## ELASTO-OPTIC, ELECTRO-OPTIC, AND MAGNETO-OPTIC CONSTANTS

When a crystal is subjected to a stress field, an electric field, or a magnetic field, the resulting optical effects are in general dependent on the orientation of these fields with respect to the crystal axes. It is useful, therefore, to express the optical properties in terms of the refractive index ellipsoid (or indicatrix):

$$\frac{x^2}{n_x^2} + \frac{y^2}{n_y^2} + \frac{z^2}{n_z^2} = 1$$

or

$$\sum_{ij} B_{ij} x_i x_j = 1 \quad (i, j = 1, 2, 3)$$

where

$$B_{ij} = \left[ \frac{1}{\epsilon} \right]_{ij} = \left[ \frac{1}{n^2} \right]_{ij}$$

$\epsilon$  is the dielectric constant or permeability; the quantity  $B_{ij}$  is called impermeability.

A crystal exposed to a *stress*  $\mathbf{S}$  will show a change of its impermeability. The photo-elastic (or elasto-optic) constants,  $P_{ijkl}$ , are defined by

$$\Delta \left[ \frac{1}{\epsilon} \right]_{ij} = \Delta \left[ \frac{1}{n^2} \right]_{ij} = \sum_{kl} P_{ijkl} S_{kl}$$

where  $n$  is the refractive index and  $S_{kl}$  are the strain tensor elements; the  $P_{ijkl}$  are the elements of a 4th rank tensor.

When a crystal is subjected to an *electric field*  $\mathbf{E}$ , two possible changes of the refractive index may occur depending on the symmetry of the crystal.

1. All materials, including isotropic solids and polar liquids, show an electro-optic birefringence (Kerr effect) which is proportional to the square of the electric field,  $\mathbf{E}$ :

$$\Delta \left[ \frac{1}{n^2} \right]_{ij} = \sum_k K_{ijkl} E_k E_l = \sum_{k,l=1,2,3} g_{ijkl} P_k P_l$$

where  $E_k$  and  $E_l$  are the components of the electric field and  $P_k$  and  $P_l$  the electric polarizations. The coefficients,  $K_{ijkl}$ , are the quadratic electro-optic coefficients, while the constants  $g_{ijkl}$  are known as the Kerr constants.

2. The other electro-optic effect only occurs in the 20 piezoelectric crystal classes (no center of symmetry). This effect is known as the Pockels effect. The optical impermeability changes linearly with the static field

$$\Delta \left[ \frac{1}{n^2} \right]_{ij} = \sum_k r_{ij,k} E_k$$

The coefficients  $r_{ij,k}$  have the name (linear) electro-optic coefficients.

The values of the electro-optic coefficients depend on the boundary conditions. If the superscripts T and S denote, respectively, the conditions of zero stress (free) and zero strain (clamped) one finds:

$$r_{ij}^T = r_{ij}^S + q_{ik}^E e_{jk} = r_{ij}^S + P_{ik}^E d_{jk}$$

where  $e_{jk} = (\partial T_k / \partial E_j)_S$  and  $d_{jk} = (\partial S_k / \partial E_j)_T$  are the appropriate piezo-electric coefficients.

The interaction between a *magnetic field* and a light wave propagating in a solid or in a liquid gives rise to a rotation of the plane of polarization. This effect is known as *Faraday rotation*. It results from a difference in propagation velocity for left and right circular polarized light.

The Faraday rotation,  $\theta_F$ , is linearly proportional to the magnetic field  $H$ :

$$\theta_F = VH$$

where  $l$  is the light path length and  $V$  is the *Verdet* constant (minutes/oersted-cm).

For ferromagnetic, ferrimagnetic, and antiferromagnetic materials the magnetic field in the above expression is replaced by the magnetization  $M$  and the magneto-optic coefficient in this case is known as the Kund constant  $K$ :

$$\text{Specific Faraday rotation } F = KM$$

In the tables below the *Faraday rotation* is listed at the saturation magnetization per unit length, together with the absorption coefficient  $\alpha$ , the temperature  $T$ , the critical temperature  $T_c$  (or  $T_N$ ), and the wavelength of the measurement.

In the tables that follow, the properties are presented in groups:

- Elasto-optic coefficients (photoelastic constants)
- Linear electro-optic coefficients (Pockels constants)
- Quadratic electro-optic coefficients (Kerr constants)
- Magneto-optic coefficients:
  - Verdet constants
  - Faraday rotation parameters

Within each group, materials are classified by crystal system or physical state. References are given at the end of each group of tables.

## ELASTO-OPTIC COEFFICIENTS (PHOTOELASTIC CONSTANTS)

Kerr Constants of Selected Liquids<sup>2</sup>

$K$  is the Kerr constant at a wavelength of 589 nm and at room temperature;  $\epsilon$  is the static dielectric constant;  $t_m$  is the melting point; and  $t_b$  is the normal boiling point

## MAGNETO-OPTIC CONSTANTS

Verdet Constants of Non-Magnetic Crystals<sup>1</sup>

$V$  is the Verdet constant;  $n$  is the refractive index; and  $\lambda$  is the wavelength. "min" is minutes of angle.

Verdet Constants of Rare-Earth Paramagnetic Crystals<sup>1</sup>

$n$  is the refractive index, and  $V$  is the Verdet constant at the wavelength and temperature indicated.

| Rare Earth       | Host             | $T/K$ | $\lambda/nm$ | $n$   | $V$<br>min/Oe cm |

**Verdet Constants of Paramagnetic Glasses<sup>1</sup>**

The Verdet constant  $V$  is given at room temperature for the wavelengths indicated.

Rare-earth phosphate glasses of composition  $R_2O_3 \cdot xP_2O_5$ , where  $x$  is given in the second column

|    |      | Verdet constant $V$ in min/Oe cm |                       |                       |                       |                       |                       |                       |                       |                       |                       |

# NONLINEAR OPTICAL CONSTANTS

H. P. R. Frederikse

The relation between the polarization density  $P$  of a dielectric medium and the electric field  $E$  is linear when  $E$  is small, but becomes nonlinear as  $E$  acquires values comparable with interatomic electric fields ( $10^5$  to  $10^8$  V/cm). Under these conditions the relation between  $P$  and  $E$  can be expanded in a Taylor's series

$$P = \epsilon_0 \chi^{(1)} E + 2\chi^{(2)} E^2 + 4\chi^{(3)} E^3 + \dots \quad (1)$$

where  $\epsilon_0$  is the permittivity of free space, while  $\chi^{(1)}$  is the linear and  $\chi^{(2)}$ ,  $\chi^{(3)}$  etc. the nonlinear optical susceptibilities.

If we consider two optical fields, the first  $E_j^{\omega_1}$  (along the  $j$ -direction at frequency  $\omega_1$ ) and the second  $E_k^{\omega_2}$  (along the  $k$ -direction at frequency  $\omega_2$ ) one can write the second term of the Taylor's series as follows

$$P_i(\omega_1, \omega_2) = 2\chi_{ijk}^{\omega_3=\omega_1 \pm \omega_2} E_j^{\omega_1} E_k^{\omega_2}$$

When  $\omega_1 \neq \omega_2$  the (parametric) mixing of the two fields gives rise to two new polarizations at the frequencies  $\omega_3 = \omega_1 + \omega_2$  and  $\omega_3' = \omega_1 - \omega_2$ . When the two frequencies are equal,  $\omega_1 = \omega_2 = \omega$ , the result is Second Harmonic Generation (SHG):  $\chi_{ijk}(2\omega, \omega, \omega)$ , while equal and opposite frequencies,  $\omega_1 = \omega$  and  $\omega_2 = -\omega$  leads to Optical Rectification (OR):  $\chi_{ijk}(0, \omega, -\omega)$ . In the SHG case the following convention is adopted: the second order nonlinear coefficient  $d$  is equal to one half of the second order nonlinear susceptibility

$$d_{ijk} = 1/2\chi^{(2)}$$

Because of the symmetry of the indices  $j$  and  $k$  one can replace these two by a single index (subscript)  $m$ . Consequently the notation for the SHG nonlinear coefficient in reduced form is  $d_{im}$  where  $m$  takes the values 1 to 6. Only noncentrosymmetric crystals can possess a nonvanishing  $d_{ijk}$  tensor (third rank). The unit of the SHG coefficients is m/V (in the MKSQ/SI system).

In centrosymmetric media the dominant nonlinearity is of the third order. This effect is represented by the third term in the Taylor's series (Equation 1); it is the result of the interaction of a number of optical fields (one to three) producing a new frequency  $\omega_4 = \omega_1 + \omega_2 + \omega_3$ . The third order polarization is given by

$$P_i(\omega_1, \omega_2, \omega_3) = g_4 \chi_{iklm} E_k^{\omega_1} E_l^{\omega_2} E_m^{\omega_3}$$

Third Harmonic Generation (THG) is achieved when  $\omega_1 = \omega_2 = \omega_3 = \omega$ . In this case the constant  $g_4 = 1/4$ . The third order nonlinear coefficient  $C$  is related to the third order susceptibility as follows:

$$C_{jklm} = 1/4\chi_{jklm}$$

This coefficient is a fourth rank tensor. In the THG case the matrices must be invariant under permutation of the indices  $k$ ,  $l$ , and  $m$ ; as a result the notation for the third order nonlinear coefficient can be simplified to  $C_{jm}$ . The unit of  $C_{jm}$  is  $\text{m}^2\text{V}^{-2}$  (in the MKSQ/SI system).

Applications of second order nonlinear optical materials include the generation of higher (up to sixth) optical harmonics, the mixing of monochromatic waves to generate sum or difference frequencies (frequency conversion), the use of two monochromatic waves to amplify a third wave (parametric amplification) and the addition of feedback to such an amplifier to create an oscillation (parametric oscillation).

Third order nonlinear optical materials are used for THG, self-focusing, four wave mixing, optical amplification, and optical conjugation. Many of these effects – as well as the variation and modulation of optical propagation caused by mechanical, electric, and magnetic fields (see the preceeding table on “Elasto-Optic, Electro-Optic, and Magneto-Optic Constants”) are used in the areas of optical communication, optical computing, and optical imaging.

# PHASE DIAGRAMS

H. P. R. Frederikse

A phase is a structurally homogeneous portion of matter. Regardless of the number of chemical constituents of a gas, there is only one vapor phase. This is true also for the liquid form of a pure substance, although a mixture of several liquid substances may exist as one or several phases, depending on the interactions among the substances. On the other hand a pure solid may exist in several phases at different temperatures and pressures because of differences in crystal structure (Reference 1). At the phase transition temperature,  $T_{tr}$ , the chemical composition of the solid remains the same, but a change in the physical properties often will take place. Such changes are found in ferroelectric crystals (example  $\text{BaTiO}_3$ ) which develop a spontaneous polarization below  $T_{tr}$ , in superconductors (example Pb) which lose all electrical resistance below the transition point, and in many other classes of solids.

In quite a few cases it is difficult to bring about the phase transition, and the high- (or low-) temperature phase persists in its metastable form. Many liquids remain in the liquid state for shorter or longer periods of time when cooled below the melting point (supercooling). However, often the slightest disturbance will cause solidification. Persistence of the high temperature phase in solid-solid transitions is usually of much longer duration. An example of this behavior is found in white tin; although gray tin is the thermodynamically stable form below  $T_{tr}$  (286.4 K), the metal remains in its undercooled, white tin state all the way to  $T = 0$  K, and crystals of gray tin are very difficult to produce.

A *phase diagram* is a map that indicates the areas of stability of the various phases as a function of external conditions (temperature and pressure). Pure materials, such as mercury, helium, water, and methyl alcohol are considered one-component systems and they have *unary* phase diagrams. The equilibrium phases in two-component systems are presented in *binary* phase diagrams. Because many important materials consist of three, four, and more components, many attempts have been made to deduce their multicomponent phase diagrams. However, the vast majority of systems with three or more components are very complex, and no overall maps of the phase relationships have been worked out.

It has been shown during the last 20 to 25 years that very useful partial phase diagrams of complex systems can be obtained by means of thermodynamic modeling (References 2, 3). Especially for complicated, multicomponent alloy systems the CALPHAD method has proved to be a successful approach for producing valuable portions of very intricate phase diagrams (Reference 4). With this method thermodynamic descriptions of the free energy functions of various phases are obtained that are consistent with existing (binary) phase diagram information and other thermodynamic data. Extrapolation methods are then used to extend the thermodynamic functions into a ternary system. Comparison of the results of this procedure with available experimental data is then used to fine-tune the phase diagram and add ternary interaction functions if necessary. In principle this approximation strategy can be extended to four, five, and more component systems.

The nearly two dozen phase diagrams shown below present the reader with examples of some important types of single and multicomponent systems, especially for ceramics and metal alloys. This makes it possible to draw attention to certain features like the kinetic aspects of phase transitions (see Figure 22, which presents a time-temperature-transformation, or TTT, diagram for the precipitation of  $\alpha$ -phase particles from the  $\beta$ -phase in a Ti-Mo alloy; Reference 1, pp. 358–360). The general references listed below and the references to individual figures contain phase diagrams for many additional systems.

**FIGURE 3.** Diagram of the principal phases of ice. Solid lines are measured boundaries between stable phases; dotted lines are extrapolated. Ice IV is a metastable phase that exists in the region of ice V. Ice IX exists in the region below  $-100^{\circ}\text{C}$  and pressures in the range 200–400 MPa. Ice X exists at pressures above 44 GPa. See Table 1 for the coordinates of the triple points, where liquid water is in equilibrium with two adjacent solid phases.

FIGURE 22. Ti-Mo system.

| Phase                  | Composition, mass % Mo | Pearson symbol | Space group  |
|------------------------|------------------------|----------------|--------------|
| $(\beta\text{Ti, Mo})$ | 0 to 100               | $cI2$          | $Im\bar{3}m$ |
| $(\alpha\text{Ti})$    | 0 to 0.8               | $hP2$          | $P6_3/mmc$   |
| $\alpha'$              | (a)                    | $hP2$          | $P6_3/mmc$   |
| $\alpha''$             | (a)                    | $oC4$          | $Cmcm$       |
| $\omega$               | (a)                    | $hP3$          | $P6/mmm$     |

(a) Metastable.

Experimental time-temperature-transformation (TTT) diagram for Ti-Mo. The start and finish times of the isothermal precipitation reaction vary with temperature as a result of the temperature dependence of the nucleation and growth processes. Precipitation is complete, at any temperature, when the equilibrium fraction of  $\alpha$  is established in accordance with the lever rule. The solid horizontal line represents the athermal (or nonthermally activated) martensitic transformation that occurs when the  $\beta$  phase is quenched.

**FIGURE 23.** The isothermal section at 900°C (1652°F) of the iron-chromium-nickel ternary phase diagram, showing the nominal composition of 18-8 stainless steel.

## HEAT CAPACITY OF SELECTED SOLIDS

This table gives the molar heat capacity at constant pressure of representative metals, semiconductors, and other crystalline solids as a function of temperature in the range 200 to 600 K.

# THERMAL AND PHYSICAL PROPERTIES OF PURE METALS

This table gives the following properties for the metallic elements:

|                           |                                                                                                            |
|---------------------------|------------------------------------------------------------------------------------------------------------|
| $t_m$ :                   | Melting point in °C                                                                                        |
| $t_b$ :                   | Normal boiling point in °C, at a pressure of 101.325 kPa (760 Torr)                                        |
| $\Delta_{\text{fus}} H$ : | Enthalpy of fusion at the melting point in J/g                                                             |
| $\rho_{25}$ :             | Density at 25 °C in g/cm <sup>3</sup>                                                                      |
| $\alpha$ :                | Coefficient of linear expansion at 25 °C in K <sup>-1</sup> (the quantity listed is $10^6 \times \alpha$ ) |
| $c_p$ :                   | Specific heat capacity at constant pressure at 25 °C in J/g K                                              |
| $\lambda$ :               | Thermal conductivity at 27 °C in W/cm K                                                                    |

# THERMAL CONDUCTIVITY OF METALS AND SEMICONDUCTORS AS A FUNCTION OF TEMPERATURE

This table gives the temperature dependence of the thermal conductivity of several metals and of carbon, germanium, and silicon. For graphite, separate entries are given for the thermal conductivity parallel ( $\parallel$ ) and perpendicular ( $\perp$ ) to the layer planes. The thermal conductivity of all these materials is very sensitive to impurities at low temperatures, especially below 100 K. Therefore, the values given here should be regarded as typical values for a highly purified specimen; the thermal conductivity of different specimens can vary by more than an order of magnitude in the low-temperature range. See Reference 2 for details.

<sup>a</sup> Values below 300 K are typical values.

\* Extrapolated.

# THERMAL CONDUCTIVITY OF ALLOYS AS A FUNCTION OF TEMPERATURE

This table lists the thermal conductivity of selected alloys at various temperatures. The indicated compositions refer to weight percent. Since the thermal conductivity is sensitive to exact composition and processing history, especially at low temperatures, these values should be considered approximate.

# THERMAL CONDUCTIVITY OF CRYSTALLINE DIELECTRICS

This table lists the thermal conductivity of a number of crystalline dielectrics, including some which find use as optical materials. Values are given at temperatures for which data are available.

# THERMAL CONDUCTIVITY OF CERAMICS AND OTHER INSULATING MATERIALS

Thermal conductivity values for ceramics, refractory oxides, and miscellaneous insulating materials are given here. The thermal conductivity refers to samples with density indicated in the second column. Since most of these materials are highly variable, the values should only be considered as a rough guide.

