Linen for household purposes

How to Stock and Arrange the Linen Cupboard

Other information of interest in connexion with this important feature of home equipment will be found under Embroidery; Furniture; Lace; Laundry; Mending; Starch; Table Laying. See also the entries Bedspread, Blanket; Cupboard; Tablecloth, Towel

Obtained from the flax plant, linen is one of the most beautiful and useful of woven fabrics. Although the improvements in the manufacture of cotton goods have led to their employment for many household and dress purposes in place of linens, the latter remain firmly in the housewife's favour on account of their superior qualities of texture and durability.

Time has little or no effect on linen, as ancient embroideries on this material prove, and it is not subject to ravages by moths. New methods of dyeing and the old ones of grass bleaching render coloured linens un-fadeable and white ones fresh after their final laundering. Half-bleached linen is much in demand for embroidered luncheon and dressing table sets, afternoon tea cloths and cushions. This apparently natural *écru* shade should, however, be artistically achieved by dyeing which is guaranteed fadeless; when the shade is merely due to partial bleaching of the linen it is not permanent and washes out to a dirty cream.

The Nature of Linen. Flax stems are about 2 ft. long; their middle parts furnish the best line, and the tops and roots become tow. The finer linens are made from the longer and better flax fibre, technically known as line. Thicker and coarser fabrics, such as crash and canvas, are made from tow. The long fibres are not actually one and indivisible, but are built up of shorter overlapping fibres $1\frac{1}{4}$ to $1\frac{3}{4}$ in. in length, glued together by a natural compound called pectose. In wear these shorter elements eventually come apart. Linen should not be boiled in soda, because washing soda weakens the pectose and disintegrates the filaments. It converts flax into fluff, and borax should be substituted as a water softener.

The strongest, but not the smoothest, sewing thread is linen, and flax thread should be used for stitching carpets, boot buttons, and for any purpose in which exceptional strength is demanded.

The expert eye can discern easily the difference between linen and cotton materials; the feel is different, and whereas linen rips with a sharp sound and the edges of the tear look smooth, cotton tears with a dull noise and the edges curl. Linen does not absorb or retain moisture so readily as cotton. If a damp cloth is passed over a length of cotton material, the surface will look rough; but if the same is done to linen, the surface of the fabric will remain unaltered.

Linen is one of the hardest textiles to dye because it is difficult to get the fast colour to penetrate far into the cloth. Successful methods are, however, absolutely guaranteed, and in made up form or by the yard for embroidery or other purposes only qualities in coloured linens which are thus guaranteed to withstand both sun and washing should be purchased.

Table Linen. Although luncheon sets and dinner sets of mats and table centre are often liked because of the ease with which they are laundered at home and because of the decorative appearance which they give to the table when of coloured, embroidered or lace trimmed linen, many housewives prefer an all over cloth for breakfast and for the formal dinner table. Coloured and checked linens are greatly liked for the breakfast table, and the latter kind are extremely cheap, effective and hard wearing, with a variety of borders in shades of blue, green, rose and yellow to tone with the breakfast service in use.

Fine linen damask has always a beautiful appearance on the dinner table. Double damask is more expensive than the single kind, but its glossy surface is far richer and being more substantial washes and wears better. Coloured damasks are also liked, especially for smaller tables. Used in harmony with glass, china and flowers or candles, rose, maize, green or écreu cloths present a most inviting appearance at luncheon or dinner. Even more beautiful are tablecloths in ivory damask. Lace trimmed cloths are also used by their fortunate possessors for festive occasions. Decorative examples in fine Irish linen trimmed with filet lace and insertions, or in coarser ivory linen with a peasant made lace, can give a handsomer effect than any other form of table covering. Napkins should match the tablecloths used, and any other linen in the room, such as a sideboard runner, should also correspond in style.

Damask table linen in course of furnishing sometimes receives an injury which develops into a crack or cut and which does not appear until the article has been laundered once or twice. As soon as such a crack develops it should be mended carefully, but the better plan is only to buy linen from a firm which would replace such an unsatisfactory article. All cloths should also be purchased fully shrunk, otherwise after washing they may run up in width to the extent of 2 in. in a yard.

Afternoon teacloths, tea napkins, bridge cloths, breakfast tray sets, cocktail sets and tray cloths are seen in almost endless variety and can be handmade in linen introducing decorations of coloured borders and appliqué embroidery, every kind of good washing lace made of linen thread, drawn thread work or crochet.

Bedroom and Kitchen Linen. Linen bed clothes that is to say, sheets and pillow-slips, bolster covers and bedspreads—make for coolness and ease. Bad sleepers and invalids find the texture of linen welcome and soothing, but others prefer cotton, especially twilled cotton. Linen hem of coloured linen to plain white sheets and pillow cases in place of the ordinary hemstitched border. The same method of decoration can be used for towels. Bolster cases are often dispensed with altogether, and a large pillow is substituted. To measure for pillow slips, run the tape measure along the pillow at the ends and sides, and allow an extra inch on both results for bulk. Hemstitched edges count as extraneous measurements.

Linen is the best choice for face towels. Fine linen huckaback with damask borders in white or colours are expensive, but wear well. Plainer towels can be trimmed at the ends with cross-stitched designs or with lace or crochet. Embroidered monograms and initials always give a distinctive touch to linen. Dressing table sets look particularly well in colours with drawn thread work corners and hems, and large monograms embroidered in satin-stitch on each piece.

For round towels and kitchen cloths linen is undoubtedly the most economical purchase in the long run. It is also a far better fabric for dusters than ordinary cotton. Glass cloths should be of linen with a small percentage of cotton to soften the material.

Sales at reliable stores very often provide good opportunities for obtaining bargains in linens. Slightly shop-soiled articles are greatly reduced, or cotton may be on the up-grade and linen down, thus enabling the store to purchase large quantities of goods at a low wholesale price and retail them cheaply.

Printed linens for covers and curtains provide excellent wear and are usually of good design, though these linens as a rule do not show quite the brilliant colour patterns available in cotton.

The Linen Cupboard. In house linen, as in other equipment for the home, space-saving ideas have limited the quantities considered necessary for the stocking of the linen-room or cupboard. In smaller houses and flats there is usually a built-in cupboard provided for linen, but, if not, a movable one should be installed. In some of the modern homes there is good accommodation for

this purpose, and the hot-water pipes pass through the large cupboard or room, which is also supplied with proper ventilation. Choose a spot near the landing radiator, kitchen range, or some other heating arrangement in the house to place a movable cupboard, if one has to be bought for the storage of linen.

Drawer accommodation should be provided for fancy tea cloths, mats, guest towels, and toilet covers which are not in constant use. Where a linen cupboard has only shelves, smaller articles can be kept in a series of cardboard boxes to ensure their freshness when required. Old sheets or discarded pillow cases make good linings for shelves, but the more excellent way is to line the shelves with chintz or cretonne. Pieces of material are cut the exact width of the shelves but twice their depth, and these pieces are bound or neatly hemmed and attached to the wooden shelves with drawing pins in such a way that the surplus depth hangs over the edge of the shelf, ready to be turned back over the piles of linen when these are arranged in their allotted spaces.

Various articles not of linen fabric are included in the term linen when it is used to denote the contents of the linen cupboard. Cotton sheets and pillow slips, bath towels, bedspreads of other materials, and blankets are all counted as house linen. When arranging the stock it is well to keep articles that are not so frequently required on the less accessible shelves and reserve a separate place for each description of linen. With a large stock shelves may be labelled and their contents specified. Single sheets, should be in a pile apart from double, cotton pillow and bolster cases separated from linen ones, large bath towels from small, and the face towels in their sets. Articles newly returned from the laundry are naturally placed at the bottom of their respective piles.

When setting up house in a small way, a useful list of linen is as follows: For the bedrooms, 2 toilet covers or dressing-table sets for each room, 3 pairs of sheets for each bed, 3 pillow slips and 3 bolster cases, or 6 pillow slips if bolsters are not used, 1 mattress cover, 2 bedspreads, 3 blankets and 1 under blanket, and for each member of the household 4 face towels and 4 bath towels, with a dozen of the former and half a dozen of the latter in reserve. For the table, 3 afternoon tea cloths, 3 best dinner table cloths, 3 others or 3 sets of mats, 3 breakfast cloths, 3 kitchen table cloths, 1½ doz. napkins, or sets to match various cloths, 6 tray cloths, 3 sideboard cloths, 1 set of dessert doilies. For the kitchen, 1 doz. each of dusters, glass cloths, tea cloths (not all to be given out at once, but in sets of 4), 6 polishing dusters, 3 oven cloths, 3 roller towels, 6 lavatory towels.

These figures will naturally require adjustment to individual household needs and the housewife's taste and discretion. With care and additions, as need arises, this amount of linen should last for years. In a large household the amount for each person may be lower in proportion. Linen can be marked free of charge when ordered at any large store. A book may be kept in the cupboard to chronicle purchases.

Good uses may be found for old linen. Face towels or pillow slips past ordinary service make excellent polishing pads for metal and furniture Turkish towels when worn out may have the best pieces cut out to be made into lavatory or floor cloths. Old tablecloths are useful for laundry work, either for ironing cloths or for wrapping up damped linen. Old sheets may be stored for spring cleaning or redecorating of rooms, when they are of value for protecting furniture from dust or paint.

LINEN BASKET. The cane basket shown at Fig 1 is not difficult to make. It should be about 24 in. high, 14 in. by 12 in. at the base and 2 in. wider at the top. Commence with a flat bottom with 12 stakes, as shown in Fig. 2, to a width of 12 in., and carry to a height of 14 in. with single cane weaving. The stakes may be held in a block of wood in which holes have been made at suitable intervals. If the upright stakes for the sides are driven in the side as suggested in Fig. 3, the outside stakes of the bottom should be of stout willow; but if the uprights are scalloped as in Fig. 4, all bottom stakes may be the same size. The upright stakes should be whole cane, No. 10 pulp cane

will do, and should be at least 3 ft. 6 in. long. The four corner sticks should be either stout whole cane, willow, or $\frac{3}{4}$ in. birch dowel. A No. 5 pulp cane should be used for weaving, but it will be advisable to use a fine whole cane for the commencing as well as for the intermediate waleing. The first stage in the weaving of the sides is shown in Fig. 3; 10 upright stakes are driven in, each alongside a bottom stake, and bent upright 14 stakes are secured to the sides, either by fitting them in a hole pierced in the side stakes of the bottom as indicated, or by the method shown in Fig. 4. The corner stakes are 24 in. high.

Linen Basket. Fig. 1. Square cane basket with lid. Fig. 2. Commencing on the bottom. Fig. 3. Upright stakes driven into sides, and weaving begun. Fig. 4. Another method, with scalloped uprights. Fig. 5. Showing how the weaving of the canes is begun. Fig. 6. Weaving round corner stake. Fig. 7. Scallom method of forming stakes for lid.

Commence weaving the sides as shown in Fig. 5 by working three lengths of cane alternately. A commences behind No. 1, is carried in front of 2 and 3, and brought to the front from behind 4 B starts from behind 2, is carried in front of 3 and 4, behind 5 and left in front of 6. C goes from 3, in front of 4 and 5, behind 6, and is left in front of 7. A is now picked up again, carried over the others in front of 5 and 6, behind 7, and left in front of 8. This is carried on until a corner is readied, when the method shown in Fig 6 is followed, A representing the first length to be carried round the corner stick. Continue completely round the four sides and repeat for another two or three rounds.

Single rod weaving should now be done to a height of 2 or 3 in., and another round of 3 rod weaving carried round. Follow this by about 10 in. of single weaving, then another 3 rod wale, as it is called, a further 5 in. of single weaving, another 3 rod wale, and finish with single weaving up to border height. Continual measurements should be made in order to obtain the necessary splay.

The lid should be made in a similar manner to the bottom, but carried to a height of 16 in. The outside stakes should in this case be stout and the ends finished off with lengths of similar stuff, bound to the outside weaving with pulp cane. Another method is to make a complete frame with stout whole cane and form the stakes by the scallom method shown in Fig 7. This will take a little longer, but forms a much neater lid.

The handle is made by bending a length of whole cane to about 2 in. diameter, binding it with either round or split cane, and attaching it to the lid with the same material; the lid is hinged by threading three or four rounds of cane under the two borders and securing the ends in the weaving. A heavier foot may be worked by turning the basket upside down, driving short lengths of cane alongside the stakes, running a row or two of a three rod wale, and then turning down the stakes to form an ordinary border.

A Round Basket. A round linen basket may be made by commencing from a suitable bottom and staking it up. The sides should be filled up with randing with a three rod wale at intervals. The lid is made like the bottom, a border being formed by inserting short lengths of cane by the side of each spoke and laying them down as a border. Owing to the difficulty of keeping the stakes upright, this basket should not be attempted by the inexperienced. *See* Basket Making; Cane; Osier.

LINENFOLD. This is a form of decoration sometimes found upon furniture and the panels of walls, dating from the 15th century. It resembles folded linen and is seen particularly upon pieces of furniture and wainscots of the Tudor period. *See* Panelling; Tudor Style.

Linenfold decoration within a moulded framework. This example was found in Somerset, on the oak panelling of a 15th century farmhouse. (By permission of the Director, Victoria and Albert Museum, S. Kensington)

Ling. *This is the popular name of the common moorland heather (Calluna vulgaris).*

LING: The Fish. Ling may be prepared according to any of the recipes given for cooking cod, a fish it somewhat resembles in appearance. The tongue and sounds of the ling are usually sold separately in a pickled form. *See* Cod; Fish.

Liniment. *See* Embrocation.

LINK. There are a number of applications of the word link. As a unit of measurement it equals 7·92 in., 100 links making a chain in land surveying.

In the valve motion and other parts of many kinds of prime movers, such as steam and gas engines, a link is a connecting-rod joining two parts of the mechanism together, and particularly described by a prefix, such as a vibrating link or a shifting link, the former performing a function in the valve motion, and the latter being used to transmit motion from one part to another.

LINNAEA. The linnaea, or twin flower, is a very pretty, trailing evergreen plant. The leaves are borne in pairs and the pink, bell-shaped flowers are in pairs on the stalk. It does well in moist peat in a cool part of the rockery. Propagation is best effected by means of division in autumn or spring.

linoleum: plain, inlaid and other kinds

With Directions for Laying, Cleaning and Polishing

The reader is advised to consult further the entries on Bathroom; Kitchen; Landing; and other rooms where Linoleum is used. See also Carpet; Floor; Furnishing; Labour Saving.

Linoleum is particularly suitable for bathrooms, nurseries, and kitchens, as its surface is impervious to moisture, grease, and dirt, and it is easy to clean and is durable. If well laid, it has no cracks or crevices to collect dust, and the cork in its composition makes it a warm and quiet floor covering. There are, however, a few conditions which make the use of linoleum as a floor covering unsuitable. It renders the floor practically air-tight, so that it is not recommended for damp ground floors.

Dampness, combined with the absence of air, causes linoleum to rot on the under surface, a condition which develops dry rot in the woodwork of the floor. Worn and uneven floors, either of boards, tiles, or bricks, such as are often found in old houses, should not be covered with linoleum, as the unevenness of the surface causes cracks to appear, thus making it anything but economical. Concrete, provided it is dry and smooth, can be covered with linoleum successfully, when fixed with special linoleum cement.

In renovating old cottages and country houses it is sometimes necessary to convert a second kitchen or washhouse into a bathroom. Linoleum or cork carpet is a suitable and warm floor covering, provided the floor is fairly level. If it is badly worn, it should be floated with cement, then covered with felt paper, and the linoleum glued in position. An underlay is obtainable which prevents water from penetrating through to the floor and is particularly suitable for putting under linoleums in bathrooms and sculleries. By using the same linoleum through several rooms on the same floor it is possible to gain unity and a feeling of greater space. This is particularly to be recommended for small houses. The rooms on the second floor often open from a centre landing or passage, and the general appearance is improved if a uniform floor covering is laid. This arrangement is also more economical, as the linoleum cuts to better advantage, and good use can be made of cuttings left over.

The width of linoleum varies, but that for covering rooms is usually 72 in. wide, the price being quoted at so much per square yard. To ensure buying the correct quantity this must be taken into account. Thus, supposing it is required to cover the entire floor of a room 9 ft. x 15 ft. This is 3yd. x 5 yd.; therefore 15 sq. yd. is necessary. This amount is contained in a length 7½ yd. long and 72 in. wide, 7½ yd. x 2 yd. = 15 sq. yd.

If a surround only is required, the amount can be calculated by deducting the area covered by the carpet from the area of the whole floor. Linoleum for covering stairs and passages can be bought either bordered or plain; the width varies, and for these purposes it is bought by length.

Varieties of Linoleum. Plain linoleum is of one colour, the price and quality varying according to its thickness. The advantage of this kind is that it goes well with either plain or patterned carpets and rugs and there is no pattern of which anyone can tire. Dark plain linoleums have the disadvantage of showing every footmark; on the contrary light shades of buff, grey, brown, or green are good colours where traffic is heavy. Inlaid linoleum has a pattern incorporating two or more colours, which cannot wear off, as it goes right through to the canvas. It is more economical to buy inlaid linoleum, although the initial cost is greater, for any floor subjected to hard wear. When buying, examine the cut edge to see if the pattern is really inlaid. Such linoleums are made in good tiled designs and to imitate parquet flooring or with a marbled effect.

Painted or printed linoleum is plain linoleum with a design printed or transferred on to the surface with paint. It is considerably cheaper than inlaid.

Whatever the nature of the floor, it should be well washed and perfectly dry before the floorcloth is laid. Any old nails or brads must be removed. Loose boards must be fixed, and any uneven edges planed off. Holes and cracks should be filled with putty or plastic wood. Linoleum is brittle, and difficult to handle without cracking in cold weather, so if the floorcloth is being laid in winter, it is better to leave it in a warm room for 48 hours before unrolling it.

A better result is obtained if a waterproof underlay or one of felt paper is first placed on the boards. This can be fixed in position by the use of a little paste or glue. The effect is the same as a carpet underlay: it acts as a cushion, deadening sound, and makes walking quieter and more pleasant.

How to Lay Linoleum. To do this successfully careful measurement and attention to detail are necessary. A plain lino shows defects and bad joins more than a patterned one, but when laying the latter extra care is needed to match the pattern successfully. Avoid unnecessary joins, and if possible arrange that there is no join at the doorway. Lay the linoleum so that as little waste as possible is incurred. A good arrangement is to cut it to run lengthwise in the opposite direction of the floorboards. The edges at the seams should be butted tightly against each other with the pattern carefully matched. Proper tacks without heads should be used, and placed about 1/6 in. from the edge and at a distance of 4 in. apart. When knocked in, the top of the tacks should be slightly sunk into the surface of the linoleum.

To cut fairly long lengths it is better to rule a pencil-line and place a long ruler, preferably one with a steel edge, on the line to guide the knife. It is not necessary to cut right down to the canvas, as, provided the knife has made an incision, it will readily break when folded back. A sharp penknife or pointed cook's knife can be employed, but, if liked, a proper linoleum knife that has a curved end may be used. Where much fitting is being done the knife requires frequent sharpening so that clean cuts can be made. Special care is needed in fitting lino round pipes, radiators, doorways, and wall projections. Whenever possible fixtures should be disconnected so that the floorcloth can be laid underneath them, thus ensuring a neater finish.

A certain amount of expansion or treading out always occurs after linoleum has been laid a short time, therefore it is customary to lay it at first temporarily, using a few tacks, but only where they are essential, and not along the sides of the room adjacent to the skirting. After the linoleum has been walked on for about two weeks it should be trimmed again where necessary and finally nailed in position.

A treatment which is even more satisfactory and practically makes a jointless flooring is to provide a small triangular moulding to match the moulding on the skirting board. The lino can then be cut $\frac{1}{4}$ in. or $\frac{1}{2}$ in. short of the skirting board. The moulding is tacked to the latter, and this keeps the lino in position and hides its edges. Laid thus the lino can expand without buckling. The moulding should not be tacked to the floorcloth, but fixed to the skirting board in such a way that when necessary the lino can be drawn from under it.

Linoleum. Fig. 1. Method of cutting, using sharp penknife or cook's knife and steel-edged ruler. Fig. 2. Use of curved lino knife for fitting linoleum round curves. The desired outline should first be pencilled.

Cleaning and Polishing. If properly cared for, linoleum retains its appearance, is easy to clean, and wears well. Wash it over with warm soapy water, but do not add washing soda or any strong cleansing powder of an alkaline nature. Alkalis act on the oil in the linoleum, removing a certain amount each time they are used in the same way as soda water removes varnish on wood.

Scrubbing is only necessary on worn and neglected floors. It is best to wash only about a yard at a time, rinse off the soapy water, and dry with a floorcloth. If soapy water is allowed to dry on dark floorcloth, white marks appear. The surface should not be swamped with water. The result of this can often be noticed by the floorcloth rotting and chipping along the edges and joins. After washing, the surface can be renewed by rubbing in linseed oil, cedar oil, or wax polish. The first is suitable when a polish is not desired, it preserves the lino as well as wax, but does not give a gloss.

The best treatment to get an excellent surface is to rub wax in thoroughly. To retain the polish, occasional applications of paste or liquid wax polishes are necessary. A mop or an electric floor polisher with a long handle makes the polishing easy. Slippery floors are caused by extravagant use of floor polish, insufficient rubbing off, or by using the paste too thick. This should be thinned in cold weather with turpentine.

Painted linoleum wears better and retains the colour if it is coated with varnish or white shellac. All dirt must first be removed and the floor thoroughly dried. Apply the varnish as evenly as possible, and leave it for at least 12 hours before the floor is used or the second coat applied. It is better to apply two thin coats, as then the varnish will probably only require renewing once a year. Varnished lino can be kept in good condition by mopping with a slightly oily mop.

LINSEED. In the form of a poultice linseed is a favourite household remedy for applying warmth and moisture to a part for relieving pain, and as a counter-irritant in deep-lying inflammation. Linseed is also largely used in the manufacture of paints.

Linseed Poultice. To make a linseed poultice, to 2 oz. of crushed linseed add 5 oz. of boiling water, or larger quantities if need be. Stir continuously while the water is being added. The poultice should be prepared immediately before use and should be applied as hot as the patient can stand it.

A flannel bag should be roughly stitched together to receive the poultice, and this will retain warmth much longer if it is overlapped all round by a piece of oiled silk or jaconet.

Linseed Tea. Linseed tea is an old-fashioned remedy in certain kidney diseases and coughs. Put 2 oz. of linseed, ½ oz. of liquorice, and a quart of boiling water in a jug. Cover, and let it stand near the fire for four hours. Strain through fine muslin. Do not crush the linseed.

LINSEED OIL. There are many uses for linseed oil in the home, particularly for polishing furniture. If an old piece of oak or other furniture does not respond to ordinary treatment, it should be washed with warm water and soap and well rubbed with linseed oil daily until the desired effect is obtained.

Mahogany is subject to a cloudiness known as bloom; this requires gentle rubbing with hot water and vinegar, and then with warm water to which linseed oil and turpentine have been added in the proportion of a dessertspoonful of each to a pint of water. Linseed oil can be used for stained and varnished floors. It should be allowed to soak in and then be rubbed off thoroughly with a clean cloth.

When whiting is used for cleaning pewter it should be moistened with linseed oil and turpentine.

Bronze ornaments may be wiped occasionally with a cloth moistened with linseed oil and polished with a dry cloth or chamois leather. Leather coverings of chairs are improved by polishing with linseed oil and vinegar in proportion of two to one. Creaky boots may be stood in a vessel containing linseed oil. *See Paint.*

LINSEY. When cloths were woven at home from linen and wool, linsey-woolsey was a coarse union fabric with linen threads in one direction and woollen in the other. Linen has been superseded for that purpose by cotton. Bag merchants still call wool and cotton stuffs linseys; as rags they are inferior in value to all-wool, and are sorted out separately.

LINT. A soft linen fabric, smooth on one side and shredded on the other, lint is used for applying ointments, lotions, and liniments, and otherwise in surgery. Lint impregnated with boric acid, salicylic acid, and other drugs can be obtained at the chemist's. These form a convenient dressing for wounds, etc., applied dry or moistened with boiled water. When used on a broken surface, the smooth side should be applied, as it is less likely to adhere than the other. *See Bandage; Dressing.*

LINTEL. In a house the lintel is a horizontal beam which supports that part of the wall built over a doorway or window. It may be constructed either of wood, metal, stone, or concrete. As to size, if a new lintel is to be used, as in the case of a new window opening, the size for a wooden lintel should be at least 4½ in. wide and 3 in. deep for a span not exceeding 3 ft.

Ferro-concrete lintels are made by building a boxing of rough wood around the opening and filling it with concrete; 2 or 3 iron bars are embedded into the concrete, and should be about ⅝ in. in diameter. Another method is to prepare the concrete lintel at least a month before it is intended to use it, making it up in a wooden mould. *See Concrete.*

LION'S TAIL. This is the common name of a greenhouse shrub, *Leonotis leonurus*, which bears whorls of scarlet flowers in winter. It is increased by cuttings in spring, and thrives in ordinary potting compost of loam with a little leaf-mould and sand. The plants may be placed out of doors for the summer, but must be brought into a slightly heated greenhouse in autumn.

LIP. The lips are subject to certain diseases and affections, among the most ordinary being chapped lips. One of the best applications for this condition is an ointment made of lanoline 1 oz. and boric acid 1 dram, or one may use ordinary boracic ointment or a mixture of four parts glycerin and one part Friar's balsam. Chapped lips should on no account be allowed to remain untreated.

Herpes of the lips is common in severe colds, little vesicles forming, which dry up after a time. They should not be pricked. Bathe with some warm boric acid solution, $\frac{1}{2}$ teaspoonful to a tumbler of water, and rub over with vaseline or cold cream. In eczema the lips are often scaly. Bathe with a lotion of one teaspoonful of glycerin to 2 tablespoonfuls of rose water; or apply cold cream, to each oz. of which is added 5 grains of salicylic acid.

Cancer of the lip is chiefly met with in men. It is often thought to be due to irritation from the short stem of a clay pipe. Because of the supreme importance of early operation, any ulcer on the lip should be brought to a surgeon's attention if it seems slow or dilatory in healing.

LIPSTICK. Lipstick can be bought at moderate prices, in all shades, and either greasy or dry, and also indelible. It is false economy to buy cheap brands as these tend to coarsen and roughen the lips. It should be applied firmly, following the natural outline of the mouth, which should then be dabbed with face tissue to remove surplus. A greasy, colourless lipstick can be applied at night, or in the day-time in the case of chapped lips. *See Beauty Culture*, etc.

LIQUEUR. The general term liqueur is applied to mixed, perfumed, or flavoured spirits, or certain wines and unsweetened spirits of superior quality remarkable for their bouquet. Thus a liqueur brandy or liqueur-whisky is a brandy or whisky of age and quality. Cognac is the chief liqueur of connoisseurs.

Among the many kinds of liqueur are Benedictine, Chartreuse, Cointreau, Curaçao, Crème de Menthe, Kummel, mostly made in France. South Africa produces a liqueur called Van der Hum, which in taste and colour somewhat resembles Benedictine but has a distinctive flavour of its own.

Many liqueurs are distilled from cherries, the best known of these being cherry brandy, cherry whisky, Kirsch, Maraschino, and Noyau. Other liqueurs are made from apricots, peaches, sloes, blackberries, and black currants. Mint is used in certain liqueurs which are famous for their digestive qualities, as crème de menthe, also caraway seeds in Kummel and aniseed in Anisette. *See Brandy; Chartreuse; Kummel; Maraschino*, etc.

Liqueur Glass. This is a small glass made to hold liqueur. Such glasses are made in various qualities, from the finest cut or engraved glass to a plain and cheap variety, and in several styles. They are often sold in sets of six with decanters and tray to match, and some of these sets are copies of antique patterns. Liqueur glasses, however, are themselves modern, their predecessors being the cordial glasses of the 18th century. *See Glass*.

LIQUIDAMBAR. The best species of this group of hardy shrubs is *styraciflua*, which is grown chiefly for its brilliant autumn leaf colouring. In time it develops into a large tree. It thrives in ordinary soil and is propagated by seeds or layers. In its native country, the United States of America, it is a valuable timber tree.

LIQUID MEASURE. This measure, used for milk, beer, and other liquids, is as follows: 4 gills = 1 pint; 2 pints = 1 quart; 4 quarts = 1 gallon. *See Gallon*.

LIQUORICE. The extract of liquorice root is used in medicine as a demulcent and as a flavouring agent. It covers the taste of ammonium chloride, cascara, and other drugs. The compound liquorice

powder which is used as a laxative contains senna and sulphur. About a teaspoonful of it should be taken in a little water in the evening.

The liquid extract is a common constituent of cough mixtures, and the dry extract of cough lozenges. Sticks of Spanish liquorice provide the drug in a handy form. Small pieces may be broken off and sucked for the relief of an irritable cough. Dyspepsia may also be relieved by it.

LIRIODENDRON. A hardy, tall-growing, flowering tree, often attaining a height of from 70 ft. to 80 ft., *Liriodendron tulipifera* likes a sandy loam, and is an ideal specimen tree for a lawn. The leaves are large, saddle-shaped, and bright green in colour, while the greenish yellow flowers are fragrant. The shape of these flowers gives the liriodendron its popular name of tulip tree. Propagation is by sowing seeds.

LISLE THREAD. The wearing power of lisle thread is well recognized, and the tops and feet of silk stockings, being the parts which receive the greater wear, are frequently made in lisle. The thread is a well-spun cotton, owing its wearing power in large measure to its tightness of twist.

LITHARGE. Litharge is made by heating lead; it has a straw-yellow colour, and is used in the making of various lead compounds. It is found in flint glass used in the pottery industries, and also in certain classes of accumulator plates. Chemically it is known as lead monoxide. *See Paint.*

LITHIUM. The salts of lithium have long been used to remove uric acid from the body in gout. This they accomplish by replacing sodium urate by the much more soluble lithium urate. Lithium salts also act as diuretics, that is, they increase the flow of the urine. The preparations mostly used are lithium carbonate, 2 to 5 gr.; lithium citrate, 5 to 10 gr.; and effervescent lithium citrate, 60 to 120 gr. The waters of Baden-Baden, Carlsbad, Kissingen, and other places contain lithia.

LITHOSPERMUM. These hardy trailing plants need peaty soil and a sunny place in the rock garden. The best is *prostratum*, Heavenly Blue, an evergreen which bears beautiful blue flowers in spring and summer. It is increased by cuttings inserted in sandy soil in a frame in July and August.

Lithospermum. The lovely blue flowers of L. prostratum in a Sussex rock garden.

LITRE. The litre is the unit of capacity in the decimal or metric system. It is equal to $\cdot 22$ gallon and, roughly speaking, $4\frac{1}{2}$ litres make 1 gallon. *See Metre.*

LIVE AXLE: Of the Motor Car. The rear or live axle of the motor car is the final step in the drive between the engine and the back wheels, and on it depends in a large measure the road speed and efficiency of the vehicle. It constitutes a rigid structure carrying the wheels and braking mechanism, supporting the weight of the car, and serving as a suitable casing for part of the transmission.

There are various patterns of live-axle-casings. The banjo design (Figs. 1 and 2) is all in one piece, and is provided with a large inspection cover which, when removed, exposes the whole of the axle drive, so that it can readily be got at for adjustment.

There are three main types of live axle in use, namely, the semi-floating, the three-quarter-floating, and the full-floating. The chief difference in design between the three types lies primarily with the method by which the wheels, or, rather, the hubs of the wheels, are mounted on or connected to the axle or axle-casing. With the semi-floating type the live axles, apart from driving the car via the road wheels, have also to sustain the full weight of the rear of the vehicle. The bearings in which the axle shafts rotate also act as the bearings for the road wheels. In the three-quarter-floating axle, intermediate in type between the semi-and full-floating axles, the road wheels have their own bearings, which run on the outside of the axle casing. The weight of the car is thus transmitted directly to the wheels. The axle shafts are supported at their outer ends by the hubs of the wheels, to which they are secured as solid: therefore, although the road wheels are stabilized by the axle shafts, a very large proportion of the bending stress in the axle shafts has been removed.

Fig. 3 is the full-floating axle, and with this the location of the road wheels is in no way dependent upon the axle shafts, as the hubs, B, are mounted on ball (or roller) bearings located on the axle sleeves. A brake drum, C, and a detachable wheel, D, are secured to each hub, B. The axle shafts, being suitably connected to the hubs, act as the driving medium only, and are not subjected to the bending stresses to which the two former types are prone. The ends of the axle shafts that enter the differential case, and engage the differential sun-wheels are splined, and are kept in place by a spring ring, E, engaging recesses in teeth, E, projecting from the ends of the wheel hubs. After undoing the nuts, B1, that lock the shafts to the road-wheel hubs, and removing the spring ring, the axles can be drawn out.

Left. Live Axle.

Fig. 1. Horizontal banjo type axle casing fitted with underneath worm drive.

Below. Live Axle. Fig. 2. General view of Fiat live axle casing of the banjo type.

Fig. 3. Sectional plan view of full-floating bevel-driven live axle; axle shafts can be withdrawn without disturbing road wheels, which are mounted on tapered roller bearings on ends of axle casing. Axle shafts do not carry any of the load. See text.

Driving and Lubrication. Methods of driving the live axles comprise the bevel and worm types. An example of the former is illustrated in Fig. 3, and of the latter in Fig. 4. The straight form of bevel gearing is not now used in cars, but has been superseded by spiral bevel gearing, as in the example illustrated. A form of double helical gearing is found on some vehicles. In the worm drive (Fig. 4) the worm is mounted in ball bearings, end play being resisted by a double thrust bearing. Worm gearing is silent in action, even when it becomes worn, but is more liable to damage in the event of lubrication failing. Should oil run short the gear may be entirely ruined during a run of a few miles under such conditions.

The lubrication of live axles must be so carried out as to ensure a proper supply to the working parts, while preventing any leakage from the ends of the axle on to the brake drums. The creeping of oil along the shafts is prevented by providing baffles, *A_v* in the axle casing, *A* (Fig. 3), and although some oil works along and serves to lubricate the roller bearings, leakage is stopped by the felt packed rings, *A₂* (Fig. 3). *See Motor Car.*

Live Axle. Fig. 4. Underneath worm drive with radial and thrust ball bearings keeping the worm in correct position.

LIVER: Nature and Diseases. The largest gland in the body is the liver, which weighs about 53 oz. in a full-grown man. The greater part lies under the ribs on the right side of the body. Above it is the diaphragm, which separates the chest from the abdominal cavity; under the liver are part of the stomach and large intestine. Attached to the undersurface is the gall bladder, the storehouse of bile which is manufactured by the liver.

The hepatic artery brings blood for nutriment of the liver; the portal vein brings blood collected from the stomach and intestines which contain all the absorbed food except the fat. The hepatic veins carry away the whole blood supply of the organ, and the bile ducts convey the bile into the intestine. The bile ducts are so arranged that while part of the bile passes directly into the intestine another part goes to be stored in the gall bladder.

The liver is composed of millions of minute cells, each of which is a factory for the production of bile, glycogen, sugar, and urea. Bile, which is a reddish-brown or dark green fluid, is an important factor in digestion; it aids the pancreatic juice, especially with digestion of fats, and stimulates the movements of the intestine. The liver receives sugar in the blood coming from the intestines and converts it into glycogen; this is stored up in large quantities after meals and is then given out as sugar to the blood as required. Urea, the poisonous substance produced from the disintegration of protein food (meat, eggs, fish, etc.), is made by the liver, as is also uric acid. These pass into the blood and are excreted from the body chiefly in the urine.

Diseases of the Liver. These may or may not be accompanied by jaundice. Some diseases cause enlargement of the liver, others diminish its size. Enlargement may be due to a number of causes, including the following. Fatty infiltration, occurring in obesity and chronic alcoholism; acute inflammation, or hepatitis, due to the poison of a fever, alcohol, etc.; chronic congestion, which may accompany indigestion; passive congestion, occurring in advanced heart or lung disease; abscess, which may be due to amoebic dysentery; and amyloid disease, the result of degenerative changes

commonly caused by syphilis.

Diminution of the liver occurs in alcoholic cirrhosis, in poisoning by phosphorus and other substances, and in certain other diseases, including acute yellow atrophy.

The term liverish feeling is synonymous with biliousness and is dealt with under that heading.

Liver Pill. Pills which relieve biliousness and increase the activity of the liver are popularly described as liver pills. A large number of drugs have this action, including podophyllin, rhubarb, aloes, calomel, colocynth, sulphate of soda and others. The following is an example of such a pill: Extract of podophyllum, gr. $\frac{1}{4}$; extract of hyocyamus, gr. 2; pill of aloes, gr. 2. One or two to be taken at bedtime. *See* Digestion; Indigestion; Jaundice.

LIVER: In Cookery. The liver of the calf, sheep, pig, and bullock are all much used in cookery. Calf's liver is generally considered the most delicate in flavour; bullock's liver is sometimes rather coarse. Liver can be fried, stewed, or served up in a number of made dishes.

To fry liver with bacon, wash 1 lb. liver in tepid salted water, dry it, and cut it into slices the way of the grain, about 1 in. thick, removing any skinny or muscular pieces. Cut off the rind and the rough brown skin from $\frac{1}{2}$ lb. fat streaky bacon, afterwards cutting the latter into thin slices.

Heat a frying-pan, lay in some slices of the bacon and fry them gently until lightly browned on each side. Take them out of the pan and keep them hot. Mix 1 oz. flour on a plate with a good seasoning of salt and pepper; draw each piece of liver through the flour and at once lay it in the hot fat in the frying-pan, and fry it slowly until it is well browned on each side. Fry a few pieces at a time, as they must not be on the top of each other. They will probably take about 10 min. to cook through.

When thoroughly cooked, lift the liver out of the pan and put it with the bacon to keep it hot. Add 1 oz. bacon or beef dripping to that in the pan, stir in $\frac{1}{2}$ oz. flour, and fry it until brown. Pour in $\frac{1}{2}$ pint stock and stir this gravy over the fire until it boils, then season it carefully. Arrange the liver neatly in a hot dish, the slices overlapping each other; strain round the thick brown gravy, and garnish with the fried bacon.

Stewed liver makes a change from fried liver, and is more digestible. Soak in salted water about an hour, dry, and cut 1 lb. liver into fairly thick slices. Melt 2 oz. dripping— either beef or bacon—in a saucepan, and when it is hot stir in 1 oz. flour and 2 tablespoonfuls finely chopped onion.

Fry these a rich brown, and stir in 1 pint good stock or water and a little meat extract. When the whole has boiled and thickened, put in the liver, a good-sized carrot, cut into cubes, a bunch of herbs, a couple of sticks of celery, chopped into small pieces, and a small teaspoonful of salt. Cover the pan and let the liver simmer for about 1 to $1\frac{1}{2}$ hours. When tender arrange it neatly on a hot dish, strain over the seasoned gravy, and garnish the liver with fried bacon or ham, and some of the cooked carrot.

Bullock's liver added to stewing steak, in the proportion of $\frac{1}{4}$ lb. liver to 1 lb. beef, makes the stew richer and more palatable. This is especially so when inferior cuts of beef are used.

An easily prepared dish is a fricassée of liver and tripe. Cut some cold, cooked tripe and some liver, equal quantities of each, into strips. Fry the liver, after soaking in salted water, and put it on a dish in the oven to keep hot. Dip the slices of tripe into seasoned flour, fry them, and add them to the liver. Next fry some sliced onions, and with them make a border round the dish. Over the whole pour some thick brown gravy or brown sauce, and serve at once.

Liver Force meat. Liver forcemeat is used for stuffing game, pigeons, quails, and other birds. It is made with $\frac{1}{2}$ lb. calf's liver, 3 oz fat bacon, $\frac{1}{2}$ onion, 1 shallot, 1 oz. dripping or butter, 1 teaspoonful mixed herbs, a pinch each of cayenne and nutmeg, and pepper and salt to taste. The liver and bacon must be finely minced and browned in the fat in a frying-pan, the onion and shallot minced, the herbs and seasoning added and all stewed gently until tender. The mixture is then pounded in a mortar, rubbed through a wire sieve, and mixed to a paste with the yolk of an egg.

Liver Sausage. Boil 1 lb. moderately lean pork, then mince it finely. Wash and dry 1 lb. sheep's or calf's liver, mince that also, and mix it with the pork. Add and mix in very thoroughly 2 small onions, chopped very finely, a level teaspoonful pepper, a dessertspoonful salt, a good pinch of powdered nutmeg and cloves, and a level dessertspoonful powdered mixed herbs, including sage. Melt 4 oz. lard and add that also.

This mixture is then put into large sausage skins, but should only fill them very loosely. Tie them at both ends, drop them into boiling water, and let them simmer for about 40 min. Drain them and hang them up until required.

Value in Therapeutics. Treatment of anaemia by feeding with about half a pound of liver, raw and cooked, each day has had favourable results. The raw liver is given in sandwiches, or a reliable extract may be chosen.

LIVERPOOL WARE. Earthenware and chinaware of Liverpool origin fall mostly within the later half of the 18th and the earlier half of the 19th century. Among the earlier pieces were punch-bowls with maritime scenes, usually in blue, often made to commemorate some famous voyage, and tavern mugs with doggerel rhymes.

There was a large output of salt-glaze and delft, sometimes recognizable by its bluish tinge, as well as ware printed by Sadler, the inventor of transfer-printing. Blue-dash chargers are large dishes

bearing crude devices of scriptural and royal personages, for cottage use. The creamware, bone-porcelain, and other Staffordshire styles which were copied at the Toxteth Park pottery for half a century after 1794 frequently bear the works name, Herculaneum. *See* Delft Ware; Lambeth Ware.

Liverpool Ware. Delft bowl with the inscription inside, 'Drink Faire, Don't Sware.' Date 1728.

LIVERY. As understood to-day a livery is the distinctive dress worn by certain classes of male servants. An example is the serviceable livery of the chauffeur. This consists of coat or overcoat and peaked cap, with breeches and leggings, the coat of Melton and other cloth being coloured grey, black, dark blue, or dark green. Liveries are usually provided by the employer. There is no tax on the wearing of a

livery, and no licence is now needed for a manservant. *See* Servant.

LIVERY CUPBOARD. This is a type of cupboard in use in England in the 15th, 16th and 17th centuries. With the allied court cupboard, it was the forerunner of the dresser and the sideboard. The livery cupboard is usually smaller than the court cupboard, and was sometimes, therefore, placed on the top of the latter. It had an open front generally decorated with a series of turned pillars. These cupboards were often placed in bedrooms so as to hold food which could serve for the long interval between the evening and the morning meal. *See* Cupboard.

THE LIVING-ROOM AND ITS FURNISHING

How to Combine Beauty with Comfort

The reader may consult the entries on the various items of furniture mentioned, e.g. Chair; Settee; Writing Table, and those on the other rooms of the house. *See* also Carpet; Colour; Cottage; Decoration; Electricity; Fireplace; Flat; Gas; House; Panelling.

As its name suggests, the living-room should be the type of sitting room which people really want to live in and not merely to use on formal occasions. In choosing decorations and furniture extreme fashions should be avoided, unless they embody some particularly apt style for the room in question; as for instance, period reproductions for an old-world setting. The largest, sunniest, and most convenient room in the house should be selected for the room in which the family will spend much of their time indoors.

In general, rooms that face south or southwest are the best lighted and most cheerful. Those with windows on two sides have advantages, whilst north rooms with a beautiful expanse of country in front are preferable to a south room that looks on to brick walls. Extension on to a loggia or a veranda is an asset to a suburban or country living-room.

Walls and Floors. The treatment of walls allows plenty of choice. Pleasing colours in paint, distemper, or wallpapers of good design cost no more to buy or to apply than ugly, drab colours. Where economy has to be studied, the decoration should receive particular care, seeing that it will have to last for years.

In many small houses and bungalows the woodwork is not painted, but merely dyed or stained to imitate different woods. A wood-preserving stain, such as solignum, should be used, and linseed oil rubbed in to make the wood water-resisting. Panelling is a favourite method of wall treatment in some of the modern as well as period living-rooms, and is especially successful when carried out in natural woods wax polished, rather than in a heavy imitation of Jacobean style.

Distemper in all shades is obtainable and has advantages. It is cheap, and can be renewed quickly without skilled labour; but for a living-room, particularly where there are children in the family, it is not always satisfactory. Even light knocks remove the surface and show plaster underneath, while fingermarks are not easily removed, and grease-marks are even more persistent. Distemper is not suitable for old walls the surface of which is bad. The better way, where it can be afforded, is to use paint or enamel. Painted walls need no attention other than washing for many years. Grained and marbled surfaces are particularly suitable for this type of sitting room, as they provide a slight, pleasing variation in colour without the tiring effect of a definite pattern. All the plainer wall surfaces possess the advantage of allowing the housewife to change the appearance of her room completely, without mural redecoration, by having a second set of curtains and covers for the furniture, or by using loose cretonne covers and light curtains in summer and showing the upholstery fabric of some durable type that will not easily soil in the winter, with curtains in a rich and warm shade of velours or velvet.

These effects of graining and marbling can be obtained in wallpaper if the expense of painting is too great. Pale tones and unbroken surfaces are, however, still better for the small room with a poor window allowance. Such treatment seems to push the walls away. Patterns or heavy panelling, on the contrary, have the effect of pulling them in.

Where there are no beams or supports which visibly mark the ceiling it is restful to have this the same colour, or a lighter tone of the same colour, as the walls. The absence of a cornice in many modern rooms increases their apparent size. Flush doors also seem to enlarge wall space, while decorated or panelled doors give interest to bigger rooms. Wooden pelmets to the windows, either in oak or stained or painted wood, are another detail which is a particularly happy idea in the modern living-room. It ensures a neat window line, and the trouble of making or changing curtains is greatly lessened if there is no valance or fabric pelmet to be considered each time of such renewal.

A living-room can be uninteresting if there is too little colour contrast and pattern; it can be cut up and made tiresome and disturbing with wrong choice of these or with too many pictures and ornaments. It is usually safe to build up from the darkest colour note on the floor to the lightest on the ceiling. Where there are old oak beams or a modern version of these, the plaster between them should be kept to a warm cream, and if the wall treatment is dark panelling a wide frieze of light colour is essential in the ordinary-sized room.

Carpets are the most suitable covering for living-room floors. It is usually desirable to strike the note of comfort which a carpet gives, but which is lacking with other floorings. Choice should be limited to hard-wearing carpets in colours that do not show every footmark or are easily damaged by mud. A too-pronounced pattern on a carpet will often destroy the harmony of a whole room. Imitation Persian carpets in velvet pile, or modern ones with geometrical designs, are suitable. The hard-wearing qualities of hair-carpet and its low price make it a most useful floor-covering where expense is of the first importance, and it is an excellent background in its natural colour for rugs. In a bungalow or cottage living-room, fibre or rush matting may be substituted, especially in the case of the week-end or summer holiday house of this type. Wide surrounds of parquet or other easily cleaned flooring are necessary in a room, which will be used by a family.

Living-room, Fig. 1. Window end of living-room in a small house near London. A novel form of diffused lighting is provided by the ceiling fitting of tubular glass attached to the cross beam.

Heating and Lighting. An open fire is the favourite means of heating, and it is more economical, especially for rooms that are in use during the whole day. Gas-fires, it is true, do away with the tilling of scuttles and cleaning of grates, but they do not convey the sense of comfort and companionship that belongs to a coal or wood fire. The brick fireplace seems particularly suitable to the country type of living-room. Bar grates can be modernised at small cost with a barless front which increases the width of the grate and brings the hot fuel further into the room. When new stoves are being fitted, the question of a sitting room stove with a boiler at the back is worth consideration. Economy of fuel combined with increased comfort is thus obtained. Stoves for use with open or closed fires which burn any kind of fuel and can be kept alight day and night are sometimes a suitable choice.

The comfort of the family also depends largely on the efficient lighting of the livingroom. The diffused type of lighting fixture is not sufficient in a room where work is done, unless separate small lamps are provided. The actual method of lighting is controlled largely by what is available. Electricity is both convenient and clean; incandescent gas gives good light, but the mantles need care or frequent renewal will be necessary. In districts where neither of these means of lighting is available, lamps burning a mixture of air and petroleum vapour and producing a 250 candle-power light are most useful for living-rooms.

Fig. 2. Old world living-room in a Sussex house. The simplicity of the wide hearth, massive beams and plaster walls is pleasantly contrasted by the comfortable armchairs and settees and enriched by the fine piece of tapestry (Humphrey & Vera Joel)

Furnishing Ideas. The furniture required naturally depends not only on the size and type of room, but also on the size and tastes of the family. Bookshelves may line the walls where the latter are literary. One writing table would not be sufficient where several members wished to use it a good deal. The addition of one or even two small bureaux solve the problem, and when shut up encroach little on the floor space. Plenty of cupboard room is an excellent feature in most cases, so that unsightly-looking working or amusement outfits can be stowed away with a minimum of fuss. If a living-room has to be used also as a dining room it is simplest to have one end devoted to this purpose.

Our illustrations provide some excellent ideas for the decoration and furnishing of delightful living-rooms. Fig. 1 shows a modern type of room in a small house near London. Essentially simple and without superfluity of pattern or ornaments, comfort is ensured by the heavy pile carpet, and by the chairs and settee upholstered in the same style of modern design. The window admits of abundance of light, and there is a door, visible on the right, which leads on to a loggia. The curtains are of a transparent, lightly patterned fabric for summer use, which gives a beautiful quality to the light from the window. The walls are painted, finished with a glossy surface, and the ceiling is the same colour except for the wooden beams. The floor is of wood blocks.

The fireplace, at the other end of the room, not seen in the photograph, is a beautiful example of modern brick, in keeping with the beamed ceiling, and is without fender or mantelpiece. Its decoration lies in the design of the brickwork on the surround and raised hearth. The writing-desk and bookcase by the fireplace are of mahogany, which wood has also been selected for the low table in the window and for the floor standard seen in the picture.

A contrast is provided in the second illustration. This living-room is in an old house in Sussex. The heavy, cross beams are worn uneven, the walls and ceilings are roughly plastered, the casement windows are diamond paned. The fireplace has a wide, tiled hearth and solid oak shelf on which are collected respectively interesting specimens of hearth furniture and some beautiful old pieces of china, quite suitable for the room. Velvet is chosen for the upholstery and curtains, except for the cane-backed and cushioned settee on the right, which is covered with shot silk rep.

Pictures are not wanted on the low walls, and also they would detract from the tapestry above this settee, and there is little wall space left with the other window, door and accommodation for books. on the right and the standard on the other side of the fireplace is equally harmonious in this room fittings have been well thought out. There is a charming bracket fixture over the armchair with its fringed shade.

Living-room: three views of a modern example. Left, top Fig. 3. A delightfully planned window treatment provides plenty of light and excellent shelf accommodation for books.

Fig. 4. The tiled fireplace surround and slightly raised hearth are balanced in design by the charming arrangement of the mantelpiece and pictures.

Fig. 5. The mirrored corner of the room, highly decorative in itself, is cleverly designed to give light to the hall through the glass door of the living-room. (Humphrey & Vera Joel)

In Figs. 3 and 4 two views of a modern living-room are shown. For a comparatively small room in a town house or flat, the decoration and furniture are beautifully designed and chosen. The panelled walls are finished in glossy enamel of a pale colour and the wide frieze and the ceiling are of the same colour, but finished with a mat surface. The fluted wooden pelmet fixture should be noted and also the beautiful window treatment of coloured net glass curtains and silk practical ones to tone with the modern carpet. The loose covers have a geometrical pattern, and an interesting feature is

the excellent accommodation for books on shelves built into the space below the windows. These shelves are divided by useful little cupboards. In Fig. 4 the fireplace is seen, with its attractive tiles, pillars and mantel treatment. The lighting fittings are particularly harmonious, with their plain shades and shields. Every detail is charmingly thought out and the placing of the pictures should be noted, and of the ornaments on the windowshelf. The one richly decorated piece of furniture in the room is the painted Czechoslovak cabinet on the left of the window.

Fig. 5 shows in detail the mirrored corner of this room, visible in the background of Fig. 4. This clever arrangement is not only an attractive decoration in itself, but it adds reflected light to the entrance hall through the glass panelled door of the living-room. The low table in front of the mirror, the Empire watch clock and the reflected ornaments add to the charm of the view of the room from the hall.

LOACH. The loach, sometimes called the stone-loach, is a fresh-water fish. It has a delicate flavour, and is not unlike the gudgeon in shape. Loach is best stewed like carp (q. v.).

LOAM. This is a soil particularly valuable for garden purposes, and its texture may be divided into three classes, heavy, medium, and light. In the former there is a good proportion of clay, with a smaller quantity evident in the medium kind; in light loam sand preponderates. All loams are invaluable and are made more fertile by liberal manuring. The heavy variety is greatly improved by an occasional liming.

For potting-composts loam is invaluable, the best being the top 3 in. from old pasture land. This should be lifted and stacked with the grass downwards, sprinkling decayed manure between each layer; it will be ready in 12 months. *See* Compost; Cucumber; Gloxinia; Soil, etc.

LOAN. A loan may be either of a sum of money or of some article which is to be returned intact. The latter kind of loan is called a bailment in law; the borrower is called a bailee and the lender a bailor of the article. The bailee is bound to take as much care of any article lent to him as a careful man would take of his own goods; if he does not do so and the article is lost or damaged, the bailee is liable to repay the loss to his bailor.

Usually no loan carries interest unless interest is agreed upon. If A agrees to lend B a sum of money and fails to lend it, B cannot bring an action for breach of contract, because he has in the eye of the law suffered no damage. A moneylender must carry out all loan transactions in his registered name at his registered office and on a special form of contract, and not otherwise. The contract must show the date of the loan, the amount of the principal and the rate of interest per cent per annum, and must be signed by the borrower. A copy must be sent to the borrower within seven days. If he transgresses this rule, the moneylender cannot recover his loan in court. *See* Building Society; Debt; Mortgage.

LOASA. Most of the loasa group of half-hardy S. American plants are annuals. The seed should be sown indoors in February, and, after once transplanting, the seedlings may be placed out of doors in June. The chief kinds are hispida, 12 inches, yellow, and lateritia, climbing, red. The last-named is known as the Chili nettle, because of its stinging hairs.

LOBELIA. The most, popular forms of lobelia, which are half-hardy garden plants, are those used for edgings to beds and borders. They are often grown as annuals from seeds sown early in spring, in well-sifted mould, with a liberal mixture of fine sand, and kept in a temperature of from 65° to 70°. The seedlings should be planted out in shallow boxes, 2 in. apart, and hardened off in a cold frame. Lobelias treated in this manner may be planted out early in June. Old plants, if lifted and

potted in autumn and kept in a heated glass-house, will provide cuttings in early spring. The herbaceous lobelias are handsome border plants, 2-3 feet high, which bloom in late summer. They are not very hardy, and in most districts must be lifted in October and stored under glass in boxes of light soil for the winter; they will provide cuttings in April, and may be planted out of doors in May. Fulgens and its variety Queen Victoria with bronze leaves and scarlet flowers are very showy. Of the latest novelties the scarlet-flowered Huntsman is splendid. *Lobelia syphilitica* has given rise to a race of plants with flowers of many colours—purple, rose, mauve, etc.; these need similar treatment to the varieties of *Lobelia fulgens*.

Lobelia. Profusely flowering plant of the Crystal Palace variety.

LOBSTER: How to Cook. It is best as a rule to buy lobsters alive, choosing those which are heavy in proportion to their size and rejecting any which have incrustations on their shells or are light and watery. The flesh of the hen lobster is inferior to that of the male, but the spawn is useful for colouring sauces, etc. The hen may be distinguished from the male lobster by its broad tail and fewer claws.

To kill a lobster, pierce the spinal cord with a skewer or a sharp knife at the joint between the body and tail shells. The fish is cooked in a pan of boiling salted water for 20 to 45 min., according to size. If lobsters are bought ready cooked, their tails should they be fresh, will spring back when straightened.

A good brand of tinned lobster can be used for made-up dishes or for salads when fresh lobster is unobtainable.

A boiled lobster may be dressed when cold by removing the two largest claws and cracking them, separating the head portion from the tail and splitting both down the middle. Take out the intestine, the stomach and the spongy-looking gills and serve the lobster on a dish with the head in an upright position and the claws and tail placed round it. Salad may be used as a garnish, and oil and vinegar served separately.

To roast a lobster, cut it lengthwise through the middle, removing the intestines, etc., and place the pieces flesh side uppermost in a roasting tin in a hot oven. Cook the fish for about ½ hour. Baste it with melted butter and season it. Garnish with slices of lemon and a few sprigs of parsley. Lobster that is to be broiled is prepared in the same way, but is cooked over the fire. The pieces are basted as for roasting, and turned once. Melted butter sauce is served with it.

Scalloped lobster is prepared by cutting the flesh of a boiled lobster into small pieces, mixing it with melted butter sauce and turning the mixture into greased scallop shells. Sprinkle some fine breadcrumbs over them, and bake them in the oven until they are lightly browned.

To devil lobster, the flesh is first finely chopped. It is then placed in a saucepan over gentle heat with a little savoury white sauce, a dessertspoonful of mustard, and pepper and salt to taste. These should all be made piping hot, and the devilled lobster served piled on hot buttered toast.

The following recipes are of various appetizing savoury or luncheon dishes which can be made up from cooked lobster. Such dishes are also useful for buffet suppers, and when nicely garnished present a particularly attractive appearance.

Lobster Bouchée. Lobster bouchées are made by cutting three slices of stale bread about 2 in. thick and then stamping them into rounds, each measuring 3 in. in diameter. Hollow out the centres, leaving a neat case of bread, and for each cut out a round top or lid. Dip the cases into milk and leave them to drain. Melt 2 oz. butter in a saucepan, stir in smoothly 1 oz. flour, and cook without browning them over the fire for a few minutes. Add $\frac{3}{4}$ pint milk or fish stock, stir until it boils, and then put in a few drops of lemon juice, and nutmeg and seasoning. Let the sauce cool slightly at the side of the fire before adding the beaten-yolk of an egg, a breakfastcupful chopped lobster meat, and 2 teaspoonfuls anchovy essence. Stir the mixture over the fire for a few minutes to cook the egg, then brush the cases and lids of bread with some beaten egg and coat them with breadcrumbs. Fry them a golden brown, and drain.

Fill each case with the lobster mixture, heaping it up slightly, put on the lid, and stick one or two pieces of lobster feeler in the top to give a decorative effect. These bouchées may be served either hot or cold.

Lobster Butter. This is a savoury butter made either from lobster spawn or coral. If the former is used, cook it in salted water until it assumes a bright red hue; then drain and dry it and pound it in a mortar with twice its quantity of butter. Finally rub it through a hair sieve. When lobster coral is used the process is the same, except that the coral is merely washed and then dried in a cool oven.

Lobster Cream. Small lobster creams are made by pounding the flesh of half an average-sized lobster with $\frac{3}{4}$ gill sauce, rubbing the mixture through a sieve, and then adding $\frac{3}{4}$ teaspoonful of anchovy essence, a little lemon juice and a small pinch of cayenne. Beat these ingredients together, adding $\frac{1}{2}$ gill whipped cream, and then turn the mixture into some small china cases. Whip another $\frac{1}{4}$ gill cream, put a little on the top of each, and then garnish with a little pounded coral of lobster rubbed through a sieve. The creams should be left to stand on ice before being served.

Lobster Cutlet. To prepare this dish, melt 1 oz. butter in a saucepan, stir in 1 oz. flour, and add a gill of water. Stir the mixture till it leaves the sides of the pan, add a small tin of lobster, finely chopped, and seasoning. Mix well, and spread in a plate to cool; then turn it on to a floured board. Shape it into cutlets, brush these over with beaten egg and coat them with breadcrumbs, and fry them. They should be served with salad if cold, or, if hot, with fried parsley and lemon. *See* Hors d'Oeuvres; Mayonnaise; Salad.

LOCKS: HOW TO FIT AND REPAIR

With Simple Instructions for Cutting Keys

This contribution describes the mechanism of the chief types of lock and gives directions for fitting them to door, lid, or drawer. The process of cutting keys is clearly explained and fully illustrated.

See further the articles Bolt; Latch; Padlock; Safe

In the home a lock is usually a piece of mechanism by which doors, drawers, or lids are secured so that they can only be opened with a key made to fit the lock. The three main types are warded, lever and pin tumbler locks, each comprising the mechanism in a case, a sliding bolt, and the key. In some types the lock is operated from the outside only; in others from either side.

A drawback lock can be opened from the inside by sliding a knob; and with a letter lock, or combination lock, the locking is effected by moving two or more disks or their equivalent; the disks are marked with letters or numerals, and when the proper ones are opposite each other the lock can be opened, but in no other manner. The disks have a notch cut in the rim, and only when these notches are in line can the lock bolt be released, the large number of possible combinations

rendering it difficult to open the lock unless the proper combination is known. This type of lock is available from the cheapest qualities to elaborate devices for a strong-room door or safe.

Warded Tumbler Locks. Figs. 1-7 illustrate the action of a warded tumbler lock. The bolt is shown in Fig. 1 as sliding in the case. The key is inserted in the keyhole and touches the edge of a notch which is cut in the bolt. As the key is turned in the direction of the arrow it presses the bolt outwards, as illustrated in Fig. 2. The key must be long enough to reach nearly to the top of the slot, but not too long, or it will not turn further, as it must do to release the key on the other side of the keyhole line, as shown in Fig. 3. From this position the key is turned until it can be pulled out of the keyhole.

Two points are now apparent. There is nothing to prevent the bolt being pushed in or out without the aid of a key, and any key that will pass the keyhole will actuate the bolt, so long as it can pass the top of the slot in the bolt. Wards are therefore introduced to prevent the key from turning unless it has an aperture to allow it to pass the wards. This is shown in Fig. 4, where two pins, A, B,

prevent the key from turning unless cut away as shown. In place of the pins a circular ward plate or ring is fitted, as at C, Fig. 4.

To prevent the bolt from being moved except by the key, another piece of apparatus is added. This is a tumbler, a flat plate of metal hinged at one end to a peg, as shown at A, Fig. 5, and pressed down by a light spring. It is generally placed in front of the bolt, with its lower edge in line with that of the bolt. A U-shaped slot is cut through the tumbler, and a peg or lug, B, is fitted to the bolt, so that when the bolt is in, the lug rests in the inner end of the leg of the tumbler slot, as at Fig. 5.

When the key is turned, it shoots the bolt as before, and, at the same time, it raises the tumbler from its starting position to the elevation, as in Fig. 6, thus bringing the slot in the tumbler in line with the lug on the bolt. This allows the lug to pass, but when the key has been further turned the tumbler falls and the bolt lug is then in the outer leg of the tumbler slot, as in Fig. 7. The tumbler holds the lug, and so prevents the bolt from being forced back.

Lever Locks. In lever locks the bolt is secured differently, and there is often a "follower," which takes the bolt with it. In Fig. 8 the lever A is shown "down" and the bolt lug B is in the inner end of the slot in the lever. The key has to raise the lever until the central slot is in line with the lug, and no more, as in Figs. 9, 10, finally allowing the lever to fall and engage the lug, as in Fig. 11, thus locking the bolt. So far the action is similar to a tumbler, but there are differences. The key must raise the levers to the correct height, and this is accomplished by shaping the top of the key accordingly, as at C, Fig. 11A; the part of the key at D throws the bolt over as before. Should the key be too long in the blank it will lift the lever too much, and the lug will engage in the lower of the notches in the lever, consequently the bolt could not be shot. Most good lever locks have three or more levers; the slots are made at varying distances from the part of the lever resting on the key, and the levers all have to be lifted simultaneously to such heights that all the slots are in line before the lug can pass and the bolt be shot. For this reason the lever lock is one of the most secure of the ordinary domestic locks.

Pin Tumbler Locks. The pin tumbler system works on an altogether different principle. As can be seen from Fig. 12, it comprises a body with a cylindrical hole, wherein turns a

cylinder of metal, into which the key is inserted, the key slot being usually corrugated. Attached to the cylinder is a connecting bar (not shown) which shoots the bolt when the cylinder is turned. The key turns the cylinder and raises the locking-pins. These pins are small pieces of steel rod that rise and fall in holes drilled in the two parts of the mechanism, as shown in Fig. 12.

Fig. 12. Pin tumbler lock, cylinder mechanism.

One set of 1 pins, of varying length, is located in the cylinder and another set in the body, the latter pressed down towards the cylinder by the little coiled springs. The top edge of the key is notched to varying depths, and as it is inserted into the slot it raises the pins. A key suitably notched for the particular lock will raise each of the cylinder pins so that it is just level with the joint between cylinder and body. When the key is fully home

all the pins are in line and level with the joint, consequently the key can be turned.

Fitting a Rim Lock. Door locks are made either right or left hand. When purchasing the lock should be held in the hand with the bolt to that side which it will occupy when in place. Then see that the keyhole is the right way round, and that the lock can be fitted to the door. Many locks are made reversible to suit any door. Fig 13 shows the rim lock, a type which is easily fixed on the outside of a door. The first thing to be done is to mark out the door by chiselling away the surplus wood. Having done this, hold the lock in position and carefully mark the position of the keyhole and the spindle hole with a bradawl on the face of the door. As nearly as possible the size of the bits for boring the holes for the keyhole and the spindle should be equal to the size of the keyhole in the lock plate and the diameter of the spindle. The lock is screwed on with round-headed screws, flat-headed screws being used for the cover plate.

Fig. 13. Cover and interior view of rim lock.

Fig. 14. Mortise lock with cover removed.

Fig. 15. Fitting mortise lock into door.

Fig. 16. Simple cupboard lock, screwed in place.

Above. Fig. 18 Cutting the recess for a drawer lock.

Left. Fig. 17. Drawer or cabinet lock, showing cover and screws employed to fix it.

The spindle knobs and escutcheon plate are placed in position, the last-named fixed with escutcheon pins. The box staple may be set in the door frame, or on a block. The lock is tested by shutting the door gently, when the bolt should shoot into the staple with a decided action and a perceptible click. There ought to be just sufficient room for the door to clear the front edge of the staple, and not too much space between the lock case and the staple when the door is shut, or the bolt may be forced open if the door is subjected to pressure.

Mortise Lock. Fig. 14 shows a type of lock which is almost invisible when fitted, being mortised in the door. It is widely used, although the deep mortise greatly weakens the door. Locks of various shapes have been put on the market to obviate this defect; some circular in section, others constructed with a narrow case, so that a fine mortise is required for their fitting. The door is first marked out and the centres of the spindle hole and keyhole, marked and drilled. The mortise is carefully cut in the ordinary way, the lock flange being recessed into the edge of the door, as shown in Fig. 15, and the lock secured with countersunk screws. A striking plate takes the place of the staple and is recessed into the edge of the frame. The holes for the lock bolts are drilled out and squared up with a chisel, and must be deep enough to allow the bolt to enter. When the plate is in line, and the bolts enter the holes properly, the plate is fixed in place with countersunk screws. The joiner uses a special long-shanked chisel with a hooked blade to cut the mortise in door (Fig. 20).

Fitting Pin Tumbler Locks. Fitting this type of lock is similar to a rim lock, with the addition of a hole which has to be drilled through the door for the passage of the lock body, which is held in place by two long screws passed through the door from the back, prior to fixing the lock case. A specially shaped washer plate is supplied to bear against the woodwork, which, by aid of the screws, clamps the lock body to the door (Fig. 19).

Lock. Fig. 19. Showing method of fitting pin tumbler lock.

Cabinet Locks. Iron cupboard locks seen in Fig. 16 are used for the doors of meat safes, presses, hot closets, and various other fittings about the house. Smaller locks (Fig. 17) such as are required for cabinets, wardrobes, chests of drawers, and other articles, are usually of brass. Their one drawback is that the bolt is very short, so that it can be pushed back and the door opened without much difficulty; extra long bolts, however, may be obtained. Cabinet locks are made in warded and lever types, the iron being warded, while the brass are lever. Some keys have a solid pin, others are hollow.

The fitting of a drawer or till lock is a simple operation, the first thing being to mark the exact centre of the front of the drawer. A recess is cut out at the back to the size of the lock case and flange by means of a fine saw and a chisel. There is a special tool made for the purpose, known as a drawer lock chisel (Fig. 20). When the correct fit has been obtained, as shown in Fig. 18, the position of the keyhole should be carefully ascertained and cut out with a bit and a keyhole saw, or a fine chisel. The lock is then screwed into place. The bolt hole in the top rail of the drawer is next made. Its correct position is ascertained by placing a little blacklead on the top of the bolt, pushing the drawer into the proper position, and turning the key so as to force the bolt on to the surface of the top rail of the drawer. If this is done several times, the shape and position for the bolt hole is clearly shown. The bolt hole may then be chiselled out to the requisite depth.

Box locks are fitted in much the same way, but the top plate carrying the lugs with which the bolts engage, has to be fitted to the lid. This operation is easily performed when the link plate has pegs or

spikes formed on the upper side, as the lock is first fitted, the link plate inserted in the lock, and the lid shut down hard on to the link. The pins hold the link, and when the lock is unbolted the lid is raised with the link in position. The recess is then marked and cut, and the link plate secured with screws.

Padlocks are in a class by themselves, as they require no fitting; they pass through a staple or any place that is to be locked, as, for example, the wheel of a bicycle to the front forks. Varieties are made with lever, tumbler, and pin tumbler mechanism, as well as simple letter mechanism. Others have a spring-back bolt that is self-locking. Where security is of importance it is a mistake to buy cheap padlocks. For an outside door a type with a short stout shackle should be chosen, as this is difficult to force, and the thick shackle would take some time to sever with a saw. It should be locked through a stout staple over a hasp. If a chain has to be used, its links should be thick enough to offer at least as much resistance as the shackle or staples. For outside use all fastenings should be as strong as possible.

When locks require to be repaired, the chief items are the replacement of broken springs, renewal of damaged pins, and rebushing of spindle holes. Most ironmongers stock a selection of springs, and their replacement involves nothing more than slipping into a notch, or refixing with a screw or rivet, according to the nature of the construction. Worn bushings can be replaced with new, or the hole can be enlarged and bushed with a ring of brass tubing soldered in place and the faces cleaned up true with a file.

Locks should be oiled occasionally, since this assists the smoothness of action and prolongs their life. The old-fashioned method of using a feather dipped in oil is useful for a simple plate or stock lock, but the only way of oiling the modern types of rim and mortise locks is to take them out and unscrew the back-plate in order to lubricate the whole of the parts. Locks should always be properly oiled before fitting.

Fig. 20. Special tools used in lock fitting. Above, long-shanked mortise chisel with hooked blade; below, drawer lock chisel

Lock stages in key cutting.

Below. Fig. 21. Filing the blank to correct thickness.

Key Cutting and Fitting. The first requirement in key cutting is to understand something of the lock the key is to actuate, and the way in which it works. The description of the types of lock in the foregoing pages should be studied, and the lock itself examined.

As a first attempt, suppose a key is to be fitted to an ordinary rim lock of the lever type; this may be dealt with on the following lines: First of all a blank must be procured from the ironmonger; a blank is a solid uncut key, and should be obtained as nearly

the correct size and shape as possible. See also that the shank of the key is long enough for the door to which it is to be fitted, so that the bow can turn on the outside. In the case of a lever lock the key has first to lift the levers, and then to throw back the follower, which takes back the bolt with it.

Therefore the next step is to file the blank to such a size that it will enter the keyhole and set against the back-plate or back part of the lock case. This is accomplished by grasping the key in a vice with the blank to the left and the shank gripped in the vice jaws.

The top of the blank is then filed down, keeping it perfectly level at the top until it will just enter the keyhole. See that the pin or the holes in the lock-case do not stop the key from entering, and that the blank is not too thick; in either of these cases the blank must be carefully filed to fit (Fig. 21). The use of a pair of calipers (Fig. 22) will be found a great assistance in the progress of the work, as they can be used to test the thickness of the blank and the height from the shank to the top of the blank.

It will facilitate matters if the lock be removed from the door and be taken to pieces, as the action can then be seen and appreciated, as is clearly shown in Figs. 13, 14, 25, etc.

Fig. 22. Testing with calipers, to ascertain size of blank. Fig. 23. Cutting the blank to actuate the various levers.

The key is first fitted to the follower as described, and then the master lever found by inspection; it can be detected, as it is the one with the slot nearest to the lower edge of the lever. The end of the blank has then to be filed down at the spot exactly opposite this lever until it will raise the lever the required amount; the other levers may be removed while this is in progress (Fig. 23).

Each lever is treated in the same way, and the series of steps thus produced on the blank are touched up here and there until the whole of the levers lift properly and the follower throws back nicely. The action should be perfect in either direction, shooting the bolt in or out with equal facility. The width of the blank may be such that it will have to be filed back or made narrower to

allow it to turn when the cover-plate is replaced; but this is an easy matter, the main thing is to remove a little metal at a time from the blank, when the result of so doing can be seen and appreciated.

The usual files for this work are the thin warding files sold in many sizes; some thick and some thin ones should be obtained. They are used in the manner shown in the illustrations, which also show progressive stages in the fitting of a key to a lock.

Left. Fig. 24. How key should fit a simple lock.

A warded key is cut on similar lines, but it may be noted that the blank can often be obtained with a number of the wards already cut, thereby reducing the amount of time and labour in fitting the key to the lock. In this case the key has to be cut away until it can be turned in the lock, as it will then throw back the follower and shoot the bolt, so all that has to be done is to file away the parts of the blank that obstruct the free turning of the key (Fig. 25).

Fig. 25. Warded key cut to clear ward ring and shown lifting tumbler.

A duplicate key can be cut by careful calipering and comparing, with the original. When the lock is accessible a film of tallow or beeswax may be applied to the blank, so that when the key is pressed against the wards they will leave a mark on the blank, and thus indicate the parts to be cut away. It is always wise to proceed slowly, and to try the key in the lock several times to note the progress of the work.

Keys for the pin tumbler type of lock are perhaps best entrusted to the locksmith, who has a special appliance for the purpose. The pattern key is clamped in the machine, and the blank is automatically cut to the same notching by a grinding wheel of the proper shape and section.

A device to render a key, and therefore a lock, more difficult to copy is to cut off a piece of the pipe or hole in the key of a pin type of key, and to fix the piece on the peg in the lock, securing it with a touch of solder (Fig. 27). Similarly, a pin can be fitted to the lock-case in those types of lock in which the key turns on a peg. It is necessary to cut back and drill out the keys to fit on to the peg,

but it is then more difficult to place the key in the lock.

Left. Fig. 26. How internal slots are cut in a key for a warded lock.

When several or a number of locks are ordered at the same time, it is possible to arrange for a master key to be cut which will unlock all or any of them, each having, of course, its own individual key. This method is commonly adopted in hotels, boarding-houses, etc. A skeleton key is one in which the major portion of the blank has been cut away to clear the wards, and is thus easily able to open the

lock, as there is no metal in the blank to obstruct the turning of the key, the only requirement then being that the height of the blank be sufficient to throw over the follower. But skeleton keys are useless against a good type of lever lock, as all the levers have to be raised to different heights; the use of picks made of thin, stiff wire is resorted to by the locksmith when a key has been lost. Most good-class locks are, however, made with safety devices that render them almost proof against picking.

LOCKER. There are many uses for lockers in the home, either as internal fittings or as receptacles for holding odds and ends. They are often provided with falling flaps, but these are only suitable when they are not more than 4 ft. or so above the ground level. The lower shelves of those filling a recess can be divided off and fitted with flaps with turn-buckles or locks; they provide good storing space, and may often save building a cupboard.

Fig. 1 shows an example of a simple locker with a falling flap secured with a padlock and staple, the whole, excepting the flap and hingeing piece, being of $\frac{3}{4}$ in. deal. First prepare the two ends to size and cut and rebate them at each end deep enough to take the false top and the bottom. The two latter are then cut out, and in length should equal the width of the job less the thickness of the projections formed by the rebates on the ends, as is shown in Fig. 4.

Glue and nail the job together, and nail on a back, 3-ply being the best stuff to use. The hingeing piece is nailed on to the front, as in Figs. 2 and 3, and must be of the same thickness as the flap. The latter may be of one piece, strengthened on the inside with battens, or for a better job may be clamped. It is hinged with ordinary brass or iron butts, and a hole cut at the bottom to allow the staple to pass through. It is better to fix this first, so that the position at which to cut the hole will be automatically marked. The top is fixed by nailing down from the top, or in another method may be screwed from the inside through the false top. Fig. 5 is another form, having a sloping top which acts as a lid. It is most suitable to be fixed to a wall, for which purpose it is necessary to fix two battens to the back to allow for clearance when the lid is raised (Fig. 7). The front, back, and sides are rebated together, as in Fig. 8, extra width being given to the front to allow for its being bevelled off at the top at the same angle as the sides. It is easier to bevel it after the job is put together. The bottom is either nailed or screwed on from underneath.

LOCKET. This old-fashioned piece of jewelry is made to hold a miniature or small portrait, or a lock of hair or other memento. *See Pendant.*

LOCKJAW. The cause of lockjaw, also called tetanus, is a microbe, the bacillus of tetanus, which is introduced into the body through some wound or cut in the skin, and produces a virulent poison. It is found in garden soil, stable sweepings and dust.

The first symptoms may be headache or languor, the muscles of the neck become stiff, then those of the jaw, and the jaws become fixed or locked. The face becomes fixed and the corners of the mouth are drawn back in a curious smile. The spasms extend to the body and legs.

As regards prevention, any dirty wound should be thoroughly cleaned up by a doctor, and according to the nature of the contamination he may consider it necessary to give a prophylactic dose of antitetanic serum.

In any case where there is stiffness of the muscles in the neighbourhood of a wound, or of the jaws and neck, the doctor should be sent for, and in the meantime the patient should be given a warm

bath and put to bed. Rest and quietness are of the utmost importance. The patient when in bed must not face the window. Draw the curtains, put a thick carpet on the floor, oil the door-lock and hinges, and remote all creaky chairs. Avoid any sudden noise, such as the banging of doors. Do not let the patient speak unless it is absolutely necessary. Cover artificial lights with a blue shade, and keep the light, natural or artificial, always dim. Observance of these nursing rules will spare the patient much agony and further his recovery.

The diet must be nutritious and fluid. The food must be given slowly, and with the greatest gentleness, to avoid causing a convulsion. The early use of antitetanic serum is important.

LOCK NUT. A lock nut is an ordinary nut used to check, or lock another nut which is screwed on to the same bolt, and prevent its further progress. For example, if a bolt is to be screwed a certain exact distance into a hole a nut is placed on it, and when the bolt has reached the required position the nut is screwed up tight, thus locking the bolt in position. Sometimes two nuts are screwed on a bolt together, the lock nut holding the first in position.

Lock nuts are secured, when necessary, by means of various patented methods in which some special arrangement is used to prevent the nut unscrewing except under the action of a spanner.

LOCOMOTIVE: BUILDING A SCALE MODEL

How to Construct a Replica of the L.N.E.R. 2-6-0 Mogul Engine

This powerful Gauge 1 Locomotive is built from a set of standard parts, and its assembly is easily accomplished with a few simple tools. Model engineers should consult also the articles on Engine; Railway. Other allied entries are Boat; Electric Motor; Yacht.

The building of scale model locomotives is a fascinating pastime, but is generally regarded as a hobby requiring considerable skill and a fair amount of experience in metal work. The Mogul locomotive for gauge 1, however, which is illustrated herewith, should present little difficulty as it is built entirely from finished standard parts obtainable from Messrs. Bassett-Lowke, Ltd., of Northampton.

The simplest tools only are required, such as soldering iron, screwdriver and pliers, and a careful inspection of the accompanying photographic illustrations will assist the worker considerably, as all the parts referred to in the following instructions are numbered. Only one example of each pair of frames, set of wheels, axles, etc., is shown in order to avoid confusion.

Locomotive. Scale model of a Mogul engine which can be built from a set of standard parts. Left, view of the chassis. The separate parts are illustrated on the next page.

Separate parts are described in the text, where directions for assembling them are also given.

Erecting the Chassis. The main frames (1) are screwed at the leading end to a cross bearer (30), and the smokebox saddle (32) is fitted between the frames by means of the lugs and slots provided. Plate (34) is next soldered, flange downwards, to the rear end of the frames, plate (25) being similarly secured at the front end, the flange being uppermost. The front buffer beam (28) and rear beam (18) are then soldered in place, the central lug on the latter extending backwards to take the pin of the tender draw-bar (5).

Axle boxes (4) are next inserted in the slots in main frames, together with their respective axles (8), and driving wheels (11, 12). Wheels are fitted with crank caps (14), those marked (13) being used for the central coupled pair (11), which are made flangeless to facilitate running on curves. The caps (13) carry the return cranks which actuate the valve gear. The wheels are finally retained by means of horn stays (21), the coupling rods (17) being slipped on the crank pins and secured by small screws. The cylinders (2) are next taken in hand, short steam pipes being soldered in position as shown. The steam control valve seen at lower end of pipe (6) is screwed in place between the frames just in front of the smoke-box saddle. The short pipes in each cylinder are next soldered into the T-pipes attached to the control valve, the cylinders being finally secured to the frames by screws.

The big ends of connecting rods (10) are slipped over the crank pins of the central coupled wheels, the little ends being attached by small pivot screws to the crossheads on the piston rods.

The assembly of the valve gear is shown in the photograph of the completed chassis. It will be seen that the vibrating lever (16) is pivoted on a screw at the top end to a small bracket on the main frames. To the middle of this lever a screw attaches one end of the valve rod (7), which is pivoted at its other end to the piston valve itself. The radius rod (9) connects lower end of lever (16) with the return crank (13).

The reverse lever bracket (20) is next screwed in position on the rear footplating, the reverse lever and rod (23) being pivoted to the bracket and steam valve reverse arm respectively. The reverse lever not only changes the direction in which the locomotive is running, but also serves to shut off steam and to control the speed.

The beading (27 and 29) is next soldered in place under the footplating, and plates (31) are screwed in position over the central axle-boxes to protect them from the flame of the lamp. The pony truck (19) is assembled by pressing on the wheel (15) to axle (3), the latter being pushed through the bearing bushes shown, the addition of a second wheel completing the unit.

The flame guards (24) are provided with lugs which fit into slots in the footplating, a twist on the underside making all secure.

To complete the chassis it is then only necessary to add the buffers (22), coupling hook (26), and the footplate steps (33).

The Boiler and Fittings. The boiler (50) is supplied as a complete unit consisting of a rolled sheet brass barrel with flanged ends and a stout central stay.

At the cab end are situated a steam whistle and a blow off cock, whilst on top of the boiler are two dummy safety valves to preserve the scale appearance of the model. The working safety valve (and filler combined) are housed in a removable dome. At the smokebox end of the boiler is attached a large displacement lubricator, connected to the steam pipe, as shown. Handrail knobs (soldered into the boiler shell) are provided, with nuts on the inside, together with the handrails, which are cut ready to length and only require soldering in position.

The other items shown, in the photograph are the complete smokebox (49) with funnel and handrails, the cab (52), and the vaporising spirit lamp (51), a twin gas burner of really efficient design and performance. A spirit measure and filling funnel are shown at Nos. 53 and 54 respectively.

The mounting of the boiler on the chassis is a comparatively simple matter, as the barrel fits at the rear end in a circular hole in the cab front, the smokebox end resting on the saddle plate (32) previously referred to.

The cab is accordingly soldered in position on the rear footplating, the plate (35) being fixed between the frames at the front of the cab with the square cut-out piece arranged to provide a hole to accommodate the reverse rod. The steam whistle and reverse lever project through slots in the cab roof. The boiler barrel is free to slide in the cab opening to allow for expansion when hot.

The steam pipe is soldered into the steam control valve, thus holding the boiler to the chassis at the smoke box end. The exhaust pipe (6) is attached to the boiler front by means of a soldered clip, the steam escaping from the tunnel. The smokebox is completed by the addition of handrails and screw bolt, the whole unit being a push-on fit over the front of the boiler.

The vaporising lamp fits into a recess between the frames and is retained by an L-shaped wire catch soldered to the rear buffet beam.

Lamp brackets are attached by means of small nuts and bolts in holes ready drilled in the front footplating, and scale model lamps are provided as a further contribution to correct detail and realism.

Constructing the Tender. The tender is of the six-wheeled type, and representative parts which are needed for its construction are shown in the accompanying photograph. The footsteps, handrail, knobs, buffers and rear coupling hook are similar to those on the engine. Building the tender from these tinplate parts constitutes quite a straightforward soldering job.

First the frames (36) are fitted, as shown, with the die cast axle box units (41), the reverse side being seen at (43). The spigots behind the spring shackles are pushed into the holes already drilled in the frames and riveted over. The hollow bearing spigots are then expanded into holes in the frames, using a tapered punch. The axle boxes are fixed on the same side of the frame plate as the flange, the semicircular slot being at back of the tender, provided to clear the nuts which secure the rear buffers to the buffer beam (42).

The frames, with axle boxes fitted, are next soldered to the sole plate (56). The wheels (47) are supplied complete on axles (44) and are simply sprung into position between the frames. The back (42) and front (46) buffer beams are soldered into position on the sole plate. Handrail knobs are then bolted to the side plates (48) and handrails soldered in place.

The end plate (57) is soldered inside the side plates, leaving a good fillet of solder to form a rounded corner. The plate (39) is soldered to the front of the tender with the flanges inside. The

completed sides with end plates are then soldered to the sole plate. Finishing touches to the tender include the fitting of the coal slide (55), the footplate (37) and the coaming plates (38). The tender is finally washed out with hot soda water to remove all traces of flux used in soldering, and is completed by the addition of the vent pipes (40), the manhole (45) and a set of lamp brackets. The completed locomotive is then tested under steam and finally painted in the colours of the chosen prototype.

Oil the axles, crank pins, valve motion joints, and other moving parts with typewriter oil, and fill the lubricator with thick cylinder oil. Fill the boiler two-thirds full with clean hot water. The lamp needs a little care in filling with methylated spirit, and the measure which is supplied by the manufacturers should be employed for the purpose. Carefully wipe off any spirit which may be spilled, or allow it to evaporate, before lighting lamp.

LOCOMOTOR ATAXIA. Uncertain gait may be one of the first symptoms of locomotor ataxia., a chronic disease of the spinal cord, which is most common in males. It may be due to alcoholism, sexual excess, syphilis, or injury to the spinal column.

The patient gradually finds that he is very liable to lose his balance unless he watches his feet. Walking becomes more difficult, and the reflexes are completely lost. Two sticks have to be used, and gradually the power of locomotion is lost entirely, together with control of the bladder. In many cases of locomotor ataxia the optic nerve is affected and total blindness may speedily ensue.

The patient should place himself under a doctor's care at the earliest possible moment. All fatigue of body and mind and worries and anxieties must be avoided, and the patient must live a simple, regular life. The patient should use alcohol very moderately or not at all. The diet should be nutritious, but not rich and stimulating. Secure a daily movement of the bowels; guard against chills and wear flannel next the skin. Take regular tepid baths.

The remedy which has met with most success is the system of exercises suggested by Fraenkel. These are designed to re-educate the patient in making the necessary movements, and they may be commenced even when he is bedridden.

Locust Tree. The locust tree is a hardy summer-leaving flowering tree, better known as the false acacia (q.v.).

LODGER. A lodger is a person who hires a room or rooms or part thereof in the house of another. He is in some respects like an ordinary tenant. If he rents a separate room, his goods are liable to be distrained upon by his landlord. His landlord's landlord can, in the first place, distrain upon all goods which he finds in the house, including those of the lodger. But the lodger can recover his goods by giving a notice in writing to the person who makes the distress containing a list of the goods claimed and a statement that they are the goods of the lodger, the terms upon which the lodger holds, i.e. weekly, monthly, etc., and at what rent, and also how much rent he owes, if any.

The lodger must pay to his landlord's landlord any rent which is overdue by him. He is then entitled to have his goods redelivered to him, and if the distraining landlord refuses to deliver them, application should be made at the nearest police court. As against his landlord, the lodger is not entitled to any special protection for his goods. He must take care of them himself. But the landlord must not be guilty of negligence, e.g. taking in a servant without a character who turns out to be a convicted thief.

A lodger should always stipulate what notice is to be given to determine the contract, and in the absence of any express agreement he is entitled to a reasonable notice. As a rule, where rent is

payable weekly a week's notice is sufficient, and where payable monthly a month's notice. The notice must expire at the end of a week or month of the tenancy.

A lodger who takes furnished rooms is in exactly the same position as one who holds unfurnished rooms, except that under the Rent Restriction Acts a lodger who takes unfurnished rooms to which the Acts still apply is protected, and cannot be turned out except by an order of the court, which order can only be made for the reasons specified in the Act. A tenant of furnished rooms is not entitled to any protection under this statute; but the lodger, even in unfurnished rooms, who by his contract is entitled to attendance is also outside the protection of the Rent Restriction Acts.

Lodgers, both men and women, are entitled to vote at both parliamentary and municipal elections, a residential qualification being sufficient. *See* Agreements: Landlord; Tenant.

LODGINGS. When lodgings or furnished rooms are required in a town which the prospective lodger does not know, an inquiry addressed to one of the local newspapers will probably be of assistance. By sending a stamped addressed envelope anyone may learn from the chief clerk of the classified advertising section which of the districts are occupied by the better type of landlady and boarding house. It is then a simple matter to advertise for rooms in one or other of these neighbourhoods, or, preferably, to make inquiries on the spot. Much can generally be learned about the character of individual houses by inquiries at local shops or from a policeman.

There are various types of lodgings, including the bed-sitting room, with or without board, in a private house, or one or more bedrooms and a sitting room where more privacy is secured, at a higher price. Lodgings may be taken in a house where the landlady supplies no meals and has little to do with her tenants. For a man this method may prove rather expensive if he has to buy all his meals outside. For a woman it often solves the problem of economical living away from home, as such rooms are usually provided with a gas-ring or some kind of gas fixture on which meals can be prepared. A third method of many landladies is to let each of the rooms of a large house at a fixed rent with breakfast, the meal being either sent up on a tray or served in the dining room as in an ordinary boarding house.

A person living in rooms should avoid making complaints, whether about food or service, except to the responsible person. Heavy luggage causes trouble to servants and often injury to walls. If a good deal of luggage is necessary, packing can be so arranged that the heaviest trunk may be put in a box-room or basement. Alteration of furnishing arrangements should not be made without the landlady's consent.

Furnished apartments are also of interest to the holiday-maker. Prices vary considerably, according to the season of the year, the highest being usually obtained during July and August. Some landladies make a weekly charge, which covers board and lodging, but the majority do the cooking and attendance, leaving the visitors to buy their own food.

Furnished apartments can be obtained by looking down the columns of the local paper or by application to the inquiry bureau which exists at nearly every British watering-place, usually under the direction of the town clerk or other municipal authority. Those requiring apartments, especially in the summer months when schools are closed, should book their rooms at least three months ahead. The letting of apartments as a means of gaining a livelihood is often the only career open to a widow with a family, or to an unmarried woman who has been left with a well furnished house without sufficient income to run it. A house must be run on sound business principles to pay. Three important aids to success are absolute cleanliness, good cooking and pleasant manners. A well-aired, well-dusted house, creates a good impression without elaborate furniture or expensive decorations. In furnishing rooms a landlady should aim at clean walls, simplicity in the floor-

coverings, with stained wood or linoleum surrounds which do not harbour the dust, good lighting suitably placed for reading, a gas-ring and a gas heating fixture where central heating is not in use, convenient bathrooms, and perfect sanitary arrangements. *See Holidays.*

LOFT. In general a loft means an upper room, a room situated above another. To-day it is used mainly for the vacant space at the top of a house, that between the joists and the rafters, and for a similar space above a stable or other outbuilding. The latter space, provided it is properly floored, is often used for storing hay or corn, or other accessories of the stable. It is sometimes used for pigeons, and on this account the term pigeon loft has come into general use. A loft of this kind can also be converted into a useful workshop or gymnasium.

In the case of a loft in a house the only difference between a loft and an attic is that the loft may be without a boarded floor, the only flooring being that provided by the joists. Such lofts are therefore useless. A loft can, however, be made serviceable, either as a store-room or a lumber-room, or even as a study or a den, by laying down a boarded floor over the joists, provided they are strong enough, and making certain other alterations.

The ceiling joists, while presumably adequate for their proper purpose, may not be strong enough to carry additional loads. Indeed, some care is needed when placing lumber in the loft, to dispose the heavy articles on that portion of the joists which gets support from walls, partitions, etc. Expert advice should be obtained on these points. The conversion of a loft, or any similar work, may come under local by-laws, and the householder should satisfy himself about this before commencing any alteration.

The entry into a loft is generally through a trap door, or through one of the upper rooms in the house. A disappearing ladder is a useful fitment. Types are illustrated in the articles on Attic and Ladder. The floor over the ceiling joists is laid with tongued and grooved floorboards at least 1 in. in thickness, which are nailed to each joist with 2½ in oval brads, driven in with a light hammer so as to minimize the vibration, which otherwise might damage the plaster ceiling underneath. Great care must be taken not to tread upon the lath and plaster work; some of the floorboards may be laid down temporarily and used to stand upon, or use may be made of any strong rough boards. Light might be admitted by means of a skylight, a window in an end wall, or a few slabs of glass substituted for roof slates, *See Attic; Ladder.*

LOGANBERRY. The general culture of the loganberry is similar to that of the raspberry. The fruit is large, deep red in colour, and of excellent flavour when thoroughly ripe. It is valuable for cooking and preserving. The plants should be about 12 ft. apart when planted to cover a trellis or against wires, and if there are two or more rows the distance between them may be about 7 ft.

The loganberry is easily propagated by bending the tips of the canes to the ground late in summer, pegging them in, and then leaving them to root. When they have rooted the cane is severed near the top, and is ready to be transferred to its fruiting quarters. The method of pruning the loganberry is by cutting out the old stems when the fruits have been gathered; the new shoots are tied to the supports.

Loganberry. Spray of leaves and large fruit that makes excellent preserves.

Loganberry Culture. 1. How to prepare the soil. 2. Shoots cut down after planting. 3. Mulching, a, in summer. 4. Training, a, new shoots for next fruiting; b, centre supports for fruiting canes; c, wires; d, canes tied to wires; e, posts with ground bases tarred. 5. Propagating single shoot held down by stone, with cut behind bud. 6. Multiple propagation. Shoots pegged down at buds to form roots.

How to Cook. The fruit of the loganberry plant is used in the same way as other cane fruits in the making of jams and jellies, and also for pies, pastries, etc. It is seasonable in July. The general directions are the same as for raspberries.

When making jam use $\frac{3}{4}$ lb. sugar and teacupful water to every 1 lb. fruit. If the fruit is very large and juicy, no water is required. Loganberries can be mixed with red currants and stewed, or made into jam, pies., etc.. in the same way as raspberries. They are also excellent mixed with apples.

In bottling loganberries, use water or syrup; $\frac{1}{2}$ lb. sugar to 5 quarts water makes a sufficiently rich syrup. The time required for boiling is $1\frac{1}{2}$ hours and the temperature should be brought up to 160° for about 5 minutes. See Jelly; Laxton berry; Pastry; Raspberry.

LOGGIA. A loggia is a pleasing addition to a house and can be put to excellent uses. It is somewhat after the nature of a veranda being part of the actual structure of the house, and is an added attraction to a seaside bungalow. It is desirable that the loggia should stand well above the level of the garden, as in this way a clear outlook will be assured. Obviously it should be erected on the sunniest side of the house, but should be carefully sheltered from extreme winds, so that it may

be a cosy outdoor room. If it is to be used for meals it should be conveniently placed with regard to the kitchen. The loggia can, if desired, be furnished and made to serve the purpose of a lounge, or even of a living-room, at least in summer. In this case its supports should admit of the fixing of screening material in times of rain and cold. The best arrangement is one embodying sliding or removable sashes that can be brought into use as required. A loggia can also be arranged so as to serve as an extension to one of the living-rooms. Its furniture should in any case be well able to stand a good deal of exposure to the weather; otherwise there will be a constant carrying of chairs and tables to and fro. The furniture of an ordinary sitting room cannot, for instance, be kept continually in a loggia without serious damage resulting.

Loggia. Fig. 1. Loggia of a stone-built Wiltshire house; it is furnished and used as a garden room.

Three Examples. The illustrations herewith show three loggias in styles specially well adapted to various types and sizes of English houses. Fig. 1 shows a loggia belonging to a Wiltshire house, which is built of local stone. It is furnished as a garden room and can be used as an open-air extension of a living-room for hot weather.

Fig. 2 shows the loggia of a Sussex house, this being a part of England for which this feature is very suitable. It is not put to any special use, but folding chairs and tables would quickly convert it into a sun parlour if required. The charmingly designed window shown at the far end gives on to the rose garden. The oil jars and lighting fittings are particularly decorative. Fig. 3 shows another sheltered loggia which opens from one of the living-rooms. It is furnished in a more solid fashion. The benches and chairs afford plenty of accommodation when meals are taken in the loggia, while the side tables and plants suggest an air of homeliness and comfort.

These loggias are each part and parcel of a house, having been included in its original design, but it is quite possible in houses of a certain type to add a loggia to the existing building. Many houses in the country have a corner that could be roofed in at little expense. It is desirable that such a corner

shall get a fair amount of sunshine and that the addition to the structure does not interfere with the adequate lighting of the adjacent rooms of the house. See Garden Furniture; House; Veranda.

Loggia. Fig. 2. Charming paved loggia of a Sussex house.

Fig. 3. Sheltered loggia furnished for summer use. (1 and 3, Courtesy of Country Life; 2, Humphrey Joel)

LOIN: Of Meat. This is a prime portion of meat, but not considered economical on account of the excess of fat. It is that portion of the animal that lies on both sides of the spine between the false ribs and the hip bone. In mutton and lamb, also in veal this portion is sold as a joint and called the loin. In beef it becomes the ribs and sirloin. In pork it is known as the hind loin and fore loin, while in bacon it is called the back. *See Bacon; Beef; Mutton; Pork.*

LOMARIA. Most of the family of ferns known as lomaria require greenhouse treatment. They have feather-shaped leaves, thrive best in shady positions in the greenhouse, and require plenty of water from spring, all through the summer, till autumn. Propagation is by spores sown in fine soil in the warm house at any time of the year. Lomaria (*Blechnum*) spicant is a hardy fern of which there are many varieties.

Lomaria. Feather-shaped fronds of a fern which requires greenhouse treatment.

LOMBARDY POPLAR. A hardy deciduous tree, *Populus nigra pyramidalis*, the Lombardy poplar thrives best in deep, moist soil, but will flourish almost anywhere. It serves as a boundary screen, or as a quick-growing lofty hedge if kept well trimmed. For small gardens it is not suitable, owing to the extent to which its roots rob the soil of moisture and nourishment. *See Poplar.*

LONDON PRIDE. One of the commonest of all garden plants, London pride (*Saxifraga umbrosa*) is familiar as an edging to shady borders. It has rosettes of evergreen leaves and in May bears graceful sprays of pinkish flowers. It flourishes in ordinary soil and pieces may be detached and replanted at any time of the year. See Border.

LONGCLOTH. This form of calico gets its name from the fact that similar cotton cloth imported 200 years ago from India was put up in long lengths, not in short pieces. It is plain woven and made square with threads just as fine and as many in one direction as in the other, so that it is equally strong in warp and weft. Woven 28 to 36 in. wide, longcloth can be bought either bleached or unbleached, and it is made in standard qualities that are denoted by trade marks.

LONG MEASURE. This is in constant use for measuring lengths of materials, ground, etc. It is as follows:

12 inches	= 1 foot
3 feet	= 1 yard
5½ yards	= 1 rod, pole, or perch
40 rods	= 1 furlong
8 furlongs	= 1 mile
3 miles	= 1 league

LONGPORT: The China. This Staffordshire ware was produced at this suburb of Burslem in the 18th century. In 1793 the Longport works were acquired by the Davenport family. See China; Davenport Ware.

LONG SIGHT. Long-sightedness, or hypermetropia, is generally due to the eyeball being shorter than the normal length from front to back. Consequently the image is focussed behind, instead of on the retina. Near objects cannot be seen distinctly; distant objects may, but this requires an effort when the long-sightedness is extreme. The cure is to wear convex glasses which will focus all rays entering the eye accurately on the retina. See Eye; Spectacles.

LOO: The Card Game. This is a game for any number of players, but six to seven is the best number. It is played with the ordinary pack of 52 cards, which rank as in whist.

The dealer deals three cards one at a time to the players, and also an extra hand, known as miss. The next card on the top of the pack is turned up for trumps. Each player in turn looks at his hand, and is asked by the dealer if he will play, or take miss, or pass.

If the player has a good hand he usually elects to play; if not, he can either take the three cards in miss or pass. In the last case he signifies by doing so that he is not taking any further part in that round of the game. Every player in turn is offered the option of playing, taking miss, or passing. As soon as one player takes miss, those who follow have only the option of playing or passing. The player who takes miss must play, no matter how bad the cards in miss may be. If only one player plays, he takes the pool. If all except the dealer pass, the latter takes the pool. The pool is formed at the beginning by each player putting in a counter.

The eldest hand of those who have agreed to play leads. He must lead according to the following rules: If he has two trumps in his hand he is compelled to lead one. If he holds the ace of trumps he must lead it, or if the ace happens to be the turn-up and he holds the king he must lead the latter. If only two players are playing, the leader, if holding two or more trumps, must play the highest. Each player must follow suit if possible, and must try to beat the last player's card. If unable to follow

suit he must trump, and if the trick has already been trumped he must over-trump if he can. The winner of each trick leads for the next, and must lead a trump if he has one.

The Pool. The pool is divided in the proportion of one-third for each trick. If one player has taken two tricks, for example, and another one, the first takes two-thirds of the pool and the second one-third. The remaining players are said to be loosed and place in the pool an amount, with the new dealer's contribution, which totals the original amount of the pool, to form the new pool. If only three players play and each takes one trick, the other players are not loosed, but the new pool is provided by the dealer. This hand is then usually known as a must, the meaning of this expression being that each player must play, whatever his cards may be, and the miss is not dealt.

LOOFAH: For Washing. The tough fibrous tissue of the fruit of the loofah plant is used for washing and other household purposes. Its rough surface has a stimulating effect upon the skin. Loofahs can also be purchased made up into washing gloves or straps, when they are bound with strong tape or webbing to prevent them from tearing where they have been cut to shape. Inner soles made of loofah for shoes are excellent wear both for summer and winter. In summer they keep the feet cool; in winter they keep them warm. Pieces of loofah may be put in kettles to prevent them from becoming furred. Such pieces can be bought from any ironmonger, and will last without attention for a long time. When they become impregnated with chalk they should be taken out and soaked.

Looking Glass. *See Mirror.*

LOOMS: FOR HOME WEAVING

Constructional Details of a Workable Pedal Loom

This contribution describes a handy type of table loom, and tells the woodworker how to make a portable loom of a larger type. The home weaver will find the craft clearly explained in the article on Weaving. See also Rug; Tapestry.

Hand looms range from a board loom such as that shown in Fig. 1, on which narrow tapestry can be woven, to the table loom shown in Figs. 2 and 3, which permits of work up to 33 in. wide, and the pedal operated loom (Fig. 4), on which a variety of fabrics up to 42 in. wide can be made.

Making a Pedal Loom. The loom illustrated in Fig. 4 differs from the conventional English type in construction (see Weaving) and might at first inspection be thought somewhat slight for its purpose. Developed from a simple Greek prototype, it has been used constantly in a weaving studio over a period of years, the design being modified as and when improvements were found desirable. The frames are held together by dowels and pegs, so that the whole structure is readily erected or taken down.

Back, front and side elevations are given in Figs. 5, 6 and 7. In conjunction with Fig. 4, they make the method of construction quite clear. The uprights should be of well seasoned hardwood, 2¼ in. by 2¼ in. They are connected by rails made of 1 in. beech dowel rod, which run through and are pegged at the ends. It will be seen that the side rails go through the intermediate short uprights on which the breast roller rests, and are pegged at the short upright so as to space the latter squarely at the proper distance from the inside of front uprights. The toothed cross bars which support the harness and sleigh are 2 in. by 1¼ in., tenoned into posts and pegged.

Left. Loom. Fig. 1. Simple board loom, arranged for weaving narrow tapestry.

The side frames are connected together by two rails at each end. These rails must come lower than the tenons of cross bar and dowels of lower rail respectively, so as to have enough wood between for adequate strength. Two brackets for warp roller are dovetailed into back posts at a height of 2 ft. 6 in. from ground, and two for breast roller into the intermediate posts at 2 ft. 2 in., both measurements being to centre of hole where it enters post. The brackets shown are made of dowel rod set in at an angle, but shaped brackets might be substituted if wished. The seat board fits on to upper side rails between front and intermediate posts, being cut round front posts. The method of constructing the frames and connecting them together permits the loom to be dismantled and packed into small compass. If portability is not desired the end rails might well be made of rectangular section stuff mortised

and tenoned to posts in the conventional way.

Loom. Fig. 4. Pedal loom on which a variety of fabrics up to 42 in. wide can be made. Its construction is illustrated next page. (Courtesy of Alston Weaving Studios)

Figs. 2 and 3. Alston table loom, a compact portable appliance which takes warps up to 33 in. wide.

The side frames are connected together by two rails at each end. These rails must come lower than the tenons of cross bar and dowels of lower rail respectively, so as to have enough wood between for adequate strength. Two brackets for warp roller are do welled into back posts at a height of 2 ft. 6 in. from ground, and two for breast roller into the intermediate posts at 2 ft. 2 in., both measurements being to centre of hole where it enters post. The brackets shown are made of dowel rod set in at an angle, but shaped brackets might be substituted if wished. The seat

board fits on to upper side rails between front and intermediate posts, being cut round front posts. The method of constructing the frames and connecting them together permits the loom to be dismantled and packed into small compass. If portability is not desired the end rails might well be made of rectangular section stuff mortised and tenoned to posts in the conventional way.

Loom: construction of a pedal type. Figs. 5-7. Back, front and side elevations.

The Rollers. The breast roller (Fig. 10) is turned from 2¼ in. stuff, and one end is left square for a distance of 4 in. Two holes for a turning stick are bored through at right angles, and the stick may be a piece of 1 in. dowel. The cane roller or warp roller is similar, but the squared end is at the opposite side. Both ends of this roller might be left square if desired. Both front and back rollers are grooved to take the cane which secures the warp in place. The groove, ½ in. square, is indicated in the diagram of the cane roller Fig. 4 shows how the rollers are mounted, on the brackets, the breast roller with its square to the right and the back roller with its square to the left, both viewed from the front of the loom (seat board). The diameter of the rollers, especially the warp roller, may be increased with advantage.

Sleigh and Harness. The sleigh or batten (Figs. 8 and 9) consists of four parts, the two sides or swords, by which it is hung from a roller supported on the rack, and two grooved rails which hold the reed. The cap, or upper rail, is free to move up in the slot in the swords, so that the reed can be inserted or removed. The lower bar is fixed by pegs to the swords, and the cap also has holes for pegs, so that it can be secured when the reed has been inserted. The reed measures about 5 in. in depth, and is held by the grooves in cap and lower rail. The slots in swords and the tenons on cap and lower rail must be accurately cut, and the peg holes in the upper part of swords should be evenly spaced so that the batten hangs level from the roller. The rack teeth, too, must be accurately cut and spaced or the sleigh will not hang squarely across the loom. The whole of this part of the loom needs especial care, and the materials must be good seasoned stuff free from shake or twist Fig. 8 is an end view of the sleigh showing slots and the tenons of rails.

The harness is shown diagrammatically at Figs 11 and 12, and is represented as the simplest form, with two heddles. The laths should be made of oak, 1 in. by ⅝ in. section. The short upper laths are slung by a loop passed round the supporting roller and through a hole in the centre of lath. The endless cords connecting short laths to heddle laths are about 40 in. long before making the knots. The connexions to pedals are clearly shown in Fig. 12 corresponding parts being lettered A and B respectively. A single cord might be taken from centre of lower lath to pedal if desired. For clearness, the heddle laths are represented with two leashes only on each pair. Slip knots in the connecting cords permit of any desired adjustment for length. The pedal boards are 4½ in wide, hinged by loops to the bottom front rail, as shown in Fig. 4, and provided with a series of holes at the other end, in one of which the cord to lower heddle lath is fastened.

The heddle leashes can be procured ready made in lots of 100, tied in 25's. A reed will be needed, and a raddle. The warping board can be made by the home worker, and full instructions will be found in the article on Weaving, where also are the necessary instructions for making the warp, entering and beaming the warp: and setting up the harness. The accessories needed, and supplies of yarn or other materials can be obtained from Alston Weaving Studios, 88, Marylebone High St..
W.I.

Fig. 12. Connexions from heddles to roller and pedals. (Courtesy of Alston Weaving Studios)

LOOP. A dress-maker's loop is used instead of an eyelet or metal eye. To work it, lay two or three threads along the material for about $\frac{1}{4}$ in., or according to the length required for the size of the hook. The threads are laid by catching up a little of the material at each end of the space, then a back-stitch is done after the last thread is laid to secure them. Fill these laid threads with buttonhole stitches and fasten them off securely into the material at the end of the loop.

LOOP HOLE. The term loop hole is applied to a series of doors or openings set vertically above each other on the floor levels of a warehouse, as a means of passing goods in and out. As a rule, a crane is fixed above the topmost loop hole. It is also used to describe a long, narrow opening in a wall, which may be glazed or otherwise.

LOOSESTRIFE. The purple loosestrife (*Lythrum salicaria*) is a familiar British plant often seen by the waterside. *Lythrum virgatum* Rose Queen is a valuable hardy garden plant; it grows 3 ft. high, thrives in ordinary soil, and bears rose-coloured flowers in summer. Propagation is effected by dividing the clumps in autumn.

LORDS AND LADIES. This is a common name for *Arum maculatum*, a familiar wild plant also known as cuckoo-pint, wake robin, and Italian arum.

LORGNETTE. A lorgnette is an eyeglass or pair of eyeglasses made to be held in the hand instead of being fixed on the nose. Tortoiseshell is frequently used for the fittings of long-handled lorgnettes, and gold for the more old-fashioned types, with springs for folding, or hinged between the glasses. These lorgnettes can be fitted with convex glasses for reading and with concave ones for distant work. See Eyeglass; Spectacles.

LOST PROPERTY. The law relating to articles lost and found is, roughly speaking, that a person who finds an article can keep it against all the world except the true owner; but if the true owner turns up he can either claim the article or its full value. An honest man who finds anything will endeavour to discover the owner; but in law he is not entitled to any reward, nor even to the expense to which he has been put.

No one is entitled to anything found on someone else's ground, not even if that ground is a railway station or a railway carriage. Articles lost in such places belong to the owners of the ground as against everybody except the true owners. Property in public vehicles must be handed to the person operating the service, and claimed within 3 months. The owner pays 3d. And 1/12 of the value if that is over 2s., but cannot be required to pay more than £2. At Scotland Yard there is a special department to deal with property lost within the London area. Individuals who find lost articles often take them to a police station, while those who have lost valuables may offer a reward for their return, publicity to this being given by the police. Anyone who keeps for himself any article he finds, believing that the owner could be found, is guilty of theft.

Railway companies have lost property offices where application should be made by persons who have lost anything while travelling, or left it in a railway carriage. The lost property will be returned to the applicants on payment of a fee.

LOTION. A liquid preparation of a drug, for external application, is known as a lotion. It is made to dry quickly by adding alcohol, and slowly by the addition of a little glycerin. Lotions are classified as antiseptic, anti-pruritic, astringent, soothing, and stimulating.

To apply an antiseptic or other lotion, soak a piece of lint in it and lay the lint on the part with the smooth part downward. Over this place a piece of oiled silk or other waterproof material, which must project about ½ in. all round the lint. Cover with a layer of cotton wool and bandage. Antiseptic lotions are also used to cleanse ulcers and wounds, a piece of lint or sponge being dipped in and then squeezed over the wound.

An evaporating lotion is used for cooling some parts of the body. It may be very grateful in headache, especially brow ache, in sprains and strains, and in acute inflammation of the skin from whatever cause. Alcohol or weak acetic acid or vinegar in water is generally employed for the purpose.

LOTTERY. A lottery is a distribution of prizes by lot or chance, e.g. a sweepstake. With certain exceptions it is illegal to print, sell, or distribute any tickets in a lottery, whether the lottery is held

in this country or abroad. It is not regarded as illegal to buy a ticket abroad, but tickets entering this country may be stopped by the Post Office.

Lotteries may legally be conducted in connexion with entertainments such as bazaars, sales of work, etc., so long as certain conditions are observed. The whole proceeds of the entertainment must be given to charity after deduction of expenses of the entertainment, including the expenses of printing lottery tickets, but no other expenses of the lottery and not more than £10 for prizes. The tickets can be sold and the result announced only during the entertainment. The lottery must not be the only substantial inducement for persons to attend the entertainment.

Private lotteries are also legal. These are lotteries which are confined to members of some society or to persons who all work or live on the same premises. All the proceeds of the lottery after deducting the expenses of printing and stationery must be used for the prizes or for the purposes of the society. A lottery of this kind must not be advertised except on the premises of the society or where the persons for whom it is promoted work or reside. The tickets must state the price, the names and addresses of the promoters and the class of persons to whom tickets may be sold, and no prize must be paid to anyone except the person to whom the ticket is sold. Tickets must only be sold for cash and must not be sent through the post. If it is desired to run a lottery in connexion with a local entertainment, it is best to consult the local police for advice.

It is illegal to run in a newspaper or in connexion with any trade or business any competition to forecast the result of a future event—e.g. who will win a football match. This does not apply to football pools. See Gambling.

LOTTO. This game is played with oblong boards or cards and counters. The cards are divided into 27 spaces, 9 in a row. Four in each row are blank and the other five are marked with numbers, which may be any figure up to 90. The 90 counters are wooden or ivory pieces, marked from 1 to 90.

The players take one or more cards each, and the banker shakes the counters one by one from a bag. As each falls he calls out the number, and the players who have that number on their cards mark it, usually by covering it with a counter. This continues until one player has covered all the numbered squares in one row on his card.

LOUD SPEAKER. The device in a radio receiving installation that changes the amplified electrical variations into sound vibrations. Practically all modern loud speakers operate on what is known as the "moving-coil" principle. A small coil is suspended between the poles of a powerful magnet, and when the low-frequency electrical variations pass through this coil it vibrates and communicates its movement to the diaphragm to which it is fixed.

In some mains-type receivers an electromagnet is used for the loud speaker and the field-winding of it made to act as a smoothing choke as well. However, a permanent magnet has the advantage of relative freedom from induced hum, and special nickel-iron alloys have been developed with which high degrees of permanent magnetism are possible.

The diaphragm is made in a conical form, as this shape is the most effective one for obtaining the greatest stiffness in the lightest construction, but the cone must be as shallow as is practicable or the diaphragm will tend to increase unduly the directional effect of the high notes. Varnished fabric or moulded fibre is employed, as such materials have the required stiffness and yet have much less natural resonance than, for example, metal.

The lower sound-wave frequencies do not leave the diaphragm directionally, but spread out widely. If some form of screen is not interposed, those leaving the front of the diaphragm will meet those leaving the back of it and there will be a neutralizing effect. That is why a loud speaker "chassis"

removed from its cabinet will sound high pitched. The cabinet acts as an intervening screen or "baffle" between the two sides of the diaphragm.

The coil of a loud speaker must be "matched" with the output circuit of the set. This is possible by winding the coil with sufficient wire to give it the necessary relatively high impedance, but it is more convenient to restrict the winding to the small dimensions which produce a low impedance and to use a step-down transformer in order to achieve "matching." This "output" transformer may be built into the loud speaker or separately contained in the set.

"Extension" loud speakers for use at points distant from the set in addition to the loud speaker in the set itself are frequently fitted with transformers having a multiplicity of connections enabling efficient matching with any type of set to be obtained. However, many receivers have special extension loud speaker terminals or sockets for connexion to low-impedance loud speakers which need not embody transformers.

The loud speaker does not, as is commonly supposed, appreciably affect the power consumption of a wireless set. For instance, in the case of a battery set no more low- or high-tension current will be consumed if the volume be increased or if one or more additional loud speakers are employed. It is true that there is a type of amplification control (known as "variable mu") which, operating in the high-frequency amplifying circuit, affects the high-tension current consumption to some slight extent; but it is, for practical purposes, a negligible effect when local and other powerful stations are being received.

The faults which can occur in a loud speaker of modern design are few in number. In the electro-magnetic (mains-driven) type the most frequent is the "burning out" of the field-winding. This often happens when the field-winding is also used as a smoothing choke. The effect is that the set is completely silenced.

A continuous buzzing, as though a large insect is beating its wings on the diaphragm, may indicate that one of the turns of wire on the moving coil has come loose. If a similar noise is heard only when there are loud passages of speech or music it may be due to the coil being out of centre and scraping against the poles of the magnet.

In choosing a loud speaker, or judging the merits of a set in respect to its loud speaker, the following points should be borne in mind. The high notes should be crisp and clean and the sibilants in speech clearly audible but not exaggerated. The low notes should sound natural and not have undue persistence or boom. A loud speaker ought not to have any "tone" of its own. It is not a musical instrument, but merely a reproducer of sounds. Any tendency to give emphasis to one or more particular frequencies is a definite fault whether it be evinced by a "mellow" booming of the bass notes or a strident emphasis of one or more of the higher frequencies. To test it, the loud speaker should be listened to carefully when it is operating at a volume slightly above that which it will normally be operated. See Wireless, etc.

LOUIS STYLE: In Furniture. This general term is applied to the four styles of furniture and decoration which were produced in France during the reigns of four of the Louis, namely—XIII, XIV, XV, and XVI.

Louis XIII. The style Louis XIII, or Louis Treize, was a reaction from that of the previous reign with its superabundance of carving and painting and rich ornament created and revived by the Renaissance. Louis XIII chairs were small and rectangular in contour, with slight frames of woods covered by well-padded velvets, tapestries and embroideries, fastened by round-headed brass nails. The arms of the chairs, however, were rarely padded; the legs were joined by stretchers. Large armoires or wardrobes, chests of drawers and knee-hole desks were embellished with inlays of coloured woods, ivory and bone, depicting flowers and birds. The walls were panelled and adorned

with mirrors. This particular style corresponded in period to the early Jacobean in England, but was far less severe.

Louis XIV. The Louis Quatorze (Louis XIV) style is a heavy classical one. The furniture was overlaid with carving, rich inlays and heavy carved metal mountings after the designs of Buhl. Some magnificent pieces were made in this style. The chairs had tall backs, square or V-shaped; the cabinets were large, glazed and often bowed. The sofas were ample in size, and for them rich brocades and tapestries of baroque designs were used. Fig. 1 shows a clock of this period with its florid design, classical pilasters, baluster rail and Buhl case with ormolu mounting. Louis XIV style greatly influenced English furnishing and decoration during the reigns of Charles II and James II. The period concluded approximately with Queen Anne style in England.

Louis Style. Fig. 1. Clock of the Louis XIV period, in a buhl and ormolu case.

Louis XV. Louis Quinze (XV) is the rococo style. The wood was heavily carved, or covered with composition moulded into enrichments of rocks, shells, waterfalls and scroll work; among the latter doves, cupids, and heads and busts of women, terminating in foliage were prominent. Much of the furniture is gilded or painted in delicate tints.

Other pieces were veneered with marquetry and decorated with heavily chased ormolu mountings as seen in the commode in Fig. 2. The chairs and couches have sweeping curved backs upholstered with tapestries, having flowers, figures, or animals worked thereon, or in flowered brocades. The woodwork is gilded. Corner cabinets and little round tables were also produced in this period. These are enriched by inlays of birds, figures and landscapes carried out in tinted and stained woods. Louis XV style was often too exaggerated and florid for real beauty. It corresponded in period with the mid-Georgian in England, but lacked the fine designs of the best English furniture and decoration of the time.

Above. Fig. 2. Commode with overlaid marquetry of mahogany, and heavily mounted with chased ormolu; period Louis XV.

Right. Fig. 3 Louis XVI chair of carved and gilded wood upholstered in tapestry. (By permission of the Director, Victoria & Albert Museum, S. Kensington)

Louis XVI. In the style Louis Seize (XVI) appear rectangular panels having simple mouldings and fluted columns, with quill and husk fillings. Dainty ribbons and bows in ormolu and marquetry surround richly painted Sèvres plaques, while silver is introduced to tone down the gilding. Red and green are the predominant colours. Tapestry from Beauvais and the Gobelins factory, and silks were used for the upholstery. The backs of the large chairs are rectangular or oval; the legs are tapered and fluted as shown in the chair illustrated in Fig. 3, which is familiar in appearance as the prototype of many pieces in suites designed for drawing rooms and labelled Louis Style.

The marquetry of the period was executed with extraordinary smoothness and finish, and the mounts of gilded bronze, which were the leading characteristics of most of the work of the 18th century, were finished with a minute delicacy of touch. The famous 18th century English cabinet makers were not greatly influenced by the Louis styles, although Chippendale furniture certainly frequently shows Louis XV ornamentations. See Buhl; Chippendale: Jacobean; Tapestry.

LOUNGE: How to Furnish. Unless the term is an affectation, to style a sitting room a lounge means that it is furnished with special regard to comfort and relaxation. It is essential that the colour scheme should be restful without being depressing and that the room should have a cosy, homely atmosphere about it, as it often takes the place of a smoking-room and combines a card-room with an informal sitting room for general family use. In country or large detached houses the lounge is usually either an

extension of the hall, or a spacious and pleasant room with access to the garden. The former type is discussed in the article on Hall, the latter is well represented in our first illustration.

With its southern outlook over the garden and cheery French windows this lounge is furnished in the most reposeful fashion with a number of large armchairs and a comfortable settee. The velvet chosen for the upholstery gives a particularly rich appearance and is an ideal fabric for a lounge.

This appearance is enhanced by the pile

carpet with its unobtrusive border and all over trellis pattern. There is nothing definitely binding to any particular period, either antique or modern, in the room. The wide planning of the brick fireplace is in perfect keeping with the rest of the decoration, and the dark note of the woodwork is repeated on the ceiling with excellent effect. On either side of the fireplace is a delightful little window with a view on to the tennis lawn. The lighting is from wall brackets and table lamps. In such a sunny room a restful and beautiful colour scheme would be evolved by choosing soft mignonette greens for the two-toned carpet, the deeper shade of green for the velvet upholstery, the lighter shade for the wallpaper. Above the mahogany picture rail the frieze and ceiling would be washed with primrose yellow in a clear pale shade. The warmth of the brick and the woodwork of the fireplace contrast happily with these colours, and the printed linen for the curtains would repeat the mellow tones of the brick in its conventional floral pattern with touches of yellow and brown on a green ground.

Lounge. Fig. 1. Corner of room showing result of harmonious planning. The restfulness of the lounge is enhanced by the velvet upholstery and the fireplace with its little windows on either side. (Humphrey & Vera Joel)

In the second illustration a different type of lounge is shown, but here again the keynote is one of restful ease. Though the divan and settee are severe of outline, in keeping with the simplicity of the style of the room, they are luxuriously comfortable. There are no pictures: no frieze or cornice, and no break in colour or glossy texture of surface between the wall and ceiling. These details increase the height and apparent size of the room and emphasize the uncommon design of the windows which add great interest to the scheme.

The upholstery in this case has been carried out in a modern heavily ribbed fabric and the curtains are of dull-surfaced silk. The carpet is a velvet pile in modern design. The built-in bookcase, the table and the two floor standards are finished with cellulose lacquer. With so much glossy paintwork it is essential that the furnishing fabrics and carpet should be mat and soft of texture. The colour scheme for such a severely simple lounge should be striking, and a beautiful effect would be

gained by using a pale French blue for the walls and ceiling, dark grey for the woodwork of the skirting, architraves of doors and windows, a lighter tone of the same grey for the upholstery fabric and the fireplace surround, and three shades of grey for the carpet. The curtains would blend with the scheme by being of shot blue and silver grey silk, but the whole room would be brightened without any disturbing effect in such a reposeful setting, by choosing lacquer red for the colour of the standard lamps, bookcase, table and leather floor cushion. The pleated lampshades would be of parchment colour tied with red and silver cords. See Colour; Decoration; Hall; Living-Room.

Lounge. Fig. 2. Modern lounge in which severity of line is delightfully contrasted with richness of furnishing fabrics and the comfort of the divan and settee. (Humphrey & Vera Joel)

Louse. *See* Lice.

LOUVRE. This is a form of ventilator, which may be made in wood, metal, glass, or other material, and consists of a framework, across which a number of parallel slats are fixed, so that they incline downwards, the bottom of one slightly below the top of the next. The louvre provides a convenient means of ventilation where it is not desired to leave a simple aperture, or to go to the expense of a sash or casement window.

Louvres are found as ventilators fixed to the top of a roof, and in other exposed positions, as their structure is of durable character, and calculated to withstand the attacks of the weather. A small louvre panel fixed in a door is a convenient method of obtaining ventilation while excluding any possibility of vision. Sometimes the word louvre is applied to a form of lantern, placed on the roofs of outbuildings for ventilation purposes. *See* House; Shutter.

Love Apple. This is an old name for the tomato (q.v.).

LOVE BIRD. This phrase is used, without any very exact meaning, for some of the small parrots. They are usually kept in pairs, although the idea of mutual affection conveyed by the name is without foundation, the birds perching together merely for the sake of warmth. Solitary love birds do not pine; if the death of one is followed by that of the other it only indicates that both were unwell together. The hardiest of the love birds is the rosy faced one. These will often breed in captivity, provided they are placed in a roomy aviary. In general, however, love birds are very delicate. The budgerigar is one of the most popular of the love birds. The breeding season is from April to July. *See* Budgerigar; Parrot.

Love Bird. Specimens of Australian Budgerigar, popularly known as Love Birds.

LOVE IN A MIST. This favourite blue-flowered hardy annual (nigella) flourishes in ordinary soil; the charm of the flowers is enhanced by the finely divided leaves which surround them. The best variety is called Miss Jekyll; it has flowers of deeper blue than the typical kind, *Nigella damascena*. Seeds are sown out of doors in April where the plants are to bloom in summer, or in early September for spring flowering.

Love in a Mist. Blooms of the rich blue variety named after Miss Jekyll.

LOVE LIES BLEEDING. This showy, hardy annual (*Amarantus caudatus*) bears crimson flowers in long drooping racemes. Seedlings, usually raised under glass in March, are planted out in June, but seeds may be sown out of doors in late April and May.

LOVING CUP. The loving cup is a large drinking vessel, usually made of silver, with two handles and sometimes three, which is filled with wine and circulated at public banquets, each guest drinking and passing it on to his right-hand neighbour.

Loving Cup. Example of a two-handled loving cup in silver, dating from 1710-11; height, 7 inches. (Victoria & Albert Museum)

Certain formalities in the use of the loving cup were formerly more strictly observed than they are to-day. Each guest as the cup reaches him rises and bows to his right-hand neighbour whose duty it is to remove the cover and hold it while the other drinks. When there is no cover it is customary for both the right and left-hand neighbours to stand up. This is a survival of Tudor times. The cup was formerly filled with wine, ale or mead, with a piece of toasted bread floating on the top; but it now generally contains spiced wine. This custom of drinking from one cup was observed at the Jewish paschal supper.

LOWBERRY. This valuable berried fruit was obtained by cross-breeding between the loganberry and the blackberry; the large fruits have a black berry-like flavour. The cultivation is similar to that of the loganberry (q.v.).

LOWESTOFT CHINA. The porcelain produced at Lowestoft during the later half of the 18th century was of the same type as Bow and Worcester. As there was no factory mark, specimens of it used to be attributed to these works, especially as the Worcester crescent was sometimes copied at Lowestoft. Because of its rarity there are a number of counterfeits of this ware.

The factory turned out bowls and useful services, with blue and red decorations, sometimes with panelled borders containing local scenes. The ware is inclined to be heavy, opaque and yellowish, with a dull and speckled glaze. Ribbed and fluted cups, decorated with detached or linked sprigs of flowers, besides embossed teapots, and pieces inscribed "a trifle from Lowestoft," may be looked for.

An unsolved mystery is the use of the term Lowestoft china for armorial ware made and painted by Chinese artists at Canton during the 18th century, and never imported into or manipulated at Lowestoft. *See China.*

Lowestoft China. Teapot and cup and saucer of the porcelain formerly produced at Lowestoft. It is decorated with a Chinese design of flowers and birds.

LOW FREQUENCY. This term is applied to alternating currents having frequencies up to about 10,000 cycles per second. There is actually no definite dividing line between high and low frequency currents, but in wireless the term low frequency is normally applied to those frequencies within the limits of audibility. See Detector; High Frequency.

LOW TENSION (L.T.). This name is given to the voltage which is applied to the filament or heater of a wireless receiving valve in contrast to the high tension voltage which is applied to the anode. In a battery operated wireless receiver, the low tension battery may take the form of a 2, 4 or 6 volt accumulator, according to the type of valves used. In the case of an "all mains" receiver, the heat current is derived from a suitable low-tension winding on the mains transformer. See Accumulator; High Tension, etc.

LUBRICATION: In the Home. There are many materials that possess properties which render them peculiarly adapted for certain forms of lubrication. Of these, a mineral oil forms the base of nearly all lubricating oils, the practical value of which depends almost entirely upon the proportion of the constituents and the method of manufacture. Broadly speaking, oil suitable for a typewriter, sewing machine, or clock is thin, almost as fluid as water, and very pale in colour. Only the very best typewriter oil should be purchased for lubricating the typewriter, and similarly the sewing machine should be oiled with good sewing-machine oil.

For clock work only the very finest specially prepared oils should be used. In ordinary household use for such purposes as oiling the bearings of a lawn mower, mangle, or other similar appliance, employed for comparatively light work and during short periods, any good quality light machine oil will give satisfactory results.

Lubricants for Bearing Surfaces. Among lubricants used for bearing surfaces are graphite, soapstone, and a variety of others which are used dry. Of these, powdered graphite gives excellent results on cast iron surfaces. Solid lubricants, when mixed with animal fats, grease, vaseline, or the like, are converted into semi-solid grease, which may be used for bearings and is excellent for small carts and the like. For some purposes vaseline is a good lubricant, especially for slow-moving shafts and bearing surfaces. Lubricants for high speed bearing surfaces, such as those in a small electric motor, require a thin oil generally an animal oil.

Objects made of wood and provided with bearing surfaces, such as the slides or bearers supporting a drawer, may need lubricating. This is best accomplished by the use of dry graphite, but in practice it can seldom be used as it tends to soil anything which comes in contact with it. Alternatively, French chalk, fuller's earth, or powdered talc, can be employed for the purpose.

The lubricating of gear wheels is difficult when they are not enclosed in a greaseproof gear-case. If they do not revolve at a high speed they can be treated either with graphite in the form of a paste or with a heavy gear oil about the thickness of stiff treacle. On small gears vaseline will often give good results.

In using lubricants for any machine in the home, it is best to wash out the bearing surfaces occasionally with paraffin, wipe the exterior clean, and oil the bearings with fresh oil. Run the machine for a minute or two to make sure the paraffin is entirely disposed of and that every part is properly oiled. Again wipe all the exterior dry and apply a few drops of new oil, which will keep the bearings in good condition and add to the life of the machine. When the bearings are to be oiled the oil holes should be cleaned out before applying the lubricant, otherwise grit and dirt are washed down into the bearing and set up a grinding action which tends to destroy it. Lubricating oils should be kept in closed containers and stored in an equable temperature. See Bicycle, Oil.

LUBRICATION FOR MOTOR VEHICLES

How to Keep Car and Cycle in Good Running Order

This article deals with a subject of importance to the motorist, who will find other useful information in the articles Motor Car; Motor Cycle and Motoring. See also Gear; Live Axle, etc.

In all modern motor car engines the lubricating oil is circulated by a pump automatically operated by the engine. This pump, which is usually little more than two gear wheels enclosed in a case, draws the oil from the crankcase sump, or a tank, and delivers it under pressure to the main bearings.

The methods employed for ensuring adequate lubrication vary in principle and detail, but roughly they may be divided into three classes as follows:

(1) Circulating Splash (sometimes called pump-and-trough). In this system the pump delivers the greater part of the oil through suitable pipes or passages to a series of troughs arranged in the crankcase below the path of the connecting rod big-end bearings. Attached to the lowest part of the latter is a small dipper which picks up the oil in the trough and throws it so that, as this is being repeated several hundred times a minute, the moving parts of the engine are working in an oil mist. Some of the oil falls into troughs attached to each main shaft bearing, to the camshaft bearings, and to others feeding the valve tappets. Again, a quantity of the oil falls into holes on the big-end bearings and into troughs at the lower ends of the cylinder bores and pistons, which carry the film of oil up the cylinder walls, while the lubricant which has been splashed into the pistons serves to lubricate the small-ends of the connecting rods.

(2) Splash and Pressure. This is a system also employing troughs under the big-end bearings, but leads from the pump are also taken to the main crankshaft bearings and sometimes to the camshaft bearings as well, thus providing a supply of oil under pressure to these important points. The reciprocating parts are lubricated in the same manner as described in the circulating-splash system.

(3) Full Pressure Lubrication. The pump delivers oil under pressure to the main bearings, and from the interior of these it passes into channels bored in the crankshaft, which communicate with similar channels in the crank pins. Thus the big-ends are lubricated from within. Similar channels take oil under pressure up ducts in the connecting rods to the small-end bearings. Surplus oil from these bearings is thrown off on to the cams, cylinders pistons, etc.

Oil Consumption. The quantity of oil consumed in a motor vehicle depends largely upon the size and general efficiency of the engine, but an average of 1,000 miles to the gallon is regarded as a satisfactory consumption in a modern engine. Even if the oil-level indicator in the sump indicates that there is a good supply after a considerable mileage has been covered, it is desirable to drain the crankcase and refill with fresh oil, as oil which has been used over and over again for long periods loses its viscosity. Moreover, it becomes contaminated with particles of carbon and with other impurities.

Special oils are now sold which have a high flash point and are known as upper cylinder lubricants. These oils are used additionally to the main supplies and are usually mixed with the petrol, and so impart to the fuel a lubricating quality which serves to keep the valve stems well lubricated. Separate containers for this upper cylinder oil are fitted on some cars.

Gear Box and Back Axle. Lubrication of the gear box and back axle (which contains the differential gear) consists mainly of making sure that these important parts have an adequate supply

of oil. The lubricant should never be allowed to be too much below the level specified by the makers. The level should not fall appreciably in 1,500 miles running.

Most cars are equipped with level-plugs (which are removed when filling the gear box or the rear axle) to indicate, by overflowing, when the correct level has been reached.

An excess of oil in a rear axle may cause the surplus to find its way on to the brake drums and so render the brakes useless. Careful attention should be paid to worm drive back axles, especially to those which have the worm on top of the wheel; any shortage of oil here will quickly render the drive inoperative.

Lubrication of the Chassis. Certain bearings on a car chassis require lubricating more frequently than others. The points needing periodical attention are the spring shackles and pins, the joints of the steering rods, the brake operating gear and the front axle steering pins. The modern method of lubricating these parts is through grease-ways supplied with grease by means of a pressure gun. The appropriate grease should be forced into the nipples on the bearings until some of the grease exudes from the end of the bearings. In some cases there is a separate nipple which is filled for each bearing, in others several bearings are fed by a group system from single nipples, and in a few from a central point, this feeding all the bearings.

Front wheel hubs require infrequent replenishment, but once every six months they should be given a fresh supply of grease to prevent the balls or rollers on the bearings from corroding. The steering box, too, should not be neglected, and should be tightly packed with a mixture of oil and grease.

Lubrication for motor cars. Fig. 1. Lubrication of the chassis: Tecalemit central system. Arrangement of pump and pipes, the latter shown in thick black lines. A, flexible tube from frame to axle. B, connexions to steering wheels.

Lubrication of car engine. Fig. 2. Diagram of fully forced system. Crankshaft is sectioned to show oil passages. Arrows indicate the path of the oil.

Motor Cycle Engines. Owing to the limited space available in a motor cycle the flywheels of the engine are usually enclosed in the crank-case, and there is seldom room for a sump in its base. In most four-stroke motor cycle engines a slow speed oil pump, driven off the timing gear, is used to supply oil in minute quantities from a reservoir to the crankcase, where it is used on the splash system, or it is carried to the big-end bearing. Hence it is distributed on the cylinder walls, and, through a hole in the partition separating crankcase and valve gear casing, to the valve gearings and tappets.

A few motor cycle engines embody a sump, in line with the practice in car engines, the pump being used to circulate the oil from the sump, through the bearings, and back to the sump. In what is known as the dry-sump system a pump serves to supply oil under pressure to the various parts of the engine and also to return the surplus to the outside reservoir.

In two stroke engines it is usually the practice to mix the oil with the petrol; the mixture varying from 30 parts petrol to 1 of oil when the engine is new, to 16 to 1 when the bearings and piston have been well run in. In this system no other provision is made for lubricating the engine. It is a simple, if crude, method of supplying oil to rapidly moving parts, but is quite satisfactory except that the carburetter is usually covered with a film of oil. If the engine is allowed to stand too long with the supply tap open, there is a possibility of the oil, heavier of course than the petrol, settling in the carburetter and so making starting difficult. Experience has shown that much trouble may be avoided if the supply tap is turned off a little while before the engine is stopped, in order that the float chamber of the carburetter is not left with a supply of the petrol mixture, as it is called.

Fig. 3. Splash system, in which dipper on connecting rod cap dips into oil trough. A, oil collector or reservoir, with feed pipe to bearing. B, oil collector cast in one with bearing.

Luggage: Every passenger by train in Great Britain is entitled to have a certain quantity of luggage carried free of charge, the amount varying with the class of ticket. Anything exceeding this weight is paid for at a fixed rate per lb. Passengers are responsible for their own luggage to the extent of seeing that, having been correctly labelled it is put into the right train, but if the company's servants once take charge of a package, the company is liable for its safety.

On most British railways luggage may be sent in advance at a fixed rate per package on production of the passenger's ticket. The charge includes collection and delivery, and notice should be given at least one day before.

Travellers by motor coach are allowed a certain amount of luggage, although this is usually confined to suit-cases and bags that can be carried in the hand.

Travelling Abroad. For continental travelling the systems vary. In some countries each passenger is allowed a certain weight of luggage free and pays on the surplus, while in others all luggage except that actually taken in the carriage must be paid for. Luggage can be registered from the station from which the boat-train leaves, and it requires no attention on the passenger's part until he reaches his destination, unless he has to submit to customs examination on crossing the frontier between two countries. As a general rule, however, registered baggage is not examined en route, but only at its final stopping place.

For sea voyages each passenger may take a certain amount of luggage in the cabin, and the rest goes in the hold, the cost of transport being included in the passage money. The requisite labels are sent by the shipping company. While few people consider it necessary to insure their luggage for an inland journey only, it is, however, a wise precaution to insure it for foreign travel.

Some Legal Points. The legal duty of the passenger consists solely in delivering his luggage to a company's servant with directions where he wishes it to go. The company must then label it and send it on, and all the passenger has to do is to claim it at its destination.

The luggage a passenger is entitled to carry free must be personal luggage, that is, such things as are ordinarily taken by a traveller for use as a traveller. If articles of merchandise are delivered to the company as passenger's luggage and are lost, the company is under no liability. They are bound to accept personal luggage up to the proper weight if properly packed, and can refuse to accept a package not addressed; but if they accept a package which is not addressed they are responsible for it. It is best to have luggage put in the guard's van; for if a passenger takes luggage with him into the carriage, to some extent he relieves the company from responsibility for its safety.

A railway company may make special conditions as to liability for the carriage of luggage by cheap or excursion trains. They are not entitled to make any special regulations exempting themselves from liability when ordinary fares are paid. If a servant carries luggage for his master as his own personal luggage, the master has no claim for its loss; and the servant cannot claim, because he has suffered no damage.

It should be noted that if the passenger has over £25 worth of articles, e.g. jewelry, etc., in his luggage, and fails to declare them, and they are lost, the railway company is not bound to pay a penny, and the whole loss falls on the owner unless the luggage is insured. *See* Holidays; Packing; Trunk.

LUMBAGO: How to Treat. Pain in the loins, or lumbago, is commonly due to fibrositis, or inflammation of the sheets of fibrous tissue surrounding and covering the muscles of the back. The fibrous tissue swells at various points and presses on nerves, giving rise to pain, which may be very sharp.

The exciting causes of an attack are cold, damp, exposure to draughts when perspiring, and muscular strain. Predisposed persons should harden themselves by a daily cold bath or sponging, and by not wearing too warm clothes. But in cold weather the small of the back should be protected. A Turkish bath will often avert an attack. Rest in bed is advisable. Apply a large, hot linseed poultice, or wring a folded piece of flannel out of hot water, sprinkle it with turpentine and put it to the back, renewing it as it cools. Dry heat can be applied by half filling a large indiarubber water-bag with hot water and placing it against the part or a piece of flannel may be applied and rubbed over with a hot flat iron.

An attempt should be made to discover the swellings on the inflamed tissue, and these should be kneaded with the thumbs, very gently to begin with, but with increasing firmness as the patient is able to bear it.

The bowels must be kept regular by occasional doses of some saline aperient. At the commencement of an attack a powder containing 5 grains each of aspirin and phenacetin may be taken several times at 3 or 4 hour intervals. Friction with stimulating liniments, such as turpentine liniment, or with Chilli paste, is useful as the acute stage passes.

LUMP. A swelling somewhere about the body is popularly referred to as a lump. In the neck it is usually an enlarged gland, the commonest cause being tuberculosis. A lump in the breasts may be due to inflammation, or to cystic or tumour formation.

Much harm results from women delaying too long to get medical advice about such a lump.

In the groin a lump is generally a hernia or rupture, but may be due to enlarged glands or other causes. *See Gland.*

LUMP SUGAR. Sugar moulded into a loaf or conical shape is broken into cubes and sold as lump sugar. Lump sugar is highly refined and is the purest sugar which can be purchased. It is, therefore, most suitable for using either with tea or coffee and also for many delicate sweets, if pounded, sifted, and given the place of castor sugar. *See Sugar.*

LUNAR CAUSTIC. Nitrate of silver, commonly known as lunar caustic, is used to remove warts and cauterize wounds. In cases of poisoning give a tablespoonful of salt in a pint of water, or the whites of 2 or 3 eggs beaten up in a pint of water. *See Wart.*

LUNATIC: The Legal Position. A lunatic is a person of unsound mind, and under English law such can be put under restraint in an asylum after certain formalities have been complied with. There are several forms of procedure in such cases. The ordinary method is by a reception order or petition, this being the one usually adopted in the case of private patients where urgent action is not essential.

Four documents are required, these being the petition itself, a statement of particulars, and two medical certificates. The petition must be signed, if possible, by the husband, wife, or nearest relative of the alleged lunatic. If this is not done the reason for another person signing it must be given. The signer of the petition must, moreover, have seen the lunatic within 14 days of the date of the petition. Attached to the petition is a statement of particulars. This must contain the name, age, sex and occupation of the person with details of his or her present illness and any previous attacks of insanity there may have been.

Most important are the two medical certificates, one of which should be signed by the usual medical attendant of the alleged lunatic. Each of the medical men must examine the patient, separately from the other, within seven days of the date of the petition.

The Medical Certificate. A medical certificate cannot be given by the petitioner himself, by the superintendent, proprietor or medical attendant of an asylum or home to which the alleged lunatic is to go. It cannot be given by any person interested in the payments on account of the lunatic or by the husband of wife, father or father-in-law, mother or mother-in-law, son or son-in-law, daughter or daughter-in-law, brother or brother-in-law, sister or sister-in-law, or by a partner or assistant of any of the foregoing.

One paragraph of the medical certificate requires two statements: "Facts indicating insanity observed by myself at the time of examination," and "facts communicated to me by others." The statements made under the first heading are the most important part of the certificate, and unless these contain evidence sufficient to convince an independent reader that the person to whom the certificate refers is insane the certificate will not be regarded as sufficient. A medical man who signs a certificate of lunacy is not allowed to continue to attend the lunatic. He is not liable to civil or criminal proceedings for any statement made therein, unless it can be proved against him that he has not acted in good faith and with reasonable care.

When they are completed the petition and other documents must be taken before a judicial authority, who is either a county court judge, a stipendiary magistrate, or a justice of the peace, specially appointed for the purpose. This authority, if satisfied with the evidence set forth, may sign the reception order forthwith, or may appoint a day, not more than seven days after the presentation of the petition, for its consideration, and may himself visit the lunatic.

Cases of Urgency. When it is urgently necessary, either for his own safety or for that of others, that a person should be put under restraint at once, the method of procedure is by an urgency order. This may be signed by the husband, wife, or other near relative of the alleged lunatic. If anyone else signs it the reason for so doing must be given. The person who signs must have seen the lunatic within two days of the date of the order. A person can only be detained under an urgency order for seven days.

If it is desired to put him under permanent restraint a petition must be presented in the way already described and he can be detained until this is settled. Slightly different forms of procedure are employed in the case of a lunatic who is wandering at large or is a pauper; of one not under proper care or control; or of one who is cruelly treated or neglected by those in charge.

Two commissioners in lunacy can sign an order for the detention of a lunatic in a recognized mental home even if there is only one medical certificate.

When once certified as insane a lunatic must be placed in an asylum or home that is under the supervision of the lunacy authorities, and if the relatives are dissatisfied with his or her treatment there an appeal can be made to the officials of the Board of Control, whose headquarters are at Metropole Buildings, Northumberland Avenue, W.C.2. *See* *Insanity*.

LUNCHEON AND LUNCHEON PARTY

Dainty Catering for Family and Guests

This is a companion article to those in our work on Dinner and Supper. Dining Room and Table Laying may be further consulted by the housewife. See also the entries on Embroidery; Glass; Mat; and the articles on Diet; Food: Picnic; Salad; Sandwich.

The family luncheon on Sunday, or everyday where there are children, is a more substantial affair than the light lunch usually served when dinner is the chief meal of the day. The tendency, however, is to simplify midday fare, and, especially in the summer, to get away from the heavy joints and puddings associated with the old-fashioned meal. Two or three times a week fish is served instead of meat for the children, and plenty of stewed fruit or fresh fruit salads and light junkets or custards are substituted in hot weather for the suet puddings so valuable as heat producing food in the winter. Variety is essential for healthy enjoyment of meals, and menus can be easily thought out by the housewife before the beginning of each week. The huge Sunday joint which used to supply cold meat on Monday and two or three made up dishes for the next day or two, of little food value in comparison with the trouble of their preparation, may save a slight effort of imagination, but it is far more profitable and interesting to evolve a series of appetizing and well balanced meals. Such forethought makes all the difference between drudgery and gratifying efficiency.

Children's Midday Meal. Particularly suitable for substantial luncheon dishes in the winter, accompanied by vegetables in season, are beefsteak and kidney pudding or pie, Irish stew, casserole stews of oxtail, beef or mutton, fresh minced steak, liver and bacon, sausages and mashed potatoes. Boiled cod or hake with egg and parsley sauce, grilled herrings, dried haddock with poached eggs, fish pie and baked whiting fillets, are all excellent substitutes for the meat course with or without a nourishing soup, according to the selection of sweet to follow. For instance, if a boiled jam roll or apple pudding is selected, the soup would not be required; but if stewed fruit or merely an open jam tart is on the luncheon menu, then, on a cold winter's day, Scotch broth or brown vegetable soup will form an admirable prelude to the meal.

In summer egg dishes are light and nourishing for children, particularly in the form of poached eggs on a vegetable such as spinach or runner beans. Many suggestions for wholesome fish and meat salads will be found in the article on that subject. These are more appetizing on a warm day than hot food. Luncheon in the garden is a pleasant meal to return to from school, and the service of this is facilitated by a trolley wagon laden with one simple hot dish in a casserole or a substantial cold one, and cold sweets. The inexpensive fruit sets of one big bowl with its smaller companions are attractive and useful adjuncts for the summer pudding course out of doors. Lemonade, pineappleade and orangeade are excellent and popular luncheon beverages.

For children who have to take their lunch to school neat little cases are obtainable either for sandwiches only, or if something more elaborate is required, fitted with cup and saucer in unbreakable ware, a thermos flask and a sandwich tin.

Some nourishing fillings for sandwiches are described in the article on Sandwich. Oatcake and cream cheese, dates, raisins, celery, tomatoes and apples are all useful varieties of food for the luncheon case. Hot soup in the thermos makes a pleasant change in winter. Cold malted milk or a fruitade, in a wicker-cased bottle, are liked in the summer. A portion of some kind of sandwich cake makes a nice sweet with a custard tart or an iced bun for a change.

The Sunday family luncheon may have to be a more Victorian meal in the larger households. Servants expect it if no one else does. Even then, cold dishes can be added to the menu in hot weather, joints can be sufficient for the day, the evening supper requiring a certain amount of left-over cold meat. The housewife can also keep her eye open for bargains in poultry and game to substitute for the sirloin of beef.

Many men if they are at home for lunch on a summer weekday really prefer a salad, bread and cheese and beer to a made-up entrée. They will often fancy a dish of hors d'oeuvres with a variety of sliced sausages. In winter a good fish or meat curry is an excellent luncheon dish, while many people who prefer a light meal serve a vegetable or macaroni au gratin, or a variety of omelette as the main dish.

Luncheon. Charming effect of a polished table laid with a dainty lace luncheon set and cut glass service. (Courtesy of Webb & Corbett)

Entertaining to Luncheon. Many housewives prefer to entertain their friends to luncheon rather than to the more elaborate meal of dinner. Sometimes such a luncheon is given before an afternoon's bridge, or a matinée, at others it is a pleasant way of seeing people who come from a distance. Visitors to luncheon on Sunday entail very little extra work in the household where a substantial midday meal is usually prepared on that day. It is

always a mistake to give too formal a character to a luncheon party, and this in itself renders service easy and makes it simple for the hostess to entertain guests in a friendly fashion who are much better off than herself. There need be little or no waiting at table.

However simple the fare the first requisite is that it should be good of its kind, the second that the table service should be dainty. Some women prefer the all over damask cloth, others lace or embroidered mats. As indicated in our illustration, a lace centre and mats show off beautiful glass to perfection, and an antique shade of lace looks particularly well on a dark polished table. In this case the table is laid for service from dishes handed round by the maid or from a side table by the hostess. The lace mats are protected by thin cork ones finished in cellulose to match the shade of the table. The effect would be spoilt if another colour intervened.

One solid course is enough as a rule at luncheon, and three or at the most four courses in all. Grape fruit, a fruit cocktail, melon or soup, are a suitable choice for the first course. Either of the first two would be served in glasses, the melon on a glass plate, and the soup in cups or small two-handled soup bowls. Sometimes in hot weather the soup is served iced. One of the small individual salads mentioned in the article on Hors d'oeuvres also makes an excellent first course for a luncheon party. Smoked salmon, salmon or prawn mayonnaise look appetizing on glass plates.

When fruit is the first course a fish or egg dish may follow either hot or cold, as taste and season of the year may decide. Veal or lamb cutlets and peas, salmi of game, casserole of chicken, beef tournedos or jugged hare are dishes which obviate the task of carving for the hostess. Vol-au-vent and various patties are often liked. Salads form a most useful series of helpful suggestions for the various courses of this meal. An iced sweet, where this can be made at home, is nearly always appreciated and petits fours may be served with it. With regard to beverages, ideas vary. Some people offer red or white wine in the winter, with whisky and beer in reserve for men who prefer them. In summer it is often enough to serve either a cider or a white wine cup, iced lemonade or beer. Many people never take alcoholic drinks at all, others never in the middle of the day. Good coffee should always be provided after luncheon, and also two or three kinds of cigarettes.

The Luncheon Set. Designs for luncheon sets consisting of a table centre and mats vary greatly in materials, colours and shapes. Sometimes three small mats go to each individual place at the table: one for the glasses used, one for the bread plate, and one for the plate on which the course is served.

Sometimes these three are combined in one oblong or oval mat large enough to hold both plates and glass. These larger shapes look particularly well in antique embroidered linen or in coloured linen decorated with appliqué motifs.

Designs for Irish crochet suitable for luncheon sets are obtainable in various books on crochet and through needlework pattern services. For a cottage set, coloured linen, canvas or raffia cloth mats are charming. They may have borders and floral designs embroidered in wool or raffia. Coloured American cloth bound with bias binding to match and decorated with appliqué cretonne flowers is also a good fabric particularly for an informal luncheon on a garden table or in the loggia.

LUNG. The lungs are two organs conical in shape, and of a spongy and very elastic substance, which fill the greater part of the chest cavity, and which contract or expand as the air is expired or inspired. The air passages in the lungs are termed bronchi. Each lung is surrounded by a double layer of serous membrane forming the pleural cavity. The right lung is divided into three lobes and the left lung into two. It is in the lungs that the blood changes its colour from the dark purplish red of venous blood to the bright red colour of arterial blood.

Diseases of the Lungs. Acute congestion of the lungs accompanies pneumonia and other inflammatory diseases of the lungs or tubes. Passive congestion is common in disease of the heart when the return of the blood from the lungs is obstructed.

Bleeding from the lung occurs in pulmonary tuberculosis, pneumonia, infarction and other disorders. An abscess in the lung may occur in pneumonia, in pulmonary tuberculosis, or from embolism.

Bronchitis consists in inflammation of the lining of the bronchi. When one or more of the bronchi become enlarged, bronchiectasis is said to be present. Emphysema is the name given to the dilatation of the air cells in the lung. One or both lungs may be affected.

Collapse of the lung is a condition in which parts of the lung contain no air and are useless for the purpose of respiration. An instance of this frequently occurs in broncho-pneumonia, especially in children, and may be signaled by the child becoming suddenly very short of breath, while the lips become blue. Should this occur, while awaiting the doctor, who should be summoned at once, the child must be placed in a warm bath and quantities of cold water should be thrown on the chest at short intervals, in order to induce deep inspirations. See Breathing; Bronchitis; Consumption; Emphysema; Empyema; Inhalation; Pleurisy; Pneumonia; Tuberculosis.

LUNGWORT. This is the common name of a hardy spring-flowering borage-like plant of low growth (*pulmonaria*), which flourishes in ordinary soil. The spotted leaves are ornamental. *Angustifolia*, 12 in., blue; *arvernensis*, 9 in., blue; *rubra*, 12 in., reddish, and *saccharata*, rose-pink, are some of the chief kinds. They are increased by division in early autumn.

LUPIN. The perennial lupin is one of the loveliest hardy garden flowers of May and June. In recent years- many new varieties have been raised of charming and varied colouring — yellow, fawn, apricot, crimson, rose, pink, etc. Some of them have been given names, but a mixed packet of good seeds will yield splendid varieties.

The lupin needs deeply dug and manured soil to be seen at its best; there, in the course of a year or two, it will develop into a large clump and will bear dozens of flower spikes. It thrives in partial shade or in a sunny place, and is planted in autumn or spring. After a few years the plants are liable to deteriorate, but fresh ones are easily raised by sowing seeds out of doors in May; the seedlings will bloom in the following and succeeding years. Lupins must not be lifted and divided. The finest modern varieties are the Russell lupins; they have exceptionally beautiful flowers.

The annual lupins are pretty plants, 2 ft. or so high, which bear flowers in blue, rose, and other colours. The showiest is *atrococcineus*, with red and white blooms. Seeds are sown out of doors in April, where the plants are to bloom in summer.

Lupin, Tall spikes of blossom of the handsome perennial lupin.

LUPUS. The skin disease known as lupus, which is the Latin word for wolf, received its name from the eating away of the tissues which often occurs in *lupus vulgaris*, one of the two forms of the disease. The other form is *lupus erythematosus*, which most commonly appears on the bridge of the nose and the cheeks, in what is termed butterfly distribution, covering them with red spots and greyish or yellow shiny scales. Septic conditions of the mouth or poisoning from some other source appears to have much to do with the cause of this form of lupus. The tubercle bacillus is the cause of *lupus vulgaris*, which is a very chronic form of tuberculosis of the skin.

Treatment consists in destroying the diseased parts by the application of germ-killing drugs or chemical caustics, removal by the knife, light treatment such as Finsen rays, X-rays, and radium. See Light; X-ray.

LURCHER. Generally a cross between a greyhound and a collie or some other sheepdog, the lurcher seems to unite the virtues of each, with an added spice of mischief. Some are so trained that to all appearances they have nothing to do with their masters if a gamekeeper or policeman happen to be met. A lurcher will hunt for game, catch hare or rabbit, and retrieve it without fuss to the hand of its owner. See Dog.

LUSTRE WARE. Pottery is said to be lustred when a part or the whole of its surface is coated with a metallic film, which imparts to it a refulgent sheen. The earliest lustre was the silver. The lustre decoration introduced into Staffordshire in the 18th century is seen at its best in some Wedgwood ware, and was manufactured at Newcastle, Sunderland, Leeds, and Swansea. It was produced by means of solutions of metallic salts, principally platinum, which gives the so-called silver lustre, gold, which is the basis also of metallic pinks and purples, and copper. Sometimes the whole surface was coated in order to impart the appearance of plated ware, a style which went out of use when electro-plating was introduced and electro-plated ware became popular.

Lustre Ware. Two-handled goblet, dating from about 1850.

Bismuth was used in Paris for producing an iridescent film resembling mother-of-pearl, and pearly ware of similar appearance is well known to collectors of Belleek and late Worcester. These modern English wares, as well as the cheap continental productions of

Belgium, Holland, and elsewhere, lack the true refulgence and gleam of the older lustre pottery. But apart from these there are available admirable reproductions of much excellence, both from modern Italian studios, and also among English craftsmen, whose work may be collected.

Lustre decoration tends, more or less, to wear off. It should be cleaned with great care, without the use of hot water. The silver lustre made a century ago is sometimes re-silvered, when intended for occasional use.

LYCASTE. This beautiful and easily managed winter and spring-flowering orchid can be grown in a greenhouse having a minimum winter temperature of 50 degrees. It should be potted in a mixture of loam, peat and sand and is propagated by division as soon as the flowering season is over. The favourite kind is *Lycaste skinneri*, which has blooms of deep blush or rose-red shade; the white variety, *alba*, is beautiful. Many others are in cultivation.

LYCH GATE. A lych gate is a covered gateway to the entrance of a building. Examples are often found at the entrance to churchyards, but in domestic architecture they form an ornamental approach to a house. A lych gate which the home worker can easily construct is shown in Figs. 1 and 2. The necessary dimensions are indicated on the diagrams.

The best wood is oak, but well seasoned deal may be used. Such a structure, if roofed with dark red sand-faced tiles and neatly finished, forms an attractive external feature of the home. Fig. 3 shows a chequerboard lych gate used in conjunction with fencing of the same type. *See Gate; Roof.*

Lych Gate. Fig. 1. Lych gate with a tiled roof which can be easily built by the amateur worker.

Fig. 3. Chequerboard lych gate constructed in sections. (Fig. 3, courtesy of T. & C. Associated Industries, Ltd.)

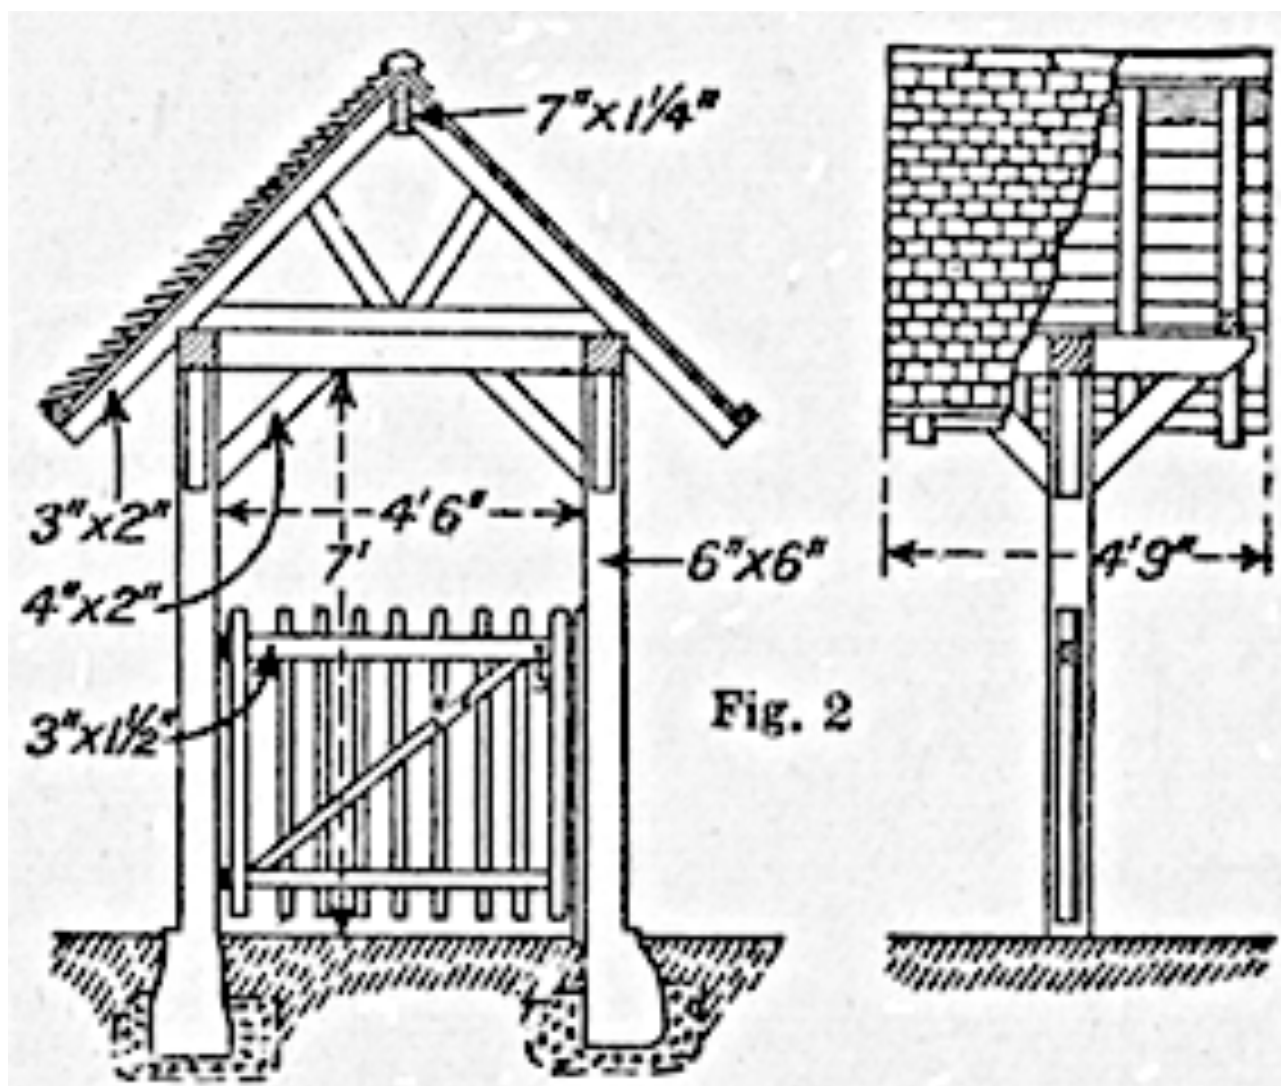

Fig. 2. Working diagrams giving dimensions.

LYCHNIS. This is the botanical name of a group of hardy summer-flowering plants which includes many of considerable garden value. The Jerusalem cross (*Lychnis chalcedonica*), 3 ft. high, with scarlet flowers, is a favourite border plant. *Lychnis (agrostemma) coronaria*, 2 ft., which has grey leaves and carmine flowers, is a splendid plant for the shady border. *Haageana*, 12-15 in. high, is very handsome; it needs well drained, rather light soil; there are several varieties of this with flowers in scarlet, rose and other colours. *Viscaria* (fl. pl.), 12 in., with rose-red flowers, is very showy. *Alpina*, 4 in., reddish, and *lagascae*, 4-6 in., rose, are suitable for the rock garden. The double white variety of *Lychnis vespertina* has fragrant flowers. *Lychnis flos-cuculi* is the wild ragged robin. Although the perennials may be increased by division in early autumn, the best way is to raise them from seeds sown in boxes of soil in a frame in May. The annual campion (*coeli-rosa*), 15 in., which bears rose-purple flowers, is sown out of doors in spring for summer bloom.

LYCIUM. The box thorn is a quick-growing hardy shrub with slender branches, especially well suited to seaside gardens. *Lycium chinense*, the favourite kind, has small purple flowers followed by red fruits. Propagation is by cuttings in autumn or by seeds sown in a frame in spring.

Lycopersicum. This is the botanical name of the tomato (q.v.).

LYCOPODIUM. Lycopodium, or club moss, is the name of a group of hardy and greenhouse perennials of somewhat moss-like growth. The hardy kinds, e.g. *clavatum* and *alpinum*, need moist peaty soil in the bog garden or rock garden. The greenhouse kinds need peaty compost and moist shady conditions: *densum* is one of the best.

LYE. The cleansing substance, or bleacher, known as lye, is a solution obtained from ashes or from substances which contain alkali, and is used in the preparation and making of soap, and as a detergent. A useful lye can be made from two parts of salt and one of caustic soda. These are mixed dry, and then diluted with water, the solution being employed for scrubbing or scouring purposes. As caustic soda has an injurious effect upon the skin, the hands should be kept free from contact with the solution. *See Bleaching.*

LYGODIUM. This is a climbing fern suitable for cultivation in a heated greenhouse in a compost of half loam and half peat with sand mixed in. The favourite kind is *Lygodium scandens*; it may be trained to cover a pillar or wire trellis.

Lygodium. Foliage of a climbing fern which is effective for training up a pillar.

LYSOL. One of the cresol antiseptics derived from coal tar is lysol, which is used in the home as a disinfectant. A 2 per cent solution in water is commonly made. The strong solution is very poisonous. In cases of poisoning, while awaiting the doctor, white of egg or oil may be given, but not water. *See Antiseptic; Cresol; Disinfectant.*

MACARONI: How to Cook. Macaroni is made from wheat finely ground and made into a stiff paste with water, which is squeezed out into long pipes through a hollow, cylindrical vessel. During this process the macaroni is partially baked, and is afterwards allowed to dry over artificial heat or in the sun.

Macaroni is cooked by being plunged into boiling water, which must continue to boil quickly, and should be well salted. About half an hour is the time usually required for boiling. The pipes should keep their shape and be quite soft. The macaroni is then drained and is ready for use.

For thickening soup, use 2 oz. cooked macaroni to about a quart of stock. It should be added to the soup almost at the last, brought to the boil, and boiled for about 5 min.

Macaroni with tomatoes makes a nutritious dish. Boil 4 oz. macaroni and make a tomato purée by rubbing a tin of tomatoes through a sieve. Let it boil up with a tablespoonful of butter melted with

the same quantity of flour and seasoning. Add the macaroni and boil it up. The macaroni and tomato can be put in a greased pie-dish with breadcrumbs and lumps of butter on the top, and placed in the oven for about a quarter of an hour.

Macaroni also combines well with fish. Have ready any boiled white fish and flake it, removing all bones and skin. Boil the macaroni, using about $\frac{1}{4}$ lb. macaroni to 1 lb. fish. Grease a pie-dish and place in it first a layer of fish then a layer of macaroni, continuing these layers until the dish is full. Seasoning should be sprinkled over each layer. Add a sprinkling of grated cheese and breadcrumbs on the top, and a few lumps of butter and bake it for about 20 min.

Another appetizing dish consists of boiled macaroni and kidney. Split and skin three sheep's kidneys, and fry them in 1 oz. smoking hot butter; then lift them out, and in the same fat lightly fry a tablespoonful of chopped onion. Stir in 1 oz. flour, and when the mixture is deep brown add the water in which the macaroni was cooked. Stir the whole until it boils and forms a smooth sauce; then strain it into a saucepan and add the macaroni and the kidneys cut into quarters. Season and simmer for 10 min., then serve on a hot dish.

Macaroni cooked according to Italian methods may be prepared from $\frac{1}{2}$ lb. macaroni, 4 oz. grated cheese, $\frac{1}{2}$ pint tomato pulp, 1 oz. butter, and seasoning to taste. Break the macaroni into 2 in. lengths, put these into a saucepan of rapidly boiling salted water and boil 30-45 min. Strain off the water, and add to the macaroni the sieved fresh or tinned tomato pulp, and a little seasoning.

Cover the pan and stir its contents over a low fire until the macaroni has absorbed sufficient tomato pulp to render the mixture thick and creamy. Add two-thirds of the cheese and butter and turn the mixture into a greased fireproof dish. Shake the remainder of the cheese over the top, and place here and there small pieces of butter. Bake the whole until the top is lightly browned, and then serve it with bread and butter.

A good cold sweet in which macaroni is an important ingredient is made by placing in a deep glass bowl alternate layers of stewed fruit and juice and cooked macaroni cut into short lengths. About two breakfastcupfuls fruit and 4 oz. macaroni will be required. Let the last layer be of macaroni, and over this pour $\frac{1}{2}$ pint of custard, sweetened and flavoured to taste. Decorate with glacé cherries.

Macaroni Cheese. A popular way of cooking macaroni for a savoury dish is to make macaroni cheese, or macaroni au gratin. For a dish to serve 4 people, boil 4 oz. macaroni till tender, and break it into small pieces after draining well. Melt 2 oz. butter and stir in a tablespoonful of flour. Add a pint of milk and bring to the boil, stirring all the time. Add 4 oz. grated cheese and stir until it becomes soft. Season well, and stir in a teaspoonful of made mustard. Grease a pie-dish and place the macaroni in it. Pour the cheese mixture over it and sprinkle the top with breadcrumbs, grated cheese, and two or three lumps of butter. Bake in a quick oven until brown, and serve very hot.

Macaroni Pudding. To make a baked macaroni pudding, boil until tender 1 oz. macaroni in a pint of boiling milk. Then draw the saucepan to the side of the fire and add 2 well-beaten eggs, sugar to taste, and any desired flavouring. Stir over gentle heat for a few minutes, then put the mixture in a greased dish and bake for about hour in a slow oven.

MACAROON. The almond-flavoured biscuit known as a macaroon is made by mixing $\frac{1}{2}$ lb. ground almonds with 1 oz. rice flour and 10 oz. castor sugar, and adding the whisked whites of 5 eggs and a few drops of flavouring. Spread the mixture evenly on wafer papers, using about one dessertspoonful for each macaroon. Blanch $\frac{1}{2}$ oz. of sweet Valencia almonds, split each into four, putting a piece in the centre of each macaroon after brushing the latter over with water. Bake the biscuits in a moderately hot oven for about 20 min.

Macaroon Jelly. A pint packet of red jelly, some macaroon biscuits and fruit are the chief ingredients required for this sweet. Arrange 8 medium-sized biscuits in the bottom of a glass or silver dish with a few small pieces of tinned pineapple and a banana split into 6. Dissolve the jelly in a pint of hot water, pour this over and leave the whole to set. Whisk the white of an egg to a stiff froth, and mix it with a gill of whisked cream, adding a dessertspoonful of castor sugar. Shake this on top of the jelly and in the centre place glacé cherries and a few pieces of pistachio nut.

Macaroon Tart. Line tartlet tins with short pastry. In the bottom of each tart put a teaspoonful of jam, cover it with the macaroon mixture, as given for making macaroon biscuits, and brush over the top with cold water. Cut some small thin strips of pastry, place two across each tart, and bake the latter in a hot oven for 15 or 20 min. *See Pastry.*

Macaroon Tarts, a popular pastry for Sunday supper.

MACARTNEY ROSE. This vigorous, almost evergreen, rose (*Rosa bracteata*) was introduced from China by Lord Macartney. The Macartney rose bears large single white flowers and is suitable only for planting against a sunny wall.

MACASSAR OIL. A good hair-dressing of this type can be made as follows: Reduce 1 oz. alkanet root to a coarse powder, in an iron mortar, and pour upon it 1 pint pure olive oil. Warm the oil, stir it occasionally, and, after an hour, strain it through fine muslin. When the oil, now coloured red, is cold, add the perfume, which is made in the following way: lemon oil, 15 drops; cinnamon oil, 10 drops; clove oil, 10 drops; and geranium oil, 2 drops.

MACE. Similar in its properties to nutmeg, mace is a highly aromatic condiment that is procured from the membrane surrounding the shell of the nutmeg. It is prepared by separating it from the nutmeg as soon as the latter is ripe, and is dried by the sun and pounded to powder. Mace is chiefly employed in the flavouring of savouries. *See Nutmeg.*

MACEDOINE. This term denotes a mixture of vegetables or fruit, usually cut into dice or small pieces. Macedoine of vegetables, which is sometimes used to garnish meat, can be bought or made at home from carrot and turnip cut into dice, fresh or bottled green peas, French beans cut into short lengths. All these must be cooked before being cut up, and then re-heated together in a little butter, and seasoned to taste. If a cold dish is being prepared, they may be mixed with mayonnaise instead of butter.

Macedoine of fruit consists of grapes, tinned pears, apricots, pineapple, etc., cut into small pieces, and set between layers of jelly. *See Jelly.*

MACKEREL: How to Cook. This fish should never be eaten unless absolutely fresh; it is in season from June to August. When fresh, the fish is a beautiful bright colour, the flesh is firm, the eyes clear, and the tail stiff and unbending. It can be cooked in a variety of ways, and the roe should be served with the fish or added to the sauce.

Baking is a favourite method of cooking. Use two good-sized mackerel and clean them, removing the heads and roe. Boil the roes in salted water, then chop them, mixing in a tablespoonful of chopped parsley, a sprinkling of thyme, and pepper and salt. Add half teacupful breadcrumbs and bind all together with a beaten egg. Split the mackerel and stuff with the preparation. Brush the fish with olive oil or melted butter, cover it with breadcrumbs and bake it until it is nicely browned. Serve with anchovy sauce.

To broil mackerel, clean and wipe the fish and split it down the back. Wipe a little olive oil over the fish, and smear the bars of the gridiron with suet. Rub over the back of the mackerel a little chopped parsley mixed with a nut of butter. Broil slowly over gentle heat for about 20 to 30 min. Serve with fennel sauce.

To fry mackerel, prepare the fish as for broiling, sprinkle it with flour and fry it in butter, over gentle heat, until nicely browned on both sides. Serve with anchovy or bechamel sauce, or with parsley butter. It can be fried in fillets; these should be dipped in egg and breadcrumbs before being fried.

Soused Mackerel. Prepare four mackerel by cleaning them and splitting them through the middle and removing the backbone. Cut each fillet into three or four pieces. Season with salt and place in a fireproof dish with 12 peppercorns, 2 bay leaves, 1 blade mace, 2 cloves, and 1 teaspoonful salt. Cover with equal quantities of vinegar and water. Cover the dish, bake slowly for 1½ hours and serve cold in the vinegar.

Preserving Mackerel. Mackerel can be preserved in districts where there is a glut of fresh fish in the following way: Clean the fish thoroughly and either fry or boil it. Divide the fish, removing the heads, bones, and skin. Rub over the flesh with the following mixture. For each dozen fish use 3 tablespoonfuls salt, 1½ oz.. black pepper, 6 or 8 cloves, a sprinkling of mace and of nutmeg. Cover the whole surface of the fish with the seasoning; and pack the fish in layers in a stone jar. Cover all over with good vinegar, and, if it is wished to keep the fish for some time before being used, pour salad oil or melted suet over the top of the jar. Do not use a glazed jar, as vinegar acts on this in an injurious manner. *See Fish; Sauce.*

MACKINTOSH. A mackintosh may be washed by first soaking it in cold water, spreading it on a table, and then scrubbing it with household soap. Rinse the mackintosh by dipping it in a tub of cold water, shake, but do not wring it, and let it dry on a coat-hanger either out of doors or near an open window. Mackintosh aprons, provided with a shiny white rubberized surface, which can be easily kept clean with a damp cloth, are worn by mothers when bathing babies; and it is usual to make up the cot of a small child with a mackintosh sheet immediately under the blanket as a protection to the mattress. *See Baby; Rubber.*

MACRAMÉ WORK. One of the oldest forms of lace-making is that known as macramé. Macramé twine, a variety of linen thread, is specially made for this work, which is done on a cushion or board. Some workers use a shallow box, measuring about 20 in. long by 10 in. wide. In this must first be placed heavy leaden weights, then a bag made of unbleached calico, and covered with coloured sateen. The bag is stuffed tightly with bran, and fits firmly and tightly into the box, reaching a little above it. Macramé frames may be purchased, but the box makes a good substitute. It is also possible to use a smooth piece of board, about a yard long and 8-10 in. wide, and fit it at each end with small, strong screws to hold the thread.

A few glass-headed toilet pins are sometimes used to keep the thread in position, and a large crochet hook to pull the threads under each other. If fine twine is used, all foundation threads should be

double. Fasten the first cord lengthways across the board or frame by tying it round the screws or pegs.

To put stitches on, fold together the two ends of a length of twine, pass them up and under the first, foundation cord, bring the ends down over it and through the loop thus formed. Draw them down lightly, and fasten as many in this manner as are needed for the length of work; then put another foundation cord just below where the threads are fastened on to the first one. Knot them on to this by taking the first thread in the right hand, passing it over and under the second foundation cord, and through the loop formed. Draw it up tightly, and do this to all before commencing the pattern.

The single-knotted bar, one of the simplest patterns, is worked thus. Having got the threads knotted on the foundation cords, hold the first thread in the left hand straight down, take the second thread in the right hand, and pass it over the first one, under and up through the loop thus made. Then hold the second thread in the right hand, and work the same stitch, with the left hand (first thread). Repeat this alternately for the length required, drawing each stitch up tightly as it is made.

Macramé twine in bright colours can also be knitted or crocheted into various articles, such as shopping bags or table mats. *See Crochet.*

MADAPOLAM. A plain cotton fabric generally sold in the bleached state, madapolam is heavier than cambric and finer than long-cloth, being made from fine-spun and good cotton.

MADEIRA: The Wine. It is said of madeira that it can never be drunk too old. It is a rich and generous wine with nutty aroma, owing its excellence to the climate of the island of Madeira, as well as to the black and white grapes from which it is made. It contains from 16 to 20 per cent of alcohol.

Madeira is served with soup, especially turtle soup, and with fish, and may be drunk instead of port as a dessert or after-dinner wine in hot weather. The best sweet variety is Malvoisie. White Sercial is dry, and a richer sort is Bual Madeira. *See Wine.*

MADEIRA CAKE. Madeira cake is made from $\frac{1}{2}$ lb. butter, 10 oz. castor sugar, 1 lb. flour, 6 eggs, a few drops of lemon essence, a thin slice of citron peel, and a pinch of salt. Cream the butter and sugar; then add the flour and eggs alternately, beating thoroughly after each addition. Mix in the salt and lemon essence, and beat well for a few minutes, afterwards pouring the mixture into a well-papered and greased tin. Bake in a moderate oven for $1\frac{1}{2}$ to 2 hours and, when half-cooked, place the peel on top.

MADEIRA VINE. An attractive half-hardy climbing plant, the Madeira vine bears fragrant flowers during autumn, and reaches a height of about 8 ft. It is most suitable for greenhouse culture, but will grow on a south wall outdoors during a warm summer. The plants are raised from tubers planted in a temperature of 55° during February.

MADLINE CAKE. Small fancy cakes coated with jam and desiccated coconut are made thus: Sieve together $\frac{1}{4}$ lb. flour and $\frac{1}{2}$ teaspoonful baking powder, and beat $2\frac{1}{2}$ oz. margarine or butter to a cream with the weight of 2 eggs in sugar. To the latter mixture add 2 eggs, beating each in separately for about 10 min.; then fold in the flour and add a little milk. Stir the mixture lightly and put it into some greased tie moulds similar in shape to small flower-pots. Bake the cakes in a hot oven for about 12 or 15 min., until they are lightly browned and spongy to the touch, and leave them to cool on a sieve. Heat about 4 tablespoonfuls jam, thinning it down with a

little water if necessary, and then rubbing it through a sieve. Brush it over the tops and sides of the cakes, and coat the sides with coconut. The top can be decorated with half a glacé cherry.

Madeline Cakes, coated with jam and coconut, a popular cake with children.

MADONNA LILY. One of the oldest and loveliest of lilies (*Lilium candidum*), this has been cultivated in British gardens for more than 300 years. The fragrant white flowers on stems 3-4 ft. high open in June.

Madwort. This is another name for the perennial yellow alyssum (q.v.).

Magdyno. See Magneto.

MAGGOT. The larvae or maggots of various flies do much damage to garden plants and crops, e.g. onion, chrysanthemum, carrot, pea, carnation, marguerite, and cineraria. The best preventive treatment is to spray the plants with an evil-smelling insecticide such as paraffin emulsion for the purpose of keeping away the flies.

MAGIC HUNDRED. This puzzle consists in arranging the numbers from 1 to 100 in ten rows in such a fashion that the total of the numbers counted in any one of three ways, horizontally, vertically, or diagonally, shall be exactly 505.

The principles upon which the solution is based are fairly easy to remember if the rows are numbered. The horizontal rows should be numbered 1 to 5 from both top and bottom.. The rows numbered 1 contain the numbers between 1 and 10 and between 91 and 100; the rows numbered 2 contain the numbers between 11 and 20 and between 81 and 90; the rows numbered 3 contain those between 21 and 30 and between 71 and 80; the two rows 4 contain those between 31 and 39 and between 60 and 70, except 61, which is compensated for by the presence of 41. The rows marked 5 contain the numbers between 42 and 59, and also 40 and 61.

The vertical rows may be lettered A, B, C, D, E from each end. In this case it will be seen that the unit figures in the A's are noughts and ones; in the B's they are twos and nines; in the C's they are threes and eights; in the D's they are fours and sevens, and in the E's they are fives and sixes. To solve the puzzle the figures should be arranged as shown, and when added up in any direction the result will be 505.

	A	B	C	D	E	E	D	C	B	A	
1	91	2	3	97	6	95	94	8	9	100	1
2	20	82	83	17	16	15	14	88	89	81	2
3	21	72	73	74	25	26	27	78	79	30	3
4	60	39	38	64	66	65	67	33	32	41	4
5	50	49	48	57	55	56	54	43	42	51	5
5	61	59	58	47	45	46	44	53	52	40	5
4	31	69	68	34	35	36	37	63	62	70	4
3	80	22	23	24	75	76	77	28	29	71	3
2	90	12	13	87	86	85	84	18	19	11	2
1	1	99	98	4	96	5	7	93	92	10	1

Two simpler puzzles of this class may be given. One is to arrange the numbers 1 to 9 in 3 rows so that the total of each row, added together in any one of the three possible ways, will be 15. The solution is:

2	9	4
7	5	3
6	1	8

A further one is to arrange the numbers 1 to 36 in six rows so that the total of each possible row shall be 111. The solution is:

8	30	27	10	25	11
35	6	33	34	1	2
17	13	22	21	24	14
20	19	16	15	18	23
5	31	4	3	36	32
26	12	9	28	7	29

MAGIC LANTERN. Lantern

used for throwing pictures on a screen. There are both standard and toy lanterns, but the principles are the same in both. They are now better-known as optical lanterns. *See* Lantern Slide; Optical Lantern.

MAGIC MUSIC. In this game one person leaves the room, while the others hide a thimble or any other small article. The absent player then returns, and his business is to find the article. He is assisted by someone playing the piano, the music being very soft when he is far from the object and becoming louder and louder as he approaches it.

MAGNESIA. The oxide of magnesium, or magnesia, is used in two forms, the light and the heavy, which are obtained respectively from the light and heavy carbonates of magnesium. All these relieve acidity and act as laxatives, and may be administered in doses of 5 to 30 grains for repeated administration and of 30 to 60 grains for a single.

MAGNESIUM: In Medicine. The salts of magnesium are frequently used in medicine on account of their antacid and purgative qualities. Magnesium sulphate, or Epsom salt, is a reliable saline purgative. White mixture is a useful laxative. It consists of magnesium sulphate, 3 drams; magnesium carbonate, 1½ drams; and peppermint water, 6 oz. The dose is ½ to 2 oz.

MAGNESIUM: In Photography. Magnesium, in ribbon or powder form, burns with a strong actinic light, and is largely used for indoor and other photographs when daylight is not available. Magnesium powder when mixed with potassium chlorate or perchlorate, or other combustible chemicals, is known as flash powder. It should not be made by the amateur, as some formulae give mixtures dangerous to prepare. *See* Flashlight.

MAGNETOS FOR MOTOR VEHICLES

Constructional Principles of These Essential Parts of the Car

This article will be found useful by the owner of a motor car or a motor cycle. He should turn to those headings, as well as to Gear; Internal Combustion Engine; Lubrication, etc.

A diagrammatic drawing of a common type of magneto is given in Fig. 1, and shows the complete wiring from the armature to the sparking plugs. The return or earth circuit via the sparking plugs is shown in dotted line. The cycle of operation is as follows: A represents the permanent stationary magnets to which are attached pole pieces, B, that are fitted so as to bring the magnetic field as close as possible to the armature D, thus intensifying the field of force. Rotating between these pole pieces is the armature D, which is constructed of an iron core, composed of a large number of thin plates tightly compressed. This is done in order to avoid waste current being generated in the core itself. On this core are wound the primary and secondary coils.

The first, the primary, consists of a few turns of fairly thick insulated wire, one end of which goes to the fixed platinum point of the contact breaker, E, and is tapped for the condenser, F, and the short circuit or earth switch, G, its other end being earthed. When the earth switch is closed, the current flows through the primary windings across the earth switch back to earth. Therefore, although the contact breaker, E, will still be operating, it will no longer be interrupting, via the platinum points, the flow of the primary circuit, so that no high-tension current will be generated in the secondary winding that goes to the sparking plugs.

The second of these coils, the secondary winding, is composed of a large number of turns of thin insulated wire, wound over the primary winding, one end of the secondary going to the condenser and the other end to the slip-ring, H, so that it is in circuit via the carbon brush, K, with the sparking plugs. The only earth, or return circuit for the secondary winding, is by way of the sparking plugs during the normal working of the magneto. The slip-ring, H, to which the end of the secondary winding is secured, is formed of a brass ring mounted at the bottom of a grooved fibre insulating collar that is mounted at the end of the armature shaft.

The contact breaker is a complete unit in itself, and is solidly secured to the end of the armature by means of a long screw. The contact breaker carries the fixed platinum point, L, which is in contact with the end of the primary winding, and the movable platinum point, M, through the medium of which the earth or return circuit of the primary winding is closed. This movable platinum point is operated by a bell-crank lever, that keeps it in contact with the stationary platinum point, L, by means of a flat steel spring. At the end of the bell-crank is inserted a hard fibre block that makes contact with the cams which are on the inside of the cover, N, that surrounds the contact breaker. The action of these cams against the fibre block of the bell-crank causes the platinum points to separate, thereby breaking down the primary circuit and causing the secondary current to be induced. Mounted on the back of the contact breaker is a small spring-fed carbon brush that makes contact with the body of the magneto and completes the earth or return circuit of the primary winding via the platinum points. Fig. 2 shows the construction of the contact breaker.

The armature cuts the field of force twice during one complete revolution. Therefore two high-tension currents will be induced, and for this reason two cams are provided on the contact cover cam ring, and are so arranged that the primary circuit is broken at the moment when the armature is approximately at right angles to the field of force, in which position the maximum intensity of induced current is produced in the secondary winding.

The functioning of the condenser is as follows: When the platinum points of the contact breaker separate, the collapse of the primary circuit has the unfortunate effect of inducing a follow-on current in the primary winding, but by interposing the condenser in the circuit, as shown in Fig. 1, this current is arrested. Instead of flowing on and leaping the platinum points it takes the easier path

into the condenser, and charges up the opposite plates with static electricity, which when fully charged discharge in opposite directions, thereby damping out the follow-on current in the primary circuit, and causing the essential immediate collapse of the field of force.

Left. Magneto, Fig. 2. Contact breaker showing a cam in action.

Right. Magneto. Fig. 3. M.L. magneto with rotating magnet and fixed primary and secondary windings.

Other Systems. Another type of magneto is employed, in which the primary and secondary windings are stationary, the permanent magnet with its pole pieces being the revolving part. A magneto of this kind is shown at Fig. 3.

In the inductor magneto there are rotating inductors of soft iron, and fixed magnets and windings. The magnetic flux through the core is reversed as the inductors revolve.

The Distributor. In the case of magnetos to be employed for engines of 4 or more cylinders it is customary to include a high-tension distributor as part of the unit; this is usually mounted at the contact breaker end, and driven by a gear wheel that is a part of the armature. As the armature gives two high-tension currents per revolution, there will be twice the number of teeth on the distributor gear wheel. For a 4-cylinder engine the armature makes two complete revolutions to fire the charge

in all 4 cylinders, and as the 4 high-tension leads go to the distributor, this will have made one complete revolution during the period.

The distributor usually consists of a fibre ring into which 4 bronze segments are embedded. Rotating in the centre is the high-tension brush driven by engaging a pinion on the gear wheel on the armature. Mounted at the back of the distributor is the spring-fed carbon brush that picks up the high-tension current from the slip-ring and passes it to the segments by way of the rotating carbon brush in the correct order of firing. In place of the brush, on some magnetos a small gap is provided at corresponding points.

With magnetos, designed for use on single and twin-cylinder V-machines, the high-tension distributor, as described, is dispensed with, and the current taken direct from the slip-ring. The only difference is that for the twin-cylinder engine the slip-ring is formed with two insulated segments, so that the spark shall go to the correct cylinder in order of firing. In the case of the magneto intended for use on twin engines, the cylinders of which are set at an angle of about 50° , it may be noted that it is impossible for the spark to take place at the most efficient position of the armature, i.e. when it is at right angles to the field of force. The reason for this is that 50° cannot be equally divided into 360° .

Care of Parts. Magneto construction of the present day is so extremely specialized that it is seldom that any derangement occurs. There are two parts that should receive periodical attention, namely, the slip-ring and the contact breaker. The slip-ring should be occasionally cleaned with a little petrol and a rag, placed over the end of a piece of wood, and held in contact with the slip-ring while the armature is rotated. If the end of the carbon brush is clogged with metal, or burnt, it should be carefully rubbed down with a piece of fine emery cloth before being replaced. With the contact breaker, the platinum points should be adjusted to separate by the correct amount, which is approximately 0.4 mm. or .015 in. (1/64 in.). If they are too wide apart, considerable difficulty will be experienced when starting up the engine by hand.

With a new magneto, the small fibre bushed-bearing, in which the steel pivot of the bell crank lever works, may be come tight. It is usually only necessary to clean the pin with metal polish, but if that is insufficient fine emery cloth may be used with care. It is inadvisable to enlarge the bush. The pin should be slightly moistened with thin oil before re-assembly. At the back of the contact breaker will be found the small carbon brush that carries the earth return of the primary circuit. This should be occasionally treated in the same way as described for the slip-ring carbon brush. All carbon brushes will at intervals require the same treatment. The magneto is a very powerful electrical machine, its power increasing in proportion to the speed of the armature. Perfect cleanliness of all its parts is absolutely essential if it is to remain in good order for long periods. Care should be taken to see that the wiring is in good order and not slack at the terminals. This applies in particular to the switch terminal on the contact breaker cover. It is not an uncommon occurrence for one of the fine strands of wire that go to form the complete cable to come adrift and make contact with the metal of the cover, thereby shorting the primary circuit. In all cases of a failure of the high-tension circuit, it is as well to examine very carefully the wiring, as well as the switch itself, before looking to the more complicated details of the system.

When replacing the contact breaker, see that the small key that locates this part with the armature is entered into the slot provided to receive it. Also, when oiling at the parts marked be careful not to overdo it, as oil may get on to the armature and damage the insulation.

The Magdyno. On motor cycles a machine is sometimes used which combines in one unit a magneto to energize the sparking plugs and a dynamo to charge a small accumulator for lighting. The current output is usually 6 volts, at 5 amps. Since, owing to limitations of space and weight, the

accumulator is small in capacity, the dynamo is kept on charge when lights are in use. There is a single drive from the engine, the dynamo being geared up from the magneto spindle Fig. 4. shows a Lucas motor-cycle magdyno.

Fig. 4. Lucas motor cycle magdyno, with small dynamo and magneto combined to form a unit in which each functions independently. The dynamo is geared up from the magneto spindle.

MAGNOLIA. The magnolia is a group of evergreen and leaf-losing shrubs or small trees of great beauty. Most of them are suitable for general planting out of doors; others need the shelter of a wall. They thrive best in loamy soil with which peat or leaf-mould has been mixed. Small trees should be planted in early autumn, as large ones are difficult to transplant successfully. They need no pruning except that which is necessary to keep the trees shapely and well balanced.

Magnolia stellata forms a bush 4 ft. or more high and bears small white flowers in March-April. Other kinds form trees 15 to 30 ft. high and bear large cup-shaped flowers. A few of the best are *conspicua* (the Yulan), white, April, *obovata* and *soulangeana*, reddish, April, and *parvi-flora*, white, May. All these lose their leaves in winter. *Magnolia grandiflora* is a vigorous evergreen with large

handsome leaves and in summer bears immense cream-white fragrant flowers; it must be planted against a sunny wall.

Magnolia. Large fragrant cream-white flowers of M. grandiflora.

Left, the white star magnolia (stellata), which blooms in March-April.

MAGPIE. Magpies are occasionally kept as pets. They need large cages and can be easily taught, so that they will go freely about the house, but they are very prone to theft. They can be fed on scraps from the table, bits of meat, raw or cooked, and ground oats. In the wild state magpies are of some assistance to the gardener, as they feed on worms, insects and snails. *See Bird Cage.*

MAGPIE MOTH. The caterpillars of this common moth, which is white with black and yellow spots, often do serious damage to gooseberry and currant bushes in early summer. Many of the caterpillars, which are marked with black and yellow, can be destroyed by shaking the bushes vigorously to cause the pests to fall to the ground and then scattering lime on them. Hand picking is also advised before the caterpillars become numerous.

Magpie Moth. Garden pest which attacks currant and gooseberry bushes.

Poisonous washes, e.g. arsenate of lead, will destroy them, but they must not be used within 3 or 4 weeks of gathering the fruits, which must be thoroughly washed. Great benefit often follows the use of caustic soda 2 oz. per gallon of water, in winter when the bushes are leafless, for the small caterpillars

hibernate in crevices on the gooseberry and currant trees.

MAH-JONGG. The Chinese game known as mah-jongg is played with dominoes made of ivory and bamboo. There are usually four players at a table, each one acting for himself, as there are no partners. The dominoes, which number 136, are arranged in 3 suits, and there are 4 sets of each. One consists of 3 honours, red, white, and green; another represents the four winds, north, south, east, and west. The third is more elaborate, consisting of 3 sets of 9 dominoes each, which are named characters, circles, and bamboos.

The object of each player is to obtain the highest scoring hand, which is called mah-jongg. Sequences of 3 cards of the same suit, or 3 of a kind and a pair make up a good hand, and extra

points are scored for various combinations which may fall to a player's lot, these adding fresh interest to the game.

MAHOGANY. Besides its rich brown red colour, and the figuring of its grain, mahogany has other qualities which make it a good furniture wood. It does not shrink or warp much, has very few knots, and seldom becomes worm-eaten; its colour darkens and improves with age, and it is obtainable in wide pieces. Glue gets a good hold on it, and a high degree of polish is easily produced on its surface.

Two kinds are in common use. The best and most expensive is known as Spanish, which comes from the W. Indies, chiefly Cuba, and has a richer colour and better figure than Honduras mahogany or baywood. The latter is plainer, straighter in grain, and is softer and lighter, but is good material, and in the best work is often used instead of pine. The best Spanish mahogany is mostly used as veneer.

Mahogany is employed for the interior fittings of houses and public buildings as well as for furniture. Handrails for staircases are often made of it, and so are counter tops and other shop and office fittings; also the woodwork of cameras and instrument cases, and interior fittings of vehicles. The colour frequently is darkened by the use of stain. A solution of bichromate of potash and water will darken it, if a little Vandyke brown or liquid ammonia is added. Oil alone may be used, or red oil may be made by soaking alkanet root in linseed oil. *See Furniture; Grain; Wood.*

MAIDENHAIR FERN. The common maidenhair fern (*Adiantum cuneatum*) is a favourite greenhouse plant and may be grown in a room window during the summer months. It needs a minimum winter temperature of 50 degrees. Two of the best varieties of the maidenhair are *gracillimum* and *Pacottii*. The finest of all maidenhair ferns is *Adiantum farleyense*, a vigorous plant with large and beautiful fronds: it must be grown in a hothouse. Two-thirds loam, one-third

peat and leaf-mould, with sand added freely, provide a suitable compost. Moist shady conditions are necessary. *Adiantum pedatum*, 18-24 inches, is hardy; *Klondyke* variety is the best. *Capillus veneris*, 6-8 inches, can be grown out of doors in mild districts; they like shade, and peat and sand should be added to the soil.

Maidenhair Fern. The delicate fronds of this beautiful fern are much used for mixing with cut flowers for buttonholes and vases.

MAIDEN PINK. This pretty low-growing pink (*Dianthus deltoides*) flourishes in sandy soil in a sunny rockery. The flowers are of carmine-rose shade; those of the variety *graniticus* are more richly coloured. This pink is easily raised from seed sown in a box of light soil out of doors, or in a frame, in May: the seedlings will flower in the following and succeeding years and should be planted permanently in autumn.

MAID OF HONOUR. A simple form of the Richmond cheese-cake known as maid of honour is made thus: Curdle 1½ pt. fresh milk by adding rennet powder as for a junket. A pinch of salt helps to separate curd from whey. Strain the curdled milk through a piece of fine, muslin, and drain the curds well before rubbing them, with ¼ lb. fresh butter, through a sieve. When this is done add the yolks of 2 eggs, beaten lightly to a froth, and also about a dessertspoonful of brandy.

