# NEUTRON SCATTERING AND ABSORPTION PROPERTIES

Norman E. Holden

This table presents an evaluated set of values for experimental quantities that characterize the properties for scattering and absorption of neutrons. The neutron cross section is given for room temperature neutrons, 20.43°C, corresponding to a thermal neutron energy of 0.0253 electron volts (eV) or a neutron velocity of 2200 meters/second. The neutron resonance integral is defined over the energy range from 0.5 eV to  $0.1 \times 10^6$  eV, or 0.1 MeV.

Bound neutron scattering lengths and neutron cross sections averaged over a Maxwellian spectrum at 30 keV for astrophysical applications are also presented. A list of the major references used is given below. The literature cutoff date is January 2003. Uncertainties are given in parentheses. Parentheses with two or more numbers indicate values to the excited state(s) and to the ground state of the product nucleus.

| 3             | Half-life                         | Half-life in decimal notation. $\mu$ s = microsecond; ms = millisecond; s = second; m = minute; h = hour; d = day; y = year.                                                                                                                                                                                                   |
| 4             | Thermal Neutron Cross Sections    | Cross sections for neutron capture reactions in units of barns ( $10^{-24}$ cm <sup>2</sup> ) or millibarns (mb). Proton, alpha production and fission reactions are designated by $\sigma_p$ , $\sigma_\alpha$ , $\sigma_f$ , respectively. Separate values are listed for isomeric production.                               |
| 5             | Neutron Resonance Integrals       | Resonance integrals for neutron capture reactions in barns ( $10^{-24}$ cm <sup>2</sup> ) or millibarns (mb). Proton, alpha production and fission reactions are designated by R.I. <sub>p</sub> , R.I. <sub><math>\alpha</math></sub> , R.I. <sub>f</sub> , respectively. Separate values are listed for isomeric production. |
| 6             | Neutron Scattering Lengths        | Bound coherent scattering lengths for neutron scattering reactions in units of femtometers (fm), which is equal to fermis ( $10^{-13}$ cm).                                                                                                                                                                                    |
| 7             | Maxwellian Averaged Cross Section | Astrophysical Cross Sections, averaged over a stellar neutron maxwellian spectrum characterized by a thermal energy of 30 keV, expressed in barns ( $10^{-24}$ cm <sup>2</sup> ), millibarns (mb) or microbarns ( $\mu$ b).                                                                                                    |

# COSMIC RADIATION

A.G. Gregory and R.W. Clay

## The Nature of Cosmic Rays

Primary cosmic radiation, in the form of high energy nuclear particles, electrons and photons from outside the solar system and from the Sun, continually bombards our atmosphere. Secondary radiation, resulting from the interaction of the primary cosmic rays with atmospheric gas, is present at sea-level and throughout the atmosphere.

The secondary radiation is collimated by absorption and scattering in the atmosphere and consists of a number of components associated with different particle species. High energy primary particles can produce large numbers of secondary particles forming an extensive air shower. Thus, a number of particles may then be detected simultaneously at sea-level.

Primary particle energies accessible in the vicinity of the earth range from  $\sim 10^8$  eV to  $\sim 10^{20}$  eV. At the lower energies, the limit is determined by the inability of charged particles to traverse the heliosphere to us through the outward-moving solar wind. The upper energy limit is set by the practicality of building detectors to record particles with the extremely low fluxes found at those energies (J.G. Wilson, 1976; O.C. Allkofer, 1975a).

## Primary Cosmic Rays

### Primary Particle Energy Spectrum

Figure 1 shows the spectrum of primary particle energies. This includes all particle species. In differential form it is roughly a power law of intensity versus energy with an index of  $\sim -3$ . There appears to be a knee (a steepening) at a little above  $10^{15}$  eV and an ankle (a flattening) above  $\sim 10^{18}$  eV. Figure 2 emphasizes the features in the spectrum at the highest energies through multiplying the flux with a strongly rising power law of energy. This figure should be used with caution as errors for the two axes are not now independent.

Data on the high energy cosmic ray spectrum are uncertain largely because of limited event statistics due to the very low flux which might best be measured in particles per square kilometer per century. The highest energy event recorded to 1995 had an energy of  $3 \times 10^{20}$  eV (D.J. Bird et al., 1993).

It is expected that the highest energy cosmic rays will interact with the 2.7 K cosmic microwave background through photoproduction or photodisintegration. These interactions will appreciably reduce the observed flux of cosmic rays with energies above  $5 \times 10^{19}$  eV if they travel further than  $\sim 150$  million light years. This process is known as the Greisen-Zatsepin-Kuz'min (GZK) cut off (P. Sokolsky, 1989).

At energies below  $\sim 10^{13}$  eV, solar system magnetic fields and plasma can modulate the primary component and Figure 3 shows the extent of this modulation between solar maximum and minimum (E. Juliusson, 1975; J. Linsley, 1981).

### Primary Particle Energy Density

If the above spectrum is corrected for solar effects, the energy density above a particle energy of  $10^8$  eV outside the solar system is found to be  $\sim 5 \times 10^5$  eV  $m^{-3}$ . As the threshold energy is increased, the energy density decreases rapidly, being  $2 \times 10^4$  eV  $m^{-3}$  above  $10^{12}$  eV and  $10^2$  eV  $m^{-3}$  above  $10^{15}$  eV. The energy density at lower energies outside the heliosphere is unknown but may be substan-

tially greater if the particle rest mass energy is included together with the kinetic energy (A. W. Wolfendale, 1979).

### Primary Particle Isotropy

This is measured as an anisotropy  $(I_{\max} - I_{\min})/(I_{\max} + I_{\min}) \times 100\%$ , where  $I$ , the intensity ( $m^{-2}s^{-1}sr^{-1}$ ), is usually measured with an angular resolution of a few degrees.

The measured anisotropy is small and energy dependent. It is roughly constant in amplitude at between 0.05 and 0.1% (with a phase of 0 to 6 hours in right ascension) for energies between  $10^{11}$  eV and  $10^{14}$  eV and appears to increase at higher energies roughly as  $0.4 \times (\text{Energy(eV)}/10^{16})^{0.5}$  up to  $\sim 10^{18}$  eV. The latter rise may well be an artifact of the progressively more limited statistics as the flux drops rapidly with energy. It appears possible that a real anisotropy has been observed at the highest energies (above a few times  $10^{19}$  eV) with a directional preference for the supergalactic plane (this plane reflects the directions of galaxies within about 100 million light years) (A.W. Wolfendale, 1979; R.W. Clay, 1987; T. Stanev et al., 1995).

### Primary Particle Composition

The composition of low energy cosmic rays is close to universal nuclear abundances except where propagation effects are present. For example, Li, Be, and B which are spallation products, are over-abundant by about six orders of magnitude.

| Composition at $10^{11}$ eV per nucleus |    |    |       |       |         |         |         |
|-----------------------------------------|----|----|-------|-------|---------|---------|---------|
| Charge                                  | 1  | 2  | (3-5) | (6-8) | (10-14) | (16-24) | (26-28) |
| % Composition                           | 50 | 25 | 1     | 12    | 7       | 4       | 4       |
| (10% uncertainty)                       |    |    |       |       |         |         | 0.1     |

Measurements at higher energies indicate that there is an increase in the relative abundances of nuclei with charge greater than 6 at energies above 50 TeV/nucleus (K. Asakimori et al., 1993) ( $1 \text{ TeV} = 10^{12} \text{ eV}$ ).

Cosmic ray composition at low energies is often quoted at a fixed energy per nucleon. When presented in this way, protons constitute roughly 90% of the flux, helium nuclei about 10% and the remainder sum to a total of about 1%.

Certain radioactive isotopic ratios show lifetime effects. The ratio of  $Be^{10}/B^9$  abundances is used to measure an "age" of cosmic rays since  $Be^{10}$  is unstable with a half life of about  $1.6 \times 10^6$  years. A ratio of 0.6 is expected in the absence of  $Be^{10}$  decay and a ratio of about 0.2 is found experimentally (E. Juliusson, 1975; P. Meyer, 1981).

At higher energies, composition determinations are indirect and are rather contradictory and controversial. Experiments aim to differentiate between broad composition models. The measurement technique is based on studies of cosmic ray shower development. A rather direct technique for such studies is to use fluorescence observations of the shower development to determine the atmospheric depth of maximum development of the shower. Such observations suggest a heavy composition (large atomic number) at energies  $\sim 10^{17}$  eV which changes with increasing energy to a light composition (perhaps protonic) above  $\sim 10^{19}$  eV (T. K. Gaisser et al., 1993).

**FIGURE 1.** The energy spectrum of cosmic ray particles. This spectrum is of a differential form and can be converted to an integral spectrum by integration over all energies above a required threshold ( $E$ ). Insofar as the spectrum approximates a power law of index  $-3$ , a simple conversion to the integral at an energy  $E/1.8$  is obtained by multiplying the differential flux by the energy and dividing by  $0.62$ .