## THERMAL CONDUCTIVITY OF GLASSES

This table gives the composition of various types of glasses and of the variability of glasses, the data should be regarded as only the thermal conductivity  $k$  as a function of temperature. Because approximate.

| Type of glass                                        | Composition               |                                                                                           | $t$<br>°C | $k$<br>W/m K |
|------------------------------------------------------|---------------------------|-------------------------------------------------------------------------------------------|-----------|--------------|

## PROPERTIES OF COMMERCIAL METALS AND ALLOYS

This table gives typical values of mechanical, thermal, and electrical properties of several common commercial metals and alloys. Values refer to ambient temperature (0 to 25 °C). All values should be regarded as typical, since these properties are dependent on the particular type of alloy, heat treatment, and other factors. Values for individual specimens can vary widely.

## HARDNESS OF MINERALS AND CERAMICS

There are several hardness scales for describing the resistance of a material to indentation or scratching. This table lists a number of common materials in order of increasing hardness. Values are given, when available, on three different hardness scales: the original Mohs Scale (range 1 to 10); the modified Mohs Scale (range 1

to 15), and the Knoop Hardness Scale. In the last case, a load of 100 g is assumed.

# ORGANIC MAGNETS

J.S. Miller

Magnetic ordering, e.g., ferromagnetism, like superconductivity, is a property of a solid, not of an individual molecule or ion, and very rarely occurs for organic compounds. In contrast to superconductivity, where all electron spins pair to form a perfect diamagnetic material, magnetic ordering requires unpaired electron spins; hence, superconductivity and ferromagnetism are mutually exclusive.

The vast majority of organic compounds are diamagnetic (i.e., all electron spins are paired), and a relative few possess unpaired electrons (designated by an arrow,  $\uparrow$ ) and are paramagnetic (PM), i.e., they are oriented in random directions. A few organic solids, however, exhibit strong magnetic behavior and magnetically order as ferromagnets (FO) with all spins aligned in the same direc-

tion. In some cases the spins align in the opposite direction and compensate to form an antiferromagnet (AF). In some cases these spins are not opposed to each other and do not compensate and lead to a canted antiferromagnet or weak ferromagnet (WF). If the number of spins that align in one direction differs from the number of spins that align in the opposite direction, the spins cannot compensate and a ferrimagnet (FI) results. Metamagnets (MM) are antiferromagnets in which all the spins become aligned like a ferromagnet in an applied magnetic field. Above the ordering or critical temperature,  $T_c$ , all magnets are paramagnets (PM). Organic magnets all possess electron spins in  $p$ -orbitals, but these may be in conjunction with metal ion-based spins.

FIGURE 1. Schematic illustration of the different types of magnetic behavior.

**Summary of the Critical Temperature,  $T_c$ , Saturation Magnetization,  $M_s$ , Coercive Field,  $H_{cr}$ , and Remanent Magnetization,  $M_r$ , for Selected Organic-Based Magnets**

| Magnet                                                                                                                                                  | Type | $T_c$ /K | $M_s$ /A m <sup>-1</sup> | $H_{cr}$ /T    | $M_r$ /A m <sup>-1</sup> |

# OPTICAL PROPERTIES OF SELECTED INORGANIC AND ORGANIC SOLIDS

L. I. Berger

Optical properties of materials are closely related to their dielectric properties. The complex dielectric function (relative permittivity) of a material is equal to

$$\varepsilon(\omega) = \varepsilon'(\omega) - j\varepsilon''(\omega),$$

where  $\varepsilon'(\omega)$  and  $\varepsilon''(\omega)$  are its real and imaginary parts, respectively, and  $\omega$  is the angular frequency of the applied electric field. For a non-absorbing medium, the index of refraction is  $n = (\varepsilon\mu)^{1/2}$ , where  $\mu$  is the relative magnetic permeability of the medium (material); in the majority of dielectrics,  $\mu \approx 1$ .

For many applications, the most important optical properties of materials are the index of refraction, the extinction coefficient,  $k$ , and the reflectivity,  $R$ . The common index of refraction of a material is equal to the ratio of the phase velocity of propagation of an electromagnetic wave of a given frequency in vacuum to that in the material. Hence,  $n \geq 1$ . The optical properties of highly conductive materials like metals and semiconductors (at photon energy range above the energy gap) differ from those of optically transparent media. Free electrons absorb the incident electromagnetic wave in a thin surface layer (a few hundred nanometers thick) and then release the absorbed energy in the form of secondary waves reflected from the surface. Thus, the light reflection becomes very strong; for example, highly conductive sodium reflects 99.8% of the incident wave (at 589 nm). Introduction of the effective index of refraction,  $n_{\text{eff}} = (\varepsilon')^{1/2} = n - jk$ , where  $\varepsilon' = \varepsilon - j\delta/\omega \varepsilon_0$ ,  $\delta$  is the electrical conductivity of the material in S/m, and  $\varepsilon_0 = 8.8542 \cdot 10^{-12}$  F/m is the permittivity of vacuum, allows one to apply the expressions of the optics of transparent media to the conductive materials. It is clear that the effective index of refraction may be smaller than 1. For example,  $n = 0.05$  for pure sodium and  $n = 0.18$  for pure silver (at 589.3 nm). At very high photon energies, the quantum effects, such as the internal photoeffect, start playing a greater role, and the optical properties of these materials become similar to those of insulators (low reflectance, existence of Brewster's angle, etc.).

The extinction coefficient characterizes absorption of the electromagnetic wave energy in the process of propagation of a wave through a material. The wave intensity,  $I$ , after it passes a distance  $x$  in an isotropic medium is equal to

$$I = I_0 \exp(-\alpha x),$$

where  $I_0$  is the intensity at  $x = 0$  and  $\alpha$  is called the absorption coefficient. For many applications, the extinction coefficient,  $k$ , which is equal to

$$k = \alpha \frac{\lambda}{4\pi},$$

where  $\lambda$  is the wavelength of the wave in the medium, is more commonly used for characterization of the electromagnetic losses in materials.

Reflection of an electromagnetic wave from the interface between two media depends on the media indices of refraction and on the angle of incidence. It is characterized by the reflectivity, which is equal to the ratio of the intensity of the wave reflected back into the first medium to the intensity of the wave approaching the interface. For polarized light and two non-absorbing media,

$$R = \frac{(N_1 - N_2)^2}{(N_1 + N_2)^2},$$

where  $N_1 = n_1/\cos\theta_1$  and  $N_2 = n_2/\cos\theta_2$  for the wave polarized in the plane of incidence, and  $N_1 = n_1\cos\theta_1$  and  $N_2 = n_2\cos\theta_2$  for the wave polarized normal to the plane of incidence;  $\theta_1$  and  $\theta_2$  are the angles between the normal to the interface in the point of incidence and the directions of the beams in the first and second medium, respectively. The reflectivity at normal incidence in this case is

$$R = [(n_1 - n_2)/(n_1 + n_2)]^2$$

For any two opaque (absorbing) media, the normal incidence reflectivity is

$$R = \frac{(n_1 - n_2)^2 + k_2^2}{(n_1 + n_2)^2 + k_2^2}.$$

In the majority of experiments, the first medium is air ( $n \approx 1$ ), and hence,

$$R = \frac{(1 - n)^2 + k^2}{(1 + n)^2 + k^2}.$$

The data on  $n$  and  $k$  in the following table are abridged from the sources listed in the references. The reflectivity at normal incidence,  $R$ , has been calculated from the last equation. For convenience, the energy  $E$ , wavenumber  $\bar{\nu}$ , and wavelength  $\lambda$  are given for the incidence radiation.

| <i>E</i> /eV                                                              | $\bar{\nu}$ /cm <sup>-1</sup> | $\lambda$ /μm | <i>n</i> | <i>n<sub>a</sub></i> | <i>n<sub>c</sub></i> | <i>k</i> | <i>k<sub>a</sub></i> | <i>k<sub>c</sub></i> | <i>R</i> | <i>R<sub>a</sub></i> | <i>R<sub>c</sub></i> |

# FERMI ENERGY AND RELATED PROPERTIES OF METALS

## Lev. I. Berger

In the classical Drude theory of metals, the Maxwell-Boltzmann velocity distribution of electrons is used. It states that the number of electrons per unit volume with velocities in the range of  $d\vec{v}$  about any magnitude  $\vec{v}$  at temperature  $T$  is

$$f_B(\vec{v})d\vec{v} = n \left( \frac{m}{2\pi k_B T} \right)^{3/2} \exp \left( -\frac{mv^2}{2k_B T} \right) d\vec{v}$$

where  $n$  is the total number of conduction electrons in a unit volume of a metal,  $m$  is the free electron mass, and  $k_B$  is the Boltzmann constant. In an attempt to explain a substantial discrepancy between the experimental data on the specific heat of metals and the values calculated on the basis of the Drude model, Sommerfeld suggested a model of the metal in which the Pauli exclusion principle is applied to free electrons. In this case, the Maxwell-Boltzmann distribution is replaced by the Fermi-Dirac distribution:

$$f(\vec{v})d\vec{v} = 2 \left( \frac{m}{h} \right)^3 d\vec{v} \left\{ \exp \left[ \left( \frac{mv^2}{2} - k_B T_0 \right) / k_B T \right] + 1 \right\}^{-1}$$

Here  $h$  is the Planck constant and  $T_0$  is a characteristic temperature which is determined by the normalization condition

$$n = \int d\vec{v} \cdot f(\vec{v})$$

The magnitude of  $T_0$  is quite high; usually,  $T_0 > 10^4$  K. So, at common temperatures ( $T < 10^3$  K), the free electron density of a metal is much smaller than in the case of the Maxwell-Boltzmann distribution. This allows us to explain why the experimental data on specific heat for metals are close to those for insulators.

The maximum kinetic energy the electrons of a metal may possess at  $T = 0$  K is called the Fermi energy, e.g.,

$$E_F = \frac{\hbar^2 k_F^2}{2m} = \left( \frac{e^2}{2k_B} \right) (k_F r_B)^2$$

where  $k_F$  is the Fermi momentum or the Fermi wave vector

$$k_F = (3\pi^2 n)^{1/3}$$

$e$  is the electron charge, and  $r_B$  is the Bohr radius

$$r_B = \hbar^2 / me^2 = 0.529 \cdot 10^{-10} \text{ m}$$

Another, more common expression for the Fermi energy is

$$E_F = \frac{1}{2} m v_F^2$$

where  $v_F = \hbar k_F / m$  is the Fermi velocity which can be expressed using the concept of the electron radius,  $r_s$ . It is equal to radius of a sphere occupied by one free electron. If the total volume of a metal sample is  $V$  and the number of conduction electrons in this volume is  $N$ , then the volume per electron is equal to

$$\frac{V}{N} = \frac{1}{n} = \frac{4}{3} \pi r_s^3$$

and

$$r_s = \left( \frac{3}{4\pi n} \right)^{1/3}$$

The following table contains information pertinent to the Sommerfeld model for some metals. The magnitudes of  $T_0$  are calculated using the expression

$$T_0 = \frac{E_F}{k_B} = \frac{58.2 \cdot 10^4}{(r_s / r_B)^2} \text{ K}$$

Ground State Properties of the Electron Gas in Some Metals

| Metal           | Valency | $n/10^{28} \text{ m}^{-3}$ | $r_s/\text{pm}$ | $r_s/r_B$ | $E_F/\text{eV}$ | $T_0/10^4 \text{ K}$ | $k_F/10^{10} \text{ m}^{-1}$ | $v_F/10^6 \text{ m s}^{-1}$ |

# ELECTRON INELASTIC MEAN FREE PATHS

Cedric J. Powell

The inelastic mean free path (IMFP) of electrons is defined as the average of distances, measured along the trajectories, that electrons with a given energy travel between inelastic collisions in the substance. It is an important parameter in analyzing results from surface-characterization techniques such as Auger electron spectroscopy, x-ray photoelectron spectroscopy, low-energy electron diffraction, and others. IMFPs can be measured by the elastic-peak electron spectroscopy technique and other methods, and they can be calculated from optical data. A detailed analysis of the experimental and theoretical considerations in obtaining reliable IMFP values can be found in reference 4.

The table below gives recommended IMFP values for several elements, simple inorganic compounds, and organic materials. Values are given in Ångström units ( $1 \text{ Å} = 10^{-10} \text{ m}$ ) for a range of

electron energies. Substances are given in alphabetical order by name, with elements and inorganic compounds listed before the organic materials.

## PHASE TRANSITIONS IN THE SOLID ELEMENTS AT ATMOSPHERIC PRESSURE

This table gives the phase transition temperatures for the elements that can exist in two or more crystalline forms (allotropes). The crystal phases are labeled by Greek letters in the most common conventions, although some variation is found. All data refer to normal atmospheric pressure.

## THERMOPHYSICAL PROPERTIES OF STAINLESS STEEL 310

Stainless steel is used in a wide variety of applications, especially at high temperatures. This table gives properties of a reference standard Stainless Steel 310 certified by the U. K. National Physical Laboratory. The properties are:

$a$ : thermal diffusivity in  $\text{mm}^2 \text{s}^{-1}$   
 $c_p$ : specific heat capacity at constant pressure in  $\text{J g}^{-1} \text{K}^{-1}$   
 $\rho$ : density in  $\text{g cm}^{-3}$   
 $k$ : thermal conductivity in  $\text{W m}^{-1} \text{K}^{-1}$

# THERMOELECTRIC PROPERTIES OF METALS AND SEMICONDUCTORS

L. I. Berger

There are three thermoelectric phenomena that result from correlation between propagation of heat through a conductor and displacement of the current carriers in the conductor. The Seebeck effect (Ref. 1) consists of formation of an electric current in an electrical circuit formed by two dissimilar conductors if the contacts between the conductors are held at different temperatures. A reverse phenomenon, the Peltier effect (Ref. 2), consists of formation of a temperature difference between the contacts in a circuit of this type if an electric current is created in the circuit by an external current source to which the circuit is connected. W. Thomson (Lord Kelvin), who explained both effects (Refs. 3,4), predicted and experimentally confirmed the existence of another thermoelectric phenomenon, named the Thomson effect, which consists of absorption or release of heat in a uniform conductor with a current passing through it when a temperature gradient (positive or negative) is present along the current direction.

The electromotive force,  $\Delta U$ , which creates the Seebeck current in the circuit, is the algebraic sum of the emf's created in each of the conductors, and is proportional to the temperature difference,  $\Delta T$ , between the electrical contact points:  $\Delta U = \Delta U_1 + \Delta U_2 = \alpha_1 \Delta T + \alpha_2 \Delta T$ . The coefficient of proportionality,  $\alpha$ , called the Seebeck coefficient or thermoelectric power or thermal electromotive force (thermal emf), of each of the two materials depends on the electrical properties and temperature of the material. The Peltier effect is measured by the amount of heat,  $\Delta Q$ , released or absorbed in a unit of time (in addition to the Joule heat) at a contact of two dissimilar conductors with electric current  $\Delta I$  passing through the contact:  $\Delta Q = \Pi \Delta I$ . Thomson showed that  $\Pi = \alpha T$ . The Thomson effect's heat,  $dQ$ , released or absorbed in a unit of time along a part of a conductor of length  $dx$  is proportional to the current magnitude  $I$ , the temperature gradient along the conductor  $\partial T/\partial x$ , and the increment  $dx$ :  $dQ = \tau I (\partial T/\partial x) dx$ . Thomson showed that the magnitude of the coefficient of proportionality,  $\tau$ , later named the Thomson coefficient, depends on only the properties of the conductor and the ambient temperature and correlates with the other thermoelectric parameters of a material through the equation  $\tau = T(\partial \alpha/\partial T)$ .

Another thermoelectric phenomenon, called the Bridgman effect or the internal Peltier effect (Ref. 5), occurs when an electric current passes through an anisotropic crystal, resulting in absorption or liberation of heat because of non-uniformity in current distribution.

In view of the correlations between  $\alpha$ ,  $\Pi$ , and  $\tau$ , we need only to present data for one of these parameters, namely, thermal emf  $\alpha$

and its dependence on temperature. These values are presented below, first for metals and then for semiconductors. In accordance with modern theory of solids, thermal emf in semiconductors is up to three or even four orders of magnitude higher than that in metals (Ref. 9).

# NOMENCLATURE FOR ORGANIC POLYMERS

Robert B. Fox and Edward S. Wilks

Organic polymers have traditionally been named on the basis of the monomer used, a hypothetical monomer, or a semi-systematic structure. Alternatively, they may be named in the same way as organic compounds, i.e., on the basis of a structure as drawn. The former method, often called “source-based nomenclature” or “monomer-based nomenclature”, sometimes results in ambiguity and multiple names for a single material. The latter method, termed “structure-based nomenclature”, generates a sometimes cumbersome unique name for a given polymer, independent of its source. Within their limitations, both types of names are acceptable and well-documented.<sup>1</sup> The use of stereochemical descriptors with both types of polymer nomenclature has been published.<sup>2</sup>

## Traditional Polymer Names

### Monomer-Based Names

“Polystyrene” is the name of a homopolymer made from the single monomer styrene. When the name of a monomer comprises two or more words, the name should be enclosed in parentheses, as in “poly(methyl methacrylate)” or “poly(4-bromostyrene)” to identify the monomer more clearly. This method can result in several names for a given polymer: thus, “poly(ethylene glycol)”, “poly(ethylene oxide)”, and “poly(oxirane)” describe the same polymer. Sometimes, the name of a hypothetical monomer is used, as in “poly(vinyl alcohol)”. Even though a name like “polyethylene” covers a multitude of materials, the system does provide understandable names when a single monomer is involved in the synthesis of a single polymer. When one monomer can yield more than one polymer, e.g. 1,3-butadiene or acrolein, some sort of structural notation must be used to identify the product, and one is not far from a formal structure-based name.

