## CHEMICAL CONSTITUENTS OF HUMAN BLOOD

This table lists typical concentrations of some of the chemical constituents of human blood. The table covers elements and compounds of relatively low molecular weight. References 1 and 4 give extensive information on enzymes, hormones, vitamins, and other blood constituents.

The values given for the normal range refer to healthy adults who have not been exposed to unusual environmental agents. In keeping with IUPAC practice, all values refer to a volume of one liter, and thus are stated in units of g/L, mg/L, µg/L or mmol/L. Many clinical test results, especially in the United States, are reported on a deciliter (dL) rather than a liter basis; thus the values in this table should be divided by 10 to place them on a dL basis. The symbols S (for serum), P (plasma), and WB (whole blood) in the second column indicate the nature of the blood sample to which the values apply. In some cases only a single mean value has been reported, rather than a range; these are given in *italics*.

The total volume of blood in a 100 kg (220 lb) adult is 7.5 L for a male and 6.7 L for a female. The corresponding volume of plasma is 4.4 L and 4.3 L, respectively (Reference 1).

Values from Reference 1 are so-called "reference values" against which clinical tests of blood chemistry are compared. In these cases the "normal range" is understood to include about 95% of the population. The remaining 5% may show values outside the normal range without necessarily implying a medical problem. Note that these reference values may vary slightly from one testing laboratory to another, depending on the detailed test procedure.

Accurate measurements on trace elements are very difficult to make, and wide variations can be found in the literature. Preferred measurement methods are discussed in References 2 and 6. Values

for the trace elements can also vary from one country to another, depending on dietary or environmental factors. Thus cadmium levels tend to be higher in Japan because of the prevalence of sea-food in the diet, and lead levels are higher in regions where lead additives are still used in gasoline. Variations with gender, age, geography, and occurrence of diseases are reviewed in Reference 6.

The Critical Values column gives levels that deviate far enough from the normal range to suggest a probable medical issue. Such values from Reference 3 are the Biological Exposure Indexes (BEI) that are specified by the American Council of Government Industrial Hygienists (ACGIH) as danger signals for the levels of pollutants in the workplace.

| Uric acid (females) | S   | mg/L        | 13           | 60   |                 | 1    |
| Valine              | S,P | mg/L        | 24           | 37   |                 | 4    |

\* Measured as the percent of hemoglobin bound to CO. Typical value for heavy smokers is 5%–10%. Major symptoms begin around 30%, and respiratory failure sets in at >60%.

\*\* This is the desirable upper limit. Values between 2000 and 2400 mg/L are considered borderline high.

# APPARENT EQUILIBRIUM CONSTANTS FOR ENZYME-CATALYZED REACTIONS

Robert N. Goldberg

This table contains values of apparent equilibrium constants  $K'$  for selected enzyme-catalyzed reactions at specified temperatures  $T$  and pHs. In those cases where the ionic strength  $I$  and/or the pMg ( $\text{pMg} = -\log_{10}[\text{Mg}^{2+}]$ ) have been reported, the values of these quantities are given. The Enzyme Commission numbers [Webb (1992)] of the enzymes that were used to catalyze the reactions are also given.

There are two fundamentally different types of equilibrium constants. This is illustrated by the following example for the hydrolysis of adenosine 5'-triphosphate (ATP) to adenosine 5'-diphosphate (ADP) and phosphate:

The apparent equilibrium constant for the overall biochemical reaction (1) is

$$K' = [\text{ADP}][\text{phosphate}]/([\text{ATP}]c^\circ) \quad (2)$$

The biochemical reactants ATP, ADP, and phosphate each exist in several different ionized and metal bound forms. For example, ATP is an equilibrium mixture of the species  $\text{ATP}^{4-}$ ,  $\text{HATP}^{3-}$ ,  $\text{H}_2\text{ATP}^{2-}$ ,  $\text{MgATP}^{2-}$ ,  $\text{MgHATP}^-$ ,  $\text{Mg}_2\text{ATP}^0$ . Additional species would also have to be considered if  $\text{Ca}^{2+}$  were present. Thus, ATP has often been denoted in the literature as  $\Sigma\text{ATP}$  or as  $(\text{ATP})_{\text{tot}}$ . When it is clear that one is dealing with total amounts of substances, it is not necessary to use either the  $\Sigma$  or "tot." Thus, these designations are not used in this table. In the above equation,  $c^\circ = 1 \text{ mol dm}^{-3}$ ; it is included to make  $K'$  dimensionless. The standard transformed Gibbs energy of reaction  $\Delta_r G'^\circ$  at specified conditions of temperature  $T$ , pressure  $P$ , ionic strength  $I$ , pH, and pMg can be calculated from  $K'$ :

$$\Delta_r G'^\circ = -RT \ln K' \quad (3)$$

The molar gas constant,  $R$ , is equal to  $8.314\,472 \text{ J K}^{-1} \text{ mol}^{-1}$ .  $\Delta_r G'^\circ$  and the apparent equilibrium constant,  $K'$ , can be used to calculate the position of equilibrium of overall biochemical reactions.

It is also possible to choose a chemical reference reaction that involves selected solute species:

The equilibrium constant for this reference reaction is

$$K = [\text{ADP}^{3-}][\text{HPO}_4^{2-}][\text{H}^+]/\{[\text{ATP}^{4-}](c^\circ)^2\} \quad (5)$$

Equations and algorithms that relate these two different types of equilibrium constants have been published [Alberty (1969), Akers and Goldberg (2001), Alberty (2003)]. To calculate the equilibrium constant  $K$  for the reference reaction from the apparent equilibrium constant  $K'$ , or vice versa, one needs the equilibrium constants for the binding of  $\text{H}^+$  and for the relevant metal ions to  $\text{ATP}^{4-}$ ,  $\text{ADP}^{3-}$ , and  $\text{HPO}_4^{2-}$ .

To avoid confusion between the two different types of equilibrium constants ( $K'$  and  $K$ ) and to avoid ambiguity about whether specific species or sums of species are intended, the word "ammonia," for example, rather than  $\text{NH}_3$  or  $\text{NH}_4^+$ , is used for total ammonia, and chemical formulas are used for specific chemical species. Other substances such as carbon dioxide ( $\text{CO}_2$ ,  $\text{HCO}_3^-$ , and  $\text{CO}_3^{2-}$ ), and phosphate ( $\text{H}_2\text{PO}_4^-$ ,  $\text{HPO}_4^{2-}$ , and  $\text{PO}_4^{3-}$ ) are treated in

the same manner. Exceptions are made for water, which is always written as  $\text{H}_2\text{O}$ , and for gaseous hydrogen and oxygen, which are written as  $\text{H}_2(\text{g})$  and  $\text{O}_2(\text{g})$ , respectively.

For symmetrical reactions, there is no concern about the units used to calculate the value of an equilibrium constant. However, care must be exercised for reactions that are not symmetrical. In such cases, the units " $\text{mol dm}^{-3}$ " have been used for all concentrations. As stated above, a  $c^\circ$  ( $1 \text{ mol dm}^{-3}$ ) is then used to make all equilibrium constants dimensionless.

All substances are assumed to be in aqueous solutions unless specified otherwise.

Values of  $\Delta_r G'^\circ$  and  $K'$  can also be calculated for many biochemical reactions by using the table "Standard Transformed Gibbs Energies of Formation for Biochemical Reactants" in Section 7 of this Handbook.

## PREPARATION OF SPECIAL ANALYTICAL REAGENTS

**Aluminon (qualitative test for aluminum).** Aluminon is a trade name for the ammonium salt of aurintricarboxylic acid. Dissolve 1 g of the salt in 1 L of distilled water. Shake the solution well to insure thorough mixing.

**Bang's reagent (for glucose estimation).** Dissolve 100 g of  $K_2CO_3$ , 66 g of KCl and 160 g of  $KHCO_3$  in the order given in about 700 mL of water at 30°C. Add 4.4 g of  $CuSO_4$  and dilute to 1 L after the  $CO_2$  is evolved. This solution should be shaken only in such a manner as not to allow entry of air. After 24 hours 300 mL are diluted to 1 L with saturated KCl solution, shaken gently and used after 24 hours; 50 mL is equivalent to 10 mg glucose.

**Barfoed's reagent (test for glucose).** See Cupric acetate.

**Baudisch's reagent.** See Cupferron.

**Benedict's solution (qualitative reagent for glucose).** With the aid of heat, dissolve 173 g of sodium citrate and 100 g of  $Na_2CO_3$  in 800 mL of water. Filter, if necessary, and dilute to 850 mL. Dissolve 17.3 g of  $CuSO_4 \cdot 5H_2O$  in 100 mL of water. Pour the latter solution, with constant stirring, into the carbonate-citrate solution, and dilute to 1 L.

**Benzidine hydrochloride solution (for sulfite determination).** Make a paste of 8 g of benzidine hydrochloride ( $C_{12}H_{10}(NH_3)_2 \cdot 2HCl$ ) and 20 mL of water, add 20 mL of HCl (sp. gr. 1.12) and dilute to 1 L with water. Each mL of this solution is equivalent to 0.00357 g of  $H_2SO_4$ .

**Bertrand's reagent (glucose estimation).** Consists of the following solutions:

1. Dissolve 200 g of Rochelle salt and 150 g of NaOH in sufficient water to make 1 L of solution.
2. Dissolve 40 g of  $CuSO_4$  in enough water to make 1 L of solution.
3. Dissolve 50 g of  $Fe_2(SO_4)_3$  and 200 g of  $H_2SO_4$  (sp. gr. 1.84) in sufficient water to make 1 L of solution.
4. Dissolve 5 g of  $KMnO_4$  in sufficient water to make 1 L of solution.

**Bial's reagent (for pentose).** Dissolve 1 g of orcinol (5-methyl-1,3-benzenediol) in 500 mL of 30% HCl to which 30 drops of a 10% solution of  $FeCl_3$  has been added.

**Boutron — Boudet soap solution:**

1. Dissolve 100 g of pure castile soap in about 2.5 L of 56% ethanol.
2. Dissolve 0.59 g of  $Ba(NO_3)_2$  in 1 L of water.

Adjust the castile soap solution so that 2.4 mL of it will give a permanent lather with 40 mL of solution (b). When adjusted, 2.4 mL of soap solution is equivalent to 220 parts per million of hardness (as  $CaCO_3$ ) for a 40 mL sample. See also Soap solution.

**Brucke's reagent (protein precipitation).** See Potassium iodide-mercuric iodide.

**Clarke's soap solution (estimation of hardness in water).**

1. Dissolve 100 g of pure powdered castile soap in 1 L of 80% ethanol and allow to stand over night.
2. Prepare a solution of  $CaCl_2$  by dissolving 0.5 g of  $CaCO_3$  in HCl (sp. gr. 1.19), neutralize with  $NH_4OH$  and make slightly alkaline to litmus, and dilute to 500 mL. One mL is equivalent to 1 mg of  $CaCO_3$ .

Titrate (1) against (2) and dilute (1) with 80% ethanol until 1 mL of the resulting solution is equivalent to 1 mL of (2) after making allowance for the lather factor (the amount of standard soap solution required to produce a permanent lather in 50 mL of distilled water). One mL of the adjusted solution after subtracting the lather factor is equivalent to 1 mg of  $CaCO_3$ . See also Soap solution.

**Cobalticyanide paper (Rinnmann's test for Zn).** Dissolve 4 g of  $K_3Co(CN)_6$  and 1 g of  $KClO_3$  in 100 mL of water. Soak filter paper in solution and dry at 100°C. Apply drop of zinc solution and burn in an evaporating dish. A green disk is obtained if zinc is present.

**Cochineal.** Extract 1 g of cochineal for 4 days with 20 mL of alcohol and 60 mL of distilled water. Filter.

**Congo red.** Dissolve 0.5 g of congo red in 90 mL of distilled water and 10 mL of alcohol.

**Cupferron (Baudisch's reagent for iron analysis).** Dissolve 6 g of the ammonium salt of *N*-hydroxy-*N*-nitrosoaniline (cupferron) in 100 mL of  $H_2O$ . Reagent good for 1 week only and must be kept in the dark.

