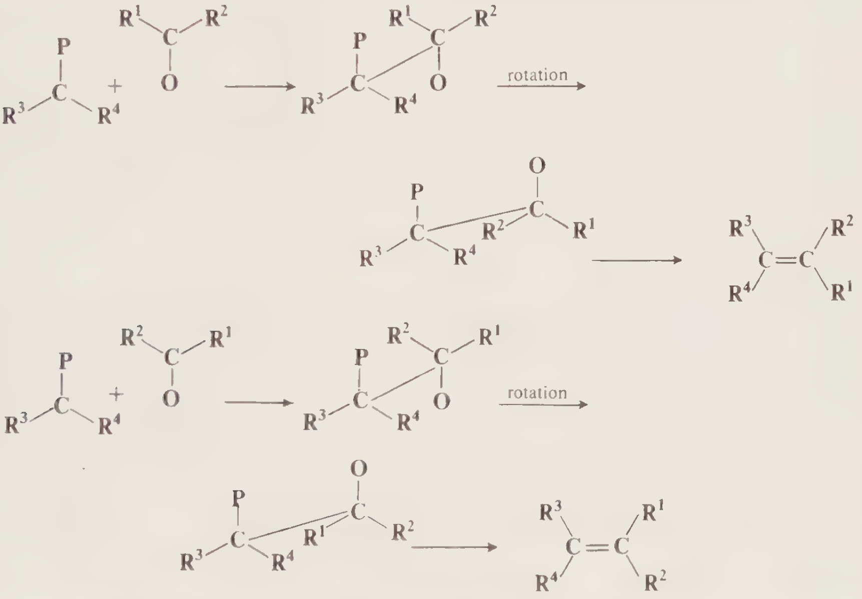
[394] McEwen, Kumli, Blade-Font, Zanger, and VanderWerf, *J. Am. Chem. Soc.* **86**, 2378 (1964).

[395] Schweizer, Crouse, Minami, and Wehman, *Chem. Commun.* 1000 (1971); Richards and Tebby, *J. Chem. Soc. C* 1059 (1971); Smith and Trippett, *J. Chem. Soc., Chem. Commun.* 191 (1972); Allen, Hutley, and Rich, *J. Chem. Soc., Perkin Trans. 2* 820 (1973); Allen, Heatley, Hutley, and Mellor, *Tetrahedron Lett.* 1787 (1974); Allen, Hutley, and Polasik, *J. Chem. Soc., Perkin Trans. 1* 619 (1975).

[396] Wittig, Weigmann, and Schlosser, *Chem. Ber.* **94**, 676 (1961).



Indeed it is generally found that ylides containing stabilizing groups or formed from trialkylphosphines give trans olefins.[397] However, ylides formed from triarylphosphines and not containing stabilizing groups often give cis or mixture of cis and trans olefins.[397] One explanation for this[390] is based on the suggestion, mentioned earlier, that in these cases steps 1 and 2 of the mechanism are simultaneous. If this is so, the reaction of the ylide with the carbonyl compound is a 2 + 2 cycloaddition, which in order to be concerted must adopt the $[_{\pi}2_s + _{\pi}2_a]$ pathway. As we have seen earlier (p. 780), this pathway leads to the formation of the more sterically crowded product, in this case the cis olefin. It is also possible to explain the formation of cis olefins and of cis-trans mixtures even in reactions in which there is a betaine intermediate if we assume that in cases where such products are formed, step 1 is irreversible. In such cases, which diastereomer forms is determined by the way the ylide and carbonyl compound line up. Once the betaine is formed, the stereochemistry of the olefin is determined by the fact that elimination is syn. The two possibilities can be shown:



The natural preference seems to be for the ylide and carbonyl compound to line up in such a way as to give the cis isomers ultimately, but the reasons for this are not clear.[398] It is also possible that cis isomers are not formed by the betaine pathway at all but only by the $[_{\pi}2_s + _{\pi}2_a]$ route.

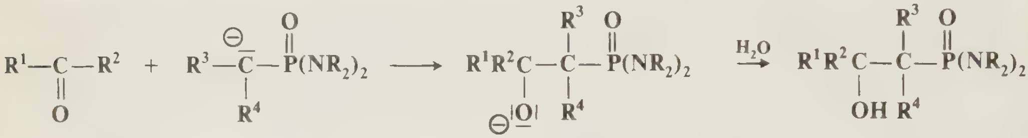
---

[397] See, for example, Ketcham, Jambotkar, and Martinelli, *J. Org. Chem.* **27**, 4666 (1962); House and Rasmusson, *J. Org. Chem.* **26**, 4278 (1961); Bestmann and Kratzer, ref. 383; Kucherov, Kovalev, Nazarova, and Yanovskaya, *Bull. Acad. Sci. USSR, Div. Chem. Sci.* 1405 (1960); Yanovskaya and Kucherov, *Bull. Acad. Sci. USSR, Div. Chem. Sci.* 1252 (1964).

[398] For possible explanations, see Bergelson, Barsukov, and Shemyakin, *J. Gen. Chem. USSR* **38**, 810 (1968); Schneider, *Chem. Commun.* 785 (1969).

The cis-trans ratio of the product can often be changed by a change in solvent or by the addition of salts. It has been found possible to control the reaction so that either the cis or the trans olefin is the main product.[399]

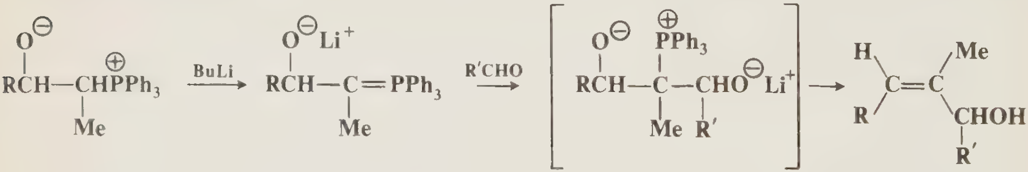
Another way of controlling the stereochemistry of the product is by use of the aforementioned phosphonic acid bisamides. In this case the betaine (77) does not undergo spontaneous elimination



77 78

but when treated with water gives the β-hydroxyphosphonic acid bisamides **78**, which can be crystallized and then cleaved to $R^1R^2C{=}CR^3R^4$ by refluxing in benzene or toluene in the presence of silica gel.[387] **78** are generally formed as mixtures of diastereomers, and these mixtures can be separated by recrystallization. Cleavage of the two diastereomers gives the two isomeric olefins.

In reactions where the betaine intermediate is present in the solution, it is possible to extend the chain further if a hydrogen is present α to the phosphorus. For example, reaction of ethylidenetriphenylphosphorane with heptanal at $-78°C$ gave the betaine **79**, which with butyllithium gave the ylide **80**. Treatment of this with an aldehyde R′CHO gave the intermediate **81**,

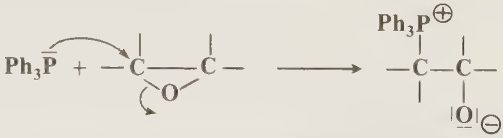


79 80 81 82

$R = n\text{-}C_6H_{13}$

which after workup gave **82**.[400] This reaction gives the unsaturated alcohols **82** stereoselectively. **80** also reacts with other electrophiles. For example, treatment of **80** with N-chlorosuccinimide or $PhICl_2$ gives the vinyl chloride $RCH{=}CMeCl$ stereoselectively, NCS giving the cis and $PhICl_2$ the trans isomer.[401] The use of Br_2 and $FClO_3$ gives the corresponding bromides and fluorides, respectively.[402] Reactions of **80** with electrophiles have been called *scoopy* reactions (α-*s*ubstitution plus *c*arbonyl *o*lefination via β-*o*xido *p*hosphorus *y*lides).[403]

The betaine can be formed in a completely different manner, by nucleophilic substitution by a phosphine on an epoxide (reaction **0-51**):



---

[399] For reviews of the stereochemistry, see Reucroft and Sammes, *Q. Rev., Chem. Soc.* **25**, 135-169 (1971), pp. 137-148, 169; Schlosser, *Top. Stereochem.* **5**, 1-30 (1970). Also see Bergelson and Shemyakin, *Tetrahedron* **19**, 149 (1963); House, Jones, and Frank, *J. Org. Chem.* **29**, 3327 (1964); Wadsworth, Schupp, Seus, and Ford, *J. Org. Chem.* **30**, 680 (1965); Bergelson, Barsukov, and Shemyakin, *Tetrahedron* **23**, 2709 (1967).

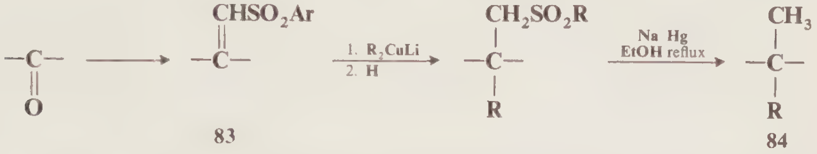
[402] Schlosser and Christmann, Ref. 401.

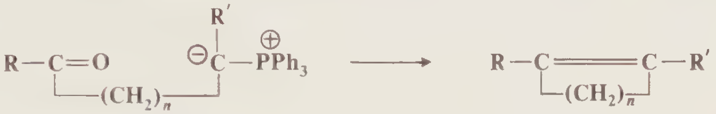
[403] Schlosser, Ref. 399, p. 22.

The betaine formed in this way, of course, can then be converted to the olefin.

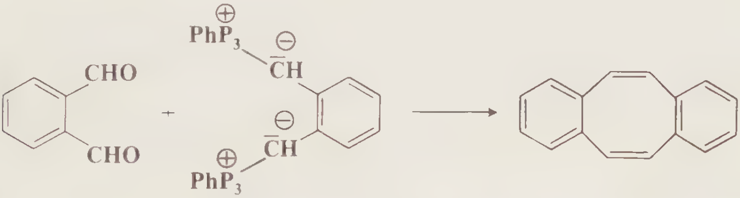
A method[404] for achieving the conversion $C{=}O \rightarrow CR_2$ (see also reactions **6-31** and **6-42**) begins with a Wittig or Horner-Emmons reaction to prepare the α,β-unsaturated aryl sulfones **83**. Treatment of **83** with a lithium dialkylcopper reagent (reaction **5-20**), followed by reduction of the sulfur linkage, gives the product **84**.



The Wittig reaction has been carried out intramolecularly, to prepare rings containing from 5 to 16 carbons,[405] both by single ring closure



and double ring closure[405a]



The Wittig reaction has proved very useful in the synthesis of natural products, some of which are quite difficult to prepare in other ways. One example out of many is the synthesis of β-carotene:[406]

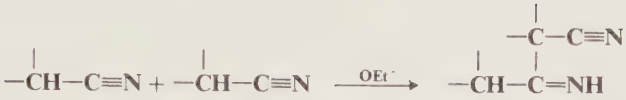
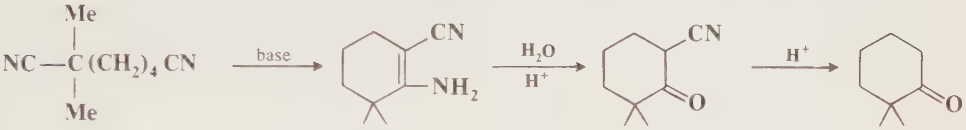
6-48 The Thorpe Reaction



$$-\overset{|}{C}H-C\equiv N + -\overset{|}{C}H-C\equiv N \xrightarrow{OEt^-} -\overset{|}{C}H-\overset{\overset{|}{-C-C\equiv N}}{\overset{|}{C}}=NH$$

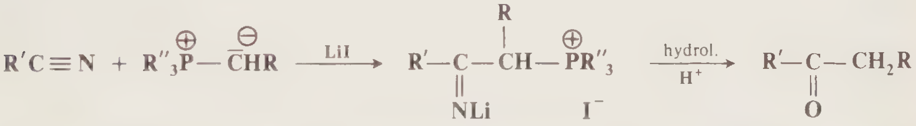
In the *Thorpe reaction*, the α-carbon of one nitrile molecule is added to the CN carbon of another, so that this reaction is analogous to the aldol condensation (**6-40**). The C=NH bond is, of course, hydrolyzable (reaction **6-2**), so that β-keto nitriles can be prepared in this manner. The Thorpe reaction can be done internally, in which case it is called the *Thorpe-Ziegler reaction*.[413] This is a useful method for closing large rings. Yields are high for five- to eight-membered rings, fall off to about zero for rings of nine to thirteen members, but are high again for fourteen-membered and larger rings if high-dilution techniques are employed. The product in the Thorpe-Ziegler reaction is not the imine, but the tautomeric enamine, e.g., **88**; if desired this can be hydrolyzed to an α-cyano ketone (reaction **6-2**), which can in turn be hydrolyzed and decarboxylated (reactions **6-5**, **2-39**). Other active compounds can also be added to nitriles. In particular, CF_3CN adds compounds ZCH_2Z, in a Knoevenagel-type reaction.[414] See also reaction **6-49**.



88

OS **53**, 98.

6-49 The Reaction of Phosphoranes with Nitriles

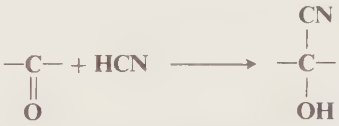


$$R'C\equiv N + R''_3\overset{\oplus}{P}-\overset{\ominus}{\overline{C}}HR \xrightarrow{LiI} R'-\underset{\underset{NLi}{\|}}{C}-\overset{\overset{R}{|}}{C}H-\overset{\oplus}{P}R''_3\quad I^- \xrightarrow[H^+]{hydrol.} R'-\underset{\underset{O}{\|}}{C}-CH_2R$$

Nitriles react with phosphoranes to give adducts which can be hydrolyzed to ketones,[415] in a reaction similar to **6-38**. The phosphoranes must be prepared from phosphonium iodides with organolithium compounds (see reaction **6-47**), or else LiI must be added to the solution. Both Li^+ and I^- are necessary for good yields. R′ may be alkyl or aryl.

J. Other Carbon Nucleophiles

6-50 The Formation of Cyanohydrins



$$-\underset{\underset{O}{\|}}{C}- + HCN \longrightarrow -\overset{\overset{CN}{|}}{\underset{\underset{OH}{|}}{C}}-$$

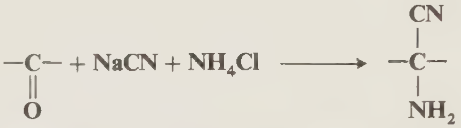
The addition of HCN to aldehydes or ketones produces cyanohydrins.[416] This is an equilibrium reaction. For aldehydes and aliphatic ketones the equilibrium lies to the right; therefore the reaction is quite feasible, except with sterically hindered ketones such as diisopropyl ketone. However, ketones ArCOR give poor yields, and the reaction cannot be carried out with ArCOAr since the equilibrium is too far to the left. With aromatic aldehydes the benzoin condensation (reaction **6-56**) competes. With α,β-unsaturated aldehydes and ketones, 1,4 addition competes (reaction **5-28**). Ketones of low reactivity can be converted to cyanohydrins by treatment with diethylaluminum cyanide Et_2AlCN (see OS **52,** 96). Frequently it is the bisulfite addition product which is treated with CN^-, in which case the reaction is actually nucleophilic substitution. This method is especially useful for aromatic aldehydes, since it avoids competition from the benzoin condensation. If desired, it is possible to hydrolyze the cyanohydrin in situ, without its isolation, to the corresponding α-hydroxy acid. This reaction is important in the *Kiliani method* of extending the carbon chain of a sugar.

The addition is nucleophilic, and the actual nucleophile is CN^-, so that the reaction rate is increased by the addition of base.[417] This was demonstrated by Lapworth in 1903, and consequently this was one of the first organic mechanisms to be known.[418]

OS **I,** 336; **II,** 7, 29, 387; **III,** 436; **IV,** 58, 506; **52,** 96. For the reverse reaction, see OS **III,** 101.

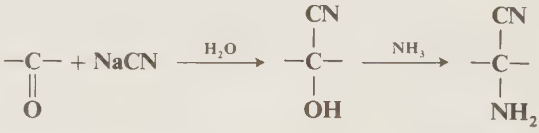
6-51 The Strecker Synthesis



$$-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}- + \mathrm{NaCN} + \mathrm{NH_4Cl} \longrightarrow -\overset{\overset{\mathrm{CN}}{|}}{\underset{\underset{\mathrm{NH_2}}{|}}{\mathrm{C}}}-$$

α-Amino nitriles can be prepared in one step by the treatment of an aldehyde or ketone with NaCN and NH_4Cl. This is called the *Strecker synthesis;* it is actually a special case of the Mannich reaction (**6-17**). Since the CN is easily hydrolyzed to the acid, this is a convenient method for the preparation of α-amino acids. The reaction has also been carried out with NH_3 + HCN and with NH_4CN. Salts of primary and secondary amines can be used instead of NH_4^+, to obtain N-substituted and N,N-disubstituted α-amino nitriles. When *formaldehyde* is treated with NaCN and the salt of an amine, the reaction is known as *cyanomethylation* of the amine. Unlike reaction **6-50,** the Strecker synthesis is useful for aromatic as well as aliphatic ketones.

There are two possible pathways for the reaction. The cyanohydrin may be produced first, and a nucleophilic substitution (reaction **0-48**) may then follow:



$$-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}- + \mathrm{NaCN} \xrightarrow{\mathrm{H_2O}} -\overset{\overset{\mathrm{CN}}{|}}{\underset{\underset{\mathrm{OH}}{|}}{\mathrm{C}}}- \xrightarrow{\mathrm{NH_3}} -\overset{\overset{\mathrm{CN}}{|}}{\underset{\underset{\mathrm{NH_2}}{|}}{\mathrm{C}}}-$$

or ammonia (or the amine) may add first to give an imine (reaction **6-14**), to which NaCN adds (reaction **6-52**):[419]

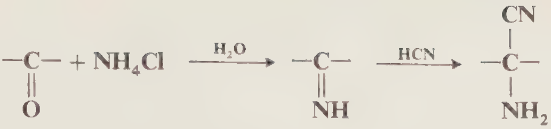
[416] For reviews, see Friedrich and Wallenfels, in Rappoport, Ref. 212, pp. 72–77; Mowry, *Chem. Rev.* **42,** 189–283 (1948); pp. 231–240.

[417] For a review, see Ogata and Kawasaki, in Zabicky, Ref. 17, pp. 21–32.

[418] Lapworth, *J. Chem. Soc.* **83,** 998 (1903).

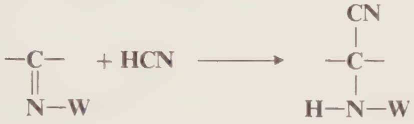
[419] For evidence that α-amino nitriles can be formed by this pathway, see Ogata and Kawasaki, *J. Chem. Soc. B* 325 (1971); Stanley, Beasley, and Mathison, *J. Org. Chem.* **37,** 3746 (1972); Walia, Bannore, Walia, and Guillot, *Chem. Lett.* 1005 (1974). For evidence for both pathways, see Taillades and Commeyras, *Tetrahedron* **30,** 2493 (1974).



$$\underset{\underset{\displaystyle O}{\|}}{-C-} + NH_4Cl \xrightarrow{H_2O} \underset{\underset{\displaystyle NH}{\|}}{-C-} \xrightarrow{HCN} \overset{\overset{\displaystyle CN}{|}}{\underset{\underset{\displaystyle NH_2}{|}}{-C-}}$$

OS **I**, 21, 355; **III**, 66, 84, 88, 275; **IV**, 274; **V**, 437.

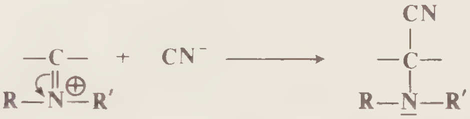
6-52 The Addition of HCN to C═N and C≡N Bonds



$$\underset{\underset{\displaystyle N-W}{\|}}{-C-} + HCN \longrightarrow \overset{\overset{\displaystyle CN}{|}}{\underset{\underset{\displaystyle H-N-W}{|}}{-C-}}$$

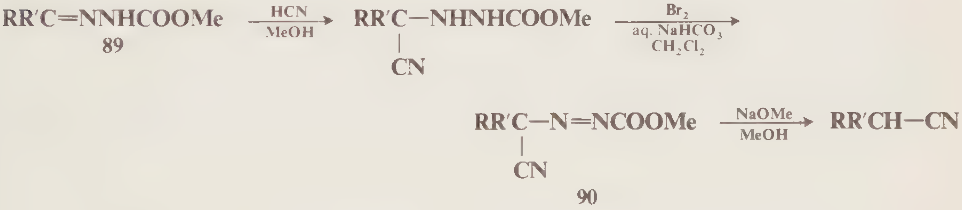
W = H, R, Ar, OH, NHAr, etc.

HCN adds to imines, Schiff bases, hydrazones, oximes, and similar compounds. CN^- can be added to iminium ions:[210]



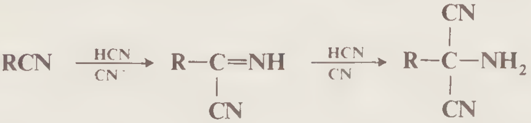
$$\underset{\underset{\displaystyle R-\overset{\oplus}{N}-R'}{\|}}{-C-} + CN^- \longrightarrow \overset{\overset{\displaystyle CN}{|}}{\underset{\underset{\displaystyle R-\underline{N}-R'}{|}}{-C-}}$$

The addition of HCN to carbomethoxyhydrazones **89**[420] provides an indirect method for achieving the conversion RR′CO → RR′CHCN.[421] The initial product is dehydrogenated with bromine (reaction **9-7**) to give a methyl dialkylcyanodiazenecarboxylate **90**, which with NaOMe in MeOH gives the nitrile:



$$\underset{\mathbf{89}}{RR'C{=}NNHCOOMe} \xrightarrow[MeOH]{HCN} \underset{\underset{\displaystyle CN}{|}}{RR'C}{-}NHNHCOOMe \xrightarrow[\substack{aq.\ NaHCO_3\\ CH_2Cl_2}]{Br_2} \underset{\mathbf{90}}{\underset{\underset{\displaystyle CN}{|}}{RR'C}{-}N{=}NCOOMe} \xrightarrow[MeOH]{NaOMe} RR'CH{-}CN$$

HCN can also be added to the C≡N bond to give iminonitriles or α-aminomalononitriles.[422]



$$RCN \xrightarrow[CN^-]{HCN} R{-}\underset{\underset{\displaystyle CN}{|}}{C}{=}NH \xrightarrow[CN^-]{HCN} R{-}\overset{\overset{\displaystyle CN}{|}}{\underset{\underset{\displaystyle CN}{|}}{C}}{-}NH_2$$

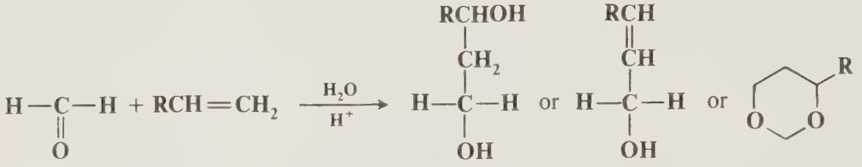
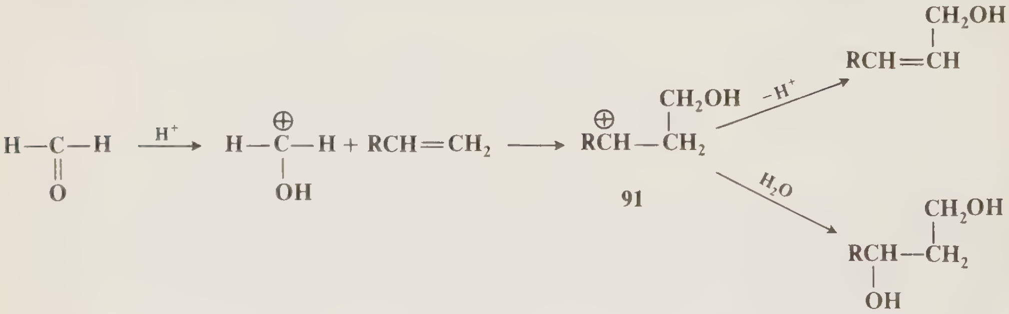
6-53 Addition of ArH to C=O, C=N, and C≡N Bonds

These reactions are discussed under aromatic substitution: **1-18, 1-23** to **1-28, 1-30,** and **1-31.**

6-54 The Prins Reaction



The addition of an olefin to formaldehyde in the presence of an acid[423] catalyst is called the *Prins reaction.*[424] Three main products are possible, and which one predominates depends on the olefin and the conditions. When the product is the 1,3-diol or the dioxane, the reaction involves addition to the C=C as well as to the C=O. The mechanism is one of electrophilic attack, on both double bonds. The acid first protonates the C=O, and the resulting carbonium ion attacks the C=C:



91 may undergo loss of H⁺ to give the olefin or may add water to give the diol.[425] It has been proposed that **91** is stabilized by neighboring-group attraction, with either the oxygen[426] or a carbon[427] stabilizing the charge (**92** and **93,** respectively). This stabilization is postulated to explain the fact that with 2-butenes[428] and with cyclohexenes the addition is anti. A backside

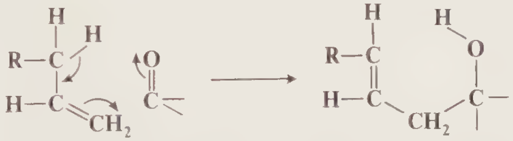
[427] Dolby, Lieske, Rosencrantz, and Schwarz, *J. Am. Chem. Soc.* **85,** 47 (1963); Dolby and Schwarz, *J. Org. Chem.* **28,** 1456 (1963); Safarov, Isagulyants, and Nigmatullin, *J. Org. Chem. USSR* **10,** 1378 (1974).

[428] Fremaux, Davidson, Hellin, and Coussemant, *Bull. Soc. Chim. Fr.* 4250 (1967).

attack of H_2O on the three- or four-membered ring would account for it. Other products are obtained too, which can be explained on the basis of **92** or **93**.[426, 427] Additional evidence for the intermediacy of **92** is the finding that oxetanes (**94**) subjected to the reaction conditions (which would protonate **94** to give **92**) give essentially the same product ratios as the corresponding alkenes.[429] An argument against the intermediacy of **92** and **93** is that not all alkenes show the anti stereoselectivity mentioned above. Indeed, the stereochemical results are often quite complex, with syn, anti, and nonstereoselective addition reported, depending on the nature of the reactants and the reaction conditions.[430] Since addition to the C=C bond is electrophilic, the reactivity of the olefin increases with alkyl substitution and Markovnikov's rule is followed. The dioxane product may arise from a reaction between the 1,3-diol and formaldehyde[431] (reaction **6-6**) or between **91** and formaldehyde, or even between the olefin and a formaldehyde dimer $HOCH_2$-$OCH_2{}^+$.[432]

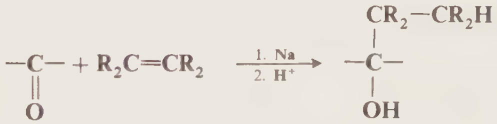
Lewis acids such as $SnCl_4$ also catalyze the reaction, in which case the species which adds to the olefins is $H_2\overset{\oplus}{C}-O-\overset{\ominus}{S}nCl_4$.[433] The reaction can also be catalyzed by peroxides, in which case the mechanism is probably a free-radical one.

The reaction has been performed with other aldehydes and even with ketones; without a catalyst, but with heat.[434] The aldehydes and ketones here are active ones, such as chloral and acetoacetic ester. The product in these cases is a β-hydroxy olefin, and a cyclic mechanism has been postulated:



This reaction is reversible, and suitable β-hydroxy olefins can be cleaved by heat (reaction **7-45**). There is evidence that the cleavage reaction occurs by a cyclic mechanism (p. 955), and, by the principle of microscopic reversibility, the addition mechanism should be cyclic too. Note that this reaction is an oxygen analog of the ene synthesis (**5-18**).

There is still another way in which olefins can be added to the C=O bond. If the two compounds are treated with sodium, there is addition accompanied by reduction:[435]



$$-\underset{\underset{O}{\|}}{C}- + R_2C{=}CR_2 \xrightarrow[2.\ H^+]{1.\ Na} -\overset{\overset{CR_2-CR_2H}{|}}{\underset{\underset{OH}{|}}{C}}-$$

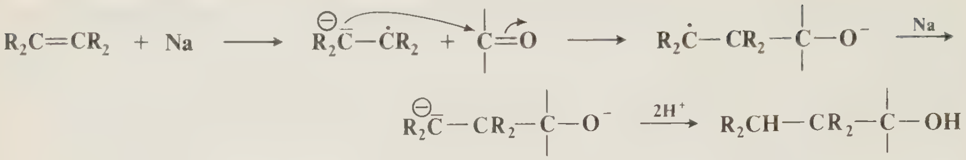
[432] Smissman, Schnettler, and Portoghese, *J. Org. Chem.* **30,** 797 (1965). See however, Gaillard, Hellin, and Coussemant, *Bull. Soc. Chim. Fr.* 3360 (1967); Dolby, Wilkins, and Rodia, *J. Org. Chem.* **33,** 4155 (1968).

[433] Yang, Yang, and Ross, *J. Am. Chem. Soc.* **81,** 133 (1959).

[434] Arnold and Veeravagu, *J. Am. Chem. Soc.* **82,** 5411 (1960); Klimova, Abramov, Antonova, and Arbuzov, *J. Org. Chem. USSR* **5,** 1308 (1969); Klimova, Antonova, and Arbuzov, *J. Org. Chem. USSR* **5,** 1312, 1315 (1969).

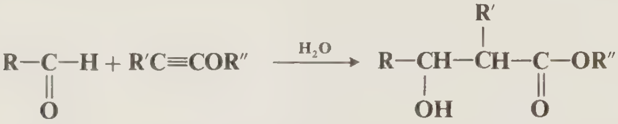
[435] Kochi, *J. Org. Chem.* **28,** 1960, 1969 (1963).

The mechanism probably involves a radical ion:



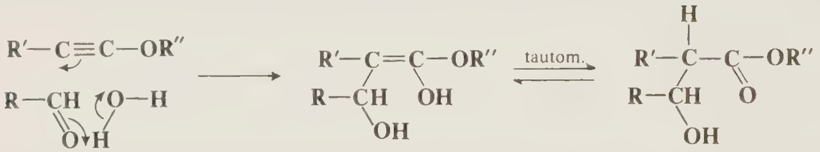
OS IV, 786.

6-55 The Addition of Triple-Bond Compounds

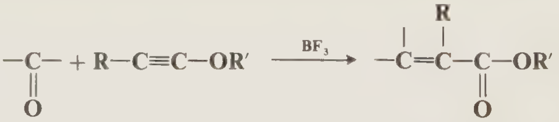


$$\mathrm{R{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}H + R'C{\equiv}COR''} \xrightarrow{\mathrm{H_2O}} \mathrm{R{-}\underset{\underset{\displaystyle OH}{|}}{CH}{-}\overset{\overset{\displaystyle R'}{|}}{CH}{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}OR''}$$

Aldehydes and water can be added to alkynyl ethers to give β-hydroxy esters.[436] The reaction is applicable to aldehydes only, but the yields rapidly diminish with chain length.[437] Formaldehyde is most commonly used. A cyclic mechanism has been suggested:

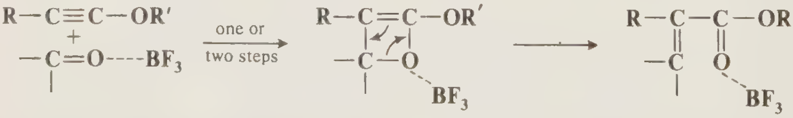


If the alkynyl ether is treated with a carbonyl compound in the absence of water but in the presence of BF_3, an α,β-unsaturated ester is produced:[438]



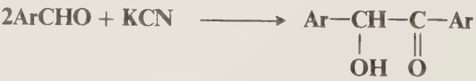
$$\mathrm{{-}\underset{\underset{\displaystyle O}{\|}}{C}{-} + R{-}C{\equiv}C{-}OR'} \xrightarrow{\mathrm{BF_3}} \mathrm{{-}\overset{|}{C}{=}\overset{\overset{\displaystyle R}{|}}{C}{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}OR'}$$

This reaction is much more general, and the carbonyl compound may be an aldehyde, ketone, ester, or amide. A cyclic mechanism has also been proposed in this case:



In an analogous reaction, ynamines $\mathrm{RC{\equiv}CNR'_2}$ react with aldehydes or ketones to give α,β-unsaturated amides $\mathrm{{-}\underset{|}{C}{=}CRCONR'_2}$.[439]

6-56 The Benzoin Condensation



$$\mathrm{2ArCHO + KCN \longrightarrow Ar{-}\underset{\underset{\displaystyle OH}{|}}{CH}{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}Ar}$$

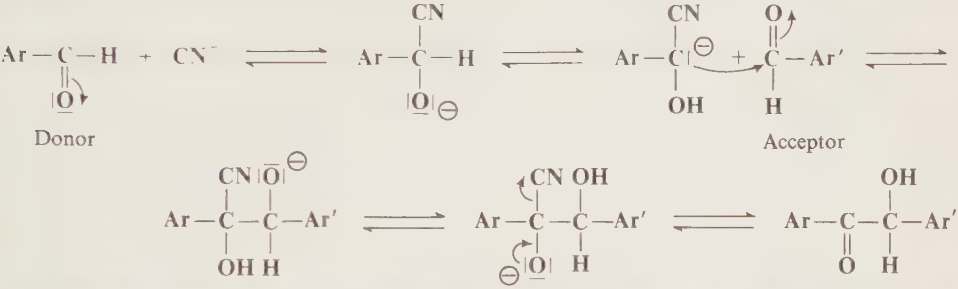
Chim. Pays-Bas* **83,** 845 (1963); Vieregge, Schmidt, Renema, Bos, and Arens, *Recl. Trav. Chim. Pays-Bas* **85,** 929 (1966).

[439] For example, see Fuks and Viehe, *Chem. Ber.* **103,** 564 (1970).

When certain aldehydes are treated with cyanide ion, *benzoins* are produced, in a reaction called the *benzoin condensation.* The condensation may be regarded as involving the addition of one molecule of aldehyde to the C═O group of another. The reaction can be accomplished only for aromatic aldehydes, though not for all of them,[440] and for glyoxals RCOCHO. The two molecules of aldehyde obviously perform different functions. The one which no longer has a C—H bond in the product is called the *donor* because it has "donated" its hydrogen to the oxygen of the other molecule, the *acceptor*. Some aldehydes can perform only one of these functions and hence cannot be self-condensed, though they can often be condensed with a different aldehyde. For example, *p*-dimethylaminobenzaldehyde is not an acceptor but only a donor. Thus it cannot condense with itself, but it can condense with benzaldehyde, which can perform both functions but is a better acceptor than it is a donor.

The following is the accepted mechanism,[441] which was originally proposed by Lapworth in 1903:[442]



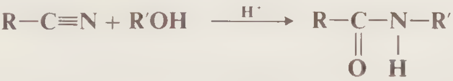
The reaction is reversible. The key step of the reaction, the loss of the aldehydic proton, can take place because the acidity of this C—H bond is increased by the electron-withdrawing power of the CN group. Thus, CN^- is a highly specific catalyst for this reaction, because, almost uniquely,[443] it can perform three functions: (1) It acts as a nucleophile; (2) its electron-withdrawing ability permits loss of the aldehydic proton; and (3) having done this, it then acts as a leaving group.

OS **I,** 94.

Reactions in Which Carbon Adds to the Hetero Atom

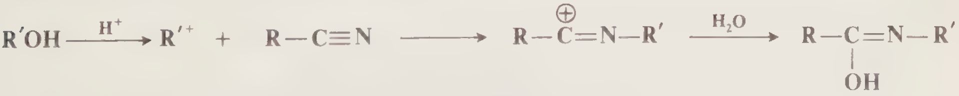
A. Oxygen Adding to the Carbon

6-57 The Ritter Reaction



$$R{-}C{\equiv}N + R'OH \xrightarrow{H^+} R{-}\underset{\displaystyle O}{\underset{\|}{C}}{-}\underset{\displaystyle H}{\underset{|}{N}}{-}R'$$

Alcohols can be added to nitriles in an entirely different manner from that of reaction **6-10.** In this reaction, the alcohol is converted by a strong acid to the carbonium ion, which adds to the negative nitrogen, water adding to the carbon:



$$R'OH \xrightarrow{H^+} R'^+ + R{-}C{\equiv}N \longrightarrow R{-}\overset{\oplus}{C}{=}N{-}R' \xrightarrow{H_2O} R{-}\underset{\displaystyle OH}{\underset{|}{C}}{=}N{-}R'$$

---

[440] For a review, see Ide and Buck, *Org. React.* **4,** 269-304 (1948).

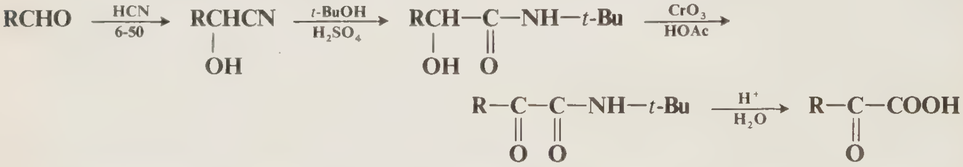
[441] For a discussion, see Kuebrich, Schowen, Wang, and Lupes, *J. Am. Chem. Soc.* **93,** 1214 (1971).

[442] Lapworth, *J. Chem. Soc.* **83,** 995 (1903), **85,** 1206 (1904).

[443] Certain thiazolium salts can also catalyze the reaction: see for example Ugai, Tanaka, and Dokawa, *J. Pharm. Soc. Jpn.* **63,** 296 (1943) [*CA* **45,** 5148]; Breslow, *J. Am. Chem. Soc.* **80,** 3719 (1958). Pyridine-2-carboxaldehyde and quinoline-2-carboxaldehyde undergo the reaction when dissolved in acetic acid in the absence of CN^-: Schaefer and Bertram, *J. Am. Chem. Soc.* **89,** 4121 (1967).

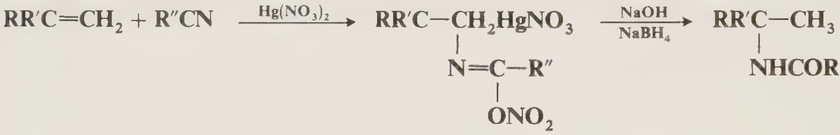
The immediate product tautomerizes to the N-alkyl amide. Only alcohols which give rise to fairly stable carbonium ions react (secondary, tertiary, benzylic, etc.); primary alcohols do not give the reaction. The carbonium ion need not be generated from an alcohol but may come from protonation of an olefin or from other sources, among them RCOOH + conc. $H_2SO_4 \rightarrow R^+$ (R in this case, tertiary only).[444] In any case, the reaction is called the *Ritter reaction.*[445] HCN also gives the reaction, the product being a formamide. Since the amides (especially the formamides) are easily hydrolyzable to amines, the Ritter reaction provides a method for achieving the conversions $R'OH \rightarrow R'NH_2$ (see reaction **0-48**) and alkene $\rightarrow R'NH_2$ (see reaction **5-9**) in those cases where R′ can form a relatively stable carbonium ion. The reaction is especially useful for the preparation of tertiary alkyl amines because there are few alternate ways of preparing these compounds. The reaction can be extended to alcohols which do not give stable carbonium ions (e.g., 1-decanol) by treating the alcohol with $Ph_2CCl^+ \ SbCl_6^-$ or a similar salt in the nitrile as solvent.[446]

α-Keto acids can be prepared from aldehydes with the aid of a Ritter reaction involving a cyanohydrin.[447]



$$RCHO \xrightarrow[6\text{-}50]{HCN} \underset{|\atop OH}{RCHCN} \xrightarrow[H_2SO_4]{t\text{-}BuOH} \underset{|\atop OH}{RCH}-\underset{\|\atop O}{C}-NH-t\text{-}Bu \xrightarrow[HOAc]{CrO_3} R-\underset{\|\atop O}{C}-\underset{\|\atop O}{C}-NH-t\text{-}Bu \xrightarrow[H_2O]{H^+} R-\underset{\|\atop O}{C}-COOH$$

Olefins of the form RCH=CHR′ and RR′C=CH_2 add to nitriles in the presence of mercuric nitrate to give, after treatment with $NaBH_4$, the same amides which would be obtained by the Ritter reaction.[448] This method has the advantage of avoiding strong acids.

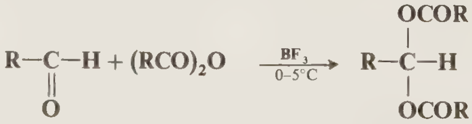


$$RR'C=CH_2 + R''CN \xrightarrow{Hg(NO_3)_2} \underset{\underset{\underset{|\atop ONO_2}{|}}{|\atop N=C-R''}}{RR'C}-CH_2HgNO_3 \xrightarrow[NaBH_4]{NaOH} \underset{|\atop NHCOR''}{RR'C}-CH_3$$

The Ritter reaction can be applied to cyanamides RNHCN to give ureas RNHCONHR′.[449]

OS **V**, 73, 471.

6-58 Acylation of Aldehydes and Ketones



$$R-\underset{\|\atop O}{C}-H + (RCO)_2O \xrightarrow[0\text{-}5°C]{BF_3} R-\overset{OCOR\atop |}{\underset{|\atop OCOR}{C}}-H$$

An acylal

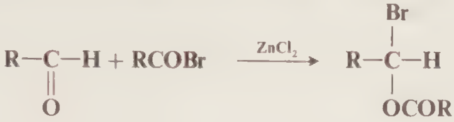
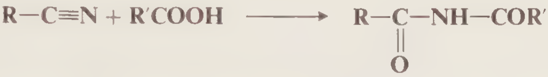
Aldehydes can be converted to acylals by treatment with an anhydride in the presence of BF_3. The reaction cannot normally be applied to ketones, though an exception has been reported when the reagent is trichloroacetic anhydride. This compound does give acylals with ketones without a catalyst.[450] In a similar reaction, aldehydes and some ketones (though not acetone) add the elements of an acyl bromide when treated with the acyl bromide and $ZnCl_2$:[451]



$$R-\underset{\underset{\displaystyle O}{\|}}{C}-H + RCOBr \xrightarrow{ZnCl_2} R-\overset{\overset{\displaystyle Br}{|}}{\underset{\underset{\displaystyle OCOR}{|}}{C}}-H$$

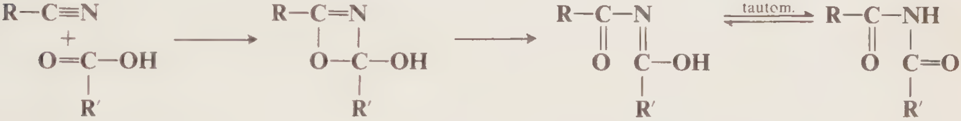
OS **IV**, 489.

6-59 The Addition of Acids to Nitriles



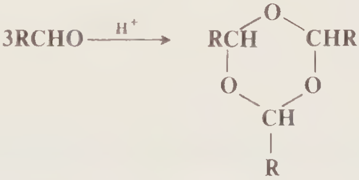
$$R-C\equiv N + R'COOH \longrightarrow R-\underset{\underset{\displaystyle O}{\|}}{C}-NH-COR'$$

Imides are the principal products when carboxylic acids are added to nitriles.[452] Several mechanisms have been proposed which more or less fit the data. In one of them the nitrogen is attacked directly by the carboxyl carbon, and in another the OH of the acid attacks the nitrile carbon and a migration of the acyl group follows. A more recently proposed mechanism is similar to the one proposed for reaction **6-55**:[453]



$$\begin{array}{c}R-C\equiv N\\+\\O=\underset{\underset{\displaystyle R'}{|}}{C}-OH\end{array} \longrightarrow \begin{array}{c}R-C=N\\ |\quad\;\;|\\ O-\underset{\underset{\displaystyle R'}{|}}{C}-OH\end{array} \longrightarrow R-\underset{\underset{\displaystyle O}{\|}}{C}-\underset{\underset{\displaystyle \underset{\underset{\displaystyle R'}{|}}{C}-OH}{\|}}{N} \xrightleftharpoons{\text{tautom.}} R-\underset{\underset{\displaystyle O}{\|}}{C}-\underset{\underset{\displaystyle \underset{\underset{\displaystyle R'}{|}}{C}=O}{|}}{NH}$$

6-60 The Addition of Aldehydes to Aldehydes



When catalyzed by acids, low-molecular-weight aldehydes add to each other to give cyclic acetals, the most common product being the trimer.[454] The cyclic trimer of formaldehyde is called *trioxane*, and that of acetaldehyde is known as *paraldehyde*. Under certain conditions, it is possible to get tetramers[455] or dimers. Aldehydes can also polymerize to linear polymers, but here a small amount of water is required to form hemiacetal groups at the ends of the chains. The linear polymer formed from formaldehyde is called *paraformaldehyde*. Since trimers and polymers of aldehydes are acetals, they are stable to bases but may be hydrolyzed by acids. Because formaldehyde and acetaldehyde have low boiling points, it is often convenient to use them in the form of their trimers or polymers.

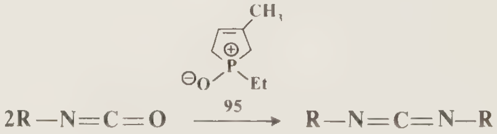
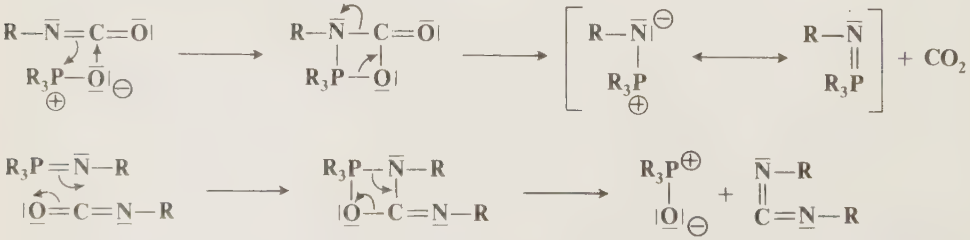
B. Nitrogen Adding to the Carbon

6-62 The Addition of Isocyanates to Isocyanates



The treatment of isocyanates with 3-methyl-1-ethyl-3-phospholene-1-oxide (**95**) represents a useful method for the synthesis of carbodiimides in good yields.[457] The mechanism does not simply involve the addition of one molecule of isocyanate to another, since the kinetics are first order in isocyanate and first order in catalyst. The following mechanism has been proposed (the catalyst is here represented as $R_3\overset{\oplus}{P}-\overset{\ominus}{O}$):[458]



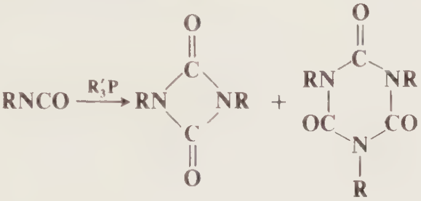
---

[456] For a review, see Zil'berman, Ref. 445, pp. 333–334.

[457] Campbell, Monagle, and Foldi, *J. Am. Chem. Soc.* **84,** 3673 (1962).

[458] Monagle, Campbell, and McShane, *J. Am. Chem. Soc.* **84,** 4288 (1962).

The first two steps together are rate-determining. According to this mechanism, one molecule of isocyanate undergoes addition to C=O and the other, addition to C=N. Evidence in favor of the mechanism is that ^{18}O labeling experiments have shown that each molecule of CO_2 produced contains one oxygen atom derived from the isocyanate and one from the phospholene oxide,[459] which is precisely what is predicted by this mechanism. Certain other catalysts are also effective.[460] When isocyanates are treated with phosphines (instead of phosphine oxides, as above), there is simple addition to give cyclic dimers and trimers:[461]



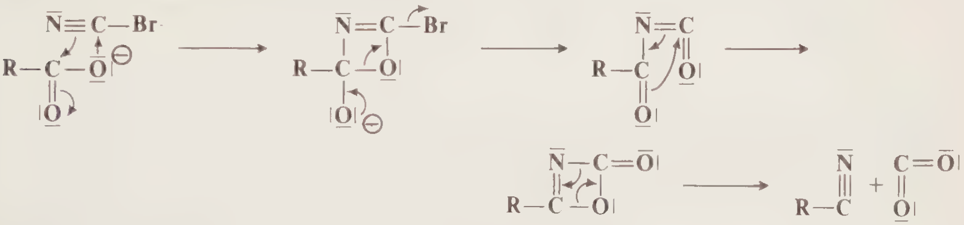
A number of other compounds also catalyze this cyclization.[462]

OS V, 501.

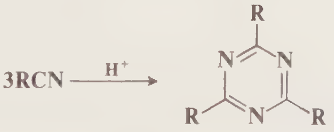
6-63 The Conversion of Acid Salts to Nitriles

$$RCOO^- + BrCN \xrightarrow{250\text{–}300^\circ C} RCN + CO_2$$

Salts of aliphatic or aromatic acids can be converted to the corresponding nitriles by heating with BrCN or ClCN. Despite appearances, this is not a substitution reaction. When $R^{14}COO^-$ was used, the label appeared in the nitrile and not in the CO_2[463] and optical activity in R was retained.[464] The acyl isocyanate RCON=C=O could be isolated from the reaction mixture; hence the following mechanism was proposed:[463]



6-64 The Trimerization of Nitriles



Nitriles can be trimerized with various acids, bases, or other catalysts. HCl is most often used, and then the reaction is similar to reaction **6-60.** However, most nitriles with an α-hydrogen do not give the reaction. Mixed triazines can be obtained from mixtures of nitriles.[465] The mechanism with HCl may be as follows:

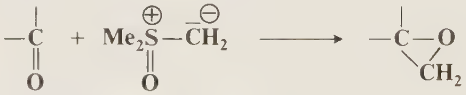
C. Carbon Adding to the Carbon. The reactions in this group (**6-65** to **6-70**) are cycloadditions.

6-65 The Formation of Epoxides from Aldehydes and Ketones



97

Aldehydes and ketones can be converted to epoxides[466] in good yields with the sulfur ylides dimethyloxosulfonium methylide (**97**) and dimethylsulfonium methylide (**98**).[467] For most purposes, **97** is the reagent of choice, because **98** is much less stable and ordinarily must be used as soon as it is formed, while **97** can be stored several days at room temperature. However, when diastereomeric epoxides can be formed, **98** usually attacks from the more hindered and **97** from the less hindered side. Thus, 4-*t*-butylcyclohexanone, treated with **97,** gave exclusively **100** while **98** gave mostly **99.**[468] Another difference in behavior between **97** and **98** is that with α,β-unsaturated ketones, **97** gives only cyclopropanes (reaction **5-53**), while **98** gives oxirane formation. Other

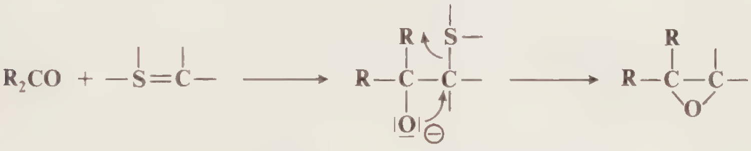
99 New bond is axial

100 New bond is equatorial

sulfur ylides have been used in an analogous manner, to transfer CHR or CR_2. Among these are $Me_2S{=}CHCOO^-$,[469] $Me_2S{=}CHPh$,[470] $Me_2S{=}CH{-}$vinyl,[471] and **117** on p. 795,[472] which transfer $CHCOO^-$, CHPh, CH—vinyl and CPh_2, respectively. Nitrogen-containing sulfur ylides, such as **118** on p. 795 and $Ph(Me_2N)SO{=}CH_2$, as well as carbanions like **120** on p. 795, have also been used.[473]

The generally accepted mechanism is



101

which is similar to that of the reaction of sulfur ylides with C=C double bonds (**5-53**).[474] The stereochemical difference in the behavior of **97** and **98** has been attributed to formation of the betaine **101** being reversible for **97** but not for the less stable **98**, so that the more hindered product is the result of kinetic control and the less hindered of thermodynamic control.[475]

The reaction of ketones with the ylide diphenylsulfoniumcyclopropylide (**102**) gives the oxaspiropentanes **103**, which, when treated with a proton or a Lewis acid, rearrange (reaction

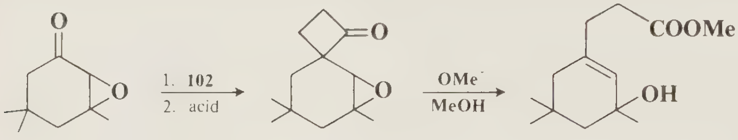
[475] Johnson, Schroeck, and Shanklin, Ref. 474.

8-3) to the cyclobutanones **104**.[476] In some cases **103** is not isolated, but directly rearranges to **104**. The overall conversion of ketone to **104** is called *spiroannulation* (see reaction **6-42** for another way of accomplishing this conversion). When the reaction is applied to epoxy ketones, e.g., **105**, the cyclobutanone product **106** is easily cleaved by refluxing with NaOMe in MeOH

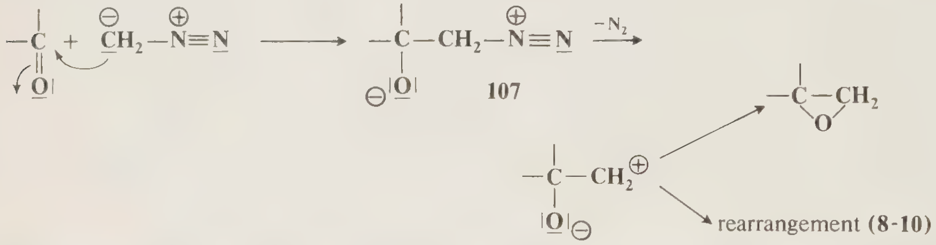


105 **106**

(similar to reaction **2-44**).[477] The net result of this method (called *secoalkylation*) is the addition of a $^-$C—C—COOR unit to the carbonyl group.

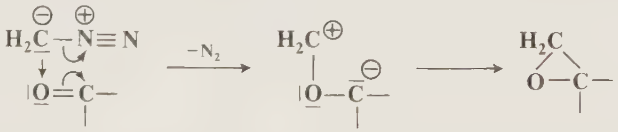
Phosphorus ylides do not give this reaction, but give reaction **6-47** instead.

Aldehydes and ketones can also be converted to epoxides by treatment with a diazoalkane,[478] most commonly diazomethane, but an important side reaction is the formation of an aldehyde or ketone with one more carbon than the starting compound (reaction **8-10**). The reaction can be carried out with many aldehydes, ketones, and quinones. A mechanism that accounts for both products is



107

Compound **107** or nitrogen-containing derivatives of it have sometimes been isolated. The last two steps leading to the epoxide (SN) may be concerted. It is also possible that another pathway exists,[479] which can lead only to the epoxide:



In one case, the conversion of a lactone C=O to the corresponding epoxide (with diazomethane) has been reported.[480]

Dihalocarbenes and carbenoids, which readily add to C=C bonds (reaction **5-53**), do not add to the C=O bonds of ordinary aldehydes and ketones, though addition to highly halogenated compounds, e.g., CCl_3CHO, CF_3COCF_3, to give the corresponding halogenated epoxides has been reported.[481]

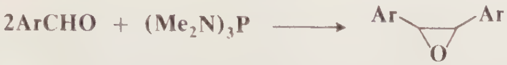
Symmetrical epoxides can be prepared by treatment of aromatic aldehydes with hexamethylphosphorus triamide.[482] It is likely that the betaine $(Me_2N)_2\overset{+}{P}CHRO^-$ is formed first and then attacks a second molecule of the aldehyde.



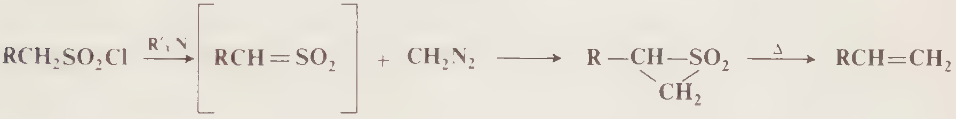
See also reaction **6-45**.

OS V, 755.

6-66 The Formation of Episulfides and Episulfones[483]

Diazoalkanes, treated with sulfur, give episulfides.[484] It is likely that $R_2C{=}S$ is an intermediate, which is attacked by another molecule of diazoalkane, in a process similar to that shown in reaction **6-65**. Thioketones *do* react with diazoalkanes to give episulfides.[485] Thioketones have also been converted to episulfides with sulfur ylides.[468]

Alkanesulfonyl chlorides, when treated with diazomethane in the presence of a base (usually a tertiary amine) give episulfones (**109**).[486] The base removes HCl from the sulfonyl halide to produce



108 **109**

the highly reactive sulfene (**108**) (reaction **7-14**), which then adds CH_2. The episulfone can then be heated to give off SO_2 (reaction **7-23**), making the entire process a method for achieving the conversion $RCH_2SO_2Cl \rightarrow RCH{=}CH_2$.[487] In a related reaction, diazoalkanes, treated with sulfur dioxide, give the symmetrical episulfones **110**.

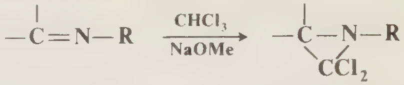
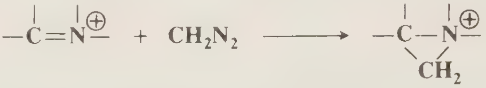
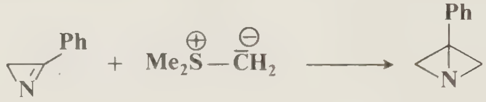
6-67 The Formation of Aziridines



There are a few reports in the literature of the preparation of aziridines by the addition of a divalent species to a C=N bond, analogous to reactions **6-65** and **6-66**.[488] In the example shown above[489] the attacking species is probably dichlorocarbene. Iminium ions[210] have been converted to quaternary aziridinium salts with diazomethane:[490]

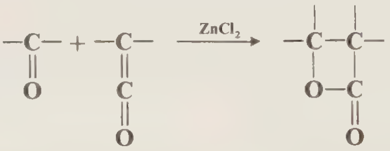


The reaction has also been performed with sulfur ylides.[468] An interesting example of the latter procedure is the reaction of 3-phenyl-2H-azirine with **98**, to give the azabicyclobutane **111**.[491]

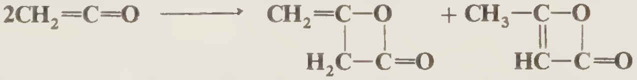


98 **111**

6-68 The Formation of β-Lactones and Oxetanes



Aldehydes, ketones, and quinones react with ketenes to give β-lactones, diphenylketene being used most often.[492] The reaction is catalyzed by Lewis acids, and without them most ketones do not give adducts because the adducts decompose at the high temperatures necessary when no catalyst is used. Ketene adds to another molecule of itself:



This dimerization is so rapid that ketene does not form β-lactones with aldehydes or ketones, except at low temperatures. Other ketenes dimerize more slowly. In these cases the major dimerization product is not the β-lactone, but a cyclobutenone (see p. 778). However, the proportion of ketene which dimerizes to β-lactone can be increased by the addition of catalysts such as triethylamine or triethyl phosphite $(EtO)_3P$.[493]

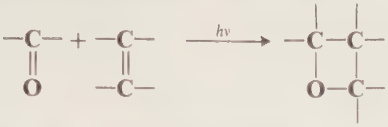
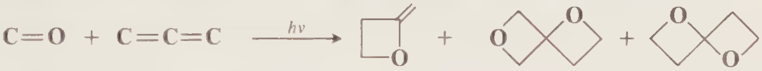
Ordinary aldehydes and ketones can add to olefins, under the influence of uv light, to give

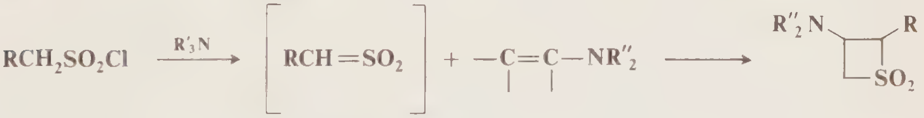


oxetanes. This reaction, called the *Paterno-Büchi reaction*,[494] is similar to the photochemical dimerization of olefins discussed at reaction **5-52.** In general, the mechanism consists of the addition of an excited state of the carbonyl compound to the ground state of the olefin, in many cases through the intermediacy of an exciplex[495] (p. 785). Both singlet (S_1)[496] and n,π^* triplet[497] states have been shown to add to olefins to give oxetanes. Yields in the Paterno-Büchi reaction are variable, ranging from very low to fairly high (80 to 90%). There are several side reactions. When the reaction proceeds through a triplet state, it can in general be successful only when the alkene possesses a triplet energy comparable to, or higher than, the carbonyl compound; otherwise energy transfer from the excited carbonyl group to the ground-state alkene can take place (triplet-triplet photosensitization, see p. 219). In most cases quinones react normally with alkenes, giving oxetane products, but other α,β-unsaturated ketones usually give preferential cyclobutane formation (reaction **5-52**). Aldehydes and ketones also add photochemically to allenes, to give the corresponding alkylideneoxetanes and dioxaspiro compounds:[498]



OS **III,** 508; **V,** 456. For the reverse reaction, see OS **V,** 679.

6-69 The Formation of Thietane 1,1-Dioxides



Sulfene

The highly reactive sulfenes,[499] generated from sulfonyl chlorides (reaction **7-14**) add to enamines to give thietane 1,1-dioxides.[500] Yields are generally good. Other electron-rich olefins, e.g., vinyl ethers and ketene acetals $R_2C{=}C(OR')_2$, also react with sulfenes to give the corresponding thietane 1,1-dioxides.[501] The reaction has been extended to ynamines, to give the corresponding unsaturated four-membered heterocycles, called thietene 1,1-dioxides.[502]

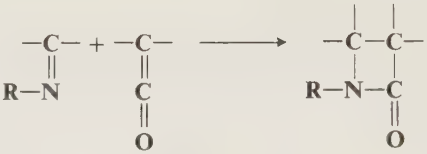
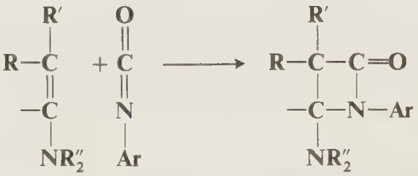
6-70 The Formation of β-Lactams



Ketenes add to imines to give β-lactams.[503] The reaction is generally carried out with ketenes of the form $R_2C{=}C{=}O$. It has not been successfully applied to $RCH{=}C{=}O$, except when these are generated in situ by decomposition of a diazo ketone (the Wolff rearrangement, reaction **8-9**) in the presence of the enamine. It has been done with ketene, but the more usual course with this reagent is an addition to the enamine tautomer of the substrate. β-Lactams have also been prepared in the opposite manner: by the addition[462] of enamines to isocyanates:[504]



The reactive compound chlorosulfonyl isocyanate[505] $ClSO_2NCO$ forms β-lactams even with unactivated alkenes,[506] as well as with allenes,[507] conjugated dienes,[508] and cyclopropenes.[509]

OS V, 673.

Addition to Isonitriles[510]

Addition to $R-\overset{\oplus}{N}\equiv\overset{\ominus}{C}$ is not simply a matter of a species with an electron pair adding to one atom and a species without a pair adding to the other, as is addition to the other types of double and triple bonds in this chapter and in Chapter 15. In these additions the electrophile and the nucleophile *both add to the carbon*. No species adds to the nitrogen, which, however, loses its positive charge by obtaining as an unshared pair one of the triple-bond pairs of electrons:

---

[501] For example, see Truce and Norell, *J. Am. Chem. Soc.* **85**, 3231 (1963); Opitz, Rieth, and Walz, *Tetrahedron Lett.* 5269 (1966).

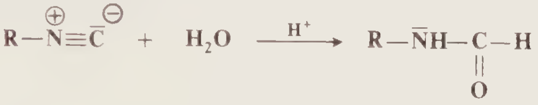
$$R-\overset{\oplus}{N}\equiv\overset{\ominus}{\overline{C}} + W + \overline{Y} \longrightarrow R-\overline{N}=\underset{\underset{Y}{|}}{C}-W$$

112

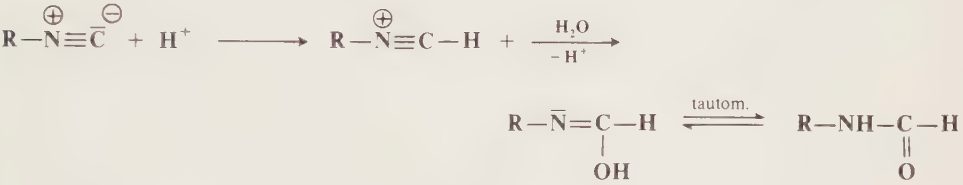
In most of the reactions considered below, **112** undergoes a further reaction, so that the product is of the form $R-\overline{N}H-\overset{|}{\underset{|}{C}}-$.

6-71 The Addition of Water to Isonitriles



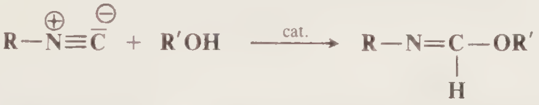
$$R-\overset{\oplus}{N}\equiv\overset{\ominus}{\overline{C}} + H_2O \xrightarrow{H^+} R-\overline{N}H-\underset{\underset{O}{\|}}{C}-H$$

Formamides can be prepared by the acid-catalyzed addition of water to isonitriles. The mechanism is probably[511]



$$R-\overset{\oplus}{N}\equiv\overset{\ominus}{\overline{C}} + H^+ \longrightarrow R-\overset{\oplus}{N}\equiv C-H + \xrightarrow[-H^+]{H_2O} R-\overline{N}=\underset{\underset{OH}{|}}{C}-H \overset{\text{tautom.}}{\rightleftharpoons} R-NH-\underset{\underset{O}{\|}}{C}-H$$

6-72 The Addition of Alcohols, Mercaptans, Amines, or Azides to Isonitriles



$$R-\overset{\oplus}{N}\equiv\overset{\ominus}{\overline{C}} + R'OH \xrightarrow{\text{cat.}} R-N=\underset{\underset{H}{|}}{C}-OR'$$

Isonitriles[512] are generally inert to alcohols in the absence of a catalyst, but the addition can be made to take place in high yields to give an alkyl formimidate by the use of certain catalysts, among them metallic copper and Cu(I) or Cu(II) oxides.[513] These compounds, as well as certain metallic salts, also catalyze the corresponding addition of primary and secondary amines, to give formamidines (respectively $RN=CHNHR'$ and $RN=CHNR'_2$).[514] In a similar manner, mercaptans give alkyl thioformamides $RN=CHSR'$.[515] Isonitriles react with azides $R'N_3$, in a reaction catalyzed with iron pentacarbonyl to give unsymmetrical carbodiimides $RN=C=NR'$.[516]

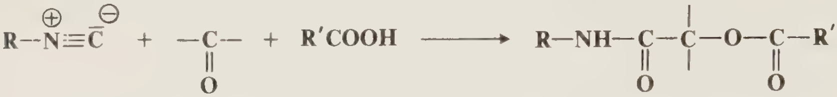
6-73 The Reduction of Isonitriles

$$R{-}\overset{\oplus}{N}{\equiv}\overset{\ominus}{\bar{C}} \quad + \quad LiAlH_4 \longrightarrow R{-}NH{-}CH_3$$

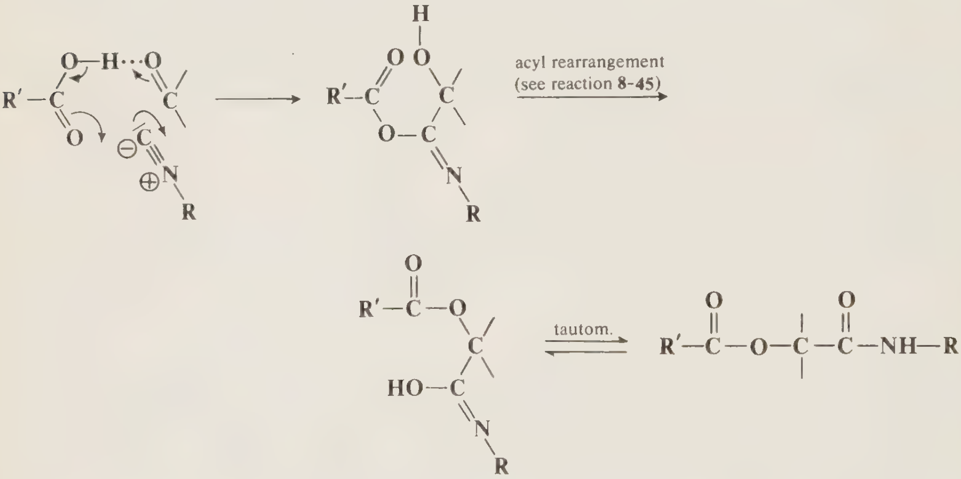
Isonitriles have been reduced to N-methylamines with lithium aluminum hydride as well as with other reducing agents.

6-74 The Passerini and Ugi Reactions[517]



$$R{-}\overset{\oplus}{N}{\equiv}\overset{\ominus}{\bar{C}} \quad + \quad -\underset{\underset{O}{\|}}{C}- \quad + \quad R'COOH \longrightarrow R{-}NH{-}\underset{\underset{O}{\|}}{C}{-}\overset{|}{\underset{|}{C}}{-}O{-}\underset{\underset{O}{\|}}{C}{-}R'$$

When an isonitrile is treated with a carboxylic acid and an aldehyde or ketone, an α-acyloxy amide is prepared. This is called the *Passerini reaction*, and the following mechanism has been postulated:



If ammonia or an amine is also added to the mixture (in which case the reaction is known as the *Ugi reaction*, or the *Ugi four-component condensation*, abbreviated 4 CC), the product is the corresponding bisamide $R'{-}\underset{\underset{O}{\|}}{C}{-}NH{-}\overset{|}{\underset{|}{C}}{-}\underset{\underset{O}{\|}}{C}{-}NH{-}R$ (from NH_3) or $R'{-}\underset{\underset{O}{\|}}{C}{-}NR''{-}\overset{|}{\underset{|}{C}}{-}\underset{\underset{O}{\|}}{C}{-}NH{-}R$ (from a primary amine $R''NH_2$). This product probably arises from a reaction between the carboxylic acid, the isonitrile, and the *imine* formed from the aldehyde or ketone and ammonia or the primary amine. The use of an N-protected amino acid or peptide as the carboxylic acid component and/or the use of an isonitrile containing a C-protected carboxyl group allows the reaction to be used for peptide synthesis.[518] When a secondary amine R''_2NH is used, the initial addition product (**113**) cannot undergo an acyl rearrangement of the same type. In methanol the acyl group cleaves, and the product is an α-amino amide, while in chloroform the acyl group migrates to the *other* nitrogen

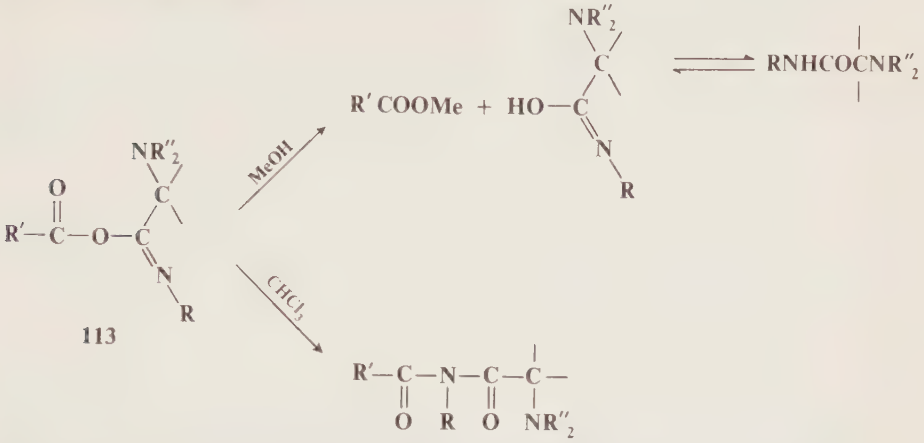
[518] For reviews, see Gokel, Hoffmann, Kleimann, Klusacek, Lüdke, Marquarding, and Ugi, Ref. 510, pp. 201–215; Ugi, *Intra-Sci. Chem. Rep.* **5**, 229–261 (1971), *Rec. Chem. Prog.* **30**, 289–311 (1969).

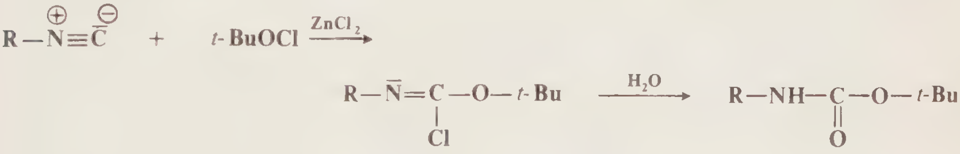


113

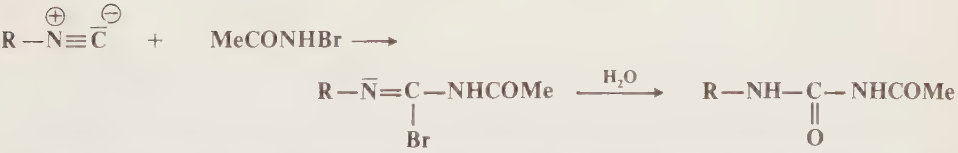
and the product is an imide containing a tertiary amine function. Intermediates corresponding to **113** have been isolated in certain cases where the carbonyl component is an aldehyde and the amine a primary amine.[519]

The Ugi reaction can also be carried out with an isonitrile, an aldehyde or ketone, and ammonia or an amine, but with some other YH substituting for the carboxylic acid, e.g., H_2O, HN_3, HNCO.

6-75 The Addition of O- and N-Halides to Isonitriles



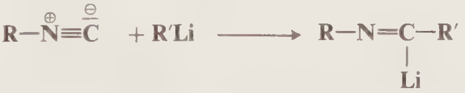
$$R-\overset{\oplus}{N}\equiv\overset{\ominus}{\bar{C}} + t\text{-BuOCl} \xrightarrow{ZnCl_2} R-\bar{N}=\underset{Cl}{\underset{|}{C}}-O-t\text{-Bu} \xrightarrow{H_2O} R-NH-\underset{O}{\underset{\|}{C}}-O-t\text{-Bu}$$



$$R-\overset{\oplus}{N}\equiv\overset{\ominus}{\bar{C}} + \text{MeCONHBr} \longrightarrow R-\bar{N}=\underset{Br}{\underset{|}{C}}-\text{NHCOMe} \xrightarrow{H_2O} R-NH-\underset{O}{\underset{\|}{C}}-\text{NHCOMe}$$

Alkyl hypochlorites and N-halo amides add to isonitriles to give, after hydrolysis, carbamates and N-acylureas (ureides), respectively.[520]

6-76 The Formation of Metalated Aldimines



$$R-\overset{\oplus}{N}\equiv\overset{\ominus}{\bar{C}} + R'Li \longrightarrow R-N=\underset{Li}{\underset{|}{C}}-R'$$

Isonitriles which do not contain an α-hydrogen react with alkyllithium compounds, as well as with

---

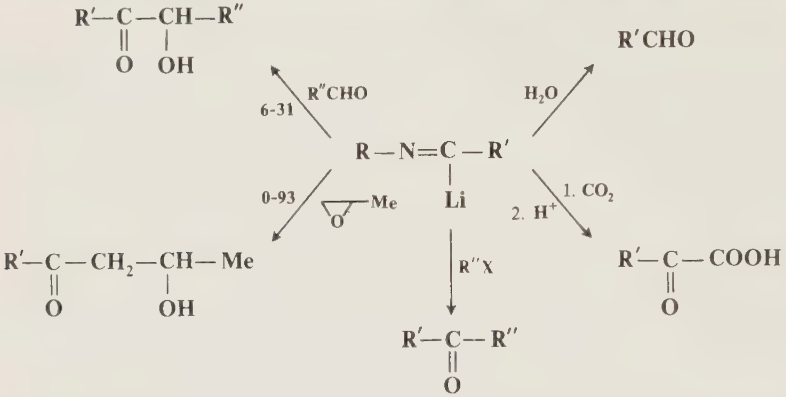
[520] Okano, Ito, Shono, and Oda, *Bull. Chem. Soc. Jpn.* **36,** 1314 (1963).

Grignard reagents, to give lithium (or magnesium) aldimines.[521] These metalated aldimines are versatile nucleophiles and react with various substrates as follows (see also reaction **8-28**):

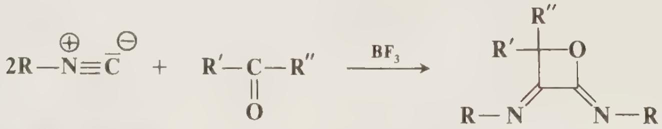


The reaction therefore constitutes a method for converting an organometallic compound R′M to an aldehyde R′CHO (see also reaction **2-31**), an α-keto acid, a ketone R′COR (see also reaction **2-31**), an α-hydroxy ketone, or a β-hydroxy ketone. In each case the C=N bond is hydrolyzed to a C=O bond (reaction **6-2**). In a reaction similar to **6-72**, aryl or α,β-unsaturated isonitriles can also be treated with active-hydrogen compounds (ZCH_2Z') in the presence of copper oxides or other copper catalysts, to give the corresponding enamines, formed by tautomerization of the initially formed aldimines.[522] Z and Z′ may be RCO, ROOC, NC, or Ph:

$$R-\overset{\oplus}{N}\equiv\overset{\ominus}{\bar{C}} + ZCH_2Z' \xrightarrow{\text{cat.}} ZZ'CH-CH=NR \xrightarrow{\text{tautom.}} ZZ'C=CH-NHR$$

OS **51,** 31.

6-77 The Formation of Four-membered Rings[523]



Isonitriles react with aldehydes and ketones in the presence of catalytic amounts[524] of BF_3 to give 2,3-diiminooxetanes.[525] These compounds can be treated with HCl to give the ring-opened compounds R′R″CClC(=NR)CONHR, which in turn can be hydrolyzed to β-chloro-α-keto amides R′R″CClCOCONHR.[526] Similar four-membered ring compounds have been prepared by reaction of isonitriles with C=N bonds[527] and with the C=C bonds of the electron-deficient olefin $(CF_3)_2C=C(CN)_2$.[528]

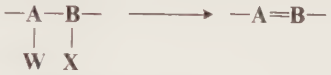
Seventeen

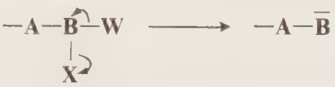
Eliminations

When two groups are lost from adjacent atoms so that a new double (or triple) bond is formed

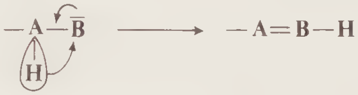


$$\underset{\displaystyle\text{W}}{-\text{A}}-\underset{\displaystyle\text{X}}{\text{B}}- \longrightarrow -\text{A}{=}\text{B}-$$

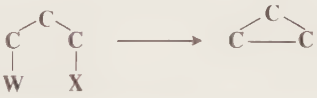
the reaction is called *β elimination*, with one atom called the α- and the other the β-atom. In an α elimination both groups are lost from the same atom, to give a carbene (or a nitrene):



This species may undergo a variety of reactions (see p. 182), but only when a hydrogen is present on A can a new double bond be formed, by a hydride shift:



In a γ elimination, a three-membered ring is formed:



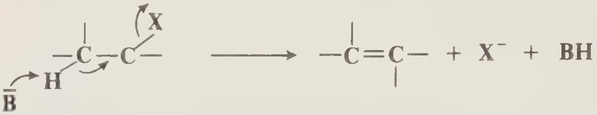
Some of these processes were discussed in Chapter 10. Another type of elimination involves the expulsion of a fragment from within a chain or ring (X—Y—Z → X—Z + Y). Such reactions are called *extrusion reactions*. This chapter discusses β elimination and (beginning on p. 956) extrusion reactions, except that β eliminations in which X and W are both hydrogen are oxidation reactions and are treated in Chapter 19.

MECHANISMS AND ORIENTATION

β elimination reactions may be divided into two types, with one type taking place largely in solution and the other (pyrolytic eliminations) mostly in the gas phase. In the reactions in solution one group leaves with its electrons, and the other without, the latter most often being hydrogen. In these cases we refer to the former group as the leaving group or nucleofuge. For pyrolytic eliminations there are two principle mechanisms, one a cyclic and the other a free-radical pathway. A few photochemical eliminations are also known (the most important is Norrish type II cleavage of ketones, discussed on p. 221), but these are not generally of synthetic importance[1] and will not be discussed further. In most β eliminations the new bonds are C=C or C≡C, and our discussion of mechanisms is largely confined to these cases.[2] Mechanisms in solution (E2, E1, E1cB) are discussed first.

The E2 Mechanism

In the E2 mechanism (elimination, bimolecular), the two groups depart simultaneously, with the proton being pulled off by a base:



The mechanism thus takes place in one step and kinetically is second order: first order in substrate and first order in base. It is analogous to the SN2 mechanism (p. 266) and often competes with it. With respect to the substrate, the difference between the two pathways is whether the species with the unshared pair attacks the carbon (and thus acts as a nucleophile) or the hydrogen (and thus acts as a base). As in the case of the SN2 mechanism, the leaving group may be positive or neutral, and the base may be negatively charged or neutral.

Among the evidence for the existence of the E2 mechanism are: (1) the reaction displays the proper second-order kinetics; and (2) when the leaving hydrogen is replaced by deuterium in second-order eliminations, there is an isotope effect of from 3 to 8, consistent with breaking of this bond in the rate-determining step.[3] However, neither of these results alone could prove an E2 mechanism, since both are compatible with other mechanisms also (e.g., see E1cB p. 904). The most compelling evidence for the E2 mechanism is found in stereochemical studies.[4] As will be illustrated in the examples below, the E2 mechanism is stereospecific: the five atoms involved (including the base) in the transition state must be in one plane. There are two ways for this to happen. The H and X may be trans to one another (A), with a dihedral angle of 180°, or

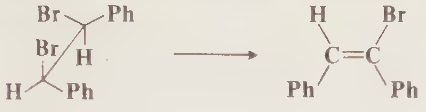
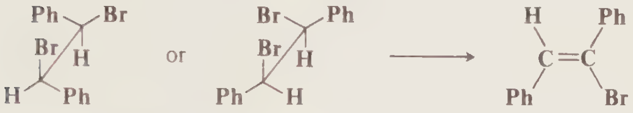
they may be cis (**B**), with a dihedral angle of 0°.[5] Conformation **A** is called *anti-periplanar*, and this type of elimination, in which H and X depart in opposite directions, is called *anti elimination*. Conformation **B** is *syn-periplanar*, and this type of elimination, with H and X leaving in the same direction, is called *syn elimination*. Many examples of both kinds have been discovered. In the absence of special effects (discussed below) anti elimination is in most cases greatly favored over syn elimination, probably because **A** is a staggered conformation (p. 125) and the molecule requires less energy to reach this transition state than it does to reach the eclipsed transition state **B**. A few of the many known examples of predominant or exclusive anti elimination follow.

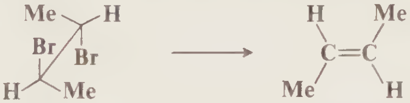
1. Elimination of HBr from *meso*-1,2-dibromo-1,2-diphenylethane gave *cis*-2-bromostilbene, while the (+) or (−) isomer gave the trans olefin. This stereospecific result, which was obtained in 1904,[6] demonstrates that in this case elimination is anti. Many similar examples have been discovered since. Obviously, this type of experiment need not be restricted to compounds which have a meso form. Anti elimination requires that an erythro *dl* pair (or either isomer) give the cis olefin, and the threo *dl* pair (or either isomer) give the trans isomer, and this has been found many times. Anti elimination has also been demonstrated in cases where the positive leaving group is not hydrogen. In the reaction of 2,3-dibromobutane with iodide ion, the two bromines are removed (reaction 7-27). In this case the meso compound gave the trans olefin and the *dl* pair the cis:[7]



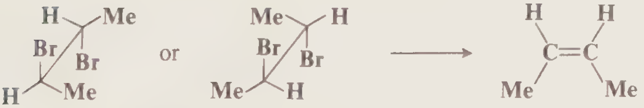
meso cis



dl pair trans



meso trans



dl pair cis

2. In open-chain compounds the molecule can usually adopt that conformation in which H and X are anti-periplanar. However, in cyclic systems this is not always the case. There are nine stereoisomers of 1,2,3,4,5,6-hexachlorocyclohexane, seven meso forms and a *dl* pair (see p. 118).

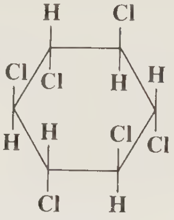
---

[5] DePuy, Morris, Smith, and Smat, *J. Am. Chem. Soc.* **87**, 2421 (1965).

[6] Pfeiffer, *Z. Phys. Chem.* **48**, 40 (1904).

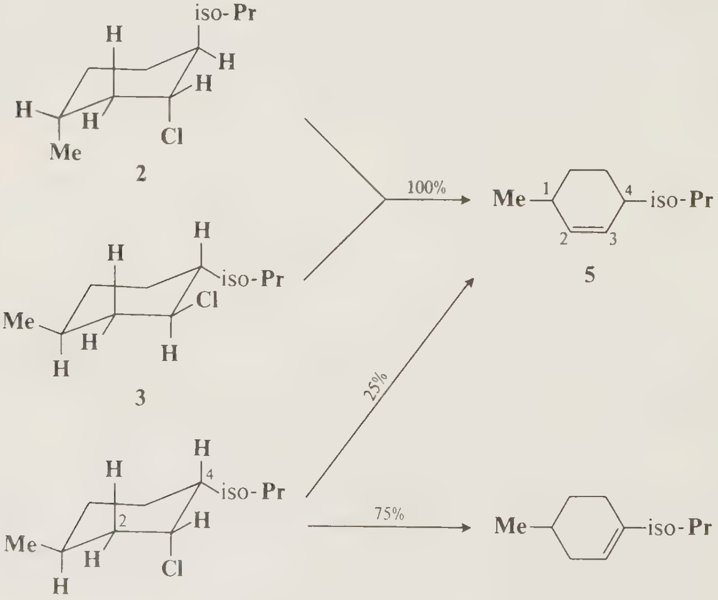
[7] Winstein, Pressman, and Young, *J. Am. Chem. Soc.* **61**, 1645 (1939).

Four of the meso compounds and the *dl* pair (all that were then known) were subjected to elimination of HCl. Only one of these (**1**, called the β-isomer) has no Cl trans to an H. Of the other isomers, the fastest elimination rate was about 3 times as fast as the slowest, but the rate for **1** was 7000 times slower than that of the slowest of the other isomers.[8] This result demonstrates that with these compounds anti elimination is greatly favored over syn elimination, though the latter must be taking place on **1**, very slowly, to be sure.



1

3. The preceding result shows that elimination of HCl in a six-membered ring proceeds best when the H and X are trans to each other. However, there is an additional restriction. Adjacent trans groups on a six-membered ring may be diaxial or diequatorial (p. 129), and the molecule is generally free to adopt either conformation, though one may have a higher energy than the other. Anti-periplanarity of the leaving groups requires that they be diaxial, even if this is the conformation of higher energy. The results with menthyl and neomenthyl chlorides are easily interpretable on this basis. Menthyl chloride has two chair conformations, **2** and **3**. **3**, in which the three substituents are all equatorial, is the more stable. The more stable chair conformation of neomenthyl chloride is **4**, in which the chlorine is axial, and there are axial hydrogens on



2 **3** **4** **5** **6**

---

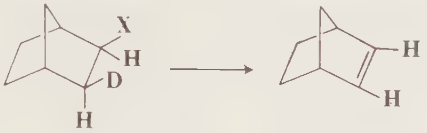
[8] Cristol, *J. Am. Chem. Soc.* **69**, 338 (1947); Cristol, Hause, and Meek, *J. Am. Chem. Soc.* **73**, 674 (1951).

both C-2 and C-4. The results are: neomenthyl chloride gives rapid E2 elimination, and the olefin produced is predominantly **6** (**6** **5** ratio is about 3 : 1), in accord with Zaitsev's rule (p. 910). Since an axial hydrogen is available on both sides, this factor does not control the direction of elimination, and Zaitsev's rule is free to operate. However, for menthyl chloride, elimination is much slower, and the product is entirely the anti-Zaitsev **5**. It is slow because the unfavorable conformation **2** has to be achieved before elimination can take place, and the product is **5** because only on this side is there an axial hydrogen.[9]

4. That anti elimination also occurs in the formation of triple bonds is shown by elimination from *cis*- and *trans*-HOOC—CH=CCl—COOH. In this case the product in both cases is HOOCC≡CCOOH, but the trans isomer reacts about 50 times as fast as the cis compound.[10]

Some examples of syn elimination have been found in molecules where H and X could not achieve an anti-periplanar conformation.

1. The deuterated norbornyl bromide (**7**, X = Br) gave 94% of the product containing no deuterium.[11] Similar results were obtained with other leaving groups, and with bicyclo[2.2.2] compounds.[12] In these cases the exo X group cannot achieve a dihedral angle of 180° with the endo β-hydrogen because of the rigid structure of the molecule. The dihedral angle here is about 120°. These leaving groups prefer syn elimination, with a dihedral angle of about 0°, to anti elimination, with an angle of about 120°.



7

2. The molecule **8** is a particularly graphic example of the need for a planar transition state. In **8** each Cl has an adjacent hydrogen trans to it, and if planarity of leaving groups were not required, anti elimination could easily take place. However, the crowding of the rest of the molecule forces the dihedral angle to be about 120°, and elimination of HCl from **8** is much slower than from corresponding nonbridged compounds.[13] (Note that syn elimination from **8** is even less likely than anti elimination.) Syn elimination can take place from the trans isomer of **8** (dihedral angle about 0°), and this isomer reacted about 8 times faster than **8**.[13]

[11] Kwart, Takeshita, and Nyce, *J. Am. Chem. Soc.* **86,** 2606 (1964).

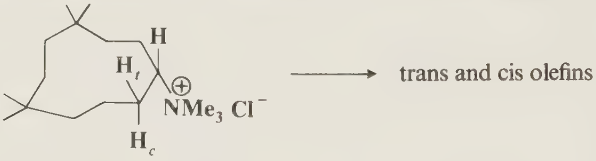
[12] For example, see Bird, Cookson, Hudec, and Williams, *J. Chem. Soc.* 410 (1963); Stille, Sonnenberg, and Kinstle, *J. Am. Chem. Soc.* **88,** 4922 (1966); Coke and Cooke, *J. Am. Chem. Soc.* **89,** 6701 (1967); DePuy, Naylor, and Beckman, *J. Org. Chem.* **35,** 2750 (1970); Brown and Liu, *J. Am. Chem. Soc.* **92,** 200 (1970); Sicher, Pánkova, Závada, Kniežo, and Orahovats, *Collect. Czech. Chem. Commun.* **36,** 3128 (1971).

[13] Cristol and Hause, *J. Am. Chem. Soc.* **74,** 2193 (1952).

The examples so far given illustrate two points. (1) Anti elimination *requires* a dihedral angle of 180°. When this angle cannot be achieved, anti elimination is greatly slowed or prevented entirely. (2) For the simple systems so far discussed syn elimination is not found to any significant extent unless anti elimination is greatly diminished by failure to achieve the 180° angle.

As noted in Chapter 4 (p. 145), six-membered rings are the only ones among rings of four to thirteen members in which strain-free anti-periplanar conformations can be achieved. It is not surprising, therefore, that syn elimination is least common in six-membered rings. Cooke and Coke subjected cycloalkyltrimethylammonium hydroxides to elimination (reaction **7-6**) and found the following percentages of syn elimination with ring size: four-membered, 90%; five-membered, 46%; six-membered, 4%; seven-membered, 31 to 37%.[14] It should be noted that the NMe_3^+ group has a greater tendency to syn elimination than do other common leaving groups such as OTs, Cl, and Br.

Other examples of syn elimination have been found in medium-ring compounds, where both cis and trans olefins are possible (p. 115). As an illustration, we can look at experiments performed by Závada, Svoboda, and Sicher.[15] These workers subjected 1,1,4,4-tetramethyl-7-cyclodecyltrimethylammonium chloride (**9**) to elimination and obtained mostly *trans*- but also some *cis*-tetramethylcyclodecenes as products. (Note that *trans*-cyclodecenes, though stable, are less stable than the cis isomers.) In order to determine the stereochemistry of the reaction, they repeated the elimination, this time using deuterated substrates. They found that when **9** was deuterated in the trans position (H_t = D), there was a substantial isotope effect in the formation of *both* cis and trans olefins but when **9** was deuterated in the cis position (H_c = D), there was *no* isotope effect in the formation of either olefin. Since an isotope effect is expected for an E2 mechanism,[16] these results indicated that *only* the trans hydrogen (H_t) was lost, whether the product was the cis or the trans isomer.[17] This in turn means that *the cis isomer must have been formed by anti elimination and the trans isomer by syn elimination.* (Anti elimination could take place from approximately the conformation shown, but for syn elimination the molecule must twist into a conformation in which the C—H_t and C—NMe_3^+ bonds are syn-periplanar.) This remarkable result, called the *syn-anti dichotomy*, has also been demonstrated by other types of evidence.[18] The fact that syn elimination in this case predominates over anti (as indicated by the formation of trans isomer in greater amounts than cis) has been explained by conformational factors.[19] The syn-anti dichotomy has also been found in other medium-ring systems (8- to 12-



9

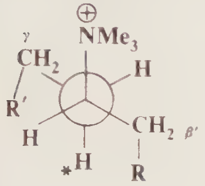
[19] For discussions, see Ref. 4.

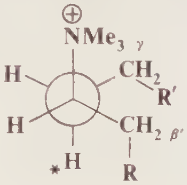
membered),[20] though the effect is greatest for 10-membered rings. With leaving groups,[21] the extent of this behavior decreases in the order $NMe_3^+ > OTs > Br > Cl$, which parallels steric requirements. When the leaving group is uncharged, syn elimination is favored by strong bases and by weakly ionizing solvents.[22]

Syn elimination and the syn-anti dichotomy have also been found in open-chain systems, though to a lesser extent than in medium-ring compounds. For example, in the conversion of 3-hexyl-4-*d*-trimethylammonium ion to 3-hexene with potassium *sec*-butoxide, about 67% of the reaction followed the syn-anti dichotomy.[23] The effects of leaving group, base strength, and solvents are similar. In general syn elimination in open-chain systems is only important in cases where substituents are found on both the β'- and the γ-carbons (the unprimed letter refers to the branch in which the elimination takes place). The factors which cause these results are not completely understood, but the following conformational effects have been proposed as a partial explanation.[24] The two anti- and two syn-periplanar conformations are, for a quaternary ammonium salt:



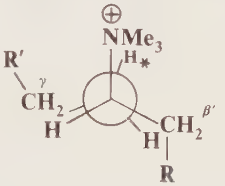
C

anti ⟶ trans



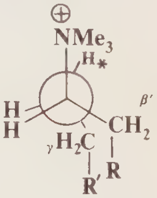
D

anti ⟶ cis



E

syn ⟶ trans



F

syn ⟶ cis

In order for an E2 mechanism to take place a base must approach the proton marked *. In **C** this proton is shielded on both sides by R and R′. In **D** the shielding is on only one side. Therefore, when anti elimination does take place in such systems, it should give more cis product than trans. Also, when the normal anti elimination pathway is hindered sufficiently to allow the syn pathway to compete, the anti → trans route should be diminished more than the anti → cis route. When syn elimination begins to appear, it seems clear that **E**, which is less eclipsed than **F**, should be the favored pathway, and syn elimination should generally give the trans isomer. In general, deviations from the syn-anti dichotomy are greater on the trans side than on the cis. Thus, trans olefins are formed partly or mainly by syn elimination, but cis olefins are formed entirely by anti elimination.

It was mentioned above that weakly ionizing solvents promote syn elimination when the leaving group is uncharged. This is probably caused by ion pairing, which is greatest in nonpolar solvents.[24a] Ion pairing can cause syn elimination with a neutral leaving group by means of the

---

[20] For example, see Coke and Mourning, *J. Am. Chem. Soc.* **90,** 5561 (1968), where the experiment was performed on cyclooctyltrimethylammonium hydroxide, and *trans*-cyclooctene was formed by a 100% syn mechanism, and *cis*-cyclooctene by a 51% syn and 49% anti mechanism.

[21] For examples with other leaving groups, see Závada, Krupička, and Sicher, *Chem. Commun.* 66 (1967), *Collect. Czech. Chem. Commun.* **33,** 1393 (1968); Svobada, Závada, and Sicher, *Collect. Czech. Chem. Commun.* **32,** 2104 (1967), **33,** 1415 (1968), Sicher, Jan, and Schlosser, *Angew. Chem. Int. Ed. Engl.* **10,** 926 (1971) [*Angew. Chem.* **83,** 1012].

[22] See for example, Sicher and Závada, *Collect. Czech. Chem. Commun.* **33,** 1278 (1968).

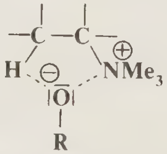
G

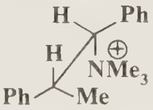
transition state shown in **G**. This effect was graphically illustrated by elimination from 1,1,4,4-tetramethyl-7-cyclodecyl bromide.[25] The ratio of syn to anti elimination when this compound was treated with *t*-BuOK in the nonpolar benzene was 55.0. But when the crown ether dicyclohexyl-18-crown-6 (p. 82) was added (this compound selectively removes K^+ from the *t*-BuO^- K^+ ion pair and thus leaves *t*-BuO^- as a free ion), the syn/anti ratio decreased to 0.12. Large decreases in the syn/anti ratio on addition of the crown ether were also found with the corresponding tosylate and with other nonpolar solvents.[26] However, with positively charged leaving groups the effect is reversed. Here, ion pairing *increases* the amount of anti elimination.[27] In this case a relatively free base (e.g., PhO^-) can be attracted to the leaving group, putting it in a favorable position for attack on the syn β-hydrogen, while ion pairing would reduce this attraction.



We can conclude that anti elimination is generally favored in the E2 mechanism, but that steric (inability to form the anti-periplanar transition state), conformational, ion-pairing, and other factors cause syn elimination to intervene (and even predominate) in some cases.

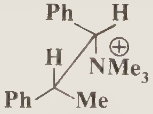
Eclipsing Effects in E2 Eliminations[28]

In the case of (1,2-diphenylpropyl)trimethylammonium ion, the threo *dl* pair (**10**) gave the trans olefin, and the erythro pair (**11**) gave the cis olefin, as expected for stereospecific anti elimination, but the threo pair reacted 57 times faster than the erythro (with OEt^- as the base).[29] For each isomer, the conformation necessary to achieve anti elimination is shown. In the threo isomer,



threo (one of the pair)

10



erythro (one of the pair)

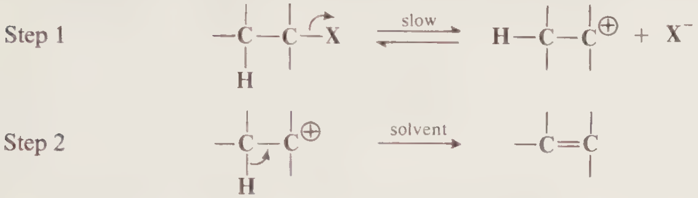
[29] Cram, Greene, and DePuy, *J. Am. Chem. Soc.* **78**, 790 (1956).

the β-phenyl group is completely staggered with respect to the other phenyl group, but in the erythro case the two phenyl groups are gauche. The latter is of course a higher-energy conformation than the former. Therefore, **10** can undergo elimination from its conformer of lowest energy, while **11** must adopt one of the higher-energy conformations, resulting in the lower rate. This type of effect is called an *eclipsing effect*. Note that eclipsing in the transition state, not in the ground state, is what matters.

The E1 Mechanism

The E1 mechanism is a two-step process in which the rate-determining step is ionization of the substrate to give a carbonium ion which rapidly loses a β-proton to a base, usually the solvent:

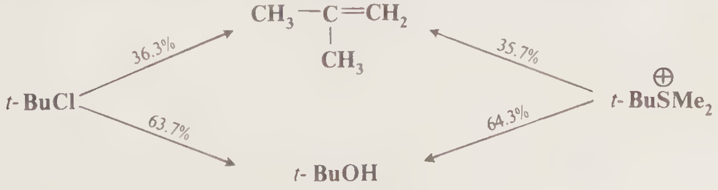


The E1 mechanism normally operates without an *added* base. Just as the E2 mechanism is analogous to and competes with the SN2, so is the E1 mechanism related to the SN1. In fact, the first step of the E1 is exactly the same as that of the SN1 mechanism. The second step differs in that the solvent pulls a proton from the β-carbon of the carbonium ion rather than attacking it at the positively charged carbon, as in the SN1 process. In a pure E1 reaction (that is, without ion pairs, etc.) the product should be completely nonstereospecific, since the carbonium ion is free to adopt its most stable conformation before giving up the proton.

Some of the evidence for the E1 mechanism is as follows:

1. The reaction exhibits first-order kinetics (in substrate) as expected. Of course the solvent is not expected to appear in the rate equation, even if it were involved in the rate-determining step (p. 201), but this point can be easily checked by adding a small amount of the conjugate base of the solvent. It is generally found that such an addition does not increase the rate of the reaction. If this more powerful base does not enter into the rate-determining step, it is unlikely that the solvent does.

2. If the reaction is performed on two molecules which differ only in the leaving group (for example, t-BuCl and $t\text{-Bu}\overset{\oplus}{\text{S}}\text{Me}_2$), the rates should obviously be different, since they depend on the ionizing ability of the molecule. However, once the carbonium ion is formed, if the solvent and the temperature are the same, it should suffer the same fate in both cases, since the nature of the leaving group does not affect the second step. This means that *the ratio of elimination to substitution should be the same*. The compounds mentioned in the example were solvolyzed at 65.3°C in 80% aqueous ethanol, with the following results:[30]



---

[30] Cooper, Hughes, Ingold, and MacNulty, *J. Chem. Soc.* 2038 (1948).

Although the rates were greatly different (as expected with such different leaving groups), the product ratios were the same, within 1%. If this had taken place by a second-order mechanism, the nucleophile would not be expected to have the same ratio of preference for attack at the β-hydrogen compared to attack at a *neutral* chloride as for attack at the β-hydrogen compared to attack at a *positive* SMe_2 group.

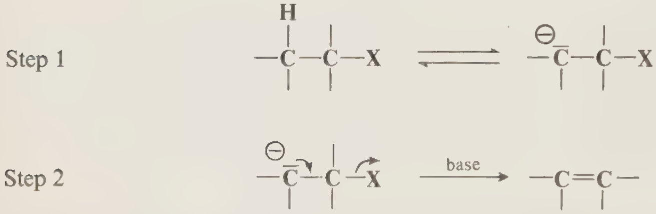
3. Many reactions carried out under first-order conditions on systems where E2 elimination is anti proceed quite readily to give olefins where a cis hydrogen must be removed, often in preference to the removal of a trans hydrogen. For example, menthyl chloride (**2**, p. 898), which by the E2 mechanism gave only **5**, under E1 conditions gave 68% **6** and 32% **5**, since the steric nature of the hydrogen is no longer a factor here, and the more stable olefin (Zaitsev's rule, p. 910) is predominantly formed.

4. If carbonium ions are intermediates, we should expect rearrangements with suitable substrates. These have often been found in elimination reactions performed under E1 conditions.

It has been shown that E1 reactions can involve ion pairs, just as is true for SN1 reactions (p. 273).[31] This effect is naturally greatest for nondissociating solvents: it is least in water, greater in ethanol, and greater still in acetic acid. It has been proposed that the ion-pair mechanism (p. 276) extends to elimination reactions too, and that the SN1, SN2, E1, and E2 mechanisms possess in common an ion-pair intermediate, at least on occasion.[32]

The E1cB Mechanism[33]

In the E1 mechanism, X leaves first and then H. In the E2 mechanism the two groups leave at the same time. There is a third possibility: the H leaves first and then the X. This is a two-step process, called the *E1cB mechanism*, or the *carbanion mechanism*, since the intermediate is a carbanion:



The name E1cB comes from the fact that it is the conjugate base of the substrate which is giving up the leaving group (see the SN1cB mechanism, p. 330). We can distinguish three limiting cases: (1) The carbanion returns to starting material faster than it forms product; step 1 is reversible. (2) Step 1 is the slow step, and formation of product is faster than return of the carbanion to starting material. In this case step 1 is essentially irreversible. (3) Step 1 is rapid, and the carbanion goes slowly to product. This case occurs only with the most stable carbanions. Here too, step 1 is essentially irreversible. Investigations of the reaction order are generally not very useful (except for case 3 which is first order) because cases 1 and 2 are second order and thus difficult or impossible to distinguish from the E2 mechanism by this procedure.[34] We would expect the greatest likelihood of finding the E1cB mechanism in substrates which have (a) a poor nucleofuge and (b) an acidic hydrogen, and most investigations have concerned such substrates. The following is some of the evidence in support of the E1cB mechanism.

[33] For reviews, see Hunter, *Intra-Sci. Chem. Rep.* 7(3), 19–26 (1973); McLennan, *Q. Rev., Chem. Soc.* **21**, 490–506 (1967).

1. The first step of the E1cB mechanism (case 1) involves a reversible exchange of protons between the substrate and the base. In that case, if deuterium is present in the base, then recovered starting material should contain deuterium. This was found to be the case in the treatment of $Cl_2C{=}CHCl$ with NaOD to give $ClC{\equiv}CCl$. When the reaction was stopped before completion, there *was* deuterium in the recovered olefin.[35] A similar result was found for pentahaloethanes.[36] These substrates are relatively acidic. In both cases the electron-withdrawing halogens increase the acidity of the hydrogen, and in the case of trichloroethylene there is the additional factor that a hydrogen on an sp^2 carbon is more acidic than one on an sp^3 carbon (p. 243). Thus, the E1cB mechanism is more likely to be found in eliminations yielding triple bonds than in those giving double bonds. Another likely place for the E1cB mechanism should be in reaction of a substrate like $PhCH_2CH_2Br$, since the carbanion is stabilized by resonance with the phenyl group. Nevertheless, no deuterium exchange was found here.[37] If this type of evidence is a guide, then it may be inferred that the E1cB mechanism (case 1) is quite rare, at least for eliminations yielding C=C double bonds. It has been pointed out[38] that even where deuterium exchange is taking place, the mechanism need not necessarily be E1cB since the exchange could be occurring without the carbanion necessarily being the species which loses the leaving group. Although this point is formally correct, it is difficult to see how it could happen in practice. A carbanion would be expected to lose the nucleofuge much more easily than the substrate.

2. We have predicted that the E1cB mechanism would be most likely to be found with substrates containing acidic hydrogens and poor leaving groups. Compounds of the type ZCH_2CH_2OPh, where Z is an electron-withdrawing group (e.g., NO_2, $SMe_2{}^+$, CN, COOR, etc.), belong to this category, because OPh is a very poor leaving group (p. 331). There is evidence to show that the mechanism here is indeed E1cB.[39] Isotope effects, measured for $MeSOCD_2CH_2OPh$ and $Me_2\overset{\oplus}{S}CD_2CH_2OPh$ with NaOD in D_2O, are about 0.7. This is compatible with an E1cB mechanism (case 1 or 3, though in this system case 1 is more likely) but not with an E2 mechanism for which an isotope effect of perhaps 5 might be expected (of course, an E1 mechanism is precluded by the extremely poor nucleofugal ability of OPh). The fact that k_H/k_D is less than the expected value of 1 is attributable to solvent and secondary isotope effects. Among other evidence for an E1cB mechanism in this system is that changes in the identity of Z had a dramatic effect on the relative rates: a span of 10^{11} between NO_2 and COO^-. Note that elimination from substrates of the type $RCOCH_2CH_2Y$ is the reverse of Michael-type addition to C=C bonds. We have seen (p. 678) that such addition involves initial attack by a nucleophile Y and subsequent attack by a proton. Thus the initial loss of a proton from substrates of this type (that is, an E1cB mechanism) is in accord with the principle of microscopic reversibility.[40]

---

[34] Case 2 cannot be distinguished from E2 by this means, because it has the identical rate law: Rate = k[substrate][B]. The rate law for case 1 is different: Rate = k[substrate][B] [BH], but this is often not useful because the only difference is that the rate is also dependent (inversely) on the concentration of the conjugate acid of the base, and this is usually the solvent, so that changes in its concentration cannot be measured.

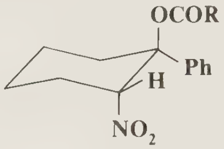
[40] Patai, Weinstein, and Rappoport, *J. Chem. Soc.* 1741 (1962).

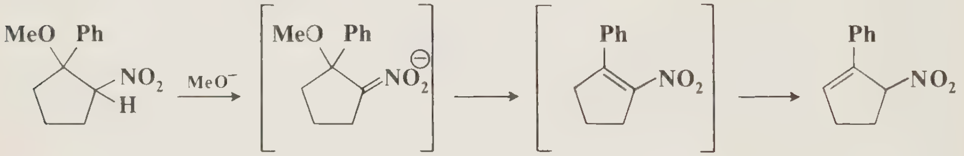
It has been suggested that all base-initiated elimination reactions wherein the proton is activated by strong electron-withdrawing groups proceed by carbanion mechanisms.[41] It may also be recalled that benzyne formation (p. 589) can also occur by such a process.

3. Of the three cases of the E1cB mechanism, the one most difficult to distinguish from E2 is case 2. One way to make this distinction is to study the effect of a change in leaving group.[42] Such a change should have a large effect on the E2 reaction (because the C—X bond is broken in the rate-determining step) but not in case 2 of the E1cB mechanism. A change in leaving group in elimination from **12,** from R = Me to R = CH_2Br, resulted in only a threefold acceleration,[43] which is much less than expected for an E2 mechanism.[44] Note that in this substrate, carbanion formation is strongly favored because of the powerful electron-withdrawing nitro group.



12

4. An example of an E1cB mechanism (case 3) has been found with the substrate **13,** which when treated with methoxide ion undergoes elimination to **15,** which is unstable under the reaction conditions and rearranges as shown.[45] Among the evidence for the proposed mechanism in this case were kinetic and isotope effect results, as well as the spectral detection of **14.**[46]



13 **14** **15**

5. In many eliminations to form C=O and C≡N bonds the initial step is loss of a positive group (normally a proton) from the oxygen or nitrogen. These may also be regarded as E1cB processes (most often case 1).

There is evidence that some E1cB mechanisms may involve carbanion ion pairs, e.g.,[47]

The E1-E2-E1cB Spectrum

In the three mechanisms so far considered the similarities are greater than the differences. In each case there is a leaving group which comes off with its pair of electrons and another group (usually hydrogen) which comes off without them. The only difference is in the order of the steps. It is now generally accepted that there is a spectrum of mechanisms ranging from one extreme, in which the leaving group departs well before the proton (pure E1), to the other extreme, in which the proton comes off first and then, after some time, the leaving group follows (pure E1cB). The *pure* E2 case would be somewhere in the middle, with both groups leaving simultaneously. However, most E2 reactions are not exactly in the middle, but somewhere to one side or the other. For example, the nucleofuge might depart just before the proton. This case may be described as an E2 reaction with a small amount of E1 character. The concept may be expressed by the question: In the transition state, which bond (C—H or C—X) has undergone more cleavage?[48] Bunnett[2] has suggested that the words *paenecarbonium* and *paenecarbanion* be used to refer to E2 transition states near the E1 and E1cB extremes, respectively.

One way to determine just where a given reaction stands on the E1-E2-E1cB spectrum is to study isotope effects, which ought to tell something about the behavior of bonds in the transition state.[49] For example, $CH_3CH_2\overset{\oplus}{N}Me_3$ showed a nitrogen isotope effect (k^{14}/k^{15}) of 1.017, while $PhCH_2CH_2\overset{\oplus}{N}Me_3$ gave a corresponding value of 1.009.[50] It would be expected that the phenyl group would move the reaction toward the E1cB side of the line, which means that for this compound the C—N bond is not so greatly broken in the transition state as it is for the unsubstituted one. The isotope effect bears this out, for it shows that, in the phenyl compound, the mass of the nitrogen has less effect on the reaction rate than it does in the unsubstituted compound. Similar results have been obtained with $\overset{\oplus}{S}R_2$ leaving groups, by the use of $^{32}S/^{34}S$ isotope effects.[51] The position of reactions along the spectrum has also been studied from the other side of the newly forming double bond by the use of H/D and H/T isotope effects,[52] although interpretation of these results is clouded by the fact that β-hydrogen isotope effects are expected to change smoothly from small to large to small again as the degree of transfer of the β-hydrogen from the β-carbon to the base increases[53] (recall—p. 205—that isotope effects are greatest when the proton is half-transferred in the transition state) and by the possibility of secondary isotope effects (e.g., the presence of a β-deuterium or tritium may cause the leaving group to depart more slowly). Other isotope effect studies have involved labeled α- or β-carbon, labeled α-hydrogen, or labeled base.[49]

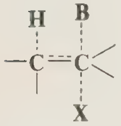
[52] For example, see Saunders and Edison, *J. Am. Chem. Soc.* **82**, 138 (1960); Hodnett and Sparapany, *Pure Appl. Chem.* **8**, 385, 537 (1964); Finley and Saunders, *J. Am. Chem. Soc.* **89**, 898 (1967); Ghanbarpour and Willi, *Justus Liebigs Ann. Chem.* 1295 (1975); Simon and Müllhofer, Ref. 50.

[53] For an example of this effect, see Cockerill, *J. Chem. Soc. B* 964 (1967).

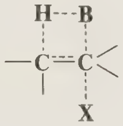
Another way to study the position of a given reaction on the spectrum involves the use of β-aryl substitution. Since a positive Hammett ρ value is an indication of a negatively charged transition state, the ρ value for substituted β-aryl groups should increase as a reaction moves from E1-like to E1cB-like along the spectrum. This has been shown to be the case in a number of studies;[54] for example, ρ values of $ArCH_2CH_2X$ increase as the leaving-group ability of X decreases. A typical set of ρ values was: X = I, 2.07; Br, 2.14; Cl, 2.61; SMe_2^+, 2.75; F, 3.12.[55] As we have seen, decreasing leaving-group ability correlates with increasing E1cB character.

The E2C Mechanism[56]

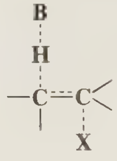
Certain alkyl halides and tosylates undergo E2 eliminations faster when treated with such weak bases as Cl^- in polar aprotic solvents or PhS^- than with the usual E2 strong bases such as RO^- in ROH.[57] In order to explain these results Parker and coworkers have proposed[58] that there is a spectrum[59] of E2 transition states in which the base may interact in the transition state with the α-carbon as well as with the β-hydrogen. At one end of this spectrum is a mechanism (called E2C) in which, in the transition state, the base interacts mainly with the carbon. The E2C mechanism is characterized by strong nucleophiles which are weak bases. At the other extreme is the normal E2 mechanism, here called E2H to distinguish it from E2C, characterized by strong bases. **16** represents a transition state which is between these extremes. Additional evidence[60] for the E2C mechanism is derived from Brönsted equation considerations (p. 235), from substrate effects, from isotope effects, and from the effects of solvents on rates.



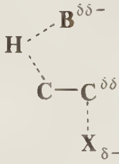
E2C



16



E2H



17

However, the E2C mechanism has been criticized, and it has been contended that all the experimental results can be explained by the normal E2 mechanism.[61] McLennan has suggested that the transition state is that shown as **17**.[61a] An ion-pair mechanism has also been proposed.[62] Although the actual mechanisms involved may be a matter of controversy, there is no doubt that a class of elimination reactions exists which is characterized by second-order attack by weak bases.[63] These reactions also have the following general characteristics:[64] (1) They are favored by good leaving groups; (2) they are favored by polar aprotic solvents; (3) the reactivity order is tertiary > secondary > primary, which is the opposite of the normal E2 order (p. 914); (4) the elimination is always anti (syn elimination is not found), but in cyclohexyl systems, a diequatorial anti elimination is about as favorable as a diaxial anti elimination (unlike the normal E2 reaction, p. 898); (5) they follow Zaitsev's rule (p. 910) where this does not conflict with the requirement for anti elimination.

Orientation of the Double Bond

With some substrates, a β-hydrogen is present on only one carbon, and (barring rearrangements) there is no doubt as to the identity of the product. For example, $PhCH_2CH_2Br$ can give only $PhCH{=}CH_2$. However, in many other cases two or three olefinic products are possible. In the simplest such case, a *sec*-butyl compound may give either 1-butene or 2-butene. There are a number of rules which enable us to predict, in many instances, which product will predominantly form.[65]

1. No matter what the mechanism, a double bond does not go to a bridgehead carbon unless the ring sizes are large enough (Bredt's rule, see p. 147). This means, for example, not only that **18** gives only **19** and not **20** (indeed **20** is not a known compound), but also that **21** does not undergo elimination.

[65] For a review of orientation in cycloalkyl systems, see Hückel and Hanack, *Angew. Chem. Int. Ed. Engl.* **6,** 534–544 (1967) [*Angew. Chem.* **79,** 555–565].

2. No matter what the mechanism, if there is a double bond (C=C or C=O) already in the molecule which can be in conjugation with the new double bond, then the conjugated product usually predominates, sometimes even when the stereochemistry is unfavorable (for an exception, see p. 913).

3. In the E1 mechanism the leaving group is gone before the choice is made as to which direction the new double bond takes. Therefore the direction is determined almost entirely by the relative stabilities of the two (or three) possible olefins. In such cases *Zaitsev's rule*[66] *operates.* This rule states that *the double bond goes mainly toward the most highly substituted carbon.* That is, a *sec*-butyl compound gives more 2-butene than 1-butene, and 3-bromo-2,3-dimethylpentane gives more 2,3-dimethyl-2-pentene than either 3,4-dimethyl-2-pentene or 2-ethyl-3-methyl-1-butene. Thus Zaitsev's rule predicts that the olefin predominantly formed will be the one with the largest possible number of alkyl groups on the C=C carbons, and in most cases this is what is found. From heat-of-combustion data (see p. 26) it is known that olefin stability increases with alkyl substitution, though just why this should be is a matter of conjecture. The most common explanation is hyperconjugation. For E1 eliminations Zaitsev's rule governs the orientation, whether the leaving group is neutral or positive, since, as already mentioned, the leaving group is not present when the choice of direction is made. This statement does not hold for E2 eliminations, and it may be mentioned here, for contrast with later results, that E1 elimination of $Me_2CHCHMe\overset{\oplus}{S}Me_2$ gave 91% of the Zaitsev product and 9% of the other.[67] However, there *are* cases in which the leaving group affects the direction of the double bond in E1 eliminations.[68] This may be attributed to ion pairs; that is, the leaving group is not completely gone when the hydrogen departs. Zaitsev's rule breaks down in cases where the non-Zaitsev product is more stable for steric reasons. Thus, E1 elimination of 2,4,4-trimethyl-2-chloropentane ($Me_3CCH_2CMe_2Cl$) gives 81% $Me_3CCH_2CMe{=}CH_2$ and 19% $Me_3CCH{=}CMe_2$.[69] The latter is less stable than the former, because it has a methyl group cis to a *t*-butyl group. An even more striking example of this effect was found in the case of 1,2-diphenyl-2-X-propanes $PhMeCXCH_2Ph$, where E1 or E1-like eliminations were reported to give about 50% $CH_2{=}CPhCH_2Ph$, despite the fact that the double bond of the Zaitsev product (PhMeC=CHPh) is conjugated with two benzene rings.[70]

4. For the anti E2 mechanism a trans proton is necessary, and if this is available in only one direction, that is the way the double bond will form. Because of the free rotation in acyclic systems (except where steric hindrance is great), this is a factor only in cyclic systems. Where trans β-hydrogens are available on two or three carbons, two types of behavior are found, depending on substrate structure and on the nature of the leaving group. Some compounds follow Zaitsev's rule and give predominant formation of the most highly substituted olefin, but others follow *Hofmann's rule: the double bond goes mainly toward the least highly substituted carbon.* Though many exceptions are known, the following general statements can be made: In most cases, compounds containing uncharged leaving groups (those which come off as negative ions) follow Zaitsev's rule, just as they do in E1 elimination, no matter what the structure of the substrate. However, elimination from compounds with charged leaving groups, e.g., NR_3^+, SR_2^+ (those which come off as neutral molecules) follow Hofmann's rule if the substrate is acyclic,[71] but Zaitsev's rule if the leaving group is attached to a six-membered ring.[72]

[71] An example of an acyclic quaternary ammonium salt which follows Zaitsev's rule is found in Feit and Saunders, *J. Am. Chem. Soc.* **92**, 5615 (1970).

[72] For examples where Zaitsev's rule is followed with charged leaving groups in cyclohexyl systems, see Gent and McKenna, *J. Chem. Soc.* 137 (1959); Hughes and Wilby, *J. Chem. Soc.* 4094 (1960); Brownlee and Saunders, *Proc. Chem. Soc.* 314 (1961); Booth, Franklin, and Gidley, *J. Chem. Soc. C* 1891 (1968). For a discussion of the possible reasons for this, see Saunders and Cockerill, Ref. 2, pp. 192–193.

Much work has been devoted to searching for the reasons for the differences in orientation. Since Zaitsev orientation almost always gives the thermodynamically more stable isomer, what needs to be explained is why in some cases the less stable Hofmann product predominates. Three explanations have been offered for the change in orientation in acyclic systems with a change from uncharged to charged nucleofuges. The first of these, by Hughes and Ingold,[73] is that Hofmann orientation is caused by the fact that the acidity of the β-hydrogen is decreased by the presence of the electron-donating alkyl groups. For example, under E2 conditions $\text{Me}_2\text{CHCHMe}\overset{\oplus}{\text{S}}\text{Me}_2$ gives more of the Hofmann product, and it is the more acidic hydrogen which is removed by the base. Of course, the CH_3 hydrogens would still be more acidic than the Me_2CH hydrogen even if a neutral leaving group were present, but the explanation of Hughes and Ingold is that acidity matters with charged and not with neutral leaving groups, because the charged groups exert a strong electron-withdrawing effect, making differences in acidity more manifest than they are with the less electron-withdrawing neutral groups.[73] The explanation of Bunnett[74] is similar. According to this, the change to a positive leaving group causes the mechanism to shift toward the E1cB end of the spectrum, where there is more C—H bond breaking in the rate-determining step and where, consequently, acidity is more important. In this view, when there is a neutral leaving group, the mechanism is more E1-like, C—X bond breaking is more important, and olefin stability determines the direction of the new double bond. On the other hand, the third explanation, by H. C. Brown, is completely different. In this picture, field effects are unimportant, and the difference in orientation is largely a steric effect caused by the fact that charged groups are usually larger than neutral ones. A CH_3 group is more open to attack than a CH_2R group, and a CHR_2 group is still less easily attacked. In addition, eclipsing effects are more important with increased substitution. For example, if we consider the case of $\text{Me}_2\text{CHCH}(\overset{\oplus}{\text{N}}\text{Me}_3)\text{CH}_2\text{Me}$, there is only one conformation (**22**) leading to Zaitsev elimination in which a hydrogen is trans to the leaving group, and this conformation is not the most stable one since there is a methyl group and not a hydrogen between the two bulky groups CH_2Me and $\overset{\oplus}{\text{N}}\text{Me}_3$. On the other hand, for Hofmann elimination there are two conformations with trans hydrogens (**23** and **24**), and one of these (**23**) is the most stable, since the $CHMe_2$ group is between two hydrogens. In molecules with a CH_3 group, the situation is still more favorable, since elimination can occur from any conformation,

---

[73] For summaries of this position, see Ingold, *Proc. Chem. Soc.* 265-274 (1962); Banthorpe, Hughes, and Ingold, *J. Chem. Soc.* 4054 (1960); Banthorpe, Ref. 2, pp. 55–59.

[74] Bunnett, Ref. 2.

and none of them can be gauche. Of course, these steric considerations also apply when the leaving group is neutral, but, according to Brown, they are much less important here because the neutral groups are smaller, do not block access to the hydrogens so much, and make the energy difference between the favorable and unfavorable conformations much less. Brown was able to show that Hofmann elimination increases with the size of the leaving group. Thus the percentage of 1-ene obtained from $CH_3CH_2CH_2CHXCH_3$ was as follows (X listed in order of increasing size): I, 30%; Br, 31%; OTs, 48%; $\overset{\oplus}{S}Me_2$, 87%; SO_2Me, 89%; $\overset{\oplus}{N}Me_3$, 98%.[75] Hofmann elimination was also shown to increase with increase in bulk of the substrate.[76] With large enough compounds, Hofmann orientation can be obtained even with halides, e.g., *t*-amyl bromide gave 89% of the Hofmann product. Even those who believe in the acidity explanations concede that these steric factors operate in extreme cases.[77]

There is one series of results which is incompatible with the steric explanation: E2 elimination from the four 2-halopentanes gave the following percentages of 1-pentene: F, 83%; Cl, 37%; Br, 25%; I, 20%.[78] The same order was found for the four 2-halohexanes.[79] Although there is some doubt about the relative steric requirements of Br, Cl, and I, there is no doubt that F is the smallest of the halogens, and if the steric explanation were the only valid one, the fluoroalkanes could not give predominant Hofmann orientation. Another result which argues against the steric explanation is the effect of changing the nature of the base. Brown and coworkers reported that the proportion of Hofmann orientation increased with increasing size of the base,[80] but in these experiments the solvent and the strength of the base were also changed, so it was not really possible to say that base size alone was responsible for the increasing Hofmann orientation. An experiment in which the effective size of the base was kept constant while its basicity was increased (by using as bases a series of $XC_6H_4O^-$ ions) showed that the percentage of Hofmann elimination increased with increasing base strength, though the size of the base did not change.[81] These results are in accord with the explanation of Bunnett, since an increase in base strength moves an E2 reaction closer to the E1cB end of the spectrum. In further experiments, a large series of bases of different kinds was shown to obey linear free-energy relationships between basicity and percentage of Hofmann elimination,[82] though certain very large bases (e.g., 2,6-di-*t*-butylphenoxide) did not obey the relationships, steric effects becoming important in these cases. Steric effects of the base can also become important in cases where the effective size of the base is increased by base association, when the leaving group is halogen or OTs.[83] Such base association effects are unimportant when the leaving group is NMe_3^+.[84]

5. Only a few investigations on the orientation of syn E2 eliminations have been carried out, but these show that Hofmann orientation is greatly favored over Zaitsev.[85]

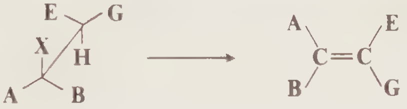
6. In the E1cB mechanism the question of orientation seldom arises because the mechanism is generally found only where there is an electron-withdrawing group in the β-position, and that is where the double bond goes.