Blanch and chop finely ½ oz. sweet almonds and 3 or 4 bitter ones, and add them with a little sugar and a sprinkling of powdered cinnamon or nutmeg. Lastly add the juice and grated rind of half a lemon. Line some patty-pans with puff pastry, fill them with the mixture, and, if desired, sprinkle with a few currants before baking them in a good hot oven. *See Cheese Cake; Pastry.*

MAINSRING. The driving spring in the mechanism of a timepiece is the mainspring, which performs the same function in any other spring-driven motor, such as that for a gramophone. It is generally in the form of a thin, flat steel grip, hardened and tempered to give it resiliency, and is coiled up by means of the winding arbor into a close, tight spiral. It exerts its power in uncoiling, thus imparting motion to the main wheel. The spring when purchased is coiled up, and is surrounded by a metal band, which prevents it uncoiling until it is removed. This should not be done until the inner end of the spring has been attached to the winding spindle and the outer end to the cage, or part to be driven. Should the retaining ring or pin be removed before the spring is under proper control, it will fly out and probably do damage. The coils of the spring should be thoroughly lubricated. *See Clock; Gramophone; Watch.*

MAINTENANCE: In Law. When a married woman is obliged to apply, apart from her husband, for parish relief, the authorities may summon the husband before the justices, and the magistrates may make an order upon him to pay such sum weekly or otherwise towards the cost of the relief of his wife as shall be deemed to be proper. They may order that this money be paid to the guardians or to the wife or any other person for the wife's benefit. This should be carefully distinguished from alimony or from the kind of order made under a separation order when the magistrates decide that a husband and wife need not live with each other.

In the divorce court, if a decree has been made at the instance of the wife for dissolution of the marriage, the court has the power to make an order upon the husband for the permanent maintenance of his wife. This may take the form of an order that he shall hand over some of his property to trustees who are to apply the income for the wife's maintenance during the remainder of her life, or it may have the form of an order that he shall pay so much a year to the lady. The court has no power to order the husband to pay a lump sum.

The provision ordered is usually a sufficient maintenance according to the rank and means of the parties. This does not mean a bare maintenance. The rule usually followed is that the husband shall allow such a sum as will make up his wife's income to one-third of the joint incomes of the parties. Thus, if the husband has £1,000 a year and the wife £200, the joint income being £1,200, the wife would be entitled to £400, i.e. £200 from the husband in addition to her own £200.

Although this is the ordinary practice, it is not invariable. Where it is possible the court will order security to be given for the payment so that the husband cannot subsequently put his money out of her reach and so deprive her of what is her due.

At one time the view was taken that such orders for maintenance should be conditional on the wife remaining single and chaste; but nowadays the court will not make any such order except in special cases, so that the allowance will be continued although the wife marries again or leads an immoral life. Sometimes under special circumstances, when the wife is the guilty party and is divorced by the husband, the court will, as a condition of granting the divorce, order the husband to make

provision for his wife; and in such cases a clause will generally be ordered to be inserted that the money shall only be paid so long as she remains single and chaste. *See* Divorce; Husband; Separation Order; Wife.

Maisonette. Literally a small house, this word is often used as a synonym for a flat. *See* Flat.

MAÎTRE D'HÔTEL. This name is given to a method of preparing sauces and other dishes by heating them up with parsley and butter flavoured with lemon juice and seasoning. Maître d'hôtel sauce is a white sauce, made with stock instead of milk, containing chopped parsley and lemon juice. Vegetables re-heated in butter and clear soup or stock to cover, and then flavoured with chopped parsley and lemon juice, are given the name of maître d'hôtel. Chives or finely chopped spring onions are often added as a garnish. Haricot or butter beans or a mixture of green peas and carrota cut into small cubes are excellent re-heated in this way.

MAIZE. This is an alternative name for the genus of fine-leaved grasses known as Indian corn. It is made into meal, which can be cooked in various ways.

Maize Meal. This meal is made from the ripe grains of maize or Indian corn, finely ground. It is useful for thickening soups, in the place of flour, and for making porridge, bread, cakes, puddings, etc. As it does not keep very well, it is advisable not to buy more than will be used at once. It will soon go bad if kept in a damp place.

Maize porridge is made by sprinkling the meal into boiling water or milk, flavoured with a little salt, and stirring it for about 10 min., until it thickens. Then add a small piece of butter and serve it hot with milk and sugar, jam or golden syrup.

Maize meal can be used for bread making, using half white flour and half maize meal. Caraway seeds are usually added.

Buns are made from 4 oz. maize flour, 1 tablespoonful golden syrup, ½ teaspoonful baking-powder, 1 oz. dripping or margarine. Mix the dry ingredients and rub in the fat. Make a hole in the centre of the flour and add the syrup. Mix it to a stiff paste with a little milk and put it into a greased tin. Add a few raisins or currants, if desired, and bake the buns in a hot oven.

The ingredients for a pudding consist of 4 oz. maize flour, 2 oz. flour, 2 oz. suet, 1 egg, 1 oz. sugar, 2 oz. dates. Mix the flours, shred and chop the suet, stone and cut up the dates. Add these to the flours with the sugar and a pinch of salt. Beat the egg and mix this in. Use a little milk in addition, if necessary, to make the mixture into a soft paste, and put it into a greased basin and steam it for 1½ hours.

Two favourite American dishes made from maize meal are Johnny cake and jolly boys. A very good Johnny cake can be made from the following recipe: Mix together 1 teacupful maize meal and 1 teacupful flour with 3 oz. sugar and a teaspoonful baking powder, also a good pinch of salt. Beat an egg with 1 gill milk; melt 1 oz. butter and stir it to the egg and milk. Pour the liquid on to the meal and beat as for batter. Turn it into a shallow tin and bake it from 30-40 min.

To make jolly boys, first scald ½ pint meal. Cream ¼ lb. butter with 6 oz. castor sugar: add 3 well-beaten eggs, then ½ pint milk which has been scalded and cooled. Cream ½ oz. yeast; mix the liquid to it by degrees and then make up into a dough, cover it over, let it rise till light and make it up into balls as for doughnuts, but rather smaller. Fry these in deep fat and roll them in sugar while hot. *See* Bread; Doughnut; Indian Corn.

MAJOLICA: The Ware. Some excellent reproductions of the majolica faience of medieval Italy, as well as original designs conceived in the same spirit, have been made at the Minton works since the middle of the last century, and similar wares were introduced by Wedgwood. They are produced by different methods, the former being made of dark clays with an opaque enamel, while the latter consist of white bodies with transparent coloured glazes.

There is a large output of reproductions of the early ware in Italy, including round and oval dishes, trenchers and shallow bowls, drug-jars and ewers.

Genuine old majolica, the noblest production of European ceramics, comprises the output of several famous Italian fabriques, notably in Urbino and its vicinity, which were at their greatest during the 15th and 16th centuries. The most characteristic ware was tin-enamelled on dark clays, covered with painted designs, and lustred with metallic sheens. Some of the finest examples were wrought in the silver-lustre at Deruta and the ruby-lustre at Gubbio. This style of pottery decoration was derived from the lustred faience of Moorish Spain, which in its turn was based upon the great lustre ware of Syria and Persia. In the Italian ware the designs were usually biblical or historical scenes.

Tazza designed by Maestro Giorgio — St. Francis receiving the Stigmata.

MAKE-UP FOR AMATEUR ACTORS

Methods and Processes Explained and Illustrated

Those readers who are interested in amateur acting should consult also the articles on Stage and Amateur Theatricals. See also Fancy Dress and Tableaux Vivants.

Amateur actors, to be successful, require a knowledge of make-up. Perhaps the most important matters that must be taken into account are the size of the hall or theatre and the brilliance of the stage lighting. If the performance is to be given in a theatre with footlights, lengths, sidelights, batons, toplights, and limelight, all natural shadows are flattened out, and it is essential in order that the expression should carry for the features of the players to be emphasized.

For this type of make-up grease-paints are the best medium to employ. They can be purchased in numbered sticks, with other requisites for make-up, at any theatrical costumier's and most large chemists' stores. The face should first be cleansed with cold cream, which is wiped off, and then the foundation paint of the desired colour is applied and smoothly worked in with the fingertips over the whole face, care being taken to come below the jawbone on to the neck, or a mask of paint will result. Then the colour is applied for the cheeks and lips, eyebrows, eye-shading and lines or shadows for older or character makeups; after that the face is powdered, and lastly the lashes are touched up. The grease-paint should be removed with cold cream or vaseline at the end of the performance, and the face rubbed clean, after which it may be lightly powdered.

Methods for Women. A straight make-up for women is obtained by using No. 1½ greasepaint, palest flesh-colour, as a foundation (for a brunette a little No. 5 yellow may be worked in with No. 2), carmine 1, or deeper shade 2, smoothly rubbed into the cheeks, as shown in Fig. 1, using only a little colour in dabs until the desired effect is reached. The shape of the lips should be improved with the lip-stick, emphasizing the bow of the upper lip if necessary, and the eyebrows carefully pencilled with a brown or black liner. Shading the eyes effectively requires a little practice. A dark blue line may be applied along the lashes, and this line should be carefully blurred to shade the lid. With a little more dark blue paint on the tip of the third finger shade under the eyebrow to the eyelid, bringing the colour just beyond the outer corner of the eye, and blending it imperceptibly with the foundation. Care is necessary or a hollow-eyed appearance results. A line drawn for about ½ in. with blue or black liner beyond the outer corner of the eye gives width. The edge of the lower lid should also be delicately shaded by using the paint on the finger-tip.

A pink powder for fair or yellow powder for dark complexions should be applied thickly. If the cheeks appear too pale, a touch of dry rouge can be added after powdering. The eyebrows should be gently brushed free of powder and then the lashes must be treated with black grease cosmetic. A small quantity is melted over a candle in a metal spoon (Fig. 2) and with a fine camel-hair brush the liquid black is applied to the lashes, as shown in Fig. 3. For neck, arms and hands a theatrical wet-white may be applied with a sponge, nibbed in smoothly with the hand and afterwards powdered with white powder.

The effect of fragile age may be got by use of 1½, with 5½ predominating for the foundation, a little rose-pink grease-paint worked into the cheek-bones, pale colour on the lips, light blue liner blended with a touch of lake liner to obtain a delicate purple for the shadows. Any faint indications of natural lines must be followed, and a high light must be put above and below a line with the 1½, also worked with the finger-tip. The cheeks should be shadowed with the blue and lake below the cheek-bone and also the hollow emphasized in the inner corner of the eye below the brow and under the eye, very little colour being used to avoid a patched appearance. The lashes should not be made up with grease cosmetic after powdering, but just brushed with water-black.

White or grey wigs for period costumes require a fair make-up such as the first one given, and the same applies to a blonde or red wig. Hair should be tightly smoothed, or plaited round the head if long and the wig drawn on from the back after the make-up is completed (Figs. 4, 5). For gipsy make-up, 5 with a little 9 (red-brown) worked into it for foundation and 9 with carmine 3 for the cheeks should be used. Bole, a red-brown powder, can be applied to neck and arms for dark or sunburnt effect.

Make-up for 1. Applying foundation of Melting black 3. Applying the fine camel-hair When fully drawn carefully head. Fig. 5. powder period

Methods for make-up for flesh pink)

foundation, with a touch of carmine 2 for colour; a rather older effect is gained by the use of 5½ and 3 with 9 for colour. The shading round the eyes should be blended with dark blue and lake liners and the eyebrows touched up with brown or black. The lashes should be made up with water-black and not grease cosmetic, unless a very romantic costume is to be worn. Lines and shadows should be added for character make-ups, Fig. 6. Whiskers, moustache and beards can be bought ready-made at a wig-maker's. They should be adjusted to the face with spirit gum (Figs. 7, 8), and a hard

Men. For a youthful men 5 and 3 (dark should be used for

effect of join is removed if crape hair of the same colour be used. A little of this should be pulled out and held near warmth to take out the crimp, and then put on with spirit gum to hide the edges. For a gipsy, Mexican, etc., make-up, 5½, 6 (greyish brown), 8 (brown) should be used, with a touch of 9 for colour, and bole for neck and hands.

Make-up for Men. Character make-up; putting in the finishing touches to the wrinkles before powdering. Figs. 7 and 8. Moustache and beard fixed to the face with spirit gum. Fig. 9. Wig adjusted correctly on forehead and pulled on from sides. Fig. 10. Join of wig band being hidden by grease-paint.

Men for make-up with period white wigs should use 2½ with a little 5 for foundation, carmine 2 for colour and a light shade of powder. The adjustment of a man's wig requires care, as the forehead piece must not show the join on the wearer's forehead.

A wig is put on after grease-paint has been applied to the face, but before powdering. The top of the forehead, which will be covered by the wig-band, should have any grease removed from it; and the wig, held by the side-springs, as seen in Fig. 9, is placed on the head with the edge in the correct place on the forehead. Placing one hand on the forehead piece to keep it steady, the back of the wig is gently drawn into position. Then the forehead band is carefully smoothed and made up to match the face, a thicker layer of paint being put along the join (Fig. 10), and worked smoothly into the forehead.

For small halls, drawing-room entertainments, open-air plays or concert work without footlights, a lighter make-up can be used. Women can either apply a day cream with a grease rouge and powder to suit their colouring or use a liquid powder with dry rouge. A slight shading of dark blue round the eyes enlarges them. The brows may be pencilled if necessary. Water-black cosmetic is usually sufficient for lashes, or the melted grease cosmetic may be used sparingly. Most men require little make-up for this class of entertainment unless the brows and lashes need emphasis with a touch of

water-black, and a little bole may be used for colour. Lines may be carefully drawn with a paint-brush and water colour.

For amateur filming the necessary make-up is a level tint all over the face. Special foundation paints are used or 2 and 5 or 5½ greasepaint for women and 5 and 6 for men. Blue must not be used for shadings round eyes, as it photographs light; brown or black should be used slightly, and eyelashes may be touched up with water-black. Brown should be used instead of red on lips, as red photographs black.

MALACCA. The malacca cane plant is *Calamus*, which can be grown in the hothouse in loam and leaf-mould, and attains an average height of from 6 ft. to 10 ft. Propagation is by seeds or suckers. The stems are split for caning purposes, though in Great Britain they rarely mature sufficiently for the purpose except under special treatment.

Malacca Canes. Although not so popular as formerly, a malacca cane is preferred by many on account of its distinctive appearance, strength, and durability. The cane or rattan from which it is cut is imported in bundles from the E. Indies, only the best canes being selected to be seasoned, cut, and polished. As the stick has no handle, all that is required to finish it is the silver or gold mount, and with ordinary care it will last a lifetime.

When the mahogany colour of a malacca becomes dull after continued use an occasional polish will restore the lustre. For this purpose there is probably nothing better than pure linseed oil applied with a rag and thoroughly rubbed in. Spirit varnish is also used. If the silver mount works loose or becomes detached, a cement or paste for resetting it can be obtained from most oilshops, or one can be made at home by melting and mixing together 6 oz. resin, 4 oz. pitch, and ½ lb. bottle wax. Attention should also be paid to the ferrule. *See* Walking Stick.

MALACHITE. A rich green stone in appearance very like marble, malachite usually has peculiar lines of light and dark shades of green. The stone is found mostly in Siberian and Australian copper mines. In Near Eastern countries it is frequently used for decorating furniture. It is inlaid into tables or employed for ornaments.

It is also used for making into cigarette boxes, snuff boxes, etc., with silver-gilt and gold mounts. Large blocks of the stone are sometimes found which command high prices when cut into vases or other ornaments. Malachite green is an aniline dye used for silk, wool, jute and leather.

MALAGA. One of the wines of Spain is malaga. It comes from the province of E. Andalusia, and is shipped from the port of Malaga. It is a blend of new and old liquor and is one of the best sweet wines which Spain produces. *See* Wine.

MALaise. As used by doctors, this word refers to the condition of languor and feverishness common in severe colds, influenza, etc. It is one of the premonitory signs of nearly all serious illnesses.

MALARIA: Its Treatment. The direct cause of malaria or malarial fever is the bite of the anopheles mosquito, by which minute animal parasites enter the red corpuscles of the blood.

There are three stages in malaria, known as the cold, the hot and the sweating stage. At the early stage diagnosis is often difficult and the condition is liable to be confused with pyaemia, typhoid, and other diseases. During the cold stage the patient is put to bed and kept thoroughly warm. In the hot stage the body should be sponged with tepid or cold water, an ice bag is applied to the head and warm drinks given. In the sweating stage the patient must be guarded against draughts and chills.

Quinine may be given at any stage. It is best to begin with a dose of 10 to 15 gr. and follow this with 5 gr. thrice daily, but larger doses are sometimes required. For children euquinine, which is tasteless, can be given.

Swamps, marshy ground and stagnant pools favour the breeding of mosquitoes, and for the prevention of malaria such spots should be drained. The larvae may be destroyed by pouring paraffin oil on the water, using 1 pint to 200 sq. ft. The larvae should be destroyed in collections of water round a dwelling-house and all tubs and water barrels should be emptied every week. Open windows may be protected with mosquito net or fine wire netting, and beds surrounded with mosquito curtains. Rooms can be cleared of mosquitoes by burning pyrethrum powder therein.

Some protection from bites is obtained by rubbing the skin with oil of peppermint, eucalyptus, lavender, rosemary, pennyroyal, or a lotion composed of 1 oz. of magnesium sulphate in 10 oz. of water. Quinine taken daily may be a powerful prophylactic, the protective dose, in the case of adults, being 5 to 10 gr daily.

MALCOLMIA. This is the botanical name of Virginian stock, a hardy annual which blooms in about six weeks from seed sowing. See Virginian Stock.

MALE FERN. This is a vigorous native fern (*Nephrodium* (*Lastrea*) *filix-mas*). Of it many beautiful named varieties have been raised, for instance, *cristata*, *furcans*, *grandiceps* and *crispa*, all of which have fronds of most graceful appearance. They will grow in any shady corner if planted in a prepared border of ordinary soil with which leaf-mould and thoroughly decayed manure have been mixed. They should be kept moist in dry weather. Autumn is the best time in which to plant the fern.

Male Fern, effective in a shady border.

MALINES FOWL. Good alike for table and egg

production, the Malines fowl possesses a long, deep, broad body and a well-developed breast, and when the cockerels are fattened they carry a wealth of white meat of very fine quality.

Malines Fowl. Prize-winning white pullet of this useful breed.

The Malines is bred in five colours: black, white, blue, cuckoo, and ermine. The black is solid and deep in colour, but does not carry quite so much green sheen as some other black fowls. The white is pure snowy white. The blue is somewhat like the slaty blue of the Andalusian; it is somewhat rare, and by some is much admired. The cuckoo is the most generally bred colour, and looks the most business-like member of the family. Its ground colour is blue-grey, the feathers being crossed by bars of a metallic blue-black shade; when exposed to the sun the colour takes on a brown-

grey appearance due to sunburn.

The chicks when newly hatched are grey on the top and creamy on the under parts. The most beautiful of all the Malines is the ermine, which is marked like light Sussex fowls, the body colour being a pure snowy white with black in the tail, wings and hackle. The male bird weighs from 9 lb. to 10 lb., and the females from 7 lb. to 8 lb. The hens are good sitters, and the chicks are hardy and mature quickly. It is a very useful and economical breed of fowl. *See Chicken; Poultry.*

MALINGERING. A hypochondriacal person may believe with too great readiness that he is suffering from some serious disease, and a craving for sympathy may be responsible for hysterical manifestations; but these conditions are quite different from malingering, which means feigning disease to secure some personal advantage, whether the avoidance of duty, the securing of a holiday, or the receipt of money as compensation for sickness. In most cases the application of appropriate tests provides evidence of malingering which is sufficiently convincing, at any rate for a medical man.

MALLET: Some Varieties. A mallet is a small hammer made of wood, such as is used for driving wooden pegs into the ground and similar purposes. The word is also used for the implement with which players strike the ball in croquet (q.v.).

The carpenter's mallet should be slightly rounded on all faces, and not square or flat as in the case of a joiner's mallet. The handle should be about 13 in. long, and reduced in size at the neck. The handle is generally grasped about two-thirds of its length from the head, and, roughly speaking, the angle of the striking faces should be such that if two battens were placed on the two striking faces of the mallet they would cross at some position near the elbow.

Fig. 1. From left to right, carpenter's, carver's, and plumber's mallets. Fig. 2.

Carpenter's mallet in use, showing how it should strike the end of the chisel. Note angle at which tools are held.

The tinman's mallet has a boxwood head about 2½ in. in diameter and is used for knocking tin-plate into any required shape. A raw hide mallet has a head made of pieces of hide, coiled round to a diameter of about 2 in. and about 4 in. in length. A hole is drilled in the raw hide, and a wooden handle inserted and pegged into place. The ends of the hide may be fastened, and in some cases are strengthened by a piece of metal. The mallet is used for sheet metal work. The carver's mallet is circular in section and somewhat conical in shape, as in Fig. 1. It is finished in this way so that the carving tools can readily be struck a blow in any desired direction, and the striking face of the mallet will be at right angles to the centre line of the tool. If this were not the case the directional control of the carving tool would be difficult.

A metal-bound mallet comprises an iron head, into which two tapered blocks of wood or hide are fitted. A bossing mallet has a pear-shaped head and plain handle. The stretching mallet is very

similar in general appearance; both are plumber's tools used in the shaping of sheet and tube lead. The mason's mallet is very similar to the carver's, but larger and heavier and a little shorter in the handle. A large circular, cast-iron mallet, known as a stob mallet, is sometimes handy for rough work.

The method of using a carpenter's mallet is illustrated in Fig. 2, showing how the tool is held. The worker should strive to strike a fair and square blow. When driving two pieces of work together, give the whole face of the mallet a share in the work, as if the blow is struck with only one corner of the head this is likely to be split, and the work is liable to be very badly bruised. *See Amateur Carpentry; Mortise.*

MALLOW. The name is applied indiscriminately to many plants and shrubs, for instance, Jew's mallow (*kerria*), rose mallow (*lavatera*), and marsh mallow (*Malva*). *See Lavatera; Malope; Malva; Marsh Mallow.*

MALMAISON CARNATION. This type of carnation, which bears unusually large and handsome blooms in early summer, is now very little grown. It has been ousted by the perpetual carnation, which has a much longer flowering period. Those who wish to grow malmaisons prefer the new perpetual flowering type, which needs the same treatment as the perpetual carnation (q.v.). Some of the best varieties are *Boadicea*, deep rose, *Hon. Charlotte Knollys*, red; *Jessie All wood*, yellow; and *Mrs. C. F. Raphael*, red.

MALMSEY. This strong, sweet liqueur wine is called by the Italians "manna to the mouth and balsam to the brain," It is made from grapes grown on the islands of the Aegean and the Levant. *See Wine.*

MALOPE. Of this flower the only kind grown in gardens is *Malope trifida*, a showy hardy annual, 2 ft. high, which bears large crimson flowers in summer. Seeds are sown out of doors in April where the plants are to bloom; the seedlings must be well thinned out to give them room for development; they ought to be 9 or 10 in. apart.

MALT. By moistening barley and allowing it to germinate malt is obtained. In this process a ferment (diastase) in the grain converts some of the starch into malt-sugar and dextrin. The grain is then dried in a kiln and the germinating process stopped.

Malt is used in brewing and distilling, and in medicine. Powdered malt is mixed with wheaten flour to form infant foods. On the addition of hot water, or hot milk and water, the diastase acts on the starch in the flour and converts it into maltose.

In making certain kinds of bread malt is employed, extract of malt being added in the proportion of 1 oz. to 3½ lb. of wholemeal flour.

Malt Extract. Liquid extracts of malt are prepared by making an infusion of malted barley and evaporating it in a low temperature until a syrupy fluid is obtained. This contains a large amount of sugar, often more than half its own weight, and is a valuable and readily digestible food.

Ground malt or malt extract mixed with wheat flour makes malted bread, the starch of which is partly changed into sugar. Dried as well as liquid malt extracts are obtainable. Mixed with arrowroot, gruel, porridge, and any kind of starchy food, they pre-digest it to some extent. They are therefore valuable in convalescence, dyspepsia, neurasthenia, tuberculosis, and whenever the digestion needs help. It must not be forgotten that their digestive action is destroyed when added to

food at a high temperature. Malt extract, either alone or combined with cod-liver oil, often has a valuable tonic effect in wasting diseases. The dose of the liquid extract of malt is 1 to 4 drams.

MALTESE DOG. The snowy little Maltese dog is animated, intelligent, very affectionate and good-tempered, cleanly in habit, and an expert in engaging little tricks. His constitution is delicate, and great care is needed in guarding him from chills. His pure white coat requires constant washing, and the long silky hairs of which it is composed quickly get matted unless the comb is used frequently. Drying after washing must be thoroughly carried out.

Much care is needed in the matter of diet, an excess of animal food producing eruptions, a deficiency causing eczema. His head is much like that of the Skye terrier. The short legs are straight and well feathered, and the feet round with black pads. The longer the coat the better, and the only markings are slight patches of lemon tint. The weight varies from 4 lb. to 10 lb., but the less it is the more valuable is the dog. *See Dog; Skye Terrier.*

Maltese Dog. A champion of this pure white, silky-coated breed of pet dog.

MALVA. The botanical name of mallow, a hardy flowering plant represented in gardens by the marsh mallow (*sylvestris*) and the musk mallow (*moschata*). They will thrive in poor soil and are perhaps better suited to the wild garden than the flower border. The most valuable is the musk mallow, 2½ ft., which bears rose-coloured flowers in summer; the white variety, *alba*, is very attractive.

MAMMILLARIA. This is a cactus of quaint, even bizarre, appearance which is easily managed if provided with the conditions suited to the cultivation of these plants —namely a sunny, airy greenhouse and a well-drained compost of loam, sand and powdered brick. They need little water and a minimum temperature of about 45° in winter. Several species are in cultivation; a few of the best are *barbata*, rose-coloured flowers, *bicolor*, purple, and *dasyacantha*, red; all are but a few inches high. *Missouriensis*, yellow, is the hardiest and in mild districts is sometimes grown on a well-drained sunny rockery.

Mammillaria. Small greenhouse cactus, showing the great number of spines.

MANCHESTER TERRIER. Owing to its great popularity in Lancashire, the black and tan terrier (q.v.) is often referred to as the Manchester terrier. *See Dog.*

MANDOLINE: How to Play. There is more than one variety of mandoline, but the Neapolitan is most in favour and is here described. The mandoline consists of three main parts: a deeply convex body, having on the upper side a flat belly or sound-board in which is a round sound-hole, below which is the bridge; the neck, having a flat fingerboard fitted with 17 frets; and the head, which is slightly bent back from the fingerboard and holds the 8 pegs for the strings. These are carried from the pegs across the nut, and over the bridge to the tail-piece at the lower end of the instrument.

The strings, 8 in number, are tuned in pairs, thus:

This, it will be seen, is identical with the tuning of the violin. The strings are usually of steel, the two lowest pairs (D and G) being wound round with fine wire. The compass is completely chromatic from the low G to the A three octaves and a note higher, though the highest five notes are not very useful. The 17 frets are necessary for the full compass, as the fretting proceeds by semitones. The table below will make this clear.

As the tuning is like that of the violin, so also is the fingering; that is on the 4th string both A flat (G sharp) and A natural will be produced by pressing the string behind the respective frets with the first finger, and B flat (A sharp) and B natural by similarly using the second finger. In order to get higher notes beyond the reach of the little finger, the hand must be shifted down the neck. If on the 4th string the B were played with the first finger, the hand is then said to be in the second position; if it played C, then it is in third position, and so on. The strings are plucked with a plectrum of horn, tortoiseshell, or some other material held in the fingers of the right hand.

Open Strings	Nut	F	F \sharp	G	G \sharp	A	B \flat	B	C	C \sharp	D	D \sharp	E	F	F \sharp	G	G \sharp	A
1 st																		
2 nd		B \flat	B	C	C \sharp	D	D \sharp	E	F	F \sharp	G	A \flat	A	B \flat	B	C	C \sharp	D
3 rd		E \flat	E	F	F \sharp	G	A \flat	A	B \flat	B	C	C \sharp	D	E \flat	E	F	F \sharp	G
4 th		A \flat	A	B \flat	B	C	C \sharp	D	E \flat	E	F	F \sharp	G	A \flat	A	B \flat	B	C

Mandoline. Table showing arrangement of notes on strings in relation to frets.

Before beginning to play, the strings must be tuned. The standard is the second pair, which must be made to agree either with an A tuning fork or with the A on the pianoforte. The latter course is necessary if the piano and the mandoline are to be played together. Having done this, tune the D strings from it, and then the G strings from the D, finally tuning the E strings from the A. It is preferable not to tune each string to the piano, as on that instrument fifths are made a shade flat, but to tune perfect fifths as violinists do. This needs a keen ear and a knowledge of the desired result, so

it is well to listen to a properly tuned violin and try to memorize the sound of the perfect fifth between each adjacent pair of strings. An easy way of testing the correctness is to press the A strings behind the fifth fret, which will give D an octave above the third string. A further test is to use the seventh fret on the D strings. If the tuning is right, the result should then be in exact unison with the A strings.

The instrument should be held with the left hand round the neck, the fingers turned over the finger-board. The performer holds it against him, the right forearm keeping it in position, while the right hand, holding the plectrum, plucks the strings just over the plate which is found on the sound-board below the sound-hole. The right wrist must be perfectly free in its action. Both down and up strokes are employed, indicated when necessary by A and V respectively.

Initial practice will be devoted to finding the open strings, using only the down stroke at first, but subsequently alternating up and down. When certainty has been attained in this, proceed to the study of fingering, for which the joints of the fingers must be squared and the tips firmly pressed upon the strings behind the proper fret. Early exercises should involve no shifting of the hand, which should be practised only when easy passages in the first, or normal, position can be played with fair facility.

As with all plucked instruments, the tone of the mandoline is evanescent; consequently, when the effect of sustained sound is wanted, it has to be suggested, rather than actually produced, by means of the tremolo, which, consists in keeping the strings in constant vibration by means of rapid alternate strokes. For this an absolutely lissom wrist is essential. From the frequency of its employment, the tremolo may be regarded as a characteristic of the mandoline, and therefore it must be carefully practised. The tuning of the Milanese mandoline, or mandurina, is shown below.

The fingering differs entirely from that of the Neapolitan mandoline, but if the principles underlying the above explanation of the Neapolitan mandoline have been clearly comprehended, anyone with aptitude and industry will soon be able to play the Milanese variety of the instrument.

MANDRAKE. This is a perennial herb of the genus *Mandragora*, which flourishes in shady corners in loamy soil. The root is often forked, with a supposed resemblance to human limbs that formerly led to various superstitious beliefs being associated with the mandrake. *Officinalis* bears blue flowers in May; *autumnalis*, purple, blooms in September.

The supposed resemblance of mandrake root to the human body has given rise to a perfectly groundless belief in its efficacy in furthering conception. The root has medicinal properties, however, and has been used as a narcotic and hypnotic. It contains an alkaloid, mandragorine, which acts similarly to atropine; and poisoning by the drug is like that due to belladonna, and should receive treatment on similar lines.

MANDREL. The steel spindle in the head stock of a lathe is a mandrel, and the name is also given to a bar of steel provided with conical holes at either end. These holes are provided to enable the bar

to be mounted upon centres in the lathe or other device, so that when the bar is revolved it will turn perfectly truly about these centres.

The bar is used to support an object to be turned in the lathe, which must have a hole through it of such a size that it will fit tightly on to the mandrel. Work so held can be machined all over, and it can be removed and replaced in the machine many times without fear of its being out of truth.

The Verschoyle patent mandrel is an inexpensive lathe for light wood and metal turning, spinning, etc. It clamps on to the edge of a bench or table and is thus very handy for the home worker who has not a permanent workshop. This particular mandrel is described and illustrated in this work in the article Lathe. *See* Candlestick.

MANETTI. This is the name of a stock, or root plant, upon which roses, chiefly of continental origin, are budded or grafted. It is not as successful or popular in Great Britain as is the *riar* rose, which it resembles. *See* Grafting; Rose.

MANGE: In Dogs. This dog disease is caused by a parasite so small as to be invisible to the naked eye, and is transferable from one animal to another. The mite that produces mange is propagated by eggs, consequently cleanliness is one of the best ways of combating it. Dirt certainly harbours mange, although it does not produce it, and if they are undisturbed the mites hatch and multiply with great rapidity.

There are two kinds of mange, follicular and sarcoptic. Follicular mange is almost incurable, the reason being that the parasite, by burrowing into the hair follicles and sebaceous glands, is almost inaccessible. The disease begins with a small circular pustular eruption, from which the hair falls, and it probably spreads all over the body, the skin becoming corrugated and of a bluish colour. There is little itching. To treat a dog suffering from this form of mange, bathe with balsam of Peru and alcohol in equal parts, or creolin and alcohol in equal parts. Some persons employ a 2 p.c. solution of formalin.

Sarcoptic, commonly called red mange, spreads rapidly, the parasites being on the surface, and the irritation is considerable. Small red spots are first seen, from which unpleasant matter is exuded. These soon spread into big patches. Powdered sulphur with 8 parts of vegetable oil is recommended, applied very liberally for a week or 10 days at intervals of 3 or 4 days. The dog's bedding should immediately be burnt and his sleeping box should be disinfected thoroughly before it is used again. *See* Dog.

MANGEL WURZEL. This root crop is an excellent food for pigs and other animals, one reason being the large amount of sugar it contains. Mangels should not be given to animals until they have been stored for some months. This should be done as early in the autumn as possible, and mangels will usually be found to keep in good condition, if required, until the following midsummer. *See* Pig.

'M' RECIPES: A SELECTION SHOWN IN ACTUAL COLOUR

Mixed Medley: Make $\frac{1}{2}$ pt. cherry jelly and leave to set. Split 4 sponge cakes and 4 sponge fingers and spread with jam. Arrange bottom halves in large shallow glass dish with cakes in centre and fingers round. Boil $\frac{1}{2}$ pt. milk. Use some to soak the sponge. Put on top halves and soak also with remainder of milk. Pour on $\frac{1}{2}$ gill sherry. Decorate with shredded almonds. Put a few pieces of stewed or tinned fruit at intervals on top of sponge fingers, pour over 1 pt. vanilla flavoured custard and leave to cool. Chop up jelly and use as garnish. *Marrow and Ginger Tart:* A flat tart filled with marrow jam. *Mousse à la Russe:* Put $\frac{1}{2}$ lb. apricot jam into a saucepan with 1 tablespoonful water, warming slightly and then rubbing through sieve. Whisk whites of 4 eggs to stiff froth, fold in the jam lightly, and pile mixture on dish in which it is to be served. Sprinkle with castor sugar and leave in cool oven to set, but avoid browning. Serve hot or cold.

MANGLES: THEIR CARE & REPAIR

Advice on an Important Feature of Laundry Work

Other entries dealing with this essential branch of domestic work include Ironing: Laundry; Starch; Soap; Wringer. See also Gear.

A mangle is a machine for pressing clothes and linen. Large articles of a plain or coarse type, such as bed sheets and towels, are generally subjected to this treatment, which is in many cases merely a preliminary to or a substitute for ironing. The art of mangling consists mainly in laying out the clothes smoothly and arranging them so that those of equal substance shall come together. This will ensure an even, regular surface and an equally good pressing for all. Most articles are folded two or three times, and come out better than when arranged in single folds. This is because the thicker the substance the tighter the pressure of the rollers. Care must be taken, however, to see that too thick a substance does not result, otherwise the rollers may be badly strained.

The ordinary mangle consists of two heavy rollers, usually of hardwood, and made to revolve by means of a cog-wheel attached to one end of the lower roller, which engages a cog attached to the spindle of a wheel turned by hand.

The rollers and cogs are fixed to an upright frame, and pressure is applied to the rollers by a tension screw which levers against the top of the frame.

A table mangle, suitable for use in small families and where space is limited, is made without a tall frame, but instead has clamps to fix it to a table or bench. The rollers measure approximately 16 in. by 3½ in., those of the standard type 21 in. by 6 in. to 27 in. by 6 in. Another model is fitted with a turn-over table; the back board is made much larger and without ledges, so that when the machine is not required for laundry work the board rests flat on the machine and forms a useful wooden table 36 in. by 20 in. Where these table mangles are not in use, and a large mangle is considered unnecessary, wringing machines are often used as substitutes. These, however, do not press the clothes in the same way as a mangle.

Mangle. Electrically driven wringer of modern type. Note soft rubber rollers, to prevent injury to buttons; and quick release lever which instantly removes pressure. (Courtesy, General Electric Co., Ltd.)

Electric Machines. Special electric washing machines with mangle and wringer combined can be obtained. Their initial cost is rather high, but they afford a great economy of space and time. In some of these machines a wringer alone is found. In such it is intended to serve the purpose of a mangle, has rollers of the finest rubber, is reversible, and can be swung to any desired position.

The illustration shows an electrically driven mangle. "Wringer" is the term nowadays more generally used. The washing-machine shown above has a detachable wringer which is afterwards replaced by an ironing "shoe." A powerful ¼ h.p. motor does all the work in an hour at the cost of ¼ unit of electricity.

Important Points. When selecting a mangle, the following points should be noted. The cog-wheels or chain should be protected with a metal case, so that children cannot get their fingers caught. At

least two whitewood shelves should be provided, the grooves for the lower one being in a sloping position, so that it can act as a drip board. The tension screw ought to produce even pressure along the length of the rollers.

The bottom roller gets greater wear, and for this reason is often made of *lignum vitae*. On no account must both lower and upper rollers be made of this or any other very hard wood, or the strain on the clothes would be too great, resulting in small holes, and in extreme cases, when wet clothes have been passed through the machine unevenly, in straight cuts in the fabrics. When renewing rollers care must be taken that the top roller is made of softer wood than the lower one.

Both rubber and wooden rollers are damaged, but chiefly the former, by wringing very hot clothes, as great heat perishes rubber. To clean rubber, washing is rarely successful; a rag moistened with turpentine is necessary to remove any soap curd and dirt which collect on rubber rollers. When not in use, the tension screw should be loosened so that no strain remains on the rollers. It is tightened up according to the thickness of the material being passed through the rollers.

The mangle should be oiled regularly with thin machine oil; thick oil collects dust and clogs the working parts. From time to time the working parts should be freed from all grease and dust; paraffin is a quick cleanser if applied on a soft cloth. The metal framework ought to be washed from time to time with warm soapy water, then rinsed in clean water. When the paint commences to chip or wear, the frame should be well rubbed down with fine glasspaper, and two coats of enamel applied. The exposure of bare ironwork may result in ironmould on the clothes.

When not in use a mangle should be covered with a dust sheet to protect it from dust and grease. It should not be stored out of doors without some protection, and if a small wooden shed or lean-to is not available, an old tarpaulin will serve.

Repairing a Mangle. After being in use for some years a mangle shows signs of wear principally in the rollers and other wooden parts. Metal parts may be replaced without difficulty if the machine is one of standard make. Of the two rollers, the bottom one wears hollow before the other, and it will pay to have them trued up once or even twice, but there is a limit to the amount a roller can be reduced in diameter without fitting new star wheels to allow for the difference.

Unless the rollers have a stout cap or ferrule on the ends there is a tendency for the wood to crack and split. Rollers that have been kept in a dry place and not used for some time are very liable to crack; unless such openings are filled up the mangle will not give satisfactory results. Small cracks may be made good with a waterproof wood-filler, worked in with a fine blade and carefully smoothed on top. When set the surface should be smoothed with glasspaper that has been wrapped over a flat piece of wood.

Newly turned surfaces should be protected with a varnish made by dissolving 2 oz. of white shellac and 2 oz. of benzoin in sufficient methylated spirit to form a paste, and then adding 1 oz. of beeswax which has been dissolved in a small quantity of turpentine. This should be applied with a pad while the roller is revolved.

The wheels, being made of cast iron, do not cost much, and it is not worth while to have new teeth fitted. If one of the cogs should get broken off, the wheel must be removed, coated with blacklead on one side so that a rubbing may be made on a piece of paper of the exact shape, including the centre hole. The maker or ironmonger will then be able to supply a new wheel from the shape provided.

In the event of the wooden handle breaking or splitting, it may be renewed by filing round the end of the iron rod and removing the washer; the new handle should be slipped in place and the end of the iron riveted over with a hammer. The drip board as well as the table is liable to wear, and if the surface is good, the strengthening battens on the ends may be replaced with new pieces. In renewing the strips use beech or sycamore.

When renewing the paintwork, the handle, guard and wheels should be taken off and the ironwork scrubbed with soda and hot water to remove grease and dirt. The framework, spring bow, handle of pressure screw, guard, bearing, fly-wheel and collar, with bolt heads, etc., should be painted in colour; the outside of wheels should be coated with Brunswick black and screws and cog surfaces coated with blacklead. In replacing the wheels, the keys should be driven in with a hammer and cold chisel.

MANHOLE. In building and other constructive work any aperture of sufficient size to permit of the passage of a man is known as a manhole. The term is also applied to smaller apertures, as, for example, those fitted to a kitchen boiler. The manholes used to cover the openings provided in the sanitary system for the cleaning out of the drains usually comprise a framework of rectangular or other shape that is built into the brickwork. The cover or lid is provided with a lip which fits into a slot or groove round the top edge of the frame. This groove should be filled with cart grease and sand, or some other composition, to render it airtight. In small work the covers are usually kept in place by their own weight and are lifted by means of grips. *See Drains.*

MANICURE. This name is given to the treatment of the hands, especially the finger nails. The set of implements and cosmetics used for this purpose can be bought separately from chemists, or complete in cases, differing in price according to size and quality. They include usually—nail polish, a polisher, a small bottle of liquid bleach, cuticle cream, orange sticks, emery board, some cotton wool, a file, and a pair of manicure scissors which have frequently short curved blades. *See Hand; Nails.*

MANNA ASH. The manna or flowering ash is *Fraxinus ornus*, a handsome small tree, which bears white blooms in early summer. The popular name of manna ash arises from the use of the exuded sap as manna. It is quite hardy and may be grown in London and other gardens.

MANSARD ROOF. This is a style of roof construction in which the roof is formed of two sections inclined at different angles, or having two separate slopes. It is often undertaken on the score of economy, as the bulk of the roof space may be used for rooms, and what would have been the outer walls are built with roofing material. Another advantage is that it reduces the height required with the steeply-pitched roof. The proportion between the slope of the lower and upper portions is important; a good outline is generally obtained by making the lower slope 60° and the upper one 30° .

The example illustrated comprises a king post, roof truss, properly framed up and strengthened with iron straps and cast-iron shoes. The tie beam is supported on a king post, which, in turn, bears upon the bottom tie beams. When modified this class of construction has many features of interest to the builder of small houses, as it is a cheap and efficient type of roof, and offers considerable scope from the architectural point of view. *See Roof.*

Mansard Roof, formed of two sections inclined at different angles.

MANSERVANT. All men who are employed in and about the house—chauffeurs, gardeners, grooms, butlers, valets, footmen. All come within the N.H.I. Act and, if employed for gain (e.g. in a hotel) within Unemployment Insurance. Private gardeners, gamekeepers and grooms, when not employed for gain, are covered by Unemployment Insurance. *See* Chauffeur; Footman; Insurance, etc.

MANTELBOARD. Some mantelshelves are so narrow that it is necessary to fit on wide boards if they are to be used to hold clocks and ornaments. A shaped mantel board, as shown in Fig. 1, is often used, the edge being covered with gimp. The best method of attaching the board to the shelf is shown in Fig. 2; this is a block of wood, notched out to the thickness of the shelf and then screwed on. One of these clips should be used at each end, as shown in the end view at Fig. 3.

Mantelboard. Fig. 1. Shaped board. Figs. 2 and 3. Method of attaching board to shelf. Fig. 4. Straight mantelboard, finished with moulding. Fig. 5. Moulding attached by rebate. Fig. 6. Brass mirror plate for fixing board to wall. Fig. 7. Decorative dentil pattern. Figs. 8 and 9. Method of securing mantelboard by means of wall holdfast.

Another form of shelf is shown in Fig. 4. An oblong board is cut to the required length and width and the front and ends finished with cabinet moulding, either glued, screwed or nailed on direct, or

rebated as suggested in the section at Fig. 5. A large variety of shapes may be obtained and picture frame moulding may be utilized. Perfectly plain lengths of board may be edged with half-round ball or Jacobean beading, and, instead of the under button, or clip, a pair of brass mirror plates for nailing to the wall may be screwed on as in Fig. 6.

A good decorative effect may be obtained by a dentil pattern, as in Fig. 7; the dentils should be square in the front view and about half the front dimension in thickness. They should be glued on a strip about double the height of the dentils. A further method of securing mantelboards is shown in Fig. 8. An ordinary wall holdfast, as in Fig. 9, should be driven in the wall with the eye uppermost and a screw driven into the board.

MANTELPIECE. For almost all practical purposes the mantelpiece and the chimney piece are identical. Strictly speaking, however, the mantelpiece is only a portion of the chimney piece, for the latter embraces the whole protective structure around the fireplace from floor to ceiling, while the mantelpiece is only its lower part. Mantelpieces are made commonly of wood, marble or iron. Iron ones can be standardized and turned out in thousands. The wooden ones are often beautifully carved, and both kinds are sometimes inlaid. Stone and faience are also used for mantelpieces.

The mantelpiece which is not in itself satisfactorily decorative should be painted or stained with due regard to the general colour scheme of the room. The wooden variety calls for no special treatment, beyond taking care to clean the work before beginning to paint, and stopping any little holes or cracks that may be visible with hard stopping.

The marble mantelpiece is very difficult to colour in a satisfactory manner. One method is to roughen the surface with sandpaper and use flat colours; another is to apply special transparent stains; but these are not very durable. Cast-iron mantelpieces are amenable to treatment if they are well sandpapered before applying the first undercoating, after which they may be painted in the same way as woodwork. *See Chimney Piece; Fireplace; Gas; Grate.*

MANTILLA. Spain's national headdress may be white or black. The material is silk blonde lace, and though a great deal of this is machine-made, the best examples of the mantilla are bobbin-made, showing the heavy floral design with finer filling lace stitches on a delicate net ground.

A mantilla is partly shaped and folded, so that when placed on the shoulders the straight piece may be drawn up and draped over the high standing comb at the back of the head, and the shaped flounce forms a graceful cape. Mantillas are sometimes worn as evening wraps. *See Lace.*

MANTLE. In one of its senses a mantle is a form of cloak. In another sense a mantle is a piece of network, conical in shape, covered with some highly refractory material, that becomes luminous under a flame and is therefore used to add to the illuminating power of gas. *See Gas Mantle.*

MANTLING. All the cloths used for women's outer coats are included under this description. The variety ranges from soft, smooth woollen velours, blanket cloth, and showy tweeds to moiré silks, matelassés and imitation furs. Mantle cloths are wind-proof in very different degrees, and for winter wear it is desirable not to choose too open a texture.

In buying mantling, regard should be paid to the back as well as the face, both as to its appearance and as to its suitability for an unlined garment. Thick, solid cloths are not easy to cut out, and require tailor's skill and heavy ironing to look well.

MANURES FOR THE GARDEN

Natural and Artificial Fertilizers and their Uses

Detailed Information on the manuring of various plants will be found under the separate headings, e.g. Asparagus; Celery; Cucumber; Endive; Horseradish, etc. See also Fertilizer: Fruit: Garden: Hotbed; Kitchen Garden, etc.

Food or stimulant for trees and plants grown in the garden consists either of the ordure of animals, farmyard manure as it is called, or of chemical or artificial fertilizers. The three chief plant foods are nitrogen, phosphates and potash. Natural or farmyard manure contains all three. A fourth substance, lime, is required, not so much, however, as a food for plants as on account of its chemical action on the soil.

Natural Manures. Natural manures and road sweepings found in or near towns are of little value, as they are usually impregnated with petrol and oil, and are therefore injurious. Spent hops, leaves and decayed green refuse are valuable manure substitutes. Among the best artificial manures, although it is really a natural product, is guano. Dried blood, bone manure and bone meal are also useful for various purposes.

A good chemical manure for general application consists of superphosphate of lime, 5 parts, and sulphate of ammonia, 2 parts; the mixture should be applied at 2 oz. per sq. yd., or diluted in water, 1 oz. per gallon.

Sulphate of ammonia and nitrate of soda are the two chief nitrogenous manures: they promote leaf growth and are used at the rate of 1-2 oz. per sq. yd. of ground. Super phosphate of lime, basic slag, and bonemeal are phos-phatic manures which help in the building tip of stems and the development of flowers and fruits. Basic slag should be applied in autumn, 4-6 oz. per sq. yd. of land, the others in spring at 2 oz. per sq. yd. Potash is present naturally in most soils, particularly in clayey ground, but it may be supplemented by the use of sulphate of potash, 1-2 oz. per sq. yard in spring and early summer. In the case of heavy soils, manure is best dug in during the autumn and winter, but with light soils this should be done in the spring. An average dressing of manure for vegetables is about 2½ cwt. to the square rod, i.e. 30¼ sq. yd. When manure has to lie for some time in a heap before it is used, it should be covered with about 6 in. of soil to preserve its essential constituents.

With the increasing use of the motor for transport and other purposes, both in town and country, farmyard and stable manure is available in less quantities than formerly. One of the most effective ways of replacing this shortage of natural manure is by growing and digging in a green crop, e.g. rape.

If sown broadcast at the rate of 1 oz. per rod on land which becomes vacant from July to the end of August, and raked into the surface soil, such crops will be ready for digging in from end of October to end of November, according to date of sowing.

Soot. One kind of manure, soot, is available for most gardens, and another, poultry manure, for many. Soot is chiefly valuable on account of the nitrogen it contains, but it also improves the working qualities of the soil. If possible, it should always be stored in a dry shed for some time before use. When used for manure lime and soot should never be mixed, or the lime will drive off the ammonia in the soot. Six cwt. of good soot is equivalent to a cwt. of sulphate of ammonia. Poultry manure should be stored in alternate layers with an equal bulk of dry soil in a convenient receptacle, or in a heap in a dry shed until it is needed. It may be turned twice or three times, and, after such treatment, should be applied to all crops at the rate of from 4 to 6 oz. per sq. yd.

Manure. 1. Liquid manure: a, solid manure in box or pan; b, wooden rest; c, lid; d, water. 2. Soot water; bag: of soot suspended from stick. 3. Open ground tank; a, sunk tank; b, brickbats; c, straw; d, manure; e, water. 4. Soft water manure: a, holed pail of manure; b, drainpipe from roof. 5. Manure stack. 6. Same with sunk pail to collect draining liquid.

Liquid Manure. Liquid manure can be made in the following ways: Take a peck of poultry manure, or a peck of sheep droppings, and place this in a 40-gallon cask. Fill this with water, and after standing 24 hours it should be ready for use. This makes an excellent manure for application to fruit, flower, and vegetable crops during the growing season, the rate being 2 gallons to the sq. yd.

Lime. Lime is most valuable on heavy clayey soils. It may be applied either in autumn or early spring, one bushel per three rods of ground, but it should not be put on at the same time as farmyard manure. It is best to do the digging and manuring in the autumn or early winter, and to apply the lime in the dry, slaked form about the beginning of March. Lime should be hoed or raked into the top 3 in. of soil; not be dug in or buried deeply.

In Bulletin 36, from which much of this information is taken, the Ministry of Agriculture makes the following suggestions about manuring the various individual crops.

Manuring Potatoes and Cabbages. In the case of potatoes where the crop is grown on the flat, sulphate of ammonia should be applied on the surface just before the first earthing up at the rate of $\frac{1}{2}$ oz. per sq. yd. or 1 lb. per rod. Where potatoes are planted in drills the sulphate of ammonia may be applied in the drills at the time of planting. Superphosphate of lime should be applied at the rate of $1\frac{1}{2}$ oz. per sq. yd. (3 lb. per rod), and may be forked in lightly before planting on the flat, or

applied in the drill at time of planting. Superphosphate and steamed bone flour may be mixed in equal proportions and applied, when planting, at the same rate.

All the members of the cabbage family respond to applications of nitrogenous manures. Sulphate of ammonia should be applied at the rate of $\frac{1}{2}$ - $\frac{3}{4}$ oz. per sq. yd. (1-1½ lb. per rod) before the first earthing up. or as soon as growth starts. Superphosphate, or superphosphate and steamed bone flour in equal proportions, should be used at the rate of 1 oz. per sq. yd. (2 lb. per rod) at the time of planting, or before the first earthing up. In inland districts, where allotment crops on light and medium soils are liable to suffer from drought, salt is very helpful. It should be applied at the rate of 1 oz. per sq. yd.

Manuring Other Crops. Crops belonging to the pea and bean family can usually provide themselves with sufficient nitrogen. A mixture of superphosphate and steamed bone flour in equal proportions should be applied to the ground before or after sowing the seed, at the rate of 1 oz. to 4 yd. in length of drill. The manure should never be sown in the bottom of the drill in direct contact with the seed. Basic slag may replace the superphosphate and steamed bone flour, and be sown at the rate of $\frac{1}{4}$ lb. to 4 yd. of drill.

For onions, leeks and celery, sulphate of ammonia should be applied at the rate of $\frac{1}{2}$ oz. per sq. yd. (1 lb. per rod), with superphosphate and steamed bone flour, mixed in equal proportions, at the rate of 1 oz. per sq. yd. On light soils, liable to dry out, salt may be given with advantage (1 oz. per sq. yd.).

These crops should all be manured in the early stages of their growth.

For carrots, parsnips and beet, sulphate of ammonia should be applied at the rate of $\frac{1}{2}$ oz. per sq. yd. after singling. Superphosphate and steamed bone flour, mixed at the rate of 1 oz. per sq. yd., should be applied before sowing the seed. On dry soils, 1 oz. of salt per sq. yd. may be applied before drilling. Lettuce, spinach, and radishes are greatly helped by applications of sulphate of ammonia, which should be applied at the rate of $\frac{1}{2}$ oz. per sq. yd. in the early stages of growth. Where radishes do not bulb readily, superphosphate, at the rate of 1 oz. per sq. yd., should be applied to the soil before sowing.

MANZANELLA. Made from a highly prized species of grape, manzanella is a fine sherry with a fragrant floral bouquet and an aromatic flavour. It is said to take its name from its similarity to a wine produced at a place called Manzanella, which is situated some 25 miles from Seville. It is a good beverage wine and goes with most table dishes *See Sherry; Wine.*

MAPLE. This is the common name of a large group of hardy trees and shrubs known botanically as acer: they thrive in ordinary well drained loamy soil. Of the trees the most familiar are the sycamore (*Acer pseudo-platanus*), Norway maple (*platanoides*), the common maple (*campestre*) and the variegated box elder (*Negundo variegatum*): the last named is a most decorative small tree with green and white leaves.

There are many beautiful varieties of the Japanese maple—shrubs which like a somewhat sheltered position: the young leaves are charmingly tinted in spring, and in some the autumn colouring is attractive. A few of the most beautiful of the Japanese maples are *roseo-marginatum*, *septemlobum elegans*, *Osakazuki* and *atropurpureum*, which are varieties of *Acer palmatum*; *aureum* and *laciniatum* are varieties of *acer japonicum*. These shrubs are slow growing. Maple sugar is made from the sap of the tree.

Uses of the Wood. The wood of the maple is light in colour, ranging from white to yellowish brown and grey. It is heavy, hard, tough, and fine-grained, with a lustrous surface, especially when cut

radially through the centre of the trunk. This sometimes has a wavy or mottled appearance showing alternate light and shade across the surface. A variety called bird's eye maple has a speckled curly grain, and is used chiefly in the form of veneer.

Maple does not easily splinter, and is excellent for floorboards and other interior fittings. It takes stain well and is easily polished. It is used for furniture, plywood, fretwood, turnery, musical instruments, dairy woodwork, wood spoons and platters, and rollers. A bog maple, cut from peat, and pale blue in colour, is sometimes used for veneer and small articles. *See Wood.*

MARABOUT. The name is that of a bird, and the original marabout was a tuft or plume of soft or grey feathers from beneath the wings and tails of storks, herons, and adjutant birds, and used as a millinery trimming. The term has been extended to cover fluffy feather trimmings, ruffles, stoles, wraps, and valuable coats having no necessary connexion with marabout birds.

Prepared feathers are braided or corded together with their soft fronds projecting to make exceedingly light trimmings weighing much less than fur and giving similar warmth. They do not wear nearly so well as fur, but often look very becoming for dressing gowns and jackets. Marabout loses substance in wear by detachment of the feathers from the central binding cords, and the articles should be handled lightly and with care. Washing is often detrimental, but marabout articles may be dipped in a warm soapy lather and dried by being shaken in front of the fire; they should not be crushed in storage.

MARASCHINO. A fine, delicately flavoured variety of cherry known as marazques is the source from which maraschino is distilled. It is a sweetish liqueur with a subtle taste, and is often used to flavour fruit salads and in some cocktails. A maraschino cherry is often placed in the half of a prepared grape-fruit, and in a cocktail glass containing a sweet liqueur. These cherries are bottled in maraschino.

MARBLE. There are many kinds of marble, some of the best of the English varieties being found in Dorset. Purbeck is a mottled grey, which takes a fine polish and is suitable for decorative work. A fine black marble, known as Mento. comes from Oalway. Connemara, a blue green, and Churchtown, a red marble, are also quarried in Ireland.

Beautiful examples from Derbyshire, Staffordshire, and Devonshire are notable for their delicate colourings, and are employed for carved table ornaments and chimney pieces. Some of the most handsome varieties come from Greece. Pure white, from Carrara, in Italy, is used for sculpture and for expensive carving and ornamental work.

Decorative Uses. The purposes for which the various kinds of marble are employed depend largely on their weather-resisting qualities. Red Ogwell, which is a particularly soft type, will not retain its fine polish out of doors, and is consequently reserved for household use. It is made into mantelpieces, fenders, and pedestals for marble or bronze figures. Dove marble, another soft variety, is of a pale grey colour, and, because of its high polish, is specially adaptable for panelling and wainscoting. Like red Ogwell and other coloured marble, it never discolours.

Mottled marble, a variety of white Sicilian, is also used for panelling, because of its fine markings, the slabs being arranged so as to form diamonds and other patterns. Unlike the coloured marbles, this is a hard type, and can be used equally well out of doors in the form of flower vases for the garden or terrace steps. Veined white Sicilian marble varies from the mottled only in the markings, and is employed for very much the same purposes.

Among the choicest and rarest of the many articles executed in marble are pictures wrought by Italian craftsmen, in almost every variety and colour of marble, including bright emerald green, the

supply of which is extremely limited, and crimson, which is equally rare. As a rule, these pictures are portraits rather than landscapes or seascapes, and usually fetch high prices. They are generally framed in mahogany or oak.

Domestic Uses. As used in the home, marble takes the form of wash-basins, table-tops, pantry shelves, mantelpieces, curbs, etc., its chief advantages being that it is sanitary, cool to the touch, and easily kept clean. Due, moreover, to its natural composition, which contains lime, it has the further property of being germ-destroying, and so is especially suitable for lavatories.

Its cooling properties are best revealed in the pantry, where, in the form of shelves and receptacles for butter, milk, etc. it is the most practical material. In the hottest weather it remains at a comparatively low temperature, and diffuses its coolness to such foods as would otherwise easily melt. For the same reason it is of essential value for storing meat. Slabs for the purpose are sold cheaply at most monumental works.

Plain marble curbs may be put together at home, parts for which may be cheaply obtained. Three blocks of the required measurements should be bought, two being of short lengths for the sides, and the other as long as the hearth itself. These blocks may be polished or unpolished. Outside the house marble is used for doorsteps and terrace ornaments.

Cleaning Marble. When discoloration occur a little crystallized oxalic acid should be dissolved in water, and the mixture applied. Meat or vegetable stains require other treatment; $\frac{1}{2}$ lb. each of stone potash and pipeclay should be mixed in water with a little oxalic acid added to form a paste. Cover the stain with this preparation and let it remain on overnight. The application should be repeated until the stain vanishes. Mineral stains, caused by rusty nails, etc., rarely yield to treatment, but may be subjected to the above application. Unpolished surfaces should be rubbed vigorously with pumice-stone and water. A polished or glossy surface can be produced by a mixture consisting of four parts of oxalic acid to one part of sulphate of lead. This should be applied with a wet flannel cloth, and a brilliancy that will last for years will then be obtained.

When marble has been exposed to the air for any length of time without attention the stains formed may be removed by first applying potash water and rubbing it down thoroughly, afterwards washing clean with first clean water and then water with a few drops of hydrochloric acid in it, although care should be taken not to add too much hydrochloric acid.

Another method that is sometimes used is to apply equal quantities of soft soap and pearl ash with a soft rag, washing it off after a few minutes with warm water, and finishing with a soft dry flannel. If there are no stains a good plan is first to rub olive oil on to the marble and then rub down thoroughly with a soft rag, or a solution of 2 oz. soda carbonate in a quart of water should be well scrubbed down the marble, finishing with a soft rag.

Marble table tops, the tops of washstands and other articles when cracked or broken may be riveted as is described in the article on the repair of crockery. The rivet holes need only be drilled half way through from the back of the material. The rivets are fixed in the holes by filling them with plaster of Paris mixed with water. The joint should not be coated with the plaster, but if desired, when the top is finished, and the marble top replaced, the crack, if at all visible, may be filled with plaster by working it in through the top and colouring with suitable pigments to match the existing work.

MARBLE CAKE. To make a marble cake, prepare and bake a cake according to directions given for Russian cake; cut this up into pieces of all shapes and sizes, and stir them into a little sieved, apricot jam melted in a pan over the fire. Line a tin with greaseproof paper, and pack in the cake mixture, blending the colours prettily. Put a lid with weights on it over the cake and leave it for an hour or two. Then turn it out carefully, putting the most level side uppermost. Pour over it some

white glacé icing and decorate the top with wavy lines of chocolate glacé icing applied with a forcing bag and plain pipe. *See Russian Cake.*

Marble Cake, a fancy cake with iced top.

Marbling. *See* Graining; Lacquer Work.

MARCOBRUNNER. This famous brand of German hock of fragrant aroma and brilliant colour is the product of the vineyard of Marcobrunn, which stands among the hills some little distance from the Rhine. The output is small, and a great deal of wine which is not grown there is sold under the name of Marcobrunner. *See Hock.*

MARE'S TAIL. This is the common name of a hardy perennial with rush-like stems. A few kinds are suitable for waterside planting, but others are weeds which thrive chiefly in boggy ground.

Mare's Tail. Hardy rush-like waterside plant.

MARGARINE. The term margarine is applied to any substance that has the same appearance as butter and that is used as a substitute for butter. Beef and mutton fat, lard, coconut, cotton seed, and pea nut oil are employed in the manufacture. After being refined they are churned with milk; colouring matter and salt are added, the latter acting as a preservative.

Margarine is a wholesome and cheap article of food. It should not be bought in large quantities. On account of the milk which it contains it does not remain in good condition indefinitely, and should be used as fresh as possible.

Although it is very suitable for some purposes, such as for making cakes and sauces, margarine is not so suitable as lard or dripping for frying, owing to the milk and salt which it contains. If occasion arises when margarine only is available for frying, the difficulty may be overcome to some extent by placing the fat in a saucepan on top of the stove or in a basin in the oven, and allowing it to remain for some time, stirring occasionally. The heat evaporates the water, and dry sediment resulting from the milk can be removed by straining.

Margarine can be used for making pastry in conjunction with lard, in the proportion of half lard and half margarine; but, it should be noted, it is not advisable to use margarine alone for making pastry.

The Law About Margarine. Any margarine or any margarine cheese that is imported into Great Britain must bear conspicuously on the ticket the words margarine, or margarine cheese, as the case may require. Margarine must not contain more than 16 per cent of water or more than 10 per cent of butter fats, nor must it contain any preservative prohibited by the regulations.

Any breach of the above provisions renders the offender, whether he be manufacturer, importer, consignor, consignee, commission agent or otherwise, liable to a penalty of £20 for the first offence, £50 for the second and £100 for any subsequent offence. The package, whether open or closed, or

durably marked, with the words margarine or margarine cheese on the top, bottom and sides in printed capital letters not less than $\frac{3}{4}$ in. square and this brand or mark must be on the package itself and not simply on a label.

Further, when these articles are exposed for sale by retail, a label must be on every parcel so exposed in such a manner as to be clearly visible to the purchaser, with the words margarine or margarine cheese marked in printed capital letters not less than $1\frac{1}{2}$ in. square. Still further, every package handed to a customer must be in a paper wrapper on which is printed in capital block letters not less than $\frac{1}{2}$ in. long and distinctly visible the words margarine or margarine cheese, and no other printed matter shall appear on the wrapper. If margarine is sold or even advertised, and the seller puts on the wrapper or package or label or in the advertisement or invoice any description other than margarine, or a name combining the word margarine with a fancy or other descriptive name approved by the Ministry of Agriculture and printed in type not larger than and in the same colour as margarine, he is guilty of an offence punishable as stated.

Margarine and butter may not be mixed. Every occupier of a margarine cheese factory and every wholesale dealer must keep a register showing the quantity and destination of each consignment of these goods sent out by him. *See Butter; Cake; Diet; Food; Pastry.*

MARGUERITE. The beautiful white and yellow marguerites (*Chrysanthemum frutescens*) are very popular plants for window-boxes, for the greenhouse and summer flower bed. They are generally raised from cuttings in autumn and grown in small pots under glass till mid-May, after which they are planted out or repotted.

Marguerite. Right. Flowers of the single variety grown as a pot plant. Left. Fine large bloom of the double white variety Mrs. Sander.

Young plants in pots can be bought cheaply from a florist in spring. They flower freely throughout the summer if planted 18 in. apart in fertile soil and watered. The double white variety Mrs. Sander is superior to the single white. Etoile d'Or is a good yellow.

The leaves of the marguerite often become badly streaked owing to the attack of a leaf-mining grub. In order to prevent flies depositing eggs, the plants should be syringed once a week with paraffin emulsion or other insecticide. Once the larvae are inside the leaves, however, the above is useless, and the only remedy for a slight attack is to dig them out, or destroy them by pinching, or stabbing them through with a needle. Burn badly-infested leaves. Marguerites are charming for indoor decoration the flowers should be cut freely throughout the summer. *See Flower Garden; Garden.*

MARCH

What to do in the Garden

Flowers

Sow hardy annuals if the soil is reasonably dry

Plant the corms of gladiolus, Cape Hyacinth and montbretia

Prune rose trees at the end of the month

Sow ten-week stocks, asters and other half-hardy annuals in the greenhouse

Plant border carnations and hardy herbaceous perennials

Prepare the site for a new lawn

Sow seeds of hardy perennials in boxes of soil in a frame

Take cuttings of border chrysanthemums

Plant the roots of poppy, anemone and ranunculus

Finish planting rose trees and hardy flowering plants and shrubs

Plant bulbs of lily auratum and other lilies

Fruit

Finish pruning and planting fruit trees

Graft fruit trees

Weed strawberry beds and plant out last autumn's runners

Disbud vines and peach trees grown under glass

Spray fruit trees with lime-sulphur

Strew fresh slaked lime on the surface of

the ground between bush fruit trees

Sow melon seeds in pots

Vegetables

Remove offsets from globe artichokes for propagation

Make a first sowing of carrot at the end of the month

Sow cauliflower in a frame or in the open

Sow leeks and onions

Get in early potatoes

Sow mustard, cress, and radishes at weekly intervals

Scatter coal ashes on young peas that are just coming up

Food in Season

Fish

Barbel; bream; brill; carp; cod; dory; eel; flounder; gurnet; haddock; halibut; herring; ling; mackerel; mullet; perch; pike; salmon; skate; smelt; sole; sprats; tench; trout; turbot; whitebait; whiting

Shellfish

Crab; crayfish; lobster; mussels; oysters; prawns; scallops; shrimps

Meat

Beef; house lamb; mutton; pork; veal; venison

Poultry & Game

Capons; capercaillie; chickens; ducks; fowls; geese; guinea-fowl; hares; landrills; ortolans; partridges; pheasants; plover; prairie hens; ptarmigan; pigeons; pullets; quail; rabbits; ruffs and reeves; snipe; teal; turkey; widgeon; wild fowl; woodcock

Vegetables

Artichoke; asparagus; beetroot; broccoli; Brussels sprouts; cabbage; cardoons; carrots; cauliflower;

celeriac; celery; chervil; chicory; cress; cucumber; endive; greens; horse-radish; leeks; lettuce; mushrooms; onions; parsnips; potatoes (new and old); radishes; salsify; savoy; Scotch kale; seakale; sorrel; spinach; tomatoes; turnips; watercress

Fruit

Apples; bananas; figs; grapes; lemons; limes; medlars; nectarines; oranges; pears; peaches; pineapple; rhubarb; various kinds of nuts

Notes for the Month

MARCH 1.—S. David's Day

MARCH 17.—S. Patrick's Day

MARCH 25.—Lady Day. Quarter Day

MARIGOLD. The common marigold is a showy dwarf plant with orange-coloured flowers. New brilliantly coloured varieties have been raised; they should be grown in preference to the old-fashioned kind. Orange King and Radio are especially fine. Once introduced into the garden, it will sow itself, and come up the next year

in profusion. It is a *Calendula*, while African and French marigolds belong to the genus *Tagetes*, producing brilliant flowers in great abundance.

African marigolds, with their large globular double flowers, are of lemon and orange: they thrive in almost any fertile, friable soil, being raised from seed under glass in February. They grow 2 to 3 ft. high.

Marigold. Left. Large, lemon-coloured, globular flowers of the African marigold. Right. Orange blooms of the common marigold.

Both single and double coloured and striped sorts of French marigolds are available, 1 to 2 ft. high, also miniature single kinds about 9 in. high *Etoile d'Or*, *Legion of Honour*, *Meteor*, *Diadem*, *Silver King*, and *Star of India* make gold edgings. *See* Fig Marigold; French Marigold; Marsh Marigold.

MARINADE. This is the name given to a brine used for sousing or pickling fish and meat. A game or meat marinade is made as follows: In a large earthenware vessel put 2 onions and 2 carrots cut into thin slices, a small handful of salt, a bunch of herbs, including sprigs of thyme, basil and sage, a few bay leaves, peppercorns, mace and cloves. Pour over these 1 pint vinegar and 2 pints cold water, cover the vessel and keep it in a cool place. The meat or game is soured in this marinade before it is cooked.

A marinade for fish can be made thus: A gill of salad or olive oil is mixed with the same quantity of white vinegar, a finely chopped onion, a bunch of herbs, and a little salt and cayenne. The fish is put in this mixture to souse, and is then broiled, or it can be baked in the marinade in the oven. *See* Mackerel; Pickle, etc.

MARINE GLUE. A special type of glue, used in ship and boat building for making watertight joints, is known as marine glue. It is generally composed of shellac, or caoutchouc mixed with turpentine or naphtha. It can be used under any circumstances where a sound waterproof glue is required. *See* Glue.

MARIPOSA LILY. This is the common name of *Calochortus*, a group of rather tender flowering bulbs. They should be grown in a bed of well-drained sandy soil in a sunny, sheltered position, as at the foot of a wall. In winter it is wise to protect the bed with a frame "light" to keep off excessive rains. The bulbs should be planted 3 in. deep in early autumn. The flowers are of many charming colours. A few of the best are *clavatus*, yellow; *lilacinus*, lilac; *amoenus*, rosy purple, and *venustus*, of which there are many varieties.

MARJORAM. The hardy aromatic herb marjoram is used in cookery for flavouring. The plants should be put in rich soil in spring in rows about 15 in, apart on a sunny border. They may be left undisturbed for 4 or 5 years, but the shoots should be gathered just when they are coming into flower, dried in a cool, shady place, and stored. Propagation is by seeds or cuttings of young shoots. Every March a top-dressing of well-decayed manure should be given.

Marjoram. Aromatic flowering herb used in cookery.

MARKET DAY. Most towns in Great Britain have markets, some once a week and some twice, the day varying. Such days are known as market days. There are no special market days in London, but in the majority of the smaller towns they are still important. *See* Early Closing.

MARKING. Marking personal and household possessions with the name or initials of their owner is usually done by means of marking ink and a pen sold for the purpose. Some people use a stencil specially made to use with marking ink. When marked each article must be left until it is dry. Tablecloths, sheets, and other items of house linen are often marked in this way with the names of their owner, and many persons so mark their pocket handkerchiefs and other possessions. Another method of marking articles of clothing is to write or print the name on a strip of cotton, or other suitable material, and then to sew this on to the garment.

Clothing and house linen can be marked in another way. This is by means of initials, which are worked on to the garment in silk or cotton thread, either in white or colour.

To mark suitcases and other luggage the initials should first be outlined in a suitable size, and then the paint, white or black oil colour, as desired, can be laid between the lines with a brush. Careful measurements are necessary in order to make the letters uniform in size and similar also in style. *See* Initial.

Marking Ink. For marking the name of the owner on clothing, a marking ink ought to be permanent in its effect, and not liable to become faint and illegible after repeated washing of the linen. The best ink for the purpose is one having nitrate of silver for a basis; but if bleaching powder is used in washing fabrics marked with this ink there is a tendency for the linen to rot into holes at the places where the marking was done. Other bases used are coal tar and aniline.

The manufacture of marking inks is somewhat complicated, but a simple form can be made by grinding Chinese ink with a little water to a thick, smooth liquid; this is dried by placing it in a warm place, and is then reduced to powder. To the powder is added a mixture of coal tar 1 part, mineral naphtha 2 parts, until a thin cream is formed. The resulting ink marks are quite permanent.

MARKING GAUGE. One of the indispensable tools of the woodworker, the marking gauge is used for marking incised lines in the direction of the grain parallel to the edge. It is illustrated and described in the article Gauge (q.v.).

MARL. Largely consisting of decomposed limestone with a small percentage of clay, marl is natural soil which possesses the property of hardening very rapidly. Ordinary marl contains from 15 to 20 per cent of carbonate of lime. Being comparatively immune from the attacks of insect pests, it is much in request for grass courts, and it is sometimes applied to the surfaces of other garden soils as a top-dressing. Marl is used with other ingredients in the preparation of cement, concrete, and other building materials. Marl grass is a pasture grass which is sometimes used in garden mixtures to match existing turf. It belongs to the clover family. *See Soil.*

MARMALADE: ORANGE AND OTHER MAKES

Directions for Using the Ingredients to the Best Advantage

This article contains advice on the best fruit to choose, as well as simple and excellent recipes.

See also Jam; Jelly

Although marmalade is the name originally given to a preserve of Seville oranges, other fruit preserves are now included as marmalades. Sweet oranges and lemons are used in conjunction with Seville oranges; lemons and tangerines make delicious preserves, and grape fruit, melons, pineapples, and quinces are also made into marmalades.

The making of marmalade is rather a tedious process, as much depends on the preparation of the fruit, and this must not be done carelessly if a good preserve is to be made. All the rinds must be shredded finely, and all pips and pith removed. The cutting can be facilitated if a marmalade machine is available; these can be bought quite reasonably, or sometimes a machine can be hired for a shilling or two. Some people prefer the peel sliced coarsely, in short sections, after the manner of Oxford marmalade, in which case it is necessary to cut it with a knife by hand.

Success in marmalade making depends on sound fruit, good sugar, and careful preparation and boiling. Experts say that the earliest shipments of Seville oranges make the finest marmalade, February and March being the best months. Certainly they are most plentiful and at their cheapest then. A good quality of fruit should always be used, and it should not be under-ripe or over-ripe. Overripe fruit is not worth preserving, as it will not keep, and the marmalade is sure to ferment and turn mouldy in a very short time. Under-ripe fruit is lacking in juice, and contains a large proportion of hard pith and skin, which has to be discarded. Also the under-ripe oranges do not contain enough pectin, the jellifying quality in the fruit which is essential. No amount of boiling will make the preserve jelly if this quality is lacking.

The best preserving sugar is necessary for a good, well-flavoured marmalade, and in the long run is most economical, as it reduces skimming to a minimum. Sugar should not be added to the marmalade until the peel and pulp are tender; it is not the sugar that needs cooking, or that causes the marmalade to jelly. Its purpose is to sweeten only.

There are numerous recipes for orange marmalade, all varying a little in accordance with the experience and tastes of the makers. The proportion of water varies in each recipe, but for general guidance it is safe to say that weight for weight of fruit and water will make a solid marmalade, and for a thinner one the water may be increased to a pint and a half for every pound of fruit.

The proportion of sugar varies greatly, though pound for pound is usually advised for all Seville oranges; the length of time for boiling varies according to the quality of the fruit.

Orange Marmalade. A good general recipe for orange marmalade is to allow a pound of sugar to each orange, a pint of water to each orange, and one lemon to every four oranges. Thus, to 12 Seville oranges allow 12 lb. sugar. 12 pints water, and 3 lemons. Wipe the oranges and lemons well, quarter them and remove peel from each quarter, and take as much pith as possible from fruit and peel. Cut up the pulp roughly with a knife or put through the marmalade machine. Remove all the

pips into a separate basin. Shred the skins finely. Put fruit and peel into an earthenware pan, cover with 11 pints water, and leave to soak for 24 hours or longer. Then put the pips with the remaining pint of water in a saucepan and simmer for an hour. Strain the liquid into the prepared fruit.

Put the soaked fruit and liquor into a preserving pan, bring to the boil and simmer for an hour. The marmalade must never boil rapidly, as this toughens the skins. Then add the sugar, stir well and simmer gently for another half hour, removing scum as it rises. Use a wooden spoon, as a metal one will taint the preserve.

Test the marmalade on a plate; if it jellies when cold it is finished, but longer boiling may be necessary. Too long boiling makes the marmalade dark and gummy, so do not leave it too long without testing.

When finished pour off into warmed, dry jars, leave until cold and cover securely, first with a piece of waxed paper on top of the preserve, and then with a thick gummed circle that comes well down the side of the jar to keep it airtight. Store in a cool, well-ventilated place.

Marmalade Machine. Type requiring the fruit to be inserted from the top. There is also an attachment at the side for cutting French or runner beans.

Jelly Marmalade. To 12 Seville oranges allow 3 sweet oranges and 2 lemons. Peel the fruit very thinly, cutting none of the white part with it. Cut the peel into the thinnest possible strips and tie them in a muslin bag big enough to allow them to swell. Remove all the white inner rind from the fruit, and cut up the fruit coarsely, making about three pieces out of each.

Leave the pips in. Put the bag of orange peel strips and the fruit into an earthenware pan, cover with 12 pints of cold water, and let it stand overnight.

Next day boil all together rather quickly for three hours, then remove the muslin bag and empty the strips into a basin. Strain the pulp twice, and add the strips to the strained liquor. Weigh it, and add an equal weight of sugar. Clean out the preserving pan, and put in the syrup and boil until it sets—about 25 or 30 minutes. Let it stand half an hour before pouring off into jars.

Lemon Marmalade. To every pound of fruit allow 3 pints of water. Slice the lemons very thinly, removing the pips. Let the fruit stand in the water for 24 hours, and let the pips soak in water to cover them. Then strain off the water from the pips and add to the rest, and boil the whole until the lemons are tender. Leave to get cool, or pour off into an earthen vessel and leave until next day. Then weigh the pulp again, and to every pound allow 1½ lb. preserving sugar. Boil again until the strips of lemon become transparent and the pulp jellies.

Tangerine Marmalade. Tangerine marmalade is made by using 6 Seville oranges, 2 sweet, 6 tangerines, and 1 lemon. Pare the fruit finely, and divide it. Put the pips to soak overnight in ½ pint water. Shred the rinds finely and weigh them, allowing 2 pints water to each lb. fruit. Let the rinds soak in this water overnight. Boil up next day, adding the water in which the pips were soaked, and continue boiling until the rinds are tender. Let the preparation stand for another day, then weigh the

rinds and allow 1 lb preserving sugar to each lb. fruit. Boil up until it reaches the jelly stage. This should take about $\frac{3}{4}$ hour.

Grape Fruit Marmalade. Wipe the fruit, remove rinds and slice thinly. Remove the white inner tissue, pith and seeds. Cut the fruit in slices. Weigh the pulp, and allow pound for pound of sugar. Put pulp and rind in a preserving pan, just cover with water and boil till rinds are tender. If the marmalade seems too bitter, the water should be changed once. When rind is soft, add the sugar, and simmer until the marmalade sets when tested on a plate.

Melon Marmalade. Canteloupe, citron, or musk melons may be used for marmalade. Quarter the melons, but do not peel them. Take out the seeds, weigh the fruit and allow a pound of sugar to every pound. Grate the melons on a suet grater, discarding the rinds. To every three pounds of pulp allow the grated rinds of two lemons and a teaspoonful of ground ginger. Put all (including sugar) into a preserving pan, and let it boil gently until it thickens and sets well. Stir steadily from time to time to make it smooth, and remove scum as it rises. When it is done pour into pots and cover while hot.

Ginger and Marrow. An excellent but cheaper marmalade of the same type as the one described is made by allowing 1 lb. sugar to each lb. vegetable marrow. To 6 lb. marrow should be added 6 lb. sugar, 6 lemons, 6 oz. green ginger, 2 oz root ginger, and $\frac{1}{2}$ teaspoonful cayenne. The marrow is pared, pips removed, and cut into square pieces of roughly 1 in. Peel lemons, shred the rinds, cut up the root ginger, and put the juice, shreds and marrow into a large pan with the ginger and sugar. Let them stand until the juice covers them. This takes about 24 hours. Boil until the marrow is quite transparent. No water is added.

Pineapple Marmalade. Remove the peel and eyes from the pineapple; pass the fruit through the mincer, weigh and allow $\frac{3}{4}$ lb. sugar to every lb. fruit. Mix the sugar and fruit well and leave in a bowl overnight. Next day put into a preserving pan and simmer gently for an hour or until it sets. The large quantity of juice in pineapple makes it unnecessary to add water. Pour the marmalade off into warm jars and tie down while hot.

Quince Marmalade. Quince marmalade is prepared by peeling and quartering the fruit, removing the cores, and then putting the latter, together with the peelings, into a pan containing just enough cold water to cover them. Boil them over a slow fire until their flavour has been well extracted. Then strain the liquid through a fine sieve and let it cool. After weighing the quinces, put them into a pan, pour the strained liquid over them, and then cook them until they are a pulp, pounding them with a spoon if necessary. For every pound of fruit add $\frac{3}{4}$ lb. preserving sugar, stirring carefully until the latter has dissolved. Boil up the marmalade and continue boiling until it sets, when it may be potted.

MARMALADE PUDDING. To make a boiled marmalade pudding, chop finely 5 oz. suet and put it into a basin with 5 oz fine breadcrumbs, 2 oz. flour, the grated rind, of a lemon, 3 oz. brown sugar, and a pinch of salt. Into a small basin put 5 oz. orange marmalade, a tablespoonful of golden syrup which has been warmed, and 2 eggs. Beat all well together, then add nearly 1 gill milk. Mix the dry ingredients, make a well in the centre, and work in the eggs and marmalade. It must then be turned into a well-greased pudding-basin or mould and steamed for $2\frac{1}{2}$ hours. It should be served with marmalade sauce.

MARMALADE SAUCE. Mix a small dessertspoonful of arrowroot into a thin paste with cold water, then add $\frac{1}{2}$ pint boiling water, stirring it into the arrowroot by degrees. Turn all into a saucepan, and boil for 2 or 3 min.; add the juice of $\frac{1}{2}$ a lemon, 1 dessertspoonful white sugar, and 2 tablespoonfuls marmalade. Simmer for 2 min. before serving, but stir all the time.

MARMOT. A somewhat harsh fur, marmot is usually of a greyish black colour in the ground, becoming lighter and more yellowish-red at the top. The hair is reddish, stiff, and often speckled with black. It is usually dyed to imitate the more costly mink, and in this form is used for making wraps and coats.

MAROCAIN. A soft lustrous material of silk or mixture of silk and wool, or of all wool, marocain can be obtained in various qualities. This material, being heavier than crêpe-de-chine, drapes well for dresses, and is also used for light-weight wraps and coats. It is obtainable in plain colours or patterned.

MARQUEE. A large tent or marquee is constructed with two upright poles with the canvas formed in a ridge between them. It is generally oval in shape, or rounded at the ends with straight sides. A marquee is often erected on a lawn for refreshment service accommodation and for sheltering the guests at social functions or during sports. *See* Tent.

MARQUETRY AND ITS PROCESSES

A Decorative Handicraft Explained and Illustrated

In addition to Inlaying and Veneer, our readers are referred to the entries on the various woods used, e.g. Ebony; Satinwood: and to the articles that can be decorated with marquetry, such as Cabinet; Grandfather Clock; Knife Box; Screen. *See* also Buhl; Louis Style.

Marquetry is a form of inlaying in which the effect is obtained by the use of veneers applied to a groundwork. The inlays and the background are cut at once, the process affording scope for many artistic and elaborate effects.

In Italy marquetry was used to decorate caskets during the 15th century. Ivory and natural woods were employed. The form known as intarsia was first executed there in the 16th century. Geometrical designs were used, but later floral and pictorial decoration was applied in this manner. By the end of the 17th century marquetry was lavishly employed on Continental furniture, and by the 18th the great English designers, with the exception of Chippendale, used it freely to decorate cabinets, bureaux and smaller pieces. The secretaire shown in the first illustration gives an idea of the delicate and beautiful design and workmanship of the best French marquetry in the 18th century. Modern English marquetry work in the form of panels chiefly used for decorating sideboards, cabinets, screens, and mirrors, shows fine design and craftsmanship. The floral panel of the fire screen illustrated is beautifully executed in woods of contrasting colours, and the panel which decorates the sectional mirror is suggestive of the charming work that can be carried out in a simpler design.

Fig. 1 illustrates the principle of marquetry work. Two sheets of veneer of different wood or colour are fastened together and a saw cut made through the two, as in Fig. 1 A. They are then separated and the pieces interchanged, as in Fig 1 B, thus obtaining the required inlay. The remaining parts (Fig. 1 C) would form another inlay, though it is seldom possible to use them for the same job, as the background usually has to match the wood of which the piece is made. In commercial work the

cutting is done with a power or treadle saw, but an ordinary fretsaw frame with a very fine blade will serve the purpose quite well.

Marquetry. Secrétaire in marquetry with inlay of flowers, marble top, ormolu mounts. The upper part has a falling front enclosing two drawers, the lower is a cupboard. French; period of Louis XV. (By permission of the Director, Victoria & Albert Museum, South Kensington)

Left. Mirror with pictorial panel in marquetry. (Courtesy of A. J. Rowley, Kensington)

Fire screen in modern marquetry, the panel being in woods of contrasting colours.

Fig. 2 shows the type of donkey used by the trade when the marquetry is still cut by hand, and is quite a simple structure to make. The worker sits astride the form and places the work between the two thicknesses of wood at the head. A firm grip is obtained by placing the foot on the treadle, which being connected to the outer thickness of wood by a rope, draws it inward toward the other. The advantage of the donkey is that the work is easily removed or altered to another position, leaving both hands free, and is fixed at an easy height.

A similar type is shown in Fig. 3, and is fixed in an ordinary bench vice, the two thicknesses being gripped with a thumbscrew. The front and main thickness should be of 1 in. stuff and the back $\frac{1}{2}$ in.

The wide range of material for inlaying is not confined to wood. Tortoiseshell, ivory, brass, and other metals have all been used, besides stained wood. The direction of the grain in the inlay plays a great part. Where the inlay occupies a small space in a large

panel, it is only necessary to put a small portion of veneer sufficient for the inlay in the required position, but in a panel such as is seen in Fig. 4, where the inlays are distributed fairly evenly over the whole panel, the inlay and background veneers should be of the same size. In this case two different woods are used for the inlays, so that three thicknesses of veneer will be used. If two panels are required six thicknesses are cut, two of each kind of wood. The cross-banded edge and the inlaid line would not be cut in the marquetry, but would be applied after it had been laid.

Either knife or saw cut veneers may be used, though if only a few thicknesses are to be cut it is advisable to use saw-cut; being thicker, it is not so liable to split during the cutting process. If knife-

cut is used, even though only one panel is required, it is generally a better plan to cut an extra panel and so get extra thickness to cut, as the firmer the substance the easier the cutting will be. All the veneers for a single panel must be either knife or saw cut, as it is impossible successfully to lay marquetry cut from veneers of different thicknesses.

Marquetry. Fig. 1. Three stages showing principle of the work. Fig. 2. Donkey with treadle. Fig. 3. Donkey which can be fixed in an ordinary bench vice. Fig. 5. Example showing use of two woods only.

A Simple Pattern. Fig. 5 is an example of marquetry using only two woods, oak and ebony, the right-hand side showing the finished panel with oak background and the left vice versa. As the design fairly covers the whole background, both sheets of veneer will be of the same size. First prepare a careful drawing of the design on paper, with the woods to be used marked (though where only one inlay is used this is hardly necessary), and make a tracing of it.

Prepare the two sheets of veneer and glue them together with thin glue, and with a sheet of paper between, so that they can be separated later. If two panels are to be out, place the oak and ebony sheets alternately, and when they are cut and separated, interchange the adjacent sheets. It is of vital importance that the thicknesses should be as close together as possible, otherwise they will be apt to split during cutting. When glueing they should be placed between two flat boards and cramped together. Paper should be put between the veneer and the boards, to prevent them from sticking one to the other.

When dry, paste the tracing on one side, and, fastening the work in the vice, cut round the design carefully right on the line with a very fine fretsaw. It is necessary to bore holes in which to start the saw, and these should be as fine as possible and in such a position as not to be noticeable; this is usually where two curves meet. The saw must be held quite square to the work, so that the parts will interchange perfectly, and should be proceeded with in such a way that the panel is not unduly weakened. Do not cut away the centre portion first, as this would render the veneer liable to split, especially when afterwards cutting the outer shape across the grain at the top and bottom. When any part is cut completely out, like the small pieces in each corner and the centre, mark on it the part from which it was cut and its position, so that it can be replaced afterwards.

Having cut the complete design, the next step is to separate the thicknesses. This is done by easing the parts away with the thin blade of a knife, so that the paper splits. If any difficulty is found from the glue having been too thick it is advisable to weaken it by placing the veneers between two sheets of damp blotting paper and laying a weight on top. The moisture will then percolate through the wood, when the pieces may be separated easily. The various portions of the adjacent sheets are interchanged and the whole glued on to a sheet of paper, using thin glue. Apply the glue sparingly, or the veneers may buckle. See that the various parts lie together flat; it may be necessary to put them under a weighted board for this purpose, though glueing down on to the paper is usually sufficient. When dry the veneer may be glued on to the groundwork.

Using Two Inlays. Fig. 6 is another example of marquetry, embodying the use of two inlays (satinwood and a green stained wood) on a mahogany background. In this case the inlays occupy a relatively small space in the panel, the flower and the base only being in satinwood and the stalk and leaves in green wood, so that it will be necessary only to cut pieces sufficiently large to cover the local inlays. The dotted lines show the position in which these are placed, the green piece being put on the mahogany background first and the two pieces of satinwood on the green wood afterwards. The tracing is pasted to the flat mahogany side, care being taken to see that the various parts of the design come opposite to their corresponding veneers. The cutting is then proceeded with in the usual way.

The lines forming the divisions to the petals in the flower are formed by saw cuts. As the whole of the flower is intended to be in satin-wood only, it is advisable not to let the division lines run quite down to the juncture with the stalk, so that the flower will remain in one piece, thus saving the unnecessary labour of putting them together again. The lines are shown running right through in the sketch, since it might be desired as an alternative to form the flower with petals of alternate satin and green wood, instead of all satin, in which case the cuts will run right through.

The necessity for good workmanship in marquetry is seen when cutting small panels. The practised fretworker will find little difficulty in cutting out the shapes, but the beginner should have some

preliminary practice in making even saw cuts before attempting any elaborate work. It is a good plan to glue odd pieces of thin fretwood of contrasting colours together with a sheet of paper between them. A suitable but simple design should be drawn on one piece, and then cut out.

The use of colour in marquetry is a valuable help in working out suitable designs. White woods, especially sycamore, can be stained by aniline dyes to almost any required shade, and brightly stained woods contrasted with dark woods will give some fine effects.

The groundwork must be of a suitable wood to hold the glue well, free from knots, and able to stand well without shrinking or twisting. It must be prepared perfectly true and flat, and must be toothed. Honduras mahogany is the ideal wood to use for a ground, though yellow pine is also good. This latter should be given a coating of size after toothting to fill in the grain, and left to dry, as otherwise when the marquetry is applied the pine would soak up more than its fair share of the glue and leave the marquetry liable to peel off.

Fig. 4. Panel with evenly distributed inlay. Fig. 6. Two inlays, satinwood and green stained wood, in a mahogany background. Fig. 7. Laying marquetry by caul method; top cross piece curved on underside. Fig. 8. Pressure applied, forcing glue outward. Fig. 9. Plan of apparatus used in this process.

Laying the Marquetry. It is not possible to lay marquetry with a hammer, as is done with some kinds of plain veneer, so what is termed the caul method is used. Figs. 7, 8, and 9 give an idea of the kind of apparatus which is wanted. The caul is a piece of wood slightly larger than the ground and about 1 in. thick, and quite flat; this is to lay on the veneer and press it equally all over. The cross-pieces are slightly longer than the width of the ground, those for the bottom being square. The top

pieces are straight on the top edge but are curved slightly on the underside (Fig. 7), so that when pressure is applied to the ends the glue will be forced from the centre outward (Fig. 8). The shaping is rather exaggerated in the diagram, but about $\frac{1}{4}$ in. will be sufficient in a length of 2 ft. The lower crosspieces must be wider than the top ones, so that the pressure bends the top pieces straight. Two cramps or handscrews are required to each crosspiece.

The ground, being ready, mark centre lines in the length and breadth of both the marquetry and the ground; this will give the exact position for it to be fixed. The lines should be marked on the paper-covered side of the marquetry. Glue both the ground and the marquetry; place the latter in position and drive in two fine veneer pins to fix it temporarily. The marquetry should be paper side upward, so that the glue grips the wood. Now lay a sheet of paper over the whole.

Heat the caul thoroughly on one side, place it on the paper and apply the centre cross-piece, tightening each cramp a little at a time so that pressure is applied gradually from the centre outward. Fix on the other crosspieces and give all the cramps an extra screw, and leave it to set. The whole process of applying the caul should be gone through as quickly as possible, because if the glue once chills it will be impossible to squeeze it out, and a repetition of the process will be required.

Cleaning Up. To clean up the work when set, a steel scraper is used, and care must be taken to work this so that it does not tear the grain up, especially where the grain of an inlay runs counter to that of the background. The job is finished off with fine glasspaper, and the two pins used temporarily to secure the veneer should be removed before cleaning.

MARRIAGE IN ITS LEGAL ASPECT

The Responsibilities of Husband and Wife Outlined

For the ceremony of marriage our readers are referred to the articles Wedding and its subsidiary entries, e.g. Bride; Trousseau. See also Divorce; Husband.

Marriage was defined according to the law of England to mean the union for life of one man and one woman to the exclusion of all others, or the union of two people who promised to go through life alone with one another. Consequently English law does not recognize polygamous marriages. In order that a marriage may be legal the following requisites must be complied with:

Husband and wife must be of marriageable age, i.e. 16 years of age. They must be of such a mental condition as enables both of them to know and appreciate the fact of the marriage. If it can be proved that one of the parties to a marriage ceremony was incapable of knowing or appreciating what he or she was doing the ceremony is null and void.

The parties must consent to the marriage, and this involves the proposition that each of them knows what the ceremony means. Instances have occurred where both boys and girls have been entrapped into marriage, being told it was something else, particularly in out-of-the-way colonies and other countries where people can go before a magistrate or other person and by signing a paper are declared to be married. Any such marriages can be nullified.

There must be no legal impediment. A table containing the list of marriages prohibited will be found in the Prayer Book. To-day a man may, however, marry (1) his deceased wife's sister; (2) his deceased brother's widow; (3) his deceased wife's brother's (or sister's) daughter; (4) the widow of the brother of his father or mother; (5) his deceased wife's father's (or mother's) sister; (6) the widow of the son of his brother or sister. A marriage according to Church of England rites may be by special licence from the Archbishop of Canterbury, by common licence from a bishop or his surrogate, after banns, or after notice to a registrar.

The Archbishop of Canterbury's licences may be given entirely at his Grace's discretion, and may authorize the marriage in any place and at any hour. The bishop's may only authorize the marriage

in a church or chapel in which banns might have been lawfully published, and the marriage must be between 8 a.m. and 6 p.m. Banns are to be published in the church, and the clergyman is entitled to seven days' notice in writing.

Publishing the Banns. Where the parties live in different parishes the incumbent of one parish shall not solemnize the marriage without a certificate from the incumbent of the other parish that the banns have been called there also. The parties must be married within three months after the publication of the banns, which are to be published in an audible manner during three succeeding morning services, or, if there is no morning service, during the evening service, and it must be on a Sunday. People who do not desire banns to be called may be married according to the rites of the Church of England after having given notice to the superintendent registrar, who publishes the notice in the proper manner for at least three weeks. In all marriages in the Church of England the ceremony must be performed by a clerk in holy orders. It is doubtful whether a deacon can perform the ceremony, though it has once been decided that he may.

Marriages may be solemnized according to the rites of other religious bodies in certain registered buildings and by registered persons, or in the presence of the civil registrar. A marriage in a register office can take place before the superintendent registrar of the district. This official is not allowed to perform a religious ceremony.

The Marriage Licence. In England and Wales marriage licences are of two kinds, those issued by the officials of the Church of England and Wales for marriage in a building belonging to that form of faith, and those issued by a registrar for marriage in a church or chapel belonging to Nonconformists and registered for marriages, or for marriage in a district register office.

As regards the Church of England marriage, licences can be obtained in London by application at the faculty office, at the vicar-general's office, and at the bishop of London's registry, by one of the parties about to be married. Elsewhere they may be obtained at the offices of the bishops' registrars, but licences obtained at a diocesan registry only enable the parties to be married in the diocese in which they are issued. Those procured at the faculty office, 23, Knightbridge Street, Doctors' Commons, London, E.C., are available for London and all England and Wales; those procured at the vicar-general's office, 1, The Sanctuary, Westminster, London, S.W.1, are available for London and all England and Wales, except the province of York.

No instructions, either verbal or in writing, can be received except from one of the parties. Affidavits, are prepared from the personal instructions of one of the parties about to be married, and the licence is delivered to the party upon payment of fees amounting to 30s. in addition to the cost of stamp, 10s. No previous notice is required, and the licence is available as soon as it is issued. The cost of licences in the country varies, according to the diocese, from £1 15s. to £2 12s. 6d.

To secure a licence for a marriage in a Nonconformist place of worship or a register office, notice must be given personally to the superintendent registrar of births, deaths, and marriages, or the deputy of such officer. One notice only is necessary, whether the parties live in the same or in different registration districts, and either party may give the notice. If both live in the same district, one of them must have lived there for 15 days before notice can be given.

If the parties are living in different districts, and both have fulfilled the necessary residential qualification, notice may be given in either district- If one only had fulfilled the qualification, the notice must be given in the district in which the residence has been fulfilled, and the other party must be resident in England or Wales when the notice is given. The notice contains particulars as to names, ages, residence, length of residence, and the building in which the marriage is to take place.

After the lapse of one weekday, not Christmas Day or Good Friday, from the date of the entry of the notice, the superintendent registrar may, provided no impediment is shown, issue his certificate and

licence for the marriage, which can then take place on any day within three months from the date of the entry of the notice. For a marriage by licence of this kind the total fees are £2 10s. 0d. For marriages in Scotland no licences are necessary, banns or notice by a registrar being substituted. They can take place in a private house or in a hotel.

Consent of Parents. The consent of parents is only necessary where one of the parties is under the age of 21. If, however, a young person under age makes a runaway match and marries without the parents' consent, and even in spite of the parents' prohibition, the marriage is lawful. Any minister or registrar, however, who marries an infant after having been prohibited to do so by the parents or guardians and also the infant himself is liable to severe penalties.

Marriages with Foreigners. In the case of marriage with a man who is a foreigner an Englishwoman may find herself awkwardly situated unless she takes care to find out how far he is at liberty to marry her, and whether or not any consents are required according to the law of his domicile. For instance, the French law is very strict, and even though a man may be an adult it requires that before he can be lawfully married he shall obtain the consent of his parents.

An Englishwoman who marries in this country a domiciled Frenchman who has not obtained the proper consents is recognized as married by the English courts, but in France her marriage is not valid. It is wise, therefore, for an Englishwoman who intends to marry a foreigner in England to make previous inquiries at the office of the consul for that country, so as to ascertain whether or not it is essential to procure anybody's consent to the marriage.

Under the Marriage With Foreigners Act, 1906, arrangements may be made with foreign states for the issue by the proper officer of those states of a certificate that due notices have been given. The foreigner may be required to give notice to the persons by or in whose presence the marriage is to be solemnized of the fact that he is subject to the marriage law of the country. He must get his government's official to issue a certificate that the notice required has been given, and that no impediment exists or that proper consents have been given. Anyone who celebrates a marriage where such a certificate is required without that certificate having been given is liable to a penalty not exceeding £100, or to imprisonment not exceeding a year. This law does not apply to marriages between two Jews solemnized according to Jewish law.

Valid and Invalid Unions. In England it is an offence punishable by fine and imprisonment to give wilfully a false name on being married, but the marriage is not rendered void. A marriage is apparently void where it is celebrated according to the rites of the Church of England after publication of banns if false names are given and both parties know that the names that have been given are false.

An Anglican marriage is void unless it is celebrated by a person in holy orders. It is also void if not celebrated in a lawful place, i.e. a church or chapel of the Church of England, a registered place of worship of any other denomination, a place authorized by the archbishop by a special licence, or a register office. As to marriages which take place abroad, the foreign law applies, save that the marriage must be of such a land that it comes within the English definition of marriage, i.e. it must not be a polygamous union.

Sometimes foreigners living in England attempt to celebrate marriages in places of their own which are not registered for the purpose. Such alleged marriages are void according to English law except, it may be, where both parties are subjects of a foreign state and they go through the ceremony of marriage within the precincts of the embassy of that particular state.

Another point to be noticed is that, although as to the form of a marriage celebrated abroad the courts in England will recognize that form, they will not recognize the validity of a marriage between English people who could not have married in Great Britain. Thus, before the passing of the Deceased Wife's Sister Act, the English courts did not recognize a marriage abroad between an Englishman and his deceased wife's sister.

Marriage at sea on a British ship is a marriage in Britain and can be celebrated by an episcopally ordained clergyman or minister. There is authority for saying that a marriage celebrated by the captain is not valid.

The law as to what constitutes a valid marriage between British subjects abroad is not altogether clear. A marriage celebrated anywhere according to the law of that country in the presence of an Anglican, Roman Catholic, or Greek clergyman is valid; but cases arise where no clergyman can be found, as, for example, in remote parts of India or Australia. It has been held in some cases that where the parties intending to go through a ceremony of marriage bound themselves by words representing the fact that they are taking each other in marriage, the marriage is lawful. On the other hand, it has been held that where two people went to the British consulate in Smyrna and were married without the presence of a clergyman it was void.

In the case of public vessels, commanding officers of a certain rank are authorized under Admiralty instructions to act as marriage officers. They can, it appears, lawfully perform the ceremony of marriage on such vessels while at foreign stations, but only if one party to the marriage is a British subject, and if the ship is not at a port or place where there are facilities for marriage in the ordinary way.

The Medical Side. A medical man is rarely consulted by persons about to marry, and in the vast majority of cases there is no need for medical advice; but, on the other hand, there are many cases where marriage should be delayed, and more than a few where it ought to be avoided altogether.

A very early marriage is usually undesirable, though there are exceptions to this rule, because the development of the body does not always correspond with age. So far as the wife is concerned a late marriage has also its risks. From the age of 30 to 35 onward the pelvis (or bony cavity at the lower part of the body) grows more solid and rigid. When a child is born, the bone-encircled outlet through which it passes does not yield so readily as it does in a younger woman, and hence labour may be slow and painful. Apart from rickets or other disease, this is not the case in a woman who marries earlier in life, has her first child before she is 30, and continues to bear children thereafter.

Probably the best time for a woman to marry is between the ages of 23 and 27. But in most cases there is no reason why she should not marry a year or two earlier or three or four years later. A woman with very narrow hips would, therefore, do well to consult a doctor before marrying, or at any rate some time before the birth of her first child is due. Sometimes the pelvis is not alone small, but misshapen, perhaps as a consequence of rickets. This, again, is a case for medical advice. Whether such a woman should marry at all is a question that will depend on the nature of the deformity.

There are certain diseases which should prevent the marriage of prudent people. Thus, serious heart disease (either in a man or a woman), Bright's disease, consumption, epilepsy, or any mental affection, makes marriage very undesirable. It is often a difficult question to answer whether an apparently normal-minded person in whose family insanity has appeared should marry. A good deal depends on the cause and type of the insanity; but medical advice should always be sought.

A woman should never marry a man who is a confirmed drunkard. Very many women make the great mistake of believing that they can reform such a man. If a man habitually drinks to excess before marriage, he will almost inevitably continue his bad habit after it. And not only will the wife suffer, but the children are very likely to turn to drink also, or to suffer from some nervous disease.

As to the marriage of cousins, it may be said that in the children of such parents any peculiarity of constitution common to both father and mother is very likely to be intensified. Cousins may, therefore, marry with safety if both are healthy and if there is no such disease as epilepsy, insanity, pronounced hysteria, etc., in their families. The danger of cousin marriages is that both may have the same kind of constitution, and, if any family disease exists, both may combine to transmit a tendency to the development of this disease in an intensified form to their children.

It was said above that both very early and late marriages are inadvisable. The same applies to the marriage of a young woman to an elderly man, or vice versa. Precisely what disparity of age is allowable it is impossible to say. Many young women can be happy with husbands considerably older than themselves, while to others life will be a continuous round of discontent. As a general rule, it is best that the wife should not be much older than the husband, and that the husband should not be more than 10—at the most 15—years older than the wife.

The Marriage Settlement. When people of means are about to marry, it is usual for them to set aside a certain amount of property to make provision both for themselves and for the offspring of the marriage. This specially applies to people with landed property which has been in a family for some time.

The form of such settlements is as follows: Two or more trustees are appointed, one by the intended wife and one by the intended husband. A deed is drawn up to which the intended husband and wife and the trustees are parties. The intended husband conveys to the trustees or transfers to them whatever property he intends to put in settlement, and the intended wife does the like. The deed directs the trustees to hold this property, until the marriage has been celebrated, for the intended husband and wife respectively; and, after the marriage, to pay the income as directed.

A Typical Example. Where the major part of the property is settled by the husband, it is usual for the income of it to be paid to him during his life, and, after his death, should he die before the wife, to pay part of the income to the wife. As to the capital, the husband is generally given a power to appoint it amongst the children of the marriage in such proportions as he thinks fit, and if he does not do so, then his wife may, if she survives him; and if neither of them does so, then the children of the marriage are to take equally. The wife's property is settled on her in the same way, herself for life, then her husband for life, and then the children as appointed.

The above describes an ordinary settlement of stocks, shares, and other invested moneys. In the case of land, however, it is different. The family estate is settled to be held by the trustees in trust for the husband for life, with an allowance to the wife; and, after the husband's death, a certain income or jointure is to be paid to the wife, a certain sum is to be paid to younger sons and to daughters when they attain the age of 21 or marry, and the land is to be held by the trustees in trust for the eldest son of the marriage in tail. This deed is called a family settlement.

A genuine marriage settlement, i.e. one made before and in contemplation of marriage, is a contract and conveyance for valuable consideration, because marriage is the most valuable of all considerations. Consequently, it cannot be attacked as fraudulent, i.e. as putting property out of the reach of creditors, unless the marriage itself was part of a scheme to defeat creditors.

If the husband who has made the marriage settlement should go bankrupt, his trustee in bankruptcy can seize for the creditors his life interest in the settled lands or funds, but he cannot seize the land itself or upset the settlement on the ground that when the husband made it he was heavily in debt. To this rule there is an exception, if a man and a woman get married on purpose so that the man can make a settlement of his property on the woman so as to put it out of their creditors' reach, the settlement can be upset as a fraudulent conveyance. But this can only happen if both the man and the woman were parties to the fraud.

The person who is to receive the rents and profits of the land through the trustees for his life is called the tenant for life, and has very extensive powers of management of the estate. Put briefly, he has power to deal with the estate almost as if he were the absolute owner of it. He can grant leases of the property, he can sell it, all except the principal manor house and any heirlooms, and even these he can sell by leave of the Court; but any capital moneys received must always be paid over to the trustees, who will invest them and only pay the income derived from them to the tenant for life.

MARRIAGE: The Card Game. This card game is suitable for two players. It is played with the piquet pack of 32 cards, i.e. all from the seven upwards, and is won by a game of 66 points. The values of the cards are as follows. The ace counts 11 points, the ten 10 points, the king 4 points, the queen 3, and the knave 2; the other three have no scoring value. Trumps are played in this game.

As in piquet and similar games, scoring is from cards in hand and from cards played. The scores for cards in hand are, for a marriage, i.e. king and queen of an ordinary suit, 20 points; and for a love, i.e. ace and ten of an ordinary suit, 30 points. For marriage and love in the trump suit these scores are doubled, i.e. 40 points and 60 points. In the outplay the counting cards played and taken give the score. Sixteen points are added for the last trick taken, and 20 points if the last six tricks have been won by one hand alone.

The players cut for deal and the lower cut deals. He gives 6 cards to each player and turns up the 13th card to show the trump suit. The remaining cards form a stock from which the players draw. The play begins by the non-dealer leading. The dealer can then, if he so wishes, play a card of another suit, as he need neither follow suit nor trump. These two cards form a trick, and the winner of this trick leads in the following one.

The winner of a trick can now declare any marriage or love he may hold; if it is good it is scored at once. Each love and marriage must always be shown before scoring for them, and one card of the proved love or marriage cannot be played at once. The winner of the trick next draws the top card from the stock and the loser draws the one below it. This occurs after every trick until the stock is exhausted, so that during the earlier part of the outplay each player has six cards in hand.

Marriages and loves can be made whenever convenient, but only by the winner of the trick immediately preceding. A declaration cannot be made after the stock is closed, nor after the first card of the eleventh trick is played. That is to say, during the last six tricks no declarations are valid. With equal loves or marriages the non-dealer or elder hand scores on declaration; the other player does not.

A player holding the seven of trumps may exchange it for the turned-up card when it is his turn to draw, and as long as the stock remains unclosed or unexhausted. When a seven or the last card from the stock is drawn, it cannot be exchanged. After drawing either player may declare the stock closed, and after that no player can draw a card from it. The one who closes it must thus win the game in the outplay by completing 66 points; if he fails to do so his opponent becomes the winner, even if he has not reached 66 points and has a score lower than that of the closer.

MARRON GLACÉ. This sweetmeat consists of chestnuts preserved in sugar. To make them, procure some large chestnuts and remove the shells. Boil the chestnuts, putting them into boiling water, for about 15 min. Drain them and remove the skins. Boil up again and continue to boil until the nuts are tender, but do not break them, Put them aside to cool, and make a syrup of 1 lb. sugar to ½ pint water and boil to the temperature of 290° F. Take up the chestnuts with a pair of sweetmeat tongs and plunge them in the syrup, one at a time. Place the chestnuts on an oiled slab to dry, not touching one another.

MARROW IN GARDEN AND KITCHEN

Its Cultivation and Some Attractive Recipes

After describing the growing of the marrow, our article goes on to deal with various ways of cooking it. See also the article on Marmalade. For further information see Frame; Greenhouse; Hotbed; Kitchen Garden: Manure; Pumpkin.

The vegetable marrow, although regarded as a vegetable in cookery, is a fruit, like the tomato and the cucumber. It is a half-hardy annual trailing plant, with edible fruit.

There are numerous varieties of the vegetable marrow. Of those with large fruits Long Green and Long White are favourites. Moore's Cream, Penny Bush, Rothschild Orange, and Table Dainty are excellent small marrows. The bush and custard marrows are less vigorous in growth than the trailing varieties.

How to Cultivate. To grow good early marrows, the seeds should be sown under glass early in April in pots of light soil, in a greenhouse in which a temperature of 50° to 55° may be safely maintained. As soon as the plants are large enough to handle, they should be shifted into 6 in. pots. Before being planted out of doors in May they should be hardened off. Marrows may be grown on turf heaps, even on a heap of garden rubbish, or on the ground level in manured soil. Three or four successional plantings may be made at intervals of a fortnight until the end of June, or seeds can be sown out of doors in May. As soon as the leading shoots reach a length of 18 in. to 2 ft. they should be pinched out, and care should be taken that the runners are trained evenly over the ground.

Marrow. Right, well-grown specimen of a green marrow. Left, a round marrow.

Marrow Culture. 1. How to prepare a mound. 2. Seed sown in pot. 3. Seedling potted-on and ready for planting out. 4. Fruiting and non-fruiting blooms: a, male; 6, female. 5. Plant in position: a, shelter; 6, glass; c, weight; d, ventilating block. 6. When and where to stop in order to swell fruits. 7. Artificial feeding: worsted taken through stem with ends in water.

Fertilization should be carried out when the first of the female blooms make their appearance. This is done by stripping male flowers of their petals and applying the pollen to the centre of the female flowers.

If the marrows are wanted for preserving, they should be cut before they are ripe, and hung up in a dry room by the bases of their stems. Marrows should always be cut before they are fully ripe, for they are then of superior flavour. The young shoots of marrow plants, when thinning is desirable, form an excellent substitute for spinach.

How to Cook. When prepared as a vegetable for table the marrow should be cut in halves or quartered, pared, and the seeds and pulp removed; but if intended for a made dish it is sometimes boiled whole, and after it is cold it is pared and sliced, as it remains firmer when treated in this manner. To serve vegetable marrow plain: Prepare it, put in boiling salted water to cover it, and boil from 20-25 min. Serve on pieces of toast with melted butter sauce poured over or handed round in a sauce boat.

Marrows can also be baked. Prepare a good-sized marrow and cut it in two lengthwise, remove the seeds and parboil it for about 10 min. It should now be stuffed with a good veal forcemeat, floured, and the two halves fastened together round the stuffing with white tape. Bake in a moderate oven about 20 min., basting it with plenty of good dripping and letting the marrow brown at the last. Just

before it is done strew brown crumbs over the top and baste them well. Serve with a good thick brown gravy poured round the base. Minced meat or ham may be added to the forcemeat.

Marrow can be added to fruit in pies and puddings or mixed with various ingredients and made into sweet dishes. In addition, marrows also make excellent preserve.

Cold cooked or parboiled marrow can be fried in butter or bacon fat and makes a good breakfast dish served with bacon.

Marrow au Gratin. Marrow au gratin is prepared by peeling a marrow, splitting it into four, then removing the seeds and washing it. Put it into a saucepan of boiling water to which a little salt and soda have been added, and boil it gently for about 15 min., or until it is tender. Mix 1½ oz. flour to a smooth paste with ½ gill cold water, and put 2½ gills milk to heat in a pan with 1½ oz. butter, and pepper and salt to taste. When the latter are hot, pour on the flour and water, bring the whole to the boil, and then simmer it for 6 min., keeping it well stirred in the meantime. Add 1 oz. grated cheese, pile the marrow on a slice of toast placed in a gratin dish and pour the sauce over it. Sprinkle an other ounce of grated cheese on top, then put the whole under the grill and brown it slightly.

Marrow au Gratin. Savoury and appetizing dish which can be prepared in half an hour.

Steamed Marrow. Steamed marrow is served on toast and covered with egg sauce. Put the prepared pieces in a steamer, add salt to taste, and cook them over boiling water until they are tender. Serve with the sieved yolk of a hard-boiled egg sprinkled over the top of the egg sauce.

Marrow Pickle. To pickle marrow chop 8 lb. into small chunks, lay them on a dish and sprinkle them with salt. Leave them thus for 12 hours, then put them into 3 quarts vinegar with a few cloves and peppercorns and 2 oz. root ginger, and boil all for 15 min. Next, mix together thoroughly 2 tablespoonfuls mustard, 1 oz. turmeric, a small piece of chopped cauliflower and 2 or 3 small chopped onions, a teacupful of sugar, and 1 quart vinegar. Pour these over the marrow, etc., bring all to boiling point, and add salt to taste. The pickle can be bottled when it is cold.

Marrow Pie. Equal quantities of marrow and apple are required for this pie. The marrow must be prepared and cut into fingers and the apples pared, cored, and divided as for apple pie. Fill the pie-dish with alternate layers of marrow and apple, strewing granulated sugar between each layer, also a little grated lemon rind. Cover the fruit with a good short crust and bake the pie in a moderate oven. The time for cooking depends on the variety of apple which is used.

MARROW: In Bones. The fatty substance in the interior of bones, which is known as the marrow, is the chief manufactory of the red corpuscles of the blood. Bone marrow is often given to people suffering from pernicious anaemia and other blood diseases. It can be used in the form of a glycerin extract, or spread like butter on bread or toast, and flavoured with a little pepper and salt.

MARSALA. The Italian wine made in the vineyards of Marsala is of the nature of sherry and Madeira, and is pale amber in colour with an attractive bouquet. It is served with soup or fish in place of sherry, and as a dessert wine. *See Wine.*

MARSH MALLOW: The Plant. This hardy biennial plant (*Malva sylvestris*), which grows wild in Britain, reaches a height of about 2 ft. and bears reddish flowers in summer. The roots are thick, long and tapering. They bend easily, are whitish-yellow outside, white and fibrous inside and abound in mucilaginous juice. They are sometimes used medicinally. The leaves of the herb should be picked and dried in August. *See* Hollyhock; Malva.

MARSH MALLOW: The Sweet. To make this, dissolve 2 oz. gum arabic in a $\frac{1}{4}$ pint water, then strain it. Put it into a small saucepan and add 4 oz. loaf sugar; stir till melted, then boil until a firm ball is obtained from the syrup. To test it drop a little into cold water, rub it between the fingers, and if it forms a ball it is ready.

Remove it from the fire, flavour it with orange flower water, and work in the stiffly beaten whites of 1 large or 2 small eggs. Spread this mixture out in a layer on a thick bed of confectioner's starch, which can be purchased at any large store. Cover it over with another layer of starch and leave it till next day. It should then be ready to cut into squares. Well dust the pieces with starch and pack them away in airtight boxes.

MARSH MARIGOLD. This decorative, water-loving plant grows about 1 ft. high, and bears yellow flowers in spring. The marsh marigolds are useful plants for the sides of lakes, streams, and pools. Water may be allowed to flow on the roots, or may simply permeate the surrounding soil. The best month in which to plant them is October. *Caltha palustris*, 12 in., is the common yellow marsh marigold, of which there are several varieties. The finest of all is *Caltha polypetala*, 18 in., with rich yellow blooms. Marsh marigolds have creeping root-stocks and are increased by division in spring. *See* Marigold.

Marsh Marigold. Clump of the golden water plant which will grow in a damp corner of the garden.

MARTEN: The Fur. Of the various kinds of fur obtained from the marten tribe, baum marten and stone marten are the best known. The finest of the baum marten skins are obtained from Norway, and are dark brown in colour. The tails, which are sometimes made to resemble sable tails, wear well, but in texture they are coarser than sable.

Stone marten wears and looks almost as well as baum marten, but the tails are not so good, and the skins have to be arranged in a special manner to obviate the marks caused by joins. Fisher fur is obtained from another species of marten and, like baum and stone marten, is employed for making stoles, wraps, muffs, etc. *See* Fisher Fur; Fur; Sable.

MARVEL OF PERU. This is the common name of *Mirabilis jalapa*. This herbaceous perennial is hardy only in well-drained soil in mild districts; in cold places, or heavy soil, the roots should be lifted in autumn and stored in boxes of soil under glass for the winter. It forms a bush about 2 ft. high and bears flowers of different colours on the same plant. If seeds are sown in a heated greenhouse in spring the seedlings will bloom in the summer of the same year.

Marvel of Peru, a showy perennial for a sunny, sheltered border.

MARZIPAN: The Sweetmeat. Marzipan is made from almond paste, coloured, shaped, and flavoured in a variety of ways. Marzipan potatoes are made by forming the almond paste, slightly flavoured, if liked, with vanilla, into the shape of very small new potatoes. Mark a few eyes on each, and roll them in a little powdered chocolate. To make cherries, colour the paste with cochineal and roll it in the hands into little balls. Very thin strips of angelica will make the stalks. With careful shaping, half-open pods

of peas can be made with almond paste coloured with spinach green; apricots, with saffron-coloured paste. Pastes coloured with cochineal and with saffron are joined to make an apple.

To make fruit marzipan, add, when making the almond paste, a tablespoonful of thick pulped fruit or jam to every lb. of sugar. Colour and flavour it as desired. When the paste is cool, roll it out to a thickness of about $\frac{1}{4}$ in., and ice it very thinly with royal icing. Cut it into any small shapes before the icing has quite set, and decorate each sweet with a tiny silver ball, scrap of angelica, or small piece of blanched nut.

Dried French plums or good prunes and good quality dates can be split in half and stuffed with coloured, flavoured marzipan. Attractive sweets are also made by moulding a ball of coloured marzipan, and pressing on to each side of it a blanched almond, or half a walnut that has been toasted for a minute or two in a moderately hot oven. *See Almond Paste; Chocolate; Icing.*

MASCARON. Also known as a macaroon, this is the name of a raised ornament found on Venetian glass and glass made in that style. It is a little blob of glass on which the impression of a mask or face is stamped while hot. The term is sometimes used when the design is a floral or other ornament.

In furniture the mascaron is the figure of a face, either of man or animal, used as a centre feature in decoration. It is found in pieces of the time of William and Mary, and frequently on those made in the Louis XIV style. *See Venetian Glass.*

Mascaron. Right. Cup with blue and white stripes, and gilt bosses of lions' heads. Right, bowl with spiral threads, gilt masks, and small bosses. (By permission of the Director, Victoria & Albert Museum, S. Kensington).

MASCOT. Anything given or acquired as a luck-bringer may be included under this term, from a tiny charm to the brass effigy on the front of a car. Copies in various materials of certain animals, such as a black cat, a pig (in bog oak the luck is supposed to be attracted when a leg of the mascot is broken off), or a blue bird; in gold or silver, the swastika (a Greek cross with each arm continued at right angles, the name meaning fortunate), the sign of the zodiac or special setting of the stone for the birth month, the numbers 7, 9 and 13, various charms in New Zealand greenstone and Egyptian scarabs, are all favourite mascots.

Mascots for motor cars are made in glass, or in brass or nickel, according to the metal work of the car for which they are destined. Those in glass are designed so that they can be illuminated from within by means of a bulb and an electric switch. These mascots are usually fitted to the bonnet, and frequently screwed on to the top of the petrol tank, the actual method of fixing them varying with the make of the car.

The jacinth and amethyst are considered particularly lucky gems, while a black opal is said to bring fortune to an artist if bought or found personally, but not if received. A gold-mounted hare's foot or monkey's paw, a four-leaved shamrock, white heather, or a coin with a hole in it, may be treasured as a talisman. The horseshoe when nailed up as a mascot must be turned with ends upward or the luck runs out. Grotesque animals or dolls come and go as fashionable mascots.

MASDEVALLIA. This orchid is suitable for cultivation in a glasshouse having a minimum temperature of 55 degrees. The plants must be potted in a compost of peat, orchid fibre and sphagnum moss, with sand and crushed charcoal added. The compost must be kept reasonably moist- throughout the year. When repotting becomes necessary it should be done in February. A few of the best kinds are Veitchiana, vermilion; ignea, reddish; and towarensis, white. There are many hybrids raised by cross-breeding between these and other species.

MASK. Any covering disguise for the face, or upper part of the face, with openings for the eyes and, if necessary, for the mouth, is called a mask. These have been used from the earliest times of the theatre on the stage.

Silk or satin half masks are worn at a masked ball, while the men and animal faces sold for the 5th of November and at Christmas time are bought by children for disguise and for fairy plays. Beautiful or grotesque masks are executed in a great variety of materials for wall decoration by oriental and other artists. The mask used in fencing is of iron netting with a padded frame fitting over the head and round the face to protect it from foil thrusts. *See* Fancy Dress.

MASK FLOWER. These half-hardy perennials (Alonsoa) bear small, snapdragon-like flowers in the summer time. They may be grown in pots under glass or be planted out for the summer. Propagation is by cuttings in a frame in August. The rose-red Alonsoa Warscewiczii is one of the showiest. The plants must be kept in a slightly heated greenhouse in winter.

MASONRY. The whole art and craft of working in stone, from the rough shaping of the block to the completion of the finished product, is known as masonry. The term is also used to describe those parts of a structure which are built in stone. Stone being expensive material to build with, only the facing stones are generally squared up and worked to a fair face. The interior of the wall is made up with rough material, and the inner face lined with the faced stone, or with brickwork.

Masonry differs from brickwork in that generally the stones vary greatly in dimensions, and call for greater skill on the part of the operatives to get a perfect bond. Walls made of stone have to be considerably thicker than those of a similar height in brickwork. Exceptions are when the walls are built with coursed stones properly squared and pointed, in which case the walls may be thinner than in brickwork.

MASSAGE. Method of curing various muscular, nervous, and vascular maladies by rubbing, stroking, kneading, and otherwise treating the muscles with the hand. The four principal actions in massage are termed pétrissage, effleurage, friction, and tapotement. Pétrissage or kneading is done by pressing the palm of the hand into the muscles, and grasping, kneading, rolling, and squeezing them by the thumb and finger. Effleurage, or stroking, should be done with the palm of the hand,

which at the end of a stroke should glide back to the starting point. Friction is a circular movement done with the finger tips or palm of the hand. Tapotement is done by the hands swinging from the wrists, and this movement should be light, sharp, springy, and very rapid.

Another division of the movements in massage is associated with the Swede, Peter Henry Ling. He divided them into three: active, passive, and resistive. Passive movements are done by the operator, active movements by the patient himself. Resistive movements are done while the patient resists, or by the patient while resistance is supplied by the operator. These movements increase circulation.

The National Hospital, Queen's Square, London, W.C., gives a recognized certificate. Students from other hospitals and schools must satisfy the examiners of the Chartered Society of Massage and Medical Gymnastics at Tavistock House (North), Tavistock Square, London, W.C.I.

MASTER: His Duties. The relation of master and servant is entered into by agreement. This need not be in writing unless the agreement is to be for more than a year from the day on which it is made. An agreement of service which does not state how long the service is to continue is supposed in English law to be for a year, but subject in practically every case to reasonable or customary notice.

In very many occupations there has grown up a customary period of notice. Thus, a domestic servant is entitled to give or receive a month's notice. The editor of a newspaper by custom is entitled to six months' notice. But most cases depend not on custom, but on what is reasonable. And what is reasonable depends upon the kind of service and the kind of engagement.

Length of Notice. It may be stated, as a general principle., that the higher the class of service the longer notice has to be given on either side, and this is because it is always more difficult for a man in a higher grade of employment to get a job than it is for a man in a lower grade, and it is also more difficult for the employer to procure a new servant of a higher grade than of a lower grade. Thus, an office boy would be entitled to a week; a managing clerk to at least a month. But as judges and juries may take different views of what is reasonable, it is always wise in a contract of service to stipulate for a particular length of notice.

It is the servant's duty to serve faithfully. This implies an obligation not to disclose his master's secrets. A servant who does this may be restrained by injunction from continuing to disclose such secrets, and is also liable for damages. It is also a servant's duty to obey orders, so long as those orders are not unreasonable. It is the master's duty to pay his servant's wages punctually and without deduction; though in a few cases, by special agreement, a master will be allowed to deduct penalties in the nature of fines for spoiled work, etc. A servant must be punctual; he must also be diligent, that is to say, he must work his best and not be guilty of slackness. If a servant, in carrying out his master's orders, incurs any liability, the master is bound to indemnify the servant against such liability.

A master is liable to outsiders for any act done by his servant within the scope of the employment. This is a very wide phrase. It does not mean that the servant must have been acting in obedience to express orders; in fact, the master may be liable under this doctrine although the servant was acting contrary to orders. Suppose, for example, a tradesman employs a motor lorry in his business, and he tells the driver that whenever he is driving down the High Street he is not to exceed a speed of 8 miles an hour because of the traffic. In disregard of these orders, the man drives at twice that speed and negligently damages another vehicle. The employer is, nevertheless, liable.

Liability for Wrong-doing. A master may even be liable for his servant's fraud. This was held in a case where the manager of a bank stated in answer to an inquiry that X Y was a person of good substance to whom credit might be allowed, although at the time he knew that X Y was in very low

water and could not meet his obligations. The bank was held liable for the fraud, because the statement was made by their servant acting within the scope of his employment.

In the same way, a servant who is employed to make contracts binds his master within the scope of his employment. For instance, if A has a shop and he employs a man to manage it, and to do those things which managers generally do, and he makes a contract such as a manager in the ordinary way would be entitled to make, A must carry out that contract or pay damages if it is broken, although he expressly told his manager not to make contracts of that particular kind.

But if the person with whom the manager was dealing had notice that the manager was not entitled to make that particular kind of contract, then A will not be liable. It is for this reason that some firms print upon their letter paper and other business documents, such as invoices, a warning that no orders are to be accepted on behalf of the firm unless countersigned by one of the directors, or something of that sort. Others give warning that no verbal orders for goods are recognized.

The servant who is guilty of a wrongful act may himself be liable as well as his master. And where the servant, acting on his master's behalf, makes a contract in his own name or without disclosing that he is a servant, the person with whom he contracts may, on discovering that he made the contract as a servant, sue the master, or may elect to sue the servant personally. If so, then the servant has a right to be indemnified by the master.

A master is not liable for any criminal offence committed by his servant unless he expressly authorized it or was in some way a party to it, in which case he can be convicted, sometimes as a principal and sometimes as aiding and abetting or as being an accessory before or after the fact. If the driver of a horse, being a servant, is guilty of cruelty to the horse, he alone is liable; but if the cruelty consists in driving a horse which was unfit to be out on the road or unfit to be employed to pull a load of such a weight, the master will also be liable if the horse was sent out with his knowledge or approval.

There are some statutes which make a master liable for offences committed by his servant, e.g. under the Licensing Acts. There are others which make the master liable in the first place, but with liberty to him to prove that the servant was really responsible and acted against orders; as, for example, certain adulteration of food prosecutions.

The Right to Dismiss. A servant who is dismissed without due notice may bring an action. The only answer to such an action is that the servant has been guilty of misconduct. Disobedience to proper orders is good ground; in the case of domestic service, immorality is a good ground; dishonesty is sufficient; so is impudent behaviour; so is persistent and gross neglect and inattention to work which is likely to cause serious loss to the employer; so is systematic unpunctuality.

A slight breach of contract will not entitle the master to dismiss a servant without notice. The misconduct must be something which amounts to a repudiation by the servant of the proper relationship between them; that is to say, something like a fundamental breach of contract. Unless the contract of service says so, a servant cannot be dismissed merely for being ill; but if the illness is of such a protracted nature or of such a kind as to render the servant permanently unfit or unfit for a long period to carry out his duties, the master may dismiss him.

If a servant has been guilty of an offence which entitles the master to dismiss him instantly, the master must either do so or forfeit his right. For example, if the servant is guilty of impudence to his master on Wednesday, and the master says nothing about it until Saturday, which is pay-day, and then on paying the wages tells the servant to go without notice because of the impudence of Wednesday, the master is wrong. He ought on the Wednesday to say, "You are dismissed now, but if you like to remain to complete your week I will allow you to do so."

It sometimes happens that a master dismisses a servant summarily without justification, and after he had dismissed him discovers that the servant has been guilty of something which would have

justified dismissal. If the servant brings an action for wrongful dismissal the master is entitled to rely for his defence upon the second ground, of which he was not aware when he dismissed the servant. *See* Character; Employers' Liability; Insurance; Workmen's Compensation.

MASTICATION. Unless food is thoroughly masticated, unnecessarily hard work is thrown on the digestive organs, and sooner or later indigestion results. Each mouthful should be chewed until it is fluid and free from lumps. Eating solid food dry ensures more thorough mastication. Starchy foods, such as bread and potatoes, should be well chewed. These are partly digested by the saliva in the mouth, and the more thoroughly the saliva is mixed with them the more easily will their digestion be completed in the intestine. Particular care should be taken with fat, cheese, hard-boiled eggs, nuts, and other substances.

Children should be taught to masticate their food thoroughly. Old people whose teeth are decayed should get artificial teeth, or, as an alternative, they should have all food cut up very finely with a mincing machine; otherwise digestive troubles, headaches, etc., will result. *See* Diet; Food; Indigestion; Teeth.

MASTIC CEMENT. Brick, burnt clay, or limestone powdered and mixed with litharge, oil, or some similar substance make what is known as mastic cement. It is used in constructional work for such details as bedding an iron casement into masonry, or the laying of a floor on a concrete or similar foundation. In making this cement care must be taken thoroughly to pulverize or grind the materials. If good results are required on fine work, the crushed material should be thoroughly sifted through a fine sieve. *See* Cement.

MASTIFF. Almost the oldest of British breeds is the mastiff, which is a most faithful custodian of home or person, and so powerful that no one dares to risk a fall with him. When carefully trained, he is not savage, but he should not be chained. Mastiffs of two colours are bred, brindle and fawn.

Mastiff. A prizewinner of this formidable English breed of house dog.

The body is massive, broad, and deep, with strong legs set wide apart, giving the dog a square appearance. He should be of great size and weight, yet active when properly proportioned. The legs, both front and back, should be straight, that is to say, the hind legs should be parallel, but the hocks fairly well bent back. Back and loins should be wide and muscular.

The head is broad between the ears; the muzzle short and broad under the eyes, and nearly parallel in width to the end of the nose. The mastiff is somewhat expensive to keep, needing plenty of meat and ample room. *See* Dog; Kennel.

MASTINE. This is a mixture used for staining wood. It is made to imitate mahogany, rosewood, light oak, weathered oak, fumed oak, and antique oak. Of the nature of an oil stain, it may, if required, be thinned with turpentine. It can be obtained in tins (1 lb., 2 lb., or 7 lb.) through any colour-man. *See* Stain; Turpentine.

MASTITIS. Inflammation of the breast, or mastitis, is usually due to the entrance of a microbe through an abrasion of the nipple. The nipples should be kept scrupulously clean with soap and water, and may then be daubed with the following: Compound tincture of lavender, 1½ oz.; glycerin, 1 dram. If the nipple becomes fissured or abraded it should be washed with boracic acid lotion after nursing and then anointed with a paste consisting of equal parts of bismuth carbonate and castor oil.

If the breast becomes painful, hot, and swollen, the child should be withdrawn. Hot fomentations are applied, and the breast and the arm on the affected side should be supported.

MASTODYNIA. The painful neuralgia of the breast known as mastodynia sometimes gives rise to a lumpy condition which may be mistaken for commencing cancer. A timely consultation with a doctor will save a lot of worry. Commonly it is an affection of pregnancy or of the period of suckling when the breast is overtaxed.

MAT: For the Floor. Hall door mats should be of good quality fibre or they quickly wear down in use. Another important point is that they should fit the doorway or the sunk space often provided for them inside the front door. Fibre centre mats are obtainable with wool borders in various colours.

For use on landings and in the hall outside the doors of various rooms if mats are required they should either match the stair carpet or be of a plain colour that tones with it, or of skin.

Mats for the bathroom may be of non-slip rubber in a wide range of colours, of coarse towelling, or of cork. In terry cloth they are patterned in good designs and all colours. Cork mats wear better if framed narrowly in wood.

For country cottage or bungalow use rush mats, or those in dyed coco fibre are suitable.

Wool mats can very easily be made at home in the same way as rugs. The necessary implements and materials are a gauge, a patent crochet hook, a pair of scissors, a piece of canvas and the wools. Charts in colour, giving suitable patterns for these mats, can be bought, or a pattern can be evolved or copied by the worker. Directions for making are given in the article on Rugs.

Making Rush Mats. Bush mats, suitable for bedrooms, kitchens, informal or bungalow living-rooms, loggias and bathrooms, can easily be made at home. The necessary rushes are sold in bundles, and all that is required besides is a packing needle and some string. Before they are used the rushes should be soaked in water for 8 or 10 hours. They can be dyed to any shade required. Most mats, however, can be made chiefly of natural coloured rushes, coloured ones being only used for forming a pattern in the centre and for making the border.

The rushes should be plaited in strands, each strand consisting of three or more rushes, according to their size and the thickness of the mat. A mat such as is here illustrated is made by stitching the plaits together round and round until they form an oval. The plaits may either be sewn flat or edgeways, whichever is preferred.

Mat. Oval-shaped mat made of rushes, suitable for kitchen or bathroom.

To work the centre of the mat, take three small plaits, one green, one natural, and one brown. Stitch them closely together to form a zigzag pattern and, when a sufficient length has been made, bind the

edges with a plait of rush in order to give the oval effect. The rest of the mat, save the border, is of plain rushes, with the plait sewn edgeways. To join the rushes, put the butt end of the new rush to the thin end of the other one, and plait it in about 4 in. from the end of the last rush. Such mats will wear better if the ends are plaited in and made neat. Any discoloured portions should be cut off. When colour is introduced care should be taken to have an even number of rows. A break in the middle of a row should be avoided.

Useful Hints. To prevent mats from curling up at the corners, as they are apt to do after a few weeks' wear, turn them occasionally and use them upside down. In the case of plain rope or hemp mats this can be done without any obvious change of effect, for the two sides are usually alike; but if they are decorative mats with coloured patterns some other method must be adopted. Weighting the corners is usually effective, but if this is done with coloured mats an oddment of material which harmonizes with the predominant shade is necessary. Cut the material into four small squares, turn them in neatly all round, then fold them into triangles and sew them on to the four corners of the mat, first inserting a tailor's lead weight in each corner. Take stitches right through the mat with a long darning needle, and sew firmly so that the weight will not strain the stitches.

Where mats are placed on linoleum the floor immediately beneath them should not be polished, otherwise they will slip when stepped on and may cause accidents. On carpeted floors, in particular, dust quickly accumulates underneath mats, and for this reason the latter should always be removed when the carpet is swept.

Coloured mats which have faded may be restored to brightness by washing them with warm, salted water, or with water to which a little vinegar has been added. If made of Indian matting they may also be scrubbed, rinsed well, and left in the open air or in a draughty place to dry. Stains which will not yield to ordinary treatment should be rubbed with benzine or washed with a solution of water and ammonia. Information about table mats may be found in the entries on Duchesse Cover, Luncheon Set, Table Hat. *See also* Embroidery: Raffia; Rug.

MATCHBOARD. One of the most useful materials for the woodworker consists of narrow, thin boards planed smooth on one side, grooved on one edge and tongued on the other. When a number of them are fitted together they form a fairly solid, firm structure, and the interlocking effect of the tongued joint makes it draughtproof.

There are several varieties of this matchboard; the ordinary kind is known as tongued, grooved, and beaded, as there is an ornamental bead worked on one side next to the tongue, thus breaking up the surface and offering scope for decorative effect. A plain matching is made without this beading, and when available is useful when a large, smooth surface of timber is required. Another type is known as tongued, grooved, and V-jointed, as the edges are bevelled, and when the boards are put together they exhibit a V-shaped groove at each joint.

Sizes vary from 3½ in. to 6 in. wide, 4½ in. being common. Thickness ranges from ¾ in. to ⅞ in., the sizes commonly used being the ½ in. and ¾ in. These sizes are nominal and actually measure slightly less, so that when reckoning by the square—that is, sufficient timber normally to cover an area of 100 sq. ft.—it will be found necessary to add about 10 per cent.

Matchboard is applied by nailing it to the wall or to thin battens fixed firmly to the walls and packed up where necessary, so that the faces of all these strips are in line. The strips should run at right angles to the direction of the joints between the boards, and should be spaced not more than 2 ft. apart for the ¾ in. matchboard.

When erecting matchboard care should be taken to get the first piece fixed right and true, as all the others will be affected. The second piece is driven home into the groove, as shown in the illustration, by means of a mallet and an odd bit of the matchboard, this being inserted into the

groove or over the tongue to prevent the edge being spoiled by hammer marks. The tongue and groove is rather tender and should not be strained, nor should the boards be allowed to lie about, as the edges are easily broken. *See Board.*

Matchboard. Showing how to use an odd piece of matchboard to drive other lengths up tightly.

MATELOTTE. This is a dish of freshwater fish stewed in a savoury manner and accompanied by a matelotte sauce. Occasionally birds are cooked in the same way. The fish should be all of one kind, and must be stewed gently in wine or stock well flavoured

with wine, also one or two carrots and onions are added to the stew, as well as some spice.

After the fish is cooked strain the liquor and add to it $\frac{1}{2}$ pint rich brown sauce and 6 mushrooms, prepared and cut in pieces. Let all boil up together, and then simmer very gently about 20 min., removing the scum as it rises. Strain this sauce and add 1 oz. butter beaten with a few drops of anchovy essence and a grate of nutmeg. Mix it well over the fire and sprinkle in a pinch of sugar. Serve the sauce poured over the fish.

MATERNITY BENEFIT. In Great Britain, under the National Health Insurance scheme, this is a benefit paid to insured persons on the birth of a child. The amount is 40s., paid to the wife of an insured man or to an insured woman on her confinement. This benefit is payable after 42 weeks have elapsed since the man or woman became insured, provided that 42 weekly contributions have been paid. An insured married woman or widow with a posthumous child receives a double maternity benefit. *See Insurance.*

MATTING. Woven rope, hemp, coconut fibre, etc., are employed to make matting, which differs from the ordinary doormat only in that the latter is cut to a certain size, while the former may be bought by the yard. Narrow lengths of it are sometimes used to cover the floor of a hall or passage, while it is also frequently laid down during furniture removals to protect a polished floor from scratches, etc. In certain illnesses where absolute quiet is essential to the patient's recovery, matting is sometimes laid down on any tiled or uncovered floors near his room so that the sound of walking may be deadened, and in severe cases it may even have to be used on the pavement outside the house.

MATTOCK. The mattock is a tool similar to a pickaxe, but having two broad blades set in different planes. Generally the blades take the form of an axe-like edge on one end and a chisel edge on the other. They are made of cast steel, the handle being inserted in a hole near the centre of the tool.

The mattock is used to loosen earth, grub out roots, and the like, the earth being turned up with the chisel end of the tool; any roots, such as would be found in grubbing operations can be cut with the axe end. The chisel end curves slightly inward to facilitate turning up the earth, while the axe end is formed practically at right angles to the helve, as in this position the tool can be used more effectively for cutting through obstructions.

MATTRESS. Mattresses are divided into two principal types, top mattresses or overlays and under mattresses or mattress supports. The first type are of two kinds stuffed overlays of hair, wool and hair, or wool only, and inner spring mattresses. Mattress supports are of four kinds, ordinary woven wire springs, spiral springs in a wooden frame, box springs and flange supports. Both types, and most makes, are made in widths of 2 ft. 6 in., 3 ft., 3 ft. 6 in., 4 ft., 4 ft. 6 in., and 5 ft.

Luxurious overlays are stuffed with pure horsehair of the best quality. Excellent mattresses are obtainable made of white wool with a layer of horsehair in the centre, while dependable overlays are stuffed with the best coloured wool. These last are heavier and less resilient than the first and second kinds. Such overlays require periodical cleaning and remaking to keep them hygienic and free from lumps. The process of cleaning and picking up the hair and wool stuffing is done by a purifying machine and the overlays are afterwards sewn into the cleaned or into new cotton tick and rebuttoned.

Inner spring mattresses are the more comfortable form of top bedding. Such a mattress may have a spring centre and thick outer padding of horsehair as seen in Fig. 1, or pocketed springs as shown in fig. 2. There is a thin layer of hair in a separate envelope of material between the outer and inner

casings of this mattress, and it is supplied with ventilators at either end, which render it hygienic. These mattresses do not, by reason of their construction, require remaking.

Left. Mattress. Fig. 1. Overlay mattress with part cut away to show construction of spring centre encased in a luxurious stuffing of hair. (Courtesy of Heal & Son)

Fig.2. Overlay mattress with pocketed springs ensuring resilience and comfort. The layer of hair stuffing is cased in an envelope of material before being sewn into the mattress. (Courtesy of Vi-Spring Products. Ltd.)

Fig. 3. Support mattress on wood frame for use on an existing bedstead with overlay mattress. (Courtesy of Staples & Co., Ltd.)

Mattress Supports. A most important adjunct to the overlay is the supporting mattress. Some overlays are deep and resilient in themselves and are therefore perfectly comfortable to sleep on when merely supported by the ordinary woven wire mattress. Added comfort may be obtained by using a protector consisting of a tick pad reinforced with a number of thin flexible strips encased in pockets sewn across the width of the pad. A flock mattress may be used as an extra support under a feather bed.

Spiral spring mattresses in good qualities are practically free from all sagging. In this form of mattress the finest make of springs should be used, otherwise they will press down in wear and the mattress ceases to provide an even surface of support. The best kinds are noiseless and rustless, and the open top of the spiral construction, as seen in Fig 3, renders the springs accessible for dusting so that they can be kept clean. Such a mattress can be fitted on to any existing bedstead and used in conjunction with a hair or hair and wool, or inner spring overlay. To get the fullest benefit from the springs the overlay should not be too thick. More expensive qualities than the one illustrated are obtainable.

The box spring mattress, in conjunction with a good overlay, makes a most comfortable bed. Such mattresses are now made to fold in three parts or in half, so that they are easier to handle. Some makes have flexible sides and the interiors consist of a multiple of small spiral springs clipped together with steel clips. There are no cord fastenings to become broken or woven wire to sag or stretch. The whole bed of springs is secured on a substantial and well-finished wood base, upholstered and covered with ticking.

The flange mattress support has an elastic top edge and is similar to the box spring mattress, with the exception of the flange frame, which is narrower at the lower part of the mattress and enables it to slip into position inside the bed frame and reduces the height without lessening the total depth of the support. Such a mattress is suitable for the lower beds designed by modern makers. The older kind of wire spring mattress is difficult to keep clean. Every week it should be brushed with a stiff, dry nailbrush, and the woodwork wiped with a damp cloth. In warm weather the cloth should be moistened with disinfectant. Once a year the wire mattress should be taken apart by having all its bolts and screws unfastened. It should then be taken out of doors and pure carbolic poured round the holes where the bolts have been. This should be followed by an application of boiling water over the carbolic. The wire springs and the woodwork should then be scrubbed with a stiff nailbrush dipped into carbolic and water. The mattress should be left outside for some hours to become thoroughly dry.

A wire mattress that has become rusty can be restored thus: Paint it all over with aluminium paint, using a small, pointed brush that will get inside the mesh. *See Bedding; Bedstead: Box Mattress; Cot; Divan.*

Maxillaria. The culture of maxillaria, a family of hothouse orchids, is the same as that for masdevallia (q.v.). *See Orchid.*

MAXINA. A sequence dance in common time, the maxina is composed of five parts. The partners stand side by side facing the line of dance, the man's shoulder just behind the girl's, her left hand in his left, her right hand passing above her shoulder to take his right.

In the first part both glide the left foot forward and count 1. Then the right foot forward and count 2. the left again, counting 3, and the right, counting 4. The partners chasse to the left, commencing with the left foot and counting 1 and 2; then to the right, starting with the right foot and counting 3 and 4. The next step is to glide the left foot forward and count 1, then the right and count 2. Both pivot round on the right foot, the girl turning under the hands, cross the left foot over the right and

count 3, then point the right foot in front and count 4. The last bar is repeated, beginning with the right foot.

The second part is simpler. Placing the left heel to the floor, both partners turning to the left, count 1, then hop on the right foot and count 2. This is repeated 8 times until a complete circle has been made.

The movements in the third part are as follows: Glide the left foot forward and count 1, then the right, and at the same time dip bending the knee, and count 2. Bring the left foot forward with the heel to the ground in front of the right foot and count 3. Close the right foot up to the left and count "and". Move the left to the rear with the toe to the floor and count 4. Repeat the movement.

Right and left glides are a feature of the fourth part. Glide the left foot forward, count 1: the right, count 2; then the left, count 3. The man closes right to left while the girl pivots round to face him, counting 4. In the fifth part both hold as for the fox trot, (q.v.), and two-step or waltz for 4 bars.

MAXIXE. Like most of the dances introduced from South America, the maxixe is danced in such a way that it can be done in long pampas grass. Thus, the feet point straight, the knees are kept a little bent and the legs, wherever possible, are kicked forward, raising the feet a little at the back to free them from the grass. The steps, on the whole, are kept small, the movement being taken from the knees and not from the hips, as in other dances keeping the upper parts of the legs comparatively still. The foot is kept almost flat, with a slight drop on to each step occupying more than one beat.

The figures may be done in almost any position. The dance usually starts in the waltz position, after which the couple may pass into an open position in which they face the same way. The arms need not be altered, but the man may take the girl's left in his right hand and either stretch it straight out or turn it at her back, as in his original position. *See Waltz.*

MAY: The Tree. This is the popular name of hawthorn (*Crataegus oxycantha*). There are varieties with white and red, single and double flowers. Under the name of whitethorn or quick it is largely used for hedge planting. *See Hawthorn; Hedge.*

MAY BUG. The may bug, also known as the cockchafer, is a rather bulky looking brown beetle, about 1 in. long and $\frac{1}{2}$ in. wide, coated with delicate down, the hind body tapering to a point beyond the wing-covers. Towards the end of May or early in June the beetle may damage the foliage of trees; but it is in the larval stage that it is most harmful. The female deposits her whitish eggs in a batch of nearly 100, a little below the surface of the soil, and the grubs for more than three years feed on the roots of grass and herbaceous plants.

The visits of rooks and starlings to the lawn should be encouraged, as they hunt systematically for the grubs, and their powerful bills enable them to reach their prey. Failing this natural remedy, infested ground should be dressed with a mixture of nitrate of soda and soot, in the proportion of $\frac{1}{2}$ cwt. of nitrate to 7 bushels of soot for $\frac{1}{4}$ acre of ground. *See Insecticide.*

May Bug or cockchafer.

MAY FLOWER. This is a hardy and evergreen creeping shrub (*Epigaea repens*), which grows well in sandy peat if planted in a shady position, and bears fragrant white flowers in May. Planting may be done during spring or autumn; propagation is by division of roots in October.

MAYONNAISE. This name is given to a sauce or salad dressing. The ingredients are: 1 yolk of egg, 1 gill salad oil, 1 teaspoonful dry mustard, 1 tablespoonful cream, $\frac{1}{2}$ teaspoonful castor sugar, 2 teaspoonfuls tarragon vinegar, 2 teaspoonfuls white vinegar, salt and pepper. Mix together the dry ingredients and the egg yolk. Whisk in, drop by drop, the salad oil, then the vinegars. Add the cream last, and very gradually. Beat all the time with a slow, regular motion, always working in one direction. At the end add a dessertspoonful of boiling water. It is essential for the success of the mayonnaise that the oil be added drop by drop and each drop mixed in thoroughly.

Mayonnaise sauce is used as a dressing for salads, with lobster, crab, chicken, salmon, etc., which are then known as lobster, crab, chicken, or salmon mayonnaise respectively.

Mayonnaise Mixer. This is the name given to a contrivance which assists in preparing mayonnaise dressing for salads, etc. The ingredients are placed in a bowl, and a small funnel, which is attached, filled with olive oil. The oil then can be mixed in drop by drop. The mixer is worked by means of a handle. *See Salad; Salmon.*

Mayonnaise Mixer fitted with funnel from which olive oil can be mixed in drop by drop.

MAZUS. This hardy herbaceous perennial of creeping growth is suitable for planting in gritty soil in the rock garden. *Mazus pumilio* and *reptans*, with purplish mauve flowers, are the species in cultivation. Propagation is by division in spring.

MEAD: How to Make. Mead is a drink made with honey, flavoured with hops. To make it, add to each gallon of water 4 lb. honey. Boil together for $\frac{3}{4}$ hour, and skim it well. Measure the liquid and allow 1 oz. hops to each gallon, then boil it up again for $\frac{1}{2}$ hour, turn it into a wooden vessel, and stand it till the next day. It must now be put into a cask, and to each 4 gallons of mead add $\frac{1}{2}$ bottle of brandy. Let it ferment, and when it has finished close the cask tightly and leave it to stand. In about eight months it will be ready to bottle.

MEADOW RUE. This is an attractive hardy herbaceous perennial with ornamental leaves and flowers of various colours in summer. They flourish in ordinary soil. The chief kinds are *Thalictrum aquilegifolium*, 3 ft., purple; *Delavayi*, 2½ ft., mauve; *dipterocarpum*, 5 ft., lavender rose; and *glaucum*, 5 ft., grey leaves and yellow flowers. *Adiantifolium*, 9 in., with fern-like leaves, is suitable for the rock garden. Propagation is by division of the plants in early autumn or spring or by sowing seeds under glass in autumn or spring.

MEADOW SAFFRON. These beautiful hardy bulbs bear crocus-like blooms in autumn. The leaves, which are very large, do not appear until spring. They should be planted in grass or among low growing evergreen plants so that the flowers are not spoilt by soil splashed up in rainy weather. The bulbs ought to be set 3 in. deep in July-August; they thrive best in well-drained loamy soil.

Colchicum autumnale, the common meadow saffron, has purplish blooms: the finest is *speciosum* with large rose-purple flowers. Propagation is by offsets which may be taken off the bulbs when the leaves have died down, or by seeds which are sown as soon as they are ripe.

Meadow Saffron. Purple crocus-like flowers of Colchicum autumnale.

MEADOW SWEET. This is the popular name of a wild plant. *Spiraea ulmaria*. It bears cream-white fragrant flowers in early summer. *See Spiraea*.

MEAL. Meal, in one sense, means grain ground to powder. There are thus various kinds of meal, e.g. barley meal, maize meal, oatmeal, and wheatmeal, although sometimes the word meal is dropped when referring to them. *See Barley; Diet; Flour; Food; Oatmeal; Wheat*.

Mealies. This is another name for maize meal or Indian corn. *See Maize*.

MEALY BUG. One of the most troublesome of the pests that damage fruit and plants cultivated under glass is the mealy bug. Its body is covered with a substance like meal, and is furnished with a number of waxy thread-like filaments, those at the tail end being the longest. The larvae are hatched from a constant succession of eggs, and soon settle down to suck the sap.

An effective remedy is thorough cleansing of leaves and shoots with an insecticide, using a small brush or a sponge. Isolated bugs are best dealt with by means of a brush dipped in methylated spirit or paraffin oil. *See Insecticide*.

MEASLES: How to Treat. Measles is an acute contagious disease which mostly attacks children, but sometimes occurs in later life. One attack is usually preventive of others. It is very infectious and generally spreads in epidemics in spring or autumn. The cause is most probably a microbe which has not yet been identified.

Infection is conveyed in the breath and saliva, from the skin if touched, and probably also by clothing and toys. About 10 days after infection the disease begins suddenly, resembling a severe cold with sneezing, running at the nose and eyes, and temperature up to 102° or 103°. Three or four days later red spots appear on the neck, face and body and tiny rose-pink spots may be seen inside the mouth. The rash begins to fade after two or three days; there follows a desquamation of fine scales and convalescence is rapid.

The chief danger with measles is to the lungs and respiratory passages; bronchitis often leads to broncho-pneumonia. Catarrhal laryngitis may occur before the eruption; as it may be due to concurrent diphtheria, the doctor should be told if a child suffering from measles becomes croupy. Inflammation of the ear may also occur.

Measles is intensely infectious before the eruption appears, and when there is reason to think a child has become infected he should be isolated at once. A large, airy top room is best. It should have a fireplace and should be kept at a moderate uniform temperature of about 65°, and the air should be moistened by means of a bronchitis kettle sending steam into the room. Moist air is necessary to soothe the irritable mucous membrane of the bronchial tubes. Screens should be placed round the bed. The healthy children should be kept as far as possible from the sickroom, or sent to another house. The diet is that for fever. The child should be sponged all over with warm water every day. Broncho-pneumonia is the most serious complication, and requires constant medical attention.

The patient should not leave bed until the temperature has been normal for seven days. A week later he may go out of doors if the weather be fine, but in cold weather not for two or three weeks. The diet must be nutritious and digestible during convalescence. Cream is a valuable food at this time, and it is advisable to give cod liver oil for 8 or 10 weeks, with iron if there is anaemia; chemical food would be a suitable form.

The safeguarding of young and delicate children from infection is of great importance. Greater care in recognizing early stages of the disease in older children and prompt isolation will be helpful. The things to watch for are a rise of temperature in the evening and swelling of the lining of the lower eyelid. If spots have appeared in the mouth it is too late, infection has probably been transmitted.

MEASUREMENT. This means the act and result of measuring. Correct measurements are necessary in order to make the various articles described in this work, and for many of these diagrams with measurements are given. With most of the woodworking articles a cutting list is supplied giving dimensions of the various pieces of wood required.

To measure the height of anything there is a simple method which most persons can put into operation. Take, for example, a flagstaff. A certain distance, say 40 ft., must be marked in a straight line from this, and a stick of a certain convenient length placed in the ground at the spot. The next step is for the measurer to go still farther away from the tree, still in a straight line, until, with his head on the ground, which must be level, he can see the top of the stick and the top of the flagstaff in the same straight line.

This spot should then be noted and carefully measured. In the present case we will assume that it is 6 ft., making the line from the flagstaff 46 ft. in all. These lines should give two imaginary triangles, as shown in the diagram.

All that now remains is to work out a sum in simple proportion. As the line C E is to the line D C, so is the line B E to the line A B, which is wanted. In the example here taken it can be assumed that the length of the stick above the ground is 4 ft. The actual sum is: As 6 is to 4, so is 46 to the answer. $\frac{4 \times 46}{6} = \frac{184}{6} = 30\frac{2}{3}$. Thus, the height of the flagstaff is 30- 2/3 ft.

In actual practice calculations will usually be less simple than the one given, but the principles are exactly the same. See Centre to Centre: Drawing, etc.

Measurement. How to calculate the height of a given object.

MAY

What to do in the Garden

Flowers

Harden off summer bedding plants

Plant half-hardy annuals raised under glass

Plant snapdragons and border chrysanthemums

Prepare sites for dahlias

Stake and tie hardy border plants

Thin out the seedlings of hardy annuals

Lift spring bulbs from flower beds and plant on a reserve border

Divide polyanthus, double daisy, and arabis and replant the pieces

Sow seeds of Chinese primula and cineraria under glass

Fruit

Spray fruit trees with the poisonous arsenate of lead or an insecticide to kill caterpillars

Pinch off the ends of vine shoots leaving only two leaves above the bunch of grapes

Disbud peach trees by gradually removing most of the young shoots. Leave one shoot at the base and another at the top of each old branch

Mulch the soil round newly-planted fruit trees with manure

Lay straw between strawberry plants

Water fruit trees on walls in dry weather

Vegetables

Sow runner and French beans and late peas

Sow the main crop of beetroot

Earth up early potatoes

Prepare trenches for celery

Sow lettuce at fortnightly intervals

Sow the rosette colewort, an autumn cabbage

Plant cucumbers in a frame

Sow vegetable marrow out of doors

Thin out superfluous seedlings of onion, carrot and other vegetables

Food in Season

Fish

Bass; bream; brill; cod; dory; eel; flounders; gurnet; hake; halibut; herring; ling; mackerel; mullet; plaice; salmon; skate; smelt; sole; trout; turbot; whitebait; whiting

Poultry & Game

Capons; chickens; ducks and ducklings; fowls; goslings; guinea fowls; hares; ortolans; pigeons; prairie hens; ptarmigan; pullets; quail; rabbits; ruffs and reeves

horseradish; leeks; lettuce; mushrooms; onions; peas; potatoes; radishes; sea-kale; sorrel; spinach; tomatoes; turnips; watercress

Shellfish

Crabs; crayfish; lobster; prawns; shrimps

Meat

Beef; lamb; mutton; veal; venison

Vegetables

Artichokes; asparagus; beans; beetroot; cabbage; cardoons; carrots; cauliflower; chervil; cress; cucumber; endive;

Fruit

Apples; bananas; cherries; figs; gooseberries; grapes; lemons; limes; melons; nuts (various); pears; pineapple; rhubarb; strawberries (hothouse)

Notes for the Month

MAY 1.—May Day. Stock Exchanges closed

MAY 12.—Anniversary of Coronation of George VI, 1937

MAY 24.—Empire Day

MAY 26.—Queen Mary's Birthday

MAY 31.—Union Day S. Africa

MEAT: Food Value. Short-fibred meat, such as the breast of chicken and game, is more digestible than long-fibred varieties. In eating the latter—beef, mutton and veal—it is well to cut them in thin pieces across the fibres. Beef is probably best when the animals are about four or five years old. They are then more nourishing, bulk for bulk, than the flesh of younger animals. Veal is less digestible than beef. The fatter the meat, the less water it contains; hence the more economical it is for people with whom it agrees. But it is also less digestible.

The amount of water in meat is very large; 1 lb. of average beef contains $\frac{3}{4}$ lb. of water and only $\frac{1}{4}$ lb. of nutritive matter. The same applies to lean mutton, lamb, veal, venison, fowl, hare, and pigeon. Pork is $\frac{3}{5}$ water and goose $\frac{2}{5}$. But very fat beef or mutton may be only $\frac{1}{2}$ water. Bacon contains very little water, only about $\frac{1}{5}$ of its weight. The calorific, or heat-giving, value of meat is very high. Too much meat eaten in summer is inclined to overheat the blood.

Beef and mutton are more digestible when under-cooked, but lamb, veal, and pork are unpalatable and unwholesome unless well cooked. Roasted meat is less digestible than boiled. The roasting or baking of meat leads, however, to the development of appetizing substances which are included under the name of osmazone. These stimulate the flow of gastric juice. The plan of stewing meat in an inner vessel within that in which the water is boiling has everything to recommend it. Casserole cooking is perhaps the best and most economical method of cooking meat, as the meat is cooked in its own juices, which are served up with it. Thus nothing is lost. On account of the high temperature, at which meat is cooked in frying it is less digestible than when cooked by other methods. All meat becomes more tender by hanging for some time, but it is not desirable to let it hang too long and allow putrefactive changes to develop. Freshly killed meat requires more time to cook than meat that has been well hung.

Hints on the choosing of meat are given under the headings for the various kinds—beef, mutton, veal, pork, etc.—in this work,

It is most essential that meat directly it comes from the butcher should be thoroughly examined and at once put away in a cool, well-ventilated larder, also that in summertime careful observation should be made that no blow-fly has had access to it.

Poisoning by Meat. The symptoms of meat poisoning come on about three or four hours after taking food, and are usually due to eating pork pies, sausages, or cold pork which has begun to putrefy, or which has been kept in a badly ventilated and unclean larder. In rare instances it takes the form of botulism.

It is generally well to give an emetic of a tablespoonful of mustard in half a pint of warm water if vomiting has not yet occurred. This should be followed by a full dose of Epsom salts, according to the patient's age. For faintness or collapse brandy or other stimulant may be given, and hot-water bottles should be placed about the patient. For severe pains put a hot linseed poultice to the abdomen. A doctor should be sent for at once.

Meat Extract. Extracts of different meats may be bought in bottles of varying sizes, and are used as stimulants or in the preparation of soups and gravies.

Meat Jelly. Jelly is extracted from the bones, gristle, and sinews of meat. To produce a jelly of any strength the bones are chopped in pieces and must not have been previously cooked. The boiling must be gentle and continuous for from 8 to 12 hours, and the scum must be carefully removed.

Knuckle of veal or mutton, also the feet, make excellent jelly, and one which, having little flavour in itself, can be readily adapted either for a sweet dish or a savoury jelly. Ox feet produce a very strong jelly, but not so delicate as calf's feet. Cow heel is obtained usually from the tripe-dresser's,

and has already been boiled; but a good jelly for mixing with milk or other ingredients is obtained from it.

Although meat jellies have little actual food value in themselves, it is possible to mix with them meat which has been cooked, pounded, and passed through a sieve, and either introduce it in the form of small shapes set in the jelly, or let it mingle with it and give a marbled appearance. Pieces of chicken or other delicate meat can be set in meat jelly, and the moulds may be decorated with leaves of aspic jelly and butter put through a forcer.

Meat Pie. There are two kinds of meat pies, those which are baked in pie-dishes, where the meat is covered over the top with pastry, and raised pies, where the meat is entirely enclosed in paste.

For the pie made in a pie-dish almost any kind of meat, poultry or game will serve, pork excepted. The pastry covering consists of puff, rough puff, or flaky paste, but it is made with a larger proportion of fat than is considered necessary for most-fruit pies. Meat pies are baked from 1½ to 2½ hours, according to size, therefore the crust must be rich with fat or it will become dry during the process of cooking.

The best meat to use for pies is that in which the fat is not superabundant, and all skin and gristle must be left out when cutting it up. In the case of poultry or game whole joints are laid in the pie-dish, but when butcher's meat is used strips or slices are cut and no bone left.

To enrich the gravy of poultry or game pies, a layer of steak pieces is laid at the bottom of the dish. Flavourings used are in accordance with the character of the meat. They may consist of shallots, parsley, herbs, mushrooms, oysters, forcemeat balls or hard-boiled eggs. Slices or dice of ham or bacon may be added with advantage.

The raised pie is made with hot-water crust. This crust, being very short, must be kept only warm enough to mould, and is always better for lying covered up with a thick cloth for some hours before it is made up. For raised pies generally pork or veal is required. Instructions for making these will be found under the headings Pork and Veal. *See also* Bacon; Botulism; Beef; Diet; Food; Game; Lamb; Mutton; Pastry; etc.

MEAT SAFE. Whether the housewife possesses a refrigerator or not the meat safe is an important item of furniture in the kitchen. This is particularly the case where larger accommodation is limited. No hot food should be placed in the refrigerator, so that a zinc-lined meat safe with ventilation regulator in which food may be put to cool is a great asset. In a small larder it is also often desirable to keep meat separate from other dishes and foods.

The newer models have table tops of white porcelain enamel, or in some cases of chromium plate. These have all the advantages of a safe and table combined and are constructed on hygienic principles with washable galvanized interiors. In some of these safes, sliding, galvanized steel-lined trays for smaller articles of perishable foods are provided. The finish of the safe is in enamel to match the woodwork of the kitchen, or in oak, and it is mounted on pivot-bearing castors, so that when in use as a table it can be easily moved to a convenient position for pastry making or other culinary preparation.

Meat safes form a part of some kitchen cabinets which are provided with a cupboard lined with galvanized steel for this purpose and properly ventilated. Small enamelled tin meat safes with panels of perforated zinc or iron wire gauze in the door and sides are also useful in the small kitchen as they take up little space and can be fixed to the wall. *See* Kitchen; Larder.

MECONOPSIS. This is a biennial and perennial herbaceous plant of great beauty. It comes chiefly from China and other far Eastern countries, and some of them have flowers of most exquisite blue colouring. The Welsh poppy (*Meconopsis cambrica*) with orange or yellow flowers is an excellent

plant for a shady wall or for shady crevices in the rock garden and often sows itself freely, but the exotic kinds require rather special treatment. They need shade and well drained though deep moist soil of peat and loam.

Aculeata, blue; *integrifolia*, yellow; *Wallichii*, blue; and *Baileyi*, blue, have flowers of exquisite beauty. These are biennials, raised each year from seeds sown in boxes of fine soil in a frame in May. If the seedlings are planted out in autumn they should be protected from excessive rains in winter by pieces of glass raised a few inches above them. *Meconopsis regia*, from Nepaul, which bears large primrose-coloured flowers, is the latest novelty in this group.

Meconopsis. Flower spike of the Himalayan poppy.

MEDICAGO. Of the large family of creeping plants bearing the name of medicago only one is worthy of cultivation in ordinary gardens. This is the Calvary clover (*Medicago echinus*), an annual raised from seeds sown under glass in April. Its yellow flowers are borne in summer, and are succeeded by quaintly twisted legumes. It is

generally grown as a pot plant in a sunny window in a mixture of loam, leaf-mould, and some old mortar.

MEDICINE: How to Give. The following are important rules to be observed carefully in administering all medicines:

Read the label every time before pouring out, and again after pouring out, the medicine. Never give medicine in the dark. Shake the bottle, even if not so directed.

Use a graduated measure always; spoons and wineglasses vary. If minims are ordered, measure them in a minim-glass; drops of some liquids are twice as large as drops of others. Never guess at a dose.

When pouring out, keep the labelled side upward. When dropping a medicine, first wet the lip of the bottle with water. Give medicines, especially cod liver oil, out of perfectly clean spoons, glasses, etc.

If ordered to take medicine before or after meals, take it 20 to 30 min. before or after, unless otherwise directed. To dull the sense of taste when taking nauseous medicine, put a little ice or peppermint in the mouth, or chew a piece of orange-peel. Castor oil is most easily taken in coffee, orange juice, grape juice, or effervescing lemonade. Unpleasant powders should be given in wafer papers, purchasable at the chemist's. A pill is most easily swallowed if the head be bent forward.

In giving medicine to a resisting child, first try firm persuasion, then bribery. If these fail, hold the nose and put the spoon far back into the mouth. The child's arms can be held to the body with a towel. (*See Dosage*).

Medicine Case that can be carried in the pocket, an article of value to travellers.

Medicine Case. A small medicine case holding some of the most useful of ordinary medicines is carried by many travellers. The one illustrated can easily be carried in the pocket. The six small bottles containing medicines that are useful to ward off a

cold, or in case of sudden illness. The medicines usually carried in cases of this kind include quinine aspirin, and sal volatile. *See First Aid.*

MEDLAR. This summer-leaving tree, *Pyrus (mespilus) germanica*, is valued for the sake of its white flowers in spring and for its curious fruits in autumn, though these are liked by few. Medlars must be left on the tree as late as possible and then stored until they are 'bletted' or have become slightly soft. The tree thrives best in rather moist but well drained loamy soil and should be planted in autumn. It is propagated by grafting on stocks of pear, quince or white thorn and makes an attractive lawn tree. The Dutch and Nottingham are the best varieties.

Medlar, showing the curious shape of the brown fruit.

Uses in Cookery. When gathered, medlars should be stored in a cool place until the early stages of decay are manifest. They are sometimes employed as dessert fruit, but are more often used for making jams and jellies.

Medlar cheese is made by cooking some medlars until they are tender in a covered jar placed in a saucepan of water, then rubbing them through a fine sieve and adding ½ lb. lump sugar and a teaspoonful of allspice to every lb. of pulp. When the sugar has dissolved boil the whole steadily until it sets firmly.

Medlar Jam. Medlars must be quite ripe and soft before they are used for jam. Wipe them with a cloth and put them in a preserving pan just covering them with water. Stir them frequently while they simmer beside the fire for 30-35 min., or

until they split. Pass the pulp through a rather coarse sieve, but fine enough to retain the seeds, and put it back in the pan with the grated rind and juice of a lemon and just under 1 lb. sugar to every lb. of fruit. The fruit should be weighed for this purpose before it is put into the preserving pan.

Boil the jam fast for 30-45 min., stirring and skimming constantly. When a little sets when dropped on a cold plate pour the jam into dry warmed jars and tie down at once.

Medlar Jelly. To make this preserve, put the ripe fruit in a stewpan and just cover it with water, adding to every 40 medlars the rind and juice of a lemon. When this has simmered for about 40 min., and all the fruit has broken, pour it into a jelly-bag and strain out the juice without any pressure. To every pint of juice add 1 lb sugar, and then boil it in the stewpan for about 1½ hours, until it sets when tested. It will need frequent stirring and skimming. Pour the jelly into dry warmed jars, and tie them down immediately. *Set Jam; Jelly.*

MÉDOC. No Bordeaux wine is entitled to the name Médoc except that made from grapes grown in the Médoc, a strip of land on the left bank of the Gironde. Some of the famous wines of the Médoc are St. Julien, St. Estephe Pauillac. St. Laurent Cantenac and Margaux. *See Bordeaux; Wine.*

MELANCHOLIA. In the form of insanity known as melancholia there is extreme mental depression, the low state of the feelings being associated with mental pain or distress. Delusions tend to develop. There is a grave risk of suicidal attempts in melancholia and in the depressed states which border on it. Such cases, therefore, require most careful supervision, and this usually means that the patient ought to be in an asylum. *See Insanity; Lunatic.*

MELIANTHUS. This is a half-hardy bushy plant, 4 ft. or so high, which has graceful decorative leaves and reddish-brown flowers. The two kinds grown are major and minor, the former being the more valuable. In a border and at the foot of a sunny wall melianthus is hardy in mild districts, but in other places the roots should be protected in autumn. Propagation is by cuttings in August, or by seeds sown in early spring under glass.

MELOCACTUS. The melocactus is a species of cactus known by various popular names, including melon cactus, pope's head, Turk's cap, and melon thistle. It has spiny, ribbed stems, topped by a sort of cylindrical cap, which gives the plant a curious appearance. Being a succulent greenhouse perennial, it requires a sunny position under glass, and a minimum winter temperature of about 45°. The plants need little water between autumn and spring.

MELON. Unlike other popular fruits, the melon can be raised from seed, but it is not hardy, and with one or two exceptions the varieties require heated houses and a temperature of 65° or 75°. The season is generally from May to October.

How to Grow. As melons love heat and moisture it is customary to grow them in pits, which are half-sunk structures with low walls, sometimes lean-to's, sometimes span-roofs, with brick-encased beds, not as a rule more than 2 ft. below the glass at the front.

When a plant is carrying several fruits, it is desirable to support them with netting.

For melons in hotbed frames less atmospheric moisture is desirable, because there is greater danger of stem canker. Syringing once a day suffices. Ventilation should be practised in fine weather. A piece of tile or slate should be placed under each fruit so as to keep it off the soil. Seeds should be sown singly in small pots of loamy soil in spring, and when the seedlings are well rooted they should be planted in mounds of loamy (turfy) soil set about 3 ft. apart on a hotbed made up in a frame or glasshouse. When the plants reach the trellis fixed beneath the roof of the latter, their tops should be pinched off to cause them to form side shoots on which male and female flowers will be borne.

An important detail of cultivation is to pollinate several blooms at the same time by transferring the pollen from the male or staminate blooms to the female or pistillate blooms: if pollination is carried out on different days the early fruits will develop fully but the others will be small. As the roots push through the mounds of soil fresh loam must be added. To prevent the trellis becoming overcrowded with leaves the ends of the shoots must be pinched off at two or three leaves beyond the fruits.

Some of the best varieties for the glasshouse are Superlative, Eastnor Castle Emerald, Gem, and King George. For cultivation in a frame Hero of Lockinge and Little Heath are suitable varieties.

Melon cut open and seeds removed in order to show the depth of the flesh.

Melon Culture.

1. How to sow seed. 2. Seedling ready for repotting.
3. Plant repotted.
4. Position on mounds in frames.
- 5 and 6. Other methods of planting. 7. Male flower.
8. Female flower.
9. Male prepared for fertilizing.
10. Pollination of female bloom.

Table Uses. In addition to its uses as dessert, melon is also frequently served as hors d'oeuvres. For this purpose it should be very cold, and is best placed on ice for some little time before it is served, together with sugar, pepper, and salt. Melon is also served as a cocktail made by peeling it when just ripe, removing the pips, and cutting the fruit into dice about $\frac{1}{2}$ in. square. Have ready 6 or 8 sundae or custard glasses, partly fill them with the diced melon, and then add a sprinkling of castor sugar and a little kirsch and maraschino mixed. Only a few drops of liqueur must be used, otherwise the delicacy of the dish will be lost. Stand the glasses on ice before serving them on small plates.

Melon Pickle. To make melon pickle, pare off the outer rind of a melon before it is quite ripe, remove the seeds and pith, and cut into cubes. Put them in an earthen vessel, cover with good vinegar, and let them remain for 10 days, then pour all into a saucepan and simmer gently until they are tender. Drain them, lay them on a hair sieve, and when cold insert a clove in each. Place the cubes once more in an earthen vessel, and pour over them a cold syrup made with sugar and water.

Let it run off them a little, then put them into pickle-jars cover them with vinegar which has been boiled and allowed to go cold; cover the jars securely. This pickle is good with roast meat. *See Greenhouse.*

MELTON: The Cloth. An old-fashioned woollen cloth, excellent for overcoatings, melton is impervious to wind pressure. Usually plain in colour, it can be recognized by its rather sharp touch. In course of finishing the cloth a nap is teased out of it, and this is cut short, leaving upright ends of wool fibre.

MENDING: A DOMESTIC NECESSITY

How to Cope with Wear and Tear in the Home

Further information about this important feature of good housekeeping will be found under such headings as Darning; Lace; Linen; Patching, etc.

A well-equipped mending basket is essential for economy in the household. A good selection of needles, cottons, silk threads and darning materials should be stocked, with various widths of elastic in black and white, tapes and bias bindings. Besides the usual cards of linen and pearl buttons an asset for the mender is a glass bottle with a wide neck into which odd buttons are dropped. It can be seen at once whether buttons required are in stock. A large safety-pin should be kept, and on this are strung loose hooks and eyes. Reels of cotton can be strung on a cord or ribbon. A small magnet on a long length of tape is useful to pick up needles which are dropped on the floor. Pieces of material left over after making garments or other articles should be tied up and kept in a muslin bag for mending purposes.

Mending. Fig. 1. How a darn can be made in damask by imitating the design; above, right preliminary stage in darning a cross cut in damask. Fig. 2. Mending a hole in fine woven material by placing a piece of net beneath it and darning over it. Fig. 3. Restoring stocking web by counterfeiting the material; this is known as

rémillage. Fig. 4. Repairing a hole in a kid glove with buttonhole stitch in silk of the same colour.

Nothing that requires mending ought to go to the laundry. If there is not time to mend the holes neatly, then the torn edges can be drawn together with coloured cotton temporarily. Before clean articles are put away they should be gone over, and any that require buttons, tapes, or other mending put on one side.

Linen tablecloths or sheets should be darned with linen floss, and an embroidery ring or hoop is a help in darning large articles. It is also possible to darn household linen and towels on the sewing machine. The foot of the machine should be removed, and the worn place slipped into an embroidery hoop and this placed underneath the needle. The machine is worked so that lines of stitching are made backwards and forwards over the worn part. The hoop is then turned round and sewing continued in the other direction till the darn is completed.

When sheets become worn in the centre, they can be cut down the middle and the raw edges hemmed. The sides should be seamed together so that the little worn parts are in the middle and the worn portion is at the outside. When this process has been carried out and the sheet again becomes worn, the unworn parts can be made into slips for underneath the pillow cases, or into bolster cases. Old linen sheets are excellent for polishing dusters when cut up and hemmed, or for bandages when torn into strips.

A tablecloth that is becoming worn along the creases can have its period of service extended if a strip 2 or 3 in. wide is cut off one side and one end. When the cloth is folded the creases will fall on different lines, thus preventing further wear on the worn lines. Tablecloths that are worn too much to mend can be made into table napkins or into centres for round table mats by cutting them to the desired size and neatly trimming the edges with suitable crochet or lace. Larger pieces may be used as tray cloths or sideboard runners and trimmed in the same way. Towels that cannot be mended again make useful face cloths, dish cloths, or polishing cloths.

Patching and Darning. Darning a damask cloth or napkin requires patience if, instead of the usual lattice work, the design is copied. Fig. 1 illustrates how a simple pattern can be copied. The lengthway threads are made in the same way as those of an ordinary darn, but the cross threads are interlaced to form a pattern. The number of threads lifted or missed depends upon the web to be imitated. A cross cut on damask can be darned by commencing, as also shown in Fig. 1, on the wrong side of the material and the needle and cotton passed alternately over and under the edges of the cut till they meet. These stitches must not be removed when this preliminary darning is finished, but are darned across in the usual way on the lines of the thread of the damask, using a finer thread than that of the material and extending the darn well beyond the cut.

Men's underwear can be strengthened by saving portions of similar worn-out garments and making a double thickness on the new garment where it is most likely to get worn. In patching garments it will be found a help if a thick pad of newspaper is placed under the part to be patched, as this aids in keeping the material in position.

In mending a worn place on fine underwear a piece of net should be placed on the wrong side under the worn place and the darn carried out over this foundation, as shown in Fig. 2. This method is useful when a blouse of fine lace or georgette is to be mended. In mending a drawn-thread tea cloth a piece of net will also be found a help. The net should be tacked round the worn place on the wrong side and the broken threads sewn on to the net in position.

It will be possible to draw the threads, with the help of a needle threaded with strong cotton, up to the edges of the cloth, and if the work is not very worn it is possible to mend almost invisibly over the foundation of the net. A net patch also makes a good foundation for darning a cotton or silk stocking. The net should be tacked on the wrong side and cut away round the darn when the task is finished. For very fine silk stockings old veiling is excellent as a foundation material for a darn. To restore stocking web the material can be counterfeited by *rémaillage*, as shown in Fig. 3. Note

setting of warp threads and the working of the weft with the needle. The stitch is brought up through the loop and between two strands and passed under two strands, as shown in Fig. 3.

To mend a tear in a tweed or woollen suit, strands of the wool should be unravelled from the seams on the wrong side. The garment should then be stretched over a pad of white paper and tacked loosely into position, the wrong side being uppermost. If the tear is jagged or three-cornered, it should be drawn into position with a coloured thread. Now darn the torn edges closely together with the strand of wool, and continue taking fresh lengths of wool as they are required until the darn is completed. This is called invisible mending.

To mend a jagged tear, buttonhole round the torn edges with silk as nearly as possible the same colour as the material. On the wrong side draw the silk threads of the buttonholing together firmly, and press with a warm iron over a damp cloth.

Mending Gloves. Kid gloves that have become worn at the tips or at the bottom of the seams can be mended by buttonholing round the worn parts with silk twist of the same colour. Turn the glove inside out and cut away the kid that is worn. Do a row of buttonholing all round the edges, then a second row of buttonholing, slipping the needle into the first row. Continue this, drawing up the hole until it is filled. Turn the glove right side out. When suède or chamois gloves wear into holes they are more successfully mended by patching. Old gloves should be kept for this purpose. The patch should be neatly sewn in with silk on the wrong side.

A jagged tear in a mackintosh can be repaired by placing the tear flat down on a table, wrong side out, and pressing the edges together under strips of sticking plaster. A rubber mackintosh can be patched if a suitable piece of patching material can be procured by using rubber solution that is sold for mending bicycle punctures.

Carpet Mending. To mend a carpet, turn it on the wrong side and lay the torn pieces in position. Buttonhole each edge with carpet flax, then draw the two edges together by means of the double row of buttonholing. If there is a considerable worn area around the tear, the carpet should be slit down and a strip, taking in the worn part, cut away. The pattern should then be carefully matched, the carpet reversed, and the join carried out as directed above, by means of buttonholing. If a carpet is worn in the centre, it can have its period of usefulness considerably extended by cutting it down and placing sides to middle. To mend linoleum, first mark out in chalk the worn part. Cut it out with a sharp knife, then lay this pattern on the new piece that is to be used for mending, and cut it out. If the linoleum is patterned, care must be taken that the patch exactly corresponds in pattern to that which it is required to replace. Glue round the edges and underneath the new piece and fit this exactly into the space in the linoleum. Press it down into position and leave it to dry. Further information about mending articles in common household use will be found under the headings Boot Repairing; Chair; Crockery; Glass; Soldering.

MENINGITIS. Inflammation of the meninges or membranes covering the brain and the spinal cord is known as meningitis, and there are several kinds.

Tubercular meningitis is most common in children between 2 and 7 years of age. It accompanies tuberculosis of other parts, and sometimes follows measles, whooping cough, or a fall. The most marked symptoms at first are intense headache, sickness, chills, and the child often utters a short, piercing cry. In all varieties of the disease treatment must be in the hands of the doctor.

Menopause. *See* Change of Life.

MENSTRUATION. The monthly flow of blood mixed with other fluids which is known as menstruation or courses begins with girls at puberty, and only ceases with the change of life. Usually the age at which it commences is from 13 to 15. At first there may be irregularity, but as a rule this is of no consequence. The discharge continues for 3 to 5 days, and should recur every 28 days. If it is excessive or there is much pain a doctor should be consulted immediately.

When menstruation occurs a girl should be careful to guard against chills and should avoid fatigue or any games that involve violent exercise. She will also be advised to keep away from dances and theatres, or any place where the air is likely to be hot and impure, and she must not touch alcohol. By attention to these points the length and the amount of the discharge will probably be lessened on future occasions. Baths, provided they are not cold, can be taken with impunity.

A great deal of ill-health in after-life results from neglect of proper precautions at the time when menstruation commences. Girls are seldom warned beforehand of what they are to expect, with the consequence that many suffer from serious nervous shock. This is particularly the case when children are away from home in a boarding-school, and are too shy to speak of the occurrence. In these circumstances, and very often even in their homes, they may receive no special care.

It is therefore of the greatest importance that mothers should understand how this function affects the health of young girls, and should see that proper precautions are taken.

Most healthy women are able to perform their domestic duties as usual during the period, but they should be careful to avoid any strain as, for instance, in running upstairs or moving furniture.

MENTHOL: Medical Uses. By cooling oil of peppermint a crystalline substance is obtained which is known as menthol or mint camphor. In medicine menthol is often used externally as a local anaesthetic, particularly in neuralgic conditions, because of the sensation of numbness and coolness it imparts when applied to the skin. For this purpose an alcoholic menthol solution may be applied by a brush or the official plaster of menthol may be used, or the menthol in the solid form may be rubbed lightly on the skin.

The application of menthol may also be of great use in itching skin complaints. It is often used to relieve some forms of nasal obstruction, and in deafness due to catarrh of the Eustachian tubes. For this purpose a small quantity of an ointment consisting of 5 grains or more of menthol in 1 oz. of vaseline may be put into each nostril. This ointment should not be put into the nose of an infant.

MENU. The French phrase *menu d'un repas* means the particulars or details of a meal or entertainment. A menu, therefore, is the whole of the dishes served at a meal, and the menu card is the card that contains particulars of each dish.

Many of the dishes that find a place on a menu retain their French names, and a knowledge of French cookery terms is necessary in order to make a selection from among them. The main groups into which the foods fall are as follows:

Dessert = dessert

Legume = vegetable

Pâtisserie = pastry

Potage, Purée, or Consommé = thick or clear soups

Viande = meat

Volaille = poultry

Hors d'oeuvres is the name given to dishes served in small quantities at the beginning of a meal as appetizers. Grape fruit and melons are often used. Entrées are served after the fish.

French Names for Foods. The French and English names of the various foods are as follow:

Abricots	apricots	Paté	pie
Agneau	lamb	Perdrix	partridge
Ananas	pineapple	Petitspois	green peas
Anchois	anchovy	Plie	plaice
Artichaut	artichoke	Poireaux	leeks
Asperges	asparagus	Poires	pears
Betterave	beetroot	Pommes	apples
Boeuf	beef	Pommes de terre	potatoes
Cabillaud	cod	Poulet	chicken
Café	coffee	Prunes	plums
Canard	duck	Raifort	horse radish
Cerises	cherries	Raisins	grapes
Choufleur	cauliflower	Ris de veau	sweetbread
Choux de Bruxelles	Brussels sprouts	Rognon	kidney
Crevettes	prawns	Saucisson	sausage (smoked)
Epinard	spinach	Saumon	salmon
Faisan	pheasant	Truite	trout
Foie	liver	Veau	veal
Fraises	strawberries	Venaison	venison
Framboises	raspberries		
Gâteau	cake		
Gibier	game		
Gigot	leg of mutton		
Glace	ice		
Hareng	herring		
Haricots blancs	haricot beans		
Haricots verts	French beans		
Homard	lobster		
Huître	oyster		
Jambon	ham		
Laitue	lettuce		
Lapin	rabbit		
Lard	bacon		
Lièvre	hare		

These foods are often accompanied by words or phrases indicating how they are cooked.

A la broche	= roasted before a fire
A la brunoise	= garnished with spring vegetables
A la crécy	= prepared with carrots
Au diable	= devilled, or with hot seasoning
Au gratin	= cooked with breadcrumbs
Au naturel	= cooked very simply, or served uncooked
Blanquette	= cooked in a thick white sauce
Chartreuse	= a mould (of fruit, jelly, or some savoury mixture)

Chaufroid	= coated with chaufroid sauce
Confit	= preserved in sugar
Compôte	= stewed (of fruit)
En cocotte	= served in a small earthenware dish
En kari	= served in curry sauce
Fourré	= coated with sugar, cream, etc.
Fricassée	= stewed with white sauce
Maître d'hôtel	= grilled
Rôti	= roasted
Sauté	= fried lightly

Soups are divided into consommé or clear, and purée or potage thick. Eggs are served à la coque, or boiled, or sur le plat, poached. The roe of fishes is known as oeufs de poisson. Fried potatoes are pommes frites, and mashed potatoes purée de pommes de terre. Café au lait is coffee with milk, or white coffee; café noir is black coffee, or coffee without milk.

For a formal dinner the following courses are usual, hors d'oeuvres, soup, fish, entrée, roast, vegetables, sweet, and savoury. For an informal dinner the hors d'oeuvres may be omitted, as may soup or fish, sweet or savoury.

A Dinner Menu. In compiling a dinner menu certain rules should be observed. For instance, the colourings of the various courses should contrast with each other and a variety of flavours be secured. The principal ingredient of one dish should not appear in another; for instance, if the soup is artichoke, artichokes should not be served as a vegetable. Two dishes of beef or mutton should not be served at the same meal; roast beef and fillets of beef, for example. Two fried dishes should not be served in succession, nor should two boiled ones. Two sauces of the same colour should not follow each other, and the same garnish should not be used on two dishes.

Variety is also desirable when two dishes are offered in the same course. For instance, if there are two soups, one should be clear and the other thick. If two fish dishes are offered, one should be plainly dressed, e.g. boiled halibut, and the other should be more elaborate, e.g. lobster cutlets. Of two entrées one should be cold and the other hot; one should be light and the other somewhat heavier. Of two sweets one should be light and cold; the other hot and more substantial. Of two savouries one should be hot and one cold.

Menu Cards. Menu cards, or cards which contain the details of the menu for a big public dinner, are usually printed, in some cases this being very elaborately done and the card artistically decorated. Menu cards suitable for the home can be bought, just as postcards can. These are headed and left blank for the cook or someone else to fill in the date and the details of the various courses. Menu cards for dinner parties and other festive occasions are often specially prepared, a design being drawn by an artist. This will frequently contain something appropriate to the particular occasion. Such cards can be obtained from a firm of printers, or are provided by the caterers.

Menu card supported in a holder consisting of a small china animal figure.

Small white marble or china tablets, with stands to match, are sometimes used as substitutes for ordinary menu cards, and on these the menu is written in pencil. Holders for menu cards can be obtained in oxidized metals, plated silver, or china, or in fancy designs suitable for a festive occasion such as a Christmas party. *See Course; Dinner.*

MERCERIZING. The result of the mercerizing process is to lend to good cotton some of the lustre of silk. Innumerable examples are found in mercerized poplin, linings, and sewing, knitting, and embroidery threads. Linen and even jute may be mercerized, but not wool.

Mercerized cotton absorbs dye much more readily than unmercerized, and should the re-dyeing of mercerized goods be attempted, care must be taken to see that the dye is thoroughly dissolved. Should any particles remain, they will lead to dark spots of colour upon the article. Drying after dyeing must be cautiously done at an even temperature, for if done before the fire with some portions exposed to more heat than others the colour will be irregular. A good plan in dyeing mercerized goods is to soak them first in water to which a little glycerin has been added.

It is only good cottons made from long fibred cotton, combed in course of manufacture, that show any adequate benefit from the treatment. One can thus be pretty sure that mercerized cotton is good material. Properly done, the process of mercerizing strengthens the article, but when badly done, ruins it. *See Cotton.*

MERCURY: The Metal. This is one of the metallic chemical elements, and is also known as quicksilver. It is fluid at ordinary temperatures, but solidifies at -38° F. and boils at 675° F. It is a very heavy metal, weighing almost $\frac{1}{2}$ lb. per cubic in. Pure mercury flows freely as a liquid, has a silvery white colour and a metallic lustre.

Mercury dissolves many metals, forming with them the alloys, known as amalgams. It is used in the manufacture of fulminate, for the percussion caps of cartridges, and is also employed in electrical appliances. It is the gauging element in thermometers, barometers, and other scientific instruments, being particularly susceptible to variations in temperature.

Another application is the mercury vapour lamp, giving a good light, but devoid of red light rays. *See Barometer; Mirror; Pendulum; Thermometer.*

MERCURY: The Drug. Employed in many different forms both externally and internally in a wide range of morbid states, mercury is one of the most valuable drugs in the pharmacopoeia, and externally is most commonly used on account of its strong antiseptic qualities. In any form the drug is always a more or less dangerous one, which should never be used except under a doctor's supervision.

It should never be forgotten that most mercury preparations are highly poisonous, particularly those used for their antiseptic action. The acute form of mercury poisoning is usually caused by swallowing corrosive sublimate. An emetic of a tablespoonful of mustard in a glass of warm water should be given and the doctor be summoned at once.

Before and after the emetic, give the beaten-up whites of four or five eggs, and then soothing drinks, such as milk, to each pint of which a wineglassful or two of olive oil is added. Put the patient to bed and keep him warm with hot-water bottles.

MERINGUE. A meringue is a mixture of whipped whites of eggs and fine white sugar. Flavouring may or may not be added. In making successful meringues two rules must be observed: whip the whites of egg really stiff, and cultivate speed in the shaping of the mixture. The least scrap of moisture or egg yolk will prevent the whites from whipping up stiffly. If the egg whites are allowed to stand overnight they will whip up more quickly.

To make the mixture, whisk the whites of 6 eggs to a firm white snow, then sift in lightly 8 oz. castor sugar. The meringue is now ready to be shaped, and this may be done with a meringue forcer fitted into a stout jean bag or with two dessertspoons. Cover a $\frac{3}{4}$ in. thick pastry board or a baking tin with white kitchen paper slightly oiled, with pure olive oil, and force or shape the meringue on to the paper. If shaped with the spoons, gather up enough mixture to fill the spoon, smooth it round the edge, scoop the meringue out with the second spoon and drop it on to the paper, turning it over. It will be an egg shape.

When all are shaped, sift over some castor sugar and bake them in a cool oven to a very light fawn colour. The oven must be really cool, and the meringues will take 2 to 3 hours to bake. When cooked, remove each meringue carefully from the paper, press in the soft portion inside, or remove it, and return them to the oven, which must be very slack until they are perfectly dry. They can then be stored in tins. Each egg-shaped piece is the half of a meringue, and must be filled with whipped and flavoured cream before being fitted to its fellow half.

This mixture is used for the decoration of many sweets. It may be made into a covering for fruits or may be forced in patterns on custards, trifles, etc. The meringue covering must always be dried in a cool oven, but the forced decorative pieces are dried on paper by themselves and fastened to the sweet with cream or fondant. Meringues are often filled with ice cream instead of whipped cream. It is necessary to put the case on ice for a little while before filling it if this is done.

Meringue Gâteau. This sweet is made by adding a pinch of salt to the whites of 3 or 4 eggs, whisking them to a stiff froth, and then folding them into 6 dessertspoonfuls of castor sugar. Heat the syrup from a small tin of red cherries, and use it to soak a sponge-cake ring. When saturated, put the ring on a dish, coat it with the meringue mixture, and leave it in a warm oven for about 20 min. so that the meringue becomes crisp and of a pale biscuit tint.

Let it get cold, then fill the centre with the cherries, piling them up high. Decorate the top with some stalks of angelica, and serve the whole with some syrup made thus: Boil 2 oz. lump sugar and a gill of water for about 6 min., then skim it well, and when it is cold stir in $\frac{1}{2}$ gill sherry and colour it with cochineal. Whipped cream sweetened and flavoured may be served separately.

Meringue Gâteau made with a centre of cherries.

Meringue Jelly. Small meringue jellies, coloured with cochineal, make an attractive party sweet. To prepare them, dissolve a pint packet of strawberry jelly in hot water, and leave it until cold, but not set. Add a pinch of salt to the whites of 2 eggs, beat them to a stiff froth, and then beat them into the cold jelly. Continue beating for about 10 min., add the colouring, and stir the whole so as to get an even effect. Pour the jelly into small wet moulds, and when set turn them on to a glass or china dish.

Meringue Jelly. A party sweet for which fruit jelly and beaten white of egg are used.

MERINO. This is the name of a Spanish breed of sheep bearing exceptionally fine, short, and wavy wool and is the original of a type now reared in many other countries; merino is thus a name for ultra-fine wool, superior to that of cross breeds, and the name of the material has been transferred to the goods that are made from it.

Merino or French merino dress stuff is a fine twill made from merino wool. At once warm and light, made usually 40-44 in. wide, and available in cream and light shades as well as in black, it is a serviceable, if old-fashioned, dress stuff. In knitted underwear merino has by long custom a different meaning, and implies a wool and cotton mixture, generally soft to the touch resembling that of pure merino wool. Merino underwear is usually cheaper than all wool, and is bought on that account and also because it shrinks less than all wool in washing.

Merino wool in any of its forms tends to shrink when washed. The tendency is seen in soft, fine baby flannels which should continually be stretched, first in one direction and then in the other, while drying. Stockings made from merino wool contract and thicken because the material felts easily. Soap assists the felting, and for this reason all soap used in washing should be carefully rinsed out.

MERTENSIA. This borage-like herbaceous perennial is suitable for the border or rock garden. It thrives in ordinary well-drained soil and is increased by division in spring or by seeds. The oyster plant (*maritima*) and *alpina* are both of low growth and bear blue flowers in early summer. Taller kinds suitable for the border are the Virginian cowslip (*pulmonarioides*) and *sibirica*: they are about 15 inches in height and bear blue flowers in May.

Mertensia. Blue flowers of the species *sibirica*, a plant suitable for a shady border.

METAL POLISH. There are two chief varieties of metal polishes. One is made up of rottenstone 2 oz., soft soap 1 oz., and strong solution of oxalic acid, sufficient to make the whole into a thick cream. The second is composed of fossil earth 2 oz., oleic acid 2 oz., oil of mirbane ½ dram, mixed into a smooth paste.

A liquid polish is made as follows: Mix soft soap 2 oz. with solution of ammonia 5 oz., and separately mix kaolin 4 oz., with petrol 9 oz. Place the two liquids in a tin and shake them well together. A simple form of metal cleaning liquid is made by dissolving oxalic acid 1 oz. in hot water, 1 pint. This is rubbed on to the tarnished brass-work with a cloth and cleaned off with a separate cloth upon which whiting has been placed. These polishes are not for silverware.

METAL SPINNING. Just as the potter moulds clay on his wheel, soft sheet metals are shaped on the lathe with smooth steel tools. Metal spinning, as it is called, is employed for making lamp containers and similar vessels, and by using wooden formers the metal can be shaped in almost any profile.

The process requires a good deal of experience in the behaviour of sheet metals when subjected to local pressure. Where large quantities of one article are required, pressing in stamping machines is resorted to; but a well-spun container of moulded form, finished in bright metal, gives a better finish than the product of the power press, unless the work is subjected to a subsequent operation while rotating in a lathe. To exemplify spinning in its simplest form, a piece of wood is held in the lathe and turned up to any desired profile, with curves and corners suitable to the thickness of the

metal which is to be spun. This former, as it is called, appears in the photographs. A special tool rest, Fig. 1. is then rigged up, which may be of the ordinary type but with a flat topped tee, having several holes in which the operator can place steel pegs to suit his own convenience. A disk of lead or soft aluminium sheet is screwed by a central screw to the former. By working the shank of the long-handled tool against the steel pegs in the tool rest, using the peg as a fulcrum, and bringing the tool up to the disk with a sweeping action, the revolving metal can be formed into shape. The metal is greased before and during the spinning operation, soft soap or vaseline being commonly used.