*Copolymers, Block Polymers, and Graft Polymers.* When more than one monomer is involved, monomer-based names are more complex. Some common polymers have been given names based on an apparent structure, as with “poly(ethylene terephthalate)”. A better system has been approved by the IUPAC.<sup>1</sup> With this method, the arrangement of the monomeric units is introduced through use of an italicized connective placed between the names of the monomers. For monomer names represented by A, B, and C, the various types of arrangements are shown in Table 1.

Table 2 contains examples of common or semi-systematic names of copolymers. The systematic names of comonomers may also be used; thus, the polyacrylonitrile-*block*-polybutadiene-*block*-polystyrene polymer in Table 2 may also be named poly(prop-2-enenitrile)-*block*-polybuta-1,3-diene-*block*-poly(ethenylbenzene). IUPAC does not require alphabetized names of comonomers within a polymer name; many names are thus possible for some copolymers.

These connectives may be used in combination and with small, non-repeating (i.e. non-polymeric) junction units; see, for example, Table 2, line 8. A long dash may be used in place of the con-

nective *-block-*; thus, in Table 2, the polymers of lines 7 and 8 may also be written as shown on lines 9 and 10.

IUPAC also recommends an alternative scheme for naming copolymers that comprises use of “copoly” as a prefix followed by the names of the comonomers, a solidus (an oblique stroke) to separate comonomer names, and addition before “copoly” of any applicable connectives listed in Table 2 except *-co-*.

Table 3 gives the same examples shown in Table 2 but with the alternative format. Comonomer names need not be parenthesized.

TABLE 1. IUPAC Source-Based Copolymer Classification

| No. | Copolymer type                                            | Connective     | Example                               |
|-----|-----------------------------------------------------------|----------------|---------------------------------------|
| 1   | Unspecified or unknown                                    | <i>-co-</i>    | poly(A- <i>co</i> -B)                 |
| 2   | Random (obeys Bernoullian distribution)                   | <i>-ran-</i>   | poly(A- <i>ran</i> -B)                |
| 3   | Statistical (obeys known statistical laws)                | <i>-stat-</i>  | poly(A- <i>stat</i> -B)               |
| 4   | Alternating (for two monomeric units)                     | <i>-alt-</i>   | poly(A- <i>alt</i> -B)                |
| 5   | Periodic (ordered sequence for 2 or more monomeric units) | <i>-per-</i>   | poly(A- <i>per</i> -B- <i>per</i> -C) |
| 6   | Block (linear block arrangement)                          | <i>-block-</i> | polyA- <i>block</i> -polyB            |
| 7   | Graft (side chains connected to main chains)              | <i>-graft-</i> | polyA- <i>graft</i> -polyB            |

TABLE 2. Examples of Source-Based Copolymer Nomenclature

| No. | Copolymer name                                                                    |
|-----|-----------------------------------------------------------------------------------|
| 1   | poly(propene- <i>co</i> -methacrylonitrile)                                       |
| 2   | poly[(acrylic acid)- <i>ran</i> -(ethyl acrylate)]                                |
| 3   | poly(butene- <i>stat</i> -ethylene- <i>stat</i> -styrene)                         |
| 4   | poly[(sebacic acid)- <i>alt</i> -butanediol]                                      |
| 5   | poly[(ethylene oxide)- <i>per</i> -(ethylene oxide)- <i>per</i> -tetrahydrofuran] |
| 6   | polyisoprene- <i>graft</i> -poly(methacrylic acid)                                |
| 7   | polyacrylonitrile- <i>block</i> -polybutadiene- <i>block</i> -polystyrene         |
| 8   | polystyrene- <i>block</i> -dimethylsilylene- <i>block</i> -polybutadiene          |
| 9   | polyacrylonitrile—polybutadiene—polystyrene                                       |
| 10  | polystyrene—dimethylsilylene—polybutadiene                                        |

TABLE 3. Examples of Source-Based Copolymer Nomenclature (Alternative Format)

| No. | Polymer name                                                      |
|-----|-------------------------------------------------------------------|
| 1   | copoly(propene/methacrylonitrile)                                 |
| 2   | <i>ran</i> -copoly(acrylic acid/ethyl acrylate)                   |
| 3   | <i>stat</i> -copoly(butene/ethylene/styrene)                      |
| 4   | <i>alt</i> -copoly(sebacic acid/butanediol)                       |
| 5   | <i>block</i> -copoly(acrylonitrile/butadiene/styrene)             |
| 6   | <i>per</i> -copoly(ethylene oxide/ethylene oxide/tetrahydrofuran) |
| 7   | <i>graft</i> -copoly(isoprene/methacrylic acid)                   |

Source-based nomenclature for non-linear macromolecules and macromolecular assemblies is covered by a 1997 IUPAC document.<sup>11</sup> The types of polymers in these classes, together with their connectives, are given in Table 4; the terms shown may be used as connectives, prefixes, or both to designate the features present.

**TABLE 4. Connectives for Non-Linear Macromolecules and Macromolecular Assemblies**

| No. | Type                                          | Connective            |
|-----|-----------------------------------------------|-----------------------|
| 1   | Branched (type unspecified)                   | branch                |
| 2   | Branched with branch point of functionality f | f-branch              |
| 3   | Comb                                          | comb                  |
| 4   | Cross-link                                    | <i>ι</i> (Greek iota) |
| 5   | Cyclic                                        | cyclo                 |
| 6   | Interpenetrating polymer network              | ipn                   |
| 7   | Long-chain branched                           | l-branch              |
| 8   | Network                                       | net                   |
| 9   | Polymer blend                                 | blend                 |
| 10  | Polymer-polymer complex                       | compl                 |
| 11  | Semi-interpenetrating polymer network         | sipn                  |
| 12  | Short-chain branched                          | sh-branch             |
| 13  | Star                                          | star                  |
| 14  | Star with f arms                              | f-star                |

Non-linear polymers are named by using the italicized connective as a *prefix* to the source-based name of the polymer component or components to which the prefix applies; some examples are listed in Table 5.

**TABLE 5. Non-Linear Macromolecules**

| No. | Polymer name                                                          | Polymer structural features                                                                                      |
|-----|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| 1   | poly(methacrylic acid)- <i>comb</i> -polyacrylonitrile                | Comb polymer with a poly(methacrylic acid) backbone and polyacrylonitrile side chains                            |
| 2   | <i>comb</i> -poly[ethylene- <i>stat</i> -(vinyl chloride)]            | Comb polymer with unspecified backbone composition and statistical ethylene/vinyl chloride copolymer side chains |
| 3   | polybutadiene- <i>comb</i> -(polyethylene; polypropene)               | Comb polymer with butadiene backbone and side chains of polyethylene and polypropene                             |
| 4   | <i>star</i> -(polyA; polyB; polyC; polyD; polyE)                      | Star polymer with arms derived from monomers A, B, C, D, and E, respectively                                     |
| 5   | <i>star</i> -(polyA- <i>block</i> -polyB- <i>block</i> -polyC)        | Star polymer with every arm comprising a tri-block segment derived from comonomers A, B, and C                   |
| 6   | <i>star</i> -poly(propylene oxide)                                    | A star polymer prepared from propylene oxide                                                                     |
| 7   | 5- <i>star</i> -poly(propylene oxide)                                 | A 5-arm star polymer prepared from propylene oxide                                                               |
| 8   | <i>star</i> -(polyacrylonitrile; polypropylene) ( $M_r$ 10000: 25000) | A star polymer containing polyacrylonitrile arms of MW 10000 and polypropylene arms of MW 25000                  |

Macromolecular assemblies held together by forces other than covalent bonds are named by inserting the appropriate italicized connective between names of individual components; Table 6 gives examples.

**TABLE 6. Examples of Polymer Blends and Nets**

| No. | Polymer name                                                                                                                     |

| 6   | [ <i>net</i> -poly(butadiene- <i>stat</i> -styrene)]- <i>ipn</i> -[ <i>net</i> -poly(4-methylstyrene- <i>i</i> -divinylbenzene)] |

## Structure-Based Polymer Nomenclature

### Regular Single-Strand Polymers

Structure-based nomenclature has been approved by the IUPAC<sup>4</sup> and is currently being updated; it is used by *Chemical Abstracts*.<sup>5</sup> Monomer names are not used. To the extent that a polymer chain can be described by a repeating unit in the chain, it can be named “poly(repeating unit)”. For regular single-strand polymers, “repeating unit” is a bivalent group; for regular double-strand (ladder and spiro) polymers, “repeating unit” is usually a tetravalent group.<sup>9</sup>

Since there are usually many possible repeating units in a given chain, it is necessary to select one, called the “constitutional repeating unit” (CRU) to provide a unique and unambiguous name, “poly(CRU)”, where “CRU” is a recitation of the names of successive units as one proceeds through the CRU from left to right. For this purpose, a portion of the main chain structure that includes at least two repeating sequences is written out. These sequences will typically be composed of bivalent subunits such as  $-\text{CH}_2-$ ,  $-\text{O}-$ , and groups from ring systems, each of which can be named by the usual nomenclature rules.<sup>6,7</sup>

Where a chain is simply one long sequence comprising repetition of a single subunit, that subunit is itself the CRU, as in “poly(methylene)” or “poly(1,4-phenylene)”. In chains having more than one kind of subunit, a seniority system is used to determine the beginning of the CRU and the direction in which to move along the main chain atoms (following the shortest path in rings) to complete the CRU. Determination of the first, most senior, subunit, is based on a descending order of seniority: (1) heterocyclic rings, (2) hetero atoms, (3) carbocyclic rings, and, lowest, (4) acyclic carbon chains.

Within each of these classes, there is a further order of seniority that follows the usual rules of nomenclature.

**Heterocycles:** A nitrogen-containing ring system is senior to a ring system not containing nitrogen.<sup>4,9</sup> Further descending order of seniority is determined by:

- the highest number of rings in the ring system
- the largest individual ring in the ring system
- the largest number of hetero atoms
- the greatest variety of hetero atoms

**Hetero atoms:** The senior bivalent subunit is the one nearest the top, right-hand corner of the Periodic Table; the order of seniority is: O, S, Se, Te, N, P, As, Sb, Bi, Si, Ge, Sn, Pb, B, Hg.

**Carbocycles:** Seniority<sup>4</sup> is determined by:

- the highest number of rings in the ring system
- the largest individual ring in the ring system
- degree of ring saturation; an unsaturated ring is senior to a saturated ring of the same size

**Carbon chains:** Descending order of seniority is determined by:

- (i) chain length (longer is senior to shorter)
- (ii) highest degree of unsaturation
- (iii) number of substituents (higher number is senior to lower number)
- (iv) ascending order of locants
- (v) alphabetical order of names of substituent groups

Among equivalent ring systems, preference is given to the one having lowest locants for the free valences in the subunit, and among otherwise identical ring systems, the one having least hydrogenation is senior. Lowest locants in unsaturated chains are also given preference. Lowest locants for substituents are the final determinant of seniority.

Direction within the repeating unit depends upon the shortest path, which is determined by counting main chain atoms, both cyclic and acyclic, from the most senior subunit to another subunit of the same kind or to a subunit next lower in seniority. When identification and orientation of the CRU have been accomplished, the CRU is named by writing, in sequence, the names of the largest possible subunits within the CRU from left to right. For example, the main chain of the polymer traditionally named “poly(ethylene terephthalate)” has the structure shown in Figure 1.

**Figure 1.** Structure-based name: poly(oxyethyleneoxyterephthaloyl); traditional name: poly(ethylene terephthalate).

The CRU in Figure 1 is enclosed in brackets and read from left to right. It is selected because (1) either backbone oxygen atom qualifies as the “most senior subunit”, (2) the shortest path length from either -O- to the other -O- is via the ethylene subunit. Orientation of the CRU is thus defined by (1) beginning at the -O- marked with an asterisk, and (2) reading in the direction of the arrow. The structure-based name of this polymer is therefore “poly(oxyethyleneoxyterephthaloyl)”, not much longer than the traditional name and much more adaptable to the complexities of substitution. As organic nomenclature evolves, more systematic names may be used for subunits, e.g. “ethane-1,2-diyl” instead of “ethylene”. IUPAC still prefers “ethylene” for the -CH<sub>2</sub>-CH<sub>2</sub>- unit, however, but also accepts “ethane-1,2-diyl”.

Structure-based nomenclature can also be used when the CRU backbone has no carbon atoms. An example is the polymer traditionally named “poly(dimethylsiloxane)”, which on the basis of structure would be named “poly(oxydimethylsilylene)” or “poly(oxydimethylsilanediy)”. This nomenclature method has also been applied to inorganic and coordination polymers<sup>8</sup> and to double-strand (ladder and spiro) organic polymers.<sup>9</sup>

### Irregular Single-Strand Polymers

Polymers that cannot be described by the repetition of a single CRU or comprise units not all connected identically in a directional sense can also be named on a structure basis.<sup>10</sup> These include copolymers, block and graft polymers, and star polymers. They are given names of the type “poly(A/B/C...)”, where A, B, C, etc. are the names of the component constitutional units, the

number of which are minimized. The constitutional units may include regular or irregular blocks as well as atoms or atomic groupings, and each is named by the method described above or by the rules of organic nomenclature.

The solidus denotes an unspecified arrangement of the units within the main chain.<sup>10</sup> For example, a statistical copolymer derived from styrene and vinyl chloride with the monomeric units joined head-to-tail is named “poly(1-chloroethylene/1-phenylethylene)”. A polymer obtained by 1,4-polymerization and both head-to-head and head-to-tail 1,2- polymerization of 1,3-butadiene would be named “poly(but-1-ene-1,4-diyl/1-vinylethylene/2-vinylethylene)”.<sup>12</sup> In graphic representations of these polymers, shown in Figure 2, the hyphens or dashes at each end of each CRU depiction are shown *completely within* the enclosing parentheses; this indicates that they are not necessarily the terminal bonds of the macromolecule.

**Figure 2.** Graphic representations of copolymers.

A long hyphen is used to separate components in names of block polymers, as in “poly(A)—poly(B)—poly(C)”, or “poly(A)—X—poly(B)” in which X is a non-polymeric junction unit, e.g. dimethylsilylene.

In graphic representations of these polymers, the blocks are shown connected when the bonding is known (Figure 3, for example); when the bonding between the blocks is unknown, the blocks are separated by solidi and are shown *completely within* the outer set of enclosing parentheses (Figure 4, for example).<sup>10,13</sup>

**Figure 3.** polystyrene—polyethylene—polystyrene.

**Figure 4.** poly[poly(methyl methacrylate)—polystyrene—poly(methyl acrylate)].

Graft polymers are named in the same way as a substituted polymer but without the ending “yl” for the grafted chain; the name of a regular polymer, comprising Z units in which some have grafts of “poly(A)”, is “poly[Z/poly(A)Z]”. Star polymers are treated as a central unit with substituent blocks, as in “tetraakis(polymethylene)silane”.<sup>10,13</sup>

### Other Nomenclature Articles and Publications

In addition to the *Chemical Abstracts* and IUPAC documents cited above and listed below, other articles on polymer nomenclature are available. A 1999 article lists significant documents on polymer nomenclature published during the last 50 years in books, encyclopedias, and journals by *Chemical Abstracts*,

IUPAC, and individual authors.<sup>14</sup> A comprehensive review of source-based and structure-based nomenclature for all of the major classes of polymers,<sup>15</sup> and a short tutorial on the correct identification, orientation, and naming of most commonly encountered constitutional repeating units were both published in 2000.<sup>16</sup>

# GLASS TRANSITION TEMPERATURE FOR SELECTED POLYMERS

Robert B. Fox

Polymer names are based on the IUPAC structure-based nomenclature system described in the table "Naming Organic Polymers". Within each category, names are listed in alphabetical order. Source-based and trivial names are also given (in italics) for the most common polymers. The table does not include polymers for which  $T_g$  is not clearly defined because of variability of structure or because of reactions taking place near the glass transition.

All values of  $T_g$  cited in this table have been determined by differential scanning calorimetry (DSC) except those values indicated by:

(D) dynamic method  
(Dil) dilatometry  
(M) mechanical method

| Polymer name                                                                                  | Glass transition temperature ( $T_g$ /K) |
|-----------------------------------------------------------------------------------------------|------------------------------------------|
| ACYCLIC CARBON CHAINS                                                                         |                                          |
| <i>Polyalkadienes</i>                                                                         |                                          |
| Poly(alkenylene) <i>Polyalkadiene</i> $-\text{[CH=CHCH}_2\text{CH}_2\text{]}-$                |                                          |
| Poly( <i>cis</i> -1-butenylene)                                                               | 171                                      |
| <i>cis</i> -1,3-polybutadiene [PBD]                                                           |                                          |
| Poly( <i>trans</i> -1-butenylene)                                                             | 215                                      |
| <i>trans</i> -1,3-polybutadiene [PBD]                                                         |                                          |
| Poly(1-chloro- <i>cis</i> -1-butenylene)                                                      | 253                                      |
| <i>cis</i> -1,3-polychloroprene                                                               |                                          |
| Poly(1-chloro- <i>trans</i> -1-butenylene)                                                    | 233                                      |
| <i>trans</i> -1,3-polychloroprene                                                             |                                          |
| Poly(1-methyl- <i>cis</i> -1-butenylene)                                                      | 200                                      |

## DIELECTRIC CONSTANT OF SELECTED POLYMERS

This table lists typical values of the dielectric constant (more properly called relative permittivity) of some important polymers. Values are given for frequencies of 1 kHz, 1 MHz, and 1 GHz; in most cases the dielectric constant at frequencies below 1 kHz does not differ significantly from the value at 1 kHz. Since the dielectric constant of a polymeric material can vary with density, degree of crystallinity, and other details of a particular sample, the values given here should be regarded as only typical or average values.