**Cupric acetate (Barfoed's reagent for reducing monosaccharides).** Dissolve 66 g of cupric acetate and 10 mL of glacial acetic acid in water and dilute to 1 L.

**Cupric oxide, ammoniacal; Schweitzer's reagent (dissolves cotton, linen, and silk, but not wool).**

1. Dissolve 5 g of cupric sulfate in 100 mL of boiling water, and add sodium hydroxide until precipitation is complete. Wash the precipitate well, and dissolve it in a minimum quantity of ammonium hydroxide.
2. Bubble a slow stream of air through 300 mL of strong ammonium hydroxide containing 50 g of fine copper turnings. Continue for 1 hour.

**Cupric sulfate in glycerin-potassium hydroxide (reagent for silk).** Dissolve 10 g of cupric sulfate,  $CuSO_4 \cdot 5H_2O$ , in 100 mL of water and add 5 g of glycerol. Add KOH solution slowly until a deep blue solution is obtained.

**Cupron (precipitates copper).** Dissolve 5 g of benzoinoxime in 100 mL of 95% ethanol.

**Cuprous chloride, acidic (reagent for CO in gas analysis).**

1. Cover the bottom of a 2-L flask with a layer of cupric oxide about 0.5 inch deep, suspend a coil of copper wire so as to reach from the bottom to the top of the solution, and fill the flask with hydrochloric acid (sp. gr. 1.10). Shake occasionally. When the solution becomes nearly colorless, transfer to reagent bottles, which should also contain copper wire. The stock bottle may be refilled with dilute hydrochloric acid until either the cupric oxide or the copper wire is used up. Copper sulfate may be substituted for copper oxide in the above procedure.
2. Dissolve 340 g of  $CuCl_2 \cdot 2H_2O$  in 600 mL of conc. HCl and reduce the cupric chloride by adding 190 mL of a saturated solution of stannous chloride or until the solution is colorless. The stannous chloride is prepared by treating 300 g of metallic tin in a 500 mL flask with conc. HCl until no more tin goes into solution.
3. (Winkler method). Add a mixture of 86 g of CuO and 17 g of finely divided metallic Cu, made by the reduction of CuO with hydrogen, to a solution of HCl, made by dilut-

ing 650 mL of conc. HCl with 325 mL of water. After the mixture has been added slowly and with frequent stirring, a spiral of copper wire is suspended in the bottle, reaching all the way to the bottom. Shake occasionally, and when the solution becomes colorless, it is ready for use.

**Cuprous chloride, ammoniacal (reagent for CO in gas analysis).**

1. The acid solution of cuprous chloride as prepared above is neutralized with ammonium hydroxide until an ammonia odor persists. An excess of metallic copper must be kept in the solution.
2. Pour 800 mL of acidic cuprous chloride, prepared by the Winkler method, into about 4 L of water. Transfer the precipitate to a 250 mL graduate. After several hours, siphon off the liquid above the 50 mL mark and refill with 7.5%  $\text{NH}_4\text{OH}$  solution which may be prepared by diluting 50 mL of conc.  $\text{NH}_4\text{OH}$  with 150 mL of water. The solution is well shaken and allowed to stand for several hours. It should have a faint odor of ammonia.

**Dichlorofluorescein indicator.** Dissolve 1 g in 1 L of 70% alcohol or 1 g of the sodium salt in 1 L of water.

**Dimethylglyoxime, 0.01 N.** Dissolve 0.6 g of dimethylglyoxime (2,3-butanedione oxime) in 500 mL of 95% ethanol. This is an especially sensitive test for nickel, a very definite crimson color being produced.

**Diphenylamine (reagent for rayon).** Dissolve 0.2 g in 100 mL of concentrated sulfuric acid.

**Diphenylamine sulfonate (for titration of iron with  $\text{K}_2\text{Cr}_2\text{O}_7$ ).** Dissolve 0.32 g of the barium salt of diphenylamine sulfonic acid in 100 mL of water, add 0.5 g of sodium sulfate and filter off the precipitate of  $\text{BaSO}_4$ .

**Diphenylcarbazide.** Dissolve 0.2 g of diphenylcarbazide in 10 mL of glacial acetic acid and dilute to 100 mL with 95% ethanol.

**Esbach's reagent (estimation of protein).** To a water solution of 10 g of picric acid and 20 g of citric acid, add sufficient water to make 1 L of solution.

**Eschka's compound.** Two parts of calcined ("light") magnesia are thoroughly mixed with 1 part of anhydrous sodium carbonate.

**Fehling's solution (reagent for reducing sugars.)**

1. Copper sulfate solution. Dissolve 34.66 g of  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  in water and dilute to 500 mL.
2. Alkaline tartrate solution. Dissolve 173 g of potassium sodium tartrate (Rochelle salt,  $\text{KNaC}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$ ) and 50 g of NaOH in water and dilute when cold to 500 mL.

Mix equal volumes of the two solutions at the time of using.

**Ferric-alum indicator.** Dissolve 140 g of ferric ammonium sulfate crystals in 400 mL of hot water. When cool, filter, and make up to a volume of 500 mL with dilute nitric acid.

**Folin's mixture (for uric acid).** To 650 mL of water add 500 g of  $(\text{NH}_4)_2\text{SO}_4$ , 5 g of uranium acetate, and 6 g of glacial acetic acid. Dilute to 1 L.

**Formaldehyde — sulfuric acid (Marquis' reagent for alkaloids).** Add 10 mL of formaldehyde solution to 50 mL of sulfuric acid.

**Froehde's reagent.** See Sulfomolybdic acid.

**Fuchsin (reagent for linen).** Dissolve 1 g of fuchsin in 100 mL of alcohol.

**Fuchsin — sulfurous acid (Schiff's reagent for aldehydes).**

Dissolve 0.5 g of fuchsin and 9 g of sodium bisulfite in 500 mL of water, and add 10 mL of HCl. Keep in well-stoppered bottles and protect from light.

**Gunzberg's reagent (detection of HCl in gastric juice).** Prepare as needed a solution containing 4 g of phloroglucinol (1,3,5-benzenetriol) and 2 g of vanillin in 100 mL of absolute ethanol.

**Hager's reagent.** See Picric acid.

**Hanus solution (for iodine number).** Dissolve 13.2 g of resublimed iodine in 1 L of glacial acetic acid which will pass the dichromate test for reducible matter. Add sufficient bromine to double the halogen content, determined by titration (3 mL is about the proper amount). The iodine may be dissolved by the aid of heat, but the solution should be cold when the bromine is added.

**Iodine, tincture of.** To 50 mL of water add 70 g of  $\text{I}_2$  and 50 g of KI. Dilute to 1 L with alcohol.

**Iodo-potassium iodide (Wagner's reagent for alkaloids).** Dissolve 2 g of iodine and 6 g of KI in 100 mL of water.

**Litmus (indicator).** Extract litmus powder three times with boiling alcohol, each treatment consuming an hour. Reject the alcoholic extract. Treat residue with an equal weight of cold water and filter; then exhaust with five times its weight of boiling water, cool and filter. Combine the aqueous extracts.

**Magnesia mixture (reagent for phosphates and arsenates).** Dissolve 55 g of magnesium chloride and 105 g of ammonium chloride in water, barely acidify with hydrochloric acid, and dilute to 1 L. The ammonium hydroxide may be omitted until just previous to use. The reagent, if completely mixed and stored for any period of time, becomes turbid.

**Magnesium uranyl acetate.** Dissolve 100 g of  $\text{UO}_2(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2\text{H}_2\text{O}$  in 60 mL of glacial acetic acid and dilute to 500 mL. Dissolve 330 g of  $\text{Mg}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 4\text{H}_2\text{O}$  in 60 mL of glacial acetic acid and dilute to 200 mL. Heat solutions to the boiling point until clear, pour the magnesium solution into the uranyl solution, cool and dilute to 1 L. Let stand over night and filter if necessary.

**Marme's reagent.** See Potassium-cadmium iodide.

**Marquis' reagent.** See Formaldehyde-sulfuric acid.

**Mayer's reagent (white precipitate with most alkaloids in slightly acid solutions).** Dissolve 1.358 g of  $\text{HgCl}_2$  in 60 mL of water and pour into a solution of 5 g of KI in 10 mL of  $\text{H}_2\text{O}$ . Add sufficient water to make 100 mL.

**Methyl orange indicator.** Dissolve 1 g of methyl orange in 1 L of water. Filter, if necessary.

**Methyl orange, modified.** Dissolve 2 g of methyl orange and 2.8 g of xylene cyanole FF in 1 L of 50% alcohol.

**Methyl red indicator.** Dissolve 1 g of methyl red in 600 mL of alcohol and dilute with 400 mL of water.

**Methyl red, modified.** Dissolve 0.50 g of methyl red and 1.25 g of xylene cyanole FF in 1 L of 90% alcohol. Or, dissolve 1.25 g of methyl red and 0.825 g of methylene blue in 1 L of 90% alcohol.

**Millon's reagent (for albumins and phenols).** Dissolve 1 part of mercury in 1 part of cold fuming nitric acid. Dilute with twice the volume of water and decant the clear solution after several hours.

**Molisch's reagent.** See 1-Naphthol.

**1-Naphthol (Molisch's reagent for wool).** Dissolve 15 g of 1-naphthol in 100 mL of alcohol or chloroform.

**Nessler's reagent (for ammonia).** Dissolve 50 g of KI in the smallest possible quantity of cold water (50 mL). Add a saturated solution of mercuric chloride (about 22 g in 350 mL of water will be needed) until an excess is indicated by the formation of a precipitate. Then add 200 mL of 5 N NaOH and dilute to 1 L. Let settle, and draw off the clear liquid.

**Nickel oxide, ammoniacal (reagent for silk).** Dissolve 5 g of nickel sulfate in 100 mL of water, and add sodium hydroxide solution until nickel hydroxide is completely precipitated. Wash the precipitate well and dissolve in 25 mL of concentrated ammonium hydroxide and 25 mL of water.

**Nitron (detection of nitrate radical).** Dissolve 10 g of nitron (1,4-diphenyl-3-(phenylamino)-1,2,4-triazolium hydroxide) in 5 mL of glacial acetic acid and 95 mL of water. The solution may be filtered with slight suction through an alundum crucible and kept in a dark bottle.

**1-Nitroso-2-naphthol.** Make a saturated solution in 50% acetic acid (1 part of glacial acetic acid with 1 part of water). Does not keep well.

**Nylander's solution (carbohydrates).** Dissolve 20 g of bismuth subnitrate and 40 g of Rochelle salt in 1 L of 8% NaOH solution. Cool and filter.

**Obermayer's reagent (for indoxyl in urine).** Dissolve 4 g of  $\text{FeCl}_3$  in 1 L of HCl (sp. gr. 1.19).

**Oxine.** Dissolve 14 g of 8-hydroxyquinoline in 30 mL of glacial acetic acid. Warm slightly, if necessary. Dilute to 1 L.

**Oxygen absorbent.** Dissolve 300 g of ammonium chloride in 1 L of water and add 1 L of concentrated ammonium hydroxide solution. Shake the solution thoroughly. For use as an oxygen absorbent, a bottle half full of copper turnings is filled nearly full with the  $\text{NH}_4\text{Cl-NH}_4\text{OH}$  solution and the gas passed through.

**Pasteur's salt solution.** To 1 L of distilled water add 2.5 g of potassium phosphate, 0.25 g of calcium phosphate, 0.25 g of magnesium sulfate, and 12.00 g of ammonium tartrate.

**Pavy's solution (glucose reagent).** To 120 mL of Fehling's solution, add 300 mL of  $\text{NH}_4\text{OH}$  (sp. gr. 0.88) and dilute to 1 L with water.

**Phenanthroline ferrous ion indicator.** Dissolve 1.485 g of 1,10-phenanthroline monohydrate in 100 mL of 0.025 M ferrous sulfate solution.

**Phenolphthalein.** Dissolve 1 g of phenolphthalein in 50 mL of alcohol and add 50 mL of water.

**Phenolsulfonic acid (determination of nitrogen as nitrate).** Dissolve 25 g of phenol in 150 mL of conc.  $\text{H}_2\text{SO}_4$ , add 75 mL of fuming  $\text{H}_2\text{SO}_4$  (15%  $\text{SO}_3$ ), stir well and heat for 2 hours at  $100^\circ\text{C}$ .

