# THERMODYNAMIC PROPERTIES AS A FUNCTION OF TEMPERATURE

L. V. Gurvich, V. S. Iorish, V. S. Yungman, and O. V. Dorofeeva

The thermodynamic properties  $C_p^\circ(T)$ ,  $S^\circ(T)$ ,  $H^\circ(T)-H^\circ(T_r)$ ,  $-[G^\circ(T)-H^\circ(T_r)]/T$  and formation properties  $\Delta_f H^\circ(T)$ ,  $\Delta_f G^\circ(T)$ ,  $\log K_f^\circ(T)$  are tabulated as functions of temperature in the range 298.15 to 1500 K for 80 substances in the standard state. The reference temperature,  $T_r$ , is equal to 298.15 K. The standard state pressure is taken as 1 bar (100,000 Pa). The tables are presented in the JANAF Thermochemical Tables format (Reference 2). The numerical data are extracted from IVTANTHERMO databases except for  $C_2H_4O$ ,  $C_3H_6O$ ,  $C_6H_6$ ,  $C_6H_6O$ ,  $C_{10}H_8$ , and  $CH_5N$ , which

are based upon TRC Tables. See the references for information on standard states and other details.

# THERMODYNAMIC PROPERTIES OF AQUEOUS IONS

This table contains standard state thermodynamic properties of positive and negative ions in aqueous solution. It includes enthalpy and Gibbs energy of formation, entropy, and heat capacity, and thus serves as a companion to the preceding table, "Standard Thermodynamic Properties of Chemical Substances". The standard state is the hypothetical ideal solution with molality  $m = 1$  mol/kg (mean ionic molality  $m_{\pm}$  in the case of a species which is assumed to dissociate at infinite dilution). Further details on conventions may be found in Reference 1.

All values refer to standard conditions of 25 °C and 100 kPa pressure.

## HEAT OF COMBUSTION

The heat of combustion of a substance at 25°C can be calculated from the enthalpy of formation ( $\Delta_f H^\circ$ ) data in the table “Standard Thermodynamic Properties of Chemical Substances” in this Section. We can write the general combustion reaction as

For a compound containing only carbon, hydrogen, and oxygen, the reaction is simply

and the standard heat of combustion  $\Delta_c H^\circ$ , which is defined as the negative of the enthalpy change for the reaction (i.e., the heat released in the combustion process), is given by

$$\begin{aligned} \Delta_c H^\circ &= -a\Delta_f H^\circ(CO_2, g) - \frac{1}{2}b\Delta_f H^\circ(H_2O, l) + \Delta_f H^\circ(C_a H_b O_c) \\ &= 393.51a + 142.915b + \Delta_f H^\circ(C_a H_b O_c) \end{aligned}$$

This equation applies if the reactants start in their standard states (25°C and one atmosphere pressure) and the products return to the same conditions. The same equation applies to a compound containing another element if that element ends in its standard reference state (e.g., nitrogen, if the product is  $N_2$ ); in general, however, the exact products containing the other elements must be known in order to calculate the heat of combustion.

The following table gives the standard heat of combustion calculated in this manner for a few representative substances.

| Molecular formula           | Name                | $\Delta_c H^\circ / \text{kJ mol}^{-1}$ | Molecular formula         | Name                 | $\Delta_c H^\circ / \text{kJ mol}^{-1}$ |

## MOLAR CONDUCTIVITY OF AQUEOUS HF, HCl, HBr, AND HI

The molar conductivity  $\Lambda$  of an electrolyte solution is defined as the conductivity divided by amount-of-substance concentration. The customary unit is  $\text{S cm}^2 \text{mol}^{-1}$  (i.e.,  $\Omega^{-1} \text{cm}^2 \text{mol}^{-1}$ ). The first part of this table gives the molar conductivity of the hydrohalogen acids at 25 °C as a function of the concentration in mol/L. The second part gives the temperature dependence of  $\Lambda$  for HCl and HBr. More extensive tables and mathematical representations may be found in the reference.