7. As already mentioned, E2C reactions show a strong preference for Zaitsev orientation.[86] In some cases this can be put to preparative use. For example, the compound $PhCH_2CHOTs$-$CHMe_2$ gave about 98% $PhCH{=}CHCHMe_2$ under the usual E2 reaction conditions (*t*-BuOK in *t*-BuOH). In this case the double bond goes to the side with more hydrogens because on that side it will be able to conjugate with the benzene ring. However, with the weak base Bu_4N^+ Br^- in acetone the Zaitsev product $PhCH_2CH{=}CMe_2$ was formed in 90% yield.[87]

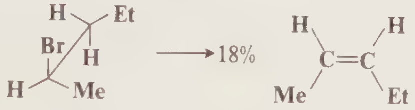
Steric Orientation of the Double Bond

When elimination takes place on a compound of the form CH_3—CABX or CHAB—CGGX, the new olefin does not have cis-trans isomerism, but for compounds of the form CHEG—CABX (E and G *not* H) (**25**) and CH_2E—CABX (**26**), cis and trans isomers are possible. When the anti E2 mechanism is in operation, **25** gives the isomer arising from trans orientation of X and H

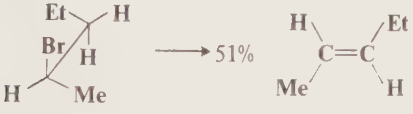


25

and, as we have seen before (p. 897), an erythro compound gives the cis olefin and a threo compound the trans. For **26** two conformations are possible for the transition state; these lead to different isomers, and often both are obtained. However, the one which predominates is often determined by the eclipsing effect (p. 902). For example, Zaitsev elimination from 2-bromopentane can occur as follows:



27



28

However, in **27** the ethyl group is between Br and Me, while in **28** it is between Br and H. This means that **28** is more stable, and most of the elimination should occur from this conformation. This is indeed what happens, and 51% of the trans isomer is formed (with KOEt) compared to 18% of the cis (the rest is the Hofmann product).[88] These effects become larger with increasing size of A, B, and E.

---

[86] For example, see Lloyd and Parker, *Tetrahedron Lett.* 637 (1971); Ono, *Bull. Chem. Soc. Jpn.* **44**, 1369 (1971); Bailey and Saunders, *J. Org. Chem.* **38**, 3363 (1973).

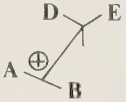
[87] Lloyd, Muir, and Parker, Ref. 64.

[88] Brown and Wheeler, *J. Am. Chem. Soc.* **78**, 2199 (1956).

However, eclipsing effects are not the only factors which affect the cis/trans ratio in anti E2 eliminations. Other factors are the nature of the leaving group, the base, the solvent, and the substrate. Not all these effects are completely understood.[89]

For syn E2 elimination, we have seen (p. 901) that formation of the trans olefin should be greatly preferred to that of the cis isomer because of eclipsing effects. In accord with this, very high trans/cis ratios, higher than would be expected on the basis of olefin stabilities alone, have been found for syn elimination of the 5-decyltrimethylammonium ion.[90]

For E1 eliminations, if there is a free carbonium ion:



(**D** may be **H**)

then it is free to rotate, and no matter what the geometry of the original compound, the more stable situation is the one where the larger of the D-E pair is opposite the smaller of the A-B pair, and the corresponding olefin should form. If the carbonium ion is not completely free, then to that extent, E2-type products are formed. Also, if a suitable neighboring group is present, there may be a neighboring-group effect, and this may affect the proportions of cis and trans olefins.

REACTIVITY

In this section we examine the effects of changes in the substrate, base, leaving group, and medium on (1) overall reactivity, (2) E1 versus E2 versus E1cB, and (3) elimination versus substitution.

Effect of Substrate Structure

1. *Effect on overall activity.* We shall refer to the carbon containing the leaving group (X) as the α-carbon, and to the carbon which loses the proton (or other positive species) as the β-carbon. Groups attached to the α- or β-carbons can exert at least four kinds of influence:

a. They may stabilize or destabilize the incipient double bond (α- or β-groups may do this).

b. They may stabilize or destabilize an incipient carbanion, affecting the acidity of the proton (β-groups only).

c. They may stabilize or destabilize an incipient carbonium ion (α-groups only).

d. They may exert steric effects (e.g., eclipsing effects) (both α- and β-groups).

Effects a and d may apply in all three mechanisms, though steric effects are greatest for the E2 mechanism. Effect b does not apply in the E1 mechanism, and effect c does not apply in the E1cB mechanism. Groups such as Ar and C=C increase the rates by any mechanism, whether they are α or β (effect a). Electron-withdrawing groups increase the acidity when in the β position, but have little effect in the α position unless they also conjugate with the double bond. Thus Br, Cl, CN, Ts, NO_2, CN, SR in the β position all increase the rate of E2 eliminations.

2. *Effect on E1 versus E2 versus E1cB.* α-Alkyl and α-aryl groups increase the extent of E1 elimination, since they stabilize the carbonium character of the transition state. That is, they shift the spectrum toward the E1 end. β-Alkyl groups also shift the mechanism toward E1, since they *decrease* the acidity of the hydrogen. However, β-aryl groups shift the mechanism the other way (toward E1cB), since they stabilize the carbanion. Indeed, as we have seen (p. 905), all

---

TABLE 1 The effect of α and β branching on the rate of E2 elimination and on the amount of olefin formed

The reactions were between the alkyl bromide and OEt^-. *The rate for isopropyl bromide was actually greater than that for ethyl bromide, if the temperature difference is considered. Neopentyl bromide, the next compound in the β-branching series, cannot be compared because it has no β-hydrogen and cannot give an elimination product without rearrangement*

Substrate	Temperature, °C	Olefin, %	Rate × 10^5 of E2 reaction	Reference
CH_3CH_2Br	55	0.9	1.6	92
$(CH_3)_2CHBr$	25	80.3	0.237	93
$(CH_3)_3CBr$	25	97	4.17	94
$CH_3CH_2CH_2Br$	55	8.9	5.3	92
$CH_3\underset{CH_3}{C}HCH_2Br$	55	59.5	8.5	92

electron-withdrawing groups in the β position shift the mechanism toward E1cB.[91] α-Alkyl groups also increase the extent of elimination with weak bases (E2C reactions).

3. *Effect on elimination versus substitution.* Under second-order conditions α branching increases elimination, to the point where tertiary substrates undergo few SN2 reactions, as we saw in Chapter 10. For example, Table 1 shows results on some simple alkyl bromides.[92–94] Similar results were obtained with $\overset{+}{S}Me_2$ as the leaving group.[95] Two reasons may be presented for this trend. One is statistical: as α branching increases, there are usually more hydrogens for the base to attack. The other is that α branching presents steric hindrance to attack of the base at the carbon. Under first-order conditions, increased α branching also increases the amount of elimination (E1 versus SN1), though not so much, and usually the substitution product predominates. For example, solvolysis of *t*-butyl bromide gave only 19% elimination[94] (compare with Table 1). β branching also increases the amount of E2 elimination with respect to SN2 substitution (Table 1), not because elimination is faster but because the SN2 mechanism is so greatly slowed (p. 315). Under first-order conditions too, β branching favors elimination over substitution, probably for steric reasons.[96] However, E2 eliminations from compounds with charged leaving groups are slowed by β branching. This is related to Hofmann's rule (p. 910). Electron-withdrawing groups in the β position not only increase the rate of E2 eliminations and shift the mechanisms toward the E1cB end of the spectrum but also increase the extent of elimination as opposed to substitution.

Effect of the Attacking Base

1. *Effect on E1 versus E2 versus E1cB.* In the E1 mechanism, an external base is generally not required: The solvent acts as the base. Hence, when external bases are added, the mechanism is shifted toward E2. Stronger bases and higher base concentrations cause the mechanism to move

toward the right of the E1-E2-E1cB spectrum (as we have written it).[97] However, weak bases in polar aprotic solvents can also be effective in elimination reactions with certain substrates (the E2C reaction, p. 908). Normal E2 elimination has been accomplished with the following bases:[98] H_2O, NR_3, OH^-, OAc^-, OR^-, OAr^-, NH_2^-, CO_3^{2-}, $LiAlH_4$, I^-, CN^-, and organic bases. However, the only bases of preparative importance in the normal E2 reaction are OH^-, OR^-, and NH_2^-, usually in the conjugate acid as solvent. Weak bases which are effective in the E2C reaction are Cl^-, Br^-, F^-, OAc^-, and RS^-. These bases are often used in the form of their R_4N^+ salts.

2. *Effect on elimination versus substitution.* Strong bases not only benefit E2 as against E1, but also benefit elimination as against substitution. With a high concentration of strong base in a nonionizing solvent, bimolecular mechanisms are favored, and E2 predominates over SN2. At low base concentrations, or in the absence of base altogether, in ionizing solvents, unimolecular mechanisms are favored, and the SN1 mechanism predominates over the E1. In Chapter 10, it was pointed out that some species are strong nucleophiles though weak bases (p. 322). The use of these obviously favors substitution, except that, as we have seen, elimination can predominate if polar aprotic solvents are used. It has been shown for the base CN^- that in polar aprotic solvents, the less the base is encumbered by its counterion in an ion pair (that is, the freer the base), the more substitution is favored at the expense of elimination.[99]

Effect of the Leaving Group

1. *Effect on reactivity.* The leaving groups in elimination reactions are similar to those in nucleophilic substitution. E2 eliminations have been performed with the following groups: NR_3^+, PR_3^+, SR_2^+, OHR^+, SO_2R, OSO_2R, OCOR, OOH, OOR, F, Cl, Br, I, and CN (*not* OH_2^+). E1 eliminations have been carried out with: NR_3^+, SR_2^+, OH_2^+, OHR^+, OSO_2R, OCOR, Cl, Br, I, and N_2^+.[100] However, the only important leaving groups for preparative purposes are OH_2^+ (always by E1) and Cl, Br, I, and NR_3^+ (usually by E2).

2. *Effect on E1 versus E2 versus E1cB.* Better leaving groups shift the mechanism toward the E1 end of the spectrum, since they make ionization easier. This effect has been studied in various ways. One way already mentioned was by a study of ρ values (p. 908). Poor leaving groups and positively charged leaving groups shift the mechanism toward the E1cB end of the spectrum because the strong electron-withdrawing field effects increase the acidity of the β-hydrogen. The E2C reaction is favored by good leaving groups.

3. *Effect on elimination versus substitution.* As we have already seen (p. 903), for first-order reactions the leaving group has nothing to do with the competition between elimination and substitution, since it is gone before the decision is made as to which path to take. However, where ion pairs are involved, this is not true, and results have been found where the nature of the leaving group does affect the product.[101] In second-order reactions, the elimination/substitution ratio is not greatly dependent on a halide leaving group, though there is a slight increase in elimination in the order I > Br > Cl. When OTs is the leaving group, there is usually much more substitution. For example, n-$C_{18}H_{37}Br$ treated with t-BuOK gave 85% elimination, while n-$C_{18}H_{37}OTs$ gave, under the same conditions, 99% substitution.[102] On the other hand, positively charged leaving groups increase the amount of elimination.

[102] Veeravagu, Arnold, and Eigenmann, *J. Am. Chem. Soc.* **86,** 3072 (1964).

Effect of the Medium

1. *Effect of solvent on E1 versus E2 versus E1cB.* With any reaction a more polar environment enhances the rate of mechanisms which involve ionic intermediates. For neutral leaving groups, it is expected that E1 and E1cB mechanisms will be aided by increasing polarity of solvent and by increasing ionic strength. With certain substrates, polar aprotic solvents promote elimination with weak bases (the E2C reaction).

2. *Effect of solvent on elimination versus substitution.* Increasing polarity of solvent favors SN2 reactions at the expense of E2. In the classical example, alcoholic KOH is used to effect elimination, while the more polar aqueous KOH is used for substitution. Charge-dispersal discussions, similar to those on p. 332,[103] only partially explain this. In most solvents SN1 reactions are favored over E1. E1 reactions compete best in polar solvents which are poor nucleophiles.

3. *Effect of temperature.* Elimination is favored over substitution by increasing temperature, whether the mechanism is first order or second order.[104]

MECHANISMS AND ORIENTATION IN PYROLYTIC ELIMINATIONS

Mechanisms[105]

A number of types of compound undergo elimination on heating, with no other reagent present. Reactions of this type are often run in the gas phase. The mechanisms are obviously different from those already discussed, since all those require a base (which may be the solvent) in one of the steps, and there is no base or solvent present in pyrolytic elimination. Two mechanisms have been found to operate. One of these involves a cyclic transition state, which may be either four-, five-, or six-membered. Examples of each size are:

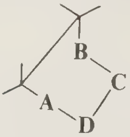
Chem.* **8,** 75–234 (1971), pp. 75–143, 207–234; in Bamford and Tipper, "Comprehensive Chemical Kinetics," vol. 5, American Elsevier Publishing Company, Inc., New York, 1972, the articles by Swinbourne, pp. 149–233 (pp. 158–188) and by Richardson and O'Neal, pp. 381–565 (pp. 381–446); Maccoll, Ref. 2, *Adv. Phys. Org. Chem.* **3,** 91–122 (1965); DePuy and King, *Chem. Rev.* **60,** 431–445 (1960). For reviews of mechanisms in pyrolytic eliminations of halides, see Egger and Cocks, in Patai, "The Chemistry of the Carbon-Halogen Bond," pt. 2, pp. 677–745, John Wiley & Sons, Inc., New York, 1973; Maccoll, *Chem. Rev.* **69,** 33–60 (1969).

In this mechanism, which is called the *Ei mechanism*, the two groups leave at about the same time and bond to each other as they are doing so. The elimination must be syn and, for the four- and five-membered transition states, the four or five atoms making up the ring must be coplanar. Coplanarity is not required for the six-membered transition state, since there is room for the outside atoms when the leaving atoms are staggered:



As in the case of the E2 mechanism, it is not necessary that the C—H and C—X bond be equally broken in the transition state. In fact, there is also a spectrum of mechanisms here, ranging from a mechanism in which C—X bond breaking is a good deal more advanced than C—H bond breaking to one in which the extent of bond breaking is virtually identical for the two bonds. Evidence for the existence of the Ei mechanism is:

1. The kinetics are first order, so that only one molecule of the substrate is involved in the reaction (that is, if one molecule attacked another, the kinetics would be second order in substrate).[106]

2. Free-radical inhibitors do not slow the reactions, so that no free-radical mechanism is involved.[107]

3. The mechanism predicts exclusive syn elimination, and this behavior has been found in many cases.[108] The evidence is inverse to that for the anti E2 mechanism and generally involves the following facts: (1) an erythro isomer gives a trans olefin, and a threo gives a cis olefin; (2) the reaction takes place only when a cis β-hydrogen is available; and (3) if, in a cyclic compound, a cis hydrogen is available on only one side, the elimination goes in that direction. We give here two examples of experimental evidence, neither of which exactly fits categories (1), (2), or (3). Elimination from the erythro (**29**) and threo (**30**) isomers of 1-acetoxy-2-deutero-1,2-diphenylethane gave in each case *trans*-stilbene, but the product from the erythro isomer retained 95% of the

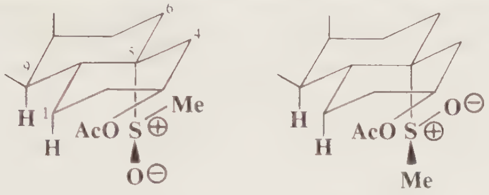
[106] O'Connor and Nace, *J. Am. Chem. Soc.* **75**, 2118 (1953).

[107] Barton, Head, and Williams, *J. Chem. Soc.* 1715 (1953).

[108] In a few instances anti or nonstereoselective elimination has been found; this behavior is generally ascribed to the intervention of other mechanisms. For example, see Bordwell and Landis, *J. Am. Chem. Soc.* **80**, 2450, 6383 (1958); Briggs and Djerassi, *J. Org. Chem.* **33**, 1625 (1968); Smissman, Li, and Creese, *J. Org. Chem.* **35**, 1352 (1970).

original deuterium, while the olefin obtained from the threo isomer retained only 26% of the deuterium.[109] In this case either the hydrogen or the deuterium could be cis to the acetoxy in either isomer, but the most favored conformations (shown) have the phenyls on opposite sides, and in these conformations **29** has a hydrogen nearest the acetoxy and **30** a deuterium. This is an eclipsing effect. The reason that 95% is not balanced by 5% (instead of 26%) is that there is an isotope effect. The other example involves a pair of steroid molecules. In 3β-acetoxy-(R)-5α-methylsulfinylcholestane (**31** shows rings A and B of this compound) and in 3β-acetoxy-(S)-5α-methylsulfinylcholestane (**32**: rings A and B), the *only* difference is the configuration of oxygen and methyl about the sulfur. Yet pyrolysis of **31** gave only elimination to the 4-side (86% 4-ene), while **32** gave predominant elimination to the 6-side (65% 5-ene and 20% 4-ene).[110] Models show that interference from the 1- and 9-hydrogens causes the two groups on the sulfur to lie *in front of it* with respect to the rings, rather than behind it. Since the sulfur is asymmetric, this means that in **31** the oxygen is near the 4-hydrogen, while in **32** it is near the 6 hydrogen. Both experiments are compatible only with syn elimination.



31 **32** **(7-13)**

4. Some of these reactions have been shown to exhibit negative entropies of activation, indicating that the molecules are more restricted in geometry in the transition state than they are in the starting compound.[106]

Where a pyrolytic elimination lies on the mechanistic spectrum seems to depend mostly on the leaving group. When this is halogen, all available evidence suggests that in the transition state the C—X bond is cleaved to a much greater extent than the C—H bond; that is, there is a considerable amount of carbonium-ion character in the transition state. This is in accord with the fact that a completely nonpolar four-membered cyclic transition state violates the Woodward-Hoffmann rules (see the similar case of reaction **5-52**). Evidence for the carbonium-ion-like character of the transition state when halide is the leaving group is that relative rates are in the order I > Br > Cl[111] (see p. 325), and that the effects of substituents on reaction rates are in accord with such a transition state.[112] Rate ratios for pyrolysis of some alkyl bromides at 320°C were: ethyl bromide, 1; isopropyl bromide, 280; t-butyl bromide, 78,000. Also, α-phenylethyl bromide had about the same rate as t-butyl bromide. On the other hand, β-phenylethyl bromide was only slightly faster than ethyl bromide. This indicates that C—Br cleavage was much more important in the transition state than C—H cleavage, since the incipient carbonium ion was stabilized by α-alkyl and α-aryl substitution, while there was no incipient carbanion to be stabilized by β-aryl substitution. These substituent effects, as well as those for β-methyl, α- and β-halo, α-methoxy, and other groups, are very similar to the effects found for the SN1 mechanism and thus in very good accord with a carbonium-ion-like transition state. For chlorides the rate ratios were less,[113] and for esters much less,[114] though still in the same order, so that these reactions are closer to a pure Ei mechanism, though the transition states still have some carbonium-ion character. Other evidence for a greater initial C—O cleavage with esters is that a series of 1-arylethyl acetates followed σ^+ rather than σ, showing carbonium-ion character at the 1 position.[115] Cleavage of xanthates (reaction **7-4**), cleavage of sulfoxides (**7-12**), the Cope reaction (**7-8**), and reaction **7-7** are probably very close to straight Ei mechanisms.

[111] Maccoll, Ref. 2, pp. 215–216.

[112] For reviews of such studies, see Maccoll, Ref. 2, Ref. 105; Maccoll, in "Theoretical Organic Chemistry, The Kekulé Symposium," pp. 230–249. Butterworth Scientific Publications, London, 1959, also see Green, Maccoll, and Thomas, *J. Chem. Soc.* 184 (1960).

There has been speculation that in certain extreme cases, cleavage of the C—X bonds runs so much ahead of cleavage of the C—H bond that it could be said that a carbonium ion is involved. This type of mechanism is very like the E1 mechanism, except that in the gas phase, where nothing is available to solvate the negative ion, it would have to remain near the carbonium ion, so that the carbonium ion and the leaving group would form an ion pair. Evidence for this view is that rearrangements are sometimes found with esters[116] and with alkyl halides. For example, pyrolysis of neopentyl chloride gave 75% HCl (despite the fact that no direct elimination is possible) and a mixture of methylbutenes (which must arise from rearrangement).[117] Rearrangements have also been found on pyrolysis of bornyl and isobornyl chlorides.[118] However, the finding of such rearrangements is not conclusive evidence for the ion-pair mechanism because the rearrangements could also be caused by catalysis by the walls of the container, and there is evidence that this is indeed so.[119] Furthermore, there is evidence that actual ion pairs cannot be involved in most pyrolytic eliminations, even those with halide leaving groups. If ion pairs were involved, then, if the reaction of an optically active starting compound were stopped before it was completed, recovered starting material would show partial racemization, as is the case in the SN1 mechanism (p. 275). However, when this experiment was performed with (+)-2-chlorooctane, recovered starting material showed no racemization.[120] Additional evidence that ion pairs are not involved in ester eliminations is that when $CH_3CO^{18}OEt$ was partially pyrolyzed, recovered starting material showed only minor ^{18}O scrambling,[121] though if an ion pair were involved the two oxygens of the CH_3COO^- ion would become equivalent.[122]

The second type of pyrolysis mechanism is completely different from the Ei mechanism and involves free radicals. Initiation occurs by pyrolytic homolytic cleavage. The remaining steps may vary, and a few are shown:

$$\begin{array}{llcl}
\text{Initiation} & R_2CHCH_2X & \longrightarrow & R_2CHCH_2\cdot + X\cdot \\
\text{Propagation} & R_2CHCH_2X + X\cdot & \longrightarrow & R_2\underset{\bullet}{C}CH_2X + HX \\
 & R_2\underset{\bullet}{C}CH_2X & \longrightarrow & R_2C{=}CH_2 + X\cdot
\end{array}$$

Termination (disproportionation)

$$2R_2\underset{\bullet}{C}CH_2X \longrightarrow R_2C{=}CH_2 + R_2CXCH_2X$$

Free-radical mechanisms are mostly found in pyrolyses of polyhalides and of primary monohalides,[123] though they have been postulated in pyrolysis of certain esters too.[124] Much less is known about these mechanisms, and we shall not consider them further. Free-radical eliminations in solution are also known but are rare.[125]

Orientation in Pyrolytic Eliminations

As in the E1-E2-E1cB mechanistic spectrum, Bredt's rule applies; and if a double bond is present, a conjugated system will be preferred, if sterically possible (p. 909). Apart from these considerations, the following statements can be made for Ei eliminations:

1. In the absence of considerations mentioned below, orientation is statistical and is determined by the number of β-hydrogens available (therefore *Hofmann's rule* is followed). For example, *sec*-butyl acetate gives 55 to 62% 1-butene and 38 to 45% 2-butene,[126] which is close to the 3 : 2 distribution predicted by the number of hydrogens available.[127]

2. A cis β-hydrogen is required. Therefore in cyclic systems, if there is a cis hydrogen on only one side, the double bond will go that way. However, when there is a six-membered transition state, this does not necessarily mean that the leaving groups must be cis to each other, since such transition states need not be completely coplanar. If the leaving group is axial, then the hydrogen obviously must be equatorial (and consequently cis to the leaving group), since the transition state cannot be realized when the groups are both axial. But if the leaving group is equatorial, then it can form a transition state with a β-hydrogen which is either axial (hence cis) or equatorial (hence trans). Thus **33**, in which the leaving group is most likely axial, does not form a double bond in the direction of the carbethoxyl group, even though that would be conjugated, because there is no equatorial hydrogen on that side. Instead it gives 100% **34**.[128]

[124] For example, see Rummens, *Recl. Trav. Chim. Pays-Bas* **83**, 901 (1964); Louw and Kooyman, *Recl. Trav. Chim. Pays-Bas* **84**, 1511 (1965).

[125] For an example, see Kampmeier, Geer, Meskin, and D'Silva, *J. Am. Chem. Soc.* **88**, 1257 (1966); Kochi, Singleton, and Andrews, *Tetrahedron* **24**, 3503 (1968); Hepinstall and Kampmeier, *J. Am. Chem. Soc.* **95**, 1904 (1973).

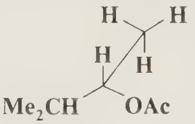
[126] Froemsdorf, Collins, Hammond, and DePuy, *J. Am. Chem. Soc.* **81**, 643 (1959); Haag and Pines, *J. Org. Chem.* **24**, 877 (1959).

[127] DePuy and King, Ref. 105, have tables showing the product distribution for many cases.

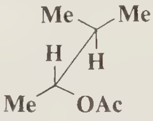
[128] Bailey and Baylouny, *J. Am. Chem. Soc.* **81**, 2126 (1959).

On the other hand, **35**, with an equatorial leaving group, gives about 50% of each olefin, even though, for elimination to the 1-ene, the leaving group must go off with a trans hydrogen.[129]

3. In open-chain systems, if there is a β-hydrogen, there is always a conformation in which it can be cis to the leaving group. However, there may be an eclipsing effect. For example, $Me_2CHCHMeOAc$ gave 80% $Me_2CHCH{=}CH_2$ and 20% $Me_2C{=}CHMe$.[126] Of the two transition states, the one which leads to the larger amount of olefin (**36**) is less eclipsed than the other (**37**). Of course this is a small effect, since a statistical distribution would give a 75 : 25 ratio, but it is probably real, since it is in the direction away from olefin stability (Zaitsev's rule) and the products from other acetates are in the same direction.



36



37

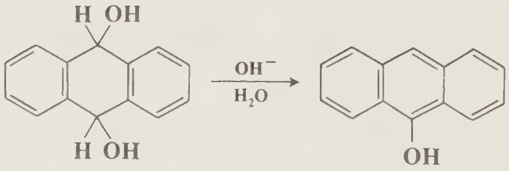
4. In some cases, especially with cyclic compounds, the more stable olefin forms and Zaitsev's rule applies. For example, menthyl acetate gives 35% of the Hofmann product and 65% of the Zaitsev, even though a cis β-hydrogen is present on both sides and the statistical distribution is the other way. A similar result was found for the pyrolysis of menthyl chloride.[130]

1,4 Conjugate Eliminations

1,4 eliminations of the type

$$\mathrm{H{-}C{-}C{=}C{-}C{-}X} \longrightarrow \mathrm{C{=}C{-}C{=}C}$$

are much rarer than conjugate additions (Chapter 15), but some examples are known. One such is[131]



REACTIONS

First we shall consider reactions in which a C=C or a C≡C bond is formed. From a synthetic point of view, the most important reactions for the formation of double bonds are **7-1** (usually by an E1 mechanism), **7-6**, **7-13**, and **7-27** (usually by an E2 mechanism), and **7-3**, **7-4**, and **7-8** (usually by an Ei mechanism). The only synthetically important method for the formation of triple bonds is **7-13**. In the second section we treat reactions in which C≡N bonds and C=N bonds are formed, and then eliminations to give C=O bonds and diazoalkanes. Finally, we discuss extrusion reactions.

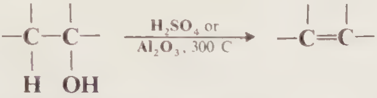
[131] Cristol, Barasch, and Tieman, *J. Am. Chem. Soc.* **77**, 583 (1955); Cristol, *Acc. Chem. Res.* **4**, 393–400 (1971).

Reactions in Which C=C and C≡C Bonds Are Formed

A. Reactions in Which Hydrogen Is Removed from One Side. In reactions **7-1** to **7-5** the other leaving atom is oxygen. In reactions **7-6** to **7-10** it is nitrogen. For reactions in which hydrogen is removed from both sides, see reactions **9-1** to **9-7.**

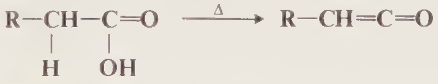
7-1 Dehydration of Alcohols



$$\underset{\mathrm{H}}{\overset{|}{\underset{|}{-\mathrm{C}}}}-\underset{\mathrm{OH}}{\overset{|}{\underset{|}{\mathrm{C}-}}} \xrightarrow[\mathrm{Al_2O_3},\ 300\ \mathrm{C}]{\mathrm{H_2SO_4}\ \text{or}} \overset{|}{-\mathrm{C}}=\overset{|}{\mathrm{C}-}$$

Dehydration of alcohols can be accomplished in several ways. H_2SO_4 and H_3PO_4 are common reagents, but in many cases these lead to rearrangement products and to ether formation (reaction **0-18**). If the alcohol can be evaporated, then vapor-phase elimination over Al_2O_3 is an excellent method since side reactions are greatly reduced. This method has even been applied to such high-molecular-weight alcohols as 1-dodecanol.[132] Other metallic oxides (e.g., Cr_2O_3, TiO_2, WO_3) have also been used, as have been sulfides, other metallic salts, and zeolites. Another method of avoiding side reactions is the conversion of alcohols to esters, and the pyrolysis of these (reactions **7-3** to **7-5**). The ease of dehydration increases with α branching, and tertiary alcohols are dehydrated so easily with even a trace of acid that it sometimes happens even when the investigator desires otherwise. It may also be recalled that the initial alcohol products of many base-catalyzed condensations dehydrate spontaneously (Chapter 16) because the new double bond can be in conjugation with one already there. Many other dehydrating agents have been used on occasion: P_2O_5, I_2, $ZnCl_2$, BF_3-etherate, dimethyl sulfoxide, $POCl_3$–pyridine, $KHSO_4$, KOH, the sulfurane $Ph_2S[OCPh(CF_3)_2]_2$,[133] and phthalic anhydride, among others. Secondary and tertiary alcohols can also be dehydrated, without rearrangements, simply on refluxing in HMPT.[134] With nearly all reagents, dehydration follows Zaitsev's rule. An exception involves the passage of hot alcohol vapors over thorium oxide at 350 to 450 C, under which conditions Hofmann's rule is followed,[135] and the mechanism is probably different.

Carboxylic acids can be dehydrated by pyrolysis, the product being a ketene:

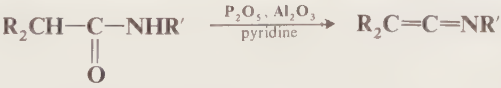


$$\mathrm{R}-\underset{\mathrm{H}}{\underset{|}{\mathrm{CH}}}-\underset{\mathrm{OH}}{\underset{|}{\mathrm{C}}}=\mathrm{O} \xrightarrow{\Delta} \mathrm{R-CH=C=O}$$

Ketene itself is commercially prepared in this manner. In a similar reaction, carbon suboxide is produced by heating malonic acid with P_2O_5:

$$\mathrm{HOOC-CH_2-COOH} \longrightarrow \mathrm{O=C=C=C=O}$$

Analogously, amides can be dehydrated with P_2O_5, pyridine, and Al_2O_3 to give ketenimines:[136]



$$\mathrm{R_2CH}-\underset{\mathrm{O}}{\underset{\|}{\mathrm{C}}}-\mathrm{NHR'} \xrightarrow[\text{pyridine}]{\mathrm{P_2O_5},\ \mathrm{Al_2O_3}} \mathrm{R_2C=C=NR'}$$

---

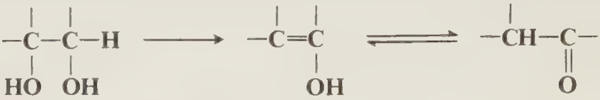
[134] Monson, *Tetrahedron Lett.* 567 (1971); Monson and Priest, *J. Org. Chem.* **36**, 3826 (1971); Lomas, Sagatys, and Dubois, *Tetrahedron Lett.* 165 (1972).

[135] Lundeen and Van Hoozer, *J. Am. Chem. Soc.* **85**, 2180 (1963), *J. Org. Chem.* **32**, 3386 (1967).

[136] Stevens and Singhal, *J. Org. Chem.* **29**, 34 (1964).

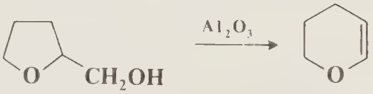
There is no way in which dehydration of alcohols can be used to prepare triple bonds: *gem*-diols and vinyl alcohols do not exist, and *vic*-diols give either conjugated dienes or lose only 1 mole of water to give an aldehyde or ketone:



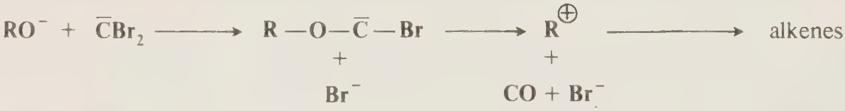
When proton acids catalyze alcohol dehydration, the mechanism is E1.[137] The principal process involves conversion of ROH to ROH_2^+ and cleavage of the latter to R^+ and H_2O (this process is not generally called E1cA, though it might be so called, by analogy to SN1cA, p. 325), though with some acids a secondary process probably involves conversion of the alcohol to an inorganic ester and ionization of *this* (illustrated for H_2SO_4):

$$\mathbf{ROH} \xrightarrow{H_2SO_4} \mathbf{ROSO_2OH} \longrightarrow \mathbf{R^+ + HSO_4^-}$$

Note that these mechanisms are the reverse of those involved in the acid-catalyzed hydration of double bonds (**5-2**), in accord with the principle of microscopic reversibility. With anhydrides, such as P_2O_5 or phthalic anhydride, as well as with some other reagents such as HMPT,[138] it is likely that an ester is formed, and the leaving group is the conjugate base of the corresponding acid. In these cases the mechanism may be E1 or E2. The mechanism with Al_2O_3 and other solid catalysts has been studied extensively but is poorly understood.[139] It has been shown that not only is ethylene produced directly from ethanol (over Al_2O_3) but that some ethylene arises from diethyl ether formed as an intermediate.[140] In some cases, rearrangements occur even with Al_2O_3, for example,[141]



Dehydration of alcohols has also been accomplished by treating the *alkoxide* form of the alcohol with bromoform.[142] This reaction is called *deoxidation*. It is known that bromoform in basic solution gives rise to dibromocarbene, and the following mechanism is likely:



$$\mathbf{RO^- + \overline{C}Br_2} \longrightarrow \begin{array}{c}\mathbf{R{-}O{-}\overline{C}{-}Br}\\ +\\ \mathbf{Br^-}\end{array} \longrightarrow \begin{array}{c}\mathbf{R^{\oplus}}\\ +\\ \mathbf{CO + Br^-}\end{array} \longrightarrow \text{alkenes}$$

Note that the cleavage of the intermediate ROCBr is analogous to cleavage of RN_2^+ (p. 327), and the product distribution is similar.[143] Benzyl alkoxides (RR′CH—CArR″O⁻) undergo elimination when treated with $AlCl_3$.[144] Hofmann orientation is observed in this reaction.

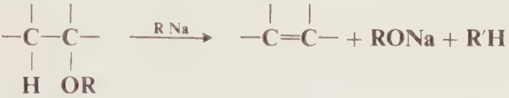
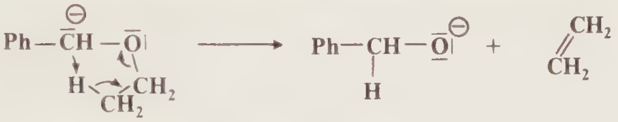
7-2 Cleavage of Ethers to Olefins



$$\underset{\mathrm{H}\quad\mathrm{OR}}{-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-} \xrightarrow{\mathrm{R\,Na}} -\overset{|}{C}=\overset{|}{C}- + \mathrm{RONa} + \mathrm{R'H}$$

Olefins may be formed by the treatment of ethers with very strong bases, such as alkylsodium or alkyllithium compounds or sodium amide,[145] though there are usually side reactions too. The reaction is aided by electron-withdrawing groups in the β-position, and, for example, $EtOCH_2$-$CH(COOEt)_2$ can be converted to $CH_2{=}C(COOEt)_2$ without any base at all, but simply on heating.[146] *t*-Butyl ethers are cleaved more easily than others. Several mechanisms are possible for the elimination. In many cases the mechanism is probably E1cB, or on the E1cB side of the mechanistic spectrum, since the base required is so strong, but it has been shown (by the use of $PhCD_2OEt$) that $PhCH_2OEt$ reacts by the five-membered Ei mechanism:[147]

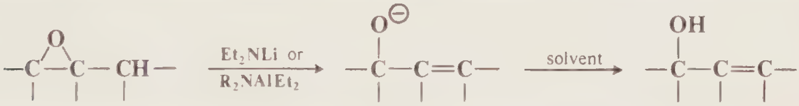


Still another possible mechanism involves carbene formation:

$$R_2CHOR' \xrightarrow{\text{base}} R_2\overset{\ominus}{\bar{C}}OR' \longrightarrow R_2\bar{C} + OR^-$$

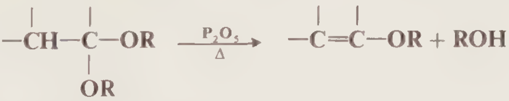
The carbene may then rearrange to an olefin (p. 183) or undergo any of the other carbene reactions. Most of the side reactions in base treatment of ethers arise from this pathway.

Epoxides can be converted to allylic alcohols by treatment with lithium diethylamide[148] or a



diethylaluminum dialkylamide,[149] though side reactions are possible. An alternative procedure is given in reaction **7-12.**

Ethers have also been converted to olefins and alcohols by passing vapors over hot P_2O_5 or Al_2O_3 (this method is similar to reaction **7-1**), but this is not a general reaction. However, acetals can be converted to vinyl ethers in this manner:



$$-\overset{|}{C}H-\overset{|}{\underset{\underset{\mathrm{OR}}{|}}{C}}-OR \xrightarrow[\Delta]{P_2O_5} -\overset{|}{C}=\overset{|}{C}-OR + ROH$$

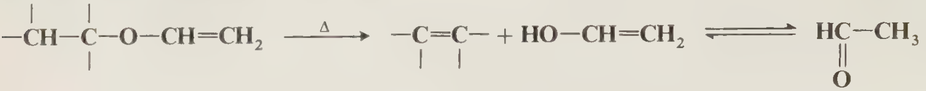
Vinyl ethers can be pyrolyzed to olefins and aldehydes in a manner similar to that of reaction **7-3**:

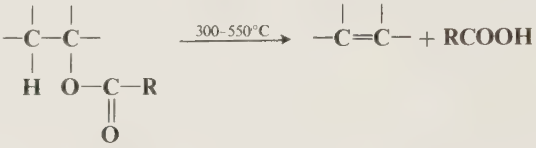


$$-\overset{|}{\mathrm{C}}\mathrm{H}-\overset{|}{\underset{|}{\mathrm{C}}}-\mathrm{O}-\mathrm{CH}{=}\mathrm{CH_2} \xrightarrow{\Delta} -\underset{|}{\mathrm{C}}{=}\underset{|}{\mathrm{C}}- + \mathrm{HO}-\mathrm{CH}{=}\mathrm{CH_2} \rightleftharpoons \underset{\mathrm{O}}{\underset{\|}{\mathrm{HC}}}-\mathrm{CH_3}$$

The mechanism is probably similar to that of reaction **7-3**.

OS **IV**, 298, 404; **V**, 25, 642, 859, 1145; **53**, 17, 116; **54**, 19, 74, 77.

7-3 Pyrolysis of Esters of Carboxylic Acids



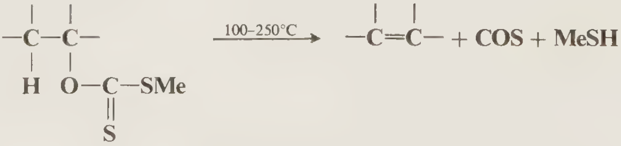
$$\begin{array}{l} -\overset{|}{\underset{|}{\mathrm{C}}}-\overset{|}{\underset{|}{\mathrm{C}}}- \\ \ \mathrm{H}\quad \mathrm{O}-\underset{\underset{\mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{R} \end{array} \xrightarrow{300\text{–}550^\circ\mathrm{C}} -\overset{|}{\mathrm{C}}{=}\overset{|}{\mathrm{C}}- + \mathrm{RCOOH}$$

Esters in which the alkyl group has a β-hydrogen can be pyrolyzed, most often in the gas phase, to give the corresponding acid and an olefin.[150] No solvent is required. Since rearrangement and other side reactions are few, the reaction is synthetically very useful and is often carried out as an indirect method of accomplishing reaction **7-1**. The yields are excellent, and the workup is easy. Many olefins have been prepared in this manner. For higher olefins (above about C_{10}) a better method is to pyrolyze the *alcohol* in the presence of acetic anhydride.[151]

The mechanism is Ei (see p. 917). Lactones can be pyrolyzed to give unsaturated acids, provided that the six-membered transition state required for Ei reactions is available (it is not available for five- and six-membered lactones, but it is for larger rings). Amides give a similar reaction but require higher temperatures.

OS **III**, 30; **IV**, 746; **V**, 235.

7-4 The Chugaev Reaction



$$\begin{array}{l} -\overset{|}{\underset{|}{\mathrm{C}}}-\overset{|}{\underset{|}{\mathrm{C}}}- \\ \ \mathrm{H}\quad \mathrm{O}-\underset{\underset{\mathrm{S}}{\|}}{\mathrm{C}}-\mathrm{SMe} \end{array} \xrightarrow{100\text{–}250^\circ\mathrm{C}} -\overset{|}{\mathrm{C}}{=}\overset{|}{\mathrm{C}}- + \mathrm{COS} + \mathrm{MeSH}$$

Methyl xanthates are prepared by treatment of alcohols with NaOH and CS_2 to give RO—CS—SNa, followed by treatment of this with methyl iodide. Pyrolysis of the xanthate to give the olefin, COS, and the mercaptan is called the *Chugaev reaction*.[152] The reaction is thus, like reaction **7-3**, an indirect method of accomplishing reaction **7-1**. Elimination is easier with xanthates than with ordinary esters, and the temperatures required are lower, which is advantageous because possible isomerization of the resulting olefin is minimized. The Chugaev reaction is used even more often than reaction **7-3**. The mechanism is Ei, similar to that of reaction **7-3**. For a time there was doubt as to which sulfur atom closed the ring, but now there is much evidence, including the study of ^{34}S and ^{13}C isotope effects, to show that it is the C=S sulfur:[153]

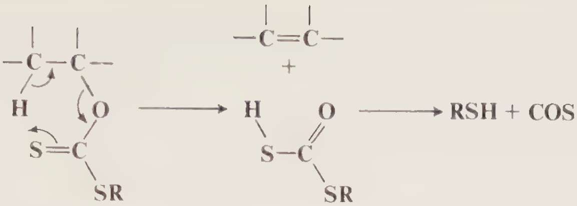
---

[150] For a review, see DePuy and King, Ref. 105, pp. 432–444.

[151] Aubrey, Barnatt, and Gerrard, *Chem. Ind.* (*London*) 681 (1965).

[152] For reviews, see DePuy and King, Ref. 105, pp. 444–448; Nace, *Org. React.* **12**, 57–100 (1962).

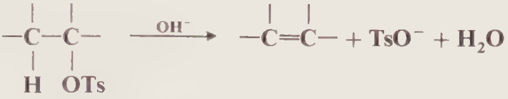
[153] Bader and Bourns, *Can. J. Chem.* **39**, 348 (1961).



The mechanism is thus exactly analogous to that of reaction **7-3**.

Similar reactions involve pyrolysis of O-alkyl dimethylthiocarbamates ROC(=S)NMe$_2$ to give olefins, COS, and Me$_2$NH,[154] and of O-alkyl imidates ROC(=NR′)R″ to give olefins and amides R″CONHR′.[155]

7-5 Decomposition of Other Esters

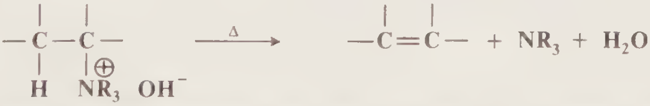


$$-\underset{\mathrm{H}}{\overset{|}{\underset{|}{C}}}-\underset{\mathrm{OTs}}{\overset{|}{\underset{|}{C}}}- \xrightarrow{\mathrm{OH^-}} -\overset{|}{C}=\overset{|}{C}- + \mathrm{TsO^-} + \mathrm{H_2O}$$

Several types of inorganic esters can be cleaved to olefins by treatment with bases. Esters of sulfuric, sulfurous, and other acids undergo elimination in solution by E1 or E2 mechanisms, as do tosylates and other esters of sulfonic acids. It has been shown that bis(tetra-*n*-butylammonium) oxalate $(\mathrm{Bu_4N^+})_2$ $(\mathrm{COO^-})_2$ is an excellent reagent for inducing tosylates to undergo elimination rather than substitution[156] (see p. 916). High yields of olefins are obtained by heating arylsulfonates in such solvents as dimethyl sulfoxide or HMPT.[157] Borates can be pyrolyzed similarly as in reaction **7-3**. Triethylammonium N-carbalkoxysulfamates derived from secondary or tertiary alcohols (prepared by $\mathrm{ROH} + \mathrm{MeOOC}\overset{-\ominus}{\mathrm{N}}\mathrm{SO_2}\overset{\oplus}{\mathrm{N}}\mathrm{Et_3} \rightarrow \mathrm{ROSO_2}\overset{-\ominus}{\mathrm{N}}\mathrm{COOMe}\quad \mathrm{HNEt_3}^+$) undergo syn elimination under mild conditions (30 to 70°C) to give good yields of alkenes.[158] Sodium N-carbalkoxysulfamates, prepared by treatment of the triethylammonium salts with NaH, can also be used.

OS **50**, 84.

7-6 Cleavage of Quaternary Ammonium Hydroxides



$$-\underset{\mathrm{H}}{\overset{|}{\underset{|}{C}}}-\underset{\mathrm{NR_3}\ \mathrm{OH^-}}{\overset{|}{\underset{|\oplus}{C}}}- \xrightarrow{\Delta} -\overset{|}{C}=\overset{|}{C}- + \mathrm{NR_3} + \mathrm{H_2O}$$

Cleavage of quaternary ammonium hydroxides is the final step of the process known as *Hofmann exhaustive methylation*, or *Hofmann degradation*.[159] In the first step a primary, secondary, or tertiary amine is treated with enough methyl iodide to convert it to the quaternary ammonium iodide (reaction **0-46**). In the second step the iodide is converted to the hydroxide by treatment with

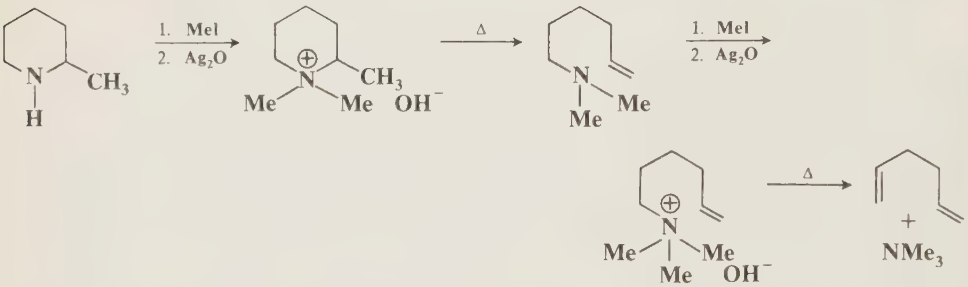
silver oxide. In the cleavage step an aqueous or alcoholic solution of the hydroxide is distilled, often under reduced pressure. The decomposition generally takes place at a temperature between 100 and 200°C. Alternatively, the solution can be concentrated to a syrup by distillation or freeze-drying.[160] When the syrup is heated at low pressures, the cleavage reaction takes place at lower temperatures than are required for the reaction in the ordinary solution, probably because the base (OH^- or RO^-) is less solvated.[161] The reaction has not been used a great deal as a synthetic tool for synthesizing olefins, though some cyclic olefins are best prepared in this way. The principal importance of the method, especially in earlier years, has been for structural determination of unknown amines. The reaction has been extremely useful, especially in the alkaloid field. In many of these compounds the nitrogen is in a ring, or even at a ring junction, and in such cases the olefin still contains nitrogen and repetitions of the process are required to remove the nitrogen completely, for example,



A side reaction involving nucleophilic substitution to give an alcohol ($R_4N^+ \ OH^- \rightarrow ROH + R_3N$) generally accompanies the normal elimination reaction[162] but seldom causes trouble. However, when none of the four groups on the nitrogen has a β-hydrogen, then substitution is the only reaction possible. On heating $Me_4N^+ \ OH^-$ in water, methanol is obtained, though without a solvent the product is not methanol but dimethyl ether.[163] When a β-hydrogen *is* present, then substitution is enhanced at the expense of elimination if one of the R groups is aryl.[164] Substitution is also enhanced when the only β-hydrogens in the molecule are present in such positions that it is not possible (or not easily possible) for any of them to be in the anti-periplanar conformation with the nitrogen. For example, *trans*-4-*t*-butylcyclohexyltrimethylammonium hydroxide (**38**), in which the trimethylamino group is in the equatorial position (the axial position is of considerably higher energy, owing to the bulk of the two groups) and consequently cannot easily assume an anti-periplanar conformation with a β-hydrogen, gave 100% MeOH when subjected to heat, while the cis isomer, in which about 50% of the molecules exist

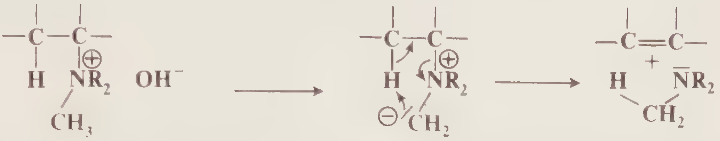
in the conformation shown in **39**, gave 92% elimination and 8% substitution.[165] However, as we have seen (p. 900), syn elimination is also possible, and in some cases even preferred.[166]

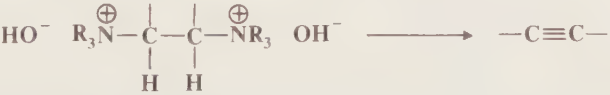
The mechanism is usually E2; Hofmann's rule is generally obeyed by acyclic, and Zaitsev's rule by cyclohexyl substrates (p. 910). In certain cases, where the molecule is highly hindered, a five-membered Ei mechanism, similar to that in reaction **7-7**, has been shown to operate. That is, the OH^- in these cases does not attract the β-hydrogen, but instead removes one of the methyl hydrogens:



The obvious way to distinguish between this mechanism and the ordinary E2 mechanism is by use of deuterium labeling. For example, if the reaction is carried out on a quaternary hydroxide deuterated on the β-carbon ($R_2CDCH_2NMe_3^+$ OH^-), then the fate of the deuterium indicates the mechanism. If the E2 mechanism is in operation, then the trimethylamine produced would contain no deuterium (which would be found only in the water). But if the mechanism is Ei, then the amine would contain deuterium. In the case of the highly hindered compound $(Me_3C)_2CDCH_2NMe_3^+$ OH^-, the deuterium did appear in the amine, demonstrating an Ei mechanism for this case.[167] However, with simpler compounds, the mechanism is E2, as shown by the fact that here the amine was deuterium-free.[168] This is also true in the case of the *cis*-norbornyl compound **7** ($X = NMe_3^+$) (p. 899), where a maximum of 6% of the elimination takes place by the Ei mechanism.[169] The mechanism here is chiefly syn E2.

When the nitrogen bears more than one group possessing a β-hydrogen, which group cleaves? The Hofmann rule says that *within* a group the hydrogen on the least alkylated carbon cleaves. This tendency is also carried over to the choice of which group cleaves: thus ethyl with three β-hydrogens cleaves more readily than any longer *n*-alkyl group, all of which have two β-hydrogens. "The β-hydrogen is removed most readily if it is located on a methyl group, next from RCH_2, and least readily from R_2CH."[170] In fact, the Hofmann rule as first stated[171] in 1851 applied only to which group cleaved, and not to the orientation within a group; the latter could not have been specified in 1851, since the structural theory of organic compounds was not formulated until 1857–1860. Of course, the Hofmann rule (applied to which group cleaves *or* to orientation within a group) is superseded by conjugation possibilities. Thus $PhCH_2CH_2NMe_2Et^+$ OH^- gives mostly styrene instead of ethylene.

Triple bonds have been prepared by pyrolysis of 1,2-bis salts:[172]



$$HO^- \; R_3\overset{\oplus}{N}-\underset{H}{\overset{|}{C}}-\underset{H}{\overset{|}{C}}-\overset{\oplus}{N}R_3 \; OH^- \longrightarrow -C{\equiv}C-$$

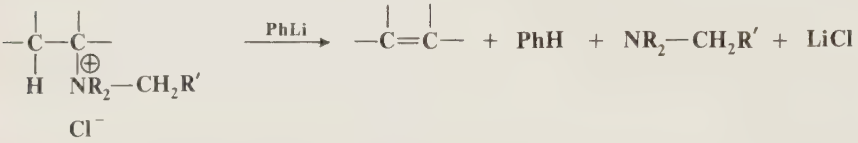
If a double bond is β,γ to the amino group, it is possible to obtain 1,4 elimination, especially if there is a group Z (such as phenyl) which stabilizes the new double bond:[173]

$$HO^- \quad R_3\overset{\oplus}{N}-CH_2-CH=CH-CH_2-Z \longrightarrow CH_2=CH-CH=CH-Z$$

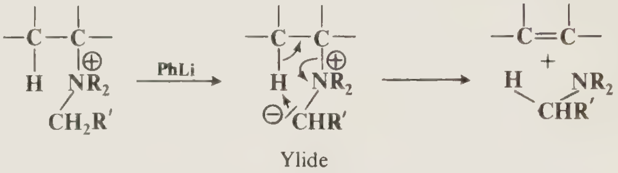
OS **IV,** 980; **V,** 315, 608; **55,** 3. Also see OS **V,** 621, 883; **53,** 13.

7-7 Cleavage of Quaternary Ammonium Salts with Strong Bases



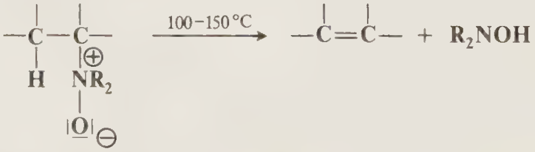
$$-\underset{H}{\overset{|}{\underset{|}{C}}}-\overset{|}{\underset{\overset{|\oplus}{NR_2-CH_2R'}}{C}}- \quad Cl^- \xrightarrow{PhLi} -\overset{|}{C}=\overset{|}{C}- + PhH + NR_2-CH_2R' + LiCl$$

When quaternary ammonium halides are treated with strong bases (e.g., PhLi, KNH_2 in liquid NH_3[174]), an elimination may occur which is similar in products, though not in mechanism, to reaction **7-6.**[175] This represents an alternative to reaction **7-6** and is done on the quaternary ammonium halide, so that it is not necessary to convert this to the hydroxide. The mechanism is Ei:



An α'-hydrogen is obviously necessary so that the ylide can be formed. This type of mechanism is called α',β elimination, since a β-hydrogen is removed by the α'-carbon. The mechanism has been confirmed by labeling experiments similar to those described at reaction **7-6,**[176] and by isolation of the intermediate ylides.[177] An important synthetic difference between this and most instances of reaction **7-6** is that syn elimination is observed here and anti elimination in reaction **7-6,** so that products of opposite configuration are formed when the olefin exhibits cis-trans isomerism.

7-8 Cleavage of Amine Oxides



$$-\underset{H}{\overset{|}{\underset{|}{C}}}-\overset{|}{\underset{\overset{|\oplus}{\underset{|\underline{O}|^{\ominus}}{NR_2}}}{C}}- \xrightarrow{100-150\,^\circ C} -\overset{|}{C}=\overset{|}{C}- + R_2NOH$$

Cleavage of amine oxides to produce an alkene and a hydroxylamine is called the *Cope reaction* (not to be confused with the Cope *rearrangement*, reaction **8-37**). It is an alternative to reactions

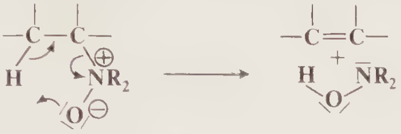
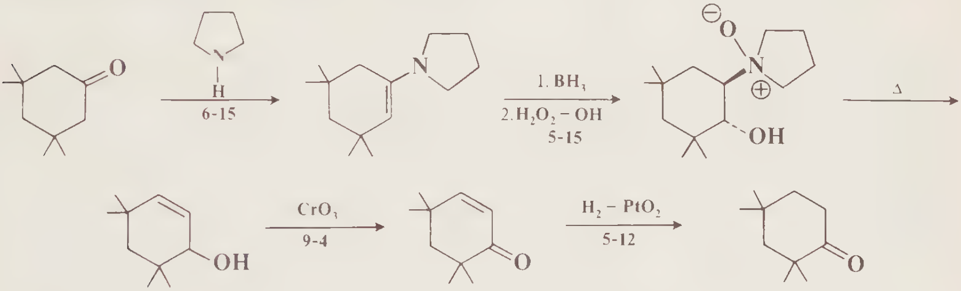
7-6 and **7-7**.[178] The reaction is usually performed with a mixture of amine and oxidizing agent (see reaction **9-29**) without isolation of the amine oxide. Because of the mild conditions side reactions are few, and the olefins do not usually rearrange. The reaction is thus very useful for the preparation of many olefins. However, it does not open 6-membered rings containing hetero nitrogen, though it does open rings of 5 and 7 to 10 members.[179] Rates of the reaction increase with increasing size of α- and β-substituents.[180] The reaction can be carried out at room temperature in dry dimethyl sulfoxide or tetrahydrofuran.[181] The elimination is a stereoselective syn process,[182] and the five-membered Ei mechanism operates:



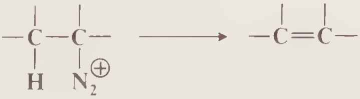
and all evidence indicates that the transition state must be planar. Deviations from planarity as in reaction **7-3** (see p. 918) are not found here, and indeed this is why six-membered heterocyclic nitrogen compounds do not react. Because of the stereoselectivity of this reaction and because of the lack of rearrangement of the products, it is useful for the formation of trans cycloolefins (eight-membered and higher).

The Cope reaction has been used as a key step in a method of achieving the indirect migration of a carbonyl group, that is, the conversion of $RCOCH_2R'$ to RCH_2COR'. The method uses the following sequence of reactions,[183] illustrated for 3,3,5,5-tetramethylcyclohexanone (see also reaction **2-12**).



OS **IV**, 612.

7-9 Olefins from Aliphatic Diazonium Salts



The treatment of aliphatic amines with nitrous acid is not a useful method for the preparation of olefins any more than it is for the preparation of alcohols (reaction **0-5**), though some olefin is usually formed in such reactions.

---

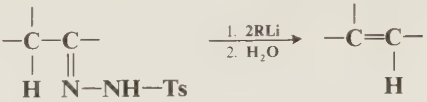
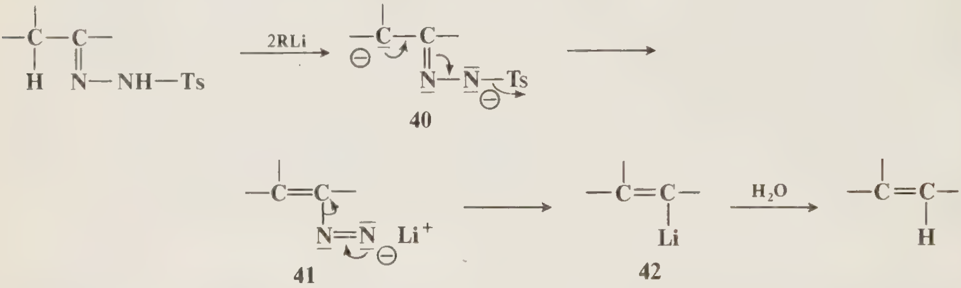
7-10 Decomposition of Toluene-*p*-sulfonylhydrazones



Treatment of the tosylhydrazone of an aldehyde or a ketone with a strong base leads to the formation of an olefin, the reaction being formally an elimination accompanied by a hydrogen shift.[183a] The reaction has been applied to tosylhydrazones of many aldehydes and ketones. Several mechanisms are possible,[184] depending on the base and the reaction conditions. The most useful method synthetically involves treatment of the substrate with at least two equivalents of an organolithium compound[185] (usually MeLi) in ether, hexane, or tetramethylenediamine.[186] This procedure gives good yields of alkenes without side reactions and, where a choice is possible, predominantly gives the less highly substituted olefin. Tosylhydrazones of α,β-unsaturated ketones give conjugated dienes.[187] The mechanism has been formulated as:



Evidence for this mechanism is: (1) two equivalents of RLi are required; (2) the hydrogen in the product comes from the water and not from the adjacent carbon, as shown by deuterium labeling;[188] and (3) the intermediates **40**, **41**, and **42** have been trapped.[189]

The reaction also takes place with other bases (e.g., NaOMe,[190] LiH,[191] Na in ethylene glycol, NaH, $NaNH_2$[192]) or with smaller amounts of RLi, but in these cases side reactions are common and the orientation of the double bond is in the other direction (to give the more highly substituted olefin). The reaction with Na in ethylene glycol is called the *Bamford-Stevens reaction.*[193] For these reactions two mechanisms are possible, a carbenoid and a carbonium-ion mechanism.[194] The side reactions found are those expected of carbenes and carbonium ions. In general, the carbonium-ion mechanism is chiefly found in protic solvents and the carbenoid mechanism in aprotic solvents. Both routes involve formation of a diazo compound (**43**) which

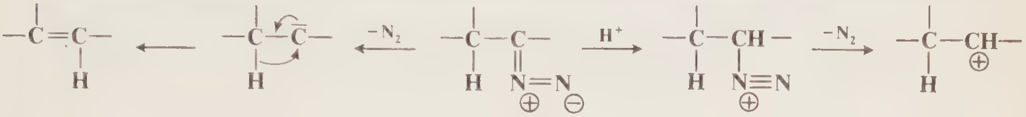
43

in some cases has been isolated.[195] In the absence of protic solvents **43** loses N_2, and hydrogen migrates, to give the olefin product. The migration of hydrogen may immediately follow, or be simultaneous with, the loss of N_2. In a protic solvent, **43** becomes protonated to give the diazonium



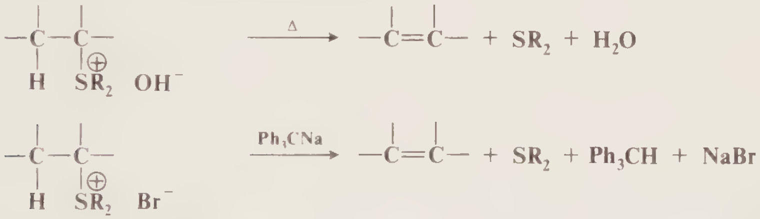
43 **44**

ion **44**, which loses N_2 to give the corresponding carbonium ion which may then undergo elimination (reaction **7-9**) or give other reactions characteristic of carbonium ions.

See also reaction **7-26**.

OS **51**, 66.

7-11 Cleavage of Sulfonium Compounds

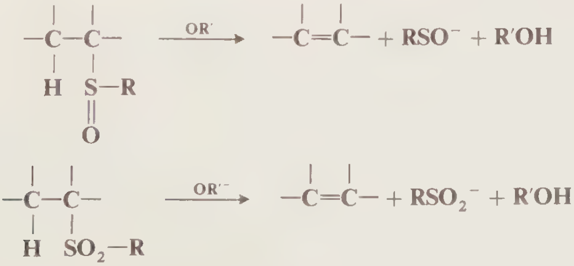


$$\underset{H}{\overset{|}{\underset{|}{-C}}}-\underset{SR_2}{\overset{|}{\underset{|\oplus}{C}}}-\;\; OH^- \xrightarrow{\Delta} -\overset{|}{C}=\overset{|}{C}- + SR_2 + H_2O$$

$$\underset{H}{\overset{|}{\underset{|}{-C}}}-\underset{SR_2}{\overset{|}{\underset{|\oplus}{C}}}-\;\; Br^- \xrightarrow{Ph_3CNa} -\overset{|}{C}=\overset{|}{C}- + SR_2 + Ph_3CH + NaBr$$

Sulfonium compounds undergo elimination similar to that of their ammonium counterparts (reactions **7-6** and **7-7**) in scope and in mechanism. The decomposition by heat of sulfonium hydroxides has been known for many years. The ylide reaction was discovered more recently.[196] Neither is important synthetically.

7-12 Cleavage of Sulfoxides, Selenoxides, and Sulfones



$$\underset{H}{\overset{|}{\underset{|}{-C}}}-\underset{\substack{S-R \\ \| \\ O}}{\overset{|}{\underset{|}{C}}}- \xrightarrow{OR'} -\overset{|}{C}=\overset{|}{C}- + RSO^- + R'OH$$

$$\underset{H}{\overset{|}{\underset{|}{-C}}}-\underset{SO_2-R}{\overset{|}{\underset{|}{C}}}- \xrightarrow{OR'^-} -\overset{|}{C}=\overset{|}{C}- + RSO_2^- + R'OH$$

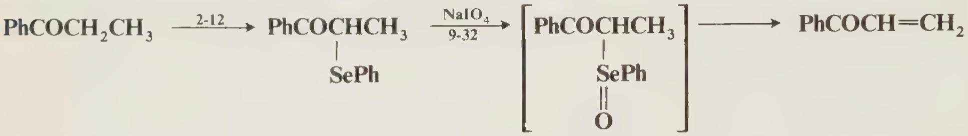
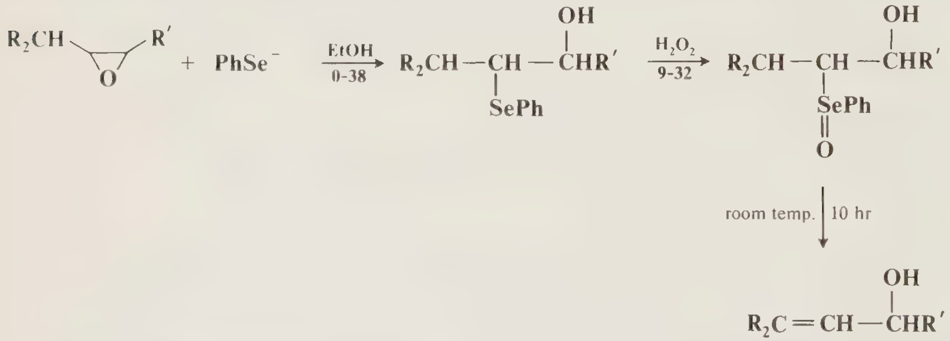
[196] Franzen and Mertz, *Chem. Ber.* **93**, 2819 (1960); Borchardt, Hargreaves, and Saunders, *Tetrahedron Lett.* 2307 (1972).

Sulfones and sulfoxides with a β-hydrogen undergo elimination on treatment with an alkoxide or, for sulfones, even with OH^-.[197] In mechanism, these reactions belong on the E1-E2-E1cB spectrum.[198] Although the leaving groups are uncharged, the orientation follows Hofmann's rule and not Zaitsev's. Sulfoxides (but not sulfones) also undergo elimination on pyrolysis at about 80°C in a manner analogous to reaction **7-8.** The mechanism is also analogous, being the five-membered Ei mechanism with syn elimination.[199] Selenoxides[200] and sulfinate esters $R_2CH{-}CHR{-}SO{-}OMe$[201] also undergo elimination by the Ei mechanism, the selenoxide reaction taking place at room temperature. Both the selenoxide[202] and sulfoxide[203] reactions have been used in a method for the conversion of ketones, aldehydes, and esters to their α,β-unsaturated derivatives (illustrated for the selenoxide). Because of the mildness of the procedure, this is probably the best means of accomplishing this conversion. The selenoxide reaction has been used in a procedure for the conversion of epoxides to allylic alcohols.[204]



$$\mathrm{PhCOCH_2CH_3} \xrightarrow{\text{2-12}} \underset{\mathrm{SePh}}{\underset{|}{\mathrm{PhCOCHCH_3}}} \xrightarrow[\text{9-32}]{\mathrm{NaIO_4}} \left[\underset{\underset{\mathrm{O}}{\Vert}}{\underset{\mathrm{SePh}}{\underset{|}{\mathrm{PhCOCHCH_3}}}}\right] \longrightarrow \mathrm{PhCOCH{=}CH_2}$$



See p. 429 for another application of the selenoxide reaction. Pyrolysis of β-hydroxy sulfoxides gives ketones,[204a] e.g.,

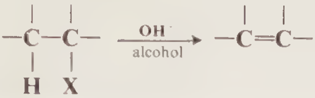
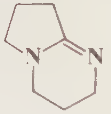
Sulfides and disulfides also undergo elimination when heated with KOH in the polar aprotic solvent HMPT.[205]

7-13 Dehydrohalogenation of Alkyl Halides

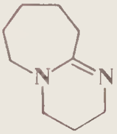


$$-\overset{|}{\underset{\substack{|\\ \mathrm{H}}}{\mathrm{C}}}-\overset{|}{\underset{\substack{|\\ \mathrm{X}}}{\mathrm{C}}}- \xrightarrow[\text{alcohol}]{\mathrm{OH}^-} -\overset{|}{\mathrm{C}}=\overset{|}{\mathrm{C}}-$$

The elimination of HX from an alkyl halide is a very general reaction and can be accomplished with chlorides, fluorides, bromides, and iodides. Hot alcoholic KOH is the most frequently used base, though stronger bases (OR^-, NH_2^-, etc.) or weaker ones (e.g., amines) are used where warranted. The bicyclic amidines 1,5-diazabicyclo[3.4.0]nonene-5 (DBN)[206] and 1,5-diazabicyclo-[5.4.0]undecene-5 (DBU)[207] are good reagents for difficult cases.[208] As previously mentioned (p. 908), certain weak bases in polar aprotic solvents are effective reagents for dehydrohalogenation. Among those most often used for synthetic purposes are LiCl or LiBr–$LiCO_3$ in dimethylformamide.[209] Dehydrohalogenation has also been effected by heating of the alkyl halide in HMPT with no other reagent present.[210]



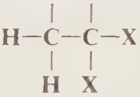
DBN



DBU

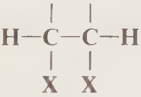
Tertiary halides undergo elimination most easily. Eliminations of chlorides, bromides, and iodides follow Zaitsev's rule except for a few cases where steric effects are important (for an example, see p. 912). Eliminations of fluorides follow Hofmann's rule (p. 912).

This reaction is by far the most important way of introducing a triple bond into a molecule.[211] This may be accomplished with substrates of the types **45** to **47**. The most commonly used base for triple-bond formation is $NaNH_2$. This base causes 1-alkynes to predominate (where possible), because it forms the salt of the alkyne, shifting any equilibrium between 1- and 2-alkynes. When the base is OH^- or OR^-, the equilibrium tends to be shifted to the internal alkyne, which is



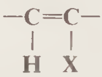
$$\mathrm{H}-\overset{|}{\underset{\substack{|\\ \mathrm{H}}}{\mathrm{C}}}-\overset{|}{\underset{\substack{|\\ \mathrm{X}}}{\mathrm{C}}}-\mathrm{X}$$

45



$$\mathrm{H}-\overset{|}{\underset{\substack{|\\ \mathrm{X}}}{\mathrm{C}}}-\overset{|}{\underset{\substack{|\\ \mathrm{X}}}{\mathrm{C}}}-\mathrm{H}$$

46



$$-\underset{\substack{|\\ \mathrm{H}}}{\mathrm{C}}=\underset{\substack{|\\ \mathrm{X}}}{\mathrm{C}}-$$

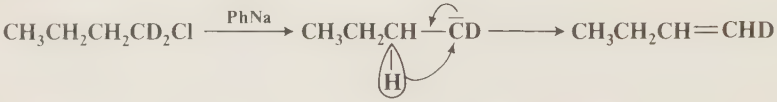
[211] For reviews, see Köbrich and Buck, in Viehe, "Acetylenes," pp. 100–134, Marcel Dekker, Inc., New York, 1969; Jacobs, *Org. React.* **5,** 1–78 (1949), pp. 1–25; Ref. 172, pp. 391–397; Köbrich, Ref. 2, pp. 50–53.

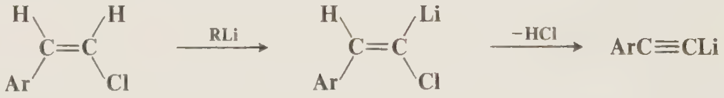
thermodynamically more stable. If another hydrogen is suitably located (for example, $-\overset{|}{C}H-CX_2-CH_2-$), then allene formation can compete, though alkynes are usually more stable.[212]

Dehydrohalogenation is generally carried out in solution, with a base, and the mechanism is usually E2, though the E1 mechanism has been demonstrated in some cases. However, elimination of HX may also be accomplished by pyrolysis of the halide, in which case the mechanism is the Ei mechanism (p. 918), or in some instances the free-radical mechanism (p. 920). Pyrolysis is normally performed without a catalyst at about 400°C. The pyrolysis reaction is not generally useful synthetically, because of its reversibility. Less work has been done on pyrolysis with a catalyst[213] (usually a metallic oxide or salt), but the mechanisms here are probably E1 or E2. It has been shown that when a very strong base is used in solution, an α-elimination mechanism through the carbene may compete with the normal E2 mechanism. This was shown by the treatment of $CH_3CH_2CH_2CD_2Cl$ with phenylsodium; the product contained $CH_3CH_2CH{=}CDH$, which arises from

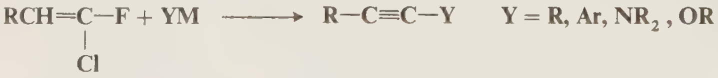


$$CH_3CH_2CH_2CD_2Cl \xrightarrow{PhNa} CH_3CH_2\underset{H}{CH}-\ddot{C}D \longrightarrow CH_3CH_2CH{=}CHD$$

and there was more of the former than of $CH_3CH_2CH{=}CD_2$, the normal E2 product.[214] Eliminations of vinyl halides to give triple bonds generally go by the E2 or E1cB mechanism. However, when the substrate is $ArCH{=}CHCl$ and the base RLi, a mechanism has been proposed in which the first step is hydrogen-lithium exchange (reaction **2-19**), followed by elimination of HCl.[215] This may be called an E2cB mechanism.



A combination elimination and substitution reaction has been used to synthesize alkynes. In this reaction a compound $RCH{=}CFCl$ is treated with YM, where M is a metal and Y may be alkyl, aryl, NR_2, or OR:



$$RCH{=}\underset{Cl}{\underset{|}{C}}-F + YM \longrightarrow R-C{\equiv}C-Y \qquad Y = R, Ar, NR_2, OR$$

Alkynes, ynamines, and acetylenic ethers can be prepared in this manner.[216]

Ketenes can be prepared by treatment of acyl halides with tertiary amines.[217] The scope is broad, and most acyl halides possessing an α-hydrogen give the reaction, but if at least one R is hydrogen, only the ketene dimer, and not the ketene, is isolated. However, if it is desired to use a reactive ketene in a reaction with a given compound, the ketene may be generated in situ in the presence of the given compound.[218]

Closely related is the reaction of tertiary amines with sulfonyl halides which contain an α-hydrogen. In this case the initial product is the highly reactive sulfene, which cannot be isolated

$$RCH_2SO_2Cl \xrightarrow{R_3N} \underset{\text{Sulfene}}{[RCH{=}SO_2]} \longrightarrow RCH{=}CHR + \text{other products}$$

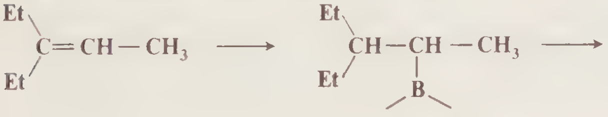
but reacts further to give various products, one of which may be the alkene which is the dimer of RCH.[219] Here too, reactions of sulfenes in situ are common (for example, see reactions **6-66**, **6-69**).

OS **IV**, 560; **V**, 294, 877; **52**, 36.

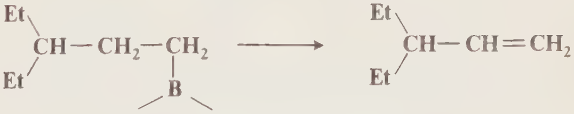
7-15 Elimination of Boranes

$$(R_2CH{-}CH_2)_3B + 3\ \text{1-decene} \rightleftharpoons 3R_2C{=}CH_2 + [CH_3(CH_2)_8CH_2]_3B$$

Trialkylboranes are formed from an olefin and BH_3 (reaction **5-15**). When the resulting borane is treated with another olefin, an exchange reaction occurs.[220] This is an equilibrium process which can be shifted by using a large excess of olefin, by using an unusually reactive olefin, or by using an olefin with a higher boiling point than the displaced olefin and removing the latter by distillation. The reaction is useful for shifting a double bond in the direction opposite that resulting from normal isomerization methods (reaction **2-2**). This cannot be accomplished simply by treatment of a borane such as **49** with an olefin, for elimination in this reaction follows Zaitsev's rule: It is in the direction of the most stable olefin, and the product would be **48** and not **51**. However, if it is desired to convert **48** to **51**, this can be accomplished by converting **48** to **49**, isomerizing **49** to **50** (reaction **8-14**), and then subjecting **50** to the exchange reaction with a higher-boiling olefin, e.g., 1-decene, whereupon **51** is produced. In the usual isomerizations (reaction **2-2**), **51** could be isomerized to **48**, but not the other way around. The reactions **49** → **50** and **50** → **51** proceed essentially without rearrangement. The mechanism is probably the reverse of borane addition (reaction **5-15**).



48 **49**



50 **51**

[218] For a review of this procedure, see Luknitskii and Vovsi, *Russ. Chem. Rev.* **38**, 487–494 (1969).

[219] For reviews of sulfenes, see Chapter 16, Ref. 499.

[220] Brown and Bhatt, *J. Am. Chem. Soc.* **88**, 1440 (1966); Brown, Bhatt, Munekata, and Zweifel, *J. Am. Chem. Soc.* **89**, 567 (1967).

A similar reaction, but irreversible, has been demonstrated for alkynes:[221]

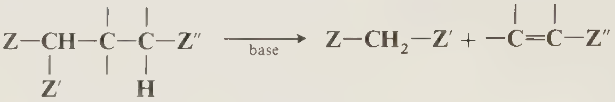
$$(\mathrm{R_2CH{-}CH_2})_3\mathrm{B} + \mathrm{R'C{\equiv}CR'} \longrightarrow 3\mathrm{R_2C{=}CH_2} + (\mathrm{R'CH{=}CR'})_3\mathrm{B}$$

7-16 Decarbonylation of Acyl Halides

$$\mathrm{RCH_2CH_2COCl} + \mathrm{RhCl(Ph_3P)_3} \xrightarrow{\Delta} \mathrm{RCH{=}CH_2} + \mathrm{HCl} + \mathrm{RhClCO(Ph_3P)_2}$$

Acyl halides containing an α-hydrogen are smoothly converted to olefins, with loss of HCl and CO, on heating with chlorotris(triphenylphosphine)rhodium, with metallic platinum, or with certain other catalysts.[222] See also reactions **4-41** and **9-14.**

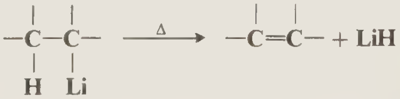
7-17 Reversal of the Michael Reaction



$$\mathrm{Z{-}}\underset{\displaystyle \mathrm{Z'}}{\underset{|}{\mathrm{CH}}}\mathrm{{-}}\underset{|}{\overset{|}{\mathrm{C}}}\mathrm{{-}}\underset{\displaystyle \mathrm{H}}{\underset{|}{\overset{|}{\mathrm{C}}}}\mathrm{{-}Z''} \xrightarrow[\text{base}]{} \mathrm{Z{-}CH_2{-}Z'} + {-}\overset{|}{\mathrm{C}}{=}\overset{|}{\mathrm{C}}\mathrm{{-}Z''}$$

Olefins can be formed on base cleavage of Michael adducts. (See reaction **5-19.** Z is defined on p. 678.) In some cases cleavage occurs simply on heating, without basic catalysis.

7-18 Pyrolysis of Alkali-Metal Organometallic Compounds

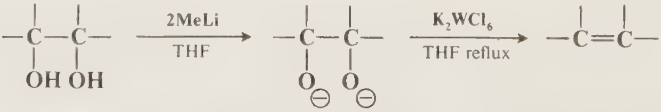


$${-}\underset{\displaystyle \mathrm{H}}{\underset{|}{\overset{|}{\mathrm{C}}}}{-}\underset{\displaystyle \mathrm{Li}}{\underset{|}{\overset{|}{\mathrm{C}}}}{-} \xrightarrow{\Delta} {-}\overset{|}{\mathrm{C}}{=}\overset{|}{\mathrm{C}}{-} + \mathrm{LiH}$$

Solid lithium hydride and an olefin can be obtained by heating alkyllithium compounds which contain a β-hydrogen.[223] With *sec*-BuLi the orientation followed Zaitsev's rule, although formation of *cis*-2-butene predominated over formation of the trans isomer.[224] The reaction has also been applied to alkylsodium and alkylpotassium compounds.[225] Grignard reagents gave olefins when thermally decomposed in nonsolvating solvents, e.g., cumene.[226]

B. Reactions in Which Neither Leaving Atom Is Hydrogen

7-19 Deoxygenation of Vicinal Diols



$${-}\underset{\displaystyle \mathrm{OH}}{\underset{|}{\overset{|}{\mathrm{C}}}}{-}\underset{\displaystyle \mathrm{OH}}{\underset{|}{\overset{|}{\mathrm{C}}}}{-} \xrightarrow[\text{THF}]{\text{2MeLi}} {-}\underset{\displaystyle \mathrm{O}^{\ominus}}{\underset{|}{\overset{|}{\mathrm{C}}}}{-}\underset{\displaystyle \mathrm{O}^{\ominus}}{\underset{|}{\overset{|}{\mathrm{C}}}}{-} \xrightarrow[\text{THF reflux}]{\mathrm{K_2WCl_6}} {-}\overset{|}{\mathrm{C}}{=}\overset{|}{\mathrm{C}}{-}$$

vic-Diols can be deoxygenated by treatment of the dilithium dialkoxide with the tungsten halide K_2WCl_6, or with certain other tungsten reagents, in refluxing tetrahydrofuran.[227] Tetrasubstituted diols react most rapidly. The elimination is largely, but not entirely, syn. Another method consists of treatment of the diol with PBr_3 in ether at low temperatures in the presence of CuBr, followed by addition of excess zinc powder.[149]

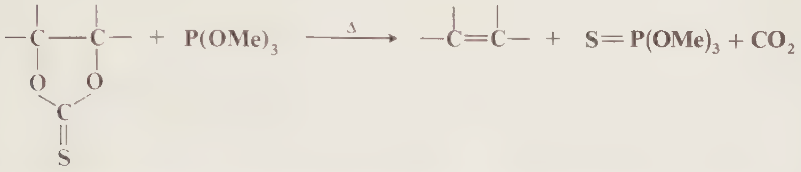
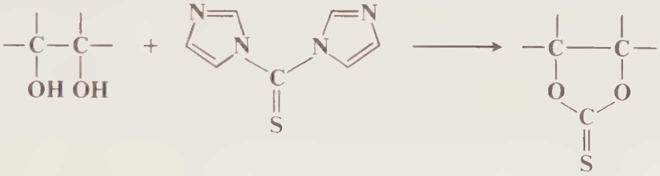
vic-Diols can also be deoxygenated indirectly, through sulfonate ester derivatives. For example, *vic*-dimesylates and *vic*-ditosylates have been converted to alkenes by treatment, respectively, with naphthalene-sodium[228] and with NaI in dimethylformamide.[229] More often, *vic*-diols are deoxygenated through cyclic derivatives (reaction **7-20**).

7-20 Cleavage of Cyclic Thionocarbonates



Cyclic thionocarbonates can be cleaved to olefins by heating with trimethyl phosphite[230] or other trivalent phosphorus compounds[231] or by treatment with bis(1,5-cyclooctadiene)nickel.[232] This is actually another method for removing *vic*-OH groups from a molecule, since the thionocarbonates can be prepared by the treatment of 1,2-glycols with N,N′-thiocarbonyldiimidazole:



The elimination is of course syn, so the product is sterically controlled, and olefins which are not sterically favored can be made in this way in high yield, for example, *cis*-$PhCH_2CH{=}CHCH_2Ph$.[233] Related reactions involve treatment of the benzaldehyde acetals (**52**) of 1,2-diols with butyllithium at room temperature,[234] and the heating of 2-ethoxy-1,3-dioxolanes (**53**) with benzoic acid.[235]

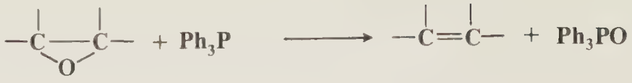
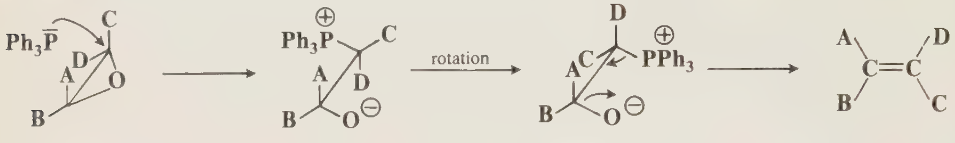
7-21 The Conversion of Epoxides to Olefins



$$-\overset{|}{C}\underset{O}{-}\overset{|}{C}- + Ph_3P \longrightarrow -\overset{|}{C}=\overset{|}{C}- + Ph_3PO$$

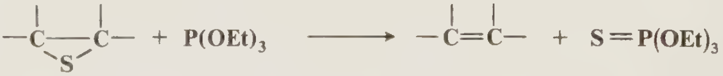
Epoxides can be converted to olefins by treatment with triphenylphosphine[236] or triethyl phosphite $P(OEt)_3$.[237] The first step of the mechanism is nucleophilic substitution (reaction **0-51**), followed by a four-center elimination. Since inversion accompanies the substitution, the overall elimination is anti; that is, if two groups A and C are cis in the epoxide, they will be trans in the olefin:



betaine

Alternatively, the epoxide can be treated with lithium diphenylphosphide Ph_2PLi, and the product quaternized with methyl iodide.[238] For another method of preparing the betaine, and hence olefins, see the Wittig reaction (**6-47**). Olefins have also been obtained from epoxides by reaction with a zinc-copper couple,[239] with atomic carbon,[240] with triphenylphosphine selenide–trifluoroacetic acid,[241] with sodium(cyclopentadienyl)dicarbonylferrate,[241a] with octacarbonyldicobalt,[242] with $TiCl_3$–$LiAlH_4$,[242a] with $K_2Fe(CO)_4$,[243] with Zn–$ZnCl_2$,[244] with $FeCl_3$–BuLi,[244a] with the tungsten reagents mentioned in reaction **7-19**,[227] and with NaI–NaOAc–Zn–AcOH.[245] The last-mentioned method is actually a variation of reaction **7-29**, since iodohydrins are intermediates.

7-22 The Conversion of Episulfides to Olefins



$$-\overset{|}{C}\underset{S}{-}\overset{|}{C}- + P(OEt)_3 \longrightarrow -\overset{|}{C}=\overset{|}{C}- + S{=}P(OEt)_3$$

Episulfides[246] can be converted to olefins in a reaction similar in appearance to reaction **7-21**.[247] However, in this case the elimination is syn, so that the mechanism cannot be the same as that of reaction **7-21**. The phosphite attacks not the carbon, but the sulfur. Among other reagents

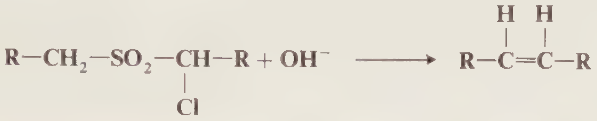
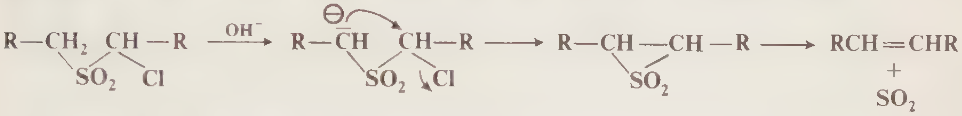
which convert episulfides to olefins are phenyllithium, lithium aluminum hydride[248] (this compound behaves quite differently with epoxides, see reaction **0-81**), and methyl iodide.[249] Episulfoxides can be converted to olefins and sulfur monoxide simply by heating.[250]

7-23 The Ramberg-Bäcklund Reaction



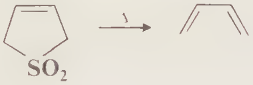
$$R{-}CH_2{-}SO_2{-}\underset{\displaystyle Cl}{\underset{|}{CH}}{-}R + OH^- \longrightarrow R{-}\overset{\displaystyle H}{\overset{|}{C}}{=}\overset{\displaystyle H}{\overset{|}{C}}{-}R$$

The reaction of an α-halo sulfone with a base to give an olefin is called the *Ramberg-Bäcklund reaction*.[251] The reaction is quite general for α-halo sulfones with an α′-hydrogen, despite the unreactivity of α-halo sulfones in normal SN2 reactions (p. 319). Halogen reactivity is in the order I > Br ≫ Cl. In general, mixtures of cis and trans isomers are obtained, but usually the less stable cis isomer predominates.[252] The mechanism involves formation of an episulfone and then elimination of SO_2. There is much evidence for this mechanism,[253] including the preparation

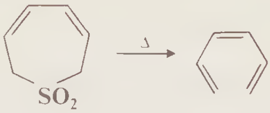


of episulfones in other ways and the demonstration that they give olefins under the reaction conditions faster than the corresponding α-halo sulfones.[254] Episulfones synthesized in other ways (e.g., reaction **6-66**) are reasonably stable compounds but eliminate SO_2 to give olefins when heated or when treated with base.

2,5-Dihydrothiophene-1,1-dioxides (**54**) and 2,7-dihydrothiepin-1,1-dioxides (**55**) undergo analogous 1,4 and 1,6 eliminations, respectively (see also reaction **7-50**). These are concerted reactions



54



55

and, as predicted by the Woodward-Hoffmann rules (p. 776), the former[255] is a suprafacial process and the latter[256] an antarafacial process. The rules also predict that elimination of SO_2 from episulfones cannot take place by a concerted mechanism (except antarafacially, which is

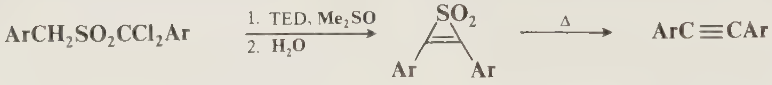
[256] Mock, *J. Am. Chem. Soc.* **91,** 5682 (1969).

unlikely for such a small ring), and the evidence shows that this reaction occurs by a nonconcerted pathway.[257] The eliminations of SO_2 from **54** and **55** are examples of *cheletropic reactions*, which are defined as reactions in which two σ bonds which terminate at a single atom (in this case the sulfur atom) are made or broken in concert.[258]

α,α-Dichlorobenzyl sulfones (**56**) react with an excess of the base triethylenediamine in dimethyl sulfoxide at room temperature to give 2,3-diarylthiiren-1,1-dioxides (**57**), which can be isolated.[259] Thermal decomposition of **57** gives the alkynes **58.** Alternatively, α,α-dichlorobenzyl sulfides $ArCH_2SCCl_2Ar$ can be converted to **58** by treatment with triphenylphosphine and *t*-BuOK in tetrahydrofuran.[260]



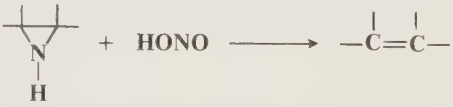
56 57 58

A Ramberg-Bäcklund–type reaction has been carried out on the α-halo *sulfides* $ArCHClSCH_2$-Ar, which react with *t*-BuOK and PPh_3 in refluxing tetrahydrofuran to give the alkenes $ArCH{=}CHAr$.[261] Another analogous reaction is treatment of α-bromo ketones $R_2CBrCOCHR_2$ with base and hydrogen peroxide to give olefins $R_2C{=}CR_2$.[262] This reaction involves a cyclopropanone intermediate (see the Favorskii rearrangement, reaction **8-8**) which loses CO on reaction with H_2O_2.

The Ramberg-Bäcklund reaction may be regarded as a type of extrusion reaction (see p. 956).

OS **V,** 877; **50,** 43, 65.

7-24 The Conversion of Aziridines to Olefins



Aziridines not substituted on the nitrogen atom react with nitrous acid to produce olefins.[263] An N-nitroso compound is an intermediate (reaction **2-50**), and other reagents which produce such intermediates also give olefins. The reaction is stereospecific: Cis aziridines give cis olefins and trans aziridines give trans olefins.[264] 3-Pyrrolines give butadienes when treated with nitrohydroxylamine, in an analogous 1,4 elimination.[265] Aziridines carrying N-alkyl substituents can

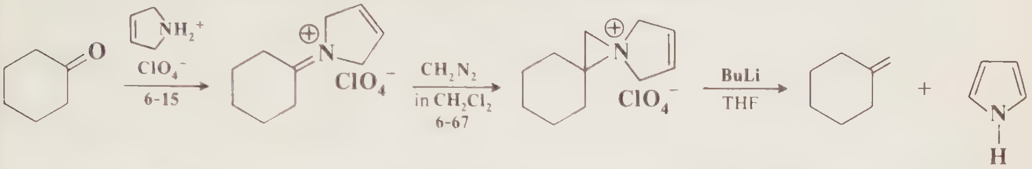
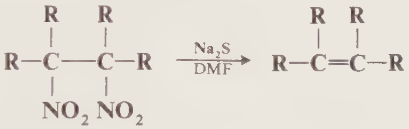
[265] Lemal and McGregor, *J. Am. Chem. Soc.* **88,** 1335 (1966).

be converted to olefins by treatment with ferrous iodide[266] or with *m*-chloroperbenzoic acid.[267] An N-oxide intermediate (reaction **9-29**) is presumably involved in the latter case. Conversion of aziridines to olefins has also been carried out photochemically.[268] An elimination reaction of aziridinium ions with butyllithium has been used as the key step in the conversion of cyclic ketones to the corresponding exo olefins, illustrated for cyclohexanol.[269]



Six-membered ring compounds with exocyclic double bonds are not easy to prepare by other methods.

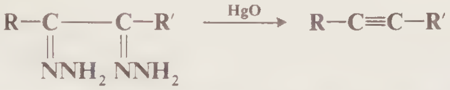
7-25 Conversion of Vicinal Dinitro Compounds to Olefins



$$\mathrm{R{-}\underset{NO_2}{\overset{R}{C}}{-}\underset{NO_2}{\overset{R}{C}}{-}R \xrightarrow[DMF]{Na_2S} R{-}\overset{R}{C}{=}\overset{R}{C}{-}R}$$

Tetrasubstituted *vic*-dinitro compounds are converted to olefins by treatment with sodium sulfide in dimethylformamide.[270] The olefins produced are free of isomers. A radical-ion mechanism has been suggested. *vic*-Dinitro compounds can be prepared by the reaction between an α,α-dinitro compound and the salt of a nitro paraffin (p. 421).

7-26 The Conversion of Dihydrazones to Alkynes

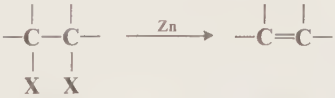


$$\mathrm{R{-}\underset{NNH_2}{\underset{\|}{C}}{-}\underset{NNH_2}{\underset{\|}{C}}{-}R' \xrightarrow{HgO} R{-}C{\equiv}C{-}R'}$$

1,2-Dihydrazones can be made to lose two moles of nitrogen to give alkynes by treatment with HgO, Ag_2O, or certain other reagents. R and R′ may be alkyl or aryl. Highly strained seven- and eight-membered cycloalkynes (see p. 147), as well as large cycloalkynes, have been obtained by this reaction.[271]

OS **IV,** 377. See also OS **55,** 73.

7-27 Dehalogenation of Vicinal Dihalides



$$\mathrm{{-}\underset{X}{\overset{|}{C}}{-}\underset{X}{\overset{|}{C}}{-} \xrightarrow{Zn} {-}\overset{|}{C}{=}\overset{|}{C}{-}}$$

Dehalogenation has been accomplished with many reagents, the most common being zinc, magnesium, and iodide ion. Among reagents used less frequently have been phenyllithium, phenylhydrazine, chromous chloride $CrCl_2$, naphthalene-sodium,[272] $Na\text{-}NH_3$,[273] $Na_2S_2O_3$ in dimethyl sulfoxide,[274] and lithium aluminum hydride.[275] Though the reaction gives good yields, it is not very useful because the best way to prepare *vic*-dihalides is by the addition of halogen to a double bond (reaction **5-30**). However, the two reactions are sometimes used to purify olefins. One useful feature of this reaction is that there is no doubt about the *position* of the new double bond, so that it can be used to give double bonds exactly where they are wanted. For example, allenes, which are not easily prepared by other methods, can be prepared from $X{-}C{-}CX_2{-}C{-}X$ or $X{-}C{-}CX{=}C{-}$ systems.[276] Cumulenes have been obtained from 1,4 elimination:

[270] Kornblum, Boyd, Pinnick, and Smith, *J. Am. Chem. Soc.* **93,** 4316 (1971).

[271] For example, see Blomquist and Liu, *J. Am. Chem. Soc.* **75,** 2153 (1953); Krebs and Kimling, *Tetrahedron Lett.* 761 (1970).

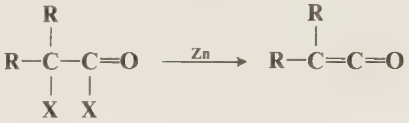
$$BrCH_2{-}C{\equiv}C{-}CH_2Br + Zn \longrightarrow CH_2{=}C{=}C{=}CH_2$$

Triple bonds can be prepared from $X{-}C{=}C{-}X$ or $X_2C{-}CX_2$ systems,[277] but availability considerations are even more extreme here.

The reaction can be carried out for any combination of halogens except where one is fluorine. Mechanisms are often complex and depend on the reagent and reaction conditions.[278] For different reagents, mechanisms involving carbonium ions, carbanions, and free-radical intermediates, as well as concerted mechanisms, have been proposed. The reaction with I^- was found to proceed with stereospecific anti orientation (p. 897); from this fact an E2 mechanism was assumed in this case, but more recent work[279] shows that the reaction is not completely stereospecific and the mechanism is more complicated. When the reagent is zinc, anti stereospecificity has been observed in some cases,[280] but not in others.[281]

OS **III,** 526, 531; **IV,** 195, 268; **V,** 22, 255, 393, 901; **50,** 21. Also see OS **IV,** 877, 914, 964.

7-28 Dehalogenation of α-Halo Acyl Halides

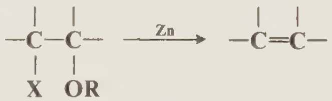


$$R_2C(X){-}C(X){=}O \xrightarrow{Zn} R_2C{=}C{=}O$$

Ketenes can be prepared by dehalogenation of α-halo acyl halides with zinc or with triphenylphosphine,[282] analogously to reaction **7-27.** The reaction generally gives good results when the two R groups are aryl or alkyl, but not when either one is hydrogen.[282a]

OS **IV,** 348.

7-29 Elimination of a Halogen and a Hetero Group



$${-}\underset{X}{C}{-}\underset{OR}{C}{-} \xrightarrow{Zn} {-}C{=}C{-}$$

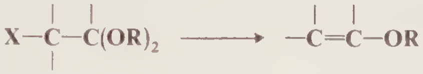
The elimination of OR and halogen from β-halo ethers is called the *Boord reaction.* It can be carried out with zinc, magnesium, or sodium. The yields are high and the reaction is of broad scope. β-Halo acetals yield vinyl ethers:

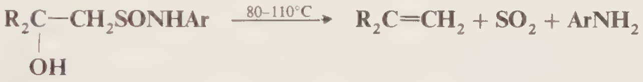


$$\mathrm{X{-}\overset{|}{\underset{|}{C}}{-}\overset{|}{C}(OR)_2 \longrightarrow {-}\overset{|}{C}{=}\overset{|}{C}{-}OR}$$

Besides β-halo ethers, the reaction can also be carried out on compounds of the formula $\mathrm{X{-}\overset{|}{\underset{|}{C}}{-}\overset{|}{\underset{|}{C}}{-}Z}$, where X is halogen and Z is OCOR, OTs,[283] NR_2,[284] or SR.[285] Z may also be OH, but then X is limited to Br and I. Like reaction **7-28,** this method ensures that the new double bond will be in a specific position. The fact that magnesium causes elimination in these cases limits the preparation of Grignard reagents from these compounds. It has been shown that treatment of β-halo ethers and esters with zinc gives nonstereospecific elimination,[286] so that the mechanism was not E2. It was postulated that the mechanism is E1cB, because of the poor leaving-group ability of OR and OCOR. On the other hand, stereospecific syn elimination has been reported for the reaction of 1-bromo-2-methoxy-1,2-diphenylethane with butyllithium in nonpolar solvents.[287] Bromohydrins can be converted to olefins (elimination of Br, OH) in high yields by treatment with $LiAlH_4$–$TiCl_3$.[287a]

OS **III,** 698; **IV,** 748; **55,** 62.

7-30 Pyrolysis of Hydroxysulfinamides



$$\mathrm{R_2\underset{\underset{OH}{|}}{C}{-}CH_2SONHAr \xrightarrow{80\text{–}110°C} R_2C{=}CH_2 + SO_2 + ArNH_2}$$

It was mentioned at reaction **6-42** (p. 857) that β-hydroxysulfinamides, on heating, undergo a syn elimination to give alkenes, SO_2, and $ArNH_2$.[288] Two other eliminations of OH and a sulfur function are also mentioned at reaction **6-42.**[289]

Fragmentations

When carbon is the positive leaving group (the electrofuge) in an elimination reaction, the reaction is called *fragmentation.*[290] These processes occur on substrates of the form $\mathrm{W{-}\overset{|}{\underset{|}{C}}{-}\overset{|}{\underset{|}{C}}{-}X}$, where X is a normal nucleofuge (e.g., halogen, OH_2^+, OTs, NR_3, etc.) and W is a positive-carbon electrofuge. In most of the cases W is HO—C— or R_2N—C—, so that the positive charge on the carbon atom is stabilized by the unshared pair of the oxygen or nitrogen, e.g.,

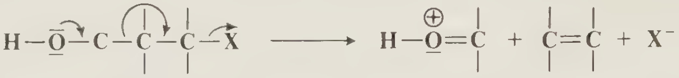
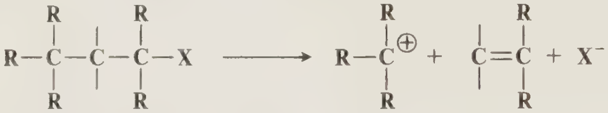
[290] For reviews, see Grob, *Angew. Chem. Int. Ed. Engl.* **8,** 535–546 (1969) [*Angew. Chem.* **81,** 543–554], *Bull. Soc. Chim. Fr.* 1360–1365 (1960), in "Theoretical Organic Chemistry, The Kekulé Symposium," pp. 114–126, Butterworth Scientific Publications, London, 1959; Grob and Schiess, *Angew. Chem. Int. Ed. Engl.* **6,** 1–15 (1967) [*Angew. Chem.* **79,** 1–14].



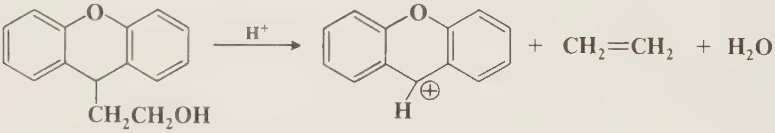
The mechanisms are mostly E1 or E2. We shall discuss only a few fragmentations, since many are possible and not much work has been done on most of them. Reactions **7-31** to **7-38** and **7-40** may be considered fragmentations. See also reactions **9-14** and **9-15.**

7-31 Fragmentation of γ-Branched Alcohols and Halides

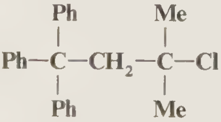


$$R-\underset{R}{\overset{R}{C}}-\overset{|}{\underset{|}{C}}-\underset{R}{\overset{R}{C}}-X \longrightarrow R-\underset{R}{\overset{R}{C}}{}^{\oplus} + \underset{|}{\overset{|}{C}}=\underset{R}{\overset{R}{C}} + X^-$$

When alkyl halides or alcohols with both α and γ branching are subjected to solvolysis, they undergo fragmentation to give an olefin and a carbonium ion. The carbonium ion then undergoes further elimination or substitution, depending on the conditions. This is of course an E1 process, with the first step being ionization of the halide or the protonated alcohol. This is another way of saying that carbonium ions of the form $R_3C-\overset{|}{\underset{|}{C}}-\overset{\oplus}{C}R_2$ find it easy to lose a relatively stable R_3C^+ carbonium ion rather than H^+. As expected for a carbonium-ion mechanism, these fragmentations occur to the greatest extent for tertiary substrates, to a smaller extent for secondary, and essentially not at all for primary substrates, even with γ branching, although they have been shown to occur for primary substrates when a very stable carbonium ion (the xanthyl cation) could be expelled:[291]

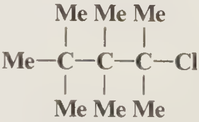


Even with apparently favorable substrates, fragmentation is not always observed. Thus, 2-methyl-4,4-triphenyl-2-chlorobutane (**59**) and 2,3,3,4,4-pentamethyl-2-chloropentane (**60**) gave no fragmentation products when solvolyzed in aqueous acetone.[292]



$$Ph-\underset{Ph}{\overset{Ph}{C}}-CH_2-\underset{Me}{\overset{Me}{C}}-Cl$$

59



$$Me-\underset{Me}{\overset{Me}{C}}-\underset{Me}{\overset{Me}{C}}-\underset{Me}{\overset{Me}{C}}-Cl$$

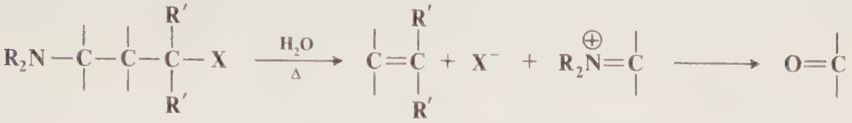
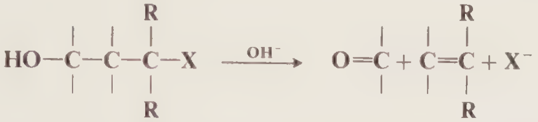
7-32 Fragmentation of γ-Amino and γ-Hydroxy Halides

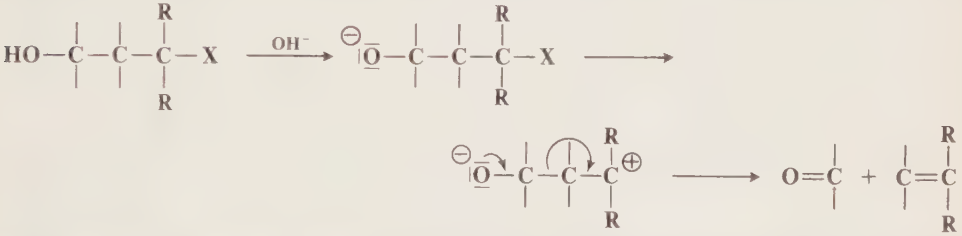


$$R_2N-C-C-CR'_2-X \xrightarrow[\Delta]{H_2O} C=CR'_2 + X^- + R_2\overset{\oplus}{N}=C \longrightarrow O=C$$



$$HO-C-C-CR_2-X \xrightarrow{OH^-} O=C + C=CR_2 + X^-$$

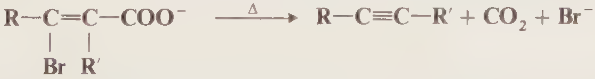
γ-Dialkylamino halides undergo fragmentation when heated with water, to give an olefin and an iminium salt, which under the reaction conditions is hydrolyzed to an aldehyde or ketone (reaction **6-2**).[293] γ-Hydroxy halides and tosylates are fragmented with base. In this instance the base does not play its usual role in elimination reactions but instead serves to remove a proton from the OH group, enabling the carbon leaving group to come off more easily:



The mechanism of these reactions is often E1, and the side reactions are similar to those in reaction **7-31.** However, in at least some cases, an E2 mechanism operates.[294] It has been shown that stereoisomers of cyclic γ-amino halides and tosylates in which the two leaving groups can assume an anti-periplanar conformation react by the E2 mechanism, while those isomers in which the groups cannot assume such a conformation either fragment by the E1 mechanism or do not undergo fragmentation at all, but in either case give rise to side products characteristic of carbonium ions.[295] In certain cases (electron-withdrawing groups in the β position, the use of poor nucleofuges such as ArCOO) an E1cB mechanism has been shown.[296]

γ-Dialkylamino alcohols do not give fragmentation, since for ionization the OH group must be converted to OH_2^+ and this would convert NR_2 to NR_2H^+, which does not have the unshared pair necessary to form the double bond with the carbon.[297]

7-33 Fragmentation of β-Halo Acrylic Acid Salts



$$R-C(Br)=C(R')-COO^- \xrightarrow{\Delta} R-C\equiv C-R' + CO_2 + Br^-$$

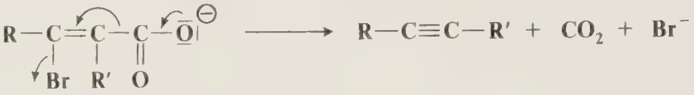
[296] Grob, Unger, Weiler, and Weiss, *Helv. Chim. Acta* **55,** 501 (1972).

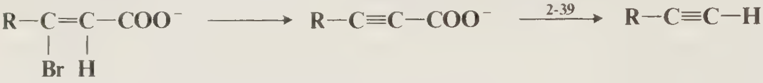
[297] Grob, Hoegerle, and Ohta, *Helv. Chim. Acta* **45,** 1823 (1962).

Salts of β-halo acrylic acids are dehalocarboxylated by heating, to give triple-bond compounds.[298] The elimination is anti, as shown by the fact that *trans*-MeCBr=CMeCOO⁻ reacts at 100°C while the cis isomer does not react. The mechanism is thus probably E2:[299]



$$\mathrm{R{-}\underset{Br}{\underset{|}{C}}{=}\underset{R'}{\underset{|}{C}}{-}\underset{O}{\underset{\|}{C}}{-}O^{\ominus}} \longrightarrow \mathrm{R{-}C{\equiv}C{-}R' + CO_2 + Br^-}$$

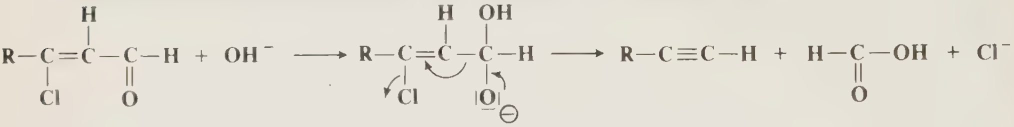
When R′ is hydrogen, then another mechanism is possible:



$$\mathrm{R{-}\underset{Br}{\underset{|}{C}}{=}\underset{H}{\underset{|}{C}}{-}COO^-} \longrightarrow \mathrm{R{-}C{\equiv}C{-}COO^-} \xrightarrow{\text{2-39}} \mathrm{R{-}C{\equiv}C{-}H}$$

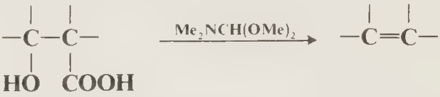
Other leaving groups (for example, OTs) may replace halogen.[300]

A similar cleavage may be effected by base treatment of β-chloroacroleins:[301]



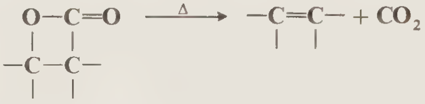
$$\mathrm{R{-}\underset{Cl}{\underset{|}{C}}{=}\overset{H}{\overset{|}{C}}{-}\underset{O}{\underset{\|}{C}}{-}H + OH^-} \longrightarrow \mathrm{R{-}\underset{Cl}{\underset{|}{C}}{=}\overset{H}{\overset{|}{C}}{-}\overset{OH}{\overset{|}{\underset{O^{\ominus}}{\underset{|}{C}}}}{-}H} \longrightarrow \mathrm{R{-}C{\equiv}C{-}H + H{-}\underset{O}{\underset{\|}{C}}{-}OH + Cl^-}$$

7-34 Decarboxylation of β-Hydroxy Carboxylic Acids and of β-Lactones



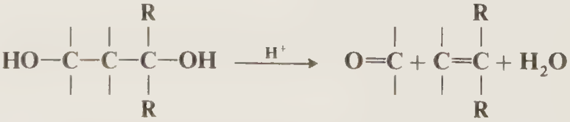
$$\mathrm{-\overset{|}{\underset{HO}{\underset{|}{C}}}-\overset{|}{\underset{COOH}{\underset{|}{C}}}-} \xrightarrow{\mathrm{Me_2NCH(OMe)_2}} \mathrm{-\overset{|}{C}{=}\overset{|}{C}-}$$

An OH and a COOH group can be eliminated from β-hydroxy carboxylic acids by refluxing with excess dimethylformamide dimethyl acetal.[302] Mono-, di-, tri-, and tetrasubstituted olefins have been prepared by this method in good yields. In a related procedure, β-lactones undergo thermal decarboxylation to give olefins in high yields. The reaction has been shown to be a stereospecific syn elimination.[303]



$$\begin{array}{c}\mathrm{O{-}C{=}O}\\ |\quad\;\; |\\ \mathrm{-C{-}C-}\\ |\quad\;\; |\end{array} \xrightarrow{\Delta} \mathrm{-\underset{|}{C}{=}\underset{|}{C}- + CO_2}$$

7-35 Fragmentation of 1,3-Diols



$$\mathrm{HO{-}\overset{|}{\underset{|}{C}}{-}\overset{|}{\underset{|}{C}}{-}\overset{R}{\overset{|}{\underset{R}{\underset{|}{C}}}}{-}OH} \xrightarrow{\mathrm{H^+}} \mathrm{O{=}\overset{|}{\underset{|}{C}} + \overset{|}{\underset{|}{C}}{=}\overset{R}{\overset{|}{\underset{R}{\underset{|}{C}}}} + H_2O}$$

---

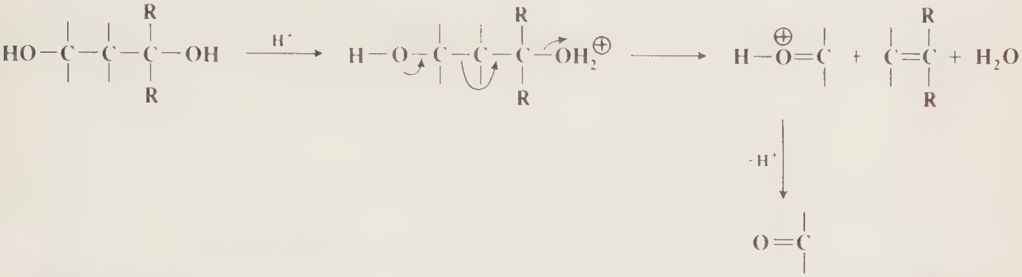
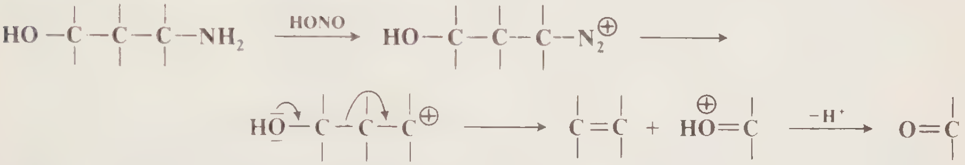
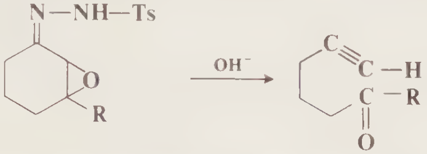
1,3-Diols in which at least one OH group is tertiary or is located on a carbon which has aryl substituents can be cleaved by acid treatment.[304] At least in some cases the mechanism seems to be E2 since anti elimination is found:[305]



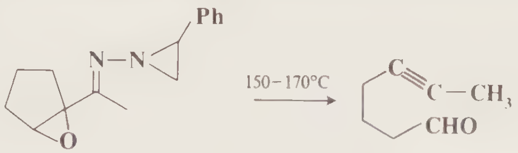
However, in other cases the mechanism is E1. Suitable β-hydroxy acids also give the reaction. As already mentioned (p. 947), γ-dialkylamino alcohols do not give fragmentation, but non-N-substituted γ-amino alcohols do give the reaction, when treated with nitrous acid, and give the same products as the corresponding 1,3-diol.[306] Here the mechanism is undoubtedly E1:



7-36 Fragmentation of α,β-Epoxy Hydrazones



Cyclic α,β-unsaturated ketones can be cleaved by treatment with base of their epoxy tosylhydrazone derivatives to give acetylenic ketones.[307] The reaction can be applied to the formation of acetylenic aldehydes (R = H) by using the corresponding 2,4-dinitrotosylhydrazone derivatives.[308] Hydrazones (e.g., **61**) prepared from epoxy ketones and ring-substituted N-aminoaziridines



61

undergo similar fragmentation when heated.[309]

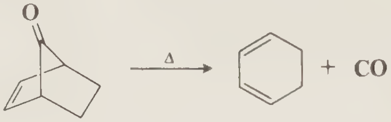
7-37 Reversal of the Diels-Alder reaction may be considered a fragmentation. See reaction **5-51.**

7-38 Elimination of CO and CO_2 from Bridged Bicyclic Compounds



62

On heating, bicyclo[2.2.1]heptenones (**62**) usually lose CO to give cyclohexadienes,[310] in a type of reverse Diels-Alder reaction. Bicyclo[2.2.1]heptadienones (**63**) undergo the reaction so readily (because of the stability of the benzene ring produced) that they cannot generally be isolated. **62** and **63** can be prepared by Diels-Alder reactions between a cyclopentadienone and an alkyne or olefin, so that this reaction is a useful method for the preparation of specifically substituted benzene rings and cyclohexadienes.[311] Unsaturated bicyclic lactones of the type **64** can also undergo the reaction, losing CO_2. See also reaction **7-49.**

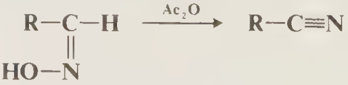
Reactions in Which C≡N or C=N Bonds Are Formed

7-39 Dehydration of Aldoximes and Similar Compounds



$$\underset{\substack{\| \\ HO—N}}{R—C—H} \xrightarrow{Ac_2O} R—C≡N$$

Aldoximes can be dehydrated to nitriles[312] by many dehydrating agents, of which acetic anhydride is the most common. Reagents which are effective under mild conditions (room temperature) are diphenyl hydrogen phosphonate[313] $(PhO)_2PHO$, *p*-chlorophenyl chlorothionoformate[314] *p*-$ClC_6H_4OC(=S)Cl$, ethyl orthoformate and H^+,[315] 2,4,6-trichloro-*s*-triazine,[316] N,N′-carbonyldiimidazole[317] (p. 365), and dicyclohexylcarbodiimide in the presence of Et_3N and Cu(II) ions.[318] The reaction is most successful when the H and OH are trans. Various alkyl and acyl derivatives of aldoximes, for example, RCH=NOR, RCH=NOCOR, $RCH=NOSO_2Ar$, etc., also give nitriles, as do chlorimines RCH=NCl (the latter with base treatment)[319] and the cobalt complexes of imines[320] (see reaction **6-14**).

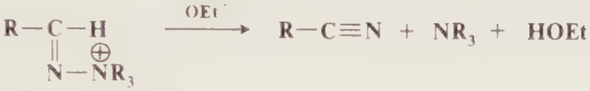
---

[310] For reviews, see Stark and Duke, Ref. 359, pp. 16–46; Allen, *Chem. Rev.* **62,** 653-664 (1962).

[311] For a review with many examples, see Ogliaruso, Romanelli, and Becker, *Chem. Rev.* **65,** 261-367 (1965), pp. 300–348.

[312] For a review, see Friedrich and Wallenfels, in Rappoport, "The Chemistry of the Cyano Group," pp. 92-96, Interscience Publishers, New York, 1970.

Quaternary hydrazonium salts (derived from aldehydes) give nitriles when treated with OEt^-:[321]

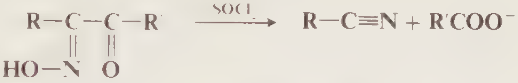


$$R-\underset{\underset{N-\overset{\oplus}{N}R_3}{\|}}{C}-H \xrightarrow{OEt^-} R-C{\equiv}N + NR_3 + HOEt$$

All these are methods of converting aldehyde derivatives to nitriles. For the conversion of aldehydes directly to nitriles, without isolation of intermediates, see reaction **6-23**.

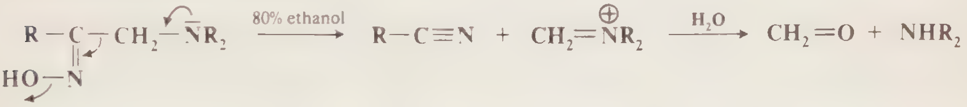
OS **II**, 622; **III**, 690.

7-40 The Conversion of Ketoximes to Nitriles



$$R-\underset{\underset{HO-N}{\|}}{C}-\underset{\underset{O}{\|}}{C}-R' \xrightarrow{SOCl_2} R-C{\equiv}N + R'COO^-$$

Certain ketoximes can be converted to nitriles by the action of proton or Lewis acids.[322] Among these are oximes of α-diketones (illustrated above), α-keto acids, α-dialkylamino ketones, α-hydroxy ketones, β-keto ethers, and similar compounds.[323] These are fragmentation reactions, analogous to reactions **7-32** and **7-35**. For example, α-dialkylamino ketoximes also give amines and aldehydes or ketones, in addition to nitriles:[324]



$$R-\underset{\underset{HO-N}{\|}}{C}-CH_2-NR_2 \xrightarrow{80\%\ ethanol} R-C{\equiv}N + CH_2{=}\overset{\oplus}{N}R_2 \xrightarrow{H_2O} CH_2{=}O + NHR_2$$

The reaction which normally occurs on treatment of a ketoxime with a Lewis or proton acid is the Beckmann rearrangement (reaction **8-21**), and fragmentations are considered side reactions, often called "abnormal" or "second-order" Beckmann rearrangements.[325] Obviously, the substrates mentioned are much more susceptible to fragmentation than are ordinary ketoximes, since in each case an unshared pair is available to assist in removal of the group cleaving from the carbon. However, fragmentation is a side reaction even with ordinary ketoximes[326] and, in cases where a particularly stable carbonium ion may be cleaved, may be the main reaction:[327]

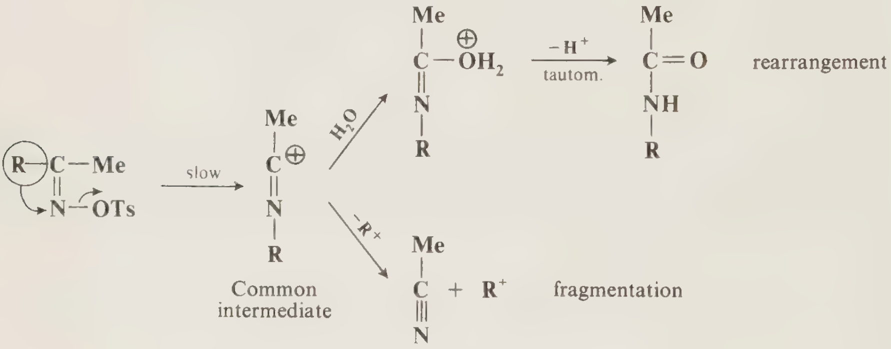
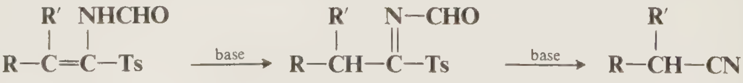
$$\mathrm{Ar_2CH{-}\underset{\underset{\displaystyle N{-}OH}{\|}}{C}{-}Me \xrightarrow{PCl_5} Me{-}C{\equiv}N + Ar_2CHCl}$$

There are indications that the mechanism at least in some cases first involves a rearrangement, and then cleavage. The ratio of fragmentation to Beckmann rearrangement of a series of oxime tosylates $\mathrm{R{-}\underset{\underset{\displaystyle NOTs}{\|}}{C}{-}Me}$ was not related to the solvolysis rate but *was* related to the stability of R^+ (as determined by the solvolysis rate of the corresponding RCl), which showed that fragmentation did not take place in the rate-determining step.[328] It may be postulated then that the first step in the fragmentation and in the rearrangement is the same and that this is the rate-determining step. The product is determined in the second step:



However, in other cases the simple E1 or E2 mechanisms operate.[329] The fragmentation of certain ketoximes to nitriles has also been carried out with tetrakis(triphenylphosphine)palladium $Pd(PPh_3)_4$.[329a] In this case the other product is the aldehyde R′CHO.

The fragmentation of N-(1-tosyl-1-alkenyl)formamides (**65**) by refluxing with NaOMe in MeOH is a step in the conversion of a ketone to a nitrile,[330] since **65** can be prepared by treatment of



$$\underset{\textbf{65}}{\mathrm{R{-}\overset{\overset{\displaystyle R'}{|}}{C}{=}\overset{\overset{\displaystyle NHCHO}{|}}{C}{-}Ts}} \xrightarrow{\text{base}} \mathrm{R{-}\overset{\overset{\displaystyle R'}{|}}{C}H{-}\overset{\overset{\displaystyle N{-}CHO}{\|}}{C}{-}Ts} \xrightarrow{\text{base}} \mathrm{R{-}\overset{\overset{\displaystyle R'}{|}}{C}H{-}CN}$$

ketones with $TsCH_2NC$ (p. 858). The overall conversion is RR′C=O to RR′CHCN.

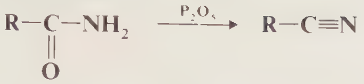
7-41 Dehydration of Unsubstituted Amides



$$\mathrm{R{-}\underset{\underset{O}{\|}}{C}{-}NH_2} \xrightarrow{\mathrm{P_2O_5}} \mathrm{R{-}C{\equiv}N}$$

Unsubstituted amides can be dehydrated to nitriles.[331] Phosphorus pentoxide is the most common dehydrating agent for this reaction, but many others, including $POCl_3$, PCl_5, CCl_4–Ph_3P,[332] $TiCl_4$–base,[333] $CHCl_3$-$PhCH_2NEt_3{}^+$ Cl^- base,[334] HMPT,[335] phosphorus tris(diethylamide) $P(NEt_2)_3$,[336] and $SOCl_2$, have also been used. It is possible to convert an acid to the nitrile, without isolation of the amide, by heating its ammonium salt with the dehydrating agent. The reaction may be formally looked on as a β-elimination from the enol form of the amide $\mathrm{R{-}\underset{\underset{OH}{|}}{C}{=}NH}$, in which case it is like reaction **7-39**, except that H and OH have changed places. In some cases, for example, with $SOCl_2$, the mechanism probably *is* through the enol form, with the dehydrating agent forming an ester with the OH group, for example, $\mathrm{R{-}\underset{\underset{OSOCl}{|}}{C}{=}NH}$, which undergoes elimination by the E1 or E2 mechanism.[337]

N-Alkyl-substituted amides can be converted to nitriles and alkyl chlorides by treatment with PCl_5. This reaction is called the *von Braun reaction* (not to be confused with the other von Braun reaction, **0-72**).

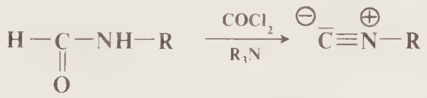
$$\mathrm{R'CONHR + PCl_5 \longrightarrow R'CN + RCl}$$

In a similar reaction, treatment of N-alkyl-substituted amides with chlorotris(triphenylphosphine)rhodium $RhCl(PPh_3)_3$ or certain other catalysts gives nitriles and the corresponding alcohols.[338] N-Sulfo chloride derivatives of amides (prepared by treatment of carboxylic acids or ketones with chlorosulfonyl isocyanate $ClSO_2NCO$) can be converted to nitriles by treatment with dimethylformamide[339] or with triethylamine.[340]

$$\mathrm{RCONHSO_2Cl} \xrightarrow[\mathrm{Et_3N}]{\mathrm{DMF\ or}} \mathrm{RCN}$$

OS **I,** 428; **II,** 379; **III,** 493, 535, 584, 646, 768; **IV,** 62, 144, 166, 172, 436, 486, 706; **50,** 18, 52.