Metal Spinning. Fig. 1. Tee rest for spinning lathe. Fig. 2. Necessary tools for the work. Fig. 3. Ballbearing tail stock spindle. Fig. 4. Stages in metal spinning: A, disk in position; B, disk being shaped; C, follower in position; D, completed shape in section. The work is shown in progress in the photographs.

Figs. 4-6 show the method of spinning an ornamental base for a vase or, other article. As the object is not pierced with a screw in the centre, the sheet metal has to be held up to the former by a revolving centre. Since a certain amount of thrust is necessary to retain it in place spinning lathes are fitted with ball-bearing back-centres (Fig. 3) to reduce the end friction. When the work has half progressed, the back-centre thrust block is replaced by a follower to prevent the work already spun from altering in shape. The job must be annealed between operations if, through tooling, the metal gets too hard to flow properly. The tools used (Fig. 2) are long, and stout enough to resist bending. The handles are held firmly under the armpit, the steel end being placed between two pins in the rest. The nose of the tool is held a little below the lathe centre at a point near the centre of the job; the pressure is applied towards the larger diameter of the disk with a sweeping movement, continuing the stroke repeatedly. On the return stroke a small pressure is maintained on the work.

Fig. 5. Method of holding tool for first stage in spinning a bowl. Fig. 6. Disk spun over to shape.

To prevent the disk buckling, a back stick is employed. This accessory is a short piece of hardwood, like an accountant's desk ruler. It is used in the left hand and held hard up against the rotating sheet metal on the side opposite to that upon which the spinning tool is operating. Rough edges of work are skimmed with a cutting tool, as used in hand metal turning. Internal work needs hook tools. Roller tools are also employed. All tool points must be quite hard and highly polished, like metal burnishers. Each job requires its own former. When the diameters of the job will not allow a solid former to be used, i.e. in spinning an object like a narrow-necked jar or a bottle, where the former would be imprisoned inside, split formers must be used.

Taking a diameter of 4 in. as an average size of work in metal spinning, the speed in revolutions per minute is approximately as follows: soft sheet iron 1/32 in. thick, 600; thicker sheets, 400; zinc, 1,200; copper, brass and aluminium, 800 to 1,000. The work requires so much skill that only the simplest jobs should be attempted at first, using the softer metals like copper and aluminium. For any but the smallest work a power lathe is desirable. *See* Chuck; Face Plate; Lathe; Mandrel; Metal Work, etc.

METAL TURNING ON SMALL LATHES

The Tools and Their Use in Various Operations

This contribution deals briefly yet comprehensively with the main processes in metal turning. Lathes suitable for the amateur are described and illustrated in the article Lathe. *See also* Metal Spinning; Metal Work, etc.

The process of removing the surface of metal in a lathe is known as metal turning. The object is attached to a rotating spindle, technically known as a mandrel, and a cutting tool is applied to the revolving work so as to produce the required shape and size with a degree of accuracy hardly obtainable in any other way. The tool may be fed up by hand, or in a sliding screw-feed tool fixing, known as a slide rest. For hand turning in metal it is of the greatest importance that the tools should be long, and have handles of adequate length and stiffness.

To obtain the maximum power over the work, the heel of the tool should be supported by the rest, the adjustable bar near to the revolving work on which it is held during the operation, well under the cutting edge, as shown in Fig. 1. The tool should be gripped firmly and, especially where iron or steel is being operated upon, the handle of the tool should receive a further support by resting in the hollow of the operators shoulder. It will tend to hit at the handle, and if not resisted this will result

in the tool getting jammed between the work and the tool rest, very possibly spoiling the one and breaking the other.

Metal Turning. Fig. 1. Showing how a hand tool cuts the metal.

The heavier jobs in metal turning are not usually set out to be accomplished by hand where a modern slide rest lathe is available. Hand turning of this character requires years of practice and great strength of wrist. When work must be done by hand the cutting must be obtained by rolling the tool on its heel, so that the point enters the metal with the cutting edge at an angle to it.

Lighter work on the softer metals, such as brass and aluminium alloys, can be operated on with much less fatigue. The tool can be held as illustrated in Fig. 2.

Skimming up a projecting rim with a hand tool, as here shown, is a quick and easy method of producing the desired result. There are many other similar operations, as, for example, the making of an odd-shaped knob, or producing a curved, conical object like a water-jet, which would prove troublesome to produce singly on a slide-rest lathe, but can be made quickly and accurately with a hand tool, using a shaped template in thin card or metal as a guide to form and size.

Fig. 2. How to hold a metal turning tool when skimming up a projecting portion of the work.

Types of Tool. Among the most useful hand tools for a metal-turning lathe is the round

nose tool shown in Fig 3, *a*. This cuts at the side to a certain extent, as well as in the front, hence its being used for the job illustrated in Fig. 2. A second implement, the side tool (Fig. 3, *b*), has a cutting edge on its left-hand side; it may have a counterpart made to the opposite hand. The pointed or graver tool, shown at *c* in Fig. 3, is another useful hand tool.

Fig. 3. Types of hand turning tools: a. round nose; b, sidetool; c, graver or diamond point.

For brass work, the nose and side tools should have flat tops, as shown in Fig. 4. For turning iron and steel a top rake is necessary (Fig. 5), to obtain the best cutting effect. A pointed hand tool is extremely useful in producing a centre pop in a piece of work revolving in a chuck, preparatory to drilling it with the drill held against and fed up by the tailstock. In producing such a centre pop, the difficulty is getting rid of the pip which so readily forms in the centre of the sinking. A sharp tool is therefore essential. Why this pip forms will be readily

understood when it is remembered that the absolute centre is not moving at all, and that the metal around it is only moving with a slow-cutting speed. The thin spike or pip, being frail, is easily broken off.

Where the tailstock of the lathe can be brought up to the work, has a suitable chuck fitted to it, and is sufficiently stiff and accurate in alinement, a special device known as a centre-drill may be used. This is, however, a matter of appliances; the mechanic should be able to produce the centre by hand.

Metal Turning. Fig. 4. Diagram showing use of flat-topped tool for brass work. Fig. 5. Use of top rake for turning iron.

Use of Chucks. Work to be turned can be held in the chuck. The self-centring chuck is the

most commonly used appliance for holding any kind of work which in itself is reasonably round. The three jaws in this type of chuck all move together radially, either towards or from the centre, according to which way the operating key is rotated. The jaws are of two patterns, outside and inside, both sets being supplied with the tool. The outside jaws are used to hold rings and disks for facing, boring, as in Fig. 6, or turning portions which are clear of the jaws. With the inside jaws, a hollow bush can be held by the internal bore, and the outside operated on almost completely. The inside can only be machined for a part of the way. The presence of the jaws of the chuck gripping the work inside tends to prevent deep boring.

Metal Turning. Fig. 6. Internal boring, showing work held in a three-jaw chuck. Fig. 7. Face plate work, showing a small piece of work clamped to plate.

The inside jaws are generally in place, because their function is also to hold small diameter rods, drills, and spindles on the outside. A self-centring chuck is only approximately accurate. For example, if a hollow bush is bored truly cylindrical on the inside, is then removed and replaced in the jaws of the chuck from this bore, and turned up outside, the outside and inside will not be concentric to a degree desirable in anything but rougher work. Independent chucks in which the four jaws are separately operated by screw keys are therefore used. The work can be tested and adjusted during the fixing up in the chuck and greater accuracy obtained. Work may be bolted to the

face plates with the part of the work to be operated upon clear of the holding-on bolts, as in Fig. 7. Here again the method of securing will depend upon the shape of the work. If it is not symmetrical the part out of balance must be counterweighted by bolting a suitable piece of metal on the opposite side. The alternative is to swing the job on centres, which is usually the method adopted for turning pins, bars, and shafts. Fig. 8 shows this arrangement.

Left. Fig. 8. Rod mounted and driven between centres.

Fig. 9. Roughing down a mandrel, a swan-necked tool being used in the slide rest.

The Mandrel. In employing the slide rest, the correct choice of methods in holding the work is as important as the actual turning. The turning of a disk absolutely true with a hole bored in its centre is not usually accomplished in a chuck. The work after boring is mounted on a mandrel, i.e. a bar previously centred and turned true on centres. It follows that, the mandrel being true, a greater degree of accuracy can be obtained than by holding the work in a chuck and adjusting it until it appears to run true.

Standard-sized mandrels can be obtained ground truly cylindrical to a high degree of accuracy. To provide for slight variations in the diameters of the holes to be accommodated, expanding mandrels, which are made to grip the work by screw-pressure, are provided. Mandrels should not be used for heavy jobs unless they are strong enough to do the work without springing.

Roughing down a mandrel is illustrated in Fig. 9. The rough bar is held between centres, driven by a carrier and cut with a swan-necked tool fixed in the slide-rest tool holder. To allow long mandrels and pins to be turned slightly taper and also to adjust parallel turning to a high degree of accuracy, most of the better lathes are fitted with a set-over arrangement on the tail stock. The centre of the latter can then be moved across the bed to alter the alinement in relation to the bed.

Internal Work. Internal turning, or boring, as it is termed, is accomplished by placing a hook tool in the holder longitudinally, as in Fig. 6. The feed-in, which increases the internal diameter of the work being operated on, involves a reversed movement of the slide-rest handle. Where it is essential that the bore of an object shall be quite true with its external diameter, it is necessary to perform both the internal and external turning operations while the work is fixed in the chuck. This has been done in the case of the piston illustrated in Fig. 6. The easting is held in the chuck by a spigot, or tenon piece formed on its head, which is afterwards sawn off. Where such an operation is impossible it is usual to bore the job out accurately, and then to remove it from the lathe. A turned mandrel is made to fit the bore tightly, and the outside operations are accomplished with the work on this true mandrel.

In feeding the tool, regularity of rotation of the hand wheel on the end of the screw should be observed. The knack of operating the feed handles with an even motion is soon obtained. Every lathe has its peculiarities. Where handles are fitted to the feed screws, the fingers and thumb alternate in propelling the screw. With a wheel, a slightly different manipulation is required, the rim of the wheel being grasped by the hand. The tool should always be kept moving slowly but evenly; if it proceeds in jerks, the work will show rings.

All screw-cutting lathes can be arranged to obtain a self-acting traverse. The lead screw which operates the sliding saddle should be connected up with a train of change wheels to give one of the finer rates of feed, i.e. 100 to 200 turns to the inch. With the self-acting feed, very fine finishes can be obtained without effort.

Screw Cutting. In screw cutting, the saddle of the lathe is traversed along the bed with a rate of feed which bears a predetermined proportion to the revolutions of the mandrel. The lead screw which guides the saddle tool holder is coupled by a train of gear wheels. These may be altered in ratio as desired. Assuming a lead screw with 1/10 pitch.

If the ratio of gears on the change-wheel quadrant is altered, say, by coupling a 20-tooth change wheel on the mandrel with a 60-wheel fixed on the end of the lead screw, that is in a proportion of one to three, then the lathe will produce three times 10 pitch, or a screw of 30 threads to the inch, on the job rotating in the lathe. Change wheels for all the usual threads are supplied with screw-cutting lathes. Odd sizes are sometimes obtainable.

Short threads can best be produced on a foot lathe by taking definite cuts along the threaded portion, stopping the lathe at the end, withdrawing the cut on the top slide rest, running the lathe backward, and advancing the cut, proceeding through the same cycle of operations without

releasing the lead screw. For longer threads, the lead screw is declutched at the end of the cut, and the saddle and slide rest traversed back by hand. The proper re-engagement of the clutch or lead screw nut may require the chalk marking of the work and the change wheels, to prevent a cross-threading cut being taken. Fig. 10 shows a screw thread that is being cut on the end of a pin supported between the lathe centres.

Fig. 10. Screw cutting in a lathe.

Hand chasing, or screw thread chasing, bears the same relation to screw cutting as hand tool work does to that requiring the slide rest. Its successful use is largely a matter of skill. It is also more usually employed in dealing with brass work and for the finer threads, such as 32, 28, 26, 19 threads per in., standard sizes for pipe work. The chaser is a hand turning tool with a cutting edge in the form of a screw thread of the particular pitch it is desired to obtain. With the work revolving, not too quickly, the hand chaser is struck in with a lateral sweep. Milling, drilling, and dividing, also the formation of scrolls, worms, and gear teeth, may be accomplished in the lathe, by the addition of suitable fitments and accessory devices.

Cutting Speeds. The cutting speeds for various metals differ. The term cutting speed must, however, not be confused with the rate of feed. The latter is dependent on the size and power of the

lathe being used. Cutting speeds are the same for any lathe. Wrought iron and steel should be turned at from 200 to 300 in. per minute, tool steels at 200, cast iron at 190 to 200, soft gunmetal at 500 to 600, and brass at 800 in. The speed is found by multiplying the revolutions of the lathe mandrel by the circumference of the work. A piece of work in cast iron, 1 in. in diameter and approximately $3\frac{1}{8}$ in. in circumference, should therefore run at from 60 to 65 revolutions per minute.

With the average foot lathe it is difficult to get a high enough speed in turning small brass work, and one low enough for a large diameter cast-iron object, and therefore a certain degree of compromise in the matter of speeds has to be accepted. Cast iron, brass, and gunmetal are not lubricated in turning operations, but to obtain a good finish on wrought iron and steel requires the use of oil, or any saponaceous solution.

METAL WORK. This term includes all the mechanical processes for the fashioning of metal. Practically speaking, all metals are worked in one of four ways: the metal is cast, rolled into sheets and bars, drawn into tubes, or extruded. Casting is perhaps the first of the metal-working processes, as it utilizes the metal practically in the raw state. Briefly, the process consists in making a pattern or mould of the shape of the desired casting, and impressing it into damp sand, thus making a hole or cavity which is subsequently filled with metal. The casting is afterwards finished by machining in a lathe, or it may be milled.

Ordinary sheet or bar metal has generally to be cut to something approximating to the desired length or size, and this is done by sawing with a hack saw or cutting with cold chisels. Metal work that calls for many joints introduces soldering and brazing, both of these being accomplished by melting another but softer metal than that to be united, and flowing it into the joint between them. In some cases welding is necessary, particularly when dealing with iron and steel. Heavy pieces of metal that cannot conveniently be shaped in other ways are often fashioned by forging. Sheet-metal work generally calls for a knowledge of rivets and riveting.

Hammers for metal work do not differ materially from those used by other trades, and may range from a light-weight riveting hammer to a heavy sledge hammer for fashioning thick pieces of metal while hot, and for delivering heavy blows in general. Files are very necessary in all classes of metal work. The average size is generally between the ranges 6 to 10 in. in length, and varying from a smooth to a coarse cut.

Drills of all kinds are necessary for making holes in metal, and are made in all sizes from something under $\frac{1}{16}$ in. upward in diameter. To rotate these drills, a hand-drilling machine is convenient up to about $\frac{3}{8}$ in. diameter. Above this size, however, a treadle apparatus or a powerful bench-drilling machine will be found necessary.

A vice of some kind is essential in metal working, and should be sufficiently robust for the class of work normally undertaken. A small vice can only be suitable for small work, but for heavier work a good substantial bench vice is necessary. Another useful metal-working tool is the grinder, and comprises a variety of different types.

All manner of turning and shaping processes on metal can be carried out with the lathe. Numerous appliances and tools are used in conjunction with it. Cold chisels form an important group of metal-working tools, and, while they are inexpensive, they are capable of much useful work in the chipping out and cutting of sheet and bar metal. Smaller tools include punches, used for riveting and for making indentations.

METER. A meter is an apparatus that records automatically the quantity of a gas or fluid passing through it. Such are used for measuring the amount of gas, electric light, and sometimes water, used in a house. Some electric light and gas meters are worked by the insertion of coins, a penny or a

shilling providing a certain amount of light, which automatically fails when the quantity is exhausted. *See* Electric Light; Gas; Water.

METHYLATED SPIRIT. Alcohol which has been rendered unfit for use as a beverage by a process of denaturizing is sold as methylated spirit and has many uses in the home. It must, however, always be most carefully handled owing to its highly inflammable nature. Naphtha and petroleum or paraffin are the agents commonly employed for denaturizing, together with a trace of blue aniline dye. The sale of methylated spirit is regulated by law, and is forbidden between 10 p.m. on Saturday and 8 a.m. on Monday.

Methylated spirit is used for heating small stoves which contain an absorbent substance, such as asbestos fibre. In filling the stove only as much spirit should be added as can be absorbed and no more. It is dangerous to add a surplus of spirit, as when lighted the flame may be carried on to the table and cause a fire.

For glass cleaning there are few things to equal methylated spirit; it is invaluable for polishing wide surfaces of glass, such as wind screens, table tops, or the glass covers sometimes inserted in polished trays. It is equally efficacious for windows, but is too expensive for the ordinary householder to use in large quantities. For small things the quantity needed is not excessive, and is well worth the outlay. A few drops on a soft cloth are generally sufficient. A little methylated spirit put in the water when rinsing white silk blouses gives gloss and firmness. Applied to brown boots the spirit removes stains and produces a fine polish. As it tends to dry up the leather, it should only be used occasionally.

For various medicinal and surgical purposes methylated spirit is of great use. If, for example, it becomes necessary to sterilize bowls or other utensils quickly and there is no time to boil them, a little of the spirit may be poured in and lighted, and when it has burnt itself out the bowl will be ready for use. Lancets or similar small instruments may be stood in methylated spirit for half an hour and are then completely sterilized. For preventing bed sores or any other form of chafing methylated spirit should be rubbed on, and the area powdered. This applies also to tender feet, or to hands which blister easily when doing unaccustomed work. Finally, it makes an excellent lotion for sprains or bruises, when added to water and applied as a compress.

METOL: The Developer. Metol is a photographic developer which gives thin, delicate negatives with full detail but little density. It is rapid in action, and is best used with a slow developer, such as hydroquinone. Metol is frequently used with pyro, the combined developer being known as pyro-metol.

The following is a formula for one-solution plain metol developer:

Metol	75 gr.
Sodium sulphite (crystals)	1¼ oz.
Sodium carbonate (crystals)	1¾ oz.
Potassium bromide	8 gr.
Water to make	10 oz.

For ordinary use take 1 oz. of the above solution and add 2 oz. of water. For portraits, add 1 oz. of water to each oz. of the stock solution.

In all developers containing metol the metol should be dissolved first, then the sulphite, followed by the other chemicals, using warm, but not hot water. The Watkins factor for metol is 30.

With some persons metol has an unpleasant action on the skin; the skin cracks and the fingers swell, resulting in broken nails and sores, which may spread to other parts of the hands. In such cases the use of the metol developer should be abandoned, though the risk of poisoning may be greatly, if not entirely, obviated by the use of rubber gloves. The poisoning may be treated by soaking the hands in

warm water and rubbing in zinc ointment, using bandages or gloves at night. The following ointment will cure the sores:

Ichthyol	1 part
Lanoline	4 parts
Boric acid	4 „
Vaseline	3 „

If a metol developer has to be used the hands should be washed frequently in clean water while at work, and afterwards washed thoroughly with warm water. *See* Developing; Pyro.

METOL-HYDROQUINONE. An excellent developer for general use is metol-hydroquinone, usually referred to as M.Q., and suitable alike for films, plates, bromide, and gaslight papers. It combines the advantages of both developers, giving the detail rendering of metol and the density and contrast of hydro-quinone. If properly made up it is clean-working and non-staining. The full quantity of sulphite given in the formulae that follow must be used. A good one-solution M.Q. developer is as follows:

Metol	20 gr.
Sodium sulphite (crystals)	1 oz.
Hydroquinone	25 gr.
Sodium carbonate (crysta	$\frac{3}{4}$ oz.
Water to make	10 „

Dissolve these in the order named, using warm (not hot) water. For use take equal parts of the solution and water. It should only be made up when wanted, and used fresh. A two-solution which will keep is made up thus, using equal parts of A and B:

solution A.

Metol	20 gr.
Sodium sulphite (crystals)	60 „
Hydroquinone	25 „
Potassium bromide	8 „
Water to make	10 oz.

solution B.

Sodium carbonate (crystals)	$\frac{1}{4}$ oz.
Water to make	10 „

The Watkins factor for M. Q. made as above is 14. M.Q. is a very suitable developer for all-round use by the amateur. As long as it is properly made up, used fresh after preparation or dilution from stock solution, it is always to be relied upon.

Developers containing hydroquinone cease to act almost entirely when the temperature falls below 60° F. If the M.Q. developer cannot be kept well above this temperature in winter it is desirable to increase the metol in the two-solution formula above to 30 gr. and reduce the hydroquinone to 15 gr. It is, of course, useless merely to warm the developer and its dish, as it will quickly take on the temperature of the dark room. *See* Developer; Developing; Hydroquinone.

METRE. This common measure of length is the unit of the metric or decimal system. It is equal to 39·37079 in., or something more than a yard. It is divided into decimetres (10), centimetres (100), and millimetres (1,000). The following table gives the equivalents of metres in yards:

Metres	Yards	Metres	Yards	Metres	Yards
1 =	1·093	8 =	8·748	60 =	65·616
2 =	2·187	9 =	9·842	70 =	76·552
3 =	3·280	10 =	10·936	80 =	87·488
4 =	4·374	20 =	21·872	90 =	98·424
5 =	5·468	30 =	32·808	100 =	109·361
6 =	6·561	40 =	43·744	200 =	218·722
7 =	7·655	50 =	54·680	400 =	437·444

The Metric System. The metric or decimal system of weights and measures is a French invention, but is used to some extent in Great Britain. It aims at uniformity and simplicity, features which are wanting in the system that has grown up in haphazard fashion in England. The alternative name, the decimal system, is due to the fact that it works in tens, simplifying calculations.

The fundamental unit of the system is the metre, a measure of length, and from it the other units are derived. The gram, which is the unit of weight, equals the weight of one cubic centimetre of pure water at its maximum density. The unit of capacity, the litre, is equal to the volume occupied by 1,000 cubic centimetres of pure water of maximum density. From these the other weights and measures are derived. The Greek words, kilo, hecto, and deca mean 1,000, 100, and 10, a kilogram being 1,000 grams and a decalitre, 10 litres. For small quantities the Latin words milli, centi and deci are used, a millimetre being 1/1000 part of a metre and a centigram 1/100 part of a gram. The capital letters K, H, and D are used for the multiples, and small letters m, c, and d for the weights and measures that are less than a unit. Kg., therefore, represents kilogram; Km., kilometre; and KL, kilolitre; mg. represents milligram; cl., centilitre; and dm., decimetre. The word myria (M) is used to represent 10,000.

In addition, there are special units for square or superficial measure. For instance, 100 square metres equal an are, and 100 ares equal one hectare. In the case of areas the multiples change by 100, not by 10 at a time, and in the case of volume, or cubic measure, they change by 1,000. Below are some of the metric weights and measures and their English equivalents:

1 metre =	39·37079 in.
1 kilometre =	0·62138 miles, or 5 furlongs
1 sq. kilometre =	247·17 acres
1 gram =	15½ grains
1 kilogram =	2·2046 lb.
1 litre =	1·75 pints

METRONOME. A metronome is a device enabling a composer to indicate with precision the speed at which he wishes his music to be performed. It is based on the principle of the pendulum, which differs, however, from that of a clock in being weighted at both ends, and in oscillating from the centre instead of from the top.

The weight upon the upper part of the rod is made to slide up or down so as to rest against certain figures engraved thereon. The figures begin at 40 or a little more at the top of the rod and progress down at intervals by two's to 60, after which they go on by threes to 72, then by fours to 120, next by sixes to 144 (where some metronomes finish), and finally by eights to 208.

The position of these figures is calculated in proportion to the heaviness of the fixed weight on the lower part of the rod, so that on the movable weight being placed against any given figure, the pendulum will swing that number of times in a minute. Consequently, all the composer has to do is to indicate the value of the note which represents the pulse or beat of his music and then to give the necessary figure. In the great majority of cases the crotchet, either plain or dotted, is the unit of speed, though the minim and the quaver are occasionally used [] = 60 therefore means that the music is to move at the rate of 60 crotchets per minute.

Metronome. Device for indicating speed at which music should be performed. (Courtesy of Hawkes & Son)

There is more than one kind of metronome. That known as the Maelzel is wound up like a clock, the mechanism being contained in a wooden case of pyramidal shape, and when the rod is released it oscillates, ticking at each swing. Sometimes there is a bell attachment, which can be adjusted so as to strike at regular periods. The Pinfold metronome has no clockwork. It swings silently on two steel points balanced on a tripod, and is set in motion by the finger. Both of these are on the double pendulum principle.

Another kind consists of a circular case containing a tape measure, which can be unwound to any given point and swung from the hand, the case forming the weight. When not in use it can be coiled up by touching a spring, and carried in the pocket. It is handy for an emergency, but is open to the objection that it cannot be in action simultaneously with musical performance.

The use of the metronome is to ascertain the general speed of the music; it should not be employed throughout a piece, except in very stubborn cases of faulty time, which it may help to correct.

MEZZANINE. This term is used in architecture to describe a storey or floor introduced between two principal floors, thus forming one small room within a larger one, lighted by a large window or windows which give light to the mezzanine floor and the other part of the floor beneath it. The arrangement of the mezzanine floor is largely governed by the architecture and plan of the building as a whole.

MICA. A mineral of complex and variable composition, mica is used in domestic work for windows for anthracite and other heating stoves, and for all purposes where translucence is desired and great heat has to be resisted. It is characterized by easy cleavage in a single direction, and may be divided to very thin sheets. When used in front of a stove it is generally about 1/20 in. thick.

Mica can be purchased from any good class oil and colourman. It is generally stocked in various sizes and shapes, and a size most appropriate to the job in hand should always be selected. If due care be exercised it can be cut to shape with a strong pair of scissors. *See Stove.*

MICE: How to Destroy. Both poison and traps are employed to destroy mice, but there is no more efficient remedy than to keep a cat in the house. Where no cat is kept mice appear sooner or later. Very often what attracts them, even where there is a cat, is a plentiful supply of food in the shape of breadcrumbs, scraps of cheese, or other fragments, or seed from bird-cages, left lying on floors or tables or shelves of cupboards.

The first precaution to be taken, therefore, is to see that all these tempting morsels for mice are carefully swept up, and cheese, sugar, grain, bread, etc., covered up, especially at night. Where poison is resorted to only small quantities should be employed, not in any case larger than a small haricot bean. Great care must be taken to prevent food from coming in contact with preparations sold for killing mice, as these usually contain phosphorus, strychnine, or arsenic.

An effective method is to bait cheese or bread with barium carbonate. After the poison has been laid all the holes should be stopped up, and a good material to use for this purpose consists of equal quantities of barium carbonate and dripping, made into a paste. The mice usually eat the poison in trying to nibble their way out. Whenever a mouse hole has been treated in this way a piece of paper may be pasted over the hole as a safeguard for pets.

Mouse Trap. The simplest pattern of mouse trap in use consists of a small piece of flat wood on which is fixed a powerful spring which operates a square-shaped wire. After the trap is baited the wire is pushed back and held by a catch, one end of which is inserted in a piece of metal on which the bait is laid. The slightest movement of the bait causes the catch to be released, and the sharp recoil of the wire, due to the spring, instantly kills the mouse. This break-back trap has almost entirely superseded the old-fashioned box trap, with wires, which closed on the mouse when it nibbled the bait. Either toasted cheese or a scrap of fat bacon is the customary bait employed, and the trap can be kept clean by being occasionally plunged into boiling water.

MICE: As Pets. Of the smaller animals that are kept as pets white or mottled mice give the least trouble. They should be purchased when quite young. For food the mice are given warm bread and milk, dry breadcrumbs and stale cake, dandelion and lettuce leaves, pieces of apple and carrot, and mixed bird seed. They should be kept in a glass-fronted and well-ventilated wooden box, in a perfectly dry and quiet place, away from direct sunlight.

The cage must be kept perfectly clean, and it is an advantage to have two cages in order that one may be in use while the other is being cleaned and dried.

A convenient cage for mice is easily made from $\frac{1}{4}$ in. wood and a few lengths of stiff wire. The base is 15 in. by 5 in., the fixed cage 10 in. long by 10 in. high, and a revolving wheel is formed from two 5 in. disks joined by 4 in. lengths of wire. The fixed cage is divided into two parts. One, 4 in. wide, is closed with a plain door, the other has a barred door formed by lengths of wire driven into strips of wood; both are hinged by nails driven in through the top and bottom pieces. Three $1\frac{1}{4}$ in. holes are bored in one disk and a similar hole in the end of fixed cage, and the revolving portion is hung so that the holes will coincide. The end supports of the cage are 7 in. by 5 in., with 2 in. cut from corners, and are joined with a 1 in. strip.

MICHAELMAS DAISY. This is the popular name of the hardy perennial aster, an important group of autumn flowering plants. They thrive in ordinary well cultivated soil and are increased by division in spring. They may be planted in autumn or spring. In the course of two years the plants form large clumps and must then be lifted, divided and replanted. The finest blooms of this plant are obtained by replanting small pieces in spring and setting several together in groups.

In recent years many beautiful new varieties having richly coloured flowers have been raised. Of the large-flowered varieties some of the best are Beauty of Ronsdorff, lilac mauve; King George, violet-blue; Perry's Favourite, rose; and Preziosa, violet-blue: these grow about 2 feet high and bloom in September.

Barr's Pink, carmine rose, $4\frac{1}{2}$ ft.; Beechwood Challenge, red, 4 ft.; Anita Ballard, lavender-blue; $4\frac{1}{2}$ ft.; Beauty of Colwall, lavender-blue, 4 ft.; Ethel Ballard, pale pink, 4 ft.; Maid of Athens, pink, $4\frac{1}{2}$

ft.; Mons, rose, 4 ft.; Mrs. George Monro, white, 4 ft.; and Peggy Ballard, mauve, 3 ft.: these bloom in September-October.

Climax, lavender-blue, 5 ft., and its white variety, alba, are handsome October-flowering varieties. Little Pink Lady and Little Boy Blue are two charming large-flowered varieties, 2-3 ft. high, which bloom in September. Acris, 2½ ft., bears a profusion of small lavender-blue flowers in August; Blue Star and Silver Gem yield dainty sprays of small flowers in September-October. Michaelmas daisies can be raised from seeds sown in boxes of soil in a frame in spring.

Michaelmas Daisy. Purplish lilac flowers of a tall free blooming variety.

MICROBE. The word microbe is applied to microscopic living things, animal and vegetable, particularly the latter. They are of various shapes, some being globular (micro-cocci), some like straight rods (bacilli), some wavy, some curved. Most microbes are harmless to man; many are very useful, as, for example, those which produce vinegar, the ripening of cheese, the nitrification of soil, etc. On the other hand, microbes are the cause of the great army of infectious diseases. *See Bacteria.*

MICROMETER. As a precision measuring instrument the micrometer is generally used in metal work, but it is applicable to the measuring of any material where extreme accuracy is called for. The principle of the micrometer is based on a screw calibrated so that readings of 1000th of an inch, or even finer, can be taken directly.

The ordinary type of micrometer is illustrated in Fig. 1, and comprises a U-shaped body. At one end is a circular projecting portion called a sleeve, which has a screw thread cut in a portion of its length. In the type of instrument to which the following description applies the pitch of the threads is 40 to the inch. Into the sleeve is screwed a spindle rotated by an outer portion called the thimble, which is milled to afford a sure grip. In some patterns this and the thimble are rigid, but in the Browne & Sharpe instrument, illustrated, a ratchet device is provided in the form of a subsidiary and smaller handle which is situated at the end of the thimble.

Micrometer. Fig. 1. Complete instrument with adjusting spanner and gauge disk.

Its function is to rotate the thimble to open the jaws of the micrometer, but to close them with a pressure determined only by the amount of friction on the spring pawl of the ratchet. When the determined pressure between the measuring faces has been reached, the ratchet will slip and the screw cannot be turned any more. As a consequence of this, it is impossible to strain it. A locking device is provided in the form of a little milled ring, situated in the upper part of the frame. This, when rotated, grips the spindle rigidly, so that if the instrument is required to measure several pieces of the same size, it can be locked and used as an ordinary fixed type of limit gauge.

The anvil is movable, and by means of the milled nut at the end of the frame opposite to the sleeve it can be drawn back, to increase the measuring range of the instrument. The pattern illustrated can

measure up to 2 in. in diameter with the anvil drawn back, and from zero to 1 in. when the anvil is pushed forward. To set the instrument, the spindle is set at zero, the anvil drawn back, and a limit gauge in the form of a circular disk inserted between the end of the spindle and the anvil. The latter is then pressed into contact with the disk, and locked in that position. Fig. 2 shows the anvil drawn back and the testing disk in position.

Fig. 2. Setting micrometer with inch gauge disk.

In use, the instrument is simply applied to the object to be gauged, the thimble rotated until it is almost in adjustment, and the final turn completed with the aid of the ratchet handle. This drives the spindle into contact with the object to be measured. The same principle is applied no matter what the shape of the object may be, so long as the spindle and anvil can bear upon it. Supposing it to be a bar of metal $1\frac{1}{8}$ in. in diameter, this reading would be taken as thousandths of an inch, as, practically speaking, all micrometers are calibrated in the same way, or else have metric readings.

Care must be taken that the metal to be gauged has a true and smooth surface; otherwise it will be impossible to obtain an accurate measurement. On the bevel edge of the thimble is a series of lines and marks, beginning at 0, the next marked division being 5, and so on by regular steps of 5 up to 20. The zero mark will also be read as 25. There are thus 25 separate divisions around the edge of the thimble. On the sleeve is a series of numbers and division marks commencing at 0 and numbered consecutively to 9 and 0. There are thus 10 spaces, each sub-divided into 4 spaces.

As the spindle is screwed, the thimble when rotated travels up and down along the sleeve, and, as it works outward, the marks on the sleeve gradually appear in regular order, 1, 2, 3, etc. The distance which is traversed by one revolution of the thimble is determined by the pitch, or number of threads per inch cut on the spindle and, as this is 40, it follows that one revolution of the thimble draws back the spindle $\frac{1}{40}$ in. The calibrations on the sleeve are spaced $\frac{1}{10}$ in. apart, and, being further divided into 4, one complete revolution of the thimble will draw it back exactly this amount, that is $\frac{1}{40}$ in. But as the rim of the thimble is divided into 25, if the thimble is only rotated to move through, say, one space on the thimble scale, the exact amount which the spindle has been drawn back will be $\frac{1}{1000}$ in., because the spindle has made $\frac{1}{25}$ of a revolution, that is $\frac{1}{25}$ of $\frac{1}{40}$ in., that is to say, $\frac{1}{1000}$ in.

All the readings are taken from the horizontal line marked on the sleeve and from the zero mark on the thimble. Consequently it is perfectly simple to measure $\frac{1}{1000}$ in., or any other number of thousandths. When using a micrometer, it is better to think in thousandths than in any other figures. For example, $\frac{1}{4}$ in. is more quickly remembered as $\frac{250}{1000}$, and similarly with other fractions. Therefore, to measure the bar known to be $1\frac{1}{8}$ in. in diameter, it is better to think of it as one inch, plus $\frac{125}{1000}$, which is exactly $\frac{1}{8}$ in. Measuring this will necessitate setting back the anvil, adjusting it to zero, and then unscrewing the thimble sufficiently to rotate $\frac{125}{1000}$. This will obviously require more than 4 revolutions, as each of these will be $\frac{25}{1000}$, making $\frac{100}{1000}$ in all. Therefore rotate the thimble until the line marked 1 is visible, when the zero on the thimble scale is exactly opposite the horizontal line. This is $\frac{100}{1000}$ and the thimble is then rotated to add the remaining $\frac{25}{1000}$.

Fix the spindle in this position, and apply it to the bar. The jaws should just go on to it smoothly and certainly, but without forcing, and without the least trace of slackness. Suppose it will not quite go on, as the bar is, say, a few thousandths over size. Release the clamp and then further unscrew the thimble, counting the number of spaces on the thimble scale which pass the zero line on the sleeve until the spindle has been drawn back sufficiently to fit on to the bar. Suppose that this is 7 spaces. This means $7/1000$ in., and thus the true reading is 1.132 in. In actual practice the readings can be taken direct by simply reading off the scale, counting the numbers of thousandths as explained above. *See Gauge; Limit Gauge.*

MICROPHONE. The microphone is in reality the electrical counterpart of the human ear. In the ear the sound waves vibrate the ear-drum, and such oscillations are then transmitted mechanically to the brain. An electrical microphone has a diaphragm corresponding to the eardrum. The oscillation alters the number and pressure of a series of contacts in an electric circuit, thus varying the electrical resistance and the strength of the current. The electricity is normally flowing steadily, but the current is altered by the vibrations of the voice. These current variations are then converted back into mechanical vibrations to give speech. The microphone, which forms part of the ordinary telephone, is shown in section in Fig. 1.

The broadcasting microphone is the first link in the transmission chain. The sound waves in the broadcasting studio are picked up by the microphone, which converts them into electrical currents. These currents are then amplified and caused to modulate the carrier wave sent out by the broadcast transmitter. Microphones are also used in conjunction with public address amplifying systems. *See Carrier Wave; Modulation; Telephone.*

Left. Fig. 1. Microphone. Contact type in telephone.

MICROSCOPE: Its Mechanism. When choosing a microscope the essentials specified below should be borne in mind. As good an instrument as the purchaser can afford should be bought, since a pound or two more on the price will add a great deal to the scope and utility of the microscope. Several firms stock second-hand microscopes, and can usually be relied upon to furnish a satisfactory instrument at a moderate price. What are known as student's instruments are turned out by leading opticians at quite low prices, and the stands embody the essential qualities desirable in a microscope for ordinary use.

The chosen instrument should be of good workmanship, rigid, firm, and free from vibration, whether it is being used in an upright, horizontal, or sloping position. All movements should work smoothly, at the same time being free from such defects as slipping. The lower priced stands are generally of the vertical or non-inclinable type. The coarse adjustment should be a rack and pinion movement, and the fine adjustment should never depend upon the direct action of springs. Instruments may be met with having a screw fine and a sliding tube coarse adjustment. A stand with a rack and pinion adjustment is preferable, even if this is the sole means of focussing the instrument. With a good coarse adjustment alone objective glasses up to $\frac{1}{6}$ in. can be focussed.

The stage should be rigid, and large enough to afford a safe support for any glass vessels the contents of which may have to be examined. The stage should be provided with spring clips, removable at will, to secure the glass microscope slides, usually 3 in. by 1 in. in size.

Microscope. Descriptive photograph illustrating the main parts of a high-power microscope.

The best form of diaphragm is the iris pattern, similar to the arrangement for stopping down a camera. This diaphragm is necessary, since the light has sometimes to be cut down or increased, and forms part of the sub-stage condenser, or that part of the instrument found under the stage. The function of the latter is to collect into a cone of large aperture the beam of light rays reflected by the mirror. This is achieved by means of a short-focus system of lenses, and the aperture may be reduced at will, by means of the diaphragm. The mirror below the condenser is reversible, one side being plane and the other concave. The plane mirror is usually employed, but the concave side should be utilized when using low powers.

The choice of eyepieces and objectives is governed by the class of work it is desired to undertake. A pair of eyepieces, magnifying the image formed by the objective 5 and 9 times respectively, and two objectives, $\frac{2}{3}$ in. and $\frac{1}{6}$ in. would be a good selection. This is the equipment suggested for the Baker stand illustrated, giving a magnification of 53 to 406. The Beck microscope shown, with two eyepieces ($\times 6$ and $\times 10$) and a $\frac{2}{3}$ in. object glass, magnifies from 62 to 110.

There remains the question of lighting, and as in Great Britain daylight of the necessary quality is usually lacking, it is better to provide an artificial light. A small incandescent mantle is suitable, but electric light is best. The bulb should be of ground glass, and if monochromatic light is required, the bulb may be tinted blue. A very easy way of doing this is to streak the glass with a blue grease pencil —of the sort which are sold for writing on glass —turning on the light and distributing the greasy material over the whole surface by means of a piece of cotton-wool, when the bulb has warmed.

Left. Microscope. Sectional diagram showing how the light passes from the reflecting mirror through the condenser to the object on the slide, and thence through lenses to the eye.

Microscope. Above, left, simple vertical stand, with rack and pinion focussing. Right, inclinable stand with rack coarse and screw fine adjustment. (Courtesy of R.J. Beck and C. Baker)

Before placing the slide on the stage, to which it will be secured by the spring clips, the eyepiece should be removed, and the mirror adjusted to give the best illumination up the tube, the iris diaphragm being fully open. The eyepiece should then be returned and the diaphragm closed down until a dim light only comes through. This should all be done with the objective nearly touching the stage. Now rack up the body tube about 1½ in., place the slide in position and, using the low-power objective and coarse adjustment, rack the tube down slowly until the blurred image of the specimen can be seen. Obtain a sharp image by means of the fine adjustment, and if the light is too dim open the diaphragm a little until the necessary illumination is obtained. Great care must be taken not to rack down too far. A broken slide is not a very serious matter, but the lens of the objective is very easily damaged, and if it is scratched or displaced its repair may be an expensive operation. If the specimen is not sufficiently magnified to bring out the desired points, substitute an objective of higher power. It will probably be necessary to readjust the fine adjustment after changing the objective.

MIDDLINGS. Middlings is the name of a meal given to poultry. It is the basis of all mashies, 1 wet or dry, and is also the meal chiefly used to dry off wet mashies. In appearance it is something like a coarse flour, but more pinky-white in colour. The more white its colour the less its feeding value. The moderately coarse pinky-hued middlings is therefore to be preferred, as the pinky part of middlings contains the wheat phosphates and the product known as cereline, which acts as a digestive agent to the rest of the meal. Middlings contain albumen, 15·6 p.c., carbo-hydrates 60·7 p.c., and fat 4·0 p.c. Giving an albuminoid ratio of 1 to 4, it is almost ideal for feeding poultry. *See* Chicken; Poultry.

MIDGE. To prevent the unwelcome attention of midges, nothing is more efficacious than rubbing the neck, wrists, and other exposed parts of the body with olive oil to which is added some oil of rosemary, lavender, eucalyptus, or pennyroyal. One teaspoonful of any one of these should be added to 1 or 2 oz. of olive oil.

The irritation from bites can sometimes be removed by applying chloroform or weak solution of ammonia. The following prescription is useful for the same purpose:

Menthol	10 gr.
Rectified Spirit	4 drams
Strong Solution of Ammonia	2 drams

The menthol should be shaken up in the spirit until it is dissolved, and the mixture added to the ammonia. *See* Bite; Sting.

MIDWIFE: Her Qualifications. A woman who attends women in childbirth is a midwife. In an emergency any woman may have to stand by another and help her but except in an emergency, it is illegal for any person to act except under supervision of a doctor unless she is a qualified doctor or has passed an examination and received a certificate of competency from the Central Midwives Board. The penalty is a fine of £10. To obtain a certificate by false statements is punishable by 12 months' imprisonment.

The Central Midwives Board has power to register midwives, to hear complaints about them, and to suspend or debar them from practice. The county (sometimes the district) council is the local supervising authority with power to investigate all charges of malpractices, neglect, and the like, and with power to report to the central board. The authority may also make grants for the training of midwives.

A person who acts as a midwife—except a neighbour acting in an emergency—is liable for damages for negligence if, through her incompetence, any harm comes to the patient. It is no answer for her to say she did her best, unless she displayed the skill and showed the knowledge of a competent midwife.

The address of the Central Midwives Board is 23, Great Peter Street, London, S.W.1.

The Central Board for Scotland is at 18, Nicolson Street, Edinburgh.

MIGNONETTE. This favourite annual, *Reseda odorata*, bears sweet-scented flowers which in modern varieties are of various shades of colour—reddish, brown, yellow, and white. This plant is rather capricious and may fail unless suitable conditions are provided. Seeds should be sown in April on well tilled soil to which lime has been added if necessary; the soil must be made firm before sowing. The seedlings must be thinned out to give the plants room to develop. *Reseda glauca*, with grey-green leaves and white flowers in summer, is a hardy border perennial.

Mignonette. Fragrant blooms of the giant variety of this old-fashioned plant.

Mignonette will bloom in winter under glass if seeds are sown in 5 in. pots in August, the seedlings being thinned out to three in each pot: they must not be transplanted. Firm loamy soil containing mortar rubble or a scattering of lime suits them best. A temperature of 50 degrees is suitable.

MIGRAINE: The Headache. Migraine or megrim may be due to such widely differing causes as eye strain, worry or fatigue of the brain, want of exercise, or a too rich diet. Not infrequently it appears to be hereditary.

There may be a sense of depression for some hours preceding the onset of the pain, which commonly begins on one side of the head. The pain is of a throbbing character, and is aggravated by noises, jarring and bright lights.

Regular daily exercise, open bedroom windows, and attention to chewing of food may help in preventing an attack. The diet should be plain. Examination of the eyes by an oculist, attention to decayed teeth and to diseased conditions of the nose and ears will be found to be worth while. When an attack threatens, a cup of hot tea or weak coffee may prevent it. Drugs are to be avoided until other measures fail. An essential part of treatment is complete rest in bed in a darkened room, with cold compresses, constantly changed, over the forehead. *See Bilioussness; Headache.*

MILDEW: How to Remove. In appearance resembling a blue or a green mould, mildew is found on jam, cheese, oranges, and other fruit, on bread that has been kept too long, and on many other foods, as well as on leather coverings of furniture, and on linen and cotton. When closely examined the fungus plant is seen to be a collection of fine threads with spore-bearing branches, which may extend in all directions if the mischief is allowed to remain undiscovered. There are several forms of mildew which may develop as a mould on food or a rust on plate.

Causes of Mildew. Damp is nearly always the predisposing cause. Clothes or food stored in damp cupboards are always liable to be affected, and such cupboards should be inspected at intervals and their contents carefully examined for any traces of mildew. Where linen or cotton are affected the marks are easily removed if the articles have not been left too long unexamined. A good plan is to wet the mildewed parts, rub them with ordinary laundry soap, and cover them with precipitated chalk, which should be rubbed well in. The clothes are then allowed to remain undisturbed for an hour or more, after which they are thoroughly rinsed out. If any traces of mildew still remain the operation should be repeated once again.

When the mildew has been allowed to spread or become settled, damp salt should be rubbed in and the clothes exposed to warm sunshine if possible; the process may have to be repeated on several days, but is nearly always successful. Strong soapsuds may be used as well as the salt. Mildew on leather can be removed by rubbing with vaseline. In the case of food it is generally sufficient to excise the portion affected.

Besides soap and water, sour milk may be used to remove mildew much in the same manner, the stains being soaked overnight and the article placed in the sun without rinsing. Lemon juice may be employed, and is effective in removing slight stains. For old and persistent stains on white fabrics potassium permanganate is sometimes employed. It is prepared by dissolving a teaspoonful of the crystals in a pint of water.

An American remedy is javelle water, which is made by dissolving 1 lb. of washing soda in a quart of water, and adding $\frac{1}{4}$ lb. of ordinary bleaching powder. It should not be applied to coloured materials. It is allowed to remain on the fabric for 1 min. only, then oxalic acid solution is applied, and the stain is dipped in water. *See Damp.*

MILDEW: In the Garden. This is one of the most troublesome diseases which affect plants and trees. It is easily recognized by the greyish mould-like substance on affected leaves and shoots. Its effect is seriously to cripple growth. Fallen leaves from diseased trees and plants ought to be gathered and burnt in autumn, for mildew is carried over the winter by resting spores. Sulphur is the best antidote. Green sulphur scattered on and among rose bushes in winter does good and in early summer spraying with liver of sulphur (potassium sulphide), 1 oz. in 2 gallons of water, is advised. Fruit trees should be sprayed with lime sulphur in spring before the blossoms open. *See Lime.*

Milfoil. Many plants suitable for the border or the rockery are comprised in the milfoil family, also known as *Achillea* (q.v.).

MILK: FRESH AND PRESERVED

Food Value and Use of this Important Article of Diet

The reader is referred from this entry to those on Diet; Invalid Cookery, and to the many on the foods in which milk is an ingredient, e.g. Butter; Cheese; Custard; Junket and the various milk puddings. *See also Basin; Jug; Lactometer; Saucepan*

Milk is called a perfect food, because it contains all the substances necessary for the growth and the work of the body. For any young animal its mother's milk normally contains these substances in the correct proportions. In the artificial feeding of infants, and when using milk in a sick or an ordinary dietary, cow's milk is generally used, though recourse is sometimes had to the milk of other animals.

Analysis of Milk. Cow's milk varies widely in quality, but it should have about the following composition:

Protein	3·5 %	Sugar	4·5%	Water	87·3 %
Fat	4%	Mineral matter	0·7%		

The total amount of solids in good milk is thus nearly 13 per cent. The milk of one cow may be half as rich again as that of another; the milk that is usually sold is a mixture of the produce of many cows, part of the cream having been removed and water added. Care should be taken, therefore, to see that the milk for the use of children and invalids is up to the average standard and free from contamination.

The specific gravity of milk is between 1028 and 1034. If water is added to the whole milk the specific gravity falls below this figure. But if some of the cream be removed it goes up. The dairyman can therefore remove part of the cream and raise the specific gravity; he can then add water and bring it down again to the normal 1028. The composition of various kinds of milk is shown approximately in the following table:

	Protein per cent	Fat per cent	Sugar per cent
Human	1·5	4·0	6·7
Cow's	3·5	4·0	4·5
Goat's	4·3	4·5	4·5
Ass's	1·6	1·0	5·5

It is obvious that cow's milk is too rich in protein when used in infant's food, and must be diluted. But when diluted it is too poor in fat and very much too poor in sugar. Sugar must therefore be added, and a little cream is also desirable—1 or 2 teaspoonfuls to the bottle. Milk contains very little iron. This is no disadvantage to infants, who are born with a large store of iron. But when an infant is pallid and anaemic it is well to give it daily a part or the whole of an egg yolk well beaten up with the milk. The quantity of yolk will depend on age and power of digestion, and this can be gauged by noting whether the child digests it well.

In consequence of its lack of iron, milk as the sole diet of adults tends to produce anaemia. Cow's milk contains all the necessary vitamins, anti-rickets, anti-scurvy, and anti-beri beri. The sugar naturally present in milk (lactose or milk sugar) differs from cane sugar. It is more easily assimilated than cane sugar, and should be used to sweeten the feed of cow's milk when the greater cost is of no consequence.

Digestive Qualities. The digestibility of milk varies according to its condition, as the following figures prove. Boiled milk takes longest to digest, but this must not be taken to mean that it is not quite as completely digested as raw milk.

	Hours
Soured milk	3
Buttermilk	3
Whole milk, raw	3½
Skimmed milk, raw	3½
Boiled milk	4

Milk clots quickly after reaching the stomach. It is sometimes advisable, therefore, to dilute it with water, lime water, or barley water for an infant, while adults should sip the milk slowly, dilute it if

necessary, and eat a biscuit or a piece of toast. For infants a good plan is to add some citrate of soda, in the proportion of 1 to 3 gr. to 1 oz. of milk. This can be obtained in 5 to 10 gr. Tablets.

Milk is so readily contaminated that it should be kept with great care. It should be delivered in closed vessels, glass bottles being best, as they are easily kept clean. It should be stored in a cool place, separate from other articles of food. It should never be kept in an open vessel or allowed to become contaminated by dust or flies. The common practice of leaving the milk outside the door in an open vessel in the morning is a dangerous one.

Contamination. The dangers arising from the contamination of milk by microbes can be largely avoided by the process known as pasteurization. To accomplish this, milk is heated to 145° or 150° and kept at this temperature for 30 min. An apparatus may be purchased for the purpose, but certified pasteurized milk can be obtained from a dairy in a sealed receptacle. In using the apparatus the water in which the bottles are placed or in the outer receptacle is brought almost to boiling, removed from the fire, and covered with a cloth for half an hour, then the milk is cooled rapidly and stored in a cool place. To protect against tuberculosis, milk should be boiled for a few minutes; this should be done where any doubt exists. Infants fed on heated milk should be given a teaspoonful of orange or grape juice once or twice a day.

Peptonized or pancreatized milk is often ordered in place of ordinary milk for invalids, infants, and persons of weak digestion. A simple method of peptonizing milk is as follows: To 2/3 pint of milk add 1/3 pint water and bring to a temperature of 140 F. The required temperature may be obtained by halving the diluted milk, bringing one-half to the boiling point and mixing it with the other. To this milk mixture are added 2 drams of pancreatic solution and 20 gr. of sodium bicarbonate. The mixture in a covered jug is kept in a warm place for 10 to 20 min., is then brought to boiling point and immediately removed from the heat.

Artificially Soured Milk. Skimmed milk contains about ¼ of the fat of whole milk; separated milk contains little or none. Buttermilk is a thickish, somewhat acid residual milk left behind after churning and removing the butter. It is often a valuable food for invalids and sickly children. Soured milk may be prepared with one of the ferments sold for the purpose, or it may be bought from a reliable dairy. The Bulgarian bacillus is the organism mainly used for the purpose.

Whey is the fluid squeezed out when milk is clotted with rennet or an acid such as white wine. It contains very little nutritious matter except sugar, but is a refreshing and slightly laxative beverage. To make whey, add 1 teaspoonful of rennet to ¾ pint of milk which is warmed to 104°; with a spoon break up the clot that forms and strain through muslin. Junket is milk clotted and partly digested with rennet. It is an extremely digestible and nourishing food.

Condensed Milk. Sold in three forms, condensed milk is either whole sweetened, whole unsweetened, or skim sweetened. In making the unsweetened variety, 3 pints of whole milk are, as a rule, evaporated down to 1 pint. This contains all the nutriment of the 3 pints, and when 2 parts of water are added to 1 part condensed milk the result is the equivalent of good cow's milk. For infants, further dilution and the addition of sugar and cream are necessary. This is an excellent food, its one disadvantage being that it keeps good for only a very short time after the tin has been opened.

Condensed whole sweetened milk is usually evaporated to the same degree. But to this is added a large quantity of sugar, which in infants may give rise to gastric fermentation. If the various brands of condensed whole milk are diluted according to the directions on the tin, the child gets insufficient fat. It may be plump and heavy, fattened by the sugar, but generally is pale and not so robust as he should be. Condensed milk is more digestible as a rule than ordinary cow's milk, and often agrees

when the latter does not, but it should only be used for a few weeks at a time, and attempts should be made to replace it as soon as possible by ordinary milk. Obviously, to supply the deficiency of fat some cream should be added. Cod-liver oil serves the same end.

Condensed skimmed milk is wholly unfitted for infants. It contains only a trace of fat, and is so sweet that if diluted sufficiently to suit the child's taste the child will be slowly starved. This should only be used for cooking purposes.

Several reliable brands of milk powder, consisting of milk from which all the water has been removed, are sold; when these are made up with water a quite satisfactory milk food for infants is obtained.

Casein, casumen, plasmon, protene, etc., are highly nutritive and very digestible. They can be added to other foods, such as puddings, soups, etc., and form an excellent article of diet for weakly people and in fevers.

Milk for Invalids. Milk and its various modifications form a most valuable food in many diseases, especially in typhoid and other fevers, acute kidney disease, ulcerated stomach, etc. In diabetes the place of milk may be taken by so-called artificial milk, which can be made as follows: Mix 4 tablespoonfuls of good fresh cream with a pint of water, and let it stand for 12 hours in a covered vessel. Then skim off the cream, and beat it up with the white of one egg, a little flavouring of salt, and $\frac{1}{2}$ pint of water.

A few small points are worth mentioning. If milk produces costiveness add some magnesia or brown sugar to it. If it lies heavy on the stomach dilute it, or eat a biscuit with it. If it causes biliousness add half a teaspoonful or less of salt to each pint. A very good way to take milk is in a custard made with gelatin, i.e. milk jelly.

Milk should not be taken at the same times as medicines, or for $\frac{1}{2}$ hour before or after. Never give a child castor oil or other medicines in milk, which would make him dislike it as a food. Remember that many infectious diseases are conveyed in milk, namely, tuberculosis, diphtheria, scarlet fever, infantile diarrhoea, so fatal in hot weather, and typhoid fever. To avoid these always boil or pasteurize the milk when there is any possibility of its being contaminated. Sometimes, but rarely, milk also causes ptomaine poisoning like meat.

Use in Cookery. Milk forms the basis of many puddings and sweet dishes, and is introduced into soups and sauces, not only to improve the colour but to enrich them and provide extra nourishment. Milk also, if made into custard with eggs, becomes a substitute for cream, and can be served with fruit pies and puddings or with stewed fruit.

In hot weather milk should be scalded in order to keep it sweet. If it should become very slightly soured it can be restored by adding a pinch of bicarbonate of soda, and it will often boil without curdling. If really sour and unfit for table use it should not be thrown away, but used in the making of cakes. Cream cheese can be made from sour milk. Wrap it in muslin and allow it to hang until all moisture has dripped from it, scald the curds, dry again, and beat up with salt and pepper to taste.

Testing the Milk. By using a simple contrivance the housewife can easily test milk at home, in order to see whether or not it has been skimmed or adulterated with water. This form of tester somewhat resembles a pocket thermometer, and is marked to scale. When slipped into the milk, it will sink until the top of the milk reaches one of the coloured divisions. The deeper the tester sinks the greater is the dilution.

Sale of Milk. In Great Britain certain standards for dried milk have been fixed by regulations for the protection of the public. No person can sell dried milk for human consumption unless it is

properly labelled to show that it contains (1) dried full cream milk, (2) dried partly skimmed milk, or (3) dried machine skimmed milk. Each class must conform to certain standards of milk fat. Some classes of dried milk must show printed warnings as 'Should not be used for babies except under medical advice,' or 'Unfit for babies,' the object being to warn parents of the abstraction of fat. Provision is made in the regulations for samples to be taken to see the public is being protected.

No person must put into circulation condensed milk which is not labelled in accordance with the condensed milk regulations. These have been designed to protect the public and to give them an indication on the labels as to the quality of the contents of the tin. Several grades are mentioned such as "condensed full cream milk," sweetened or unsweetened as the case may be. In the case of skimmed milk it must show on the label "condensed machine skimmed milk" or "condensed skimmed milk," "sweetened" or "unsweetened" to indicate what the tin contains. Standards of milk fat are fixed for each grade and samples are taken periodically to protect the public and to see if the regulations are being carried out.

MILK BISCUIT. A variety of milk biscuit especially useful for the preparation of savouries can be made thus: Warm 1 oz. butter and $\frac{1}{4}$ pint milk in a saucepan over the fire, and when they are hot pour them gradually on to $\frac{1}{2}$ lb. flour previously sieved with teaspoonful baking-powder. Add $\frac{1}{2}$ teaspoonful salt. Stir all to a smooth paste and roll it out as thinly as possible on a floured pastry board. Cut it into rounds each about $1\frac{1}{2}$ in. in diameter, prick them, put them on a greased baking tin, and bake for about 20 min. When cold pack them in an airtight tin.

MILK FEVER. Fever occurring about the third day after childbirth, when the secretion of milk by the breasts is becoming established, used to be called milk fever, but the term and the idea underlying should be dropped. Its existence should always be brought to the notice of the doctor.

MILK JELLY. This dish, which is suitable for invalids, is made as follows: Heat a pint of milk with the thinly cut rind of a quarter of a lemon, but do not allow the milk to boil. Then add $1\frac{1}{2}$ oz. white sugar and $\frac{1}{2}$ oz. sheet gelatine, and stir the mixture until it is dissolved and is the consistency of cream. Pour it into a wetted mould and leave it until set.

Milk jellies can also be made by using the ordinary packet jellies and making them with milk instead of water. A little hot water, not boiling, should first make the jelly liquid, a pint packet of jelly being made up to a pint with cold milk. Stir it well and pour it into a wetted mould to set.

A double colour effect can be obtained by the use of two jellies, lemon and raspberry, the raspberry being made with milk, as already described, to fill half the mould, and the lemon, which has been made in the ordinary way, added before the raspberry jelly is quite set.

MILK PUNCH. To make this, take a pint of milk, 2 oz. loaf sugar, $\frac{1}{2}$ gill cream, and a tablespoonful each of brandy and rum. Boil the milk, dissolve the sugar in it, strain it, and when it is cool freeze it partly. Then add the cream, which should be well whipped, and the two spirits. Mix them all together and freeze the mixture further. It should be served in small china cups with a little nutmeg or cinnamon grated over it.

Milk Vetch, clump of an effective rockery plant.

MILK VETCH. This shrub and perennial (astragalus) bears pea-shaped flowers in summer, and thrives in ordinary soil. Most of them are of little value as decorative garden plants.

The goat's thorn (*tragacantha*) is a low shrub, with spiny branches, which bears lilac-coloured blooms. *Monspessulanus*, a trailing plant for the rockery, has reddish-purple flowers. Propagation is by seeds sown as soon as they are ripe in late summer.

MILKWEED. The best of the milkweeds (*Asclepias*) for the garden is *tuberosa*, commonly called the butterfly weed. This is a perennial, 2 ft. high, which bears showy orange-coloured flowers. It needs soil consisting largely of peat or leaf-mould, and must be planted in a somewhat shady place.

MILK WORT. This is a genus of shrubs and perennials (*Polygala*) some of which are suitable for the greenhouse, others for planting out of doors. They bear pea-shaped flowers of various colours. *Polygala dalmaisiana*, which bears purplish flowers in spring, thrives under glass if potted in a compost of loam, peat and sand. Propagation is by cuttings in summer. The plants should be pruned as soon as the flowers are over. *Polygala chamaebuxus* is a low-growing rock garden plant with pale yellow flowers, needing sandy, peaty soil. It is propagated by seeds and division.

Milkwort. Yellow flowers of the species chamae-buxus in a rock garden.

MILLET. This name has been applied indiscriminately to the plants of at least four different families, but the generally accepted millet is the hardy annual *Panicum*, which thrives in any ordinary soil and position on a sunny border. The seeds should be sown in March or April, and the plants thinned out later on, as desired. The flower sprays will be ready for cutting for the purposes of indoor decoration about the month of July.

Millet is not used as a food in Great Britain. In countries where Indian corn and other grains do not grow well the seeds are ground into meal for breads. *See Bread.*

MILLIAMMETER. This is a form of ammeter designed to measure current in thousandths of an ampere. It is a useful instrument for the owner of a broadcast receiving set. With the aid of a milliammeter it is a simple matter to determine the anode current taken by the valves, and thus to make sure that they are being operated correctly. In making such a test the milliammeter is connected between the high-tension lead from the H.T. battery or eliminator and the appropriate H.T. + terminal on the set. (The + terminal of the meter is joined to the high-tension lead.) For sets employing up to four valves, a meter having a range of 0-25 milliamperes is suitable. *See Electricity; High Tension; etc.*

MILLINERY. The term millinery comprises the making and trimming of women's hats and also the fashioning of various trimmings and shapes. *See Hat, Head Lining.*

MILLING. This is a process of removing metal by a rotating cutter from a piece of work which is bolted down to a table capable of sliding sideways and endways and vertically. In effect, milling is the exact opposite of turning. The tool used in a lathe is held in slides against the rotating work. In a milling machine the work is held and the cutter, which may be provided with several cutting edges or teeth on its periphery and sides, is rotated.

Small lathes are often fitted with attachments which, in effect, convert the tool into a species of milling machine. Some have only a very limited range. Where the lathe has a compound rest, the most obvious additional device which will provide the third direction of movement is the vertical slide. The work can be bolted to this and brought up to a milling cutter fixed in a chuck on the lathe mandrel. Slotting and grooving can be accomplished in this way within the limits of the stroke of the vertical slide. In some cases the vertical slide is arranged to hold a spindle, running in plain or ball bearings, with a pulley at one end and a chuck for holding the cutters at the other. The body of the appliance is bolted to the vertical slide of the milling attachment, and the spindle is driven by what is termed the overhead gear in referring to foot lathes.

Milling. Complete indexing, milling and gear cutting attachment fitted to a 3½ in. centre lathe. (Courtesy of Drummond Bros., Ltd.)

This gear consists of an overhead countershaft driven from the foot motor, and a system of pulleys which will drive the milling spindle, but at the same time allow for any change in the position of the milling spindle, both in setting up the work and during the cutting operations. Where the cutter is driven from such a separate and self-contained spindle, the mandrel would be fixed. The work is bolted to the face plate or otherwise fixed to the mandrel. The mandrel may be held by tightening the bearings, but this is an expedient which should only be adopted in an emergency. The lathe should be fitted with a dividing apparatus.

MILLIPEDE. This is a troublesome soil pest which may do much damage to bulbs and the roots of plants. It is black or brown, with numerous feet, and curls up when disturbed. It should not be confused with the beneficial centipede, which is flat, lighter in colour, and has only one pair of feet to each segment of the body. A fumigant of 1 lb. of naphthaline and 1 stone of lime, mixed and used at the rate of 1 lb. per square yard, should be dug in infested soil. Millipedes are frequently found in large numbers in leaf-mould; this should be sprayed with formalin, 1 tablespoonful to a gallon of water, and covered with sacking. *See Centipede; Insecticide.*

Millipede, a harmful soil pest.

MILTONIA. An easily grown family of orchids suitable for cultivation in a heated glasshouse. They prefer a shady corner of the house, and may be cultivated in pots or pans in a mixture of peat, moss, and charcoal. They need an average temperature of 70° in summer, 60° in autumn and winter, with plenty of water, except when the temperature is at its lowest. They rest during winter, and the bulbs should be separated early in the year to increase stock.

Miltonias flower in summer. They are excellent orchids for beginners and amateurs who have the necessary heat at their disposal. There are many beautiful varieties of *Miltonia vexillaria*, the chief species. *See* Orchid.

Miltonia. Hothouse orchid, the flowers of which are marked with colour on a light ground.

MIMOSA. So extremely sensitive is the mimosa or sensitive plant (*Mimosa pudica*) that the leaves will fold up at the slightest touch. The plant belongs to a small family of greenhouse perennials with diminutive acacia-like foliage.

Mimosas should be grown in a mixture of two parts loam, one part leaf-mould, and a good sprinkling of sand. While young the plants require warm-house treatment, but a cool greenhouse will suit them in the mature stage. Propagation is by seeds sown in heat in spring.

MIMULUS. This is the scientific name of the musk, or monkey flower. The common yellow musk (*Mimulus moschatus*) has unfortunately lost its fragrance.

MINA. This half-hardy climbing annual, *Mina lobata*, bears showy yellow and crimson flowers in summer. It is raised from seeds sown in a heated greenhouse in early spring and the plants are set out of doors in May against a trellis, arch or veranda. The seedlings may be repotted and grown in the greenhouse.

MINCE: How to Prepare. The colour of a meat mince must be appetizing and the consistency creamy. It must be thoroughly hot, yet must only just reach boiling point, or the fragments of meat will resemble scraps of leather. It must also be skilfully seasoned.

Cut about 1 lb. cold meat free from bones and uneatable pieces into very small cubes, or run it through the mincing machine. Fry 1 tablespoonful finely chopped onion and 1 oz. flour a rich brown in 2 oz. hot beef dripping. Stir in gradually $\frac{3}{4}$ pint good stock, and continue stirring it until the sauce boils. Cool it a little and lay in the meat.

Bring to the boil, then cover the pan and let it stand by the side of the fire until the meat is well flavoured with the gravy and soft through; this will take at least $\frac{1}{2}$ hour. Serve in a hot dish within a border of toast sippets or mashed potato. A savoury method of using up the remains of a cold joint or portions of game or poultry is to mince the meat and heat it in thickened gravy or sauce. Remove all the flesh from the bones and clear it from skin and gristle. The bones and trimmings should be added to the stockpot. Now chop the meat or pass it through the mincer and mix it in with the gravy or sauce, which should be ready boiling.

Slightly season the meat before adding it to the liquor. Boil it up and let it simmer for 8 min., never longer. The sauce should be brown or white, according to the nature of the meat which is to be used, and a plain dish of minced poultry or game is always garnished with sippets, toast for brown meats and fried bread for white meats.

Mince can be adapted for various side dishes, or entries, but the foundation is the same, only the solidity and flavour of the sauce is altered according to the character of the meat. *See* Croquette; Cutlet; Galantine; Shepherd's Pie.

MINCEMEAT. The ingredients for making mincemeat vary considerably, almost every cook having her own recipe.

To make a plain mincemeat, pare, core and chop up finely 2 lb. apples, then add 1 lb. each of currants, stoned and chopped raisins, and brown sugar, $\frac{1}{2}$ lb. very finely chopped suet, $\frac{1}{4}$ lb. candied peel, chopped very small, a level dessertspoonful powdered allspice, a pinch of salt, and the juice and grated rind of 2 lemons. A little brandy or rum may be used to moisten it, and a little raisin or other wine. Mix the ingredients very thoroughly, cover with a cloth, and let the mincemeat stand for some hours before putting it into small jars and tying them down.

A rich mincemeat is made as follows. Chop $\frac{1}{2}$ lb. beef suet very finely, and mix with it $\frac{1}{2}$ lb. currants, and 6 oz. mixed candied peel, cut up very small. Add $\frac{1}{2}$ lb. chopped, stoned raisins, 1 lb. apples, pared, cored and chopped, and 2 oz. blanched shredded almonds, and mix all together. Next chop up $\frac{1}{4}$ lb. lean cold roast beef, or of fresh boiled ox-tongue, and add it to the other ingredients, with 6 oz. of brown sugar, $\frac{1}{2}$ oz. of allspice, $\frac{1}{2}$ a grated nutmeg, the juice and grated rind of a lemon, and a teaspoonful salt. When all these ingredients have been thoroughly blended, press them down in the basin and pour over them $\frac{1}{2}$ gill brandy and $\frac{1}{2}$ gill port or sherry. Cover the basin, and let it stand for 24 hours before putting the mincemeat into small jars and tying them down.

Mincemeat should be made at least a fortnight before it is required, so that the flavours of the various ingredients will have time to blend. It should be stored in a cool, dry place, and preferably in small jars, for, if a large jar of mincemeat is opened, the portion that is not used soon becomes too dry. Mincemeat should never be dry and crumbly, nor should it be too moist, or the undercrust of the mince pies will not rise.

Mince Pie. To make mince pies, grease some rather deep patty pans, and line them with good short or flaky paste, rolled quite thin. Put in plenty of mincemeat, and cover with another round of paste, moistening the edges and pressing them together. Make a little hole in the top of each pie, and brush them over with beaten white of egg, before baking them in a good oven for 20-30 min.

They are best re-heated by being put on a baking-sheet in a moderate oven for a few minutes. If the oven is too hot, and there is risk of their burning, it is desirable to leave the oven door ajar. *See* Christmas; Pastry.

MINCING MACHINE. Frequently known as the mincer, this is a useful kitchen appliance for desiccating foodstuffs; for instance, cutting up pieces of cold beef or cold mutton so that they can be cooked in various savoury ways. There are several kinds on the market, most of them being made so that they can be fastened quite easily on to the edge of the kitchen table. Before it is put away all the component parts of the mincer should be carefully cleaned and dried.

A typical example of the popular type of machine comprises a cast-iron receptacle with a bell-mouthed top and a screw clamp arrangement at the bottom for attachment to a table. The bell-mouthed opening or hopper, with spiral grooves at right angles, forms part of the tunnel in which a screw or worm rotates. One end of the tunnel is closed and formed into a bearing for the spindle of the worm. The other end is open and has an outlet for the minced food. The outlet aperture is covered by a circular steel plate with holes. The second plate is attached to the outer edge of the worm spindle, and this also has holes in it, but of smaller size. A crank and handle are provided for rotation of the worm.

The food is cut up and put into the hopper mouth, and as the handle is rotated the pieces are pressed down on top of the worm, which forces them through the tunnel and out through the apertures in the steel plates or knives. As one of these knives is fixed and the other movable, the action is analogous to that of cutting with scissors. The function of the worm and the shaped grooves in the tunnel is to

propel the foodstuffs towards the cutting knives. These knives cut up the food as it emerges and deliver it in small pieces, when it is ready for whatever cooking operation is necessary.

Mincing Machine. Fig. 1. Typical domestic mincer in use.

Fig. 2. Component parts shown separately.

Fig. 3. Fixed knife blade securely fixed, and stop piece in position.

The food is cut up and put into the hopper mouth, and as the handle is rotated the pieces are pressed down on top of the worm, which forces them through the tunnel and out through the apertures in the steel plates or knives. As one of these knives is fixed and the other movable, the action is analogous to that of cutting with scissors. The function of the worm and the shaped grooves in the tunnel is to propel the foodstuffs towards the cutting knives. These knives cut up the food as it emerges and deliver it in small pieces, when it is ready for whatever cooking operation is necessary.

Parts of the Mincer. Fig. 1 shows the mincer in use, and Fig. 2 the component parts. It will be observed that the crank is attached to the end of the worm shaft by a thumbscrew, and that the boss of the crank has a triangular-shaped hole in it, which fits on a corresponding boss on the end of the worm spindle. The thumb-screw forces the crank into close contact with the tapered triangular end of the shaft. The other end of the worm is provided with a thumb nut, and the end of the worm is formed with a pair of flats, which engage in a slot formed in the centre of the moving knife. The fixed cutter has a circular hole in the centre in which the worm shaft rotates. The cutter is prevented from moving by a small projecting peg, which engages in a slot in the top of the mincer.

Fig. 3 shows the fixed plate in position, the fixed blade fitting into a recess formed in the end of the mincer. It is important to see that the fixed blade fits properly into the recess, and that it is free from little pieces of bone or other hard material which would prevent it bedding down flat. The moving blade should bear evenly against the fixed blade; the pressure between them is regulated by means of a wing nut and can be varied by tightening or slackening the nut. The crank should always be

attached firmly to the worm spindle, as if it is allowed to get slack it will speedily wear the hole and the boss will no longer function properly. The crank ought always to be placed and tightened on the spindle before tightening the cutting blades; if this is not done, the blades may draw the worm too far through the tunnel, with the result that when the thumbscrew is tightened up on the crank handle, it will be found to jam the spindles.

Usually this class of mincer is made of malleable cast iron galvanized, and with ordinary care it will give years of satisfactory service. Spare knives are generally supplied with it. When they become badly worn it is possible to re-sharpen them by grinding the surfaces, or by cleaning out the holes so that the edges are perfectly square and clean. Grinding may be effected by sprinkling emery powder on a piece of sheet glass, moistening it with oil, and then grinding the knives by pressing them down on the glass and rubbing them on the surface with a slightly rotary movement.

Other varieties of mincer are made larger in capacity than the small household type illustrated. In some varieties the knife blades are attached to the worm shaft, while others have a glass hopper.

MINDERERUS SPIRIT. The solution of ammonium acetate, or mindererus spirit, is a useful and much prescribed diuretic. The dose is from 2 to 6 fluid drams. It has also a mild diaphoretic action, and is thus a valuable ingredient in fever mixtures. *See* Diuretic.

MINERAL WATER. In a popular sense effervescent waters containing carbonic acid gas only, such as soda water, or carbonic acid and some flavouring substance, as lemonade, ginger ale, etc., are classed as minerals or mineral waters: but more strictly mineral waters are those which contain inorganic salts in sufficient amount to be active. These are of two classes: effervescent waters containing carbonic acid and some medicinal salts such as Seltzer, Apollinaris, Rosbach, and sparkling Malvern; mineralized waters which contain no carbonic acid and do not effervesce.

All aerated or carbonated waters have a soothing effect on the mucous membrane of the stomach, and assist digestion, but if taken in excess they cause indigestion and flatulence. Mineralized waters are used as table waters or for the medicinal effect, according to the quantity of mineral matter contained.

Kinds of Mineral Water. Table waters should not contain more than one per cent of mineral matter. Most of them are slightly alkaline, and when used to dilute acid wines they partly neutralize the retarding influence of the wine on digestion. Among these are Apollinaris, Johannis, Kronthal, Perrier, Seltzer, sparkling Malvern, and Vichy. Some act on the bowels, some on the kidneys.

The laxative waters, having a mild effect on the bowels, include Contrexeville, Harrogate, Kissingen, Kronthal (red label), Seltzer. The purgative waters, containing sodium and magnesium sulphates, and known as bitter waters, include Apenta. Franz Josef, Huyadi Janos, Kissingen. Among the diuretic, kidney-stimulating waters are Apollinaris, Cheltenham, Harrogate, Johannis, Kronthal, Marienbad, Seltzer, Vichy. At various spas there are waters containing iron and arsenic.

Indiscriminate indulgence in active mineral waters is to be deprecated just as much as indiscriminate drugging of any sort. The water used must be appropriate to the unhealthy state which it is proposed to remedy, and this necessitates expert advice. Moreover, the use of any mineral water at home may fail to benefit, whereas its use at the source, where the treatment may also include baths and other means, and which entails rest of body and mind, may be thoroughly successful. *See* Ginger Beer; Lemonade, etc.

MINIATURE. These portraits were at first painted in body-colour on vellum or on playing-cards, and afterwards on ivory or paper in transparent colour. An interesting class comprises those done in plumbago, and also in Indian ink, sometimes imitating the effect of line-engraving.

The possessor of portrait miniatures should guard them from excessive heat, damp and sunlight. They are quickly ruined if hung in window embrasures or beside the fireplace. Those which are painted on ivory, after the Cosway manner, are liable to fade if freely exposed. Should they be valuable it is best to keep them in closed cabinet-trays.

Ivory miniatures are best mounted, not on stout card, which tends to expand and contract, but on thin notepaper, with dilute gum-arabic. After being pressed dry they may lie bound to the glass with gold-beater skin, or surrounded by a velvet pad to exclude dust. When spots of mildew appear they should be removed with a silk handkerchief, and if the white pigment has blackened it may be scraped away. Most ivories, especially of the 18th century, tend to warp and split, and any serious damage should only be remedied by a miniaturist.

Minim. This measure of capacity is much used by chemists. 60 minims make one fluid drachm or dram. *See Apothecaries' Weight.*

MINISTER'S CAT. This popular indoor game can be played by any number up to about 20. The first player opens it by saying, 'The minister's cat is an avaricious cat,' or uses some other adjective beginning with A. The other players in turn describe the cat, each using a different adjective, but all beginning with the letter A. When this has gone round the players take up the letter B, and so on throughout the alphabet. If a player fails to find a word he either pays a forfeit or drops out of the game, as may have been arranged.

MINK: The Fur. This fur is highly valued for coats and wraps and possesses a rich appearance. Though expensive it repays good workmanship, as it has excellent wearing qualities. Canadian mink, one of the best-known varieties, has short hair varying in colour from pale to rich brown, while Japanese mink, another good species, is of a more yellow hue, and the fur is short. *See Fur.*

MINORCA: The Fowl. Black minorcas enjoy a reputation as layers of large white eggs, and their precocity, hardiness, and adaptability to all soils and place, confined or otherwise, make them one of the most useful of all breeds. In general appearance they are not unlike the leghorns, having the red face and white ear-lobes, but a much larger comb. They also average in weight 2 lb. or 3 lb. heavier and, though not generally acknowledged as such, are not to be despised as table birds. In addition to the single-combed variety of minorca fowl there is also a rose-comb and a white variety, both of which have a large following. *See Fowl; Poultry.*

MINT. This is a hardy perennial plant, with aromatic herbage, which flourishes in ordinary soil. It should be planted in early spring, and, as it spreads freely, the plants should be lifted and replanted once in every 4 or 5 years, otherwise it runs to stalk instead of to leaf. To force mint the roots should be lifted in autumn and placed in boxes of potting soil in a slightly heated glasshouse. Moisture and warmth will ensure a crop by Christmas time. One of the numerous varieties of mint, *Mentha Requeni*, is peppermint, and is best grown as a tiny trailing plant in the rock garden. For the purposes of distillation the shoots should be picked when the flowers are upon them. Shade and moisture are the two chief requirements of mints of all kinds.

Mint. Leaves of the aromatic herb much used in cooking.

Uses for Flavouring. On account of its aromatic properties mint is much used in cookery for flavouring sauces, salads, and soup. It is also employed in the preparation of a drink called mint julep. Spearmint is considered the best variety for culinary purposes. Mint is full grown in June and lasts well till August, when it begins to flower. It should then be plucked, dried, and stored in airtight tins or bottles, for winter use. Dried mint is served with some soups and added to seasonings occasionally. When fresh mint is not obtainable, powdered mint may be used as a substitute.

Mint Culture.

1. Root of mint.
2. Same planted in box:
a, fine soil; b, rough soil; c, crocks.
3. Cutting badly cut and planted.
4. Properly prepared cutting.
5. Same well planted on sand base.
6. Wrong way to use dibber. 7. Correct use of dibber.

Mint Julep. To make this, place 3 sprigs of fresh gathered young mint in a tumbler and partially fill it with sherry. In a second tumbler put sufficient pounded ice to half fill it. Pour the mint and sherry over this. Transfer the julep from one tumbler to the other several times, then place it on ice for a few minutes.

Mint Sauce. To make mint sauce, chop finely the leaves from 6 or 8 sprigs of mint, and put them into a sauce tureen with 8 lumps sugar, pour over them 2 tablespoonfuls boiling water, stir well, and let all stand for a few minutes; then add about ½ pint vinegar.

Mint Vinegar. This is made by filling loosely a pickle bottle with leaves of young mint, and adding sufficient white wine vinegar to cover them. Tie the bottle down securely, and after 3 weeks strain into another bottle and cork it firmly. This is good for winter use.

MINTON WARE. The productions of the Minton works at Stoke stand in the front rank of modern Staffordshire ceramics. They embrace a wide range of styles, both useful and ornamental. Some early Minton resembles Derby and Spode, and may sometimes be recognized by its mark, such as the double L of Sèvres enclosing an M, or later on the arrowhead device which represents ermine in heraldry. There were also descriptive marks, such as Amherst Japan. Later productions included vases and plaques in a white relief called *pâte-sur-pâte*, which rivals in beauty Wedgwood jasper. These wares usually bear the name Minton sometimes inscribed upon a globe, or surmounted by a crown.

Minton ware. Porcelain bowl dating from about 1800, decorated with Greek key pattern and figures. (British Museum)

Among the new developments were Parian statuettes and groups, and reproductions of medieval majolica, besides Persian style faience, and Sèvres porcelain. A fine hard-paste body was introduced for the manufacture of domestic china. A distinctive shape of tea-cup has been given the name of Minton. The Minton works have also played a predominant part in the development of the manufacture of tiles for paving floors and lining walls. See Staffordshire Chinaware.

Mirabilis. The botanical name of the plant popularly called the Marvel of Peru (q.v.).

MIRRORS FOR DECORATIVE PURPOSES

Choice and Arrangement of Antique and Modern Styles

Other aspects of this subject are dealt with under such headings as Cheval Glass: Dressing Table; Toilet Mirror. See also Dining Room; Hall; Living-Room; and the entries on Gesso; Gilding; Lead Art Craft; Silvering

A mirror may be described as a reflecting surface usually made of glass and lined at the back with silver or another brilliant metal. Mirrors are often given pride of place in rooms and halls to-day as they are not only decorative, but lend an appearance of space and, by reflection, increase the light in dark corners and passages. Another use of mirror glass is for framing and lining niches or the upper parts of glazed cupboards or recesses, so that the ornaments on the shelves may be reflected and their decorative value enhanced. Finger plates for doors and curtain pelmets are also fashioned of mirror glass, while whole panels are introduced into doors for rooms and cupboards and as reflectors on walls.

In the case of such panels they are most effectively used where it is desired to give an air of brightness, as, for instance, in a basement room or dark hall; otherwise the effect might be rather garish and restless. In page 23 an excellent example of the use of mirror panels in a dark corner is

illustrated. The mirror inset of the heavy wooden overmantel is now less frequently seen, the place of the latter being taken by one of the charming modern mirrors, with inlaid or marquetry decoration, or by an antique example of beautiful workmanship. Many clever reproductions of old mirrors are obtainable. The frame in others is genuine, but the glass has been replaced so skilfully that it is quite difficult to detect the modern touch.

In buying an old mirror this matter of the glass is one to which the purchaser should give attention. Often it is so spotted owing to the corroding of the silver backing, that its decorative value is reduced to a minimum unless it is resilvered. For practical purposes also, nothing is more uncomfortable than a reflecting surface pitted with spots. With the exception of a really valuable antique piece, which should not be tampered with, the practice of resilvering is quite legitimate. Many mirrors of comparatively recent date have become spotted through careless usage or damp.

Mirrors should be hung in such a position that they are not above the eye level, and are not crowded by pictures or other mural decoration. In the case of a small framed mirror, it is best given a slightly forward tilt, as this allows the air to get to the back. The back board of the mirror should not be cracked and left unrepaired, or such a crack will, in the course of time, appear as a mark on the face of the glass.

When choosing a mirror for a room it must obviously be in harmony with the style of the furniture and decorations. An old gilt frame will look merely shabby amongst very new surroundings which demand severity of outline or a brilliant surface to all accessories and ornaments.

Early English Mirrors. The earliest domestic mirrors used in England were of polished steel, which were found in large houses of the 16th and early 17th centuries. A corporation of glass mirror makers, however, was formed in Venice in 1564, and probably a few examples of their work filtered through to England, being sent as gifts to members of the royal family and other important personages. Glass mirrors, therefore, were very rare in the time of Elizabeth and James I, and authorities are inclined to suspect the genuineness of any that are said to date from that period.

Mirror makers were brought to England, and the first patent for manufacture was obtained by Sir Robert Mansel in 1615. But the most important manufactory established was that of the duke of Buckingham at Lambeth about 1673; to collectors of old furniture mirrors made there are usually regarded as the earliest specimens obtainable. They had bevelled edges which in themselves show certain characteristics of genuine hand work. The angle between the bevel and the flat surface of the mirror is not mechanically sharp; but is somewhat round, and occasionally various facets can be distinguished gradually melting from the level plane of the glass to the angle of the bevel.

Although few examples of the actual glass used in mirrors of the late 17th century are still in existence their frames are of much interest. Grinling Gibbons carved a number of them very elaborately, and some frames are to be found embroidered with panels of needlework. Others are made of silver or of marquetry and lacquered wood. In the Stuart period frames were usually rectangular, with or without a pediment, and this style was still made in the early part of Queen Anne's reign. A beautiful example of such a mirror in walnut and marquetry, with a semicircular pediment is shown in Fig. 1.

Queen Anne Mirrors. A familiar form of Queen Anne mirror frame has a graceful arched top, sometimes surmounted by a cresting elaborately ornamented. The lovely example shown in Fig. 2 is framed in walnut partly gilded. The bird on the pediment is an exquisite piece of carved decoration. Owing to the difficulty of making large-sized plates at this period a tall mirror would show two plates of glass joined in the middle just beneath the spring of the arch. Nearly all Queen Anne mirrors now show considerable defects, being spotty and damaged at the back. Although the most beautiful frames were designed at or about this time, the mirrors made in the William and Mary and

Queen Anne periods were not all graceful. Some were, in fact, ugly, owing to their over elaborate crestings or pediments which exaggerated fashion made the rest of the frames appear insignificant, while the carving and ornaments were occasionally coarse and of poor design.

Mirror. L-R. Figs. 1 and 2. Examples of the Queen Anne period; left, in walnut and marquetry; right, with walnut and gilded frame (Courtesy of Gill & Reigate). Fig. 3. Early eighteenth century mahogany mirror with gilt moulding inside the frame.

A favourite frame for the commoner type of mirror was a prominent half-round section of walnut. Many examples of this style are seen in toilet mirrors, and some of these are inlaid. Such frames are reproduced to-day for so-called Queen Anne style cheval glasses. Other mirrors were decorated with lacquer work, and gesso was used throughout the 18th century on many gilded frames.

To collectors the most prized mirrors are those containing the original Vauxhall glass of the early part of the 18th century. The best are the wide bulbous ones inlaid with floral arabesques, and having mouldings which may be as much as 7 in. wide. Some valuable ones have marquetry frames, the marquetry being designed in elaborate scroll work.

Georgian Mirrors. An early Georgian mirror with a mahogany frame is illustrated in Fig. 3, and a somewhat later example in Fig. 4. The former has gilt moulding on the side of the frame, while the latter, which is elaborately decorated, is also gilded and carved. The workmanship of these is very fine, and they are typical of the early Georgian period, but they lack the supreme grace of the best Queen Anne mirrors. The superior beauty of Fig. 2 to that of Fig. 4 in the balance of the design exemplifies this.

Wall mirrors designed by Chippendale, the brothers Adam, Hepplewhite and Sheraton were often elaborately carved with classical decorations following in the main the French styles of the period. Chippendale designed many mirrors in Gothic and other architectural styles. During the mid-Georgian period frames of a more severe outline were fashionable. Robert Adam introduced Wedgwood plaques or medallions in the centre of surmounting decorations to mirrors which were sometimes composed of three plates of glass, a larger one in the middle, and smaller ones at the sides.

Mirror. L-R. Fig. 4. Mirror in carved mahogany frame, English make, dating from about 1740. Fig. 5. Convex mirror in an elaborately carved and gilt wood frame, with candle sconces, dating from about 1790. Fig. 6. Modern mirror wall decoration made in panes and studded rosettes of glass (Humphrey & Vera Joel). (Fig. 4, by permission of the Director, Victoria & Albert Museum, S. Kensington; Fig. 5, courtesy of Gill & Reigate).

Circular convex mirrors were introduced towards the conclusion of the 18th century, and the fashionable furnisher of the day produced a great variety of frames. The one illustrated in Fig. 5 has a deeply moulded gilt frame enriched with balls and surmounted by a carved bird. Candle sconces are fitted to the sides. In some examples these had cut glass drops suspended from them.

Pier glasses date from the end of the 18th century, for it then became possible to get much larger sheets of glass than were hitherto available. Moreover, plate glass, which had been first made in France a century before, was now to a certain extent used for looking glasses.

These large mirrors were fixed to the walls between windows, with console tables beneath, or over the mantelshelf, a position which was utilized for their display to even greater elaboration in the Victorian period.

It was in the early part of the 19th century that the mirror began to be employed in the backs of sideboards, at first in a simple circular convex form. Mirrors were also fitted into the lids of worktables, and the toilet table was developed with the mirror as part of the piece of furniture. Cheval glasses were more commonly seen at this time, for the sizes of sheets of glass had increased so that it was possible to provide a mirror to give a full reflection of the figure at a reasonable cost.

In modern furnishing coloured mirror glass is utilized for wall decoration. Mirrors are also seen with chromium plated frames in severely simple outlines. Pewter frames, with inner borders of coloured glass, ornamented with glass rosettes and studs, are copied from Italian work. Mirrors composed of separate panels and studded with glass rosettes form beautiful mural decorations, as shown in Fig. 6, with its Gothic design. Another beautiful modern mirror decorated with a marquetry panel is illustrated in page 126.

MIRZAPORE CARPET. Large quantities of these Indian floor-coverings are imported into Great Britain. They are woven in symmetrical patterns supplied by European buyers to the factories, which turn out each quality at a uniform price per square yard.

Those which are loosely woven, of short-staple wool, are the least durable. Large numbers have a light cream tone predominating in the field, with strong reds, blues, and greens, which do not mellow with age, but acquire a faded look. Nevertheless, they are among the least expensive of any oriental floor-coverings, and are often useful for hall or landing in small sizes, and for study or smoking room furnished in simple but solid style. They are unsuitable for living-rooms as they are not sufficiently hard wearing to stand family use.

MISTLETOE. This is a parasitic evergreen which grows on the oak, poplar, apple and other trees. Its berried shoots are in great demand for Christmas decorations. The mistletoe is dioecious, i.e. male and female flowers are on separate plants, therefore all mistletoe does not bear berries. It is established by rubbing a few ripe seeds in cracks of branches of suitable trees in March. The seeds must be protected from birds by netting or other covering. Mistletoe grows very slowly for several years. In Christmas decoration schemes mistletoe is generally a characteristic feature, its pale colours contrasting with the vivid hues of the holly. *See Christmas.*

Mistletoe. Sprig of this traditional Christmas decoration.

MISTLETOE CACTUS. The popular name of the genus of flowering plants *Rhipsalis* is suggested by its appearance. These plants are more curious than beautiful, and are little grown. They thrive in loam, with a liberal proportion of Broken crock at the bottom of the pot, in order to ensure good drainage. Propagation is by cuttings in sandy loam. It is wise to leave them in the sun for a few days before inserting them, as this reduces the tendency to damping off. *Cassytha* is the best-known species of this cactus.

Mistletoe Cactus. Fruit and leaves of the species cassytha.

MISTRESS. A lady who employs a servant is not bound to give the servant a character, but if she does she must give one honestly. A mistress is not entitled to break open a servant's box without a search warrant, or to deduct (for breakages from the girl's wages unless the servant has expressly contracted that this may be done. She is entitled to obedience to all reasonable commands; and it is a reasonable command to request the servant to wear a proper uniform and also to keep reasonable hours. *See Master; Servant.*

MITE: In the Garden. One of the most serious garden pests is the mite, which attacks black currant bushes, causing the buds to become swollen and useless. Swollen buds should be picked off and burnt and old branches or parts of them must be pruned out as soon as the fruits are gathered. The best treatment is to spray with lime sulphur every 10 days between mid-March and mid-May.

The pear-leaf mite forms blister-like spots on the surface of leaves. All leaves attacked should be removed and burnt; trees should be given a lime-sulphur spraying in early spring. The filbert bud is a microscopic mite which is found on the buds of filbert, hazel, and cob-nut. The damage is similar to that done by the big bud, and similar treatment is required. *See* Big Bud; Insecticide; Lime.

MITE: On Poultry. Poultry suffer from the attacks of certain mites. Some live on the birds at night, the red hen-mite, for instance; others are permanent parasites, e.g. itch mites, which live at the base of the feathers, and cause the birds to eat them; and others live under the skin and cause scabby growths, such as are sometimes seen on the legs of fowls.

The best method of dealing with these mites is by cleansing operations. The poultry house should be fumigated with bi-sulphide of carbon or another agent, while some paraffin in the cleansing wash is excellent for the perches. For the mites that cause feather-eating the bird should be isolated and oil of cloves rubbed into the affected part. *See* Poultry.

MITRE JOINTS IN WOODWORK

How to Make and Use a Mitre Box and a Shooting Board

This contribution supplements those on Moulding-and Picture Frame. The principal Woodwork joints are dealt with under specific headings, and other valuable hints are given in the general article on Joint. *See* Cabinet Making; Door; Drawer, etc.

The term mitre is applied to various kinds of joints formed between two pieces of material, as, for example, in picture frames and mouldings. The ends are butted together in such a way that the joint between them bisects the angle between the external edges of the material. A right-angle mitre is one in which the mouldings are at right angles, the angle of the joint being therefore 45°. The particular object of using the mitre is two-fold: the contours of the moulding should exactly meet and flow into each other at the joints, and the inner and outer faces of the moulding should not expose any end grain.

Mitred joints are often keyed at the corners with a plain or dovetailed key, examples of both of which are illustrated. The simple, flat key shown in Fig. 2 is fitted in very small work, by making a saw-cut in the ends of the mitred parts of the frame. In stronger work the key is sawn from hardwood, say, about ¼ in. thick, and is fitted into slots made in the ends of the mitred joints by sawing and chiselling. The grain of the key is set to run parallel with one of its edges, with the result that when fitted in place it has the greatest strength. The keyed dovetailed mitre joint in Fig. 3 is suitable for framing intended to withstand considerable stress, and is simply an ordinary mitred joint with a double dovetail formed across it. Into the double dovetail a piece of X-shaped hardwood is fitted; when this is pressed into its place in the slots which are cut for the purpose, the joint is firmly held.

One of the difficulties in mitreing a joint is to determine the correct angle for the mitre. Normally, the surface of the mitred joint will be upright, or at right angles to the flat surface, but it will be inclined to some angle across the length of the moulding. There are various ways by which this angle may be determined. It can be ascertained by calculation, but the simplest method for the amateur is to make a full or scale size drawing of the parts to be mitred. This drawing need not be anything more elaborate than a series of parallel lines, the spaces being equal in width to the width of the moulding to be cut.

An example is given in Fig. 1, and from this it will be seen that the parallel lines representing the mitreing intersect at the corner, or angles, as at A, B, and C. The correct angle to cut the mitre is determined by joining the intersections of the two inner lines to that of the two outer lines, as at D

C. Having ascertained this angle, the bevel square is set to it, and the angle marked upon the moulding, which is then sawn off, and the ends planed or shot true.

*Right. Mitre Joint.
Fig. 2. Keyed mitre
joint shown
separated.*

Fig. 3. Key in place in one half of a dovetail mitre joint.

Fig. 4. Mitre angle being marked on the moulding with a bevel square.

In this work, the lengths of all mitreings may be measured to the inside or from the outside, the latter being usually the most convenient method. Fig. 4 shows how the mitre is marked with the bevel square. To facilitate marking a standard mitre template can be used. This is a combination of a mitre template and a square. It can be purchased, or a similar instrument made up from a piece of wood. The wooden template is simply a piece of wood with a lip, or guide surface, upon it, and the ends accurately mitred to the angles desired.

Mitre Box. A box for the cutting of material up to 5 in. square can be made from 3 pieces of deal, planed up true on the faces and edges and measuring 6 in. wide and 1 in. thick. The length of the 3 pieces should be about 2 ft. (Fig. 6 gives the dimensions.) The pieces are nailed together to form a trough-shaped open box (Fig. 5). Two battens, 2 in. wide and about $\frac{1}{2}$ in. thick, are nailed across the tops of the side pieces to keep them from spreading or opening, but before finally fixing them it is necessary to test the uprightness of the side pieces, as the angle between them and the baseboard must be exactly 90° . This testing is done by placing a set square on the box and adjusting until the sides are correct, when the battens may be fastened.

The next step is to mark out the sides for the cuts which guide the saw while cutting the moulding. Mark off in the centre of the block a line at right angles to the length of the box; project this line to the face of each of the side pieces, and saw through to this line. Then set a bevel square exactly at

45°, mark this angle on the upper edges of the side pieces, square off on each of the outer sides of the side pieces, and again saw through. Repeat this operation on the opposite hand, and the mitre box is complete and ready for use. Fig. 6 shows the plan of the box and the correct angles marked out. Fig. 5 shows how the hand saw should be held in sawing the moulding, and how it works through the saw-cuts.

The moulding to be cut is pressed into the lower corner of the box and held with the left hand, while the saw is manipulated with the right.

A mitre block, useful for cutting small mouldings, is illustrated in Figs. 7, 8, and 9. It may be composed of a baseboard, 18 in. long, 6 in. wide, and 1 in. thick, and a second board of the same length, about 3 in. wide and about 1½ in. thick, which is glued and dowelled to the baseboard. It is marked off with angles and sawn through as before. This type is used in a similar manner to the mitre box. The first pattern is generally more convenient for amateur use, as it keeps the saw upright.

If it is intended to use either of these blocks for a great deal of work, an improvement is to line the guide faces with strips of brass, to prevent the sides of the saw wearing away the material and thereby making it inaccurate and unreliable in use.

Mitre Box. Fig. 5. Home made mitre box in use. Fig. 6. Plan of mitre box, showing correct angles.

Fig. 7. Solid mitre block. Fig. 8. Section of block, showing necessary measurements.

Mitre Shooting Board. After moulding has been sawn to the requisite angle to make the mitre, the end of the material is planed up true with a mitre shooting board, as in Fig. 10. This appliance may be made from a piece of deal about 9 in. wide and 1 in. thick, to one side of which is glued and dowelled a narrower board about 3 in. wide and $\frac{3}{4}$ in. thick. At the extreme left-hand end a third block is glued and screwed with its edge exactly at right-angles to that of the 'fence' or guide batten. This third block is used for accurately shooting the end grain of the wood at 90°.

Another piece of batten is glued and dowelled to the top of the fence at about the middle of its length, and this piece has its edges cut and planed to the desired angles, forming a mitre template. The complete shooting board is shown in Fig. 11. The work to be planed is held against this angle block with the left hand, and a jack plane is laid on its side, resting upon the baseboard, with the sole of the plane against the edge of the fence. The plane is pushed up and down with the right hand and the moulding fed towards it, thereby cutting the end of the moulding and producing a surface which is flat, but is inclined at the same angle as that of the guide piece or template.

Guide pieces or blocks can be made to any desired angle and interchanged according to requirements. If the board is intended for regular use it should be grooved on the underside of the baseboard and have strong battens screwed to it to prevent it warping or winding; when not in use it should be hung up and given a precautionary coat of varnish or paint.

MITTENS. Knitted mittens for men may be worked in a good 5-ply fingering, which makes them comfortable in wear, yet warm and strong enough to be worn for ordinary sports, and for shooting and motoring when it is desirable to have the fingers free and uncovered.

To make a pair big enough to fit a hand that usually takes size 8 in kid, 3 oz. White Heather 5-ply fingering will be required, with No. 14 steel knitting needles. The one illustrated had the top of the hand and the top of the thumb where the single ribbing occurs worked with needles one size smaller than the rest of the mitten. This helps to close them to the hand, but it is not absolutely necessary to use other needles if they are not at hand, as the ribbing serves the same purpose.

How to Knit. To begin, cast 24 stitches on each of 3 needles, making 72 altogether; join them into a round as for stocking knitting, and work a plain round through the back of the stitches to give a firm edge. For the wristlet, work in ribbing consisting of knit 2 stitches and purl 2 alternately all round; this is known as double rib, to distinguish it from the single rib at the top of the mitten, which consists of knit 1 stitch and purl 1 all round. Repeat the double rib for 32 rounds, then knit a plain round, taking together every fifth and sixth stitches to reduce the round to 60 stitches. Knit 6 more plain rounds for the hand on these 60 stitches, then begin the making of the thumb gusset.

Arrange the stitches on the needles as follows: 24 on each of 2 needles and 12 on the third, which is the gusset needle. The first round begins on the needle containing 12 stitches, and is worked as

follows: Knit 12, then lift up the loop right under this last stitch and knit it; finish the round plain. Now knit 3 rounds without any increase on the gusset. For the fifth round, knit 12 stitches on the gusset needle, lift up the loop below the 12th stitch and knit it. Now lift up the loop below the last stitch on the needle and knit it, then, knit the last stitch. Finish this round plain, then do three more complete rounds plain. In the next round increase again after the 12th stitch, and again below the last stitch before knitting the latter off the needle. Continue working in this way with three rounds between every increase round, until there are 29 stitches on the gusset needle altogether. This completes the thumb gusset.

Mittens. Man's knitted mitten for use when shooting or motoring.

The top of the hand is now continued above the thumb. To divide the thumb stitches, first knit 11 stitches off the gusset needle, and pass the remaining 18 stitches on a safety-pin to put them aside for the present. Cast 4 stitches on the same gusset needle, and these will come at the back of the thumb, and link up the hand stitches into a complete round. Knit the remainder of the stitches in the round, then knit 18 rounds of plain knitting on all these stitches. Finally do 10 rounds of single ribbing to close in the top of the mitten, and cast off fairly loosely, so that the edge is not too tight. To complete the thumb, take the stitches off safety-pin and divide them equally between two needles, then lift up 4 stitches at the back of the thumb, where they were cast on before, putting the needle through the edge of these 4 stitches and knitting the loop so picked up. Join these stitches into a round and knit 6 rounds plain. In the next round knit together the second and the third of the 4 stitches that have been picked up at the back of the thumb and do 5 rounds of single ribbing to match the top of the hand, and cast off. The second mitten is the same, as they are reversible. *See Glove.*

MIXED GRILL. A good mixed grill is provided by cooking together in front of a clear fire or beneath a or electric grill a sheep's kidney, a slice of bacon, a chop or a piece of steak, and two or three mushrooms, or a tomato. Trim the chop or steak neatly, cut open the kidney and remove the skin and core, peel the mushrooms or cut the tomato in half. Brush all over with a little melted butter, and sprinkle them with pepper. Rub the gridiron with a piece of suet and heat it. Cook the meat for 10 or 15 minutes, adding the mushrooms when it is half done. Serve the grill on a hot dish, with a little lemon juice sprinkled on each mushroom. *See Grilling.*

MOCASSIN: How to Make. The N. American Indian word mocassin describes a style of heelless slipper. As worn by the Indians, it is made of deerskin and ornamented with embroidery and beadwork. Mocassins are easily made at home. Soft suède, which can be bought in many colours, is a suitable material. The lining can be of lamb's wool, or any soft, fleecy woollen material, while appliqué suède flowers in contrasting colours or coloured beads are effective for decorating. Mocassins are made in one piece, which is cut large enough to cover the sole of the foot and to draw up round the instep. To make them from suède, procure two good-sized skins of the desired shade. Use the sole of a shoe as a guide in cutting out and cut the skins in an oval about 3 in. larger than the sole all the way round. Punch holes $\frac{1}{2}$ in. apart with a stiletto round the edges and cut some thin strips, of the suède, about $\frac{1}{4}$ in. thick. Thread these in and out of the holes, leaving plenty of length of the suède as draw strings. Put the foot into the flat part and draw up the suède strings round the instep, fastening securely when the right aperture is secured.

The mocassin should fit snugly and yet be loose enough to allow the foot easily to be slipped in. If the size should be too big, make the mocassin smaller by punching an inner series of holes and drawing the thread through these, cutting away the surplus material. The fullness should be arranged to come at the toe end and at the heel. If preferred, instead of gathers at the back, the fullness can be folded in two pleats, or a slit can be made and a triangular piece cut out, the ends

being neatly drawn together with strong thread.

When the mocassin fits correctly, cut out in the same way a piece of rabbit fur for lining, making it about 1 in. larger than the suède. Pin it, or tack it over in pleats, to make it the same size in the foot, then cut away the surplus fur underneath the pleats and sew the pieces securely together, on the wrong side.

Mocassin. Pair of mocassins of coloured pigskin, decorated in poker work and lined with silk.

Next turn the fur right side out and slip it into the suède mocassin, allowing the fur edges to overlap the suède and to form an edging. Cut out a triangle of suède to cover the toe front and nick this along the edges to make a fringe. Tack this on to the top of the mocassin to neaten the part that has been gathered, using a contrasting coloured thread. This triangle can be trimmed with beads, or have a design cut out and a strip of brightly coloured suède slipped underneath to show the pattern. If lambswool or any woollen material is used as a lining, the two edges should be sewn together, and bound with ribbon or narrow fur. Mocassins can also be made from coloured pigskin and decorated with poker work. The toe piece has a suitable design traced on it. This is outlined in poker work and afterwards coloured.

The mocassins illustrated are thonged round the toe piece, and this is attached to the main part of the shoe, which is finished by thonging and lined with velour.

Heavy wool-backed velour, the kind of which curtains and furnishing coverings are made, is a suitable material for mocassins.

Mocassins made in this way look well lined with the same material, so that the velour should be cut out and made to fit the foot on the wrong side as well as on the right side. Stitch all the pieces firmly in position, then slip the lining right side out and into the outside piece. Sew the edges together and bind them with a ribbon ruching or narrow fur. Cut out a single triangle in velour for the top piece and embroider this boldly in thick wool or chenille, then tack it in position. *See Leather; Poker Work.*

MOCHA: The Coffee. Mocha is a variety of Arabian coffee, excellent in flavour and quality, which is used in the same way as other varieties of coffee, but rather less is required, as the flavour is strong. The name of mocha is often given to cakes, biscuits, etc., in which coffee flavouring is used. *See Coffee; Coffee Cream Sandwich.*

MOCHA: The Glove Leather. Real Mocha leather, as used for gloves, is a strong heavy skin prepared with a soft, velvety surface and wears better than suède, with which it is sometimes confused. Suède is glove leather finished flesh-side out, but in mocha the hair side is uppermost, although the grain surface is rubbed away.

Mocha is an especially suitable material for men's and winter gloves, for slippers, tobacco pouches, sports coats, and aviation clothing. Its freshness can be renewed by the use of a wire-bristled brush.

Mocha is obtainable in several colours, and especially in brown shades. *See* Glove; Leather; Tobacco Pouch, etc.

MOCHA FINGER. To make the iced, finger-shaped cakes known as mocha fingers, break 2 eggs into a basin, add to them 3 oz. castor sugar, and whisk them well for about 10 min. or until they are thick. Fold in $\frac{1}{2}$ lb. sieved flour, adding a little milk if required, and put the mixture into some well-greased tins.

Bake the cakes in a hot oven until they are of a pale biscuit tint, and leave them to cool on a sieve before coating them with coffee icing. A small piece of shelled walnut may be placed in the centre of each cake. *See* Coffee Icing.

MOCK HARE. To make this, fry 3 oz. bacon cut into dice in a stewpan, and when it is lightly browned add $1\frac{1}{2}$ lb. stewing beef, cut into small pieces and coat with seasoned flour. Continue frying for a few minutes, then add $\frac{3}{4}$ pint stock, a bouquet garni, some grated lemon rind, and an onion stuck with cloves. Stew all slowly in a covered pan until the beef is tender, then put in a wineglassful of port, some lemon juice and red currant jelly and serve it with forcemeat balls. *See* Bouquet Garni; Forcemeat.

MOCK ORANGE. This is one of the loveliest of all hardy flowering shrubs. Its botanical name is *Philadelphus*. It is often miscalled *syringa*. The mock orange flourishes in well tilled soil, flowers in early summer and is increased by cuttings inserted out of doors in autumn. The common mock orange (*coronarius*) grows 10-12 ft. high, and bears white fragrant flowers; *grandiflorus* has finer flowers but they have little scent. In recent years many beautiful cross-bred mock oranges of less vigorous growth have been raised; they are ideal flowering shrubs. Some of the best are *Virginal*. *Rosace*, *Bouquet Blanc* and *Dame Blanche*, all bearing white double flowers. *Lemoinei*, a slender growing shrub 4 ft. high, bears small white flowers freely. These newer kinds must be pruned as soon as the flowers have faded by cutting out old branches and shortening others to where fresh strong shoots are developing.

Mock Orange. Fragrant white blooms and glossy leaves of this beautiful flowering shrub.

MOCK TURTLE SOUP Blanch half a calf's head for 10 min., put it into a stewpan with a gammon rasher cut into dice and about 2 lb. knuckle of veal, well chopped, 2 carrots, 2 turnips, 2 leeks, $\frac{1}{2}$ head celery, or a teaspoonful of celery seed tied in muslin, an onion stuffed with 2 cloves, a bouquet garni, and 2 shallots. Add 3 quarts cold water and set the soup on the fire to boil; skim it well and let it simmer gently for about 3 hours.

When the head is tender remove the pan from the fire. Take up the head on to a dish and bone it, removing the tongue. Strain the stock and put it on to boil, and while it is heating up brown 2 oz. flour with $1\frac{1}{2}$ oz. butter in a small saucepan; stir continually with a wooden spoon, and when it is a dark brown colour mix in by degrees sufficient of the hot stock to make a thin paste. Pour this to the stock, which should now be boiling, and cook for 5 min., stirring all the time. Remove the scum as it rises.

Add 2 glasses sherry, the juice of $\frac{1}{2}$ a lemon, and seasoning to taste. Cut about half the meat from the head into dice, lay these in a tureen and pour over them the boiling soup.

Mock turtle soup may also be served clear, in which case follow the above recipe, but omit the butter and flour. Also after the stock is made it must be allowed to get cold so that every particle of fat may be removed. It should be clarified as described for clear soup. *See Soup.*

MODELLING. The modelling of animals is an attractive pastime. Bears, lions, and many other animals can be sawn to shape from thin pieces of wood, provided with separate legs obtained from similar pieces, and assembled together. They should be very strongly made, and all the joints well glued and pinned together. Bright colours and simple outlines should be the guiding features.

Plasticine, plaster, and similar materials also lend themselves to the construction of toys. Modelling in cork may also be included and may comprise nothing more elaborate than a few quaint figures oil painted, or may take the form of a model of a house, bridge, or any other building made up from small pieces of cork fixed together with seccotine and pins.

The use of large pieces of cork, together with other materials, such as cardboard, stiff paper, brown paper, green baize, and linen, enables more ambitious work to be carried out. Particularly interesting is the modelling to scale of an old village. Paper pulp, made by soaking old newspapers and then thoroughly straining out the water, provides a material, when mixed with gum, that can be modelled into shapes that are difficult to obtain in any other way. Further particulars are given in the article on Papier Mâché.

An interesting occupation is to reproduce to a small scale either a favourite seaside resort or some notable or historic scene. In carrying out this work, cork should be the main material used, as it is easily shaped with a sharp knife. Large pieces of work may be modelled in sections and glued together, and if the surface of the material is coated with size, oil paints can be employed with considerable effect.

Another excellent material for modelling is chalk, which is obtainable quite easily in many parts of the country. It can be cut to all sorts of shapes with no other tool than a penknife, and it forms an ideal material for relief carving. Scale models of stone buildings may be made by using sawn blocks of chalk; a fine tenon saw will serve, and the surfaces can be joined by first coating them with size and applying seccotine when dry.

The chalk can be stained and coloured with water colour. Various stages in the development of architecture may be shown by utilizing cork and chalk, and the materials may be combined in making scale models of famous buildings and old ruins. If chalk in blocks is not readily obtainable, a good substitute, easily worked, can be made from plaster of Paris mixed with water and poured into rough moulds. Gesso and barbola paste can also be used for this purpose.

Modelling Wax. For modelling flowers and fruits pure beeswax is used with a small proportion of lard or olive oil. The wax employed for kindergarten purposes contains beeswax, paraffin wax, sesame oil and sulphur. *See Gesso; Papier Mâché; Sealing Wax.*

MODILLION. This is a word used in architecture to describe a block or bracket used beneath a Corinthian or other cornice, and when so used it is generally enriched or modelled. When employed in a cornice of the Roman-Ionic order, it is plainer in character to suit its surroundings. *See Capping.*

MODULATION. In wireless telephony, this is the procedure whereby oscillations of audible frequency (speech, music, etc.) are caused to vary the amplitude of the carrier wave (e.g. that sent out by a broadcast transmitter). *See Carrier Wave; Microphone; Telephone.*

MOELLON. A mixture used in mason's work, and composed of rubble, stone, and mortar, is known as moellon. It is employed as a filling to fill up the cavities between two wall faces built with blocks of stone.

MOHAIR: The Fabric. Properly used, the term mohair signifies yarn or fabric made from the hair of the Angora goat. The fabric resembles alpaca, though somewhat coarser. Mohair goods are familiar in several forms, and at one time the braids used on coats and costumes were of this material, instead of artificial silk, as at present. The bootlaces described as mohair are actually cotton. Mohair mats and door slips are much used, and most astrakhan, Persian lamb, Teddy bear fabrics, and imitation tiger skin rugs are mohair.

As a dress stuff mohair is generally made with half cotton, and although cool, clean, bright and durable, it is somewhat stiff and not suitable for draped dresses. Manufactured by a special process, mohair and mohair and wool dress goods can be made more lissom. Mats and rugs are often made partly in plain and partly in curled plush. When used as floor rugs the material is sewn upon a heavy jute backing. Mohair plush travelling and motor rugs wear well, take little damage from wetting, and dust is easily shaken from them. Upholstery mohair fabrics are durable and possess a good dust-resisting surface. *See* Bootlace; Upholstery.

MOIRÉ. In order to see a moiré appearance take any light, plain, open-textured fabric like thin silk or cambric, fold it lightly and hold the doubled material up to a good light. An irregularly clouded figure formed by the crossing of the lines will be seen. These markings, or waterings as they are called, can be permanently fixed upon suitable cloths. Goods with ribbed surfaces give the best results, and the larger and less uniform these figures are the more they are admired.

The markings are made by laying one wet surface of cloth over another and using very heavy pressure to impress the ribbedness of one surface upon the other. That is not the only method, for moiré markings of a less uneven character are obtainable by embossing the cloth between engraved, countersunk rollers under heavy pressure. Moiré markings are seen on silk ribbons and dress silks, on velvet, worsted moreens and the cotton material known as moirette, as well as on bookbinding cloths.

MOLASSES. The term molasses is seldom used in English cookery books, but in America the word is used synonymously with treacle. Molasses are the drainings of the raw sugar; while treacle is the syrup which runs from sugar during the process of refinement. *See* Sugar; Treacle.

MOLASSINE. This name is that of a variety of meals and biscuits designed to meet the requirements of dog owners and poultry keepers. The biscuits are liked by dogs, and for the poultry farmer practically everything is supplied from chick food to meals for laying hens. *See* Dog; Poultry.

MOLE: The Fur. This is not a hard-wearing fur, the leather being very thin, but what it loses in wear is compensated to some extent by the artistic shapes into which its pliancy and softness allow it to be made. Moleskin may be cleaned by means of hot bran which is rubbed in with the tips of the fingers. For cutting the skins of the mole an extremely sharp knife should be utilized, the skin split up the belly, the head and feet cut off, when the carcass can be readily removed. The skin, freed of dirt and blood, should be stretched on a board, fur side under, and fastened at the corners with tacks. It should be allowed to dry, and when a sufficient quantity has been collected the skins should be sent to a furrier to be dressed. *See* Fur.

MOLE: On the Skin. Certain tumour formations in the skin are known as moles. In one form they exist as slight elevations of the skin of a light brown to a black colour, and are not infrequently the site of hairs.

Several ways of removal of moles are available to the surgeon, including carbonic acid snow, electrolysis, X-rays, and excision.

It cannot be too strongly emphasized, however, that any attempt at home treatment of moles by caustics or any similar means is most dangerous, nearly always increasing the disfigurement, and possibly converting into a malignant growth. See Birthmark; Electrolysis.

MOLE: In the Garden. Generally the mole is of service to agriculture as an exterminator of grubs, slugs, wireworms, and other harmful things, but it can only be regarded as a pest where the flower or vegetable garden is concerned. Unless quickly caught it will cause great harm, particularly among rows of potatoes or other vegetables growing in well manured, loose drills of soil.

The best way to capture moles is by means of an iron mole trap, seeking the run with a spade, and setting the trap across with a covering of earth. When handling the trap gloves must be worn, otherwise moles, with their acute sense of smell, will avoid the trapped run, and take to another. It is useless to place the trap in a mole-hill. Another remedy is to make holes here and there with a dibber, drop in pieces of carbide, filling the holes with soil packed fairly tight. Dogs, such as the sharp fox terrier, may quickly be trained to watch for moles at work.

The animals usually work at 2 a.m., 6 a.m., and again at 9 p.m. Round about these times their heaving up of earth may be noticed; but the watcher must approach his quarry very gently, as they are extremely sensitive to vibration and smell.

MOLE CRICKET. This fierce-looking insect with lobster-like head and clawed forefeet is sometimes seen in the garden. It lacerates the roots of plants as it burrows with its mole-like forelegs. It may be drowned with paraffin emulsion poured down its holes. In some localities a thin stick is thrust down, and often the insect will grasp this, allowing itself to be drawn to the surface and killed.

MOMORDICA. These climbing plants are valued for the sake of their ornamental fruits, which are suitable for cultivation in a hothouse. They are raised from seeds sown under glass in spring, grown in large flower pots or planted in a border of soil and trained on a trellis or other support. The balsam apple (*Momordica balsamina*), an annual with orange coloured fruits, is one of the chief species.

Momordica. Climbing plant with ornamental foliage and reddish fruit, also known as balsam apple.

MONARCH OF THE EAST. This is a half-hardy tuberous rooted plant (*Sauromatum guttatum*), which will flower on the mantelshelf of a living-room. The inflorescence is in the form of a greenish-purple spathe, somewhat similar to that of the arum lily. The tuber should be purchased in the autumn and will then come into bloom during winter or early spring. When the stem has died down the tuber should be potted or it may be planted out of doors for the summer months. The

leaves will then develop. When these have died down the tuber is taken out of the soil and again placed on the mantelshelf.

MONARDA. This is the botanical name of a scented-leaved hardy herbaceous perennial, known as sweet bergamot and bee balm. *See* Bergamot.

MONEY ORDER. In Great Britain money can be sent through the ordinary post by means of money orders and postal orders. Money orders are more suitable for uneven sums of money, such as £2 7s. 8d., and for comparatively large ones. They can be purchased from any post office that is also a money order office, for any amount up to £40. The charges for an order are 4d. for one under £3; 6d. for one between £3 and £10; 8d. for one between £10 and £20; 10d. for one between £20 and £30; 1s. for one between £30 and £40.

An order is made payable at a particular money order office, and there the person to whom the money is sent must go to obtain it. On giving his name, the amount of the order and other particulars, it will be paid. Money orders can be sent by telegraph from any money order office, the extra charge being the cost of the telegram and 2d.

Money orders can also be sent to nearly all parts of the British Empire and to France, Italy, and other European countries, also to the U.S.A. and Japan. The charges vary, but particulars can be obtained from any post office. To certain countries money orders can be sent by telegram. *See* Postal Order.

MONEYWORT. This is the popular name of *Sibthorpia europaea*, a hardy creeping plant with small, pale pink, snapdragon-like flowers in summer. A shady place in the rock garden is suitable, or it and the coloured-leaved varieties may be grown in suspended pots or baskets in the greenhouse. Propagation is by division in spring.

Monkey Flower. This is another name for the plant usually known as musk (q.v.).

MONKEY FUR. Employed almost exclusively for trimming purposes, monkey fur has a somewhat shaggy unkempt appearance, and takes the form of narrow strips which may be purchased by the yard. Like all other dark-coloured skins, monkey fur may be cleaned by means of silver sand.

MONKEY NUT. In Great Britain the monkey nut, or pea nut, is a hothouse annual. The seeds may be sown in a temperature of about 70° in springtime, in pots, in a mixture of loam, leaf-mould, and sand. The yellow flowers are borne in May and June, and the seed pod usually droops and ripens in the soil. There is only one species, *Arachis hypogaea*.

MONKEY PUZZLE TREE. The name of monkey puzzle is given to a cone-bearing tree, *Araucaria imbricata*, with wide-spreading branches, which curve upward. The foliage is stiff and sharp at the edges. This tree thrives best in country gardens in deep loamy soil. It is apt to lose its lower branches in towns and suburbs. The only other *Araucaria* which is cultivated in Great Britain is *A. excelsa*, which is a half-hardy tree; small specimens make good room plants.

MONKSHOOD. Monkshood is the common name which is given to aconite by reason of its hooded flowers. Although poisonous in all its parts, monkshood is an attractive and free-flowering perennial of distinct value in the garden, especially in shady places. The common blue monkshood is *Aconitum napellus*; the blue and white variety, *bicolor*, is more attractive. *Wilsoni* and *Fischeri*

are other good blue monkshoods. The plants, which grow 3-5 ft. high, should be left undisturbed, as they are slow in establishing themselves. *See* Aconite.

Monkshood. Free-flowering garden plant. See article above.

MONOGRAM. Two or more capital letters combined in one form what is termed a monogram. A good example of this is seen in the diphthong *Æ*. Initials formed into a monogram and cut out in thin tin or zinc can be used for marking linen, books, etc. Another method is to engrave or etch the monogram on silver.

In designing a monogram, legibility must be considered, and in arranging initials it is often advisable to give prominence to the initial letter of the surname; this may be effected by enlarging the letter or by utilizing colour.

Roman lettering lends itself to artistic arrangements, the best method being

to commence with the principal letter, work out as many combinations as possible, and then decide on the best. A symmetrical letter is the easiest to commence with, and where other letters can be arranged in an O or C, the work will be comparatively simple. Some combinations of letters are very awkward to arrange, but it is generally only a matter of practice.

Examples of two and three letter symmetrical as well as non-symmetrical arrangements are illustrated. All the examples are suitable for stencil cutting, but care must be taken to arrange the ties between the letters. Monograms are quite as effective in embroidery as initial letters, the method employed in stitching being the same. Interlaced letters as the O entwined, or the C placed back to back, are often mistaken for monograms, but they are ciphers. *See* Initial; Lettering; Stencilling.

Monogram. Examples of monograms, composed of two or more letters, suitable for stencil cutting.

MONSTERA. Only one species of this evergreen climbing hot-house plant, *Monstera deliciosa*, is usually cultivated. It has large green, lace-like leaves and many surface roots; the flowers, which come in summer-time, are yellow, and are followed by fruits. The plants require a damp, warm position in the heated house, in the usual mixture, and should be inserted in springtime. They require liberal syringing during the summer months, and may be propagated by cuttings.

MONTBRETIA. This is a splendid late summer flower in shades of orange, orange-crimson and yellow. The flowers are in spikes which rise above the iris-like leaves. The older kinds, e.g. *crocsmiaeflora* and *Pottsii*, may be planted out of doors in spring and left undisturbed for several years until they become overcrowded; they ought then to be lifted, divided and replanted in autumn. Recently many handsome new large-flowered varieties have been raised; it is usual to start the corms of these into growth in pots of soil placed in a frame in March and to plant them out of doors in May. They should be lifted and stored for the winter to obtain the finest results. A few of the best of the newer sorts are *His Majesty*, crimson and old gold; *Goldfinch*, yellow; *Lemon Queen*, pale

yellow; Marjorie, orange-yellow and crimson. There are numerous others. Montbretias thrive in ordinary well-tilled soil; on heavy land leaf-mould and sand should be mixed in.

Montbretia. Hardy plant with brilliantly coloured flowers ranging from red to pale yellow.

MONTEITH. The name is given to a vessel made in the eighteenth century, and used for cooling wine glasses. Not unlike a punchbowl, it is usually of silver, and has a scalloped edge and a movable or open-work rim. *See* Punch Bowl.

MONTH. This is a period of time. There are 12 months in the year, known as calendar months, to distinguish them from the period of 4 weeks, which is known as a lunar month. The number of days in each calendar month is as follows:

Jan. 31	May 31	Sept. 30
Feb. 28 or 29	June 30	Oct. 31
March 31	July 31	Nov. 30
April 30	Aug. 31	Dec. 31

Legally a month usually means a calendar month. A person whose salary is paid by the month receives 12 payments a year, receiving the same amount for the 28 days of February as for the 31 of March. Likewise a person who gives or receives a month's notice must reckon it, not as four weeks, but as a calendar month. A notice given on Feb. 19 takes effect on March 19, and so on. Each of the months has certain special features for the gardener and the housewife, and these are given in this work under the various headings. *See* April; Calendar; February; March, etc.

Monthly Rose. This is another name for the China rose. *See* China Rose; Rose.

MOODS: The Game. The game of moods affords a pleasant variant at parties, especially those for adults or elder children. One person leaves the room, and the others decide what mood they will be in. They may choose a laughing mood, an insolent mood, a sorrowful mood, or any other. Then the person outside returns and asks questions from the players in turn, the object being to find out from his method of answering what mood has been chosen. When he has guessed correctly another player takes his place. Any question is permissible. The game is also known as adverbs.

MOON DAISY. The moon daisy (*Pyrethrum* (*chrysanthemum*) *religinosum*) will grow almost anywhere under any conditions, reaching a height of 4 ft., and flowering profusely with large daisy-like flowers during late summer. It is excellent for garden decoration or for yielding flowers for cutting. It should be planted in autumn or spring, and increased by division of roots during the same periods. It is advisable to lift roots and divide them every three years. *See* Chrysanthemum; Daisy.

Moon Daisy. Profusely flowering plant useful both for garden borders and for house decoration.

MOONSEED. The leaves of the moonseed, or *Menispermum*, are not unlike those of the ivy. The plant is a hardy flowering climber with yellow blossoms in summer and grape-like black fruits later on. *Menispermum canadense* is of rapid growth, and suitable for covering walls, arbours, fences, pergolas, trellises, etc. Moonseed thrives in almost any soil and situation, and is propagated by cuttings or division of the roots. It should be pruned early in the year.

MOONWORT. Soldanella, or moonwort, is a family of rock garden plants of the primula order, with bell-shaped, nodding, fringed flowers in spring; height about 3 in. The favourite is *Soldanella alpina*, with violet-coloured flowers; *pusilla* has blooms of similar colour. The moonworts like a compost of loam and peat with sand. They are best suited by a damp position, and will not thrive on a hot, dry site. They should be protected by raised pieces of glass in winter to keep off excessive rains. Propagation is by division in the case of strong tufts in September. The plants may be raised from seed sown in a frame when ripe.

Moonwort. Bell-shaped flowers of this Alpine plant.

MOP: For House Work. There is a use for mops of all sizes in the ordinary household. Most people are familiar with the long-handled type, invaluable for dusting and polishing floors and wainscot. Such mops, if well shaken after use, do not need washing often.

A small mop, the head of which is made of unbleached cotton, soft and absorbent, may be used for washing up. It saves the hands, and is particularly useful for cleaning jugs or cups or any kind of fluted work. These mops should be treated like dishcloths, and be washed in soda-water after use, and hung up to dry. Their cost is so moderate that they can be replaced frequently, and there is no need for them to grow dirty or straggly. They are usually provided with a loop at the end of the handle by which they can be suspended above the sink.

MORaine GARDENING. The possession of a moraine, which, in gardens, is a mixture 12-18 in. deep of stones with a little sifted soil added, enables the gardener to cultivate certain difficult high alpine plants with greater success than is possible in the rock garden proper. The reason is that the perfect drainage afforded by the moraine keeps the plants reasonably dry in winter yet conserves the moisture in summer. Such difficult alpine plants as *eritrichium*, *Gentiana verna*, *Dianthus alpinus* and others should be planted in a moraine; there also the silvery saxifrages, dwarf campanulas and others flourish.

MOREEN. Shiny on the underside, ribbed and with wavy moiré markings on the upper surface, moreen is usually self-coloured. Both moreen and moirette can be used with good effect to make blotting-book covers, stout curtains for cupboards and alcoves, and they wear well as covers for cushions and chairs. *See Moiré.*

MOREL. The edible fungus morel, similar to the mushroom in appearance, is considered by epicures to be superior to it in flavour. *See Mushroom.*

MORELLO CHERRY. The dark-red morello cherry flourishes in chalky soil, and may be grown as a standard in the open or against a north wall. The morello cherry is not suitable for dessert

purposes, as its acids never turn to sugar so completely as they do in other varieties, and its flavour is not pleasing to the palate. *See* Cherry; Cherry Brandy; Fruit.

MORINA. The chief species of the hardy herbaceous perennial morina is longifolia. This has thistle-like, spine-edged leaves and whorls of purple flowers in summer; its height is about 2 ft. It likes a friable soil. Propagation is by division in autumn or spring, or by seeds.

Morina. Thistle-like foliage and purple flower of the species longifolia.

MORNING GLORY. This is one of the many names of the genus of plants Ipomea. It includes stove, greenhouse and hardy annual and perennial climbers, all belonging to the order Convolvulus (q.v.).

Morning Glory. Specimen of the flowers produced by this climbing plant.

MORNING ROOM. As its name implies, the morning room serves the purpose of a breakfast room or a sitting room in the early part of the day.

A morning room should face south-east, more east than south, so as to make the most of the morning sunshine. Its furniture may consist of a round or oval table for breakfast or an informal lunch, a bureau for correspondence and the keeping of the household books, a firm table which can be used for sewing, a cupboard for keeping needlework and odds and ends, or an oak chest, and a couple of comfortable chairs in addition to those needed for the table. *See* Sitting Room.

MORNING SICKNESS. One of the earliest signs of pregnancy is sickness, which commonly occurs when the patient rises. It commences towards the end of the first month, and continues for a month or two, not usually lasting beyond the fourth month. Sometimes it occurs in the evenings, and at times the sickness may continue throughout the day. In that case medical treatment is necessary.

In ordinary cases no treatment is called for. It is a good practice, however, to take a tumbler of hot water or a cup of very weak tea on awakening, and to remain in bed for an hour afterwards. If constipation exists, a purgative should be taken occasionally. A useful laxative consists of 1 oz. each of confection of sulphur and confection of senna.

MOROCCO. This is a variety of leather. Originally it was made from goat skin by the Moors, and won a great reputation owing to the way in which it was prepared, one point being that it was dyed before it was tanned. To-day, in addition to genuine morocco made from goat skins, there is imitation morocco made from calf skins and sheep skins. Indeed, owing to the fact that the graining and finish, which are the distinctive mark of morocco, can be imitated by machinery, morocco can

be made from all varieties of thin leather. It is used, among other things, for binding books, handbags, and covering furniture. *See* Leather; Upholstery.

MORSE CODE. This is a system of signals for radio, telegraphic or visual communication, whereby letters of the alphabet, numerals, punctuation marks, etc., are transmitted either as a series of dots or dashes, or as a combination of both. The International Morse code signals are given below.

A dash is of longer duration than a dot, being equal in length to three dots. The time interval between signals which together make up any particular letter is equal to one dot. The interval between any two letters is equal to three dots, and the interval between any two words is equal in duration to five dots. Full details of the various signals and abbreviations used in radio are given in the Handbook for Wireless Telegraph Operators published by H.M. Stationery Office. This can be obtained from Adastral House, Kingsway, London, W.C., or through any bookseller.

MORTAR. Mortar is a mixture of lime and sand, or similar materials used for making the joints between brickwork and in numerous other building operations. Its purpose is three-fold: to distribute the pressure or weight through the brickwork, to cause the bricks to adhere, or bind together, and as a non-conductor, preventing the transmission of heat and sound, and rendering the wall impervious to water. These functions are governed largely by the proportions of the mortar and the method by which it is applied. The strength and impermeability of the wall depend very largely upon the mortar. Bad mortar allows wet and rain to find a way through the wall; it rapidly crumbles away, and is invariably the chief cause of the rapid deterioration of the building. On the other hand, a good mortar makes a wall drier, stronger, and more durable.

In many districts of England and Wales the by-laws provide for the quality of the mortar which shall be used, and generally these require that all brick and stone work shall be put together with good mortar, or good cement, and that the mortar must be composed of lime and clean sharp sand, without earthy matter, in the proportion of 1 part of lime to 3 parts of sand. Portland cement mortar may be made with good quality Portland cement, in the proportion of 4 parts of sand to 1 part of cement.

In the preparation of ordinary mortar the first consideration is the quality of the lime. Excellent mortar can be made with lime, such as lias limes, mixed with sand in the proportion of 1 to 2. The Portland cement should conform to the standard specification of the British Portland cement manufacturers. It is best to purchase the lime from a reliable builder's merchant, and to specify a hydraulic lime, such as, for example, blue lias.

Slaking the Lime

Lime has to be slaked, by adding water to quicklime. One way is to excavate a cavity in the ground, line it with rough boards, put the rough, or lump, lime into the hole, cover it with water, and leave it for about a month, at the end of which time the lime will be in a soft, creamy-like state, and should be entirely free from lumps of any kind. The lime should be kept covered while it is slaking, to prevent the dust and dirt getting into it, but the covering should be supported on rough bricks or posts, so that air can have free access to the surface of the lime.

If the lime is not properly slaked, it will continue to work and expand, with the result that the mortar joints will be cracked, or, in bad cases, the brickwork itself may be displaced. Another method sometimes used, especially for small, quick jobs, is to mix the lime and sand together in the proportion of 2 parts of sand to 1 of lime, and sprinkle them with water from a watering-can having a rose head, applying as much water as the material can absorb, repeating the process from time to time during the day, continuing until the lime is thoroughly slaked. In any case, the lime should be left as long as possible to temper.

When Portland cement is used for making mortar, the mixture should be knocked up, or prepared, immediately prior to its application, as cement mortar sets hard very quickly, and must be used immediately it has been prepared; otherwise it will become set. After that stage has been reached, if it is again knocked up, and more water is added to make the mixture workable, it will seriously diminish its strength. Lime hardens by exposure to the air, whereas Portland cement hardens by the presence of water. For this reason, lime mortar should only be used in dry situations, and cement always where dampness has to be resisted.

When applying the mortar, the bricks should be dipped in water or otherwise wetted, as if they are used dry, they will absorb moisture too quickly for the mortar, with the result that it will crack or may possibly crumble.

Lime mortar works with a fat or greasy feeling, whereas cement mortar is very harsh, and far more difficult to use, for which reason a common practice is to make up a mortar composed of 1 part cement, $\frac{1}{2}$ part of lime, and 2 or 3 parts sand. This mixture works much better, and for many

purposes is quite satisfactory. Mortar is applied with a trowel or float, according to the nature of the work. In bricklaying, it is most important that the vertical joints between the various brick courses be thoroughly filled up, or flushed up, as it is termed, with mortar. Walls are covered with mortar, the process being known as rendering (q.v.). Various modifications of the constituents of mortar are used for such specific purposes as plastering the interior of a room, or plastering on lathing.

Mortar Board. Boards that are fastened together with battens to make a table or platform about 3 ft. square are used to support a quantity of mortar, and should be placed adjacent to the spot where the work is being done. Almost any strong, fairly smooth boards will do, the only requirement being a level and solid surface. The boards should not be badly split, nor should they have holes through them; otherwise a large quantity of mortar will find its way through and be wasted. *See* Brick; Cement; Plaster.

MORTGAGE. A mortgage is a sum of money borrowed on the security of buildings and land. The person who lends the money has control of the property, which is conveyed to him by legal documents. He is called the mortgagee; the person who borrows the money is the mortgagor.

Many houses are built with borrowed money, and building societies, bankers, insurance companies, and private individuals, usually through their solicitors, lend money in this way. In each case a mortgage is created. They will lend usually up to two-thirds of the value of the house or land. The interest charged depends upon the state of the money market, and is usually paid every six months. The mortgagee can withdraw his money at any time upon giving the necessary notice, which is normally three months.

If the money is not repaid, or if the interest is in arrears, the mortgagee can either sell the property or foreclose. In the former case he must hand over to the owner of the property any balance that remains after the mortgage, interest and expenses have been met. Foreclosing means that the mortgagee becomes the owner of the property. To do this he must obtain an order from a court of law that unless the borrower pays up within a fixed time he shall lose his equity of redemption, i.e. the right to repay the mortgage. If the mortgagee sells the property and does not realize sufficient to pay the principal, interest, and costs, he can sue the borrower for any balance. Sometimes second mortgages are created, but these rank, both as regards capital and interest, after first mortgages.

Stamp Duties. The stamp duties payable when mortgages are created are at the rate of 2/6 for every £100. Under £100 they are 3d for £10, 8d. for £25, and 1/3 for £50. Persons who lend money on mortgage should see that the mortgaged property is fully insured by the borrower. Those who borrow should see that the interest is paid promptly, while it is to the advantage of both to keep the property in good condition, although the mortgagee has no liability in this direction. Borrowers are well advised if they provide for the gradual repayment of the money borrowed. Building societies usually stipulate that this shall be done, and arrange for mortgages to be repaid by instalments extending over a fixed period of years. In such cases a payment weekly, monthly or quarterly, as the case may be, includes both the interest and a sum towards the repayment of the debt.

The power to call in mortgages, and the raising of interest thereon beyond a certain figure, is restricted in certain cases under the Rent Restriction Acts, which were introduced during the period of the Great War and have since been amended several times. *Set* Building; Building Society; House; Rent.

MORTISE AND TENON JOINTS

Methods of Making and Their Use in Amateur Carpentry

For fuller information our readers are advised to turn to the wood-working articles, especially Amateur Carpentry; Chisel; Dowelling; Joint; Lock; Tenon; and to those on the various pieces for which mortises are necessary, e.g. Cabinet; Cupboard; Door; Dresser.

In woodwork and building construction a mortise is a rectangular hole formed to receive a peg, or tenon, shaped on the part to be jointed. Of its varieties the simplest consists of a mortise, or slot, cut in the centre of a beam, to receive the tenon on the end of an

upright, as shown in Fig. 1.

Mortise. Showing examples of the leading types of mortise joints. Fig. 1. Plain mortise and tenon joint. Fig. 2. Simple mortise and bare-faced tenon.

The bare-faced tenon in Fig. 2 has only one shoulder, the other side being flush with the face of the post. It is used when one side of a rail has to be flush with the stile, or post, while the other side is set back from the face. The tenon may or may not pass through the post where the mortise is cut. In the closed mortise the tenon is surrounded by wood on all four sides and the end, and the mortise does not pass right through the wood, but terminates at a distance from the face. When the work is completely finished, the joint between the rail and post is not visible, except as a line of demarcation between the two parts. It is therefore often used in cabinet work, and is also used for the better class of door frame.

The joint shown in Fig. 3 is a haunched mortise; the tenon is cut back for the bulk of its length, but a small projecting portion is left at the side to provide a maximum grip on the post. The slot mortise in Fig. 4 is merely a slot cut in the end of one part to receive the tenon formed on the other part. The adjustable slot mortise and tenon in Fig. 5 are only used where it is desired to exert pressure upon some projecting part of the framework, as, for example, the canvas of an oil painting. The wedges are driven in, and the parts of the framework separated, thus tightening up the canvas.

When the tenon does not pass right through the mortise it is known as a stub tenon. The oblique mortise and tenon in Fig. 6 is used for joints on the ends of braces and struts, and apart from the fact that the shoulders and end of the tenon and two sides of the mortise have to be cut at an angle instead of square, they follow the same principle as the ordinary mortise.

The mortises for a corner post have to be cut with all faces at right angles to each other, consequently the two mortises will have to meet in the centre of the material. They are therefore generally haunched and the rail is mitre tenoned, as in Fig. 7. A double mortise (Fig. 8) is often used in jointing a broad rail into a stile or post.

Fig. 3. Haunched single mortise and tenon. Fig. 4. Slot mortise and tenon. Fig. 5. Adjustable slot mortise and tenon, as used on stretcher of an artist's canvas. Fig. 6. Oblique mortise and tenon. Fig. 7. Mitred tenons and mortise for use in table legs, etc. Fig. 8. Double haunched mortise and tenon. Fig. 9. Fox wedges for securing tenon into mortise.

A good method of making a rigid mortise and tenon joint is known as the fox wedge tenon (Fig. 9). The mortise does not go right through the wood, but terminates at a distance from the face, and the walls of the mortise are cut to an angle, so that the bottom of the mortise in the wood is wider than the mouth, or entrance. The tenon is cut to a width that will just enter the mortise. Two or more wedges are then made of hardwood and inserted in saw cuts made in the end of the tenon. When the joint is to be finally assembled the parts are glued, the wedges just inserted into the slots, and the joint driven home with a mallet, or clamped up tightly, with the result that virtually an internal dovetail joint is formed which possesses very great strength. A similar system of wedging is often adopted where the tenon passes right through the mortise. In this case the wedges are driven in from the outside and serve to make a perfectly rigid joint. Wedges of this class are always used when the end of the tenon is accessible.

General Principles. Usually, mortise and tenon joints are secured by glueing and wedging, by pins or by draw boring. The proportion of the mortise and tenon in the case of a stub and through mortise should be about one-third the thickness of the material. It is imperative that the walls of the mortise be square to each other and to the joint faces. Similarly, the tenon must be square on all its sides, the two shoulders in line, square with the joint faces.

The general procedure in the making of any mortised joint consists firstly in marking accurately on the wood. This should be done with a scribe and set-square, and the lines should be squared right around the material, marking first the length of the mortise. The width is set out with the aid of a mortise gauge (Fig. 12), which is used to scribe lines on both sides of the part to be mortised. There is thus a rectangular space marked out on opposite sides of the wood, indicating the material to be removed. The tenon should similarly be marked out, with the same setting of the mortise gauge.

Mortise. Fig. 10. Showing method of using mortise chisel. Fig. 11. How the tenons are cut. Fig. 12. Mortise gauge, which marks two lines simultaneously.

The mortise is then cut by drilling holes in the material with a centre-bit, keeping just within the lines. This removes the bulk of the timber and the remainder is cut out with a chisel, preferably a pattern known as a mortise chisel, which has a very strong handle and is used with a mallet (Fig. 10). It is driven down into the wood as far as possible, withdrawn, and the chips removed from the hole; further chiselling continues until the bulk of the hole has been cut half-way through. The timber is then turned over and similarly cut from the opposite side.

The final fitting may be completed with an ordinary firmer chisel by careful paring. As a guide to the eye, an ordinary set-square should be set by the side of the work, this being an aid to keeping the chisel correctly upright while cutting out the mortise. The tenon may be cut out almost entirely with the aid of a hand or tenon saw, as shown in Fig. 11, by carefully sawing down the lines. The saw cuts should be kept to the outside [of the lines, so that a small amount of material has to be chiselled away to make a perfect fit. The two parts should be tried together from time to time, and carefully fitted by cutting away all the high places, whose presence is determined by the shining portions of the wood, caused by the friction of one part upon the other. The tenon should be tested with a square to see if the tenon or the mortise is at fault, and any irregularities corrected accordingly. If the joint is to be wedged, a space must be left into which the wedges can be driven.

The mortise chisel is sharpened in a similar way to an ordinary chisel, but the angle is steeper and the cutting edge rounded. When using the gauge, it is customary to set the pins to the breadth of the mortise chisel nearest to the size of mortise desired. One of the marking pins is attached to the glider that works on the stem, and is adjusted by a screw at the bottom of it. The other of the two pins is attached rigidly to the stem. The head slides on the stem, and consequently two separate

adjustments are available; first, by adjusting the two marking pins to the required width and secondly by sliding the head to such a position on the stem that it will mark a mortise at the correct distance from the marking face.

MORTISE LOCK. A special type of lock, known as a mortise lock, is so made and fitted into its case that it can be mortised into the edge of a door, leaving only the bolt and catch protruding, with the turning knobs on either side of the door.

Mortise locks may be obtained in various patterns and shapes, from a very thin-cased pattern, which may be fitted into a narrow slot in the door stile, to the ordinary type of mortise lock about the same size as a rim lock. Another type is that known as the barrel mortise lock, which may be fitted into a hole bored in the door with a twist bit or auger. Mortise locks are generally of the warded tumbler type, and in the case of some of the smaller varieties, such as the small barrel mortise lock, only one bolt is provided which is locked by the key, and which also prevents the handle from being turned. Instructions for fitting mortise locks are given in the article Lock (q.v.).

MORTLAKE WARE. The earthenware produced at the Thames-side village of Mortlake, for about 70 years after the middle of the 18th century, was almost as famous in its day as its pictorial tapestry. Any pieces offered as Mortlake should, be viewed with the utmost reserve, because there have not been identified enough typical specimens on which to base an assured judgement. There was a factory for common tin-enamelled or delft ware, ranging from large punch-bowls, painted with flowers and medallions, to blue landscape tiles. Another factory, founded by Joseph Kishere, who marked the ware with his name, turned out a sound, domestic stoneware of the drab or brown type, which was also produced at Fulham. This was sometimes decorated in low-relief with hunting and convivial scenes, but apparently never reached a high standard of artistic merit. It is not unlikely that pieces of Mortlake origin are concealed in museums under more famous names. *See* Fulham Ware.

MOSAIC: As a Decoration. This attractive process consists of embedding small pieces of stone or other material in cement to form a pattern or design. It is much employed because of its durability, cleanliness and comparative noiselessness to the tread, as well as for its ornamental effects. The materials employed comprise marble, pottery, and glass.

There are two varieties of mosaic paving, known respectively as the Roman and the Venetian. In the former, a foundation of concrete is prepared and the top of it coated with a thickness of about $\frac{3}{4}$ in. of neat cement. This is floated off to a level surface, and into it are pressed small pieces of marble, of various colours, principally white, red, black, cream, brown and green.

Burnt clay or ceramic mosaic, with blocks $\frac{1}{2}$ to 1 in. square, beside being cheaper and more durable, is available in a wider range of tints. Clay cube is best adapted for regular geometrical designs, because it does not admit of being trimmed, as marble does, to fit the interstices of a pictorial design. When the mosaic consists of a groundwork of stone of one colour with a simple border in another kind of stone, the border may be set in position first and the remainder of the spaces filled in with self-colour stone.

When a pictorial design is wanted the design is first drawn up full size on a large sheet of paper, or several sheets if the area to be covered is of any size. The stones are glued to the paper, placing the face side of the stone against the paper. The concrete foundation should previously have been prepared, and when the design is finished on the paper, a floating coat of neat cement is worked on the concrete. The paper is lifted and turned over on the wet cement and pressed into position. The stones should be pressed into the cement sufficiently to hold them in position, and as soon as the cement has become thoroughly set, the paper is damped and removed from the stones.

The design will appear in outline form on the foundation, and the spaces between the outline of the design are filled in with other pieces of stone bedded in cement, the whole being levelled as much as possible and finished by polishing. The cement joint should form an integral part of the design; when the blocks are fitted so closely to obliterate the joint the result is artistically weak.

Venetian Mosaic. Venetian or terrazzo mosaic employs marble chips, that are crushed into irregular shapes and sorted out into grades ranging from $\frac{3}{16}$ in. to $\frac{3}{4}$ in. mesh. In this style the cement becomes a filling rather than a joint, and is usually coloured in a contrasting tint. The marble fragments are spread upon the cement, larger pieces being strewn upon them here and there, thickly or sparingly, and the interstices filled with smaller chips. The whole is then levelled by heavy rollers. Sometimes a border is formed in a darker tint, or in marble cube design.

When mosaic tesserae are applied to walls and ceilings they are usually only half as thick as paving cubes. Wall mosaic is most satisfying when carried out in simple and unpretentious designs, with restrained colourings in the borders.

Glass Mosaic. The use of glass mosaic for mural decoration, in emulation of the Byzantine examples, is associated with public rather than domestic buildings. The tesserae, varying from $\frac{1}{4}$ in. to $\frac{3}{4}$ in. square by $\frac{3}{16}$ in. thick, are made of opaque glass pastes, and are available in thousands of tints. Glass-and-gold, formed by fusing gold-leaf between two layers of transparent glass, is commonly employed as a filling for the pictorial design. Fig. 1 shows the pattern drawn on the paper and the process of sticking the stones thereon. Fig. 2 illustrates a mosaic design transferred to the slab and some of the stones standing up in readiness for filling in the groundwork. Fig. 3 shows the Venetian system with some of the wood battens in position and others removed to receive the coloured stones for the border design.

Mosaic. Fig. 1. Roman mosaic. The pattern has been drawn on paper and the process of sticking on the cubes begun.

Fig. 2. Design transferred to slab and groundwork being filled in. Fig. 3. Venetian mosaic, showing groundwork laid before rolling; two of the wooden battens have been removed.

MOSAIC: In Potatoes. This disease, which attacks some varieties of the potato more than others, is frequently responsible for light crops in gardens and allotments. It may be recognized by the mottling of the foliage. Coupled with this there is usually a crinkling of the leaves, a waviness in the outline of the leaflets, and other indications that the leaves are not normal. In severe attacks a dwarfing tendency is frequently seen, and with it

goes a marked reduction in the yield. The disease is distributed by means of the seed tubers; therefore tubers from infected plants should on no account be put aside for seed. Infected plants should be immediately destroyed, as they never recover from an attack. *See* Potato.

MOSELLE. The vineyards of the lower Moselle yield very fine white wines of the hock character, dry, delicate, and with an attractive bouquet. The best are Piesporter, Brauneberger, Zeltinger and Berncastler Doktor. Moselle is an excellent beverage drink, going well with most sorts of food. Sparkling Moselle, though apt to be a little over-sweet, is a pleasant wholesome wine. The alcoholic strength of the Moselle wines ranges between 17 per cent and 25 per cent of proof spirit. *See* Hock; Wine.

MOSQUITO. As some kinds of mosquitoes carry the infection of yellow fever and malaria it is important in infected districts to take active measures to destroy the larvae. An efficient method is to pour paraffin oil on all ponds and stagnant pools, using one pint to each 200 sq. ft. of water surface. Cisterns and water barrels should be emptied once a week. Old tins, tubs, and other receptacles for water should not be left lying around the dwelling. Oils of pennyroyal or lavender sometimes keep mosquitoes away if a few drops be sprinkled on the bedclothes, or on exposed parts of the body.

Where the insects abound, mosquito curtains should be used round the bed, and windows that are kept open in the evening should be guarded by fine wire or muslin netting.

Mosquito Bites. Mosquito bites are often very troublesome. As a preventive for warding off the attacks of these insects the following lotion will be found useful:

Oil of lavender	20 minim.
Oil of eucalyptus	2 drams
Spirit of camphor	1 oz.
Soap liniment	1 oz.

A little of the lotion should be applied to the skin of the hands, wrists, ankles and the neck when the mosquitoes are about. For relieving the irritation the following preparation can be used:

Menthol	15 gr.
Alcohol (90 per cent)	1½ oz.
Strong solution of ammonia	½ oz.

Dissolve the menthol in the alcohol, and then add the ammonia. Dab on to stings and bites as often as required.

MOSS. The popular name moss, which belongs strictly to plants of the Musci family, is applied indiscriminately to many plants. Moss is generally a nuisance on gravel walks. The method of eradication usually practised is to sprinkle the walks well with rock-salt during showery weather. A better way, however, is to brush the surface of the gravel with a strong solution of bluestone, or sulphate of copper. The brushing should be done carefully, and the copper solution kept away from turf edgings or bed or border plants.

Fruit trees are often attacked by various growths which are loosely described as mosses. A precautionary measure is to spray with caustic soda (1 lb. in 10 gallons of water) in winter. When

moss is found on lawns it is usually a sign of malnutrition. Rake the surface of the lawn over and give it a dressing of rich sifted soil in springtime.

MOSS CAMPION. A very beautiful plant for the rock garden is *Silene acaulis*, or the moss campion. It is of low moss-like growth and bears rose-pink flowers in spring. It is most likely to bloom well if grown in a moraine. *See Moraine Gardening.*

MOSS ROSE. The variety of rose known as the moss rose is interesting owing to the mossy growth which surrounds its stems and the bases of its flowers. The principal varieties are as follows: *Blanche Moreau*, white; *Crested Moss*, rose; *Little Gem*, crimson; *Mdme. Moreau*, rose. Moss roses should be grown in rich soil: pruning in March is done by cutting out weak shoots and shortening the others. *See Green Fly; Rose.*

Moss Rose. Variety of rose so called from a mossy growth on the stems.

MOTH. These winged insects, though similar to butterflies in general appearance, are as a rule not so brightly coloured. The body is usually larger and more furry, and most varieties fly principally at night.

Moths in the Garden. The caterpillars of three moths do great damage to fruit trees in the spring. These are the winter moth, the mottled umber, and the march moth, all being sometimes known as winter moths. Practically every form of standard and bush fruit is attacked by these pests. The caterpillars appear early in spring and feed during the entire period in which fruit trees are making their foliage, causing sometimes great havoc.

Winter Moths. Winter moths may be controlled both by grease-banding the trees in autumn, to catch the wingless females as they ascend the trunks, or by spraying the foliage with a tar-oil wash in winter, to kill the larvae. After the blossoms have fallen in spring, spraying with the poisonous lead arsenate, 4-5 lb. in 100 gallons of water, is recommended. *See Buff-tip Moth; Figure of Eight Moth; Grease; Hornet Moth; Insecticide, etc.*

MOTH BALL. The round balls sold as moth balls consist of naphthalene, a product of the distillation of coal tar. Naphthalene is a cheaper substance than camphor for placing among furs and woollen goods to preserve them from moths. The smell of naphthalene is considered objectionable by many, and on this account moth bricks are made from a mixture of equal parts of cedar dust, camphor, and naphthalene, made into a brick by mixing with strong soap and water. *See Clothes; Clothes Moth; Fur.*

MOTHER. The mother of a legitimate child is its guardian after the father. The father is entitled to name a guardian for his children after his death, but the mother is entitled to act with that guardian. A court of law will not allow a man who separates from his wife to take away from her young children. If he does so the court will invariably order them to be returned to their mother, unless she is not a fit and proper person to have the custody of the children.

In the matter of religious education the father is entitled to the deciding word. If, either before or after marriage, a man and woman have agreed that the children, or some of them, shall be brought up in one creed, the father can in law go back on his word and bring them up in another. But if they

have begun to be educated in one religion, so that a change would unsettle them, the court will forbid the change.

A mother who has property or means is liable to maintain her children. She is also liable, along with the father, under the various statutes which relate to the care of children. The mother of an illegitimate child is its only parent in law, and the putative father has no control over it. If the mother of a child marries a man, that man becomes responsible for the maintenance of the child until it can maintain itself, just as if it were his own. *See* Child; Father; Husband; Illegitimacy, etc.

MOTHER-EVE'S PUDDING. To make this pudding, allow 6 oz. breadcrumbs, 5 oz. castor sugar, 6 oz. currants, 6 apples, 3 eggs, a pinch of salt and of nutmeg. Crumb the bread very finely, and pare and chop the apples. Clean the currants and stone them. Mix the dry ingredients together and beat the eggs, then beat in the eggs and stir all well together. Butter a pudding basin and put in the mixture. Cover it with greased paper and steam the pudding for 3 hours.

MOTHER-OF-PEARL. The oyster shells from which the chief supply of mother-of-pearl is obtained are found off the coasts of N. Australia and New Guinea, some of the specimens measuring from 6 in. to 9 in. in diameter and weighing several pounds each. The inside surface of the shell is mostly white, but some are of a smoky black colour.

By jewellers and silversmiths mother-of-pearl is very largely employed. It is used for buttons, studs, and cuff links; for the handles of fruit knives and forks and pocket knives. It is cut into round or oval-shaped beads for necklets and rosaries. Cabinet makers use it for inlaying, and large quantities are employed for this purpose in the manufacture of Oriental furniture, especially small decorative tables.

MOTHER OF THOUSANDS. This is the only species of the saxifrages, *S. sarmentosa*, which is commonly grown under glass. It is useful both for hanging baskets and pots.

The soil should be three parts loam, one part leaf-mould and sand. Propagation is by inserting the plantlets in sandy soil in the propagator in spring or summer. A cool greenhouse suits it well, or it is a valuable adjunct to the indoor rock garden or fernery. The variety tricolor likes a warm greenhouse. The time for re-potting is the spring.

Linaria cymbalaria, also known as pedlar's basket, is sometimes given this name. It is a creeping outdoor plant suitable for rockeries and old walls.

MOTHER'S HELP. The duties of a mother's help are not very clearly defined, but should be arranged definitely between employer and employee at the time of engagement. As a rule, the post involves work ranging from that of a nursery governess to that of an ordinary nurse, a certain degree of education being generally expected.

Primarily, the post means care of the children and charge of their wardrobe. The mother's help is expected to be a good needlewoman, able to make simple frocks for her charges, and to do any necessary mending. She may also be expected to do a certain amount of washing, and to be responsible for the general turn-out of the children. If there is also household work to do, it will usually be only of the lighter kinds. *See* Insurance.

MOTH ORCHID. The hothouse orchid belonging to the genus *Phalaenopsis*, and known as the moth orchid, requires a stove temperature, and should be grown in pans or baskets suspended from the roof of the house. The handsom varieties of *Miltonia vexillaria* are most popular. *See* Orchid.

MOTIF: In Needlework. A motif is a piece of lace or embroidery set into a background of ordinary material to form a trimming. There are crochet and knitted lace motifs in ovals, oblongs, circles, and squares, embroidery motifs of all shapes and sizes, and real lace motifs such as those made with Honiton braid and pillow laces, which take the shapes of flowers, butterflies, etc.

There are several methods of mounting motifs to the material. The first is to tack the motif on the right side of the material, sew down with a small hemming stitch, in the case of knitting or crochet, taking one hemming stitch through each stitch of knitting or crochet. The material is then cut away at the back of the motif, leaving about $\frac{1}{4}$ in. to turn back a little hem or only leaving about $\frac{1}{8}$ in. and buttonholing the raw edge. A second method is to buttonhole the motif to the material on the right side, and cut away the material at the back of it just below the wrong side of the buttonhole stitches. Another method which gives a strong edge and a neat finish is carried out thus: Lay the motif on the right side of the material and pin it down so that the edges are quite taut and in the correct position. Now draw a pencil line on the material right round the motif, then remove the latter from the material. With embroidery cotton and a fine crewel needle, buttonhole all round the pencilled outline so that the pearl edge of the buttonhole stitch comes right on the pencil line. When the buttonholing is completed, take the motif and sew it, stitch by stitch, to the buttonholing. If the pencilling and sewing are on the correct line, the motif should be an exact fit, and the material at the back can be cut away. *See Appliqué; Embroidery; Lace, etc.*

MOTOR. This name is employed for any machine which changes some form of energy into mechanical power, e.g. an electric motor, petrol engine or water power motor. *See Electric Motor; Internal Combustion Engine; Mangle; Water Motor.*

MOTOR CARS: HINTS FOR OWNER-DRIVERS

How to Choose a Car and Maintain it Economically

The important subject of the motor car is dealt with in this Encyclopedia in this article, in one on Motoring and in a number of subsidiary entries, e.g. Brake; Clutch; Front Axle; Gear; Internal Combustion Engine; Live Axle; Lubrication. *See also Garage.*

The prospective purchaser of a car should carefully consider his requirements before placing an order. There are hundreds of different models from which to choose, which perhaps renders the question somewhat difficult to the novice, but he need have no fear about the capabilities as an efficient touring machine of any car now made, whatever its price. The suitability of a car, therefore, is narrowed down to requirements.

For example, it would be unwise to decide on a baby car if the purchaser's family party consisted of four stout persons, for although the car would carry such a load, and the engine have no difficulty in propelling it, the party would hardly be comfortable. On the other hand it would not be wise to buy a large car because of its good value (there are many such cars now available) if the taxation and general running expenses rendered motoring costs a severe drain on the buyer's income.

The Horse Power of Cars. Motor cars are taxed on what is known as the 15s. per horse power basis, the horse power being calculated on the Royal Automobile Club formula, which takes into account only the diameter of the cylinders of the engine and not the stroke. The R.A.C. rating is also accepted as a guide when the question of insurance costs is being considered.

Modern cars may roughly be divided into four different types. (1) Small cars of 750 c.c. to 850 c.c. (7 and 8 horse power for taxation purposes). (2) Light cars between 850 c.c. and 1,300 c.c. (9 to 12 horse power, R.A.C. rating). (3) Medium cars up to 2,000 c.c. (13 h.p. to 20 h.p.). (4) Large cars, over 2,000 c.c. (19 horse power and over).

A large car is very little more difficult to handle than a small car, but usually the novice has more confidence if he begins with a small car. The cost of a small car is as low as £120, and may be as high as £250 if the bodywork be of a special character. The running costs are exceptionally low; 40 or more miles to the gallon of petrol and at least 1,000 miles to the gallon of lubricating oil are obtainable. The licence costs £6 5s. and the insurance about £8 to £10 per annum. The fee for a driving licence is 5s., so if it is possible to garage a small car at home the total overhead charges are about £18 5s. 0d. per annum.

Should it be necessary to accommodate the car in an outside garage, the charges vary according to locality, but 6s. a week may be regarded as a fair charge for a small car. In the provinces this charge may be lower, while if the car be kept in a public garage with a number of other cars it may be lower still. The latter procedure involves a possibility of the car sustaining damage through being moved about to facilitate the handling of other cars in the garage. The advantages of a private garage to the owner-driver who looks after the car himself are considerable. It will enable him to give regular attention to lubrication and to make small adjustments and thus keep his car in good tune while reducing to a minimum the risk of breakdown from any minor defect.

Motor Car. Fig. 1, Sectional diagram of typical modern six cylinder engine with principal parts indicated.

Small Cars. The types of small car available are many, and include open two-seater two-seater coupé, four-seater open tourer, and small four-seater saloon with or without a sunshine sliding roof. The open cars are equipped with hoods and efficient side screens which make them almost equal in comfort to the closed types; nevertheless, unless the buyer particularly desires an open car, a closed car is likely to give greater satisfaction, especially one with a sliding roof.

In small cars the space available is somewhat restricted, with the result that in most cases only two doors are provided, access to the rear seats being obtained by folding one of the front seats. Four-door bodies on small cars are not general, but are obtainable on certain chassis.

As a rule the engines fitted to these small cars are of the four-cylinder type and give the vehicle a range of speed from walking pace to about 65 miles an hour.

Three speeds forward and a reverse gear are usually provided, but there are small cars available with four speeds forward. The advantages of the extra gear ratio are more apparent with a small car than with the larger types, since the load is relatively greater in the case of the small car. Included also in this class to a minor extent is the small six cylinder vehicle in which a comparatively large engine is fitted in a small chassis, with the result that an exceptionally good performance is obtained, the weight being low and the power high.

The Light Car. In the popular light car class two-door bodies are the exception, and four-door bodies the rule. Costs are considerably higher, so that if four persons are to be the usual load and a low price is an essential factor, the prospective buyer should make his selection with some care, and not decide hurriedly. The range of selection is very wide, and although this class of car is naturally more expensive than a small car, the value is in every way as good. The annual tax is from £8 to £12 and insurance costs about the same figure. The driving licence remains the same (5s.) irrespective of the type of vehicle. Although the majority of cars in this category are of the four-cylinder type, a number have six-cylinder engines.

Everything else being equal, a six-cylinder engine is much better balanced, and smoother in its operation than the four-cylinder engine, although it is an axiom that a good four is better than a poor six. A car with a six-cylinder engine costs a little more to run, both in fuel and taxation, the extra expense amounting to about 15 per cent.

Medium Size Cars. Next in popularity to the small car, this class contains mostly six-cylinder engines, though there are a number with four-cylinder engines, and eight-cylinder power units are included in the specification of a few. The 'eight' if of equal quality is slightly superior to a 'six,' since the turning effort is almost as smooth as that of an electric motor, and gear changing is reduced to a minimum.

The Large Car. Among the large cars are to be found some of the cheapest now on the market. These are of American design, of the mass production type, and are most efficient, although the costs in fuel, taxation and insurance are necessarily high compared with the smaller British designed cars. The horse power is 20 or more.

Coachwork. There are several different methods of constructing coachwork, including 1, all steel; 2, metal panelling; 3, fabric covered; and 4, coach built.

The all-steel body is constructed of sheet steel pressings, and is only found on cars sold in large quantities, since the tools necessary for their production are very costly and thousands of bodies of one pattern must be made to make the proposition an economical one. All-steel bodies are immensely strong, and a car may roll right over in an accident with little risk of the body collapsing. The metal panelled body has a wood frame (ash) to which the steel or aluminium panels are affixed. This system of construction is more costly than the above, but it allows of economical production in smaller quantities.

The fabric-covered body is similar to the last dealt with, and at one time where small outputs were concerned was in favour because of its cheapness. It lacked robustness, however, and with the advance in metal-body construction, the fabric type has become obsolete.

The coach built system differs only in detail from the methods of the old fashioned coachbuilders. Every body so made may be regarded as built to measure. For that reason, it is very costly, and is only to be found on the highest priced chassis.

Running Costs. It is possible to arrive at a fairly accurate estimate of the probable running costs of a car, though the actual figure will be largely affected by the annual mileage and the general character of the roads over which the car is mainly used. If the vehicle is driven in all weathers, this must be taken into account also.

The tabulated costs given in Fig. 2 will serve as a basis for the intending motorist, who will thus be able to form an idea beforehand of his likely expenditure on the type of car in view. Actual running costs in the first few weeks can be compared with those given here, and the latter adjusted as necessary.

Motor Car. Fig. 2. Table showing approximate running costs for various cars.

The table deals with 8, 12, 15, and 20 h.p. cars, but it must be pointed out that the weight of the car has to be taken into consideration, since a light car rated at 8 h.p. may weigh from 8 or 9 cwt. to 18 cwt. (the latter figure applying to a saloon body). Thus, while the running costs for the lightest might be less than those specified, the saloon type 9 h.p. car might be practically as expensive to run as a 12 h.p. car of 19 cwt. or so. The table is based on a new car used over a period of three or four years.

The expenditure falls under three main heads: depreciation, standing charges, and running expenses. A new car falls in market value directly it is brought into use, and depreciates by about 30 per cent in its first year, so that this loss in capital value must be reckoned with. In succeeding years the rate of depreciation is less, but the motorist, to be on the safe side, should write off his purchase price

over a period of at least six or seven years, as after this lapse of time the car may fetch less than 10 per cent of its original cost.

Standing charges, including items like tax, licence, insurance, association subscriptions, and the rent of a garage, are independent of the annual mileage or the use made of the car, and are governed only by time.

Running expenses include petrol, oil, tires, and such costs as repairs, maintenance, and the special expenses incurred on the road, i.e. occasional garaging, parking, etc.

Some motorists lay up the car during the winter months. If in any case the car would not be much used during the period, the owner will be able to make a substantial cut in his annual expenses, since the amount of tax and insurance premium payable are lessened, and the running costs cease for the time being. The question of insurance is gone into fully in the subsequent article on motoring.

Motor Car. Two modern British types. Left (Fig. 3), six-light saloon body on 25 h.p. Wolseley Super-Six. Particular attention has been given to vision and ventilation. Right (Fig. 4), coupé model Morris Ten which has a fixed head fitted with a sliding roof. The wide doors provide exceptionally easy entry and egress, and general roominess is an attractive feature of this up-to-date bodywork.

Motor Car. Fig. 5. Morris 'Eight' chassis, smallest of the current range. Note the long rear springs, the wide frame, and the position of the battery on the dashboard.

Motor Car. Fig. 6. Sparking plug, showing how gap between points of plug may be measured.

Care of the Car. We now proceed to consider the question of keeping the car in good condition. The information given here will enable the motorist to detect running and other faults and to apply the necessary remedies before they develop into serious defects.

By consulting the fault-finding tables, Fig. 8, p. 233 and 234, in conjunction with the numbered paragraphs, the motorist may obtain considerable assistance when endeavouring to ascertain the cause of a breakdown.

At a first glance the magnitude of the tables may lead him to suppose that the possible troubles of mechanically driven vehicles are legion; but, in point of fact, it is quite common for a car to remain in very fair order for a whole season without mechanical adjustment.

The procedure by which defects may be traced is simple, as the following example, taken from the first of the tables, will show. Suppose, for instance, that the engine will not start. On inspecting the carburetter it is found to flood properly, and a spark is passing across the points of the sparking plug. Then the reason for the trouble will probably be found in the starter and the causes 1 to 6 in the chart should be studied and considered.

Motor Car. Fig. 7. Flooding the carburetter: a preliminary test in checking the fuel feed.

Before passing to the detailed paragraphs it is essential that the term good running order should be properly understood, since the meaning conveyed by it to the ordinary motorist is very different from that placed upon it by the enthusiast. The former is content so long as the car does not actually break down, and loses sight of the fact that some of the faults enumerated may be actually in existence, and may sooner or later cause serious trouble. The enthusiast is never satisfied unless the engine is in perfect tune, developing its full horse-power

with a reasonable consumption of petrol and oil, the transmission is working efficiently, and the chassis and bodywork generally are in good order and condition. To ensure this over a long period calls for regular attention.

The book of instructions sent out by the maker of the car should be carefully read, as it will amplify the hints given in this article, and will further deal with the special characteristics of the vehicle in question. The following numbered paragraphs are intended to be used in conjunction with the fault-finding tables:

1. If the cause of the engine failing to move is an exhausted battery it is probable that a faint click will be heard as the starter switch is pressed, indicating that the Bendix pinion has moved slightly. If the battery is completely exhausted, however, even this indication will be absent. The quickest test is to switch on the lights.
2. Failure of the starter switch may be checked by connecting the battery voltmeter across the contacts after closing the switch. There will be no voltage reading if the switch is in good order. If it is out of order a reading will be given. If the Startix automatic switch is being used and there is no response when it is switched on, the switch should be turned to 'hand' and an attempt made to start the engine by the ordinary process of pressing the starter button.

4 and 5. If, when the starter button is pressed or the Startix turned to 'automatic' there is no turning of the engine, two possible faults should be looked for, meshing of the starter pinion and a frozen water pump. In very cold weather it may happen that the water in the pump will freeze, even though the water in the radiator has been kept from freezing by suitable coverings or heaters. On such an occasion the pressing of the starter switch will simply produce a metallic thud, but will not turn the engine. No second attempt should be made if a frozen pump is suspected until this possibility has been eliminated, because if the engine is turned while there is ice in the pump, the pump vanes will probably be sheared. The small tap situated at the base of the pump should be turned on to see if water flows freely, and even then some further precautions should be taken because, although there may be free water in the pump, there may also be solid pieces of ice.

If the failure of the starter to turn the engine is due to the jamming of the starter pinion with the teeth on the flywheel the car should be placed in gear with the switch off, and should then be rocked

to and fro. This will sometimes free the pinion. Afterwards the pinion should be cleaned and lubricated.

A good general test switch the headlights on, and then to go and stand in front of the car and ask a friend to press the starter button. If the lights are very markedly dimmed the fault may almost certainly be attributed to the battery.

6. Dirt is the most common cause of starter failure. The brushes may be sticking in the holders or the commutator may be dirty. The armature coils may be burnt out, or there may be a short-circuit fault in the field coils.

10. Gummy pistons are most often caused by the use of the wrong kind of oil. In cold weather a change of oil to one of the lighter grades recommended by the manufacturers is a precaution which must be taken if gummed-up pistons are to be avoided.

11, 12 and 13. Petrol Failures. In tracing trouble due to petrol failure, and including failure of the mixture to reach the cylinders, the first step is to ensure that the petrol tap is on and that there is no blockage in the pipe line. Should the vacuum feed (if fitted) be at fault the only cure immediately possible to the driver on the road is a smart blow on the external casing of the apparatus. This will often free the valves if one of them is stuck. Further attention to the Autovac must consist in seeing that the gauze filter is clean, and that the air vent hole in the main tank filler cap is not choked. All unions and pipes must also be checked for leakage and the petrol pipes must be cleared by blowing through them.

Occasionally in engines fitted with large choke tubes where the suction on the induction system is unusually low, as when driving for long periods at full throttle, the vacuum tank may dry up. This fault can be overcome simply by closing the throttle for a brief period occasionally. A device known as a 'vacuum booster' may be fitted to overcome this trouble and admit of long periods at full throttle without failure of the fuel supply, but these devices necessitate resetting of the carburation.

If the air vent at the top of the main tank in the vacuum feed apparatus gets blocked up the tank may collapse as a result of the excessive reduction in pressure brought about by the pumping action of the engine.

14. Petrol pumps of the positive type are now the commonest form of supply system. The pump of the A.C. type is worked off the engine camshaft, a diaphragm forming the pumping element. This type of pump should never be dismantled, because a special tool is needed for reassembling it. Failures are extremely rare, but if one does occur a new pump must be fitted and the old sent for repair.

Faults which can be corrected may be briefly mentioned, although most of them are obvious if the trouble has definitely been traced to the pump. First of all, the glass bowl through which the petrol passes to the pumping chamber may be loose. The cork gasket should be examined to see that it seats properly. A dirty filter gauze may be cleaned by removing the glass bowl and cleaning it. The valve plug on top of the pump may have become loose. It can be tightened with a spanner. If there is a leakage of fuel at the diaphragm the screws on the cover must be tightened alternately. It should be remembered that the pump must not be dismantled.

Electrical fuel pumps are used in a large number of modern cars. They are operated from the battery of the car, and are usually connected up with the ignition switch so that no petrol can be pumped when the switch is off. The system is worked by means of an electro-magnet and a bellows. In the Autopulse pump the connexion should be made to the coil terminal of the ignition switch or to the switch wire terminal of the coil. If the pump operates for a long period before the engine is started

(it can be heard working clearly) after switching on, the indication is that there is a leak on either the suction or the delivery side of the pump. If the leak is on the suction side the pump will work rapidly and air bubbles will be seen in the filter glass. The fittings to the tank should be checked over.

If the pump works exceptionally slowly the leak is probably on the delivery side, and the fittings between pump and carburetter need examining. The valves in this pump are directly under the filter base, and may be reached by removing the cap screw on the top of the pump and lifting off the glass. The two brass screws which are then revealed should then be undone and the valves cleaned. In replacing the valves the one on the tank side must be replaced with the flange uppermost and the other with the flange downwards.

In setting the driving screw which regulates the stroke of the pump, a gap of about 0.04 in. should be left between the bottom of the armature and the top of the magnet. No oil of any kind should be permitted in the Autopulse mechanism.

15, 16, 17 and 18. An air lock in the pipe line may cause a very puzzling form of trouble. The trouble may be manifested only at certain times and may be particularly elusive. Much has been done to eliminate air locks by running the fuel pipes smoothly and avoiding sharp bends and curves. In addition, the positive petrol pumps have greatly reduced the chances of trouble of this kind. If an air lock should occur the pipe should be taken down and blown through. If the trouble is persistent the pipe should be examined to see if it passes very close to some hot part of the engine, such as the exhaust manifold or exhaust pipe. The heat from the exhaust system has been known to cause vaporization leading to air or vapour locks in the system.

Water in the carburetter may also cause a trouble which is difficult to diagnose. Intermittent missing and irregular running with occasional popping in the exhaust are the usual symptoms. The engine will suddenly lose power and spit, and then as suddenly regain its power. A very dirty filter will cause a more regular form of faulty running, such as a falling-off in power, difficult starting and perhaps over-heating.

19. Flooding of the carburetter may be caused by a dirty or sticking needle valve or by -a punctured float. The adjustment of the counterweights which determine the movement of the needle valve may be incorrect. Or their pins and holes may be corroded through the use of unsuitable petrol. The pins may be bent. A leaking float can be detected by taking the float out and waving it about, when the petrol inside will be heard splashing about. The petrol should be removed by first placing the float under very hot water and watching for bubbles. These will indicate the position of the puncture. The float should then be turned down until the point from which the bubbles are coming is at the bottom, and held thus until all the petrol has been driven out by the heat of the surrounding hot water. When the float is cold again soldering may be attempted, although it is not advisable, because it is an exceedingly difficult task to solder a float satisfactorily. A new float is the best cure of the trouble.

Motor Car. Fig. 8. Fault-finding chart which, in conjunction with numbered paragraphs in text, will assist in tracing the cause of a defect or breakdown.

ENGINE WILL NOT START	Starter	Engine immovable	1	Battery run down

Motor Car. Fig. 9. Correct setting of gap in contact breaker is of great importance with coil ignition. A feeler gauge is essential.

Motor Car. Three important points in keeping a car free from faults. Right, fig. 10. Holding a high tension lead near the cylinder block in checking ignition system.

Left, fig. 11. Checking for coil breakdown with a 'test gap.'

Fig. 12 (right): all terminals should be kept clean and bright.

20, 21, 22, 23 and 24. Ignition Troubles.

When a fault has definitely been traced to the ignition and it is found that there is no spark at the plugs, the preliminary precautions are to see that the switch is on and that there is no shorting in the switch wire. The simplest method to ensure this is temporarily to detach the switch wire altogether. The contact breaker points will then be examined and the gap checked. In a magneto the rocker arm should be examined to see that it is not sticking. If it is found to be sticking it must be removed and the bearing eased very carefully.

Difficulty in starting when a magneto is fitted may often be traced to a partially burnt-out armature winding. It is a difficult trouble to run to earth, and the best system is the replacement of the magneto by another one for trial purposes.

25. A faulty condenser is usually indicated by signs of burning at the platinum make-and-break points. The condition of the condenser may be checked by applying test leads to the end plates of the condenser for a second or so. On discharge the condenser should give a sharp crackling spark. If the condenser is definitely at fault it must be replaced, for repairs are not practicable except with special equipment. Sometimes magneto magnets lose their magnetism, but this fault is much rarer than is generally supposed.

A good test of the magneto primary winding is made with a piece of thin paper inserted between the contact breaker points. The armature is turned slowly with the paper between the points and then without it. Without it there should be a strong pull; but with the paper between the points there should be scarcely any pull at all. A defective primary winding will be indicated if a weak pull is obtained under both conditions.

26. Plug points have to be in exceedingly bad adjustment if they are to cause real trouble in starting if the rest of the electrical equipment is in perfect order. But if the magneto is weak the smallest mal-adjustment of the plug points will prevent the engine from starting. A sparking plug which fires when tested by laying it on the cylinder block may fail when it is under pressure within the cylinder. Leaky insulation is sometimes extremely difficult to detect. A slight crack in the porcelain may ruin the plug, but be scarcely noticeable by eye. The best way to check plugs is to introduce a complete new set. If after that the engine runs well and the fault is cured, then a plug fault is certain and steps may be taken to try to ascertain which of the old set of plugs is causing the trouble. (*See Fig. 6*).

27, 28, 29, 30, 31, 32 and 33. In coil ignition the main principles of tracing and curing faults remain the same as for magneto ignition, but faults are more readily tracked down with coil ignition. A coil may be checked by removing the high-tension lead and screwing on in its place a piece of copper wire. This should then be bent over so that its end comes within about a quarter of an inch of the base of the coil so as to form a test spark gap. One of the primary leads from the battery to the coil is then quickly touched on to its terminal. If a long silent spark occurs at the test gap the coil may be assumed to be in good condition. If the spark makes a loud crackling sound the indication is that the primary winding is shorting. Erratic running of the engine indicates faulty adjustment of the contact breaker points. These should be set with scrupulous accuracy (*Figs. 9-11*).

The distributor with its brush should be inspected for any defect, and a broken circuit is checked by turning the engine until the contact points close, and noting if the ammeter shows the usual reading. If there is no reading the low-tension cables and connexions should be traced by starting at the battery and following through to coil and contact breaker and then back to the battery or earth. Low-tension connexions have much to do with the satisfactory working of a coil ignition system. All terminals must be clean and bright.

A ballast resistance is included in the primary circuit to prevent damage to the primary circuit winding at low speeds. The resistance prevents excessive current going through the primary circuit. If the ignition is left switched on for a long period the ballast resistance will take up some of the current and help to safeguard the windings; but it may not succeed in doing so entirely, and a damaged ignition coil is likely to result if the ignition switch is left on for a very long period.

Misfiring. The faults indicated by the numbers from **34** to **43** have either already been dealt with or else have self-evident cures. Numbers **44**, **45** and **46** are mechanical faults and their cures are also self-evident. One cause of a sticking valve, however, is not so obvious, and that occurs when the valve-stem gets dry and tends to bind in its guide. A rough and ready cure for this form of binding which sometimes cures the trouble completely is to mix with the petrol a small quantity of lubricating oil. Special oils are sold expressly for this purpose, it being contended by their makers

that the valves run more freely and the upper part of the cylinders gets better lubrication when there is a small admixture of oil in the petrol. However that may be, it is certain that the cure for a sticking valve is sometimes effected by adding oil to the petrol.

Motor Car. Fig. 13. Tappet or valve clearance is measured by a feeler gauge inserted between end of valve stem and head of screw A, which is screwed into or out of tappet C to adjust clearance, and is locked in position by lock-nut B.

55, 56, 57, 58, 59, 60 and 61. When the engine refuses to idle, blockage of the slow running jet may be the cause. Correction of this fault entails the partial dismantling of the carburetter to extract the jet for examination; any foreign matter should then be ejected by forcing it out of the jet orifice with air. Another common cause of poor slow running is the presence of air leaks.

There are numerous classes of air leakage into the induction system which may upset the carburation. Wear may occur between the valve stems and guides, in which case new guides should be fitted. Air leakage may also occur through wear at the throttle bearings. The remedy in this case is to rebush or pack the bearings. All joints of the induction system should be overhauled and bolted up tight. Another source of leakage may be the connexion to the suction-operated windscreen wiper, which, if faulty or broken, may quite upset the slow running and starting.

Other reasons for poor idling are maladjustment of the throttle stop or sticking of the accelerator control. In the former case the screw on the throttle arm should be turned so that the butterfly valve is set more closely; if the accelerator is jamming attention should be turned to the ball-joints on the rods, the pedal anchorage and the return spring.

Excessive clearance between the valves and tappets will cause an engine to cease running below a certain speed, and when checking over for this fault particular attention should be given to all the tappets, a feeler gauge being used (as in Fig. 14). Where any engine has been in service for a long time pitted and burnt valves may be suspected as the probable cause of poor slow running.

When an engine loses power the trouble will probably be due to the fault indicated by the number **62**, and clearance of the main or running jet will immediately effect a cure. On the other hand, progressive loss of power suggests that the engine is heavily carboned up, and removal of the cylinder head, the grinding of the valves and a thorough removal of carbon deposit from the combustion chambers, ports and pistons will be called for. Excessive carbon deposit is most frequently caused by badly worn pistons and cylinders and also by worn piston rings or worn grooves. Through excessive clearance at these points oil is sucked up during the induction stroke and deposited in the combustion chamber and on the piston, and is burnt by the heat generated during the power stroke, thus forming, together with road dust, a hard deposit.

This deposit is liable to become incandescent and ignite the fresh mixture before the end of the compression stroke. When this happens it will be seen that instead of the piston rising on compression, it will be rising against the very high pressure of the prematurely exploded charge. This fault is commonly known as pre-ignition, and can only be cured by a renewal of the worn parts responsible, or by frequently removing the cylinders or cylinder heads and carefully scraping away all signs of carbon deposit. Pre-ignition causes knocking, and reduces the power which can be developed.

Poor compression may be due to various causes; for instance, the pistons and cylinders may be badly worn. Other causes include: a broken piston ring; piston ring slots in line; piston rings loose in their grooves; and a scored cylinder wall, due to the gudgeon pin working out at one end of the

piston. Defective pistons or piston rings must be replaced. If the valves are properly ground in, they will not give any trouble for some considerable time.

The joint between detachable head and cylinder casing should be examined, as the gasket may be defective, or the holding-down bolts not tightened up uniformly. If the cylinders are worn oval or scored, regrinding and filling of the scores will be necessary. Thin, hard steel liners may be forced in after the cylinders have been suitably enlarged in which case it may be possible to utilize the old pistons. A gasket which is defective in any way should not be used. It is advisable always to keep a spare gasket in hand.

Motor Car. Fig. 14. Method of adjusting valve clearances with a feeler gauge. Tappets of an overhead valve system are being adjusted.

A weak valve spring should be replaced by a new one since it will not return the valve to its seating quickly enough when the engine is running at high speeds. It is futile to attempt to stretch it. The only remedy for broken valve springs is a replacement. When a valve is fitted the seating should be re-cut, as the original face angle will probably have been altered during

regrinding. The stem of the valve must move freely, but must not be loose in the guide, and it should be the same length as the old one.

An elusive cause of loss of compression is a stretched valve stem or too little tappet clearance preventing the valve from seating properly when the engine is hot. The engine should be turned until the cam is clear of the tappet, the valve then being seated, and the tappet should be adjusted to give the clearance specified by the makers of the engine. This varies considerably, but for most side valve engines a tappet clearance of $\cdot004$ in. is suitable for the inlet valve and $\cdot005$ in. for the exhaust valve. For overhead valve engines the clearance is slightly greater. A feeler gauge should be used, and the adjustments should be made when the engine is warm. It is safer to have too much than too little clearance.

If the silencer is allowed to become choked with soot the exhaust gases will not be able to escape quickly enough to allow the engine to develop its proper power when running at high speeds. This trouble may never arise if the silencer is of sufficient size and of good design and if carburation is satisfactory.

The air supply to the carburetter must be properly proportioned to the amount of petrol supplied if even running and full power with economy of petrol consumption are to be obtained. Carburetters vary so greatly in construction that it is impossible to give any rules for the adjustment of air and petrol which would be generally applicable. It may be stated, however, as a general rule, in the case of an over-rich mixture, that it is safer to increase the size of the choke than to decrease the size of the jet, while for a weak mixture it is better to increase the size of the jet.

To obtain maximum power at high speed it is advisable to keep the diameter of the choke tube as large as possible, thereby avoiding throttling of the gases. The carburetter should always be kept correctly adjusted for slow running, such adjustment being made when the engine is hot. Instructions for tuning can usually be obtained from the makers.

Overheating of the engine is due to failure of lubrication, shortage of cooling water, choked water pipes or cooling elements, a worn water circulating pump, a slack belt driving the fan or water pump, a choked silencer, imperfect carburation or ignition too far retarded.

Motor Car. Fig. 15. Tracing knocks in power unit with screwdriver. The sounds are thus amplified and their source is easily located.

The oil level in the sump should never be allowed to get low; it is best to replenish it frequently and keep the sump full. If the oil is dirty or contains sludge it must be drained off, the sump flushed out with flushing oil, and refilled; this should, in fact, be done about every 1,500-2,000 miles or according to maker's instructions.

If any of the oil pipes or passages have become choked they must be cleaned even though the engine may have to be partly dismantled. Pumps, whether of the gear wheel, plunger, or rotating vane type, must be replaced or repaired if they do not force oil through properly.

The radiator should always be filled, and replenished with rain or other soft water, thus avoiding any deposit of lime in the system, which would result from the use of hard water; such deposit, unless very hard, can be removed by running the engine for a short time with a strong solution of common soda and water in the cooling system. After this mixture is drained off the system must be well washed out before it is refilled with soft water.

An imperfect mixture results from the carburetter not being properly adjusted, or not of a suitable size for the engine to which it is fitted. Until this is corrected unsatisfactory running at varying engine speeds will be certain to occur.

Since water is heavier than petrol and the two do not mix, the water remains at the bottom of the tank or in the float chamber of the carburetter. With a properly designed tank, water can be present in some quantity without any getting through into the carburetter, since the outlet pipe usually projects slightly above the bottom of the tank. If, however, only a little water passes into the float chamber it may get into the jet orifice and cause irregular running. If sufficient water passes through it will entirely stop the flow of petrol, thereby making it impossible to keep the engine running at all. The tank and the float chamber must be drained completely and thoroughly cleansed.

For protection against water in the carburetter a precaution is to use a chamois leather filter when refilling the tank. With petrol station pumps this precaution is hardly necessary, as the pumps incorporate a filter which will normally be found satisfactory; but if at some wayside garage it becomes necessary to fill the tank from a can the chamois leather filter is of value.

The usual causes of clutch slip are faulty adjustment, insufficient spring pressure or the presence of oil on the friction faces, but the different types of clutch vary greatly. A weak spring or springs where no adjustment is provided should be replaced by new, and this should be obtained from the makers to ensure correct strength. With clutches working in oil, slipping may be due to worn plates, worn or missing cork inserts, or weak springs; or a thorough cleansing and fresh lubricant may be necessary. A little oil on a dry plate clutch is soon burnt off, but continued leakage from the engine into the clutch pit may account for persistent slipping.

Some clutches have an adjustable stop by which the position of the clutch pedal can be determined, so that it is advisable first to make sure that this stop is not preventing the clutch from entering into full engagement. The clutch cannot engage properly if the pedal arm is forced hard up against the under side of the floor board. It should be half an inch clear when the clutch is engaged. Unnecessary wear of the ball thrust bearing will also result from this defect. A slipping clutch, if allowed to cool, and provided the engine is not speeded up unduly, will often hold for a short

period, thus enabling the motorist to reach a garage or his home if only a short distance has to be travelled. The troubles enumerated under **81, 83 and 84**, however, rule out any possibility of proceeding without the car being towed. All the defects indicated by the numbers **85 to 92** demand immediate attention.

98, 99, 100, 102, 103, 104, 105 and 106. The defects indicated under these numbers are due to neglect and, with the exception of those caused by wear of the frictional linings, are easily remedied by cleaning, oiling and adjustment.

Defects in the steering of a vehicle may arise from any one or more of the causes given under the numbers **107 to 119**. Soft tires or tires inflated to different pressures will make the steering stiff and cause a bias or drag towards one side.

Assuming the tires are properly inflated, a persistent drag to one side may be the result of excessive wear in one of the steering head bearings, thus preventing the tire of the road wheel concerned from making contact with the road at the proper point, and upsetting any centre-point steering features which the vehicle may possess. An excessive amount of free play will be due to wear of the worm or other steering mechanism and possibly the joints of the steering transmission. In most cases adjustment is possible. In worm gearing the worm can often be turned to a new position. Should the steering become stiff, attention should be given to lubrication, particularly of the steering heads and the worm, screw, or other operating mechanism.

Lack of proper attention to the lubrication of such parts as the spring shackle pins, the brake control joints, and the leaves of the springs, is a frequent cause of intermittent squeaks and rattles while the car is travelling. Other causes may be loose mudguard stays, slack holding down bolts for the running boards, worn windscreen fittings, perished felt, leather, rubber or other seating strips on which the edges of the bonnet rest.

Binding of the brakes or slipping of the clutch may be responsible for poor acceleration. The hand brake may have been left on. Want of lubrication, apart from increasing the difficulty of applying the brakes, may cause them to remain in engagement after the hand lever or pedal has been released. One or more of the holding-off springs may have broken, leaving the brake shoes in contact with the drum. If the shoes are set too close to the drums the flexing of the springs may cause intermittent contact between shoes and drums.

If the brakes are not used for any part of a run the drums should be cool to the touch. If they are not or even warm there is some continuous or intermittent binding. One way of testing brake adjustment is by feeling whether the drums have heated uniformly at the end of a run when they have had normal use. The operating connexions on an overheated drum should be slacked off, or vice versa.

A fierce clutch which grips suddenly and starts the car with a jerk may cause serious damage to the transmission, and may even twist and ultimately break the axle driving shafts. A possible but not very likely cause is want of alinement, due to wear of the central spigot bearing between rear end of crankshaft and forward end of clutch shaft.

The various types of clutch differ so much from one another that it is difficult to give any generally applicable rules, but mention may be made particularly of the following: In the widely used single-plate clutch in which friction disks made of asbestos fabric reinforced with brass wire are interposed between the metal driving and driven disks, fierceness can be cured by injecting a little thin oil into the clutch. Very little is sufficient to soften the asbestos surfaces slightly, although any excess is soon burnt off.

Clutches employing cork inserts engaging metal plates always run in oil, and fierceness may be due to the oil being too thin or the clutch requiring cleansing or renewal of the oil.

Breakdowns on the Road. Should the engine fail to run or to start, the trouble is probably some comparatively minor derangement of the ignition or the carburation. In the event of a breakdown on the road the cause should be investigated as follows: First make sure that the petrol is turned on and is available at the carburetter jets. Then find out whether there is a spark at the plugs by removing one of the high tension leads from a plug terminal and holding it so that the terminal on the wire is close to but not touching some metal part of the engine. Then get an assistant to turn the engine by the starting handle and watch for a spark to jump across the intervening gap.

Should the spark be present, the question as to whether the gap between the points of the sparking plug is correct should next be investigated and the procedure outlined in the various headings above may then be followed; it is probable that the trouble will be located long before a more serious breakdown need be contemplated.

Fig. 16. Typical chassis lubrication calendar, giving a general indication as to how often the different points should be lubricated if satisfactory performance and long life are to be secured. If the mileage is small the car should receive some attention every week.

MOTOR CYCLES: BUYING AND RUNNING THEM

Facts and Figures as Aids to Economy and Efficiency

The information given in this article is supplemented by that in the entries on the various parts of the machine, e.g. Brake; Carburetter. See also Garage; Gear; Lubrication and the article following on Motoring.

The prospective motor cyclist should refer to the legal portion of the succeeding article on Motoring, where full particulars are given about the necessary preliminaries such as registration, the procuring of a car licence and a driving licence, and insurance.

All types of motor cycle are essentially more economical than cars, and the lighter machines afford the cheapest possible form of travel, for their cost is less than that of a season ticket on the railway.

The chief objection to using a motor cycle for business purposes throughout the year is the exposure of the rider. This is not particularly serious when direct transport from the home to the office or factory is desired; a machine of moderate horse power can be equipped with windscreen and legshields, so that the driver can keep dry and warm in light waterproof overalls. But if the rider's duties involve numerous stoppages he will be bound to make calls in muddied overalls, which is usually objectionable. No elderly person with a weak heart or chest should face the exposure of a motor cycle, or the exertion of using the foot starter; but to the rest of the community, including women, the motor cycle offers the cheapest means of private transport, available either for pleasure or for utility purposes. Serious stoppages are extremely uncommon with a machine of good class, and petty stoppages are soon set right on the road.

It is not possible to generalize about the cost of owning and running a machine, as the market embraces a great variety of types ranging from the motor-assisted bicycle, selling at £15 and weighing no more than 100 lb., up to the 8 h.p. leviathan, capable of 100 miles per hour and catalogued at £150, whilst sidecars and three-wheeled runabouts are obtainable at any figure from £50 upwards.

Motor Cycle. Fig. (Left) B.S.A. 350 c.c. single-cylinder model. Fig. 2 (Right) Norton Type 18 with overhead valve engine of 490 c.c. capacity (Courtesy of 'The Motor Cycle.')

The £15 machine will go anywhere, and costs about 2s. in out-of-pocket expenses for every 100 miles it covers, whilst its annual overhead charges are limited to tax and insurance, possibly £3 in all. The expenses rise in proportion to the cost, weight and power of the machine. Some suggestions on choosing a machine follow.

The £15 Lightweight. These light machines have been introduced as the result of their popularity on the European Continent, where they are sold by the thousand to the artisan class, and employed for travelling to work during the week and for pleasure at weekends. They are taxed in Great Britain at a reduced rate of 12s. per annum. When the machine has been bought, it can be run 5,000 miles for a total outlay of about £8 to £10. It is actually easier to ride than a pedal cycle and far more comfortable, as its extra weight (about 100 lb.) steadies it, and the large tires and saddle insulate the rider from bumps and vibration. It will climb any main road hill, and though its maximum speed does not exceed 35 miles an hour, it will average with ease over 20 miles per hour all day long.

Larger Bicycles. The touring classes include machines from 2½ horse power to 8 horse power, varying in price from £25 to £150. The more powerful a machine is, the more it will cost to run, and the more difficult it will be to handle when its engine is stopped; for example, in wheeling it out of its shed. In this touring class the machine of 350 c.c. (about 2½ h.p.) is the most practical. Smaller engines must be geared rather low to enable the machine to climb steep hills and to maintain a good speed against a head wind.

Motor Cycle. Fig. 3. Constructional features embodied in a well-known British type, Francis-Barnett 'Cruiser,' in which gear-box and crankcase are cowled in, showing also leg shields (Courtesy of 'The Motor Cycle')

But a $2\frac{3}{4}$ horse power engine has ample power for all ordinary purposes, and can be run quietly like a good car. It is the best all-round machine for young and middle-aged people, and is quite suitable for the beginner, being easy to start, inexpensive to maintain, not cumbrous to handle in the garage, and a splendid goer. The more powerful types of 500 c.c. ($3\frac{1}{2}$ h.p.) and upwards, may fairly be compared to the sports cars. They are unnecessarily powerful, and are chiefly bought by the sporting type of rider, who has no objection to weight, and indulges at times in very high speeds. Alternatively, the big-engined bicycle may be used for pulling a sidecar.

Overhauling. One advantage which the motor cycle has over a car is the simplicity with which it can be dismantled for overhaul and periodical adjustment. Routine attention consists of keeping the engine free of excessive carbon deposits, attending to the sparking plug so that the gap is correctly adjusted, cleaning the carburetter and (in four-stroke engines) maintaining the valve tappet clearances at the right setting. At intervals other matters must be attended to. The transmission, particularly the short countershaft chain connecting the engine to the gearbox, must also be attended to from time to time, and the brakes, clutch and engine controls must, in addition, be adjusted in order to take up the wear that develops in all types of machines after long periods of service.