# PRESSURE-VOLUME-TEMPERATURE RELATIONSHIP FOR POLYMER MELTS

Christian Wohlfarth

Numerous theoretical equations of state for polymer liquids have been developed. These, at the minimum, have to provide accurate fitting functions to experimental data. However, for the purpose of this table, the empirical Tait equation along with a polynomial expression for the zero pressure isobar is used. This equation is able to represent the experimental data for the melt state within the limits of experimental errors, i.e., the maximum deviations between measured and calculated specific volumes are about 0.001-0.002 cm<sup>3</sup>/g.

The general form of the Tait equation is:

$$V(P,T) = V(0,T)\{1 - C \ln[1 + P/B(T)]\} \quad (1)$$

where the coefficient  $C$  is usually taken to be a universal constant equal to 0.0894.  $T$  is the absolute temperature in K and  $P$  the pressure in MPa. The volume  $V$  is the specific volume in cm<sup>3</sup>/g. The Tait parameter  $B(T)$  has the very simple meaning that it is inversely proportional to the compressibility  $\kappa$  at constant temperature and zero pressure:

$$\kappa(0,T) = -[1/V(0,T)](dV/dP) = C/B(T) \quad (2)$$

The  $B(T)$  function is usually given by:

$$B(T) = B_0 \exp[-B_1(T-273.15)] \quad (3)$$

but, sometimes a polynomial expression is used:

$$B(T) = b_0 + b_1(T-273.15) + b_2(T-273.15)^2 \quad (4)$$

The zero-pressure isobar  $V(0,T)$  is usually given by:

$$V(0,T) = A_0 + A_1(T-273.15) + A_2(T-273.15)^2 \quad (5)$$

where  $A_0, A_1, A_2$  are specific constants for a given polymer (the expression  $T-273.15$  is used because fitting to the zero-pressure isobar is usually done in terms of Celsius temperature). Other forms for  $V(0,T)$  are also found in the literature, such as

$$V(0,T) = A_3 \exp[A_4(T-273.15)] \quad (6)$$

or

$$V(0,T) = A_5 \exp(A_6 T^{1.5}) \quad (7)$$

where  $A_3$  and  $A_4$  or  $A_5$  and  $A_6$  are again specific constants for a given polymer.

The Tait equation is particularly useful to calculate derivative quantities, such as the isothermal compressibility and the thermal expansivity coefficients. The isothermal compressibility  $\kappa(P,T)$  is derived from equation (1) as:

$$\kappa(P,T) = -(1/V)(dV/dP) = 1/[P + B(T)][1/C - \ln(1 + P/B(T))] \quad (8)$$

and the thermal expansivity  $\alpha(P,T)$  as:

$$\alpha(P,T) = (1/V)(dV/dT) = \alpha(0,T) - PB_1\kappa(P,T) \quad (9)$$

where  $\alpha(0,T)$  represents the thermal expansivity at zero (atmospheric) pressure and is calculated from any suitable fit for the zero-pressure volume, such as equations (5) through (7) above.

Because polymer melt PVT-behavior depends only slightly on polymer molar mass above the oligomeric region, usually no information is given in the original literature for the average molar mass of the polymers.

Table 1 summarizes the polymers or copolymers considered here and the experimental ranges of pressure and temperature over which data are available. In Table 2 the Tait-equation functions, with parameters obtained from the fit, are given for 90 polymer or copolymer melts.

# UPPER CRITICAL (UCST) AND LOWER CRITICAL (LCST) SOLUTION TEMPERATURES OF BINARY POLYMER SOLUTIONS

Christian Wohlfarth

Liquid-liquid demixing in solutions of polymers in low molar mass solvents is not a rare phenomenon. Demixing depends on concentration, temperature, pressure, molar mass and molar mass distribution function of the polymer, chain branching and end groups of the polymer, the chemical nature of the solvent, isotope substitution in solvents or polymers, chemical composition of copolymers and its distributions, and other variables. Phase diagrams of polymer solutions can therefore show a quite complicated behavior when they have to be considered in detail (see Ref. 1a).

Polymer solutions can undergo demixing when cooling a homogeneous solution as well as when heating such a solution. The corresponding cloud-point curves show a maximum (UCST behavior) or a minimum (LCST behavior). For common polymer solutions, the LCST region is at higher temperatures (in many cases near the critical temperature of the solvent) than the UCST region. The temperature range between both extrema provides the essential information where the one-phase region of a polymer solution can be found. In the case of monodisperse polymers the extrema are equal to the critical points. However, in the case of polydisperse polymers with distribution functions, these extrema are threshold temperatures whereas the critical point shifts to higher concentrations on the shoulder of the cloud-point curve. Usually, the critical concentration is much more strongly influenced than the critical temperature. Thus, the table below does not distinguish between threshold and critical temperatures.

UCST and LCST values depend somewhat on pressure. LCST values in the table are usually given at the vapor pressure of the solvent at this temperature. UCST values are measured in most cases at normal pressure; data at higher pressures are neglected here. The interested reader can find such information, for example, in Refs. 76, 84, 104, 157, 165, 177, 185-187, or 192.

However, UCST and LCST values of a given polymer/solvent pair depend strongly on the molar mass of the polymer. In the case of monodisperse polymers, this dependency can be described in good approximation by the so-called Shultz-Flory plot (see Refs. 6 and 8):

$$\frac{1}{T_{\text{crit}}} = \frac{1}{\theta} \left[ 1 + \text{const.} \left( \frac{1}{\sqrt{r}} - \frac{1}{2r} \right) \right] \quad (1)$$

where  $r$  denotes the number of segments of a polymer (being proportional to the degree of polymerization or to the molar mass or molar volume of the polymer). Extrapolation to  $r \rightarrow \infty$ , i.e., to infinite molar mass, leads to the value of the  $\theta$ -temperature. This  $\theta$ -temperature is the highest temperature for UCST behavior or the lowest temperature for LCST behavior and a given polymer/solvent pair. In the case of polydisperse polymers, the segment number in equation (1) is to be replaced by its weight average,  $r_w$  (related to  $M_w$ ). The constant in equation (1) reflects further thermodynamic properties of the given polymer/solvent pair, but should not depend on molar mass. A detailed discussion can be found in Ref. 1b.

The printed table in the *Handbook* provides only one data line for a given polymer/solvent pair and does not show the molar mass dependence of UCST or LCST data. The entire table with all data at different molar masses for many of the systems is given in the electronic version, however. Nevertheless, the necessary molar mass information for a system is always provided in the table by the corresponding number average,  $M_n$ , mass average,  $M_w$ , or viscosity average,  $M_\eta$ , values of the polymer as given in the original sources.

| Polymer                                                                       | $M_n/\text{g mol}^{-1}$ | $M_w/\text{g mol}^{-1}$ | $M_\eta/\text{g mol}^{-1}$ | Solvent                           | UCST/K | LCST/K | Ref |

# VAPOR PRESSURES (SOLVENT ACTIVITIES) FOR BINARY POLYMER SOLUTIONS

Christian Wohlfarth

The vapor pressure of a binary polymer solution is given by the activity of the solvent A,  $a_A$ . Solvent activities in polymer solutions are measured either by the isopiestic method applying a reference system whose solvent activity is precisely known or by determining the solvent partial pressure,  $P_A$ , and calculating the activity of the solvent by equation (1):

$$a_A = (P_A/P_A^s) \exp \left[ \frac{(B_{AA} - V_A^L)(P - P_A^s)}{RT} \right] \quad (1)$$

where  $B_{AA}$  is the second virial coefficient,  $P_A^s$  is the saturation vapor pressure, and  $V_A^L$  is the molar volume of the pure solvent A at the measuring temperature  $T$ . The exponential term is neglected in quite a lot of original papers, however, and only the reduced vapor pressures are given (such data are indicated by an asterisk in the table below). Vapor pressures of polymer solutions have been measured since the 1940s, but the amount of experimental data for polymer solutions is still relatively small in comparison to low-molecular mixtures and solutions. The data scatter with respect to temperature, concentration, molar mass, and other polymer characterization variables. Furthermore, the concentration range for measuring vapor pressures in good thermodynamic quality is often limited to the polymer mass fraction range between 0.4 and 0.85. A recent review on methods for the measurement of vapor pressures/solvent activities of polymer solutions and on related problems is given in Ref. [1]. Experimental data have been collected in several books [2-6].

The table in this *Handbook* provides data for a number of polymer solutions as smoothed values over the complete range of solvent activities between 0 (polymer mass fraction = 1) and 1 (polymer mass fraction = 0). For this purpose, the data were selected from data books [4-6] as well as from a number of original sources [7-22] which are not included in these books. The appropriate data were smoothed. The final table provides then the polymer mass fractions at given fixed solvent activities between 0.1 and 0.9. Of course, the user must keep in mind that the activity vs. concentration range of the experimental data is sometimes smaller than the below given complete range, thus the smoothed data should be used with sufficient care.

Generally, vapor pressures or solvent activities of binary polymer solutions depend on molar mass. However, for high molecular weight polymers (well above the oligomer region), this molar-mass dependence can be neglected in many cases. Therefore, the table below presents only data for polymer solutions where the number average molar mass,  $M_n$ , is in the order of  $10^5$  g/mol or even higher, therefore, the molar mass is not specified. The temperature is

stated, even though the temperature dependence of  $a_A$  is relatively small for the temperature ranges where most of the experimental data exist.

# SPECIFIC ENTHALPIES OF SOLUTION OF POLYMERS AND COPOLYMERS

Christian Wohlfarth

Enthalpies of solution or mixing, expressed as the enthalpy change per unit mass of polymer, are given in the table at infinite dilution, i.e., a very small amount of polymer and a large excess of solvent were mixed isothermally to form a homogeneous solution. By thermodynamics,  $\Delta_{\text{sol}} H_{\text{B}}^{\infty}$  or  $\Delta_{\text{M}} H_{\text{B}}^{\infty}$  are obtained from the following derivatives:

$$\Delta_{\text{sol}} H_{\text{B}}^{\infty} = \lim_{m_{\text{B}} \rightarrow 0} (\partial \Delta_{\text{sol}} h / \partial m_{\text{B}})_{P,T,m_{\text{J} \neq \text{B}}} \quad (1)$$

$$\Delta_{\text{M}} H_{\text{B}}^{\infty} = \lim_{m_{\text{B}} \rightarrow 0} (\partial \Delta_{\text{M}} h / \partial m_{\text{B}})_{P,T,m_{\text{J} \neq \text{B}}} \quad (2)$$

with a unit of J/g. Thus, they are the partial specific enthalpies of solution or mixing of the polymer B at infinite dilution where  $\Delta_{\text{sol}} h$  or  $\Delta_{\text{M}} h$  is the extensive enthalpy of the solution or mixing process.

The state of the polymer before dissolution can significantly affect the enthalpy of solution. The dissolving of a semicrystalline polymer requires an additional amount of heat associated with the disordering of crystalline regions. Consequently, its enthalpy of

solution is usually positive and depends on the degree of crystallinity of the given polymer sample. An amorphous polymer below its glass transition temperature,  $T_{\text{g}}$  (see the  $T_{\text{g}}$ -table of this Section), often dissolves with the release of heat. The enthalpy of solution of a glassy polymer is additionally dependent to some extent on the thermal history of the glass-forming process. An amorphous polymer above  $T_{\text{g}}$  can show endothermic or exothermic dissolution behavior depending on the nature of the solvent and the interaction energies involved as is the case for any enthalpy of mixing. This enthalpy of mixing is then independent of any crystalline or glassy aspects of the polymer. It can be obtained without difficulties for liquid/molten polymers mixed with a solvent. Therefore, the enthalpies given in the table are either enthalpies of solution or enthalpies of mixing, depending on the state of the polymer.

The enthalpies depend on temperature and molar mass. The necessary molar mass information for a system is provided in the table (if available) by the corresponding number average,  $M_{\text{n}}$ , mass average,  $M_{\text{w}}$ , or viscosity average,  $M_{\text{v}}$ , values of the polymer as given in the original sources. Outside the oligomer range, specific enthalpies of solution or mixing do not remarkably depend on molar mass, however. More enthalpy data of polymer-solvent systems can be found in Ref. 106.

| Polymer                                       | $M_{\text{n}}/\text{g/mol}$ | $M_{\text{w}}/\text{g/mol}$ | $M_{\text{v}}/\text{g/mol}$ | Solvent               | $T/\text{K}$ | $\Delta H_{\text{B}}^{\infty}/\text{J/g}$ | Ref. |

# SOLUBILITY PARAMETERS OF SELECTED POLYMERS

Christian Wohlfarth

The concept of cohesive energy density and solubility parameter was introduced by Hildebrand:

$$\delta^2 = \frac{\Delta U_m^{LV}}{V_m} = \frac{\Delta H_m^{LV} - RT}{V_m} \quad (1)$$

$V_m$  is the molar volume,  $\Delta U_m^{LV}$  is the molar energy of vaporization, and  $\Delta H_m^{LV}$  is the molar enthalpy of vaporization. Units for the solubility parameter are  $(\text{MPa})^{1/2} = (\text{J}/\text{cm}^3)^{1/2} = 0.4887(\text{cal}/\text{cm}^3)^{1/2}$ . The energy of vaporization is not accessible for polymers, but cohesive energy density of polymers can be determined from  $PVT$ -data. However, common ways for determining polymer solubility parameters use thermodynamic properties of polymer solutions and their relations to excess enthalpy or excess Gibbs energy per unit volume. These excess quantities are related to the (square) difference between the solubility parameters of solvents and polymers, i.e.  $(\delta_1 - \delta_2)^2$ .

$$\frac{H^E}{V} \sim (\delta_1 - \delta_2)^2 \quad \text{or} \quad \frac{G^E}{V} \sim (\delta_1 - \delta_2)^2 \quad (2)$$

Often, the Flory-Huggins solvent-polymer interaction parameter is applied instead of  $H^E$  or  $G^E$ . There are some books (Refs. 1–3) giving details for such procedures as well as extensive tables of polymer solubility parameters from which the table below is extracted. Methods for calculating solubility parameters can be found in Refs. 4–7.

# ASTRONOMICAL CONSTANTS

Victor Abalakin

The constants in this table are based originally on the set of constants adopted by the International Astronomical Union (IAU) in 1976. Updates have been made when new data were available. All values are given in SI Units; thus masses are expressed in kilograms and distances in meters.

The astronomical unit of time is a time interval of one day (1 d) equal to 86400 s. An interval of 36525 d is one Julian century (1 cy).

### Defining constants

Gaussian gravitational constant

$$k = 0.01720209895 \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}$$

Speed of light

$$c = 299792458 \text{ m s}^{-1}$$

### Primary constants

Light-time for unit distance (1 ua)

$$\tau_A = 499.004786 \text{ s}$$

Equatorial radius of Earth

$$a_e = 6378140 \text{ m}$$

Equatorial radius of Earth (IUGG value)

$$a_e = 6378136 \text{ m}$$

Dynamical form-factor for Earth

$$J_2 = 0.001082636$$

Geocentric gravitational constant

$$GE = 3.986004 \times 10^{14} \text{ m}^3 \text{ s}^{-2}$$

Constant of gravitation

$$G = 6.67428 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}$$

Ratio of mass of moon to that of Earth

$$\mu = 0.01230002$$

$$1/\mu = 81.300587$$

General precession in longitude, per Julian century, at standard epoch J2000

$$\rho = 5028''.796$$

Obliquity of the ecliptic at standard epoch J2000

$$\varepsilon = 23^\circ 26' 21''.448$$

### Derived constants

Constant of nutation at standard epoch J2000

$$N = 9''.2025$$

Unit distance ( $ua = c\tau_A$ )

$$ua = 1.49597871464 \times 10^{11} \text{ m}$$

Solar parallax ( $\pi_0 = \arcsin(a_e/ua)$ )

$$\pi_0 = 8''.794143$$

Constant of aberration for standard epoch J2000

$$\kappa = 20''.49552$$

Flattening factor for the Earth

$$f = 1/298.256 = 0.00335282$$

Heliocentric gravitational constant ( $GS = A^3 k^2 / D^2$ )

$$GS = 1.32712438 \times 10^{20} \text{ m}^3 \text{ s}^{-2}$$

Ratio of mass of sun to that of the Earth ( $S/E = (GS)/(GE)$ )

$$S/E = 332946.0$$

Ratio of mass of sun to that of Earth + moon

$$(S/E)/(1 + \mu) = 328900.56$$

Mass of the sun ( $S = (GS)/G$ )

$$S = 1.98844 \times 10^{30} \text{ kg}$$

### Ratios of mass of sun to masses of the planets

Mercury

$$6023600$$

Venus

$$408523.7$$

Earth + moon

$$328900.56$$

Mars

$$3098708$$

Jupiter

$$1047.349$$

Saturn

$$3497.898$$

Uranus

$$22902.98$$

Neptune

$$19412.24$$

## PROPERTIES OF THE SOLAR SYSTEM

The following tables give various properties of the planets and characteristics of their orbits in the solar system. Certain properties of the sun and of the earth's moon are also included.