7-42 Conversion of N-Alkylformamides to Isonitriles



$$\mathrm{H{-}\underset{\underset{O}{\|}}{C}{-}NH{-}R} \xrightarrow[\mathrm{R_3N}]{\mathrm{COCl_2}} \overset{\ominus}{\underline{C}}{\equiv}\overset{\oplus}{N}{-}R$$

Isonitriles can be prepared by elimination of water from N-alkylformamides with phosgene and a tertiary amine.[341] Other reagents, among them TsCl in quinoline, $POCl_3$ in pyridine, chlorodimethylformiminium chloride[342] $Me_2N{=}CHCl^+\ Cl^-$, $Ph_3P\text{–}CCl_4\text{–}Et_3N$,[343] and $Ph_3PBr_2\text{–}Et_3N$,[344] have also been employed.

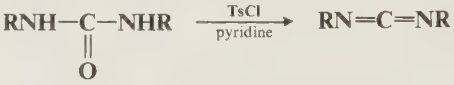
7-43 Dehydration of N,N′-Disubstituted Ureas and Thioureas



$$RNH\text{—}\underset{\underset{O}{\|}}{C}\text{—}NHR \xrightarrow[\text{pyridine}]{\text{TsCl}} RN{=}C{=}NR$$

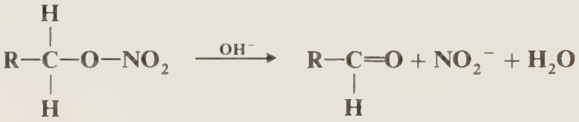
Carbodiimides[345] can be prepared by the dehydration of N,N′-disubstituted ureas with various dehydrating agents, among which are TsCl in pyridine, $POCl_3$, PCl_5, P_2O_5–pyridine, and $Ph_3PBr_2\text{–}Et_3N$.[344] H_2S can be removed from the corresponding thioureas by treatment with HgO, NaOCl, phosgene,[346] or diethyl azodicarboxylate–triphenylphosphine.[347]

OS **V**, 555.

Reactions in Which C=O Bonds Are Formed

Many elimination reactions in which C=O bonds are formed were considered in Chapter 16, along with their more important reverse reactions. Also see reactions **2-39** to **2-41** and **4-42.**

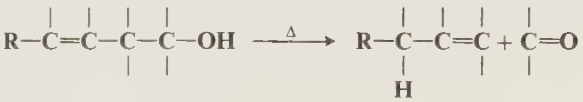
7-44 Alkaline Hydrolysis of Nitrates



$$R\text{—}\overset{\overset{H}{|}}{\underset{\underset{H}{|}}{C}}\text{—}O\text{—}NO_2 \xrightarrow{OH^-} R\text{—}\underset{\underset{H}{|}}{C}{=}O + NO_2^- + H_2O$$

Nitrates of primary or secondary alcohols can be hydrolyzed with base to give aldehydes or ketones,[348] but other reactions compete: hydrolysis to the alcohol (reaction **0-4**) and elimination to the olefin (reaction **7-5**). Compounds in which R is aryl give the highest yields. The mechanism is E2[349] (often expressed as Eco2 when applied to this reaction, to indicate that a C=O bond is being formed). This is an indirect method of oxidation of alcohols to aldehydes or ketones. (See reaction **9-4.**)

7-45 Pyrolysis of β-Hydroxy Olefins



$$R\text{—}\overset{|}{C}{=}\overset{|}{C}\text{—}\underset{|}{\overset{|}{C}}\text{—}\underset{|}{\overset{|}{C}}\text{—}OH \xrightarrow{\Delta} R\text{—}\underset{\underset{H}{|}}{\overset{|}{C}}\text{—}\overset{|}{C}{=}\underset{|}{\overset{|}{C}} + \underset{|}{\overset{|}{C}}{=}O$$

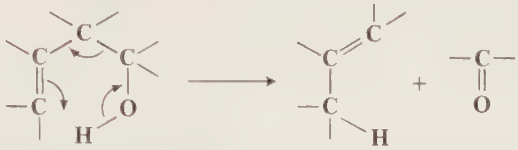
β-Hydroxy olefins are cleaved when pyrolyzed to give olefins and aldehydes or ketones.[350] Olefins produced in this way are quite pure, since there are no side reactions. The mechanism has been shown to be Ei, primarily by observations that the kinetics are first order[351] and that, for ROD, the deuterium appeared in the allylic position of the new olefin.[352]

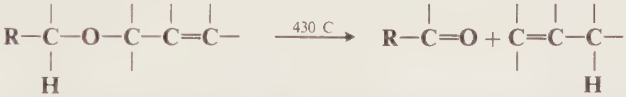


An example of this reaction is the pyrolysis of ricinoleic acid

$$CH_3(CH_2)_5CHOHCH_2CH{=}CH(CH_2)_7COOH \rightarrow CH_3(CH_2)_5CHO + CH_2{=}CH(CH_2)_8COOH$$

β-Hydroxyacetylenes react similarly to give the corresponding allenes and carbonyl compounds.[353] The mechanism is the same despite the linear geometry of the triple bonds.

7-46 Pyrolysis of Allyl Ethers



$$\mathrm{R{-}\underset{H}{\overset{|}{C}}{-}O{-}\underset{|}{\overset{|}{C}}{-}\overset{|}{C}{=}\overset{|}{C}{-}} \xrightarrow{430\ \mathrm{C}} \mathrm{R{-}\overset{|}{C}{=}O + \underset{|}{\overset{|}{C}}{=}\overset{|}{C}{-}\underset{H}{\overset{|}{C}}{-}}$$

Pyrolysis of allyl ethers which contain at least one α-hydrogen gives olefins and aldehydes or ketones. The reaction is closely related to reaction **7-45**, and the mechanism is also Ei, though not exactly analogous.[354] Note that this mechanism is the reverse of that of the ene synthesis (**5-18**). Homoallylic ethers can be pyrolytically cleaved via an eight-membered cyclic transition state to give an aldehyde and two alkenes.[355]

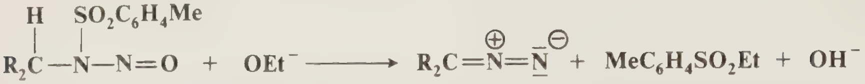
Reactions in Which N=N Bonds Are Formed

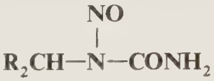
7-47 Eliminations to Give Diazoalkanes



$$R_2\overset{H}{C}-\overset{SO_2C_6H_4Me}{N}-N=O + OEt^- \longrightarrow R_2C=\overset{\oplus}{N}=\overset{\ominus}{\underline{N}} + MeC_6H_4SO_2Et + OH^-$$

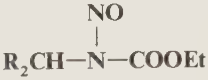
Various N-nitroso-N-alkyl compounds undergo elimination to give diazoalkanes.[356] One of the most convenient methods for the preparation of diazomethane involves base treatment of N-nitroso-N-methyl-*p*-toluenesulfonamide (illustrated above, with R = H).[357] However, other compounds commonly used are (base treatment is required in all cases):

N-Nitroso-N-alkylureas



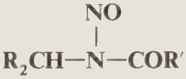
$$R_2CH-\overset{NO}{N}-CONH_2$$

N-Nitroso-N-alkylcarbamates



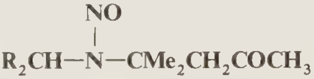
$$R_2CH-\overset{NO}{N}-COOEt$$

N-Nitroso-N-alkyl amides



$$R_2CH-\overset{NO}{N}-COR'$$

N-Nitroso-N-alkyl-4-amino-4-methyl-2-pentanones



$$R_2CH-\overset{NO}{N}-CMe_2CH_2COCH_3$$

All these compounds can be used to prepare diazomethane, though the sulfonamide, which is commercially available, is most satisfactory. (N-Nitroso-N-methylcarbamate and N-nitroso-N-methylurea give good yields, but are highly irritating and carcinogenic.[358]) For higher diazoalkanes the preferred substrates are nitrosoalkylcarbamates.

Most of these reactions probably begin with a 1,3 nitrogen-to-oxygen rearrangement, followed by the actual elimination (illustrated for the carbamate):

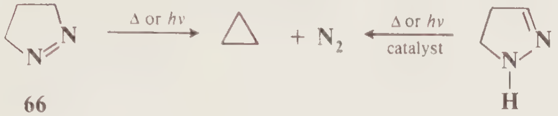
$$\mathrm{X{-}Y{-}Z} \longrightarrow \mathrm{X{-}Z} + \mathrm{Y}$$

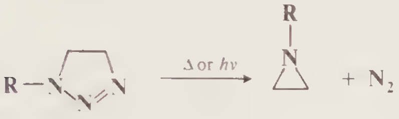
does not fit the definition but is often also classified as an extrusion reaction.

7-48 Extrusion of N_2 from Pyrazolines, Pyrazoles, and Triazolines

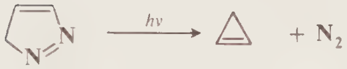


66

67



68



69

1-Pyrazolines (**66**) can be converted to cyclopropanes and N_2 on photolysis[360] or pyrolysis.[361] The tautomeric 2-pyrazolines (**67**), which are more stable than **66**, also give the reaction, but in this case an acidic or basic catalyst is required, the function of which is to convert **67** to **66**.[362] In the absence of such catalysts, **67** do not react.[363] In a similar manner, triazolines (**68**) are converted to aziridines.[364] Side reactions are frequent with both **66** and **68**, and some substrates do not give the reaction at all. However, the reaction has proved synthetically useful in many cases. In general, photolysis gives better yields and fewer side reactions than pyrolysis with both **66** and **68**. 3*H*-Pyrazoles (**69**) are stable to heat, but in some cases can be converted to cyclopropenes on photolysis,[365] though in other cases other types of products are obtained.

There is much evidence that the mechanism of the 1-pyrazoline reactions generally involves diradicals,[366] though the mode of formation and detailed structure (e.g., singlet versus triplet) of

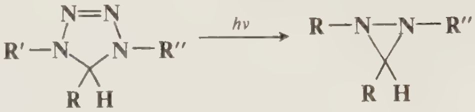
these radicals may vary with the substrate and reaction conditions. The reactions of the 3*H*-pyrazoles have been postulated to proceed through a diazo compound which loses N_2 to give a vinylcarbene.[367]

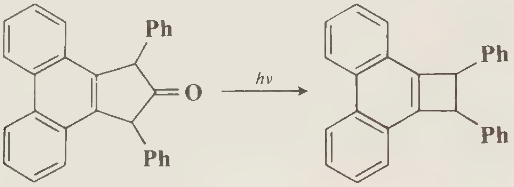
$$\mathbf{69} \xrightarrow{h\nu} -\overset{|}{C}=\overset{|}{C}-\overset{|}{C}N_2 \longrightarrow -\overset{|}{C}=\overset{|}{C}-\overset{|}{\underline{C}} \longrightarrow \triangle$$

Δ^2-Tetrazolines can be photolyzed to diaziridines.[368]



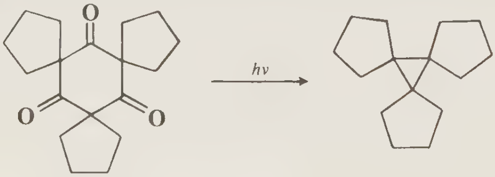
OS V, 96, 929.

7-49 Extrusion of CO or CO_2



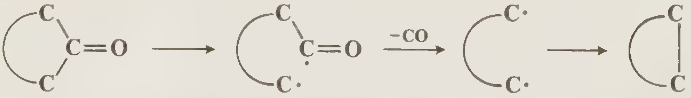
70 **71**

Though the reaction is not general, certain cyclic ketones can be photolyzed to give ring-contracted products.[369] In the example above, the tetracyclic ketone **70** was photolyzed to give the diphenylphenanthro(*l*)cyclobutene compound **71.**[370] Another example is formation of trispiro-[4.0.4.0.4.0]pentadecane by extrusion of three moles of CO from the triene **72.**[371]



72

The mechanism probably involves a Norrish type I cleavage (p. 221), loss of CO from the resulting radical, and recombination of the radical fragments.



Certain lactones extrude CO_2 on heating or on irradiation, examples being pyrolysis of 7-chloro-6,8-dimethyl-1,4,5-benzoxadiazepin-2-one (**73**) to give the corresponding indazole **74**,[372]

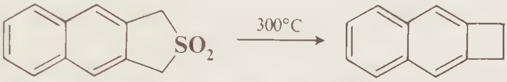
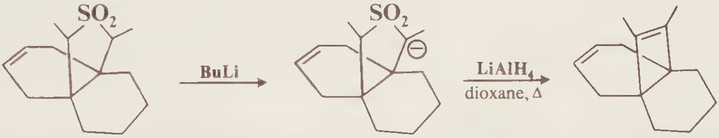
7-50 Extrusion of SO_2



In a reaction similar to **7-49,** certain cyclic sulfones extrude SO_2 on heating to give ring-contracted products.[374] Like **7-49,** this is not a general reaction, but it can be useful in certain cases, for example, in the preparation of naphtho(*b*)cyclobutene shown above.[375] In a different kind of reaction, five-membered cyclic sulfones can be converted to cyclobutenes by treatment with butyllithium followed by $LiAlH_4$,[376] e.g.,



SO_2
BuLi
SO_2
⊖
$LiAlH_4$
dioxane, Δ

This method is most successful when both the α and α′ positions of the sulfone bear alkyl substituents. See also reaction **7-23.**

When cycloalkylidene peroxides (e.g., **75**) are heated in an inert solvent (e.g., decane), extrusion of CO_2 takes place, and the products are the cycloalkane containing three carbon atoms less than the starting peroxide, and the lactone containing two carbon atoms less.[377] The reaction is called the *Story synthesis*.[378] The two products are formed in comparable yields, usually about 15 to 25% each. Although the yields are not high, the reaction is useful because there are not many other ways to prepare large rings. The same products are obtained by photolysis, but yields are generally lower. The reaction is versatile, having been used to prepare rings of every size from 8 to 33 members. The method is also applicable to dimeric cycloalkylidene peroxides, in which case the cycloalkane and lactone products result from loss of two molecules and one molecule of CO_2, respectively, e.g.,

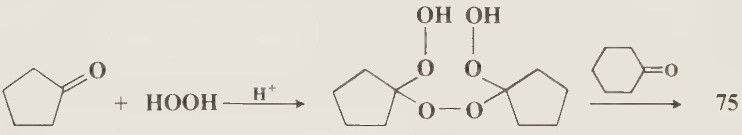
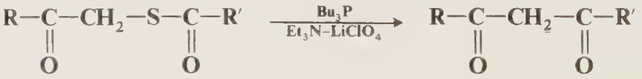
Dimeric and trimeric cycloalkylidene peroxides containing certain ring substituents (e.g., Me, *t*-Bu, OMe) also give the reaction.[379]

Both dimeric and trimeric cycloalkylidene peroxides can be synthesized by treatment of the corresponding cyclic ketones with H_2O_2 in acid solution,[380] or in the presence of an ion-exchange resin.[381] The trimeric peroxide is formed first and is subsequently converted to the dimeric compound.[382] Mixed trimeric peroxides (e.g., **75**) can be prepared[383] by formation of 1,1′-dihydroperoxycycloalkyl peroxides (e.g., **76**) and treatment of these with cyclic ketones.



76

7-52 Formation of β-Dicarbonyl Compounds by Extrusion of Sulfur



$$R-\underset{\underset{O}{\|}}{C}-CH_2-S-\underset{\underset{O}{\|}}{C}-R' \xrightarrow[Et_3N-LiClO_4]{Bu_3P} R-\underset{\underset{O}{\|}}{C}-CH_2-\underset{\underset{O}{\|}}{C}-R'$$

Thioesters containing a β-keto group in the alkyl portion can be converted to β-diketones by treatment with a tertiary phosphine under basic conditions.[384] The starting thioesters can be prepared by the reaction between a thiol acid and an α-halo ketone (similar to reaction **0-26**).

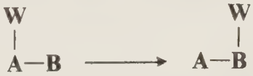
Eighteen

Rearrangements

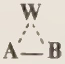
In a rearrangement reaction a group moves from one atom to another in the same molecule.[1] Most are migrations from an atom to an adjacent one (called 1,2 shifts)



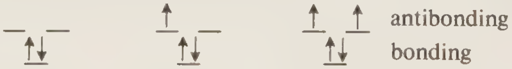
$$\overset{W}{A}-B \longrightarrow A-\overset{W}{B}$$

but some are over longer distances. The migrating group (W) may move with its electron pair (these may be called *nucleophilic* or *anionotropic* rearrangements; the migrating group may be regarded as a nucleophile), without its electron pair (*electrophilic* or *cationotropic* rearrangements; in the case of migrating hydrogen, *prototropic* rearrangements), or with just one electron (free-radical rearrangements). The atom A is called the *migration origin*, and B is the *migration terminus*. However, there are some rearrangements which do not lend themselves to neat categorization in this manner. Among these are those with cyclic transition states (reactions **8-32** to **8-45**).

As we shall see, nucleophilic 1,2 shifts are much more common than electrophilic or free-radical 1,2 shifts. The reason for this can be seen by a consideration of the transition states (or in some cases intermediates) involved. We represent the transition state or intermediate for all three cases by **1**, in which the two-electron A—W bond overlaps with the orbital on atom B, which contains zero, one, and two electrons, in the cases of nucleophilic, free-radical, and electrophilic migration, respectively.



1



Nucleophilic Free radical Electrophilic

The overlap of these orbitals gives rise to three new orbitals, which have an energy relationship similar to those on p. 53 (one bonding and two degenerate antibonding orbitals). In a nucleophilic migration, where only two electrons are involved, both can go into the bonding orbital, and **1** is a low-energy transition state; but in a free-radical or electrophilic migration, there are, respectively, three or four electrons which must be accommodated, and antibonding orbitals must be occupied. It is not surprising therefore that, when 1,2 electrophilic or free-radical shifts are found, the migrating group W is usually aryl or some other group which can accommodate the extra one or two electrons and thus effectively remove them from the three-membered transition state or intermediate (see **37** on p. 976).

In any rearrangement we may in principle distinguish between two possible modes of reaction: In one of these the group W becomes completely detached from A and may end up on the

---

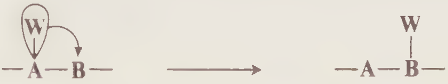
[1] For monographs, see Stevens and Watts, "Selected Molecular Rearrangements," Van Nostrand Reinhold Company, London, 1973; Mayo, "Molecular Rearrangements," 2 vols., Interscience Publishers, New York, 1963. For a review of many of these rearrangements, see Collins and Eastham, in Patai, "The Chemistry of the Carbonyl Group," vol. 1, pp. 761–821, Interscience Publishers, New York, 1966. See also the series *Mechanisms of Molecular Migrations*.

B-atom of a different molecule (*intermolecular* rearrangement), and in the other W goes from A to B in the *same* molecule (*intramolecular* rearrangement), in which case there must be some continuing tie holding W to the A—B system, preventing it from coming completely free. Strictly speaking, only the intramolecular type fits our definition of a rearrangement, but the general practice, which is followed here, is to include under the title "rearrangement" all net rearrangements whether they are inter- or intramolecular. It is usually not difficult to tell whether a given rearrangement is intramolecular or not. The most common method involves the use of *crossover* experiments. In this type of experiment, rearrangement is carried out on a mixture of W—A—B and V—A—C, where V is closely related to W (say, methyl versus ethyl) and B to C. In an intramolecular process only A—B—W and A—C—V are recovered, but if the reaction is intermolecular, then not only will these two be found, but also A—B—V and A—C—W.

MECHANISMS

Nucleophilic Rearrangements[2]

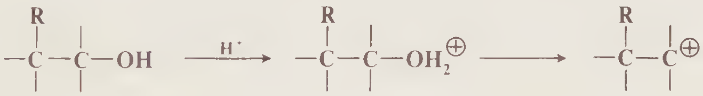
Broadly speaking, such rearrangements consist of three steps, of which the actual migration is the second:



$$\overset{W}{-A-B-} \longrightarrow -A-\overset{\overset{W}{|}}{B}-$$

This process is sometimes called the Whitmore 1,2 shift.[3] Since the migrating group carries the electron pair with it, the migration terminus B must be an atom with only six electrons in its outer shell (an open sextet). The first step therefore is creation of a system with an open sextet. Such a system can arise in various ways, but two of these are the most important:

1. *Formation of a carbonium ion.* Carbonium ions can be formed in a number of ways (see p. 159), but one of the most common methods when a rearrangement is desired is the acid treatment of an alcohol:

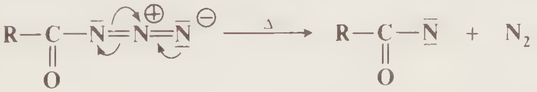


$$-\underset{|}{\overset{\overset{R}{|}}{C}}-\underset{|}{\overset{|}{C}}-OH \xrightarrow{H^+} -\underset{|}{\overset{\overset{R}{|}}{C}}-\underset{|}{\overset{|}{C}}-OH_2^{\oplus} \longrightarrow -\underset{|}{\overset{\overset{R}{|}}{C}}-\underset{|}{\overset{|}{C}}^{\oplus}$$

2

These two steps are of course the same as the first two steps of the SN1cA or the E1 reactions of alcohols.

2. *Formation of a nitrene.* The decomposition of acyl azides is one of several ways in which nitrenes are formed (see p. 185):



$$R-\underset{\overset{\|}{O}}{C}-\bar{N}=\overset{\oplus}{N}=\bar{N}^{\ominus} \xrightarrow{\Delta} R-\underset{\overset{\|}{O}}{C}-\bar{N} + N_2$$

3

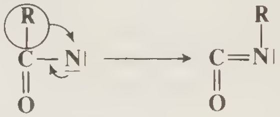
After the migration has taken place, the atom at the migration origin (A) must necessarily have an open sextet. In the third step this atom acquires an octet. In the case of carbonium ions, the most common third steps are combinations with a nucleophile (rearrangement with substitution) and loss of a hydrogen (rearrangement with elimination).

---

[2] For a review, see Wheland, "Advanced Organic Chemistry," 3d ed., pp. 550–619, John Wiley & Sons, Inc., New York, 1960.

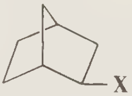
[3] It was first postulated by Whitmore, *J. Am. Chem. Soc.* **54**, 3274 (1932).

Though we have presented this mechanism as taking place in three steps, and some reactions do take place in this way, in many cases two or all three steps are actually simultaneous. For instance, in the nitrene example above, as the R migrates, an electron pair from the nitrogen moves into the C—N bond to give a stable isocyanate:



In this example, the second and third steps are simultaneous. It is also possible for the second and third steps to be simultaneous even when the "third" step involves more than just a simple motion of a pair of electrons. Similarly, there are reactions in which the first two steps are simultaneous; that is, there is no actual formation of a species such as **2** or **3**. In these instances it may be said that R assists in the removal of the leaving group, with migration of R and the removal of the leaving group taking place simultaneously. Many investigations have been carried out in attempts to determine, in various reactions, whether such intermediates as **2** or **3** actually form, or whether the steps are simultaneous (see, for example, the discussions on pp. 966, 1003), but the difference between the two possibilities is often subtle, and the question is not always easily answered.

Evidence for this mechanism is that rearrangements of this sort occur under conditions where we have previously encountered carbonium ions: SN1 conditions, Friedel-Crafts alkylation, etc. Solvolysis of neopentyl bromide leads to rearrangement products, and the rate increases with increasing ionizing power of the solvent but is unaffected by concentration of base,[4] so that the first step is carbonium-ion formation. The same compound under SN2 conditions gave no rearrangement, but only ordinary substitution, though slowly. Thus with neopentyl bromide, formation of a carbonium ion leads only to rearrangement. Carbonium ions usually rearrange to more stable carbonium ions. Thus the direction of rearrangement is usually primary → secondary → tertiary. Neopentyl (Me_3CCH_2), neophyl ($PhCMe_2CH_2$), and norbornyl (e.g., **4**) type systems are especially prone to carbonium-ion rearrangement reactions.



4

We have previously mentioned (p. 152) that stable tertiary carbonium ions can be obtained, in solution, at very low temperatures. Nmr studies have shown that when these solutions are warmed, rapid migrations of hydride and of alkyl groups take place, resulting in an equilibrium mixture of structures.[5] For example, the *t*-pentyl cation (**5**)[6] equilibrates as follows:[7]

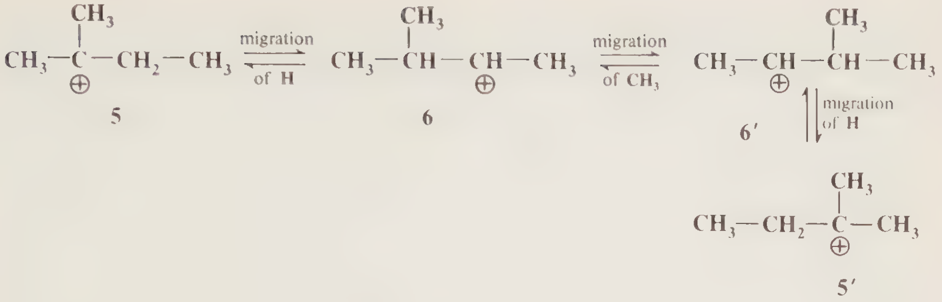
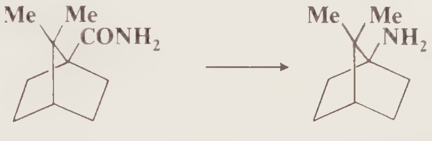
[7] Carbonium ions which rearrange to give products of identical structure (e.g., **5** ⇌ **5′**, **6** ⇌ **6′**, or **89** or **90** on p. 302) are called *degenerate carbonium ions*. Many examples are known. For reviews, see Leone, Barborak, and Schleyer, in Olah and Schleyer, Ref. 5, vol. 4, pp. 1837–1939 (1973); Leone and Schleyer, *Angew. Chem. Int. Ed. Engl.* **9**, 860–890 (1970) [*Angew. Chem.* **82**, 889–919].



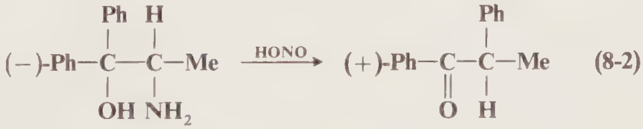
The Actual Nature of the Migration

Most nucleophilic 1,2 shifts are intramolecular: W does not become free but always remains connected in some way to the substrate. Apart from the evidence from crossover experiments, the strongest evidence is that, when the group W is chiral, the configuration is *retained* in the product. For example (+)-PhCHMeCOOH was converted to (−)-PhCHMeNH_2 by the Curtius (**8-18**), Hofmann (**8-17**), Lossen (**8-19**), and Schmidt (**8-20**) reactions.[8] In these reactions the extent of retention varied from 95.8 to 99.6%. Retention of configuration in the migrating group has been shown many times since.[9] Another experiment demonstrating retention was the easy conversion of **7** to **8**.[10]



7 **8**

Neither inversion nor racemization could take place at a bridgehead. There is much other evidence that retention of configuration usually occurs in W, and inversion never.[11] However, this is not the state of affairs at A and B. In many reactions, of course, the structure of W—A—B is such that the product has only one steric possibility at A or B or both, and in most of these cases nothing can be learned. But in cases where the steric nature of A or B can be investigated, the results are mixed. It has been shown that either inversion or racemization can occur at A or B. Thus the following conversion proceeded with inversion at B:[12]



$$(-)\text{-Ph}-\underset{\text{OH}}{\overset{\text{Ph}}{\text{C}}}-\underset{\text{NH}_2}{\overset{\text{H}}{\text{C}}}-\text{Me} \xrightarrow{\text{HONO}} (+)\text{-Ph}-\underset{\text{O}}{\overset{\text{Ph}}{\overset{\|}{\text{C}}}}-\underset{\text{H}}{\text{C}}-\text{Me} \qquad (8\text{-}2)$$

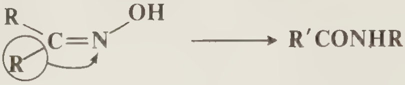
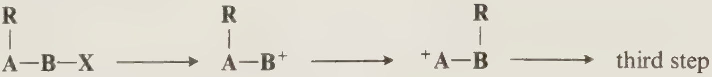
[12] Bernstein and Whitmore, *J. Am. Chem. Soc.* **61,** 1324 (1939).

and inversion at A has been shown in other cases.[13] However, in many other cases, racemization occurs at A or B or both.[14] It is not always necessary for the product to have two steric possibilities in order to investigate the stereochemistry at A or B. Thus, in most Beckmann rearrangements (reaction **8-21**), only the group trans (usually called *anti*) to the hydroxyl group migrates:



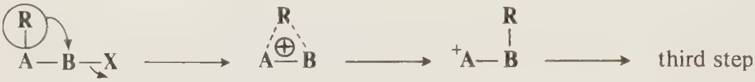
showing inversion at B, though no optical activity is involved.

This information tells us about the degree of concertedness of the three steps of the rearrangement. First we shall look at the migration terminus B. If racemization is found at B, then it is probable that the first step takes place before the second, and that a carbonium-ion carbon (or other sextet atom) is present at B:



$$\begin{array}{l}R\\|\\A{-}B{-}X\end{array} \longrightarrow \begin{array}{l}R\\|\\A{-}B^+\end{array} \longrightarrow \begin{array}{r}R\\|\\{}^+A{-}B\end{array} \longrightarrow \text{third step}$$

With respect to B this is an SN1-type process. If inversion occurs at B, then it is likely that the first two steps are concerted, that a carbonium ion is *not* an intermediate, and that the process is SN2-like:



9

In this case participation by R assists in removal of X in the same way that neighboring groups do (p. 279). Indeed, R *is* a neighboring group here, and the only difference is that, in the case of the neighboring-group mechanism of nucleophilic substitution, R never becomes detached from A, while in a rearrangement the bond between R and A is broken. In either case, the anchimeric assistance results in an increased rate of reaction. Of course, for such a process to take place, R must be in a favorable geometrical position (R and X anti-periplanar; see for example, p. 329). **9** may be a true intermediate or only a transition state, depending on what migrates. In certain cases of the SN1-type process, it is possible for migration to take place with net retention of configuration at the migrating terminus because of conformational effects in the carbonium ion.[15]

Cram[11] presents a full discussion of these points, but we summarize a few conclusions here:

1. The SN1-type process occurs mostly when B is a tertiary atom or has one aryl group and at least one other alkyl or aryl group. In other cases, the SN2-type process is more likely. Inversion of configuration (which indicates an SN2-type process) has been shown for a neopentyl substrate by the use of the chiral neopentyl-1-*d* alcohol.[16] On the other hand, there is other evidence that neopentyl systems undergo rearrangement by a carbonium-ion (SN1-type) mechanism.[17]

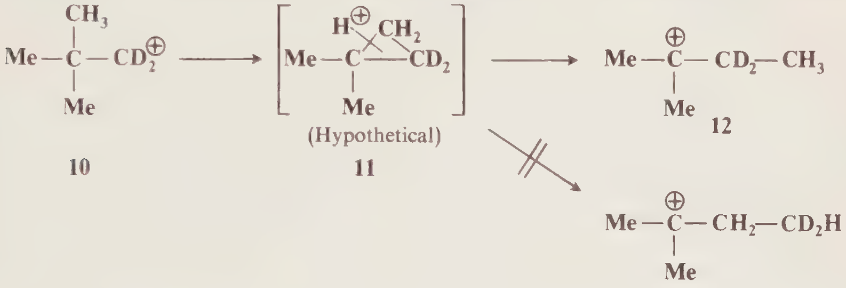
2. The question as to whether **9** is an intermediate or a transition state has been much debated. When R is aryl or vinyl, then **9** is probably an intermediate, and the migrating group lends anchimeric assistance[18] (see p. 293 for resonance stabilization of this intermediate when R is aryl). When R is alkyl, **9** is a protonated cyclopropane (edge- or corner-protonated; see p. 693). There is much evidence that in simple migrations of a methyl group, the bulk of the products formed do not arise from protonated cyclopropane *intermediates*. Evidence for this statement has already been given (p. 300). Further evidence was obtained from experiments involving labeling. Rearrangement of the neopentyl cation labeled with deuterium in the 1 position (**10**) gave only *t*-pentyl products with the label in the 3 position (derived from **12**), though if **11** were an intermediate, the cyclopropane ring could just as well cleave the other way to give *t*-pentyl derivatives labeled in the 4 position (derived from **13**).[19]



10 **11** **12** **13**

Another experiment which led to the same conclusion was the generation, in several ways, of $Me_3C^{13}CH_2^+$. In this case the only *t*-pentyl products isolated were labeled in C-3, that is, $Me_2\overset{\oplus}{C}-{}^{13}CH_2CH_3$ derivatives; no derivatives of $Me_2\overset{\oplus}{C}-CH_2{}^{13}CH_3$ were found.[20] Though the bulk of the products are not formed from protonated cyclopropane intermediates, there is considerable evidence that at least in 1-propyl systems, a small part of the product can in fact arise from such intermediates.[21] Among this evidence is the isolation of 10 to 15% cyclopropanes (mentioned on p. 300). Additional evidence comes from propyl cations generated by diazotization of labeled amines ($CH_3CD_2CH_2^+$, $CH_3CH_2CD_2^+$, $CH_3CH_2{}^{14}CH_2^+$), where isotopic distribution in the products indicated that a small amount (about 5%) of the product had to be formed from protonated cyclopropane intermediates, e.g.,[22]

$$CH_3CH_2CD_2NH_2 \xrightarrow{HONO} \sim 1\%\ C_2H_4D-CHD-OH$$

$$CH_3CD_2CH_2NH_2 \xrightarrow{HONO} \sim 1\%\ C_2H_4D-CHD-OH$$

$$CH_3CH_2{}^{14}CH_2NH_2 \xrightarrow{HONO} \sim 2\%\ {}^{14}CH_3CH_2CH_2OH + \sim 2\%\ CH_3{}^{14}CH_2CH_2OH$$

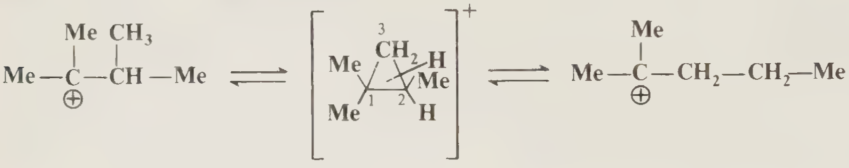
Even more scrambling was found in trifluoroacetolysis of 1-propyl-1-^{14}C-mercuric perchlorate.[23] However, protonated cyclopropane intermediates accounted for less than 1% of the products from diazotization of labeled isobutylamine[24] and from formolysis of labeled 1-propyl tosylate.[25]

It is likely that protonated cyclopropane transition states or intermediates are also responsible for certain non-1,2 rearrangements. For example, in super-acid solution, the dimethylisopropylcarbonium ion (**14**) is in equilibrium with the dimethyl-*n*-propylcarbonium ion (**16**). It is not

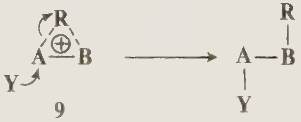


14 **15** **16**

possible for these to interconvert solely by 1,2 alkyl or hydride shifts unless primary carbonium ions (which are highly unlikely) are intermediates. However, the reaction can be explained[26] by postulating that (in the forward reaction) it is the 1,2 bond of the intermediate or transition state **15** that opens up rather than the 2,3 bond, which is the one which would open if the reaction were a normal 1,2 shift of a methyl group. In this case opening of the 1,2 bond produces a tertiary cation, while opening of the 2,3 bond would give a secondary cation. (In the reaction **16** → **14**, it is of course the 1,3 bond which opens.)

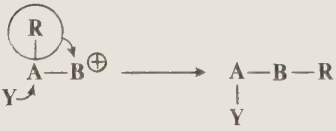
3. There has been much discussion of H as migrating group. There is no conclusive evidence for the viewpoint that **9** in this case is a true intermediate or that it is not, though both positions have been argued (see p. 301).

The stereochemistry at the migration origin A is less often involved, since in most cases it does not end up as a tetrahedral atom; but when there is inversion here, there is an SN2-type process at the beginning of the migration. This may or may not be accompanied by an SN2 process at the migration terminus B:



9

inversion at A and B



inversion at A only

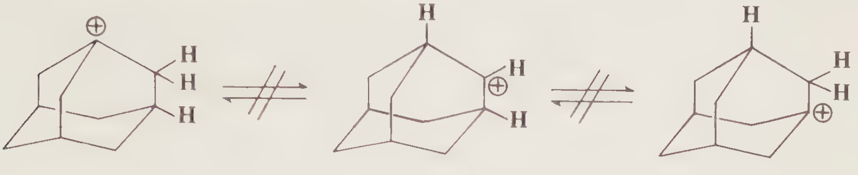
In some cases it has been found that, when H is the migrating species, the configuration at A may be *retained*.[27]

There is evidence that the configuration of the molecule may be important even where the leaving group is gone long before migration takes place. For example, the 1-adamantyl cation (**17**) does not equilibrate intramolecularly even at temperatures up to 130°C,[28] though open-chain (e.g., $\mathbf{5} \rightleftharpoons \mathbf{5'}$) and cyclic tertiary carbonium ions undergo such equilibration at 0°C or below. On the basis of this and other evidence it has been concluded that for a 1,2 shift of hydrogen or methyl to proceed as smoothly as possible, the vacant *p* orbital of the carbon bearing the positive charge and the sp^3 orbital carrying the migrating group must be coplanar,[28] which is not possible for **17**.



17 **17′**

Migratory Aptitudes[29]

In many reactions there is no question about which group migrates. For example, in the Hofmann, Curtius, and similar reactions there is only one possible migrating group in each molecule, and one can measure migratory aptitudes only by comparing the relative rearrangement rates of different compounds. In other instances there are two or more potential migrating groups, but which migrates is settled by the geometry of the molecule. The Beckmann rearrangement (reaction **8-21**) provides an example. As we have seen, only the group trans to the OH migrates. In compounds whose geometry is not restricted in this manner, there still may be eclipsing effects (see p. 902), so that the choice of migrating group is largely determined by which group is in the right place in the most stable conformation of the molecule.[30] However, in some reactions, especially the Wagner-Meerwein (**8-1**) and the pinacol (**8-2**) rearrangements, the molecule may contain several groups which, geometrically at least, have approximately equal chances of migrating, and these reactions have often been used for the direct study of relative migratory aptitudes. In the pinacol rearrangement there is the additional question of which OH group leaves and which does not, since a group can migrate only if the OH group on *the other* carbon is lost.

We deal with the second question first. To study this question, the best type of substrate to use is one of the form  $\underset{\mathrm{OH}}{R_2\overset{|}{C}}-\underset{\mathrm{OH}}{\overset{|}{C}R'_2}$, since the only thing that determines migratory aptitude is which OH group comes off. Once the OH group is gone, the migrating group is determined. As might be expected, the OH which leaves is the one whose loss gives rise to the more stable carbonium ion. Thus 1,1-diphenylethanediol (**18**) gives diphenylacetaldehyde (**19**) and not phenylacetophenone

---

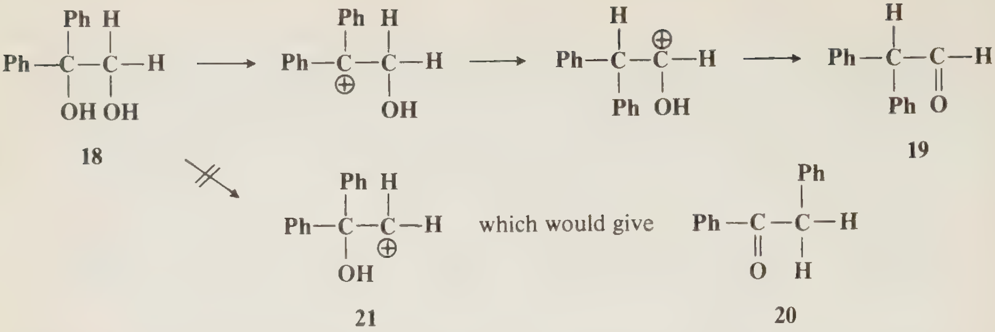
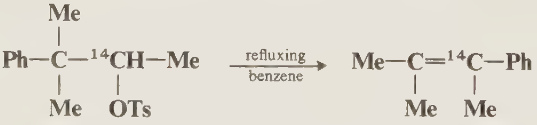
[29] For a discussion, see Ref. 2, pp. 573–597.

[30] For a discussion, see Cram, Ref. 11, pp. 270–276. For an interesting example, see Nickon and Weglein, *J. Am. Chem. Soc.* **97,** 1271 (1975).



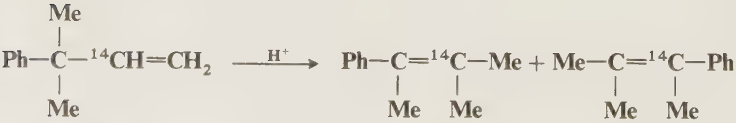
(**20**). Obviously, it does not matter in this case whether phenyl has a greater inherent migratory aptitude than hydrogen or not. Only the hydrogen can migrate because **21** is not formed. As we have already seen, carbonium-ion stability is enhanced by groups in the order aryl > alkyl > hydrogen, and this normally determines which side loses the OH group. However, exceptions are known, and which group is lost may depend on the reaction conditions (for an example, see the reaction of **43**, p. 983).

In order to answer the question about inherent migratory aptitudes, the obvious type of substrate to use (in the pinacol rearrangement) is $\mathrm{RR'\underset{OH}{C}{-}\underset{OH}{C}RR'}$, since the same carbonium ion is formed no matter which OH leaves, and it would seem that a direct comparison of the migratory tendencies of R and R′ is possible. On closer inspection, however, we can see that several factors are operating. Apart from the question of possible conformational effects, already mentioned, there is also the fact that whether the group R or R′ migrates is determined not only by the relative inherent migrating abilities of R and R′ but also by whether the group which does *not* migrate is better at stabilizing the positive charge which will now be found at the migration origin.[31] Thus, migration of R gives rise to the cation $\mathrm{R'\overset{\oplus}{C}(OH)CR_2R'}$, while migration of R′ gives the cation $\mathrm{R\overset{\oplus}{C}(OH)CRR'_2}$, and these cations have different stabilities. It is possible that in a given case R might be found to migrate less than R′ not because it actually has a lower inherent migrating tendency, but because it is much better at stabilizing the positive charge. In addition to this factor, migrating ability of a group is also related to its capacity to render anchimeric assistance to the departure of the nucleofuge. An example of this effect is the finding that in the decomposition of the tosylate **22** only the phenyl group migrates, while in acid treatment of the



$$\mathrm{Ph{-}\overset{\displaystyle Me}{\underset{\displaystyle Me}{C}}{-}\underset{\displaystyle OTs}{^{14}CH}{-}Me} \xrightarrow[\text{benzene}]{\text{refluxing}} \mathrm{Me{-}\underset{\displaystyle Me}{C}{=}\underset{\displaystyle Me}{^{14}C}{-}Ph}$$

22



$$\mathrm{Ph{-}\overset{\displaystyle Me}{\underset{\displaystyle Me}{C}}{-}{^{14}CH}{=}CH_2} \xrightarrow{\mathrm{H^+}} \mathrm{Ph{-}\underset{\displaystyle Me}{C}{=}\underset{\displaystyle Me}{^{14}C}{-}Me} + \mathrm{Me{-}\underset{\displaystyle Me}{C}{=}\underset{\displaystyle Me}{^{14}C}{-}Ph}$$

23

---

[31] For example, see Howells and Warren, *J. Chem. Soc., Perkin Trans. 2* 1645 (1973); McCall, Townsend, and Bonner, *J. Am. Chem. Soc.* **97**, 2743 (1975).

corresponding alkene **23**, there is competitive migration of both methyl and phenyl (in these reactions ^{14}C labeling is necessary to determine which group has migrated).[32] Both **22** and **23** give the same carbonium ion, and the differing results must be caused by the fact that in **22** the phenyl group can assist the leaving group, while no such process is possible for **23**. This example clearly illustrates the difference between migration to a relatively free carbonium-ion terminus and one that proceeds with the migrating group lending anchimeric assistance.

It is not surprising therefore that clear-cut answers as to relative migrating tendencies are not available. More often than not migratory aptitudes are in the order aryl > alkyl, but exceptions are known, and the position of hydrogen in this series is often unpredictable. In some cases migration of hydrogen is preferred to aryl migration; in other cases migration of alkyl is preferred to that of hydrogen. Mixtures are often found, and the isomer which predominates often depends on conditions. For example, the comparison between methyl and ethyl has been made many times in various systems, and in some cases methyl migration and in others ethyl migration has been found to predominate.[33] However, it can be said that among aryl migrating groups, electron-donating substituents in the para and meta positions increase the migratory aptitudes, while the same substituents in the ortho positions decrease them. Electron-withdrawing groups decrease migrating ability in all positions. The following are a few of the relative migratory aptitudes determined for aryl groups by Bachmann and Ferguson:[34] *p*-anisyl, 500; *p*-tolyl, 15.7; *m*-tolyl, 1.95; phenyl, 1.00; *p*-chlorophenyl, 0.7; *o*-anisyl, 0.3. For the *o*-anisyl group, the poor migrating ability probably has a steric cause, while for the others there is a fair correlation with activation or deactivation of electrophilic aromatic substitution, which is what the process is, with respect to the benzene ring.

Memory Effects[35]

Solvolysis of the endo bicyclic compound **24** (X = ONs[36] or Br) gave mostly the bicyclic allylic alcohol **27**, along with a smaller amount of the tricyclic alcohol **31**; while solvolysis of the exo

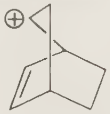
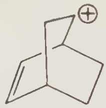
isomers **28** gave mostly **31,** with smaller amounts of **27.**[37] Thus the two isomers gave entirely different ratios of products, though the carbonium ion initially formed (**25** or **29**) seems to be the same for each. In the case of **25,** a second rearrangement (a shift of the 1,7 bond) follows, while with **29** it is an intramolecular addition of the carbonium-ion carbon to the double bond which follows. It seems as if **25** and **29** "remember" how they were formed before they go on to give the second step. Such effects are called *memory effects,* and other such cases are also known.[38] The causes of these effects are not well understood, though there has been much discussion. One possible cause is differential solvation of the apparently identical ions **25** and **29.** Other possibilities are: (1) that the ions have geometrical structures which are twisted in opposite senses (e.g., a twisted **29** might have its positive carbon closer to the double bond than a twisted **25**); (2) that ion pairing is responsible;[38a] and (3) that nonclassical carbonium ions are involved.[39] One possibility that has been ruled out is that the steps **24** → **25** → **26** and **28** → **29** → **30** are concerted, so that **25** and **29** never exist at all. This possibility has been excluded by several kinds of evidence, including the fact that **24** gives not only **27,** but also some **31;** and **28** gives not only **31,** but also some **28.** This means that some of the **25** and **29** ions interconvert, a phenomenon known as *leakage.*



Twisted **29**



Twisted **25**

Longer Nucleophilic Rearrangements

The question as to whether a group can migrate with its electron pair from A to C in W—A—B—C or over longer distances has been much debated. Although claims have been made that alkyl groups can migrate in this way,[40] the evidence is that such migration is extremely rare, if it occurs at all. One experiment which demonstrated this was the generation of the 3,3-dimethyl-1-butyl cation $Me_3CCH_2CH_2^+$. If 1,3 methyl migrations are possible, this cation would appear to be a favorable substrate for them, since such a migration would convert a primary cation into the tertiary 2-methyl-2-pentyl cation $Me_2\overset{\oplus}{C}CH_2CH_2CH_3$, while the only possible 1,2 migration (of hydride) would give only a secondary cation. However, no products arising from the 2-methyl-2-pentyl cation were found, the only rearranged products being those formed by the 1,2 hydride migration.[41] 1,3 Migration of bromine (but not chlorine) has been reported.[42]

However, most of the debate over the possibility of 1,3 migrations has concerned not methyl or bromine but 1,3 hydride shifts.[43] There is no doubt that *apparent* 1,3 hydride shifts take place

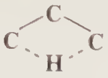
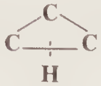
[43] For reviews, see Fry and Karabatsos, in Olah and Schleyer, Ref. 5, vol. 2, pp. 527–566; Reutov, *Pure Appl. Chem.* **7,** 203–227 (1963).

(many instances have been found), but the question is whether they are truly direct hydride shifts or whether they occur by another mechanism. There are at least two ways in which indirect 1,3 hydride shifts can take place: (1) by successive 1,2 shifts or (2) through the intervention of protonated cyclopropanes (see p. 968). A direct 1,3 shift would have the transition state **A**, while the transition state for a 1,3 shift involving a protonated cyclopropane intermediate would resemble

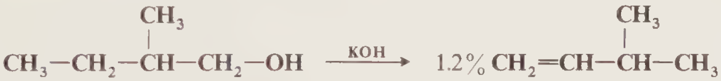


A



B

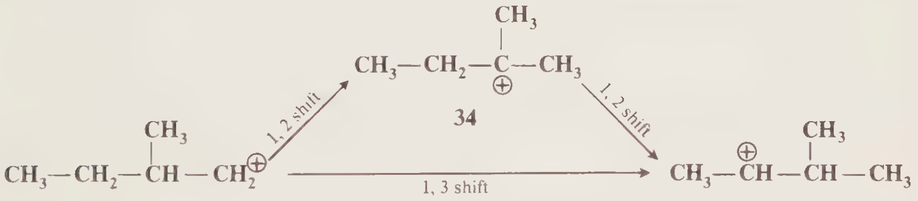
B. The evidence is that most reported 1,3 hydride shifts are actually the result of successive 1,2 migrations,[44] but that in some cases small amounts of products cannot be accounted for in this way. For example, the reaction of 2-methyl-1-butanol with KOH and bromoform gave a mixture of olefins, nearly all of which could have arisen from simple elimination or 1,2 shifts of hydride or alkyl. However, 1.2% of the product was 3-methyl-1-butene (**32**):[45]



$$CH_3{-}CH_2{-}\overset{\displaystyle CH_3}{\overset{|}{C}H}{-}CH_2{-}OH \xrightarrow{KOH} 1.2\%\ CH_2{=}CH{-}\overset{\displaystyle CH_3}{\overset{|}{C}H}{-}CH_3$$

32

Hypothetically, **32** could have arisen from a 1,3 shift (direct or through a protonated cyclopropane) or from two successive 1,2 shifts:



33 **35**

However, the same reaction applied to 2-methyl-2-butanol gave no **32**, which demonstrated that **35** was not formed from **34**. The conclusion was thus made that **35** was formed directly from **33**. This experiment does not answer the question as to whether **35** was formed by a direct shift or through a protonated cyclopropane, but from other evidence[46] it appears that 1,3 hydride shifts that do not result from successive 1,2 migrations usually take place through protonated cyclopropane intermediates (which, as we saw on p. 967, account for only a small percentage of the product in any case). However, there is evidence that direct 1,3 hydride shifts by way of **A** may take place in super-acid solutions.[47]

---

[44] For example, see Bundel', Levina, Krzhizhevskii, and Reutov, *Doklad. Chem.* **181,** 583 (1968); Bundel', Levina, Prokhorenko, and Reutov, *Doklad. Chem.* **188,** 732 (1969); Fărcaşiu, Kascheres, and Schwartz, *J. Am. Chem. Soc.* **94,** 180 (1972).

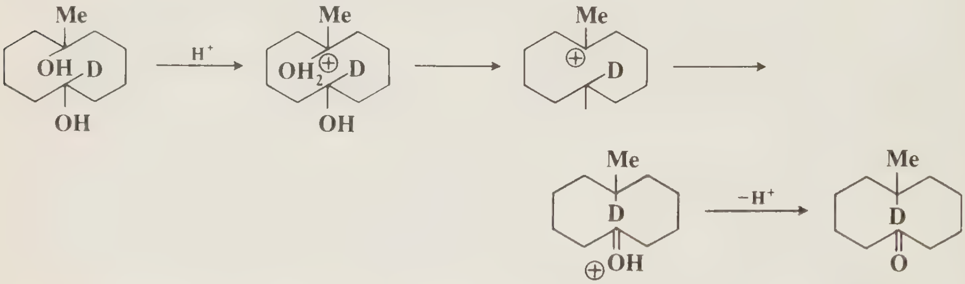
[46] For example, see Brouwer and van Doorn, *Recl. Trav. Chim. Pays-Bas* **88,** 573 (1969); Dupuy, Goldsmith, and Hudson, *J. Chem. Soc., Perkin Trans. 2* 74 (1973); Hudson, Koplick, and Poulton, *Tetrahedron Lett.* 1449 (1975); Fry and Karabatsos, Ref. 43.

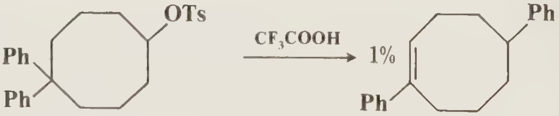
[47] Saunders and Stofko, *J. Am. Chem. Soc.* **95,** 252 (1973).

Even longer hydride shifts have been reported. $CH_3(CH_2)_5CH{=}CH_2$, when treated with peroxytrifluoroacetic acid (reaction **5-39**), gave mostly the unrearranged product, 1,2-octanediol. But small amounts of the 1,3-, 1,4-, 1,5-, 1,6-, and 1,7-diols were also obtained.[48] These products could have arisen from successive 1,2 shifts, but the ratio of the yields obtained makes it unlikely. It has been reported that the ion $Me_2CHCH_2CH_2\overset{\oplus}{C}HOH$ undergoes a 1,4 hydride shift to give the ion $Me_2\overset{\oplus}{C}CH_2CH_2CH_2OH$.[49]

Although direct nucleophilic rearrangements over distances greater than 1,2 are rare (or perhaps nonexistent) when the migrating atom or group must move along a chain, this is not so for a shift across a ring of 8 to 11 members. Many such transannular rearrangements are known.[50] Several examples are given on p. 146. We look at the mechanism of one of these:[51]

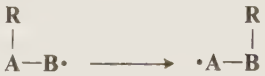


It is noteworthy that the *methyl* group does not migrate in this system. It is generally true that alkyl groups do not undergo transannular migration. In most cases it is hydride which undergoes this type of migration, though a small amount of phenyl migration has also been shown:[52]



Free-Radical Rearrangements[53]

1,2-Free-radical rearrangements are much less common than the nucleophilic type previously considered, for the reasons mentioned on p. 962. Where they do occur, the general pattern is similar. There must first be generation of a free radical, and then the actual migration in which the migrating group moves with one electron:



$$\overset{\displaystyle R}{\underset{}{A}}\!-\!B\cdot \longrightarrow \cdot A\!-\!\overset{\displaystyle R}{B}$$

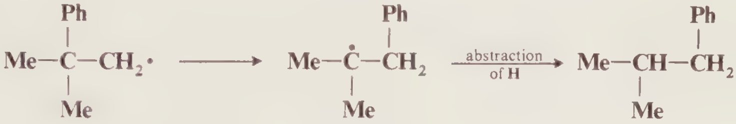
Soc.* **18**, 243–269 (1964); Pryor, "Free Radicals," pp. 266–284, McGraw-Hill Book Company, New York, 1966; Freidlina, Kost, and Khorlina, *Russ. Chem. Rev.* **31**, 1–18 (1962); Walling, in Mayo, Ref. 1, pp. 407–455.

Finally, the new free radical must stabilize itself by a further reaction. The order of radical stability leads us to predict that here too, as with carbonium-ion rearrangements, any migrations should be in the order primary → secondary → tertiary, and that the logical place to look for them should be in neopentyl and neophyl systems. The most common way of generating free radicals for the purpose of detection of rearrangements is by decarbonylation of aldehydes (reaction **4-41**). In this manner it was found that neophyl radicals *do* undergo rearrangement. Thus, $PhCMe_2CH_2CHO$ treated with di-*t*-butyl peroxide gave about equal amounts of the normal product $PhCMe_2CH_3$ and the product arising from migration of phenyl:[54]



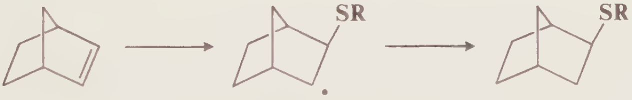
$$\mathrm{Me{-}\overset{Ph}{\underset{Me}{C}}{-}CH_2\cdot} \longrightarrow \mathrm{Me{-}\underset{Me}{\dot{C}}{-}\overset{Ph}{CH_2}} \xrightarrow[\text{of H}]{\text{abstraction}} \mathrm{Me{-}\underset{Me}{CH}{-}\overset{Ph}{CH_2}}$$

Many other cases of aryl free-radical migration have also been found.[55]

It is noteworthy that the extent of migration is much less than with the corresponding carbonium ions: Thus in the example given there was only about 50% migration, whereas the carbonium ion would have given much more. Also noteworthy is that there was no migration of the methyl group. In general it may be said that free-radical migration of alkyl groups does not occur at ordinary temperatures. Many attempts have been made to detect such migration on the traditional neopentyl and bornyl types of substrates. However, alkyl migration is not observed,[56] even in substrates where the corresponding carbonium ions undergo facile rearrangement.[57] Another type of migration which is very common for carbonium ions, but which is not observed for free radicals, is 1,2 migration of hydrogen. We confine ourselves to a few examples of the lack of migration of alkyl groups and hydrogen:

1. 3,3-Dimethylpentanal ($EtCMe_2CH_2CHO$) gave no rearranged products on decarbonylation.[58]

2. Addition of RSH to norbornene gave only *exo*-norbornyl sulfides, though **36** is an intermediate, and the corresponding carbonium ion cannot be formed without rearrangement.[59]



36

3. It was shown[60] that no rearrangement of isobutyl radical to *t*-butyl radical (which would involve the formation of a more stable radical by a hydrogen shift) took place during the chlorination of isobutane.

[54] Winstein and Seubold, *J. Am. Chem. Soc.* **69,** 2916 (1947); Seubold, *J. Am. Chem. Soc.* **75,** 2532 (1953). For the observation of this rearrangement by esr, see Hamilton and Fischer, *Helv. Chim. Acta* **56,** 795 (1973).

[55] For example, see Curtin and Hurwitz, *J. Am. Chem. Soc.* **74,** 5381 (1952); Wilt and Philip, *J. Org. Chem.* **24,** 441 (1959), **25,** 891 (1960); Pines and Pillai, *J. Am. Chem. Soc.* **82,** 2921 (1960); Pines and Goetschel, *J. Am. Chem. Soc.* **87,** 4207 (1965); Cote and Vittimberga, *J. Am. Chem. Soc.* **93,** 276 (1971).

[56] Formal migration of alkyl has been observed, but by an elimination-addition mechanism: Berson, Olsen, and Walia, *J. Am. Chem. Soc.* **84,** 3337 (1962).

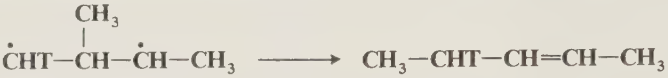
[57] For a summary of unsuccessful attempts, see Slaugh, Magoon, and Guinn, *J. Org. Chem.* **28,** 2643 (1963).

[58] Seubold, *J. Am. Chem. Soc.* **76,** 3732 (1954).

[59] Cristol and Brindell, *J. Am. Chem. Soc.* **76,** 5699 (1954).

[60] Brown and Russell, *J. Am. Chem. Soc.* **74,** 3995 (1952). See also Desai, Nechvatel, and Tedder, *J. Chem. Soc. B* 386 (1970).

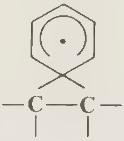
However, 1,2 migration of alkyl groups has been shown to occur in certain *diradicals*.[61] For example, the following rearrangement has been established by tritium labeling.[62]



$$\dot{C}HT-\overset{CH_3}{\overset{|}{C}H}-\dot{C}H-CH_3 \longrightarrow CH_3-CHT-CH=CH-CH_3$$

In this case the fact that migration of the methyl group leads directly to a compound in which all electrons are paired undoubtedly contributes to the driving force of the reaction.

The fact that aryl groups migrate, but generally alkyl groups and hydrogen do not, leads to the proposition that **37**, in which the odd electron is not found in the three-membered ring, may be an intermediate. There has been much controversy on this point, but the bulk of the evidence indicates that **37** is a transition state and not an intermediate. Among the evidence is the failure to observe **37** by esr,[63] a technique which can detect free radicals with extremely short lifetimes (p. 170).[64]



37

Besides aryl, vinyl,[65] and acetoxy groups[66] also migrate. Vinyl groups migrate by way of a cyclopropylcarbinyl radical intermediate,[67] while the migration of acetoxy groups involves the five-membered transition state shown.[68] In addition, migration has been observed for chloro (and to a much lesser extent bromo) groups. For example in the reaction of $Cl_3CCH=CH_2$ with bromine under the influence of peroxides, the products were 47% $Cl_3CCHBrCH_2Br$ (the normal addition product) and 53% $BrCCl_2CHClCH_2Br$, which arose by rearrangement:

Chem. Soc.* **91,** 2111 (1969); Gajewski and Burka, *J. Am. Chem. Soc.* **94,** 8857, 8860, 8865 (1972); Adam and Aponte, *J. Am. Chem. Soc.* **93,** 4300 (1971).

[63] Kochi and Krusic, *J. Am. Chem. Soc.* **91,** 3940 (1969); Edge and Kochi, *J. Am. Chem. Soc.* **94,** 7695 (1972).

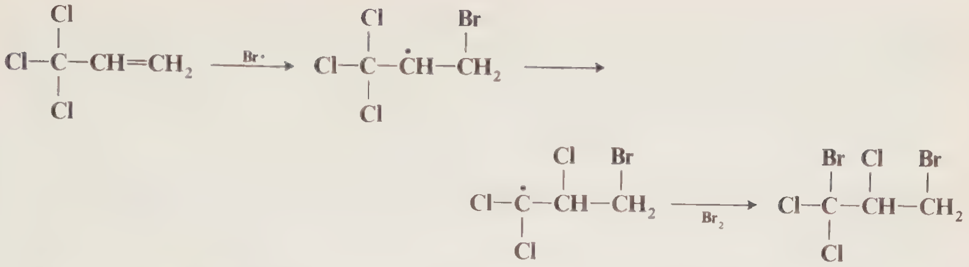
[64] For other evidence, see Martin, *J. Am. Chem. Soc.* **84,** 1986 (1962); Rüchardt and Hecht, *Tetrahedron Lett.* 957 (1962), *Chem. Ber.* **98,** 2460, 2471 (1965); Rüchardt and Trautwein, *Chem. Ber.* **98,** 2478 (1965).

[65] For example, see Slaugh, Mullineaux, and Raley, *J. Am. Chem. Soc.* **85,** 3180 (1963); Slaugh *J. Am. Chem. Soc.* **87,** 1522 (1965).

[66] Surzur and Teissier, *C. R. Acad. Sci., Ser. C* **264,** 1981 (1967); *Bull. Soc. Chim. Fr.* 3060 (1970); Tanner and Law, *J. Am. Chem. Soc.* **91,** 7535 (1969); Julia and Lorne, *C. R. Acad. Sci., Ser. C* **273,** 174 (1971); Lewis, Miller, and Winstein, *J. Org. Chem.* **37,** 1478 (1972).

[67] For evidence for this species, see Montgomery, Matt, and Webster, *J. Am. Chem. Soc.* **89,** 923 (1967); Montgomery and Matt, *J. Am. Chem. Soc.* **89,** 934, 6556 (1967).

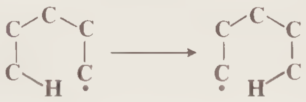
[68] Beckwith and Tindal, *Aust. J. Chem.* **24,** 2099 (1971); Beckwith and Thomas, *J. Chem. Soc., Perkin Trans. 2* 861 (1973).



In this particular case the driving force for the rearrangement is the particular stability of dichloroalkyl free radicals. Nesmeyanov, Freidlina, and coworkers have extensively studied reactions of this sort.[69] It has been shown that the 1,2 migration of Cl readily occurs if the migration origin is tertiary and the migration terminus primary.[70] Migration of Cl and Br could take place by a transition state in which the odd electron is accommodated in a vacant *d* orbital of the halogen.

In summary then, 1,2 free-radical migrations are less prevalent than the analogous carbonium-ion processes and are important only for aryl, vinyl, acetoxy, and halogen migrating groups. The direction of migration is normally toward the more stable radical, but "wrong-way" rearrangements are also known.[71]

Despite the fact that hydrogen atoms do not migrate 1,2, longer free-radical migrations of hydrogen are known. The most common are 1,5 shifts, but 1,6 and longer shifts have also been found. The possibility of 1,3 hydrogen shifts has been much investigated, but it is not certain if any actually occur. If they do they are rare, presumably because the most favorable geometry for C---H---C in the transition state is linear, and this geometry cannot be achieved in a 1,3 shift. 1,4 shifts are definitely known, but still not very common. These long shifts may be regarded as internal abstractions of hydrogen (for reactions involving them, see **4-7** and **8-46**):



Transannular shifts of hydrogen atoms have also been observed.[72] A few shifts longer than 1,2 have been noted for aryl, but not for alkyl or halogen groups.

Electrophilic Rearrangements[73]

Rearrangements in which a group migrates without its electrons are much rarer than the two kinds previously considered, but the general principles are the same. There is first created a carbanion (or other negative ion), and the actual rearrangement step involves migration of a group without its electrons:

---

[69] For reviews, see Nesmeyanov, Freidlina, Kost, and Khorlina, *Tetrahedron* **16,** 94–105 (1961); Freidlina, Kost, and Khorlina, Ref. 53, pp. 6–11; Freidlina, Ref. 53, pp. 231–249.

[70] See for example, Skell, Pavlis, Lewis, and Shea, *J. Am. Chem. Soc.* **95,** 6735 (1973); Chen, Tang, Montgomery, and Kochi, *J. Am. Chem. Soc.* **96,** 2201 (1974).

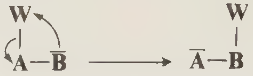
[73] For reviews, see Jensen and Rickborn, "Electrophilic Substitution of Organomercurials," pp. 21–30, McGraw-Hill Book Company, New York, 1968; Cram, "Fundamentals of Carbanion Chemistry," pp. 223–243, Academic Press, Inc., New York, 1965.



The product of the rearrangement may be stable or may react further, depending on its nature (see also pp. 982–983).

REACTIONS

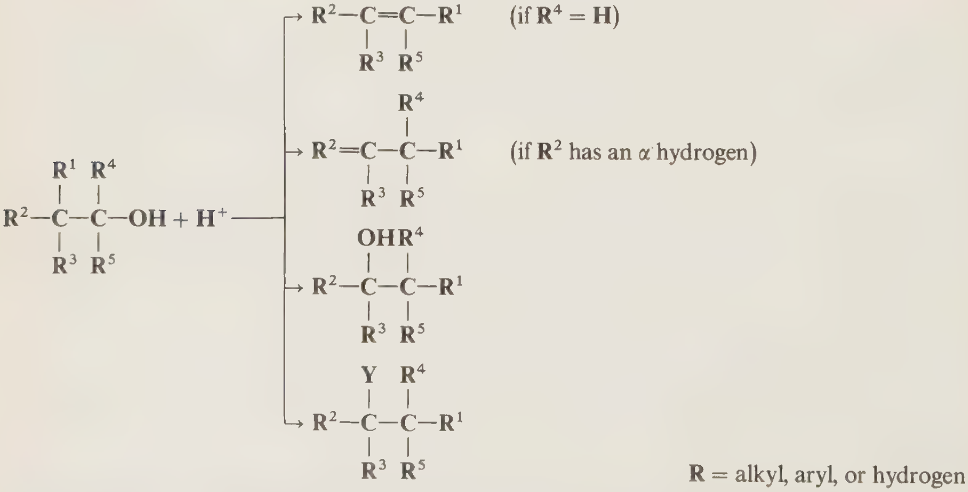
The reactions in this chapter are classified into three main groups. 1,2 Shifts are considered first. Within this group, reactions are classified according to (1) the identity of the substrate atoms A and B and (2) the nature of the migrating group W. In the second group are the cyclic rearrangements. The third group consists of rearrangements which cannot be fitted into either of the first two categories.

Reactions in which the migration terminus is on an aromatic ring have been treated under aromatic substitution. These are reactions **1-34** to **1-40**, **1-44**, **3-26** to **3-29**, and, partially, **1-41**, **1-47**, and **1-48**. Double-bond shifts have also been treated in other chapters, though they may be considered rearrangements (p. 303, p. 528, and reaction **2-2**). Two other reactions which may be regarded as rearrangements are the Willgerodt reaction (**9-76**) and the decomposition of tertiary hypochlorites (**4-42**).

1,2 Rearrangements

A. Carbon-to-Carbon Migrations of R, H, and Ar

8-1 Wagner-Meerwein and Related Reactions

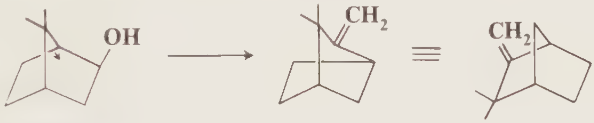


When alcohols are treated with acids, simple substitution (e.g., reaction **0-67**) or elimination (reaction **7-1**) usually accounts for most or all of the products. But in many cases, especially where two or three alkyl or aryl groups are on the β-carbon, some or all of the product is rearranged.

These rearrangements are called *Wagner-Meerwein rearrangements*.[74] As pointed out previously (p. 963), the carbonium ion which is a direct product of the rearrangement must stabilize itself, and most often it does this by the loss of a hydrogen β to it, so that the rearrangement product is usually an olefin. The proton lost may be R^4 (if this is a hydrogen) or an α-proton from R^2 (if it has one). If there is a choice of protons, Zaitsev's rule (p. 910) governs the direction, as we might expect. Sometimes a different positive group is lost instead of a proton.[75] Less often, the new carbonium ion stabilizes itself by combining with a nucleophile instead of losing a proton. The nucleophile may be the water which is the original leaving group, so that the product is a rearranged alcohol, or it may be some other species present, which we have called Y. Rearrangement is usually predominant in neopentyl and neophyl types of substrates, and with these types normal nucleophilic substitution is difficult (normal elimination is of course impossible). Under SN2 conditions substitution is extremely slow,[76] and under SN1 conditions carbonium ions are formed which rapidly rearrange. However, free-radical substitution, unaccompanied by rearrangement, can be carried out on neopentyl systems, though, as we have seen (p. 975), neophyl systems undergo rearrangement as well as substitution.

Wagner-Meerwein rearrangements were first discovered in the bicyclic terpenes, and most of the early development of this reaction was with these compounds.[77] For this reason they are often illustrated with an example from the terpenes, e.g.,

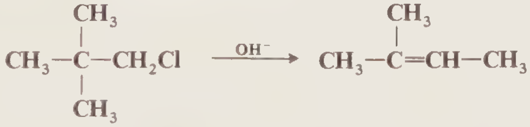
Example *a*



Isoborneol Camphene

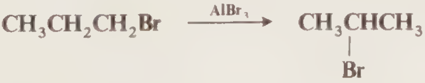
However, they may be illustrated in simpler systems:

Example *b*



$$CH_3-\underset{CH_3}{\overset{CH_3}{C}}-CH_2Cl \xrightarrow{OH^-} CH_3-\overset{CH_3}{C}=CH-CH_3$$

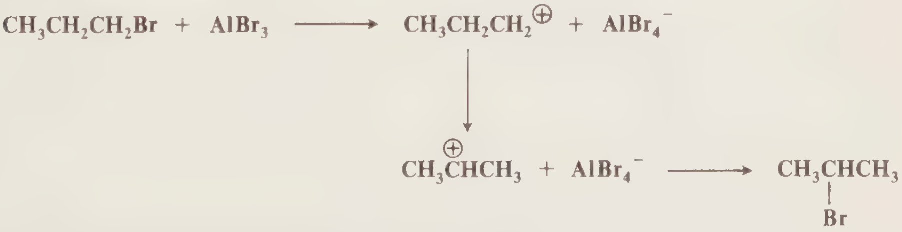
Example *c*



$$CH_3CH_2CH_2Br \xrightarrow{AlBr_3} CH_3\underset{Br}{CH}CH_3$$

These examples illustrate the following points:

1. Hydride ion may migrate. In example *c*, it was hydride that shifted, and not bromide:



$$CH_3CH_2CH_2Br + AlBr_3 \longrightarrow CH_3CH_2CH_2^{\oplus} + AlBr_4^-$$

$$\downarrow$$

$$CH_3\overset{\oplus}{C}HCH_3 + AlBr_4^- \longrightarrow CH_3\underset{Br}{CH}CH_3$$

---

[74] For a review, see Pocker, in Mayo, Ref. 1, vol. 1, pp. 6–15.

[75] For example, see Grob, Hoegerle, and Ohta, *Helv. Chim. Acta* **45**, 1823 (1962).

[76] See however, Chapter 10, Ref. 228.

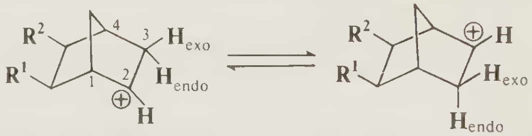
[77] For a review of rearrangements of bicyclic systems, see Berson, in Mayo, Ref. 1, pp. 111-231. For reviews of the Wagner-Meerwein rearrangement applied to natural products, see Mayo, Ref. 1, as follows: King and Mayo, pp. 813–840 (terpenes); Warnhoff, pp. 842–879 (alkaloids); Wendler, pp. 1020–1028 (steroids). For a review concerning pinanes, see Banthorpe and Whittaker, *Q. Rev., Chem. Soc.* **20**, 373–387 (1966).

2. The leaving group does not have to be H_2O, but it may be any departing species whose loss creates a carbonium ion, including N_2 from aliphatic diazonium ions[78] (see the section on leaving groups in nucleophilic substitution, p. 325). Also rearrangement may follow when the carbonium ion is created by addition of a proton or other positive species to a double bond. Even alkanes give rearrangements when heated with Lewis acids, provided there is some species present initially to form a carbonium ion from the alkane.

3. Example *c* illustrates that the last step may be substitution instead of elimination.

4. Example *b* illustrates that the new double bond is formed in accord with Zaitsev's rule.

2-Norbornyl cations, besides displaying the 1,2 shifts of a CH_2 group previously illustrated for the isoborneol → camphene conversion, are also prone to rapid hydride shifts from the 3 to the 2 position (known as 3,2 shifts). These 3,2 shifts usually take place from the exo side;[79] that is, the 3-exo hydrogen migrates to the 2-exo position.[80] This stereoselectivity is analogous to the behavior we have previously seen for norbornyl systems, namely, that nucleophiles attack norbornyl cations from the exo side (p. 295), and that addition to norbornenes is also usually from the exo direction (p. 690).



The direction of rearrangement is usually in the direction of the most stable carbonium ion (or free radical), which is tertiary > secondary > primary, but rearrangements in the other direction have also been found, and often the product is a mixture corresponding to an equilibrium mixture of the possible carbonium ions. The favored direction may be counter to carbonium-ion stability if the new carbonium ion can stabilize itself more easily than the original one.

The term "Wagner-Meerwein rearrangement" is not precise. Some use it to refer to all the rearrangements in this section and in **8-2.** Others use it only when an alcohol is converted to a rearranged olefin. Terpene chemists call the migration of a methyl group the *Nametkin rearrangement*. The term *retropinacol rearrangement* is often applied to some or all of these. Fortunately, this disparity in nomenclature does not seem to cause much confusion.

Sometimes several of these rearrangements occur in one molecule either simultaneously or in rapid succession. A spectacular example is found in the triterpene series. Friedelin is a triterpenoid

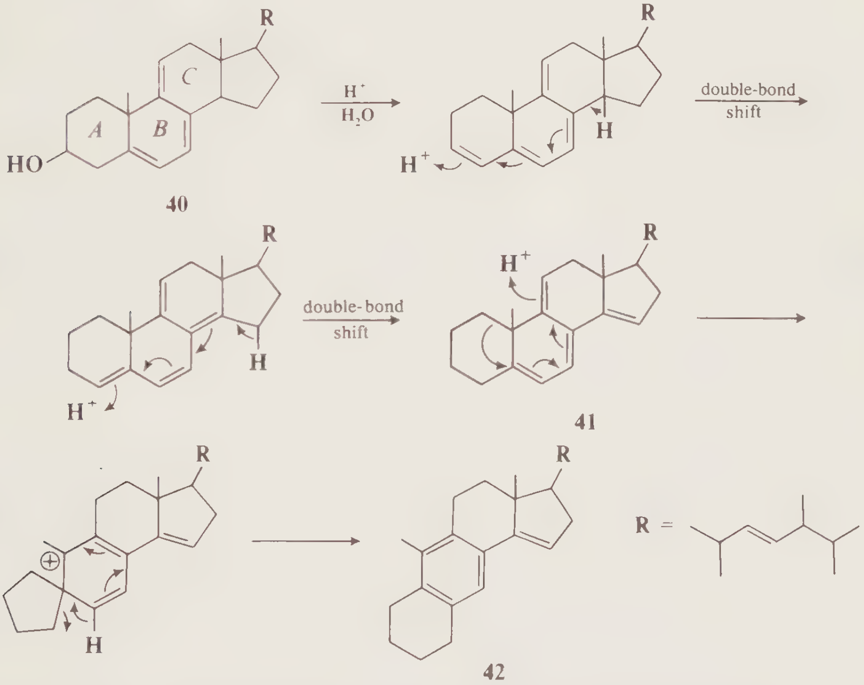
[79] For example, see Kleinfelter and Schleyer, *J. Am. Chem. Soc.* **83,** 2329 (1961); Collins, Cheema, Werth, and Benjamin, *J. Am. Chem. Soc.* **86,** 4913 (1964); Berson, Hammons, McRowe, Bergman, Remanick, and Houston, *J. Am. Chem. Soc.* **89,** 2590 (1967).

[80] For examples of 3,2 endo shifts, see Bushell and Wilder, *J. Am. Chem. Soc.* **89,** 5721 (1967); Wilder and Hsieh, *J. Org. Chem.* **36,** 2552 (1971).

ketone found in cork. Reduction gives 3β-friedelanol (**38**). When this compound is treated with acid, 13(18)-oleanene (**39**) is formed.[81] In this case *seven* 1,2 shifts take place. On removal of H_2O from position 3 to leave a positive charge, the following shifts occur: hydride from 4 to 3; methyl from 5 to 4; hydride from 10 to 5; methyl from 9 to 10; hydride from 8 to 9; methyl from 14 to 8; and methyl from 13 to 14. This leaves a positive charge at position 13, which is stabilized by loss of the proton at the 18 position to give the 13(18)-ene. Until the elimination, each time a positive charge is formed, migration of a hydride or a methyl moves in to fill it, leaving another positive charge, which must be filled in its turn. All these shifts are stereospecific, the group always migrating on the side of the ring system on which it is located; that is, a group above the "plane" of the ring system (indicated by a solid line in **39**) moves above the plane, and a group below the plane (dashed line) moves below it. It is probable that the seven shifts are not all concerted, though some of them may be, for intermediate products can be isolated.[82] As an illustration of point 2 (p. 980), it may be mentioned that friedelene, derived from dehydration of **38**, also gives **39** on treatment with acid.[83]

An interesting Wagner-Meerwein rearrangement is found in the steroid series. The *A-B-C* rings of a steroid are changed from an angular (phenanthrene-like) arrangement to a linear (anthracene-like) one. This is called the *anthrasteroid rearrangement*, and it may be illustrated for dehydroergosterol (**40**):



The product is anthraergostapentaene (**42**). The intermediate **41** has been isolated.

It was mentioned above that even alkanes undergo Wagner-Meerwein rearrangements if treated with Lewis acids and a small amount of initiator. An interesting application of this reaction is the conversion of tricyclic molecules to adamantane and its derivatives.[84] It has been found that *all* tricyclic alkanes containing 10 carbons are converted to adamantane by treatment with a Lewis acid such as $AlCl_3$. If the substrate contains more than 10 carbons, alkyl-substituted adamantanes are produced. Some examples are

Diamantane

If 14 or more carbons are present, the product may be diamantane or a substituted diamantane.[85] These reactions are successful because of the high thermodynamic stability of adamantane, diamantane, and similar diamond-like molecules. Best yields are obtained by the use of "sludge" catalysts[86] (i.e., a mixture of AlX_3 and *t*-butyl bromide or *sec*-butyl bromide) or by passing the substrate in the gas phase through a tube containing a chlorinated platinum-alumina catalyst.[87] Though it is certain that these adamantane-forming reactions take place by nucleophilic 1,2 shifts, the exact pathways are not easy to unravel because of their complexity.[88] Treatment of adamantane-2-^{14}C with $AlCl_3$ results in total carbon scrambling on a statistical basis.[89]

As already indicated, the mechanism of the Wagner-Meerwein rearrangement is usually nucleophilic. Free-radical rearrangements are also known (see the mechanism section of this chapter), though virtually only with aryl migration. However, carbanion mechanisms (electrophilic) have also been found.[73] Thus Ph_3CCH_2Cl treated with sodium gave Ph_2CHCH_2Ph along with unrearranged products.[90] The intermediate is $Ph_3C\bar{C}H_2^{\ominus}$, and the phenyl moves without its electron pair. There is evidence that the reaction involves a tight ion pair.[91] Only aryl and not alkyl groups migrate by the electrophilic mechanism (p. 962), and a transition state analogous to **37** is likely.[92] An apparently similar migration of a benzyl group has been shown not to be an electrophilic migration, but to proceed through an elimination-addition mechanism.[93]

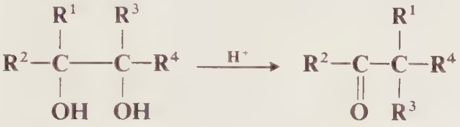
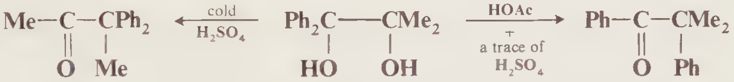
8-2 The Pinacol Rearrangement



$$\mathrm{R^2{-}\underset{\underset{\displaystyle OH}{|}}{\overset{\overset{\displaystyle R^1}{|}}{C}}{-}\underset{\underset{\displaystyle OH}{|}}{\overset{\overset{\displaystyle R^3}{|}}{C}}{-}R^4} \xrightarrow{H^+} \mathrm{R^2{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}\underset{\underset{\displaystyle R^3}{|}}{\overset{\overset{\displaystyle R^1}{|}}{C}}{-}R^4}$$

R = alkyl, aryl, or hydrogen

When *vic*-diols are treated with acids, they can be rearranged to give aldehydes or ketones, though elimination without rearrangement can also be accomplished. This reaction is called the *pinacol*, or the *pinacol-pinacolone rearrangement;* the reaction gets its name from the typical compound pinacol $Me_2COHCOHMe_2$, which is rearranged to pinacolone Me_3CCOCH_3.[94] The reaction has been accomplished many times, with alkyl, aryl, and hydrogen as migrating groups. In most cases each carbon has at least one alkyl or aryl group, and the reaction is most often carried out with tri- and tetrasubstituted glycols. As mentioned earlier, glycols in which the four R groups are not identical can give rise to more than one product, depending on which group migrates (see p. 969 for a discussion of migratory aptitudes). Mixtures are often produced, and which group preferentially migrates may depend on the reaction conditions as well as on the nature of the substrate. Thus the action of cold, concentrated sulfuric acid on **43** produces mainly the ketone **44** (methyl



$$\underset{\mathbf{44}}{\mathrm{Me{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}\underset{\underset{\displaystyle Me}{|}}{C}Ph_2}} \xleftarrow[\mathrm{H_2SO_4}]{\text{cold}} \underset{\mathbf{43}}{\mathrm{Ph_2\underset{\underset{\displaystyle HO}{|}}{C}{-}\underset{\underset{\displaystyle OH}{|}}{C}Me_2}} \xrightarrow[\substack{\text{a trace of}\\ \mathrm{H_2SO_4}}]{\mathrm{HOAc}\ +} \underset{\mathbf{45}}{\mathrm{Ph{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}\underset{\underset{\displaystyle Ph}{|}}{C}Me_2}}$$

44 **43** **45**

migration), while treatment of **43** with acetic acid containing a trace of sulfuric acid gives mostly **45** (phenyl migration).[95] If at least one R group is hydrogen, then aldehydes can be produced as well as ketones. Generally, aldehyde formation is favored by the use of mild conditions (lower temperatures, weaker acids), because under more drastic conditions the aldehydes may be converted to ketones (reaction **8-4**).

The mechanism involves a simple Whitmore 1,2 shift. The ion **46** (where all four R groups are Me) has been trapped by the addition of tetrahydrothiophene.[96] It may seem odd that a migration

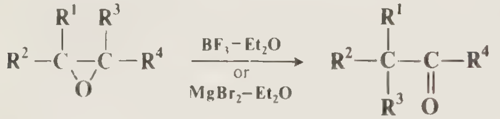
46

takes place when the positive charge is already at a tertiary position, but carbonium ions stabilized by an oxygen atom are even more stable than tertiary alkyl cations (p. 156). There is also the driving force supplied by the fact that the new carbonium ion can immediately stabilize itself by losing a proton.

It is obvious that other compounds in which a positive charge can be placed on a carbon α to one bearing an OH group can also give this rearrangement. This is true for β-amino alcohols, which rearrange on treatment with nitrous acid (this is called the *semipinacol* rearrangement), iodohydrins, for which the reagent is mercuric oxide or silver nitrate, and allylic alcohols, which can rearrange on treatment with a strong acid which protonates the double bond. A similar rearrangement is given by epoxides, when treated with acidic[97] reagents such as BF_3-etherate or $MgBr_2$-etherate, or sometimes by heat alone.[98] It has been shown that epoxides are intermediates



R = alkyl, aryl, or hydrogen

in the pinacol rearrangements of certain glycols.[99] Among the evidence for the mechanism given is that $Me_2COHCOHMe_2$, $Me_2COHCNH_2Me_2$, and $Me_2COHCClMe_2$ gave the reaction at different rates (as expected) but yielded the *same mixture* of two products—pinacol and pinacolone—indicating a common intermediate.[100]

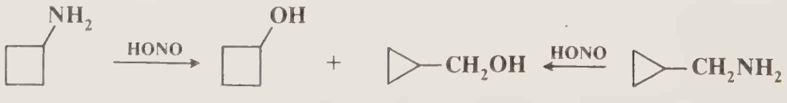
8-3 Expansion and Contraction of Rings



When a positive charge is formed on an alicyclic carbon, migration of an alkyl group can take place to give ring contraction, producing a ring which is one carbon smaller than the original.

Note that this change involves conversion of a secondary to a primary carbonium ion. In a similar manner, when a positive charge is placed on a carbon α to an alicyclic ring, ring expansion can take place.[101] The new carbonium ion, and the old one, may then give products by combination with a nucleophile (e.g., the alcohols shown above), or by elimination, so that this reaction is really a special case of reaction **8-1.** Often, both rearranged and unrearranged products are formed, so that, for example, cyclobutylamine and cyclopropylmethylamine give similar mixtures of the two alcohols shown above on treatment with nitrous acid (a small amount of 3-buten-1-ol is also produced). When the carbonium ion is formed by diazotization of the amine, the reaction is called the *Demyanov rearrangement*,[102] but of course similar products are formed when the carbonium ion is generated in other ways. The expansion reaction has been performed on rings of C_3 to C_8,[103] but yields are best with the smaller rings, where relief of small-angle strain provides a driving force for the reaction. The contraction reaction has been applied to four-membered rings, and to rings of C_6 to C_8, but contraction of a cyclopentyl cation to a cyclobutylmethyl system is generally not feasible because of the additional strain involved. Strain is apparently much less of a factor in the cyclobutyl-cyclopropylmethyl interconversion (for a discussion of this interconversion, see p. 298).

---

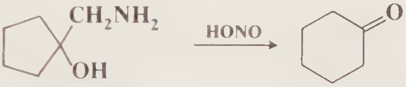
[97] Epoxides can also be rearranged with basic catalysts, though the products are usually different. For a review, see Yandovskii and Ershov, *Russ. Chem. Rev.* **41,** 403-410 (1972).

[98] For a review, see Parker and Isaacs, *Chem. Rev.* **59,** 737-799 (1959), pp. 772-778.

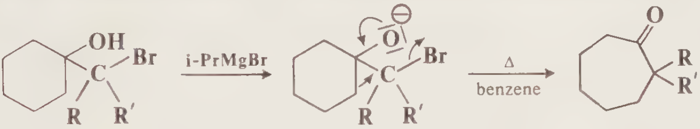
[99] See for example, Matsumoto, *Tetrahedron* **24,** 6851 (1968); Pocker and Ronald, *J. Am. Chem. Soc.* **92,** 3385 (1970), *J. Org. Chem.* **35,** 3362 (1970); Tamura and Moriyoshi, *Bull. Chem. Soc. Jpn.* **47,** 2942 (1974).

[100] Pocker, *Chem. Ind.* (*London*) 332 (1959).

Ring expansions of certain hydroxyamines, e.g.,

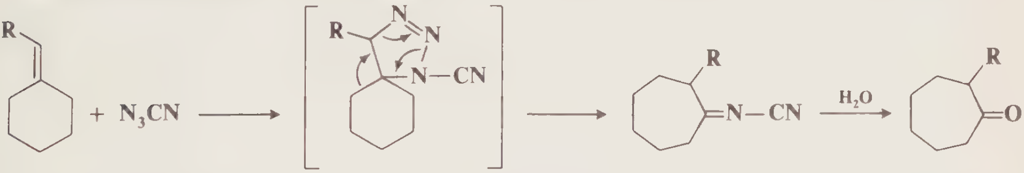


are analogous to the semipinacol rearrangement (**8-2**). This reaction is called the *Tiffeneu-Demyanov ring expansion.* These have been performed on rings of C_4 to C_8, and the yields are better than for the simple Demyanov ring expansion. A similar reaction has been used to expand rings of from five to eight members.[104] In this case, a cyclic bromohydrin of the form **47** is



47 **48**

treated with a Grignard reagent which, acting as a base, removes the OH proton to give the alkoxide **48.** Refluxing of **48** brings about the ring enlargement. The reaction has been accomplished for **47** in which at least one R group is phenyl or methyl,[105] but fails when both R groups are hydrogen.[106] A related ring expansion involves treatment of an exocyclic olefin (which



---

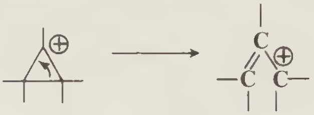
[105] Sisti, *J. Org. Chem.* **35,** 2670 (1970), *Tetrahedron Lett.* 3305 (1970); Sisti and Meyers, *J. Org. Chem.* **38,** 4431 (1973); Sisti and Rusch, *J. Org. Chem.* **39,** 1182 (1974).

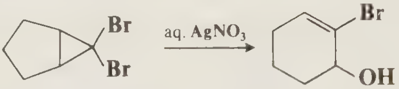
[106] Sisti, *J. Org. Chem.* **33,** 3953 (1968).

can be prepared by reaction **6-47**) with cyanogen azide.[107] The azide adds to the double bond in a 1,3 dipolar addition (**5-50**) to give a triazolidine intermediate which undergoes ring expansion. The cyanamide product is easily hydrolyzed to a cyclic ketone.

A positive charge generated on a three-membered ring gives "contraction" to an allylic cation.



We have previously seen (p. 321) that this is the reason nucleophilic substitutions are not feasible at a cyclopropyl substrate. The reaction is often used to convert cyclopropyl halides and tosylates to allylic products, especially for the purpose of ring expansion, an example being[108]



The stereochemistry of these cyclopropyl cleavages is governed by the principle of orbital symmetry conservation (for a discussion, see p. 1034).

Three-membered rings can also be cleaved to unsaturated products in at least two other ways. (1) On pyrolysis, cyclopropanes may undergo "contraction" to propenes.[109] In the simplest case, cyclopropane gives propene when heated to 400 to 500°C. The mechanism is generally regarded[110] as involving a diradical intermediate[111] (recall that free-radical 1,2 migration is possible for diradicals, p. 976). (2) The generation of a carbene or carbenoid carbon in a three-membered ring can lead to allenes, and allenes are often prepared in this way.[112] In contrast, the generation of a carbene or carbenoid at a cyclopropylmethyl carbon gives ring expansion.[113]

[108] Skell and Sandler, *J. Am. Chem. Soc.* **80,** 2024 (1958).

[109] For reviews, see Bergman, in Kochi, Ref. 53, vol. 1, pp. 191–237; Frey, *Adv. Phys. Org. Chem.* **4,** 147–193 (1966), pp. 148–170; Breslow, in Mayo, Ref. 1, pp. 234–245.

[110] For evidence that diradical intermediates may not be involved, at least in some cases, see Fields, Haszeldine, and Peter, *Chem. Commun.* 1081 (1967); Parry and Robinson, *Chem. Commun.* 1083 (1967); Holbrook and Parry, *J. Chem. Soc. B* 1019 (1970); Clifford and Holbrook, *J. Chem. Soc., Perkin Trans. 2* 1972 (1972); Baldwin and Grayston, *J. Am. Chem. Soc.* **96,** 1629, 1630 (1974).

[111] We have seen before that such diradicals can close up to give cyclopropanes (reaction **7-48**). Therefore, pyrolysis of cyclopropanes can produce not only propenes but also isomerized (cis → trans or optically active → inactive) cyclopropanes. See for example Berson and Balquist, *J. Am. Chem. Soc.* **90,** 7343 (1968); Carter and Bergman, *J. Am. Chem. Soc.* **90,** 7344 (1968); Bergman and Carter, *J. Am. Chem. Soc.* **91,** 7411 (1969).

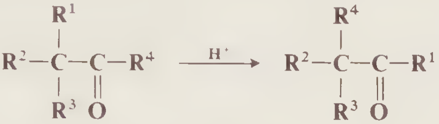
[112] For a review, see Kirmse, "Carbene Chemistry," 2d ed., pp. 462–467, Academic Press, Inc., New York, 1971.

[113] For a review, see Gutsche and Redmore, Ref. 101, pp. 111–117.

Formation of cyclobutenes also takes place when cyclopropylmethyl bromides and tosylates are treated with *t*-BuOK in dimethyl sulfoxide, but in this case the mechanism does not involve a carbene or carbenoid pathway.[114]

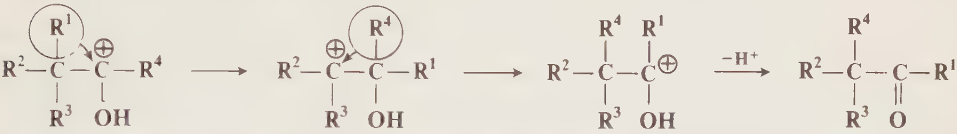
OS **III,** 276; **IV,** 221, 957; **V,** 306, 320; **51,** 60.

8-4 Acid-catalyzed Rearrangements of Aldehydes and Ketones

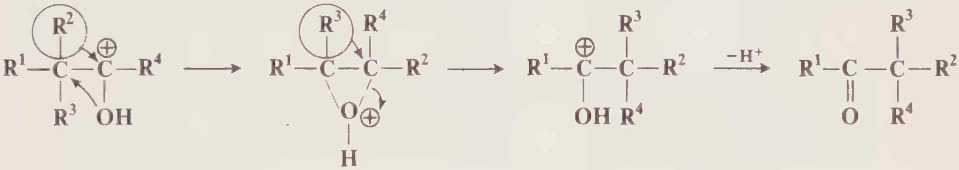


$$R^2-\underset{R^3}{\overset{R^1}{\overset{|}{\underset{|}{C}}}}-\underset{O}{\underset{\|}{C}}-R^4 \xrightarrow{H^+} R^2-\underset{R^3}{\overset{R^4}{\overset{|}{\underset{|}{C}}}}-\underset{O}{\underset{\|}{C}}-R^1$$

Rearrangements of this type, where a group α to a carbonyl "changes places" with a group attached to the carbonyl carbon, occur when migratory aptitudes are favorable.[115] R^2, R^3, and R^4 may be alkyl or hydrogen. Aldehydes have been converted to ketones, and ketones to other ketones (though more drastic conditions are required for the latter), but no rearrangement of a ketone to an aldehyde ($R^1 = H$) has so far been reported. There are two mechanisms,[116] each beginning with protonation of the oxygen and each involving two migrations. In one mechanism the migrations are in opposite directions:[117]



In the other pathway the migrations are in the same direction. The actual mechanism of this pathway is not certain, but an epoxide (protonated) intermediate[118] is one possibility:[119]



If the reaction is carried out with ketone labeled in the C=O group with ^{14}C, then the first pathway predicts that the product will contain all the ^{14}C in the C=O carbon, while in the second pathway the label will be in the α-carbon (demonstrating migration of oxygen). The results of such experiments[120] have shown that in some cases only the C=O carbon was labeled, in other cases only the α-carbon, while in still others both carbons bore the label, indicating that in these cases both pathways were in operation. With α-hydroxy aldehydes and ketones, the process may stop after only one migration (this is called the *α-ketol rearrangement*).

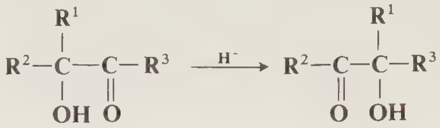
[118] Zook, Smith, and Greene, *J. Am. Chem. Soc.* **79,** 4436 (1957).

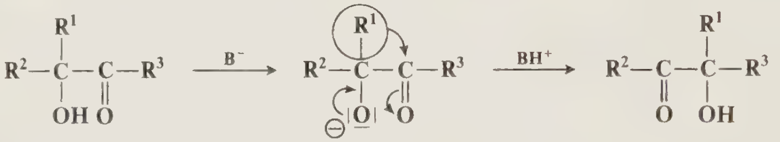
[119] Some such pathway is necessary to account for the migration of oxygen which is found. It may involve a protonated epoxide, a 1,2-diol, or simply a 1,2 shift of an OH group.

[120] See for example, Barton and Porter, *J. Chem. Soc.* 2483 (1956); Fry, Carrick, and Adams, *J. Am. Chem. Soc.* **80,** 4743 (1958); Fry and Corkern, *J. Am. Chem. Soc.* **89,** 5894 (1967); Oka and Fry, *J. Org. Chem.* **35,** 2801 (1970); Remizova and Zalesskaya, *J. Gen. Chem. USSR* **34,** 1398 (1964); Zalesskaya and Remizova, *J. Gen. Chem. USSR* **35,** 29 (1965).

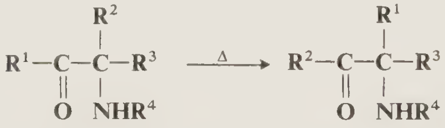


$$R^2-\underset{\displaystyle OH}{\overset{\displaystyle R^1}{C}}-\underset{\displaystyle \| \atop O}{C}-R^3 \xrightarrow{H^-} R^2-\underset{\displaystyle \| \atop O}{C}-\underset{\displaystyle OH}{\overset{\displaystyle R^1}{C}}-R^3$$

The α-ketol rearrangement can also be brought about by base catalysis, but only if the alcohol is tertiary, since if R^1 or R^2 = hydrogen, enolization of the substrate is more favored than rearrangement.



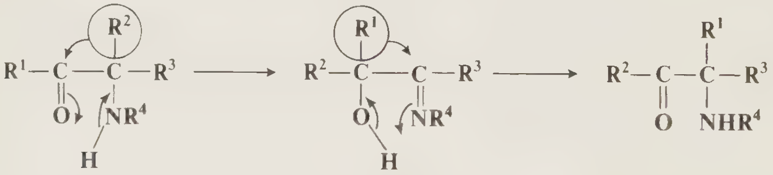
8-5 Thermal Rearrangement of Amino Ketones



$$R^1-\underset{\displaystyle \| \atop O}{C}-\underset{\displaystyle NHR^4}{\overset{\displaystyle R^2}{C}}-R^3 \xrightarrow{\Delta} R^2-\underset{\displaystyle \| \atop O}{C}-\underset{\displaystyle NHR^4}{\overset{\displaystyle R^1}{C}}-R^3$$

R = alkyl, aryl

When heated, ketones containing an α secondary amino group may undergo a rearrangement,[121] similar in appearance to reaction **8-4**, in which two R groups "change places."[122] R may be alkyl or aryl. The mechanism is different from that of reaction **8-4**, though it also involves two migrations in opposite directions. In this case the 1,2 migrations of R are accompanied by 1,4 migration of hydrogen between O and N:



49

The mechanism predicts that when heated, α-hydroxy imines (**49**) in which the OH group is tertiary should rearrange to α-amino ketones, and this has been found to be the case. The reaction has been used for ring enlargement, e.g.,[123]

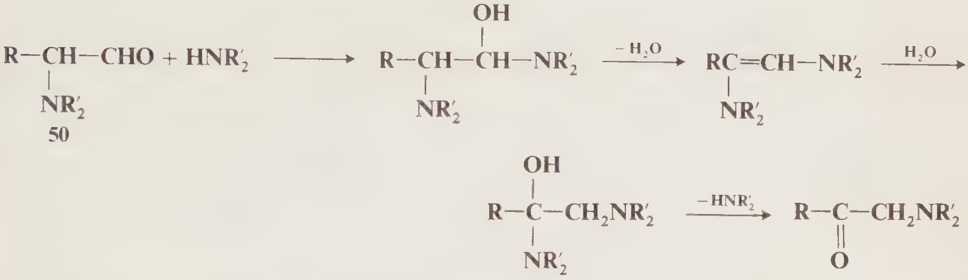
[123] Stevens, Klundt, Munk, and Pillai, *J. Org. Chem.* **30**, 2967 (1965).

Unbranched aldehydes containing an α tertiary amino group (**50**) rearrange spontaneously to α-amino ketones.[124] The mechanism is quite different from that of the ketone reaction given

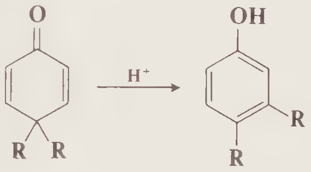


$$\underset{\substack{|\\ NR'_2}}{R-CH}-CHO + HNR'_2 \longrightarrow R-\underset{\substack{|\\ NR'_2}}{CH}-\overset{\substack{OH\\ |}}{CH}-NR'_2 \xrightarrow{-H_2O} R\underset{\substack{|\\ NR'_2}}{C}=CH-NR'_2 \xrightarrow{H_2O} R-\underset{\substack{|\\ NR'_2}}{\overset{\substack{OH\\ |}}{C}}-CH_2NR'_2 \xrightarrow{-HNR'_2} R-\underset{\substack{\|\\ O}}{C}-CH_2NR'_2$$

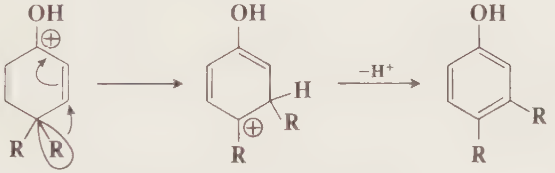
50

above and involves an elimination-addition sequence. The R'_2NH needed to initiate the reaction is probably formed by the reaction of **50** with small amounts of water present.[125]

8-6 The Dienone-Phenol Rearrangement



Compounds in which a cyclohexadienone has two alkyl groups in the 4 position undergo, on acid treatment, migration of one of these groups to a position allylic to the hydroxy group generated by protonation of the oxygen:



51 52

The driving force in the overall reaction (the *dienone-phenol rearrangement*) is of course creation of an aromatic system.[126] The anthrasteroid rearrangement (p. 981) is closely related. It may be noted that ions **51** and **52** are arenium ions (p. 454), the same as those generated by attack of an electrophile on a phenol.[127] Sometimes, in the reaction of a phenol with an electrophile, a kind of reverse rearrangement (called the *phenol-dienone rearrangement*) takes place, though without an actual migration.[128] An example is

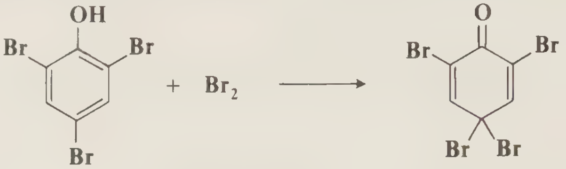
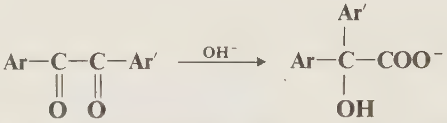
Migr.* **1**, 247–313 (1968); Shine, "Aromatic Rearrangements," pp. 55–68, American Elsevier Publishing Company, New York, 1967; Waring, *Adv. Alicyclic Chem.* **1**, 129–256 (1966), pp. 207–223. For a review of other rearrangements of cyclohexadienones, see Miller, *Acc. Chem. Res.* **8**, 245–256 (1975).

[127] For evidence that these ions are indeed intermediates in this rearrangement, see Vitullo, *J. Org. Chem.* **34**, 224 (1969), *J. Org. Chem.* **35**, 3976 (1970); Vitullo and Grossman, *J. Am. Chem. Soc.* **94**, 3844 (1972).

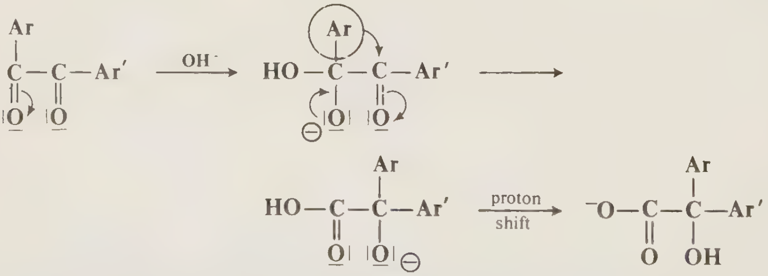


8-7 The Benzil–Benzilic Acid Rearrangement



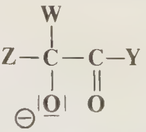
$$\text{Ar}-\underset{\substack{\|\\ \text{O}}}{\text{C}}-\underset{\substack{\|\\ \text{O}}}{\text{C}}-\text{Ar}' \xrightarrow{\text{OH}^-} \text{Ar}-\overset{\substack{\text{Ar}'\\ |}}{\underset{\substack{|\\ \text{OH}}}{\text{C}}}-\text{COO}^-$$

When treated with base, α-diketones rearrange to give the salts of α-hydroxy acids, a reaction known as the *benzil-benzilic acid rearrangement* (benzil is PhCOCOPh; benzilic acid is $Ph_2COHCOOH$).[129] Though the reaction is usually illustrated with aryl groups, it can also be applied to aliphatic diketones and to α-keto aldehydes. The use of alkoxide ion instead of OH^- gives the corresponding ester directly,[130] though alkoxide ions which are readily oxidized (such as OEt^- or $OCHMe_2^-$) are not useful here since they reduce the benzil to a benzoin. Aroxide ions (OAr^-) are not strong enough bases for the reaction. The mechanism is similar to the rearrangements in reactions **8-1** to **8-4**, but there is a difference: The migrating group does not move to a carbon with an open sextet. The carbon has an octet but can still accept a group with its pair of electrons by releasing a π pair of electrons from the C=O bond to the oxygen. The first step is attack of the base at the carbonyl group, the same as the first step of the tetrahedral mechanism of nucleophilic substitution (p. 308) and of many additions to the C=O bond (Chapter 16):



The mechanism has been intensively studied, and there is much evidence for it.[129] The reaction is irreversible.

There are other related reactions in which an intermediate of the form



$$\text{Z}-\overset{\substack{\text{W}\\ |}}{\underset{\substack{|\\ \ominus|\underline{\text{O}}|}}{\text{C}}}-\underset{\substack{\|\\ \text{O}}}{\text{C}}-\text{Y}$$

53

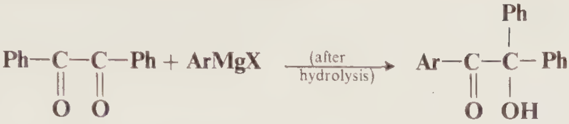
[128] For a review, see Ershov, Volod'kin, and Bogdanov, *Russ. Chem. Rev.* **32,** 75–93 (1963).

[129] For a review, see Selman and Eastham, *Q. Rev., Chem. Soc.* **14,** 221–235 (1960).

[130] Doering and Urban, *J. Am. Chem. Soc.* **78,** 5938 (1956).

is formed and then rearrangement follows. An example is

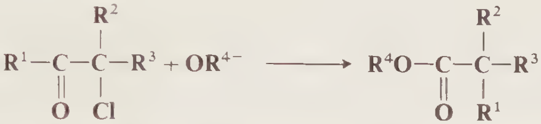


$$\text{Ph}-\underset{\underset{\displaystyle \text{O}}{\|}}{\text{C}}-\underset{\underset{\displaystyle \text{O}}{\|}}{\text{C}}-\text{Ph}+\text{ArMgX}\xrightarrow[\text{hydrolysis)}]{\text{(after}}\text{Ar}-\underset{\underset{\displaystyle \text{O}}{\|}}{\text{C}}-\underset{\underset{\displaystyle \text{OH}}{|}}{\overset{\overset{\displaystyle \text{Ph}}{|}}{\text{C}}}-\text{Ph}$$

In the intermediate **53**, for the benzilic acid rearrangement, Z = OH, W and Y = R, Ar, or H; for the benzilic ester case, Z = OR, W and Y = R or Ar; for the Grignard example shown, Z, W, and Y all = Ar. In other cases, W and Z may be ArNH, ArCO, RCO, etc., and Y may be OH, RCO, etc. The base-catalyzed α-ketol rearrangement (reaction **8-4**) also belongs to this group of reactions, with W and Z = R or Ar; Y = R, Ar, or H.

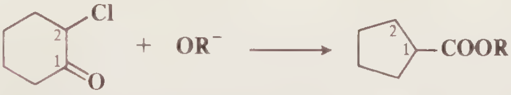
OS **I,** 89.

8-8 The Favorskii Rearrangement



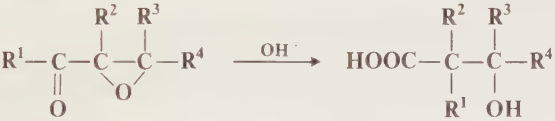
$$\text{R}^1-\underset{\underset{\displaystyle \text{O}}{\|}}{\text{C}}-\underset{\underset{\displaystyle \text{Cl}}{|}}{\overset{\overset{\displaystyle \text{R}^2}{|}}{\text{C}}}-\text{R}^3+\text{OR}^{4-}\longrightarrow \text{R}^4\text{O}-\underset{\underset{\displaystyle \text{O}}{\|}}{\text{C}}-\underset{\underset{\displaystyle \text{R}^1}{|}}{\overset{\overset{\displaystyle \text{R}^2}{|}}{\text{C}}}-\text{R}^3$$

The reaction of α-halo ketones (chloro, bromo, or iodo)[131] with alkoxide ions to give rearranged esters is called the *Favorskii rearrangement.*[132] The use of hydroxide ions or amines as bases leads to the free acid (salt) or amide, respectively, instead of the ester. Cyclic α-halo ketones give ring contraction:



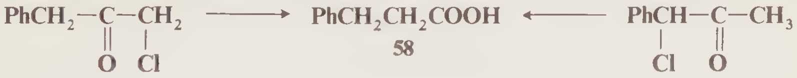
54 **55**

The reaction has also been carried out on α-hydroxy ketones[133] and on α,β-epoxy ketones:[134]



The fact that an epoxide gives a reaction analogous to a halide indicates that the oxygen and halogen are leaving groups in a nucleophilic substitution step.

Through the years the mechanism of the Favorskii rearrangement has been the subject of much investigation, and at least five different mechanisms have been proposed. However, the finding[135] that **56** and **57** *both* give **58** (this behavior is typical) shows that any mechanism where



$$\text{PhCH}_2-\underset{\underset{\displaystyle \text{O}}{\|}}{\text{C}}-\underset{\underset{\displaystyle \text{Cl}}{|}}{\text{CH}_2}\longrightarrow \text{PhCH}_2\text{CH}_2\text{COOH}\longleftarrow \text{PhCH}\underset{\underset{\displaystyle \text{Cl}}{|}}{}-\underset{\underset{\displaystyle \text{O}}{\|}}{\text{C}}-\text{CH}_3$$

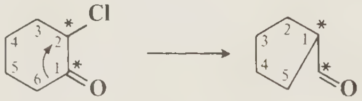
[133] Craig, Dinner, and Mulligan, *J. Org. Chem.* **37,** 3539 (1972).

[134] See for example, House and Gilmore, *J. Am. Chem. Soc.* **83,** 3972 (1961); Mouk, Patel, and Reusch, *Tetrahedron* **31,** 13 (1975).

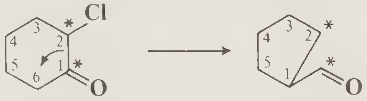
[135] McPhee and Klingsberg, *J. Am. Chem. Soc.* **66,** 1132 (1944); Bordwell, Scamehorn, and Springer, *J. Am. Chem. Soc.* **91,** 2087 (1969).

the halogen leaves and R^1 takes its place is invalid, since in such a case **56** would be expected to give **58** (with $PhCH_2$ migrating), but **57** should give PhCHMeCOOH (with CH_3 migrating). That is, in the case of **57**, it was PhCH that migrated and not methyl. Another important result was determined by radioactive labeling. **54**, in which C-1 and C-2 were equally labeled with ^{14}C, was converted to **55**. The product was found to contain 50% of the label on the carbonyl carbon, 25% on C-1, and 25% on C-2.[136] Now the carbonyl carbon, which originally carried half of the radioactivity, still had this much, so that the rearrangement did not directly affect *it*. However, if the C-6 carbon had migrated to C-2, then the other half of the radioactivity would be only on C-1 of the product:



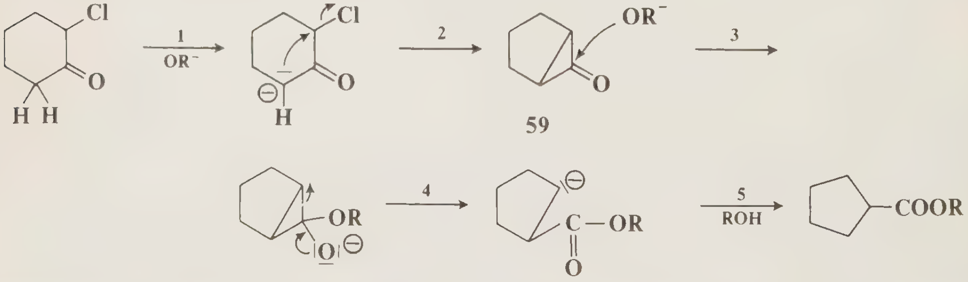
54

On the other hand, if the migration had gone the other way—if the C-2 carbon had migrated to C-6—then this half of the radioactivity would be found solely on C-2 of the product:



54

The fact that C-1 and C-2 were found to be equally labeled showed that *both migrations occurred*, and with equal probability. Since C-2 and C-6 of **54** are not equivalent, this means that there must be a symmetrical intermediate. The type of intermediate which best fits the circumstances is a cyclopropanone,[137] and the mechanism is formulated:



59

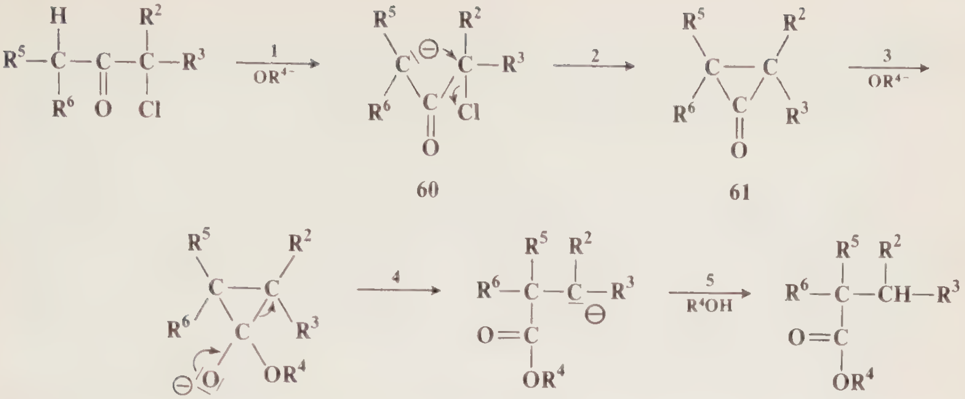
A preliminary migration of the chlorine from C-2 to C-6 was ruled out by the fact that recovered **54** had the same isotopic distribution as the starting **54**.

For the general case the mechanism is (replacing R^1 of our former symbolism with CHR^5R^6, since it is obvious that for this mechanism an α-hydrogen is required on the nonhalogenated side of the carbonyl):

---

[136] Loftfield, *J. Am. Chem. Soc.* **73**, 4707 (1951).

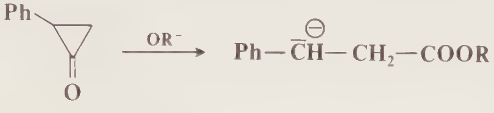
[137] Although cyclopropanones are very reactive compounds, several of them have been isolated. For reviews of cyclopropanone chemistry, see Wasserman, Clark, and Turley, *Top. Curr. Chem.* **47**, 73–156 (1974); Turro, *Acc. Chem. Res.* **2**, 25–32 (1969).



60

61

59 is a symmetrical compound, and the three-membered ring can be opened with equal probability on either side of the carbonyl, accounting for the results with ^{14}C. In the general case, **61** is not symmetrical and should open on the side which gives the more stable carbanion.[138] This accounts for the fact that **56** and **57** give the same product. The intermediate in both cases is **62**, which



62

always opens to give the carbanion stabilized by resonance. Though the cyclopropanone intermediate (**61**) has not been isolated, it has been trapped;[139] and cyclopropanones synthesized by other methods have been shown to give Favorskii products on treatment with NaOMe or other bases.[140] The question of the exact timing of the steps involved has been much investigated. One possibility is that proton loss takes place simultaneously with formation of the cyclopropane; that is, that steps 1 and 2 are concerted. However, after an extensive study, Bordwell and coworkers have concluded that these steps are not concerted, and that the carbanion **60** is an intermediate.[141] In some cases step 2 is rate-determining,[142] and in other cases step 1 (proton removal).[143] Another question involves step 2. Does the Cl^- leave before the ring closes (SN1), or is attack by the carbanionic carbon simultaneous with the departure of the Cl^- (SN2)? Evidence for an SN2 mechanism at least in some cases is the fact that the diastereomers **63** and **64** reacted stereospecifically to give, respectively, **65** and **66** when treated with NaOMe in an ether solvent.[144]

[138] Factors other than carbanion stability (including steric factors) may also be important in determining which side of an unsymmetrical **61** is preferentially opened. See for example, Rappe and Knutsson, *Acta Chem. Scand.* **21,** 2205 (1967); Rappe, Knutsson, Turro, and Gagosian, *J. Am. Chem. Soc.* **92,** 2032 (1970).

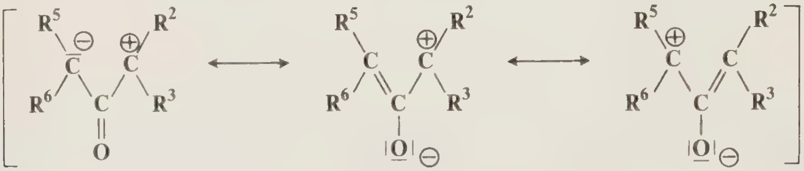
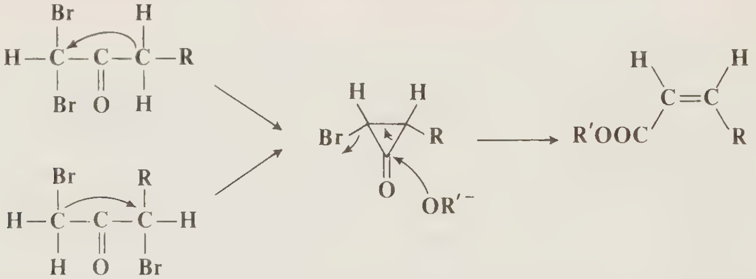
63 **65** **64** **66**

This result demonstrates that inversion of configuration has taken place at the carbon attached to the chlorine, as required by the SN2 mechanism. However, the same reaction in methanol is not stereospecific,[145] and an SN1 mechanism (which requires a dipolar intermediate **67**[146]) may take place in such cases.[147]

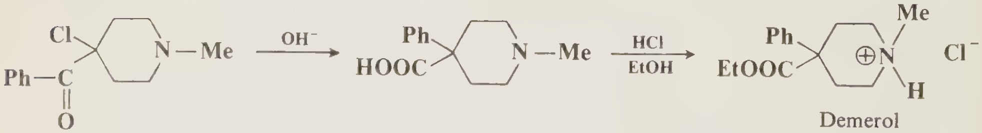


67

When the Favorskii rearrangement is applied to α,α-dihalo ketones containing an α′-hydrogen[148] or to α,α′-dihalo ketones containing an α-hydrogen,[149] the product is an α,β-unsaturated ester. In either case the same cyclopropanone is formed. Ring opening is different here, involving simultaneous elimination of halide ion:



The mechanism discussed is in accord with all the facts when the halo ketone contains an α-hydrogen on the other side of the carbonyl group. However, ketones which do not have a hydrogen there also rearrange to give the same type of product. This is usually called the *quasi-Favorskii rearrangement*. An example is found in the preparation of Demerol:[150]



Demerol

---

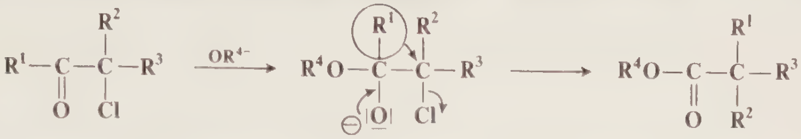
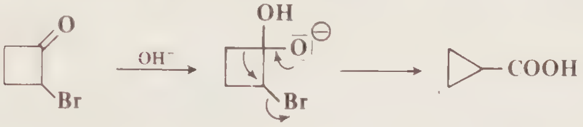
[149] Rappe and Adeström, *Acta Chem. Scand.* **19,** 383 (1965); Rappe, *Acta Chem. Scand.* **20,** 862 (1966); Rappe, *Acta Chem. Scand.* **17,** 2766 (1963).

[150] Smissman and Hite, *J. Am. Chem. Soc.* **81,** 1201 (1959).

The quasi-Favorskii rearrangement obviously cannot take place by the cyclopropanone mechanism. The mechanism which is generally accepted (called the *semibenzilic mechanism*[151]) is a base-catalyzed pinacol rearrangement-type mechanism similar to that of reaction **8-7.** This mechanism



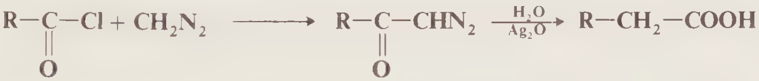
requires inversion at the migration terminus, and this has been found.[152] It has been shown that even where there *is* an appropriately situated α-hydrogen, the semibenzilic mechanism may still operate. One such example is the ring contraction of α-halocyclobutanones[153] (for these



substrates, boiling water may be all that is necessary; a stronger base is not always required). The semibenzilic mechanism has been shown for these compounds by experiments involving deuterium labeling, as well as by other experiments.[154] In at least one case it has been shown that an α-halo ketone with an α′-hydrogen can give the Favorskii reaction by either the cyclopropanone or the semibenzilic mechanism, depending on the experimental conditions.[155]

OS **IV,** 594; **53,** 123.

8-9 The Arndt-Eistert Synthesis



$$\mathrm{R{-}\underset{\underset{O}{\|}}{C}{-}Cl + CH_2N_2 \longrightarrow R{-}\underset{\underset{O}{\|}}{C}{-}CHN_2 \xrightarrow[Ag_2O]{H_2O} R{-}CH_2{-}COOH}$$

In the *Arndt-Eistert synthesis* an acyl halide is converted to a carboxylic acid with one additional carbon.[156] The first step of this process is reaction **0-116.** The actual rearrangement occurs in the second step on treatment of the diazo ketone with water and silver oxide or with silver benzoate and triethylamine. This rearrangement is called the *Wolff rearrangement*. It is the best method of increasing a carbon chain by one if a *carboxylic acid* is available (reactions **0-103** and **6-35** begin with alkyl halides). If an alcohol R′OH is used instead of water, the ester RCH_2COOR' is isolated directly. Similarly, ammonia gives the amide. Other catalysts are sometimes used, e.g., colloidal platinum, copper, etc., but occasionally the diazo ketone is simply heated or photolyzed in the presence of water, an alcohol, or ammonia, with no catalyst at all. The photolysis method often gives better results than the silver catalysis method. Of course diazo ketones prepared in any other way also give the rearrangement. The reaction is of wide scope. R may be alkyl or aryl and may contain many functional groups including unsaturation, but not including groups acidic enough to react with CH_2N_2 or diazo ketones (e.g., reactions **0-6** and **0-28**). Sometimes the reaction is performed with other diazoalkanes (that is, $R'CHN_2$) to give RCHR′COOH. The reaction has been used for ring contraction of cyclic diazo ketones;[157] e.g.,[158]

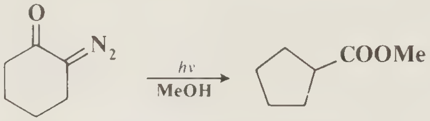
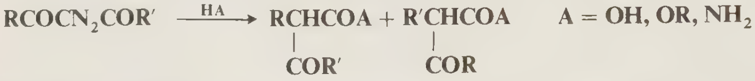
Rev.* **36,** 260–272 (1967); Weygand and Bestmann, *Angew. Chem.* **72,** 535–554 (1960), *Newer Methods Prep. Org. Chem.* **3,** 451–508 (1964); Smith, in Mayo, Ref. 1, pp. 528–550, 558–564; Eistert, *Newer Methods Prep. Org. Chem.* **1,** 513–570 (1948); Bachmann and Struve, *Org. React.* **1,** 38–62 (1942).