**Phloroglucinol solution (pentosans).** Make a 3% phloroglucinol (1,3,5-benzenetriol) solution in alcohol. Keep in a dark bottle.

**Phosphomolybdic acid (Sonnenschein's reagent for alkaloids).**

1. Prepare ammonium phosphomolybdate and after washing with water, boil with nitric acid and expel  $\text{NH}_3$ ; evaporate to dryness and dissolve in 2 M nitric acid.
2. Dissolve ammonium molybdate in  $\text{HNO}_3$  and treat with phosphoric acid. Filter, wash the precipitate, and boil with aqua regia until the ammonium salt is decomposed. Evaporate to dryness. The residue dissolved in 10%  $\text{HNO}_3$  constitutes Sonnenschein's reagent.

**Phosphoric acid — sulfuric acid mixture.** Dilute 150 mL of conc.  $\text{H}_2\text{SO}_4$  and 100 mL of conc.  $\text{H}_3\text{PO}_4$  (85%) with water to a volume of 1 L.

**Phosphotungstic acid (Schcibicr's reagent for alkaloids).**

1. Dissolve 20 g of sodium tungstate and 15 g of sodium phosphate in 100 mL of water containing a little nitric acid.
2. The reagent is a 10% solution of phosphotungstic acid in water. The phosphotungstic acid is prepared by evaporating a mixture of 10 g of sodium tungstate dissolved in 5 g of phosphoric acid (sp. gr. 1.13) and enough boiling water to effect solution. Crystals of phosphotungstic acid separate.

**Picric acid (Hager's reagent for alkaloids, wool and silk).**

Dissolve 1 g of picric acid in 100 mL of water.

**Potassium antimonate (reagent for sodium).** Boil 22 g of potassium antimonate with 1 L of water until nearly all of the salt has dissolved, cool quickly, and add 35 mL of 10% potassium hydroxide. Filter after standing overnight.

**Potassium-cadmium iodide (Marme's reagent for alkaloids).**

Add 2 g of  $\text{CdI}_2$  to a boiling solution of 4 g of KI in 12 mL of water, and then mix with 12 mL of saturated KI solution.

**Potassium hydroxide (for  $\text{CO}_2$  absorption).** Dissolve 360 g of KOH in water and dilute to 1 L.

**Potassium iodide — mercuric iodide (Brucke's reagent for proteins).** Dissolve 50 g of KI in 500 mL of water, and saturate with mercuric iodide (about 120 g). Dilute to 1 L.

**Potassium pyrogallate (for oxygen absorption).** For mixtures of gases containing less than 28% oxygen, add 100 mL of KOH solution (50 g of KOH to 100 mL of water) to 5 g of pyrogallol. For mixtures containing more than 28% oxygen the KOH solution should contain 120 g of KOH to 100 mL of water.

**Pyrogallol, alkaline.**

1. Dissolve 75 g of pyrogallol in 75 mL of water.
2. Dissolve 500 g of KOH in 250 mL of water. When cool, adjust until sp. gr. is 1.55.

For use, add 270 mL of solution (2) to 30 mL of solution (1).

**Rosolic acid (indicator).** Dissolve 1 g of rosolic acid in 10 mL of alcohol and add 100 mL of water.

**Scheibler's reagent.** See Phosphotungstic acid.

**Schiff's reagent.** See Fuchsin-sulfurous acid.

**Schweitzer's reagent.** See Cupric oxide, ammoniacal.

**Soap solution (reagent for hardness in water).** Dissolve 100 g of dry castile soap in 1 L of 80% alcohol (5 parts alcohol to 1 part water). Allow to stand several days and dilute with 70% to 80% alcohol until 6.4 mL produces a permanent lather with 20 mL of standard calcium solution. The latter solution is made by dissolving 0.2 g of  $\text{CaCO}_3$  in a small amount of dilute HCl, evaporating to dryness and making up to 1 L.

**Sodium bismuthate (oxidation of manganese).** Heat 20 parts of NaOH nearly to redness in an iron or nickel crucible and add slowly 10 parts of basic bismuth nitrate which has been previously dried. Add 2 parts of sodium peroxide, and pour the brownish-yellow fused mass onto an iron plate to cool. When cold, break up in a mortar, extract with water, and collect on an asbestos filter.

**Sodium hydroxide (for  $\text{CO}_2$  absorption).** Dissolve 330 g of NaOH in water and dilute to 1 L.

**Sodium nitroprusside (reagent for hydrogen sulfide and wool).**

Use a freshly prepared solution of 1 g of sodium nitroferricyanide in 10 mL of water.

**Sodium oxalate (primary standard).** Dissolve 30 g of the commercial salt in 1 L of water, make slightly alkaline with sodium hydroxide, and let stand until perfectly clear. Filter and evaporate the filtrate to 100 mL. Cool and filter. Pulverize the residue and wash it several times with small volumes of water. The procedure is repeated until the mother liquor is free from sulfate and is neutral to phenolphthalein.

**Sodium plumbite (reagent for wool).** Dissolve 5 g of sodium hydroxide in 100 mL of water. Add 5 g of litharge (PbO) and boil until dissolved.

**Sodium polysulfide.** Dissolve 480 g of  $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$  in 500 mL of water, add 40 g of NaOH and 18 g of sulfur. Stir thoroughly and dilute to 1 L with water.

**Sonnenschein's reagent.** See Phosphomolybdic acid.

**Starch solution.**

1. Make a paste with 2 g of soluble starch and 0.01 g of  $\text{HgI}_2$  with a small amount of water. Add the mixture slowly to 1 L of boiling water and boil for a few minutes. Keep in a glass stoppered bottle. If other than soluble starch is used, the solution will not clear on boiling; it should be allowed to stand and the clear liquid decanted.
2. A solution of starch which keeps indefinitely is made as follows: Mix 500 mL of saturated NaCl solution (filtered), 80 mL of glacial acetic acid, 20 mL of water and 3 g of starch. Bring slowly to a boil and boil for 2 minutes.
3. Make a paste with 1 g of soluble starch and 5 mg of  $\text{HgI}_2$ , using as little cold water as possible. Then pour about 200 mL of boiling water on the paste and stir immediately. This will give a clear solution if the paste is prepared correctly and the water actually boiling. Cool and add 4 g of KI. Starch solution decomposes on standing due to bacterial action, but this solution will keep well if stored under a layer of toluene.

**Stoke's reagent.** Dissolve 30 g of  $\text{FeSO}_4$  and 20 g of tartaric acid in water and dilute to 1 L. Just before using, add concentrated  $\text{NH}_4\text{OH}$  until the precipitate first formed is redissolved.

**Sulfanilic acid (reagent for nitrites).** Dissolve 0.5 g of sulfanilic acid in a mixture of 15 mL of glacial acetic acid and 135 mL of recently boiled water.

**Sulfomolybdic acid (Froehde's reagent for alkaloids and glucosides).** Dissolve 10 g of molybdic acid or sodium molybdate in 100 mL of conc.  $\text{H}_2\text{SO}_4$ .

**Tannic acid (reagent for albumin, alkaloids, and gelatin).** Dissolve 10 g of tannic acid in 10 mL of alcohol and dilute with water to 100 mL.

**Titration mixture (residual chlorine in water analysis).** Prepare 1 L of dilute HCl (100 mL of HCl (sp. gr. 1.19) in sufficient water to make 1 L). Dissolve 1 g of *o*-tolidine in 100 mL of the dilute HCl and dilute to 1 L with dilute HCl solution.

**Trinitrophenol solution.** See Picric acid.

**Turmeric tincture (reagent for borates).** Digest ground turmeric root with several quantities of water which are discarded. Dry the residue and digest it several days with six times its weight of alcohol. Filter.

**Uffelmann's reagent (turns yellow in presence of lactic acid).**

To a 2% solution of pure phenol in water, add a water solution of  $\text{FeCl}_3$  until the phenol solution becomes violet in color.

**Wagner's reagent.** See Iodo-potassium iodide.

**Wagner's solution (used in phosphate rock analysis to prevent precipitation of iron and aluminum).** Dissolve 25 g of citric acid and 1 g of salicylic acid in water and dilute to 1 L. Use 50 mL of the reagent.

**Wij's iodine monochloride solution (for iodine number).**

Dissolve 13 g of resublimed iodine in 1 L of glacial acetic acid which will pass the dichromate test for reducible matter. Set aside 25 mL of this solution. Pass into the remainder of the solution dry chlorine gas (dried and washed by passing through  $\text{H}_2\text{SO}_4$  (sp. gr. 1.84)) until the characteristic color of free iodine has been discharged. Now add the iodine solution which was reserved, until all free chlorine has been destroyed. A slight excess of iodine does little or no harm, but an excess of chlorine must be avoided. Preserve in well stoppered, amber colored bottles. Avoid use of solutions which have been prepared for more than 30 days.

**Wij's special solution (for iodine number).** To 200 mL of glacial acetic acid that will pass the dichromate test for reducible matter, add 12 g of dichloramine T (*N,N*-dichloro-4-methylbenzenesulfonamide), and 16.6 g of dry KI (in small quantities with continual shaking until all the KI has dissolved). Make up to 1 L with the same quality of acetic acid used above and preserve in a dark colored bottle.

**Zimmermann-Reinhardt reagent (determination of iron).**

Dissolve 70 g of  $\text{MnSO}_4 \cdot 4\text{H}_2\text{O}$  in 500 mL of water, add 125 mL of conc.  $\text{H}_2\text{SO}_4$  and 125 mL of 85%  $\text{H}_3\text{PO}_4$ , and dilute to 1 L.

**Zinc chloride solution, basic (reagent for silk).** Dissolve 1000 g of zinc chloride in 850 mL of water, and add 40 g of zinc oxide. Heat until solution is complete.

**Zinc uranyl acetate (reagent for sodium).** Dissolve 10 g of  $\text{UO}_2(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2\text{H}_2\text{O}$  in 6 g of 30% acetic acid with heat, if necessary, and dilute to 50 mL. Dissolve 30 g of  $\text{Zn}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{H}_2\text{O}$  in 3 g of 30% acetic acid and dilute to 50 mL. Mix the two solutions, add 50 mg of NaCl, allow to stand overnight and filter.

## STANDARD SOLUTIONS OF ACIDS, BASES, AND SALTS

For each compound listed, the last column of this table gives the mass in grams which is contained in 1 liter of a solution whose amount-of-substance concentration divided by the equivalence factor of the compound equals 0.1 mol/L. In the older literature such a solution is often referred to as a "decinormal solution" (0.1 N).

## STANDARD SOLUTIONS OF OXIDATION AND REDUCTION REAGENTS

For each reagent listed, the last column of this table gives the mass in grams which is contained in a solution whose amount-of-substance concentration divided by the equivalence factor of the compound equals 0.1 mol/L. The equivalence factor given refers to the most common reactions of the reagent. In the older literature such a solution is often called a "decinormal solution" (0.1 N).

# ACID-BASE INDICATORS

A. K. Covington

The first part of this table lists some common acid-base indicators in alphabetical order along with the approximate pH range(s) at which a color change occurs. Following this is a table of the same indicators ordered by pH range, which includes the nature of the color change, instructions on preparation of the indicator solution, and the acid dissociation constant  $pK$ , when available.

The color code is:

|               |            |                  |
|---------------|------------|------------------|
| C = colorless | A = amber  | B/G = blue-green |
| Pk = pink     | Y = yellow | V = violet       |
| R = red       | B = blue   | P = purple       |
| O = orange    |            |                  |

# FLUORESCENT INDICATORS

Jack DeMent

Fluorescent indicators are substances that show definite changes in fluorescence with change in pH. Some fluorescent materials are not suitable for indicators since their change in fluorescence is too gradual. Fluorescent indicators find greatest utility in the titration of opaque, highly turbid or deeply colored solutions. A long wavelength ultraviolet ("black light") lamp in a dimly lighted room provides the best environment for titrations involving fluorescent indicators, although bright daylight is sometimes sufficient to evoke a response in the bright green, yellow and orange fluores-

cent indicators. Titrations are carried out in non-fluorescent glassware. One should check the glassware prior to use to make certain that it does not fluoresce due to the wavelengths of light involved in the titration. The meniscus of the liquid in the burette can be followed when a few particles of an insoluble fluorescent solid are dropped onto its surface.