Explanations of the column headings:

- *Mass*: mass of the planet in units of  $10^{24}$  kg
- *Radius*: radius at the equator in km
- *Density*: mean density in  $\text{g/cm}^3$
- *Flattening*: degree of oblateness, defined as  $(r_e - r_p)/r_e$ , where  $r_e$  and  $r_p$  are the equatorial and polar radii, respectively
- *Potential coefficients*: coefficients in the spherical harmonic representation of the gravitational potential  $U$  by the equation

$$U(r, \phi) = (GM/r) [1 - \sum_n (a/r)^n P_n(\sin \phi)],$$

where  $G$  is the gravitational constant,  $r$  the distance from the center of the planet,  $a$  the radius of the planet,  $M$  the mass,  $\phi$  the latitude, and  $P_n$  the Legendre polynomial of degree  $n$ .

- *Gravity*: acceleration due to gravity at the surface
- *Escape vel.*: velocity needed at the surface of the planet to escape the gravitational pull
- *Dist. to sun*: semi-major axis of the elliptical orbit in astronomical units (1 ua  $\approx 1.496 \cdot 10^8$  km)
- $e$ : eccentricity of the orbit
- *Ecliptic angle*: angle between the planetary orbit and the plane of the earth's orbit around the sun
- *Inclin.*: angle between the equatorial plane of the planet and the plane of the planetary orbit
- *Orbit period*: period of revolution around the sun measured in years
- *Rotation period*: period of rotation of the planet measured in hours. A negative value indicates retrograde rotation.
- *Albedo*: ratio of the light reflected from the planet to the light incident on it
- *No. of satellites*: Number of confirmed satellites; this includes satellites that have not been named.
- $T_{\text{sur}}$ : mean temperature at the surface
- $P_{\text{sur}}$ : pressure of the atmosphere at the surface

The last four entries in the table are *dwarf planets* as defined by the International Astronomical Union. These are bodies in orbit around the sun that are massive enough to adopt a near-spherical shape as a result of their self-gravity, but are appreciably smaller than the major planets. *Plutoids* form a subset of the dwarf plan-

ets; their orbits are larger than that of Neptune (see Ref. 9). As of 2008, the IAU has recognized the names for three plutoids: Pluto, Eris, and Makemake.

The following general information on the solar system is of interest:

Mass of the earth =  $M_e = 5.9736 \cdot 10^{24}$  kg  
 Total mass of planetary system =  $2.669 \cdot 10^{27}$  kg =  $447 M_e$   
 Total angular momentum of planetary system =  $3.148 \cdot 10^{43}$  kg m<sup>2</sup> s<sup>-1</sup>  
 Total kinetic energy of the planets =  $1.99 \cdot 10^{35}$  J  
 Total rotational energy of planets =  $0.7 \cdot 10^{35}$  J

Properties of the sun:

Mass =  $1.9884 \cdot 10^{30}$  kg =  $332943 M_e$   
 Radius =  $6.9551 \cdot 10^8$  m  
 Surface area =  $6.079 \cdot 10^{18}$  m<sup>2</sup>  
 Volume =  $1.409 \cdot 10^{27}$  m<sup>3</sup>  
 Mean density =  $1.411$  g/cm<sup>3</sup>  
 Gravity at surface =  $27398$  cm/s<sup>2</sup>  
 Escape velocity at surface =  $6.177 \cdot 10^5$  m/s  
 Effective temperature =  $5780$  K  
 Total radiant power emitted (luminosity) =  $3.8427 \cdot 10^{26}$  W  
 Surface flux of radiant energy =  $6.322 \cdot 10^7$  W/m<sup>2</sup>  
 Flux of radiant energy at the earth (Solar Constant) =  $1366.4$  W/m<sup>2</sup> (Ref. 8)

[illegible]

## SATELLITES OF THE PLANETS

This table gives characteristics of the known satellites of the planets. The parameters covered are:

- Orbital period in units of earth days. An R following the value indicates a retrograde motion.
- Distance from the planet, as measured by the semi-major axis of the orbit
- Eccentricity of the orbit
- Inclination of the satellite orbit with respect to the equator of the planet
- Mass of the satellite in kilograms
- Radius of the satellite in kilometers
- Geometric albedo, which is a measure of the fraction of incident sunlight reflected by the satellite.

Since this is a very active field of research, the Internet sites listed below should be consulted for the most recent data.

\* In June 2008 the International Astronomical Union decided on the name *plutoid* for the category of transneptunian dwarf planets. Plutoids are celestial bodies in orbit around the sun at a semimajor axis greater than that of Neptune and sufficiently massive to adopt a near-spherical shape. See <[www.iau.org/public\\_press/news/release/iau0804/](http://www.iau.org/public_press/news/release/iau0804/)>.

# MASS, DIMENSIONS, AND OTHER PARAMETERS OF THE EARTH

This table is a collection of data on various properties of the Earth. Most of the values are given in SI units. Note that 1 ua (astronomical unit) = 149,597,870 km.

## ACCELERATION DUE TO GRAVITY

The acceleration due to gravity is tabulated here as a function of latitude and height above the earth's surface. Values were calculated from the expression

$$g/(\text{m/s}^2) = 9.780356 (1 + 0.0052885 \sin^2 \phi - 0.0000059 \sin^2 2 \phi) - 0.003086 H$$

where  $\phi$  is the latitude and  $H$  is the height in kilometers.

# DENSITY, PRESSURE, AND GRAVITY AS A FUNCTION OF DEPTH WITHIN THE EARTH

This table gives the density  $\rho$ , pressure  $p$ , and acceleration due to gravity  $g$  as a function of depth below the earth's surface, as calculated from the model of the structure of the earth in Reference 1. The model assumes a radius of 6371 km for the earth. The boundary between the crust and mantle (the Mohorovicic discontinuity) is taken as 21 km, while in reality it varies considerable with location.

## OCEAN PRESSURE AS A FUNCTION OF DEPTH AND LATITUDE

The following table is based upon an ocean model which takes into account the equation of state of standard seawater and the dependence on latitude of the acceleration of gravity. The tabulated pressure value is the excess pressure over the ambient atmospheric pressure at the surface.

## PROPERTIES OF SEAWATER

In addition to the dependence on temperature and pressure, the physical properties of seawater vary with the concentration of the dissolved constituents. A convenient parameter for describing the composition is the salinity,  $S$ , which is defined in terms of the electrical conductivity of the seawater sample. The defining equation for the practical salinity is:

$$S = a_0 + a_1 K^{1/2} + a_2 K + a_3 K^{3/2} + a_4 K^2 + a_5 K^{5/2},$$

where  $K$  is the ratio of the conductivity of the seawater sample at 15°C and atmospheric pressure to the conductivity of a potassium chloride solution in which the mass fraction of KCl is 0.0324356, at the same temperature and pressure. The values of the coefficients are:

$$\begin{aligned} a_0 &= 0.0080 & a_3 &= 14.0941 \\ a_1 &= -0.1692 & a_4 &= -7.0261 \\ a_2 &= 25.3851 & a_5 &= 2.7081 \\ \Sigma a_i &= 35.0000 \end{aligned}$$

Thus when  $K = 1$ ,  $S = 35$  exactly ( $S$  is normally quoted in units of ‰, i.e., parts per thousand). The value of  $S$  can be roughly equated with the mass of dissolved material in grams per kilogram of seawater. Salinity values in the open oceans at mid latitudes typically fall between 34 and 36.

It is customary in oceanography to define the pressure at a given point as the pressure due to the column of water between that point and the surface. Thus by convention  $P = 0$  at the sea surface. To a good approximation the pressure in decibars (dbar) can be equated to the depth in meters. Thus at 45° latitude the pressure is 5000 dbar at 4902 m, 10000 dbar at 9700 m.

The first table below gives several properties of seawater as a function of temperature for a salinity of 35. The second and third give density and electrical conductivity as a function of salinity at several temperatures, and the fourth lists typical concentrations of the main constituents of seawater as a function of salinity. The final table gives the freezing point as a function of salinity and pressure.

## ABUNDANCE OF ELEMENTS IN THE EARTH'S CRUST AND IN THE SEA

This table gives the estimated abundance of the elements in the continental crust (in mg/kg, equivalent to parts per million by mass) and in seawater near the surface (in mg/L). Values represent the median of reported measurements. The concentrations of the less abundant elements may vary with location by several orders of magnitude.

## SOLAR SPECTRAL IRRADIANCE

The solar luminosity (total radiant power emitted) is  $3.86 \cdot 10^{26}$  W, of which  $1373 \text{ W/m}^2$  reaches the top of the earth's atmosphere. To a zeroth approximation the sun can be considered a black body with an effective temperature of 5780 K, which implies a peak in the radiation at around  $0.520 \text{ }\mu\text{m}$  ( $5200 \text{ }\text{\AA}$ ). The actual solar spectral emission is more complex, especially at ultraviolet and shorter wavelengths. The graph below, which was taken from Reference 1, summarizes the solar irradiance at the top of the atmosphere in the range 0.3 to  $10 \text{ }\mu\text{m}$ .

## U.S. STANDARD ATMOSPHERE (1976)

A Standard Atmosphere is a hypothetical vertical distribution of atmospheric temperature, pressure, and density that is roughly representative of year-round, midlatitude conditions. Typical uses are to serve as a basis for pressure altimeter calibrations, aircraft performance calculations, aircraft and rocket design, ballistic tables, meteorological diagrams, and various types of atmospheric modeling. The air is assumed to be dry and to obey the perfect gas law and the hydrostatic equation which, taken together, relate temperature, pressure, and density with vertical position. The atmosphere is considered to rotate with the Earth and to be an average over the diurnal cycle, the semiannual variation, and the range from active to quiet geomagnetic and sunspot conditions.

The U.S. Standard Atmosphere (1976) is an idealized, steady-state representation of mean annual conditions of the Earth's atmosphere from the surface to 1000 km at latitude 45° N, as it is assumed to exist during a period with moderate solar activity. The defining meteorological elements are sea-level temperature and pressure and a temperature-height profile to 1000 km. The 1976 Standard Atmosphere uses the following sea-level values that have been standard for many decades:

Temperature — 288.15 K (15 °C)  
Pressure — 101325 Pa (1013.25 mbar, 760 mm of Hg, or 29.92 in. of Hg)

Density — 1225 g/m<sup>3</sup> (1.225 g/L)  
Mean molar mass — 28.964 g/mol

The parameters included in this condensed version of the U.S. Standard Atmosphere are:

$Z$  — Height (geometric) above mean sea level in meters  
 $T$  — Temperature in kelvins  
 $P$  — Pressure in pascals (1 Pa = 0.01 millibars)  
 $\rho$  — Density in kilograms per cubic meter (1 kg/m<sup>3</sup> = 1 g/L)  
 $n$  — Number density in molecules per cubic meter  
 $\nu$  — Mean collision frequency in collisions per second  
 $l$  — Mean free path in meters  
 $\eta$  — Absolute viscosity in pascal seconds (1 Pa s = 1000 cP)  
 $k$  — Thermal conductivity in joules per meter second kelvin (W/m K)  
 $\nu_s$  — Speed of sound in meters per second  
 $g$  — Acceleration of gravity in meters per second square

The sea-level composition (percent by volume) is taken to be:

|                          |                          |
|--------------------------|--------------------------|
| N <sub>2</sub> — 78.084% | He — 0.000524            |
| O <sub>2</sub> — 20.9476 | Kr — 0.000114            |
| Ar — 0.934               | Xe — 0.0000087           |
| CO <sub>2</sub> — 0.0314 | CH <sub>4</sub> — 0.0002 |
| Ne — 0.001818            | H <sub>2</sub> — 0.00005 |

The  $T$  and  $P$  columns for the troposphere and lower stratosphere were generated from the following formulas:

|                                            | $T/K$                      | $P/\text{Pa}$                       |
|--------------------------------------------|----------------------------|-------------------------------------|
| $H \leq 11000 \text{ m}$                   | $288.15 - 0.0065 H$        | $101325(288.15/T)^{-5.25577}$       |
| $11000 \text{ m} < H \leq 20000 \text{ m}$ | 216.65                     | $22632 e^{-0.00015768832(H-11000)}$ |
| $20000 \text{ m} < H \leq 32000 \text{ m}$ | $216.65 + 0.0010(H-20000)$ | $5474.87(216.65/T)^{34.16319}$      |

where  $H = rZ/(r + Z)$  is the geopotential height in meters and  $r$  is the mean Earth radius at 45° N latitude, taken as 6356766 m. For altitudes up to 32 km,  $\rho = 0.003483677(P/T)$  in the units used here. Formulas for the other quantities may be found in the references.

## GEOGRAPHICAL AND SEASONAL VARIATION IN SOLAR RADIATION

This table gives the amount of solar radiation reaching a unit area at the top of the earth's atmosphere per day as a function of latitude and approximate date. It is based upon a solar constant (total energy per unit area at the earth's average orbital distance) of 1373 W/m<sup>2</sup>. Absorption of radiation by the atmosphere is not taken into consideration.

## INFRARED ABSORPTION BY THE EARTH'S ATMOSPHERE

Several constituents of the earth's atmosphere absorb infrared radiation. At ground level the strongest absorbers are  $\text{H}_2\text{O}$  and  $\text{CO}_2$ , but 30 to 40 other compounds can make significant contributions. The centers of the most important absorption bands are listed below:

| Molecule             | Vibrational mode          | Band center in $\text{cm}^{-1}$ |
|----------------------|---------------------------|---------------------------------|
| $\text{H}_2\text{O}$ | Bend                      | 1595                            |
| $\text{H}_2\text{O}$ | Symmetric O-H stretch     | 3657                            |
| $\text{H}_2\text{O}$ | Antisymmetric O-H stretch | 3756                            |
| $\text{CO}_2$        | Bend                      | 667                             |
| $\text{CO}_2$        | Antisymmetric C-O stretch | 2349                            |
| $\text{O}_3$         | Bend                      | 701                             |
| $\text{O}_3$         | Antisymmetric O-O stretch | 1042                            |
| $\text{O}_3$         | Symmetric O-O stretch     | 1103                            |
| $\text{N}_2\text{O}$ | Bend                      | 589                             |
| $\text{N}_2\text{O}$ | N-O stretch               | 1285                            |
| $\text{N}_2\text{O}$ | N-N stretch               | 2224                            |
| $\text{CO}$          | C-O stretch               | 2143                            |
| $\text{CH}_4$        | Degenerate deformation    | 1306                            |
| $\text{CH}_4$        | Degenerate stretch        | 3019                            |

The HITRAN Molecular Spectroscopy Database (References 1 and 2) is a compilation of wavenumbers and intensities of more than 1.7 million spectral lines of atmospheric constituents. It is a valuable resource for calculating transmission of the atmosphere, radiative energy transfer, and other phenomena. The graph below, which was supplied by Walter J. Lafferty (Reference 3), gives the transmittance of the atmosphere for one set of conditions.

Transmittance of U.S. Standard Atmosphere at Ground Level for a Path of 1 km at 296 K

## ATMOSPHERIC CONCENTRATION OF CARBON DIOXIDE, 1958–2004

The data in this table were taken at the Mauna Loa Observatory in Hawaii and represent averages adjusted to the 15th of each month. The last column gives the average over the year. The concentration of CO<sub>2</sub> is given in parts per million by volume. Data from other measurement sites may be found in Reference 1.

The first graph illustrates the seasonal variation of CO<sub>2</sub> concentration and the steady increase over the last 45 years. The second graph summarizes the growth in the emissions of CO<sub>2</sub> into the atmosphere as a result of burning of fossil fuels (Reference 2).

## MEAN TEMPERATURES IN THE UNITED STATES, 1900–1992

Historical records of atmospheric temperatures have been analyzed to obtain mean temperatures in °C for 23 climatically distinct regions of the United States. The table below gives the average over these 23 regions, which cover completely the contiguous 48 states. Data for the individual regions and for other parts of the world may be found in the references.

The data are presented as temperature anomalies, i.e., as deviations (in °C) from the average temperature at each individual recording station over a 1961–1990 reference period. The trend in the temperature anomaly thus gives an indication of the long-term variation in average temperatures.

CY Mean: Calendar year mean (January–December)

Winter: December–February

Spring: March–May

Summer: June–August

Fall: September–November

## GLOBAL TEMPERATURE TREND, 1856–2004

This table and graph summarize the trend in annual mean global surface temperature from 1856 to 2004. The values were calculated from mean temperature anomalies by assuming an absolute global mean of 14.00°C, which is the best estimate for the 1961–1990 period. The 95% confidence interval for the annual mean temperature values since 1951 is  $\pm 0.12^{\circ}\text{C}$ ; prior to 1900 this interval is  $\pm 0.18^{\circ}\text{C}$ .

Annual Mean Global Temperature in  $^{\circ}\text{C}$

# ATMOSPHERIC ELECTRICITY

Hans Dolezalek, Hannes Tammet, John Latham, and Martin A. Uman

## I. SURVEY AND GLOBAL CIRCUIT

Hans Dolezalek

The science of atmospheric electricity originated in 1752 by an experimental proof of a related earlier hypothesis (that lightning is an electrical event). In spite of a large effort, in part by such eminent physicists as Coulomb, Lord Kelvin, and many others, an overall, proven theory able to generate models with sufficient resolution is not yet available. Generally accepted and encompassing text books are now more than 20 years old. The voluminous proceedings of the, so far, nine international atmospheric electricity conferences (1954 to 1992) give much valuable detail and demonstrate impressive progress, as do a number of less comprehensive textbooks published in the last 20 years, but a general theory as indicated above is not yet created. Only now, certain related measuring techniques and mathematical possibilities are emerging.

Applications to practical purposes do exist in the field of lightning research (including the electromagnetic radiation emanating from lightning) by the establishment of lightning-location networks and by the now developing possibility to detect electrified clouds which pose hazards to aircraft. Application of atmospheric electricity to other parts of meteorology seems to be promising but so far has seldom been instituted. Because some atmospheric electric signals propagate around the earth and because of the existence of a global circuit, applications for the monitoring of global change processes and conditions are now being proposed. Significant secular changes in the global circuit would indicate a change in the global climate; the availability of many old data (about a span of 100 years) could help detect a long-term trend.