**FIGURE 2.** Energy spectrum at the highest energies. This spectrum (after Yoshida et al., 1995) has the differential spectrum multiplied by energy cubed. It is from a compilation of a number of measurements and indicates the good general agreement at the lower energies and a spread due to inadequate statistics at the highest energies.

**FIGURE 3.** Energy spectrum of particles at lower energies. (a) Solar minimum proton energy spectrum. (b) Solar maximum proton energy spectrum. (c) Gamma-ray energy spectrum. (d) Local interstellar electron spectrum.

### Primary Electrons

Primary electrons constitute about 1% of the cosmic ray beam. The positron to negative electron ratio is about 10% (J. M. Clem et al., 1995).

### Antimatter in the Primary Beam

The ratio of antiprotons to protons in the primary cosmic ray beam (at about 400 MeV) is about  $10^{-5}$ . At about 10 GeV the ratio is about  $10^{-3}$ . At the highest measured energies (10 TeV), the upper limit to the ratio is about 20% (S. Orito et al., 1995; M. Amenomori et al., 1995).

### Primary Gamma-Rays

The flux of primary gamma-rays is low at high energies. At 1 GeV the ratio of gamma-rays to protons is about  $10^{-6}$ . The arrival directions of these gamma-rays are strongly concentrated in the plane of the Milky Way although there is a diffuse, near isotropic background flux and some point sources have been detected.

Since the absorption cross section for gamma-rays above 100 MeV is approximately 20 mbarn/electron, less than 10% of gamma-rays reach mountain altitudes (A. W. Wolfendale, 1979; P. F. Michelson, 1994).

### Sea Level Cosmic Radiation

The sea level cosmic ray dose is 300 millirad-yr<sup>-1</sup> and the sea level ionization is  $2.2 \times 10^6$  ion pairs m<sup>-3</sup>s<sup>-1</sup>. The sea level flux has a soft component, which can be absorbed in about 100 mm of lead (about 100 g·cm<sup>-2</sup> of absorber) and a more penetrating (largely muon) hard component. The sea level radiation is largely produced in the atmosphere and is a secondary component from interactions of the primary particles. The steep primary energy spectrum means that most secondaries at sea level are from rather low energy primaries. Thus the secondary flux is dependent on the solar cycle and the geomagnetic latitude of the observer.

### Absolute Flux of the Hard Component

Vertical Integral Intensity  $I(0) \sim 100 \text{ m}^{-2}\text{s}^{-1}\text{sr}^{-1}$

Angular dependence  $I(\theta) \sim I(0) \cos^2(\theta)$

Integrated Intensity  $\sim 200 \text{ m}^{-2}\text{s}^{-1}$

(O.C. Allkofer, 1975b).

### Flux of the Soft Component

In free air, the soft component comprises about one third of the total cosmic ray flux.

### Latitude Effect

The geomagnetic field influences the trajectories of lower energy cosmic rays approaching the Earth. As a result, the background flux is reduced by about 7% at the geomagnetic equator. The effect decreases towards the poles and is negligible at latitudes above about 40°.

### Flux of Protons

The proton component is strongly attenuated by the atmosphere with an attenuation length (reduction by a factor of e) of about 120 g·cm<sup>-2</sup>. It constitutes about 1% of the total vertical sea level flux.

### Absorption

The soft component is absorbed in about 100 g·cm<sup>-2</sup> of matter. The hard component is absorbed much more slowly:

Absorption in lead, 6% per 100 g·cm<sup>-2</sup>

Absorption in rock, 8.5% per 100 g·cm<sup>-2</sup>

Absorption in water, 10% per 100 g·cm<sup>-2</sup>

(Absorption for depths less than 100 g·pd cm<sup>-2</sup> is given by K. Greisen, 1943.)

### Altitude Dependence

The cosmic ray background in the atmosphere has a maximum intensity of about 15 times that at sea level at a depth of about 150 g·cm<sup>-2</sup> (15 km altitude). At maximum intensity, the soft and hard components contribute roughly equally but the hard component is then attenuated more slowly (S. Hayakawa, 1969).

### Cosmic Ray Showers

High energy cosmic rays produce particle cascades in the atmosphere which can be detected at sea level provided that their energy exceeds about 100 GeV (such low energy cascades may be detected by using the most sensitive atmospheric Cerenkov detectors). The primary particle progressively loses energy which is transferred through the production of successive generations of secondary particles to a cascade of hadrons, an electromagnetic shower component (both positively and negatively charged electrons and gamma-rays) and muons. The secondary particles are relativistic and all travel effectively at the speed of light. As a result, they reach sea level at approximately the same time but, due to Coulomb scattering (for the electrons) and production angles (for the pions producing the muons), are spread laterally into a disk-like shower front with a characteristic lateral width of several tens of meters and thickness (near the central shower core) of 2 to 3 m. The number of particles at sea level is roughly proportional to the primary particle energy:

Number of particles at sea level  $\sim 10^{-10} \times \text{energy (eV)}$ .

At altitudes below a few kilometers, the number of particles in a shower attenuates with an *attenuation length* of about 200 g·cm<sup>-2</sup>.

i.e., particle number = original number  $\times \exp[-(\text{depth increase})/200]$

The above applies to an individual shower. The rate of observation of showers of a given size (particle number at the detector) at different depths of absorber attenuates with an *absorption length* of about 100 g·cm<sup>-2</sup> (J.G. Wilson, 1976).

### Atmospheric Background Light from Cosmic Rays

Cosmic ray particles produce Cerenkov light in the atmosphere and produce fluorescent light through the excitation of atmospheric molecules.

### Cerenkov Light

High energy charged particles will cause the emission of Cerenkov light in air if their energies are above about 30 MeV (electrons). This threshold is pressure (and hence altitude) dependent. A typical Cerenkov light pulse (at sea level, 100 m from the central shower core) has a time spread of a few nanoseconds. Over this time, the photon flux between 430 and 530 nm would be  $\sim 10^{14} \text{ m}^{-2}\text{s}^{-1}$  for a primary particle energy of  $10^{16} \text{ eV}$ . For comparison, the night sky background flux is  $\sim 6 \times 10^{11} \text{ photons m}^{-2}\text{s}^{-1}\text{sr}^{-1}$  in the same wavelength band (J.V. Jelley, 1967).

### Fluorescence Light

Cosmic ray particles in the atmosphere excite atmospheric molecules which then emit fluorescence light. This is weak compared to the highly collimated Cerenkov component when viewed in the direction of the incident cosmic ray particle but is emitted

isotropically. Typical pulse widths are longer than 50 ns and may be up to several microseconds for the total pulse from distant large showers (R.M. Baltrusaitis et al., 1985).

## Effects of Cosmic Rays

### Cerenkov Effects in Transparent Media

Background cosmic ray particles will produce Cerenkov light in transparent material with a photon yield between wavelengths  $\lambda_1$  and  $\lambda_2$

$$\sim (2\pi/137)\sin^2(\theta_c) \int_{\lambda_1}^{\lambda_2} d\lambda / \lambda^2 \text{ photons(unit length)}^{-1}$$

where  $\theta_c$  (the Cerenkov angle) =  $\cos^{-1}(1/\text{refractive index})$ .

This background light is known to affect light detectors, e.g., photomultipliers, and can be a major source of background noise (R.W. Clay and A.G. Gregory, 1977).

### Effects on Electronic Components

If background cosmic ray particles pass through electronic components, they may deposit sufficient energy to affect the state of, e.g., a transistor flip-flop. This effect may be significant where reliability is of great importance or the background flux is high. For instance, it has been estimated that, in communication satellite operation, an error rate of about  $2 \times 10^{-3}$  per transistor per year may be found. Permanent damage may also result. A significant error rate may be found even at sea level in large electronic memories. This error rate is dependent on the sensitivity of the component devices to the deposition of electrons in their sensitive volumes (J.F. Ziegler, 1981).

### Biophysical Significance

When cosmic rays interact with living tissue, they produce radiation damage. The amount of the damage depends on the total dose of radiation. At sea level, this dose is small compared with doses from other sources but both the quantity and quality of the radiation change rapidly with altitude. Approximate dose rates under various conditions are:

Dose rates (mrem.yr<sup>-1</sup>)  
 Sea level cosmic rays, 30  
 Cosmic rays at 10 km (subsonic jets), 2000  
 Cosmic rays at 18 km (supersonic transports), 10,000  
 (c.f., mean total sea level dose, 300)

Astronauts would be subject to radiation from galactic (0.05 rads per day) and solar (a few hundred rads per solar flare) cosmic rays as well as large fluxes of low energy radiation when passing through the Van Allen belts (about 0.3 rads per traverse).