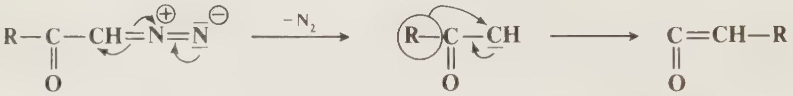


Unsymmetrical diacyldiazomethanes (prepared as in reaction **2-9**) can rearrange to give two isomeric products:[159]



$$RCOCN_2COR' \xrightarrow{HA} \underset{\displaystyle COR'}{RCHCOA} + \underset{\displaystyle COR}{R'CHCOA} \qquad A = OH, OR, NH_2$$

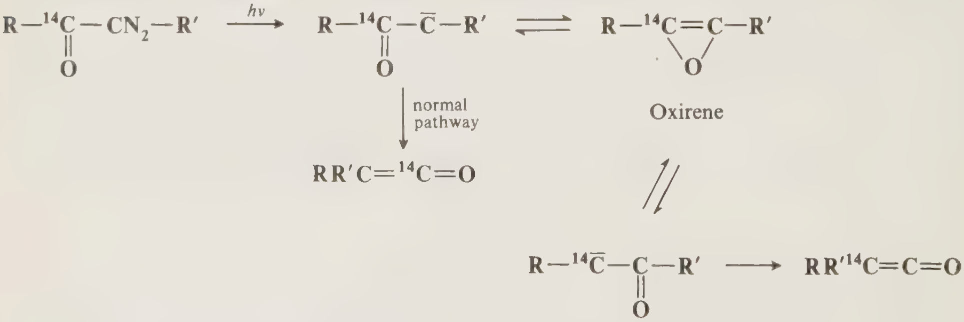
The mechanism is generally regarded to involve formation of a carbene. It is the divalent carbon which has the open sextet and to which the migrating group brings its electron pair:



$$R-\underset{\displaystyle O}{\overset{\|}{C}}-CH{=}\overset{\oplus}{N}{=}\overset{\ominus}{N} \xrightarrow{-N_2} R-\underset{\displaystyle O}{\overset{\|}{C}}-\ddot{C}H \longrightarrow \underset{\displaystyle O}{\overset{\|}{C}}{=}CH-R$$

The actual product of the reaction is thus the ketene, which then reacts with water (reaction **5-2**), an alcohol (reaction **5-5**), or ammonia or an amine (reaction **5-9**). Particularly stable ketenes (for example, $Ph_2C{=}C{=}O$) have been isolated, and others have been trapped in other ways (e.g., as β-lactams,[160] reaction **6-70**). The purpose of the catalyst is not well understood, though many suggestions have been made. This mechanism is strictly analogous to that of the Curtius rearrangement (reaction **8-18**). Although the mechanism as shown above involves a free carbene, and there is much evidence to support this,[161] it is also possible that at least in some cases the two steps are concerted and a free carbene is absent.

When the Wolff rearrangement is carried out photochemically, the mechanism is basically the same, but another pathway can intervene. Some of the ketocarbene originally formed can undergo a carbene-carbene rearrangement, through an oxirene intermediate. This was shown by ^{14}C labeling



---

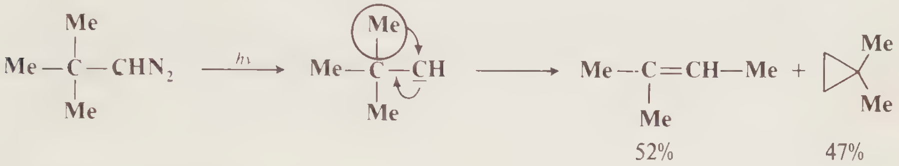
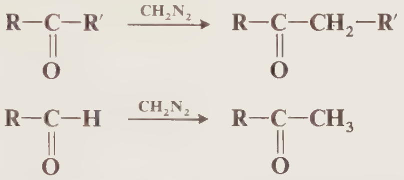
experiments, where diazo ketones labeled in the carbonyl group gave rise to ketenes which bore the label at both C=C carbons.[162] In general, the smallest degree of scrambling (and thus of the oxirene pathway) was found when R′ = H. The oxirene pathway is not found in the thermal Wolff rearrangement. It is likely that an excited singlet state of the carbene is necessary for the oxirene pathway to intervene.[163]

Other 1,2 alkyl migrations to a carbene or carbenoid terminus are also known,[164] e.g.,[165]



OS **III**, 356; **50**, 77; **52**, 53.

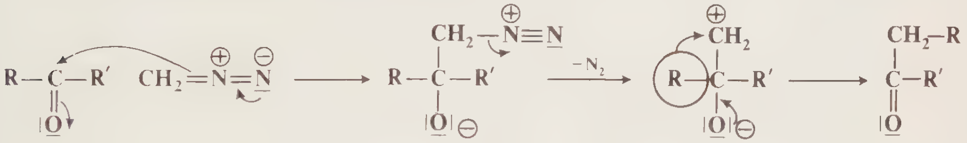
8-10 Homologization of Aldehydes and Ketones



$$R-\underset{\underset{O}{\|}}{C}-R' \xrightarrow{CH_2N_2} R-\underset{\underset{O}{\|}}{C}-CH_2-R'$$

$$R-\underset{\underset{O}{\|}}{C}-H \xrightarrow{CH_2N_2} R-\underset{\underset{O}{\|}}{C}-CH_3$$

Aldehydes and ketones can be converted to their homologs with diazomethane.[166] Formation of the epoxide (reaction **6-65**) is a side reaction. Although this reaction appears superficially to be similar to the insertion of carbenes into C—H bonds (reaction **2-18**), the mechanism is quite different, and this reaction is a true rearrangement. No free carbene is involved. The first step is an addition to the C=O bond of the aldehyde or ketone:



68 **69**

The betaine **68** can sometimes be isolated. As shown on p. 886, **69** can also go to the epoxide. The evidence for this mechanism is summarized in the review by Gutsche.[166] It may be noted that this mechanism is essentially the same as in the apparent "insertions" of oxygen (reaction **8-23**) and nitrogen (reaction **8-20**) into ketones. Although the mechanism normally does not involve a free carbene, it has been shown that free carbene does give similar products. Thus, acetone, treated with carbene, gave methyl ethyl ketone (undoubtedly by insertion into the C—H bond) and 1,1-dimethylethylene oxide.[167]

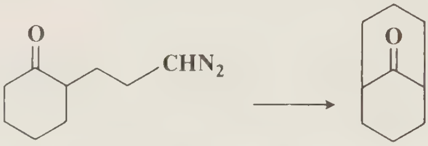
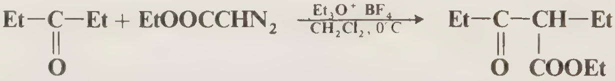
[167] Bradley and Ledwith, *J. Chem. Soc.* 3480 (1963).

Aldehydes give fairly good yields of methyl ketones; that is, hydrogen migrates in preference to alkyl. The most abundant side product is not the homologous aldehyde, but the epoxide. However, the yield of aldehyde at the expense of methyl ketone can be increased by the addition of methanol. If the aldehyde contains electron-withdrawing groups, the yield of epoxides is increased and the ketone is formed in smaller amounts, if at all. Ketones give poorer yields of homologous ketones. Epoxides are usually the predominant product here, especially when one or both R groups contain an electron-withdrawing group. The yield of ketones also decreases with increasing length of the chain. The use of boron trifluoride[168] or aluminum chloride[169] increases the yield of ketone.[170] Cyclic ketones, three-membered[171] and larger, behave particularly well and give good yields of ketones with the ring expanded by one.[172] Aliphatic diazo compounds ($RCHN_2$ and R_2CN_2) are sometimes used instead of diazomethane, with the expected results.[173] An interesting example is the preparation of bicyclic compounds from alicyclic compounds with a diazo group in the side chain, e.g.,[174]



Ethyl diazoacetate can be used analogously, in the presence of a Lewis acid or of triethyloxonium fluoroborate,[175] e.g.,

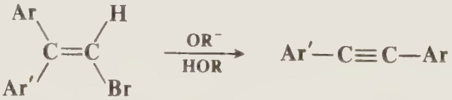


$$\underset{\text{O}}{\overset{}{\text{Et}-\underset{\Vert}{\text{C}}-\text{Et}}} + \text{EtOOCCHN}_2 \xrightarrow[\text{CH}_2\text{Cl}_2,\ 0^\circ\text{C}]{\text{Et}_3\text{O}^+\ \text{BF}_4^-} \text{Et}-\underset{\underset{\text{O}}{\Vert}}{\text{C}}-\underset{\underset{\text{COOEt}}{|}}{\text{CH}}-\text{Et}$$

When unsymmetrical ketones were used in this reaction (with BF_3 as catalyst), the less highly substituted carbon preferentially migrated.[176]

OS IV, 225, 780.

8-11 The Fritsch-Buttenberg-Wiechell Rearrangement



The rearrangement of 1,1-diaryl-2-haloethylenes to diarylacetylenes with strong bases[177] is called the *Fritsch-Buttenberg-Wiechell rearrangement*.[178] Alkoxide ions, sodium amide, and alkyl- and aryllithiums have been used as bases. The order of halide reactivity is $Br > I \gg Cl$.[179] There are two main side reactions, which may predominate. One of these is simple nucleophilic substitution of the halide by the base (for example, $Ar_2C{=}CHBr + OEt \rightarrow Ar_2C{=}CHOEt$), and the other, which occurs with alkyl- and aryllithiums, is halogen-metal interchange (reaction **2-38**). In the latter case the olefin goes to $Ar_2C{=}CHLi$, which may be converted to $Ar_2C{=}CHCOOH$ with CO_2 or to $Ar_2C{=}CH_2$ with water. The reaction has also been applied to compounds of the type $ArRC{=}CHBr$ and $(R'_2C{=}CH)RC{=}CHCl$,[180] but $R_2C{=}CHBr$ do not generally give the rearrangement. Ketene aminals of the form $(R_2N)_2C{=}CHCl$ can be similarly converted to ynediamines $R_2NC{\equiv}CNR_2$.[181]

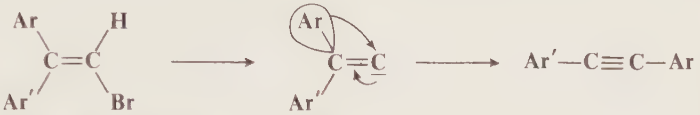
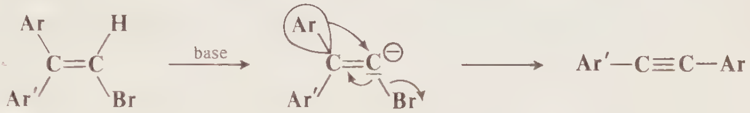
In this rearrangement, a hydrogen and a halogen are removed from the same carbon on treatment with a base, and it is tempting to assume that a carbene intermediate is involved here (see p. 181):



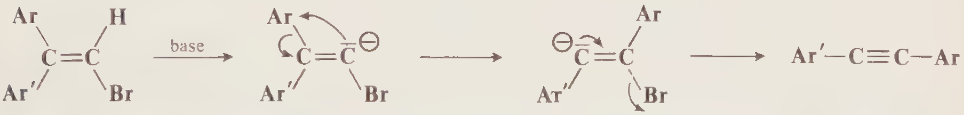
However, a major piece of evidence against this mechanism is that the reaction is stereoselective: The predominant migrating group is the one trans to the halogen. This was determined by the use of two different aryl groups and the labeling of one of the ethylenic carbons with ^{14}C.[182] A free carbene should be symmetrical, and it should not matter which group migrates.[183] Other evidence against the carbene mechanism is that products of carbene insertion or addition are not found. If we reject the carbene mechanism, there are still two major possibilities.[184] The aryl group may migrate with (mechanism *a*) or without (mechanism *b*) its electrons:

Mechanism *a*



70

Mechanism *b*



Although we have shown these mechanisms with two and three steps, respectively, it is also possible that two or three of the steps are concerted. The principal way of distinguishing between mechanisms *a* and *b* is the study of the effects of substituents on the migrating group. In mechanism *a* the reaction with respect to the migrating group is electrophilic aromatic substitution, with a transition state in which the ring is positively charged. Electron-donating substituents in the ortho or para position should aid the migration, and withdrawing substituents should hinder it. In mechanism *b* the reaction is nucleophilic aromatic substitution, with a negatively charged transition state, and the effect of substituents should be just the opposite. The results are in accord with mechanism *a*.[185] The question remains as to whether it is a one-step or two-step process. There is evidence that, at least in some cases, there is a two-step mechanism: the intermediate **70** has been isolated as the lithium compound and on heating gave the diarylacetylene;[186] and hydrogen-deuterium exchange has been shown.[179] However, it may be that in other cases the two steps are concerted. The fact that the reaction is stereoselective does not *require* that the reaction be concerted, since vinyl carbanions can hold their configurations (p. 165).

[180] Fienemann and Köbrich, *Chem. Ber.* **107**, 2797 (1974).

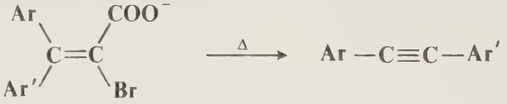
[181] Delavarenne and Viehe, *Chem. Ber.* **103**, 1209 (1970).

[182] Curtin, Flynn, and Nystrom, *J. Am. Chem. Soc.* **80**, 4599 (1958); Bothner-By, *J. Am. Chem. Soc.* **77**, 3293 (1955).

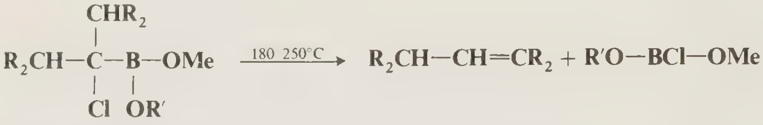
[183] It has been shown [Tadros, Sakla, Ishak, and Armanious, *J. Chem. Soc.* 4218 (1963)] that the reaction of 1-phenyl-1-*p*-anisyl-2-bromoethylene with sodium glycoxide in boiling ethylene glycol is not stereoselective, the anisyl group preferentially migrating, whether cis or trans. It may be that the mechanism in this case is different or, more simply, that here the olefin isomerizes before migration takes place.

[184] An *intermolecular* mechanism was ruled out by crossover experiments and by the fact that a substituent on a migrating ring is found in the same position in the product.

A similar rearrangement has been carried out on salts of 3,3-diaryl-2-halopropenoic acids:[187]



8-12 Rearrangement of α-Chloroboronic Acids



$$R_2CH-\underset{Cl}{\overset{CHR_2}{C}}-\underset{OR'}{B}-OMe \xrightarrow{180\text{–}250^\circ C} R_2CH-CH{=}CR_2 + R'O-BCl-OMe$$

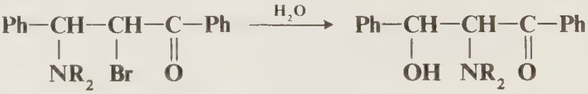
71

When α-chloroboronic esters (**71**) are heated at 180 to 250°C, loss of B and Cl takes place, accompanied by 1,2 migration of hydrogen (in some cases, alkyl), to give high yields of the corresponding alkenes.[188] The R groups may be the same or different. **71** can be prepared starting from alkenes, by the following route,[189] so that the overall reaction is a method for the dimerization of alkenes with the addition of an extra carbon atom.

$$\text{alkene} \xrightarrow[5\text{-}15]{H_2BCl,\ Et_2O} (R_2CH)_2BCl \xrightarrow{R'OH} (R_2CH)_2BOR' \xrightarrow[Et_3COLi]{Cl_2CHOMe} \mathbf{71}$$

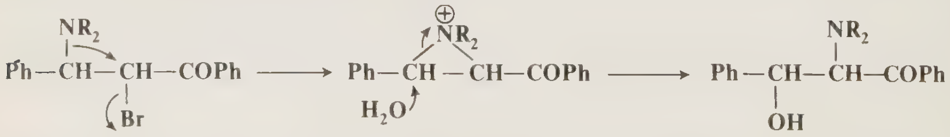
B. Carbon-to-Carbon Migrations of Other Groups

8-13 Migrations of Halogen, Hydroxyl, Amino, etc.



$$Ph-\underset{NR_2}{CH}-\underset{Br}{CH}-\underset{O}{\overset{}{C}}-Ph \xrightarrow{H_2O} Ph-\underset{OH}{CH}-\underset{NR_2}{CH}-\underset{O}{C}-Ph$$

When a nucleophilic substitution is carried out on a substrate which has a neighboring group (p. 279) on the adjacent carbon, then if the cyclic intermediate is opened on the opposite side, the result is migration of the neighboring group. In the example shown above (NR_2 = morpholino)[190] the reaction took place as follows:



---

[185] Köbrich and Trapp, *Z. Naturforsch.* **18,** 1125 (1963), *Chem. Ber.* **99,** 680 (1966); Jones and Damico, *J. Am. Chem. Soc.* **85,** 2273 (1963); Köbrich, Trapp, and Hornke, *Tetrahedron Lett.* 1131 (1964), *Chem. Ber.* **100,** 961 (1967).

[186] Köbrich and Trapp, Ref. 185.

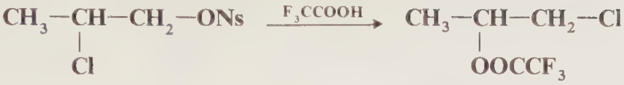
[187] Köbrich and Fröhlich, *Chem. Ber.* **98,** 3637 (1965); Köbrich, Reitz, and Schumacher, *Chem. Ber.* **105,** 1674 (1972).

[188] Katz, Carlson, and Brown, *J. Org. Chem.* **39,** 2817 (1974). See also Brown, Katz, and Carlson, *J. Org. Chem.* **40,** 813 (1975).

[189] Carlson, Katz, and Brown, *J. Organomet. Chem.* **67,** C39 (1974).

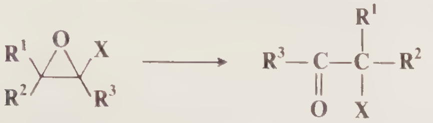
[190] Southwick and Walsh, *J. Am. Chem. Soc.* **77,** 405 (1955).

Another example is[191] (ONs = nosylate, see p. 326):



$$CH_3-\underset{\displaystyle Cl}{CH}-CH_2-ONs \xrightarrow{F_3CCOOH} CH_3-\underset{\displaystyle OOCCF_3}{CH}-CH_2-Cl$$

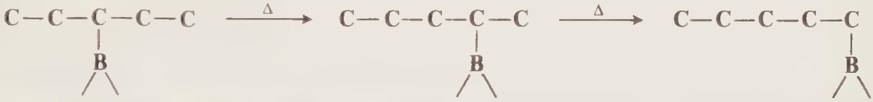
α-Halo and α-acyloxy epoxides undergo ready rearrangement to α-halo and α-acyloxy ketones, respectively.[192] These substrates are very prone to rearrange, and often do so on standing without



X=F, Cl, Br, or OCOR

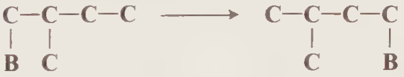
a catalyst, though in some cases an acid catalyst is necessary. The reaction is essentially the same as the rearrangement of epoxides shown in reaction **8-2**, except that in this case halogen or acyloxy is the migrating group (as shown above; however, it is also possible for one of the R groups -alkyl, aryl, or hydrogen -to migrate instead, and mixtures are sometimes obtained).

8-14 Migration of Boron



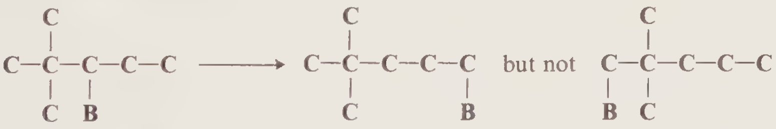
$$C-C-\underset{\underset{\wedge}{B}}{C}-C-C \xrightarrow{\Delta} C-C-C-\underset{\underset{\wedge}{B}}{C}-C \xrightarrow{\Delta} C-C-C-C-\underset{\underset{\wedge}{B}}{C}$$

When a nonterminal borane is heated at temperatures ranging from 100 to 200°C, the boron moves toward the end of the chain.[193] The reaction is catalyzed by small amounts of borane or other species containing B—H bonds. The boron can move past a branch, e.g.,



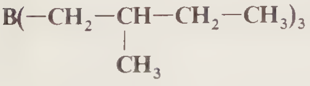
$$\underset{B}{C}-\underset{C}{C}-C-C \longrightarrow C-\underset{C}{C}-C-\underset{B}{C}$$

but not past a double branch, e.g.,



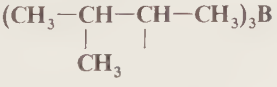
$$C-\underset{C}{\overset{C}{C}}-\underset{B}{C}-C-C \longrightarrow C-\underset{C}{\overset{C}{C}}-C-C-\underset{B}{C} \quad \text{but not} \quad C-\underset{B}{\overset{C}{C}}-\underset{C}{C}-C-C$$

The reaction is an equilibrium: **72**, **73**, and **74** each gave a mixture containing about 40% **72**, 1% **73**, and 59% **74**. The migration can go quite a long distance. Thus $(C_{11}H_{23}CHC_{11}H_{23})_3B$



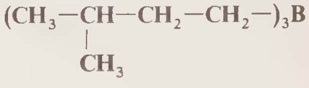
$$B(-CH_2-\underset{CH_3}{CH}-CH_2-CH_3)_3$$

72



$$(CH_3-\underset{CH_3}{CH}-\underset{|}{CH}-CH_3)_3B$$

73



$$(CH_3-\underset{CH_3}{CH}-CH_2-CH_2-)_3B$$

74

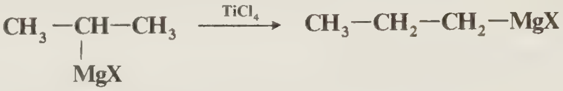
Chem.* **214**, 70 (1974); Smolina, Gopius, Us, Shchekut'eva, and Reutov, *Doklad. Chem.* **216**, 427 (1974), *J. Org. Chem. USSR* **10**, 908 (1974); Smolina, Medvedev, Ignatov, and Reutov, *J. Org. Chem. USSR* **10**, 1337 (1974).

[192] For a review, see McDonald, *Mech. Mol. Migr.* **3**, 67-107 (1971).

[193] Brown, "Hydroboration," pp. 136-149, W. A. Benjamin, Inc., New York, 1962; Brown and Zweifel, *J. Am. Chem. Soc.* **88**, 1433 (1966).

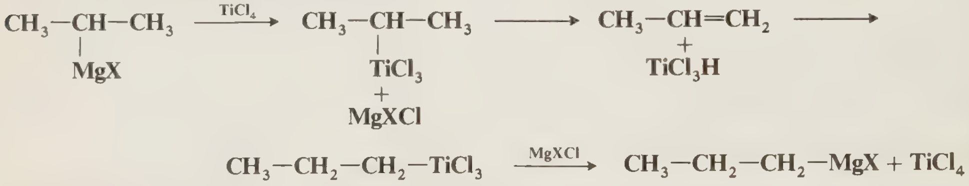
was completely converted to $(C_{23}H_{47})_3B$, involving a migration of 11 positions.[194] If the boron is on a cycloalkyl ring, it can move around the ring; if an alkyl chain is also on the ring, the boron may move from the ring to the chain, ending up at the end of the chain.[195] The reaction is useful for the migration of double bonds in a controlled way (see reaction **2-2**). The mechanism may involve elimination-addition (see reactions **7-15** and **5-15**).[196]

8-15 Rearrangement of Grignard Reagents



$$\mathrm{CH_3-\underset{\displaystyle MgX}{\underset{|}{CH}}-CH_3 \xrightarrow{TiCl_4} CH_3-CH_2-CH_2-MgX}$$

The MgX of Grignard reagents[197] can migrate to terminal positions in the presence of small amounts of $TiCl_4$.[198] The mechanism proposed consists of metal exchange (reaction **2-34**), elimination-addition, and metal exchange:

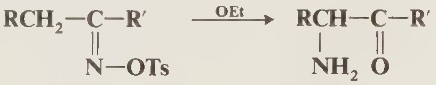


$$\mathrm{CH_3-\underset{\displaystyle MgX}{\underset{|}{CH}}-CH_3 \xrightarrow{TiCl_4} CH_3-\underset{\displaystyle TiCl_3 \atop {+ \atop MgXCl}}{\underset{|}{CH}}-CH_3 \longrightarrow \underset{TiCl_3H}{\overset{CH_3-CH=CH_2}{+}} \longrightarrow}$$

$$\mathrm{CH_3-CH_2-CH_2-TiCl_3 \xrightarrow{MgXCl} CH_3-CH_2-CH_2-MgX + TiCl_4}$$

The addition step is similar to reaction **5-15** or **5-16** and follows Markovnikov's rule, so that the positive titanium goes to the terminal carbon.

8-16 The Neber Rearrangement



$$\mathrm{RCH_2-\underset{\displaystyle N-OTs}{\underset{\|}{C}}-R' \xrightarrow{OEt} R\underset{\displaystyle NH_2}{\underset{|}{CH}}-\underset{\displaystyle O}{\underset{\|}{C}}-R'}$$

α-Amino ketones can be prepared by treatment of ketoxime tosylates with a base such as ethoxide ion or pyridine.[199] This is called the *Neber rearrangement*. R is usually aryl, though the reaction has been carried out with R = alkyl or hydrogen. R′ may be alkyl or aryl but not hydrogen. The Beckmann rearrangement (reaction **8-21**) and the abnormal Beckmann reaction (elimination to the nitrile, reaction **7-40**) may be side reactions, though these generally occur in acid media. A similar rearrangement is given by N,N-dichloroamines of the type $RCH_2CH(NCl_2)R'$, where the product is also $RCH(NH_2)COR'$.[200] The mechanism of the Neber rearrangement is as follows:[201]

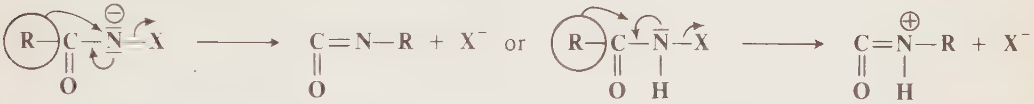
[201] Cram and Hatch, *J. Am. Chem. Soc.* **75,** 33 (1953); Hatch and Cram, *J. Am. Chem. Soc.* **75,** 38 (1953).

The best evidence for this mechanism is that the azirine intermediate has been isolated.[202] In contrast to the Beckmann rearrangement, this one is sterically indiscriminate:[203] both a syn and an anti ketoxime give the same product. Where there are two possible C—H groups to which the nitrogen can migrate, the more acidic proton is lost. The mechanism as shown above consists of three steps, the last being hydrolysis of an imine (reaction **6-2**). However, it is possible that the first two steps are concerted, and it is also possible that what is shown as the second step is actually two steps: loss of OTs to give a nitrene, and formation of the azirine. In the case of the dichloroamines, HCl is first lost to give  $RCH_2\underset{\underset{NCl}{\|}}{C}R'$, which then behaves analogously.[204] N-Chloroimines prepared in other ways also give the reaction.[205] Analogously, N-chloroimino esters  $RCH_2\underset{\underset{NCl}{\|}}{C}OR'$ give α-amino ortho esters $RCH(NH_2)C(OR')_3$,[206] or α-amino esters $RCH(NH_2)COOR'$,[207] each of which can be hydrolyzed to α-amino acids.

OS **V**, 909.

C. Carbon-to-Nitrogen Migrations of R and Ar. The reactions in this group are nucleophilic migrations from a carbon to a nitrogen atom. In each case the nitrogen atom either has six electrons in its outer shell (and thus invites the migration of a group carrying an electron pair) or else loses a nucleofuge concurrently with the migration (p. 964). Reactions **8-17** to **8-20** are used to prepare amines from acid derivatives. Reactions **8-20** and **8-21** are used to prepare amines from ketones. The mechanisms of reactions **8-17, 8-18, 8-19,** and **8-20** (with carboxylic acids) are very similar and follow one of two patterns:



Some of the evidence[208] is: (1) Configuration is retained in R (p. 965); (2) the kinetics are first order; (3) intramolecular rearrangement is shown by labeling; and (4) no rearrangement occurs *within* the migrating group, e.g., a neopentyl group on the carbon of the starting material is still a neopentyl group on the nitrogen of the product.

In many cases it is not certain whether the nucleofuge X is lost first, creating an intermediate nitrene[209] or nitrenium ion, or whether migration and loss of the nucleofuge are simultaneous, as shown above.[210] It is likely that both possibilities can exist, depending on the substrate and reaction conditions, and that there is a spectrum of mechanisms.

8-17 The Hofmann Rearrangement

$$RCONH_2 + NaOBr \longrightarrow R{-}N{=}C{=}O \xrightarrow{\text{hydrol.}} RNH_2$$

In the *Hofmann rearrangement*, an unsubstituted amide is treated with sodium hypobromite (or sodium hydroxide and bromine, which is essentially the same thing) to give a primary amine which has one carbon fewer than the starting amide.[211] The actual product of the reaction is the isocyanate, but this compound is seldom isolated since it is usually hydrolyzed under the reaction conditions. R may be alkyl or aryl, but if it is an alkyl group of more than about six or seven carbons, low yields are obtained unless Br_2 and NaOMe are used instead of Br_2 and NaOH.[212] Under these conditions the product of addition to the isocyanate is the carbamate RNHCOOMe (reaction **6-8**), which is easily isolated or can be hydrolyzed to the amine. Side reactions when NaOH is the base are formation of ureas RNHCONHR and acylureas RCONHCONHR by addition, respectively, of RNH_2 and $RCONH_2$ to RNCO (reaction **6-18**). If acylureas are desired, they can be made the main products by using only half the usual quantities of Br_2 and NaOH. Another side product, though only from primary R, is the nitrile derived from oxidation of RNH_2 (reaction **9-6**). Imides react to give amino acids; e.g., phthalimide gives *o*-aminobenzoic acid. α-Hydroxy and α-halo amides give aldehydes and ketones by way of the unstable α-hydroxy- or α-haloamines. However, a side product with an α-halo amide is a *gem*-dihalide. Ureas analogously give hydrazines. This reaction is sometimes called the *Hofmann degradation*, but this name is easily confused with reaction **7-6.**

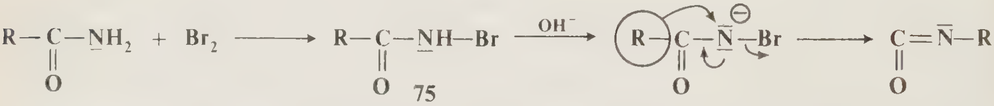
[208] For a discussion of this mechanism and of the evidence for it, see Smith, in Mayo, Ref. 1, vol. 1, pp. 528–550.

[209] For a review of rearrangements involving nitrene intermediates, see Boyer, *Mech. Mol. Migr.* **2**, 267–318 (1969). See also Ref. 217.

[210] The question is discussed by Lwowski, in Lwowski, "Nitrenes," pp. 217–221, Interscience Publishers, New York, 1970.

The mechanism follows the pattern outlined on p. 1003:



The first step is an example of reaction **2-54,** and the intermediate N-halo amides (**75**) have been isolated. In the second step, **75** loses a proton to the base. **75** is acidic because of the presence of two electron-withdrawing groups (acyl and halo) on the nitrogen. It is possible that the third step is actually two steps: loss of bromide to form a nitrene, followed by the actual migration, but most of the available evidence favors the concerted reaction.[213]

A similar reaction can be effected by the treatment of amides with lead tetraacetate.[214] In this case the initial isocyanate and the amine formed from it react with the acetic acid liberated from the lead tetraacetate to give, respectively, ureas and amides. If the reaction is carried out in the presence of an alcohol, carbamates are formed (reaction **6-8**).

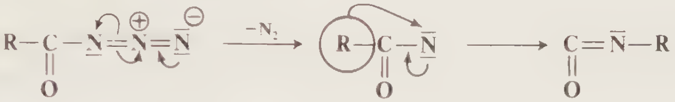
8-18 The Curtius Rearrangement

$$RCON_3 \xrightarrow{\Delta} R{-}N{=}C{=}O$$

The *Curtius rearrangement* involves the pyrolysis of acyl azides to yield isocyanates.[215] The reaction gives good yields of isocyanates, since no water is present to hydrolyze them to the amine. Of course, they can be subsequently hydrolyzed, and indeed the reaction *can* be carried out in water or alcohol, in which case the products are amines, carbamates, or acylureas, as in reaction **8-17.** This is a very general reaction and can be applied to almost any carboxylic acid: aliphatic, aromatic, alicyclic, heterocyclic, unsaturated, and containing many functional groups. Acyl azides can be prepared as in reaction **0-63** or by treatment of acylhydrazines (hydrazides) with nitrous acid (analogous to reaction **2-49**). The Curtius rearrangement is catalyzed by Lewis or protic acids, but these are usually not necessary for good results.

The mechanism is similar to that in reaction **8-17:**

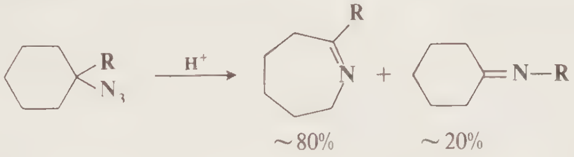


Also note the exact analogy between this reaction and reaction **8-9.** However, in this case, there is no evidence for a free nitrene, and it is probable that the steps are concerted.[216]

Alkyl azides can be similarly pyrolyzed to give imines, in an analogous reaction:[217]

$$R_3CN_3 \xrightarrow{\Delta} R_2C{=}NR$$

The R groups may be alkyl, aryl, or hydrogen, though if hydrogen migrates, the product is the unstable $R_2C{=}NH$. The mechanism is essentially the same as that of the Curtius rearrangement. However, in pyrolysis of tertiary alkyl azides, there is evidence that free alkyl nitrenes are intermediates.[218] The reaction can also be carried out with acid catalysis, in which case lower temperatures can be used, though the acid may hydrolyze the imine (reaction **6-2**). Cycloalkyl azides give ring expansion.[219]



Aryl azides also give ring expansion on heating, e.g.,[220]

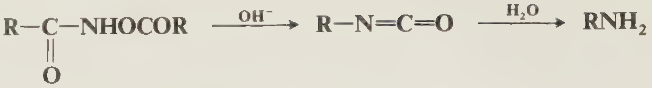
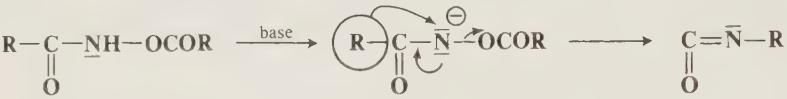
8-19 The Lossen Rearrangement



$$R-\underset{\underset{O}{\|}}{C}-NHOCOR \xrightarrow{OH^-} R-N=C=O \xrightarrow{H_2O} RNH_2$$

The O-acyl derivatives of hydroxamic acids[221] give isocyanates when treated with bases, or sometimes even just on heating,[222] in a reaction known as the *Lossen rearrangement*. The mechanism is similar to that of reactions **8-17** and **8-18:**



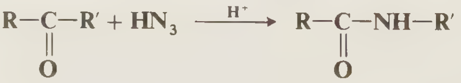
This reaction is performed much less often than reactions **8-17, 8-18,** or **8-20** because hydroxamic acids are not readily available. The reaction can be carried out under particularly mild conditions by treatment of a hydroxamic acid with 1-benzyl-3-dimethylaminopropylcarbodiimide, which is water-soluble.[223] It is possible to convert ArCOOH to $ArNH_2$ in one step by heating the acid with nitromethane in polyphosphoric acid. The hydroxamic acid is an intermediate, and this is actually a Lossen rearrangement.[224]

8-20 The Schmidt Reaction

$$RCOOH + HN_3 \xrightarrow{H^+} R-N=C=O \xrightarrow{H_2O} RNH_2$$

There are actually three reactions called by the name *Schmidt reaction*, involving the addition of hydrazoic acid to carboxylic acids, aldehydes and ketones, and alcohols and olefins.[225] The most common is the reaction with carboxylic acids, illustrated above. Sulfuric acid is the most common catalyst, but Lewis acids have also been used. Good results are obtained for aliphatic R, especially for long chains. When R is aryl, the yields are variable, being best for sterically hindered compounds like mesitoic acid. This method has the advantage over reactions **8-17** and **8-18** that it is just one step (in practice, not in mechanism) from the acid to the amine, but conditions are more drastic.[226] Under the acid conditions employed, the isocyanate is virtually never isolated, though this has been accomplished.[227]

The reaction between a ketone and hydrazoic acid is a method for "insertion" of NH between the carbonyl group and one R group, thus converting a ketone into an amide:[228]



$$R-\underset{\underset{O}{\|}}{C}-R' + HN_3 \xrightarrow{H^+} R-\underset{\underset{O}{\|}}{C}-NH-R'$$

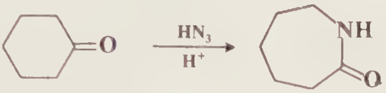
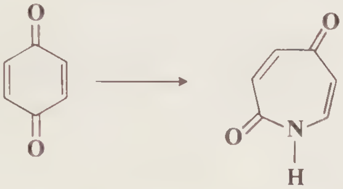
[227] Rutherford and Newman, *J. Am. Chem. Soc.* **79**, 213 (1957).

[228] For reviews, see Koldobskii, Tereshchenko, Gerasimova, and Bagal, *Russ. Chem. Rev.* **40**, 835–846 (1971); Beckwith, in Zabicky, "The Chemistry of Amides," pp. 137–145, Interscience Publishers, New York, 1970; Smith, in Mayo, Ref. 1, vol. 1, pp. 507–527.

Either or both of the R groups may be aryl. In general, dialkyl ketones and cyclic ketones react more rapidly than alkyl aryl ketones, and these more rapidly than diaryl ketones. The latter require sulfuric acid and do not react in concentrated HCl, which is strong enough for dialkyl ketones. Dialkyl and cyclic ketones react sufficiently faster than diaryl or aryl alkyl ketones or carboxylic acids or alcohols—that these functions may be present in the same molecule without interference. Cyclic ketones give lactams:



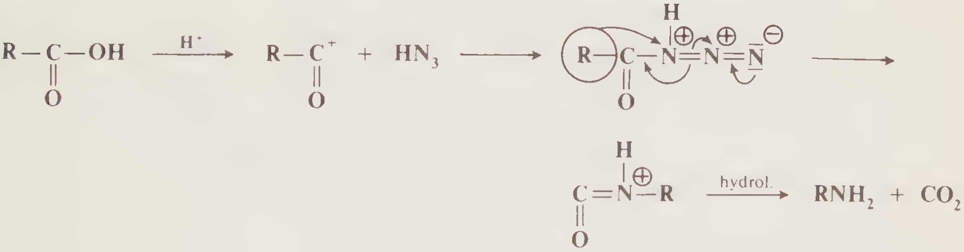
and quinones give 1*H*,2*H*,5*H*,-2,5-azepindiones:[229]



With alkyl aryl ketones, it is the aryl group that generally migrates to the nitrogen, except when the alkyl group is bulky.[230] The reaction has been applied to a few aldehydes, but rarely. With aldehydes the product is usually the nitrile (reaction **6-23**). Even with ketones, conversion to the nitrile is often a side reaction, especially with the type of ketone that gives reaction **7-40.** Aromatic aldehydes and ketones containing an *o*-hydroxy group give *o*-hydroxy aromatic amides when treated with NaOH and monochloroamine NH_2Cl.[231]

Alcohols and olefins react with HN_3 to give alkyl azides, which in the course of reaction rearrange in the same way as discussed in reaction **8-18.**[217]

The mechanism with carboxylic acids is similar to that of reaction **8-18,** except that it is the protonated azide which undergoes the rearrangement:



The first step is the same as that of the AAC1 mechanism (p. 351), which explains why good results are obtained with hindered substrates. The mechanism with ketones is[232]

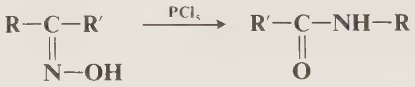
76

Note the similarity of this mechanism to those of "insertion" of CH_2 (reaction **8-10**) and of O (reaction **8-23**). The three reactions are essentially analogous, both in products and in mechanism.[233] Also note the similarity of the latter part of this mechanism to that of the Beckmann rearrangement (reaction **8-21**).

OS **V**, 408. See also OS **V**, 623.

8-21 The Beckmann Rearrangement



$$\underset{\displaystyle \underset{\text{N—OH}}{\|}}{\text{R—C—R}'} \xrightarrow{PCl_5} \underset{\displaystyle \underset{\text{O}}{\|}}{\text{R}'\text{—C—NH—R}}$$

When oximes are treated with PCl_5, concentrated H_2SO_4, or a number of other reagents, they rearrange to substituted amides, in a reaction called the *Beckmann rearrangement*.[234] Among the reagents used have been concentrated H_2SO_4, PCl_5 and ether, formic acid, liquid SO_2, PPh_3-CCl_4,[235] HMPT,[236] P_2O_5-methanesulfonic acid,[237] HCl-HOAc-Ac_2O, and polyphosphoric acid.[238] The group which migrates is generally the one trans to the hydroxyl, and this is often used as a method of determining the configuration of the oxime. However, it is not unequivocal. It is known that with some oximes the cis group migrates and that with others, especially where R and R′ are both alkyl, mixtures of the two possible amides are obtained. However, this behavior does not necessarily mean that the cis group actually undergoes migration. In most cases the oxime undergoes isomerization under the reaction conditions *before* migration takes place.[239] The scope of the reaction is quite broad. R and R′ may be alkyl, aryl, or hydrogen. However, hydrogen very seldom *migrates*, so that the reaction is not generally a means of converting aldoximes to unsubstituted amides $RCONH_2$. This conversion can be accomplished, though, by treatment of the aldoxime with nickel acetate under neutral conditions[240] or by heating the aldoxime for 60 hr at 100°C after it has been adsorbed onto silica gel.[241] As in the case of the Schmidt rearrangement, when the oxime is derived from an alkyl aryl ketone, it is generally the aryl group which preferentially migrates. The oximes of cyclic ketones give ring enlargement,[242] e.g.,

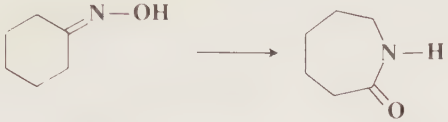
[237] Eaton, Carlson, and Lee, *J. Org. Chem.* **38**, 4071 (1973).

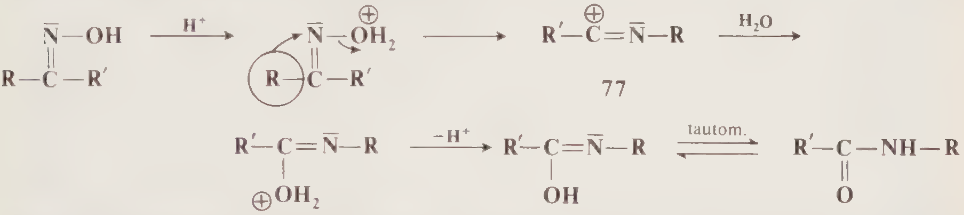
[238] For reviews of Beckmann rearrangements with polyphosphoric acid, see Beckwith, in Zabicky, Ref. 228, pp. 131–137; Uhlig and Snyder, *Adv. Org. Chem.* **1**, 35–81 (1960), pp. 65–68; Popp and McEwen, *Chem. Rev.* **58**, 321–401 (1958), pp. 370–374.

[239] Lansbury and Mancuso, *Tetrahedron Lett.* 2445 (1965), have shown that some Beckmann rearrangements are *authentically* nonstereospecific.

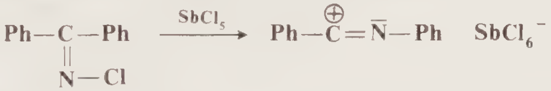


Not only do oximes undergo the Beckmann rearrangement, but so also do esters of oximes with many acids, organic and inorganic. A side reaction with many substrates is the formation of nitriles (the "abnormal" Beckmann rearrangement, reaction **7-40**).

In the first step of the mechanism, the OH group is converted by the reagent to a better leaving group. After that, the mechanism follows a course analogous to that for the Schmidt reaction of ketones (**8-20**) from the formation of **76** on:[243]



The other reagents convert OH to an ester leaving group (for example, $OPCl_4$ from PCl_5 and OSO_2OH from concentrated H_2SO_4[244]). Alternatively, the attack on **77** can be by the leaving group, if different from H_2O. An intermediate of the form **77** has been isolated by Grob and coworkers from treatment of the N-chloroimine of benzophenone



and found to have a linear geometry.[245] These workers also showed that the rate of solvolysis of the oxime tosylate from cyclohexanone was about the same (actually a little greater) as that from diethyl ketone, even though the intermediate **77** from the cyclic compound cannot be linear. They thus concluded that, in this case at least, **77** cannot be formed in the rate-determining step, and that it is formed in this manner:[246]

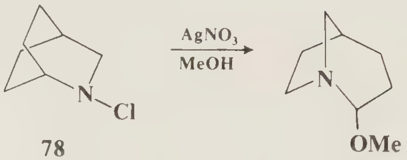
[246] For another example of intramolecular migration of the nucleofuge, see Kukhtenko, *J. Org. Chem. USSR* **7,** 327 (1971).

The rearrangement has also been found to take place by a different mechanism, involving formation of a nitrile by fragmentation, and then addition by a Ritter reaction (**6-57**).[247] Beckmann rearrangements have also been carried out photochemically.[248]

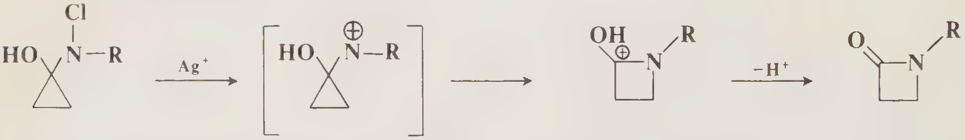
OS **II,** 76, 371.

8-22 Stieglitz and Related Rearrangements



78

Besides the reactions discussed at **8-17** to **8-21**, a number of other rearrangements are known in which an alkyl group migrates from C to N. Certain bicyclic N-haloamines, for example N-chloro-2-azabicyclo[2.2.2]octane (**78**), undergo rearrangement when solvolyzed in the presence of silver nitrate.[249] This reaction is similar to the Wagner-Meerwein rearrangement (**8-1**) and is initiated by the silver-catalyzed departure of the chloride ion. A nitrenium-ion-type transition state (p. 186) is undoubtedly involved.[250] Similar reactions have been used for ring expansions and contractions, analogous to those discussed for reaction **8-3.**[251] An example is the conversion of 1-(N-chloroamino)cyclopropanols to β-lactams.[252]



The name *Stieglitz rearrangement* is generally applied to the rearrangements of trityl N-haloamines and hydroxylamines. These reactions are similar to the rearrangements of alkyl

$$\mathrm{Ar_3CNHX} \xrightarrow{\text{base}} \mathrm{Ar_2C{=}NAr}$$

$$\mathrm{Ar_3CNHOH} \xrightarrow{\mathrm{PCl_5}} \mathrm{Ar_2C{=}NAr}$$

azides (reaction **8-18**), and the name Stieglitz rearrangement is also given to the rearrangement of trityl azides. Another similar reaction is the rearrangement undergone by tritylamines when treated with lead tetraacetate.[253]

$$\mathrm{Ar_3CNH_2} \xrightarrow{\mathrm{Pb(OAc)_4}} \mathrm{Ar_2C{=}NAr}$$

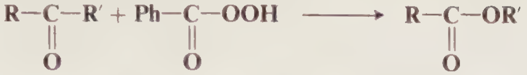
D. Carbon-to-Oxygen Migrations of R and Ar

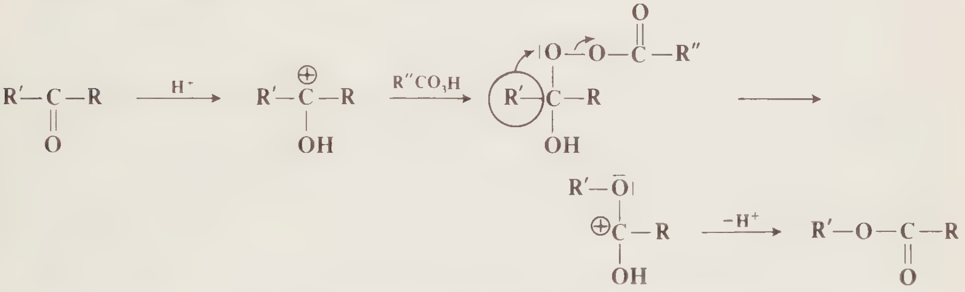
8-23 The Baeyer-Villiger Rearrangement



$$R{-}\underset{\displaystyle O}{\underset{\|}{C}}{-}R' + Ph{-}\underset{\displaystyle O}{\underset{\|}{C}}{-}OOH \longrightarrow R{-}\underset{\displaystyle O}{\underset{\|}{C}}{-}OR'$$

The treatment of ketones with peracids such as perbenzoic or peracetic acid, or with other peroxy compounds in the presence of acid catalysts, gives esters by "insertion" of oxygen. The reaction is called the *Baeyer-Villiger rearrangement*.[254] A particularly good reagent is peroxytrifluoroacetic acid. Reactions with this reagent are rapid and clean, giving high yields of product, though it is often necessary to add a buffer such as Na_2HPO_4 to prevent transesterification of the product with trifluoroacetic acid. The reaction is often applied to cyclic ketones to give lactones. For acyclic compounds, R′ must usually be secondary, tertiary, or vinylic, although primary R′ has been rearranged with peroxytrifluoroacetic acid,[255] with BF_3–H_2O_2,[256] and with $K_2S_2O_8$–H_2SO_4.[257] For unsymmetrical ketones the approximate order of migration is tertiary alkyl > secondary alkyl, aryl > primary alkyl > methyl. Since the methyl group has a low migrating ability, the reaction provides a means of cleaving a methyl ketone R′COMe to produce an alcohol or phenol R′OH (by hydrolysis of the ester R′OCOMe). Diaryl ketones give the reaction but are seldom used preparatively. The migrating ability of aryl groups is increased by electron-donating and decreased by electron-withdrawing substituents. Enolizable β-diketones do not react. α-Diketones can be converted to anhydrides. With aldehydes, migration of hydrogen gives the carboxylic acid, and this is a way of accomplishing reaction **4-6.** Migration of the other group would give formates, but this seldom happens, though in some cases aryl aldehydes have been converted to formates[258] (see also the Dakin reaction in **9-13**).

The mechanism[259] is similar to those of the analogous reactions with hydrazoic acid (reaction **8-20** with ketones) and with diazomethane (reaction **8-9**):



One important piece of evidence for this mechanism was that benzophenone-^{18}O gave ester entirely labeled in the carbonyl oxygen, with none in the alkoxyl oxygen.[260] Carbon-14 isotope-effect studies on acetophenones have shown that migration of aryl groups takes place in the rate-determining step,[261] demonstrating that migration of Ar is concerted with departure of OCOR″.[262] (It is hardly likely that migration would be the slow step if the leaving group departed first to give an ion with a positive charge on an oxygen atom, which would be a highly unstable species.)

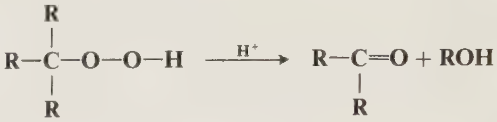
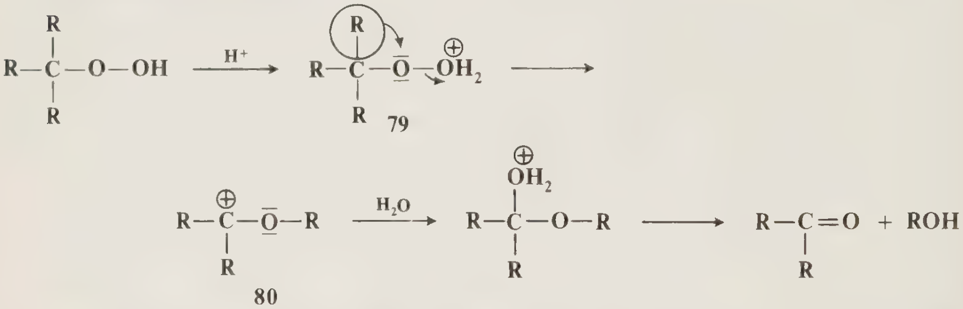
8-24 Rearrangement of Hydroperoxides



$$R_3C{-}O{-}O{-}H \xrightarrow{H^+} R_2C{=}O + ROH$$

Hydroperoxides (R = alkyl, aryl, or hydrogen) can be cleaved by proton or Lewis acids in a reaction whose principal step is a rearrangement.[263] The reaction has also been applied to peroxy esters $R_3COOCOR'$, but less often. When aryl and alkyl groups are both present, migration of aryl dominates. Among alkyl groups the migratory order is tertiary R > secondary R > Pr ≈ H > Et ≫ Me.[257] It is not necessary actually to prepare and isolate hydroperoxides. The reaction takes place when the alcohols are treated with H_2O_2 and acids. Migration of an alkyl group of a primary hydroperoxide provides a means for converting an alcohol to its next lower homolog ($RCH_2OOH \rightarrow CH_2{=}O + ROH$).[257]

The mechanism is as follows:

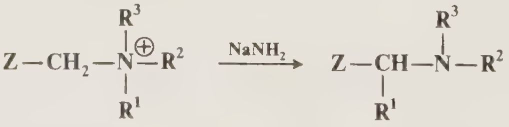


The last step is hydrolysis of the unstable hemiacetal. Alkoxycarbonium-ion intermediates (**80**, R = alkyl) have been isolated in super-acid solution, at low temperatures, and their structures proved by nmr.[264] The protonated hydroperoxides (**79**) could not be observed in these solutions, evidently reacting immediately on formation.

OS V, 818.

E. Nitrogen-to-Carbon and Oxygen-to-Carbon Migration

8-25 The Stevens Rearrangement



$$Z{-}CH_2{-}\overset{\oplus}{N}R^1R^2R^3 \xrightarrow{NaNH_2} Z{-}CH(R^1){-}NR^2R^3$$

---

[261] Palmer and Fry, *J. Am. Chem. Soc.* **92,** 2580 (1970). See also Mitsuhashi, Miyadera, and Simamura, *Chem. Commun.* 1301 (1970). For secondary isotope-effect studies, see Winnik, Stoute, and Fitzgerald, *J. Am. Chem. Soc.* **96,** 1977 (1974).

[262] In some cases the rate-determining step has been shown to be the addition of peracid to the substrate [see for example, Ogata and Sawacki, *J. Org. Chem.* **37,** 2953 (1972)]. Even in these cases it is still highly probable that migration is concerted with departure of the nucleofuge.

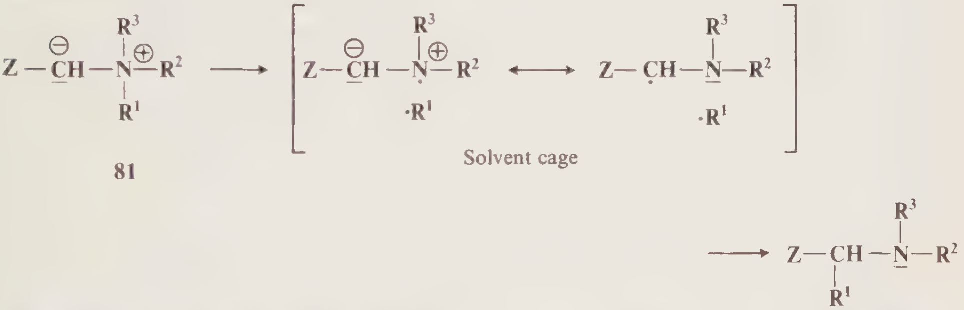
[263] For a review, see Lee and Uff, Ref. 254, pp. 445–449.

[264] Sheldon and van Doorn, *Tetrahedron Lett.* 1021 (1973).

In the *Stevens rearrangement* a quaternary ammonium salt containing an electron-withdrawing group Z on one of the carbons attached to the nitrogen is treated with a strong base (such as NaOR or $NaNH_2$) to give a rearranged tertiary amine. Z is a group such as RCO, ROOC, phenyl, etc.[265] The most common migrating groups are allyl, benzyl, benzhydryl, 3-phenylpropargyl, and phenacyl, though even methyl migrates to a sufficiently negative center.[266] When an allyl group migrates, it may or may not involve an allylic rearrangement within the migrating group (see reaction **8-40**), depending on the substrate and reaction conditions. In a few cases the reaction has been applied to compounds without a Z group, but stronger bases are required and yields are often low.[267]

The mechanism has been the subject of much study.[268] That the rearrangement is intramolecular was shown by crossover experiments, by ^{14}C labeling,[269] and by the fact that retention of configuration is found at R.[270] The first step is loss of the acidic proton to give the ylide **81**, which has been isolated.[271] The finding[272] that CIDNP spectra[273] (p. 171) could be obtained in many instances shows that in these cases the product is formed directly from a free-radical precursor. The following radical-pair mechanism was proposed.[274]

Mechanism *a*



81

The radicals do not drift apart because they are held together by the solvent cage.[274a] According to this mechanism, the radicals must recombine rapidly in order to account for the fact that R^1 does not racemize. Other evidence in favor of mechanism *a* is that in some cases small amounts of coupling products (R^1R^1) have been isolated,[275] which would be expected if some $\cdot R^1$ leaked from the solvent cage. However, not all the evidence is easily compatible with mechanism *a*.[276] It is possible that another mechanism (*b*) similar to mechanism *a*, but involving ion pairs in a solvent cage instead of radical pairs, operates in some cases. For a number of years it was generally believed that the Stevens rearrangement takes place by a one-step electrophilic migration (mechanism *c*), but doubt was cast on this pathway by the following result: Optically active **82** rearranged to **83** (with the benzyl and not the allyl migrating) and **84** (by a 1,4 shift). The benzyl group retained its configuration in **83**, as expected, but also in **84**.[277] If the benzyl group were migrating without its electrons (mechanism *c*), then it would have to move over this long distance either as a relatively free carbonium ion (and be racemized) or in an SNi′ process (p. 305) (and be inverted):

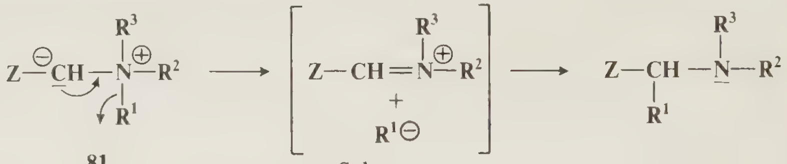
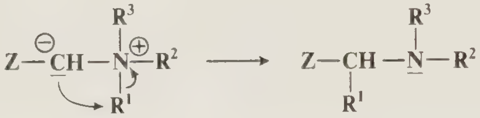
Mechanism *b*

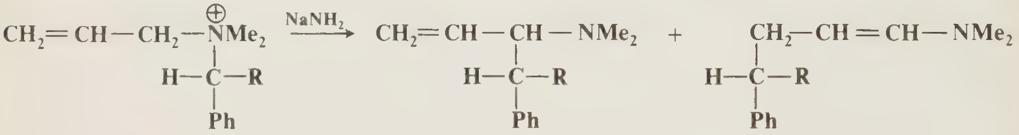


81

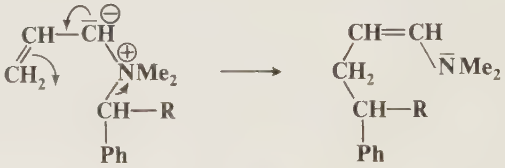
Mechanism *c*



81



82 **83** **84**



In neither case would there be retention. Therefore, the 1,4 shift appears to operate by mechanism *a* or *b*. If the 1,4 shift operates by mechanism *a* or *b*, it is unlikely that the 1,2 shift has a different mechanism. An additional argument against mechanism *c* is that the principle of orbital symmetry conservation requires that a concerted migration of this type take place with inversion at R′.[278] A migration with retention is forbidden (see p. 1042). Since the actual migration takes place with retention, it cannot, according to this argument, proceed by a concerted mechanism (mechanism *c*).[279] However, in the case where the migrating group is allylic a concerted mechanism can also operate (reaction **8-40**). An interesting finding which is compatible with all three mechanisms is that optically active allylbenzylmethylphenylammonium iodide (asymmetric nitrogen, see p. 89) gave optically active product:[280]

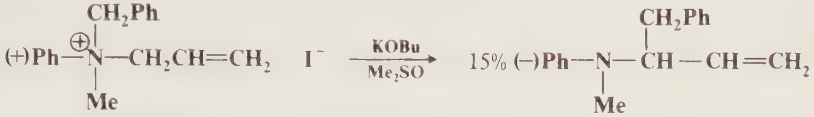
---

[276] See for example, Pine, Catto, and Yamagishi, *J. Org. Chem.* **35**, 3663 (1970).

[277] Jenny and Druey, *Angew. Chem. Int. Ed. Engl.* **1**, 155 (1962) [*Angew. Chem.* **74**, 152].

[278] Woodward and Hoffmann, "The Conservation of Orbital Symmetry," p. 131, Academic Press, Inc., New York, 1970.

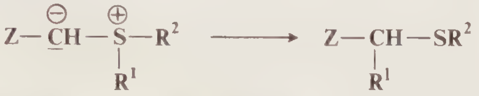
[279] It has been argued that the rearrangement takes place by a concerted mechanism, in violation of the orbital symmetry rules: Dewar and Ramsden, *J. Chem. Soc., Perkin Trans. 1* 1839 (1974).



$$(+)\mathrm{Ph}-\overset{\mathrm{CH_2Ph}}{\underset{\mathrm{Me}}{\overset{\oplus|}{\mathrm{N}}}}-\mathrm{CH_2CH{=}CH_2}\quad \mathrm{I^-}\ \xrightarrow[\mathrm{Me_2SO}]{\mathrm{KOBu}}\ 15\%\ (-)\mathrm{Ph}-\underset{\mathrm{Me}}{\mathrm{N}}-\overset{\mathrm{CH_2Ph}}{\mathrm{CH}}-\mathrm{CH{=}CH_2}$$

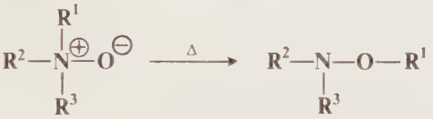
The Sommelet-Hauser rearrangement competes when Z is an aryl group (see reaction **3-27**). Hofmann elimination competes when one of the R groups contains a β-hydrogen atom (reactions **7-6**, **7-7**).

Sulfur ylides containing a Z-group give an analogous rearrangement, often also referred to as a Stevens rearrangement.[281] In this case too, there is much evidence (including CIDNP) that a



$$\mathrm{Z}-\overset{\ominus}{\underline{\mathrm{C}}\mathrm{H}}-\underset{\mathrm{R^1}}{\overset{\oplus}{\mathrm{S}}}-\mathrm{R^2}\ \longrightarrow\ \mathrm{Z}-\underset{\mathrm{R^1}}{\mathrm{CH}}-\mathrm{SR^2}$$

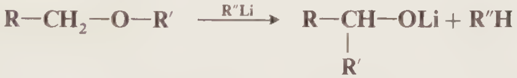
radical-pair cage mechanism is operating,[282] except that when the migrating group is allyl, the mechanism may be different (see reaction **8-40**). Another reaction with a similar mechanism[283] is the *Meisenheimer rearrangement*,[284] in which certain tertiary amine oxides rearrange on heating to give substituted hydroxylamines. The migrating group R^1 is almost always allylic or benzilic.



$$\mathrm{R^2}-\overset{\mathrm{R^1}}{\underset{\mathrm{R^3}}{\overset{\oplus}{\mathrm{N}}}}-\mathrm{O}^{\ominus}\ \xrightarrow{\Delta}\ \mathrm{R^2}-\underset{\mathrm{R^3}}{\mathrm{N}}-\mathrm{O}-\mathrm{R^1}$$

R^2 and R^3 may be alkyl or aryl, but if one of the R groups contains a β-hydrogen, the Cope elimination reaction (**7-8**) often competes.

8-26 The Wittig Rearrangement



$$\mathrm{R-CH_2-O-R'}\ \xrightarrow{\mathrm{R''Li}}\ \mathrm{R}-\underset{\mathrm{R'}}{\mathrm{CH}}-\mathrm{OLi}+\mathrm{R''H}$$

The rearrangement of ethers with alkyllithiums is called the *Wittig rearrangement* (not to be confused with the Wittig reaction, **6-47**) and is similar to reaction **8-25**.[265] However, a stronger base is required (e.g., phenyllithium or sodium amide). R and R′ may be alkyl, aryl, or vinyl.[285] Also, one of the hydrogens may be replaced by an alkyl or aryl group, in which case the product is the salt of a tertiary alcohol. Migratory aptitudes here are allyl, benzyl > ethyl > methyl >

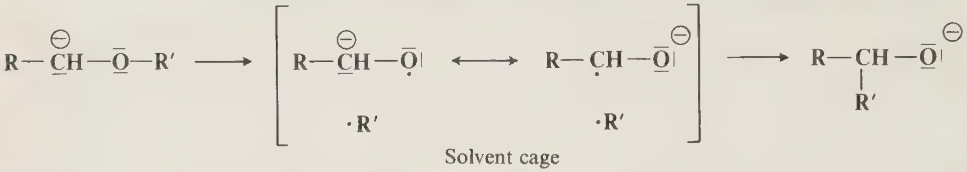
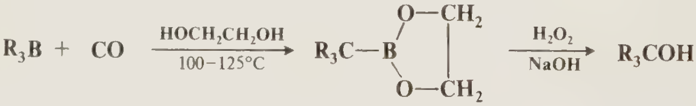
phenyl.[286] The following radical-pair mechanism[287] (similar to mechanism *a* of reaction **8-25**) is likely, after removal of the proton by the base. One of the radicals in the radical pair is a ketyl



radical. Among the evidence for this mechanism is: (1) The rearrangement is largely intramolecular; (2) migratory aptitudes are in the order of free-radical stabilities, and not of carbanion stabilities[288] (which rules out an ion-pair mechanism similar to mechanism *b* of reaction **8-25**); (3) aldehydes are obtained as side products;[289] (4) partial racemization of **R**′ has been observed[290] (the remainder of the product retained its configuration); (5) crossover products have been detected;[291] and (6) when ketyl radicals and R′· radicals from different precursors were brought together, similar products resulted.[292] However, there is evidence that at least in some cases the radical-pair mechanism accounts for only a portion of the product, and some kind of concerted mechanism can also take place.[293] Most of the above investigations were carried out with systems where R′ is alkyl, but a radical-pair mechanism has also been suggested for the case where R′ is aryl.[294] When R′ is allylic a concerted mechanism may operate (reaction **8-40**).

F. Boron-to-Carbon Migrations.[295] For another reaction involving boron-to-carbon migration, see reaction **0-101.**

8-27 Conversion of Boranes to Tertiary Alcohols



85

Trialkylboranes (which can be prepared from olefins by reaction **5-15**) react with carbon monoxide[296] at 100 to 125°C in the presence of ethylene glycol to give the 2-bora-1,3-dioxolanes **85**, which are easily oxidized (reaction **2-26**) to tertiary alcohols.[297] The R groups may be primary, secondary, or tertiary, and may be the same or different,[298] though a general method for the preparation of trialkylboranes with all three groups different is not yet available. Yields are high, and the reaction is quite useful, especially for the preparation of sterically hindered alcohols such as tricyclohexylcarbinol and tri-2-norbornylcarbinol, which are difficult to prepare by reaction **6-31.** Heterocycles in which boron is a ring atom react similarly (except that high CO pressures are required), and cyclic alcohols can be obtained from these substrates.[299] The

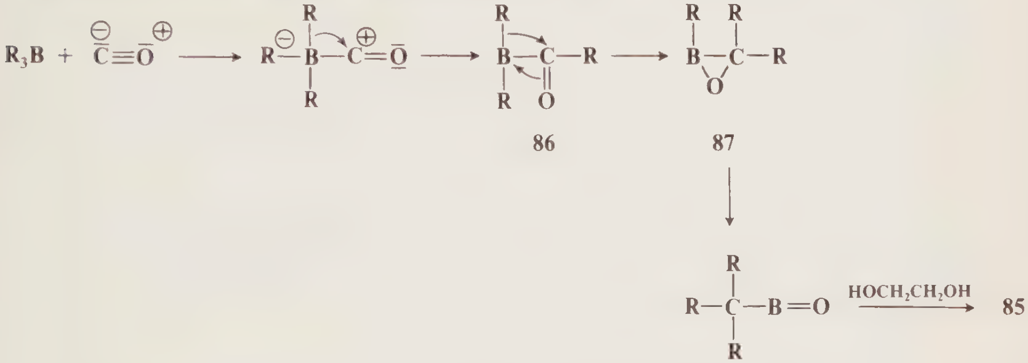
preparation of such heterocyclic boranes was discussed in reaction **5-15.** The overall conversion of a diene or triene to a cyclic alcohol has been described by H. C. Brown as "stitching" with boron, and "riveting" with carbon.

Though the mechanism has not been investigated thoroughly, it has been shown to be intramolecular, by the failure to find crossover products when mixtures of boranes are used.[300] The following scheme, involving three boron-to-carbon migrations, has been suggested.



86 **87**

88

The purpose of the ethylene glycol is to intercept the boronic anhydride **88,** which otherwise forms polymers which are difficult to oxidize. As we shall see in reactions **8-28** and **8-29,** it is possible to stop the reaction after only one or two migrations have taken place.

There are two other methods for achieving the conversion $R_3B \rightarrow R_3COH$, which often give better results: (1) treatment with α,α-dichloromethyl methyl ether and the base lithium triethyl-

Method 1 $$R_3B + CHCl_2OMe \xrightarrow[\text{2. } H_2O_2-NaOH]{\text{1. } LiOCEt_3-THF} R_3COH$$

Method 2 $$R_3B + CN^- \xrightarrow{\text{THF}} \underset{\textbf{89}}{R_3\overset{\ominus}{B}-CN} \xrightarrow[\text{2. } NaOH-H_2O_2]{\text{1. excess } (CF_3CO)_2O} R_3COH$$

Greenville, SC

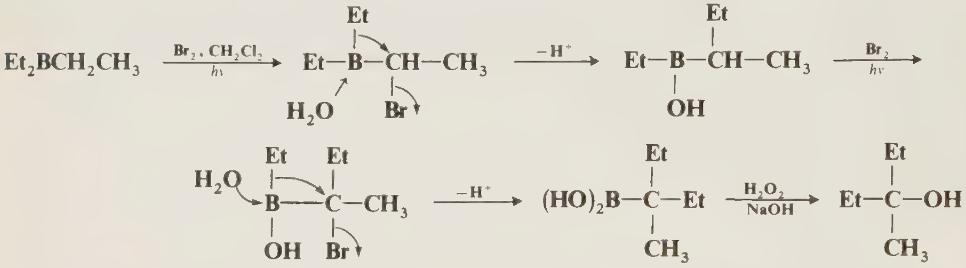
carboxide,[301] and (2) treatment with a suspension of sodium cyanide in tetrahydrofuran followed by reaction of the resulting trialkylcyanoborate **89** with an excess (more than 2 moles) of trifluoroacetic anhydride.[302] All the above migrations take place with retention of configuration at the migrating carbon.

Another method converts a trialkylborane to a tertiary alcohol in which only two of the R groups are derived from the borane. In this method the borane is treated with a 1-lithio-1,1-bis(phenylthio)alkane, then with $HgCl_2$, and the product finally oxidized.[303] This method can be

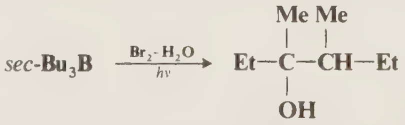
$$R_3B + R'\overset{\ominus}{\bar{C}}(SPh)_2 \longrightarrow R_3\overset{\ominus}{B}-CR'(SPh)_2 \longrightarrow R_2B-CRR'SPh \xrightarrow[2.\ H_2O_2-OH^-]{1.\ HgCl_2} R_2R'COH$$

adapted to the preparation of secondary alcohols R_2CHOH ($R' = H$) if three equivalents of $HgCl_2$ are used.[303a]

A different kind of borane-to-tertiary-alcohol conversion involves treatment of a tri-*n*-alkylborane with 2 moles of bromine or N-bromosuccinimide in the presence of water and light, followed by oxidation.[304] In this reaction, illustrated for triethylborane, bromination steps (reaction **4-1**)

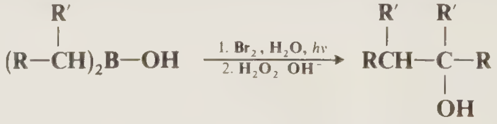


are followed by migration steps. Tri-*sec*-alkylboranes give corresponding products, but in lower yields. However, when tri-*sec*-alkylboranes are treated with only 1 mole of Br_2, in the presence of water and light, only one migration takes place and the product is a tertiary alcohol derived from two alkyl groups.[305]



$$sec\text{-}Bu_3B \xrightarrow[h\nu]{Br_2\text{-}H_2O} Et-\underset{OH}{\overset{Me}{C}}-\overset{Me}{CH}-Et$$

Extension of this reaction to boranes of the form RR′R″B, where R″ is thexyl, permits combination of R and R′, since thexyl neither can be α-brominated, nor does it migrate.[306] Alternatively, tertiary alcohols derived from one migration can also be prepared by starting with dialkylborinic acids.[307]



$$(R-\overset{R'}{CH})_2B-OH \xrightarrow[2.\ H_2O_2\ OH^-]{1.\ Br_2,\ H_2O,\ h\nu} R\overset{R'}{CH}-\underset{OH}{\overset{R'}{C}}-R$$

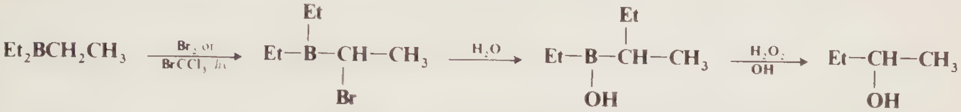
[306] Brown, Yamamoto, and Lane, *Synthesis* 304 (1972).

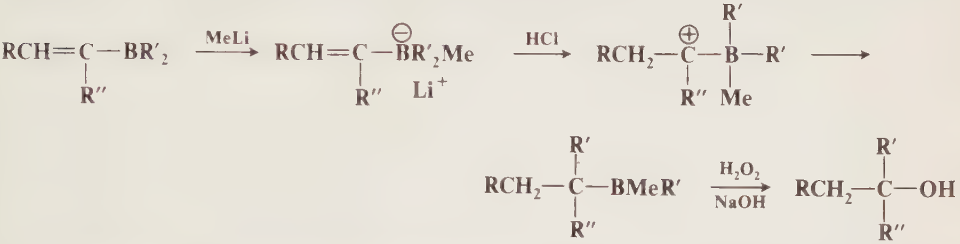
[307] Brown and Lane, *Synthesis* 303 (1972).

When tri-*n*-alkylboranes are treated with 1 mole of Br_2, or with bromotrichloromethane, under the influence of light, in the absence of water, the α-bromoboranes can be isolated.[308] Treatment of these with nucleophiles,[309] such as H_2O or pyridine, followed by oxidation, produces secondary alcohols.



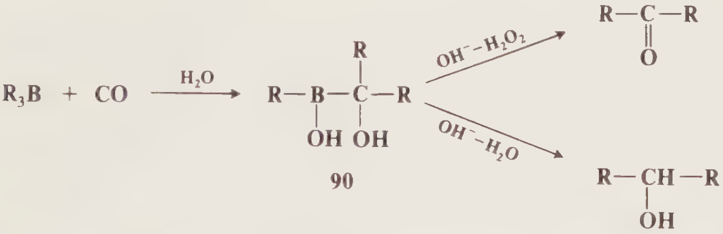
$$\mathrm{Et_2BCH_2CH_3} \xrightarrow[\mathrm{BrCCl_3},\ h\nu]{\mathrm{Br_2\ or}} \mathrm{Et{-}\overset{Et}{B}{-}\underset{Br}{CH}{-}CH_3} \xrightarrow{\mathrm{H_2O}} \mathrm{Et{-}\underset{OH}{B}{-}\overset{Et}{CH}{-}CH_3} \xrightarrow[\mathrm{OH^-}]{\mathrm{H_2O_2}} \mathrm{Et{-}\underset{OH}{CH}{-}CH_3}$$

Secondary and tertiary alcohols can also be prepared from vinyldialkylboranes (R″ = alkyl or hydrogen; prepared by addition of R_2BH to alkynes, reaction **5-15**), by treatment with methyllithium followed by HCl, and oxidation of the product.[310] This migration proceeds with retention of configuration in R′.



$$\mathrm{RCH{=}\underset{R''}{C}{-}BR'_2} \xrightarrow{\mathrm{MeLi}} \mathrm{RCH{=}\underset{R''}{C}{-}\overset{\ominus}{B}R'_2Me\ \ Li^+} \xrightarrow{\mathrm{HCl}} \mathrm{RCH_2{-}\underset{R''}{\overset{\oplus}{C}}{-}\underset{Me}{\overset{R'}{B}}{-}R'} \longrightarrow \mathrm{RCH_2{-}\underset{R''}{\overset{R'}{C}}{-}BMeR'} \xrightarrow[\mathrm{NaOH}]{\mathrm{H_2O_2}} \mathrm{RCH_2{-}\underset{R''}{\overset{R'}{C}}{-}OH}$$

8-28 Conversion of Boranes to Secondary Alcohols or Ketones



$$\mathrm{R_3B + CO} \xrightarrow{\mathrm{H_2O}} \mathrm{R{-}\underset{OH}{B}{-}\underset{OH}{\overset{R}{C}}{-}R} \quad \begin{cases} \xrightarrow{\mathrm{OH^-{-}H_2O_2}} \mathrm{R{-}\underset{\|\atop O}{C}{-}R} \\ \xrightarrow{\mathrm{OH^-{-}H_2O}} \mathrm{R{-}\underset{OH}{CH}{-}R} \end{cases}$$

90

If the reaction between trialkylboranes and carbon monoxide (**8-27**) is carried out in the presence of water followed by addition of NaOH, the product is a secondary alcohol. If H_2O_2 is added along with the NaOH, the corresponding ketone is obtained instead.[311] Various functional groups (e.g., OAc, COOR, CN) may be present in R without being affected,[312] though if they are in the α or β position relative to the boron atom, difficulties may be encountered. The reaction has been extended to the formation of unsymmetrical ketones by use of a borane of the form $R_2R'B$, where one of the groups migrates much less readily than the other (migratory aptitudes are in the order primary > secondary > tertiary). For example, *n*-alkyldicyclohexylboranes gave good yields of alkyl cyclohexyl ketones.[300] When R′ is thexyl, it is always the other two groups which migrate, so the product from a borane RR′R″ (R″ = thexyl) is the ketone RCOR′.[313] However, the thexyl reaction suffers from the disadvantage that carbonylation of boranes containing a thexyl group requires CO pressures of 70 atm. Cyclic thexylboranes give cyclic ketones,[314] e.g.,

---

[308] Brown and Yamamoto, *J. Am. Chem. Soc.* **93,** 2796 (1971), *Chem. Commun.* 1535 (1971); Brown and DeLue, *J. Am. Chem. Soc.* **96,** 311 (1974).

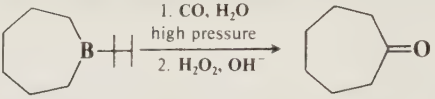
[309] This conversion can also be induced by electrophiles, such as $AlCl_3$: Brown and Yamamoto, *J. Chem. Soc., Chem. Commun.* 71 (1972).

[310] Zweifel and Fisher, *Synthesis* 339 (1974). See also Zweifel, Fisher, and Horng, *Synthesis* 37 (1973).

[311] Brown and Rathke, *J. Am. Chem. Soc.* **89,** 2738 (1967).

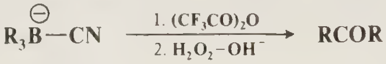
[312] Brown, Kabalka, and Rathke, *J. Am. Chem. Soc.* **89,** 4530 (1967).

[313] Brown and Negishi, *J. Am. Chem. Soc.* **89,** 5285 (1967); Negishi and Brown, *Synthesis* 196 (1972).



The reaction follows the mechanism shown in reaction **8-27** until formation of the borepoxide **87.** In the presence of water the third boron → carbon migration does not take place, because the water hydrolyzes **87** to the diol **90.**

Trialkylboranes can also be converted to ketones by the cyanoborate procedure, mentioned in reaction **8-27.** In this case the procedure is similar, but use of an equimolar amount of trifluoroacetic anhydride leads to the ketone rather than the tertiary alcohol.[315] By this procedure thexylboranes RR′R″B (R″ = thexyl) can be converted to unsymmetrical ketones RCOR′ without the use of high pressures. Like the carbon monoxide procedure, this method tolerates the presence of various functional groups in R. Another method involves the treatment of borinic acid esters (which can be prepared by treatment of dialkylchloroboranes with alcohols) with α,α-dichloromethyl methyl ether and lithium triethylcarboxide.[316] This method does not waste an R group

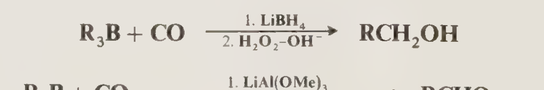


$$R_3\overset{\ominus}{B}\text{—CN} \xrightarrow[\text{2. } H_2O_2\text{–}OH^-]{\text{1. } (CF_3CO)_2O} RCOR$$

89

$$R_2BCl + R'OH \longrightarrow R_2BOR' \xrightarrow[\text{2. } H_2O_2\text{-}OH^-]{\text{1. } CHCl_2OMe,\ LiOCEt_3 \quad THF,\ 25°C} R_2CO$$

and is carried out under mild conditions. In still another procedure ketones are prepared by the reaction between dialkylchloroboranes and lithium aldimines[317] (which can be prepared by reaction **6-76**).



$$R_2BCl + R''\text{—N=}\underset{\displaystyle Li}{\underset{|}{C}}\text{—}R' \xrightarrow[\text{2. } H_2O_2\text{-}OH^-]{\text{1. HCN or PhCHO}} R\text{—}\underset{\displaystyle O}{\underset{\|}{C}}\text{—}R'$$

For another conversion of trialkylboranes to ketones, see reaction **8-31.** For other conversions of boranes to secondary alcohols, see reaction **8-27.**

8-29 Conversion of Boranes to Primary Alcohols or Aldehydes

$$R_3B + CO \xrightarrow[\text{2. } H_2O_2\text{-}OH^-]{\text{1. } LiBH_4} RCH_2OH$$

$$R_3B + CO \xrightarrow[\text{2. } H_2O_2\text{-}NaH_2PO_4\text{-}Na_2HPO_4]{\text{1. } LiAl(OMe)_3} RCHO$$

When the reaction between a trialkylborane and carbon monoxide (**8-27**) is carried out in the presence of a reducing agent such as lithium borohydride or lithium trimethoxyaluminum hydride, the reducing agent intercepts the intermediate **86,** so that only one boron-to-carbon migration takes place, and the product is hydrolyzed to a primary alcohol or oxidized to an aldehyde.[318] This procedure wastes two of the three R groups, but this problem can be avoided by the use of B-alkyl-9-BBN derivatives (p. 432). Since only the 9-alkyl group migrates, this method permits the conversion in high yield of an alkene to a primary alcohol or aldehyde containing one more carbon.[319] When B-alkyl-9-BBN derivatives are treated with CO and lithium tri-*t*-butoxyaluminum hydride, other functional groups (e.g., CN and ester) may be present in the alkyl group without being reduced.[320]

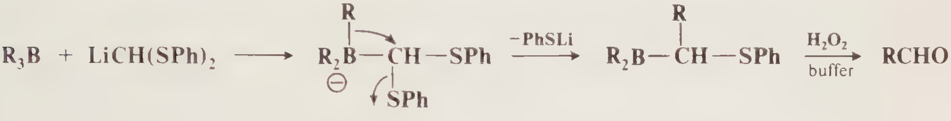
Another preparation of aldehydes utilizes α-lithiated thioacetals **91**, which react with trialkyl-

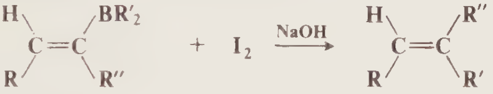


$$R_3B + LiCH(SPh)_2 \longrightarrow R_2\overset{\ominus}{B}(R)-CH(SPh)-SPh\ Li^+ \xrightarrow{-PhSLi} R_2B-CH(R)-SPh \xrightarrow[\text{buffer}]{H_2O_2} RCHO$$

91 **92**

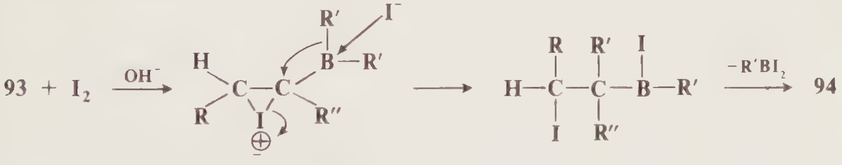
boranes to give, after migration of R, the boranes **92**, which are oxidized to aldehydes with hydrogen peroxide.[321] The method can be adapted to the preparation of ketones by the use of $LiCR'(SPh)_2$ instead of **91**.

8-30 Conversion of Vinylboranes to Alkenes



93 94

The reaction between trialkylboranes and iodine to give alkyl iodides was discussed at reaction **2-28.** When the substrate contains a vinyl group, the reaction takes a different course, with one of the R′ groups migrating to the carbon, to give alkenes **94.**[322] The reaction is stereospecific in two senses: (1) If the groups R and R″ are cis in the starting compound, they will be trans in the product. (2) There is retention of configuration within the migrating group R′.[323] Since vinylboranes can be prepared from alkynes (**5-15**), this is a method for the addition of R′ and H to a triple bond. If R″ = H, the product is a cis alkene. The mechanism is believed to be



When R′ is vinyl, the product is a conjugated diene.[324]

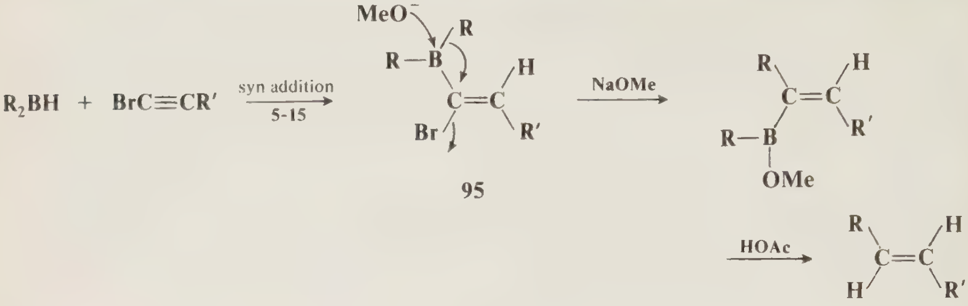
[324] Zweifel, Polston, and Whitney, *J. Am. Chem. Soc.* **90,** 6243 (1968); Brown and Ravindran, *J. Org. Chem.* **38,** 1617 (1973).

In another procedure, the addition of a dialkylborane to a 1-haloalkyne produces an α-halovinylborane (**95**). Treatment of this with NaOMe gives the rearrangement shown, and protonolysis

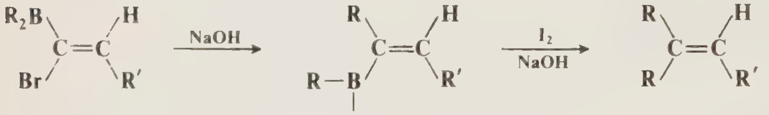


95

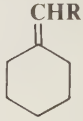
96

of the product produces the trans alkene **96**.[323] If R is a vinyl group the product is a 1,3-diene.[325] If one of the groups is thexyl, then the other one migrates.[326] This extends the scope of the synthesis, since dialkylboranes where one R group is thexyl are easily prepared.

A combination of both of the procedures described above results in the preparation of trisubstituted olefins.[327] The entire conversion of haloalkyne to **97** can be carried out in one reaction



95 **97**



98

vessel, without isolation of intermediates. If R_2BH is a heterocyclic borane, the product is an exocyclic olefin, e.g., **98.**

Trans alkenes **96** can also be obtained by treatment of **93** (R″ = H) with cyanogen bromide or cyanogen iodide in CH_2Cl_2.[328]

8-31 Formation of Alkynes, Alkenes, and Ketones from Boranes and Acetylides

$$R'_3B + RC{\equiv}CLi \longrightarrow \underset{\textbf{99}}{RC{\equiv}C{-}\overset{\ominus}{B}R'_3,\ Li^+} \xrightarrow{I_2} RC{\equiv}CR'$$

A hydrogen directly attached to a triple-bond carbon can be replaced in high yield by an alkyl or an aryl group, by treatment of the lithium acetylide with a trialkyl- or triarylborane, followed by reaction of the lithium alkynyltrialkylborate **99** with iodine.[329] R′ may be primary or secondary alkyl as well as aryl, so the reaction has a broader scope than the older reaction **0-102.** R may be alkyl, aryl, or hydrogen, though in the last-mentioned case satisfactory yields are obtained only if lithium acetylide–ethylenediamine is used as the starting compound.[330] When the starting compound is $ClC\equiv CLi$, the Cl is also replaced and the product is the symmetrical alkyne $RC\equiv CR$.[331] The reaction is similar to the one mentioned in **8-30**, in that iodine causes a migration of R′ from boron to carbon, but the mechanism of the migration step may be different. Methanesulfinyl chloride MeSOCl has been used instead of iodine, but yields are lower.[332] The reaction may be adapted to the preparation of alkenes by treatment of **99** with a carboxylic acid

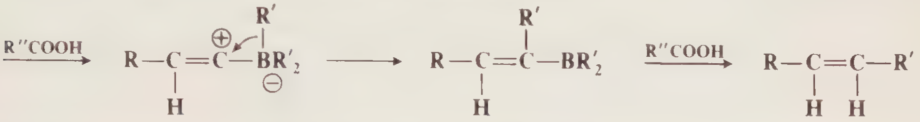
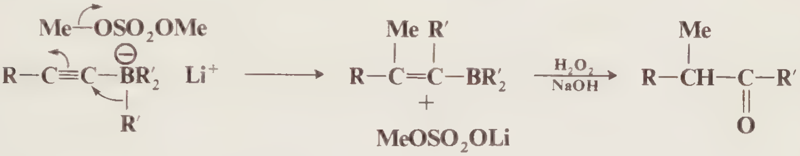
99



such as propionic acid.[333] This reaction is partially stereoselective, with mostly cis alkene generally produced.

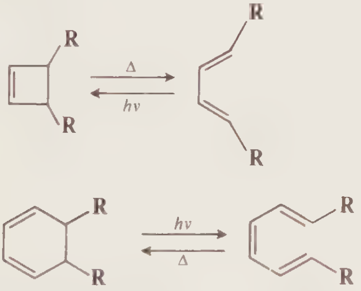
Treatment of **99** with an electrophile, such as methyl sulfate, allyl bromide, or triethyloxonium borofluoride, followed by oxidation of the resulting vinylborane gives a ketone (illustrated for methyl sulfate):[334]



Non-1,2 Rearrangements

A. Electrocyclic Rearrangements

8-32 Electrocyclic Rearrangements of Cyclobutenes and 1,3-Cyclohexadienes



Cyclobutenes and 1,3-dienes can be interconverted by treatment with uv light or with heat. The thermal reaction is generally not reversible (though exceptions[335] are known), and many cyclobutenes have been converted to 1,3-dienes by heating at temperatures between 100 and 200°C.

[331] Yamada, Miyaura, Itoh, and Suzuki, *Tetrahedron Lett.* 1961 (1975).

[332] Naruse, Utimoto, and Nozaki, *Tetrahedron Lett.* 1847 (1973).

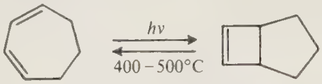
[334] Pelter, Harrison, and Kirkpatrick, Ref. 333. See also Pelter, Harrison, and Kirkpatrick, *Tetrahedron Lett.* 4491 (1973); Utimòto, Furubayashi, and Nozaki, *Chem. Lett.* 397 (1975).

[335] For example, see Shumate, Neuman, and Fonken, *J. Am. Chem. Soc.* **87**, 3996 (1965); Gil-Av and Herling, *Tetrahedron Lett.* 1 (1967); Doorakian and Freedman, *J. Am. Chem. Soc.* **90**, 3582 (1968); Brune and Schwab, *Tetrahedron* **25**, 4375 (1969).

The photochemical conversion can in principle be carried out in either direction, but most often 1,3-dienes are converted to cyclobutenes rather than the reverse, because the dienes are stronger absorbers of light at the wavelengths used.[336] In a similar reaction, 1,3-cyclohexadienes interconvert with 1,3,5-trienes, but in this case the ring-closing process is generally favored thermally, and the ring-opening process photochemically, though exceptions are known in both directions.

Some examples are



100

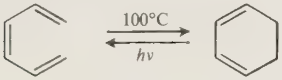
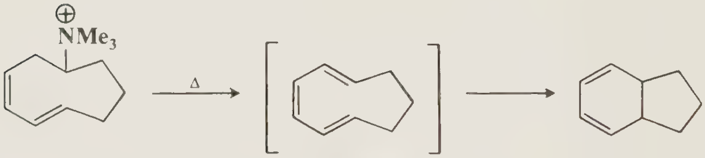
4-Methoxytropone

101

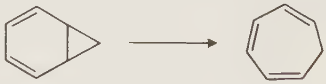
Ref. 338





Not isolated

Note that in the second example the tropone is a 1,3,5-triene, but in this case reacts as a 1,3-diene (see p. 1032). An interesting example of a 1,3-cyclohexadiene-1,3,5-triene interconversion is the reaction of norcaradienes to give cycloheptatrienes.[339] Norcaradienes give this reaction so readily (because they are *cis*-1,2-divinylcyclopropanes, see p. 1045) that they cannot generally be isolated, though some exceptions are known[340] (see also p. 792).



Norcaradiene

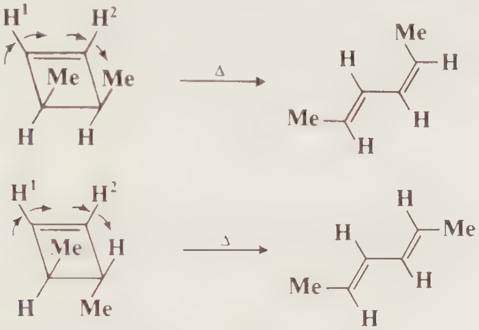
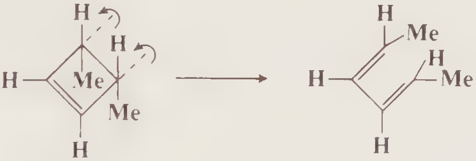
Engl.* **6,** 402–413 (1967) [*Angew. Chem.* **79,** 446–458]; Vogel and Günther, *Angew. Chem. Int. Ed. Engl.* **6,** 385–401 (1967) [*Angew. Chem.* **79,** 429–446]; Vogel, *Pure Appl. Chem.* **20,** 237–262 (1969).

[340] See Chapter 15, Refs. 745 and 746.

These reactions, called *electrocyclic rearrangements*,[341] take place by pericyclic mechanisms. The evidence for this comes from stereochemical studies, which show a remarkable stereospecificity whose direction depends on whether the reaction is induced by heat or light. For example, it was found for the thermal reaction that *cis*-3,4-dimethylcyclobutene gave only *cis,trans*-2,4-hexadiene, while the trans isomer gave only the trans-trans diene:[342]



This is evidence for a four-membered cyclic transition state and arises from *conrotatory* motion of the C-1 and C-2 hydrogens. That is, as H¹ moves up, H² moves down. It is called conrotatory because they both move clockwise (or both counterclockwise). The other possibility (*disrotatory* motion) would have one moving clockwise while the other moves counterclockwise. Another way to look at this is to observe the motions of the methyl groups and of the C-3 and C-4 hydrogens. In conrotatory motion they rotate in the same direction (and the cis isomer gives the cis-trans diene):[343]



On the other hand, in a disrotatory motion, in which they moved in opposite ways, the cis isomer would have given the cis-cis diene (shown), or the trans-trans diene:

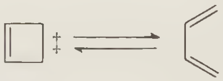
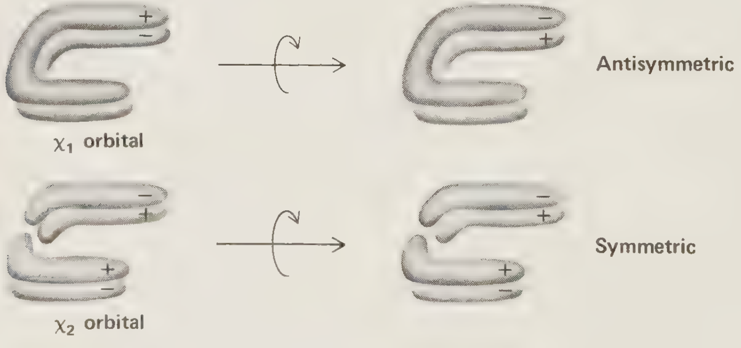
[343] This picture is from Woodward and Hoffmann, *J. Am. Chem. Soc.* **87**, 395 (1965), who coined the terms conrotatory and disrotatory.

If the motion had been disrotatory, this would still have been evidence for a cyclic mechanism. If the mechanism were a diradical or some other kind of noncyclic process, it is likely that no stereospecificity of either kind would have been observed. The reverse reaction is also conrotatory. In contrast, the photochemical cyclobutene-1,3-diene interconversion is *disrotatory* in either direction. On the other hand, the cyclohexadiene-1,3,5-triene interconversion shows precisely the opposite behavior. The thermal process is *disrotatory*, while the photochemical process is *conrotatory* (in either direction). These startling results are a consequence of the symmetry rules mentioned in Chapter 15 (p. 767).[344] As in the case of cycloaddition reactions, we may use the correlation diagram or the orbital frontier approach.[345]

The Correlation Diagram Method

Let us consider the cyclobutene-1,3-diene interconversion. The orbitals to be correlated are the four π orbitals of the diene (p. 33) and the two π and the two σ orbitals (marked ‡) of the cyclobutane. First we examine the case where the reaction proceeds in a conrotatory manner. As in Chapter 15, we draw the orbitals involved and examine each one to see if it is symmetric or antisymmetric. However, in this case it is not possible to use a *plane of symmetry* as our symmetry element, because no plane of symmetry is present throughout the course of the reaction.[346] An alternating axis of symmetry is present, however, and we may use this instead. The procedure in using such an axis is to rotate the entire orbital through 180°. If it then coincides with itself, it is symmetric. If all signs are changed, it is antisymmetric. For example, if the χ_1 orbital of a 1,3-diene is rotated through 180° (turned upside down) the signs are inverted, so it is antisymmetric with respect to this operation (the same orbital would be symmetric with respect to a plane





---

[345] For reviews, see Woodward and Hoffmann, Ref. 278, pp. 38–64; Fukui and Fujimoto, *Mech. Mol. Migr.* **2,** 117–189 (1969). See also Chapter 15, Ref. 614.

[346] A plane of symmetry is present before the reaction begins and after it is over, but not during the reaction. Examine the σ and σ^* orbitals in Figure 1. The curved arrows show the direction in which the orbitals must move in a conrotatory process. It may be seen that the plane of symmetry present in the cyclobutene disappears soon after the reaction begins.

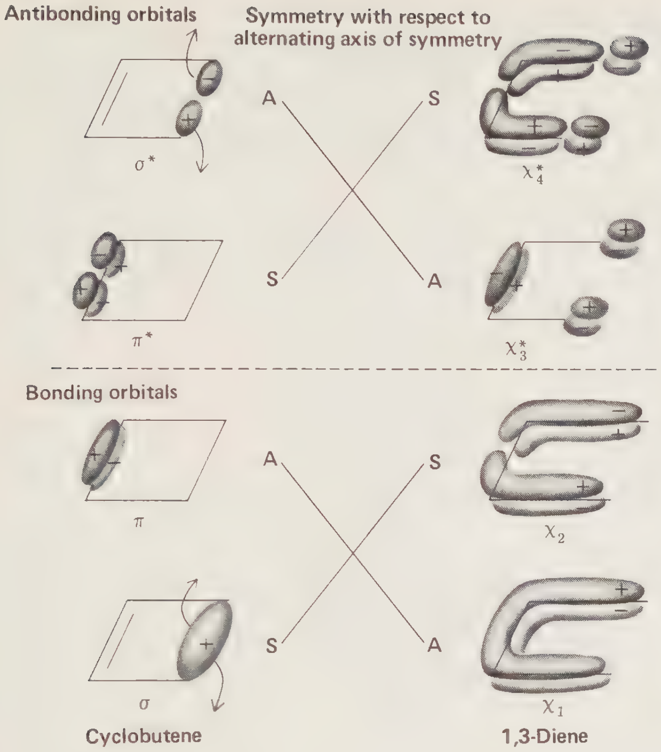

Figure 1 Correlation diagram for a conrotatory cyclobutene-1,3-diene interconversion.

of symmetry, but that does not concern us here). On the other hand, if the same operation is performed on the χ_2 orbital no change in sign is observed, and this orbital is symmetric with respect to an alternating axis of symmetry. Performing the same operation on all eight of our orbitals gives the correlation diagram shown in Figure 1. As the diagram shows, the conrotatory reaction is thermally allowed in both directions because only the two lower orbitals are occupied, and no occupied orbital is forced to move from a bonding to an antibonding condition.

Now let us examine the disrotatory reaction. In this case, a plane of symmetry is present throughout the course of the reaction (see the arrows on the σ and σ^* orbitals in Figure 2), and we can easily construct the correlation diagram shown in Figure 2. Again, only the lower two orbitals are occupied. Because this reaction requires an occupied bonding orbital to be converted to an antibonding orbital, it is thermally forbidden in either direction.[347] For the photochemical reactions, these predictions are reversed. In this case, whether we start with the cyclobutene or with the 1,3-diene, initial promotion of an electron means that *three* orbitals are occupied in the starting compound, so that the conrotatory process (Figure 1) is now forbidden in either direction (because it requires an increase in energy of either the π^* or the χ_3^* orbital, depending on the

direction), and the disrotatory process (Figure 2) is now allowed (because there is essentially no change in orbital energies). We can therefore see why, in either direction, the thermal reaction follows the conrotatory pathway, and the photochemical reaction, the disrotatory pathway.

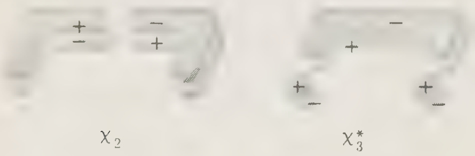
The Frontier Orbital Method[348]

As applied to these reactions, the frontier orbital method may be expressed: *A σ bond will open in such a way that the resulting p orbitals will have the symmetry of the highest occupied π orbital of the product*. In the case of cyclobutenes, the highest occupied π orbital of the product in the thermal reaction is the χ_2 orbital (Figure 3). Therefore, in a thermal process, the cyclobutene

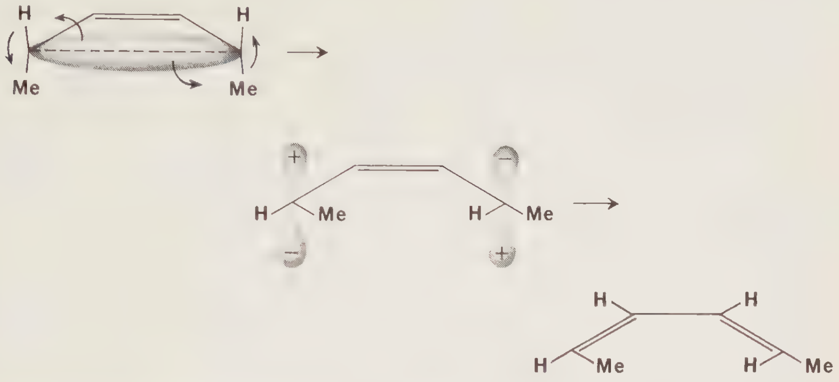
---

[348] See Chapter 15, Ref. 619.

Figure 3 Symmetries of the χ_2 and χ_3* orbitals of a conjugated diene.

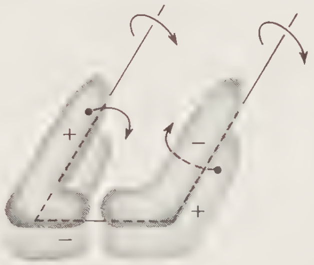


must open so that on one side the positive lobe lies above the plane, and on the other side below it. Thus the substituents are forced into conrotatory motion:



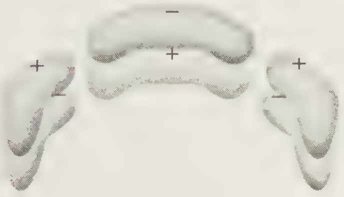
On the other hand, in the photochemical process, the highest occupied π orbital of the product is now the χ_3 orbital (Figure 3), and in order for the p orbitals to achieve this symmetry (the two plus lobes on the same side of the plane), the substituents are forced into disrotatory motion.

We may also look at this reaction from the opposite direction (ring closing). For this direction the rule is that *those lobes of orbitals which overlap (in the highest occupied molecular orbital) must be of the same sign.* For thermal cyclization of butadienes, this requires conrotatory motion:

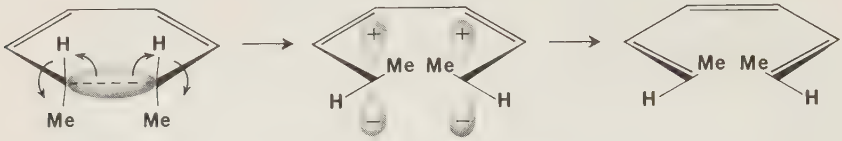


In the photochemical process the highest occupied orbital is the χ_3 orbital, so that disrotatory motion is required for lobes of the same sign to overlap.

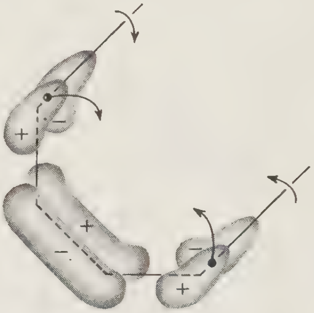
Both the correlation diagram and the frontier orbital methods can also be applied to the cyclohexadiene-1,3,5-triene reaction; in either case the result predicted is that for the thermal process only the disrotatory pathway is allowed, and for the photochemical process, only the conrotatory. For example, for a 1,3,5-triene, the symmetry of the highest occupied molecular orbital is



In the thermal cleavage of cyclohexadienes, then, the positive lobes must lie on the same side of the plane, requiring disrotatory motion:

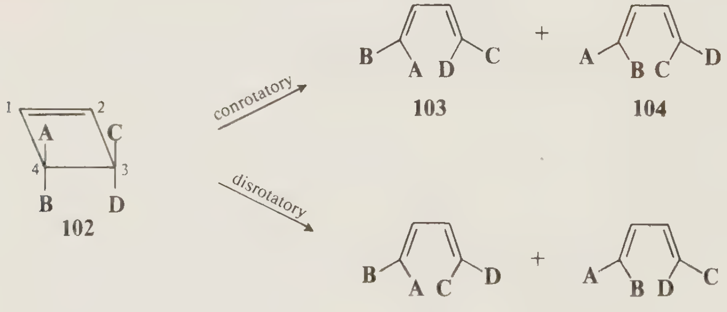


Disrotatory motion is also necessary for the reverse reaction, in order that the orbitals which overlap may be of the same sign:



All these directions are reversed for photochemical processes, because in each case a higher orbital, with inverted symmetry, is occupied.

In the most general case, there are four possible products which can arise from a given cyclobutene or cyclohexadiene, two from the conrotatory and two from the disrotatory pathway. For example, conrotatory ring opening of **102** gives either **103** or **104**, while disrotatory opening gives either **105** or **106**. The orbital symmetry rules tell us when a given reaction will operate by the conrotatory and when by the disrotatory mode, but they do not say which of the two possible conrotatory or disrotatory pathways will be followed. It is often possible, however, to make such predictions on steric grounds. For example, in the opening of **102** by the disrotatory pathway, **105** arises when groups A and C swing in toward each other (clockwise motion around C-4, counterclockwise around C-3), while **106** is formed when groups B and D swing in, and A and C swing out (clockwise motion around C-3; counterclockwise around C-4). We therefore predict that when A



102 **103** **104** **105** **106**

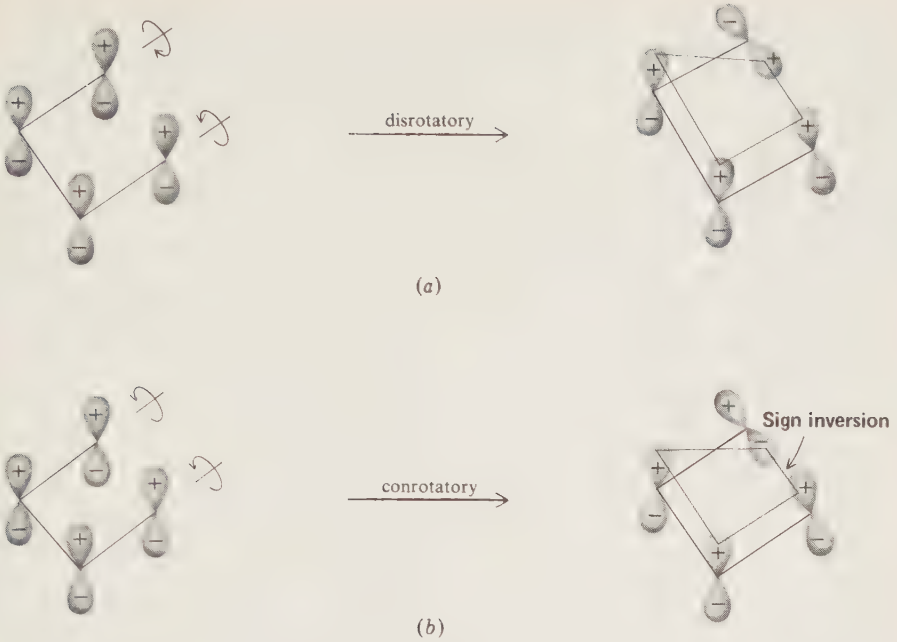


Figure 4 The 1,3-diene-cyclobutene interconversion. The orbitals shown are *not* molecular orbitals, but a basis set of *p* atomic orbitals. (*a*) Disrotatory ring closure gives zero sign inversions. (*b*) Conrotatory ring closure gives one sign inversion. We could have chosen to show any other basis set (for example, another basis set would have two plus lobes above the plane and two below, etc.). This would change the number of sign inversions, but the disrotatory mode would still have an even number of sign inversions, and the conrotatory mode an odd number, whichever basis set was chosen.

and C are larger than B and D, the predominant or exclusive product will be **106,** rather than **105.** Predictions of this kind have largely been borne out.[349]

It is possible to relate the orbital symmetry rules to the Hückel aromaticity rule discussed in Chapter 2. Hückel's rule, which states that a cyclic system of electrons will be aromatic (hence stable) when it consists of $4n + 2$ electrons, applies of course to molecules in their ground states. In applying the orbital symmetry principle we are not concerned with ground states, but with transition states. In the present method[350] we do not examine the molecular orbitals themselves, but rather the *p* orbitals before they overlap to form the molecular orbitals. Figure 4 shows such a set of *p* orbitals (called a *basis set*) for a 1,3-diene. It is seen that disrotatory ring closing (Figure 4*a*) results in overlap of plus lobes only, while in conrotatory closing (Figure 4*b*) there is one overlap of a plus with a minus lobe. In the first case we have zero sign inversions, while in the second there is one sign inversion. For such pericyclic reactions, if there are *zero or an even number* of sign inversions, we call it a *Hückel system.* If there is an *odd number* of sign inversions, we call it a *Möbius system* (note the similarity to the Möbius strip, which is a mathematical surface, shown in Figure 5). The orbital symmetry rules may then be stated:[350] *A thermal peri-*

---

[349] For example, see Baldwin and Krueger, *J. Am. Chem. Soc.* **91,** 6444 (1969); Spangler and Hennis, *J. Chem. Soc., Chem. Commun.* 24 (1972).

[350] Zimmerman, *J. Am. Chem. Soc.* **88,** 1564, 1566 (1966), *Acc. Chem. Res.* **4,** 272–280 (1971); Jefford and Burger, *Chimia* **25,** 297–307 (1971).

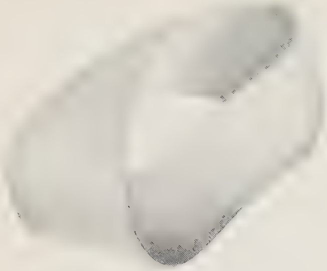

Figure 5 A Möbius strip. Such a strip is easily constructed by twisting a thin strip of paper 180° and fastening the ends together.

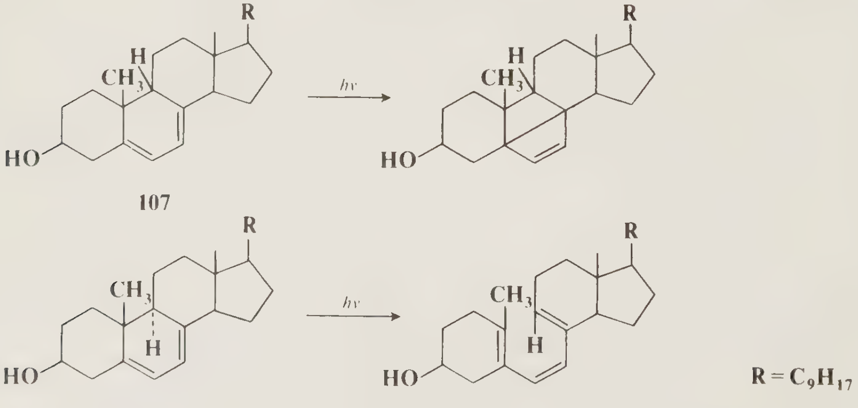
cyclic reaction involving a Hückel system is allowed only if the total number of electrons is $4n + 2$. *A thermal pericyclic reaction involving a Möbius system is allowed only if the total number of electrons is* $4n$. For photochemical reactions, these rules are reversed. Thus the thermal cyclobutene-1,3-diene interconversion, which has four electrons, is allowed to proceed only if the transition state has an odd number of inversions (Möbius). As shown in Figure 4, this requires a conrotatory path for this system. In contrast, the photochemical process requires a Hückel system, and hence a disrotatory path. Diagrams similar to those in Figure 4 may be drawn for the cyclohexadiene-1,3,5-triene interconversion. For this case also, the disrotatory pathway is a Hückel system and the conrotatory pathway a Möbius system, but since six electrons are involved here, the thermal reaction follows the Hückel pathway and the photochemical reaction the Möbius pathway. The Hückel-Möbius approach has the advantage over the correlation diagram approach that it is not necessary to determine the symmetries of the orbitals, which permits it to be applied to transition states with no symmetry (see p. 773).

Cyclohexadienes are of course 1,3-dienes, and in certain cases it is possible to convert them to cyclobutenes instead of to 1,3,5-trienes.[351] An interesting example is found in the pyrocalciferols. Photolysis of the syn isomer **107** (or of the other syn isomer, not shown) leads to the corre-



107

108 **109**

$R = C_9H_{17}$

---

[351] For a discussion of the factors favoring either direction, see Dauben, Kellogg, Seeman, Vietmeyer, and Wendschuh, *Pure Appl. Chem.* **33**, 197–215 (1973).

sponding cyclobutene,[352] while photolysis of the anti isomers (one of them is **108**) gives the ring-opened 1,3,5-triene **109.** This difference in behavior is at first sight remarkable, but is easily explained by the orbital symmetry rules. Photochemical ring opening to a 1,3,5-triene must be conrotatory. If **107** were to proceed by this pathway, the product would be the triene **109,** but this compound would have to contain a *trans*-cyclohexene ring (either the methyl group or the hydrogen would have to be directed inside the ring). On the other hand, photochemical conversion to a cyclobutene must be disrotatory, but if **108** were to give this reaction, the product would have to have a trans-fused ring junction. Compounds with such ring junctions are known (p. 118) but are very strained. Stable *trans*-cyclohexenes are unknown (p. 147). Thus, **107** and **108** give the products they do owing to a combination of orbital symmetry rules and steric influences. Note that **100** and **101** (p. 1024) can be opened thermally, though high temperatures are required. The orbital symmetry rules require concerted thermal ring opening in these systems to be conrotatory, but this is impossible here for similar reasons. It is possible that a diradical mechanism is operating, though it has been suggested that concerted disrotatory pathways are allowed in these cases.[353]

The 1,3-diene-cyclobutene interconversion can even be applied to benzene rings. For example,[354] photolysis of 1,2,4-tri-*t*-butylbenzene (**110**) gives 1,2,5-tri-*t*-butyl[2.2.0]hexadiene (**111,** a Dewar benzene).[355] The reaction owes its success to the fact that once **111** is formed it cannot, under the conditions used, revert to **110** by either a thermal or a photochemical route. The orbital symmetry rules prohibit thermal conversion of **111** to **110** by a pericyclic mechanism, because thermal conversion of a cyclobutene to a 1,3-diene must be conrotatory, and conrotatory reaction of **111** would result in a 1,3,5-cyclohexatriene containing one trans double bond (**112**), which is of course too strained to exist. **111** cannot revert to **110** by a photochemical pathway either, because light of the frequency used to excite **110** would not be absorbed by **111.** This is thus another example of a molecule which owes its stability to the orbital symmetry rules (see p. 787). Pyrolysis of **111** does give **110,** probably by a diradical mechanism.[356] Dewar benzenes bearing a chlorine or bromine in the 1 position (**113,** X = Cl or F) are converted to the corresponding benzenes much more rapidly.[357] This has been attributed to stabilization by the electron-withdrawing halogen of the disrotatory transition state.[357]

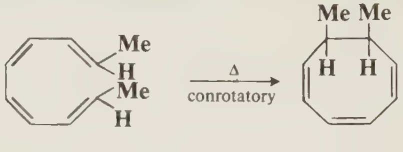
Soc.* **93,** 6092 (1971); van Tamelen, *Acc. Chem. Res.* **5,** 186–192 (1972). As mentioned on p. 787 (Ref. 704) Dewar benzenes can be photolyzed further to give prismanes.

[356] See for example, Oth, *Recl. Trav. Chim. Pays-Bas* **87,** 1185 (1968); Adam and Chang, *Int. J. Chem. Kinet.* **1,** 487 (1969); Lechtken, Breslow, Schmidt, and Turro, *J. Am. Chem. Soc.* **95,** 3025 (1973).

[357] Breslow, Napierski, and Schmidt, *J. Am. Chem. Soc.* **94,** 5906 (1972).

A number of electrocyclic reactions have been carried out with systems of other sizes, for example, conversion of the 1,3,5,7-octatetraene **114** to the cyclooctatriene **115**.[358] The stereochemistry of these reactions can be predicted in a similar manner. The results of such predictions can be summarized according to whether the number of electrons involved in the cyclic process is of the form $4n$ or $4n + 2$ (where n is any integer including zero).

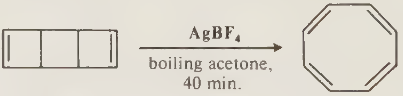


114 **115**

	Thermal reaction	**Photochemical reaction**
$4n$	conrotatory	disrotatory
$4n + 2$	disrotatory	conrotatory

Although the orbital symmetry rules predict the stereochemical results in almost all cases, it is necessary to recall (p. 775) that they only say what is allowed and what is forbidden, but the fact that a reaction is allowed does not necessarily mean that that reaction takes place, and if an allowed reaction does take place, it does not *necessarily* follow that a concerted pathway is involved, since other pathways of lower energy may be available.[359]

As was the case for 2 + 2 cycloaddition reactions (**5-52**), certain forbidden electrocyclic reactions can be made to take place by the use of metallic catalysts.[360] An example is the silver ion–catalyzed conversion of tricyclo[4.2.0.0^{2,5}]octa-3,7-diene (**116**) to cyclooctatetraene.[360a] This conversion is very slow thermally (that is, without the catalyst) because the reaction must take place by a disrotatory pathway, which is disallowed thermally. There is evidence that in reactions such as this, the metallic ion coordinates with the π electrons, in effect removing them from the transition state, so that the allowed process is now disrotatory instead of conrotatory.[361]



116

The ring opening of cyclopropyl cations (pp. 321, 986) is an electrocyclic reaction and is governed by the orbital symmetry rules.[362] For this case we may invoke the rule that the σ bond opens in such a way that the resulting p orbitals have the symmetry of the highest occupied orbital of the product, in this case an allylic cation. We may recall that an allylic system has three molecular orbitals (p. 34). For the cation, with only two electrons, the highest occupied of these is the one of lowest energy (**A**). Thus, the cyclopropyl cation must undergo a disrotatory

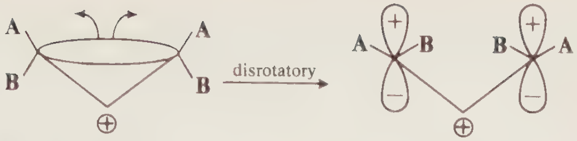
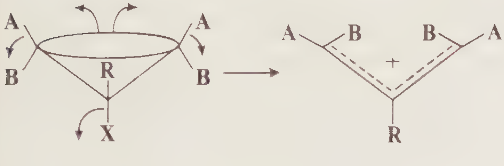
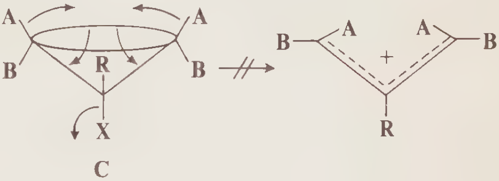
A



ring opening in order to maintain the symmetry. (Note that, in contrast, ring opening of the cyclopropyl *anion* must be conrotatory, since in this case it is the next orbital of the allylic system which is the highest occupied, and this has the opposite symmetry.[363]) However, it is very difficult (perhaps impossible) to generate a free cyclopropyl cation (p. 250), and it is likely that in most (perhaps all) cases, cleavage of the σ bond is concerted with departure of the leaving group in the original cyclopropyl substrate. This of course means that the σ bond provides anchimeric assistance to the removal of the leaving group (an SN2-type process), and we would expect that such assistance should come from the back side. This has an important effect on the direction of ring opening. The orbital symmetry rules require that the ring opening be disrotatory but, as we have seen, there are two disrotatory pathways, and the rules do not tell us which is preferred. But the fact that the σ orbital provides assistance from the back side means that the two substituents which are trans to the leaving group must move *outward* and not inward.[364] Thus, the disrotatory pathway which is followed is the one shown in **B**, and not the one shown in **C**, because

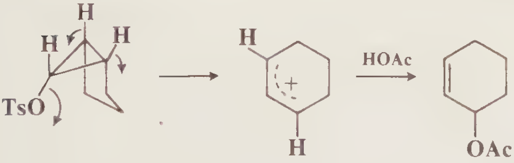


B

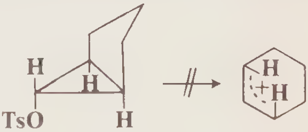


C

the former puts the electrons of the σ bond on the side opposite that of the leaving group.[365] Strong confirmation of this picture[366] comes from acetolysis of *endo*- (**117**) and *exo*-bicyclo[3,1,0]-hexyl-6-tosylate (**118**). The groups trans to the tosylate must move outward. For **117** this means



117



118

---

[363] For evidence that this is so, see Newcomb and Ford, *J. Am. Chem. Soc.* **96,** 2968 (1974).

[364] This statement was first proposed by DePuy, Schnack, Hausser, and Wiedemann, *J. Am. Chem. Soc.* **87,** 4006 (1965).

[365] It has been suggested that the pathway shown in C is possible in certain cases: Hausser and Grubber, *J. Org. Chem.* **37,** 2648 (1972); Hausser and Uchic, *J. Org. Chem.* **37,** 4087 (1972).

[366] There is much other evidence. For example, see Jefford and Medary, *Tetrahedron Lett.* 2069 (1966); Jefford, Yen, and Medary, *Tetrahedron Lett.* 6317 (1966); Jefford and Wojnarowski, *Tetrahedron Lett.* 199 (1968); Jefford and Hill, *Tetrahedron Lett.* 1957 (1969); Schleyer, Van Dine, Schöllkopf, and Paust, *J. Am. Chem. Soc.* **88,** 2868 (1966); Schleyer, Sliwinski, Van Dine, Schöllkopf, Paust, and Fellenberger, *J. Am. Chem. Soc.* **94,** 125 (1972); Sliwinski, Su, and Schleyer, *J. Am. Chem. Soc.* **94,** 133 (1972); Sandler, *J. Org. Chem.* **32,** 3876 (1967); Ghosez, Laroche, and Slinckx, *Tetrahedron Lett.* 2767 (1967); Ghosez, Slinckx, Glineur, Hoet, and Laroche, *Tetrahedron Lett.* 2773 (1967); Parham and Sperley, *J. Org. Chem.* **32,** 924, 926 (1967); Parham and Yong, *J. Org. Chem.* **33,** 3947 (1968); Baird and Reese, *Tetrahedron Lett.* 2117 (1969); Baird, Lindsay, and Reese, *J. Chem. Soc. C* 1173 (1969); Reese and Shaw, *J. Am. Chem. Soc.* **92,** 2566 (1970).

that the two hydrogens can go outside the framework of the six-membered ring, but for **118** they are forced to go inside. Consequently, it is not surprising that the rate ratio for solvolysis of **117**/**118** was found to be greater than 2.5 × 10^6, and that at 150°C **118** did not solvolyze at all.[367] This evidence is kinetic. Unlike the cases of the cyclobutene-1,3-diene and cyclohexadiene-1,3,5-triene interconversions, the direct product here is a cation, which is not stable but reacts with a nucleophile and loses some of its steric integrity in the process, so that much of the evidence has been of the kinetic type rather than from studies of product stereochemistry. However, it has been shown by investigations in super acids, where it is possible to keep the cations intact and to study their structures by nmr, that in all cases studied the cation which is predicted by these rules is in fact formed.[368] In another product study, it was shown that when the nucleophile is the same as the leaving group (isomerization of cyclopropyl chlorides to allyl chlorides), it reenters from the same side from which it departed.[369]

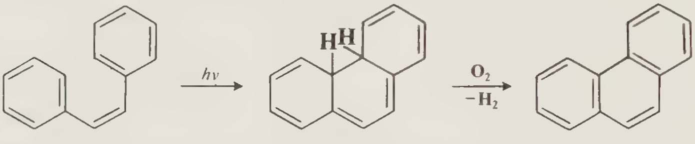
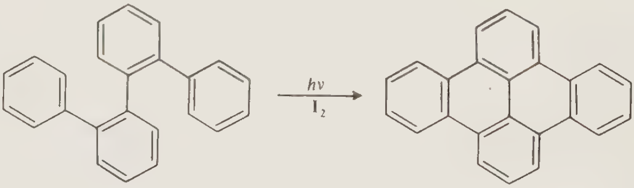
8-33 Conversion of Stilbenes to Phenanthrenes



Stilbenes can be converted to phenanthrenes by irradiation with uv light in the presence of an oxidizing agent such as dissolved molecular oxygen, $FeCl_3$, or iodine.[370] The reaction is a photochemically allowed conrotatory[371] conversion of a 1,3,5-hexatriene to a cyclohexadiene, followed by removal of two hydrogen atoms by the oxidizing agent. The intermediate dihydrophenanthrene has been isolated in one case.[371a] The use of substrates containing hetero atoms (e.g., PhN=NPh) allows the formation of heterocyclic ring systems. The actual reacting species must be the *cis*-stilbene, but *trans*-stilbenes can often be used, because they are isomerized to the cis isomers under the reaction conditions. The reaction can be extended to the preparation of many fused aromatic systems, e.g.,[372]



though not all such systems give the reaction.[373]

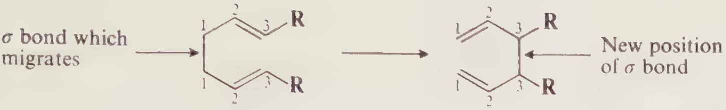
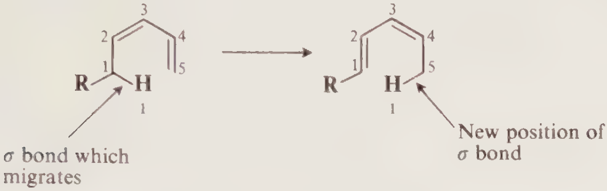
B. Sigmatropic Rearrangements. A sigmatropic rearrangement is defined[374] as migration, in an uncatalyzed intramolecular process, of a σ bond, adjacent to one or more π systems, to a new position in a molecule, with the π systems becoming reorganized in the process. Examples are



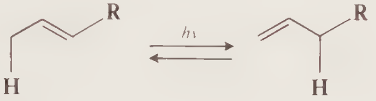
Reaction **8-37**
A [3,3] sigmatropic rearrangement



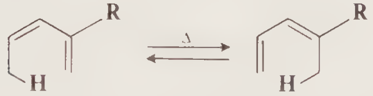
Reaction **8-34**
A [1,5] sigmatropic rearrangement

The *order* of a sigmatropic rearrangement is expressed by two numbers set in brackets: [*i,j*]. These numbers can be determined by counting the atoms over which each end of the σ bond has moved. Each of the original termini is given the number 1. Thus in the first example above, each terminus of the σ bond has migrated from C-1 to C-3, so the order is [3,3]. In the second example the carbon terminus has moved from C-1 to C-5, but the hydrogen terminus has not moved at all, so the order is [1,5].