The concept of the "global circuit" is based on the theory of the global spherical capacitor: both, the solid (and liquid) earth as one electrode, and the high atmospheric layers (about the ionosphere) as the other, are by orders of magnitude more electrically conductive than the atmosphere between them. According to the "classical picture of atmospheric electricity", this capacitor is continuously charged by the common action of all thunderstorms to a d.c. voltage difference of several hundred kilovolts, the earth being negative. The much smaller but still existing conductivity of the atmosphere allows a current flowing from the ionosphere to the ground, integrated for all sink areas of the whole earth, of the order of 1.5 kA. In this way, a global circuit is created with many generators and sink-areas both interspaced and distributed over the whole globe, all connected to two nodes: ionosphere and ground. Within the scope of the global circuit, for each location, the current density (order of several pA/m<sup>2</sup>) is determined by the voltage difference between ionosphere and ground (which is the same for all locations but varying in time) and the columnar resistance reaching from the ground up to the ionosphere (in the order of  $10^{17} \Omega\text{m}^2$ ).

Natural processes, especially meteorological processes and some human activity, which produce or move electric charges ("space charges") or affect the ion distribution, constitute local generators and thereby "local circuits", horizontally and/or in parallel or antiparallel to the local part of the global circuit. In many cases, the local currents are much stronger than the global ones, making the measurement of the global current at a given location and/or during a period of time very difficult or, often, impossible. The strongest local circuits usually occur with certain weather conditions (precipitation, fog, high wind, blown-up dust or snow, heavy cloudiness) which make measurement of the global circuit impossible everywhere: but even in their absence local generators exist in varying magnitudes and of different characters. The separation

of the local and global shares in the measured values of current density is a central problem of the science of atmospheric electricity. Aerological measurements are of high value in this regard.

The above description is within the "classical picture" of atmospheric electricity, a group of hypotheses to explain the electrification of the atmosphere. It is probably fundamentally correct but certainly not complete; it has not yet been confirmed by systems of measurements resulting in no inner contradictions. In particular, extraterrestrial influences must be permitted; their general significance is still under debate.

Within this "classical picture" a kind of electric standard atmosphere may be constructed as shown in Table 1.

Values with a star, \*, are rough average values from measurement. A star in parentheses, (\*), points to a typical value from one or a few measurements. All other values have been calculated from starred values, under the assumption that at 2 km 50% and at 12 km 90% of the columnar resistance is reached. Voltage drop along one of the partial columns can be calculated by subtracting the value for the lower column from that of the upper one. Columnar resistances, conductances, and capacitances are valid for that particular part of the column which is indicated at the left. Capacitances are calculated with the formula for plate capacitors, and this fact must be considered also for the time constants for columns.

According to measurements,  $U$ , the potential difference between 0 m and 65 km may vary by a factor of approximately 2. The total columnar resistance,  $R_c$ , is estimated to vary up to a factor of 3, the variation being due to either reduction of conductivity in the exchange layer (about lowest 2 km of this table) or to the presence of high mountains; in both cases the variation is caused in the troposphere. Smaller variations in the stratosphere and mesosphere are being discussed because of aerosols there. The air-earth current density in fair weather varies by a factor of 3 to 6 accordingly. Conductivity near the ground varies by a factor of about 3 but only decreasing; increase of conductivity due to extraordinary radioactivity is a singular event. The field strength near the ground varies as a consequence of variations of air-earth current density and conductivity from about 1/3 to about 10 times of the value quoted in the table. Conductivity near the ground shows a diurnal and an annual variation which depends strongly on the locality: air-earth current density shows a diurnal and annual variation because the earth-ionosphere potential difference undergoes such variations, and also because the columnar resistance is supposed to have a diurnal and probably an annual variation.

Conductivities and air-earth current densities on high mountains are greater than at sea level by factors of up to 10. Conductivity decreases when atmospheric humidity increases. Values for space charges are not quoted because measurements are too few to allow calculation of average values. Values of parameters over the oceans are still rather uncertain.

Theoretically, in fair-weather conditions, Ohm's law must be fulfilled for the electric field, the conduction current density, and the electrical conductivity of the atmosphere. Deviations point to shortcomings in the applied measuring techniques. Data which are representative for a large area (in the extreme, "globally representative data", i.e. data on the global circuit), can on the ground be obtained only by stations on an open plane and only if local generators are either small or constant or are independently measured. Certain measurements with instrumented aircraft provide globally representative information valid for the period of the actual measurement.

**TABLE 1. Electrical Parameters of the Clear (Fair-Weather) Atmosphere, Pertinent to the Classical Picture of Atm. Electricity (Electric Standard Atmosphere)**

| Part of atmosphere for which the values are calculated (elements are in free, cloudless atmosphere) | Currents, $I$ , in A; and current densities, $i$ , in A/m <sup>2</sup> | Potential differences, $U$ , in V; field strength $E$ in V/m; $U = 0$ at sea level | Resistances, $R$ , in $\Omega$ ; columnar resistances, $R_c$ , in $\Omega$ m <sup>2</sup> and resistivities, $\rho$ , in $\Omega$ m | Conductances, $G$ , in $\Omega^{-1}$ ; columnar conductances $G_c$ , in $\Omega^{-1}$ m <sup>2</sup> ; total conductivities, $\gamma$ , in $\Omega^{-1}$ m <sup>-1</sup> | Capacitances, $C$ , in F; columnar capacitances, $C_c$ , in F m <sup>-2</sup> and capacitivities, $\epsilon$ , in F m <sup>-1</sup> | Time constants $\tau$ , in seconds |
|-----------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| Volume element at about sea level, 1 m <sup>3</sup>                                                 | $i = 3 \times 10^{-12}$                                                | $E_0 = 1.2 \times 10^{2*}$                                                         | $\rho_0 = 4 \times 10^{13}$                                                                                                         | $\gamma_0 = 2.5 \times 10^{-14}$                                                                                                                                         | $\epsilon_0 = 8.9 \times 10^{-12*}$                                                                                                 | $\tau_0 = 3.6 \times 10^2$         |
| Lower column of 1 m <sup>2</sup> cross section from sea level to 2 km height                        | $i = 3 \times 10^{-12}$                                                | At upper end: $U_1 = 1.8 \times 10^5$                                              | $R_{c1} = 6 \times 10^{16}$                                                                                                         | $G_{c1} = 1.7 \times 10^{-17}$                                                                                                                                           | $C_{c1} = 4.4 \times 10^{-15}$                                                                                                      | $\tau_{c1} = 2.6 \times 10^2$      |
| Volume element at about 2 km height, 1 m <sup>3</sup>                                               | $i = 3 \times 10^{-12}$                                                | $E_2 = 6.6 \times 10^1$                                                            | $\rho_2 = 2.2 \times 10^{13(*)}$                                                                                                    | $\gamma_2 = 4.5 \times 10^{-14}$                                                                                                                                         | $\epsilon_2 = 8.9 \times 10^{-12*}$                                                                                                 | $\tau_2 = 2 \times 10^2$           |
| Center column of 1 m <sup>2</sup> cross section from 2 to 12 km                                     | $i = 3 \times 10^{-12}$                                                | At upper end: $U_m = 3.15 \times 10^5$                                             | $R_{cm} = 4.5 \times 10^{16}$                                                                                                       | $G_{cm} = 5 \times 10^{-17}$                                                                                                                                             | $C_{cm} = 8.8 \times 10^{-16}$                                                                                                      | $\tau_{cm} = 1.8 \times 10^1$      |
| Volume element at about 12 km height, 1 m <sup>3</sup>                                              | $i = 3 \times 10^{-12}$                                                | $E_{12} = 3.9 \times 10^0$                                                         | $\rho_{12} = 1.3 \times 10^{12(*)}$                                                                                                 | $\gamma_{12} = 7.7 \times 10^{-13}$                                                                                                                                      | $\epsilon_{12} = 8.9 \times 10^{-12}$                                                                                               | $\tau_{12} = 1.2 \times 10^1$      |
| Upper column of 1 m <sup>2</sup> cross section from 12 to 65 km height                              | $i = 3 \times 10^{-12}$                                                | At upper end: $U_u = 3.5 \times 10^5$                                              | $R_{cu} = 1.5 \times 10^{16}$                                                                                                       | $G_{cu} = 2.5 \times 10^{-17}$                                                                                                                                           | $C_{cu} = 1.67 \times 10^{-16}$                                                                                                     | $\tau_{cu} = 6.7 \times 10^0$      |

Note: All currents and fields listed are part of the global circuit, i.e., circuits of local generators are not included. Values are subject to variations due to latitude and altitude of the point of observation above sea level, locality with respect to sources of disturbances, meteorological and climatological factors, and man-made changes. For more explanations, see text.

## II. AIR IONS

### Hannes Tammet

The term "air ions" signifies all airborne particles which are the carriers of the electrical current in the air and have drift velocities determined by the electric field.

The probability of electrical dissociation of molecules in the atmospheric air under thermodynamic equilibrium is near to zero. The average ionization at the ground level over the ocean is  $2 \cdot 10^6$  ion pairs  $\text{m}^{-3}\text{s}^{-1}$ . This ionization is produced mainly by cosmic rays. Over the continents the ionizing radiation from soil and from radioactive substances in the air each add about  $4 \cdot 10^6 \text{ m}^{-3}\text{s}^{-1}$ . The total average ionization rate of  $10^7 \text{ m}^{-3}\text{s}^{-1}$  is equivalent to  $17 \mu\text{R/h}$  which is a customary expression of the background level of the ionizing radiations. The ionization rate over the ground varies in space due to the radioactivity of soil, and in time depending on the exchange of air between the atmosphere and radon-containing soil. Radioactive pollution increases the ionization rate. A temporary increase of about 10 times was registered in Sweden after the Chernobyl accident in 1986. The emission of  $\text{Kr}^{85}$  from nuclear power plants can noticeably increase the global ionization rate in the next century. The ionization rate decreases with altitude near the ground and increases at higher altitudes up to 15 km, where it has a maximum of about  $5 \cdot 10^7 \text{ m}^{-3}\text{s}^{-1}$ . Solar X-ray and extreme UV radiation cause a new increase at altitudes over 60 km.

Local sources of air ions are point discharges in strong electric fields, fluidization of charged drops from waves, etc.

The enhanced chemical activity of an ion results in a chain of ion-molecule reactions with the colliding neutrals, and, in the first microsecond of the life of an air ion, a charged molecular cluster called the *cluster ion* is formed. According to theoretical calculations

in the air free from exotic trace gases the following cluster ions should be dominant:

A measurable parameter of air ions is the electrical mobility  $k$ , characterizing the drift velocity in the unit electric field. The mobility is inversely proportional to the density of air, and the results of measurements are as a rule reduced to normal conditions. According to mobility the air ions are called: fast or small or light ions with mobility  $k > 5 \cdot 10^{-5} \text{ m}^2\text{V}^{-1}\text{s}^{-1}$ , intermediate ions, and slow or large or heavy ions with mobility  $k > 10^{-6} \text{ m}^2\text{V}^{-1}\text{s}^{-1}$ . The boundary between intermediate and slow ions is conventional.

Cluster ions are fast ions. The masses of cluster ions may be measured with mass spectrometers, but the possible ion-molecule reactions during the passage of the air through nozzles to the vacuum chamber complicate the measurement. Mass and mobility of cluster ions are highly correlated. The experimental results<sup>5</sup> can be expressed by the empirical formula

$$m \approx \frac{850 \text{ u}}{[0.3 + k / (10^{-4} \text{ m}^2\text{V}^{-1}\text{s}^{-1})]^3}$$

where  $u$  is the unified atomic mass unit.

The value of the transport cross-section of a cluster ion is needed to calculate its mobility according to the kinetic theory of Chapman and Enskog. The theoretical estimation of transport cross-sections is rough and cannot be used to identify the chemi-

cal structures of cluster ions. Mass spectrometry is the main technique of identification of cluster ions.<sup>2</sup>

Märk and Castleman<sup>4</sup> presented an overview of over 1000 publications on the experimental studies of cluster ions. Most of them present information about ions of millisecond age range. The low concentration makes it difficult to get detailed information about masses and mobilities of the natural atmospheric ions at ground level. The results of a 1-year continuous measurement<sup>6</sup> are as follows:

|                                | + ions | - ions | unit                                          |
|--------------------------------|--------|--------|-----------------------------------------------|
| Average mobility               | 1.36   | 1.56   | $10^{-4}\text{m}^2\text{V}^{-1}\text{s}^{-1}$ |
| The corresponding mass         | 190    | 130    | u                                             |
| The corresponding diameter     | 0.69   | 0.61   | nm                                            |
| The average concentration      | 400    | 360    | $10^6\text{m}^{-3}$                           |
| The corresponding conductivity | 8.7    | 9.0    | fS                                            |

The distribution of tropospheric cluster ions according to the mobility and estimated mass is depicted in Figure 1.

The problems and results of direct mass spectrometry of natural cluster ions are analyzed by Eisele<sup>2</sup> for ground level and by Meyerott, Reagan and Joiner<sup>5</sup> for stratospheric measurements. Air ions in the high atmosphere are a subject of ionospheric physics.

During its lifetime (about 1 min), a cluster ion at ground level collides with nearly  $10^{12}$  molecules. Thus the cluster ions are able to concentrate trace gases of very low concentration if they have an extra high electron or proton affinity. For example, Eisele<sup>2</sup> demon-

strated that a considerable fraction of positive atmospheric cluster ions in the unpolluted atmosphere at ground level probably consist of a molecule derived from pyridine. The concentration of these constituents is estimated to be about  $10^{-12}$ . Therefore, air-ion mass and mobility spectrometry is considered as a promising technique for trace analysis in the air. Mass and mobility spectrometry of millisecond-age air ions has been developed as a technique of chemical analysis known as "plasma chromatography".<sup>1</sup> The sensitivity of the detection grows with the age of the cluster ions measured.

The mechanisms of annihilation of cluster ions are ion-ion recombination (on the average 3%) and sedimentation on aerosol particles (on the average 97% of cluster ions at ground level). The result of the combination of a cluster ion and neutral particle is a charged particle called an *aerosol ion*. In conditions of detailed thermodynamic equilibrium the probability that a spherical particle of diameter  $d$  carries  $q$  elementary charges is calculated from the Boltzmann distribution:

$$p_q(d) = (2\pi d/d_0)^{1/2} \exp(-q^2 d_0/2d)$$

where  $d_0 = 115$  nm (at  $18^\circ\text{C}$ ). The supposition about the detailed equilibrium is an approximation and the formula is not valid for particles less than  $d_0$ . On the basis of numerical calculations by Hoppel and Frick<sup>3</sup> the following charge probabilities can be derived:

| $d$          | 3     | 10   | 30  | 100 | 300 | 1000 | 3000 | nm                                            |
|--------------|-------|------|-----|-----|-----|------|------|-----------------------------------------------|
| $P_0$        | 98    | 90   | 70  | 42  | 24  | 14   | 8    | %                                             |
| $P_{-1}+P_1$ | 2     | 10   | 30  | 48  | 41  | 25   | 15   | %                                             |
| $P_{-2}+P_2$ | 0     | 0    | 0   | 10  | 23  | 21   | 14   | %                                             |
| $P_{q>2}$    | 0     | 0    | 0   | 0   | 12  | 40   | 63   | %                                             |
| $k_1$        | 15000 | 1900 | 250 | 28  | 5.1 | 1.11 | 0.33 | $10^{-9}\text{m}^2\text{V}^{-1}\text{s}^{-1}$ |

FIGURE 1. Average mobility and mass spectra of natural tropospheric cluster ions. Concentrations of the mobility fractions were measured in a rural site every 5 min over 1 year.<sup>6</sup> Ion mass is estimated according to the above empirical formula.

FIGURE 2. Mobility and size spectra of tropospheric aerosol ions.<sup>6</sup> The wide bars mark the fraction concentrations theoretically estimated on the basis of the standard size distribution of tropospheric aerosol. The pin bars with head + and - mark average values of positive and negative aerosol ion fraction concentrations measured in a rural site every 5 min during 4 months.

The last line of the table presents the mobility of a particle carrying one elementary charge. The distribution of the atmospheric aerosol ions over mobility is demonstrated in Figure 2.

Although the concentration of aerosol in continental air at ground level is an order of magnitude higher than the concentration of cluster ions, the mobilities of aerosol ions are so small that their percentage in air conductivity is less than 1%.

A specific class of aerosol ions are condensed aerosol ions produced as a result of the condensation of gaseous matter on the cluster ions. In aerosol physics the process is called ion-induced nucleation; it is considered as one among the processes of gas-to-particle conversion. The condensed aerosol ions have an inherent charge. Their sizes and mobilities are between the sizes and mobilities of cluster ions and of ordinary aerosol ions. Water and standard constituents of atmospheric air are not able to condense on the cluster ions in the real atmosphere. Thus the concentration of condensed aerosol ions depends on the trace constituents in the air and is very low in unpolluted air. Knowledge about condensed aerosol ions is poor because of measurement difficulties.

## III. THUNDERSTORM ELECTRICITY

**John Latham**

The development of improved radar techniques and instruments for in-cloud electrical and physical measurements, coupled with a much clearer recognition by the research community that establishment of the mechanism or mechanisms responsible for electric field development in thunderclouds, culminating in lightning, is inextricably linked to the concomitant dynamical and microphysical evolution of the clouds, has led to significant progress over the past decade.