Both astronauts and SST travellers would be subject to a small flux of low energy heavy nuclei stopping in the body. Such particles are capable of destroying cell nuclei and could be particularly harmful in the early stages of the development of an embryo. The rates of heavy nuclei stopping in tissue in supersonic transports and spacecraft are approximately as follows:

Stopping nuclei ((cm<sup>3</sup> tissue)<sup>-1</sup> hr<sup>-1</sup>)  
 Supersonic transport (16 km), 0.0005  
 Supersonic transport (20 km), 0.005  
 Spacecraft, 0.15  
 (O. C. Allkofer, 1975a; O. C. Allkofer et al., 1974).

## Carbon Dating

Radiocarbon is produced in the atmosphere due to the action of cosmic ray slow neutrons. Solar cycle modulation of the very low energy cosmic rays causes an anticorrelation of the atmospheric <sup>14</sup>C activity with sunspot number with a mean amplitude of about 0.5%. In the long term, modulation of cosmic rays by a varying magnetic field may be important (A.A. Burchuladze et al., 1979).

## Practical Uses of Cosmic Rays

There are few direct practical uses of cosmic rays. Their attenuation in water and snow have, however, enabled automatic monitors of water and snow depth to be constructed. A search for hidden cavities in pyramids has been carried out using a muon "telescope".

## Other Effects

Stellar X-rays have been observed to affect the transmission times of radio signals between distant stations by altering the depth of the ionospheric reflecting layer. It has also been suggested that variations in ionization of the atmosphere due to solar modulation may have observable effects on climatic conditions.

# TECHNIQUES FOR MATERIALS CHARACTERIZATION

## Experimental Techniques Used to Determine the Composition, Structure, and Energy States of Solids and Liquids

H.P.R. Frederikse

The many experimental methods, originally designed to study the chemical and physical behavior of solids and liquids, have grown into a new field known as Materials Characterization (or Materials Analysis). During the past 30 years a host of techniques aimed at the study of surfaces and thin films has been added to the many tools for the analysis of bulk samples. The field has benefited particularly from the development of computers and micro-processors, which have vastly increased the speed and accuracy of the measuring devices and the recording of their output. Materials characterization was and is a very important tool in the search for new physical and chemical phenomena. It plays an essential role in new applications of solids and liquids in industry, communications, and medicine. Many of its techniques are used in quality control, in safety regulations, and in the fight against pollution.

In most Materials Characterization experiments the sample is subjected to some kind of radiation: electromagnetic, acoustic, thermal, or particles (electrons, ions, neutrons, etc.). The surface

analysis techniques usually require a high vacuum. As a result of interactions between the solid (or liquid) and the incoming radiation a beam of a similar (or a different) nature will emerge from the sample. Measurement of the physical and/or chemical attributes of this emerging radiation will yield qualitative, and often quantitative, information about the composition and the properties of the material being probed.

The modern tendency of describing practically everything in this world by a combination of a few letters (acronyms) has also penetrated the field of Materials Characterization. The table below gives the meaning of the acronym for every technique listed, the form and size of the required sample (bulk, surface, film, liquid, powder, etc.), the nature of the incoming and of the emerging radiation, the depth and the lateral spatial resolution that can be probed, and the information obtained from the experiment. The last column lists one or two major references to the technique described.

# SYMMETRY OF CRYSTALS

L. I. Berger

The ability of a body to coincide with itself in its different positions regarding a coordinate system is called its symmetry. This property reveals itself in iteration of the parts of the body in space. The iteration may be done by reflection in mirror planes, rotation about certain axes, inversions and translations. These actions are called the symmetry operations. The planes, axes, points, etc., are known as symmetry elements. Essentially, mirror reflection is the only truly primitive symmetry operation. All other operations may be done by a sequence of reflections in certain mirror planes. Hence, the mirror plane is the only true basic symmetry element. But for clarity, it is convenient to use the other symmetry operations, and accordingly, the other aforementioned symmetry elements. The symmetry elements and operations are presented in Table 1.

The entire set of symmetry elements of a body is called its symmetry class. There are thirty-two symmetry classes that describe all crystals that have ever been noted in mineralogy or been synthesized (more than 150,000). The denominations and symbols of the symmetry classes are presented in Table 2.

There are several known approaches to classification of individual crystals in accordance with their symmetry and crystallochemistry. The particles that form a crystal are distributed in certain points in space. These points are separated by certain distances (translations) equal to each other in any chosen direction in the crystal. Crystal lattice is a diagram that describes the location of particles (individual or groups) in a crystal. The lattice parameters

are three non-coplanar translations that form the crystal lattice. Three basic translations form the unit cell of a crystal. August Bravais (1848) has shown that all possible crystal lattice structures belong to one or another of fourteen lattice types (Bravais lattices). The Bravais lattices, both primitive and non-primitive, are the contents of Table 3.

Among the three-dimensional figures, there is a group of polyhedrons that are called regular, which have all faces of the same shape and all edges of the same size (regular polygons). It has been shown that there are only five regular polyhedrons. Because of their importance in crystallography and solid state physics, a brief description of these polyhedrons is included in Table 4.

The systematic description of crystal structures is presented primarily in the well-known *Strukturbericht*. The classification of crystals by the *Strukturbericht* does not reflect their crystal class, the Bravais lattice, but is based on the crystallochemical type. This makes it inconvenient to use the *Strukturbericht* categories for comparison of some individual crystals. Thus, there have been several attempts to provide a more convenient classification of crystals. Table 5 presents a compilation of different classifications which allows the reader to correlate the *Strukturbericht* type with the international and Schoenflies point and space groups and with Pearson's symbols, based on the Bravais lattice and chemical composition of the class prototype. The information included in Table 5 has been chosen as an introduction to a more detailed crystallophysical and crystallochemical description of solids.

TABLE 1. Symmetry Operations and Elements

| Symmetry operation                                                          | Symmetry element          |                                       |             | Presentation on the stereographic projection                                          |                                                                                       |

<sup>a</sup> The first letter denotes the crystal system: triclinic (a), monoclinic (m), orthorhombic (o), tetragonal (t), hexagonal (h) and cubic (c). Trigonal (rhombohedral) system is denoted by combination hR. The second letter of Pearson's symbol denotes lattice type: primitive (P), edge-(base-) centered (C), body-centered (I) or face-centered (F). The following number denotes number of atoms in the crystal unit cell.

<sup>b</sup> Standard ASTM E157-82a has the Bravais lattices designations as following: C – primitive cubic; B – body-centered cubic; F – face-centered cubic; T – primitive tetragonal; U – body-centered tetragonal; R – rhombohedral; H – hexagonal; O – primitive orthorhombic; P – body-centered orthorhombic; Q – base-centered orthorhombic; S – face-centered orthorhombic; M – primitive monoclinic; N – centered monoclinic; A – triclinic.

# IONIC RADII IN CRYSTALS

Ionic radii are a useful tool for predicting and visualizing crystal structures. This table lists a set of ionic radii  $R_i$  in Å units for the most common coordination numbers  $CN$  of positive and negative ions. The values are based on experimental crystal structure determinations, supplemented by empirical relationships, and theoretical calculations. The notation sq after the coordination number indicates a square configuration, while py indicates pyramidal.

The advice of Howard T. Evans and Marvin J. Weber in preparing this table is appreciated.

# POLARIZABILITIES OF ATOMS AND IONS IN SOLIDS

H. P. R. Frederikse

The polarization of a solid dielectric medium,  $\mathbf{P}$ , is defined as the dipole moment per unit volume averaged over the volume of a crystal cell. A component of  $\mathbf{P}$  can be expanded as a function of the electric field  $\mathbf{E}$ :

$$P_i = \sum_j a_j E_j + \sum_{jk} b_{jk} E_j E_k$$

For relatively small electric fields in isotropic substances  $\mathbf{P} = \chi_e \mathbf{E}$ , where  $\chi_e$  is the electric susceptibility. If the medium is made up of  $N$  atoms (or ions) per unit volume, the polarization is  $\mathbf{P} = N \mathbf{p}_m$  where  $\mathbf{p}_m$  is the average dipole moment per atom. The polarizability  $\alpha$  can be defined as  $\mathbf{p}_m = \alpha \mathbf{E}_0$ , where  $\mathbf{E}_0$  is the local field at the position of the atom. Using the Lorentz method to calculate the local field one finds:

$$\mathbf{P} = N\alpha(\mathbf{E} + 4\pi\mathbf{P}) = \chi_e \mathbf{E}$$

Together with the definition of the dielectric constant (relative permittivity),  $\epsilon = 1 + 4\pi\chi_e$ , this leads to:

$$\alpha = \frac{3}{4\pi N} \left( \frac{\epsilon - 1}{\epsilon + 2} \right)$$

This expression is known as the Clausius-Mossotti equation.