## STANDARD KCl SOLUTIONS FOR CALIBRATING CONDUCTIVITY CELLS

This table presents recommended electrolytic conductivity ( $\kappa$ ) values for aqueous potassium chloride solutions with molalities of 0.01 mol/kg, 0.1 mol/kg and 1.0 mol/kg at temperatures from 0°C to 50°C. The values, which are based on measurements at the National Institute of Standards and Technology, provide primary standards for the calibration of conductivity cells. The measurements at 0.01 and 0.1 molal are described in Reference 1, while those at 1.0 molal are in Reference 2. Temperatures are given on the ITS-90 scale. The uncertainty in the conductivity is about 0.03% for the 0.01 molal values and about 0.04% for the 0.1 and 1.0 molal values. The conductivity of water saturated with atmospheric CO<sub>2</sub> is given in the last column. These values were subtracted from the original measurements to give the values in the second, third, and fourth columns. All  $\kappa$  values are given in units of 10<sup>-4</sup> S/m (numerically equal to  $\mu$ S/cm).

The assistance of Kenneth W. Pratt is appreciated.

# EQUIVALENT CONDUCTIVITY OF ELECTROLYTES IN AQUEOUS SOLUTION

Petr Vanýsek

This table gives the equivalent (molar) conductivity  $\Lambda$  at 25 °C for some common electrolytes in aqueous solution at concentrations up to 0.1 mol/L. The units of  $\Lambda$  are  $10^{-4} \text{ m}^2 \text{ S mol}^{-1}$ .

For very dilute solutions, the equivalent conductivity for any electrolyte of concentration  $c$  can be approximately calculated using the Debye–Hückel–Onsager equation, which can be written for a symmetrical (equal charge on cation and anion) electrolyte as

$$\Lambda = \Lambda^\circ - (A + B\Lambda^\circ)c^{1/2}$$

For a solution at 25 °C and both cation and anion with charge |1|, the constants are  $A = 60.20$  and  $B = 0.229$ .  $\Lambda^\circ$  can be found from the next table, “Ionic Conductivity and Diffusion at Infinite Dilution.” The equation is reliable for  $c < 0.001 \text{ mol/L}$ ; with higher concentration the error increases.

# IONIC CONDUCTIVITY AND DIFFUSION AT INFINITE DILUTION

Petr Vanyšek

This table gives the molar (equivalent) conductivity  $\lambda$  for common ions at infinite dilution. All values refer to aqueous solutions at 25°C. It also lists the diffusion coefficient  $D$  of the ion in dilute aqueous solution, which is related to  $\lambda$  through the equation

$$D = (RT / F^2)(\lambda / |z|)$$

where  $R$  is the molar gas constant,  $T$  the temperature,  $F$  the Faraday constant, and  $z$  the charge on the ion. The variation with temperature is fairly sharp; for typical ions,  $\lambda$  and  $D$  increase by 2 to 3% per degree as the temperature increases from 25°C.

The diffusion coefficient for a salt,  $D_{\text{salt}}$ , may be calculated from the  $D_+$  and  $D_-$  values of the constituent ions by the relation

$$D_{\text{salt}} = \frac{(z_+ + |z_-|)D_+D_-}{z_+D_+ + |z_-|D_-}$$

For solutions of simple, pure electrolytes (one positive and one negative ionic species), such as NaCl, equivalent ionic conductivity  $\Lambda^\circ$ , which is the molar conductivity per unit concentration of charge, is defined as

$$\Lambda^\circ = \Lambda_+ + \Lambda_-$$

where  $\Lambda_+$  and  $\Lambda_-$  are equivalent ionic conductivities of the cation and anion. The more general formula is

$$\Lambda^\circ = \nu_+\Lambda_+ + \nu_-\Lambda_-$$

where  $\nu_+$  and  $\nu_-$  refer to the number of moles of cations and anions to which one mole of the electrolyte gives a rise in the solution.

# MEAN ACTIVITY COEFFICIENTS OF ELECTROLYTES AS A FUNCTION OF CONCENTRATION

The mean activity coefficient  $\gamma$  of an electrolyte  $X_a Y_b$  is defined as

$$\gamma = (\gamma_+^a \gamma_-^b)^{1/(a+b)}$$

where  $\gamma_+$  and  $\gamma_-$  are activity coefficients of the individual ions (which cannot be directly measured). This table gives the mean activity coefficients of about 100 electrolytes in aqueous solution as a function of concentration, expressed in molality terms. All

values refer to a temperature of 25°C. Substances are arranged in alphabetical order by formula.

\* The anion is H<sub>2</sub>PO<sub>4</sub><sup>-</sup>.\*\* The anion is HPO<sub>4</sub><sup>-2</sup>.