In this table the indicators are arranged by approximate pH range covered. In the case of some of the dyestuffs the end point may vary slightly with the source or manufacturer.

| pH 0 to 2                                 |      |                                              |                        |
|-------------------------------------------|------|----------------------------------------------|------------------------|
| Indicator                                 | C.I. | From pH                                      | To pH                  |

# ELECTROCHEMICAL SERIES

Petr Vanýsek

There are three tables for this electrochemical series. Each table lists standard reduction potentials,  $E^\circ$  values, at 298.15 K (25 °C), and at a pressure of 101.325 kPa (1 atm). Table 1 is an alphabetical listing of the elements, according to the symbol of the elements. Thus, data for silver (Ag) precede those for aluminum (Al). Table 2 lists only those reduction reactions that have  $E^\circ$  values positive in respect to the standard hydrogen electrode. In Table 2, the reactions are listed in the order of increasing positive potential, and they range from 0.0000 V to + 3.4 V. Table 3 lists only those reduction potentials which have  $E^\circ$  negative with respect to the standard hydrogen electrode. In Table 3, the reactions are listed in the order of decreasing potential and range from 0.0000 V to –4.10 V. The reliability of the potentials is not the same for all the data. Typically, the values with fewer significant figures have lower

reliability. The values of reduction potentials, in particular those of less common reactions, are not definite; they are subject to occasional revisions.

*Abbreviations:* ac = acetate; bipy = 2,2'-dipyridine, or bipyridine; en = ethylenediamine; phen = 1,10-phenanthroline.

# REDUCTION AND OXIDATION POTENTIALS FOR CERTAIN ION RADICALS

Petr Vanýsek

There are two tables for ion radicals. The first table lists reduction potentials for organic compounds which produce anion radicals during reduction, a process described as  $A + e^- \rightleftharpoons A^-$ . The second table lists oxidation potentials for organic compounds which produce cation radicals during oxidation, a process described as  $A \rightleftharpoons A^+ + e^-$ . To obtain reduction potential for a reverse reaction, the sign for the potential is changed.

Unlike the table of the Electrochemical Series, which lists *standard* potentials, values for radicals are experimental values with experimental conditions given in the second column. Since the measurements leading to potentials for ion radicals are very dependent on conditions, an attempt to report standard potentials for radicals would serve no useful purpose. For the same reason, the potentials are also reported as experimental values, usually a half-wave potential ( $E_{1/2}$  in polarography) or a peak potential ( $E_p$  in cyclic voltammetry). Unless otherwise stated, the values are reported vs. SCE (saturated calomel electrode). To obtain a value vs.

normal hydrogen electrode, 0.241 V has to be added to the SCE values. All the ion radicals chosen for inclusion in the tables result from electrochemically reversible reactions. More detailed data on ion radicals can be found in the *Encyclopedia of Electrochemistry of Elements*, (A. J. Bard, Ed.), Vol. XI and XII in particular, Marcel Dekker, New York, 1978.

Abbreviations are: CV — cyclic voltammetry; DMF — *N,N*-Dimethylformamide;  $E_{swp}$  — potential sweep;  $E^\circ$  — standard potential;  $E_p$  — peak potential;  $E_{p/2}$  — half-peak potential;  $E_{1/2}$  — half wave potential; *M* — mol/L; MeCN — acetonitrile; pol — polarography; rot Pt disk — rotated Pt disk; SCE — saturated calomel electrode; TBABF<sub>4</sub> — tetrabutylammonium tetrafluoroborate; TBAI — tetrabutylammonium iodide; TBAP — tetrabutylammonium perchlorate; TEABr — tetraethylammonium bromide; TEAP — tetraethylammonium perchlorate; THF — tetrahydrofuran; TPACF<sub>3</sub>SO<sub>3</sub> — tetrapropylammonium trifluoromethanesulfite; TPAP — tetrapropylammonium perchlorate; and wr — wire.

## Reduction Potentials (Products are Anion Radicals)

| Substance                    | Conditions/electrode/technique              | Potential<br>V (vs. SCE) |
|------------------------------|---------------------------------------------|--------------------------|
| Acetone                      | DMF, 0.1 <i>M</i> TEABr/Hg/pol              | $E_{1/2} = -2.84$        |

# pH SCALE FOR AQUEOUS SOLUTIONS

A.K. Covington

A Working Party of IUPAC, after extensive considerations over five years, has recently produced a report (1) which sets pH firmly within the International System of Units (SI). A summary of these important developments is given below.

The concept of pH is unique amongst the commonly encountered physicochemical quantities in that, in terms of its definition,

$$\text{pH} = -\lg a_{\text{H}} \quad (1)$$

it involves a single ion quantity, the activity of the hydrogen ion, which is immeasurable by any thermodynamically valid method and requires a convention for its evaluation.

pH was originally defined by Sørensen (2) in terms of the concentration of hydrogen ions (in modern nomenclature) as  $\text{pH} = -\lg (c_{\text{H}}/c^\circ)$  where  $c_{\text{H}}$  is the hydrogen ion concentration in  $\text{mol dm}^{-3}$ , and  $c^\circ = 1 \text{ mol dm}^{-3}$  is the standard amount concentration. Subsequently (3), it was accepted as more satisfactory to define pH in terms of the relative activity of hydrogen ions in solution

$$\text{pH} = -\lg a_{\text{H}} = -\lg (m_{\text{H}}\gamma_{\text{H}}/m^\circ) \quad (2)$$

where  $a_{\text{H}}$  is the relative (molality basis) activity and  $\gamma_{\text{H}}$  is the molal activity coefficient of the hydrogen ion  $\text{H}^+$  at the molality  $m_{\text{H}}$ , and  $m^\circ$  the standard molality. The quantity pH is intended to be a measure of the activity of hydrogen ions in solution. However, since it is defined in terms of a quantity that cannot be measured by a thermodynamically valid method, eqn.(2) can only be considered a *notional definition* of pH.

pH being a single ion quantity, it is not determinable in terms of a fundamental (or base) unit of any measurement system, and there is difficulty providing a proper basis for the traceability of pH measurements. A satisfactory approach is now available in that pH determinations can be incorporated into the International System (SI) if they can be traced to measurements made using a method that fulfils the definition of a 'primary method of measurement' (4).

The essential feature of a primary method is that it must operate according to a well-defined measurement equation in which all of the variables can be determined experimentally in terms of SI units. Any limitation in the determination of the experimental variables, or in the theory, must be included within the estimated uncertainty of the method if traceability to the SI is to be established. If a convention were used without an estimate of its uncertainty, true traceability to SI would not be established. The electrochemical cell without liquid junction, known as the Harned cell (5), fulfils the definition of a primary method for the measurement of the acidity function,  $p(a_{\text{H}}\gamma_{\text{Cl}})$ , and subsequently of the pH of buffer solutions.

The Harned cell is written as

and contains a standard buffer, S, with chloride ions, as potassium or sodium chloride, added in order to use the silver-silver chloride electrode as reference electrode. The application of the Nernst equation to the spontaneous cell reaction of Cell I:

yields the potential difference  $E_1$  of the cell (corrected to 1 atm (101.325 kPa), the partial pressure of hydrogen gas used in electrochemistry in preference to 100 kPa) as

$$E_1 = E^\circ - (RT/F) \ln 10 \lg [(m_{\text{H}}\gamma_{\text{H}}/m^\circ)(m_{\text{Cl}}\gamma_{\text{Cl}}/m^\circ)] \quad (3)$$

which can be rearranged, since  $a_{\text{H}} = m_{\text{H}}\gamma_{\text{H}}/m^\circ$ , to give the acidity function

$$p(a_{\text{H}}\gamma_{\text{Cl}}) = -\lg(a_{\text{H}}\gamma_{\text{Cl}}) = (E_1 - E^\circ)/[(RT/F) \ln 10] + \lg(m_{\text{Cl}}/m^\circ) \quad (4)$$

where  $E^\circ$  is the standard potential difference of the cell, and hence of the silver-silver chloride electrode, and  $\gamma_{\text{Cl}}$  is the activity coefficient of the chloride ion.

The standard potential difference of the silver/silver chloride electrode,  $E^\circ$ , is determined from a Harned cell in which only HCl is present at a fixed molality (e.g.  $m = 0.01 \text{ mol kg}^{-1}$ )

The application of the Nernst equation to the HCl cell (Ia) gives

$$E_{\text{Ia}} = E^\circ - (2RT/F) \ln 10 \lg [(m_{\text{HCl}}/m^\circ)(\gamma_{\pm\text{HCl}})] \quad (5)$$

where  $E_{\text{Ia}}$  has been corrected to 1 atmosphere partial pressure of hydrogen gas (101.325 kPa) and  $\gamma_{\pm\text{HCl}}$  is the mean ionic activity coefficient of HCl.

Values of the activity coefficient ( $\gamma_{\pm\text{HCl}}$ ) at molality  $0.01 \text{ mol kg}^{-1}$  and various temperatures were given by Bates and Robinson (6). The standard potential difference depends on the method of preparation of the electrodes, but individual determinations of the activity coefficient of HCl at  $0.01 \text{ mol kg}^{-1}$  are more uniform than values of  $E^\circ$ . Hence the practical determination of the potential difference of the cell with HCl at  $0.01 \text{ mol kg}^{-1}$  is recommended at 298.15 K at which the mean ionic activity coefficient is 0.904. (It is unnecessary to repeat the measurement of  $E^\circ$  at other temperatures but simply to correct published smoothed values by the observed difference in  $E^\circ$  at 298.15 K)

In national metrology institutes (NMIs), measurements of Cells I and Ia are often done simultaneously in a thermostat bath. Subtracting eqn.(5) from (3) gives

$$\Delta E = E_1 - E_{\text{Ia}} = - (RT/F) \ln 10 \{ \lg [(m_{\text{H}}\gamma_{\text{H}}/m^\circ)(m_{\text{Cl}}\gamma_{\text{Cl}}/m^\circ)] - \lg [(m_{\text{HCl}}/m^\circ)^2 \gamma_{\pm\text{HCl}}] \} \quad (6)$$

which is independent of the standard potential difference. Therefore, the subsequently calculated pH does not depend on the standard potential difference and hence does not depend on the assumption that the standard potential of the hydrogen electrode is zero at all temperatures. Therefore, the Harned cell gives an exact comparison between hydrogen ion activities at different temperatures.

The quantity  $p(a_{\text{H}}\gamma_{\text{Cl}}) = -\lg (a_{\text{H}}\gamma_{\text{Cl}})$ , on the left hand side of (4), is called the acidity function (5). To obtain the quantity pH according to eqn. (2) from the acidity function, it is necessary to evaluate  $\lg \gamma_{\text{Cl}}$  independently. This is done in two steps: (i) the

value of  $\lg(a_{\text{H}}\gamma_{\text{Cl}})$  at zero chloride molality,  $\lg(a_{\text{H}}\gamma_{\text{Cl}})^{\circ}$ , is evaluated and (ii) a value for the activity of the chloride ion  $\gamma_{\text{Cl}}^{\circ}$ , at zero chloride molality (sometimes referred to as the limiting or 'trace' activity coefficient) is calculated using the Bates-Guggenheim convention (7). The value of  $\lg(a_{\text{H}}\gamma_{\text{Cl}})^{\circ}$  corresponding to zero chloride molality is determined by linear extrapolation of measurements using Harned cells with at least three added molalities of sodium or potassium chloride ( $I < 0.1 \text{ mol kg}^{-1}$ ).

The value of  $\lg(a_{\text{H}}\gamma_{\text{Cl}})^{\circ}$  corresponding to zero chloride molality is determined by linear extrapolation of measurements using Harned cells with at least three added molalities of sodium or potassium chloride ( $I < 0.1 \text{ mol kg}^{-1}$ ) in accord with eqn. (7):

$$-\lg(a_{\text{H}}\gamma_{\text{Cl}}) = -\lg(a_{\text{H}}\gamma_{\text{Cl}})^{\circ} + Sm_{\text{Cl}} \quad (7)$$

where  $S$  is an empirical, temperature dependent, constant.