The total polarization associated with atoms, ions, or molecules is due to three different sources:

1. Electronic polarization arises because the center of the local electronic charge cloud around the nucleus is displaced under the action of the field:  $\mathbf{P}_e = N\alpha_e \mathbf{E}_0$  where  $\alpha_e$  is the *electronic polarizability*.

2. Ionic polarization occurs in ionic materials because the electric field displaces cations and anions in opposite directions:  $\mathbf{P}_i = N\alpha_i \mathbf{E}_0$ , where  $\alpha_i$  is the *ionic polarizability*.
3. Orientational polarization can occur in substances composed of molecules that have permanent electric dipoles. The alignment of these dipoles depends on temperature and leads to an *orientational polarizability* per molecule:  $\alpha_{or} = p^2/3kT$ , where  $p$  is the permanent dipole moment per molecule,  $k$  is the Boltzmann constant, and  $T$  is the temperature.

Because of the different nature of these three polarization processes the response of a dielectric solid to an applied electric field will strongly depend on the frequency of the field. The resonance of the electronic excitation in insulators (dielectrics) takes place in the ultraviolet part of the spectrum; the characteristic frequency of the lattice vibrations is located in the infrared, while the orientation of dipoles requires fields of much lower frequencies (below  $10^{10}$  Hz). This response to electric fields of different frequencies is shown in Figure 1. Values of the electronic polarizabilities for selected atoms and ions are given in Table 1.

 Values are appropriate for cgs units. To convert to SI, use the relation  $\alpha(\text{SI})/\text{C m}^2\text{V}^{-1} = 1.11265 \cdot 10^{-16} \alpha(\text{cgs})/\text{cm}^3$

# CRYSTAL STRUCTURES AND LATTICE PARAMETERS OF ALLOTROPES OF THE ELEMENTS

H. W. King

The crystal structures of the allotropic forms of the elements are presented in terms of the Pearson symbol, the Strukturbericht designation, and the prototype of the structure. The temperatures of the phase transformations are listed in degrees Celsius and the pressures are in GPa. A consistent nomenclature is used, whereby all allotropes are labeled by Greek letters. The lattice parameters of the units cells are given in nanometers (nm) and are considered to be accurate to  $\pm 2$  in the last reported digit.

This compilation is restricted to changes in crystal structures that occur as a result of a change in temperature or pressure. Low-

temperature structures are included for the diatomic and rare gases, which show many similarities with respect to the metallic elements. The elements identified with an asterisk (\*) have polymorphic structures based on different molecular configurations. The crystal data given for these elements refer to the most stable structure at room temperature.

Reprinted with the permission of ASM International from T.B. Massalski, Ed., *Binary Alloy Phase Diagrams*, ASM International, Metals Park, Ohio, 1986; certain data on rare earth elements were provided by K.A. Gschneidner.

# LATTICE ENERGIES

H. D. B. Jenkins and H. K. Roobottom

## THERMOCHEMICAL CYCLE AND CALCULATED VALUES

Table 1 contains calculated values of the lattice energies (total lattice potential energies),  $U_{\text{POT}}$ , of crystalline salts,  $M_aX_b$ .  $U_{\text{POT}}$  is expressed in units of kilojoules per mole,  $\text{kJ mol}^{-1}$ . M and X can be either simple or complex ions. Substances are arranged by chemical class.

Also listed in the table is the lattice energy,  $U_{\text{POT}}^{\text{BFHC}}$ , obtained from the application of the Born - Fajans - Haber cycle (BFHC) described below, using the "Standard Thermochemical Properties of Chemical Substances" table in Section 5 of this *Handbook*, References 1 through 4, and certain other data which are given in Table 3 below.

The lattice enthalpy,  $\Delta H_L$ , is given by the cycle:

where (ss) is the standard state of the element concerned.

The lattice enthalpy,  $\Delta H_L$ , is obtained using the equation:

$$\Delta H_L = a\Delta_f H^\circ(M^{b+}, g) + b\Delta_f H^\circ(X^{a-}, g) - \Delta_f H^\circ(M_aX_b, c)$$

and is further related to the total lattice potential energy,  $U_{\text{POT}}$ , by the relationship:

$$\Delta H_L = U_{\text{POT}} + \left[ a \left( \frac{n_M}{2} - 2 \right) + b \left( \frac{n_X}{2} - 2 \right) \right] RT$$

where  $n_M$  and  $n_X$  equal 3 for monatomic ions, 5 for linear polyatomic ions and 6 for polyatomic non-linear ions.

## METHOD OF ESTIMATION OF VALUES NOT TABULATED

In cases where the lattice energy is not tabulated and we want to furnish an estimate, then the Kapustinskii equation<sup>5</sup> can be used to obtain a value (in  $\text{kJ mol}^{-1}$ ):

$$U_{\text{POT}} = \frac{121.4z_a z_b \nu}{(r_a + r_b)} \left( 1 - \frac{0.0345}{(r_a + r_b)} \right)$$

where  $z_a$  and  $z_b$  are the moduli of the charges on the  $\nu$  ions in the lattice and  $r_a$  and  $r_b$  (in nm) are the thermochemical radii given in Table 2. The  $r_a$  for metal ions is taken to be the Goldschmidt<sup>6</sup> radius.

To cite an example, if we wish to estimate the lattice energy of the salt  $[\text{NH}_4^+][\text{HF}_2^-]$  using the above procedure, we see that Table 2 gives the thermochemical radius ( $r_a$ ) for  $\text{NH}_4^+$  to be 0.136 nm and that for  $\text{HF}_2^-$  ( $r_b$ ) to be 0.172 nm. The lattice potential energy is then estimated to be  $700 \text{ kJ mol}^{-1}$  compared with the calculated value of  $705 \text{ kJ mol}^{-1}$  and the Born - Fajans - Haber cycle value of  $658 \text{ kJ mol}^{-1}$ .

## THE MADELUNG CONSTANT AND CRYSTAL LATTICE ENERGY

If  $U$  is the crystal lattice energy and  $M$  is the Madelung constant, then<sup>a</sup>

$$U = \frac{NMz_iz_j e^2}{r} (1 - 1/n)$$

| Substance                                     | Ion type                             | Crystal form <sup>b</sup> | $M$                  |
|-----------------------------------------------|--------------------------------------|---------------------------|----------------------|
| Sodium chloride, NaCl                         | M <sup>+</sup> , X <sup>-</sup>      | FCC                       | 1.74756              |
| Cesium chloride, CsCl                         | M <sup>+</sup> , X <sup>-</sup>      | BCC                       | 1.76267              |
| Calcium chloride, CaCl <sub>2</sub>           | M <sup>++</sup> , 2X <sup>-</sup>    | Cubic                     | 2.365                |
| Calcium fluoride (fluorite), CaF <sub>2</sub> | M <sup>++</sup> , 2X <sup>-</sup>    | Cubic                     | 2.51939              |
| Cadmium chloride, CdCl <sub>2</sub>           | M <sup>++</sup> , 2X <sup>-</sup>    | Hexagonal                 | 2.244 <sup>c</sup>   |
| Cadmium iodide (α), CdI <sub>2</sub>          | M <sup>++</sup> , 2X <sup>-</sup>    | Hexagonal                 | 2.355 <sup>c</sup>   |
| Magnesium fluoride, MgF <sub>2</sub>          | M <sup>++</sup> , 2X <sup>-</sup>    | Tetragonal                | 2.381 <sup>c</sup>   |
| Cuprous oxide (cuprite), Cu <sub>2</sub> O    | 2M <sup>+</sup> , X <sup>- -</sup>   | Cubic                     | 2.22124              |
| Zinc oxide, ZnO                               | M <sup>++</sup> , X <sup>- -</sup>   | Hexagonal                 | 1.4985 <sup>c</sup>  |
| Sphalerite (zinc blende), ZnS                 | M <sup>++</sup> , X <sup>- -</sup>   | FCC                       | 1.63806              |
| Wurtzite, ZnS                                 | M <sup>++</sup> , X <sup>- -</sup>   | Hexagonal                 | 1.64132 <sup>c</sup> |
| Titanium dioxide (anatase), TiO <sub>2</sub>  | M <sup>4+</sup> , 2X <sup>- -</sup>  | Tetragonal                | 2.400 <sup>c</sup>   |
| Titanium dioxide (rutile), TiO <sub>2</sub>   | M <sup>4+</sup> , 2X <sup>- -</sup>  | Tetragonal                | 2.408 <sup>c</sup>   |
| β-Quartz, SiO <sub>2</sub>                    | M <sup>4+</sup> , 2X <sup>- -</sup>  | Hexagonal                 | 2.2197 <sup>c</sup>  |
| Corundum, Al <sub>2</sub> O <sub>3</sub>      | 2M <sup>3+</sup> , 3X <sup>- -</sup> | Rhombohedral              | 4.1719               |

<sup>a</sup>  $N$  is Avogadro's number,  $z_i$  and  $z_j$  are the integral charges on the ions (in units of  $e$ ), and  $e$  is the charge on the electron in electrostatic units ( $e = 4.803 \times 10^{-10}$  esu).  $r$  is the shortest distance between cation-anion pairs in centimeters. Then  $U$  is in ergs ( $1 \text{ erg} = 10^{-7} \text{ J}$ ).