## ENTHALPY OF DILUTION OF ACIDS

The quantity given in this table is  $-\Delta_{\text{dil}}H$ , the negative of the enthalpy (heat) of dilution to infinite dilution for aqueous solutions of several common acids; i.e., the negative of the enthalpy change when a solution of molality  $m$  at a temperature of 25°C is diluted with an infinite amount of water. The tabulated numbers thus represent the heat produced (or, if the value is negative, the heat absorbed) when the acid is diluted. The initial molality  $m$  is given in the first column. The second column gives the dilution ratio, which is the number of moles of water that must be added

to one mole of the acid to produce a solution of the molality in the first column.

# ENTHALPY OF SOLUTION OF ELECTROLYTES

This table gives the molar enthalpy (heat) of solution at infinite dilution for some common uni-univalent electrolytes. This is the enthalpy change when 1 mol of solute in its standard state is dissolved in an infinite amount of water. Values are given in kilojoules per mole at 25°C.

# CHEMICAL KINETIC DATA FOR STRATOSPHERIC MODELING

The present compilation of kinetic data represents the 12th evaluation prepared by the NASA Panel for Data Evaluation. The Panel was established in 1977 by the NASA Upper Atmosphere Research Program Office for the purpose of providing a critical tabulation of the latest kinetic and photochemical data for use by modelers in computer simulations of stratospheric chemistry. The recommended rate data and cross sections are based on laboratory measurements. The major use of theoretical extrapolation of data is in connection with three-body reactions, in which the required pressure or temperature dependence is sometimes unavailable from laboratory measurements, and can be estimated by use of appropriate theoretical treatment. In the case of important rate constants for which no experimental data are available, the panel may provide estimates of rate constant parameters based on analogy to similar reactions for which data are available.

Rate constants are expressed in the form  $k(T) = A \exp(-E/RT)$ , where  $A$  is the pre-exponential factor,  $E$  the activation energy,  $R$  the gas constant, and  $T$  the absolute temperature. Uncertainties are expressed by the factor  $f$ , e.g., a value of  $4.2 \times 10^{-10}$  with  $f = 2$  indicates that the true value is believed to lie between  $2.1 \times 10^{-10}$  and  $8.4 \times 10^{-10}$ . The value of  $f$  at other temperatures may be calculated from  $f(298)$ , given in the last column, by:

$$f(T) = f(298) \exp[(\Delta E/R)(1/T - 1/298)],$$

where  $\Delta E/R$  is the uncertainty in  $E/R$ .

Table 1 covers rate constant data on second order reactions, grouped by class, while Table 2 covers association reactions. Relevant equilibrium constant data are given in Table 3. All concentrations are measured in molecules  $\text{cm}^{-3}$ . Notes on each reaction, as well as related photochemical data, may be found in the reference.

The assistance of Robert Hampson is gratefully acknowledged.

# KINETIC DATA FOR COMBUSTION MODELLING

D. L. Baulch, C. J. Cobos, R. A. Cox, C. Esser, P. Frank, Th. Just, J. A. Kerr,  
M. J. Pilling, J. Troe, R. W. Walker, and J. Warnatz

The following tables present evaluated rate constants and other chemical kinetic data required for modelling the combustion of hydrocarbons. The compilation was prepared as part of the project "Kinetics and Mechanisms of Chemical Processes in Combustion", which is one of the projects in the third European Community Energy Research and Development Program. The tables are reprinted from the *Journal of Physical and Chemical Reference Data* by permission of the authors and the American Institute of Physics.

Table 1 lists all the reactions studied and gives the recommended rate constant  $k$  for every bimolecular reaction, as well as the applicable temperature range and the associated error limits. Where more than one set of products is possible, rate constants or branching ratios are given for all channels considered feasible. The data for decomposition reactions and combination reactions are given in Tables 2 and 3, respectively. The reference includes a detailed data sheet for each reaction listed here, covering the thermodynamic data, kinetic measurements, and reliability assessments.

## ELECTRICAL CONDUCTIVITY OF WATER

This table gives the electrical conductivity of highly purified water over a range of temperature and pressure. The first column of conductivity data refers to water at its own vapor pressure. Equations for calculating the conductivity at any temperature and pressure may be found in the reference.

## ELECTRICAL CONDUCTIVITY OF AQUEOUS SOLUTIONS

The following table gives the electrical conductivity of aqueous solutions of some acids, bases, and salts as a function of concentration. All values refer to 20 °C. The conductivity  $\kappa$  (often called specific conductance in older literature) is the reciprocal of the resistivity. The molar conductivity  $\Lambda$  is related to this by  $\Lambda = \kappa/c$ , where  $c$  is the amount-of-substance concentration of the electrolyte. Thus if  $\kappa$  has units of millisiemens per centimeter (mS/cm), as in this table, and  $c$  is expressed in mol/L, then  $\Lambda$  has units of S cm<sup>2</sup> mol<sup>-1</sup>. For these electrolytes the concentration  $c$  correspond-

ing to the mass percent values given here can be found in the table "Concentrative Properties of Aqueous Solutions" in Section 8.