Pillion Riding. Coroners and magistrates often denounce the practice of carrying a passenger on the carrier of a motor cycle. It is by no means so dangerous as might be supposed. The insurance companies frame their premiums in accordance with accurate statistics. If a motor cyclist wishes to carry a pillion passenger, he must pay an extra 50 per cent, on his premium. Obviously two people will be endangered in any accident with a pillion rider aboard, and we should therefore expect the premiums charged to be double that for a solo machine, instead of being, as they are in fact, only 50 per cent, higher.

Undoubtedly the presence of an extra weight of perhaps 10 st. or more at the stern of the machine must affect control to some extent; but the insurance data suggest that the added risk is negligible, and is really limited to the chance of two people being hurt instead of one. On the other hand, it is

obvious that nobody should carry a pillion passenger until he has ridden several thousand miles alone, and has become a tolerably expert driver. It is an offence to take a passenger on anything but a proper seat.

Sidecars. Despite the introduction of the cheap motor car the sidecar retains its popularity. Quite a serviceable sidecar outfit of $2\frac{3}{4}$ - $3\frac{1}{2}$ horse power can be bought complete for about £50, half the cost of the smallest new car. Running costs show a similar ratio, as the tax and insurance, fuel bill and tire bill of the small car will be twice as heavy. It is true that a second-hand small car can be bought for £50, but its maintenance costs will exceed those of a new 8 horse power car, and compare somewhat unfavourably with those of a cheap sidecar. An 8 horse power sidecar is probably slightly more expensive to run than a baby car.

Three-Wheelers. There are a few excellent three wheelers on the market, which on the average cost about the same as a small four-wheeled car both to buy and to run. Having three tracks, they are less comfortable than a baby car on an inferior road; but, as they have plenty of engine power in proportion to their weight, the road performance is extremely vivacious by comparison, and this attraction explains their continued survival.

Specification. As motor cycles are designed by experts who are themselves practical riders, and who can only keep in business by offering the public a machine which is good value for the money, it is unnecessary to discuss specification in detail, with one exception. Some of the cheaper machines have acetylene lamps, or some other inexpensive form of illuminant. There is only one really satisfactory type of lighting, namely, electric lighting from a battery, the battery being charged by a dynamo driven off the engine. Except where, for reasons of sheer economy, every shilling counts, this type of lighting should be specified, as no other system is really efficient and convenient at night.

Purchasing the Machine. The motor cycle should be bought locally, if possible. The agent receives a commission on the sale of a new machine, and is expected to give his customer a certain amount of service, especially if the customer is a beginner. But if a customer residing in Westmorland, for example, buys from a London dealer, he cannot hope for any free service. There is only one exception to this rule of buying locally. If a man is buying his second or third machine he may wish to 'trade off' the old machine in part payment for the new one. If he lives in a remote place, his local dealer may lack facilities for re-selling second hand machines, and may make him a much poorer allowance than a big London dealer will. In such cases it may pay to sacrifice the service facilities in return for a higher exchange allowance.

Learning to Ride. The three requisites are a good handbook, a friend to act as a tutor, and a suitable machine. Excellent handbooks are published by the motor cycling journals and other firms. A local rider will always give the initial instruction on some quiet road, and confidence comes with amazing rapidity, as the machine is so low and steady that from the outset it feels much safer than a pedal cycle. An initial apprenticeship on a pedal cycle is always desirable, as it familiarises the rider with various road emergencies, and gives him a certain amount of road sense. But such an apprenticeship is not essential, and many men and women take up motor cycling without ever having learned to ride a pedal cycle.

The beginner need not be afraid of damaging the machine. It is not in the least likely that he will do it any harm, provided always that he lubricates the engine adequately. If he under-oils it he may wreck the engine in five miles. Therefore he should not attempt to run it until he has had the

lubrication system thoroughly explained, and ever afterwards he should verify his oiling at short intervals until he learns to recognize, from the beat of his engine, whether it is properly oiled or not. The working of a typical simple splash lubrication system is illustrated in Fig. 6. The tool bag will contain a booklet explaining this important matter in detail, and any local rider will demonstrate its action to him.

Fig. 5

Fig. 6

Motor Cycle. Fig. 5. Diagram illustrating operation of the valves of a single-cylinder four-stroke engine.

Before he risks a solitary ride, he should further ask his dealer or a friend to show him how to mend a puncture. In all probability his tires will not puncture for 3,000 miles, but he cannot turn a heavy machine upside down to get at the tire, as he would with a pedal cycle, so a practical demonstration will be of real value.

Before taking to the road the beginner should master the art of stopping the machine. The engine can be stopped in two ways, either by shutting the throttle or lifting the exhaust valve. Two brakes are available for bringing the machine to a stop—a rear brake, operated by a pedal, and a front brake operated by a pull-up lever under the right grip of the handle bar. Some novices are a little apt to become excited in any sudden emergency, and to lose their heads. They should school themselves to shut off the engine and apply the brakes instinctively.

The ordinary traffic signals must be given. These are explained and illustrated in the article on motoring that follows. Very abrupt braking should never be attempted on wet, greasy surfaces, or on loose gravelly roads. Except on firm surfaces the brakes should be applied progressively and firmly, rather than abruptly. Generally speaking, all changes of speed should be executed smoothly, without jerk. High speed should be entirely eschewed except on deserted roads, and the novice should not attempt high speed for at least three months after starting to ride.

Starting the Engine. A lonely novice is apt to experience some trouble in starting engines of 350 c.c. and over; the smaller engines never give any serious trouble in this respect. Such an experience should not discourage the tiro. Even racing engines of 500 c.c. are tolerably easy to start when they are tackled in the right way, and the owner will soon learn how to operate the controls so as to obtain a prompt start. If his difficulties persist, he should ask the dealer or an expert local rider to give him a demonstration, both with the engine cold and with the engine warm.

The first essential is that the engine should be free; it is quite impossible to start a stiff engine easily. For this reason the proper amount of the correct oil should be used, since cold oil, used to excess, gums up a piston rather tightly. If the engine is cold the carburetter should be tickled rather liberally, but this should be omitted when the engine is warm. For the rest the spark should be advanced about two-thirds; note the exact setting whenever a specially easy start is obtained. The throttle should be opened very little. Here, again, it pays to note the exact position when success results.

If there is an air lever, it should be shut with a cold engine, and perhaps opened a shade when the engine is warm. If there is a mixture lever, it should be set at 'rich' with a cold engine, and at 'weak' with a warm engine. The kick starter should be gently felt until it encounters the maximum resistance, from which it should be allowed to return to its topmost position. It may then be eased a fraction of an inch past this position by gently pressing it with the valve lifter raised. The engine should then respond to a strong downward thrust with the foot, the valve lifter being dropped as soon as the kick starter begins to move down.

Trouble on the Road. Nothing is more bewildering to the novice than a complete stoppage of his engine when he has not the faintest conception of the cause. The handbooks referred to above will give him an encyclopedic analysis of the various possibilities, together with much assistance in effecting a diagnosis and in executing a repair. Such a handbook should be carried in the pocket. At the worst, he need not be seriously disturbed, as there is a splendid camaraderie of the road, and before long some more expert rider is likely to come to his assistance.

However, it may set the beginner's mind working in a scientific direction if the key to all diagnosis of motor troubles is briefly summarized here.

A petrol engine must work subject to three conditions, namely: (1) If it is in perfect order mechanically. (2) If a proper spark is occurring at the points of the sparking plug. (3) If the carburetter is delivering the correct charge of gas. In other words, the cause of a stoppage is concerned with the ignition, with the gas charge, or with the engine. If the beginner can clear up this initial problem, he can at once dismiss from his mind two-thirds of the potential troubles and concentrate on tracking down his actual trouble in a very restricted field.

The trained rider looks the machine over swiftly when a stop occurs. He makes sure, perhaps, that petrol is reaching the carburetter by pressing the tickler. He eyes the engine to see if he can spot any broken part, and touches his kick-starter to see if the valve tappets are working normally. (The operation of the valves of a single cylinder side-valve, four-stroke motor cycle, engine is diagrammatically shown in Fig. 5). If all is well so far, he forms a preliminary expectation that the trouble is ignition, and unscrews his sparking plug. Very probably the points are fouled with carbon or bridged with soot or oil; he cleans the plug and goes on his way in a couple of minutes.

Sometimes matters are not so simple as this. Perhaps the plug looks clean and healthy. In this case he may test the spark. This is done by jamming it (with cable still attached) in some nook on the cylinder head, so that only the thick end of the plug touches the machine. He then raises the valve-lifter and kicks the starter. A splendid spark jumps the plug points, so that his trouble is not connected with the ignition. Perhaps 90 per cent of motor cycle stops are due to dirty plugs, and if

the novice carries a spare plug and inserts it under such circumstances, he will surmount most of his early stops. As the spark is perfect the rider has eliminated a third of the field of possible trouble, and he next suspects his carburetter. This embodies one or more very fine holes through which petrol is forced to vaporise it into gas. It is a simple matter for a speck of dirt to seal these spraying holes and in this way to stop the production of gas.

His next step will be to take out the jet, as it is called, hold it up to the light and peep through it. A carburetter booklet in the tool-bag will contain sketches indicating the jet and the manner of dismantling the carburetter. If the jet is stopped up, he blows through it or clears it with a fine wire, and all is well. He must, however, be very careful not to alter the size of the jet by using the wire or a needle roughly. Only in the case of a mechanical breakage will further progress be impossible. This is an extremely rare happening, and is best solved by 'flagging' a passing lorry and getting the driver to transport the machine to the nearest garage. The principles and working of two-stroke and four-stroke engines are dealt with in the article on Internal Combustion Engine; systems of Lubrication are explained under that entry, while there is much information of use to the motor cyclist in the article on Motoring.

MOTORING AND MOTOR LAW

Instructions for Driving, Licensing and Insuring the Car

As a preceding article has dealt with the choice and care of the car, this one deals with the duties and responsibilities of the owner and the driver, especially as affected by the important Road Traffic Acts of 1930 and 1934, and regulations. In the legal section the prospective motorist will find information about the necessary preliminaries such as registration, the procuring of car licence and driving licence, and insurance. *See* Number Plate.

The management of a motor car on the road is perhaps a nervous undertaking for the first 100 miles or so, but afterwards, when the handling of the car has become more or less automatic, there is a danger that the driver may become too confident, too casual, or too daring. It is not possible to teach oneself to drive from books alone, and it is inadvisable to learn to drive on one's own car. The dealer who supplies the new car can usually provide a suitable tutor, and a car. There are also many schools where one may learn the essential mechanics of a car and how to drive it.

The new motorist must pass an official test before being granted a driving licence. He must feel at home in the car and should have reached that stage when the various sequences of operation are more or less automatic before he enters for the test. This is not difficult, although when gear changing the novice may at first be somewhat awkward. To change gear without noise requires a great deal of practice and is a matter of doing the right thing at exactly the right time.

Changing Gear. The speed of the sliding gear wheels on the main or final driving shaft is controlled by the speed of the road wheels. The fixed gears on the lay shaft are always driven by the clutch shaft, their speed corresponding to that of the engine when the clutch is engaged. Therefore, if a silent gear change is to be made, the speeds of the teeth of the two wheels to be engaged must be as nearly as possible the same at the instant the change is made.

Changing up from a low gear to a higher is easier than changing down. With most cars all that is necessary is to de-clutch with the accelerator pedal raised so that the engine speed will decrease. After a second or two the higher gear may be quietly engaged and the clutch may then be re-engaged and the engine accelerated.

Briefly, this procedure is as follows:

1. Accelerate the car up to about 8 miles per hour in first gear.
2. Let the accelerator pedal come right up.
3. Press the clutch pedal right down.
4. Move the gear lever out of the first gear notch.
5. Wait for engine speed to decrease a little.
6. Move gear lever into the second gear notch.
7. Let the clutch pedal in smoothly but quickly.
8. Press down the accelerator pedal.

The same procedure is followed when changing up into higher gears.

The main point to remember when changing down to a lower gear is that the engine speed is higher in relation to the speed of the car when one of the lower ratios is used than when in top gear. In top gear the engine shaft rotates about five times to one of the road wheels, in the middle gear of a three-speed gear box about nine to one, and in the bottom gear, about fourteen to one. When a lower gear is to be engaged, therefore, it is first necessary to increase the engine speed with the gear in neutral.

Motoring. Fig. 1. Gear selecting lever for Wilson gear box.

Below. Fig. 2. Diagrammatic sketch showing arrangement of gear wheels. (1. Improved Gears, Ltd. 2. 'The Autocar')

To change down, by the method known as double clutching, the accelerator pedal should be eased slightly, the clutch pedal pressed down and the gear lever moved into neutral. The engine will

accelerate when free and the clutch should be quickly re-engaged. This raises the speed of the gears on the counter-shaft. The clutch pedal should again be depressed, and the gear lever moved into the desired position when the clutch is once more engaged, and the engine accelerated. If this operation is well practised, slowly at first, and gradually speeding up, the driver of the car will be enabled to carry out this apparently complicated operation in about a second of time at any speed.

This procedure may be summarised as follows:

1. Ease the accelerator pedal slightly.
2. Depress the clutch pedal.
3. Slip the gear lever into neutral.
4. Engage the clutch again to speed up the clutch shaft and countershaft gear wheels.
5. Depress the clutch pedal.
6. Slip the gear lever into the lower gear position.
7. Let the clutch pedal up again, quickly but smoothly.

Motoring. Fig. 3. Skidding. A. How to steer out of a skid. B. How steering the car in the wrong direction will increase skid.

It is possible after some practice to make these changes so rapidly that they may be described as two quick dabs on the clutch pedal made in time with the two movements of the gear lever. Whether the accelerator pedal is kept hard down or is eased slightly depends upon the characteristics of the car. The former is better if it can be managed.

Gear changing difficulties are, however, entirely eliminated in the Wilson pre-selective gear box, in which a small lever, carried on the steering column, as shown in Fig. 1, is set by the fingers before making the change. The gear is not changed until the clutch pedal is depressed and re-engaged.

The gear itself is shown diagrammatically in Fig. 2 with the several epicyclic groups spread out, but actually all four groups are close together. Each group consists of a central sun wheel, an outer toothed ring or annulus, and several planet pinions meshing with both the sun wheel and annulus, the different sets being interconnected as shown. To engage the several lower gears, brakes (not shown in the drawing) are applied to one or more of the outer members as required. The direct speed is obtained by engaging the top gear clutch.

The reader is reminded that the brakes, clutch, and accelerator pedals should not be pressed or released violently. A progressive action is desirable, especially in the case of the accelerator. Further, excessive use of the brakes is not recommended; in fact a good driver rarely uses his brakes, but relies generally upon his engine and supplements its retarding effect by the brakes when descending steep gradients or stopping. An exception to this occurs, however, when the roads are slippery, as mentioned in the section below.

Skidding. Side slipping or skidding with rare exceptions always affects the back wheels, and is due to excessive retardation by the brakes acting on the wheels themselves or on the propeller shaft, or by the engine acting as a brake. The last mentioned is often overlooked, but it is sufficient to start a skid on roads which are only half wet, as when rain has just started or when the surface is drying. It is inadvisable at such times either to apply the hand brake or to use the engine as a brake, since both act on the rear wheels only. Brakes applied to the front wheels alone cannot cause a skid, and

skidding is very improbable with cars having four wheel brakes properly adjusted. Fig. 3 shows, A, how to steer out of a skid, and B, how to steer the car in the wrong direction will increase skid.

The New Car. The following hints will be found of value to the owner of a new car. When taking delivery ask the agent to explain thoroughly the controls and general details of the car, and to go over the important subjects dealt with in the instruction book. The first 500 or 1,000 miles are the most important in the life of a new car, and a limit of 30 miles an hour on top gear during this period will save a considerable amount of expense in the future, while in addition it will improve the ultimate performance of the motor car when it has been 'run in.' Lower limits should be observed on the lower gears in order to avoid excessive engine speed.

An engine should always be given the opportunity of warming up from cold for a few minutes before starting off on the road, to enable the oil to thin down and pass through the bearings and on to the cylinder bores. When the oil-pressure gauge drops back to the normal running point the engine will be warm enough. After the first 500 miles change the oil in the engine sump. The old oil has been subjected to heavy work with tight engine bearings, and will have lost its viscosity and contain impurities. Check the tire pressures at regular intervals. A tire gauge is essential for this purpose.

The new owner should learn how best to start the engine without using the starting motor several times on each occasion. There is a certain position for the throttle, ignition, and strangler controls which will give the quickest start, either by hand or when using the starting motor. Learn to understand the ammeter on the instrument board, and the readings shown when some or all of the lights are used, and when the dynamo switch is in the 'off,' 'charge,' or 'summer charge' and 'winter charge' positions. Remember that coil ignition takes a fair amount of current from the accumulator, and that, if the ignition is left in the 'on' position for some time when the engine is not running, there will be a considerable drain on the accumulator. The accumulator should be inspected every fortnight or less according to mileage, and the level of the acid maintained about $\frac{1}{4}$ in. above the tops of the plates by adding distilled water.

Washing the Car. Some sort of routine in washing a car is essential if time is to be saved. (See Figs. 4-9.) A good strong sponge should be used for the exterior, including wings, but not for the wheels, bumpers, and so forth. The chamois leather which is used for drying off the exterior of the car can be used for cleaning the interior, and this leather should be kept near the driver's seat for occasional cleaning of the windscreen or windows on a long journey. A spot of grease will ruin a chamois leather; and it is well to beware of the grease that exudes from lubrication nipples and spring leaves under the car. The law requires a fire extinguisher or supply of sand to be kept in the garage when petrol is stored there. Any in the tank counts as stored petrol.

Use gentle flow of water and sponge for coachwork; and Fig. 7. Powerful stream of water and stiff brush for undersides of wings. Fig. 8. A long handled mop is helpful for quick wash-down. Fig. 9. Finish off with coachwork polish. (Reproduced by courtesy of The Light Car & Cyclecar)

Motoring Holidays. The cost of motoring holidays varies enormously. On the one hand they can be very expensive, and, on the other hand, the cost can be actually less than that incurred when staying at home. One expense that is often overlooked is that of buying meals away from home, an item which alone can easily exceed the entire cost of keeping the car in commission. It is worth remembering that picnic meals cost little, if any, more than those partaken at home. A tour in which the party puts up at a different hotel every night is the most expensive way of holiday-making with a motor car. To tour from a centre is cheaper. In this case the party stays for some time at an hotel, boarding-house or rooms and explores the neighbourhood in the car. The other extreme is to carry tents for camping. Tents and equipment may be hired at very reasonable charges. It is possible to sleep in some cars. (See Figs. 10, 11 & 12.)

Another form of holiday is a camping tour with a caravan towed by the car. Caravans may be hired at very reasonable rates, and any car over 9 horse-power will be found sufficiently powerful for this purpose. An actual holiday for two persons with a car and an 8 ft. trailer caravan worked out at under £19 for three weeks, or about £3 3s. per head per week.

Motoring. Recognized signals given by police and other traffic controllers. See text. (From the Highway Code, by permission of H.M. Stationery Office)

Traffic Signals. The Highway Code issued by the Ministry of Transport includes a system of standard signals to be used by the police or other official traffic controllers, and also signals which the driver of a car should employ to give notice of his intentions. The police signals are as follow:

- (1) A vehicle approaching the policeman is halted by extending the right arm and hand at full length upwards with the palm of the hand towards the vehicle. Where two vehicles are approaching along different roads, the policeman faces the vehicle to be stopped.
- (2) A vehicle approaching from behind is halted by extending the left arm and hand horizontally, with the back of the hand towards the vehicle.
- (3) Vehicles approaching simultaneously from in front and from behind necessitate the use of both arms as described under (1) and (2). This signal is commonly used at cross roads.
- (4) To bring on a vehicle from his front, the policeman beckons on the driver with the right hand and forearm: he should look towards the driver to show clearly that the signal is intended for him.
- (5) When the policeman is releasing traffic which has been stopped, or is bringing on vehicles from his right, he looks towards the driver and beckons him on with the right arm but without turning his body.
- (6) When bringing on vehicles from his left he looks in that direction, and gives a similar signal to that in (5), but with the left arm.

Motoring. Recognized signals given by driver to indicate his intentions to others. See text. (From the Highway Code, by permission of Controller of H.M. Stationery Office)

The recognized signals to be given by the driver are as follow:

- (7) A warning that a driver is going to slow down or stop or turn to the left is given by extending the right arm and hand horizontally towards the offside of the car with the palm downwards and moving the hand slowly up and down.
- (8) When about to turn to the right, the right arm and hand are extended horizontally straight out from the offside of the vehicle with the palm towards the front.

- (9) An invitation to a following vehicle to overtake on the right is given by extending the right arm and hand downwards and moving them backwards and forwards so as to beckon the vehicle forward.
- (10) The desire to go straight ahead is indicated to the traffic controller by moving the hand and forearm well forward and backward in a vertical plane.
- (11) When desiring to turn to the left the hand and arm are pointed in that direction across the body in a definite manner so that the signal may be readily seen.
- (12) When wishing to turn to the right the arm should be extended horizontally with the palm towards the front, this signal being identical with number (8) above.

Legal Considerations: Buying a Car. A motorist who proposes to sell his present car and buy another one will, as a rule, receive a larger price for his old car if he arranges to get a new car of the same make and 'trades-in' his old car in part exchange. It is always advisable to do business with a dealer who holds an agency for the car to be bought. The terms of the sale of the old car should be put into writing (a letter signed by the purchaser will be sufficient), otherwise the purchaser can legally refuse to take the car. The agreement does not require any stamp. If any accessories fitted on to the car are not to be sold this should be made clear at the time of sale and committed to writing also.

The prices quoted for new cars are usually ex-works, that is, the purchaser will be required to pay the cost of delivery from the manufacturer's works in addition to the price quoted. Most makers give guarantees with their cars and several include free service for some time after delivery. This guarantee and service only apply to parts of the car which the makers have themselves manufactured; but similar guarantees are usually also given by the makers of the accessories.

In the case of second hand cars there is no maker's guarantee, but some dealers themselves guarantee the car for some months. In most cases, however, the purchaser must take the car as he finds it, and so, unless he knows something of its history, he will usually be well advised to spend a few pounds on having the car overhauled by some expert and a report obtained before purchasing. The motoring associations make examinations of this kind for a small fee.

A prospective purchaser should remember that the mere fact that the seller holds a registration book for the car in which his name appears as that of the registered owner does not necessarily mean that he has any right to sell the car. Cars held on the hire purchase system are registered in the name of the hirer and not in the name of the hire purchase company to which the car really belongs. If the hirer sells the car he does so in breach of his contract with the hire purchase company and they will be entitled to retake the car from any purchaser, who will thus lose the car without compensation, although he can recover the money he paid for it from the seller if he can find him.

Registration and Licence. Before the purchaser can drive the car he must see that it is registered and licensed and provide himself with an insurance certificate and driving licence. An insurance certificate or cover note must be produced before a road licence can be obtained. If the car is a new one, the dealer will usually arrange for its licensing and registration, and hand to the purchaser the registration book. If the dealer does not do this, the purchaser must himself obtain the registration book and licence from his local council. In the case of second-hand cars, the purchaser must get the registration book from the seller, insert his own name and address in the book and send it at once to his local council. Any licence in force for the car at the time it is bought will continue in force until the date on which it expires.

A licence may be taken out either for the whole or the remainder of any current year, ending December 31st, or for the whole or the remainder of any of the four quarters of the year ending March 24th, June 30th, September 30th or December 31st. If a licence is required, say, in May until

the end of August, two licences will have to be taken out, one for the remainder of the quarter ending June 30th, and then, at the end of that quarter, another licence for the quarter ending September 30th. If the car is not to be used in September, a rebate will be made if the licence is surrendered before the end of August.

Cost of the Licence. The annual duty on a car used for private purposes is 15s. for every unit of horse power, with a minimum of £4 10s. Goods vehicles are taxed according to unladen weight, the minimum (for vehicles under 12 cwt.) being £10 a year. The duty on motor cycles is 12s. for vehicles not over 150 c.c. capacity, 22s. 6d. for vehicles over that capacity but not exceeding 250 c.c., and £2 5s. for vehicles over that weight. Where a bicycle was first licensed before January 1st, 1933, and does not exceed 224 lb. in weight, the duty is only 22s. 6d. even though it exceeds 250 c.c. The duty on a sidecar is an additional 15s.

The licence may be renewed at any time within the fortnight preceding the date on which it expires. The authorities usually allow also a fortnight after the expiry of a licence for its renewal, but motorists should be careful not to use a vehicle during the period after the licence has elapsed unless they intend to renew the licence, as the police frequently take the registration numbers of vehicles seen on the road during that period and institute proceedings if the licence is not ultimately renewed. The maximum penalty for using a vehicle not properly licensed is a fine of £20 or three times the licence duty, whichever is the greater.

If any alteration is made to the car—e.g. by painting it another colour, or using a vehicle licensed for private use as a commercial vehicle, or if the owner changes his address, the registration book must be sent to the local council with particulars of the alterations. It should be noted that the owner must not himself alter the book, except in the case of change of address.

The Insurance Certificate. The insurance certificate will be obtained from the company with whom the vehicle is insured. Every motorist is now compelled to insure against injuries to third parties, excluding passengers travelling in the car, otherwise than for hire, or servants of the owner. The first step in taking out an insurance policy is the filling up of the proposal form. This form contains a number of questions which the motorist must answer relating to (1) the occupation of the motorist; (2) the nature of the risk to be covered and particulars of the vehicle; (3) the previous driving record of the motorist, including details of any accidents in which he has been involved. It is most important that all these questions should be correctly answered, for an inaccurate answer, even if made innocently and even if quite immaterial to the risk, may enable the insurance company to escape liability under the policy. In addition to answering carefully all questions that he is asked, the motorist must also disclose any fact known to him which would be likely to affect the mind of the insurance company in deciding whether or not they should accept the risk.

When the insurance company receive the proposal form they may not issue a policy at once. There may be some inquiries to be made in consequence of the answers in the proposal form, and until these inquiries have been completed no policy is issued, but a cover note is sent to the motorist. Once this has been issued, the motorist is as fully insured as though he had the policy, but the cover note is only valid for a short time—usually 14 days.

If the policy has not been issued before the expiry of the 14 days the motorist must apply to the insurance company to have the cover note extended. When the company have made all inquiries as to the answers in the proposal form they will either issue a policy or else refuse to accept the risk and return the premium paid, less a proportionate sum for the period during which the motorist has been covered by the cover note.

Penalties for Non-Insurance

It is now a very serious offence to use or to allow anyone else to use a vehicle which is not covered by insurance. The insurance must be against injury to third parties; a motorist is not required to insure against injury to himself or to his non-paying passengers, or against damage to the property of third parties, although every motorist should include these risks in his policy. The penalty for using a vehicle not properly covered is a fine not exceeding £50 or three months' imprisonment, or both. Disqualification from holding a driving licence for at least 12 months will follow automatically, unless there are special reasons why the disqualification should not be imposed.

The insurance certificate or cover note must be produced on demand to any police constable while the vehicle is on the road, and also after an accident involving personal injuries (see below). If the driver is unable to produce the certificate at the time, he may avoid a prosecution by taking the certificate in person within five days to some police station selected by him when asked to produce it.

Driving Licence. Driving licences are issued by the local council. Anyone who drives a motor vehicle without a licence or who employs any unlicensed person to drive is liable to a fine of £20 for the first offence and £50 or six months' imprisonment for later offences. The licence costs five shillings and lasts for twelve months. The licence must be produced to any policeman under penalty of a fine not exceeding five shillings. A motorist will not, however, be fined for failing to produce his licence if he produces it in person within five days at some police station mentioned by him when he is first asked for the licence.

The minimum ages at which persons may drive are sixteen for motor cycles or invalid carriages, seventeen for ordinary motor cars, and twenty-one for heavy motorcars.

Before a licence can be obtained the applicant must make a declaration as to his physical fitness in which he must answer questions relating to various ailments. If he has suffered from epilepsy, any mental disorder, attacks of dizziness or fainting, or if he is unable to read at a distance of 25 yards (with glasses if worn) the number plate of a motor car, he will not be allowed to obtain a licence. If he is suffering from some other disability he may obtain a licence if he passes a special driving test, usually in a vehicle specially constructed for a disabled driver.

Persons not suffering from any disability are also required to pass a driving test unless they held a driving licence before April 1st, 1934. A provisional licence valid for three months may be obtained (cost 5s.). An L sign must be carried, and a qualified driver must always accompany the learner.

The applicant must know the Highway Code and prove he is able to drive the vehicle for which he wishes to obtain a licence. A licence to drive a motor cycle does not entitle the holder to drive a motor car. The fee for a driving test is 5s. Any person who has failed may apply again after one month.

When a driver has been convicted of any motoring offence, particulars of the conviction may be ordered to be endorsed on his driving licence, and these endorsements will be copied on to any new licence. It is a serious offence to apply for a new licence without disclosing the fact that the old one was endorsed.

Disqualifications from driving may be imposed on a conviction for many motoring offences, and in the case of some offences—e.g. driving while under the influence of drink or drugs—must be imposed unless special mitigating circumstances are present. While disqualified, the driver is liable to imprisonment if he drives any motor vehicle. The disqualification may be for any period, varying from a few weeks to life. Where the disqualification is for a longer period than six months, the driver may apply to the court after six months to have the disqualification removed, and if this application is refused, he may repeat it at intervals of not less than three months.

Brakes and Lights. Every motor vehicle must have two independent brakes in good working order. No vehicle must be excessively noisy, either on account of lack of repair of the vehicle or the faulty packing or adjustment of its load. Both owner and driver will be liable to a fine if this regulation is not observed. The driver must be at all times in a position from which he can have full control of the vehicle.

Every motor car must carry two white lights to the front and one red lamp to the rear during the hours of darkness. In 'summer time' this means from one hour after sunset until one hour before sunrise, and during the rest of the year from half an hour after sunset until half an hour before sunrise. Bicycles without sidecars require only one front lamp and a rear lamp. All lamps (except those not over 7 watts and fitted with frosted glass) must be so constructed that the beam of light from them can be deflected downwards or downwards and to the left by some device so as not to dazzle any person standing more than 25 feet away and with his eye level not less than 3 feet 6 in. above the ground level. Every bulb showing a light to the front must have the wattage marked on it. In many towns local regulations permit vehicles to remain in parking places without lights. Information as to local regulations is contained in the Motorist's Pocket-book, which may be obtained from the local registration authority. All windscreens must be of safety glass.

Speed Limit. Every motor vehicle is limited to a speed of 30 m.p.h. in a built-up area. Certain vehicles have to observe a speed limit even though not in a built-up area, e.g. a motor car drawing a two-wheeled trailer, all the tires being pneumatic. Buses and coaches are limited to 30 m.p.h., and lorries over 2½ tons to 20 m.p.h. Every motor car and motor cycle (except a motor cycle with an engine not over 100 c.c.), if it was registered for the first time on or after October 1st, 1937, must carry some form of speedometer. The penalty for exceeding the speed limit is a fine of not exceeding £20 for the first offence and £50 for later offences.

Driving Offences. Dangerous driving is a serious offence, and it is also an offence to drive without due care and attention, or without reasonable consideration for other persons using the road, under the Road Traffic Act, 1930. Anyone who drives a motor vehicle while under the influence of drink or drugs is liable to a fine not exceeding £50 or imprisonment for not more than four months, and to more severe penalties for later convictions. Pillion riding otherwise than astride on a properly secured seat is illegal. Drivers must strictly obey all police signals, and stop when requested to do so by a police officer, under penalty of a fine of £5. It is an offence to leave a vehicle standing in a dangerous position, whether in the town or country, and also an offence to obstruct traffic. No motor vehicle must be driven on to any land that is not part of a road, or on to any common land. A vehicle may, however, be parked on any land (not common land or private property) within 15 yards of a road.

Motorists entering strange towns should proceed carefully until they have familiarised themselves with any local by-laws relating to the passing of tramcars and similar matters. The useful Motorists' Pocket Book, already referred to, contains a list of these local regulations, and may be obtained from most local councils. In many towns in Scotland it is an offence to pass a tramcar on the near side while passengers are boarding or alighting. Although such regulations are not found in England, the same effect may be produced by a prosecution for dangerous or careless driving.

Accidents. When a vehicle is concerned in any accident causing injury or damage to any person, vehicle or animal (including sheep or dogs but not poultry) the driver must stop and, if required, must give his name and address and produce his insurance certificate. If for any reason he does not do this, he must report the accident and produce his certificate at a police station, or to a police officer, as soon as possible, and in any event within 24 hours of the accident.

A driver concerned in an accident should be careful not to make any admissions as to his liability, for if he does so his insurance company may repudiate liability. He should get the name and address of the person injured, or the driver of the other vehicle, and also the names and addresses of any witnesses. He should also find out if he can whether the witnesses think he is to blame for the accident.

The points of importance to be considered are (1) the side of the road on which he was driving at the time of the accident; (2) the speed at which he was travelling; (3) the exact width of the road and the state of its surface, etc.; (4) the place on the road at which the collision took place, measured exactly from the kerb or other mark; (5) the position measured in the same way of the vehicles after the accident; (6) the movements of the other party immediately before the accident, including such matters as speed, signals, etc. No attempt should be made to deal with any claim. The accident should be notified to the insurance company and the whole matter left in their hands.

A motorist is liable for all damage to property or injury to persons caused by his negligent driving. It is impossible to say generally what constitutes negligent driving. It may not be negligent to drive at 60 miles per hour on a clear straight road, whereas it may be grossly negligent to drive at 10 miles per hour in a crowded street on a wet night. Each case must be decided on its own facts. It may be said that anyone who departs from the ordinary rules of good driving will probably be held liable for any accident that may result.

Where both persons concerned have been negligent, neither will be able to recover damages against the other. This will not affect persons who are passengers in a vehicle which has been negligently driven. Thus, if Jones and Smith both drive negligently and collide, neither can recover against the other, but any passenger in either vehicle can recover against either Jones or Smith or both. Persons who give lifts to strangers in the country would do well to bear this in mind. Insurance against injuries to passengers (not carried for gain) is not compulsory and drivers who wish to be covered against this risk should see that it is included in their policy.

When anyone is killed as the result of an accident the driver of any vehicle concerned will be required to give evidence at the inquest and the coroner's jury may bring in a verdict of manslaughter against the driver. In such a case the driver will later be tried for this serious crime, but before he can be convicted it must be proved that he has been guilty of gross negligence, something more than the negligence necessary to make him liable in a civil action for damages and amounting to a reckless disregard for human life.

MOTTLED SOAP. The name is given to a variety of soap containing coloured markings similar to the veins in marble. The mottled soap was formerly made from kitchen refuse, and the marbling was produced naturally from impurities in the fats or alkalis employed in the boiling.

The red mottled soap known as Castile soap owes its colour to the addition of green copperas, and being made with olive oil or similar oil produces a pure soap. *See Soap.*

MOULD: On Meat. Meat which is kept too long is acted upon by certain bacteria which cause it to become unfit for food. With the increased use of small household cold storage safes, various kinds of moulds will be seen upon meat, especially raw meat awaiting cooking. While harmful bacteria develop very slowly under cold storage conditions, moulds of fungous origin are frequently seen on the surface of the meat. Unlike bacteria, these moulds do not give rise to substances which are poisonous to human beings, and therefore do not render the meat unfit for food. In most cases the moulds are superficial and can be wiped off with a cloth. Black spot mould is the worst kind and penetrates most, but even this can be cut away with a very thin layer of meat, and the joint cooked with safety.

A common mould is the white one, the product of a moist atmosphere in the cold safe. In appearance it is very similar to that often seen upon cheese.

The most favourable condition for the growths of moulds is a humid atmosphere in safes or pantries at about freezing temperatures. With care mould growths can be avoided; they are unsightly even if harmless.

MOULD: The Disease. The term mould is applied to a fungoid disease attacking plants in garden and greenhouse. For practical purposes it is synonymous with mildew (q.v.).

MOULD: In Gardening. Mould or loam in gardening is the top spit of earth which has been acted upon by atmospheric influences; it forms the base of potting composts. Commonly the term is used to express soil suitable for potting purposes, such as that obtained from old turves stacked and limed until they are well matured. *See* Compost; Potting; Soil.

MOULD: In Cookery. This is a shape made of tin, aluminium, china, glass, pewter, or enamel, into which jellies, blancmange, cake and pudding mixtures, etc., are poured. These moulds vary greatly in size and design.

Where kitchen equipment is limited and only two moulds are provided, it is a good plan to choose one rather plain oval shape and one border mould. Both sweet and savoury jellies can be moulded in the former and the latter can be used for fish or poultry or meat mousse or galantine dishes, the centre, when turned out, being filled with a salad covered with mayonnaise sauce. The border mould is also useful for shaping home-made sponge cakes.

Ordinary pudding basins can be used as moulds should there be a shortage of the latter. When greasing fancy moulds it is necessary to go into every part of the design. Pure olive oil is more satisfactory to use than butter for this purpose. *See* Butter; Cheese; Ice; Jelly.

MOULDING. A moulding is a strip of wood or other material worked to an ornamental pattern on one or more of its faces. In architecture, mouldings may be worked in stone or brickwork, or other material of which the building is made, to relieve the surface and act as an adornment. They are generally found in the form of curved section strings at the bases and jambs, and are used round openings for doors and windows. The householder is mostly concerned with mouldings for the embellishment of the interior of the house. Patterns are obtainable from timber merchants. Figs. 1-34 illustrate a number of useful mouldings which the amateur can procure from any good dealer in woodwork hobbies materials.

In the first row are beads, astragals and panel mouldings; Nos. 10, 11, 12 are rebated panel mouldings; 16, 17, 18 are for lid or plinth; 19 is a grooved drawer bottom moulding. In the fourth row are grooved corner moulding, edge moulding (23), glue blocking (24, 25), and a door closing moulding (28). Bottom row shows tray moulding (29, 30), solid cornice (31), door frame moulding (32), and cornice (33). Nos. 13, 14, 20, 26, 27, 31 and 34 are in oak, 16, 17, 18 in hazel walnut, and the rest in suitable hardwood.

Cabinet mouldings are made in a variety of patterns and in many different sizes for the decoration of furniture. Picture mouldings are in a class by themselves, and are dealt with in the article on picture framing. *See* Capping; Ceiling; Chest; Corner Dresser; Cupboard; Doll's House; Door; Grandfather Clock; Picture Framing; Wardrobe, etc.

Moulding. Figs. 1-34. Stock patterns which the home worker can procure from a timber merchant. The principal types are described in the text.

MOULTING: Of Birds. Moulting is the process by which every year birds renew their plumage, shedding their old feathers and growing new ones. As far as the ordinary householder is concerned its interest is confined to the fowls, ducks, pigeons, parrots, or other kinds he happens to keep.

Although not a disease, moulting is a certain strain on the constitution of the bird, and care should therefore be taken that it is in good condition when the season for it begins. Precautions should be taken against damp, but as a rule very little change of diet is desirable, although this does good with some kinds of birds—pigeons, for instance.

Fowls. In the case of the domestic fowl the process of putting on new plumage, starts in July and goes on until September, some birds moulting early and others late. Poultry keepers should endeavour to get their fowls to moult early, so that, the birds may recover and get their new plumage before the cold weather sets in, and much can be done by judicious management. As a rule young hens moult far more easily than old ones, the average time occupied by the former being from 6 to 8 weeks. An old hen will sometimes take 3, 4, and even 5 months. Generally speaking, the average time is about 3 months.

The easiest way to accelerate the moult is to curtail the food supply of the birds, feeding sparingly for about two weeks and then giving them plenty of food of a nitrogenous character. Extra feeding should not begin until the fowls are actually in moult, that is to say, when the new feathers are growing. Feathering will be greatly assisted by giving each fowl a pinch of sulphur in its soft food every day. A little sunflower seed or hemp seed with the evening grain food is helpful.

Warm weather is more conducive to a rapid moult than when it is cold and wet, and care should be taken throughout to keep the birds warm. While the moulting season is on, the run will be littered with feathers, and these should be cleared away daily.

Pigeons and Canaries. With pigeons moulting usually begins in April, and attention should be paid to the diet and general conditions. In particular the bird should be kept warm and protected from draughts, as a chill may have the effect of stopping the moult and will affect the health of the bird. It is well during moulting to feed a pigeon on bread soaked in water to which a little salt has been added.

Canaries require special care when they are moulting. They should be kept in an even temperature, and for this reason the cage should be hung in a fairly warm room during winter, and well covered up at night. The bath need not be altered in any way, but it is often beneficial to add to the water some iron in the form of citrate. *See* Canary; Parrot; Pigeon; Poultry.

MOUNTAIN ASH. A summer-leaving tree, with ornamental foliage, flowers and berries, the mountain ash (*Pyrus aucuparia*) is particularly suited for culture in suburban gardens, as it will flourish in a smoky atmosphere. Its usual height in and about London is from 15 ft. to 20 ft. It may be increased by seed. The white flowers are borne in May and June, and are followed in the autumn by deep orange or scarlet berries.

MOUNTAIN AVENS. A family of hardy evergreen trailing rock garden plants, of which the species *Dryas octopetala*, a native plant of great beauty, is found on the mountains of various parts of the United Kingdom. The flowers have eight petals, are about 1 in. in diameter, and are white, with conspicuous yellow stems. *Dryas Drummondii* has yellow flowers; both bloom in summer.

Propagation is by division in spring, or by seeds sown in the spring when available. They flourish in a moist, peaty soil, and should be planted in autumn or spring.

Mountain Avens. Delicate dowers of an evergreen trailing plant resembling those of the anemone

MOUNTAIN BLADDER FERN. The common name of *Cystopteris*, a genus of beautiful hardy ferns which flourish in a compost of loam, leaf-mould, sand and mortar rubble in a shady part of the rock garden. *Fragilis* and *montana* are two favourite sorts of the fern.

MOUNTAIN BUCKLER FERN. This is a species of *Nephrodium*, a genus of easily cultivated and strong-growing ferns which embraces the common male fern. It is useful for odd shady corners or exposed portions of a fernery where choicer kinds would fail. Ordinary soil with which leaf-mould has been mixed is suitable. *See* Fern; Garden.

Mountain Buckler Fern. An easily cultivated fern which grows to a height between one and two feet. It is useful for odd corners where a more delicate variety would fail.

MOUNTAIN CLEMATIS. This is a beautiful climbing plant (*Clematis montana*) bearing white flowers in May; it grows very quickly and is ideal for trellises and pergolas, as well as for covering porches and the fronts of houses. *Clematis montana rubens* has rose-red flowers. *See* Clematis.

MOUNTAIN SPINACH. The mountain spinach, or *Atriplex hortensis*, is raised from seed like the ordinary spinach. The leaves are cut, cooked, and eaten as spinach. A red-leaved variety is sometimes grown in the flower garden for the sake of its colour in summer. *See* Garden; Spinach.

MOUNTING: Of Pictures. Photographs and pictures are usually improved by careful mounting, the mount consisting of a sheet or frame of paper or cardboard, of white or that colour which most-heightens the effect of the picture. It may vary in size from one very little larger than the picture to one several times its size. Occasionally, when used simply for stiffening, it is of the same size. Photographs, prints, etchings, pencil and black-and-white drawings, etc., and also small lightly-tinted water-colours look well when fixed before a solid mount. Mounts of larger and heavier pictures should be in the form of frames of cardboard with bevelled edges. Such mounts are not infrequently a part of the frame, in which case they may slope slightly back from frame to picture. By means of a mount an oval, round, or oblong picture can be inserted in a square frame. Oil pictures rarely require mounts.

The size, shape, and colour of the mount depend entirely upon the picture, and can only be decided by individual judgement. The picture need not necessarily be placed in the centre of the mount; it may be nearer the top than the bottom, though not vice versa. It is well to note, also, that a bold or darkly-coloured picture will be enhanced by a dark or dull-coloured mount, while a picture in pencil or delicately tinted will be killed by a dark one. The mount should never be bright in colour.

Cutting the Mounts. Mount-cutting is simple work, and requires but a few tools. Although a penknife may be used, the best results are obtained with a mount-cutter's knife, as illustrated in Fig. 1. In addition a steel straight edge with one edge bevelled, a 2 ft. rule, a pair of compasses with a pencil point, and a tee square, are necessary. First cut the mount to fit the frame, and then mark the amount of opening required. There are two methods of doing this; either rule the lines very faintly on the mount or place the picture in position on top of the mount, and then prick the corners carefully with a pin.

To cut out a square or rectangular mount as shown somewhat exaggerated in Fig. 2, place the straight edge a little way from the line or points, grasp the handle of the knife firmly in the right hand, and with the left pressing on the straight edge make a complete slanting cut along the line as in Fig 3. Repeat this on the three sides, and if necessary ease the corners so that they come away

clean. The picture is fastened to the back with a little fish glue smeared on the extreme edge, or it may be secured by pasting narrow strips on the back of the picture and mount. It is essential to the appearance of a cut-out mount that the mitre cut at the corners should be clean. The long cuts should be made in one stroke, and this is not difficult with thin mounts, but in cutting thick cardboard the knife must be very sharp, and it must go through the materials, as two attempts will spoil the effect. The cutting of round and elliptical openings must be done freehand. It is not possible to have a stock of shapes to suit all openings, but with practice in straight cutting without a straight edge it will not be found difficult to round corners and follow curves. Mounting boards, which are obtained from dealers in artist's materials, are supplied in thicknesses known as 4, 6, 8, 10, and 12 sheet, and in sizes from quarter royal, 11½ in. by 9¼ in., to antiquarian, 53 in. by 35 in. Gilt mounts are often used for water colours, and although the cut edges will be white, they can be gilded by using gold leaf. Brush the back of the leaf with gold size, both being obtainable from an artist's colourman, and when dry cut into strips a little wider than the bevelled cut. Moisten the size with a camel-hair brush dipped in water, and place the strips on the bevel with the top edge true with the surface. Press gently with a soft rag, and when all the edges are covered turn the mount over and press the projecting edges of the leaf on the back and give a final rub with the rag. *See Passe Partout; Picture Framing.*

Mounting. Fig. 1. Knife for cutting a mount.

Fig. 2. Mount cut, showing bevelled edge of opening.

Fig. 3. Diagram showing angle at which knife is held.

MOUNTING: Of Photographs. When an adhesive is to be applied to the whole of the back of a print, for mounting it on a card or heavy paper, it should contain a minimum of moisture, and be used very sparingly to avoid cockling of print or mount. The best adhesive for this purpose is that sold as photo mountant, of which dextrine is the principal component.

A similar paste mountant can quite easily be made at home as follows: Mix ½ lb. of the best white dextrine (the best quality only should be used) with cold water to make a smooth creamy paste, taking small quantities of dextrine with a very little water and adding further dextrine and water as required. When the paste is thoroughly mixed, stir in 20 or 30 drops of oil of cloves or cinnamon and 5 oz. of water.

Boil in a clean saucepan until clear. Set it aside in a straight-mouthed jar, such as the white jars used for holding marmalade, to cool, and keep it covered. These mountants are very economical in use,

and a small quantity on the tip of the finger or brush need only be used, rubbing it well into the back of the print. Other mountants are made of paste and arrowroot. To mount a photograph or print it should first be made properly flat and be trimmed square, Non-photographic prints are sometimes best flattened by damping slightly on the back; but care should be taken to see that the print is not damaged, and in the case of old and valuable prints it is better to avoid damping.

If the mount of a photograph is to show when framed it should be chosen to harmonize, rather than to contrast, with the colour of the photograph. Probably the best mount is a good white card or stiff paper. Only good quality card or paper should be used, as the cheaper kinds are not really white and have a tendency to yellow within a comparatively short time.

If photographs or prints are not to be mounted close up, i.e. the mount is to show, the print should be arranged so that it is exactly central on the mount but with more margin below it than above. If the margin is equal top and bottom as well as both sides it will give the appearance of being mounted too low. The best rule is to have the margins at top and sides equal, and the bottom margin half as deep again. The place to be occupied by the print on the mount should be measured out and marked at each corner with pencil dots. A little mounting paste is then rubbed into the surface of the mount and the whole of the back of the print is treated with mountant.

The print is placed immediately in position on the mount and pressure applied by rubbing all over with a clean rag or handkerchief. A roller squeegee may be used instead if clean paper is interposed between the photograph and the roller. As soon as it is seen that the print adheres all over, it is put away under pressure.

For photographs or prints that are to be mounted in portfolios or albums, or framed up by passe-partout method, it is sufficient to mount them by the corners or edges with gum or seccotine.

The most effective and permanent method of mounting photographs and prints, and one in which there is no risk of damaging the print, is that described in the article Dry Mounting. In any mountant that is used, particularly in the case of photographs, it is essential that no acid should be present, since this will almost certainly cause stains and spots to appear on the face of the print after a little while. *See Dry Mounting; Passe Partout; Paste; Photography; Picture Framing.*

MOURNING. The conventions governing the wearing of mourning have been greatly relaxed, and the mourners themselves usually decide how long they will wear black, and to what extent it shall be unrelieved. Heavy crape is now seldom worn, but no hard and fast rule can be laid down in these matters. Purple in all its shades, black and white mixtures, and greys are considered as half mourning. For a very near relation, i.e. for a parent, it is usual to wear mourning for a year, and it is quite permissible to wear white collars, furs or scarves to relieve the black. Mourning is worn at a funeral by persons attending as a mark of respect, even if they are not closely related.

Mourning for men is simpler than for women. It is usually considered sufficient if a man wears a black tie and a black band on his left arm. At a funeral the ordinary black morning coat with dark striped trousers is the correct wear. *See Crape; Funeral.*

Mouse. *See Mice.*

Mouse-ear Chickweed. White flowers and silvery leaves of a plant suitable for edging.

MOUSE-EAR CHICKWEED. This rampant perennial

creeping plant is suitable for rockeries or edgings to borders. It should be planted in autumn or spring. The flowers are white and the leaves silvery green. *Cerastium tomentosum* and *C. Biebersteinii* are the chief kinds. They spread very quickly and are easily propagated by detaching rooted pieces.

MOUSSE: How to Make. Literally mousse means something of a light, mossy texture. In cookery it is either a very delicate steamed pudding, a meat dish made with cream and gelatine, or a kind of ice pudding, packed into a mould or case and immersed in ice or placed in an ice cave without the contents having been frozen in a cylinder or freezer. The mousse is sometimes served in pyramidal form, but more often turned out of a plain mould whole, when made as an ice pudding; but it is the texture which is most important, and this should always be spongy.

To make the steamed mousse, cream together 4 oz. butter with four tablespoonfuls pounded lump sugar, add the yolks of 8 eggs and vanilla or some delicate flavouring. Whisk over hot water until the custard thickens, then fold in the whites of the eggs, beaten to a stiff froth. Turn the whole into a plain soufflé mould, prepared by being greased with olive oil and lightly floured, and steam it in the oven for 35 min. To steam it, place the mould into a pan three-parts filled with boiling water. The mould and the pan must be covered. Serve the mousse with a custard sauce.

To make an iced mousse, beat up over hot water $\frac{1}{2}$ pint syrup with 6 yolks and 1 whole egg until the mixture is thick enough to coat a spoon; it should resemble a sponge. Remove it from the heat and continue beating until it is cold. Add any flavouring desired, sugar, a wineglassful of liqueur, and $\frac{1}{2}$ pint whipped cream. Turn it into the mould, and plunge into ice and salt, making sure that no ice can penetrate it. As the mixture is very light, it requires careful handling when being turned out.

Chicken and ham mousse is a favourite buffet dish for parties. The ingredients required are 4 breakfast cups cold chicken and ham, $\frac{1}{2}$ pint chicken stock, $\frac{3}{4}$ oz. gelatine, 1 gill cream, and seasoning. The meat is finely minced and pounded in a mortar or rubbed through a sieve. Dissolve the gelatine in a little stock and add it with the rest of the stock to the meat. Season with pepper, salt and a squeeze of lemon juice. Whip the cream stiffly and fold into the mixture. Put in a mould to set. Garnish with chopped parsley and serve with salad. *See* Chicken; Ice; Mould.

MOUSSELINE. The usual French form of the English word muslin is applied especially to mousselines de soie, or silk muslins, which are thin, light, and usually coloured silks. Mousseline de laine, or wool muslin, is also known as delaine.

MOUTHWASH. The following are useful mixtures for cleansing the mouth and preserving the teeth. A teaspoonful of the first is diluted in half tumbler of water:

Thymol	1 part	Rectified spirit	300 parts
Benzole acid	10 parts	Carbolic acid	15 minims
Oil of eucalyptus	10 „	Bicarbonate of soda	2 drams
Oil of peppermint	2 „	Glycerin	1 oz. And Rose water to make 8 oz.

A third mouth wash is composed of compound solution of thymol R.P.C. mixed with 3 or 4 parts of water. *See* Teeth.

MUCOUS MEMBRANE. The membrane which lines the mouth, nose, respiratory passages, gullet, stomach, intestine, etc., is called a mucous membrane, and it always secretes mucus, a viscid and tenacious fluid. Its structure varies greatly in different parts. A cold in the head is inflammation of the mucous membrane of the nose chambers caused by microbes.

MUFFIN: How to Bake. A kind of light yeast dough is made up into flat cakes, called muffins, and baked on a muffin plate or griddle. Sift into a basin 1½ lb. fine flour, adding 1 teaspoonful salt. Cream 1 oz. dried yeast with ½ oz. castor sugar until it liquefies, then mix in very smoothly 1 pint warm milk. Make a well in the centre of the flour, pour in the liquid, and work in sufficient flour to make a batter. Cover the basin with a clean thick cloth and stand it to rise in a warm place.

Rub 1 oz. butter in 2 oz. flour till quite fine, then beat in by degrees ¼ pint warm milk; stir this into the risen batter and beat all together well; ½ hour is not too long. Now add sufficient flour to make a soft dough—very little may be required. Set it to rise again until it is very light and spongy. Make it up into round flat cakes, and bake them on a griddle greased lightly with mutton fat, turning each cake over as it begins to colour. A little extra flour may be needed when making the muffins in order to mould them.

Muffin. Plate of the favourite tea cakes ready for toasting, splitting and buttering.

Muffins should be toasted gradually or they are inclined to become heavy. Warm the muffin and nearly part it before beginning to toast it. Then toast each outer side, pull them apart, butter the inside of each half, set one on the top of the other, and keep very hot while dealing in like manner with the remainder. Muffins must not be cut with a knife, but should be pulled with the fingers. A proper bright bakestone is made for baking muffins, but a thick griddle makes a good substitute.

MUFFINEER. This word is used for a pepper castor greatly valued by collectors. They were first made in England about 1700, the early ones being shaped in the form of a cylinder with a domed or curved top, and with a lid that can be taken off. A little later the more graceful, vase-shaped article was introduced into the country. Muffineers are found both in silver and Sheffield plate and in a great variety of shapes. Some are plain, but others are decorated, piercing being a form of ornamentation used on them. Some are part of a set that includes salt cellars and a mustard pot, and a few have glass liners inside. The perforations for the pepper are often artistically done.

Small muffineers are sometimes filled with salt and placed on the afternoon tea table. They thus serve the purpose of seasoning muffins or crumpets. *See. Pepper Pot; Sifter; Silver.*

Muffineer. Four beautiful examples in silver of old-fashioned pepper pots. All belong to the Georgian period, dating from 1716 to 1792. (Courtesy of Chapple & Mantell)

MUFFLE. In a particular type of furnace the heat from the fire is made to pass around an inner or oven-like member. This is termed a muffle furnace, and a small one may be used by the home worker. The muffle furnace is employed in the enamelling of jewelry, and also in the heating of tools for hardening. *See Enamelling; Furnace.*

MUFFLED GLASS. This term is used for a particular type of glass, the characteristics of which are similar to sheet glass. It is blown into cylinders in a similar fashion, but is distinguished by a surface ripple, which is more marked on one side of the sheet than on the other, and varies considerably. It possesses considerable brilliance, and is sometimes used for leaded light work. Muffled glass takes its name from the fact that the cylinders in which it is made are generally known as muffs.

MUFFLER: How to Knit. This article, strictly speaking, is a square of silk or other material measuring about 30 or 40 in., used for tying round the neck. The word is, however, chiefly used for a scarf worn as a protection against the cold and may be woven or knitted of silk or wool.

A knitted muffler is very simple to make, and can be easily adapted to college or club colours, or striped with two other shades or colours. The amounts of wool used are given below, so that the corresponding quantities can be obtained in any colours desired.

For a muffler measuring 41 in. long by 9 in. wide the following quantities of 4 ply Beehive Scotch fingering will be required: 4 oz. in the main colour, 1 oz. for wide dark stripes, and $\frac{1}{2}$ oz. of a lighter shade for the narrow stripes. Use No. 9 bone knitting needles for a fairly close stitch at a tension of 7 stitches to the inch in width. The pattern is moss stitch, which is compact and very suitable. It consists of knit one stitch and purl one stitch alternately to the end of the row, then as an even number of stitches is cast on, the second row will begin with purl 1, then knit 1, and repeat alternately to the end of the row. For this width cast on 70 stitches and proceed in the moss stitch, changing the colours as follows: Work 3 in. in the main colour, then $\frac{1}{2}$ in. in the light, 2 in. in dark, $\frac{1}{2}$ in. in light. Now work 30 in. in the main colour, and work off the following end in colours to correspond with the first end of the muffler. Always change the colours on the same side of the knitting, and when changing to the new colour cut off the old, leaving a few inches hanging, and knit it in with the new, doing one stitch with the first colour and the next stitch with the second colour alternately until the old end is knitted in. At the end cast off fairly loosely so that one end is not contracted any more than the cast-on edge. *See Knitting; Scarf.*

MUG. The mug is an old form of drinking vessel, still used by children and in public-houses. It is really a small edition of the tankard. Mugs are mostly made of the cheaper kinds of earthenware for children, with the exception of silver christening mugs. They are also made of silver and Sheffield plate. The silver mugs sought by collectors sometimes date back as far as the late 17th century. *See Pewter; Silver; Tankard.*

Mug. Silver mug, barrel-shaped, with engraved lines, 1795. (Courtesy of Chapple & Mantell)

MULBERRY. The mulberry tree is valuable, for its appearance, its flowers and its fruit. The black mulberry, *Morus nigra*, may be grown anywhere in light, deep loam. It should be planted in autumn. In addition, the white mulberry and the red mulberry are well known. All these have heart-shaped leaves with toothed edges, and inconspicuous, greenish-white unisexual flowers, produced in spikes and wind-fertilized. The tree takes some time to establish itself and is slow growing.

The method of propagation is by cuttings, or even by pieces of the branches broken off and stuck in deep, moist soil in the autumn, or seeds may be sown in sandy soil in the greenhouse in spring.

The leaves of the mulberry are the best food for silkworms. For this purpose the white mulberry is particularly grown in China and elsewhere. To feed home-grown silkworms, however, the leaves of the excellent fruit-producing black mulberry will be found equally efficacious.

The fruit, which resembles that of a large raspberry or blackberry in appearance, should not be gathered until it is ready to drop. As a matter of fact, it usually drops unexpectedly before it is gathered, and therefore the mulberry should always be planted as a lawn tree; where this is done the fruit can then drop uninjured into the grass.

Mulberry. Rich fruit somewhat resembling that of the raspberry or blackberry, excellent for dessert.

How to Cook. Mulberries may be eaten as dessert, preserved by bottling, made into wine or jam or a flavouring syrup, and also included in fruit compôtes, salads, and ices. They can be cooked in the same way as raspberries, and are particularly good when stewed in syrup and served with custard or cream, or made into pies and tarts.

Mulberry Cream. This is prepared by stalking 1 pint mulberries, putting them into a pan with $\frac{1}{4}$ lb. sugar and the juice of a lemon, and cooking them gently until they are tender. When cold, put the fruit into a glass dish and pile on top of it $\frac{1}{2}$ pint cream and the whites of two eggs whipped separately, then stirred lightly together, sweetened to taste, and flavoured with vanilla. A cheaper dish can be made by covering the fruit with custard and just before serving adding a meringue of whites of eggs and castor sugar. (*See Meringue.*)

Mulberry Jam. To make mulberry jam put 2 lb. stalked and rather unripe mulberries into an enamel pan with $\frac{1}{2}$ pint water, stew them gently until they are soft and then add $1\frac{1}{2}$ lb. preserving sugar and the grated rind and strained juice of a lemon. Bring all these to the boil over a low fire, stirring all the time, and continue boiling until the jam will set when tested on a cold plate. Take off any scum that rises, then pour the jam into pots and tie them down. This will make only a small amount of jam.

Mulberry Wine. To make this drink, pour 1 gallon boiling water over 2 lb. mulberries, let them stand for 24 hours and then strain off the liquor, pressing the fruit against the side of the vessel to extract the juice. Measure the latter and put it into a preserving pan, with $\frac{1}{4}$ oz. ground ginger, a clove, and sugar in the proportion of 2 lb to every gallon of liquor. Boil the whole gently for about an hour, skimming it whenever necessary; let it cool to about 98° F., and stir in $\frac{1}{4}$ teaspoonful of brewer's yeast. Pour the wine into a cask, cover the bung with a cloth, and let it stand for two weeks; then add $\frac{1}{8}$ pint brandy, and cork tightly. The wine will be ready for use in about six months.

MULBERRY BUSH: The Game. This is one of the most familiar of the singing games. All the players join hands in a ring, and dance round and round singing:

Here we go round the mulberry bush, the mulberry bush, the mulberry bush;
Here we go round the mulberry bush on a cold and frosty morning.

This serves as an introduction, and is sung to the same tune as 'Here we go gathering nuts in May.' The next movement is for the children to drop hands and sing: 'This is the way we wash our hands,' repeating it in the same fashion as before, with appropriate gestures, and ending with the same refrain. 'This is the way we go to school' shows the children crawling round with drooping heads and depressed faces, while 'This is the way we come home from school' is the signal for them to skip round.

Hair brushing, putting on shoes, going for walks, learning to dance, and a host of other movements may be introduced, and between each the opening verse must be sung, during which the players join hands again and dance round in a circle.

MULCHING. This term is applied in gardening to the act of spreading a layer of some protecting material upon the ground above the roots of plants to preserve them from frost or drought. The mulch generally consists of well-rotted stable manure, tan, coconut fibre, decaying leaves or the leaves of fern or of bracken. *See Loganberry.*

Mulching.

- 2 and 3. *Wrong ways of mulching bushes.*
4. *Correct method.*
5. *How to mulch a standard.*
6. *How to mulch a wall tree.*
7. *Good method of mulching plants.*

MULLEIN. This is a hardy biennial or perennial of great decorative value in the garden. Most of them are vigorous leafy plants with tall spikes of bloom in summer. The best perennials are *Chaixii*, yellow, 3 ft.; *nigrum*, yellow, 2-3 ft.; *densiflorum*, yellow, 3 ft.; and *phoeniceum*, various colours, 2 ft. Of the biennials (those which bloom the year following seed-sowing and then perish) one of the best is *olympicum*, yellow, 4 to 5 ft. Many beautiful cross-bred varieties have been raised. Two of the best are *Cotswold Queen*, salmon-bronze, and *Gainsborough*, yellow. The mulleins thrive in ordinary soil and may be planted in autumn. The perennials can be increased by division at these seasons; biennials are raised from seeds sown in May.

Mullein. Yellow blooms of a vigorous hardy plant.

Mullet. This is a general name for two different fish, both of which are good eating. *See* Fish; Grey Mullet; Red Mullet.

MULLING. Heating, sweetening and seasoning wine or other liquor with spices is called mulling. Wine can be mulled by heating it to a certain temperature and then adding to it some sugar and also a little nutmeg.

Mulled Ale. The following is a good recipe for mulled ale: Put $\frac{1}{2}$ pint ale, a little ginger, a clove, a small piece of butter and teaspoonful sugar into a saucepan and bring to boiling-point. Beat up 2 eggs with a tablespoonful cold ale, pour the boiling ale into them and then into a large jug. Pour the contents rapidly from one large jug to another for some minutes; then return the liquor to the saucepan and heat it again to nearly boiling point. Serve the ale very hot.

MULLION WINDOW. This is a window in which the upright divisions are built in the window frame, and generally form a part of the structure of the building, the mullion being more or less in the nature of a post or support for the lintel. The type is particularly applicable to constructions in stone. *See* Window.

MUMPS: The Treatment. The chief characteristic of mumps is the swelling of the salivary glands, the disease, which is highly contagious, being communicated by the breath and saliva of the patient. The incubation period is from 2 to 3 weeks; the quarantine period is 25 days.

Languor and feverishness are amongst the earliest symptoms with pain in the glands, especially near the angle of the jaw, and swelling of the parotid gland near the lobe of the ear. The breath becomes offensive, and there is an increased flow of saliva.

The patient should be kept in bed for a week or 10 days and in his room for another week. He should have a fluid diet. A warm poultice or a pad of cotton wool should be applied to the swollen face. The mouth must be frequently rinsed with warm water containing a little permanganate of potash. When the patient leaves the sickroom, the bedding, carpet, and everything in the room should be thoroughly disinfected.

MUNTIN. This is the name given to that portion of a door framing which forms the centre uprights between the middle and top and bottom rails. It is tenoned into them, and is used in all panelled

doors, and in other cases where the width of doors or the framework of panelling is divided into two or more panels. *See Door.*

MURIATE OF POTASH. Used as a fertilizer, muriate of potash, which is a mineral salt containing about 48 per cent of pure potash, is very soluble and is readily absorbed by plants. The sulphate of potash is more generally accepted as a plant food, mixing well with other components and giving good results. Muriate should not be used in larger quantities than 4 lb. to the square rod.

MUSA. The musa, or banana, is a hothouse family of vigorous, large-leaved perennial plants. The height is from 4 ft. to 10 ft. Musas are best started in pots or tubs in early spring, in a mixture of loam and sand. The plants should be well watered and syringed frequently. *Musa ensete* is chiefly used for decorative purposes in sunken pots or tubs in the sub-tropical garden. It may be safely placed out of doors in June and taken in again in September. If the plants are grown under glass to yield fruit *Musa cavendishiana* is recommended.

Musa. Leaves and fruit of the large hothouse plant, better known as the banana.

MUSCADEL. The name of muscadel is given to strong French and Italian wines, both white and red, such as the *Lacryma Christi* (q.v.) of Naples. *See Wine.*

MUSCAT. The name is given to one of the most highly esteemed grapes in cultivation. One of its most deliciously flavoured varieties. Muscat of Alexandria, was introduced from the East some two centuries ago, and from its small berries are obtained the sultanas of commerce. Other good muscats are Mrs. Pince, Lady Hastings, and Prince of Wales. Under proper cultivation muscats bear long, tapering bunches of sweet, rich, fleshy berries, but they require a high temperature. *See Dessert; Grape; Vine.*

MUSCATEL. Muscatels are a variety of sun-dried raisin that is appreciated as a dessert dish. The muscatels are large and juicy, of a purplish colour, and are usually served piled on a dessert dish, the raisins being retained on their branches. Shelled almonds are served with muscatels.

Muscatel Pudding. A baked fruit pudding is made with muscatels by mixing 1 lb. self-raising flour with $\frac{1}{2}$ lb. finely chopped suet, $\frac{1}{4}$ lb. sugar, $\frac{3}{4}$ lb. stoned muscatels, $\frac{1}{4}$ lb. candied peel cut into small pieces, and a little grated nutmeg; to these add a beaten egg previously mixed with $\frac{1}{2}$ pint milk and water used in equal proportions. Beat the whole well, and then pour it into a greased pie-dish. Bake the pudding in a moderately hot oven for $1\frac{1}{2}$ hours. This is sufficient for about 8 persons. *See Dessert; Raisin.*

MUSCLE. Muscles are of various shapes. Some, like the biceps, are rather spindle-shaped; others, like the sartorius, form long, narrow ribbons, and others still, like those in the anterior abdominal

wall, form broad, thin sheets. A muscle is enclosed in a sheath, and is found to be made up of bundles of fibre, separated by connective tissue.

Muscle possesses irritability; that is, it responds to some kind of irritation. Normally, the excitation is nervous energy, but an electric current, the striking of a muscle, and other causes will also evoke a response. This takes the form of contraction; a muscle fibre, and therefore the whole muscle, becomes shorter and thicker in response to the excitation.

Muscles perform a large volume of work. They are enabled to do this by the oxidation, or combustion, of sugar supplied to them by the blood, of which they receive a generous supply. But just as the combustion of fuel may not only supply energy for an engine, but also heat, so the combustion of sugar in a muscle liberates heat, so that blood coming from a muscle is hotter than that which goes into it. This, in fact, is the chief source of the heat of the body, and explains why a person who is cold desires to move about.

Fatigue supervenes sooner or later when a muscle is being continuously exercised, and is due rather to the accumulation of waste products and, notably, sarco-lactic acid, than to the using up of available fuel. Massage, by improving the circulation through a muscle and washing out this acid, helps to remove the sense of fatigue.

Injuries and Diseases. Overstretching of a muscle is described as a strain. There is pain and stiffness. The muscle should be rested and, if necessary, hot or cold applications will relieve pain. Early massage and gentle movements are necessary. A muscle may be ruptured by violent stretching; when it is contracted, or by a blow when it is in this condition. The severed fibres contract and leave a gap which is more evident if an effort is made to move the muscle, the severed ends gathering into knots. The limb should be placed in such a position as to put the muscle at rest and shorten it as much as possible.

Inflammation of a muscle, or myositis, may be due to one of the causes of inflammation (q.v.) in any situation, and if this cause be a microbe an abscess may result. The general symptoms and treatment of these conditions are described under their respective headings. Muscular rheumatism is inflammation in the connective tissue mingled throughout a muscle—a fibrositis.

A painful spasm of a muscle is usually referred to as cramp. Pain in a muscle without obvious signs of inflammation is spoken of as myalgia; it is generally due to rheumatism. An intensive use of muscles leads to an increase in their size, or hypertrophy. Disease, on the other hand, causes a diminution in size, or atrophy. There may be a progressive muscular atrophy involving all parts of the body. See Backache; Cramp; Fibrositis; Lumbago; Rheumatism; Sprain.

MUSHROOMS: GROWING AND COOKING

Advice About an Appetizing and Nutritious Food

This article describes in detail various ways in which mushrooms can be grown, afterwards dealing with methods of cooking them. See Frame; Hotbed; Manure: Savoury, etc.

Rich in nitrogenous matter and easily digested, the mushroom is a highly nutritious fungus which grows luxuriantly and very rapidly in warm, showery weather. The utmost care, however, is necessary in detecting the nature of the fungus, as the non-edible variety, which is poisonous, is similar in appearance to the edible fungus.

The edible mushroom has a dry pleasant smell, its flesh is dry and brittle, and the outer skin peels off easily. Deaths occur annually through the eating of poisonous fungi, under the impression that they are mushrooms.

Mushroom. Plate of the nutritious edible fungus which can be grown from spawn in a cellar or shed, and cooked in many attractive ways.

Testing Mushrooms. To test mushrooms, sprinkle a little salt on the spongy part and leave it for a few minutes. If the flesh turns yellow, the fungus is poisonous; if it turns black it is wholesome. Another test is to use a silver spoon while cooking the mushrooms. The silver will be blackened if any injurious property is present. When poisonous mushrooms are eaten, if the effects come on quickly the early symptoms are giddiness, dimness of sight, and weakness. If the poisonous effects are delayed, the symptoms are irritation, pain, vomiting and purging. An emetic of two tablespoonfuls of common salt in a glass of water should be given at once, and afterwards a dose of castor oil.

Hints on Growing. In England mushrooms are generally gathered in the fields during the late summer months, and are most easily found in the early morning. They can, however, be cultivated, and in Bulletin 34 the Ministry of Agriculture give some information on this subject. If kept for any time after being gathered, mushrooms become unwholesome, and may become poisonous. Any portion that is not eaten should be thrown away, as there is some risk of the development of poisonous properties if cooked mushrooms are kept for a day or so, or are served re-cooked. Intending growers of mushrooms will be well advised to buy spawn from a manufacturer of good repute. It is sold in the form of 'bricks.' Pure-culture spawn should be obtained.

The manure intended for the beds should be very carefully selected and prepared. Manure containing peat, sawdust, or chip litter, and that from horses under veterinary treatment, should be avoided. The manure should contain some straw litter. When the required quantity has been collected the longest straw should be shaken out with a fork and stacked in a dry place for use later in covering the finished bed. The rest of the manure should then be stacked in a heap. If very dry it should be watered.

The heap should now remain untouched for 3 or 4 days, during which time a considerable heat will develop. It should then be turned, care being taken to turn the outside portions into the centre of the new heap. If still dry a little more water should be added and the heap left to heat up again for a further 2 or 3 days and again turned as before. If the dung is good and not too old, no further turning should be necessary. When opened up it should be hot and steaming, moist, but not wet, and should smell strongly of ammonia. If in this condition it is ready for making into beds. Where possible the manure should be prepared under cover but in open sheds. If prepared in the open the heap should be protected from heavy rains.

For indoor culture almost any place can be used providing an equable temperature of about 50° can be maintained. Indoor beds, except in glasshouses, may be made at any time. The beginner should not, however, attempt to make beds during the months of May, June, and July, as the higher atmospheric temperature during these months necessitates considerable judgement in the use of water in the preparation of the manure and beds. Outdoor beds are usually made up in late summer.

Beds for Mushrooms. The most common types of beds are flat and ridge. For indoor culture, where space is limited, flat beds are chiefly used. The size of the bed will depend upon the weight

of manure available, one ton making 6 sq. yd. of bed 9 in. deep. Where artificial heat is available, a depth of 6 in. may be sufficient, but where there is a possibility of low temperature, the bed may be made as deep as 15 in.; 9 to 12 in., however, is the common range of depth. Before commencing to lay the bed, the site which it is to occupy should be carefully cleaned and dusted over with slaked lime.

The site should then be carefully marked out, and the manure spread evenly to a depth of 10 in., beating it down with a fork as the spreading proceeds. It should now be trodden down compactly. This will reduce the depth to about 6 or 7 in.

The successful construction of a ridge bed requires considerable experience. The usual ridge bed is, in section, the shape of a triangle with the top cut off, 2 ft. 6 in. along the base, 2 ft 6 in. high, and 6 in. along the top. The length will depend upon the amount of manure and space available, 1 ton of manure usually making 2½ yd. of bed. When the base has been accurately marked out, the manure should be carefully and evenly spread the whole length to a depth of 18 in. and firmly trodden down. A further 18 in. should then be added and trodden down in a like manner.

The bed should now be 2 ft. high of tightly packed manure with a lot of loose overhanging material on the sides. This should be removed with a fork and placed on the top, bringing the height up to 3 ft. The top and sides should be thoroughly beaten until perfectly compact, smooth and even, any loose material being swept up and set aside for use in the next bed. To prevent evaporation, the beds should be lightly covered with the long litter, previously shaken, and protection from rain should be provided for all outdoor beds.

If the processes described have been properly carried out, the temperature of the beds should now commence to rise, and to follow the progress of the heating a thermometer should be inserted in the bed, the bulb being at least 3 in. deep. Special thermometers reading up to 160° to 200° F., protected by a wood or metal case.

When the temperature at 3 in. below the surface has steadily dropped to 85° F. for flat, and 80° F. for ridge beds, the beds are ready for spawning. There is much difference of opinion as to the correct temperature for spawning, but as the spawn is only inserted on the surface there is no risk of it being killed unless the inside heat again rises above 85° F. If the temperature is allowed to drop to 75° F it is possible that the spawn will not develop or will develop very slowly and cause long delay in the production of mushrooms.

Inserting the Spawn

The bricks of spawn, if very dry and if the bed is also rather dry, should be dipped in water before use. Each brick should then be broken into 8 pieces, as nearly as possible of equal size. The pieces of spawn should be inserted in the bed in diagonal lines as nearly as possible 9 in. apart in all directions. Pure-culture spawn is superior to the old-fashioned brick spawn, and is now used extensively. After spawning it is advisable to allow the beds to rest a few days before soiling or casing.

In casing a ridge bed it is best to begin to apply the soil to a height of 1 ft. and a thickness of about 2 in., beating it lightly with the smooth back of a spade to make it bind. This process is repeated another foot in height, leaving only the top and a small portion on each side to be completed in a similar manner.

The casing of a flat bed is a comparatively simple matter, but care should be taken to see that the soil is uniform in thickness and firmly beaten down. The bed should now be covered to a depth of 12 in. to 18 in., according to the atmospheric temperature, with the straw litter shaken out in preparing the manure, supplemented, if necessary, with new straw. Outdoor beds in cold weather will need straw mats or hurdles in addition. In frosty weather a little artificial heat will be needed in

vineries or other glasshouses and in unprotected sheds. In normal circumstances mushrooms will begin to appear in six to eight weeks.

Mushrooms will thrive best in a damp atmosphere, and the beds should, therefore, be watered until damp but not wet. If the casing of soil becomes dry, it should be very lightly watered with a fine rose, going over the bed several times if necessary. On beds in unheated sheds the water used in cold weather should be lukewarm. Watering, if properly done, should not be required more than once a week.

In normal circumstances the bed will need picking over three times a week, but in cold weather the progress of the crop will indicate how often picking is required. The bed should be uncovered piece by piece, each portion being covered again as soon as the mushrooms have been picked. They should not be cut, but carefully pulled, bringing away a little soil with the root-like threads of mycelium. The ends are now cut off into a refuse basket and the mushrooms freed from any soil, placed stem upwards in the basket. The holes made by pulling should be filled with new soil.

Mushroom Growing. 1. Outdoor bed against wall: a, top manure; b, well trod bottom manure. 2. Same with spawn in position: a, top straw; b, soil; c, spawn. 3. Outdoor mound: a, top manure; b, firmly packed manure. 4. Same completed; a, straw; b, soil; c, spawn. 5. Hotbed for cellars: a, manure; 6, spawn; c, soil; d, straw. 6. Tub culture. 7. Box culture: a, manure; b, soil. 8. Button. 9. Manure. 10. Old mushroom. (By special arrangement with Amateur Gardening)

How to Cook. Mushrooms can be cooked in many ways and combined with other foods. They are also used in sauces and ketchups, while button mushrooms are excellent pickled.

To prepare stewed mushrooms, rub off the outside skin with a flannel dipped in salt and put them into a stewpan with 2 oz. butter that has first been melted. Add 1 teaspoonful salt and half the quantity of pepper and stew gently until tender. Serve on a hot dish. Stewed mushrooms can also be served on toast. Stew as above, but add 1 teaspoonful grated lemon rind and a blade of mace. Add a white roux made from a dessertspoonful of flour stirred into a tablespoonful of melted butter. Stir this into the mushrooms, and serve them on a slice of fried bread or buttered toast.

Creamed mushrooms make a good entrée. Trim and rub with a flannel dipped in salt $\frac{1}{2}$ pint button mushrooms. Dissolve 2 oz. butter in a stewpan, and stir in 1 teaspoonful flour; add the mushrooms, 1 tablespoonful chopped parsley, and $\frac{1}{2}$ teaspoonful salt. Stir, cooking slowly, for about 10 min., then beat up the yolks of 2 eggs with 1 tablespoonful cream, and add this gradually to the mushrooms. Stir together for a few minutes, then serve the mushrooms in the sauce.

To grill mushrooms, cut away the stems and rub off the outside skin with a flannel dipped in salt. Butter the bars of the gridiron and place the mushrooms on the bars, sprinkling them with salt. Serve them, when thoroughly cooked, on buttered toast, or as an accompaniment to grilled steaks, chops, bacon, etc.

Mushrooms and scrambled eggs are made by melting 2 oz. butter in a pan and simmering in it a $\frac{1}{4}$ lb. prepared mushrooms cut into small pieces. When they have cooked for about $\frac{1}{4}$ hour, add salt and pepper to taste, and when tender add 2 beaten eggs, and stir all together until the eggs are cooked. Serve the mixture on hot buttered toast.

Mushroom Croquette. Croquettes or fritters made from mushrooms and boiled rice are prepared thus: Peel and stalk $\frac{1}{2}$ lb. mushrooms, put them into a saucepan with sufficient milk and water to cover them, and stew them for about $\frac{1}{2}$ hour, or until they are tender. Then strain off the stock, chop the mushrooms coarsely, and mix them with 1 teacupful boiled rice, 2 teaspoonfuls chopped parsley, and the same quantity of chopped onion. Melt $\frac{1}{2}$ oz. butter in another pan, stir in $\frac{1}{2}$ oz. flour, add the mushroom stock, and stir until it boils.

Put in the mushrooms, etc., and a beaten egg, and stir all over the fire until they are well mixed. Season the mixture carefully, turn it on to a plate to cool, and then shape it into even-sized balls. Brush these over with egg, coat them with breadcrumbs, and fry them in smoking hot fat. When they are a golden brown colour drain them on kitchen paper, and serve them garnished with fried parsley and cut lemon.

Mushroom Patty. Mushroom patties are made by cutting up into dice and then stewing $\frac{1}{2}$ lb. mushrooms, and stirring in about two tablespoonfuls white roux or plain white sauce. Line some patty tins with puff paste and fill them with the mushroom mixture, placing a cover of pastry on the top. Bake them in a moderate oven for about half hour.

Mushroom Pickle. Button mushrooms only should be used to make this pickle. Stalk, wash and dry them thoroughly, and then rub off the skins with salt. Put them into a pan at the side of the fire and let them cook slowly in the liquid which the salt draws out of them. Continue cooking until this liquid has been evaporated; then season the mushrooms to taste with mace and pepper, cover them with vinegar, and bring the whole to the boil. Boil it slowly for a few minutes, and let it cool slightly before pouring it into bottles or jars. When the pickle is cold tie it down, making the jar airtight.

MUSHROOM CAKE. Mushroom-shaped cakes coated with almond paste and chocolate butter icing, to give them a realistic appearance, can be made from a rich plain cake mixture baked in small cake tins for about 12 min., or until they are spongy.

Mushroom Cakes, consisting of a plain cake mixture coated with almond paste and chocolate butter icing to give them a realistic appearance.

When the cakes have cooled, level them to the required shape, and brush the sides and bottoms with white of egg. Cut the almond paste into rounds, stand a cake on each, and then mould the paste round it, leaving the tops uncovered. Trim off the rough edges, and place the cakes in a warm oven for 20 min., so that the paste may set. Then leave them to cool, and reserve any trimmings of almond paste for the stalks. Make the butter icing and ice the tops of the cakes by forcing the icing through a rose tube fixed to an icing bag. Start from the centre of the cakes and continue in straight lines to the edge where the almond paste begins. Mould the remainder of the latter into thick stalks, and stick one in the centre of each cake. *See Almond Paste; Chocolate Roll; Icing; Madeira Cake.*

MUSICAL CHAIRS. Musical chairs is an indoor game, the popularity of which is by no means confined to children. A line of chairs is placed down the centre of the room, there being one chair fewer than the number of players. They are arranged alternately, one chair facing one way and the next the other. Somebody then plays the piano, and the players run round the line of chairs until the music suddenly stops, when each person sits down in the nearest chair. The player who fails to secure a seat is out of the game. A chair is then removed from one end of the line and the game continues with the recommencement of the music. It ends when only two people are left to circle round and round a single chair, the one who first occupies it when the music stops being the winner. Where there are many players and not sufficient chairs available this game can be played equally well by putting a line of people instead of chairs, standing each with one hand on his hip, alternate left and right. The players have to put their arms through the arms of the improvised chairs when the music stops.

Musical bumps is popular with children. It is played in the same way as musical chairs, but when the music stops all the children sit down on the ground. The last one to do this is out of the game. *See Children's Party.*

MUSK: The Plant. The favourite musk is *Mimulus moschatus*. Before it lost its scent this was a popular window plant, seen in almost every cottage window. The variety *Harrisonii* has larger flowers. Rooted pieces should be potted in March, several in a 5 in. pot in a compost of sand and leaf-mould. *Mimulus moschatus* may also be grown out of doors. Other showy musks are *luteus*, yellow, and the numerous highly-coloured hybrids which have been raised; between *luteus* and *guttatus*. They are commonly known as monkey musks. Seeds are sown in May to produce flowering plants the following year. *Whitcroft Scarlet* is a brilliant dwarf kind.

Musk. One of the handsome monkey musks.

MUSK: The Perfume. One of the strongest of perfumes, musk is a dried glandular secretion obtained from the musk deer. Musk is very expensive, but it retains its odour for a long time, and for this reason is added to other perfumes in order to render them more durable. A cheaper substitute is synthetic musk, which is made from a coal tar product, toluene. *See Scent.*

Musk Mallow. This is a hardy herbaceous perennial plant, also called Moschata. *See Malva.*

MUSK ROSE. The popular name of *Rosa moschata* is musk rose. It is a very vigorous climber with clusters of white flowers. The leaves are greyish-green. It should be planted in autumn and allowed plenty of room for development, for it makes rampant growth. *See Rose.*

Musk Rose. White flowers and greyish-green leaves of this climber.

MUSLIN. The successful employment of white muslin is a matter of skill and taste in adding colour touches in the form of a simple ribbon or in other ways. Muslin is again used for dressing table flounces over pale coloured sateens, and cushion covers and curtains to match look dainty in a country bedroom.

Sprigged or embroidered muslins are pretty for summer curtains. Madras muslin and silk muslin are obtainable for this purpose in exquisite designs and colourings. White muslin is easily tinted with the dyes and dolly-sticks used for curtains. In washing spotted muslin it is well to see whether the dots have actually been woven in or merely attached.

Plain muslins equally suitable for dresses, glass or long window curtains, bedspreads, and cushion covers are always procurable, and when they have served for one purpose they can frequently be turned to another. Muslins which have been soft can be stiffened by starching and ironing, and be used for foundations for other light stuffs. Spare muslin comes in for wrapping up food, making fly-proof covers for meat and milk. A heavy bead edging round a little mat of spare muslin converts it into an efficient cover for milk-jugs.

Kitchen strainers can be improvised from muslin, and it has many other household uses in making poultice covers, bandages, stretched on frames to prevent the entry of flies through open windows, diffusers for amateur photographers and for drying and polishing. *See Dressing Table; Organdie.*

MUSLINET. Made with coarser threads and in more open texture than fine muslin, muslinet is intermediate between muslin and net. Muslinet makes cheap window curtains.

MUSQUASH. Used mainly in the manufacture of fur coats, musquash, which is obtained from the musk rat, is a somewhat coarse but hard-wearing fur of glossy appearance. Usually dark brown in colour, it is frequently shorn and dyed to imitate sealskin. A more valuable type is known as natural black musquash. *See Fur.*

MUSSEL. Of all the shell-fish mussels are the least digestible, and should be eaten sparingly. They have a redeeming feature in that they cleanse themselves of any pollutions in about four days if put into water free from contamination. In order to make mussels quite safe for human consumption, a medical man has invented a system by which shellfish are immersed in a large volume of sea water

freshly sterilized by means of chlorine for periods of 24 hours. In the case of mussels two such periods only are necessary. The mussels so treated are packed in bags and have special labels attached to them which the public are advised to look for.

To prepare mussels for eating, they should be allowed to soak for some time in cold water and the shells scrubbed with a stiff brush.

The water should be frequently changed in order to get rid of sand. When the mussels have soaked sufficiently, put them in an iron saucepan, without water, over gentle heat. As soon as the shells open they are ready to be served in the shells with brown bread and butter after all foreign bodies have been removed, special care being taken to remove the green grass-like 'beard' that is to be found in every mussel. Vinegar or lemon juice should be taken with mussels to counteract any irritants or poisonous substances.

Stewing the Mussels. To stew mussels, boil them, then take them from their shells and carefully remove the beards. Strain all the liquor from the mussels into a pan. To every quart of mussels allow 4 oz. butter. Roll this in flour and melt the butter with the liquor. Add the mussels with a spoonful of chopped parsley, a sprinkling of pepper and salt, and a spoonful of lemon juice. Shake the contents of the pan and simmer for about 10 min. Serve with sippets of toast.

Scalloped Mussels. To make scalloped mussels, prepare them as directed above. Take the mussels out of the shells and remove the beard. Strain the liquor and add to it 4 oz. butter rolled in flour. When the butter is melted, add the mussels and simmer for 5 min. Butter a scallop shell and sprinkle it with browned crumbs. Put in a layer of mussels, then a layer of crumbs with a piece of butter on top. Continue this until the shell is filled. Pour the liquor over and brown the dish under the browning shelf of the oven.

Poisoning by Mussels. The popular idea that cooking destroys all poisons does not apply to mussels, which are often virulently poisonous whether raw or cooked. There is nothing to indicate this fact before they are eaten. The poison is present chiefly in the liver of the mussel.

The symptoms are of two types. In some cases the patient suffers from irritation in the stomach, colic, vomiting, purging, cramp in the limbs, and nettlerash. In others he becomes numb and cold, the pupils of his eyes dilate, paralysis may develop, and he may become comatose. So virulent is the poison that death sometimes occurs within two hours.

As quickly as possible give an emetic composed of a tablespoonful of mustard in a large tumbler of warm water. As soon as the patient has vomited, give him a dose of 1 to 2 oz. of castor oil. If he becomes very weak before the arrival of the physician, weak brandy in tablespoonful doses every half-hour may be administered. The patient should be kept warm, and poultices or hot-water bags may be applied to the abdomen.

MUSSEL SCALE. Mussel scales are injurious to apples and less frequently to pears and currants, black and red. The insects also attack hawthorn, broom, and other plants. Trees that grow against walls suffer more than others, as the pests flourish most in warm, sheltered situations. The injury to the tree is caused by the loss of sap which is sucked up and devoured by the pests.

In the case of a bad attack, the trees or bushes should be sprayed when dormant, November to February, with an oil emulsion made as follows:

Paraffin oil	1 gal.
Soft soap	1½-2 lb.
Water	10 gal.

The soap is first dissolved in about a gallon of boiling water. The soap solution is then removed from the fire, and the paraffin is at once added, the whole being emulsified by squirting the liquid back into itself with a hand syringe. The strong emulsion may be kept until required for use, when the remaining 9 gallons of water should be added and the whole thoroughly stirred or emulsified again with the hand syringe.

If the pest has not been dealt with in winter—the best time—it may be greatly reduced by spraying when the eggs are hatching, about the end of May or early June. At this period a weak paraffin emulsion has proved satisfactory, and probably any other contact insecticide, such as nicotine and soap, would do as well. A suitable paraffin emulsion may be made as recommended in paragraph above, but using the ingredients in the following proportions:

Paraffin	2 pints
Soft soap	1 lb.
Water	10 gal.

See Apple; Insecticide; Pear; Spraying.

MUSTARD: The Plant. The hardy annual mustard plant is usually grown for table purposes in conjunction with cress. Seeds may be sown on the surface of fine soil at the end of March, watered in, and followed by successive sowings every week until September.

Mustard and cress may be grown indoors all the year round by sowing seed on the surface of shallow pans or boxes of soil, watering in with tepid water, and keeping warm, or grown on flannel placed in a dish and kept moist in a sunny window. The true mustard is *Sinapis*. Mustard should be sown 3 days later than cress.

Use for Sandwiches. The young leaves of mustard, which have a pleasant and rather pungent flavour, can be mixed with cress into a green salad or may be used alone with bread and butter and salt. Mustard and cress makes excellent light sandwiches. The leaves should be washed thoroughly in cold, slightly salted water, to remove any seed cases or grit, and then swung in a salad shaker until dry. As a garnish for cold meats, etc., mustard and cress is invaluable; also, if a little is thrown into a saucepan of soup a few moments before serving, the flavour of the soup will be very much improved. *See Cress.*

MUSTARD: The Condiment. Two varieties of mustard plant, the black and the white, are cultivated in England, the mustard of commerce being the powdered seed of both. The black variety contains a volatile oil from which mustard derives its pungent odour, and this is accentuated by the use of turmeric for the bright yellow colour of the powder.

As a condiment mustard is taken with beef, pork, bacon, cheese, and other foods, though not usually with mutton; it also enters largely into the composition of most piquant sauces and dressings. To prepare it for table use, a small quantity of the powder is mixed in a cup with a few drops of water to the consistency of a thick paste, all lumps being broken up. More water is added, stirring all the time, until the mustard is just thick enough to lie on the edge of a plate without running down. The addition of a little salt is held to improve the flavour of mustard. It is best to make only a small supply at a time, and to replenish the mustard pot with freshly made condiment.

A very pleasant table mustard and one which will keep can be made by dissolving 1½ oz. salt in 1 pint boiling water, then pour it upon 1 oz. grated horse-radish, and let it stand 24 hours. Strain it and mix in, by degrees, sufficient dry mustard to make a smooth rather stiff paste. Equal quantities of horse-radish, chilli and tarragon vinegar can be substituted for the water.

French Mustard. French mustard is made from the black mustard seeds, which are much more pungent than the white or yellow seeds. Steep them in vinegar, garlic, thyme, mint, and tarragon until a full-flavoured vinegar is obtained, then grind the mustard seeds and pound them, adding vinegar by degrees to work them into a paste. Season it with salt.

Mustard Pots. A mustard pot is one of the members of a cruet or condiment set. It takes a large number of forms, and is in various sizes, but is usually fitted with a hinged lid and supplied with a spoon to match. Sets are made in glass and in coloured pottery, comprising a mustard pot, one or two pepper pots and salt cellars. Mustard pots should match in style the other condiment containers on the table. The better pieces are in silver with glass liners.

Old silver mustard pots are much valued by collectors. They date, as far as England is concerned, from about 1750, and were often, as they are to-day, made with salt cellar and pepper pot to match. The majority are glass lined, the glass being usually blue, but occasionally rose in colour. The marks may be on the front, near the handle, or on the bottom, and, like all lidded articles, the cover should bear the same initials as the body. Some examples are beautifully decorated, those pierced and engraved with festoons and rosettes being especially noteworthy.

The three mustard pots illustrated are beautiful examples chosen out of a large selection in order to give an idea of the varied shapes in which these articles were made. Mustard pots, remarkable for the beauty of their chased work, were made in Sheffield plate, and there is a representative collection of these in the Victoria and Albert Museum, South Kensington. *See Silver.*

Mustard Pot. Three silver mustard pots of the Georgian period. 1. Example with beautiful pierced body showing blue inner receptacle, 1770. 2. Pot with dome-shaped lid and fluted base, 1802. 3. Octagonal specimen mounted on a pedestal, 1775. (Courtesy of Chapple & Mantell)

MUSTARD: Its Medical Uses. In medicine mustard is used as a handy and reliable emetic, and also as an external application. As an emetic, the dose for an adult is a tablespoonful in half glass of water. Externally, mustard acts as a counter-irritant, and may be applied as a plaster or a poultice. The most convenient form for use is the mustard leaf.

Mustard Plasters. To make a plaster, mix the mustard with cold water to form a thin paste, and spread upon brown paper. A little vinegar increases the strength. The mustard may be covered with a layer of muslin. A poultice is made by sprinkling a linseed meal or other poultice with mustard and covering it with muslin. The plaster or poultice may generally be kept on for 15-30 min., but for not more than 10 min. with young children or sensitive and delicate adults. A safe plan in the case of children is to mix the mustard with 2 or 3 times its weight of common or corn flour. The part may then be covered with a layer of cotton wool. When the plaster or poultice is removed, the skin should be wiped clean from all traces of the mustard, using for the purpose a very soft cloth.

Mustard Bath. For a bath the mustard should be made into a thin paste with cold water, and then stirred into the bath. For a foot bath add 1 to 2 tablespoonfuls of mustard to each gallon of water; the water should be as hot as can be comfortably borne. For a sitz bath, a tablespoonful of mustard should be used for each gallon of water. For the full bath of about 30 gallons of water, $\frac{1}{4}$ lb. to $\frac{1}{2}$ lb.

of mustard may be used. The temperature should be about blood temperature. This is an admirable cure for chills, commencing colds, sleeplessness, etc.

MUTISIA. The kind generally cultivated is *Mutisia decurrens*, a climbing perennial which is not hardy except in a few exceptionally mild places. The flowers, which open in summer, are of orange-yellow colouring. Propagation is by cuttings under glass in spring. The plants may be grown in a greenhouse from which frost is excluded.

MUTTON: VALUE AND COOKING METHODS

The Housewife's Guide to a Popular Article of Food

In addition to similar articles on Beef; Lamb, Pork, readers are referred to Boning; Breast; Carving; Diet; Food; Meat, etc., and other entries dealing with the subject of food. See also Caper Sauce; Gold Meat: Cutlet; Haricot Mutton; Mince; Onion Sauce.

Being highly nutritious and yet easy of digestion, mutton is preferable to beef for delicate persons or young children. The best meat is obtained from a sheep from 3 to 6 years old; under that age the flesh does not acquire the flavour of choice mutton. The leg is the most economical joint, as there is less bone and waste in proportion to the flesh; but it is liable to become tainted sooner than other portions of the carcass, especially if the kernel is not at once removed.

Leg of Mutton. A leg of mutton about 7 lb. in weight and a shoulder about 5 lb. are good average joints for family consumption. Mutton should be cooked rather longer than beef in proportion to its weight, as it should not be underdone, with exception of chops and cutlets, which may be slightly under-cooked if preferred. Mutton requires due attention when roasting, for if not thoroughly basted and the temperature regulated it will be dry and hard.

The leg can be boiled or roasted, but sometimes it is boned, stuffed with sage and onions, and trussed in an oblong shape, slightly flattened both sides, and baked or braised. It is then called mock duck. If intended for invalid diet, vegetables must be omitted when boiling a leg of mutton; but when served as a family joint it is usual to cook carrots and turnips with it, and to hand them separately as a vegetable, either whole or mashed.

For a braised leg of mutton a very small joint is the best. Remove the kernels and trim the leg neatly; it should then be partly roasted and afterwards braised on a bed of vegetables, adding 1 or 2 slices of fat bacon and a bouquet garni. Care must be taken to turn the meat in the braise. The gravy, after being strained, must have the fat skimmed off before reducing it and pouring it over the meat.

Shoulder and Other Parts. Shoulders of mutton should never be boiled; they are too fat to allow of the meat looking appetizing, and the flavour is insipid. They should either be roasted or braised—roasted for preference—and served with a sauce which has some distinct flavour, such as onion. They may be boned and stuffed by the method described earlier in this articles for the leg.

The haunch (hind quarter) should hang as long as possible without being allowed to become tainted; then the shank should be removed and the flap trimmed, and it should be roasted and served with rich gravy. Red currant jelly should always be served as an accompaniment to this joint.

The saddle (double loin) before being roasted must be trimmed and the flaps folded under. A small skewer must be run through the kidney in each loin to prevent it becoming detached. The tail is left on, but is split in half and curled over each side the reverse way. A 10 lb. saddle will take from 2 to 2½ hours to roast. It must be remembered that the loin is not such a thick joint as the leg, and does not take so long in proportion to cook. Serve with good gravy and red currant jelly.

Loin of mutton can be roasted whole, but must never be boiled. When roasted, superfluous fat must be cut away, and it is easier to carve if the chine bone is sawn off.

The breast is usually boiled, but can be boned, coated with stuffing, rolled up, and roasted, as described under the heading Breast. The neck is an economical joint for family consumption. When sold in the piece it is known as the target and comprises the best end, middle neck and scrag end, and is very cheap if the whole is bought. The best end can be roasted or made into cutlets, the middle neck can be used for Irish stew, or a ragout with or without the scrag, while the latter can be made into broth.

Mutton Broth. Cut up 1 lb. scrag into small pieces, and put these, together with the bones and a quart of cold water, into a saucepan over the fire. Add a little salt, bring the broth to the boil, and after skimming it add 1½ dessertspoonfuls rice, a leek, and a piece each of carrot, turnip, and celery cut up small. Simmer the whole for about 2 hours, then skim it again; take out the bones, add 1½ teaspoonfuls chopped parsley and seasoning to taste, and serve. Mutton broth is often made with bones only, no meat.

Mutton Chop. Grilling is the best way of cooking mutton chops, but they may also be fried or steamed. For grilling they should be at least 1 in. in thickness and should be cut from a well-hung piece of mutton. Rid them of skin and any superfluous fat, and after trimming the edges flatten them with a cutlet bat and brush them over with melted butter. Place them on a hot gridiron before the fire or under a gas griller and cook them for about 10 min. This is the approximate time required, but it will naturally vary with the thickness of the meat. Serve the chops garnished with watercress, and with a pat of maitre d'hôtel butter on top of each.

To fry mutton chops, prepare them in the same way as for grilling, omitting, however, to brush them over with butter. Melt a lump of butter in a frying-pan, and when it is smoking hot put in the chops. Brown them on both sides, and when cooked, as they should be in 8-10 min., drain and serve them in the same way as grilled chops. Mutton chops may be steamed by trimming and flattening them as already described, and placing them on a greased plate over a pan half filled with boiling water. Dust them lightly with salt, cover them with greased paper, and then with a basin. Take care that the water in the pan continues to boil, and add more if necessary during the course of cooking. After about 15 min. turn the chops, and continue cooking them for another 15 min.

Mutton. Left, side view of the carcass of a sheep, showing position of joints into which it is cut by the butcher.

Right, back view, showing the position of the joint known as the saddle.

Kebobbed Mutton. Mutton kebobbed makes a choice dish, and one that can be cooked in the Dutch oven. Remove the meat whole from a loin of mutton and cut it into steaks, trimming off some of the fat. Mix with some breadcrumbs a little sweet herbs, a sprinkling of grated nutmeg, salt and pepper. Dip each steak into beaten egg, then into the prepared crumbs; place the steaks together as if they had not been cut asunder, and tie them back into shape with string. Cook them either in the Dutch oven or in a baking-tin in a fire oven, basting them with good dripping and a small lump of butter. When serving pour off the fat, sprinkle a little flour over the tin, mix it with the sediment from the meat, and stir into it by degrees $\frac{1}{2}$ pint of good gravy. Add a little mushroom ketchup, boil up well, and pour this liquor round the meat.

Uses of Cold Mutton. Suggestions for doing up cold mutton are given under various headings. Excellent minced, curried, stewed in a casserole or made into a shepherd's pie, it may also be used to prepare the following dish: Free the meat from skin and gristle, then weigh out $\frac{3}{4}$ lb. and mince it finely. Melt a lump of butter about the size of an egg in a saucepan, add a breakfastcupful of tomatoes—previously skinned and rubbed through a fine sieve—the minced meat, three well-beaten eggs, pepper and salt. Stir the whole over the fire, taking care that it does not burn, and when it is thoroughly hot, dish it on slices of toast, with chopped parsley on top.

To utilize the knuckle end of a cooked leg of mutton, trim it neatly and then put it into a pan containing a pint of hot, brown gravy made from meat extract. Add a tablespoonful of Worcester sauce or ketchup, a little allspice, and a large grated onion. Cover the pan, and let its contents stew slowly at the side of the fire for about an hour, or until the meat is thoroughly heated. In the meantime, cook 2 oz. macaroni, cut into short lengths; wash and peel 2 large carrots and turnips, cut them with a vegetable cutter into balls about the size of marbles, and cook them in boiling salted water until they are tender. Dish the stewed knuckle on a hot dish, place a paper frill round the bone, and strain the sauce round. Around the meat arrange alternate heaps of vegetable and macaroni, sprinkling a little chopped parsley over the latter as a garnish.

Another good way of using up cold roast or curried mutton is to make it into croquettes. To prepare these wash $\frac{1}{4}$ lb. rice and boil till tender in plenty of fast-boiling salted water. Drain off the water thoroughly, and put the rice on a plate in the oven to dry.

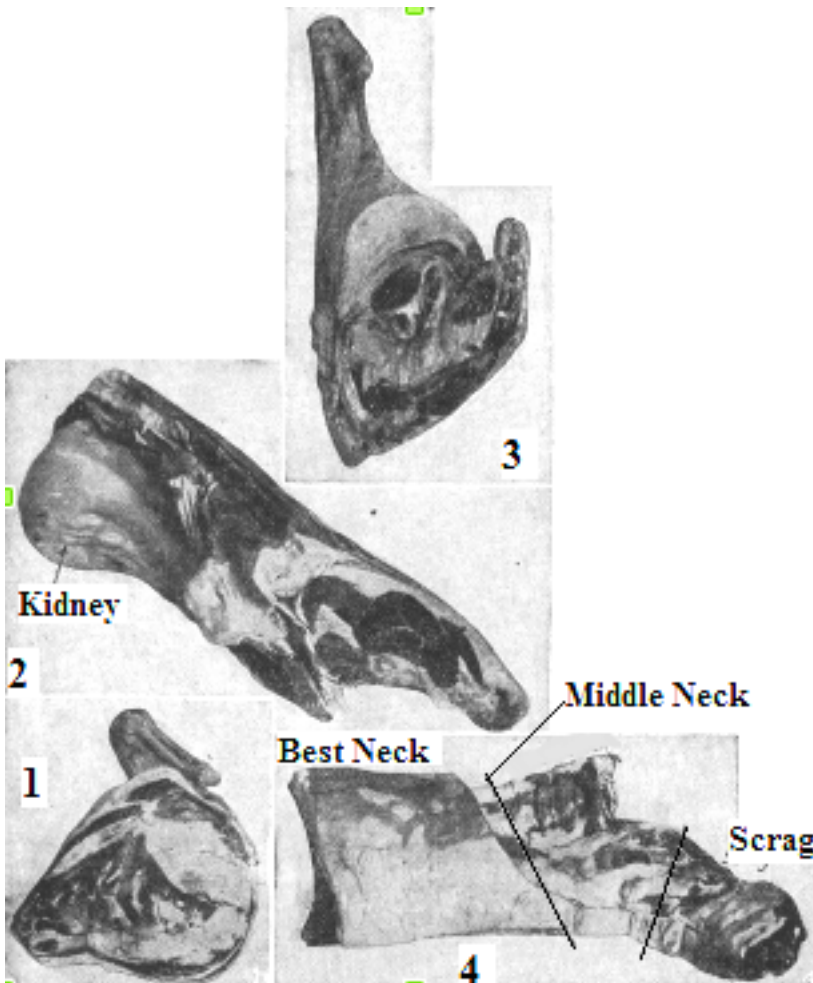

Fry a teaspoonful chopped onion in 1 oz. dripping in a saucepan, and when it is well browned add $\frac{1}{2}$ oz. flour and $\frac{1}{2}$ dessertspoonful curry powder frying these for a couple of minutes. Pour in $\frac{1}{4}$ pint stock, stir the mixture until it boils, and then add $\frac{1}{2}$ lb. finely chopped cold mutton, 1 teaspoonful lemon juice, the cooked rice, some salt and pepper to taste, and lastly the beaten egg. Mix all these ingredients thoroughly together, spread the mixture evenly on a plate, mark it into even-sized divisions, and leave it until it has become cold.

Shape the divisions into neat balls, brush the latter over with beaten egg, and cover them with breadcrumbs. Put plenty of frying fat in a pan over the fire, and when a bluish smoke rises from it put in the croquettes, frying them a golden brown. Drain them, and serve them on a lace paper garnished with pieces of fried parsley.

Either the shoulder or the neck may be done up as a stew or ragout in a casserole. Cut up 2 lb. into neat pieces, removing any superfluous fat and bone, and fry them lightly in 1 oz. butter melted in a casserole. When slightly browned on both sides take out the meat and put in its stead 2 shredded onions, 2 carrots cut into dice, and $\frac{1}{2}$ oz. flour. When these ingredients have browned thoroughly, pour in $1\frac{1}{2}$ pints warm stock or water, stirring all the time, and bring the whole to the boil.

Then put in the meat, a bay leaf, 2 oz. pearl barley which has been soaked overnight, and seasoning. Place the lid on the casserole and gently simmer its contents in a moderate oven until the barley is

soft. Then skim off the fat, take out the bay-leaf, and serve the ragout in the casserole. If the barley absorbs the stock, more must be added.

Mutton: the joints.

1. Shoulder.

2. Loin, showing position of kidney under the fat.

3. Leg. All are good joints for roasting.

4. Target, showing the positions and shape of the scrag end, middle neck and best neck.

MUZZLE. In Great Britain the Ministry of Agriculture and Fisheries possesses the power to make orders regarding the muzzling of dogs, the seizure, detention and disposal (including destruction) of unmuzzled dogs, and the recovery from the owners of the expenses incurred in respect of their detention. Orders may be made to prevent dogs from straying between sunset and sunrise. If an offence is being

committed in respect of any dog, the dog may be treated as a stray. A muzzling order may be revoked or altered from time to time, and may be made to apply either to the whole country or to a particular area.

The effect of a muzzling order is that any person who keeps a dog is liable to a fine and to pay the cost of the summons if the dog is found in any public place unmuzzled, whether it is the person's fault or not. It will not avail him to prove that the dog was muzzled when he let it out and that some one must have stolen the muzzle; nor that the dog escaped unmuzzled through the negligence of a third person.

Muzzle. Fig. 1 (left). Wire muzzle for a Pekinese or other small dog. Fig. 2 (above). One made of leather and wire, suitable for a terrier

Apart from muzzling orders, the Town Planning Act, which applies to most towns in England, makes it an offence to allow a ferocious dog to be at large unmuzzled, i.e. to be in a public street or place. The word allow implies knowledge on the part of the dog owner. It is a moot point whether this means knowledge that the dog is ferocious, or knowledge that the dog is at large.

Types of Muzzle. Dog muzzles are of two kinds, the leather and the wire cage shape. The latter is usually ordered by the authorities in outbreaks of rabies. It is not as comfortable as a leather one, and if the latter fits properly it should be equally effective. In the wire muzzle for a toy dog, shown in Fig. 1, a small pad has been arranged so as to avoid pressure of the wire joint on the animal's head. Fig 2 shows a combination of leather and wire for a larger dog. Whichever type of muzzle is used, care should be taken to get one of the proper size that does not pinch the animal's jaws too closely together. *See Dog.*

MYOPIA. The technical name for short sight is myopia. Parallel rays of light falling on the cornea are focussed in front of the retina, or, in other words, the eye is too long. The condition may be progressive, and it is desirable that children who are shortsighted should not have their books or similar work too close to the eyes, not nearer than 10 to 13 in , also that the type should be large and the light good. *See Eye; Spectacles.*

MYOSOTIDIUM. The perennial plant myosotidium also known as the Chatham Island forget-me-not, is a difficult plant to grow, but when it succeeds it becomes a very handsome object, bearing flowers like very large forget-me-nots. It requires a moist, sheltered position, and must be grown in loamy soil. It does best in maritime counties in the south-west district. Propagation is by seeds, which should be sown in the summer.

Myosotis. This is the botanical name for the popular hardy plant forget-me-not (q.v.).

MYRICA. Of these hardy shrubs, one, *Myrica gale*, grows wild in boggy ground in parts of the British Isles. *Myrica cerifera* is known as the wax myrtle; it has fragrant leaves and the fruits exude a wax-like substance. Another kind is *Myrica californica*.

Myrica gale, a British plant with fragrant leaves, suitable for growing in moist, peaty soil.

Using the Wax. The wax from the minute fruits, which are known as candle berries, can be obtained in the following way: A pot of boiling water is prepared, into which the berries are placed; the wax melts and floats on the surface of the water, from which it is collected and fashioned into little candles, which give off a delightful fragrance when burnt. Such candles would make excellent Christmas decorations.

MYROBALAN PLUM. Used as an alternative to privet and quick the myrobalan plum (*Prunus cerasifera*) is often seen in hedges. Its variety *atropurpurea* has purplish leaves. When full grown the myrobalan plum is from 8 ft. to 10 ft. in height, and in

favourable situations has reddish fruit in the autumn. Plants may be successfully raised from fruit stones. *See*. Hedge.

MYRRH: The Herb. Myrrh, or sweet cicely, *Myrrhis odorata*, is a hardy perennial herb with sweet-smelling leaves and white flowers. It thrives in the open border in any soil, and reaches a height of about 2 ft. Propagation is by seed, or division of the roots.

Medicinal Uses. The gum resin known as myrrh is the product of the balsamodendron, a small tree grown in Arabia and elsewhere in the East. Combined with borax, as in the following prescription, myrrh is a favourite gargle in inflamed conditions of the tongue, cheeks, or gums, and in a relaxed throat.

Tincture of myrrh	4 fluid drams
Borax	24 gr.
Glycerin	1 fluid dram
Eau-de-Cologne to make	2 oz.

A teaspoonful of the above mixture should be used in a small glass of water as a mouth-wash or gargle. The tincture of myrrh is given in doses of $\frac{1}{2}$ to 1 dram. *See* Mouthwash.

Myrrh. Much-divided leaves of the sweet-scented herb Myrrhis odorata.

MYRTLE. The fragrant myrtle (*Myrtus communis*) is a greenhouse and half -hardy evergreen shrub which can only be grown out of doors in mild districts, or against Avails with winter protection in cold localities. The flowers are white and fragrant; they produce black fruits. Myrtles do best in fertile loamy soil, well lightened with leaf -mould and said. They require a good deal of water in summer, and will benefit by frequent syringing Any necessary pruning should be done in spring. Propagation is by cuttings in sandy soil under a hand-light in summer.

Myrtle. Fragrant white flowers of the evergreen shrub which needs a sheltered outdoor situation.

NAILS AND HOW TO USE THEM

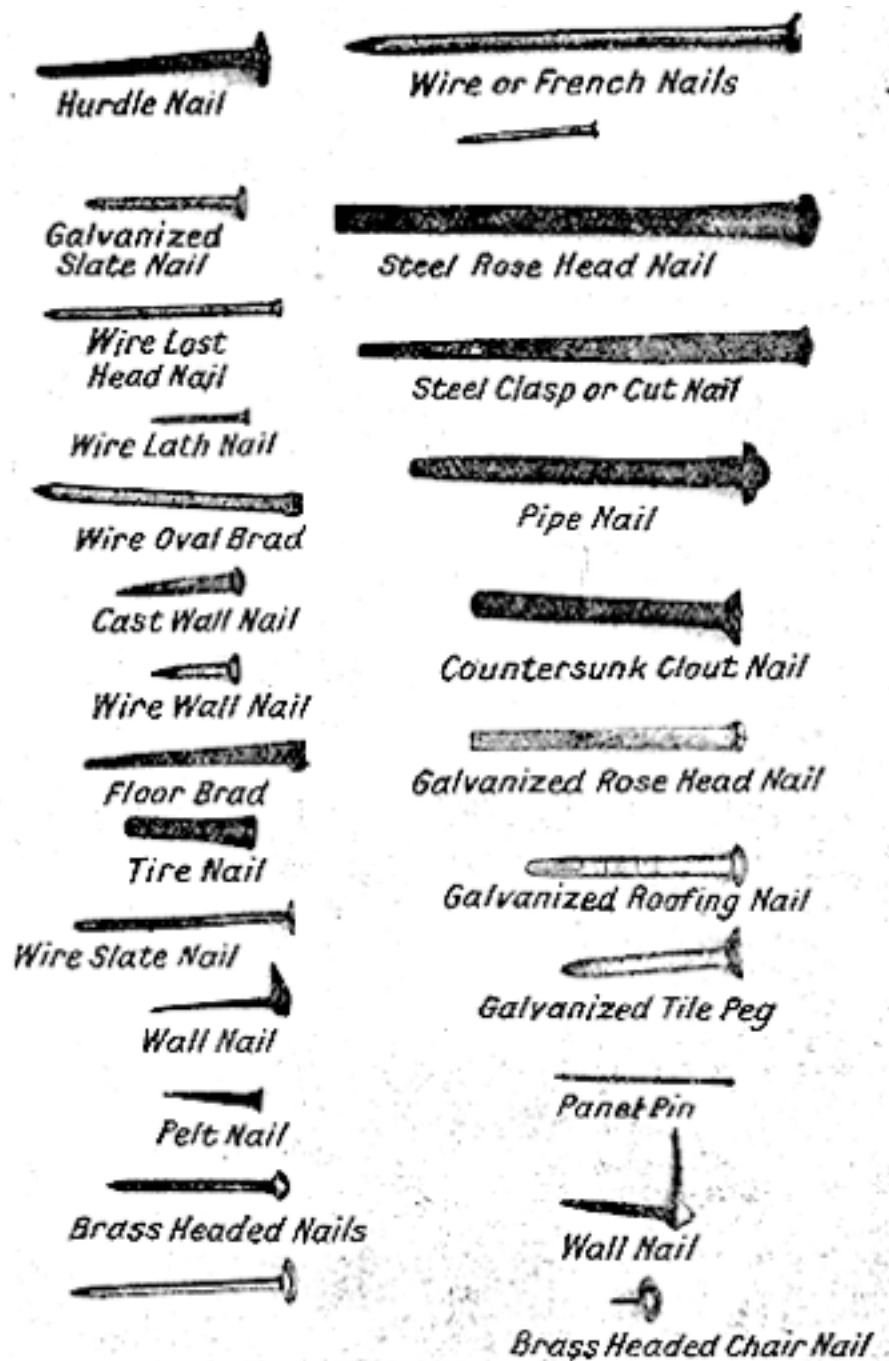

The Various Kinds and their Proper Uses

This article suggests reference to almost all the woodworking articles in this work. Of these only a few can be mentioned, e.g. Amateur Carpentry; Cabinet Making; Capping; Door; Drawer. See also Brad; Clasp Nail; Clout Nail.

Of the many varieties of nail in use a number are illustrated in Fig. 1. Iron and steel nails are liable to rust if exposed to the air or allowed to become damp. They should be kept in their original packets or arranged in a box divided into sections.

French or wire nails are made in sizes from 1 in. to 6 in. long, and in various thicknesses. Useful sizes in the 1 in. length are known as 16 gauge, in the 1½ in. 13 gauge, in the 2 in. 11 gauge, and in the 6 in. 4 gauge. The oval wire nail or brad does not hold so well as the French nail, but it has less tendency to split the wood, and for internal work the head, being long and narrow, easily sinks into the grain of the wood and is almost invisible. The shanks of the oval and wire nails are generally roughened near the head, so that they hold better in the wood and there is a smaller chance of their coming loose.

Cut nails are made by punching from sheets of thin metal. They are rectangular in section, and generally tapered or wedge-shaped. The amateur will find it wise to use this class of nail only when the work is fairly substantial and not less than 1 in. in thickness, otherwise the wood is likely to split. The ordinary cut clasp nail is provided with a T-shaped head, so that when driven into the wood it draws the two parts firmly together.

Nail. Fig. 1. Typical varieties of nails; their uses are described in the text.

The floor nail has an L-shaped head, and is used almost exclusively for nailing down floorboards to the joists, the purpose of the projecting piece on the head being to draw the floorboards tightly against the joists. The wall nail is a stout round nail, resembling a thick French nail, and is intended generally for driving into brick-work. Rose-headed nails are made with a round and modelled head and long, flat pin; they are used in exterior work where the head will be exposed; the large area under the head serves to hold one part to another. Joiner's brads are a variety of floor brads, ranging in length from $\frac{3}{4}$ in. to 2 in.; being small in size they are useful for nailing on the backs of furniture and similar purposes. Hob nails are generally used on the soles of boots, but as they are of variously shaped heads they are often employed as a decorative device on doors. The lath nail is a form of wire nail with a broad, flat head, intended chiefly for nailing laths to the stud partition intended to be plastered; a variety is made in the form of a cut lath nail.

Cast wall nails are often utilized for garden purposes in the training of plants; they should be driven into the mortar joints in the brickwork, since, not being very strong, they are liable to break if driven into hard material. Clout nails have a very broad head circular in section, and are made in the form of a wire or wrought nail. They are employed for fastening roofing felt and similar material.

Brass-headed nails are made in many fancy patterns, the heads being of polished brass. They are intended for the support of pictures or for fastening an overmantel or similar pieces of furniture to the wall, the brass heads alone being visible. Brass-headed nails of small size are used for many decorative purposes. The panel pin is a fine wire nail with a conical-shaped head of small diameter. It is invaluable for fastening two pieces of thin material together and should always be used with thin wood of any description. Although the nails are small in diameter, they are very efficient and hold well.

Nail. Fig. 2. Nails set diagonally draw a joint up tightly.

Use of the Hammer. The whole secret of driving a nail lies in the use of the hammer. It should be held rather loosely and near the end of the shaft. The nail must be struck fair and square on the head, and the hammer should fall in a straight line with the path of the nail otherwise the nail will not be driven in straight. There are other methods, however, beside the ordinary one of driving the nail straight in. For example, if a nail be driven at an angle through a piece of wood it will drive the wood in the direction in which the nail is pointing. Consequently, if two boards are to be nailed on to joists or battens, the joint between the boards can be brought close up by first nailing one of the boards and then nailing the second with the nails inclining toward the board already fixed. This is illustrated in Fig. 2. Another way of driving nails is known as dovetailing, in which each nail is driven at an angle into the wood so that it can be drawn out readily. A common method of driving a nail to prevent its being withdrawn is known as clenching (Fig. 3). The nail is driven Nail. Fig. 2. Nails set diagonally draw a joint up tightly. Fig. 3. Clenching a nail; right to left are shown the three stages in the process right through the material so that about $\frac{1}{2}$ in. projects on the opposite side. This portion is then struck with the hammer near the point so that the pointed end of the nail is bent over. Further blows drive the remainder of the projecting portion down into the work. The object of first knocking over the point is that the point may then be driven into the wood, thereby holding the clench firmly.

The work to be nailed should rest upon a solid base, as it is very difficult to drive a nail into a springy piece of wood. If no support is available, it will be necessary to hold a hammer, or some heavy tool, behind the place where the nail is to be driven through the thinner piece of material into the thick.

Splitting of the wood is a frequent cause of trouble. It is always advisable to make small holes with a bradawl through wood that is liable to split, and then drive the nails through the holes. In very hard wood it is sometimes difficult to drive a nail unless a hole is bored first, but in this case the hole should be somewhat less than the diameter of the nail, so that the latter may get a firm hold. Another point is to avoid having two nails in the same grain of wood. The nails should be zigzagged, or staggered, as in Fig. 4, so that each nail is separated by as much untouched wood as possible.

Right. Fig. 3. Clenching a nail: right to left are shown the three stages in the process.

Left. Fig. 4. Correct spacing of each nail in different grain of wood.

Right. Fig. 5. Secret nailing, left to right: Chip turned up; nail partly driven home; punching nail home; opposite arrow, chip pressed home on nail head.

Fig. 6. Skew nailing an upright to a horizontal member.

Secret Nailing. When several boards are to be laid and nailed so that the joints do not show a great deal, a method of diagonal nailing may be used. The nails can then be driven diagonally into the edge of one plank so that when the next plank is placed against it and driven home the nail will be invisible. Generally this method is adopted with rebated boards so that the second plank may interlock the first. Another method of secret nailing consists of making an incision into the wood with a tool like a very fine gouge. This raises a shaving, which is bent back and the nail driven in the cavity and punched well down, as in Fig. 5. The shaving is glued and then pressed back into position, and after the glue has set the face should be sandpapered till smooth and all traces of the nail is lost.

In good work the nails are always punched below the surface of the wood, and especially should this be done when the work is to be finished by painting, as the nail holes may then be filled with putty or one of the numerous stoppings on the market. Nail punches or nail sets are made for this special purpose, but almost any plain punch will answer. Cross nailing, Fig. 6, or skew nailing, as it is sometimes called, is generally used to fix the uprights on to the bottom plate. It consists in driving the nails diagonally through the lower part of the upright into the bottom plate.

NAILS: Their Care. Growth at the root of the nail constantly pushes it forward, hence the need for cutting or filing. In the case of finger-nails the points may be rounded; toe-nails must be left square. Nail-biting is a habit with many children, sometimes persisting on to later life, and mothers cannot be too decided in checking it while the child is young. Something bitter, such as aloes or quinine, should be put on the finger-tips. If this fails, mustard may be used, but only while the mother or nurse keeps watch, as he might put his fingers to his eyes. A child who is inclined to bite his nails will generally do so on first waking from sleep, so it is well to put the hands in gloves when putting him to rest.

If nails are filed daily with an emery board, they will be kept nicely shaped and always the desired length. They should not be filed down at the sides (a common fault), as this removes the support from the tip, causing it to break. After washing, an orange stick dipped in cuticle remover should be passed all round the cuticle, pressing it back very gently. The nails should be washed in soapy water at night, dried carefully, and cuticle cream applied with an orange stick. Varnish can be bought in all shades, liquid or cream, and should be applied with firm, downward strokes. A nail varnish can be made of paraffin wax 1 drachm, chloroform 2 fluid ounces, and peroxide of hydrogen or lemon juice are occasionally used for bleaching discoloured nails.

Abscess in the Nail. An abscess may form under the nail or at the root as the result of some injury, or a small infected wound such as may be caused by a splinter of wood. The pressure of the confined pus (matter) causes severe pain. When an abscess threatens, the end of the finger should be wrapped in lint soaked in hot solution of boric acid (one teaspoonful to the pint of water). The lint should be removed frequently or covered with oiled silk or a large rubber finger-stall. The hand should be kept well raised by means of a sling. If the abscess forms, relief can be obtained only by having it opened and letting the matter escape. Inflammation of the nail matrix, or onychia, may arise from several causes, including infection by the microbes which produce suppuration.

Toe Nails. With ingrowing toe nails the edge of the nail, by pressing against the soft skin near it, may set up great irritation. They are caused chiefly by wearing boots and shoes which are too narrow. Harm is also done by rounding the toe nails when cutting.

Keep the edge of the nail from getting embedded in the flesh by forcing a small piece of cotton wool under it. The pressure can be eased by soaking for 10 min. in very hot water, and gently scraping the centre with a sharp knife. It will be easy to raise the corner of the nail and put in the

cotton wool, which should be well pressed in under the nail. This wool must be renewed morning and night. Keep the toe nail cut square and in a perfect state of cleanliness, and wear sufficiently easy boots and shoes, and the trouble will disappear.

The Nail Brush. The choice of a nail brush ranges from a very plain, cheap article to the superior varieties, which may be regarded as a better investment.

A convenient addition is often made by fixing a thin brush of one row of short, stiff bristles flat to the back, this being helpful in cleaning the under surface of nails. A concave back may have two or three rows of knots so arranged that each row brushes a different part simultaneously. In all qualities the knots may be either punched into holes by a machine process or hand-made, the knots being drawn into position by wire.

Too hard a nail brush is deleterious to the nails. On the other hand, a brush of which the bristles have become soft can be slightly stiffened by being rinsed in cold water after each time of using. The brush should never be allowed when wet to rest on the back, as if this is done frequently the bristles are apt to rot at the root. *See Brush; Foot; Hand.*

NAINSOOK: The Material. Although a very thin cotton material, a good quality of nainsook wears fairly well for children's finer undergarments. It has not quite the strength of a cambric made with more threads in the square inch and should be washed and ironed with extra care.

NAMES: SOME LEGAL CONSIDERATIONS

With Suggestions on the Choice of Christian Names

This contribution concludes with a list of some of the more popular Christian names in use in Great Britain with the meaning of each. *See Christening; Naturalization.*

The names given to a child, together with its surname, are told to the registrar when the birth is registered, and are recorded by him. When a child is baptized, its Christian names are pronounced by the clergyman or other person officiating at the baptism, and are entered in the parish or other register. The names are thus on record for all time, and cannot legally be changed except by deed poll, although in practice many persons add an additional name to those given at baptism. This should be done cautiously, however, as it may be difficult for a man who has made himself known as Thomas Wilson Jones to prove that he is the Thomas Jones entitled to a legacy of £5,000 under an uncle's will.

Changing a Name. In Great Britain an alien is not allowed to change his name without the leave of the Home Secretary. A British subject can, however, change his name and can in effect call himself anything he pleases. This, however, is subject to the requirements of the Business Names Registration Act, which makes it compulsory for anyone who carries on a business not in his own name to register the name of the business and his own name as proprietor, and to put his real name on all his business notepaper, etc.

Subject to this, anyone who wishes to change his name may do so without any formalities at all. If, however, he wishes for any reason to put the fact on record so that it shall be easy to trace the fact that he has changed his name, the easiest way to do it is to have a deed drawn up in which he declares that he, John Scott, intends for the future to take the name of Moncrieff. This deed he can enrol at the royal courts of justice. He will be well advised also to advertise in a few leading newspapers. There is a 10s. stamp on the deed and a small fee for enrolment. Some persons, however, obtain a royal licence, the fee for which is about £40.

Wills and settlements relating to family properties sometimes contain what is called a name and arms clause. The estate is given to somebody, very often a man who has married the female heir to the property, upon the condition that he shall assume for himself and his children the name and arms of the original family. In such a case it is proper to apply for the royal licence and also to the College of Heralds for a grant of the arms.

Giving a False Name. Anyone, other than an alien and except under the Business Names Act, may call himself any name he likes, unless he assumes a name which he has never previously been known by for purposes of deceit. In such cases he may easily find himself prosecuted for obtaining money or goods by falsely pretending he is Jones when he is really Smith.

It is also an offence to give a false name on applying for a licence or publication of banns for purposes of marriage. But supposing a man for some reason of his own, as, for instance, that he does not like his father's name, chooses to call himself by another name, any legal transaction that he enters into in his adopted name is perfectly good.

No one may change his Christian name, i.e. the name in which he is baptized. But anyone can use any first name he pleases and give up using his Christian name. If within 12 months of the registration of a birth the parents wish to add a name, as, for instance, on baptism, or a mistake has been made about the name, the new name can be added by the registrar of births. But if, however, the new name is one which has been added on baptism, a certificate from the clergyman or minister must be produced. Every limited company must show in all trade circulars and letters the present Christian name and surname of each of its directors and also any former Christian names and surnames, nationality if not British, and the nationality of origin if he has changed his nationality.

Christian Names. An enormous number of Christian names, both for boys and girls, are in existence, and parents are sometimes bewildered when they have to choose a name for a child. This is especially so in modern times, because so many children are given two or three Christian names. In former days one was deemed sufficient. The choice is usually fairly easy in the case of an eldest son or daughter, for there is almost always a family association with certain names.

Long association has in practice given certain families a claim on certain names. The eldest son of the Knightleys must be Rainald, and the eldest son of the Wakes, Hereward. The Percies have a long association with Algernon, the Bridgemans with Orlando, the Curzons with Nathaniel, and the Yorkes with Philip. Parents bearing the surname of Raleigh can hardly refrain from naming a son Walter, and the Sidneys have a like affection for Philip. Some persons like to go back to a fairly remote ancestor for a name. An early Winston Churchill accounts for the names of the English politician and the American novelist.

Reasons for the Choice

Associated with this practice is that of giving children a surname as a Christian name. This is frequently the maiden name of the mother; less frequently that of some distinguished family to which the child is allied. This accounts partly for the use of Percy, Douglas, and Neville as Christian names, and for the linking of Gascoyne Cecil, Spencer Churchill, and Godolphin Osborne.

Millions of persons, however, are without known associations with the distant past, while younger sons and daughters must be named, for boys cannot, in practice, like the ex-princely family of Reuss, be all named Heinrich and then numbered.

A favourite plan is to give a child a name or names borne by a godparent, and this, a practice of great antiquity, accounts for many Christian names. Another plan is to name a child after the saint on whose day it was born. Thus a child born on Oct. 18 will be named Luke if a boy and Lucy if a

girl. A boy born on Nov. 30 will be named Andrew. Associated with this is the practice of naming a boy Noel if born at Christmas, and a girl May or June if born in one of these months.

Fashion, however, plays a large part in the naming of children. Sometimes it shows itself in vagaries which cannot always be explained. A name, Joan or Alan, suddenly becomes popular. At other times the fashion can be traced, and in this royalty plays a large part. This accounts for the popularity of George and Charlotte for a century after the marriage of George III; for the later vogue which Albert enjoyed, and the still later one of David used in the royal family for the Prince of Wales.

Great men, too, leave their mark on Christian names. The vogue which Arnold and Stanley enjoyed in the 19th century was due to the fame of the schoolmaster of Rugby and the explorer of Africa. Gordon is another case in point, while later Peter became popular owing to the play *Peter Pan*. The Great War led to a demand for names borne by the soldiers and sailors who distinguished themselves during that period.

The most popular Christian names, however, are still the simple ones originally borne by the saints, John and Mary, Margaret and Thomas, for example. This is due perhaps, less to their religious associations than to the fact that they are found in almost every family circle, and are, therefore, sure to be chosen very frequently. Allied to this are the patriotic associations which are responsible for the frequency of Robert and Andrew in Scotland and Patrick in Ireland.

One class of girls' names consists of those which are formed from masculine ones, thus following a Roman model. These include the many feminines of John—Joanna, Jane, Joan, and others—while Philippa, Josephine, and Wilhelmina are other examples. In this way girls can perpetuate the name of a father or a distinguished member of the family. Another class of names for girls is taken from flowers and plants, Rose, Lily, and Ivy, for instance, the one chosen being perhaps the mother's favourite flower. Another draws upon the various Christian and other virtues, whether in English, as Hope and Faith, or in Latin, as Vera.

In choosing a name it is well to consider whether the child can in this way be linked to the family to which he or she belongs by blood. On the other hand, this should not be carried too far and relationships with great families assumed without examination. If the names of the near relations, parents, and grandparents are already taken by elder brothers and sisters, a search may be made for more distant ancestors.

A consideration of importance is euphony. Preference should be given to a name that sounds well when linked with other Christian names and with the surname. Henry Higgins or Robert Robertson do not sound particularly well; still less so does Montagu Tigg. Combinations such as Victoria Alexandra and Irene Phyllis also lack euphony. On the contrary, Mary Morrison and John Lindley have simple dignity. Algernon and Reginald go well with some surnames but ill with others, and the same can be said of many other names. In some cases the obstacle to euphony is in the surname, and the choice of a Christian name should avoid accentuating this. Parents and godparents should also avoid giving children names the initials of which may form an unpleasant word. For instance, a girl whose surname is Dawson or Davis should not be named Margaret Alice, nor a boy with the surname of Gillespie be christened Douglas Orme.

Below we give a list of many of the names in general use in the British Isles for both girls and boys, with the meaning of each.

Names for Girls

Ada—rich gift	Iris—a flower
Agnes—pure (Gr.)	Jane, Janet, Jean,
Alice—noble cheer	Jessie or Joan—fem. of John
Amy—beloved	Joyce—merry
Ann or Anne—grace (Heb.)	Kate, Katherine. See Catherine
Barbara—foreign	Kathleen—Irish form of Catherine
Beatrice—blessed	Laura—laurel (Lat.)
Bertha—bright	Lily or Lilian—lily
Beryl—soothsayer	Mabel—lovable
Betty or Bessy—dim. of Elizabeth	Madge—dim. of Margaret
Blanche—white	Margaret—pearl
Brenda—sword	Marjorie or Marjory—form of Margaret
Bridget—strength	Marion—form of Mary
Caroline—fem. of Charles	Mary—bitterness
Catherine—pure	Matilda—mighty battle maiden
Charlotte—fem. of Charles	Maud or Maude—form of Matilda
Christine—Christian	May—dim. of Mary or Margaret
Clara—bright	Mildred—gently strict
Constance—faithful	Millicent—strong in work
Daisy—pearl (Persian)	Muriel—myrrh
Diana—goddess	Nancy—grace (Heb.)
Dorothy or Dora—gift of God	Nora—dim. of Honoria or Eleanor
Edith—rich gift	Olga—holy or light
Eileen—Irish form of Helen	Olive—fem. of Oliver
Elizabeth—oath of God	Rhoda—rose (Gr.)
Ellen—form of Helen	Rosalind, Rose or Rosa)—rose
Elsie—dim. of Elizabeth	Ruth—friend (Heb.)
Emily—crafty	Sarah or Sara—princess (Heb.)
Emma—industrious	Sheila—blind (Lat.)
Esther—star (Assyrian)	Sophia or Sophie—wisdom
Ethel—noble	Stella—star
Eva, Eve or Evelyn—life (Heb.)	Susan—lily (Heb.)
Fanny—free (from Frances)	Sybil or Sybyl—prophetess
Florence—flowering	Ursula—little bear
Frances—free	Vera—truth
Geraldine—firm spear (fem. of Gerald)	Violet—violet
Gertrude—spear maiden	Winifred—friend of peace
Gladys—lame (Welsh form of Claudia)	
Grace—thanksgiving	
Gwendolen—white bow	
Hannah—grace (Heb.)	
Harriet—home ruler	
Helen—torch (Gr.)	
Hilda—battle maiden	
Irene—peace	

Names for Boys

Adam — man (Heb.)	Herbert — bright warrior
Adrian — from Adria (the town)	Humphrey — support of peace
Alan or Allan — cheerful	Ian — Gaelic form of John
Albert — nobly bright	Ivan — Russian form of John
Alexander — helper of men (Gr.)	James or Jacob — supplanter (Heb.)
Alfred — wise in counsel	John — God's gift (Heb.)
Algernon — whiskered	Joseph — increase (Heb.)
Andrew — manly (Gr.)	Julian or Julius — downy beard
Angus — great virtue (Celt)	Lawrence — laurel crowned
Anthony or Antony — worthy of praise	Leonard — lion strong
Archibald — holy prince	Leopold — prince of the people
Arnold — eagle strong	Lewis — famous in war
Arthur — noble	Lionel — young lion
Basil — kingly (Gr.)	Llewellyn — lion like
Bernard — bear-like	Luke — born at daybreak
Bertram — bright raven	Malcolm — servant of Columbia
Brian — strong (Celt)	Marcus — English variant of Mark
Cecil — blind	Mark — sprung from Mars
Charles — man (Tent.)	Marmaduke — sea leader (Celt)
Christopher — Christ bearer	Martin — of Mars, warlike
Clarence — famous or bright	Matthew — God's gift
Claud or Claude — lame	Maurice — Moorish (Lat.)
Cuthbert — great splendour	Michael — like God (Heb.)
Cyril — lordly	Nicholas — victory of the people (Gr.)
David — beloved (Heb.)	Noel — Christmas
Denis or Denys or Dennis — from Dionysos (Gr.)	Norman — Northman
Donald — proud chief	Oliver — olive tree
Douglas — dark water	Oscar — bounding warrior
Duncan — brown chief	Oswald — heavenly power
Edgar — rich spear	Owen — young warrior (Celt)
Edmund — great protection	Patrick — noble (Lat.)
Edward — rich guard	Paul — small (Lat.)
Eric — powerful	Percy or Percival — meaning doubtful
Ernest — earnest	Peter — stone or rock
Evan — young warrior	Philip — lover of horses
Francis or Frank — free	Ralph or Randolph — wolf of fame
Frederick — peaceful ruler	Raymond — wise protection
Geoffrey — God's peace	Reginald — great sense
George — husbandman	Richard — stern king
Gerald — firm spear	Robert or Robin — bright in fame
Godfrey — God's peace	Roger — spear of fame
Guy — sense (Celt)	Ronald — great sense
Harold — warrior might	Rowland or Roland — fame of the land
Harry or Henry — home ruler	Rupert — form of Robert

Samuel—asked of God (Heb.)

Simon—obedient (Heb.)

Stanley—a place name

Stephen—crown (Gr.)

Theodore—gift of God (Gr.)

Thomas—twin

Timothy—honoured by God (Lat.)

Victor—conqueror (Lat.)

Vincent—conquering (Lat.)

Vivian—lively

Walter—great warrior

Wilfred—great peace

William—helmet of resolution

NAME PLATES FOR PRIVATE HOUSES

Graceful Styles and Novel Ideas for Town and Country Homes

Several ways of making name plates are suggested in this article and practical directions are given. See also the articles on Chip Carving; Lead Art Craft; Lettering; Repoussé Work; Stencilling; Woodcarving

While the chief use of a name plate is to indicate the house as a guide to visitors and tradesmen, the decorative side of this accessory need not be overlooked. In choosing a style the type of house will be borne in mind. What would look pretentious on a cottage porch may be quite in keeping with the entrance of a large house on the outskirts of a town, and what would be somewhat aggressive on a terrace door, will be pleasantly arresting on that of a seaside bungalow.

In town streets of any length it is always advisable to have a number as well as a name on the gate or door. There is nothing so irritating for those visiting a house for the first time as the search for a name only, without the assistance of a number, in a row of villas which all look alike. It is also a convenience where the front door is only a little way from the gate, and the latter does not mask the former, if name and number are repeated on the door. Taxi-drivers and tradesmen frequently only look at doors in such cases. At night the name on the door can be lighted by a lantern fitting, or, where there is a porch by a lighting fixture in the roof of this. If there is a glass fanlight the number can be written on the middle pane, or better still for visibility, on a glass lamp projecting from it.

For houses where the front door is concealed behind a high gate and brick walls the name plate can be placed symmetrically to balance the letter box or number, or can be affixed to the gate where this is of wrought iron, the plate taking the form of a circular iron disk with the name in neat lettering.

As a general rule, in choosing a name plate for a town house the simpler it is the better.

Name Plate. Fig. 1. Name plate for a town house which, by means of plain but dignified lettering, does not detract from the beautiful design of the doorway.

The first illustration shows an example of a suitably designed and perfectly placed name plate for a decorative door. For the 18th century style of entrance the name plate looks best either just above the door, or on the upper part of the door itself when the panelling permits. Displays of name and number on the walls at the side of the door, or painted on the columns, when such an entrance possesses these, take away from the beauty of the doorway. Any exaggerated type of lettering would be disfiguring.

Name Plate. Fig. 2. Name plate on a sign-holder for a picturesque house or Tudor cottage. The design is cut out of wrought iron plate. (Courtesy of Capt. G. C. Clark)

In the country, signposts and wrought iron brackets are sometimes utilized to carry more ornamental name plates. Such a style can be delightful for a picturesque stone-tiled house or a thatched cottage, as shown in Fig. 2. The name plate illustrated is cut out of wrought iron plate. It will never wear out, warp or crack, and such plates can be obtained in a variety of designs. Painted signboards are suitable and gay for a seaside bungalow, if carried out in a modern design descriptive of the title, and have the advantage of being little likely to be passed by unnoticed when suspended from a wrought iron bracket. As the colours used to paint such a sign will be exposed to the weather, paints with a hard glossy surface should be chosen.

Suitable for a sedate little house, either in town or in country village, is the name plate shown in Fig. 3, with its white painted wooden letters on a base which matches the door in colour. Perfectly simple in form, it is the position of the plate which attracts the eye in this case and is far more effective placed on the wall than on the door itself. On a chestnut pale gateway, or any rustic entrance, the incised wood name plate illustrated in Fig. 4 is the most suitable.

Plate. Fig. 3. Suitable for a small house standing back from the street, the colour contrast of the unobtrusive name plate catches the eye.

Constructive Details. For a house the size of a name plate varies not only in accordance with the amount of the lettering thereon, but also with the style chosen. The smallest size is about 10 by 3 in. Brass plates used for business or professional purposes vary from 8 by 5 in. to 18 by 12 in. on the average, and are engraved with one line or two line lettering in sizes from $\frac{1}{2}$ in. to $3\frac{1}{2}$ in. Name plates are also employed indoors for various purposes, to distinguish particular rooms, or for drawer fronts and boxes.

Name plates can be made up from various materials, the choice being governed to some extent by considerations of durability and appearance. For exterior work oak, copper, brass, and lead are good both on the score of durability and of general suitability. Ornamentation may be effected by various processes. In the case of a wooden name plate, the letters may be incised as in Fig. 4, or may be raised by carving. Another method is to cut the letters to shape from comparatively thin material, and apply them to the plate. Such a plate is seen in Fig. 3. Here the wooden letters are painted, but wooden letters may be left in the natural colour and glued and tacked to a dark stained base, or the letters might be dark and the base light. Poker work and chip carving are applicable to wooden plates; stencilling and painting in colours are also employed.

Fig. 4. Incised lettering on a wooden base forms a simple but effective name plate for the chestnut pale gateway of the cottage type of residence. (Humphrey & Vera Joel)

A name plate may be made in wrought iron. Pierced metal, and applied metal letters are other processes. For brass and copper, engraving is generally adopted. Leaded letters applied on glass is another suitable method of making a name plate, which is described in the article on Lead Art Craft.

Wooden and lead letters can be obtained in various sizes. All that has to be done with these is to get a baseboard, say a piece of oak, and clean it up smooth in the vice, and mould or otherwise decorate the edges. The lettering should be set up by temporarily fixing a batten towards the lower part of the plate and placing the separate letters upon it, arranging them until the space between them is

accurate and pleasing to the eye, noting each of the characters, marking their position on the baseboard, glueing and pinning if necessary. When dry, the edges of the letters can be modelled or left plain, and the background coloured, oiled or polished. If the name plate is not exposed to the weather, the letters could be cut from good plywood.

In making a repoussé name plate the design should be drawn and a tracing made. The latter is transferred in reverse to the back of the metal plate, which is then mounted on to a cement block and the work of embossing proceeded with. The article on Repoussé work should be referred to.

A simple way to make a name plate for a protected doorway is to build the letters up from thin strips of wood, such as can be obtained for strip work. The lettering is marked out on the baseboard, and pieces of the wood strip cut off to the right length. These have then to be glued and pinned to the baseboard. The construction is illustrated in Figs. 5 and 6, which show the baseboard prepared, the method of applying the letters when cut to shape, and also the building up of others. Curved or rounded letters are represented by short straight pieces; but if these are carefully cut, they have a certain quaint charm.

Name Plate. Fig. 5. Building up wooden letters on a base. Fig. 6. Fixing the letters by means of glue.

NANDINA. The flowering shrub *Nandina domestica* is not hardy, and therefore requires to be planted against a sunny wall, even in southern and western districts. It has large decorative leaves and blush-coloured flowers in summer and is suited by ordinary soil.

NANKEEN. Now a yellow or drab pocketing or corset twill, nankeen was originally handmade in China from cotton of a natural yellow colour, and was used for breeches and men's waistcoats. In order to secure good nankeen pocketing material ask for stout double-warp twill. Nankeen is best laundered by immersing it in cold salted water for 24 hours before washing and hanging it up to dry without wringing it.

NANKEEN LILY. This is the popular name of the beautiful hardy lily (*Lilium testaceum*) that owes its name to its nankeen-yellow flowers. *See* Lily.

NAP: The Game. Nap or Napoleon is a card game for any number of players, but it is best played by five or six. An ordinary pack of 52 cards is used, and the cards rank as in whist.

In the simple game of nap each player is dealt five cards, and the eldest hand has the right of first call, the call passing as usual to the left. Each player calls according to the number of tricks he can make up to five tricks, or nap. Any player who cannot beat the previous player's call says 'pass.' Whoever makes the highest call has the privilege of leading, and all the other players play against him. The first card led by the player making the highest call makes the trump suit. Players must follow suit if possible, but if not may trump as desired. They are not bound to try to win a trick. The winner of each trick leads for the next.

The caller is only paid for the number of tricks he declared, though he may make one or two more. Similarly, if he fails to make the number of tricks nominated, he only pays on the amount of his call. The game is usually played for money, and payment given for each trick. Thus at halfpenny nap a player will receive 1½ d. from every other player for a successful call of three, and pay out 1½ d. to every player if he fails to make his call. Usually, on the Napoleon call, he receives double stakes for winning, i.e. 5d. at halfpenny nap, but only pays out normal stakes, 2½d., if he loses. Often even money is paid out on this call, i. e. 6d. and 3d. Respectively.

Variations of the Game. The above is the ordinary game of nap. In the first variation there is a call known as Wellington. By this call the player undertakes not only to take all five tricks, but at double the usual stakes. Wellington can only be called if nap has already been called by a previous player.

An adaptation from solo whist is the call misery, by which a player undertakes to lose all five tricks. There are, of course, no trumps, and the call ranks between the ordinary calls of three and four tricks, and is paid for as for a call of three.

Sir Garnet is an extra hand of five cards dealt face downwards on the table. Each player in turn has the privilege of taking the hand up and combining it with his own, throwing away the five cards he does not want, but any player who does this must declare nap.

NAP CLOTH. An old favourite for winter coats, woollen nap cloth is warm without being unduly heavy. The nap is produced by a process of rubbing, and the motions of the rubbing surfaces control the pattern. Besides the pimples, large or small, of Petersham nap there are also wavy naps, known sometimes as Elysians or Witney naps.

The weakness of nap cloth is that the surface rubs smooth at the points of most friction, and in the cheapest qualities this defect soon appears. Nap cloths are made at widely differing prices, and the best are much the most satisfactory in the end.

NAPHTHA. The liquid product obtained by distilling wood or paraffin is known as wood naphtha or mineral naphtha. Wood naphtha has solvent properties similar to methylated spirit; it is used by French polishers as a solvent for shellac.

Mineral naphtha is not so volatile as petrol, but it possesses similar cleansing properties, and can be employed for removing grease and oil from fabrics. Allied to it is the solvent naphtha obtained from coal tar of the gas works. This form is employed as a solvent for india-rubber and in the manufacture of rubber waterproof articles.

NAPHTHALENE. Obtained by distillation from coal tar, naphthalene is a white crystalline solid with a peculiar odour, and when cast into globular forms it is known, but not correctly, as carbon or camphor balls. It is used principally as a disinfectant and insecticide.

Placed among furs and woollen goods stored away during the summer, the odour acts as a deterrent of moths. Before storing the furs they should be enclosed in airtight bags with a few lumps of naphthalene. The odour which is communicated to the furs is removed by hanging the furs or garments in the air for some time, preferably in the sun.

NAPKIN: For the Table. The ordinary fabric for table napkins is damask linen. If a cloth is in use the napkins should match in pattern or style. Coloured damask napkins are obtainable in sets which include a tablecloth. Coloured plain linen napkins and cloths are easily made at home with hemstitched borders. Breakfast napkins can be of checked linen or gingham, with or without a border of plain colour, to correspond with the breakfast cloth. An advantage in using the fancy style of napkins is that they are more easily laundered than damask ones, which require careful starching to bring out the glossy beauty of the fabric.

For use with decorative cloths and luncheon sets, napkins may be embroidered or lace edged to match. As a change from the more ordinary bought varieties in damask, fancy napkins made at home to suit different table sets are charming accessories to a well-laid meal. If damask napkins are bought they should be of good quality, because inferior weaves will not stand the frequent laundering required and are therefore not really an economy. Embroidered monograms or initials look well on good linen napkins of all kinds.

In a household the supply of napkins should be at the rate of at least four for each person with an allowance for visitors according to probable requirements. When purchasing napkins which are sometimes stocked un-hemmed, these will be hemmed free of charge at a good shop, and also, in common with other house linen, will be

marked free of charge.

When making dinner napkins an average size is 24 in. square; but smaller sizes may be made for breakfast or fancy napkins. Those used for afternoon tea may be 12 in. square and should be very

daintily scalloped or lace edged to suit the cloth or style of the tea service. Beautiful sets can be embroidered in Renaissance or Richelieu cut work, less formal ones with cross-stitch in colours.

Paper serviettes sometimes do duty for napkins at informal meals, picnics, children's parties and in the nursery or schoolroom. Coloured or patterned, such serviettes may be purchased in packets at most stationers. Suitable designs are obtainable for Christmas parties, and colours should be selected to enhance the bright appearance of the table and harmonize with floral decorations of the room. The advantage of paper serviettes on such occasions is that they can be thrown away after each meal and thus save laundry work. For children plain white should be in ordinary use as bright colours on paper are apt to run.

Folding Napkins. For the family table the simplest methods of folding are most suitable, and where napkins are in use for several days' meals, a ring should be provided for each person. When entertaining and embroidered or lace-trimmed napkins are in use they are merely folded flatly into neat squares or oblongs and laid for each person on the bread plate on the left to balance the glasses, or between the knives and forks. Should the hostess prefer to fold starched napkins more elaborately two methods are illustrated by diagrams.

The method of folding that produces the roll-holder seen in Fig. 5 consists in laying the napkin flat on the table and folding it carefully in three so as to make two creases. This will give the result shown in Fig. 1. Then fold lengthwise in two so as to make a crease, and turn it back again. This crease is represented by the dotted line. From the middle, fold over the right side as seen in Fig. 2; then turn the napkin over and do the same thing on the other side. This produces Fig. 3. Turn the napkin over again, fold up the bottom ends, Fig. 4, and then complete the shape by taking the bottom corners and inserting them well into each other.

The bishop style is achieved by laying the napkin flat on the table and bringing the bottom edge up in one fold, making the size of the whole one-third less. A reference to Fig. 6 will make the process clearer. Fold the single layer of the upper part in between the two layers of the lower half, making three thicknesses, as in Fig 7, and then, by creasing over, find the centre of Fig. 7, and fold in the edges at each side to meet this line, Fig. 8.

The top right-hand corner must now be brought down, and the bottom left-hand corner up, as in Fig. 9. Turn this over and lay it on the table according to Fig. 10, and fold the top over to meet the bottom, Fig. 11. Turn this over to get Fig. 12. The dotted lines show the fold on which the right-hand part must be brought over, the angle E being tucked under the folds. This gives Fig. 13. Turn the whole over again to produce Fig. 14. Tuck in the right-hand corner of this exactly as in the last process and the finished shape, Fig. 15, will result. This must be opened out by pushing the fingers into the opening underneath. *See Drawn Thread Work; Embroidery; Hemstitch; Linen; Table Laying.*

Napkin. Method of making the bishop style. Fig. 6. Napkin with one-third of width turned up. Fig. 7. Upper single layer folded between lower layers. Fig. 8. Three-fold length with ends touching. Fig. 9. Top right and bottom left corners turned to centre. Fig. 10. Napkin turned over. Fig. 11. Top folded over to bottom. Fig. 12. Turned over, dotted lines showing fold to which the point E must come. Fig. 13. Point E tucked in. Fig. 14. Napkin turned over again. Fig. 15. Finished shape resulting from other point being tucked in.

Napkin Rings. The most important point about a napkin ring is that it should be individual, so that napkins shall not get mixed up when laying the table. Various devices are adopted for distinguishing rings, the simplest being to have an initial or monogram engraved, carved, or painted on them. Sometimes they are numbered, or, in the case of children, wooden rings are painted with some simple design and with the child's name in block letters. More elaborate enamelled rings may have a different design on each one of a set of rings, or they may have the same design but a different colour for the background.

Simple but pretty rings are made of strips of white linen, cut with one pointed end and just long enough to go round the napkin when rolled up. Each ring is fastened by means of a loop and button, and has a different flower, fruit or bird design embroidered on it. A tiny single hem is turned up all round and the edges are buttonholed.

Wooden rings can be obtained for enamelling or painting. Having sandpapered the ring, the selected design may be stencilled and painted in oil colours, afterwards varnishing the ring. Bronze colours may be used or the ring may be decorated with Chinese lacquer work. Metal rings can be ornamented by piercing or by repoussé work. Instructions for carrying out these processes will be found under their own headings.

Making the Rings. A pleasing type of ring takes the form of a hexagon and can be made from brass, pewter, copper or silver. A set of such rings could be worked out using a different predominant colour for the background in each case.

Suitable proportions are given in Fig. 1, and it will be seen that in the first stages the metal is simply a strip. It should be perfectly flat and accurately marked out where the bends are to be made.

The next stage is the bending of the strip, as shown in Fig. 2, to the correct angle. This must be bent very carefully, otherwise the ring will be unequal and look very bad. A large size hexagon nut such as is used by engineers for large-size bolts is very useful as a guide in bending to the proper angle. The two ends of the ring may either be butted, and silver soldered, or made slightly to overlap, and then soft soldered, as in Fig. 3. Allowance for the jointing must be made when fixing the proportions of the strip. Having soldered the joint, all six faces should be cleaned up with fine emery paper and neatly grained. Then the finest grain emery paper should be struck across the surface in one direction only until the whole exhibits a uniform surface. The next step is to decide upon a suitable design, such as that shown in Fig. 1, and carry it out with some of the specially

prepared enamel as described in lacquer work on metal, or with the regulation stove enamel. The paint is applied with a very small brush in the manner illustrated in Fig. 4, and naturally calls for the greatest care if a satisfactory result is to be achieved. When this part of the work has been finished, the ring must be dipped in lacquer varnish in order to preserve it from the atmosphere. The result is seen in Fig 5. *See* Embroidery; Enamelling; Lacquer Work; Piercing; Repoussé Work; Stencilling, etc.

Fig. 2. Showing how to bend the metal strip on a large hexagonal nut held in the vice. Fig. 3. Soldering the ends together. Fig. 4. Application of prepared enamels with a small brush. Fig. 5. The finished ring.

NAPKIN: For the Baby. Turkish towelling is the best material to use for infants' napkins, owing to its absorbent quality. The squares may be bought separately or the material may be purchased by the yard and cut up and hemmed at home. *See* Baby.

NAPLES CAKE. This is a mixture which is baked in six rounds, each rather less than $\frac{1}{2}$ in. thick. When the layers are cooked and cold they are piled one on the top of the other with a filling of preserve between them. The preserve must be rich and should be passed through a hair sieve, or minced nuts and whipped cream may be used as a filling.

Naples Cake, consisting of layers of cake with fillings of preserve, the top layer being iced.

The top of the cake is decorated with an even coating of

almond icing and finished with sugar icing and a border of crystallized fruits or flowers, as shown in the illustration. For the mixture 1 lb. fine flour will be required, also $\frac{1}{2}$ lb. butter, $\frac{1}{2}$ lb. castor sugar, the grated rind of a lemon, one tea-spoonful orange-flower water, 7 oz. ground sweet almonds, and 1 oz. pounded bitter almonds. Rub the butter into the flour, add the other dry ingredients with a pinch of salt, mix well, and then make into a paste with the yolks of 4 eggs.

The mixture is made up into rounds and baked in a slow oven till crisp and firm and about the colour of shortbread. Small flan hoops may be used to keep the rounds in shape. *See Almond Paste; Icing.*

NARCISSUS. This is the most popular of all the spring-flowering bulbs; there are many types or classes and numerous varieties of each type. The classification is based on the length of the cup or crown, the central part of the flower, in comparison with the outer part called the perianth.

The first class or group is the trumpet, in which the trumpet is as long as or longer than the perianth. Varieties in this group are usually called daffodils. Some of the best are King Alfred, Emperor, Empress, Horsfieldii, Glory of Leiden and Mme. de Graaff.

The second group of incomparabilis or chalice-cupped narcissi consists of flowers in which the cup is not less than one-third the length of the perianth. Popular varieties are Sir Watkin, Beauty, Gloria Mundi, Croesus and Golden Frilled.

In the Barri or star narcissi the cup is less than one-third as long as the perianth. Favourite varieties are Barri conspicuus, Albatross, Red Beacon and Seagull.

The Leedsii narcissi are beautiful flowers with pale perianth and cup. Mrs. Langtry, Waterwitch, Duchess of Westminster and White Lady are well known varieties. Then there are the poet's narcissi, jonquils, double daffodils, and various species or wild types, among which are many charming miniatures.

Narcissus. Blooms of the favourite variety, Barri conspicuus.

In recent years innumerable new and beautiful varieties have been raised; some of them cost as much as 30 guineas a bulb. The greatest advance has been in the intense and brilliant colouring of the cup or crown, which is in striking contrast with the pale or yellow perianth. One or two new trumpet daffodils are of pale salmon colouring, and no doubt as the years pass this will be intensified.

Narcissi thrive in ordinary soil, but flourish best in that of loamy character, which does not dry out in summer. The bulbs should be planted in September-October, about 3 in. deep. They are invaluable in spring flower beds, in the herbaceous border and shrubbery, and look particularly well in grass. If grown in grassland the grass must

not be cut until the leaves have died down. Bonemeal, to the amount of 2 oz. for every square yard, is the best fertilizer to mix with the soil. The bulbs may remain undisturbed for years, until they become crowded; they ought then to be lifted in July, separated, and replanted at once or in early autumn.

In Pots and Bowls. Daffodils and narcissi make admirable pot plants for the greenhouse in early spring. The bulbs should be potted in September-October, in loamy soil, placed out of doors and covered with old sifted ashes. In six or eight weeks they will be well rooted and should be taken out, shaded for a few days and then placed under glass. After the flowers are over the bulbs may be planted out.

Narcissi and daffodils do well in bowls of fibre in the home; they should be kept in a cool, dark place for six weeks before being brought to the light. The bunch-flowered narcissi may be grown in bowls of fibre or in bowls of pebbles and water.

A few of the most beautiful of the miniature kinds, suitable for well-drained soil in the rock garden, are angel's tears daffodil (*Narcissus triandrus*), hoop petticoat daffodil (*Narcissus bulbocodium*), and *Narcissus cyclamineus*. These are also admirable bulbs to grow in pots in the unheated greenhouse.

Pests of the Bulb. The chief pest is the bulb mite. The simple remedy is to dust the affected part with flowers of sulphur. To bulbs in the ground the application of a tepid solution of sulphide of potassium, 1 lb. to a quart, is recommended.

The narcissus fly sometimes affects the bulbs. The presence of the fly can be detected by pinching the neck of the bulb. If the neck feels soft, the bulb should be cut open at the top and the eggs taken out and burnt. There is, of course, a risk that the bulb will be killed also, but this is a risk that is necessary to run for the sake of the others. It has been found by experiment that immersion of bulbs in hot water for one hour at a temperature of 110° F. is fatal to the larvae of narcissus flies. This investigation has been carried further, and developed also in the direction of eelworm control. As the latter is the more serious pest and most difficult to kill, the treatment found efficient for its eradication may be adopted as a combined measure for both eelworm and narcissus fly larvae. This consists in soaking the bulbs at a temperature of 110° F. for three hours. *See* Bulb; Daffodil; Flower Garden; Jonquil, etc.

NARTHECIUM. A hardy herbaceous, iris-like plant, *Narthecium ossifragum*, the bog asphodel, is suitable for moist soil by the side of ponds. Planting is done in spring or autumn in boggy peat, or ordinary soil mixed with sand and leaf-mould. Plants are best propagated by division in spring or autumn. *Narthecium* grows 10 in. high and bears yellow flowers during July.

NASAL CATARRH. Inflammation of the lining membrane of the nose is usually accompanied by a mucous discharge, and hence is known as catarrh. This may occur in an acute or chronic form, and be due to such irritants as dust, snuff, tobacco smoke, or other irritating vapours, or to microbic infection, the most frequent example of the latter being the common cold.

In acute cases smoking should be discontinued, the room should be kept at an even temperature, though well ventilated, while quinine and other remedies prove useful when given inwardly. A chronic nasal discharge calls for douching or spraying, and probably surgical treatment of sources of irritation within the nose. *See* Cold; Nose.

Nasal Douche. *See* Douche.

Nasturtium. Brilliantly coloured flowers of the climbing and border plant.

NASTURTIUM. The most important of the true nasturtiums is the watercress, but the name is commonly used to describe the annual tropaeolums, of which there are both climbing and low growing varieties. The former are useful for covering trellises, fences and other supports in summer; the dwarf varieties are invaluable for poor soil and dry sunny places. Seeds are sown out of doors in April, where the

plants are to bloom. There are numerous varieties with blooms in yellow, orange, crimson and other showy colours. See *Tropaeolum*.

Nasturtium Culture. 1. Seeds correctly sown. 2. Seedlings ready for planting out. 3. Support for climbers. 4. Planting on wall: a, boards; b, soil. 5 and 6. Tubers. 7. Tuber planted with room for top dressing. 8. How to curl roots round pot. 9. Roots curled and top dressing (c) added.

Uses of the Plant. Both the flowers and leaves of the nasturtium plant are used for salad making, and as a filling for sandwiches, while the seeds are pickled as a substitute for capers. The flowers, because of their bright colour, also form an excellent garnish.

Nasturtium Pickle. The seeds required for making nasturtium pickle should be gathered ripe in dry weather, as any dampness may spoil the pickle. Spread the seeds in one layer over a large dish, leave them for 1 or 2 days, and turn them about each day. Then put them into a jar and sprinkle with salt.

To prepare the pickling vinegar, simmer for 40 min. some white wine vinegar with garlic and spice, allowing 1 clove of garlic, 1 chopped shallot, and $\frac{1}{2}$ oz. mixed allspice, cloves, and mace, to each quart of vinegar. The spices are tied in muslin and afterwards removed.

When the vinegar has simmered the allotted time, give it a quick boil up and pour it over the nasturtiums. Let all go quite cold before bottling the pickles, and remove the spices. Keep the pickle 4 months before using.

Nasturtium Vinegar. To make nasturtium vinegar, fill a wide-mouthed bottle with some full-blown nasturtium flowers, add $\frac{1}{2}$ a clove of garlic and a finely-chopped shallot, and pour over them as much vinegar as the bottle will hold. Let the whole stand for two months before rubbing it through a fine sieve; then add a little cayenne pepper and salt, and keep the vinegar corked until required. *See* Vinegar.

NATIONALITY. In Great Britain nationality depends in the first place upon birth. A person born within the British Dominions is of British nationality, but, subject to the rule that if he be born of a father who is an alien, he can, when he is 21, or as soon thereafter as possible, renounce his British nationality and take that of his father.

In some countries a child takes the nationality of the father wherever the birth takes place, so that it is quite possible for a boy to be English by English law and German by German law. It is also possible, according to recent English decisions, for a person to have no nationality at all. If, according to the law of the state of which he was a natural citizen, he was entitled to renounce that nationality and he has renounced it, and has not acquired another nationality, then he is not a national of any country for the time being.

A woman who marries an alien does not lose her British nationality unless she acquires her husband's nationality, by his country's law, on the marriage. *See* Naturalization.

NATIONAL MARK. This consists of a map of England and Wales in silhouette, with the words 'produce of England and Wales' inscribed in a circle placed centrally in the map within which circle is a design representing the Union Jack. Its object is to secure for home-grown meat, poultry, fruits, vegetables, eggs, canned goods, etc., the same commercial advantages as are at present enjoyed by imported supplies. Among foodstuffs to which the scheme is applied are eggs, tomatoes, apples, pears, broccoli, wheat flour, canned peas, fruits, cider, etc.

The packer is bound to state on the label of the package the variety of the article, his own name or identification mark, the grade, the date of the packing, and either the weight or the number of the contents. The advantage of this label is that it gives the purchaser all the information required, and it is not even necessary for him to see the contents of an unopened package. In 1931 a shop for the sale of national mark goods was opened in London.

NATURAL COLOUR. Any fabric which has not been treated with a dye is said to be of natural colour, but the term is applied particularly to woollen underclothes of a grey or biscuit colour, and to shantung silks. One advantage of buying natural-coloured clothes is that they cannot fade through exposure to the sun or lose their colour in the wash, as most dyed materials may do.

The term natural colour is also applied to flesh-tinted face powders.

NATURALIZATION: The Law. Naturalization takes place where a person is made a British subject by a certificate of the home secretary. A natural-born British subject is one born within his Majesty's dominions and allegiance; one born out of British dominions, but whose father was at the time of the child's birth a British subject, either by birth or naturalization; or one born on board a British ship in foreign or territorial waters.

The child of a British subject is to be deemed to have been born within his Majesty's allegiance if born in a place where by treaty or otherwise his Majesty exercises dominion over British subjects, e.g. if born in Turkey before the abolition of the capitulations by the Treaty of Lausanne, or in one of the independent native states where the British are not subject to the local native courts. A child, born on a foreign ship in British territorial waters is not born British by reason of that fact.

An alien who wishes to become naturalized must make application to the Home Office in writing, and must show that he has either resided in British dominions for not less than 5 years, or been in the service of the crown for not less than 5 years during the 8 years preceding the application. The residence required of not less than 5 years must not be less than 1 year immediately preceding the application, and 4 years in any British dominion, the whole 5 years to be within the 8 years preceding the application. The applicant must show that he is of good character, and has an adequate knowledge of the English language. Further, he must satisfy the Home Office that he intends to reside permanently in a British dominion, or else to enter or continue in the service of the crown.

Change of Natonality. When a British woman marries an alien she loses her British nationality except when the marriage does not confer on her her husband's nationality. On her husband's death or on divorce she may obtain a certificate of naturalization without any requirements as to residence; he may also dispense with the residential qualification in other special cases to the extent of not requiring that the 4 years' residence or 5 years' service shall have been within the 8 years preceding the application for naturalization.

An applicant who bases his certificate on service under the crown should procure a certificate from the department under which he served (e.g. foreign office, colonial office, etc.). The home secretary may also treat a period spent in the service of the crown abroad as equivalent to a period of residence in Great Britain. If a person applying for naturalization has minor children not British born, he may apply to have them included in the certificate. If they are so included they become British, but on attaining majority may make a declaration of alienage.

When doubts have been raised the home secretary may grant a certificate to anyone upon whose British nationality questions have arisen. This certificate must state that it is given to resolve doubts, and is not an admission by the holder of a certificate that he ever was an alien.

When the home secretary is satisfied that a certificate of naturalization has been obtained by false representations or fraud, or suppression of material facts, or that the person in question has shown himself by act or speech to be disaffected or disloyal to the crown, the certificate is to be revoked.

In addition, the certificate is to be revoked if the home secretary is satisfied that the holder has during any war unlawfully traded or communicated with the enemy, or with a subject of an enemy state, or has knowingly engaged or assisted in any business which might help the enemy. A certificate must also be revoked if it is shown that the holder was not of good character at the date of its grant, or that since the grant of the certificate he has for seven years resided out of the British dominions, except in the service of the crown or as the accredited representative of some British subject or firm. The home secretary shall also revoke the certificate where the holder within 5 years of the date thereof has been sentenced by any court in a British dominion to imprisonment for not less than 12 months, or penal servitude, or a fine of not less than £100.

The consequences of revocation are that the person becomes an alien again, and the home secretary may order that his wife and children shall also cease to be British subjects. In default of a special order the wife and children remain British. But such an order is not to be made against a woman who was by birth a British subject, unless she personally has been guilty of such conduct as would have been sufficient to justify revocation if she had held a certificate. *See Name.*

NAUSEA: How to Treat. The sensation of sickness or an inclination to vomit is denoted by the term nausea; there may be retching at the same time. The most frequent causes are sea-sickness; food not easily digested or even poisonous; pregnancy (morning sickness); offensive smells or tastes; poisoning; indulging too freely in fermented liquors; tickling in the throat, as in chronic pharyngitis; the onset of febrile disorders; stones in the kidney; diseases of the stomach, etc. A

severe knock on the head will often give rise to a feeling of sickness, and with some people any acute pain, or even excitement, may produce this effect.

The patient should lie down on his left side in a quiet room in a subdued light, with the head on a low pillow, taking care that he is comfortably warm, but not overheated. He should not be permitted to talk much or make any attempt to amuse himself by reading. Slowly sipping a glass of soda-water or other effervescing drink may help to relieve the condition. Should the feeling of nausea continue, a mustard plaster may be applied to the pit of the stomach.

If the feeling of nausea still continues, or constantly recurs, it is most important that the cause should be ascertained. If it is likely to be caused by irritants, food, or poisons in the stomach, give an emetic consisting of a tablespoonful of mustard in a glass of warm water. Afterwards give sips of cold or of soda-water, though some get more benefit from sips of hot water.

If the nausea is caused by tickling in the throat, or violent coughing, a draught of cold water, if it can be swallowed, will be found helpful at the moment. A gargle should be used to tone up the throat, such as the following:

Tincture of myrrh	2½ drams
Glycerin of borax	1 oz.
Distilled water	8 oz.

For the feeling of nausea induced by seasickness it is well for the traveller to lie down, if possible, on deck, but weather will not always permit of this. He should be warmly covered with a rug. Chloretone is often successful in preventing this complaint. As soon as he feels equal to it the patient should have a light meal, such as a basin of soup or gruel, or perhaps some cold chicken. He should avoid any rich or greasy food. *See Biliaryness; Gastritis Morning Sickness, etc.*

NEAPOLITAN ICE. To make this sweet meat beat the white of an egg and add to it a tablespoonful of water strongly flavoured with liqueur. Rub 1 lb. icing sugar through a fine hair sieve, and into the white of egg, etc., stir enough of it to make a dry yet pliable mixture which can be easily moulded in the fingers. Dust a pastry board with some more icing sugar and knead the mixture on it until it is smooth. Divide it into 3 portions, colouring one with cochineal and flavouring it with raspberry essence; another with finely grated chocolate and using vanilla essence to flavour, and leaving the third portion its natural colour and using any flavouring desired.

Roll out each piece to about ⅛ in. in thickness, arrange the colours one on top of the other, brushing between each slab with a little cold water. Press them firmly together, trim the edges evenly, and brush over the top with a little melted coating chocolate. Let this surface dry before turning over the sweetmeat and coating the other side in the same way. Sprinkle over all a little finely desiccated coconut, and with a sharp knife cut the sweetmeat into slices of cubes. They will require about 24 hours for drying. *See Chocolate.*

Neapolitan Violet. This is a favourite double mauve variety of the sweet violet. *See Viola; Violet.*

NECK: In Human Beings. It is most important that nothing tight should be worn round the neck; giddiness is often due to this cause. Special care on this point should be taken by people who are inclined to suffer from apoplexy or any kind of fits, or those with short necks. During sleep always leave the neck as free as possible, and take especial care that in a child's night clothing the neckband is loose.

Stiff neck is a form of rheumatism of the muscles, generally caused by a chill. A person who is liable to suffer in this way should be careful never to sit in a draught. Discretion must be exercised in the use of furs, etc., round the neck, as they may make the part too warm and expose to chill later.

Glands in the Neck. In swollen glands the condition may arise from a bad cold, adenoids or diseased tonsils, bad teeth, or in young children from the cutting of teeth. A more serious cause is tubercular disease. No treatment other than the removal of the cause may be needed. The glands should be protected from irritation. When the enlargement is caused by the tubercle germ the general health should first be attended to. Do not paint the enlarged glands with iodine unless instructed to do so by the doctor, who should always supervise the treatment.

Wry neck may be an affliction from birth or have come on later. It is caused by the muscles of the neck contracting, and so drawing the head to one side. When the condition is congenital treatment by manipulation may be successful if it is commenced early enough, so no time should be lost in procuring medical advice. Full throat results from enlargement of the thyroid gland in front of the windpipe.

Care of the Neck. The back of the neck should be protected from hot sunshine, as this part of the body is particularly sensitive and blisters are painful. Sunburn and freckles on the neck may be reduced by a bleaching lotion composed of equal parts of lemon juice, rose-water, and peroxide of hydrogen. This lotion is also helpful for removing discoloration after wearing a dark fur round the neck. Suitable emollient or astringent cosmetics should be applied, after scrubbing twice weekly with superfatted soap and a soft nail-brush.

A good line of neck is best preserved by proper carriage of the head. An ugly defect noticeable sometimes in middle age is an accumulation of fat at the back of the neck. The following exercise will help to correct this condition and restore suppleness:

Stand erect, with hands on hips. Bend head and rotate it very slowly up towards the right, then, with head back, down to the left and round. Repeat several times and then reverse the direction, keeping up on the left and down on the right. *See Face: Goitre: Stiff Neck: Throat.*

NECK: In Cookery. In beef that portion of the ox which lies between the head and the chuck ribs is called the neck.

In mutton the neck portion extends from the head to the loin, and is divided into the scrag, middle neck, where the shoulder has been detached, and best end of the neck. In veal, as in mutton, all meat between the head and the loin is called the neck. The scrag piece is used for boiling or stewing, and the best end can be either boiled, stewed, braised, roasted or divided into cutlets.

In pork, that part of the neck which joins the head is called the spare-rib, and can be roasted, or it is sometimes added to the head when making brawn. When cured as bacon the neck part next the head becomes the collar and is a good piece for boiling.

It must be remembered that meat is cut up differently in various parts of Great Britain, and that the joints are not always named alike. *See Beef; Joint; Mutton; Pork, etc.*

NECKLACE. Of the expensive necklaces pearl ones are the most generally worn. Filigree necklaces and varieties of designs in enamel work, or composed of medallions or jewelled plaques, are worn when fashion permits.

In choosing a necklace, whether of a valuable or inexpensive kind, regard should be paid to the shape of the neck. Women with short, thick necks should not wear large ornaments round the throat, but select a necklace which by falling well below the base of the neck has a slimming effect. A woman or girl with a thin or long neck is usually suited best by a necklace which fits the throat

closely. While pearls suit nearly everyone, coloured necklaces should be chosen with due regard to the eyes of the wearer. For instance, gold and amber shades are particularly becoming to brown eyes, while jade enhances hazel eyes, and blue stones will give a deeper colour to grey or blue eyes. *See Jewelry; Pearl, etc.*

NECTARINE. This is a smooth-skinned type of peach, and is cultivated in exactly the same way. Some of the best varieties are Downton, Lord Napier, Early Rivers, Elruge, and Spencer. *See Bottling; Fruit; Peach.*

Nectarine. Smooth-skinned type of peach which is a delicious dessert fruit.

NEEDLE. Needles for sewing purposes are sold cheaply in small packets, and can be bought either in one particular size or in varying sizes. Needles used on damp materials should be wiped thoroughly before being put away, or they will rust and become unfit for further use. A little asbestos powder in needle packets will prevent rust. Rusty needles should be passed backwards and forwards through an emery cushion. In warm weather this makes them easier to use if it is done occasionally while working.

The threading of a needle is facilitated by holding the eye before a sheet of paper or any white object.

Other kinds of needles used in the home include knitting needles, varieties of which are described in the article on Knitting, special packing needles, larding needles, and gramophone needles.

When a splinter of a needle is broken off in the palm, the finger, or elsewhere, a doctor should be consulted at once with a view to its removal. If there is any delay the splinter may move away from its point of entry. X-rays are invaluable in localizing such fragments. It is usually necessary to open down on the needle, but this is often possible under a local anaesthetic.

Needle Case. Various kinds of needle cases are easily made, and provide a good means of saving needles which might otherwise be lost or allowed to rust. The simplest is made by sewing together in the form of a book a few small pieces of flannel cut to a uniform size. Flannel is preferable to other cloths for this purpose because, being composed of wool, it is a better preventive of rust. A small leather case to which the leaflets can be stitched, or some stiff cardboard covered with satin, makes the whole stronger and more compact. *See Gramophone; Knitting; Mending; Needlework; Woolwork.*

NEEDLEWORK. The art known as needlework can be summed up as a knowledge of how to make the best use of needle and thread. Under this wide term come many variations, such as tapestry, crewel, and appliqué work, other embroidery of all kinds, lace and beadwork in which a needle is used, darning, and plain sewing, as well as knitting, netting, and crochet.

Plain needlework is the first essential to learn. Besides its practical value, it teaches neatness, cleanliness in handling delicate materials, and accuracy, and gives scope for artistic expression. Those who have all their needlework done for them need a knowledge of it in order to be able to distinguish good work from bad, and those who must do their own will find a good groundwork of plain needlework helpful for everyday use, and with such a knowledge, proficiency in fancy work is more easily achieved.

Objections are raised against handwork on the ground that it is not worth while, as machines can copy most of the stitches, and that it is unhealthy work. Machine work may be a good substitute, but for fine materials it can never equal handwork, and a certain amount of the latter is always necessary.

Conditions of Work. For the sake of one's health it is important never to sit in a stooping position; see that the chair and table suit each other in height, and hold the work so that it is only necessary to bend the head a little. When doing a piece of work that requires pinning down, such as the stroking of gathers on a large piece of work, never pin to the knee, but use a weighted cushion placed on the table, so that when pinned the work is at a convenient height for manipulation. Always sit so that the light comes over the shoulder; never work in a dim light, and avoid using black or very dark materials when working in an artificial light. Choose a steel thimble rather than a silver or bone one. The latter soon splits and silver ones wear thin quickly.

Needles, Scissors and Thread. Use rather short needles for ordinary plain sewing and longer ones for dressmaking, while darning needles should be longer still, with a long eye. The needle should be a little thicker than the working thread, so as to make a smooth passage for the latter through the material. Bent needles should not be used.

Two kinds of scissors are indispensable, a large pair with a blunt and sharp end (the latter always being kept down) for cutting out large pieces of material, and a small pair with two very sharp points for cutting fine materials and embroidery. See that the handles are large and smoothly rounded, as if they are too tight they mark the hand and hurt the thumb.

When using tacking threads keep a reel of tacking cotton, which is much cheaper than sewing cotton, and answers the purpose just as well. The most efficient work is done through the work being tacked into the correct position first, sticking pins in is the lazy method, except in very few instances. Do not put a long thread in the needle for ordinary sewing; about 18 in. is quite enough.

Fox tacking, a very long thread can be used, as several stitches can be put in at once before drawing up the whole length of thread. In the case of cotton from the reel, thread the needle with the end just cut off the reel, as the opposite end is likely to be more trouble to thread through splitting. Cotton for sewing, whether from skein or reel, should always be cut, as breaking weakens it at that point. *See Buttonhole; Embroidery; Hem; Seam; Tapestry.*

NEEDLEWORK PICTURE. Pictures worked with the needle are rarely of earlier date than the middle of the 17th century, they bear a resemblance to tapestry on a small scale. The design is worked in silk on a brownish linen canvas in tent stitch or petit point. The costumes of the figures are easily recognizable and often date the picture.

More valuable are the examples of stump work, which is a form of raised and embossed needlework in feather stitch. A typical example of the Stuart period consists of figures of the king and queen, trees, birds, marine monsters, caterpillars, and other subjects all quaintly woven together in a picture measuring, perhaps, 2 ft. by 1½ ft. The caterpillar, being an emblem of the Stuarts, gives the date to the picture, which is encrusted with seed pearls, sequins, and spangles.

The stumps were followed by elaborate beadwork depicting animals, fish, trees, etc., with a landscape background. Many tent-stitch pictures of Queen Anne's reign are extant, and they show a considerable advance in workmanship. Somewhere about the close of the 18th century Georgian black and white pictures were produced; in these a drawing was made on white satin or sarsenet, and worked upon in black silk or in colours to imitate engravings of landscapes and buildings, as well as figures. Sometimes parts of these pictures were done in Indian ink. Sampler and fire-screen

work in wool came later. The technical name for needlework pictures is acupictura. *See* Embroidery; Fire Screen; Sampler; Tapestry; Woolwork.

Needlework Picture. Beautiful example about 100 years old, of this form of embroidery. The picture is worked in black silk on a white corded silk background, the clouds being put in with Indian ink.

NEGATIVES AND THEIR CARE

Some Useful Information for the Amateur Photographer

This article, which contains a section on the storing of negatives, suggests reference to other articles dealing with photography. Among such are Developing; Enlarging; Film; Fixing; Panchromatic; Photography; Plate; Washing.

A negative is a photographic plate which after development shows the image reversed, blacks being represented by clear spaces and high lights by dense portions, varied according to the high and low tones in the original object. When sensitive paper is placed in contact with it and exposed to light, a positive is produced showing all the tones and details of the original. Negatives may be on glass, roll films, flat films, when they are thicker and stiffer than roll films, or else on paper.

It is open to the amateur to vary the quality of his negatives in the course of development according to the purpose for which the negative is required. Roughly speaking, negatives may be divided into three classes, vigorous or contrasting, normal, thin or soft. This is most satisfactorily achieved, not by varying the developer, but by increasing or reducing the time of development. The amateur will always find it best to confine himself to the use of a particular developer which he knows well, and he will find that the makers of practically all the standard plates and films give development tables

with several standard developers showing the time of development required for each of the three classes of negatives described.

The vigorous or contrasting negative is roughly one which gives a brilliant print on silver paper (P.O.P) and a very brilliant one with sharp blacks and whites, on ordinary gaslight paper. It gives prints which are particularly suitable for reproduction by the half-tone process in newspapers or magazines. The normal negative gives good prints on either silver or gaslight paper, and, although it is not so suitable for half-tone reproduction, prints made from it are somewhat more artistic, contrasts being not so strong. The thin negative is always required when it is to be used for enlarging, unless great contrast is required; it also gives the most pleasing results in portrait work.

Defects and Stains. Defects of various kinds, chemical and physical, are liable to occur in negatives even with the careful worker. Treatment of the negatives after development, fixing, and drying are complete is always a risky matter, involving the possibility of making things worse and sometimes of ruining the negative altogether. In all photographic processes prevention is better than cure, and the amateur should take every possible care to ensure cleanliness at all stages; this cleanliness is not a mere matter of soap and water, but is a chemical question, as described under Developing, Fixing, and Washing.

Chemical dust in the dark room, caused by solutions spilled on the floor and allowed to dry, often gives rise to spots on a negative. Dust in a dark slide or in the air of the dark room when the slides are being loaded will cause pinholes on the plates.

By taking care in these and similar directions negative defects may be very largely prevented. It is not a wise plan to wipe a plate to free it from dust before placing it in the slide. The photographer can rely upon the plate being absolutely free from dust when he unpacks it from the maker's, since extraordinary care is taken to prevent the deposit of dust at all stages of the manufacture. In fact, brushing the plate attracts dust to it by slightly electrifying the film. When the plate is removed from the slide after exposure it may be tapped sharply on the glass side with the knuckles to remove any dust particles that may have settled on it during exposure in the camera. This will prevent, to a large extent, the pinholes caused by dust on the plate during development.

Physical defects in a negative most often met with are frilling, blistering, small holes, pinholes due to dust, as explained above, and drying marks. The treatment of pinholes consists in filling up or spotting up the holes in the negative with Indian ink. Small round holes larger than pinholes are due to air bubbles which have clung to the plate or film and have prevented the developer acting at that particular spot. They are best avoided, particularly if tank development is employed, by getting rid of the air in the water. This can be achieved by boiling the water steadily for ten minutes before use and allowing it to cool undisturbed. In dish development wipe over the plates gently in the developing dish with a pad of cotton wool.

Frilling, in which the edge of the film is separated from the glass, and blistering, in which the film rises in small blisters, are both due to solutions of different temperatures. and are particularly liable to occur if a somewhat warm developer is followed by a cold fixing solution. Their occurrence in hot weather may be easily avoided by the use of a combined fixing and hardening bath.

Drying marks are due to unequal drying of the negative after washing, and are very troublesome. If a number of negatives are put in a negative rack with insufficient air space between them, particularly in damp weather, it is probable that they will be found after some hours to have dried round the edges, but still to be wet and swollen with moisture in the middle. The centre will dry if the negative is taken out of the rack, but will show a permanent mark or line round the part that was dried last. Re-soaking the negative for an hour or more in water that is not too cold, i.e. about 60 degrees, and drying with the negative stood on edge in a place where air has free access, will sometimes remove or reduce the mark. Generally it cannot be so cured. It is best prevented by

seeing that air has free access to the negative when drying and avoiding the use of racks in which negatives are not well spaced out.

Chemical defects, i.e. stains, are largely due to lack of cleanliness in the various processes as already explained. Stains may also arise from specific chemical causes. Contact of a negative with sensitive paper in the presence of moisture will cause silver stains, which, if large, may be reduced by careful rubbing with a pad of cotton wool and a little globe polish or finely powdered pumice, followed by a strong hypo bath. A small stain may be almost entirely got rid of by prolonged immersion in the ordinary toning and fixing solution used for silver prints.

Pyro stain can be removed if the negative is not allowed to dry after the ordinary washing, by a clearing bath made up as follows:

Alum	½ oz.
Hydrochloric acid (pure)	1 dr.
(or citric acid)	¼ oz.
Water	10 oz. or
Hypo	1 dr.
Thiocarbamide	10 gr.
Sodium bisulphite	½ dr.
Water	1 oz.

These baths are also useful as general cleaning baths, where marks or stains cannot be removed by other methods.

Ordinarily there is no objection to pyro stain, as it improves the printing quality of the negative, unless it is very deep.

How to Store Negatives. The amateur photographer is quickly faced with the problem of storing his negatives. When the number to be kept rises above forty or fifty, some methodical arrangement becomes necessary. Probably more damage is done to negatives in the way of scratches, finger-marks, etc., by repeated handling than by any other means.

Negative. Card-index box for storing negatives, each one being enclosed in a special envelope.

Many devices are on the market, but it is easy to contrive an arrangement which is both less expensive and bulky than many of the commercial negative cabinets. For negatives that are not more than a quarter plate or 9 by 12 cm. in size an ordinary 6 by 4 card-index box, as seen in the illustration, supplies the best solution of the problem.

The negatives are kept each in a negative envelope, with short details and a number outside. Proper negative envelopes, or ordinary envelopes of the best quality only, should be used, as the chemicals used in making cheap paper are liable to affect the negatives.

The negatives should be classified under a few general headings according to the photographer's particular interests, such as landscapes, portraits, family groups, sport, etc., devoting a box or a portion of a box to each classified heading. Under each heading, the negatives are arranged in alphabetical order, with guide cards, as seen in the photograph, on the ordinary card-index system.

The negatives thus supply their own index, and no other is required. In this system film and glass negatives can be kept together without harm. Another method, where shelf room is available and a large number of negatives of larger sizes have to be stored, is to arrange them in envelopes in a numbered order, standing on edge on the shelves with partitions for every fifty negatives. Short details are noted on the flap of the envelope and a separate index is kept. A small number of negatives may be kept in their original boxes, separated by means of sheets of pure paper, with a list on the top of each box. Film negatives are much more easily stored than glass negatives. Special albums are sold for them of the correct size, consisting of transparent envelopes into which the films are slipped, space for a list of the contents of the album being provided.

NEGLIGENCE: In Law. Negligence has been defined as the doing of something which a reasonably prudent man would not do, or the omission to do something which a reasonably prudent man would do, having regard to the circumstances. In practice, the judge or jury has always to find whether the act complained of amounts to negligence; but no action will lie for damages unless the plaintiff can first establish that there was some duty cast upon the defendant to be careful.

Such a duty may arise by contract or otherwise. For example, if A engages to drive B from London to Brighton in his motor car for payment, A is clearly under a contractual duty to be careful both as to the condition of his car and as to the manner of his driving; and should any injury befall B because A drove rashly or carelessly, or because the car had not been properly overhauled for the journey, B can sue A for negligence. The duty to be careful may be a public one, e.g. it is everybody's duty to walk, ride, or drive in a public highway carefully. To rush along without any heed to the safety of others is negligence.

A duty may arise by implication. If a man invites people to come on his premises on business common to both, e.g. a gas fitter ordered to come and mend a pipe, it is his duty to have the premises in such a state as to be reasonably safe. Invitation in this sense may be implied; for instance, a shopkeeper is said to invite people to enter his premises with a view to becoming purchasers. To a guest a man merely owes the duty not to have traps on the premises, by which is meant concealed dangers.

Negligence in Driving. The most frequent cause of action is for negligent driving by the driver of a public or private vehicle. When anyone undertakes to do anything which requires special skill or knowledge, and which may cause injury or damage when performed unskilfully or ignorantly, it is no defence to say, 'I did my best,' unless, indeed, the act was done in an emergency, as where a layman, no doctor being present, tries to help someone who appears to be in a dangerous condition; and where an unskilled person tries to mend a broken pipe because no plumber can be found, and only succeeds in making matters worse. No action can be brought for negligence unless the plaintiff has suffered injury or pecuniary loss.

The damage must not be too remote. Thus, if A is run down by B's negligent driving, and has to suffer the amputation of an arm or the loss of an eye, and A's rich uncle, who had left A all his property, alters his will and cuts A out on the ground that he will not leave his property to a fellow with only one arm and one eye, or A was to have married an heiress, who jilts him because of his altered appearance, A cannot claim against B the loss of his uncle's fortune, or the profitable marriage. The loss is too remote.

The damages in such a case will be loss of wages, salary, or profits of business or profession while laid up; medical expenses; expenses of convalescence, and any extra nourishment required; depreciation in the labour market, if any; compensation for pain, suffering, and disfigurement.

Other Kinds of Negligence. There are other forms of negligence that concern the householder. For instance, when coal is delivered it is often shot into the cellar through a coal shoot or hole in the pavement covered with an iron grating. Care should be taken not to leave the shoot unguarded, and the occupier of the premises should make sure that the grating is replaced after the coal has been shot into the cellar.

Damages may be recovered where a fire that has been caused through negligence spreads to adjacent property. Thus, if a haystack takes fire and some cottages near are burned down, the owner of the haystack is liable. A tenant is responsible for the condition of the chimneys of his house; if one which has not been swept gets on fire and the sparks set light to a neighbour's fowl-house or other building, damages may be claimed against the tenant. Areas or cellars adjoining a street must be kept properly fenced to prevent accident, and the occupier is responsible if any person falls down and sustains injury through insufficient fencing, *See Accidents; Driving; Flat; House; Landlord; Motoring; Repairs.*

NEGUS. Wine, usually port, mixed with hot water, spiced and sugared, is known as negus. Port wine negus is made from the following recipe: Put 1 pint of port wine into a jug, into which pour the juice of a lemon, $\frac{1}{4}$ lb. sugar, and a little grated nutmeg. Add 1 quart boiling water and serve when cool. Sherry negus is made in similar fashion, and a wineglassful of noyau or maraschino may be added. *See Wine.*

NEIGHBOUR. Disputes between neighbours arise about such things as fences, overhanging trees, party walls, rights of way and water, rights of light, and rights of support.

The remedy for interference with any of these rights is by injunction and damages.

The right of support for land of one neighbour by the adjacent land of another is a natural right of property, so long as the land which claims support is in its natural state unencumbered by buildings. In other words. B must not excavate his land so near to the edge of A's as to cause the latter to fall in. If A has a building on his land, and his neighbour B digs on his own land in such a way as to cause A's building to crack or fall, A may or may not have a legal remedy. He has such a remedy if his building has stood with the support of his neighbour's land for 20 years, but not otherwise, unless, indeed, B may have granted him by deed or sold to him for value the right of support for his building.

When two houses or more are built so that they support each other if they are built at the same time, the law implies a mutual easement or right of support. If the owner of a middle house in a row wishes to pull down and rebuild, he must prop up the houses on both sides during the process.

If a neighbour's tree overhangs a man's fence, he can cut it off level with the fence, but must not pluck the apples from the overhanging boughs. If the tree is a poisonous one, and his cattle eat of it and die, the neighbour must pay their value.

A man may not take or collect upon his land anything of dangerous character which, if it breaks loose, will damage his neighbour or his neighbour's property, upon penalty of being liable to pay all the damage done if the dangerous thing escapes. This not only applies to dangerous animals, but also to such things as artificial collections of water. Where a man made a reservoir and it burst, he was held liable for the damage caused to his neighbour's property by the flood, though he was able to prove that he had not been guilty of any negligence, having employed skilful engineers, and supplied them with the best of material for the construction of the reservoir *See Fence; Hedge; Nuisance.*

NEILLIA. These are spiraea-like hardy, leaf-losing shrubs of which *Neillia opulifolia* is the most useful. It bears white flowers in May. A variety named *lutea*, which has yellow leaves, is

ornamental. These shrubs thrive in ordinary soil and are propagated by cuttings in sandy soil in a frame in summer.

NELUMBIUM. This is a greenhouse aquatic perennial plant belonging to the water-lily family. The rhizomes should be planted in a pool or tub of tepid water at the bottom of which a layer of loam has been placed. The chief kind is *Nelumbium speciosum*, with white, sweet-scented flowers tipped with rose.

NEMESIA. This beautiful half-hardy annual, 8-12in. high, bears brilliantly-coloured flowers in blue, crimson, orange, yellow, rose and other colours. It is invaluable for summer flower-beds and for groups in the herbaceous border. Blue Gem is a particularly attractive variety. Seeds are sown under glass in March and the seedlings are planted out of doors in May.

Nemesia. Brilliantly-coloured blooms of a half-hardy annual which flowers all through the summer.

NEMOPHILA. This pretty, low-growing, blue-flowered hardy annual is easily raised in ordinary soil in a sunny border. Seeds are sown out of doors in March-April where the plants are to bloom in summer. A sowing may be made in September to provide spring flowers.

NEPAUL POPPY. This is the popular name of *Meconopsis nepalensis*, a lovely biennial plant which bears yellow, poppy-like flowers in summer. It is raised from seeds sown in fine soil in a frame in May and the seedlings, when large enough, are planted in well-drained, loamy soil in partial shade. It is a good plan to place a covering of glass over them to keep off excessive wet in winter.

Left. Nepaul Poppy, a showy biennial for a sheltered spot in the garden.

NEPETA. The favourite plant in this group is the mauve catmint (*Nepeta mussinii*) which has grey leaves and bears a profusion of lavender-mauve flowers in June and July. It nourishes in ordinary well-drained soil and is easily propagated by cuttings in summer. The mauve catmint is a delightful flowering plant, often used as an edging; it also looks well in a wall or by the side of garden steps. The variegated ground ivy (*Nepeta glechoma variegata*), with green and white leaves, is a useful carpeting plant for damp places.

Nepeta. The mauve catmint, a summer flowering border plant.

NEPHRODIUM. Many species of nephrodium are tropical ferns which need to be grown in a moist, warm glasshouse. The commonest hardy kind is the male fern (*Nephrodium filix-mas*) of which there are many beautiful named varieties, these are admirable ferns for a shady border. Leaf-mould should be added freely to the soil. Planting is best done in autumn.

Nerine. This is an alternative name for the bulbous flowering plant known as the Guernsey lily (q.v.).

Nerium. The greenhouse evergreen flowering shrub nerium is better known under its popular name of oleander (q.v.).

NERTERA. The small perennial nertera is called depressa or coral-berried duckweed. Its tiny flowers are followed by round berries of reddish orange. Although the plants are of perennial character they require protection during hard weather, a suitable place to plant them being a moist and sheltered position in a shady rockery. Spring is the most suitable time for planting, and propagation is by means of division. Nertera makes a pretty pot plant for the greenhouse.

NERVOUSNESS. The apprehensive excitable state of mind and body connoted by nervousness is a sure sign that the general health is not at its best. It may be brought about by exhausting mental work, or by some occupation which does not allow of sufficient exercise for health. Another common cause is exhausting the body by leading a dissipated life. Nervousness may be the result of a sudden shock or accident; in some cases it is inherited.

In every way a quiet, healthy life should be led. A daily cold or tepid bath must be taken in the morning, followed by a rub down with a fairly rough towel. Diet should be plain but nourishing. Tea or coffee may be taken weak and in moderation, but alcohol in all forms should be avoided. Strictly regular hours should be observed. Plenty of fresh air is another essential.

In Children. A child with any tendency to nervousness demands constant and careful watching. Treatment is on the lines described above for diet and exercise, with a warm bath at night to promote sleep. Such a child should not be left alone or forced to go to sleep in the dark. It is most important that his nurse, or whoever has charge of him, should be kind and patient, but firm. He must be taught as far as possible not to give way to his temper, which will naturally often be irritable. At the same time, constant scolding and worrying over trifles likely to annoy the child must be avoided, and the person with him should be of a cheerful disposition.

Under these conditions the child may be the better for a tonic, and one likely to suit him is:

Iron and quinine citrate	45 gr.
Spirit of chloroform	40 m.
Syrup of lemon	2½ dr.
Water to make	4 oz.