<sup>b</sup> FCC = face centered cubic; BCC = body centered cubic.

<sup>c</sup> For tetragonal and hexagonal crystals the value of  $M$  depends on the details of the lattice parameters.

The Born Exponent,  $n$  is:

| Ion type                                                | $n$ |
|---------------------------------------------------------|-----|
| He, Li <sup>+</sup>                                     | 5   |
| Ne, Na <sup>+</sup> , F <sup>-</sup>                    | 7   |
| Ar, K <sup>+</sup> , Cu <sup>+</sup> , Cl <sup>-</sup>  | 9   |
| Kr, Rb <sup>+</sup> , Ag <sup>+</sup> , Br <sup>-</sup> | 10  |
| Xe, Cs <sup>+</sup> , Au <sup>+</sup> , I <sup>-</sup>  | 12  |

For a crystal with a mixed-ion type, an average of the values of  $n$  in this table is to be used (6 for LiF, for example).

# ELASTIC CONSTANTS OF SINGLE CRYSTALS

H. P. R. Frederikse

This table gives selected values of elastic constants for single crystals. The values believed most reliable were selected from the original literature. The substances are arranged by crystal system and, within each system, alphabetically by name. A reference to the original literature is given for each value; a useful compilation of published values from many sources may be found in Reference 1 below.

Data are given for the single-crystal density and for the elastic constants  $c_{ij}$ , in units of  $10^{11}$  N/m<sup>2</sup>, which is equivalent to  $10^{12}$  dyn/cm<sup>2</sup>.

## ELECTRICAL RESISTIVITY OF PURE METALS

The first part of this table gives the electrical resistivity, in units of  $10^{-8} \Omega \text{ m}$ , for 28 common metallic elements as a function of temperature. The data refer to polycrystalline samples. The number of significant figures indicates the accuracy of the values. However, at low temperatures (especially below 50 K) the electrical resistivity is extremely sensitive to sample purity. Thus the low-temperature values refer to samples of specified purity and treatment. The references should be consulted for further information on this point, as well as for values at additional temperatures.

The second part of the table gives resistivity values in the neighborhood of room temperature for other metallic elements that have not been studied over an extended temperature range.

## ELECTRICAL RESISTIVITY OF SELECTED ALLOYS

These values were obtained by fitting all available measurements to a theoretical formulation describing the temperature and composition dependence of the electrical resistivity of metals. Some of the values listed here fall in regions of temperature and composition where no actual measurements exist. Details of the procedure may be found in the reference.

Values of the resistivity are given in units of  $10^{-8} \Omega \text{ m}$ . General comments in the preceding table for pure metals also apply here

<sup>a</sup> Uncertainty in resistivity is  $\pm 2\%$ .

<sup>b</sup> Uncertainty in resistivity is  $\pm 3\%$ .

<sup>c</sup> Uncertainty in resistivity is  $\pm 5\%$ .

<sup>d</sup> Uncertainty in resistivity is  $\pm 7\%$  below 300 K and  $\pm 5\%$  at 300 and 400 K.

<sup>e</sup> Uncertainty in resistivity is  $\pm 7\%$ .

<sup>f</sup> Uncertainty in resistivity is  $\pm 8\%$ .

<sup>g</sup> Uncertainty in resistivity is  $\pm 10\%$ .

<sup>h</sup> Uncertainty in resistivity is  $\pm 12\%$ .

<sup>i</sup> Uncertainty in resistivity is  $\pm 4\%$ .

<sup>j</sup> Uncertainty in resistivity is  $\pm 1\%$ .

<sup>k</sup> Uncertainty in resistivity is  $\pm 3\%$  up to 300 K and  $\pm 4\%$  above 300 K.

<sup>m</sup> Uncertainty in resistivity is  $\pm 2\%$  up to 300 K and  $\pm 4\%$  above 300 K.

# PERMITTIVITY (DIELECTRIC CONSTANT) OF INORGANIC SOLIDS

H. P. R. Frederikse

This table lists the permittivity  $\epsilon$ , frequently called the dielectric constant, of a number of inorganic solids. When the material is not isotropic, the individual components of the permittivity are given. A superscript S indicates a measurement made under constant strain ("clamped" dielectric constant). If the constraint is removed, the measurement yields  $\epsilon^T$ , the "unclamped" or free dielectric constant.

The temperature of the measurement is given when available; the symbol r.t. indicates a value at nominal room temperature. The

frequency of the measurement is given in the last column (i.r. indicates a measurement in the infrared).

Substances are listed in alphabetical order by chemical formula.

# CURIE TEMPERATURE OF SELECTED FERROELECTRIC CRYSTALS

H. P. R. Frederikse

The following table lists the major ferroelectric crystals and their Curie temperatures,  $T_C$ .

# PROPERTIES OF ANTIFERROELECTRIC CRYSTALS

**H. P. R. Frederikse**

Some important antiferroelectric crystals are listed here with their Curie Temperatures  $T_C$ . The last column gives the constant  $T_0$  which appears in the Curie-Weiss law describing the dielectric constant of these materials above the Curie Temperature:

$$\epsilon = \text{const.}/(T - T_0)$$

| Name or acronym                | Formula                                | $T_C/\text{K}$ | $T_0/\text{K}$ |

# PROPERTIES OF SUPERCONDUCTORS

L. I. Berger and B. W. Roberts

The following tables include superconductive properties of selected elements, compounds, and alloys. Individual tables are given for thin films, elements at high pressures, superconductors with high critical magnetic fields, and high critical temperature superconductors.

The historically first observed and most distinctive property of a superconductive body is the near total loss of resistance at a critical temperature ( $T_c$ ) that is characteristic of each material. Figure 1(a) below illustrates schematically two types of possible transitions. The sharp vertical discontinuity in resistance is indica-

tive of that found for a single crystal of a very pure element or one of a few well annealed alloy compositions. The broad transition, illustrated by broken lines, suggests the transition shape seen for materials that are not homogeneous and contain unusual strain distributions. Careful testing of the resistivity limit for superconductors shows that it is less than  $4 \times 10^{-23}$  ohm cm, while the lowest resistivity observed in metals is of the order of  $10^{-13}$  ohm cm. If one compares the resistivity of a superconductive body to that of copper at room temperature, the superconductive body is at least  $10^{17}$  times less resistive.

**FIGURE 1.** Physical properties of superconductors. (a) Resistivity vs. temperature for a pure and perfect lattice (solid line); impure and/or imperfect lattice (broken line). (b) Magnetic-field temperature dependence for Type-I or "soft" superconductors. (c) Schematic magnetization curve for "hard" or Type-II superconductors.

The temperature interval  $\Delta T_c$ , over which the transition between the normal and superconductive states takes place, may be of the order of as little as  $2 \times 10^{-5}$  K or several K in width, depending on the material state. The narrow transition width was attained in 99.9999% pure gallium single crystals.

A Type-I superconductor below  $T_c$ , as exemplified by a pure metal, exhibits perfect diamagnetism and excludes a magnetic field up to some critical field  $H_c$ , whereupon it reverts to the normal state as shown in the  $H$ - $T$  diagram of Figure 1(b).

The magnetization of a typical high-field superconductor is shown in Figure 1(c). The discovery of the large current-carrying capability of  $Nb_3Sn$  and other similar alloys has led to an extensive study of the physical properties of these alloys. In brief, a high-field superconductor, or Type-II superconductor, passes from the perfect diamagnetic state at low magnetic fields to a mixed state and finally to a sheathed state before attaining the normal resistive state of the metal. The magnetic field values separating the four stages are given as  $H_{c1}$ ,  $H_{c2}$ , and  $H_{c3}$ . The superconductive state below  $H_{c1}$  is perfectly diamagnetic, identical to the state of most pure metals of the "soft" or Type-I superconductor. Between  $H_{c1}$  and  $H_{c2}$  a "mixed superconductive state" is found in which fluxons (a minimal unit of magnetic flux) create lines of normal flux in a superconductive matrix. The volume of the normal state is proportional to  $-4\pi M$  in the "mixed state" region. Thus at  $H_{c2}$  the fluxon density has become so great as to drive the interior volume of the superconductive body completely normal. Between  $H_{c2}$  and  $H_{c3}$  the superconductor has a sheath of current-carrying superconductive material at the body surface, and above  $H_{c3}$  the normal state exists. With several types of careful measurement, it is possible to determine  $H_{c1}$ ,  $H_{c2}$ , and  $H_{c3}$ . Table 6 contains some of the available data on high-field superconductive materials.