The Bates-Guggenheim convention (7) assumes that the trace activity coefficient of the chloride ion  $\gamma_{\text{Cl}}^{\circ}$  is given by

$$\lg \gamma_{\text{Cl}}^{\circ} = -A I^{1/2} / (1 + Ba I^{1/2}) \quad (8)$$

where  $A$  is the Debye-Hückel temperature dependent constant (limiting slope),  $a$  is the *mean* distance of closest approach of the ions (ion size parameter),  $Ba$  is set equal to  $1.5 (\text{mol kg}^{-1})^{-1/2}$  at all temperatures in the range  $5\text{--}50^{\circ}\text{C}$ , and  $I$  is the ionic strength of the buffer (which for its evaluation requires knowledge of appropriate acid dissociation constants).

The various stages in the assignment of primary standard pH values are combined in eqn. (9), which is derived from eqns. (4), (5) and (8)

$$\text{pH(PS)} = \lim_{m_{\text{Cl}} \rightarrow 0} \{ (E_1 - E^{\circ}) / [(RT/F) \ln 10] + \lg(m_{\text{Cl}}/m^{\circ}) \} - AI^{1/2} / [1 + 1.5 (I/m^{\circ})^{1/2}] \quad (9)$$

In order for a particular buffer solution to be considered a primary buffer solution, it must be of the "highest metrological" quality (4) in accordance with the definition of a primary standard. It is recommended that it have the following attributes (9):

1. High buffer value in the range  $0.016\text{--}0.07 (\text{mol OH}^{-})/\text{pH}$ .
2. Small dilution value at half concentration (change in pH with change in buffer concentration) in the range  $0.01\text{--}0.20$ .
3. Small dependence of pH on temperature less than  $\pm 0.01 \text{ K}^{-1}$ .
4. Low residual liquid junction potential  $< 0.01$  in pH.
5. Ionic strength  $\leq 0.1 \text{ mol kg}^{-1}$  to permit applicability of Bates-Guggenheim convention.
6. NMI certificate for specific batch.
7. Reproducible purity of preparation (lot to lot differences of  $|\Delta\text{pH(PS)}| < 0.003$ ).
8. Long term stability of stored solid material.

Values for the above and other important parameters for the primary and secondary buffer materials are given in Table 1.

### Primary Standard Buffers

As there can be significant variations in the purity of samples of a buffer of the same nominal chemical composition, it is essential that the primary buffer material used has been certified with values that have been measured with Cell I. The Harned cell is used

by many national metrological institutes for accurate measurements of pH of buffer solutions.

Typical values of the pH(PS) of the seven solutions from the six accepted primary standard reference buffers, which meet the conditions stated above, are listed in Table 2. Batch-to-batch variations in purity can result in changes in the pH value of samples of at most 0.003. The typical values in Table 2 should not be used in place of the certified value (from a Harned cell measurement) for a specific batch of buffer material.

The required attributes listed above effectively limit the range of primary buffers available to between pH 3 and 10 (at  $25^{\circ}\text{C}$ ). Calcium hydroxide and potassium tetraoxalate are excluded because the contribution of hydroxide or hydrogen ions to the ionic strength is significant. Also excluded are the nitrogen bases of the type  $\text{BH}^{+}$  (such as tris(hydroxymethyl)aminomethane and piperazine phosphate) and the zwitterionic buffers (e.g. HEPES and MOPS (10)). These do not comply because either the Bates-Guggenheim convention is not applicable, or the liquid junction potentials are high. This means the choice of primary standards is restricted to buffers derived from oxy-carbon, -phosphorus, -boron and mono, di- and tri-protic carboxylic acids. The uncertainties (11) associated with Harned cell measurements are calculated (1) to be 0.004 in pH at NMIs, with typical variation between batches of primary standard buffers of 0.003.

### Secondary Standards

Substances that do not fulfil all the criteria for primary standards, but to which pH values can be assigned using Cell I are considered to be secondary standards (Table 3). Reasons for their exclusion as primary standards include difficulties in achieving consistent and suitable chemical quality (e.g. acetic acid is a liquid), suspected high liquid junction potential, or inappropriateness of the Bates-Guggenheim convention (e.g. other charge-type buffers). The uncertainty is higher (e.g. 0.01) for biological buffers. Certain other substances, which cannot be used in cells containing hydrogen gas electrodes, are also classed as secondary standards.

### Calibration Procedures

#### (a) One-point calibration

A single point calibration is insufficient to determine both slope and one-point parameters. The theoretical value for the slope can be assumed but the practical slope may be up to 5% lower. Alternatively, a value for the practical slope can be assumed from the manufacturer's prior calibration. The one-point calibration therefore yields only an estimate of pH(X). Since both parameters may change with age of the electrodes, this is not a reliable procedure.

#### (b) Two-point calibration [target uncertainty: $0.02\text{--}0.03$ at $25^{\circ}\text{C}$ ]

In the majority of practical applications, glass electrodes cells are calibrated by a two-point calibration, or bracketing, procedure using two standard buffer solutions, with pH values,  $\text{pH}(S_1)$  and  $\text{pH}(S_2)$ , bracketing the unknown  $\text{pH}(X)$ . Bracketing is often taken to mean that the  $\text{pH}(S_1)$  and  $\text{pH}(S_2)$  buffers selected from Table 2 should be those that are immediately above and below  $\text{pH}(X)$ . This may not be appropriate in all situations and choice of a wider range may be better.

- (c) Multi-point calibration [target uncertainty: 0.01-0.03 at 25 °C].

Multi-point calibration is carried out using up to five standard buffers. The use of more than five points yields no significant improvement in the statistical information obtainable.

Details of uncertainty computations (11) have been given (1).

### Measurement of pH and choice of pH Standard Solutions

- 1a) If pH is not required to better than  $\pm 0.05$  any pH standard solution may be selected.
- 1b) If pH is required to  $\pm 0.002$  and interpretation in terms of hydrogen ion concentration or activity is desired, choose a standard solution, pH(PS), to match X as closely as possible in terms of pH, composition and ionic strength.
- 2) Alternatively, a bracketing procedure may be adopted whereby two standard solutions are chosen whose pH values, pH(S1), pH(S2) are on either side of pH(X). Then if the corresponding potential difference measurements are  $E(S1)$ ,  $E(S2)$ ,  $E(X)$ , then pH(X) is obtained from

$$\text{pH}(X) = \text{pH}(S1) + [E(X) - E(S1)] / \%k$$

where  $\%k = 100[E(S2) - E(S1)] / [\text{pH}(S2) - \text{pH}(S1)]$  is the apparent percentage slope. This procedure is very easily done on some pH meters simply by adjusting downwards the slope factor control with the electrodes in S2. The purpose of the bracketing procedure is to compensate for deficiencies in the electrodes and measuring system.

### Information to be given about the measurement of pH(X)

The standard solutions selected for calibration of the pH meter system should be reported with the measurement as follows:

System calibrated with pH(S) = .... at ...K.

System calibrated with two primary standards, pH(PS1) = .... and pH(PS2) = .... at ....K.

System calibrated with  $n$  standards, pH(S1) = ...., pH(S2) = .... etc. at ....K.

### Interpretation of pH(X) in terms of hydrogen ion concentration

The defined pH has no simple interpretation in terms of hydrogen ion concentration but the mean ionic activity coefficient of a typical 1:1 electrolyte can be used to obtain hydrogen ion concentration subject to an uncertainty of 3.9% in concentration, corresponding to 0.02 in pH.

# PRACTICAL pH MEASUREMENTS ON NATURAL WATERS

A. K. Covington and W. Davison

(1) Dilute solutions and freshwater including 'acid-rain' samples ( $I < 0.02 \text{ mol kg}^{-1}$ )

Major problems could be encountered due to errors associated with the liquid junction. It is recommended that either a free diffusion junction is used or it is verified that the junction is working correctly using dilute solutions as follows. For commercial electrodes calibrated with IUPAC aqueous RVS or PS standards, the  $\text{pH(X)}$  of dilute solutions should be within  $\pm 0.02$  of those given in Table 1. The difference in determined  $\text{pH(X)}$  between a stirred and unstirred dilute solution should be  $< 0.02$ . The characteristics of glass electrodes are such that below pH 5 the readings should be stable within 2 min, but for pH 5 to 8.8 or so minutes may be necessary to attain stability. Interpretation of  $\text{pH(X)}$  measured in this way in terms of activity of hydrogen ion,  $a_{\text{H}^+}$ , is subject<sup>1</sup> to an uncertainty of  $\pm 0.02$  in pH.

(2) Seawater

Measurements made by calibration of electrodes with IUPAC aqueous RVS or PS standards to obtain  $\text{pH(X)}$  are perfectly valid. However, the interpretation of  $\text{pH(X)}$  in terms of the activity of hydrogen ion is complicated by the non zero residual liquid junction potential as well as by systematic differences between electrode pairs, principally attributable to the reference electrode. For 35‰ salinity seawater ( $S = 0.035$ )  $a_{\text{H}^+}$  calculated from  $\text{pH(X)}$  is typically 12% too low. Special seawater pH scales have been devised to overcome this problem:

(i) The total hydrogen ion scale,  $\text{pH}_T$ , is defined in terms of the sum of free and complexed (total) hydrogen ion concentrations, where

$$^T C_{\text{H}} = [\text{H}^+] + [\text{HSO}_4^-] + [\text{HF}].$$

$$\text{So, } \text{pH}_T = -\log ^T C_{\text{H}}$$

Calibration of the electrodes with a buffer having a composition similar to that of seawater, to which  $\text{pH}_T$  has been assigned, results in values of  $\text{pH}_T(\text{X})$  (Tables 2, 3) which are accurately interpretable in terms of  $^T C_{\text{H}}$ .

(ii) The free hydrogen ion scale,  $\text{pH}_F$ , is defined, and fully interpretable, in terms of the concentration of free hydrogen ions.

$$\text{pH}_F = -\log [\text{H}^+]$$

Values of  $\text{pH}_F$  as a function of temperature have been assigned to the same set of  $\text{pH}_T$  seawater buffers, and so alternatively can be used for calibration (Tables 2, 3)<sup>2,3</sup>

(3) Estuarine water

Prescriptions for seawater scale buffers are available for a range of salinities. Reliable estuarine pH measurements can be made by calibrating with a buffer of the same salinity as the sample. However, these buffers are difficult to prepare and their use presumes prior knowledge of salinity of the sample. Interpretable measurements of estuarine pH can be made by calibration with IUPAC aqueous RVS or PS standards if the electrode pair is additionally calibrated using a 20‰ salinity seawater buffer.<sup>4</sup> The difference between the assigned  $\text{pH}_{\text{sws}}$  of the seawater buffer and its measured  $\text{pH(X)}$  value using RVS or PS standards is

$$\Delta \text{pH} = \text{pH}_{\text{sws}} - \text{pH(X)}$$

Values of  $\Delta \text{pH}$  should be in the range of 0.08 to 0.18. It empirically corrects for differences between the two pH scales and for measurement errors associated with the electrode pair. The  $\text{pH(X)}$  of samples measured using IUPAC aqueous buffers, can be converted to  $\text{pH}_T$  or  $\text{pH}_F$  using the appropriate measured  $\Delta \text{pH}$ :

$$\text{pH}_T = \text{pH(X)} - \Delta \text{pH}$$

$$\text{or } \text{pH}_F = \text{pH(X)} - \Delta \text{pH}$$

This simple procedure is appropriate to pH measurement at salinities from 2‰ to 35‰. For salinities lower than 2‰ the procedures for freshwaters should be adopted.