The dose for an eight-year-old child is a teaspoonful three times a day after meals. Nervous children sometimes develop St. Vitus's dance. *See Hysteria; Neurasthenia; St. Vitus's Dance.*

NET. Net is an open fabric of twine, silk, or other material, and is employed for a great number of domestic and other purposes. Nets are used for several games, e.g. lawn tennis and table tennis, and are much employed in the garden for keeping birds away from fruit. *See Badminton; Butterfly; Netting; Tennis Net.*

NET: The Dress Material. Nets are made chiefly in two materials, cotton and silk, cotton being most employed. They are made with both coarser and finer threads, and in meshes of different shapes and sizes. Hexagonal mesh is the most common. Mechlin is hexagonal, Lille is diamond shaped, and some are square or filet, much used in dyed shades for curtains. Network forms an integral part of the design of hand-made laces. *See Filet Lace; Lace.*

NET BALL. This is played with a large ball and two nets for the goals. The ball is the same as is used in Association Football. The field of play should measure 100 ft. long and 50 ft. wide, but the game can be played on a smaller piece. The usual number of players is seven a side, but this, too, can be varied.

Net Ball, an outdoor game for girls. The illustration shows a shot made for goal.

In the centre of each end line the goals are fixed. Each goal is a single upright post, to which an iron ring, 15 in. in diameter, is fitted. This should be 10 ft. above the ground and should project 6 in. from the post. Attached to a ring is a net, open at the bottom, and the ball must pass through this in order to score a goal. Around each goal a semicircle, having a radius of 16 ft., is drawn; this is known as the shooting circle. In the centre of the field is a circle 4 ft. in diameter. If a smaller field of play is used, these measurements should be reduced in proportion. The playing field is divided into three courts of equal size by lines drawn from side to side.

The seven players, in a full game, are: goal scorer, attack, attacking centre, centre, defending centre, defence, and goalkeeper. The game begins with one of the two umpires bouncing the ball in the centre circle, while the players stand, each party on its own side of the circle, the centres in front and the others behind them. After one of the centres has caught the ball, the game proceeds, the aim of each player being to throw the ball to a colleague or prevent an opponent from securing it. They try to get it to the player who stands within the shooting circle; when he or she gets it, his or her aim is to throw it into the net.

As in football, there are penalties for getting offside and other offences, and the rules for throwing the ball in after it has gone out of play are very much the same as at association football. Two players of one side must not hold the ball at the same time, nor must a player carry it. Obstruction is also an offence. The penalties are a free pass or a free throw at goal.

NETTING: How to Make. Netting for lawn tennis, fishing, garden purposes and hammocks is usually bought, but it can be made at home. The necessary implements consist of a piece of bone, steel, or wood, made with notched ends, called the needle (Fig. 1), and a smooth flat or round rod

called the mesh or gauge. The circumference of the mesh used controls the size of the loops, and meshes can be bought in numbered sizes. A lead-weighted heavy cushion is required, or in the case of coarse twine netting, a stirrup to slip over the left foot and provide a fixed point to pull upon may be used. To this cushion or stirrup a cord is attached to form the foundation loop; the first loop or loops of the net are cast upon this foundation. Netting consists of loops of thread called stitches, secured by knots.

The thread may be fine silk for netted purses, knitting cotton, crochet cotton, cabled twines, or tarred string. Knots of different kinds are made for different purposes; loops of different shapes and sizes can be worked into a pattern, and different colours of thread can be introduced. The work is done a row at a time, and sufficient thread for one row should be wound upon the needle at the start.

Netting stitches are oblong or square and the patterns are produced in plain netting by the different ways of passing the thread over the mesh and the manner of connecting the loops, as well as by the various sized meshes. Plain netting is given the simplest form of pattern by the last method. Two or three rows are worked over a narrow mesh and then the same number over a coarser one, continuing the use of first one mesh and then the other at regular intervals.

Left. Netting a strawberry bed, showing method of supporting the mesh on stakes driven into the ground. (Courtesy of Amateur Gardening)

Plain netting is the one to learn first. The mesh is taken in the left hand, thumb on top and fingers beneath. The mesh is held close to the foundation loop and the thread is passed over the mesh and two forefingers. The thread is brought under the mesh and placed under the thumb; then it is put round the hand and held by the little finger. The needle thus brought in front of the mesh is passed

under the first loop between mesh and finger, and into the foundation loop and the thread is drawn tight close to the mesh.

The fisherman's knot is made by holding mesh and needle in the manner described, and passing the thread round the mesh but not over the fingers, then passing the needle upwards through the loop that is to be made, drawing the loop up to the mesh and holding the thread tight under the thumb. The thread is allowed to fall to the left, and the needle is put upward behind the loop and the thread is drawn tight.

The work may be begun, with only a single loop directly attached to the foundation; or as many as 100 loops of fine silk may be cast on the foundation, as in making long netted-silk purses. Steel or ivory netting needles are used for finer work of this kind. An example, showing the stages of constructing the simplest form of wide meshed netting, is illustrated in Figs. 2 to 8. A foundation stick is used for this; in the case of fine netting, a foundation loop of coarse thread takes the place of the stick. The first stage is to wind the string on to the needle. One end of the string is looped and tied over the centre prong, as shown in Fig. 2, and the string is then turned around the needle lengthways between the jaws of the slotted end, passed over the point of the prong at the top and on alternate sides of the prong, until sufficient string has been wound. This operation is shown in Fig. 3.

The next step is to provide the foundation stick. Make a bridle of string and attach it to a nail or other convenient point of support on the wall, work bench, or any other suitable place, and attach the free end of the string to it by means of an ordinary reef knot. Then, holding the mesh stick, in the left hand, pass the needle behind it, underneath and across the front of the mesh stick and on to the back of the foundation stick to the position shown in Fig. 4.

Next bring the needle with the string down over the front of the foundation stick and pass the point of the needle between the strings (Fig. 5). This forms a knot and the string is then drawn up tight, thereby bringing the mesh stick nearly into contact with the foundation stick, as in Fig. 6. The requisite number of throws are then cast in this manner on the foundation stick until the end of the stick is reached or the requisite number of casts have been made. The foundation stick is then removed, the mesh stick turned over and the finishing point made the starting-point of the next row. Then, holding the mesh stick in the left hand, the needle is passed over the mesh stick, behind it, and then through the first mesh of the row, as shown in Fig. 7. The thumb is then placed on the string around the mesh stick and the needle passed beneath the first mesh of the completed row, making sure that the string is tight round the mesh stick; this is accomplished by the pressure of the thumb and forefinger of the left hand, as shown in Fig. 8. The needle is then drawn right through and drawn up tightly, thus completing the mesh. This operation is completed until the end of the row is reached, the mesh stick turned over, and the operation repeated until a sufficient size of net is completed.

For garden purposes old fish netting is useful in several ways. Generally it is used to cover young growing fruit trees to protect them from the ravages of birds and frost. Pockets of such netting are also useful if suspended in hammock-like fashion beneath wall and standard fruit-trees in order to catch the ripe fruit when it falls. It is likewise employed to keep off the attacks of wasps and other flying pests. See Hammock; Knot; Wire Netting.

NETTLE. The stinging nettle is one of the most difficult weeds to eradicate; the only way is continually to hoe off the tops of the plants as they push through the soil. If this is done for 2 or 3 years the plants will dwindle and perish. They can be destroyed by spraying or dusting with sodium chlorate, a highly inflammable chemical.

Uses of the Plant. The young shoots of the stinging nettle can be cooked and served in the same way as greens, but they make a more palatable dish if they are blanched first, and then cooked like spinach. Nettles are also used to make broth or vegetable soups, or added as a flavouring, but they have a bitter taste.

The traditional remedy for a nettle sting is to rub the part affected with a bruised dock leaf, and this is usually efficacious; but a better cure is to use cold water. A handkerchief should be soaked and tied over the part stung, when immediate relief will usually follow. If the sting is very severe, the bandage may be changed as soon as the cold feeling dies away. A solution of bicarbonate of soda and water is also useful in this connexion, while leaves of rosemary, mint and sage also afford relief. *See Sting.*

Nettle Toast. This is a good substitute for spinach on toast. To prepare, wash and boil about 2 lb. of young nettle leaves and tops, chop them finely, and put them in a pan with 1 oz. butter, a little lemon juice, salt and pepper. Stir these over the fire until the butter has melted; then pile the mixture on 3 or 4 rounds of buttered toast.

NETTLERASH. This skin ailment, the medical name of which is urticaria, is characterized by whitish firm elevations or wheals surrounded by a red base. They come out quite suddenly and often vanish just as quickly. They itch, sting, and burn as when one is stung by a nettle. In infants they are very common, appearing as red pimples.

In older children and adults the following causes may produce an attack: Eating shell fish, mushrooms, cheese, eggs, crabs, lobsters, pork, pickles, pastry, strawberries; wearing rough flannel garments next the skin; violent emotion; the irritation caused by worms in the intestine; goutiness; taking certain drugs, such as quinine, copaiba, turpentine; the use of irritating cosmetics and hair dyes; the bites and stings of wasps, bees, caterpillars, jellyfish, bugs, and lice, and contact with nettles and other stinging plants.

In treatment the cause should first be ascertained. If it is acid indigestion, a dose of 10 to 15 gr. of bicarbonate of soda in a wineglass of plain water may bring relief. If the affection is severe in children and accompanying digestive disorders, give an emetic (q.v.), and when this has acted give one to three teaspoonfuls of castor oil. Regulate the diet, experimenting to find out the food which seems to disagree. If flannel irritates the skin, wear cotton, linen, or silk.

To relieve the itching (q.v.) many simple remedies are available, among which the following are the best: Dissolve a teaspoonful of bicarbonate of soda in a tumbler of warm water and sponge the itching part with it; sponge with solution of carbolic acid (1 in 40); apply calamine lotion with a soft sponge or piece of lint.

Young children should be prevented from scratching by sewing the sleeves of their nightdress to the body of the garment, or by loosely tying the hands to the waist.

NEURALGIA. The acute, paroxysmal pain that is usually known as neuralgia is most often felt in the head or face, though it may attack any part of the body. In neuralgia attacking the nerves of the face and head, a decayed tooth is probably the most frequent origin of the mischief. Other common causes are eyestrain, irritation in the nose or ears, and exposure to cold. In the cases of persons predisposed to neuralgia, sitting in a draught may suffice to set up a severe attack.

If the teeth are decayed, the dentist's services must be sought. If the patient is suffering from eyestrain, an oculist must be consulted. When gout, rheumatism, Bright's disease, or any other general affection is present, it must be treated appropriately at the same time that local measures are taken to relieve the pain.

Change of air is often one of the best remedies, especially in the case of nervous women. The patient must have plenty of sleep, and spend a good part of the day in the open air. The diet should be generous and contain abundance of fats, such as fat bacon, butter, and cream. When the patient is gouty, however, a strict vegetarian diet often effects a speedy cure. Neurotic patients sometimes derive much benefit from ammoniated tincture of valerian: Cod liver oil is a valuable medicine in many cases, and may be combined with malt and hypophosphites.

There are many useful measures for the relief of pain during an acute attack. Let the patient have perfect quiet. Warmth to the affected part will frequently give relief, such as a flannel or sponge dipped in water as hot as can be borne. Dry heat is sometimes preferable. Relays of heated flannel or cotton wool may be applied, or a hot-water bottle is effective.

For neuralgia in the face or head a bran poultice will often prove a good remedy. Let the patient go to bed and be warmly covered. Make a poultice of bran and put the face down on it. After using heat great care must be taken not to get fresh cold in the face. Have ready a shawl to throw over the head in passing from one room to another through a cold passage or staircase.

The number of drugs that may give relief in one case or another is considerable. If one fails, another should be tried, but always under medical direction. *See* Faceache; Tic Douloureux.

NEURASTHENIA. This term, as generally understood by the layman, refers to all those forms of nervous disorder which are functional in character, such as hysteria. The medical profession, however, limit the term to a particular form of these disorder characterized by increased susceptibility to fatigue.

Neurasthenia in adolescence is often associated with the difficulties arising from physical development. Failure on the part of parents or teachers to appreciate these difficulties and impart clean, wholesome, and truthful information on the essential facts of life often contributes to the condition. Later in life neurasthenia may result from any form of mental strain, such as overwork, anxiety, fright or shock; physical accidents, particularly in circumstances in which the individual has no time to pull himself together to meet the shock, as, for example, a railway accident, or chronic ill-health.

The most marked symptom of neurasthenia is the readiness with which the person complains of fatigue with either physical or mental effort. Other noticeable symptoms are pain or feeling of pressure in the head, pain in the back, disorders of sensation, insomnia, and indigestion. Flushing of the skin and sweating may be present, and there is often considerable loss of weight.

In adolescence treatment should be directed towards establishing a more normal and healthy frame of mind. Difficulties should be investigated and explained, care being taken that nothing is said that is calculated to reduce self-respect or increase any apprehension or feeling of guiltiness.

In older persons only palliative measures, as a rule, can be adopted. When the condition results from strain or overwork, a holiday, rest in the country, or a sea voyage may be recommended. In cases due to chronic ill-health efforts should be directed towards remedying the bodily condition which is at fault, particular attention being paid to the state of the bowels and to the condition of the teeth and of the gums. Drugs to produce sleep should be avoided if possible. Alcohol, if taken at all, should be indulged in very sparingly.

NEURITIS: Its Treatment. Inflammation of a nerve is known as neuritis, and it may be limited to one nerve, as in sciatica and inflammation of the facial nerve; when it affects a number of nerves it is termed multiple neuritis. Exposure to cold is one of the commonest causes of local neuritis. Multiple or peripheral neuritis is the result of poison in the blood, the most common cause being the taking of alcohol continually over a long period. The symptoms are tingling in the limbs, twitching of the muscles followed by loss of muscular power, and acute pains.

Diagram showing the various fibres entering into the composition of an ordinary nerve, and the kind of impulses that they carry upwards or downwards, and the functions disturbed in neuritis.

Alcoholic Neuritis. This is the commonest of all the forms of multiple neuritis and arises from excessive drinking. Drinkers of spirits are more liable to develop it than those who indulge in beer or wine. The sufferers are usually those who take moderate quantities for a long period rather than those who give way to occasional excess. It is more common amongst women than men and occurs most frequently between the ages of thirty and forty.

Lead and Arsenical Poisoning. Painters, plumbers, and men employed in white-lead factories supply most of the cases of lead neuritis, but water and cider have been known to carry the poison. All parts of the system may be affected by lead, but in the majority of cases its action is confined to certain nerves of the forearm, producing wrist drop.

Habits of personal cleanliness and Government regulations of a preventive character have greatly reduced the prevalence of lead neuritis in Great Britain.

A single large dose of arsenic has been known to cause multiple neuritis, but it usually arises from the swallowing of a minute quantity frequently repeated. Weakness and wasting of the limbs are the leading symptoms, the legs being affected before the arms.

Neuritis from Germ Infection. Nearly one quarter of the cases of diphtheria subsequently suffer from neuritis. Most are mild, symptoms being a nasal quality of the voice, a temporary dimness of vision, or a slight weakness in the hands and feet. In more severe cases the soft palate and the muscles of swallowing are attacked. The patient is liable to regurgitate liquids through the nose during swallowing, and is unable to suck, gargle or blow out the cheeks. The voice may become hoarse or even be lost. Occasionally diphtheritic neuritis attacks the nerves which regulate the heart and the diaphragm, and there is then danger to life.

The vast majority recover completely within a few weeks. The early use of antitoxin has led to a diminution in the number of cases.

For the relief of pain, nothing is better than frequent warm fomentations. After the application of these the limb should be wrapped in a thick layer of cotton wool. Occasional dose of aspirin, phenacetin or acetanilide may also be required to subdue severe spasms.

Diet should be generous, with modifications if required for gouty or diabetic cases. Abundant fresh air and sunlight should be ensured throughout this illness. Great care must be exercised to prevent the development of contractions.

Rest and warmth are essential conditions in treatment. Cover the part with a thick layer of cotton wool, and bandage it loosely. If the arm is affected, put it in a sling; if the leg suffers, the patient must lie down a good deal. Drugs such as those used in neuralgia may be given to relieve pains. In chronic neuritis massage and mineral baths are recommended with occasional blisters and full doses of iodide of potassium.

NEVIUSA. The deciduous flowering shrub called neviusa alabamensis belongs to the order of Rosaceae, and bears the popular name of Alabama snow wreath. The plant bears whitish flowers along its shoots during summer. Ordinary well-drained soil suits it. It is propagated by cuttings of half-ripe wood inserted in sandy soil under a hand-light or cold frame during the summer.

NEWEL POST. The post in which the steps of a winding stair are fitted is called a newel post. The term is also applied to the posts situated at the top and bottom of an ordinary staircase, which act as supports for the handrail.

In a small house the newel post may be made from deal about 3 in. square, and tenoned into the timber framing of the staircase, if on the upper floor. On the ground floor such a post would be similarly mortised into the floor joists and into the string of the staircase. It is often capped with a rectangular block.

In more important work the newel post may well form a prominent feature, especially when it is carved or fashioned into the pedestal for a lamp fitted with electric light or gas. An alternative is to mount a statuette on the top of the post, or to carve the head of a lion or some other animal in a conventional manner. The general character of the work should harmonize with the rest of the staircase, and be in keeping with the architecture of the home itself. *See Staircase.*

NEWFOUNDLAND DOG. With the St. Bernard, the Newfoundland shares the distinction of being essentially a life-saving dog. His powerful frame, deep chest, capacious ribs, broad loins and heavily-boned legs, together with his thick coat, mark him out as an ideal water dog. He can swim in almost any sea, and many stories are told of Newfoundlands that have rescued human beings.

They may be all black, or white and black, or white and bronze, the latter being popularly called Landseers, after the painter who immortalized them. The eyes should be dark brown in colour, light ones being objectionable, as they are in most breeds. The head is less massive than in that of the St. Bernard, but at the same time it should be big and broad, as befits the body. The coat is flat and dense, rather coarse in texture, and of an oily nature, so as to resist the water. The gait usually has a slight roll. A weak loin or cow-hocks are most undesirable. The height of a dog is about 28 in., weight from 140 to 150 lb., bitches being 2 in. less, and weighing from 110 to 120 lb. *See Dog; Kennel.*

Newfoundland Dog. Champion of this powerful breed of life-saving dog which excels in swimming.

NEWMARKET. This card game, sometimes called stops, can be played by any number of persons between three and eight. Two packs are necessary, also a number of counters, which should be distributed among the players.

To begin the game, four cards are taken from one pack and are laid out upon the table. On these each player puts his stake, whatever he pleases, although sometimes a limit is agreed upon; he can put it all on one card, or divide it between two, three, or four. The cards of the other pack, having been shuffled and cut, are dealt out one by one to the players, and an extra card in every round is placed on the table. These extra cards are known as the stops.

The deal over, the player on the left of the dealer leads. He can lead any card in his hand, provided it is the lowest of the suit in question, and he continues to place cards upon it as long as he can keep up a sequence. When the sequence fails, the next player continues, and so the game goes on until the sequence is broken, because the necessary card is among the stops. The one who played the last card before the stop then leads, and so the game continues until the cards are all out. The interest of the game lies in the fact that when a player plays a card that is a duplicate of one of the four cards of the other pack, he is entitled to all the stakes that have been placed thereon. In this game the ace is counted as the lowest card.

NEW YEAR. In Scotland New Year's Day is still regarded from the popular standpoint as a more important festival than Christmas, although the latter has accquired greatly increased importance of late years, and is almost universally celebrated exactly as in the south. The closing week of the year has thus a double significance across the Tweed, and also in a lesser degree in the north of England, where the New Year ceremonies are popular. In Scotland New Year's Day is a bank holiday.

Parties arranged for New Year's Eve usually begin at 9 o'clock, and should be so arranged that the guests are all together by a few minutes before 12. In many houses it is customary to brew punch or some other liquor, and hand it round, so that, when the clock strikes, the health of the New Year may be drunk with due honours. The darkest member of the party should slip out of the house at the crucial moment and demand entrance so that the first footing shall be lucky. After the New Year has been thus ushered in the guests, host and hostess join hands and sing Auld Lang Syne. *See* Christmas; Hogmanay.

NEW ZEALAND BROOM. The broom-like half-hardy evergreen shrub, bearing the name of New Zealand broom or *Notospartium Carmichaeliae*, requires the protection of a wall, except in the warmer parts of the country. It bears pink, pea-shaped flowers during late summer. Propagate by seeds.

NEW ZEALAND FLAX. This name is given to an ornamental plant, *Phormium tenax*, a striking perennial distinguished by its long, erect, dark green leaves, about 4 ft. in height. The yellow or reddish-yellow flowers are produced in August.

This graceful plant looks well in a sheltered position near water, but it is rather tender, especially while young, and should have the rootstock protected with ashes or litter in winter. It likes a friable, sandy loam. Propagation is by seed in heat in spring, or by division at that season. There are several varieties, with variegated leaves.

New Zealand Flax. Hardy perennial for the waterside garden, with long, erect leaves and reddish flowers.

NEW ZEALAND HOLLY. This name is given to a group of evergreen shrubs which thrive in loamy soil and peat in a sunny position. The chief kind is *Osmanthus aquifolium*, a Japanese shrub, 5 ft. high, with holly-like leaves; it bears white flowers in winter.

NEW ZEALAND SPINACH. A hardy annual plant, the New Zealand spinach is cultivated in many gardens as a substitute for summer spinach. The seeds may be sown in March in sandy soil in the heated greenhouse, and the young plants placed out-of-doors in May. Seeds may also be sown in the open ground in May if heat is not available. The tips of the shoots should be picked off frequently, whether required for cooking or not. The plants should be put out in rows about 3 ft. apart, and the leaves cut and treated in the same way as spinach (q.v.)

NICANDRA. This tender border plant is sometimes called the apple of Peru. It is an annual plant, growing about 18 in. high, and bearing showy white and violet-blue flowers during summer. It should be raised from seeds sown in heat during February or March, the seedlings being transplanted to boxes, hardened off, and planted out in June. *See* Border.

Nicandra. Trumpet-shaped flowers of the annual border plant sometimes known as apple of Peru.

NICHE. This shallow recess in a wall can always be used to good effect in the decorative scheme of a room, hall, landing or staircase. Niches are usually either domed or rectangular, but occasionally the top is in the form of a pointed arch. A delightful fitment for a living-room, when building, is a larger domed niche with shelves for china, flanked by two smaller rectangular niches with bookshelves, the lower part of each recess being fitted as a cupboard.

Simple decoration sets off a niche either by framing with narrow mirror glass, or woodwork, or plaster

ornament and moulding, using a contrasting colour for the interior of the niche to that employed for the walls, or by painting a design within the niche itself as shown in the illustration. In this case recesses either side of the chimney breast have been utilized to hold decorative china, the design of the rising sun being painted in gold. A niche over a fireplace forms a pleasing alternative to the conventional overmantel, and can be either lined with mirror glass, gold or silver leaf, or merely contain some beautiful object. *See* Drawing Room; Recess; Shelf.

Niche in a chimney recess. It is ornamented with a design of a rising sun and contains old china. (Humphrey & Vera Joel)

NICKEL. Nickel is a white metal which takes a brilliant polish and resists atmospheric corrosion very well. Numerous household articles made of iron or steel are often nickel plated, for instance, scissors, thimbles, pins, pliers, and other small tools, small keys, etc. The process is used also for handle bars and other parts of bicycles, and similar metal fittings. Nickel-plated articles that get rubbed in use keep themselves bright, but such as are not exposed to occasional friction get dull in time, though slowly; they may then, however, be polished in a few seconds by merely wiping or washing off dirt and rubbing with a cloth or leather.

NICKEL. Nickel is a white metal which takes a brilliant polish and resists atmospheric corrosion very well. Numerous household articles made of iron or steel are often nickel plated, for instance, scissors, thimbles, pins, pliers, and other small tools, small keys, etc. The process is used also for handle bars and other parts of bicycles, and similar metal fittings. Nickel-plated articles that get rubbed in use keep themselves bright, but such as are not exposed to occasional friction get dull in time, though slowly; they may then, however, be polished in a few seconds by merely wiping or washing off dirt and rubbing with a cloth or leather.

The nickel coating generally adheres firmly enough to stand service conditions, but it may sometimes get chipped or worn off in places, exposing an ugly black patch due to the corrosion of the underlying steel. Nothing but replating will then restore the appearance of the article. *See* Electro-plating; Enamelling.

NICOTINE. Tobacco contains, amongst other substances, a liquid alkaloid called nicotine. The drug has been used in medicine as an anti-spasmodic in tetanus and strychnine poisoning, but is rarely employed. It has a marked effect in raising blood pressure, resembling adrenaline in this respect. Pipe mixtures are said to contain most, cigarettes less, and Havana cigars the least nicotine. Many, but not all, of the evil effects of smoking to excess are due to the amounts of nicotine constantly being absorbed.

This alkaloid or juice plays an important part in the colouring of pipes; but it is injurious to the tongue and throat of the smoker, and should not be allowed to accumulate in the stem, where it forms a soft, dark deposit. It may be removed with a small wire brush.

Where boiling water is available, a simple and effective method is to hold the bowl of the pipe tightly against the hot water tap, so that a strong jet of boiling water is forced through the stem, and thoroughly cleanses it of the nicotine. The process is much accelerated if the mouthpiece is removed and the end of a wire covered with soap is inserted into the stem, and the soap well worked in. This absorbs or loosens the nicotine, which is then easily washed away when the pipe is held under the tap. Any ordinary wire is suitable; a wire paper clip may be straightened out and used effectively as a pipe cleaner.

Another method is to heat the wire in the fire until it is red-hot, and then plunge it into the stem of the pipe. The nicotine is burnt up in this way by repeated applications of the wire; but the use of soap and boiling water is cleaner and more effective. The mouthpiece can be treated in the same manner.

Garden Uses. Nicotine is also useful to the gardener. Nicotine soap wash, as it is called, is a very useful contact insecticide which is recommended for the destruction of apple aphids by the Ministry of Agriculture (Leaflet 106). It is made up as follows:

Nicotine (95-99 per cent)	$\frac{3}{4}$ oz.
Soap (soft)	$\frac{1}{2}$ lb.
Water (soft)	10 gal.

If the water is hard, 1 lb. of soap should be used. Dissolve the soap in hot water, dilute to the required strength, add the nicotine, and stir well. If soft soap is unobtainable, hard soap should be used instead. It will also kill apple sucker, capsid bugs, young caterpillars, and other garden pests. *See* Apple; Insecticide; Pipe; Smoking; Tobacco.

NIELLO. This Italian word is used for a process of decorating metal with incised designs filled with a black alloy. To some extent it resembles both inlaying and enamelling. The alloy is one of sulphur with silver, copper, or lead. Niello is used also for the piece of work decorated in this fashion, and for an impression on paper taken from the engraved and incised surface before the niello alloy has been laid therein. *See* Enamelling; Inlaying.

NIEREMBERGIA. The species *rivularis* is a pretty creeping plant suitable for the rock garden. It bears white pink-tinged flowers and thrives in a compost of loam, leaf-mould and sand. Propagation is by division in spring. *Nierembergia frutescens* grows 18-20 in. high and bears beautiful blue flowers in summer; it is increased by cuttings which should be taken in July or August.

Nierembergia rivularis, a beautiful creeping perennial for the rock garden.

NIGELLA. This is the botanical name of a favourite hardy annual, love-in-a-mist, which bears blue flowers in summer. Seeds are sown out of doors in spring where the plants are to bloom.

NIGHT BLINDNESS. The condition of partial inability to see at night or at other times when the light is dim is known as nyctalopia, or night blindness. Sometimes it may be caused by the eye having been exposed to too strong a light. In most cases the abnormality is hereditary. It may be a symptom of changes in the eye due to syphilis, when treatment for this disease will be urgently

necessary. Apart from congenital cases treatment must commence with complete rest of the eyes, and it is usually necessary to improve the health by a generous dietary and tonics. *See* Blind; Eye.

NIGHT LATCH. This is a kind of latch which can only be opened by a key on the outside, but can be opened on the inside by turning a knob with the hand. It is a very convenient form, as it enables the door to be securely fastened against anyone who is not in possession of a key. It can be obtained in either the warded or in the lever pattern, and also in the pin tumbler form.

The keys are generally small, and so are convenient for carrying in the pocket, and owing to this advantage night latches are often fitted to hall doors. The latch is fixed to the door so that the case is on the inside, while the keyhole is cut through from the outside. The care and attention which should be given to this type of latch is the same as should be given to other locks and latches, and includes periodical oiling. *See* Latch; Lock.

NIGHT LIGHT. A form of short candle that gives a feeble light over long periods, as during the night, is termed a night light. It is often used in the nursery, and is also employed in photographic dark-lamps as an illuminant.

The two varieties in use consist of the short, thick cylinder and the pyramid shape. The former consists of a paper case into which melted paraffin wax or candle material has been poured, having in the centre a flax wick supported upon a tin disk. The night light of this form is placed in a saucer of water in use. It lasts about 8 hours. The pyramid or cone form of night light has a base of plaster of Paris, which supports the wick of rush-pith. This variety is generally burnt in glass dishes without water.

NIGHTMARE. The feeling of oppression and terror, accompanied by horrible dreams, to which the name of nightmare is given, is not, uncommonly the result of some digestive disturbance. Either the evening meal has been too heavy, or something has upset the stomach. People who suffer from nightmare should take their last heavy meal not later than three hours before bedtime, and avoid all mental work, such as study or engrossing reading, for the last two hours before retiring.

The mattress should be hard and smooth. The pillow should be just thick enough to leave the neck comfortable. The bedclothes should be light. The feet must be kept warm, if necessary, by wearing socks or by the use of a hot-water bottle. The patient must not lie on his back. To prevent this, if necessary, tie a cork or large spool over the lower part of the back where the spine is prominent. Constipation must be prevented. When an attack of nightmare is followed by inability to sleep, a glass of warm water with a tablespoonful of whisky, or a teaspoonful of sal volatile, will often prove an effectual remedy.

Nervous and delicate children often suffer from night terrors, and will wake crying out in fear. In nervous children the injury of repeated attacks may be considerable. The trouble is often due to a badly ventilated room or the use of heavy bedclothes. A more common cause is indigestion, resulting from faulty feeding. Over-pressure at school, great excitement before bedtime, a fright, or a creepy story told to the child may sometimes give rise to one of these painful attacks.

The child should be examined by a doctor for adenoids or other affections. The bedroom should be airy, and the bedclothes light but sufficiently warm. If the child is constipated, an aperient such as castor oil, $\frac{1}{2}$ to 1 teaspoonful, should be given. The mother should see that the child has only a light supper, no pastry, meat, or anything difficult to digest. Milk and biscuits or bread-and-butter will generally be found the best fare for a child late at night. In some cases a small cup of beef tea given the last thing at bedtime will stop the trouble.

When the child cries out, it is generally best to go to him quickly, as the presence of a grown-up person will tend to soothe his fears. When he is quiet, give a small drink of water and change his position, and it will be found that he readily sleeps again. Never under any circumstances speak impatiently to a child who wakes in fear, as it will only increase his distress. It is a great mistake to send a child to bed in a dark room when he dreads the dark. In these cases where night terrors are troublesome a night light should be placed in such a position that it will not throw shadows on the ceilings or walls, and if possible the child should not be left alone.

NIGHT-SCENTED STOCK. This is the popular name of *Matthiola bicornis*, a hardy annual, 10 in. or so high. It bears small lilac coloured blooms which give off a delicious fragrance in the evening. Seeds are sown out of doors in spring where the plants are to bloom.

NIGHTSHADE. The deadly nightshade is *Atropa belladonna*, the berries of which are poisonous. *See Atropine; Belladonna; Deadly Nightshade.*

NIGHT WEAR CASES AND SACHETS

Decorative Suggestions for these Bedroom Accessories

For further helpful information the housewife is referred to the articles on Appliqué Work; Drawn Thread Work; Embroidery; Leather Work; Painting on Textile Fabrics; Ribbon Work; Richelieu Work.

In spite of the endless choice of cases to hold night gowns and pyjamas which can be bought inexpensively in the shops today—cases ranging from plain and elegant envelopes of linen to the elaborate case made in the shapes of animals—it is still pleasant and amusing, besides being very economical, to make one's own cases at home to match the furnishings of a bedroom, or to make a special case to present to a friend.

Before the work of making a nightdress case is begun, the future setting of it, and especially the bed cover, should be considered carefully. For a severely furnished room with a plain coverlet a simple case of linen-decorated with broderie anglaise or edged with buttonholed scalloping, and embroidered with an initial (see Fig. 1) is most suitable. For a bedroom with prettier and softer furnishings, a nightdress case made of satin, interwoven ribbons or georgette, or a silk padded case scented with lavender or pot pourri would be more fitting.

Night Wear Cases. Fig. 1. Case made from linen, with scalloped edges and initial embroidered on flap.

Simple Cases. To make the simplest kind of nightgown case, half a yard of linen or artificial silk, 36 in. wide, is required. Cut out of this material a strip measuring 15 in. by 36 in., and fold it into three so that the flap and the case underneath measure 15 in. by 12 in. Sew up the sides with a single seam, the raw edges of which are afterwards bound on the inside, and neatly hem all round the flap. The edges of the flap can then be trimmed with lace or

fringe, and an initial can either be transferred and then embroidered, or appliquéd to the material.

The case illustrated in Fig. 1 was made in a deep shade of lavender linen and edged with pale green scalloping and green French satin stitch spots. The initial was also embroidered in green.

When an edge is scalloped in this way, the tracing for the scalloping and the actual embroidery should be done before the case is made up, so that it is possible to seam the sides in such a way that the case does not show beyond the scalloped edge of the flap.

The simple case can be elaborated in endless ways. Small flower groups (see article on Embroidery) can be embroidered in colour, or gay little figures or designs can be worked in cross-stitch. Fig. 2 shows a nightdress case with a slightly elaborated flap and embroidered with gaily coloured flowers. It is very fresh and charming, and washes and irons beautifully.

The transfer for this design, the "Garden Gate," Transfer No. 1,139, may be obtained by sending a 6d. postal order to the "Good Needlework Magazine" Transfer Department, 21, Whitefriars Street, London, E.C.4. Callers may obtain the transfer at the same price from the Paper Pattern Dept., D. H. Evans & Co., Ltd., Oxford Street, London, W.1.

Simple cases for pyjamas can be made from velvet sheepskin or suede. They are cut out in the same way as the nightdress cases, and the seams are thonged. The flap can either be left loose or fastened down by means of one or two press-studs (see Leather Work). Alternatively the case can be made without a flap, and the top edges closed with a lightning fastener. The front can be decorated with a stencilled or tooled design or monogram.

Amusing sachets or cases can be made of felt, with peasant figures or dancers of gaily coloured felt appliquéd on the flap, and bound with felt of a bright contrasting colour.

Noah's Ark Case. A delightful case for the pyjamas of nursery folk is illustrated in Fig. 3. It is made of linen, red for the roof, fawn or cedar brown for the walls and bright blue for the hull. The embroidery, which is of the simplest description, is done with one skein each of red, blue, cedar, darker brown and black stranded cotton. The preliminary stitching of the edges of the various pieces must be done firmly and neatly or the case will not wash and wear well.

First cut out the linen according to the diagrams in Fig. 3. Turnings are allowed for. Tack down a neat hem all round the red roof piece, sloping sides first and then the two straight edges. Hem the tops and bottoms of the two cedar pieces, using one thread of matching stranded cotton and tack down a single $\frac{1}{4}$ in. turning along the sides.

Along the bottom of the front wall, having first drawn or traced the design, embroider the figures, door and windows. Fold the blue piece for the hull in half lengthwise and join the sides with French seams. Then tack down a single $\frac{1}{4}$ in. turning all round the remaining edge.

Next tack the walls into position in the hull, the hem just under the turning, making sure they are in the centre of the hull and using three blue threads and $\frac{1}{4}$ in. long blanket stitches with $\frac{1}{4}$ in. spaces between. Blanket-stitch all round the top of the boat, thus attaching the front walls to the front of the boat and the back wall to the back of the boat. Tack the walls together at each side and blanket-stitch them together with matching cotton, using a smaller stitch and spacing.

Fold the roof in half and stitch the top edges (X and Y) firmly to the top of the front wall (points A and B). Tack the lower back edge of the roof to the back wall. Now blanket-stitch in red, as before, all round the roof, fastening down the back, but leaving the front loose open. Slip-stitch together the ends of the boat projecting from the walls.

Fig. 2. Nightdress case with elaborated flap, embroidered with gaily coloured flowers(Courtesy, Good Needlework Magazine)

More Elaborate Sachets. Beautiful nightdress sachets can be made from shot silk. The simplest is oblong in shape bound with a heavy silk or tinsel cord. For this cut four pieces of taffeta shot mauve and blue or flame and gold or whatever colouring is most suitable for the room—measuring 17 in. by 13 in. Cut two shapes of cotton wool half an inch smaller than the taffeta all round. Lay one piece of taffeta for lining on a top piece and seam all round the edges, leaving about 6 in. open. Tack a wadding shape on the lining at the extreme edge and turn them all inside out. Finish off the last 6 in. invisibly and prepare the second padded half of the sachet in the same way. Stitch the two

pads together and leave one side open to slip the nightdress in. Trim with the cord and a motif of padded flowers or one in gold or silver embroidery. Such motifs can be obtained ready made or hand embroidered. Gold is used for a shot silk with yellow in it, silver for blue or mauve.

A pretty trimming is made by using a 2 in. wide tinsel gauze ribbon and a gold or silver lace to finish the front of the sachet. Take running-stitches along the edge of the ribbon and draw up to fit the sides of the sachet. Tack it into position round the edges and stitch a narrow tinsel lace on one side of it facing the centre of the sachet, and another on the outside of the ribbon and on the edge of the sachet. The inner lace trimming should lie flat on the edge of the gauze and on the sachet and the outer lace trimming should be slightly gathered.

A very attractive black satin case may be made from two ovals of black satin, two of pink taffeta and two of wadding and trimmed with a basket of silk flowers in vivid colourings and with a gold insertion and lace each $\frac{1}{4}$ in. wide. First cut an oval measuring 16 in. by 19 in. deep.

Lay this pattern on double black satin and cut out two ovals; then cut out two more of the same size from rose pink taffeta and two more a trifle smaller from wadding.

On one of the black satin ovals the basket of flowers is arranged. A suitable design may be accomplished by means of appliqué work (q.v.) by painting on the satin, by embroidering the flowers or by making them in ribbon work (q.v.) The basket is made from five rows of the gold insertion sewn over a piece of gold coloured satin shaped like a basket. Stitch it down on the sachet and arrange the flowers over it.

Lay a taffeta and a satin oval face to face and seam them together three-quarters of the way round. Lay a wadding oval on the taffeta one and catch it down with slip-stitches all round the edge. Turn the seamed ovals right side out, and the wadding will be in its correct position between them. Finish off the last part of the seam invisibly. Seam the remaining three ovals in the same way. Slip-stitch the two padded halves together, leaving them open for about eight inches at the left-hand side. The nightdress is slipped in here.

All round the edge of the top oval, with the basket on it, stitch a strip of gold insertion $\frac{3}{4}$ in. wide, gathering it on the inner edge to fit the curve of the oval. Then, round the extreme edge of the sachet stitch a strip of gold lace about $\frac{3}{4}$ in. wide gathered slightly along the straight edge. These laces must, of course, be stitched only to the top oval where the sachet is left open at the side.

A circular sachet can be made in the same way as the oval one previously described, merely cutting out and making circular pads instead of oval ones. A pretty finish is shown in Fig. 4. This sachet is lined with pink silk and covered first in black satin, and then has a top covering of gathered black georgette. The trimming consists of a large shaded pink silk rose and green silk leaves (q.v.).

Night Wear Sachet. Fig. 4. Circular sachet of gathered black georgette over black satin, trimmed with a large shaded pink silk rose.

Cedar front wall

Cedar back wall

Night Wear Case. Fig. 3. This Noah's Ark design in coloured linen makes a practical and amusing pyjama case for a child. The roof lifts up for the pyjamas to be put in or taken out. (Courtesy, Good Needlework Magazine)

Nine Bark. This hardy deciduous shrub is known botanically as *Neillia* (q.v.).

NIPPLE: Its Care. That portion of a woman's breast by which milk is conveyed to the child should be prominent in the healthy, well-developed woman, and especially so during pregnancy and after childbirth. Great care should be taken that the clothing is never sufficiently tight across this part of the body to crush the nipples.

If through pressure or any other cause the nipples are not sufficiently developed for it to be easy to suckle the child, the following treatment should be carried out. During the last few weeks of pregnancy the expectant mother should gently pull out the nipples each day, using cotton wool and a little vaseline. For the last two months before the child is born bathe the nipples night and morning with eau-de-Cologne (1 part eau-de-Cologne to 3 parts of water). After bathing, dry with a soft cloth or piece of flannel.

After childbirth the nipples must be carefully attended to. They should be bathed with boric solution (a teaspoonful of boracic acid to the pint of water) before and after suckling, and then carefully dried with cotton wool. Should cracking or chapping take place, smear with a paste made of equal

parts of bismuth carbonate and castor oil between feedings, and have a nipple shield for the child to draw the milk through.

Sometimes when the nipples are very sore it is necessary to keep the child from suckling for a few days, and then the milk must be drawn from the breast by means of a shield with tube and teat attached, or a breast pump. Sometimes while a woman is suckling her child a small abscess forms on the nipple. This should be opened by the doctor, and dressed with antiseptic lotions, etc.

Eczema of the nipple may be very troublesome. It results from neglect of cleanliness after suckling. The nipples swell, and become more or less raw. There is usually some pain and itching and the skin around the nipple may become involved. If the outbreak of eczema is severe, the child should be weaned. Bathe the parts with an alkaline lotion such as bicarbonate of soda (1 dram to $\frac{1}{2}$ pint of water), carefully dry with a piece of clean, soft linen, then apply zinc ointment, lanoline cream, or the paste above mentioned, and cover with lint or linen. *See Baby.*

Nit. *See Lice.*

NITRATE: For the Garden. In gardening the term nitrate usually means nitrate of soda, though sometimes it is applied also to nitrate of potash. Nitrate of soda is a particularly good stimulant for vegetables in spring and early summer, as it helps on the growth. It must be used with care, as it promotes luxuriant leafage. One oz. per sq. yard is sufficient. One oz. dissolved in 1 gallon of water makes a good plant stimulant. Nitrate of potash is very stimulating, as it contains 15 per cent of nitrogen and 40 per cent of potash, but is too expensive for general use. *See Garden; Lime; Manure.*

NITRATE OF SILVER. Also known as lunar caustic, nitrate of silver is much used in medicine, in the form of crystals or moulded into pencils or sticks. It is largely used as a caustic for the removal of warts, proud flesh, etc. A solution forms a useful astringent spray for an inflamed pharynx or larynx, and a weaker solution may be used as a gargle. If it is desired to stop the local action of the nitrate use a little common salt. Internally it is frequently prescribed as a remedy for gastric or duodenal ulcers, diarrhoea, and chronic catarrh of the stomach.

In poisoning by nitrate of silver there is vomiting, purging, severe inflammation of stomach and intestine, and also violent pain. The treatment while awaiting the doctor consists in administering a strong solution of common salt, keeping the patient warm, and giving milk, olive oil, and soothing liquids.

NITRE: Its Household Uses. Potassium or sodium nitrate, known as nitre, is chiefly used in the household as a meat preservative, retaining the red colour of the meat better than common salt. For making a pickle for hams, a mixture of common salt 3 lb., nitre 2 lb., and boric acid 1 lb. is usually employed. Nitre is also a constituent of fertilizers. As an example, a mixture of equal parts of nitre and phosphate of potash is employed. One teaspoonful of this powder dissolved in a gallon of water is used for watering plants in pots; for outdoor plants the proportion is one tablespoonful to every gallon.

In medicine nitrate of potassium, also known as saltpetre, is frequently used in fever mixtures on account of its mild diuretic and diaphoretic effects. Poisoning may result from large doses, usually taken in mistake for sodium sulphate or for Epsom salts. The symptoms are vomiting, purging, with blood in the stools, suppression of urine and sometimes convulsions. While awaiting the doctor, if vomiting has not occurred it may be induced by giving an emetic, e.g. common salt, or by tickling the back of the throat. Thereafter milk and olive oil may be given, and hot poultices or fomentations applied to the abdomen to relieve pain.

Nitre Paper. The breathing in of the smoke from burning nitre papers often gives relief to people who suffer from asthma. Nitre paper may be prepared at home in the following way: Take 6 oz. of saltpetre and put in a pint of water, which should be nearly boiling. Let the saltpetre thoroughly dissolve, and then dip into the solution pieces of white blotting-paper a few inches square. Let them thoroughly soak, and then lift out and allow to dry, but not near a fire. To use them, fold like a tent, then place on a dish or in the fender, and light at the folds so that they burn slowly. Two or three may be burnt one after the other in the patient's room. *See Asthma.*

NITRIC ACID. Aqua fortis or nitric acid is a strong mineral acid which gives off irritant fumes when exposed to the air. It is a powerful caustic. Poisoning by nitric acid is indicated by yellow discoloration of the lips. Alkalis such as chalk, bicarbonate of soda, etc., should be administered as antidotes.

Nitric acid has many applications in industry for such purposes as the manufacture of explosives and aniline dyes.

Nitric acid is poisonous and the fumes given off are injurious to health. It should never be left loose, but kept in a well-stoppered bottle, stored in a safe place, and prominently labelled.

The use of nitric acid in the home is restricted chiefly to such operations as the etching of metals, although in the form of a salt, such as nitrate of silver, there are important applications in photography. Barium nitrate and strontium nitrate are used for the manufacture of many kinds of fireworks. When used as a very weak solution in water nitric acid forms a useful cleansing agent for badly discoloured brass, copper, and similar alloys; but the metal must be thoroughly scoured in boiling soda water immediately afterwards, as the action, unless stopped, will corrode the metal. *See Caustic; Poisoning.*

NITRITE OF AMYL. This very volatile liquid is usually inhaled, but it may also be swallowed. Nitrite of amyl is much used in angina pectoris and other convulsive attacks. The dose for inhalation is 3 to 5 minims. This is supplied in thin glass capsules, one of which the patient places in a corner of his handkerchief, crushes between finger and thumb, and then inhales the vapour. This should be done slowly, for the action of the drug is extremely sudden, and at first may cause alarm.

NITRO-CELLULOSE FINISHES. These are enamels and lacquers prepared by dissolving nitro-cellulose in special solvents and incorporating pigments to give the desired colour or tint. The drying, which is rapid, takes place by evaporation of the solvent. Cellulose finishes, as these products are usually described, are prepared specifically for spraying or for brush application. The former class is extensively used for industrial work (e.g. in enamelling coachwork, furniture, etc.). The home worker can obtain a portable spraying outfit with "pistol," foot pump, and air reservoir, for about 50s.

Brushing finishes are obtainable in a wide range of attractive colours, and, though slower than the spray class, are comparatively rapid in drying. The technique of their application presents no difficulty. It is described in detail in the article on Enamel.

The brushes used should be rubber set ones having soft bristles, and care should be taken not to mix together the products of different makers, since the base or solvent used might be different in nature and composition. For a like reason both undercoating and finishing coat should be those of the same maker.

The solvents employed are inflammable, and the material should not be used near a fire or any open flame. When the work is done indoors the room should be well ventilated.

NITROGEN: For the Garden. Plants need nitrogen when they are without vigour and their foliage has a washed-out, pale-green appearance. Application of a quick working nitrogenous manure, such as nitrate of soda, in small quantities will rapidly encourage new growth, and restore health to a sickly plant.

Soot contains a percentage of nitrogen, and apart from its value in this respect is useful in making a plant's immediate vicinity distasteful to slugs and other pests: it must not be used carelessly, however, as it is injurious to the leaves of tender plants.

Sulphate of ammonia is preferable to nitrate of soda, 1 oz. to the sq. yd. making a good ground dressing, or 1 oz. to the gallon in solution. Generally it is unnecessary to apply nitrogenous manure to leguminous crops, as these naturally draw the element from the atmosphere and in conjunction with bacteria convert it into food form. *See Fertilizer; Guano; Manure.*

THE NOAH'S ARK AND ITS CONTENTS

How to Make a Popular Nursery Toy

This work contains numerous articles dealing with children's amusements and nursery matters generally. Among them are Doll; Knitted Toys; Rocking Horse; Toys. *See also Nursery.*

Arks containing animals can be bought in a number of sizes, from small ones including only a dozen or so animals to quite large ones with two or three hundred. The animals are almost always in

wood. In the larger arks they are made in pairs, each pair representing an animal or bird, with other wooden figures representing Noah and the members of his family.

Noah's Ark. Fig. 1. Small Noah's ark which can be easily made by following the directions given in this article.

A typical ark (Fig. 1) is made with $\frac{1}{4}$ in. and $\frac{3}{16}$ in. wood. The base is $12\frac{1}{2}$ in. by $3\frac{1}{2}$ in. by $\frac{1}{4}$ in., shaped at each end and chamfered along the lower comers. The ends are 5 in. by $2\frac{7}{8}$ in. by $\frac{1}{4}$ in., with the top corners sloped off to $3\frac{1}{2}$ in., and the sides are cut from $\frac{3}{16}$ in. wood to $8\frac{1}{2}$ in. by $3\frac{1}{2}$ in. Glue and brad the sides to the ends, and then attach in the same way to the base, leaving an equal amount at the sides and ends. The slope of the ends should be carried along the top edges of the sides with a smoothing plane. The roof is made from two pieces of $\frac{3}{16}$ in. wood, both $9\frac{1}{2}$ in. long, one $2\frac{5}{8}$ in., and the other $2\frac{1}{2}$ in. The wider piece is glued and bradded on one side, over-lapping the apex of the ends by $\frac{3}{16}$ in., and the other piece is attached with two or three strips of linen or canvas, which measure about 1 in. by $\frac{5}{8}$ in.

The outside of the ark is coated with white or cream paint and the imitation timber work and windows indicated by grey and black paint. The effect may be brightened up by using red and blue if desired. A narrow slit should be made in the hinged lid and a piece of wire cut from the end of a hairpin driven in the side to project through the opening. The roof should be coated with glue, and covered while sticky with finely granulated cork and flat particles of straw. A catch is attached to the top to fit in a loop made in the wire.

Any number of figures and animals may be placed inside. They should be cut out with a fretsaw from planed fretwood; yellow pine is best, but either whitewood or satin walnut may be used. The simplest way of making the figures is to shape them out of round wood, as in Fig. 2. Pine or deal is the easiest to cut, but whitewood is stronger. First cut off a number of lengths about $1\frac{3}{4}$ in. from $\frac{3}{8}$ in. round, and mark off $\frac{7}{8}$ in. or so and $\frac{1}{2}$ in. above, as indicated at A. Place a knife on these marks and cut into the wood, rolling it backward and forward to form the cuts shown at B. Cut down as at C, and then make other cuts as at D, these being $\frac{1}{8}$ in. apart, and finish with a file.

Fig. 2. Progressive stages in carving the human inhabitants of a Noah's ark.

The next stage, shown at E, is done with a narrow-bladed penknife and finished quite round. This leaves the back to be cut flat, as at F. To complete the figure, the arms, $\frac{3}{4}$ in. by $\frac{1}{8}$ in. by $\frac{1}{16}$ in., should be tapered slightly and glued on, leaving

the painting to finish. Much time can be saved in making these figures by turning them on a lathe to the stage shown at E, the back, arms, and painting only being left. The body is usually painted in one colour, the top, forming the hat, in another, and the head pale pink, with the features indicated by spots of black paint.

The Animals. These are drawn on the wood and cut to shape, some from $\frac{3}{16}$ in., others from $\frac{1}{4}$ in. and $\frac{5}{16}$ in. wood. Three typical examples are illustrated. The horse, cow, pig, sheep, and similar shaped animals, are made by taking the block shape as left by the fretsaw (shown in Fig. 3, A), and forming the legs by making a tenon saw cut across, as indicated at B. The ears are formed by cutting a V-shaped nick, as at C, and the horns of the cow by fitting in a shaped piece of $\frac{1}{16}$ in. wood in a saw-cut made in the head, as at D.

Noah's Ark. Fig. 3. A, fretwood block; B, legs formed by tenon saw-cut; C, ears formed by V-shaped nick; D, use of a shaped piece of wood for horns.

Most of the blanks, after they have been divided by the saw to form the legs, are given a slight shape by cutting off the sharp edges. Some of the animals will bear a little more modelling to give a good shape to the head, particularly with the dog, sheep, and birds. In the latter the beak should be brought to a point by cutting the wood outwards as in sharpening a pencil. It is usual to give a little shape to the sides of the

birds, slightly tapering them towards the tail, but keeping the latter portion full width so that it will stand properly. Both the cat and the cow are made wider at the back; this can be done before the legs are cut, but it is not difficult to cut a slice off each side when cutting the corners off. As it is usual to make the animals in pairs, time is saved in cutting out if two pieces of wood are fastened together. To prevent the saw from catching, both of the pieces should be pasted on a sheet of paper. Although ordinary paint may be used for finishing the animals, it is usual to employ a spirit varnish coloured with aniline dyes. Ordinary shellac varnish is expensive for large work, but a coating of size applied to the work beforehand will prevent the varnish soaking into the wood. A

good varnish paint may be made by dissolving resin in methylated spirit and adding a little dye, but this method is not suitable for bright colours.

Another method of forming small animals is to cut the plain shape out of thin fretwood and form the legs with separate pieces of wood. The legs may be made movable by cutting to a larger shape and riveting them. By using this method, which is only suitable for animals more than 1 in. high, the trunk of the elephant, the horns of the cow, ears of other animals, or wings of birds may be made to move, as shown in Fig. 4.

Noah's Ark. Fig. 4. Three typical animals, elephant, cow, and duck, cut out of thin fret-wood, and made with movable limbs.

A good method is to cut the animals out in $\frac{3}{16}$ in. fretwood and mount them on suitable bases. Unless it is desired to model the shapes, they may be rapidly sawn from prepared wood, sycamore, satin or black walnut being suitable. The shapes are drawn out on thin white paper, keeping as closely as possible to the proportions shown in Fig. 5. Ordinary drawing-paper is too thick for this purpose. In order to obtain a good line for the saw to run against, the pencil lines on the drawing should be outlined in Indian ink.

The usual method is to fill the whole of the shape in with black; the white paper shows up clearly against the black, and helps in cutting a true shape. The paper is pasted to the wood, which must have a true and smooth surface. In order to ensure that every portion of the paper adheres to the wood, it is advisable to use a roller or a soft piece of rag, and carefully press down the surface, working with another piece of paper over it from the centre to the outside. (The article on Fretwork should be referred to for useful hints on this point.)

When the paper is dry, drill holes in all the enclosed spaces. In dealing with the elephant, for instance, five holes will be required, one between the trunk and the tusk, three underneath between the legs, and the fifth at the back for the tail. If possible, the continuation of the lines of the limbs, indicated by black lines on the illustrations, should be made by saw-cuts; this is only possible when the figures are mounted. All the lines should be sawn square, and particular care exercised in turning the corners. The shape of the head may be quite spoilt if the saw-cut is allowed to stray, and as the animals are so small, even a slight difference in a saw-cut may be disastrous. When all the shapes have been cut out, both surfaces should be rubbed over with glass-paper; the paper is cleaned off with a coarse grade and finished with a fine.

Methods of Attachment. There are various methods of attaching the animals to a base: one is to glue them on as in Fig. 5. The bases are $\frac{3}{16}$ in. thick, $\frac{3}{4}$ in. wide, and long enough to take the whole length of the bottom strip with about $\frac{1}{8}$ in. to spare at both ends. In order that the glue joint should hold securely, the surface of the shape fitting on the base must be quite level; this may be ensured by rubbing each strip on a flat piece of fine glass-paper, holding it quite upright.

Another method is to fit and glue the cutout shapes in a grooved base, as in Fig. 6. A long strip of $\frac{3}{4}$ in. by $\frac{3}{16}$ in. wood can be prepared by using plywood and gauging lines in the centre to the required width. The cutting edge of the gauge must be sharpened, and the cut must be deep enough to carry it below the thickness of the first layer of the plywood; the waste can be removed with an $\frac{1}{8}$ in. chisel.

The strongest method of securing the shapes is to tenon and glue them into slots cut into the base, as shown in Figs. 7 and 8. If this method is decided on, there is no need, as a general rule, to make

more than two slots, and in many shapes one will be sufficient. The wolf requires three slots, the bear two and the chicken one; these will serve the purpose of examples.

Larger fretwork sets of moving animals can be made by utilizing the same shapes drawn out to a larger scale and cut out in thicker wood. The four-legged animals are the most difficult to make. For the bull, one piece for the head is cut out as indicated at A, Fig. 9, two pieces for the body, two pieces each for the front legs above and below the knee, as indicated at B and C, similar pieces for the back legs D and E, and one for the tail F. Small round-headed nails and thin washers will be required for fixing, as shown in the section at G. If the joints are riveted up tightly by tapping the end of the nails with a hammer, it is possible to stand up the animal in any position. The separate ears and horns that are to be fixed to the head are shown at H and K.

Noah's Ark. Figs. 5-8. Animals cut out in fretwood and mounted on suitable bases, showing use of glue joint, groove, and tenon respectively. Figs. 9-10. Fretwood animals with movable limbs which can be jointed with small nails and washers. An explanation of the lettering is given in the text.

The ostrich shown at Fig. 10 may be jointed up in the same way as the bull, but it will not be necessary to joint the legs.

NOGGIN, A measure of capacity for the sale of liquids known as a noggin is normally a gill, or quartern. By liquid measure, the noggin has a capacity of 8·665 cubic in., or ·1420 of a litre. In old wine measure 4 gills or noggins made a pint. The measure is a variable one, and to some extent is used as a convenient term to describe a portion, or helping, rather than a unit of measurement. For instance, if the liquid purchased were measured by the old Winchester gallon, one of which is only ·8831 of the imperial gallon, the noggin would be 14 p.c. or thereabout less than the imperial. The word is also applied to a small wooden vessel.

NOGGING: In Brickwork. Although mostly found in brickwork, nogging may also consist of pieces of wood built into a masonry wall upon which to fix other woodwork, such as a window frame; or it may be used as a tie, or stiffener for the wall. In half-timber work, in which the houses were built with a framework of heavy timber, the spaces between the parts of the framing were often filled in with bricks in the manner illustrated, and this is known as nogging.

Nogging. Example of nogging in brickwork in an old half-timber house.

Most of this old work is held in high esteem, owing to the arrangement of the bricks (often in a herringbone or other ornamental pattern), and the natural weathering which has produced fine colouring effects. *See Brick.*

NOISETTE: In Cookery. Noisette is the name given to small round pieces of meat cut from the fillet or loin, all fat removed, and fried quickly in dripping without coating. The noisettes are then served with a garnish of vegetables. Sometimes they are covered with brown meat glaze. *See Beef.*

NOISETTE: The Rose. This is the name of an old-fashioned type of rose, raised by a Monsieur Noisette, by cross-breeding between the musk and China roses. Few varieties are grown nowadays, but W. A. Richardson, orange yellow, and Aimée Vibert, white, are still popular. *See Rose.*

NOLANA. Sometimes called the Chilian bellflower, this is an annual. It may be raised from seeds sown in heat during spring, and transplanted in May, or it may be sown in patches, in April, where it is to flower. *Atriplicifolia*, with blue flowers, is the chief species.

Nolana. Blue flowers of the species atriplicifolia.

NONPAREIL. The handsome cage bird called nonpareil is a native of warmer parts of N. America, and is about the size of the British linnet. It is kept chiefly on account of its bright plumage; the song, though soft and pleasing, being little more than a repetition of short notes, like the song of the yellow hammer.

The head and neck above are rich purple blue the other upper parts are diversified with yellow, green, and red, and the lower parts are red. The hen bird is more soberly coloured; the upper parts green-olive and the lower parts yellow. Its natural food is seeds and insects. In the aviary it should be given seeds: millet, rice, canary, and poppy; also flies and other small insects.

NOODLE, or Nouille. A paste made from flour, eggs, and salt, which is known as noodle or nouille paste, may be used with equal success as a foundation for savoury dishes, a pudding, or as a garnish. It is also known as ribbon macaroni.

To make it, sift $\frac{1}{2}$ lb. flour on a pastry board, then melt $\frac{1}{2}$ teaspoonful salt in sufficient water to dissolve it. Make a well in the centre of the flour, add the salt and the yolks of 5 eggs and incorporate these ingredients, working in the flour from round the hollow first. The paste must be kneaded thoroughly and vigorously. When well worked, sprinkle it with a few drops of water, make it into a ball, roll it in a clean cloth and let it lie for an hour or two, or till wanted. If the eggs are small an extra yolk may be required, but the paste, although pliable, should be very stiff.

After standing an hour or so roll the paste very thinly and cut it into strips six to seven inches wide. Roll the strips up tightly and cut them across with a sharp knife into narrow strips about an eighth of an inch wide. Shake these out and straighten them, dredging them with a little flour. Put them into fast boiling salted water, stir them for a few minutes to keep them separated, and then boil them for 10 minutes. Lift out and drain them through a sieve or colander and put them in layers in a buttered baking dish, with grated cheese between the layers. Put a good layer of grated cheese and fine breadcrumbs on top, pour over a little oiled butter and bake in a quick oven until well browned.

Noodle Dishes. A savoury dish is made by cutting the quantity of noodle paste given above into strips and parboiling them in boiling water to which salt has been added, and draining them on a sieve. Then put them into a stewpan with 3 gills strong well-flavoured chicken or veal stock, 1 oz. butter, a little grated nutmeg, mace, pepper and salt. Place the lid on the stewpan, with a piece of greaseproof paper underneath it, set the pan on the stove over slow heat, and simmer gently until the noodles have absorbed all of the stock.

Then take it up, add a teacupful cream, 1½ oz. butter and mix these in with the contents of the pan by lifting them up with a fork and turning them over. Pile them up on a hot dish scatter over a thick layer of grated cheese and the yolk of a hard-boiled egg which has been passed through a wire sieve. Put the dish in the oven to colour the cheese, and send it to table garnished with croûtes of fried bread.

To make a sweet pudding, prepare ¾ lb. noodle paste, then lay aside ⅓ of it. Treat the remainder as in the recipe for a savoury but substitute 3 gills milk for the stock and add also 2 oz. butter 4 oz. sugar, a pinch of salt and flavouring of vanilla or any other essence preferred. About ¾ hour will be sufficient to allow for the pastry strips to absorb the milk. When ready mix in 4 well-beaten eggs. Take the remainder of the pastry strips and coil them closely round a well-buttered plain mould. Turn into the centre the prepared noodles put the mould on a thick baking sheet and bake till it is a fawn colour. *See Ravioli.*

NORFOLK CAKE. To make a Norfolk cake which is a kind of rich bread, take 1¾ lb. flour and sift it into a basin with ½ teaspoonful salt. Cream ¾ oz. (lightweight) yeast with 1 teaspoonful castor sugar. Melt 6 oz. butter in 3 gills water, and when cool mix it smoothly with the yeast. Turn the liquid into the centre of the flour, make it into a dough, and knead it thoroughly. Set it to rise covered with a cloth, and when very light make into round cakes and bake about 20 min. in a hot oven. Brush over the tops of the cakes, when baked with milk or eggs. *See Yeast.*

NORFOLK DUMPLING. Norfolk dumplings may be served either with boiled meats or as a sweet with butter and sugar preserve, or a sweet sauce. They should be made with about 1 lb. of very light white bread dough and each piece of dough should weigh roughly about 1½ oz. before it is boiled.

Make up the dumplings into smooth round balls and drop them, if to be served with meat into the pan in which the meat is boiling, about 20 min before it is cooked. If they are intended as a sweet, drop them into a pan of fast-boiling, clear water and cook them from 15 to 20 min. When placed on the dish each should be torn apart with two forks, and a lump of butter and sugar inserted, the halves being closed together again. Sometimes jam sauce accompanies the dish, but on no account must these dumplings be cut asunder with a knife.

As it is not always possible to be provided with yeast dough or to make it, use instead a dough made with flour, salt, baking powder, and sufficient milk or water to mix it to a stiff paste. Knead quite smooth and shape and boil as directed above. One teaspoonful baking powder should raise ½ lb. flour. *See Dough; Dumpling.*

NORFOLK ISLAND PINE. This is the common name of a half-hardy tree. *Araucaria excelsa*, which in Great Britain must be grown under glass. It is familiar as a pot plant, and is largely used for room and window decoration. Propagation is by cuttings in spring under glass. It should be potted in a compost of sandy loam with a little peat added.

NORFOLK LATCH. This is a form of thumb latch. It comprises three parts. One consists of a metal plate on which is fixed a handle, a hole being formed in the plate at a convenient distance

above the top of the handle, through which passes the latch. The end of the latch is flattened so that the thumb can be placed upon it while the fingers grip the handle. The other parts consist of the catch and the keep, the catch being operated by the latch, while the keep engages the catch so that the door cannot be opened unless the catch is raised. When fitted, the Norfolk latch should be so placed that the handle and latch are fixed on one side of the door, while a hole is formed through the door so that the latch can operate the catch, which is placed on the opposite side of the door. The keep is placed on the door post to correspond with the catch. The door may be opened on both sides, on one by depressing the latch and on the other by raising the other end. *See Door. Latch.*

Norfolk Latch. Door in part section, showing how latch and catch are fitted

NORFOLK PUDDING. For this pudding take 1½ lb. good cooking apples; any sort which are quick cookers will be suitable. Make a batter with 3 eggs, ½ lb flour, salt, and 1 pint new milk. Grease a pie-dish thickly with butter, lay in it the apples, which should have been peeled and cored. Fill the hole where the core has been with sugar well flavoured with pounded clove or grated lemon rind Pour over the apples the batter, and bake in a moderate oven about half hour. Try the apples to see if they are quite cooked before removing the pudding from the oven.

NOSE. The nose consists of bone and cartilage. Two nasal bones compose the bridge, from which are continued the cartilages or movable portion of the nasal organ. The interior is divided into two portions by a partition termed the septum. From the nostrils the cavities run backwards for about 2 in. and open into the naso-pharynx.

The nasal organ is very liable to catarrhal inflammation, as in what is popularly termed a cold in the head. Adenoids tend to keep up a chronic catarrh, and boils often cause trouble.

Nose Bleeding. Bleeding of the nose, or epistaxis, may be due to such general causes as severe anaemia, scurvy, or plethora, a full-blooded condition of the head. Local causes are blows, ulcers, and picking of the nose. In cases where the bleeding is excessive any of the following measures may be used to stop it: raise the arms above the head and have someone apply cracked ice in a towel to the nose and back of the neck; or lay a cloth soaked in very cold water over the nose; inject very cold water into the nostrils; gently squeeze the nose between the finger and thumb, the patient lying down quietly. Sit on a chair with the head thrown back as far as possible and put the feet in hot water. Relief can generally be obtained by snuffing up a weak solution of alum, such as 10 gr. to 1 oz. of water.

Injuries to the Nose. Children sometimes push into the nose peas, fruit stones, buttons, or even slate pencils, which lead to swelling, discharge, and bleeding. Before this foreign body has become fixed it can be treated by pressing the finger on the other side of the nose while the patient blows down forcibly. Another method is to administer snuff or tickle the nostril with a feather to induce sneezing. The nostril may be syringed gently with warm water. The mother should never attempt to remove the obstruction by pressing any instrument into the nose, as this may lead to serious damage to the organ.

Most frequently chronic redness of the nose is caused by indigestion. Some people are particularly prone to this disfigurement, and suffer after exposure to wind or sun. The indigestion must be prevented by proper dieting. The following may be applied nightly to the nose with advantage:

Precipitated sulphur	4 dr.
Glycerin	2 „
Alcohol (90 %)	½ oz.
Rose water	3 oz.
Lime water	3 „

For this trouble, too, everything should be done to improve the general circulation. A daily tepid bath, followed by a brisk rub down with a rough towel, and regular brisk outdoor exercise, are two invaluable measures. A tonic such as Easton's syrup should be taken for a few weeks. For covering over the disfiguring redness, a liquid to dry on and leave a powder is sometimes to be preferred to the ordinary face powders. The following is a simple preparation of this sort:

Pure oxide of zinc	1 oz.
Glycerin	1 dr.
Rose water	4 oz.
Essence of rose	15 drops

Before applying, shake the bottle well, and then pour a little into a saucer and, with a fine brush, paint the liquid lightly over the nose. Then gently remove with a soft linen handkerchief any excess of the powder, and allow the remainder to dry in. *See* Adenoids; Blackhead; Breathing; Cold; Douche; Eustachian Tube; Nasal Catarrh.

NOSE BIT. This is a brace bit in the form of a semicircular sectioned tool with a lip at the cutting end. It is used for boring holes in wood, particularly when the hole is to be bored in the same direction as the grain of the wood, as the lip at the end of the bit enables the core of the hole to be drawn out. *See* Bit.

NOSING: In Woodwork. This is a term commonly applied to any projecting rounded edge. A typical example is that usually found on the tread of a step in a flight of stairs. There is also the nosing of flat lead roofs, a roll placed on the edge of the lead flat when the sides of the roof are slated.

Other examples of nosing are found on the edges of window boards, or the projecting portions of a table. It is one of the most practical finishes, as it does not hold dust, is easily worked, and has no sharp corners to wear rapidly or give trouble.

In working nosings the rough and ready way, which often gives excellent results, is to plane over the two corner edges at an angle of 45° and then plane off the 4 corner edges which will result from

the first planing. This produces 9 flat surfaces on the edge, and it only remains to plane off these edges one into the other. Another plan is to use a hollow plane, or spokeshave, and produce the required shape by virtue of that of the cutter. Generally, however, both of these implements are used after the edge has been roughly rounded. In either case, the finish should be effected with fine sandpapering.

Nosing. The use of a smoothing plane to form a plain nosing.

NOTEPAPER: Its Varieties. The sizes of notepaper in most general use are Czarina (6 by 4½ in.), Octavo (7 by 4½), Viscount (6½ by 5), Imperial (7½ by 5¾). Some people prefer single sheets to folded notepaper, and these are usually in sizes known as Post Octavo, Diamond, and 6th Avenue.

There are various finishes in all the qualities. The best known of these are linen finish, which is a trifle rough; white wove; and cream laid, which is smooth. Parchment is more expensive. Bond is another white, smooth finish. Vellum is not much used in notepaper as, although quite smooth, it has rather a dull appearance. Hand-made deckle-edged paper is the most expensive. Notepapers are obtainable in various shades, including mauve, yellow, orange, green and blue, in linen and smooth makes. Envelopes are sold to match, generally at the rate of 100 envelopes to 120 sheets of note paper (5 quires).

The water mark in notepaper is not peculiar to any particular make or size. It appears in every quality except the very cheapest.

The best kind of mourning paper is called Italian, and can be bought in all the finishes except cream-laid, where the colour is unsuitable. The black border is in three sizes— narrow, medium, and broad. These vary somewhat according to the make.

If it is desired to have an address at the head of the paper, an address die can be purchased. Embossing presses for home use, complete with die and counterpart and brass paper gauge, are obtainable.

NOTICE: In Law. When the occupier of a house or flat intends to leave at the expiration of his tenancy the landlord has a right to be informed in good time, so that he can arrange to find another tenant. What notice is required in a particular instance depends almost entirely on the nature of the tenancy and the terms of the agreement. An important point to bear in mind is that the notice must be given by a certain date, and failure to observe this condition will invalidate it.

When a house is taken on a three or five or seven years' lease the tenancy determines automatically when the last year has expired, and no notice is legally necessary; but if the tenant stays on without entering into any fresh agreement he becomes a yearly tenant. Six months' notice has to be given on a yearly tenancy, and it must expire on that day of the year on which the tenancy commenced. For example, if a yearly tenancy commences on June 24, notice will in that case be given on the following December quarter day, this being six months prior to the date on which the tenancy expires.

Small houses and tenements are taken by the quarter, month, or week, as the case may be, and the notice required on either side is three months, one month, or a week.

Thus in the case of a weekly tenant he must give seven days' notice, expiring on the day the rent is due, usually a Saturday. Unfurnished apartments are commonly engaged for a year or for six

months, and a quarter's notice is stipulated for. Furnished apartments are usually engaged by the week, and subject to a week's notice being given on either side.

Should a tenant fail to give notice at the proper time the landlord may and generally will hold him to the terms of his agreement, with the result that he becomes liable for another quarter's rent, and so has to remain considerably longer than he had intended. He should be careful not to make any agreement, either verbal or written, in respect of any new house he intends to move into until he has given proper notice to his present landlord.

Another form of notice is that given to or by a servant. Domestic servants being almost invariably engaged and paid by the month, a month's notice on either side is the general rule. If it is desired to terminate the engagement at short notice, a month's wages must be given instead. A servant is always entitled to her proper notice unless she has been guilty of serious misconduct. *See* Distrain; House; Landlord; Master; Rent.

Written Notices. Even where there is a written agreement, a verbal notice is perfectly in order; but it is best to put it in writing, with date and signature. It may be delivered into the landlord's own hands or sent by registered post or delivered at the door. In the latter case the correct procedure, although it is not always done, is to keep a copy of the notice and get it signed with the date by the person who receives the original document on the landlord's behalf. These regulations were modified to a large extent by the operation of the Rent Restriction Acts.

NOTIFICATION. The occurrence in any dwelling of certain diseases must be notified to the medical officer of health as soon as the diagnosis has been made. Among the diseases to be notified are the following: smallpox, scarlet fever, cholera, diphtheria, membranous croup, erysipelas, typhus, enteric, typhoid and relapsing fever, acute primary pneumonia, acute influenzal pneumonia, tuberculosis, ophthalmia neonatorum, cerebro-spinal fever, acute poliomyelitis, acute polioencephalitis, plague, dysentery, and, if contracted in England or Wales, malaria. From time to time other diseases may be made notifiable.

In urgent cases it is customary to telephone notification of infectious diseases, so as to secure the earlier removal of the patient to an isolation hospital, but the written statutory notification should also be made at the earliest possible moment. There is a penalty for failing to notify. Legally the obligation to notify falls on the doctor, and also on the householder or person in charge of the patient, but in practice it suffices if the doctor notifies. The object is that the disease may be prevented from spreading.

When lead, phosphorous, arsenical or mercurial poisoning, or anthrax, is contracted in any factory, the fact must be at once notified to the chief inspector of factories by any medical practitioner called in to visit, or attending on the case, who believes the patient to be suffering from any such condition, unless the case has been previously notified. To the Home Office must also now be notified cases of epitheliomatous ulceration due to tar, paraffin, and similar substances, and of chrome ulceration due to chromic acid and some of its salts.

The birth of a child must be notified within 36 hours after the birth to the medical officer of health. This applies to stillborn children. In addition to this it is necessary to comply with the requirements as to the registration of births. *See* Birth; Death; Infectious Diseases.

NOTTINGHAM STONEWARE. This is a form of pottery made in and around Nottingham in the 17th and 18th centuries. It is a fine stoneware with a lustrous brown glaze, and is represented to-day chiefly by jugs and pots. A good example is shown in the illustration. Nottingham ware is not unlike that known as Fulham ware, which was started by John Dwight about 1670. The Nottingham potters, who flourished in the 18th century, owed something to the influence of Dwight, and

something also to the German stoneware that was imported into England in the 17th century. *See Stoneware.*

Nottingham Stoneware. Right. Mug in this form of brown glazed pottery, dating from about 1700.

Left. Two-handled pot in Nottingham Stoneware, inscribed "John Buttler and Katherine His Wife, June 11th, 1746".
(British Museum)

NOUGAT. The blanching of 3 oz. almonds and a few pistachio nuts is the first step to be taken in making French nougat. After the skins have been removed, dry the nuts thoroughly and put them on a plate near the fire to warm. In the meantime, stir 2 oz. each honey and icing sugar, together with the whisked white of an egg and a few halved glacé cherries, in a pan over the fire, and continue stirring until they are cooked. Drop a little of the nougat into cold water, when it should break evenly and be crisp.

Move the pan to the side of the fire, stir in the nuts, and then turn the whole on to a slab sprinkled with icing sugar. Mould it first into the shape of a ball, and then press it into a small shallow confectionery box lined with wafer paper. Place another sheet of this on top, and then leave the nougat to get cold, when it may be cut into square or oblong-shaped pieces.

Nougat, a delicious sweetmeat made with icing sugar, almond, honey, and white of egg.

Another kind of nougat can be made by blanching and cutting up and then drying $\frac{1}{2}$ lb. almonds. Put $\frac{3}{4}$ lb. castor sugar and a dessertspoonful of lemon juice into a lined saucepan, stir them over gentle heat with a wooden spoon until they acquire a pale brown colour, and then add the almonds. Turn the

whole on to an oiled or buttered slab, press it out with a hot, wet knife, and then mark it into squares or strips, breaking these apart when the nougat is cold.

For chocolate nougat, cook together 1 oz. each butter and grated chocolate, $\frac{1}{2}$ gill water, 1 teaspoonful glucose, and $\frac{1}{2}$ lb. sugar, and when they are dissolved boil the syrup to 240° F. Then draw the pan to the side of the fire, add 2 oz. shredded nuts and some vanilla flavouring, and stir the whole till it thickens. Let it cool in a tin lined with waxed paper.

Another variation of chocolate nougat is made by cutting the ordinary nougat into squares and dipping them in coating chocolate. *See Chocolate.*

NOUGATINE. To make these cakes, prepare about 6 oz. short crust pastry, and with it line some greased cake tins. Beat 2 oz. butter and the same quantity of castor sugar to a cream, then beat in an egg, and add also 1 oz. cake or breadcrumbs, 1 oz. ground almonds, and about $\frac{1}{4}$ teaspoonful ratafia essence. Half fill each pastry case with the mixture, sprinkle the top with a few chopped almonds, and bake the cakes in a moderate oven for about 20 min. When the cakes have cooled brush a little warmed apricot jam over them. *See Pastry.*

Nougatines, made of short crust filled with a rich mixture and sprinkled with chopped almonds.

Noyau. Noyau, or crème de Noyau, is a sweet cordial flavoured with burnt bitter almonds. *See Liqueur.*

NOYEAU. This is a rich, creamy sweetmeat. To make noyau with honey, dissolve $\frac{3}{4}$ lb. granulated sugar in a scant gill of water and when no grains of sugar are left whole place the pan on the fire. Just as it is on the point of boiling add $2\frac{1}{2}$ oz. glucose and boil till the temperature reaches 244° . Rinse out a bowl with cold water and pour the sugar into it, stir it round with a wooden spoon till creamy, and then add 2 tablespoonfuls honey, which should be liquefied by being heated over boiling water. Add also some delicate flavouring, such as orange flower water or vanilla.

The noyau must now be worked like fondant, and at the same time 3 oz. almonds, blanched, dried, and cut into halves or quarters, according to size, must be introduced and mixed in. When ready to mould the sweet should be soft and creamy, and then should be pressed into a shallow, oblong box if there is no noyau frame available.

The box should be lined with wafer paper, but it is sufficient to line it with wax paper and have merely a layer of wafer paper at the bottom and on the top. The mixture should be about $\frac{3}{4}$ in. thick and quite level. Just before placing the wafer paper on the top, brush it over lightly with cold water. Weight it to keep it in place and put away the noyau in a cool place to grow firm. When set cut it into bars.

Noyau can be made with preserve instead of honey. The jam must be pressed through a hair sieve and the colour restored with cochineal if red jam, or a little saffron colouring if yellow; jam invariably loses colour when sieved. Either apricot or raspberry jam is most suitable. Add some suitable essence, such as vanilla, orange, or almond, as well as a few drops of flavouring corresponding to the fruit of which the jam is composed.

NUISANCE. A nuisance in a public health sense means the commission of any act by the occupier of property which is either dangerous to the public health or a source of general annoyance to the community. Such things as choked drains, water closets that are out of order, or even the keeping of animals in too great numbers or in unsuitable places, are instances of the former kind; and the emission of black smoke of the latter kind. The matter can be dealt with by summons before magistrates; and sometimes the local sanitary authority can obtain a warrant to enter premises and search for and abate a nuisance found there.

Public Nuisances. A public nuisance not in a public health sense consists of the doing of some act which constitutes an interference with public rights to use what may be termed public property. Such nuisances may be restrained by injunction at the suit of the attorney-general. The latter is,

however, as a rule, only the nominal plaintiff, merely lending his name to the real plaintiff. Instances of public nuisances are obstructions on a highway and to navigation of rivers.

Private Nuisances. Private nuisance, which gives rise to an action for damages and an injunction, consists in some interference by the defendant with the plaintiff's right of property, that is, with his enjoyment of his own property, but not amounting to trespass. Thus, to interfere with a right of way is a nuisance; so it is to block up or diminish another's ancient lights; so also to use adjoining land or buildings in such a way as to unduly interfere with the reasonable comfort and enjoyment of his own property by a neighbour, as by setting up a noisy or evil smelling or smoky business next door. It must not be supposed that everything of which neighbours may complain amounts to a nuisance. For example, a man may object to a butcher's shop being set up next door to him; but so long as the butcher conducts his business properly he need take no notice of such complaints. On the other hand, if he allows offensive smells to penetrate into adjoining property, a nuisance will be created for which he is liable. The principle is that every man has a right to enjoy the comfort of his house or to conduct his business without let or hindrance, provided that he on his side does nothing that can reasonably be held to be prejudicial to his neighbours. See *Animals*; *Drains*; *Negligence*; *Pig*; *Tenant*.

NUMBER PLATE. This term is used to describe a plate which bears a number, such as may be seen attached to an entrance door or gate. It is often made in china or earthenware, with a glazed white surface bearing the number in black. Others are engraved or etched in copper or carved in hardwood.

Motor Car Plates. All cars must have number plates attached at the front and back in prominent positions. The plates must be rectangular, the letters and figures being in line or the letters above the figures. Each letter and figure must be $3\frac{1}{2}$ in. high and every part of it must be $\frac{5}{8}$ in. wide. The space between adjoining letters and figures must be $\frac{1}{2}$ in. A margin of $\frac{1}{2}$ in. must be left between the nearest part of any letter or figure and the top and bottom of the black surface upon which they are inscribed. When the letters are placed above the figures, a space of $\frac{3}{4}$ in. must be left between the two lines, but when the identification marks are in line a gap of $1\frac{1}{2}$ in. between the last letter and the first figure is required.

The plate itself should be black, and the letters and figures painted on it with white or aluminium paint, though sometimes they are stamped on the plate, the raised marks being painted or stove enamelled. The driver must do all he can to prevent the plates from being obscured by dirt, luggage or straps, and to ensure that the rear plate is so illuminated that it can be read easily at night. If he fails to show he has taken all reasonable steps to keep them clean and clear of obstruction he will be liable to a fine not exceeding £20 for a first offence and £50 for subsequent offences.

On motor cycles the front plate may be placed parallel with the front wheel. The rear number plate of a motor car or cycle must be illuminated at night. New regulations as to the visibility of number plates from points to the back (or front) and side of the vehicle apply from October 1st, 1938, to vehicles first registered on or after that date, and on October 1st, 1941, these regulations apply to all vehicles. See *Motoring*: Name Plate.

NUMBNESS. Generally numbness is caused by bad circulation, and often takes place in one portion of the body only, especially the fingers, which will become white and almost without feeling. Treat by rubbing gently till warmth is restored. Keep the patient in a warm room and give him hot drinks. People who suffer in this way should not use cold water to wash with, and should take great care to keep both feet and hands thoroughly warm during the winter.

Numbness may be caused by pressure on a nerve supplying the part. This sort passes off as soon as the pressure is removed. Numbness is not uncommon in hysteria, neuritis and other nervous diseases.

NUN'S VEILING. As a light, warm wool material giving good wear and less inclined to shrink than flannel this fabric is popular for babies' frocks and children's dresses. It is an excellent material for winter nightdresses. Cream nun's veiling yellowed by age can be improved by bleaching, and re-dyes well.

NUPHAR. This is a hardy aquatic plant of the water-lily family. *Nuphar lutea* is the commonest; it bears yellow *nymphaea*-like flowers in summer. One better suited to small ponds is *Nuphar minimum*. Planting should be done in April May: the roots are put in a basket of soil and sunk to bottom of pool.

NURSE: For Children. A nurse's work in any household consists of the care of the children, their clothes, and the rooms they use. If she is engaged as fully trained she must understand the diet suitable for varying ages and conditions, and the amount of sleep, air, and exercise necessary to health. In most households the nurse will undertake the washing of the baby clothes and the woollies of the older children. If she is also able to make, mend, and knit, all the better. Instead of being off duty one half-day or evening a week, many children's attendants prefer to have a whole day free once a month. It makes a bigger break in the monotony of nursery routine, and as they are out of doors every day, they do not require the fresh air like other maids. Time off during the Sunday should be given to the nurse as a matter of course.

An under-nurse, or nursemaid working under an experienced nurse, receives from her training in the handling of children and nursery routine. She must be healthy, willing, obedient and teachable; not too small or young, or she will be unable to do the heavier work, such as carrying coals and trays, scrubbing floors and general cleaning of the nurseries. Her duties usually include the washing and dressing of the older children. It is wise to leave the training of her to the nurse in charge, and her off-duty time should never be the same as that of the upper nurse.

The Uniform. The indoor uniform of a children's nurse may be somewhat similar to that of hospital and district nurses, and consists of a washable linen frock, a bibbed apron of white linen, and a small cap to match. In some cases a white overall is worn and the cap is replaced by a square of linen, folded triangle-wise, and fastened round the head. The colour of her outdoor uniform is generally of dark grey or other subdued shade, such as navy blue or dark brown.

There are institutions for the training of nurses, and from these they can be obtained. One such is the Norland Institute 10, Pembridge Square, London. W.2. Nurses must be insured under the National Health Insurance scheme.

NOVEMBER

What to do in the Garden

Flowers

Plant hardy leaf-losing trees and shrubs, roses and hardy herbaceous perennials. Plant May-flowering tulips. Finish planting spring bulbs, wallflower, forget-me-not, polyanthus, and other early plants. Dig and manure vacant ground and lime the surface. Apply sand to lawns on clayey soil. Cut down and burn the dead stems of hardy herbaceous plants. Burn garden refuse regularly and thus destroy many pests. Maintain a temperature of 50-55 degrees in the greenhouse to ensure a

display of perpetual carnation, primula, etc. Water greenhouse plants very carefully, moistening the soil only when it is moderately dry. Ventilate regularly in mild weather. Bulbs of daffodil, hyacinth, and tulip may still be potted.

Fruit

Begin to prune fruit trees out of doors as soon as all the leaves have fallen. Root prune vigorous fruit trees which do not crop well. Look over fruits in store and remove any which show signs of decay. Plant fruit trees in deeply dug soil, using little or no manure. Apply basic slag to fruit plantations, using 4 oz. per square yard of ground. Strawberries in pots should be placed under glass to provide early fruits. Vines and peach trees under glass should be kept perfectly cool; no heat is necessary and free ventilation is beneficial. Prune vines under glass.

Vegetables

Sow seeds of small salad crops in frames on hotbeds. Give air to vegetables in cold frames whenever possible. Trench ground for new asparagus beds. Take up beetroots and store them where frost cannot get at them. Dig and manure all vacant ground. Celery should have its last earthing up. Leeks should be earthed up also. Leave parsnips in the ground, but take up and store full-grown carrots. Hoe turnips, young carrots, and autumn-sown onions.

Food in Season

Fish

Barbel; bream; brill; carp; cod; dory; eel; flounder; gurnet; haddock; hake; halibut; herring; ling; mackerel; mullet; perch; pike; plaice; salmon (Canadian); skate; smelts; soles; sprats; turbot; whiting.

Shellfish

Crab; crayfish; lobster; mussels; oysters; scallops; shrimps.

Meat

Beef; lamb; mutton; pork; veal; venison.

Game & Poultry

Black game; capercailzie; capon; chicken; ducks; fowls; geese; grouse; hares; larks; landrails; partridges; pheasants; pigeons; pintail; plover; ptarmigan; pullets
Artichokes; beetroot; broccoli; Brussels sprouts; cabbage; red cabbage; carrots; cardoons; cauliflower; celeriac; celery; chervil; cress; cucumber; endive; greens; horseradish; leeks; lettuce; mushrooms (cultivated); onions; parsnips; potatoes; savoy; spinach; tomatoes; turnips; turnip tops; watercress.

Fruit

Apples; bananas; chestnuts; cranberries; figs; filbert; grapes; lemons; medlars; melons; oranges; pears; pineapple; pomegranates; plums (Californian); quinces; walnuts.

Notes for the Month

November 1.—All Saints' Day. Stock Exchanges closed. Elections for city and borough councils outside London. November 9.—Lord Mayor's Day. November 11.—Armistice Day. November 30.—S. Andrew's Day.

The Nursery and Its Essential Features

Pleasing and Healthful Arrangements for the Children's Quarters

This article deals with the decoration and furniture of the nursery. Entries bearing on the same subject are Baby Chair; Baby Walker; Cot; Play Pen. See also the articles on Baby; Child; Toys; and those on Central Heating; Electricity; frieze.

The ideal arrangement in a roomy house is to have separate day and night nurseries with bathroom exclusively devoted to their occupants. Unfortunately this is not possible in a big percentage of homes, and the tendency in modern building is rather to decrease than increase the number of rooms, while the rents of town flats and maisonettes necessarily limit space for many families. The essential thing about nursery quarters, whether combined or in separate parts, is that the children may be able to develop in them to the best advantage both mentally and physically.

Where only one room is available it should be particularly light and airy, and if possible have a S.W. or S.E. aspect. It should be large enough to allow of proper air space at night, and, to accommodate one nurse and child, should not be less than 12 ft. square or, if oblong, about 14 ft. by 10 ft. Windows should be large enough to admit plenty of light and air, and should in all cases be effectually barred across the openings. In town houses where a nurse is in charge nurseries are best situated at the top of the house. The children thus get better light and air and are away from the coming and going of the household on the lower floors. There should be a safety gate at the top of the stairs.

If two rooms are available it is better to keep the larger for the night nursery. The size of the room for play and meals is not so important, but naturally the more space there is here, too, the jollier it is. For a small playroom the lighter and scantier the furniture the better. Many pieces get in the way of free movements and cause unnecessary knocks and falls. Warmth and air without draughts, so essential for children, are more difficult to regulate in the very small room in cold weather and there should be an upper ventilator to the window.

Perhaps one of the greatest advantages of two rooms is that as children are sensitive to their surroundings the disappearance of all suggestion of daytime activities and exciting toys or games and the appearance of all that gives the idea of quiet restfulness is conducive to sleep. Certainly the two rooms give delightful scope for decoration. The brighter colours and gay cretonnes, pictorially dramatic events painted on screen, frieze or furniture, or worked on rugs and cushions, are usually kept (with discretion) for the day nursery, while the quiet tones predominate in the night nursery and the furniture is of simple bedroom type.

Suitable Decoration. It is pleasant to think that the days are gone when anything was good enough for the nursery, and that architects and furniture designers have concentrated in producing charming quarters for small children; that shops and stores and firms dealing in floorings, wallpapers, fabrics, furniture, china, bed and meal time accessories, stock and manufacture all kinds of pleasing articles especially for the use of nursery folk. On the other hand, in some of the super-decorated nurseries, specialization is overdone. The colours employed are too glaring, the white furniture is varnished to a dazzling degree, stencilled or painted with strange creatures, while the antics of a medley of grotesques straggle over the walls and screens, appearing on chinaware and table cloths at meal times—to say nothing of bibs and feeders—on the down quilt and foot of the cot at night, all over the linoleum and the cretonne curtains. Mother Goose, in some cases, is even painted flying across the ceiling with favourite characters attendant, to add to the restless effect.

All this lavish ornamental stimulation is probably as bad for quick-witted or highly strung children as the neglect of their peculiar requirements was in the past. Modern life tends to make children

more active minded. Mechanical toys and gramophones, the ordinary events of an everyday walk, for those who live in large towns, the general noise and bustle around them, are quite sufficiently exciting without the distracting the painted dado can be distempered to match, or in a lighter tone which is carried over the ceiling. A varnished or washable wall paper with an unobtrusive pattern is a better alternative to paint than is distemper. A paper with a deep cream ground looks well with either a coloured paint to tone with the turmoil of a nursery where things appear seldom to stand still and nearly every spot tells an adventurous story. Small children certainly like bright colours, but it is not necessary to surround them with these. Instead of highly decorated walls, flat paint in a pale shade is desirable; but the colour chosen should be soft and beautiful.

Rushing from the idea of exuberant ornament one does not want to fall into the other extreme of a nursery like a hospital ward, so severely painted in white and so strictly hygienic in its furnishing that no child could regard it as a homely playroom or place for cosy rest. After all the room is for the child not an exhibit for visitors, or a place where cleanliness, however important, is the only consideration. It serves his purpose if he can live his life happily in it, and his life is mainly occupied in eating, sleeping and play. The last is of immense importance to him and means not only amusement, but development and education. He wants to bring furniture and accessories into his own scheme of things, and up to this point specially designed surroundings are helpful, beyond it they probably retard his mental growth, as they provide too many cut and dried ideas and do not allow scope for his inventive mind or individuality.

Choice of actual colour for the walls must be governed, as in other rooms, by the aspect. When there are two nurseries, either a pleasant pale green, dove grey or blue are good for the sleeping room, as these shades are conducive to rest. Should the room be dully situated pale pink is more soothing than yellow, which, however, is an admirable choice in a clear shade for the playroom. Dark or violent colours are obviously a mistake for walls, but a lighter colour or deeper tone may be employed for skirting, door and window frames.

When possible enamel should be used. Although the first cost is greater, it lasts far longer than distemper and can be washed clean from grease and finger marks, which distemper cannot be. Where expense has to be considered, the part of the wall above the painted dado can be distempered to match, or in a lighter tone which is carried over the ceiling. A varnished or washable wall paper with an unobtrusive pattern is a better alternative to paint than is distemper. A paper with a deep cream ground looks well with either a coloured paint to tone with the pattern, or with natural oak woodwork. White should not predominate on the walls, either painted or papered, as the glaring effect of this may have a deleterious effect on children's eyes. The smaller and darker the nursery the more important it is to keep the mural decoration plain and of a pale colour that is also suitable for the ceiling (such as pink, primrose, or deep cream) so that the impression of space may be given and the light increased by reflection.

Nursery. Fig. 1. Day nursery with plenty of window, light, air, and floor space. The walls are hung with gaily patterned paper and the rest of the equipment is simple but charming.

For a day nursery a plywood dado has been employed with success. Blackboard panels are placed at intervals. These are covered with a specially prepared black paper on which the children can draw with chalks to their heart's content. The drawing can be easily rubbed off and the black renewed occasionally by an application of special waterproof ink. The rest of the dado is painted in a light colour to match the walls above it. The children use the plywood as a picture gallery, and with drawing pins affix any posters, prints or cards which they fancy. Sometimes unbleached calico is used as a surface for the dado, and decorated with cutouts of gummed coloured paper. The children copy simple designs, directed and helped only when necessary. These panels and blackboards afford endless amusement and waken the child's creative and artistic powers. Another idea is a notice board covered with serge or baize on which cuttings from a children's paper or cards which he receives are pinned.

Where there is only a single nursery these excellent ideas need not be abandoned if one end of the room is kept as the playroom and the plywood dado or board is limited to that part. When pictorial wall panels are employed these also need not be repeated on those portions of the wall visible from the cots, which can be further separated by the use of draught screens. Nursery pictures, whether applied or detachable in frames, should be hung at a level where they can be easily seen by the children. Where the latter are old enough they should be encouraged to choose such things for themselves. Pictures, if any, should be few and restful in the night nursery.

A nursery bathroom provided with a sink, gas ring, a baby's bath, as well as the usual one, and a lavatory basin, and large enough to contain a gas fire and plenty of airing accommodation solves the problem of where to wash up the meal crockery, etc., and where to do the essential laundry. In the bigger household friction is often avoided by making the nursery quarters self-contained with store cupboard on the landing and built-in cupboards for linen and utensils.

Heating a Nursery. Central heating is a desirable method of warming the nursery. Gas fires combined with rings are very suitable and economical, especially for the night nursery, where a coal fire which requires making up is disturbing. On the gas ring foods are heated and also water as needed.

A closed anthracite stove or fire is suitable and ensures a warm room in winter. The open coal fire, though it means more work, is often liked for the day nursery. If the existing grate is unsatisfactory, a slow combustion stove may be chosen and if it has hobs on either side, these will heat irons, water or food. The day nursery should be kept at a temperature of 60° to 65° F., while that of the night nursery should be at least 55° F.

In districts where gas and electric light are not available a modern type of oil stove, provided it is of good solid make with a firm base, is suitable for warming the night nursery. A strong fireguard of wire mesh must be placed round an open fire, electric, coal, oil or gas stove. The top of the fireguard should be securely fixed to the mantelpiece or wall with neat iron hooks. A useful type of inner fire guard is illustrated earlier in this work, but a nursery fender should be used as well, with an outside rail for airing clothes.

Electric lights should be shaded. If oil lamps are used these should be placed on brackets or shelves at such a height that there is no possibility of their being knocked over. A hanging green nursing lamp is useful for the night nursery. Dark blinds or practical curtains of light resisting fabric are essential for the windows. These curtains should be of a washable material such as Bolton sheeting. Cretonne should be lined unless blinds are also provided for the night nursery.

Floor Coverings. Cork carpet is much used for floors, but is not so suitable as linoleum. The rough surface of the former allows dirt to penetrate, so that it is less easy to clean thoroughly with soap and water. Carpets are not recommended, as they hold both dust and dirt. Linoleum on a Linovent

underlay is the best choice, with one or two washable rugs. Inlaid rubber floorings are suitable, as they are waterproof, warm and noiseless. Where there is a good floor of wood blocks, these are left bare with the exception of the rugs. Sometimes the door is coloured or stained and finished with waterproof varnish; but these bare floor treatments have the disadvantage of not being so comfortable for the toddler, who spends much of his time on the floor. Also, nursery floors should not be polished, as this leads to many tumbles and accidents. Practical floor cushions which harmonize with the room and are covered in terry cloth or some such pleasant material should be provided. A cretonne floor mattress is also a very useful accessory.

Furnishing the Room. Furniture for the nursery should have rounded corners, be light, strong and washable. In the night nursery natural oak is often used. Here the furniture should be that of an ordinary simple bedroom, the cots standing out in the room with air circulating round them, but free from draughts. A cot should be on castors and should not be placed between a window and the fireplace, or between a window or door without the protection of an efficient draught screen. A really comfortable bed should be provided for the nurse. There should be neither cot nor bed valances. Pretty washable bedspread and cot coverlets should tone with the curtains. A trolley service wagon is useful when the nursery is in a flat, or when day and night nurseries are on the same floor.

The day nursery may have oak or painted wood furniture. A firm table is essential for meals, an ironing table, a comfortable armchair and one or two ordinary sized chairs, and a baby's chair. Otherwise the furniture for small children should be to scale. It should include low shelves for toys, or a practical cupboard, low tables on which to place toys or games while being used, low chairs, and if possible an indoor play pen and a wide cushioned window seat or a settee.

Painted furniture can be renovated with a coat of fresh enamel at small cost. Elm or oak lasts well, but mahogany is not so suitable for the nursery. The old wheelback windsor chairs are hardy and ornamental and have no sharp corners. They can frequently be picked up inexpensively at second-hand shops. A plain kitchen table is not to be despised, and an oak chest of drawers and linen chest may be acquired. Some modern nurseries have cupboards built into the external wall, with ventilators, and these make an airy and cool receptacle for milk and food. The nursery crockery and table linen should be chosen to tone with the scheme of decoration, and bright colours with cheery but not ugly designs are desirable.

Nursery Fig. 2. Small nursery, a feature of which is the folding wooden play pen set on a thick rush mat. This is a boon to busy mothers, for a toddling child can thus be left in safety (Courtesy of Heal & Co.)

Planning of Nurseries. Our first illustration is of a nursery in a modem house planned with wide bay windows, of which the children have the benefit on the first floor.

There is a washable wallpaper in a softly multicoloured pattern, but the curtains are of heavy cotton fabric with an unobtrusive floral sprig and the simple wicker chairs and table are of plain type, so that the patterned effect is not overdone. Jaspé linoleum in a soft shade of blue, to tone with the ground of the wallpaper and curtains, would provide the flooring. The two pieces of oak furniture enhance the light colours of the rest of the room, while the toy chest on wheels, the little gate-leg table and low chairs could be painted in dove grey, the colour used for the woodwork of the room. There is nothing exciting or ugly in the whole scheme. The night nursery (not shown) is furnished in the same style, but with plain walls.

A day and night nursery combined is shown in Fig. 2. This is planned on simple but pleasant lines. No childish decorations appear on walls, floor or furniture. The few pictures are restfully coloured, the linoleum and curtains could be in soft leaf-green, and the walls of rose pink with a paler shade of pink for the ceiling. The furniture is of natural, unstained oak, light in colour and unpolished except by hand rubbing. Comfort for the toddler, when busily engaged within the folding play-pen, is insured by the thick rush mat.

A large room in a town house has been converted into the day nursery seen in Fig. 3. The windows are high up, so a play house has been constructed by a handyman with a staircase and roof sufficiently strong to bear the weight of the children with perfect safety. The roof is on the window level. It is in turn a roof garden, a fortress, and a place for playing games where toys will not be disturbed. The lower part of the window, hidden by the safety surround of plywood, is well barred. The door into the play house is practical and there is an electric light fitting inside. There are also shelves and an individual locker for each child. In this room there are no decorations beyond the pleasant colour scheme of corn-coloured paint for the dado, with deep cream distempered walls and ceiling and paint work in blue in order to match the curtains.

Fig. 3. A nursery which will delight the average child. It has a large play house fitment, the roof of which is reached by a miniature stairway, and affords a playing platform at window level. A swing hung from the ceiling is made safe by the use of strong netting instead of rope. (Courtesy of Our Homes and Gardens)

Fig. 4. An attic is here shown adapted to a sleeping and play room. There is a comfortable window seat with toy cupboards underneath and a delightful idea is the notice board.

A modern day and night nursery is shown in Fig. 4. This is a country attic room, and the delightful window treatment, with its dainty voile curtains, dark blinds and cushioned seat, is the principal feature. The

linoleum is in two shades of brown, and is laid over a sound-deadening felt paper. More decoration is allowed on the walls in this room, but the cots (not seen in the picture) are placed and screened, so that no exciting things are visible to their occupants at night. Favourite nursery rhyme figures have been stencilled on the frieze, and a few on the piece of wall by the novel book-house, and on the wastepaper basket. There is safety ventilator for the lower part of the sash window. The walls and ceiling are painted deep cream, and the woodwork ivory.

Nursery. Fig. 5. Ingenious piece of furniture which folds into a compact cupboard when not in use and when open provides a desk and many shelves. (Courtesy of Gill & Reigate, Ltd.)

The nursery cupboard, made of oak, illustrated in Fig. 5, is most useful. When not required for play it folds away into a compact cupboard. When open it is a delightful piece of furniture on whose shelves toy-rooms or shops can be built. There is also space for picture books and a lift-up flap desk at which painting or scribbling can be done in comfort. The chair shown in Fig. 6 is a particularly useful and comfortable one designed for mother or nurse. It is well upholstered and possesses two large hinged box drawers for all sorts of requisites and a sliding leg rest. There are also receptacles for books and oddments under either arm.

Fig. 6. Comfortable work chair for mother or nurse. Under the seat are two large hinged drawers and a sliding leg rest. (Courtesy of Gill & Reigate, Ltd.)

NURSING IN THE SICK ROOM

Simple Suggestions for Looking After Invalids

In addition to the articles on the various illnesses, e.g. Chickenpox; Measles, the reader is advised to consult the entries Bedmaking; Bedroom; Disinfection; Hot Pack; Hot-water Bottle; Infectious Disease. *See also Invalid Cookery*

Home nursing comes into the experience of almost everyone, and there are certain general rules which should be observed. The sick room must be cleaned and dusted every day; ashes raked out of the fire and cleared away; no soiled linen or dressings left littered about. All these matters may be attended to when the patient is the least fatigued or distressed, and with as little fuss and clatter as possible. Unless the doctor in attendance orders otherwise, the patient must be washed all over once daily.

The process is as follows: Take the patient's temperature. Put the fresh clothes to warm if the weather is cold. Fill the hot bottle. Shut the window. Fill a basin with water as hot as the hand can bear. Have soap and towel handy. Remove sheets and superfluous coverings from the bed, remembering always to keep one of the blankets over the patient. Now roll the patient into an old blanket or thick bath-towel, and wash quickly and thoroughly, not forgetting to wipe quite dry. Wash and dry each part separately, and cover immediately with the bath-blanket. Wash the back especially well, and note any pressure marks which might develop into bed sores. All sores should be reported at once to the doctor. Water beds and ring pillows can always be borrowed or bought if required.

Remove the bath-blanket, still keeping the patient covered with the upper blanket, put on warm, fresh clothes, and brush and comb the hair. If the doctor permits, the invalid can be lifted out on to a chair or couch when the bed is re-made, but this is not at all necessary, for the under-sheet and blanket can be rolled under the body and renewed. It is important that all under-sheets and blankets be free from creases and crumbs. All this is best done in the morning; but restlessness and sleeplessness in the evening are often relieved by sponging the face and hands.

In all cases of pneumonia, high-fever, or gastritis, the mouth should receive special attention. It should be cleaned out before and after food with glycerin and borax, or glycerin and lemon.

The diet of all invalids should be light and easily digested, and the doctor's orders must be obeyed implicitly. The food should be given at regular intervals in appetizing form, and never kept in the sick room. Medicine and treatment must be given at the hours ordered but the patient should not be wakened.

The regular action of the bowels should be encouraged daily, and the urine measured and saved for the doctor if required. The bedpans and urinals must be kept spotlessly clean and well scoured with hot soda water or disinfectant every day; they should be covered with a cloth when carried to or from the room. It is a great comfort to an invalid if such utensils are warmed with hot water before use, and warmth also aids the evacuation of the bowels and the passing of urine. If the

patient is in a recumbent position a small pillow or pad placed under the back relieves pressure when the bedpan is in use. Except in chest or kidney cases the windows should be opened wide after the action of the bowels. Any difficulty in the daily functions must be noted and reported.

All matters likely to alarm or agitate must be kept from the invalid, and visitors to the room should avoid any appearance of anxiety or fussiness. Every effort should be made to aid adequate rest and sleep. A gloved hand may be used for putting coals on the fire, or lumps may be wrapped in newspaper. Small coal and damp dust in a blue sugar bag, if placed at the back of a fire, will keep it in for hours at night.

Infectious Diseases. Infectious illnesses require special preventive measures in a private house. A sheet soaked in a strong solution of carbolic or lysol should be hung over the bedroom door and kept damp. Carpets and curtains must be removed at once from the bedroom and suitably disinfected, and the floor must be washed over at least once a day with disinfectant. All soiled clothes and bed linen must be removed in a covered pail, and immersed in strong disinfectant if they cannot be at once boiled in a copper. With typhoid all the motions and urine should be disinfected for 4 hours before being emptied down the drain.

An enveloping overall and cap should be worn by anyone entering the room, and removed on leaving. Hands and nails must be well scrubbed and disinfected, and if possible different shoes worn outside the sick room. Anyone nursing an infectious case, especially measles, diphtheria, and scarlet fever, should gargle her throat 2 or 3 times a day with a very weak solution of disinfectant. All cups, spoons, and utensils of every description must be kept apart.

Looking after the Nurse. Special care should be given to the health of the friend, relative, or trained nurse upon whom falls the responsibility and care of the patient. Her meals must be regular and sustaining, and always served in a room other than the patient's room. A trained nurse takes her meals with the family, never with the domestic staff. If she is on night duty she must be given a good digestible meal on rising and before she returns to her work. Provision must also be made for a meal or meals during the night.

Most trained nurses are prepared to do 12 hours' continuous duty, but the untrained woman should not undertake more than 8 or 10 hours'. On being relieved from duty, all persons would be well advised to take brisk outdoor exercise. If the case is specially fatiguing, a long bus or motor ride is refreshing, or a seat in a quiet part of the garden with a congenial book. The recreation should extend over a minimum of two hours. Night nurses will find outdoor exercise especially beneficial, as it stimulates the circulation and produces a certain amount of fatigue, so that sleep, even by daylight, comes more easily.

The minimum of sleep allowed is seven hours, and if possible eight hours' consecutively. Those doing night work should be shown especial consideration, and be given the quietest room in the house, at the greatest possible distance from the sick room. All members of the household should be warned of her hours of slumber. Where a trained nurse is employed, her advice must be followed as to her own meals, etc.

A trained nurse can usually be procured from the private staff of one of the great hospitals, from a co-operative society, or on the personal recommendation of the doctor in charge of the case. In the two former cases the nurse will be under the rules laid down by the hospital or institution from which she comes, and the fees will not be paid to her direct, but to the hospital. Should she be a private individual working single-handed she will have her own regulations and will be paid direct. The weekly fee does not include the nurse's laundry, which is also payable by the employer.

As a general rule a nurse supplied by a society or institution is not allowed to remain more than three months with one case. It is, however, usually possible to have this time extended under certain

circumstances, but six months is the extreme limit allowed. Nurses working privately are free to make their own arrangements. Male nurses are procurable for chronic cases with male patients who require much lifting or moving, or for mental cases. As to off-duty time, they must be treated exactly as the female nurse.

NURSING HOME. The charges made by a nursing home vary with the locality and with the room; but the charge invariably includes the patient's entire board and lodging, together with expert attendance by trained nurses. As a rule the doctor's fees are extra, though where a patient is in the doctor's own nursing home the medical fees are occasionally included. In surgical cases the surgeon's fee is paid separately, but his visits to the patient while in the home are included in the charge for the operation.

People who cannot afford nursing home fees can frequently arrange to be taken into a private ward of one of the great hospitals, where charges are considerably lower. In London and many other large cities there are also institutions endowed by charitable bequests where persons of small means are received at almost nominal prices.

NUT: In Engineering. A nut is a fastening device, generally with a hole in it, the sides of which are screw threaded. It is employed in conjunction with a screwed bolt or stud, or fixed on to a cylindrical piece having screw threads corresponding to those in the nut. See Bolt; Castle Nut; Lock Nut; Stud.

NUT: The Shrub. The name nut is generally applied to the genus *Corylus*, which includes the cob, hazel, and filbert. All are summer leafing shrubs, and may be grown in any open sunny position, either as a plantation or as hedge plants, for which latter purpose they are splendidly adapted. A stock can be raised from nuts sown in the open garden in autumn. Suckers may be taken from old plants in October, and replanted. *See* Chestnut; Cob Nut; Walnut, etc.

NUT: As Food. A highly nutritious food is provided by nuts, but they are indigestible unless very thoroughly masticated. When eaten largely it is best to grind them, or to buy one of the preparations sold by vegetarian depots. Nuts contain a large quantity of both protein and fat. Coconuts and Brazil nuts are very indigestible. Chestnuts are the most easily digested, and next in order come walnuts and pea-nuts. Walnuts are said to be laxative when eaten between meals.

The following table shows the average composition of nuts in common use:

Nuts	Water	Carbo-Hydrate	Protein	Fat
Almond	6	10	24	54
Brazil	5	7	17	67
Chestnut (fresh)	38	45	6	8
Pea-nut	9	19	28	42
Coconut	47	8	5	36
Walnut (dried)	4½	7½	15½	63
Filbert	3¾	13	16	65

The chestnut is especially useful as food; it is rendered far more wholesome by being thoroughly boiled for 10 min., and afterwards roasted. Nuts can be dangerous to people with weak stomachs and to young children.

Nuts are employed in cake-making and confectionery, and form an important ingredient of such foods as nut butter, nut galantine, nut sandwiches, etc. Chestnuts are used in a variety of ways, which include the making of a special forcemeat for foods, while almonds, walnuts, coconut, and

pistachio nuts, sometimes shredded and coloured, decorate cakes, trifles, fruit ices, chocolates, and creams.

Nut Bread. Nut bread can be made by mixing together 2 breakfastcupfuls wholemeal flour, half that quantity self-raising flour, $\frac{2}{3}$ breakfastcupful brown sugar, 3 teaspoonfuls baking-powder, 1 teaspoonful bicarbonate of soda, and 1 cupful chopped walnuts. Add a pinch of salt, and mix the whole to a fairly stiff paste with 1 pint milk, either fresh or sour. Turn the mixture into a greased tin, and bake for about 1 hour in a fairly hot oven, testing with a skewer to see if it is done.

Nut Butter. To make nut butter, shell and skin some nuts of any kind, grind them to a powder, and then pound them in a mortar with the butter. When a smooth paste is formed, the butter may be put into jars and used as required. *See* Almond; Brazil Nut; Chestnut; Coconut; Vegetarian Cookery; etc.

NUTCRACKERS. The implement that is used for cracking a nut consists of two levers, or hand grips, joined at one end by a small link piece on which each of the levers is separately jointed. The nut is placed as near to the joint between the two levers as possible, and when pressure is brought to bear on the ends the shell of the nut is cracked. Nut crackers are made of steel, brass, and other metals, usually electro or silver plated.

The designs vary, some being grotesque in appearance, others ornately carved, and the rest plain. In some varieties, of which the pair of nutcrackers on the right of the illustration is an example, the levers are so jointed to the link piece that when they are turned over or reversed they come close together, and are used for cracking small nuts, but when turned in the opposite direction the space between the levers is larger, and will take any size nut.

Nutcrackers. Strong plated silver nutcrackers, the pair on the left being provided with special teeth for cracking Brazil nuts.

NUTMEG. The fruit of a tropical plant known as *Myristica moschata* is the nutmeg, of which there are many varieties with different names, but none are suitable for practical cultivation in Great Britain.

In a grated form nutmeg is used as a flavouring for various kinds of food, and to milk puddings particularly lends a distinctive taste. The essential oil is used as a perfume, and also made into a flavouring essence which is useful in cookery and confectionery. It is made by adding 1 oz. of the essential oil of nutmeg to 1 pt. of rectified spirits.

In medicine nutmeg acts as a carminative and may be given in indigestion accompanied by flatulence. It is sometimes used in mixtures as a flavouring agent; for example, it does well in a mixture containing ferrous sulphate. It has also a somewhat narcotic effect. Its preparations are: the powdered seed, dose, 5 to 15 gr.; the oil, $\frac{1}{2}$ to 3 minims; and the spirit, 5 to 20 minims. Large doses produce poisonous effects.

Nutmeg Grater. This is a small device of pierced tin by means of which nutmegs are grated to powder. *See* Grater; Junket.

NUTRIA. The durable fur obtained from the rodent known as the coypu, a species of beaver, is of a warm golden brown shade. Nutria is specially dressed to resemble the more costly beaver. Sometimes it is given a silvered effect. It is chiefly used for fur coats, and for winter trimmings for women's cloth coats. *See Fur.*

NUTS IN MAY. This popular game can be played by any number of children up to 20 or a few more. It is most suitable for indoors, but can also be played outdoors. The players are divided into two equal parties and, standing in line and holding hands, these face each other, leaving as much space as possible in the centre. One line then advances and retreats, singing this verse as they march to and fro:

Here we come gathering nuts in May.
Nuts in May, nuts in May,
Here we come gathering nuts in May
On a cold and frosty morning.

The other side does the same, singing the second verse as they march:

Who will you have for nuts in May,
Nuts in May, nuts in May.
Who will you have for nuts in May
On a cold and frosty morning?

The first side quickly choose one of their opponents, whose name is inserted in the verse which they sing as again they march to and fro.

We will have (Ethel) for nuts in May
Nuts in May, nuts in May,
We will have (Ethel) for nuts in May,
On a cold and frosty morning.

The side to which the chosen player belongs takes up the song, asking:

Who will you send to fetch her away,
Fetch her away, fetch her away?
Who will you send to fetch her away.
On a cold and frosty morning?

The side which has named the player names one of its own members to fetch her away thus:

We will send (Mabel) to fetch her away.
Fetch her away, fetch her away.
We will send (Mabel) to fetch her away.
On a cold and frosty morning.

The two chosen players advance for a tug of war. A mark is made on the ground by laying down a handkerchief or in some other way, and the two, having clasped hands, tug. The one who is pulled over the mark joins the side to which the winner belongs. The verses are then gone through again

with the side that sang the second verse last time now taking the first and it can continue until one side is reduced to few or no players. *See Children's Party.*

NUTTALIA. This is a hardy leaf-losing shrub, *Nuttalia cerasiformis*, which grows 4-5 feet high. It bears white flowers in early spring: the flowers are not particularly attractive. A crop of red fruits will result if bushes bearing male and female flowers are planted. It thrives in ordinary soil, and may be increased by division in autumn.

NUT WEEVIL. There are two weevils destructive to nuts, one attacking the kernels and the other the foliage. Remedies are free dressing of soil round the bushes with a soil fumigant during winter or early spring, and spraying with a good wash in May. Where bushes are badly infested with leaf-weevil the branches should be shaken over sheets of paper smeared with some sticky substance to catch the weevils as they fall. *See Insecticide.*

Nymphaea. This is the botanical name of the family of aquatic plants called water lilies (q.v.).

OCTOBER

What to do in the Garden

Flowers

Plant hyacinth, tulip, daffodil and other springflowering bulbs in beds and borders.

Plant wallflower, forget-me-not, polyanthus and other spring-flowering plants.

Lay down turf to make a new lawn.

Prepare the ground for rose trees by digging deeply and manuring.

Lift and store tuberous begonia and dahlia as soon as the plants are spoilt by frost.

Plant border carnation, sweet william, Canterbury bell and bulbs of Spanish and English irises.

Sow sweet peas in pots or boxes of soil in a garden frame.

Take cuttings of leaflosing shrubs and insert them in sandy soil out of doors.

Insert cuttings of evergreens in sandy soil in a frame or on a sheltered border.

Lift summer bedding plants and place in pots or boxes of soil under glass to supply cuttings in spring.

Move Chinese primula, cineraria, and herbaceous calceolaria from the frame to a greenhouse.

Lift and repot arum lilies and place under glass.

Pot spring-flowering bulbs, set them out of doors and cover with old ashes for 6 weeks.

Re-arrange and replant the hardy flower border.

Fruit

Gather apples and pears on dry days only.

Lift, root-prune and replant fruit trees where necessary.

Take off runners from strawberries and manure between the rows.

Cut out old fruiting canes from raspberries.

Take cuttings of gooseberries and currants and set in sandy soil out of doors.

Prune black-currant bushes by cutting out old branches or parts of them.

Prune loganberries and blackberries by cutting out the canes which have borne fruit.

To ripen late grapes ventilate the glasshouse freely, keep the hot-water pipes warm and the atmosphere dry.

Vegetables

Lift and store beetroot, carrot and late potatoes.
 Dig and manure all vacant land, leaving the surface rough.
 Lift and force rhubarb roots for an early supply of produce.
 Plant lettuce and endive in a cold frame.
 Plant spring cabbages.
 Gather all green tomatoes and place in a box in a warm room to ripen.
 Lime land which is infected with the club root disease.
 Look over potatoes in store and remove decaying tubers.
 Burn the haulm of potatoes to destroy disease spores.
 Complete the earthing up of celery.
 Sow seeds of Brussels sprouts in a frame.
 Pot cauliflowers and keep them in a frame for the winter.

Food in Season

Fish

Barbel; bream; brill; carp; cod; dory; eel; flounder; gurnet; haddock; hake; halibut; herring; mackerel; mullet (red and grey); perch; pike; plaice; salmon (Canadian); skate; smelts; sprats; soles; tench; turbot; whiting.

Shellfish

Crabs; crayfish; lobster; mussels; oysters; prawns; scallops; shrimps.

Meat

Beef; lamb mutton; pork; veal; venison.

Poultry and Game

Black game; capercailzie capons; chickens; ducks; fowls; geese; grouse; hares; larks; partridges; pheasant; pigeons; pintail; plover; ptarmigan; pullets; rabbits; snipe; teal; turkey; turkey poults; widgeon.

Vegetables

Artichokes (globe and Jerusalem); aubergines beans (French); beetroot; broccoli; Brussels sprouts; cabbage; cardoons; carrots; cauliflower; celeriac; celery; chervil; cress; cucumber; endive; greens; horseradish; leeks; lettuce; mushrooms; onions; parsnips; potatoes; red cabbage; savoy; scarlet runners sorrel; spinach; tomatoes; turnips; vegetable marrow; watercress.

Fruit

Apples; bananas; blackberries; cranberries; damsons; figs grapes; lemons; limes; medlars; melons; nectarines; nuts (various); Oranges; peaches; pears; pineapple; plums (Californian); pomegranate; quinces; sloes.

Notes for the Month

October 1.—Pheasant shooting begins

October 21.—Trafalgar Day

October 31.—Hallow-e'en

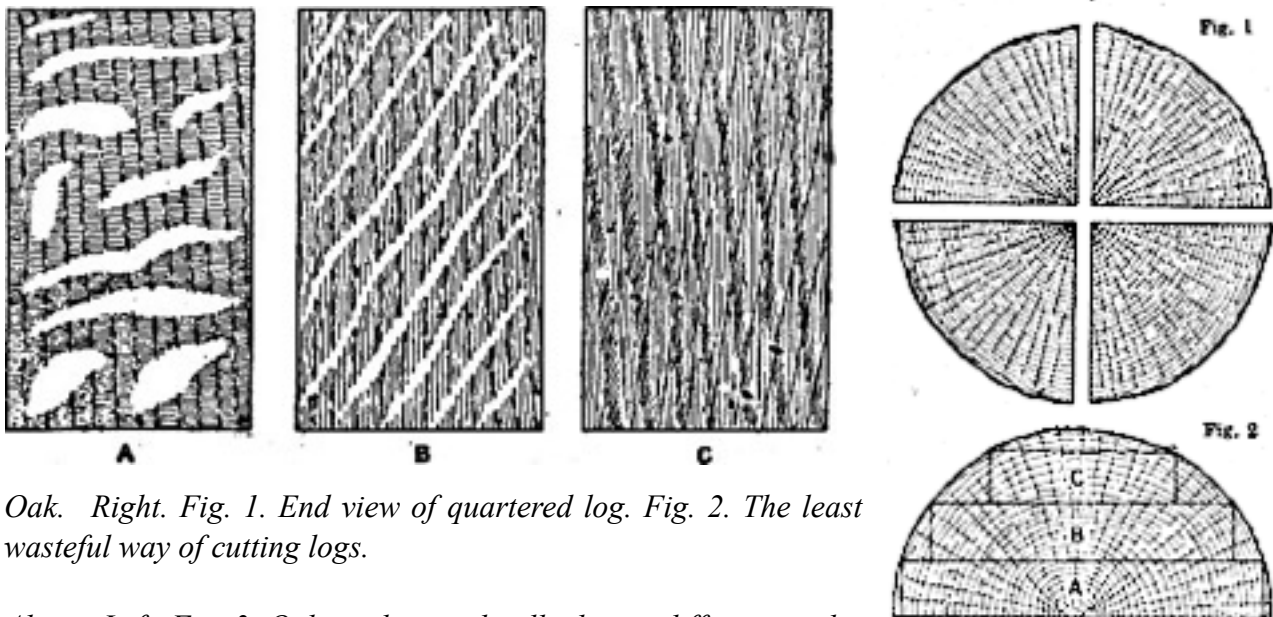

OAK: The Tree. The chief native British tree, *Quercus robur*, or the oak, is useful alike for timber and ornamental purposes. There are evergreen oaks and others, the bark of which yields cork. Ordinary trees for lawn and specimen purposes can be raised from acorns planted in autumn at a depth of about 6 in. When the trees are about 1 ft. in height they should be planted out about 1 ft. apart every way, and again transplanted, when the sturdiest specimens still survive.

The planting of oak trees in gardens is not recommended; it is a task for the forester in the plantation. An occasional tree to celebrate a coming of age or other festive event will be quite sufficient for the welfare of an ordinary garden. Acorns gathered in autumn will germinate if sown during the following spring.

OAK: The Timber. There is no other wood equal to English oak in durability, hardness, toughness, weight and flexibility. It has great strength in proportion to its weight and is subject to very little warping and shrinking. If only one or two of these qualities are wanted to predominate, other woods can be found that are superior to oak in one or two respects, but are inferior to it in others.

A good proportion of oak is cleft instead of sawn, that is, it must be sawn across the grain but is split lengthwise. The cleavage follows the grain, and for many purposes the wood is stronger than it would be if sawn. The cleft pieces are not so straight as sawn ones, but they may be planed or turned and retain the advantages of cleft wood. Wheel spokes and ladder rounds are made in this way. Pales for fences and hurdles are used roughly cleft, and rails for field gates are often cleft. Sawn wood, however, is cheaper than cleft.

No wood, except perhaps mahogany, has been so much used for English furniture. Oak is also used in building. Rooms are occasionally panelled in oak, while in large houses and public buildings it is sometimes used for floors, staircases, doors and other interior woodwork. Oak contains an acid which corrodes iron and causes a dark stain in the wood around the metal.

Oak. Right. Fig. 1. End view of quartered log. Fig. 2. The least wasteful way of cutting logs.

Above. Left. Fig. 3. Oak cut longitudinally, but at different angles in relation to rings and medullary rays of trunk.

Difference in Grain. In reducing logs to boards a large proportion of oak is quartered, that is, all the saw cuts or lines of cleavage are in a radial direction from the centre of the trunk, the same as the medullary rays. A log is treated in the first place as in Fig. 1, which gives eight radial surfaces. A thickness is sawn from each of these and then further radial cuts may be made on the remainder, or it may be cut in any way which happens to be most economical. To cut a log entirely in radial directions wastes material, because a number of comparatively useless wedges are left after pieces of parallel thickness have been cut. Quartered oak, therefore, is more expensive than plain oak, for the amount of waste is a great deal smaller when a log is sawn in parallel slabs, as in Fig. 2.

The difference in appearance is shown in Fig. 3. At A in Figs. 2 and 3 there are quartered surfaces, showing what is called the silver grain. At B and C the appearance changes, being farther away from the radial direction and cutting at a tangent to the annual rings. The surface at A (Fig. 3) is preferred, partly for appearance, but mainly because the piece is supposed to be more flexible and will shrink and warp less than that at C, besides which it is more waterproof. For the latter reason the staves for liquor casks are always cut to present this face. The silver grain seen in radial cuts is much more marked in oak than in any other wood. Cleaving should always be done in the radial direction.

Wainscot oak means the same as quartered oak. Pollard oak has twisted and knotted grain, due to the tree having had its top and branches lopped.

Bog oak is found in Ireland in a fossilized state underground, still hard and sound but black in colour; it is occasionally used for veneer and for small fancy articles.

How to Polish Old Oak. There are several polishes for old oak. One of the best is made by dissolving $\frac{1}{4}$ oz. each of shredded beeswax and brown sugar in a pint of warm beer. This should be applied while it is warm and then allowed to dry on the wood, afterwards being polished with a soft cloth.

To restore dirty old oak furniture, it is well to clean it thoroughly first. This can be done by adding 1 lb. of American potash to 3 pints of boiling water and applying it with a swab made by tying a piece of coarse rag round a stout stick or lath. The hands must not be put into the mixture or the skin will be injured. After going over the work a few times it will be soft enough to be scrubbed off. This must be done with a fibre brush, not a hair brush. When all the dirt has been removed the work must be allowed to get dry, when it will be ready for the necessary repairs. The work must next be oiled with linseed oil and given a coat of yellowish polish. When this is dry it should be rubbed with fine glass-paper, and any new wood shaded by mixing a little vandyke brown with yellow polish or gas black, if necessary. It should be laid on with a camel-hair brush. To remove the linseed oil, the whole of the work should be rubbed over with a little turpentine and should then be wax-polished.

Use of Stains. Oak is brown of various shades, and in finished work its colour is often darkened or otherwise changed. It is easily darkened and improved in a number of ways. Oil may be rubbed into it for this purpose, or a solution of bichromate of potash and water applied, or it can be fumed with ammonia. Stains used are vandyke brown, burnt umber, yellow ochre and others, generally with ammonia. Brunswick black and turpentine make a brown stain. All these can be diluted to make the shade required. Aniline dyes are used also, sometimes for other colours than the natural ones of wood. Care should be taken, when reproducing the oak colour for Jacobean style furniture or panelling, not to err on the dark side. The wood should show a rich brown finish.

Finishes for Oak. Antique oak, as it is called, can be made by darkening the wood, which must be straight-grained oak, with burnt umber, or vandyke brown, or a mixture of both, or with burnt

umber and drop black. Antique oak stain can be made from 1 lb. of raw umber, 2 lb. of vandyke brown, and $\frac{1}{2}$ lb. of drop black, all ground in oil. Mix them all with a pint of the best brown japan, and thin the liquid for use with turpentine. Several coats of ammonia water will also give the antique appearance, which can be simulated in another way with a stain of iron filings in vinegar or with a concentrated solution of permanganate of potash.

Cathedral oak is another good finish; it shows best on white oak nicely prepared. To make it the surface should first be glass-papered smooth, after which a stain made from 2 oz. of permanganate of potash in two quarts of water should be applied. Let this dry, and then rub it over lightly with fine glasspaper. Give it another coat of the stain, and when this is dry glasspaper it again lightly and apply a coat of black filler. Wipe this off at once and let the work stand for the night; in the morning glasspaper it lightly, and give it a coat of white shellac. When this is dry, glasspaper it lightly again and wax finish the oak. As the finish must be quite flat, the wax should not be rubbed.

Flemish Finish for Quartered Oak.

Flemish oak finish can only be used on the best quarter-sawed oak. The wood should be glasspapered and then a coat of Flemish water stain applied. This is made by dissolving $\frac{1}{2}$ lb. of bichromate of potash in a gallon of water. Having been strained, this should be applied with a bristle brush. When it is dry, glasspaper the oak again. Mix up some japan and drop black with turpentine, making it very thin, and give the work a coat of this stain. Wipe it off clean in a few minutes, and then apply a coat of orange shellac. After the work has stood for a few hours it should be smoothed up with glasspaper and another coat of shellac given. When it is hard it may be rubbed with pumice-stone powder. Flemish oak should never be finished with a lustre, nor should the wood pores be filled.

Mission oak can be produced in several ways, the idea being to show a dead black effect in the grain of the wood with a kind of greyish cast to it. The stain should be made from 1 lb. of drop black, in oil, and $\frac{1}{2}$ oz. of rose pink, in oil, thinned with a gill of good japan drier and $1\frac{1}{2}$ pints of turpentine, the whole being strained through double cheese cloth. Japan colours can be used in place of oil colours, but in this case the drier must be omitted and a little rubbing varnish added to bind the stain. It should be finished with wax.

For forest green oak mix together 1 lb. of chrome green and $\frac{1}{2}$ lb. of chrome yellow, both of medium shade. Apart from these, mix 3 pints of turpentine, a pint of raw linseed oil and a little good white japan. Thin the colour mixture with the latter, and apply one coat of it to the wood. When it is dry apply to it a coat of white shellac coloured with a little turmeric and a few crystals of green aniline. This, too, should be finished with wax.

For silver-grey oak, make the surface perfectly smooth with sandpaper and then stain it with a preparation of silver nitrate, 1 part in 50 parts of water, both by weight. Apply two coats of this, then a coat of commercial hydrochloric acid, and when it is dry apply a coat of ammonia water of ordinary strength. If the work can be left to dry in the dark the effect will be better. The finish may be in oil or varnish, but it must not be lustrous, or the effect will be spoiled. See Fumed Oak; Furniture; Graining; Hall; Panelling; Stain.

OATMEAL. For growing children oatmeal is a valuable food, as it is rich in phosphates and promotes the formation of bone and the nerve constituents of the body; but it must always be given with discretion, and be discarded for a time if it causes any apparent digestive trouble. For delicate persons or those pursuing sedentary occupations oatmeal is considered rather difficult of digestion, and if served to invalids it should be considerably thinner than for those in health, and on no account should butter be dissolved in it. Some people should never eat oatmeal at all in bulk, and if

cakes or scones are made for them, a proportion of ordinary household flour should be mixed in with the meal.

Oatmeal can be cooked in many ways, the most common preparation being porridge, but a variety of other dishes can be made, and it is also employed for biscuits, cakes, scones, and puddings.

Oatmeal requires to be stored with care, and should never be used if it is stale or is impregnated with a strong taste of some article of food with which it may have come in contact. It should always be placed at once in a well-covered store-jar or a wooden receptacle, and it should be examined frequently to see that it is in good condition.

Oat Cake. To each lb. oatmeal allow 1 pint boiling water, with $\frac{1}{2}$ oz. salt butter or lard melted in it to make the cakes crisp. The water should be poured over the meal, and the whole made up very quickly into a fairly stiff dough.

Roll it out about as thin as a half-crown piece, form it into a round, and cut it across and across again. Bake the cakes on a girdle and, when they are a light brown underneath set them before the fire to dry and colour slightly on the top; also to induce the edge to curl over a little. When quite dry and crisp the cakes may be stored ready for use.

A recipe containing a proportion of flour, more suitable for people who cannot take oatmeal in bulk, is as follows: $\frac{1}{2}$ lb. medium oatmeal, $\frac{1}{2}$ teaspoonful salt, $\frac{1}{4}$ teaspoonful cream of tartar, 4 oz. flour, 3 oz. butter or lard, $\frac{1}{4}$ teaspoonful bicarbonate soda, 3-4 tablespoonfuls milk. Mix all dry ingredients thoroughly, rub in the fat, and form into a stiff paste with milk. Bake as in previous recipe.

Oatmeal Biscuit. A good biscuit is made by mixing together $\frac{1}{2}$ lb. medium oatmeal, 4 oz. flour, $\frac{1}{2}$ teaspoonful salt, and $\frac{1}{4}$ teaspoonful bicarbonate soda. Dissolve 2 oz. butter in 3 tablespoonfuls of warm milk, pour this into the dry ingredients, and make the whole up into a dough. Set it aside to become firm, and then roll it out and cut it into biscuit shapes; then prick each and bake them in a good oven about 6 min. To make these biscuits sweet add 1 to $1\frac{1}{2}$ oz. castor sugar to the flour.

Oatmeal Cake. Small cakes are made with oatmeal flour and golden syrup, from the following recipe: Sieve together $\frac{3}{4}$ lb. fine oatmeal, $\frac{1}{4}$ lb. flour, and $\frac{1}{2}$ level teaspoonful bicarbonate soda, adding to them 2 oz. candied peel cut into small pieces. Into a saucepan over the fire put 4 oz. margarine, the same quantity of granulated sugar, and $\frac{1}{2}$ lb. golden syrup, heating them until the sugar has dissolved, but taking care that they do not boil. When they have cooled, pour them into a well made in the centre of the oatmeal, etc., and mix the whole to a rather stiff consistency. Turn the mixture into some small greased cake-tins, and bake the cakes in a moderately hot oven for about 20 min.

Oatmeal Scone. Mix together 3 oz. medium oatmeal, 2 oz. flour, a pinch of salt, 1 teaspoonful cream of tartar, and $\frac{1}{2}$ teaspoonful bicarbonate of soda; rub in 1 oz. fat, and then add 3 oz. mashed potatoes. Mix these ingredients well, adding enough milk to form a dough; then turn the mixture on to a floured board, roll it out about $\frac{1}{2}$ in. thick, and cut it into rounds. Bake the scones on a greased tin in a hot oven or on a girdle. They can then be buttered, and eaten hot or cold. See Gruel; Porridge; Scone.

OBESITY: Its Treatment. The abnormal development of fat throughout the body produces obesity, and an excess of fat is a menace to health. Normally fat is chiefly found under the skin, under the membrane lining the abdomen and covering the bowels, and between the muscle fibres. Any large increase of this fat is associated with weakness of the muscular tissue. Hence arises

sluggish action of the bowels and inability to take much exercise on account of the state of the muscles generally, and because shortness of breath and palpitation are easily induced through enfeeblement of the heart muscle. Stout people stand acute diseases badly. There is a tendency for any individual to put on fat after the age of 40, more especially women. But the condition is largely due to over-eating and over-drinking, combined with too little exercise.

A person who is in danger of becoming stout should increase his outdoor exercise, and restrict his intake of fat-forming foods, i.e. fats and carbohydrates, especially the latter, e.g. sugar, bread, milk, milk puddings, malt liquors, and sweet wines. He should be sparing in liquids at meals. Green vegetables may be taken freely.

When an unwholesome degree of corpulence already exists, vigorous exercise may be impossible, and to begin with gentle walking on the level may be all that can be attempted. As the powers increase, the rate should be faster and the hills should be taken. In some cases it may be desirable that a course of massage should precede or supplement exercise out of doors. In these cases, a strict diet must be prescribed and systematically followed.

After the patient's weight has been reduced one or two stones or so, a special diet which he can keep to indefinitely should be devised. This should be moderate in amount, with no potatoes or sweet foods, no sugar in the tea or coffee, and a minimum of bread—about 4 oz. In place of sugar in the tea or coffee saccharin tablets, which can be obtained from any chemist, may be employed. Fatty meats, such as goose and pork, also salmon, eels, and herrings should be strictly forbidden.

The diet, however, should include plenty of such vegetables as cabbage, spinach, etc., as on account of their bulk they give a sense of satisfied appetite, Peas, broad beans, lentils, carrots, parsnips, and beetroot should be avoided. Ale, beer, stout, sweet wines and spirits should be given up entirely.

Artificial nostrums should be avoided and drugs are only to be taken on medical advice. Some of those popularly recommended are useless, others are harmful. A Turkish bath may be useful, but must only be taken after the patient has been examined by a doctor as to his fitness for it. See Diet; Exercise.

Occasional Table. Example in mahogany with circular top; 18th century. (Victoria & Albert Museum, S. Kensington)

OCCASIONAL TABLE. By this name is understood tables that are only used occasionally and for casual purposes, being thus the opposite of dining tables, kitchen tables, and others that have a definite use. They are generally small and light, so that they can easily be moved about, and are chosen to suit the other furniture of the room. Nests of three or four tables are useful and obtainable in lacquered, painted and polished woods. When not all required the largest of these tables gives accommodation for books and flowers, etc., the smaller sizes being neatly stowed away underneath it. Low tables are convenient for use beside a settee or divan; Moorish designs

look well with oriental surroundings and small gate-leg tables are popular for oak furnished rooms. Reproductions of the table illustrated are suitable with mahogany furniture and are particularly graceful in shape. See Gate-leg Table; Table.

ODONTOGLOSSUM. One of the most beautiful orchids, this is suitable for cultivation in a glasshouse having a minimum winter temperature of 45-50 degrees. During summer cool moist conditions, ensured by free ventilation, shade from sunshine and syringing between the plants, are

necessary. The pots should be filled to the extent of one-third their depth with drainage: a suitable compost consists of orchid fibre, peat and sphagnum moss in equal parts. Repotting is done in February or towards the end of summer; the pseudo-bulbs must be set on the surface of the compost.

Odontoglossum crispum and its varieties, which are heavily blotched with various colours on a white ground, are particularly beautiful, the long arching sprays of bloom being most decorative. Other easily grown kinds are *harryanum*, *Rossii*, *luteo-purpureum*, *grande* and *citrosmum*. Innumerable crossbred or hybrid *odontoglossums* are raised annually, and these are now chiefly grown; the flowers are of brilliant and fascinating colours. Orchid growers' catalogues should be consulted. *See* Orchid.

OFFAL. The term includes the heart, liver, kidneys, head, tail, and most edible pieces of an animal killed for food which are not sold in joints. In fish, offal denotes low grade and very inferior fish. *See* Heart; Kidney; Liver.

OHM. The chief unit of electrical resistance is the ohm. It is that resistance which will limit the current produced by a pressure of one volt to one ampere. Other units are the megohm (a million ohms), and the microhm (one millionth of an ohm). *See* Electricity.

OIL: For Domestic Use. The grade of mineral oil mainly used as fuel in the house is that known as kerosene or paraffin oil. The heavier grades of petroleum known as fuel oil are used to fire domestic boilers and to a limited extent for cooking purposes. A steam or air jet is required to atomise them before burning and a gravity or pressure feed is necessary.

Kerosene can be applied practically to all the domestic heating and cooking purposes to which coal gas is put, and it has the advantage that the appliances employed in burning it are self-contained and do not involve the installation of permanent piping. For heating, various forms of oil stove can be purchased. Needing no flue, they can be moved about from place to place as required; and as all the heat they produce passes into the room, they are very efficient and can warm the air of an apartment to a comfortable temperature in a very short time. On the other hand, they do not ventilate the room, and the products of combustion are not carried away. Further, the effect of such stoves soon dies away after they have been extinguished.

For cooking, oil-burning appliances are made in many sizes, from single-burner stoves that serve to boil a kettle up to those with an oven and several burners which will boil, steam, fry, and bake and perform every cooking operation required. Representative types are illustrated in the article Cooker. The burners fitted in oil heating and cooking appliances are of two kinds. In one the oil is sucked up from the reservoir to the flame by means of wicks, either straight or circular, which resemble those employed in lamps except that they are larger. In the other form the oil, by a slight pressure produced in the reservoir by a hand pump, is forced up to a point above the flame, and after being vaporized by the heat passes to the burner, where it is mixed with air and burnt as a gas. In this form there are no wicks, and consequently the trouble of trimming is avoided. Oil stoves of any kind must be kept scrupulously clean.

With the pressure type of burner, the nozzle through which the vaporized oil issues before being burnt has first of all to be heated up (usually by burning a small quantity of methylated spirit in a small trough surrounding the burner), before the issuing oil will ignite. Also the pressure inside the oil container has to be pumped up before lighting up, and from time to time during use, in order to force the oil out through the nozzle in a fine spray.

Fig. 1 shows a pressure type heater in which an asbestos mantle is raised to a high degree of incandescence, a copper reflector projecting the heat out into the room. It holds 1½ pints of oil, which is enough for ten burning hours.

Of the wick burner pattern the heater illustrated in Fig. 2 is typical. It consumes about half a pint of paraffin per hour. If the wick of this stove is kept free from carbon deposit (which can be rubbed off with a piece of newspaper every time before the stove is lit), and the burner kept clean, there is very little danger of smell, and the stove needs no special attention when starting up or burning.

Small oil engines are useful as a means of providing power for such purposes as driving electric generators or pumping water from wells. In the article on Internal Combustion Engine is illustrated a type which is started up on petrol and then runs on paraffin oil.

Oil. Fig. 1. Pressure type of oil heating lamp. (Courtesy of Tilley Lamp Co.)

Right. Oil. Fig. 2. Useful wick type heating stove. It consumes about half a pint of paraffin oil per hour. (Anglo-American Oil Co., Ltd.)

Oil Fuel for Boilers. The use of fuel oil for central heating and hot-water supply presents a number of advantages, apart from the question of cost, in which latter respect fuel oil at about 75s. per ton compares with coke at 35s. per ton. A fully automatic system can be arranged, controlled by thermostats. There is a saving in labour, of course, since no stoking is needed and there are no clinkers or ashes to remove. Fuel oil can be bought economically in lots of two tons (approximately 500 gallons), and costs from 3½ d. to 4d. per gallon. A storage tank holding 3 tons is desirable, and this if rectangular in shape would be about 6 ft. by 5 ft. by 4 ft. The tank need not be indoors, but can be located in some corner of the garden and screened by a hedge, etc. Delivery from the oil wagon is carried out in a few minutes, the oil being pumped direct into the consumer's tank.

Fig.3. Section of Ideal Britannia boiler showing oil firing.

Two representative systems are here illustrated. Fig. 5 shows a hand-operated oil burner working on the rotary principle, a system which is applicable to quite small

installations. In this type of burner the oil is delivered into a cone shaped cup revolving at high speed, and is thrown off the edge in a finely divided spray. The air necessary for combustion is supplied by a fan, driven by a small electric motor. Fig. 6 shows the burner fitted to a central heating boiler. The oil feed is by gravity, from a storage tank (capacity 300 gallons) a few feet above the burner level. When arranged for automatic control the ignition is by means of an incandescent electric element at the nozzle, which is switched on and off by thermostatic control.

Fig.4. Automatic oil burner for central heating boiler. (Courtesy of National Radiator Co., Ltd.; and of York Automatic Oil Burners)

Fig. 5. Ray Midget fuel oil burner with hinge plate mounting, permitting easy access. (Courtesy of Ray Oil Burner Products)

A burner of the pressure jet class is illustrated in Fig. 4. Oil is fed under pressure through an atomizing nozzle and issues as a fine spray, being mixed with air supplied by a blower. A small electric motor drives the oil pump and blower, and a transformer furnishes the high voltage ignition current. The apparatus, once started, is automatic in action, and needs no attendance. A thermostat in the flue shuts off the ignition current as soon as the burner is alight and functioning regularly. Another thermostat, connected with the boiler, shuts off the apparatus when a prearranged water temperature is reached, and a room thermostat in one of the apartments switches off the burner when the desired room temperature is attained. A temperature drop of from two to ten degrees (as pre-arranged) causes the switches to be operated in the reverse manner, so that the burner is started up again and the atomized oil spray simultaneously ignited.

Fig. 6. Ray Midget burner fitted to central heating boiler.

Householders who desire fuller information about oil fired boiler plants should write to the fuel oil department of Shell-Mex & B. P., Ltd., Fuel Oil Department, Shell-Mex House, Victoria Embankment, London, W.C.2. This firm maintains a staff to advise interested persons on the selection of appropriate equipment. *See* Cooker; Fuel Heating; Lamp; Lighting.

OIL: In Cookery. Olive oil is the best of all oils for the purposes of cookery. When pure it is practically tasteless and of a pale yellow colour with a slight tinge of green. Only the best quality should be employed. Olive oil is the foundation of mayonnaise sauce and most salad creams. It also enters into the composition of dressings for plain salads. It renders fritter batters exceedingly light, and is often used for the purpose of frying. In Jewish cookery oil is always used.

When moulds or slabs have to be greased in sweet-making oil is employed. Creams and delicate dinner sweets are set in oiled moulds. Almond oil may be used in place of olive oil for this purpose. Oil of any quality or description is not adapted for making pastry or good cakes, but fish may be preserved in oil. If oil has been kept in store some time and has deteriorated, it can be improved by turning it into a larger bottle and pouring upon it cold water, then shaking it vigorously and letting it stand two hours. When decanting the oil the rancid matter is detained by the water.

OIL: In Medicine. There are two distinct classes of oils. The first consists of the fixed oils, such as linseed, flaxseed, olive, almond, coconut, castor, cod liver, and other oils. Except for cod liver oil all these are of vegetable origin. The second class consists of the essential or volatile oils, including the oils of peppermint, cloves, caraway, cinnamon, dill, lemon, juniper, rosemary, etc.

Some of the fixed oils are nourishing foods, and most of them form soothing applications to inflamed surfaces. Others are valuable medicines, e.g. cod liver oil in consumption and other diseases. The essential oils, which are distilled from plants, stimulate the appetite and promote digestion, or act as an anti septic. *See* Castor Oil; Cod Liver Oil; Linseed Oil, etc.

Oilcloth. *See* Linoleum.

OILING. Suitably prepared oils are employed for lubricating machinery of all kinds, and oil serves also as the vehicle for many semi-liquid lubricants. The oiling of domestic appliances is dealt with

in the article on Lubrication, which is followed by one devoted to the oiling of motor vehicles. *See Grease; Lubrication; Motor Car.*

OILSKIN. Cotton cloth coated with boiled linseed oil and dried takes the yellow appearance of a cured animal skin and becomes waterproof and airtight. Seamen's overalls made from this material are called oilskins. They are stiff and heavy, and cold to the touch.

Lighter oilskins made in oiled silk are translucent and made into women's wet-weather coats. The fabric is lighter in weight and dyed in pretty colours, but it tends to tear easily. Efficient ventilation is a difficulty, as body moisture condenses upon the underside of the cold wet garment. Oiled silk is used for bathroom curtains.

OILSTONE. Various kinds of hard stone, composed mainly of silica and quartz, when smoothed and polished and suitably mounted are invaluable for sharpening knives and tools of all kinds. Oilstones are usually lubricated with machine oil; in a few cases water is used for the purpose.

For the amateur, who will mostly use the oilstone for sharpening chisels, plane irons, gouges, and the like, the Washita stone is as good as any. A convenient size is about 9 in. long, 2 in. wide, and 1 in. thick. The stone should be fine in grain, free from cracks or hard places, and should cut freely and not exhibit any tendency to choke readily. These features are only detected when the stone has been in use for a time; and when a good stone has been found, it should be retained and used until it is entirely worn out. A finer-grain stone, known as the Arkansas, is also a natural stone. It is more expensive than the Washita, but more useful for sharpening delicate tools requiring a very keen edge.

Rougher oilstones, such as the India, are made of various compositions, employing emery and carborundum; they are very quick cutting. A carborundum stone will cut almost as quickly as a fine file, and if much work is to be done, it will pay to have one of this class of stone for rough sharpening; and a finer-grained stone for the setting and finishing-off touches. For sharpening gouges, a number of bevelled slips are obtainable, shaped to suit the curvature of the gouge. Diagonal shaped stones, square, and tapered slips, as they are called, are also available for appropriately shaped tools.

Using the Stone. The whole secret of tool sharpening consists in rubbing the tool on the stone so that the cutting edge is formed at the right angle. Figs. 1-3 illustrate the correct methods of holding a chisel, plane iron, and gouge on an oilstone. In the case of the chisel, this is first ground on a grindstone to the proper angle, and then the extreme end, or cutting edge of the tool, is sharpened on the oilstone by rubbing the chisel on the stone, using the greatest length of the stone and pushing the chisel backward and forward with a regular, steady motion.

Press upon the chisel with the fingers of the left hand, while the right hand guides the direction of the tool. If the chisel is allowed to rock about the cutting edge will be rounded instead of flat, with the result that the tool will not hold its edge for any length of time. The great object should be so to sharpen the edge that the end of the chisel is straight and square with the sides, but the face inclined at a slightly steeper angle than the other bevelled portion produced by the grinding process.

The plane iron is sharpened in a similar manner, except that, as it is much broader, it may be necessary to sweep the iron diagonally across the stone, so that all the parts receive their full share of it. The gouge is sharpened by rolling it to and fro, and at the same time traversing it up and down on the face of the stone, thus sharpening the whole of the cutting edge. In general, when sharpening cutting tools, keep the handle as low down as is consistent with easy sharpening, as the longer the cutting edge, the keener will be the tool.

Oilstone. Figs. 1 and 2. How a chisel and a wide plane iron are held while being sharpened on an oilstone. Fig. 3. Finish of stroke when sharpening a gouge; see also Fig. 4.

After the stone has been in use for a time it becomes hollow in the centre and generally rough towards the ends, and will then require rubbing down. This can be done by grinding, holding the oilstone against the side of the revolving grindstone and lubricating it with water and a little sharp sand.

What are known as ragstones are a rough sort of whetstone, and the coarsest kind is the sandstone, with which gardeners sharpen scythes. This is an example of dry sharpening. See Grindstone; Hone; Knife; Razor.

Fig. 4. Showing use of oilstone slip for sharpening edge of hollow-ground gouge.

OINTMENT. A preparation that has the consistency of butter and is intended to keep some medicinal agent in close contact with a skin or other surface is called an ointment. The basis may be lard, lanoline, vaseline, cocoa-butter, goose fat, or a mixture of one or more of these with sweet almond oil, olive oil, glycerin, spermaceti, wax, suet, etc. Water is added for the cooling effect of its evaporation. Thus the soothing cold cream is made of wax, spermaceti, sweet almond oil, and rose water.

When rubbed into the skin fatty substances are absorbed to some extent, and carry with them any contained medicament. They soften and clear the skin, and protect it. If the skin is dry and chapped, an ointment containing a little glycerin is a good remedy for keeping it soft and pliable.

Among the most commonly used ointments are:

Boric acid ointment, a mild antiseptic, for wounds and abrasions.

Zinc ointment mildly astringent and soothing; good for ulcers and burns.

Lead carbonate ointment, for sore and inflamed surfaces.

Calamine ointment soothing and astringent.

Yellow oxide of mercury ointment full strength or with an equal quantity of vaseline makes a golden ointment for eye complaints.

Mercurial ointment, or blue butter applied to rheumatic joints and enlarged glands.

Tar ointment, for scalp skin eruptions, eczema.

Sulphur ointment, for scabies, or itch.

Stavesacre ointment, for head lice and other parasites.

Capsicum ointment, or Chilli paste, a counter-irritant which may be used instead of a mustard plaster.

OLD AGE. As people advance in age various changes in the body cause them to feel the cold more acutely than formerly. They should be dressed warmly, wear woollen garments next the skin and have a fire whenever at all chilly.

Daily exercise in the open air is good as long as it is possible to take it, but avoid over-fatigue and exposure to wet weather and cold winds. Great care must be taken to keep the skin in a healthy condition by taking a warm bath at least once a week, and sponging the skin daily and rubbing with a moderately rough towel. Constipation is often a trouble, and should on no account be neglected. Regulate the bowels by giving moderate doses of simple aperients, such as a teaspoonful of confection of senna or liquorice powder at night when necessary. Sleeplessness is sometimes also very troublesome, but hypnotic drugs must be used with great caution.

An old man or woman requires only a small quantity of food compared with a young and active adult. As age advances the quantity of food taken must be diminished, or otherwise indigestion, rheumatism, skin troubles, and other penalties will have to be paid. In middle-aged and elderly people all the organs work less actively than in the vigorous period of life.

The food should be light and given in small quantities. As a rule four light meals a day should be given. The principal meal should be taken in the middle of the day. Although the diet should be varied, not more than two, or at the utmost three, dishes should be partaken of at any one meal. Most old people should eat vegetables sparingly, as they are apt to cause flatulent indigestion. Fruit is most suitable in a cooked state. If eaten raw, it should be perfectly ripe. If inclined to put on fat, an elderly person should be sparing in the use of sugar, starchy foods, and fats. Oatmeal is too difficult of digestion, but on the other hand the prepared or patent wheaten foods are especially suitable.

An old person should depend largely on milk for his nourishment. This he should take in sips, spending about 20 min. in drinking a half pint. If stimulants are taken at all, the quantity should be small—not more than a single glass of the stronger wines, or two glasses of a light dinner wine, or a little whisky or brandy well diluted. The best time to take any of these is at dinner. Sometimes, a tablespoonful of whisky in hot milk at bedtime will prevent sleeplessness. *See Diet; Sleep.*

‘N’ AND ‘O’ RECIPES: A SELECTION IN ACTUAL COLOUR

Orange Trifle: Split 6 sponge cakes, spreading cut sides with marmalade. Arrange lower halves in glass dish. Boil 1 gill milk. Pour some over cakes and add $\frac{1}{4}$ gill orange wine. Sprinkle over all grated rind of a large orange. Fit on top halves and soak with remainder of milk, $\frac{1}{4}$ gill wine, and strained juice of the orange. Peel another orange thinly. Cut peel into fancy shapes and divide fruit into quarters. Remove pips and arrange slices between the sponge cakes. Separate yolks from whites of two eggs. Beat up yolks with another whole egg, adding 1 pt. Milk, $1\frac{1}{2}$ dessertspoonfuls sugar and a few pieces orange rind. Pour all into a jug. Stand in hot water over fire, stirring until contents thicken, but do not boil. Take out rind and leave custard to cool. Decorate sponge cakes with shredded almonds. Pour custard over, covering the whole with white of 2 eggs whipped to stiff froth and mixed with 2 dessertspoonfuls castor sugar. Decorate with crystallized

violets and the cut orange peel. Norfolk Pudding: For pudding shown above make a very rich batter, sweetened to taste. Add by degrees $\frac{1}{2}$ pt. cream and flavour with 2 tablespoonfuls orange-flower water. Fill buttered pudding cups half full and bake until risen to top of cup.

OLD AGE PENSIONS. In Great Britain most persons are entitled, on reaching the age of 70, or in certain cases 65, to receive an old age pension. The amount of this is normally 10s. a week, but those with an income of over a certain amount are only entitled to smaller sums. Normally the pension begins at 70, but persons who have insured under the national health insurance scheme and their wives are entitled to pensions on reaching 65, without any inquiry as to their other means.

To be entitled to a pension at the full rate a person's income must not exceed £26 5s., or £52 10s. in the case of husband and wife living together, but in arriving at this figure no account is taken of the first £39 of unearned income, or in the case of a married couple the first £78. Thus, a person with a total income of just under £65 5s. a year or a couple with just under £130 10s. can receive old age pensions at the full rate.

Pensions below 10s. a week are given to those whose incomes, after the first £39 has been deducted, are as follows:

Between	£26 5s.	And	£31 10s.	8s. 0d. per	week
„	£31 10s.	„	£36 15s.	6s. 0d. „	„
„	£36 15s.	„	£42	4s. 0d. „	„
„	£42	„	£47 5s.	2s. 0d. „	„
„	£47 5s.		£49 17s. 6d.	1s. 0d. „	„

In the case of a married couple living together, these sums are doubled.

To receive a pension a person must have been a British subject for 10 years, and must have resided within the United Kingdom for at least 12 years since reaching the age of 50. A British subject is defined as a person born in the United Kingdom, or the child of a British father, or a person who has taken out a naturalization certificate. Persons who receive outdoor relief can also receive pensions, but indoor paupers are not eligible, nor are persons who are in prison or are in a mental hospital during the time they are actually detained.

Blind persons are entitled to receive pensions when they are 40 years old, the conditions being similar to those for others at 70. To secure a pension on this account the person must be so blind that he or she cannot perform work for which sight is essential.

Estimation of Income. In estimating the income account is taken of the income the person is likely to receive during the succeeding year and of the yearly value of any advantage or benefit enjoyed by him, such as the right of living rent free. No account, however, need be taken of the yearly value of any advantage accruing from the use or enjoyment of furniture or personal effects or of the first £25 of capital in possession of the claimant. The next £375 of capital is regarded as earning interest at the rate of 5 per cent., and all capital in excess of this at 10 per cent. In the case of a married couple living together these figures are doubled.

When a husband and wife are living together in the same house the means of either is taken as one-half of the total means of the couple. Thus, a man who has an income of £50 a year is entitled to the full pension if he has a wife living with him who is without separate income, or if the incomes of the two do not exceed £52 10s. a year. Old age pensions cannot be alienated.

Method of Application. The conditions outlined above permitting, the first step is to apply for the necessary forms at any post office. These must be filled up by the claimant and the statements made attested by reliable witnesses. They should then be returned to the postmaster of the post office where the pensioner wishes to receive his pension, or to the local pension officer.

The pensions are paid every Friday at the various post offices, generally to the pensioner in person, although a relative or friend can receive them in case the pensioner is unable to get about. The pension book must be presented and stamped each time. In each locality a pensions officer controls the distribution of pensions, and to him all complaints in connexion therewith should be made. He is also responsible for investigating cases.

Ireland was included in the scheme of old age pensions, but this liability was transferred in 1922 to the Parliaments of the Irish Free State and Northern Ireland, who now pay them. Australia and New Zealand have also old age pension schemes. *See Insurance: Pension.*

OLD MAID. This card game is suitable for two or more players. One card is taken from the full pack, usually a queen; a variation is to take out one card haphazard, the card not being shown. Supposing, however, that a queen is removed, the cards are shuffled and dealt round one at a time to all the players until the pack is exhausted. Each player then looks at his cards and throws out of his hand into the centre of the table all pairs, e.g. two kings, two sevens, etc.

When all pairs have been thrown out by each player, the one on the left of the dealer offers his cards, face downward, to his left-hand neighbour, who can draw any card he chooses. If the player draws a card which pairs with one in his hand he throws the pair so made into the centre of the table; if not, he places it amongst the cards he already holds, and offers his cards in turn to the next player to draw from, and so on.

In the course of time all the cards, except one queen, are paired. It is the object of each player to try to pass this queen on to the next player. The holder of the unpaired queen is old maid. With the variation of discarding any unknown card no one has any idea of which card in the pack will make him or her old maid, and this form of the game is often preferred.

OLD MAN. This is one of the many names of the shrubby *Artemisia abrotanum*. It has fragrant foliage, and is known also as lad's love, wormwood, southernwood, and by many other names. It is an old-fashioned country cottage garden plant. *See Southernwood.*

OLD MAN CACTUS. A member of the *Pilocereus* group of cactaceous plants, and one of the most popular in small collections is *P. senilis*. This name, in conjunction with its remarkable covering of long white hairs, has made it familiar as the old man cactus. *See Cactus.*

OLD MAN'S BEARD. This is one of the popular names for *Clematis vitalba*, which is familiar in British hedgerows and also known as traveller's joy. Its roots are in demand as a stock upon which to graft the choicer kinds of clematis. It blooms in July and bears large clusters of greenish-white flowers. The seeds are provided with long hairs which become covered with a soft pale grey fluff, from which the plant takes this name. Old man's beard is useful for covering bare banks or for training over trellises and tree stumps. *See Clematis.*

OLEANDER (*Nerium oleander*). This is a beautiful flowering shrub suitable for cultivation in pots under glass. A temperature of 45-50 degrees is high enough in winter; its rose-coloured blooms are borne during the summer months. It should be potted in pots or tubs of loamy soil enriched with decayed manure. During the summer months the oleander requires an abundance of water, and must be fully exposed to the sunshine in order that the stems may be well ripened. The oleander often

fails to bloom well because of the neglect to remove the shoots, while they are small, that develop at the base of the flower buds. If allowed to remain they grow and the flower buds perish. This shrub flowers most freely when well rooted in the pot or tub: weak liquid manure should be given occasionally in summer.

Oleander. A favourite greenhouse and conservatory shrub which bears rose-coloured blooms in summer.

OLEARIA. This is the name of a group of evergreen shrubs of which the favourite kind is *Olearia Haastii*. This reaches a height of 3 or 4 ft. and bears white daisy-like flowers in August. It makes a useful ornamental garden hedge as it is of compact growth. *Olearia stellulata*, 2-3 ft., bears white flowers in early summer; it blooms very freely in a sheltered place in mild districts, but it is less hardy than *Haastii*.

Olearia macrodonta, a more vigorous shrub, is suitable only for the milder counties of England. These shrubs need no pruning other than that required to keep them shapely, which should be done after flowering. Propagation is by cuttings in a frame in summer.

OLIVE: The Shrub. A group of evergreen trees and shrubs is called the olive. It includes the common olive (*Olea europaea*), which is a distinctive feature of the landscape in southern Europe, and may be grown in this country only in mild places or against a wall in other gardens. The olive oil of commerce is obtained from the fruits. Propagation is by means of cuttings or seeds.

Uses of the Fruit. The green fruit of the olive yields olive oil, and is also pickled and sold in bottles and tins for cooking purposes. The oil, which is contained in the flesh, and not in the stone of the olive, is the very finest which can be used for all purposes of cookery. It is excellent for dressing salads, frying, making light batters, and for preparing entrées.

Stuffed olives make an appetizing dish for hors d'oeuvres. Spanish olives should be used, as the Italian variety is small and more oily to taste. Various mixtures can be prepared for the filling, which must be of a savoury character, or a savoury butter can be used. To prepare the olive for stuffing or cooking by other methods, it must be stoned or turned. To do this, start from the top and pare it round and round, using a small, sharp-pointed knife and shaping it like a spiral. Keep the knife close to the stone all the time to avoid losing the flesh. After the stone is removed and the filling inserted, form the olive into its correct shape again. A special fruit stoner, which is scissor-shaped, holding the olive in a metal circle and ejecting the stone by means of a prong, can be obtained cheaply. The stuffing is inserted in the cavity.

A good way of preparing these savoury olives is to fill them with anchovy butter and serve them on small, thin rounds of bread and butter, each about the size of a two shilling piece. Shell 2 or 3 hard-boiled eggs and separate the whites from the yolks, chopping up the former and rubbing the latter through a sieve. Spread some of the yolk on the rounds of bread and butter, press an olive on each in an upright position, and garnish with the chopped white.

Olives à l'Indienne provide another way of preparing stuffed olives. Cut a hard-boiled egg into halves, remove the yolk, and slice the white into rings. Pound the yolk with 1 oz. butter, a teaspoonful of mustard and 2 oz. chutney, and use this mixture for filling the stoned olives. Cut some brown bread into small rounds, spread any remaining stuffing over them, place a ring of white

of egg on each, and put an olive in the centre. Arrange them on a glass or silver dish. *See Anchovy Butter; Hors d'Oeuvres.*

Olive Savouries, made with hard-boiled eggs, olives and small rounds of bread and butter.

Olive Oil. By pressing the ripe fruit of the olive tree olive oil is obtained. It is a valuable food, and is also a mild

aperient. For people who suffer from mild constipation, a tablespoonful taken every night will often prove most beneficial. As an enema it is very useful for constipation with the presence of hardened faeces in the bowel. Large quantities are sometimes given to people suffering from gall stones. For burns and scalds olive oil is one of the best remedies for immediate use when the skin is not broken.

OLIVINE. The word olivine is used to describe a large number of stones of the semiprecious variety, among which are the chrysolite and peridot. Usually they vary in colour from straw-yellow to dark yellowish green, but the best specimens are of a rich green hue.

OLLA PODRIDA. The Spanish national dish known as olla podrida consists of a stew made with fresh and salt meats, poultry, and vegetables, all cut small and highly flavoured with garlic and pepper. The whole is stewed for a considerable time in a closed pot or jar.

OMELETTE. An omelette is a preparation of eggs fried in a small pan with butter, and served either as a sweet or savoury. Success depends largely on the dexterity with which the pan is handled as well as on the quality of the ingredients and the way in which the eggs are beaten. The yolks and whites should be well mixed but not frothed except in the case of the soufflé varieties. The best pans for the purpose are those with slightly sloping sides, and the pan must not be either too thin or too large. If it is too thin the omelette will burn before it is cooked through, and if it is too large the mixture will spread like a pancake. The omelette pan should be kept for omelettes only, and should not often be washed out. Rub it with soft paper to clean it. The eggs should be new laid and the butter perfectly fresh.

If a savoury omelette is made, with the addition of meat or fish, this must be ready cooked and seasoned and all bones removed. When the omelette is nearly finished the savoury mixture is laid on it, and the sides folded over with a flexible or palette knife. Cheese or fine herbs are mixed in with the eggs. For kidney omelettes the kidney is first chopped up finely and cooked 10-15 minutes in butter before putting in the centre of the plain omelette. If shallots are used they must always be chopped and fried first of all. Three or four eggs may be cooked in a 7 in. pan, and 2 eggs should be allowed for each person.

The most approved method for making omelettes is to heat 2 oz. butter in the pan till smoking hot, then pour in 4 eggs well beaten, and seasoned if for savoury omelette. Stir them and as they begin to set and brown underneath, fold over the side of the omelette near the handle of the pan into the middle, then fold over the other side, making an oval cushion shape. Add meat, fish, kidney, mushrooms, etc., before folding for savoury omelettes. Turn it on to a hot dish.

Sweet Omelettes. These are made and fried as savoury omelettes, but $\frac{1}{2}$ oz. sugar is added to the eggs instead of seasoning, and jam is laid on the omelette before folding. When dished, sugar

should be sprinkled over. Use a stiff kind of jam. Lemon omelettes are made by adding lemon curd instead of jam. For rum omelettes the spirit should be poured over just before serving, and lighted. A good-sized omelette can be made by breaking 2 eggs into a basin, beating them slightly, and then adding $\frac{1}{2}$ teaspoonful of chopped parsley, and some salt and pepper to taste. Melt $\frac{1}{2}$ oz. butter in an omelette pan; pour in the egg mixture, stir it for a few seconds, and, as it sets, lift it up and allow the liquid portion to flow to the bottom of the pan. Lift this again, and then double the omelette over and slip it on to the paper doily arranged on a hot dish. The omelette should be quite soft and flaky in the middle. It can be varied by adding a tablespoonful of grated cheese, chopped cooked ham or meat, or cooked and seasoned tomato, or cooked fish, flaked and seasoned, or cooked mushrooms, immediately before it is doubled over.

Friars Omelette. This is made with a purée of apples sweetened and flavoured, then butter and eggs mixed in, $1\frac{1}{2}$ lb. apples requiring 2 oz. butter and 2 eggs. Butter a baking-dish and coat it with a thick layer of breadcrumbs. Pour in the purée, cover it with another thick layer of crumbs, strew over it small pieces of butter, and bake it for 15 min. in a moderate oven. Serve the omelette with cream and sugar. It will be found sufficient for 4 persons.

Omelette Soufflé. To make omelette soufflé, work together the yolks of 4 eggs and 3 oz. castor sugar until they form a thick yellow cream, then add $\frac{1}{2}$ oz. flour, $\frac{1}{2}$ teaspoonful vanilla and 6 stiffly beaten whites of eggs. Pour the mixture into a well-buttered au gratin dish and bake it in a moderate oven for 10-15 min. or until it is pale brown in colour and spongy to the touch. Dust it with castor sugar and serve it immediately. A little jar may be put in the centre of the soufflé before it is baked. *See Soufflé.*

OMPHALODES. These are annual or perennial plants with forget-me-not-like flowers. Most of them are suitable only for the rock garden. The chief kinds are cappadocica, 12 in.; nitida, 12 in., verna 6 in.; and luciliae, 6 in. All have blue flowers. They need slight shade and well-drained, gritty, sandy loam. During winter they should be protected by pieces of glass raised a few inches above them to keep off excessive rain. Propagation is by seeds sown in spring. *Omphalodes linifolia* is a hardy annual, 8-10 in., which bears white flowers. Seeds are sown in the rock garden in spring for summer flowers. All bloom early in summer.

ONCIDIUM. This is the name of a showy group of orchids some of which must be grown in a hot house, while others flourish under the same conditions as *odontoglossum* (q.v.). The prevailing colour of the flowers of many kinds is yellow with reddish-brown markings. The plants must be watered sparingly after the year's growth is finished. *Kramerianum* and *papilio* are favourite sorts for the hot house; *concolor*, *varicosum* and *marshallianum* are among those suitable for the cool house.

ONE STEP. The one step is similar to the quickstep in construction, but is danced to 2-4 instead of common time. Some of the steps in this dance may be used in the one step, but owing to the quicker time the simplest ones are best. The dancing should be very smooth. The three-step turn is used, that is, turning on every third step, both to the right and reverse. As in the quickstep, the man begins with the right foot and the girl with the left. See Dancing; Fox Trot; Quickstep.

ONIONS: IN GARDEN AND KITCHEN

The Growing and Cooking of this Useful Vegetable

For additional information on this and kindred subjects see the article Kitchen Garden; also Chive; Flavouring; Garlic; Goose; Leek; Pickles; Shallot; Vegetarian Cookery.

How to Grow Onions. 1. Seed sowing in box; a, crops; b, leaves; c, compost; d, fine sandy soil; e, glass. 2. Seed sowing in pot; a crops; 6. leaves; c, rough soil; d, compost; e, sandy soil. 3. Exhibition growing; a, sandy soil; b, rich compost; c, leaves; d, crops. 4. Transplanted seedlings; a, rough soil; b, compost; c, sandy soil; d, how to lift for planting out. 5. Planting; a, wrong; b, right. 6, Soil preparation; a, good manure or vegetable refuse; b, top soil; c, top dressing of soot, wood ashes and soil. 7 and 8. Onion fly and its result. 9. Thinning; a, fine bulb resulting. 10. Soil clearing to mature bulbs. 11. Top tying for exhibition. 12. Rope of onions for storing.

The culture of this vegetable is not difficult if the soil is suitable, but for good results a deep rich loam is necessary.

In preparing the soil, the best manure is undoubtedly well-rotted stable manure, applied to the ground in the autumn before cultivation commences. Soot, soon after sowing, and nitrate of soda when the plants make their appearance, are also recommended as stimulants. A dressing of salt applied a fortnight before sowing, and dug in if the rain has not already washed it in, is also a useful aid. If the soil is light, cow manure is necessary.

The main crop of onion seed should be sown in March, choosing a day when the ground is as dry as possible. It should be put in in drills or rows about 9 in. or 1 ft. apart, and lightly covered with soil.

After sowing, however, the surface of the soil must be dusted with soot, and pressed down firmly by a light roller.

A second sowing of onions should be made in August, when the method of procedure is similar. As soon as the young onions are large enough they should be thinned out. The thinnings are useful as spring onions: the plants should be left at 6 in. apart.

For pickling onions, seed may be sown in May, in poor soil. Thinning need not be drastic, and the bulbs will be ready for pulling by the autumn. The crop of ordinary onions will be ready for handling about the middle of September, when they should be taken up, cleaned, and put in a dry shed or sunny position in the open air, if the weather is favourable, until they are ready for storing.

There are many different sort of onions. Ailsa Craig is one of the best as regards shape, size, flavour, and keeping properties. Others for various uses are Lemon Rocca, Giant Rocca, and Tripoli, usually sown in August. White Spanish, Nuneham Park, James' Long Keeping, Premier and Cranston's Excelsior, are suitable for spring sowing.

Onion. Well-grown bulbs of a variety of this useful and nutritious vegetable.

Gathering the Onions. The time which is best for gathering onions is about the middle of September, when the tops begin to wither and the plants can be pulled up easily. They must be laid out to dry in a cool, airy place, and then made up into reeves. This is done by fastening the tails together with a strand of matting, and forming them into a rope with the onions appearing in even rows all along. This rope should be about 1 yard long, and is called the reeve. It can be hung in a corner of the larder for convenience. Onions keep better when reeved.

Diseases of Onions. One of the chief diseases of onions is known as the white rot. In some parts of England it is called mildew and in Bedfordshire it is mouldy nose. In Leaflet 62 the Ministry of Agriculture deals with the best method of combating the disease. Widely distributed throughout the country, it is specially common where onions have been cultivated for a long time. During the early months of summer it causes much destruction, both to spring and autumn sown plants.

Onion Pests. The worst trouble with which growers have to deal is the onion maggot, which may ruin the young plants if not checked or destroyed. In some gardens the crop is more liable to serious attack than in others. When the seedlings are thinned out care must be taken to tread the soil firmly alongside the remaining plants. Sawdust soaked in paraffin and scattered alongside the rows helps to keep away the onion fly, and frequent dustings of soot are helpful. Flaked naphthalene scattered along the rows is another deterrent. Seedlings which are attacked by the maggot should be uprooted and burnt. An occasional sprinkling on the soil of nitrate of soda or sulphate of ammonia, 1 oz. to the yard run of row, stimulates the growth of the seedlings and thus does good. Mildew often attacks the onion crop. Badly affected plants should be burnt and the other sprayed with a solution of liver of sulphur, 1 oz. in 2 gallons of water.

The Cooking of Onions. By the cook the onion may be regarded equally as a vegetable and a condiment, and is, in fact, almost indispensable as an adjunct to soups, stews, and made dishes of all kinds. When eaten raw it is nourishing and stimulating, but difficult to digest. Much of the

pungent property of the onion is dispersed by boiling, and if blanched before the actual cooking commences it is much less likely to disagree, and forms, to most tastes, a pleasanter and milder vegetable.

When roasted, the onion should be previously blanched or parboiled, and it will be more wholesome and lose some of its richness. Fried onions, also, might with advantage be subjected to this treatment.

The small round onion is the correct kind to use for making pickled onions or for mixing with other for this purpose. Spanish onions are in season in the autumn and winter, when they are imported in a dry state. The Spanish onion is much larger than the British variety, and is better for serving as a vegetable and also for roasting. Being milder in quality, it has not the pungency that is required for flavouring soups and stews. Other varieties of the onion used in cookery are leeks, shallots, chives, and garlic.

Onions leave a most pungent and unpleasant odour on any cookery utensils used in their preparation. Table knives and forks, also, if onions form part of the menu, require special cleansing; this applies particularly to onions served in a raw state, as in salads, etc. The forks should be cleansed in hot suds, with a small piece of whiting in the water, and may be rubbed lightly with cut lemon; if so, they must be rinsed before being wiped. The knife blades, after washing, should be thrust into earth or coffee grounds and then rinsed, wiped, and cleaned as usual.

The board on which onions are cut should be rubbed with vinegar or lemon before being scrubbed. Silver sand should be sprinkled on the board before the brush is applied.

Never use a pastry board in preparing any kind of vegetable; a distinct board must be kept for this purpose. It is better, also, to keep one knife only for onions, and to mark it in some manner that can be easily recognized. To remove the odour and stain of onion from hands, rinse them well in cold water, and rub with cut lemon or pumice-stone before washing them with soap.

Braised Onions. To braise onions, remove the skins from medium-sized Spanish onions, Heat a piece of butter or good beef dripping and fry the onions (whole) lightly on all sides. Then pour in brown stock or gravy to come half-way up the onions, season with pepper and salt, and let them cook gently in the oven or on top of the stove until tender when tested with a fork or skewer. Then thicken the stock with a little flour or cornflour and pour over the onions to serve.

Roasted or Baked Onions. Remove the untidy outer skin from the onions, but do not peel them. Put them, with their skins on, into boiling salted water and let them boil quickly for an hour. Then take them up, dry them, and wrap each in a piece of buttered paper, and bake in a moderate oven about two hours or until tender. They may be served in their skins and melted butter handed with them; or peeled, with oiled butter or brown sauce poured over.

Onion Sauce. This sauce is served usually with roast mutton or boiled rabbit. When apple sauce does not accompany goose or ducks onion sauce may take its place. It forms sometimes a garnish for cutlets or, if made rather thicker, a coating.

To make it, boil till tender 1 lb. onions. Peel and blanch them, then drain and chop very fine. Put 1 pint milk into a bright saucepan, add onions with 1 tablespoonful flour mixed in with them. Bring all to the boil, stirring to keep the sauce smooth; add 1 oz. butter and seasoning of salt and pepper. Simmer it for 5 min. and serve very hot.

Onion sauce for an entrée is prepared thus: Peel and boil in salted water 1 lb onions. After 55 min. pour off the first water and boil till tender in fresh water; drain and chop very fine. Return them to the pan with 2 oz. butter, $\frac{3}{4}$ oz. flour, $\frac{1}{2}$ pint milk, 1 gill cream, and seasoning. Simmer for 10 min., then pass through a hair sieve or a tammy cloth.

Onion Vinegar. All that is required to make onion vinegar is to steep 1 oz. of chopped onion and shallot in 1 pint of white wine vinegar for a fortnight. This condiment gives a piquant flavour to salad dressings and mayonnaise.

Medical Uses. Boiled Spanish onions, taken freely, are said to benefit people suffering from boils. A poultice made of onions is an old-fashioned remedy often used to hasten the breaking of a boil. To use in this way, roast the onions, and mash them before spreading on a piece of muslin or linen and applying to the spot. Both onions and garlic are slightly aperient and diuretic.

Onion Sellers. In the autumn, generally in October, the onion sellers from Brittany arrive in Great Britain and may be seen at all coast towns and villages, and even far inland, going from door to door, offering their wares for sale. These consist of strings of French onions slung from long poles which the Breton fishermen carry on their shoulders.

These onions are somewhat milder in flavour than those which are grown in British soil, and consequently they are of practical use to many housewives for the preparation of dishes in which onions form an ingredient, especially when only a mild flavouring is desired. The Breton onions are plaited together in strands, a convenient arrangement for hanging up in the pantry or from the rafters of country kitchens. They are specially good for flavouring soup.

ONONIS. This is a low-growing hardy shrub or herbaceous perennial which bears pea-shaped flowers in summer. The pink flowered rest harrow (*Ononis spinosa*) is a British plant. Some of the best kinds for gardens are *fruticosa* and *rotundifolia*, with rose pink blooms, and *aragonensis*, yellow, which reaches a height of 18 in. or so. They need well-drained soil and a position fully exposed to the sun; they are usually grown in the rock garden. Propagation is by cuttings in a frame in summer or by sowing seeds. It is important that the shoots should be shortened after flowering.

ONOPORDON. This giant thistle-like plant is suitable for the wild garden, edge of the woodland, or the back of a large herbaceous border. They reach a height of 6 ft. or even 8 ft. in good soil, and have pale purplish flower heads. One of the best is *Onopordon acanthium*, known as the Scotch thistle. They are raised from seeds sown out of doors in spring.

ONOSMA. This is the name of an important race of rock-garden plants. The species demand hot and dry positions, with light, well-drained loam and a little lime.

The plants are of varying heights, ranging from mere inches to a foot or so. One species, *Onosma taurica*, is the old garden favourite golden drop.

But there are lesser known and equally attractive kinds, including *albo-roseum*, white, changing to pink; and *taurica*, yellow. All bloom from June onward, and can be raised from seed or propagated by cuttings. Protect in winter by raised pieces of glass. See Golden Drop; Rock Garden.

Onosma. Bell-shaped flowers of this well known rock garden plant.

ONYX. A variety of tinted agate, onyx is formed of alternative layers of white and coloured chalcedony. It is used in jewelry, for bead necklaces, and fancy ornaments.

Black onyx is used with diamonds in rings, pendants, and other ornaments. *See Jewelry.*

OOLONG TEA. Oolong is a black China tea somewhat resembling in flavour a green tea, and of a rather light character. Oolong teas are sometimes exported from Japan. *See China Tea; Tea.*

OPAL. The most costly of these gems are known as precious opals, and have rainbowlike tints of pink and red; fire opals are of a rich orange-red colour, while cat's eye opals which are rare and usually of a green colour, have in their centre a wavy line similar to that in a cat's eye. Other kinds include the black and the common opal. The latter is the least valuable. Opals are cut in cabochon form and never into facets. They combine especially well with diamonds or silver. *See Jewelry.*

OPERA GLASSES. It is desirable that the selection of opera glasses should be made by the person who is going to use them. Those with bending bars in the middle, so that they can be adjusted to the width between the eyes are a convenience; also it is desirable to have large diameter lenses in both the object glasses and eye pieces. The advantage of the larger lenses is that they allow more light to enter the eyes, and therefore in a theatre the visual results are better.

Opera glasses should not be selected of too high a power, because if it is so, not only is the light reduced, but the field of vision is greatly curtailed. Opera glasses are sometimes covered with leather, pearl, tortoiseshell, and ivory; fancy glasses are made with small lenses to keep down the weight. The aluminium pattern enables glasses with large lenses to be practically the same weight as others with small lenses.

Opera Glasses fitted with long handle to facilitate holding.

Opera glasses are made so that very little dust can penetrate, and with ordinary use they should last many years without being touched inside. When they have to be cleaned on the inside all that is necessary is to unscrew the cell which holds the lens and wipe it lightly with clean chamois leather, which will not scratch or injure it. The lenses should be taken out one at a time, cleaned and replaced; this ensures their going

back in their original position. The outside surfaces should be cleaned with chamois leather. The lenses ought not to be touched except when they require cleaning, as small particles of grit are liable to get on the surface of the glasses and will greatly impair their value.

The usual magnification of opera glasses is about $2\frac{1}{2}$ diameters. A simple way to judge the magnification is to look at a brick wall through the glass with one eye only, but keeping both eyes open. The image seen through the glass will cover the space of bricks which are seen with the other eye.

Ophioglossum. This is the botanical name for the adder's tongue fern (q.v.).

OPHRYS. Some wild orchids of Great Britain are called by this name. The favourites are the bee orchid (apifera), purplish and green; spider orchid (aranifera), brown and green; and fly orchid (muscifera), green and reddish. They are all low-growing plants which flower in early summer. They should be planted in the rock garden in slight shade, in loamy, chalky soil.

Ophthalmia. See Conjunctivitis.

OPIUM. The dried juice obtained by cutting into the unripe capsules of the white poppy (*Papaver somniferum*) is a useful remedy in medicine. Crude opium contains a number of alkaloids, of which morphine, which may be present to the extent of 12 p.c., is the most important. Opium acts as an anodyne and narcotic almost entirely in virtue of the morphine it contains. It is used in various forms to relieve pain, and in the treatment of insomnia, but should never be given except under medical supervision. It is definitely dangerous to young children.

The best antidote in poisoning by opium is permanganate of potassium, enough dissolved in half a glass of water to make a deep red solution. After this hot, strong coffee should be given freely, and the patient must at all costs be kept awake.

In 1925 an international convention was signed at Geneva. This provided for the establishment of a board of control to suppress the illicit traffic in drugs derived from opium. This was followed by another Geneva convention in 1931 which resulted in the passing of the Dangerous Drugs Act, 1932.

OPIUM POPPY. This is a very showy and easily grown hardy annual (*Papaver somniferum*), of which there are many brilliantly coloured varieties, e.g. The Mikado, Cardinal, White Swan, and Carnation-flowered. The plants grow 18-24 in. high, and have greyish leaves. Seeds are sown out of doors in March-April where the plants are to bloom in summer. The opium of commerce is obtained from *Papaver somniferum*.

Opium Poppy. Showy blooms of this hardy annual.

OPOSSUM: The Skin. There are two varieties of opossum, one of a delicate bluish-grey colour and the other a hard, wiry fur of a brownish shade, known as American opossum. Both kinds are used for trimming purposes, especially on winter coats of velour cloth. See Fur.

OPTICAL LANTERNS IN THE HOME

The Nature and Use of Projection Apparatus

The reader is referred from this article to those on Lantern Slide and Lens, where related information will be found. See also Enlarging.

The optical lantern is generally understood to be a modern form of magic lantern, taking the standard 3¼ in. square slides and having an improved optical system with an efficient and powerful source of illumination. The lantern most frequently consists of a well-ventilated box of wood or metal in which is an illuminant with a reflector behind it. Opposite the light is a condenser, which is an arrangement of one or more large lenses. Its purpose is to collect the light rays and throw them through a lantern slide placed on the other side of the condenser. The picture is thus cast into the front lens, usually called an objective, which focusses the picture and throws it in a highly magnified form upon a screen.

For home work the common form of japanned tin or Russian iron lantern, burning oil, has been very popular, but acetylene, spirit, electric and other illuminants have displaced the oil lamp. Many of the modern electric lanterns are specially suitable for the home, because of the possibility of connecting them to the ordinary house supply. High power metal filament lamps are used. Most

lanterns are made to take any form of illuminant that may be convenient. The actual lantern remains the same, but the chimney and internal arrangements will depend upon the kind of light used.

Bi-unial (double) and tri-unial (triple) lanterns are used for dissolving views. A lantern-slide picture is projected in the usual way by one of the lanterns upon the screen; the second picture is then shown over the first one upon the screen, when the first one is made to fade out, usually by lowering the light. In this way day scenes are made to dissolve into night scenes and summer scenes into winter scenes.

The Optical System. Standard lanterns have condensers measuring 4 in. to 4½ in. in diameter. The circular condenser must be at least 4 in. in diameter to illuminate the standard 3¼ in. square slide. The condenser consists usually of two lenses, called a plano-convex compound, mounted in a cell with the flat surfaces outward. A condenser should never be suddenly heated or allowed to cool too rapidly, because of the danger of cracking. The lenses should fit loosely in the cell, and the latter should be provided with suitable holes for ventilation. The heat generated during a show causes the glass to expand slightly, and if this expansion is not allowed for the glasses will crack.

Various parts of the optical system. A, illuminant; B, condenser; C, slide stage; D, objective.

Optical Lantern. Electric projection lantern for lecture hall or classroom, adapted for lenses of 8 to 18 in. focus. (Courtesy of Ensign, Ltd.)

The objective is often a lens of the Petzval type, like a photographic portrait lens; it is generally about 2 in. in diameter and from 5½ in. to 6 in. in focus. Upon the focus of the lens depends the size of the picture upon the screen; or, in other words, the distance of the lantern from the screen.

The 5½ or 6 in. focus lens commonly supplied with lanterns for use at home gives, approximately, a 5 ft. picture 10 ft. from the screen, a 6 ft. picture at 12 ft., a 7 ft. picture at 14 ft., and so on, the picture being half as high as the distance measures. For large halls, objectives of longer focus are used. Thus with an objective of 12 in. focus the lanternist would get, using the same lantern and condenser, a 2½ ft. picture at 10 ft., and 3 ft. picture at 12 ft. Put in another way, if the lantern is 12 ft. from the screen, then a 4 in. objective would give a 9 ft. picture, a 5 in. one of 7 ft., a 7 in. one of 5 ft., and an 8 in. a picture of 4½ ft.

The size of picture obtainable depends upon the quality of the light employed. With an oil lantern it is rarely possible to enlarge the 3¼ in. slide to more than 5 ft. and get at the same time a brilliant

picture. It is better to have, say, a 4 ft. bright picture than a dull one of 6 ft. in diameter. With incandescent gas or acetylene good 6 ft. pictures are possible if the illuminants work well, while with the electric gas-filled lamps 8 ft. can easily be obtained.

Aldis Epidiascope for projecting opaque and solid objects, shown in part section. This apparatus gives a circular projection of up to 12 ft. 2 in. diameter.

Optical Lantern: action of condenser lens. R, source of light; A and B, normal path of light ray, if no condenser is used; L, objective lens on which the light rays are made to converge by the condenser lens, C; S, slide.

The Screen. The screen upon which the pictures are shown deserves more attention than is usually given to it. If the best results are wanted, it is not enough to hang up an ordinary white linen or calico sheet and project the picture upon it. A lantern sheet or screen should be quite white and absolutely opaque. Opaqueness is necessary to keep the light and the picture upon the surface, and so reflect rather than absorb it. When an ordinary sheet is used much of the light cast upon it goes through and is lost, the picture suffering from lack of brilliancy and clearness of outline.

The best screen on which to show lantern pictures, small and large, is a whitewashed or distempered plaster wall, which absorbs no light; for the same reason white cardboard is also excellent. Opaque screens of a size large enough for home work are to be had from the makers of lanterns and accessories.

The aluminium lantern illustrated is one of a class developed in recent years. It has a superior lens system, and the illuminant is a 500-watt electric lamp which can be connected to the house lighting circuit. The back of the globe is silvered to act as a reflector. The bellows extension permits the use of lenses having a focus of 8 in. to 18 in., giving a distance from the screen of 20 ft. to 75 ft., according to the lens employed. This model is particularly suitable for lecture halls or classrooms, but a smaller one, designed on similar principles, is available for home entertainment.

Projection of Opaque Objects. At lectures, demonstrations, etc., it is often necessary to show an enlarged image of an opaque object, such as a picture, diagram, or page of letter-press from a book. An optical lantern for projecting on to a screen the image of an opaque object is known as an episcopes. Such an apparatus is generally, however, designed to show transparent slides also, when it is termed an epidiascope. The opaque object is placed on a platform beneath the apparatus, and is illuminated by one or more powerful electric lamps. The light rays reflected upward from the object are passed through a lens system and projected on to a screen. We illustrate a type of epidiascope in which one objective is used for the dual purpose, the movement of a lever converting it from episcopic projection to lantern slide use, and vice versa.

OPTICIAN. A person who makes or sells spectacles or other optical instruments is called an optician. A doctor who specializes in disorders of the eye is an oculist, and his work deals very largely with errors of refraction, for which glasses have to be prescribed. Many opticians also test vision and prescribe glasses where these are necessary.

People who have little knowledge of optical work, and who are in no sense opticians, frequently undertake to supply glasses, which may be either unnecessary or actually harmful. The bona-fide optician is skilled in making up and fitting glasses; he is depended on to supply lenses of the precise kind and strength required. He also may have skill in sighttesting, and amongst opticians there are many who have qualified for a diploma in the subject. See Eye; Sight Testing.

OPUNTIA. The cactaceous plant called opuntia includes the Indian fig, prickly pear. Barbary fig, and other natives of Central America. Most of them need ordinary treatment in the greenhouse in rich loam, with a liberal admixture of lime or old mortar; they must be watered sparingly in winter. The hardy species need similar soil in a sunny, sheltered situation in the garden. Propagation is by seeds or cuttings. Among the hardy kinds are monacantha and raffinesque. See Indian Fig; Prickly Pear.

ORANGES AND ORANGE DISHES

A Popular and Health-giving Fruit in Appetizing Forms

Marmalade is one of the entries in our work to which reference should be made; others are Candied Peel; Crystallized Fruit. See also Diet; Fruit; Icing; Jelly; Tangerine.

The orange is an evergreen flowering shrub belonging to the Citrus family, which embraces the lemon, tangerine, grape-fruit, and citron, as well as the Seville or marmalade orange. Oranges may be grown from pips planted in pots in loamy soil. The temperature of a cool greenhouse is all that is necessary, and the pots or tubs may be stood out of doors on verandas or in porches during the

summer months. The small Otaheite orange is the best fruiting variety for amateurs. Seedling plants are slow in reaching the fruiting stage.

Orange. Leaves and ripe fruit of a variety of orange known as the Otaheite.

Chief Varieties. Of the two main varieties of this fruit, sweet oranges are used for eating and dessert purposes, while the bitter sorts are employed chiefly in making marmalade. There are a large number of varieties of the sweet orange, each having its characteristics. The fruit which comes from St. Michael in the Azores has a specially choice flavour and is juicy and seedless. Majorca also produces seedless oranges, while Malta is celebrated for its

blood oranges, the pulp being of a dark crimson colour and very sweet and juicy. The Lisbon variety has a thick rind like that of Jaffa, while the China orange is thin, and the juice very abundant. The rind of the Mandarin is thick, heavy, and loosely attached to the pulp, the fruit being of excellent flavour. Tangerines are amongst the smallest of oranges, being flat in shape and possessing an aromatic flavour.

Sweet oranges are imported from Alicante and other parts of Spain, but the most important variety from this country is the Seville orange, which is extremely bitter in taste, and dark coloured with a rough skin. Sweet oranges of good size and excellent quality, both seedless and other kinds, are grown in Australia and South Africa, and are on sale in most towns in Great Britain. One of the largest varieties is the American navel orange, so called from a characteristic formation on the top of the fruit, which is oval in shape. This variety of orange is also grown in South Africa.

Amongst the many uses of the orange, the fruit may be preserved in sugar as a sweetmeat. The peel of the bitter orange is candied and is much employed in confectionery. In an early stage the small green fruit, no larger than berries, is used in the manufacture of the liqueur known as curaçao. The bergamot perfume is distilled from the rind of Italian oranges, and a liqueur named rosoglio is also made in some parts of Italy from oranges. An essential oil is obtained from the rind of both sweet and bitter oranges, and is sold by most perfume dealers.

Medicinal Value. Both sweet and bitter oranges are used in medicine, but chiefly the latter, which are of great value in the sick room. Only the juice, however, should be given to invalids or young children, as the pulp is very difficult to digest. Squeeze the orange juice into a glass and give in that way. A teaspoonful of orange juice should be given once or twice a day to hand-fed babies to prevent scurvy, for which it is also a remedy.

For a patient who is thirsty, a welcome drink can be made by pouring over the thinly cut peel of an orange a pint of nearly boiling water. Add 4 tablespoonfuls loaf sugar, and let it stand for an hour; then put to it the juice of 3 oranges, and strain. Serve quite cold.

An excellent tonic for promoting appetite and aiding digestion can be made by taking 2 oz. dried orange peel, the fresh rind of 2 lemons, and pouring over them 1 pint boiling water. Let it stand for an hour, then strain. Take $\frac{1}{2}$ wineglassful twice a day, half an hour before luncheon and before dinner.

From the flowers of the orange a water is distilled which has a beautiful perfume. Besides this, other preparations of orange used in medicine are the tincture and the syrup, the dose of each being $\frac{1}{2}$ to 1 dram; these both act as flavouring agents, and the tincture also as a tonic and appetizer.

Uses in Cookery. Oranges are a very useful cookery ingredient and can be employed in a variety of dishes, such as pies, tartlets, creams, jellies, cheese cakes, cakes, and salads. The flavour is delicious in icings and sweet fillings, and the juice is in some cases added to rich, made gravies.

Orange Basket. The sweet known by this name is made by cutting 2 or 3 ripe oranges into halves, scooping out the pulp and mashing it up in cold water, making about $\frac{1}{2}$ pint liquor in all. Add sugar to taste, and after letting the liquor stand for a couple of hours, strain it through muslin.

Add $\frac{1}{4}$ oz. isinglass and just warm the whole over the fire until the former melts. Colour it pale pink with a little cochineal, and then pour it into the halved orange skins, leaving these in a cool place to set. When the jelly is firm, handles to complete the basket-like effect can be made from thin strips of angelica, bent over.

Orange Baskets, a novel method of serving jelly made from the fruit.

Orange Biscuit. Boil 6 Seville oranges in 2 or 3 waters till the bitterness has almost disappeared. Cut them in quarters and remove all the inside. Beat the peel very fine in a mortar then weigh

the pulp thus obtained. Add an equal weight of castor sugar and work both to a firm paste. Spread it smoothly on a dish or tin, set it in a cool oven to dry, and when dried sufficiently to shape cut it into fingers. Dry these again, turn them upside down, and return them to the oven so that all moisture may be absorbed. Store them in tins. These biscuits should be about $\frac{1}{8}$ in. thick, and are useful as wafers to serve with ice cream.

A spongy biscuit can be prepared by beating 2 eggs with 4 oz. castor sugar until thick and quite light. Mix in the grated rind of an orange with 1 teaspoonful orange flower water. Sift 4 oz. flour with a pinch of salt and fold it into the sponge. Bake it in little paper cases, and when almost cooked dredge it with sugar. Finish baking afterwards. These biscuits are sometimes iced, and in that case the icing should be mixed with some of the orange-juice.

Orange Cake. A sandwich cake flavoured with orange can be made by beating $\frac{1}{2}$ teacupful butter or margarine and 2 teacupfuls sugar to a cream, adding separately 2 eggs, and then beating the mixture well. Pour in $\frac{1}{2}$ teacupful milk, then add 1 lb. sieved flour, grated rind of the orange, and 1 teaspoonful baking-powder, and continue beating. Line a tin with greased paper, put in the mixture, and bake it until it is firm and lightly browned. When cold, split it into two and spread the sides with a gill or more of whipped and sweetened cream, flavoured with orange essence.

Another cake filling is made by mixing the strained juice of 2 or 3 oranges with $\frac{1}{4}$ lb. castor sugar, gradually adding to them the grated rinds, 2 tablespoonfuls cornflour and a gill of water. Mix all to a smooth paste, then stir in 1 oz. melted butter and stand the basin over a saucepan of hot water. Stir its contents over the fire until they become creamy and taste cooked; then leave them to cool. When cold, stir in the whites of 2 eggs and spread the filling over the cut sides of the cake, afterwards putting the latter together again. If it has risen too much in the centre, level it with a knife before icing.

Orange Cream. To make this sweet, cut 2 oranges into halves and remove the pulp carefully, so as not to split the rinds. Extract the pips, rub the pulp through a fine sieve and mix with it 3 dessertspoonfuls castor sugar. Whip a gill of cream until it thickens, add half of it to the orange pulp

and sugar and fold in also the stiffly whisked white of an egg. Dissolve $\frac{1}{4}$ oz. leaf gelatine in $\frac{1}{2}$ gill water, strain it into the other ingredients and mix all thoroughly. Half-fill each orange-case with the mixture, and when the latter is set, decorate the top with the remainder of the cream and a few pieces of angelica on top.