8-34 [1,*j*] Sigmatropic Migrations of Hydrogen



[1,3]



[1,5]

Many examples of thermal or photochemical rearrangements in which a hydrogen atom migrates from one end of a system of π bonds to the other have been reported,[375] though the reaction is subject to geometrical conditions. Pericyclic mechanisms are involved, and the hydrogen must, in the transition state, be in contact with both ends of the chain at the same time. This means that for [1,5] and longer rearrangements, the molecule must be able to adopt the cisoid conformation. Furthermore, there are two geometrical pathways by means of which any sigmatropic rearrangement can take place, which we illustrate for the case of a [1,5] sigmatropic rearrangement,[376] starting with a substrate of the form **119**, where the migration origin is an asymmetric carbon atom, and U ≠ V. In one of the two pathways, the hydrogen moves along the top or

antarafacial

bottom face of the π system. This is called *suprafacial migration.* In the other pathway, the hydrogen moves *across* the π system, from top to bottom, or vice versa. This is *antarafacial* migration. Altogether, a single isomer like **119** can give four products. In a suprafacial migration, H can move across the top of the π system (as drawn above) to give the *R,Z* isomer, or it can rotate 180° and move across the bottom of the π system to give the *S,E* isomer.[377] The antarafacial migration can similarly lead to two diastereomers, in this case the *S,Z* and *R,E* isomers.

In any given sigmatropic rearrangement, only one of the two pathways is allowed by the orbital symmetry rules; the other is forbidden. To analyze this situation we cannot use correlation diagrams, because there is no element of symmetry present throughout the course of the reaction (a plane of symmetry may be present in the transition state, but not before or after). Therefore we will use a modified frontier orbital approach.[378] We will imagine that in the transition state the migrating H atom breaks away from the rest of the system, which we may treat as if it were a free radical. Note that this is not what actually takes place; we merely imagine it in order to be able to analyze the process. In a [1,3] sigmatropic rearrangement the imaginary transition state consists of a hydrogen atom and an allyl radical. The latter species (p. 34) has three π orbitals, but the only one which concerns us here is the highest occupied orbital which, in a thermal

---

[377] Since we are using the arbitrary designations U, V, Y, and Z, we have been arbitrary in which isomer to call *R,Z* and which to call *S,E*.

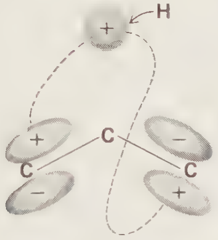
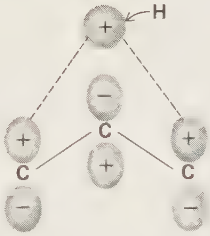
Imaginary
transition state
for a [1,3]
sigmatropic
rearrangement

rearrangement, is **D**. The electron of the hydrogen atom is of course in a 1*s* orbital, which has only one lobe. The rule governing sigmatropic migration of hydrogen is that *the H must move from a plus to a plus or from a minus to a minus lobe, of the highest occupied molecular orbital; it cannot move to a lobe of opposite sign.*[379] Obviously, the only way this can happen in a thermal [1,3] sigmatropic rearrangement is if the migration is antarafacial. Consequently, the rule predicts that antarafacial thermal [1,3] sigmatropic rearrangements are allowed, but the suprafacial pathway is forbidden. However, in a photochemical reaction, promotion of an electron means that **E** is now the highest occupied π orbital; the suprafacial pathway is now allowed, and the antarafacial pathway forbidden.



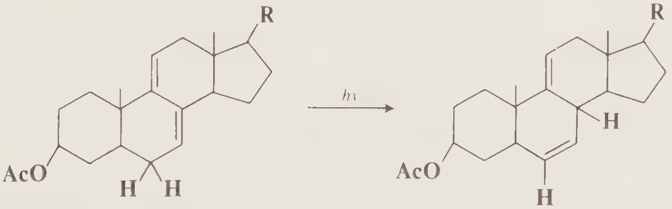
D



E

A similar analysis of [1,5] sigmatropic rearrangements shows that in this case the thermal reaction must be suprafacial and the photochemical process antarafacial. For the general case, with odd-numbered *j*, we may say that [1,*j*] suprafacial migrations are allowed thermally when *j* is of the form $4n + 1$, and photochemically when *j* has the form $4n - 1$; the opposite is true for antarafacial migrations.

The actual reported results bear out this analysis. Thus a thermal [1,3] migration is allowed to take place only antarafacially, but such a transition state would be extremely strained, and thermal [1,3] sigmatropic migrations of hydrogen are unknown. On the other hand, the photochemical pathway allows suprafacial [1,3] shifts, and a few such reactions are known, an example being[380]

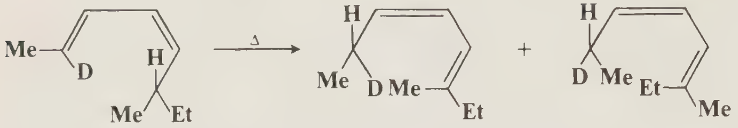


---

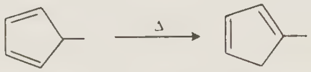
[379] This follows from the principle that bonds are formed only by overlap of orbitals of the same sign. Since this is a concerted reaction, the hydrogen orbital in the transition state must overlap simultaneously with one lobe from the migration origin and one from the terminus. It is obvious that both of these lobes must have the same sign.

[380] Dauben and Wipke, *Pure Appl. Chem.* **9**, 539–553 (1964), p. 546. For another example, see Kropp, Fravel, and Fields, *J. Am. Chem. Soc.* **98**, 840 (1976).

The situation is reversed for [1,5] hydrogen shifts. In this case the thermal rearrangements, being suprafacial, are quite common, while photochemical rearrangements are rare.[381] Examples of the thermal reaction are



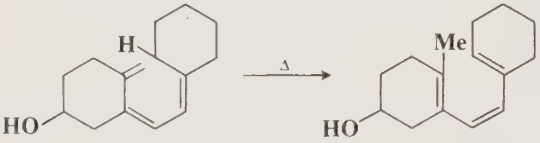
Ref. 382

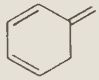


Ref. 383

Note that the first example bears out the stereochemical prediction made earlier. Only the two isomers shown were formed.

With respect to [1,7] hydrogen shifts, the orbital symmetry rules predict that the thermal reaction must be antarafacial. Unlike the case of [1,3] shifts, the transition state is not too greatly strained, and such rearrangements have been reported, e.g.,[384]



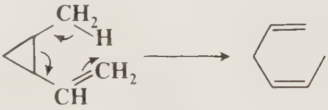


120

Photochemical [1,7] shifts are suprafacial, and not surprisingly, many of these have been observed.[385]

The orbital symmetry rules also help us to explain, as on pp. 787 and 1033, the unexpected stability of certain compounds. Thus, **120** could, by a thermal [1,3] sigmatropic rearrangement, easily convert to toluene, which of course is far more stable because it has an aromatic sextet. Yet **120** has been prepared and is stable at dry ice temperature and in dilute solutions.[386]

Analogs of sigmatropic rearrangements in which a cyclopropane ring replaces one of the double bonds are also known, for example:[387]



A homodienyl [1,5] shift

---

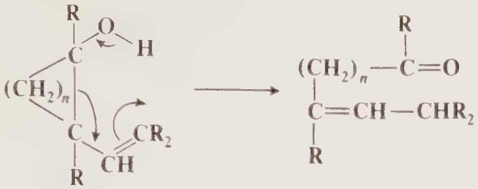
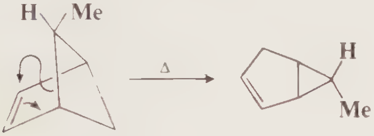
Chem.* **688,** 28 (1965); Ohloff, *Tetrahedron Lett.* 3795 (1965); Jorgenson and Thacher, *Tetrahedron Lett.* 4651 (1969); Corey, Yamamoto, Herron, and Achiwa, *J. Am. Chem. Soc.* **92,** 6635 (1970). See also Crandall and Watkins, *Tetrahedron Lett.* 1717 (1967).

The reverse reaction has also been reported.[388] 2-Vinylcycloalkanols[389] undergo an analogous reaction, as do cyclopropyl ketones (see p. 1052 for this reaction).

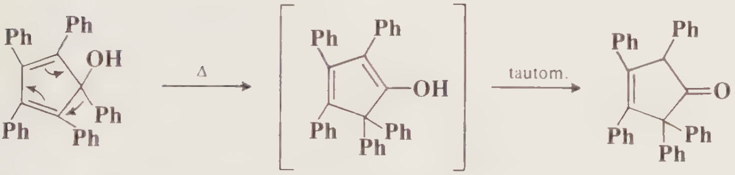


Simple nucleophilic, electrophilic, and free-radical 1,2 shifts may also be regarded as sigmatropic rearrangements (in this case [1,2] rearrangements). We have already (p. 962) applied similar principles to such rearrangements to show that nucleophilic 1,2 shifts are allowed, but the other two types are forbidden unless the migrating group has some means of delocalizing the extra electron or electron pair.

8-35 [1,*j*] Sigmatropic Migrations of Carbon



[1,3] migration of alkyl[390]



[1,5] migration of phenyl[391]

Sigmatropic migrations of alkyl or aryl groups[391a] are less common than the corresponding hydrogen migrations.[392] When they do take place, there is an important difference. Unlike a hydrogen atom, whose electron is in a 1*s* orbital which has only one lobe, a carbon free radical has its odd electron in a *p* orbital which has *two lobes of opposite sign*. Therefore, if we draw the imaginary transition states for this case (see p. 1039), we see that in a thermal suprafacial [1,5] process (**F**), symmetry can be conserved only if the migrating carbon moves in such a way that the lobe which was originally attached to the π system remains attached to the π system. This can

---

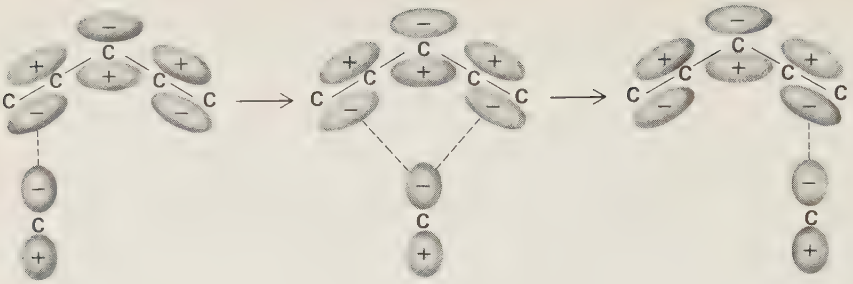
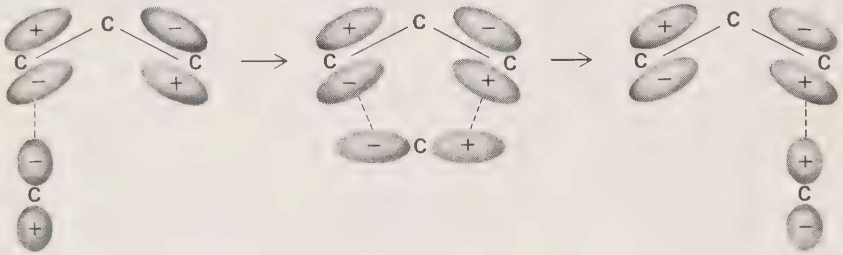
[391a] For a review, see Spangler, Ref. 375.

[392] It has been shown that methyl and phenyl have lower migratory aptitudes than hydrogen in thermal sigmatropic rearrangements: Shen, McEwen, and Wolf, *Tetrahedron Lett.* 827 (1969); Miller, Greisinger, and Boyer, *J. Am. Chem. Soc.* **91,** 1578 (1969).



F

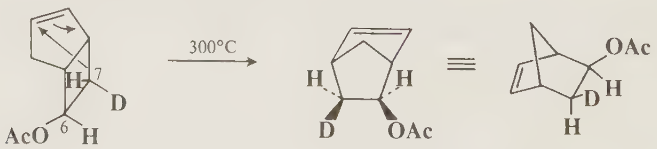
happen only if configuration is *retained within the migrating group.* On the other hand, a thermal suprafacial [1,3] migration (**G**) *can* take place if the migrating carbon switches lobes. If the migrating



G

carbon was originally bonded by its minus lobe, it must now use its plus lobe to form the new C—C bond. Thus configuration in the migrating group will be *inverted.* From these considerations we predict that suprafacial [1,j] sigmatropic rearrangements in which carbon is the migrating group are always allowed, both thermally and photochemically, but that thermal [1,3] migrations will proceed with inversion, and thermal [1,5] migrations with retention of configuration within the migrating group. More generally, we may say that suprafacial [1,j] migrations of carbon in systems where $j = 4n - 1$ proceed with inversion thermally and retention photochemically, while systems where $j = 4n + 1$ show the opposite behavior. Where antarafacial migrations take place, all these predictions are of course reversed.

The first laboratory test of these predictions was the pyrolysis of deuterated *endo*-bicyclo[3.2.0]-hept-2-en-6-yl acetate (**121**), which gave the *exo*-deuterio-*exo*-norbornyl acetate **122**.[393] Thus, as



121 **122**

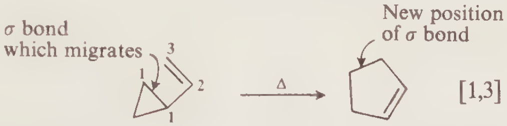
predicted by the orbital symmetry rules, this thermal suprafacial [1,3] sigmatropic reaction took place with complete inversion at C-7. Similar results have been obtained in a number of other cases.[394] However, because rotation of the C-7 carbon is required to be clockwise, the pathway leading to inversion can be blocked by the introduction into **121** of an endo methyl group at C-7, in which case the reaction takes place with predominant retention.[395] It has been suggested that an orbital-symmetry-forbidden concerted reaction takes place in these cases.[396] Photochemical suprafacial [1,3] migrations of carbon have been shown to proceed with retention, as predicted.[397]

---

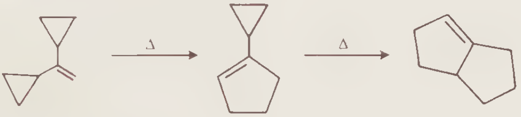
[393] Berson and Nelson, *J. Am. Chem. Soc.* **89**, 5503 (1967); Berson, *Acc. Chem. Res.* **1**, 152–160 (1968).

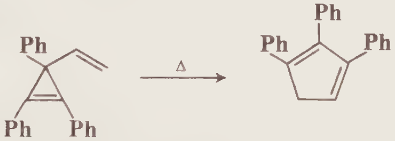
[1,3] antarafacial migrations of carbon are predicted by the orbital symmetry rules to take place with retention at the migrating carbon if thermal, and inversion if photochemical. Despite the seeming geometrical barrier to such reactions, instances of both these processes have been reported.[398] The prediction that thermal suprafacial [1,5] migrations of carbon take place with retention has also been confirmed.[399]

8-36 Conversion of Vinylcyclopropanes to Cyclopentenes



The thermal expansion of a vinylcyclopropane to a cyclopentene ring[400] is a special case of a [1,3] sigmatropic migration of carbon, though it can also be considered an internal $[_\pi2 + {}_\sigma2]$ cycloaddition reaction (see reaction **5-52**). The reaction has been carried out on many vinylcyclopropanes bearing various substituents in the ring or on the vinyl group and has been extended to 1,1-dicyclopropylethene[401] and to vinylcyclopropenes.[402]





Various heterocyclic analogs are also known, for example:[403]

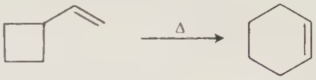
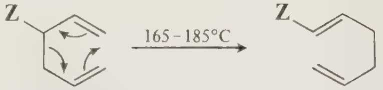
Vinylcyclobutenes can be similarly converted to cyclohexenes,[404] but larger ring compounds do not generally give the reaction.[405]



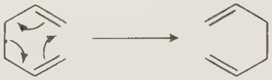
The mechanisms of these ring expansions are not certain. Both concerted[406] and diradical[407] pathways have been proposed, and it is possible that both pathways operate, in different systems.

8-37 The Cope Rearrangement



Z = **Ph**, **RCO**, etc.

When 1,5-dienes are heated, they isomerize, in a [3,3] sigmatropic rearrangement known as the *Cope rearrangement* (not to be confused with the Cope elimination reaction, **7-8**).[408] When the diene is symmetrical about the 3,4 bond, we have the unusual situation where a reaction gives a product which is identical with the starting material:[409]



Therefore, a Cope rearrangement can be detected only when the diene is not symmetrical about this bond. Any 1,5-diene gives the rearrangement; for example, 3-methyl-1,5-hexadiene heated to 300°C gives 1,5-heptadiene.[410] However, the reaction takes place more easily (lower temperature required) when there is a group on the 3- or 4-carbon with which the new double bond can conjugate. The reaction is obviously reversible and produces an equilibrium mixture of the two 1,5-dienes, which is richer in the thermodynamically more stable isomer. However, the reaction cannot be reversed for 3-hydroxy-1,5-dienes, because the product tautomerizes to the ketone or aldehyde:

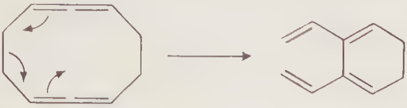
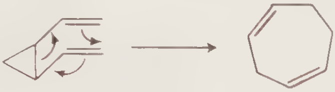
[409] Note that the same holds true for [1,*j*] sigmatropic reactions of symmetrical substrates (reactions **8-34, 8-35**).

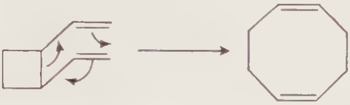
[410] Levy and Cope, *J. Am. Chem. Soc.* **66,** 1684 (1944).

This has been called the *oxy-Cope rearrangement*.[411] The 1,5-diene system may be inside a ring, or it may be part of an allenic system (this example illustrates both of these situations):[412]



but the reaction does not take place when one of the double bonds is part of an aromatic system, e.g., 4-phenyl-1-butene. When the two double bonds are in vinyl groups attached to adjacent ring positions, then the product is a ring which is four carbons larger. This has been applied to divinylcyclopropanes and cyclobutanes:[413]





Indeed, *cis*-1,2-divinylcyclopropanes give this rearrangement so rapidly that they generally cannot be isolated at room temperature,[414] though exceptions are known.[415] When heated, 1,5-diynes are converted to 3,4-dimethylenecyclobutenes.[416] A rate-determining Cope rearrangement is

followed by a very rapid electrocyclic (**8-32**) reaction.

The interconversion of 1,3,5-trienes and cyclohexadienes (in reaction **8-32**) is very similar to the Cope rearrangement, though in the case of reaction **8-32** the 3,4 bond goes from a double bond to a single bond rather than from a single bond to no bond.

As we have indicated with our arrows, the mechanism of the Cope rearrangement is a simple six-centered pericyclic process. Since the mechanism is so simple, it has been possible to study some rather subtle points, among them the question of whether the six-membered transition state is in the boat or the chair form. For the case of 3,4-dimethyl-1,5-hexadiene it was demonstrated conclusively that the transition state is in the chair form. This was shown by the stereospecific nature of the reaction: The meso isomer gave the cis-trans product, while the *dl* compound gave the trans-trans diene.[417] Now if the transition state is in the chair form (taking the meso isomer, for example), one methyl must be "axial" and the other "equatorial" and the product must be the cis-trans olefin:

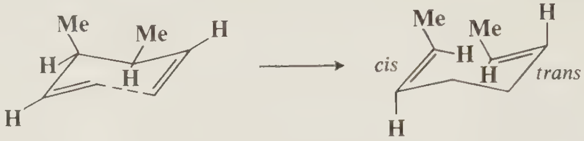
[414] Unsubstituted *cis*-1,2-divinylcyclopropane is fairly stable at −20°C: Brown, Golding, and Stofko, *J. Chem. Soc., Chem. Commun.* 319 (1973); Schneider and Rebell, *J. Chem. Soc., Chem. Commun.* 283 (1975).

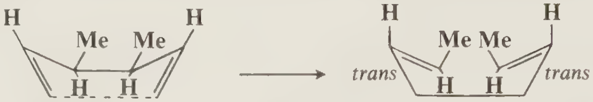
[415] See for example, Brown, *Chem. Commun.* 226 (1965); Schönleber, *Chem. Ber.* **102,** 1789 (1969); Bolesov, Ii-hsein, and Levina, *J. Org. Chem. USSR* **6,** 1791 (1970); Baldwin and Ullenius, *J. Am. Chem. Soc.* **96,** 1542 (1974).

[416] For a review, see Huntsman, *Intra-Sci. Chem. Rep.* **6,** 151–159 (1972).

[417] Doering and Roth, *Tetrahedron* **18,** 67 (1962). See also Hill and Gilman, *Chem. Commun.* 619 (1967); Goldstein and DeCamp, *J. Am. Chem. Soc.* **96,** 7356 (1974); Hansen and Schmid, *Tetrahedron* **30,** 1959 (1974).

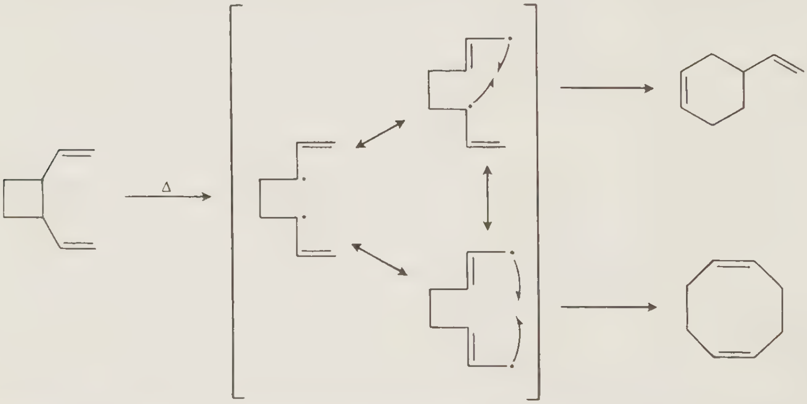


There are two possible boat forms for the transition state of the meso isomer. One of these leads to a trans-trans product:



and the other to a cis-cis olefin. For the *dl* pair the predictions are just the opposite: There is just one boat form, and it leads to the cis-trans olefin, while one chair form ("diaxial" methyls) leads to the cis-cis product and the other ("diequatorial" methyls) predicts the trans-trans product. Thus the nature of the products obtained demonstrates that the transition state is a chair and not a boat.[418] However, 3,4-dimethyl-1,5-hexadiene is free to assume either the chair or boat (it prefers the chair), but other compounds are not so free. Thus 1,2-divinylcyclopropane (p. 1045) can react *only* in the boat form, demonstrating that such reactions are not impossible.

Not all Cope rearrangements proceed by the cyclic six-centered mechanism. Thus *cis*-1,2-divinylcyclobutane (p. 1045) rearranges smoothly to 1,5-cyclooctadiene, since the geometry is favorable. The trans isomer also gives this product, but the main product is 4-vinylcyclohexene (resulting from reaction **8-36**). This reaction can be rationalized as proceeding by a diradical mechanism,[419] though it is possible that at least part of the cyclooctadiene produced comes from a prior epimerization of the *trans*- to the *cis*-divinylcyclobutane followed by Cope rearrangement of the latter.[420]



---

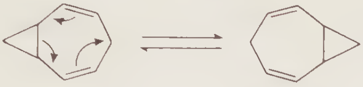
[418] Preference for the chair transition state is a consequence of orbital symmetry relationships: Hoffmann and Woodward, *J. Am. Chem. Soc.* **87**, 4389 (1965); Fukui and Fujimoto, *Tetrahedron Lett.* 251 (1966).

[419] Hammond and De Boer, *J. Am. Chem. Soc.* **86**, 899 (1964); Trecker and Henry, *J. Am. Chem. Soc.* **86**, 902 (1964). Also see Gibson and Pettit, *J. Am. Chem. Soc.* **87**, 2620 (1965); Berson and Dervan, Ref. 407; Dolbier and Mancini, *Tetrahedron Lett.* 2141 (1975).

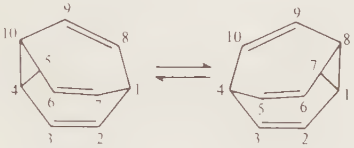
[420] See for example, Berson and Dervan, *J. Am. Chem. Soc.* **94**, 8949 (1972). For a similar result in the 1,2-divinylcyclopropane series, see Baldwin and Ullenius, Ref. 415.

It has been suggested that another type of diradical two-step mechanism may be preferred by some substrates.[421] In this pathway, the 1,6 bond is formed before the 3,4 bond breaks.

It was pointed out earlier that a Cope rearrangement of 1,5-hexadiene gives 1,5-hexadiene. This type of rearrangement, in which the product is equivalent to the starting compound, is called a *degenerate Cope rearrangement*. Another molecule which undergoes a degenerate Cope rearrangement is bicyclo[5.1.0]octadiene (**123**).[422] At room temperature the nmr spectrum of this compound is in accord with the structure shown. At 180°C it can be converted by a Cope reaction to a compound equivalent to itself. The interesting thing is that at 180°C the nmr spectrum shows that what exists is an equilibrium mixture of the two structures. That is, at this temperature the molecule rapidly (faster than 10^3 times per second) changes back and forth between the two structures. This is called *valence tautomerism* and is quite distinct from resonance, even though only electrons shift.[423] The positions of the nuclei are not the same in the two structures. Molecules like **123** which exhibit valence tautomerism (in this case at 180°C) are said to have *fluxional* structures. It may be recalled that *cis*-1,2-divinylcyclopropane does not exist at room temperature because it rapidly rearranges to 1,4-cycloheptadiene (p. 1045), but in **123** the *cis*-divinylcyclopropane structure is frozen into the molecule in both structures. Several other compounds in which this situation holds are also known. Of these, *bullvalene* (**124**) is especially interesting. The Cope rearrangement shown changes the position of the cyclopropane ring from 4,5,10 to 1,7,8. But the molecule could also have undergone rearrangements to put this ring at 1,2,8 or 1,2,7.



123 **123**



124

Any of these could then undergo several Cope rearrangements. In all there are 10!/3, or more than 1.2 million tautomeric forms, and the cyclopropane ring can be at any three carbons which are adjacent. Since each of these tautomers is equivalent to all the others, this has been called an infinitely degenerate Cope rearrangement. Bullvalene has been synthesized and its proton nmr spectrum determined.[424] At −25°C there are two peaks with an area ratio of 6 : 4. This is in accord with a single nontautomeric structure. The six are the vinyl protons and the four are the allylic ones. But at 100°C the compound shows only one nmr peak, indicating that we have here a truly unique situation where the compound rapidly interchanges its structure among 1.2 million equivalent forms.[425]

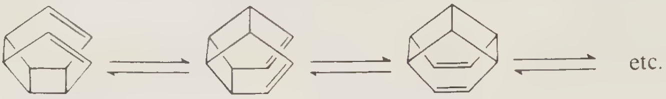
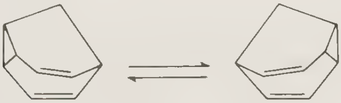
The ^{13}C nmr spectrum of bullvalene also shows only one peak at 100°C.[426] Another compound for which degenerate Cope rearrangements result in equivalence for all the carbons is

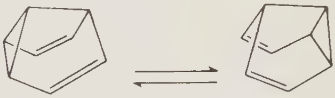


125

hypostrophene (**125**).[427] In the case of the compound *barbaralane* (**126**) (bullvalene in which one CH=CH has been replaced by a CH_2):



126



127

there are only two equivalent tautomers.[428] However, nmr spectra indicate that even at room temperature a rapid interchange of both tautomers is present, though by about −100°C this has slowed to the point where the spectrum is in accord with a single structure. Corresponding behavior, both at 25°C and at −100°C, is exhibited by substituted barbaralanes in which the CH_2 group has been replaced by CHOH, CHCl, CO, and $C(SR)_2$.[429] In the case of *semibullvalene* (**127**) (barbaralane in which the CH_2 has been removed), not only is there a rapid interchange at room temperature, but even at −110°C.[430] **127** has the lowest energy barrier of any known compound capable of undergoing the Cope rearrangement.[431]

The molecules taking part in a valence tautomerization need not be equivalent. Thus, nmr spectra indicate that a true valence tautomerization exists at room temperature between the cycloheptatriene **128** and the norcaradiene **129**.[432] In this case one isomer (**129**) has the *cis*-1,2-divinyl-

---

[425] A number of azabullvalenes (**124** containing heterocyclic nitrogen) have been synthesized, and these too have fluxional structures when heated, though with fewer tautomeric forms than bullvalene itself: Paquette and Barton, *J. Am. Chem. Soc.* **89**, 5480 (1967); Paquette, Barton, and Whipple, *J. Am. Chem. Soc.* **89**, 5481 (1967); Wegener, *Tetrahedron Lett.* 4985 (1967); Paquette, Malpass, Krow, and Barton, *J. Am. Two $(\mathbf{CH})_6$ compounds

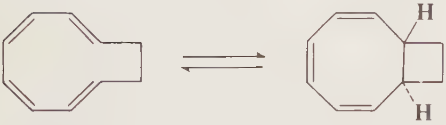
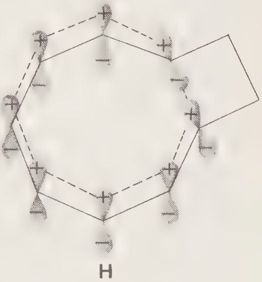
An interesting example of a valence tautomerization was reported for the molecules (*E*,*Z*,*Z*,*E*)-1,3,5,7-cyclodecatetraene (**140**) and *trans*-bicyclo[6.2.0]deca-2,4,6-triene (**141**), which rapidly interconvert at temperatures above 50°C[435] (an electrocyclic reaction, **8-32**). The transition state for



140 **141**



---

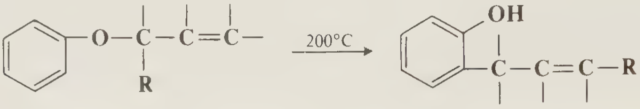
[433] For reviews of rearrangements and interconversions of $(CH)_n$ compounds, see Scott and Jones, *Chem. Rev.* **72**, 181–202 (1972); Balaban, *Rev. Roum. Chim.* **11**, 1097–1116 (1966).

[434] The structures of all possible $(CH)_n$ compounds, for $n = 4, 6, 8$, and 10, are shown in Balaban, Ref. 433.

[435] Staley and Henry, *J. Am. Chem. Soc.* **92**, 7612 (1970); **93**, 1294 (1971).

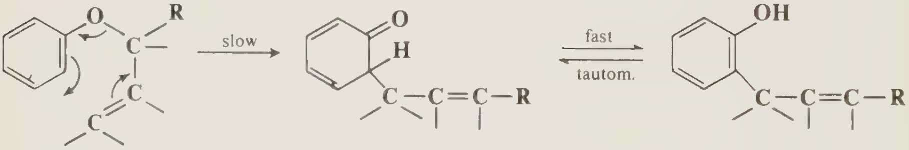
this interconversion (**H**) consists of eight electrons connected in a Möbius array (that is, with one sign inversion, see p. 1031). Since the number of electrons is of the form 4*n*, the Möbius is the only allowed pathway for a thermal reaction (p. 1032).

8-38 The Claisen Rearrangement



Allyl aryl ethers, when heated, rearrange to *o*-allylphenols in a reaction called the *Claisen rearrangement*.[436] If both ortho positions are filled, the allyl group migrates to the para position (this is often called the *para-Claisen rearrangement*). Sometimes some para product is obtained even if one or both ortho positions are free,[437] though in general it may be said that, when one or both ortho positions are open, the product is the *o*-allylphenol and that, when both ortho positions are blocked, the product is the para compound. There is no reaction when the para and both ortho positions are filled. Migration to the meta position has not been observed. In the ortho migration the allyl group always undergoes an allylic shift. That is, as shown above, a substituent α to the oxygen is now γ to the ring (and vice versa). On the other hand, in the para migration there is never an allylic shift: the allyl group is found exactly as it was in the original ether. Propargyl groups (that is, groups with a triple bond in the appropriate position) do not generally give the reaction.

The mechanism is a concerted pericyclic [3,3] sigmatropic rearrangement and accounts for all these facts. For the ortho rearrangement:



Evidence is the lack of a catalyst, the fact that the reaction is first order in the ether, the absence of crossover products when mixtures are heated, and the presence of the allylic shift, which is required by this mechanism. The allylic shift for the ortho rearrangement (and the absence of one for the para) has been demonstrated by ^{14}C labeling, even when no substituents are present. Studies of the transition-state geometry have shown that, like the Cope rearrangement, the Claisen rearrangement prefers a chair-like transition state.[438] When the ortho positions have no hydrogen, a second [3,3] sigmatropic migration (a Cope reaction) follows:

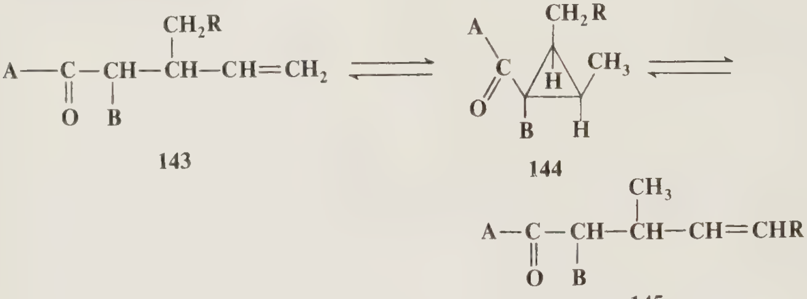
This rearrangement, which has been called an *enolene rearrangement*, a *homodienyl* [1,5] *sigmatropic hydrogen shift* (see p. 1040), and a [1,5] *homosigmatropic rearrangement*, involves a shift of three electron pairs over *seven* atoms. It has been found that this "abnormal" Claisen rearrangement is general and can interconvert the enol forms of systems of the types **143** and **145** through the cyclopropane intermediate **144**.[442]



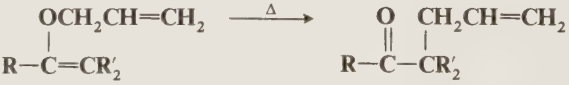
$$\underset{\mathbf{143}}{\text{A}-\underset{\underset{\text{O}}{\|}}{\text{C}}-\underset{\underset{\text{B}}{|}}{\text{CH}}-\overset{\overset{\text{CH}_2\text{R}}{|}}{\text{CH}}-\text{CH}{=}\text{CH}_2} \rightleftharpoons \mathbf{144} \rightleftharpoons \underset{\mathbf{145}}{\text{A}-\underset{\underset{\text{O}}{\|}}{\text{C}}-\underset{\underset{\text{B}}{|}}{\text{CH}}-\overset{\overset{\text{CH}_3}{|}}{\text{CH}}-\text{CH}{=}\text{CHR}}$$

143 **144** **145**

A = **H** , **R** , **Ar**, **OR** , etc.
B = **H**, **R** , **Ar** , **COR** , **COAr** , **COOR** , etc.

Since the Claisen rearrangement mechanism does not involve ions, it should not be greatly dependent on the presence or absence of substituent groups on the ring. This is the case. Electron-donating groups increase the rate, and electron-withdrawing groups decrease it, but the effect is small, with the *p*-amino compound reacting only about 10 to 20 times faster than the *p*-nitro compound.[443] However, solvent effects are greater: Rates varied over a 300-fold range when the reaction was run in 17 different solvents.[444] An especially good solvent is trifluoroacetic acid, in which the reaction can be carried out at room temperature.[445] Most Claisen rearrangements are performed without a catalyst, but $AlCl_3$ or BF_3 is sometimes used.[446] In this case it may become a Friedel-Crafts reaction, with the mechanism no longer cyclic,[447] and ortho, meta, and para products may be obtained.

Allyl ethers of enols (allyl vinyl ethers) also undergo the Claisen rearrangement; in fact it was discovered with these compounds first:[448]



$$\text{R}-\overset{\overset{\text{OCH}_2\text{CH}{=}\text{CH}_2}{|}}{\text{C}}{=}\text{CR}'_2 \xrightarrow{\Delta} \text{R}-\overset{\overset{\text{O}}{\|}}{\text{C}}-\overset{\overset{\text{CH}_2\text{CH}{=}\text{CH}_2}{|}}{\text{CR}'_2}$$

In these cases of course the final tautomerization does not take place even when R′ = H, since there is no aromaticity to restore, and ketones are more stable than enols. The mechanism is similar to that with allyl aryl ethers. One experiment which demonstrated this was the conversion of optically active **146** to **147** which was still optically active.[449] This is another example of asymmetric induction (p. 107):

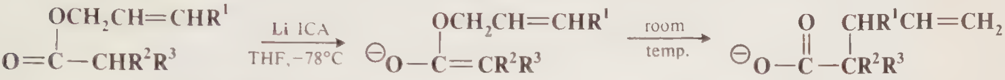
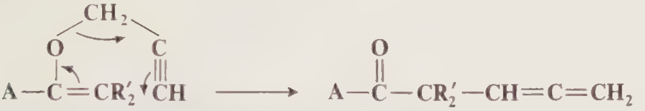
146 **147**

It is possible to treat ketones with allyl alcohol and an acid catalyst to give γ,δ-unsaturated ketones directly, presumably by initial formation of the vinyl ethers, and then Claisen rearrangement.[450] In an analogous procedure, the enolates of allylic esters [formed by treatment of the esters with lithium isopropylcyclohexylamide (ICA)] rearrange to γ,δ-unsaturated acids.[451]



A number of expected analogs of the Claisen rearrangement are known,[452] e.g., rearrangement of $ArNHCH_2CH{=}CH_2$,[453] of N-allyl enamines $R_2C{=}CRNRCR_2CR{=}CR_2$,[454] and of $RC(OCH_2CH{=}CH_2){=}NR$.[455] Propargyl vinyl compounds give allenic aldehydes, ketones, esters, or amides:[456]



A = H, R, OR, NR$_2$

Under strenuous conditions (potassium *t*-butoxide in *t*-butyl alcohol at 350°C for 24 hr) the reaction has even been extended to a carbon analog: a mixture of 1-phenylbutenes was placed in equilibrium with a mixture of 1-(*o*-tolyl)propenes.[457] The conversion of allyl aryl thioethers $ArSCH_2CH{=}CH_2$ to *o*-allylthiophenols (the thio-Claisen rearrangement) is not feasible, because the latter are not stable[458] but react to give bicyclic compounds.[459] However, many allyl vinyl sulfides do give the rearrangement,[460] and this has been used in a synthesis of γ,δ-unsaturated

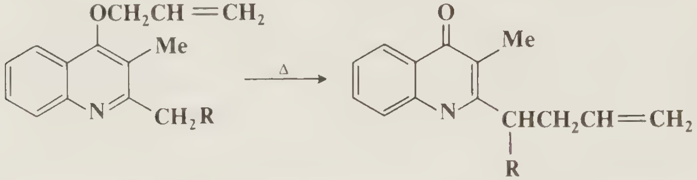
aldehydes.[461] A similar reaction has been applied to enolates of dithio esters.[462]

In some cases rearrangement has been shown to go to the α-position of a meta side chain:[463]



The mechanism of this process is the same as that of the para-Claisen rearrangement.

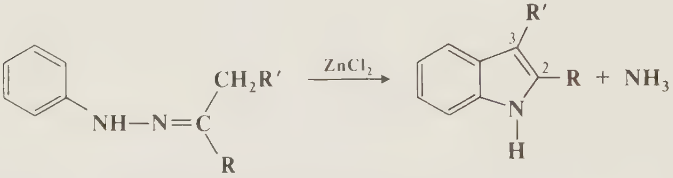
8-39 The Fischer Indole Synthesis



When arylhydrazones of aldehydes or ketones are treated with a catalyst, elimination of ammonia takes place and an indole is formed, in a reaction called the *Fischer indole synthesis.*[464] Zinc chloride is the catalyst most frequently employed, but dozens of others, including other metal halides, proton and Lewis acids, and certain transition metals have also been used. Arylhydrazones are easily prepared by the treatment of aldehydes or ketones with phenylhydrazine (reaction **6-21**) or by aliphatic diazonium coupling (reaction **2-7**). However, it is not necessary to isolate the arylhydrazone. The arylhydrazine can be treated with a mixture of the aldehyde or ketone and the catalyst, and this is now common practice. In order to obtain an indole, the aldehyde or ketone must be of the form $RCOCH_2R'$ (R = alkyl, aryl, or hydrogen). When R is hydrogen or methyl, then this group is always found at the 2 position of the indole, and R′ at the 3 position. When the aldehyde or ketone is of the form $CH_3COCHR'_2$ ($R' \neq$ hydrogen), then the product is

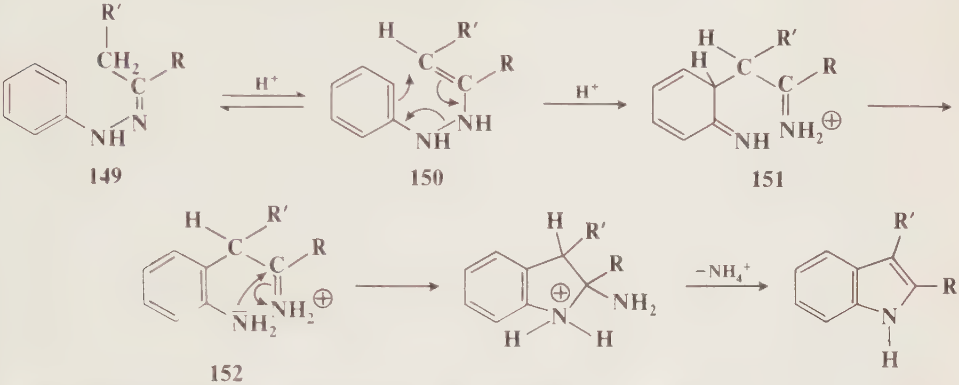
148

usually **148**, though exceptions are known.[465] For compounds of the form $RCH_2COCHR'_2$, a mixture of both types is obtained.

At first glance the reaction does not seem to be a rearrangement. However, the key step of the mechanism is a [3,3] sigmatropic rearrangement:[466]



There is much evidence for this mechanism, for example, (1) the isolation of **152**,[467] (2) the isolation of side products which could only have come from **151**,[468] and (3) ^{15}N labeling experiments which showed that it was the nitrogen farther from the ring which was eliminated as ammonia.[469] The main function of the catalyst seems to be to speed the conversion of **149** to **150**. The reaction can be performed without a catalyst.

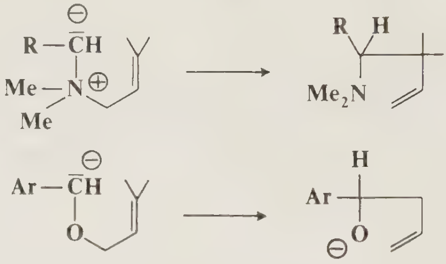
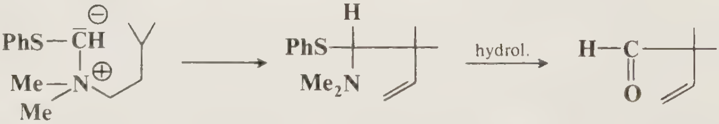
[469] Clausius and Weisser, *Helv. Chim. Acta* **35**, 400 (1952).

Sulfur ylides bearing an allylic group are converted on heating to unsaturated sulfides.[470] This is a concerted [2,3] sigmatropic rearrangement and has also been demonstrated for the analogous cases of nitrogen ylides[471] and the conjugate bases of allylic ethers,[472] as well as certain other systems.[473] It has even been extended to all-carbon systems.[474]



Since the reactions involve migration of an allylic group from a sulfur, nitrogen, or oxygen atom to an adjacent negatively charged carbon atom, they are special cases of the Stevens or Wittig rearrangements (reactions **8-25, 8-26**). However, in this case the migrating group *must* be allylic (in reactions **8-25** and **8-26** other groups may also migrate). Thus, when the migrating group is allylic, there are two possible pathways: (1) the radical-ion or ion-pair mechanisms (**8-25, 8-26**) and (2) the concerted pericyclic [2,3] sigmatropic rearrangement. These can easily be told apart, since the latter always involves an allylic shift (as in the Claisen rearrangement), while the former pathway does not. Of course, migration of groups other than allylic can take place only by the radical-ion or ion-pair mechanisms, because the orbital symmetry rules forbid a concerted mechanism for 1,2 shifts.

If an OR or SR group is attached to the negative carbon, the reaction becomes a method for the preparation of β,γ-unsaturated aldehydes, because the product is easily hydrolyzed.[475]



Another [2,3] sigmatropic rearrangement converts allylic sulfoxides to allylically rearranged alcohols by treatment with a thiophilic reagent such as trimethyl phosphite.[476] In this case the

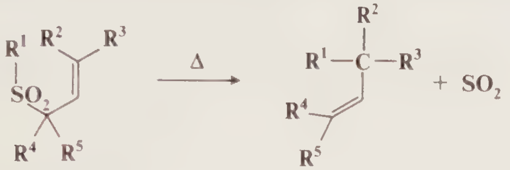
migration is from sulfur to oxygen. [2,3] oxygen-to-sulfur migrations are also known.[477] The Sommelet-Hauser rearrangement (**3-27**) is also a [2,3] sigmatropic rearrangement.

In a closely related reaction, allylic sulfones on heating rearrange with simultaneous loss of SO_2 to give alkenes.[478]



C. Other Cyclic Rearrangements

8-41 Metathesis of Olefins

$$CH_3CH{=}CHCH_2CH_3 \xrightarrow[WCl_6,\ EtOH]{EtAlCl_2} CH_3CH{=}CHCH_3 + CH_3CH_2CH{=}CHCH_2CH_3$$

When olefins are treated with certain catalysts (most often tungsten or molybdenum complexes), they are converted to other olefins in a reaction in which the alkylidene groups ($R^1R^2C{=}$) have become interchanged by a process schematically illustrated by the equation:

$$\begin{array}{c} R^1R^2C{=}CR^1R^2 \\ + \\ R^3R^4C{=}CR^3R^4 \end{array} \rightleftharpoons \begin{array}{ccc} R^1R^2C & + & CR^1R^2 \\ \| & & \| \\ R^3R^4C & & CR^3R^4 \end{array}$$

The reaction has been variously called *metathesis*, *dismutation*, and *disproportionation* of olefins.[479] In the example shown above, 2-pentene (either cis- trans, or a cis-trans mixture) is converted to a mixture of about 50% 2-pentene, 25% 2-butene, and 25% 3-hexene. The reaction is an equilibrium, and the same mixture can be obtained by starting with equimolar quantities of 2-butene and 3-hexene.[480] In general, the reaction can be applied to a single unsymmetrical olefin, giving a mixture of itself and two other olefins, or to a mixture of two olefins, in which case the number of different molecules in the product depends on the symmetry of the reactants. As in the case above, a mixture of $R^1R^2C{=}CR^1R^2$ and $R^3R^4C{=}CR^3R^4$ gives rise to only one new olefin ($R^1R^2C{=}CR^3R^4$), while in the most general case, a mixture of $R^1R^2C{=}CR^3R^4$ and $R^5R^6C{=}CR^7R^8$ gives a mixture of 10 olefins: the original 2 plus 8 new ones. With simple alkenes the proportions of products are generally statistical,[481] which limits the synthetic utility of the reaction, since the yield of any one product is low. However, in some cases one alkene may be more or less thermodynamically stable than the rest, so that the proportions are not statistical. Furthermore, it may be possible to shift the equilibrium. For example, 2-methyl-1-butene gives rise to ethylene and 3,4-dimethyl-3-hexene. By allowing the gaseous ethylene to escape, the yield of 3,4-dimethyl-3-hexene can be raised to 95%.[482] As expected for an equilibrium process, both cis and trans alkenes are produced, with the more stable trans isomers usually predominating.[483]

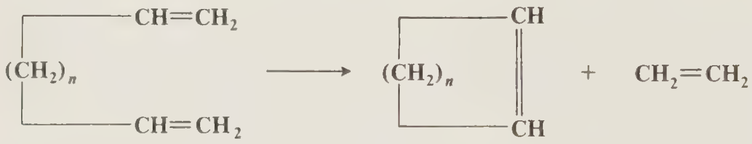
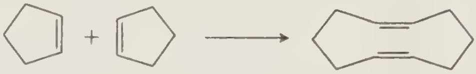
Many catalysts, both homogeneous[484] and heterogeneous,[485] have been used for this reaction. Some of the former[486] are WCl_6–EtOH–$EtAlCl_2$,[481] $MoCl_2(NO)_2(Ph_3P)_2$–$EtAlCl_2$,[487] WCl_6–BuLi,[488] and WCl_6–$LiAlH_4$,[489] while among the latter are oxides of Mo, W, and Re deposited on alumina or silica gel.[490] In general, the former group are more useful for synthetic purposes. By choice of the proper catalyst, the reaction has been applied to terminal and internal alkenes, straight chain or branched. The effect of substitution on the ease of reaction is $CH_2\!= \; > RCH_2CH\!= \; > R_2CHCH\!= \; > R_2C\!=$. Dienes may react intermolecularly or intramolecularly,[491] e.g.,



Cyclic olefins give dimeric dienes,[492] e.g.,



However, the products can then react with additional monomers and with each other, so that polymers are generally produced, and the cyclic dienes are obtained only in low yield. The reaction between a cyclic and a linear olefin can give a ring-opened diene:[493]

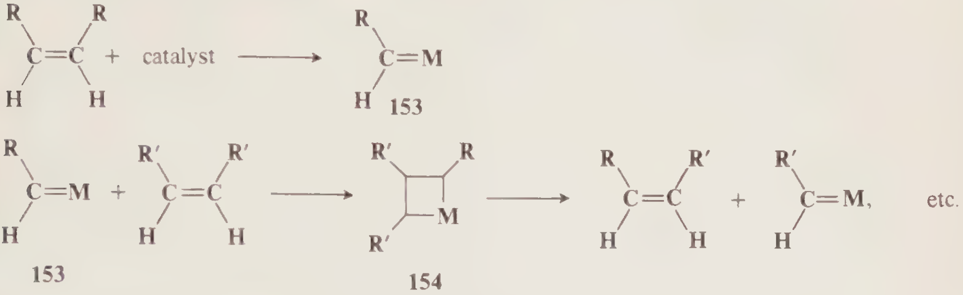
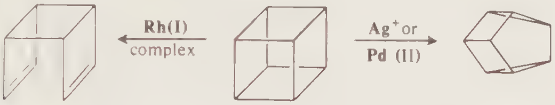
When the catalyst is supported tungsten oxide, the reaction can be applied to triple bonds:[494]

$$2RC{\equiv}CR' \rightleftharpoons RC{\equiv}CR + R'C{\equiv}CR'$$

The mechanism is not completely understood.[495] Several mechanisms have been suggested,[496] but the most likely is a chain process involving the intervention of a metal-carbene (**153**) and a four-membered ring containing a metal (**154**).[497]



8-42 Metal-ion-catalyzed σ-Bond Rearrangements



155 Cubane Cuneane

Many highly strained cage molecules undergo rearrangement when treated with metallic ions such as Ag^+, Rh(I), or Pd(II).[498] The bond rearrangements observed can be formally classified into two main types: (1) 2 + 2 ring openings of cyclobutanes and (2) conversion of a bicyclo-[3.3.0] system to a bicyclopropyl system. The molecule cubane supplies an example of each type (see above). Treatment with Rh(I) complexes converts cubane to tricyclo[$4.2.0.0^{2,5}$]octa-3,7-diene (**155**),[499] an example of type 1, while Ag^+ or Pd(II) causes the second type of reaction, producing cuneane.[500] Other examples are:

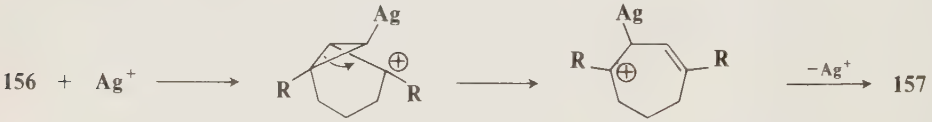
158 is the 9,10-dicarbomethoxy derivative of *snoutane* (pentacyclo[3.3.2.0^{2,4}.0^{3,7}.0^{6,8}]decane).

The mechanisms of these reactions are not completely understood, though relief of strain undoubtedly supplies the driving force. The reactions are thermally forbidden by the orbital symmetry rules, and the role of the catalyst is to provide low-energy pathways so that the reactions can take place. The type-1 reactions are the reverse of the catalyzed 2 + 2 ring closures discussed at reaction **5-52.** The following mechanism, in which Ag$^+$ attacks one of the edge bonds, has been suggested for the conversion of **156** to **157**:[504]



Simpler bicyclobutanes can also be converted to dienes, but in this case the products usually result from cleavage of the central bond and one of the edge bonds.[505] For example, treatment of **159** with AgBF$_4$,[506] (C$_6$F$_5$Cu)$_4$,[507] or [(π-allyl)PdCl]$_2$[508] gives a mixture of **160** and **161** result-

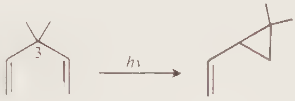
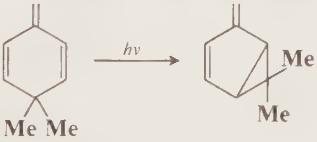
ing from a formal cleavage of the $C_1—C_3$ and $C_1—C_2$ bonds (note that a hydride shift has taken place). The use of $[Rh(CO)_2Cl]_2$,[509] $[Ru(CO)_3Cl_2]_2$,[509] or $Pd(PhCN)_2Cl_2$[508] cleaves **159** in a different way, giving **162** and **163.** Although **162** could formally have arisen from a 2 + 2 ring opening with the $C_1—C_3$ bond intact, isotopic labeling has shown that this is not the case, at least for the rhodium complex. It was the $C_1—C_3$ and $C_2—C_3$ bonds which cleaved in this case.[509]

8-43 The Di-π-methane Rearrangement



1,4-Dienes carrying alkyl or aryl substituents on C-3[510] can be photochemically rearranged to vinylcyclopropanes in a reaction called the *di-π-methane rearrangement.*[511] An interesting example is conversion of 1-methylene-4,4-dimethyl-2,5-cyclohexadiene to 2-methylene-6,6-dimethylbicyclo-[3.1.0]-3-hexene.[512] For most[513] 1,4-dienes it is only the singlet excited states which give the



reaction; triplet states generally take other pathways. For unsymmetrical dienes, the reaction is regiospecific: The more conjugated double bond is the one which is converted to the cyclopropane ring. Thus **166** gave **167** and not **168.**[514] The mechanism may be described by the di-

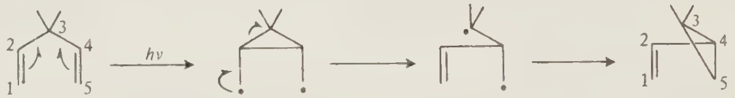
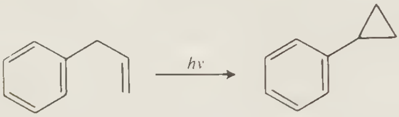
168
Not formed

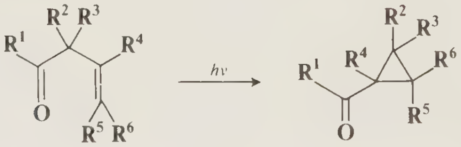
radical pathway given[515] (the C-3 substituents act to stabilize the radical), though the species



shown are not necessarily intermediates, but may be transition states. It has been shown, for the case of certain substituted substrates, that configuration is retained at C-1 and C-5 and inverted at C-3.[516]

The reaction has been extended to allylbenzenes[517] (in this case C-3 substituents are not required) and to β,γ-unsaturated ketones[518] (the latter reaction, which is called the oxa-di-π-methane rearrangement, occurs only from the triplet state).





When photolyzed, 2,5-cyclohexadienones can undergo a number of different reactions, one of which is formally the same as the di-π-methane rearrangement.[519] In this reaction, photolysis of the substrate **169** gives a bicyclo[3.1.0]hex-2-enone **174**.[520] Though the reaction is formally the same (note the conversion of **164** to **165** above), the mechanism is different from that of the di-π-methane rearrangement, because irradiation of a ketone can cause an $n \rightarrow \pi^*$ transition, which is of course not possible for a diene lacking a carbonyl group. The mechanism[520] in this case has been formulated as proceeding through the excited triplet states **171** and **172.** In step 1, the

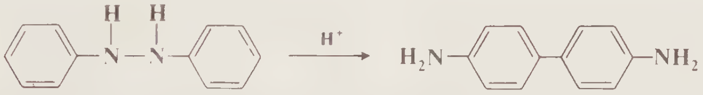
molecule undergoes an $n \rightarrow \pi^*$ excitation to the singlet species **170** which crosses to the triplet **171**. Step 3 is a rearrangement from one excited state to another. Step 4 is a $\pi^* \rightarrow n$ electron demotion (an intersystem crossing from $T_1 \rightarrow S_0$, see p. 218). The conversion of **173** to **174** actually consists of two 1,2 alkyl migrations (a one-step process would be a 1,3 migration of alkyl to a carbonium-ion center, see p. 972): The old $C_6—C_5$ bond becomes the new $C_6—C_4$ bond, and the old $C_6—C_1$ bond becomes the new $C_6—C_5$ bond.[521] This double-migration process is called the *slither mechanism*, as opposed to the single 1,3 migration, which in this case would be the *pivot mechanism*.

2,4-Cyclohexadienones also undergo photochemical rearrangements, but the products are different, generally involving ring opening.[522]

8-44 The Benzidine Rearrangement



When hydrazobenzene is treated with acids, it rearranges to give about 70% 4,4′-diaminobiphenyl (benzidine) and about 30% 2,4′-diaminobiphenyl (**175**). This reaction is called the *benzidine rearrangement* and is general for N,N′-diarylhydrazines.[523] Usually, the major product is the 4,4′-diaminobiaryl, but four other products may also be produced. These are the 2,4′-diaminobiaryl (**175**), already referred to, the 2,2′-diaminobiaryl (**176**), and the *o*- and *p*-arylaminoanilines (**177**

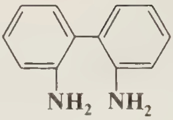
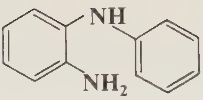
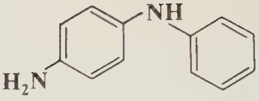
175



176



177



178

and **178**), called *semidines*. The 2,2′-diaminobiaryl and the *p*-semidine are formed less often and in smaller amounts than the other two side products. Usually, the 4,4′-diaminobiaryl predominates, except when one or both of the para positions of the diarylhydrazine are occupied. However, the 4,4′-diamine may still be produced, even if the para positions are occupied. If SO_3H, COOH, or Cl (but not R, Ar, or NR_2) is present in the para position, it may be ejected. With dinaphthylhydrazines, the major products are not the 4,4′-diaminobinaphthyls, but the 2,2′ isomers. Another side reaction is disproportionation to $ArNH_2$ and ArN═NAr. For example, p,p'-PhC_6H_4NH-NHC_6H_4Ph gives 88% disproportionation products at 25°C.[524]

The mechanism has been exhaustively studied, and several mechanisms have been proposed. At one time it was believed that NHAr broke away from ArNHNHAr and then became attached to the para position to give the semidine (**178**), which then went on to product. The fact that semidines could be isolated lent this argument support, as did the fact that this would be analogous to the rearrangements considered in Chapter 11 (reactions **1-36** to **1-40**). However, this theory was killed when it was discovered that semidines could not be converted to benzidines under the reaction conditions. Cleavage into two independent pieces (either ions or free radicals) has been ruled out by many types of crossover experiments, which always show that the two rings of the starting material are in the product; that is, ArNHNHAr′ gives no molecules (of any of the five products) containing two Ar groups or two Ar′ groups, and mixtures of ArNHNHAr and Ar′NHNHAr′ give no molecules containing both Ar and Ar′. An important discovery was the fact that although the reaction is always first order in substrate, it may be either first[525] or second[526] order in $[H^+]$. The generalized rate law is (S = substrate):

$$\frac{-d(S)}{dt} = k_2[S][H^+] + k_3[S][H^+]^2$$

However, the values of k_2 and k_3 are such that with some substrates the reaction is entirely first order in $[H^+]$, while with others it is entirely second order in $[H^+]$, regardless of the acidity. With still other substrates, the reaction is first order in $[H^+]$ at low acidities and second order at higher acidities. With the latter substrates fractional orders can often be observed,[527] because at intermediate acidities both processes take place simultaneously. These kinetic results seem to indicate that the actual reacting species can be either the monoprotonated substrate $\mathrm{ArNH\overset{\oplus}{N}H_2Ar}$ or the diprotonated $\mathrm{Ar\overset{\oplus}{N}H_2\overset{\oplus}{N}H_2Ar}$. A mechanism which accounts for most of the known facts was devised by Banthorpe, Hughes, and Ingold. This mechanism, called the "polar-transition-state" mechanism, has the electrons moving around a ring, with the rings linking up in the 2,2′, 4,4′, or 2,4′ manner. These intermediates can go to product, they can convert from one to another (shown for the 2,2′ → the 4,4′), or they can go to semidine (shown for 2,2′ → the *o*-semidine):

The diion **179** was obtained as a stable species in super-acid solution at −78°C by treatment of hydrazobenzene with FSO_3H-SO_2 (SO_2ClF).[528] Though the mechanism shown above begins with the diprotonated substrate, the polar-transition-state mechanism can also account for the reaction with monoprotonated substrate. Another mechanism, called the "π-complex mechanism," was proposed by Dewar;[529] it envisions cleavage of the monoprotonated substrate into two parts which are held together by a π-orbital overlap between a filled orbital of the benzene-type ring and an empty orbital of the other.[530]

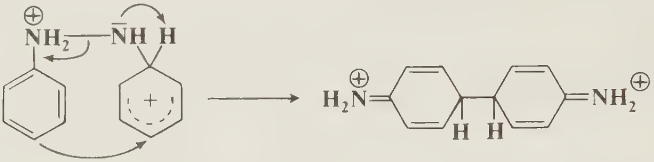
[528] Olah, Dunne, Kelly, and Mo, *J. Am. Chem. Soc.* **94**, 7438 (1972).

[529] Dewar, in Mayo, Ref. 1, vol. 1, pp. 323–344.

[530] For a criticism of this proposal, see Banthorpe, *Chem. Rev.* **70**, 295–322 (1970), pp. 315–317, 322.

Since the rings are held together at the centers, it is easy to see how they can rotate to form the various products. In this view the role of the second proton is to attack the complex in the rate-determining step.

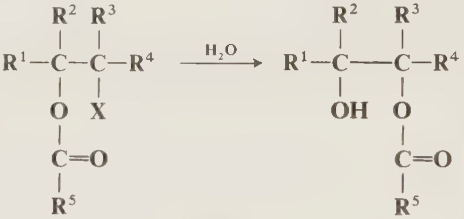
Another proposal is that the second proton protonates one of the ring carbons (in the ipso position) and that the mechanism is simply an electrophilic substitution (shown for formation of the 4,4′-diaminobiphenyl, but the other products can be similarly rationalized).[531] A radical cation mechanism has also been proposed.[532] Complicating matters further was the discovery that the rearrangement can proceed without any acid at all, merely on heating.[533] Photochemical benzidine rearrangements are also known.[534]



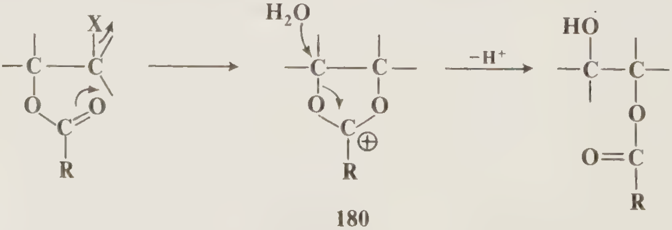
179

Despite the immense amount of work done on this unique reaction, it seems that much more needs to be done before a mechanism is established on which all can agree.

8-45 Acyl Rearrangements



There are two basic kinds of acyl rearrangements. One of these, illustrated above, involves migration of an acyloxy group to a position formerly occupied by a leaving group, and the replacement of the acyloxy group by a nucleophile. The reaction is similar in appearance to reaction **8-13**, but the mechanism is not entirely the same. The acyloxy group does replace the leaving group in an SN2 process and is replaced in turn by another SN2 process (as in reaction **8-13**), but it is not the alkyl oxygen which attacks, but the acyl oxygen; that is, the transition state is five-membered and not three-membered:



180

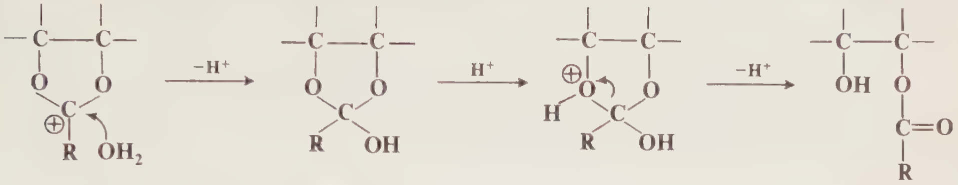
[531] Allan, *Tetrahedron Lett.* 4225 (1971), *Monatsh. Chem.* **106**, 429 (1975); Olah et al., Ref. 528. For a criticism of this proposal, see Banthorpe, *Tetrahedron Lett.* 2707 (1972).

[532] For example, see Svanholm, Bechgaard, Hammerich, and Parker, *Tetrahedron Lett.* 3675 (1972).

[533] Shine and Trisler, *J. Am. Chem. Soc.* **82**, 4054 (1960); Banthorpe and Hughes, *J. Chem. Soc.* 2849, 2860 (1964); Banthorpe, *J. Chem. Soc.* 2854 (1964).

[534] See for example, Cheng and Shine, *J. Org. Chem.* **39**, 2835 (1974).

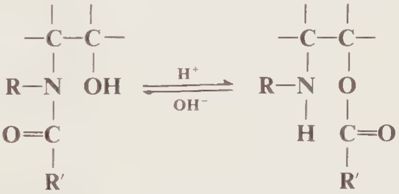
180 can be opened in two ways: (1) attack by the nucleophile at the position which is more favorable, the reaction thus becoming either a nucleophilic substitution by the neighboring-group mechanism or a rearrangement (this path is shown above), or (2) attack at the *carbonyl* carbon:



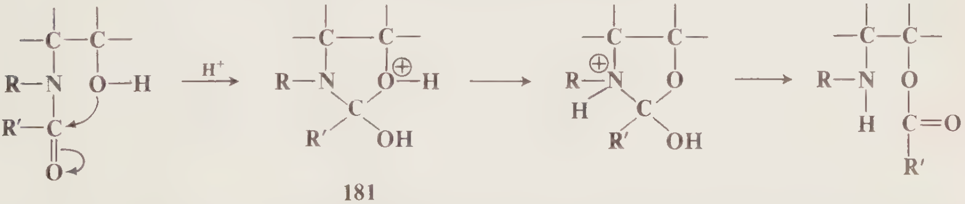
181

Of course, ring opening in the other direction gives the substitution and not the rearrangement product. When the nucleophile is water, then rearrangement by path 1 or by path 2 gives the same product, and similarly for substitution. The paths may be told apart by the difference in stereochemical consequences. For rearrangement, path 1 requires inversion at both carbons, while path 2 requires retention at the migration origin (C-1) and inversion at the terminus (C-2). Substitution by path 1 involves retention at both carbons, while path 2 predicts retention at C-1 and inversion at C-2. The leaving group may be halo, OTs, OH_2^+, or any other good SN leaving group. Besides water, the nucleophile may be ROH or RCOOH, in which case OR or OCOR appears in the product instead of OH. However, with these nucleophiles the reaction proceeds only by path 1, or if it does take path 2, then the reaction stops at the ortho ester stage (**181**, with OR or OCOR instead of OH). Analogous reactions have been carried out with nitrogen or sulfur replacing one or both of the acyloxy oxygens.

In the second type of acyl rearrangement,[535] there is a 1,4 or longer migration of an acyl (RCO) or an acyloxy (ROCO) group from one hetero atom to another, e.g.,



This type of reaction is undergone by N- and O-acylated amino alcohols and conceivably by monoacylated 1,2-diamines and 1,2-glycols and the sulfur analogs of these compounds, though not many of these possibilities have been examined. The mechanism is



181

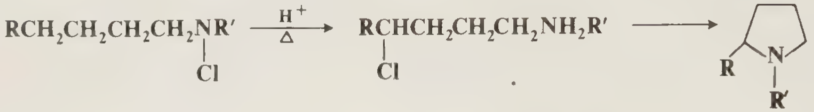
In this particular case, nitrogen-to-oxygen migration can be accomplished with acids (which stabilize the amine as the salt) and the reverse oxygen-to-nitrogen migration with bases. The stereochemistry must involve retention at both carbons.[536] These reactions are actually internal examples of alcoholysis of amides (p. 367) and of acylation of amines by esters (reaction **0-57**). Transannular rearrangements of this type have also been reported.

---

[535] For a review, see Pavlova and Rachinskii, *Russ. Chem. Rev.* 37, 587–602 (1968).

There are no *Organic Syntheses* references, but see OS V, 650 for a related reaction.

8-46 The Hofmann-Löffler and Related Reactions



A common feature of the reactions in this section[537] is that they serve to introduce functionality at a position remote from functional groups already present. As such they have proved very useful in synthesizing many compounds, especially in the steroid field (see also reactions **9-3** and **9-16**). When N-haloamines in which one alkyl group has a hydrogen in the 4 or 5 position are heated with sulfuric acid, pyrrolidines or piperidines are formed, in a reaction known as the *Hofmann-Löffler reaction* (also called the *Hofmann-Löffler-Freytag reaction*).[538] R′ is normally alkyl, but the reaction has been extended to R′ = H by use of concentrated sulfuric acid solution and ferrous salts.[539] The first step of the reaction is a rearrangement, with the halogen migrating from the nitrogen to the 4 or 5 position of the alkyl group. It is possible to isolate the resulting haloamine salt, but usually this is not done, and the second step, the ring closure (reaction **0-46**), takes place. Though the reaction is most often induced by heat, this is not necessary, and irradiation and chemical initiators (e.g., peroxides) have been used instead. The mechanism is of a free-radical type, with the main step involving an internal hydrogen abstraction.[540]

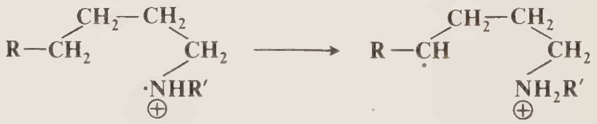
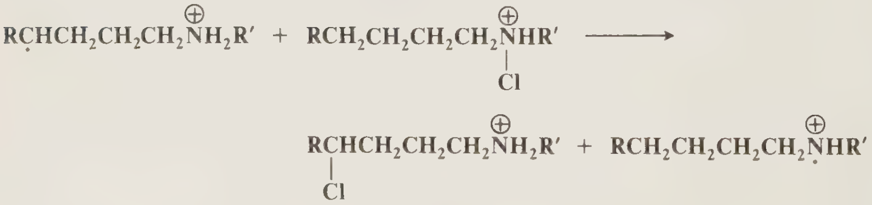
$$RCH_2CH_2CH_2CH_2\underset{\underset{\displaystyle Cl}{|}}{N}R' \xrightarrow{H^+} RCH_2CH_2CH_2CH_2\overset{\oplus}{\underset{\underset{\displaystyle Cl}{|}}{N}}HR' \longrightarrow RCH_2CH_2CH_2CH_2\overset{\oplus}{\underset{\bullet}{N}}HR' + Cl\cdot$$

Propagation





$$R\underset{\bullet}{C}HCH_2CH_2CH_2\overset{\oplus}{N}H_2R' + RCH_2CH_2CH_2CH_2\overset{\oplus}{\underset{\underset{\displaystyle Cl}{|}}{N}}HR' \longrightarrow R\underset{\underset{\displaystyle Cl}{|}}{C}HCH_2CH_2CH_2\overset{\oplus}{N}H_2R' + RCH_2CH_2CH_2CH_2\overset{\oplus}{\underset{\bullet}{N}}HR'$$

etc.

---

[536] Confirmation that this reaction gives retention at the migration terminus while the other type of acyl rearrangement gives inversion was obtained by ^{18}O labeling: Welsh, *J. Org. Chem.* **32,** 119 (1967).

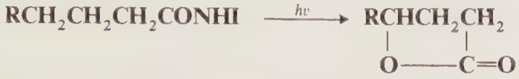
[537] For a review of the reactions in this section, see Carruthers, "Some Modern Methods of Organic Synthesis," pp. 172–197, Cambridge University Press, London, 1971.

[538] For reviews, see Sosnovsky and Rawlinson, *Adv. Free-Radical Chem.* **4,** 203–284 (1972), pp. 249–259; Deno, *Methods Free-Radical Chem.* **3,** 135–154 (1972), pp. 136–143; Wolff, *Chem. Rev.* **63,** 55–64 (1963).

[539] Schmitz and Murawski, *Chem. Ber.* **99,** 1493 (1966).

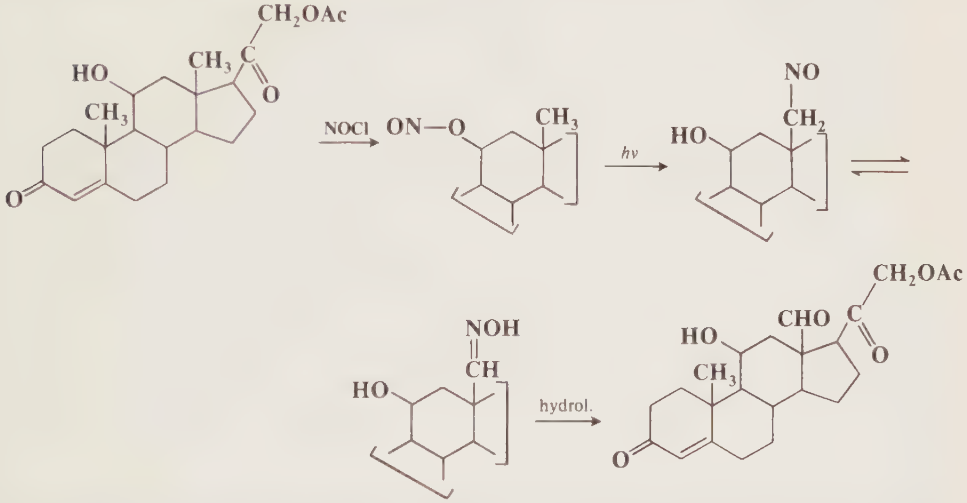
[540] Wawzonek and Thelan, *J. Am. Chem. Soc.* **72,** 2118 (1950).

A similar reaction has been carried out on N-halo amides, which give γ-lactones:[541]

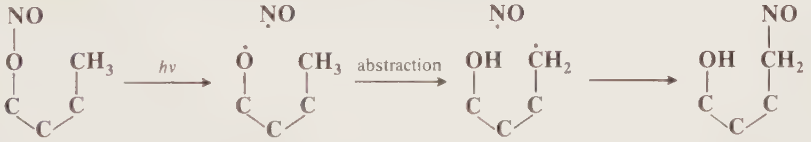


$$\mathrm{RCH_2CH_2CH_2CONHI} \xrightarrow{h\nu} \begin{array}{l}\mathrm{RCHCH_2CH_2} \\ \;\;|\qquad\;\;\; | \\ \;\mathrm{O}\text{——}\mathrm{C{=}O}\end{array}$$

Another related reaction is the *Barton reaction*,[542] by means of which a methyl group in the δ position to an OH group can be oxidized to a CHO group. The alcohol is first converted to the nitrite ester. Photolysis of the nitrite results in conversion of the nitrite group to the OH group, and nitrosation of the methyl group. Hydrolysis of the oxime tautomer gives the aldehyde, e.g.,[543]



This reaction takes place only when the methyl group is in a favorable steric position. The mechanism is similar to that of the Hofmann-Löffler reaction.[544]



This is one of the few known methods for effecting substitution at an angular methyl group. Not only $\mathrm{CH_3}$ groups but also alkyl groups of the form $\mathrm{RCH_2}$ and $\mathrm{R_2CH}$ can give the Barton reaction if the geometry of the system is favorable. An $\mathrm{RCH_2}$ group is converted to the oxime R(C=NOH)[545] (which is hydrolyzable to a ketone) or to a nitroso dimer, while an $\mathrm{R_2CH}$ group gives a nitroso compound $\mathrm{R_2C(NO)}$. With very few exceptions, the only carbons which become nitrosated are those in the position δ to the original OH group, indicating that a six-membered transition state is necessary for the hydrogen abstraction.

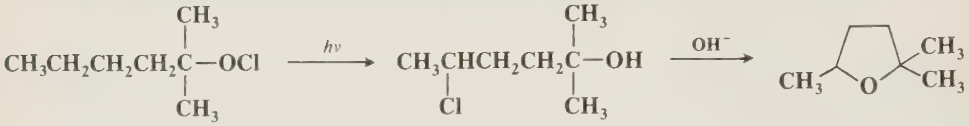
[544] Kabasakalian and Townley, *J. Am. Chem. Soc.* **84**, 2711 (1962); Akhtar, Barton, and Sammes, *J. Am. Chem. Soc.* **87**, 4601 (1965).

[545] For an example, see Reimann and Sarre, *Can. J. Chem.* **49**, 344 (1971).

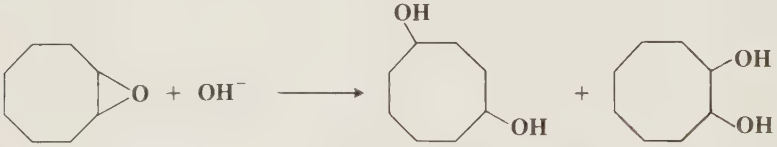
Another reaction with a similar mechanism is the photolytic conversion of tertiary hypohalites to δ-chloro alcohols, which can then be cyclized to tetrahydrofurans.[546]



OS III, 159.

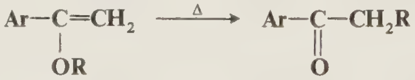
D. Noncyclic Rearrangements

8-47 Hydride Shifts



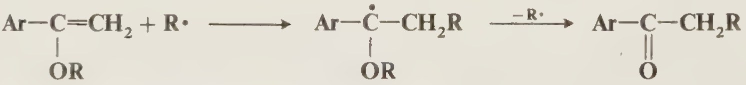
The above is a typical example of a transannular hydride shift. The 1,2-glycol is formed by a normal epoxide hydrolysis reaction (**0-8**). For a discussion of 1,3 and longer hydride shifts, see p. 972.

8-48 Rearrangement of Enol Ethers and Tosylates



$$\mathrm{Ar{-}\underset{\substack{|\\ OR}}{C}{=}CH_2} \xrightarrow{\Delta} \mathrm{Ar{-}\underset{\substack{\|\\ O}}{C}{-}CH_2R}$$

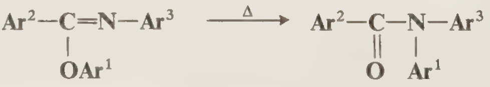
When vinyl ethers of the form $\mathrm{ArC(OR){=}CH_2}$ are heated, they rearrange to ketones. This is a 1,3 shift of R from O to C.[547] It is an intermolecular process and involves free radicals.[548] After some type of initiation step, the propagation steps are



$$\mathrm{Ar{-}\underset{\substack{|\\ OR}}{C}{=}CH_2 + R\cdot} \longrightarrow \mathrm{Ar{-}\underset{\substack{|\\ OR}}{\dot{C}}{-}CH_2R} \xrightarrow{-\mathrm{R}\cdot} \mathrm{Ar{-}\underset{\substack{\|\\ O}}{C}{-}CH_2R}$$

In a reaction with a similar mechanism, enol tosylates $\mathrm{RC(OTs){=}CHR'}$ are converted by heat or photolytically to α-tosyl ketones $\mathrm{RCOCHR'Ts}$.[549]

8-49 The Chapman Rearrangement



$$\mathrm{Ar^2{-}\underset{\substack{|\\ OAr^1}}{C}{=}N{-}Ar^3} \xrightarrow{\Delta} \mathrm{Ar^2{-}\underset{\substack{\|\\ O}}{C}{-}\underset{\substack{|\\ Ar^1}}{N}{-}Ar^3}$$

In the *Chapman rearrangement*, N,N-diaryl amides are formed when aryl imino esters are heated.

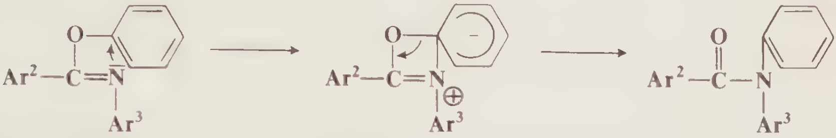
Soc.* **83**, 2213 (1961). For a review for the case of hypobromites, see Brun and Waegell, *Tetrahedron* **32**, 517–527 (1976).

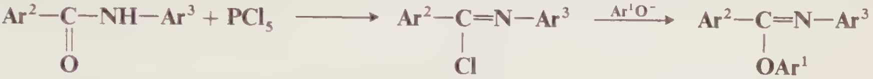
[547] For a review of 1,3 migrations of R, see Landis, *Mech. Mol. Migr.* **2**, 43–63 (1969).

[548] Wiberg, Kintner, and Motell, *J. Am. Chem. Soc.* **85**, 450 (1963), and references cited therein.

[549] Frydman and Mazur, *J. Am. Chem. Soc.* **92**, 3203 (1970).

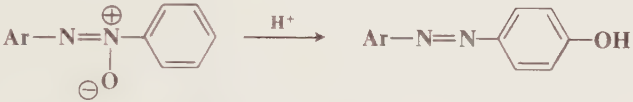
The reaction is similar in appearance to reaction **8-48**.[550] Best yields are obtained in refluxing tetraethylene glycol dimethyl ether (tetraglyme),[551] though the reaction can also be carried out without any solvent at all. Many groups may be present in the rings, for example, alkyl, halo, OR, CN, COOR, etc. Aryl migrates best when it contains electron-withdrawing groups. On the other hand, electron-withdrawing groups in Ar^2 or Ar^3 decrease the reactivity. The products may be hydrolyzed to diarylamines, and this is a method for preparing these compounds. The mechanism is different from that of reaction **8-48** and probably involves an intramolecular[552] aromatic nucleophilic substitution, resulting in a 1,3 oxygen-to-nitrogen shift. Imino esters can be prepared from N-aryl amides by reaction with PCl_5, followed by treatment of the resulting imino chloride with an aroxide ion.[553] Imino esters with any or all of the three groups being alkyl also rearrange, but they require catalysis by H_2SO_4 or a trace of methyl iodide or methyl sulfate.[547] The mechanism is different, however, involving an intermolecular process. This is also true for derivatives of formamide (Ar^2 = H).





$$Ar^2-\underset{\underset{O}{\|}}{C}-NH-Ar^3 + PCl_5 \longrightarrow Ar^2-\underset{\underset{Cl}{|}}{C}=N-Ar^3 \xrightarrow{Ar^1O^-} Ar^2-\underset{\underset{OAr^1}{|}}{C}=N-Ar^3$$

8-50 The Wallach Rearrangement



182 **183**

The conversion of azoxy compounds, on acid treatment, to *p*-hydroxy azo compounds (or sometimes the *o*-hydroxy isomers[554]) is called the *Wallach rearrangement*.[555] Although the mechanism[556] is not completely settled, the following facts are known: (1) The para rearrangement is intermolecular.[557] (2) When the reaction was carried out with an azoxy compound in which the N—O nitrogen was labeled with ^{15}N, *both* nitrogens of the product carried the label equally,[558] demonstrating that the oxygen did not have a preference for migration to either the near or the far ring. This shows that there is a symmetrical intermediate. (3) Kinetic studies show that two protons are normally required for the reaction.[559] The following mechanism,[560] involving the symmetrical intermediate **185**, has been proposed to explain the facts.[561]

It has proved possible to obtain **184** and **185** as stable acids in super-acid solutions.[528] Another mechanism, involving an intermediate with only one positive charge, has been proposed for certain substrates at low acidities.[562]

When other nucleophiles are used, it may be possible to obtain *o*- or *p*-substituted azo compounds as products. For example, azoxybenzene reacts with aryl sulfonyl chlorides $ArSO_2Cl$ to give *o*- and *p*-arenesulfonyloxaazobenzenes $PhN{=}NC_6H_4OSO_2Ar$.[563]

A photochemical Wallach rearrangement is also known: The product is the *o*-hydroxy azo compound, the OH group is found in the farther ring, and the rearrangement is intramolecular.[564]

Nineteen

Oxidations and Reductions

First we must examine what we mean when we speak of oxidation and reduction. Inorganic chemists define oxidation in two ways: loss of electrons and increase in oxidation number. In organic chemistry, these definitions, while still technically correct, are not easy to apply. While electrons are directly transferred in some organic oxidations and reductions (see p. 1075), the mechanisms of most of these reactions do not involve a direct electron transfer. As for oxidation number, while this is easy to apply in some cases, e.g., the oxidation number of carbon in CH_4 is -4, in most cases attempts to apply the concept lead to fractional values or to apparent absurdities. Thus, carbon in propane has an oxidation number of -2.67 and in butane of -2.5, though organic chemists seldom think of these two compounds as being in different oxidation states. An improvement could be made by assigning different oxidation states to different carbon atoms in a molecule, depending on what is bonded to them (for example, the two carbons in acetic acid are obviously in different oxidation states), but for this a whole set of arbitrary assumptions would be required, since the oxidation number of an atom in a molecule is assigned on the basis of the oxidation numbers of the atoms attached to it. There would seem little to be gained by such a procedure. What organic chemists have done—though more by custom than by any formal agreement—is to set up a series of functional groups, in a qualitative way, arranged in order of increasing oxidation state, and then to define oxidation as *the conversion of a functional group in a molecule from one category to a higher one*. Reduction is the opposite. For the simple functional groups this series is shown in Table 1.[1] It should be noted that this classification applies only to a single carbon atom or to two adjacent carbon atoms. Thus 1,3-dichloropropane is in the same oxidation state as chloromethane, but 1,2-dichloropropane is in a higher one. Obviously, such distinctions are somewhat arbitrary, and if we attempt to carry them too far, we shall find ourselves painted into a corner. Nevertheless the basic idea will serve us well. It should be noted that conversion of any compound to another in the same category is not an oxidation or a reduction. Most oxidations in organic chemistry involve a gain of oxygen and or a loss of hydrogen. The reverse is true for reductions.

Of course, there is no oxidation without a concurrent reduction. However, we classify reactions as oxidations or reductions depending on whether the *organic compound* is oxidized or reduced. In some cases both the oxidant and reductant are organic, and we will consider those reactions separately.

MECHANISMS

It must be noted that our definition of oxidation has nothing to do with mechanism. Thus the conversions of bromomethane to methanol with KOH (reaction **0-1**) and to methane with $LiAlH_4$ (reaction **0-77**) have the same SN2 mechanisms, but one is a reduction (according to our

---

[1] For more extensive tables, with subclassifications, see Soloveichik and Krakauer, *J. Chem. Educ.* **43**, 532–535 (1966).

TABLE 1 Categories of simple functional groups arranged according to oxidation state

Oxidation is the conversion of a functional group in a molecule to a higher category; reduction is conversion to a lower one. Conversions within a category are neither oxidations nor reductions. The numbers given at the bottom are only approximations

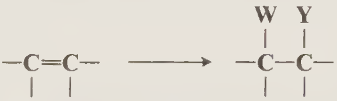
−4	−2	0	+2	+4

definition), and the other is not. It is impractical to consider the mechanisms of oxidation and reduction reactions in broad categories in this chapter as we have done for the reactions considered in Chapters 10 to 18.[2] The main reason is that the mechanisms are too diverse, and this in turn is because the bond changes are too different. For example, in Chapter 15, all the reactions involved the following bond change (with respect to the substrate):



$$-\underset{|}{C}=\underset{|}{C}- \longrightarrow -\underset{|}{\overset{\overset{W}{|}}{C}}-\underset{|}{\overset{\overset{Y}{|}}{C}}-$$

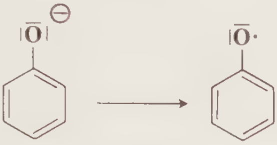
and a relatively few mechanisms covered all the reactions. But for oxidations and reductions the bond changes are far more diverse. Another reason is that the mechanism of a given oxidation or reduction reaction often varies greatly with the oxidizing or reducing agent employed. Very often the mechanism has been studied intensively for only one or a few of many possible agents. A third reason is closely related: As a class, less work has been done on the mechanisms of oxidation-reduction reactions than on the reactions covered in previous chapters. However, in recent years the pace in the area has been increasing rapidly, and it is likely that before long this reason will no longer apply.

---

[2] For monographs on oxidation mechanisms, see "Oxidation in Organic Chemistry," Academic Press, New York, pt. A [Wiberg (ed.)], 1965; pt. B [Trahanovsky (ed.)], 1973; Waters, "Mechanisms of Oxidation of Organic Compounds," John Wiley & Sons, Inc., New York, 1964; Stewart, "Oxidation Mechanisms," W. A. Benjamin, Inc., New York, 1964. For a review, see Wiberg, *Surv. Prog. Chem.* **1**, 211–248 (1963).

Though we therefore do not cover oxidation and reduction mechanisms in the same way as we have covered other mechanisms, it is still possible to list a few broad mechanistic categories. In doing this, we follow the scheme of Wiberg.[3]

1. *Direct electron transfer.* We have already met a few reactions in which the reduction is actually a direct gain of electrons or the oxidation a direct loss of them. An example is the Birch reduction (reaction **5-13**), where sodium directly transfers an electron to an aromatic ring. An example from this chapter is found in the bimolecular reduction of ketones (reaction **9-67**), where again it is a metal which supplies the electrons. This kind of mechanism is found largely in three types of reaction:[4] (a) the oxidation or reduction of a free radical (oxidation to a positive or reduction to a negative ion), (b) the oxidation of a negative ion or the reduction of a positive ion to a comparatively stable free radical, and (c) electrolytic oxidations or reductions (an example being the Kolbe reaction, **4-38**). An important example of the second type is oxidation of amines and phenolate ions:



These reactions occur easily because of the relative stability of the radicals involved.[5]

2. *Hydride transfer.*[6] In some reactions a hydride ion is transferred to or from the substrate. The reduction of epoxides with $LiAlH_4$ is an example (reaction **0-81**). Another is the Cannizzaro reaction (**9-74**), in which one organic species transfers a hydride ion to another and is itself oxidized, while the other is reduced. Reactions in which a carbonium ion abstracts a hydride ion belong in this category:[7]

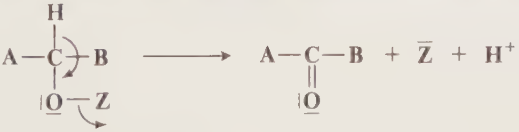
$$\mathbf{R^+ + R'H \longrightarrow RH + R'^+}$$

3. *Hydrogen-atom transfer.* Many oxidation and reduction reactions are free-radical substitutions and involve the transfer of a hydrogen atom. For example, one of the two main propagation steps of reaction **4-1** involves abstraction of hydrogen:

$$\mathbf{RH + Cl\cdot \longrightarrow R\cdot + HCl}$$

This is the case for many of the reactions of Chapter 14.

4. *Formation of ester intermediates.* A number of oxidations involve the formation of an ester intermediate (usually of an inorganic acid), and then the cleavage of this intermediate:



---

[4] Littler and Sayce, *J. Chem. Soc.* 2545 (1964).

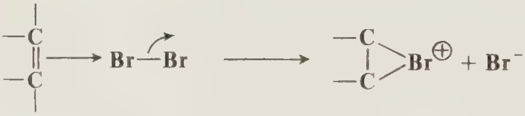
[5] For a review of the oxidation of phenols, see Mihailović and Čeković, in Patai, "The Chemistry of the Hydroxyl Group," pt. 1, pp. 505–592, Interscience Publishers, New York, 1971.

[6] For reviews, see Deno, Peterson, and Saines, *Chem. Rev.* **60,** 7–14 (1960); Kursanov and Parnes, *Russ. Chem. Rev.* **30,** 598–602 (1961).

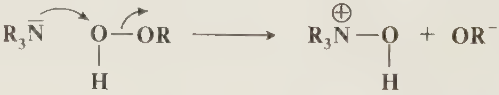
[7] For a review of these reactions, see Nenitzescu, in Olah and Schleyer, "Carbonium Ions," vol. 2, pp. 463–520, Interscience Publishers, New York, 1970.

Z is usually CrO_3H, MnO_3, or a similar inorganic acid moiety. One example of this mechanism was seen in reaction **4-6**, where A was an alkyl or aryl group, B was OH, and Z was CrO_3H. Another is the oxidation of a secondary alcohol to a ketone (reaction **9-4**), where A and B are alkyl or aryl groups and Z is also CrO_3H. In the lead tetraacetate oxidation of glycols (reaction **9-8**) the mechanism also follows this pattern, but the positive leaving group is carbon instead of hydrogen. It should be noted that the cleavage shown is actually an example of an E2 elimination mechanism. Reaction **7-44** is another example.

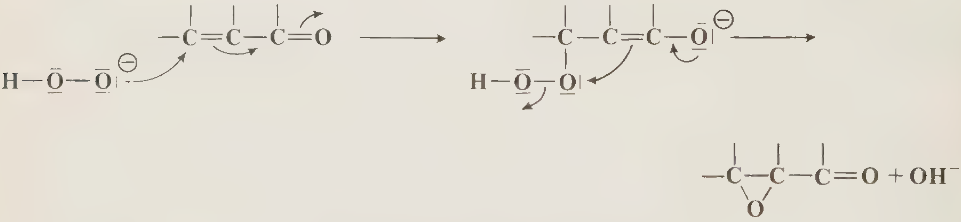
5. *Displacement mechanisms.* In these reactions the organic substrate uses its electrons to cause displacement on an electrophilic oxidizing agent. One example is the addition of bromine to an olefin (reaction **5-30**).



An example from this chapter is found in reaction **9-29**:



6. *Addition-elimination mechanisms.* In the reaction between α,β-unsaturated ketones and alkaline peroxide (reaction **5-40**), the oxidizing agent adds to the substrate, and then part of it is lost:



In this case the oxygen of the oxidizing agent was in oxidation state −1 and the OH^- departed with its oxygen in the −2 state, so it was reduced and the substrate oxidized. There are several reactions which follow this pattern of addition of an oxidizing agent and the loss of part of the agent, usually in a different oxidation state. Another example is the oxidation of ketones with SeO_2 (reaction **9-16**). This reaction is also an example of category 4, since it involves formation and E2 cleavage of an ester. This example shows that these six categories are not mutually exclusive.

REACTIONS

In this chapter, the reactions are classified by the type of bond change occurring to the organic substrate, in conformity with our practice in the other chapters. This means that there is no discussion in any one place of the use of a particular oxidizing or reducing agent, e.g., acid dichromate or $LiAlH_4$ (except for a discussion of selectivity of reducing agents, p. 1116). Some oxidizing or reducing agents are fairly specific in their action, attacking only one or a few types of substrate. Others, like acid dichromate, permanganate, $LiAlH_4$, and catalytic hydrogenation, are much more versatile.[8]

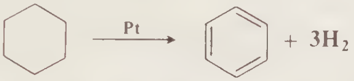
When an oxidation or a reduction could be considered in a previous chapter, this was done. For example, the catalytic hydrogenation of olefins is a reduction, but it is also an addition to the C=C bond and was treated in Chapter 15. In this chapter are discussed only those reactions which do not fit into the nine categories of Chapters 10 to 18. An exception to this rule was made for reactions which involve elimination of hydrogen (**9-1** to **9-7**), which were not treated in Chapter 17 because the mechanisms generally differ from those in that chapter.

Oxidations[9]

The reactions in this section are classified into groups depending on the type of bond change involved. These groups are: eliminations of hydrogen, reactions involving cleavage of carbon-carbon bonds, reactions involving replacement of hydrogen by oxygen, reactions in which oxygen is added to the substrate, and oxidative coupling.

A. Eliminations of Hydrogen

9-1 Aromatization of Six-membered Rings



Six-membered alicyclic rings can be aromatized in a number of ways.[10] Aromatization is accomplished most easily if there are already one or two double bonds in the ring or if the ring is fused to an aromatic ring. The reaction can also be applied to heterocyclic five- and six-membered rings. Many groups may be present on the ring without interference, and even *gem*-dialkyl substitution does not always prevent the reaction: In such cases one alkyl group often migrates or is eliminated. However, more drastic conditions are usually required for this. In some cases OH and COOH groups are lost from the ring. Cyclic ketones are converted to phenols. Seven-membered and larger rings are often isomerized to six-membered aromatic rings, though this is not the case for partially hydrogenated azulene systems (which are frequently found in nature); these are converted to azulenes.

[9] For books on oxidation reactions, see Chinn, "Selection of Oxidants in Synthesis," Marcel Dekker, Inc., New York, 1971; Augustine and Trecker, "Oxidation," 2 vols., Marcel Dekker, Inc., New York, 1969, 1971. See also Ref. 2.

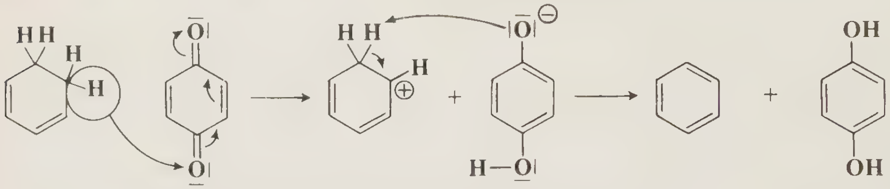
[10] For reviews, see Valenta, in Bentley and Kirby, Ref. 8, pp. 1–76; House, Ref. 8, pp. 34–44; Plattner, *Newer Methods Prep. Org. Chem.* **1,** 21–59 (1948).

There are three types of reagents most frequently used to effect aromatization.

1. Hydrogenation catalysts[11] such as platinum, palladium, nickel, etc. In this case the reaction is the reverse of double-bond hydrogenation (reactions **5-12** and **5-13**), and presumably the mechanism is also the reverse of that one, though not much is known. The substrate is heated with the catalyst at about 300 to 350°C. The reactions can often be carried out under milder conditions if a hydrogen acceptor, such as maleic acid, cyclohexene, or benzene, is present to remove hydrogen as it is formed. The acceptor is reduced to the saturated compound. It has been reported that dehydrogenation of 1-methylcyclohexene-1-^{13}C over an alumina catalyst gave toluene with the label partially scrambled throughout the aromatic ring.[12]

2. The elements sulfur and selenium, which combine with the hydrogen evolved to give, respectively, H_2S and H_2Se. Little is known about this mechanism either.[13]

3. Quinones,[14] which become reduced to the corresponding hydroquinones. Two important quinones often used for aromatizations are chloranil (2,3,5,6-tetrachloro-1,4-benzoquinone) and DDQ (2,3-dichloro-5,6-dicyano-1,4-benzoquinone).[15] The latter is more reactive and may be used in cases where the substrate is difficult to dehydrogenate. The mechanism involves a transfer of hydride to the quinone oxygen, followed by the transfer of a proton to the phenolate ion:[16]



Other reagents which have been used are atmospheric oxygen, MnO_2,[17] SeO_2, BuLi-N,N,N′,N′-tetramethylethylenediamine,[18] Ph_3COH in CF_3COOH,[19] and activated charcoal.[20] The last-mentioned reagent also dehydrogenates cyclopentanes to cyclopentadienes. In some instances the hydrogen is not released as H_2 or transferred to an external oxidizing agent but instead serves to reduce another molecule of substrate. This is a disproportionation reaction and may be illustrated by the conversion of cyclohexene to cyclohexane and benzene.

Aromatization reactions have been particularly important in the proof of structure of many cyclic natural products, especially steroids and terpenes. Diels-Alder adducts (which must contain at least one double bond) are also frequently aromatized.[21]

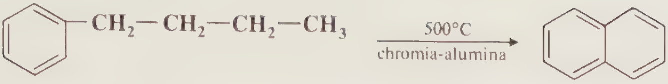
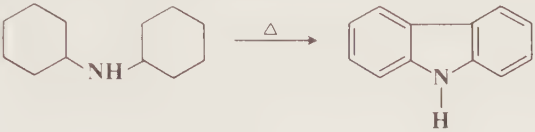
9-2 Cyclodehydrogenation

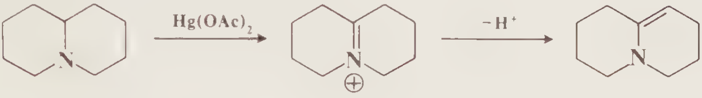


Many aliphatic chains of at least six carbons have been pyrolyzed over chromia-alumina catalysts to yield aromatic compounds.[22] Where structural features permit (as in the reaction illustrated above), bicyclic and polycyclic compounds can be formed. Many heterocyclic aromatic compounds have also been made in this way. In some cases the chains are unsaturated and the only loss of hydrogen is from ring closure, but in other cases ring closure and aromatization (reaction **9-1**) take place concurrently. The majority of rings formed in this reaction are six-membered, but five-membered rings can also be formed, an example being[23]



The mechanism of these reactions is complex.[24]

9-3 Dehydrogenations Yielding Carbon-Carbon Bonds



1

Dehydrogenation of an aliphatic compound to give a double bond in a specific location is not usually a feasible process, though industrially mixtures of olefins are obtained in this way from mixtures of alkanes (generally by heating with chromia-alumina catalysts). There are, however, some notable exceptions, and it is not surprising that these generally involve cases where the new double bond can be in conjugation with a double bond or with an unshared pair of electrons already present. One example is the synthesis developed by Leonard and coworkers[25] in which tertiary amines give enamines when treated with mercuric acetate[26] (see the example above). In this case the initial product is the iminium ion **1** which loses a proton to give the enamine. In another example, the oxidizing agent SeO_2 can in certain cases convert a carbonyl compound to an α,β-unsaturated carbonyl compound by removing H_2[27] (though this reagent more often gives reaction **9-16**). This reaction has been most often applied in the steroid series, an example being[28]

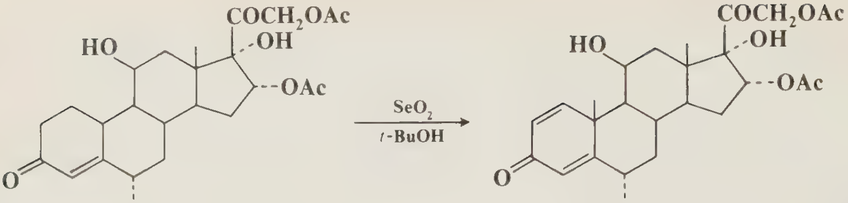
[27] For reviews, see Jerussi, *Sel. Org. Transform.* **1,** 301–326 (1970), pp. 315–321; Trachtenberg, in Augustine, Ref. 9, pp. 166–174.

[28] Bernstein and Littell, *J. Am. Chem. Soc.* **82,** 1235 (1960).



Similarly, SeO_2 has been used to dehydrogenate 1,4-diketones[29] ($RCOCH_2CH_2COR \rightarrow RCOCH{=}CHCOR$) and 1,2-diarylalkanes ($ArCH_2CH_2Ar \rightarrow ArCH{=}CHAr$). These conversions can also be carried out by certain quinones, most notably DDQ (see reaction **9-1**).[15] Simple aldehydes and ketones have been dehydrogenated (e.g., cyclopentanone → cyclopentenone) by $PdCl_2$[30] and by oxygen in the presence of a group VIII metal such as Pd(II) and a cocatalyst such as Cu(II) or a quinone.[31] (For an indirect method for the dehydrogenation of simple aldehydes, ketones, and esters, see reaction **7-12.**)

An entirely different approach to specific dehydrogenation has been reported by R. Breslow[32] and by J. E. Baldwin.[33] By means of this approach it was possible, for example, to convert 3α-cholestanol (**2**) to 5α-cholest-14-en-3α-ol (**3**), thus *introducing a double bond at a specific site remote from any functional group*. This was accomplished by conversion of **2** to the ester **4**, followed by irradiation of **4**, which gave 55% **6** which was then hydrolyzed to **3**. The radiation excites the benzophenone portion of **4** (p. 223), which then abstracts hydrogen from the 14 position to give the diradical **5** which undergoes another internal abstraction to give **6.** In other cases, diradicals like **5** may close to a macrocyclic lactone (reaction **9-16**). In an alternate approach,[34] a 9(11) double bond was introduced into a steroid nucleus by conversion of the *m*-iodo ester 7 to the radical **8** (for example, by treatment with $PhICl_2$ and uv light), which abstracts hydrogen regiospecifically from the 9 position, resulting in chlorination at that position. Dehydrohalogenation of **9** gives the 9(11)-unsaturated steroid **10.** In contrast, use of the para isomer of 7 results in chlorination at the 14 position, and loss of HCl gives the 14-unsaturated steroid. These reactions are among the very few ways to introduce functionality at a specific site remote from any functional group (see also **9-16**).

9-4 Oxidation or Dehydrogenation of Alcohols to Aldehydes and Ketones

$$\mathrm{RCH_2OH} \xrightarrow[\text{chromite}]{\text{copper}} \mathrm{RCHO}$$

$$\mathrm{RCHOHR'} \xrightarrow[\mathrm{H_2SO_4}]{\mathrm{K_2Cr_2O_7}} \mathrm{RCOR'}$$

Primary alcohols can be converted to aldehydes, and secondary alcohols to ketones, in four main ways:[35]

1. *With strong oxidizing agents.*[36] Secondary alcohols are easily oxidized to ketones by acid dichromate[37] at room temperature or slightly above. Though this is the most common reagent, many other strong oxidizing agents (for example, $KMnO_4$, Br_2, MnO_2, ruthenium tetroxide,[38] etc.) have also been employed. A solution of chromic acid and sulfuric acid in water is known as the *Jones reagent.*[39] When secondary alcohols are dissolved in acetone,[40] titration with the Jones reagent oxidizes them to ketones rapidly and in high yield without disturbing any double or triple bonds which may be present (see reaction **9-11**), and without epimerizing an adjacent asymmetric center.[41] The Jones reagent also oxidizes primary allylic alcohols to the corresponding aldehydes.[42] MnO_2 is also a fairly specific reagent for OH groups and is often used to oxidize allylic alcohols to α,β-unsaturated aldehydes or ketones. For acid-sensitive compounds a CrO_3-pyridine complex can be used.[43] Most of these oxidizing agents have also been used to convert primary alcohols to aldehydes, but precautions must be taken so that the aldehyde is not further oxidized to the acid (reaction **9-22**).[44] One way to halt oxidation is by evaporation of the aldehyde as it is formed. The following are among the oxidizing agents which have been used to convert at least some primary alcohols to aldehydes: dimethyl sulfoxide (see reaction **9-20**), ceric ammonium nitrate,[45] dipyridine Cr(VI) oxide,[46] $Na_2Cr_2O_7$ in water,[47] pyridine-dichromate,[48] $Na_2Cr_2O_7$–H_2SO_4 in dimethyl sulfoxide,[49] CrO_3-dimethylpyrazole complex,[50] pyridinium chlorochromate,[50a] Ag_2CO_3-on-celite,[51] hot nitric acid in aqueous glyme,[52] iodosobenzene PhIO,[53]

silver(II) picolinate,[54] and $Pb(OAc)_4$-pyridine.[55] Most of these reagents also oxidize secondary alcohols to ketones. Reagents which can be used specifically to oxidize a secondary OH group in the presence of a primary OH group are Cl_2-pyridine[56] and Ag_2CO_3-on-celite.[57]

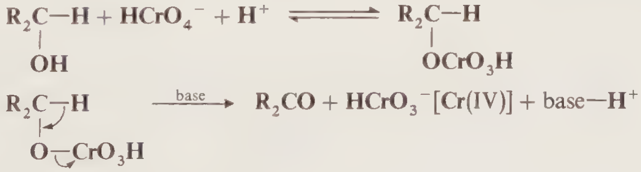
2. *By catalytic dehydrogenation.*[58] For the conversion of primary alcohols to aldehydes, dehydrogenation catalysts have the advantage over strong oxidizing agents that further oxidation to the acid is prevented. Copper chromite is the agent most often used, but other catalysts, e.g., silver and copper, have also been employed. Many ketones have also been prepared in this manner. Catalytic dehydrogenation is more often used industrially than as a laboratory method. However, a convenient laboratory procedure using copper oxide has been reported.[59]

3. *The Oppenauer oxidation.* When a ketone in the presence of base is used as the oxidizing agent (it is reduced to a secondary alcohol), the reaction is known as the *Oppenauer oxidation.*[60] This is the reverse of the Meerwein-Ponndorf-Verley reaction (**6-27**), and the mechanism is also the reverse. The ketones most commonly used are acetone, methyl ethyl ketone, and cyclohexanone. The most common base is aluminum *t*-butoxide. The chief advantage of the method is its high selectivity. Though the method is most often used for the preparation of ketones, it has also been used to prepare aldehydes.

4. *With* N-*bromosuccinimide or related compounds.* These compounds are selective oxidizing agents and often oxidize OH groups without disturbing other oxidizable groups.[61] N-Bromosuccinimide does not oxidize aliphatic primary alcohols, but N-chlorosuccinimide does. With these reagents it is often possible to oxidize only one of several OH groups which may be present in a molecule. The reactions readily proceed in the dark, so that the mechanism is not of the free-radical type, but involves attack by positive halogen.

Primary and secondary alcohols can also be oxidized, indirectly, through their esters (see reaction **9-20**). In some cases, isolation of the ester is not required, and the alcohol can then be oxidized to the aldehyde or ketone in one step. Alkoxide ions can be oxidized to aldehydes or ketones in good yield by photooxidation with O_2[62] (singlet O_2 is the oxidizing agent here; see reactions **4-8, 5-41**).

The mechanism of oxidation with acid dichromate has been intensively studied.[63] The currently accepted mechanism is essentially that proposed by Westheimer.[64] The first two steps constitute an example of category 4 (p. 1075).



$$\underset{\displaystyle OH}{R_2C{-}H} + HCrO_4^- + H^+ \rightleftharpoons \underset{\displaystyle OCrO_3H}{R_2C{-}H}$$

$$\underset{\displaystyle O{-}CrO_3H}{R_2C{-}H} \xrightarrow{\text{base}} R_2CO + HCrO_3^-[Cr(IV)] + \text{base}{-}H^+$$

[64] Westheimer, *Chem. Rev.* **45**, 419–451 (1949), p. 434; Holloway, Cohen, and Westheimer, *J. Am. Chem. Soc.* **73**, 65 (1951).

$$R_2CHOH + Cr(IV) \longrightarrow R_2\dot{C}OH + Cr(III)$$
$$R_2\dot{C}OH + Cr(VI) \longrightarrow R_2CO + Cr(V)$$
$$R_2CHOH + Cr(V) \longrightarrow R_2CO + Cr(III)$$

The base in the second step may be water, though it is also possible[65] that in some cases no external base is involved, and that the proton is transferred directly to one of the CrO_3H oxygens, in which case the Cr(IV) species produced would be H_2CrO_3. Part of the evidence for this mechanism was the isotope effect of about 6 found on use of MeCDOHMe, showing that the α-hydrogen is removed in the rate-determining step.[66] Note that, as in reaction **4-6,** the substrate is oxidized by three different oxidation states of chromium.[67]

With other oxidizing agents, mechanisms are less clear. It seems certain that some oxidizing agents operate by a hydride-shift mechanism,[68] for example, dehydrogenation with triphenylmethyl cation[69] and the Oppenauer oxidation, and some by a free-radical mechanism, for example, oxidation with $S_2O_8^{2-}$ [70] and with VO_2^+.[71] A summary of many proposed mechanisms is given by Littler.[72]

Secondary alkyl ethers can be oxidized to ketones by bromine (e.g., $Me_2CHOCHMe_2 + Br_2 \rightarrow Me_2CO$).[73] Primary alkyl ethers give carboxylic acids (reaction **9-22**). Acetals can be oxidized to esters with peracetic acid[74] or with ozone.[75]

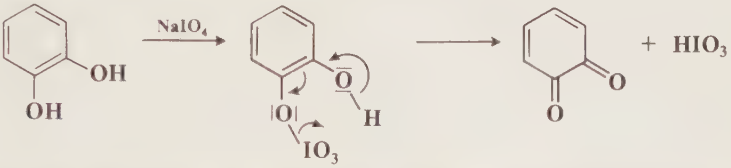
Ortho and para diols are easily oxidized to *ortho-* and *para*-quinones, respectively.[76] Either or both OH groups can be replaced by NH_2 groups to give the same products, though for the preparation of *ortho*-quinones only OH groups are normally satisfactory. The reaction has been successfully carried out with other groups para to OH or NH_2: halogen, OR, Me, *t*-Bu, and even H, though with the last yields are poor. Many oxidizing agents have been used: acid dichromate, lead tetraacetate, HIO_4, and atmospheric oxygen, to name a few. A particularly effective reagent for rings with only one OH or NH_2 group is $(KSO_3)_2N{-}O\cdot$ (dipotassium nitrosodisulfonate; Fremy's salt), which is a stable free radical.[77] The reaction is not exactly analogous to reaction **9-4**, which is an elimination to form a C=O bond. This reaction may be looked on as a 1,6 elimination of two hydrogens.

Less is known about the mechanism than is the case for reaction **9-4** but, as in that case, it seems to vary with the oxidizing agent. For oxidation of catechol with $NaIO_4$, it was found that the reaction conducted in $H_2{}^{18}O$ gave unlabeled quinone,[78] so that the following mechanism, which is an example of category 4 (p. 1075), was proposed:



However, for autoxidations (i.e., with atmospheric oxygen) a free-radical mechanism is known to operate.[79]

9-6 Dehydrogenation of Amines

$$RCH_2NH_2 \xrightarrow[2.\ H_2O]{1.\ IF_5} RCN$$

Primary amines at a primary carbon can be dehydrogenated to nitriles. The reaction has been carried out in a variety of ways: by treatment with IF_5,[80] lead tetraacetate,[81] nickel peroxide,[82] silver(II) picolinate,[83] N-bromosuccinimide and triethylamine,[84] or Cl_2–$NaHCO_3$ followed by CsF,[85] and also catalytically.[86] Secondary amines can sometimes be dehydrogenated to imines.[87] Primary alcohols and aldehydes can be converted directly to nitriles by air oxidation in the presence of ammonia, a strong base (such as OMe^-), and a copper complex.[88] This reaction is a combination of three reactions: oxidation of the alcohol to the aldehyde (reaction **9-4**), formation of the imine (reaction **6-14**), and dehydrogenation of this to the nitrile.

Another reaction which involves dehydrogenation to an imine which then reacts further is the reaction of primary or secondary amines with palladium black.[89] The imine initially formed by

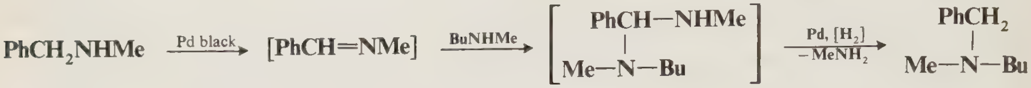
the dehydrogenation reacts with another molecule of the same or a different amine to give an aminal, which loses NH_3 or RNH_2 to give a secondary or tertiary amine. An example is the reaction between N-methylbenzylamine and N-methylbutylamine, which produces 95% N-methyl-N-butylbenzylamine. Another method for the conversion of primary to secondary amines ($2RNH_2 \rightarrow R_2NH$) involves treatment with a catalytic amount of sodium hydride.[90] This reaction also involves an imine intermediate.



$$\mathrm{PhCH_2NHMe} \xrightarrow{\text{Pd black}} [\mathrm{PhCH{=}NMe}] \xrightarrow{\text{BuNHMe}} \begin{bmatrix} \mathrm{PhCH{-}NHMe} \\ | \\ \mathrm{Me{-}N{-}Bu} \end{bmatrix} \xrightarrow[-\mathrm{MeNH_2}]{\mathrm{Pd,\ [H_2]}} \begin{matrix} \mathrm{PhCH_2} \\ | \\ \mathrm{Me{-}N{-}Bu} \end{matrix}$$

9-7 Oxidation of Hydrazines, Hydrazones, and Hydroxylamines

$$\mathrm{Ar{-}NH{-}NH{-}Ar} \xrightarrow{\mathrm{NaOBr}} \mathrm{Ar{-}N{=}N{-}Ar}$$

N,N′-Diarylhydrazines (hydrazo compounds) are oxidized to azo compounds by several oxidizing agents, including NaOBr, HgO, $CuCl_2$, and air and NaOH.[90a] The reaction is also applicable to N,N′-dialkyl- and N,N′-diacylhydrazines. Hydrazines (both alkyl and aryl) substituted on only one side also give azo compounds,[91] but these are unstable and decompose to give nitrogen and the hydrocarbon:

$$\mathrm{Ar{-}NH{-}NH_2} \longrightarrow [\mathrm{Ar{-}N{=}NH}] \longrightarrow \mathrm{ArH + N_2}$$

When hydrazones are oxidized with HgO, Ag_2O, or certain other oxidizing agents, diazo compounds are obtained (see also reaction **7-26**):

$$\mathrm{R_2C{=}N{-}NH_2} \xrightarrow{\mathrm{HgO}} \mathrm{R_2C{=}\overset{\oplus}{N}{=}\overset{\ominus}{N}}$$

Diazo ketones have been prepared from glyoxal monohydrazones by oxidation with MnO_2:[92]

$$\mathrm{Ar{-}CO{-}C{=}N{-}NH_2 + MnO_2} \longrightarrow \mathrm{Ar{-}CO{-}CN_2}$$

The glyoxal monohydrazones were synthesized by treatment of phenacyl bromides ($ArCOCH_2Br$) with hydrazine.[92] Hydrazones of the form $ArCH{=}NNH_2$ react with HgO in the solvent diglyme, 1,2-dimethoxyethane, ethanol, or tetrahydrofuran to give nitriles ArCN.[93] Aromatic hydroxylamines are easily oxidized to nitroso compounds, most commonly by acid dichromate.[94]

$$\mathrm{Ar{-}NH{-}OH} \xrightarrow{\mathrm{CrO_3}} \mathrm{Ar{-}N{=}O}$$

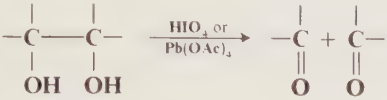
B. Oxidations Involving Cleavage of Carbon-Carbon Bonds[95]

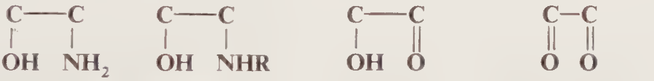
9-8 Oxidative Cleavage of Glycols and Related Compounds



1,2-Glycols are easily cleaved under mild conditions and in good yield with periodic acid or lead tetraacetate.[96] The products are 2 moles of aldehyde, or 2 moles of ketone, or 1 mole of each, depending on the groups attached to the two carbons. The yields are so good that olefins are often converted to glycols (reaction **5-39**) and then cleaved with HIO_4 or $Pb(OAc)_4$ rather than being cleaved directly with ozone (reaction **9-10**) or dichromate or permanganate (reaction **9-11**). A number of other oxidizing agents also give the same products, among them activated MnO_2,[97] thallium(III) salts,[98] and O_2 catalyzed by Co(III) salts.[99] The reaction has also been carried out electrochemically.[100] Permanganate, dichromate, and several other oxidizing agents also cleave glycols, giving carboxylic acids rather than aldehydes, but these reagents are seldom used synthetically.

The two reagents (periodic acid and lead tetraacetate) are complementary, since periodic acid is best used in water and lead tetraacetate in organic solvents. When three or more OH groups are located on adjacent carbons, then the middle one (or ones) is converted to formic acid. This reaction is used a great deal in carbohydrate chemistry, more for structure identification than for preparative purposes.

Similar cleavage is undergone by other compounds which contain oxygens or nitrogens on adjacent carbons:

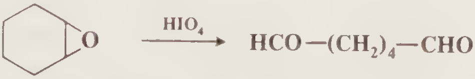


β-Amino alcohols

α-Hydroxy aldehydes and ketones

α-Diketones
α-Keto aldehydes
Glyoxal

α-Diketones are also cleaved by alkaline H_2O_2, to give two molecules of carboxylic acid. HIO_4 has been used to cleave epoxides to aldehydes,[101] e.g.,



α-Hydroxy acids and α-keto acids are not cleaved by HIO_4 but are cleaved by $Pb(OAc)_4$, alkaline H_2O_2, and other reagents. These are oxidative decarboxylations. α-Hydroxy acids give aldehydes or ketones, and α-keto acids give acids:

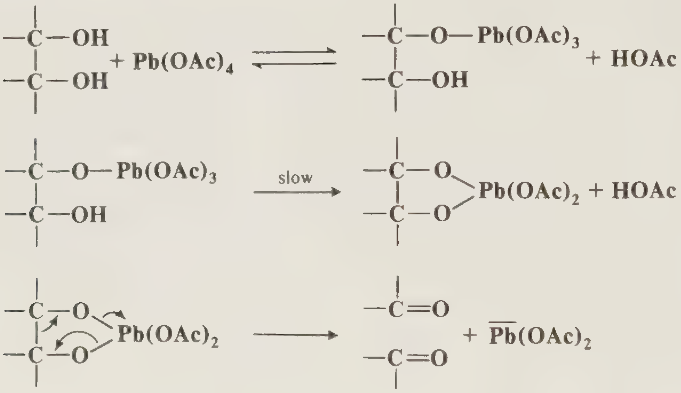
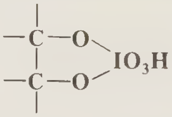
Also see reactions **0-13**, **9-14**, and **9-15**.

The mechanism of glycol oxidation with $Pb(OAc)_4$ was proposed by Criegee:[102]



This mechanism is supported by these facts: (1) the kinetics are second order (first order in each reactant); (2) added acetic acid retards the reaction (drives the equilibrium to the left); and (3) cis glycols react much more rapidly than trans glycols.[103] For periodic acid the mechanism is similar, with the intermediate[104]



However, the cyclic-intermediate mechanism cannot account for all glycol oxidations, since some glycols which cannot form such an ester (for example, **11**) are nevertheless cleaved by lead tetraacetate (though other glycols which cannot form cyclic esters are *not* cleaved, by either

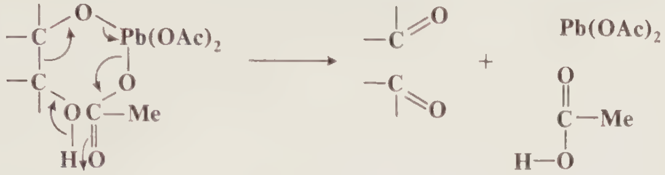
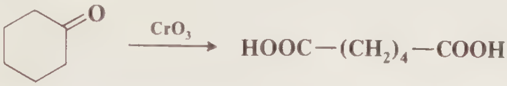
reagent[105]). To account for cases like **11**, a cyclic transition state has been proposed:[103]



Oxidation by strong oxidizing agents (for example, CrO_3) is probably also through a cyclic intermediate, at least for open-chain and cis cyclic diols,[106] though with some reagents a free-radical mechanism has been demonstrated.[107]

OS **IV**, 124.

9-9 Oxidative Cleavage of Ketones, Aldehydes, and Alcohols



Oxidative cleavage of open-chain ketones or alcohols[108] is seldom a useful preparative procedure, not because these compounds do not undergo oxidation (they do, with the exception of diaryl ketones) but because the result is generally a hopeless mixture. However, the reaction is quite useful for cyclic ketones and the corresponding secondary alcohols, the dicarboxylic acid being prepared in good yield. The formation of adipic acid from cyclohexanone (shown above) is an important industrial procedure. Acid dichromate and permanganate are the most common oxidizing agents, though autoxidation (oxidation with atmospheric oxygen) in alkaline solution has also been used.[109] The mechanism for the cleavage of ketones by strong oxidizing agents is probably through the enol form.[110] The process may be illustrated for chromic acid:

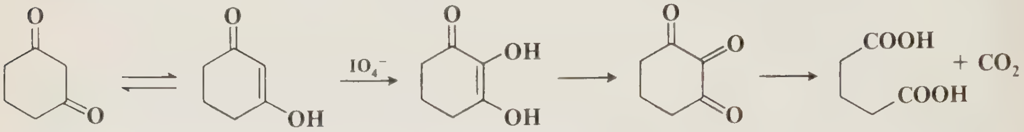
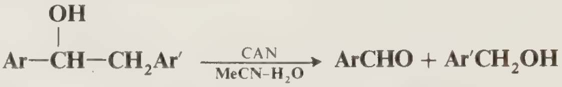
The formation of the chromium ester from the enol is similar to the bromination of ketones (reaction **2-4**). A similar mechanism was demonstrated for nitric acid.[111] However, in some cases, the ketone is attacked directly, and not through the enol.[112]

Cyclic 1,3-diketones, which exist mainly in the monoenolic form, can be cleaved with sodium periodate, with loss of one carbon, e.g.,[113]



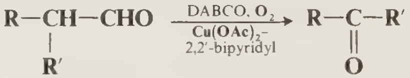
The species which actually undergoes the cleavage is the triketone, so that this is an example of reaction **9-8.**

1,2-Diarylethanols (as well as certain other alcohols) react with ceric ammonium nitrate (CAN) to give cleavage products.[114] The mechanism involves free radicals.



$$\mathrm{Ar{-}\overset{\displaystyle OH}{\overset{|}{C}}H{-}CH_2Ar'} \xrightarrow[\text{MeCN-H}_2\text{O}]{\text{CAN}} \mathrm{ArCHO + Ar'CH_2OH}$$

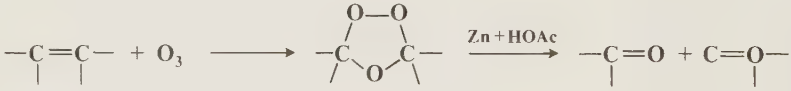
Straight-chain aldehydes can be degraded to lower homologs, one step at a time $[CH_3(CH_2)_n\text{-}CHO \rightarrow CH_3(CH_2)_{n-1}CHO]$, by treatment with O_2 and a cupric acetate–pyridine–triethylamine catalyst.[115] A similar method has been used to cleave branched aldehydes. In this reaction, air is bubbled through a solution of the aldehyde, 1,4-diazabicyclo[2.2.2]octane (DABCO), and a cupric acetate–2,2′-bipyridyl complex in dimethylformamide to give the ketone with one less carbon.[116]



$$\mathrm{R{-}\underset{\underset{\displaystyle R'}{|}}{C}H{-}CHO} \xrightarrow[\text{Cu(OAc)}_2\text{–}\atop \text{2,2'-bipyridyl}]{\text{DABCO, O}_2} \mathrm{R{-}\underset{\underset{\displaystyle O}{\|}}{C}{-}R'}$$

OS **I,** 18; **IV,** 19; **55,** 67.