- A. 25 ml of 0.2 molar KCl + *x* ml of 0.2 molar HCl.  
 B. 50 ml of 0.1 molar potassium hydrogen phthalate + *x* ml of 0.1 molar HCl.  
 C. 50 ml of 0.1 molar potassium hydrogen phthalate + *x* ml of 0.1 molar NaOH.  
 D. 50 ml of 0.1 molar potassium dihydrogen phosphate + *x* ml of 0.1 molar NaOH.  
 E. 50 ml of 0.1 molar tris(hydroxymethyl)aminomethane + *x* ml of 0.1 M HCl.  
 F. 50 ml of 0.025 molar borax + *x* ml of 0.1 molar HCl.  
 G. 50 ml of 0.025 molar borax + *x* ml of 0.1 molar NaOH.  
 H. 50 ml of 0.05 molar sodium bicarbonate + *x* ml of 0.1 molar NaOH.  
 I. 50 ml of 0.05 molar disodium hydrogen phosphate + *x* ml of 0.1 molar NaOH.  
 J. 25 ml of 0.2 molar KCl + *x* ml of 0.2 molar NaOH.

Final volume of mixtures = 100 ml.

## DISSOCIATION CONSTANTS OF INORGANIC ACIDS AND BASES

The data in this table are presented as values of  $pK_a$ , defined as the negative logarithm of the acid dissociation constant  $K_a$  for the reaction

Thus  $pK_a = -\log K_a$ , and the hydrogen ion concentration  $[H^+]$  can be calculated from

$$K_a = \frac{[H^+][B^-]}{[BH]}$$

In the case of bases, the entry in the table is for the conjugate acid; e.g., ammonium ion for ammonia. The  $OH^-$  concentration in the system

can be calculated from the equation

$$K_b = K_{\text{water}}/K_a = \frac{[OH^-][NH_4^+]}{[NH_3]}$$

where  $K_{\text{water}} = 1.01 \times 10^{-14}$  at 25 °C. Note that  $pK_a + pK_b = pK_{\text{water}}$ .

All values refer to dilute aqueous solutions at zero ionic strength at the temperature indicated. The table is arranged alphabetically by compound name.

# DISSOCIATION CONSTANTS OF ORGANIC ACIDS AND BASES

This table lists the dissociation (ionization) constants of over 1070 organic acids, bases, and amphoteric compounds. All data apply to dilute aqueous solutions and are presented as values of  $pK_a$ , which is defined as the negative of the logarithm of the equilibrium constant  $K_a$  for the reaction

i.e.,

$$K_a = [H^+][A^-]/[HA]$$

where  $[H^+]$ , etc. represent the concentrations of the respective species in mol/L. It follows that  $pK_a = pH + \log[HA] - \log[A^-]$ , so that a solution with 50% dissociation has pH equal to the  $pK_a$  of the acid.

Data for bases are presented as  $pK_a$  values for the conjugate acid, i.e., for the reaction

In older literature, an ionization constant  $K_b$  was used for the reaction  $B + H_2O$

$\rightleftharpoons BH^+ + OH^-$ . This is related to  $K_a$  by

$$pK_a + pK_b = pK_{water} = 14.00 \quad (\text{at } 25^\circ\text{C})$$

Compounds are listed by molecular formula in Hill order.

# CONCENTRATIVE PROPERTIES OF AQUEOUS SOLUTIONS: DENSITY, REFRACTIVE INDEX, FREEZING POINT DEPRESSION, AND VISCOSITY

This table gives properties of aqueous solutions of 66 substances as a function of concentration. All data refer to a temperature of 20°C. The properties are:

Mass %: Mass of solute divided by total mass of solution, expressed as percent.

$m$  Molality (moles of solute per kg of water).

$c$  Molarity (moles of solute per liter of solution).

$\rho$  Density of solution in g/cm<sup>3</sup>.

$n$  Index of refraction, relative to air, at a wavelength of 589 nm (sodium D line); the index of pure water at 20°C is 1.3330.

$\Delta$  Freezing point depression in °C relative to pure water.

$\eta$  Absolute (dynamic) viscosity in mPa s (equal to centipoise, cP); the viscosity of pure water at 20°C is 1.002 mPa s.

Density data for aqueous solutions over a wider range of temperatures and pressures (and for other compounds) may be found in Reference 2. Solutes are listed in the following order:

|                                                     |                                |                                |
|-----------------------------------------------------|--------------------------------|--------------------------------|
| Acetic acid                                         | Lithium chloride               | 2-Propanol                     |
| Acetone                                             | Magnesium chloride             | Silver nitrate                 |
| Ammonia                                             | Magnesium sulfate              | Sodium acetate                 |
| Ammonium chloride                                   | Maltose                        | Sodium bicarbonate             |
| Ammonium sulfate                                    | Manganese(II) sulfate          | Sodium bromide                 |
| Barium chloride                                     | D-Mannitol                     | Sodium carbonate               |
| Calcium chloride                                    | Methanol                       | Sodium chloride                |
| Cesium chloride                                     | Nitric acid                    | Sodium citrate                 |
| Citric acid                                         | Oxalic acid                    | Sodium hydroxide               |
| Copper sulfate                                      | Phosphoric acid                | Sodium nitrate                 |
| Disodium ethylenediamine tetraacetate (EDTA sodium) | Potassium bicarbonate          | Sodium phosphate               |
| Ethanol                                             | Potassium bromide              | Sodium hydrogen phosphate      |
| Ethylene glycol                                     | Potassium carbonate            | Sodium dihydrogen phosphate    |
| Ferric chloride                                     | Potassium chloride             | Sodium sulfate                 |
| Formic acid                                         | Potassium hydroxide            | Sodium thiosulfate             |
| D-Fructose                                          | Potassium iodide               | Strontium chloride             |
| D-Glucose                                           | Potassium nitrate              | Sucrose                        |
| Glycerol                                            | Potassium permanganate         | Sulfuric acid                  |
| Hydrochloric acid                                   | Potassium hydrogen phosphate   | Trichloroacetic acid           |
| Lactic acid                                         | Potassium dihydrogen phosphate | Tris(hydroxymethyl)methylamine |
| Lactose                                             | Potassium sulfate              | Urea                           |
|                                                     | 1-Propanol                     | Zinc sulfate                   |

Data in this table were calculated from the equation,  $\log_{10} K_w^* = A + B/T + C/T^2 + D/T^3 + (E + F/T + G/T^2) \log_{10} \rho_w^*$ , where  $K_w^* = K_w/(\text{mol kg}^{-1})$ , and  $\rho_w^* = \rho_w/(\text{g cm}^{-3})$ . The parameters are:

A = -4.098                      E = +13.957  
 B = -3245.2 K                F = 1262.3 K  
 C = +2.2362  $\times 10^5$  K<sup>2</sup>      G = +8.5641  $\times 10^5$  K<sup>2</sup>  
 D = -3.984  $\times 10^7$  K<sup>3</sup>

## IONIZATION CONSTANT OF NORMAL AND HEAVY WATER

This table gives the ionization constant in molality terms for H<sub>2</sub>O and D<sub>2</sub>O at temperatures from 0 to 100°C at the saturated vapor pressure. The quantity tabulated is  $-\log K_w$ , where  $K_w$  is defined by

$$K_w = m_+ \times m_-$$

and  $m_+$  and  $m_-$  are the molalities, in mol/kg of water, for H<sup>+</sup> and OH<sup>-</sup>, respectively.

# SOLUBILITY OF SELECTED GASES IN WATER

L. H. Gevantman

The values in this table are taken almost exclusively from the International Union of Pure and Applied Chemistry "Solubility Data Series". Unless noted, they comprise evaluated data fitted to a smoothing equation. The data at each temperature are then derived from the smoothing equation which expresses the mole fraction solubility  $X_1$  of the gas in solution as:

$$\ln X_1 = A + B/T^* + C \ln T^*$$

where

$$T^* = T/100 \text{ K}$$

All values refer to a partial pressure of the gas of 101.325 kPa (one atmosphere).

The equation constants, the standard deviation for  $\ln X_1$  (except where noted), and the temperature range over which the equation applies are given in the column headed Equation constants. There are two exceptions. The equation for methane has an added term,  $DT^*$ . The equation for  $\text{H}_2\text{Se}$  and  $\text{H}_2\text{S}$  takes the form,

$$\ln X_1 = A + B/T + C \ln T + DT$$

where  $T$  is the temperature in kelvin.

Solubilities given for those gases which react with water, namely ozone, nitrogen oxides, chlorine and its oxides, carbon dioxide, hydrogen sulfide, hydrogen selenide and sulfur dioxide, are recorded as bulk solubilities; i.e., all chemical species of the gas and its reaction products with water are included.

| Gas                                          | T/K    | Solubility ( $X_1$ )              | Equation constants           | Ref. |

# SOLUBILITY OF CARBON DIOXIDE IN WATER AT VARIOUS TEMPERATURES AND PRESSURES

The solubility of CO<sub>2</sub> in water, expressed as mole fraction of CO<sub>2</sub> in the liquid phase, is given for pressures up to atmospheric and temperatures of 0 to 100 °C. Note that 1 standard atmosphere equals 101.325 kPa. The references give data over a wider range of temperature and pressure. The estimated uncertainty is about 2%.

## AQUEOUS SOLUBILITY AND HENRY'S LAW CONSTANTS OF ORGANIC COMPOUNDS

The solubility in water of about 1300 organic compounds, including many compounds of environmental interest, is tabulated here. When data are available, values are given at several temperatures between 0 °C and 100 °C. Solids, liquids, and gases are included; additional data on gases can be found in the table "Solubility of Selected Gases in Water" in Section 8.

Solubility of solids is defined as the concentration of the compound in a solution that is in equilibrium with the solid phase at the specified temperature and one atmosphere pressure. For liquids whose water mixtures separate into two phases, the solubility given here is the concentration of the specified compound in the water-rich phase at equilibrium. In the case of gases (i.e., compounds whose vapor pressure at the specified temperature exceeds one atmosphere) the solubility is defined here as the concentration in the water phase when the partial pressure of the compound above the solution is 101.325 kPa (1 atm). Values for gases are marked with an asterisk.

The solubility values in this table are expressed as mass percent of solute,  $s = 100w_2$ , where the mass fraction  $w_2$  is defined as

$$w_2 = m_2 / (m_1 + m_2)$$

where  $m_2$  is the mass of solute and  $m_1$  the mass of water. For convenience, the solubility expressed in grams of solute that will dissolve in 1 kilogram of water is tabulated in the adjacent column to mass percent. For compounds with low solubility (e.g.,  $s < 1\%$ ), that column is, to a high approximation, numerically identical to the solubility expressed in grams of solute per liter of solution.

The mass fraction  $w_2$  is related to other common measures of solubility as follows:

|                                                  |                                                           |
|--------------------------------------------------|-----------------------------------------------------------|
| Molality:                                        | $m_2 = 1000 w_2 / M_2 (1 - w_2)$                          |
| Molarity:                                        | $c_2 = 1000 \rho w_2 / M_2$                               |
| Mole fraction:                                   | $x_2 = (w_2 / M_2) / \{ (w_2 / M_2) + (1 - w_2) / M_1 \}$ |
| Mass of solute per<br>100 g of H <sub>2</sub> O: | $100w_2 / (1 - w_2)$                                      |
| Mass of solute per<br>liter of solution:         | $1000 \rho w_2$                                           |

Here,  $M_2$  is the molar mass of the solute,  $M_1 = 18.015$  g/mol is the molar mass of water, and  $\rho$  is the density of the solution in g/mL.

Data have been selected from evaluated sources wherever possible, in particular the *IUPAC Solubility Data Series*. Many values come from experimental measurements reported in the *Journal of Chemical and Engineering Data* and the *Journal of Chemical Thermodynamics*, as well as critical review papers in the *Journal of Physical and Chemical Reference Data*. The primary source for each value is listed in the column following the solubility values; additional references of interest are sometimes given. Many of the references contain solubility data at other temperatures and pH values and in the presence of other compounds. The user is cautioned that wide variations of data are found in the literature for the lower solubility compounds. The references should be consulted for more information on these compounds.

The table also contains values of the Henry's Law constant  $k_H$ , which provides a measure of the partition of a substance between the atmosphere and the aqueous phase. Here,  $k_H$  is defined as the limit of  $p_2/c_2$  as the concentration approaches zero, where  $p_2$  is the

partial pressure of the solute above the solution and  $c_2$  is the concentration in the solution at equilibrium (other formulations of Henry's Law are often used; see Reference 5). The values of  $k_H$  listed here are based on direct experimental measurement whenever available, but many of them are simply calculated as the ratio of the pure compound vapor pressure to the solubility. This approximation is reliable only for compounds of very low solubility. In fact, values of  $k_H$  found in the literature frequently differ by a factor of two or three, and variations over an order of magnitude are not unusual (Reference 5). Therefore, the data given here should be taken only as a rough indication of the true Henry's Law constant, which is difficult to measure precisely.