High-field superconductive phenomena are also related to specimen dimension and configuration. For example, the Type-I superconductor, Hg, has entirely different magnetization behavior in high magnetic fields when contained in the very fine sets of filamentary tunnels found in an unprocessed Vycor glass. The great majority of superconductive materials are Type-II. The elements in very pure form and a very few precisely stoichiometric and well annealed compounds are Type I with the possible exceptions of vanadium and niobium.

**Metallurgical Aspects.** The sensitivity of superconductive properties to the material state is most pronounced and has been used in a reverse sense to study and specify the detailed state of alloys. The mechanical state, the homogeneity, and the presence of impurity atoms and other electron-scattering centers are all capable of controlling the critical temperature and the current-carrying capabilities in high-magnetic fields. Well annealed specimens tend to show sharper transitions than those that are strained or inhomogeneous. This sensitivity to mechanical state underlines a general problem in the tabulation of properties for superconductive materials. The occasional divergent values of the critical temperature and of the critical fields quoted for a Type-II superconductor may lie in the variation in sample preparation. Critical temperatures of materials studied early in the history of superconductivity must be evaluated in light of the probable metallurgical state of the material, as well as the availability of less pure starting elements. It has been noted that recent work has given extended consideration to the metallurgical aspects of sample preparation.

Symbols in tables:  $T_c$ : Critical temperature;  $H_0$ : Critical magnetic field in the  $T = 0$  limit;  $\theta_D$ : Debye temperature; and  $\gamma$ : Electronic specific heat.

TABLE 1. Selective Properties of Superconductive Elements

| Element   | $T_c$ (K)       | $H_0$ (oersted)      | $\theta_D$ (K) | $\gamma$ (mJ mol <sup>-1</sup> K <sup>-1</sup> ) |

TABLE 4. Superconductive Compounds and Alloys

All compositions are denoted on an atomic basis, i.e., AB, AB<sub>2</sub>, or AB<sub>3</sub> for compounds, unless noted. Solid solutions or odd compositions may be denoted as A<sub>x</sub>B<sub>1-x</sub> or A<sub>z</sub>B. A series of three or more alloys is indicated as A<sub>x</sub>B<sub>1-x</sub> or by actual indication of the atomic fraction range, such as A<sub>0-0.6</sub>B<sub>1-0.4</sub>. The critical temperature of such a series of alloys is denoted by a range of values or possibly the maximum value.

The selection of the critical temperature from a transition in the effective permeability, or the change in resistance, or possibly the incremental changes in frequency observed by certain techniques is not often obvious from the literature. Most authors choose the

mid-point of such curves as the probable critical temperature of the idealized material, while others will choose the highest temperature at which a deviation from the normal state property is observed. In view of the previous discussion concerning the variability of the superconductive properties as a function of purity and other metallurgical aspects, it is recommended that appropriate literature be checked to determine the most probable critical temperature or critical field of a given alloy.

A very limited amount of data on critical fields,  $H_c$ , is available for these compounds and alloys; these values are given at the end of the table.

A. Superconductors with  $T_c < 10$  K

# HIGH TEMPERATURE SUPERCONDUCTORS

C. N. R. Rao and A. K. Raychaudhuri

The following tables give properties of a number of high temperature superconductors. Table 1 lists the crystal structure (space group and lattice constants) and the critical transition temperature  $T_c$  for the more important high temperature superconductors so far studied. Table 2 gives energy gap, critical current density, and penetration depth in the superconducting state. Table 3 gives electrical and thermal properties of some of these materials in the normal state. The tables were prepared in November 1992 and updated in November 1994.

# ORGANIC SUPERCONDUCTORS

H.P.R. Frederikse

Although the vast majority of organic compounds are insulators, a small number of organic solids show considerable electrical conductivity. Some of these materials appear to be superconductors. The superconducting organics fall primarily into two groups: those containing fulvalenes (pentagonal rings containing sulfur or selenium) and those based on fullerenes, involving the nearly spherical cluster  $C_{60}$ .

The transition temperatures  $T_c$  of the fulvalene derivatives are shown in Table 1. The abbreviations of the various molecular groups are listed in Table 2 and their chemical structures are depicted in Figure 1. Most of the  $T_c$ 's are between 1 and 12 K. Several of the compounds only show superconductivity under pressure.

The fullerenes are  $A_3C_{60}$  compounds, where A represents a single or a combination of alkali atoms. The  $C_{60}$  cluster is shown in

Figure 2a, while Figure 2b illustrates how the alkali atoms fit into the  $A_3C_{60}$  molecule to form the A15 crystallographic structure. Their superconducting transition temperatures range from 8 to 31.3 K (see Table 3).

# PROPERTIES OF SEMICONDUCTORS

L. I. Berger

The term *semiconductor* is applied to a material in which electric current is carried by electrons or holes and whose electrical conductivity, when extremely pure, rises exponentially with temperature and may be increased from its low “intrinsic” value by many orders of magnitude by “doping” with electrically active impurities.

Semiconductors are characterized by an energy gap in the allowed energies of electrons in the material that separates the normally filled energy levels of the *valence band* (where “missing” electrons behave like positively charged current carriers “holes”) and the *conduction band* (where electrons behave rather like a gas of free negatively charged carriers with an effective mass dependent on the material and the direction of the electrons’ motion). This energy gap depends on the nature of the material and varies with direction in anisotropic crystals. It is slightly dependent on

temperature and pressure, and this dependence is usually almost linear at normal temperatures and pressures.

Data are presented in five tables. Table 1 lists the main crystallographic and semiconducting properties of a large number of semiconducting materials in three main categories: “Tetrahedral Semiconductors” in which every atom is tetrahedrally coordinated to four nearest neighbor atoms (or atomic sites) as for example in the diamond structure; “Octahedral Semiconductors” in which every atom is octahedrally coordinated to six nearest neighbor atoms—as for example the halite structure; and “Other Semiconductors.”

Table 2 gives electrical, magnetic, and optical properties, while Tables 3 and 4 give more details on the semiconducting properties and band structures of the most common semiconductors. Table 5 lists semiconducting minerals with typical resistivity ranges.

TABLE 1. Physico-Chemical Properties of Semiconductors (Listed by Crystal Structure)

| Substance                                                                                                                           | Molecular weight | Average atomic weight | Lattice parameters (Å, room temp.) | Density (g/cm <sup>3</sup> ) | Melting point (K)                                   | Microhardness, N/mm <sup>2</sup> (M-Mohs Scale) | Specific heat, J/kg-K (300 K) | Debye temp. (K) | Coefficient of thermal linear expansion [10 <sup>-6</sup> K <sup>-1</sup> (300K)] | Thermal conductivity [mW/cm-K (300K)] |

TABLE 5. Resistivity of Semiconducting Minerals

| Mineral                                                          | $\rho$ (ohm · m)                                 | Mineral                                                                     | $\rho$ (ohm · m)                                |
|------------------------------------------------------------------|--------------------------------------------------|-----------------------------------------------------------------------------|-------------------------------------------------|
| Diamond (C)                                                      | 2.7                                              | Pentlandite, (Fe, Ni) <sub>4</sub> S <sub>4</sub>                           | 1 to 11 × 10 <sup>-6</sup>                      |
| Sulfides                                                         |                                                  | Pyrrhotite, Fe <sub>7</sub> S <sub>4</sub>                                  | 2 to 160 × 10 <sup>-6</sup>                     |
| Argentite, Ag <sub>2</sub> S                                     | 1.5 to 2.0 × 10 <sup>-3</sup>                    | Pyrite, FeS <sub>2</sub>                                                    | 1.2 to 600 × 10 <sup>-3</sup>                   |
| Bismuthinite, Bi <sub>2</sub> S <sub>3</sub>                     | 3 to 570                                         | Sphalerite, ZnS                                                             | 2.7 × 10 <sup>-3</sup> to 1.2 × 10 <sup>4</sup> |
| Bornite, Fe <sub>2</sub> S <sub>3</sub> · $n$ Cu <sub>2</sub> S  | 1.6 to 6000 × 10 <sup>-6</sup>                   | Antimony-sulfur compounds                                                   |                                                 |
| Chalcocite, Cu <sub>2</sub> S                                    | 80 to 100 × 10 <sup>-6</sup>                     | Berthierite, FeSb <sub>2</sub> S <sub>4</sub>                               | 0.0083 to 2.0                                   |
| Chalcopyrite, Fe <sub>2</sub> S <sub>3</sub> · Cu <sub>2</sub> S | 150 to 9000 × 10 <sup>-6</sup>                   | Boulangerite, Pb <sub>5</sub> Sb <sub>3</sub> S <sub>11</sub>               | 2 × 10 <sup>3</sup> to 4 × 10 <sup>4</sup>      |
| Covellite, CuS                                                   | 0.30 to 83 × 10 <sup>-6</sup>                    | Cylindrite, Pb <sub>3</sub> Sn <sub>4</sub> Sb <sub>2</sub> S <sub>14</sub> | 2.5 to 60                                       |
| Galena, PbS                                                      | 6.8 × 10 <sup>-6</sup> to 9.0 × 10 <sup>-2</sup> | Franckeite, Pb <sub>5</sub> Sn <sub>3</sub> Sb <sub>2</sub> S <sub>14</sub> | 1.2 to 4                                        |
| Haverite, MnS <sub>2</sub>                                       | 10 to 20                                         | Hauchecornite, Ni <sub>4</sub> (Bi, Sb) <sub>2</sub> S <sub>14</sub>        | 1 to 83 × 10 <sup>-6</sup>                      |
| Marcasite, FeS <sub>2</sub>                                      | 1 to 150 × 10 <sup>-3</sup>                      | Jamesonite, Pb <sub>4</sub> FeSb <sub>6</sub> S <sub>14</sub>               | 0.020 to 0.15                                   |
| Metacinnabarite, HgS                                             | 2 × 10 <sup>-6</sup> to 1 × 10 <sup>-3</sup>     | Tetrahedrite, Cu <sub>3</sub> SbS <sub>3</sub>                              | 0.30 to 30,000                                  |
| Millerite, NiS                                                   | 2 to 4 × 10 <sup>-7</sup>                        | Arsenic-sulfur compounds                                                    |                                                 |