Orange Cream, halved orange skins filled with a cream mixture and decorated with angelica.

Orange Fool. Peel and then mash 3 or 4 large oranges to a pulp, rub the latter through a sieve to rid it of pips, and then mix it with 1 pint custard. Let the mixture stand in a cool place so that it may thicken, then put it into custard glasses and pile a little whipped cream on top of each. If preferred, $\frac{1}{2}$ pint cream may be substituted for the custard.

Orange Fritters. These are made by peeling some oranges, breaking them into quarters, removing the white skin, and then sprinkling them with castor sugar. Leave them thus for about 15 min., then drain and coat them with frying batter. Have ready a pan of smoking hot fat, put in the slices of orange, and fry them till they are a golden brown. Drain them from the fat, dredge them with some more castor sugar, and serve at once. Allow half an orange for each person.

Orange Pudding. A small orange pudding can be made by mixing together $1\frac{1}{2}$ oz. castor sugar and the grated rind of an orange and putting them into a basin with 2 oz. finely chopped suet, the same quantity of breadcrumbs, 1 oz. rice flour, $\frac{1}{2}$ teaspoonful baking-powder, and a good pinch of salt. Into the centre of these ingredients strain the juice of half an orange and a well-beaten egg, mixing all well and adding a little milk if necessary. Turn the mixture into a greased basin or mould, cover it with a piece of greased paper, and steam it for two hours or more. This pudding should be served with orange sauce.

A baked orange pudding can be made by peeling 6 oranges, breaking them into small sections and after removing the seeds, putting them into a pudding dish. Sprinkle over them $\frac{1}{2}$ lb. castor sugar, and leave them to soak therein while preparing the following mixture: Stir together a tablespoonful of cornflour and a little cold milk, and when they are smoothly mixed add them, together with a well-beaten egg, to a pint of milk that has not quite reached boiling point. Stir the whole until it thickens, then pour it over the fruit and on top spread the stiffly beaten whites of two eggs. Bake the pudding until it is firm and lightly browned.

Orange Sauce. This sauce is made by warming the strained juice of half an orange, together with the rind and 2 oz. sugar, in a small pan near the fire. When the sugar has melted, add a teaspoonful of cornflour mixed smoothly with a small teacupful of water. Stir the sauce until it boils; then simmer it for a few minutes to cook the cornflour before serving.

Orange Syrup. When orange flavouring is required this syrup may be used with excellent results. To make it, squeeze the juice from 12 oranges, strain it, and then boil it up in a saucepan with $\frac{3}{4}$ lb. lump sugar. When it thickens, skim and bottle it.

Orange Tart. To make this, rub the grated rind of 2 oranges with 2 heaped tablespoonfuls sugar and then cream these with 2 oz. butter. Add to them the yolks of 2 eggs, 2 oz. finely crushed biscuit, and

the strained juice of the fruit. Then beat the whites of eggs to a stiff froth, stir them in, and pour the mixture into a tart tin lined with puff pastry (see Pastry). Bake the tart in a fairly hot oven until the pastry is lightly browned and the mixture set. Just before serving, sprinkle the surface of the tart with castor sugar.

ORANGEADE. To make orangeade, pare the rinds of 3 ordinary and 1 Seville orange and put them into a jug; pour on them 1 pint boiling water and let them steep, covered up, for 6 hours. Make a syrup with $\frac{1}{2}$ lb sugar and $1\frac{1}{2}$ pints water, and add it to the steeped rinds, together with the juice of the oranges from which the rinds have been taken, and the juice of 3 additional oranges. Stir the whole well and when cool strain it through muslin. The juice of a lemon may replace that of one orange.

ORANGE BALL TREE. This is the popular name of a handsome hardy flowering shrub (*Buddleia globosa*). It thrives in ordinary soil, reaches a height of 8-10 ft., and bears round heads of yellow flowers in summer. Any required pruning to keep the bush shapely should be done after flowering. Propagation is by cuttings in a frame in August. *Buddleia variabilis* and its finer varieties *veitchiana* and *magnifica* bear racemes of mauve flowers, which attract the butterflies and bees, in July and August. They must be hard pruned in spring.

Orange-ball Tree. Evergreen shrub with globular yellow flowers which will brighten a dull garden.

ORANGE BITTERS. An excellent recipe for orange bitters is the following: Take 1 oz. Seville orange peel, $\frac{1}{2}$ oz. gentian root, $\frac{1}{4}$ oz. cardamoms. Husk the cardamoms and crush them with the gentian root. Place the whole in a wide-mouthed bottle and cover it with brandy or whisky. Allow the mixture to remain for 12 days, then strain it and bottle it off for use, adding 1 oz. lavender drops.

ORANGE BRANDY. March is the best time to make orange brandy. Place in a stone jar the rinds of 6 oranges cut thin and add $\frac{1}{2}$ pint orange juice strained, and $\frac{1}{2}$ gallon good brandy. After 3 days add about 1 lb. loaf sugar, stir till the sugar is dissolved, and let the liquid stand for a day. Then strain it, pour it into bottles and cork it tightly. It improves with age. *See Brandy.*

ORANGE LILY. This is the common name of *Lilium croceum*, a hardy lily, which bears brilliant orange-coloured blooms in summer on stems 2-3 ft. high. It thrives in ordinary soil; the bulbs should be planted 3 in. deep in the autumn.

ORANGE LIQUEUR. This drink is made by peeling 2 Seville oranges and 2 small lemons, putting the peel into a jar with $1\frac{1}{2}$ pt. whisky and 7 oz. lump sugar, corking it down tightly and leaving it for 5 or 6 days. Keep it well shaken daily, then strain it through muslin, or a very fine strainer, and bottle it for use. *See Liqueur.*

ORANGE WINE. In making this wine 8 large Seville oranges should be allowed to each gallon of cold water. Put 4 of these into the water with the peel on; pare the other four, cut them into halves and then add them to those in the water, saving the peel for other purposes. Leave the whole for 10 days, stirring it two or three times daily; then strain it through a hair sieve and add 4 lb. lump sugar to every gallon of liquor. When the sugar has dissolved the wine may be put into a cask. Bung it loosely for three or four days, then tighten the bung and after six months bottle for use.

ORANGES AND LEMONS. This is one of the old singing games, and is still much in vogue for small children. Two people join hands, making an arch beneath which the others have to pass. As height is important it is better for adults to take this part. The children then form into a chain, each child with his hands on the shoulders of the one in front of him, and pass under the arch formed by the two adults. Meanwhile all sing the following rhyme:

Oranges and lemons, say the bells of St. Clement's;
 You owe me five farthings, say the bells of St. Martin's.
 When will you pay me? say the bells of Old Bailey.
 When I grow rich, say the bells of Shoreditch.
 When will that be ? say the bells of Stepney.
 I do not know, says the great bell of Bow.
 Here comes a candle to light you to bed,
 And here comes a chopper to chop off your head.

When the last couplet is reached the two adults drop their hands over one of the chain, imprisoning him. He is then asked whether he prefers oranges or lemons, and having made his choice in a whisper, he is put behind the person representing that fruit, a matter which has been settled by the two before the commencement of the game. When all the players have been captured in this fashion and are ranged behind one or other of the adults, the game ends in a tug-of-war between the two parties, the first couple still holding hands. *See Children's Party.*

ORCHARD. The best spot for an orchard or fruit garden is one that is sheltered from north and east winds, as far as possible, and has a southern or south-western aspect. Loamy soil is best, but other kinds can be made suitable by cultivation. A gentle slope is better than a dead level ground, on account of drainage.

Young standard trees may be planted in pasture land in which to form an orchard, and in that case they should be put in about 30 ft. apart every way. Such land may be used for sheep, but in the home garden orchard the usual plan is to economise space by planting bush fruits, strawberries, etc., between the large fruits. When an orchard is first planted the young trees should be staked until they are thoroughly established, and the soil round the trees must be kept clear of grass.

The grass should always be kept closely grazed, preferably by turning sheep into it, and must never be allowed to get so long and rank that it has to be cut with a scythe or mower. *See Apple; Cherry; Fruit; Pruning; Strawberry, etc.*

ORCHARD HOUSE. A heated greenhouse used almost entirely for the culture of fruit is known as an orchard house. It may be either lean-to or span in structure. *See Apricot; Grape; Greenhouse; Nectarine; Peach; Pineapple, etc.*

Odontoglossum Henry VII

ORCHIDS: POSSIBLE VARIETIES FOR THE AMATEUR

General instructions for the choice and culture of orchids in an amateur's greenhouse are given under the heading *Orchids*. (Courtesy of Charlesworth & Co., Ltd., Hayward's Heath)

ORCHIDS: VARIETIES AND THEIR CULTIVATION

Beautiful Flowers that the Amateur Gardener can Grow

This article is a companion to those on Daffodil; Iris; Lily; Rose and others throughout our work.

See also Greenhouse and the entries on the various orchids, e.g. Cattleya; Miltonia.

Orchids are rightly regarded as the most fascinating of all flowering plants grown under glass; there are many genera or groups, innumerable species, and an untold number of varieties and hybrids. Orchid growers raise new hybrids or crossbreeds annually, and these now form the bulk of the orchids grown by those who specialise in these flowers.

Epiphytal Orchids. 1. Wood basket for drooping species. 2. Another type of hanging basket. 3. Plant grown upon sphagnum covered bark. 4. How to pot erect-growing kinds: a, crocks and charcoal; b, peat and sphagnum; c, sphagnum moss.

For the purposes of cultivation orchids are grouped in three classes according to the temperature of the glasshouse suited to their needs. Some must be grown in a hothouse having a minimum winter temperature of 65-70 degrees. Others are suited to what is called the intermediate house, with a minimum winter temperature of 60 degrees, and cool house orchids will thrive in a greenhouse in which the temperature does not fall below 45-50 degrees in winter. Orchids suitable for the greenhouse are odontoglossum, Ada aurantiaca, odontioda, lycaste, cypripedium, and masdevallia. Those which should be grown in the intermediate house are cymbidium, cattleya, laelia, epidendrum, oncidium, miltonia, so phronitis, coelogyne and dendrobium. Orchids which need the conditions of a hothouse are vanda, aerides, phalaenopsis and calanthes.

Some of the chief kinds suitable for cultivation by amateurs are dealt with in the following notes. For particulars of species and the countless beautiful hybrids now available the catalogues of orchid growers should be consulted.

Some Examples. A charming orchid suitable for the cool house is the orange scarlet *Ada aurantiaca*. Repotting is necessary when new growths are about 3 in. long, a suitable compost being fibre, oak leaves, and sphagnum moss.

Cattleya is an orchid of exquisite shape and delicate colours, containing species excellent for the warm and intermediate houses. Pot culture is necessary, in a compost of fibre, peat, and sphagnum moss, plants being repotted every 2 years with removal of all decayed or dead roots and bulbs. Each plant should be dealt with as soon as new growth has reached about 3 in., using fresh small pots in scrupulously clean condition.

The free flowering *Coelogyne cristata* has blossoms of white and a yellow lip. Being very shallow rooting, it is best grown in an orchid pan in the intermediate house. When repanning becomes necessary, an operation not often required, a compost of peat and sphagnum moss should be employed. Large plants are to be encouraged if free flowering is required.

Orchid: some greenhouse varieties. Top, left to right: Laelio-cattleya St George, Coelogyne cristata, and Oncidium papilio. Bottom. Odontoglossum crispum, and Cypripedium Germaine opoix.

Cymbidium is a magnificent orchid for amateurs, suitable for the intermediate or even the cool house. Plants should be repotted very firmly in a mixture of loam, leaf-mould, peat, and sand, damping it well, and placing upon plenty of well-cleansed crocks.

Cypripedium is an extensive genus containing many species and hybrids. It is a bulbless kind, producing leafy growths, and bearing, as a general rule, large, handsome blooms, popularly known as lady's slippers, on stiff, erect spikes. These orchids bloom successfully in turfy peat and a little loam, sweetened with charcoal.

Some of the beautiful genus Dendrobium are suitable for amateur cultivation, either in cool or warm house, the following being recommended: Falconeri, Jamesianum, which are cool house kinds; nobile and thyrsiflorum, for warm house cultivation. Suitable compost is turfy peat and sphagnum moss.

Disa grandiflora, commonly called the flower should of the gods, bears blossoms of bright scarlet with light markings during October. It requires special cultivation. From spring until autumn the compost must be kept in a state of even sponginess, but without excess of moisture; during winter the plants are best in a light position at the coolest end of the house. From April to September the plants may be placed in shady frames out of doors. A suitable compost consists of equal parts of peat and living sphagnum moss, with a little sand. Pots or pans must be perfectly clean and well drained.

Epidendrum vitellinum majus is the name of an orchid bearing orange-scarlet flowers on erect spikes, with summer and autumn flowering forms. It may be grown in pots, pans, or baskets, $\frac{2}{3}$ full of clean crocks, topped with a compost of 2 parts fibrous peat, some sphagnum moss, and silver sand $\frac{1}{4}$ of the whole.

All dead and decayed roots, leaves, or bulbs should be removed before repotting, and the plants kept on the dry side during winter to prevent spotting of leaves.

The genus Laelia contains some beautiful species. Kinds recommended are anceps, autumnalis and praestans. Laelias have been crossed with Cattleyas, and the hybrids known as Laelio-cattleyas are vigorous and free flowering. A fine example of the many hybrids is known as St. George. Flowers are all very widely varied in this section, spikes producing 2, 3, and sometimes 4 and 5 on a spike. No class of orchid is more suitable for a house where a minimum temperature of 50° can be maintained. A winter-flowering orchid that does well in a cool house is Lycaste Skinneri.

Orchid: three hardy kinds. Left to right: Bee orchid, a small orchid for the rock garden; Madeira orchid, a plant needing a damp situation: and Calypso borealis, bearing purple, white-lipped flowers.

moss in equal parts, with a surface layer of the latter. Repotting every second year is beneficial.

Masdevallia ignea produces large bright scarlet blossoms during the summer months. This orchid is suitable for the intermediate house.

Miltonia exhibits great variety of colour, from purest white to a lovely shade of rose. Vexillaria will grow in a warm, mixed greenhouse if placed in a light position at its warmest end. It is best cultivated in a pot containing 3 parts of clean crocks, then a compost of fibrous peat, chopped sphagnum moss, and charcoal, with a surface of sphagnum.

The various hybrids of odontioda combine the bright red colourings of Cochlioda with the varied shades of odontoglossum. They should be grown in a cool greenhouse. A compost of osmunda fibre

and fresh sphagnum moss in equal portions is employed, together with a little decayed oak leaves; the whole is made damp and placed in a perfectly clean pot containing 2 parts of clean crocks.

Odontoglossum is an extremely beautiful genus of orchids which contains many gems for the cool house, bearing sprays or branching spikes of blossoms, each varying from 5 to about 40 in number. The colour is infinitely varied, ranging through transparent white, chocolate, violet-purple, claret, yellow, lilac, and chestnut, with spottings and markings in perfect harmony. Two of the most popular species are *crispum* and *grande*, but there are many others.

Abundant air is essential, with nicely diffused sunlight whenever available. When in full growth, and while flowering, water must be copious and free; but after flowering only sufficient moisture should be allowed to prevent the soil becoming dry. Broadly, the plants require a long resting period, covering a couple of months. Suitable compost contains 2 parts fibrous peat and $\frac{1}{2}$ a portion each of sphagnum moss and charcoal, top-dressed with a layer of fresh moss. It is important to note that regular damping-down must be maintained during summer to keep the atmosphere uniformly moist.

The choice greenhouse variety *Oncidium papilio* is illustrated here. *Crispum*, *concolor*, *flexuosum*, *Marshallianum*, *tigrinum* and *varicosum Rogersii* may be selected. The compost is composed of oak leaves and polypodium fibre. Flower spikes must be removed directly they begin to fade.

Pests and diseases will not give great trouble amongst orchids if house and plants are kept thoroughly clean. New plants should always be thoroughly inspected for parasites before placing them with general stock; and where insects appear thorough cleansing with insecticide is the rule. The plants may be steeped in warm solution, provided this is done very carefully. Common pests are slugs, green-fly, thrips, mealy bug, wood-lice, cockroaches, and red-spider.

Wild Orchids. There are some beautiful flowers among the hardy orchids, some of which grow wild in Britain. They are most likely to flourish if planted in the rock garden in slight shade in a compost of loam, peat, and sand.

The bee orchis (*ophrys apifera*), spider orchis (*ophrys aranifera*) and fly orchis (*ophrys muscifera*) need chalky, loamy soil. Other beautiful hardy orchids are the Madeira orchid (*orchis foliosa*), purplish, 19-24 in.; the Marsh orchid (*orchis latifolia*), purplish, 12-15 in.; the spotted orchid (*orchis maculata*) 8-10 in., with spotted leaves and rose purple flowers; lady's slipper (*cypripedium spectabile*), 18 in., white and rose; butterfly orchid (*habenaria bifolia*), 12 in., white; *epipactis latifolia*, 12-18 in., greenish purple; and *blettia hyacinthina*, 12 in., purple.

ORCHIS. This is the name of a genus of hardy orchids. Some of them grow wild in Great Britain. A description of the different species will be found in the article on orchid above.

ORGANDIE. The thin, semi-transparent material known as organdie is used for summer dresses, women's collars and cuffs, for glass curtains, and for night wear cases and handkerchief sachets. It can be obtained in colours, and its chief virtue lies in the stiffness which prevents it from creasing so easily as most of the other cotton summer fabrics. To achieve the best effect, coloured organdie, when used for non-transparent articles, needs a foundation of the same shade, while collars of this material need to be tacked in position, otherwise their stiffness will not allow them to lie neatly over the dress. *See Starch.*

ORIEL: The Window. This term is used to describe a particular form of window, the characteristics of which are that it is overhanging, or projecting, divided into different bays, and located upon an upper floor. It is also used to describe a recess within a room. *See Window.*

Oriental Poppy. This vigorous hardy perennial (*Papaver orientale*) bears large showy flowers in May and June. *See* Poppy.

ORIGANUM. This is the botanical name of a group of low-growing herbs. The most familiar is the marjoram (*Origanum vulgare*), which is raised from seeds sown out of doors in spring. *Origanum dictamnus*, called pink hops and dittany, is a pretty little pot plant with bunches of pink hop-like flowers: it can be increased by cuttings of the young shoots. *See* Marjoram.

ORLOFF: The Fowl. This breed of Russian fowl possesses what is known as a raspberry comb with small feathers growing between the little rounded nodules. This distinguishes it above all other breeds in Great Britain. The Orloff is bred in five colours, mahogany, spangled, black, white, and blue. It is a muffed breed and also bearded, but it is a good laying breed and a non-sitter. Eggs average 7 or 8 to the lb. Adult cocks weigh 8 lb. to 10 lb. and hens 6 lb. to 8 lb. They do well either kept semi-intensively or on free range.

The mahogany variety are the most handsome; next to them come the spangles. The mahogany chicks are like Rhode Island red chicks. The spangles vary, being either buff or buff with a brown stripe down the back, and sometimes almost white. Chicks of the other varieties follow their colour. *See* Chicken; Fowl; Poultry.

ORMOLU. From the time of Louis XIV to the First Empire, French cabinet makers employed for the enrichment of their productions bronze mountings, which were cast, chased, and gilded. Similar metalwork was used for the mounting of porcelain and stone vases, and for the fabrication of clock cases, wall brackets, mirror frames, and the like.

Ormolu. Oblong table with rounded ends, three drawers and fluted legs, mounted with chased ormolu. French: period of Louis XVI. (By permission of the Director, Victoria & Albert Museum, S. Kensington)

The castings at their best were exquisitely chiselled, and finished with a mixture of gold and mercury, sometimes tinted, such as the greenish ormolu of Gouthière and other masters. Similar mountings were used by some English makers, but very sparingly; Adam is said to have employed French and Italian artists for the purpose. The plain brasswork, gilded or ungilded, to be seen on the door fittings of 18th-century English furniture is not ormolu, which is essentially chased and gilded bronze.

The metal mounts used on modern reproductions of old furniture, although often styled ormolu, are usually finished by more or less superficial methods of electro-gilding, by cheap spirit lacquer, or by the water-gilding employed by French makers for current styles of ormolu clocks and the like. Copies made by the galvanic battery can be detected by the granulated surface on the back. The modern alloys contain much zinc, with a thin gold or lacquer wash, and readily lose their brilliance, especially when exposed to gas fumes. The imitation mounts may be made to appear old by chemical means. Good reproductions exist, but are costly to make.

Collectors seldom meet with old mountings in a detached form, because anything of the kind worth having can generally be turned to better advantage on faked furniture. Sometimes the metal handles of broken vases, lion masks, inkstands, and other ornamental pieces may be acquired as examples

of French chiselling. They should be examined with caution, and accepted only if they possess some artistic merit of their own. Old ormolu should never be cleaned with metal pastes nor touched up with gold varnish, but should be treated carefully with dry leathers. *See* Directoire Style; Louis Style; Marquetry.

ORNAMENTAL GRASS. Many beautiful annual grasses are suitable for association with cut flowers in summer or for winter decoration, and for growing in pots. Seeds are sown out of doors in March-April where the plants are to bloom. The right time to gather these grasses is just before the blooms are fully open. After cutting they should be exposed to the sun until thoroughly dry.

The following are particularly recommended: hare's tail, love grass, Job's tears, animated oat, quaking grass, squirrel-tail, feather, cloud, golden spiked, and three-horned grass. *See* Flower Garden; Garden; Grass.

ORNITHOGALUM. This group of hardy and greenhouse bulbs contains several valuable garden flowers. The commonest is the Star of Bethlehem (umbellatum), which bears star-like greenish-white flowers in spring and will thrive in shady places out of doors. Other hardy kinds are pyramidale and arabicum, both with white flowers, and nutans, greenish-grey: they grow from 12-18 inches high. The bulbs should be planted in September and October. Arabicum and lacteum are often grown in pots in the cool greenhouse.

ORPINGTON DUCK. Although smaller than the Aylesbury, the buff Orpington duck is hardly inferior to it as a table bird, and it is a prolific layer. Its general characteristics are a good carriage and an aspect of alertness. The drakes attain a weight of from 7 lb. to 9 lb., and the ducks from 6 lb. to 8 lb. There is an offshoot from this breed known as the blue Orpington, which lays large eggs and is a good table bird. Blue Orpingtons are of active habit and mate without the aid of pond or stream. *See* Duck.

ORPINGTON FOWL. This breed has a reputation as a layer of fair-sized tinted eggs and as a table bird. There are varieties in several colours, the buff being the most largely kept. They are very hardy and do well under any conditions, and as sitters and mothers they are unequalled. When fully matured the male birds should weigh between 9 lb. and 10 lb., and the hens between 7 lb. and 8 lb. No other fowl presents such a perfect combination of excellent laying and table qualities. *See* Fowl; Poultry.

Orpington, a breed of fowl unequalled for its all-round qualities.

ORRIS ROOT. The root of the iris, the blue flag of suburban gardens, is largely used in various toilet preparations under the name of orris root. Roots of the following irises lend themselves to treatment: *Iris Germanica*, *I. Florentina*, and *I. pallida*.

Because its scent resembles that of the violet, orris root is employed in the making of violet powder, and a perfume known as essence of violets is distilled from it. *See* Flag; Iris; Scent.

ORTHOCHROMATIC PLATE. In photography partially correct rendering of colours is obtained by the use of special plates or films with or without light filters. Such plates or films are said to be

orthochromatic or isochromatic. They are made more sensitive to greens and yellows than ordinary plates by being specially sensitized with eosin or erythrosin dyes, and are intended to be used with yellow light filters. In some cases a yellow dye is included in the emulsion on the plate, no separate light filter then being required.

All these plates give better renderings of greens and yellows in landscape and other objects containing colour. The undue influence of blue and ultra-violet rays seen in ordinary plates is reduced by the yellow filter or dye without serious increase in exposure. They are still, however, not sufficiently sensitive to reds and even yellows; for truly orthochromatic results panchromatic plates and films must be used. In practice the usefulness of orthochromatic plates lies in the fact that improved renderings of colours are obtained with little increase in exposure, and that the red light can still be used in the dark room if care is taken to see that the plate is exposed to it as little as possible during development. In some plates in which the filter is included as a yellow dye in the emulsion the speed of the plate is slightly increased.

Orthochromatic roll films, as well as self-screened plates, can be used without a filter, but even with these slightly better results can be obtained if a filter is used. Both with these and with the plates designed for use with filters only a pale screen, such as the Kodak K1 or the Ilford A (alpha), which increases exposure by two, should be used. Deeper filters not only increase the exposure, but tend to overcorrect and give unnatural results. In artificial light and at sunset, when there is a good deal of yellow in the light, all these plates can be used without a filter. *See Light Filter; Panchromatic.*

ORTOLAN. The small birds known as ortolans are about the size of larks and are in season in September. They are rare in England, being mostly imported from Belgium, but are considered a delicacy. Ortolans are usually dressed with savoury forcemeats and laid in cases or on croûtes of fried bread.

Cooking the Bird. To cook them make a rich liver farce, using 1 fowl's liver or a corresponding portion of calf's liver to each bird. Fry the liver with 2 or 3 rashers of fat bacon cut in dice, adding 1 tablespoonful dried sweet herbs which have been passed through a fine sieve, a little grated nutmeg, and seasoning of pepper and sauce. Pound the liver and press it through a sieve, then mix with it 2 tablespoonfuls panada or fine breadcrumbs and the yolks of two eggs— enough for 4 fowls' livers. Take 6 rounds of bread about $\frac{1}{2}$ in. thick and rather larger than the ortolan, make an incision all round the edge, leaving a narrow border, then fry these croûtes to a light brown. Take them up and scoop out a hollow in the centre, which must be lined with a portion of the farce; place in each an ortolan and spread over a small lump of butter. Bake in the oven about 15 min. When ready, glaze them and dish, pouring over and round some rich brown sauce to which has been added a glass of madeira.

These birds are sometimes fried in a small amount of salad oil with a little chopped shallot, a few chopped mushrooms, chopped truffle, chopped parsley, and a little grated nutmeg. Cook for 10 min., then add a lump of glaze, 2 or 3 tablespoonfuls brown sauce, and the juice of half a lemon. Divide the birds in cases or on croûtes, pour over them the contents of the saucepan and place them in the oven for 10 min. to brown. Then dish and serve them with rich brown gravy.

OSCILLATIONS. These are high-frequency alternating currents which flow round a circuit containing inductance and capacity, when the circuit is supplied with energy from some external source, such as a broadcast transmitter or other generator of high-frequency currents.

A wireless set may itself produce oscillations through the misuse of reaction. These oscillations if permitted to flow back into the aerial circuit may heterodyne the carrier wave of a broadcasting station and thus cause interference to nearby receivers. A condition governing the issue of a

receiving licence is that reaction must not be used in this way. When a set is oscillating the received broadcasting will be distorted, and if the tuning control is varied squeals will be heard in the loud speaker or telephones. The reaction control knob should be immediately readjusted. The oscillating state may be purposely produced for some specific reason, as in superheterodyne receivers, etc. But it may occur where not required, as in "straight" receivers, due to bad design or maladjustment. *See Alternating Current; Heterodyne; High Frequency.*

OSIERS FOR BASKET MAKING

Apparatus and Weaving Methods Fully Explained

This article may be described as a continuation of the one under the heading of Basket Making. Entries on other related handicrafts will be found throughout the work, examples being Cane; Raffia; Rush Work; Wicker Work. *See also Linen Basket.*

In Great Britain there are about 40 varieties of the osier used by the basket-maker. They are grown in the low-lying land of the river valleys. When cut the osiers are known as rods and are sold as either green, brown, buff, or white. The freshly-cut green are partially dried in stook in the field and are afterwards stacked in a shed or in the open and thatched until quite dry, losing 50 per cent, in weight. Fully matured brown rods are used for coarse basketry in making all kinds of hampers and fruit baskets. Buff rods are prepared by removing the bark from either green or brown rods after they have been boiled in water from 2 to 5 hours; they are then dried in the sun to intensify the colour.

Osier. Fig. 1. Typical rod for basket work. Fig. 2. Board for holding work and block which secures upright stakes.

White rods are prepared by removing the bark from green rods, either directly after cutting or after they have been kept during the summer stacked with the bottoms in running water.

Peeling is effected by splitting the bark by pulling the rods between a pair of upright iron rods, termed a break, and then removing the bark by hand.

A rod has 4 parts, as shown in Fig. 1: the butt A, the top B, the belly C, and the back D. All rods are sorted into lengths; the short lengths of brown are called luke, the medium lengths long small, threepenny, and middle-boro, and the long are great or rods. Buff and white rods in the small lengths are termed tack and small. Brown rods must be soaked from 2 to 7 days according to size before they can be used, buff and white rods from half to 4 hours, and allowed to mellow for several hours. The uprights or "sticks" used for bottoms are cut from osiers of 2 or 3 years' growth for large baskets. The radials in a round bottom or cover are also termed sticks.

Tools Required. The tools and apparatus used in working osiers comprise a lapboard and a screwblock (Fig. 2), the former for holding the work in progress and the latter for securing the upright stakes in square work. A shop knife (Fig. 3) is used for cutting the rods; a picking knife (Fig. 4) for trimming the short ends and bending; bodkins (Fig. 5) for preparing a path for the

insertion of rods; a maul (Fig. 6) for a hammer; a commander (Fig. 7) for straightening stout rods. Shears for cutting (Fig. 8) are required, and 3 or 4 way cleaves (Fig. 9) for splitting. A shave (Fig. 10) is employed for trimming the split rods to form skein, the latter being similar in appearance to chair cane, and used for finishing handles, etc. The worker also needs a lead weight to keep the work on the lap board, a yard measure, a piece of sponge, and a grease-horn for use with the bodkin.

Tools used in working osiers. Figs. 3 and 4. Knives for cutting and trimming. Fig. 5. Bodkin. Fig. 6. Maul. Fig. 7. Commander. Fig. 8. Shears for cutting. Fig. 9. Cleave for splitting. Fig. 10. Shave for trimming split rods to form skein.

Methods of Weaving. Single weaving (Fig. 11) between stakes is done in square work by slyp- ing (Fig. 12) or trimming the butts of upright sticks and securing them in the screwblock. The rod is slightly bent as it is carried round each stick, and when the end uprights are negotiated, the rod is gradually brought upright, passed round the stick and worked down on top of the others. Slewing, as it is usually called (Fig. 13) is a quick method of weaving, several rods being worked at the same time. It is employed for rough work, but is not so neat or strong as single or randed weaving. If, however, the rods are the same size, the weaving can be kept level. Bye-stakes are used mainly in round work, and consist of supplementary stakes inserted between the original stakes and held in place by the first rows of weaving, called the upsett.

Fitching (Fig. 14) is a method of working two rods alternately under and over each other, so as to hold a stake or bye-stake at each turn. It is useful for open work when it is not necessary to fill up the sides of a basket with weaving. It may be commenced

with either the tops or butts, and in practice the rods are worked one after the other in the order shown. Cross fitching is done with double stakes in cases where the stakes are crossed, a common method of dealing with open-sided baskets. The foot of a basket is formed by driving short stakes in the sides when the work is upside- down: the rods are laid down and worked in the same way as a border. Oval bottoms (Fig. 15) are formed by a slath (Fig. 16), and the sticks or radials separated by working a pair of rods together.

A pair of rods worked alternately over and under each other, the reverse of a fitch, is called a pair. This method is used in forming round bottoms and also in adding a second round of weaving on top of a fitch.

Picking is the operation of cutting off the projecting ends of rods which are left after the weaving is completed. The edge of the knife must be very sharp, and care must be taken at first to avoid cutting the woven rods. Sufficient material should be left to prevent the end working out past the stake. Pricking up the stakes to bring them to an upright position ready for weaving the upright sides is effected by the point of the shop knife. This operation prevents the bark or skin from breaking, but this is effective only if the rod has been properly soaked and allowed to become mellow.

Osier, Fig. 11. Single weaving. Fig. 12. Trimmed butt of upright stick. Fig. 13. Weaving with several rods at a time. Fig. 14. Rods worked alternately under

and over, enclosing a stake at each turn. Figs. 15 and 16. Oval bottom formed by a slath. Figs. 17 and 18. Scallomed work.

Scallomed Work. This method (Fig. 17) is used in making a frame for a bottom or cover and also for staking some forms of basket. It consists of making a long cut at the butt end of a rod (Fig. 18) so that the rod may be turned round the frame and held in place by the next stake. It is useful in making light round and oval baskets and all kinds of covers where lightness and strength are required. The frame to which the scallom rod is attached is called a hoop. Any kind of shape can be made. Scallomed stakes are commonly used in the light and cheap hampers made with slewed weaving. This is because they can be made in much less time.

Preparing Skein. Skein formed by the trimming of split osiers is used in covering handles and for filling up the sides of small baskets used for holding letters and for picnic, lunch, and linen baskets. The method of preparation is to take a long, straight, dry white rod and cut a few inches off the top. Suitable cuts are made at the top, either 2 or 3 according to the cleave used, and then it is pushed down towards the butt, the rod being guided with the hand in order to ensure a uniform cleavage. The split length is placed pith side uppermost on the shave. The distance between the plate and the knife edge should be carefully adjusted to take off the pith first. The length is again passed under

the knife, set a little closer to the face, and a further shaving taken off, this operation being repeated until a finely shaved and even skein is produced. It is necessary to keep the rod close to the face of the shave, and it is usual to use a leather thumb stall. The upright shave is used when even finer skeins are required. The skeins are used after dipping in water; they do not require soaking, the process being called lapping when they are wrapped round a handle.

Osier. Fig. 19. Alternative to plaiting. Fig. 20. Effective close weaving. Fig. 21. Method of working a border. Fig. 22. Strengthening stakes for a border. Figs. 23-27. Progressive stages in the making of an upright plait. Details are given in the text.

Stakes. Stakes to form the framework of a basket are generally chosen from the stouter lengths of osier. They should be straight and smooth, the hand being used to press the successive rows of weaving down on one another. In square work where the stakes are held in a screwblock, when they are termed sticks, they should be of the same size and the ends trimmed with the knife. Stakes to form the upright framework are driven in alongside bottom sticks after being slipped or pointed, room for them being provided by means of the bodkin. In the sides of square bottoms the outside

sticks in the bottom must be pierced by the bodkin and the pointed stake driven in after being dipped in water.

In driving a stake home, it should be grasped firmly in the left hand a few inches above where it enters the weaving, and the right hand should be slid down the rod on to the left. A fair amount of force should be used, especially when the stake is nearly far enough in. An odd number of stakes is necessary in slewed work, but is not required in randed work.

After the stakes have been pricked up, the tops should be gathered together and held within a hoop. In siding up or weaving, the stakes must be kept upright and parallel with each other when working straight sides, and when doing work where the sides are splayed outward or worked inward the spacing should be quite even. It is important that the rods used in siding up should be worked to the stakes by pressure of the left thumb. As it is essential to the appearance of the resulting work that the stakes should be even, the latter should be held in the right hand while the left hand shapes the weaving. Herein lies the whole art of basketwork.

Tracking. This is a method of finishing covers, and is an alternative to a plait. The method is as follows (Fig. 19): Place the first rod behind the second and leave it in front of the third. The second should be placed behind the third and left in front of the fourth. Place an extra rod in front of the first, place the two in front of the third, behind the fourth, and leave in front of the fifth. Next place the third alongside these two, add a second rod in front of the second, and place them both in front of the fourth, behind the fifth and in front of the sixth, with the fourth alongside. Continue with the first two of the three (the remaining one, the first commenced with having done its work), place in front of the fifth, behind the sixth and in front of the seventh. To continue, place the fifth alongside, dropping the outside of the three at each stroke, and when the round is complete work each one of the rods through to its proper place.

Upsett is the commencement of the weaving in all except the coarsest work and comprises two, three, or more rods worked alternately on the upright stakes to secure them firmly in position. Wale is the name given to the stroke used in upsetting and other parts of weaving, and formed by working two or more rods alternately, one by one, in front of two or more stakes, and then behind one. Weaving is effected in osiers by coarse randing for heavy work with stakes $2\frac{1}{2}$ in. apart, slight randing with stakes 2 in. apart, light randing with stakes $1\frac{1}{2}$ in. apart, and fine or close randing with stakes about 1 in. to $1\frac{1}{4}$ in. apart, the work being driven in close with the iron. Rib-randing (Fig. 20) is an effective method of siding up, and consists of working each rod alternately in front of two and behind one for two strokes before being worked out in simple randing.

Borders. Simple borders are worked as at Fig. 21, but the stakes may be strengthened beforehand by working the triple twist shown at Fig. 22. This form of stroke may take the place of fitting where extra fullness is desired. Another method of forming a finishing border is the plait, of which there are two forms, upright and flat. The upright plait is made by bending down each upright stake, or spoke, in turn, and placing each one behind the next one on the right as shown at Fig. 23. When the last stake is reached it will have to be threaded under the first one that has been turned down, as at Fig. 24. Each stake is now taken in turn and placed under the next on the right and made to stand vertically alongside the second stake, the last one being threaded through, as at Fig. 25. Each stake is now threaded to the front, behind the stake next but one to it, as at Fig. 26, and then each stake in turn is crossed over, the two stakes lying together and passed to the inside, as at Fig. 27. Any surplus ends left on the inside of the basket should be cut off.

Figs. 28-32. Stages in weaving a flat plait, used for arms and backs of chairs, etc.

The Flat Plait. This plait, used for finishing trays, arms and backs of chairs and other pieces of basketwork is more difficult to make than the upright form, but if it is followed out with actual material, the following instructions, with

the accompanying illustrations, will simplify the work. On the surface the finished plait appears continuous.

Commence by turning down three stakes as shown at A, B, and C at Fig. 28. The stake at A is curved round to the right, passed over B and C and placed in front of D, which is now turned down over it and the end left in front as shown at Fig. 29. The stake at B is now picked up and carried in front of the next two and the first upright of those standing is turned over on it as at E. The same method is followed with C, but, before the upright at F is brought down over it, the stake A, which was left on the inside, is brought across C, and then F, as shown at Fig. 30, is brought down beside it and the two are treated as one stake. At this stage of the work there are three rods outside, one being a double stake, and two rods inside. The first of the three is taken round the first upright stake to the inside, crossed with the first of the two to the outside and then the upright stake is drawn down. This method is continued, remembering to draw down the upright stake at every cross of the osier. When the double rods are reached they should be treated as one, both inside and outside. When the triple rods are reached, the two longer or outside ones are used, the shortest one being dropped and cut off at the finish. When the last upright stake has been turned down, there will be three triple rods outside and two double rods inside the basket. The method as far as this is illustrated at Fig. 31.

The first two long rods on the outside should be passed under the first stake A, which was turned down, leaving the short one as usual to be cut off at the finish. The next two long rods are passed over the first stake A, and under B, the second that was turned down. The remaining two long rods are passed over the first two, A and B, and carried under the third, C; this gives five double rods on the inside of the basket. Each two in turn should now be threaded to the outside under each single stake, as shown at Fig. 32, until all the five pairs are threaded to the outside. There are now five double rods on the outside, and the longer of the two is threaded from the underside, through the first single stake. Follow to the inside of the basket, and out again to make it double, like the rest of

the plait. A bodkin will be needed to lift the stakes in order to make room for the last five single rods.

OSMANTHUS. This is the name of a hardy evergreen shrub. The most useful variety is the Japanese *Osmanthus aquifolium*, which has holly-like leaves, small white fragrant flowers in winter, and grows 4-5 ft. high. Peat and loam should be added to the soil before planting. Propagation is by cuttings in a frame in August.

OSPREY. Osprey, aigrette, and egret are terms used to denote the decorative tufted head plumes of the egret, or smaller white heron. Osprey is the trade name for the egret, but the real osprey is a bird of another species known also as the fishing hawk. *See* Aigrette.

OSTRICH FERN. This is the popular name of *Onoclea sensibilis*, a handsome North American hardy fern, 18-24 in. high. It flourishes in deep, moist soil in a shady place. Like the Royal fern it bears spores on special fronds, not, as in most ferns, on the backs of the ordinary fronds. *Onoclea (struthiopteris) germanica* is another striking species. *See* Royal Fern.

OSWEGO TEA. This is another name for bergamot, botanically *Monarda didyma*, which bears various other popular names, including bee balm and horsemint. It is a hardy perennial, with sage-scented leaves and bright scarlet flowers in summer. *See* Bergamot.

OTTO CYCLE. This is the cycle of operations by which many types of internal combustion engines function. The cycle is made up of four strokes: induction, the fresh gases are drawn into the cylinder; compression, the gases are compressed; explosion, the gases are fired (power stroke); and exhaust, the exploded gases are expelled. *See* Internal Combustion Engine.

OTTOMAN. A stuffed seat without a back, the ottoman is not often seen except in the form of a floor pouffe or box ottoman, its place having been taken by the divan. The Victorian types of ottoman are sometimes divided in the centre with a long padded roll about 12 in. in diameter; others have a centre rail, with a padded top. *See* Box Ottoman; Divan; Pouffe; Victorian Style.

OTTO OF ROSES. Known also as attar or ottar of roses, this perfume is obtained from an oil distilled from rose petals, damask and musk roses being the kinds generally used. Because of the large quantities of petals needed in its manufacture, otto of roses is comparatively costly. What remains after distillation is made into rose water. *See* Rose Water; Scent.

OUNCE. This measure of weight is in constant use when buying meat, groceries, etc.; 16 oz. go to the pound avoirdupois and 12 oz. to the pound troy. The ounce avoirdupois contains 437½ grains and the troy 480.

In the ordinary way the ounce is divided into 16 drams, but apothecaries divide it into 8. They use it for measuring medicines, when one tablespoonful is equal to ½ fluid ounce, as the apothecaries call it. A dessertspoonful equals ¼ fluid ounce, and a teaspoonful ⅛ fluid ounce. The usual abbreviation for ounce is oz., which is used throughout this work. *See* Avoirdupois; Troy.

OUTHOUSE. An outhouse is a small shed or building, remote from the dwelling. Most householders at some time or other feel the need for a small outhouse, for storing garden tools, minor crops such as apples, potatoes, and the like. Some small buildings are obtainable

commercially in the form of sections ready built up, so that the householder can erect them by simply bolting the sections together.

Examples of this class are available in timber, others clothed with asbestos cement sheets, and in a number of combinations of both methods, varieties being covered with galvanized iron and roofed with the same material, with tarred felt, bituminous sheeting, or other proprietary material.

By-laws. An important point before ordering or arranging for the building of an outhouse is to ascertain the requirements of the building by-laws, as there are sometimes certain restrictions to be observed and certain formalities to be gone through, these varying considerably with the particular district.

It is well to bear in mind that to be a tenant's fixture it is generally understood that the building is of a portable nature, resting upon the ground or upon some brick or cement footings, and not a permanent building. *See* Fixtures; Shed; Workshop.

OVEN. Whereas most of the operations performed in cookery, such as boiling, frying, and stewing can usually be carried out upon an open fire grate, a small oil or spirit stove, or gas ring, those for which an oven is used cannot be managed at all without the oven.

Nothing can be more aggravating than an ineffective or inefficient oven, and more failures occur in cooking through the use of an underheated or overheated oven than from any other cause. The article on Baking may be consulted by the housewife. Particulars about ovens in connexion with gas, electric and oil cookers are given in the article on Cookers, while further information about ovens is in the entry on Range. *See* Anthracite; Baking; Cooker; Dutch Oven; Grate; Hot Water Supply; Range; Stove.

OVERALL. This is a garment which is worn by large numbers of men and women as a means of protecting their clothes while at work. Workers in shops, factories and offices, doctors, artists, sculptors, nurses, and the woman at home, all find it equally valuable, while it is also a useful garment for children to wear while at play.

OVERCASTING. This is the name applied to a stitch that is largely used in dressmaking for finishing the raw edges of seams, to prevent the threads from ravelling or fraying. As a rule, the stitch is worked along each edge of the seam separately, though in some cases it is worked over the two edges at once; but here it should be noted that for the latter method the seam must be well pressed beforehand, as no thorough pressing can be done after the stitch is taken over both edges. The stitch should be worked with cotton or sylko, according to the nature of the fabric.

To work it, secure the end of the cotton in the material at the left-hand end of the seam with one or two back-stitches, and push the needle through the material towards you, a few threads below the edge; draw through, and again push through from back to front a little further along towards the right. Repeat until the seam is done, and lightly press to take out any puckered effect. Do not draw the cotton tightly when making the stitches, or a puckered effect is bound to ensue, and to get a neat effect make the stitches all of the same size and to slant at the same angle.

When oversewing a curved seam, in order to prevent any dragging, first snip the seam edges at intervals with the scissors, and round off the corners caused by the snipping. *See* Seam.

OVERDRAFT. This is a banker's term for a loan made to a customer on a current account. When by chance or design a customer has drawn out from the bank more than he has put therein, an overdraft results. Overdrafts can be obtained by customers from their banks, provided the security offered is regarded as adequate. *See* Banking.

OVERFLOW PIPE. Any pipe that is connected to the water system for the purpose of discharging an abnormal rise in the height of the normal water level is an overflow pipe. Generally, in the home,

such a pipe is connected to the hot or cold water tanks to avoid the flooding of the premises. In the case of the ordinary cold water tank or cistern, such an overflow pipe should be as large in diameter as the supply pipe. It should have a regular gentle fall from the point where it leaves the cistern to the point of discharge, which should be over a gutter or in some place where the water can get away without running or splashing on to the building.

Overflow Pipe. Showing how the pipe should slope gradually from the cistern to the outfall.

It is advisable that the overflow pipe be visible, so that should the water be wasting, its loss will speedily be made apparent, and the cause can be remedied. Generally, an overflow will be due to the failure of the ball valve. In a hot-water tank, the overflow pipe is generally arranged in such a manner that it acts as an expansion pipe. It relieves the tank of all pressure due to the generation of steam or the expansion of the water, and acts as an overflow should the cistern flood.

Such an overflow pipe is usually set in a vertical position and terminates in an elbow or bend at water level. This is because the water as it heats will rise, and a certain amount of such expansion is not detrimental to the system; it is only when the expansion is above the level of the water supply that it should be possible for it to drain away. The overflow pipe should be kept clear, especially at the outer end, which in time may get choked up with leaves. It should be regularly examined and any obstructions removed.

Overflow pipes generally take the form of a short pipe passing through the wall and merely projecting into the air. This arrangement is usually satisfactory, as it is seldom, if ever that the water overflows through it. They are provided as a safety device. The materials for such pipes may be lead, wrought iron, galvanized iron, brass or copper. Of these, galvanized iron or galvanized steel is the most durable. *See Plumbing; Tap; Water Supply.*

OVERMANTEL. This, as the name suggests, is a fixture over the mantelpiece. Such fixtures are made chiefly of wood, which may be oak, walnut, mahogany, or enamelled or painted deal. They are made in a great variety of styles, with inset mirrors which may be square round or oval. Unless the overmantel forms an integral part of the chimney piece, it is often the better plan to remove it and to use a panel of embroidery, a flower or landscape painting, a mirror or merely a good ornament on the mantelshelf, according to the type of fireplace and style of the room. *See Chimney Piece; Dining Room; Drawing Room; Fireplace; Mirror.*

OVOLO PLANE. This is a specially shaped plane, which is used for working an ovolo moulding on wood. The usual form is made in beech, and the sole shaped to a reverse of the shape of the moulding which the plane will produce. The plane iron is similar to other plane irons, but is shaped on the cutting edge to correspond with that of the ovolo moulding. In use the plane is traversed along the wood in the same way as a jack plane, but should be guided on the wood either by a fence

or temporary strip tacked to it, or by careful manipulation of the plane, especially when commencing operations. If this is not done the shape of the moulding will vary in respect to the edge of the work.

In sharpening such a plane iron, it will be necessary to use an oilstone slip, of a shape and size to suit the curvature of the plane iron, employing this as though it were a file, to work up a keen cutting edge. The care is similar to that of other wooden planes. *See Plane.*

Ovolo Plane. A common type of the tool in use.

OXALIC ACID: Poisoning By. Because of its resemblance to Epsom salts, oxalic acid, which is popularly known as salts of sorrel, or lemon, and acid of sugar, may be taken accidentally. When strong oxalic is swallowed violent inflammation of the stomach and intestines immediately follows. Following on an intensely sour taste, a burning pain is felt in the throat and stomach; vomiting occurs, and often the vomit contains blood. Collapse soon ensues from the severe pain, and this may pass into stupor, and death may speedily take place.

Treatment must be very prompt to give any chance of life. While awaiting the doctor, if vomiting has not occurred, give an emetic of a tablespoonful of mustard in $\frac{1}{2}$ pint of tepid water, but only if dilute acid has been taken. As an antidote, give chalk, or 2 tablespoonfuls of magnesia mixed with water. Bicarbonate of soda or potash, or ammonia, should not be given, as these form soluble compounds with the poison. Put the patient on a couch, cover him warmly, and surround his body with 5 or 6 hot-water bottles.

OXALIS. Of these low-growing plants, some of them are hardy, while others are suitable only for cultivation in the greenhouse. Of the former a charming kind is the wood sorrel (*Oxalis acetosella*), which grows wild in Britain and is suitable for shady places in the rock garden; it bears white flowers in spring, and is sometimes sold as shamrock. The two best hardy kinds for the rock garden are *adenophylla*, pink, and *enneaphylla* white they like partial shade and a compost of peat and sandy loam. A familiar plant in many gardens is the bronze-leaved yellow-flowered *Oxalis corniculata rubra*, which spreads rapidly and soon becomes a weed. The rose-coloured *floribunda* is a beautiful plant to grow in pots under glass.

OX CHEEK: How to Cook. Ox cheek makes a substantial and appetizing dish if baked, or it can be made into a very good soup or stew. The cheek should come ready cleaned from the butcher, but requires soaking and well washing before any attempt is made to cook it.

After it is thoroughly clean, place it in a large saucepan and cover it with warm water, add a teaspoonful of salt, and boil it up. As the scum rises take it off, and, when clear, let it simmer for an hour. Lift it out of the pan. let it cool a little and then bone it carefully. This must be accomplished with a sharp cook's knife to avoid ragged appearance.

While the cheek is boiling a good stuffing must be made. Spread it in the boned ox cheek, roll it up and tie or skewer it securely in an oblong shape. Bake in a moderate oven for $1\frac{1}{2}$ hours, basting frequently, and serve with a good, thick brown gravy.

To make soup, prepare ox cheek as for baking, and place it in a pan with enough cold water to cover it well, and $\frac{1}{2}$ oz. Salt. When it boils, skim it and add 2 onions, 2 carrots, 1 turnip, and $\frac{1}{2}$ head of celery. All vegetables must be prepared and cut up. Add a bouquet garni. Let the cheek simmer $2\frac{1}{2}$ hours, then lift it out and remove the meat from the bones. Strain the stock, clear it of fat, and thicken it with brown roux. Cut the meat into squares, boil it up in the soup, and pour into the tureen. The bones will make a good addition to the stock-pot. *See Beef.*

OX-EYE DAISY. This is the common name of *Chrysanthemum leucanthemum*, a familiar wild flower of Britain. May Queen is a splendid variety for the garden. The Shasta daisy or hardy marguerite (*Chrysanthemum maximum*) is a vigorous hardy border plant, 2-3 ft. high, bearing large, white, longstemmed flowers in summer. Particularly fine varieties are Mayfield Giant and Rentpayer. *Buphthalmum salicifolium*, another ox-eye, bears large bright yellow flowers in late summer; it grows 2 ft. high. Propagation is by division in autumn.

Ox-eye Daisy. Large white blooms of an easily grown plant.

OXFORD FRAME. A characteristic of the Oxford picture frame is the arrangement of the corners, which cross or overlap, and are not mitred in the usual way. The frame may be made in any wood, but one of the hardwoods, such as oak, is perhaps the most appropriate. The frame may be plain or have chamfered edges. *See Picture.*

OXFORD SHIRTING. The most usual pattern of Oxford shirting is a neat check in blue and white or red and white. It is rather warmer and thicker than ordinary calico, and hence specially suitable for winter wear. There are imitation Oxford shirtings with a printed instead of a woven coloured pattern. In the real article the pattern is the same back and front.

OXGALL. Purified ox bile is sometimes used in medicine, chiefly as a laxative. It stimulates the action of the liver and emulsifies fats. It also acts as an antiseptic. The dose is 5 to 75 gr. of fresh ox bile, which may be taken as a bolus, wrapped up in wafer paper, or in capsules.

Oxidation. *See Rust: Verdigris.*

OXIDIZING: Of Metals. Oxidizing is a term given to the coloration of metal objects by changing the surface to a brown-bronze or black tint by a chemical or electro-chemical process. As every metal is attacked by chemicals in varying degrees and with various results, it is best to treat each separately. In general there are three methods, chemical, electro-deposition, and heat treatments, which latter may or may not introduce chemical changes in the surface.

The amateur can electro-plate on base metals some of the finer metals, such as copper, silver, nickel, brass or gold, with a view to applying an oxidizing process. Among these preparatory processes brassing may be mentioned, silver, nickel and copper plating being referred to under the heading of electroplating (q.v.). It is usual to adopt a brass coating on the baser metals, iron, zinc, white-metal alloys, etc. The finishing coat for oxidizing may be applied as in the case of a solid brass. The electro-deposit should be thick enough to withstand the penetration of the chemicals used in colouring.

Most of the chemicals employed are highly poisonous, and the greatest care should be taken in handling them and in disposing of the spent solutions so that no danger to animals or human beings is incurred.

The brass plating bath may be made of 1 oz. each of zinc and copper sulphate, 2 oz. of carbonate of potash, and 3 oz. of cyanide of potassium. The first two are dissolved in hot water, the potassium carbonate separately, and added a little at a time. The cyanide is made up into a 25 per cent solution and mixed with the others, stirring the bath all the while, the final result being a muddy yellow liquid of about 2¼ pints in bulk.

The solution is boiled for about, half an hour, filtered, and watered out to 2½ pints. The intensity of the current largely controls the depositing. If the coating is too white, denoting the zinc, a reduction of the current will deposit more copper. Brass may be used for the anode, but separate strips of copper and zinc are perhaps better. It is best to deposit mainly copper towards the end of the process. For coppering only, the solution is the same except for the zinc sulphate, and a copper anode would obviously be employed. The processes involving electro-deposition require electrical power of low voltage and comparatively large amperage. The article on Electro-plating should be consulted for further details.

Treatment of Silver. Silver oxidizing is a process with quite a misleading name, as silver oxide is not formed, and is not a part of the colouring film. Sulphur is the chief agent. For oxidizing silver or silver plated articles from light golden to brownish black, a hot solution of barium sulphide, 1 oz. to the gallon of water, is often employed. The work, if not just emerging from a plating process, must be cleaned in a hot potash solution, rinsed, and given an acid dip, swilling afterwards in a large body of water, and then passed through a cyanide dip, rinsed in hot water, and dried. For producing a matt surface, the acid dip is composed of sulphuric acid, 1 part; nitric acid, 2 parts; sodium chloride (common salt) and zinc sulphate, each about one-tenth of an ounce to the pint.

When in the oxidizing solution the silver work is shaken about until the desired blue-black density is obtained. It is afterwards rinsed in boiling water. Oxidized silver work can be locally lightened as desired. Brushing with bristle brushes and pumice powder will give a grey colour, and the original silver may be exposed where necessary for artistic effect by rubbing in the pumice powder with the fingers. Varnishing may be accomplished with a colourless varnish of the nitro-cellulose type, or one of the proprietary brands of lacquer may be used.

Another oxidizing formula is ½ oz. of potassium sulphide and 1 oz. of ammonium carbonate to the quart. The solutions are mixed separately and worked hot. This coating is quite robust, and will stand the scratch brushing process employed in ordinary plating. The work only requires immersing for a short period. To produce a matt, or dead surface, the article should be dipped in a sulphate of copper bath, after electro-plating with silver in the ordinary way. A frosted white results, and the whole or portions of the work may be treated to obtain the desired effect.

The paste method involves a mixture of plumbago (black lead) and turpentine, with a little red ochre or rouge. It is spread over the work and allowed to dry. The parts in relief in the article are then rubbed with a chamois leather or soft rag dipped in methylated spirit. This is only applicable to engraved, moulded, or chased articles, and, with such, gives the old silver effect. The work can be cleaned off in a caustic potash or cyanide bath. Sulphuring silver gives a blued steel colour. The work is subjected to the action of sulphur fumes in a tin box with a tray to hold red hot charcoal or cinders. Powdered sulphur is spread over the cinders and the lid closed with the work suspended in the fumes. The work must be quite clean both chemically and mechanically.

Oxidizing Copper. For copper a solution of ammonium sulphide, $\frac{1}{2}$ to 1 oz. to the quart of water, is used. The depth of tone, light brown to black, depends on the time of immersion, and the temperature of the bath, and the colour is more completely controlled if the bath is not hot. The work can be lightly scratch-brushed and rinsed. The uniformity of colour, independently of the cleanliness of the work, depends on the purity of the copper; therefore, it is better with objects that have been coppered by electrodeposition. In any case, a copper article might be passed through a copper plating bath as a preliminary, to improve the surface for oxidizing.

Potassium sulphide, $\frac{1}{4}$ oz. to the quart of water, with a few drops of ammonia, provides a brown tone imitating Japanese bronze work. The solution is used warm. Copper nitrate, 8 oz. to the pint of water, gives a deep black tone. It is used warm and the work should be immersed several times, allowing it to dry between the dippings. Brass oxidizing is more difficult to control and to predetermine in the matter of colour, because of the varying characteristics of the alloy. Such work is often plated with copper first.

Iron and Steel. In iron and steel oxidizing, brown colours may be obtained by covering the work with a paste of antimony chloride and olive oil in equal parts and heating it slightly for 12 hours. The paste is rubbed off with a soft cloth and finished with a waxed brush. The work requires a preliminary cleaning in a pickle of nitric acid. A black colour may be obtained on iron or steel by an immersion in a hot solution of sodium thiosulphate, $\frac{1}{2}$ oz. to the pint, and greys in a hot pickle made by diluting a mixture of 2 oz. of arsenious oxide in strong hydrochloric acid in one gallon of water. The heat treatment of iron and steel by the Bower-Barff process provides a protective coating of black oxide of iron, Fe_3O_4 and involves heating the work to redness in superheated steam.

Perfect cleanliness is absolutely necessary in the colouring of metals by any of the processes described, and it must be remembered that acids do not remove grease, and contact with oily or naturally greasy fingers should be avoided. If ostensibly clean objects are handled promiscuously before oxidizing they are likely to show marks where the oxidizing reactions have been prevented by the finger marks. The use of rubber fingerstalls or gloves is to be recommended in all operations where they can be employed. Permanent results are also often dependent on the final lacquering, many suitable coloured and colourless varnishes being obtainable. *See* Bronzing; Electro-plating; Patina.

Ox-lip. This is the popular name of *Primula elation*. *See* *Primula*.

OX-TAIL SOUP. Cut into joints 2 ox tails, dividing the pieces in as uniform a size as possible, and soak them for an hour in cold water, adding $\frac{1}{2}$ oz. salt to 3 pints of water. Remove the pieces and wipe them dry, then fry them in 2 oz. butter or good clarified dripping until of a rich brown colour. Put them into a stewpan with 2 quarts stock, 1 good-sized onion stuffed with 2 cloves, 1 carrot, 3 sticks of celery, or celery seed if the fresh vegetable is not available, and a bouquet garni. Let all boil up. skim and simmer for 3 hours or until the meat is tender.

Remove the pieces of tail and thicken the liquor after carefully clearing it of fat. The thickening should be made by frying 2 oz. flour in 1 oz. butter and then thinning it down to a liquid with a little stock. Add by degrees to the soup and boil for a few minutes. Meanwhile boil in clear stock or water a medium-sized carrot, turnip, and onion, prepared and cut in julienne shape. Strain when cooked. Put the pieces of tail into a tureen and strain the soup, boiling, over them, then add the shredded vegetables. Give the soup a stir and serve hot. Keep the tails hot while thickening the soup. *See* Casserole.

OX TONGUE. In town an ox tongue can always be procured ready pickled from the butcher, and all that remains to be done is to soak it, thoroughly wash it, and boil it, putting it into cold water and letting it come very slowly to the boil. After it has been skimmed it should simmer 3½ to 4 hours, according to size, and be allowed to go cold in the water in which it has boiled. Take it up, remove the white skin and trim the root. The tongue may then be skewered into shape on a dish, with a rolling-pin underneath to support it. When cold, remove rolling-pin and pour liquid glaze over to coat the tongue. Or it may be pressed into a round mould or cake-tin and covered with a plate, and a

weight on top and left till cold. Ox Tongue, shaped and pressed, a delicious cold dish for breakfast or supper.

Ox Tongue, shaped and pressed, a delicious cold dish for breakfast or supper.

A fresh tongue, one that has not been pickled, is sometimes prepared and cooked, but before boiling it blanch it in order to remove the white skin. The root must be well trimmed, and it is better to soak the tongue before blanching it.

Serve hot with a piquant sauce. When boiling a fresh tongue use stock instead of water, and add soup vegetables to flavour it. *See Glaze.*

OXYGEN. About one-fifth of the atmosphere consists of oxygen, which is a colourless, tasteless gas. By the act of breathing, oxygen in the air is drawn into the lungs and becomes absorbed by the blood, which gives out, in exchange, carbonic acid gas.

Oxygen is also necessary to combustion. The air in a closed room becomes used up by breathing and by using coal gas or candles for lighting, its place being taken by carbonic acid. This carbonic acid if it accumulates beyond a certain quantity makes the air unfit for people to breathe. That is why it is so necessary to have a room well ventilated. An open fireplace is of great assistance in this; fresh air should be admitted by the windows.

Oxygen is sometimes inhaled by people who suffer from illnesses which cause difficulty in breathing, e.g. pneumonia, and for this purpose it is stored in cylinders, obtained through a chemist. *See Ozone; Ventilation.*

OXYMEL. An old-fashioned yet valuable remedy for cold and sore throat is made of vinegar and honey, and is known as oxymel. Mix together 2 oz. of vinegar and 2 oz. of water and add to 1 lb. of honey. Stir well together, and put in a jar, which should be kept covered. Give as a dose a teaspoonful three or four times a day.

By mixing squill vinegar with the honey, oxymel of squill is formed. It is obtained made up from a chemist's. This is used as an expectorant, the dose for an adult being ½ to 1 dram. It is a favourite remedy in the bronchial troubles of children. A child of six would be given a fourth of a teaspoonful of it in water every three or four hours.

OXYTROPIS. This perennial plant, 12 in. or so high, is popularly known as milk vetch. It bears small, pea-shaped flowers in summer. They need a warm, sunny place and light soil. Ochroleuca, yellow; Lambertii, carmine-rose, are two of the best.

OYSTER. Although oysters do not suit everyone, they are to most people very digestible when eaten raw. Cooking makes them hard and tough, and they are not recommended in this state to people whose digestion is weak. The composition of the oyster is as follows: Water, 88 per cent; protein, 6 per cent; and carbohydrate, 3 or 4 per cent. It will be remembered that they are out of season during the four months of the year whose names do not contain an 'r' in them, e.g.. May, June, July, and August.

It is not advisable to drink spirits with oysters, as this may retard digestion. If from any cause troublesome symptoms should arise after eating oysters, a glass of milk frequently gives relief. Unopened oysters improve if kept some days and fed with oatmeal which fattens them and makes them more luscious. The small native oyster is considered best for taking raw, but the large sorts can be used for soups and stews.

To prepare oysters to be eaten raw, first scrub the shells. Hold the oyster in a thickly folded cloth in the palm of the left hand, with the hollowed shell downwards to hold the liquor. Work an oyster-knife, or a sharp tin-opener, between the two shells with a see-saw action till enough of the knife is inserted to force them apart. Remove all bits of shell. Serve the oysters in the deep halves of their shells, standing on ice if possible. Lemon cayenne, and thin brown bread-and-butter should always be served. Grated horseradish, Tabasco sauce, and celery (when in season) are also liked by some people. Raw oysters may be served as cocktails (q.v.)

Cooking Oysters. In cookery the oyster is used for small savoury dishes stuffing, and sauce. It is sometimes bearded, blanched and added with the strained liquor to a steak-pie or pudding. It is also fried in a light fritter batter, after coating with egg and bread crumbs.

Oyster Aigrette. This dish can be made by putting pint water and 1 oz. butter in a pan over the fire, and when they boil adding to them 4 oz. sieved Vienna flour. Take the pan from the fire, beat its contents until they are smooth, and then cook them over gentle heat until the panada leaves the sides of the pan. Let the mixture cool a little, then beat in separately 2 eggs and an extra yolk, and add 3 oz. grated Parmesan cheese and seasoning to taste. Turn the whole on to a plate where it may cool; then beard a dozen oysters and season them with cayenne and lemon juice.

Have ready a deep pan of smoking hot fat, and into it dip a dessertspoon. Then half fill the latter with some of the cheese mixture, make a hollow in the centre, and in it lay an oyster, covering it up with a little more of the mixture. Drop the aigrette from the spoon into the pan; prepare 11 more in the same way, and fry them slowly for about 5 min. After draining, serve them with thin rolled brown bread and butter, cayenne and lemon.

Oyster Force meat. Oyster forcemeat is used for stuffing boiled or roast turkey. To make it, beard 18 oysters and cut them into quarters, then mix them with $\frac{1}{2}$ pint breadcrumbs, $\frac{1}{2}$ teaspoonful dried mixed herbs, 1 oz. finely chopped suet, and seasoning to taste. Bind the mixture with a beaten egg, adding more beaten egg or a little milk if necessary.

Oyster Fricassée. A nice fricassée of oysters can be made by boiling up a dozen oysters in their liquor, straining them, and then reserving the liquor. Melt 1 oz. butter in a small pan, stir in the same quantity of flour, and then add the oyster liquor by degrees, stirring the whole until it boils. Continue cooking for a few minutes, then move the pan to the side of the fire and add the yolks of 2 eggs, the oysters, a squeeze of lemon juice, and seasoning to taste. Dry toast should be served with this dish, which is suitable for invalids.

Oyster Patty. The cases are prepared first for oyster patties. Take $\frac{1}{2}$ lb. best puff paste for these and roll it out about $\frac{1}{4}$ in. thick or rather more. It is impossible to give the exact depth as so much depends on the pastry maker and the size required. Cut out 10 or 12 rounds of paste with a small round cutter. Mark out a smaller round in the centre, using another cutter not quite so large, but do not cut right through.

Cook till the pastry is quite done and a fine brown. Now lift the cases on to a wire tray, remove the small centre round, scoop out any uncooked paste and lay aside ready for the filling.

Blanch 2 dozen oysters for a few minutes, drain and beard them, and cut each in two. Now mix them with a rich white sauce, add a wineglassful of white wine and some of the oyster liquor. Fill the cases, cover with the lids, and re-heat or serve cold. An average size for the case is $2\frac{1}{2}$ to 3 in. across.

Oyster Sauce. Blanch 18 oysters in their own liquor, adding a glass of white wine: beard them, and clarify and save the liquor. Put into a saucepan 2 oz. butter and, when melted, cook in it for 4 min., without browning, the same amount of flour. Add by degrees 1 pint warm milk or white stock and simmer till all is cooked and quite smooth. Add seasoning, a little grated nutmeg, the oyster liquor, 1 teaspoonful lemon juice, also the oysters. Heat up before serving. *See* Patty; Soufflé.

OYSTER GRAIN. This term is used by furniture collectors and others. It refers to veneered pieces of walnut which, owing to the appearance and direction of the grain, resemble the insides of oyster shells. It is frequently found on Queen Anne furniture. *See* Queen Anne Style.

OYSTER SHELL. When heated until they crumble, or when ground, oyster shells make a useful addition to potting composts. These shells can also be put to good use in a fowl-run if they are first crushed to a fine powder. In this form they supply hens with the necessary amount of lime to ensure the laying of hardshelled eggs.

OYSTER SHELL SCALE. Various fruit trees are attacked by this scale insect. The Ministry of Agriculture suggests the following methods of dealing with the pest.

The oyster shell scale is much reduced in numbers by the attacks of its natural enemies. One valuable enemy is a jet-black ladybird with two red spots on its wing-cases. When buying young stock all trees bearing scales or showing the characteristic little white scars should be rejected, unless the seller can guarantee that the stock has been fumigated with hydrocyanic acid gas or otherwise cleared of scales. The scale insects can be killed by thoroughly washing the trees in winter with lime-sulphur.

OZONE. When electric currents are passed through oxygen, as in working an electrical machine, a peculiar odour becomes noticeable. This is due to the formation of ozone, which is a form of oxygen. It exists in the air, but in populous neighbourhoods becomes used up by combining with carbon particles in the air. It is abundant in the air at the seaside and up mountains. It is a powerful oxidizing agent, and in virtue of this property is employed as a disinfectant. An excess of ozone may produce headache, cough, etc. *See* Oxygen.

PACK. In the medical sense a pack is a covering in which the patient's body is swathed. A hot pack is used to promote perspiration in disorders of the kidneys and other complaints; and a cold pack for reducing the temperature in high fevers. *See* Cold Pack; Hot Pack.

PACKING. In packing clothes, the first thing to decide is the number and kind of boxes required, which will vary according to the contemplated length of absence from home, the number of persons travelling, and the nature of the wardrobe that it will be necessary to take. The expanding type of suitcase often is sufficient for the short holiday; or another convenient form of luggage is a very light suitcase, with a stronger one for heavier articles.

To pack, place the suitcases on stands or on a bed, when care should be taken to spread something over the coverlet first. Into one of the cases should be put, well wrapped up, boots and shoes. Books, woollen garments, stockings, collar box, and any hard or heavy articles are wedged in as flat as possible, so that at the top there is room to lay heavy outer sports clothes and rolled-up felt, woollen or cloth hats or caps.

In the other suitcase a woman would put light underwear, night wear and dressing-gown, laid flat between layers of tissue-paper; then a light coat, frocks or suits, with a good roll of tissue-paper wherever they are folded.

Packing Men's Clothes

A man might pack the second suitcase in this way: To obtain full advantage of the flat surface, begin with evening clothes folded according to the length of the case, with a layer of soft paper at each fold. Then, sandwiched between pyjamas and light underwear, come the shirts. Evening shirts should be reversed the way of the laundry, folding them so that the fronts are inside and thus protected, the ends being carefully tucked into the neckband. Place all these flat with handkerchiefs and tie-case nicely levelled against them, and then on the top fold the suits and flannels.

Men's clothes should be tightly packed, so if the suitcase is not quite full, it is better to put in an extra garment than to risk the shifting about of all the contents. A heavy dressing-gown, if required, may be put into the first suitcase, a thin one into the second. All toilet things, including bottles, can go into the small case, and as this would be carried, there is little risk of breakage.

For the luxurious traveller, the American wardrobe trunk saves much trouble. These travelling wardrobes, however, are too expensive for general use, so where a large quantity of clothes has to be packed, evening and other dainty frocks can be carefully folded, with plenty of soft paper, in cardboard boxes, which keeps off the pressure of heavier clothes, and placed at the bottom of a trunk. When packing hats into a tray or hat-box the insides of the hats may be filled with such articles as handkerchiefs, gloves, and ties.

A large hold-all and a big folding basket are both excellent things to keep open till the last moment for forgotten family necessities. A baby's things can be packed in its bath with fitted lid strapped securely on to it, and where a perambulator is taken, a number of necessary things can be stowed away in it under the waterproof cover. Careful overhauling of the family wardrobe several days before the actual day of departure greatly facilitates packing.

Packing for domestic purposes usually requires a strong container, and some wood wool, shavings, crumpled newspaper, or bran. Large articles, such as a piece of furniture or a perambulator, are wrapped up in sacking, making up ropes of straw, and winding it round all the exposed parts, or entirely covering it with the sacking sewn together at the joints by means of a packing-needle (see Needle) and pack thread, which is fine, thin string, but strong enough to ensure firm stitching. Wheeled vehicles should be made up so that the packing does not prevent the wheels rotating, and they can then be moved about as required very easily instead of having to be lifted and carried.

Packing Fruit and Flowers. Fruit is difficult to pack if it is to arrive at its destination in sound condition, but it can be placed in hay or straw, if both of these are perfectly dry, fresh, and clean. The householder will generally prefer to use a light wooden box as a container, with paper and bran as packing material. This gives entirely satisfactory results, if a layer of bran is placed on the

bottom, and then a layer of crumpled paper, as illustrated. Each article should be separately wrapped in tissue-paper, bran poured round it, then covered with another layer of paper, another layer of bran, and so on until the case is full. Flowers to be sent by parcel post are best packed in a stout cardboard-box. They should be made up into bunches and wrapped in tissue-paper with slightly moistened moss or grass round the stems; this is secured by more tissue-paper and inserted into the box, and the cavities filled with tissue-paper. *See* China; Crate; Parcel; Removal.

Fruit will travel safely if each item is wrapped in tissue paper and placed between layers of crumpled paper and bran.

PAD. This word is used to denote several different articles. There is the writing pad or block; the boot pad, made of velvet, for polishing boots; the pad of lint, or gauze and cotton wool, used in surgical dressings, and the ink pad used with a rubber stamp. *See*

Dressing; First Aid; Rubber Stamp.

PADLOCK. This is a form of detachable lock, intended to hang on the part to be fastened. The usual type comprises a case containing the lock mechanism having on one part of it a shackle or curved metal bar, so that it can be hinged or turned, and the opposite end fastened to the lock case by the lock bolt and mechanism. Patterns are made of japanned or galvanized iron. Common ones have a one-wheel ward, or a sham lever mechanism. Better types have two or three ward wheels and levers, the mechanism being similar in principle to other forms of locks. The cylinder or pin tumbler system is adapted to the mechanism of the padlock, and such locks possess all the well-known advantages of that system. Some very small padlocks are made with a simple spring lock. Another type with a small metal key is convenient for locking small articles, e.g. cash boxes. *See* Bolt; Door; Lock.

Pad Saw. *See* Keyhole.

PAGODA TREE. This is a small family of hardy and greenhouse flowering shrubs, known as Sophora. The only one worthy of note, except in large collections, is *S. japonica*, a summer-leaving shrub with bluish-green leaves and white flowers. It should be planted in autumn, pruned in February, and is propagated by seeds or by division. There are a few varieties which need only ordinary greenhouse treatment. *See* Shrub.

Pail. *See* Bucket.

PAILLASSE. This word is sometimes used for an under mattress. Originally a paillasse was a small bed of straw or chaff. As comfort became more general this was used to put beneath mattresses or beds of a better kind.

PAIN: Its Relief. Pain is of many different kinds. It may be constant, or only occurring at intervals. Sometimes it is dull and aching as in chronic rheumatism or sharp and cutting, as in pleurisy;

throbbing as in the case of an abscess, or burning or smarting, as when the skin is inflamed. Pain is not always felt at the exact spot where the harm is. For instance, neuralgia may be felt in the head, and the cause be a bad tooth.

One great use of pain is that it draws attention to disease which might otherwise be overlooked. In times of great excitement or when the mind is fully occupied, it is possible to forget even severe pain. Pain is, however very exhausting, and if only for that reason calls for relief.

In treatment the first consideration is, if possible, to get at the root of the trouble. If an unsound tooth is causing neuralgia have it removed. An abscess in the same way should be lanced. It is generally possible to relieve pain, for the time at least, by giving drugs, which quieten the nerves and dull the senses, either simple analgesics like phenacetin or aspirin or narcotics. Care must be taken in using analgesic remedies, and narcotics should only be taken under medical observation.

For home treatment, nothing is more likely to succeed in soothing pain than heat, especially when it is combined with moisture. For internal pains, a hot-water bottle may be useful, or fomentations (q.v.) of hot water. For pain in the chest, arising from cold, a mustard and linseed poultice is a soothing remedy. A mustard poultice may also relieve lumbago.

Electrical currents are often successful, and in some cases ionization. Friction will sometimes give relief in muscular pain, as in chronic rheumatism, and the use of a little camphor, well rubbed in by the hand, will often ease joints that are stiff. A strong cup of coffee will often remove a bad headache. It must be remembered that quiet is often desired by persons in pain, and this, together with rest and warmth, will go far to relieve many forms of suffering. *See* Embrocation; Fomentation; Linseed Mustard; Neuralgia; Poultice ; etc.

PAINTS & PAINTING IN HOME DECORATION

The Best Methods and Materials for Paint Work and its Cleaning

The following is one of the many articles that deal with the question of decorating the home, others that fall into this category including Enamel; Graining; Panelling Paperhanging, etc.

Certain precautions have to be exercised in paint work of almost every kind. If the paint is to dry nicely, the surface to which it is applied must be clean and free from grease or dirt; the paint itself must be of good quality and suited to the class of work; while the material to be painted must be prepared by coating it with mixtures known under such names as fillers, stopping and undercoating. The brush also should be of suitable shape, size and quality.

Paint is applied to improve the appearance and to assist in the preservation of the object painted. It has also a sanitary and hygienic value. If the surface to be painted is greasy and dirty, and the paint is applied to it in this state, it is obvious that the dirt will remain, although covered by the paint. The proper method is to remove the dirt and grease before applying the paint, and this can be done by scrubbing with hot water and soda.

The Ingredients of Paint. In connexion with the home, painting is generally done with oil colour paint, but in a more comprehensive sense it includes the use of water paints and other decorative material applied in the form of paint. There are also available the various nitro-cellulose finishes (*see* Enamel).

Oil paints often have white lead as a base, or body. This material has great covering power and weathers well, but as it is very poisonous, a zinc white base, composed of oxide of zinc, which does not possess the poisonous qualities of white lead, is largely employed.

The base is diluted with a thinner, generally composed of linseed oil, and both this and the base should be of first quality. Oil of turpentine, commonly called turps, is also used for thinning the

base and making the paint more easily worked; but it reduces the protective qualities of the paint, and if used in excess produces a thin, quick-drying coat, which dries with a dead or flat surface.

For the purpose of hastening the drying of the oil in the paint, materials known as dryers are used. For dryers, terebene is often added to make the paint dry quickly, but litharge, lead acetate, zinc sulphate, and red lead are very much used. A common practice is to embody with the base some other material, known as a filler, which is added by paint makers, and varies according to the purpose of the paint. Silica or barytes may be used for a paint to be applied to woodwork; while silicates, alumina, whiting, and gypsum are used in paint for masonry and metal work.

The ordinary linseed oil is obtainable in two forms, raw and boiled. The raw oil is used for delicate work, pale colours, and internal work, and the boiled oil for general external use. Owing to the cost of turpentine, a number of substitutes for this material are obtainable, and although the genuine turpentine is to be preferred, the substitutes answer very well for most paint work. Pigments are finely ground colouring materials used to colour paint for ornamental purposes and to give opacity. They are made from various animal and mineral substances, and are obtainable either as finely ground powders or ground in oil; in the latter case they are pastelike in substance, and are used in that form for tinting oil paint. Knotting and fillers ready for use can be purchased from most oil shops.

Ready mixed paints, if made by a reputable firm, are very convenient to the amateur; but for matching up existing work, or preparing a special tint, it is preferable to use white lead, or zinc white, diluted with linseed oil or turpentine, and stained or coloured by mixing with it sufficient of the desired colour to impart the requisite tint. Many of the ready mixed paints are available either in the form of the common paint, which dries with a lustreless surface, or with the addition of a little varnish, which results in the paint drying with a semi-glossy surface. Generally the common paint answers very well for the second coat and the varnish paint for the finishing coat. Water paints are really a form of distemper, in paste or powder form, and only require to be mixed with water. For interiors they are particularly effective.

Paint. Fig. 1. Implements which are essential for the amateur painter. Reading in rows from left to right: paint kettle, tin of paint, blow lamp, putty knife, sponge, dusting brush, hacking knife, stripping knife.

The technique for applying cellulose finishes is explained in the article on Enamel (q.v.).

To carry out painting work properly the amateur should possess several clean tins with handles, known as painters' kettles, a large sized sponge, a good piece of pumice-stone, a blow lamp for burning off the old paint, a

scraper, or stripping knife, hacking and stopping knives for cleaning out the bad places and working the stopping into them. These are illustrated in Fig. 1.

When the colours are to be blended, a clean earthenware jar is required for mixing, a palette and palette knife, and some fine muslin for straining are necessary. A dusting brush, leather, clean duster, and regular painter's apron are very handy, and the amateur will find it a good plan to wear a pair of old gloves.

Paint Brushes. A selection of brushes for general use consists of an oval ground brush about 2 in. wide, a varnish brush about 1 in. wide, two or three sash tools of various sizes, and a fitch about ½

in. wide for painting the edges of narrow work. The best brushes are made of hogs' bristles; some are adulterated by the addition of vegetable fibre.

The size of a brush is denoted by a number, 1-0, up to 8-0, and 10-0, the latter being for house painters. In some cases the bristles are bound to the stock or handle with cord or twine, in others with copper wire or tin band or ferrule. The bristles are arranged to form flat, oval, or round brushes, and for general purposes the oval is preferred. Smaller sizes, termed sash tools, are useful when painting the smaller surfaces in door and window frames.

There are also brushes for dusting the surfaces preparatory to putting on the colour. They are usually round in shape, with much longer bristle than ordinary brushes, curving outward. Brushes for varnish are of a finer bristle, and flat or oval; the former are bound with tin, and will be found most useful for general purposes.

A brush known as a stippler is used for going over painted surfaces whilst still wet to remove brush marks. It is a large, flat brush, rather wider than a boot brush, and the bristles are set so closely together that when the brush is lightly and evenly dabbed all over the surface, a minute and even granulation results.

Paint. Fig. 2. Common types of paint brush in everyday use. A, long-handled brush for decorative work. B, washing-off brush. C, sash tool for general work. D, small distemper brush. E, metal-bound varnish brush. F, ground flat bristle brush for enamel work.

Brushes for use with cellulose finishes should be set in rubber, as the solvent employed would dissolve the binding material of the ordinary type of brush.

On no account should a new brush be put into immediate use without some previous preparation. The bristles will have become dry since the brush was made, and are liable to come out on to the painted surface spoiling the work and ruining the brush. All new brushes should be soaked in clean cold water for at least 24 hours. This will cause the bristles and the stock to swell so that they will not so readily part company. Brushes bound with a tin band should not be soaked for quite so long, or the band may burst.

New brushes should not be placed in upright position when soaking, but should be laid in a flat, shallow vessel, and this also applies to brushes that have been lying aside unused for some time. Brushes should never be put away without cleaning them of paint, this can be accomplished by washing thoroughly in a little turpentine, and rubbing dry with a clean cloth.

A loop of string should be tied on the end, and the brush hung up, the bristles being covered with paper to exclude dust. Treated in this manner brushes will last much longer.

Exterior Work. As an example of outdoor work, suppose it is desired to paint the rainwater gutters and down pipes with, for example, middle purple brown. The first step is to rub down the old paintwork, if in fair condition, give it a coat of anti-rust priming, and after this is dry apply two coats of ready mixed varnish paint (Fig. 3). A wooden fence, if in fair condition, should first be brushed down with a stiff bristle brush, like a scrubbing brush, dusted with a dusting brush, given a good coat of undercoating of any reputable make intended for outside work, or known as outside quality, and then given a coat of the common ready mixed paint; when this is dry and hard a coat of

ready mixed varnish paint is applied. If the work is not in good condition, the old paint should be burned off with a blow lamp, the surface levelled up with stopping, and the painting operations proceeded with as if for new work.

On the exterior woodwork of the house the windows may require the old paint to be burnt off with a blow lamp. Fig. 4 shows this operation in progress. When the paint is slightly warmed and burnt with the flame from the blow lamp, this has the effect softening it, and it is then cleaned off with a stripping-knife, as shown. The work should receive one or two coats of good quality outside undercoating or stopping, and be finished with two coats of ready mixed paint.

A door is treated in the same way, except that it should receive particular attention in the way of stopping all the cracks and holes. This may be effected with any of the special stoppings sold for the purpose, or ordinary putty may be used if the work be given a primary coat of undercoating, the putty being applied after this has dried.

If a particularly good finish is required, the work should be well sandpapered when the undercoating is thoroughly dry. Exterior stone or cement work should be prepared by brushing it over with a hard brush, filling in the holes or cracks with Keene's cement, and preparing the surface with red lead priming. This is followed with a coat of stopping or undercoating of outside quality, and finished with the paint, or may be painted with liquid cement, if cement colour is preferred.

Indoor Work. Interior work is prepared in the same way as the exterior, except that more attention should be given to the surface to make it as smooth as possible. This is followed with a primer or undercoating of inside quality, and the work then painted in the desired colour.

In painting new wood all the knots should first be brushed over with knotting, and then given a coat of priming or undercoating, the work well glasspapered and cracks stopped up where necessary.

To stop the pores of the wood and make a good foundation for the paint, apply one coat of stopping or first undercoat, sandpaper this when it is quite dry, dust it down, and give it a coat of undercoating or flat paint, and then finish it with a glossy or flat paint, whichever is desired.

The flat, or wall paints, as they are called, are intended specially for painting walls; but if the surface is new plaster the result is seldom entirely satisfactory. The procedure is to apply a priming coat and follow this with a flat colour, using the primer supplied by the makers of the wall paint. Water paints are generally applied to plaster work after it has been given a coat of size or priming, whichever is recommended by the makers of the particular paint to be used.

Wooden floors are often painted in the same way as any other work, so far as the preliminary cleaning and preparing are concerned, but the finishing may be carried out with one of the special floor paints.

Ironwork. The decoration or repainting of a stove is often carried out with a good quality Brunswick black when a glossy effect is required, but if a dull or so-called antique black is wanted, it is best to use Berlin black. If either of these colours is too thick to work nicely, it may be thinned with oil of turpentine. For painting radiators, interior water-pipes, cisterns, and the like, an aluminium paint is very effective. The first thing is to thoroughly clean the ironwork, removing all traces of rust either by scraping or by using a wire brush, as in Fig. 5. Water should never be applied to metal work; if necessary use instead one of the recognized paint removers, or wipe over the metal work with a rag saturated in turpentine.

When undertaking any painting operations, it is best to work in dry weather, and this applies specially to outdoor work. The paint should never be applied on a damp surface, as the dampness will almost certainly make the paint crack and peel off. To avoid dust settling on the wet paint surface, when dealing with interior work, water should be sprinkled on the floor, Or wet cloths may be placed about the room to keep the dust down, and the doors and windows should be kept closed.

Paint. Fig. 3. Applying anti-rust priming to a rain-water pipe. Fig. 4. Process of burning and scraping off the old paint by means of a blow lamp and stripping-knife. Fig. 5. Cleaning radiator pipes with a wire brush before applying a new coat of paint.

Cleaning Paintwork. One of the simplest methods of cleaning painted woodwork is as follows: The surface is first washed over with warm water which has been whisked into a soapy lather with a good soap, clean, soft flannel being used for this

purpose. The surface is gone over a second time with a cloth dipped in clear warm water and left to dry. A clean flannel is soaked in linseed oil, and when it has absorbed all the oil it is put aside until it is just moistened with the oil. The wood work is then wiped over with the oily cloth, rubbing it one way all the time. This process makes the paint look like new, and the linseed oil applied in the operation acts as a preservative to the wood.

Where the paint is very dirty the following method may be tried: To 2 quarts of hot water allow 2 tablespoonfuls of turpentine and 1 of skimmed milk or milk and water. Stir these ingredients together and add just enough soft soap to make the mixture soapy, but not a thick lather. The paint should be gone over with a clean flannel dipped into the preparation and wrung out so that the woodwork does not become sloppy. When all the paint has been wiped over, it is gone over again with a clean dry flannel, and will then be found to have taken on a nice lustre.

Paint that is badly soiled should be cleaned with a mixture of whitening and soap flakes. To make this, a packet of soap flakes is dissolved in sufficient hot water to make a thick, creamy lather. Crush to a powder a lump of whitening, and add enough of this powder to the soap lather to make it creamy.

Two bowls of hot water and the whitening and soap mixture in a basin should be at the worker's hand. A clean piece of rag is moistened from the one bowl of water, dipped in the whitening and soap, and then rubbed well into the dirty paintwork. It is advisable only to attempt to clean a small surface at once. When the stain has been gone over with the preparation, the rag is dipped in the bowl of clean water and the paint wiped over with this. Another dry rag is used for wiping it dry. The whole surface of the paint is cleaned in this way.

White paint can be cleaned with onion water. Boil 3 or 4 onions, or more if a large surface is to be cleaned, until all the goodness has gone out of them; then strain off the liquid. This can be used without soap for cleaning white paint. A clean rag should be dipped in the onion water and this rubbed over the paint. Polishing should be done with a dry duster, but a very slight rubbing up will result in a high gloss on the paint.

Milk can be used for white paint, or milk and water, the same method being followed as with the onion water. Fuller's earth can be used instead of soap for cleaning white or coloured paint; it is useful for cleaning a painted wainscot that has become very grimy. The fuller's earth is made into a paste with water, and a rag dipped into this is applied to the paintwork. A clean rag is used to wipe away the preparation and another rag to polish the paint after it has been cleaned. Soda should never be used. An excellent result is obtained after any of the above methods of cleaning have been followed if a little furniture cream is rubbed into the woodwork and a final polish given with a duster.

Paint Stains. Paint marks on clothes should be treated while they are still wet, otherwise they may be difficult to remove. Wipe off as much of the paint as possible, then rub the affected part with spirits of turpentine or spirits of wine, applying it with a soft rag or flannel. The same method should be adopted for dry paint marks, though the result may be less successful. If preferred, benzine may be used instead, but owing to its inflammable nature the operation should be carried out in the open air well away from any flame or fire.

Health Precautions. The smell of paint is unpleasant to most people, frequently causing headache and a feeling of nausea. When a house must be freshly painted, have it done if possible, in warm, dry weather, so that the windows can be kept open and the paint dry quickly. If green paint is being used, special care should be taken that it is free from arsenic. A freshly painted room should never be slept in until the paint has been dry for quite two days, and in winter a fire will be necessary in the room as well as open windows.

Painter's colic is chronic lead poisoning due to a want of care in cleaning the hands before taking food on the part of those who handle paint. In the case of an attack an emetic should be given at once.

Little children are always inclined to carry everything to their mouths, and therefore gaily painted toys should not be given them.

PAINT BOX. This may be purchased empty, designed to hold either water colour paints in pans or tubes, or tubes of oil colour, or may be obtained stocked with the requisite colours and brushes. The choice of a box depends to a large extent upon the nature of the work which is to be carried out by its aid. Thus, if most of the work is to be done out of doors, a more portable box will be necessary than when working in a studio or painting room. The simplest, and probably the most useful, is the small japanned tin variety with sections for colours; pencils, etc. Water colour boxes can be obtained in miniature sizes for sketching at any good artist's colour shop.

For oil colours a convenient size measures 10 in. by 6 in. by 1 in., and contains 12 tubes, with two glass bottles, one containing linseed oil (purified), and the other spirits of turpentine, fitches, pencils, etc., and a palette. If the colours are chosen carefully, with due regard to the type of work to be carried out, a box of this size will be found to answer most purposes satisfactorily. Cheap colours naturally lack the purity, transparency of tone, and smoothness of texture which accompany the better qualities, and they are also inclined to lack permanency.

The particular oil colours and brushes selected will depend upon the lines to be followed, but the following gives a suitable selection for general work: flake white, vandyke brown, light red, ivory black permanent blue burnt sienna, yellow ochre, raw sienna, and Prussian blue, in 4 in. tubes; with Naples yellow, chrome No. 1, vermilion, and crimson lake, in 2 in. tubes.

A 4 in. tube of McGuilph should be obtained in addition. This is the medium most generally used to mix or thin the colours and consists of a mixture of mastic varnish, linseed oil, etc. If it is intended

to specialize in landscape work, Indian red, burnt umber, raw umber and terra vert should be included, in which case it will be necessary to substitute 2 in. tubes for some of the 4 in. ones.

A useful selection of brushes consists of 2 sable and 2 squirrel hair brushes, 3 flat hog-hair brushes French if possible. Nos. 1, 3, and 5; and a larger one, No. 11. A palette knife dippers and cleaning rag are also necessary.

PAINTED CUP. This is a half-hardy perennial, botanically known as *Castilleja*, with floral leaves, or bracts. Three species are in cultivation, *pallida coccinea*, and *animate*, all requiring a very sunny and sheltered position, with protection during the winter. Planting is best done in April, from seedlings which are raised in heat and then hardened off in a cold frame.

PAINTING ON TEXTILE FABRICS

Simple Ways of Decorating Accessories for Home and Dress

Directions for other methods of applying ornamental designs to fabrics are given in the articles Embroidery; Pattern Printing; Pen Painting; Poker Work; Stencilling. For further related information see Bag; Fan Gesso Work; Lampshade; Needlework Picture; Pencil Painting.

In common with other decorative arts for the home worker, painting on silk, satin, georgette, velvet, gauze, cloth or linen depends almost entirely for success on suitable choice of design and colouring for the article selected to be ornamented in this manner. Painting on linen or canvas can be particularly beautiful when employed for panels to be used as mural decorations or to be framed and glazed as fire screens. Special mediums are required for painting on woven fabrics and can be obtained at shops which stock colours and materials for artistic crafts.

Perhaps one of the most important things is to find the correct consistency of the colour, for the material on which one is working. For instance, a delicate, transparent effect is essential for linen and taffeta, while velvet or cloth must be treated with opaque methods. Satin in light colours requires the delicate method, and in dark colours the opaque. Either effect may be successful on gauze.

Ivory coloured taffeta or satin can be painted in a style which has somewhat the appearance of etching. It is done with moist water colours, fine sable brushes, preferably Nos. 1, 2, or 3, and delicate effects are obtained by using tints of sepia or black. The piece of silk or satin, with white blotting paper beneath, is fixed to a drawing-board with drawing-pins, and the selected design is drawn in pencil or transferred by means of tracing paper. The outline is lightly defined with a brush and the shadows indicated. The brush must not be too full. Details are added and shading accomplished by cross-hatching lines, sky and water being lightly washed in. Seascapes are successfully copied in this method and old prints.

A combination of needlework stitches to raise portions of the design and of painting produces beautiful and uncommon panels for small screens or for use, under glass tops, on dressing tables. Flower pieces can be painted in the same way, but require flat washes of delicate colour after the manner of old prints. For other styles of painting on silk suitable for lampshades or candle shields the reader may consult the article on Lampshade. These methods can be adapted for designs for dessert doilies and for handkerchief sachets. Black or blue carbon paper should not be used for transferring designs on to delicate materials, but the design should be traced on to tracing paper, turned so that the heavily pencilled lines face the material and these are then gone over with a bone or ivory tracer. Special transfers may also be obtained from a good art department in a store.

Ordinary oil colours or stencil colours can be employed for painting on textiles, but must be used with the correct medium to prevent the paint from running or cracking. Pen painting is also used, and is described under a separate heading. It is well to avoid loaded materials. The preparation used

to stiffen certain silks may appear on the painted surface like specks of gummy substance. Such a material should, if possible, be washed before painting, in order to remove the dressing.

An Effective Method. A good method of decorating gauze, silk, satin or cloth is by using a special outfit of colours made for painting on these fabrics. A feature of this style of painting is a raised edge which forms a setting for the design and makes it effective for such accessories as satin night wear sachets, pochettes, cushions or gauze doilies. Bronze colours are used to outline the work, but these must be employed very cautiously or a garish appearance will result. Special coloured gold and silver flakes are also obtainable.

Painting on Textile Fabrics. Fig. 1. Making the raised outline on a gauze dessert doily. The tin nozzle is screwed on to the tube of special enamel. A thin, even line flows through the hole in the nozzle and resembles a fine cord on the work. (Courtesy of Winsor & Newton)

To paint a set of dessert doilies a 7 in. square of silk gauze will be required for each piece. Place this over the design selected (if a transfer is used, lay a piece of tracing paper between it and the gauze or the transfer ink may spoil the material) on a drawing-board covered with clean white blotting paper. Pin the gauze, as shown in Fig. 1, on to the board with drawing-pins. Do not stretch too tightly. On a saucer or china palette put out a little of the colours required; thin with turpentine and a little medium. A No. 3 sable brush can be used for filling in the design. The colour must be laid evenly on the gauze and the paler shades used first. When these are dry the darker shades are painted in.

The blotting paper should not be removed until the painting is finished. The colours percolate through the gauze to some extent, and unless left on the blotting paper or tracing paper till dry, the tints will be very pale.

The raised edge is made almost as if using a funnel for forcing icing on a decorated cake. A tiny paper cone can be used, filled two-thirds full with special enamel, the top turned over and pressed down till the bag is taut, and then a minute hole cut at the point. The bag is held between first finger and thumb and the point must not touch the work or the hole will be stopped up and the line become

uneven. The enamel flows in a thin line to form a fine cord. A tube of silver or gold flake or a bronze powder as used in gesso work is kept at hand to sprinkle over the line. This is allowed to dry and then the surplus flake is removed with a soft brush. For rather bolder outline a tin nozzle can be fixed to the tube of enamel and used as shown in Fig. 1. Nozzles are obtainable in two sizes.

Fig. 2. Suède cloth pochette decorated with a conventional design in special

colours for painting on fabrics and outlined with gold. (Courtesy of Winsor & Newton)

When painting on dark materials, as, for instance, dark satin for a nightdress sachet, yellow carbon paper can be used for transferring the design. Fix the work as already described. To paint, first fill in the design with white to kill the dark material and proceed, using stencil oil colours. Outline with the enamel, putting the small nozzle on the tube, and dust on gold flake for flowers and silver for leaves.

The pochette illustrated in Fig. 2 was made of beige suède cloth, but such a design could be equally well painted on a moiré pochette. The design should be traced by means of a yellow carbon. The flowers are painted in blues and shades of pink to deep rose, and the leaves in soft greens. Either barbola colours or special silk colours can be used. Outline very finely, using gold bronze dusted over the enamel.

Fig. 3. Georgette scarf with floral design painted in pastel shade; of green, mauve, blue and pink. (Courtesy of Winsor & Newton)

An idea for a scarf end is illustrated in Fig. 3, which is equally adaptable to a work bag. If using georgette or other transparent material in a pale colour for a scarf proceed as described for the doily. The art of painting on all such fabrics is to use as little colour as possible, leaving the material itself to form the high lights. The design was worked out in pastel shades of pink, mauve, blue and yellow with green for the leaves. Green and gold flakes were used for the enamel outline of the leaves and the flower outlines were covered with flakes to match. The design is repeated on the other end of the scarf. The special paints, medium, tin nozzles, paper cones, enamel and flakes used for this work are known as Dargeena materials for painting on fabrics. Other somewhat similar paints are known as Silkart.

Washable silks and georgettes which have been painted with these colours can be cleansed in a lather of good soap flakes and warm water.

The best method is to shake the article up and down in the lather in a glass preserving jar with a screw top.

Having rinsed it, press the article gently with a clean cloth to absorb the moisture, then iron carefully, placing a clean cloth between the material and the iron. Iron on the wrong side, and use a blanket or a soft folded towel to avoid flattening the raised edge.

Painting on Linen. When painting on linen, canvas or Arras cloth, oriental designs or simple tapestry ones are most suitable to use. A delicate, dull-surfaced effect is obtainable on such fabrics which is quite desirable for these designs when treated artistically. Oil stencil colours may be used with the correct stencil medium. Use a clean brush for each fresh colour. For a frieze or big panel, lay the piece of fabric flat on a large board and pin down the section which is being worked on. The design may be traced, ironed off from a transfer, or drawn freehand.

A good method of painting on linen, and one which has the advantage of being clean and simple to use, is by means of Aquarello water colour sticks and pencils. The sticks are for filling in large surfaces of colour and the pencils for outlining and washes over small spaces. The pencils are often used alone, and an experimental outfit can be purchased for 2s. The coloured leads are soluble in

water, can be applied to a linen or other textile surface, are fadeless and washable when properly fixed, and the colours can be blended.

The decorative linen panel with its Japanese design illustrated in Fig. 4 is coloured by means of Aquarello. Such a panel, measuring about 27 in. long and 18 in. wide, would when framed in narrow black and glazed form a delightful picture above a fireplace. The fabric to be painted is placed over white blotting paper and pinned down to a drawing-board. For a design similar to the one illustrated a Japanese print could be copied on to the linen in pencil, but the amateur, unless skilled in drawing, should practise with some simple design, such as a galleon in full sail or a floral pattern which can be traced in the ordinary way. Scraps of linen will do to experiment on before attempting an ambitious panel. Unbleached linen gives a beautiful effect, a white pencil being used for high lights and the colour of the linen being left in places for half tones.

To paint, dip a paint brush in water and moisten a small portion of the design. The colour is applied in strokes with the stick or pencil and afterwards distributed evenly with the brush. Be careful not to spread the water over the edge of a piece of the design where a firm outline is desired for the particular colour. Fill in the tints as desired, beginning with the pale ones. Detail can be superimposed by outlining with a pencil dipped in water. Before using carmine, yellow or sap green, fill in the portions of the design with the white pencil and work the colours over white.

Painting on Textile Fabrics. Fig. 4. Linen panel with Japanese design painted with water colour pencils. (Courtesy of Hazel, Watson & Viney)

For darkening red, and for outlining when shading, as for instance, on the red Japanese bridge in the illustration, use violet over scarlet. For darkening green, as for the detail of the foliage, use dark blue over green; to darken orange, use carmine for the shaded portions. To lighten any colour use the white pencil, either over or under the colour.

After completing the art work, allow the material to dry thoroughly. To fix, dissolve one tablespoonful of plain gelatine in a pint of hot water. When cool lay the painted linen in it. Take out without wringing, lay it flat on a towel, and leave it for 24 hours to set. Then press out by ironing on the right side. When soiled, the panel, or other article made of linen painted in this method, can be washed in the following way. Put three tablespoonfuls of table salt in a quart of water and let the fabric soak for five minutes. Then wash lightly in soap flakes. Rinse in clean cool water without wringing. Lay smoothly on a towel, roll up for a few minutes, and then iron on the right side.

Water colour pencil painting can also be used on georgette and other silks. It has a softer appearance on these fabrics than the other colouring mediums already described, but some excellent effects are possible.

PALETTE. A palette is usually oblong or oval in shape, and occasionally it is made to fold. Artists who work a great deal in the studio often use a large palette known as an elbow palette, which is shaped to fit the arm, and may be 16 in. to 18 in. long. A palette may be made of various materials, such as Honduras or Spanish mahogany, baywood, sycamore, satinwood, 3-ply wood, porcelain,

etc. It should be sufficiently light to cause no inconvenience when held in the hand for any length of time, and yet it should be thick enough to ensure it against warping.

To obtain and preserve a good surface on a wooden palette, take a piece of superfine sandpaper, rub gently but firmly all over, along the grain of the wood, and when satisfactorily smoothed pour a small quantity of fat oil on the palette, or use olive oil if fat oil is not procurable. Then spread all over with a rag, allow it to soak in for a few minutes, and remove the surplus. This process must be repeated until the desired gloss is obtained, which will probably take about a week. The final result, however, makes the trouble well worth while.

No oil colour should be allowed to stay on the palette after finishing for the day. All colour must be carefully removed with the palette knife and placed either upon a porcelain palette, into small cups and saucers, or even upon a sheet of glass, and placed under water. The palette should then be rubbed over until clean with a rag moistened with spirits of turpentine, and finished off with an oily rag.

Another variety is the scene-painter's palette, which is really a board 3 ft. 6 in. by 2 ft. 6 in. by $\frac{3}{4}$ in. thick, around three sides of which are small compartments, wherein are placed the various colours to be used on the screen or cloth, mixed with the fixing medium, size, etc., and blended in the centre space. This palette is stood firmly upon a stand or upon a pair of small trestles.

Palette Knife. This is used mainly for scraping the paint from the surface of a wooden palette, and is made of highly tempered steel, tapered to a round end, and fitted in a wooden handle. It should be kept perfectly clean and bright, and when not in use coated with vaseline or oil. In the bold and massive style of oil painting, the palette knife is often used to spread the colour on the canvas; and, when used with care, paint may be removed from a canvas as from a palette. A palette knife is a most useful kitchen implement for turning omelettes, etc.

Pallet. Strictly speaking, a pallet is a mattress made of straw. The word, however, is sometimes used for a mattress of any kind.

PALLOR. In most people pallor is an indication of ill-health. It is a common symptom among persons who live without sufficient light or fresh air, or who are overworked, or have not enough nourishing food. It is also often to be noticed in growing children, who by their rapid development have exhausted their strength. This must be treated by more fresh air and sunlight, better food and iron tonics, etc. A child who is not sent to bed in good time will invariably have a pale face.

A sudden pallor may occur from emotions either of joy or sorrow, a sudden shock, or a fit of passion. A sudden pallor which is not evanescent may be an indication of an internal bleeding. In those who are naturally pale the mucous membranes, e.g. the inner surface, of the lower eyelids and the gums maintain a good colour. If these are also pale, anaemia (q.v.) is present.

PALM. The common name of several groups or genera of evergreen plants which are natives of tropical and sub-tropical countries. One palm, *chamaerops excelsa*, is hardy in sheltered gardens in mild districts in this country, but others must be grown in a heated greenhouse. Several palms will flourish in a room window and small plants are grown in large numbers for room and table decoration.

The palms of chief value for cultivation in Great Britain under glass are *cocos*, *geonoma*, *corypha*, *kentia*, *latania*, *phoenix* and *rhapsis*.

Although if planted in a bed of soil in a large conservatory most of them will develop into large specimens, they are generally grown in pots or tubs, in which they will flourish for many years and remain of moderate size. The most suitable potting compost consists of two-thirds loam and one-

third peat with sand added freely: the pots must be well drained. Propagation is by seeds sown in pots or boxes of soil in a hothouse. Palms need shade from bright sunshine and thrive best in moist, rather warm conditions.

Cocos weddelliana is one of the daintiest of small palms for table decoration. *Cocos flexuosa* and *cocos plumosa* are more vigorous. The fan palm, *corypha australis*, is of less graceful growth, but hardier than *cocos*.

Palm. The species Corypha australis, a decorative pot plant

Another fan palm is *latania borbonica*; both are suitable for rooms, though their large leaves take up a good deal of space. *Geonoma gracilis*, *kentia belmoreana* and *kentia fosteriana* are palms which are in great demand for room and window decoration owing to their graceful habit of growth.

The date palm, *phoenix dactylifera*, is of less value in greenhouses and conservatories than *phoenix canariensis*, which develops into a large specimen. The palm called *rhaps flabelliformis* differs from the others in habit of growth: instead of being restricted to a single stem it becomes bushy owing to the development of suckers or shoots which grow from the base.

How to Grow Palms. 1. Sowing the gooseberry-like seeds: a, drainage; b, leaves; c, find sandy peat. 2. Box plunged under frame: a, manure; b, heat pipes. 3. Seed soaking for 24 hours before sowing: a, heat pipes. 4. Seedling potted: a, crocks; b, cinders; c, compost. 5. How to water palms. 6. Root-bound plant needing repotting. 7. Repotting in larger pot: a, new compost firmly rammed round old root ball; b, cinders; c, drainage. 8. Soot suspended in water for palm manure. 9. Effect of scale insect on palms.

PALMETTE. In architecture a palmette is a pattern in flat relief which ornaments plain headings at the head of a pillar or capital. In Greek and Roman architecture the design is usually of a fan-tail or palm shape. It is similar to the anthemion, an ornament in the form of a patternized flower or leaf used largely for decorative purposes, such as the honeysuckle ornament. *See Adam Style.*

PALMISTRY FOR THE AMATEUR

An Entertaining Feature for a Garden Party

This article is one of those that deal with the social and recreative side of life, others in the same class being Evening Party; Garden Party Amateur Theatricals. *See also Bazaar.*

The amateur palmist is often a successful entertainer at garden or indoor parties or charity fêtes. Out of doors she should be provided with a small tent, which may be decorated with stencilled black cats, crescent moons, signs of the zodiac, etc, and indoors with either a curtained alcove, or screened comer in which to receive her clients singly. Sometimes she wears a Spanish gipsy's costume, or eastern garb with a yashmak, and an aromatic brazier may add a touch of mystery.

Sitting opposite her subject at a small table, she can most conveniently study hands lying loosely on a cushion. A magnifying glass may be used, and a good light is essential. The hands should be laid palm downward at first in order to observe the nails and relative length of fingers to thumb. For a strong will the thumb should reach the middle joint of the first finger. Short shaped nails are a sign of critical faculty and fondness for detail; round nails indicate hasty temper; broad nails, sarcasm and love of argument; filbert-shaped nails, refinement, but lack of aggressive power unless allied to a strong thumb. In turning over the hands hold the palms firmly to ascertain whether hard or soft; the hard palm is one of the signs of strength, the soft of luxury; a long palm denotes obstinacy and selfishness; a wide palm courage; a narrow, bigotry. It should be remembered that good or bad qualities are often emphasized or neutralized by comparing one point with another.

Types of Hands. When the hands are lying palm upward they should be classified as one of seven types. The elementary has short, stiff fingers and palm large in proportion, indicating small brain power or self-control. The spatulate has wide, flattened-out finger tips, and broad rather thick palm equal in length to middle finger, indicating self-reliance, courage, patriotism, love of property; but if the heart line be poor, arrogance and lack of sympathy. The square has squared finger tips and firm, flat palm, indicating love of order, business acumen, and conventionality, but with undeveloped mounts of Venus and Luna, hypocrisy.

The conical has tapering fingers and smooth, slender palm, indicating love of beauty, refinement, good taste, but with small thumb and poor headline, laziness and discontent. The philosophical has tapering or square finger tips, and knotted joints; a long hand, indicating deep reasoning power and appreciation of beauty, with the dominating interest of truth. The psychical type has rounded finger tips, narrow palm and slender thumb, indicating idealism, imagination, and occultism. The mixed has one finger spatulate, another tapering, and so on, indicating a person with facility for many things; but in a weak hand, indicating instability.

The Mounts. The next points to be studied are the mounts or fleshy risings on the palms. Jupiter's mount is at the root of the first finger and shows generosity and ambition; if rising excessively arrogance is denoted, or if deficient, selfish coldness. Saturn's mount is at the base of the second finger, and indicates prudence and wisdom; if highly developed it denotes occultism, if excessively so a tendency to melancholia, and if deficient insignificance. Apollo's mount, at the base of the third finger, indicates love of beauty, artistic talent, and desire for recognition; if excessive it denotes vanity and love of notoriety at any cost; if deficient, materialism dominates the rest of the character.

Mercury's mount is at the base of the little finger and indicates love of change and excitement, activity and cheerfulness, good practical capacity or inventive power; if excessive it denotes an inordinate desire for gain; if deficient, a lack of brain power. There are two mounts of Mars, one below Mercury's, on the percussion of the hand and the other below Jupiter's. If full, both mounts denote courage; the former also passive endurance and coolness in emergency, the latter leadership; if excessive they indicate tyranny and violence; if deficient, lack of self-command and timidity. Luna's mount is opposite the root of the thumb and indicates imagination and romance; if excessive, it denotes love of mystery, caprice or morbidity; if it is deficient, lack of imagination. The mount of Venus is the lower part of the thumb and indicates love of beauty, harmony and pleasure; if excessive it denotes inconstancy and luxurious tastes; if deficient, coldness and lack of sympathy. A hand in which all the mounts are equally developed shows a well-balanced character. In a spatulate hand a good Mercury's mount indicates scientific ability, or with both mounts of Mars full, a soldier or sportsman. In a mixed hand a good Apollo's mount with Luna's well developed denotes the characteristics of a practical artist.

Palmistry. Diagram of left hand illustrating principal lines and significant parts. Fingers: A, Jupiter B, Saturn; C, Apollo; D, Mercury; three phalanges shown numbered. On the hand, 1, 2, 3, and 4 are mounts of Jupiter, Saturn, Apollo, and Mercury respectively; 5, mount of Luna; 6, mount of Venus; 7 and 8, mounts of Mars. Principal lines: E E, life; F F, head; G G, heart; H H, fate; X X, Apollo.

Meanings of the Lines. The principal lines of the hand are the lines of life, of the heart, head, fate, fortune and health. Red lines are an indication of cheerfulness and vitality; pale lines of weak character, purple lines of melancholy. Chained or broken lines are a sign of obstacles or weakness, wavy lines of periodical bad luck. Double lines are good; sometimes the second line appears by the side of a break, counteracting the misfortune or ill-health which would otherwise be denoted. Many lines on a palm, besides the six mentioned, indicate a nervous temperament, capable of keen joy or sorrow, while few extra lines may be taken to mean that the subject is not easily impressed or worried by surroundings. Lines on the left hand are said to denote the character and fate at birth, on the right what the subject or circumstances make them.

A good life line should be clear cut and surround the base of the thumb, starting from midway between the fork of the thumb and root of first finger. A break indicates illness or an accident, if shown in the right as well as the left hand. Fine lines crossing the life line from the mount of Venus indicate the influence of other persons.

The line of head should go right across the palm near the middle and be clearly defined. Should it join the beginning of the life line it shows lack of self-confidence, but if there be much space between the two lines rashness is denoted. Many small lines crossing the head line indicate

headaches, and if it lie close to the heart line it is a sign that the heart rules the head. A fork at the end with a good mount of Mercury means argumentative power; with the mounts of Apollo and Luna well developed, literary ability.

The heart line starts beneath Mercury's mount and crosses to Jupiter's. Without branches it indicates a loveless life, forked under the first finger, ideal affection. When it ends between the first and second fingers it denotes a temperament lonely from inadaptability.

The line of fate runs up the centre of the hand more or less to Saturn's mount. If this line be clear and long it may balance a poor life line, especially with a good mount of Mercury. Age on the fate line is reckoned from the wrist upwards (the opposite applies to the life line), the head line cutting it at about 30, the heart line at 45 and the rest of the fate shown above. Should the upper portion be firm and clear, in contrast to the lower, success or happiness will come rather late in life.

Sometimes this line is missing, in which case the existence is uneventful. If it goes direct from the wrist to Saturn's mount it means good fortune without much struggle for its attainment. When broken below the head line it is an indication of mental and moral struggle, but if the line of fortune be good and the fate line start again, success will eventually be achieved. If the fate line is broken, but a second line starts by the break and carries on to Saturn's mount, it means that a new career is entered upon; when lined or chained at the beginning it indicates an unhappy childhood.

The line of fortune, or Apollo, may start from near the life line, from the fate line or from the heart line, and goes to the root of the third finger, denoting success in art, fame, riches or honour. Should this line be absent, even with a good fate line, the subject will have to work hard with small success. With a well-developed mount of Venus, music or painting is indicated; with a good mount of Luna and forked head line, literature; with a spatulate third finger and full mount of Apollo, dramatic work. Should the line be weak before meeting the heart line and then clear above, it shows that difficulties arising in the way of artistic success will be, or have been, overcome.

The marriage line is on the percussion of the band, at the side of Mercury's mount and above the heart line, running horizontally with the latter. An early marriage is indicated by the line being near the root of the finger; midway between that and the heart line the marriage would be about 30, lower down at 35 or later. A line from the mount of Venus will probably be found to cut the life line at the age.

Should the marriage line be forked on Mercury's mount it is a sign of separation, and many small lines on the percussion denote short love affairs. A second deep line, if the first be cut through, denotes a second marriage. Small vertical lines to the root of the little finger from the marriage line are said to indicate children. The ring of Venus encloses the mounts of Saturn and Apollo, and when clear and unbroken is a sign of ardour, ability, and a sensitive nature.

Three good lines across the wrist at the base of the palm are said to denote prosperity and to strengthen the life and fate lines. Crosses on lines are indications of trouble, the nature of which is decided by the line on which they appear. Stars are taken to be circumstances outside control. On Jupiter's mount a star means ambition, gratified by others; on Saturn's, undeserved misfortune; on Apollo's, celebrity; on Mercury's, dishonesty; on the mount of Venus, a happy marriage. A star on the life line signifies a catastrophe, on the head line an accident. Squares indicate protection from some evil; a square round a star nullifies a bad meaning and intensifies a good one. A triangle, formed on a line by two other small lines, is an indication of added power.

PALM OIL. The yellow solid fat yielded by a W. African palm is used in the manufacture of soap, and, when purified, as one of the ingredients in margarine. On account of its rich yellow colour palm oil is employed for colouring pomades, only a small proportion, 1 dram to 1 oz., of other fats being required. *See Oil.*

PALPITATION. In health the action of the heart is not noticed. Under certain circumstances, however, a violent, irregular beating or fluttering may take place, causing distinct and often most unpleasant feelings in the chest. Any strong emotion, such as fear, joy, sorrow, or anger, may bring this about. A very common cause is indigestion, and a heavy or unwholesome meal taken late at night will frequently bring on an attack. Too much tea, coffee, or alcohol, or excessive smoking, are other frequent causes. Palpitation is a symptom of anaemia and some diseases of the heart.

The cause should be ascertained, and if anaemia, indigestion, or any similar condition is present, it should be rectified. When associated with a nervous condition, a healthy, regular life is the best remedy.

During an attack give the patient air, and let him keep still, lying down, but with the head and shoulders well raised on pillows, as palpitation is wont to give a feeling of suffocation. A teaspoonful of sal volatile given in three-quarters of a wineglassful of water will help to relieve the patient; or a little brandy or whisky will answer the same purpose. A large mustard plaster applied over the heart will be beneficial. *See Heart.*

PAMPAS GRASS. With its tall silvery plumes in autumn the hardy perennial pampas grass attains a height of from 6 ft. to 8 ft.; the small flowers are white, blue, or yellow, according to species. It is useful as a centre group or specimen on lawns, and is propagated by seeds. It prefers shelter to sun, and the plumes may be gathered for the purpose of indoor decoration as soon as they are developed.

The technical name is *Gynerium argenteum*.

Pampas Grass. Tall plume-like seed heads and foliage of a hardy perennial useful for an open space in a large garden.

PAN. A pan is a broad, shallow vessel used for cooking and other purposes in the home. Pans are of several kinds, each made to suit the purposes to which it is put, e.g. frying pan, porridge pan, preserving pan, etc. *See Baking; Bed-Pan; Bread Pan; Frying Pan; Saucepan, etc.*

PANADA. The meaning of panada is bread soaked or boiled with milk or water. The term is applied to any thick boiled paste made with flour, butter, and water, or flour and milk, as the basis of a savoury or sweet dish. For example, water, butter, and flour boiled together to form the foundation of choux pastry is called a panada.

To make a bread panada, place the crumb of a new roll or a small portion of the crumb of a loaf in a stewpan with about a teacupful of water and a little salt. Boil until it becomes a pulp and add more water, as that which was first put in boils away or is absorbed. When quite soft remove it from the fire and beat in quickly the yolks of 2 or 3 eggs, previously whipped together. Sugar may be added to taste, also flavouring of nutmeg, cinnamon or lemon, and a glass of wine, if approved of, for those who are adults. Milk panada is made much in the same way, but the bread should be boiled with as little water as possible, and when cooked new milk should be added to it, and it should be flavoured and sweetened to taste. The milk should not be allowed quite to boil, but must be very hot. *See Cream Bun; Pastry.*

PANAMA HAT. This is a very light, folding hat made from the young leaf of a palm which grows in America. The leaf is finely plaited into hats, which can be rolled up into very small compass, and are prized for their lightness, flexibility and wearing quality.

Though Panama hats seldom or never wear out they become tanned with the sun or soiled, and need periodical cleaning. This can be done at home by rubbing the hat all over with a clean rag soaked in lemon juice, which has a whitening effect, or by using a straw hat cleaning preparation obtainable at a chemist's. *See Hat.*

PANCAKE. How to Make. The success of this dish depends on the quality of the ingredients employed, fresh eggs and pure milk being essential, and on the thorough beating. The fat also in which the cakes are fried should be white and tasteless, and should not have been used previously for any other purpose.

For family use an economical batter will answer the purpose, and to make this, take 1 pint milk, 3 eggs, $\frac{1}{2}$ lb. fine flour, and a saltspoonful salt. Sift the flour and salt together in a basin, make a well in the centre of the flour and beat in the eggs one by one, using only sufficient of the flour to form a thin paste. By degrees beat in of the milk and the remainder of the flour, and continue beating until the whole looks light and frothy. The consistency of the batter while beating should be that of thick cream.

When mixed, add by degrees the milk left over, pour the whole into a jug and put it by for an hour or two, giving it an occasional stir. Before frying, have ready, melted in a small saucepan, some lard or clarified fat. Pour in enough fat to cover the bottom of the pan, let it become smoking hot, then add a thin layer of batter, move pan about until batter spreads evenly, and fry it until the underside is a rich brown. Toss the cake, or turn it with a thin aluminium slice, and fry the other side. To toss the pancake, shake the pan gently until the pancake slips down over the edge of the pan, give pan a sharp, upward flick with the wrist, when cake will turn completely over into the pan. When brown drain it on a hot dish covered with kitchen paper, dust it with castor sugar, sprinkle it with lemon juice, roll up, and keep hot until the other pancakes are fried.

Left. Pancakes, a dish widely recognized as the Shrove Tuesday sweet. Right. Pancake. Tossing the half-cooked pancake, to try the other side.

Castor sugar should be handed round with them, also lemon cut into convenient pieces. To vary the flavour, jam or orange may be substituted for the lemon. A richer batter may be made by increasing the number of eggs to 5, and decreasing the milk by 2 tablespoonfuls for each egg that is added.

Irish pancakes are made with 4 yolks and 2 whites of egg to each $\frac{1}{2}$ pint milk. To make them, melt in the milk $1\frac{1}{2}$ oz. butter and $1\frac{1}{2}$ oz. castor sugar. Whip the eggs well and stir them into the milk, then beat to them by degrees a small teacupful of flour. Fry these pancakes without turning them, and use a very thin layer of batter. They should be piled, when dished, one on top of the other and served with sugar and whipped cream.

French Pancakes. The French pancake differs in method, as the yolks and whites of the eggs are whipped separately. For a dish of French pancakes, take 5 eggs; separate the yolks and beat them up with 3 oz. castor sugar and the same quantity of very fine sifted flour; add the juice of $\frac{1}{2}$ a lemon and a $\frac{1}{4}$ of the peel grated. By degrees beat in $\frac{3}{4}$ pint of milk. Now fold in lightly the whipped whites of the eggs. Half fill buttered saucers with the mixture. Bake in a quick oven 15-20 min. Turn out on to sugared paper, put a spoonful of jam in middle, and fold.

Yeast pancakes are made from the same mixture as doughnuts and cooked in the same way, but are rolled into small, round, flat cakes about $\frac{1}{2}$ in. thick. Jam is put on one piece and another piece put on top and the two pressed well together before frying.

Savoury Pancakes. For savoury pancakes an ordinary batter may be used, and about 4 oz. of finely chopped cooked game or chicken, well seasoned, should be added just before frying. The batter should be flavoured with parsley, herbs, a shallot or chive chopped fine, 4 oz. meat to 1 pint of batter.

PANCHROMATIC PHOTOGRAPHY

Modern Methods of Obtaining Correct Colour Values

The use of panchromatic plates and films for correct rendering of colours into black and white is shown in this article to be simple and well within the capabilities of the amateur photographer. See
Developing; Photography; Portraiture.

Photography with panchromatic plates and films makes it possible to secure the very best representation of coloured subjects in monochrome. The ordinary photographic plate is far more sensitive to rays of blue light than the eye, and also to ultra-violet rays, which the eye does not perceive at all. In addition it is very slightly sensitive to red, which it renders as black (hence the red darkroom lamp) and is not sufficiently sensitive to yellows and greens. The effect given by an ordinary plate is very similar to that gained by looking through dark blue glasses, such as are used by climbers for overcoming the glare from sunlight on expanses of snow.

It is not merely that all objects are seen through the blue glass as one colour or monochrome. The relative brightness of the different colours has changed; bright yellows, reds and greens become dark, while blues and violets, which are usually seen as dark colours, become light. Further, the clouds in the blue sky have disappeared. Orthochromatic plates and films overcome the difficulty to a certain extent, but they give very little help in dealing with the renderings of reds and browns, and are not perfect in their translation of yellows.

Films of the Selochrome and Verichrome type are very highly orthochromatic and are completely satisfactory for many purposes.

In conjunction with them filters may be used to improve the colour rendering, but with orthochromatic materials the use of very heavy filters is not advisable.

Panchromatic plates and films give a fairly good representation of coloured subjects even when used alone, but to secure absolutely correct rendering of coloured subjects in monochrome filters must be used. The filter may be looked upon as a fine adjustment whose function is to make the colour sensitivity curve of the emulsion resemble that of the human eye. But it must not be forgotten that filters can be used for other purposes than to secure correct translation of colours into monochrome. In many cases it may be desired to increase the contrast between adjacent colours, and this can easily be done by choosing a suitable filter. The use of panchromatic plates and films in conjunction with filters gives the photographer complete control over the tonal contrast of the different parts of a coloured subject. For correct representation in monochrome the Ilford Gamma or the Kodak K.3 should be used, but where the lighting conditions are such that the use of one of

these filters would mean too long an exposure the Ilford Beta should be used. The best form of light filter is that which consists of dyed gelatine, either used alone or mounted with Canada balsam between glass. Filters in which the glass itself is stained are not usually so satisfactory as it is difficult to get exactly reproducible results in stained glass. The gelatine filters can be bought and used either in the form of gelatine film or as film cemented between plates of thin glass. Ordinary glass or thin plate which has been optically worked may be used. The latter is much more expensive, but with a high-class, long-focus anastigmat lens it is essential since ordinary glass is liable to impair the definition.

The filter is conveniently used in front of the lens in a holder with a spring adaptor to clip over the lens mount.

Filters to be used with Kodak and Ilford Panchromatic materials, with times of exposure (daylight only), subjects and the comparative exposures, are given in next page.

Exposure factors of Kodak and Ilford filters are average figures and only to be considered correct when used with Kodak and Ilford panchromatic materials respectively. Weather conditions and different forms of artificial light will affect the figures to a considerable extent. Ilford Limited make a filter called the H.W. which, when used with panchromatic materials in half-watt light, produces a result similar to the appearance of the subject when seen in daylight.

Care should, of course, be taken to see that exposure is reasonably accurate. The amateur photographer will find a reliable exposure meter (q.v.) of great assistance.

There is now a wide range of panchromatic materials, films and plates from which to choose, from slow fine-grain emulsions to specially fast products designed for action photography, for artificial light work, banquet and theatre photography. Coupled with recent advances in camera design and especially with the wide-aperture lenses now available there are very few places indeed where action pictures cannot be secured. In portrait work, even of the snapshot variety, and with portraits taken out of doors, very great improvements will be obtained by the use of panchromatic films. Almost all complexions have small patches of hardly visible red, which the ordinary plate reproduces as black blotches. It also accentuates wrinkles and freckles, and red or golden hair comes out much too dark. A panchromatic plate or film with a K.1½ or Alpha filter overcomes these difficulties without making it necessary to retouch the negative. In landscape work the ordinary plate renders the sky as a harsh solid white, since it is unduly sensitive to the blue of the sky, so that the white clouds are altogether lost, that portion of the negative receiving relatively greater exposure than the foreground portion. With panchromatic plates and films it is possible to get clouds and landscape on the same negative, as the filter keeps back a portion of the blue rays. Moreover, a landscape usually contains many different tones of greens and yellows which ordinary plates reproduce in monochrome.

Striking examples of the improvements achieved by panchromatic films and plates are shown in the illustrations. The panchromatic rendering is enormously superior in every case to that of the ordinary plate.

The fact that panchromatic plates and films are sensitive to all the colours of the spectrum makes it necessary to use some extra care when handling them in the darkroom. The red lamp is quite unsafe and only the very feeblest of green lights of special quality can be permitted. Safelights for panchromatic materials are made, such as the Ilford G and the G.B., the latter being advised for the fastest films and plates. Even with these safelights, hypersensitive plates may not be more than glimpsed. However, with a little practice it becomes an easy matter to develop in total darkness using the safelight only to illuminate the clock. Under these conditions development is carried out by the time and temperature method.

Panchromatic Photography. These two photographs, taken from precisely the same viewpoint and under similar conditions of lighting, demonstrate the superior tone and detail renderings obtained with a panchromatic film in conjunction with a filter. Left: photo taken on non-colour-sensitive material. Right: results obtained with a panchromatic film. The fine richness of tone and rendering of the sky and clouds seen in the latter are entirely lacking in the former. (Courtesy of Ilford, Ltd.)

Panchromatic Photography. Left, inlaid mahogany cabinet photographed on an ordinary plate. Right, the same cabinet photographed on a Kodak Eastman panchromatic film with G colour filter, showing the amount of detail obtained and the superiority in colour rendering.

Photograph taken on a plate with ordinary uncorrected emulsion on a sunny but misty November day. Detail in the distance is badly rendered and the sky is an unnatural hard white.

Below. Left. The same scene taken on a Kodak Eastman panchromatic film with a Kodak G filter. Panchromatic films and plates are particularly valuable in landscape photography.

PANCRATIUM. This is the name of a genus of vigorous bulbs of which the chief favourite is *Pancratium fragrans*. It bears umbels or bunches of white sweet-scented flowers and must be grown in a hothouse in a compost of loam, peat, and sand. During the period when the bulbs are at rest little water is needed, but in the growing season the soil must be kept thoroughly moist. *Pancratium illyricum* is hardy in sheltered places in mild districts.

PANCREAS. The pancreas performs a double duty. It supplies a juice which helps to digest food in the stomach, and also an essential hormone for the blood. Owing to its deep, sheltered position, injuries of the pancreas are rare. Diseases are rare but grave. Acute haemorrhagic pancreatitis is sometimes fatal, as is also cancer of the pancreas. Among the causes of chronic pancreatitis are alcoholism and arterio-sclerosis.

PANEL: In Woodwork. The term panel is used for an area recessed below the general surface. Usually the panel is a piece of wood separate from the framework enclosing it, and in the majority of cases it is thinner.

Filter	Exposure Factor A.	Uses	Relative Factor B.
K 1	1½	Snapshot ; minimum exposures	3
K 1½	3	Best correction for orthochromatic plates	5-8
Ilford Alpha (a)	1½-2	Most ordinary subjects, short exposures	3-4
K 2 Ilford Beta (B)	3	General use, landscape, portrait, snapshots with fast lenses	8-10
K 3	4½	Correct renderings of difficult subjects	—
Ilford Gamma (γ)	4	Correct renderings, all colours, coloured pictures and objects	—
Kodak G (orange) Ilford Avio!	6 1½-2	Telephotography, to overcome haze in landscapes	2-3
Kodak A (red)	12	Furniture, etc., with reds and yellows	—
Kodak F (deep red)	24	Great contrast for deep reds and browns in old furniture	—
Ilford Delta (δ)	4	For strong rendering of clouds	—

(A) Exposure factor for panchromatic plates or films.
(B) Relative exposure factor for orthochromatic plates or films.
For Kodak Verichrome film the exposure factors are as follows :
K 1 = 2 ; K 1½ = 4 ; K 2 = 8
Ilford Limited manufacture three filters particularly suitable for orthochromatic materials, viz: Chromatic I, II, & III.

Roughly speaking, the object of the panel is threefold. It is the result of an effort to obtain lightness in construction without detracting from the strength of the work; it reduces the risk of warping and splitting, and it effects an economy in material. Fig. 1 shows a panel of $\frac{1}{2}$ in. material surrounded by a framework of 1 in. stuff. The requisite strength is maintained by the grain of the top and bottom rails running at right angles to that of the panel, and at the same time preventing it from twisting. Fig. 2 shows how the panel is held in the framework within a groove without being fixed, so that it is free to shrink independently of the frame, thus lessening the risk of splitting. If the panel in Fig. 1 had been glued in, or otherwise rigidly fixed to the frame, the pull caused by its shrinkage, as shown by the arrows, would be opposed by the fixed resistance of the top and bottom rails, and this would result in splitting.

Where a panel is not grooved into the frame, but kept in position by two mouldings, as in Fig. 3, the nails holding the mouldings must be driven into the frame as shown, and must not pass through the panel. When it is desired to groove a panel of more than $\frac{5}{16}$ in. thick into a framework of 1 in. stuff, the panel should be bevelled off at the edges, as in Fig. 2. The panel should fit hand tight in the groove, and the best method of testing it is to groove a spare piece of wood, called a mullet (Fig. 4), with the same size of groove as that to be worked on the frame, and test this round the edge of the panel.

False and Raised Panels. A false form of panel is shown in Fig. 5, a moulding being mitred round a solid piece of wood to give a panelled effect. Fig. 6 shows a particularly effective type known as a raised panel. The stuff is first thickened, and the width of the bevelled portion and its inner and outer depths gauged round. It is then rebated down to the shallowest gauge line, working across the grain first, and then bevelled down to the lower gauge line, care being taken to prevent the comers from chipping out; the small hollow moulding is worked last. First thickness the stuff carefully, or the bevelling will result in the edges being uneven in thickness.

All the stuff used for the panel should be as clean as possible, and when the work is to be polished should, wherever possible, be of one piece. Very wide panels are jointed up in their width, using either dowels or a tongued and grooved joint when the wood is sufficiently thick to take them.

Another type of panel is that used when conditions require that the panel shall finish flush with the framework, as in certain large table tops. The face side is rebated, forming a tongue which fits into the groove in the frame, as in Fig. 7. A good plan is to run a bead along the rebated edge of the panel with the grain, as shown. The reason this is done is that in the event of the panel shrinking the open joint will not be so noticeable.

The best method of securing a panel not grooved into the framework is to pin a bead in the rebate at the back, as in Fig. 8.

This not only leaves it quite free to shrink independently, but the panel can be removed easily by raising the beads.

Fig. 9 is a decorative panel for use in oak work; as in the case of the other panels, the mouldings are attached to the framework and not to the panel. Fig. 10 shows the main construction, consisting of a plair square edged frame mortised together and having pieces planted on to the edge wherever the break-forward parts occur.

A rebated moulding is mitred round as shown, and the panel is then cut to a corresponding shape and fastened in with beads. *See Cupboard; Dado; Door; Hall. (See next page for details.)*

Woodwork.

PANEL DOCTOR. A panel doctor is one who attends persons who are insured under the national health insurance scheme. The majority of general practitioners take panel patients. With certain limitations insured persons can choose their own doctor, but if a particular doctor has already as many insured persons as he is allowed he is not available. Also, a change of doctor can only be made twice a year. On accepting a patient, the doctor signs the insured person's card, and the latter is then entitled to free medical attention from him. *See Insurance.*

PANELLING: ANTIQUE AND MODERN WORK

A Beautiful Form of Household Decoration

Practical advice is given here about the actual performance of the work. Attention may be drawn to such articles as Ceiling; Chimney Piece; Decoration; Dining Room; Hall; House; Library; also Georgian Style; Jacobean Style; Linenfold; Oak; Paperhanging.

Panelling may be described as covering the surface of a wall, door, ceiling, or other part of a building with panels, which are raised or sunk compartments, generally framed at the edges. The materials used are wood, stone, and plaster.

Panelled walls in the interiors of houses in England date from medieval times and in crude form appeared before tapestry began to be used. Panelling was not unknown to the Normans, but it was during the period of Gothic architecture known as Early English that it began to develop in this country. In work of the 12th and 13th centuries the square panels were ornamented and the larger ones were often deeply recessed, so as to form niches with trefoil heads and sometimes with canopies.

History of Panelling. In the Decorated or second period of English Gothic architecture, the enrichments of the panel became more elaborate, and the latter were often filled with shields, foliage, or figures. The use of panels became very common in the third period, known as Perpendicular, when the walls of the buildings of importance were frequently entirely covered with long, short, or square panels, the square ones being frequently filled with almost every kind of ornament. Most of the existing examples, however, are not earlier than the 17th century, though Tudor panelling, often with characteristic linenfold ornamentation, is still seen. All through the 18th century panelling was employed in comparatively small houses, and its use was not seriously interfered with or lessened until the introduction of cheap wallpaper.

In Elizabethan and Jacobean work the small wood panel appeared sometimes with an inlay of coloured wood, and with gradually increasing elaboration of the moulding of its frame. The plaster panels of the ceilings of the time became correspondingly rich in decoration.

A typical room showing the fine workmanship in English panelling of the early 17th century would include the following elements: The overmantel consists of the royal arms carved in very high relief and having on either side a niche between two partially fluted columns; the whole rests on a long shelf, decorated with flat strapwork ornament, and supported by two terminal figures. The panelling is divided at intervals by pilasters with flat strapwork. The cornice is enriched with a dentil moulding and brackets, and the frieze beneath has similar strapwork ornament.

After the middle of the 17th century the size of these wood panels was greatly increased, and towards 1700 they developed the long oblong of the Palladian style with bolder mouldings. In the 18th century the taste of Robert Adam reduced the size of the panel to more reasonable proportions, especially in his treatment of doors. About the same time the moulding was simplified, and it became the fashion to paint panels in white or cream. Later developments are seen in Fig. 1.

There is no form of wall treatment which has so satisfactory a relationship to the structure of the building as panelling. It should be designed to fit in with chimney breast, door, and windows,

forming altogether a co-ordinated scheme. The careful design of panelling can correct an unsatisfactorily proportioned room, modifying its apparent length, height, or width. Panelling is in itself a decoration, and although it is a background to furniture, it essentially restricts freedom of applied ornamentation to the walls in the form of pictures and other hanging details.

*Panelling. Above. Fig. 1. Pine panelling in a Georgian room of about 1785. Note the simple, shallow panels, the restrained use of rich carving, the decorative ceiling cornices and the niche shelves.
(By permission of the Director, Victoria & Albert Museum, South Kensington)*

Left. Fig. 2. Example of English old oak panelling, showing the characteristic small size of the panels.

Fig. 3. Fine example of early English work in heavily carved panelling. (By permission of the Director, Victoria Albert Museum, South Kensington).

Modern Panelling. For modern rooms, which are very often too high for their length, it is usually satisfactory to stop the panelling at about 7 or 8 in. from the ceiling. This leaves a frieze above, between the upper moulding of the panelling and the cornice. It presents an opportunity for introducing a valuable decorative feature which may be treated in numberless ways. Should the panelling be dark brown, however, it is wise to allow the frieze and ceiling to be cream or a very pale buff or apricot shade to preserve a large area for reflecting light into the room, for one of the drawbacks of dark panelling is its absorption of light. It is not a good reflecting surface. On the other hand, a room may be treated with deal or pine in panel formation from skirting to cornice, the whole wall being then painted or stippled any desired tint, ivory, pale or deep green, or grey being common, and the moulding picked out with a lighter or deeper colour, or with gold or silver leaf. Painted panelling also looks well with modern furniture when the colour is stippled and shaded to deeper tones towards the mouldings. Grained effects may be used to imitate cedar, mountain ash, or walnut. Beautiful and dignified panelling for hall and staircase or dining room is carried out in the grained effects enriched with judiciously applied gold ornaments and mouldings.

British Columbia pine is used for modern panelling either with a waxed satin finish, which lends a fawn shade to the figuring of the wood, or stained and finished in brown. Another British Empire timber employed is Canadian birch, with a silver-grey finish which looks well when inlaid with a cross-banding of black to divide the panels. The rapid progress made in the manufacture of plywood brings panelling effects within reach of many more people. The most beautiful woods, by means of improved veneering methods, are obtainable at a fraction of the cost of the old style panelling. Any kind of classical panelling can be fitted in an existing house at a reasonable price.

A point to be taken into consideration with regard to this form of mural decoration by those who are building or reconstructing houses to be newly furnished is the fact that far fewer accessories and pieces will be required in a panelled room than in one that is painted or papered. Many ornaments or pictures simply kill the design of a well panelled room. When building, panelling lends itself naturally to the inclusion in the dining or living-room of built-in furniture such as cupboards, bookcases, niches with shelves and sideboards. A great saving in buying such or equivalent pieces of furniture is therefore effected, and a uniform result obtained which makes a harmonious setting for beautiful furnishing fabrics in styles selected to correspond with the panelling of the room.

An additional point in favour of natural timber panelling is that such decoration does not involve the recurring expense of periodical renewal, whereas the sum spent on repainting and papering the walls—for instance—of a hall and staircase in one's own house would be considerable over a period of years.

The development of modern wallpaper decoration has placed at the disposal of the builder an almost infinite variety of imitation panelled walls. Many patent materials are employed in the design of papers which closely reproduce the effect of wood. The danger of this imitation panelling is its facility of application, for under inexpert or careless handling it can easily be made to look as though its features do not fit the room, and the essence of the decorative value of panelling lies in its close relationship to existing structural features. The greatest care is necessary to select imitation panelling of such proportions of moulding, rail and panel as suit the size, shape and style of the room to be treated.

Repairs to Panelling. The framing of panelled work is not so liable to faults as the panels themselves, which, owing to excessive shrinkage or decay, sometimes require attention. Those portions which, owing to decay, are in need of repair, should be cut out as far as possible at an oblique angle, and new material, matching in grain and colour, carefully fitted and glued into position. The removal of a defective panel is not difficult if the framing is moulded on the edges,

the method being to cut away the moulding surrounding the panel in the form of a rebate. After the panel has been repaired or renewed, the original moulding is reproduced in the form of beading and glued and bradded into position.

For plain work, apart from taking the whole of the job down so as to work from the rear, the only method of dealing with a defective panel is to cut away sufficient wood from stiles and rails to allow of its removal. In this case the rebates should be very carefully trued up, using a straightedge, so that new pieces, matching in grain and colour, can be glued in when the panel has been fitted in.

Panelling a Room. Panelling can be done by the home worker in two chief ways. He can use grooved framing, or may employ a perfectly plain framework and secure the panels with suitable beading, the latter being much the simpler method. Although oak is generally used for the whole of the work, a good effect is obtained by using deal for the framework. This can be stained to a suitable colour, and the fitted panels cut from oak plywood. The use of plywood is preferable to thin boards, as the beauty of the grain is retained and it is not liable to shrink. Ready machined oak or other hardwood can be obtained which is grooved for panelling. Some has a 3/16 in. groove for use with plywood.

Panelling. Fig. 4. Applying the ceiling boards before panelling with strips of wood.

Fig. 5. Panelling with rough-hewn oak strips on a plaster ceiling.

Fig. 6. Wall hung with oak-grained paper and panelled with stained deal strips.

In the older types of panelling the panels were small, and two characteristic examples are illustrated in Figs. 1 and 2. Fig. 3 is a close-up of a finely carved example of early English oak panels, which shows the possibilities in this

direction.

The preliminary work is much the same in all the various methods adopted, and consists in working on the wall a series of vertical and horizontal strips of wood known as rough grounds. The grounds should be approximately 2 in. wide and about 3/4 in. thick. The purpose is to produce a fair surface on which to work the panelling and fix it to the wall. The room should be planned out and working drawings prepared, showing where each panel is to go, the grounds then being fixed accordingly. In general it will be necessary to have grounds at every corner, on every angle, one almost at the top of

the wall, and one close to the bottom, where the skirting board is located. This latter, if only a plain board, should be removed, and can be replaced later.

Only a part of the wall will be panelled in some cases, as, for example, a dado, or a $\frac{3}{4}$ in panel taken only to the frieze, or picture rail. The ground having been prepared, the panels are then applied.

A simple way of simulating real panelling, or procuring a panelled effect, is by the use of plywood, or alternatively one of the modern building or panel boards. If this latter is used as a groundwork the whole wall surface may be covered, and the panelled effect obtained by employing beads or moulded strips of wood properly jointed at all intersections. These strips will be simply nailed to the grounds with small oval brads, or panel pins, punched below the surface of the strips, and the holes stopped with putty, coloured to suit the finishing colour. If 3 ply boards are used as the groundwork they may be attached similarly to rough grounds, and Fig. 4 shows this operation in progress on a ceiling.

Framed Panelling. The foregoing method, although it produces a panelled effect, cannot be considered as true panelling. The framework, which is represented by the strips, should, in fact, be a framing constructed as such with proper joints, and the edges grooved or rebated to receive the panels, which are fitted in them in the same way as the glass is fixed in a picture frame. The panels may be plain, as in Fig. 1, and the pilaster enriched by carving, or the upper panels only may be carved, as in Fig. 2, or each panel may be separately carved as in Fig. 3. The examples given will serve as a guide for amateur work. When the wall panelling is framed up, it is fixed to the ground as already described, and the joints are fastened. Care must be taken to ensure that they always meet where they will be covered by another panel moulding or pilaster. Ceilings may be panelled on the same principle as the walls, or by framing the work in sections. Often a ceiling is panelled in fibrous plaster moulds, or enrichments, which are worked on to it while the ceiling is being made. Good results are obtained by the use of strips of rough-hewn oak about 3 or 4 in. wide and about $\frac{1}{2}$ in. thick, which may be placed on the plaster ceiling, to represent the exposed edges of the joists; when carefully done, it gives an air of spaciousness to the room, as shown in Fig. 5.

Imitation Oak Panelling. Where it is desired to give a panelled effect in a simple and inexpensive fashion, an oak grained paper may be employed. The whole surface is first covered with the special paper, applied in the same way as ordinary wallpaper, and the panels then formed by pasting on strips of moulded and grained paper. The skirting board should be stained to a dark brown colour, and simply finished with a plain chamfered edge. The frieze or picture moulding is treated in a similar way. If the worker cares to go to the trouble of forming the panels of thin strips of deal, planted on and stained to match the grained paper, the result, as will be evident from Fig. 6, is hardly distinguishable from real panelling.

Various methods of employing embossed and other panels with wallpaper are described in the articles on Paperhanging and Wallpaper.

PANEL PIN. The fine straight nail known as a panel pin is used for cabinet work and other woodworking processes. It has a flat head with a tapered portion that blends into the shank of the nail. For many domestic purposes a panel pin 1 in. long and 16 gauge can very well take the place of a larger nail. *See Nail.*

PANEL WARMING. This is the name given to a method of central heating in which the heating units (hot-water pipe coils or electrically heated elements) are embedded in the ceiling and sometimes in the walls. Claims made for this method of warming are that the heat is distributed almost solely by radiation at comparatively low temperatures, being projected from the warmed

surface of the ceiling; that there is an absence of the stuffy condition sometimes associated with convection warming systems; and that a reasonable amount of air movement for ventilating the apartment is possible without any great heat losses. *See Central Heating.*

PANICUM. Of this ornamental grass there are both hardy and greenhouse kinds. *Panicum variegatum* has green and white leaves, and is a popular greenhouse plant, being useful as an edging for the staging. It is easily increased by division. *Panicum miliaceum* is the millet. Some of the best hardy kinds are *plicatum* and *virgatum*

Panicum. Green and white decorative leaves of the greenhouse plant P. variegatum. (Courtesy of Amateur Gardening)

PANSY. This is a popular hardy, summerflowering perennial of which there are many fine strains and named varieties. *Viola tricolor*, or heartsease, is the chief species or wild type from which the pansy has been developed during many years. Bedding pansies are commonly raised from seeds sown in boxes of fine soil in a frame in May or June, the seedlings being planted on a reserve border when large enough and finally set out in autumn where they are to bloom the following summer. Named varieties are propagated by cuttings made from flowerless shoots in July-August, and inserted in sandy soil in a frame. Planting out of doors is done in autumn or spring.

Pansy blooms of mixed colours.

drainage. 4. Good type of seedling. 5. Bad cutting. 6. Sturdy cutting with heel (a). 7. Potting a cutting; a, sand.

Named varieties of show and fancy pansies grown for exhibition are given special cultivation, and the number of blooms on each plant is limited. Pansies flourish best in deep loamy soil in slight shade, but they will grow in ordinary well-tilled soil and flower throughout many weeks if care is taken to remove the faded blooms.

PANTHER LILY. This is the popular name of *Lilium pardalinum*, one of the showiest lilies for the garden. It grows 5 ft high and bears very handsome flowers, orange flushed with red and marked with dark spots.

PANTILE. This is the name given to a form of clay tile used for roof covering. It is usually hollow or semicircular in cross section. Some are not curved in this way, as, for example, the Roman pantile. The pantile is one of the cheapest forms of tiling. It is a thick tile, dark red in colour, and about 155 tiles will be found necessary to cover a roof surface of 100 sq. ft., or a space measuring 10 by 10 ft. Some pantiles are made of asbestos cement and other materials, and these are light in weight, while retaining the appearance and quality of the old-fashioned clay tile. *See House; Roof; Tile.*

Pantile. Two types of this roof covering: felt, interlocking form: right, Roman pantile.

PANTOGRAPH: For Copying Drawings. This is a simple piece of apparatus made of 4 narrow strips of wood drilled with holes at definite positions and pivoted together. It is used for copying drawings, maps, etc., to an enlarged or reduced scale. It is provided with a screw at one end for fixing to the drawing board, a pointer for following the lines of the original drawing, and a pencil for tracing the

new drawing. It is simple in action, does its work accurately, and saves a great amount of time and labour.

Pantograph. Instrument set for enlarging drawing of vase to twice its original size. See text.

In the diagram above the pantograph is set for enlarging to twice the original size. The point A is fixed to the board; at B is a pointer which is moved along the lines of the original drawing, and the pencil point at C traces the lines on the drawing paper. The joint at D is fixed, but those at E and F are adjustable, and are altered to suit the proportions of the required enlargement. For reducing, the tracing point is placed at C, and the pencil transferred to B. By making B the fixed point, with the pointer and pencil at the opposite points A and C, a drawing can be reproduced the same size as the original.

To fit up the instrument, the fixed pivot at A is secured to the left-hand side of a drawing board, and the original drawing is pinned so that the tracing point is about the centre of the drawing when the arms of the pantograph are parallel. The sheet of drawing paper is pinned down centrally under the pencil point and set square with the drawing. Providing that the point of the pencil is sharp, and the correct distance from the paper, there is no need to watch it, attention being devoted to moving the tracing point on the drawing to be copied. If the original drawing is very small, great care must be taken to move the pointer accurately, as any mistake will be doubled on the resulting enlargement. The instrument may be purchased quite cheaply from a dealer in artist's materials.

PANTRY. In a small house a pantry is an aid to service if it is well fitted with a sink and cupboards, and adjacent to the dining room. Washing up of silver, glass and table china may be done there, and the articles put away on their proper shelves. Dessert, wines or spirits, cakes for afternoon tea, and supplies of tea and coffee may be kept in a cupboard in the pantry and also the requisites for their service. An electric kettle and chafing dish or a gas ring are most useful. Sometimes a small cooker is included in pantry equipment for convenience when the cook is out and the mistress of the house wishes to prepare a hot meal. The pantry is also a place where flowers can be arranged and the silver and ornamental pieces of brass cleaned without disturbing arrangements in the kitchen. Where the latter is of the compact labour-saving type, a pantry is sometimes built in preference to a scullery.

The sink should be placed near a window with a draining board on either side. An enclosed dresser where the best china and glass can be kept on the upper shelves and silver in baize-lined drawers below is a convenient fitment. Shelves for vases and trays, a small cupboard for jam, pickles, sauces and condiments in use, and for supplies from which the dishes and containers can be replenished, are also necessary, together with a small table or a table shelf which can be folded down when not in use.

Pantry. Labour-saving pantry situated between kitchen and dining room. Used plates and dishes can be placed on the folding shelf which, when closed, conceals the service hatch.

The most satisfactory plan is to locate the pantry between the dining room and kitchen, as shown in our illustration of a modern labour-saving arrangement in a small house. There are communicating doors and also a service hatch. Used plates and dishes may be placed on the folding shelf, which when closed conceals the hatch. The china is transferred directly from the shelf to the sink, which has a constant hot water supply. By such an arrangement the process of washing up is simplified.

A pantry sink should be glazed white, straight-sided and deep. The outlet should be closed with a plug so that the sink itself can be used for washing up. A papier mâché bowl should be kept to hand for fragile china and good glass.

Where there is choice in the matter electric light should be preferred to any other illuminant. As the pantry is intended for storage of food and the larder may be situated here, the greatest care must be taken to keep it well ventilated. This can be assisted by fitting an air brick or ventilation shaft in the bottom of the wall, just above floor level. To prevent the entry of flies, the window opening can be covered with perforated zinc or wire gauze, or a clean muslin curtain can be fixed in a small frame to be inserted in the opening. See Dining Room; Kitchen; Larder; Service Hatch; Sink.

PAP AVER. This is the botanical name of the poppy, a race of showy plants including annual, biennial, and perennial species. The first class contains the opium poppy and the popular Shirley strain, whilst the biennials and perennials include those important garden favourites the Oriental and Iceland poppies respectively. *See Poppy.*

PAP BOAT. This name is given to a little bowl, good examples of which are sought by collectors. They were first made in England early in the 17th century. Usually of silver, they are about 4 in. long. Some are pinched in the middle in order to afford a holding grip.

Pap Boat. Example of this shallow antique silver bowl, period of George III. (Chapple & Mantell)

PAPER: Its Uses. Lace papers for decorative purposes are sold in packets in the form of doilies and dish papers. Both white and tinted papers of light quality are made into frills for decorating cutlets, hams, or pie-dishes; others are specially made for sweet cases, dish collars, and tray cloths. Crinkled papers, either quite plain or with designs in colour, are employed for making paper serviettes. Coloured papers are obtainable for lining cupboard shelves and chests of drawers.

Semi-transparent grease-proof paper is used for lining cake tins and for other similar culinary purposes.

Kitchen wrapping papers of cheap quality, white or brown, are sold mostly in double crown size, 20 in. by 30 in., or demy, 17½ in. by 22½ in. Toilet rolls of thin manilla or other paper are generally retailed in 12 oz. rolls. Blotting paper is usually supplied for home use in pads, but may be purchased in demy sheets of various colours. Tissue paper, sold in sheets a trifle under double crown size, is used for wrapping plate, packing dresses, polishing mirrors, cleaning lamp glasses, wrapping up flowers, etc.

For firelighting purposes pieces of twisted paper can be used instead of firewood. These are made about the same size as the ordinary sticks, and sometimes bent or even doubled up to suit the requirements of the grate. When properly twisted they burn slowly, giving out a strong heat, and are effective in kindling coal. In addition these pieces of twisted paper are economical.

Paper, especially coloured crêpe paper, can be used for decorative purposes in a variety of ways. Artificial flowers and Christmas decorations can be made from it. *See Artificial Flowers; Candlesshade; Christmas; Notepaper; Papier Mâché.*

PAPER BAG COOKERY. The main principle of this system of cooking is to enclose the food in a greaseproof, airtight paper bag, and place it on the wire grid of an oven or on a trivet. It is an economical method of cooking, as less heat is required in the oven than when cooking is done by

the more usual means. The greaseproof paper has the effect also of retaining all the natural juices in the food, thus rendering it more nourishing and digestible.

Special bags are sold for cooking purposes. A bag that is at all damaged should never be used. Before the food is put into the bags they must be well greased inside with butter, lard, or olive oil. Any projecting edges of the food, meat or fish bones that might tear the bag, must be removed. Small fish, fillets or fish cutlets, chops and steaks can be cooked in the oven in paper bags. Brush over the fish or meat with oiled dripping or butter, season it with pepper and salt, and slip it into the well-greased paper bags. Place these on the grid of the oven, which should be hot, turn down the heat after 5 min., and in 15 to 20 min. they will be cooked.

PAPER ENAMEL. The name is given to brands of prepared enamel intended for application to paper. A typical use is in the enamelling of a moulded paper ceiling, the enamel imparting a pleasing finish and at the same time making it durable and damp resisting. *See Enamelling.*

PAPERHANGING FOR WALLS AND CEILINGS

Practical Instructions on the Re-decoration of Rooms

This article belongs to the important group that deal with the decoration of the house, among these being Colour; Dado; Decoration; Distemper; Enamel; Paint; Panelling; Wallpaper. See also the articles on the various rooms, e.g. Bathroom; Bedroom; Dining Room; Kitchen.

Paperhanging is the process of covering the surface of wall or ceiling with paper manufactured for the purpose, applied with the aid of a suitable adhesive. The tools necessary are a large pair of scissors with blades about 7 in. long; a large paste brush; a brush with long bristles closely set into the back, which is also its handle, used for smoothing the paper when putting it on the wall; a roller about 8 in. long covered with thick felt; another an inch wide for rolling edges; a stripping knife and a plumb bob and line.

A table is required on which to paste the lengths of paper; a width of 24 in. is necessary and the length should be 6 ft. A couple of light planks hinged or fastened together side by side makes a good table. These must be supported at a height of about 2 ft. 6 in., preferably by trestles, although boxes or other supports can be utilized.

Wallpapers are produced to accord with the purpose of every type of room and in a great number of different qualities. Papers with well distributed patterns show joins least when hung, and if of medium weight are among the easiest to apply. Quite plain papers require greater skill to hang successfully. Between these two types there is a large variety of mottled, grained, stippled and indefinitely patterned papers, which give excellent results and are easy to handle.

Wallpapers of light and nondescript tints (cream, fawn, etc.) can be used in any room, but bright colours and deep shades have definite character and use. Bright yellow and orange can be employed for hall and staircase; amber, maize and golden tints for sitting room, lounge or dining room. Browns and greens are also in favour for dining rooms. Mottled effects resembling vellum and old parchment are very decorative.

Choosing Paper. When selecting paper the purpose or use of the room should be given first consideration, and the aspect is of scarcely less importance. Warm tints, such as yellow, brown, and shades of red are helpful in north and east rooms. Blue and grey should be reserved for rooms with southerly aspects. Special types of paper are made for particular purposes. White grounds with "satinette" prints are made for ceilings, also embossed papers. Some of these with definitely geometrical patterns are also useful for dado decoration. Bathroom papers should be either varnished or of the "sanitary" type. The latter is printed with an oil medium, so that the colour is

unaffected by moisture. The most satisfactory treatment for bathroom walls is, however, to hang an unvarnished paper and apply the varnish after it is hung. By so doing the joins of the paper are sealed. Two coats of size must be given before varnishing.

Quantity of Paper Needed. To estimate the quantity required to cover the walls of a room, add the total length of the room to the width, multiply by twice the height, and divide this total by the area of one piece of paper in square feet, which may be taken as approximately 60 sq. ft. The result is the number of pieces required. When measuring the room, include the window openings, fireplace, and doors, as in practice it is found that by including them in the whole area it allows for cutting and waste in the paper. The following table gives the number of pieces required for a room, provided the height to cornice and total feet run in inches round the walls are known.

The scale is for papers of English measurements (21 in. by 11½ yd. approximately). For papers 7½ yards long 28 in. wide add to the left table in the proportion of 1 in 7.

In dealing with ceilings, multiply length by breadth in feet and divide by 54. The result will give approximately the number of pieces required.

Stripping Old Paper. Old paper should be stripped before new is hung, not only for hygienic reasons, but also because paste perishes in the course of time and the application of new paper is likely to raise

Feet run including Doors and Windows	Height in feet from Cornice to Skirting								
	7½	8	8½	9	9½	10	10½	11	11½
28	4	4	4	4	4	5	5	5	5
32	4	4	5	5	5	5	5	6	6
36	5	5	5	5	6	6	6	7	7
40	5	5	6	6	6	7	7	7	8
44	6	6	6	7	7	7	8	8	8
48	6	6	7	7	7	8	8	9	9
52	7	7	7	8	8	9	9	9	10
56	7	8	8	8	9	9	10	10	10
60	8	8	8	9	9	10	10	11	11

68	9	9	9	10	10	11	12	12	13
72	9	10	10	11	11	12	12	13	13
76	9	10	10	11	12	12	13	13	14
80	10	11	11	12	12	13	14	14	15
84	10	11	12	12	13	14	14	15	16
88	11	12	12	13	13	14	15	16	16
92	11	12	13	13	14	15	16	16	17
96	12	13	13	14	15	15	16	17	18
100	12	13	14	14	15	16	17	18	18

blisters which cannot be smoothed out. If, for some reason, old paper cannot be removed, all edges and angles of walls should be carefully examined and loose places pasted down. When dry, a coat of size should be given over the whole surface. It is advisable to obtain the best powder size and mix according to the printed instructions. Size should be diluted so that when cold it will set in a weak jelly. It is better to apply two coats of weak size than one strong coat.

Old paper is removed by saturation with water until it has penetrated to the plaster. The stripping knife is then used to release the paper, and must be handled so that the points do not damage the plaster. The vigorous use of the knife is unnecessary. It is better to apply more water. A large distemper brush is best for wetting the paper. Commence at the top of the wall, working right and left as far as the arm can reach, and proceed downward. A sponge wrung out in clean water must be used frequently to absorb the water which will collect at the skirting. After stripping, the wall should be sponged with clean water, and when dry a coat of size should be given.

Papering New Walls. New walls are sometimes distempered and left for a while before papering, on account of the risk of detriment to the colours if papered before the walls are properly matured. If, however, the risk of discoloration is accepted it is wise to hang inexpensive papers at first, choosing those in which shades of maize and yellow predominate, and avoiding blue and green as much as possible. Light grounds with well covered patterns are very serviceable.

If possible a “lining” paper should be hung as a preparatory whenever good quality papers are to be used. Lining gives a uniform surface which enables good joins in the finished work to be made more easily. Lining paper is of distinct value on outside walls, especially if their surface is of hard and non-absorbent nature. On such walls in cold and damp weather moisture readily condenses inside and is frequently the cause of paper loosening at the edges.

Before hanging, wallpaper needs to be trimmed. It is sometimes possible to have this done by machine when purchased, but it is not difficult to accomplish by hand. Take a low seat and, with the legs extended, unroll a piece of paper, holding the end in the left hand and letting the roll rest on the feet. Operate the scissors with the right hand whilst the left rolls up the paper on the lap. The paper must be trimmed to the edge of the pattern, or to the line which on many papers is printed to ensure accuracy (Fig. 1).

Making Paste. Good paste powder, to be mixed with either hot or cold water, can be procured in convenient size packages, but the best paste, however, is home-made. To 3½ lb. of best household flour add only sufficient cold water to make a stiff batter. Mix in a clean pail and add 1 gallon of boiling water in which two small tablespoonfuls of ground alum have been boiled. The batter should be well beaten up as the water is added, and the paste should be free from lumps or it will need straining through butter muslin. When the paste is cool cover the top with a little cold water to prevent a crust forming, and then leave it to get cold. This paste should be of a stiff consistency, requiring thinning with cold water before use.

Paste should not be used thinner than can be easily spread. A stout paper can be pasted with thicker paste than one of less substance. Heavily embossed papers may require paste to which a little glue has been added. The glue should be made in the usual way and poured on to the paste whilst hot, mixing thoroughly. Alum must be omitted from paste if the latter is to be used for papers with any “gold” or metal in their printing. Washing soda must be added to the water instead, but not more than ¼ oz. for 1 lb. of flour.

Cutting Paper to Length. Before pasting, the rolls must be cut into the required length. If the paper is plain or does not require special matching at the edges, this length will be the vertical dimension of the space to be papered plus six inches, this for trimming at top and bottom (i.e. 3 in. at each end).

If the paper is patterned further consideration is necessary. The design must be examined and choice made of a suitable place for finishing at the top so that the details of the pattern shall be as complete as possible. It is wise to select the most important details and choose a line across the width so that these shall not be mutilated. At the bottom of the wall the line is not so important, but with care it is often possible to arrange that the lengths are finished so that both top and bottom are pleasantly completed. Three inches beyond the line selected for finishing at top and bottom must be allowed for trimming.

Always examine the edges of rolls before trimming, to see whether there are marks indicating where the pattern joins. These joining points are given in cases where any difficulty might arise, also arrows showing the correct way up.

Pattern Repeats. In large patterns it may be that the important features do not repeat horizontally on each length but on alternate lengths. This characteristic constitutes a “drop” repeat, and in such cases the second length requires consideration at top and bottom in the same manner as the first. It is advisable before cutting to unroll three trimmed rolls on the floor, joining up the pattern and laying rods at top and bottom, the distance between the rods being the vertical dimensions to be papered. Thus the choice of line for finishing on both lengths is easily made.

To take the curl out of the roll of paper unroll about 24 in. and let it drop over the edge of the table and back to it. Hold the opened roll in the left hand on the edge, with the right hand lightly pressing on the face of the paper. Then with the left draw the paper upward between the right hand and table edge. Repeat the operation two or three times and the most obstinate curl will be flattened.

Pasting the Paper. When the line for cutting and dimension are decided, the paper can be unrolled on the table face upward, with the uncurled end dropping over one end of the table, the dimension marked off and the required length cut. Repeat this until the roll is finished. Then turn the lengths face downward, any surplus beyond the ends of the table being equally distributed right and left. Push all the lengths about 6 in. away from the front edge of the table, then bring the top length toward the front, so that its front edge is quite level with the front edge of the table, and at the same time, with the right hand, pull the length so that its left end is resting on the table ready for pasting. Work the paste from the centre towards the edges, completing the left and farther edge before the front edge. The paper should be lifted between finger and thumb (as shown in Fig. 2), while the edges are pasted, so that the paste does not get on the face of the paper.

When rather more than half the length is pasted it must be folded over, pasted surface to pasted surface, being held as shown in Fig. 3, edges meeting exactly and lightly pressed with the hand. This folded piece can be folded again and the folds drawn to the left end of the table so that the unpasted right end can be dealt with in the same manner.

The right end should be folded over with the extreme end overlapping about an inch and then turned back, so that it can be gripped when releasing the folds for hanging. The extreme end of the left fold should be turned up in the same way, but no pasted surface must be left exposed between these two ends. When complete, the pasted length can be lifted off the table and placed on one side whilst another length is pasted, unless the paper is thin or absorbent, when it may be necessary to hang immediately after pasting. Avoid the use of sloppy paste. Enough paste must be applied so that when the paper is folded over the surfaces will just slide easily under slight hand-pressure to bring the edges together. Heavy papers may require to be “freshened up” with a second application of paste. It is no use to attempt to hang paper before it has become supple; this does not mean saturated, however. A little experience will quickly enlighten the worker on these points, and the processes themselves which, to the reader, may appear elaborate will be found simple in practice.

Where to Begin the Work. Paperhanging should be begun at an angle of the room nearest to the light. If there are two important windows, start work centrally between them, working away to right and left. In this way succeeding lengths on each side are laid towards the light. The work should be finished in an angle where any join would be inconspicuous.

Presuming that the first length of paper is to be hung at the angle of a wall, commence by marking off the width of the paper from the angle at a point at about half the height to be papered. Using the plumb bob and line as a guide, mark several points above and below the centre so that a vertical line can be made by using a straight edge. This line is to be the guide in hanging the first length. If a long flank is to be hung, succeeding lengths should be tested with the plumb line and corrections made, if necessary. It is advisable to plumb a line at every angle, as walls are rarely as accurate as the paper-hanger's joins need to be.

When ready for hanging take a length of the folded paper on the left forearm, the top nearer to the body (Fig. 4), mount the steps (which should be placed so that they are opened out in the direction away from the space to be papered), and when sufficiently high easily to reach the top, take the near loose end between finger and thumb of each hand and let the length fall gently, opening the pasted surfaces in falling. Apply the top of the length lightly against the top of the line, allowing the 3 in. surplus for trimming to hang over. With the left hand holding the left top, use the right hand to adjust the edge of the paper against the line. Run the hand lightly up and down the edge, then use the smoothing brush, smooth in toward the centre, upward and downward. When the paper is smoothed out hold the surplus top edge with the left hand and press the paper with the right hand against cornice or picture rail, and then with the back of the scissors, or a soft pencil, run a line along where the paper has to be cut off. Pull the paper away sufficiently to enable the scissors to be accurately handled, and when cut replace the end and fit down, making a good finish (Fig 5).

The lower portion of the paper has to be dealt with in similar manner. Fig. 6 shows how the lower end is taken between finger and thumb and opened out. The bottom edge is finished the same way as the top. Use the padded roller lightly to get rid of blisters. In the case of embossed papers use the smoothing brush only for this.

The second length must be hung to fit closely up to the first (Fig. 7). The position of the steps must be reversed for this length, as the adjustment is to be made in the opposite direction in relation to the plumbed line. When several lengths have been hung the edges should be rolled down, but not immediately after hanging.

Below: Paperhanging.

Fig. 1. Trimming edge with scissors.

Fig. 2. Pasting. Edge lifted to prevent paste getting on face of paper.

Fig. 3. Folding pasted paper, edges meeting. Left end folded over with turn-up for gripping.

Fig. 4. Carrying paper on the forearm, top end toward body.

Fig. 5. Finishing the top. Paper is pressed against picture rail, surplus being held down while a line is marked. Paper is then drawn down slightly, cut, and replaced.

Fig. 6. Loosening lower fold. Turned back edge underneath is drawn gently downward until fold is undone.

Fig. 7. Making butt joint. Hanging second length, working towards the light. Paper is held by right hand so that right side does not quite touch the wall, whilst with the left the edge is adjusted.

(From photographs specially taken for this work by arrangement with Arthur Sanderson and Sons, Ltd.)

How to Paper Ceilings. Ceilings are papered in the same way, but the paper has to be folded in a number of short folds after pasting. These are made under one another in succession until the length is in a neat pile of folds which must be turned upside down, and can be held on a roll of paper in the left hand, whilst the right opens out the folds, adjusts and brushes the paper on the ceiling.

Papers in high relief require to be well pasted, and need time for the paste to render them applicable. The raised pattern should be carefully guarded, and rollers should not be used except on flat surfaces which adhere to the wall or ceiling. Manufacturers of these relief materials issue special instructions for hanging, and these should be carefully observed.

Borders are frequently used with un-patterned papers, and present no difficulty in hanging, except that they must to be placed with accuracy so that paste is not transferred to the paper which the border does not cover. Borders which have a "cut-out" edge are generally supplied perforated in the roll, and should be pasted before tearing apart. Any waste lengths of paper are useful for laying borders on, face downward, for pasting. Use fairly stiff paste for this purpose.

Panels. Panelling with borders is a very effective method of decoration and adds importance to the appearance of a room. Special borders termed “stiles” are made for the purpose and can be obtained in several widths, the narrower being used for bedroom and the wider for reception rooms. Setting out requires to be carefully done, and the proportion of the panels in the relation of height to width is important. A rectangular panel does not look well if the width is more than three-quarters its height. A square panel is satisfactory, as is also a double square. Very fine examples of panelling are frequently to be found in Georgian and Adam houses.

General Hints. Old distemper should be removed by scraping and washing before papering. Walls that have been painted should be cut down with coarse glass paper, treated with clearcole and then lined, otherwise the paper will not adhere but open at the joins. If a straight edge is not available, lines can be “snapped” on a wall by the use of a chalked line, this being a fine cord covered with coloured chalk. Fasten the line with pins at the ends or otherwise hold it tautly in position, lift the centre and let it snap, when a chalk impression will be left on the wall. Printed instructions for hanging papers are frequently enclosed in rolls by the makers. Such instructions should be carefully followed.

PAPER KNIFE. Used for cutting paper and opening envelopes, etc., the paper knife is obtainable in a large number of shapes and sizes in gold, silver, ivory, mother of pearl, bone, wood and other materials. Small paper knives can be made from old piano keys, which are often discarded as useless at a piano repairer’s. If the ivory or composition is scraped with broken pieces of glass to clean and level the surface, the edges filed to shape and smoothed with glass paper, they may be polished with French chalk mixed to a paste with sweet oil, applied with a nail brush and finished with a soft rag.

The fretworker can exercise his craft to advantage in cutting out shapes both in wood and metal, utilizing initials and monograms as ornamentation for the handle. Boxwood, sycamore, and ebony are all useful for this purpose. The design is drawn out on a sheet of paper and filled in with ink, afterwards being pasted on the wood. In working out suitable designs, especially in lettering, ties must be provided to keep the design together.

The metalworker can utilize copper, brass, and silver, working out flat forms with pierced, engraved, etched, or repoussé ornamentation. The metal may be left quite smooth and bright, polished up with pumice powder applied with a hard brush, and then lacquered.

PAPER NEGATIVE. Negatives on sensitized paper instead of film or glass have their uses, and special sensitized paper of various speeds can be obtained from the photographic dealers. Exposure and development are on normal lines, but the developer must be a clean, non-staining one, such as metol-hydro-quinone, azol, kodol, etc.

The chief use for paper negatives is in the production of enlarged negatives, for producing large prints by the platinotype or carbon processes, as well as for obtaining a considerable number of copies of an ordinary bromide enlargement. A positive or transparency is required for each of these purposes, and can be made by contact from the original negative on a slow-speed plate, the method being the same as in the production of a positive transparency for a lantern slide (q.v.). When this transparency has been obtained, it is placed in the enlarging lantern, and the necessary enlargement made on ordinary thin bromide paper or the special negative paper, the latter showing less grain. With the enlarged paper negative so obtained as many large prints as are required can be made by contact, or the carbon or platinotype processes.

Paper negatives offer special facilities for easy, broad retouching. If for instance in a landscape it is desirable to strengthen the high lights (the parts that print, white), it is only necessary to work with

a pencil on the back of the paper negative. Similarly, if a light background is required to a portrait, appropriate and judicious working on the back of the paper negative will produce the effect in the positive print, without betraying the fact that retouching had been done. Alternatively strengthening of the shadows can be done by ordinary methods of retouching on the positive transparency before the print is taken of the enlarged negative. See Carbon Printing; Developing; Enlarging; Negative; Platinotype; Printing.

PAPIER MÂCHÉ: PLAIN AND DECORATED

How to Make Useful Household Pieces

Additional information on the subject of decorating papier mâché articles can be found under the headings Italian Renaissance Work; Lacquer Work; Pattern Printing; Stencilling. See also Artificial Flowers; Paste; Tray; Victorian Style.

Papier mâché is manufactured from highly compressed paper pulp moulded to shape during the process of making and then painted and varnished or enamelled. The commercial articles are machine made, but papier mâché can be made at home. Vases, bulb bowls, trays, fire screens, powder bowls, waste paper tubs, and washing-up basins can be constructed from materials which cost very little beyond the time and skill expended on them.

Although used for the simplest objects, this material affords a light and excellent basic composition for painting and lacquer work and has been decorated for centuries by artist craftsmen of many nations. Our first illustration shows a beautiful example of a Persian papier mâché box with an exquisitely painted design. In the 17th century this material was employed for lovely Persian bookcovers, and much early English lacquer work was done on papier mâché trays.

Papier Mâché. Fig. 1. Antique Persian box in papier mâché with inscription "The work of Mirza Ali Muhammad, Irani".

Moulding the Shape. For a first attempt a bowl or tray should be made, as the method is simple. Procure a bowl of china or metal to serve as a mould. Take any old newspapers or magazines and tear them into irregular shaped pieces, the size depending on whether a small or large object is being made. On no account must the

paper be cut; tearing gives it a bevelled edge, which ensures a better fit when pasted on to the mould. Leave the paper in water until it is thoroughly soaked through, and meanwhile prepare some ordinary flour paste, to which a little alum is added, as this makes the paste more adhesive. It should not be very thick, but should be of a semiliquid consistency.

Coat the inside of the bowl with soft soap, to prevent the paper sticking to it. Then take the paper from the water, dipping one piece at a time in the paste and drawing it through the fingers to make sure the paste is evenly distributed. Spread the paper over the bottom of the bowl. Repeat the process until the whole of the interior is evenly covered; each piece must overlap slightly so that

they adhere to each other. Allow the paper to extend from 1½ in. to 2 in. beyond the rim of the bowl, and continue laying on the pieces of paper until the layers are 1/16-1/8 in. deep.

Large objects require to be thicker, whilst small bowls need not be more than 1/16 in. thick. Now place the bowl before a bright fire or in a moderate oven until thoroughly dry. Draw a pencil line round the rim of the mould on to what will be the outside of the new bowl. Remove the mould, and with a sharp keyhole saw or strong scissors cut off the edge along the pencil line. Rub down this edge as well as the whole of the interior and exterior of the papier mâché bowl, first with a medium, then with a fine glass paper. Number 00 is best for the final rubbing down. To finish, size, paint, and varnish the object. A bowl or anything that is being used for a mould can be equally well coated with the paper from the outside as shown in Fig. 2. This method is necessitated when the mould in use is vase-shaped.

Papier mâché. Fig. 2. The paper is torn into irregular pieces, soaked in water, then covered evenly with paste and spread, each piece overlapping the other, on the surface of the bowl or other mould.

For a washing-up bowl, such as that illustrated in Fig. 3, two or three coats of ordinary white enamel are most suitable for the interior, while blue, grey, or brown can be used for the outside. Very attractive and decorative bulb bowls can be made by painting the inside in some bright colour that contrasts with the outside, such as orange and black, primrose or grey and apple green. A still more artistic effect is obtained by lacquer decoration in colours as well as gold, bronze, and silver. A fruit bowl lacquered black with a design of gold or merely lined with gold is uncommon, and goes well with schemes where a brilliant colour would be out of keeping. Stencils can be employed with good results, and so can gesso decoration. A good hard varnish must be used in the case of bulb bowls to withstand the damp from the fibre.

Papier mâché. Fig. 3. Bowl which lessens the risk of breakage when washing up; and a tray enamelled in bright colours. (Courtesy of Staines Kitchen Equipment)

A tray or any article which tapers towards the bottom can be made in the way described. One like that illustrated in Fig. 3 can be modelled on an old tin tray and enamelled in a bright colour.

Should there be no object handy that can be used for a mould, a lump of modelling clay may be shaped into the form desired. A simple method is

to roll out the clay on a board in the same way as pastry to a thickness of 1 in., and cut it out into circular pieces varying from the smallest to the largest diameter. Place one on to the board and build up the mould with the rounds in required order of size, filling in the steps between each layer with clay. If the mould is not going to be used immediately, keep it covered with damp cloths to prevent

cracks appearing. Well cover the clay model with soft soap and also the board round it for about 4 in., or the edge of the paper will stick to the board. The procedure is then the same as before.

Any skilled worker who wishes to produce narrownecked vases, jugs, etc., in papier mâché, can first make 2 models in clay, each one a longitudinal section of the object. The edges of the papier mâché, after the preliminary moulding has been completed as already described, are cut absolutely true and then glued together; when the glue is quite set 2 or 3 coatings of paper are applied to the outside of the vase or jug. These last coats of paper must not be dried artificially, but merely left in a dry room, or the object will warp and get out of shape, as it has no mould inside.

To make a waste paper tub or basket from papier mâché is an easier task. An old size tin, or any other round tin of suitable dimensions, will make a good model. Failing a tin, a piece of stout cardboard can be rolled to fit a circular bottom, then glued and allowed to harden. Plasticine is used to round off the join on the outside so that any cracks are eliminated in the finished article and it is given a slightly moulded base. The procedure is the same as for the bowl in Fig. 2. Special attention must be paid to the rubbing down, as if the surface is large any roughness will be very noticeable. The old papier mâché workers used pumice-stone for the final rubbing down, and then polished the work laboriously with a chamois leather. This was worth while, as it produced an excellent surface for decoration.

Flower, sporting or other prints form excellent panels for decorating such articles after the final enamelling is completed. In order to ensure better wear the whole article is varnished after the print or, if preferred, a hand-coloured panel has been pasted on and outlined with black. The top is given a finish of gold or silver bronze paint outlined with black. Mottled paper may be used to line the basket or it may be finished in enamel. Chinese lacquer designs are particularly suitable for a handsome waste-paper tub. Cheap enamel dishes and sugar basins make serviceable moulds for small trays and bowls.

Decorated Panels. A papier mâché panel for a table top or fire screen is made on any flat tin or metal plate. If really good decoration is intended by a skilled amateur, the old method of making the panel may be followed. An odd length of cheap mat-surfaced wallpaper is quite a satisfactory substitute for the special paper that was used. About 12 sheets should be cut out of the desired size for the panel.

The metal plate is oiled before the first damped sheet is laid and covered with paste and alum. The old workers used a mixture of glue, flour and resin. Another sheet was laid over perfectly flat and then plate and sheets were placed in a cool oven to dry. The surface was then rubbed down with pumice-stone to ensure smoothness before the next sheet was applied. All the sheets were thus applied and dried in the oven before the panel was completed and strong enough for a table top or tray. To form a moulded edge the paper would be taken over the edge of the metal shaped by hand and cut off with keyhole saw.

In some of the beautiful floral designs of the first half of the 19th century pearl was used, as in the table top shown in Fig. 4. In others large flowers and leaves were painted in bronze colours and gold. After 1845 oil colours and bronze colours were utilized in the same designs. Pearl was still employed, but was less seen as the more gorgeously coloured designs became popular.

The pearl effect was gained by use of thin layers of nautilus shells and these were stuck on to the surface of the papier mâché with glue. In modern papier mâché decoration the thinnest shells obtainable for artificial flower making can be specially cut and coloured with spirit stains sold for the purpose. Fish scales can also be used. Very rich effects can be obtained by use of such shells or scales for portions of flowers with oil and bronze colours, for other portions and for leaves, when carrying out a floral design for a panel.

Fig. 4. Beautiful early 19th century example of a papier mâché table top, decorated with shell, bronze and colour.

Care of Papier Mâché. Old pieces of decorated papier mâché require careful cleaning. Sometimes a beautiful piece has been so neglected that the original colour and lustre seem quite lost. A soft flannel, dampened with a very little pure curd soap on it is the best cleansing agent. When the dirt has been removed the papier mâché must be gently dried with a flannelette

duster, a little furniture cream put on with the tip of a finger and the surface immediately polished with an old piece of softest silk. Valuable decorated papier mâché articles should not be exposed to damp, and should liquid be spilt on tray or table top it should be dried off at once.

PAPILLON. This toy dog is popularly known as the butterfly dog owing to the supposed resemblance of the ears to the wings of a butterfly. They were introduced into England during 1923. The papillon has a very profuse coat of a silky texture, and the large ears can be well feathered. It is a loosely coupled little dog with a wedge-shaped head. The body colour is white and the markings either lemon, brindle, brown or black. If these are evenly distributed it gives a better appearance to the dog. The smaller they are the more highly esteemed, providing the dog has quality in other respects. The Papillon Club has done a great deal for this breed. *See Dog.*

PAPYRUS. The ornamental grass of Egypt that is known as papyrus requires aquatic treatment in a heated glasshouse. It attains a height of about 6 ft., and has dark green leaves. Cultivation is in pots of loam, leaf-mould and sand, plunged in tubs or tanks of water. Propagation is by division of the root stock. The name papyrus is applied to the writing material made from the stem, and to a manuscript written on this substance.

PARADISE: In Budding. This is the name of a variety of crab which is used as a stock on which to bud apple trees, particularly those grown in the form of pyramids, low bushes, or trained trees. It is known as the dwarfing stock because it induces a dwarf, sturdy and early-maturing growth in the apples budded on it. The true broad-leaved paradise stock is recommended for budding the trees. *See Apple; Grafting.*

PARADISIA. This hardy perennial grows 2 to 3 ft. high, and has grass-like leaves and white flowers in early summer. *Paradisialia liliastrium* (*Anthericum liliastrium*) flourishes in ordinary garden soil. It is known as St. Bruno's lily.

PARAFFIN. The name of paraffin is applied to a whole series of organic substances, which includes marsh gas, naphtha, benzene, petrol, petroleum lamp oil, heavier lubricating oils, vaseline petrolatum, cosmoline, adepsine, and the hard paraffin of which candles are made.

Paraffin oil, which is also known as kerosene, is chiefly used for illuminating and heating purposes. The thinness of the oil gives it the peculiar property of spreading or creeping, so that it is important when filling lamps to avoid excess of oil. After filling a lamp all traces of oil on the outside of the container should be wiped off, as otherwise the unpleasant smell of paraffin will be given off when the lamp is lighted.

Heavy paraffin oil forms the base of lubricants for sewing machines and lawn-mowers, and a good deal of petrol is made from paraffin. Floor-sweeping compound is made by mixing 1 pint of paraffin oil with 10 lb. of dry sawdust. This is used for hardwood floors, a little being sprinkled on the floor before it is swept. *See* Burner; Lamp; Oil, etc.

Paraffin Wax. The white solid that is obtained as a residue in the purification of petroleum resembles white beeswax, for which it is a cheap substitute. The chief commercial use is in the manufacture of candles. As a floor polish, paraffin wax is made into a paste with either oil of turpentine or a mixture of equal parts of paraffin oil and benzine. Paraffin wax has another important application for electrical insulating.

Some Medical Uses. In therapeutics liquid, soft and hard paraffin and paraffin oil or petroleum are utilized. It should be noted that liquid paraffin is quite a different thing from paraffin oil. Liquid paraffin is used internally as a laxative and also in the form of petroleum emulsion to aid assimilation of food. It is often used to spray the pharynx and the nose. Soft paraffin or vaseline is an excellent basis for ointments. Hard paraffin is sometimes injected under the skin of the nose to correct deformities. Paraffin oil is applied to the head to kill lice.

PARALLEL BARS. One of the most commonly used of all gymnastic apparatus, parallel bars are subjected to considerable strain, and must be strongly made. The framework may be of deal or pitch pine, but the bars are always of straight-grained ash, and in the best apparatus they have a core of steel. A satisfactory pair of bars (Fig. 1) can be made in the following manner with ordinary deal and two lengths of selected ash. The width between the centres of the bars for home use should be 2 ft., but they can be wider apart if required. The total height is 4 ft., with fixed bars which are 8 ft. long.

The bottom framework is made from 5 in. by 3 in. wood, planed smooth and true to these sizes; but 6 in. by 4 in. deal can be used, and when passed through the planing machine will not be much larger than 5½ in. by 3½ in. Two grooves marked out on the long pieces are the exact width of the wood, and 12 in. from each end. Gauge lines are marked half-way down, and the waste removed with a chisel (Fig. 2). The cross pieces are 4 ft. long; the grooves are the same width and depth as the others, and 9½ in. from each end. The ends of all four pieces should be rounded.

The four uprights are tenoned into the base, and are cut to 4 ft. from 5 in. by 3 in. wood. The ends are marked down 3 in. for the tenon; then 1 in. from the edges and ½ in. from the sides, as shown at A, Fig. 3. The tenons are then sawn down as shown at B. Corresponding mortises are cut in the bottom framing as indicated at Fig. 4; an enlarged view of one corner is shown at C. Each of the uprights is now tapered, lines being marked as shown at D, Fig. 5, and sawn down; the top is hollowed, E; the sides planed, F, and finally the top corners are chamfered, G.

The uprights are glued and wedged in position as shown in the section at Fig. 6, leaving the 8 ft. ash poles to fit in position. First smooth the wood carefully with glasspaper, and then provide eight 4½ in. steel ribbed brackets and attach them to the underside of poles and sides of uprights with round-headed screws. The uprights are also strengthened with large steel brackets, 10 in. by 14 in. Owing to the sides being tapered they must be let into the wood as shown at Fig. 7. The bottom can be boarded in by nailing on 2 in. by 1 in. strips on the inside of the long bottom lengths, and then

fitting 1 ft. 7 in. lengths of 1 in. floor boarding between. The framework may be painted or varnished, but the bars themselves are left clean from the glasspaper.

PARALYSIS: Its Causes. Paralysis is the loss of power to contract the voluntary muscles. There are two sharply divided groups, namely, paralysees which are hysterical and those which are of organic origin. Hysterical paralysis may follow a physical or a mental shock. The physical cause most frequently responsible has been a railway accident. Mental causes include disappointments in love, grief, fright, anxiety, overwork, prolonged strain, etc. In a large number of cases, however, these influences are merely the precipitating factors, the condition being due fundamentally to some psychic influence.

Hysterical paralysis differs from organic paralysis in that in theory every case is curable, and in practice the great majority are cured, this being effected by purely psychical methods.

Organic paralysis is due to injury or disease of the nerves or brain. A common cause is apoplexy or stroke, due to rupture of a blood vessel in the brain, with resulting damage to the nerve cells in the neighbourhood. A familiar form is locomotor ataxia, a condition characterized in the early stage by inability to control the muscles, thus leading to an irregular jerky gait. Neuritis, or degeneration of the nerves, may result from prolonged alcoholism or chronic poisoning by lead or arsenic. Infantile paralysis is a condition, seen most often in young children, in which paralysis of one or more limbs supervenes. The treatment for organic paralysis varies very much with the cause. When due to definite disease, the treatment must be directed towards combating that disease. In acute cases the patient should be kept in bed, and care must be taken in preventing the formation of bed sores (q.v.).

Paralysis of the Insane. This disease is due to inflammatory and degenerative changes in the brain, by reason of which both mental disorder and paralysis of muscles occur. It occurs mostly in middle life among men who have overtaxed their brains or put a prolonged strain on the nervous system. Injury to the head, abuse of alcohol, and worry favour the onset of the disease.

In a majority of cases it is advisable to remove the patient to a mental hospital, and very often this should be done early in the disease, both in the interests of the family and of the patient himself. *See* Infantile Paralysis; Insanity; Locomotor Ataxia.

PARAMIDOPHENOL. The photographic developers of the paramidophenol class are very clean and stainless in working, and keep well in a single stock solution, needing only the addition of water before use. They are effective for all kinds of photographic work. The best known examples are azol, kodol, rodinal, and rytol. Taking azol as an example, the following are the quantities to be used:

	Azol	Potassium bromide 10 %	Water to make
Plates and films (normal development)	20 drops	—	1 oz.
Gaslight papers (soft or normal grades)	40 „	2 to 5 drops	1 „
Do. (vigorous grade)	40 „	10 „	1 „
Bromide papers	15 „	—	1 „

The Watkins factor for development with azol is 30 for average contrast. The detailed tables for development by time and temperature for all the plates and films on the market are published by the makers of the azol developer. *See* Developing.

'P' RECIPES: A SELECTION SHOWN IN ACTUAL COLOUR.

Peach Trifle: Made as Fruit Trifle, using strawberry jam instead of apricot, and tinned peaches instead of fruit salad. Add ½ wineglassful of rum to syrup. Pineapple Trifle: Take a tower-shaped sponge cake and cut off a neat slice from top. Then cut cake in half and spread bottom piece with apricot jam. Strain syrup from large tin pineapple, heat up with 1 wineglassful sherry, and soak jam-covered cake with some of it. Place other half of cake on top, cover with jam and soak in syrup. Scoop out a hole in centre of top portion, and put chopped pineapple into it. Cover with slice cut from top of cake. Pour over remainder of syrup. Make 1 pt. thick, vanilla-flavoured custard, and when cool pour it over cake. Decorate with whipped cream, glacé cherries and angelica. Polo Cakes: Line some patty tins with rich shortcrust pastry. Prepare filling from weight of 3 eggs in butter, flour and castor sugar, 3 eggs and an extra yolk, ½ teaspoonful milk, 3 oz. almonds, some red currant jelly and a little pink or white icing. Cream together the butter and sugar, then add eggs and extra yolk one by one, beating each well in. Sieve together the flour and baking-powder, add lightly to mixture, and then stir in milk. Fill cases 3 parts full with mixture and bake in moderate oven until a pale biscuit colour. Leave to cool. Then brush sides with a little melted jelly and sprinkle with chopped almonds. Force a round of icing on top.

PARAPET. A low wall or parapet is often used to protect gutters and roofs of houses, and it should be periodically examined to see that it is perfectly sound, and not liable to crash to the ground. A consideration with the roof and guttering, when a parapet forms part of the building, is that the mortar is liable to weather very rapidly, and the result is that a heavy fall of snow or other cause may result in the parapet being entirely demolished. A preventive of this is to rake the mortar joints, and then to re-point them with cement mortar. The parapet illustrated below is shown with simple capping. In many types of building a parapet of stone or cement is employed as a decorative feature. These weather rapidly owing to their exposed position and the smoke from adjacent chimneys, and can be treated effectively with proprietary brands of waterproofing materials.

Parapet of brickwork built on a house for the purpose of protecting roof and gutters.

A simple treatment available to the amateur is the use of a cement wash composed of equal portions of Portland cement and sand, brushing it on with an old stiff brush. Where the parapet is painted, it requires to be given a fresh coat at least once in every three years with a thoroughly durable and first-grade paint of outdoor quality. *See Wall.*

PARCEL: How to Pack. If a parcel must be made of several items of divergent sizes and shapes, the only safe plan is to procure a cardboard or wooden box large enough to take them all. Any crevices should be tightly packed with a stuffing of crumpled newspaper to prevent the contents from moving. Breakable goods such as bottles of medicine should be wrapped in corrugated cardboard before being put into paper, the outside of the parcel being marked "Glass, with care."

A parcel which is of considerable weight, or which is being sent a long distance, should be wrapped in paper, firmly tied with plenty of string and addressed. Then the whole process should be repeated. The second wrapping gives extra solidity and strength, and the second addressing provides for the accident of one being torn off in transit. Photographs should be sent in the special wrappers, backed with cardboard, which are sold for the purpose; failing these, the parcel or envelope containing them should be stiffened with a sheet or two of cardboard.

Book Parcels. A book should be placed in such a way that the edges of the cover cannot suffer. One method is to enclose it, as shown in Fig. 1, between two boards, cut $\frac{1}{4}$ in. larger on every side than the book covers, and to tie this up carefully before wrapping in strong paper. Another method is to use corrugated cardboard.

This is cut roughly cross-shaped, as shown in Fig. 2, the broad centre-piece folding over the spine and front edges of the book, the narrower length protecting the upper and lower edges. The corrugated side of the cardboard is placed innermost, and the cut edges must overlap those of the book. If packed in this way, however, it will not travel by book post, which demands open ends. If no cardboard is available, a book can be first wrapped in several thicknesses of newspaper.

String of suitable thickness should never be spared, and it should be fastened tightly. Each parcel should be addressed very clearly, in full, and twice over. This may be done on the outer wrapping itself, if the paper is of a colour and surface to take ink well: otherwise labels, one stick-on and one tie-on, should be used. A parcel of a fragile nature should always be addressed on an accompanying tie-on label and not on the parcel itself, as the heavy stamping of the postmark, if made on the parcel, may crush the contents. Parcels intended for registration are not accepted for delivery by the post office unless every intersection and knotting of the string is sealed with sealing-wax. Also, the outer paper wrapping or box must be intact.

All these precautions apply with double force to the sending of Christmas parcels, for at that season the mails are so crowded that they may receive rougher handling than usual. Gift parcels not intended to go through the post may be wrapped in gaily-designed papers and tied with tinsel ribbons.

PARCEL POST. In Great Britain goods, provided the parcel does not exceed 15 lb. in weight, can be sent through the post office. The parcel can be handed in at any post office, where it is weighed and stamped. In rural districts it can be handed to a postman. The charges (1935) are:

Under 3 lb., 6d.

Between 3 lb. and 4 lb., 7d.

Between 4 lb. and 5 lb., 8d.

Between 5 lb. and 6 lb., 9d.

Between 6 lb. and 7 lb., 10d.

Between 7 lb. and 8 lb., 11d.

Between 8 lb. and 15 lb., 1s. 0d.

The parcel must not exceed 3 ft. 6 in. in length, nor 6 ft. in length and girth combined. It should be marked parcel post and bear on it the name and address of the sender. A parcel can be registered at a cost of 3d., which payment carries with it the right to compensation for loss or damage up to a maximum of £5. For 4d. compensation can be obtained up to a maximum of £20, and every additional 1d. means an additional £20 for compensation up to a maximum of 1s. 11d. for £400. Compensation up to a limit of £2 will be given on unregistered parcels if the sender obtains a certificate when sending. To secure compensation the parcel must be securely packed, while it will not be paid for damage to eggs and other very fragile articles.

Parcels can also be sent to British possessions and to most foreign countries. The maximum weight of the parcel that can be sent varies, but in no case does it exceed 22 lb. Parcels up to this weight can be sent to France. These parcels are subject to the ordinary custom duties. The charges and regulations as to size vary, but the information can be obtained from any post office. Parcels sent to most countries can be insured, but not registered. The insurance is limited to £400, for which a payment of 5s. 10d. is necessary.

Parcel. How to pack a book. 1. One method is to place it between boards before wrapping in paper. 2. Corrugated cardboard cut to the shape required. 3. Cardboard folded over. 4. Wrapping in stout paper. 5. One end folded and strong string tied tightly. 6. Finished parcel calculated to defy rough postal treatment.

Parcels by Air. Parcels can be sent by air to foreign destinations under the same general conditions as if sent through the post in the ordinary way. They can be handed in at any post office that accepts parcels for abroad. A special blue air mail label must be affixed to the address label of the parcel and to the relative despatch note, and the words air mail should be written conspicuously on the cover of the parcel. In addition to the more rapid transit, an air parcel is usually given a speedy

clearance at the customs. The Post Office issues regularly an air mail leaflet which gives full details about this service.

PARCHMENT. Made from the skins of sheep, goats, and other animals, parchment is used for bookbinding and illuminating, coarser kinds being used for drumheads, banjos, and tambourines. It is prepared by freeing the skin from hair and flesh while it is attached to a stout wooden frame, subsequent treatment being similar to that adopted for leather.

For the repair of musical instruments it is not necessary to use new material; old deeds, which are often obtainable, are quite suitable. For use in the panels of lamp shades, parchment may be made nearly transparent by soaking a thin skin in a strong lye of wood ashes, wringing it out again and again until it is fairly transparent. It may then be varnished with mastic varnish. Staining is effected with aniline dyes or waterproof inks, but the skins must be stretched tight while drying. Illuminated parchment which has become dirty and greasy may be cleaned with benzine, and if the colours require touching up, ordinary water colours mixed with Chinese white can be used, but specially prepared colours are supplied for the purpose. Stiff parchment will soften in water, but a fairly permanent flexibility is obtained by soaking the skin in glycerin. For new drumheads or tambourines preliminary soaking in water will be quite sufficient.

The parchment mainly used in the home is known as vegetable parchment, and is made by dipping ordinary, unsized paper for a few seconds in diluted sulphuric acid in the proportions of one part of acid with half its volume of water. It is thoroughly washed in water and acquires a parchment-like texture and becomes about five times stronger than ordinary paper. It is impervious to water but is rendered soft and limp when dipped in it. The stout qualities are used for bookbinding, and although not so durable as animal parchment, it may be worked up in the same way. For making lampshades and covering small screens or writing desk sets it is very useful, as it may be varnished to render it more durable; it can be stained to any colour and may be painted.

Such parchment is employed for covering jars containing preserves or anything that can be contained in a jar from which air must be excluded. Several thicknesses are obtainable, but before use it should be cut to the approximate shape and dipped in water to soften it. Owing to its property of stretching when wet, care must be taken to prevent it soaking too long; if this is allowed and the jar is covered with it and tied up tightly, it is very likely to split when it dries.