All values of  $k_H$  refer to 25 °C. If the vapor pressure of the compound at 25 °C is greater than one atmosphere, it can be assumed that the  $k_H$  value has been calculated as  $101.325/c_2$ . The source of the Henry's Law data is given in the last column. The air-water partition coefficient (i.e., ratio of air concentration to water concentration when both are expressed in the same units) is equal to  $k_H/RT$  or  $k_H/2.48$  in the units used here.

Compounds are listed by systematic name. To locate a compound by molecular formula or CAS Registry Number, use the indexes to the table "Physical Constants of Organic Compounds" in Section 3, which point to the entry in that table from which the name can be determined.

# AQUEOUS SOLUBILITY OF INORGANIC COMPOUNDS AT VARIOUS TEMPERATURES

The solubility of over 300 common inorganic compounds in water is tabulated here as a function of temperature. Solubility is defined as the concentration of the compound in a solution that is in equilibrium with a solid phase at the specified temperature. In this table the solid phase is generally the most stable crystalline phase at the temperature in question. An asterisk \* on solubility values in adjacent columns indicates that the solid phase changes between those two temperatures (usually from one hydrated phase to another or from a hydrate to the anhydrous solid). In such cases the slope of the solubility vs. temperature curve may show a discontinuity.

All solubility values are expressed as mass percent of solute,  $100w_2$ , where

$$w_2 = m_2 / (m_1 + m_2)$$

and  $m_2$  is the mass of solute and  $m_1$  the mass of water. This quantity is related to other common measures of solubility as follows:

Molarity:  $c_2 = 1000 \rho w_2 / M_2$

Molality:  $m_2 = 1000 w_2 / M_2 (1 - w_2)$

Mole fraction:  $x_2 = (w_2 / M_2) / \{ (w_2 / M_2) + (1 - w_2) / M_1 \}$

Mass of solute per 100 g of  $H_2O$ :  $r_2 = 100 w_2 / (1 - w_2)$

Here  $M_2$  is the molar mass of the solute and  $M_1 = 18.015$  g/mol is the molar mass of water.  $\rho$  is the density of the solution in  $g\ cm^{-3}$ .

The data in the table have been derived from the references indicated; in many cases the data have been refitted or interpolated in order to present solubility at rounded values of temperature. Where available, values were taken from the IUPAC *Solubility Data Series* (Reference 1) or the related papers in the *Journal of Physical and Chemical Reference Data* (References 2 to 5), which present carefully evaluated data.

The solubility of sparingly soluble compounds that do not appear in this table may be calculated from the data in the table "Solubility Product Constants". Solubility of inorganic gases may be found in the table "Solubility of Selected Gases in Water".

Compounds are listed alphabetically by chemical formula in the most commonly used form (e.g., NaCl,  $NH_4NO_3$ , etc.).

# SOLUBILITY PRODUCT CONSTANTS

The solubility product constant  $K_{sp}$  is a useful parameter for calculating the aqueous solubility of sparingly soluble compounds under various conditions. It may be determined by direct measurement or calculated from the standard Gibbs energies of formation  $\Delta_f G^\circ$  of the species involved at their standard states. Thus if  $K_{sp} = [M^+]^m [A^-]^n$  is the equilibrium constant for the reaction

where  $M_m A_n$  is the slightly soluble substance and  $M^+$  and  $A^-$  are the ions produced in solution by the dissociation of  $M_m A_n$ , then the Gibbs energy change is

$$\Delta G^\circ = m \Delta_f G^\circ (M^+, aq) + n \Delta_f G^\circ (A^-, aq) - \Delta_f G^\circ (M_m A_n, s)$$

The solubility product constant is calculated from the equation

$$\ln K_{sp} = -\Delta G^\circ / RT$$

The first table below gives selected values of  $K_{sp}$  at 25°C. Many of these have been calculated from standard state thermodynamic data in References 1 and 2; other values are taken from publications of the IUPAC Solubility Data Project (References 3 to 7).

The above formulation is not convenient for treating sulfides because the  $S^{2-}$  ion is usually not present in significant concentrations (see Reference 8). This is due to the hydrolysis reaction

which is strongly shifted to the right except in very basic solutions. Furthermore, the equilibrium constant for this reaction, which depends on the second ionization constant of  $H_2S$ , is poorly known. Therefore it is more useful in the case of sulfides to define a different solubility product  $K_{spa}$  based on the reaction

Values of  $K_{spa}$ , taken from Reference 8, are given for several sulfides in the auxiliary table following the main table. Additional discussion of sulfide equilibria may be found in References 7 and 9.

# SOLUBILITY CHART

Abbreviations: **W**, soluble in water; **A**, insoluble in water but soluble in acids; **w**, sparingly soluble in water but soluble in acids; **a**, insoluble in water and only sparingly soluble in acids; **I**, insoluble in water and acids; **d**, decomposes in water. \* Indicates two modifications of the salt.

| No. |                                                  | Al                                              | NH <sub>4</sub>                                 | Sb                                              | Ba                                              | Bi                                              | Cd                                              | Ca                                              | Cr                                              | Co                                              | Cu                                              | Au (I)            | Au (II)                        | H                                               | Fe (II)                           | Fe (III)                          |

## REDUCTION OF WEIGHINGS IN AIR TO VACUO

When the mass  $M$  of a body is determined in air, a correction is necessary for the buoyancy of the air. The corrected mass is given by  $M + kM/1000$ , where  $k$  is a function of the material used for the weights, given by

$$k = 1000\rho_{\text{air}}(1/\rho_{\text{body}} - 1/\rho_{\text{weight}})$$

and  $\rho$  is density. The table below is computed for an air density of 0.0012 g/cm<sup>3</sup> and for densities of three common weights:

| Density of<br>body (g/cm <sup>3</sup> ) | Value of $k$ for weights of: |       |              |
|-----------------------------------------|------------------------------|-------|--------------|
|                                         | Pt-Ir                        | Brass | Quartz or Al |
| 0.5                                     | 2.34                         | 2.26  | 1.95         |
| 0.6                                     | 1.94                         | 1.86  | 1.55         |
| 0.7                                     | 1.66                         | 1.57  | 1.26         |
| 0.8                                     | 1.44                         | 1.36  | 1.05         |
| 0.9                                     | 1.28                         | 1.19  | 0.88         |
| 1.0                                     | 1.14                         | 1.06  | 0.75         |
| 1.1                                     | 1.04                         | 0.95  | 0.64         |
| 1.2                                     | 0.94                         | 0.86  | 0.55         |
| 1.3                                     | 0.87                         | 0.78  | 0.47         |
| 1.4                                     | 0.80                         | 0.72  | 0.40         |
| 1.5                                     | 0.74                         | 0.66  | 0.35         |
| 1.6                                     | 0.69                         | 0.61  | 0.30         |
| 1.7                                     | 0.65                         | 0.56  | 0.25         |

platinum-iridium (21.6 g/cm<sup>3</sup>), brass (8.5 g/cm<sup>3</sup>), and aluminum or quartz (2.65 g/cm<sup>3</sup>).

## PROPERTIES OF CARRIER GASES FOR GAS CHROMATOGRAPHY

The following is a list of carrier gases sometimes used in gas chromatography, with properties relevant to the design of chromatographic systems. All data refer to normal atmospheric pressure (101.325 kPa).

$M_r$ : Molecular weight (relative molar mass)  
 $\rho_{25}$ : Density at 25 °C in g/L  
 $\lambda$ : Thermal conductivity in mW/m °C  
 $\eta$ : Viscosity in  $\mu\text{Pa s}$  (equal to  $10^{-3}$  cP)  
 $c_p$ : Specific heat at 25 °C in J/g °C

## SOLVENTS FOR ULTRAVIOLET SPECTROPHOTOMETRY

This table lists some solvents commonly used for sample preparation for ultraviolet spectrophotometry. The properties given are:

- $\lambda_c$ : cutoff wavelength, below which the solvent absorption becomes excessive.  
 $\epsilon$ : dielectric constant (relative permittivity); the temperature in °C is given as a superscript.  
 $t_b$ : normal boiling point.

## $^{13}\text{C}$ CHEMICAL SHIFTS OF USEFUL NMR SOLVENTS

The following table gives the expected carbon-13 chemical shifts, relative to tetramethylsilane, for various useful NMR solvents. In some solvents, slight changes can occur with change of concentration.<sup>2,3</sup>

## MASS SPECTRAL PEAKS OF COMMON ORGANIC SOLVENTS

The strongest peaks in the mass spectra of 375 important organic solvents and other liquid reagents are listed in this table. The *e/m* value for each peak is followed by the relative intensity in parentheses, with the strongest peak assigned an intensity of 100. The peaks for each compound are listed in order of decreasing intensity. Compounds are listed by the name used in this *Handbook*, with other common names given in parentheses.

Data on the physical properties of the same compounds may be found in Section 15 in the table *Laboratory Solvents and Other Liquid Reagents*.

## SOLUBILITY OF COMMON SALTS AT AMBIENT TEMPERATURES

This table gives the aqueous solubility of selected salts at temperatures from 10°C to 40°C. Values are given in molality terms.

## FLAME AND BEAD TESTS

### Flame Colorations

#### Violet

Potassium compounds. Purple red through blue glass. Easily obscured by sodium flame. Bluish-green through green glass. Rubidium and cesium compounds impart same flame as potassium compounds.

#### Blues

Azure — Copper chloride. Copper bromide gives azure blue followed by green. Other copper compounds give same coloration when moistened with hydrochloric acid.

Light blue — Lead, arsenic, selenium.

#### Greens

Emerald — Copper compounds except the halides, and when not moistened with hydrochloric acid.

Pure green — Compounds of thallium and tellurium.

Yellowish — Barium compounds. Some molybdenum compounds. Borates, especially when treated with sulfuric acid or when burned with alcohol.

Bluish — Phosphates with sulfuric acid.

Feeble — Antimony compounds. Ammonium compounds.

Whitish — Zinc.

#### Reds

Carmine — Lithium compounds. Violet through blue glass.

Invisible through green glass. Masked by barium flame.

Scarlet — Strontium compounds. Violet through blue glass.

Yellowish through green glass. Masked by barium flame.

Yellowish — Calcium compounds. Greenish through blue glass.

Green through green glass. Masked by barium flame.

#### Yellow

Yellow — All sodium compounds. Invisible with blue glass.

### Bead Tests

Abbreviations employed: s = saturated; ss = supersaturated; ns = not saturated; h = hot; c = cold

#### Borax Beads

| Substance  | Oxidizing flame                       | Reducing flame                      |
|------------|---------------------------------------|-------------------------------------|
| Aluminum   | Colorless (h, c, ns); opaque (ss)     | Colorless; opaque (s)               |
| Antimony   | Colorless; yellow or brownish (h, ss) | Gray and opaque                     |
| Barium     | Colorless (ns)                        |                                     |
| Bismuth    | Colorless; yellow or brownish (h, ss) | Gray and opaque                     |
| Cadmium    | Colorless                             | Gray and opaque                     |

## SOLUBILITY OF HYDROCARBONS IN SEAWATER

Concern about pollution of the oceans has stimulated measurements of the solubility of organic compounds in seawater. This table gives the solubility of several hydrocarbons in seawater. The data are derived from a review in the IUPAC Solubility Data Series (Reference 1).

Solubility is expressed in this table as parts per million by mass, i.e.,

$$S/\text{ppm}(\text{mass}) = 10^6 \times w_2 = 10^6 \times m_2/(m_1 + m_2)$$

where  $m_1$  and  $m_2$  are the masses of solvent (seawater) and solute, respectively, under saturation conditions, and  $w_2$  is the mass fraction. Since the solubilities in this table are very low, the value of  $S$  is effectively the mass of hydrocarbon in grams per 1000 kg of seawater.