9-10 Ozonolysis



12

When compounds containing double bonds are treated with ozone, usually at low temperatures, they are converted to compounds called ozonides (**12**) which can be isolated but, because some of them are explosive, are more often decomposed with zinc and acetic acid or catalytic hydrogenation to give 2 moles of aldehyde, or 2 moles of ketone, or 1 mole of each, depending on the groups attached to the olefin.[117] The decomposition of **12** has also been carried out with many other reducing agents, among them trimethyl phosphite[118] and dimethyl sulfide.[119] However, ozonides can also be *oxidized* with oxygen, peracids, or H_2O_2 to give ketones and/or carboxylic acids or *reduced* with $LiAlH_4$, $NaBH_4$, BH_3, or catalytic hydrogenation with excess H_2 to give 2 moles of alcohol.[120] Ozonides can also be treated with ammonia, hydrogen, and a catalyst to give the corresponding amines.[121] Ozonolysis is therefore an important synthetic reaction. In the past it was also very valuable for location of the double bonds in unknown compounds, though with the advent of instrumental methods of structure determination, this usage has declined.

A wide variety of olefins undergo ozonolysis, including cyclic ones, where cleavage gives rise to one bifunctional product. The reaction has often been carried out on compounds containing more than one double bond; generally the bonds are all cleaved. In some cases, especially when bulky groups are present, conversion of the substrate to an epoxide (reaction **5-40**) becomes an important side reaction and can be the main reaction.[122] Ozonolysis of triple bonds is less common, and the reaction proceeds less easily, since ozone is an electrophilic agent[123] and therefore prefers double to triple bonds (p. 686). Compounds which contain triple bonds generally give carboxylic acids, though sometimes ozone oxidizes them to α-diketones. Acetylenic ethers give α-keto esters:[124] $RC{\equiv}COR' \rightarrow RCOCOOR'$. Aromatic compounds are also attacked less readily than olefins, but they have often been cleaved. Aromatic compounds behave as if the double bonds in the Kekulé structures were really there. Thus benzene gives 3 moles of glyoxal (HCOCHO), and *o*-xylene gives a glyoxal MeCOCHO MeCOCOMe ratio of 3 : 2 : 1, which shows that in this case cleavage is statistical. With polycyclic aromatic compounds the site of attack depends on the structure of the molecule and on the solvent.[125]

Although a large amount of work has been done on the mechanism of ozonization (formation of **12**), not all the details are known. The knowledge we have about the mechanism is largely due to Criegee.[126] The first step of the Criegee mechanism is a 1,3 dipolar addition (reaction **5-50**) of ozone to substrate to give the "initial" or "primary" ozonide **13** (also called *molozonide*[127]).[128] This species is highly unstable and opens up to give the zwitterion **14**, which then cleaves into an aldehyde or ketone (**16**) and a different zwitterion (**15**):[129]

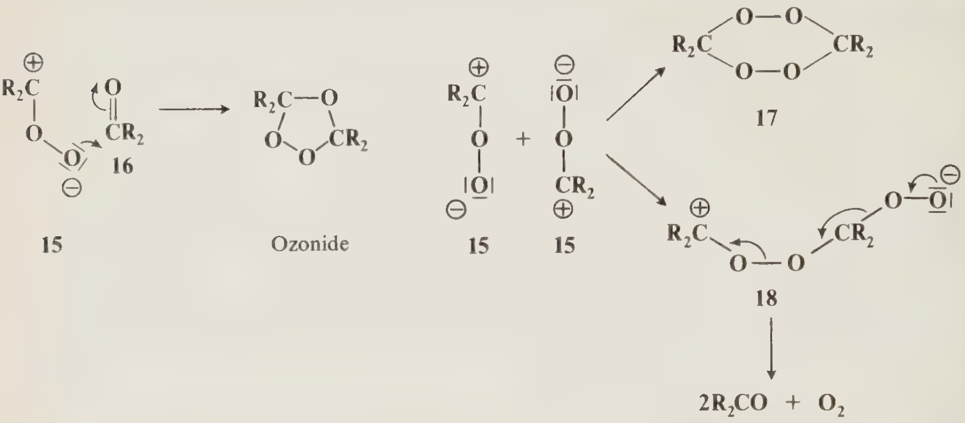
[127] Actually, the name molozonide was coined by Staudinger [*Ber.* **58**, 1088 (1925)] to refer to a different structure, but many authors use this name for **13**.

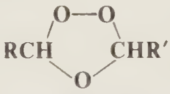
[128] Criegee did not specify the structure of this species, but it has been isolated and observed in solution and seems to have the structure **13**: Criegee and Schröder, *Chem. Ber.* **93**, 689 (1960); Bailey, Thompson, and Shoulders, *J. Am. Chem. Soc.* **88**, 4098 (1966); Durham and Greenwood, *J. Org. Chem.* **33**, 1629 (1968); Bailey, Carter, Fischer, and Thompson, *Can. J. Chem.* **51**, 1278 (1973); Hull, Hisatsune, and Heicklen, *J. Am. Chem. Soc.* **94**, 4856 (1972); Alcock and Mile, *J. Chem. Soc., Chem. Commun.* 575 (1973), 5 (1976).

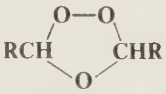
[129] It has been proposed on the basis of valence bond calculations that the ground state of **15** (R = H) is actually a singlet diradical rather than a zwitterion: Wadt and Goddard, *J. Am. Chem. Soc.* **97**, 3004 (1975).

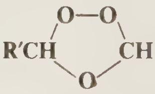
15 may then undergo various reactions, three of which lead to normal products. One of these is a recombination with **16**, the second a dimerization to the bisperoxide **17**, and the third a kind



of dimerization to the zwitterion **18**.[130] If the first path is taken (this is normally possible only if **16** is an aldehyde; most ketones are not reactive enough[131]), then hydrolysis of the ozonide gives the normal products. If **17** is formed, then hydrolysis of it gives one of the products, and of course **16**, which then does not undergo further reaction, is the other. **18**, if formed, can decompose directly, as shown, to give the normal products and oxygen. In protic solvents, **15** is converted to a hydroperoxide, and these have been isolated, for example,  $Me_2C(OOH)—OMe$ from $Me_2C{=}CMe_2$ in methanol. Further evidence for the mechanism is that **17** can be isolated in some cases, e.g., from $Me_2C{=}CMe_2$. But perhaps the most impressive evidence comes from the detection of cross products. In this mechanism, the two parts of the original olefin break apart and then recombine to form the ozonide. In the case of an unsymmetrical olefin RCH=CHR′ there should then be three ozonides:







since there are two different aldehydes **16** and two different zwitterions **15**, and these can recombine in the three ways shown. Actually *six* ozonides, corresponding to the cis and trans forms of these three, were isolated and characterized for methyl oleate.[132] Similar results have been reported for smaller olefins, e.g., 2-pentene, 2-hexene, 4-nonene, and even 2-methyl-2-pentene.[133] The last-mentioned case is especially interesting, since it is quite plausible that this unsymmetrical olefin would cleave in only one way, so that only one ozonide (in cis and trans versions) would be found; but this is not so, and three were found for this case too. However, terminal olefins give little or no cross ozonide formation.[134] In general, the less alkylated end of the olefin tends to go to **16** and the other to **15**.[135] Still other evidence for the Criegee mechanism is: (1) When $Me_2C{=}CMe_2$ was ozonized in the presence of HCHO, then the ozonide **19** could

---

[130] Fliszár, Gravel, and Cavalieri, *Can. J. Chem.* **44**, 67, 1013 (1966); Fliszár and Chylińska, *Can. J. Chem.* **45**, 29 (1967), **46**, 783 (1968).

[131] It follows that tetrasubstituted alkenes do not normally give ozonides. However, they do give the normal cleavage products (ketones) by the other pathways.

[132] Riezebos, Grimmelikhuysen, and van Dorp, *Recl. Trav. Chim. Pays-Bas* **82**, 1234 (1963); Privett and Nickell, *J. Am. Oil Chem. Soc.* **41**, 72 (1964).

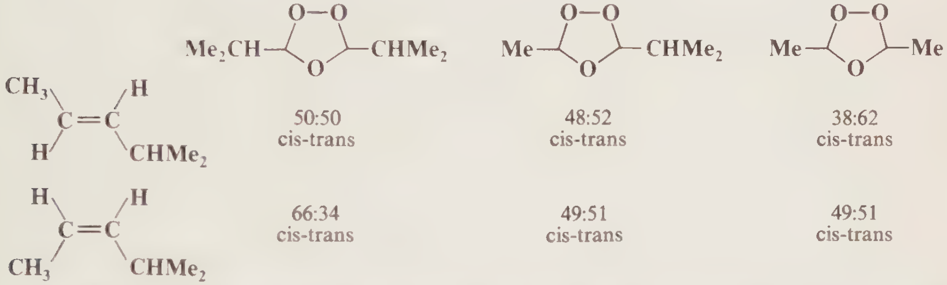
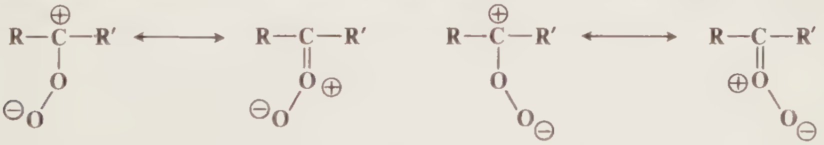
19

be isolated;[136] (2) **15**, prepared in an entirely different manner (photooxidation of diazo compounds), reacted with aldehydes to give ozonides;[137] and (3) cis and trans olefins generally give the same ozonide, which would be expected if they cleave first.[138] However, this was not true for $Me_3CCH{=}CHCMe_3$, where the cis olefin gave the cis ozonide (chiefly), and the trans gave the trans.[139] The latter result is not compatible with the Criegee mechanism. Also incompatible with the Criegee mechanism was the finding that the cis/trans ratios of symmetrical (cross) ozonides obtained from *cis*- and *trans*-4-methyl-2-pentene were not the same:[140]



If the Criegee mechanism operated as shown above, the cis/trans ratio for each of the two cross ozonides would have to be identical for the cis and trans olefins, since in this mechanism they are completely cleaved.

Several mechanistic proposals have been offered to explain the stereochemical results. One proposal[141] is that the Criegee mechanism basically operates, but with the following refinements: (1) The formation of **13** is stereospecific, as expected from a 1,3 dipolar cycloaddition. (2) Once they are formed, **15** and **16** remain attracted to each other, much like an ion pair. (3) **15** exists in



syn-**15** *anti*-**15**

---

[135] This is also true when the less alkylated end contains an aryl group: Keaveney, Berger, and Pappas, *J. Org. Chem.* **32,** 1537 (1967); Keaveney and Pappas, *Tetrahedron Lett.* 841 (1969); Fliszár and Granger, *J. Am. Chem. Soc.* **91,** 3330 (1969); **92,** 3361 (1970). See also Fliszár and Renard, *Can. J. Chem.* **48,** 3002 (1970).

[136] Even ketones can react with **15** to form ozonides, provided they are present in large excess: Criegee and Korber, *Chem. Ber.* **104,** 1812 (1971).

[137] Murray and Suzui, *J. Am. Chem. Soc.* **95,** 3343 (1973); Higley and Murray, *J. Am. Chem. Soc.* **96,** 3330 (1974).

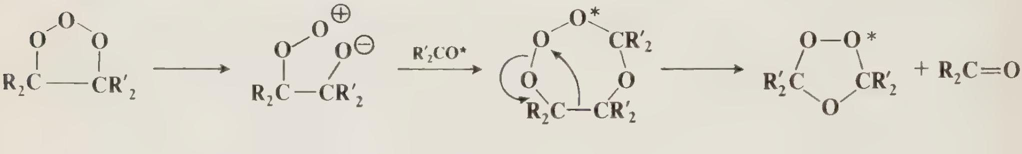
[138] See for example Murray and Williams, *J. Org. Chem.* **34,** 1896 (1969).

[139] Schröder, *Chem. Ber.* **95,** 733 (1962).

[140] Murray, Youssefyeh, and Story, *J. Am. Chem. Soc.* **88,** 3143, 3655 (1966); Story, Murray, and Youssefyeh, *J. Am. Chem. Soc.* **88,** 3144 (1966). Also see Greenwood, *J. Am. Chem. Soc.* **88,** 3146 (1966).

[141] Bauld, Thompson, Hudson, and Bailey, *J. Am. Chem. Soc.* **90,** 1822 (1968); Lattimer, Kuczkowski, and Gillies, *J. Am. Chem. Soc.* **96,** 348 (1974); Bailey, Rustaiyan, and Ferrell, *J. Am. Chem. Soc.* **98,** 638 (1976).

syn and anti forms, which are produced in different amounts and can hold their shapes, at least for a time. This is plausible if we remember that a C=O canonical form contributes to the structure of **15.** (4) The combination of **15** and **16** is also a 1,3 dipolar cycloaddition, so configuration is retained in this step too. Another proposal is entirely different. In this proposal[142] too, the Criegee mechanism basically operates, but there is another pathway which becomes important when large groups are present. In this pathway, the initial ozonide opens up to a zwitterion (**20**), as in the Criegee pathway, *but the charges are reversed.* **20** can now combine



20 **21** **22**

with a molecule of aldehyde or ketone (previously formed by operation of the normal Criegee pathway on another molecule of initial ozonide) to give the seven-membered ring compound **21.** Breakdown of **21** gives the cross ozonide **22.** Since **22** was not formed directly from two independent fragments, the stereochemical behavior can be explained by a consideration of the most favored conformations of **21.** Since in this pathway one of the aldehyde or ketone molecules which was originally present in the initial ozonide has been replaced in **22** by another aldehyde or ketone molecule (it may of course be another molecule of the same compound), the pathway may be called the *aldehyde interchange mechanism.* A number of attempts have been made to distinguish these mechanisms by ^{18}O labeling, making use of the fact, mentioned above, that mixed ozonides (e.g., **19**) can be isolated when an external aldehyde is added. In all three mechanisms a zwitterion reacts with a carbonyl compound to give an ozonide, directly or indirectly, but in the aldehyde interchange mechanism the oxygen atom of the carbonyl group ends up as one of the peroxide oxygens (see the asterisks above), while in either the Criegee or the modified zwitterion mechanism this oxygen appears as the ether oxygen (see the reaction between **15** and **16,** earlier). Several experiments of this kind, wherein ^{18}O-labeled aldehyde is added to the ozonolysis mixture and the resulting ozonide analyzed to determine the position of the ^{18}O label, have been carried out, but unfortunately the results are not entirely unequivocal. With low-molecular-weight alkenes and phenyl alkenes the label appears entirely in the ether oxygen,[143] but with larger alkyl alkenes, where the aldehyde interchange mechanism is predicted[142] to make a substantial contribution, conflicting results have been reported.[144]

Ozonolysis in the gas phase is not generally carried out in the laboratory. However, the reaction is important because it takes place in the upper atmosphere and contributes to air pollution. It has been proposed that mechanisms in the gas phase are different from those in solution.[145]

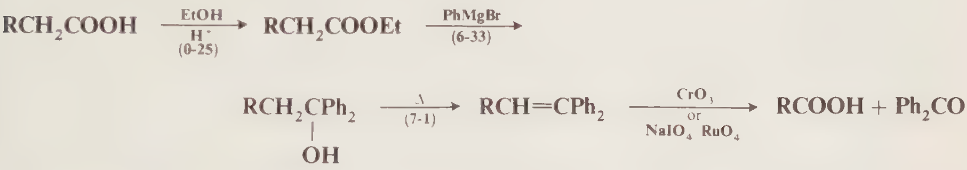
9-11 Oxidative Cleavage of Double Bonds

$$R_2C{=}CHR \xrightarrow{CrO_3} R_2C{=}O + RCOOH$$

Double bonds can be cleaved by many oxidizing agents, the most common of which are neutral or acid permanganate and acid dichromate. The products are generally 2 moles of ketone, 2 moles of carboxylic acid, or 1 mole of each, depending on what groups are attached to the olefin. With ordinary solutions of permanganate or dichromate yields are generally low, and the reaction is seldom a useful synthetic method; but high yields can be obtained by oxidizing with $KMnO_4$ dissolved in benzene containing the crown ether dicyclohexyl-18-crown-6 (see p. 82).[146] The crown ether coordinates with K^+, permitting the $KMnO_4$ to dissolve in benzene. Another reagent frequently used for synthetic purposes is the *Lemieux-von Rudloff reagent:* HIO_4 containing a trace of MnO_4^-.[147] The MnO_4^- is the actual oxidizing agent, being reduced to the manganate stage, and the purpose of the HIO_4 is to reoxidize the manganate back to MnO_4^-. Another reagent which behaves similarly is $NaIO_4$-ruthenium tetroxide.[148] The *Barbier-Wieland procedure* for decreasing the length of a chain by one carbon involves oxidative cleavage by acid dichromate ($NaIO_4$-ruthenium tetroxide has also been used), but this is cleavage of a 1,1-diphenyl olefin, which generally gives good yields:



$$RCH_2COOH \xrightarrow[\substack{H^+ \\ (0\text{-}25)}]{EtOH} RCH_2COOEt \xrightarrow[(6\text{-}33)]{PhMgBr} \underset{\displaystyle OH}{RCH_2CPh_2} \xrightarrow[(7\text{-}1)]{\Delta} RCH{=}CPh_2 \xrightarrow[\substack{\text{or} \\ NaIO_4\ RuO_4}]{CrO_3} RCOOH + Ph_2CO$$

With certain reagents, the oxidation of double bonds can be stopped at the aldehyde stage, and in these cases the products are the same as in the ozonolysis procedure. Among these reagents are chromyl chloride,[149] chromyl trichloroacetate,[150] and $NaIO_4$–OsO_4.[151]

The mechanism of oxidation probably involves in most cases the initial formation of a glycol (reaction **5-39**), or at least a cyclic ester, and then further oxidation as in reaction **9-8.**[152] In line with the electrophilic attack on the olefin, triple bonds are more resistant to oxidation than double bonds.

Aromatic rings can be cleaved with strong enough oxidizing agents. An important laboratory reagent for this purpose is ruthenium tetroxide along with a cooxidant such as $NaIO_4$ or NaOCl (household bleach may be used).[153] Examples[154] are the oxidation of naphthalene to phthalic acid[155] and, even more remarkably, of cyclohexylbenzene to cyclohexanecarboxylic acid[156] (note

[150] Schildknecht and Föttinger, *Justus Liebigs Ann. Chem.* **659,** 20 (1962).

[151] Pappo, Allen, Lemieux, and Johnson, *J. Org. Chem.* **21,** 478 (1956).

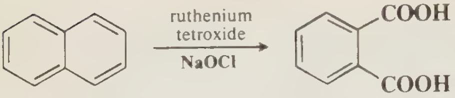
[152] There is evidence that oxidation with Cr(VI) in aqueous acetic acid involves an epoxide intermediate: Awasthy and Roček, *J. Am. Chem. Soc.* **91,** 991 (1969); Roček and Drozd, *J. Am. Chem. Soc.* **92,** 6668 (1970). See also Erickson and Clark, *Tetrahedron Lett.* 3997 (1969).

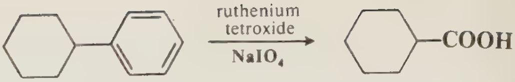
[153] Ruthenium tetroxide is an expensive reagent, but the cost may be greatly reduced by the use of an inexpensive cooxidant such as NaOCl, the function of which is to oxidize RuO_2 back to ruthenium tetroxide.

[154] For other examples, see Piatak, Herbst, Wicha, and Caspi, *J. Org. Chem.* **34,** 116 (1969); Wolfe, Hasan, and Campbell, *Chem. Commun.* 1420 (1970); Ayres and Hossain, *Chem. Commun.* 428 (1972).

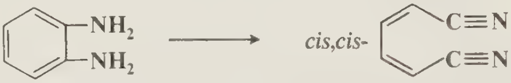
[155] Spitzer and Lee, *J. Org. Chem.* **39,** 2468 (1974).

[156] Caputo and Fuchs, *Tetrahedron Lett.* 4729 (1967).





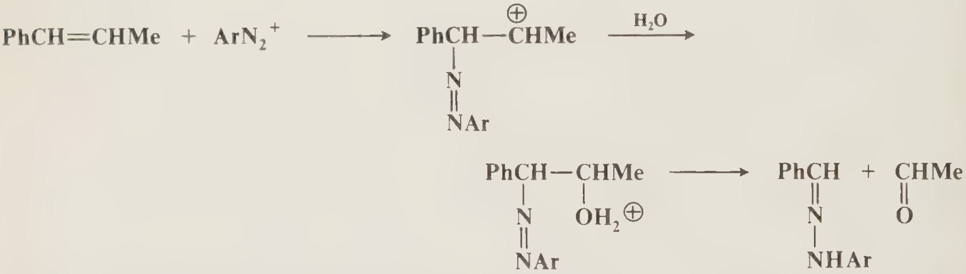
the contrast with reaction **9-12**). Another reagent which oxidizes aromatic rings is air, catalyzed by V_2O_5. The oxidations of naphthalene to phthalic anhydride and of benzene to maleic anhydride (p. 726) by this reagent are important industrial procedures. *o*-Diamines have been oxidized with nickel peroxide and with lead tetraacetate:[157]



Double bonds can be cleaved in other ways. Treatment with NH_2NH^- gives a hydrazone:[158]

$$R_2C{=}CR_2 + NH_2NH^- \longrightarrow R_2CH_2 + R_2C{=}NNH_2$$

Certain olefins can be cleaved with diazonium salts to give aldehydes or ketones and arylhydrazones:[159]



$$PhCH{=}CHMe + ArN_2^+ \longrightarrow \begin{array}{l} \oplus \\ PhCH-CHMe \\ \;\;| \\ \;\;N \\ \;\;\| \\ \;\;NAr \end{array} \xrightarrow{H_2O}$$

$$\begin{array}{l} PhCH-CHMe \\ \;\;|\qquad\;\; | \\ \;\;N \quad\; OH_2^{\oplus} \\ \;\;\| \\ \;\;NAr \end{array} \longrightarrow \begin{array}{l} PhCH \\ \;\;\| \\ \;\;N \\ \;\;| \\ NHAr \end{array} + \begin{array}{l} CHMe \\ \;\;\| \\ \;\;O \end{array}$$

Terminal triple bond compounds can be cleaved to carboxylic acids with thallium(III) nitrate ($RC{\equiv}CH \rightarrow RCOOH$).[160]

OS **II,** 53, 523; **III,** 39, 234, 449; **IV,** 136, 484, 824; **V,** 393; **55,** 67. Also see OS **II,** 551.

9-12 Oxidation of Aromatic Side Chains

$$ArR \xrightarrow{KMnO_4} ArCOOH$$

Alkyl chains on aromatic rings can be oxidized to COOH groups by many oxidizing agents, including permanganate, nitric acid, and acid dichromate. The method is most often applied to the methyl group, though longer side chains can also be cleaved. However, tertiary alkyl groups are resistant to oxidation, and when they *are* oxidized, ring cleavage usually occurs too.[161] It is usually difficult to oxidize an R group on a fused aromatic system without cleaving the ring or oxidizing it to a quinone (reaction **9-19**). However, this has been done (e.g., 2-methylnaphthalene was converted to naphthoic acid) with aqueous $Na_2Cr_2O_7$.[162] Functional groups may be present anywhere on the side chain and, if in the α-position, greatly increase the ease of oxidation.

[158] Kauffmann, Henkler, Kosel, Rauch, Schultz, and Weber, *Angew. Chem. Int. Ed. Engl.* **1,** 456 (1962) [*Angew. Chem.* **74,** 650].

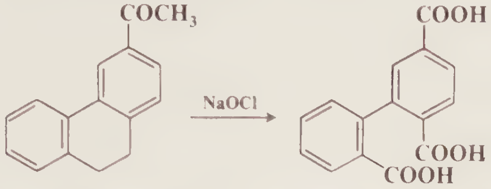
[159] Marxmeier and Pfeil, *Chem. Ber.* **97,** 815 (1964), *Justus Liebigs Ann. Chem.* **678,** 28 (1964).

[160] McKillop, Oldenziel, Swann, Taylor, and Robey, *J. Am. Chem. Soc.* **95,** 1296 (1973).

[161] Brandenberger, Maas, and Dvoretsky, *J. Am. Chem. Soc.* **83,** 2146 (1961).

[162] Friedman, Fishel, and Shechter, *J. Org. Chem.* **30,** 1453 (1965).

However, an exception is an α-phenyl group. In such cases the reaction stops at the diaryl ketone stage. Molecules containing aryl groups on different carbons cleave so that each ring gets one carbon atom, e.g.,

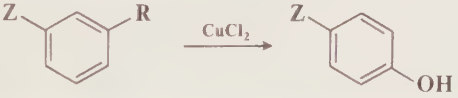


It is possible to oxidize only one alkyl group of a ring that contains more than one. The order of reactivity[163] toward most reagents is $CH_2Ar > CHR_2 > CH_2R > CH_3$.[164] Groups on the ring which are susceptible to oxidation (OH, NHR, NH_2, etc.) must be protected. The oxidation can be performed with oxygen, in which case it is autoxidation, and the mechanism is like that in reaction **4-8**, with a hydroperoxide intermediate. With this procedure it is possible to isolate ketones from $ArCH_2R$.

The mechanism has been studied for the closely related reaction: $Ar_2CH_2 + CrO_3 \rightarrow Ar_2C{=}O$.[165] A deuterium isotope effect of 6.4 was found, indicating that the rate-determining step is either $Ar_2CH_2 \rightarrow Ar_2CH\cdot$ or $Ar_2CH_2 \rightarrow Ar_2CH^+$. Either way this explains why tertiary groups are not converted to COOH and why the reactivity order is $CHR_2 > CH_2R > CH_3$, as mentioned above. Both free radicals and carbonium ions exhibit this order of stability (Chapter 5). The two possibilities are examples of categories 2 and 3 (p. 1075). Just how the free radical or carbonium ion goes on to the product is not known. $Ar{-}\overset{|}{\underset{|}{C}}{-}OH$ may be an intermediate, in which case the further reaction would be like that in reaction **9-4.**

OS **I,** 159, 385, 392, 543; **II,** 135, 428; **III,** 334, 420, 740, 791, 820, 822; **V,** 617, 810.

9-13 Oxidative Cleavage of Alkyl Groups from Rings



It is possible to replace an alkyl group on a ring by an OH group. When the alkyl group is one oxidizable to COOH (reaction **9-12**), then cupric salts are oxidizing agents, and the OH group is found in a position ortho to that occupied by the alkyl group.[166] What happens here is an initial oxidation to COOH, and then an example of reaction **3-20.**[167] This reaction is used industrially to convert toluene to phenol.

In a different kind of reaction, the methyl group of trinitrotoluene can be oxidized to an OH group in the *same* position with $Na_2Cr_2O_7$, H_2SO_4, and HNO_3.[168] The sequence in this case seems to be (1) oxidation to COOH, (2) nucleophilic substitution of the COOH by NO_3^-, and (3) hydrolysis of the nitrate ester.

---

[163] Oxidation with Co(III) is an exception. The methyl group is oxidized in preference to the other alkyl groups: Onopchenko, Schulz, and Seekircher, *J. Org. Chem.* **37,** 1414 (1972).

[164] For example, see Foster and Hickinbottom, *J. Chem. Soc.* 680 (1960); Ferguson and Wims, *J. Org. Chem.* **25,** 668 (1960).

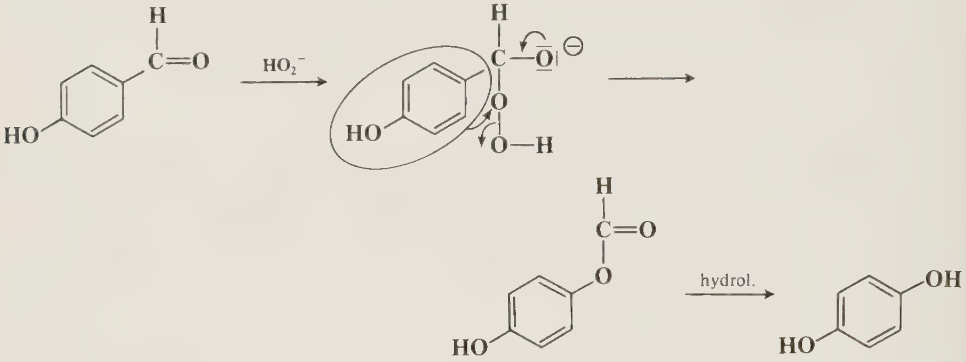
[165] Wiberg and Evans, *Tetrahedron* **8,** 313 (1960).

[166] Kaeding, *J. Org. Chem.* **26,** 3144 (1961).

[167] For a discussion, see Lee and van den Engh, in Trahanovsky, Ref. 1, pp. 91–94.

[168] Dacons, Adolph, and Kamlet, *Tetrahedron* **19,** 791 (1963); Adolph, Dacons, and Kamlet, *Tetrahedron* **19,** 801 (1973).

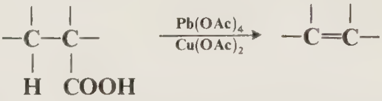
In a third kind of reaction, an aromatic aldehyde ArCHO or ketone ArCOR′ is converted to a phenol ArOH on treatment with alkaline H_2O_2,[169] but there must be an OH or NH_2 group in the ortho or para position. This is called the *Dakin reaction.*[170] The mechanism is probably similar to that of the Baeyer-Villiger reaction **(8-23)**:



OS **I,** 149; **III,** 759.

9-14 Oxidative Decarboxylation

$$RCOOH \xrightarrow{Pb(OAc)_4} ROAc$$



$$\underset{H}{\overset{|}{\underset{|}{-C}}}-\underset{COOH}{\overset{|}{\underset{|}{C-}}} \xrightarrow[Cu(OAc)_2]{Pb(OAc)_4} \overset{|}{-C}=\overset{|}{C-}$$

Carboxylic acids can be decarboxylated with lead tetraacetate[171] to give a variety of products, among them the ester ROAc (formed by replacement of COOH by an acetoxy group), the alkane RH (see reaction **2-39**), and, if a β-hydrogen is present, the alkene formed by elimination of H and COOH, as well as numerous other products arising from rearrangements, internal cyclizations,[172] and reactions with solvent molecules. When R is tertiary, the chief product is usually the alkene, which is often obtained in good yield. High yields of alkenes can also be obtained when R is primary or secondary, in this case by the use of $Cu(OAc)_2$–$Pb(OAc)_4$ instead of $Pb(OAc)_4$.[173] In the absence of $Cu(OAc)_2$, primary acids give mostly alkanes (though yields are generally low), and secondary acids may give esters or alkenes. Esters have been obtained in good yields from some secondary acids, from β,γ-unsaturated acids, and from acids in which R is a benzylic group. γ-Keto acids give good yields of α,β-unsaturated ketones.[174] Other oxidizing agents, including Co(III), Ag(II), Mn(III), and Ce(IV) have also been used to effect oxidative decarboxylation.[175]

[170] See Schubert and Kintner, in Patai, Ref. 35, pp. 749–752.

[171] For a review, see Sheldon and Kochi, *Org. React.* **19,** 279–421 (1972).

[172] For examples, see Moriarty, Walsh, and Gopal, *Tetrahedron Lett.* 4363 (1966); Davies and Waring, *J. Chem. Soc. C* 1865, 2337 (1968).

[173] Bacha and Kochi, *Tetrahedron* **24,** 2215 (1968); Ogibin, Katzin, and Nikishin, *Synthesis* 889 (1974).

[174] Sane, Divakar, and Rao, *Synthesis* 541 (1973); Mc Murry and Blaszczak, *J. Org. Chem.* **39,** 2217 (1974). See also Hertzler, Berdahl, and Eisenbraun, *J. Org. Chem.* **33,** 2008 (1968).

[175] For references, see Trahanovsky, Cramer, and Brixius, *J. Am. Chem. Soc.* **96,** 1077 (1974). See also Dessau and Heiba, *J. Org. Chem.* **40,** 3647 (1975).

The mechanism with lead tetraacetate is generally accepted to be of the free-radical type.[176] First there is an interchange of ester groups:

$$\text{Pb(OAc)}_4 + \text{RCOOH} \longrightarrow \underset{\textbf{23}}{\text{Pb(OAc)}_3\text{OCOR}} \quad \text{or} \quad \underset{\textbf{24}}{\text{Pb(OAc)}_2\text{(OCOR)}_2}$$

Then follows a free-radical chain mechanism (shown for **23**, though **24** and other lead esters may behave similarly)

$$\text{Initiation} \qquad \underset{\textbf{23}}{\text{Pb(OAc)}_3\text{OCOR}} \longrightarrow \dot{\text{P}}\text{b(OAc)}_3 + \text{R}\cdot + \text{CO}_2$$

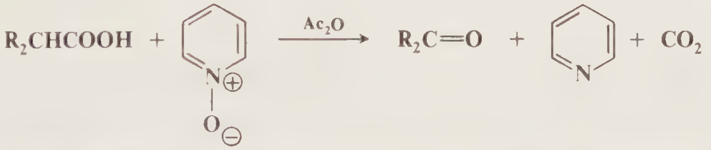
$$\text{Propagation} \qquad \text{R}\cdot + \text{Pb(OAc)}_3\text{OCOR} \longrightarrow \text{R}^+ + \dot{\text{P}}\text{b(OAc)}_2\text{OCOR} + \text{OAc}^-$$

$$\dot{\text{P}}\text{b(OAc)}_2\text{OCOR} \longrightarrow \text{Pb(OAc)}_2 + \text{R}\cdot + \text{CO}_2$$

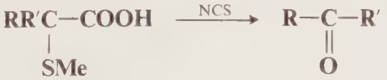
Products can then be formed either from R· or R^+. Primary R· abstract H from solvent molecules to give RH. R^+ can lose H^+ to give an alkene, react with HOAc to give the ester, react with solvent molecules or with another functional group in the same molecule, or rearrange, thus accounting for the large number of possible products. R· can also dimerize to give R—R. The effect of Cu^{2+} ions[177] is to oxidize the radicals to alkenes, thus producing good yields of alkenes from primary and secondary substrates. Cu^{2+} has no effect on tertiary radicals, because these are efficiently oxidized to alkenes by lead tetraacetate.

$$-\underset{|}{\text{C}}\text{H}-\underset{|}{\dot{\text{C}}}- + \text{Cu}^{2+} \rightarrow -\underset{|}{\text{C}}=\underset{|}{\text{C}}- + \text{H}^+ + \text{Cu}^+$$

In another type of oxidative decarboxylation, carboxylic acids (or their anhydrides) are converted by pyridine N-oxide in the presence of acetic anhydride to aldehydes or ketones with one less carbon atom.[178]



In still another type, α-methylthio carboxylic acids can be decarboxylated to the corresponding ketones with N-chlorosuccinimide (NCS) in an alcohol solvent containing $NaHCO_3$.[179]



$$\text{RR}'\underset{\underset{\text{SMe}}{|}}{\text{C}}-\text{COOH} \xrightarrow{\text{NCS}} \text{R}-\underset{\underset{\text{O}}{\|}}{\text{C}}-\text{R}'$$

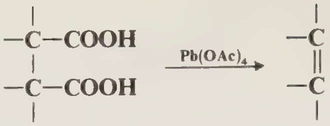
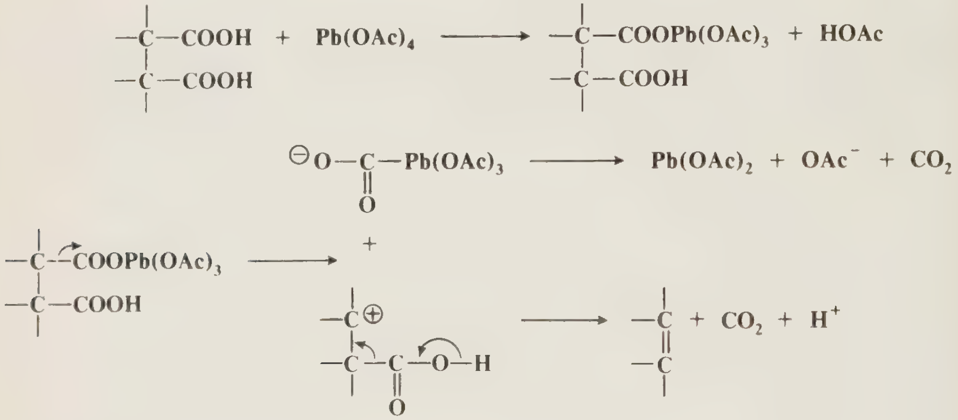
9-15 Bisdecarboxylation

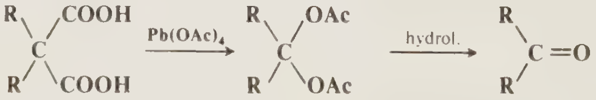


Compounds containing carboxyl groups on adjacent carbons (succinic acid derivatives) can be bisdecarboxylated with lead tetraacetate.[171] The reaction is of wide scope, and many such compounds have successfully given the reaction. The elimination is stereoselective, but not stereospecific (both *meso*- and *dl*-2,3-diphenylsuccinic acid gave *trans*-stilbene),[180] and a concerted mechanism is thus unlikely (see Chapter 15). The following mechanism is not inconsistent with the data:



though a free-radical mechanism seems to hold in some cases.

Compounds containing geminal carboxyl groups (disubstituted malonic acid derivatives) can also be bisdecarboxylated with lead tetraacetate, *gem*-diacetates (acylals) being produced, which are easily hydrolyzable to ketones:[181]



Bisdecarboxylation of succinic acid derivatives to give alkenes has also been carried out by treatment of the corresponding anhydrides with nickel, iron, or rhodium complexes,[182] by decomposition of the corresponding bis peresters,[183] and electrolytically.[184]

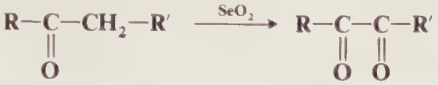
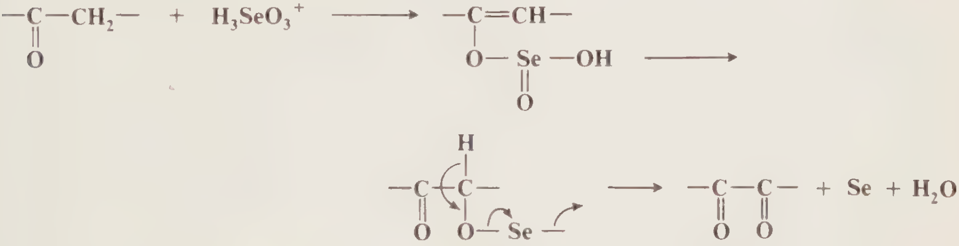
C. Reactions Involving Replacement of Hydrogen by Oxygen

9-16 Oxidation of Methylene to Carbonyl



$$R-\underset{\underset{O}{\|}}{C}-CH_2-R' \xrightarrow{SeO_2} R-\underset{\underset{O}{\|}}{C}-\underset{\underset{O}{\|}}{C}-R'$$

Methyl or methylene groups α to a carbonyl can be oxidized with selenium dioxide to give, respectively, α-keto aldehydes and α-diketones.[185] The reaction can also be carried out α to an aromatic ring or to a double bond, though in the latter case hydroxylation (see reaction **4-4**) is the more common result. Although SeO_2 is the reagent most often used, the reaction has also been carried out with N_2O_3 and other oxidizing agents. Substrates most easily oxidized contain two aryl groups on CH_2, and these substrates can be oxidized with many oxidizing agents (see reaction **9-12**). Monoaryl alkanes have been oxidized to alkyl aryl ketones with several oxidizing agents, including CrO_3-acetic acid,[186] ceric ammonium nitrate,[187] and a silver ion–persulfate couple,[188] as well as with SeO_2. With these substrates the oxidation sometimes takes place on the β-carbon (e.g., $PhCH_2CH_3 \rightarrow PhCH_2CHO$). It has been shown for the case where chromyl chloride is the oxidizing agent that there is initial α oxidation followed by rearrangement.[189] Alkenes of the form $C{=}C{-}CH_2$ have been oxidized to α,β-unsaturated ketones by sodium dichromate in $HOAc$-Ac_2O, by *t*-butyl chromate in CCl_4-$HOAc$-Ac_2O,[190] by CrO_3-pyridine complex,[191] and by mercuric salts.[192] CrO_3-pyridine has also been used to convert alkynes of the form $C{\equiv}C{-}CH_2$ to α-keto acetylenes.[193] Two mechanisms have been suggested for the reaction with SeO_2. One of these involves a selenate ester of the enol.[194]



In the other proposed mechanism[194a] the principal intermediate is a β-ketoseleninic acid  $-\overset{\overset{O}{\|}}{C}CH\overset{\overset{O}{\|}}{Se}OH$, and a selenate ester is not involved.

It has proved possible to convert CH_2 to $C{=}O$ groups even if they are not near any functional groups, indirectly, by the remote oxidation method of Breslow (see reaction **9-3**). In a typical

25 **26** **27** **28**

example, the keto ester **25** was irradiated to give the hydroxy lactone **26**, which was dehydrated to **27**. Ozonolysis of **27** gave the diketo ester **28**, in which the C-14 CH_2 group of **25** has been oxidized to a C=O group.[195] The reaction was not completely regiospecific: **28** comprised about 60% of the product, with the remainder consisting of other compounds in which the keto group was located at C-11, C-12, C-15, and other positions along the carbon chain. When longer chains were used (C_{18}, C_{20}), the reaction was less regiospecific, the maximum percentage of any single product being about 20%. The method has also been applied in the steroid series, with greater regiospecificity.[196] In the method so far described, the reaction takes place because one portion of a molecule (the benzophenone moiety) abstracts hydrogen from another portion of the same molecule; that is, the two portions are connected by a series of covalent bonds. However, the reaction can also be carried out where the two reacting centers are actually in different molecules, providing the two molecules are held together by hydrogen bonding. For example, one of the CH_2 groups of *n*-hexadecanol hemisuccinate $CH_3(CH_2)_{14}CH_2OCOCH_2CH_2COOH$ was oxidized to a C=O group by applying the above procedure to a mixture of it and benzophenone-4-carboxylic acid *p*-$PhCOC_6H_4COOH$ in CCl_4.[197]

9-17 Oxidation of Arylmethanes

$$ArCH_3 \xrightarrow{CrO_2Cl_2} ArCHO$$

Methyl groups on an aromatic ring can be oxidized to the aldehyde stage by several oxidizing agents. The reaction is a special case of reaction **9-16**. When the reagent is chromyl chloride (CrO_2Cl_2), the reaction is called the *Étard reaction*,[198] and the yields are high.[199] Another oxidizing agent is a mixture of CrO_3 and Ac_2O. In this case the reaction stops at the aldehyde stage because the initial product is $ArCH(OAc)_2$ (an acylal), which is resistant to further oxidation. Hydrolysis of the acylal gives the aldehyde.

[195] Breslow and Winnik, *J. Am. Chem. Soc.* **91**, 3083 (1969).

[196] Breslow and Baldwin, *J. Am. Chem. Soc.* **92**, 732 (1970).

[197] Breslow and Scholl, *J. Am. Chem. Soc.* **93**, 2331 (1971).

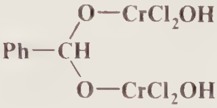
[198] The name Etard reaction is often applied to any oxidation with chromyl chloride, e.g., oxidation of glycols (reaction **9-8**), olefins (reaction **9-11**), etc.

[199] For a review, see Hartford and Darrin, *Chem. Rev.* **58**, 1-61 (1958), pp. 25-53.

Among other oxidizing agents which have been used to accomplish the conversion of $ArCH_3$ to ArCHO are ceric ammonium nitrate[200] and silver(II) oxide.[201] Oxidation of $ArCH_3$ to carboxylic acids is considered at reaction **9-12.**

Conversion of $ArCH_3$ to ArCHO can also be achieved indirectly by bromination to give $ArCHBr_2$ (reaction **4-1**), followed by hydrolysis (reaction **0-2**).

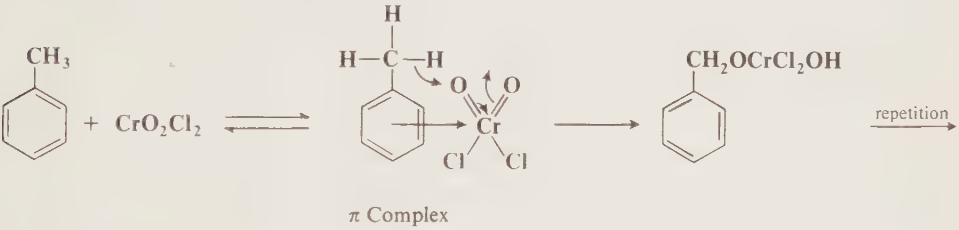
The mechanism of the Étard reaction is not completely known.[202] An insoluble complex is formed on addition of the reagents, which is hydrolyzed to the aldehyde. The complex is probably a kind of acylal, but what the structure is is not fully settled, though many proposals have been made as to its structure and as to how it is hydrolyzed.[199] It is known that $ArCH_2Cl$ is not an intermediate (see reaction **9-20**), since it reacts only very slowly with chromyl chloride. Magnetic susceptibility measurements[203] indicate that the complex from toluene is **29,** a structure first



29

proposed by Étard. According to this proposal the reaction stops after only two hydrogens have been replaced because of the insolubility of **29.** There is disagreement on how **29** is formed, assuming that the complex has this structure. Both an ionic[204] and a free-radical[205] process have been proposed:

Ionic process:



Free-radical process:

$$\mathrm{ArCH_3 + Cl_2CrO_2 \longrightarrow ArCH_2\cdot + HO\dot{C}rOCl_2}$$

$$\mathrm{ArCH_2\cdot + HO\dot{C}rOCl_2 \longrightarrow ArCH_2OCrCl_2OH \xrightarrow{\text{repetition}}}$$

An entirely different structure for the complex was proposed by Nenitzescu and coworkers.[206] On the basis of esr studies they proposed that the complex is $PhCH_2OCrCl_2OCrOCl_2OH$, which is isomeric with **29.** However, this view has been challenged by Wiberg and Eisenthal,[205] who interpret the esr result as being in accord with **29.** Still another proposal is that the complex is composed of benzaldehyde coordinated with reduced chromyl chloride.[207]

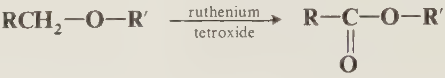
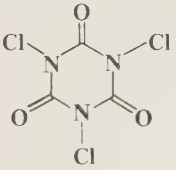
9-18 Oxidation of Ethers to Esters and Related Reactions

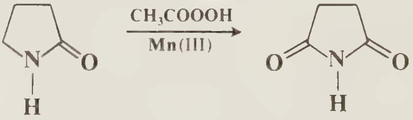


$$RCH_2{-}O{-}R' \xrightarrow[\text{tetroxide}]{\text{ruthenium}} R{-}\underset{\underset{O}{\|}}{C}{-}O{-}R'$$

Ethers in which at least one group is primary alkyl can be oxidized to the corresponding esters in high yields with ruthenium tetroxide.[208] Cyclic ethers give lactones. The reaction, which is a special case of **9-16,** has also been accomplished with CrO_3 in sulfuric acid[209] and with trichloroisocyanuric acid (**30**) in the presence of an excess of water.[210] In a similar reaction, lactams (e.g., **31**) can be converted to cyclic imides by oxidation with a hydroperoxide or peracid and an Mn(II) or Mn(III) salt.[211] Certain tertiary amines containing a methyl group can be oxidized to formamides ($R_2NCH_3 \rightarrow R_2NCHO$) by MnO_2,[212] CrO_3-pyridine,[213] O_2 and platinum,[214] or other oxidizing agents, but the reaction is not general.

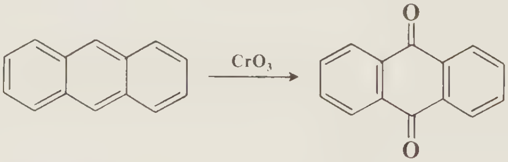


30



31

9-19 Oxidation of Aromatic Hydrocarbons to Quinones



Condensed aromatic systems (including naphthalenes) can be directly oxidized to quinones by various oxidizing agents.[215] Yields are generally not high. Benzene cannot be so oxidized by strong oxidizing agents but can be electrolytically oxidized to benzoquinone.

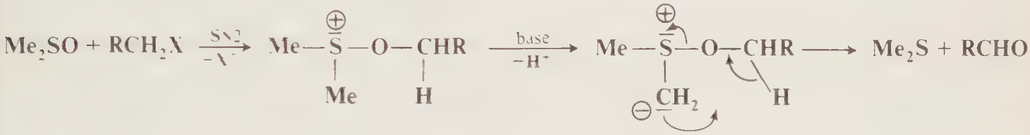
9-20 Oxidation of Primary Halides and Esters of Primary Alcohols to Aldehydes

$$RCH_2Cl \xrightarrow{(CH_3)_2SO} RCHO$$

Primary alkyl halides (chlorides, bromides, and iodides) can be oxidized to aldehydes easily and in good yields with dimethyl sulfoxide.[216] Tosyl esters of primary alcohols can be similarly converted to aldehydes,[217] and epoxides give α-hydroxy ketones or aldehydes.[218] The reaction with tosyl esters represents an indirect way of oxidizing primary alcohols to aldehydes (reaction **9-4**). This type of oxidation can also be carried out without isolation of an intermediate ester: The alcohol is treated with dimethyl sulfoxide, dicyclohexylcarbodiimide (DCC),[219] and anhydrous phosphoric acid.[220] In this way a primary alcohol can be converted to the aldehyde with no carboxylic acid being produced.[221]

Similar oxidation of alcohols has been carried out with dimethyl sulfoxide and other reagents in place of DCC: acetic anhydride,[222] SO_3-pyridine-triethylamine,[223] tosyl chloride,[224] chlorine,[225] mercuric acetate,[226] $AgBF_4$ and Et_3N,[227] $(CF_3SO_2)_2O$,[228] KI and $NaHCO_3$,[229] methanesulfonic anhydride,[224] and cyanuric chloride,[224] among others.

Chloroformate esters RCH_2OCOCl can also be oxidized to aldehydes by treatment with dimethyl sulfoxide followed by Et_3N.[230] The mechanism of these dimethyl sulfoxide oxidations is probably as follows:[231]



32 **33**

though in some cases the base abstracts a proton directly from the carbon being oxidized, in which case the ylide **33** is not an intermediate. Alkoxysulfonium salts **32** have been isolated.[232] This mechanism predicts that secondary compounds should be oxidizable to ketones, and this is the case. In a related procedure for the oxidation of alcohols, the intermediate **32**[233] is formed without the use of dimethyl sulfoxide by treating the substrate with a complex generated from chlorine or N-chlorosuccinimide and dimethyl sulfide.[234]

---

[216] Nace and Monagle, *J. Org. Chem.* **24,** 1792 (1959); Kornblum, Jones, and Anderson, *J. Am. Chem. Soc.* **81,** 4113 (1959); Johnson and Pelter, *J. Chem. Soc.* 520 (1964); Traynelis and Hergenrother, *J. Am. Chem. Soc.* **86,** 298 (1964). For reviews, see Durst, *Adv. Org. Chem.* **6,** 285–388 (1969), pp. 343–356; Epstein and Sweat, *Chem. Rev.* **67,** 247–260 (1967).

[219] The DCC is converted to dicyclohexylurea, which in some cases is difficult to separate from the product. One way to avoid this problem is to use a carbodiimide linked to an insoluble polymer: Weinshenker and Shen, *Tetrahedron Lett.* 3285 (1972).

[232] Torssell, *Tetrahedron Lett.* 4445 (1966); Johnson and Phillips, Ref. 231; Khuddus and Swern, *J. Am. Chem. Soc.* **95,** 8393 (1973).

Another way to oxidize primary alkyl halides to aldehydes is by the use of hexamethylenetetramine followed by water. However, this reaction, called the *Sommelet reaction*,[235] is limited to benzylic halides. The reaction is seldom useful when the R in RCH_2Cl is alkyl. The first part of the reaction is conversion to the amine $ArCH_2NH_2$ (reaction **0-47**), which can be isolated. Reaction of the amine with excess hexamethylenetetramine gives the aldehyde. It is this last step which is the actual Sommelet reaction, though the entire process can be conducted without isolation of intermediates. Once the amine is formed, it is converted to an imine ($ArCH_2N{=}CH_2$) with formaldehyde liberated from the reagent. The key step then follows: transfer of hydrogen from another mole of the arylamine to the imine:

$$\mathbf{ArCH_2N{=}CH_2 + ArCH_2NH_2 \longrightarrow ArCH_2NHCH_3 + ArCH{=}NH}$$

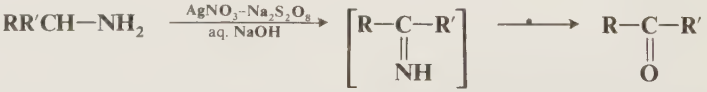
This last imine is then hydrolyzed by water to the aldehyde. Alternatively, the benzylamine may transfer hydrogen directly to hexamethylenetetramine, converting the latter to methylamine. The other product of the reaction is methylamine or $ArCH_2NHCH_3$, depending on whether hexamethylenetetramine is in excess or not. The actual mechanism of the hydrogen-transfer step is in doubt, but it probably begins with a hydride shift. Primary amines (including alkyl RCH_2NH_2) can also be oxidized to imines (and hence hydrolyzed to aldehydes or ketones) by benzophenone and uv light.[236]

Other reagents which convert benzylic halides to aldehydes are 2-nitropropane-NaOEt in EtOH,[237] mercury(I) nitrate followed by ethanolic alkali,[238] and pyridine followed by *p*-nitrosodimethylaniline and then water. The latter procedure is called the *Kröhnke reaction.* Primary halides in general have been oxidized to aldehydes by trimethylamine oxide $Me_3\overset{\oplus}{N}-\overset{\ominus}{O}$,[239] and by K_2CrO_4 in HMPT in the presence of a crown ether.[239a] The former procedure has also been applied to primary tosylates.[239]

Benzyl sulfides $ArCH_2SR$ can be oxidized to aldehydes ArCHO by dimethyl sulfoxide in the presence of certain acyl halides (e.g., benzoyl chloride).[240]

OS **II**, 336; **III**, 811; **IV**, 690, 918, 932; **V**, 242, 668, 825, 852, 872. Also see OS **V**, 689.

9-21 Oxidation of Amines to Aldehydes or Ketones



$$\mathrm{RR'CH{-}NH_2 \xrightarrow[\text{aq. NaOH}]{AgNO_3{-}Na_2S_2O_8} \left[\begin{matrix}R{-}C{-}R'\\ \|\\ NH\end{matrix}\right] \longrightarrow \begin{matrix}R{-}C{-}R'\\ \|\\ O\end{matrix}}$$

Primary aliphatic amines can be oxidized to aldehydes or ketones by reaction with Ag(II), prepared in situ by treatment of silver nitrate with sodium persulfate.[241] The reaction consists of dehydrogenation to the imine (reaction **9-6**), followed by hydrolysis. Other reagents which have been used are nitrosobenzene[242] (for benzylamines), 3,5-di-*t*-butyl-1,2-benzoquinone,[243] certain mesitylglyoxals,[243] and aqueous NaOCl with phase-transfer catalysts.[243a] Benzylic amine salts $PhCH_2CHRNR'_2H^+ \ Cl^-$ (R,R′ = H or alkyl) give benzaldehydes or aryl ketones when heated in dimethyl sulfoxide.[244] The reaction has also been accomplished by conversion of the amine to an oxaziridine and hydrolysis of this:[244a]

---

[233] It has been suggested that in the DCC reaction, **32** is not involved, but the ylide **33** is formed directly from a precursor containing DCC and dimethyl sulfoxide: Torssell, Ref. 232; Moffatt, *J. Org. Chem.* **36,** 1909 (1971).

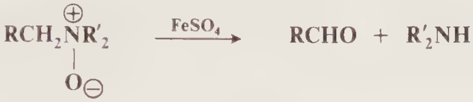
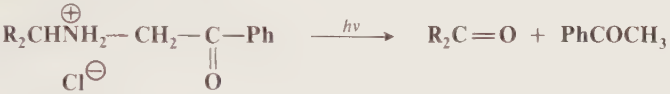
Primary, secondary, and tertiary aliphatic amines have been cleaved to give aldehydes, ketones, or carboxylic acids with aqueous bromine[245] and with neutral permanganate.[246] The other product of this reaction is the amine with one less alkyl group. A similar reaction has been performed on α-amino ketones, with mercuric acetate, to give 1,2-dicarbonyl compounds.[247] Tertiary amine oxides with one primary alkyl group can be cleaved to aldehydes and secondary amines by treatment with iron(III) salts.[248]



$$RCH_2\underset{O^{\ominus}}{\overset{\oplus}{N}}R'_2 \xrightarrow{FeSO_4} RCHO + R'_2NH$$

In still another procedure, phenacyl amides of primary amines are converted to aldehydes or ketones by photolysis of their salts.[249]



$$R_2CH\underset{Cl^{\ominus}}{\overset{\oplus}{N}}H_2-CH_2-\underset{O}{\underset{\|}{C}}-Ph \xrightarrow{h\nu} R_2C{=}O + PhCOCH_3$$

This is a Norrish type II reaction (p. 221).

9-22 Oxidation of Primary Alcohols to Carboxylic Acids

$$RCH_2OH \xrightarrow{CrO_3} RCOOH$$

Primary alcohols can be oxidized to carboxylic acids by many strong oxidizing agents including chromic acid, permanganate, and nitric acid. The reaction may be looked on as a combination of reactions **9-4** and **4-6.** When acid conditions are used, a considerable amount of ester RCOOR is often isolated, though this is probably not formed by a combination of the acid with unreacted alcohol, but by a combination of intermediate aldehyde with unreacted alcohol to give an acetal or hemiacetal, which is oxidized to the ester.[250] Lactones can be prepared by oxidizing diols in which at least one OH is primary.[251] Primary alkyl ethers can be selectively cleaved to carboxylic acids by aqueous Br_2[73] ($RCH_2OR' \rightarrow RCOOH$).

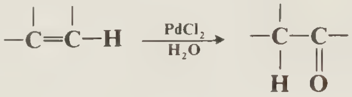
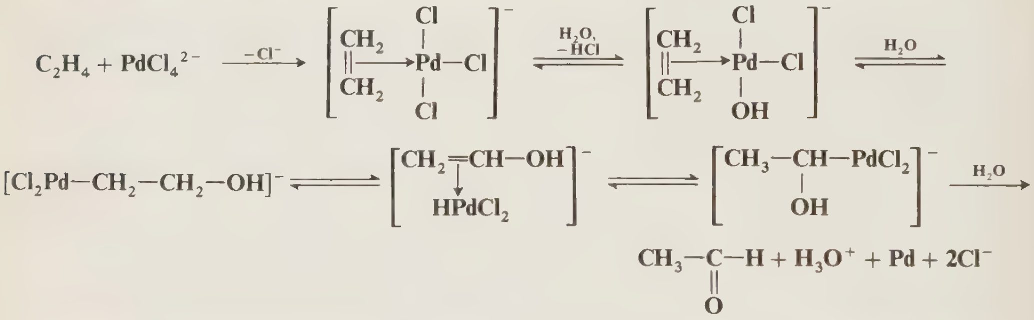
9-23 Oxidation of Olefins to Aldehydes and Ketones



$$-\overset{|}{C}=\overset{|}{C}-H \xrightarrow[H_2O]{PdCl_2} -\underset{H}{\underset{|}{\overset{|}{C}}}-\underset{O}{\underset{\|}{C}}-$$

Monosubstituted and 1,2-disubstituted olefins can be oxidized to aldehydes and ketones by palladium chloride and similar salts of noble metals.[252] 1,1-Disubstituted olefins generally give poor results. The reaction is used industrially to prepare acetaldehyde from ethylene, but it is also suitable for laboratory preparations. The palladium chloride is reduced to palladium. Because the reagent is expensive, the reaction is usually carried out with a cooxidant, most often $CuCl_2$, whose function is to reoxidize the Pd to Pd(II). The $CuCl_2$ is reduced to Cu(I), which itself is reoxidized to Cu(II) by air, so that atmospheric oxygen is the only oxidizing agent actually used up. Many other cooxidants have been tried, among them O_3, Fe^{3+}, and PbO_2. Aqueous sulfolane is a good solvent for the oxidation of long-chain alkenes.[253] The principal product is an aldehyde only from ethylene: With other olefins Markovnikov's rule is followed, and ketones are formed predominantly. The generally accepted mechanism involves π complexes of palladium.[254]



$$C_2H_4 + PdCl_4^{2-} \xrightarrow{-Cl^-} \left[\begin{matrix} & Cl \\ CH_2 & | \\ \| \longrightarrow & Pd-Cl \\ CH_2 & | \\ & Cl \end{matrix}\right]^- \overset{H_2O,\ -HCl}{\rightleftharpoons} \left[\begin{matrix} & Cl \\ CH_2 & | \\ \| \longrightarrow & Pd-Cl \\ CH_2 & | \\ & OH \end{matrix}\right]^- \overset{H_2O}{\rightleftharpoons}$$

$$[Cl_2Pd-CH_2-CH_2-OH]^- \rightleftharpoons \left[\begin{matrix} CH_2=CH-OH \\ \downarrow \\ HPdCl_2 \end{matrix}\right]^- \rightleftharpoons \left[\begin{matrix} CH_3-CH-PdCl_2 \\ | \\ OH \end{matrix}\right]^- \xrightarrow{H_2O}$$

$$CH_3-\underset{O}{\underset{\|}{C}}-H + H_3O^+ + Pd + 2Cl^-$$

This mechanism accounts for the fact, established by deuterium labeling, that the four hydrogens of the acetaldehyde all come from the original ethylene and none from the solvent.

Similar reactions have been carried out with other oxidizing agents. An example involving migration of an alkyl group instead of hydrogen is oxidation of $Me_2C{=}CMe_2$ with peroxytrifluoroacetic acid–boron trifluoride to give Me_3COMe (pinacolone).[255] This reaction consists of epoxidation (**5-40**) followed by pinacol rearrangement of the epoxide (**8-2**). Other reagents used have

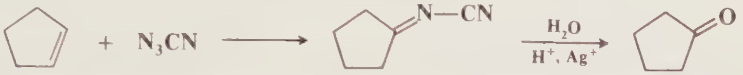
been chromyl chloride[256] (e.g., $Me_3CCH_2CMe{=}CH_2 \rightarrow Me_3CCH_2CHMeCHO$), $Pb(OAc)_4$–F_3CCOOH[257] (e.g., $PhCH{=}CH_2 \rightarrow PhCH_2CHO$), thallium(III) nitrate-methanol[258] (e.g., cyclohexene → cyclopentanecarboxaldehyde), Cl_2 or Br_2 and $AgNO_3$,[259] $HgSO_4$–H_2O,[260] and $Hg(OAc)_2$ followed by $PdCl_2$.[261] An indirect method involves reaction with cyanogen azide to give alkylidene cyanamides, which can be hydrolyzed to ketones,[262] e.g.,



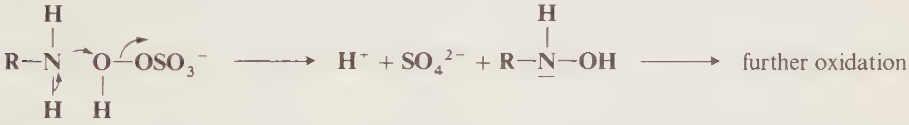
Alkenes have also been converted to more highly oxidized products. Examples are: (1) Treatment with *t*-amyl hydroperoxide and molybdenum salts gives α-hydroxy ketones.[263] (2) 1,2-Disubstituted and trisubstituted alkenes give α-chloro ketones when oxidized with chromyl chloride in acetone: $RCH{=}CR'R'' \rightarrow RCOCClR'R''$.[264] (3) $KMnO_4$ in acetic anhydride oxidizes large-ring cycloalkenes to 1,2-diketones.[265]

OS **51,** 4.

9-24 Oxidation of Primary Amines to Nitroso Compounds

$$ArNH_2 \xrightarrow{H_2SO_5} Ar{-}N{=}O$$

Primary aromatic amines can be oxidized[266] to nitroso compounds. Most often the conversion is accomplished by Caro's acid (H_2SO_5) or with H_2O_2 in HOAc,[267] but the reaction has also been performed with OF_2.[268] Hydroxylamines, which are probably intermediates in most cases, can sometimes be isolated, but under the reaction conditions they are generally oxidized to the nitroso compounds. Primary aliphatic amines can also be oxidized in this manner, but the nitroso compound is stable only if there is no α-hydrogen. If there is an α-hydrogen, the compound tautomerizes to the oxime.[269] The mechanism with H_2SO_5 has been postulated to be an example of category 5 (p. 1076):[270]



$$R{-}\underset{H}{\overset{H}{N}}\;\;\underset{H}{O}{-}OSO_3^- \longrightarrow H^+ + SO_4^{2-} + R{-}\overset{H}{\underline{N}}{-}OH \longrightarrow \text{further oxidation}$$

9-25 Oxidation of Primary Amines, Oximes, or Nitroso Compounds to Nitro Compounds

$$R_3CNH_2 \xrightarrow{KMnO_4} R_3CNO_2$$

$$R_2C{=}NOH \xrightarrow{F_3CCOOOH} R_2CHNO_2$$

Primary amines at a tertiary carbon can be oxidized to nitro compounds in excellent yields with $KMnO_4$.[271] This type of nitro compound is not easily prepared in other ways. Primary amines at a secondary carbon and primary aromatic amines[272] can be oxidized to nitro compounds with various peracids, including peracetic, peroxytrifluoroacetic, and *m*-chloroperbenzoic acids. Primary aromatic amines have also been oxidized to nitro compounds with *t*-butyl hydroperoxide in the presence of certain molybdenum and vanadium compounds.[273] Primary, secondary, and tertiary alkyl primary amines have been oxidized to the corresponding nitro compounds with ozone, but yields are low.[274] Oximes can be oxidized to nitro compounds with peroxytrifluoroacetic acid, among other ways.[271] Aromatic nitroso compounds are easily oxidized to nitro compounds by many oxidizing agents.[275]

OS **III,** 334; **V,** 367, 845; **52,** 77.

9-26 Oxidation of Mercaptans and Other Sulfur Compounds to Sulfonic Acids

$$RSH \xrightarrow{HNO_3} RSO_3H$$

Mercaptans, sulfoxides, sulfones, disulfides,[276] and other sulfur compounds can be oxidized to sulfonic acids with many oxidizing agents, though for synthetic purposes the reaction is most important for mercaptans.[277] Among oxidizing agents used are boiling nitric acid and barium permanganate. Autoxidation (oxidation by atmospheric oxygen) can be accomplished in basic solution.[278] The oxidation of RCH_2SCOR (prepared by reaction **5-7**) to RCH_2SO_3H with H_2O_2–HOAc affords a preparation of aliphatic sulfonic acids from olefins.[279] Aliphatic mercaptans can be oxidized to sulfinic acids with *m*-chloroperbenzoic acid in CH_2Cl_2.[280] Mercaptans can also be oxidized to disulfides (reaction **9-37**).

OS **II,** 471; **III,** 226. Also see OS **V,** 1070.

9-27 Oxidation of Mercaptans and Other Sulfur Compounds to Sulfonyl Halides

$$RSH + Cl_2 \xrightarrow{H_2O} RSO_2Cl$$

Oxidation of mercaptans with chlorine and water gives sulfonyl chlorides directly.[281] Among other sulfur compounds which give the same reaction are sulfides, disulfides, thiocyanates, thio-acetates RSCOMe, Bunte salts (see reaction **0-42**), and isothiuronium salts (see reaction **0-38**). The method has also been used for the preparation of sulfonyl bromides, fluorides, and iodides. R may be primary or secondary alkyl, or aryl, but not tertiary alkyl.

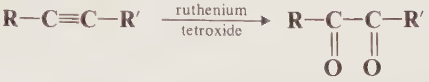
D. Reactions in Which Oxygen is Added to the Substrate

9-28 The Oxidation of Alkynes to α-Diketones



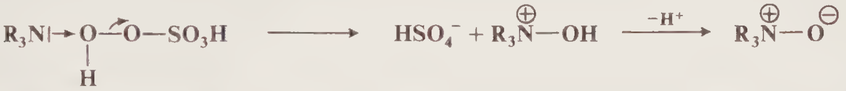
$$R-C\equiv C-R' \xrightarrow[\text{tetroxide}]{\text{ruthenium}} R-\underset{\underset{O}{\|}}{C}-\underset{\underset{O}{\|}}{C}-R'$$

Internal alkynes have been oxidized to α-diketones by several oxidizing agents, including ruthenium tetroxide,[282] neutral $KMnO_4$,[283] SeO_2 with a small amount of H_2SO_4,[284] N-bromosuccinimide in anhydrous dimethyl sulfoxide,[285] and thallium(III) nitrate.[160] Ozone generally oxidizes triple-bond compounds to carboxylic acids (reaction **9-10**), but α-diketones are sometimes obtained instead. SeO_2 with a small amount of H_2SO_4 oxidizes arylacetylenes to α-keto acids ($ArC\equiv CH \rightarrow ArCOCOOH$).[284]

9-29 Oxidation of Tertiary Amines to Amine Oxides

$$R_3N \xrightarrow{H_2O_2} R_3\overset{\oplus}{N}-\overset{\ominus}{O}$$

Tertiary amines can be converted to amine oxides by oxidation. Hydrogen peroxide is often used, but peracids are also important reagents for this purpose. Pyridine and its derivatives are oxidized only by peracids.[286] In the attack by hydrogen peroxide there is first formed a trialkylammonium peroxide, a hydrogen-bonded complex represented as $R_3N{\cdot}H_2O_2$, which can be isolated.[287] The decomposition of this complex probably involves an attack by the OH^+ moiety of the H_2O_2. Oxidation with Caro's acid has been shown to proceed in this manner:[288]

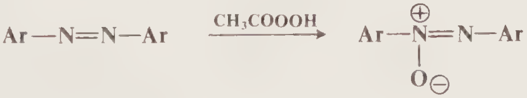


$$R_3N| \rightarrow \underset{\underset{H}{|}}{O}-O-SO_3H \longrightarrow HSO_4^- + R_3\overset{\oplus}{N}-OH \xrightarrow{-H^+} R_3\overset{\oplus}{N}-\overset{\ominus}{O}$$

This mechanism is the same as that of reaction **9-24**, and the products differ only because tertiary amine oxides cannot be further oxidized. The mechanism with other peracids is probably the same. The reaction has also been carried out with hydroperoxides in the presence of V or Mn complexes.[289]

OS **IV**, 612, 704, 828; **50**, 56.

9-30 Oxidation of Azobenzenes to Azoxybenzenes



$$Ar-N=N-Ar \xrightarrow{CH_3COOOH} Ar-\underset{\underset{O^{\ominus}}{|}}{\overset{\oplus}{N}}=N-Ar$$

---

[282] Gopal and Gordon, *Tetrahedron Lett.* 2941 (1971).

[283] Khan and Newman, *J. Org. Chem.* **17**, 1063 (1952).

[285] Wolfe, Pilgrim, Garrard, and Chamberlain, *Can. J. Chem.* **49**, 1099 (1971).

[286] For a review, see Katritzky and Lagowski, "Chemistry of the Heterocyclic N-Oxides," pp. 21–72, 539–542, Academic Press, Inc., New York, 1971.

[287] Oswald and Guertin, *J. Org. Chem.* **28**, 651 (1963).

[288] Ogata and Tabushi, *Bull. Chem. Soc. Jpn.* **31**, 969 (1958).

[289] Kuhnen, *Chem. Ber.* **99**, 3384 (1966); Sheng and Zajacek, *J. Org. Chem.* **33**, 588 (1968).

Azo compounds can be oxidized to azoxy compounds by peracids[290] or by hydroperoxides and molybdenum complexes.[291] The mechanism is probably the same as that of reaction **9-29.**[292]

9-31 Oxidation of Isonitriles to Isocyanates

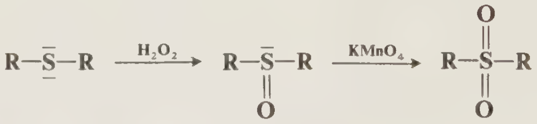
$$R-\overset{\oplus}{N}\equiv\overset{\ominus}{\bar{C}} \xrightarrow[\text{Me}_2\text{SO}]{\text{Cl}_2} R-N=C=O$$

Isonitriles have been oxidized to isocyanates with HgO and with O_3, as well as with a halogen and dimethyl sulfoxide (or pyridine N-oxide). In the latter case the oxidizing agent is the halogen, which converts the isonitrile to $R-N=CCl_2$ which is hydrolyzed to the isocyanate.[293] Isonitriles can also be oxidized by nitrile oxides, which are thus reduced to nitriles:[294]

$$Ar-C\equiv\overset{\oplus}{N}-\overset{\ominus}{\underline{\bar{O}}}| + R-\overset{\oplus}{N}\equiv\overset{\ominus}{\bar{C}} \longrightarrow Ar-C\equiv N + R-N=C=O$$

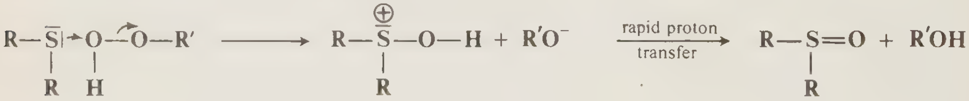
Cyanide ion has been oxidized to cyanate ion with many oxidizing agents. When isonitriles are oxidized by thallium(III) nitrate in the presence of methanol, carbamates are formed, by reaction of the initially formed isocyanate with the methanol (reaction **6-8**).[295]

9-32 Oxidation of Sulfides to Sulfoxides and Sulfones



$$R-\underline{\bar{S}}-R \xrightarrow{H_2O_2} R-\underset{\underset{O}{\|}}{\bar{S}}-R \xrightarrow{KMnO_4} R-\overset{\overset{O}{\|}}{\underset{\underset{O}{\|}}{S}}-R$$

Sulfides can be oxidized to sulfoxides by 1 mole of 30% H_2O_2 or by many other oxidizing agents,[296] including iodobenzene dichloride $PhICl_2$,[297] $NaIO_4$,[298] *t*-BuOCl,[299] and peracids. Sulfoxides can be further oxidized to sulfones by another mole of H_2O_2, $KMnO_4$, or a number of other agents. If enough oxidizing agent is present, sulfides can be directly converted to sulfones without isolation of the sulfoxides. These reactions give high yields, and many functional groups do not interfere.[300] When the oxidizing agent is a peroxide, the mechanism of oxidation to the sulfoxide is similar to that of reaction **9-29:**[301]



$$\underset{R}{\underset{|}{R-\bar{S}|}}\rightarrow \underset{H}{\underset{|}{O}}-O-R' \longrightarrow R-\underset{\underset{R}{|}}{\overset{\oplus}{S}}-O-H + R'O^- \xrightarrow[\text{transfer}]{\text{rapid proton}} R-\underset{\underset{R}{|}}{S}=O + R'OH$$

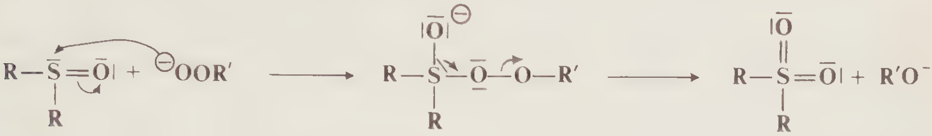
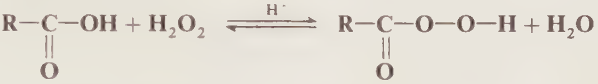
The second oxidation, which is normally slower than the first[302] (which is why sulfoxides are so easily isolable), has the same mechanism in neutral or acid solution, but in basic solution it has been shown that the conjugate base of the peroxy compound ($R'OO^-$) also attacks the SO group as a nucleophile:[303]



OS V, 791; **50,** 31, 33. Also see OS V, 723.

9-33 Oxidation of Carboxylic Acids to Peroxy Acids

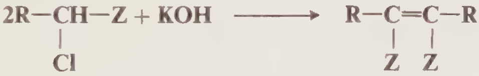


$$\underset{\underset{O}{\|}}{R-C}-OH + H_2O_2 \xrightleftharpoons{H^+} \underset{\underset{O}{\|}}{R-C}-O-O-H + H_2O$$

The oxidation of carboxylic acids with H_2O_2 and an acid catalyst is the best general method for the preparation of peroxy acids.[304] The most common catalyst for aliphatic R is concentrated sulfuric acid. The reaction is an equilibrium and is driven to the right by removal of water or by the use of excess reagents. For aromatic R the best catalyst is methanesulfonic acid, which is also used as the solvent.

E. Oxidative Coupling

9-34 Coupling Involving Carbanions



$$2R-\underset{\underset{Cl}{|}}{CH}-Z + KOH \longrightarrow R-\underset{\underset{Z}{|}}{C}=\underset{\underset{Z}{|}}{C}-R$$

Alkyl halides with an electron-withdrawing group on the halogen-bearing carbon can be dimerized to olefins by treatment with bases. Z may be nitro, aryl, etc. Although carbene intermediates have sometimes been suggested, it is likely that in most cases the mechanism[305] involves nucleophilic substitution followed by elimination[306] (illustrated for benzyl chloride):

$$PhCH_2Cl \xrightarrow{\text{base}} Ph\overset{\ominus}{\bar{C}}HCl \xrightarrow[S_N]{PhCH_2Cl} PhCHClCH_2Ph \xrightarrow{-HCl} PhCH{=}CHPh$$

In a related reaction, diarylmethane dihalides Ar_2CX_2 have been dimerized to tetraaryl alkenes $Ar_2C{=}CAr_2$ with sodium selenide,[307] with copper,[308] and with iron pentacarbonyl.[309] Other dimerizations leading to alkenes have been performed on phosphorus compounds. The ylides $ArCH{=}PPh_3$ and $ArCOCH{=}PPh_3$ have been dimerized to $ArCH{=}CHAr$ and $ArCOCH{=}CHCOAr$ with, respectively, oxygen[310] and selenious acid H_2SeO_3.[311] Phosphonium periodates $RCH_2\overset{+}{P}Ph_3\ \ IO_4^-$ react with bases such as NaOEt or $NaNH_2$ to give alkenes $RCH{=}CHR$.[312] Aryl diazomethanes $ArCHN_2$ are oxidized to $ArCH{=}CHAr$ by ceric ammonium nitrate.[313]

---

[302] There are some reagents which oxidize sulfones in preference to sulfoxides, e.g., $NaMnO_4$: see Henbest and Khan, *Chem. Commun.* 1036 (1968).

[304] For a review of the preparation of peroxy acids, see Swern, in Swern, "Organic Peroxides," vol. 1, pp. 313–516, Interscience Publishers, New York, 1970.

[305] For discussion, see Saunders and Cockerill, "Mechanisms of Elimination Reactions," pp. 548–554, John Wiley & Sons, Inc., New York, 1973.

[306] For example, see Hauser, Brasen, Skell, Kantor, and Brodhag, *J. Am. Chem. Soc.* **78,** 1653 (1956); Hoeg and Lusk, *J. Organomet. Chem.* **5,** 1 (1966); Reisdorf and Normant, *Organomet. Chem. Synth.* **1,** 375 (1972); Hanna and Wideman, *Chem. Ind. (London)* 486 (1968).

[307] Okamoto and Yano, *J. Org. Chem.* **34,** 1492 (1969).

[308] Buckles and Matlack, *Org. Synth.* **IV,** 914.

[309] Coffey, *J. Am. Chem. Soc.* **83,** 1623 (1961).

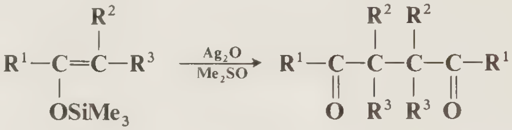
A somewhat different type of coupling is observed when salts of β-keto esters, arylacetonitriles $ArCH_2CN$, and other compounds of the form ZCH_2Z' are treated with an oxidizing agent such as iodine,[314] PbO_2,[315] Cu(II) salts,[316] or a Cu-amine-O_2 system,[317] e.g.,

$$Ar_2CH_2 \xrightarrow[\text{liq. NH}_3]{NaNH_2} Ar\overset{\ominus}{C}H \quad + \quad I_2 \longrightarrow Ar_2CH{-}CHAr_2$$

In this case the product is a substituted alkane rather than an alkene. The reaction with I_2 has been applied to enolates of monoesters to give succinic esters.[317a]

OS **II,** 273; **IV,** 372, 869, 914. Also see OS **I,** 46; **IV,** 877.

9-35 Dimerization of Silyl Enol Ethers or of Lithium Enolates

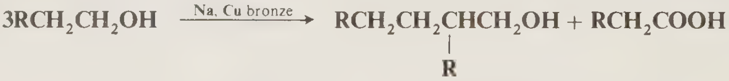


$$R^1-\underset{OSiMe_3}{C}=\overset{R^2}{C}-R^3 \xrightarrow[Me_2SO]{Ag_2O} R^1-\underset{O}{\overset{}{C}}-\underset{R^3}{\overset{R^2}{C}}-\underset{R^3}{\overset{R^2}{C}}-\underset{O}{C}-R^1$$

Silyl enol ethers can be dimerized to symmetrical 1,4-diketones by treatment with Ag_2O in dimethyl sulfoxide or certain other polar aprotic solvents.[318] The reaction has been performed with R^2, R^3 = hydrogen or alkyl, though best yields are obtained when $R^2 = R^3 = H$. In certain cases, unsymmetrical 1,4-diketones have been prepared by using a mixture of two silyl enol ethers.

In a similar reaction, lithium enolates $RC(Li){=}CH_2$ were dimerized to 1,4-diketones $RCOCH_2CH_2COR$ with $CuCl_2$ in dimethylformamide at −78°C.[319]

9-36 The Guerbet Reaction



$$3RCH_2CH_2OH \xrightarrow{\text{Na, Cu bronze}} RCH_2CH_2\underset{R}{C}HCH_2OH + RCH_2COOH$$

Primary alcohols couple in the manner shown when treated with sodium or another base and copper bronze, Raney nickel, or other hydrogenation catalysts. The reaction, called the *Guerbet reaction,* involves three molecules of alcohol, one of which is oxidized to the acid. Yields are about 30 to 50%.[320] The mechanism probably involves conversion of the alcohol to the aldehyde

RCH_2CHO, followed by aldol condensation with loss of water to give $RCH_2CH{=}CRCHO$, and reduction of this by transfer hydrogenation (p. 710) to give the product.[321] The carboxylic acid is formed by disproportionation of some of the aldehyde.

9-37 Oxidation of Mercaptans to Disulfides

$$2RSH \xrightarrow{H_2O_2} RSSR$$

Mercaptans are easily oxidized to disulfides.[322] Hydrogen peroxide is the most common reagent, but many oxidizing agents give the reaction, though strong ones may give reaction **9-26.** Even the oxygen in the air oxidizes mercaptans on standing, if a small amount of base is present. The reaction is reversible (see reaction **9-65**), and the interconversion between cysteine and cystine is an important one in biochemistry. Thiol acids can likewise be coupled:

$$2RCOS^- + I_2 \longrightarrow RCOSSCOR$$

The mechanism has been studied for several oxidizing agents and varies with the agent.[323] For oxygen it is[324]

$$\begin{aligned}
RSH + B^- &\rightleftharpoons RS^- + BH\\
RS^- + O_2 &\longrightarrow RS\cdot + \dot{O}_2{}^-\\
RS^- + \dot{O}_2{}^- &\longrightarrow RS\cdot + O_2{}^{2-}\\
2RS\cdot &\longrightarrow RSSR\\
O_2{}^{2-} + BH &\longrightarrow OH^- + B^- + O_2
\end{aligned}$$

With respect to the sulfur, this mechanism is similar to that of reaction **4-15**, involving as it does loss of a proton, oxidation to a free radical, and radical coupling.

Unsymmetrical disulfides can be prepared by treatment of a mercaptan RSH with diethyl azodicarboxylate $EtOOCN{=}NCOOEt$ to give an adduct, to which another mercaptan R′SH is then added, producing the disulfide RSSR′.[325] Another method involves treatment of R′SH with a thiophthalimide (**34**).[326]

TABLE 2 The ease of reduction of various functional groups toward catalytic hydrogenation[329]

The groups are listed in approximate order of ease of reduction

Reaction	Substrate	Product	
0-83	RCOCl	RCHO	Easiest
9-49	RNO_2	RNH_2	
5-12	RC≡CR	RCH=CHR	
6-27	RCHO	RCH_2OH	
5-12	RCH=CHR	RCH_2CH_2R	
6-27	RCOR	RCHOHR	
0-80	$ArCH_2OR$	$ArCH_3$ + ROH	
6-29	RC≡N	RCH_2NH_2	
5-13			
9-44	RCOOR′	RCH_2OH + R′OH	
9-41	RCONHR′	RCH_2NHR	
5-13			Most difficult
9-40	$RCOO^-$		Inert

9-38 Oxidation of Amines to Azo or Azoxy Compounds

$$ArNH_2 \xrightarrow{MnO_2} Ar{-}N{=}N{-}Ar$$

Primary aromatic amines have been oxidized to azo compounds by a variety of oxidizing agents, among them MnO_2, lead tetraacetate, O_2 and a base, and sodium perborate in acetic acid. *t*-Butyl hydroperoxide has been used to oxidize certain primary amines to azoxy compounds.[327]

OS **V**, 341.

Reductions: Selectivity

It is often necessary to reduce one group in a molecule without affecting another reducible group. It is usually possible to find a reducing agent which will do this. The most common broad-spectrum reducing agents are the metal hydrides[328] and hydrogen (with a catalyst). Many different metal-hydride systems and hydrogenation catalysts have been investigated in order to find conditions under which a given group will be reduced without reducing another group in the same molecule. In Tables 2, 3, and 4 are listed the reactivity of various functional groups toward catalytic hydrogenation, $LiAlH_4$, and, BH_3, respectively.[329, 330] Table 5 shows which groups can be reduced by catalytic hydrogenation and various metal hydrides.[331] Of course, these tables cannot be exact, for the nature of R and the reaction conditions obviously affect reactivity. Nevertheless, the tables do give a fairly good indication of which reagents reduce which groups.

---

[327] Kosswig, *Justus Liebigs Ann. Chem.* **749**, 206 (1971).

[328] For discussions of selectivity with metal hydride reducing agents, see Brown, "Boranes in Organic Chemistry," pp. 209–251, Cornell University Press, Ithaca, N.Y., 1972; Rerick, in Augustine, "Reduction," pp. 1–94, Marcel Dekker, Inc., New York, 1968; Walker, *Chem. Soc. Rev.* **5**, 23–50 (1976).

[329] Taken from House, Ref. 8, p. 9.

[330] Tables 3 and 4 are from Brown, Ref. 328, pp. 213 and 232, respectively.

[331] Except for the column on catalytic hydrogenation, these data are from Brown, Ref. 328, p. 251.

TABLE 3 The ease of reduction of various functional groups with $LiAlH_4$ in ether[330]

However, $LiAlH_4$ is a very powerful reagent, and much less selectivity is possible here than with most of the other metal hydrides

Reaction	Substrate	Product	
6-27	RCHO	RCH_2OH	Easiest
6-27	RCOR	RCHOHR	
9-47	RCOCl	RCH_2OH	
9-44	Lactone	Diol	
0-81		RCH_2CHOHR	
9-44	RCOOR′	$RCH_2OH + R'OH$	
9-40	RCOOH	RCH_2OH	
9-40	$RCOO^-$	RCH_2OH	
9-41	$RCONR'_2$	$RCH_2NR'_2$	
6-29	RC≡N	RCH_2NH_2	
9-49	RNO_2	RNH_2	
9-72	$ArNO_2$	ArN=NAr	Most difficult
5-12	RCH=CHR		Inert

$LiAlH_4$ is a very powerful and unselective reagent. Consequently, other metal hydrides are generally used when selectivity is required. As mentioned on p. 833, a number of less reactive (hence more selective) reagents have been prepared by replacing some of the hydrogens of $LiAlH_4$ with alkoxy groups (by treatment of $LiAlH_4$ with ROH).[332] Most of the metal hydrides are nucleophilic reagents and attack the carbon atom of a carbon-hetero single or multiple bond. However, BH_3 [333] and AlH_3 [334] are electrophiles (Lewis acids) and attack the hetero atom. This accounts for the different patterns of selectivity shown in the tables.

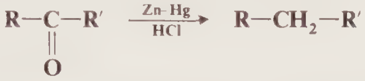
The reactions in this section are grouped into classifications based on bond changes, similar to those used for the oxidation reactions. These sections are: reactions involving replacement of oxygen by hydrogen, reactions in which an oxygen is removed from the substrate, reduction with cleavage, and reductive coupling.

A. Reactions Involving Replacement of Oxygen by Hydrogen.

In reactions **9-39** to **9-43**, a C=O is reduced to a CH_2 group.

9-39 Reduction of Carbonyl to Methylene in Aldehydes and Ketones



$$R-\underset{\underset{O}{\|}}{C}-R' \xrightarrow[HCl]{Zn-Hg} R-CH_2-R'$$

There are various ways of reducing the C=O group of aldehydes and ketones to CH_2.[339] The two most important methods are the *Clemmensen reduction* and the *Wolff-Kishner reduction* (in the Russian literature this is called the *Kizhner reaction*). The Clemmensen reduction consists of heating the aldehyde or ketone with zinc amalgam and aqueous HCl.[340] Ketones are reduced more often than aldehydes. In the Wolff-Kishner reduction,[341] the aldehyde or ketone is heated with hydrazine hydrate and a base (usually NaOH or KOH). The *Huang-Minlon modification*[342] of the Wolff-Kishner reaction, in which the reaction is carried out in refluxing diethylene glycol, has completely replaced the original procedure. The reaction can also be carried out under more moderate conditions (room temperature) in dimethyl sulfoxide with potassium *t*-butoxide as base.[343] The Wolff-Kishner reaction can also be applied to the semicarbazones of aldehydes or ketones. The Clemmensen reduction is usually easier to perform, but it fails for acid-sensitive and high-molecular-weight substrates. For these cases the Wolff-Kishner reduction is quite useful. For high-molecular-weight substrates, a modified Clemmensen reduction, using activated zinc and gaseous HCl in an organic solvent such as ether or acetic anhydride, has proved successful.[344] The Clemmensen and Wolff-Kishner reactions are complementary, since the former uses acidic and the latter basic conditions.

Both methods are fairly specific for aldehydes and ketones and can be carried out with many other functional groups present. However, certain types of aldehydes and ketones do not give normal reduction products. Under Clemmensen conditions,[345] α-hydroxy ketones give either ketones (hydrogenolysis of the OH, reaction **0-79**) or olefins, and 1,3-diones usually undergo rearrangement, e.g.,[346]

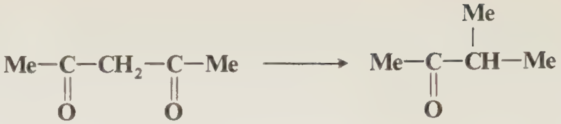
[345] For a review of Clemmensen reduction of diketones and unsaturated ketones, see Buchanan and Woodgate, *Q. Rev., Chem. Soc.* **23,** 522–536 (1969).

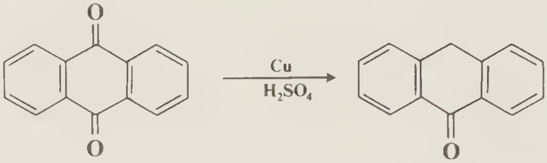
[346] Cusack and Davis, *J. Org. Chem.* **30,** 2062 (1965); Wenkert and Kariv, *Chem. Commun.* 570 (1965); Galton, Kalafer, and Beringer, *J. Org. Chem.* **35,** 1 (1970).



$$\mathrm{Me{-}}\underset{\underset{\displaystyle\mathrm{O}}{\|}}{\mathrm{C}}\mathrm{{-}CH_2{-}}\underset{\underset{\displaystyle\mathrm{O}}{\|}}{\mathrm{C}}\mathrm{{-}Me} \longrightarrow \mathrm{Me{-}}\underset{\underset{\displaystyle\mathrm{O}}{\|}}{\mathrm{C}}\mathrm{{-}}\overset{\overset{\displaystyle\mathrm{Me}}{|}}{\mathrm{CH}}\mathrm{{-}Me}$$

A similar rearrangement is observed on Clemmensen reduction of unsaturated cyclic ketones.[347] Neither method is suitable for α,β-unsaturated ketones. These give pyrazolines[348] under Wolff-Kishner conditions, while under Clemmensen conditions both groups of these molecules may be reduced or if only one group is reduced, it is the C=C bond. Sterically hindered ketones are resistant to both the Clemmensen and Huang-Minlon procedures but can be reduced by vigorous treatment with anhydrous hydrazine.[349] In the Clemmensen reduction, pinacols (reaction **9-67**) are often side products.

Other reagents have also been used to reduce the C=O of aldehydes and ketones to CH_2. Among these are catalytic hydrogenation at 180 to 250°C and, for aryl ketones (ArCOR and ArCOAr), $LiAlH_4$–$AlCl_3$,[350] Li–NH_3,[351] or trialkylsilanes in trifluoroacetic acid.[352] The latter two reagents also reduce aryl aldehydes ArCHO to methylbenzenes $ArCH_3$.[353] Aliphatic aldehydes RCHO can be reduced to RCH_3 with the sandwich compound titanocene dichloride $(C_5H_5)_2TiCl_2$.[354] One carbonyl group of 1,2-diketones can be selectively reduced by H_2S with an amine catalyst[355] or by HI in refluxing acetic acid.[356] One carbonyl group of quinones can be reduced with copper and sulfuric acid or with tin and HCl:[357]



An indirect method of accomplishing the reaction is reduction of tosylhydrazones ($R_2C{=}N{-}NHTs$) to R_2CH_2 with $LiAlH_4$, $NaBH_4$, BH_3, catecholborane, or $NaBH_3CN$.[358] The reduction of α,β-unsaturated tosylhydrazones with $NaBH_3CN$ or with catecholborane proceeds with migration of the double bond to the position formerly occupied by the carbonyl carbon, even if this removes the double bond from conjugation with an aromatic ring.[359] Another indirect method

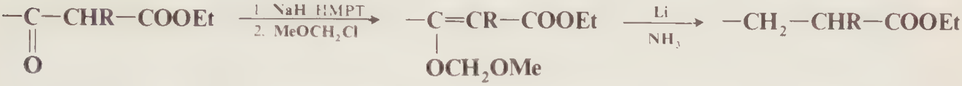
[359] Hutchins, Kacher, and Rua, *J. Org. Chem.* **40,** 923 (1975); Kabalka, Yang, and Baker, *J. Org. Chem.* **41,** 574 (1976); Taylor and Djerassi, *J. Am. Chem. Soc.* **98,** 2275 (1976).

is conversion of the aldehyde or ketone to a dithioacetal or ketal, and desulfurization of this (reaction **4-37**). In still another indirect method, the ketone function of β-keto esters is reduced by conversion to the methoxymethyl enol ether, followed by treatment of this with lithium in liquid NH_3.[360]



$$\underset{\underset{\displaystyle O}{\|}}{-C}-CHR-COOEt \xrightarrow[\text{2. MeOCH}_2\text{Cl}]{\text{1. NaH HMPT}} \underset{\underset{\displaystyle OCH_2OMe}{|}}{-C}=CR-COOEt \xrightarrow[NH_3]{Li} -CH_2-CHR-COOEt$$

The first step in the mechanism[361] of the Wolff-Kishner reaction consists of formation of the hydrazone (reaction **6-21**):

$$R_2C=O \longrightarrow R_2C=N-NH_2$$

It is this species which undergoes reduction in the presence of base, most probably in the following manner:

$$R_2C=N-NH_2 \overset{OH^-}{\rightleftarrows} R_2CH-N=NH + OH^- \longrightarrow R_2CH-N=N^{\ominus} + H_2O$$

$$R_2CH-N=N^{\ominus} \xrightarrow{-N_2} R_2\bar{C}H^{\ominus} \xrightarrow{H_2O} R_2CH_2 + OH^-$$

Regarding the mechanism of the Clemmensen reduction, nothing much can be said. What has been reported in the literature is so contradictory[362] that no conclusions can be drawn, except that the corresponding alcohol is not an intermediate, since alcohols prepared in other ways fail to give the reaction. Note that the alcohol is not an intermediate in the Wolff-Kishner reduction either.

9-40 Reduction of Carboxylic Acids to Alcohols

$$RCOOH \xrightarrow{LiAlH_4} RCH_2OH$$

Carboxylic acids are easily reduced to primary alcohols by $LiAlH_4$.[363] The reaction does not stop at the aldehyde stage (but see reaction **0-84**). The conditions are particularly mild, the reduction proceeding quite well at room temperature. Other hydrides have also been used, but not $NaBH_4$ (see Table 5). Catalytic hydrogenation is also generally ineffective. Borane is particularly good for carboxyl groups (Table 4) and permits selective reduction of them in the presence of many other groups[364] (though the reaction with double bonds takes place at about the same rate).[365] Aluminum hydride reduces COOH groups without affecting carbon-halogen bonds in the same molecule. A particularly mild reduction method consists of treatment of the carboxylic acid with N-ethyl-5-phenylisoxazolium 3-sulfonate, followed by $NaBH_4$ in aqueous solution.[366]

9-41 Reduction of Amides to Amines

$$\mathrm{RCONH_2} \xrightarrow{\mathrm{LiAlH_4}} \mathrm{RCH_2NH_2}$$

Amides can be reduced[367] to amines with $LiAlH_4$ or by catalytic hydrogenation, though high temperatures and pressures are usually required for the latter. Even with $LiAlH_4$ the reaction is more difficult than the reduction of most other functional groups, and often other groups can be reduced without disturbing an amide function. $NaBH_4$ by itself does not reduce amides, though it does so in the presence of $CoCl_2$[368] or of a carboxylic acid such as acetic or trifluoroacetic acid.[368a] Substituted amides can be similarly reduced:

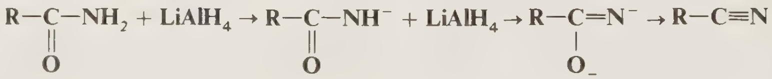
$$\mathrm{RCONHR'} \longrightarrow \mathrm{RCH_2NHR'}$$
$$\mathrm{RCONR'_2} \longrightarrow \mathrm{RCH_2NR'_2}$$

Borane is a good reducing agent for all three types of amides.[369] Another method for the reduction of mono- and disubstituted amides in high yields consists of treatment with triethyloxonium fluoroborate $Et_3O^+\ BF_4^-$ to give the imino ether fluoborate $RC(OEt){=}NR_2^+\ BF_4^-$, followed by reduction of this with $NaBH_4$ in ethanol.[370] Still another reagent which reduces disubstituted amides to amines is trichlorosilane.[371]

With some $RCONR'_2$, $LiAlH_4$ causes cleavage, and the aldehyde (reaction **0-85**) or alcohol is obtained. Thioamides can be reduced with hydrogen and Raney nickel.[372] Lactams are reduced to cyclic amines in high yields with $LiAlH_4$, though cleavage sometimes occurs here too. Imides are generally reduced on both sides, though it is sometimes possible to stop with just one. Both cyclic and acyclic imides have been reduced in this manner, though with acyclic imides cleavage is often obtained, e.g.,[373]

$$\mathrm{PhN(COMe)_2} \longrightarrow \mathrm{PhNHEt}$$

Nitriles have been isolated as intermediates in the treatment of unsubstituted amides with $LiAlH_4$.[374] The following mechanism has been proposed for the conversion of the amide to the nitrile:[374]



$$\mathrm{R-\underset{\underset{\displaystyle O}{\|}}{C}-NH_2 + LiAlH_4 \rightarrow R-\underset{\underset{\displaystyle O}{\|}}{C}-NH^- + LiAlH_4 \rightarrow R-\underset{\underset{\displaystyle O_-}{|}}{C}{=}N^- \rightarrow R-C{\equiv}N}$$

OS **IV**, 339, 354, 564; **54**, 88.

9-42 Reduction of Esters to Ethers

$$\mathrm{RCOOR'} \xrightarrow[\mathrm{LiAlH_4}]{\mathrm{BF_3\text{-}etherate}} \mathrm{RCH_2OR'}$$

Esters and lactones have been reduced to ethers, though the more usual course is the obtention of 2 moles of alcohol (reaction **9-44**). Reduction to ethers has been accomplished with a reagent prepared from BF_3-etherate and either $LiAlH_4$, $LiBH_4$, or $NaBH_4$,[375] with trichlorosilane and uv light,[376] and with catalytic hydrogenation. The reaction with the BF_3 reagent apparently succeeds with secondary R′, but not with primary R′, which give reaction **9-44.** Lactones give cyclic ethers.[377] Thiol esters RCOSR′ have been reduced to sulfides RCH_2SR'.[378]

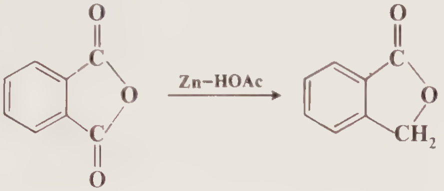
9-43 Reduction of Cyclic Anhydrides to Lactones



Cyclic anhydrides can give lactones if reduced with Zn–HOAc, hydrogen and platinum or $RuCl_2(Ph_3P)_3$,[379] $NaBH_4$,[380] or even $LiAlH_4$, although with the last-mentioned reagent diols are the more usual product (reaction **9-46**). Open-chain anhydrides either are not reduced at all (e.g., with $NaBH_4$), or give 2 moles of alcohol.

There are no *Organic Syntheses* references, but see OS **II,** 526, for a related reaction.

9-44 Reduction of Esters to Alcohols

$$\mathbf{RCOOR'} \xrightarrow{LiAlH_4} \mathbf{RCH_2OH + R'OH}$$

$LiAlH_4$ reduces esters to give 2 moles of alcohol.[381] The reaction is of wide scope and has been used to reduce many esters. Where the interest is in obtaining R′OH, this represents a method of "hydrolyzing" esters. Lactones yield diols. $LiBH_4$ also gives the reaction. $NaBH_4$ reduces phenolic esters, especially those containing electron-withdrawing groups,[382] but its reaction with other esters is usually so slow that such reactions are seldom feasible (though exceptions are known[383]), and it is generally possible to reduce an aldehyde or ketone without reducing an ester function in the same molecule. However, $NaBH_4$ reduces esters in the presence of certain compounds (see Table 5). With the reagent $NaBH(OMe)_3$ it is possible to reduce a secondary ester function $R_2CHCOOR'$ in the presence of a tertiary ester function R_3CCOOR'.[384] Esters can also be reduced to alcohols by hydrogenation over copper chromite catalysts,[385] though high pressures and temperatures are required. Ester functions generally survive low-pressure catalytic hydrogenations. Before the discovery of $LiAlH_4$, the most common way of carrying out the reaction was with sodium in ethanol, a method known as the *Bouveault-Blanc procedure*. This procedure is still sometimes used where selectivity is necessary. See also reactions **9-42** and **9-45.**

9-45 Reduction of Carboxylic Acids and Esters to Alkanes

$$\mathrm{RCOOR'} \xrightarrow{(\mathrm{C_5H_5})_2\mathrm{TiCl_2}} \mathrm{RCH_3 + R'OH}$$

The reagent titanocene dichloride reduces esters in a manner different from that of reactions **9-42** or **9-44**. The products are the alkane RCH_3 and the alcohol R'OH.[354] The mechanism probably involves an alkene intermediate. Aromatic acids can be reduced to methylbenzenes by a procedure involving refluxing first with trichlorosilane in MeCN, then with tripropylamine added, and finally with KOH and MeOH (after removal of the MeCN).[386] The following sequence has been suggested:[386]

$$\mathrm{ArCOOH} \quad \overset{\mathrm{SiHCl_3}}{} \quad (\mathrm{ArCO})_2\mathrm{O} \xrightarrow[\mathrm{R_3N}]{\mathrm{SiHCl_3}} \mathrm{ArCH_2SiCl_3} \xrightarrow[\mathrm{MeOH}]{\mathrm{KOH}} \mathrm{ArCH_3}$$

Esters of aromatic acids are not reduced by this procedure, so that an aromatic COOH group can be reduced in the presence of a COOR' group.[387] *o*- and *p*-hydroxybenzoic acids and their esters have been reduced to cresols $HOC_6H_4CH_3$ with sodium bis(2-methoxyethoxy)aluminum hydride $NaAlH_2(OC_2H_4OMe)_2$.[388]

Carboxylic acids can also be converted to alkanes, indirectly, by reduction of the corresponding tosylhydrazides $RCONHNH_2$ with $LiAlH_4$ or borane.[389]

9-46 Reduction of Anhydrides to Alcohols

$$\mathrm{RCOOCOR} \xrightarrow{\mathrm{LiAlH_4}} \mathrm{2RCH_2OH}$$

$LiAlH_4$ usually reduces open-chain anhydrides to give 2 moles of alcohol. With cyclic anhydrides the reaction with $LiAlH_4$ can be controlled to give either diols or lactones[390] (see reaction **9-43**).

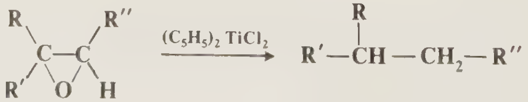
9-47 Reduction of Acyl Halides to Alcohols

$$\mathrm{RCOCl} \xrightarrow{\mathrm{LiAlH_4}} \mathrm{RCH_2OH}$$

Acyl halides are reduced[391] to alcohols by $LiAlH_4$ or $NaBH_4$, as well as by other metal hydrides (Table 5), but not by borane. The reaction may be regarded as a combination of reactions **9-39** and **0-77**.

OS **IV**, 271.

9-48 Complete Reduction of Epoxides



$$\mathrm{R'{-}\overset{\overset{\textstyle R}{|}}{C}H{-}CH_2{-}R''}$$

---

[391] For a review of the reduction of acyl halides, see Wheeler, in Patai, "The Chemistry of Acyl Halides," pp. 231–251, Interscience Publishers, New York, 1972.

Though the usual product of epoxide reductions is the alcohol (reaction **0-81**), 1,2-epoxides are reduced all the way to the alkane by titanocene dichloride.[354]

9-49 Reduction of Nitro Compounds to Amines

$$\mathbf{RNO_2} \xrightarrow[\text{HCl}]{\text{Zn}} \mathbf{RNH_2}$$

Both aliphatic[392] and aromatic nitro compounds can be reduced to amines, though the reaction has been applied much more often to aromatic nitro compounds, owing to their greater availability. Many reducing agents have been used to reduce aromatic nitro compounds, among them Zn, Sn, or Fe (or sometimes other metals) and acid, catalytic hydrogenation,[393] AlH_3–$AlCl_3$, hydrazine and a catalyst,[394] dodecacarbonyltriiron[$Fe_3(CO)_{12}$]-methanol,[395] $TiCl_3$,[396] and sulfides such as NaHS, $(NH_4)_2S$, or polysulfides. The reaction with sulfides or polysulfides is called the *Zinin reduction.*[397] The reagent sodium dihydro(trithio)borate $NaBH_2S_3$ reduces aromatic nitro compounds to amines,[398] but aliphatic nitro compounds give other products (see reaction **9-62**). In contrast, $LiAlH_4$ reduces aliphatic nitro compounds to amines, but with aromatic nitro compounds the products with this reagent are azo compounds (reaction **9-72**). Most metal hydrides, including $NaBH_4$ and BH_3, do not reduce nitro groups at all, though aromatic nitro compounds have been reduced to amines with $NaBH_4$ and various catalysts, such as $NiCl_2(PPh_3)_2$ or $CoCl_2$.[399] Treatment of aromatic nitro compounds with $NaBH_4$ alone has resulted in reduction of the *ring* to a cyclohexane ring with the nitro group still intact[400] or in cleavage of the nitro group from the ring.[401] With $(NH_4)_2S$ or other sulfides or polysulfides it is often possible to reduce just one of two or three nitro groups on an aromatic ring or on two different rings in one molecule.[402] The nitro groups of N-nitro compounds can also be reduced to amino groups, e.g., nitrourea $NH_2CONHNO_2$ gives semicarbazide $NH_2CONHNH_2$.

With some reducing agents, especially with aromatic nitro compounds, the reduction can be stopped at an intermediate stage, and hydroxylamines (reaction **9-51**), hydrazobenzenes (reaction **9-73**), azobenzenes (reaction **9-72**), and azoxybenzenes (reaction **9-71**) can be obtained in this manner. However, nitroso compounds, which are often postulated as intermediates, are too reactive to be isolated, if indeed they are intermediates (see however, reaction **9-50**). Reduction by metals in mineral acids cannot be stopped, but always produces the amine. The mechanisms of these reductions have been very little studied, though it is usually presumed that, at least with some reducing agents, nitroso compounds and hydroxylamines are intermediates. Both of these types of compounds give amines when exposed to most of these reducing agents (reaction **9-52**), and hydroxylamines can be isolated (reaction **9-51**). With metals and acid the following path has been suggested:[403]

9-50 Reduction of Nitro Compounds to Nitroso Compounds

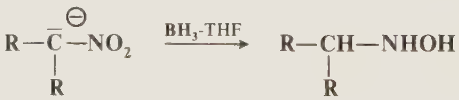
$$ArNO_2 \xrightarrow[H_2O]{h\nu,\ CN^-} ArNO$$

Certain aromatic nitroso compounds can be obtained in good yields by irradiation of the corresponding nitro compounds in 0.1 *M* aqueous KCN with uv light.[404] When nitro compounds are treated with most other reducing agents, nitroso compounds are either not formed or react further under the reaction conditions and cannot be isolated.

9-51 Reduction of Nitro Compounds to Hydroxylamines

$$ArNO_2 \xrightarrow[H_2O]{Zn} ArNHOH$$

When aromatic nitro compounds are reduced with zinc and water under neutral conditions, hydroxylamines are formed. Borane in tetrahydrofuran reduces *aliphatic* nitro compounds (in the form of their salts) to hydroxylamines:[405]



$$R{-}\overset{\ominus}{\underset{R}{C}}{-}NO_2 \xrightarrow{BH_3\text{-}THF} R{-}\underset{R}{CH}{-}NHOH$$

OS **I,** 445; **III,** 668; **IV,** 148; **52,** 77.

9-52 Reduction of Nitroso Compounds and Hydroxylamines to Amines

$$RNO \xrightarrow[HCl]{Zn} RNH_2$$

$$RNHOH \xrightarrow[HCl]{Zn} RNH_2$$

---

[404] Petersen and Letsinger, *Tetrahedron Lett.* 2197 (1971); Vink, Cornelisse, and Havinga, *Recl. Trav. Chim. Pays-Bas* **90,** 1333 (1971).

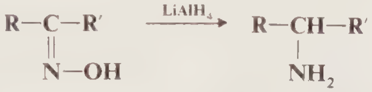
[405] Feuer, Bartlett, Vincent, and Anderson, *J. Org. Chem.* **31,** 2880 (1965).

Nitroso compounds and hydroxylamines can be reduced to amines by the same reagents which reduce nitro compounds (reaction **9-49**). N-Nitroso compounds are similarly reduced to hydrazines:[406]

$$R_2N{-}NO \longrightarrow R_2N{-}NH_2$$

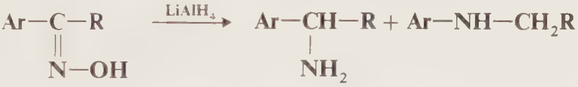
OS **I,** 511; **II,** 33, 202, 211, 418; **III,** 91; **IV,** 247.

9-53 Reduction of Oximes to Primary Amines or Aziridines



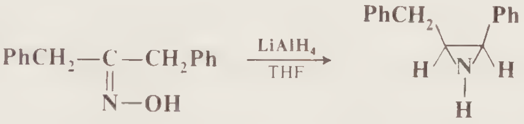
$$\underset{\displaystyle N{-}OH}{\overset{}{R{-}\underset{\|}{C}{-}R'}} \xrightarrow{LiAlH_4} \underset{\displaystyle NH_2}{R{-}\underset{|}{C}H{-}R'}$$

Both aldoximes and ketoximes can be reduced to primary amines with $LiAlH_4$. The reaction is slower than with ketones, so that, for example, $PhCOCH{=}NOH$ gave 34% $PhCHOHCH{=}NOH$.[407] Other reducing agents which give this reduction are zinc and acetic acid, sodium ethoxide, BH_3 at 105 to 110 C,[408] bis(2-methoxyethoxy)aluminum hydride,[409] sodium dihydro(trithio)borate,[410] and sodium and an alcohol.[411] Catalytic hydrogenation is also effective.[412] With some oximes (usually aromatic), secondary amines arising from a rearrangement are side products and sometimes the main products:[413]



$$\underset{\displaystyle N{-}OH}{Ar{-}\underset{\|}{C}{-}R} \xrightarrow{LiAlH_4} \underset{\displaystyle NH_2}{Ar{-}\underset{|}{C}H{-}R} + Ar{-}NH{-}CH_2R$$

With certain oximes (e.g., those of the type $ArCH_2CR{=}NOH$), treatment with $LiAlH_4$ gives aziridines,[414] e.g.,



Hydrazones, arylhydrazones, and semicarbazones can also be reduced to amines with various reducing agents, including Zn–HCl and H_2 and Raney nickel.

Oximes can also be reduced to hydroxylamines (reaction **6-28**).

OS **II,** 318; **III,** 513; **V,** 32, 83, 373, 376.

9-54 Reduction of Miscellaneous Nitrogen Compounds

$$R{-}N{=}C{=}O \xrightarrow{LiAlH_4} R{-}NH{-}CH_3$$

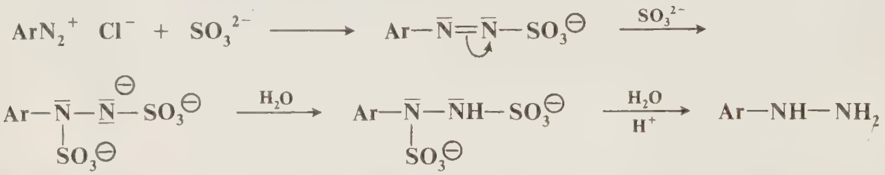
$$R{-}N{=}C{=}S \xrightarrow{LiAlH_4} R{-}NH{-}CH_3$$

$$Ar{-}N{=}N{-}Ar \xrightarrow[\text{catalyst}]{H_2} Ar{-}NH{-}NH{-}Ar$$

$$R{-}N_3 \xrightarrow{LiAlH_4} RNH_2$$

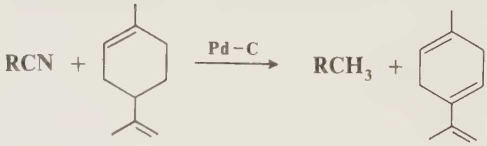
$$ArN_2^+ \ Cl^- \xrightarrow{Na_2SO_3} ArNHNH_2$$

Isocyanates and isothiocyanates are reduced to methylamines, and azides to primary amines, on treatment with $LiAlH_4$. Sulfonyl azides RSO_2N_3 have been reduced to sulfonamides RSO_2NH_2 by irradiation in isopropyl alcohol,[415] and with NaH.[416] $LiAlH_4$ does not usually reduce azo compounds[416a] (indeed these are the products from $LiAlH_4$ reduction of nitro compounds, reaction **9-72**), but these can be reduced to hydrazo compounds by catalytic hydrogenation or with diimide[417] (see reaction **5-12**). Diazonium salts are reduced to hydrazines by sodium sulfite. This reaction probably has a nucleophilic mechanism:[418]



The initial product is a salt of a hydrazinesulfonic acid, which is converted to the hydrazine by acid treatment. Diazonium salts can also be reduced to arenes (reaction **4-24**).

A cyano group can be reduced to a methyl group by treatment with a terpene such as limonene (which acts as reducing agent) in the presence of palladium-charcoal.[419] H_2 is also



Limonene

effective, though higher temperatures are required. R may be alkyl or aryl.

OS **I**, 442; **III**, 475; **V**, 586. Also see OS **V**, 43.

9-55 Reduction of Sulfonyl Halides to Mercaptans

$$RSO_2Cl \xrightarrow{LiAlH_4} RSH$$

Mercaptans can be prepared by the reduction of sulfonyl halides[420] with $LiAlH_4$. Usually, the reaction is carried out on aromatic sulfonyl chlorides. Zinc and acetic acid, and HI, also give the reduction. Disulfides RSSR can also be produced.[421] For the reduction of sulfonyl chlorides to sulfinic acids, see reaction **0-122**.

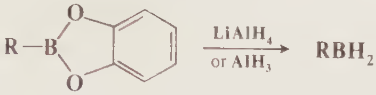
OS **I**, 504; **IV**, 695; **V**, 843.

9-56 Reduction of Borinates to Boranes

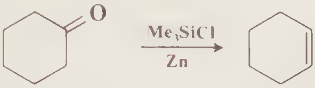
$$R_2BOAr \xrightarrow{LiAlH_4} R_2BH$$

Aryl dialkylborinates can be reduced to dialkylboranes in high yield with $LiAlH_4$.[422] In a similar reaction, monoalkylboranes can be prepared by the reduction of B-alkylcatecholboranes (p. 560) with $LiAlH_4$ or AlH_3.[423]



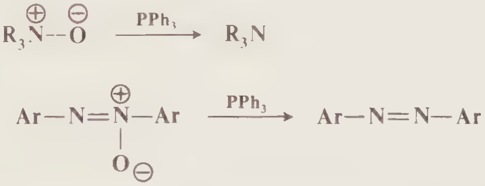
B. Reactions in Which an Oxygen Is Removed from the Substrate

9-57 Reduction of Cyclic Ketones to Cycloalkenes



Cyclic ketones can be directly reduced to cycloalkenes by treatment with chlorotrimethylsilane and zinc.[424] Halogen and ester groups are not affected. Yields are best for six-membered rings. There are many indirect methods for achieving this conversion, among them formation and decomposition of the tosylhydrazone (reaction **7-10**).

9-58 Reduction of Amine Oxides and Azoxy Compounds



$$R_3\overset{\oplus}{N}\text{--}\overset{\ominus}{O} \xrightarrow{PPh_3} R_3N$$

$$Ar\text{—}N{=}\underset{\underset{O^{\ominus}}{|}}{\overset{\oplus}{N}}\text{—}Ar \xrightarrow{PPh_3} Ar\text{—}N{=}N\text{—}Ar$$

Amine oxides[425] and azoxy compounds (both alkyl and aryl) can be reduced practically quantitatively with triphenylphosphine. Other reducing agents, e.g., $LiAlH_4$, H_2–Ni, H_2–Pd, PCl_3, and sulfur, have also been used. Nitrile oxides[426] $R\text{—}C{\equiv}\overset{\oplus}{N}\text{—}\overset{\ominus}{O}$ can be reduced to nitriles with trialkylphosphines.[427]

OS **IV**, 166.

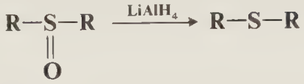
[427] Grundmann and Frommeld, *J. Org. Chem.* **30**, 2077 (1965).

9-59 Reduction of Sulfoxides and Sulfones



$$R{-}\underset{\underset{O}{\|}}{S}{-}R \xrightarrow{LiAlH_4} R{-}S{-}R$$

Sulfoxides can be reduced to sulfides, by $LiAlH_4$ and other reagents, among them HI, dichloroborane $BHCl_2$,[428] trichlorosilane $SiHCl_3$,[429] tributyltin hydride Bu_3SnH,[430] $SnCl_2$–HCl,[431] $TiCl_3$,[432] PCl_3,[433] H_2–Pd–C,[433a] $NaBH_3CN$ and 18-crown-6[434] (see p. 82), acetyl chloride,[435] I_2–SO_2–pyridine,[435a] and Ph_3P.[436] Sulfones, however, are usually stable to reducing agents, though they have been reduced to sulfides with diisobutylaluminum hydride $(i\text{-}Bu)_2AlH$.[437] A less general reagent is $LiAlH_4$, which reduces some sulfones to sulfides, but not others.[438] Both sulfoxides and sulfones can be reduced by heating with sulfur (which is oxidized to SO_2), though the reaction with sulfoxides proceeds at a lower temperature. It has been shown by using substrate labeled with ^{35}S that sulfoxides simply give up the oxygen to the sulfur, but that the reaction with sulfones is more complex, since about 75% of the original radioactivity of the sulfone is lost.[439] This indicates that most of the sulfur in the sulfide product comes in this case from the *reagent*.

9-60 The Conversion of Nitro Compounds to Isocyanates or Isothiocyanates

$$ArNO_2 + CO \xrightarrow[\substack{FeCl_3,\\ 500\text{ atm},\\ 190^\circ C}]{Rh\text{-}C} ArNCO$$

Aromatic nitro compounds can be converted to isocyanates directly by treatment at high pressures with CO and a catalyst consisting of a noble metal (Pd–C or Rh–C) and a Lewis acid.[440] Yields are not high. In a similar reaction, aromatic nitro compounds are converted to isothiocyanates by heating in an autoclave with CS_2 and a base, e.g., NaOMe or NaSPh.[441] In this method pressures are lower and yields are higher.

9-61 Reduction of Hydroperoxides

$$R{-}O{-}O{-}H \xrightarrow{LiAlH_4} ROH$$

Hydroperoxides can be reduced to alcohols with $LiAlH_4$ or Ph_3P,[442] or by catalytic hydrogenation. This functional group is very susceptible to catalytic hydrogenation, as shown by the fact that a double bond may be present in the same molecule without being reduced.[443]

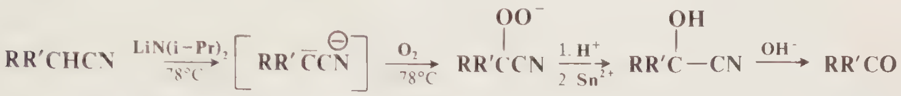
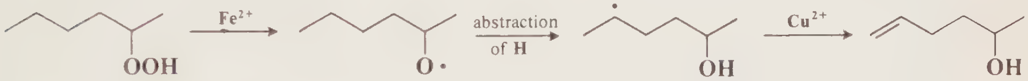
The reaction is an important step in a method for the oxidative decyanation of nitriles containing an α-hydrogen.[444] The nitrile is first converted to the α-hydroperoxy nitrile by treatment with base at −78°C followed by O_2. The hydroperoxy nitrile is then reduced to the cyanohydrin which is cleaved (the reverse of reaction **6-50**) to the corresponding ketone. The method is not successful for the preparation of aldehydes (R′ = H).



$$\mathrm{RR'CHCN} \xrightarrow[78^\circ\mathrm{C}]{\mathrm{LiN(i\text{-}Pr)_2}} \left[\mathrm{RR'\overset{\ominus}{\bar{C}}CN}\right] \xrightarrow[78^\circ\mathrm{C}]{\mathrm{O_2}} \mathrm{RR'\overset{OO^-}{\overset{|}{C}}CN} \xrightarrow[2\ \mathrm{Sn^{2+}}]{1.\ \mathrm{H^+}} \mathrm{RR'\overset{OH}{\overset{|}{C}}{-}CN} \xrightarrow{\mathrm{OH^-}} \mathrm{RR'CO}$$

When alkyl hydroperoxides are treated with ferrous sulfate and cupric acetate in acetic acid, the OOH group is reduced to OH, but a double bond is also introduced in the 3,4 or 4,5 position,[445] e.g.,

When there is a choice, the double bond is formed in the least substituted position. This reaction can be applied to primary, secondary, or tertiary hydroperoxides. A free-radical mechanism is involved:



9-62 Reduction of Aliphatic Nitro Compounds to Oximes or Nitriles

$$\mathrm{RCH_2NO_2} \xrightarrow{\mathrm{SnCl_2}} \mathrm{RCH{=}NOH}$$

Nitro compounds which contain an α-hydrogen can be reduced to oximes with stannous chloride or with other reagents, among them Co–Cu(II) salts in alkanediamines,[446] Zn dust in HOAc,[447] $CrCl_2$,[448] and (for α-nitro sulfones) $NaNO_2$.[449]

Primary aliphatic nitro compounds can be reduced to nitriles with sodium dihydro(trithio)-borate.[398] Secondary compounds give mostly ketones (e.g., nitrocyclohexane → 45% cyclohexanone,

$$\mathrm{RCH_2NO_2} \xrightarrow{\mathrm{NaBH_2S_3}} \mathrm{RC{\equiv}N}$$

30% cyclohexanone oxime, and 19% N-cyclohexylhydroxylamine). Tertiary aliphatic nitro compounds do not react with this reagent. See also reaction **9-49.**

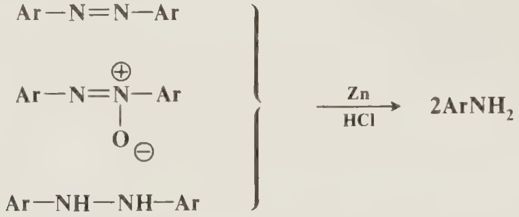
C. Reduction with Cleavage

9-63 Reduction of Azo, Azoxy, and Hydrazo Compounds to Amines



Azo, azoxy, and hydrazo compounds can all be reduced to amines.[449a] Metals (notably zinc) and acids, and $Na_2S_2O_4$, are frequently used as reducing agents. Borane reduces azo compounds to amines, though it does not reduce nitro compounds.[450] $LiAlH_4$ does not reduce hydrazo compounds or azo compounds, though with the latter, hydrazo compounds are sometimes isolated. With azoxy compounds, $LiAlH_4$ gives only azo compounds (reaction **9-58**).

OS **I,** 49; **II,** 35, 39; **III,** 360. Also see OS **II,** 290.

9-64 Reduction of Peroxides

$$R—O—O—R \xrightarrow{LiAlH_4} 2ROH$$

Peroxides are cleaved to 2 moles of alcohol by $LiAlH_4$ or by catalytic hydrogenation. Peroxides can be reduced to ethers with $P(OEt)_3$:[451]

$$ROOR + P(OEt)_3 \longrightarrow ROR + OP(OEt)_3$$

In a similar reaction, disulfides RSSR′ can be converted to sulfides RSR′ by treatment with tris(diethylamino)phosphine $(Et_2N)_3P$.[452]

9-65 Reduction of Disulfides to Mercaptans

$$RSSR \xrightarrow[H^+]{Zn} 2RSH$$

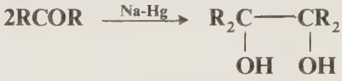
Disulfides can be reduced to mercaptans by mild reducing agents[453] such as zinc and dilute acid or Ph_3P and H_2O.[454] The reaction can also be accomplished simply by heating with alkali.[455] $LiAlH_4$ has also been used.

OS **II,** 580. Also see OS **IV,** 295.

9-66 Reduction of Ozonides. See reaction **9-10**

D. Reductive Coupling

9-67 Bimolecular Reduction of Aldehydes and Ketones to Pinacols



$$2RCOR \xrightarrow{Na\text{-}Hg} \underset{OH}{R_2C}—\underset{OH}{CR_2}$$

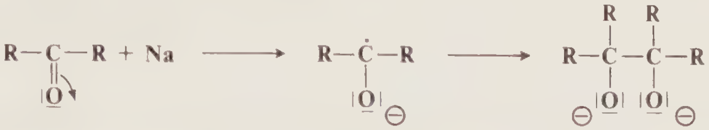
[453] For a review, see Wardell, in Patai, Ref. 277, pp. 220–229.