## ENERGY CONTENT OF FUELS

Several fuels are compared in this table with respect to their energy content per unit mass and the amount of CO<sub>2</sub> released per unit of available energy. The energy content is taken to be the negative of the standard enthalpy of combustion (see the table “Heat of Combustion” in this section for more details). The energy is assumed to be released by combustion with oxygen at normal atmospheric pressure, with products of gaseous CO<sub>2</sub> and liquid H<sub>2</sub>O at room temperature. This quantity is often called the “gross heat of combustion” to distinguish it from the “net heat of combustion,” for which the water remains in the gas state. The latter quantity is typically 5% to 10% less than the values given here.

The energy content is given both in SI units of MJ/kg and conventional units of BTU/lb. Values for the fossil fuels and other materials are typical; individual samples show wide variations.

The last column gives the grams of carbon released as carbon dioxide per megajoule of energy. Examination of the table shows

that the minimum CO<sub>2</sub> release occurs for fuels that have a high ratio of hydrogen to carbon. Furthermore, fuels containing oxygen have a lower energy content and higher CO<sub>2</sub> release than hydrocarbons with the same number of carbon atoms.

<sup>a</sup> Assumed to be 95% methane, 2.5% ethane, and 2.5% inert compounds; however, the actual composition varies widely (see Reference 4).

## ENTHALPY OF HYDRATION OF GASES

The molar enthalpy of hydration  $\Delta_{\text{hyd}}H^\infty$  is defined as the enthalpy change when one mole of an ideal gas is dissolved in an infinite amount of water. Another term for this quantity is enthalpy (heat) of solvation in water at infinite dilution. The enthalpy of hydration influences the distribution of a volatile compound between the aqueous solution phase and air and is thus important in fields such as environmental science, geochemistry, and chemical engineering. It is related to the enthalpy of solution of the liquid or solid phase,  $\Delta_{\text{sol}}H^\infty$ , by

$$\Delta_{\text{hyd}}H^\infty = \Delta_{\text{sol}}H^\infty - \Delta_{\text{vap}}H^0$$

where  $\Delta_{\text{vap}}H^0$  is the molar enthalpy of vaporization. This table gives the molar enthalpy of hydration for a number of common substances.

# THERMOPHYSICAL PROPERTIES OF AIR

Eric W. Lemmon

These tables summarize the thermophysical properties of air in the liquid and gaseous states as calculated from the pseudo-pure fluid equation of state of Lemmon et al. (2000). The first table refers to liquid and gaseous air at equilibrium as a function of temperature. The tabulated properties are the bubble-point pressure (i.e., pressure at which boiling begins as the pressure of the liquid is lowered); the dew-point pressure (i.e., pressure at which condensation begins as the pressure of the gas is raised); density ( $\rho$ ); enthalpy ( $H$ ); entropy ( $S$ ); isochoric heat capacity ( $C_v$ ); isobaric heat capacity ( $C_p$ ); speed of sound ( $u$ ); viscosity ( $\eta$ ); and thermal conductivity ( $\lambda$ ). The first line of identical temperatures is the bubble-point (liquid) and the second line is the dew point (vapor). The normal boiling point of air, i.e., the temperature at which the bubble-point pressure reaches 1 standard atmosphere (1.01325 bar), is 78.90 K (−194.25 °C).

The second table gives the properties of air along various isobars. An entry with non-integer temperatures in the isobar section indicates a phase transition (liquid–vapor) at these temperatures; property values are then given for both phases. These are identi-

fied by the high densities in the liquid and the low densities in the vapor. Additional calculations at state points not listed below can be obtained by using the NIST program REFPROP (<http://www.nist.gov/srd/nist23.htm>).

<sup>a</sup> Freezing point for the liquid state.

## FIXED POINT PROPERTIES OF H<sub>2</sub>O AND D<sub>2</sub>O

Temperatures are given on the IPTS-68 scale.

## THERMAL CONDUCTIVITY OF SATURATED H<sub>2</sub>O AND D<sub>2</sub>O

This table gives the thermal conductivity  $\lambda$  for water (H<sub>2</sub>O or D<sub>2</sub>O) in equilibrium with its vapor. Values for the liquid ( $\lambda_l$ ) and vapor ( $\lambda_v$ ) are listed, as well as the vapor pressure.