Field studies indicate that in most thunderclouds the electrical development is associated with the process of glaciation, which can occur in a variety of incompletely understood ways. In the absence of ice, field growth is slow, individual hydrometeor charges are low, and lightning is produced only rarely. Precipitation — in the solid form, as graupel — also appears to be a necessary ingredient for significant electrification, as does significant convective activity and mixing between the clouds and their environments, via entrainment.

Increasingly, the view is being accepted that charge transfer leading to field-growth is largely a consequence of rebounding collisions between graupel pellets and smaller vapor-grown ice crystals, followed by the separation under gravity of these two types

of hydrometeor. These collisions occur predominantly within the temperature range  $-15$  to  $-30^{\circ}\text{C}$ , and for significant charge transfer need to occur in the presence of supercooled cloud droplets.

The field evidence is inconsistent with an inductive mechanism, and extensive laboratory studies indicate that the principal charging mechanism is non-inductive and associated — in ways yet to be identified — with differences in surface characteristics of the interacting hydrometeors.

Laboratory studies indicate that the two most favored sites for corona emission leading to the lightning discharge are the tips of ephemeral liquid filaments, produced during the glancing collisions of supercooled raindrops, and protuberances on large ice crystals or graupel pellets. The relative importance of these alternatives will depend on the hydrometeor characteristics and the temperature in the regions of strongest fields; these features are themselves dependent on air-mass characteristics and climatological considerations.

A recently identified but unresolved question is why, in continental Northern Hemisphere thunderclouds at least, the sign of the charge brought to ground by lightning is predominantly negative in summer but more evenly balanced in winter.

## IV. LIGHTNING

**Martin A. Uman**

From both ground-based weather-station data and satellite measurements, it has been estimated that there are about 100 lightning discharges, both cloud and ground flashes, over the whole earth each second; representing an average global lightning flash density of about  $6\text{ km}^{-2}\text{yr}^{-1}$ . Most of this lightning occurs over the earth's land masses. For example, in central Florida, where thunderstorms occur about 90 days/yr, the flash density for discharges to earth is about  $15\text{ km}^{-2}\text{yr}^{-1}$ . Some tropical areas of the earth have thunderstorms up to 300 days/yr.

Lightning can be defined as a transient, high-current electric discharge whose path length is measured in kilometers and whose most common source is the electric charge separated in the ordinary thunderstorm or cumulonimbus cloud. Well over half of all lightning discharges occur totally within individual thunderstorm clouds and are referred to as intracloud discharges. Cloud-to-ground lightning, however, has been studied more extensively than any other lightning form because of its visibility and its more practical interest. Cloud-to-cloud and cloud-to-air discharges are less common than intracloud or cloud-to-ground lightning.

Lightning between the cloud and earth can be categorized in terms of the direction of motion, upward or downward, and the sign of the charge, positive or negative, of the developing discharge (called a *leader*) which initiates the overall event. Over 90% of the worldwide cloud-to-ground discharges is initiated in the thundercloud by downward-moving negatively charged leaders and subsequently results in the lowering of negative charge to earth. Cloud-to-ground lightning can also be initiated by downward-moving positive leaders, less than 10% of the worldwide cloud-to-ground lightning being of this type although the exact percentage is a function of season and latitude. Lightning between cloud and ground can also be initiated by leaders which develop upward from the earth. These upward-initiated discharges are relatively rare, may be of either polarity, and generally occur from mountaintops and tall man-made structures.

We discuss next the most common type of cloud-to-ground lightning. A negative cloud-to-ground discharge or *flash* has an overall duration of some tenths of a second and is made up of vari-

ous components, among which are typically three or four high-current pulses called *strokes*. Each stroke lasts about a millisecond, the separation time between strokes being typically several tens of milliseconds. Such lightning often appears to “flicker” because the human eye can just resolve the individual light pulse associated with each stroke. A drawing of the components of a negative cloud-to-ground flash is found in Figure 3. Some values for salient parameters are found in Table 1. The negatively charged *stepped leader* initiates the first stroke in a flash by propagating from cloud to ground through virgin air in a series of discrete steps. Photographically observed leader steps in clear air are typically 1  $\mu$ s in duration and tens of meters in length, with a pause time between steps of about 50  $\mu$ s. A fully developed stepped leader lowers up to 10 or more coulombs of negative cloud charge toward ground in tens of milliseconds with an average downward speed of about  $2 \times 10^5$  m/s. The average leader current is in the 100 to 1000 A range. The steps have pulse currents of at least 1 kA. Associated with these currents are electric- and magnetic-field pulses with widths of about 1  $\mu$ s or less and risetimes of about 0.1  $\mu$ s or less. The stepped leader, during its trip toward ground, branches in a downward direction, resulting in the characteristic downward-branched geometrical structure commonly observed. The electric potential of the bottom of the negatively charged leader channel with respect to ground has a magnitude in excess of  $10^7$  V. As the leader tip nears ground, the electric field at sharp objects on the ground or at irregularities of the ground itself exceeds the breakdown value of air, and one or more upward-moving discharges (often called upward leaders) are initiated from those points, thus beginning the *attachment process*. An understanding of the physics of the attachment process is central to an understanding of the operation of lightning protection of ground-based objects and the effects of lightning on humans and animals, since it is the attachment process that determines where the lightning connects to objects on the ground and the value of the early currents which flow. When one of the upward-moving discharges from the ground (or from a lightning rod or an individual) contacts the tip of the downward-moving stepped leader, typically some tens of meters above the ground, the leader tip is effectively connected to ground potential. The negatively charged leader channel is then discharged to earth when a ground potential wave, referred to as the first *return stroke*, propagates continuously up the leader path. The upward speed of a return stroke near the ground is typically near one third the speed of light, and the speed decreases with height. The first return stroke produces a peak current near ground of typically 30 kA, with a time from zero to peak of a few microseconds. Currents measured at the ground fall to half of the peak value in about 50  $\mu$ s, and currents of the order of hundreds of amperes may flow for times of a few milliseconds up to several hundred milliseconds. The longer-lasting currents are known as *continuing currents*. The rapid release of return stroke energy heats the leader channel to a temperature near 30,000 K and creates a high-pressure channel which expands and generates the shock waves that eventually become thunder, as further discussed later. The return stroke effectively lowers to ground the charge originally deposited onto the stepped-leader channel and additionally initiates the lowering of other charges which may be available to the top of its channel. First return-stroke electric fields exhibit a microsecond scale rise to peak with a typical peak value of 5 V/m, normalized to a distance of 100 km by an inverse distance relationship. Roughly half of the field rise to peak, the so-called “fast transition”, takes place in tenths of a microsecond, an observation that can only be made if the field propagation is over a highly conducting surface such as salt water.

After the first return-stroke current has ceased to flow, the flash, including charge motion in the cloud, may end. The lightning is then called a single-stroke flash. On the other hand, if additional charge is made available to the top of the channel, a continuous or *dart leader* may propagate down the residual first-stroke channel at a typical speed of about  $1 \times 10^7$  m/s. The dart leader lowers a charge of the order of 1 C by virtue of a current of about 1 kA. The dart leader then initiates the second (or any subsequent) return stroke. Subsequent return-stroke currents generally have faster zero-to-peak rise times than do first-stroke currents, but similar maximum rates of change, about 100 kA/ $\mu$ s. Some leaders begin as dart leaders, but toward the end of their trip toward ground become stepped leaders. These leaders are known as *dart-stepped leaders* and may have different ground termination points (and separate upward leaders) from the first stroke. Most often the dart-stepped leaders are associated with the second stroke of the flash. Nearly half of all flashes exhibit more than one termination point on ground with the distance between separate terminations being up to several kilometers. Subsequent return-stroke radiated electric and magnetic fields are similar to, but usually a factor of two or so smaller, than first return-stroke fields. About one third of all multiple-stroke flashes has at least one subsequent stroke which is larger than the first stroke.

Cloud-to-ground flashes that lower positive charge, though not common, are of considerable practical interest because their peak currents and total charge transfer can be much larger than for the more common negative ground flash. The largest recorded peak currents, those in the 200- to 300-kA range, are due to the return strokes of positive lightning. Such positive flashes to ground are initiated by downward-moving leaders which do not exhibit the distinct steps of their negative counterparts. Rather, they show a luminosity which is more or less continuous but modulated in intensity. Positive flashes are generally composed of a single stroke followed by a period of continuing current. Positive flashes are probably initiated from the upper positive charge in the thundercloud charge dipole when that cloud charge is horizontally separated from the negative charge beneath it, the source of the usual negative cloud-to-ground lightning. Positive flashes are relatively common in winter thunderstorms (snow storms), which produce few flashes overall, and are relatively uncommon in summer thunderstorms. The fraction of positive lightning in summer thunderstorms apparently increases with increasing latitude and with increasing height of the ground above sea level.

Distant lightning return stroke fields are often referred to as sferics (called “atmospherics” in the older literature). The peak in the sferics frequency spectrum is near 5 kHz due to the bipolar or ringing nature of the distant return-stroke electromagnetic signal and to the effects of propagation.

Thunder, the acoustic radiation associated with lightning, is sometimes divided into the categories “audible”, sounds that one can hear, and “infrasonic”, below a few tens of hertz, a frequency range that is inaudible. This division is made because it is thought that the mechanisms that produce audible and infrasonic thunder are different. Audible thunder is thought to be due to the expansion of a rapidly heated return stroke channel, as noted earlier, whereas infrasonic thunder is thought to be associated with the conversion to sound of the energy stored in the electrostatic field of the thundercloud when lightning rapidly reduces that cloud field.

The technology of artificially initiating lightning by firing upward small rocket trailing grounded wire of a few hundred meters length has been well-developed during the past decade. Such “triggered” flashes are similar to natural upward-initiated discharges from tall structure. They often contain subsequent strokes which,

FIGURE 3. Sequence of steps in cloud-to-ground lightning.

when they occur, are similar to the subsequent strokes in natural lightning. These triggered subsequent strokes have been the subject of considerable recent research.

Also in the past 10 years or so sophisticated lightning locating equipment has been installed throughout the world. For example, all ground flashes in the U.S. are now centrally monitored for research, for better overall weather prediction, and for hazard warning for aviation, electric utilities and other lightning-sensitive facilities.

Information on lightning physics can be found in M. A. Uman, *The Lightning Discharge*, Academic Press, San Diego, 1987; on lightning death and injury in *Medical Aspects of Lightning Injury*, C. Andrews, M. A. Cooper, M. Darveniza, and D. Mackerras, Eds.,

CRC Press, 1992. Ground flash location information for the U.S., in real time or archived, is available from Geomet Data Service of Tucson, AZ, which is also a source of the names of providers of those data in other countries.

Table 2 has data for cloud-to-ground lightning discharges bringing negative charge to earth. The values listed are intended to convey a rough feeling for the various physical parameters of lightning. No great accuracy is claimed since the results of different investigators are often not in good agreement. These values may, in fact, depend on the particular environment in which the lightning discharge is generated. The choice of some of the entries in the table is arbitrary.

**TABLE 2. Data for Cloud-to-Ground Lightning Discharges**

|                                                                    | Minimum <sup>a</sup> | Representative values | Maximum <sup>a</sup> |
|--------------------------------------------------------------------|----------------------|-----------------------|----------------------|
| Stepped leader                                                     |                      |                       |                      |
| Length of step, m                                                  | 3                    | 50                    | 200                  |
| Time interval between steps, $\mu\text{s}$                         | 30                   | 50                    | 125                  |

| Time to half of peak current, $\mu\text{s}$                        | 10                   | 50                    | 250                  |
| Charge transferred excluding continuing current, coulombs          | 0.02                 | 3                     | 20                   |
| Channel length, km                                                 | 2                    | 5                     | 15                   |
| Lightning flash                                                    |                      |                       |                      |
| Number of strokes per flash                                        | 1                    | 4                     | 26                   |
| Time interval between strokes in absence of continuing current, ms | 3                    | 60                    | 100                  |
| Time duration of flash, s                                          | $10^{-2}$            | 0.5                   | 2                    |
| Charge transferred including continuing current, coulombs          | 3                    | 30                    | 200                  |

<sup>a</sup> The words maximum and minimum are used in the sense that most measured values fall between these limits.

<sup>b</sup> Speeds of propagation are generally determined from photographic data and are "two-dimensional". Since many lightning flashes are not vertical, values stated are probably slight underestimates of actual values.

<sup>c</sup> First return strokes have longer times to current peak and generally larger charge transfer than do subsequent return strokes.

## SPEED OF SOUND IN VARIOUS MEDIA

The speed of sound in various solids, liquids, and gases is given in these tables. While only a single parameter  $v$  is needed for liquids and gases, sound propagation in isotropic solids is characterized by three velocity parameters. For a solid of infinite extent (or of finite extent if all dimensions are much larger than a wavelength), there are two relevant quantities,

$v_l$ : velocity of longitudinal waves  
 $v_s$ : velocity of shear waves.

For a cylindrical rod with diameter much smaller than a wavelength,

$v_{\text{ext}}$ : velocity of extensional waves along the rod. (Torsional waves in the rod are propagated at the same speed as shear waves in an infinite solid.)

Table 1 lists values for a variety of solid materials. Table 2 covers gases liquids and gases; values for cryogenic liquids are given at the normal boiling point. Table 3 gives the speed of sound in pure

water and in seawater of salinity  $S = 3.5\%$  as a function of temperature. All values are in meters per second and are given for normal atmospheric pressure.

# ATTENUATION AND SPEED OF SOUND IN AIR AS A FUNCTION OF HUMIDITY AND FREQUENCY

This table gives the attenuation and speed of sound as a function of frequency at various values of relative humidity. All values refer to still air at 20 °C.

## SPEED OF SOUND IN DRY AIR

Eric W. Lemmon

These values were calculated from the equation of state for dry air (average molecular weight 28.96) treated as a real gas. Values refer to standard atmospheric pressure. The speed of sound varies only slightly with pressure; at two atmospheres and  $-100\text{ }^{\circ}\text{C}$  the value decreases by 0.16%, while at two atmospheres and  $80\text{ }^{\circ}\text{C}$  the speed increases by 0.05%. For additional values, see the table in Section 6 labeled "Thermophysical Properties of Air."

## CHARACTERISTICS OF HUMAN HEARING

The human ear is sensitive to sound waves with frequencies in the range from a few hertz to almost 20 kHz. Auditory response is usually expressed in terms of the *loudness level* of a sound, which is a measure of the sound pressure. The reference level, which is given in the unit *phon*, is a pure tone of frequency 1000 Hz with sound pressure of 20  $\mu\text{Pa}$  (in cgs units,  $2 \cdot 10^{-4} \text{ dyn/cm}^2$ ); loudness level is usually expressed in decibels (dB) relative to this reference level. If a normal observer perceives an arbitrary sound to

be equally loud as this reference sound, the sound is said to have the loudness level of the reference. The sensitivity of the typical human ear ranges from about 0 dB, the threshold loudness level, to about 140 dB, the level at which pain sets in. The minimum detectable level thus represents a sound wave of pressure 20  $\mu\text{Pa}$  and intensity (power density)  $10^{-16} \text{ W/cm}^2$ .

The following figure illustrates the frequency dependence of the threshold for an average young adult.

The relation between loudness level and frequency for a typical person is expressed by the following table:

| Sound pressure level<br>in dB relative to 20 $\mu\text{Pa}$ | Frequency in Hz |     |      |      |      |       |
|-------------------------------------------------------------|-----------------|-----|------|------|------|-------|
|                                                             | 125             | 500 | 1000 | 4000 | 8000 | 10000 |
| 10                                                          |                 |     | 10   | 18   |      |       |
| 20                                                          |                 | 16  | 20   | 28   | 11   |       |
| 30                                                          | 4               | 27  | 30   | 37   | 21   | 17    |
| 40                                                          | 17              | 39  | 40   | 45   | 30   | 26    |
| 50                                                          | 34              | 52  | 50   | 54   | 38   | 35    |
| 60                                                          | 52              | 65  | 60   | 64   | 47   | 44    |
| 70                                                          | 70              | 76  | 70   | 73   | 56   | 54    |
| 80                                                          | 86              | 86  | 80   | 83   | 66   | 64    |
| 90                                                          | 98              | 96  | 90   | 94   | 77   | 74    |
| 100                                                         | 108             | 105 | 100  | 106  | 88   | 86    |

Thus, a 10,000 Hz tone at a pressure level of 50 dB seems equally loud as a 1000 Hz tone at a pressure of 35 dB.

The term *noise* refers to any unwanted sound, either a pure tone or a mixture of frequencies. Since the sensitivity of the ear is fre-

quency dependent, as illustrated by the above table, noise level is expressed in a frequency-weighted scale, known as A-weighting. Decibel readings on this scale are designated as dBA. Typical noise levels from various sources are illustrated in this table:

| Source                             | Noise level in dBa |
|------------------------------------|--------------------|
| Rocket engine                      | 200                |
| Jet aircraft engine                | 160                |
| Light aircraft, cruising           | 140                |
| Tractor, 150 hp                    | 115                |
| Electric motor, 100 hp at 2600 rpm | 105                |
| Pneumatic drill                    | 100                |
| Subway train                       | 90                 |
| Vacuum cleaner                     | 85                 |
| Heavy automobile traffic           | 75                 |
| Conversational speech              | 65                 |
| Whispered speech                   | 40                 |
| Background noise, recording studio | 25-30              |

Recommended noise thresholds in the workplace have been established by the American Conference of Government Industrial

Hygienists. Some examples of the maximum safe levels for different daily exposure times are given below.

| Duration of exposure | Max. level in dBa |
|----------------------|-------------------|
| 24 h                 | 80                |
| 8 h                  | 85                |
| 4 h                  | 88                |
| 1 h                  | 94                |
| 30 min               | 97                |
| 15 min               | 100               |
| 2 min                | 109               |
| 28 s                 | 115               |
| 0.11 s               | 139               |

No exposure greater than 140 dBa is permitted. Further details may be found in Reference 3.