| Mineral                                    | $\rho$ (ohm · m)             |
|--------------------------------------------|------------------------------|
| Molybdenite, MoS <sub>2</sub>              | 0.12 to 7.5                  |
| Cobaltite, CoAsS                           | 6.5 to $130 \times 10^{-3}$  |
| Enargite, Cu <sub>3</sub> AsS <sub>4</sub> | 0.2 to $40 \times 10^{-3}$   |
| Gersdorffite, NiAsS                        | 1 to $160 \times 10^{-6}$    |
| Glaucoodote, (Co, Fe)AsS                   | 5 to $100 \times 10^{-6}$    |
| Antimonide                                 |                              |
| Dyscrasite, Ag <sub>3</sub> Sb             | 0.12 to $1.2 \times 10^{-6}$ |
| Arsenides                                  |                              |
| Allemontite, SbAs <sub>3</sub>             | 70 to 60,000                 |
| Lollingite, FeAs <sub>2</sub>              | 2 to $270 \times 10^{-6}$    |
| Nicollite, NiAs                            | 0.1 to $2 \times 10^{-6}$    |
| Skutterudite, CoAs <sub>3</sub>            | 1 to $400 \times 10^{-6}$    |
| Smaltite, CoAs <sub>2</sub>                | 1 to $12 \times 10^{-6}$     |
| Tellurides                                 |                              |
| Altaite, PbTe                              | 20 to $200 \times 10^{-6}$   |
| Calavarite, AuTe <sub>2</sub>              | 6 to $12 \times 10^{-6}$     |
| Coloradoite, HgTe                          | 4 to $100 \times 10^{-6}$    |

| Mineral                                                            | $\rho$ (ohm · m)               |
|--------------------------------------------------------------------|--------------------------------|
| Arsenopyrite, FeAsS                                                | 20 to $300 \times 10^{-6}$     |
| Hessite, Ag <sub>2</sub> Te                                        | 4 to $100 \times 10^{-6}$      |
| Nagyagite, Pb <sub>6</sub> Au(S,Te) <sub>14</sub>                  | 20 to $80 \times 10^{-6}$      |
| Sylvanite, AgAuTe <sub>4</sub>                                     | 4 to $20 \times 10^{-6}$       |
| Oxides                                                             |                                |
| Braunite, Mn <sub>2</sub> O <sub>3</sub>                           | 0.16 to 1.0                    |
| Cassiterite, SnO <sub>2</sub>                                      | $4.5 \times 10^{-4}$ to 10,000 |
| Cuprite, Cu <sub>2</sub> O                                         | 10 to 50                       |
| Hollandite, (Ba, Na, K) Mn <sub>8</sub> O <sub>16</sub>            | 2 to $100 \times 10^{-3}$      |
| Ilmenite, FeTiO <sub>3</sub>                                       | 0.001 to 4                     |
| Magnetite, Fe <sub>3</sub> O <sub>4</sub>                          | $52 \times 10^{-6}$            |
| Manganite, MnO · OH                                                | 0.018 to 0.5                   |
| Melaconite, CuO                                                    | 6000                           |
| Psilomelane, BaMn <sub>9</sub> O <sub>18</sub> · 2H <sub>2</sub> O | 0.04 to 6000                   |
| Pyrolusite, MnO <sub>2</sub>                                       | 0.007 to 30                    |
| Rutile, TiO <sub>2</sub>                                           | 29 to 910                      |
| Uraninite, UO <sub>2</sub>                                         | 1.5 to 200                     |

# DIFFUSION DATA FOR SEMICONDUCTORS

B. L. Sharma

The diffusion coefficient  $D$  in many semiconductors may be expressed by an Arrhenius-type relation

$$D = D_0 \exp(-Q/kT)$$

where  $D_0$  is a frequency factor,  $Q$  is the activation energy for diffusion,  $k$  is the Boltzmann constant, and  $T$  is the absolute temperature. This table lists  $D_0$  and  $Q$  for various diffusants in common semiconductors.

Abbreviations used in the table are

- AES – Auger Electron Spectroscopy
- DLTS – Deep Level Transient Spectroscopy
- SEM – Scanning Electron Microscopy
- SIMS – Secondary Ion Mass Spectrometry
- $D(c)$  – Concentration Dependent Diffusion Coefficient
- $D_{\max}$  – Maximum Diffusion Coefficient
- (f) – Fast Diffusion Component
- (i) – Interstitial Diffusion Component
- (s) – Slow Diffusion Component
- (||) – Parallel to  $c$  Direction
- ( $\perp$ ) – Perpendicular to  $c$  Direction

| Semiconductor | Diffusant | Frequency factor,<br>$D_0$ (cm <sup>2</sup> /s) | Activation energy,<br>$Q$ (eV) | Temperature range (°C) | Method of measurement           | Ref. |
|---------------|-----------|-------------------------------------------------|--------------------------------|------------------------|---------------------------------|------|
| Si            | H         | $6 \times 10^{-1}$                              | 1.03                           | 120–1207               | Electrical and SIMS             | 1    |
|               | Li        | $2.5 \times 10^{-3}$                            | 0.65                           | 25–1350                | Electrical                      | 2    |
|               | Na        | $1.65 \times 10^{-3}$                           | 0.72                           | 530–800                | Electrical and flame photometry | 3    |
|               | K         | $1.1 \times 10^{-3}$                            | 0.76                           | 740–800                | Electrical and flame photometry | 3    |
|               | Cu        | $4 \times 10^{-2}$                              | 1.0                            | 800–1100               | Radioactive                     | 4    |

# PROPERTIES OF MAGNETIC MATERIALS

H. P. R. Frederikse

## Glossary of Symbols

| Quantity                            | Symbol                 | Units                           |                      |
|-------------------------------------|------------------------|---------------------------------|----------------------|
|                                     |                        | SI                              | emu                  |
| Magnetic field                      | $H$                    | $\text{A m}^{-1}$               | Oe (oersted)         |
| Magnetic induction                  | $B$                    | T (tesla)                       | G (gauss)            |
| Magnetization                       | $M$                    | $\text{A m}^{-1}$               | $\text{emu cm}^{-3}$ |
| Spontaneous magnetization           | $M_s$                  | $\text{A m}^{-1}$               | $\text{emu cm}^{-3}$ |
| Saturation magnetization            | $M_0$                  | $\text{A m}^{-1}$               | $\text{emu cm}^{-3}$ |
| Magnetic flux                       | $\Phi$                 | Wb (weber)                      | maxwell              |
| Magnetic moment                     | $m, \mu$               | $\text{A m}^2$                  | erg/G                |
| Coercive field                      | $H_c$                  | $\text{A m}^{-1}$               | Oe                   |
| Remanence                           | $B_r$                  | T                               | G                    |
| Saturation magnetic polarization    | $J_s$                  | T                               | G                    |
| Magnetic susceptibility             | $\chi$                 |                                 |                      |
| Magnetic permeability               | $\mu$                  | $\text{H m}^{-1}$ (henry/meter) |                      |
| Magnetic permeability of free space | $\mu_0$                | $\text{H m}^{-1}$               |                      |
| Saturation magnetostriction         | $\lambda (\Delta l/l)$ |                                 |                      |
| Curie temperature                   | $T_C$                  | K                               | K                    |
| Néel temperature                    | $T_N$                  | K                               | K                    |

Magnetic moment  $\mu = \gamma \hbar J = g \mu_B J$

where

$\gamma$  = gyromagnetic ratio;  $J$  = angular momentum;  $g$  = spectroscopic splitting factor ( $\sim 2$ )