Vegetable parchment is an excellent material for making moth-proof bags; it can be obtained in large sheets; it is not expensive, and when the bags are properly made the contents are airtight as well as moth-proof. The bags should be made with a double fold at the edges secured with thin fish glue rubbed on evenly. *See* Candlesshade; Lampshade.

PAREGORIC. Compound tincture of camphor, commonly known as paregoric, is much used in cough mixtures, and also for the relief of colicky pains. It contains, besides camphor, aniseed, benzoic acid, and opium. In view of the presence of opium, which gives paregoric its soothing effect, the remedy should not be used except under medical direction.

Parent. *See* Father; Guardian; Mother.

PARFAIT. Except for the fact that it is usually richer in cream and served in tall glasses, a parfait is an iced sweet, similar to a sundae, made with fruit syrup, grated nuts, ice cream and whipped cream.

PARGING. The process in building known as parging renders the inner surfaces of a brick-built flue smooth and fire resisting. Parging is similar in its essentials to cement rendering, and various

mixtures are used by different operatives. A commonly used composition is one part of Portland cement to two parts of good, clean, sharp sand, the proportions being gauged by bulk.

In some cases a mixture of fireclay and cement is used, but generally much of the parging of a flue is done with ordinary lime mortar.

Parging is done as the work proceeds, that is, as the bricklayers construct the flue; the inner surface is rendered with the cement and trowelled off smooth.

PARIAN WARE. The most valued period of the statuary porcelain known as Parian ware lasted for about 30 years after 1845. Invented in the Copeland works, as the outcome of a search for the lost secret of Derby biscuit ware, it was adopted at the Minton, Wedgwood, Worcester, and other factories. Some early figures are recognizable by having a small proportion of glass mixed with the body-paste, but the finest were made of china-clay and felspar alone, in a mixture which enabled them to be fired at a lower temperature than ordinary bone-porcelain.

The best examples, pure white and unglazed, are superior in transparency to the opaque Derby biscuit, and have the general effect of the Carrara marble, which they sought to emulate. Sometimes a lead glaze was added, and this was especially well done at Longton. Unfortunately the designs are not particularly good. Unglazed Parian should be kept clean with pure water, in the same way as biscuit, because of its porous surface. *See China.*

Parian Ware. Statuette in pure white unglazed porcelain. (Courtesy of W. T. Copeland & Sons)

PARING CHISEL. The blade of a paring chisel is considerably longer than that of the ordinary firmer chisel, and there are two forms, the ordinary parallel type of blade, and that with a bevelled edge. The latter is preferable for paring, that is, cutting wood across the grain, as the blade is thin at the edges.

Since the tool is intended chiefly for cutting across the grain, it must be kept in very good condition, properly ground and well sharpened. It is handled in substantially the same way as the ordinary firmer chisel. Under some conditions the extra length of blade is an advantage, as, for example, when working at the bottom of a deep slot for a mortise, or under any other conditions where a deep hole has to be dealt with. Paring chisels are generally obtainable in widths from $\frac{1}{4}$ in. to 2 in., and the sizes most useful for the amateur are $\frac{1}{4}$, $\frac{3}{8}$, $\frac{1}{2}$, $\frac{3}{4}$ and 1 in. *See Chisel.*

PARIS. The hardy perennial known as Herb Paris grows about 10 in. high, bears yellowish-green flowers, and is suitable for a moist and shady position. It is planted in autumn or spring, and propagated by division of roots during the same periods.

PARIS GREEN. This is an arsenical insecticide made of aceto-arsenate of copper, and is highly poisonous, particularly if inhaled in its ordinary powder form. A preparation known as Blundell's paste is the safest form in which it can be used. The paste is not soluble, but may be mixed as a fluid at the rate of 1 oz. to 10 gallons of water, with an addition of 4 oz. lime. It is used as a fine spray, the mixture being constantly stirred during use. It is efficacious as a wash insecticide for fruit trees, but when applied to the peach, nectarine, or apricot, the quantity of paste must be reduced by

$\frac{1}{4}$ oz. Trees should not be sprayed when in flower. It is best applied just before the buds open, and directly the petals begin to fall. *See* Insecticide.

PARKIN. This is a Yorkshire speciality. To make it, allow $\frac{1}{2}$ lb. butter or margarine to $1\frac{1}{2}$ lb. treacle, $\frac{1}{2}$ lb. brown sugar, 2 lb. oatmeal, 1 lb. flour, 1 oz. ground ginger. Dissolve the butter in the treacle over gentle heat or by standing at the side of the fire. Stir in the sugar and the ginger and mix the flour and the oatmeal together. Stir in the flour and oatmeal and mix with a wooden spoon. Add 1 or 2 beaten eggs and a little milk if necessary to mix to a soft but fairly stiff consistency. Put in a greased pudding tin. It should be 1 in. in thickness. Bake in moderate oven 40-50 min. Let it cool in the tin, then cut in squares and store in airtight tin.

PARLOUR. This old-fashioned name for a sitting room or drawing room is still preserved by some people who own period houses, or who furnish a cottage sitting room in old-world style. The parlour should suggest the cosiness of a Queen Anne style (q.v.) of sitting room and stuffiness or formality should be wholly absent from its furnishing. *See* Furniture.

PARLOURMAID. A good parlourmaid can command high wages, and is next in importance to the cook as far as female servants are concerned. Where there is no butler she is responsible for the glass and silver, and for the care and decanting of wines. She also waits at table, answers the front door, ushers in and announces guests, and takes in afternoon tea. All the dining room table work is hers. She is, moreover, expected to act as valet to any gentlemen in the house, laying out their dress clothes and keeping their wardrobe brushed and tidy. *See* Insurance; Servant.

PARMA VIOLET. This is a free-flowering and fragrant variety bearing blossoms of pale bluish lavender. It is largely grown for market purposes. It is excellent for culture in frames. *See* Violet.

PARMESAN CHEESE. This is made from skimmed milk. It is not used until it is several months old, and the best varieties are kept for two or three years before being sent to market.

In most localities, Parmesan cheese is bought already grated, as it is used to garnish savoury dishes, soups, and salads, It is however, rather expensive. *See* Cheese.

PARQUET AND WOOD BLOCK FLOORING

Effective Methods of Decoration and Construction in Floor Coverings

An article that should be consulted in connexion with this subject is the one on Floor. *See* also Carpet; Polishing; Rug; the entries on the various rooms of the house, e.g. Dining Room; Drawing Room; and those on the various woods, e.g. Oak.

The name is used to denote a floor of wood arranged in diaper formation. It is constructed by cutting thin boards into geometrically shaped pieces, and laying them down to form a pattern, much in the same way that tiles are laid. The thickness of the wood may be as much as an inch, but is usually thinner, $\frac{1}{4}$ in. being common.

Parquet is mostly laid over existing floor boards, and may be regarded not as true construction, but as decoration. On the other hand, wood blocks are frequently employed in the way parquet is used, but laid on a solid foundation, such as concrete, forming part of the structural floor; but this is not true parquet. Almost any geometrical pattern can be rendered in parquet, consistent with the limitations of the material, which does not admit of very small detail. Both types of flooring are illustrated and described below. Instructions are also given for preparing and laying wood blocks which the amateur can make from commercial timber.

Austrian oak is generally used for parquet, owing to its close, even grain and freedom from knots. It has a rich, uniform colour, but is comparatively soft, easily showing marks. English oak is employed, but is uneven in quality, figure, and colour. Russian, Japanese and American oak are also used, and a very fine floor can be constructed of teak from Rangoon or Java. The best kind of parquet is what is called plated, consisting of about 5/16 in. oak or teak pressed upon a backing of 1 in. deal. This method prevents buckling, and is suitable for the best class of inlaid work. Parquet is usually laid down in made-up panels, varying from 12 in. to 1 yd. Square.

Parquet. Fig. 1. Design in two different coloured woods with simple border.

Fig. 2. Showing use of both rectangular and square slabs.

Fig. 3. Plan of room showing parquet design to be used, and arrangement of border.

Before the laying of a parquet floor can be commenced a design has first to be drawn. To do this, the room is measured, the size of the angles being noted as well as the length, breadth and the various breaks, such as the breasting of the fireplace, and a scale drawing of the plan is made on paper. Two typical designs with borders are shown in Figs. 1 and 2. When a decorative border is

required, it is made sufficiently wide to extend beyond any of the smaller breaks or projections of the walls, so that the plain centre portion will thus finish against a straight line, as in Fig. 3. All larger projections or recesses must be followed round. From this drawing, the number of blocks required can be estimated and the length of the border decided upon.

The next consideration is the groundwork upon which the parquetry is to be laid. In new buildings it is usual first to lay a counterfloor on to the joists, this consisting of deal battens $\frac{3}{4}$ in. thick placed diagonally and butted square into each other at the ends so that the joints will run diversely to those of the upper flooring. When levelled and cleaned off, this forms a good surface for the laying. In older houses a common practice is to disguise well-worn deal floors with a layer of thin parquetry.

It is essential that the boards are first levelled, and any weak or creaking boards either replaced or the cause of the trouble rectified. The levelling is done by planing, first transversely across the grain with a jack plane, and finishing off with trying plane, the edges by the walls being brought to the general level with a rebate plane. It is very seldom that all the blocks are laid individually in position direct on the floor. The usual procedure is to build up the individual patterns on a bench and then to apply these patterns to the floor.

Fig. 4 shows a complete pattern ready for fixing. With very thin parquetry and in the cheaper kinds there is sometimes no binding joint between the blocks. In this case the patterns are built up on the bench and a piece of canvas glued to the back. When set they are placed in position on the groundwork and nailed through the face, the nails being punched in. Long thin nails are used, similar in shape to pins used for laying oil cloth, having no heads and tapering to a point. In better-class work, and in the thicker varieties, the sides of the blocks are grooved to receive metal tongues, or are dowelled.

Wherever possible the patterns are first built up, this being comparatively easy when the blocks are dowelled. The decorative borders are treated in a similar way, being put together in lengths of about 18 in. to 3 ft., according to the pattern.

Figs. 5 and 6 show methods of securing the blocks to the floor when it is required that no nail holes shall show on the surface. In Fig. 5 the block is fitted over the tongue of the preceding block and a nail driven askew through the groove at the other side, so forcing the block well towards the preceding one and making a close joint. The procedure is repeated with another block as shown, the grooves of both blocks being thus automatically locked with one nail. The dowelled example in Fig. 6 is treated in a similar way, so that one nail locks the adjacent ends of two blocks. For first-class work the blocks are also glued in position, the underside being left roughened so that the glue will obtain a firmer grip.

In all phases of the work it is customary to fix the border before filling in the centre. This requires some care when turning it round shaped projections and recesses, as all parts should fit perfectly to obtain a good result. In the event of a large bow window requiring a curved bordering, a template of the shape is made and the pattern drawn on it. The blocks are then assembled on this and fastened together in sections their relative positions being marked so that they may be reassembled in position on the floor. It is advisable to commence with all awkward portions such as this, fitting the straight pieces to them. In order to keep the pattern regular and symmetrical, the main lines of the design should be marked out on the floor (as indicated in Fig 3), and the sections of parquet laid in accordance with them. When no decorative border is required, a length of stuff is first mitred round the edge, as in Fig. 7; this not only gives a finished appearance to the completed parquet floor, but forms a straight clean edge to fit the pattern against. It also obviates the necessity of cutting the blocks round any awkward projections in the walls, and is occasionally useful in the event of two opposite walls being slightly out of parallel, as the two strips may be tapered, thus leaving their inner edges equidistant throughout their length. In all cases where the parquetry is not finished against a wall, as for instance by the hearth and the door in Fig. 7, a batten should be mitred round as a protection to the edge. When parquetry is laid on an already existing floor, the door, if it opens inwards into the room, must be taken down, and a strip equal to the total thickness of the parquetry sawn off the bottom.

When the laying has been completed, the whole surface is levelled with a smoothing plane and finished off with a steel scraper and glasspaper. If the blocks have been laid in sections comprising a complete pattern, only the juncture of the several patterns will require planing, the individual sections having been trued up on the bench prior to being laid.

The usual polish for these floors is wax thinned out with turpentine, the mixture being rubbed well in and left to stand for a day before being polished with dry dusters or with a brush. In some cases a

body of french polish is put on to keep the dirt from begriming the surface. Another method is oil polishing, which has the advantage of not being so liable to tread off or mark; it takes, however, a great deal of labour to keep it in a fair condition of freshness.

Parquet. Fig. 4. Pattern unit of grooved blocks ready to fix. Fig. 5. Blocks fixed by tongues and grooves. Fig. 6. Blocks fixed by dowels. Fig. 7. Plan of floor where no border is required. Fig. 8. Sections through three types of block. Fig. 9. Section through entire wood block flooring. Fig. 10. Blocks fitted by means of dowels, showing the order in which they are laid (herringbone floor).

Wood Block Floors. The laying of the thicker wood block floors entails a more elaborate process; no nails are used to fix it, the blocks being held down through the medium of a coating of mastic beneath. Fig. 8 shows sections through a few types of block, the under sides and edges being grooved in the form of a dovetail into which the mastic is forced, forming an exceedingly strong fixture. When the blocks are to be laid on a counter floor, a mixture of glue and whitening is used to fix the blocks, but in other work a mixture of pitch and coal tar is often used.

Fig. 9 shows a section through the flooring. A bed of concrete about 6 in. to 1 ft. in thickness is first put down and allowed to harden thoroughly. It is essential that this should completely dry, as otherwise the moisture will cause the woodwork to swell. This bedding is levelled by floating a coat of cement over the top, and is again left to set, the time varying according to the weather. In some cases a series of plugs are floated in the concrete level with the surface of the cement at a distance of about 6 ft. apart, as in Fig. 9, and to these the blocks are screwed.

The lower sketch in Fig. 8 shows a method of interlocking the blocks with tongues fitting into grooves cut in the side of the blocks. Another system is that in Fig. 10, in which the same result is obtained by dowels. When laying the blocks the latter are stacked in a handy pile, and a small portion of the floor boarded round to keep the mastic in bounds and to prevent it from spreading over too large an area at a time.

The mastic is then poured within the space at boiling heat and the blocks quickly rubbed in position, having been first dipped in the mastic up to about half their thickness. The size of the area boarded off will vary according to the number of men engaged on the task, two men being able to tackle an area of about 2 yards. Fig. 10 shows a herringbone floor, the blocks being numbered to show the order in which they are laid. When the work has been completed it should be left to set for a few days, and is then levelled off.

Parquet. Simple wood block flooring which the home worker can prepare. Fig. 11. Cutting strip to length with a sawing guide. Fig. 12. Planing the ends of the blocks. Fig. 13 Testing for length with a simple gauge. Fig. 14. Laying and fitting the blocks. Fig. 15. Corner of floor when completed.

Making Wood Blocks. The amateur can readily construct a wood block floor covering from strip material. This may be oak or any other ornamental wood, or it may be ordinary builder's deal of the

kind sold as door stopping and known as 4 in. by $\frac{1}{2}$ in., but which actually measures $3\frac{3}{4}$ in. wide and $\frac{7}{16}$ in. thick. It is cut to lengths of $11\frac{1}{4}$ in., as the length of the strip must be exactly equal to three times its width. If some other width material is used the length should be adjusted accordingly. It is important that the stuff should be uniform in width and thickness. The timber merchant will thickness the strips, and plane them on three surfaces. If the whole supply is bought at one time the wood can be put through the machine without altering the gauges, so that uniformity is assured. Suitable oak strips, $\frac{1}{2}$ in. by 4 in., may be procured from any good supplier of woodwork and turnery materials.

If the worker has a lathe with a saw table attachment, or a small treadle saw table, the work of cross cutting the strips to size will be greatly reduced. Failing this, a simple sawing gauge should first be made, such as that illustrated in Fig. 11. This comprises a baseboard constructed from 9 in. by 1 in. deal. At the left-hand end a cross batten is secured by screws. Two tapering upright pieces are screwed to the sides of the board, and a vertical saw-cut made through them exactly $11\frac{5}{16}$ in. from the inside edge of batten. The extra $\frac{1}{16}$ in. is provided to allow of the end grain of the material being planed up.

A few pieces only should be cut out at the start, and the ends planed by the use of an ordinary shooting board, as in Fig. 12. A smoothing plane or jack plane may be used. To ensure all the pieces of timber being of uniform length, they should be inserted into a gauge, as in Fig. 13, comprising a wooden baseboard to which cross pieces of batten are fitted to either end, the space between the inner faces being exactly $11\frac{1}{4}$ in.

Having prepared a few lengths in this way, they should be tested by laying three of them side by side and placing a fourth at right angles across them. The ends of the cross piece should exactly coincide with the outer sides of the three pieces. Should there be any variation, adjustment should be made accordingly until the length is exactly three times the breadth. This having been determined, the necessary number of blocks may be prepared. If it is desired to stain them, this can be done before commencing to lay the blocks, as the colour effect is better than if the blocks are stained after they are in position.

Forming the Pattern

The next step is to determine the pattern. Generally the blocks can be laid direct on the floor boards, provided the latter are reasonably level and sound. They may be attached by glueing the underside of the blocks and further secured by secret nailing. A long strip of stopping equal in thickness to the blocks and about 2 in. broad is fitted all around the walls, butting against the skirting board. If the latter is unequal, or displaced, the stopping should be accurately scribed to fit, so that when secured in its place the narrow strip of wood will fit tightly against the skirting and present a perfectly straight lining on the other side; the object is to provide a good working surface against which to build the blocks.

Fundamentally, all wood block floors are laid on geometrical lines, and consequently they must start on some straight line, and anything in the nature of curved work is practically impossible. Having prepared the strips for a sufficient area for the room, and glued and bradded them to the floor, the blocks may be laid in position as in Fig 14. They are laid one after the other, so that the second row overlaps the first by the width of one block. A fair number of blocks should be laid, commencing with one corner, before they are glued, just to get an idea of their arrangement and the way in which they are to be placed, after which they may be drawn aside and glued and bradded to the floor. In this case 1 in. oval brads will be strong enough for the purpose; they are driven diagonally through the edge of the block, the heads of the nails being punched into the wood.

The work proceeds in the same manner until the opposite corner is reached, but as it is possible that the distance to be covered will not be an exact multiple of the lengths of the blocks, it is best to lay

one complete row and ascertain whether they will fit exactly, or whether some of them must be cut specially. There are several ways of dealing with the problem. In some the blocks are laid from corner to corner, and the closers or specially cut pieces fitted about the middle of the room. In others the fit is arranged in the most inconspicuous corner, or at some other part of the room—as, for example, where the chimney breast or other projections intercept the natural run of the blocks. The blocks should be driven up closely into contact with a mallet. The result of laying them thus is shown in Fig. 15.

Good results are obtained by the use of strips of darker coloured wood, inserted in the form of a framework or border. Fig. 16 represents a small panel such as might be needed in a recess, or at the entrance to a room. Alternatively, a series of such patterns can be laid over the whole area of the floor. The method of laying these follows the same lines already indicated, and comprises an outer string, or framework, and then a row of blocks, followed by a second string. The panel is filled in with other blocks laid in a herringbone pattern. To complete this, the ends of the blocks are cut to an angle, and other small angular pieces cut and fitted to fill up the odd spaces. If the proportions are carefully arranged, these special cut blocks will be few in number, but they add to rather than detract from the appearance of the job when finished. If it is desired to fit the blocks without any angular cutting, another pattern than the herringbone must be used.

It will be found best to make a large scale drawing showing the arrangement of the blocks, or to lay them out on the floor before commencing the actual work, as often a slight modification in the size and proportion will enable blocks to be used without cutting them specially to fit.

Where the floor is very uneven the blocks may be bedded in mastic cement, or superimposed on thin felt paper, such as is used under linoleum. It should be a hard variety that will not yield unduly, as if it does the blocks might be displaced. A little care in laying them, and especially in the nailing, will result in a satisfactory job. Such a floor covering is extremely attractive in appearance, has the merits of being durable, and is by no means expensive when made up in the manner suggested.

Parquet. Fig. 16. Wood block flooring, showing good effect resulting from dark-coloured stringing and centre panel in herringbone blocks.

PARRISH'S FOOD. The compound syrup of iron phosphate, B.P. C., that is known also as chemical food or Parrish's syrup, is one of the most useful tonics for children who are weak and anaemic and have lost appetite. The dose for an adult is $\frac{1}{2}$ to 2 drams, and that for a child can be calculated according to the rule given in the article on dosage Parrish's food is often given in combination with cod liver oil. *See Dosage.*

PARROT. The method of keeping the bird upon a perch, with a long, light chain attached to the leg, is better than the small cage, for it enables the bird to move freely, to descend to the floor and to stretch its wings. Such a perch may in fine weather, be transferred to the garden, and if on such occasions the chain can be attached to the branch of a tree so much the better. Indoors, the length of the chain must not permit the bird to reach any of the furniture, or the latter will be spoiled by the powerful beak.

The Cage. In any case, a cage must be provided for sleeping, and the perches should be of two thicknesses, one about $\frac{1}{2}$ in. and the other $\frac{3}{4}$ in. in diameter. The best cage is the large square metal one, with a tray floor which can be withdrawn for cleaning. The tray should be covered thickly with dried garden mould, which is better than sand, and there should be a block or thick stick of soft, unsplinterable wood to engage the bird's bill. Water for drinking ought not to be kept in the cage; it should be given morning and evening, and then withdrawn. The bath should be provided daily outside the cage; if the bird objects to a wet bath, a pan of dusty earth may take its place, and will be used for dusting the plumage.

Parrot. Left, bird of dove-grey plumage, with pink tail, one of the best talkers. Right, red and blue macaw. (W. S. Berridge, F.Z.S.)

Food. Food must be varied, and no meat or meat products should be given. Hemp and canary seed may be offered, and to these may be added sunflower, maize and oats. The bird will show a marked preference for one or more of these, and an objection to, or at least a distaste for, some others. The favoured food should be adopted for its staple rations. Nuts should be added as their seasons come round: filberts, Brazil, walnut, chestnut, or a slice of coconut, with an occasional apple, pear, orange, banana, a few dates or a raw carrot. A dry biscuit or an unbuttered crust of bread may be given at times; also a knob of sugar. Coarse sand or fine gravel must be provided, from which the parrot will select grams for furnishing its gizzard, without which birds cannot assimilate their food. It is important to notice the effect of the various foods on the parrot's health. Certain foods may be found to produce diarrhoea, others constipation. Either conditions will be mitigated by at once

giving a few drops of castor oil floated on the drinking water, and the bill of fare should be amended accordingly. The suspected food may not be a harmful one, but its proportions may need reducing. An unsuitable position for the cage may cause catarrh, bronchitis or inflammation of the lungs. A large percentage of parrots die soon after their arrival, as the result of the unsuitable conditions of the voyage; and, therefore, if possible, a bird should only be purchased when it is known to have been in Great Britain for several months.

Indigestion is probably caused by a lack of grit in the gizzard. Yawning and distaste for food indicate biliousness, and may be put right by a pinch of carbonate of soda in the drinking water for two or three days. A fit of giddiness may be the result of indigestion, and the castor oil treatment may dispose of it; if not, it may be due to the presence of intestinal worms, for whose ejection a little scraped areca nut should be given. In the case of catarrh, five or six drops of tincture of aconite in water will abate the symptoms. Feather plucking is due usually to the presence of parasites under the plumage, which should be dusted with pyrethrum powder.

The most popular bird, undoubtedly, is the African grey or ash-coloured parrot, which holds the premier position for its linguistic attainments and its general good qualities.

Since May, 1930, the importation of parrots into Great Britain has been prohibited, on account of parrot disease. *See Psittacosis.*

PARROT TULIP. This variety of tulip has curiously cut or lacinated petals to its flowers, which are vivid and of many hues, like the plumage of the parrot. *See Tulip.*

PARSLEY: How to Grow. This herb is in great demand for garnishing purposes. It is raised from seeds sown out of doors in April and again towards the end of July; the seedlings should be thinned out till they are 6 or 8 in. apart.

As the leaves become tough and coarse, cut them off to induce fresh growth, especially when the plants show signs of beginning to flower. It may be necessary to protect parsley from frost with mats or a frame. The botanical name of parsley is *Carum petroselinum*.

Parsley. Bunch of the curly-leaved variety of this useful culinary herb.

Uses in Cookery. To prepare parsley to be finely chopped for garnishing, first blanch it by washing it well and picking it free from the stalks. Put it into a pan with a little cold salted water and bring to the boil. Strain off the liquid and dry the parsley in a towel. Now chop it with a sharp knife or chopper. When fine enough place on a clean towel and hold the parsley under the tap squeezing the towel, until the water runs away green. Wring dry in a dry cloth, and use. When parsley is being used for seasoning, care should be taken that too much is not used, as its flavour is extremely penetrating.

Fried parsley is used for garnishing certain hot dishes. After the parsley has been picked, washed and dried well, it should be put in a wire basket and fried in hot fat for about 1 min. It should then be quite crisp. If stored in an airtight tin, fried parsley can be kept for some days. To dry parsley for

winter use, it should be picked during May June or July, on a dry day. After well washing, strip the leaf off the stalk and dry it in a moderate oven until crisp. Rub it with the hands into a powder, and sieve. Store it in airtight bottles, which should be labelled.

Parsley can be preserved whole by washing and then plunging it into salted boiling water for 2 min. Let it then drain on the hot plate of the stove or in the oven, and when quite dry store it in an airtight bottle in a dry place. Before using, soak it for a few minutes in warm water.

Parsley Sauce. To make good parsley sauce, use a tablespoonful each of chopped parsley, butter, and flour, and $\frac{1}{2}$ pint of liquid, which may be either fish stock, milk, or equal quantities of each. Dissolve the butter in a small saucepan and stir in the flour. Cook for 2 min., then add the liquid and stir until it boils. Season to taste, and add the parsley. Do not let the parsley boil in the sauce or its colour will be spoiled. *See Cod; Fish.*

PARSLEY FERN. This is the popular name of *Allosorus crispus*, a hardy fern. 6 in. or so high. It is suitable for planting in shady crevices in the rock garden or dry wall in a compost of loam, peat and sand.

PARSNIP. This invaluable hardy root-vegetable is in season from late autumn until early spring. It is raised from seeds sown in March-April in deeply dug land free from fresh manure; friable soil which the roots can penetrate easily is required. The most economical practice is to sow groups of three or four seeds at 9 in. intervals along the drill: only one seedling must be left in each group. The drills should be about an inch deep. Alternatively seeds may be sown thinly along the drill and the seedlings thinned to 9 in. apart.

Parsnip. Fine specimens of a root vegetable of considerable food value.

During the summer months the soil between the rows, which should be 15 in. apart, must be hoed frequently. In late autumn, winter and early spring the roots are dug as required. In frosty weather it is wise to cover some of the roots with straw or other protective material to prevent the ground being frozen, and thus allow the roots to be lifted. The Student is a popular variety of parsnip possessing large, long roots. Tender and True is considered to be of better flavour.

How to Cook. The root of the parsnip furnishes a valuable food which contains a large percentage of sugar. As a vegetable it can be cooked in a variety of ways, either boiled, fried, stewed, or used with other ingredients. It is cooked after the same manner as the carrot, and when boiled or stewed is usually served with lumps of butter.

To prepare them for boiling, wash and scrape them clean or peel them thinly, remove the tops and throw them into cold water. Then slice them according to size, and put them into a saucepan of

slightly salted boiling water. Cook them slowly for about 1 hour, testing them with a fork to see if they are tender. Serve with white sauce.

Fried parsnips, which are usually served with roast mutton, are prepared by first boiling them and then cutting them into strips. Dip each strip in batter or in egg and breadcrumbs and then fry in hot fat.

Creamed parsnips are made by first boiling the parsnips, cutting them into slices, and then spreading the latter with butter. Lay them in a vegetable dish and cover with white sauce. *See Carrot; Kitchen Garden.*

Parsnip Growing. 1 and 2. Parsnip fly and larva. 3 and 5. Wasteful sowing and the result. 4 and 6. Economical sowing and its produce. 7. Misshapen roots through shallow digging and obstructions. 8. Result of deep digging and no manure. 9-11. Exhibition parsnip: 9. Crowbar hole filled with fine soil (a). 10. Seeds sown. 11. Resulting root. 12. Storing in box of sand. 13. Storing in clamp: a, sand; b, straw; c, earth; d, vent.

Partan. In Scotland the crab is called a partan, and crab sauce is known as partan sauce. *See Crab.*

PARTERRE. Used in connexion with gardens, a parterre is a formal arrangement of flower beds with walks of turf or gravel between. *See Garden; Italian Garden.*

PARTITION: How to Erect. An internal wall that divides a room into two compartments is known as a partition. When built of ordinary bricks laid with a simple bond such a partition is fireproof and

practically soundproof. Another method is to build it of coke breeze blocks, bedding these in cement mortar.

With the foregoing materials a firm foundation has to be provided. In most cases, where the partition is in the nature of an addition to an existing building, the only practical plan is to take a piece of stout timber, preferably oak, equal in breadth to that of the building bricks or blocks. In the case of bricks, this may be reckoned as $4\frac{1}{2}$ in.; for coke breeze blocks or slabs allow $2\frac{1}{2}$ to 3 in. The timber should be continuous from one side of the outer wall to the other. Alternatively it should extend for the whole length of the new partition, and should be placed in position regardless of any doorway that it may be intended to provide in the partition wall.

The opening will, in any case, have to be made up of a framework consisting of uprights of timber at least as wide as the thickness of the intended partition, and 2 in. or more in thickness. These should be mortised and tenoned into the floor plate, provided with a head or cross piece, as for example at the top of the door, and built into a plate, or piece of timber forming the top of the partition. In some cases the uprights may be joined to existing woodwork, such as ceiling joists. The essential point is to provide continuous uprights from the floor to the ceiling level, or some other strong support at the top. The continuous floor plate tends to keep the partition in line, and after the partition is up it is quite simple to cut away the unwanted piece at the bottom of the doorway opening. The wall is then erected on the top of the floor plate, built up to the framing around the door or any other openings, and continued to the top. The surfaces must be rendered with cement or worked up to a good face with a rough coat of plaster known as a pricking up coat, and finished with a fine or setting coat. The door is then hinged in the opening and finished in the usual way.

Partition. Attic bedroom panelled in "Sundeala" wall board.

Use of Wall Board. A much simpler partition can be made up with timber framing, covered with asbestos cement sheet, plywood, or any of the patent wall or building boards. The timber is fixed to the floor, uprights erected around the doorway openings, and the other studs spaced so that an upright is available for supporting the edges of each of the sheets. For

example, if the wall boards are 4 ft. wide, the studs may be spaced about 2 ft. centres, three of them being available for the support of one sheet. This saves cutting the sheets to waste, and also obviates the need of fitting extra studs.

The studs should be not less than 3 in. wide and 2 in. thick, and should be supported by uniform braces nailed between them, or jointed with a halving joint or some similar simple joint. Both sides of the work are finished up smooth and level, and consequently all the studs should be of the same thickness to provide a level surface whereon to nail the wall board. One side is fixed first, and then the other side, and the joints covered with strips of wood moulding to form panels, or finished in

any desired manner. The result is a very light partition, which is both easily constructed and fairly soundproof.

Partition. Diagram of portion of wall, showing wall boards nailed on cross pieces and studding. With some of the patent boards, of which several are obtainable, the makers advise that the edges should not be nailed, or that one edge only in each direction should be nailed. A gap of about $\frac{1}{4}$ in. should be left between the edges of adjacent sheets, to allow for expansion and consequent movement.

If a soundproof partition is desired, a special form of building board can be obtained which has sound-absorbing qualities. Other varieties are waterproofed, fitting them for external use, and these are dealt with in the article on Wall Board (q.v.).

Lath and Plaster. An excellent partition is made by making up a stud or framework as previously described and covering it with plasterers' laths nailed on with lath nails about 1 in. long and leaving a gap between each lath of $\frac{3}{8}$ in. When completed the surfaces are plastered with a pricking-up coat and the whole brought to a fine and true surface with a hard plaster.

The advantage of this type of partition is that the surface is perfectly smooth and can be worked into any existing wall arrangements. The doorway should be finished with an architrave, and such items as the skirting-board, picture rail and so forth, can easily be matched up to the existing work and continued across the partition at the same levels. A partition made in this way should not normally be distempered or papered until at least six months after it has been built, as it may spoil the distemper and discolour the paper. There are compositions available which are claimed to overcome this difficulty, and can be used on practically wet plaster. One of these may be used if it is imperative to complete the decoration very quickly.

A point to be noted with all partitions is they should be fitted into the existing walls as strongly as possible.

In the case of the stud partition, that is, one made of wooden uprights, the uprights should be securely spiked to the wall, taking care to set it up perfectly plumb and true with the aid of a plumb bob and line, or with a plumb rule.

In the case of a partition made of brick to be bonded into a wall of similar material, the plaster should be cut away closely and neatly. If the existing walls are 9 in. thick, a few of the stretchers may be cut out about every 2 ft. apart and the new work bonded into the existing work by setting the brick halfway into the existing wall from which the stretcher has been removed and half in the partition wall. When coke breeze blocks are used, short stout pieces of iron may be embedded between the bricks of the existing wall and set on the top of the breeze blocks.

The amateur should obtain expert advice before interfering in any way with the walls or principal timbers of the house. Apart from considerations of safety, such an operation may be contrary to provisions of a lease or tenancy agreement, or may need approval by a local authority.

PARTRIDGE: How to Cook. For some dishes old birds may be used, but for roasting or broiling they must be young. The flesh of the young birds is easily digested, and is most suitable for invalids, and is highly nutritious.

To distinguish the age of the birds it is necessary, when purchasing, to examine the bills and the pinions, also to notice the colour of the legs. If they are young, the bill will be of a dark tint, and the legs will be yellow, while the flesh of the pinions will be tender when pressed, and the long wing feathers will be pointed. If old, the bills will be whitish, the legs blue, and the long wing feathers rounded. If stale, the vent has a greenish appearance. At the present day game is eaten much fresher than formerly, but partridge should always hang for at least a week.

General rules for cooking partridges and for making pies, puddings, or entrées from these birds are the same as for other game, and will be found under that heading.

Cooking with Cabbage. One of the most tasty methods of cooking partridge is to stew with cabbage. Savoy cabbage is best, as it seems to impart a peculiarly agreeable flavour to the birds. Prepare and truss a brace of partridges and fry them in a stewpan with 4 rashers of bacon and 1 oz. butter, then add 1 gill stock. Have ready a savoy cabbage well washed and drained. Cut it into slices, put it in the stewpan with the partridges, and stew for 1 hour, turning the birds occasionally. To serve, dish the rashers and lay the partridge on them, and arrange the cabbage and liquor round the dish.

Another way of cooking these birds with cabbage is to roast them for 10 min. and then cut them into neat pieces. Butter a plain charlotte mould, about a 3 pint size will do, and cover the bottom with a layer of savoy cabbage which has been cooked, pressed, seasoned and softened with butter. Place on the prepared cabbage a layer of pieces of partridge, and fill up the cavities with cabbage to ensure an even surface. Lay over the partridge 6 thin slices of pickled pork, add the remainder of the bird, and over that the rest of the cabbage; press all well down into the mould and tie over the

top a stout piece of buttered paper. Put the chartreuse into a moderate oven for from 15 to 20 min., taking care that it does not brown. When cooked, turn it over on to a hot dish, lift up the mould, and serve with a rich brown gravy round. This dish can also be made with old birds.

Braising. To braise partridges prepare 2 or 3 birds as for roasting, with bacon tied over the breasts, put them in a casserole with 1 oz. butter. Moisten with 1 pint good stock and a wineglassful port or madeira, then season, add a bouquet garni and close the casserole tightly down by laying a buttered paper over the top underneath the lid. Cook gently in a moderate oven till the birds are tender. Serve them on a block of fried bread, and keep hot. Strain the liquor from the braise, thicken it with flour, skim it free from fat and pour it over and round the birds. Garnish with fried button mushrooms or any suitable dressed vegetable. If the sauce seems scanty prepare a little extra rich brown sauce and serve it in a sauceboat. *See* Devilling; Game; Pheasant.

PARTRIDGE BERRY. This is the popular name of a low-growing hardy evergreen shrub, *Gaultheria procumbens*. It bears white flowers in spring and red berries in autumn, and needs loamy or peaty soil and partial shade. *Gaultheria shallon*, 3 ft. high, is a valuable evergreen shrub, with blush coloured flowers in spring and dark fruits later on, which is useful for planting in shady places; peat and loam should be added to the soil.

PASQUE FLOWER. This is the common name of the *Anemone pulsatilla*, a hardy plant which bears beautiful mauve coloured flowers in April and May. It grows about 10 in. high and flourishes in loamy soil with which lime or mortar rubble has been mixed. It likes partial shade. *See* Anemone.

PASSAGE. In the domestic sense this word is employed for the space in the house that leads from one room to another, or from a front or back door to the rooms. It is practically covered by the articles on hall, landing, and staircase. *See* Hall; Landing; Staircase.

PASS BOOK. This name is given to the book which shows the receipts and payments of a banking account. The book is supplied by the bank to the customers, and the items are entered by the bank officials. It is desirable that a pass book should be sent to the bank for the latter purpose at least once a quarter and that the customer should inspect it now and again. *See* Banking; Cheque.

PASSE PARTOUT. The method of framing by means of passe-partout binding, for photographs, prints, small drawings and water-colours, is frequently more effective than by a raised frame. All that is required for framing a picture by this method is a piece of glass, mount, and cardboard back identical in size, 2 small metal hangers, made much on the principle of brass paper fasteners, a small pot of gum, and a roll of passe-partout binding. The binding should harmonize with the mount, being best, as a rule, darker in colour, while both should harmonize with the picture. Bindings can be obtained in a large range of colours, widths, and surfaces.

In the cardboard back, about 1 to 1½ in. from the top and equidistant from the sides, punch two small holes, and into these fix the metal hangers. It is important that these should be at exactly equal distances both from top and sides, or the picture will not hang straight. Next fix the picture to the mount and the mount to the back by means of dabs of gum at the corners. Make sure the glass is quite clean, then place it flat on the table on a piece of paper ruled with straight lines to indicate the required depth of the framing. This will act as a guide in getting the passe partout straight.

Cut 2 pieces of binding 1 in. longer than the sides of the glass, moisten about half the width, and apply immediately to the glass so that the edges just reach the ruled lines and ½ in. juts out at either end. Press them down until firmly fixed. Turn the glass over and put on it the picture, mount, and

back. Moisten the projecting binding, fold it over the back, and press it down until set. Cut off the ends, both top and bottom, to about $\frac{1}{8}$ in. from the glass.

Cut 2 pieces of binding 1 in. longer than the top and bottom of the glass and mitre them at each end, so that the shorter side is exactly the length of the space between the side bindings. Moisten the shorter side of each strip, apply them to the glass, and press them down. Be sure that the part fixed to the glass is exactly the same in width as at the sides. Turn the picture over and fix the rest of the binding as before, folding in the ends neatly.

Passe Partout. The raised framing of a picture. Fig. 1. The cardboard backing is pierced with holes for hangers. Fig. 2. Two lengths of cardboard strips are cut off to the exact length of the glass. Fig. 3. A piece of gold passe-partout binding $\frac{1}{2}$ in. longer than the cardboard strip is cut off, moistened and laid on it, being firmly pressed down with a bone creaser. Fig. 4. Glue is applied lightly to the two covered strips and they are then placed in position on the glass exactly level with the edge. Fig. 5. Two more lengths of cardboard strips are cut to fit exactly between those glued on the glass, the ends being mitred, and the same process of glueing is followed. Fig. 6. Two pieces of binding of the chosen style are cut 1 in. longer than the picture, and laid over the inner binding about $\frac{1}{32}$ of an inch from inner edge. Picture, backing board, mount and glass are placed together and the binding brought over to the back. The corners are finished as shown. Fig. 7. Two pieces of binding the exact length of the remaining sides are cut and applied. Fig. 8. The finished picture. (Courtesy of Dennison Manufacturing Co., Ltd.)

Making a Raised Frame. The passe-partout method of framing can also be applied to make a raised frame. The articles required for this include, as well as those mentioned, some strips of pasteboard, $\frac{1}{4}$ to $\frac{1}{2}$ in. wide, and 2 rolls of binding, one for the frame itself, the other for a frame lining. Fix the metal hangers in the back, Fig. 1 and fasten picture, mount, and back together as described above. Cut off 2 strips of the pasteboard exactly the length of the glass, Fig. 2, and also cut off 2 pieces of gold binding $\frac{1}{2}$ in. longer, Fig 3. Moisten the binding and cover the pasteboard with it carefully and evenly; then gum lightly the underside of the strips, Fig. 4, and fix them to the glass, level with the edges.

Two strips of cardboard must now be cut for top and bottom, to fix exactly between the side pieces. Fig. 5. These are also covered with binding, so that the binding projects $\frac{1}{2}$ in. or $\frac{1}{4}$ in. at each end, according to the depth of the pasteboard. These ends of binding should be cut off at an angle of 45° before the pasteboard is gummed and fixed in place on the glass. Moisten the triangular ends and fix down to neaten the corners. The passepartout framing is then carried out as described in the earlier method, the inner binding being all but covered by the outer framing, Figs. 6 and 7. Many variations of both these methods will suggest themselves, but should not be tried until the simple passe-partout framing can be carried out easily and with perfect neatness. *See Mounting.*

PASSION FLOWER. The passion flower belongs to a family of climbing plants which are mostly natives of Central and Southern America. Most of them need the temperature of the hothouse, but there are two hardy sorts which are the most important. These are *Passiflora caerulea*, the beautiful blue passion flower, and its white variety, Constance Elliott. They will thrive in any good ordinary soil with the protection of a south or west wall. When the plants have filled the space allotted to them they should be pruned in spring; otherwise little pruning is needed.

The hothouse kinds have flowers of various rich colours. They must be potted up in the ordinary mixture of loam, leaf-mould, and silver sand, or in beds of 2 ft. wide by at least 1 ft. in depth. They can be trained up rafters or walls, and need pruning just as do the outdoor varieties. A temperature of between 60° and 70° should be maintained.

Passion Flower. The blue passion flower. Passiflora caerulea, and its white variety are suitable for planting against a sunny wall.

PASSOVER CAKE. The Jewish cakes which are eaten at the feast of the Passover are made from 1 lb. best flour, $\frac{1}{4}$ teaspoonful salt, and enough cream to mix the whole to a stiff paste. Sieve the flour and salt into a basin, warm them before the fire and then stir in the cream. Roll the pastry out thinly on a floured board, then stamp it into large rounds and cook these on a girdle over the fire. When one side begins to blister, turn the cake and cook on the other side. They should be crisp and of a pale brown colour when cooked.

PASTE: Various Kinds. A paste made of flour and water is capable of joining many light articles. To make the ordinary household paste, mix 1 lb. wheaten flour with 1 oz. alum and add 4 pints of cold water, stirring all the time. Run the mixture through a sieve to ensure that no lumps remain, then transfer to a saucepan and boil for five minutes, stirring all the time. The paste will be thick, and to ensure it keeping for a few weeks add as a preservative thirty drops of oil of cloves and the same quantity of carbolic acid.

For Mounting. As an adhesive for mounting photographs it is necessary to avoid the use of acid ingredients, such as alum, as this would act on the photograph and cause it to fade. Professional photographers use freshly made starch paste, made by first mixing powdered starch with a little water to form a paste and then adding boiling water, stirring all the time. Dextrin can be employed

for an adhesive that keeps, one pound of dextrin being boiled with 25 oz. of water until it has dissolved, then, after adding 30 drops of oil of cloves as a preservative, pour into small jars for use.

For Paperhanging. Paste for paperhanging is made from 3½ lb. flour mixed with cold water to a stiff batter. A gallon of boiling water is then added, in which two tablespoonfuls of ground alum have been boiled. The top of the paste should be covered when cold with a little cold water to prevent the formation of a crust. This paste should be quite stiff, and requires thinning down with cold water before use. It should not be employed thinner than can easily be spread.

For Linoleum. A paste for linoleum is made by mixing the rye flour with cold water to a somewhat stiffer consistency, and adding boiling water. Some glue size is melted down and added to the paste whilst both are hot. They should be well stirred and allowed to cool, when the paste will be ready for use. The more size that is used, the stronger the paste will be. Alum may be used as a preservative. In connexion with leather or strong papier mâché work, a paste which is similar to linoleum paste is prepared, but instead of employing size, powdered resin is added. Boiling should be slow, and the paste should be of the consistency of butter.

PASTE: In Jewelry. A certain colourless flint glass of the hardest and densest kind, known as vitreous paste, is used to imitate diamonds; for other stones the glass is melted with various coloured oxides. In the 18th century a Viennese, Joseph Strass, invented a fine quality of paste, which has since been known by the name of strass. It possesses almost the brilliancy of diamonds, but as this brilliancy was obtained by a greater amount of oxide of lead in its composition the paste lost some of its hardness. For the best paste jewels, the strass is cut, ground, polished and faceted with exactly the same care as are precious stones.

It is usually set with a solid backing, as the foil enhances the sparkle of the paste, but some of the finest qualities stand the test of the open setting. This is particularly the case with coloured strass. So beautiful were the imitations of rubies, sapphires, emeralds and amethysts that in the 18th century some court jewellers preferred to carry out their creations in paste rather than real gems. With the former they could obtain a truer colour in flawless pieces of exactly the size required. With real gems the design had to be subordinated to the stones, and the matching of flawless stones of a good colour for a large ornament presented great difficulties, with emeralds almost an impossibility. Spanish paste of this period has a great value for collectors, while French and English designs were also of great beauty. Lovely pieces were made on a background of dark blue paste with raised floral designs in diamond paste, a style mostly used in marquise rings and watches. Other beautiful pieces are the miniature frames often surmounted with scroll or ribbon paste work. In the English Georgian paste the stones were cut large and square, well faceted, and often mounted in gold, whereas the French and Spanish designers used silver.

Modern paste is either carried out in replicas of the fashionable jewels, or the old designs are copied for shoe buckles, and other ornaments. In the first case the paste is purely an imitation: in the second, it makes no pretence at being real stones, and if the designs are good it has a beauty of its own. This is especially the case with shoe buckles. The square shapes with large stones well set in straight lines show the Georgian influence; the delicate scroll and spray work, the French.

A paste composition is used to imitate turquoises successfully for fancy ornaments and also for cameos, intaglios, and Egyptian scarabs. Paste will not scratch glass as a diamond will, and a test is applied in which an aluminium pencil is drawn across the surface of a jewel to be tested; if paste, a silvery line remains; if natural stone there is no such result.

PASTEBOARD. A form of cardboard composed of layers of thin card united with paste and consolidated under pressure is known as pasteboard. It is a strong material which has many uses in the home, the use to which it is most commonly put being in making small boxes and crates for the storage or packing of goods for transit.

PASTEL PICTURE. Although less affected by damp than are water-colours, pastels should be guarded against it, by using cork disks behind the frames. The effect of fixatives, such as shellac, is always deleterious, and spraying with a diffuser or varnishing with a brush is fatal to the soft bloom of untouched crayon-work. It should therefore be framed and glazed. A grey or stone coloured mount is most usually suitable, and a narrow black or brown frame should be selected. During the 18th century portrait-pastels were often executed in several media. Thus the portrait might be drawn in crayon on a landscape background in water-colour or gouache, and the detail heightened by the pencil. Mixed drawings of this kind do not bear exposure to strong light with the same impunity as pure pastel, and therefore need special care.

PASTEURISATION. This process destroys nearly all germs. By keeping milk at a temperature between 145° F. and 150° F. for not less than half an hour it becomes pasteurised. The milk may be in bottles which are put into a saucepan or a special container, or a double saucepan may be used. At dairies which are authorised to supply certified pasteurised milk an approved apparatus must be used. It is to be noted that children fed on pasteurised milk should be given a teaspoonful of grape or orange juice once or twice every day. *See* Baby; Diet; Milk.

PASTRY FOR PIES, TARTS AND PATTIES

Popular Recipes for Plain and Rich Varieties

Under this heading are included the ordinary pastries. Fancy kinds such as Genoese and Flan pastry are given under their respective headings. See also entries on the various pies and tarts, e.g. Apple Pie; Apricot Tart; Giblet Pie; and those on Banbury Cake; Cheese Cake; Cream Bun; Patty; etc.

Pastry consists of a preparation of flour, fat and water with the occasional addition of baking powder, eggs, sugar, and lemon juice. The proportion of fat to flour and the methods in which they are mixed make the difference between one kind of pastry and another.

Flaky pastry is intended principally for covering meat pies, mince pies, sausage rolls, etc., and sometimes for covered fruit pies. But both flaky and puff pastry are often used to make light fancy cakes with fillings of jam or cream or currants, such as the cases of Banbury cakes, Vanilla cream slices, jam puffs or patties. Short pastry is used for fruit tarts, jam tarts and tartlets, or any sweet pudding where a soft mixture is baked in a pastry-lined dish. Hot water pastry makes the correct crust for raised pies, and choux pastry is necessary for éclairs.

Two rules must be borne in mind for successful pastry making. Everything must be as cold as possible, except in the case of hot water crust and the fancy pastries, which are in a class to themselves, and the pastry must be handled as little and as lightly as possible.

An ordinary plain rolling pin is best, not one with revolving handles. The glass rolling pins that can be filled with cold water are excellent for pastry. A slab of marble or plate glass or a table with an enamelled metal top is better than a wooden pastry board for rolling out the pastry. All baking tins should be thick or they will warp and spoil the shape of small pastries. A thick tin also prevents burning at the bottom of mince pies or patties.

The best white flour should always be used, and this must be quite dry and cold, and sieved before use. Use a knife for mixing as much as possible, then use the finger tips to finish. Work away from the heat and keep the hands as cool as possible. Margarine alone should never be used for pastry, as

it does not contain animal fat, and the oil in it would make the pastry hard and dry. Good lard alone is best for plain pastry, or a mixture of lard and margarine can be used, and butter for puff pastry.

The pastry must be mixed to a soft dough that leaves the sides of the bowl clean. It is impossible to give the exact amount of water required as flours vary in texture. If the pastry is too wet or too dry it will be tough when baked. Use as little flour as possible when rolling out, as too much spoils its appearance when cooked. Do not press heavily when rolling, but use short, firm strokes. Get the pastry to an even thickness; the edges must not be thinner than the rest.

Much good pastry is ruined in baking. A hot oven must be used for ordinary pastry (375 to 380 degrees) and for puff pastry a very hot oven (400 degrees). Otherwise the fat will liquefy before the starch cells in the flour have burst to absorb it, and the pastry will be heavy and oily. Cold air and sudden draught will cause the pastry to fall and be heavy. The oven door should not be opened until the pastry has had time to get well risen and set. Uncooked pastry will keep fresh for several days if wrapped in greaseproof paper and kept in a cool place. Patty or tartlet tins or pie dishes do not need greasing when good pastry is used, as it contains sufficient fat to prevent sticking.

Short Pastry. The ingredients required for this are $\frac{1}{2}$ lb. flour, 4 oz. lard, $\frac{1}{4}$ teaspoonful salt, $\frac{1}{2}$ teaspoonful baking powder, and cold water to mix. Rub the lard into the flour until it looks like breadcrumbs. Add the dry ingredients and mix well. Mix stiffly with cold water, using a knife. Work lightly with the fingers until smooth, using a little more water or flour until it is quite pliable. Roll out at once on a floured board and use as required.

Flaky Pastry. A good recipe for flaky pastry needs the following ingredients and method of making. Take $\frac{1}{2}$ lb. flour, 6 oz. lard and margarine mixed, $\frac{1}{4}$ teaspoonful salt, a squeeze of lemon juice, cold water. Mix flour and salt in a basin. Divide the fat into four portions, and rub one portion into the flour. Mix to an elastic dough with lemon juice and water. Roll into an oblong strip on a floured board. Flake one portion of the fat down two-thirds of the pastry, leaving the third portion nearest without fat on it. Fold in three from the lower end. Give one-half turn so that open edges are opposite, press these edges lightly with rolling pin to close them, roll out to an oblong the same as before. Repeat the process until all the fat is worked in, fold up the pastry and set aside for an hour. Roll out once more (five times in all), cut to required shape and use. Brush with beaten egg and bake in a hot oven. A larger proportion of fat to flour is used for flaky pastry, but no baking powder is necessary.

Puff Pastry. To make this rich pastry take $\frac{1}{2}$ lb. flour, $\frac{1}{2}$ lb. cooking butter, $\frac{1}{2}$ teaspoonful lemon juice, $\frac{1}{4}$ teaspoonful salt, cold water. Press the butter to an even oblong shape in a floured cloth. Rub a small piece of the butter into the flour, add the salt. Mix to an elastic consistency with the lemon juice and water, and work lightly until smooth. Roll out into a square, not too thin. Put the square pat of butter into the centre of the pastry and fold it over, so that there is a parcel of butter wrapped up in pastry. Roll out into a long strip, press gently at first with the rolling pin so that the butter is gradually absorbed into the pastry. Fold in three and roll out again, keeping the open ends to and from you while rolling. Fold and roll out again, then set aside in a cool place for an hour. Roll out twice more and set aside again. Then roll out twice more (folding pastry between each time) and use. Puff pastry should be rolled out seven times in all.

Rough Puff Pastry. This is really a simpler form of puff pastry, requiring less rolling, and less shortening is used. Take $\frac{1}{2}$ lb. flour, 6 oz. lard and margarine mixed, $\frac{1}{4}$ teaspoonful salt, squeeze of lemon juice, cold water. Mix the flour and salt, cut the shortening into pieces the size of a walnut and mix them into the flour. Mix to an elastic dough with the lemon juice and cold water. Turn on to

a floured board and knead lightly and quickly until smooth and of an even texture. Roll out and fold four times. Stand aside in a cold place for an hour or longer, then roll out and use. Bake in a hot oven.

Hot Water Crust. Contrary to the general rules for making pastry, this paste must be made in a warm atmosphere, and it should never be allowed to get very cool. The ingredients required are $\frac{3}{4}$ lb. flour, $\frac{1}{4}$ lb. lard, 1 egg yolk, $\frac{3}{4}$ teaspoonful salt, about a gill of milk and water. Add salt to flour. Put milk and water and lard in a saucepan and bring to the boil. Add egg yolk to flour, stir in the liquid and mix with a knife until smooth. Leave it, covered with a cloth, in a warm place for an hour or so, then knead it for about ten minutes. Keep warm and use for raised pies as required.

Choux Pastry. This delicate type of pastry is used for making cream buns and éclairs. A good recipe requires 1 oz. sugar, 3 oz. butter, 6 oz. flour, 3 eggs, a few drops of vanilla, $\frac{1}{2}$ pint water. Put into a saucepan over the fire the sugar, butter and $\frac{1}{2}$ pint water. When these are boiling, stir in the flour quickly, beating the mixture till smooth and cooking it till it leaves the sides of the pan clear. Then take it from the fire, let its contents cool slightly before beating in the eggs, one at a time, and flavour the whole with the vanilla. Spread the mixture on a plate to cool before using it and then bake in a slow oven till it is pale brown in colour.

Pastry Brush. Pastry brushes are used for greasing baking tins and applying raw egg and other coatings for pastry. They are made of white French bristle of various lengths in metal bands or socket handles. For those used in grease it is essential they should not depend entirely on cement to hold the bristles together. Oily substances will penetrate to the roots of the bristles, with the result that loose hairs come out in use. There are various patent or machine-made brushes which claim to be indestructible, and as pressure is employed as an additional security in these, they are to be preferred to ordinary cement-set brushes.

As in the case with all utensils used in the preparation of food, care is necessary to ensure that the brushes are kept clean. Apart from dust and particles of the ingredients used that may adhere to a sticky brush, grease remaining round the roots of the bristles will turn sour, and if in contact with a metal band will produce verdigris. The brush should be thoroughly washed out in a cup of hot water on every occasion after use. Brushes used for egg should not be put into hot water, as it sets the egg. Stand the brush in a jar filled with cold water and rinse under running tap.

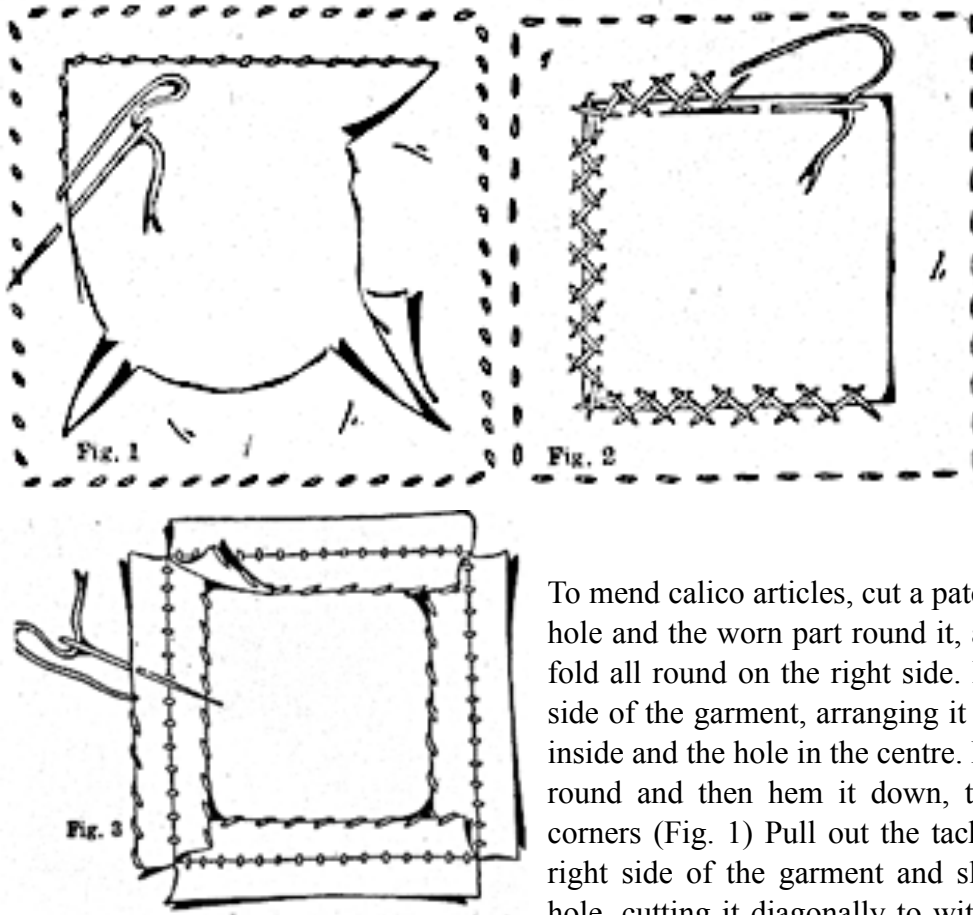

PASTY. Every kind of meat, fish, or sweet that is enclosed entirely in pastry is called a pasty, if baked without the aid of a tin or dish other than the baking-sheet on which it is laid. The shape is immaterial, but usually it takes the form of a half circle. Pasties make a useful variety of meat pie, especially for picnic open-air luncheons, as knives and forks need not be carried for service.

The pasty is an economical method of using up odd pieces of pastry left over from pie-making. A plain short crust is most suitable, and the meat or fruit must be cut fine, and well seasoned or flavoured. If the pasty is to be filled with jam or fruit, take care that this is placed right in the centre of the round, so that when the paste is folded over the jam or fruit juice does not escape through the edges. These should be moistened and well pressed together. *See Apple Turnover; Cornish Pasty.*

PATCHESI. This indoor game is a variant of the race game. It is played by four persons. The board is arranged with the part in which the play takes place in the form of a Greek cross with the home or goal in the centre. The only other implements required are dice. Each player has one arm of the cross, which is divided into squares arranged in three rows, and three counters, which he moves over the squares in accordance with his throws of the dice. Each player must first move his men

along one of the outer rows towards the centre, then back along the other outer row, and finally down the centre row to the goal. The one who reaches this first wins the game. *See Race Game.*

PATCHING. The method used for patching depends upon the article to be patched. Usually a patch is sewn on the wrong side, but one made of printed material is best put on the right side. If the patch is to form one with the garment, care must be taken that the pattern matches and does not break up the surface. This result would obviously be difficult to obtain if the patch were put on the wrong side of the material.

Patching. Fig. 1. Right side of calico sheet, showing hemming and arrangement of corners. Fig. 2. Herringbone stitch used in patching flannel. Fig. 3. Overcasting edge to prevent fraying when patching thick material.

To mend calico articles, cut a patch a little larger than the hole and the worn part round it, and turn down a narrow fold all round on the right side. Place this on the wrong side of the garment, arranging it so that the folds will be inside and the hole in the centre. Pin it in place, tack it all round and then hem it down, taking extra care at the corners (Fig. 1) Pull out the tacking stitches turn to the right side of the garment and slip the scissors into the hole, cutting it diagonally to within about $\frac{1}{4}$ in. of each corner (Fig. 1). Cut out the worn portion, leaving a

narrow edge of uniform width all round; turn this edge in and sew it down neatly. The patch is then finished, and only needs to be pressed with a warm iron.

When patching flannel, the right and wrong sides of the material should be determined, the former being the more fluffy. Each side should be cut straight enough to keep it to the same thread, and herringbone stitch is used for sewing the patch (Fig. 2). Fig. 3 shows a good method for thick materials. Lay the patch on the garment, making it 1 in. larger all round than the hole. Turn in and tack a single hem, $\frac{1}{2}$ in. deep, all round the wrong side of the hole and a similar one round the wrong side of the patch. Fit the patch into the hole and overcast them together. Overcast the raw edges to prevent the patch fraying, and then press the patch well on the right side. For very fine work a darned-in patch is the best. The patch must fit right into the hole and the edges be darned together. *See Darning; Mending.*

PATCHOULI PLANT. This name is given to one of the varieties of the greenhouse foliage plant *Coleus*, most of which are grown for their begonia-like leaves and their value as summer bedding-

out plants. *C. aromatica* has a leaf, however, from which a one-time favourite perfume was obtained.

PATCHWORK AND ITS DECORATIVE USES

Ornamental Designs with Scraps of Silk, Leather, Lace and Paper

The reader is referred to the articles on Appliqué and Embroidery for the stitches used in patchwork. See also Cushion; Lace; Leather Work; Paste; Picture; Pouffe.

Patchwork with a suitable assortment of colours and materials and a skilful method of assembling and joining the pieces can be raised to the level of an applied art if a good design is first originated, or copied, and the requisite patches are cut and joined to carry out the definite pattern or pictorial effect selected. The materials cost practically nothing, but the results can be richly decorative.

Designs must have suitable relation to the objects to be made or partially covered with patchwork. They must also be chosen with regard to the materials that the worker wishes to utilize. It is a mistake to mix patches of heavy weight with thin fabrics; the pieces should be of average substance throughout the work. For instance, leather and stout cloth, velours or velvet, may be used together, and a simple geometrical design should be chosen for their patchwork; silks, satins and lightweight velvets should be assembled for more intricate designs in which fancy stitchery may play an important part; lace should be mixed only with net or openwork embroideries such as *Broderie Anglaise*; paper patchwork must be entirely of paper, though this may be tinselled or of any colour required by the design.

The completed piece of patchwork made from woven fabrics or leather usually requires to be backed or lined with a suitably strong piece of material. As paste is employed to assemble paper patches on to cardboard or strong cartridge or parchment paper, it is necessary to provide a background when the design is completed.

Leather and Velvet Patchwork. Ornamental and durable accessories for the home can be made from patches of coloured leathers or from mixing these with other suitable materials. Floor cushions and pouffes, sofa cushions for lounge or dining room, and pyjama cases are among the best articles on which to use leather patchwork. Cuttings from leatherwork should be saved or can be purchased cheaply. A good effect is obtained by working light and dark brown leathers in *parquetry* patterns. Harlequin patterns of diamond-shaped pieces also look well in three or more shades. Details about cutting leather, sewing and thonging are given in the article on Leather Work. Thonging can be employed for joining larger patches of stout leathers and for making an edging to a cushion or pouffe.

Round leather cushions for cars and cloth floor cushions in contrasting colours may be adapted to patchwork of leather, velvet and cloth pieces. Care must be taken not to employ too many colours and to balance any change by a corresponding change in the other stripes.

In this style of patchwork patterned materials are hardly ever successful in combination with plain scraps. The only exception would be in the case of some very boldly designed piece of velvet in which the pattern made a distinct motif which could be utilized as a central piece in the same way that a *marquetry* panel decorates inlay. Linoleum, tiles and inlaid wood all may offer useful suggestions for geometrical patterns.

Whether leather alone or with fabrics is used, or velvets and cloths are combined, it is essential when planning the pattern to have a definite colour scheme in mind. The larger the patches the more important it is that they should harmonize with the room in which the finished article will be used. When patches are intended to match each other they must be cut to exactly the same size. It is a good plan to make a template for each required shape out of cardboard to guide the scissors. The

patches should be cut larger than the template to allow for turnings. Pieces of writing paper may then be cut to the exact size of the template and pasted lightly to the back of the leather or velvet patches in order to ensure even turnings.

Templates would be too laborious a method to adopt for patterns except in the case of simple designs requiring only a few shapes. It is advisable at first to use straight-sided patches. Squares, oblongs, triangles, stripes, diamonds, and hexagons or stars need less skill in joining than curved pieces. Some excellent designs for suède-finished leather and velvet patchwork for cushions, telephone book covers and tops of floor pouffes can be evolved from stained glass window paper. The lines of the leading can be traced out with the aid of carbon paper on an unbleached calico or linen foundation, the colours of the patches carefully selected and cut out from separate transfers of their respective shapes made from the stained glass window pattern on to tracing paper. No allowance for turnings is needed, because the joins are covered by narrow gimp or a tinsel braid.

Patchwork of Thin Materials. For articles such as handkerchief or nightdress sachets and workbags, scraps of coloured ribbons arranged in striped designs with zigzag or triangular borders will form neat patchwork. A piece of floral silk or satin may be chosen as a central motif and framed with scraps of ribbon which tone with material used for the rest of the article and with the motif. Fancy stitches may be introduced for joining pieces or for adding interest to designs. Buttonhole, ornamental blanket-stitch and satin-stitch are useful: while feather-stitch (q.v.) or faggoting (q.v.) are very suitable for linen patchwork.

Faggoting may be used to assemble scraps of linen, poplin or casement cloth for runners and mats. Patchwork in four colours such as grey, green, pink and rose, or brown, beige, yellow and orange, is effective for these. The scraps should be cut into squares or oblongs and arranged so that the colours balance nicely. One shade should be chosen for the narrow border to be faggoted to the joined patches, and the embroidery cotton used for the faggoting should match this. A good effect is gained by cutting the central oblong or square also of this shade and larger than the rest of the patches. Individual taste will evolve many ideas on these lines. Borders may be of narrow lace if a remnant is forthcoming from the scrap bag, or edges may be scalloped.

Pictorial designs can utilize a number of colours and fabrics. Really fine work is done on pieces of canvas with contrasting materials and a variety of stitches to outline detail and supply shading. Such work requires very careful planning, and it is best to begin with a simple landscape scene copied from a small poster. Floral designs can be built up from scraps of cretonnes, cutting out flowers and leaves to make a panel. Patchwork designs should always be conventional when used for large panels. When really well executed they form admirable wall decorations.

Lace Patchwork. Oddments of real lace or of good machine-made pieces are often to be found in the housewife's scrap bag. These can be turned to excellent account for table mats and runners. A paper pattern of the desired shape is cut out and the pieces of lace are planned out on it to form a pattern. For a set of table mats a number of pieces are required. The store at home may be eked out with remnants which may be purchased at a sale for a small sum.

The table centre would be planned out on a stout brown paper pattern cut out with a diameter of 19 in. Next cut out six brown paper patterns for the plate mats, 9 in. in diameter, and then six for the glass mats, of 6 in. Start work on several of the smaller ones, as it is easier to plan out the pieces on two or three at once. A motif is required for the centre of each mat as shown in Fig. 1, and then strips or pieces of any different kinds of lace are utilized to fill the space. The method of working is shown in Fig. 2, where a duchesse cover is illustrated in preparation. The patchwork is completed by an edging lace. This edging should match in all the pieces of one set, and may have to be specially purchased in a good remnant. A narrow Bucks or Valenciennes lace is the best choice for

this purpose. The motifs for the table mats need not match, and a rather more important one should be chosen for the table centre. Lace crochet motifs can be used.

Patchwork. Fig. 1. Table mat of lace patchwork. Many scraps of lace are arranged round a central motif.

Below. Patchwork in lace. Fig. 2. Duchesse cover in preparation, showing how the different pieces of lace are arranged on a brown paper pattern. The patchwork is finished by an edging of lace.

To make the mats the central motif is pinned to a brown paper pattern with the right side downwards next to the paper. Use small pins. Then the rest of the pieces are also pinned in position, just touching sufficiently to be whipped together. Finally, the edging lace is gathered just enough to make it lie flat round the edge and also pinned into place, then all the pieces are tacked and the pins removed. Overcast all the seams with tiny stitches. When the mat is thus completely sewn together on the wrong side, the brown paper is removed and the mat is carefully pressed. It may be lined with fine washing net to increase durability. No. 40 white cotton should be used double, as the lace must be strongly sewn together.

Paper Patchwork. The 18th century craft of making patchwork pictures from scraps of coloured papers has recently been revived. An easy and far less artistic development of this work was the patchwork from coloured scraps, such as are stuck on the outside of Christmas crackers and flowers, from cards, etc., which were assembled, gummed on to screens and other articles, and then varnished. Many Victorian screens and papier mâché boxes and brackets were decorated in this manner.

The exquisitely delicate picture illustrated in Fig. 4 of violets and primroses in a bowl is a return to the 18th century method. Nothing but coloured paper is used, each petal, leaf and flower centre is cut out separately and pasted on the background, and no drawing is done first on the paper either before or after it is cut. The most beautiful colours can be obtained from using good coloured advertisements and cutting out each tiny section from these in the tint required. The effect is mosaic-like when finished, glazed and framed.

Bolder designs may be executed in foil papers. These are sometimes applied to glass, being pasted on to the reverse side, an idea which is utilized as a decoration for trays, which are afterwards backed and framed with wood. The foils in which chocolates are wrapped are used, and any oddments of gold or silver paper to make up the designs.

Some of the most beautifully executed patchwork pictures are done by those who have no skill with the pencil. A sense of colour is necessary and accuracy with the scissors, which in this work are the artist's implement. Figs. 3 and 5 are examples of decorative designs done in this way and copied from 18th century chintz patterns. Specially prepared coloured papers gummed at the back can be

bought for this work, but the better way is to store up a collection of scraps of every conceivable shade and kind of paper from cuttings of brown and blue grocery bags to scarlet tea wrappings, and from silver paper to fragments of wallpapers.

Patchwork in paper. Fig. 3. Example of pictorial patchwork copied from an old Georgian chintz, the design being entirely made from small scraps of coloured paper.

Left. Fig. 4. Primroses and violets in a bowl, cut out of coloured paper and pasted on a background, form a charming picture.

Fig. 5. Paper patchwork picture suitable for wall decoration.

PÂTÉ DE FOIE GRAS. The livers of geese are prepared and sold as a table delicacy under this name. To serve the foie gras on toast, make croûtes of bread. Pound the foie gras and mix it with a little Worcester sauce and seasoning. Pile it lightly on the croûtes.

Another savoury dish prepared from foie gras is made by melting 2½ oz. butter in a frying pan over the fire, putting in 6 or 8 water or milk biscuits, and heating them slowly. While they are heating, turn the biscuits frequently in order that they may soak up as much of the butter as is possible. When they are ready, lift them on to a dish, dust them with pepper, and place on each a small heap of foie gras, which should first be rubbed through a sieve with ½ oz. butter and a squeeze of lemon juice. Put the dish into the oven for a few minutes until the foie gras is thoroughly hot, then sprinkle each biscuit with a little chopped parsley, and serve them at once. A small tin of pâté de foie gras is required for this recipe.

Foie gras may be used for sandwiches and is also served in aspic jelly. Rinse some small dariole moulds in cold water, and pour into them a little aspic jelly to coat the top of each mould to about the thickness of half a crown. Allow this jelly to set, using ice if time is of importance: then decorate it with pretty shapes of cut truffle and chilli, forming a pleasing design in red and black. Set this with a little more jelly, and, when firm, place in each mould a small, ball-shaped piece of foie gras. Finally fill up the moulds with more jelly, then leave them to set, when they may be turned out on to a dish. About $\frac{1}{2}$ pint aspic jelly, a small pot of foie gras, 1 or 2 picked chillies and a small truffle would be sufficient to make six savouries.

PATENT LEATHER. New shoes of patent leather will wear much longer than usual if treated to a liberal application of vaseline and put aside for a week so that the grease may soak in. This not only softens the leather, but also prevents cracking.

In cold weather, before being placed on the feet, the surface of the leather should be warmed gently before a fire or with a warm hand. The fact that the patent leather will not stretch like ordinary leather should always be borne in mind. If the shoes are tight when bought, no amount of wearing will ease them until they crack.

Glycerin and castor oil are good dressings for patent leather, but only a very small smear should be used, and that rubbed well in and then rubbed off again. Special transparent dressings for patent leather, which can be obtained at most shoe retailers, are also to be recommended.

Old patent shoes sometimes become lined or covered with crow's-foot cracks. A rag dipped in turpentine and rubbed well over the surface will be found to anneal these cracks, and with a little patience the surface will be restored to its original gloss. *See Boots.*

PATENT MEDICINE. Proprietary remedies on which duty has been paid, represented by an official stamp affixed to the containing bottle or packet, are patent medicines. In no sense does the patent medicine stamp indicate an official guarantee of the composition or efficacy of the preparation. The stamp is merely a receipt for the payment of a tax. Patent medicines are generally advertised as a remedy for some form of disease. Some, in fact, are stated to contain, in the one preparation, a "cure" for many and varied diseases.

The danger in using patent medicines is that even although they may relieve some symptom, the patient may be suffering from a disease which requires urgent and thorough treatment, and which would be discovered if a doctor were consulted. It profits a man little to have his cough lessened when this is really due to consumption of the lungs.

PATERA. A patera is a circular ornament used on furniture to give accent to various parts of the design. It is found on Adam and Hepplewhite furniture. On the carved friezes of bookcases, wardrobes, and secretaires it is separated by lengths of vertical fluting, and is a common ornament at the angles of the panels of cupboard doors.

PATHS AND THEIR ARRANGEMENT

Materials and Plans that Give the Best Results

The reader interested in this subject is referred to the entries on the various materials used for paths, e.g. Asphalte; Brick; Concrete; Gravel; Tile; and to those on Dutch Garden; Flower Garden; Lawn and the like. See also Border; Crazy Paving; Edging; Paving.

The construction of a path depends largely upon the location and style of the house and the nature of the subsoil. The materials with which it is made may be gravel, asphalt, tar paving, bricks, stone, cinders, tiles, mosaic, or concrete. The path to the entrance door, which will naturally take as direct

and straight a course as possible, should measure at least 4 ft. in width, and be very substantially made. The path to a tradesmen's entrance will generally be taken in as inconspicuous a manner as possible to the rear of the premises. Another form of path is the one that is often found entirely surrounding a house, this kind being generally made of concrete.

In the garden the lay-out of the paths is a matter of much importance, especially when space is restricted, as by the careful planning of the paths and the correct disposition of the floral masses it is possible to obtain a sensation of distance which would otherwise be lacking.

If the garden is of considerable size, a good plan is to make a principal path going direct from the house to some conspicuous point, such as a summer-house or sundial, and from this to take other paths in different directions and turn these about in order to give an air of seclusion and distance. In formal gardens, such as Dutch gardens, straight paths crossing each other at right angles are effective. These can be paved or laid with grass. Grass paths are also attractive in a rose garden or beside a herbaceous border.

Path. Fig. 1. Making a brick path. The coarser soil is first rammed down, and above this the bricks are bedded, either in sand, as shown, or in mortar. Fig. 2. The finished path after grouting with cement.

Brick and Tile Paths. The choice of materials is a matter of individual selection. Gravel is pleasing in appearance, durable, and, if well laid, gives a good dry surface. An entrance path will probably be best constructed in brick or tile. This can be done by excavating the top soil and building up a hard, solid bed of gravel, hard core, or rubble, ramming this well down in the earth and grading it, with the coarsest at the bottom and the finest at the top, not forgetting to provide for drainage according to the site.

The bricks, which should be laid to a fall to drain off surface water, may then be bedded on this foundation, either in sand (Fig. 1), or, if preferred, in cement or lime mortar. If the bricks are bedded in sand it will be best to grout them in with cement mortar (Fig. 2). A liquid mixture of cement and water is poured over the surface of the bricks and well brushed into the cracks with a stiff-bristled brush. The surface is well washed over with water and scraped clean while the mortar is still green.

Tiles can be dealt with in a similar manner, but the edge or kerb must be made sufficiently strong to bear the weight of persons walking on the path, and may take the form of tiles, bull-nose bricks, or other material. Concrete may be employed, either in slabs and in different colours, or broken into pieces, using black coloured mortar in which to bed the concrete. Another variation is the use of York stone paving, either in hewn slabs or in random pieces, laid down like crazy paving.

Mosaic (q.v.) is expensive and more suitable for internal use, as in a courtyard or for the floor in a porch. Where quantities of broken stone are available, or small cubes of granite, an excellent composition path is made by lining the sides with bricks and placing other bricks to form a simple pattern, connecting the two side courses of brickwork. The spaces between are filled with lime or cement mortar, the cubes of granite or the broken pieces bedded into it, and the whole beaten down

smoothly with the aid of a rammer and a board laid on the surface. After the cement is set, and while it is still green, the surface is well washed with water and scrubbed.

Cobbles. Another style is provided by cobble stones bedded in cement mortar, and used with a brick or rough-hewn granite edging or kerb. In some districts it is possible to obtain old granite blocks originally used for street paving, and these, if not too badly worn, make an excellent path, and may be laid as if they were bricks.

A Substitute for Asphalte. Asphalte paths and courtyards are convenient, but difficult for the amateur to lay, unless the area to be covered is large enough to warrant the expense of obtaining use of the necessary heating oven and rammers. A convenient substitute is to use a mixture of 95 p.c. by weight of stone-dust—obtainable from a mason's yard—and 5 p.c. of tar. The proportion of 5 p.c. of tar should not be exceeded or the mixture will not set hard. In laying this paving material, the earth must be well rammed or tramped to make it solid. Two inches of the mixture is then applied, and thoroughly well rolled or tramped. The finished thickness should not be less than 2 in.

The pathways in the garden itself need not necessarily be built up with such hard and impervious materials as the foregoing, but could be left in the form of natural grass paths, the borders being defined by floral plots. Where much traffic is expected on such a path, stepping stones made of random pieces of flagstone or granite, sunk in just below the surface of the grass so that the grass may be cut with a lawn mower, will take a good deal of wear, and at the same time will look very picturesque.

Cinder Paths. A simple path can be made with cinders removed from the grates and saved until the quantity is sufficient. Suitable material can often be obtained from the local gas-works for a little more than the cost of cartage. The foundation may be composed of odd pieces of brick or stone, etc. The first thing to be done is to mark out the position of the path with a garden line, a number of pegs being driven in as a further guide. The top surface of the marked-out path should then be removed to a depth of 2 or 3 in. Into the shallow trench thus formed is put the foundation material, and the whole is firmly rammed in.

On ground intended to be turfed the margins of the path may be defined by an edging of rough boards, between which the path is laid, turf being brought up close to the edging outside (Fig. 3).

The cinders are graded according to size; they are placed with the coarser grade at the bottom,

gradually working up to the finest grade, which should be on the surface. A better result will be obtained if each layer of the cinders is firmly rammed or rolled down. Then give the completed path a good rolling and watering, so as to ensure its being firm, and to prevent it from picking up on to the boots when walked upon.

Fig. 3. Rough boards set up parallel to each other to form the limits of a narrow path.

Concrete Tiles. Concrete paving tiles in various colours are available, and form a durable and comparatively inexpensive material for paths. A typical product is made in 9 in. square, 9 in. by 4½

in. and 12 in. by 12 in., with a thickness of $1\frac{1}{2}$ and $1\frac{1}{2}$ in. Larger sizes (2 ft. 3 in. by 1 ft. 6 in., 1 ft. 6 in. by 9 in. etc.) are supplied in a thickness of 2 in.

The diagrams given in Fig. 4 show various ways of laying the above. A space of half an inch is left between tiles, which may be laid in mortar or cement. Another method is to spread a thin layer of sand or sifted earth over the prepared foundations, and then to lay the tiles in position, pressing them firmly in place. The joints are afterwards filled in with earth or sand.

A path should require little or nothing in the way of care and attention or repairs, except at very infrequent intervals; but generally all paths composed of rubble, cinders, clinker, gravel, and the like may wear into grooves and hollows. In such a case break up the surface, and re-lay with the old material and a top dressing of clean, fine material, well rolled and watered, and with a nicely cambered surface.

Path. Fig. 4. Diagrams showing various ways of laying concrete tiles; these form a durable material for paths.

Below. Fig. 5. Formal design of concrete tiles which make an effective entrance path. They are obtainable in various colours. (Courtesy of Noelite, Ltd.)

PATIENCE: SOME GAMES EXPLAINED

A Popular Pastime for Winter Evenings

For the purpose of this article a number of patience games have been selected and the way to play them explained. Those interested in cards will find entries on such card games as Bezique; Bridge; Cribbage; Nap; Piquet; Whist, etc.

The name patience is given to certain card games which are usually played by a single person, although there are a few for two people. They are played with one or two packs of cards, but there are a certain number for which three packs are necessary. There are a great number of these games, but the main principles are the same, to get the cards into a certain order. Some of the games are pure luck, but in others there is scope for a certain amount of foresight.

Carpet Patience. Patience games may be divided into those played with one pack and those played with two. Of the former, carpet patience, a very simple game, may be mentioned first. For this lay out, face upward, 20 cards in four rows of five to form the carpet.

Below these place the four aces as they appear. The rest of the pack forms the stock. The object of the game is to form on each of the aces a sequence in suit up to the king. For this purpose any two is transferred from the carpet to its position on the ace, and then a three, and so on. Vacant spaces in the carpet are filled from the stock and the game proceeds as long as possible on these lines. When no further progress can be made the player must deal the stock of cards, face upward, in a heap, known as the waste, and vacancies in the carpet must be filled from these. The top card of the waste can, if suitable, be played on to one of the sequences.

Sultan Patience. To play this patience, take out the four kings and the ace of hearts for foundations on which to build. After the remaining cards have been shuffled and the pack cut, four other cards are dealt out to be the foundations of four other piles. The actual building then begins on the nine foundation cards. On the king of hearts, who is the sultan, only a descending sequence of hearts can be built. On the three other kings an ascending sequence of the suit to which each belongs beginning with the ace, can be built. On the ace of hearts an ascending sequence of hearts can be built, and when this is in line with the descending sequence on the king, the cards are transferred from the latter to the ace, leaving the king alone. On the four other cards a descending sequence of any suit can be built, and the exposed card can, if suitable, be transferred to one of the five piles of which four kings and an ace are the foundations. These are seen in the illustration above.

The cards not wanted for any of these nine piles are put, face upward, on a rubbish heap, and the top one can be used whenever suitable. After the cards have been dealt, those in the rubbish heap are dealt out again. They may either, by being unsuitable, block the game, or may enable the five main foundations to work out. If this is done the sultan will be surrounded by four piles, on the top of each being a queen.

Sir Tommy. Sir Tommy is another variety that is played with a single pack. Its object is to build up four packs of cards from the ace to the king, but it is not necessary to follow suit in so doing. The cards, having been well shuffled, are played out. Four of them are put down for the foundations, and there is no rubbish heap. As the aces appear they are placed below the four existing foundations, and the object of the game is to build on them at every opportunity.

If the cards dealt will not go on to an ace pack, they must be placed on one of the four others, and this usually presents a difficulty. It is not easy to decide, for instance, whether a six should go on a

five or on a knave, and high cards must often be placed upon low ones. If the kings and other high cards come out fairly late, the patience is almost impossible to accomplish. Some players keep one pack for the high cards, and this is desirable.

Patience. Fig. 1. The nine foundation cards laid out to begin the game of Sultan Patience, with the king of hearts, or sultan, in the middle.

Demon Patience. Demon patience requires only a single pack. Having shuffled and cut the cards, deal 13 of them, one on top of the other, to a stock. Then deal four others out in a row and another one to begin a row above them. This serves as a foundation card, and as they appear the other three cards of the same value as this one are placed with it to form the four foundations. Thus, if an eight is the card first placed there, the other three will also be eights. On these foundations any suitable exposed card, in ascending sequence of suit, can be played, the exposed cards being the top

ones of the four packets on the lower row and the top one of the stock. The ascending sequence goes to the king and then to ace, two, and so on, until the 13 cards are in place.

Exposed cards can be placed, not only on foundations in ascending sequence of suit, but on to four depots in descending sequence of alternate colour. A sequence of cards, or any portion of a sequence, can be transferred at any time from one depot to another, provided the proper sequence and alteration of colour are preserved. When 11 of the cards in stock have been taken, either of the remaining two may be played. A space occurs when all the cards in a depot have been played, and this must be filled by using the top card of the stock. After the stock has been exhausted it may be filled with any exposed card.

The cards remaining in hand after the initial deals are dealt in batches of three face upward to a rubbish heap, and the top card of each then becomes an exposed card. Such can be played either on foundations or depots, when the card immediately below it becomes exposed. When only two cards of the pack are left in hand they are dealt separately, and either or both can be played. When all are placed the rubbish heap should be picked up, turned face downward, and dealt out again, the cards from it being played until the patience comes out or is blocked.

Patience. Fig. 2. The game of Divorce Patience in progress, with odd cards on aces, top row; even cards on twos, middle row; rubbish heaps, bottom row.

Divorce Patience. Divorce patience is played with a single pack. Going through the cards, the player forms of them four heaps of rubbish, keeping out only the aces and twos. He can distribute the cards to the various rubbish heaps as he likes. The aces and twos he places in two rows, aces above and twos below, the suits corresponding to each other. His aim is to build on each of these eight cards, in alternate numbers and alternate colours.

In this game, odd cards are placed on the aces and even ones on the twos. For instance, on a black ace a red three must be placed, then a black five, a red seven, and so on up to the king. On a black two a red four must be placed, and so on up to the queen. The pack is only gone through once; the player should concentrate, therefore, on distributing his cards to the waste heaps in a way that will assist in filling up the eight piles. It is advisable, for instance, to keep one pile in each row for kings and queens, as if they are distributed over all they will block the lower cards. If the game succeeds, the kings and queens will all be found wrongly mated.

Waning Moon Patience. Of the many patiences that are played with two packs of cards, one of the best is known as the waning moon patience, the name being due to the formation of the cards. Having shuffled the two packs together, lay out 13 piles of 3 cards each in a semicircle. As the aces appear place them on the inner side of this, and build upon them according to suit. Any of the 13 exposed cards in the outer row can be moved on to the aces in an upward sequence or transferred to another packet in a downward sequence, taking care to follow suit.

When this process stops, the remaining cards should be played out to a rubbish heap, placing them whenever possible on the piles. In case all the cards from one of the 13 piles have been transferred, any exposed card may be placed in the vacant spot. It is well to take one from a packet rather than from the rubbish heap, and the player is allowed to examine the piles in order to see which to move. The patience is worked out when all the eight inner piles are finished with a king on top of each.

Cock o' the North. Cock o' the North is a good game. Shuffle well the two packs of cards and count out eight piles of four cards each. These should be placed on the player's right. Four of these packets must have their laces downward and four upward. After this, deal out eight cards and place this pile in the centre of the eight; this centre pile must be placed face upward. The remaining cards are dealt out, but before this is done the player should examine the piles; if one of the top cards of a pile that lies face upward is an ace or a two, this can be taken out and employed for a foundation card.

The patience is built up on 16 cards, beginning with the aces and the twos, eight of each. On the aces all uneven numbers to the king are placed, and on the twos are the even numbers to the queen. Whenever an ace or a two appears it is placed as a foundation card.

If any exposed card on the piles at the side becomes suitable, it can be taken away and used. The top card of the rubbish heap can also be taken, whenever possible, in order to build up a sequence; but if there is a card on the pile and on the heap of the same value, the former must be taken.

At the end of the deal take the eight cards in the centre of the side piles, or as many of them as are left, and spread them out. If any are found suitable, place them in position on the 16 piles. Next turn up the top cards of the four piles that are placed face downward and, if these are suitable, use them. When no further progress is possible, take up all the side piles and shuffle them with the cards of the rubbish heap. Then deal them out as before. Two of these deals are allowed, by which time the cards should all be in position.

Legitimist Patience. Two packs are also required for legitimist patience. Having shuffled them well, take out a king and lay it on the table; then deal out the other cards, placing in a row queen, knave, ten, nine, eight, seven, and six from any suit and throwing the rest on to a rubbish heap.

These eight cards are the foundations, and as the remainder are dealt out they are built upon these in an ascending scale. The cards that cannot be placed go to the rubbish heap, which may be turned over once and suitable cards from it placed in position. The object of the game is to get 13 cards on each pile.

Miss Milligan. Miss Milligan requires two packs of cards. Having been shuffled together and cut, eight of them should be dealt, face upward, in a row to eight depots. Any aces that come out at this time, or later, are taken to form eight foundations, which are placed below the depots. The object of the patience is to build on the foundations, eight suits in ascending sequence. Exposed cards, which are the top cards of the eight depots, are played in ascending sequence of suit to foundations, or in descending sequence of alternating colours to other depots. A complete sequence of any number of cards may be transferred bodily from one depot to another, provided the proper sequence and alterations of colour are maintained. Portions of a sequence cannot, however, be transferred except the top card, which can be moved at any time. A space occurs when all the cards of a depot have been played. Such spaces can only be filled by a king or sequence to a king. If this is not possible, it must be left vacant for the time.

When all available cards have been taken from the depots, a second eight cards should be dealt to them, and in this way any spaces which may have occurred will be filled. The available exposed cards should then be played, after which another row should be dealt out, and this continues until all the cards have been played out. It should be noted that in each round cards must be dealt to all the depots before any one of them is played out.

Quadrilateral Patience. For quadrilateral patience two full packs of cards are also required. Having shuffled both together, deal six packets out in a row, three cards being in each packet. They should be face upward. Then lay out six more packets of three each, three on the right and three on the left, in such a fashion that with those already in position they make three sides of a square. The space in the centre will be filled with the eight sequences, the building up of which is the player's aim.

The sequences start with the next card turned up. Whatever this is, each sequence will start with one of the same value. For instance, if it is a three each sequence will run in suit from the three to the two. The player should first note whether there is among the twelve exposed cards one or more that will serve as foundations, i.e. that correspond in number with the one just turned up. If so, that card is taken away and laid next the original foundation card. The player should next consult the exposed cards to see if he can pack any of them in descending sequence of suit for use later. He may be able to place a seven on an eight, or a queen upon a king.

Having done all possible in this direction, the player must deal out the remaining cards to a rubbish heap, laying out any foundation cards as they appear, and whenever possible playing the other cards on to one of the 12 packets or one of the eight foundations. When any packet is exhausted, he can place there a card, either from the rubbish heap or from one of the other packets. The latter is better, as it gives greater opportunities for working off the cards. The cards are only dealt out once, but when this is over the player is allowed to take five cards from the bottom of the rubbish heap and spread them out. This will help to place further cards, and may enable the game to be completed.

Khedive Patience. Khedive patience is not difficult to work out. Having shuffled the 2 packs, lay 25 cards out in 5 rows, 9 cards in the bottom one, then 7, then 5, then 3, and then 1, the whole resembling a pyramid. From these cards the player chooses one as the base card. This should be a two, if there is one, or, if not, another low card, say a three or a four. This should be placed on one side, and as the other 7 cards of the same value appear they should be placed at one side or the other

until there are 8 altogether. On these 8 cards sequences in their own suit must be built up. Any suitable card can be taken from the table and the vacancy made filled up from the pack. When no more progress can be made in this way, the remaining cards should be dealt out and a rubbish heap formed from which any vacancies are filled. If the patience works out, the pyramid of cards will totally disappear, as will the rubbish heap which feeds it.

PATINA. In furniture, this term is applied to the metallic appearance of the surface of old wood. It is regarded as a sign of age, and therefore is valued by collectors. Patina cannot properly be produced by the application of varnish or polish. It comes after years of careful cleaning and rubbing, and as a rule the upper surfaces or those that catch the dust have the finest patina.

The term patina is applied also to the characteristic appearance taken on by old bronze and copper articles, which is the result of chemical action. It is simulated more or less successfully by treating new pieces with various chemical solutions, and can be imitated also by painting such articles with one or other of the special preparations sold for the purpose.

Artificial Patina on Metals. A patina can be imparted to bronze and copper in the manner here described. A green patina is produced on bronze by brushing the article with a solution made by dissolving 16 gm. sal-ammoniac and 4 gm. sodium bicarbonate in 1 litre vinegar. After this operation the bronze is placed for a time in a box, in which carbon dioxide will be evolved. The process is repeated until the desired degree of colour is obtained.

A bright green patina can be obtained on copper by preparing 10 per cent solutions of nitrate of copper, sal-ammoniac and calcium chloride. A mixture made from 10 parts each solution is brushed on to the article and allowed to dry.

Another method for copper, which results in an antique green patina, is to lay on the following mixture quickly and allow it to dry: 7½ gm. sal-ammoniac; 7½ gm. common salt, 15 gm. liquid ammonia. Several applications are necessary. Some care is necessary in using these processes, and the worker is recommended to test the solution on an odd piece of metal before proceeding with a larger job.

PATRINIA. This is a hardy biennial plant sometimes called eastern valerian. It bears graceful foliage and fragrant yellow flowers. The chief species grown in gardens are *palmata*, *villosa*, and *scabioscaefolia*, which require a sunny position in ordinary soil. *Patrinia* is raised by seed sown outdoors in spring, or increased by division of roots in March or October.

PATTERN: For Dressmaking. Generally a pattern is cut out in paper for one side of the garment only. A whole pattern is unnecessary, because the half can be set on double material and a whole shape cut out more easily and quickly. It is only when the two sides are different in shape that it is necessary to have a pattern of the whole garment. They are designed to meet seasonal requirements and cut out in various stock sizes; that is to say, the models are made on perhaps 4 or 6 stands of varying average sizes, ranging from small to very large.

If any alteration is made, whether it is merely a simple one for size, or a big adaptation, the pattern should always be tried on after the alteration is completed, so that the exact effect may be judged. One of the rules of the home dressmaker should be to pin up and fit on a pattern before cutting the material. Only in this way can it be seen whether the desired size and style are there, and so perhaps save spoiling the material.

The best course to pursue when a pattern is to be altered in any way is to take the parts to be altered and cut them in newspaper, and to carry out the alterations on these newspaper parts first of all, so that the original pattern is still available.

Another essential is to note whether turnings are allowed on the pattern, and, if not, to take care to leave enough on all the edges for fitting, seams, and hems. It is a good plan, after cutting the material, and before removing the pattern, to chalk or tack round the material close up to the pattern edges, so as to see exactly what turnings must be taken up everywhere.

As a rule, paper patterns can be obtained through pattern services in connexion with fashion or needlework journals and magazines, and through special pattern cutting agencies.

Paper patterns of all kinds are supplied by some of the fashion papers published by the Amalgamated Press, Ltd., especially Home Fashions and Children's Dress, obtainable, either in person or through the post. Periodicals for women, such as Woman and Home, Woman's Pictorial, etc., issue fashion supplements.

PATTERN: In Metal Work. Patterns are replicas of an object to be subsequently made in metal, and more particularly for the purpose of forming depressions in the moulding box, into which the molten metal is poured in the production of the castings. *See Casting.*

PATTERN PRINTING ON WOVEN & HARD FABRICS

Simple Methods for Applying an Effective Art Craft

The reader interested in art crafts will find information related to this article in the entries on Dyeing; Glass Ware; Lampshade; Painting on Textile Fabrics; Stencilling; Transfer.

Pattern printing within the limits of simple designs is one of the easiest of the genuine art crafts, and can be used to decorate many objects in the home. Another excellent service which its study can render is the training of school children by cultivating their appreciation of line and colour when forming patterns. Results are accomplished with comparative quickness and at a very small cost. The materials for the craft are simple to use, and obtainable through any artists' colourman.

Two of its advantages are that it can be successfully carried out almost from the first attempt, and that fabrics can be printed with washable and permanent colours. The most delicate georgette scarf can be patterned without injury, while pieces of silk or cotton which have lost colour can be renovated with pleasing results. This is particularly the case with unpatterned window curtains, bedspreads and cushion covers, the fabric of which is not worn out, but the original colours have been laundered to a drab shade. Re-dyed and bordered with pattern printing, articles which have been considered unsightly and practically worthless are transformed into attractive furnishings.

In addition to the articles to be decorated, all that is required to print in almost any colour on woven fabrics, or on hard surfaced ones, such as glass, wood and pottery, are pattern printing liquid colours in bottles and tubes of oil colours; a set of a dozen pattern printing sticks; a palette containing small square pads to hold the colour; a saucer or white tile for oil colours; some rubber stamps (or these can be cut on ordinary pieces of rubber, as will be explained later in the article); pieces of lino; a bottle of copal and one of wood varnish. Bronze powders and stencil medium can be utilized in this work when it is wished to gain a richly decorative effect.

The liquid colours in bottles are specially prepared for printing on soft materials and are of the exact consistency for immediate use, while oil colours must be used for printing on glass, wood or pottery.

Oil colours may be used on woven fabrics when thinned with turpentine, but the results are not so satisfactory except for surfaces which remain flat, such as lampshades or sachets. Soft fabrics tend to become stiff when printed with oil colours, and if the pattern is large the fabric thus treated may not hang or drape in good folds.

Printing on Textiles. Some soft materials are more absorbent after washing, and thus receive colour more easily; this applies to cotton and linen. Silks and other thin woven fabrics need not be washed before printing is done. A few experiments on scraps of material washed and unwashed can be made before starting to print any larger piece. Throughout the work it is advisable to have a small piece of the same material at hand on which to make a few trials and to see the effect of combinations of colour. The best way to become accustomed to the printing process is to collect some scraps of differently textured and coloured materials and make experiments, rather than risk spoiling a piece of work.

The method of working is well illustrated in Fig. 1 An inexpensive tray cloth is being printed in chrome orange, chrome yellow and ivory black. The article is laid on a board which has been padded with sheets of newspaper and a sheet of white blotting paper on top of these. Drawing pins keep the work taut and straight. A little pattern printing colour (or oil colour if preferred) is spread on to the pads in the palette. The pattern stick (one is seen in use and others required for the pattern are on the table ready to hand) has been pressed on to the colour so that the end of the stick is evenly covered and is now being pressed on to the cloth to make the print. The actual process is simplicity itself.

The colours provided—red, orange, yellow, green, blue and violet—are brilliant and pure. Mixed with white or grey as well as with one another, hundreds of distinct shades and hues can be obtained, ranging from deep full tones to delicate pastel tints. As experiments are made with the printing sticks, and each separate shape appears on the fabric, patterns will be found with delightful ease. For those who wish to try experiments before attempting original designs, transfers printed full size on thin paper are obtainable for scarves, table mats, cushion covers, etc. Possibilities of combinations of printing forms can be seen from the study of one or two transfers.

Although colour is a matter of taste, there are certain rules which are useful to remember with reference to harmony of tints. Any pure colour will harmonize with black and white or grey or with itself mixed with black or white to make deeper or paler tones. Two colours will harmonize if grey is mixed with both. Brilliant effects require marked contrasts, such as blue and orange, purple and green; quiet restful effects can be worked with tones of the same colours, or with those which are closely related, such as blue and violet, or yellow and green.

A trial border can be quickly printed on a piece of nainsook. First take a pattern stick which prints a half-inch square and place it diagonally and join to it a quarter-inch square. Repeat the arrangement along the border. This is such a simple pattern that it may seem uninteresting, but it is useful for experiment with even pressures of the printing sticks, and also for colour combination, while it forms a good surround for more elaborate designs. With regard to colour it will soon be seen that the small squares look better in a darker shade and the large squares in a lighter. With three or four printing sticks, printing different geometrical shapes, a number of simple borders can be worked, and the most interesting experiments can be made in colour.

In Fig. 1 the simple pattern would not be effective if orange or black had been used for the large squares. By keeping these in the palest of the three tones selected they do not overpower the tiny black squares set diagonally, nor the orange circles, and thus balance is preserved in the design. It is necessary from the beginning of learning this craft to consider not only which colours go well together, but how much of each colour is required, and on which part of the pattern it can most decoratively be employed. Most people will want to originate designs after they have practised a few simple borders and patterns and used a transfer, ironed off on to the object to be printed in the ordinary way. Pattern printing paper is obtainable, which is marked with quarter-inch squares, on which the designs can be worked out with gouache colours. In this way the effect of tones and shapes can be judged and well balanced to suit the particular object.

When completed the original design may be transferred to the fabric in one of two ways. (1) If the material is very thin the design can be placed underneath and will show through sufficiently to guide the printer. (2) If the fabric is not semi-transparent, a sheet of transfer paper will be required. This transfer paper must not be confused with the pattern printing transfers. It is coated on one side with red, blue or black, and is used in the same way as carbon paper.

At the other end of some of the printing sticks are more fanciful shapes which greatly facilitate the production of elaborate designs, and give interest to the patterns, once the simple process has been mastered.

Printing on Hard Surfaces. Wood printing sticks are not suitable for printing on wood, pottery or metal. Such unyielding surfaces require a softer substance, and india-rubber is the ideal material for this purpose. Flower and other shaped stamps are obtainable, or pieces of soft india-rubber can be cut to correspond with the wooden printing sticks. Another way of turning rubber into interesting shapes is to heat a knitting needle, and when red hot burn round holes with the end, and lines with the side of the needle, on the pieces of rubber.

Pattern Printing. Fig. 1. Printing a pattern on a white tray cloth by means of wooden printing sticks and washable printing colours.

For all hard surfaces the oil colours in tubes are used. The colour is squeezed out on to a piece of thick glass or a white tile, a little varnish is used with it, and it is spread evenly so that a palette knife will just take it up when the printing rubber or stamp is pressed into it. When the colour is dry the whole work should receive a coat of varnish.

The application of pattern printing to pottery and wood is illustrated in the various diagrams shown in Fig. 2. Pattern transfers cannot be used for such pieces of work, as it would be impossible on a hard and curved surface to keep a transfer in position. After the proposed pattern has been sketched out on a piece of paper, the worker will need to make dots with pencil or coloured crayon directly on to the article to be printed. For this type of work the simpler the designs the better. In Fig. 2, G to N show a variety of print forms that go to make up patterns. In A, nothing but different sizes of squares are used. D shows the formation of the print from the rubber used for printing all but the straight lines on the vase B. The pattern on the candlestick F was entirely evolved from repetition of print G. A collection of articles, including a silk scarf, wooden candlestick, pottery case and papier mâché bowl, are shown in Fig. 3, all of which have been decorated by the simplest of designs in pattern printing.

Printing from Linoleum Blocks. Another way of making printing shapes is cutting them from thick linoleum. This method can be practised on small pieces. Special cutting tools are obtainable and comprise dividers, gouges and outline knives of assorted sizes. Printing by hand from lino and wood blocks is a more advanced form of pattern printing. The design may be drawn directly on to

the linoleum, but usually it is traced on to tissue paper, with Indian ink. The surface of the lino is covered with gum and then placed down on the tracing. The lino block is next turned face upward, and any bubbles on the paper are pressed out with a scrubber or rubber covered roller.

After the gum is set the block may be cut. With the knife cut round the edge of the design. A clearing cut is then made, sloping inwards the base of the first one, leaving a V-shaped trench round the design. The portions of the design not required to print are then cut away with a small gouge, or a wider one is used for larger waste pieces. Very beautiful results can be obtained from these printing blocks, but such a development cannot be dealt with adequately here. Interesting shapes cut into lino can, however, be utilized to give freer scope to original ideas. These are mounted with glue on to pieces of wood and used in much the same way as the printing sticks, but as lino is rather unyielding it is not so suitable for hard surfaces, though good results have been obtained on wood and papier mâché.

Pattern Printing. Fig. 2. Diagrams showing pottery and wooden articles decorated with pattern printing executed by means of rubber prints and oil colours. See text.

Pattern Printing. Fig. 3. Examples of pattern printing on silk, pottery, papier mâché and wooden articles.

PATTY: How to Make. A small pie or pastry case filled either with meat, fish, jam, or some savoury or sweet mixture is known as a patty. The cases may be open or covered, and sometimes they are baked in small, round tins called patty pans. If the case is of puff or rough puff pastry it should be cut out of a sheet of pastry about $\frac{1}{4}$ in. thick with a sharp, round cutter and baked on a steel baking sheet wetted with cold water. When properly prepared and baked in a hot oven, the rounds will rise to the correct height for oyster or any other variety of savoury patty.

The cutter should be rather larger than the size desired, as when the cases rise in the oven they diminish somewhat in circumference. When the rounds are laid on the baking sheet, an inner circle should be marked on the surface with a smaller cutter, leaving a margin round the edge. This inner portion forms a lid for savoury or jam patties, and must be removed as soon as the case comes out of the oven. The patty must now be cleared of all loose uncooked paste inside and then will be ready to fill.

Cold cooked chicken, game, meat, fish, mushrooms, oysters, shellfish, ham, hard-boiled eggs, etc., chopped finely and mixed with a savoury white sauce, are used to fill the patty cases, which are then given the name of their contents. The small round of pastry is placed on top of the filling. They can be served hot or cold. For jam patties any kind of jam can be used.

Meat Patties. Meat patties made with plain short or flaky pastry should be baked in patty pans. A round layer of pastry forms the base of the patty, a portion of prepared meat is heaped in the centre of the round, and a second round of pastry moistened at the edge is placed over for a cover. An incision is made in the top, and the patty after being glazed is ready to bake. Add also a little stock or water and bake about 15 min. in a good oven.

Patty Pans. A small round tin known as a patty pan, having a depression in the middle and varying in size, is used for baking tartlets, etc. After use they should be wiped out with clean kitchen paper and should not be washed unless they have become covered with jam fruit syrup, or meat gravy. *See Prawn Patty.*

PAULOWNIA. The hardy summer flowering tree *Paulownia imperialis* is highly ornamental having very large heart-shaped or lobed downy leaves and violet flowers of tubular shape.

The Paulownia likes a deep, loamy soil in a sheltered but sunny position, and abundance of moisture. Propagation is by seeds sown in heat in spring, and by cuttings inserted in sandy soil under a bell-glass or handlight in summer. This tree is suitable only for planting in comparatively mild districts.

PAVING: Method of Laying. As applied to domestic work, paving is a floor or path laid with large slabs of stone, but in a wider sense may include concrete, brick, tile, tar-macadam, asphalt, or any impervious material of a hard and durable nature. Examples are found in the paved courtyard, terrace, or paved entrance path, while in many country homes the floor of the kitchen dairy, and sometimes the living-rooms, are paved with stones, tiles, or brick.

Should a stone paving have to be laid, it is customary to make a foundation of hard core, well rammed and consolidated, and then to lay a bed of finer stuff about 2 in. thick, topping this with cement mortar or lime mortar, embedding the stones in it, and completing the work by grouting with cement. Bricks or tiles may be laid in a similar manner. The joints should not be too narrow; $\frac{1}{2}$ in. is not too wide, as wide joints improve the appearance of such a floor. Smooth bricks specially intended for paving and burnt to the right degree of hardness are obtainable, but ordinary hard stock bricks or rough bricks are quite serviceable for the purpose.

Care must be taken that the joints are properly broken, that is, that no two bricks stand exactly opposite one another, as they do the joints will be in line with each other, and the pavement would not be so durable. After all the bricks are set in position they are beaten down by laying a board on top of them and hammering it with a rammer or heavy mallet. The whole is then well grouted, thin cement brushed into all the joints, and the bricks cleansed with clean water after the mortar has set. *See Concrete; Crazy Paving; Path, etc.*

PAWL. A pivoted check, known as a pawl, is used in connexion with a ratchet, or similar mechanical device. Its function is to permit rotation in one direction and not in another. A common form of pawl consists of a pear-shaped piece of metal, the broadened end of which is pivoted to the one member and the narrow end rounded off to some pointed shape, so that it can engage in the teeth of a ratchet wheel or other device.

A pawl is sometimes made reversible, or double ended, so that in the one position it will permit of rotation in a right-handed direction, and when in the other position in a left-handed direction. Common applications are found in machinery, and clocks and watches of all kinds, where a pawl is used as a check or detent to the main spring.

PAYING GUEST. Unlike the ordinary lodger, a paying guest is a person who shares the family life of the people with whom he or she boards. The usual arrangement is for an inclusive fee to be charged, and for the person to be treated exactly like a guest, to be given the best of which the household is capable.

Legally, the position of a paying guest is that of a boarder; for in essence his contract is one for board and lodging. The only difficulty ever likely to arise is as to the length of notice to be given on either side to terminate the contract; so that both host and guest should be careful to make an express stipulation on this point. There is also an implied undertaking on the part of the host to provide food and accommodation reasonably adequate according to the sum paid by the guest; and one by the guest to behave in a proper manner in the house. Indeed, it would probably be held that these stipulations were conditions upon the breach of which by the one, the other party would have the right to terminate the contract. *See Boarding House; Lodgings.*

PEA. This is the name both of a certain plant (*Pisum sativum*) and of its seeds that are used, either green or dried, for culinary purposes. The plant is more usually spoken of in the plural, under which heading it appears in this work. Other members of the same family, for instance, the sweet pea, everlasting pea, and glory pea, are grown for their flowering qualities. *See Everlasting Pea; Glory Pea; Peas; Sweet Pea.*

PEA BEETLE. A little insect that is often very destructive to seed is the pea beetle. It lays eggs in immature pods, and these hatch into legless grubs, which eat their way into seeds and pupate in the cavities. Seed containing this pest usually fails to germinate, imported seed being more likely to be infested than home-grown samples. There is no reliable remedy, and all infested seed must be burnt. *See Peas.*

PEACH. The peach is one of the most delicious of fruits. In Great Britain it can be grown to perfection out of doors, but only on a sunny wall. One variety, named Breda, may succeed as a standard tree in the open garden in mild districts. Peach trees grown under glass, either in a heated or unheated glasshouse, yield exceptionally fine fruits. The cultivation of the peach tree requires care, otherwise disappointment is almost certain. Unless the soil is naturally loamy old turf soil and

decayed manure must be added before the trees are put in. Planting should be done in autumn. When the trees are in bloom it may be necessary to protect the flowers from damage by frost. Pruning is a detail of great importance in the management of peach trees. In spring fresh shoots will develop freely on the old branches, and if all are allowed to remain the tree will be spoilt. All except two shoots on each branch of the past year's growth should be removed while they are small. One must be left at the top and another near the base: the remainder should be rubbed off, a few at a time, during a period of two or three weeks. This practice is termed disbudding. In late summer, when all the fruits have been gathered, the final pruning takes place: it is done by cutting out the branches of the previous year's growth and tying in the new shoots to replace them. Thus a considerable part of a peach tree is renewed yearly. Shoots which grow one year bear fruits the following year and are then cut out.

Peach. Two specimens of the downy-skinned and luscious dessert fruit. (Courtesy of Amateur Gardening)

*Peach. Pink blossoms of *Prunus persica*, a double variety.*

Peach trees grown under glass need similar treatment: if early fruits are required their development may be hastened by maintaining a warm and moist atmosphere in the glasshouse when the fruits are about one third full size. Amateurs will achieve success by ventilating the glasshouse freely during the summer months. Some of the best varieties are Royal George, Stirling Castle, Barrington, Early Rivers, and Grosse Mignonne.

Peach leaf curl, a disease which causes blister-like patches on the leaves, is often troublesome. It can be prevented by spraying with Burgundy mixture in February.

The Fruit. No preserved or foreign peach possesses the delicate flavour of the English fruit, but imported peaches of best quality also appear as dessert fruit. The second quality and preserved or canned peaches may be converted into many sweets and are not expensive.

Imported or home grown peaches may be preserved as follows: Pare the fruit, which must not be quite ripe, and cut it into halves, removing the stone. Blanch the kernel. Boil the peaches gently in syrup, then pour them into an earthen vessel and leave all night. The following morning drain them, boil up the syrup and let it thicken, then simmer the fruit in it for about 15 min., and it will be ready to bottle. Add the blanched kernels of the stones, if desired.

Peaches make a good filling for a flan if cooked in syrup a few minutes, or they may form centres for small tartlets, with or without whipped cream. They may also be added to trifles and other light sweets.

To stew peaches, gently simmer the contents of a tin of peaches in syrup for 5 min., and dish the fruit with syrup poured over. Colour the syrup with cochineal before adding to the fruit. Serve with cream or custard. To make the syrup, strain through a hair sieve the liquor from the peaches, add 4 oz. white sugar, and boil till reduced to a fairly thick syrup.

Peaches, either fresh or tinned, may be used for a jelly, a tart, or a sauce in the same way as apricots are used.

Outdoor Peach. Cultivation. 1. Planting in loamy soil: a, heavy loam and old mortar; b, original top spit; c, bottom soil opened with brick-bats. 2. Planting on wet soil: a, heavy loam; b, original top spit; c, brick-bats; d, concrete; e, drain. 3. Planting on shallow soil: a, subsoil removed and replaced by good compost. 4. Shallow planting of a wall tree. 5. How to distinguish buds: a, fruit buds; b, growth buds. 6. Remove front and back branches. 7. Stopping laterals at base of fruits and keeping to one leaf. 8. Disbudding; growths at a and b to remain unchecked.

Peach Cups. Drain the fruit from a large tin of peaches, and arrange each half in a shallow dish with the cut side uppermost. Sweeten and flavour a gill of cream, whisk it until it thickens, and then heap some of it in the centre of each peach. Place a crystallized violet on top and round it some small leaves of angelica. Strain the syrup round and serve.

Peach Cups, halved peaches filled with cream and served with the fruit syrup.

Peach Gâteau, a trifle made with tinned peaches, sponge cake, cream and blanched almonds.

Peach Gâteau. To make this trifle, a border ring of sponge cake, a large tin of peaches, cream and flavouring are required. Put the sponge cake in a glass or silver

dish, soak it with f gill sherry and a little of the peach syrup, and then stick into it 2 oz. blanched and skinned almonds cut lengthways into thin slices. Round the base of the ring place 2 or 3 peaches cut into quarters; pile the remaining fruit and syrup in the centre, and over them shake $\frac{1}{2}$ pint stiffly whisked cream flavoured with vanilla and sweetened to taste. Garnish the top with a few crystallized violets.

Peach Jam. This is made by peeling and cutting into halves 6 lb. peaches. These should be put into an enamel or steel preserving pan with $\frac{3}{4}$ lb. loaf sugar to each lb. of fruit. Boil for about an hour, stirring frequently to prevent burning. When almost set add the kernels, which should previously have been removed from the stones and blanched. Put into jars and cover each with paper dipped in brandy. *See Nectarine.*

PEA-NUT. The pea-nut is valuable because of its oil, and forms the foundation of many nut butters. As well as being eaten as dessert, these nuts are sometimes ground or flaked and then mixed with fresh mashed fruit, such as strawberries or raspberries, or sprinkled over the surface of stewed fruit, sundaes or ices.

Pea-nuts lightly browned in hot butter and then seasoned with salt are quickly and simply prepared. Shell and skin about a quart of nuts, and toss them gently in a pan containing 2 oz. smoking hot butter. When they are of a pale brown colour lift them out, drain them, and coat them lightly with salt to which a little cayenne pepper has been added. Dry the nuts in a cool oven, shake off any loose salt, and, when they are cold, store in tins till needed, or eat them hot.

Pea-nut sandwiches are made from finely ground or grated nuts from which the skins have been first removed. Mix these with half their weight of fresh butter or whipped cream, season the mixture highly, and spread between thin slices of brown or white unbuttered bread. Pea-nuts are often added to toffee in the same way as almonds. *See Almond Toffee.*

PEARS: IN GARDEN AND HOUSEHOLD

Directions for Growing and Preparing a Popular Table Fruit

This article is on the same lines as those that deal with the Apple, Cherry and Plum; the growing and cooking of the fruit are described, and then follow the various dishes that can be made from it.

See further Diet; Fruit; Grafting; Grease; Pruning.

The pear is one of the most delicious of all hardy fruits and is especially well suited to cultivation in the milder parts of England and Wales; elsewhere the choice varieties should be grown on a sunny wall. When budded on the pear stock the tree will reach a height of 20 ft. or more and live to a great age; in this form it is suitable for orchard planting. Pear trees budded on the quince stock are more suitable for gardens, for they are of less vigorous growth and take up far less room; they may be set at 10 to 12 ft. apart. Trees on the pear stock are usually grown in the form of standards; those on the

quince stock may be bushes, pyramids, cordons, fan-trained or horizontal espaliers. Those planted against a wall are cordon, fan-trained or horizontal espaliers. Pear trees prefer well-drained loamy soil, but they will thrive in ordinary garden ground that is not waterlogged, provided they are planted in a sunny position. In heavy soil it is wise to plant the trees at such a depth that the uppermost roots are covered only by 2 or 3 in. of soil; mortar rubble may be mixed in freely with advantage.

Pear. The variety called *Charles Ernest*, a dessert pear of fine rich flavour that ripens late.

Pears: their cultivation and the insects that attack them. 1. How to plant a standard pear tree. 2. Planting a dwarf. 3. Pear trained as a maiden. 4. As a double cordon. 5. As a triple cordon. 6. As an espalier. 7. Showing how a newly planted tree should be mulched. 8. Social sawfly. 9. Vapourer caterpillar. 10. Pear midge. 11. Grub of pear midge. (By special arrangement with Amateur Gardening)

During the first few years pear trees usually make luxuriant growth but bear little fruit; to counteract this tendency it is a good plan to lift young trees (other than standards) every autumn for the first two or three years after planting, shorten long, thick roots, and replant at once, taking care to keep the uppermost roots near the surface. If this procedure is followed there will be less need for severe branch pruning, with consequent advantage to the trees.

Pruning in summer and in winter is necessary. In summer the side shoots on the main branches should be shortened to within about six leaves of the base of the current year's growth; from the middle to the end of July is the best time for this work. Care must be taken not to prune natural fruit spurs—those short stunted shoots on which blossom buds form naturally.

At the winter pruning, which should be done in December or January, the side shoots are again pruned, to within about three buds of the base of the past summer's growth. Branches which tend to block up the centre of the tree or to cause overcrowding should be cut out; this thinning out is important, for fruit buds will not form unless the shoots are fully exposed to air and light.

It is necessary to make a careful selection of varieties, for some are more reliable in cropping than others. Some of the most suitable for general cultivation in the open garden are Conference (a very regular cropper), Fertility, Williams's Bon Chrétien, Souvenir du Congrès, Durondeau, Emile d'Heyst, Louise Bonne of Jersey, Jargonelle, Fordante d'Automne and Charles Ernest. The most delicious pear of all, Doyenné du Comice, is suitable for cultivation as a cordon or as on a trellis in the open garden, and trained tree or cordon on a sunny wall. Late varieties of pears such as Winter Nelis, Glou Morceau, Passe Colmar and Olivier de Serres need a warm wall to enable them to ripen thoroughly.

Pears suitable for planting as orchard standards are Jargonelle, Williams's Bon Chrétien, Fertility, Conference, Hessel, Lammas, Beurré d'Amanlis and Emile d'Heyst. Good cooking pears are Vicar of Winkfield, Uvedale's St. German and Catillac. The best time to plant pear trees is in autumn as soon as the leaves have fallen, but the work may be carried out between then and the middle of March in mild weather.

Mature trees which are carrying full crops are benefited by manuring from the time the pears have fairly started swelling. Sewage is excellent, but it is wise to use a special phosphatic manure also, because phosphoric acid is essential to fruit development. Mineral superphosphate is one of the cheapest forms of phosphate fertilizer, and is soluble; 1 oz. to the gallon of water is a suitable quantity. Heavily laden trees are also benefited by a mulch of manure.

Pests of the Pear. The enemies of pears are in the main, those of the apple, with the difference, which is in favour of the pear, that it is on the whole the healthier tree.

Black spot is one of the worst fungus pests of pears. By this is meant the spotting, generally followed by cracking, which affects the fruit. It is worst in badly drained soil, but it may be serious in drained land if the soil is poor. Consideration should be given to the drainage and the condition of the soil. Spray with Bordeaux mixture in spring.

Caterpillars which attack pears in spring should be combated by autumn grease banding and spring spraying with arsenate of lead, 1 lb. to 25 gallons of water. For oyster scale, lime, lime-salt and lime-sulphur sprays generally are effective, but in bad cases the branches should be scrubbed with a paraffin and soft soap emulsion.

Aphides are often troublesome, especially in dry spells. Paraffin and soft soap, or 1½ lb. washing soda and ½ lb. soft soap in 20 gallons of water, or 5/8 oz. commercial nicotine and ½ lb. soft soap in 10 gallons of water, will check aphides. The last remedy is the best, if applied very hot where the leaves are badly curled. Pear slug is best fought with nicotine, a wineglassful to 3 gallons of water.

Injury to fruit by birds and wasps has also to be thought of. Birds may start pecking the fruit before it is ripe. This can be combated with snares to some extent, but netting the trees is the only sure remedy. If there is not a great deal of fruit to deal with, a strip of cotton wool may be tied loosely round the stalk, and it generally answers; but specially fine fruits may be enclosed in large gauze bags, which baffle both birds and wasps. If wasps are numerous, an endeavour should be made to find their nests and to destroy them at night with hot tar or by other means.

Pear Midge. The presence of this pest, which is very detrimental to pear trees, especially the early flowering varieties, usually first becomes evident from the rapid falling of the young fruit when about the size of marbles. Upon examination the freshly fallen fruit will usually be found to be deformed and much distorted. Upon cutting open an attacked fruitlet, a blackened mass of pulp and excreta with a number of the small, whitish yellow maggots will be found.

In small gardens where only bush fruits are grown the best remedy is the handpicking and destruction of all infested fruit, with repeated shallow cultivation of the ground beneath the trees in June and July. In large orchards great benefit has been derived from stocking heavily with poultry in April, May, and June, which is the time when the flies are appearing from the ground, and while the maggots are leaving the fruit.

On light soils an application of kainit, spread very evenly at the time the maggots are falling, is said to give very good results. Other potash manures will probably answer the purpose as well as kainit. Spraying the ground or grass beneath affected trees, when the midges are appearing in the spring, with soap and water, 1 lb. soft soap to 10 gallons of water, will kill the midges before they start egg-laying. The spraying should be done on dull days or early in the morning. The information given here is taken from Leaflet 26 issued by the Ministry of Agriculture.

Gathering Pears. Pears are ready for gathering when the stalks part readily from the tree under gentle pressure, even if they are not ripe. As a matter of fact, most pears should be gathered before they are quite ripe. Some need to be eaten almost off the tree, but others, including the William and the Jargonelle, are best gathered a few days in advance of full ripeness and laid in a cool room. Gentle pressure with the finger near the stalk affords a very fair clue to ripeness. If the fruit is quite hard, and particularly if it has little smell, it is not ready for eating. If it yields a little and has a pronounced aroma it is ready.

Pears that will keep till spring are best gathered in the latter part of October, before severe frost comes; a few degrees of frost will not hurt them. If these late pears are gathered much before mid-October they are apt to shrivel. The fruit keeps well in a dark, cool, sweet, frost-proof place. As a rule, it improves in flavour if it is kept for a few hours in a warm place before being placed on the table.

The amenable nature of pears, which makes them well adapted for formal training and restrictive pruning, renders them well suited for orchard house culture. They do well in large pots, in a compost mainly composed of fibrous loam. With support in the form of liquid manure while the fruit is swelling they will furnish excellent crops of splendid fruit.

Uses of the Wood. The wood is hard and heavy with a short and close grain. As it cuts cleanly in all directions it is an excellent wood for carving, but it seasons badly, and without care in the cutting and drying is apt to warp and twist. It absorbs stain well, and as a result most of the dyed stringing and banding material is prepared from it. Mathematical instruments such as rules, tee squares, and set squares are made from it.

Methods of Cooking. For many dishes ripe pears are most suitable, but for baking or stewing, hard green pears are the best.

To bake pears, wipe 6 hard, green pears, but do not pare them; lay them on a tin plate and bake them in a slow oven. They will take a long time to cook. When nearly soft flatten them with a wooden spoon, and continue cooking until done. Serve as for baked apples, with sifted sugar sprinkled over.

Stewed pears can be used as the foundation of many dinner sweets. Peel very evenly 4 large stewing pears, cut each in half and remove the core without taking away the piece of stalk. As they are divided plunge them into cold water to prevent them from turning black. When all are finished, take them out of the water and put them into a stewing jar or block-tin saucepan with 5 oz. granulated sugar and sufficient water to cover them. Add the thinly pared rind of $\frac{1}{2}$ a lemon, 2 cloves, 2 allspice (bruised), and enough cochineal to colour the syrup a good pink. Cover them close and stew for 3 or 4 hours. When tender, which can be ascertained by running a straw through one of them, lift them out and strain the liquor over them. If the liquor is very thin, boil it sharply for a few minutes.

Pears à la Ricardo. To make this pretty sweet put the stewed pears into a glass dish, pour the syrup over, and then make a small red jelly. Whip a gill of cream till it nearly hangs on the whisk, into it stir $\frac{1}{2}$ oz. preserved ginger cut into small dice, and then blend it lightly with the stiffly whipped white of an egg. Heap the mixture roughly over the pears, and decorate the top with lines of chopped jelly and $\frac{1}{2}$ oz. Ratafias.

Pears à la Ricardo, made with stewed pears and cream, and decorated with chopped jelly.

Pear Conserve. To make this jelly conserve take 6 lb. ripe, juicy pears, pare them thin, core them and cut them into quarters. Cook them till quite soft, using a little water. Strain all the liquid out of the pulp through a cloth or fine hair sieve as when making other fruit jellies. Measure the liquid and add an equal proportion of sugar. Boil the mixture until a jelly is obtained, then strain into glass jars.

Pear Dainty. Stewed pears also form the foundation of this sweet. To make it, cut a slice from the top of a round sponge-cake, scoop out the centre to form a case, and in the meantime stew 1 lb. peeled and sliced pears in sufficient sweetened water to cover them. When they are tender, leave them to cool, and then add 6 oz. ground almonds, putting the mixture into the case. Replace the top of the cake and cover with halves of blanched almonds. Prepare some custard with 2 dessertspoonfuls custard powder, 3 dessertspoonfuls sugar, 1 pint milk, and some almond flavouring, and, when cold, pour it round the cake. Whisk the white of an egg to a stiff froth, stir into it 1 gill whipped cream, sweeten and flavour the mixture with almond essence, and pile it high in the centre of the cake.

Pear Mould. To make this, mix dessertspoonful custard powder to a smooth paste with a little milk taken from pint. Boil the remainder, add it to the paste, stirring all the time, and then flavour it with a little vanilla.

Pear Mould, the centre of which is filled with tinned pears and whipped cream.

While it is cooling, rub a small tinful of pears through a sieve, then add the pulp, together with 1½ dessertspoonfuls castor sugar, to the custard.

Fold the stiffly whisked whites of 2 eggs into the pulp, etc., and lastly strain in ½ oz. leaf gelatine dissolved in ½ gill warm pear syrup. Mix all together, pour them into a border mould, and leave until set. The centre may be filled with some more tinned pears and whipped cream.

PEARL: Real and Artificial. Pearls can be divided into three classes. These are the natural pearls found in certain kinds of shellfish, cultivated pearls which are produced partly by natural and partly by artificial means, and the wholly artificial pearls. The first named are the only ones that may justly be described as genuine, but cultivated pearls are also valuable, and far more costly than the manufactured specimens. Various makes of imitation pearls can be obtained, some of them being patented.

The value of real pearls is determined by their freedom from defects and also by their size, shape and colour. The round ones are the most precious, and next to these rank the button-shaped varieties. Pear-shaped pearls are cheaper, though large and faultless specimens command high prices. Black pearls are rare and costly. They have two lustres, one being grey and the other green. Black hematite, which is used to imitate black pearls, can always be detected by its considerably heavier weight.

Pink pearls are no less valuable than white ones, but they are often peculiarly shaped. Pearls of many other shades of colour can also be obtained, and are seen in great variety in some famous necklaces.

The best deep sea pearls are liable to deteriorate unless they receive proper care. The brilliancy of colour and the lustre which makes a pearl so attractive soon disappears if it is allowed to come into frequent contact with rough surfaces, or to be damped by perspiration which contains uric acid. When the outer surface only is damaged, however, it can sometimes be successfully removed. The underlying layers of nacre will be found still to contain the orient tints, though not with the same degree of lustre or brilliancy as the outer surface. The natural lustre of pearls is often lost through keeping these gems for long periods in jewel-cases. A sun bath generally improves them.

The irregular surfaces found on the inside of the oyster shell, mostly semicircular or oval in shape, are known as blister pearls. These are used largely in jewelry in combination with coloured or semi-precious stones, such as amethysts, aquamarines, topazes and tourmalines. The price commanded by semi-circular pearls is small compared with the amount that would be realized for a spherical pearl of corresponding size.

Cultivated Pearls. People in Japan cultivate pearls by performing a small operation on the oyster, which enables a bead to be introduced into the flesh, and in the course of time the oyster covers the bead with nacre. There is also another method of introducing a bead. This is by cementing it into the shell and leaving it for a year, or several years, until the oyster has covered it with one or several layers of nacre, thus giving the bead a covering which is the same as the exterior of a pearl that might otherwise have taken many years to produce.

These pearls are usually composed of a core of mother-of-pearl, and, except by expert examination, there is no means of detecting them from the naturally formed pearls. Those pearls which are

cemented into the shells of molluscs only receive a covering on the upper side; consequently, after they are removed from the oyster, they are cut into half-rounds. These are used for mounting into such articles as rings, brooches and pendants. It has been laid down by English law that these cultivated pearls must not be offered as genuine pearls, notwithstanding that the orient sheen thereon is actually the result of the work of the oyster.

Artificial Pearls. Really good imitation pearls are artistic productions. These are made by covering a solid bead, either of glass or mother-of-pearl, with a series of layers of collodion; in colour, weight, and outward appearance they are exact reproductions of the best deep-sea pearls. Such pearls can be hardened off so as to give them increased durability and also to enable them to be cleaned by washing with soap and water.

Some artificial pearls are filled with matter obtained from fish scales, and bear an extraordinary resemblance to the real gems. They are made by blowing thin beads or bulbs of glass and then injecting into them a mixture obtained by soaking the scales in water and mixing the sediment that results with some liquid ammonia. It forms a coating inside the bead which gives the latter just the right shade. Melted white wax is afterwards poured in to increase the weight and durability of the bead, and the shiny exterior, in order to hide the fact that it is made of glass, is dulled by the application of chemicals. Such pearls are frequently blown to the irregular shape that distinguishes a great number of the large genuine pearls.

Imitation pearls in necklaces can be detected by the following simple tests, which, of course, do not apply to cultivated pearls. Gently place the point of a needle on the exterior of the pearl immediately above the point where the hole has been drilled. If it makes a mark, or if by a slight movement of the point of the needle it scratches the pearl, then it is safe to assume that it is an imitation with a core of some solid material with a vellum-like covering.

If the needle makes no impression on the exterior, there is a possibility that it is an artificial pearl which has a glass exterior filled with a mixture of wax and fish-scales. A further test should then be applied by pushing the point of the needle gently into the hole of the pearl. If it is one of the filled varieties, the probing will disclose that the interior has a filling of soft material into which the needle point can be inserted. If the pearl is a real one, the needle will make no impression when pushed against any part of the wall of the hole.

Cleaning Pearls. Pearls may appear to lose their lustre and require cleaning. They can be washed in soapsuds and lukewarm water and then dried. It is important thoroughly to dissolve the soap before putting a ring or other piece of jewelry into the lather, and afterwards to rinse it in clean water. It is then dropped into a saucer filled with jeweller's sawdust, which is shaken up and absorbs the moisture on the pearls. The ring is taken from the sawdust and brushed with a camel hair brush or a dry tooth-brush so that no particles of sawdust adhere to the setting. *See Jewelry; Necklace.*

Pearl Barley. The grain of barley stripped of its husk and rounded by grinding is known as pearl barley. *See Barley.*

PEARMAIN: The Apple. This class of dessert and culinary apples is of very old standing. Varieties in cultivation include Blue, Adams's, Hornead's, Claygate, Herefordshire, and the popular dessert variety Worcester. The latter is an early eating apple of high colour and free bearing. *See Apple.*

Peas: Growing and Cooking

How Gardener and Cook can Secure Good Results

In connexion with this subject the reader should consult our article Kitchen Garden. See those on other vegetables, e.g. Cabbage; Carrot; Potato; Spinach also Coral Spot.

Green peas are the most delicious of all summer vegetables, and by making successive sowings from March to June it is possible to produce excellent peas from June until September. Success depends chiefly on correct cultivation of the soil: this must be dug deeply, enriched with manure and not be deficient in lime. After the soil has been dug and manured a scattering of lime may be applied with advantage, especially on freshly cultivated ground, and on old garden land which has been well manured annually during a period of years. On poor or shallow soil peas are not a success: growth will be poor and the yield small.

The seeds should be sown thinly in a double row in a 12 in. wide shallow trench, 1 to 2 in. deep, taken out on land that has been prepared in the way advised. When the earliest rows are 2 or 3 in. high the soil should be drawn up to them with a hoe as a protection from cold winds and to some extent from birds; it may be necessary to protect the seedlings from birds by using the special pea guards, or fish netting. Tall varieties must be staked in good time, for once the seedlings are allowed to fall over they become bent and rarely do so well as others which were supported early.

The dwarf varieties of peas have been improved so much in recent years that many gardeners now grow them almost exclusively in preference to the tall varieties; the latter, however, still yield the largest crops, and if pea sticks can be obtained cheaply or free of cost it pays to grow the taller peas. If, however, pea sticks are expensive in the grower's locality the dwarf varieties of peas are to be recommended.

Some of the best of these are the following which reach a height of about 18 in.: Peter Pan, Laxtonian, Prince Arthur and Little Marvel. Others which reach a height of about 2 ft. are Daisy, Abundance, Stratagem and Giantstride. Excellent tall peas are Rentpayer, Senator, of which an illustration is given in the next page, Prince of Wales and Eureka. For a late sowing in June, Autocrat or Gladstone are recommended. The distance between rows of tall peas should be equal to the height of the plants. For an early crop, seeds of a dwarf variety are sown in greenhouse or frame (January), seedlings in March.

The way to maintain an unbroken succession of fresh green peas is to sow a row every fortnight or so from the middle of March to the middle of May, or even later if necessary. It is a mistake to make one large sowing if peas are wanted throughout as long a period as possible. Quite Content and V.C.. which produce immense pods, are favourite exhibition varieties.

Diseases of Peas. Peas are subject to a number of diseases. One of these is powdery mildew. The leaves of the peas show yellowish-green blotches, which gradually increase in size until the whole of the foliage changes to a yellow colour, and soon wilts and dies. When badly attacked a row of peas presents the appearance of having been whitewashed. (For pea pests, diseases, etc., see Ministry of Agriculture Bulletin 81.)

To control this disease spraying is effective, provided it is begun early enough. It should be carried out before mildew appears in June and July, using liver of sulphur, 1 oz. in 4 gallons of water.

Pea mildew, although liable to be confused with powdery mildew, is really quite different from it and requires different treatment. In it the leaves first become covered with a delicate white mould, which soon changes to a pale pinkish-grey colour, and may pass unnoticed until its presence is indicated by the wilting and yellowing of the leaves. The powdery appearance of the mould, characteristic of the other mildew, is entirely absent in this case. When this disease is present the

peas should be sprayed with Bordeaux mixture at half strength. This can be made from 1½ lb. of copper sulphate or bluestone and ¾ lb. of quicklime to 25 gallons of water.

Pea Maggot. This is the name of the maggot that infests pods of culinary peas. As soon as the maggots are hatched they gnaw their way through the skin and devour the seed. When the larva is satisfied it leaves the pod and hides in the soil for its pupal stage, emerging as a moth in June, and immediately depositing eggs in clusters.

There is no real remedy for the pest, and all that can be done is to sprinkle soot over the foliage in early June evenings.

How to grow Peas. 1. Ideal soil preparation. 2. Sowing drills: A, intercropping. 3. Bad method of sowing. 4 and 5. Two good methods of placing seeds. 6 and 7. How to sow in pots: a, fine soil; b, good soil; c, leaves.

Peas. Specimen pods of a popular green pea, the variety known as Senator.

Peas. 1. Sowing in old turves: *a*, sowing method; *b*, seed closed in; *c*, seedlings ready for permanent planting. 2. Same in position: *a*, rich soil; *b*, manure or vegetable refuse. 3. Seed sown in egg-shell. 4. Support for young seedlings. 5. Protection from birds. 6. Protection for early sowings: *a*, boards; *b*, glass. 7. Seedlings hoed up. 8. Good sticking: *a*, cross support. 9. Another method: *a*, support for wire; *b*, canes fixed to same. 10. Pea thrip. 11. Pea maggot. 12 and 13. Pea weevil and its caterpillar.

Pea Weevil. Weevils will attack peas, and if disturbed will instantly drop to the ground and appear dead. The weevils are about $\frac{1}{4}$ in. long. Seedlings should have sand and paraffin sprinkled round them, or be sprayed with an arsenate of lead wash.

How to Cook Peas. To boil green peas, first put on the fire a good-sized saucepan of water to boil, with sufficient salt, 3 or 4 sprigs of fresh green mint, and 3 lumps of sugar. While the water is boiling, shell the peas, then put them into the water and cook for 20 min., or according to the age of the peas. Drain them, remove the mint, and dish them in a very hot dish in which 1 oz. butter has been allowed to melt. Stir them lightly in with the butter and scatter over the top a little chopped mint.

Green peas are frequently served with fried or boiled ham, and make an appetizing dish. The peas should be cooked as for plain boiled peas, except that the chopped mint is omitted on the top. They may be dished separately and accompany boiled ham or gammon, or the bacon may be fried and laid on the top of the peas. Gammon rashers about $\frac{1}{2}$ in. thick are best for this dish. When boiled ham or bacon is to be served with peas they are sometimes boiled in the same saucepan, the peas

being added about $\frac{1}{2}$ an hour before the ham is done. This method improves the flavour of each. The ham used must not be too salt and no extra salt should be put into the saucepan.

Peas may be steamed by placing them in a jar with a little sugar, salt, mint, and 2 tablespoonfuls water, covering the jar tightly and then putting it into a saucepan of boiling water. Keep the water boiling rapidly for about $\frac{1}{2}$ hour, and add more if necessary.

Cold cooked peas can be used for saladmaking. Poach 2 or 3 eggs, cut the edges neatly, and leave them to get cold. In the meantime bind a small teacupful of cooked peas with a little mayonnaise sauce, and add seasoning to taste. Place each egg in the centre of a fresh lettuce leaf laid in a salad bowl, put some peas on top, and cover with a little more mayonnaise.

Green pea soup is made by putting 1 quart shelled green peas into a large saucepan with 2 oz. raw bacon cut in dice, $1\frac{1}{2}$ oz. butter, 1 large onion (peeled and sliced), and a few sprigs of green mint and parsley. Set the pan over a gentle heat and stir well until all ingredients are thoroughly rubbed together, then add 1 gill water and cook until the peas are quite tender. Sprinkle over 1 oz. flour and mix in smoothly. Pour over 1 quart stock which has been flavoured with vegetables, and mash the peas as much as possible against the sides of the saucepan while pouring. Simmer gently for 10 min., then pass the contents of the pan through a wire sieve. Boil up, add more seasoning if required, and 1 gill boiling milk or cream. Serve with dice of toast, also remove fat from the top of the soup before serving.

Bottled or tinned peas, when required, should be turned into a colander, and washed thoroughly with boiling water. A little mint, butter, salt, and sugar should be added to the pan in which the peas are heated; actual cooking is unnecessary. Packet peas, with which directions for preparing are usually supplied, need to be soaked in boiling water overnight before they are cooked.

PEASE PUDDING. To make this, soak 1 pint split peas overnight, and in the morning wash and pick them and tie them loosely in a large pudding cloth, giving them plenty of room to swell. Boil them for 4 hours, and when quite tender rub them through a coarse wire sieve or colander. Add to them 2 oz. butter or good beef dripping, and season them with salt and pepper. Mix all well together and tie once more in a cloth, but this time draw it tight round the peas. Boil it again for from 20 to 30 min.

Peasgood's Nonsuch. This is a favourite autumn cooking apple of large size and handsome appearance. *See Apple.*

PEAT: As Fuel. For use as fuel peat is cut in turves from a foot or two below the surface during the summer, stacked edgewise to dry, and turned every day or two until the drying is complete; this takes 10 to 12 days. It is then carted home and piled under cover in an outhouse, or erected into a rick and roughly thatched for winter use.

The heating value of peat is a little more than half that of a similar weight of coal. It is therefore much bulkier in proportion to the time it burns, and large wooden peat vases, twice the size of the average coal scuttle, are placed in rooms where it is burnt to hold it, and refilled once or twice a day. Peat makes very much less dirt than coal, and has a pleasant fragrance when alight, but owing to the rate at which it burns it requires more frequent attention than is given to a coal fire.

When lighting a peat fire it should be remembered that it will not catch from paper. A good handful of thoroughly dry wood is needed to start it, and very little peat should be added until the wood is well alight. Large unbroken turves should never be put on to a newly lighted fire, or they will extinguish it. The proper plan is to break them up small between the fingers, and to feed the fire with them gradually, giving entire attention to it for the first 10 minutes.

When the fire has well started the hearth should be piled up with large sods of peat, using plenty of them. They will appear at first to kill the blaze, but it will soon shoot up again. If possible a proportion of coal should be used, starting the fire well with coal, and then piling the peat up high over it. Such a fire will last well, look very cheery, and throw out a great deal of heat. A pair of bellows should never be absent from a peat fireside; they put new life into the fire when it dwindles unexpectedly. *See Fire; Fuel.*

PEAT: For Garden Use. A soil which is made up chiefly of decayed leaves and other vegetable matter is known in gardening as peat. It represents the early stages of the transition of wood into coal. It needs to be mixed with loam and sand for ordinary plant culture. It is used extensively as a mulch.

PEBBLE WARE. This is a term used by Josiah Wedgwood to describe earthenware products in which the effect of crystalline rocks was imitated by means of differently coloured clays. In these materials he turned out flower-pots, basins, plates, inkstands, and candlesticks, but especially vases, all simulating natural crystalline stones.

Egyptian pebble was made of coloured clays, with veining; when spotted with blue it was called variegated pebble. Some of the specific imitations, such as verde antique, agate, porphyry, serpentine, and granite, always bore these names, although they are all varieties of pebble ware. The earliest pieces, made by colouring cream bodies, can be distinguished by the light tint of the edges. Afterwards the veining was made to run through the substance by means of bands of clay incorporated in the paste. *See Jasper Ware; Wedgwood.*

PÊCHE MELBA. A fancy name for ice cream made with peaches is pêche Melba. The peaches are divided in half, stoned, and steeped in liqueur, with a sprinkling of sugar added. They are served with a surround of rich ice cream, and garnished with whipped cream arranged in the centre. *See Ice.*

PECK. This measure of weight is used for potatoes and other vegetables; also for fruit. Ordinarily, a peck consists of 14 lb., and four pecks make a bushel. Apples, however, are usually sold 10 lb. to the peck, and onions often 12 lb. *See Dry Measure.*

PECTIN. This is a substance allied to gum which is found in ripe fruits and causes jams and jellies to set. Before cooking it exists as pectose, and is converted into pectin by the heat of the process. If too much heat is employed the pectin is changed in character and no longer gelatinizes the jam. On this account too much boiling should be avoided in the preparation of fruit jams.

Apples and gooseberries contain more pectose than soft fruits such as raspberries, strawberries, and plums, and this is why strawberry or other jam often contains a small proportion of apple or gooseberry pulp or juice. Unripe fruit contains very little pectose, hence the necessity of employing only ripe fruit in jam making. The setting properties of crab-apple jelly are due to the large proportion of pectose contained in crab-apples. A pectin preparation for adding to jams and jellies when making these can be obtained at grocery stores. *See Jam; Jelly.*

PEDIMENT. This word meant originally the triangular finish placed over the cornice that rested on the column of a Greek temple. It thus resembles the gable in Gothic architecture. Its chief use to-day is in connexion with furniture, being seen on English furniture most usually in the form of a broken pediment. The tops of bookcases and cabinets have the sides of the triangle, that would otherwise reach an apex, stopped short of it. This form of pediment was used by Chippendale and is

seen in Georgian style rooms over doors and fireplaces. Occasionally the pediment takes another form; a semicircular one is shown under the heading Mirror. *See* Door; Georgian Style.

Pedlar. *See* Hawker.

PEEL. Peel is a skin or rind, the word being especially applied to the skin of fruit. This skin should in most cases be removed before the fruit is eaten. Certain peels, e.g. that of the lemon, have many culinary uses. *See* Candied Peel; Lemon.

PEGAMOID. This is a substitute for leather, and is used for upholstery. It is easily cleaned with soap and water, and kept in condition with ordinary furniture polish. Like all leather surfaces, it becomes cracked with continual use; if treated with one of the specially prepared paints sold for the purpose, the surface can be rendered equal to new. *See* Upholstery.

PEKINESE DOG. The Pekinese is an affectionate little dog, purely domestic and of engaging manners. Its head is broad and flat between the long, drooping, heart-shaped ears; the muzzle short, broad and wrinkled, and with the broad nose black. The large dark eyes are round, bright and prominent. The body, broader in front, has a dense undercoat covered with rather coarse though soft, long, flat hair; the legs, feet and tail profusely feathered. Any colour is allowable, self, or patched, but the golden-tan, self-coloured dogs are the truest to type. The maximum weight is 10 lb., but smaller dogs are more desirable (minimum 5 lb.). *See* Dog; Kennel.

Pekinese Dog. Prize-winner of this favourite breed of long-haired toy dogs.

PEKOE. The fine variety of China tea known as Pekoe is very suitable for mixing with Indian, Ceylon, or other teas. The leaves are picked when the plant is young, and has the down upon it. From the pleasant aroma of this tea it is often called the flowery Pekoe. *See* Tea.

PELARGONIUM. The two most popular kinds are the ivy-leaved and the zonal pelargoniums, the latter being commonly but erroneously known as

zonal geraniums. Both are valued for planting in summer beds, and the ivy-leaved varieties are well suited to filling vases in the flower garden or hanging baskets in a porch, veranda or window box. They are propagated by cuttings taken from flowerless shoots in August, inserted in pots or boxes of very sandy soil and placed in a cold frame. During the winter the cuttings must be kept in a greenhouse heated sufficiently to keep out frost; a temperature of 45 to 50 degrees is high enough to ensure their safety. In autumn or in spring the rooted cuttings are potted singly in 3 in. pots in a compost of sandy loam; they may be repotted in 5 in. pots before being hardened off ready for planting out of doors early in June.

The old plants should be lifted early in October: if placed in pots or boxes of soil and kept under glass safe from frost in winter and spring they may be planted out in June. Old plants are useful for garden vases and for filling the centres of flower beds. A method sometimes employed by those who have no greenhouse is to shake the roots of zonal pelargoniums free from soil in autumn and

hang them, roots downwards, in a cellar or other frost-proof place for the winter; it is however less satisfactory than potting them and keeping them inside a room window.

Pelargonium. Ivy-leaved variety in a terrace vase.

Right. Fine head of a zonal pelargonium.

A few of the best varieties of zonal pelargonium are Paul Crampel, red; King of Denmark, salmon; Henry Jacoby, crimson; Queen of the Belgians, white. There are innumerable others. Two favourite varieties of ivy-leaved pelargoniums are Madame Crousse, salmon-pink; and Souvenir de Charles Turner, carmine-rose.

Certain pelargoniums are grown for the sake of their coloured leaves, but they are less popular than they were some years ago. Flower of Spring, green and white leaves; Crystal Palace Gem, yellowish leaves; and Swanley Bronze, with bronze-coloured leaves, are some of them. Then there are the tricolorleaved pelargoniums, of which Mrs. Pollock is a great favourite.

The show and fancy pelargoniums are still favourite plants for cottage windows where, during the summer months, they may be seen in full beauty in almost any part of the country. They are valuable for conservatory decoration. When the flowers are over the plants should be partially dried off by giving less water for 3 or 4 weeks; the shoots are then cut back, the plants repotted, and grown in a cold frame until autumn, when they should be placed in a slightly heated glasshouse. Cuttings made from the fresh shoots will form roots in pots of sandy soil in a frame.

Scented-leaved pelargoniums are rarely seen nowadays, but they are worth adding to a collection of greenhouse plants, for they are easily grown in a temperature of about 50 degrees if potted in sandy loamy soil. Zonal pelargoniums will flower in winter in a greenhouse temperature of 50 to 60 degrees if they are propagated by cuttings in March. During the summer months the plants must be grown in a cold sunny frame and all flower buds should be picked off. In late September they should be placed in the greenhouse. The final potting is in 5 in. or 6 in. pots, using a compost of turfy loam with a little sand and decayed manure. *See Geranium.*

Pelargonium. Method of culture. 1. Suitable cutting. 2. Cuttings in a box. 3. Cuttings in a pot. 4. Single cutting potted right. 5. Cutting potted wrong. 6 and 7. Cuttings wrongly prepared. 8. Cuttings correctly taken just below a joint. 9. Where to pinch to secure bushy plants. 10. Plant with old stem pruned and soil-ball reduced. 11. Same repotted to provide cuttings. 12. How to hang old plants during the winter. (By special arrangement with Amateur Gardening)

PELMANISM. This game depends largely upon the memory. It is played with a pack of ordinary cards, which, instead of being dealt in the usual way, are laid face downward on the table unsymmetrically, each card separate. The first player turns up a card, shows it to the others, and lays it down again in the same place, face downward. A second card is treated in the same way. Subsequent players turn up a card, and if a similar card has already been turned up they can pair it off, providing they can remember its position. If they succeed in pairing it the two cards are then removed from the game. This is done by each player in turn, and the one who has most pairs at the end of the game is the winner.

PELMET. This is the furnishing accessory which surmounts the curtains of a window and hides the pole or rod and rings. Woven fabric pelmets are usually of the same material as the curtains, but occasionally a contrasting treatment is employed by making the pelmet to match an appliqué trimming or border. In such a case the pelmet is often trimmed with appliqué of the material used for the main body of the curtains. The difference between a textile pelmet and a valance is that the latter is pleated or gathered, while the former is shaped to fit. It may be trimmed with a fringe, scalloped, or stepped and braided, or curved at each end as shown in Fig. 1. It requires lining with

the same material used for the curtains or to tone with them, and often also to be interlined with canvas. The pelmet is fixed on to a pelmet board, as illustrated in Fig. 2 below.

Pelmet. Fig. 1. Fringed and braided silk pelmet fixed to pelmet board with moulded front.

Below. Fig. 2. Sectional view of board with pelmet attached.

Many window treatments now incorporate a glass, wooden or metal pelmet. Mirror glass is used divided into sections which are held in position with silver-headed nails or glass studs. Coloured glass which matches the colours of the curtains is effective for pelmets. Oak or painted wood moulded pelmets are also seen, while designs in plywood are suitable for bedrooms and modern bungalows. Aluminium and chromium plate are also used for this purpose. The advantage of hard surface fabrics for pelmets is that they do not require to be taken down when the curtains are changed, but are simply cleaned with a damp cloth and polished. Illustrated ideas for pelmets are seen in the article on Curtain.

Pelmet Board. This name is given to the support which holds a pelmet or a pleated valance in position. It consists of a strip of wood that is sometimes provided with a wide moulding on the front edge and ends. The pelmet is attached either directly to the front edge or behind the moulding. In addition, the rods on which the curtains are hung are generally attached to the pelmet board. An illustration of a pelmet fitted to a board with a moulded front is shown in Fig. 1. The side view in Fig. 2 gives a section showing how the moulding may be attached to the board and the position of the silk pelmet and curtain rod, which is held in position with screw hooks. Small iron brackets are used to secure the pelmet board in its proper position. *See Bay Window; Curtain; Living-Room; Mirror.*

PEMBROKE TABLE. This is a name given to an oblong table with two leaves, which may either hang down or, supported by brackets, be raised to the level of the rest of the piece. The leaves may be either oblong or semicircular, and the table is made in oak and mahogany, as well as in the cheaper woods. Pembroke tables of the 18th century have frequently edgings of marquetry, and on some is the serpentine line favoured by Hepplewhite and his followers. *See Table.*

PENCIL PAINTING. Pencils specially prepared for this work are known as Aquarello and are obtainable in 24 colours. They may be used dry, as ordinary coloured pencils, or with water and a brush when pencil painting can be accomplished on paper, textile fabrics, leather and wood.

There are two methods of working the colours. Part of a design is filled in with the desired tint, as if using an ordinary crayon, and then spread and smoothed with a brush dipped in water. This results in beautiful clear wash effects of non-fading colour.

The other method of application is to damp the paper, or portion of a design on a piece of fabric, slightly with a clean, wet brush and then draw in with strokes of the pencil the colour required.

Unless there is an excess of water the colour will not run, but in this way shades can be softly blended.

Pencil Painting. Outlining the design on a parchment spill holder with a water colour pencil. The boxes have been decorated with pencil colours applied dry and spread with a brush dipped in water.

To make a strong outline the pencil itself is dipped in water and used, as shown in the illustration. The conventional design on a parchment covered spill holder is being drawn before being filled in.

Colours may be superimposed and may be distributed over large surfaces by means of a piece of damped felt wrapped round the index finger.

The simplicity of the outfit will appeal to many people, and pencil painting is a delightful and clean method of colouring for children to use. It is excellent for sketching or for map tinting, and may also be used for colouring photographs on either dull or glossy paper. For this last purpose the pencil is applied dry, and the markings are then gone over with a damped brush. If too much colour is applied, or it is put in the wrong place, erasures can be made before water has been used to spread the tint evenly.

The wooden boxes shown in the illustration were first painted a pale colour. The rose designs may be transferred or copied, but original designs can be created. Before using carmine for the red rose on the small box and yellow for that on the cigarette box, the flower was filled in with the white pencil and the colour worked over the white. For shading the red, violet was used, orange for the yellow rose, and blue over the green for shading the leaves. For the high lights a little more of the white pencil was used over the colour. Leather is pencil painted in the same way as wood. For either work to ensure permanence against wear, spray with an ordinary solution of shellac and alcohol, or brush over with clear varnish, to protect the design. The application of pencil painting to woven fabrics is dealt with in the article *Painting on Textile Fabrics*. See *Transfer*; *Writing Desk Set*.

Pendant. Eighteenth century piece in gold set with diamonds.

PENDANT. The most valuable of these neck ornaments are made of gold and are set with diamonds, sapphires, and other precious stones, while platinum and pearls are also used for them. Pendants are also made in rolled gold and enamelled silver.

Yet another type of pendant is of carved or plain amber, jade or ivory.

Such pendants often form part of a necklace composed of beads to match, with or without metal chain-work or filigree connecting links. Other pendants are usually worn on chains which match the metal of which they are made. *See Enamelling; Jewelry.*

PENDULUM. A clock depends for its timekeeping upon the proper working and adjustment of the pendulum. The motion of a pendulum is controlled by the laws of gravity; if free from friction and atmospheric pressure, it would swing for an indefinite period at a uniform rate. The time of vibration of a pendulum depends entirely on its length.

It is the same for a given length whether the pendulum swings through a long arc or a short one, the velocity being proportionate to the height the pendulum falls in its swing. The length is the distance from the point of support to the centre of gravity of the pendulum bob and rod; the shorter the rod the greater the number of the vibrations. Lengthening the rod reduces the speed of the clock, and shortening the rod increases the speed. The length of a seconds pendulum is taken as the basis: in the latitude of London this is approximately 39·14 in., and a rod of this length will make 60 vibrations per minute, or, in other words, will take one second to swing from one side of its stroke to the other. Cheap clocks generally run at a speed of 120 or more, hence the pendulum must be shorter than 39 in. in length. The length varies as the square of the time of vibration, hence a pendulum to beat at 120 per minute will only need to be 9·75 in. long.

The following table gives some of the lengths and corresponding vibration rates:

Length of Pendulum in.	Vibration Rate in.
14·1	100
11·6	110
9·75	120
8·3	130
7·2	140
6·25	150
5·5	160
4·0	185
2·5	240

The length of pendulum arranged for a clock is governed as a rule by the amount of room available in the clock-case. The

clock, through its wheels and pinions geared up to suit the length of the pendulum, transmits the number of vibrations in the form of seconds, minutes and hours recorded on the dial by the hands.

Ordinary pendulums vary slightly with changes of temperature, which cause the metal rods of which most of them are made to expand or contract, thus lengthening or shortening the pendulum, with the result that the clock goes slower or faster. Where very accurate time is required pendulums are made to compensate, and there are several ways of doing this.

Modern science has produced a metal known as Invar steel, which requires no compensation and has the lowest known coefficient of expansion. This is generally used where very accurate timekeeping is required. A wood rod, well french polished, with a lead bob, also makes a good pendulum, as wood is not much affected by temperature. The spring by which a pendulum is suspended should always be as thin as possible, just of sufficient strength to keep the pendulum from rolling or wobbling.

Regulating the Pendulum. The regulating of a clock consists in getting the pendulum to make the correct number of vibrations so as to record the right time. This is done by lengthening or shortening the pendulum. In most clocks the bottom part of the rod is fitted with a screw, on which is a knurled nut. On this nut rests the bob which slides up or down on the rod, so that by turning the nut the bob is raised or lowered as required. In doing this, great care must be taken not to buckle the suspension spring, as a distorted spring will very often cause bad timekeeping. A good plan is to hold the bob with one hand and turn the nut with the other.

When a clock requires regulating it should first be noted how much it is out in a given time. The pendulum should be altered accordingly, shortening it to make the clock go faster, and lengthening it to make it go slower. The result should be watched to see what difference the alteration has made over the same period, and from this it will then be possible to gauge exactly what further alteration is required. A long pendulum will require moving a greater distance than a short one for the same error. Some clocks are provided with a means of regulation from the front of the dial.

French clocks use what is known as a Brocot regulator. Over the top of the figure 12 is a small square, which is turned with a key that works a slide up and down the suspending spring of the pendulum. On account of backlash between the two toothed wheels employed, this device is often not very reliable, and the slide should be observed to see just how much it is moved by turning the key. English clocks use a different method, known as a rise and fall. This is a rocking bar across the top of the clock plates, the pendulum being hung on one end, the other end working on an eccentric snail at the back of the dial, with an arbor through the dial, to which is fixed a pointer or hand. By turning this the bar is moved up or down, by this means drawing the suspension spring between two brass jaws underneath the bar. *See Clock; Grandfather Clock.*

PENNISETUM. Of these ornamental grasses only one, *Pennisetum longistylum*, is usually grown in gardens. It is 18 in. high and bears spikes of purplish flowers in summer. Seeds are sown out of doors in April where the plants are to bloom.

PENNYROYAL. This aromatic herb (*Mentha pulegium*) thrives in ordinary soil and is propagated by cuttings in spring. If these are severed beneath the soil they will possess a few roots and soon become established.

PENNYWEIGHT. This measure is used in Troy weight, 24 grains going to a pennyweight; 20 pennyweights make an ounce. The usual abbreviation is dwt. *See Troy Weight.*

PENNYWORT. Sometimes called navelwort, and botanically known as *Cotyledon umbilicus*, pennywort is a succulent plant which may be found growing wild in crevices of rocks and ancient walls in the west and southwest of England and Wales. It has orbicular leaves and bears erect spikes of drooping cylindrical yellowish-green flowers during June. Its rounded fleshy leaves have depressed centres. It is useful for wall-gardening and for outdoor ferneries, but requires mild climatic conditions.

PEN PAINTING. This form of decoration can be applied to cotton, silk, velvet, leather, papier mâché, wood, pottery, glass and metal. Oil colours are used with a special powder and medium, pens, palette, palette knife, drawing pins, drawing board, and a sheet of clean white blotting paper are also required.

When used on textile fabrics care is necessary to prevent spreading of the oil colour. This may be achieved by removing the work from the drawing board immediately the pen painting is finished and placing it on a sheet of clean blotting paper which has been dusted over with absorbent powder.

The back of the silk or other fabric must touch the powder while the colours are drying and this prevents their tendency to spread.

Wooden articles to be decorated in this manner should be lacquered or enamelled first, the design being pounced on when the background is quite dry. Glass and pottery must be washed, rinsed in cold water, and polished with methylated spirit. Colours will not adhere to a greasy surface. Stencilled designs may be outlined in pen painting.

Floral and conventional designs are the most suitable for pen painting. The finished appearance of the work has some resemblance to embroidery as the strokes of the pen by means of which the oil colours are laid on take the form of stitches.

The first step is to trace the design on to the fabric in the case of textiles, to pounce it on for wood or to paste it on the reverse side for pen painting on glass. Designs may also be placed under gauze, which is an admirable fabric for pen painting. Black gauze mounted afterwards on satin is effective when pen painted for central pieces on nightdress, glove or handkerchief sachets. In white it is used

for dessert doilies, such as those illustrated in Fig. 1. Silk gauze is obtainable for the work by the yard or in pieces; also traced gauze doilies and table centres for pen painting.

Pen Painting. Fig. 1. Two of a set of dessert doilies, each of which is decorated with a different flower.

Special oil colours are sold for this purpose. A convenient method of mixing is to squeeze a little white on to the palette and mix the powder with it till it is of the consistency of thick cream and no specks of free powder are left. The white is then tinted a very pale shade colour required and a third of it put aside. The remainder is tinted a deeper shade and half of this is put aside, while the part left over is coloured a still darker shade. This gives a medium tone for a flower, leaf or groundwork, a pale tone for high lights and a dark tone for shadows. The various colours may be prepared in this way, and a drop of medium should be added to each before starting work.

Fig. 2. Glass vase decorated in pen painting with design of mimosa in natural colours.

The three shades of a colour actually in use may be placed on the blade of an old table knife. A long, thin piece of colour is then modelled on the knife and picked up with the pen and applied to the fabric as if making a down stroke in writing, a slight but even pressure being maintained. This is followed by further strokes until the design is filled in; the darker and lighter tones of the colours being used for the high lights and shadows. Practice soon teaches the worker just how to gain good effects from the direction of the strokes. A set of dessert doilies with a different flower on each one is an excellent piece of work to undertake after experiments have been made on a few scraps of silk or cotton to gain some skill with the strokes.

English and French makes of pens are obtainable for a few pence a dozen. Bronze and lustre powders can be used to give a richly varied appearance to designs. The former are painted on finely with a No. 1 sable brush, using the quick-drying medium supplied for them. The latter are dusted over portions of the work, while still wet, to give a raised effect. For instance, they were used to give a touch of realism to the mimosa leaves and flowers on the glass vase in Fig. 2. The leaves were worked first in greens and while wet covered with green lustre powder. When this was dry enough for the surplus powder to be shaken off, the mimosa was painted in with the pen in chrome yellow and white. This was covered with yellow lustre powder to give the fluffy look to the mimosa balls.

One advantage of pen painting is that it can be done rapidly. It takes some time to dry however, one week being the usual time allowed in winter. Afterwards the work may be brushed, washed, or rubbed without harmful results. If the colours fade with time, they can be freshened by a second but light application of paint. *See* Painting on Textile Fabrics; Stencilling; Transfer.

PENSION. A pension is really an annual payment made to elderly or infirm persons in recognition of past services. Officers of the army and navy and civil servants enjoy pensions if they have served a certain period, and many businesses have pension schemes for their employees, among these being the banks and insurance companies. Many local authorities, such as town and urban councils, have also pension schemes, and pensions are also provided by some trade unions.

Pensions are either contributory or non-contributory. Those given by the state to officers and civil servants are non-contributory, i.e. no deduction is made from the salary on this account. Most other schemes are contributory, i.e. the employee pays from his salary a certain amount each week, month, or quarter towards his pension, usually something from 3 to 5 p.c. If he dies before he becomes entitled to a pension, his relatives, in most cases, receive the amount he has paid in to the fund. In some schemes the firm pays a sum equal to the total contributions of the employees; in others it makes itself responsible for the whole, except that part paid by the employee.

The amount given as pension varies, depending upon the salary received and the length of service. In the civil service the maximum pension is one-half the salary for 40 years' service. In addition, however, a substantial sum is given to the retiring civil servant in the form of a gratuity. The pension is calculated, moreover, on the salary received at the time of retirement, i.e. when it is highest. Other pensions are usually calculated according to the length of service with a maximum of two-thirds of the annual salary. Some pension schemes, but not all, provide pensions for the widows of employees. These may be as much as one-third of the salary.

State Schemes. In the United Kingdom of Great Britain and Northern Ireland, and also in other parts of the British Empire, there are state schemes for providing pensions. One of these is the non-contributory scheme for old-age pensions, which, at the rate of 10s. a week, are paid to all persons whose means are below a certain figure on reaching the age of 70. The other scheme provides pensions at the age of 65 for persons who are insured under the national health insurance scheme. These are contributory, combined weekly payments being made for health and pension.

Persons who do not come within these schemes may become special voluntary contributors if their income does not exceed £400 a year (women £250). Persons under 55 on January 3rd, 1938, may enter before January 3rd, 1939, but after that time no one may enter after the age of 40. Firms wishing to establish a pension scheme should consult an actuary, as only an expert who is acquainted with the conditions of the business in question can estimate its cost. For purposes of income tax pensions are treated as earned income. *See* Annuity; Income Tax; Insurance; Old Age Pensions.

PENTSTEMON. This is an invaluable hardy or half-hardy plant suitable for the rock garden and flower beds and borders. The florists' varieties of pentstemon are popular late summer flowers: new ones are raised annually and the size and colouring of the blooms have been greatly improved: they vary from white through pink to scarlet and through rose to carmine and purple. The plants are about 2 ft. high and are very showy from July onwards. Catalogues give long lists of named varieties. The small-flowered section of pentstemon has become popular in recent years. The plants are of slender, graceful growth about 18 in. high and bloom freely; a few of the best are Newbury Gem, Southgate Gem and Myddleton Gem.

The usual method of propagating the named varieties of pentstemon is by cuttings of flowerless shoots inserted in a bed of sandy soil in a cold frame in September; if the frame is kept closed for a few weeks they will soon form roots. The plants may remain undisturbed until April or early May, when they are planted out of doors. A better plan is to pot them singly in 3 in. pots in spring. Pentstemons can be raised from seeds, and those who do not wish to possess certain named varieties will find this method satisfactory if seeds of a good strain are obtained. From seeds sown in a heated glasshouse in January or February the plants will bloom the same year. A summer sowing in a garden frame will yield plants that will flower the following year. The florists' varieties of pentstemon are not thoroughly hardy, therefore annual propagation is advisable. Plants in warm, sheltered places may live through the winter; if they do they ought to be pruned in spring.

The Pentstemon, a showy plant for the garden border.

Among the species of wild types of pentstemon there are several beautiful flowers. The loveliest of all is the blue heterophyllus, which needs well-drained soil and is suitable for the rock garden. Barbatus, 3 ft., is a good border plant which bears red flowers in late summer.

PEONY. There are two kinds of peony, one a hardy herbaceous perennial, the other a shrub commonly called tree peony. The former is of chief value in British gardens. There are innumerable varieties with single or double flowers in many charming colours, and well-established plants provide a brilliant display of bloom in May and June. These plants thrive best in deeply cultivated soil which has been enriched with decayed manure; they must be watered freely in dry weather, and an annual mulch or soil covering of manure in spring is beneficial. The best time to plant is in September-October. Peonies are often slow in becoming established; they should therefore be left

undisturbed as long as they continue to flourish. When after some years they become overcrowded the roots should be lifted, separated into pieces in early autumn, and replanted.

Peony: two beautiful varieties. Left, flower of the fragrant white herbaceous albiflora; right, rose-shaped flower of a variety of tree peony.

Peony Culture. 1. Good soil preparation. 2. First year: planting with lilies between. 3. Second year: middle plant removed; tulips and lilies between. 4. How to lift a plant. 5. How to divide. 6. Planting in grass: a, rich compost. 7. How to mulch a peony plant.

The old crimson peony, *officinalis*, which has reddish shoots in spring and bears large, handsome blooms, and the white *albiflora* are still deservedly popular and should be included in every collection. Growers' catalogues list a large number of varieties which have been raised by cross-breeding.

The tree peony, *Paeonia moutan*, from Japan, and its varieties (which bear chiefly Japanese names) are shrubs several feet in height, which bear large, handsome blooms in early summer. Although these shrubs are hardy they start growing early in the spring, and must therefore have a sheltered situation, preferably one facing south or west. They flourish best in loamy soil. *Paeonia lutea* is a tree peony from China, and cross-breeding between this and the Japanese tree peony has produced new varieties. Pron. Pee-on-e.

PEONIES: COLOUR AND FORM FOR GARDEN DECORATION

*One of the showiest and most satisfactory of summer flowers.
Instructions for the culture of these and other varieties are given in page 550.
(Courtesy of Kelway & Son, Langport)*

PEPPER: The Plant. The pepper plant belongs to a family of hothouse and greenhouse shrubs of the genus *Piper*. In Great Britain they are cultivated chiefly for their foliage. They require stove culture in a mixture of loam, leaf-mould and sand, and need a temperature varying from 60° to 80°, according to the period of the year. Propagation is by cuttings in springtime. The flowers are insignificant.

PEPPER: The Condiment. Both the white and black pepper are obtained from the seed of the E. Indian pepper plant. The white variety, which is less pungent than the other, and is produced by allowing the berries to ripen more fully, is used as a condiment for the table, but the black gives the best results in cookery.

Cayenne and Other Peppers. Cayenne pepper is employed in sauces and for seasoning white made dishes; it is also served as a table condiment. It is obtained from the chilli or capsicum, and the preparation may be undertaken at home. Open the pods, remove the seeds, and pound them in a mortar with $\frac{1}{4}$ of their weight in salt. Sometimes a small portion of wheaten flour is added. Dry the pulp thus obtained, pass it through a sieve, and preserve in bottles corked tightly. About 50 chillies are needed to make 1 oz. cayenne pepper. Nepaul-krona, and coralline are other varieties of red pepper. Long pepper is imported from India, and Neilgherry pepper is prepared from a yellow variety grown in the Neilgherry hills. It is usually mixed with cumin and other aromatic spices. Mignonette pepper is a coarse-ground rather whitish variety, mild in character.

Pepper Grinder in painted porcelain and silver. The peppercorns are inserted in a semicircular groove at the top, and ground pepper is sprinkled from the base.

Medical Uses. Pepper has various uses in medicine, either as a counter-irritant, a stimulant, or to prevent flatulence, but must be taken in small quantities, otherwise it will set up irritation of the stomach and other organs. It may be used instead of a mustard plaster by steeping black pepper in alcohol, then spreading it on brown paper, covering with muslin and applying it to the skin for a few minutes.

Where a stimulant is urgently needed, and no brandy, sal volatile, etc., is at hand, pepper will supply the want. Give about 15 gr. of ground black pepper in milk; it will act as a powerful restorative.

Peppercorn. This is the seed of the pepper plant before being ground, and it is valuable for the adequate seasoning of stock and stews. In order to distinguish the quality, observe that the seeds or corns are not broken. They should be whole, firm, and clean-looking. (See Allspice; Capsicum; Chilli).

Pepper Pots. Pepper pots, or castors, are made of various materials. Cut glass ones, with silver tops, are found in condiment sets, and there are aluminium ones for kitchen use. They are also made in earthenware, generally as part of a set. For the dining room pepper pots are made of silver. Sheffield plate, and electro-plate, and are usually bought in pairs to match salt cellars and mustard pots.

Pepper pots of silver were first produced about 1700. They were cylindrical in shape, with a curved or domed top, which was perforated. Later the vase design was used for them, and, known as

castors, they were made to form part of a set of three, two being for pepper and one for sugar. Pots in Sheffield plate were at first made on the same lines as those in silver, but afterwards other features were introduced. Some of the pieces were pierced, and, like the salt cellars, were fitted with glass liners. Bead edging is found on many of the antique pepper pots, which are sometimes called dredgers or muffineers. See Muffineer; Sheffield Plate; Silver, Table Laying.

PEPPERMINT. This hardy perennial herb may be grown in any rich, moist soil, and is well suited for the rock garden, or in rockwork by the side of a sunken walk. The flowers and young foliage should be gathered for the purpose of distillation. Peppermint should be freely and constantly watered in dry weather.

Essence of Peppermint. Extract of peppermint is used for flavouring certain kinds of sweetmeats and digestive lozenges, while the essence is made into cordials. A favourite dessert sweet consists of mild peppermint creams made with fondant and coated with unsweetened chocolate.

Medical Uses. The fragrance and stimulating properties of peppermint are due to an essential oil which gives it a value as a medicine in digestive troubles. It is given to infants in the form of peppermint water in doses of 1 teaspoonful several times a day. One or 2 drops of oil of peppermint on a lump of sugar will generally give relief in cases of flatulence.

Indigestion can frequently be relieved by taking a strong peppermint lozenge after a meal. These lozenges can be obtained in a variety of different degrees of strength, suited to all tastes; but when required medicinally the extra-strong ones should be used. For these purposes peppermint is usefully combined with bicarbonate of soda, as in soda-mint tablets. There is also a spirit of peppermint, the dose of which is 5 to 20 minims.

Peppermint Cordial. In order to make peppermint cordial, simmer 1 lb. loaf sugar with 1 pint boiling water for 10 min. One tablespoonful honey should then be added, and when the mixture is nearly cold 30 drops essence of peppermint. It should then be bottled.

Peppermint Cream. *See Sweets.*

PEPPER'S GHOST. The illusion which is known as Pepper's ghost is quite easy to produce. Take a large piece of transparent glass and incline it on a stage at an angle of 45°. The person to be reflected must stand in a hole or pit below this glass, with a strong light falling on him, but so that he cannot be seen by those who are watching the performance. His image, however, will be clearly reflected from the glass, and he appears to be behind it, thus producing the striking illusion of a ghost. *See Children's Party: Stage.*

PEPPER SPICE. A spice which may be used to flavour stuffing, galantine, etc. can be made from 3 tablespoonfuls each dried bay leaves and dried thyme, 2 tablespoonfuls each dried marjoram and rosemary, 1½ tablespoonfuls each grated nutmeg, powdered mace, and black pepper, and 1 teaspoonful cayenne. Stalk the herbs, then pound them, with the spice and peppers, to a fine powder. Rub the whole through a fine sieve, then put it into dry, well-corked bottles.

PERAMBULATORS AND PUSH CARS

Up-to-date Types and Some Notes on Repairing

Reference should also be made to the articles Baby, Nursery; and others dealing with child life. See also Ball Bearings; Lubrication; Tire.

The shape and design of baby carriages have changed of late years, the older high-built type of pram having been superseded by cars having a much lower built body and smaller wheels. The deep, low-built body affords the infant more protection from draughts, and keeps the weight low down and minimises the risk of over-balancing.

The chief requirements for a baby carriage are safety, comfort, and strength. It is essential that the carriage should be well sprung. The coach itself is often suspended by leather straps, thus preventing any vibration and shock to the baby.

The wheels should be fitted with rustless hubs, and when price is not the first consideration, with ball bearings. The latter make the running of the machine much easier and less lubrication is required. Thick wired-on tires should be chosen.

The bodies are now often made of pressed steel, the beading or other ornamentation being integral with the material, and not applied thereto as in the case of wood perambulators. The surface is finished with nitro-cellulose enamel. These prams are easily cleaned, and the surface is not liable to chip. All the bright parts of the chassis can be protected from rust by chromium plating, which is standard on all good prams.

Perambulator: Figs. 1 and 2. Two models, both of which have deep, low-built, steel bodies, and wheels with ball bearings and rustless spokes and hubs. The car on the left is fitted with mudguards and a foot brake.

(Courtesy of Dunkley Safety Prams and of Lines Bros., Ltd.)

Instead of the ordinary waist strap, a patent safety strap is better; this costs only a trifle more and makes it impossible for the child to fall out of the pram. It is important that the hood and apron are efficient, fit well, and are stormproof. Extra fittings are mudguards to fit over the back wheels, a chain brake for attaching to the rim of the wheel when the car is left standing, and a holder for an umbrella. The brake should be procured, as it is not safe to leave the pram standing without one.

Even on almost level ground, baby can rock or shake the car and so cause it to start in motion, while on an incline the employment of a brake is imperative if accidents are to be avoided.

The question of size is important in small houses, flats, and in the type of house where the hall consists of a narrow passage. The storage space must be considered, and the overall length and width should be measured, as in some models the handles extend 1 ft. to 1½ ft. beyond the carriage body. Folding handles can be had on some models, the levers being hinged so as to fold across the top or down against the body.

For two children a well-proportioned double carriage can be obtained. It is wider in the bed, a little longer, and has two hoods, and a special-shaped apron to protect the inmates from rain.

Folding Baby Carriages. In some circumstances it may be difficult to house an ordinary pram, and one of the folding variety must be procured. Great care should be exercised in its selection, and the purchaser should not be induced to buy one of the ordinary low-built folding push cars. This type of car, though it may have an extension and provide a suitable bed length, has not the comfort necessary for a baby's first carriage, and serious curvature of the spine may result from their use in the upright position in the case of infants. For an older child the push car has its uses, as it is portable and can be taken away on holidays. It is employed normally in the erect position, with the child sitting up, and can be arranged at will to allow the occupant to rest in a reclining posture. Good examples of both types of car are illustrated.

Perambulator. Left. Fig. 3. Baby carriage with folding movement.

Care and Repair. Perambulators wear well and last a long time if care is taken of them. The hubs should be oiled regularly, and the carriage dusted inside and out whenever necessary. Mud that has been allowed to dry should not be scraped off, as this damages and scratches the enamel, but should be washed off, using an old sponge or flannel, then dried with a cloth. On no account dry a pram, hood, or apron in front of the fire; the rain should be wiped off with a cloth and the pram allowed to dry slowly, as heat perishes rubber cloth and spoils painted surfaces.

Beeswax dissolved in turpentine or any good wax polish can be applied to keep the pram in good condition. It produces a brilliant polish, feeds the wood and protects the steel part from rusting and the leather cloth from cracking.

The points that most usually call for attention are the tires, hubs, and hood. Pneumatic tires may be treated in the same way as cycle tires; when the ordinary solid tire breaks or wears it must be replaced by a new one. To do this, the first step is to remove the old tire. Sometimes tires are secured by cement, and in such cases will have to be warmed. For this purpose the wheel should be taken off from the pram, the dust cap on the end of the axle being first removed by means of a spanner; when it has been taken off it reveals the end of the axle.

In many prams the wheel is held on by a split pin and a washer known as a D washer; it has a flat part formed on it which engages on a flat on the axle, the purpose being to prevent the washer rotating. The split pin is removed by pinching the two ends together with pliers and bending them until they are in line with the hole, then gently pressing the pin out through the hole in the axle. The

D washer is drawn off and the wheel removed. Wheels with ball bearings may be dealt with in the same way as described for bicycle wheels.

In cases where the tire has been fitted with tire cement the rim of the wheel may be slightly warmed and the tire prized off with a strong screwdriver or tire lever. There are now two courses open, at least with many sizes of pram tire. Either a complete new tire can be purchased of the correct size, ready to be sprung on to the rim of the wheel, or a sufficient length of pram tiring with a coiled wire embedded in the interior can be purchased. The former course is only suitable for small-diameter wheels.

As a general rule this class of tire is fitted by warming the rim of the wheel, laying a little tire cement in the bottom of the rim, immediately inserting the tire in place and springing it over the rim. In the case of the continuous tiring, the first step is to measure the length needed. This is done by coiling the tire round the rim and cutting it off about $1\frac{1}{2}$ to 2 in. shorter than the length round the rim, the amount varying with the diameter of the wheel and that of the tire. The next step is to saw the tire asunder with a hacksaw, supporting the tiring in one side of the vice and manipulating the hack-saw with one hand while supporting the other end of the tiring with the other hand. Having cut it off, the ends of the wire are joined together by screwing one end into the other. To do this, it is necessary to twist up the length of tiring into three coils and place the two ends of the wire in register. On releasing the tire, it will uncoil itself, the ends will be firmly screwed into each other, and the tire will be found to be complete.

The next step is to spring the tire on to the wheel. This is best accomplished by gradually working it on with the thumbs. The fingers and the hands should grasp the rim of the wheel and the tire firmly, so that it cannot possibly slip and spring off, while the thumbs are pressed over, gradually springing the tire into position on the rim. Before replacing the wheel the bearings are overhauled, hub and wheel cleaned up, and the axle cleaned and oiled with light machine oil. After this, the D washer, split pin and dust cap are replaced.

After the pram has been in service for some time it may well receive a thorough overhaul. It should be taken to pieces, commencing at the top and removing the hood, cushions, etc., and taking off the body from the chassis. The axles, if bolted to it, can be unfastened from the framework or springs and every part dismantled. The whole should be cleaned, and the metal parts wiped over with a rag saturated in paraffin oil, which will remove the bulk of the grease, then they may be finished off with a clean rag. Leather suspension straps can receive a dressing of harness oil.

All metal parts that have been painted should be well rubbed down with coarse sandpaper and smoothed off with fine sandpaper, taking care to remove all traces of rust. They may be painted with one or other of the special cycle enamels on the market, which give an excellent result if the maker's instructions are carefully carried out. It is seldom worth while to repaint the bodywork. Many prams now have pressed steel bodies and are cellulose enamelled, a method giving a hard and durable surface. Scratched paintwork can be touched up with a paint of the appropriate colour.

The upholstery may be renovated with one of the leather revivers on the market. The axles and the underframe, or chassis, should then be put together, the wheels refixed, and the straps fixed in their positions. To refix the body will necessitate an assistant, one to hold up the body while the other fastens the straps to the hangers. The lining of the hood may require renewing, and to do this the old lining may be used as a pattern by which to prepare the new one.

Repairs to a Folding Perambulator

Folding cars call for somewhat different treatment, as their construction is not the same as that of the ordinary type of pram. The folding car is largely constructed of strips of metal joined by rivets. The wheels can be removed and re-tired in the same manner as already described. Sometimes the rivets wear and get slack, and the frame may not fold up properly. To remedy this, the rivet should

be removed by filing off the shank where it has been burred over and carefully punching it out. Obtain a new one of requisite size, place it in position and rivet it up, holding a heavy hammer against the head and riveting with a light ball peine or riveting hammer.

Perambulator Repairs.
Fig. 6. Replacing a solid tire: sawing off length of tiring with hack-saw. Fig. 7. Tire twisted up in coil and wire ends joined. Fig. 8. Renewing worn-out rivets of a folding perambulator; a heavy hammer is held against the head of the rivet, and the riveting is done with a ball peine hammer.

The bodywork of this class of pram is constructed chiefly with

waterproof material and suspended from wooden bars attached to the metal frame. To remove the body it is necessary to withdraw the nails and screws which secure it to these wooden bars. The front part of the body is secured by rivets to a cross-bar of metal forming part of the framework, and if this has to be removed the heads will have to be filed off and the rivets punched out. When the body has been removed it can be renovated with leather reviver, or may be re-covered with new material, using the old as a pattern. If the upholstery is sound, but the padding solidified, remove the covering, tease the flock or padding and re-cover as before. When replacing the body, be sure it is securely fixed to the wooden bars and strongly riveted at the front.

The hood is removed by unfastening the screws which secure it to the wooden bars, as generally this type of hood is made up to give a kind of parallel motion arrangement, on nickel-plated metal strips, which allows the hood to fall forward or backward as desired. When overhauling such a pram, the hood and body should be removed, all the joints well oiled and all traces of oil wiped off the exterior. The whole of the metal work should be cleaned down and re-enamelled.

PERCH: The Fish. Perch is in season from the end of May till the beginning of the following February. The fish, which varies in size from 1 lb. to 3 lb., should be cooked and eaten as soon as possible after being caught. It is difficult to scale, and sometimes the scaling is left till after it is cooked; but it is better to plunge the fish for a minute or two into boiling water and remove the scales before dressing it. The blanching will facilitate cleaning it.

Perch can be fried according to the general instructions given for frying fish.

To stew perch, prepare a large fish and stuff it with a rich veal stuffing, tying it together. Put into a stewpan 1½ pints good stock, add an onion and carrot prepared and cut small, also a bouquet garni. Lay the fish in the pan and pour over it a large wine-glassful of port. Season it and stew it in the oven for 20 min. or longer, according to the size. Dish the fish, strain the liquor, reduce it till thick and add some matelotte sauce. *See Fish; Matelotte.*

PERCOLATOR. The apparatus known as a percolator is designed to enable liquid to pass slowly through a porous material, as in a coffee-pot or a filter. In the former a perforated metal or china plate divides an upper compartment from a lower. In a filter the separator is often made of porous earthenware through which water drips from the upper vessel to the lower and is purified in the process. *See* Coffee.

PERENNIAL. In gardening a perennial is a tree, shrub or plant which persists or lives on from year to year. Herbaceous perennials are those plants of which the stems and leaves die down in autumn but the root-stock lives and produces fresh growth in spring. Familiar hardy herbaceous perennials are lupin, delphinium, peony, and phlox. Hardy shrubby perennials, i.e. trees and shrubs, are usually increased by cuttings in a frame in August or out of doors in autumn, or by layering in summer; herbaceous perennials are increased by division in autumn or spring. Perennials may also be raised from seeds.

PERESKIA. A greenhouse succulent of perennial growth, pereskia is also known as the Barbados gooseberry. Two species are cultivated in Great Britain, *aculeata* and *bleo*, and these are grown as stocks upon which to graft the epiphyllum or leaf-flowering cactus.

Perfume. *See* Scent.

PERGOLAS: IN WOOD AND BRICKWORK

The Construction of a Decorative Garden Feature

Gardening is represented by a great variety of articles. These, in addition to those on the flowers and plants, will be found under such headings as Arch; Rustic Work; Trellis. *See* also Flower Garden; Garden; Path; Rambler, etc.

A charming addition to any garden is a pergola. It is not only an admirable device for displaying the colours of flowering climbers, but is a means of providing a shady walk, as it is essentially intended for spanning a straight walk or path. In its simplest form the pergola is a skeleton structure, made up from prepared or rough timber, composed of uprights, spaced about 6 ft. to 8 ft. apart, connected together by longitudinal members, and cross-bars spanning the path. These should be at least 7 ft., and preferably 8 ft., in height, so that when they are covered with climbing plants there will be still sufficient room to walk beneath them.

Oak is one of the best materials, but any durable wood may be used. Larch and chestnut are suitable.

Some excellent effects are obtained by the use of rough hewn timber, especially oak, which may be worked somewhat on the lines indicated in Fig. 1. The bases of the posts should be charred or creosoted to preserve them from decay; they will last indefinitely if embedded in concrete. The posts may be about 4 in. square, connected together by horizontal members about 2 ft. 6 in. from the ground, and roughly mortised and tenoned and pegged together. The other longitudinal members are similarly mortised and tenoned and notched to receive the cross-pieces. They are further notched on their upper side to receive the lighter timbers, which are set on edge in the notches and laid longitudinally. Another method is to use rough poles, such as larch, and simply build up the structure by nailing suitable longitudinal, and cross members to the uprights. This can be done with stout 4 in. wire nails.

Pergola. Fig. 1. Good effect obtained by the use of rough-hewn oak, the uprights and rails being mortised and tenoned to each other.

A pergola nearly always spans one of the principal paths, the ground being marked out with lines, as in setting out the foundations of a building.

Pegs are placed on every spot where an upright is to be fixed, and the lines removed. If the poles are of any size, the holes should be dug to a depth of about 2 ft., according to the nature of the soil, and the first post set up in position, plumbing it to ensure its being upright. The earth is then filled in the hole around the butt of the post, and well rammed and consolidated. The butts could be concreted in if desired.

Pergola. Fig. 2. Permanent structure made with pillars of brickwork and an open roof of timber, stained to a dark colour, over which roses, clematis, etc., will climb.

The next to erect is that on the opposite side of the path, adjacent to the first; that is, assuming that the pergola is to be straight, otherwise the procedure will be slightly varied. This is set up in a similar manner, and then the two posts at the opposite ends of the pergola are similarly erected and plumbed. The height for the posts is then determined, a batten being tacked across them at the required height and tested for level, after which the tops are sawn off flush with the batten.

The other posts are erected in a similar manner, and as the first and last posts in the line have already been plumbed and levelled, all that is necessary is to stretch a line tightly between the two end posts, and adjust the remaining posts accordingly.

Having fixed all the uprights, the next step is to fix the lower horizontal members, nailing these firmly to the uprights, as if this is done securely planks can be laid across them from side to side, to facilitate the fixing of the upper members, which may then be nailed in position. During the progress of the work the posts should be sighted from end to end by looking along them to see if

any of them are displaced when the error will be immediately perceived and corrected. Hence when the horizontal and longitudinal members are fixed, and the cross members nailed into position, there will be little fear of the pergola going out of shape.

Should the ground undulate, the top of the pergola may either be made level or can follow the curvature of the earth. In the former the post of the lowest point of the pergola should be the first to be erected. When a pergola is to be erected over a curving path, regular spacing is determined by the use of two batons, one the length of the space between the poles, and the other the width between them.

Pergola. Fig. 3. Charming arrangement at the entrance to a rose garden. The wooden uprights are connected by wires along which are trained single and double varieties of climbing roses.

A permanent structure can be made with pillars of brickwork as in Fig. 2, and is often of architectural value to connect the house with some special feature of the garden.

The brick pillars should be set up on a concrete foundation. Gaps should be left in the brickwork for the reception of the horizontal members, which are slipped into place, or built in while the brickwork proceeds. The work is completed by an open roof of timber, which may be stained to a dark colour.

After a pergola has been erected it is a very difficult matter to paint or colour it at any subsequent time, as all the climbers will have to be removed, and re-trained after the paint is dry. Consequently it is most economical to use a naturally durable material such as oak or brick, and to treat the less durable material with generous coats of wood preservative before attempting to train the plants around them.

PERIDOT. This deep yellowish-green stone is a species of olivine and is the month stone for September. It can be set in gold or dull silver, and harmonizes well with pink or white topaz, but needs diamonds to display its beauty to the best advantage.

PERILLA. The half-hardy annual perilla, which comes from China and has purplish ornamental foliage, is often used for summer bedding. It may be raised from seed sown in heat during March, the seedlings being transplanted and hardened off for planting out in June.

PERISTERIA. This stove evergreen orchid, *Peristeria elata*, is sometimes known as the dove flower; the fragrant blooms, white marked with purple, appear in summer. It is best grown in well-drained pots or teak baskets, and needs little water during the resting period. *See* Orchid.

PERITONITIS. Inflammation of the peritoneum, the serous membrane which lines the abdominal cavity and surrounds the greater parts of the contents, is called peritonitis. This lining membrane is liable to infection from perforating ulcers and abscesses of the stomach and other abdominal organs; also infection may result through penetrating wounds, and other causes.

An acute attack generally begins with chilly sensations or violent shivering. The temperature rises quickly, and there is frequently an intense sickening pain in the abdomen. Any movement increases the pain, so that the patient is even afraid to talk, breathe, or cough, and lies on his back with the legs drawn up and likes to have the shoulders raised to relax the abdominal muscles. The pulse rises to 120 beats or more per minute. Vomiting sometimes begins early, and causes great agony. Great distension by gases occurs. Constipation comes on quickly.

To give the patient any chance of recovery an immediate operation is necessary. In the meantime, to relieve pain, apply hot linseed meal poultices every 2 hours, covering them with cotton wool or flannels wrung out of hot water and frequently renewed.

PERIWINKLE: The Plant. This name is popularly given to the *Vinca*, a small family of hardy herbaceous perennial plants. They like a shady position and may be planted at any time between autumn and spring. The flowers are blue or white, and propagation is by division of the roots in springtime. The common kinds are major, 20 in. high, and minor, 6 in. or so high. Both are suitable for planting beneath trees. There is a variety with green and white leaves. *Vinca rosea*, a tropical plant, is suitable only for cultivation under glass.

Periwinkle. Star-like blue flowers of the low-growing glossy-leaved shrub that loves the shade.

PERMANGANATE OF POTASH. This salt occurs in dark purple crystals, which give a deep violet-red colour to water in solution. Permanganate of potash is a very efficient antiseptic, disinfectant, and deodorizer, removing offensive smells and killing harmful bacteria.

The best way to keep it is in solution in distilled water, dissolving 1 oz. in a pint of water. For use this must be further diluted as follows: As a gargle, 1 oz. of the strong solution to a pint of water. As a wash for ulcers and wounds, 2 or 2½ oz. to a pint of water.

Discoloration of the hands or linen caused by potassium permanganate may be removed by a solution of oxalic acid. It may be used as an application for insect bites and stings, and the crystals are rubbed into incisions made over snake bites.

In offensive sweating of the feet a weak solution should be used as a footbath once a day or oftener.

PERNETTYA. This beautiful low growing hardy evergreen shrub, 12-30 in. high, is valued for the sake of its large, brightly coloured berries in autumn and early winter. The white flowers are borne in May. The species in cultivation is *Pernettya mucronata*, and there are many varieties with berries of various colours—crimson, rose, mauve and purple, as well as white. These shrubs like peat soil,

but will thrive in loam that is free from lime; they must be kept moist in dry weather. Propagation is by division in autumn or by cuttings and layers in July-August.

PERNICIOUS ANAEMIA. A very severe form of anaemia, which nearly always ends in death within 3 to 12 months, is termed pernicious anaemia. The disease is most common in people of middle age, and appears to be associated with poisoning from septic stumps or other septic foci about the body. The pallor of the skin has a lemon-yellow tint. *See Anaemia.*

PEROWSKIA. This handsome shrubby hardy perennial is strongly scented with the perfume of the common sage. Its erect stems, bearing large terminal panicles of violet-blue flowers upon silver-grey growth, are most attractive during September. There are four species, the chief being *P. atriplicifolia*, 4 ft. high, which must be planted in a well-drained position where it can get full sunshine. It is best propagated by cuttings planted in light soil, under a handlight, during early summer.

PEROXIDE OF HYDROGEN. When diluted with an equal quantity of water, peroxide of hydrogen may be used as a lotion for wounds and ulcers of all sorts. A teaspoonful made up to two tablespoonfuls with water makes a useful mouth wash or gargle for septic conditions in the mouth or throat; and the same may be used for cleansing the nose or ear.

Hydrogen peroxide is a good application for insect bites and stings. A teaspoonful added to the water used for cleaning the teeth not only helps to preserve their whiteness, but also prevents pyorrhoea. Teeth discoloured through smoking should be rubbed with a piece of cotton wool dipped in undiluted peroxide. It bleaches the hair to a yellow colour, and is frequently used for this purpose. In the case of dark-haired people bleaching will diminish the disfigurement of superfluous hairs on the face. In speaking of hydrogen peroxide the B.P. 10 volume solution is usually meant.

PERRIER WATER. The natural mineral water known as Perrier water is derived from a spring at the village of Vergese, near Nismes, in France. It contains a small quantity of alkaline carbonates and is an excellent table water. *See Mineral Water.*

PERRON. This is a term applied to almost any type of external staircase leading to a house, but it is generally presumed that the entrance door is above ground level.

PERRY. Perry is the fermented juice of the pear, just as cider is the fermented juice of the apple; the difference between them is slight, but perry as a rule is lighter in colour. It does not taste strongly of the pear; on the contrary, a thoroughly fermented pear-juice made from a vintage pear may give a liquor that is indistinguishable from a good dry cider. The pear required for perry making is a hard astringent fruit, that good for eating being unsuitable for perry. When gathered, the fruit should be sufficiently mature and should not be stored for longer than a fortnight before use.

Perry is made in the same way as cider. It ferments better if a proportion, say 20 per cent, of bitter-sweet apples, or even crab-apples, is included among the pears at the time of crushing. *See Cider; Pear.*

PERSIAN CARPET. Persian carpets and rugs normally have cotton warps and wefts. In some classes the design, made of dyed or undyed yarns, is always fastened to the warp with Sehna or Persian knot, in which the yarn is passed under the first warp thread and over it and under the next before reappearing between them. The Ghiordes or Turkish knot, found in all Anatolians and Caucasians, whose warps and wefts are wool., as well as in some Persians and Turcomans, lays the

yarn over two warp threads, passes it under both, and then brings both ends through between them. The pile or nap is afterwards produced by severing the loops of the knots.

The Sehna knot may be right-handed or left-handed, so that the nap points either to the right or to the left top corner. With the symmetrigoal Ghiordes knot the nap always runs in a forward direction. The lustrous sheen possessed by all Persian carpets and rugs is due to the wool being washed in soft running water, leaving the natural grease unaffected. Their durability is aided by their harmless vegetable dyes. Silk is seldom used, except in some uncommon classes, notably the Kashans, not to speak of the modern commercial reproductions done in inferior dyes at Kaisariyeh. Undyed camel hair sometimes appears in field or border in Hamadan rugs, but a good deal of so-called camel is goat. The gravest defect in modern fabrics is the substitution of the old vegetable dyes by aniline products, which perish the yarns and cannot be mellowed. It is now the custom in the carpet trade to describe most Oriental carpets as Persian no matter from whence they come.

Tabriz rugs almost always have florid medallion centres filling the whole field. This style they share with Kirmans, whose dyes are always good; but Kirman designs made at Tabriz to dealers' orders are not always guiltless of aniline. Medallions, with or without corner-pieces, also characterize the Ghorevan fabrics, which are almost always in carpet sizes only. Pole-medallions, which run in a series with the axes projecting, are a great feature of the Hamadan and Shiraz looms. Birds and animals, diagonal stripes, and other motives are also common Shiraz styles.

Very attractive is a diaper pattern of small repeated objects, carried out in restrained and yet gleaming tones. This is much favoured for small rooms, because it does not dwarf their dimensions, and harmonizes with neutral furnishings and wall-hangings. Of these the most famous are the Feraghans, which are highly esteemed in the East when made with the Herat design, a rosette between two lanceshaped, fish-like leaves. The field may be dark blue or rose-red and ivory, with ivory and greenish border tones; if there is much yellow, and the Ghiordes knot is present, it should be noted that the piece cannot possibly be antique. Saraband is usually diapered with the pear or cone design, arranged with the stems in opposite directions; in the style of Khorasan and Herat the pears all face the same way. The most charming of Sarabands have borders of small conventionalized flowers linked up by a trailing vine, notably rich rose or blue pieces with ivory borders.