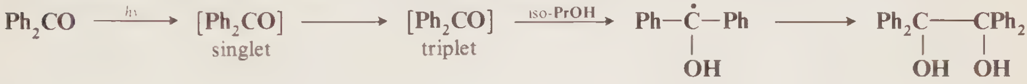
[454] Overman, Smoot, and Overman, *Synthesis* 59 (1974).

[455] For discussions, see Danehy and Hunter, *J. Org. Chem.* **32,** 2047 (1967); Danehy, in Kharasch and Meyers, Ref. 276, pp. 337–349.

Pinacols can be synthesized by reduction of aldehydes and ketones with active metals such as sodium, magnesium, or aluminum.[456] Aromatic ketones give better yields than aliphatic ones. The use of a Mg–MgI_2 mixture has been called the *Gomberg-Bachmann pinacol synthesis*. As with a number of other reactions involving sodium, there is a direct electron transfer here, converting the ketone or aldehyde to a ketyl, which couples:



The dimerization of ketones to pinacols can also be accomplished photochemically; and indeed this is one of the most common photochemical reactions.[457] The substrate, which is usually a diaryl or aryl alkyl ketone (though a few aromatic aldehydes and dialkyl ketones have been dimerized), is irradiated with uv light in the presence of a hydrogen donor such as isopropyl alcohol, toluene, or an amine.[458] In the case of benzophenone, irradiated in the presence of isopropyl alcohol, the ketone molecule initially undergoes $n \rightarrow \pi^*$ excitation, and the singlet species thus formed crosses to the T_1 state with a very high efficiency. The T_1 species abstracts hydrogen from the alcohol (p. 223) and then dimerizes. The iso-PrO• radical, which is formed by this process, donates H• to another molecule of ground-state benzophenone, producing acetone and another molecule of **35**. This mechanism[459] predicts that the quantum yield for the



35

$$\text{iso-PrO}\cdot + Ph_2CO \longrightarrow Me_2CO + \underset{\mathbf{35}}{Ph_2COH}$$

disappearance of benzoquinone should be 2, since each quantum of light results in the conversion of 2 moles of benzophenone to **35**. Under favorable experimental conditions the observed quantum yield does approach 2. Benzophenone abstracts hydrogen with very high efficiency. Other aromatic ketones are dimerized with lower quantum yields, and some (e.g., *p*-aminobenzophenone, *o*-methylacetophenone) cannot be dimerized at all in isopropyl alcohol (though *p*-aminobenzophenone, for example, can be dimerized in cyclohexane[460]). The reaction has also been carried out electrochemically.[461]

Pinacols have also been obtained by treatment of carboxylic acids with butyllithium and $TiCl_3$ (2RCOOH → RCHOH—CHOHR), but yields are low.[462]

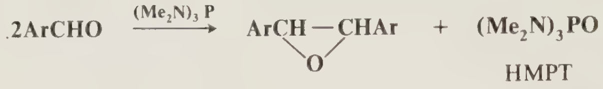
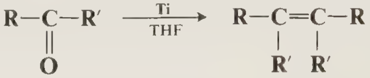
9-68 Bimolecular Reduction of Aldehydes and Ketones to Epoxides



Aromatic aldehydes can be dimerized to epoxides by treatment with hexamethylphosphorus triamide.[463] The reagent[464] is converted to hexamethylphosphoric triamide (HMPT). The reaction can be used for the preparation of mixed epoxides by the use of a mixture of two aldehydes in which the less reactive aldehyde predominates. Epoxides have also been prepared by treatment of aromatic aldehydes or ketones with the anions $(Me_2N)_2\overset{\ominus}{P}{=}O$ and $(EtO)_2\overset{\ominus}{P}{=}O$ (derived, respectively, by treatment with an alkali metal of HMPT or triethyl phosphite).[465]

OS V, 358.

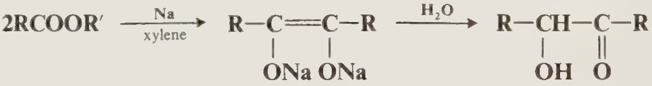
9-69 Bimolecular Reduction of Aldehydes or Ketones to Alkenes



$$\underset{\underset{O}{\|}}{R{-}C{-}R'} \xrightarrow[\text{THF}]{\text{Ti}} R{-}\underset{R'}{\underset{|}{C}}{=}\underset{R'}{\underset{|}{C}}{-}R$$

Aldehydes and ketones, both aromatic and aliphatic (including cyclic ketones), can be converted in high yields to dimeric alkenes by treatment with an active titanium metal powder prepared from $TiCl_3$ and K in dry tetrahydrofuran.[466] The reaction has also been accomplished with Mg and a $TiCl_3$–THF complex,[467] with $TiCl_4$ and zinc,[468] and with certain compounds prepared from WCl_6 and either lithium, lithium iodide, or an alkyllithium[469] (see reaction **7-19**).

9-70 The Acyloin Condensation



$$2RCOOR' \xrightarrow[\text{xylene}]{\text{Na}} R{-}\underset{ONa}{\underset{|}{C}}{=}\underset{ONa}{\underset{|}{C}}{-}R \xrightarrow{H_2O} R{-}\underset{OH}{\underset{|}{CH}}{-}\underset{O}{\underset{\|}{C}}{-}R$$

36

When esters are heated with sodium in refluxing ether or benzene, a bimolecular reduction takes place, and the product is an α-hydroxy ketone (called an acyloin).[470] The reaction, called the *acyloin condensation*, is quite successful when R is alkyl. Acyloins with long chains have been prepared in this way, for example, $R = C_{17}H_{35}$, but for high-molecular-weight esters, toluene or xylene is used as the solvent. The acyloin condensation has been used with great success, in boiling xylene, to prepare cyclic acyloins from diesters.[471] The yields are 50 to 60 % for the preparation of 6- and 7-membered rings, 30 to 40 % for 8- and 9-membered,[472] and 60 to 95 % for rings of 10 to 20 members. Even larger rings have been closed in this manner. This is the best way of closing rings of 10 members or more. The reaction has been used to close 4-membered rings,[473] though this is generally not successful. Small traces of oxygen greatly reduce the yields; hence the reaction must be conducted in an extremely pure nitrogen atmosphere. The presence of double or triple bonds does not interfere.[474] Even a benzene ring may be present, and many paracyclophane derivatives (**37**) with $n = 9$ or more have been synthesized in this manner.[475]

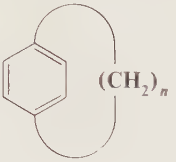
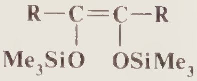
[471] For a review of cyclizations by means of the acyloin condensation, see Finley, *Chem. Rev.* **64**, 573–589 (1964).

[472] Yields of nine-membered ring products can be increased by adding a homologous diester, e.g., dimethyl tridecanedioate: Finley and Sasaki, *J. Am. Chem. Soc.* **88**, 4267 (1966).



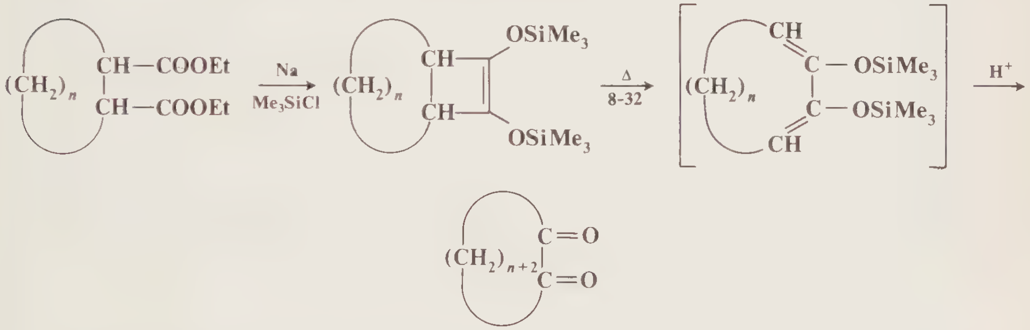
37



$$\begin{array}{c} R-C=C-R \\ \;\;\;\,| \quad\;\; | \\ Me_3SiO \quad OSiMe_3 \end{array}$$

38

Yields in the acyloin condensation can be improved by running the reaction in the presence of chlorotrimethylsilane Me_3SiCl, in which case the dianion **36** is converted to the bis silyl enol ether **38**, which can be isolated and subsequently hydrolyzed to the acyloin with aqueous acid.[476] Among other things, this method inhibits the Dieckmann condensation[477] (**0-111**), which otherwise competes with the acyloin condensation when a five-, six-, or seven-membered ring can be closed (note that the ring formed by a Dieckmann condensation is always one carbon atom smaller than that formed by an acyloin condensation of the same substrate). The Me_3SiCl method is especially good for the closing of four-membered rings,[478] and this reaction has been used in a procedure for ring enlargement of a cyclic diester by two carbons.[479]



The mechanism is not known with certainty, but it is usually presumed that the diketone RCOCOR is an intermediate,[480] since small amounts of it are usually isolated as side products,

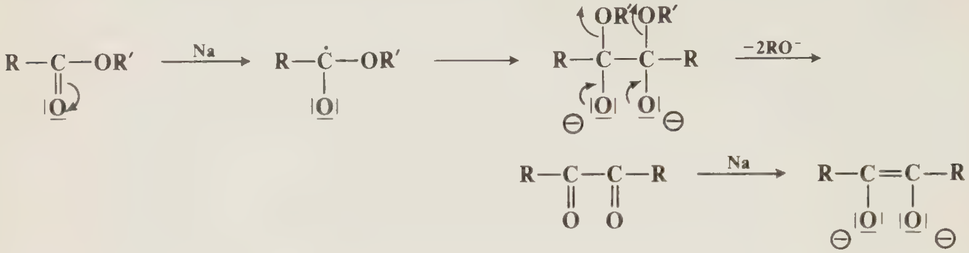
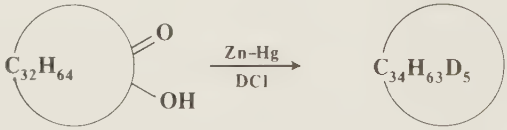
and when it is resistant to reduction (for example, *t*-Bu—CO—CO—*t*-Bu), it is the major product. A possible sequence (analogous to that of reaction **9-67**) is



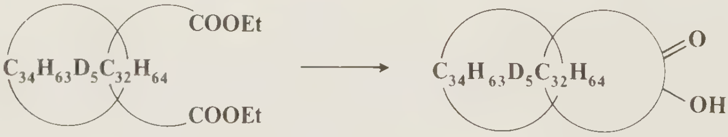
In order to account for the ready formation of large rings, which means that the two ends of the chain must approach each other even though this is conformationally unfavorable for long chains, it may be postulated that the two ends become attached to nearby sites on the surface of the sodium.

The acyloin condensation was used in an ingenious manner to prepare the first reported catenane (see p. 85). The catenane (**41**) was prepared by a statistical synthesis (p. 85) in the following manner: An acyloin condensation was performed on the diethyl ester of the C_{34} dicarboxylic acid (tetratriacontandioic acid) to give the cyclic acyloin **39.** This was reduced by a Clemmensen reduction with DCl in D_2O instead of HCl in H_2O, thus producing a C_{34} cycloalkane containing deuterium (**40**):[481]



39 **40**

40 contained about five atoms of deuterium per molecule. The reaction was then repeated, this time *in a* 1 : 1 *mixture of xylene and* **40** *as solvent.* It was hoped that some of the molecules of ester would be threaded through **40** before they closed:

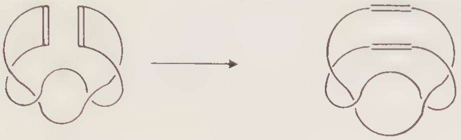


41

The first thing that was done with the product was to remove by chromatography the **40** which had been used as the solvent. The remaining material still contained deuterium, as determined by infrared spectra, even with all the **40** gone. This was strong evidence that the material consisted not only of **39**, but also of **41.** As further evidence, the mixture was oxidized to open up the acyloin rings (reaction **9-8**). From the oxidation product was isolated the C_{34} diacid (as expected), *containing no deuterium*, and **40,** containing deuterium. The total yield of **41** and **39** was 5 to 20%, but the percentage of **41** in this mixture was only about 1 to 2%.[481] This synthesis of a catenane produced only a small yield and relied on chance, on the probability that a diester molecule would be threaded through **40** before it closed. Another statistical synthesis makes use of the olefin metathesis reaction (**8-41**).[482] When this is applied to large-ring dienes, some of the molecules become twisted (**42**) before the reaction takes place. When such a molecule reacts, the product is the catenane **43.** Mass spectral evidence shows that some catenanes are indeed formed.

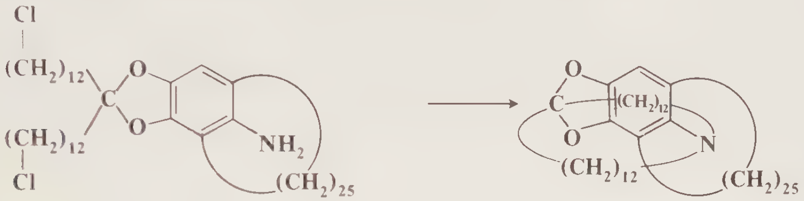
---

[481] This work was done by Wasserman, *J. Am. Chem. Soc.* **82,** 4433 (1960).



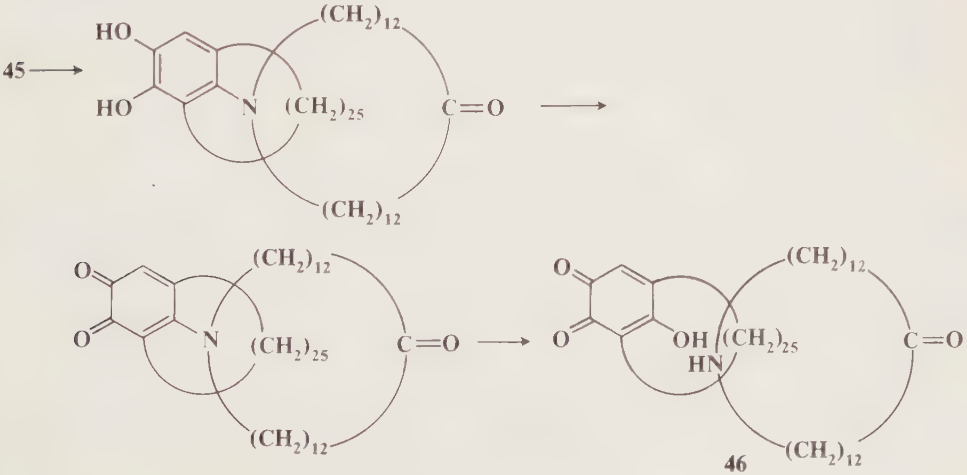
42 **43**

A catenane has also been prepared by a *directed* synthesis.[483] The key step here was formation of a tertiary amine by reaction **0-46.**



44 **45**

Sterically, one of the halide groups of **44** is above the plane, and the other below it, so that ring closure must occur *through* the 28-membered ring. After **45** was formed, the acetal was cleaved (reaction **0-7**). It was then necessary to cleave the remaining bond holding the two rings together, the C—N bond. This was done by oxidation to the *ortho*-quinone (reaction **9-5**), which converted the amine function to an enamine, which was hydrolyzable (reaction **6-2**) with acid to give the catenane (**46**):



---

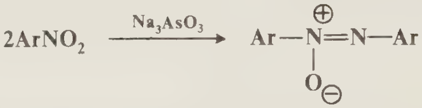
Ber.* **98,** 2906 (1965), **99,** 2689 (1966), **100,** 2021 (1967), *Justus Liebigs Ann. Chem.* **695,** 65 (1966). For the preparation of a [3]catenane by a similar approach, see Schill and Zürcher, *Angew. Chem. Int. Ed. Engl.* **8,** 988 (1969) [*Angew. Chem.* **81,** 996 (1969)].

The original large ring (of **44**) was closed by a Thorpe-Ziegler reaction (**6-48**) after an attempted acyloin condensation proved unsuccessful.

OS **II,** 114; **IV,** 840.

9-71 Reduction of Nitro to Azoxy Compounds



$$2ArNO_2 \xrightarrow{Na_3AsO_3} Ar{-}\overset{\oplus}{N}(O^{\ominus}){=}N{-}Ar$$

Azoxy compounds can be obtained from nitro compounds with certain reducing agents, notably sodium arsenite, sodium ethoxide, lead,[484] $NaBH_4$-$CoCl_2$,[485] and glucose.[486] KBF_4 produces azoxy compounds only when there are electron-withdrawing groups on the ring.[487] On the other hand, the reagent thallium produces azoxy compounds only when electron-withdrawing groups (and phenolic and amino groups) are absent.[488] The most probable mechanism with most reagents is that one molecule of nitro compound is reduced to a nitroso compound and another to a hydroxylamine (reaction **9-51**), and these combine (reaction **2-53**). The combination step is rapid compared to the reduction process.[489] Nitroso compounds can be reduced to azoxy compounds with triethyl phosphite or triphenylphosphine[490] or with an alkaline aqueous solution of an alcohol.[491]

OS **II,** 57.

9-72 Reduction of Nitro to Azo Compounds

$$2ArNO_2 \xrightarrow{LiAlH_4} Ar{-}N{=}N{-}Ar$$

Nitro compounds can be reduced to azo compounds with various reducing agents, of which $LiAlH_4$ and zinc and alkali are the most common.[492] With many of these reagents, slight differences in conditions may lead either to the azo or azoxy (reaction **9-71**) compound. Analogously to reaction **9-71,** this reaction may be looked on as a combination of ArN=O and $ArNH_2$ (reaction **2-52**). However, when the reducing agent was $HOCH_2CH_2ONa$[493] or $NaBH_4$,[494] it was shown that azoxy compounds were intermediates. Nitroso compounds can be reduced to azo compounds with $LiAlH_4$.

OS **III,** 103.

9-73 Reduction of Nitro to Hydrazo Compounds

$$2ArNO_2 \xrightarrow[NaOH]{Zn} Ar{-}NH{-}NH{-}Ar$$

Nitro compounds can be reduced to hydrazo compounds with zinc and sodium hydroxide, or electrolytically, or with $LiAlH_4$ mixed with a metal chloride such as $TiCl_4$ or VCl_3.[495] The reduction has also been accomplished with hydrazine hydrate and Raney nickel.[496]

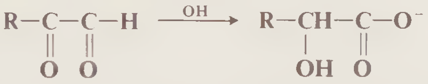
Reactions in Which an Organic Substrate Is Both Oxidized and Reduced

Some reactions which belong in this category have been considered in earlier chapters. Among these are the Tollens' condensation (reaction **6-46**), the benzil-benzilic acid rearrangement (reaction **8-7**), and the Wallach rearrangement (reaction **8-50**).

9-74 The Cannizzaro Reaction

$$2\mathrm{ArCHO} \xrightarrow{\mathrm{NaOH}} \mathrm{ArCH_2OH} + \mathrm{ArCOO^-}$$

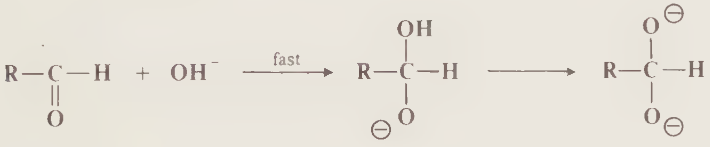
Aromatic aldehydes, and aliphatic ones with no α-hydrogen, give the *Cannizzaro reaction* when treated with NaOH or other strong bases.[497] In this reaction one molecule of aldehyde oxidizes another to the acid and is itself reduced to the primary alcohol. Aldehydes with an α-hydrogen do not give the reaction, because when these compounds are treated with base the aldol condensation (reaction **6-40**) is much faster.[498] Normally, the best yield of acid or alcohol is 50% each, but this can be altered in certain cases. When the aldehyde contains a hydroxide group in the ring, then excess base oxidizes the alcohol formed, and the acid can thus be prepared in high yield (the OH^- is reduced to H_2). On the other hand, high yields of alcohol can be obtained from almost any aldehyde by running the reaction in the presence of formaldehyde. In this case the formaldehyde reduces the aldehyde to alcohol and is itself oxidized to formic acid. In such a case, where the oxidant aldehyde differs from the reductant aldehyde, the reaction is called the *crossed Cannizzaro reaction.* The Tollens' condensation (reaction **6-46**) includes a crossed Cannizzaro reaction as its last step. α-Keto aldehydes give internal Cannizzaro reactions:



$$\mathrm{R{-}C({=}O){-}C({=}O){-}H} \xrightarrow{\mathrm{OH}} \mathrm{R{-}CH(OH){-}C({=}O){-}O^-}$$

This product is also obtained on alkaline hydrolysis of compounds of the formula $RCOCHX_2$. Similar reactions have been performed on α-keto acetals[499] and γ-keto aldehydes.

The mechanism of the Cannizzaro reaction involves a hydride shift (an example of mechanism type 2, p. 1075). First OH^- adds to the C=O to give **47**, which may lose a proton in the basic solution to give the diion **48**.



$$\mathrm{R{-}C({=}O){-}H} + \mathrm{OH^-} \xrightarrow{\text{fast}} \mathrm{R{-}C(OH)(O^-){-}H} \longrightarrow \mathrm{R{-}C(O^-)_2{-}H}$$

47 **48**

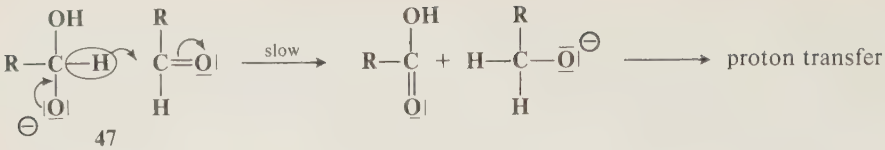
The strong electron-donating character of O^- greatly facilitates the ability of the aldehydic hydrogen to leave with its electron pair. Of course this effect is even stronger in **48**. When the hydride does leave it attacks another molecule of aldehyde. The hydride may come from **47** or **48**:

---

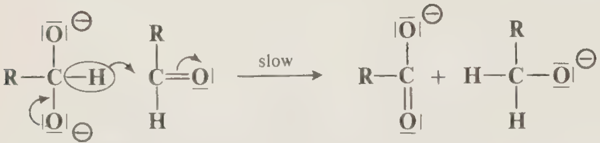
[497] For a review, see Geissman, *Org. React.* **2**, 94–113 (1944).

[498] An exception is cyclopropanecarboxaldehyde: van der Maeden, Steinberg, and de Boer, *Recl. Trav. Chim. Pays-Bas* **91**, 221 (1972).

[499] Thompson, *J. Org. Chem.* **32**, 3947 (1967).



47



48

If the hydride ion comes from **47**, then the final step is a rapid proton transfer. In the other case, the acid salt is formed directly, and the alkoxide ion acquires a proton from the solvent. Evidence for this mechanism is: (1) The reaction may be first order in base and second order in substrate (thus going through **47**) or, at higher base concentrations, second order in each (going through **48**); and (2) when the reaction was run in D_2O, the recovered alcohol contained no α-deuterium, indicating that the hydrogen comes from another mole of aldehyde and not from the medium.[500]

OS **I,** 276; **II,** 590; **III,** 538; **IV,** 110.

9-75 The Tishchenko Reaction

$$2\mathrm{RCHO} \xrightarrow{\mathrm{Al(OEt)_3}} \mathrm{RCOOCH_2R}$$

When aldehydes, with or without α-hydrogen, are treated with aluminum ethoxide, one molecule is oxidized and another reduced, as in reaction **9-74,** but here they are found as the ester. The process is called the *Tishchenko reaction.* Crossed Tishchenko reactions are also possible. With more strongly basic alkoxides, such as magnesium or sodium alkoxides, aldehydes with an α-hydrogen give the aldol condensation. Like reaction **9-74,** this reaction has a mechanism that involves hydride transfer.[501] The Tishchenko reaction can also be catalyzed by boric acid.[502]

OS **I,** 104.

9-76 The Willgerodt Reaction

$$\mathrm{ArCOCH_3} \xrightarrow{\mathrm{(NH_4)_2S_x}} \mathrm{ArCH_2CONH_2} + \mathrm{ArCH_2COO^-}\ \ \mathrm{NH_4^+}$$

In the *Willgerodt reaction* a straight- or branched-chain aryl alkyl ketone is converted to the amide and/or the ammonium salt of the acid by heating with ammonium polysulfide.[503] The carbonyl group of the product is always at the end of the chain. Thus $ArCOCH_2CH_3$ gives the amide and the salt of $ArCH_2CH_2COOH$, and $ArCOCH_2CH_2CH_3$ gives derivatives of $ArCH_2$-CH_2CH_2COOH. However, yields sharply decrease with increasing length of chain. The reaction has also been carried out on vinyl and ethynyl aromatic compounds and on aliphatic ketones, but yields are usually lower in these cases. The use of sulfur and a dry primary or secondary amine (or ammonia) as the reagent is called the *Kindler modification* of the Willgerodt reaction.[504] The product in this case is $Ar(CH_2)_nCSNR_2$, which can be hydrolyzed to the acid.[505] Particularly good results are obtained when morpholine is used as the amine.

---

[500] Fredenhagen and Bonhoeffer, *Z. Phys. Chem., Abt. A* **181,** 379 (1938); Hauser, Hamrick, and Stewart, *J. Org. Chem.* **21,** 260 (1956).

[502] Stapp, *J. Org. Chem.* **38,** 1433 (1973).

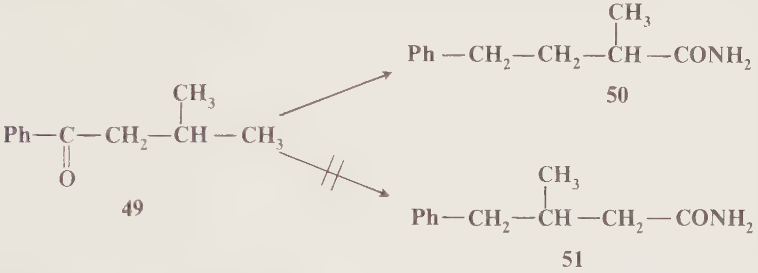
[503] For reviews, see Brown, *Synthesis* 358–375 (1975); Wegler, Kühle, and Schäfer, *Angew. Chem.* **70,** 351-367 (1958), *Newer Methods Prep. Org. Chem.* **3,** 1–51 (1964); Carmack and Spielman, *Org. React.* **3,** 83–107 (1946).

Compounds of the form $ArCOCH_3$ (acetophenones) can be converted to arylacetic acid derivatives in an entirely different manner. The reaction consists of treatment of the substrate with thallium(III) nitrate in acidic methanol, and the product is a methyl arylacetate.[506] Yields

$$\mathrm{ArCOCH_3} \xrightarrow[\mathrm{MeOH-H^+}]{\mathrm{Tl(NO_3)_3}} \mathrm{ArCH_2COOMe}$$

are moderate to high.

The mechanism of the Willgerodt reaction is not completely known, but some conceivable mechanisms can be excluded by the facts which are known. Thus, one might suppose that the alkyl group becomes completely detached from the ring and then attacks it with its other end. However, this possibility is ruled out by experiments such as the following: When isobutyl phenyl ketone (**49**) is subjected to the Willgerodt reaction, the product is **50**, and not **51**, which would arise if the end carbon of the ketone became bonded to the ring in the product:[507]



49 **50** **51**

This also excludes a cyclic-intermediate mechanism similar to that of the Claisen rearrangement (reaction **8-38**). Another important fact is that the reaction is successful for singly branched side chains, such as **49**, but not for doubly branched side chains, as in $PhCOCMe_3$.[507] Still another piece of evidence is that compounds oxygenated along the chain give the same products; thus $PhCOCH_2CH_3$, $PhCH_2COMe$, and $PhCH_2CH_2CHO$ all give $PhCH_2CH_2CONH_2$.[508] All these facts point to a mechanism consisting of consecutive oxidations and reductions along the chain. Just what form these take is not certain, though a number of theories have been proposed. Initial reduction to the hydrocarbon may be ruled out, since alkylbenzenes do not give the reaction. In certain cases imines[509] or enamines[510] have been isolated from primary and secondary amines, respectively, and these have been shown to give the normal products, leading to the suggestion that they may be reaction intermediates.

Appendix A

The Literature of Organic Chemistry

All discoveries made in the laboratory must be published somewhere if the information is to be made generally available. A new experimental result which is not published might as well not have been obtained, insofar as it benefits the entire chemical world. The total corpus of chemical knowledge (called *the literature*) is located on the combined shelves of all the chemical libraries in the world. If anyone wishes to learn whether the answer to any chemical question is known and, if so, what the answer is, he has only to turn to the contents of these shelves. Indeed the very expressions "is known," "has been done," etc., really mean "has been published." To the uninitiated, the contents of the shelves may appear formidably large, but fortunately the process of extracting information from the literature of organic chemistry is usually not difficult and often not even time-consuming. In this appendix we shall examine the literature of organic chemistry, confining our attention chiefly to the results of laboratory work, rather than those of industrial organic chemistry.[1] The literature can be divided into two broad categories, *primary sources* and *secondary sources*. A primary source publishes the original results of laboratory investigations. Books, indexes, and other publications which cover material which has previously been published in primary sources may be called secondary sources. It is because of the excellence of the secondary sources in the field of organic chemistry (especially *Chemical Abstracts* and Beilstein) that literature searching is comparatively not difficult. The two chief kinds of primary source are journals and patents. There are several types of secondary source.

PRIMARY SOURCES

Journals

For the last hundred years, nearly all new work in organic chemistry (except for that which has been disclosed in patents) has been published in journals. There are thousands of journals which publish chemical papers, in many countries and in many languages. Most are published by chemical and other scientific societies, but some are published by private companies. Some print papers covering all fields of science; some are restricted to chemistry; some to organic chemistry; and there are a few that are still more specialized. Fortunately for the sanity of organic chemists, the vast majority of important papers in "pure" organic chemistry (as opposed to "applied") are published in relatively few journals, perhaps 60 or fewer. Of course, this is still a large number (and it is growing all the time), especially since some are published weekly and some semimonthly, but it is considerably smaller than the total number of journals (perhaps as high as 10,000) which publish chemical articles.

---

[1] For monographs on the chemical literature, see Woodburn, "Using the Chemical Literature," Marcel Dekker, Inc., New York, 1974; Mellon, "Chemical Publications," 4th ed., McGraw-Hill Book Company, New York, 1965; Crane, Patterson, and Marr, "A Guide to the Literature of Chemistry," 2d ed., John Wiley & Sons, Inc. New York, 1957. For a three-part article on the literature of organic chemistry, see Hancock, *J. Chem. Educ.* **45,** 193–199, 260–266, 336–339 (1968).

In addition to ordinary papers, there are two other types of publications in which original work is reported: *notes* and *communications*. A note is a brief paper, usually published without a summary (most papers are published with summaries or abstracts prepared by the author). Otherwise, a note is similar to a paper. In recent years, the use of notes has been declining, and some journals no longer publish them. Communications (also called *letters*) are also brief and also usually without summaries (though some journals now publish summaries along with their communications, a welcome trend). However, communications differ from notes and papers in three respects:

1. They are brief, not because the work is of small scope, but because they are condensed. Usually they include only the most important experimental details or none at all.
2. They are of immediate significance. Journals which publish communications make every effort to have them appear as soon as possible after they are received. Some papers and notes are of great importance, and some are of lesser importance; but all communications are supposed to be of high importance.
3. Communications are preliminary reports, and the material in them may be republished as papers or notes, at a later date, in contrast to the material in papers and notes, which cannot be republished.

Although papers (we use the term in its general sense, to cover notes and communications also) are published in many languages, the English-speaking chemist is in a fairly fortunate position. At present more than half of the important papers in organic chemistry are published in English. Not only are American, British, and British Commonwealth journals published almost entirely in English, but so are many others around the world. There are predominantly English-language journals published in Japan, Italy, Czechoslovakia, Sweden, the Netherlands, Israel, and other countries. Most of the articles published in other languages have summaries, or at least titles, printed in English also. Furthermore, the second most important language (in terms of the number of organic chemical papers published) is Russian, and most of these papers are available in English translation, though in most cases 6 months to a year later. A considerable number of important papers are published in German and French, and these are generally not available in translation, so that the organic chemist should have at least a reading knowledge of these languages. An exception is the journal *Angewandte Chemie*, which in 1962 became available in English under the title *Angewandte Chemie International Edition in English*. Of course, a reading knowledge of French and German (especially German) is even more important for the older literature. Before about 1920, more than half of the important chemical papers were in these languages. It must be realized that the original literature is never obsolete. Secondary sources become superseded or outmoded, but nineteenth-century journals may be found in most chemical libraries and are still consulted. Table 1 presents a list of the more important current journals which publish original papers[2] and communications in organic chemistry.[3] Some of them also publish review articles, notes on meetings, book reviews, and other material. Changes in journal title are not infrequent; footnotes to the table indicate some of the more important, but some of the other journals listed have also undergone title changes.

Patents

In many countries, including the United States, it is possible to patent a new compound or a new method for making a known compound (either laboratory or industrial procedures), so long as the compounds are useful. It comes as a surprise to many to learn that a substantial proportion

---

[2] In Table 1 notes are counted as papers.

[3] See Mellon and Crane, Patterson, and Marr, Ref. 1, for longer lists of journals, including discontinued ones.

TABLE 1 A list of the more important current journals which publish original papers in organic chemistry, listed in alphabetical order of *Chemical Abstracts* abbreviations, which are indicated in boldface

Also indicated are the principal languages (E = English, G = German, F = French, R = Russian), the number of issues per year as of 1976 (exclusive of issues devoted entirely to indexes), and whether the journal primarily publishes papers (including in some cases notes) (P) or communications (C)

[4] These journals are available in English translation; see Table 2.

[5] These journals also publish review articles.

[6] Former title: **Canadian Journal of Research, Section B.**

[7] Former title: **Berichte der deutschen chemischen Gesellschaft.**

[8] Division of *C. R.* into four sections began in 1966. Series C covers all fields of chemistry. The other series cover physics, geology, etc.

[9] Successor to **Proceedings** of the **Chemical Society**, which appeared from 1957 to 1964.

[10] Beginning with 1966, and until 1971, *J. Chem. Soc.* was divided into three sections, *A*, *B*, and *C*. Starting with 1972, Section *B* became *Perkin Trans. 2*, and Section *C* became *Perkin Trans. 1*. Section *A* (Physical and Inorganic Chemistry) was further divided into *Faraday* and *Dalton Transactions*.

[11] *Pure Appl. Chem.* publishes IUPAC reports and lectures given at IUPAC meetings.

TABLE 2 Journals from Table 1 which are available in English translation
The numbers are keyed to those of Table 1; the year of first translation is given in parentheses

2. Angewandte Chemie, International Edition in English (1962)
18. Doklady Chemistry (English Translation) (1956)
24. Bulletin of the Academy of Sciences of the USSR, Division of Chemical Science (1952)
52. Journal of General Chemistry of the USSR (1949)
53. Journal of Organic Chemistry USSR (1965)

of the patents granted (on the order of 20 to 30%) are chemical patents. Chemical patents are part of the chemical literature, and both U.S. and foreign patents are regularly abstracted by *Chemical Abstracts*. In addition to learning about the contents of patents from this source, chemists may consult the *Official Gazette* of the U.S. Patent Office, which, published weekly and available in most libraries, lists titles of all patents issued that week. Bound volumes of all U.S. patents are kept in a number of large libraries, including the New York Public Library, which also has an extensive collection of foreign patents. Photocopies of any U.S. patent and of most foreign patents can be obtained at low cost from the U.S. Patent Office, Washington, D.C., 20231. In addition, *Chemical Abstracts* lists, in the introduction to the first issue of each volume, instructions for obtaining patents from 26 countries. The same compound or method is often patented in several countries. In such cases, *CA* abstracts only the first patent but relates the numbers of similar patents in a *patent concordance*, carried in each issue.

Although patents are often very useful to the laboratory chemist, and no literature search is complete which neglects relevant patents, as a rule they are not so reliable as papers. There are two reasons for this:

1. It is in the interest of the inventor to claim as much as possible. Therefore he may, for example, actually have carried out a reaction with ethanol and with 1-propanol, but he will claim all primary alcohols, and perhaps even secondary and tertiary alcohols, glycols, and phenols. An investigator repeating the reaction on an alcohol which the inventor did not use may find that the reaction gives no yield at all. In general, it is safest to duplicate the *actual examples* given, of which most chemical patents contain one or more.

2. Although legally a patent gives an inventor a monopoly, it is up to him to protect any alleged infringements in court, and this may cost a good deal of money. Therefore some patents are written so that certain essential details are concealed or entirely omitted. This practice is not exactly cricket, because a patent is supposed to be a full disclosure, but patent attorneys are generally skilled in the art of writing patents, and procedures given are not always sufficient to duplicate the results.

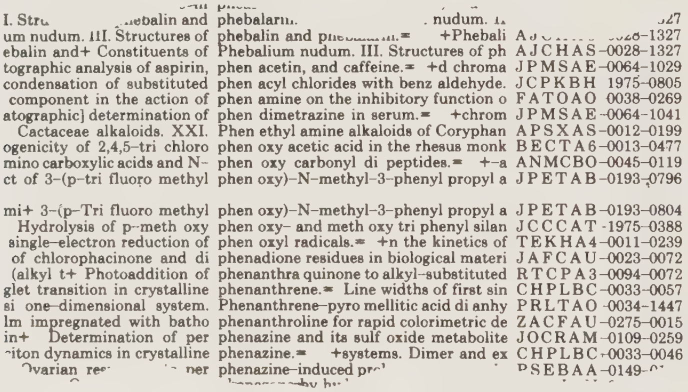
Fortunately, the above statements do not apply to all chemical patents: many make full disclosures and claim only what was actually done. It must also be pointed out that it is not always possible to duplicate the work reported in *every* paper in a journal. In general, however, the laboratory chemist must be more wary of patents than of papers.

SECONDARY SOURCES

Journal articles and patents contain virtually all of the original work in organic chemistry. However, if this were all—if there were no indexes, guides, review articles, and other secondary sources—the literature would be unusable, because it is so vast that no one could hope to find anything in particular. Fortunately, the secondary sources are excellent. They are of various kinds, and the categories tend to merge. Our classification is somewhat arbitrary.