# INTERSTELLAR MOLECULES

Frank J. Lovas and Lewis E. Snyder

A number of molecules have been detected in the interstellar medium, in circumstellar envelopes around evolved stars, and comae and tails of comets through observation of their microwave, infrared, or optical spectra. The following list gives the molecules and the particular isotopic species that have been reported so far. Molecules are listed by molecular formula in the Hill order. All species not footnoted otherwise are observed in interstellar clouds, while some are also found in comets and circumstellar clouds. The list was last updated in October 2008 and lists 162 molecules (298 isotopic forms).

|                                 |                                  |                                   | S <sub>2</sub>                | Sulfur              | S <sub>2</sub> <sup>b</sup>                |

*l*- before the isotopic species indicates a linear configuration, while *c*- indicates a cyclic molecule.

<sup>a</sup> Reported only in circumstellar clouds.

<sup>b</sup> Reported only in comets.

## WEATHER-RELATED SCALES

### Saffir-Simpson Hurricane Scale

- **Tropical Storm**  
Winds 39–73 mph
- **Category 1 Hurricane** — winds 74–95 mph (64–82 knots); pressure greater than 980 mbar; storm surge 3–5 ft (1.0–1.7 m)  
No real damage to buildings. Damage to unanchored mobile homes. Some damage to poorly constructed signs. Also, some coastal flooding and minor pier damage.  
— Examples: Irene 1999 and Allison 1995
- **Category 2 Hurricane** — winds 96–110 mph (83–95 knots); pressure 979–965 mbar; storm surge 6–8 ft (1.8–2.6 m)  
Some damage to building roofs, doors and windows. Considerable damage to mobile homes. Flooding damages piers and small craft in unprotected moorings may break their moorings. Some trees blown down.  
— Examples: Bonnie 1998, Georges (FL & LA) 1998 and Gloria 1985
- **Category 3 Hurricane** — winds 111–130 mph (96–113 knots); pressure 964–945 mbar; storm surge 9–12 ft (2.7–3.8 m)  
Some structural damage to small residences and utility buildings. Large trees blown down. Mobile homes and poorly built signs destroyed. Flooding near the coast destroys smaller structures with larger structures damaged by floating debris. Terrain may be flooded well inland.  
— Examples: Keith 2000, Fran 1996, Opal 1995, Alicia 1983 and Betsy 1965

- **Category 4 Hurricane** — winds 131–155 mph (114–135 knots); pressure 944–920 mbar; storm surge 13–18 ft (3.9–5.6 m)  
More extensive curtainwall failures with some complete roof structure failure on small residences. Major erosion of beach areas. Terrain may be flooded well inland.  
— Examples: Hugo 1989 and Donna 1960
- **Category 5 Hurricane** — winds 156 mph and up (135+ knots); pressure less than 920 mbar; storm surge 19+ ft (5.7+ m)  
Complete roof failure on many residences and industrial buildings. Some complete building failures with small utility buildings blown over or away. Flooding causes major damage to lower floors of all structures near the shoreline. Massive evacuation of residential areas may be required.  
— Examples: Andrew (FL) 1992, Camille 1969 and Labor Day 1935

### Fujita Tornado Damage Scale

The original Fujita Scale was modified by NOAA in February 2007 and is now called the Enhanced Fujita Scale (EF). It is an operational scale based on the estimated speed of three-second wind gusts, as indicated by typical damage levels. The table below describes the damage levels according to the original scale. In the enhanced scale, the damage is measured by a more elaborate set of criteria (see <http://www.spc.noaa.gov/efscale/ef-scale.html>).

| EF Number | 3 s Gusts (mph) | Typical damage (according to the original Fujita Scale)                                                                                                                                                                |
|-----------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0         | 65–85           | <b>Light damage.</b> Some damage to chimneys; branches broken off trees; shallow-rooted trees pushed over; sign boards damaged.                                                                                        |
| 1         | 86–110          | <b>Moderate damage.</b> Peels surface off roofs; mobile homes pushed off foundations or overturned; moving autos blown off roads.                                                                                      |
| 2         | 111–135         | <b>Considerable damage.</b> Roofs torn off frame houses; mobile homes demolished; boxcars overturned; large trees snapped or uprooted; light-object missiles generated; cars lifted off ground.                        |
| 3         | 136–165         | <b>Severe damage.</b> Roofs and some walls torn off well-constructed houses; trains overturned; most trees in forest uprooted; heavy cars lifted off the ground and thrown.                                            |
| 4         | 166–200         | <b>Devastating damage.</b> Well-constructed houses leveled; structures with weak foundations blown away some distance; cars thrown and large missiles generated.                                                       |
| 5         | Over 200        | <b>Incredible damage.</b> Strong frame houses leveled off foundations and swept away; automobile-sized missiles fly through the air in excess of 100 meters (109 yd); trees debarked; incredible phenomena will occur. |

### Beaufort Wind Scale

The Beaufort Wind Scale was devised by British Rear-Admiral Sir Francis Beaufort in 1805 based on observations of the effects of the wind.

| Force | Wind (knots) | WMO classification | Appearance of wind effects                                 |                                                                |
|-------|--------------|--------------------|------------------------------------------------------------|----------------------------------------------------------------|
|       |              |                    | On the water                                               | On land                                                        |
| 0     | < 1          | Calm               | Sea surface smooth and mirror-like                         | Calm, smoke rises vertically                                   |
| 1     | 1–3          | Light Air          | Scaly ripples, no foam crests                              | Smoke drift indicates wind direction, still wind vanes         |
| 2     | 4–6          | Light Breeze       | Small wavelets, crests glassy, no breaking                 | Wind felt on face, leaves rustle, vanes begin to move          |
| 3     | 7–10         | Gentle Breeze      | Large wavelets, crests begin to break, scattered whitecaps | Leaves and small twigs constantly moving, light flags extended |

| Force | Wind (knots) | WMO classification | Appearance of wind effects                                                                                               |                                                                                        |
|-------|--------------|--------------------|--------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
|       |              |                    | On the water                                                                                                             | On land                                                                                |
| 4     | 11–16        | Moderate Breeze    | Small waves 1–4 ft. becoming longer, numerous whitecaps                                                                  | Dust, leaves, and loose paper lifted, small tree branches move                         |
| 5     | 17–21        | Fresh Breeze       | Moderate waves 4–8 ft taking longer form, many whitecaps, some spray                                                     | Small trees in leaf begin to sway                                                      |
| 6     | 22–27        | Strong Breeze      | Larger waves 8–13 ft, whitecaps common, more spray                                                                       | Larger tree branches moving, whistling in wires                                        |
| 7     | 28–33        | Near Gale          | Sea heaps up, waves 13–20 ft, white foam streaks off breakers                                                            | Whole trees moving, resistance felt walking against wind                               |
| 8     | 34–40        | Gale               | Moderately high (13–20 ft) waves of greater length, edges of crests begin to break into spindrift, foam blown in streaks | Whole trees in motion, resistance felt walking against wind                            |
| 9     | 41–47        | Strong Gale        | High waves (20 ft), sea begins to roll, dense streaks of foam, spray may reduce visibility                               | Slight structural damage occurs, slate blows off roofs                                 |
| 10    | 48–55        | Storm              | Very high waves (20–30 ft) with overhanging crests, sea white with densely blown foam, heavy rolling, lowered visibility | Seldom experienced on land, trees broken or uprooted, "considerable structural damage" |
| 11    | 56–63        | Violent Storm      | Exceptionally high (30–45 ft) waves, foam patches cover sea, visibility more reduced                                     |                                                                                        |
| 12    | 64+          | Hurricane          | Air filled with foam, waves over 45 ft, sea completely white with driving spray, visibility greatly reduced              |                                                                                        |

### Wind Chill

The following chart prepared by the U. S. National Weather Service gives the temperature perceived by an average person as a function of the real air temperature and the wind speed. The current scale was adopted in 2001.

## GLOBAL WARMING POTENTIAL OF GREENHOUSE GASES

The Global Warming Potential (GWP) of a gas is a measure of the degree, relative to carbon dioxide, to which the presence of that gas in the atmosphere will contribute to a long-term increase in global temperature. The calculation of the GWP for a given gas takes into account the efficiency of the gas in absorbing solar radiation (primarily determined by the infrared spectrum of the compound) and the time the compound will remain in the atmosphere before it is removed by natural processes. Thus if a pulse of 1 kg of the gas is emitted to the atmosphere at the same time as a pulse of 1 kg of CO<sub>2</sub>, the GWP compares the warming effect of the gas relative to CO<sub>2</sub> over various time horizons.

This table, which is taken from the 2007 report of the Intergovernmental Panel of Climate Change (IPCC), gives the life-time in years and the radiative efficiency in watts per square meter for a concentration of one part per billion for the major compounds identified in the Kyoto Protocol as contributing to global climate change. Radiative efficiency is a measure of the radiative forcing that influences the energy balance in the Earth-atmosphere system. The last four columns of the table give the Global Warming Potential, first as estimated in 1995 for a 100 year time horizon, and then as estimated with improved data in 2007 for 20-,

100-, and 500-year horizons. The calculation of a GWP involves a number of assumptions, and other measures have been proposed (see Reference).

The list of compounds includes those identified in the Montreal Protocol as contributing to ozone depletion, since these compounds also contribute to global warming. It also includes compounds used or proposed as replacements for the ozone-depleting compounds but which still have global warming potential.

## MAJOR WORLD EARTHQUAKES

The United States Geological Survey maintains a database of historic earthquakes throughout the world (Reference 1). The table below is extracted from that database; it includes about 300 major earthquakes, based upon the magnitude and the degree of destruction. All recorded earthquakes of magnitude 7.5 or greater are listed, even if the fatalities are unknown or small. The death toll is often a rough estimate; in many cases the true toll could be much greater. More details on the exact location and degree of destruction can be found in References 2 and 3.

The magnitude is given on the Richter scale, which was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The magnitude of an earthquake is measured by the logarithm of the amplitude of waves recorded by seismographs. Adjustments are included for the variation in the distance between the various seismographs and the epicenter of the earthquake. On

the Richter Scale, magnitude is expressed in whole numbers and decimal fractions, e.g. 6.3. Because of the logarithmic basis of the scale, each whole number increase in magnitude represents a ten-fold increase in measured amplitude; as an estimate of energy, each whole number step in the magnitude scale corresponds to the release of about 31 times more energy than the amount associated with the preceding whole number value.

## STANDARD ITS-90 THERMOCOUPLE TABLES

The Instrument Society of America (ISA) has assigned standard letter designations to a number of thermocouple types having specified emf-temperature relations. These designations and the approximate metal compositions which meet the required relations, as well as the useful temperature ranges, are given below:

|        |                                                      |                |
|--------|------------------------------------------------------|----------------|
| Type B | (Pt + 30% Rh) vs. (Pt + 6% Rh)                       | 0 to 1820°C    |
| Type E | (Ni + 10% Cr) vs. (Cu + 43% Ni)                      | –270 to 1000°C |
| Type J | Fe vs. (Cu + 43% Ni)                                 | –210 to 1200°C |
| Type K | (Ni + 10% Cr) vs. (Ni + 2% Al + 2% Mn + 1% Si)       | –270 to 1372°C |
| Type N | (Ni + 14% Cr + 1.5% Si) vs. (Ni + 4.5% Si + 0.1% Mg) | –270 to 1300°C |
| Type R | (Pt + 13% Rh) vs. Pt                                 | –50 to 1768°C  |
| Type S | (Pt + 10% Rh) vs. Pt                                 | –50 to 1768°C  |
| Type T | Cu vs. (Cu + 43% Ni)                                 | –270 to 400°C  |

The compositions are given in weight percent, and the positive leg is listed first. It should be emphasized that the standard letter

designations do not imply a precise composition but rather that the specified emf-temperature relation is satisfied.

The first set of tables below lists, for each thermocouple type, the emf as a function of temperature on the International Temperature Scale of 1990 (ITS-90). The coefficients in the equation used to generate the table are also given. The second set of tables gives the inverse relationships, i.e., the coefficients in the polynomial equation which expresses the temperature as a function of thermocouple emf. The accuracy of these equations is also stated.

Further details and tables at closer intervals may be found in Reference 1.

Temperature ranges and coefficients of equations used to compute the above table: The equations are of the form:  $E = c_0 + c_1 t + c_2 t^2 + c_3 t^3 + \dots + c_n t^n$ , where E is the emf in millivolts, t is the tem-

perature in degrees Celsius (ITS- 90), and  $c_0, c_1, c_2, c_3$ , etc. are the coefficients. These coefficients are extracted from Reference 1.

Temperature ranges and coefficients of equations used to compute the above table: The equations are of the form:  $E = c_0 + c_1 t + c_2 t^2 + c_3 t^3 + \dots + c_n t^n$ , where E is the emf in millivolts, t is the tem-

perature in degrees Celsius (ITS- 90), and  $c_0, c_1, c_2, c_3$ , etc. are the coefficients. These coefficients are extracted from Reference 1.

Temperature ranges and coefficients of equations used to compute the above table: The equations are of the form:  $E = c_0 + c_1 t + c_2 t^2 + c_3 t^3 + \dots c_n t^n$ , where E is the emf in millivolts, t is the temperature in degrees Celsius (ITS-90), and  $c_0, c_1, c_2, c_3$ , etc. are the coefficients. In the 0°C to 1372°C range there is also an exponen-

tial term that must be evaluated and added to the equation. The exponential term is of the form:  $c_0 e^{c_1 (t-126.9686)^2}$ , where t is the temperature in °C, e is the natural logarithm base, and  $c_0$  and  $c_1$  are the coefficients. These coefficients are extracted from Reference 1.

Temperature ranges and coefficients of equations used to compute the above table: The equations are of the form:  $E = c_0 + c_1 t + c_2 t^2 + c_3 t^3 + \dots c_n t^n$ , where E is the emf in millivolts, t is the tem-

perature in degrees Celsius (ITS-90), and  $c_0, c_1, c_2, c_3$ , etc. are the coefficients. These coefficients are extracted from Reference 1.

NOTE—The above coefficients are extracted from Reference 1 and are for an expression of the form shown in Section 10.3.2. They yield approximate values of temperature that agree within  $\pm 0.04$  °C with the values given in Table 10.16.

# LABORATORY SOLVENTS AND OTHER LIQUID REAGENTS

This table summarizes the properties of 575 liquids that are commonly used in the laboratory as solvents or chemical reagents.

The properties tabulated are:

|              |                                                                                                                       |
|--------------|-----------------------------------------------------------------------------------------------------------------------|
| $M_r$ :      | Molecular weight                                                                                                      |
| $t_m$ :      | Melting point in °C                                                                                                   |
| $t_b$ :      | Normal boiling point in °C                                                                                            |
| $\rho$ :     | Density in g/mL at the temperature in °C indicated by the superscript                                                 |
| $\eta$ :     | Viscosity in mPa s (1 mPa s = 1 centipoise) at 25 °C                                                                  |
| $\epsilon$ : | Dielectric constant at ambient temperature (15 to 30 °C)                                                              |
| $\mu$ :      | Dipole moment in D                                                                                                    |
| $c_p$ :      | Specific heat capacity of the liquid at constant pressure at 25 °C in J/g K                                           |
| vp:          | Vapor pressure at 25 °C in kPa (1 kPa = 7.50 mmHg)                                                                    |
| FP:          | Flash point in °C                                                                                                     |
| Fl.Lim:      | Flammable (explosive) limit in air in percent by volume                                                               |
| IT:          | Autoignition temperature in °C                                                                                        |
| TLV:         | Threshold limit for allowable airborne concentration in parts per million by volume at 25 °C and atmospheric pressure |

Data on the temperature dependence of viscosity, dielectric constant, and vapor pressure can be found in the pertinent tables in this *Handbook*.

## DEPENDENCE OF BOILING POINT ON PRESSURE

The normal boiling point of a liquid is defined as the temperature at which the vapor pressure reaches standard atmospheric pressure, 101.325 kPa. The change in boiling point with pressure may be calculated from the representation of the vapor pressure by the Antoine Equation,

$$\ln p = A_1 - A_2/(T + A_3)$$

where  $p$  is the vapor pressure,  $T$  the absolute temperature, and  $A_1$ ,  $A_2$ , and  $A_3$  are constants. This table, which has been calculated using the Antoine constants in Reference 1, gives values of  $\Delta t/\Delta p$  for a number of liquids, in units of both °C/kPa and °C/mmHg. The correction to the boiling point is generally accurate to 0.1 to 0.2 °C as long as the pressure is within 10% of standard atmospheric pressure.

A slightly less accurate estimate of  $\Delta t/\Delta p$  may be obtained from the Clausius-Clapeyron equation, with the assumption that the

change in volume upon vaporization equals the ideal-gas volume of the vapor. This leads to the equation

$$\Delta t/\Delta p = RT_b^2/p_0 \Delta_{\text{vap}} H(T_b)$$

where  $R$  is the molar gas constant,  $p_0$  is 101.325 kPa,  $T_b$  is the normal boiling point temperature (absolute), and  $\Delta_{\text{vap}} H(T_b)$  is the molar enthalpy of vaporization at the normal boiling point. Values of the last quantity may be obtained from the table "Enthalpy of Vaporization" in Section 6.