$\mu_B$  = bohr magneton =  $9.2741 \cdot 10^{-24} \text{ J/T} = 9.2741 \cdot 10^{-21} \text{ erg/G}$

Earth's magnetic field  $H = 56 \text{ A m}^{-1} = 0.7 \text{ Oe}$

For iron:  $M_0 = 1.7 \cdot 10^6 \text{ A m}^{-1}$ ;  $B_r = 0.8 \cdot 10^6 \text{ A m}^{-1}$

$1 \text{ Oe} = (1000/4\pi) \text{ A m}^{-1}$ ;  $1 \text{ G} = 10^{-4} \text{ T}$ ;  $1 \text{ emu cm}^{-3} = 10^3 \text{ A m}^{-1}$

$1 \text{ maxwell} = 10^{-8} \text{ Wb}$

$\mu_0 = 4\pi \cdot 10^{-7} \text{ H m}^{-1}$

## Relation Between Magnetic Induction and Magnetic Field

**FIGURE 1.** Typical curve representing the dependence of magnetic induction  $B$  on magnetic field  $H$  for a ferromagnetic material. When  $H$  is first applied,  $B$  follows curve **a** as the favorably oriented magnetic domains grow. This curve flattens as saturation is approached. When  $H$  is then reduced,  $B$  follows curve **b**, but retains a finite value (the remanence  $B_r$ ) at  $H = 0$ . In order to demagnetize the material, a negative field  $-H_c$  (where  $H_c$  is called the coercive field or coercivity) must be applied. As  $H$  is further decreased and then increased to complete the cycle (curve **c**), a hysteresis loop is obtained. The area within this loop is a measure of the energy loss per cycle for a unit volume of the material.

**FIGURE 2.** Schematic curve illustrating the  $B$  vs.  $H$  dependence for hard and soft magnetic materials. Hard materials have a larger remanence and coercive field, and a correspondingly large hysteresis loss.

## Magnetic Susceptibility of the Elements

**FIGURE 3.** Molar susceptibility of the elements at room temperature (cgs units of  $10^{-6} \text{ cm}^3/\text{mol}$ ). Values are not available for  $Z = 9, 61$ , and  $84-89$ ; Fe, Co, and Ni ( $Z = 26-28$ ) are ferromagnetic. Data taken from the table "Magnetic Susceptibility of the Elements and Inorganic Compounds" in Section 4.

### Applications of High-Permeability Materials

#### Applications

#### Requirements

##### Power applications

Distribution and power transformers

Low core losses, high permeability, high saturation magnetic polarization

High-quality motors and generators, stators and armatures, switched-mode power supplies

##### Instrument transformers

Audiofrequency transformers

Low core losses, high permeability, high magnetic polarization

Pulse transformers

High permeability

##### Cores for inductor coils

Audiofrequency

Low hysteresis, high permeability

Carrier frequency

Very low hysteresis and eddy current loss

Radiofrequency

High permeability at low fields

##### Miscellaneous

Relays, switches  
Earth leakage circuit }

High permeability, low remanence, low coercivity

Magnetic shielding

Low core loss for AC applications

## Saturation Magnetostriction of Selected Materials

The tabulated parameter  $\lambda_s$  is related to the fractional change in length  $\Delta l/l$  by  $\Delta l/l = (3/2)\lambda_s(\cos^2\theta - 1/3)$ , where  $\theta$  is the angle of rotation.

| Material                                                         | $\lambda_s \times 10^6$ |

# ELECTRON WORK FUNCTION OF THE ELEMENTS

The electron work function  $\Phi$  is a measure of the minimum energy required to extract an electron from the surface of a solid. It is defined more precisely as the energy difference between the state in which an electron has been removed to a distance from the surface of a single crystal face that is large enough that the image force is negligible but small compared to the distance to any other face (typically about  $10^{-4}$  cm) and the state in which the electron is in the bulk solid. In general,  $\Phi$  differs for each face of a mono-crystalline sample.

Since  $\Phi$  is dependent on the cleanliness of the surface, measurements reported in the literature often cover a considerable range. This table contains selected values for the electron work function of the elements which may be regarded as typical values for a reasonably clean surface. The method of measurement is indicated for each value. The following abbreviations appear:

TE – Thermionic emission  
PE – Photoelectric effect  
FE – Field emission  
CPD – Contact potential difference  
polycr – Polycrystalline sample  
amorp – Amorphous sample

Values in parentheses are only approximate.

## SECONDARY ELECTRON EMISSION

The secondary emission yield, or secondary emission ratio,  $\delta$ , is the average number of secondary electrons emitted from a bombarded material for every incident primary electron. It is a function of the primary electron energy  $E_p$ . The maximum yield  $\delta_{\max}$  corresponds to a primary electron energy  $E_{p\max}$  (see figure). The two primary electron energies corresponding to a yield of unity are denoted the first and second crossovers ( $E_I$  and  $E_{II}$ ). An insulat-

ing target, or a conducting target that is electrically floating, will charge positively or negatively depending on the primary electron energy. For  $E_I < E_p < E_{II}$ ,  $\delta > 1$  and the surface charges positively provided there is a collector present that is positive with respect to the target. For  $E_p < E_I$  or  $E_p > E_{II}$ ,  $\delta < 1$ , and the surface charges negatively with respect to the potential of the source of primary electrons.

| Element      | $\delta_{\max}$ | $E_{p\max}$ (eV) | $E_I$ (eV) | $E_{II}$ (eV) | Element | $\delta_{\max}$ | $E_{p\max}$ (eV) | $E_I$ (eV) | $E_{II}$ (eV) |

# OPTICAL PROPERTIES OF SELECTED ELEMENTS

J. H. Weaver and H. P. R. Frederikse

These tables list the index of refraction  $n$ , the extinction coefficient  $k$ , and the normal incidence reflection  $R$  ( $\phi = 0$ ) as a function of photon energy  $E$ , which is expressed in electron volts (eV). To convert the energy in eV to the wavelength in  $\mu\text{m}$ , use  $\lambda = 1.2398/E$ . To compute the dielectric function  $\tilde{\epsilon} = \epsilon_1 + i\epsilon_2$  from the complex index of refraction  $\tilde{N} = n + ik$ , use  $\epsilon_1 = n^2 - k^2$  and  $\epsilon_2 = 2nk$ .

The optical constants in these tables are abridged from three more extensive tabulations:

- *Optical Properties of Metals* (OPM), Volumes I and II, *Physics Data*, Nr. 18-1 and 18-2, J. H. Weaver, C. Krafka, D. W. Lynch, and E. E. Koch, Fachinformationzentrum, Karlsruhe, Germany.
- *Handbook of Optical Constants* (HOC), Vol. I, 1985, and Vol. II, 1991. E. D. Palik, Ed., Academic Press, Inc., London.
- *American Institute of Physics Handbook* (AIPH), 3rd Edition, D. E. Gray, Ed., McGraw-Hill, New York, 1972.

The first two of these major sources provide detailed comparisons of all optical data available in the literature at the time of the compilation. For critical applications the reader should refer to the original work. References for individual metals and semiconduc-

tors are listed at the end of the tables. Generally, tabulated values for the optical properties are accurate to better than 10%. Data in parentheses are extrapolated or interpolated values. For most elements the spectral range covered is from the far infrared (0.010 or 0.10 eV) to the far ultraviolet (10, 30 or 300 eV). The intervals between successive energies in the tables are chosen in such a way that the major spectral features are preserved.

Very small values of  $k$  are expressed in exponential notation, e.g., 1.23E-5 means  $1.23 \times 10^{-5}$ .

The following table is convenient for associating the energy entries in these tables with the corresponding wavelengths:

| $\lambda$         | E/eV    | $\lambda$ | E/eV   |
|-------------------|---------|-----------|--------|
| 1 mm              | 0.00124 | 6000 Å    | 2.066  |
| 500 $\mu\text{m}$ | 0.00248 | 5000 Å    | 2.480  |
| 100 $\mu\text{m}$ | 0.01240 | 4000 Å    | 3.100  |
| 50 $\mu\text{m}$  | 0.02480 | 3000 Å    | 4.133  |
| 10 $\mu\text{m}$  | 0.12398 | 2000 Å    | 6.199  |
| 5 $\mu\text{m}$   | 0.24797 | 1000 Å    | 12.398 |
| 1 $\mu\text{m}$   | 1.240   | 400 Å     | 30.996 |

| Energy<br>(eV)   | $n$    | $k$     | $R(\phi = 0)$ | Energy<br>(eV) | $n$   | $k$   | $R(\phi = 0)$ | Energy<br>(eV) | $n$   | $k$   | $R(\phi = 0)$ |
|------------------|--------|---------|---------------|----------------|-------|-------|---------------|----------------|-------|-------|---------------|