Listings of Titles

The profusion of original papers is so great that publications which merely list the titles of current papers find much use. Such lists are primarily methods of alerting the chemist to useful papers published in journals which he does not normally read. There are two "title" publications covering the whole of chemistry. One of these, *Current Contents Physical and Chemical Sciences,*[12] which began in 1967 and appears weekly, contains the contents pages of all issues of about 700 journals in chemistry, physics, mathematics, and allied sciences. Russian titles are translated into English, but the titles of German and French papers are mostly given in the original. Each issue contains an author index, which, however, lists only the first-named author of each paper. The author's address is also given, so that one may write for reprints. The other "title" publication is *Chemical Titles*, begun in 1961, which is published by Chemical Abstracts Service and is produced by a computer. This biweekly publication lists titles from about 710 chemical journals. All the titles are given in English. The most useful aspect of this publication is the way the titles are given. They are listed in alphabetical order of *every word in the title*, except for such words as "the," "of," "investigation," "synthesis," etc. (each issue contains a list of words prevented from indexing). This means that a title containing seven significant words is listed seven times. Furthermore, at each listing are given the words which immediately precede and follow the alphabetically listed word (called the *keyword*). For example, two short portions of the issue of July 14, 1975, appear thus:



```

---

[12] Title pages of organic chemistry journals are also carried by *Current Contents Life Sciences*, which is a similar publication covering biochemistry and medicine.

Note that a paper entitled "Darzens Condensation. III. Effects of Substituents on the Rate of Condensation of Substituted Phenacyl Chlorides with Benzaldehyde" is listed under *phenacyl* and under *condensation* (twice). It is also listed under *Darzens*, *rate*, *acyl*, *chlorides*, *benzaldehyde*, and *aldehyde*, making nine listings in all. Certain words (e.g., phenacyl, benzaldehyde) are broken into two or more parts so that additional listings may be obtained. The = sign indicates the end of a title. The value of the index is increased by a "wraparound" feature. If the keyword ends (or begins) the title, what would otherwise be empty space is filled by as many words from the *beginning* (or the end) of the title as will fit. For example, at the entry under the keyword *phenanthrene*, in the above example, appears the title "Line Widths of First Singlet Transition in Crystalline Phenanthrene." The computer has room in front of the keyword only for *glet transition in crystalline*. The remainder of the title, *Line widths of first sin* is therefore placed at the end of the line. Where the wraparound feature is used but the entire title still will not fit, the symbol + is given. This type of listing is called a *Keyword-in-Context* (KWIC) index and is obviously highly useful. For example, anyone interested in thiadiazole or any of its derivatives has only to look it up in *Chemical Titles* to find at once all the papers (in that issue) in which this word appears in the title (the July 14, 1975, issue contains eight such listings). The code number given at each entry refers to the source. For example, for the title on the Darzens condensation, mentioned above, the number is JCPKBH-1975-0805. The symbols have the following meanings: JCPKBH means *J. Chem. Soc., Perkin Trans. 2;* 1975 is the volume number (actually in this instance 1975 is the year, because this journal has no volume numbers); and 0805 is the page number (805). In the second section of each issue (called the Bibliography) the complete titles and the authors are given. Incidentally, this Bibliography duplicates, for the journals which they both cover, the listings in *Current Contents Physical and Chemical Sciences*, since the complete contents of journals are given in order of page number. Each issue of *Chemical Titles* has an author index, covering all authors, not just the first author, but addresses are not given.

Abstracts

Listings of titles are valuable, as far as they go, but they do not tell what is in the paper, beyond the implications carried by the titles. From the earliest days of organic chemistry, abstracts of papers have been widely available, often as sections of journals whose principal interests lay elsewhere.[13] At the present time there are only two publications entirely devoted to abstracts covering the whole field of chemistry. One of these, *Referativnyi Zhurnal, Khimiya*, which began in 1953, is published in Russian and is chiefly of interest to Russian-speaking chemists. The other is *Chemical Abstracts*. This publication, which appears weekly, prints abstracts in English of virtually every paper containing original work in pure or applied chemistry published anywhere in the world. Approximately 14,000 journals are covered, in many languages. In addition, *CA* publishes abstracts of every U.S., Austrian, British, Canadian, French, German, and South African patent of chemical interest, as well as of many patents from 19 other countries. *CA* lists and indexes but does not abstract review articles and books. The abstracts currently appear in 80 sections, of which sections 21 to 34 are devoted to organic chemistry, under such headings as Noncondensed Aromatic Compounds, Heterocyclic Compounds (One Hetero Atom), Terpenoids, etc. Each abstract of a paper begins with a heading which gives (1) the abstract number;[14] (2) the title of the paper; (3) the authors' names as fully as given in the paper; (4) the authors' addresses; (5) the abbreviated name of the journal (see Table 1);[15] (6) the year, volume, issue, and page numbers; and (7) the language of the paper. In earlier years *CA* gave the language only if it differed from the language of the journal title. Abstracts of patents begin with the title, inventor and company (if any), patent number, patent class number, date patent issued, date patent applied for, and number of pages in the patent. The body of the abstract is a concise summary of the information in the paper. For certain common journals, e.g., *J. Am. Chem. Soc.*, *J. Org. Chem.*, *J. Chem. Soc.*, the author's summary (if there is one) is used in *CA* as it appears in the original paper, with perhaps some editing and additional information. Each issue of *CA* contains an author index, a patent number index, a patent concordance (see p. 1147), and a keyword index, similar to the KWIC index of *Chemical Titles* (p. 1149). However, the words in the *CA* keyword index are taken from the titles *and* the texts or contexts of the abstracts. No words are given before the keyword and only two or three after. Of course, these additional words are less necessary here, since the user can immediately refer to the abstract, while in *Chemical Titles* no information is given beyond the title.

---

[13] For example, *Chem. Ind. (London)* and *Synthesis* publish abstracts of papers which appear in other journals. In the past, such journals as *J. Am. Chem. Soc.*, *J. Chem. Soc.*, and *Ber.* also did so.

[14] Beginning in 1967. See p. 1151.

[15] These abbreviations are changed from time to time. Therefore the reader may notice inconsistencies.

Chemical Abstracts is, of course, highly useful for "current awareness"; it allows one to read, in one place, abstracts of virtually all new work in chemistry, though its large size puts a limit on the extent of this type of usefulness. *CA* is even more useful as a repository of chemical information, a place for finding out what was done in the past. This value stems from the excellent indexes, which enable the chemist in most cases quickly to ascertain where information is located. From the time of its founding in 1907 until 1961, *CA* published annual indexes.[16] Since 1962 there are two volumes published each year, and a separate index is issued for each volume. For each volume there is an index of subjects, authors, formulas, and patent numbers. Beginning in 1972 the subject index has been issued in two parts, a chemical substance index and a general subject index, which includes all entries which are not the names of single chemical substances. However, the indexes to each volume become essentially superseded as collective indexes are issued. The first collective indexes are ten-year (decennial) indexes, but the volume of information has made five-year indexes necessary in recent years. Collective indexes so far published or planned are:

Coll. index	Subject	Chemical substance	Author	Formula	Patent number
1	1907–1916		1907–1916		
2	1917–1926		1917–1926		1907–1936
3	1927–1936		1927–1936	1920–1946	
4	1937–1946		1937–1946		1937–1946
5	1947–1956		1947–1956	1947–1956	1947–1956
6	1957–1961		1957–1961	1957–1961	1957–1961
7	1962–1966		1962–1966	1962–1966	1962–1966
8	1967–1971		1967–1971	1967–1971	1967–1971
9	1972–1976	1972–1976	1972–1976	1972–1976	1972–1976

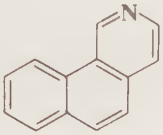
Thus a user of the indexes at this time would consult the collective indexes through 1971 or 1976 and the semiannual indexes thereafter.

Beginning with the eighth collective index period, *CA* has published an *Index Guide*. This publication gives structural formulas and/or alternate names for thousands of compounds, as well as many other cross references. It is designed to help the user efficiently and rapidly to find *CA* references to his subjects of interest in the general subject, formula, and chemical substance indexes. There is an *Index Guide* for the eighth collective index, covering 1967–1971. Beginning with 1972, a number of changes were introduced into the *CA* indexing practices, including some nomenclature changes, as well as improvements in content, range, and format. The *Index Guide* for vol. 76 (January-June 1972) is a guide to these changes. Annual cumulative supplements have been issued thereafter, and they will all be cumulated in the vol. 85 *Index Guide*. Thus at this time, a user would consult the 1967–1971 *Index Guide* for the eighth collective index period; while for the ninth collective index period one would consult first the most recent annual *Index Guide Supplement* and then the vol. 76 *Index Guide*.

---

[16] The subject and formula indexes for 1960 and 1961 are each in two parts: January to June, and July to December.

Along with each index (annual, semiannual, or collective) appears an index of ring systems. This valuable index enables the user to ascertain immediately if any ring system appears in the corresponding subject or chemical substance index and under what names. For example, someone wishing to determine whether any compounds containing this ring system



Benz(*h*)isoquinoline

are reported in the 1967–1971 collective index (even if he or she did not know the name) would turn to the listing **6, 6, 6** (since the compound has three rings of six members each), under which he or she would find the sublisting $C_5N—C_6—C_6$ (since one ring contains five carbons and a nitrogen while the others are all-carbon), under which is listed the name benz(*h*)isoquinoline, as well as the names of 37 other systems $C_5N—C_6—C_6$. A search of the subject index under these names will give all references to these ring systems which have appeared in *CA* from 1967 to 1971.

Before 1967, *CA* used a two-column page, with each column separately numbered. A row of letters from *a* to *h* appeared down the center of the page. These letters are for the guidance of the user. Thus an entry 7337*b* refers to the *b* section of column 7337. In early years superscript numbers, e.g., 4327^5, were used in a similar manner. In very early years these numbers were not printed on the page at all, though they are given in the decennial indexes, so that the user must mentally divide the page into nine parts. Beginning with 1967, abstracts are individually numbered, and column numbers are discarded and replaced with page numbers. Therefore, beginning with 1967, index entries give abstract number rather than column number. The abstract numbers are followed by a letter which serves as a check character to prevent miscopying errors in computer handling. To use the *CA* subject, chemical substance, and formula indexes intelligently requires practice, and the student should familiarize himself with representative volumes of these indexes and with the introductory sections to them, as well as with the *Index Guides*.

The indexes today are as complete as the *CA* staff can make them: about one-half of the total *CA* effort goes into indexes. However, in earlier years, especially before 1920, *CA* indexes were not so complete.

CA uses the *Hill system* for its formula indexes: formulas are listed in order of (1) number of carbon atoms; (2) number of hydrogen atoms; and (3) other elements in alphabetical order. Thus, all C_3 compounds are listed before any C_4 compound; all C_5H_7 compounds before any C_5H_8 compound; $C_7H_{11}Br$ before $C_7H_{11}N$; $C_9H_6N_4S$ before C_9H_6O, etc. Deuterium and tritium are represented by D and T and treated alphabetically; e.g., C_2H_5DO after C_2H_5Cl and before C_2H_5F or C_2H_6.

Although *CA* and *Referativnyi Zhurnal, Khimya* are currently the only chemical abstracting publications which cover the entire field of chemistry, there were a number of earlier abstracting publications which have now ceased publication. The most important of these are *Chemisches Zentralblatt* and *British Abstracts*. These publications are still valuable because they began before *CA* and can therefore supply abstracts for papers which appeared earlier than 1907. Furthermore, even for papers published after 1907, *Zentralblatt* and *British Abstracts* are often more detailed. *Zentralblatt* was published, under various names, from 1830 to 1969.[17] *British Abstracts* was a separate publication from 1926 to 1953, but earlier abstracts from this source are available in the *Journal of the Chemical Society* from 1871 to 1925.

Another publication should also be mentioned here. *Current Abstracts of Chemistry and Index Chemicus*, begun in 1960, and appearing weekly, is largely devoted to printing structural formulas of all *new* compounds appearing in about 110 journals, with monthly formula, subject, author, and journal indexes, which are cumulated semiannually and annually.

Beilstein

This publication is so important to organic chemistry that it deserves a section by itself. Beilstein's "Handbuch der organischen Chemie" (in German), usually referred to as *Beilstein*, lists all the known organic compounds which were reported in the literature during its period of coverage. For each compound the following data are given: all names, the molecular formula, the structural formula, all methods of preparation (briefly, e.g., "by refluxing 1-butanol with NaBr and sulfuric acid"), physical constants such as melting point, refractive index, etc., other physical properties, chemical properties including reactions, occurrence in nature (i.e., which species it was isolated from), biological properties if any, derivatives with melting points, analytical data, and any other information which has been reported in the literature. Equally important, for every piece of information, a reference is given to the original literature. Some compounds are discussed in two or three lines, and others require several pages. The value of such a work should be obvious to all.

For many years a degree of training was required in order to use Beilstein, but the publication of a formula index now makes it fairly easy to use. The first three editions are obsolete. The fourth edition (*vierte Auflage*) covers the literature from its beginnings through 1909. This edition, called *das Hauptwerk*, consists of 27 volumes. The compounds are arranged in order of a system which is too elaborate to discuss fully here.[18] The compounds are divided into three divisions which are further subdivided into "systems":

Division	Volumes	System numbers
I. Acyclic compounds	1–4	1–449
II. Carbocyclic compounds	5–16	450–2359
III. Heterocyclic compounds	17–27	2360–4720

Das Hauptwerk is still the basis of Beilstein and has not been superseded. The later literature is covered by supplements, which have been arranged to parallel *das Hauptwerk*. The same system is used, so that the compounds are treated in the same order. The first supplement (*erstes*

---

[17] An "obituary" of *Zentralblatt*, by Weiske, which gives its history and statistical data about its abstracts and indexes, was published in the April 1973 issue of *Chem. Ber.* (pp. I–XVI).

[18] An English-language guide to the Beilstein system has recently been published: Weissbach, "A Manual for the Use of Beilstein's Handbuch der Organischen Chemie," Springer-Verlag, New York, 1976. An older work, which many students will find easier to follow, is by Huntress, "A Brief Introduction to the Use of *Beilstein's Handbuch der Organischen Chemie*," 2d ed., John Wiley & Sons, Inc., New York, 1938. For a brief description of the system, see Hendrickson, Cram, and Hammond, "Organic Chemistry," 3d ed., McGraw-Hill Book Company, New York, 1970.

Ergänzungswerk) covers 1910–1919; the second supplement (*zweites Ergänzungswerk*) covers 1920–1929; the third supplement (*drittes Ergänzungswerk*) covers 1930–1949; and the fourth supplement (*viertes Ergänzungswerk*) covers 1950–1959. Like *das Hauptwerk*, each supplement contains 27 volumes,[19] except that supplements 3 and 4 have been combined beginning with vol. 17, so that for vols. 17 to 27 the combined third and fourth supplement covers the years 1930–1959. Each supplement has been divided into volumes in the same way as *das Hauptwerk*, and, for example, compounds found in vol. 3, system number 199, of *das Hauptwerk* will also be found in vol. 3, system number 199, of each supplement.[20] To make cross-referencing even easier, each supplement gives, for each compound, the page numbers at which the same compound may be found in the earlier books. Thus, on page 545 of vol. 6 of the third supplement, under the listing phenetole are found the symbols (H 140; E I 80; E II 142) indicating that earlier information on phenetole is given on page 140 of vol. 6 of *das Hauptwerk*, on page 80 of the first and page 142 of the second supplement. Furthermore, each page of the supplements contains, at the top center, the corresponding page numbers of *das Hauptwerk*. Since the same systematic order is followed in all five series, location of a compound in any one series gives its location in the other four. If a compound is found, for example, in vol. 5 of *das Hauptwerk*, one has but to note the page number and scan vol. 5 of each supplement until that number appears in the top center of the page (of course, the same number may cover several pages). Of course, many compounds are found in only one, two, three, or four of the series, since no work may have been published on that compound during the period covered. Although a given volume of Beilstein is complete to the end of the time period specified, volumes in the second, third, and fourth supplements often contain material which goes considerably beyond that period. For example, p. 3962 of vol. 1 of the fourth supplement (1950–1959) contains references to papers published in 1968 and 1971.

Volumes 28 and 29 of Beilstein are subject and formula indexes, respectively. The most recent complete edition of these volumes is part of the second supplement, and it makes the earlier indexes obsolete, since these indexes are collective: they cover *das Hauptwerk* and the first two supplements. For vol. 1 there is a cumulative subject and a cumulative formula index, which combine *das Hauptwerk* and all four supplements.[20a] It is likely that similar cumulative indexes will be issued for subsequent volumes. For English-speaking chemists (and probably for many German-speaking chemists) the formula indexes are more convenient. Of course, one must still know some German, for most formula listings contain the names of many isomers. If a compound is found only in *das Hauptwerk*, the index listing is merely the volume and page numbers, for example, **1**, 501. Roman numbers are used to indicate the supplements, for example, **26**, 15, I 5, II 7. Thus the subject and formula indexes lead at once to locations in *das Hauptwerk* and the first two supplements (and, for vol. 1, for the third and fourth supplements as well). Locating the compound in the third and fourth supplements is then simple (if that volume has already appeared) by the page-number indication mentioned above. However, the most recent edition of vols. 28 and 29 obviously can contain only compounds which have appeared in the literature before 1930. In order to ascertain if a particular compound which is not listed in vol. 28 or 29 is listed in the third and/or fourth supplements, one can follow one of two procedures. Each separately bound portion of each volume of the third and fourth supplements has its own subject and formula indexes, and several of the volumes have cumulative subject and formula indexes as well (for all the parts of one or two volumes).[21] If one knows (from an approximate knowledge of the system) in which volume the compound is likely to be found, the searcher can turn to the indexes of that volume or (with a little extra labor) can look in all the indexes. The other procedure is to learn the system—which was done by most organic chemists before the appearance of the original formula index.[18] Even an approximate knowledge of the system often helps. Like *CA*, the formula index of Beilstein uses the Hill system for arrangement of formulas (see p. 1151).[22]

---

[19] In some cases, to keep the system parallel and to avoid books which are too big or too small, volumes are issued in two or more parts, and, in other cases, two volumes are bound as one.

[20] The fourth supplement (which will eventually cover vols. 1 to 16), and the combined third and fourth supplements (which will cover vols. 17 to 27) are not yet complete. At this writing portions of vol. 2 of the former and vol. 18 of the latter are the latest to have appeared.

[20a] Most page number entries in the combined indexes for vol. 1 contain a letter, e.g., $CHBr_2Cl$ 67f, II 33a, III 87d, IV, 81. These letters tell where on the page to find the compound and are useful because the names given in the index are not necessarily those used in the earlier series. The letter a means the compound is the first on its page, b is the second, etc. No letters are given for the fourth supplement.

There is also a fourth division of Beilstein (systems 4721 to 4877) which covers natural products of uncertain structure: rubbers, sugars, etc. These are treated in vols. 30 and 31, which do not go beyond 1935 and which are covered in the collective indexes. No supplements to them have appeared.

Compendia and Tables of Information

In addition to Beilstein, there are many other reference works in organic chemistry which are essentially compilations of data. These books are very useful and often save the research worker a great deal of time. In this section we discuss some of the more important of such works.

1. Some years ago a work was announced which was to be the English equivalent of Beilstein: Elsevier's "Encyclopedia of Organic Chemistry." Three volumes were published, in more than 15 parts: vol. 12, bicyclic compounds; vol. 13, tricyclic compounds; and vol. 14, tetra- and higher-cyclic compounds. These volumes cover many natural products, especially terpenes and steroids. Although the production of the earlier volumes in the series has now been abandoned, these volumes remain valuable.

2. The fourth edition of the "Dictionary of Organic Compounds" (editorial board: Heilbron, Cook, Bunbury, and Hey), 5 vols., Oxford University Press, New York, 1965, contains brief listings of more than 40,000 organic compounds, giving names, structural formulas (in cases where there might be doubt), physical properties and derivatives, with references. For many entries additional data concerning occurrence and biological activity are also given. The arrangement is alphabetical. Annual supplements have appeared since 1965. The Fifth Cumulative Supplement (1969) combines the first five supplements, and the Tenth Cumulative Supplement (1974) combines the next five. A formula index to the main work and the Fifth Cumulative Supplement appeared in 1971.

3. A multivolume compendium of physical data is Landolt-Börnstein's "Zahlenwerte und Funktionen aus Physik, Chemie, Astronomie, Geophysik, und Technik," 6th ed., Springer-Verlag OHG, Berlin, 1950–. This compendium, which is not yet complete, lists a great deal of data, some of which are of interest to organic chemists, e.g., indexes of refraction, heats of combustion, optical rotations, and spectral data. Literature references are given for all data.

4. "The Handbook of Chemistry and Physics," Chemical Rubber Publishing Company, Cleveland, Ohio (fondly called the "rubber handbook"), which is revised annually (55th ed., 1974–1975), is a valuable repository of data quickly found. For organic chemists the most important table is "Physical Constants of Organic Compounds," which lists names, formulas, color, solubilities, and physical properties of thousands of compounds and occupies nearly half of the volume. However, there are many other useful tables. A similar work is Lange's "Handbook of Chemistry," 11th ed., McGraw-Hill Book Company, New York, 1973.

---

[21] The third supplement has cumulative indexes for vol. 5, vol. 6, vols. 7–8, vols. 9–10, and vols. 12–14. The subject indexes for vols. 7–8, 9–10, 11, and 12–14 are in English as well as German.

[22] The now obsolete formula index to the first supplement (which included *das Hauptwerk*) uses another system, called the *Richter system*, in which formulas are listed according to how many different elements they contain.

5. A list of most of the known natural compounds, e.g., terpenes, alkaloids, carbohydrates, to which structures have been assigned, along with structural formulas, melting points, optical rotations, and references, is provided in Devon and Scott, "Handbook of Naturally Occurring Compounds," 3 vols., Academic Press, Inc., New York, 1972–. Supplements are planned.

6. Dreisbach, "Physical Properties of Chemical Compounds," Advances in Chemistry Series nos. 15, 22, 29, American Chemical Society, Washington, D.C., 1955–1961, lists many physical properties of more than 1000 organic compounds.

7. Physical properties of thousands of organometallic compounds, with references, are collected in three large compendia: Dub, "Organometallic Compounds," 2d ed., 3 vols. with supplements and index, Springer-Verlag, New York, 1966–1975; Hagihara, Kumada, and Okawara, "Handbook of Organometallic Compounds," W. A. Benjamin, Inc., New York, 1968; and Kaufman, "Handbook of Organometallic Compounds," D. Van Nostrand Company, Inc., Princeton, N.J., 1961.

8. "The Merck Index of Chemicals and Drugs," 9th ed., Merck and Company, Rahway, N.J., 1976, is a good source of information about chemicals of medicinal importance. Many drugs are given three types of name: *chemical name* (which is the name an organic chemist would give it; of course, there may well be more than one); *generic name*, which must be placed on all containers of the drug; and *trade names*, which are different for each company which markets the drug. For example, the generic name for 1-(4-chlorobenzhydryl)-4-methylpiperazine dihydrochloride is chlorcyclazine hydrochloride. Among the trade names for this drug, which is an antihistamine, are Trihistan, Perazil, and Diparalene. The "Merck Index" is especially valuable because it gives all known names of all three types for each compound, and the names are cross-indexed. The index also gives, for each compound, the structural formula, physical properties, medicinal and other uses, toxicity indications, and references to methods of synthesis. The "Merck Index" also includes a lengthy list of organic name reactions, with references, as well as miscellaneous tables.

9. There are two publications which list properties of azeotropic mixtures. Timmermans, "The Physico-Chemical Constants of Binary Systems in Concentrated Solutions," 4 vols., Interscience Publishers, Inc., New York, 1959–1960, with supplements beginning 1965, is by far the more comprehensive. The other is "Azeotropic Data," 2 vols., Advances in Chemistry Series no. 6 and no. 35, American Chemical Society, Washington, D.C., 1952, 1962.

10. Calculated boiling points at many pressures are given for many compounds in Dreisbach, "Pressure-Volume-Temperature Relationships of Organic Compounds," McGraw-Hill Book Company, New York, 1952.

11. A useful source of derivative melting points is "Handbook of Tables for Organic Compound Identification," 3d ed., Chemical Rubber Publishing Company, Cleveland, Ohio, 1967.

12. Thousands of dipole moments, with references, are collected in McClellan, "Tables of Experimental Dipole Moments," W. H. Freeman and Company, San Francisco, 1963.

13. "Tables of Interatomic Distances and Configurations in Molecules and Ions," London Chemical Society Special Publication no. 11, 1958, and its supplement, Special Publication no. 18, 1965, include bond distances and angles for hundreds of compounds, along with references.

14. "The Ring Index," American Chemical Society, Washington, D.C., 1960, with supplements beginning 1963, lists, in a systematic order, names and formulas of all ring systems in the literature. References are given for each system.

15. The Sadtler Research Laboratories publish large collections of ir, uv, nmr, and other spectra, in loose-leaf form. Indexes are available.

16. Infrared, uv, nmr, Raman, and mass spectral data, as well as melting-point, boiling-point, solubility and density data, for 21,000 organic compounds are collected in the "Atlas of Spectral Data and Physical Constants for Organic Compounds," 2d ed., 6 vols., CRC Press, Cleveland, Ohio, 1973, edited by Grasselli and Ritchey. It differs from the Sadtler collection in that the data are given in tabular form (lists of peaks) rather than reproductions of the actual spectra, but this book has the advantage that all the spectral and physical data for a given compound appear on one line. References are given to the Sadtler and other collections of spectra. Volumes 5 and 6 contain indexes of spectral peaks for ir, uv, nmr, ^{13}C nmr, mass, and Raman spectra, as well as formula and physical constant indexes.

17. The "Aldrich Library of Infrared Spectra," 2d ed., Aldrich Chemical Company, Milwaukee, Wis., 1975, by Pouchert, contains more than 10,000 ir spectra so arranged that the user can readily see the change which takes place in a given spectrum when a slight change is made in the structure of a molecule.

18. An extensive list of visible and uv peaks is given in "Organic Electronic Spectral Data," Interscience Publishers, New York. Ten volumes have appeared so far, covering the literature through 1968.

19. A collection of 500 ^{13}C nmr spectra is found in Johnson and Jankowski, "Carbon-13 NMR Spectra," John Wiley & Sons, Inc., New York, 1972.

Reviews

A review article is an intensive survey of a rather narrow field; e.g., the titles of some recent reviews are "Advances in Oxazole Chemistry,"[23] "Synthesis of Cyclic Compounds via Copper-Isonitrile Complexes,"[24] and "Chemical Shift Nonequivalence in Prochiral Groups."[25] A good review article is of enormous value, because it is a thorough survey of all the work done in the field under discussion. Review articles are printed in review journals and in certain books. The most important review journals in organic chemistry (though none except *Synthesis* is exclusively devoted to organic chemistry) are, with the year of founding, principal languages, and issues per year:

Accounts of Chemical Research (1968)	E	12
Angewandte Chemie (1888)	G	24
and its English translation:		
Angewandte Chemie, International Edition in English (1962)	E	12
Chemical Reviews (1924)	E	6
Chemical Society Reviews (1947)[26]	E	4
Synthesis (1969)	EG	12
Topics in Current Chemistry (1949)[27]	EG	Irreg.
Uspekhii Khimii (1932)	R	12
and its English translation: **Russian Chemical Reviews** (1960)	E	12

Some of the journals listed on p. 1145, notably the *Bull. Soc. Chim. Fr.*, *Tetrahedron*, and *J. Organomet. Chem.* also publish occasional review articles.

There are several open-ended serial publications which are similar in contents to the review journals but are published irregularly (seldom more often than once a year) and are hardbound. Some of these publish reviews in all fields of chemistry; some cover only organic chemistry; and some specialize further. The coverage is indicated by the titles. When referring to these references, some chemists treat them as books and some as journals (as does *Chemical Abstracts*). In this book we have followed the latter course. Some of the more important such publications, with *CA* abbreviations, are

There are several publications which provide listings of review articles. One, "Index of Reviews in Organic Chemistry," compiled by Lewis, Chemical Society, London, 1971, is a classified listing of review articles from about 1960 (in some cases much earlier) to about 1970, in alphabetical order of topic. Thus four reviews are listed under "Knoevenagel condensation," five under "Inclusion compounds," and one under "Vinyl ketones." There is no index. Annual supplements have appeared beginning in 1972. Another list of review articles (unclassified, but with author and subject indexes) is found in Kharasch, Wolf, and Harrison, "Index to Reviews, Symposia Volumes, and Monographs in Organic Chemistry," Pergamon Press, New York. Three volumes have so far appeared, covering 1940–1960 (published 1962); 1961–1962 (published 1964); and 1963–1964 (published 1966). Classified lists of review articles on organometallic chemistry are found in articles by Smith and Walton[29] and by Bruce.[30] A similar list for heterocyclic chemistry is found in an article by Katritzky and Weeds.[31]

---

[28] This series ceased publication with vol. 6.

[31] Katritzky and Weeds, *Adv. Heterocycl. Chem.* **7**, 225–299 (1966).

Annual Reviews

The review articles discussed in the previous section are each devoted to a narrow topic covering the work done in that area over a period of years. An annual review is a publication which covers a broad area but limits the period covered, usually to 1 or 2 years.

1. The oldest annual review publication which is still publishing is *Annual Reports on the Progress of Chemistry*, published by the Chemical Society (London), which began in 1905, and which covers the whole field of chemistry. Since 1967, it has been divided into two sections. Organic chemistry is found in Section B.

2. Because the number of papers in chemistry has become so large, the Chemical Society has recently begun to publish annual-review-type volumes of smaller scope, called *Specialist Periodical Reports*. Among those of interest to organic chemists are "Aliphatic Chemistry" (vol. 2 covers 1972); "Aromatic and Heteroaromatic Chemistry" (vol. 2 covers 1972–1973); "Photochemistry" (vol. 5 covers 1972–1973); "Alicyclic Chemistry" (vol. 2 covers 1972); "Carbohydrate Chemistry" (vol. 7 covers 1973); "The Alkaloids" (vol. 4 covers 1972–1973); and "Terpenoids and Steroids" (vol. 4 covers 1972–1973).

3. An annual-review-type publication devoted to the broad field of organic chemistry is the "MTP International Review of Science, Organic Chemistry," published by Butterworth and Company, London, and University Park Press, Baltimore. *Series One*, consisting of 10 volumes plus an index volume, was published in 1973, and covers 1970–1971. Further series are planned, each to cover a 2-year period. The same publishers also publish similar series of volumes devoted to physical and to inorganic chemistry.

4. "Organic Reaction Mechanisms," published by John Wiley & Sons, Inc., New York, is an annual survey which covers the latest developments in the field of mechanisms. The first volume, covering 1965, appeared in 1966.

5. There are two annual reviews devoted to progress in organic synthesis. Theilheimer, "Synthetic Methods of Organic Chemistry," S. Karger Verlag, Basel, is an annual compilation, beginning in 1946, of new methods for the synthesis of organic compounds, arranged according to a system based on bond closings and bond breakings. Equations, brief procedures, yields, and literature references are given. Volume 28 was issued in 1974. Volumes 3 and 4 are available only in German, but all the rest are in English. There is an index to each volume. Cumulative indexes appear in every fifth volume. Beginning with vol. 8, each volume includes a short summary of trends in synthetic organic chemistry. A more recent series is "Annual Reports in Organic Synthesis," Academic Press, Inc., New York, which has covered the literature of each year since 1970. Equations are listed, with yields and references, according to a fairly simple system.

6. The *Journal of Organometallic Chemistry* several times a year publishes annual surveys arranged according to metallic element. For example, vol. 95, published in August 1975, contains annual surveys for 1973 of organic compounds containing Li, Mg, Pb, Cu, Ag, and Au; and for 1974 of organic compounds containing V, Nb, Ta, and the lanthanides and actinides. These annual reviews formerly appeared in *Organometallic Chemistry Reviews, Section B*, which was a separate journal published from 1968 to 1974. Still earlier (for 1964–1966), these reviews were published in book form.

General Treatises

There are a number of large-scale multivolume treatises which cover the whole field of organic chemistry or large areas of it.

1. "Rodd's Chemistry of Carbon Compounds," edited by Coffey, Elsevier Publishing Company, Amsterdam, is a treatise consisting of five main volumes, each of which contains several parts.

Publication began in 1964 and is not yet complete. The organization is not greatly different from most textbooks, but the coverage is much broader and deeper. Supplements to some of the volumes have already appeared. An earlier edition, called "Chemistry of Carbon Compounds," edited by Rodd, was published in 10 parts from 1951 to 1962.

2. Houben-Weyl's "Methoden der organischen Chemie," Georg Thieme Verlag KG, Stuttgart, is a major treatise in German devoted to laboratory methods. The fourth edition, which was begun in 1952 and consists of 16 volumes, some in several parts, is edited by E. Muller. The first four volumes contain general laboratory methods, analytical methods, physical methods, and general chemical methods. The later volumes are devoted to the synthesis of specific types of compounds, e.g., hydrocarbons, oxygen compounds, nitrogen compounds, etc.

3. Grignard's "Traité de chimie organique," 23 vols., Masson et Cie, 2d ed., Paris, 1947–1955, is another treatise which covers the whole field of organic chemistry. The coverage, which is by functional groups, is broad and deep.

4. A major treatise devoted to experimental methods of chemistry is "Techniques of Chemistry," edited by Weissberger, John Wiley & Sons, Inc., New York. This publication, which began in 1970, so far consists of eight volumes, most of them in several parts, covering such topics as electrochemical and spectral methods, kinetic methods, photochromism, and organic solvents. "Techniques of Chemistry" is a successor to an earlier series, called "Techniques of Organic Chemistry," which appeared in 14 volumes, some of them in more than one edition, from 1945 to 1969. The later volumes of this series have not yet been superseded.

5. "Comprehensive Chemical Kinetics," edited by Bamford and Tipper, 1969–, Elsevier Publishing Company, Amsterdam, is a multivolume treatise covering the area of reaction kinetics. Six of these volumes (not all published at the time of writing) deal with the kinetics and mechanisms of organic reactions in a thorough and comprehensive manner.

6. Three multivolume treatises which cover specific areas are Elderfield, "Heterocyclic Compounds," John Wiley & Sons, Inc., New York, 1950–; Manske and Holmes, "The Alkaloids," Academic Press, Inc., New York, 1950–; and Simonson, Owen, Barton, and Ross, "The Terpenes," Cambridge University Press, London, 1947–1957.

Monographs and Treatises on Specific Areas

Organic chemistry is blessed with a large number of books devoted to a thorough coverage of a specific area. Many of these are essentially very long review articles, differing from ordinary review articles only in size and scope. Some of the books are by a single author, and others have chapters by different authors but all are carefully planned to cover a specific area. Many of these books have been referred to in footnotes in appropriate places in this book. Several companies have published series of monographs of which we shall mention four of the most notable.

1. A series of unrelated monographs covering various areas of organic chemistry is published by Academic Press, Inc., New York. Thirty-one titles have been published so far. Typical books in the series are Johnson, "Ylid Chemistry," 1966; Ugi, "Isonitrile Chemistry," 1971; Trost and Melvin, "Sulfur Ylides," 1975; Cram, "Fundamentals of Carbanion Chemistry," 1965; Shamma, "The Isoquinoline Alkaloids," 1972; and Rochester, "Acidity Functions," 1970.

2. Wiley-Interscience publishes a series called "The Chemistry of Functional Groups," under the general editorship of Patai. Each volume deals with the preparation, reactions, and physical and chemical properties of compounds containing a given functional group. Volumes covering 16 functional groups have appeared so far, including books on alkenes, cyano compounds, amines, carboxylic acids and esters, quinones, etc. Several more are planned.

3. A series of monographs on reaction mechanisms is published by the Elsevier Publishing Company. Among the books so far published in this series are Bunton, "Nucleophilic Substitution at a Saturated Carbon Atom," 1963; Norman and Taylor, "Electrophilic Substitution in Benzenoid Compounds," 1965; Miller, "Nucleophilic Aromatic Substitution," 1968; Shine, "Aromatic Rearrangements," 1967; and Buncel, "Carbanions," 1974.

4. A series of monographs on "Reactive Intermediates in Organic Chemistry," under the general editorship of Olah, is published by Wiley-Interscience. One or more volumes each on carbonium ions, carbenes, nitrenes, halonium ions, free radicals, and radical ions have already appeared. Other volumes are planned.

Textbooks

There are many excellent textbooks in the field of organic chemistry. We restrict ourselves to listing only a few of those published since 1969. Some of these are first-year texts, and some are advanced (advanced texts generally give references; first-year texts do not, though they may give general bibliographies, suggestions for further reading, etc.); some cover the whole field, and others cover reactions, structure, and/or mechanism only. All the books listed here are not only good textbooks but valuable reference books for graduate students and practicing chemists.

Alder, Baker, and Brown: "Mechanism in Organic Chemistry," Wiley-Interscience, New York, 1971.

Ternay: "Contemporary Organic Chemistry," W. B. Saunders Company, Philadelphia, 1976.

Other Books

In this section we mention several books which do not fit conveniently into the previous categories. All have to do with laboratory synthesis.

1. *Organic Syntheses*, published by John Wiley & Sons, Inc., New York, is a collection of procedures for the preparation of specific compounds. The thin annual volumes have appeared each year since 1921. The procedures for each 10- (or 9-) year period are collected in cumulative volumes, in this manner:

Annual volumes	Collective volumes
1–9	**I**
10–19	**II**
20–29	**III**
30–39	**IV**
40–49	**V**

The advantage of the procedures in *Organic Syntheses*, compared with those found in original journals, is that these procedures are *tested*. Each preparation is carried out first by its author and then by a member of the *Organic Syntheses* editorial board, and only if the yield is essentially duplicated is the procedure published. While it is possible to repeat most procedures given in journals, this is not always the case. All *Organic Syntheses* preparations are noted in Beilstein and in *CA*. In order to locate a given reaction in *Organic Syntheses*, the reader may use the OS references given in the present volume (through OS **55**); the indexes in *Organic Syntheses* itself; Sugasawa and Nakai; "Reaction Index of Organic Syntheses," John Wiley & Sons, Inc., New York, 1967 (through OS **45**); or Shriner and Shriner, "Organic Syntheses Collective Volumes I, II, III, IV, V Cumulative Indices," John Wiley & Sons, Inc., New York, 1976. A similar publication is *Organic Photochemical Syntheses*, also published by John Wiley & Sons, Inc.; vol. 1 appeared in 1971.

2. Volume 1 of "Reagents for Organic Synthesis," by Fieser and Fieser, John Wiley & Sons, Inc., New York, 1967, is a 1457-page volume which discusses, in separate sections, some 1120 reagents and catalysts. It tells how each reagent is used in organic synthesis (with references) and, for each, tells which companies sell it, or how to prepare it, or both. The listing is alphabetical. Four additional volumes have so far been published, which continue the format of vol. 1, and add more recent material.

3. "Survey of Organic Synthesis," by Buehler and Pearson, John Wiley & Sons, Inc., New York, 1970, discusses hundreds of reactions used to prepare the principal types of organic compounds. The arrangement is by chapters, each covering a functional group, e.g., ketones, acyl halides, amines, etc. Each reaction is thoroughly discussed and brief synthetic procedures are given. There are many references.

4. A similar publication is Sandler and Karo, "Organic Functional Group Preparations," 3 vols., Academic Press. Inc., 1968–1972 (part of the series of Academic Press monographs mentioned on p. 1159). This publication covers more functional groups than Buehler and Pearson.

5. An older book of a similar type is "Synthetic Organic Chemistry," by Wagner and Zook, John Wiley & Sons, Inc., New York, 1953, which discusses, in separate numbered sections, the scope and limitations of 576 reactions, divided into 39 chapters, each of which covers the preparation of a specific type of compound, e.g., olefins, cyanides, lactones. An important and useful feature of the book is the large number of tables which list the best method of preparation, the yield, and physical constants, for thousands of compounds containing no more than two functional groups. References are given for all data.

6. "Compendium of Synthetic Methods," by Harrison and Harrison, John Wiley & Sons, Inc., New York, contains equations describing the preparation of about 4000 monofunctional and difunctional compounds, with references. Two volumes have been published so far (1971, 1974).

7. Two books which are rich in experimental procedures, both translated from the German, are Weygand and Hilgetag, "Preparative Organic Chemistry," edited by Hilgetag and Martini, John Wiley & Sons, Inc., New York, 1972; and Becker et al., "Organicum," translated by Hazzard, Addison-Wesley Publishing Company, Inc., Reading, Mass., 1973.

LITERATURE SEARCHING

Information about a Specific Compound

Most organic chemists find it necessary, occasionally or frequently, to search the literature for information concerning specific compounds. They may need to know if a compound has ever been prepared and if so, how, and/or they may be seeking a melting point, an ir spectrum, or some other property. The directions for this particular type of literature search are so much more specific than for other searches that we discuss them first. Someone who wants all the information that has ever been published on any compound begins by consulting the formula index to the second supplement of Beilstein (p. 1153), which quickly shows whether the compound is mentioned in the literature through 1929. If it is there, the searcher turns to the pages indicated, where all methods used to prepare the compound are given, as well as all physical properties, with references. If the compound is in a volume of Beilstein of which the third and/or fourth supplement has been published, it may be found there, by the method described on p. 1153. If the compound is not listed in the cumulative formula index (and is thus absent from the literature through 1929), the next step is to ascertain whether it is in the third or fourth supplement, which is done as described on p. 1154. If the compound is in vol. 1, for which a cumulative formula index is already available, much of this labor is unnecessary, since this index will give, in one place, the Beilstein locations in *das Hauptwerk* and all four supplements. At this point the investigator will know (1) all information published through 1959,[32] 1949,[33] or 1929,[34] or (2) that the compound is not mentioned in the literature through 1959,[32] 1949,[33] or 1929.[34] In some cases, scrutiny of Beilstein will be sufficient, perhaps if only a boiling point or a refractive index is required. In other cases, especially where specific laboratory directions are needed, the investigator will have to turn to the original papers.

To carry the search past 1929 (or 1949 or 1959), the chemist next turns to the collective formula indexes of *Chemical Abstracts:* 1920–1946; 1947–1956 (if these periods were not covered by Beilstein); 1957–1961; 1962–1966; 1967 1971; 1972–1976; such later collective indexes as have appeared; and the semiannual indexes thereafter. If a given formula index contains only a few references to the compound in question, the pages or abstract numbers will be given directly in the formula index. However, if there are many references, the reader will be directed to see the chemical substance index or (before 1972) the subject index for the same period; and here the number of page or abstract numbers may be very large indeed. Fortunately, numerous subheadings are given, and these often help the user to narrow the search to the more promising entries. Nevertheless, one will undoubtedly turn to many abstracts which do not prove to be helpful. In many cases, the information in the abstracts will be sufficient. If not, the original references must be consulted. In some cases (the index entry is marked by an asterisk or a double asterisk) the compound is not mentioned in the abstract, though it is in the original paper or patent. Incidentally, all entries in the *CA* indexes which refer to patents are prefixed by the letter P. Since 1967, the prefixes B and R have also been used, to signify books and reviews, respectively. Since 1965, each compound listed in any index of *CA* has carried a *CAS registry number*. This is a number, generated by a computer, which is assigned to each distinctly definable chemical entity and remains invariant, no matter what names are used in the literature. The registry numbers greatly facilitate computer searching. So far registry numbers have been assigned to more than 3 million substances.

---

[32] For compounds which would naturally belong to a volume for which the fourth or combined third-fourth supplement has already been published.

[33] For compounds which would naturally belong to a volume for which the third supplement has been published but not the fourth.

[34] For compounds which would naturally belong to a volume for which the combined third-fourth supplement has not yet been published.

By the procedure outlined above, all information regarding a specific compound which has been published up to about a year before the search can be found by a procedure which is always straightforward and which in many cases is rapid (if the compound has been reported only a few times). Equally important, if the compound has not been reported, the investigator will know that, too. It should be pointed out that, for common compounds, such as benzene, ether, acetone, etc., trivial mentions in the literature are not indexed (so that they will not be found by this procedure), only significant ones. Thus, if acetone is converted to another compound, an index entry will be found, but not if it is used as a solvent or an eluent in a common procedure.

There are several methods for learning whether a compound is mentioned in the literature after the period covered by the latest semiannual formula index of *CA*. One may consult *Chemical Titles* and the KWIC index (p. 1150) at the end of each issue of *CA*. In these cases, of course, it is necessary to know what name might be used for the compound. The name is not necessary for *Current Abstracts of Chemistry and Index Chemicus* (p. 1152); one consults the monthly formula indexes. However, these methods are far from complete. *Current Abstracts of Chemistry and Index Chemicus* lists primarily *new* compounds, those which would not have been found in the earlier search. As for *Chemical Titles*, the compound can be found only if it is mentioned in the title. The KWIC indexes in *CA* are more complete, being based on internal subject matter as well as title, but they are by no means exhaustive. Furthermore, all three of these publications lag some distance behind the original journals, though *Chemical Titles* is very close. There is no method for the *complete* location of all references to a compound after the period covered by the latest semiannual formula index of *CA*.

The complete procedure described above may not be necessary in all cases. Often all the information one needs about a compound will be found in one of the handbooks (p. 1154), in the "Dictionary of Organic Compounds" (p. 1154), or in one of the other compendia listed in this chapter, most of which give references to the original literature.

Other Searches[35]

There is no definite procedure for making other literature searches. If a chemist wishes to know all that is known about the mechanism of the reaction between aldehydes and HCN, or which compounds of the general formula Ar_3CR have been prepared, or which are the best catalysts for Friedel-Crafts acylation of naphthalene derivatives with anhydrides, or where the group $C(NH_2){=}NH$ absorbs in the ir, he or she is dependent on his or her ingenuity and knowledge of the literature. If a specific piece of information is needed, he or she may be able to find it in one of the compendia mentioned previously. If the topic is more general, it is often the best procedure to begin by consulting one or more monographs, treatises, or textbooks, which will give general background information and often provide references to review articles and to original papers. For example, Olah's treatise on Friedel-Crafts reactions (Ref. 166 in Chapter 11) should certainly be consulted on the Friedel-Crafts topic mentioned above. In many cases this is sufficient, but when a complete search is required, it is necessary to consult the *CA* subject and/or chemical substance indexes, where the ingenuity of the investigator is most required, for now it must be decided which words to look under. If one is interested in the mechanism of the reaction between aldehydes and HCN, one might look under "aldehydes," or "hydrogen cyanide"; or even under "acetaldehyde" or "benzaldehyde," etc., but then the search is likely to prove long. A better choice in this case would be "cyanohydrin," since these are the normal products, and references there would be fewer. It would probably be a waste of time to look under "mechanism." In any case, many of the abstracts would prove not to be helpful. Literature searching of this kind is necessarily a wasteful process. Of course, the searcher would not consult the *CA* annual indexes but only the collective indexes as far as they go and the semiannual indexes thereafter. If it is necessary to search before 1907 (and even before 1920, since *CA* was not very complete from 1907 to about 1920), recourse may be made to *Chemisches Zentralblatt* (p. 1152) and to the abstracts in the *Journal of the Chemical Society* (p. 1152).

---

[35] This discussion is necessarily short. For much more extensive discussions, see Mellon, Ref. 1, pp. 218–229; Crane, Patterson, and Marr, Ref. 1, pp. 297–325.

Science Citation Index

A publication which can greatly facilitate literature searching is the computer-produced *Science Citation Index* (*SCI*), begun in 1961. This publication, which is quite different from any other mentioned in this chapter, gives a list of all papers in a given year which have cited a given paper, patent, or book. Its utility lies in the fact that it enables the user to search *forward* from a given paper or patent, rather than backward, as is usually the case. For example, suppose a chemist is familiar with a paper by Corey, Weinshenker, Schaaf, and Huber [*J. Am. Chem. Soc.* **91,** 5675 (1969)] entitled "Stereo-controlled Synthesis of Prostoglandins $F_{2\alpha}$ and E_2 (*dl*)." The chemist is easily able to begin a search for earlier papers by using references supplied in this paper and can then go further backward with the aid of references in those papers, etc. But for obvious reasons the paper itself supplies no way to locate *later* papers. *SCI* is designed to make up for this gap. The citation index of *SCI* lists all papers, patents, or books cited in a given year or quarter (by first author only) and then gives a list of papers which have done the citing. The index is published quarterly and cumulated annually. For example, column 7226 of the 1974 *Citation Index* shows that the Corey paper mentioned above was cited as a footnote in 19 papers published in 1974 or late 1973. It is reasonable to assume that most of the papers which cited the Corey paper were on closely related subjects. For each of the 19 papers are listed the first author, journal abbreviation, volume and page numbers, and year. In a similar manner, if one consulted *SCI* for all the years from 1969 on, one would have a complete list of all papers which cited that paper. One could obviously broaden the search by then consulting *SCI* (from 1974 on) for papers which cited these 19 papers and so on. Papers, patents, or books listed, for example, in the 1974 *SCI* may go back many years; e.g., a paper published by Einstein in 1906 is included. The only requirement is that a paper published in 1974 (or late 1973) has mentioned the earlier paper in a footnote. The arrangement of cited papers or books is alphabetical by cited first author and then by cited year. The arrangement of patents is by country and then by patent number.

SCI covers about 2500 journals in the physical and biological sciences, as well as in medicine, agriculture, technology, and the behavioral sciences. In addition to the Citation Index, each quarterly and annual *SCI* also includes three other indexes. One of these, called *Source Index*, is similar to the *CA* author index. It lists the titles, journal abbreviations, column and page numbers, and year, of all papers published by a given author during that quarter or year. All authors are listed; not just first authors. The second, called the *Corporate Index*, lists all publications which have been published from a given institution during that period, by first author. Thus the *Corporate Index* for 1974 lists 25 papers by 21 different first authors emanating from the Saratov State University, Saratov, USSR. However, it is necessary to be careful in using the *Corporate Index*, since slight differences in the way the addresses were originally given in the journals cause the institution to be listed in different places. Thus, the 1974 *Corporate Index* has separate listings for Univ. Massachusetts, Chem. Dept., Amherst, Mass., 01002, USA; Univ. Massachusetts, Dept. Chem., Amherst, Mass., 01002, USA, and Univ. Massachusetts, Dept. Chem., Amherst, Mass., USA. The third index included in *SCI* is the *Permuterm*[36] *Subject Index*. This index alphabetically lists every significant word in the titles of all papers published in that year or quarter, paired with all other significant words in the same title. Thus, for example, a title with 7 significant words will appear at 42 separate places in the index. Each of the 7 words appears 6 times as the main word, each time paired with a different word as the co-word. The user is then led to the *Source Index*, where the full reference is given.

The publishers of *SCI* also produce another publication, called *Index to Scientific Reviews*, which appears semiannually (the second issue of each year cumulates the first). This publication, which began in 1974, is very similar to *SCI*, but confines itself to listing citations to review articles. The citations come from about 2500 journals in the same general areas as are covered by *SCI*. The review articles cited appeared in about 150 review journals and books, as well as in those journals which publish occasional review articles. Like *SCI*, the *Index to Scientific Reviews* contains citation, source, corporate, and Permuterm indexes.

How to Locate Journal Articles

Having obtained a reference from Beilstein, *SCI*, *CA*, a treatise, or some other source, one often needs to consult the original journal (the location of patents is discussed on p. 1147). The first step is to ascertain the full name of the journal, since it is the abbreviation which is generally given. Of course, everyone should be familiar with the abbreviations of the very important journals, such as *J. Org. Chem.*, *Chem. Ber.*, etc., but references are often found to journals whose titles are not at all familiar (e.g., *K. Skogs Lantbruksakad. Tidskr.* or *Nauchn. Tr. Mosk. Lesotekh. Inst.*). In such cases, one consults the *Chemical Abstracts Service Source Index* (*CASSI*), which contains the names of all of the journals covered by *CA* from 1907 to 1974 (even those which are no longer published), with the most recent abbreviations in bold print. The journals are listed in alphabetical order of the *abbreviations*, not of the titles. Journal title changes have not been infrequent, and *CASSI* also contains all former names, with cross references to the current names. Quarterly supplements to *CASSI* have appeared since 1975, listing new journals and recent changes in journal titles. It should be pointed out that, while many publications use the *CA* abbreviations, not all do. The student will find that usages vary from country to country, and even from journal to journal within a country. Furthermore, the *CA* abbreviations change from time to time.

Once the complete title is known, the journal can easily be obtained if it is in the library customarily used by the chemist. If not, one must use another library, and the next step is to find out which libraries carry the journal. *CASSI* answers this question too, since it carries a list of some 398 libraries in the United States and foreign countries, and *for each journal it tells which of these libraries carries it*, and furthermore, if the holdings are incomplete, which volumes of that journal are carried by each library. It may be possible to visit the closest library personally. If not, many of these libraries maintain one or more of the following services: lending, microfilms, photocopying; and a copy of the article may be obtained in one of these ways, photocopying being most common. Photocopies of original Russian articles can be obtained from Chemical Abstracts Service, The Ohio State University, Columbus, Ohio, 43210.

Appendix B

Classification of Reactions by Type of Compound Synthesized

Acetals and Ketals

0-14 Reaction between alkoxides and *gem*-dihalides (Williamson)
0-19 Transetherification
0-80 Reduction of ortho esters
0-84 Reduction of mesylate esters
0-92 Reaction between Grignard reagents and ortho esters
5-5 Addition of alcohols or phenols to triple bonds
5-48 Addition of acetals to vinyl ethers
6-4 Alcoholysis of nitro compounds
6-6 Addition of alcohols to aldehydes or ketones
6-54 Addition of aldehydes to olefins (Prins)
6-60 Trimerization and polymerization of aldehydes

Acetylenes (*see* Alkynes)

Acids (*see* Carboxylic Acids, Sulfonic Acids)

Acylals

5-6 Addition of acids to alkynes
6-58 Acylation of aldehydes or ketones
9-15 Bisdecarboxylation of malonic acids
9-17 Oxidation of arylmethanes with CrO_3 and Ac_2O

Acyl Halides

0-75 Reaction between acids and inorganic acid halides
0-76 Conversion of acid derivatives to acyl halides
4-3 Halogenation of aldehydes
4-23 Chlorocarbonylation of alkanes
5-1 Addition of hydrogen halides to ketenes
5-23 Free-radical addition of acyl halides to olefins
5-38 Reaction between olefins, carbon monoxide, and $PdCl_2$

Acyloins (*see* Hydroxy Aldehydes and Ketones)

Alcohols (*see also* Diols, Hydroxy Esters, etc.)

0-1 Hydrolysis of alkyl halides
0-4 Hydrolysis of inorganic esters
0-5 Diazotization of primary aliphatic amines
0-7 Hydrolysis of vinyl ethers, acetals, or ortho esters
0-11 Hydrolysis of esters
0-13 Decarbonylation of acids
0-19 Transetherification
0-25 Transesterification
0-30 Reaction between acids and esters
0-54 Ammonolysis of esters
0-68 Cleavage of ethers with concentrated acids
0-80 Reduction of acetals or ortho esters
0-81 Reduction of epoxides
0-92 Cleavage of acetals or ortho esters with Grignard reagents
0-93 Reaction between Grignard reagents and epoxides
0-118 Hydrolysis of sulfonic esters
1-13 Alkylation of aromatic rings with ethylene oxide
1-25 Hydroxyalkylation of aromatic rings
2-22 Reaction between Grignard reagents and oxygen
4-4 Hydroxylation at an aliphatic carbon
5-2 Hydration of olefins
5-15 Hydroboration-oxidation of alkenes
5-16 Oxidation of alanes
5-20 Addition of organometallic compounds to unsaturated alcohols
5-23 Free-radical addition of alcohols to olefins
6-27 Reduction of aldehydes or ketones
6-31 Addition of Grignard reagents to aldehydes or ketones
6-34 Addition of Grignard reagents to esters or acyl halides

6-54 Reaction between aldehydes, olefins, and sodium
7-2 Alkaline cleavage of ethers
7-41 Reaction of N-substituted amides with certain catalysts
8-1 Rearrangement of alcohols or olefins (Wagner-Meerwein)
8-3 Expansion and contraction of rings (Demyanov)
8-23 Cleavage of methyl ketones with peracids (Baeyer-Villiger)
8-24 Cleavage of hydroperoxides
8-26 Rearrangement of ethers upon treatment with alkyllithiums (Wittig)
8-27 From boranes and CO, or CN^-, or $CHCl_2$-OMe; from boranes and bromine
8-28 From boranes, CO, water, and NaOH
8-29 From boranes, CO, and $LiAlH_4$
8-40 [2,3] sigmatropic rearrangements of allylic ethers or allylic sulfoxides
8-46 Photolysis of hypohalites
9-9 Oxidative cleavage of certain alcohols
9-10 Reduction of ozonides
9-36 Coupling of primary alcohols (Guerbet)
9-40 Reduction of carboxylic acids
9-44 Reduction of esters
9-45 Reduction of carboxylic esters with titanocene dichloride
9-46 Reduction of anhydrides
9-47 Reduction of acyl halides
9-61 Reduction of hydroperoxides
9-64 Reduction of peroxides
9-74 Reaction between aldehydes and base (Cannizzaro)

Aldehydes (*see also* Dicarbonyl Compounds, Unsaturated Carbonyl Compounds, etc.)

0-2 Hydrolysis of *gem*-dihalides
0-4 Hydrolysis of vinyl esters of inorganic acids
0-7 Hydrolysis of vinyl ethers, acetals, thioacetals, etc.
0-11 Hydrolysis of vinyl esters
0-83 Reduction of acyl halides
0-84 Reduction of carboxylic acids, esters, or anhydrides
0-85 Reduction of amides
0-97 Alkylation and hydrolysis of imines
0-99 Alkylation and hydrolysis of dithianes
0-100 Alkylation and hydrolysis of oxazines and similar compounds
0-101 Reaction of diazo aldehydes with boranes
0-104 Carbonylation of alkyl halides
0-107 Reaction between formates or formamides and organometallic compounds
0-113 Formylation of carboxylic acid salts
0-117 Reaction between formic acid, another acid, and thorium oxide
1-16 Formylation of aromatic rings with formamides and $POCl_3$ (Vilsmeier)
1-17 Formylation of aromatic rings with carbon monoxide and HCl (Gatterman-Koch)
1-18 Formylation of aromatic rings with HCN and HCl (Gatterman)
1-19 Formylation of aromatic rings with formyl fluoride
1-20 Formylation of aromatic rings with dichloromethyl methyl ether
1-21 Formylation of aromatic rings with chloroform (Reimer-Tiemann)
1-45 Reaction between arylcarbinols and diazonium salts (Stiles-Sisti)
2-31 Carbonylation of organometallic compounds
2-39 Decarboxylation of α-keto or glycidic acids
3-17 Alkylation of aromatic aldehydes
3-27 Rearrangement of aromatic amino sulfides (Sommelet-Hauser)
4-18 Arylation of allylic alcohols
4-21 Formylation of nitrogen heterocycles
4-30 Reaction of diazonium salts with oximes, followed by hydrolysis
5-3 Hydration of acetylene
5-15 Hydrolysis of unsaturated boranes
5-19 Addition of aldehydes to activated olefins (Michael)
5-20 Addition of organometallic compounds to unsaturated aldehydes
5-21 Addition of boranes to unsaturated aldehydes
5-26 Hydroformylation of olefins (oxo process)
6-2 Hydrolysis of imines, oximes, hydrazones, or other C═N compounds
6-4 Hydrolysis of primary nitro compounds (Nef)
6-30 Reduction of nitriles
6-34 Addition of Grignard reagents to formamides
6-36 Reaction of alkyllithium compounds with oxazines and oxazolines
6-42 Reaction of aldehydes or ketones with boron methides
6-76 Hydrolysis of metalated aldimines
7-1 Dehydration of 1,2-diols
7-2 Pyrolysis of vinyl ethers
7-32 Fragmentation of γ-amino or γ-hydroxy halides
7-35 Fragmentation of 1,3-diols or γ-amino alcohols

7-40 Fragmentation of certain ketoximes
7-44 Alkaline hydrolysis of nitrates
7-45 Pyrolysis of β-hydroxy olefins
7-46 Pyrolysis of allyl ethers
8-2 Rearrangements of diols (pinacol)
8-10 Homologization of aldehydes
8-17 Reaction between α-hydroxy or α-halo amides and NaOBr (Hofmann)
8-24 Cleavage of hydroperoxides
8-29 Treatment of boranes with CO and LiAl(OMe)$_3$ or α-lithiated thioacetals
8-46 Photolysis of nitrites, followed by hydrolysis (Barton)
9-4 Oxidation of primary alcohols
9-8 Oxidative cleavage of glycols or related compounds
9-9 Oxidative cleavage of certain alcohols; degradation of aldehydes
9-10 Ozonolysis of olefins
9-11 Oxidative cleavage of certain olefins
9-14 Oxidative cleavage of carboxylic acids
9-16 Oxidation of activated methyl groups
9-17 Oxidation of arylmethanes (Étard)
9-20 Oxidation of primary halides or esters of primary alcohols
9-21 Oxidation of amines
9-23 Oxidation of olefins with noble-metal salts

Alicyclic Compounds

0-86 Internal coupling (Wurtz)
0-94 Reaction between epoxides and phosphorus ylides
0-96 Internal malonic ester synthesis
0-100 Cyclization of halogen-containing oxazines
0-101 Cyclization of haloboranes
0-111 Internal condensation of diesters (Dieckmann)
0-117 Ketonic decarboxylation of dicarboxylic acids
1-13 Intramolecular Friedel-Crafts alkylation
1-14 Scholl ring closure
1-15 Intramolecular Friedel-Crafts acylation
1-26 Cyclodehydration of aldehydes and ketones
2-17 The reaction of ethyl α-(bromomethyl)-acrylate with enamines
2-18 Intramolecular insertion of carbenes
3-16 Cyclization of dihalobiphenyls
4-15 Coupling of terminal diynes (cycloalkynes)
4-16 Intramolecular arylation (Pschorr)
4-35 Coupling of dienes through borane intermediates
5-6 Cyclization of olefinic acids
5-13 Reduction of aromatic rings
5-17 Cyclization of dienes
5-18 Internal ene reactions
5-20 Cyclization of unsaturated Grignard reagents
5-25 Hydrocarboxylation of dienes
5-50 Cycloaddition of allylic anions or cations to olefins
5-51 Addition of olefins to dienes (Diels-Alder)
5-52 Dimerization of olefins
5-53 Addition of carbenes or carbenoids to olefins or alkynes
5-54 Tetramerization of alkynes
5-55 Other cycloaddition reactions
6-31 Ring closure of halo carbonyl compounds
6-40 Internal aldol condensation
6-47 Internal Wittig reactions
6-48 Cyclization of dinitriles (Thorpe-Ziegler)
7-48 Extrusion of N$_2$ from pyrazolines or pyrazoles
7-49 Extrusion of CO from cyclic ketones
7-50 Extrusion of SO$_2$ from cyclic sulfones
7-51 Decarboxylation of cyclic peroxides (Story)
8-1 Wagner-Meerwein rearrangements to give cyclic products
8-3 Expansion and contraction of rings (Demyanov)
8-5 Ring expansion of amino ketones
8-8 Ring contraction of halo ketones (Favorskii)
8-9 Ring contraction of cyclic diazo ketones (Wolff)
8-27 Treatment of cyclic boranes with CO
8-28 Treatment of cyclic boranes with CO, H$_2$O, NaOH, and H$_2$O$_2$
8-32 Cyclization of conjugated dienes and trienes
8-35 $[1,j]$ sigmatropic migrations of carbon
8-36 Ring expansion of vinylcyclopropenes and cyclobutenes
8-37 Ring expansion of vinylcycloalkanes; cyclization of diynes
8-41 Metathesis of dienes
8-42 Metal-ion-catalyzed σ-bond rearrangements
8-43 The di-π-methane rearrangement
9-57 Reduction of cyclic ketones to cycloalkenes
9-70 Condensation of diesters (acyloin)

Alkanes (*see also* Alicyclic Compounds)

0-77 Reduction of alkyl halides
0-78 Reduction of tosylates and similar compounds
0-79 Hydrogenolysis of alcohols
0-82 Reduction of primary amines or quaternary ammonium or phosphonium salts
0-86 Coupling of alkyl halides (Wurtz)

0-87 Coupling of alkyl halides with organometallic reagents
0-89 Reaction between organometallic reagents and alkyl sulfates or sulfonates
0-90 Coupling of alcohols
0-92 Reaction between Grignard reagents and ethers
0-99 Reduction of dithianes
1-46 Reduction of aromatic ethers
2-16 Alkylation of alkanes
2-18 Insertion of carbenes
2-21 Reaction between organometallic compounds and acids
2-39 Decarboxylation of carboxylic acids
2-40 Cleavage of tertiary alkoxides
2-44 Cleavage of nonenolizable ketones
2-45 Cleavage of ketones with amide ion (Haller-Bauer)
2-46 Cleavage of alkanes
2-47 Decyanation of nitriles
4-14 Coupling of alkanes
4-34 Coupling of Grignard reagents
4-35 Coupling of boranes
4-36 Coupling of other organometallic compounds
4-37 Desulfurization of sulfur compounds
4-38 Decarboxylative dimerization (Kolbe)
4-41 Decarbonylation of aldehydes
5-12 Reduction of olefins and alkynes
5-13 Reduction of aromatic rings
5-14 Reductive cleavage of cyclopropanes
5-16 Hydrolysis of alanes
5-17 Addition of alkanes to olefins
5-24 Reductive coupling of olefins
6-31 Reaction of ketones with trimethylaluminum
6-34 Reaction of carboxylic acids with trimethylaluminum
6-47 From unsaturated sulfones and organometallic compounds
9-7 Oxidation of hydrazines
9-11 Cleavage of olefins with hydrazinium ion
9-14 Oxidative decarboxylation of carboxylic acids
9-39 Reduction of aldehydes or ketones (Wolff-Kishner; Clemmensen)
9-45 Reduction of carboxylic acids or esters
9-48 Reduction of epoxides
9-54 Reduction of cyano to methyl groups

Alkenes (*see also* Alicyclic Compounds, Unsaturated Acids, Unsaturated Alcohols, etc.)

0-7 Acid cleavage of *t*-butyl ethers
0-69 Reduction of α-keto epoxides
0-77 Reduction of unsaturated halides
0-82 Reductive cleavage of enamines
0-86 Coupling of vinyl halides
0-87 Coupling of unsaturated halides with organometallic reagents
0-88 Coupling of allylic halides, tosylates, or acetates
0-90 Coupling of allylic alcohols with organometallic reagents
0-91 Coupling of allylic esters with organometallic reagents
2-2 Migration of double and triple bonds
2-21 Hydrolysis of vinylsilanes
2-31 Reaction of Grignard reagents or nickel complexes with CO
2-39 Decarboxylation of unsaturated acids
4-17 Arylation of olefins (Meerwein)
4-18 Arylation of olefins by organopalladium compounds
4-32 Dimerization of allylic iodides
4-34 Dimerization of allylic Grignard reagents
4-36 Dimerization of vinyl organometallic reagents
4-37 Desulfurization of thiophenes
4-38 Additive dimerization of olefins and carboxylic acids
5-12 Selective reduction of alkynes or allenes
5-13 Reduction of aromatic rings
5-17 Dimerization of olefins
5-18 The ene synthesis
5-21 Addition of triallylboranes to triple bonds
5-51 Addition of olefins to dienes (Diels-Alder)
5-53 Addition of carbenes to aromatic rings
5-54 Tetramerization of alkynes
5-55 Dimerization of dienes
5-56 Addition of two alkyl groups to an alkyne
5-59 Reaction of diphenylacetylene with methylsulfinyl carbanion
6-31 Reaction of *gem*-dimetallic compounds with aldehydes or ketones
6-42 Addition to aldehydes or ketones of α-sulfinyl carbanions
6-44 Reaction between anhydrides and aldehydes
6-47 Reaction between phosphorus ylides and aldehydes or ketones (Wittig)
6-66 Reaction of sulfonyl halides with tertiary amines and diazoalkanes
7-1 Dehydration of alcohols
7-2 Alkaline cleavage of ethers
7-3 Pyrolysis of carboxylic esters
7-4 Pyrolysis of xanthates (Chugaev)
7-5 Cleavage of inorganic esters and sulfonates

7-6	Cleavage of quaternary ammonium hydroxides (Hofmann)
7-7	Cleavage of quaternary ammonium salts
7-8	Cleavage of amine oxides (Cope)
7-9	Cleavage of aliphatic diazonium salts
7-10	Decomposition of tosylhydrazones
7-11	Cleavage of sulfonium compounds
7-12	Cleavage of sulfoxides, selenoxides, and sulfones
7-13	Dehydrohalogenation of alkyl halides
7-14	Reaction of sulfonyl halides with tertiary amines
7-15	Elimination of boranes
7-16	Decarbonylation of acyl halides
7-17	Cleavage of Michael adducts
7-18	Pyrolysis of alkali organometallic compounds
7-19	Deoxygenation of *vic*-diols
7-20	Cleavage of cyclic thionocarbonates
7-21	Deoxidation of epoxides
7-22	Desulfurization of episulfides
7-23	Reaction of α-halo sulfones with bases (Ramberg-Bäcklund)
7-24	Reaction of aziridines with nitrous acid
7-25	Denitration of *vic*-dinitro compounds
7-27	Dehalogenation of *vic*-dihalides
7-29	Elimination of a halo and a hetero group (Boord)
7-30	Pyrolysis of hydroxy sulfinamides
7-31	Fragmentation of γ-branched alcohols or halides
7-32	Fragmentation of γ-amino or γ-hydroxy halides
7-34	Decarbonylation of β-hydroxy carboxylic acids and of β-lactones
7-35	Fragmentation of 1,3-diols or γ-amino alcohols
7-38	Elimination of CO and CO_2 from bridged bicyclic compounds
7-45	Pyrolysis of β-hydroxy olefins
7-46	Pyrolysis of allyl ethers
7-53	Twofold extrusion from certain cyclic molecules
8-1	Rearrangement of alcohols and olefins (Wagner-Meerwein)
8-3	Expansion and contraction of rings (Demyanov)
8-9	Rearrangement of carbenes or carbenoids
8-12	Rearrangement of α-haloboronic acids
8-30	Reaction between vinylboranes and iodine or NaOMe
8-31	Reaction of lithium alkynyltrialkylborates with carboxylic acids
8-32	Electrocyclic rearrangements of cyclobutenes and cyclohexadienes
8-34	[1,*j*] sigmatropic migrations of hydrogen
8-35	[1,*j*] sigmatropic migrations of carbon
8-36	Rearrangement of 1,5-dienes (Cope)
8-40	[2,3] sigmatropic rearrangements of unsaturated sulfones
8-41	Metathesis of olefins
8-42	Cyclobutane reversions
8-43	The di-π-methane rearrangement
9-3	Dehydrogenation of diarylalkanes; remote dehydrogenation
9-14	Oxidative decarboxylation of carboxylic acids
9-15	Bisdecarboxylation of succinic acids
9-34	Oxidative coupling of halides
9-39	Reduction of α-hydroxy ketones; of unsaturated tosylhydrazones
9-57	Reduction of cyclic ketones
9-69	Bimolecular reduction of aldehydes or ketones

Alkyl Halides (*see also* Dihalides, Halohydrins, etc.)

0-65	Halide exchange (Finkelstein)
0-66	Reaction between inorganic esters and halide ions
0-67	Reaction between alcohols and hydrogen halides or inorganic acid halides
0-68	Cleavage of ethers with HI or HBr
0-70	Cleavage of esters with LiI
0-72	Cleavage of tertiary amines (von Braun)
0-73	Cleavage of amines with hydrohalic acids
0-74	Conversion of sulfur compounds to halides
0-77	Reduction of dihalides
0-87	Coupling of dihalides with Grignard reagents
0-99	Homologization of primary halides
1-13	Reaction between aromatic rings and carbon tetrachloride
1-27	Haloalkylation of aromatic rings
2-28	Halogenation of organometallic compounds
2-38	Exchange between halides and organometallic compounds
4-1	Free-radical halogenation
4-2	Allylic halogenation
4-32	Reaction of boranes with allyl iodide and O_2
4-39	Decarboxylative halogenation (Hunsdiecker)
4-42	Decomposition of tertiary hypochlorites
5-1	Addition of hydrogen halides to olefins

5-23 Free-radical addition of alkyl halides to olefins
5-30 Addition of halogens to olefins or alkynes
5-37 Addition of alkyl or aryl halides to olefins
7-41 Reaction of N-substituted amides with PCl_5 (von Braun)

Alkynes (*see also* Alkynyl Halides, Alkynyl Ethers)

0-88 Propargylation of alkyl halides
0-92 Alkylation of alkynyl ethers
0-102 Alkylation at an acetylenic carbon
2-2 Triple-bond migration
2-39 Decarboxylation of acetylenic acids
2-45 Cleavage of α,β-acetylenic acid derivatives with amide ion
3-14 Reaction between aryl iodides and copper acetylides
4-15 Coupling of alkynes (Eglinton)
4-20 Arylation of alkynyl iodides
4-34 Dimerization of alkynyl organometallic compounds
7-6 Pyrolysis of bisquaternary ammonium hydroxides
7-13 Dehydrohalogenation of dihalides or vinyl halides
7-23 Decomposition of thiiren-1,1-dioxides
7-26 Reaction of bistosylhydrazones with metallic oxides
7-27 Dehalogenation of tetrahalides
7-33 Fragmentation of β-halo acrylic acid salts or α-chloroacroleins
8-11 Rearrangement of vinyl halides (Fritsch-Buttenberg-Wiechell)
8-31 From boranes and lithium acetylides
8-41 Metathesis of alkynes

Alkynyl Halides

2-28 Reaction of acetylide ions with halogens

Alkynyl Ethers

7-13 Reaction between vinylidine dihalides and amide ion

Allenes

0-77 Reduction of propargyl halides
0-91 Reaction between propargyl esters and organometallic reagents
2-2 Rearrangement of alkynes
6-47 Reaction of phosphoranes with ketenes or CO_2
7-13 Dehydrohalogenation of dihalides
7-27 Dehalogenation of tetrahalides or dihaloalkenes
7-45 Pyrolysis of β-hydroxy alkynes
8-3 Contraction of three-membered rings
8-38 Rearrangement of propargyl vinyl compounds

Amidals (*see* Bisamides)

Amides (*see also* Bisamides)

0-12 Cleavage of an alkyl group from N-*t*-butyl amides
0-53 Reaction between secondary amines and chloroform
0-54 Amination of acyl halides
0-55 Amination of anhydrides
0-56 Amination of acids
0-57 Amination of esters
0-58 Amination of amides
0-59 Amination of other acid derivatives
0-60 N-Alkylation of amides
0-105 Carbonylation of alkyl halides
1-6 Amidation of aromatic rings with hydroxamic acids
1-22 Carbamoylation of aromatic rings (Gatterman)
1-24 Amidation of aromatic rings with isocyanates
1-39 Rearrangement of N-halo-N-acyl aromatic amines (Orton)
2-11 Insertion by nitrenes
2-31 Carbamoxylation of organometallic compounds
2-45 Cleavage of ketones with amide ion (Haller-Bauer)
2-47 Decyanation of cyano amides
2-55 Carbonylation of amines
3-6 N-Arylation of amides
4-13 Reaction of aldehydes with ammonia
4-22 Carbamidation of nitrogen heterocycles
5-3 Hydration of ynamines
5-9 Addition of amides to olefins; addition of amines to ketenes
5-23 Free-radical addition of amides to olefins
5-25 Hydrocarboxylation of olefins in the presence of amines
6-5 Partial hydrolysis of nitriles
6-16 Reductive alkylation of amines (Leuckart)
6-37 Addition of Grignard reagents to isocyanates
6-57 Addition of alcohols or other carbonium-ion sources to nitriles (Ritter)
6-71 Addition of water to isonitriles

7-4	Pyrolysis of O-alkyl imidates
8-8	Rearrangement of α-halo ketones in the presence of amines (Favorskii)
8-9	Rearrangement of diazo ketones in the presence of amines (Arndt-Eistert)
8-17	Reaction between amides, lead tetraacetate, and acetic acid
8-20	Reaction between ketones and hydrazoic acid (Schmidt)
8-21	Rearrangement of oximes (Beckmann)
8-49	Rearrangement of aryl imidates (Chapman)
9-18	Oxidation of tertiary amines
9-76	Oxidation of aryl ketones with ammonium polysulfide (Willgerodt)

Amidines

0-36	Reaction of N-alkylimino esters with secondary amines
0-57	Amination of imino esters
5-9	Addition of amines to ketenimines
6-19	Addition of ammonia or amines to nitriles or nitrilium salts
6-72	Reaction of amines with isocyanides

Aminals

6-15	Addition of amines to aldehydes or ketones

Amine Oxides

9-29	Oxidation of tertiary amines

Amines (*see also* Cyanoamines, Amino Acids, etc.)

0-12	Hydrolysis of amides
0-36	Reduction of N-alkylimino esters
0-39	Cleavage of quaternary ammonium salts
0-46	Alkylation of ammonia or amines
0-47	Reaction between alkyl halides and hexamethylenetetramine
0-48	Indirectly, from alcohols
0-49	Transamination
0-50	Alkylation of amines with diazo compounds
0-52	Amination of alkanes
0-60	Hydrolysis of phthalimides (Gabriel)
0-73	Cleavage of aromatic amines or quaternary ammonium salts
0-82	Reduction of quaternary ammonium salts or aziridines; monomethylation of arylamines
0-92	Cleavage of amine ethers with Grignard reagents
0-99	Alkylation and hydrolysis of N-nitro compounds
0-118	Hydrolysis of sulfonamides
1-6	Direct amination of aromatic rings
1-28	Aminoalkylation of aromatic rings
1-36	Rearrangement of N-nitroamines
1-37	Rearrangement of N-nitrosoamines (Fischer-Hepp)
1-38	Rearrangement of triazenes
1-40	Rearrangement of aryl alkyl ammonium salts (Hofmann-Martius)
2-10	Amination at an activated position
2-29	Conversion of organometallic compounds to amines
2-47	Decyanation of cyanoamines
3-6	Arylation of ammonia or amines
3-7	Reaction between naphthols, bisulfite ion, and ammonia or amines (Bucherer)
3-18	Amination of heterocyclic nitrogen compounds (Chichibabin)
3-19	Direct amination of activated aromatic rings
3-20	Amination of aromatic acids
3-27	Rearrangement of benzyl quaternary ammonium salts (Sommelet-Hauser)
3-28	Rearrangement of aryl hydroxylamines
4-37	Desulfurization of thioamides
5-9	Addition of ammonia or amines to olefins
5-20	Addition of organometallic compounds to allylic amines
5-23	Free-radical addition of amines to olefins
5-27	Aminomethylation of alkenes
5-44	Bisamination of alkenes
6-2	Hydrolysis of imines, enamines, and iminium ions
6-3	Hydrolysis of isocyanates or isothiocyanates
6-5	Hydrolysis of cyanamides
6-10	Reduction of N-alkylimino esters
6-14	Addition of ammonia to aldehydes
6-16	Reductive alkylation of ammonia or amines
6-17	Reaction between aldehydes, ammonia or amines, and an active hydrogen compound (Mannich)
6-28	Reduction of imines, hydrazones, or other compounds containing the C=N bond
6-29	Reduction of nitriles or nitrilium ions
6-34	Addition of Grignard reagents to formamides
6-36	Addition of Grignard reagents to imines
6-73	Reduction of isonitriles
7-6	Cleavage of quaternary ammonium hydroxides (Hofmann)
7-7	Cleavage of quaternary ammonium salts

7-30 Pyrolysis of hydroxysulfinamides
7-40 Fragmentation of certain ketoximes
8-17 Reaction between amides and NaOBr (Hofmann)
8-18 Rearrangement of acyl azides in the presence of water (Curtius)
8-19 Rearrangement of hydroxamic acids (Lossen)
8-20 Addition of hydrazoic acid to carboxylic acids (Schmidt)
8-22 Rearrangement of N-haloamines
8-25 Rearrangement of quaternary ammonium salts (Stevens)
8-40 [2,3] sigmatropic rearrangements of quaternary ammonium salts
8-44 Rearrangement of benzidines
9-6 Conversion of primary to secondary amines by dehydrogenation
9-10 Reaction between ozonides, ammonia, and hydrogen
9-21 Oxidative cleavage of amines
9-41 Reduction of amides
9-49 Reduction of nitro compounds
9-52 Reduction of nitroso compounds or hydroxylamines
9-53 Reduction of oximes
9-54 Reduction of isocyanates, isothiocyanates, or azides
9-58 Reduction of amine oxides
9-63 Reduction of azo, azoxy, or hydrazo compounds

Amino Acids and Esters

0-12 Hydrolysis of lactams
0-46 Amination of halo acids
0-57 Ammonolysis of β-lactones
0-96 Alkylation of N-acetylaminomalonic ester (Sorensen)
2-8 Nitrosation at a carbon bearing an active hydrogen and reduction of the resulting oxime or nitroso compound
6-5 Hydrolysis of cyanohydrins
6-17 Reaction between aldehydes, ammonia, and carboxylic acids
6-32 Reaction of imines, zinc, and halo esters
6-44 Reduction of azlactones
6-51 Addition of cyanide and ammonium ions to aldehydes or ketones, followed by hydrolysis (Strecker)
8-16 Rearrangement of N-halo imino esters
8-17 Reaction between imides and NaOBr (Hofmann)
8-45 Rearrangement of hydroxy amides

Amino Carbonyl Compounds

0-48 Amination of α-hydroxy ketones
0-49 Transamination of Mannich bases
1-40 Photolysis of acylated arylamines
6-17 Reaction between aldehydes, ammonia, and aldehydes, ketones, or esters (Mannich)
6-36 Reaction of iminium ions with enol borinates
8-5 Rearrangement of amino ketones or aldehydes
8-16 Rearrangement of ketoxime tosylates (Neber)
8-25 Rearrangement of quaternary ammonium salts (Stevens)

Amino Ethers

0-20 Alcoholysis of aziridines

Amino Mercaptans

0-51 Amination of episulfides
1-9 Sulfurization of aromatic amines (Herz)

Anhydrides

0-29 Reaction of acyl halides with acid salts
0-30 Dehydration of acids
0-34 Reaction of acid derivatives with inorganic acids
4-10 Acyloxylation of aldehydes
5-6 Addition of acids to ketenes
5-23 Free-radical addition of anhydrides to olefins
8-23 Reaction between α-diketones and peroxy compounds (Baeyer-Villiger)
9-11 Oxidation of aromatic rings

Arenes

0-77 Reduction of aryl and benzylic halides
0-79 Hydrogenolysis of benzyl alcohols
0-80 Reduction of benzylic ethers
0-86 Coupling of halides containing aryl groups
0-87 Coupling of aryl halides with organometallic reagents
0-90 Coupling of benzylic alcohols
1-13 Alkylation of aromatic rings (Friedel-Crafts)
1-14 Arylation of aromatic rings (Scholl)
1-25 Diarylation of ketones
1-26 Ring closure of aryl-substituted carbonyl compounds
1-41 Cleavage or rearrangement of alkyl arenes
1-42 Decarbonylation of aromatic aldehydes
1-43 Decarboxylation of aromatic acids

1-46	Reduction of aromatic ethers
1-47	Desulfonation of aromatic sulfonic acids
1-48	Dehalogenation of aryl halides
1-50	Hydrolysis of organometallic compounds
2-39	Decarboxylation of α-aryl acids
2-40	Cleavage of tertiary alkoxides
2-44	Cleavage of aryl ketones
2-45	Cleavage of aryl ketones with amide ions (Haller-Bauer)
2-47	Decyanation of aryl nitriles
3-9	Reduction of phenols, phenolic ethers, or phenolic esters
3-10	Reduction of aromatic nitro compounds
3-13	Coupling of organometallic compounds with aryl ethers
3-16	Coupling of aryl iodides (Ullmann)
3-17	Alkylation with organolithium compounds
4-16	Free-radical arylation by diazonium salts (Gomberg-Bachmann, Pschorr)
4-19	Free-radical arylation by peroxides
4-20	Photochemical arylation
4-24	Reduction of diazonium salts
4-29	Dimerization of diazonium salts
4-34	Dimerization of Grignard reagents
4-35	Dimerization of arylboranes
4-36	Dimerization of other organometallic compounds
4-37	Reduction of sulfur compounds
4-41	Decarbonylation of aromatic aldehydes
5-24	Reductive coupling of olefins
5-54	Trimerization of alkynes
6-31	Alkylation-reduction of aromatic aldehydes and ketones
6-42	Addition of nitro compounds to pyrylium ions
6-47	Reaction between ylides and pyrylium salts
7-38	Diels-Alder reactions of cyclopentadienones with alkynes
8-33	Photolysis of stilbenes to phenanthrenes
9-1	Aromatization of six-membered rings
9-2	Cyclodehydrogenation of aliphatic chains
9-7	Oxidation of hydrazines
9-34	Dimerization of arenes
9-39	Reduction of aromatic aldehydes
9-45	Reduction of aromatic acids

Aryl Halides

1-12	Halogenation of aromatic compounds
1-39	Rearrangement of N-haloamines (Orton)
1-43	Replacement of aromatic COOH by halogen
1-47	Replacement of aromatic SO_2Br by halogen
1-48	Migration of halogen
2-28	Reaction of aryl organometallic compounds with halogens
3-8	Aryl halide exchange
3-24	Reaction between diazonium salts and iodide ion
3-25	Heating of diazonium fluoborates (Schiemann)
4-25	Reaction between diazonium salts and CuCl or CuBr (Sandmeyer)
4-39	Decarboxylative halogenation (Hunsdiecker)
4-41	Decarbonylation of acyl halides

Azides

0-63	Alkylation or acylation of azide ion
2-30	Reaction of Grignard reagents with tosyl azide
2-49	Reaction between hydrazines and nitrous acid
2-51	Reaction of amine anions with tosyl azide
3-23	Reaction of diazonium salts with azide ion
4-39	Reaction of acyl peroxides with copper azide
5-10	Addition of hydrazoic acid to double bonds
5-35	Addition of halogen azides to double bonds
5-43	Treatment of olefins with sodium azide, ferrous ion, and hydrogen peroxide
8-18	Reaction between hydrazides and nitrous acid
8-20	Reaction between alcohols or olefins and hydrazoic acid

Azines

6-21	Addition of hydrazine to aldehydes or ketones

Aziridines

0-46	Cyclization of haloamines
0-48	Cyclization of amino alcohols
5-35	From β-iodo azides
5-45	Reaction of alkenes with azides
6-36	Reaction between Grignard reagents and oximes
6-45	Reaction of imines with α-halo carbonyl compounds
6-67	Addition of divalent carbon to C=N bonds
7-48	Extrusion of N_2 from triazolines
9-53	Reduction of oximes

Azlactones

6-44	Condensation between aldehydes and N-acylglycines (Erlenmeyer)

Azo Compounds

1-4 Coupling of diazonium salts with aromatic rings
1-38 Rearrangement of aryl triazenes
1-45 Reaction between aromatic alcohols and diazonium salts (Stiles-Sisti)
1-50 Reaction between organometallic compounds and diazonium ions
2-7 Aliphatic diazonium coupling
2-52 Reaction of amines with nitroso compounds (Mills)
4-29 Coupling of aryl diazonium salts
8-50 Rearrangement of azoxy compounds (Wallach)
9-7 Oxidation of hydrazines
9-38 Oxidation of amines
9-58 Reduction of azoxy compounds
9-72 Reduction of nitro compounds

Azoxy Compounds

2-53 Reaction of nitroso compounds with hydroxylamines
9-30 Oxidation of azo compounds
9-38 Oxidation of amines
9-71 Reduction of nitro or nitroso compounds; reaction between nitroso compounds and hydroxylamines

Benzoins (*see* Hydroxy Aldehydes and Ketones)

Bisamides

6-15 Addition of amides to aldehydes or ketones
6-61 Addition of nitriles to aldehydes
6-74 Reaction between isonitriles, acids, amines, and aldehydes or ketones (Ugi)

Bisulfite Addition Compounds (*see* Hydroxy Sulfonic Acids)

Boranes

2-34 Reaction between boron halides and Grignard reagents
5-15 Hydroboration of olefins or alkynes
7-15 Exchange reaction between boranes and olefins
8-14 Migration of boron
9-56 Reduction of borinates

Bunte Salts

0-42 Reaction between alkyl halides and thiosulfate ion

Carbamates

0-48 Heating of N-carbalkoxylsulfamate salts of alcohols
0-54 Reaction between chloroformates and primary amines
0-64 Reaction between alkyl halides, ethanol, and thiocyanate ion
0-73 Cleavage of tertiary amines with ClCOOPh
2-11 Insertion by nitrenes
2-45 Cleavage of α,β-acetylenic esters with amide ion
5-9 Addition of carbamates to olefins
6-8 Addition of alcohols to isocyanates
6-10 Reaction of alcohols with ClCN
6-75 Addition of alkyl hypochlorites to isonitriles
8-17 Reaction between amides, bromine, and alkoxides (Hofmann); reaction between amides, lead tetraacetate, and acetic acid
8-18 Rearrangement of acyl azides in the presence of alcohols (Curtius)
9-31 Oxidation of isonitriles in the presence of alcohols

Carbodiimides

6-62 Addition of isocyanates to isocyanates
6-72 Reaction of azides with isocyanides
7-43 Dehydration of ureas and thioureas

Carbonates

0-22 Alcoholysis of phosgene
4-10 Reaction of aromatic compounds with peroxycarbonate

Carboxylic Acids

0-3 Hydrolysis of 1,1,1-trihalides
0-7 Hydrolysis of ortho esters
0-9 Hydrolysis of acyl halides
0-10 Hydrolysis of anhydrides
0-11 Hydrolysis of esters
0-12 Hydrolysis of amides
0-23 Alcoholysis of anhydrides
0-55 Amination of anhydrides
0-70 Cleavage of esters with LiI
0-75 Exchange between acids and acyl halides
0-96 Malonic ester synthesis
0-98 Alkylation of carboxylic acid salts
0-100 Hydrolysis of oxazines
0-105 Carbonylation of alkyl halides and other substrates
1-22 Carboxylation of aromatic rings with carbonyl halides

1-23 Carboxylation of aromatic rings with carbon dioxide (Kolbe-Schmitt)
1-43 Rearrangement of aromatic carboxylate ions
2-39 Decarboxylation of dicarboxylic acids
2-42 Basic cleavage of β-keto esters or β-diketones
2-43 The haloform reaction
2-44 Cleavage of nonenolizable ketones
3-15 Carboxylation of aryl bromides
3-26 Rearrangement of aromatic nitro compounds upon treatment with cyanide ion (von Richter)
4-6 Oxidation of aldehydes
5-2 Addition of water to ketenes
5-3 Hydrolysis of alkynyl halides
5-15 Oxidation of 1,1-diboranes
5-17 Addition of carbonium ions to 1,1-dichloroethene; addition of carboxylates to olefins
5-23 Free-radical addition of acids to olefins
5-25 Hydrocarboxylation of olefins
6-4 Hydrolysis of primary nitro compounds
6-5 Hydrolysis of nitriles
6-35 Addition of Grignard reagents to carbon dioxide
6-42 Reaction of ketones with tosylmethyl azide, followed by hydrolysis
6-47 Reaction of phosphoranes with CO_2
7-3 Pyrolysis of carboxylic esters
7-40 Fragmentation of certain ketoximes
8-8 Rearrangement of α-halo ketones (Favorskii)
8-9 Rearrangement of diazo ketones (Arndt-Eistert)
9-8 Oxidative cleavage of α-diketones and α-keto acids
9-9 Oxidative cleavage of ketones and secondary alcohols
9-10 Oxidation of ozonides; ozonolysis of alkynes
9-11 Oxidative cleavage of olefins, terminal alkynes, or aromatic rings
9-12 Oxidation of aromatic side chains
9-21 Oxidation of amines
9-22 Oxidation of primary alcohols or ethers
9-74 Reaction between aldehydes and base (Cannizzaro)
9-76 Oxidation of aryl ketones by ammonium polysulfide (Willgerodt)

Carboxylic Esters (*see also* Dicarbonyl Compounds, Unsaturated Esters, etc.)

0-7 Hydrolysis of ortho esters
0-13 Decarbonylation of α-keto esters
0-22 Alcoholysis of acyl halides
0-23 Alcoholysis of anhydrides
0-24 Esterification of acids
0-25 Transesterification
0-26 Alkylation of acid salts
0-27 Cleavage of ethers with anhydrides
0-28 Alkylation of acids with diazo compounds
0-97 Alkylation of esters
0-100 Alkylation and alcoholysis of oxazines
0-101 Reaction of halo esters or diazo esters with boranes
0-105 Carbonylation of alkyl halides and other substrates
0-106 Reaction between Grignard reagents and chloroformates
0-107 Reaction between Grignard reagents and carbonates
0-114 Reduction of β-carbalkoxyphosphoranes
1-33 Acyloxylation of aromatic rings
2-25 Esterification of enolates with acyl peroxides
2-31 Carbonylation of organometallic compounds
2-42 Base cleavage of β-keto esters
3-4 Reaction between aryl halides and acid salts
3-14 Arylation of esters
3-15 Carbalkoxylation of aryl iodides
4-10 Free-radical acyloxylation
4-22 Carbalkoxylation of nitrogen heterocycles
4-39 Reaction between silver salts and iodine (Simonini)
5-3 Hydration of acetylenic ethers
5-5 Addition of alcohols or phenols to ketenes
5-6 Addition of acids or acyl peroxides to olefins
5-19 Addition of esters to activated olefins (Michael)
5-23 Free-radical addition of esters to olefins
5-25 Hydrocarboxylation of olefins in the presence of alcohols
5-39 Addition of acid salts to olefins
5-57 Dicarbalkoxylation of olefins and acetylenes
6-7 Reductive acylation of ketones
6-10 Alcoholysis of nitriles
8-8 Rearrangement of α-halo ketones (Favorskii)
8-9 Rearrangement of diazo ketones in the presence of alcohols (Arndt-Eistert)
8-23 Reaction between ketones and peroxy compounds (Baeyer-Villiger)
9-4 Oxidation of acetals
9-14 Reaction between carboxcylic acids and lead tetraacetate

9-18 Oxidation of ethers
9-22 Oxidation of primary alcohols
9-75 Reaction between aldehydes and aluminum ethoxide (Tishchenko)
9-76 Reaction of acetophenones with $Tl(NO_3)_3$

Catenanes

9-70 Acyloin condensation or other methods

Cyanamides

0-72 Cleavage of tertiary amines with cyanogen bromide (von Braun)

Cyanates

0-14 Reaction of aroxides and cyanogen halides

Cyano Acetals

0-103 Reaction between ortho esters and HCN

Cyanoamines

0-48 Amination of cyanohydrins
6-17 Reaction between aldehydes, ammonia, and nitriles (Mannich)
6-51 Addition of cyanide and ammonium ions to aldehydes or ketones (Strecker)
6-52 Addition of HCN to C=N or C≡N bonds

Cyano Carbonyl Compounds

0-96 Alkylation of cyano carbonyl compounds
0-103 Reaction between lactones and cyanide ion
0-109 Acylation of nitriles by acyl halides
0-112 Acylation of nitriles by esters
0-115 Reaction between acyl halides and CuCN
2-17 Cyanoethylation of enamines; reaction of enamines with cyanogen chloride
3-14 Arylation of cyano carbonyl compounds
5-19 Addition to olefins (Michael)
5-22 Acylation of unsaturated nitriles
5-24 Mixed coupling of unsaturated nitriles and esters
5-28 Addition of HCN to unsaturated aldehydes, ketones, or esters
6-42 Addition of cyano carbonyl compounds to aldehydes or ketones (Knoevenagel)
6-48 Condensation of nitriles (Thorpe)
9-34 Dimerization of cyano carbonyl compounds

Cyanohydrins (*see* Hydroxy Nitriles)

Cycloalkanes and Alkenes (*see* Alicyclic Compounds)

Dialdehydes (*see* Dicarbonyl Compounds)

Diazo Compounds

0-116 Reaction between acyl halides and diazomethane
2-9 Reaction of active-hydrogen compounds with tosyl azide
2-48 Diazotization of α-amino esters and similar compounds
6-42 Addition of diazo esters to aldehydes
7-47 Elimination from N-nitroso-N-alkyl compounds
9-7 Oxidation of hydrazones

Diazonium Salts

1-5 Direct diazotization of aromatic rings
2-48 Diazotization of primary amines

1,2-Dicarbonyl Compounds

0-55 Reaction between α-amino acids and trifluoroacetic anhydride
0-108 Dimerization of acyl halides
0-111 Condensation between esters and ethyl oxalate
0-112 Acylation of 1,3-dithianes, followed by hydrolysis
3-15 Carbalkoxylation of aryl iodides
6-2 Treatment of acyl azides successively with Ph_3P, water, and nitrous acid
6-44 Hydrolysis of azlactones
6-57 Hydrolysis of α-keto amides
6-76 Reaction of metalated aldimines with CO_2
6-77 Hydrolysis of diiminooxetanes
9-10 Ozonization of alkynes or aromatic rings
9-16 Oxidation of ketones with selenium dioxide
9-21 Oxidative cleavage of α-amino ketones
9-23 Oxidation of olefins
9-28 Oxidation of alkynes
9-70 Ring enlargement of cyclic diesters

1,3-Dicarbonyl Compounds

0-96 Alkylation at a carbon bearing an active hydrogen
0-109 Acylation at a carbon bearing an active hydrogen
0-110 Acylation of ketones by anhydrides
0-111 Acylation of esters by esters (Claisen; Dieckmann)
0-112 Acylation of ketones by esters
0-113 Acylation of carboxylic acid salts
2-15 Acylation of acetals or ketals followed by hydrolysis
2-17 Acylation of enamines followed by hydrolysis (Stork)
2-25 Esterification of enolates with acyl peroxides

3-14 Arylation at a carbon bearing an active hydrogen
5-19 Addition of active-hydrogen compounds to olefins (Michael)
5-23 Free-radical addition of 1,3-dicarbonyl compounds to olefins
6-32 Reaction between nitriles, zinc, and α-halo esters (Reformatsky)
6-35 Addition of CO_2 to *gem*-dimetallic compounds
6-42 Addition of 1,3-dicarbonyl compounds to aldehydes or ketones (Knoevenagel)
6-43 Carboxylation of ketones and esters
7-17 Cleavage of Michael adducts
7-52 Extrusion of sulfur from β-keto thiol esters
8-9 Rearrangement of diacyldiazomethanes
8-10 Reaction of ketones with ethyl diazoacetate
9-34 Dimerization of β-keto esters or similar compounds

1,4-Dicarbonyl Compounds

0-7 Cleavage of furans
0-86 Coupling of α,α′-dibromo ketones
1-15 Acylation of aromatic rings by succinic anhydride
5-19 Addition of active-hydrogen compounds to olefins (Michael)
5-22 Acylation of unsaturated ketones or alkynes
5-50 Reaction between ketene and diazo ketones
5-57 Dicarbalkoxylation of olefins and acetylenes
5-58 Reaction between alkynes, alkyl halides, and alcohols
9-35 Dimerization of silyl enol ethers or of lithium enolates

Dicarboxylic Acids (*see* Dicarbonyl Compounds, Carboxylic Acids)

Dicyano Compounds

0-96 Alkylation of malononitriles
3-14 Arylation of malononitriles
5-19 Addition of nitriles to unsaturated nitriles (Michael)
5-24 Reductive coupling of acrylonitrile
6-42 Addition of malononitriles to aldehydes or ketones (Knoevenagel)
6-52 Addition of HCN to nitriles
9-11 Oxidation of *o*-diamines

Diesters (*see* Dicarbonyl Compounds)

Dihalides and Polyhalides

0-69 Treatment of epoxides with $SOCl_2$ or Ph_3P and CCl_4
0-77 Reduction of trihalides
2-39 Decarboxylation of trihalo acids
2-43 The haloform reaction
4-1 Free-radical halogenation
5-1 Addition of hydrogen halides to alkynes
5-30 Addition of halogens to olefins or alkynes
5-37 Free-radical addition of polyhalides to olefins
6-26 Reaction of PCl_5, SF_4, or other reagents with aldehydes, ketones, or other C=O compounds

Diketones (*see* Dicarbonyl Compounds)

Dinitro Compounds

0-62 Reaction between salts of nitro compounds and silver nitrate
4-12 Nitration of paraffins
5-43 Addition of N_2O_4 to olefins

gem-Diols (Hydrates)

6-1 Hydration of aldehydes

1,2-Diols

0-8 Hydrolysis of epoxides
5-39 Hydroxylation of olefins
9-67 Bimolecular reduction of aldehydes or ketones

1,3-Diols

6-46 Condensation between formaldehyde and aldehydes or ketones (Tollens)
6-54 Addition of aldehydes to olefins (Prins)

Disulfides

0-41 Reaction between alkyl halides and disulfide ion
3-5 Reaction between aryl halides and disulfide ion
3-29 The Smiles rearrangement
9-37 Oxidation of mercaptans
9-55 Reduction of sulfonyl halides

Dithiols

6-12 Addition of H_2S to carbonyl compounds or imines

Enamines

5-9 Addition of amines to triple-bond compounds
6-15 Addition of amines to aldehydes or ketones

6-17 Reaction between formic acid, secondary amines, and active-hydrogen compounds (Mannich)
6-34 Reaction between Grignard reagents and formamides
6-76 Reaction of isonitriles with active-hydrogen compounds
9-3 Dehydrogenation of tertiary amines

Enolate Ions

2-3 Treatment of aldehydes or ketones with base
2-20 Treatment of active-hydrogen compounds with base

Enol Ethers and Esters

0-17 O-Alkylation of carbonyl compounds with diazo alkanes
0-19 Transetherifications
0-22 Reaction between acyl halides and active-hydrogen compounds
0-25 Transesterifications
0-26 Acylation of vinyl halides
0-96 Alkylation with ortho esters
0-109 O-Acylation of 1,3-dicarbonyl compounds
5-5 Addition of alcohols or phenols to alkynes; addition of aldehydes or ketones to ketene
5-6 Addition of acids to alkynes
6-6 Addition of alcohols to aldehydes or ketones
6-47 Reaction of α-alkoxy phosphoranes with aldehydes or ketones
7-2 Cleavage of acetals
7-29 Elimination from β-halo acetals

Enol Thioethers

5-7 Addition of mercaptans to alkynes
6-12 Reaction of aldehydes or ketones with mercaptans

Enynes

5-17 Dimerization of acetylenes

Episulfides

0-39 Reaction between epoxides and phosphine sulfides
5-32 Cyclization of β-halo disulfides
6-66 Reaction of diazoalkanes with sulfur or thioketones

Epoxides

0-15 Cyclization of halohydrins
0-18 Cyclization of 1,2-glycols
5-40 Epoxidation of olefins
6-31 Reaction of carbonyl compounds with *gem*-dihalides and Li or BuLi
6-45 Condensation between aldehydes and α-halo esters, ketones, or amides (Darzens)
6-65 Addition of sulfur ylides or diazomethane to aldehydes or ketones
9-68 Bimolecular reduction of aldehydes or ketones

Esters (*see* Carboxylic Esters, Inorganic Esters)

Ethers (*see* also Hydroxy Ethers, etc.)

0-7 Cleavage of oxonium ions
0-11 Reaction between esters and alkoxide ion
0-14 Reaction between alkoxides or aroxides and alkyl halides (Williamson)
0-16 Reaction between alkoxides or aroxides and inorganic esters
0-17 Alkylation of alcohols or phenols with diazo compounds
0-18 Dehydration of alcohols
0-19 Transetherification
0-21 Alkylation of alcohols with onium salts
0-31 Exchange of ethers and oxonium salts
0-68 Cleavage of oxonium salts
0-80 Reduction of acetals or ketals
0-92 Reaction between Grignard reagents and acetals or ketals
2-24 Reaction between Grignard reagents and *t*-butyl peresters
3-4 Reaction between aryl halides and alkoxides or aroxides
4-7 Cyclization of alcohols with lead tetraacetate
4-37 Desulfurization of hemithioacetals
5-5 Addition of alcohols or phenols to olefins
5-15 Hydroboration-reduction of acetylenic acetals
5-23 Free-radical addition of ethers to olefins
5-48 Addition of acetals to vinyl ethers
6-7 Reductive alkylation of alcohols
9-42 Reduction of esters
9-64 Reduction of peroxides

Formazans

2-7 Coupling of diazonium salts with arylhydrazones

Fulvenes

6-42 Condensation between cyclopentadiene and aldehydes or ketones

Glycidic Esters

5-40 Epoxidation of α,β-unsaturated esters
6-45 Condensation between aldehydes or ketones and α-halo esters (Darzens)

Grignard Reagents (*see* Organometallic Compounds)

Halo Acids, Esters, Aldehydes, Ketones (*see* Halo Carbonyl Compounds)

Haloamines

5-33 Addition of N-haloamines to unsaturated compounds

N-Haloamines and Amides

2-54 Halogenation of amines or amides

Halo Carbonyl Compounds

0-71 Reaction of diazo ketones with hydrohalic acids
2-4 Halogenation of aldehydes or ketones
2-5 Halogenation of acids (Hell-Volhard-Zelinskii) and acid derivatives
5-30 Addition of halogens to ketenes
5-31 Addition of HOBr or HOCl to triple bonds; addition of chlorine acetate or $PdCl_2$–$CuCl_2$–HOAc to olefins
5-37 Reaction of enol borinates with bromine, followed by hydrolysis
5-38 Addition of acyl halides to olefins
6-42 From ketones, lithiocyclopropyl phenyl sulfide, and bromine
6-58 Reaction between acyl bromides and aldehydes or ketones
8-13 Rearrangement of halo epoxides
9-23 Oxidation of certain alkenes with chromyl chloride

Halo Ethers and Acetals

2-4 Halogenation of acetals or ketals
5-31 Addition of hypohalites to double bonds; reaction of Br_2 and NaOMe with alkenyl boronic acids
6-25 Addition of alcohols and hydrogen halides to aldehydes or ketones

Haloformic Esters

0-22 Alcoholysis of phosgene

Halohydrins

0-69 Cleavage of epoxides with hydrogen halides
5-31 Addition of hypohalous acids to olefins

Halo Sulfoxides and Sulfones

2-6 Halogenation of sulfoxides and sulfones
5-32 Addition of sulfonyl halides to olefins

Hemiacetals

6-6 Addition of alcohols to aldehydes or ketones

Hemiaminals

6-14 Reaction between aldehydes or ketones and ammonia
6-15 Reaction between aldehydes or ketones and amines

Hemihydrates

6-1 Hydration of aldehydes

Hemimercaptals

6-12 Addition of mercaptans to aldehydes or ketones

Heterocyclic Compounds (*see also* Epoxides, Episulfides, Aziridines, Lactams, Lactones, Anhydrides, Imides)

0-15 Cyclization of halohydrins (cyclic ethers)
0-18 Cyclization of glycols (cyclic ethers; furans)
0-19 Reaction of diols with acetals (cyclic acetals)
0-39 Reaction of dihalides with sulfide ion (cyclic sulfides)
0-46 Cyclization of haloamines (cyclic amines)
0-56 Dimerization of amino acids (diketopiperazines)
0-61 Reaction between ureas and malonic esters or between carbonates and malonamides (cyclic ureides)
1-9 Sulfurization of aromatic rings (cyclic sulfides)
1-15 Intramolecular acylation
1-24 Intramolecular amidation of aromatic rings
1-26 Cyclization of amides with $POCl_3$ (isoquinolines); reaction between aromatic amines, glycerol, sulfuric acid, and nitro compounds (quinolines); reaction between phenols and β-keto esters (coumarins)
2-7 Intramolecular aliphatic diazonium coupling (pyridazines)
2-11 Intramolecular nitrene insertion
3-6 Intramolecular arylation of amines (cyclic amines)
3-14 Intramolecular arylation of active-hydrogen compounds

3-17	Arylation of heterocyclic nitrogen compounds
3-18	Amination of heterocyclic nitrogen compounds
4-7	Cyclization of alcohols with lead tetraacetate (tetrahydrofurans)
4-16	Intramolecular arylation (Pschorr)
4-21	Alkylation and arylation of nitrogen heterocycles
4-22	Carbalkoxylation and carboamidation of nitrogen heterocycles
5-7	Addition of H_2S to conjugated diynes (thiophenes)
5-9	Addition of ammonia or primary amines to conjugated diynes (pyrroles)
5-13	Hydrogenation of heterocyclic aromatic rings
5-15	Addition of boranes to dienes (cyclic boranes)
5-32	Addition of sulfur dichloride to dienes
5-40	Epoxidation of C=N compounds (oxaziranes)
5-41	Photooxidation of dienes (cyclic peroxides)
5-45	Addition of aminonitrenes to triple bonds (1-azirines); addition of nitrenoids to C=N or C=O bonds (diaziridines, oxaziranes)
5-46	Photolysis or thermolysis of vinyl azides (1-azirines)
5-50	1,3-Dipolar addition to double or triple bonds
5-51	Diels-Alder addition involving hetero atoms
5-53	Expansion of heterocyclic rings upon treatment with carbenes
5-55	Other cycloaddition reactions
6-6	Formation of cyclic acetals; reaction between diketones and acids (furans, pyrans)
6-12	Addition of H_2S to aldehydes or ketones (cyclic mercaptals)
6-14	Reaction between aldehydes and ammonia (cyclic amines)
6-15	Intramolecular addition of amines to carbonyl groups (cyclic imines)
6-19	Reaction of dinitriles with ammonia (cyclic imidines)
6-21	Reaction between hydrazines and β-diketones or β-keto esters (pyrazoles; pyrazolones)
6-28	Reduction of N-alkylpyridinium salts (dihydropyridines)
6-36	Alkylation of salts of nitrogen heterocyclic compounds (cyclic amines)
6-42	Reaction of ketones with tosylmethylisocyanide (oxazolines)
6-54	Reaction between alcohols and aldehydes (dioxanes)
6-60	Trimerization of aldehydes (trioxanes)
6-62	Dimerization or trimerization of C=N compounds
6-64	Trimerization of nitriles (triazines)
6-68	Addition of olefins to aldehydes or ketones (oxetanes)
6-69	Reaction of sulfenes and enamines (thietane-1,1-dioxides)
6-77	Reaction of isonitriles with aldehydes or ketones (diiminooxetanes)
7-23	Reaction of dichlorobenzyl sulfones with base (thiiren-1,1-dioxides)
7-48	Extrusion of N_2 from tetrazolines (diaziridines)
7-49	Extrusion of CO_2 from benzoxadiazepinones (indazoles)
7-53	Condensation of thiobenzilic acid with aldehydes or ketones (oxathiolan-5-ones)
8-18	Curtius rearrangement of cycloalkyl or aryl azides
8-22	Rearrangement of N-haloamines (cyclic amines)
8-36	Ring expansion of N-acylaziridines (oxazoles)
8-39	Cyclization of arylhydrazones (Fischer indole synthesis)
8-46	Acid-catalyzed rearrangement of N-haloamines (pyrrolidines; piperidines—Hofmann-Löffler)
9-1	Aromatization of heterocyclic rings
9-2	Cyclodehydrogenation
9-39	Reduction of α,β-unsaturated ketones (pyrazolones)
9-41	Reduction of lactams (cyclic amines)
9-42	Reduction of lactones (cyclic ethers)

Hydrates (*see gem*-Diols)

Hydrazides

0-54	Acylation of hydrazines with acyl halides
0-57	Acylation of hydrazines with esters

Hydrazines

3-18	Hydrazination of heterocyclic nitrogen compounds
5-9	Addition of hydrazines to olefins
8-17	Reaction between ureas and NaOBr (Hofmann)
9-52	Reduction of N-nitroso compounds
9-54	Reduction of azo compounds or diazonium salts
9-73	Reduction of nitro compounds

Hydrazo Compounds (*see* Hydrazines)

Hydrazones

2-7	Aliphatic diazonium coupling
6-21	Addition of hydrazines to aldehydes or ketones
9-11	Cleavage of double bonds with hydrazinium ion or diazonium salts

Hydroperoxides

0-32	Reaction between alkyl or acyl halides and hydrogen peroxide
2-22	Reaction between Grignard reagents and oxygen
4-8	Autoxidation; reaction of alkenes with singlet oxygen
5-7	Addition of mercaptans to olefins in the presence of oxygen

Hydroxamic Acids

0-54	Acylation of hydroxylamine with acyl halides
0-57	Acylation of hydroxylamine with esters
6-4	Hydrolysis of aliphatic nitro compounds

Hydroxy Acids

0-11	Hydrolysis of lactones
1-23	Carboxylation of phenols
2-22	Oxidation of dilithiated carboxylic acids
3-20	Hydroxylation of aromatic acids
6-5	Hydrolysis of cyanohydrins
6-32	Reaction between aldehydes or ketones and zinc carboxylates
6-42	Addition of dianions of carboxylic acids to ketones
8-7	Rearrangement of benzils
8-8	Rearrangement of α,β-epoxy ketones (Favorskii)
9-74	Reaction between keto aldehydes and base

Hydroxy Aldehydes and Ketones

0-6	Hydrolysis of diazo ketones
0-99	Reaction between dithiane salts and epoxides
0-100	Alkylation of oxazines with epoxides
1-34	Rearrangement of phenolic esters (Fries)
2-17	Alkylation of enamines with epoxides
4-4	Hydroxylation of ketones
6-27	Monoreduction of α-diketones
6-40	Condensation of aldehydes and/or ketones (aldol)
6-42	Reaction of ketones with tosylmethylazide and thallium ethoxide, followed by hydrolysis; reaction of aldehydes, ketones, or esters with methoxyvinyllithium
6-46	Condensation of formaldehyde with aldehydes or ketones (Tollens)
6-56	Condensation of aromatic aldehydes (benzoin)
6-76	Reaction of metalated aldimines with aldehydes or epoxides
8-4	Rearrangement of α-hydroxy aldehydes or ketones
8-7	Reaction between benzils and Grignard reagents
9-20	Oxidation of epoxides
9-23	Oxidation of alkenes
9-70	Condensation of esters (acyloin)

Hydroxyamines and Amides

0-51	Amination of epoxides
3-28	Rearrangement of aryl hydroxylamines (Bamberger)
4-4	Hydroxylation of amides
4-5	Hydroxylation of amines
5-42	Oxyamination of double bonds
6-14	Addition of ammonia to aldehydes or ketones
6-15	Addition of amines or amides to aldehydes or ketones
6-32	Reaction between aldehydes or ketones, zinc, and halo amides
6-36	Addition of Grignard reagents to oximes
8-45	Rearrangement of amino esters

Hydroxy Esters

0-25	Transesterification of lactones
0-105	Carbonylation of epoxides
4-4	Hydroxylation of esters
6-32	Reaction between aldehydes or ketones, zinc, and α-halo esters (Reformatsky)
6-41	Condensation between esters and aldehydes or ketones
6-42	Addition of α-metalated esters to ketones
6-55	Addition of aldehydes to alkynyl ethers
8-7	Rearrangement of benzils by means of alkoxide ion
8-45	Rearrangement of esters

Hydroxy Ethers

0-20	Alcoholysis of epoxides

Hydroxylamines

5-9	Addition of hydroxylamine to olefins
6-28	Reduction of oximes
7-8	Cleavage of amine oxides (Cope)
8-25	Rearrangement of N-oxides (Meisenheimer)
9-24	Oxidation of primary amines
9-51	Reduction of nitro compounds

Hydroxy Mercaptans and Sulfides

0-38 Reaction between epoxides and NaSH
0-39 Reaction between epoxides and mercaptides
6-12 Addition of H_2S to aldehydes or ketones

Hydroxy Nitriles

0-103 Reaction between epoxides and cyanide ion
6-32 Reaction between aldehydes and ketones, zinc, and halo nitriles
6-42 Addition of nitriles to ketones
6-50 Addition of HCN to aldehydes or ketones

Hydroxy Sulfonic Acids

0-44 Reaction between epoxides and bisulfite ion
6-13 Addition of bisulfite ion to aldehydes or ketones

Imides (including Ureides)

0-54 Reaction between acyl halides and lithium nitride
0-55 Amination of anhydrides
0-60 N-Alkylation of imides
0-61 N-Acylation of amides or imides
5-9 Addition of imides to olefins
5-25 Hydrocarboxylation of unsaturated amides
6-59 Addition of acids to nitriles
6-62 Dimerization and trimerization of isocyanates
6-74 Reaction of isonitriles, carboxylic acids, aldehydes or ketones, and secondary amines (Ugi)
6-75 Addition of N-halo amides to isonitriles
8-17 Reaction between amides and NaOBr (Hofmann)
8-18 Rearrangement of acyl azides in the presence of water (Curtius)
9-18 Oxidation of lactams

Imines

2-8 Reaction between active-hydrogen compounds and nitroso compounds
5-9 Addition of amines to triple-bond compounds
6-14 Addition of ammonia to aldehydes or ketones
6-15 Addition of amines to aldehydes or ketones
6-29 Reduction of nitrilium ions
6-38 Addition of Grignard reagents to nitriles
6-47 Addition of ylides to nitroso compounds
6-76 Reaction of isocyanides with organometallic compounds (metalated imines)
8-18 Pyrolysis of alkyl or aryl azides
8-22 Rearrangement of trityl N-haloamines and hydroxylamines (Stieglitz)
9-6 Dehydrogenation of secondary amines

Imino Esters (Imidates) and Their Salts

0-36 Reaction between oxonium ions and amides
1-30 Reaction of phenols with nitriles
5-72 Reaction of isonitriles with alcohols
6-10 Alcoholysis of nitriles (Pinner)
8-49 From amides

Inorganic Esters

0-33 Reaction of alcohols or alkyl halides with inorganic acids or halides
2-26 Oxidation of trialkylboranes
3-8 Reaction between aryl halides and $POCl_3$
5-4 Addition of inorganic acids to olefins

Isocyanates

0-54 Reaction between amines and phosgene
0-61 Reaction between oxalyl chloride and unsubstituted amides
0-64 Alkylation or acylation of cyanate ion
2-55 Carbonylation of amines
5-11 Addition of cyanic acid to vinyl ethers
5-36 Addition of iodine isocyanate to double bonds
8-17 Reaction between amides and NaOBr (Hofmann)
8-18 Rearrangement of acyl azides (Curtius)
8-19 Rearrangement of hydroxamic acids (Lossen)
8-20 Addition of hydrazoic acid to carboxylic acids (Schmidt)
9-31 Oxidation of isonitriles
9-60 Reaction of nitro compounds with CO

Isonitriles

0-53 Reaction between primary amines and chloroform
0-103 Reaction between alkyl halides and cyanide ion
7-42 Elimination of water from N-alkylformamides

Isothiocyanates

0-54 Reaction between amines and thiophosgene
0-64 Alkylation or acylation of thiocyanate ion
3-22 Reaction between diazonium salts and thiocyanate ion
6-20 Addition of amines to carbon disulfide
9-60 Reaction of nitro compounds with CS_2

Isothiuronium Salts

0-38 Reaction between alkyl halides and thiourea

Ketals (*see* Acetals)

Ketenes

7-1 Pyrolysis of carboxylic acids
7-14 Dehydrohalogenation of acyl halides
7-28 Dehalogenation of α-halo acyl halides
8-9 Rearrangement of diazo ketones (Wolff)

Ketenimines

0-100 Reaction of oxazines with butyllithium
6-47 Reaction between phosphoranes and isocyanates
7-1 Dehydration of amides

Keto Acids, Aldehydes, and Esters (*see* Dicarbonyl Compounds)

Ketones (*see also* Dicarbonyl Compounds, Unsaturated Carbonyl Compounds, etc.)

0-2 Hydrolysis of *gem*-dihalides
0-4 Hydrolysis of enol esters of inorganic acids
0-7 Hydrolysis of enol ethers, ketals, thioketals, etc.
0-11 Hydrolysis of enol esters
0-26 Alcoholysis of enol esters
0-30 Reaction between enol esters and carboxylic acids
0-77 Reduction of halo ketones
0-82 Reduction of diazo ketones
0-88 Coupling of halo ketones with lithium alkylcopper reagents
0-95 Arylation of diazo ketones or diazo esters
0-96 Acetoacetic ester synthesis and similar reactions
0-97 Alkylation of ketones
0-99 Alkylation and hydrolysis of dithianes and similar compounds
0-100 Alkylation and hydrolysis of oxazines
0-101 Reaction of halo ketones or diazo ketones with boranes
0-104 Carbonylation of alkyl halides
0-106 Reaction between acyl halides and organometallic compounds
0-107 Reaction between other acid derivatives and organometallic compounds
0-109 Acylation of active-hydrogen compounds followed by cleavage
0-112 Reduction of β-keto sulfoxides
0-113 Acylation of carboxylic acid salts followed by cleavage
0-114 Reduction of β-keto alkylidene phosphoranes
0-117 Ketonic decarboxylation
1-15 Acylation of aromatic rings (Friedel-Crafts)
1-22 Reaction between aromatic rings and phosgene
1-30 Acylation of aromatic rings with nitriles (Hoesch)
1-34 Rearrangement of phenolic ethers (Fries)
1-40 Photolysis of acylated arylamines
1-45 Reaction between arylcarbinols and diazonium salts (Stiles-Sisti)
1-50 Reaction of aryltrimethylsilanes with acyl chlorides
2-2 Rearrangement of hydroxy olefins
2-17 Alkylation of enamines followed by hydrolysis (Stork)
2-31 Carbonylation of organometallic compounds
2-39 Decarboxylation of β-keto acids or esters
2-40 Cleavage of tertiary alkoxides
2-41 Replacement of a carboxyl group by an acyl group
2-42 Basic cleavage of β-diketones
3-14 Arylation of ketones
4-18 Arylation of allylic alcohols
4-21 Acylation of nitrogen heterocycles
4-23 Free-radical acylation of alkanes
4-30 Reaction of diazonium salts with oximes, followed by hydrolysis
4-42 Decomposition of tertiary hypochlorites
5-3 Hydration of alkynes or allenes
5-6 Cyclization of olefinic acids
5-13 Reduction of phenols
5-15 Oxidation of boranes; hydrolysis of unsaturated boranes
5-19 Addition of ketones to activated olefins (Michael)
5-20 Addition of organometallic compounds to unsaturated ketones
5-21 Addition of boranes to unsaturated ketones
5-23 Free-radical addition of aldehydes or ketones to olefins
5-25 Hydrocarboxylation of dienes
5-26 Hydroacylation of alkenes
5-53 Hydrolysis of bicyclo[4.1.0]heptanes
6-2 Hydrolysis of imines, oximes, hydrazones, and other C=N compounds
6-4 Hydrolysis of secondary aliphatic nitro compounds (Nef)
6-33 Reaction between lithium carboxylates and alkyllithium compounds
6-38 Addition of Grignard reagents to nitriles
6-46 Methylation of ketones with formaldehyde

6-49 Reaction of phosphoranes with nitriles
6-76 Reaction of alkyl halides with metalated aldimines
7-1 Dehydration of 1,2-diols
7-8 Indirect migration of C=O via a Cope elimination
7-12 Pyrolysis of β-hydroxy sulfoxides
7-32 Fragmentation of γ-amino or γ-hydroxy halides
7-35 Fragmentation of 1,3-diols or γ-amino alcohols
7-40 Fragmentation of certain ketoximes
7-44 Alkaline hydrolysis of nitrates
7-45 Pyrolysis of β-hydroxy olefins
7-46 Pyrolysis of allyl ethers
8-2 Rearrangement of glycols and related compounds (pinacol)
8-3 Ring expansion of certain hydroxyamines (Tiffeneu-Demyanov)
8-4 Acid-catalyzed ketone rearrangements
8-10 Homologization of aldehydes or ketones
8-17 Reaction between α-hydroxy or α-halo amides and NaOBr (Hofmann)
8-24 Cleavage of hydroperoxides
8-28 Treatment of boranes with CO and H_2O, followed by NaOH and H_2O_2; or with CN^- followed by trifluoroacetic anhydride; from dialkylchloroboranes
8-31 Treatment of lithium alkynyltrialkylborates with electrophiles
8-48 Rearrangement of enol ethers
9-4 Oxidation of secondary alcohols
9-8 Oxidative cleavage of glycols and related compounds
9-9 Oxidative degradation of aldehydes
9-10 Ozonolysis of olefins
9-11 Oxidative cleavage of olefins
9-12 Oxidation of diarylmethanes
9-14 Oxidative cleavage of carboxylic acids
9-15 Bisdecarboxylation of malonic acids
9-16 Oxidation of activated methylene groups
9-20 Oxidation of secondary alkyl halides and tosylates
9-21 Oxidation of amines
9-23 Oxidation of olefins with noble-metal salts
9-39 Reduction of diketones or quinones
9-61 Oxidative decyanation of nitriles

Lactams

0-56 Cyclization of amino acids
0-57 Reaction between lactones and ammonia or amines
0-60 Cyclization of halo amides
5-9 Addition of lactams to olefins
5-25 Hydrocarboxylation of unsaturated amines
6-32 Reaction between imines, zinc, and halo esters
6-47 Reaction between imides and phosphoranes
6-70 Addition of ketenes to imines; addition of enamines to isocyanates
8-20 Reaction between cyclic ketones and hydrazoic acid (Schmidt)
8-21 Rearrangement of oximes of cyclic ketones (Beckmann)

Lactones

0-24 Cyclization of hydroxy acids
0-26 Cyclization of halo acids
5-6 Cyclization of olefinic acids
5-25 Hydrocarboxylation of unsaturated alcohols
5-47 Reaction of alkenes with manganese(III) acetate
6-47 Reaction of anhydrides with phosphoranes
6-68 Addition of ketenes to aldehydes or ketones
7-49 Extrusion of CO_2 from 1,2-dioxolane-3,5-diones
7-51 Decarboxylation of cyclic peroxides (Story)
8-23 Reaction between cyclic ketones and peroxy compounds (Baeyer-Villiger)
8-46 Rearrangement of N-halo amides
9-18 Oxidation of cyclic ethers
9-22 Oxidation of diols
9-43 Reduction of cyclic anhydrides

Mercaptals

5-7 Addition of mercaptans to alkynes
6-12 Addition of mercaptans to aldehydes or ketones

Mercaptans

0-11 Hydrolysis of thiol esters
0-38 Reaction of alkyl halides with NaSH; cleavage of isothiuronium salts
1-9 Sulfurization of aromatic compounds (Herz)
2-27 Reaction between Grignard reagents and sulfur
3-5 Reaction between aryl halides and NaSH
3-22 Reaction between diazonium salts and NaSH
5-7 Addition of H_2S to olefins
9-55 Reduction of sulfonyl halides
9-65 Reduction of disulfides

Metallocenes

2-34 Reaction between sodium cyclopentadienylide and metal halides

Monoesters of Dicarboxylic Acids

0-23 Alcoholysis of cyclic hydrides
0-25 Equilibration of dicarboxylic acids and esters
0-113 Acylation of carboxylic acid salts with chloroformates or carbonates
6-10 Alcoholysis of cyano acids

Nitriles (*see also* Dicyano Compounds, Cyano Carbonyl Compounds, etc.)

0-97 Alkylation of nitriles
0-101 Reaction of halo nitriles or diazo nitriles with boranes
0-103 Reaction between alkyl halides and cyanide ion
1-31 Direct cyanogenation of aromatic rings
2-32 Cyanogenation of organometallic compounds
2-39 Decarboxylation of α-cyano acids
3-11 Reaction between aryl halides and CuCN (Rosenmund–von Braun)
3-12 Cyanide fusion of sulfonic acid salts
3-14 Arylation of nitriles
4-28 Reaction between diazonium salts and CuCN (Sandmeyer)
4-39 Reaction of acyl peroxides with copper cyanide
4-41 Decarbonylation of aromatic acyl cyanides
5-19 Addition to activated olefins (Michael)
5-21 Addition of boranes to acrylonitrile
5-23 Free-radical addition of nitriles to olefins
5-28 Addition of HCN to olefins
6-5 Exchange of nitriles with carboxylic acids
6-23 From aldehydes
6-42 Reaction of ketones with tosylmethylisocyanide
6-44 From rhodanine
6-52 Reaction of HCN with carbomethoxy hydrazones, followed by treatment with Br_2 and then methoxide ions
6-63 Reaction between acid salts and BrCN
7-39 Dehydration of aldoximes and similar compounds
7-40 Fragmentation of ketoximes
7-41 Dehydration of amides
9-6 Dehydrogenation of amines
9-7 Oxidation of hydrazones
9-58 Reduction of nitrile oxides
9-62 Reduction of nitro compounds with $NaBH_2S_3$

Nitro Compounds

0-62 Reaction between alkyl halides and nitrite ion
0-96 Alkylation of nitro compounds
1-2 Nitration of aromatic rings
1-36 Rearrangement of N-nitro aromatic amines
2-39 Decarboxylation of α-nitro acids
2-50 N-Nitration of amines or amides
3-17 Methylation of aromatic nitro compounds
4-12 Nitration of paraffins
4-26 Reaction between diazonium salts and sodium nitrite
4-40 Decarboxylative nitration
5-19 Addition to activated olefins (Michael)
5-34 Addition of NOCl and other nitrogen compounds to olefins
5-43 Addition of N_2O_4 and other nitrogen compounds to olefins
6-42 Addition of nitro compounds to aldehydes or ketones
6-43 Carboxylation of nitro compounds
9-25 Oxidation of primary amines, oximes, or nitroso compounds

Nitrogen Ylides

2-19 Treatment of quaternary ammonium salts with organometallic compounds

Nitrones

0-35 Alkylation of oximes

Nitroso Compounds

1-3 Nitrosation of aromatic rings
1-37 Rearrangement of N-nitroso aromatic amines (Fischer-Hepp)
1-43 Nitrosative decarboxylation of aromatic acids
2-8 Nitrosation at a carbon bearing an active hydrogen
2-50 Reaction between secondary amines or amides and nitrous acid
5-34 Addition of NOCl to olefins
5-43 Addition of N_2O_3 to olefins
8-46 Photolysis of nitrites (Barton)
9-7 Oxidation of hydroxylamines
9-24 Oxidation of primary amines
9-50 Reduction of nitro compounds

Olefins (*see* Alkenes)

Organometallic Compounds

0-87 Reaction of alkyllithiums with alkylcopper reagents
2-19 Metalation of susceptible positions with organometallic compounds
2-20 Metalation of susceptible positions with metals or strong bases

2-21 Cleavage of alkyl groups from di- or polyvalent organometallic compounds
2-33 Reaction between an organometallic compound and a metal
2-34 Reaction between an organometallic compound and a metal halide
2-35 Reaction between an organometallic compound and an organometallic compound (exchange)
2-37 Metalation of alkyl or aryl halides with metals
2-38 Metalation of alkyl or aryl halides with organometallic compounds
4-31 Reaction of diazonium salts with metals
5-16 Hydrometalation of alkenes
8-15 Rearrangement of Grignard reagents

Ortho Esters

0-14 Reaction of alkoxides with 1,1,1-trihalides (Williamson)
0-19 Transetherification
6-6 Addition of alcohols to formic acid
6-9 Reaction between imino ester salts and alcohols

Osazones

6-21 Addition of hydrazines to α-hydroxy aldehydes or ketones

Oxime Ethers

0-17 Alkylation of oximes with diazo compounds
0-35 Alkylation of oximes with alkyl sulfates

Oximes

2-8 Nitrosation at a carbon bearing an active hydrogen
5-34 Addition of NOCl to olefins
6-22 Addition of hydroxylamine to aldehydes or ketones
8-46 Photolysis of nitrites (Barton)
9-24 Oxidation of aliphatic primary amines
9-62 Reduction of nitro compounds

Oxiranes (*see* Epoxides)

Oxonium Salts

0-31 Reaction between alkyl halides and ethers or ketones

Ozonides

9-10 Ozonolysis of olefins

Peresters

0-32 Reaction of acyl halides with hydroperoxides

Peroxides (*see also* Hydroperoxides, Peresters)

0-32 Reaction of alkyl and acyl halides with sodium or hydrogen peroxide
4-9 Reaction between hydroperoxides and susceptible hydrocarbons
5-5 Oxymercuration-reduction of alkenes in the presence of a hydroperoxide
5-41 Photooxidation of dienes
7-51 Reaction of ketones with H_2O_2

Peroxy Acids

9-33 Oxidation of carboxylic acids

Phenols

0-7 Acid cleavage of alkyl aryl ethers
0-11 Hydrolysis of phenolic esters
0-33 Cleavage of phenolic ethers with sulfonic acids
0-39 Cleavage of phenolic ethers
0-68 Cleavage of phenolic ethers with HI or HBr
0-92 Cleavage of aryl ethers with Grignard reagents
1-32 Electrophilic hydroxylation of aromatic rings
1-34 Rearrangement of phenolic esters (Fries)
1-35 Rearrangement of phenolic ethers
1-48 Debromination of bromophenols
2-22 Oxidation of Grignard reagents
2-23 Oxidation of arylthallium compounds
3-1 Hydrolysis of aryl halides and other compounds
3-2 Reaction between naphthylamines and bisulfite ion (Bucherer)
3-3 Alkali fusion of sulfonates
3-20 Nucleophilic hydroxylation of aromatic acids
3-21 Hydrolysis of diazonium salts
3-28 Rearrangement of N-hydroxylamines
4-5 Free-radical hydroxylation of aromatic rings
6-27 Reduction of quinones
8-6 The dienone-phenol rearrangement
8-23 Cleavage of aryl ketones with peracids (Baeyer-Villiger)
8-38 Rearrangement of allyl aryl ethers (Claisen)
8-50 Rearrangement of azoxy compounds (Wallach)
9-1 Aromatization of cyclic ketones

9-13 Oxidative cleavage of alkylbenzenes or aromatic aldehydes
9-44 Reduction of phenolic esters

Phosphines

0-46 Reaction between alkyl halides and phosphine
0-82 Reduction of quaternary phosphonium salts
2-34 Reaction between phosphorus halides and Grignard reagents

Phosphonates

6-47 Reaction between alkyl halides and phosphites

Phosphoranes

0-114 Acylation of phosphoranes
6-47 Treatment of phosphonium ions with alkyllithiums; addition of halocarbenes to phosphines

Quaternary Ammonium and Phosphonium Salts

0-46 Alkylation of amines (Menschutkin) or phosphines
5-9 Addition of tertiary amines to alkenes
6-47 Reaction of phosphines with Michael olefins or with alkyl halides

Quinones

1-15 Intramolecular Friedel-Crafts acylation of diaryl ketones
9-5 Oxidation of phenols or aromatic amines
9-19 Oxidation of aromatic hydrocarbons

Schiff Bases (*see* Imines)

Selenides

0-39 Selenylation of alkyl halides
2-12 Selenylation of aldehydes, ketones, and esters
2-27 Selenylation of organometallic compounds

Semicarbazones

6-21 Addition of semicarbazide to aldehydes or ketones

Sulfenimides

0-60 Reaction of alkyl halides with $(PhS)_2NLi$

Sulfenyl Chlorides

4-11 Chlorosulfenation

Sulfides

0-39 Reaction between alkyl halides and mercaptides or Na_2S
0-99 Alkylation of sulfides
1-9 Sulfurization of aromatic rings
1-29 Thioalkylation of aromatic rings
2-12 Sulfenylation of ketones and esters
2-27 Reaction between Grignard reagents and sulfur
3-5 Reaction between aryl halides or phenols and mercaptides or Na_2S
3-22 Reaction between diazonium salts and mercaptides or Na_2S
4-33 Reaction of boranes with disulfides
5-7 Addition of mercaptans to olefins
5-32 Addition of sulfenyl chlorides to olefins
7-11 Cleavage of sulfonium compounds
8-25 Rearrangement of sulfonium salts (Stevens)
8-40 [2,3] sigmatropic rearrangements of sulfur ylides
9-42 Reduction of thiol esters
9-59 Reduction of sulfoxides or sulfones
9-64 Reduction of disulfides

Sulfinic Acids and Esters

0-74 Cleavage of sulfoxides
0-122 Reduction of sulfonyl chlorides
2-27 Reaction of Grignard reagents with SO_2
3-29 The Smiles rearrangement
4-27 Reaction of diazonium salts with $FeSO_4$ and Cu
7-12 Cleavage of sulfones
9-26 Oxidation of mercaptans

Sulfonamides

0-60 N-Alkylation of sulfonamides
0-96 Alkylation of sulfonamides
0-101 Reaction of halo sulfonamides with boranes
0-120 Reaction between sulfonyl halides and ammonia or amines
5-9 Addition of sulfonamides to olefins
9-54 Reduction of sulfonyl azides

Sulfones

0-43 Reaction between alkyl halides and sulfinates
0-96 Alkylation of sulfones
0-97 Alkylation of sulfones
0-101 Reaction of halo sulfones with boranes
0-112 Reaction between esters and methylsulfonyl carbanion
0-123 Reaction between sulfonic acid derivatives and Grignard reagents

1-10 Sulfonylation of aromatic rings
3-5 Reaction between aryl halides and sulfinates
5-19 Addition of sulfones to activated olefins (Michael)
5-20 Addition of organometallic compounds to unsaturated sulfones
5-32 Addition of sulfonyl halides to olefins
6-42 Addition of sulfones to aldehydes or ketones (Knoevenagel)
8-48 Rearrangement of enol tosylates
9-32 Oxidation of sulfides or sulfoxides

Sulfonic Acid Esters

0-33 Reaction between alcohols or ethers and sulfonic acids
0-96 Alkylation of sulfonic acid esters
0-97 Alkylation of sulfonic acid esters
0-101 Reaction of halo sulfonic acid esters with boranes
0-119 Alcoholysis of sulfonic acid derivatives
1-33 Reaction between arylsulfonyl peroxides and aromatic rings
5-4 Addition of sulfonic acids to olefins
6-42 Addition of sulfonic acid esters to aldehydes or ketones (Knoevenagel)

Sulfonic Acids

0-44 Reaction between alkyl halides and sulfite ion
0-118 Hydrolysis of sulfonic acid derivatives
1-7 Sulfonation of aromatic rings
1-44 Sulfonation with rearrangement (Jacobsen)
1-47 Migration of sulfo groups
2-13 Sulfonylation of aldehydes, ketones, or acids
3-5 Reaction between aryl halides or arylamines and sulfite ion
5-8 Addition of sodium bisulfite to olefins
9-26 Oxidation of mercaptans or other sulfur compounds

Sulfonium Salts

0-39 Reaction between alkyl halides and sulfides

Sulfonyl Azides

0-120 Reaction between sulfonyl halides and azide ion

Sulfonyl Halides

0-121 From sulfonic acids and derivatives
1-8 Halosulfonation of aromatic rings
2-27 Reaction of Grignard reagents with sulfuryl chloride or with SO_2 followed by X_2
4-11 Free-radical halosulfonation (Reed)
4-27 Reaction of diazonium salts with SO_2 and $CuCl_2$
9-27 Oxidation of mercaptans and other sulfur compounds

Sulfoxides

0-96 Alkylation of sulfoxides
0-112 Reaction between esters and methylsulfinyl anion
1-9 Sulfurization of aromatic rings with thionyl chloride
2-27 Reaction of Grignard reagents with sulfinic esters
5-20 Addition of organometallic compounds to unsaturated sulfoxides
6-42 Addition of sulfoxides to aldehydes or ketones (Knoevenagel)
9-32 Oxidation of sulfides

Sulfur Ylides

2-14 Reaction between sulfoxides and active-hydrogen compounds

Thioamides

1-24 Amidation of aromatic rings with isothiocyanates
6-37 Addition of Grignard reagents to isothiocyanates
9-76 Reaction of ketones with sulfur and ammonia or amines

Thiocarbamates

2-55 Treatment of amines with CO and disulfides
6-5 Hydrolysis of thiocyanates
6-8 Addition of alcohols to isothiocyanates

Thiocyanates

0-45 Reaction between alkyl halides and thiocyanate ion
1-11 Thiocyanation of aromatic rings
3-5 Reaction between aryl halides and thiocyanate ion
3-22 Reaction between diazonium salts and thiocyanate ion
4-39 Reaction between acyl peroxides and copper thiocyanate

Thioethers (*see* Sulfides)

Thiol Acids and Esters

0-40 Reaction between acid derivatives and mercaptans or H_2S

1-22 Reaction of aromatic rings with alkyl thiolchloroformates
1-30 Reaction between aromatic rings and thiocyanates
5-3 Hydration of acetylenic thioethers
5-7 Addition of thiol acids to olefins; addition of mercaptans to ketenes
5-25 Hydrocarboxylation of olefins in the presence of mercaptans
6-39 Addition of Grignard reagents to carbon disulfide

Thiols (*see* Mercaptans)

Thioketones

6-12 Addition of H_2S to aldehydes or ketones

Thioureas (*see* Ureas)

Triazenes

1-4 Reaction between aromatic amines and diazonium salts
2-50 Reaction between amines and diazonium salts

Unsaturated Acids, Esters, Aldehydes, Ketones (*see* Unsaturated Carbonyl Compounds)

Unsaturated Alcohols and Phenols

0-97 Rearrangement of allylic sulfoxy compounds
5-21 Reaction of boranes with unsaturated epoxides
6-27 Reduction of α,β-unsaturated aldehydes or ketones
6-31 Addition of vinyl or alkynyl organometallic compounds to aldehydes or ketones
6-42 Condensation of alkyne salts with aldehydes or ketones
6-47 Reaction of certain ylides with aldehydes (scoopy reactions)
6-54 Addition of aldehydes to olefins (Prins)
7-2 Reaction of epoxides with strong bases
7-12 From epoxides via selenoxide cleavage
8-3 Ring opening of cycloalkyl carbonium ions
8-38 Rearrangement of allyl aryl ethers (Claisen)
9-61 Reaction of alkyl hydroperoxides with $FeSO_4$ and $Cu(OAc)_2$

Unsaturated Carbonyl Compounds

0-97 Alkylation of esters with allylic halides
0-99 Hydrolysis of bis(methylthio)alkenes
0-105 Carbonylation of allylic halides
2-2 Isomerization of α-hydroxy alkynes
2-15 Acylation of olefins
5-19 Addition to activated alkynes (Michael)
5-20 Addition of vinyl organometallic compounds to unsaturated carbonyl compounds
5-25 Hydrocarboxylation of triple bonds
5-38 Addition of acyl halides to triple bonds
5-48 Hydrolysis of alkoxy acetals
5-58 Carboxylation of halides with insertion of acetylene
6-17 Reaction between aldehydes, ammonia, and aldehydes, ketones, or esters (Mannich)
6-32 Reaction between aldehydes or ketones, zinc, and α-halo esters (Reformatsky); reaction of ketones with alkyl lithiotrimethylsilylacetates
6-34 Carbonation of vinyl ate complexes
6-40 Condensation of aldehydes and/or ketones (aldol)
6-41 Condensation between esters and aldehydes or ketones
6-42 Condensation between active-hydrogen compounds and aldehydes or ketones (Knoevenagel)
6-44 Condensation between anhydrides and aldehydes (Perkin)
6-47 Condensation between β-carboxy phosphoranes and aldehydes or ketones
6-55 Addition of aldehydes, ketones, esters, or amides to alkynyl ethers
7-3 Pyrolysis of lactones
7-12 Cleavage of carbonyl-containing selenoxides and sulfones
7-36 Fragmentation of epoxy hydrazones
8-6 The phenol-dienone rearrangement
8-8 Rearrangement of dihalo ketones (Favorskii)
8-34 Rearrangement of vinylhydroxycyclopropanes
8-37 Rearrangement of 3-hydroxy-1,5-dienes; rearrangement of vinylhydroxycyclopropanes
8-38 Rearrangement of allyl vinyl ethers (Claisen)
8-40 [2,3] sigmatropic rearrangements
9-3 Dehydrogenation of aldehydes or ketones
9-14 Decarboxylation of γ-keto acids
9-16 Oxidation of a methylene group α to a double or triple bond

Unsaturated Ethers

0-96 Alkylation of allylic ethers
5-15 Oxidation of alkenylborane ethers

Unsaturated Nitriles, Nitro Compounds, and Sulfonic Esters

0-97 Alkylation of nitriles with allylic halides
5-19 Addition to activated alkynes (Michael)
5-28 Addition of HCN to alkynes
5-34 Addition of nitryl chloride to triple bonds
6-42 Condensation between active-hydrogen compounds and aldehydes or ketones (Knoevenagel)

Ureas and Thioureas

0-58 Exchange of ureas
2-45 Cleavage of α,β-acetylenic amides with amide ion
2-55 Carbonylation of amines
6-3 Hydrolysis of isocyanates
6-18 Addition of amines to isocyanates or isothiocyanates
6-20 Addition of amines to CO_2 or CS_2
6-57 Addition of alcohols or other carbonium-ion sources to cyanamides (Ritter)
8-17 Reaction between amides and lead tetraacetate

Ureides (*see* Imides)

Urethanes (*see* Carbamates)

Vinyl Ethers (*see* Enol Ethers)

Vinyl Halides

2-28 Halogenation of alkenyl organometallic compounds
5-1 Addition of hydrogen halides to triple bonds
5-30 Halogenation of alkynes or allenes
5-37 Addition of alkyl halides to triple bonds
5-38 Addition of acyl halides to triple bonds
6-26 Addition of PCl_5 to aldehydes or ketones
6-47 Reaction of halophosphoranes with aldehydes or ketones; reaction of certain ylides with halogen compounds (scoopy reactions)

Xanthates

6-11 Addition of alcohols to carbon disulfide
7-4 Reaction of alcohols with NaOH and CS_2, followed by methyl iodide

Ylides (*see* Nitrogen Ylides, Sulfur Ylides, Phosphoranes)

Ynamines

7-13 Reaction between vinylidine dihalides and amide ion
8-11 Rearrangement of ketene aminals

Subject Index

- AAC1 mechanism, 349–352, 356, 364, 365
- AAC2 mechanism, 349–352, 355, 364
- AAL1 mechanism, 350, 352, 356, 364
- AAL2 mechanism, 350–352
- Absolute configuration, 98–103, 107
- Abstraction: by carbenes, 184, 553
  - by free radicals, 177, 221, 223, 621, 625–628, 681, 1133
    - neighboring-group assistance, 624
    - polar transition states, 621–622, 627
  - of halogens, 628
  - of hydride ions, 152, 401, 724, 1075
  - internal, 643, 977, 1068, 1069, 1080, 1081, 1102
  - by nitrenes, 185
- Abstract publications, 1149–1152
- Acetaldehyde: cleavage of, 574
  - conformation of, 128
  - formation of, 696, 1108
  - in the haloform reaction, 575
  - hydration of, 804
  - reaction: with ammonia, 817
    - with formaldehyde, 863
  - trimerization of, 881
- Acetals: acylation of, 547
  - bromination of, 538
  - condensation: with enol acetates, 852
    - with silyl enolates, 851
  - conversion to enol ethers, 925
  - formation of, *see* 1166
  - formylation of, 547
  - hydrolysis of, 344–346
  - oxidation of, 1084
  - as protecting groups, 346, 357
- Acetals:
  - reaction: with active hydrogen compounds, 421
    - with enol ethers, 758
    - with organometallic compounds, 416, 843
  - reduction of, 402
  - transacetalation of, 360, 811
- Acetate ions, as nucleophiles, 324
- Acetic acid: as an acidic solvent, 232
  - acidity of, 239, 244, 245
  - decarboxylation of, 569
  - dimers of, 76
  - in ethylation of amines, 820
- Acetic anhydride: in dehydrations, 369, 950, 1099
  - formation of, 702
  - reaction: with acetals, 547
    - with alcohols, 926, 1105
    - with aldehydes or ketones, 880 881
    - with amines, 368, 835
    - with ethers, 368
- Acetoacetic ester (*see* Ethyl acetoacetate)
- Acetoacetic ester synthesis, 419-421
- Acetone: basicity of, 226
  - bromination of, 204
  - hydration of, 804-805
  - in Mannich reaction, 822
  - oxidation of alcohols, 1083
  - reaction with chloroform, 854
- Acetone hydrate, 805
- Acetonitrile, 423

- Acetoxy ketones, 400
- Acetylacetone, 339
- N-Acetylaminomalonic ester, 420
- Acetyl chloride, 693, 1130
- Acetylene: acidity of, 163, 229
  - addition of RH, 735
  - conversion: to unsaturated esters, 799-800
    - to vinylacetylene, 726
  - excited state, 213
  - reaction with aromatic rings, 485
  - trimerization and tetramerization of, 795-796
- Acetylenes (*see* Alkynes)
- Acetylenic acid esters and amides, cleavage of, 576
- Acetylide ions: acylation of, 446
  - alkylation of, 434–435, 1022
  - formation of, 555
  - halogenation of, 560
  - reaction: with aldehydes and ketones, 856
    - with boranes, 1022
- Acetyl nitrate, 474, 650, 755
- Acetyl tosylate, 369
- Achiral, definition of, 86
- Acid-base theory, 225–245
- Acid catalysis, 235–236, 802
- Acid dichromate (*see* Chromic acid)
- Acids (*see* Carboxylic acids; Sulfonic acids; *etc.*)
- Acid solvents, 231-232
- Acid strengths, 225-231
  - of carbon acids, 160-161
  - determination of, 231-232, 554
  - effects: of medium on, 243–245
    - of structure on, 238–243
  - of excited states, 214
  - of Lewis acids, 237, 241–242
  - tables of, 227–230, 240, 244
- Aci forms, 74, 808
- Acroleins, 732

Acrylonitrile: as a dienophile, 761*n.*
  dimerization of, 778
  formation of, 739
  Michael-type reactions of, 549, 679, 700*n.*, 703*n.*, 705*n.*, 727*n.*
Actinometers, 224
Activated complexes, 192, 199
  of chiral molecules, 104
Activating groups: in electrophilic aromatic substitution, 459–466
  in nucleophilic aromatic substitution, 591–593
Activation energy, 192, 459
Active hydrogen, definition of, 557
Active hydrogen compounds: acylation of, 441–442
  acyloxylation of, 648
  addition to multiple bonds, 679, 727–728, 734–735
  alkylation of, 418–432
  amination of, 544
  arylation of, 604–605
  condensation: with aldehydes and ketones, 854–859
    with CO_2 and SO_2, 859–860
    with nitriles, 873
  conversion: to diazo compounds, 543
    to enolate ions, 555
    to sulfur ylides, 545
  cyanation of, 564
  dimerization of, 1114
  formation of, 441–447
  in Mannich reaction, 821
  nitration of, 650
  nitrosation of, 542
  reaction: with acyl peroxides, 558
    with diazonium ions, 541
    with isonitriles, 894
    with nitroso compounds, 543
Acylals, formation of, *see* 1166
Acylation: at an aliphatic carbon, 439–448, 546–547
  of alkylbenzenes, 468
  of amides and imides, 389
  of amines and ammonia, 382–388, 1068
  of aromatic rings, 458, 490–493, 503
  of cyclohexane, 659
  definition of, 265
Acylation:
  of dioxane, 659
  of enamines, 549
  of heterocycles, 658
  of multiple bonds, 733–734
C-Acylation versus O-acylation, 337, 441
N-Acylation of amides and imides, 389
Acyl azides, 388, 391, 668, 963, 1005
N-Acylaziridines, 407, 1043
Acyl cations, 156, 492–493, 546, 702, 737
Acyl cleavages, 573–576
Acylcobalt tetracarbonyls, 546
Acyl cyanides, 668, 670
Acyl fluorides, 399, 829
N-Acylglycines, 861
Acyl halides: addition to multiple bonds, 735
  alcoholysis of, 361
  in the Arndt-Eistert synthesis, 995–996
  complexes of, 491, 493, 546
  conversion: to acyl isocyanates, 391
    to amides, 382
    to anhydrides, 369, 373
    to azides, 391
    to imides, 389
    to ketenes, 439, 441
    to ortho thioesters, 816
    to other acyl halides, 399
    to peroxides, 371
    to thiol acids and esters, 375–376
    to trifluorides, 829
  coupling of, 441
  decarbonylation of, 670, 938
  dehydrohalogenation of, 936 937
  formation of, *see* 1166
  halogenation of, 540
  in hydroacylation of alkenes, 738
  hydrolysis of, 347–348
  reaction: with active hydrogen compounds, 441
    with aldehydes and ketones, 881
    with alkenes, 546
    with aromatic rings, 490–493, 519
    with copper cyanide, 448
    with diazomethane, 448
    with disodium tetracarbonyl ferrate, 436
Acyl halides:
  reaction: with dithiane salts, 446
    with enamines, 549
    with ethers, 395
    with Grignard reagents, 844
    with multiple bonds, 747–748
    with phosphoranes, 447
  reduction of, 405, 406, 1124
  in reductive acylation of ketones, 812
O-Acylhydroxamic acids, 1006
Acyl hypohalites, 669
Acyl isocyanates, 390, 391, 883
Acyl isothiocyanates, 391
Acyl nitrates, 669
Acylnitrenes, 185, 544
Acyloin condensation, 1134–1136, 1138
Acyloxy amides, 892
Acyloxy epoxides, 1001
Acyloxy groups, migration of, 1066–1068
Acyloxylation, 504–505, 648–649
Acylphenols, 506
Acyl rearrangements, 892, 1066–1068
Acyl sulfonylhydrazides, 407
N-Acylureas (*see* Ureides)
O-Acylureas, 365
Adamantanes: chirality of, 92
  formation of, 982
1-Adamantyl cation, 157, 969
2-Adamantyl substrates, solvolysis of, 316
Addition to multiple bonds, 188, 672–894
1,4-Addition, 679, 683–684, 694
Addition compounds, 78–85
Addition-elimination mechanism, 585*n.*
  in electrophilic substitution, 479, 546
  in free radical arylation, 655, 656
  in nucleophilic substitution, 311–313, 600, 603, 607, 608
  in oxidations, 1076
Additive dimerization, 667–668
Adipic acid, 1089
AdN-*E* mechanism, 312
Ad3 mechanism, 675
Air (*see* Autoxidation; Oxygen)
Alane (*see* Aluminium hydride)
Alanine, 102

- Alcoholic KOH, 917, 935
- Alcohols: acidity of, 239, 244
  - addition to multiple bonds, 699–701, 734–735, 810–814, 827–828, 879–880
  - in alkylation of heterocycles, 658
  - basicity of, 243
  - carbonium ions from, 152, 154
  - carboxylation of, 437
  - cleavage of, 572, 1012, 1090
  - conversion: to alkyl halides, 392–394
    - to N-alkylphthalimides, 389
    - to amides, 651
    - to amines, 379–380
    - to inorganic esters, 372
    - to nitriles, 435, 1085
    - to tetrahydrofurans, 643–644
  - coupling of, 415, 1114–1115
  - dehydration of, 359, 923–924
  - formation of, 928, *see also* 1166
  - fragmentation of, 946
  - in the haloform reaction, 575
  - in hydrocarboxylation, 737
  - hydrogenolysis of, 402
  - in Mannich reaction, 821
  - as nucleophiles, 357–366
  - nucleophilic substitution of, 325–326
  - oxidation of, 1082–1084, 1089, 1090, 1107–1108
  - protection of, 700
  - reaction: with acetylene, CO, and a halide, 799–800
    - with aromatic rings, 485, 487, 488
    - with chloroboranes, 1020
    - with diazo ketones, 995
    - with dichloroethene, 724
    - with isonitriles, 891
    - with $LiAlH_4$, 833, 1117
    - with mercaptans, 374
    - with sulfonic acid derivatives, 451
    - with thionyl chloride, 302
  - rearrangement of, 963, 978, 1007, 1012
  - reductive alkylation of, 812
  - resolution of, 109
- Alcoholysis: of acyl halides, 361
  - of amides, 367, 1068
  - of anhydrides, 362
  - of epoxides, 360–361
  - of esters, 365–367
- Alcoholysis:
  - of nitriles, 664–665
- Aldehyde ammonias, 816
- Aldehyde interchange mechanism, 1094
- Aldehydes: acylation of, 880–881
  - in acylation of heterocycles, 658
  - acyloxylation of, 648
  - addition to multiple bonds, 727, 734, 735, 881, 882
  - in the aldol condensation, 849–853
  - alkylation of, 422, 423, 608
  - arylation of, 608
  - benzoin condensation of, 878–879
  - bimolecular reduction of, 1132–1134
  - Cannizzaro reaction of, 1139–1140
  - cleavage of, 1090
  - condensation: with active hydrogen compounds, 854–859
    - with anhydrides, 860–862
    - with aromatic rings, 498–502
    - with esters, 853–854, 862–863
    - with halo esters, 862–863
    - with isonitriles, 894
    - with phosphoranes, 864–871
    - with thiobenzilic acid, 961
  - conversion: to acetals, 810–812
    - to amides, 651
    - to anhydrides, 648
    - to dihalides, 828–829
    - to epoxides, 884–887
    - to formates, 1011
    - to halo alcohols and ethers, 827–828
    - to ketones, 424, 426, 997
    - to nitriles, 827, 1085
    - to oximes, 825–826
    - to phenols, 1098
    - to unsaturated aldehydes, 934, 1080
  - cyclodehydration of, 500
  - decarbonylation of, 513–514, 669–670, 975
  - enolization of, 536
  - formation of, 221, *see also* 1167
  - halogenation of, 638
  - homologization of, 997–998
- Aldehydes:
  - in Mannich reactions, 820–823
  - oxidation of, 641–643, 1011
  - in Passerini reaction, 892
  - photochemistry of, 220, 221
  - protection of, 810, 831
  - reaction: with alcohols, 810–812
    - with alkenes, 877, 889
    - with alkynyl ethers, 878
    - with amines, 817–823, 826
    - with ammonia, 816–817, 819–823
    - with HCN, 874
    - with hydrazines, 824–826, 1119
    - with ketenes, 701, 888
    - with mercaptans or H_2S, 814–816
    - with metalated aldimines, 894
    - with multiple bonds and CN^- ion, 734
    - with nucleophiles, 802
    - with organometallic compounds, 836–843
    - with sodium bisulfite, 816
    - with water, 804–805
    - with ynamines, 878
  - reactivity of, 803
  - rearrangement of, 987–988, 1007, 1054
  - reduction of, 829–834, 1119–1121
  - in reductive alkylations, 812, 819–820
  - in Reformatsky reaction, 841–843
  - resolution of, 108
  - in the Ritter reaction, 880
  - selenation of, 545
  - sulfonation of, 545
  - in Tishchenko reaction, 1140
  - in Tollen's reaction, 863
  - in Willgerodt reaction, 1141

Aliphatic substitution (*see* Electrophilic substitution; Free-radical substitution; Nucleophilic substitution)
Alkali fusion of aryl sulfonates, 596, 599
Alkaloids, rearrangement of, 979*n*.
Alkanes: acidity of, 240
  acylation of, 546
  addition to alkenes, 723
  alkylation of, 547–548
  amination of, 381
  carbonium ions from, 152, 980
  carboxylation of, 437
  chlorocarbonylation of, 659
  chlorosulfonation and chlorosulfenation of, 649
  cleavage of, 576–577
  conversion: to hydroperoxides, 644–646
    to peroxides, 647
  coupling of, 651
  dehydrogenation of, 1079
  dipole moments of, 19–20
  formation of, *see* 1168
  halogenation of, 631–636
  hydrogen exchange of, 532, 711
  hydroxylation of, 639
  insertion by carbenes, 551
  nitration of, 649–650
  nitrosation of, 543
  positions of abstraction, 626
  reaction: with aromatic rings, 486
    with nitrenes, 544
  rearrangement of, 980–982
Alkenes: acylation of, 546, 733–734
  acyloxylation of, 648
  addition: of active hydrogen compounds, 727–728
    of alcohols and phenols, 699–701
    of alkanes and alkenes, 723–725
    of alkyl halides, 746–747
    of ammonia and amines, 704–706
    of boranes, 719–722, 732–733
    of carbenes and carbenoids, 788–795
Alkenes: addition:
    of carboxylic acids, 690, 701–702
    of cyanic acid, 707
    of deuterium, 715
    to formaldehyde, 876–877
    of haloamines, 744
    of halo azides, 745
    of HCN, 739
    of HOX and ROX, 741–743
    of hydrazoic acid, 707
    of hydrogen halides, 690, 694–696
    of iodine isocyanate, 746
    of mercaptans and H_2S, 703–704
    to nitriles, 880
    of nitrogen compounds, 704–707, 744–746, 754–761
    of organometallic compounds, 728–731
    of polyhalo alkanes, 747
    of RH, 723–735
    of sodium bisulfite, 704
    of sulfonic acids, 699
    of sulfur compounds, 703–704, 743
    of sulfuric acid, 699
  addition reactions: mechanisms, 672–687
    orientation and reactivity, 687–691
    stereochemical orientation, 690–691
  alkylation of, 656
  allylic halogenation of, 636–638
  allylic hydroxylation at, 639
  amination of, 544
  aminomethylation of, 738–739
  arylation of, 655–657
  bisamination of, 755
  carbonium ions from, 152, 154
  complexes of, 79–81, 96, 677
  conformation of, 138
  conversion: to aziridines, 756
    to cyclopropanes, 788–795
    to halo nitro and nitroso compounds, 744, 745
    to hydroperoxides, 645–647
    to lactones, 757
  2 + 2 cycloadditions of, 766–788, 890
  dicarbalkoxylation of, 799
Alkenes:
  Diels-Alder reactions of, 761–777, 950
  1,3-dipolar additions to, 758–761
  double bond migration in, 528–529, 533–536, 701, 711–713, 937, 1037–1041, 1120
  epoxidation of, 690, 750–752
  exchange with boranes, 937
  formation of, 192, 221, *see also* 1169
    mechanisms, 895–922
  formylation of, 547
  halogenation of, 739–741
  hydration of, 696–697
  hydroacylation of, 738
  hydroboration of, 690, 718–722
  hydrocarboxylation of, 736–737
  hydroformylation of, 738
  hydrogenation of, 707–715
  hydrometalation of, 722
  hydroxylation of, 748–750
  metathesis of, 1057–1059
  nitration of, 650
  oxidation of, 1101, 1108–1109
  oxidative cleavage of, 1095–1096
  oxyamination of, 754
  oxymercuration of, 690
  ozonolysis of, 1090–1094
  photolysis of, 222
  positions of abstraction, 626–627
  reaction: with aromatic rings, 485, 486, 488
    with cyanogen azide, 985–986
    with 1,1-dichloroethene, 724
    with mercury salts, 698
    with palladium cyanide, 564
    with singlet oxygen, 646–647, 753
  rearrangement of, 980, 1007, 1037–1041
  reductive coupling of, 735–736
  resolution of, 111
  stability of, 910

    - with Grignard reagents, 844
    - with organometallic compounds, 440
  - rearrangement of, 511, 1003–1004
  - reduction of, 406–407, 836, 1122
- Amide N-sulfo chlorides, 953
- Amidines, formation of, *see* 1172
- Aminals, 818, 822, 1086
- Amination: of active hydrogen compounds, 544
  - of alkenes, 544
  - of aromatic rings, 478–479, 609, 610
  - of heterocycles, 608–609
- Amine ditosylates, 327
- Amine oxides: cleavage of, 920, 930–931, 1107
  - formation of, 1111
  - optical activity of, 89
  - rearrangement of, 1015
  - reduction of, 1129
- Amines: acidity of, 240
  - acylation of, 382–388, 1068
  - addition to multiple bonds, 704–706, 734, 735, 755
  - C-alkylation of, 428–429
  - aminoalkylation of, 502
  - in aminomethylation of alkenes, 738–739
  - basicity of, 240, 242
  - cleavage of, 368, 397, 1107
  - in complexes, 80–82
  - conversion: to alkyl halides, 397
    - to azides, 581
    - to azo compounds, 581

- Amines: conversion:
    - to enamines, 1079
    - to halides, 661
    - to phenols, 596
    - to quinolines, 501
    - to triazenes, 580
  - coupling of, 651
  - coupling with diazonium ions, 477
  - dehydrogenation of, 1085–1086
  - diazotization of, 327, 329–330, 344, 578–579, 967, 968
  - N-ethylation of, 820
  - formation of, *see* 1172
  - formylation of, 493, 496
  - Friedel-Crafts reactions of, 486, 491
  - halogenation of, 482, 483
  - N-halogenation of, 582
  - in the hydrocarboxylation reaction, 737
  - hydroxylation of, 640
  - introduction of diazonium groups, 477
  - in Mannich reaction, 820–823
  - nitration of, 474–475
  - N-nitration of, 580
  - nitrosation of, 476, 477
  - N-nitrosation of, 580
  - as nucleophiles, 377–388, 598–600, 704–706, 817–824
  - nucleophilic substitutions of, 327
  - optical activity of, 90
  - oxidation of, 1085, 1104, 1106–1107, 1109–1111, 1116
  - protection of, 383, 451
  - reaction: with acyl halides, 382, 936–937
    - with alcohols, 379
    - with aldehydes, 651
    - with alkyl halides, 377–378
    - with alkyl sulfates and sulfonates, 378
    - with amides, 388
    - with anhydrides, 383
    - with aryl compounds, 586, 598–600
    - with carbon monoxide, 582–583
    - with carboxylic acids, 384
    - with carboxylic esters, 386
    - with chloroform, 382
- Amines: reaction:
    - with cyanogen bromide, 397
    - with cyanohydrins, 379
    - with diazo compounds, 380
    - with epoxides, 381
    - with formaldehyde and aromatic rings, 502
    - with α-halo ketones, 991
    - with heterocycles, 609
    - with isonitriles, 891
    - with ketones, 832
    - with palladium complexes, 754
    - with sulfonyl halides, 451, 937
  - rearrangement of, 510–511, 984–985, 1010
  - reduction of, 404
  - reductive alkylation of, 819–820
  - in Strecker synthesis, 874
  - thioalkylation of, 502
  - thiocyanation of, 482
  - transamination of, 380
  - in Ugi reaction, 892–893
  - in Willgerodt reaction, 1140–1141
- Amino acids: conversion: to fluoro acids, 397
    - to keto acids, 384
    - to lactams, 384

  conjugation with double bonds, 141–142, 694, 1040
  2 + 2 cycloadditions of, 787
  formation of, 179, 300, 306, 408, 418, 432–433, 551, 788–795, 957
  hydration of, 693, 794
  hydrogenolysis of, 717
  pyrolysis of, 986
  reaction: with acetyl chloride, 693
    with aromatic rings, 486
Cyclopropanes: reaction:
    with hydrogen bromide, 691
    with lead tetraacetate, 691
    with sulfuric acid, 693
    with trifluoracetic acid, 691
  strain in, 141
Cyclopropanones, 410, 790, 805, 942, 992–994
Cyclopropenes: formation of, 790–791, 957
  strain in, 146
Cyclopropenones, 54, 791
Cyclopropenyl anion, 55–56
Cyclopropenyl cation, 54, 56
Cyclopropyl, as neighboring group, 289–290
Cyclopropylbenzene, 463
Cyclopropyl carbanions, 163, 165, 1035
Cyclopropyl cations, 986, 1034–1036
Cyclopropyl halides, reduction of, 400
Cyclopropyl ketones, 1041
Cyclopropylmethyl cations, 155, 285, 298–300
Cyclopropylmethyl systems: reaction with *t*-BuOK, 987
  solvolysis of, 298–300
Cyclopropyl radicals, 628
Cyclopropyl substrates, nucleophilic substitution at, 321, 986
Cyclopropyl tosylate, 250
Cysteine, 110, 1115

D (dissociation energy), 26, 174–175, 626, 627, 630, 635
DABCO, 1090
Dakin reaction, 1098
Dammaradienol, 725
Darzen's condensation, 862–863

D configuration, 98–99
DDQ, 1078, 1080
DDT, 342, 499
Deactivating groups: in electrophilic aromatic substitution, 459–466
  in nucleophilic aromatic substitution, 591–593

Deamination, 404, 660
Decarbonylation, 669–670
  of acyl halides, 670, 938
  of aldehydes, 669–670, 975
  of bicyclo[2.2.1]heptenones, 950
  of esters and acids, 356, 444
Decarboxamination, 572
Decarboxylation: of aliphatic acids, 419, 420, 443, 569–572, 854
  of aromatic acids, 514
  of azo acids, 541, 542
  with concomitant acylation, 573
  of hydroxy acids, 860–861, 948
  ketonic, 448
  of β-lactones, 948
  oxidative, 1098–1100
Decarboxylative dimerization, 667
Decarboxylative halogenation, 668–669
Decarboxylative nitration, 669
Decene, 937
Decyanation, 577, 1131
Decyanoethylation, 679*n*.
Dediazonation, 660
Degenerate Cope rearrangements, 1047–1049
Dehalocarboxylation, 948
Dehalogenation: of aryl halides, 517
  of dihalides, 897, 943–944
  of halo acyl halides, 944
Dehydration: of alcohols, 359–360, 923–924
  of N-alkylformamides, 953
  of amides, 923, 953
  of carboxylic acids, 923
  of oximes, 950–951
  of ureas, 954
Dehydroannulenes, 64–66, 652
Dehydrobenzenes, 589
Dehydroergosterol, 981
Dehydrogenation, 1077–1086
Dehydrohalogenation: of acyl halides and sulfonyl halides, 936–937
  of alkyl halides, 935–936
  mechanism, 897–899, 902, 903, 907–910, 912, 913, 915–917, 919, 921
Delépine reaction, 378
Demerol, 994
Demyanov reaction, 985
Deoxidation, 924
Deoxycholic acid, 84, 109
Deoxygenation, 1129–1131
  of aldehydes and ketones, 182
  of diols, 938–939
Desulfonation, 517
Desulfurization, 427, 666–667
Deuteration: of aldehydes and ketones, 537
  of alkanes, 400, 532
  of aromatic rings, 473–474
Deuterioaniline, 508
Deuterium, 532, 711, 713, 715
Deuterium bromide, 676, 677
Deuterium isotope effects, 204–207
Deuterogenation of alkenes, 711, 713, 715
Dewar benzenes, 787, 788, 796, 1033, 1049
Dewar structures, 29
Dextro isomer, 86
Diacyldiazomethanes, 996
Diacyl peroxides: cleavage of, 176
  halogenation of, 668
  reaction with alkenes, 702
    with aromatic rings, 504
    with enolates, 558
Dialdehydes, formation of, 419, 547, 854, 1091
gem-Dialkali metal compounds, 554
Dialkylalkenylalane reagents, 730
Dialkylalkoxyboranes, rearrangement of, 1000
Dialkylamine ketoximes, 951
Dialkylaminobenzyl alcohols, 516
Dialkylaminosulfur trifluorides, 393, 829
Dialkylchloroboranes, 561, 720, 1000, 1020
Dialkylformamides, conversion to aldehydes, 440
Dialkylthioboranes, 719
1,1-Dialuminum compounds, 722
Diamagnetic ring current (*see* Ring currents)
Diamantanes, formation of, 982
Diamines: formation of, 381, 755
  oxidation of, 1096
gem-Diamines, hydrolysis of, 346
Diaminoaluminum hydrides, 405, 406
Diaminobiphenyls, formation of, 1063–1066
1,6-Diaminocyclodecane, 145
Diarylalkanes, 1080
Diarylethanes, formation of, 485
Diarylhaloalkenes, rearrangement of, 998–1000
Diarylhalopropenoic acids, 1000
Diarylhydrazines, rearrangement of, 1063–1066
Diarylmethanes, oxidation of, 1097, 1101
Diarylmethyl halides, solvolysis of, 271, 272
Diarylthallium trifluoroacetates, 558
2,3-Diarylthiiren-1,1-dioxides, 942
Diastereomers, 113
  definition of, 104
  separation of, 108–110
Diastereotopic atoms, groups, and faces, 122–123
Diatropic compounds, 41–42, 46, 49, 61–65, 68
Diaxial addition, 691
1,5-Diazabicyclo[3.4.0]nonene-5, 935
1,4-Diazabicyclo[2.2.2]octane, 1090
1,5-Diazabicyclo[5.4.0]undecene-5, 935
Diazenes, 660
Diazides, 755
Diaziridines: chirality of, 91
  formation of, 756, 757, 958
Diazirines, 182
Diazo aldehydes: formation of, 578
  reaction with boranes, 434
Diazo alkanes, 933
  addition to multiple bonds, 759
  arylation of, 418
  conversion: to alkyl fluorides, 396
    to ethers, 358–359
  dimerization of, 1114
  formation of, 543, 956, 1086
  protonation of, 327
  reaction: with aldehydes and ketones, 886, 998
    with amides, 389
    with amines, 380
    with carboxylic acids, 369
    with iminium ions, 888

Diazo alkanes: reaction:
    with sulfur and sulfur compounds, 887
  rearrangement of, 996, 997
Diazo esters: arylation of, 418
  formation of, 578–579, 855
  reaction: with aldehydes, 855
    with boranes, 434
Diazoethane, 448
Diazohydroxides, 330, 477
Diazo ketones: arylation of, 418
  conversion: to ethers, 358
    to halo ketones, 396
  formation of, 448, 543, 578, 1086
  hydrolysis of, 344
  reaction: with boranes, 434
    with carboxylic acids, 369
    with ketenes, 760
    with triphenylphosphine, 806
  rearrangement of, 995–996
  reduction of, 404
Diazomethane: in Arndt-Eistert synthesis, 995
  formation of, 956
  in generation of CH_2, 179, 180, 182, 183, 792
  in methylation: of alcohols and phenols, 358
    of amines, 380
    of carboxylic acids, 369
  reaction: with acyl halides, 448, 995
    with aldehydes and ketones, 886, 997-998
    with aromatic rings, 792
    with iminium ions, 888
Diazo nitriles: formation of, 578
  reaction with boranes, 434
Diazonium coupling, 477, 541–542
Diazonium fluoborates, 610, 611
Diazonium ions: in arylation:
    of alkenes, 655
    of aromatic rings, 653–654
  conversion: to aldehydes and ketones, 663
    to alkenes, 931
    to azides, 611
    to bromides, 661
    to chlorides, 661
    to fluorides, 611–612
    to iodides, 611
    to nitriles, 662
    to nitro compounds, 662
Diazonium ions: conversion:
    to organometallic compounds, 663
    to phenols, 610
    to sulfur compounds, 610–611
  coupling of, 470, 477, 541–542
  dediazonation of, 660
  dimerization of, 662
  formation of, 290, 344, 477–478, 578–579
  in nucleophilic aliphatic substitution, 327–330
  reaction: with alkenes, 747, 1096
    with amines, 580
    with dialkylaminobenzyl alcohols, 516
    with nucleophiles, 587, 610–612
    with organometallic compounds, 519
  rearrangements of, 587, 980
  reduction of, 660, 1128
Diazosulfides, 611
Diazotization, 578–579, 593
  of alkylamines, 327
  of amides, 353, 356
  of amino acids, 397
  of anthranilic acid, 590
  of cyclic amines, 984–985
Diazo transfer reaction, 543, 581
Dibenzocyclooctadiendiyne, 59
1,1-Dibora compounds, 721
Diborane, 718
Dibromobenzene, 149
Dibromocarbene, 180, 789, 924
Dibromocyclohexane, 129
1,2-Dibromoethane, 126, 134
Dibromoisocyanuric acid, 483, 582
Dibromo ketones: alkylation of, 410
  coupling of, 408
1,2-Dibromo-1,2,3,4-tetrachloroethane, 636
1,2-Di-*t*-butylbenzene, 149
Di-*t*-butylbenzoquinone, 1107
Dibutylcopperlithium, 563
Di-*t*-butyl ether, formation of, 357
Di-*t*-butyl glutarates, 854
Di-*sec*-butylmercury, 522
Di-*t*-butyl peroxide, 669
2,6-Di-*t*-butylpyridine, 150
Dicarbalkoxylation of multiple bonds, 799
Dicarbanions, as nucleophiles, 337
Dicarboxylic acids: acidity of, 242
  bisdecarboxylation of, 1100
  cyclization of, 448
  formation of, 736, 845, 1089, 1090
  monoesters, formation of, 362, 367, 447, 814
Dicarboxylic esters: cyclization of, 444, 1134–1136
  formation of, 419, 443, 604, 727, 735, 799, 854
Dichloroalkenes, hydrolysis of, 342
Dichloroaluminum hydride, 403
N,N-Dichloroamines, 582, 1002
Dichloroaniline, 510
Dichlorobenzenes, 149, 517, 594
Dichlorobenzyl sulfides, 942
Dichlorobenzyl sulfones, 942
Dichlorobis(benzonitrile)palladium(II), 1061
Dichloro 1,2-bis(diphenylphosphine) ethane nickel(II), 411
Dichlorobis(triphenylphosphine)nickel, 415
Dichlorobis(triphenylphosphine)palladium, 438
Dichloroborane, 720
Dichlorocarbene, 178, 180, 181, 343, 382, 496, 789, 792, 793, 888
Dichlorocyclohexane, conformations of, 129
Dichlorodicyanobenzoquinone, 1078, 1080
Dichlorodifluoroethene, 777, 778, 782
Dichloroethane, 126
Dichloroethene, 724
Dichloromethane, hydrolysis of, 342, 343
Dichloromethyl methyl ether, 495, 1000, 1017, 1020
Dichlorotris(triphenylphosphine)ruthenium, 1123, 1125*n*.
Dicobalt octacarbonyl, 562, 738, 739, 796, 940
"Dictionary of Organic Compounds," 1154
1,1-Dicyano-2,2-bis(trifluoromethyl)ethene, 894

Dicyanocarbene, 788, 790, 792
Dicyano compounds: cyclization of, 823, 873
  formation of, *see* 1178
2-(Dicyanomethylene)-1,1,3,3-tetracyanopropene, 240
Dicyclohexylcarbodiimide: in formation: of amides, 384–385
    of anhydrides, 369
    of diazo ketones, 448
    of esters, 364
    of ethers, 360

  conversion: to acetals, 810–811
    to cyclic ethers, 359, 360
    deoxygenation of, 938–939
    formation of, 347, 748, 856, 863, 876, 1070, 1123, 1124, 1132–1133
    fragmentation of, 948–949
    hydrogenolysis of, 402
    oxidation of, 1108
  rearrangement of, 983–984
gem-Diols, 804–805
1,4-Dioxane, as nucleophile, 278–279
1,3-Dioxanes: conformation of, 132
  formation of, 876–877
Dioxoaspiro compounds, 889
Dioxetanes, 753, 754
1,2-Dioxolane-3,5-diones, 959
Dioxovanadium(V) ion, 1084
2,3-Diphenylbutadiene, 800
Diphenylcarbamoyl chloride, 497
Diphenyl hydrogen phosphonate, 951
Diphenylketene, 888
Diphenylmethyl carbanions, 162
Diphenylmethyl cations, 155
3-(Diphenylmethylene)-6-(triphenylmethyl)-1,4-cyclohexadiene, 173
Diphenyloxathiolan-5-ones, 961
Diphenyl phosphoroazidate, 376
Diphenylpicrylhydrazyl, 174
Diphenylsulfoniumcyclopropylide, 885
Diphenylsulfoniumisopropylide, 795, 885
Diphenyltin hydride, 833
Di-π-methane rearrangement, 1061–1063
1,3,-Dipolar addition, 751, 756, 758–761, 986, 1091, 1093, 1094
Dipole moments, 19–20
  of alkylbenzenes, 70
  to determine configuration, 116
  to determine conformation, 134
  of excited states, 214
Dipotassium nitrosodisulfonate, 1085
Diradical character of aromatic compounds, 54, 56, 57
Diradical mechanisms, 221, 766, 775, 779, 781–783, 785, 787, 788, 791, 957, 986, 1033, 1046, 1047, 1062–1063, 1080, 1081, 1102
Diradicals, 175–176, 976
Disiamylborane, 718, 719, 721, 1118
Dismutation of alkenes, 1057
Disodium tetracarbonyl ferrate, 405, 406, 436, 438
Disproportionation: of alkenes, 1057
  of free radicals, 177
  of NH, 186
Disrotatory motion, 1025–1035
Dissociation energies, 26
Dissolving metal reductions, 715

Disulfide ions, 376, 597
Disulfides: conversion to alkenes, 935
  desulfurization of, 665
  formation of, *see* 1178
  oxidation of, 1110
  reaction: with amines and CO, 583
    with boranes, 663
    with diazonium ions, 611
    with enolates, 545
  reduction of, 1132
N,N-Disulfonimides, 404
Disulfur dichloride, 481, 483
1,3-Dithianes, 734
  acylation of, 446
  alkylation of, 426–428
  condensation with ketones, 855
  conformation of, 132
Dithioacetals, 666
Dithiocarbamic acid, 824
Dithio esters, 1054
gem-Dithiols, 815
Dithiomethylene ketones, 860
1,8-Di-*o*-tolynaphthalene, 149
Ditosylamines, 368
Ditosylates, 939
Divinylchloroboranes, 665
Divinylcyclobutanes, 1045, 1046
Divinylcyclopropanes, 1024, 1045 -1047
Divinylmercury compounds, 561
Divinylmethyl cations, 154
Diynes: formation of, 651–653, 664, 665
  reaction: with ammonia and amines, 705
    with hydrogen sulfide, 704
  rearrangement of, 1045
Doebner-Miller reaction, 501
Doebner modification, 856
d orbitals, 5, 8
Double bond compounds, electronic structure of, 12–13
Double bond migrations, 528–529, 533–536, 701, 711–713, 937, 1037 1041, 1120
  (*See also* Rearrangements, allylic)
Doublets, 171
Drugs, naming of, 1155
Duff reaction, 496

E (bond energy), 26–28, 31
Eclipsed conformation, 125, 126
Eclipsing conformation, 127
Eclipsing effects, 128, 133, 145
  in eliminations, 902–903, 911, 913, 919, 922
  in rearrangements, 969
Eclipsing strain, 145, 146, 249 250
Eco2 mechanism, 954
EDA complexes, 79–83, 785
EEDQ, 385
Eigenfunctions, 3
Eigenvalues, 3
Ei mechanism, 917–922, 925–927, 929–931, 934, 936, 955
E isomer, 113
Eglinton reaction, 651–652
Elbs reaction (cyclodehydration), 488
Elbs reaction (hydroxylation), 640
Electrical effects, 246, 248
Electrochemical oxidation, 1077*n*.
Electrochemical reductions, 1077*n*.
Electrocyclic rearrangements, 1023–1036, 1045, 1049
Electrofugal, definition of, 187
Electrolysis of carboxylate ions, 667
Electron-donating groups, 21–22, 38, 246
  effect: on abstraction by free radicals, 627
    on addition reactions, 684–686, 803
    on Birch reduction, 716
    on carbene additions, 791
    on Diels–Alder reaction, 765, 766
    on electrophilic substitution, 460–463, 530
    on free-radical aromatic substitution, 629
    on migratory aptitudes, 971
    on nucleophilic substitution, 320
    on rearrangements, 999, 1011, 1052
    on Wittig reaction, 865, 868
Electron donor-acceptor(EDA) complexes, 79–83, 785
Electronegativity, 19–21
Electronic structures, 7–17
Electron paramagnetic resonance, 170
Electron spin, 7
Electron spin resonance (esr), 170–171, 175, 180, 412, 588, 625, 682, 716, 1103
Electron transfer, 1075
Electron-withdrawing groups, 21-22, 38, 247
  effects: on abstraction by free radicals, 627
    on addition reactions, 684–686, 803
    on Birch reduction, 716
    on carbene additions, 791
    on Diels-Alder reaction, 765, 766
    on electrophilic substitution, 460–463, 530
    on eliminations, 905, 911, 914, 915
    on free-radical aromatic substitution, 629
    on migratory aptitudes, 971
    on nucleophilic substitution, 320
    on rearrangements, 998, 999, 1011, 1052, 1071
    on Wittig reaction, 865, 868
Electrophile, definition of, 187
Electrophilic addition: to cyclopropane rings, 692–694
  to multiple bonds, 672–678, 682–683
  orientation and reactivity in, 684–691
Electrophilic radicals, 627, 687
Electrophilic rearrangements, 962, 977–978, 982–983
Electrophilic substitution: aliphatic, 520–583
  aromatic, 453–519
    in definition of aromaticity, 41
    of nonbenzenoid aromatic compounds, 46, 47, 50, 51, 59, 61, 63, 64, 67
  at nitrogen, 578–583
Element effect, 312, 586
α Elimination, 181–182, 185, 567, 568, 789, 895, 936
α′,β Elimination, 929, 930
β Eliminations, 895-961
  entropy of, 192
  of hydrogen, 1077–1086, 1131

β Eliminations
  mechanism and orientation, 895–922
  types of, 189
γ Eliminations, 895
1,4 Elimination, 922, 930, 941, 942, 944
Elimination-addition mechanism: of carbamates, 352
  of esters, 353
  in hydrogen exchange, 532
  in nucleophilic substitution, 314–315, 327, 588
  in rearrangements, 975*n*., 983, 989, 1002
  at sulfur, 450
Elsevier's "Encyclopedia", 1154
Emde reduction, 404
Enamines: acylation of, 549
  acyloxylation of, 648
  alkylation of, 548–550
  cleavage of, 404
  2 + 2 cycloadditions of, 779, 782*n*., 889, 890
  fluorination of, 538
  formation of, *see* 1178
  hydrolysis of, 346, 807
  reaction: with active-hydrogen compounds, 727
    with alkynes, 726
  tautomerism of, 74
Enamino nitriles, 873
Enantiomers: definition of, 86
  nomenclature of, 105
Enantiomorphs, 86
Enantiotopic atoms, groups, and faces, 120–123
Endo addition, 690–691, 764, 765, 776–777
Endo isomers, 119
Energy of light, 208
Energy barriers to rotation, 125–128, 134
Energy cascade, 215, 218
Ene synthesis, 639, 647, 726, 877, 955, 1037*n*.
Enolate ions, 73, 162
  acylation of, 441–447
  alkylation of, 336, 338, 418–426
  cyanation of, 564
  esterification of, 558
  formation of, 424, 537, 555
  halogenation of, 538–539
  hydroxylation of, 640
Enolate ylides, 866
Enol borinates: conversion to enolate ions, 425
  formation of, 732–733
  halogenation of, 539
  reaction: with bromine, 747
    with iminium ions, 847
Enol content of carbonyl compounds, 72
Enolene rearrangement, 1052
Enol esters: condensation with acetals, 852
  conversion to enolate ions, 424
  formation of, *see* 1179
  hydrolysis of, 353
  reaction: with alcohols, 366–367
    with carboxylic acids, 370
  transesterification of, 366
Enol ethers: addition of ROX, 742
  cycloaddition reaction of, 779, 889–890
  fluorination of, 538
  formation of, *see* 1179
  halogenation, 538–539
  hydrolysis of, 344, 346
  pyrolysis of, 926
  reaction: with acetals, 758
    with alkenes, 700
    with cyanic acid, 707
  rearrangement of, 1070
  transetherification of, 360
Enol form in tautomerism, 72, 536–537
  halogenation of, 538–539
Enolization, as side reaction in Grignard addition, 838–840, 844
Enol thioethers, 428, 779
  formation of, 703, 816
Enol tosylates, 1070
Enthalpy, 190–191
  of activation, 192, 203, 334
Entropy, 190–191, 770, 797
  of activation, 192–193, 203, 280, 334, 618, 919
  effects on acid strength, 244–245
Envelope conformation, 133
Enynes: addition reactions, 684, 686, 705, 783
  in the Diels-Alder reaction, 763
  formation of, 726
  halogenation of, 741
E1cA mechanism, 924
E1cB mechanism, 904–907, 913–917, 925, 947
E1-E2-E1cB spectrum, 907–908, 911, 914–917
E1 mechanism, 903–904, 910, 914–917, 920, 924, 946, 947, 949
Ephedrine, 109
Epimers, definition of, 105
Episulfides: amination of, 381
  conversion to alkenes, 940
  formation of, 375, 743, 887
  nucleophilic substitutions of, 326, 340
Episulfones, 887, 941
Epoxidation, 690, 749–752
Epoxides: alcoholysis of, 360
  amination of, 381
  carboxylation of, 437, 438
  cleavage of, 1087
  conversion: to alkenes, 940
    to allylic alcohols, 925, 934
    to halohydrins, 395
    to hydroxy mercaptans and sulfides, 374, 375
    to hydroxy sulfonic acids, 376–377
  formation of, 281, 1091, *see also* 1179
  hydrolysis of, 347
  nucleophilic substitutions of, 326, 340–341
  oxidation of, 1105
  reaction: with acetylide ions, 434
    with active hydrogen compounds, 421
    with aldehydes, 812
    with cyanide ion, 435
    with dithiane salts, 427
    with enamines, 549
    with metalated aldimines, 894
    with organometallic compounds, 417
    with oxazine ions, 430
    with phosphoranes, 418
    with triphenylphosphine, 381
    with vinyl sulfides, 428
  rearrangement of, 984, 1070
  reduction of, 403, 1124–1125
3,4-Epoxy-1-butene, 733
3,4-Epoxy-1-butyne, 733
Epoxy esters, 862
Epoxy hydrazones, 949
Epoxy ketones, 396, 752, 884, 886, 991
Epr, 170
Equatorial bonds, 128–132, 134
Equilibration of carbonyl compounds, 537

Erlenmeyer azlactone synthesis, 861
Erythro configuration, 106
Erythro isomers, 280, 290
Eschweiler-Clarke procedure, 820
Esr (*see* Electron spin resonance)
Esterification of acids, 248, 363–365
Esters (*see* Carboxylic esters; Inorganic esters; *etc.*)
E^s values, 258, 687
Étard reaction, 1102–1104
Ethane: acidity of, 163, 229
  conformations of, 124–126
  conversion to *t*-butyl cation, 154, 548
  heat of atomization, 27
  reaction with super acid, 154
Ethanedithiol, 815
Ethanol, 226, 660
Ethanolamines, 380, 381
Ethanolysis of alkyl halides, 248
Ethers: acidity of, 240
  acyloxylation of, 648
  addition to multiple bonds, 734, 735
  alkylation of, 420
  in alkylation of heterocycles, 658
  autoxidation of, 645
  basicity of, 243
  cleavage of, 344, 346, 368, 369, 372, 394, 515–516, 955
  cleavage to alkenes, 347, 905, 906, 925–926
  conversion: to amines, 598
    to nitriles, 603
    to oxonium salts, 370
    to phenols, 596
  coupling of, 651
  demethylation of, 374
  formation of, *see* 1179
  halogenation of, 632
  hydrolysis of, 357
  nucleophilic substitution of, 325–326
  oxidation of, 1084, 1104, 1108
  reaction: with aromatic rings, 486
    with carboxylic acids, 365
    with organometallic compounds, 416–417, 604
  rearrangement of, 1015–1016, 1050–1054
  reduction of, 402, 516–517, 602–603
Ethers:
  transetherification of, 360, 597
Ethoxide ions, 951, 1002
N-Ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline, 385
2-Ethoxy-1,3-dioxolanes, 939
Ethoxymethylcarbonylcopper, 423
4-Ethoxy-2-oxazoline, 859
α-Ethoxyvinyl carbanion, 734
Ethyl acetate, 423, 555
Ethyl acetoacetate: addition to multiple bonds, 727
  alkylation of, 337, 419, 420
  condensation with aldehydes, 854
  cyanation of, 564
  tautomerism of, 72–73
Ethylaluminum dichloride, 1057, 1058
Ethylation of ethylbenzene, 460
3-Ethyl-2-azidobenzothiazolium fluoroborate, 543
Ethylbenzene, 460, 512, 513
Ethyl bromocyanoacetate, 433
Ethyl α-(bromomethyl)-acrylate, 549
1-Ethyl-4-carbomethoxypyridinium ion, 334–335
Ethyl carbonate, 440, 443, 445, 446
Ethyl chloroformate, 440, 447, 550
Ethyl diazoacetate, 998
Ethylene: acidity of, 163, 229
  bonding in, 12–13
  conversion: to acetaldehyde, 1108
    to ethyl ketones, 436
    to unsaturated esters, 800
  dimerization of, 767–771, 773–774
  electronic structure of, 12, 16, 37
  excited states, 214, 674
Ethylenediaminechromium(II), 408
Ethylene glycol, 1016, 1017
Ethylene oxide, 141, 486, 864
Ethyl ethylthiomethyl sulfoxide, 427, 734
Ethyl fluoride, reaction with SbF_5, 152
Ethyl formate, 444
Ethyl group, migration of, 971
Ethylidenetriphenylphosphorane, 870
Ethyl iodide, 171
Ethyl lithioacetate, 555, 855
Ethyl lithiotrimethylsilylacetate, 843
Ethyllithium, 171
Ethylmagnesium bromide, 167–169, 550

  of activation, 191–193, 334
Free-radical addition: to cyclopropane rings, 694
  to multiple bonds, 680–682, 684, 703, 801–802
    orientation and reactivity in, 687–691
Free-radical cyclization, 681, 689
Free radical eliminations, 920–921
Free radical mechanisms, 619–625, 680–682, 974–977
  definition of, 187
  of Grignard reagent formation, 567–568
Free-radical polymerization, 681
Free-radical rearrangements, 177, 625, 962, 974–977, 1013, 1015, 1016, 1068–1070
Free radicals, 151, 170–178
  bridged, 624
  cleavage of, 176, 221
  hyperconjugation in, 71
  in nucleophilic substitutions, 273
  oxidation of, 1075
  polar character of, 259, 627–628
  produced by photochemical reactions, 215, 218, 220
  reactivity of, 630
  reduction of, 1075
  stability of, 688
Free radical substitution, 467, 619–671
Free radical transition states, polar character of, 621, 627
Free valence, 69, 467
Fremy's salt, 1085
3β-Friedelanol, 981

Friedel-Crafts acylation, 490–493, 503
  at an aliphatic carbon, 546
  of multiple bonds, 747–748
Friedel-Crafts alkylation, 485–489
  of alkenes, 723–724, 746–747
  reversal of, 512–513
Friedel-Crafts arylation, 490
Friedel-Crafts catalysts, 486, 491
Friedel-Crafts heteroalkylations, 498–503
Friedelin, 139, 980
Friedlander quinoline synthesis, 818
Fries rearrangement, 505–507
Fritsch-Buttenberg-Wiechell rearrangement, 998–1000
Frontier-orbital method, 773–777, 780–781, 1028–1030, 1034, 1038–1039, 1041–1042
F strain, 242
Fulvenes, 46, 709, 730, 855, 856
Fumaric acid, 116, 117, 123
Furans: in the Diels-Alder reaction, 763
  electronic structure, 45
  Friedel-Crafts reactions of, 486, 491
  hydrolysis of, 346
  orientation in, 466
  reduction of, 715
Furfurals, 360
Fused-ring compounds: alkylation of, 657
  aromatic substitution of, 466, 467
  Friedel-Crafts reactions of, 486, 490, 491
  isomerism of, 118
𝔉 values, 257

Gabriel synthesis, 388, 599
Gallium hydride, 722
Gammexane, 741
Gatterman amide synthesis, 497
Gatterman-Koch reaction, 494
Gatterman method, 662
Gatterman reaction (formylation), 495, 503
Gatterman reaction (halogenation), 661
Gauche conformation, 126, 144
Gauche effect, 127*n*.
General acid catalysis, 345, 346, 387, 473, 677, 805
  definition, 235, 236
General base catalysis, 366, 386, 805
  definition, 236
Generic names, 1155
Gerade orbitals, 9, 211, 213
Girard's reagents T and P, 825
Glaser reaction, 652
Glucose, 1138
Glucosides, 132
Glyceraldehyde, 98
Glyceric acid, 98
Glycerol, 501
Glycidic acids, decarboxylation of, 570
Glycidic esters, formation of, 751, 862–863
Glycols (*see* Diols)
Glyoxal monohydrazones, 1086
Glyoxals, 879, 1087, 1091
Gomberg-Bachmann pinacol synthesis, 1133
Gomberg-Bachmann reaction, 653
Gomberg reaction, 653–654
Grignard reaction, 836–841
Grignard reagents: addition to multiple bonds, 729–731, 836–840, 844–848
  conjugate addition of, 729
  conversion: to alkenes, 938
    to amines, 561, 562
    to azides, 562
    to sulfur compounds, 559–560
  coupling of, 664
  cyanation of, 564
  formation of, *see* 1186
  halogenation of, 560
  hydrolysis of, 518, 556
  in metalation reactions, 554
  optically active, 523
  reaction: with acetals, 416
    with acid derivatives, 439–441
    with alcohols, 415
    with aldehydes, 836–840
    with alkynes, 519, 554
    with azo compounds, 608
    with bromohydrins, 985
    with C=N compounds, 845–847
    with CO, 563
    with CO_2, 844–845
    with CS_2, 848
    with diazonium salts, 519
Grignard reagents: reaction:
    with diketones, 991
    with epoxides, 417
    with ethers, 416, 604
    with halides, 409–412, 414
    with iminium salts, 430, 846
    with isocyanates, 847
    with isonitriles, 894
    with ketones, 836–840
    with metal halides, 565
    with naphthalene, 607
    with nitriles, 847–848
    with ortho esters, 416
    with oxygen, 557
    with peresters, 558
    with sulfates and sulfonates, 415
    with sulfonyl chlorides, 452
  rearrangement of, 1002
  structure of, 167–169
Grignard's "Traité," 1159
Ground state of atoms, 6–7
Group electronegativities, 18–19
Grunwald-Winstein equation, 334, 336
S-Guaiazulene, 51
Guaiol, 51
Guanidine, 389, 824
Guerbet reaction, 1114–1115
Guest in inclusion compounds, 83, 84

H_0 and similar functions, 233–235
Half-chair conformation, 133
Half-life, 202
Halide exchange, 269, 391, 399, 601
Halide ions: as leaving groups, 312, 325, 586, 594–595, 916
  as nucleophiles, 601
  nucleophilicity of, 322–323
  reaction with carboxylic acids and lead tetracetate, 668
Haller-Bauer reaction, 576
Halo acetals, 538, 742, 945
Halo acids: conversion: to amino acids, 377
    to lactones, 367
  decarboxylation of, 570
  formation of, *see* 1180
  lactonization of, 363
  in Reformatsky reaction, 841
Halo acrylic acids, 947

Halo acyl halides: conversion to ketenes, 944
  formation of, 540, 741, 748
Halo alcohols, 947, 1070
α-Halo alcohols, 827, 828
Halo aldehydes, formation of, *see* 1180
Haloalkylation, 501–502
Halo alkynes: coupling of, 652
  formation of, 560
  hydrolysis of, 698
  reaction with boranes, 1022
Halo amides, 744, 841, 862, 863, 1004
N-Halo amides: addition to multiple bonds, 744
  conversion to lactones, 1069
  formation of, 582
  reaction with isonitriles, 893
  rearrangement of, 510, 1004
Haloamines: conversion to alkenes, 945
  formation of, 744, 1068
  fragmentation of, 947
  reaction: with arenes, 478
    with $C{=}N$ compounds, 757
N-Haloamines, 626, 633, 634, 1010, 1068
  formation of, 582
Halo azides: conversion: to aziridines, 745
    to azirines, 757
  formation of, 745
  reduction of, 745
Halobenzenes: nitration, 464
  rearrangement of, 515–516
Halocarbenes, 551, 788, 789, 792, 864, 865
Halo carbonyl compounds, reaction with active-hydrogen compounds, 727
Halocyclobutanones, 995
Halo disulfides, 743
Halo epoxides, rearrangement of, 1001
Halo esters: condensation: with aldehydes and ketones, 862
    with imines, 863
  conversion to alkenes, 945
  formation of, *see* 1180
  reaction with boranes, 432–434
  rearrangements of, 1066–1067
  in the Reformatsky reaction, 841–842
Halo ethers: conversion to alkenes, 944–945
  formation of, 742, 827
  reaction with magnesium, 567
Haloformic esters, formation of, 361
Haloform reaction, 574–575
Halogen, migration of, 1000
Halogenation: of acids and acid derivatives, 540
  of aldehydes, 537–539, 638
  of alkanes, 631–636
  of alkyl halides, neighboring groups in, 623–625
  at an allylic position, 636–638
  of aromatic rings, 482–485
  of ketones, 537–539
  of multiple bonds, 739–741
  of organometallic compounds, 560–561
  of sulfoxides and sulfones, 540–541
N-Halogenation, 582
Halogen dance, 518
α-Halo Grignard reagents, 566, 568
Halohydrins: conversion to alkenes, 945
  formation of, 395, 741–742
  rearrangement of, 984, 985
Halo ketones: cyclization of, 837
  Darzen's reaction of, 862
  formation of, *see* 1180
  reaction: with boranes, 432–434
    with thiol acids, 960
  rearrangement of, 991–995
  reduction of, 401
Halo nitriles, 432–434, 841, 862
Halo nitro compounds, formation of, 744, 745
Halo nitroso compounds, formation of, 744, 745
Halonium ions, 283–284, 327, 597
α-Halo organolithium compounds, 566, 568
α-Halo organometallic compounds, 182
α-Halo organopotassium compounds, 568
α-Halo organosodium compounds, 568
Halo oximes, formation of, 744
Halo sulfides: conversion to alkenes, 945
  formation of, 743
α-Halo sulfides, 942, 1112*n.*
Halo sulfonation, 481
Halo sulfones: conversion to alkenes, 941
  Darzen's reaction of, 862
  formation of, 540, 541, 743
α-Halo sulfonyl derivatives, reaction with boranes, 432–434
Halo sulfoxides, formation of, 540
Halo tosylates, 945
β-Halo unsaturated sulfones, formation of, 743
α-Halo vinylboranes, 1022
Hammett acidity function, 233
Hammett equation, 252–259, 320, 470, 594
Hammond postulate, 194–195, 316, 459, 688

Hydrogen peroxide:
  reaction: with alkenes, 748–750
      and azide ions, 755
    with bromo ketones, 942
    with Bunte salts, 376
    with ketones, 960, 1011
Hydrogen sulfide, as nucleophile, 374–376, 703–704, 814, 815, 1120
Hydrolysis: of acetals, 344–346
  of acyl halides, 347
  of alkyl halides, 249, 341
  of alkyl nitrates, 954
  of amides, 248, 353–356
  of anhydrides, 348
  of aryl halides, 595–596
  of boranes, 710–712
  of Bunte salts, 374
  of carboxylic esters, 198, 248, 254, 257, 309, 316, 349–353
  of C═N compounds, 806–807
  of cyclopropanes, 693, 794
  of diazo ketones, 344
  of diazonium ions, 344, 610
  of dihalides, 341–342
  of dihalo ketones, 1139
  of enamines, 807
  of enol borinates, 732
  of enol ethers, 344, 346
  of epoxides, 347
  of haloalkynes, 698
  of inorganic esters, 343
  of isocyanates, 807
  of isothiocyanates, 807
  of nitriles, 809–810
  of nitro compounds, 808–809
  of ortho esters, 344–346
  of oxazines and oxazolines, 430, 431
  of sulfonic acid derivatives, 450
  of trihalides, 342
  of vinylboranes, 733
Hydrometalation, 722, 794
  (*See also* Hydroboration)
Hydroperoxide ion, 371
Hydroperoxides: addition to alkenes, 700
  in alkylation of heterocycles, 658
  conversion to peroxides, 647
  formation of, 1092, *see also* 1182
  oxidation: of amines, 1111
    of azo compounds, 1112
    of lactams, 1104
  reaction with acyl halides, 371
  rearrangement of, 1012
  reduction of, 1130–1131
Hydroperoxy sulfides, 704
Hydroquinones, 84, 660, 830
Hydroxamic acids: in amidation of arenes, 479
  formation of, 382, 386, 808
  in the Nef reaction, 808
  rearrangement of, 1006
Hydroxide ion, as nucleophile, 341–357, 595–596, 698, 990, 991
Hydroxy acids: cleavage of, 1087–1088
  decarbonylation of, 356
  decarboxylation of, 948
  formation of, *see* 1182
  fragmentation of, 948, 949
  lactonization of, 363
Hydroxy aldehydes: cleavage of, 850, 1087
  conversion to osazones, 825
  formation of, *see* 1182
  rearrangement of, 988
Hydroxyalkylation, 498–499, 502
Hydroxy alkynes: conversion to unsaturated ketones, 536
  pyrolysis of, 955
  rearrangement of, 306
Hydroxy amides: formation of, *see* 1182
  rearrangement of, 1004, 1067
Hydroxyamines: cleavage of, 1087
  conversion to aziridines, 379
  formation of, *see* 1182
  fragmentation of, 947, 949
  rearrangement of, 965, 984, 985
Hydroxy azo compounds, formation of, 1071–1072
Hydroxybenzoic acids, 242
Hydroxy enol ethers, 859
Hydroxy esters: formation of, *see* 1182
  rearrangements of, 1066–1067
Hydroxy ethers, formation of, 360–361
Hydroxy imines, rearrangement of, 988
Hydroxy ketones: cleavage of, 850, 1087
  conversion: to amino ketones, 379
    to osazones, 825
  formation of, *see* 1182
  rearrangement of, 988, 991
  reduction of, 1119
Hydroxy ketoximes, 951
Hydroxylamine, 382, 386, 478, 609, 705, 825–827
Hydroxylamine ethers, 478
Hydroxylamines, 1125
  formation of, *see* 1182
  oxidation of, 1086, 1109
  reaction with nitroso compounds, 581
  rearrangement of, 616–617, 1010
  reduction of, 1126–1127
Hydroxylamine-O-sulfonic acid: reaction: with aldehydes and ketones, 825, 827
    with aromatic rings, 478
    with boranes, 561, 706
    with sulfonamides, 404
  reduction, of double bonds, 709, 712, 714
Hydroxylamine-O-sulfonic acids, conversion to oxaziranes, 757
Hydroxylation: at an alipholic carbon, 639–640
  of alkenes, 748–750
  of aromatic acids, 609
  of aromatic rings, 504, 640
Hydroxyl groups, migration of, 1000
Hydroxyl radicals, 640
Hydroxy mercaptans, formation of, 374, 814
Hydroxy nitriles, formation of, *see* 1183
α-Hydroxynitriles (*see* Cyanohydrins)
β-Hydroxyphosphonic bisamides, 870
4-Hydroxypyridine, 74
Hydroxy sulfides, formation of, 375, 815
Hydroxysulfinamides, 857, 945
Hydroxy sulfonic acids, formation of, 376–377, 816
Hydroxy sulfoxides, 857, 934
α-Hydroxy thiols, 814
Hydroxy tosylates, fragmentation of, 947

Hyperconjugation, 69–71, 153, 173, 206, 463
Hypobromous acid, 483, 741
Hypochlorous acid, 483, 741–742
Hypoiodous acid, 741
Hypophosphorus acid, 660, 661
Hypostrophene, 1048, 1049
Hypsochromic shifts, 211, 212

+*I* and −*I* groups, 21
Imidates (*see* Imino esters)
Imidazoles, 366, 407
Imidazolides, 353, 365, 371
Imides: N-acylation, 389
  addition to multiple bonds, 705
  N-alkylation of, 388
  formation of, *see* 1183
  N-halogenation of, 582
  hydrolysis of, 353
  reaction with phosphoranes, 872
  rearrangement of, 1004
  reduction of, 1122

Trifluorotoluene, 342
Trigonal hybridization, 11
1,1,1-Trihalides: conversion to ortho esters, 357
  formation of, 570
  hydrolysis of, 342
  reaction with aromatic rings, 485
  reduction of, 400
1,1,1-Trihalo ketones, 388, 575
Triiron dodecacarbonyl, 535, 1125
Triisobutylaluminum, 1077*n*.
Triketones, formation of, 446
Trimethylaluminum, 415, 837, 844
Trimethylamine, basicity of, 242, 243

Trimethylamine oxide, 559, 1106
Trimethylbenzene, 469
Trimethylbismuth, 172, 173
Trimethyl borate, 557
Trimethylenemethane, 176
Trimethylphenylstannanes, 476
Trimethyl phosphate, 368
Trimethyl phosphite, 939, 1056–1057, 1090
Trimethylsilylbenzenes, cleavage of, 469
Trimethylsilyl sulfides, 376
Trimethylsulfonium ion, 163
Trinitrobenzene, 80, 81, 475
Trinitrofluorene, 80
Trinitrophenol, 1097
Trinitrophenyl halides, 593
Trinitrotoluene, 1097
Trioxane, 658, 881
Triphenylcarbinol, 1078
Triphenylchloromethane, 155, 485, 489
Triphenylcyclopropene, 56
Triphenylcyclopropenyl cation, 54–55
Triphenylene, 44
Triphenylgermylbenzenes, cleavage of, 469
Triphenylmethane, 239
Triphenylmethyl carbanions, 162
Triphenylmethyl cation, 155, 158, 273
Triphenylmethyl compounds, rearrangement of, 1010
Triphenylmethyl isocyanide, 564
Triphenylmethyl radical, 173, 175, 273, 630, 654
Triphenylmethylsodium, 422, 853, 933
Triphenylphosphine: in halide formation, 398
  reaction: with alcohols and CCl_4, 394
    with amides and CCl_4, 953, 954
    with azo sulfides, 961
    with carboxylic acids and CCl_4, 398
    with diazo ketones, 806
    with epoxides, 381, 940
    with halo acyl halides, 944
    with oximes and CCl_4, 1008
    with perfluorocyclobutene, 678
Triphenylphosphine: reaction: with sulfides, 942
  reduction: of amine oxides, 1129
    of aryl halides, 518
    of azoxy compounds, 1129
    of disulfides, 1132
    of nitroso compounds, 1138
    of sulfoxides, 1130
Triphenylphosphine dibromide, 379, 395, 399, 601, 954
Triphenylphosphine selenide, 940
Triphenylphosphine sulfide, 375
Triphenyl phosphite, 646
Triphenyltin hydride, 518, 812
Triple-bonds: electronic structure of, 13–14
  migration of, 534
  in rings, 147
Triple-decker sandwich compounds, 47
Triplet carbenes, 178–180, 184, 553–554, 791
Triplet diradicals, 176, 785
Triplet nitrenes, 184, 756
Triplet states, 210, 211, 214–233, 889, 1060–1063, 1133
  energies of, 219
  nomenclature of, 213
Triplet-triplet transfer, 219
Tripropylcyclopropenyl cation, 54
Triptycene, 763
Tris(acetylacetonate)iron, 577
Trisalkylaminoboranes, 385
Trisalkylthioboranes, 376
Tris(diethylamino)phosphine, 961, 1132
1-Trishomobarrelyl cation, 157
Tris(pentafluorphenyl)-methane, 239
Tris[3-trifluoroacetyl-*d*-camphorato]-europium(III), 112
Tris[3-trifluoroacetyl-*d*-nopinonato]-europium(III), 112
Tris(triphenylphosphine)-bromorhodium, 730
Trithianes, 814, 815
Trithiapentalenes, 68
Tritiation of aromatic rings, 473, 474
Tritium isotope effects, 205
Trityl (*see under* Triphenylmethyl)
Trivinylmethyl cations, 154–155
Tröger's base, 91
Tropic acid, 822
Tropine, 822
Tropinone, 822
Tropolones, 49
Tropone, 49, 1024
Tropylium ion, 48, 489
Truxillic acids, 786
Truxinic acids, 116, 786
Tungsten complexes, 1057, 1058
Tungsten hexachloride, 1057, 1058, 1134
Tungsten oxides, 923, 1058–1059
Tunneling, 205*n.*
Twistane, 129
Twist conformation, 128–129, 132
Two-electron, three-center bond, 297, 299, 532
Twofold extrusion, 961
Two-ion catalysis, 524
Two-stage mechanism, 591
Types I and II cleavage (*see* Norrish Type I cleavage; Norrish Type II cleavage)

Udenfriend's reagent, 640
Ugi reaction, 892–893
Ullmann reaction (biaryl synthesis), 606–607
Ullmann reaction (ether synthesis), 597
Ultraviolet spectra, 209
Umbrella effect, 90, 165
Undecyl radicals, 622*n.*, 628
Ungerade orbitals, 9, 211, 213
Unsaturated acids: cyclization of, 701–702
  cycloadditions of, 783
  decarboxylation of, 569–571
  formation of, *see* 1190
  reduction of, 709
Unsaturated acyl chlorides, formation of, 438
Unsaturated alcohols: cleavage of, 877
  formation of, *see* 1190
  isomerization to ketones, 536
  pyrolysis of, 954–955
  rearrangement of, 1044
Unsaturated aldehydes: aldol condensation of, 850
  chlorination of, 538*n.*
  cleavage of, 850

Unsaturated aldehydes:
  conversion: to amides, 651
    to quinolines, 501
  epoxidation of, 752
  formation of, *see* 1190
  reaction: with active hydrogen compounds, 727
    with ammonia, 817
    with boranes, 732–733
    with organometallic compounds, 728–731, 837
  rearrangements of, 1052
  reduction of, 400, 708, 831
Unsaturated amines, formation of, 544, 726, 1056
Unsaturated expoxides, reduction of, 403
Unsaturated esters: alkylation of, 423
  condensation with aldehydes and ketones, 853
  epoxidation of, 751
  formation of, *see* 1190
  reaction: with active hydrogen compounds, 727
    with α-hydroxy-α-cyano carbanions, 734
    with organometallic compounds, 728–731
    with silyl enol ethers, 728
  rearrangement of, 1052
Unsaturated ethers, formation of, 420, 721
Unsaturated Grignard reagents, cyclization of, 730
Unsaturated ketones: in the aldol condensation, 850
  alkylation of, 423, 425, 550
  chlorination of, 538*n.*
  cleavage of, 850
  conversion: to epoxides, 751, 752, 884
    to quinolines, 501
  cyclization of, 726
  cycloadditions of, 783–784
  epoxidation of, 752
  formation of, *see* 1190
  fragmentation of, 949
  hydrogenation of, 931
  reaction: with active hydrogen compounds, 727
    with boranes, 732–733, 747
    with HCN, 739
Unsaturated ketones: reaction:
    with α-hydroxy-α-cyano carbanions, 734
    with iodine azide, 745
    with organometallic compounds, 728–731, 837
    with silyl enol ethers, 728
  rearrangements of, 1052, 1062
  reduction of, 830, 1120
Unsaturated nitriles: alkylation of, 423
  formation of, 423, 435, 739
  reaction with α-hydroxy-α-cyano carbanions, 734
Unsaturated nitro compounds, formation of, 744, 854
Unsaturated phenols, formation of, *see* 1190
Unsaturated rings, strain in, 146–148
Unsaturated sulfides, formation of, 1056
Unsaturated sulfones, 871
  epoxidation of, 752
  formation of, 838
  reaction with organometallic compounds, 729
Unsaturated tosylhydrazones, 1120
Urea, 83–84, 109, 388, 497, 509
Ureas: dehydration of, 954
  formation of, *see* 1191
  rearrangement of, 1004
Ureides, formation of, *see* 1183
Urethanes (*see* Carbamates)

Valence-bond method, 8–9, 29–31
  free valence in, 69
Valence isomerism, 788
Valence tautomerism, 1047–1050
Vanadium pentoxide, 1096
Vanadium trichloride, 1138
van der Waals forces, 75, 83
Vibrational levels, 209, 214–218, 220
Vilsmeier-Haack reaction, 493
Vilsmeier reaction, 493, 547, 748
Vinyl acetate, 400
Vinylacetylene, 726
Vinylaluminum compounds, 411, 561, 665, 794, 836, 845
Vinylboranes, 733, 1021, 1023
Vinylcarbenes, 958
Vinyl chloride, structure of, 34
Vinylcopper compounds, 561, 665, 799
2-Vinylcycloalkanols, 1041
Vinylcyclobutenes, 1044
Vinylcyclopropanes, 1043, 1061–1062
Vinylcyclopropenes, 1043
Vinyldialkylboranes, 1019
Vinyl ethers (*see* Enol ethers)
Vinyl Grignard reagents, 566
Vinyl groups, migration of, 976, 977
Vinylic azides, 757
Vinylic carbanions, 165, 528, 686, 1000
Vinylic cations, 156–157, 313–314, 318, 534, 686, 690
Vinylic cyanides, 435
Vinylic epoxides, 417
Vinylic halides: carbalkoxylation of, 437
  conversion: to alkynes, 935–936
    to amides, 389
    to enol acetates, 368
  coupling of, 408–409, 411, 413
  formation of, *see* 1191
  reduction of, 400
Vinyllithium compounds, 411, 565
Vinylology, 423, 850, 853, 860
Vinyl polymerization, 160, 177
Vinylsilanes, 557
Vinylsilver compounds, dimerization of, 665
Vinyl sulfides (*see* Enol thioethers)