Some classes have fields of large floral designs without any medallion suggestion, especially in the extensive output of the Sultanabad district. From here come showy carpets with florid borders of a type much affected for Axminster squares. The mechanical symmetry of these reproductions lacks the appeal of the unspoiled native craftsmanship. Other better Persian designs are copied freely in the British factories, and such carpets, whether Wilton or Axminster, are a good choice for dining room or living-room. *See* Carpet; Dining Room; Rug.

Persian Cat. *See* Cat.

PERSIAN CYCLAMEN. This is the popular name for *Cyclamen persicum*, an attractive winter- and spring-flowering plant for the amateur's greenhouse. Some varieties of this cyclamen have prettily fringed petals, whilst others bear quaint butterfly-like flowers. *See* Cyclamen.

PERSIAN LAMB. A fur often confused with astrakhan, which it somewhat resembles, Persian lamb is a curly black skin of remarkable softness and durability. Rain does not affect it, and therefore, unlike most furs, it may be worn with safety in wet weather. Its natural colour is a rusty black, but it is dyed to a much deeper shade.

PERSIAN LILAC. This is the popular name of *Syringa persica*, a graceful hardy shrub. It grows to a height of 4 ft., and bears lilac-coloured fragrant blooms in May.

PERSIMMON. Of the several kinds of persimmon the best known is *Diospyros kaki*. This is a small leaf-losing tree which, if grown in large pots in a sunny, airy greenhouse, will yield its orange-yellow, plum-like fruits. In mild districts it may be grown on a sunny wall out of doors.

PERSPIRATION. The sweat glands, the essential purpose of which is to extract water from the blood and pour it out on the surface of the skin, are scattered all over the body. They are especially numerous on the soles of the feet and the palms of the hands. Perspiration, although we are insensible of it, is continually flowing. The average amount of perspiration, sensible and insensible, in the 24 hours is about 2 lb., but exercise or heat increases the amount to an enormous extent.

The chief function of perspiration is to regulate the heat of the body. People who do not sweat easily are very liable to heat stroke if they find themselves under conditions which provoke this. Perspiration, therefore, fulfils an exceedingly important function, and care should be taken, by keeping the skin clean, to give it free exit.

Excessive perspiration chiefly affects the armpits, groin, and feet, and is sometimes associated with an offensive odour. The parts should be washed once a day at least with cold water and soap, dried thoroughly, and powdered freely with boric acid. In the case of the feet the powder should go well in between the toes, and the inside of the socks should also be powdered. Shoes should be worn for the sake of coolness. The following powder could be used instead: Salicylic acid 15 gr., powder starch 50 gr., powdered talc to 1 oz. For the armpits the following powder may be dusted on several times a day after washing the parts and drying them thoroughly:

Oil of rose geranium	6 minims
Salicylic acid	1 dram
Zinc oleate powder	3 oz.
Powdered starch	3 „

For the feet these lotions are useful, applied daily: 1 oz. formalin in 2 pints water, or water coloured red with permanganate of potash, or a 2 per cent ointment of salicylic acid in vaseline may be used. Those who perspire freely should always wear woollen underclothing.

Perspiration stains on clothes should be treated promptly with fresh lemon juice and then washed in warm soapy water. If this treatment is not successful at first it may be repeated, but the lemon juice should not be allowed to remain on for more than a few minutes, otherwise it may itself injure the colour of the material.

PERUVIAN BALSAM. Known sometimes as balsam of Peru, this is the exudation from the trunk of a Central American tree. Externally, it acts as a disinfectant and as a stimulant when applied to a raw surface. Its chief use externally is as a parasiticide in the treatment of scabies, nits in the hair, etc. It exerts a stimulant and antiseptic action on the lining of the bronchial tubes, and is therefore often included in expectorant mixtures in the treatment of chronic bronchitis.

When poured upon a fresh wound and covered with a bandage, Peruvian balsam has a healing and antiseptic action, and the balsam need not be changed for many days.

PERUVIAN LILY. This is the popular name of *Alstroemeria*, hardy tuberous-rooted plants which grow from one to three feet high and bear showy, amaryllis-like flowers in summer. In some gardens, especially those having well-drained soil, they give no trouble, and in fact sometimes

become rather a nuisance by spreading rapidly. In others where the soil is clayey it must be made suitable by adding leaf-mould and sand very freely. The Peruvian lilies need a sunny place and appreciate such shelter as is provided by a wall or fence. The roots should be planted 5 in. or 6 in. deep in spring. Some of the best kinds are aurantiaca, orange flushed with red, chilensis and its varieties in many rich colours, and the lighter shades of pink and orange. Propagation is effected by lifting and dividing the roots in spring or by sowing seeds under glass in early spring.

Peruvian Lily. Bulbous plant of vivid hue well suited for growing in a sunny border or rockery. (Courtesy of Amateur Gardening)

PETASITES. The winter heliotrope (petasites fragrans) is useful for planting in the wild garden or woodland for the sake of its white fragrant flowers, which open in February, when few other plants are in bloom. It grows 12 in. or so high and spreads so rapidly as to become a nuisance in small gardens.

Peter's Pence. In certain localities this name is given to the honesty (q.v.).

PETROIL. This is the name given to a system of lubrication in internal combustion engines in which the lubricating oil is mixed with the petrol in the main tank of the machine. *See* Internal Combustion Engine; Lubrication.

PETROL, or Gasoline. These names are used for the lighter distillates obtained from crude oil. Petrol is highly inflammable, and its vapour, when mixed with air, is explosive. Regulations require petrol for motor vehicles to be kept in metal vessels. Not more than 60 gallons (inclusive of the petrol in the tank of any motor vehicle) may be kept in one storage place.

Petrol must not be kept in vessels of over 2 gallons capacity (other than the tank of a motor vehicle), unless the storage place is more than 20 ft. from any building or public footpath, and notice is given to the local authority. If the storage place is within 20 ft. of any building, stack of timber or other inflammable substance, no petrol may be kept except in the tank of the vehicle and in not more than two 2 gallon cans carried on the vehicle unless notice is given.

Petrol must not be used near fire or a naked light nor in any storage place except as fuel for a motor vehicle, or in quantities not over one gill for cleaning or repairing. Petrol must never be poured down a drain. The filling up of the petrol tank should never be done in the presence of a naked light. An electric light or some form of safety lamp only should be used. One or two pails full of sand should be kept handy in case of fire, or a better plan would be to install one of the chemical fire extinguishers. Small fires can usually be smothered with a damp cloth or sacking.

Water should not be used if petrol takes fire, as the petrol will float on top and thus be distributed over the floor of the building.

A point to remember is that insurance companies will not accept liability should it be proved that even as little as one tin of petrol is kept on the premises in which the car is garaged, unless the amount and method of storage are stated at the time the policy is effected. This does not apply to petrol in the tank of the car or motor cycle at the time.

Cleaning Uses. As a cleaning agent for clothes, petrol has few equals. Serge, silk, satin, felt, and velour garments of all kinds, provided that they are not of too light a colour, can be cleaned with it. It should be noted that the petrol vapour may travel a considerable distance and be ignited by a fire or lamp. Many fatalities have been caused thus.

This work is best done in daylight, out of doors, and the petrol in any case must be kept a safe distance away from a fire or naked light. See Dry Cleaning.

Petroleum. See Paraffin.

Petrol Gas. See Air Gas.

PETSAI. The Chinese cabbage or petsai resembles a cos lettuce in appearance with pale green leaves and thick midribs. The former are eaten like kale, and the latter, with sauce, like seakale. Seed may be obtained from specialist seedsmen, and is best sown during July. *See Seakale.*

Petunia. Favourite greenhouse plant bearing flowers ranging from pink to crimson and purple.

PETUNIA. This half-hardy flowering plant is suitable for cultivation in the greenhouse and for planting in flower beds out of doors in summer. Though they are perennials and can be increased by cuttings under glass in spring, if it is wished to perpetuate named or special varieties, it is usual nowadays to treat them as half-hardy annuals and raise them every year from seeds sown in a heated glasshouse in February. Those which bear double flowers must be propagated by cuttings: these are more suitable for cultivation in pots under glass than out of doors. A compost of loam, leaf-mould, decayed manure and sand will ensure fine plants.

PEWTER: The Metal. A silvery-grey metal, very soft and ductile, pewter is composed of a similar group of metals to those known as Britannia metals, or alloys which contain a large amount of tin. Pewter is used in the form of sheet, and can be cast in a ladle or in a simple furnace. In some typical compositions of pewter the percentages of the metals are as follows:

Tin	Antimony	Copper	Zinc	Lead
91·5	6	1	-	1·5
88	8	2	-	2
88·5	7	2·5	3·5	1·5

If bismuth is added to the extent of 5 per cent the melting-point of the alloy is lowered. Copper and antimony both tend to harden the alloy. With lead there is the danger of lead poisoning. Pewter melts at about 400° F, a temperature only one third that necessary to melt aluminium or brass; it can, therefore, be fused in a ladle over a gas-ring or fire. Articles to be made in pewter in the form of castings are first modelled or a pattern made, and the mould is prepared with moulding sand or

plaster of Paris. The latter must be well dried before the metal is poured. The casting is finished by polishing in the lathe.

Left. Pewter. Fig. 1. Bavian spout pot, dating from 1740-50.

Right. Pewter. Fig. 2. Pair of Flemish candlesticks, 36 in. high, c. 1740.

Below. Pewter for the Collector. Fig. 3. Left to right: French lidded measure, c. 1690-1710; English porringer of Charles II period; Scottish tappit hen, 1750; English bleeding bowl, Stuart period; French lidded measure of about 1710. At the back is an English dish, 1780-90.

(Courtesy of H. & A. Kimbell)

Suitable solders for

pewter are composed as follows: 1 part each of bismuth and tin, melts at 286° F.; 3 parts tin, 1 part lead, melts at 334° F.; 1 part bismuth, 2 parts tin, melts at 336° F.; 1 part bismuth, 3 parts tin, melts at 392° F. A commonly used solder alloy consists of 1 part of bismuth, 1 part of tin, and 2 parts of lead. The larger amount of lead may be safely used on outside work. Of the fluxes for pewter work Gallipoli oil, tallow, resin, and chloride of zinc are the most used. The

oil is to be preferred, and can generally be purchased from first-class supply shops. This is simply applied to the work and the solder run on in the usual way.

To get a bright finish on pewter the piece should be first cleaned with benzoline to remove any fingermarks and then rubbed all over, both the worked and unworked parts, with ordinary knife powder until the necessary polish has been given. If after cleaning as described the owner desires what is known as a satin finish to his pewter, he should obtain some very fine powder, such as is used by dentists, and use it on a flannel to polish the piece. The flannel should be rubbed round, not up and down.

PEWTER COLLECTING. The great charm of pewter is the pearly grey colour, and there is no other exactly like it. The beginner will do well to study the collection in a good museum, and make up his mind to specialize in one branch of pewter, not necessarily to the exclusion of any other in the case of a good specimen presenting itself.

Medieval and Elizabethan pewter is rare. Jacobean is scarce and costly, Georgian is rather decadent in form and in taste. Bavarian and Flemish pewter of the 18th century was often beautifully designed, but most foreign examples, except some French ware, are apt to be poor in the

composition of the alloy, i.e. there is too much lead. Victorian pewter beer-mugs are found in collections side by side with possibly a set of recent French or Belgian measures of the metric system, very plain, and with very ugly lids.

Irish and Scottish pewter is almost invariably good, and some of the finest pewter in the world is probably Scottish ecclesiastical ware. Salt cellars, candlesticks or candle-boxes may appeal to some; inkstands and snuff-boxes to others; spoons, again, a fascinating subject with a very special literature of its own, may attract others. Plates of good quality by a well-known maker are worth picking up if reasonable in price. Dishes fetch far more, and a boar's head dish 24 in. in diameter is worth many pounds. Jugs are effective pieces for display, and so are chocolate and coffee pots. Some collectors may feel drawn to the collecting of church plate. References to pewter flagons and patens may be found in the county books dealing with church plate; but there is much faked church plate in the market. Jacobean flagons are dignified and of sterling quality as a rule. Georgian church plate is heavy and rather dull. Church plate is sometimes made of Britannia metal, which the collector must avoid.

A small collection of pewter may be displayed to advantage on a Welsh dresser or an antique style oak sideboard or buffet. The plates will look well placed on edge, and the table portion will serve for a few choice exhibits, such as tappit-hens (see Fig. 3) or large tankards. A few small cups may be permitted on the shelves in front of the plates. The drawers in the dresser, or the cupboards at the sides, may be used for small exhibits, such as spoons.

For those who specialize in small articles such as snuff-boxes or spoons, the only satisfactory method of display is in a curio table with a glazed top.

It is no use to put pewter with brass tobacco-boxes, steel candle-snuffers, china and Sheffield plate, all mixed up together. Pewter also suffers from being placed in a room where decoration and furniture are of too ornate a description to make a good setting. It looks best with oak or plain mahogany furniture and in the rather old-world type of living-room, dining room or hall. To realize the effect of pewter properly displayed, a visit to the Victoria and Albert Museum may be recommended. If any specimens of pewter are imperfect through age, accident, or carelessness, they may be displayed in a cabinet just as specimens, or they may be restored by a careful restorer, to render them capable of the ordinary handling to which they may be subjected.

It is possible to lacquer the pewter, when it has once been properly cleaned, with an acetone varnish, which is transparent and not offensive in appearance. It is, however, far more satisfactory to clean the pewter to a certain point of brightness, not too silverlike, then smear it over with a rag which has some vaseline upon it. Rub it well with a clean, soft velvet cloth, and afterwards at intervals, as the Japanese are said to do to their wonderful metal work, polish with an old silk handkerchief.

Phacelia. Bell-shaped flowers of the species known as campanularia of this American annual.

PHACELIA. The most beautiful flowering plant in this group or genus is *Phacelia campanularia*. This annual should be sown out of doors in April where the plants are to bloom in summer; it grows 9 or 10 in. high and bears bell-shaped flowers of rich blue colouring. It thrives best in a sunny place and in well-drained soil.

PHAIUS. This is a very old type of terrestrial orchid requiring cultivation in a stove-house, and it is, therefore, beyond the scope of most amateurs. There are several species in cultivation, all of which grow some 2 ft. in height, and bear blossoms of various colours. *See* Orchid.

PHALAENOPSIS. This is a most graceful orchid with flowers on long arching stems. It is grown in baskets or suspended pots in a warm greenhouse in a compost consisting of sphagnum moss and a little orchid fibre. A minimum winter temperature of about 60 degrees is necessary. They need moist, shady conditions in summer and a good deal of water while growing freely, but drier conditions in winter. The flowers are white marked with various shades of colour. *Schilleriana* and *sanderiana* are two well known ones, but the newer hybrids are now chiefly grown.

PHARYNGITIS. Inflammation of the pharynx, the cavity behind the nose and mouth, is of three main varieties: acute simple pharyngitis, commonly called sore throat; chronic pharyngitis, frequently occurring in singers, speakers, street hawkers, and others who overtax their vocal organs; and acute phlegmonous, a serious but rare affection.

In acute simple pharyngitis, or sore throat, the inflammation is superficial. The common cause is exposure and catching cold. The patient has a feeling of tenderness, dryness, and tickling in the throat. He sneezes, coughs, has a headache, and loses his appetite.

Usually the inflammation lasts only a few days or a week. The patient should remain in bed if he desires a speedy cure. To relieve the congestion and discomfort in the throat, give ice to suck, and apply a flannel wrung out of hot water to the throat. Inhalations of steam give relief. A good application to the throat is glycerin of borax. When the inflammation has subsided the patient should use a gargle of a ½ teaspoonful either of glycerin of tannic acid or of alum, in a wineglass of water; or the glycerin may be painted on. He should keep to a liquid diet.

Chronic pharyngitis, or clergyman's sore throat, is caused most frequently by over-use of the voice. The patient should give his voice a long rest, and go to live in a warm, dry climate if possible. He must give up smoking and drinking alcohol if these habits are practised. The pharynx may be sprayed with a 1 per cent solution of carbolic acid once or twice a day. An excellent gargle is made of 1 dram each of common salt, bicarbonate of soda, and borax in a pint of tepid water. *See* Throat. Pron. Far-in-'ji-tis.

PHEASANT. Pheasants are in season from Oct. 1 to Feb. 12, and should be hung for 12 to 15 days. Pheasants may be tested for age by examining the wing feathers and the spurs in the cock bird. The spurs in an old bird are long and sharp; in a young bird they are short or round and blunt.

In preparing a pheasant for cooking it is trussed like a chicken and stuffed and roasted as described under the heading Game. A medium-sized bird takes 30-35 min. to roast, but the time varies according to the size of the bird and the heat of the oven.

Pheasant. Roast pheasant, garnished with tail feathers and served on a bed of watercress.

Pheasant and Macaroni. Roast pheasant larded and served with macaroni affords a change from the ordinary method of dressing. Only young pheasants are suitable for this dish. Lard closely the breasts of a brace of pheasants with small strips of larding bacon, using about 6 oz.; cover with thickly buttered paper, and roast for 25 min. in a moderate oven. Then remove the paper and return the birds to the fire or oven for 10 min. longer.

While the birds are cooking prepare the macaroni. Cook 1 lb. small macaroni till tender in plenty of boiling salted water, strain it and return to the stewpan with 2 oz. butter and 1 teacupful tomato sauce and the same of brown gravy. Mix well and let all become very hot, then season with white pepper and add 3 oz. grated cheese. Do not stir the ingredients to mix them, but toss them over and over with a fork. Arrange the macaroni on a dish, sprinkle over a little more cheese and pour over another teacupful of gravy, then serve the pheasant on the top of the macaroni.

A Pheasant Entrée. An excellent method of cooking pheasant as an entrée is called the gipsy way. Truss the bird as for boiling and put it into a stewpan or casserole with 6 oz. bacon cut in dice; the bacon should not be too lean. Add 2 oz. butter and a tooth of garlic, and fry all together until the bird is brown. It must be turned over while frying, so that the breast may become as well coloured as the back. Now pour away the surplus fat and add 2 peeled and sliced Spanish onions, 4 peeled and sliced large tomatoes, and 2 wineglasses sherry. Season to taste. Put the lid on the stewpan, see that it fits well, and stew gently for $\frac{3}{4}$ hour, giving the pan every now and then a gentle shake. When cooked add a dust of pimento pepper, and dish up with the gravy and vegetables poured round it on the dish. The remains of cold pheasant may be used up in any of the methods described under the general heading of Game in this work. *See Casserole; Chicken; Fowl; Game; Partridge.*

PHEASANT'S EYE. This is the popular name of adonis, a genus of spring-flowering hardy herbaceous perennials suitable for the rock garden. The best known is *Adonis amurensis*, which grows 12 in. high, has deeply cut, almost fern-like leaves, and large yellow buttercup-like flowers in March-April. *Vernalis*, 9 in., bears smaller yellow flowers in spring. Loamy soil with which leaf-mould has been mixed suits these plants. The annual kinds, autumnal is, bright red flowers in late summer, and *aestivalis*, red flowers in June-July, are raised from seeds sown out of doors in April in a sunny place in light soil.

PHLEBITIS. Inflammation of a vein, or phlebitis, may be of a septic or a simple character. Septic phlebitis may be caused by organisms circulating in the blood, or by such organisms being introduced through a wound or making their way into the vein from septic tissues which surround it. It is a very dangerous condition, as clotting, or thrombosis, occurs in the vein, and the clot becomes infected.

Simple phlebitis is more prone to occur in the gouty and in those who are anaemic. It is more likely also to occur in veins that have been in a varicose condition for a long time, or in veins in which the circulation has been sluggish for a long time.

The occurrence of phlebitis is marked by pain and tenderness in the line of the affected vein, which is felt to be firm and cord-like. If the vein is superficial the skin over it is reddened and somewhat swollen. If a large deep vein of a limb is involved, the limb below the site of the mischief becomes progressively swollen and brawny to the touch.

A person suffering from phlebitis should rest in bed, and if the affection is in one of the veins of a lower limb, as it most commonly is, the limb should be swathed in cotton wool and elevated on a pillow. Pain may be relieved by smearing glycerin of belladonna along the line of tenderness. The weight of the bedclothes should be taken off the limb by using a bed-cradle. Large doses of sodium or potassium citrate are sometimes given in order to lessen the risk of thrombosis. *See Varicose Veins.*

PHENACETIN. Phenacetin is a colourless, tasteless, crystalline substance which is only slightly soluble in water. Its chief use in medicine is in the relief of pain. In the treatment of severe neuralgic

headache, migraine, dysmenorrhoea, the lightning pains of locomotor ataxia, phenacetin in 5 gr. doses every hour until 3 or 4 doses have been taken often gives great relief. Further, to safeguard against the possibility of heart depression following on the drug's action, phenacetin is often prescribed with caffeine, as in the following powder: caffeine citrate 2 gr., phenacetin 5 gr.

In poisoning by an overdose of phenacetin an irregular, fluttering pulse, slow breathing, blueness about the face, profuse perspiration, and a general condition of collapse, which may even lead to death, are the commonest symptoms. Treatment consists in applying warmth to the body by hot-water bottles, warm blankets, etc., and in administration of some stimulant, spirits or sal volatile. The patient should remain in bed for a day or two after the symptoms of poisoning have passed off, to avoid all risk of heart failure.

Philately. *See* Stamp Collecting.

PHILODENDRON. The hothouse plant called philodendron has heart-shaped or arrow-shaped leaves, usually of a very vivid green in colour. The plants require a mean average temperature of 60°, in pots in a mixture in which leaf-mould and peat predominate. They are useful for training up pillars and covering ugly walls, but their flowering properties are negligible. Propagation is by cuttings at any season of the year. Water should be given freely daily.

PHLOMIS. This is a shrubby or partly shrubby plant of sage-like appearance which flourishes in sunny places if set in well drained soil. The most handsome of all is the Jerusalem sage (*Phlomis fruticosa*), a shrub 4-5 ft. high with grey leaves and bearing yellow flowers in summer, it is increased by cuttings placed in sandy soil in a frame in July and August.

PHLOX. The herbaceous perennial phloxes are invaluable border plants which are in full beauty in July and August. They flourish remarkably in the cooler northern districts, and in southern gardens are best suited by being planted in slight shade. They must have deeply dug soil enriched by manure; they are not a success in poor, dry ground. If the plants are allowed to remain undisturbed for 2 or 3 years they form splendid clumps.

Propagation is by division in early autumn or by taking cuttings of the young shoots in spring and setting them in sandy soil in a slightly heated glasshouse. The finest heads of bloom are obtained by lifting a few plants in autumn, placing them in boxes in a slightly heated glasshouse, and inserting the fresh shoots as cuttings early in spring. If put out in April-May each plant will bear one splendid head of bloom.

Phlox. Flowers of the herbaceous phlox, a splendid border plant which blooms in July-August.

Many new varieties of phlox are introduced almost every year, and for them the nurserymen's catalogues should be consulted. A few beautiful ones are Le Mahdi, Europa, Rijnstroom, F. A. Buchner, and Eliz. Campbell. The half-hardy annual phlox Drummondii, of which there are varieties bearing flowers of various colours, is an excellent summer bedding plant, for it blooms for many weeks. It is raised from seeds sown in a heated glasshouse in February-March, the seedlings being planted out of doors in May.

The dwarf trailing phloxes suitable for the rock garden are charming plants which soon spread into wide masses if planted in slight shade in a compost of loam, leaf-mould and sand. They are increased by cuttings inserted in sandy soil beneath a handlight as soon as the plants have finished flowering. The favourite is the moss pink (*Phlox subulata*), of which there are several beautiful named varieties, e.g. G. F. Wilson, mauve; the Bride, white; and Vivid, rose. *Phlox amoena* bears large rose-coloured flowers. All these dwarf phloxes bloom in spring.

PHOENIX. Of this palm, which is not hardy in Great Britain, the chief species is the date palm (*Phoenix dactylifera*). It is less decorative as a pot or tub plant when grown under glass in this country than *Phoenix canariensis*, a tall graceful palm for large conservatories. *Phoenix rupicola* is another attractive kind and *Roebelini*, a less vigorous palm, is particularly useful. These palms thrive in a compost of half loam and half peat with sand added freely. They need moist shady conditions and a minimum winter temperature of 50-55 degrees. Propagation is by means of seeds sown in pots of soil plunged in fibre in a case in the hot house.

Phormium. *See* New Zealand Flax.

PHOSPHATE: In Medicine. The salts formed by the union of phosphoric acid and bases are called phosphates. They are used in medicine as tonic remedies, in the syrup of iron phosphates, the compound syrup of iron phosphates, B.P.C., or chemical food, Easton's syrup and similar preparations. Sodium phosphate and effervescent sodium phosphate are used as aperients.

PHOSPHATE: In Gardening. The fertilizers known as phosphates are essential in the garden for the well-being of plants, as their action directly affects fruiting and flowering. These phosphates consist of various proportions of phosphoric acid combined with bases of organic mineral substances such as potash and lime.

One of the most valuable combinations is superphosphate of lime, which, in good commercial samples, contains about 25 per cent of soluble phosphates. This phosphatic manure is best applied during spring, lightly forking it in 2 or 3 weeks before sowing or planting. It is most suitable for land with tendency towards lightness. On heavy, clayey soil another phosphoric manure, basic slag, is to be preferred.

Bones are valuable for the phosphates they contain, and are commercialized in a substance known as steamed bone flour, which is a great acquisition wherever phosphatic food is required. Other phosphatic manures are phosphate of ammonia and phosphate of potash, both particularly valuable as liquid stimulant for pot plants, and used in the proportion of ½ oz. to a gallon of water. *See* Fertilizer: Gardening: Manure.

PHOSPHORUS. Ordinary phosphorus is a peculiar waxy solid substance which, when exposed to the air, rapidly oxidizes and readily bursts into flame. It therefore must be kept under water, in which fluid it is insoluble. Phosphorus has the characteristic of being luminous or glowing in the dark. There are several kinds; the white or yellow is virulently poisonous, and the red or amorphous is not poisonous. Poisonous phosphorus is present in some matches and in many rat poisons.

Poisoning by Phosphorus. One of the first symptoms of acute phosphorus poisoning is a burning sensation, or a taste something resembling that of garlic, in the mouth. Then a burning pain may be felt in the throat and stomach. The patient vomits, and if the matter brought up is examined in the dark it may be seen to glow. Purging occurs in some cases.

The doctor must be sent for without delay. Meanwhile, give a very weak solution of permanganate of potassium, or oil of turpentine, the French variety for choice. It may be given in doses of thirty minims every half-hour. The patient should be given soothing drinks, such as barley-water, linseed tea, and gum-water. He must not be given castor oil, or any other oil, butter, fat, milk, or eggs, for three or four days.

PHOTINIA. Of this genus of shrubs the most valuable in gardens in this country is the Chinese hawthorn, *photinia serrulata*, an evergreen which will reach a height of 10 feet or more: it bears white flowers in June and the reddish-tinted young leaves are attractive. This shrub is not very hardy and except in mild districts should be planted against a sunny wall.

PHOTOGRAPHY: HOW TO GET GOOD RESULTS

Hints and Suggestions for Snapshots and Advanced Work

For advice about the choice of a camera and the details of photographic processes the reader is referred to the specific headings Camera; Developing; Enlarging; Fixing; Negative; Printing; Washing, etc. See also Landscape Photography; Lens; Panchromatic.

Amateur photographers may, roughly, be divided into two classes—those who regard, consciously or unconsciously, the camera as a machine in which all that has to be done is to press the button, while the camera and the chemist do the rest; and those who regard photography as a hobby without limit in interest and knowledge.

For those in the class first mentioned the principal considerations are the methods of obtaining the results they want with a minimum of trouble, and the complete exclusion of the chemical side of photography. So limited, photography can nevertheless be made an interesting and valuable hobby if the limitations are frankly accepted, and a few rules studied and intelligently applied. Photography of this kind is generally spoken of as snapshot photography.

Photographers of the second type develop out of the first, because they find that the best way of learning how to improve their results is to make some study of each branch of photographic work, and, in particular, to develop their own negatives and to make their own prints and enlargements. Each of the separate operations is dealt with in detail in other parts of this Encyclopedia. Here will be given an outline of the subject in two sections, one for the taker of snapshots and the other for the amateur with wider aims.

For the beginner the simplest, and in many ways the most satisfactory, type of camera is the box-form or other type of fixed-focus roll-film camera, provided he accepts its limitations and does not expect a camera which is designed for snapshots in strong outdoor light to produce indoor portraits. It is still a common delusion that a really good photograph can only be obtained by the use of a first-class camera with a very expensive lens. It is far more probable that the beginner will produce good photographs with the simple box-form camera than with a more elaborate camera possessing an expensive lens. It is simply a question of knowing what the camera and its lens can do.

The Camera. Two things which the beginner should bear in mind from the first time he uses his camera are, first, that it is not a press-the-button machine, but a tool which requires practice for its proper use; second, that as it is a snapshot camera to be held in the hand, successful snapshots can only be obtained in strong light out of doors. Although the simplest box camera can be used on a stand or steadied on a wall or a chair while a time exposure is given, which means any exposure lasting longer than 1/15 to 1/20 sec., the beginner will generally wish to snap everything.

Whether he has a cheap camera or an expensive and elaborate one, it is impossible to overcome the difficulty that a large number of subjects are not sufficiently well lighted to permit successful

snapshots. This does not mean, of course, that no results at all will be obtained, but that the photograph will not be a good one; it will either give a grey, flat print with poor detail, or, where shadows are included, harsh and unnatural contrasts will appear.

Roughly, it may be said that with a fairly cheap hand camera, having a lens working at about $f/12$ (Kodak 1), sunshine, or sunlight reflected off large white clouds in a blue sky is necessary for a successful snapshot, and this only in summer time. This applies to cameras with shutters marked as working at a speed of $1/25$ sec., which usually means between and $1/20$ sec., and $1/30$ sec. With better lenses working at $f/8$, as found on the slightly more expensive types of roll film camera, successful results may be obtained in slightly dull summer light and midday winter sunshine. It is clear, therefore, that the beginner is limited in his snapshots almost entirely by the question of light. Light is very deceptive, and when it appears bright to the eyes it may be weak from the point of view of the camera, as, for instance, sunlight under trees. The only thing that will show definitely the strength of the light is an exposure meter (q.v.), and the beginner is strongly advised to make use of one.

The kind of camera referred to is known as the fixed-focus type, i.e. there is no trouble with focussing; so long as the camera is held more than a minimum distance away from the object to be photographed everything will be in focus and shown sharply in the resulting photograph. This distance may be taken normally as about 4 yd. It is only necessary to see that no object at a shorter distance comes in the picture as seen in the viewfinder. If it does it will appear blurred and disproportionate in size in the photograph, spoiling it accordingly.

Securing Good Snapshots. The following simple rules, if carefully attended to, will do much towards securing successful snapshot photographs:

See that the object to be photographed is included completely in the view-finder. Photographs in which the top of a person's hat, or the feet, or the top of a building or other object is cut off are bad. All that is necessary is to get farther away from the object. A little practice at judging distances, experimenting on a friend or an inanimate object at distances from 4 to 12 or 15 yd., will be very helpful.

Hold the camera firmly with both hands and perfectly level. If it is pointed upward, persons and buildings will look as if they were falling backward; pointed downward they will appear to be falling forward.

Look at the object squarely. Practise looking in the view-finder before exposing; but when exposing, fix the eyes on the subject. The ordinary viewfinder is too small to show detail, and the only way to be certain of snapping at the right moment is to look at the object.

Take a breath before snapping, and hold it as the shutter release is pressed; this prevents movement of the camera during the instant of exposure. Exposure should be made by a firm and deliberate movement and not sharply, which may mean jerkily. Do not take a snapshot with the sun shining on the lens. With the box-form camera the lens is set inside the box, and is fairly well shielded, but with the folding camera the lens mount is shallow and affords little shade for the lens. Sunlight shining into the lens will be found to give flat, misty results.

While perfectly clear photographs are obtained with the sun shining from behind, results will usually be secured with the sun to one side or a little towards the front, for then some shadows will be included in the picture, which will improve it.

Do not attempt to take distant views and wide landscapes with a snapshot camera. They are beyond its scope.

As far as possible, prevent people staring directly into the camera. The best snapshots are obtained when the subject is not aware that he is being photographed. This hint applies particularly to groups and street scenes.

Do not be afraid of over-exposure, except by the sea. At least 90 per cent of amateurs' failures are due to under-exposure, though it may not always be recognized. Use an exposure meter occasionally.

When the films or plates have been developed and prints made there is usually a chance of improving the photograph by trimming it. With a small camera not possessing a focussing screen it is not possible to ensure that nothing but the picture required will appear on the print, particularly in the case of snapshots. In fact, the small view-finder usually provided with roll-film cameras makes it dangerous to attempt to give the whole film to the subject or person snapped, for if this is done there is a probability that something will be missing in the photograph. See, therefore, that sufficient margin is given, but cut it off when the print is made. Many photographs are greatly

improved by trimming off unnecessary sky or foreground, or cutting out intruding objects. Examples are given in Figs. 3 and 5.

Photography. Fig. 1. The optipod, a substitute for a tripod, holding a camera to a fence, walking-stick, or other object, to permit time exposures. (Courtesy of Kodak. Ltd.)

These photographs, taken more or less by chance from an amateur's collection of snapshots containing many successful pictures, show several faults common to a large proportion of snapshots. One is insufficient care in choosing the view-point, getting too far from or too near to the object of the picture.

Left. Photography. Faults in amateur snapshots. Fig. 2. Camera not held straight, too much foreground, unwanted piece of sky, and white post clashing in interest with the house.

Right. Fig. 3. Improvement by trimming print. Building is falling backward because camera was tilted upward.

Often a movement of a few feet to one side or forwards will obviate difficulties and prevent foreground objects bulking too largely or getting too much foreground. Another fault is not holding the camera straight.

If the printing of the snapshots is left to the chemist or photographic dealer he can be relied upon to make the prints on paper best suited to the particular negatives. A matt or semi-matt surface paper

gives softer and more pleasing results than glossy paper (unless the sharpest detail is required, as when the photograph is to be reproduced in a newspaper or book), and the amateur will do well to ask for his prints to be made on these matt papers.

Do not blame the chemist if the photographs turn out badly. Grey and flat prints are almost invariably due to badly exposed negatives. The modern business of developing and printing amateurs' negatives is so well organized and carried out on the scientific principles of time and temperature development that properly exposed negatives will result in good bright prints. If the results are poor, use an exposure meter.

When the amateur has produced a fairly good proportion of successful snapshots he will usually want to pursue his hobby further. The first step to a completer knowledge is to undertake part, if not all, of his own developing and printing. If he uses roll films he cannot do better than obtain a film-developing tank, such as the Kodak or Ensign. He is strongly advised not to attempt hand development until the correct methods semi-automatically obtained by the tank have familiarized him with the appearance of good negatives. Even if he uses plates or flat films he should employ a developing tank in the same way before he attempts dish development by the dark room lamp.

No written description can convey a clear idea of the appearance of a correctly exposed and developed negative, and the amateur without this knowledge who attempts development by the aid of the dark room lamp is almost certain to go wrong. With some films and plates and developers the image flashes up quickly in the developing bath and there is the consequent temptation to take the negative out lest it be over-developed, whereas the truth is that after the image has appeared time is required to build it up in the negative. A negative which looks bright and full of detail under the red lamp will give flat and grey prints after fixing, because it has been removed from the developer before development is complete. With other films, plates, and developers the reverse is the case, and the image appears slowly. The safest rule is to follow the scientific methods of development by time and temperature according to the tables given with most developers.

Do not make any attempt to correct either over- or under-exposure by varying the time of development. Older text books are full of "dodges" for correcting faults in exposure, but modern scientific working has proved them to be useless, at least as far as the amateur is concerned.

While still using his camera largely as a hand camera the amateur can enlarge its scope greatly by providing a stand or tripod for it, so that time exposures may be given under the many conditions when snapshots are bound to be failures. Even without a tripod a little ingenuity will find support by pressing the camera firmly against a post, tree, fence, or wall, or placing it an top of a wall or post packed level with small stones. A simple device for fixing the camera is the Kodak Optipod, shown in Fig. 1, by means of which any convenient tree, fence, or even a walking stick may be used. With the latter it is quite possible to hold the camera sufficiently steady to give $1/5$ or $1/2$ sec. exposure.

Next, the use of different shutter speeds has to be studied. If the camera has only one speed usually marked $1/25$ sec. but actually somewhat slower, this can be overcome to some extent by closing or opening the diaphragm. By closing the diaphragm, i.e. using a smaller stop, as explained under F/ numbers, the exposure is shortened, and vice versa.

The best way of increasing the range of photographic possibilities is to invest in a camera with a fairly good lens with an aperture of about $f/6.8$, and, perhaps even more important, a really good shutter giving accurate speeds of from 1 sec. To $1/100$ sec. It is the lack of a slow shutter speed that is the greatest fault in cheap hand cameras. With the slower speeds, say or $1/5$ or $1/2$ sec., good photographs can often be obtained, the camera being steadied, when a snapshot would mean bad under exposure.

The amateur must practise the technique of his hobby until he can obtain negatives fully exposed and fully, but not over, developed, sharply focussed, clean, and without stains, holes, spots,

scratches, or finger marks. At the same time, if he is properly ambitious, he will consider the elementary rules in the artistic arrangement of his photographs in the posing of the original subject, whether personal or natural and in the production of his prints.

Pointing the camera at a beautiful scene and pressing the button will not necessarily produce a beautiful photograph. The camera does not see as the eye. Its range is limited and it is far less selective. Looking at a scene that impresses one, the unimportant and perhaps unpleasant items are passed over and hardly noticed in the general impression of pleasure. The camera sees all and records all with a fidelity that may have a disastrous result. Some selectivity is therefore essential. A lamp post can be avoided by moving the camera a foot or two to one side. Similarly, obtrusive objects which would fill the foreground of the photograph are often reduced in importance by moving back.

Photography. Fig. 4. Intended to be a photograph of the distant church, this is mainly a picture of fallen tree-trunks and empty sky. Fig. 5. Cut down print which, if enlarged, would make a much better picture than the original snapshot.

Some Useful Hints. Following are a few hints which will help in the production of satisfactory photographic pictures, even of the simplest and most unambitious kind.

Do not get objects of different or opposing interest in the picture. In other words, concentrate on the subject to be photographed, and let the background be no more than background. In most cases it is the foreground that makes the photograph.

Do not have the most interesting object in the middle of the picture. The centre is the weakest point. Keep the principal subject slightly to one side, or slightly above or slightly below the middle. On the other hand, do not arrange the picture so that the eye is led out of it towards the side. A river, for instance, should come out of the picture at the bottom right or left corner, not at the side.

Avoid bare expanses of sky or flat foreground. Trim off the print at top and bottom to reduce these defects. Plain white skies do not exist in nature, and if panchromatic plates or films are not used, so that sky and clouds are included on the negative, either print in clouds from a special cloud

negative, taken at the same time as the particular landscape, or trim the print down so that the minimum amount of sky is shown.

In photographing buildings, much better and more interesting pictures will be obtained if parts, details such as doors, windows, glimpses down aisles or through arches, are taken, rather than if the whole, inside or outside, is attempted. This rule frequently applies to landscape subjects, particularly wooded scenes, as explained under Landscape Photography.

PHOTOGRAVURE. Photogravures that have been damaged by exposure, dirt or grease can be cleaned by immersion for several hours in benzine in a flat, shallow photographic dish. The dish must be kept covered, and no naked lights permitted in the room, owing to evaporation of highly inflammable vapour. Afterwards dry and brush over with clean, soft linen. This removes grease and dirt held by it. Other discolorations can be got rid of by bathing in hydrogen peroxide, 10 vols. strength diluted with 1 part of water, in a photographic dish, the photogravure being exposed to strong daylight while in process of immersion.

An alternative method is to follow the benzine bath with a prolonged immersion in sodium carbonate solution, 2 oz. of washing soda to 8 oz. of water, finishing by thorough washing in running water to remove all soda. *See* Carbro Process; Printing.

Phthisis. *See* Consumption.

PHYLLOCACTUS. The phyllocactus has large flat stems, no leaves, and red, white, or pink flowers borne chiefly in summer. It is one of the favourite cacti for cultivation in pots under glass. It should be potted in well-drained pots in a compost of sandy loam with which broken brick or mortar rubble has been mixed. A sunny, airy greenhouse suits this plant best; it must be safe from frost in winter. Propagation is by means of cuttings. During summer the phyllocactus needs a good deal of water, but little in winter. There are numerous named varieties with large showy flowers.

PHYLLOSTACHYS. Of this hardy bamboo several species are of considerable ornamental value. A position sheltered from cold winds is most suitable, and deep loamy soil that does not dry out in hot weather is required. Bamboos do not flourish in poor, dry soil. Some of the most decorative species are aurea, which has yellow stems, fastuosa, flexuosa, henonis and the blackstemmed nigra. All are of tall and graceful growth. The whangee cane for walking purposes is furnished by these bamboos. The old canes or stems ought to be cut out in April. Propagation is by lifting and dividing the clumps in September or May.

PHYLLOXERA. Also known as the vine louse, this small insect is very injurious to vines, and although more prevalent in America and upon the continent of Europe than in Great Britain, it is scheduled by the Ministry of Agriculture as a notifiable pest. An attack may be recognized by the warty or knotty appearance of both foliage and roots. As a rule the remedy is complete destruction of infected vines, thorough cleansing of the vinery, and the introduction of new border soil. The Ministry of Agriculture must be notified at once of the appearance of the pest, failing which a heavy penalty may be imposed.

PHYSALIS. This is the botanical name of a hardy herbaceous perennial known as Chinese lantern or winter cherry. It is grown for the sake of the enlarged, orange-coloured lantern-like calyces which enclose the true fruits; they are in full beauty in late summer and early autumn and are cut for decorative use indoors in winter. The leafy stems die down in autumn, and at that season the plants

may be increased by lifting and dividing the clumps. The sorts with the finest "lanterns" are Franchetti and Bunyardi. *Physalis edulis* is the Cape gooseberry.

PHYSIANTHUS. The evergreen greenhouse flowering, climbing plant *Physianthus albens* attains a height of from 10 to 15 ft. It has red and white flowers, borne in early summer. It should be planted in a large pot or tub, in the ordinary potting mixture, and placed in such a position that it can be trained up walls, rafters, or pillars. Propagation is by seeds or cuttings in spring. In some parts of the country it is known as the white bladder flower, on account of the downy and bladder-like appearance of its blossoms.

PHYSICAL TRAINING. Systematic training for the promotion of health and the development of the body can take many forms. One of the most convenient, because it is practised without apparatus, is the Swedish system, often referred to as free movements. It was an important part of the training of the British soldier during the Great War, and forms the basis of the syllabus of physical exercises for public elementary schools issued by the Board of Education. It is divided into groups, each concentrating on a certain part of the body, and in this way muscles are brought into play which have hitherto been dormant, or nearly so.

One result of the system is to develop the chest and increase its measurement. To do this the gymnast takes deeper and more complete inspirations, filling the lungs with fresh air to their maximum capacity. This habit of adequate respiration, which is one of the main features of the system, tends to improve the general health and fitness. It cannot be too strongly emphasized that correct breathing is a vitally important factor in all branches of physical training. Much benefit may be derived by taking 10 to 15 minutes' Swedish drill night and morning. If performed indoors a window should always be opened to permit of good air being breathed. *See* Breathing; Drill; Dumb Bells; Exercise Gymnastics; Indian Club.

PIANOS: MECHANISM, CHOICE AND CARE

With Instructions about Doing a Few Elementary Repairs

Owing to the presence of a Piano in almost every home this article is one of the most important of those dealing with musical matters. Others are Flute; Harp; Player Piano; Violin. *See* further Gramophone etc.

A piano is a percussion instrument having steel strings struck by felted hammers which are set in motion by the depression of keys. The keyboard consists of a recurring series of long (white) and short (black) levers or keys, seven of the former and five of the latter in each octave. No pianos are now made of less compass than seven octaves A to A, while most modern instruments have this compass extended to C.

Parts of the Instrument. To each note there are three strings (trichord), except in the lower part of the compass, where spun copper covered strings are used, two to each note as a rule, but in the lowest octave of all only one. All these strings of varying thickness and length are stretched from the wrest pins over upper and lower bridges to other pins on the frame, and are subjected to a very high tension, the pull of which in a concert grand amounts to some tons, to withstand which there is a frame of iron or steel.

In most modern pianos the strings are made to cross one another so that the greater length thus obtainable in a smaller case may produce more sonority. This is called overstringing. Behind or under the strings lies the soundboard, usually of Swiss pine or fir, joined up and varnished.

The action consists of several independent but co-ordinated parts, which move on a key being struck and impel the hammer against its string, at the same time providing that it recoils instantly. An important part of the action consists of the dampers, which are small pads of felt lying upon the strings to prevent them vibrating. They are lifted off in the process of playing, and remain off so long as the key or keys are held down. Upon the latter being released, the damper falls upon its string and stops or damps its vibrations. In the very highest part of the compass they are not necessary, as the extreme shortness of the strings renders the sound very evanescent. The whole of this action is contained within a wooden frame, enabling it to be removed bodily.

Lastly, there are the pedals, of which there are usually two. The right or sustaining pedal, when depressed, suspends the whole of the damper action, irrespective of the fingers. In a grand piano the left pedal shifts the action, so that the hammer escapes striking one string of the three. The unstruck one however vibrates sympathetically, thus producing a different quality of tone. But in most uprights, either the hammers are shifted nearer to the strings so as to lessen the force of impact, or else a strip of felt is interposed between the hammer and the strings. This last is called the celeste pedal. In both instances the very characteristic *una corda* effect is lost.

When the strings are horizontal the instrument is either a grand or a square, the latter being very rare in Great Britain. The more usual form of instrument is that in which the strings are stretched from top to bottom, known as an upright; if of larger make, an upright grand; if of smaller, a cottage piano; or smaller still, a pianette. Naturally, the larger the instrument the fuller and stronger the tone, because more sonorous strings can be used. As regards the case, this is sometimes of solid oak, mahogany, or American walnut, but as a general rule it is either stained in imitation of ebony or rosewood, or else it is veneered in walnut.

There are other terms connected with the case which need explanation. The lid is the top of the instrument. It is usually divided into two halves, the front half working on a long hinge. The front panel is immediately below this, and upon it are fixed the music rest and the sconces. The bottom panel is just above the pedals. The fall covers the keyboard, and is joined to the hollow by a long hinge. In some pianos there is a name board bearing the maker's name, though this is generally placed upon the fall. The trusses are the more or less ornamental supports under the keyboard on the right and left.

Choosing a Piano. In choosing a piano the purchaser should be prepared to spend as much as he can afford, as cheap pianos are seldom good investments. To the uninitiated eye the instrument may appear as highly finished as a more expensive one, and its tone may even seem as good, but it is unlikely to wear well. It is therefore advisable to go to a maker or dealer of reputation, and to avoid places where pianos are a mere side line to other articles. It is best to pay cash down if possible, as most firms are then ready to make a substantial concession. If this be not possible, there is the instalment system. It is usual to have an agreement, and it is well to make sure that it is not one-sided and wholly against the purchaser if he should, by any chance, fall behind in any of his payments.

The first test of a piano is that of the tone. Everybody has his own personal preferences, but, in general terms the tone should be full, mellow, and powerful, without any trace of hardness or harshness. A good tone has depth and richness, whereas a poor one, despite apparent brightness, seems shallow and all on the surface, lacking singing quality. Avoid a brittle high register, like playing on glass, and what is called a tubby bass, i.e. weight of tone without richness. If the buyer is also a player, he can judge for himself, but otherwise he should enlist the help of a friend. The tone should exhibit perfect evenness throughout the compass, without a single break. This evenness can easily be tested by playing scales in single notes at various speeds up and down the piano.

The repetition should be perfect. Try several different notes, high, medium, and low, by playing each as rapidly as the fingers can move. Test the damper by playing passages and staccato chords—without pedal, of course—and listen for the instant cessation of vibration. What is termed an underdamper action will be found to give the best results, as the damping is quicker and more effective. Try the pedals and see that they are doing their work well. Pay particular attention to the touch, which should respond to the wishes of the player as expressed through his fingers. Persons accustomed to an old, well-worn piano sometimes think that the touch of a new one is stiff, whereas it really is better regulated and more calculated to produce all shades of tone. Notice whether the white keys are ivory or celluloid. The latter substance is more generally used to-day. Ivory is greatly to be preferred, but it adds to the cost. As to the case, the best makes are distinguished by good taste rather than by assertive ornamentation, which in a well-furnished room is apt to prove an eyesore.

It is quite possible to pick up a bargain in the shape of a second-hand piano, especially when one hears of it privately; also, most makers and dealers have such instruments either returned from hire or taken in part payment for new ones. But the purchaser should be wary of pianos included in catalogues of after-season sales, especially if they are by obscure makers. A second-hand piano should be tested in the same way as a new one, but it is advisable to see, at the same time, if the hammers are much cut by use, and whether moth has attacked the felt, bushes, etc.

A piano is very susceptible to changes in the atmosphere and temperature. It is best placed against an inside wall, at a fair distance from it; if possible, a cross position is preferable. In no case should it be near the fire, close to a window, or next a door through which there is a strong current of air; all these will cause it to go out of tune.

It is not advisable to place objects such as books, ornaments, or vases of flowers on the lid of the piano. They lead to disagreeable jarring or buzzing, and if water is spilt more damage may be done in a minute than can be remedied in a month. Open the lid frequently so as to ventilate the interior. Condensation of moisture on cool surfaces is common in every room, and this can as easily happen inside the piano as outside it. So-called ornamental covers should also be taboo. The use of insulators or glass cups, though sometimes necessary to protect the instrument from damp, may not only cause inconvenience to the player but also put undue strain on the pedals through raising the piano too high. A foot rest should therefore be used in such cases.

It is the custom for the firm which sells the piano to tune it for 6 months free of charge, after which it is the duty of the purchaser to see that he gets a competent tuner. It is false economy to save a few shillings a year by employing an inferior man. The piano should be tuned at least four times a year, or oftener if it is much in use. Sometimes little defects will develop which should be left to the tuner to remedy.

Cleaning the Piano. Once a year the piano should have a spring clean, for dust and fluff will find their way into the best-cared-for instrument, and cannot but affect the tone. First open the lid back, and then remove both top and bottom panels by undoing the hooks, buttons or stays by which they are kept in place. Next take off the fall and hollow, which will be quite easily done. To take out the action, turn back the catches on each side, firmly grasp the frame at the sides, give it a slight pull forward, and the whole can be lifted out. It should then be placed upright on the floor in some position where it will be in no danger of falling.

Now remove the keys in regular order from the bottom to the top, and place them on a table. They are all numbered, but it will be convenient to preserve the proper sequence. In removing them, ease them gently off their pins. With a light brush of soft hair, or of feathers, dust down the strings, and then remove all dirt from the bed underneath the keyboard and from the base of the instrument, being careful not to damage any of the baize bushes. On no account use a duster unless it is

perfectly dry. When the cleaning is over, replace all the parts in the inverse order to which they were taken out.

Ivory has a natural tendency to turn yellow with age, but this discoloration may be retarded, even if it cannot be wholly prevented, by cleaning the keys frequently from the dirt and perspiration which fingers are bound to deposit. They can be well rubbed with a chamois leather wrung almost dry; the rubbing is done with the tip of the finger, so as to avoid any damp coming into contact with the wood at the side of the key, each key being immediately dried with a soft cloth.

Very occasionally the ivory may be rubbed over with a little uncoloured methylated spirit; this will help to keep it white. Another recipe which has been recommended is to use lemon juice instead of spirit. If the keys are very discoloured it is best to seek expert advice. The case should be dusted lightly with a soft cloth; hard dusting with harsh material rubs the dirt into the polish, thus destroying its lustre. Never use furniture cream; use, instead, a soft cloth, very slightly damp, sprinkle a few drops of paraffin upon it, and apply it lightly. To prevent any damage from moths, camphor balls may be employed.

Simple Repairs. While the services of a competent tuner should be utilized regularly to keep the piano in playable condition, small breakages sometimes occur in the interval between his calls and cause considerable annoyance by putting the instrument out of use for the time being. Although interference with the mechanism of a piano by an inexperienced person is to be deprecated, there are certain minor repairs that can be undertaken by the handyman. The following hints are intended more particularly for the benefit of those in remote districts who cannot call in the expert at a moment's notice.

Broken Strings. One of the most frequent troubles is the breaking of a string. In the case of a steel string this may affect either one note or two adjacent notes. The portions of the wire that has snapped should be cut off as close as possible to the tuning pins in the wrest-plank and the loose portions carefully drawn out. This prevents any jangling noise in playing the instrument, but it reduces either one note to a monochord or two adjacent notes to bichords, and consequently decreases their volume.

This procedure should be followed in regard to the covered strings, except that the bottom portion need only be eased off the hitch pin and drawn out. In the case of a bichord there will still be one string playable, but a single string note will be dumb. In the latter case care should be exercised, when playing, either to miss the corresponding key or to touch it as lightly as possible to avoid breaking the section of the action. Since there is nothing now to stop the travel of the hammer, breakage of the tape or of one of the flanges of the action may result. The broken pieces of wire or string must be retained to serve as a pattern for replacement.

Broken Hammer Shank. Another occasional mishap is the breaking of a hammer shank. If the fracture is a fairly long one, the two pieces can be jointed together with seccotine and bound round with strong silk or linen thread. If, owing to short grain in the wood, the break gives insufficient glueing surface, it can be spliced temporarily by means of a thin piece of light wood glued on immediately in front of the shank, so as to resist the force of the blow, and this splint should be strengthened as before with silk or thread wrapping. Care should be taken, however, not to increase the weight of the shank more than can be avoided, since this, in turn, will affect the weight of the touch.

Where a permanent repair is desired, the procedure is to remove the broken pieces of shank from the hammer head and butt. This is done by melting the glue in both joints by means of a small blow lamp, or, failing this, a petrol filled cigarette lighter which does not give off smoke. Whatever form

of heat is applied, care must be taken not to scorch the wood. When the glue is sufficiently softened, the pieces of shank can be twisted or pulled out. Where the application of heat is ineffective, the shank must be cut off at the point where it enters the head or butt and the remaining piece drilled out. Care must be taken not to enlarge the diameter of the original holes, and the drill must follow the original direction of the holes. This is particularly necessary in regard to the head, and the need for this caution will be appreciated by noting the angle at which the head is fixed on the shank.

Making a New Shank. Before extracting the broken shank it is better to shape the new one. This should preferably be made of the same wood as the rest of the set—mahogany, cedar, maple, etc.—but if this is not readily obtainable a shank can be made from a piece of thin dowelling. The grain should run in the direction of its length to lessen the risk of the shank snapping under the force of the blow. A piece longer than will be necessary, should be cut from the dowelling and glass-papered down to the thickness of the original shank. It should then be slightly filed at one end to fit into the hole in the hammer head. When filing, the shank must be kept turning in the hand to ensure its being perfectly round. An alternative method is to use two long files. One file is laid on a bench or other flat surface and the tip of the shank to be inserted in the head is placed on it. With a stroke of the other file the tip is made to travel under pressure between the two and the fibres of the wood are thus compressed until the diameter is sufficiently reduced to allow the shank to enter the hole and fit tightly but without having to be forced in.

When a satisfactory fit has been obtained a small groove is made with a marking gauge along the tip to allow the surplus glue to escape. To fix the shank to the head a blob of seccotine is dropped into the hole and the shank is turned in the fingers as it is pressed home so as to form a ring of seccotine at the edge of the hole. The other end of the shank is prepared and fitted into the butt in the same way, but the shank must first be cut to the correct length. It is essential that the length should be exact, otherwise the hammer will not hit the strings at the correct nodal point and impurity of tone will result.

To arrive at the correct length, the measurement of one of the adjacent hammers is taken from the small centre pin in the flange (to which the butt is hinged) to the centre of the wooden portion of the hammer head. This measurement is usually about $5\frac{1}{8}$ in. but it may be slightly more. The new hammer shank is then roughly tipped to allow it to enter right down to the bottom of the hole in the butt. The measurement of the new shank is then taken from centre pin to centre of head, and the difference between this and the first measurement cut off the new shank. The latter is then re-tipped and fixed in the butt as already described. To allow the hammer to be turned to form the ring of seccotine the tape should first be carefully taken off the check wire.

Replacing the Hammer. In replacing, care must be taken to see that all the parts of the section are in their correct position. When forming the ring, the hammer head must be left in correct position, and to ensure this the hammer is carried forward to its note and the nose of the hammer placed in contact with all the strings forming that note.

In many pianos, especially overstrungs, the hammers are on the slant, and the new hammer must be in line with its neighbours to prevent fouling. To obtain this slant the tip of the shank that enters the butt, after being prepared, is filed slightly on the side opposite to that to which it inclines. Should the hammer after fixing not be quite in correct alinement, it has to be “cast.” This is done by heating the shank—the petrol lighter will serve for this purpose—and bending it either with the finger or pliers in the required direction. The hammer should be held in position till the shank has cooled and set. This operation must be performed gradually and repeated till the required position is attained. The butt should be held firmly while casting, to prevent strain or breakage, and the casting should not be done till the seccotine has thoroughly hardened. Should a hammer head become loose this can be easily refixed with seccotine, care being taken that the head is in correct position in regard to its neighbours and its note as already mentioned. A broken tape can be temporarily repaired by fixing the broken ends with seccotine to a backing of narrow tape.

Repairs to Keys. In regard to the keys, a scraping or creaking noise is sometimes caused by a chip or shaving on one key rubbing against another. This should be removed with a chisel working the way of the grain. Should two keys rub together at the front the piano has to be opened out and the

faulty key taken off the pins. Underneath the front of the key will be found an oval-shaped pin. This should be very slightly turned with the pliers so that its flattened side inclines to the front only just sufficient to give clearance. If turned too far, or if the pin is roughened with the pliers, the key will stick. If clearance between two keys cannot be obtained in this way it means the key has warped and requires the tuner's attention.

Where an ivory or celluloid front or head has come off a key these can be readily refixed with seccotine after the old glue has been carefully removed from both surfaces. Ordinary glue should not be used for fixing celluloid, as it is apt to cause discoloration.

The Pedals. In regard to pedal troubles, an annoying squeak sometimes occurs. This may simply mean that the pedal hinge requires oiling, but it may also arise from two rockers rubbing together or the front rocker fouling the inside of the bottom door. Where this occurs sufficient wood can be removed with a chisel from the offending rocker to give clearance. The replacement of a broken pedal is better left to the tuner.

PICKLE. Foods steeped in a preservative, such as salt, prepared brine, vinegar, or some similar acid, are known as pickled or pickles. Vegetables such as onions, beetroot, red cabbage, and cucumber are either pickled separately or together. Fish or meat may be pickled, as, for example, salmon, herrings, pork, or beef. Walnuts or tomatoes also may be pickled, the former alone, and the latter usually as an ingredient in a mixed pickle.

An excellent pickle is made with celery and tomatoes boiled with vinegar, sugar, and spices in the proportion of 2 heads of celery broken small to 9 tomatoes, 1 breakfastcupful sugar, $\frac{3}{4}$ breakfastcupful vinegar, 1 tablespoonful salt, and $\frac{1}{2}$ teaspoonful each cloves, allspice, cinnamon, and mustard. All the ingredients should be brought slowly to boiling point in a preserving pan and simmered for $1\frac{1}{2}$ hours. While hot the pickle should be poured into jars or bottles and sealed up.

Some vegetables require a more highly spiced vinegar than others. Cauliflowers pickled separately should be cut into sprays, soaked for 9 days in brine, blanched for 10 min., dried and put into jars with spiced vinegar poured over them. To make this allow $\frac{1}{2}$ oz. mixed pickling spice to 1 pint malt vinegar, boil, add 1 teaspoonful salt, boil again for 5 min. Strain over the cauliflower and allow to grow cold before putting into jars. Always tie pickles down very closely, and after a week or two, if the vinegar has been absorbed, fill up the jars with a further supply. For French beans, lay in brine as for cauliflowers, then boil them in the liquor, adding a tablespoonful of vinegar until they acquire a good green colour. Use the pickle vinegar hot.

For cucumber pickle use very small cucumbers. Rub them all over with salt, then cover them and leave them for 9 days, turning them each day. Drain and cut them into cubes, and lay them in a basin lined with well-washed and dried cabbage leaves. Pour over them enough boiling vinegar to cover them; lay over the top more leaves, and leave them in a warm place all night. Next day strain off the vinegar and drain the cubes. Prepare the basin again, using fresh leaves; arrange the pieces in it and pour the vinegar over them again, after boiling it up. Cover as before with leaves and set to steep. This process must be repeated for 2 more days, when the colour of the cubes should be much improved. Now put the cucumber into jars, boil up the vinegar with pickling spice, let it go cold, and fill up the jars.

Onions should not be used for about a month after pickling. Peel a pint of the pickling variety, sprinkle with salt and leave overnight; then put them into some boiling spice-flavoured vinegar. The latter may be prepared from 1 pint white wine vinegar, $\frac{1}{4}$ oz. allspice, $\frac{1}{2}$ oz. white peppercorns, 1 or 2 cloves, and 1 teaspoonful salt. Let them boil, and then simmer for a few minutes and skim the top before putting in the onions. The whole should cook for about 5 min. before being poured into a jar and tied down.

Piccalilli. This mixed pickle is composed of various vegetables cut into portions and flavoured with hot spices. It is made as follows Prepare a small cauliflower and cut the flower part into neat pieces, peel $\frac{1}{2}$ pint button pickling onions, string 18 French beans, peel 12 small shallots, then cut into cubes 4 oz. vegetable marrow, also prepared, and wipe 12 gherkins.

Soak these vegetables in brine with 3 or 4 capsicums for 9 days, but dry them well before pouring on them the following pickle; also add 3 cloves of garlic. For the pickle, to 1 quart white wine vinegar add $\frac{3}{4}$ oz. salt, $\frac{3}{4}$ oz. sliced ginger, $\frac{1}{4}$ oz cloves, 1 dram each mace, black pepper, and white pepper, and $\frac{1}{2}$ dram cayenne pepper.

Steep the spices in the vinegar, letting it remain in a warm place for 3 days, then boil it up slowly. Mix 2 oz. Dry mustard and $\frac{1}{2}$ oz. turmeric to a thin paste with a little cold vinegar and add to the boiling spiced vinegar. Now add the vegetables and boil all together for 5 min., then set to cool, and when quite cold put into jars. If very hot pickle is not desired, lessen the amount of cayenne pepper. If all these vegetables are not obtainable at one time, make up the pickle with those which can be had, and add the missing ingredients as soon as available. This pickle improves with keeping, so that a little delay in finishing it will not harm it.

Pickled Herrings. Soused or pickled herrings can be bought in a prepared form and are then ready to eat immediately, or may be soured at home. Dutch pickled herrings are imported in flat tubs. To prepare these wash thoroughly and soak for 2-3 hours in milk. Cut off the heads and tails and divide the fish into fillets about 1 in. thick. Pour vinegar over them, or a sauce composed of 3 tablespoonfuls salad oil, 2 tablespoonfuls mixed vinegars, such as chilli, tarragon, herb, or tomatoes, and 1 teaspoonful each chopped parsley and shallot, and a seasoning of pepper.

The herrings may be garnished with slices of hard-boiled egg, but root chicory, or some suitable salad herb, or a well-mixed plain salad, may be served with them. Salt should be sprinkled to taste. Salted herrings make a good luncheon dish.

Pickle Fork. These forks are usually made of silver or electro-plate with bone, ivory or mother-of-pearl handles, or entirely of the metal. A variation is a telescopic pickle fork. This fork lengthens so that when pickles are low in the containers they can be easily reached. A substitute for a pickle fork, and one which is useful for such varieties of pickles as walnuts, which might split if pierced with a fork, has spoon-shaped ends. These open and close by manipulation of the spring top. *See* Beef; Herring; Marinade; Pork; Red Cabbage; Walnut.

PICK-UP. This is a device for reproducing gramophone records electrically, and is used in conjunction with a wireless receiving apparatus. The pick-up is the electrical equivalent of the sound box used in the ordinary gramophone, and in its elementary form may comprise a permanent magnet having an armature arranged so as to pivot freely between the magnet pole pieces. The

armature may have a chuck for holding the gramophone needle, or alternatively the needle itself may form the armature. A winding of silk or enamel covered copper wire surrounds the magnet pole pieces or the armature.

Pick-up, a device for reproducing gramophone records electrically

In operation the needle and therefore the armature vibrates in sympathy with the undulations of the sound channels on the record, thus causing changes in the magnetic field produced by the permanent magnet. These changes are communicated to the coil winding and voltages are set up across its ends. These voltages are then applied by way of the pick-up leads to the grid and negative filament, or grid bias negative, of a low-frequency amplifying valve, and magnified up to a strength sufficient to work a loud speaker.

A pick-up requires careful and skilled design in order to avoid unpleasant resonances and undue wear of the record. A good pick-up employed in conjunction with a properly designed low-frequency magnifier and a cone or moving coil loud speaker will give excellent reproduction over the range of musical frequencies covered by the record.

The average pick-up is highly sensitive, and in many cases two low-frequency amplifying stages will give ample volume for domestic purposes. In the case of the less sensitive pick-ups the detector valve of a wireless receiver employing two low-frequency stages may be arranged so as to act as an additional amplifying valve, the pick-up being switched directly into the grid circuit of this valve.

Switching in the Pick-up

A single pole change-over switch is required, the connexions being as follows: The lead joining the grid condenser and one side of the grid leak to the grid of the detector valve is disconnected from the grid terminal on the detector valve-holder and transferred to one side of the change-over switch. The centre or common terminal of the switch is connected to the grid of the detector valve, and the remaining terminal on the switch is joined to one side of the pick-up. The remaining side of the pick-up is connected to the 1½ or 3 volt grid bias negative socket on the grid battery.

Thus in one position of the switch the set functions as a wireless receiver in the normal manner, whilst in the other position of the switch the pick-up is connected in circuit with the low-frequency magnifier, the high-frequency side of the receiver being disconnected. This switching scheme may also be employed in sets which incorporate only one low-frequency stage.

If a volume control is not already included in the low-frequency circuit of the receiver, it is advisable to connect a potentiometer having a suitable resistance value directly across the pick-up itself. This method, in addition to providing an efficient control of volume, also prevents overloading of the first amplifying valve.

The pick-up leads should not be permitted to trail across the set or to become entangled with the loud-speaker leads, since this is liable to cause instability. It is frequently beneficial to earth the pick-up tone arm. *See Gramophone.*

PICNICS: SUITABLE FARE AND ACCESSORIES

How to Plan, Pack, and Serve in Appetizing Fashion

Suggestions for menus and special picnic ware are given in this article. See also the entries Luncheon; Salad; Sandwich.

Whether a picnic is at the bottom of the garden, in a hut on the beach, or in some far-distant beauty-spot, its essential characteristic is lack of formality. In summer, when sunny days permit, tea, luncheon or supper out of doors can be a delightful form of entertaining guests, or of varying the monotony of home meals for the family, especially during holiday times. Success in all cases though mainly dependent on a factor outside the control of the organizer or hostess, namely, the weather, is also subject to good planning, good fare, and a suitable location.

The meal selected is a matter of choice, though tea-picnics are the most usual, largely because they are the easiest to arrange. When the entertainment is simply and solely a picnic for children, where tea is served and games played afterwards, woods are popular for the actual meal, but there should

be an open space near for the games. Rounders is often part of the programme, and sports with prizes are sometimes organized. The ideal place may be some distance away, and means of locomotion have to be studied. A small party may pack into a car: a larger one may have the use of cars which are loaned by friends; but where a number of children are being entertained, brakes or a private omnibus may be hired, a method which usually gives great enjoyment to the guests.

The food need not be elaborate for such a picnic: but there must be plenty of it. It is astonishing how hungry people get in the open air. This does not mean that anything is good enough to offer the guests. The bread used for the fish-paste, egg and cress, mustard and cress, and cucumber sandwiches should be both brown and white and as fresh as is consistent with neat making. Crusts are better left on, both for reasons of economy and also because the sandwiches keep a better shape. Bridge rolls, slightly sweetened brioches, and currant bread are all excellent for children's tea picnics, whether only buttered or sandwiched with jam, honey and sliced banana, walnuts and raisins or lemon curd.

Butter should be creamed before spreading, and fillings should be generous enough to prevent any reproaches of dry or dull fare, but not so generous that they ooze out uncomfortably at the first bite. Bought sandwiches are seldom the success that nicely home-made ones are. To keep the bread fresh wrap them in waxed greaseproof paper first, and then fold up in wet butter-muslin.

Very rich cakes are not only too expensive, but out of place at such a picnic. All the sponge-mixtures are liked, including jam sponge sandwiches, Swiss rolls, simple layer cakes and sponge fingers. Rock cakes, dough-nuts and the various plain and fruit buns are also suitable, while a tin of good mixed biscuits and another of ginger-nuts are a stand-by at a large party. Fruit that is simple to pack, such as apples, bananas, oranges and cherries, is a good choice, and better than too many sweets or chocolate. Some of these may be provided for the finish of the entertainment, or done up in fancy boxes and coloured papers and given away as prizes for the games.

Plenty to drink is an essential factor of success, but it need not all or always be tea. When a large number of children have to be catered for, it is often difficult to make tea for everyone. Home-made lemonade in concentrated form sometimes solves the difficulty if water to add is either carried or obtainable from some cottage near at hand. Each child at such a picnic usually brings his own mug. Tea is provided in vacuum flasks for the grown-up members of the party, or a kettle, tea-infuser and stove are part of the equipment. Some children, however, would regard the picnic as a failure unless they were allowed to collect sticks, lay a fire and boil the kettle for tea. Lemonade is useful even when tea is also provided, as everyone gets thirsty after playing games.

Picnic Luncheons. The same type of fare can be taken for the family luncheon on the beach, or when blackberrying some distance from home, if the sandwiches have more substantial fillings or home-made Cornish pasties, veal and ham pie or patties (these last are convenient because they do not necessitate knives and forks) are added to the menu. Anchovy or any other savoury hard-boiled egg dish and individual salads packed in cardboard cases with a box of small gruyère or other cheeses to be eaten with buttered bread, rolls, or biscuits are also simple to prepare. Home-made potato and onion salad with ham and tongue or beef sandwiches make a favourite meat course. Creams and jellies may be taken in their moulds. Tomatoes and soft fruit can be carried in punnets. Raspberries or strawberries should be well covered with cabbage leaves and placed so that they will not be crushed in transit.

When a picnic is given with a view to entertaining guests in an informal manner, a slightly more elaborate equipment and menu may be required and prepared. Where practical, it is a good plan for the hostess to name in the invitations an hour when she will ring up the various guests to confirm arrangements. This obviates the bad weather uncertainty. Often if all preparations for food have been made and the ensuing day proves wet, the party can be given in the house, and the guests will

enjoy a help-yourself cold luncheon almost as much as the proposed picnic. A good menu would be either anchovy eggs or prawns in aspic, chicken and ham (in portions), or veal and ham pie or chicken sandwiches, salad, fruit-jelly and cheese biscuit sandwiches or cheese straws and a variety of small genoese pastries. If fruit salad is taken it may be packed in a container with a screw lid, and cream is better whipped before starting, and taken in a glass jar with a screw top. Mayonnaise dressing for the salad can be packed in the same way. Coffee may be carried in a vacuum flask either hot or iced. A jar of pickles may be added and condiments must not be forgotten.

For a grown-up party a cocktail is sometimes needed. This is best carried in a shaker containing a vacuum for freezing mixture. A pleasant non-alcoholic drink to vary lemonade is ginger ale punch, made from 3 oranges, 3 lemons, 2 grape fruit, 1 pint ginger ale, 4 oz. castor sugar and 1 pint water. The juice is squeezed from the fruit and the ginger ale, water and sugar added and allowed to stand. Some people take a large jug, squeezer and ingredients and make this punch on the spot. Menus for picnic suppers are exactly the same as for luncheons. For moonlight parties hot soup and hot coffee are generally appreciated.

Picnic Accessories. A ground-sheet of mackintosh covered with a rug makes good seating accommodation for children. A few cushions can be carried if the picnic is by car and add to the comfort, while a folding table and chairs which stow away into a suitcase are other useful pieces of equipment. Picnic bags for holding vacuum flasks upright and cases of picnic ware in place of the more old-fashioned baskets are made to suit all requirements. The case illustrated in Fig. 1 contains a complete outfit for luncheon and tea for four people, and is very light in weight. The plates, tumblers and cups are of non-fragile ware in brilliant colours, and food-containers, flasks, spoons and knives are all packed into a conveniently small space. Tumblers in the same ware are obtainable in a separate leather case, and plates, cups and saucers may also be purchased singly as required. A useful accessory is a combined corkscrew and stopper opener.

Left. Picnic. Fig. 1. Luncheon and tea outfit for four persons. The gaily-coloured ware is non-fragile, very light, and easily packed. (Courtesy of Messrs. Beattl)

Below. Fig. 2. A jug-shaped vacuum flask is convenient for hot coffee. Cardboard plates covered with waxed paper; salad trays, and cases to hold individual portions of jelly are useful items.

Left. Fig. 3. Wicker-encased bottle and jar, cane spoon, fork and knife set, willow-pattern plates and checkered paper napkins make a simple but attractive spread.

Fig. 4. Inexpensive accessories in aluminium include a billy-can and glass-lined jars and food-carrier with screw lids.

Tea if carried in vacuum flasks should have milk and sugar packed separately. An excellent idea invented for use with a thermos flask is a tea-infuser.

This simple but ingenious device provides a method for brewing tea when required. The flask is filled with boiling water, tightly corked until tea is wanted, when the requisite number of spoonfuls are placed in the infuser, which is provided with a hook for attachment to the rim. When put into the flask the beverage is quickly ready to serve freshly made. Should ice cream be a part of the menu, a general-purpose thermos jar is obtainable with wide opening to permit easy filling, emptying and cleaning. Separate containers can be stowed inside such a jar when it is wished to take several iced or hot dishes, the food being retained hot or cold for several hours. Another method for providing ice cream at a picnic is to take a half-minute freezer.

The vacuum jug shown in Fig. 2 is particularly useful for carrying hot coffee. The soufflé dishes to hold individual portions of creams or jellies (these may be poured in hot and left to set), the spoons and straws, cardboard tumblers, salad trays, meat and cheese plates also shown are convenient items, none of which cost more than 8d. a dozen. The willow pattern papier mâché plates seen in Fig. 3 are a change from white ones. Picnic flasks and jars, wicker-covered with screw stoppers, are very inexpensive, while cane spoons, knives and forks cost a few pence the set. Checkered paper cloths and napkins provide a pleasing note of colour.

Aluminium accessories include those shown in Fig. 4. The glass-lined jars are most practical for butter, jam, pickles or whipped cream. The boiler or billy-can for use with stove and solidified methylated spirit packs into small space for picnic use. Collapsible sandwich tins are other convenient items for packing. A small model oil-stove has two burners, and the whole folds up into a case. This is most useful for picnic meals on an extended scale when camping or touring and more hot food requires preparation daily.

PICOT. In needle work a picot is a tiny loop, and a picot edging is a favourite trimming for the edges of such soft materials as crêpe-de-chine, satin, taffetas, net, voile, and even lace. These looped edgings are very easy to work, and are usually carried out in embroidery cotton or in silk.

One effective type of picot edging is shown in Fig. 1. It consists of a series of small loops of embroidery thread, between each two loops a simple oversewing or buttonhole stitch being made in the material, to ensure that if one loop is accidentally dragged, it will not pucker up the rest of the loops. Although this edging is easy to work, care has to be taken to make the loops of an even length, otherwise the effect will be spoiled. It should also be noted that the edge to be trimmed must first be neatly faced in or hemmed. Commence at the left-hand end of the edge by pushing the needle through the material from the back to front. Carry the needle a little farther along towards the right, and again push it through the edge in the same way, and draw through the cotton or silk until a loop of the size desired is made; then make a tiny buttonhole stitch in the material immediately to the right of the loop. Continue in this way along the edge, and fasten off on the wrong side.

Another type of picot is shown in Fig. 2. This is a buttonholed picot, and is much used in Richelieu work to decorate the many buttonholed bars or strands which form the open-work part of this embroidery. A trimming for collars, cuffs, or house linen can be made by buttonholing the material edge and working these picots at frequent intervals. The edge that is to be decorated in this way need not be previously neatened, because the buttonholing will itself make it quite neat.

Commence by buttonholing along the edge of the material, beginning at the right-hand end; then when the position at which the first picot is to be made is reached, work 3 more buttonhole stitches. Carry the needle back to the right, and slip it through the head of the first of these 3 stitches, and draw through to leave a tiny loop of the cotton or silk. Buttonhole stitch along this loop in the same way as a loop is made for fastening purposes, and when the left-hand side of the loop is reached, proceed to buttonhole the edge as before, until ready to make the next loop.

If desired, the loop can be made thicker by carrying the needle back to the left side before buttonholing it, slipping it through the last stitch, and then carrying it back to the right-hand side, as before. In this way there will be 3 strands of cotton in the loop over which to buttonhole. If the loops are set fairly closely together, the edging is a pretty finish for table mats.

If desired, the loop can be made thicker by carrying the needle back to the left side before buttonholing it, slipping it through the last stitch, and then carrying it back to the right-hand side, as before. In this way there will be 3 strands of cotton in the loop over which to buttonhole. If the loops are set fairly closely together, the edging is a pretty finish for table mats.

Imitation picot edging is formed of a line of hemstitching which is worked by machine, and afterwards has the outer cord cut away, to leave the cut bars of the hemstitching forming a series of cut ends, as in Fig. 3. To obtain this picot, simply run a coloured tacking along the edge that is to be trimmed, and take the fabric to a sewing-machine shop to be hemstitched along this line; then cut the outer cord of the hemstitching away. With this edging there is no need to hem or face in the edge of the material.

There are many other picot edgings. A length of crochet chain, for instance, sewn along the edge of a tray cloth or runner in a series of loops is very effective, or it may be worked directly on to an open-meshed material, passing the crochet-hook through the edge after each loop of chain is made, and-making it secure by means of a double crochet. Picots in crochet are chiefly used to form a background or filling for Irish crochet and to make a picot edge on narrow edgings and laces. *See Crochet; Embroidery; Richelieu Work.*

Picot. Fig. 1. How to make an ornamental looped edge. Fig. 2. Buttonholed picot used in openwork embroidery. Fig. 3. Substitute for picot formed by a cut line of hem-stitching.

PICOTEE. This old type of border carnation has a narrow band of colour at the edges of the petals. There are two types of picotees, the white ground and yellow ground, the edge being of various colours— rose, red, purple, or scarlet. Picotees need the same cultivation as border carnations.

PICTURES AND PICTURE FRAMES

How to Hang and Frame Prints and Paintings

This article is one of those that deal with decorative accessories for the home; others being Curtain; Mirror; Rug. See also Cornice; Drawing Room; Living-Room; Panelling; Passe Partout; Queen Anne Style; Victorian Style.

A picture is one of two things, either simply a decoration upon the wall, or else the illusion of a landscape or figure subject seen through a hole in the wall. Frames for the first type of pictures

should be merely borders or part of the whole scheme of the picture; for the second type they should have some solidity or depth which gives them power to divide the pictures from their surroundings.

The earliest frames were architectural in design. Most pictures being painted for churches, altarpiece frames were in the same character as the arches of Gothic buildings. The Italian frames of the Renaissance period were made exactly like doorways and windows enclosing painted portraits and classical figures with an illusion of reality. The frames had the same upright columns, lintels, sloping base lines and pediments of the windows and doors of the period.

With the introduction of landscape painting pictures became popular and enclosure for protection was necessary. Metal frames finely decorated with leaves and festoons were produced in France. Gilded and carved wood and gesso decoration followed, and many beautiful frames were designed in England. At the beginning of the nineteenth century it became the fashion to frame everything from a miniature to a huge landscape in gilt frames to match, irrespective of style of picture. Later in the century the walls of living-rooms were completely covered with pictures, the gilded frames of which were usually of more importance than the paintings.

To-day framing varies from the strip mouldings, cut in lengths and mitred at the corners to the specially designed carved frames taking into consideration light and shade effects and period of pictures. The art of framing and hanging pictures is governed by three things —place, picture and period. With regard to place, there should be general agreement with surroundings. In modern rooms a few prints and pictures of the decorative type look well when framed or re-framed to suit the furnishing schemes selected. Flat frames of harmonious colour are the best choice. Old frames do not mix happily with modern ornamental accessories.

Pictures of the second type of interest, historical, portraits, landscapes or figure pieces, must be considered on their own claims. Sometimes they are too heavy for the living-rooms, but may look well in the hall or on the staircase. Oil paintings require well recessed and not flat frames. Carving is added so that light and shade shall play on the surface of the frame. In this style of picture such framing does not detract from the interest, but adds to it. The frames should also possess such features in their designs as connect them with the school to which the painting belongs in style and period. These features may be studied at big picture galleries with representative collections. Another interesting thing to note is that mouldings and ornaments will correspond with those in use on furniture, etc., of the period and the influence of Chippendale, Robert Adam, and other great designers can be seen.

Generally speaking, a better effect is gained by hanging pictures, with the exception of one over the mantelshelf, at the same level all round than by arranging them at different levels. On panelled walls any haphazard hanging or mixture of frames would spoil the decorative scheme of the room. The tendency is to hang them too high; the lower edge of the picture itself, not of the frame, should in most cases be on the eye-level of the beholder when standing. By inclining the frames slightly forward the reflection of the glass is avoided and also the accumulation of dust.

Care of Pictures. Old frames should never be regilded without discrimination, especially as much modern gilding is far from being durable. The brass hooks used on picture-rails tend to disintegrate where gas is used, and may cause pictures to fall. Heavy frames should be supported by three vertical wires or chains, because this minimizes the risk attending the slipping of one of them. When the glass is being cleaned pads may be placed behind the upper edge of the frame, to keep the picture rigid; otherwise the supports may become dislodged. Fly-marks may be removed by a damp cloth or brush, the spot being dried immediately after. Mildew will usually brush off. If for any reason a canvas is unglazed, it may be kept in condition by means of a dry feather and a silk handkerchief.

The task of cleaning or restoring pictures is best entrusted to an experienced person. If they are antique canvases, covered with the grime of generations, they may without much risk be sponged over with warm water. Soap should not be applied without experience, and acid and alkaline fluids are risky. The darkened condition of many pictures is due either to the excessive use by the artist of siccatives, or to the action of time. Such pictures cannot be properly renovated, and when they are retouched or repainted the modern pigments may not age in the same way as the original ones, so that the picture comes to look patchy and unpleasing. Sometimes the original canvas has been so weakened that it needs rebacking. All these vicissitudes demand much skill in their treatment.

Hanging Pictures. Pictures should be suitably framed and hung against a background that will enhance their beauty. A picture rail is a convenience where large pictures are to be placed, except in a panelled or period room, when, unless the pictures can be themselves treated as panels, they must be placed with great discretion and hung so that neither wires nor supports show.

It is not a difficult matter to fix a picture rail. The succeeding article on this subject should be referred to. Brass hooks for the picture rail can be obtained with a stamped decoration (Fig. 1), or plain.

Picture Hanging. Fig. 1. Brass hook for picture rail. Fig. 2. Hanger for wall with no rail. Fig. 3. Hanger fixed with a single steel pin. Fig. 4. Brass picture chain.

The best way of hanging pictures on walls not provided with rail or rods is by means of one of the picture suspenders which can be obtained from the ironmonger. That shown in Fig. 2 is attached with long fine steel pins driven into the wall at a slight inclination, and will hold a picture up to 50 lb. in weight. Another form of hook shown in Fig. 3 is fixed with a single pin, and is made in sizes to hold weights of 30, 40, 70, and 100 lb.; the method of fixing is shown on the right. These pins are intended for plaster walls; for brick-faced walls the best method is to use an ordinary stout brass-headed nail, but the wall should be plugged first. This may be done by using a small cold chisel and then filling the hole with a wooden peg, or by the fibre plug method. Ordinary cord is convenient for hanging small pictures, but it is not advised for heavy ones. Stranded picture wire is much more suitable for general use. Brass picture chain as shown in Fig. 4 is known as patent chain, but ordinary brass jack chain with plain round double links can be used. Stout brass screw eyes should be fastened in the back of the frame about half-way down the width of the top piece. Pictures that require a tilt should have the screw eyes about a quarter of the way down the sides of the frame.

In hanging a picture, sufficient wire or chain should be provided to support it at the approximate height; the final adjustment is made by shortening or lengthening the wire at one of the screw eyes at the back of the frame. Although a single length of wire attached to two screw eyes and supported on one hook will be sufficient for pictures of ordinary size, it will be necessary to use two separate lengths for heavy oil paintings or large engravings. Stout screw eyes should be driven in the frame, and the chain carried vertically to nails or hooks on the rail.

Picture Framing. Although the majority of picture frames are put together with the mitre joint, one which is usually regarded as troublesome to deal with, there is nothing specially difficult about it if

proper tools are used. A fine backsaw is the first requirement. It is almost useless to attempt to use a coarse one, as it is sure to splinter out the grain, and will probably ruin the mitre block on which the mitres are cut. The mitre block is a device for cutting mitres accurately without elaborate marking out. The important point about it is that on no account must the saw be forced in it. It is purely a guide for the saw, so that the latter must run freely in it.

A useful appliance, though it is not an absolute necessity, is a mitre cramp. This holds the parts of the joint firmly together whilst the nails are being driven in. A hammer and punch are also needed. The Warrington type hammer is the most convenient, but practically any kind of carpenter's hammer can be used.

Picture Framing. Fig. 1. Section through moulding, showing rebate.

Fig. 2. How overall size of frame is ascertained.

Materials. It is usual to buy picture frame moulding ready made, as it is so cheap and cleanly finished that it does not pay to attempt to make it. All sorts of patterns are obtainable. Some are in plain wood, oak or some other hardwood, and may be just moulded or be partly embellished with an embossed design. The latter type looks attractive, but calls for extra care in mitreing because the pattern must be balanced.

Another type of moulding has a highly polished surface of composition. Here, again, care is needed in order to avoid chipping. A third kind of moulding is gilt. This usually has a fine, smooth finish and gives a different effect from those frames in which gold paint is applied after the frame has been put together. All picture mouldings have one point in common in that they have a rebate at the back in which to accommodate the picture and glass.

Other materials include cheap thin wood backing. Practically any thin wood can be used. Plywood is excellent for the purpose.

Picture Framing. Fig. 3. Cutting mitre, using mitre block. Fig. 4. Nailing mitre in cramp.

A good quality glass should be used, one of a good clear transparency, which will not give the picture a distorted appearance due to inequalities in thickness. Some brown paper to back the whole, screw eyes to hold the cord, and a few picture sprigs are the only other requirements.

As the picture has to fit in the rebate of the moulding, the size of the frame must be based on the rebate size. Fig. 1 is a section through a picture moulding and shows the rebate clearly. As a practical example, assume that a picture measuring 10 in. by 7 in. has to be framed. Whilst the rebate size is all-important it is necessary to ascertain the overall size because, when the moulding is placed on the mitre block, the back edge touches the kerf in the block. This back edge necessarily represents the overall size.

Fig. 2 shows how the calculation is made. The moulding should be measured on the under side from the rebate to the back edge, not the complete width. In this case it measures 1 in. Consequently, the overall length is 10 in. (the picture length) plus 1 in. at each end (the moulding), giving a total measurement of 12 in. To this it is advisable to add, say, 1/16 in. to allow clearance for the picture. Similarly, the height becomes 9 in. full. The rebate causes a margin of the picture to be hidden all round. If this is to be avoided the picture must be stuck on to a slightly larger sheet of paper so that only the projecting part of the paper is hidden.

Cutting the Mitres. Place a piece of moulding on the mitre block and, holding it firmly against the back, cut one mitre as shown in Fig. 3. Notice that back of the moulding touches the kerfs in the mitre block, not the rebate side. The reason for this is that the saw is not so liable to split out the grain as would be the case if the moulding were reversed. If cut carefully no trimming is necessary. From the point of the mitre mark the overall length along the back of the moulding. Place it again on the mitre block with the mark slightly to one side of the kerf in the block. In this way the mark is just left in when the second mitre is cut. If this were not done the frame would be a trifle under size. Proceed similarly with the opposite side, but take the length from the piece already cut, this is because the opposite pieces must be exactly the same length. When the two remaining sides have

been cut the four pieces can be tried together on a flat board. Some workers prefer to trim the mitres on a mitre shooting board, but this should not be necessary if the work has been done carefully.

Assembling the Frame. There are various ways of doing this. Those who have a mitre cramp will find this a great advantage. The mitres of two adjacent pieces are glued and placed quickly in the cramp. When the members of the moulding coincide exactly the tightening screws are turned, and two nails are driven in, one in each direction. Fig. 4 shows the procedure.

In the case of extra tough wood it is a good plan to first drill fine holes.

Next the two opposite pieces are put together in the same way, so that the work at this stage is in the form of two letters L. The moulding can be taken out of the cramp immediately after the nails have been driven in and punched home. It is now merely a matter of joining together the two parts, and this is done in exactly the same way.

Fig. 5. Upper piece of moulding is placed slightly high to counteract downward slip.

If a mitre cramp is not available the bench vice can be used to hold the one piece whilst the nails are being knocked in. In this case it is essential to drill a hole in the upper piece and drive in a nail so that it just projects at the mitre. Otherwise the blows of the hammer simply cause the upper piece to slip down. In any case a small amount of slipping is to be expected, and for this reason it is necessary to place the upper piece a trifle high, as shown in Fig. 5. The hammering soon brings it to the correct position. Fig. 6 shows the work in the vice.

Picture Frame. Fig. 6. Putting mitre together in bench vice.

A point always to be remembered is that nearly all picture moulding are thinner towards the rebate. Consequently the nails must be so placed that they go into solid wood. Nothing looks worse than for a nail to emerge at the surface of the moulding. If this should happen the nail should be tapped back and withdrawn, and another nail driven into a more solid part of the moulding.

When assembling the mitres in the vice the left hand should always hold the upper piece of moulding, partly to steady it and partly to prevent it from turning on the nail. It may be found after all four sides have been put together that the frame "winds" slightly, that is, the four pieces are not in a true plane. This is easily ascertained by laying the frame on a flat board. If it is not true the two diagonally opposite corners will stand up a trifle. This is easily corrected by placing the frame face

downwards and tapping the corners lightly with the hammer, care being taken not to break the joints.

Fig. 7. Assembling frame with string and wedges.

A third method of putting together a frame is shown in Fig. 7. It has the advantage that no nails are driven in until after the glue has set. There is thus no danger of the joints slipping. All the mitres are glued and the four

parts are laid in position on a flat board. To squeeze out any surplus glue the parts of each mitre should be rubbed together. A piece of strong string is then tied around the whole, thus binding the sides together. To force the joints tightly together eight small pieces of wood are cut out, and two are passed between the string and the moulding at each side near the centre. By sliding the pieces towards the corners the string is tightened. At least twelve hours must elapse before the string can be taken off and the nails driven in.

No matter which method of assembling is adopted, it is important that any surplus glue is cleaned off before it hardens. It is difficult to remove hard glue cleanly, and it looks most unsightly in a joint. If the glue is used carefully and sparingly it will not be squeezed out on the surface of the moulding. If it should ooze out it can be wiped off with a swab damped with hot water.

Putting in the Glass. If the worker has a glass cutter he can easily cut his own glass. Probably the majority, however, will prefer to take the frame to a glazier, who will cut a piece of glass to size. After the glass has been thoroughly cleaned and polished it should be laid in the rebate, care being taken not to finger-mark the inner side. The picture is laid over this and a piece of backing prepared. If thin wood is not available a piece of stout cardboard can be substituted. It should be of such a thickness that the back is level with the back of the frame.

Picture Frame. Fig. 8. Back of picture, showing sprigs and paper backing.

To hold it in position a few picture sprigs are driven in all round as shown in Fig. 8. These are headless and can be tapped down so that they scarcely project. A piece of brown paper is pasted down over the whole. This gives a neat finish and excludes all dust. Small screw eyes can be put in at the sides to hold the cord.

To hide the nail holes plastic wood or wax should be pressed in. If the latter is used it should be heated and dropped in from a

pointed match stick. When it has cooled it can be levelled down with glass paper. If the frame is to be stained or painted this should be done before the glass and picture are inserted.

PICTURE RAIL. As a rule the wooden moulding or rail incorporated into a wall surface to support pictures and other ornaments should be at a height equal to the architraves on the door, but space may require this to be raised or lowered. Several typical sections are illustrated.

In new work the picture rails are generally fixed to rough grounds embedded in the plaster, oval brads being used which are punched below the surface, the holes being made good with putty or hard stopping. In a room devoid of a rail the picture rail may be fixed by the use of wall plugs and screws, the holes for the latter being carefully stopped.

Picture Rail. Fig. 1. Typical examples of simple picture rail mouldings shown in section.

Occasionally the picture rail may have to be cut and removed to permit a wardrobe or other article of furniture to stand flat against the wall. This is accomplished by sawing the moulding across with a fine-toothed tenon saw, placing a piece of card above and below the moulding so that the saw will not damage the plaster. To repair such a moulding will require a new piece of the same section, which is cut to fit between the existing ends of the picture rail and painted or stained to match the existing work.

Picture Rail. Fig. 2. Method of fixing a rail to rough grounds embedded in the plaster.

Metal picture hangers are used which are curved in such a way that they fit securely over the edge of the moulding, thus doing away with the necessity for nails, and allowing the position of the pictures to be changed at will, without any disfigurement of the walls.

PIE. In some parts of the country the words pie and tart are interchangeable, but usually there is a distinction between them, a tart being open and baked in a shallow tin, while a pie, with few exceptions, is deeper and has a covering of pastry. *See Apple Pie; Fish; Game; Pastry, etc.*

PIECRUST: On Furniture. In furniture design this term is used for a certain kind of edging sometimes found on small tables. It is waved or scalloped and is raised above the flat centre because the latter has been worked down with the tool. It is chiefly seen on mahogany tables of the time of Chippendale style.

PIER: In Building. As used in domestic building construction a pier is a stone or brick pillar, or a projection built out from the face of a wall to strengthen it or to carry any excess of local weight. A small portable building is often arranged to rest on a number of low brick piers. Timber plates are supported by the piers, and the floor of the building rests on these plates (*see* Garage). The piers will be proportioned to the size and weight of the building, but for most erections in connexion with the home the piers will suffice if built in 9 in. brickwork.

The first step is to excavate the soil until a sufficiently firm bottom is reached; a bed of concrete about 18 in square and 6 in. to 9 in. thick should be laid at the bottom and as soon as the concrete is set the brick piers can be erected upon it. The simplest plan is to build the four corner piers first and then level them, if necessary laying one or two courses of tiles, but getting the heights uniform. The intermediate piers may then be built, levelling them by stretching a line tightly between the corner piers and resting upon the tops. The remaining piers can then be built up, and the line will serve to keep them uniform both as regards direction and height. After the mortar has set hard the timbers may be bedded on the top of the piers and the building completed. *See* Brick; House.

PIERCING IN METAL WORK

Directions About a Graceful Form of Ornamentation

This contribution is one of those dealing with the decorative working of metals. *See* also Bent IronWork; Metal Work; Napkin Ring; Repoussé.

For the home craftsman, pierced metal work offers a very attractive occupation, and many of the articles which the amateur metal worker produces can be ornamented by piercing. It does not cost a great deal for the apparatus, neither does it require a work bench, the only real essentials being a good, firm table and a steady light. The tools are few and inexpensive, the most important being a metal- piercing saw, a work table known as a sawing table, and a cramp to affix it to the table.

The table can be made from a piece of 1 in. deal with a V-shaped piece cut from the front part. This open portion is to allow the saw to move while the jaws or side pieces support the metal. The width and shape of the opening can be modified to suit the work in hand. The material used for pierced metal work is thin sheet metal, either brass, copper, zinc, or pewter, and generally No. 24 gauge. The thickest metal that can be cut by hand is about No. 16 in copper or brass.

Piercing. Fig. 1. Design for pierced metal napkin ring laid flat and showing the measurements of the piece of metal necessary for the work.

As a task for the beginner the napkin ring shown in Fig. 2 can be cut in copper, brass, or pewter, about No. 20 gauge in thickness. It is a D-shaped ring ornamented with a monogram. The expanded design is given in Fig. 1, the leading dimensions being indicated. In cutting the desired monogram it is essential that the letters be formed by removing the metal around them, and that they have sufficient support from the framework. The articles on Initial, Lettering, and Monogram will form a guide in making the design.

Fig. 2. Napkin ring, the making of which is described here.

A full-size design should be prepared on thin paper, and the sheet of metal is cut with a pair of tinman's snips to a rectangular shape with overall dimensions a little larger than the design. The metal is then flattened and cleaned up on the surface with fine emery paper. The design is placed over a piece of carbon paper and is transferred to the metal by going over it with a blunt pencil.

The next step is to cut the outside of the metal to shape, doing this with a pair of snips or sawing it with the piercing saw if the outline is at all intricate. A pair of cutting snips with bent jaws would be a useful addition to the tool kit, and is employed for cutting curved outlines. A small hole must be made through the metal just inside one of the lines that define the outline of one of the larger holes. This may be done either with a small drill in a hand-drilling machine, or, in the case of thin materials, with an awl. The rough edges of the metal on the under side of the hole should be filed flat with the end of a small file or cleared away with a countersink, as unless this is done there is a risk of a projection catching on the surface of the sawing table and spoiling the cut or breaking the saw blade. It will save trouble to make all the holes at the start, so that the sawing can continue without interruption.

The piercing-saw is clearly shown in Fig. 4. The saw clamp nearest the handle is fixed to the latter, and the one at the end of the frame is free to slide in and out of a square hole in the frame. This clamp is adjustable by means of a small thumb nut; its purpose is to tighten the blade when it has been fixed in the clamps.

The effective length of the frame can be altered by sliding the back of the frame in or out after loosening the locking screw.

To fix a saw blade in the frame, first see that the teeth are pointing downward, that is, towards the wooden handle. For exterior work, fasten the saw into the top clamp, then press the end of the frame against the edge of the table, thus causing the frame to spring a little; keep the frame in this position and fix the blade into the lower clamp, and screw the thumb nut tightly. The spring of the frame will tighten the blade, and further pressure can be brought on it by tightening the thumb nut at the end of the frame, thus drawing the clamp and the saw very tight. When the saw is twanged like a harp string, it should give out a decided musical note. It is very important that the blade be tight, or it will not cut properly and will speedily break.

On internal work the saw has to be passed through the hole in the metal, as shown in Fig. 3 when it can be tightened as described, although some workers prefer to fasten and unfasten the top clamp, as then the work can rest on the left hand while the right is employed in clamping the blade.

The next stage in the work is to fasten the saw table to the work bench with screws or with the clamp, and rest the work on the top of the saw table with the part to be pierced over the hole therein, and with the edge of the part to be cut as near to the sides of the table as is possible. Then with the left hand hold the metal firmly to the table, and with the right commence the sawing.

The whole of the cutting is done on the down stroke, and on the up stroke the saw blade should pass as easily through the saw cut as possible. Keep the saw perfectly upright, as in Fig. 4, and make about 2 strokes per second. Maintain this rate of progress, and continue the cutting steadily with an even pressure throughout the whole of the time the blade is at work. When the blade is working on a straight line there is not so much risk of it breaking; when cutting curved parts the blade must be kept going steadily all the while, as if it is twisted in the hole it will be almost certain to break. Should the blade show the slightest tendency to stick, it can be lubricated with a little oil or tallow. When the first hole has been cut the others can be dealt with in the same way. The saws are made in various grades, or numbers of teeth to the inch, and as a general guide it can be taken that the harder the metal the greater the number of teeth per inch will be needed.

After the pattern has been cut out in this way, the edges may be a little rough, and it will be advisable to clean them up with fine files. The work can be held in the hand, as in Fig 5, or the metal can be grasped in the vice between two pieces of board. When filing, watch the progress carefully, as a few careless strokes with a file will destroy the appearance of the whole design. The metal is fashioned to the desired curvature by bending it over a shaped wooden block with the hands, finishing by gentle hammering with a repoussé or other flat-faced hammer, as in Fig. 6. The joint is afterwards brazed or silver soldered, and the work is then cleaned up. Finally it is polished, lacquered, or plated, whichever is found to be most suitable to it.

Fig. 3. Threading the saw for internal work.

Fig. 4. How the saw and work table are used.

Fig. 5. Filing the edges true with a jeweller's needle file.

Fig. 6. Shaping the ring on a wooden block, after which the joint is brazed or silver soldered, and the ring finished by polishing, plating, or lacquering.

PIER GLASS. Strictly speaking a pier glass is a mirror of such shape and size that it can be fixed between two windows, the name being due to the fact that the word pier in one of its senses means the wall space between two openings. Pier glasses were seen in the great houses of the 18th century, and often pier tables were made to match them. Their principal features were their size and the richness and elaboration of their carving and gilding. The phrase, however, is now used somewhat loosely for a looking-glass suitable for the dining room, drawing room, or one of the other reception rooms of the house. *See Cheval Glass; Dressing Table; Mirror.*

PIERIS. This is an evergreen flowering shrub belonging to the heather family. It bears panicles of white blooms in the spring and early summer months. It likes peaty soil, but will flourish in loamy soil which is free from lime. Planting should be done in September or in April-May. The hardiest kinds are floribunda and japonica, which grow 3-4 ft. high and flower in April-May. A more vigorous and less hardy kind is Pieris formosa, which is chiefly suitable for planting in mild districts. Little pruning is needed, but the shrubs should be clipped lightly when the period of flowering is over. Propagation is by seeds and layers.

Pieris, a hardy evergreen shrub with heather-like flowers in spring and early summer.

PIER TABLE. This is one of the several forms of the occasional or side table. The name was first given to a table designed to stand against a wall between windows, the reason being that the wall space there is sometimes called a pier. Seen in the more affluent houses of the 18th century, many of them had marble tops and were designed in the Louis style, although they were also made by the great English cabinet makers. Some of them were made to match the pier glass beneath which they were placed. To-day a pier table is a light table, the marble top having given way to a wooden one, made to stand at the side of a room. Its usual form is a reproduction of the antique example illustrated. *See Table.*

Pier Table. Antique example veneered with satinwood and other woods. English, about 1770-80. (By special permission of the Director, Victoria and Albert Museum. S. Kensington)

PIETRA-DURA. This is a form of Italian inlaid work in which marbles, agates, or other hard stones are inlaid in wood or marble and known as pietra-dura. Used in the decoration of furniture it is sometimes called Roman Mosaic, but should be distinguished from mosaic proper, which is embedded in cement.

PIGS AND PIGKEEPING

The Feeding and Housing of These Profitable Animals

Country readers, in addition to this contribution, may consult with advantage such articles as Duck; Goat; Poultry. See also Bacon; Ham; Pork.

It is essential that before entering upon pig keeping persons shall make themselves acquainted with the regulations of the local sanitary authority. These vary from place to place, being more stringent in urban areas than in rural ones.

Making a Start. When this matter has been satisfactorily settled, the next point to consider is the type of pig that should be kept. Before making a choice the pig keeper should decide whether he intends to breed from it or to keep it as a store or a fat pig; in the latter case he should decide whether he intends to convert it into pork or bacon. Whichever his intention may be, he is advised to select the breed or type of pig that is most popular in his district for the purpose for which he requires it. Whatever breed or cross is selected, it is advisable to choose the offspring of a well-bred dam of good conformation. It is also important that the sire should be purebred and that the sire and dam should not be too closely related.

Pig. Berkshire pig, a profitable breed, producing fine hams.

It is advisable to start pig keeping with a newly weaned pig, about eight weeks old, care being taken to secure as good a specimen as possible. An extra shilling or two spent on a good pig will be amply repaid. At the same time, the buyer should not devote too much attention to fancy points. Above all, he must have an animal with a vigorous constitution; a greedy, lusty fellow, active on his legs, lengthy and round in shape, with a clean and pliable skin, covered with a fine coat of soft, glossy hair.

Sow of the Middle White breed, a prolific variety that matures early.

Feeding the Pig. For several weeks after weaning the pig should receive its

food in a moderately sloppy condition, slightly warm if the weather is cold. The food should be easily digestible and may consist of potatoes, turnips, and other vegetables, together with table scraps and grease from the kitchen and a little middlings or sharps. The roots and vegetable matter should be boiled together and afterwards well mashed and mixed, the meal being incorporated at the same time. Water should be added, or preferably a little skim milk, to give the whole the consistency of gruel. A newly weaned pig will usually require about 2 lb. of food per day,

irrespective of added water, and, in the absence of milk, half the food should consist of middlings or similar material.

The young pig should be fed regularly three times a day, the amount of food being gradually increased. Caution is necessary in the use of kitchen waste, as such material frequently contains salt and soda in such quantities as to be highly prejudicial to young pigs. Dried blood, meat meal, fish meal, and linseed cake meal, all have a high content of easily digestible flesh-forming material, and are, therefore, suitable for feeding to young pigs, a little at a time only being given.

As the pig is naturally a grazing animal it is important that succulent vegetable food should form part of its food at all seasons of the year. The importance of feeding green fodders to young growing animals has been emphasized by research, which has shown that substances necessary to normal rapid growth, absent in the feeding stuffs generally given to sty-fed pigs, are present in green fodders. In the summer succulent green food is generally plentiful enough.

Young grass from the wayside, weeds from the garden, and similar material will all be picked over by a young, growing pig to its advantage. Tender young clover and lucerne are excellent green foods for pigs. Lucerne especially is valuable in that it is available early and late in the year, several cuts being obtainable annually. A small patch of ground could well be spared for this highly nutritious forage plant. Rape, vetches, and rye supply highly nutritious green food at times when such material is scarce. For the supply of the necessary succulent food in the dead of winter recourse must be had to potatoes, turnips, mangolds, sugar beet, artichokes, parsnips, etc. Of these, potatoes and sugar beet are the most valuable, 4 lb. of each being considered equivalent to 1 lb. of cereal meal.

For the first month or two the pig should be allowed a moderate amount of exercise. An occasional run outside its sty will tend to promote a healthy appetite and will also encourage growth. When the pig reaches about 100 lb. in live weight this should be curtailed, and feeding should be rather more forced. Wheat offals, accompanied by a little rice meal, maize meal, or barley meal, may be given more freely, and the supply of the more bulky vegetable food should be reduced.

The pigkeeper should note that the method of feeding pigs is most important, if the best quality meat is to be obtained. In a good carcass the flesh should be solid, of uniform consistency, and fine texture, evenly streaked with fat and lean, of a bright fresh colour, and not watery. The fat should be firm and white and remain hard at ordinary temperatures, while a thin, smooth and mellow skin is desirable.

To obtain the above qualities a proper food ration is necessary; anyone situated near milk, butter and cheese factories, who can obtain the waste by-products and use them with meal, has the ideal ration for producing good quality pork and bacon. An unbalanced ration consisting chiefly of oily foods, with maize and rice meal, produces dark coarse flesh and soft spongy fat. A suitable carcass for the fresh pork trade has the following characteristics:

Head, light and medium size. Shoulders, light and fine. Back, firm and level; ribs well sprung. Belly, straight underline; nicely lined with flair. Hams, plump, deep and well let down. Flank, thick and streaky. Bone, fine.

The Ministry of Agriculture give the following conformation which the Wiltshire bacon trade requires:

Back, long and level, with ribs well sprung. Sides, level and moderately deep. Hams, broad, wide and deep to hock; tail set high. Belly and flank, thick with straight underline. Shoulders, light and on a line with forelegs below, and with sides laterally; free from wrinkles and coarseness. Flank, alined with the sides. Head, neck and jowl, light. Legs, short and set apart; the pig should stand well up on the tips of the toes. Bone, fine. Skin, free from coarseness and wrinkles. Hair, fine.

The pork section of the National Federation of Meat Traders' Associations states, in summarising points to be borne in mind by pig breeders, that "Large and middle white and Welsh breeds, or pigs produced by crossing large black or Berkshire sows with these breeds, are suitable for the pork market. The boar should not be black, as the trade strongly objects to black porkers."

If carefully fed from the start a pig should weigh from 170 lb. to 180 lb. live weight when about 5 or 6 months old. It is then ready for killing. The dressed carcass should then weigh from 130 lb. to 140 lb. The amount of food required at this stage will be from 5 lb. to 6 lb. of meals or their equivalent each day. If kept alive beyond this stage the rate of increase gradually slackens, while the amount of food necessary to produce each additional lb. of pig becomes greater. Fat bacon and fat pork, however, are more useful as food than are their lean equivalents, especially in winter, and the person who only fattens one pig for his own use will be well advised to keep this factor in mind. He may prefer to feed his pigs to a heavier weight than 180 lb.

In the absence of straw, dried bracken, grass and leaves make a thoroughly satisfactory bedding for pigs. Every effort should be made to provide an abundant supply, especially in cold weather, when the pig prefers to curl up in bed, and is content with the minimum of exercise. When it is remembered that food is more expensive in winter than in summer, and that it takes more food in winter to produce, a lb. of pork, the supreme importance of comfort during the coldest season of the year is apparent.

Building a Piggery. The main essentials of a pigsty are comfortable and clean conditions. A dry bed, combined with suitable ventilation and the absence of draughts, promotes the general health of the animals, prevents chills and rheumatism, and minimizes the risk of disease.

The foundation must be dry and, if conditions permit, it should face south. Access to a small paddock is a distinct advantage. Openings in the wall and roof, through which the passage of air can be easily regulated, should be provided in order that the temperature may be kept as even as possible throughout the year. A close, stuffy atmosphere destroys the appetite and is as harmful as a cold sty. Provision for suitable lighting may be made either in the walls or in the roof.

A simple type of sty is illustrated in Fig. 1, which indicates the general arrangement of the structure. The total area occupied by the double structure is 15 ft. by 18 ft. The covered portion is 6 ft. from front to back, leaving an open space of 9 sq. ft. for each enclosure. Details of the outer walls and door as well as the brick floor to the pen are shown in Fig. 2. Such an erection provides accommodation for two sows and their litter. In this case the sty is located in the angle of a wall and the roof plate rests on the wall of the adjoining building. The same lines of treatment may be followed if the pigkeeper prefers to build an independent structure, when, of course, four walls will be needed.

The first step in construction is to mark out the ground with pegs and lines and excavate the top soil, digging a shallow trench, which is filled in with concrete and the top surface levelled off. The whole surface should be covered with concrete at least 9 in. thick. A fall is preferably arranged to the front of the pen and an outlet provided to any convenient drain; in its absence a sump should be built and drain pipes taken to a cesspool, or some other sanitary arrangements made for dealing with the liquid manure. When the concrete has set sufficiently, the walls may be put up, preferably in 9 in. work, but in the case of small pens it may be possible to utilize $\frac{1}{2}$ brick thickness, that is, walls only $4\frac{1}{2}$ in. thick, using strong cement mortar made of 1 part Portland cement and 2 parts sand. The brickwork should be continued to plate height and the roof furnished with stout rafters or other roofing material.

The floor should be floated off with at least 1 in. thickness of strong cement mortar, unless it is finished with regulation stable tiles. The surface should be brushed over with a stiff-bristled broom as soon as the cement is steady, or partly set, to roughen it, so that the pigs can maintain a sure

footing on it. A stout wooden rail raised on posts 9 in. high and 9 in. from the wall will prevent the sow crushing the young ones when she lies down. The walls are rendered with cement and finished with limewash as desired. A strong door of substantial pattern must be provided for at some part of the pen, and is needed for the covered part or house as well. Provision should be made for light and air in the way of small windows, which can be merely openings, or else they may be partially closed with wood shutters or with perforated metal. Pigs must not be kept in such a manner that they constitute a nuisance, and in most places there are by-laws which must be complied with by those who keep them.

Pigsty. Left. Fig. 1. An easily constructed pigsty in brickwork with a felt-covered timber roof. It is situated in the angle formed by two walls, and will provide accommodation for two sows and their litters. Right. Fig. 2. Same pigsty shown left, giving details of door, brick floor, surrounding wall, etc.

Cooking Hints. When pickled, dried and cured, pig's cheek is known as bath chap, but it is also sold simply pickled. Bath chap needs to be soaked before being cooked, but pickled cheek usually requires a thorough washing. Both are cooked in the same way.

Pig's Feet. There are various ways of cooking pig's feet, but broiling and frying are perhaps the best. To do this, wash two feet thoroughly, scraping the skin with a knife, then cut them in two and let them soak for about an hour in salted water. Wash them again in fresh water, tie them together and put them into a pan containing 1 pint water and $\frac{1}{2}$ gill vinegar which have been previously heated over the fire.

Boil up the whole, and after removing the scum from the top put in a small onion, a bunch of herbs, and salt to taste. Cover the pan and cook its contents very slowly until they are tender, then take out the feet, bone them and season them to taste. They can be eaten hot or cold. If they are to be fried, spread a little pork sausage meat over the cut sides of the flesh, and fit the pieces together again to form their original shape. Roll them lightly in flour, coat them with egg and breadcrumbs, and fry them in a pan of hot fat.

To broil, cook and bone them, brush them over with melted butter, coat with breadcrumbs, and cook over a clear fire. Apple sauce (q.v.) makes a good accompaniment.

Pig's Head. The most usual method of cooking this is to steep it in a salt pickle comprising 1 lb. salt and 1½ oz. saltpetre and then to boil it, and serve it hot with cabbage or beans; or to boil it in a cloth, press it between two weights, and serve cold.

For pickling, scald the head in boiling water for a few minutes, scraping off the hairs with a knife, then cut it open and remove the brains, eyes, and snout. Wash it thoroughly, leave it overnight in a pan of strongly salted water, and then rinse it in fresh water. Rub it all over with the salt mixture and leave it thus for about 6 days, turning and basting it daily. Before boiling, wash the head again to remove the surplus brine, then put it into a pan containing just enough water to cover it. Boil this up, removing any scum from the top, and then cook the head slowly until it is tender. Serve it garnished with the cooked tongue, skinned and neatly sliced.

To prepare the cold dish boil up a salted pig's head in a pan containing sufficient warm water to cover it, take the scum from the top, and then let the whole simmer for about 2 hours. When tender, take it out of the pan to cool, skin and slice the tongue, and split the head in two, removing the bones. Season it to taste, and on one half of the head place the slices of tongue putting the other half on top to form a sandwich. Tie the whole in a pudding-cloth, cook it again for the same length of time as before, and then press it between two weights, leaving it to get cold. It should then be served thinly sliced.

PIGEON. Anyone wishing to keep pigeons should think carefully before securing stock. The climate and the available accommodation must be considered. If one is living in a town many of the most beautiful and picturesque pigeons cannot be kept. Birds such as Fantails, Jacobins Trumpeters, Fairy Swallows, Muffed-legged Tumblers are sorry-looking objects when they are forced to live in the atmosphere of an industrial district like Manchester or Leeds, but in the open country they will do well.

Birds of delicate-coloured plumage and markings are also unsuitable for town life Dragoons, Antwerps, Snow Homers, Carriers, Scandaroons, and English Owls thrive best in the country. Of those which thrive in almost any climate may be mentioned Archangels, Tipplers, Flying Homers, Magpies, Nuns, Short and Long-faced Tumblers, Barbs, Turbits, African Owls, Pouters, Pigmy Pouters, Norwich and Holle Croppers, Brummers, Swifts and Modenas. The best breeds for a beginner to choose from are the short, hard-feathered birds such as Archangels, Long-faced Tumblers, Exhibition Flying Homers, Magpies, Nuns and Modenas.

Before deciding upon any particular breed the novice should visit one of the shows which are held in all parts of the country from September till February and select one which is the best adapted to the environment in which the birds will have to be kept.

Feeding the Birds. As to food, maple peas, tares, dari and wheat in equal proportions make good feeding for the smaller breeds. The larger ones may be given beans, and small maize in addition. Green food in the form of lettuce, cabbage or some of the succulent weeds found in the garden, chopped up fine and given in a bowl twice or thrice a week will be much appreciated. A handful of mixed small seeds and rice may be given as a tit-bit once a week.

The breeding season extends from February till July. It is unwise to prolong it, as it interferes with the proper casting of the feathers in the moulting season. Unless a bird moults freely its health will be impaired.

Young pigeons are cared for by their parents for the first month. After that the old birds leave them to themselves, and set about raising another family. A hen pigeon when she goes to nest lays her first egg at night, and the second about noon on the second day after. The period of incubation is 18 days.

Pigeon: Four breeds that are general favourites. 1. The nun, an attractive toy pigeon. 2. Norwich cropper, a pouter pigeon. 3. Homer or homing pigeon. 4. Mottled tumbler. (By courtesy of Pigeons and The Pigeon World)

The Pigeon House. Before purchasing any birds a house in which to keep them is needed. The papers devoted to pigeons contain advertisements of many such. The majority of pigeon keepers use home-made erections, chiefly because they can adapt the house to its surroundings. The best form of building for the purpose is a strongly made wooden shed built of 1 in. tongued and grooved boards. The roof should be covered, on top of the boards, with either galvanized iron sheets or asphalte felt. The outside walls may be covered with either tar or paint. The former is more lasting,

the latter more pleasing to the eye. Dark-green paint with the window and door frames in white is attractive. The inside should be painted light blue or whitewashed.

Each house should possess a wired-in aviary, or flight, extending the whole width of the front, and about 10 ft. or 12 ft. long. Stout $\frac{3}{4}$ in. wire netting should be used, which if tarred every summer will last many years.

If success is to be attained and a race of strong, healthy birds built up they must never be overcrowded. A shed 8 ft. by 6 ft. with a span roof 6 ft. 6 in. at the eaves will give accommodation for eight pairs of the smaller breeds or six of the larger. The floor of the house should be covered to the depth of 3 in. with coarse sawdust, which should be renewed frequently. It will last much longer if the droppings are removed from the top every week. The floor of the aviary should be dug out to a depth of 2 ft., and filled with broken bricks, or clinkers, to within 4 in. of the top. This should be covered with coarse sand, which should be rolled hard, the top swept or scraped every week, and the whole of the sand renewed every six months.

Ordinary bracket perches fixed to the wall will suit any of the breeds recommended to the beginner. Good nest boxes may be made from the ordinary sugar boxes which are sold by grocers. These should be laid on the floor. Glazed earthenware nest pans should be used. The box should contain sawdust to the depth of 1 in., and the nest pan also; short pieces of soft straw 4 to 6 in. long may be given to the birds for nesting material. Large open pans of earthenware or zinc are best for baths, and fountains for drinking water. Never let the birds drink the bathing water if it can be avoided. Drinking water should be given fresh daily. The bath water should be renewed twice a week. *See Dove.*

How to Cook. Wild or wood pigeons should always be roasted, but the house pigeon may be served in a variety of ways. When buying these birds, select those with comparatively small eyes, soft, red and tender feet, and necks covered with bright, neat-looking feathers of much the same colour as those on the rest of the body. The spurs of the male bird should be short and round.

To roast pigeons, pluck, draw and singe them, then wash and truss them. Leave the feet on, but scald and scrape them. Lay a shallot inside each bird, dust with pepper and salt then tie over the breast a rasher of fat bacon. Roast for 20 to 25 min., and baste frequently, using clear beef dripping or butter. Just before dishing, dredge the birds with flour, then baste and return to the fire or oven to finish cooking. Bread sauce and a good brown gravy should be served with them, and the stock with which the gravy is made should be flavoured with the giblets. If liked, roast pigeon may be stuffed with pigeon forcemeat.

To broil pigeons, split the birds down the back, spread them open, rub them with butter, season and broil them over a clear fire or under a gas griller. Before dishing, rub them once more with butter, sprinkle over them some chopped parsley and a few grains of cayenne pepper.

Pigeon Forcemeat. A good stuffing for pigeons can be made from the livers of these birds. Parboil 2 of these, chop and mix them with $\frac{1}{2}$ dessertspoonful chopped shallot, 6 dessertspoonfuls breadcrumbs and 2 oz. chopped fat bacon. Season the mixture with pepper and salt and a little grated nutmeg, and bind it with the yolk of an egg and, if needed, a little milk.

Pigeon Pie. Take 4 young pigeons and $\frac{3}{4}$ lb. rump steak, 4 oz. prepared and chopped mushrooms, 4 shallots, also peeled and chopped, 1 dessertspoonful chopped parsley, 2 hard-boiled eggs, and seasoning. Cut each bird in halves and fry the pieces sharply for 2 or 3 min. to colour them. Cut the steak into slices, roll them and dip them in pepper, salt, and flour. Lay them at the bottom of a pie-dish, then sprinkle over half the mushroom, parsley, and shallot. Arrange the pieces of pigeon over the steak, sprinkle on them the remainder of the mushroom, etc., and season.

The eggs must be cut in quarters and fitted in among the portions of pigeon; moisten with $\frac{1}{2}$ pint good stock. Cover with rough puff pastry (*see* Pastry) in the usual way, decorate the centre with pastry leaves, egg the top of the pie, and bake about $1\frac{1}{2}$ hours. Before serving, fill up the pie with gravy and replace the pastry ornament with the feet in the opening on the top of the lid. The feet of the birds should be scalded, scraped, blanched, and glazed with meat glaze.

Pigeon Ragoût. To make this ragoût, bone and stuff 4 pigeons with veal stuffing (*see* Force meat), but add to this 2 oz. chopped fat bacon and the chopped livers of the birds. Flour the pigeons and fry them a good brown in bacon fat. Then put them into a casserole, cover them with stock, adding 4 oz. prepared mushrooms cut in strips, 1 carrot cut in dice, and a sliced onion. Pour in a wineglassful port and a tablespoonful orange juice. Season to taste, boil up and stew gently about 1 hour. Garnish with croûtes of fried bread or of puff pastry.

Pigeon Soup. Make 2 quarts stock well flavoured with vegetable, and add the giblets of the birds to be used. Truss 4 old pigeons brown them in a frying-pan, using butter to fry them, and turning them in order to brown them all over. Drain them from the fat and add them to the stock, which must be ready boiling on the fire. Cook all gently for one hour, then remove them from the soup, skim it free from fat after straining it, and thicken it with brown roux. Serve with dice of fried bread. Fillets cut from the birds may be served in this soup, or the pigeons may be laid aside whole and used up for some made dish. If the soup is too pale, colour it with a little browning.

PIGEON BREAST. The serious deformity of the human chest, in which the ribs are flattened so as to throw forward the breast-bone, is known as pigeon breast. It occurs in rickety children who suffer from some bronchial affection, which prevents the free entrance of air into the chest, and is then due to the effect of atmospheric pressure on the softened ribs. *See* Rickets.

PIKE: The Fish. This large fresh-water fish requires careful cleansing or it is apt to retain its muddy flavour.

When the pike does not exceed 4 or 5 lb. in weight it is known as a luce or jack. Large pike are considered better than small ones. The flesh when cooked should look white and firm, but it will improve by keeping for about two days in a cool larder before it is dressed. The roe of the pike should be thrown away. When scaling the fish lay it on a dish in the sink and pour boiling water over it.

To bake a pike whole, choose a fish weighing about 8 lb. Wash, scale, and draw out the gills, trim off the fins, and then wash the fish again before wiping it dry. Fill it with a well-seasoned veal stuffing (*see* Force meat) and sew it up, then truss it in the shape of an S; score the fish each side in several places and lay it in a rather deep baking tin. Add not less than 6 oz. butter or clear beef dripping, 3 peeled and chopped shallots, 2 oz. prepared and chopped mushrooms, 1 small onion stuffed with 4 cloves, a bouquet garni, and $\frac{1}{2}$ pint good stock to which has been added a wineglassful of sherry. Cover the fish with a well-buttered paper and bake it for an hour in a good oven, basting frequently.

As soon as it is ready dish it, removing the trussing strings. Pour off from the pan all surplus fat and stir in $\frac{1}{2}$ pint stock. Have ready $\frac{1}{2}$ pint well-flavoured brown sauce, add it to the stock, mix all together and turn the whole into a stewpan, boiling it till it is reduced to the right consistency. Skim it free from fat or scum, add 1 oz. butter, a little anchovy essence, the juice of $\frac{1}{2}$ a lemon, 2 wineglasses sherry, and seasoning of cayenne pepper. Strain this sauce over and round the pike.

Cold Pike. Prepare the fish and truss it as in the preceding recipe, and then make the following broth: Fry for 10 min. in $\frac{1}{2}$ gill salad oil 2 onions and a carrot, both prepared and sliced, 2 rashers bacon cut in strips, a bouquet garni, 3 allspice, and 4 cloves, and when the vegetables are ready pour into the pan 2 quarts white stock, add some white wine if liked and 1 dessertspoonful salt. Simmer for an hour, and strain. Boil the fish in this until tender—about $\frac{3}{4}$ hour for an average sized fish. Let it lay in the broth overnight. Then drain it, remove the trussing strings, and dish it.

Coat it with mayonnaise sauce. A pike of 9 lb. is sufficient for from 10 to 12 persons. The fish may be reheated in the broth and served hot with tartare sauce. Like all fresh-water fish, pike is better boiled in prepared liquor than in water. The liquor need not be thrown away, as it can be used up for making fish soup or sauces. If kept more than three days boil it up again. *See Fish.*

PIKELET. These are sometimes known as Lancashire girdle cakes. The ingredients are $\frac{1}{2}$ lb. flour, $\frac{1}{2}$ teaspoonful salt, $\frac{1}{2}$ teaspoonful bicarbonate of soda, 1 teaspoonful cream of tartar, 2 teaspoonfuls castor sugar, one egg, $\frac{1}{4}$ pint water and $\frac{1}{4}$ pint milk. Mix flour and all dry ingredients, beat in yolk of egg, milk and water. Beat well, then fold in the stiffly beaten white of egg. Pour in tablespoonfuls on a hot greased girdle. Cook until brown underneath, then turn with a knife and brown on reverse side. Butter and serve very hot. If left to go cold before using toast them on both sides before a clear fire. *See Girdle.*

PILASTER. This term is used in architecture to describe a form of pillar partly embedded in a wall. It is a feature of many buildings, and examples are also found in shop fronts and as decorative features of chimney pieces and furniture. In panelled rooms symmetry is often attained by the use of a pilaster to balance some other feature; the face is panelled or moulded and carved to harmonize with the other decoration. *See Panelling.*

PILCHARD. The small salt-water fish known as pilchard somewhat resembles the herring in appearance and taste, but it is more oily and it has a fin in the centre of the back and not near the tail. Pilchards are caught in large quantities off the coast of Cornwall, and are in season from the middle of July till the end of November. They deteriorate rapidly after being caught, and usually are at once salted and kept in barrels or tinned in oil.

Pilchards may be cooked according to most of the methods employed for herrings, and in some parts of Britain they are made into pies. They must be soaked overnight and then placed in a pie dish with alternate layers of leeks and covered with short pastry. Bake about 30-40 min. *See Herring; Pastry.*

PILE: In Textile Fabrics. Velvet and velveteen are cloths with comparatively short pile, whereas plush has a longer pile. Other pile fabrics are in common use, one of them being Turkish towelling, in which the pile consists of loops. The imitation fur fabrics, such as astrakhan, are piled, and so are many carpets. In Genoa velvet, as used in furnishings, there are two heights, and often colours, of pile forming a decorative pattern. Pile fabrics are generally warmer than cloths made without pile. The wear comes not on the sides but on the ends of the fibres, and for this reason properly made pile goods are durable. A beauty, depth, and richness are obtained for carpets, furniture and hangings in velvet piles which cannot be obtained in non-piled materials. Pile surfaces have their disadvantages, for sometimes their surface is a clinging one, and they harbour dust. The pile can be pulled out of new carpets by careless use of carpet-sweepers. The longer the pile in fabrics of any kind the greater is its tendency to become laid. *See Carpet; Velvet.*

PILES. Congested and varicose conditions of the veins at the lower ends of the bowel are the cause of piles. There are two varieties, external and internal, but both may be present.

Anything which produces an obstruction in the circulation of the blood in the abdomen is a predisposing factor. Constipation is one of the most frequent causes. Congestion of the liver acts in the same way, and piles are common in beer and spirit drinkers, and also in those who eat largely, or live a sedentary life. Sitting on the grass, a stone or a cold seat may bring on an attack by chilling.

External piles form dark brown folds of skin running out from the anus. They are soft, but when filled with blood large and hard. Friction and want of cleanliness may cause them to inflame. With internal piles the first symptoms may be a little bleeding. As a rule, they give no pain, but cause a sensation of fullness in the bowel, and they may cause straining at stool.

Constipation must be prevented. Eat wholemeal bread, stewed prunes, apples, and other fruits, and plenty of vegetables. Violent purgatives of any kind are bad, while aloes are particularly to be avoided. Regular, moderate exercise should be taken, the best form being a brisk walk of two miles a day. The sufferer should take great pains to avoid much standing about and cold feet; he should never sit on the ground or on a cold seat; he should take little or no alcohol, strong tea or coffee. Another important rule is to keep the affected parts perfectly clean by washing and sponging. When piles become inflamed the patient should keep his bed and send for the doctor.

When the acute stage of the inflammation has passed off, the official ointment of gall and opium may be used applied on lint, or witch hazel ointment. When internal piles come down or prolapse at stool, they should be gently pushed back with the fingers. Should bleeding occur thoroughly smear a small plug of cotton wool with witch hazel ointment and gently push it into the bowel.

PILLAR. In architecture a pillar is a rigid upright support capable of standing alone and supporting an object or part of a building. Pillars may be employed for a portico or entrance porch, for a pergola, or as part of the structure of a house. Pillars have a definite decorative value, and the architect employs them in this way as well as to perform some useful purpose. Unlike a column, a pillar does not of necessity conform to any defined rules of proportion or period, but the characteristics of the recognized periods of architecture are generally taken as the basis in preparing a design. *See* Porch.

PILLAR ROSE. This term is used to distinguish varieties of climbing or rambling roses which are suitable for training on poles or pillars from 6 to 8 ft. in height. For the taller pillars some of the rambler roses are suitable: Minnehaha, Hiawatha, Lady Gay, Sander's White, Lady Godiva, Blush

Rambler and Dr. Van Fleet. Some of the best climbing roses for pillars 6 ft. or more high are Scarlet Climber, Mme. A. Carrière, Lemon Pillar, Climbing Ophelia, Climbing Lady Hillingdon and Lady Waterlow. *See* Rose.

Pillion Seat. Fig. 1. Lycett seat with back rest.

PILLION SEAT: On Motor Cycle. This is an auxiliary seat attached to the carrier at the rear of a motor cycle or side car combination. Two types are here illustrated. It is against the law to carry more than one passenger on the pillion seat of a motor cycle, and the person carried must sit astride on a properly secured seat. This law does not apply to a motor cycle with side car. Side saddles may

be used only when a motor cycle is attached to a side car.

The holder of a provisional driving licence on a solo motor bicycle cannot take as a pillion passenger anyone who has not either held a driving licence for at least two years or passed the driving test. *See Motor Cycle.*

Fig. 2. Another type with adjustable folding foot rests.

PILLOW. The ordinary pillow is made of goose feathers or of down, enclosed in a cover or tick of white fustian, which must be firmly and strongly sewn, so that no feathers can escape. A pillow requires to be unmade, stoved, picked over, and remade from time to time; but this need not be done so often if it is sewn into a plain linen underslip, and kept thoroughly well shaken and beaten.

Down pillows are nearly twice as expensive as good feather pillows, but they have the disadvantage that they are very hot, and many people like them to be replaced in summer by feather pillows. The ordinary English pillow is oblong in shape, about 27 in. by 18 in. But the square pillow, which may be as large as 27 in. by 27 in., is most comfortable if it is used with what is known as a wedge bolster. This is like a tiny mattress, about 5 in. deep at the back and sloping down to about $\frac{1}{2}$ in. in front.

Children must have pillows thinly filled, so that the head is only very slightly raised. Low pillows are better for adults, too, and the modern tendency to do away with the bolster is a recognition of this.

Pillow Case. Pillow cases, or, as they are sometimes called, pillow slips, are obtainable in cotton and linen. Linen is much the best, for it not only wears and washes extremely well, but is smoother and cooler, and therefore more comfortable than cotton. The cases vary in size, so that before buying a pillow case the pillow it is to cover should be measured. If a pillow case is too small the pillow will be hard and unyielding; if it is too large the pillow will be untidy.

Frequently the slip is a plain bag, fastened at one end with linen buttons or tapes. It may be decorated with a hemstitched border or a frill, or with lace and rows of hemstitching. Unless for fancy pillows for day time use or ornament, embroidery should be absent or kept to the corners of the case only. When making a pillow case, it is best not to fasten the buttons directly to the end, but to make a flap of double material, about $2\frac{1}{2}$ in. wide, that will fold down over the end of the other side of the pillow. The buttons are then sewn inside the flap, so that they are invisible when the case is fastened. *See Linen; Quilt.*

PILLOW LACE. Lace made with many threads on a cushion or pillow is popularly known as pillow lace. This term is somewhat misleading and such handmade lace is more correctly termed bobbin lace, as many needlepoint laces, in which a single needle and thread are used, are made on pillows. *See Lace.*

PILOCEREUS. This is a genus of greenhouse cacti, without leaves, and with fleshy, spiny stems. A familiar example is old man cactus. The genus properly is classified under the name *cereus*. *See Cactus.*

PILOT CLOTH. Other colours can be had, but pilot cloths are commonly blue. They are heavy woollens intended originally for pea-jackets, such as ship pilots wear as a protection from wind and rain.

The cheaper kinds are thick but hard, and in looking at them carefully the blue colour is seen to be cloudy and lighter on the surface of the short nap than in the body of the material.

PIMENTA. This evergreen shrub needs greenhouse treatment as far as Great Britain is concerned. Bearing white and red flowers in early summer, *Pimenta acris* is vigorous and needs a lot of space. It should be pruned in the spring, and propagation is by cuttings.

Pimento Pepper. This is an alternative name for Jamaica pepper, better known as allspice (q. v.)

PIMPERNEL. One of the prettiest of British wild flowers is the scarlet pimpernel (*Anagallis arvensis*), a common weed in gardens. Of others grown for their decorative effect in flower beds and borders the prettiest are *Anagallis linifolia*, of which the varieties *Parksii*, red, and *Phillipsii*, blue, are the best. They grow only about 6 in. high and are useful edging plants. Seeds are sown under glass in April and the seedlings are planted out of doors in May. The bog pimpernel (*Anagallis tenella*) is a pretty pink-flowered trailing plant suitable for moist places in the rock garden or bog garden.

PIMPLE. Papules, which are small, solid prominences of the skin, are popularly called pimples. They vary in shape, and may be pointed, round, or flat on the top. Common examples are the eruptions of chicken-pox, acne, and boils in their earliest stages. They should not be rubbed. In many cases a little boric ointment removes pimples, but more energetic treatment may be necessary.

PINCERS. An indispensable tool in the home is a pair of pincers for pulling out nails and other purposes. The ordinary type has a pair of broad jaws and two handles, one with a knob and the other with a fork or claw end. This is inserted under the head of the nail and used to prize it up sufficiently to enable the jaws to get a firm hold under the head, after which the pincers are closed together and pressed over sideways, thus withdrawing the nail, which may subsequently be pulled out. The cost of a good tool is so little that it is worth while to get a really serviceable and well made pair of pincers.

Types of pincers, the upper pair being a shoemaker's tool, the lower ordinary carpenter's pincers.

Shoemakers' pincers have grooved and serrated jaws, with an upstanding block formed on one of them. They are employed for pulling leather into shape, and the block is used to get a good pull, being rested against some firm part to obtain a good purchase.

PINCHBECK. From its resemblance to the precious metal, pinchbeck has been popularly termed Brummagem gold. It was to the men and women of the 18th and early 19th centuries what rolled gold and gold filled articles are to those of to-day, with this difference, that the supply was much more limited. Consequently, it has a distinct value to the collector of antique jewelry.

Modern inventions, such as gold-filled products, have superseded pinchbeck in Great Britain, but a variety of it is in use in Switzerland and other continental countries, for cheap jewelry and articles made to imitate gold.

The collector should beware of the modern imitations of old pinchbeck, many of which are difficult to distinguish from the genuine article, but, as a rule, are not so carefully made and are distinctly inferior in artistic quality. Examples of old pinchbeck that are worth acquiring include snuff-boxes and patch-boxes, with slips of onyx or agate forming the top and bottom; vinaigrettes, various kinds of buckles, bracelets, and other articles of jewelry set with tortoiseshell, mother-of-pearl, amethysts or topazes. Ring and jewel caskets can occasionally be picked up which are a valuable addition to any collection; these are beautifully ornamented with agate, onyx, cairngorm, or lapis lazuli. *See Jewelry.*

PINCHING. This is a gardening term which means cutting off or pinching off the tips of shoots or branches to force the development of others and thus ensure well-branched trees or plants. *See Pruning.*

PINCUSHION. The simplest form is a little bag stuffed with bran and sewn up at the end. Bran is the best material to use, as it is much lighter than sawdust and has not its tendency to absorb damp. The covering material should be strong and closely woven, so that the pinheads cannot pass through and the bran cannot come out through the pinholes. For this reason it is always best to make a bag for the bran, then to cover it with another material such as silk or velvet and edge with a narrow cord. The daintiest dressing table pincushions have detachable, washable covers of embroidered muslin, the cushion being covered with pink, blue, or mauve satin.

PINCUSHION FLOWER. This is the old name for scabious, a plant much in demand for cutting purposes. There are annual, biennial, and perennial kinds. The finest of all is the Caucasian scabious, which is popular not alone for garden decoration, but as an exceedingly beautiful florists' flower. *See Scabious.*

PINE. The word is often used loosely to describe various cone-bearing trees, but correctly it is the popular name of those contained in the genus *Pinus*. Some of the pines are of great value as a windscreen for the protection of choicer trees and plants: they are particularly useful for planting in exposed sea-coast gardens. They are evergreen and rather slow growing.

It is wise to plant small trees about 2 ft. high, for they become established more quickly than larger ones. The Austrian pine (*Pinus laricio nigricans*) is a most valuable windbreak tree. *Pinus insignis*, which is chiefly suitable for mild districts is also a good shelter tree. The most familiar of all is the Scots pine, *Pinus sylvestris*, a tall handsome tree which reaches a height of 80 ft. or more and will thrive in very exposed places. It furnishes the timber known as deal.

Some of the pines are suitable for planting as ornamental lawn trees in large gardens. One of the most distinct is the umbrella pine (*Pinus pinea*), a flat-topped tree of distinctive growth which can be recommended for gardens in the milder counties. Others are the blue pine (*excelsa*), with grey-green leaves, and the Corsican pine (*laricio*), which flourishes in poor soil. The pines are propagated by seeds sown out of doors as soon as they are mature.

Uses of the Wood. The name pine is applied to several varieties of timber, the produce of trees which grow extensively in Europe and N. America. The Scots fir, which is common all over the north of Europe, is called northern pine, or red, yellow, or white deal, according to its character. It is the wood commonly used in carpentry, in house-building, for outdoor work and rough work

generally. It is cheap, not heavy or difficult to work, and durable, varying in character according to locality and conditions of growth.

Other varieties of pine come from North America, an important one being yellow pine. It is a pale honey-yellow in colour, light, soft, straight-grained and uniform in texture, easy to work, has very few knots, and shrinks and warps very little. For these reasons it is the wood preferred by pattern-makers. It is not employed for outdoor work, but in joinery and cabinet-work it is the best kind of softwood, and in furniture it often forms a ground for veneer. Mouldings, panels, and frames are made of it.

Another American wood is pitch pine, highly resinous, strong, and heavy; and is therefore much used for piles, struts, and the like. Reddish-yellow in colour, it has strongly marked annual rings that show as alternating light and dark streaks in the grain, sometimes with a wavy figure, and is rather difficult to work owing to its resinous character. Being clean and attractive when varnished, it is sometimes used for bedroom furniture and also for flooring purposes. In general, however, it is unsuitable for indoor work, especially when close joints are needed, as it shrinks badly. Pitch pine takes varnish much better than it does paint. *See Deal; Wood.*

PINEAPPLE: How to Grow. Mainly owing to the great quantities of this fruit which are imported the pineapple is now rarely cultivated in Great Britain, although for delicacy of flavour the home-grown pine is unsurpassed. The best method of cultivation is to prepare a bed 3 ft. in depth of fresh leaves in a deep garden frame or pit, which is heated, cover the leaves with a 12 in. layer of loamy soil, and plant the pines in this at about 2½ ft. apart. Considerable artificial warmth is required; the winter temperature should be about, 65 degrees. If only a few plants are grown they should be potted in large flower pots 10 in. or 12 in. in diameter. Propagation is easily effected by suckers or offshoots, which, if potted and kept in a moist hothouse, will form roots. The leafy top of a ripe fruit may be made to form roots in the same way.

The botanical name of the pineapple is *Ananassa sativa*. A variety named The Queen is best for cultivation under glass in Great Britain. (*See Greenhouse*)

Serving the Fruit. To prepare the fresh fruit for the table, cut it into slices with a silver or stainless knife and cut off the rind, taking care to remove all the woody part. When canned, pineapple retains much of its flavour, and can be served alone with the syrup poured round it, mixed with other fruits to form a compôte or fruit salad, or cut up to make pineapple flans, fritters, etc. Crystallized or glacé pineapple may also be bought in rings or chunks.

Pineapple jelly is made as other table jellies. For fritters this fruit is used either fresh or tinned, and the batter is the same as that given in the recipe for Apple Fritters (q.v.). Tinned pineapple is used for a flan. It can also be used as a filling for turnovers and tartlets and to decorate small cakes or layer cakes though glacé pineapple is more often used for cakes.

Pineapple Cup. Peel a small pineapple and cut it in thin slices. Sprinkle it well with castor sugar and let it stand 6 hours. Put the trimmings of the fruit into a bright stewpan, cover them with cold water, and then boil up, skim, and simmer them till the flavour is extracted. Strain this essence over the fruit, add the juice of 2 oranges, 6 oz. castor sugar, and 1½ pints white burgundy. Stir and then cover over, and keep in a cold place. When required add a syphon of soda or seltzer water.

Pineapple Mould. Mix a dessertspoonful chocolate powder to a smooth paste with a little milk taken from ½ pint; boil up the remainder of the latter and stir it into the chocolate. When it has cooled slightly, add it to a beaten egg, strain the whole into a jug placed in a saucepan of cold water

planting in the bog garden or moist spots in the rock garden. One of the prettiest of these flowers is *grandiflora*, with violet-blue flowers; the blooms of *alpina* are white marked with yellow. The leaves are hairy and secrete a fluid to trap small insects.

PINHOLE PHOTOGRAPHY. A minute hole in a light-tight box forms a substitute for a lens. The apparatus is simple, and no focussing is required. It may easily be improvised for testing purposes from any rectangular light-tight box at one end of which is fitted a very thin metal plate, such as a piece of copper foil, and at the other a photographic plate kept in place by a clip. A small hole is made in the copper foil with the point of a needle, and kept covered until exposure is made.

The late Alfred Watkins, of Hereford, prepared a table for sizes of pinholes based upon the use of sewing-needles which are standard in size; metal disks pierced with standard-size holes for pinhole cameras can be obtained from dealers which can be fitted into the ordinary camera in place of the lens. While the distance between the hole and the plate does not affect focussing, it does affect the size of the image thrown on the plate, the greater the distance between hole and plate the larger the image.

The sizes of holes to give the best definition for any particular distance between hole and plate, and a means for calculating the approximate exposure, are given in Mr. Watkins' table as follows:

Needle	Diameter	Best Distance	Calculate Exposure
No.	in.	Hole to Plate	as for
1	1/22	40	f/96 x 60
4	1/28	20	f/80 x „
5	1/31	15	f/75 x „
7	1/39	10	f/60 x „
8	1/44	8	f/56 x „
10	1/54	5	f/40 x „
12	1/62	3½	f/35 x „

Thus, if the pinhole is to be used in an ordinary camera with a total extension of 8 in., the hole should not be made with a needle larger than No. 8. The actual exposure is then calculated by referring to an exposure meter or table. Having calculated the exposure according to the speed of the plate and actual lighting conditions at the aperture or f/No. given in the table for the size of pinhole in use, it is multiplied by 60, the resulting exposure being in seconds.

Alternatively the figure obtained may be reckoned as minutes. Thus, for instance, on a bright summer day, using No. 8 pinhole, the meter may give sec. for f/56; this is reckoned as ⅓ min., or 20 sec. The hole made by the needle must be perfectly clean, and any burr made in piercing the foil carefully rubbed down with emery paper or file. Only in a very bright light can the image be seen on a focussing screen. Therefore a good view finder is essential.

The larger the plate used in a pinhole camera the larger the angle of view, and this property makes the pinhole very valuable in cramped places, such as buildings in narrow streets or interiors where it is impossible to get sufficiently far away with an ordinary camera to include the whole subject. For landscape purposes with an ordinary lens the angle of view may vary from 20° to 50°. With a pinhole it may be anything up to 100°.

Another useful property of the pinhole camera is that its image is mathematically correct, and may be used for calculating heights and distances. The size of the image depends upon (1) the size of the object; (2) distance from object to pinhole; and (3) distance between plate and pinhole. It is directly proportional to (1) and (3) and inversely proportional to (2), so that if two qualities are known the

over the fire and cook it until the custard thickens. Then take it from the pan, add 3 dessertspoonfuls castor sugar, and leave it to get cold.

Rub the contents of a small tin of pineapple through a sieve, and mix the pulp with the chocolate custard. Put $\frac{1}{2}$ oz. leaf gelatine in a saucepan with $\frac{1}{2}$ gill pineapple syrup, let it dissolve slowly, and then strain it into the whole. Pour the mixture into a wet border mould, leave it to set, and after turning it out fill up the centre with a gill of stiffly whisked cream sweetened and flavoured to taste.

Pineapple Pudding. To make pineapple pudding, 3 oz. crystallized pineapple should be used, but the fresh or tinned fruit will do quite well if the juice is drained away. Put into a stewpan $\frac{1}{2}$ pint milk with 3 oz. sugar, and as soon as it comes to the boil draw it back from the fire and stir in quickly 4 oz. fine sifted flour, then return it to the heat and beat it well. As soon as the paste ceases to adhere to the saucepan it is done. Let it cool slightly and mix in the well-beaten yolks of 3 eggs, add also the pineapple, chopped, and then fold in the whipped whites of the eggs. Pour it into a buttered mould and steam for $1\frac{1}{4}$ hours. Serve it with sweet sauce. If crystallized pineapple is used, flavour the sauce with a few drops of pineapple essence. If fresh or tinned fruit, make the sauce with the juice or liquor in the tin. *See* Fruit Salad; Marmalade; Salad.

PINEAPPLE FLOWER. Alternatively known as *Eucomis*, the pineapple flower, which belongs to the order Liliaceae, is a half-hardy bulb, succeeding in sandy loam in a cool house. As a rule it is grown only in pots in the greenhouse, but in mild districts and in sheltered positions it will sometimes do well out of doors. It reaches a height of about 2 ft., and flowers in August. Propagation is by offsets in spring. The species *punctata*, green and rose, is usually grown.

Pineapple Flower, a bulb suitable for pot cultivation.

PINE WEEVIL. Sometimes known as the conifer beetle, this is a pest which devours the bark of such trees as pine, firs and spruce. Eggs hatch out into fleshy white larvae, about $\frac{1}{2}$ in. long, pupating in autumn, and emerging as weevils in June. All old stumps of the trees mentioned should be cleared away and all branches of infested trees well shaken to cause the pests to fall upon sheets of paper spread beneath; they are then collected and burnt. *See* Insecticide.

PING PONG. This game is an indoor form of lawn tennis. Rules were drawn up and an association formed, but after a time the game began to be called table tennis. The ping pong association was therefore dissolved and the game is now governed by rules drawn up by the Table Tennis Association. *See* Table Tennis.

Pinguicula alpina, a hardy perennial bearing yellow-tipped, white flowers, suitable for the bog garden.

PINGUICULA. Butterwort is the common name of this group of low-growing hardy plants. They form rosettes of leaves, bear violet-like flowers on slender stalks in May and are suitable for

planting in the bog garden or moist spots in the rock garden. One of the prettiest of these flowers is *grandiflora*, with violet-blue flowers; the blooms of *alpina* are white marked with yellow. The leaves are hairy and secrete a fluid to trap small insects.

PINHOLE PHOTOGRAPHY. A minute hole in a light-tight box forms a substitute for a lens. The apparatus is simple, and no focussing is required. It may easily be improvised for testing purposes from any rectangular light-tight box at one end of which is fitted a very thin metal plate, such as a piece of copper foil, and at the other a photographic plate kept in place by a clip. A small hole is made in the copper foil with the point of a needle, and kept covered until exposure is made.

The late Alfred Watkins, of Hereford, prepared a table for sizes of pinholes based upon the use of sewing-needles which are standard in size; metal disks pierced with standard-size holes for pinhole cameras can be obtained from dealers which can be fitted into the ordinary camera in place of the lens. While the distance between the hole and the plate does not affect focussing, it does affect the size of the image thrown on the plate, the greater the distance between hole and plate the larger the image.

The sizes of holes to give the best definition for any particular distance between hole and plate, and a means for calculating the approximate exposure, are given in Mr. Watkins' table as follows:

Needle	Diameter	Best Distance	Calculate Exposure
No.	in.	Hole to Plate	as for
1	1/22	40	f/96 x 60
4	1/28	20	f/80 x „
5	1/31	15	f/75 x „
7	1/39	10	f/60 x „
8	1/44	8	f/56 x „
10	1/54	5	f/40 x „
12	1/62	3½	f/35 x „

Thus, if the pinhole is to be used in an ordinary camera with a total extension of 8 in., the hole should not be made with a needle larger than No. 8. The actual exposure is then calculated by referring to an exposure meter or table. Having calculated the exposure according to the speed of the plate and actual lighting conditions at the aperture or f/No. given in the table for the size of pinhole in use, it is multiplied by 60, the resulting exposure being in seconds.

Alternatively the figure obtained may be reckoned as minutes. Thus, for instance, on a bright summer day, using No. 8 pinhole, the meter may give sec. for f/56; this is reckoned as ⅓ min., or 20 sec. The hole made by the needle must be perfectly clean, and any burr made in piercing the foil carefully rubbed down with emery paper or file. Only in a very bright light can the image be seen on a focussing screen. Therefore a good view finder is essential.

The larger the plate used in a pinhole camera the larger the angle of view, and this property makes the pinhole very valuable in cramped places, such as buildings in narrow streets or interiors where it is impossible to get sufficiently far away with an ordinary camera to include the whole subject. For landscape purposes with an ordinary lens the angle of view may vary from 20° to 50°. With a pinhole it may be anything up to 100°.

Another useful property of the pinhole camera is that its image is mathematically correct, and may be used for calculating heights and distances. The size of the image depends upon (1) the size of the object; (2) distance from object to pinhole; and (3) distance between plate and pinhole. It is directly proportional to (1) and (3) and inversely proportional to (2), so that if two qualities are known the

third is easily calculated. Thus, to find the size of an object, the distance (2) being known, multiply the size of the image on the photograph produced by the camera by (2) and divide by (3). If the size be known and the distance required, divide (1) by the size of the image and multiply by (3). *See* Exposure: F/Numbers; Lens.

PINION. A small cog wheel that engages with another cog wheel usually of a greater diameter is termed a pinion, and is constructed of either steel, cast iron, brass, phosphor bronze, or even vulcanized fibre.

Apart from its use in transmitting rotary motion the pinion is extensively used in conjunction with a rack, as for example in the focussing arrangement of a microscope. Very small pinions, such as are used in clock and watch making, are generally machined from pinion wire, which is manufactured in lengths, diameter, tooth sections, and numbers of teeth according to requirements. *See* Gear.

PINK. The pink is one of the most delightful of all the old-fashioned garden flowers and unsurpassed as an edging plant for beds and borders. Its grey leaves are attractive all the year round, and it yields a profusion of fragrant flowers in spring. There are two chief classes, the border and the alpine or rock garden pinks. The border pinks flourish best in well-drained rather light soil; clayey soil can be made suitable by adding leaf-mould, sand and grit. Planting may be done in autumn or spring.

Pink: two beautiful varieties. Left, fine flowers of Dianthus Herbertii: right, blooms of the variety known as Queen Mary.

Propagation is by cuttings taken in June or July and inserted in sandy soil out of doors and covered with a bell glass or handlight. In four or five weeks the cuttings will be rooted and the covering can be removed; they may be planted out in autumn. Two kinds of cuttings are

used—the piping, which is the top of a shoot pulled put, and the ordinary cutting, 3 in. or so long, made by severing the shoot just beneath a joint and removing the lowest leaves. Pinks can also be increased by layering. The double white, named Mrs. Sinkins, is still the favourite border variety but others are listed in catalogues. There are some beautiful flowers in the Herbertii strain of pinks. The old laced pinks are seldom grown now, but varieties may be obtained from specialists.

In recent years the perpetual flowering or Allwoodii pinks have been raised and have become very popular. There are many named varieties in rich and varied colours. They are increased by cuttings or by layering in summer. Border pinks are very easily raised from seeds sown in boxes of light soil in a frame in May; the seedlings will be large enough to plant out of doors in autumn.

The alpine pinks are exquisite rock garden flowers suitable for planting in gritty soil in sunny places. The most popular of all is the Cheddar pink (*Dianthus caesius*), which forms a wide low tuft of leaves and bears small rose-coloured blooms in June. The Maiden pink (*Dianthus deltoides*), carmine rose; the alpine pink (*alpinus*), rose; fragrans, white; and the glacier pink (*neglectus*), rose red, are other beautiful sorts. *Alpinus* and *neglectus* are the most difficult to manage successfully;

they need thorough drainage and gritty, loamy soil containing lime. These two, together with glacialis, should be tried in the moraine. *See* Border; Carnation.

How to grow Pinks. 1. Layering an old plant; a, fine soil over layers. 2. Rooted layer. 3. Same transplanted to shallow drill with sand at base. 4. Cutting or piping. 5. Same prepared with leaf tips removed (b) and properly planted; a, very sandy compost. 6. Propagation under handlight; a, fine sandy soil; b, sand; c, soil; d, crocks; e, handlight; f, box.

PINKING. Pinking is a good method of finishing the edges of material that is not suitable for the usual double turning. The edge is scalloped in small triangles or halfdiamond shapes. This is done to prevent the material from ravelling along the raw edge, and to neaten the appearance.

To pink an edging, ordinary sharp scissors may be used. A line of tacking should be run along the edge where the head of the scallops is to lie, or a scalloped transfer can be ironed on to the material to act as a guide. The material should then be folded between each scallop, and a slanting cut made to the depth required or to the line of tacking. If the pinking is to be carried out on oilcloth or leather, the points can be faintly drawn in with chalk or pencil.

PINS AND NEEDLES. The prickling sensation, popularly termed pins and needles, is one form of paraesthesia, or a disturbance of sensation, which may be experienced on parts of the body in nervous and other diseases. These may be due simply to debility, and an iron tonic may cause their disappearance.

Pint. This measure is used for milk, beer, and other liquids. It consists of 4 gills, and 2 pints make a quart.

PINTAIL: The Duck. A pintail is a type of wild duck that derives its name from its long, pointed tail. It is almost invariably roasted, and, except for the fact that the feet are usually left on, it should be prepared and trussed in the same way as an ordinary duck. About 20 min. is the time required for roasting, and because the flesh of the pintail is rather dry it should be basted frequently. Serve it with some sharp sauce and garnish it with watercress and cut lemon. *See Duck.*

PIP. The kernel or seed of fruit, as of an apple, pear, or cherry, is known as the pip. Although plants and trees may be raised from pips the process is not advocated for practical purposes, because most of the seedlings would be worthless, and the trees are slow in reaching the fruit-bearing stage unless budded on other stocks. For those who nevertheless desire to experiment in the propagation of fruit from pips the following information will be useful.

For apples and pears the pips may be sown when fully ripe, in pots of sandy loam, and placed in a cold frame. Watering must be very moderate until the seedlings have grown 3 or 4 in., and then they are transplanted to open ground. Further periodical transplantings will be required as the trees increase in size, and they will probably bear fruit in 6 to 10 years after the original sowing. Apricots, cherries, damsons, and plums, as well as apples, pears, peaches and nectarines, may be raised in a similar manner. Amongst other fruits likely to give results from pips are raspberries and strawberries. *See Apricot; Cherry; Pear.*

PIPE: For Smoking. Wood of various kinds is used in the manufacture of pipes. Briar is the favourite, but Australian myall-wood, ebony, cherry, and other kinds of wood are also employed. A good pipe is made from thoroughly seasoned wood, and the harder it is the better. It should have a nice straight grain, without knots or flaws of any kind. The colour varies from rich shades of chestnut or walnut, with a tinge of red, to the glossy black, which many smokers prefer.

For the mouthpiece vulcanite, made or finished by hand, is the material chiefly used. A silver band or mount at the end of the stem is a customary ornament.

Regular smokers usually keep one or two good briars for everyday use, reserving the meerschaum, should they possess one, for occasional enjoyment together with such varieties as the cherrywood or the corn-cob. The two latter are amongst the cheapest and simplest types, consisting of the hollowed-out bowl of cherrywood or cob, into which the stem is thrust. Patent varieties are on the market, the object of which is to collect or get rid of liquid accumulations of nicotine.

When smoking a pipe for the first time, shred some tobacco well and pack about a third of a charge smoothly and evenly in the bowl, being careful not to ram it right down to the bottom of the pipe. Light the tobacco carefully, making sure that the whole top of the surface is aglow, and smoke it indoors, very slowly. If the tobacco burns down one side, as a result of bad packing or a strong draught, the new wood is bound to suffer from the unequal distribution of the heat. It will suffer equally from excessive heat developed by too rapid drawing at the pipe. A new pipe should be cleared gently of all unconsumed tobacco each time it is smoked. Never refill and relight it; nor, indeed, any pipe while it is still hot from a previous smoke.

A pipe should not be knocked against the heel or the hob or mantelpiece, or, when out of doors, on a wall or post or railing, to get rid of the unconsumed residue of tobacco, as this very often results in cracking the pipe. All such remaining tobacco should be removed by scraping it out gently with the blade of a pocket-knife. *See Tobacco.*

PIPE: For Gas, Water, Steam. Pipes of all kinds play an important part in the home. Water is brought into the house through a lead pipe and taken to a cistern or receptacle in the roof. When it is

intended to fit a hot-water supply the pipe is generally of iron and may be plain or galvanized, the latter resisting the attack of rust. In some cases the water is supplied through a copper pipe, especially in connexion with hot-water supply in districts where the water has a corroding action on iron. Gas is conducted through a rough iron pipe known as gas-barrel, which is made of wrought iron and is measured by the nominal bore of the pipe. Thus a $\frac{1}{2}$ in. gas pipe means that the pipe measures $\frac{1}{2}$ in. internal diameter, while the outside is about $\frac{3}{4}$ in. diameter. Hot water barrel and steam pipe or barrel, stronger varieties, are measured in the same manner.

In contradistinction to gas-barrel, brass and copper pipes are measured by the outside diameter and are purchasable in various thicknesses or gauge sizes.

The higher the number the thinner the tube; a normal thickness for gas fittings is No. 16 gauge, nominally $\frac{1}{16}$ in. thick. This class of pipe is made in two grades. The one most generally used is made with a seamed or brazed joint; a superior tube is known as seamless and is made from the solid. The latter, or triplet drawn, as it is sometimes called, is usually more accurate to size and forms a stronger tube than the seamed. Larger diameters such as 2 in. and upward are made in thin gauges.

Pipes are jointed in various ways, according to their nature and purpose; for example, gas and hot water pipes are connected by means of fittings with screw threads cut on or in them, and screwing to corresponding threads cut on the pipe. Lead and compo pipes are joined by a soldering process, and the joint is known as a wiped joint. Brass and copper pipes are joined with screwed fittings, and also by brazing and soldering to suitable fittings.

Joints in Gas or Hot Water Barrel. Instructions for manipulating lead piping are given in the article on Plumbing. The amateur should be very chary of doing anything to the gas service pipes, as there are many snags for the inexperienced. Gas barrel, however, has many other uses than its most common one, and can be employed in conjunction with certain stock fittings to make stanchions, handrails, etc.

The home worker may at some time or other wish to alter his hot water supply system, or, for example, take a branch from the existing water pipe to a fresh point. This may be accomplished by unfastening one of the joints of the existing pipe, after having turned off the water, or isolated that part of the pipe so that the water cannot escape. If there is a T-piece in a convenient position and the outlet from the T-piece has been plugged, the best plan is to commence the new work from it. In Fig. 1 such a pipe is shown, the plug being removed with a spanner or pipe wrench.

A piece of pipe has to be cut to length, as in Fig. 2, the ends of the pipe rounded off with a file, and the scale, or hard outer surface, removed by filing, as in Fig. 3. The pipe is set vertically in a strong vice, or horizontally in a proper pipe vice, and a thread cut upon it with stocks and dies, as in Fig. 4. To test the thread, a socket or other standard screwed fitting should be tried in place, to ensure that a perfect fit results; if necessary the die is adjusted and run over the pipe again, so that the fitting screws on evenly and firmly. Both ends of the pipe should be treated in the same way.

The next step is to screw the pipe into the T and to make the joint water or gas tight with a mixture of red lead and gold size or a good thick paint.

This is smeared on with a brush, a few fibres of hemp twisted into the screw thread, and the pipe screwed into the T-piece (Fig. 5). To prevent the pipe sagging it may be supported temporarily with a nail, pipe hook, or a strut of wood. If it is desired to terminate the branch at one end of the length of pipe, this can be effected by screwing an elbow on the end of the pipe and screwing a plug into it, but if it is necessary to carry the pipe upward or downward, a sufficient length of it must be screwed into the elbow and T or branch fitting.

A great point is to make the screw threads a good fit, to make them tight with the aid of red lead, and to cut the lengths correctly at the start. Another point to bear in mind is to work progressively

from one end upward, otherwise it will be necessary to use connectors. These are long sockets, and to use them one of the ends of the pipes to be jointed must be screwed for a sufficient length to allow the socket to screw right on to it. The ends of the pipe are then drawn as close to one another as possible, the socket unscrewed from one and partly on to the other, both of them being secured with locknuts tightened up on the ends of the socket, as in Fig. 6. The nuts have to be fitted before the socket is screwed on. A sound joint is made with twists of hemp soaked in a mixture of red lead and gold size.

When an iron pipe is to be joined to a lead pipe it is necessary to use a brass union fitting and to solder the lead pipe to the tail of the union; otherwise the fitting work may proceed as described. *See Overflow.*

Pipe Joints. Left. Fig. 1. Removing plug from T-piece. Fig. 2. Cutting pipe to correct length by means of a hack-saw.

Fig. 3. The end of the pipe must be filed up before screwing is begun.

Below. Fig. 4. The threads are cut with a large-sized stock and dies.

Left. Fig. 5. The pipe joint shown painted and being screwed up with the wrench.

Fig. 6. Joint made with a connector and two locknuts.

PIPE CLAY. White clay resembling potter's clay is used for making tobacco pipes and other purposes. The peculiarity of this variety of clay is that it is soft and greasy to the touch and very tenacious. When used for whitening leather parts of military accoutrements its adhesiveness is increased by adding white of egg to a thick cream made by rubbing pipe clay with water.

PIPING: In Gardening. This is the name given to a special kind of cutting used in propagating pinks; it consists of the top of a shoot pulled out instead of being severed with a knife. To take a piping, the top end of a shoot is held in the right hand, while the left hand grasps the stem. The right hand gently but firmly pulls the stem apart, showing a hollow pipe, like a quill or tube.

These pipings, when taken, are planted in a mixture of silver sand and finely-sifted soil, watered and covered with a handlight until they have rooted, when they may be planted out. Pipings may be taken at any time during July and August. *See* Carnation; Garden; Layering; Pink.

Piping: In Needlework. A length of piping cord encased in a tube of material is employed in dressmaking and in making covers, cushions, etc., to finish off the edges, in an ornamental manner. If these edges are curved, the piping is made separately, and applied afterwards.

To make it, take a crossway strip of material 1½ in. wide or more, according to the thickness of the piping cord, which may be had in many different sizes. Fold one of the longer edges over nearly down to the other, and slip the cord up into the fold; then tack along close up to the cord to keep it in position. Lay the piping over the right side of the article to be piped so that the narrower of the two strip edges faces this, and the cord lies inward; then stitch the strip down to the article close up to the cord. Roll the cord upward so that it lies along the top of the article, and hem down the wider of the two raw edges. If the edge that is to be piped is quite straight, it is just sufficient to turn the edge of the material itself in over the cord, and to run along close up to it; but this cannot be done if the piping is to be of a contrasting colour, as often happens. Piping can be used in rows as an ornamental trimming, by taking up a tuck in the material and setting the cord at the back of the fabric, so that this may be picked up inside the tuck, which is then stitched. Sometimes the material is pushed along the piping, to give a rucked effect. This style is used in making cushions.

Piping in Needlework. How the cord is enclosed in a tube of material.

PIPPIN. A popular type of apple is known by this name, well known examples being Cox's Orange pippin, Allington, Kerry, King of the Pippins, King's Acre, Sturmer, Normandy and Summer Golden pippin. The first named is the finest dessert apple known.

Normandy Pippins. Dried apple rings are sold as Normandy pippins, although they are sometimes known as biffins. They may be used for winter fruit salads and puddings, but require to be washed thoroughly before use and to be steeped in cold water for 24 hours. *See* Apple; Dried Fruit.

PIQUÉ. A material often used for making detachable coat-slips, collars and cuffs, piqué is generally white or light-coloured. The surface is ribbed into cords, and in true piqué these run crossways on the cloth, although lengthwise cords are often sold under the same name. The cloth is a strong cotton one which wears and washes well. A silk material ribbed to look like this cotton cord is known as silk piqué.

Piqué embroidery is a form of white stitchery upon a strong foundation. The outlines are traced by a cord made in crochet chains or overcast, while the fillings are in different stitches to imitate a figured material, such as linen damask.

PIQUET: How to Play. Piquet is a card game for two players, and is played with a pack of cards from which all from the six to the two have been thrown out. The 32 cards rank as in whist, and the ace is high in cutting and play. There are no trumps.

The dealer deals 12 cards, 2 or 3 at a time, to his opponent and himself, face downward. The remaining 8 cards are placed on the table face downward in a pack of 5 laid across a pack of 3. The object of the game is to score for certain combinations held in the hand, and afterwards by the winning of tricks. First of all each player examines his 12 cards, and begins to declare, beginning with the dealer's opponent. If the latter finds that he has no king, queen or jack in his hand, he calls out *carte blanche*, and scores 10 points. If the dealer also has *carte blanche*, he does not announce it until his opponent has discarded.

The dealer's opponent may discard any number of cards from 1 to 5, and at least one. Whatever number he discards he takes a corresponding number from the top of the pack. If he does not take 5, he may look at those he leaves. If he takes 3, for example, he may look at the next 2. The dealer then discards and draws a corresponding number of cards from the pack. He is bound to discard one card, and may take all the cards which remain, if he wishes. He may look at any of the cards he leaves behind, but if he does so his opponent has the right to look at them as well, either after playing his first card or naming the suit that he intends to play.

The hands being made up, the dealer's opponent begins to declare his hand. He first calls the point. This is the suit which has the greatest pip value. The player first of all announces how many cards of his longest suit he has. If he has more cards than the dealer, the latter says *Good*, and his opponent scores the point. If he has less, the dealer says *Not good*, and scores the point. If the number of cards is equal the pips are counted, aces counting as 11, court cards as 10, and the other cards at their face value. If the pips are equal, neither player scores the point. The point cards must be shown to a player's opponent when demanded.

Each card in a point scores one. A point of six counts 6, for example.

The second call is sequence, three or more cards of a suit in order. The player with the longest sequence counts it. If the number of cards in the sequences are equal, the highest sequence scores. The player with the best sequence also counts all other sequences he may hold, his opponent counting none. If the best sequences are equal, neither side scores. A sequence of 3 cards counts 3 points; of 4 cards, 5 points; and of any greater number, 10 points plus the number of cards in the sequence.

Thus a sequence of 6 counts 16 points. As with the point, sequence must be shown when demanded. The third call is triplets or fours. These are 3 or 4 cards alike, as 3 kings or 4 aces, and the best scores. Three of a kind counts 3 points; 4 of a kind, 14 points. The player with all highest triplet or 4 counts all others in his hand, his opponent counting none. The hands must be called in the regular order: point, sequence, triplets or fours.

How to Score. Each card led counts one point, and as each point in declaring and afterwards is made, the players announce their total score. If the dealer's opponent scores 30 points by declaring his combinations and by the cards he leads before the dealer scores, he scores an additional 30 points, known as *piquet*. If either player reaches 30 before playing a card and before his opponent scores, he scores an additional 60 points for *repique*. The dealer's opponent leads and adds one point as he does so, and the dealer must follow suit. If the winner of a trick also led, he counts one

for his next lead, but if the other player wins the trick he counts one for winning it, as well as one in the usual way for his next lead. The winner of the last trick always scores one extra point, no matter which player led.

If each player wins 6 tricks it is a tie; the player who wins more than 6 tricks scores 10 points for cards, and the player who wins every trick scores 40 points for capot. This score includes the point for the last trick. The game is 100 or 101 points up, and scoring is in the following order, since each player may actually be able to make sufficient points to score the 100 or 101, and so the order of scoring becomes important. Carte blanche is scored first, and then point, sequences, fours and triplets, points made in play, and finally the cards.

In Rubicon piquet there is no definite score. Each game consists of 6 deals, and the player making the highest aggregate wins. The winner deducts the loser's score from his own and adds 100 points. If the loser fails to reach 100 points the winner adds the loser's score and 100 points to his own. Pron. Pik-et.

PISÉ-DE-TERRE. This is the name given to the building of walls and structures with earth. Shuttering is erected to the thickness of the wall, and the earth is filled in and rammed thoroughly. Sometimes the base is made of several courses of brick or stone, to protect the pisé-de-terre from dampness.

PISTACHIO. The small green kernel of the pistachio nut is used in cookery as a decoration for either meat or sweet dishes. In galantine these nuts are often introduced into the forcemeat stuffing, forming a contrast in colour to the red tint of the tongue or ham or the black of the truffle. Pistachios enter into the composition of various dinner sweets much in the same manner as almonds. Pounded or chopped pistachios may be made into sauces for puddings by employing any method adapted to almonds.

Pistachio Cream. To make this cream, blanch and peel 2 oz. pistachio kernels and pound them in a mortar with a few drops of rose water. Make a rich custard, using $\frac{3}{4}$ pint milk, the yolks of 3 eggs, and $2\frac{1}{2}$ oz. castor sugar. Cool the custard slightly, then mix in by degrees the pounded nuts and, in order to heighten the colour, add, if necessary, a little spinach-green or sap-green colouring.

Dissolve 1 oz. leaf gelatine in 2 tablespoonfuls water, and after the custard and the nuts have been passed through a sieve add the gelatine. Last of all fold in lightly $\frac{3}{4}$ pint whipped double cream, and pour at once into a mould rinsed out with melted jelly and decorated suitably. Set it on ice and turn it out of the mould when the cream is to be served. The custard must not be quite cold when the gelatine is added, or it will begin to set before the cream can be mixed with it.

PISTON. In an engine the piston is a moving part that has a free reciprocating movement in the cylinder and takes the pressure of the expanding gas, thus transforming it into mechanical motion, via the connecting rod and the crankshaft.

The piston of an internal combustion engine as used on motor vehicles is of the type known as trunk piston, being long as compared with that of a steam engine. It serves as a guide for the small end of the connecting rod to which it is connected by a gudgeon pin.

Pistons for petrol engines are constructed of cast iron, machined as light as possible, of aluminium alloy, and of aluminium and bronze (Fig. 1). Generally the top, or piston head, is flat, and bevelled at the edge, although sometimes a slightly domed head is employed. In the majority of 2 stroke engines the piston is provided with a specially shaped deflector on the head.

The purpose of this is to direct the path of the burnt gases, as well as to retard the moment at which the fresh gases will unavoidably come in contact with the tail-end of the burnt gases.

Piston. Fig. 1. Diagram showing types of piston used in internal combustion engine design, left-right:

A, cast iron;

b, aluminium;

C, aluminium and bronze.

Fig. 2 (above). Types of piston ring.

Fig. 3 (below). Scraper rings, showing oil channel.

Left.

Fig. 4. Removing piston rings by means of strips of tin inserted and worked round.

The fitting of a piston in a cylinder is not sufficient in itself to prevent leakage of compression between the two surfaces, and for this reason what are known as piston rings are fitted in grooves machined round the piston, which by expanding against the cylinder wall prevent a leakage at this point.

Piston rings are always made of close grained cast iron, machined all over, and ground to a fine limit so as to ensure a perfect fit in the groove. There are several methods by which a perfectly uniform expansion of the ring is assured, so that it exerts an equal pressure on the cylinder wall over the whole of its diameter. By the first method the inside diameter of the ring is machined slightly eccentric to the outside diameter, and slotted or cut through at the thinnest part; by this means the bending moment will be equal from any point, thus allowing the ring to keep a perfect circle when closed to the diameter of the cylinder.

By the second method the rings are turned a little larger in diameter than the cylinder, slotted to leave a gap, and sprung into the cylinder. The gap must be large enough, when the piston is in place, to allow for proper expansion of the ring.

In another method, the inside diameter of the ring is machined from the same centre as the outside diameter, and slotted. It is then permanently expanded, so as to give the necessary tension when closed to the diameter of the cylinder, by means of hammer blows at close intervals round the inside diameter.

The rings are arranged so that the gaps do not fall in line. In order to obtain as perfect a compression as possible, some makers fit two thin rings in one groove, placing the slots on opposite sides; by this arrangement loss of compression via the slots is greatly reduced. This has led to the

introduction of the double twist piston ring shown in Fig. 2, which presents an unbroken surface to the cylinder wall over the whole of its diameter.

Methods of shaping the slots so that as little compression as possible shall get away at this point are shown in Fig. 2. Scraper rings of various constructions are fitted to remove surplus oil from the wall of the cylinder, one being located usually at the lowest of the grooves, just above the gudgeon pin. Small holes in the piston wall carry the oil thus removed to the inside. The ring is grooved, chamfered or stepped, and has a sharp edge for scraping off the oil (Fig. 3).

The removal of the cast iron rings from the piston is a job that calls for considerable care, and is best carried out as follows: Obtain 3 or 4 strips of sheet tin about $\frac{3}{8}$ in. wide, and insert them all side by side at one point between the ring and the piston. Next work them round to the positions shown in Fig. 4. By so doing it will be an easy matter to remove the rings without fear of breakage. Never attempt to remove more than one ring at a time. To replace the rings, it is a good plan to use the strips as a means of keeping the middle ring, where three are used, from entering either the top or bottom groove.

On examining the rings one or more may be found to have extensive brown marks on the face. This will mean that the ring so marked is a bad fit to the cylinder wall. The only cure is to fit a new ring. In the case of one ring only being so marked, a varying degree of porosity of the cast iron, causing unequal heat distortion, will be the most likely reason; but where all the rings are affected, then a badly worn cylinder is responsible. After a considerable mileage the rings may be found to be slack in the grooves. The only remedy is to have the grooves turned true, and a new set of rings fitted.

It is essential to the proper functioning of piston rings that all carbon deposit is removed from the bottom of the grooves, and a blunt instrument only that will not damage the walls of the grooves should be used for the purpose. *See Internal Combustion Engine; Motor Car.*

PIT: A Card Game. Pit is a card game played by 3 to 7 people with a special pack of cards, and is so called from the slang name for American corn exchanges, which are known as pits. The cards number 63, and contain 7 suits of 9 cards each. The number of suits used must correspond with the number of players. The cards are named after the cereals wheat, corn, oats, barley, etc., and the object of each player is to obtain a complete set or corner in one cereal before any other player.

The cards are shuffled and dealt one at a time in the usual way. The suits are of varying values, which are indicated on the cards. Thus, wheat may be 100, corn 75, and so on. The game is won by the player who first succeeds in scoring 500 points by the corners he makes in any cereal. A minute is allowed players to sort their cards and the pit is then opened. Each player tries to exchange cards he does not want for an equal number of cards he does, but without naming the actual suits he wants. Every player shouts out the number of cards he wants, and tries to shout down the opposing players. "Trade two," shouts one player; "three," cries another; "four," yells a third, and so on. The cards traded must be all of the same suit. Immediately a suit is complete the player shouts out "Corner in wheat," or whatever cereal it may be. After each corner the player is credited with its value, and the cards are shuffled and dealt afresh.

PITCH. Pitch is the black residue in the distillation of tar. Vegetable pitch is produced in Sweden, and mineral pitch is obtained in large quantities from gas-tar. Damp walls are effectively treated by painting them with melted pitch. Another method is to paper the walls with paper impregnated with soft pitch. Other uses to which pitch is applied are as a component of briquettes, for making black varnish, as a waterproof coating for roads, and as a protective paint for iron.

Yellow Burgundy pitch is used in making plasters which are applied to the chest in affections of the lungs. The pitch is melted and spread on thin leather by means of a hot iron. The plasters are also applied to the loins in lumbago and for relieving rheumatic pains.

PITCHER PLANT. The peculiarity from which the pitcher plant obtains its name is the fact that the mid-ribs of the leaves extend beyond the ends, and each forms a sort of jug or pitcher with a lid.

When a fly or other insect happens to fall into the pitcher, its slippery mouth, which is also furnished with stiff hairs or bristles, prevents the escape of the insect. The leaves are green, sometimes with brown or red blotches, and the plants should be grown in a hothouse, in baskets of peat and sphagnum moss, suspended from the roof of the house. They require plenty of moisture, and should be shaded from the sun.

Pitcher Plant. Curious hot-house plant known botanically as Nepenthes.

The botanical name of the pitcher plant is *Nepenthes*, but there is another genus with the same English name and of similar habit. This is *Sarracenia*, the side saddle plant, or American pitcher plant. It flourishes in peat and moss, and will thrive in a cool house. There are several sorts, with flowers of various colours. The *Sarracenia* requires very little water in the winter-time. The pitchers are richly marked, and possess the same insect-entrapping qualities as *Nepenthes*. One kind, *S. purpurea*, is hardy, and may be grown in the bog garden, or in a moist corner of the rock garden, in a peaty soil. The surface of the soil should be kept covered with moss. All kinds are increased by division in early spring.

PITCHFORK. The sharp-pronged instrument known as a pitchfork is chiefly used in farmwork, for forking hay or manure and for other purposes. The common type has two slightly curved steel prongs about 1 ft. in length and spaced from 6 to 9 in. apart. At the back end of the prongs two lugs are formed, and to the inside of them is attached a long handle, usually of ash or hickory. The length of the handle is about 5 ft., with a diameter of 1½ in. to 2 in. The ends of the prongs are often turned out slightly at the ends to enable the fork to retain the load it has picked up.

A common use of the pitchfork is in the construction of hayricks, the tool being used to toss the sheaves from the hay cart to the top of the rick. Another application is in the distribution of manure over a field. The pitchfork is almost exclusively used for farm and smallholder's work.

Pitch Pine. *See Pine.*

PITTOSPORUM. This group of evergreen shrubs or small trees is hardy only in the milder parts of the country. They thrive in sandy, loamy soil to which a little peat may be added with advantage. In other districts they should be planted against a sunny wall, or in tubs, and kept under glass safe from frost in winter. *Tobira* and *undulatum*, with white sweet-scented flowers, and *eugenioides*, with pale fragrant blooms, are some of the best. Propagation is by cuttings placed in sandy soil in a frame in August.

PLACKET. The slit or opening in the side of a skirt is usually known as a placket. It should be just large enough to enable the skirt to be put on and taken off with ease, and is prepared by opening the

seam from the waist downward. Two pieces of material, each about $\frac{1}{2}$ in. longer than the opening and 4 in. and 2 in. wide respectively, are then required. The wider piece serves as an underlap, being doubled over and sewn to the left side of the skirt, while the remaining piece is faced to the right side. Press studs are generally used to fasten.

PLAGUE. The acute infectious disease known as plague, bubonic plague, or black death, has spread over the world at various periods, causing a heavy mortality. It is endemic in E. Asia. It is due to infection with the bacillus pestis, which may gain access to the body in food, by inhalation, or by the bites of fleas or other wounds. Rats are mainly responsible for its spread. Preventive measures include isolation and disinfection, the destruction of rats and other vermin. Curative measures include various sera.

PLAICE. The freshness of plaice can be determined by the orange-coloured spots with which the fish is covered. These should be bright, any tendency to dullness being an indication that the fish is stale. To prepare stuffed plaice, wash, clean, and dry the fish, remove the fins and head, and slit the fish down the centre to the bone, making the incision on the side covered with black skin. Lift the flesh with the knife on both sides of the bone, and fill as full as possible with forcemeat, and then lay the plaice in a tin containing a little melted butter or margarine. Brush some of the fat over the top of the fish, sprinkle the latter with brown breadcrumbs, and bake it in a warm oven for about $\frac{1}{2}$ hour, basting it occasionally with the fat. Sprigs of parsley and slices of lemon may be used as a garnish. A suitable sauce such as maître d'hôtel or tomato sauce should be served in a sauce-boat. Complete instructions for filleting and frying plaice are given under the heading Fish (q.v.).

Plaice au gratin may be prepared by washing a plaice, trimming the tail, and removing the fins, eyes, and dark skin. Put it in a gratin dish, place over it 1 oz. butter cut into small pieces, and add also $\frac{1}{2}$ gill milk and salt and pepper to taste. Put the fish in a moderately hot oven, cover it with a plate, and bake it for about 20 min. Pour what remains from $\frac{1}{2}$ pint of milk into a saucepan, heat it up with 1 oz. butter and seasoning to taste, and when it is warm pour it over 1 oz. flour previously mixed to a smooth, thick paste with a little water. Put the whole back into the saucepan, stir it well until it boils, continue boiling for 6 min., and then stir in 1 dessertspoonful grated cheese. Take the fish from the oven, pour the boiling sauce over it, and on top sprinkle another dessertspoonful grated cheese. Return to the oven or place under the grill until the cheese melts and browns.

Fillets of plaice may also be served thus: Mix together 3 tablespoonfuls white breadcrumbs, 1 dessertspoonful grated cheese, a finely chopped shallot, and a skinned and mashed tomato. Season them with pepper and salt, add sufficient egg to bind them, and spread the mixture over the fillets. Roll them up, stand them in a buttered tin or pie-dish, and put any of the mixture that remains on top. Cover the fish with a buttered paper, bake it in the oven for 15 min., and when cooked lift it on to a dish, pouring some hot tomato sauce and sprinkling a few browned crumbs over each fillet. *See* Fish; Food; Forcemeat; Frying; Maître d'Hôtel.

PLAN: Of a Building. A drawing giving details of construction and arrangement of the parts of some object or piece of work is known as a plan, and refers more particularly to architectural drawings of buildings. Plans of machinery are generally termed working drawings, and similar drawings of boats are called the lines. Plans of buildings are prepared to a uniform scale of $\frac{1}{8}$ in. to 1 ft. for the general arrangement drawings, the elevation of the exterior and the disposition of the rooms. Drawings on a larger scale of $\frac{1}{2}$ in. to 1 ft. are employed for the purpose of constructional details. *See* Architecture; House.

PLANES: VARIETIES AND THEIR USES

The Care and Manipulation of these Important Tools

The amateur woodworker may be reminded that this Encyclopedia is full of articles giving detailed directions about making various items of furniture, for many of which a knowledge of planing is essential. In addition there are articles on the various types of plane, e.g. Jack Plane; Ovolo; Plough; Rebate Plane; Router; Smoothing Plane. *See further Amateur Carpentry; Tools.*

The carpenter's plane is used for producing a smooth flat surface on wood. In its simplest form it consists of a steel blade which is passed through a wood or metal block, the cutting edge projecting slightly below the bottom. The blade, which is inclined at an angle, is secured in its place with a wedge or some other device, and in the larger varieties a handle is fitted to the tool. In some planes the blade, or plane iron, is single; in others it is composed of two separate portions, the cutting iron and the back or covering iron.

The bottom of the hole where the blade protrudes is known as the mouth, and the upper portion as the throat, and it is important that the mouth should be just wide enough to allow the shavings to come away freely and pass through it; if too wide this will not press down the fibres of the wood in front of the plane iron, which consequently will have a tendency to tear the work badly. The principle on which any plane works is that the cutting iron is so ground and sharpened that the shavings are chiselled off with a regular and uniform motion, working with the grain and not against it. The function of the plane is to guide the direction or course of the plane iron, and to regulate the depth of the cut. In metal-bodied planes with screw adjustments etc., the principle is the same.

The amateur should possess a jack plane, trying plane, and smoothing plane: with these three practically any ordinary flat work can be tackled. Other planes that may be added as occasion requires are the rebate, compass, plough, fillister, bead, round, and hollow planes, and a variety of various shapes generally used for making different kinds of mouldings; also a small metal block plane and router. When the expense is not too great, one of the Stanley universal planes will carry out a wide variety of jobs, including all kinds of moulds, ploughing, tonguing, and grooving. The wooden plane is generally made of beech, which has a close grain and is fairly hard. The purchaser should see that the grain on the end of the plane is as nearly horizontal as possible, or level with the sole, or bottom of the plane. If short, whitish lines are visible, known as medullary rays, these should be as nearly as possible at right angles to the sole of the plane, as such a tool will wear better than one in which these lines are at another angle. If the plane has been made by a reputable maker, it can reasonably be expected to be true and free from warp or twist; but this can generally be told by holding the plane horizontally on a level with the eyes, and looking along the level of the sole. The body of a new wooden plane should be soaked in raw linseed oil before using it for the first time.

To remove the iron of a jack plane, or trying plane, grasp the plane in the left hand, the thumb pressing upon the iron, and the fingers grasping the bottom or sole of the plane. With the aid of a hammer strike a sharp blow near the end of the plane, as in Fig. 1. This will loosen the wedge, which can be withdrawn and the blade lifted out. The two irons are separated by laying them on the bench, holding them firmly in the left hand, and manipulating a screwdriver, as in Fig. 2. The plane iron should rest on or be firmly held by some support such as the bench. When the screw is loose the back iron is slid along the slot cut in the plane iron until the screw is opposite a large diameter hole, when it can be lifted out of its place. The iron is sharpened in the manner described in the articles on Grinding and Oilstone. The cover iron is then replaced; the edge should be about $\frac{1}{8}$ in.

or less from the cutting edge of the plane iron. The cover rests upon the front of the plane iron, that is, the side that is not ground.

Plane. Fig. 1. How to remove the iron of a jack.

Left. Fig. 2. Unscrewing the back iron. Fig. 3.

Fig. 4. Typical iron plane with principal parts named.

Left. Loosening the wedge of a smoothing plane.

The blade is replaced and held as if taking the plane apart, while the wedge is tapped lightly in position with a hammer sufficiently to hold the iron. The plane is tilted at an angle, and the edge of the iron will be seen to protrude slightly. If it does not, it may be tapped out gently by tapping the opposite end with the hammer, or be adjusted by the

screw device on an iron plane. The iron should project slightly less than 1/16 in. from the sole of the plane, and should project evenly over the whole breadth of the blade, except the corners, which will be slightly rounded off in the grinding process. The wedge should be secured tightly, and the plane is ready for use.

A smoothing plane is adjusted in the same way, except that to loosen the plane iron, the back of the plane is struck with the hammer (Fig. 3). In the case of metal planes the various adjusting devices are operated. Fig. 4 shows a metal trying plane with the location and purpose of the various adjustments indicated.

Plane. Fig. 5. Using a smoothing plane.

Fig. 6. Using a fillister plane to form a rebate.

Manipulation of the Tool. Most planes are held and used with both hands; in general, the right hand grasps the handle of the plane, such as a jack plane, or the back part of a smaller plane, such as a smoothing plane. Some very small planes may be held in the right hand only; they are used for chamfering the edge or cleaning up any little roughness on the end of a piece of wood, or for work on curved surfaces, but are seldom of use in making a really flat surface. The correct method of using a smoothing plane is illustrated in Fig. 5, which shows the disposition of the hands and the style of shaving that should be produced. Rebate planes and similar planes used for making mouldings are held in the manner indicated in Fig. 6, which shows a fillister plane employed making a rebate.

Plane. Fig. 7. Start of the stroke with a jack plane.

Fig. 8. How the plane is held at the finish of the stroke.

Fig. 9. Shooting the edge of a board with a jack plane.

Figs. 7 and 8 show the beginning and ending of a planing movement with a jack plane. The top front of the plane is grasped between the fingers and thumb of the left hand, and the handle held in the right. The object should be to thrust the plane forward in a straight line, keeping it level. A tendency to roll the plane may be detected by the tool inclining to lift at one corner, and this may be checked by control with the hands and arms.

If the edge of a board is to be planed, the tool is grasped in a different manner. It may be held as in Fig. 9, the first finger of the right hand being extended as shown, and the left hand resting on the top of the plane. With this grip it is possible to judge whether the plane is being held level or not.

Planing to thicknesses and widths is simply a question of gauging. The principle is to establish a flat surface, or face side, then one edge. These are marked off and gauged to the desired thickness, for which purpose special hardwood gauges can be prepared, or, as in gauging the thickness of a panel, grooves can be ploughed into a small piece of wood, and this is applied to the edge of the panel to correct the planing.

When planing curved surfaces, always work downhill; never attempt to plane uphill against the grain of the wood. When planing end grain, do not plane straight across the grain, but work from each side across the end grain to the middle; or slightly bevel one corner of the board and plane across the end grain to this bevel; or clamp it to an odd piece of wood on the far side of the board, and plane right across. If these precautions are not observed, the wood will split. Another aid is to

hold the plane diagonally, or slanting, across the board, but to push the plane bodily in a straight line.

Before attempting to plane wood it is essential that the plane iron is very sharp, and it must be rubbed up on an oilstone when this becomes necessary. For rough work the plane iron should project considerably; for smoothing, a less amount, and for a fine finish the least amount it is possible to set it at. When the plane is cutting properly, the shaving should come away with a clear, decided sound.

PLANE: The Tree. The hardy summer-leafing plane tree, ranging in height from 60 ft. to 80 ft., will thrive in the gardens of smokeladen towns and cities when all other trees fail as the bark is shed annually. Many fine examples are to be seen in London and other English cities. *Platanus acerifolia* (London plane) and *orientalis* are the chief kinds; they flourish in ordinary soil and may, if it is necessary to keep them within bounds, be pruned hard every few years. They are not, however, suitable for small gardens. The planes can be increased by cuttings set out of doors in late autumn.

PLANK. This is the name given to sawn timber 11 in. or more wide, and from 2½ in. to 6 in. thick, but the word is commonly applied to all sorts of boards. Examples are seen in planks of a platform, in planks used in scaffolding and general building purposes, and in boat building.

For cabinet making it is very often cheaper to purchase a plank and have it sawn into boards, the charge for the saw cuts being a few pence. An objection, however, is that the boards may wind or twist after sawing from the plank, so that a period of seasoning is desirable before using the stuff for anything important. Care should be taken in selecting a plank for conversion, and an end grain showing the heart should be avoided unless several thin boards of narrow width are required. In planning the number of boards due allowance must be made for the thickness of the saw cuts. For example, a 6 in. plank can be sawn into four 1 in. and two ½ in. boards, each being full in thickness.

PLANT. Some authorities define a plant as a living organism, diversified in structure and possessing organs of nutrition and reproduction. The former comprise root, stem, and leaves, functioning for purposes of respiration, circulation and growth. The latter include the flower, with its calyx and corolla, and stamens and anthers, the male organs; pistil, stigma, and ovary, the female organs. Male and female organs may be contained in one flower, or they may be borne on different plants; some examples carry male and female flowers separately on the same plant.

PLANTAIN: The Fruit. The plantain is a fruit belonging to the banana family, of which the scientific name is *Musa*. The very large outsize fruits, often attaining a curved length of 8 or 9 in., which are sold in Great Britain as bananas, are really plantains. They may also be distinguished by their thick, tough skins. Real bananas are much smaller, softer, and have thinner, velvety skins. The culture of plantains is as for bananas (q.v.).

PLANTAIN: A Garden Weed. Two plantains (*Plantago major* and *P lanceolata*) compel the attention of the gardener because they are common weeds of the lawn. They spread rapidly by means of self-sown seeds and should be uprooted with a bent-pronged weeding fork while small. A little sulphate of ammonia or lawn sand, if placed on the plantains in settled dry weather, will destroy them. Or they can be killed by means of a special weed eradicator which liberates a supply of weed killer when thrust into the plantains.

PLANTAIN LILY. This group of hardy herbaceous perennials, 2 ft. or so high, is valued for its large ornamental leaves and spikes of small white or lavender coloured lily-like flowers in summer.

They flourish either in sunny or partially shaded places in well drained loamy soil and are increased by division in spring. Snails are very fond of the leaves, and if not destroyed often spoil the beauty of the plants. The plantain lilies are first-rate for cultivation in tubs and develop into large handsome plants in a few years; the varieties with coloured leaves are particularly well suited to this purpose. The chief kinds are *Fortunei*, *glauca*, which has grey-blue leaves, *Sieboldina*, and *subcordata*. Two low-growing kinds suitable for edging or for cultivation in pots are *lancifolia* and *tardiflora*.

PLANT HOUSE. A glasshouse built for the cultivation of plants and fruits which are not sufficiently hardy to be grown out of doors or are improved by the shelter thus afforded. The stove or hothouse is for tropical plants; its minimum winter temperature is about 65 degrees. The greenhouse or conservatory artificially warmed to maintain a minimum temperature of about 50 degrees is for the cultivation of half-hardy and subtropical plants. In the cold or unheated greenhouse many hardy rock and border plants can be grown in pots, as well as grapes, peaches and tomatoes, either in pots or planted in a border of soil. During the spring and summer months half-hardy flowering plants, e.g. *fuchsia*, tuberous *begonia*, zonal geranium and *gloxinia*, may be grown. There are two chief types of glasshouses, the span roof and the lean-to, the latter being built against a wall. A garden frame is indispensable to the possessor of a glasshouse; there the plants are propagated and kept until well developed. A pit is a frame or small glasshouse the floor of which is below the ground level; it is often used for the cultivation of melons and cucumbers. Special glasshouses are constructed for the various classes of stove, intermediate and coolhouse orchids. *See Greenhouse.*

PLANTING. The best times to plant are autumn and spring, the former period being preferable for hardy perennials and leaf-losing trees and shrubs. Evergreens may be planted in September-October, or in April and May. Early planting, either in spring or autumn, is sound practice, when preceded by thorough preparation of soil.

The method of making holes just sufficiently large to accommodate cramped roots should be avoided; they must be opened enough to provide ample space, with a little to spare, when roots are spread out horizontally. The value of trenching land before planting is great. *See Digging; Mulching; Trenching.*

PLANT LICE. The name is applied to the various types of aphids, such as the green fly, which do great harm to all kinds of plants by sucking sap. Infested plants out of doors should be syringed, during a dry evening, with an insecticide, or with a homely remedy made of soft soap and quassia chips in solution. In the greenhouse fumigation with a suitable fumigating compound, such as a nicotine preparation, may be found to be necessary.

The best treatment for apple, plum, and other trees infested with lice is to spray the lower leaf surface frequently with an insecticide. Certain garden insects, including the ladybird, ichneumon fly, etc., are voracious devourers of plant lice. *See Insecticide.*

PLAQUE. Ornamental tablets of metal, porcelain, majolica ware, ivory, plaster, marble, etc., usually carved or decorated in some manner, are known as plaques.

With the exception of polychrome enamels, such as the 16th century masterpieces of Limoges, metal plaques are usually wrought in low relief. They may be hammered out in repoussé, or cast and chased, as in the case of ormolu or gilt bronze, being sometimes oval portraits in the manner of large medallions, sometimes round or oblong scenes of classical or local interest. If they are of actual value, as examples of antique work, they should be protected by appropriate glazing.

Ceramic plaques of value usually take the form of old delft, either Dutch or English, of majolica, or the jasper-ware plaques introduced by Josiah Wedgwood.

PLASHING. This is a method of repairing or confining a hedge by bending shoots towards the roots and cutting the stems half through. In this way the sap is still allowed to circulate, the stems remain alive, and unruly ones become pliable enough to twist among others. Care must be taken that the plashed stems, or branches, are not cut more than half through, otherwise they will die. Proper trimming and attention to hedges in season will generally obviate any necessity for plashing. *See Hedge.*

PLASTER AND PLASTERING METHODS

The Effective Treatment of Walls and Ceilings

For further details about work of this kind the reader should turn to the article House. See also Ceiling; Cornice; Float; Frieze; Hawk; Lath; Mortar; Partition, etc.

Plaster is the name given to calcareous compounds with a base of calcium sulphate. In the general use of the word, as applied to building operations, it refers to a mixture of lime, sand, and water, generally with the addition of plaster of Paris, or some other material to accelerate its setting. The general use for plaster, as far as the amateur is concerned, will be in the plastering and repair of wall surfaces.

The plaster for a wall is applied in 2 or 3 separate coats. The first, or pricking up coat, is applied with coarse stuff composed of a good chalk lime, coarse, clean, sharp sand, and clean ox hair. For the mix-up the sand is arranged in the form of a hollow basin, preferably rested on boards (Fig. 1); but if the ground is impervious, such as a concreted floor, it can be set direct upon it. The lime should previously have been thoroughly slaked, and is used in the form of a putty with a consistency not unlike that of thick cream.

This is sifted through a sieve, which may be rested upon a couple of poles or boards upon the surface, and water is run through it, if necessary, to ensure that no lumps of the lime are prevented from being mixed with the sand, which should previously have been sifted for a similar reason. The hair, when purchased, is in a clotted state and all lumpy. It is separated by placing some of it on a board and beating it with two sticks, one held in each hand, so as to separate the hairs without breaking them. The hair when beaten is disposed over the slaked lime, and the whole of the sand and lime turned over and thoroughly well mixed with larry and shovel. The mixture should be just wet enough to mix evenly. The larry is a broad bladed tool resembling a hoe. In the blade is a large hole, which aids the mixing of the plaster.

The mass that is thus prepared should be heaped up and left to temper for as long as possible before using. Coarse stuff made in this way can be used at once, but the longer it is left to temper, the more satisfactory the plaster. The usual proportions are 1 of lime, 3 of sand, and 1 lb. of hair for every cubic foot of coarse stuff. The object of mixing the hair is to bind the plaster together and make it more tenacious.