## STANDARD DENSITY OF WATER

This table gives the density  $\rho$  of water in the temperature range from 0°C to 100°C at a pressure of 101325 Pa (one standard atmosphere). From 0°C to 40°C the values are taken from the IUPAC publication in Reference 1 and refer to standard mean ocean water (SMOW), free from dissolved salts and gases. SMOW is a standard water sample of high purity and known isotopic composition. Methods of correcting for different isotopic compositions are discussed in Reference 1. The remaining values are taken from the NIST Chemistry WebBook, Reference 2.

Note that the IUPAC values refer to the IPTS-68 temperature scale, while the NIST values are based on the ITS-90 scale (where the normal boiling point is 99.974°C). The conversion between these scales can be found in Sec. 1. The difference between the scales leads to a difference in the density of water of about 20 ppm in the neighborhood of 100°C and much less at lower temperatures.

# VOLUMETRIC PROPERTIES OF AQUEOUS SODIUM CHLORIDE SOLUTIONS

This table gives the following properties of aqueous solutions of NaCl as a function of temperature and concentration:

All data refer to a pressure of 100 kPa (1 bar). The reference gives properties over a wider range of temperature and pressure.

Specific volume  $v$  (reciprocal of density) in  $\text{cm}^3/\text{g}$   
 Isothermal compressibility  $\kappa_T = -(1/v)(\partial v/\partial P)_T$  in  $\text{GPa}^{-1}$   
 Cubic expansion coefficient  $\alpha_v = (1/v)(\partial v/\partial T)_P$  in  $\text{K}^{-1}$

## VAPOR PRESSURE OF ICE

The values of the vapor (sublimation) pressure of ice in this table were calculated from the equation recommended by the International Association for the Properties of Steam (IAPS) in 1993. Temperature values correspond to the ITS-90 temperature scale. The uncertainty in the pressure is estimated to be 0.1% for  $t > -25^{\circ}\text{C}$  and 0.5% for  $t < -25^{\circ}\text{C}$ . The first entry in the table is the triple point of water.

# VAPOR PRESSURE AND OTHER SATURATION PROPERTIES OF WATER

Eric W. Lemmon

This table summarizes the vapor pressure, enthalpy (heat) of vaporization, and surface tension of water as accepted by the International Association for the Properties of Water and Steam ([www.iapws.org](http://www.iapws.org)) for general and scientific use. The vapor pressure and heat of vaporization are calculated from the equation of state of Wagner and Pruss (Ref. 1). The temperature scale is ITS-90. Additional calculations at state points not listed below can be obtained by using the NIST Standard Reference Data program REFPROP ([www.nist.gov/srd/nist23.htm](http://www.nist.gov/srd/nist23.htm)) or the water-specific program Steam ([www.nist.gov/srd/nist10.htm](http://www.nist.gov/srd/nist10.htm)).

## MELTING POINT OF ICE AS A FUNCTION OF PRESSURE

This table gives values of the melting temperature of ice at various pressures, as calculated from the equation for the ice I - liquid water phase boundary recommended by the International Association for the Properties of Steam (IAPS). Temperatures are on the ITS-90 scale. See the Reference for information on forms of ice that exist at higher pressures. The transition points for transformations of the various forms of ice (in each case in equilibrium with liquid water) are:

|                  |           |            |
|------------------|-----------|------------|
| ice I - ice III  | 209.9 MPa | -21.985 °C |
| ice III - ice V  | 350.1     | -16.986    |
| ice V - ice VI   | 632.4     | 0.16       |
| ice VI - ice VII | 2216      | 82         |

# THERMOPHYSICAL PROPERTIES OF WATER AND STEAM

Eric W. Lemmon

These tables summarize the thermophysical properties of water and steam at equilibrium as accepted by the International Association for the Properties of Water and Steam ([www.iapws.org](http://www.iapws.org)) for general and scientific use. The thermodynamic properties are calculated from the equation of state of Wagner and Pruss (Ref. 6). The reference state for these tables is the liquid at the triple point, at which the internal energy and entropy are taken as zero. These tables refer to states at 1 bar (100 kPa) pressure with temperatures in °C in the first section; liquid and gaseous states at equilibrium as a function of temperature in the second section; and properties along isobars in the third section. The tabulated properties are pressure ( $P$ ), density ( $\rho$ ), enthalpy ( $H$ ), entropy ( $S$ ), isochoric heat capacity ( $C_v$ ), isobaric heat capacity ( $C_p$ ), speed of sound ( $u$ ), viscosity ( $\eta$ ), thermal conductivity ( $\lambda$ ), and static dielectric constant ( $D$ ). In the saturation tables, the first line of identical temperatures is for the liquid state and the second line is for the vapor state. A duplicate entry in the isobar section indicates a phase transition (liquid-vapor) at that temperature; property values are then given for both phases. These are identified by the high densities in the liquid and the low densities in the vapor. The temperature scale is ITS-90. Additional calculations at state points not listed below can be obtained by using the NIST Standard Reference Data program REFPROP (Ref. 5) or the water-specific program Steam (Ref. 2).