The temperature and salinity of each measurement are given in the table. Salinity is a standardized measure of the concentration of dissolved salts, as explained in the table "Properties of Seawater" in Section 14. Salinity values in the open oceans at mid-latitude typically fall between 34 and 36.

Reference 1 gives details of the method of measurement and an indication of the reliability of the measurements.

# SOLUBILITY OF ORGANIC COMPOUNDS IN PRESSURIZED HOT WATER

Liquid water at elevated temperatures and pressures, but still in the subcritical region, is of interest as a solvent in various laboratory and industrial processes. In effect, this means water at a temperature between about 100°C and 373°C, the critical temperature, and at pressures up to 400 bar or greater. Since the dielectric constant of water decreases with increasing temperature, the solubility of many compounds, especially non-polar compounds, increases dramatically at higher temperature. The fact that solubility can be fine-tuned by controlling temperature and pressure makes pressurized hot water a useful tool in various extraction and reaction processes.

This table gives a sample of the variations of solubility with temperature and pressure for several compounds, mostly hydrocarbons. The solubility is expressed in both mole fraction of solute,  $x_2$ , and mass percent,  $100w_2$ , where  $w_2$  is the mass fraction. More information is available in the references.

## PROTON NMR SHIFTS OF COMMON ORGANIC SOLVENTS

The table below lists the  $^1\text{H}$  chemical shifts for over 300 organic solvents and liquid reagents. The solvent in which the shift was measured is given in the second column. Shifts are given in parts per million relative to tetramethylsilane (TMS) and are listed in order of smallest to largest shift. In many cases the peaks show additional small splittings. Compounds are listed by the name used in this *Handbook*, with other common names given in parentheses.

# BOND LENGTHS IN CRYSTALLINE ORGANIC COMPOUNDS

The following table gives average interatomic distances for bonds between the elements H, B, C, N, O, F, Si, P, S, Cl, As, Se, Br, Te, and I as determined from X-ray and neutron diffraction measurements on organic crystals. The table has been derived from an analysis of high-precision structure data on about 10,000 crystals contained in the 1985 version of the Cambridge Structural Database, which is maintained by the Cambridge Crystallographic Data Center. The explanation of the columns is:

Column 4:  $m$  is the median in Å units of all values.  
 Column 5:  $\sigma$  is the standard deviation in the sample.  
 Column 6:  $q_1$  is the lower quartile for the sample (i.e., 25% of values are less than  $q_1$  and 75% exceed it).  
 Column 7:  $q_u$  is the upper quartile for the sample.  
 Column 8:  $n$  is number of observations in the sample.  
 Column 9: Notes refer to the footnotes in Appendix 1.

Column 1: Specification of elements in the bond, with coordination number given in parentheses, and bond type (single, double, etc.). For carbon, the hybridization state is given.  
 Column 2: Substructure in which the bond is found. The target bond is set in boldface. Where X is not specified, it denotes any element type. C# indicates any sp<sup>3</sup> carbon atom, and C\* denotes an sp<sup>3</sup> carbon whose bonds, in addition to those specified in the linear formulation, are to C and H atoms only.  
 Column 3:  $d$  is the unweighted mean in Å units of all the values for that bond length found in the sample.

References to special cases are given in a shorthand form and listed in Appendix 2. Further information on the method of analysis of the data may be found in the reference cited below.

The table is reprinted with permission of the authors, the Royal Society of Chemistry, and the International Union of Crystallography.

## Appendix 1. (Footnotes to Table)

- Sample dominated by B–CH<sub>3</sub>. For longer bonds in B–CH<sub>3</sub> see LITMEB10 [B(4)–CH<sub>3</sub> = 1.621–1.644 Å].
- p(π)–p(π) Bonding with Bsp<sup>2</sup> and Nsp<sup>2</sup> coplanar (τBN = 0 ± 15°) predominates. See G. Schmidt, R. Boese, and D. Bläser, *Z. Naturforsch.*, 1982, **37b**, 1230.
- 84 observations range from 1.38 to 1.61 Å and individual values depend on substituents on B and O. For a discussion of borinic acid adducts see S. J. Rettig and J. Trotter, *Can. J. Chem.*, 1982, **60**, 2957.
- See M. Kaftory in 'The Chemistry of Functional Groups. Supplement D: The Chemistry of Halides, Pseudohalides, and Azides', S. Patai and Z. Rappoport, Eds., Wiley: New York, 1983, Part 2, ch. 24.
- Bonds which are endocyclic or exocyclic to any 3- or 4-membered rings have been omitted from all averages in this section.
- The overall average given here is for Csp<sup>3</sup>–Csp<sup>3</sup> bonds which carry only C or H substituents. The value cited reflects the relative abundance of each 'substitution' group. The 'mean of means' for the 9 subgroups is 1.538 (σ = 0.022) Å.
- See F. H. Allen, (a) *Acta Crystallogr.*, 1980, **B36**, 81; (b) 1981, **B37**, 890.
- See F. H. Allen, *Acta Crystallogr.*, 1984, **B40**, 64.
- See F. H. Allen, *Tetrahedron*, 1982, **38**, 2843.
- See F. H. Allen, *Tetrahedron*, 1982, **38**, 645.
- Cyclopropanones and cyclobutanones excluded.
- See W. B. Schweizer and J. D. Dunitz, *Helv. Chim. Acta*, 1982, **65**, 1547.
- See L. Nørskov-Lauritsen, H.-B. Bürgi, P. Hoffmann, and H. R. Schmidt, *Helv. Chim. Acta*, 1985, **68**, 76.
- See P. Chakrabarti and J. D. Dunitz, *Helv. Chim. Acta*, 1982, **65**, 1555.
- See J. L. Hencher in 'The Chemistry of the C≡C Triple Bond', S. Patai, Ed., Wiley, New York, 1978, ch. 2.
- Conjugated: torsion angle about central C–C single bond is 0 ± 20° (*cis*) or 180 ± 20° (*trans*).
- Unconjugated: torsion angle about central C–C single bond is 20–160°.
- Other conjugative substituents excluded.
- TCNQ is tetracyanoquinodimethane.
- No difference detected between C2 ≈ C3 and C3 ≈ C4 bonds.
- Derived from neutron diffraction results only.
- Nsp<sup>3</sup>: pyramidal; mean valence angle at N is in range 108–114°.
- Nsp<sup>2</sup>: planar; mean valence angle at N is ≥ 117.5°.
- Cyclic and acyclic peptides.
- See R. H. Blessing, *J. Am. Chem. Soc.*, 1983, **105**, 2776.
- See L. Lebioda, *Acta Crystallogr.*, 1980, **B36**, 271.
- n* = 3 or 4, i.e. tri- or tetra-substituted ureas.
- Overall value also includes structures with mean valence angle at N in the range 115–118°.
- See F. H. Allen and A. J. Kirby, *J. Am. Chem. Soc.*, 1984, **106**, 6197.
- See A. J. Kirby, 'The Anomeric Effect and Related Stereoelectronic Effects at Oxygen', Springer, Berlin, 1983.
- See B. Fuchs, L. Schleifer, and E. Tartakovsky, *Nouv. J. Chim.*, 1984, **8**, 275.
- See S. C. Nyburg and C. H. Faerman, *J. Mol. Struct.*, 1986, **140**, 347.
- Sample dominated by P–CH<sub>3</sub> and P–CH<sub>2</sub>–C.
- Sample dominated by C\* = methyl.
- See A. Kalman, M. Czugler, and G. Argay, *Acta Crystallogr.*, 1981, **B37**, 868.
- Bimodal distribution resolved into 22 'short' bonds and 5 longer outliers.
- All 24 observations come from BUDTEZ.
- 'Long' O–H bonds in centrosymmetric O---H---O H-bonded dimers are excluded.
- N–N bond length also dependent on torsion angle about N–N bond and on nature of substituent C atoms; these effects are ignored here.
- N pyramidal has average angle at N in range 100–113.5°; N planar has average angle of ≥ 117.5°.
- See R. R. Holmes and J. A. Deiters, *J. Amer. Chem. Soc.*, 1977, **99**, 3318.
- No detectable variation in S=O bond length with type of C-substituent.

## Appendix 2

## STRUCTURE OF FREE MOLECULES IN THE GAS PHASE

This table gives information on the geometric structure of selected molecules in the gas phase, including the overall geometry, interatomic distances, and bond angles. The molecules have been chosen to provide data on a wide variety of chemical bonds and to illustrate the influence of molecular environment on bond distances and angles. The table is restricted to molecules with conventional covalent or ionic bonds, but it should be pointed out that structure data on many loosely bonded complexes of the van der Waals type have recently become available. The references below contain data on many molecules that are not included here and give additional information such as uncertainties and isotopic variations.

The two techniques for gas phase structure determination are spectroscopy and electron diffraction. The following codes are used to indicate the method used for each set of data:

ED – Gas phase electron diffraction  
MW – Microwave spectroscopy, including both measurements in bulk gases and molecular beams  
IR – Infrared spectroscopy  
R – Raman spectroscopy  
UV – Electronic spectroscopy in the ultraviolet and visible regions, including fluorescence measurements  
ESR – Electron spin resonance.

In some cases data from two sources have been combined to derive the structure; these are labeled by “ED, MW,” for example.

Because of the internal vibrations that are present in all molecules, even in their lowest energy state, the definition of interatomic distance is not a simple matter. The ideal measure is the equilibrium distance in the hypothetical non-vibrating state, designated by  $r_e$ . This is the value of the separation of the atoms at the minimum of the potential function that describes the forces between the two atoms. All other measures represent some form of average, generally complex, over the vibrational motions. Since the potential function is asymmetric and less steep at distances beyond the potential minimum, the average distance is normally greater than  $r_e$ . Distances determined by electron diffraction (ED) represent an average over all vibrational states that are populated at the temperature of the measurement; the most common measure is designated  $r_g$ . Distances determined by spectroscopy (MW, IR, R, or UV) through measurements on the ground vibrational state of the molecule, designated by  $r_0$ , describe some form of average, not easily defined, over the zero-point vibrations. Another measure that is frequently used in microwave spectroscopy is the “substitution” distance  $r_s$ , which is operationally defined through a series of measurements on different isotopic species. In simple cases,  $r_s$  often lies between  $r_0$  and  $r_e$  and is therefore a closer approximation to  $r_e$ . Several other types of averages have been used; good discussions can be found in Volumes II/25 and II/28 of the *Landolt-Börnstein* series (Reference 1) and in References 4 and 5.

Unless otherwise specified, distances and angles given in this table are  $r_0$  values if the method is spectroscopic and  $r_g$  values if the method is electron diffraction. When given, equilibrium and substitution distances are designated by  $r_e$  and  $r_s$ , respectively.

Many interatomic distances and angles calculated by *ab initio* techniques have been reported in the recent literature. However, it should be emphasized that all data in this table are obtained from direct experimental measurements. In a few cases, *ab initio* calculations of vibration-rotation interaction constants have been combined with the primary experimental measurements to derive  $r_e$  values in the table.

The number of significant figures in the values is an indication of the precision of the measurement; thus a distance quoted to three decimal places is probably reliable to about 0.005 Å or better. However, discrepancies between  $r_e$ ,  $r_0$ , and  $r_g$  values for the same bond are often the order of 0.01 Å because of vibrational averaging considerations, so care must be taken in comparing bond distances in different molecules. Some distances in simple molecules are given here to four or five decimal places, but little chemical significance can be attached to differences beyond the third decimal place.

The table is presented in two parts: Part A covers molecules that do not contain carbon while Part B lists carbon-containing molecules. Because many of the entries in Part A are free radicals or other transient species whose systematic chemical names are unfamiliar, the listing in Part A is in order of chemical formula. Part B is ordered by name. In both parts the second column gives information on the overall configuration of the molecule, often indicated by the point group of the equilibrium geometry. Columns 3 through 8 give the values of the bond distances and angles, and the last column indicates the experimental method. Distances are given in Å units, where 1 Å =  $10^{-10}$  m or 0.1 nm. Angles are given in degrees.

The efforts of Kozo Kuchitsu in preparing an earlier version of this table and in giving advice on the new version are gratefully acknowledged.