## PERMITTIVITY (DIELECTRIC CONSTANT) OF WATER AT VARIOUS FREQUENCIES

The permittivity of liquid water in the radiofrequency and microwave regions can be represented by the Debye equation (References 1 and 2):

$$\epsilon' = \epsilon_{\infty} + \frac{\epsilon_s - \epsilon_{\infty}}{1 + \omega^2 \tau^2}$$

$$\epsilon'' = \frac{(\epsilon_s - \epsilon_{\infty})\omega\tau}{1 + \omega^2 \tau^2}$$

where  $\epsilon = \epsilon' + i\epsilon''$  is the (complex) relative permittivity (i.e., the absolute permittivity divided by the permittivity of free space  $\epsilon_0 = 8.854 \cdot 10^{-12} \text{ F m}^{-1}$ ). Here  $\epsilon_s$  is the static permittivity (see Reference 3 and the table "Thermophysical Properties of Water and Steam" in this Section);  $\epsilon_{\infty}$  is a parameter describing the permittivity in the high frequency limit;  $\tau$  is the relaxation time for molecular orientation; and  $\omega = 2\pi f$  is the angular frequency. The values in this table have been calculated from parameters given in Reference 2:

|                     | 0 °C  | 25 °C | 50 °C |
|---------------------|-------|-------|-------|
| $\epsilon_{\infty}$ | 5.7   | 5.2   | 4.0   |
| $\tau/\text{ps}$    | 17.67 | 8.27  | 4.75  |

Other useful quantities that can be calculated from the values in the table are the loss tangent:

$$\tan \delta = \epsilon'' / \epsilon'$$

and the absorption coefficient  $\alpha$  which describes the power attenuation per unit length ( $P = P_0 e^{-\alpha l}$ ):

$$\alpha = \frac{\pi f \epsilon''}{c \sqrt{\epsilon'}}$$

and  $c$  is the speed of light. The last equation is valid when  $\epsilon''/\epsilon' \ll 1$ .

# THERMOPHYSICAL PROPERTIES OF FLUIDS

Eric W. Lemmon

These tables give thermodynamic and transport properties of a variety of fluids, as generated from the equations of state presented in the references below. The properties tabulated are pressure ( $P$ ), density ( $\rho$ ), enthalpy ( $H$ ), entropy ( $S$ ), isochoric heat capacity ( $C_v$ ), isobaric heat capacity ( $C_p$ ), speed of sound ( $u$ ), viscosity ( $\eta$ ), thermal conductivity ( $\lambda$ ), and static dielectric constant ( $D$ ). All extensive properties are given on a mass basis. Not all properties are included for every substance. The references should be consulted for information on the uncertainties.

Values are given first along the saturation line. The first two points are the properties at the triple point. The final line gives the properties at the critical point. Two lines are given for each temperature (except at the critical point); the first line gives the values of the liquid phase (note the high density) and the second line gives the values of the vapor phase (at low densities). Following the saturation tables, values are given as a function of temperature for several isobars. A duplicate entry in the isobar section indicates a phase transition (liquid–vapor) at that temperature; property values are then given for both phases. The phase can be determined by noting the sharp decrease in density between two successive temperature entries; all lines above this point refer to the liquid phase, and all lines below refer to the gas phase. If there is no sharp discontinuity in density, all data in the table refer to the supercritical region (*i.e.*, the isobar is above the critical pressure). If the first temperature in the isobars is not an integer, this state point refers to the properties of the liquid at the melting line.

All temperatures are given on ITS-90, except those for oxygen (Ref. 16) and helium (Ref. 13), where the source equations of state still use the IPTS-68 temperature scale. Nitrogen, oxygen, and argon use a reference state based on zero enthalpy in the gas phase at 0 K; parahydrogen, helium, methane, and ethane use a reference state of zero enthalpy and entropy at the saturated liquid state at the normal boiling point; and propane and carbon dioxide use a reference state of 200 kJ kg<sup>-1</sup> and 1 kJ kg<sup>-1</sup> K<sup>-1</sup>, respectively, at -40 °C. Additional calculations at state points not listed below and for fluids not contained here can be obtained at the NIST Chemistry WebBook website ([webbook.nist.gov/chemistry/fluid/](http://webbook.nist.gov/chemistry/fluid/)), or by using the NIST Standard Reference Data program REFPROP (Ref. 9).

# VIRIAL COEFFICIENTS OF SELECTED GASES

Henry V. Kehiaian

This table gives second virial coefficients of about 110 inorganic and organic gases as a function of temperature. Selected data from the literature have been fitted by least squares to the equation

$$B/\text{cm}^3\text{mol}^{-1} = \sum_{i=1}^n a(i)[(T_0/T) - 1]^{i-1}$$

where  $T_0 = 298.15$  K. The table gives the coefficients  $a(i)$  and values of  $B$  at fixed temperature increments, as calculated from this smoothing equation.

The equation may be used with the tabulated coefficients for interpolation within the indicated temperature range. It should not be used for extrapolation beyond this range.

Compounds are listed in the modified Hill order (see Introduction), with carbon-containing compounds following those compounds not containing carbon.

A useful compilation of virial coefficient data from the literature may be found in the reference.

## VAN DER WAALS CONSTANTS FOR GASES

The van der Waals equation of state for a real gas is

$$(P + n^2 a/V^2)(V - nb) = nRT$$

where  $P$  is the pressure,  $V$  the volume,  $T$  the temperature,  $n$  the amount of substance (in moles), and  $R$  the gas constant. The van der Waals constants  $a$  and  $b$  are characteristic of the substance and are independent of temperature. They are related to the critical temperature and pressure,  $T_c$  and  $P_c$ , by

$$a = 27R^2T_c^2/64P_c \quad b = RT_c/8P_c$$

This table gives values of  $a$  and  $b$  for some common gases. Most of the values have been calculated from the critical temperature and pressure values given in the table "Critical Constants" in this section. Van der Waals constants for other gases may easily be calculated from the data in that table.

To convert the van der Waals constants to SI units, note that 1 bar L<sup>2</sup>/mol<sup>2</sup> = 0.1 Pa m<sup>6</sup>/mol<sup>2</sup> and 1 L/mol = 0.001 m<sup>3</sup>/mol.

## MEAN FREE PATH AND RELATED PROPERTIES OF GASES

In the simplest version of the kinetic theory of gases, molecules are treated as hard spheres of diameter  $d$  which make binary collisions only. In this approximation the mean distance traveled by a molecule between successive collisions, the mean free path  $l$ , is related to the collision diameter by:

$$l = \frac{kT}{\pi\sqrt{2}Pd^2}$$

where  $P$  is the pressure,  $T$  the absolute temperature, and  $k$  the Boltzmann constant. At standard conditions ( $P = 100,000$  Pa and  $T = 298.15$  K) this relation becomes:

$$l = \frac{9.27 \cdot 10^{-27}}{d^2}$$

where  $l$  and  $d$  are in meters.

Using the same model and the same standard pressure, the collision diameter can be calculated from the viscosity  $\eta$  by the kinetic theory relation:

$$\eta = \frac{2.67 \cdot 10^{-20} (MT)^{1/2}}{d^2}$$

where  $\eta$  is in units of  $\mu\text{Pa s}$  and  $M$  is the molar mass in g/mol. Kinetic theory also gives a relation for the mean velocity  $\bar{v}$  of molecules of mass  $m$ :

$$\bar{v} = \left( \frac{8kT}{\pi m} \right)^{1/2} = 145.5(T/M)^{1/2} \text{ m/s}$$

Finally, the mean time  $\tau$  between collisions can be calculated from the relation  $\tau\bar{v} = l$ .

The table below gives values of  $l$ ,  $\bar{v}$ , and  $\tau$  for some common gases at 25 °C and atmospheric pressure, as well as the value of  $d$ , all calculated from measured gas viscosities (see References 2 and 3 and the table "Viscosity of Gases" in this section). It is seen from the above equations that the mean free path varies directly with  $T$  and inversely with  $P$ , while the mean velocity varies as the square root of  $T$  and, in this approximation, is independent of  $P$ .

A more accurate model, in which molecular interactions are described by a Lennard-Jones potential, gives mean free path values about 5% lower than this table (see Reference 4).

## INFLUENCE OF PRESSURE ON FREEZING POINTS

This table illustrates the variation of the freezing point of representative types of liquids with pressure. Substances are listed in alphabetical order. Note that 1 MPa = 0.01 kbar = 9.87 atm.

## CRITICAL CONSTANTS

The parameters of the liquid–gas critical point are important constants in determining the behavior of fluids. This table lists the critical temperature, pressure, and molar volume, as well as the normal boiling point, for over 1000 inorganic and organic substances. The properties and their units are:

$T_b$ : Normal boiling point in kelvins at a pressure of 101.325 kPa (1 atmosphere); an “s” following the value indicates a sublimation point (temperature at which the solid is in equilibrium with the gas at a pressure of 101.325 kPa)

$T_c$ : Critical temperature in kelvins

$P_c$ : Critical pressure in megapascals

$V_c$ : Critical molar volume in cm<sup>3</sup>/mol

The number of digits given for  $T_b$ ,  $T_c$ , and  $P_c$  indicates the estimated accuracy of these quantities; however, values of  $T_c$  greater than 750 K may be in error by 10 K or more. Although most  $V_c$  values are given to three figures, they cannot be assumed accurate to better than a few percent. All values are experimentally determined except for a few values, indicated by an asterisk\*, that are based on extrapolations. Methods of measurement are described and critiqued in Reference 1.

Some of the compounds in the table undergo thermal decomposition at temperatures near the critical temperature. The listed values were obtained by pulse heating methods, as described in the references by Nikitin, et al. (References 16, 31, 48, 50, etc.).

Many of the critical constants in this table are taken from reviews produced by the IUPAC Commission on Thermodynamics (References 1–9). Compounds are listed alphabetically by name, with compounds not containing carbon preceding those that do contain carbon.

## SUBLIMATION PRESSURE OF SOLIDS

This table gives the sublimation (vapor) pressure of some representative solids as a function of temperature. Entries include simple inorganic and organic substances in their solid phase below room temperature, as well as polycyclic organic compounds which show measurable sublimation pressure only at elevated temperatures. Substances are listed by molecular formula in the Hill order. Values marked by \* represent the solid-liquid-gas triple point. Note that some pressure values are in pascals (Pa) and others are in kilopascals (kPa). For conversion, 1 kPa = 7.506 mmHg = 0.0098692 atm.

## VAPOR PRESSURE

This table gives vapor pressure data for about 1800 inorganic and organic substances. In order to accommodate elements and compounds ranging from refractory to highly volatile in a single table, the temperature at which the vapor pressure reaches specified pressure values is listed. The pressure values run in decade steps from 1 Pa (about 7.5  $\mu$ m Hg) to 100 kPa (about 750 mm Hg). All temperatures are given in  $^{\circ}$ C.

The data used in preparing the table came from a large number of sources; the main references used for each substance are indicated in the last column. Since the data were refit in most cases, values appearing in this table may not be identical with values in the source cited. The temperature entry in the 100 kPa column is close to, but not identical with, the normal boiling point (which is defined as the temperature at which the vapor pressure reaches 101.325 kPa). Although some temperatures are quoted to 0.1  $^{\circ}$ C, uncertainties of several degrees should generally be assumed. Values followed by an "e" were obtained by extrapolating (usually with an Antoine equation) beyond the region for which experimental measurements were available and are thus subject to even greater uncertainty.

Compounds are listed by molecular formula following the Hill convention. Substances not containing carbon are listed first, followed by those that contain carbon. To locate an organic compound by name or CAS Registry Number when the molecular formula is not known, use the table "Physical Constants of Organic Compounds" in Section 3 and its indexes to determine the molecular formula. The indexes to "Physical Constants of Inorganic Compounds" in Section 4 can be used in a similar way.

More extensive and detailed vapor pressure data on selected important substances appear in other tables in this section of the *Handbook*. These substances are flagged by a symbol following the name as follows:

- \* See "Vapor Pressure of Fluids at Temperatures below 300 K"
- \*\* See "IUPAC Recommended Data for Vapor Pressure Calibration"
- \*\*\* See "Vapor Pressure of Ice" and "Vapor Pressure and other Saturation Properties of Water"

The following notations appear after individual temperature entries:

- s — Indicates the substance is a solid at this temperature.
- e — Indicates an extrapolation beyond the region where experimental measurements exist.
- i — Indicates the value was calculated from ideal gas thermodynamic functions, such as those in the *JANAF Thermochemical Tables* (see Reference 8).
